# A few Smarandache Integer Sequences 

Henry lbstedt

Abstract
This paper deals with the analysis of a few Smarandache Integer Sequences which first appeared in
Properties of the Numbers, F. Smarandache, University of Craiova Archives, 1975 . The first four sequences are recurrence generated sequences while the last three are concatenation sequences.

The Non-Arithmetic Progression: $\left\{a_{i}: a_{i}\right.$ is the smallest integer such that $a_{i}>a_{i-1}$ and such that for $k \leq i$ there are at most $t-1$ equal differences $\left.a_{k}-a_{k_{1}}=a_{k_{1}}-a_{k_{2}}=\ldots=a_{k_{t-2}}-a_{k_{t-1}}\right\}$
A strategy for building a t-term non-arithmetic progression is developed and computer implemented for $3 \leq t \leq 15$ to find the first 100 terms. Results are given in tables and graphs together with some observations on the behaviour of these sequences.

The prime-Product Sequence: $\left\{t_{\mathrm{n}}: \mathrm{t}_{\mathrm{n}}=\mathrm{p}_{\mathrm{n}} \#+1, \mathrm{p}_{\mathrm{n}}\right.$ is the n th prime number $\}$, where $p_{\mathrm{n}} \#$ denotes the product of all prime numbers which are less than or equal to $p_{n}$.
The number of primes $q$ among the first 200 terms of the prime-product sequence is given by $6 \leq q \leq 9$. The six confirmed primes are terms numero $1,2,3,4,5$ and 11 . The three terms which are either primes or pseudo primes (according to Fermat's little theorem) are terms numero 75, 171 and 172. The latter two are the terms $1019 \#+1$ and $1021 \#+1$.

The Square-Product Sequence: $\left\{t_{n}: t_{n}=(n!)^{2}+1\right\}$
As in the previous sequence the number of primes in the sequence is of particular interest. Complete prime factorization was carried out for the first 37 terms and the number of prime factors $f$ was recorded. Terms 38 and 39 are composite but were not completely factorized. Complete factorization was obtained for term no 40 . The terms of this sequence are in general much more time consuming to factorize than those of the prime-product sequence which accounts for the more limited results. Using the same method as for the prime-product sequence the terms $t_{n}$ in the interval $40<n<200$ which may possible be primes were identified. There are only two of them, term \#65: $\mathrm{N}=(65!)^{2}+1$ which is a 182 digit number and term \#76: $\mathrm{N}=(76!)^{2}+1$ which has 223 digits.

The Prime-Digital Sub-Sequence: The prime-digital sub-sequence is the set $\left\{M=a_{0}+a_{1} \cdot 10+a_{2} \cdot 10^{2}+\ldots a_{k} 10^{k}: M\right.$ is a prime and all digits $a_{0}, a_{1}, a_{2} \ldots a_{k}$ are primes $\}$
A proof is given for the theorem: The Smarandache prime-digital sub sequence is infinite, which until now has been a conjecture.

Smarandache Concatenated Sequences: Let $G=\left\{g_{1}, g_{2}, \ldots . g_{k}, \ldots.\right\}$ be an ordered set of positive integers with a given property $G$. The corresponding concatenated $S$. $G$ sequence is defined through $S . G=\left\{a_{i}: a_{1}=g_{1}, a_{k}=a_{k-1} \cdot 10^{1+\log _{10} g_{k}}+g_{k}, k \geq 1\right\}$.

The S.Odd Sequence: Fermat's little theorem was used to find all primes/pseudo-primes among the first 200 terms. There are only five cases which all were confirmed to be primes using the elliptic curve prime factorization program, the largest being term 49:
135791113151719212325272931333537394143454749515355575961636567697173757779818385878991939597
Term \#201 is a 548 digit number.
The S.Even Sequence: The question how many terms are nth powers of a positive integer was investigated. It was found that there is not even a perfect square among the first 200 terms of the sequence. Are there terms in this sequence which are $2 \cdot \mathrm{p}$ where p is a prime (or pseudo prime)? Strangely enough not a single term was found to be of the form $2 \cdot \mathrm{p}$.

The S.Prime Sequence: How many are primes? Again we apply the method of finding the number of primes/pseudo primes among the first 200 terms. Terms \#2 and \#4 are primes, namely 23 and 2357. There are only two other cases which are not proved to be composite numbers: term \#128 which is a 355 digit number and term \#174 which is a 499 digit number.

