

# An Assessment on Irrevocable Compression of Encrypted Grayscale Image

K. Porkumaran, S. Manimurugan, Pradeep P Mathew

**Abstract**— *This paper may deals with the miscellaneous troubles that may be occurs during the irrevocable compression applied on an encrypted grayscale image. This work is a comparative learn with diverse methods of irrevocable compression such as Compressive sensing technique and Iterative reconstruction technique on encrypted grayscale image. But they practiced a multiplicity of limitations. The major obscurity is to achieve higher compression ratio as well as the better quality of the reconstructed image. The higher compression ratio and the smoother the original image may furnish the better quality of the reconstructed image.*

**Index Terms**— *Image compression, image encryption, image decryption, image decompression, image reconstruction.*

## I. INTRODUCTION

Compression of encrypted grayscale image has paying attention in the recent years with enormous research interest. To diminish redundancy initially compress the image then encryption is applied to the compressed image is the traditional method of securely transmitting the image[1]. The decryption operation as well as the decompression procedure may be performed at the receiver side to attain the reconstructed image. In case of various applications, some data needs to send out from sender to the receiver and keeps the information confidential to the network operator. So sender should encrypt the original image and the network provider may compress the encrypted grayscale image without any awareness regarding the original data. Decompression as well as decryption might be performed to renovate the original image. Compressive sensing is an emerging area, which gained a bunch of significance due to its ability to renovate the sparse signal from comparatively minor illustration set[2]. This may provides an innovative method of signal compression whose scrupulous function is the irrevocable compression of encrypted data. Compression as well as the encryption is necessary while an image is transmitting over insecure bandwidth limited channel. Comprehensible structure of the image may be improved to incomprehensible structure by an encryption technique, which makes the encrypted grayscale image difficult to achieve compression by using any effortless classical compression algorithm. But the network operator is enforced to compress the encrypted grayscale image due to the constraint of bandwidth. For such scenarios to compress the data, projected techniques

are based on distributed source encoding (DSC) [3]. Since the encryption key is recognized at the decoder, DSC utilizes the relationship between the encryption key and encrypted data. In this case, relationship such as statistics of the information source affected the compression efficiency. Correlation can be modeled by a binary symmetric correlation; while [4] the binary image is assumed to be sparse. To improve the compression efficiency, higher memory models [5] were used to model correlation. Since good compression does not achieve by extending these to gray scale images and hence [6] propose to apply encryption on the prediction errors follow a Laplacian density function to achieve good compression along with good security. Good compression can be obtained, since the prediction errors follow a Laplacian density function.

On the basis of theory of source coding with the side information at the decoder, the performance of compressing encrypted data is similar [15] that of nonencrypted data. Lossy compression of encrypted Gaussian sequence is presented in [16]. The original binary image is encrypted by adding pseudorandom string and with respect to low-density parity-check (LDPC) channel code [17], the encrypted data are compressed by judgment the syndromes. Using LDPC codes, for both memory less sources and sources with hidden [18] Markov correlation are studied. In [19], a few methods are introduced for lossless compression of encrypted color and gray images. In a progressive manner, the encrypted grayscale image is decomposed in [20] and the most significant bits in high levels are compressed using rate-compatible punctured turbo codes. Some algorithms for compressing encrypted data and demonstrate blind compression of encrypted video are presented in [21]. In the encryption domain, the signal processing using homomorphic calculation is discussed in [22] and [23].

## II. COMPRESSIVE SENSING TECHNIQUE ON ENCRYPTED GRAYSCALE IMAGE

Compressive sensing technique is one of the irrevocable compression method developed on the encrypted grayscale image to conquer the troubles that faced on this area. This technique is introduced to accomplish lossy compression on encrypted grayscale image and a basis pursuit algorithm is appropriately adapted to enable joint decompression and decryption. The encryption is applied on the image in the spatial domain and which is performed by some linear procedure. At the encoder, the image is unnecessary to be transformed and transformation basis is only required at decoder. The compressed sensing encoded data itself is very secured [7] because of which information owner can relax his own security requirements.

## A. Encryption of Grayscale Image

Cipher text can be generated by means of a linear procedure on the image pixels. An encryption matrix is used to signify the linear process operation which generates various random seed. Cipher text is generated by applying encryption on the image in the spatial domain. The image can be converted into a single column vector. Snake pattern is followed to vectorize the image, which improves compression efficiency. Encryption is applied upon single column vector by a linear transformation of the pixels to acquire the cipher text. A permutation matrix is a binary matrix that obtained by randomizing the rows of an identity matrix. The index for this randomization can be generated with an initial random seed by pseudo random index generator, shared to the decoder by a secured channel. Permutation based linear encryption techniques can be referred in [12]. Spectral permutation based encryption system for speech encryption may described in [13]. Hadamard transform can also be used in the encryption stage [14]. Encryption procedure can be represented by a linear transformation matrix.

