Rating Estimation in MD Recommender Systems

Combined Reduction-Based and Traditional CF Approaches

Multi-Level Rating Estimation Problem

Implementation and Evaluation of MD Approach

Experimental Setup

Evaluating the Reduction-Based Approach

Performance Metric

Will help to determine which method performs better

- ▶ MAE is an example of statistical accuracy measure
- ▶ F-measure is an example of decision-support accuracy metric
- ▶ The latter suit recommender systems better

$\mu_{A,X}(Y)$ is an **abstract performance metric** where

- ▶ A – a recommendation algorithm
- ▶ X – training set of known ratings
- ▶ Y – evaluation set of known ratings , where $X \cup Y = \emptyset$

Performance Metric II

For each $d \in Y$

- ▶ $d.R$ is user-specified rating for that data point
- ▶ $d.R_{A,X}$ is rating predicted by algorithm A trained on X

Then $\mu_{A,X}(Y)$ for MAE is defined as

$$\mu_{A,X}(Y) = \frac{1}{|Y|} \sum_{d \in Y} |d.R_{A,X} - d.R|$$

We assume that A is a traditional collaborative filtering method

Combined Approach

1. Use known ratings to **determine contextual segments** that outperform traditional CF method (offline)
2. **Predict the rating** by using the best contextual segment and the 2D recommendation algorithm (real-time)

Determining High-Performing Contextual Segments

Input: $T, R_{A,T}, \mu, N$

Output: $SEGM(T)$ - a set of contextual segments on which the reduction-based approach on algorithm A outperforms the pure algorithm A.

Algorithm:

1. Let $SEGM(T)$ initially be the set of all **large** contextual segments for the set or ratings T .
2. For each segment $S \in SEGM(T)$ compute $\mu_{A,S}(S)$ and $\mu_{A,T}(S)$. Keep only those for which $\mu_{A,S}(S) \gg \mu_{A,T}(S)$
3. Discard $S \in SEGM(T)$ for which $\exists Q : S \subset Q, \mu_{A,Q}(Q) > \mu_{A,S}(S)$

Estimating the Rating

Input: $SEGM(T) = \{S_1, \dots, S_k\}$ where $\mu_{A,S_i}(S_i) \geq \mu_{A,S_j}(S_j), i \geq j$

d – data point for which we want to estimate the rating

Output: $d.R$ – estimated rating for d .

Algorithm:

Multi-Level Rating Estimation Problem

Implementation and Evaluation of MD Approach

Experimental Setup

Evaluating the Reduction-Based Approach

Multi-Level Rating Estimation Problem

Estimate unknown individual ratings in terms of known aggregate and known individual ratings.

▶ $R(JD, action) = 6$

▶ $R(JD, Gladiator) = 7$

▶ $R(JD, Matrix) = 3$

⇒ $R(JD, OtherMovie) = ?$

More Formal Definition

Assume

- ▶ $R_a(JD, action)$ actual rating assigned by JD himself
- ▶ $R_c(JD, action)$ rating computed from individual ratings $R(JD, x)$
- ▶ X_r a set of action movies that John has already rated
- ▶ X_{nr} a set of yet unrated action movies, $X_r \cup X_{nr} = action$

Assign ratings to $R(JD, x), x \in X_{nr}$ to minimize

$$|R_a(JD, action) - R_c(JD, action)|$$

- ▶ There might be infinite number of solutions

Linear Example

Assume

- ▶ AVG is the aggregation function
- ▶ $X_{nr} = \{y_1, \dots, y_k\}$

Then we want to find $R(JD, y_1), \dots, R(JD, y_k)$ s.t.

- ▶ $R(JD, y_1) + \dots + R(JD, y_k) = c$
- ▶ $c = (|X_r| + |X_{nr}|) \cdot R_a(JD, action) - \sum_{x \in X_r} R(JD, x)$

Another Reason for Aggregate Hierarchies

Under some assumptions

- ▶ The estimation error for aggregate rating is smaller than the estimation error for individual ratings.

The assumptions are

- ▶ the rating estimation function $R_c(u, i) = R_a(u, i) + \varepsilon(\mu, \sigma^2)$
- ▶ the rating aggregation function (AVG)
- ▶ the accuracy measure (MAE)

The general case is an open research question.

Rating Estimation in MD Recommender Systems

Combined Reduction-Based and Traditional CF Approaches

Multi-Level Rating Estimation Problem

Implementation and Evaluation of MD Approach

Experimental Setup

Evaluating the Reduction-Based Approach

Setup for Evaluation

- ▶ Implement a movie RS
- ▶ Unlike MovieLens add contextual information
 - ▶ *When, Where, With whom*
- ▶ No aggregation hierarchies
 - ▶ Show that contextual information does matter
 - ▶ Reduction-based approach does not fit with aggregation hierarchies
 - ▶ Use of hierarchies requires larger amounts of more detailed data

Contextual Dimensions

- ▶ Time (*Weekday, weekend, don't remember*)
 - ▶ If seen on weekend, was it opening weekend for the movie (*yes, no, don't remember*)
- ▶ Place (*cinema, home, don't remember*)
- ▶ Companion (*alone, with friends, boyfriend/girlfriend, family, others*)

Data Collection

- ▶ Rate movies from 1 to 13
- ▶ Participants were 117 college students
- ▶ 1755 ratings entered over a period of 12 months
- ▶ Those who rated fewer than 10 movies were dropped out
- ▶ Finally 1457 ratings from 62 students for 202 movies
- ▶ 10% - evaluation dataset (D_E)
- ▶ 90% - modelling dataset (D_M)

Significance of Dimensions

Which dimensions make significant difference in rating estimations?

- ▶ Partition ratings into categories, e.g. *Time* and *Place*
- ▶ Compute average rating per student in each category
- ▶ Apply a paired comparison test (t-test)

All dimensions appear to be significant.