## I. The Non-Arithmetic Progression

This integer sequence was defined in simple terms in the February 1997 issue of Personal Computer World. It originates from the collection of Smarandache Notions. We consider an ascending sequence of positive integers $a_{1}, a_{2}, \ldots a_{n}$ such that each element is as small as possible and no $t$-term arithmetic progression is in the sequence. In order to attack the problem of building such sequences we need a more operational definition.

Definition: The $t$-term non-arithmetic progression is defined as the set:
$\left\{a_{i}: a_{i}\right.$ is the smallest integer such that $a_{i}>a_{i-1}$ and such that for $k \leq i$ there are at most $t-1$ equal differences $\left.a_{k}-a_{k_{1}}=a_{k_{1}}-a_{k_{2}}=\ldots=a_{k_{t-2}}-a_{k_{t-1}}\right\}$

From this definition we can easily formulate the starting set of a t-term non-arithmetic progression:

$$
\{1,2,3 \ldots . . t-1, t+1\} \text { or }\left\{a_{i}: a_{i}=i \text { for } i \leq t-1 \text { and } a_{t}=t+1 \text { where } t \geq 3\right\}
$$

It may seem clumsy to bother to express these simple definitions in stringent terms but it is in fact absolutely necessary in order to formulate a computer algorithm to generate the terms of these sequences.

Question: How does the density of a $t$-term non arithmetic progression vary with $t$. i.e. how does the fraction $\mathrm{a}_{k} / \mathrm{k}$ behave for $\mathrm{t} \geqslant 3$ ? ${ }^{1}$

Strategy for building a $t$-term non-arithmetic progression: Given the terms $a_{1}, a_{2}, \ldots a_{k}$ we will examine in turn the following candidates for the term $a_{k+1}$ :

$$
a_{k+1}=a_{k}+d, d=1,2,3, \ldots
$$

Our solution is the smallest $d$ for which none of the sets

$$
\left\{a_{1}, a_{2}, \ldots a_{k} a_{k}+d, a_{k}+d-e, a_{k}+d-2 e, \ldots a_{k}+d-(t-1) \cdot e: e \geq d\right\}
$$

contains a t-term arithmetic progression.
We are certain that $a_{k+1}$ exists because in the worst case we may have to continue constructing sets until the term $a_{k}+d-(t-1)$ e is less than 1 in which case all possibilities have been tried with no $t$ terms in arithmetic progression. The method is illustrated with an example in diagram 1 .

In the computer application of the above method the known terms of a no $t$-term arithmetic progression were stored in an array. The trial terms were in each case added to this array. In the example we have for $d=1, e=1$ the array: $1,2,3,5,6,8,9,10,11,10,9,8$. The terms are arranged in ascending order: $1,2,3,5,6,8,8,9,9,10,10,11$. Three terms 8,9 and 10 are duplicated and 11 therefore has to be rejected. For $d=3, e=3$ we have $1,2,3,5,6,8,9,10,13,10,7,4$ or in ascending order: $1,2,3,4,5,6,7,8,9,10,10,13$ this is acceptable but we have to check for all values of $e$ that produce terms

[^0]which may form a 4-term arithmetic progression and as we can see from diagram 1 this happens for $d=3, e=4$, so 13 has to be rejected. However, for $d=5, e=5$ no 4-term arithmetic progression is formed and $e=6$ does not produce terms that need to be checked, hence $a_{9}=15$.

| $c^{\prime}=5$ | $e=5$ |  |  |  |  | 5 |  |  |  |  | 10 |  |  |  |  | 15 | accept 15 |

Diagram 1 . To find the $9^{m}$ term of the 4 -term non-arithmetic progression.
Routines for ordering an array in ascending order and checking for duplication of terms were included in a $Q B A S I C$ program to implement the above strategy.

Diagram 2. $a_{k} / k$ for non-arithmetic progressions with $t=3.4,5, \ldots$. 15 . Bars are shown for $k=$ multiples of 10 .

Results and observations: Calculations were carried out for $3 \leq t \leq 15$ to find the first 100 terms of each sequence. The first 65 terms and the $100^{\text {th }}$ term are shown in table 1 . In diagram 2 the fractions $a_{k} / k$ has been chosen as a measure of the density of these sequences. The looser the terms are packed the larger is $a_{k} / k$. In fact for $t>100$ the value of $a_{k} / k=1$ for the first 100 terms.

