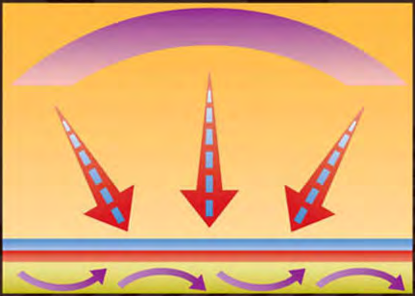
FUNDAMENTALS OF HEAT and MASS TRANSFER

SEVENTH EDITION



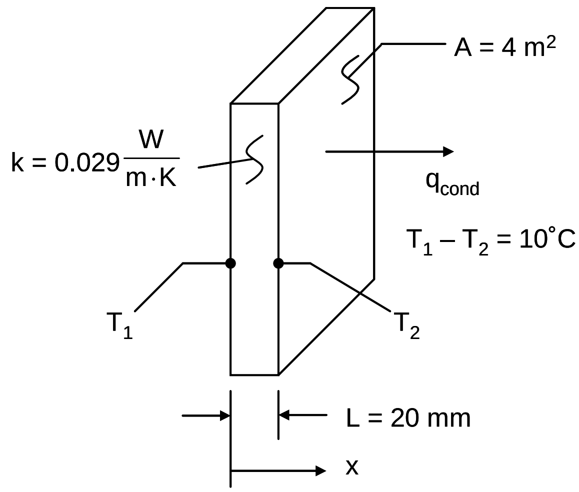
INSTRUCTOR'S SOLUTIONS MANUAL

PROBLEM 1.1

KNOWN: Thermal conductivity, thickness and temperature difference across a sheet of rigid extruded insulation.

FIND: (a) The heat flux through a 2 m × 2 m sheet of the insulation, and (b) The heat rate through the sheet.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in the x-direction, (2) Steady-state conditions, (3) Constant properties.

ANALYSIS: From Equation 1.2 the heat flux is

$$q''_x = -k\frac{dT}{dx} = k\frac{T_1 - T_2}{L}$$

Solving,

$$q''_x = 0.029\frac{W}{m \cdot K} \times \frac{10\ K}{0.02\ m}$$

$$q''_x = 14.5\frac{W}{m^2}$$ <

The heat rate is

$$q_x = q''_x \cdot A = 14.5\frac{W}{m^2} \times 4\ m^2 = 58\ W$$ <

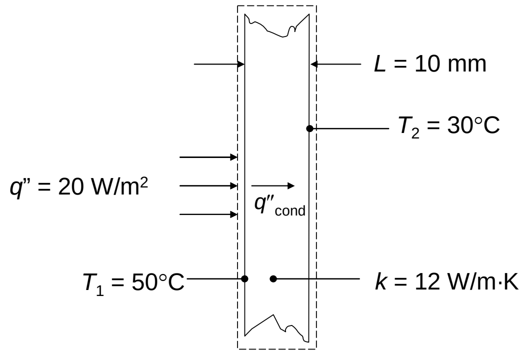
COMMENTS: (1) Be sure to keep in mind the important distinction between the heat flux (W/m^2) and the heat rate (W). (2) The direction of heat flow is from hot to cold. (3) Note that a temperature *difference* may be expressed in kelvins or degrees Celsius.

PROBLEM 1.2

KNOWN: Thickness and thermal conductivity of a wall. Heat flux applied to one face and temperatures of both surfaces.

FIND: Whether steady-state conditions exist.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) No internal energy generation.

ANALYSIS: Under steady-state conditions an energy balance on the control volume shown is

$$q''_{\text{in}} = q''_{\text{out}} = q''_{\text{cond}} = k(T_1 - T_2)/L = 12\ \text{W/m}\cdot\text{K}(50°\text{C} - 30°\text{C})/0.01\ \text{m} = 24{,}000\ \text{W/m}^2$$

Since the heat flux in at the left face is only 20 W/m^2, the conditions are not steady state. <

COMMENTS: If the same heat flux is maintained until steady-state conditions are reached, the steady-state temperature difference across the wall will be

$$\Delta T = q''L/k = 20\ \text{W/m}^2 \times 0.01\ \text{m}/12\ \text{W/m}\cdot\text{K} = 0.0167\ \text{K}$$

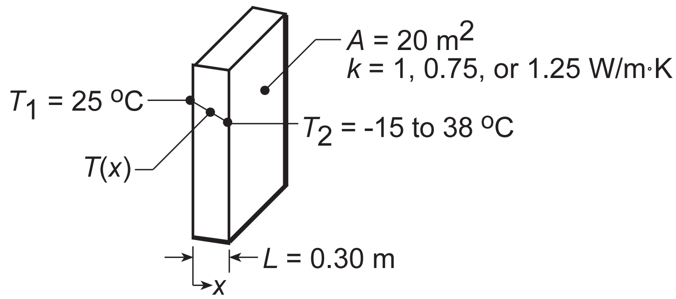
which is much smaller than the specified temperature difference of 20°C.

PROBLEM 1.3

KNOWN: Inner surface temperature and thermal conductivity of a concrete wall.

FIND: Heat loss by conduction through the wall as a function of outer surface temperatures ranging from -15 to 38°C.

SCHEMATIC:



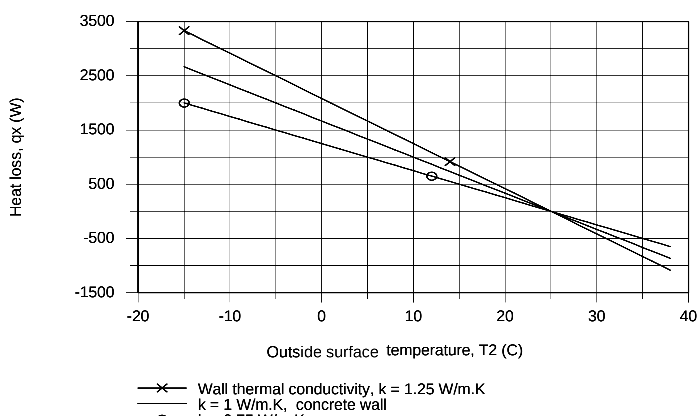
ASSUMPTIONS: (1) One-dimensional conduction in the x-direction, (2) Steady-state conditions, (3) Constant properties.

ANALYSIS: From Fourier's law, if q_x'' and k are each constant it is evident that the gradient, $dT/dx = -q_x''/k$, is a constant, and hence the temperature distribution is linear. The heat flux must be constant under one-dimensional, steady-state conditions; and k is approximately constant if it depends only weakly on temperature. The heat flux and heat rate when the outside wall temperature is T_2 = -15°C are

$$q_x'' = -k\frac{dT}{dx} = k\frac{T_1 - T_2}{L} = 1\,W/m\cdot K\,\frac{25^\circ C - \left(-15^\circ C\right)}{0.30\,m} = 133.3\,W/m^2 . \qquad (1)$$

$$q_x = q_x'' \times A = 133.3\,W/m^2 \times 20\,m^2 = 2667\,W . \qquad (2) <$$

Combining Eqs. (1) and (2), the heat rate q_x can be determined for the range of outer surface temperature, $-15 \le T_2 \le 38°C$, with different wall thermal conductivities, k.



For the concrete wall, k = 1 W/m·K, the heat loss varies linearly from +2667 W to -867 W and is zero when the inside and outer surface temperatures are the same. The magnitude of the heat rate increases with increasing thermal conductivity.

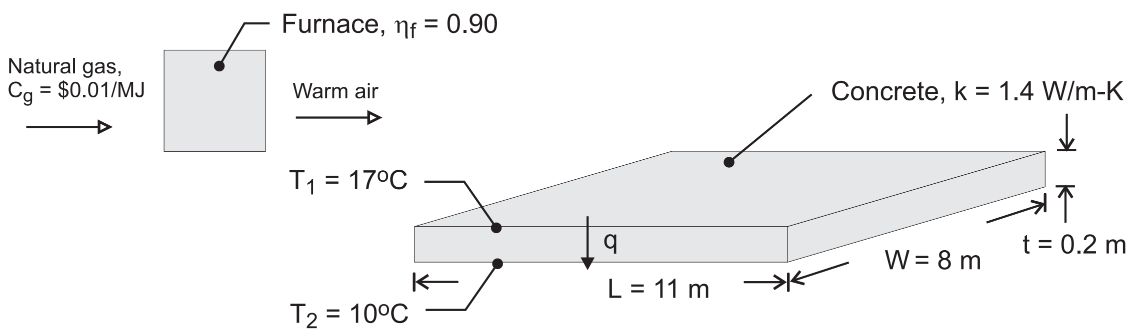
COMMENTS: Without steady-state conditions and constant k, the temperature distribution in a plane wall would not be linear.

PROBLEM 1.4

KNOWN: Dimensions, thermal conductivity and surface temperatures of a concrete slab. Efficiency of gas furnace and cost of natural gas.

FIND: Daily cost of heat loss.

SCHEMATIC:



ASSUMPTIONS: (1) Steady state, (2) One-dimensional conduction, (3) Constant properties.

ANALYSIS: The rate of heat loss by conduction through the slab is

$$q = k\,(LW)\frac{T_1 - T_2}{t} = 1.4\,W/m\cdot K\,(11\,m \times 8\,m)\frac{7°C}{0.20\,m} = 4312\ W \qquad <$$

The daily cost of natural gas that must be combusted to compensate for the heat loss is

$$C_d = \frac{q\,C_g}{\eta_f}(\Delta t) = \frac{4312\,W \times \$0.02/MJ}{0.9 \times 10^6 J/MJ}(24\,h/d \times 3600\,s/h) = \$8.28/d \qquad <$$

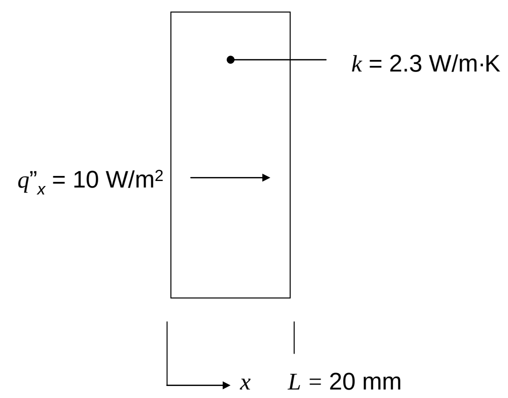
COMMENTS: The loss could be reduced by installing a floor covering with a layer of insulation between it and the concrete.

PROBLEM 1.5

KNOWN: Thermal conductivity and thickness of a wall. Heat flux through wall. Steady-state conditions.

FIND: Value of temperature gradient in K/m and in °C/m.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties.

ANALYSIS: Under steady-state conditions,

$$\frac{dT}{dx} = -\frac{q_x''}{k} = -\frac{10\ \text{W/m}^2}{2.3\ \text{W/m}\cdot\text{K}} = -4.35\ \text{K/m} = -4.35\ °\text{C/m} \qquad <$$

Since the K units here represent a temperature *difference*, and since the temperature difference is the same in K and °C units, the temperature gradient value is the same in either units.

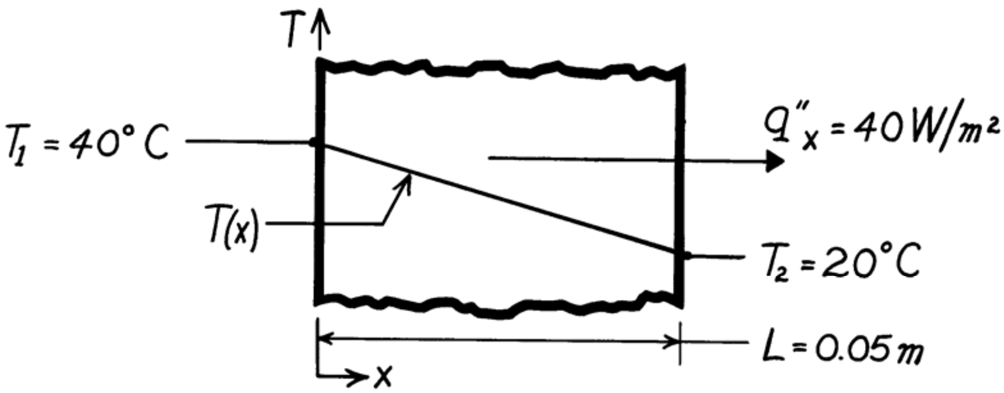
COMMENTS: A negative value of temperature gradient means that temperature is decreasing with increasing *x*, corresponding to a positive heat flux in the *x*-direction.

PROBLEM 1.6

KNOWN: Heat flux and surface temperatures associated with a wood slab of prescribed thickness.

FIND: Thermal conductivity, k, of the wood.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in the x-direction, (2) Steady-state conditions, (3) Constant properties.

ANALYSIS: Subject to the foregoing assumptions, the thermal conductivity may be determined from Fourier's law, Eq. 1.2. Rearranging,

$$k = q''_x \frac{L}{T_1 - T_2} = 40 \frac{W}{m^2} \frac{0.05m}{(40\text{-}20)^\circ C}$$

$$k = 0.10 \; W/m \cdot K. \qquad <$$

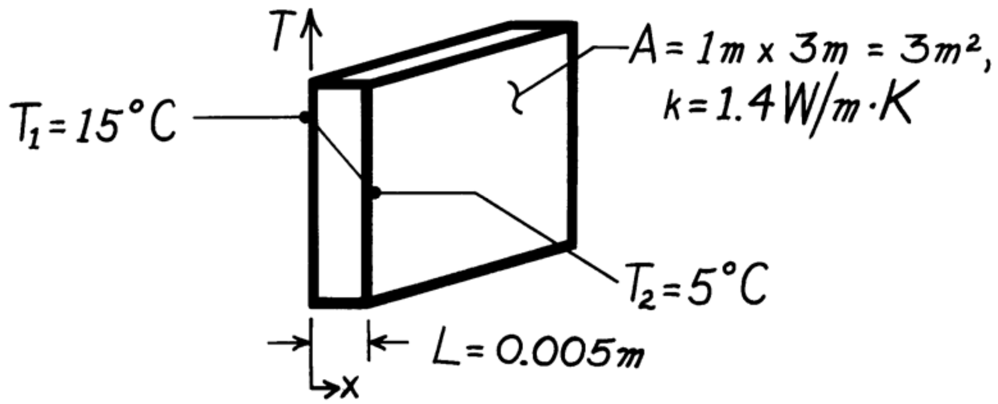
COMMENTS: Note that the °C or K temperature units may be used interchangeably when evaluating a temperature difference.

PROBLEM 1.7

KNOWN: Inner and outer surface temperatures of a glass window of prescribed dimensions.

FIND: Heat loss through window.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in the x-direction, (2) Steady-state conditions, (3) Constant properties.

ANALYSIS: Subject to the foregoing conditions the heat flux may be computed from Fourier's law, Eq. 1.2.

$$q''_x = k \frac{T_1 - T_2}{L}$$

$$q''_x = 1.4 \frac{W}{m \cdot K} \frac{(15\text{-}5)^\circ C}{0.005m}$$

$$q''_x = 2800 \ W/m^2.$$

Since the heat flux is uniform over the surface, the heat loss (rate) is

$$q = q''_x \times A$$

$$q = 2800 \ W/m^2 \times 3m^2$$

$$q = 8400 \ W.$$ <

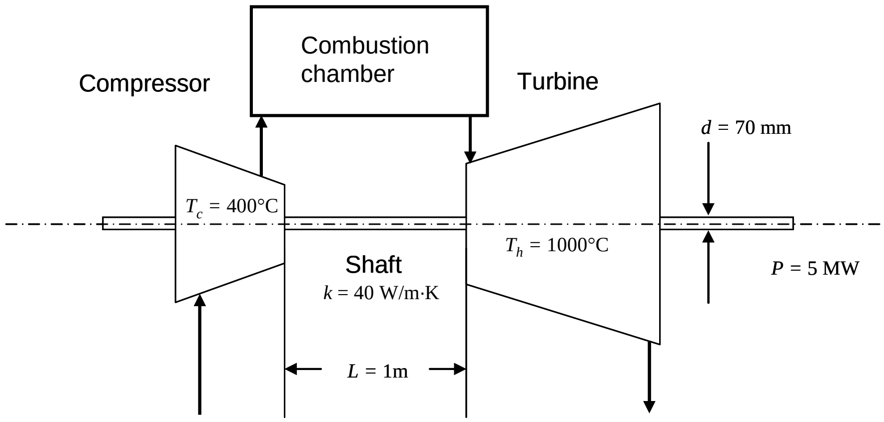
COMMENTS: A linear temperature distribution exists in the glass for the prescribed conditions.

PROBLEM 1.8

KNOWN: Net power output, average compressor and turbine temperatures, shaft dimensions and thermal conductivity.

FIND: (a) Comparison of the conduction rate through the shaft to the predicted net power output of the device, (b) Plot of the ratio of the shaft conduction heat rate to the anticipated net power output of the device over the range $0.005\text{ m} \le L \le 1\text{ m}$ and feasibility of a $L = 0.005$ m device.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Net power output is proportional to the volume of the gas turbine.

PROPERTIES: Shaft (given): k = 40 W/m·K.

ANALYSIS: (a) The conduction through the shaft may be evaluated using Fourier's law, yielding

$$q = q''A_c = \frac{k(T_h - T_c)}{L}\left(\pi d^2/4\right) = \frac{40\text{W/m}\cdot\text{K}(1000-400)°\text{C}}{1\text{m}}\left(\pi(70\times10^{-3}\text{m})^2/4\right) = 92.4\text{W}$$

The ratio of the conduction heat rate to the net power output is

$$r = \frac{q}{P} = \frac{92.4\text{W}}{5\times10^6\text{W}} = 18.5\times10^{-6}$$ <

(b) The volume of the turbine is proportional to L^3. Designating L_a = 1 m, d_a = 70 mm and P_a as the shaft length, shaft diameter, and net power output, respectively, in part (a),

$$d = d_a \times (L/L_a);\ P = P_a \times (L/L_a)^3$$

and the ratio of the conduction heat rate to the net power output is

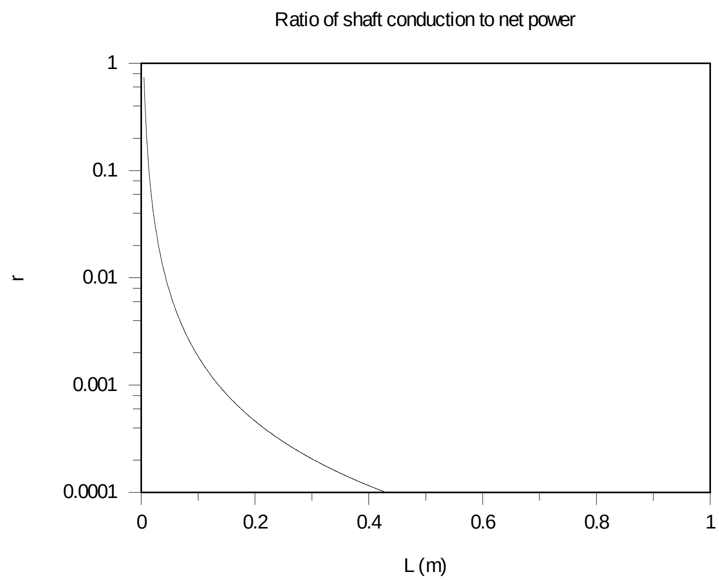
$$r = \frac{q''A_c}{P} = \frac{\dfrac{k(T_h - T_c)}{L}\left(\pi d^2/4\right)}{P} = \frac{\dfrac{k(T_h - T_c)}{L}\left(\pi\left(d_a L/L_a\right)^2/4\right)}{P_a(L/L_a)^3} = \frac{\dfrac{k(T_h - T_c)\pi}{4} d_a^2 L_a/P_a}{L^2}$$

$$= \frac{\dfrac{40\text{W/m}\cdot\text{K}(1000-400)°\text{C}\pi}{4}(70\times10^{-3}\text{m})^2\times1\text{m}/5\times10^6\text{W}}{L^2} = \frac{18.5\times10^{-6}\text{m}^2}{L^2}$$

Continued…

PROBLEM 1.8 (Cont.)

The ratio of the shaft conduction to net power is shown below. At L = 0.005 m = 5 mm, the shaft conduction to net power output ratio is 0.74. The concept of the very small turbine is not feasible since it will be unlikely that the large temperature difference between the compressor and turbine can be maintained. <



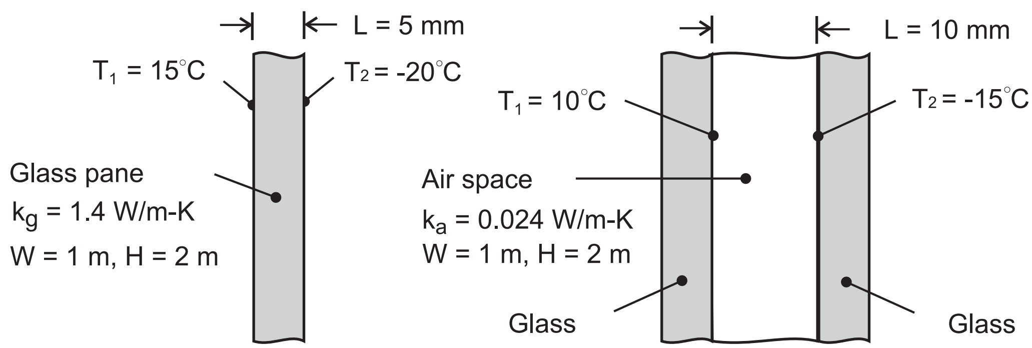
COMMENTS: (1) The thermodynamics analysis does not account for heat transfer effects and is therefore meaningful only when heat transfer can be safely ignored, as is the case for the shaft in part (a). (2) Successful miniaturization of thermal devices is often hindered by heat transfer effects that must be overcome with innovative design.