## B. Compression of Encrypted Image

Compressing sensing technique is used for the compression of cipher text. The encryption matrix is engaged at the compressor while the compressor receives the encrypted data. Random measurements are computed by projecting the encrypted data onto the Gaussian random measurements basis  $F$  of size  $M \times N$  at the compressor. Compression is achieved since the number of measurements  $M < N$ . Compression ratio as well as the reconstruction performance determined by the factor  $M$  the number of measurements. It is very complicated to calculate  $M$ , since the original image is unavailable at the compressor and it depends on the sparsity factor. The sparsity may be adjusted by transforming and making the coefficients to go to zero which is unattainable in this case due to the unavailability of original image. So  $M$  is choose for a given target bit rate. The decoder will estimate the sparsity factor which depends on the value of  $M$ . The quality of the image reconstruction is enhanced by higher values of  $M$ , which enables more coefficients.

A second level of security can be provided by the compressive sensing technique along with compression. The measurement matrix cannot be generated exactly without the access to the random key. Without the access to the actual measurement matrix, computationally it is impossible to decode properly as shown [7]. This reduces the encryption time which helps the information owner to relax his security requirements of the encryption function. The sampled values was quantized by a Lloyd quantizer for a given bit rate and that was transmitted to the decoder. The final bit rate is a function that depends on both the quantization levels and the number of measurements. To obtain best performance, target bit rate a trade off is required between the quantizer levels and  $M$ . It is difficult to optimize the cost function involving the quantizer levels and  $M$  with final rate, since the original image is unavailable at the encoder. At lower quantization levels, both sparse location estimation accuracy and sparse

signal amplitudes depends on the quantization noise. The effect of quantization noise become negligible and quality of image reconstruction depends only on the factor  $M$  while the quantization level increases beyond a certain level. Fix the number of quantization levels and only vary  $M$  for a given bit rate to obtain a good performance.

## C. Image Reconstruction

The compressed data stream received from a public channel along with keys from a separate secure channel at the decoder. The exact matrices will be generated with the help of these keys. Image reconstruction process may involve both decompression and decryption. Here decoding based on basis pursuit, since it performs better than existing algorithms. Greedy based algorithms are computationally efficient is direct and easy. The customized optimization problem is solved to recover the sparse signal, as it's the first step of joint decoding. The whole of the image of block size  $N$  was considered to be encoded and decoded in this sensing technique. Dimension  $N$  increases with the increase in reconstruction performance [9].  $O(N^3)$  is the computational complexity of solving decoding. Thus there exist a swapping between performance and complexity. The data can be divided into smaller blocks and encoding and decoding is performed on each of the smaller blocks to reduce the computational complexity.

## III. ITERATIVE RECONSTRUCTION TECHNIQUE ON ENCRYPTED GRAYSCALE IMAGE

Lossy Compression and iterative reconstruction technique is a narrative system for irrevocable compression of encrypted grayscale image with flexible compression ratio, which can be obtained by image encryption, tailor-made compression and iterative decompression phases [2]. Redundant and trivial data may be detached by the network provider and iterative procedure may be used to regain the principal content of the original image. Compression parameters are the significant factors that involve the compression ratio as well as the quality of the reconstructed image. The better quality of reconstructed image can be achieved by higher compression ratio as well as smoother the image. With a slight degradation of encryption security and reconstruction quality, improve the compression efficiency.

A pseudorandom permutation is used to encrypt an image and then by discarding the excessively rough and fine information of coefficients in the transform domain to compress the encrypted data. The receiver has the compressed data as well as the permutation way, with the aid of spatial correlation in natural image. By iteratively updating the values of the coefficients, the receiver can reconstruct the principal content of the actual image.

### A. Image Encryption

In [23] and [24], there are a number of permutation-based image methods used. The original image should be in uncompressed format and each pixel have a gray value which may be between 0 and 255, and that can be represented by 8 bits. Total number of pixels is the product of number of rows and number of columns and the total number of bits is the product of total number of pixel and 8. The data sender pseudorandomly permutes the total number of pixels for the image encryption and by the help of secret key, the permutation way is determined. The pixel-sequence can be shown as encrypted data. In the encryption phase, the pixel values are not masked and only the pixel positions are permuted. The attacker cannot recover the original content from the encrypted grayscale image with ordinary size and fluctuation. The permutation-based encryption can be used in most scenarios without a requirement of perfect secrecy although there is a leakage of statistical information.