In table 1 there is an interesting leap for $t=3$ between the $64^{\text {th }}$ and the $65^{\text {th }}$ terms in that $a_{64}=365$ and $a_{65}=730$. Looking a little closer at such leaps we find that:

Table 1. The 65 first terms of the non-arithmetic progressions for $t=3$ to 15 .

| 100 | 977 | 360 | 179 | 183 | 130 | 139 | 138 | 126 | 109 | 109 | 108 | 108 | 113 |

| Leap starts at | Leap finishes at |  |  |
| :--- | :--- | :--- | :--- |
| 5 |  | 10 |  |
| 14 | $=3 \cdot 5-1$ | 28 | $=2.14$ |
| 41 | $=3 \cdot 14-1$ | 82 | $=2.41$ |
| 122 | $=3.41-1$ | 244 | $=2.122$ |
| 365 | $=3.122-1$ | 730 | $=2.365$ |

Does this chain of regularity continue indefinitely?
Sometimes it is easier to look at what is missing than to look at what we have. Here are some observations on the only excluded integers when forming the first 100 terms for $t=11,12,13$ and 14 .

For $t=11: 11,22,33,44,55,66,77,88,99 \quad$ The $n t h$ missing integer is $11 \cdot n$
For $\mathrm{t}=12: 12,23,34,45,56,67,78,89,100 \quad$ The n th missing integer is $11 \cdot \mathrm{n}+1$

For $t=13: 13,26,39,52,65,78,91,104$
The n th missing integer is $13 \cdot \mathrm{n}$

For $t=14: 14,27,40,53,66,79,92,105$
The n th missing integer is $13 \cdot \mathrm{n}+1$
Do these regularities of missing integers continue indefinitely? What about similar observations for other values of $t$ ?

## II. The Prime-Product Sequence

The prime-product sequence originates from Smarandache Notions. It was presented to readers of the Personal Computer World's Numbers Count Column in February 1997.

Definition: The terms of the prime-product sequence are defined through $\left\{t_{n}: t_{n}=p_{n} \#+1, p_{n}\right.$ is the $n t h$ prime number\}, where $p_{n} \#$ denotes the product of all prime numbers which are less than or equal to $\mathrm{p}_{\mathrm{n}}$.

The sequence begins $\{3,7,31,211,2311,30031, \ldots\}$. In the initial definition of this sequence $t_{1}$ was defined to be equal to 2 . However, there seems to be no reason for this exception.

Question: How many members of this sequence are prime numbers?
The question is in the same category as questions like 'How many prime twins are there?, How many Carmichael numbers are there?, etc.' So we may have to contend ourselves by finding how frequently we find prime numbers when examining a fairly large number of terms of this sequence.

From the definition it is clear that the smallest prime number which divides $t_{n}$ is larger than $p_{n}$. The terms of this sequence grow rapidly. The prime number functions prmdiv(n) and $n x t p r m(n)$ built into the Ubasic programming language were used to construct a prime factorization program for $n<10^{19}$. This program was used to factorize the 18 first terms of the sequence. An elliptic curve factorization program, ECM.UB, conceived by Y. Kida was adapted to generate and factorize further terms up to and including the 49 th term. The result is shown in table 2 . All terms analysed were found to be square free. A scatter diagram, Diagram 3, illustrates how many prime factors there are in each term.

The 50 th term presented a problem. $\mathrm{t}_{50}=126173 \cdot \mathrm{n}$, where n has at least two factors. At this point prime factorization begins to be too time consuming and after a few more terms the numbers will be too large to handle with the above mentioned program. To obtain more information the method of factorizing was given up in favor of using Fermat's theorem to eliminate terms which are definitely not prime numbers. We recall Fermat's little theorem:

If $p$ is a prime number and $(a, p)=1$ then $a^{p-1} \equiv 1(\bmod p)$.
$a^{n-1} \equiv 1(\bmod n)$ is therefore a necessary but not sufficient condition for $n$ to be a prime number. If $n$ fills the congruence without being a prime number then $n$ is called a pseudo prime to the base $a$, $\operatorname{psp}(\mathrm{a})$. We will proceed to find all terms in the sequence which fill the congruence

$$
a^{t_{n}-1} \equiv 1\left(\bmod t_{n}\right)
$$

for $50 \leq n \leq 200$. $\mathrm{t}_{200}$ is a 513 digit number so we need to reduce the powers of a to the modulus $\mathrm{t}_{\mathrm{n}}$ gradually as we go along. For this purpose we write $t_{n}-1$ to the base 2 :

$$
\mathrm{t}_{\mathrm{n}}-1=\sum_{k=1}^{m} \delta(k) \cdot 2^{k}, \text { where } \delta(\mathrm{k}) \varepsilon\{0,1\}
$$