PROBLEM 1.9

KNOWN: Width, height, thickness and thermal conductivity of a single pane window and the air space of a double pane window. Representative winter surface temperatures of single pane and air space.

FIND: Heat loss through single and double pane windows.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction through glass or air, (2) Steady-state conditions, (3) Enclosed air of double pane window is stagnant (negligible buoyancy induced motion).

ANALYSIS: From Fourier's law, the heat losses are

Single Pane: $$q_g = k_g A \frac{T_1 - T_2}{L} = 1.4\ \text{W/m}\cdot\text{K}\left(2\text{m}^2\right)\frac{35\ ^\circ\text{C}}{0.005\text{m}} = 19,600\ \text{W}$$ <

Double Pane: $$q_a = k_a A \frac{T_1 - T_2}{L} = 0.024\left(2\text{m}^2\right)\frac{25\ ^\circ\text{C}}{0.010\ \text{m}} = 120\ \text{W}$$ <

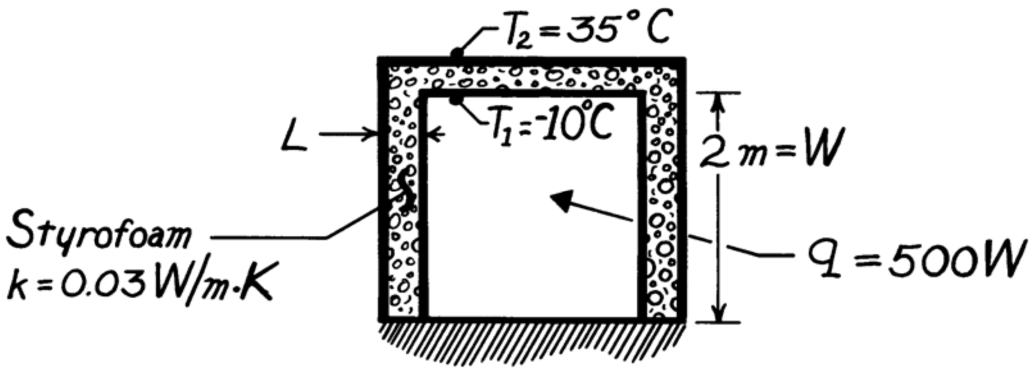
COMMENTS: Losses associated with a single pane are unacceptable and would remain excessive, even if the thickness of the glass were doubled to match that of the air space. The principal advantage of the double pane construction resides with the low thermal conductivity of air (~ 60 times smaller than that of glass). For a fixed ambient outside air temperature, use of the double pane construction would also increase the surface temperature of the glass exposed to the room (inside) air.

PROBLEM 1.10

KNOWN: Dimensions of freezer compartment. Inner and outer surface temperatures.

FIND: Thickness of styrofoam insulation needed to maintain heat load below prescribed value.

SCHEMATIC:



ASSUMPTIONS: (1) Perfectly insulated bottom, (2) One-dimensional conduction through 5 walls of area $A = 4m^2$, (3) Steady-state conditions, (4) Constant properties.

ANALYSIS: Using Fourier's law, Eq. 1.2, the heat rate is

$$q = q'' \cdot A = k \frac{\Delta T}{L} A_{total}$$

Solving for L and recognizing that $A_{total} = 5 \times W^2$, find

$$L = \frac{5\, k\, \Delta T\, W^2}{q}$$

$$L = \frac{5 \times 0.03 \text{ W/m} \cdot \text{K} \left[35 - (-10)\right]^{\circ}\text{C} \left(4\text{m}^2\right)}{500 \text{ W}}$$

$$L = 0.054\text{m} = 54\text{mm}.$$ <

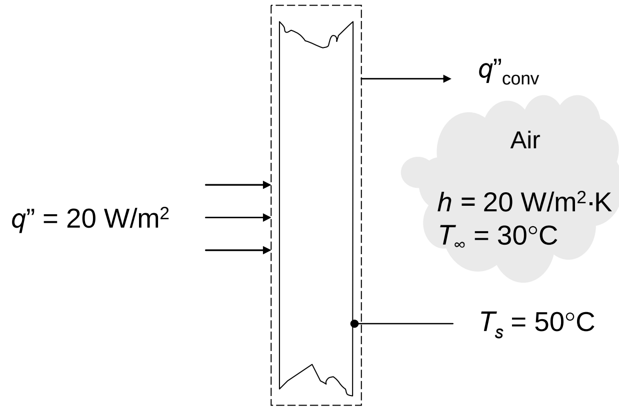
COMMENTS: The corners will cause local departures from one-dimensional conduction and a slightly larger heat loss.

PROBLEM 1.11

KNOWN: Heat flux at one face and air temperature and convection coefficient at other face of plane wall. Temperature of surface exposed to convection.

FIND: If steady-state conditions exist. If not, whether the temperature is increasing or decreasing.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) No internal energy generation.

ANALYSIS: Conservation of energy for a control volume around the wall gives

$$\frac{dE_{st}}{dt} = \dot{E}_{in} - \dot{E}_{out} + \dot{E}_g$$

$$\frac{dE_{st}}{dt} = q''_{in}A - hA(T_s - T_\infty) = \left[q''_{in} - h(T_s - T_\infty)\right]A$$

$$= \left[20\ \text{W/m}^2 - 20\ \text{W/m}^2 \cdot \text{K}(50°\text{C} - 30°\text{C})\right]A = -380\ \text{W/m}^2 A$$

Since $dE_{st}/dt \neq 0$, the system is not at steady-state. <

Since $dE_{st}/dt < 0$, the stored energy is decreasing, therefore the wall temperature is decreasing. <

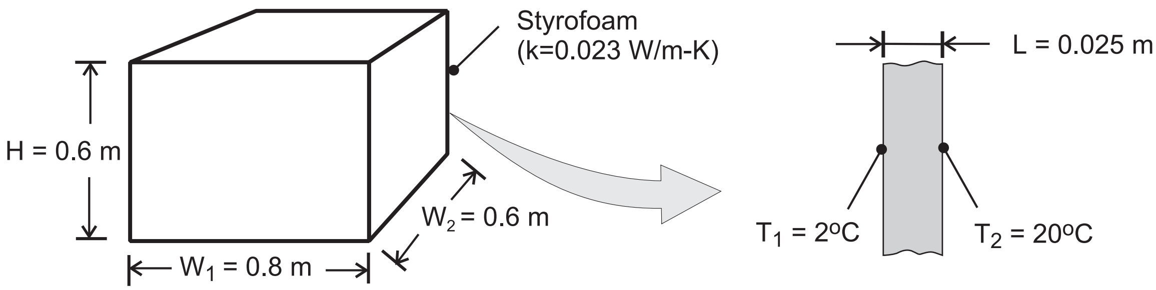
COMMENTS: When the surface temperature of the face exposed to convection cools to 31°C, $q_{in} = q_{out}$ and $dE_{st}/dt = 0$ and the wall will have reached steady-state conditions.

PROBLEM 1.12

KNOWN: Dimensions and thermal conductivity of food/beverage container. Inner and outer surface temperatures.

FIND: Heat flux through container wall and total heat load.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat transfer through bottom wall, (3) Uniform surface temperatures and one-dimensional conduction through remaining walls.

ANALYSIS: From Fourier's law, Eq. 1.2, the heat flux is

$$q'' = k\frac{T_2 - T_1}{L} = \frac{0.023\ \text{W/m}\cdot\text{K}\ (20-2)^\circ\text{C}}{0.025\ \text{m}} = 16.6\ \text{W/m}^2 \qquad <$$

Since the flux is uniform over each of the five walls through which heat is transferred, the heat load is

$$q = q'' \times A_{total} = q''\left[H\left(2W_1 + 2W_2\right) + W_1 \times W_2\right]$$

$$q = 16.6\ \text{W/m}^2\left[0.6\text{m}\left(1.6\text{m} + 1.2\text{m}\right) + \left(0.8\text{m} \times 0.6\text{m}\right)\right] = 35.9\ \text{W} \qquad <$$

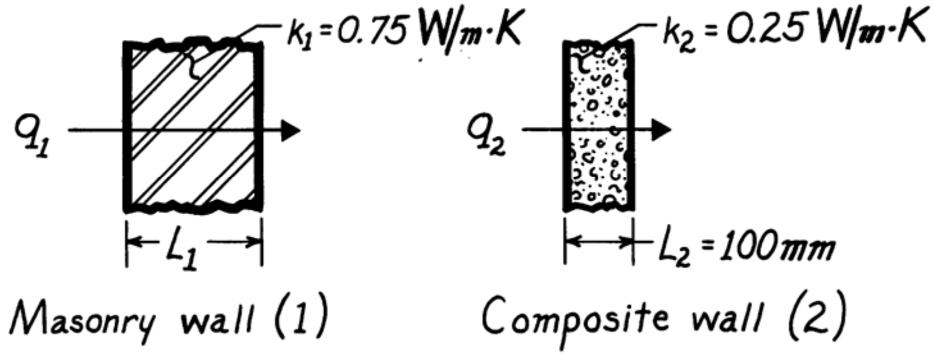
COMMENTS: The corners and edges of the container create local departures from one-dimensional conduction, which increase the heat load. However, for H, W_1, W_2 >> L, the effect is negligible.

PROBLEM 1.13

KNOWN: Masonry wall of known thermal conductivity has a heat rate which is 80% of that through a composite wall of prescribed thermal conductivity and thickness.

FIND: Thickness of masonry wall.

SCHEMATIC:



ASSUMPTIONS: (1) Both walls subjected to same surface temperatures, (2) One-dimensional conduction, (3) Steady-state conditions, (4) Constant properties.

ANALYSIS: For steady-state conditions, the conduction heat flux through a one-dimensional wall follows from Fourier's law, Eq. 1.2,

$$q'' = k \frac{\Delta T}{L}$$

where ΔT represents the difference in surface temperatures. Since ΔT is the same for both walls, it follows that

$$L_1 = L_2 \frac{k_1}{k_2} \cdot \frac{q_2''}{q_1''}.$$

With the heat fluxes related as

$$q_1'' = 0.8\, q_2''$$

$$L_1 = 100\text{mm} \frac{0.75\ \text{W/m}\cdot\text{K}}{0.25\ \text{W/m}\cdot\text{K}} \times \frac{1}{0.8} = 375\text{mm}. \qquad <$$

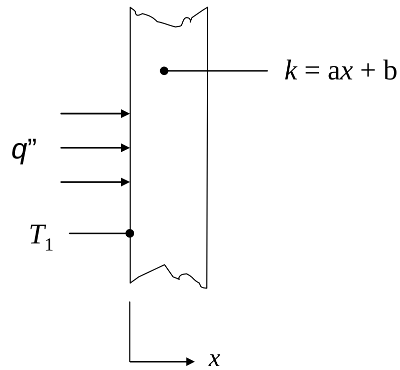
COMMENTS: Not knowing the temperature difference across the walls, we cannot find the value of the heat rate.

PROBLEM 1.14

KNOWN: Expression for variable thermal conductivity of a wall. Constant heat flux. Temperature at x = 0.

FIND: Expression for temperature gradient and temperature distribution.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction.

ANALYSIS: The heat flux is given by Fourier's law, and is known to be constant, therefore

$$q_x'' = -k\frac{dT}{dx} = \text{constant}$$

Solving for the temperature gradient and substituting the expression for k yields

$$\frac{dT}{dx} = -\frac{q_x''}{k} = -\frac{q_x''}{ax+b}$$ <

This expression can be integrated to find the temperature distribution, as follows:

$$\int\frac{dT}{dx}dx = -\int\frac{q_x''}{ax+b}dx$$

Since $q_x'' = \text{constant}$, we can integrate the right hand side to find

$$T = -\frac{q_x''}{a}\ln(ax+b)+c$$

where c is a constant of integration. Applying the known condition that $T = T_1$ at x = 0, we can solve for c.

Continued…

PROBLEM 1.14 (Cont.)

$$T(x=0) = T_1$$

$$-\frac{q''_x}{a}\ln b + c = T_1$$

$$c = T_1 + \frac{q''_x}{a}\ln b$$

Therefore, the temperature distribution is given by

$$T = -\frac{q''_x}{a}\ln(ax+b) + T_1 + \frac{q''_x}{a}\ln b$$ <

$$= T_1 + \frac{q''_x}{a}\ln\frac{b}{ax+b}$$ <

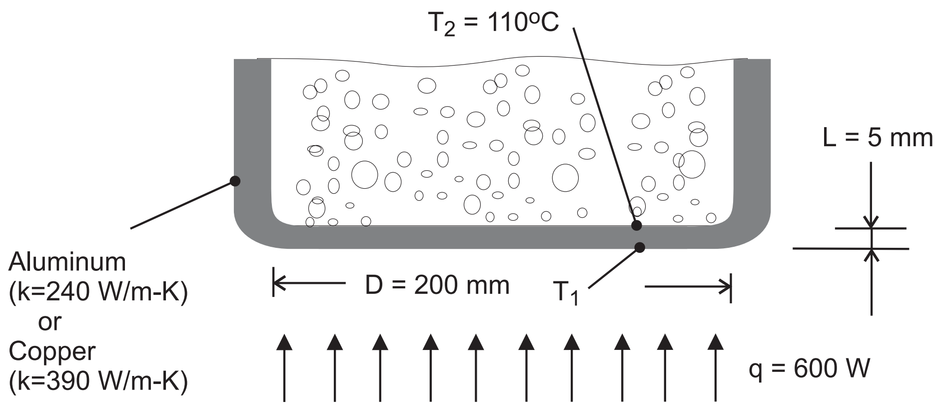
COMMENTS: Temperature distributions are not linear in many situations, such as when the thermal conductivity varies spatially or is a function of temperature. Non-linear temperature distributions may also evolve if internal energy generation occurs or non-steady conditions exist.

PROBLEM 1.15

KNOWN: Thickness, diameter and inner surface temperature of bottom of pan used to boil water. Rate of heat transfer to the pan.

FIND: Outer surface temperature of pan for an aluminum and a copper bottom.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, steady-state conduction through bottom of pan.

ANALYSIS: From Fourier's law, the rate of heat transfer by conduction through the bottom of the pan is

$$q = kA\frac{T_1 - T_2}{L}$$

Hence,

$$T_1 = T_2 + \frac{qL}{kA}$$

where $A = \pi D^2/4 = \pi(0.2\text{m})^2/4 = 0.0314\ \text{m}^2$.

Aluminum: $$T_1 = 110\ ^\circ\text{C} + \frac{600\text{W}(0.005\ \text{m})}{240\ \text{W/m}\cdot\text{K}\left(0.0314\ \text{m}^2\right)} = 110.40\ ^\circ\text{C}$$ <

Copper: $$T_1 = 110\ ^\circ\text{C} + \frac{600\text{W}(0.005\ \text{m})}{390\ \text{W/m}\cdot\text{K}\left(0.0314\ \text{m}^2\right)} = 110.24\ ^\circ\text{C}$$ <

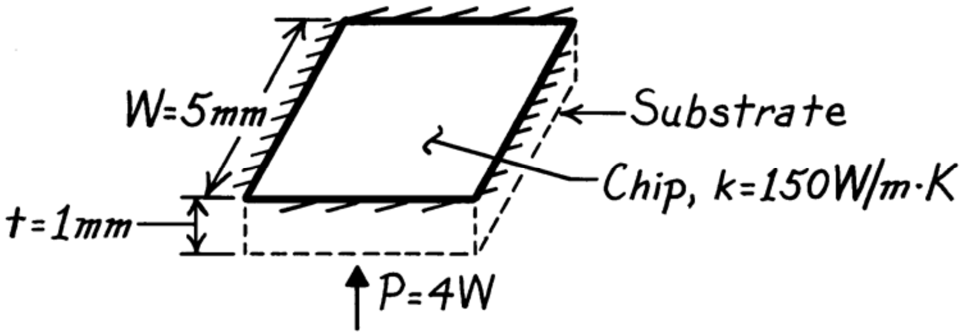
COMMENTS: Although the temperature drop across the bottom is slightly larger for aluminum (due to its smaller thermal conductivity), it is sufficiently small to be negligible for both materials. To a good approximation, the bottom may be considered *isothermal* at T ≈ 110 °C, which is a desirable feature of pots and pans.

PROBLEM 1.16

KNOWN: Dimensions and thermal conductivity of a chip. Power dissipated on one surface.

FIND: Temperature drop across the chip.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Uniform heat dissipation, (4) Negligible heat loss from back and sides, (5) One-dimensional conduction in chip.

ANALYSIS: All of the electrical power dissipated at the back surface of the chip is transferred by conduction through the chip. Hence, from Fourier's law,

$$P = q = kA\frac{\Delta T}{t}$$

or

$$\Delta T = \frac{t \cdot P}{kW^2} = \frac{0.001\ \text{m} \times 4\ \text{W}}{150\ \text{W/m} \cdot \text{K}\left(0.005\ \text{m}\right)^2}$$

$$\Delta T = 1.1^\circ\ \text{C}. \qquad <$$

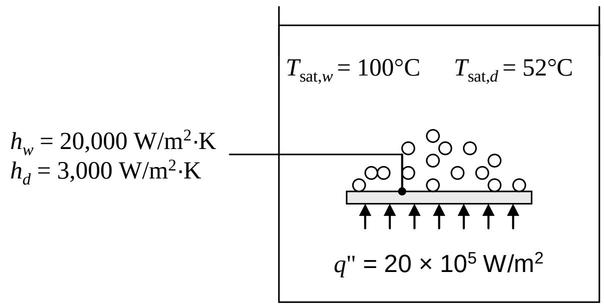
COMMENTS: For fixed P, the temperature drop across the chip decreases with increasing k and W, as well as with decreasing t.

PROBLEM 1.17

KNOWN: Heat flux and convection heat transfer coefficient for boiling water. Saturation temperature and convection heat transfer coefficient for boiling dielectric fluid.

FIND: Upper surface temperature of plate when water is boiling. Whether plan for minimizing surface temperature by using dielectric fluid will work.

SCHEMATIC:



ASSUMPTIONS: Steady-state conditions.

PROPERTIES: $T_{sat,w}$ = 100°C at p = 1 atm.

ANALYSIS: According to the problem statement, Newton's law of cooling can be expressed for a boiling process as

$$q'' = h(T_s - T_{sat})$$

Thus,

$$T_s = T_{sat} + q''/h$$

When the fluid is water,

$$T_{s,w} = T_{sat,w} + q''/h_w = 100°C + \frac{20 \times 10^5 \text{ W/m}^2}{20 \times 10^3 \text{ W/m}^2 \cdot \text{K}} = 200°C$$

When the dielectric fluid is used,

$$T_{s,d} = T_{sat,d} + q''/h_d = 52°C + \frac{20 \times 10^5 \text{ W/m}^2}{3 \times 10^3 \text{ W/m}^2 \cdot \text{K}} = 719°C$$

Thus, the technician's proposed approach will not reduce the surface temperature. <

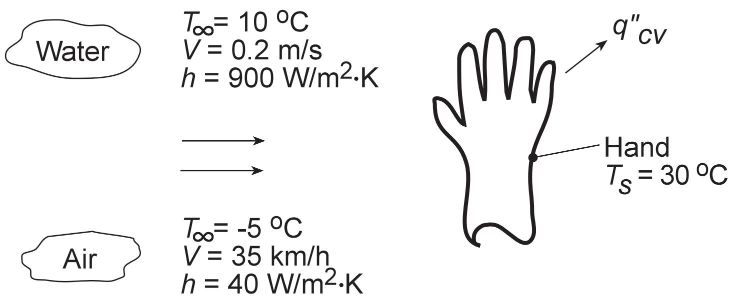
COMMENTS: (1) Even though the dielectric fluid has a lower saturation temperature, this is more than offset by the lower heat transfer coefficient associated with the dielectric fluid. The surface temperature with the dielectric coolant exceeds the melting temperature of many metals such as aluminum and aluminum alloys. (2) Dielectric fluids are, however, employed in applications such as *immersion cooling* of electronic components, where an electrically-conducting fluid such as water could not be used.

PROBLEM 1.18

KNOWN: Hand experiencing convection heat transfer with moving air and water.

FIND: Determine which condition feels colder. Contrast these results with a heat loss of 30 W/m^2 under normal room conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Temperature is uniform over the hand's surface, (2) Convection coefficient is uniform over the hand, and (3) Negligible radiation exchange between hand and surroundings in the case of air flow.

ANALYSIS: The hand will feel colder for the condition which results in the larger heat loss. The heat loss can be determined from Newton's law of cooling, Eq. 1.3a, written as

$$q'' = h\left(T_s - T_\infty\right)$$

For the air stream:

$$q''_{air} = 40\,W\big/m^2 \cdot K\left[30-\left(-5\right)\right]K = 1{,}400\,W\big/m^2 \qquad <$$

For the water stream:

$$q''_{water} = 900\,W\big/m^2 \cdot K\left(30-10\right)K = 18{,}000\,W\big/m^2 \qquad <$$

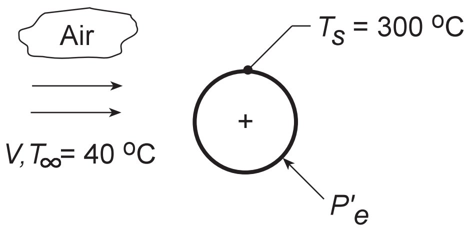
COMMENTS: The heat loss for the hand in the water stream is an order of magnitude larger than when in the air stream for the given temperature and convection coefficient conditions. In contrast, the heat loss in a normal room environment is only 30 W/m^2 which is a factor of 400 times less than the loss in the air stream. In the room environment, the hand would feel comfortable; in the air and water streams, as you probably know from experience, the hand would feel uncomfortably cold since the heat loss is excessively high.