### B. Compression of Encrypted Grayscale Image

A majority of pixels are converted to a series of coefficients using an orthogonal transform in the compression stage. To reduce the data amount, the excessively rough and fine information in the coefficients is removed. The network provider divides the permuted pixel sequence into two parts. The first part is called rigid pixels, which is made up of a set of pixels. The remaining pixels are called elastic pixels, which is the second part. This classification of pixels may be depends on a variable whose value is within zero and one. To calculate the coefficients, orthogonal transform is performed in the elastic pixels. Public orthogonal matrix can be generated by orthogonalizing a random matrix. Calculate the  $s_k$  value [1] for each coefficient where  $M$  is the system parameter the values can be assigned for the purpose of implementation. Mod operation as well as round operation may perform here whereas the round operation returns the nearest integer and the mod operation gets the remainder. The data amount for representing the elastic pixels are reduced within a small  $M$ . The fine information as well as the rough information is discarded and the information on the medium level only remains. The loss of the fine information cannot affect the quality of the reconstructed image seriously and an iterative reconstruction procedure will be used to retrieve rough information. Consider the values of  $s_k$  as a set of digits in a notational system with a base  $M$ , since its value is within zero and  $M-1$ . The set of  $s_k$  is segmented into many pieces with  $L_1$  digits and calculated the decimal value of each digit piece. Each decimal value is converted into  $L_2$  bits in a binary notation system. The data of rigid pixels, the bits generated from all pieces of  $s_k$  and the values of different parameters are collected to produce the compressed data of encrypted grayscale image. The compression ratio is the ratio between the amounts of the compressed data and the original image data is calculated, which may depends only on the value of  $M$  and the value of the variable used to classify pixels into rigid and elastic, since the data amount of parameters is small.

### C. Image Reconstruction

A receiver can reconstruct the principal content of the original image with the compressed data and the secret key. Obtain the gray values of rigid pixels, the values of each  $s_k$ , and the values of all the parameters by decompose the compressed data. Receiver can calculate  $L_2$  with the knowledge of  $M$  and  $L_1$  and by converting binary blocks with  $L_2$  bits into digit pieces in an  $M$ -ary notational system to get the values of  $s_k$ . Then the receiver can retrieve the positions of the rigid pixels, according to the secret key. The original gray values at the positions can be exactly recovered, which distribute over the entire image.

**Fig. 1 a) Original image Lena, (b) Encrypted grayscale image, (c) the medium reconstructed image from compressed data, and (d) the final reconstructed grayscale image.**

The values of the elastic pixels are estimated as the values of rigid pixels nearest to them. We can find the nearest rigid pixel for each elastic pixel and observe the value of rigid pixel as the estimated value of the elastic pixel. Consider the average value as the estimated value of the elastic pixel, if there are several nearest pixels with the same distance. The estimated values are comparable to the corresponding original values due to the spatial correlation in the natural image. By exploiting the information of  $s_k$ , the estimation will be iteratively updated. Calculate the coefficients by rearranging the estimated values of elastic pixels using the same permutation way. Modify the coefficients to the closest values reliable with the corresponding  $s_k$  and execute inverse transform. The average energy difference between the two versions of elastic pixels can be calculated. If the average energy difference is not less than given threshold, for each elastic pixel, compare the average value of its four neighbor pixels as its new estimated value. Otherwise terminate the iteration process.

**TABLE I Comparison of the irrevocable compression methods on encrypted grayscale image.**

Parameters	Techniques	
	Comprehensive Sensing	Iterative Reconstruction
Compression Ratio	High	High
PSNR Value	Low	High
Quality	Poor	Good
Complexity	High	Low

The relative study of irrevocable compression methods such as Compressive sensing technique and Iterative reconstruction technique of encrypted grayscale image, on the basis of a variety of parameters such as Compression Ratio, PSNR value, Resolution, Complexity and the quality of the image is represented in the above TABLE 1.

## IV. CONCLUSIONS

In this paper we discussed about miscellaneous irrevocable compression techniques on the encrypted grayscale image. We have considered the difficulty of irrevocable compression of encrypted grayscale image data. The application of classical compression techniques is unfeasible for the compression of encrypted grayscale image. Compression sensing technique helps to understand lossy compression on encrypted grayscale image, where a basis pursuit algorithm is appropriately modified to enable joint decompression and decryption. The encryption is functional on the image in the spatial domain and which is performed by some linear operation. At the encoder, the image is not necessary to be altered and transformation basis is only required at decoder. This compression technique provides a better compression ratio where as the quality of the reconstructed image is not considered. Lossy Compression and iterative reconstruction technique helps to realize irrevocable compression of encrypted grayscale image with flexible compression ratio, which can be obtained by image encryption, tailor-made compression and iterative decompression phases. Redundant and trivial data may be detached by the network provider and iterative procedure may be used to convalesce the principal content of the original image. This technique provides higher compression ratio as well as the better quality of reconstructed image but the security of encryption is weaker. In the future, the irrevocable compression of grayscale image encrypted by more secure methods will be studied.