From this we have

$$
a^{t_{n}-1}=\prod_{k=1}^{m} a^{\delta(k) \cdot 2^{k}}
$$

Diagram 3. The number of prime factors in the first 49 terms of the prime-product sequence.
This product expression for $a^{t_{n}-1}$ is used in the following Ubasic program to carry out the reduction of $a^{t_{n}-1}$ modulus $t_{n}$. Terms for which $\delta(k)=0$ are ignored in the expansion were the exponents $k$ are contained in the array $E \%$. The residue modulus $t_{n}$ is stored in $F$. In the program below the reduction is done to base $\mathrm{A}=7$.

This program revealed that there are at most three terms $t_{n}$ of the sequence in the interval $50 \leq n \leq 200$ which could be prime numbers. These are:

Term \#172. $N=1021 \#+1 . N$ is a 428 digit number.
$\mathrm{N}=208325544418697180526278559204028744572686528568890074734049007840181457187286244301915872863$ 160885721486313893793092847430169408859808718870830265977538813177726058850383316252820523111213 067921935404833217036456300717761688853571267150232508655634427663661803312009807112476455894240 568090534683239067457957262234684834336252590008874119591973239736134883450319130587753586846905 76146066276875058596100236112260054944287636531

The last two primes or pseudo primes are remarkable in that they are generated by the prime twins 1019 and 1021.

Summary of results: The number of primes $q$ among the first 200 terms of the prime-product sequence is given by $6 \leq q \leq 9$. The six confirmed primes are terms numero $1,2,3,4,5$ and 11 . The three terms which are either primes or pseudo primes are terms numero 75, 171 and 172. The latter two are the terms $1019 \#+1$ and $1021 \#+1$.

## III. The Square-Product Sequence

Definition: The terms of the square-product sequence are defined through $\left\{\mathrm{t}_{\mathrm{n}}: \mathrm{t}_{\mathrm{n}}=(\mathrm{n}!)^{2}+1\right\}$
This sequence has a structure which is similar to the prime-product sequence. The analysis is therefore carried out almost identically to the one done for the prime-product sequence. We merely have to state the results and compare them.

The sequence begins $\{2,5,37,577,14401,518401, \ldots\}$
As for the prime-product sequence the question of how many are prime numbers has been raised and we may never know. There are similarities between these two sequences. There are quite a few primes among the first terms. After that they become more and more rare. Complete factorization of the 37 first terms of the square-product sequence was obtained and has been used in diagram 4 which should be compared with the corresponding diagram 3 for the prime-product sequence.

[^1]Diagram 4 is based on table 3 which shows the prime factorization of the 40 first terms in the squareproduct sequence. The number of factors of each term is denoted f . The factorization is not complete for terms numero 38 and 39 . A + -sign in the column for findicates that the last factor is not a prime. The terms of this sequence are in general much more time consuming to factorize than those of the prime-product sequence which accounts for the more limited results in this section. Using the same method as for the prime-product sequence the terms $t_{n}$ in the interval $40<n<200$ which may possible be primes were identified. There are only two of them:

Term \#65. $\mathrm{N}=165!$ 1 $^{2}+1 . \mathrm{N}$ is a 182 digit number.
680237402890783289504507819726222037929025769532713580342793801040271006524643826496596237244465781514128589 96571534385340563792951822384455180747800576000000000000000000000000000001

Term \#76 $\mathrm{N}=\left(7611^{2}+1 . \mathrm{N}\right.$ is a 223 digit number.

## IV. The Smarandache Prime-Digital Sub-Sequence

Definition: The prime-digital sub-sequence is the set $\left\{M=a_{0}+a_{1} \cdot 10+a_{2} \cdot 10^{2}+\ldots a_{k} 10^{k}: M\right.$ is a prime and all digits $\mathrm{a}_{0}, \mathrm{a}_{1}, \mathrm{a}_{2} \ldots \mathrm{a}_{\mathrm{k}}$ are primes $\}$

The first terms of this sequence are $\{2,3,5,7,23,37,53,73, \ldots\}$. Sylvester Smith [1] conjectured that this sequence is infinite. In this paper we will prove that this sequence is in fact infinite. Let's first calculate some more terms of the sequence and at the same time find how many terms there is in the sequence in a given interval, say between $10^{k}$ and $10^{k+1}$. The program below is written in Ubasic. One version of the program has been used to produce table 4 showing the first 100 terms of the sequence. The output of the actual version has been used to produce the calculated part of table 5 which we are going to compare with the theoretically estimated part in the same table.