PROBLEM 1.19

KNOWN: Power required to maintain the surface temperature of a long, 25-mm diameter cylinder with an imbedded electrical heater for different air velocities.

FIND: (a) Determine the convection coefficient for each of the air velocity conditions and display the results graphically, and (b) Assuming that the convection coefficient depends upon air velocity as $h = CV^n$, determine the parameters C and n.

SCHEMATIC:



V(m/s)	1	2	4	8	12
P'_e (W/m)	450	658	983	1507	1963
h ($W/m^2\cdot K$)	22.0	32.2	48.1	73.8	96.1

ASSUMPTIONS: (1) Temperature is uniform over the cylinder surface, (2) Negligible radiation exchange between the cylinder surface and the surroundings, (3) Steady-state conditions.

ANALYSIS: (a) From an overall energy balance on the cylinder, the power dissipated by the electrical heater is transferred by convection to the air stream. Using Newton's law of cooling on a per unit length basis,

$$P'_e = h(\pi D)(T_s - T_\infty)$$

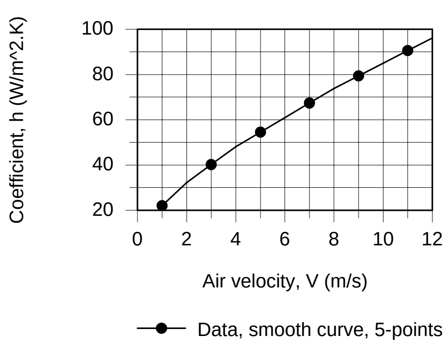
where P'_e is the electrical power dissipated per unit length of the cylinder. For the V = 1 m/s condition, using the data from the table above, find

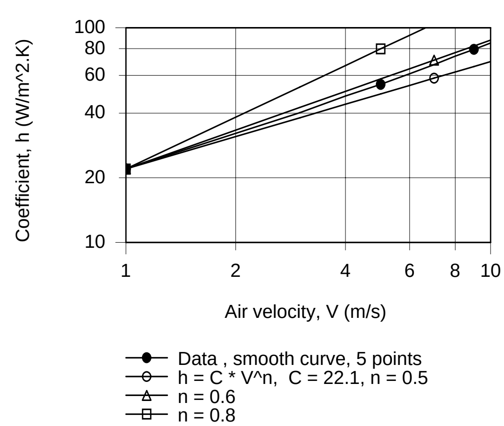
$$h = 450\,\text{W/m} \Big/ \pi \times 0.025\,\text{m}(300-40)^\circ\text{C} = 22.0\,\text{W}\Big/\text{m}^2\cdot\text{K} \qquad <$$

Repeating the calculations, find the convection coefficients for the remaining conditions which are tabulated above and plotted below. Note that h is not linear with respect to the air velocity.

(b) To determine the (C,n) parameters, we plotted h vs. V on log-log coordinates. Choosing C = 22.12 $W/m^2\cdot K(s/m)^n$, assuring a match at V = 1, we can readily find the exponent n from the slope of the h vs. V curve. From the trials with n = 0.8, 0.6 and 0.5, we recognize that n = 0.6 is a reasonable choice.

Hence, C = 22.12 and n = 0.6. <





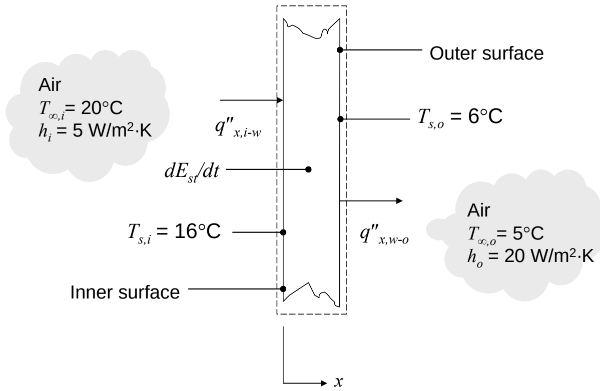
COMMENTS: Radiation may not be negligible, depending on surface emissivity.

PROBLEM 1.20

KNOWN: Inner and outer surface temperatures of a wall. Inner and outer air temperatures and convection heat transfer coefficients.

FIND: Heat flux from inner air to wall. Heat flux from wall to outer air. Heat flux from wall to inner air. Whether wall is under steady-state conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible radiation, (2) No internal energy generation.

ANALYSIS: The heat fluxes can be calculated using Newton's law of cooling. Convection from the inner air to the wall occurs in the positive x-direction:

$$q''_{x,i-w} = h_i(T_{\infty,i} - T_{s,i}) = 5\ \text{W/m}^2 \cdot \text{K} \times (20°\text{C} - 16°\text{C}) = 20\ \text{W/m}^2 \quad <$$

Convection from the wall to the outer air also occurs in the positive x-direction:

$$q''_{x,w-o} = h_o(T_{s,o} - T_{\infty,o}) = 20\ \text{W/m}^2 \cdot \text{K} \times (6°\text{C} - 5°\text{C}) = 20\ \text{W/m}^2 \quad <$$

From the wall to the inner air:

$$q''_{w-i} = h_i(T_{s,i} - T_{\infty,i}) = 5\ \text{W/m}^2 \cdot \text{K} \times (16°\text{C} - 20°\text{C}) = -20\ \text{W/m}^2 \quad <$$

An energy balance on the wall gives

$$\frac{dE_{st}}{dt} = \dot{E}_{in} - \dot{E}_{out} = A(q''_{x,i-w} - q''_{x,w-o}) = 0$$

Since $dE_{st}/dt = 0$, the wall *could be* at steady-state and the *spatially-averaged* wall temperature is not changing. However, it is possible that stored energy is increasing in one part of the wall and decreasing in another, therefore we cannot tell if the wall is at steady-state or not. If we found $dE_{st}/dt \neq 0$, we would know the wall was not at steady-state. <

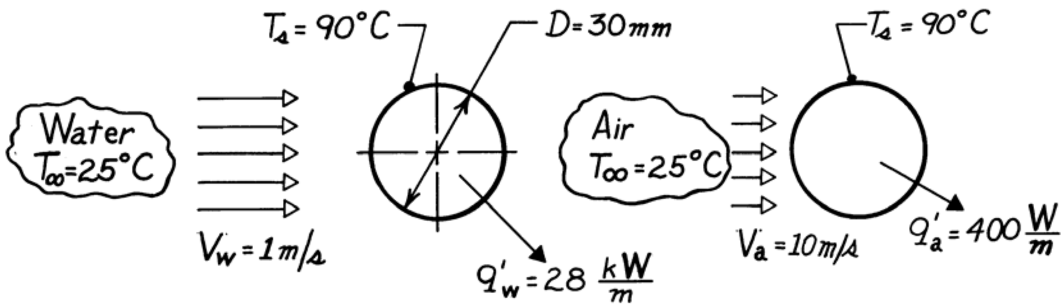
COMMENTS: The heat flux from the wall to the inner air is equal and opposite to the heat flux from the inner air to the wall.

PROBLEM 1.21

KNOWN: Long, 30mm-diameter cylinder with embedded electrical heater; power required to maintain a specified surface temperature for water and air flows.

FIND: Convection coefficients for the water and air flow convection processes, h_w and h_a, respectively.

SCHEMATIC:



ASSUMPTIONS: (1) Flow is cross-wise over cylinder which is very long in the direction normal to flow.

ANALYSIS: The convection heat rate from the cylinder per unit length of the cylinder has the form

$$q' = h(\pi D)\ (T_s - T_\infty)$$

and solving for the heat transfer convection coefficient, find

$$h = \frac{q'}{\pi D\ (T_s - T_\infty)}.$$

Substituting numerical values for the water and air situations:

Water $$h_w = \frac{28 \times 10^3\ \text{W/m}}{\pi \times 0.030\text{m}\ (90\text{-}25)^\circ\ \text{C}} = 4{,}570\ \text{W/m}^2 \cdot \text{K}$$ <

Air $$h_a = \frac{400\ \text{W/m}}{\pi \times 0.030\text{m}\ (90\text{-}25)^\circ\ \text{C}} = 65\ \text{W/m}^2 \cdot \text{K}.$$ <

COMMENTS: Note that the air velocity is 10 times that of the water flow, yet

$$h_w \approx 70 \times h_a.$$

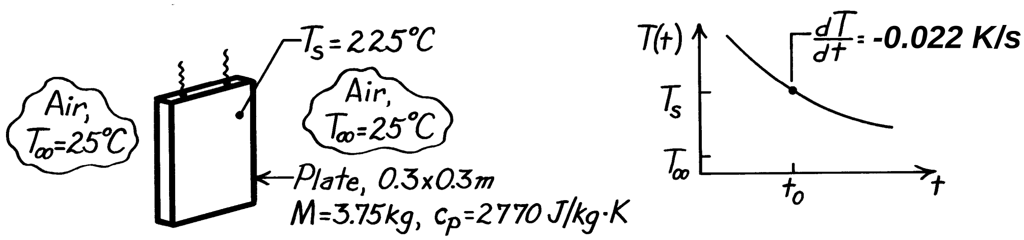
These values for the convection coefficient are typical for forced convection heat transfer with liquids and gases. See Table 1.1.

PROBLEM 1.22

KNOWN: Hot vertical plate suspended in cool, still air. Change in plate temperature with time at the instant when the plate temperature is 225°C.

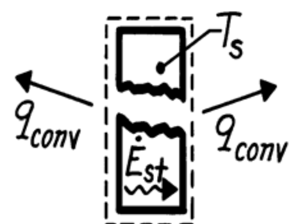
FIND: Convection heat transfer coefficient for this condition.

SCHEMATIC:



ASSUMPTIONS: (1) Plate is isothermal, (2) Negligible radiation exchange with surroundings, (3) Negligible heat lost through suspension wires.

ANALYSIS: As shown in the cooling curve above, the plate temperature decreases with time. The condition of interest is for time t_o. For a control surface about the plate, the conservation of energy requirement is



$$\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st}$$

$$-2hA_s\left(T_s - T_\infty\right) = Mc_p\frac{dT}{dt}$$

where A_s is the surface area of one side of the plate. Solving for h, find

$$h = \frac{Mc_p}{2A_s\left(T_s - T_\infty\right)}\left(\frac{-dT}{dt}\right)$$

$$h = \frac{3.75\text{ kg} \times 2770\text{ J/kg}\cdot\text{K}}{2 \times \left(0.3 \times 0.3\right)\text{m}^2\left(225 - 25\right)\text{K}} \times 0.022\text{ K/s} = 6.3\text{ W/m}^2\cdot\text{K}$$ <

COMMENTS: (1) Assuming the plate is very highly polished with emissivity of 0.08, determine whether radiation exchange with the surroundings at 25°C is negligible compared to convection.

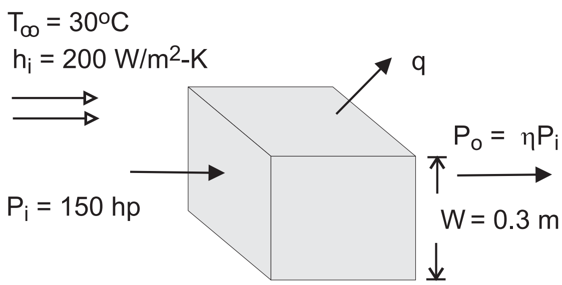
(2) We will later consider the criterion for determining whether the isothermal plate assumption is reasonable. If the thermal conductivity of the present plate were high (such as aluminum or copper), the criterion would be satisfied.

PROBLEM 1.23

KNOWN: Width, input power and efficiency of a transmission. Temperature and convection coefficient associated with air flow over the casing.

FIND: Surface temperature of casing.

SCHEMATIC:



ASSUMPTIONS: (1) Steady state, (2) Uniform convection coefficient and surface temperature, (3) Negligible radiation.

ANALYSIS: From Newton's law of cooling,

$$q = hA_s\left(T_s - T_\infty\right) = 6\,hW^2\left(T_s - T_\infty\right)$$

where the output power is ηP_i and the heat rate is

$$q = P_i - P_o = P_i\left(1-\eta\right) = 150\,\text{hp} \times 746\,\text{W/hp} \times 0.07 = 7833\,\text{W}$$

Hence,

$$T_s = T_\infty + \frac{q}{6\,hW^2} = 30°\text{C} + \frac{7833\ \text{W}}{6 \times 200\ \text{W/m}^2 \cdot \text{K} \times \left(0.3\,\text{m}\right)^2} = 102.5°\text{C} \qquad <$$

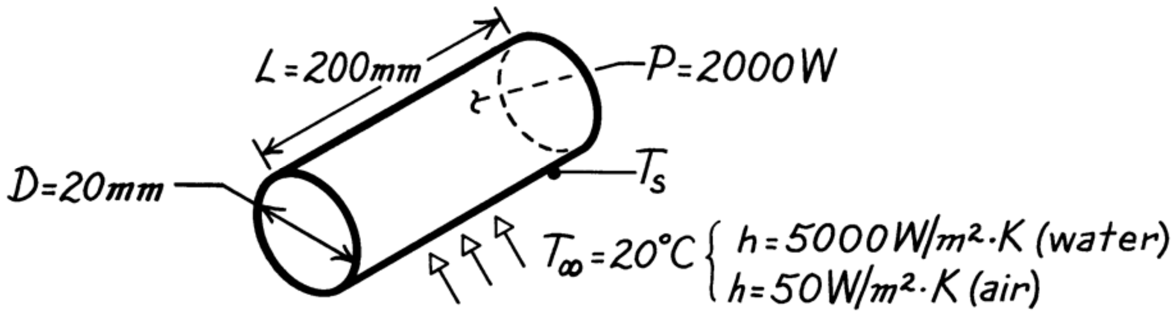
COMMENTS: There will, in fact, be considerable variability of the local convection coefficient over the transmission case and the prescribed value represents an average over the surface.

PROBLEM 1.24

KNOWN: Dimensions of a cartridge heater. Heater power. Convection coefficients in air and water at a prescribed temperature.

FIND: Heater surface temperatures in water and air.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) All of the electrical power is transferred to the fluid by convection, (3) Negligible heat transfer from ends.

ANALYSIS: With P = q_{conv}, Newton's law of cooling yields

$$P = hA\left(T_S - T_\infty\right) = h\pi DL\left(T_S - T_\infty\right)$$
$$T_S = T_\infty + \frac{P}{h\pi DL}.$$

In water,

$$T_s = 20^\circ C + \frac{2000\ W}{5000\ W/m^2 \cdot K \times \pi \times 0.02\ m \times 0.200\ m}$$

$$T_s = 20^\circ C + 31.8^\circ C = 51.8^\circ C. \quad <$$

In air,

$$T_s = 20^\circ C + \frac{2000\ W}{50\ W/m^2 \cdot K \times \pi \times 0.02\ m \times 0.200\ m}$$

$$T_s = 20^\circ C + 3183^\circ C = 3203^\circ C. \quad <$$

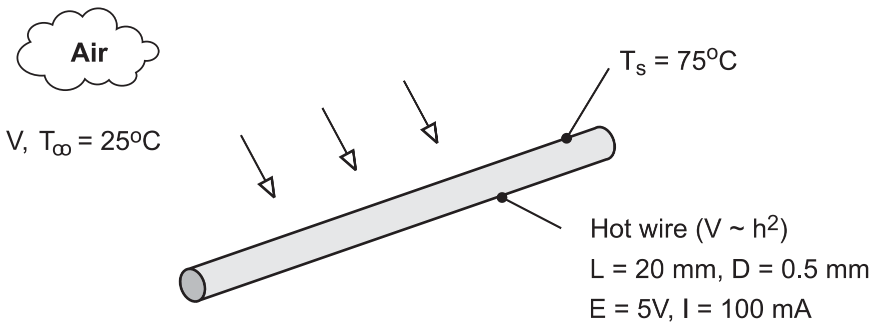
COMMENTS: (1) Air is much less effective than water as a heat transfer fluid. Hence, the cartridge temperature is much higher in air, so high, in fact, that the cartridge would melt. (2) In air, the high cartridge temperature would render radiation significant.

PROBLEM 1.25

KNOWN: Length, diameter and calibration of a hot wire anemometer. Temperature of air stream. Current, voltage drop and surface temperature of wire for a particular application.

FIND: Air velocity

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat transfer from the wire by natural convection or radiation.

ANALYSIS: If all of the electric energy is transferred by convection to the air, the following equality must be satisfied

$$P_{elec} = EI = hA\left(T_s - T_\infty\right)$$

where $A = \pi DL = \pi\left(0.0005\text{m} \times 0.02\text{m}\right) = 3.14 \times 10^{-5}\text{m}^2.$

Hence,

$$h = \frac{EI}{A\left(T_s - T_\infty\right)} = \frac{5\text{V} \times 0.1\text{A}}{3.14 \times 10^{-5}\text{m}^2\left(50\ ^\circ\text{C}\right)} = 318\ \text{W/m}^2 \cdot \text{K}$$

$$V = 6.25 \times 10^{-5} h^2 = 6.25 \times 10^{-5}\left(318\ \text{W/m}^2 \cdot \text{K}\right)^2 = 6.3\ \text{m/s}$$ <

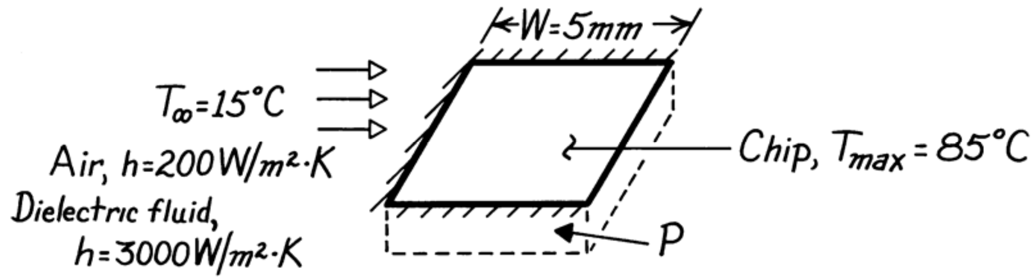
COMMENTS: The convection coefficient is sufficiently large to render buoyancy (natural convection) and radiation effects negligible.

PROBLEM 1.26

KNOWN: Chip width and maximum allowable temperature. Coolant conditions.

FIND: Maximum allowable chip power for air and liquid coolants.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat transfer from sides and bottom, (3) Chip is at a uniform temperature (isothermal), (4) Negligible heat transfer by radiation in air.

ANALYSIS: All of the electrical power dissipated in the chip is transferred by convection to the coolant. Hence,

$$P = q$$

and from Newton's law of cooling,

$$P = hA(T - T_\infty) = h\,W^2(T - T_\infty).$$

In *air*,

$$P_{max} = 200\ \text{W/m}^2\cdot\text{K}(0.005\ \text{m})^2(85 - 15)\ {}^\circ\text{C} = 0.35\ \text{W}.$$ <

In the *dielectric liquid*

$$P_{max} = 3000\ \text{W/m}^2\cdot\text{K}(0.005\ \text{m})^2(85\text{-}15)\ {}^\circ\text{C} = 5.25\ \text{W}.$$ <

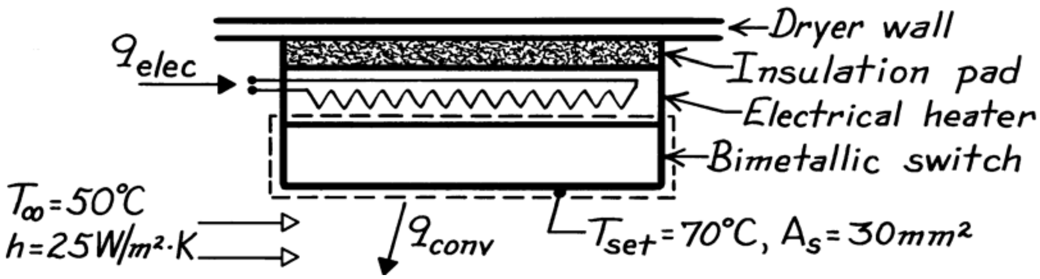
COMMENTS: Relative to liquids, air is a poor heat transfer fluid. Hence, in air the chip can dissipate far less energy than in the dielectric liquid.

PROBLEM 1.27

KNOWN: Upper temperature set point, T_{set}, of a bimetallic switch and convection heat transfer coefficient between clothes dryer air and exposed surface of switch.

FIND: Electrical power for heater to maintain T_{set} when air temperature is T_∞ = 50°C.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Electrical heater is perfectly insulated from dryer wall, (3) Heater and switch are isothermal at T_{set}, (4) Negligible heat transfer from sides of heater or switch, (5) Switch surface, A_s, loses heat only by convection.

ANALYSIS: Define a control volume around the bimetallic switch which experiences heat input from the heater and convection heat transfer to the dryer air. That is,

$$\dot{E}_{in} - \dot{E}_{out} = 0$$
$$q_{elec} - hA_s\left(T_{set} - T_\infty\right) = 0.$$

The electrical power required is,

$$q_{elec} = hA_s\left(T_{set} - T_\infty\right)$$

$$q_{elec} = 25\ \text{W/m}^2 \cdot \text{K} \times 30 \times 10^{-6}\ \text{m}^2 \left(70 - 50\right)\text{K} = 15\ \text{mW}. \qquad <$$

COMMENTS: (1) This type of controller can achieve variable operating air temperatures with a single set-point, inexpensive, bimetallic-thermostatic switch by adjusting power levels to the heater.

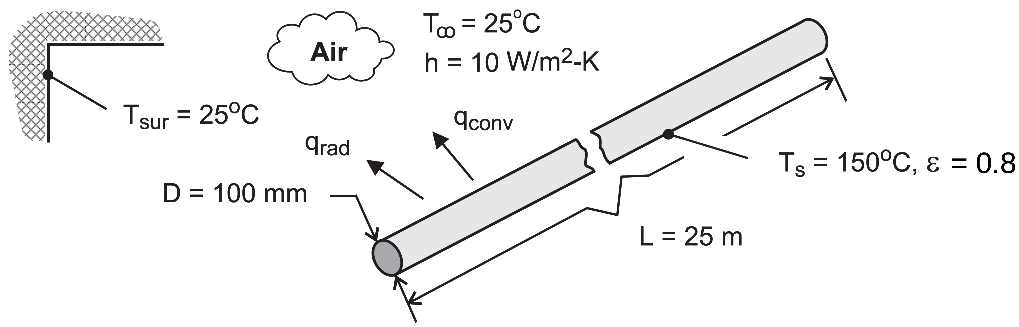
(2) Will the heater power requirement increase or decrease if the insulation pad is other than perfect?

PROBLEM 1.28

KNOWN: Length, diameter, surface temperature and emissivity of steam line. Temperature and convection coefficient associated with ambient air. Efficiency and fuel cost for gas fired furnace.

FIND: (a) Rate of heat loss, (b) Annual cost of heat loss.

SCHEMATIC:



ASSUMPTIONS: (1) Steam line operates continuously throughout year, (2) Net radiation transfer is between small surface (steam line) and large enclosure (plant walls).

ANALYSIS: (a) From Eqs. (1.3a) and (1.7), the heat loss is

$$q = q_{conv} + q_{rad} = A\left[h\left(T_s - T_\infty\right) + \varepsilon\sigma\left(T_s^4 - T_{sur}^4\right)\right]$$

where $A = \pi DL = \pi\left(0.1\text{m} \times 25\text{m}\right) = 7.85\text{m}^2$.

Hence,

$$q = 7.85\text{m}^2\left[10\ \text{W/m}^2 \cdot \text{K}\left(150 - 25\right)\text{K} + 0.8 \times 5.67 \times 10^{-8}\ \text{W/m}^2 \cdot \text{K}^4\left(423^4 - 298^4\right)\text{K}^4\right]$$

$$q = 7.85\text{m}^2\left(1,250 + 1,095\right)\text{W/m}^2 = \left(9813 + 8592\right)\text{W} = 18,405\ \text{W} \qquad <$$

(b) The annual energy loss is

$$E = qt = 18,405\ \text{W} \times 3600\ \text{s/h} \times 24\text{h/d} \times 365\ \text{d/y} = 5.80 \times 10^{11}\ \text{J}$$

With a furnace energy consumption of $E_f = E/\eta_f = 6.45 \times 10^{11}\ \text{J}$, the annual cost of the loss is

$$C = C_g E_f = 0.02\ \$/\text{MJ} \times 6.45 \times 10^5 \text{MJ} = \$12,900 \qquad <$$

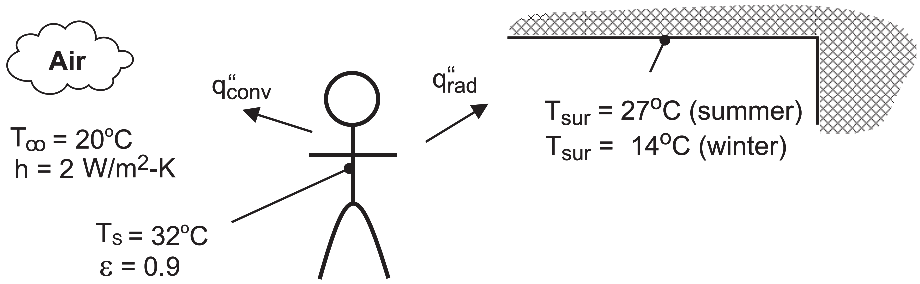
COMMENTS: The heat loss and related costs are unacceptable and should be reduced by insulating the steam line.

PROBLEM 1.29

KNOWN: Air and wall temperatures of a room. Surface temperature, convection coefficient and emissivity of a person in the room.

FIND: Basis for difference in comfort level between summer and winter.

SCHEMATIC:



ASSUMPTIONS: (1) Person may be approximated as a small object in a large enclosure.

ANALYSIS: Thermal comfort is linked to heat loss from the human body, and a *chilled* feeling is associated with excessive heat loss. Because the temperature of the room air is fixed, the different summer and winter comfort levels cannot be attributed to convection heat transfer from the body. In both cases, the heat flux is

Summer and Winter: $q''_{conv} = h\left(T_s - T_\infty\right) = 2\ W/m^2 \cdot K \times 12\ ^\circ C = 24\ W/m^2$

However, the heat flux due to radiation will differ, with values of

Summer: $q''_{rad} = \varepsilon\sigma\left(T_s^4 - T_{sur}^4\right) = 0.9 \times 5.67 \times 10^{-8} W/m^2 \cdot K^4 \left(305^4 - 300^4\right) K^4 = 28.3\ W/m^2$

Winter: $q''_{rad} = \varepsilon\sigma\left(T_s^4 - T_{sur}^4\right) = 0.9 \times 5.67 \times 10^{-8} W/m^2 \cdot K^4 \left(305^4 - 287^4\right) K^4 = 95.4\ W/m^2$

There is a significant difference between winter and summer radiation fluxes, and the chilled condition is attributable to the effect of the colder walls on radiation.

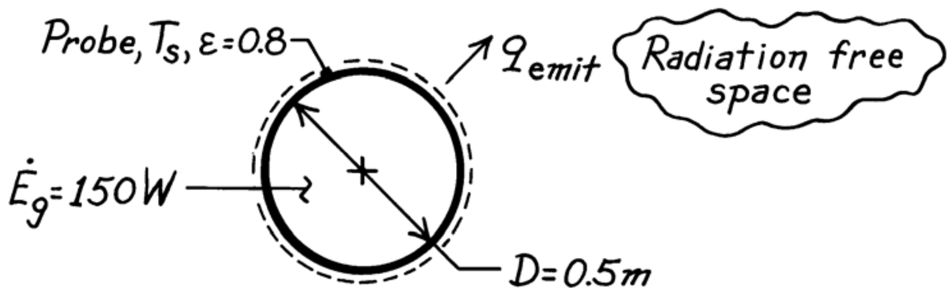
COMMENTS: For a representative surface area of A = 1.5 m^2, the heat losses are q_{conv} = 36 W, $q_{rad(summer)}$ = 42.5 W and $q_{rad(winter)}$ = 143.1 W. The winter time radiation loss is significant and if maintained over a 24 h period would amount to 2,950 kcal.

PROBLEM 1.30

KNOWN: Diameter and emissivity of spherical interplanetary probe. Power dissipation within probe.

FIND: Probe surface temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible radiation incident on the probe.

ANALYSIS: Conservation of energy dictates a balance between energy generation within the probe and radiation emission from the probe surface. Hence, at any instant

$$-\dot{E}_{out} + \dot{E}_g = 0$$

$$\varepsilon A_s \sigma T_s^4 = \dot{E}_g$$

$$T_s = \left(\frac{\dot{E}_g}{\varepsilon \pi D^2 \sigma}\right)^{1/4}$$

$$T_s = \left(\frac{150\text{W}}{0.8\pi(0.5\text{ m})^2 5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4}\right)^{1/4}$$

$$T_s = 254.7\text{ K.}$$ <

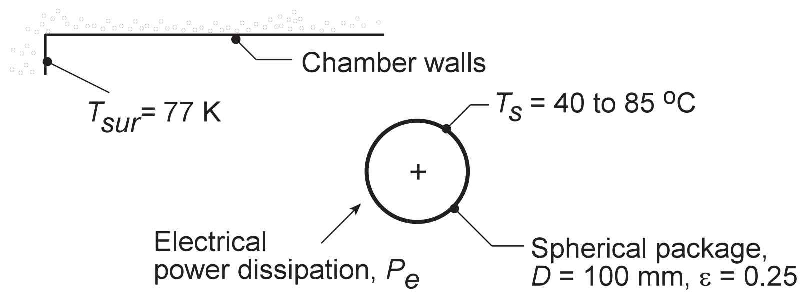
COMMENTS: Incident radiation, as, for example, from the sun, would increase the surface temperature.

PROBLEM 1.31

KNOWN: Spherical shaped instrumentation package with prescribed surface emissivity within a large space-simulation chamber having walls at 77 K.

FIND: Acceptable power dissipation for operating the package surface temperature in the range T_s = 40 to 85°C. Show graphically the effect of emissivity variations for 0.2 and 0.3.

SCHEMATIC:



ASSUMPTIONS: (1) Uniform surface temperature, (2) Chamber walls are large compared to the spherical package, and (3) Steady-state conditions.

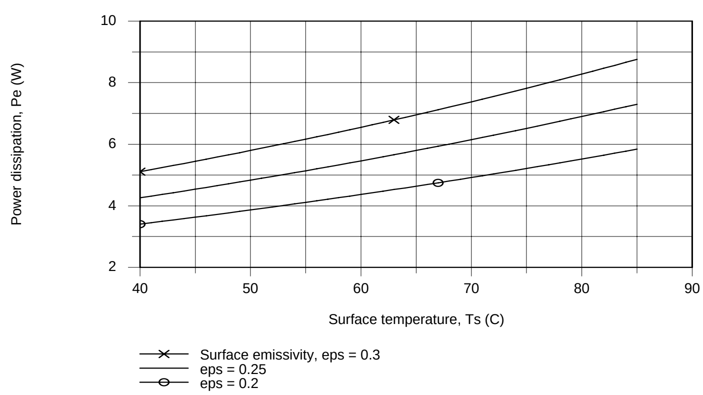
ANALYSIS: From an overall energy balance on the package, the internal power dissipation P_e will be transferred by radiation exchange between the package and the chamber walls. From Eq. 1.7,

$$q_{rad} = P_e = \varepsilon A_s \sigma \left(T_s^4 - T_{sur}^4 \right)$$

For the condition when T_s = 40°C, with $A_s = \pi D^2$ the power dissipation will be

$$P_e = 0.25\left(\pi \times 0.10^2\ m^2\right) \times 5.67 \times 10^{-8}\ W/m^2 \cdot K^4 \times \left[(40 + 273)^4 - 77^4 \right] K^4 = 4.3\ W$$ <

Repeating this calculation for the range 40 ≤ T_s ≤ 85°C, we can obtain the power dissipation as a function of surface temperature for the ε = 0.25 condition. Similarly, with 0.2 or 0.3, the family of curves shown below has been obtained.



COMMENTS: (1) As expected, the internal power dissipation increases with increasing emissivity and surface temperature. Because the radiation rate equation is non-linear with respect to temperature, the power dissipation will likewise not be linear with surface temperature.

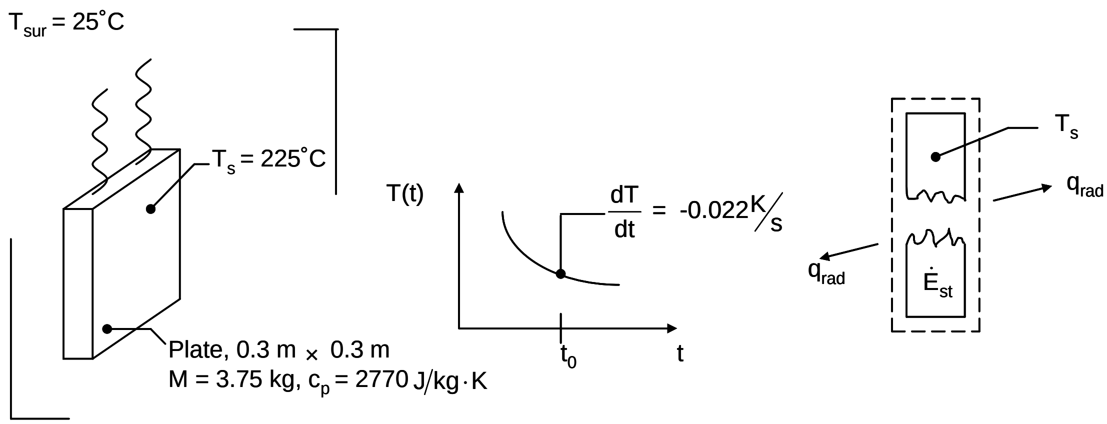
(2) What is the maximum power dissipation that is possible if the surface temperature is not to exceed 85°C? What kind of a coating should be applied to the instrument package in order to approach this limiting condition?

PROBLEM 1.32

KNOWN: Hot plate suspended in vacuum and surroundings temperature. Mass, specific heat, area and time rate of change of plate temperature.

FIND: (a) The emissivity of the plate, and (b) The rate at which radiation is emitted from the plate.

SCHEMATIC:



ASSUMPTIONS: (1) Plate is isothermal and at uniform temperature, (2) Large surroundings, (3) Negligible heat loss through suspension wires.

ANALYSIS: For a control volume about the plate, the conservation of energy requirement is

$$\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st} \tag{1}$$

where $\dot{E}_{st} = Mc_p \dfrac{dT}{dt}$ (2)

and for large surroundings $\dot{E}_{in} - \dot{E}_{out} = A\varepsilon\sigma(T_{sur}^4 - T_s^4)$ (3)

Combining Eqns. (1) through (3) yields

$$\varepsilon = \frac{Mc_p}{A\sigma}\frac{\frac{dT}{dt}}{(T_{sur}^4 - T_s^4)}$$

Noting that $T_{sur} = 25^\circ C + 273\ K = 298\ K$ and $T_s = 225^\circ C + 273\ K = 498\ K$, we find

$$\varepsilon = \frac{3.75\ kg \times 2770 \frac{J}{kg \cdot K} \times (-0.022 \frac{K}{s})}{2 \times 0.3\ m \times 0.3\ m \times 5.67 \times 10^{-8} \frac{W}{m^2 \cdot K^4}(498^4 - 298^4)\ K^4} = 0.42$$ <

The rate at which radiation is emitted from the plate is

$$q_{rad,e} = \varepsilon A\sigma T_s^4 = 0.42 \times 2 \times 0.3\ m \times 0.3\ m \times 5.67 \times 10^{-8} \frac{W}{m^2 \cdot K^4} \times (498\ K)^4 = 264\ W$$ <

COMMENTS: Note the importance of using kelvins when working with radiation heat transfer.

PROBLEM 1.33

KNOWN: Exact and approximate expressions for the linearized radiation coefficient, h_r and h_{ra}, respectively.

FIND: (a) Comparison of the coefficients with ε = 0.05 and 0.9 and surface temperatures which may exceed that of the surroundings (T_{sur} = 25°C) by 10 to 100°C; also comparison with a free convection coefficient correlation, (b) Plot of the relative error (h_r - r_{ra})/h_r as a function of the furnace temperature associated with a workpiece at T_s = 25°C having ε = 0.05, 0.2 or 0.9.

ASSUMPTIONS: (1) Furnace walls are large compared to the workpiece and (2) Steady-state conditions.

ANALYSIS: (a) The linearized radiation coefficient, Eq. 1.9, follows from the radiation exchange rate equation,

$$h_r = \varepsilon\sigma\left(T_s + T_{sur}\right)\left(T_s^2 + T_{sur}^2\right)$$

If $T_s \approx T_{sur}$, the coefficient may be approximated by the simpler expression

$$h_{r,a} = 4\varepsilon\sigma\bar{T}^3 \qquad \bar{T} = \left(T_s + T_{sur}\right)/2$$

For the condition of ε = 0.05, T_s = T_{sur} + 10 = 35°C = 308 K and T_{sur} = 25°C = 298 K, find that

$$h_r = 0.05 \times 5.67 \times 10^{-8}\,\text{W/m}^2\cdot\text{K}^4\,(308 + 298)\left(308^2 + 298^2\right)\text{K}^3 = 0.32\,\text{W/m}^2\cdot\text{K} \qquad <$$

$$h_{r,a} = 4 \times 0.05 \times 5.67 \times 10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left((308 + 298)/2\right)^3\text{K}^3 = 0.32\,\text{W/m}^2\cdot\text{K} \qquad <$$

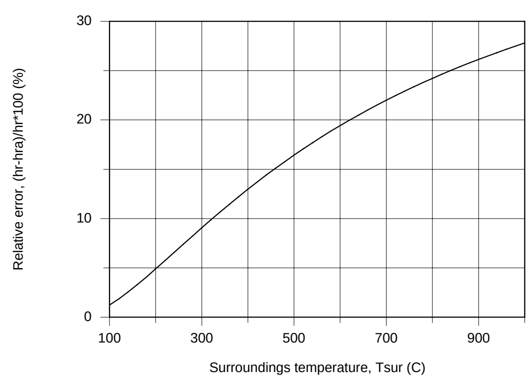
The free convection coefficient with T_s = 35°C and T_∞ = T_{sur} = 25°C, find that

$$h = 0.98\Delta T^{1/3} = 0.98\left(T_s - T_\infty\right)^{1/3} = 0.98(308 - 298)^{1/3} = 2.1\,\text{W/m}^2\cdot\text{K} \qquad <$$

For the range T_s - T_{sur} = 10 to 100°C with ε = 0.05 and 0.9, the results for the coefficients are tabulated below. For this range of surface and surroundings temperatures, the radiation and free convection coefficients are of comparable magnitude for moderate values of the emissivity, say ε > 0.2. The approximate expression for the linearized radiation coefficient is valid within 2% for these conditions.

(b) The above expressions for the radiation coefficients, h_r and $h_{r,a}$, are used for the workpiece at T_s = 25°C placed inside a furnace with walls which may vary from 100 to 1000°C. The relative error, (h_r - h_{ra})/h_r, will be independent of the surface emissivity and is plotted as a function of T_{sur}. For T_{sur} > 200°C, the approximate expression provides estimates which are in error more than 5%. The approximate expression should be used with caution, and only for surface and surrounding temperature differences of 50 to 100°C.

		Coefficients (W/m²·K)		
T_s (°C)	ε	h_r	$h_{r,a}$	h
35	0.05	0.32	0.32	2.1
	0.9	5.7	5.7	
135	0.05	0.51	0.50	4.7
	0.9	9.2	9.0	

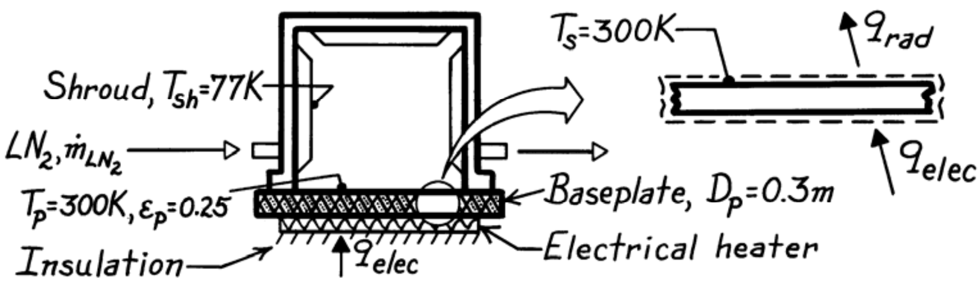


PROBLEM 1.34

KNOWN: Vacuum enclosure maintained at 77 K by liquid nitrogen shroud while baseplate is maintained at 300 K by an electrical heater.

FIND: (a) Electrical power required to maintain baseplate, (b) Liquid nitrogen consumption rate, (c) Effect on consumption rate if aluminum foil (ε_p = 0.09) is bonded to baseplate surface.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) No heat losses from backside of heater or sides of plate, (3) Vacuum enclosure large compared to baseplate, (4) Enclosure is evacuated with negligible convection, (5) Liquid nitrogen (LN_2) is heated only by heat transfer to the shroud, and (6) Foil is intimately bonded to baseplate.

PROPERTIES: Heat of vaporization of liquid nitrogen (given): 125 kJ/kg.

ANALYSIS: (a) From an energy balance on the baseplate,

$$\dot{E}_{in} - \dot{E}_{out} = 0 \qquad q_{elec} - q_{rad} = 0$$

and using Eq. 1.7 for radiative exchange between the baseplate and shroud,

$$q_{elec} = \varepsilon_p A_p \sigma \left(T_p^4 - T_{sh}^4\right).$$

Substituting numerical values, with $A_p = \left(\pi D_p^2/4\right)$, find

$$q_{elec} = 0.25\left(\pi(0.3\text{ m})^2/4\right)5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4\left(300^4 - 77^4\right)\text{K}^4 = 8.1\text{ W}. \qquad <$$

(b) From an energy balance on the enclosure, radiative transfer heats the liquid nitrogen stream causing evaporation,

$$\dot{E}_{in} - \dot{E}_{out} = 0 \qquad q_{rad} - \dot{m}_{LN2} h_{fg} = 0$$

where $\dot{m}_{LN2}$ is the liquid nitrogen consumption rate. Hence,

$$\dot{m}_{LN2} = q_{rad}/h_{fg} = 8.1\text{ W}/125\text{ kJ/kg} = 6.48\times10^{-5}\text{ kg/s} = 0.23\text{ kg/h}. \qquad <$$

(c) If aluminum foil (ε_p = 0.09) were bonded to the upper surface of the baseplate,

$$q_{rad,foil} = q_{rad}\left(\varepsilon_f/\varepsilon_p\right) = 8.1\text{ W}\left(0.09/0.25\right) = 2.9\text{ W}$$

and the liquid nitrogen consumption rate would be reduced by

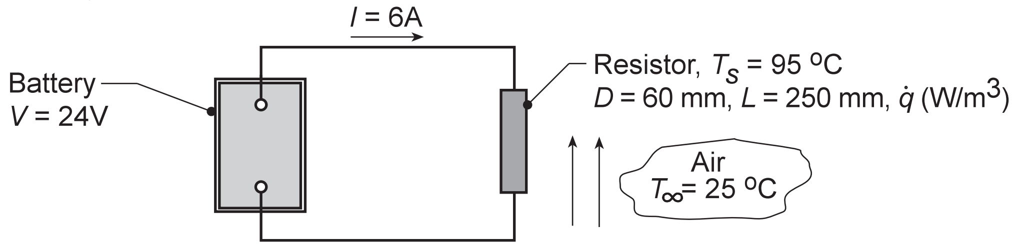
(0.25 - 0.09)/0.25 = 64% to 0.083 kg/h. <

PROBLEM 1.35

KNOWN: Resistor connected to a battery operating at a prescribed temperature in air.