## Ubasic program

## Theorem:

The Smarandache prime-digital sub sequence is infinite.

Proof:
We recall the prime counting function $\pi(x)$. The number of primes $\mathrm{p} \leq \mathrm{x}$ is denoted $\pi(\mathrm{x})$. For sufficiently large values of $x$ the order of magnitude of $\pi(x)$ is given by $\pi(x) \approx \frac{x}{\log x}$. Let a and $b$ be digits such that $a>b \neq 0$ and $n(a, b, k)$ be the approximate number of primes in the interval ( $b \cdot 10^{k}, a \cdot 10^{k}$ ). Applying the prime number counting theorem we then have:

$$
\begin{equation*}
n(a, b, k) \approx \frac{10^{k}}{k}\left(\frac{a}{\log 10+\frac{\log a}{k}}-\frac{b}{\log 10+\frac{\log b}{k}}\right) \tag{1}
\end{equation*}
$$

Potential candidates for members of the prime-digital sub sequence will have first digits $2,3,5$ or 7 , i.e. for a given $k$ they will be found in the intervals $\left(2 \cdot 10^{k}, 4 \cdot 10^{k}\right),\left(5 \cdot 10^{k}, 6 \cdot 10^{k}\right)$ and $\left(7 \cdot 10^{k}, 8 \cdot 10^{k}\right)$. The approximate number of primes $n(k)$ in the interval ( $10^{k}, 10^{k+1}$ ) which might be members of the sequence is therefore:

$$
\begin{equation*}
\mathrm{n}(\mathrm{k})=\mathrm{n}(4,2, \mathrm{k})+\mathrm{n}(6,5, \mathrm{k})+\mathrm{n}(8,7, \mathrm{k}) \tag{2}
\end{equation*}
$$

The theoretical estimates of n in table 5 are calculated using (2) ignoring the fact that results may not be all that good for small values of $k$.

We will now find an estimate for the number of candidates $\mathrm{m}(\mathrm{k})$ which qualify as members of the sequence. The final digit of a prime number $>5$ can only be $1,3,7$ or 9 . Assuming that these will occur with equal probability only half of the candidates will qualify. The first digit is already fixed by our selection of intervals. For the remaining $k-1$ digits we have ten possibilities, namely $0,1,2,3,4,5,6,7,8$ and 9 of which only $2,3,5$ and 7 are good. The probability that all $\mathrm{k}-1$ digits are good is therefore $(4 / 10)^{k-1}$. The probability $q$ that a candidate qualifies as a member of the sequence is

$$
\begin{equation*}
q=\frac{1}{2} \cdot\left(\frac{4}{10}\right)^{k-1} \tag{3}
\end{equation*}
$$

The estimated number of members of the sequence in the interval $\left(10^{k}, 10^{k+1}\right)$ is therefore given by $\mathrm{m}(\mathrm{k})=\mathrm{q} \cdot \mathrm{n}(\mathrm{k})$. The estimated values are given in table 5. A comparison between the computer count and the theoretically estimated values shows a very close fit as can be seen from diagram 5 where $\log _{10} \mathrm{~m}$ is plotted against k .

Diagram 5. logio $m$ as a function of $k$. The upper curve corresponds to the computer count.
For large values of k we can ignore the terms $\frac{\log a}{k}$ and $\frac{\log b}{k}$ in comparison with $\log 10$ in (1). For large k we therefore have

$$
n(a, b, k) \approx \frac{(a-b) 10^{k}}{k \log 10}
$$

and (2) becomes

$$
\begin{equation*}
n(k) \approx \frac{4 \cdot 10^{k}}{k \log 10} \tag{2'}
\end{equation*}
$$

Combining this with (3) we get

$$
\begin{equation*}
m(k) \approx \frac{5 \cdot 2^{2 k}}{k \log 10} \tag{4}
\end{equation*}
$$

From which we see (apply for instance l'Hospital's rule) that $\mathrm{m}(\mathrm{k}) \rightarrow \infty$ as $\mathrm{k} \rightarrow \infty$. A fortiori the primedigital sub sequence is infinite.