FIND: (a) Considering the resistor as the system, determine corresponding values for $\dot{E}_{in}(W)$, $\dot{E}_g(W)$, $\dot{E}_{out}(W)$ and $\dot{E}_{st}(W)$. If a control surface is placed about the entire system, determine the values for $\dot{E}_{in}$, $\dot{E}_g$, $\dot{E}_{out}$, and $\dot{E}_{st}$. (b) Determine the volumetric heat generation rate within the resistor, $\dot{q}$ (W/m^3), (c) Neglecting radiation from the resistor, determine the convection coefficient.

SCHEMATIC:



ASSUMPTIONS: (1) Electrical power is dissipated uniformly within the resistor, (2) Temperature of the resistor is uniform, (3) Negligible electrical power dissipated in the lead wires, (4) Negligible radiation exchange between the resistor and the surroundings, (5) No heat transfer occurs from the battery, (5) Steady-state conditions in the resistor.

ANALYSIS: (a) Referring to Section 1.3.1, the conservation of energy requirement for a control volume at an instant of time, Equation 1.12c, is

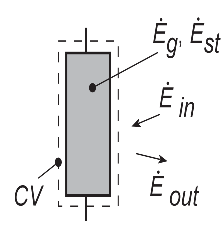
$$\dot{E}_{in} + \dot{E}_g - \dot{E}_{out} = \dot{E}_{st}$$

where $\dot{E}_{in}$, $\dot{E}_{out}$ correspond to *surface* inflow and outflow processes, respectively. The energy generation term $\dot{E}_g$ is associated with conversion of some other energy form (chemical, electrical, electromagnetic or nuclear) to thermal energy. The energy storage term $\dot{E}_{st}$ is associated with changes in the internal, kinetic and/or potential energies of the matter in the control volume. $\dot{E}_g$, $\dot{E}_{st}$ are *volumetric* phenomena. The electrical power delivered by the battery is P = VI = 24V×6A = 144 W.

Control volume: Resistor.

$\dot{E}_{in} = 0$ $\quad$ $\dot{E}_{out} = 144\,W$ <

$\dot{E}_g = 144\,W$ $\quad$ $\dot{E}_{st} = 0$

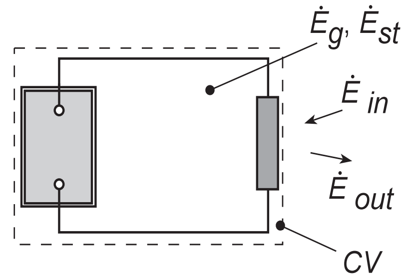


The $\dot{E}_g$ term is due to conversion of electrical energy to thermal energy. The term $\dot{E}_{out}$ is due to convection from the resistor surface to the air.

Continued...

PROBLEM 1.35 (Cont.)

Control volume: Battery-Resistor System.



$$\dot{E}_{in} = 0 \qquad \dot{E}_{out} = 144\,\text{W} \quad <$$
$$\dot{E}_g = 144\text{W} \qquad \dot{E}_{st} = 0$$

Since we are considering conservation of thermal and mechanical energy, the conversion of chemical energy to electrical energy in the battery is irrelevant, and including the battery in the control volume doesn't change the thermal and mechanical energy terms

(b) From the energy balance on the resistor with volume, $\forall = (\pi D^2/4)L$,

$$\dot{E}_g = \dot{q}\forall \qquad 144\,\text{W} = \dot{q}\left(\pi(0.06\,\text{m})^2/4\right)\times 0.25\,\text{m} \qquad \dot{q} = 2.04\times 10^5\ \text{W/m}^3 \quad <$$

(c) From the energy balance on the resistor and Newton's law of cooling with $A_s = \pi DL + 2(\pi D^2/4)$,

$$\dot{E}_{out} = q_{cv} = hA_s\left(T_s - T_\infty\right)$$

$$144\,\text{W} = h\left[\pi\times 0.06\,\text{m}\times 0.25\,\text{m} + 2\left(\pi\times 0.06^2\ \text{m}^2/4\right)\right](95-25)^\circ\,\text{C}$$

$$144\,\text{W} = h[0.0471 + 0.0057]\text{m}^2\,(95-25)^\circ\,\text{C}$$

$$h = 39.0\,\text{W/m}^2{\cdot}\text{K} \quad <$$

COMMENTS: (1) In using the conservation of energy requirement, Equation 1.12c, it is important to recognize that $\dot{E}_{in}$ and $\dot{E}_{out}$ will always represent *surface* processes and $\dot{E}_g$ and $\dot{E}_{st}$, *volumetric* processes. The generation term $\dot{E}_g$ is associated with a *conversion* process from some form of energy to *thermal energy*. The storage term $\dot{E}_{st}$ represents the rate of change of *internal kinetic, and potential energy*.

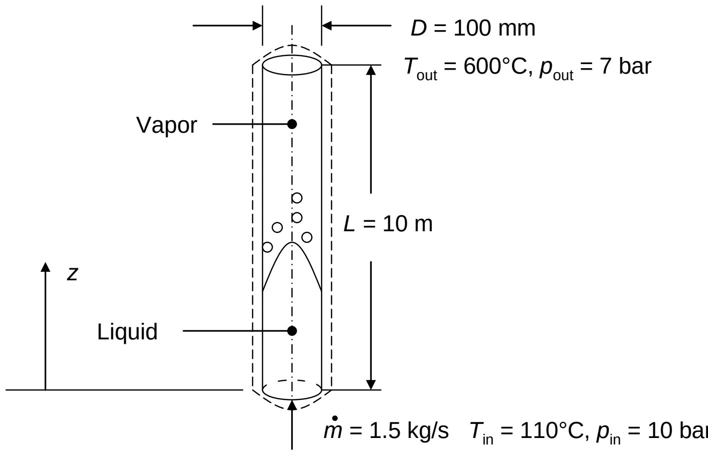
(2) From Table 1.1 and the magnitude of the convection coefficient determined from part (c), we conclude that the resistor is experiencing forced, rather than free, convection.

PROBLEM 1.36

KNOWN: Inlet and outlet conditions for flow of water in a vertical tube.

FIND: (a) Change in combined thermal and flow work, (b) change in mechanical energy, and (c) change in total energy of the water from the inlet to the outlet of the tube, (d) heat transfer rate, *q*.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform velocity distributions at the tube inlet and outlet.

PROPERTIES: Table A.6 water (T = 110°C): ρ = 950 kg/m^3, (T = (179.9°C + 110 °C)/2 = 145°C): c_p = 4300 J/kg·K, ρ = 919 kg/m^3. Other properties are taken from Moran, M.J. and Shapiro, H.N., *Fundamentals of Engineering Thermodynamics*, 6th Edition, John Wiley & Sons, Hoboken, 2008 including (p_{sat} = 10 bar): T_{sat} = 179.9°C, i_f = 762.81 kJ/kg; (p = 7 bar, T = 600°C): i = 3700.2 kJ/kg, υ = 0.5738 m^3/kg.

ANALYSIS: The steady-flow energy equation, in the absence of work (other than flow work), is

$$\dot{m}\left(u + pv + \tfrac{1}{2}V^2 + gz\right)_{\text{in}} - \dot{m}\left(u + pv + \tfrac{1}{2}V^2 + gz\right)_{\text{out}} + q = 0$$
$$\dot{m}\left(i + \tfrac{1}{2}V^2 + gz\right)_{\text{in}} - \dot{m}\left(i + \tfrac{1}{2}V^2 + gz\right)_{\text{out}} + q = 0 \qquad (1)$$

while the conservation of mass principle yields

$$V_{\text{in}} = \frac{4\dot{m}}{\rho\pi D^2} = \frac{4\times 1.5\text{ kg/s}}{950\text{ kg/m}^3\times\pi\times(0.100\text{ m})^2} = 0.201\text{ m/s}\ ;\ V_{\text{out}} = \frac{\upsilon 4\dot{m}}{\pi D^2} = \frac{0.5738\text{ m}^3/\text{kg}\times 4\times 1.5\text{ kg/s}}{\pi\times(0.100\text{ m})^2} = 110\text{ m/s}$$

(a) The change in the combined thermal and flow work energy from inlet to outlet:

$$\begin{aligned} E_{i,\text{out}} - E_{i,\text{in}} &= \dot{m}(i)_{\text{out}} - \dot{m}(i)_{\text{in}} = \dot{m}(i)_{\text{out}} - \dot{m}[i_{f,\text{sat}} + c_p(T_{\text{in}} - T_{\text{sat}})] \\ &= 1.5\text{ kg/s}\times\left(3700.2\text{ kJ/kg} - [762.81\text{ kJ/kg} + 4.3\text{ kJ/kg}\cdot\text{K}\times(110-179.9)^\circ\text{C}]\right) \\ &= 4.86\text{ MW} \end{aligned}$$ <

where $i_{f,sat}$ is the enthalpy of saturated liquid at the phase change temperature and pressure.

(b) The change in mechanical energy from inlet to outlet is:

Continued…

PROBLEM 1.36 (cont.)

$$E_{m,\text{out}} - E_{m,\text{in}} = \dot{m}(\tfrac{1}{2}V^2 + gz)_{\text{out}} - \dot{m}(\tfrac{1}{2}V^2 + gz)_{\text{in}}$$

$$= 1.5 \text{ kg/s} \times \left(\tfrac{1}{2}\left[(110 \text{ m/s})^2 - (0.201 \text{ m/s})^2 \right] + 9.8 \text{ m/s}^2 \times 10 \text{ m} \right) = 9.22 \text{ kW} \qquad <$$

(c) The change in the total energy is the summation of the thermal, flow work, and mechanical energy change or

$$E_{\text{in}} - E_{\text{out}} = 4.86 \text{ MW} + 9.22 \text{ kW} = 4.87 \text{ MW} \qquad <$$

(d) The total heat transfer rate is the same as the total energy change, $q = E_{\text{in}} - E_{\text{out}} = 4.87$ MW <

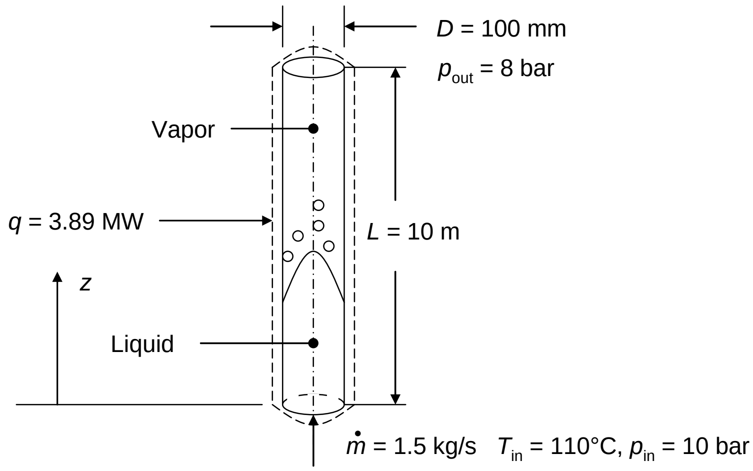
COMMENTS: (1) The change in mechanical energy, consisting of kinetic and potential energy components, is negligible compared to the change in thermal and flow work energy. (2) The average heat flux at the tube surface is $q'' = q/(\pi DL) = 4.87\text{MW}/(\pi \times 0.100 \text{ m} \times 10 \text{ m}) = 1.55 \text{ MW/m}^2$, which is very large. (3) The change in the velocity of the water is inversely proportional to the change in the density. As such, the outlet velocity is very large, and large pressure drops will occur in the vapor region of the tube relative to the liquid region of the tube.

PROBLEM 1.37

KNOWN: Flow of water in a vertical tube. Tube dimensions. Mass flow rate. Inlet pressure and temperature. Heat rate. Outlet pressure.

FIND: (a) Outlet temperature, (b) change in combined thermal and flow work, (c) change in mechanical energy, and (d) change in total energy of the water from the inlet to the outlet of the tube.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible change in mechanical energy. (3) Uniform velocity distributions at the tube inlet and outlet.

PROPERTIES: Table A.6 water (T = 110°C): ρ = 950 kg/m^3, (T = (179.9°C + 110 °C)/2 = 145°C): c_p = 4300 J/kg·K, ρ = 919 kg/m^3. Other properties are taken from Moran, M.J. and Shapiro, H.N., *Fundamentals of Engineering Thermodynamics*, 6th Edition, John Wiley & Sons, Hoboken, 2008 including (p_{sat} = 10 bar): T_{sat} = 179.9°C, i_f = 762.81 kJ/kg; (p = 8 bar, i = 3056 kJ/kg): T = 300°C, υ = 0.3335 m^3/kg.

ANALYSIS: (a) The steady-flow energy equation, in the absence of work (other than flow work), is

$$\dot{m}\left(u + pv + \tfrac{1}{2}V^2 + gz\right)_{\text{in}} - \dot{m}\left(u + pv + \tfrac{1}{2}V^2 + gz\right)_{\text{out}} + q = 0$$
$$\dot{m}\left(i + \tfrac{1}{2}V^2 + gz\right)_{\text{in}} - \dot{m}\left(i + \tfrac{1}{2}V^2 + gz\right)_{\text{out}} + q = 0 \qquad (1)$$

Neglecting the change in mechanical energy yields

$$\dot{m}(i_{\text{in}} - i_{\text{out}}) + q = 0$$

The inlet enthalpy is

$$i_{\text{in}} = i_{f,\text{in}} + c_p(T_{\text{in}} - T_{\text{sat}}) = 762.81\ \text{kJ/kg} + 4.3\ \text{kJ/kg}\cdot\text{K} \times (110 - 179.9)°\text{C} = 462.2\ \text{kJ/kg}$$

Thus the outlet enthalpy is

$$i_{\text{out}} = i_{\text{in}} + q/\dot{m} = 462.2\ \text{kJ/kg} + 3890\ \text{kW}/1.5\ \text{kg/s} = 3056\ \text{kJ/kg}$$

Continued…

PROBLEM 1.37 (cont.)

and the outlet temperature can be found from thermodynamic tables at p = 8 bars, i = 3056 kJ/kg, for which

$$T_{out} = 300°C$$

(b) The change in the combined thermal and flow work energy from inlet to outlet:

$$E_{i,out} - E_{i,in} = \dot{m}(i_{out} - i_{in}) = q = 3.89 \text{ MW} \qquad <$$

(c) The change in mechanical energy can now be calculated. First, the outlet specific volume can be found from thermodynamic tables at T_{out} = 300°C, p_{out} = 8 bars, υ = 0.3335 m^3/kg. Next, the conservation of mass principle yields

$$V_{in} = \frac{4\dot{m}}{\rho\pi D^2} = \frac{4 \times 1.5 \text{ kg/s}}{950 \text{ kg/m}^3 \times \pi \times (0.100 \text{ m})^2} = 0.201 \text{ m/s} \; ; \; V_{out} = \frac{\upsilon 4\dot{m}}{\pi D^2} = \frac{0.5738 \text{ m}^3/\text{kg} \times 4 \times 1.5 \text{ kg/s}}{\pi \times (0.100 \text{ m})^2} = 63.7 \text{ m/s}$$

The change in mechanical energy from inlet to outlet is:

$$E_{m,out} - E_{m,in} = \dot{m}(\tfrac{1}{2}V^2 + gz)_{out} - \dot{m}(\tfrac{1}{2}V^2 + gz)_{in}$$
$$= 1.5 \text{ kg/s} \times \left(\tfrac{1}{2}\left[(63.7 \text{ m/s})^2 - (0.201 \text{ m/s})^2\right] + 9.8 \text{ m/s}^2 \times 10 \text{ m}\right) = 3.19 \text{ kW} \qquad <$$

(d) The change in the total energy is the summation of the thermal, flow work, and mechanical energy change or

$$E_{in} - E_{out} = 3.89 \text{ MW} + 3.19 \text{ kW} = 3.89 \text{ MW} \qquad <$$

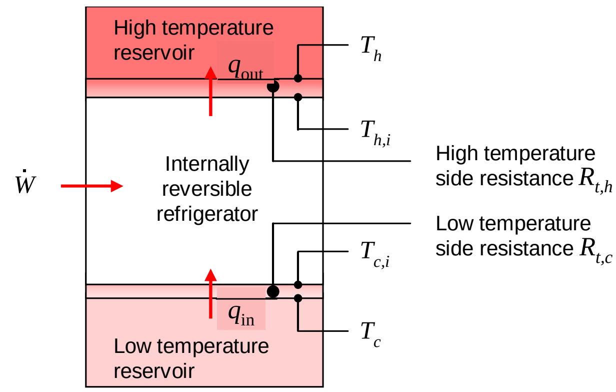
COMMENTS: (1) The change in mechanical energy, consisting of kinetic and potential energy components, is negligible compared to the change in thermal and flow work energy. (2) The average heat flux at the tube surface is $q'' = q/(\pi DL) = 3.89 \text{ MW}/(\pi \times 0.100 \text{ m} \times 10 \text{ m}) = 1.24 \text{ MW/m}^2$, which is very large. (3) The change in the velocity of the water is inversely proportional to the change in the density. As such, the outlet velocity is very large, and large pressure drops will occur in the vapor region of the tube relative to the liquid region of the tube.

PROBLEM 1.38

KNOWN: Hot and cold reservoir temperatures of an internally reversible refrigerator. Thermal resistances between refrigerator and hot and cold reservoirs.

FIND: Expressions for modified Coefficient of Performance and power input of refrigerator.

SCHEMATIC:



ASSUMPTIONS: (1) Refrigerator is internally reversible, (2) Steady-state operation.

ANALYSIS: Heat is transferred from the low temperature reservoir (the refrigerated space) at T_c to the refrigerator unit, through the resistance $R_{t,c}$, with $T_c > T_{c,i}$. Heat is rejected from the refrigerator unit to the higher temperature reservoir (the surroundings), through the resistance $R_{t,h}$, with $T_{h,i} > T_h$. The heat input and output rates can be expressed in a manner analogous to Equations 1.18a and 1.18b.

$$q_{in} = (T_c - T_{c,i}) / R_{t,c} \tag{1}$$

$$q_{out} = (T_{h,i} - T_h) / R_{t,h} \tag{2}$$

Equations (1) and (2) can be solved for the internal temperatures, to yield

$$T_{h,i} = T_h + q_{out} R_{t,h} = T_h + q_{in} R_{t,h} \left(\frac{1 + \text{COP}_m}{\text{COP}_m} \right) \tag{3}$$

$$T_{c,i} = T_c - q_{in} R_{t,c} \tag{4}$$

In Equation (3), q_{out} has been expressed as

$$q_{out} = q_{in} \left(\frac{1 + \text{COP}_m}{\text{COP}_m} \right) \tag{5}$$

using the definition of COP_m given in the problem statement. The modified Coefficient of Performance can then be expressed as

Continued…

PROBLEM 1.38 (Cont.)

$$\mathrm{COP}_m = \frac{T_{c,i}}{T_{h,i} - T_{c,i}} = \frac{T_c - q_{\text{in}} R_{t,c}}{T_h + q_{\text{in}} R_{t,h}\left(\dfrac{1+\mathrm{COP}_m}{\mathrm{COP}_m}\right) - T_c + q_{\text{in}} R_{t,c}}$$

Manipulating this expression,

$$\left(T_h - T_c + q_{\text{in}} R_{t,c}\right)\mathrm{COP}_m + q_{\text{in}} R_{t,h}(1+\mathrm{COP}_m) = T_c - q_{\text{in}} R_{t,c}$$

Solving for COP_m results in

$$\mathrm{COP}_m = \frac{T_c - q_{\text{in}} R_{\text{tot}}}{T_h - T_c + q_{\text{in}} R_{\text{tot}}}$$ <

From the definition of COP_m, the power input can be determined:

$$\dot{W} = \frac{q_{\text{in}}}{\mathrm{COP}_m} = q_{\text{in}} \frac{T_h - T_c + q_{\text{in}} R_{\text{tot}}}{T_c - q_{\text{in}} R_{\text{tot}}}$$ <

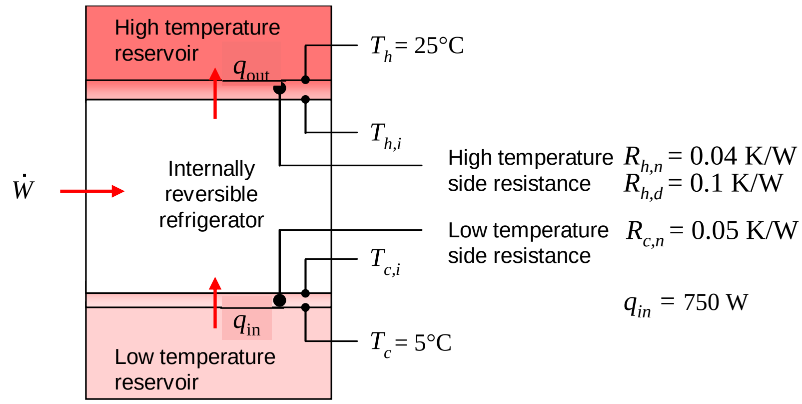
COMMENTS: As q_{in} or R_{tot} goes to zero, the Coefficient of Performance approaches the maximum Carnot value, $\mathrm{COP}_m = \mathrm{COP}_C = T_c /(T_h - T_c)$.