## V. Smarandache Concatenated Sequences

Smarandache formulated a series of very artificially conceived sequences through concatenation. The sequences studied below are special cases of the Smarandache Concatenated $S$-sequence.

Definition: Let $\mathrm{G}=\left\{\mathrm{g}_{1}, \mathrm{~g}_{2}, \ldots . \mathrm{g}_{\mathrm{k}}, \ldots.\right\}$ be an ordered set of positive integers with a given property G . The corresponding concatenated S.G sequence is defined through

$$
S . G=\left\{a_{i}: a_{1}=g_{1}, a_{k}=a_{k-1} \cdot 10^{1+\log _{10} g_{k}}+g_{k}, k \geq 1\right\}
$$

In table 6 the first 20 terms are listed for three cases, which we will deal with in some detail below.
Table 6. The first 20 terms of three concatenated sequences

Case I. The S.odd sequence is generated by choosing $G=\{1,3,5,7,9,11, \ldots .$.$\} . Smarandache asks how$ many terms in this sequence are primes and as is often the case we have no answer. But for this and the other concatenated sequences we can take a look at a fairly large number of terms and see how frequently we find primes or potential primes. As in the case of prime-product sequence we will resort to Fermat's little theorem to find all primes/pseudo-primes among the first 200 terms. If they are not too big wee can then proceed to test if they are primes. For the S.odd sequence there are only five cases which all were confirmed to be primes using the elliptic curve prime factorization program. In table 7 \# is the term number, L is the number of digits of N and N is a prime number member of the S.odd sequence.:

Table 7. Prime numbers in the S.odd sequence

| $\#$ | L | N |
| :--- | :--- | :--- |
| 2 | 2 | 13 |
| 10 | 15 | 135791113151719 |
| 16 | 27 | 135791113151719212325272931 |
| 34 | 63 | 135791113151719212325272931333537394143454749515355575961636567 |
| 49 | 93 | 135791113151719212325272931333537394143454749515355575961636567697173757779818385878991939597 |

Term \#201 is a 548 digit number.
Case 2. The S.even sequence is generated by choosing $G=\{2,4,6,8,10, \ldots \ldots\}$. The question here is : How many terms are nth powers of a positive integer?

A term which is a $n t h$ power must be of the form $2^{n}$ a where a is an odd nth power. The first step is therefore to find the highest power of 2 which divides a given member of the sequence, i.e. to determine n and at the same time we will find a. We then have to test if a is a $\mathrm{n} t h$ power. The Ubasic program below has been implemented for the first 200 terms of the sequence. No $n t h$ powers were fond.

Ubasic program: (only the essential part of the program is isted)

```
6 0 N = 2
70 for U%=4 to 400 step 2
80 D%=int(log(U%)/log(10))+1 'Determine length of U%
90 N=N*'10^D%+U% 'Concatenate U%
100 A=N:E%=0
110 repeat
120 Al=A:A=A\2:inc E% 'Determine E% (=n)
130 unfil res<<0
```

```
132 dec E%:A=Al 'Determine A (=a)
140 B=round(A^(1/E%))
150 if B^E%=A then print E%,N 'Check if a is a nthpower
160 next
170 end
```

So there is not even a perfect square among the first 200 terms of the S.even sequence. Are there terms in this sequence which are $2 \cdot \mathrm{p}$ where p is a prime (or pseudo prime). With a small change in the program used for the S.odd sequence we can easily find out. Strangely enough not a single term was found to be of the form $2 \cdot \mathrm{p}$.

Case 3. The S.prime sequence is generated by $\{2,3,5,7,11, \ldots\}$. Again we ask: - How many are primes? - and again we apply the method of finding the number of primes/pseudo primes among the first 200 terms.

There are only 4 cases to consider. Terms \#2 and \#4 are primes, namely 23 and 2357. The other two cases are: term \#128 which is a 355 digit number and term \#174 which is a 499 digit number.

```
#128

Are these two numbers prime numbers?

[^0]:    ${ }^{1}$ This question is slightly different from the one posed in the Personal Computer World where aiso a wider definition of a t-term non arithmetic progression is used in that it allows $a_{2}>_{1}$ to be chosen arbitrarily.

[^1]:    Diagram 4. The number of prime factors in the first 40 terms of the square-product sequence.