PROBLEM 1.39

KNOWN: Hot and cold reservoir temperatures of an internally reversible refrigerator. Thermal resistances between refrigerator and hot and cold reservoirs under clean and dusty conditions. Desired cooling rate.

FIND: Modified Coefficient of Performance and power input of refrigerator under clean and dusty conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Refrigerator is internally reversible, (2) Steady-state operation, (3) Cold side thermal resistance does not degrade over time.

ANALYSIS: According to Problem 1.38, the modified Coefficient of Performance and power input are given by

$$\text{COP}_m = \frac{T_c - q_{\text{in}} R_{\text{tot}}}{T_h - T_c + q_{\text{in}} R_{\text{tot}}} \tag{1}$$

$$\dot{W} = q_{\text{in}} \frac{T_h - T_c + q_{\text{in}} R_{\text{tot}}}{T_c - q_{\text{in}} R_{\text{tot}}} \tag{2}$$

Under new, clean conditions, with $R_{\text{tot},n} = R_{h,n} + R_{c,n} = 0.09$ K/W, we find

$$\text{COP}_{m,n} = \frac{278\text{ K} - 750\text{ W} \times 0.09\text{ K/W}}{298\text{ K} - 278\text{ K} + 750\text{ W} \times 0.09\text{ K/W}} = 2.41$$ <

$$\dot{W}_n = 750\text{ W} \frac{298\text{ K} - 278\text{ K} + 750\text{ W} \times 0.09\text{ K/W}}{278\text{ K} - 750\text{ W} \times 0.09\text{ K/W}} = 312\text{ W}$$ <

Under dusty, conditions, with $R_{\text{tot},d} = R_{h,d} + R_{c,n} = 0.15$ K/W, we find

$$\text{COP}_{m,d} = \frac{278\text{ K} - 750\text{ W} \times 0.15\text{ K/W}}{298\text{ K} - 278\text{ K} + 750\text{ W} \times 0.15\text{ K/W}} = 1.25$$ <

Continued...

PROBLEM 1.39 (Cont.)

$$\dot{W}_d = 750 \text{ W} \frac{298 \text{ K} - 278 \text{ K} + 750 \text{ W} \times 0.15 \text{ K/W}}{278 \text{ K} - 750 \text{ W} \times 0.15 \text{ K/W}} = 600 \text{ W} \quad <$$

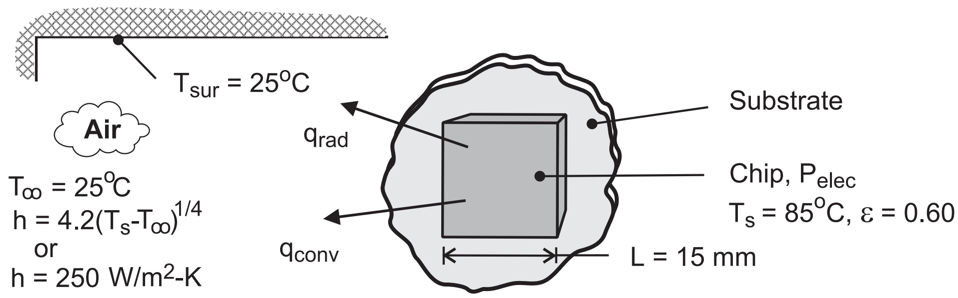
COMMENTS: (1) The cooling rates and power input values are time-averaged quantities. Since the refrigerator does not run constantly, the instantaneous power requirements would be higher than calculated. (2) In practice, when the condenser coils become dusty the power input does not adjust to maintain the cooling rate. Rather, the refrigerator's *duty cycle* would increase. (3) The ideal Carnot Coefficient of Performance is $COP_C = T_c/(T_h - T_c) = 14$ and the corresponding power input is 54 W. (4) This refrigerator's energy efficiency is poor. Less power would be consumed by more thoroughly insulating the refrigerator, and designing the refrigerator to minimize heat gain upon opening its door, in order to reduce the cooling rate, q_{in}.

PROBLEM 1.40

KNOWN: Width, surface emissivity and maximum allowable temperature of an electronic chip. Temperature of air and surroundings. Convection coefficient.

FIND: (a) Maximum power dissipation for free convection with $h(W/m^2 \cdot K) = 4.2(T - T_\infty)^{1/4}$, (b) Maximum power dissipation for forced convection with $h = 250\ W/m^2 \cdot K$.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Radiation exchange between a small surface and a large enclosure, (3) Negligible heat transfer from sides of chip or from back of chip by conduction through the substrate.

ANALYSIS: Subject to the foregoing assumptions, electric power dissipation by the chip must be balanced by convection and radiation heat transfer from the chip. Hence, from Eq. (1.10),

$$P_{elec} = q_{conv} + q_{rad} = hA(T_s - T_\infty) + \varepsilon A \sigma \left(T_s^4 - T_{sur}^4\right)$$

where $A = L^2 = (0.015m)^2 = 2.25 \times 10^{-4} m^2.$

(a) If heat transfer is by natural convection,

$$q_{conv} = C\,A\left(T_s - T_\infty\right)^{5/4} = 4.2\ W/m^2 \cdot K^{5/4}\left(2.25 \times 10^{-4} m^2\right)(60K)^{5/4} = 0.158\ W$$

$$q_{rad} = 0.60\left(2.25 \times 10^{-4} m^2\right) 5.67 \times 10^{-8}\ W/m^2 \cdot K^4 \left(358^4 - 298^4\right) K^4 = 0.065\ W$$

$$P_{elec} = 0.158\ W + 0.065\ W = 0.223\ W$$ <

(b) If heat transfer is by forced convection,

$$q_{conv} = hA\left(T_s - T_\infty\right) = 250\ W/m^2 \cdot K\left(2.25 \times 10^{-4} m^2\right)(60K) = 3.375\ W$$

$$P_{elec} = 3.375\ W + 0.065\ W = 3.44\ W$$ <

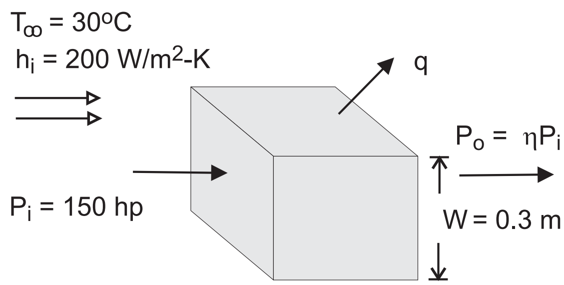
COMMENTS: Clearly, radiation and natural convection are inefficient mechanisms for transferring heat from the chip. For T_s = 85°C and T_∞ = 25°C, the natural convection coefficient is 11.7 $W/m^2 \cdot K$. Even for forced convection with h = 250 $W/m^2 \cdot K$, the power dissipation is well below that associated with many of today's processors. To provide acceptable cooling, it is often necessary to attach the chip to a highly conducting substrate and to thereby provide an additional heat transfer mechanism due to conduction from the back surface.

PROBLEM 1.41

KNOWN: Width, input power and efficiency of a transmission. Temperature and convection coefficient for air flow over the casing. Emissivity of casing and temperature of surroundings.

FIND: Surface temperature of casing.

SCHEMATIC:



ASSUMPTIONS: (1) Steady state, (2) Uniform convection coefficient and surface temperature, (3) Radiation exchange with large surroundings.

ANALYSIS: Heat transfer from the case must balance heat dissipation in the transmission, which may be expressed as $q = P_i - P_o = P_i(1 - \eta) = 150\text{ hp} \times 746\text{ W/hp} \times 0.07 = 7833\text{ W}$. Heat transfer from the case is by convection and radiation, in which case

$$q = A_s\left[h\left(T_s - T_\infty\right) + \varepsilon\sigma\left(T_s^4 - T_{sur}^4\right)\right]$$

where $A_s = 6\,W^2$. Hence,

$$7833\,\text{W} = 6\left(0.30\,\text{m}\right)^2\left[200\,\text{W/m}^2\cdot\text{K}\left(T_s - 303\text{K}\right) + 0.8\times5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left(T_s^4 - 303^4\right)\text{K}^4\right]$$

A trial-and-error solution yields

$$T_s \approx 373\,\text{K} = 100°\text{C}$$ <

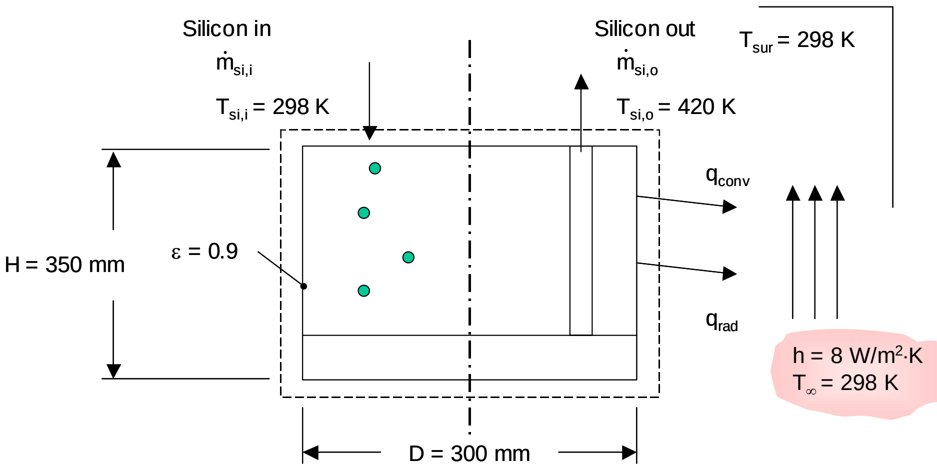
COMMENTS: (1) For $T_s \approx 373$ K, $q_{conv} \approx 7{,}560$ W and $q_{rad} \approx 270$ W, in which case heat transfer is dominated by convection, (2) If radiation is neglected, the corresponding surface temperature is T_s = 102.5°C.

PROBLEM 1.42

KNOWN: Process for growing thin, photovoltaic grade silicon sheets. Sheet dimensions and velocity. Dimensions, surface temperature and surface emissivity of growth chamber. Surroundings and ambient temperatures, and convective heat transfer coefficient. Amount of time-averaged absorbed solar irradiation and photovoltaic conversion efficiency.

FIND: (a) Electric power needed to operate at steady state, (b) Time needed to operate the photovoltaic panel to produce enough energy to offset energy consumed during its manufacture.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Large surroundings, (3) Constant properties, (4) Neglect the presence of the strings.

PROPERTIES: *Table A-1*, Silicon (T = 298 K): c = 712 J/kg·K, ρ = 2330 kg/m^3, (T = 420 K): c = 798 J/kg·K.

ANALYSIS: (a) At steady state, the mass of silicon produced per unit time is equal to the mass of silicon added to the system per unit time. The amount of silicon produced is

$$\dot{m} = W_{si} \times t_{si} \times V_{si} \times \rho = 0.085\text{m} \times 150 \times 10^{-6}\text{m} \times 0.020\text{m/min} \times (1/60)\text{min/s} \times 2330\text{kg/m}^3 = 9.90 \times 10^{-6}\text{kg/s}$$

At steady state, $\dot{E}_{in} = \dot{E}_{out}$ where

$$\dot{E}_{\text{in}} = P_{\text{elec}} + \dot{m}cT_{\text{si},i} = P_{\text{elec}} + 9.90 \times 10^{-6}\frac{\text{kg}}{\text{s}} \times 712\frac{\text{J}}{\text{kg}\cdot\text{K}} \times 298\text{K} = P_{\text{elec}} + 2.10 \text{ J/s} = P_{\text{elec}} + 2.10 \text{ W}$$

and

$$\dot{E}_{\text{out}} = \dot{m}cT_{\text{si},o} + \left[2\pi D^2/4 + H\pi D\right]\left[h(T_s - T_\infty) + \varepsilon\sigma(T_s^4 - T_{\text{sur}}^4)\right]$$

$$= 9.9 \times 10^{-6}\frac{\text{kg}}{\text{s}} \times 798\frac{\text{J}}{\text{kg}\cdot\text{K}} \times 420\text{K} + \left[2\pi \times (0.3\text{m})^2/4 + 0.35\text{m} \times \pi \times 0.3\text{m}\right]$$

$$\times\left[8\frac{\text{W}}{\text{m}^2\cdot\text{K}} \times (320 - 298)\text{K} + 5.67 \times 10^{-8}\frac{\text{W}}{\text{m}^2\cdot\text{K}^4} \times 0.9 \times \left((420\text{K})^4 - (298\text{K})^4\right)\right] = 645 \text{ W}$$

Therefore,

Continued…

PROBLEM 1.42 (Cont.)

$$P_{elec} = 645\text{ W} - 2.10\text{ W} = 643\text{ W}$$ <

(b) The electric energy needed to manufacture the photovoltaic material is

$$E_m = P_{elec}/(W_s V_s) = 643\text{ W}/(0.085\text{ m}\times 0.020\text{ m/min}\times(1/60)\text{ min/s}) = 22.7\times 10^6\text{ J/m}^2 = 22.7\times 10^3\text{ kJ/m}^2$$

The time needed to generate E_m by the photovoltaic panel is

$$t = E_m / q''_{sol}\eta = 22.7\times 10^6\text{ J/m}^2/(180\text{W/m}^2\times 0.20) = 630\times 10^3\text{s} = 175\text{ h}$$ <

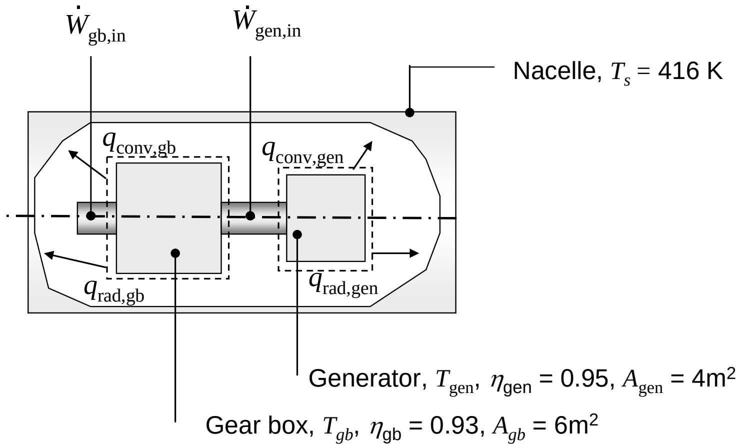
COMMENTS: (1) The radiation and convection losses are primarily responsible for the electric power needed to manufacture the photovoltaic material. Of these, radiation losses dominate, with radiation responsible for 87% of the losses. The radiation losses could be reduced by coating the exposed surface of the chamber with a low emissivity material. (2) Assuming an electricity cost of \$0.15/kWh, the electric cost to manufacture the material is 22.7×10^3 kJ/m^2 × (\$0.15/kWh) × (1h/3600s) = \$0.95/m^2. (3) In this solution, a reference state of 0 K is tacitly assumed for the silicon for the energy inflow and outflow terms, however the reference state for the equations for energy inflow and outflow cancel. (4) This problem represents a type of *life cycle analysis* in which the energy consumed to manufacture a product is of interest. The analysis presented here does not account for the energy that is consumed to produce the silicon powder, the energy used to fabricate the growth chamber, or the energy that is used to fabricate and install the photovoltaic panel. The actual time needed to offset the energy to manufacture and install the photovoltaic panel will be much greater than 175 h. See Keoleian and Leis, "Application of Life-cycle Energy Analysis to Photovoltaic Module Design, *Progress in Photovoltaics: Research and Applications*, Vol. 5, pp. 287-300, 1997.

PROBLEM 1.43

KNOWN: Surface areas, convection heat transfer coefficient, surface emissivity of gear box and generator. Temperature of nacelle. Electric power generated by the wind turbine and generator efficiency.

FIND: Gear box and generator surface temperatures.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Interior of nacelle can be treated as large surroundings, (3) Negligible heat transfer between the gear box and the generator.

ANALYSIS: Heat is generated within both the gear box and the generator. The mechanical work into the generator can be determined from the electrical power, $P = 2.5 \times 10^6$ W, and the efficiency of the generator as

$$\dot{W}_{gen,in} = P/\eta_{gen} = 2.5\times10^6\,\text{W}/0.95 = 2.63\times10^6\,\text{W}$$

Therefore, the heat transfer from the generator is

$$q_{gen} = \dot{W}_{gen} - P = 2.63\times10^6\,\text{W} - 2.5\times10^6\,\text{W} = 0.13\times10^6\,\text{W}$$

The heat transfer is composed of convection and radiation components. Hence,

$$\begin{aligned} q_{gen} &= A_{gen}\left[h\left(T_{gen}-T_s\right)+\varepsilon\sigma\left(T_{gen}^4-T_s^4\right)\right] \\ &= 4\text{m}^2\times\left[40\frac{\text{W}}{\text{m}^2\cdot\text{K}}\left(T_{gen}-416\text{K}\right)+0.90\times5.67\times10^{-8}\frac{\text{W}}{\text{m}^2\cdot\text{K}^4}\left(T_{gen}^4-\left(416\text{K}\right)^4\right)\right] \\ &= 0.13\times10^6\text{W} \end{aligned}$$

The generator surface temperature may be found by using a numerical solver, or by trial-and-error, yielding

T_{gen} = 785 K = 512°C <

Continued...

PROBLEM 1.43 (Cont.)

Heat is also generated by the gear box. The heat generated in the gear box may be determined from knowledge of the heat generated cumulatively by the gear box and the generator, which is provided in Example 3.1 and is $q = q_{gen} + q_{gb} = 0.33 \times 10^6$ W. Hence, $q_{gb} = q - q_{gen} = 0.33 \times 10^6\text{W} - 0.13 \times 10^6\text{W} = 0.20 \times 10^6\text{W}$ and

$$q_{gb} = A_{gb}\left[h\left(T_{gb} - T_s\right) + \varepsilon\sigma\left(T_{gb}^4 - T_s^4\right)\right]$$

$$= 6\text{m}^2 \times \left[40\frac{\text{W}}{\text{m}^2\cdot\text{K}}\left(T_{gb} - 416\text{K}\right) + 0.90 \times 5.67 \times 10^{-8}\frac{\text{W}}{\text{m}^2\cdot\text{K}^4}\left(T_{gb}^4 - \left(416\text{K}\right)^4\right)\right]$$

$$= 0.20 \times 10^6\text{W}$$

which may be solved by trial-and-error or with a numerical solver to find

$$T_{gb} = 791 \text{ K} = 518°\text{C}$$ <

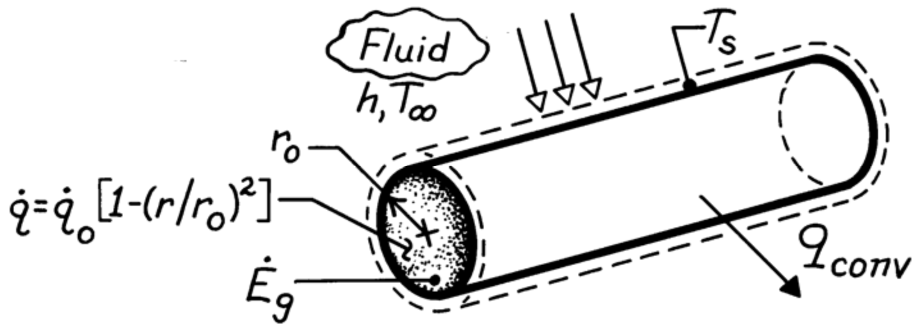
COMMENTS: (1) The gear box and generator temperatures are unacceptably high. Thermal management must be employed in order to generate power from the wind turbine. (2) The gear box and generator temperatures are of similar value. Hence, the assumption that heat transfer between the two mechanical devices is small is valid. (3) The radiation and convection heat transfer rates are of similar value. For the generator, convection and radiation heat transfer rates are $q_{conv,gen} = 5.9 \times 10^4$ W and $q_{rad,gen} = 7.1 \times 10^4$ W, respectively. The convection and radiation heat transfer rates are $q_{conv,gb} = 9.0 \times 10^4$ W and $q_{rad,gb} = 11.0 \times 10^4$ W, respectively, for the gear box. It would be a poor assumption to neglect either convection or radiation in the analysis.

PROBLEM 1.44

KNOWN: Radial distribution of heat dissipation in a cylindrical container of radioactive wastes. Surface convection conditions.

FIND: Total energy generation rate and surface temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible temperature drop across thin container wall.

ANALYSIS: The rate of energy generation is

$$\dot{E}_g = \int \dot{q} dV = \dot{q}_o \int_0^{r_o} \left[1-\left(r/r_o\right)^2\right] 2\pi r L dr$$

$$\dot{E}_g = 2\pi L \dot{q}_o \left(r_o^2/2 - r_o^2/4\right)$$

or per unit length,

$$\dot{E}'_g = \frac{\pi \dot{q}_o r_o^2}{2}. \qquad <$$

Performing an energy balance for a control surface about the container yields, at an instant,

$$\dot{E}'_g - \dot{E}'_{out} = 0$$

and substituting for the convection heat rate per unit length,

$$\frac{\pi \dot{q}_o r_o^2}{2} = h\left(2\pi r_o\right)\left(T_s - T_\infty\right)$$

$$T_s = T_\infty + \frac{\dot{q}_o r_o}{4h}. \qquad <$$

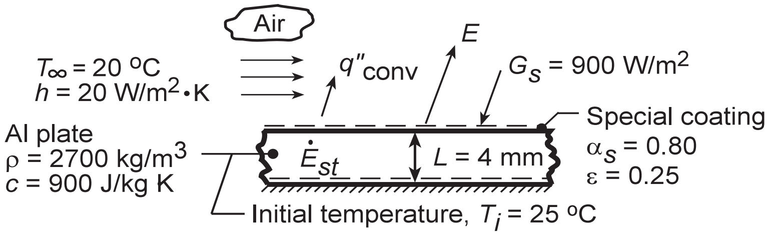
COMMENTS: The temperature within the radioactive wastes increases with decreasing r from T_s at r_o to a maximum value at the centerline.

PROBLEM 1.45

KNOWN: Thickness and initial temperature of an aluminum plate whose thermal environment is changed.

FIND: (a) Initial rate of temperature change, (b) Steady-state temperature of plate, (c) Effect of emissivity and absorptivity on steady-state temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible end effects, (2) Uniform plate temperature at any instant, (3) Constant properties, (4) Adiabatic bottom surface, (5) Negligible radiation from surroundings, (6) No internal heat generation.

ANALYSIS: (a) Applying an energy balance, Eq. 1.12c, at an instant of time to a control volume about the plate, $\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st}$, it follows for a unit surface area.

$$\alpha_S G_S \left(1\,m^2\right) - E\left(1\,m^2\right) - q''_{conv}\left(1\,m^2\right) = (d/dt)(McT) = \rho\left(1\,m^2 \times L\right)c\,(dT/dt).$$

Rearranging and substituting from Eqs. 1.3 and 1.5, we obtain

$$dT/dt = (1/\rho Lc)\left[\alpha_S G_S - \varepsilon\sigma T_i^4 - h\left(T_i - T_\infty\right)\right].$$

$$dT/dt = \left(2700\,kg/m^3 \times 0.004\,m \times 900\,J/kg\cdot K\right)^{-1} \times$$

$$\left[0.8 \times 900\,W/m^2 - 0.25 \times 5.67 \times 10^{-8}\,W/m^2\cdot K^4\,(298\,K)^4 - 20\,W/m^2\cdot K\,(25-20)^\circ C\right]$$

$$dT/dt = 0.052^\circ\,C/s\,.$$ <

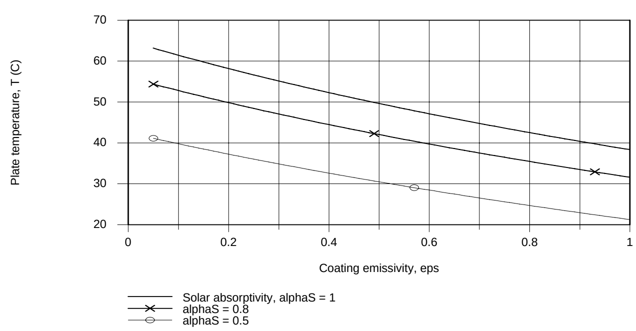
(b) Under steady-state conditions, $\dot{E}_{st} = 0$, and the energy balance reduces to

$$\alpha_S G_S = \varepsilon\sigma T^4 + h\left(T - T_\infty\right) \qquad (2)$$

$$0.8 \times 900\,W/m^2 = 0.25 \times 5.67 \times 10^{-8}\,W/m^2\cdot K^4 \times T^4 + 20\,W/m^2\cdot K\,(T - 293\,K)$$

The solution yields T = 321.4 K = 48.4°C. <

(c) Using the IHT *First Law Model* for an *Isothermal Plane Wall*, parametric calculations yield the following results.



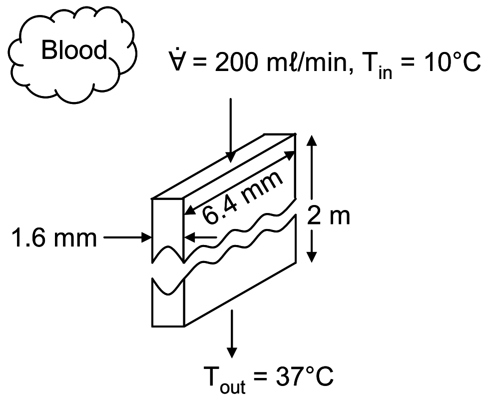
COMMENTS: The surface radiative properties have a significant effect on the plate temperature, which decreases with increasing ε and decreasing α_S. If a low temperature is desired, the plate coating should be characterized by a large value of ε/α_S. The temperature also decreases with increasing h.

PROBLEM 1.46

KNOWN: Blood inlet and outlet temperatures and flow rate. Dimensions of tubing.

FIND: Required rate of heat addition and estimate of kinetic and potential energy changes.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Incompressible liquid with negligible kinetic and potential energy changes, (3) Blood has properties of water.

PROPERTIES: Table A.6, Water ($\overline{T} \approx 300$ K): $c_{p,f} = 4179$ J/ kg· K, $\rho_f = 1/v_f = 997$ kg/m^3.

ANALYSIS: From an overall energy balance, Equation 1.12e,

$$q = \dot{m} c_p (T_{out} - T_{in})$$

where

$$\dot{m} = \rho_f \dot{\forall} = 997 \text{ kg/m}^3 \times 200 \text{ m}\ell\text{/min} \times 10^{-6} \text{ m}^3/\text{m}\ell \,/\, 60 \text{ s/min} = 3.32 \times 10^{-3} \text{ kg/s}$$

Thus

$$q = 3.32 \times 10^{-3} \text{ kg/s} \times 4179 \text{ J/kg} \cdot \text{K} \times (37^{\circ}\text{C} - 10^{\circ}\text{C}) = 375 \text{ W} \qquad <$$

The velocity in the tube is given by

$$V = \dot{\forall}/A_c = 200 \text{ m}\ell\text{/min} \times 10^{-6} \text{ m}^3/\text{m}\ell \,/\, (60 \text{ s/min} \times 6.4 \times 10^{-3} \text{ m} \times 1.6 \times 10^{-3} \text{ m}) = 0.33 \text{ m/s}$$

The change in kinetic energy is

$$\dot{m}(\frac{1}{2}V^2 - 0) = 3.32 \times 10^{-3} \text{ kg/s} \times \frac{1}{2} \times (0.33 \text{ m/s})^2 = 1.8 \times 10^{-4} \text{ W} \qquad <$$

The change in potential energy is

$$\dot{m}gz = 3.32 \times 10^{-3} \text{ kg/s} \times 9.8 \text{ m/s}^2 \times 2 \text{ m} = 0.065 \text{ W} \qquad <$$

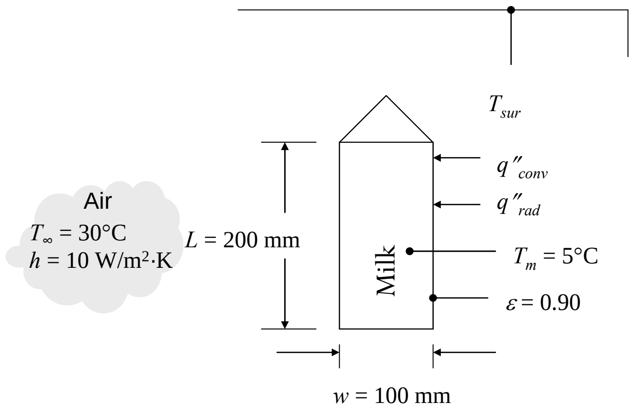
COMMENT: The kinetic and potential energy changes are both negligible relative to the thermal energy change.

PROBLEM 1.47

KNOWN: Dimensions of a milk carton. Temperatures of milk carton and surrounding air. Convection heat transfer coefficient and surface emissivity.

FIND: Heat transferred to milk carton for durations of 10, 60, and 300 s.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat transfer from bottom surface of milk carton and from top surface since it is not in contact with cold milk, (2) Radiation is to large surroundings at the air temperature.

ANALYSIS: The area of the four sides is $A = 4L \times w = 4(0.2 \text{ m} \times 0.1 \text{ m}) = 0.08 \text{ m}^2$. Thus,

$$q = (q_{\text{conv}} + q_{\text{rad}}) = hA(T_\infty - T_s) + \varepsilon\sigma A(T_{\text{sur}}^4 - T_s^4)$$
$$= 10 \text{ W/m}^2 \cdot \text{K} \times 0.08 \text{ m}^2 (30°\text{C} - 5°\text{C}) + 0.90 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times 0.08 \text{ m}^2 \left((303 \text{ K})^4 - (278 \text{ K})^4\right)$$
$$= 20.0 \text{ W} + 10.0 \text{ W} = 30.0 \text{ W}$$

For a duration of 10 s,

$Q = q\Delta t$ = 30.0 W × 10 s = 300 J <

Similarly, Q = 1800 J and 9000 J for durations of 60 and 300 s, respectively. <

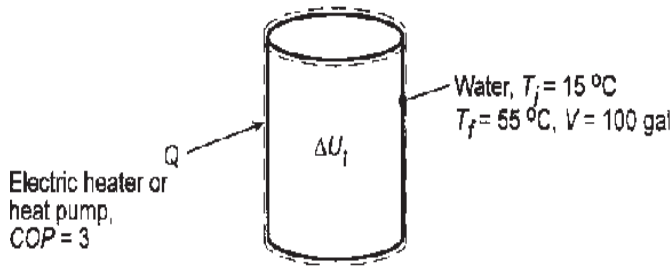
COMMENTS: (1) The predicted heat transfer rates do not account for the fact that the milk temperature increases with time. If the increase in milk temperature were accounted for, the values of Q would be less than calculated. (2) If the coefficient of performance of the refrigerator is 2, COP = Q/W = 2, then the required work input to re-cool the milk after leaving it in the kitchen for 300 s is 4500 J. At an electricity price of $0.18/kW·h, this would cost about $0.0002, which is insignificant. Preventing bacterial growth is a more important reason to return the milk to the refrigerator promptly. (3) The analysis neglects condensation that might occur on the outside of the milk carton. Condensation would increase the rate of heat transfer to the milk significantly, increasing the importance of returning the milk to the refrigerator promptly.

PROBLEM 1.48

KNOWN: Daily hot water consumption for a family of four and temperatures associated with ground water and water storage tank. Unit cost of electric power. Heat pump COP.

FIND: Annual heating requirement and costs associated with using electric resistance heating or a heat pump.

SCHEMATIC:



ASSUMPTIONS: (1) Process may be modeled as one involving heat addition in a closed system, (2) Properties of water are constant.

PROPERTIES: Table A-6, Water (T_{avg} = 308 K): $\rho = v_f^{-1}$ = 993 kg/m^3, $c_{p,f}$ = 4.178 kJ/kg·K.

ANALYSIS: From Eq. 1.12a, the daily heating requirement is $Q_{daily} = \Delta U_t = Mc\Delta T$ $= \rho Vc\left(T_f - T_i\right)$. With V = 100 gal/264.17 gal/m^3 = 0.379 m^3,

$$Q_{daily} = 993\,kg/m^3\left(0.379\,m^3\right)4.178\,kJ/kg\cdot K\left(40^\circ C\right) = 62,900\,kJ$$

The annual heating requirement is then, $Q_{annual} = 365\,days\left(62,900\,kJ/day\right) = 2.30\times10^7$ kJ, or, with 1 kWh = 1 kJ/s (3600 s) = 3600 kJ,

$$Q_{annual} = 6380\,kWh$$ <

With electric resistance heating, $Q_{annual} = Q_{elec}$ and the associated cost, C, is

$$C = 6380\,kWh\left(\$0.18/kWh\right) = \$1150$$ <

If a heat pump is used, $Q_{annual} = COP\left(W_{elec}\right)$. Hence,

$$W_{elec} = Q_{annual}/\left(COP\right) = 6380\,kWh/\left(3\right) = 2130\,kWh$$

The corresponding cost is

$$C = 2130\,kWh\left(\$0.18/kWh\right) = \$383$$ <

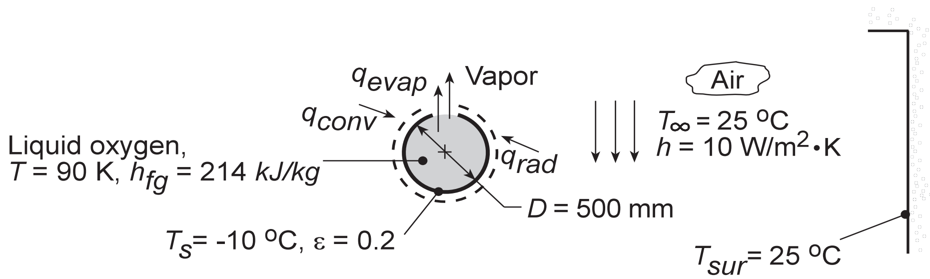
COMMENTS: Although annual operating costs are significantly lower for a heat pump, corresponding capital costs are higher. The feasibility of this approach depends on other factors such as geography and seasonal variations in COP, as well as the time value of money.

PROBLEM 1.49

KNOWN: Boiling point and latent heat of liquid oxygen. Diameter and emissivity of container. Free convection coefficient and temperature of surrounding air and walls.

FIND: Mass evaporation rate.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Temperature of container outer surface equals boiling point of oxygen.

ANALYSIS: (a) Applying mass and energy balances to a control surface about the container, it follows that, at any instant,

$$\frac{dm_{st}}{dt} = -\dot{m}_{out} = -\dot{m}_{evap} \qquad \frac{dE_{st}}{dt} = \dot{E}_{in} - \dot{E}_{out} = q_{conv} + q_{rad} - q_{evap}\,. \tag{1a,b}$$

With h_f as the enthalpy of liquid oxygen and h_g as the enthalpy of oxygen vapor, we have

$$E_{st} = m_{st} h_f \qquad q_{evap} = \dot{m}_{out} h_g \tag{2a,b}$$

Combining Equations (1a) and (2a,b), Equation (1b) becomes (with $h_{fg} = h_g - h_f$)

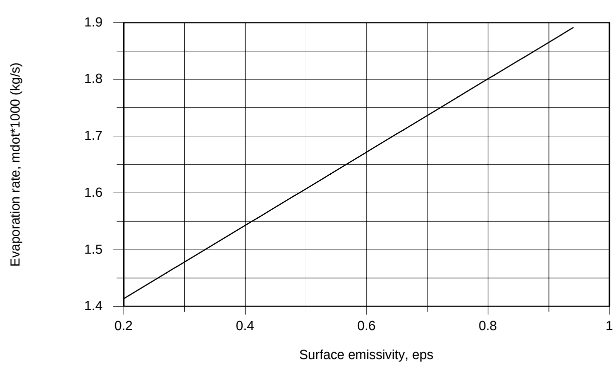
$$\dot{m}_{out} h_{fg} = q_{conv} + q_{rad}$$

$$\dot{m}_{evap} = \left(q_{conv} + q_{rad}\right)/h_{fg} = \left[h\left(T_\infty - T_s\right) + \varepsilon\sigma\left(T_{sur}^4 - T_s^4\right)\right]\pi D^2 \big/ h_{fg} \tag{3}$$

$$\dot{m}_{evap} = \frac{\left[10\,W/m^2 \cdot K\left(298 - 263\right)K + 0.2 \times 5.67 \times 10^{-8}\,W/m^2 \cdot K^4\left(298^4 - 263^4\right)K^4\right]\pi\left(0.5\,m\right)^2}{214\,kJ/kg}$$

$$\dot{m}_{evap} = \left(350 + 35.2\right)W/m^2\left(0.785\ m^2\right)\Big/214\,kJ/kg = 1.41 \times 10^{-3}\,kg/s\,.$$ <

(b) Using Equation (3), the mass rate of vapor production can be determined for the range of emissivity 0.2 to 0.94. The effect of increasing emissivity is to increase the heat rate into the container and, hence, increase the vapor production rate.



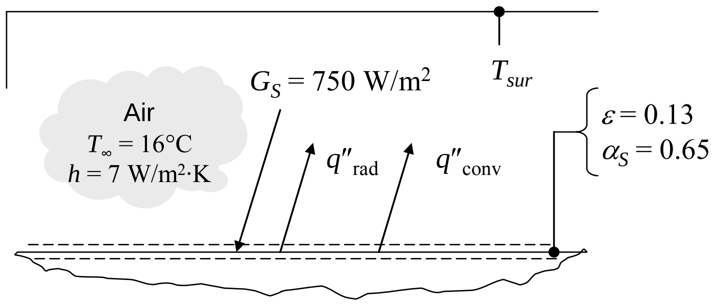
COMMENTS: To reduce the loss of oxygen due to vapor production, insulation should be applied to the outer surface of the container, in order to reduce q_{conv} and q_{rad}. Note from the calculations in part (a), that heat transfer by convection is greater than by radiation exchange.

PROBLEM 1.50

KNOWN: Emissivity and solar absorptivity of steel sheet. Solar irradiation, air temperature and convection coefficient.

FIND: Temperature of the steel sheet to determine cat comfort.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Bottom surface of steel is insulated, (3) Radiation from the environment can be treated as radiation from large surroundings, with $\alpha = \varepsilon$, (4) $T_{sur} = T_\infty$.

ANALYSIS: Performing a control surface energy balance on the top surface of the steel sheet gives (on a per unit area basis)

$$\alpha_S G_S - q''_{rad} - q''_{conv} = 0$$
$$\alpha_S G_S - \varepsilon\sigma(T_s^4 - T_{sur}^4) - h(T_s - T_\infty) = 0$$

$$0.65 \times 750 \text{ W/m}^2 - 0.13 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 (T_s^4 - (289 \text{ K})^4) - 7 \text{ W/m}^2 \cdot \text{K}(T_s - 289 \text{ K}) = 0$$
$$2562 \text{ W/m}^2 - 7.37 \times 10^{-9} \text{ W/m}^2 \cdot \text{K}^4 T_s^4 - 7 \text{ W/m}^2 \cdot \text{K } T_s = 0$$

Solving this equation for T_s using IHT or other software results in $T_s = 350$ K = 77°C. A temperature of 60°C is typically safe to touch without being burned. The steel sheet would be uncomfortably hot or even cause burning. <

COMMENTS: The individual heat flux terms are

$$\alpha_s G_s = 488 \text{ W/m}^2$$
$$q''_{rad} = \varepsilon\sigma(T_s^4 - T_{sur}^4) = 59 \text{ W/m}^2$$
$$q''_{conv} = h(T_s - T_\infty) = 428 \text{ W/m}^2$$

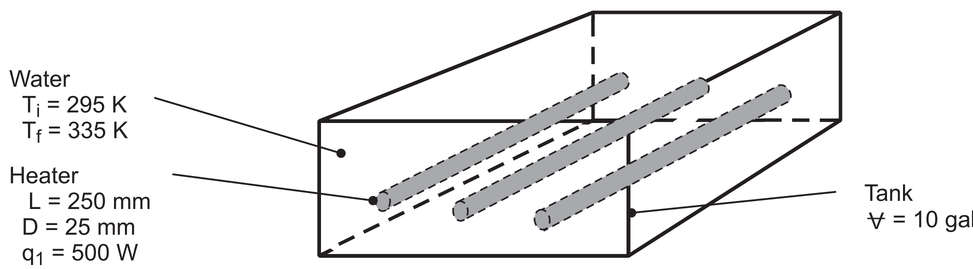
None of these is negligible, although the radiation exchange with the surroundings is smaller than the solar radiation and convection terms.

PROBLEM 1.51

KNOWN: Initial temperature of water and tank volume. Power dissipation, emissivity, length and diameter of submerged heaters. Expressions for convection coefficient associated with natural convection in water and air.

FIND: (a) Time to raise temperature of water to prescribed value, (b) Heater temperature shortly after activation and at conclusion of process, (c) Heater temperature if activated in air.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss from tank to surroundings, (2) Water is *well-mixed* (at a uniform, but time varying temperature) during heating, (3) Negligible changes in thermal energy storage for heaters, (4) Constant properties, (5) Surroundings afforded by tank wall are large relative to heaters.

ANALYSIS: (a) Application of conservation of energy to a closed system (the water) at an instant, Equation (1.12c), with

$$\dot{E}_{st} = dU_t/dt, \quad \dot{E}_{in} = 3q_1, \quad \dot{E}_{out} = 0, \text{ and } \dot{E}_g = 0,$$

$$\text{yields } \frac{dU_t}{dt} = 3q_1 \text{ and } \rho\forall c\frac{dT}{dt} = 3q_1$$

Hence, $\int_0^t dt = \left(\rho\forall c/3q_1\right)\int_{T_i}^{T_f} dT$

$$t = \frac{990\ \text{kg/m}^3 \times 10\text{gal}\left(3.79\times10^{-3}\text{m}^3/\text{gal}\right)4180\text{J/kg}\cdot\text{K}}{3\times500\ \text{W}}\left(335-295\right)\text{K} = 4180\ \text{s}$$ <

(b) From Equation (1.3a), the heat rate by convection from each heater is

$$q_1 = Aq_1'' = Ah\left(T_s - T\right) = \left(\pi DL\right)370\left(T_s - T\right)^{4/3}$$

Hence, $T_s = T + \left(\frac{q_1}{370\pi DL}\right)^{3/4} = T + \left(\frac{500\ \text{W}}{370\ \text{W/m}^2\cdot\text{K}^{4/3}\times\pi\times0.025\ \text{m}\times0.250\ \text{m}}\right)^{3/4} = \left(T+24\right)\text{K}$

With water temperatures of $T_i \approx 295$ K and $T_f = 335$ K shortly after the start of heating and at the end of heating, respectively, $T_{s,i} = 319$ K and $T_{s,f} = 359$ K <

(c) From Equation (1.10), the heat rate in air is

$$q_1 = \pi DL\left[0.70\left(T_s - T_\infty\right)^{4/3} + \varepsilon\sigma\left(T_s^4 - T_{sur}^4\right)\right]$$

Substituting the prescribed values of q_1, D, L, $T_\infty = T_{sur}$ and ε, an iterative solution yields

$T_s = 830$ K <

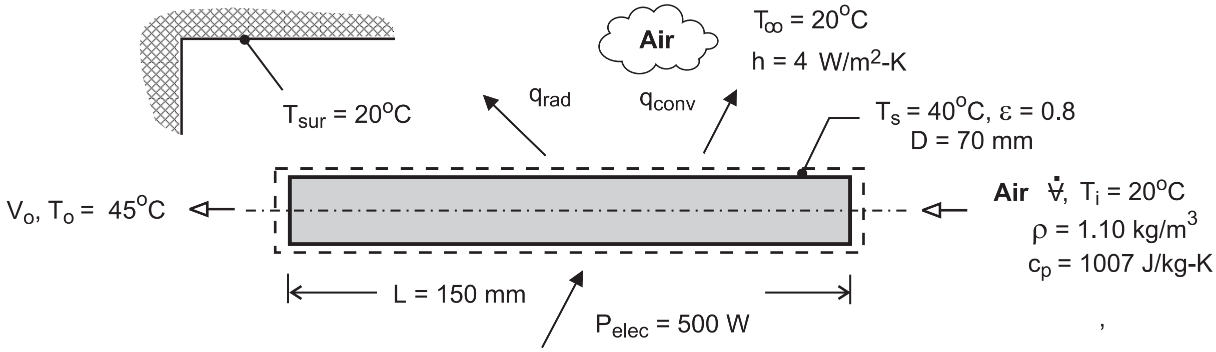
COMMENTS: In part (c) it is presumed that the heater can be operated at $T_s = 830$ K without experiencing burnout. The much larger value of T_s for air is due to the smaller convection coefficient. However, with q_{conv} and q_{rad} equal to 59 W and 441 W, respectively, a significant portion of the heat dissipation is effected by radiation.

PROBLEM 1.52

KNOWN: Power consumption, diameter, and inlet and discharge temperatures of a hair dryer.

FIND: (a) Volumetric flow rate and discharge velocity of heated air, (b) Heat loss from case.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Constant air properties, (3) Negligible potential and kinetic energy changes of air flow, (4) Negligible work done by fan, (5) Negligible heat transfer from casing of dryer to ambient air (Part (a)), (6) Radiation exchange between a small surface and a large enclosure (Part (b)).

ANALYSIS: (a) For a control surface about the air flow passage through the dryer, conservation of energy for an open system reduces to

$$\dot{m}(u+pv)_i - \dot{m}(u+pv)_o + q = 0$$

where u + pv = i and $q = P_{elec}$. Hence, with $\dot{m}(i_i - i_o) = \dot{m}c_p(T_i - T_o)$,

$$\dot{m}c_p(T_o - T_i) = P_{elec}$$

$$\dot{m} = \frac{P_{elec}}{c_p(T_o - T_i)} = \frac{500\text{ W}}{1007\text{ J/kg}\cdot\text{K}(25^\circ\text{C})} = 0.0199\text{ kg/s}$$

$$\dot{\forall} = \frac{\dot{m}}{\rho} = \frac{0.0199\text{ kg/s}}{1.10\text{ kg/m}^3} = 0.0181\text{ m}^3/\text{s} \quad <$$

$$V_o = \frac{\dot{\forall}}{A_c} = \frac{4\dot{\forall}}{\pi D^2} = \frac{4\times 0.0181\text{ m}^3/\text{s}}{\pi(0.07\text{ m})^2} = 4.7\text{ m/s} \quad <$$

(b) Heat transfer from the casing is by convection and radiation, and from Equation (1.10)

$$q = hA_s(T_s - T_\infty) + \varepsilon A_s\sigma\left(T_s^4 - T_{sur}^4\right)$$

where $A_s = \pi DL = \pi(0.07\text{ m}\times 0.15\text{ m}) = 0.033\text{ m}^2$. Hence,

$$q = 4\text{W/m}^2\cdot\text{K}\left(0.033\text{ m}^2\right)\left(20^\circ\text{C}\right) + 0.8\times 0.033\text{ m}^2\times 5.67\times 10^{-8}\text{ W/m}^2\cdot\text{K}^4\left(313^4 - 293^4\right)\text{K}^4$$

$$q = 2.64\text{ W} + 3.33\text{ W} = 5.97\text{ W} \quad <$$

The heat loss is much less than the electrical power, and the assumption of negligible heat loss is justified.

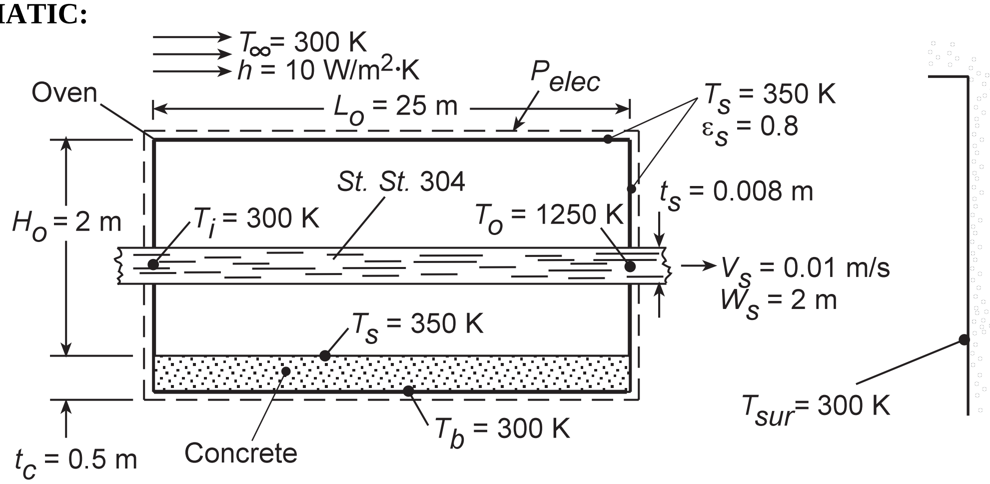
COMMENTS: Although the mass flow rate is invariant, the volumetric flow rate increases because the air is heated in its passage through the dryer, causing a reduction in the density. However, for the prescribed temperature rise, the change in ρ, and hence the effect on $\dot{\forall}$, is small.

PROBLEM 1.53

KNOWN: Speed, width, thickness and initial and final temperatures of 304 stainless steel in an annealing process. Dimensions of annealing oven and temperature, emissivity and convection coefficient of surfaces exposed to ambient air and large surroundings of equivalent temperatures. Thickness of pad on which oven rests and pad surface temperatures.

FIND: Oven operating power.

SCHEMATIC:



ASSUMPTIONS: (1) steady-state, (2) Constant properties, (3) Negligible changes in kinetic and potential energy.

PROPERTIES: Table A.1, St.St.304 $\left(\overline{T} = \left(T_i + T_o\right)/2 = 775\,K\right)$: ρ = 7900 kg/m^3, c_p = 578 J/kg·K; Table A.3, Concrete, T = 300 K: k_c = 1.4 W/m·K.

ANALYSIS: The rate of energy addition to the oven must balance the rate of energy transfer to the steel sheet and the rate of heat loss from the oven. Viewing the oven as an open system, Equation (1.12e) yields

$$P_{elec} - q = \dot{m}c_p(T_o - T_i)$$

where q is the heat transferred from the oven. With $\dot{m} = \rho V_s\left(W_s t_s\right)$ and

$$q = \left(2H_oL_o + 2H_oW_o + W_oL_o\right)\times\left[h\left(T_s - T_\infty\right) + \varepsilon_s\sigma\left(T_s^4 - T_{sur}^4\right)\right] + k_c\left(W_oL_o\right)\left(T_s - T_b\right)/t_c\,,$$

it follows that

$$P_{elec} = \rho V_s\left(W_s t_s\right)c_p\left(T_o - T_i\right) + \left(2H_oL_o + 2H_oW_o + W_oL_o\right)\times$$
$$\left[h\left(T_s - T_\infty\right) + \varepsilon_s\sigma\left(T_s^4 - T_{sur}^4\right)\right] + k_c\left(W_oL_o\right)\left(T_s - T_b\right)/t_c$$

$$P_{elec} = 7900\,kg/m^3 \times 0.01 m/s\left(2\,m \times 0.008\,m\right)578 J/kg\cdot K\left(1250 - 300\right)K$$
$$+\left(2\times 2m \times 25m + 2\times 2m\times 2.4m + 2.4m\times 25m\right)[10 W/m^2\cdot K\left(350 - 300\right)K$$
$$+0.8\times 5.67\times 10^{-8}\,W/m^2\cdot K^4\left(350^4 - 300^4\right)K^4] + 1.4 W/m\cdot K\left(2.4m\times 25m\right)\left(350 - 300\right)K/0.5m$$

$$P_{elec} = 694{,}000 W + 169.6 m^2\left(500 + 313\right)W/m^2 + 8400 W$$

$$= \left(694{,}000 + 84{,}800 + 53{,}100 + 8400\right)W = 840 kW$$ <

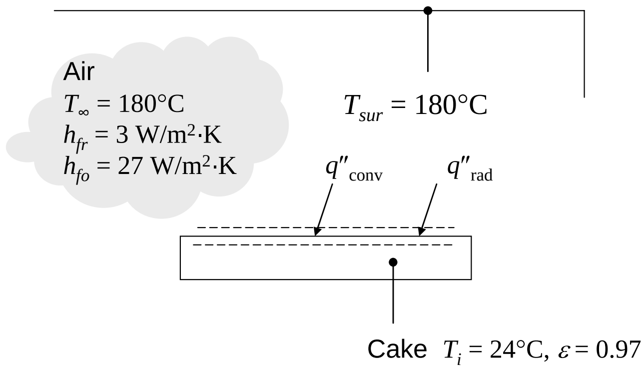
COMMENTS: Of the total energy input, 83% is transferred to the steel while approximately 10%, 6% and 1% are lost by convection, radiation and conduction from the oven. The convection and radiation losses can both be reduced by adding insulation to the side and top surfaces, which would reduce the corresponding value of T_s.

PROBLEM 1.54

KNOWN: Temperatures of small cake as well as oven air and walls. Convection heat transfer coefficient under free and forced convection conditions. Emissivity of cake batter and pan.

FIND: Heat flux to cake under free and forced convection conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Large surroundings.

ANALYSIS: The heat flux to the cake pan and batter is due to convection and radiation. With the surface temperature equal to T_i, when the convection feature is disabled,

$$q''_{fr} = (q''_{\text{conv}} + q''_{\text{rad}}) = h_{fr}(T_\infty - T_i) + \varepsilon\sigma(T_{\text{sur}}^4 - T_i^4)$$

$$= 3\text{ W/m}^2\cdot\text{K}(180°\text{C} - 24°\text{C}) + 0.97\times 5.67\times 10^{-8}\text{ W/m}^2\cdot\text{K}^4\left((180+273\text{ K})^4 - (24+273\text{ K})^4\right) \quad <$$

$$= 470\text{ W/m}^2 + 1890\text{ W/m}^2 = 2360\text{ W/m}^2$$

When the convection feature is activated, the heat flux is

$$q''_{fo} = (q''_{\text{conv}} + q''_{\text{rad}}) = h_{fo}(T_\infty - T_i) + \varepsilon\sigma(T_{\text{sur}}^4 - T_i^4)$$

$$= 27\text{ W/m}^2\cdot\text{K}(180°\text{C} - 24°\text{C}) + 0.97\times 5.67\times 10^{-8}\text{ W/m}^2\cdot\text{K}^4\left((180+273\text{ K})^4 - (24+273\text{ K})^4\right) \quad <$$

$$= 4210\text{ W/m}^2 + 1890\text{ W/m}^2 = 6100\text{ W/m}^2$$

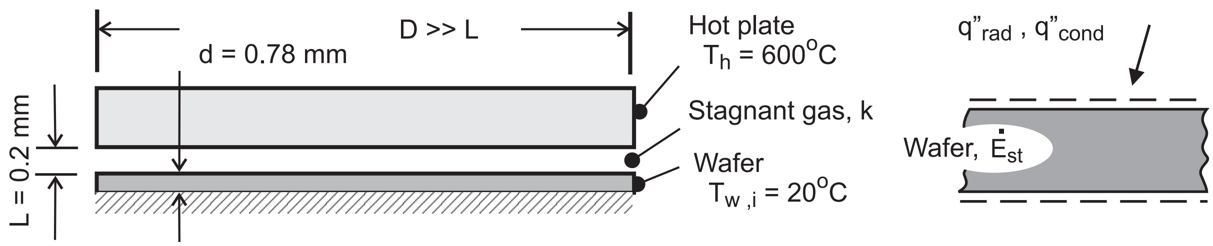
COMMENTS: Under free convection conditions, the convection contribution is about 20% of the total heat flux. When forced convection is activated, convection becomes larger than radiation, accounting for 69% of the total heat flux. The cake will bake faster under forced convection conditions.

PROBLEM 1.55

KNOWN: Hot plate-type wafer thermal processing tool based upon heat transfer modes by conduction through gas within the gap and by radiation exchange across gap.

FIND: (a) Radiative and conduction heat fluxes across gap for specified hot plate and wafer temperatures and gap separation; initial time rate of change in wafer temperature for each mode, and (b) heat fluxes and initial temperature-time change for gap separations of 0.2, 0.5 and 1.0 mm for hot plate temperatures 300 < T_h < 1300°C. Comment on the relative importance of the modes and the influence of the gap distance. Under what conditions could a wafer be heated to 900°C in less than 10 seconds?

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions for flux calculations, (2) Diameter of hot plate and wafer much larger than gap spacing, approximating plane, infinite planes, (3) One-dimensional conduction through gas, (4) Hot plate and wafer are blackbodies, (5) Negligible heat losses from wafer backside, and (6) Wafer temperature is uniform at the onset of heating.

PROPERTIES: Wafer: ρ = 2700 kg/m^3, c = 875 J/kg·K; Gas in gap: k = 0.0436 W/m·K.

ANALYSIS: (a) The radiative heat flux between the hot plate and wafer for T_h = 600°C and T_w = 20° C follows from the rate equation,

$$q''_{rad} = \sigma\left(T_h^4 - T_w^4\right) = 5.67\times10^{-8}\,W/m^2\cdot K^4\left((600+273)^4 - (20+273)^4\right)K^4 = 32.5\,kW/m^2 \quad <$$

The conduction heat flux through the gas in the gap with L = 0.2 mm follows from Fourier's law,

$$q''_{cond} = k\frac{T_h - T_w}{L} = 0.0436\,W/m\cdot K\frac{(600-20)K}{0.0002\ m} = 126\ kW/m^2 \quad <$$

The initial time rate of change of the wafer can be determined from an energy balance on the wafer at the instant of time the heating process begins,

$$\dot{E}''_{in} - \dot{E}''_{out} = \dot{E}''_{st} \qquad \dot{E}''_{st} = \rho c\, d\left(\frac{dT_w}{dt}\right)_i$$

where $\dot{E}''_{out} = 0$ and $\dot{E}''_{in} = q''_{rad}$ or q''_{cond}. Substituting numerical values, find

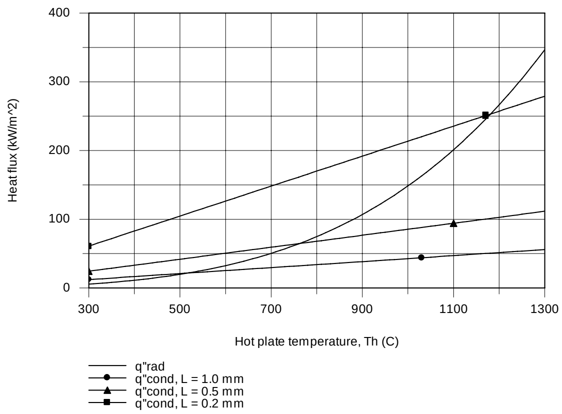
$$\left.\frac{dT_w}{dt}\right)_{i,rad} = \frac{q''_{rad}}{\rho c d} = \frac{32.5\times10^3\,W/m^2}{2700\,kg/m^3\times875\ J/kg\cdot K\times0.00078\ m} = 17.6\ K/s \quad <$$

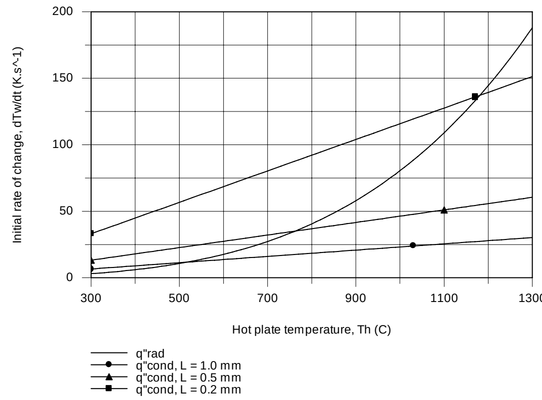
$$\left.\frac{dT_w}{dt}\right)_{i,cond} = \frac{q''_{cond}}{\rho c d} = 68.6\ K/s \quad <$$

Continued …..

PROBLEM 1.55 (Cont.)

(b) Using the foregoing equations, the heat fluxes and initial rate of temperature change for each mode can be calculated for selected gap separations L and range of hot plate temperatures T_h with T_w = 20°C.





In the left-hand graph, the conduction heat flux increases linearly with T_h and inversely with L as expected. The radiative heat flux is independent of L and highly non-linear with T_h, but does not approach that for the highest conduction heat rate until T_h approaches 1200°C.

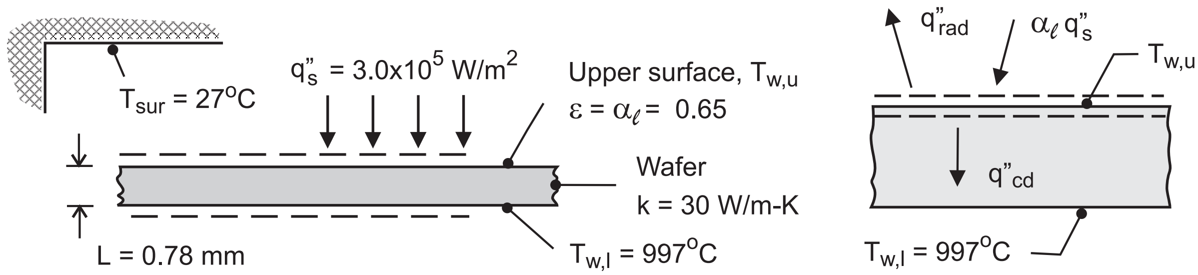
The general trends for the initial temperature-time change, $(dT_w/dt)_i$, follow those for the heat fluxes. To reach 900°C in 10 s requires an average temperature-time change rate of 90 K/s. Recognizing that (dT_w/dt) will decrease with increasing T_w, this rate could be met only with a very high T_h and the smallest L.

PROBLEM 1.56

KNOWN: Silicon wafer, radiantly heated by lamps, experiencing an annealing process with known backside temperature.

FIND: Whether temperature difference across the wafer thickness is less than 2°C in order to avoid damaging the wafer.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in wafer, (3) Radiation exchange between upper surface of wafer and surroundings is between a small object and a large enclosure, and (4) Vacuum condition in chamber, no convection.

PROPERTIES: Wafer: k = 30 W/m·K, $\varepsilon = \alpha_\ell = 0.65$.

ANALYSIS: Perform a surface energy balance on the upper surface of the wafer to determine $T_{w,u}$. The processes include the absorbed radiant flux from the lamps, radiation exchange with the chamber walls, and conduction through the wafer.

$$\dot{E}''_{in} - \dot{E}''_{out} = 0$$

$$\alpha_\ell q''_s - q''_{rad} - q''_{cd} = 0$$

$$\alpha_\ell q''_s - \varepsilon\sigma\left(T^4_{w,u} - T^4_{sur}\right) - k\frac{T_{w,u} - T_{w,\ell}}{L} = 0$$

$$0.65\times3.0\times10^5 W/m^2 - 0.65\times5.67\times10^{-8} W/m^2\cdot K^4\left(T^4_{w,u} - (27+273)^4\right)K^4$$

$$-30 W/m\cdot K\left[T_{w,u} - (997+273)\right]K/0.00078\ m = 0$$

$$T_{w,u} = 1273\,K = 1000°C$$ <

COMMENTS: (1) The temperature difference for this steady-state operating condition, $T_{w,u} - T_{w,l}$, is larger than 2°C. Warping of the wafer and inducing slip planes in the crystal structure could occur.

(2) The radiation exchange rate equation requires that temperature must be expressed in kelvin units. Why is it permissible to use kelvin or Celsius temperature units in the conduction rate equation?

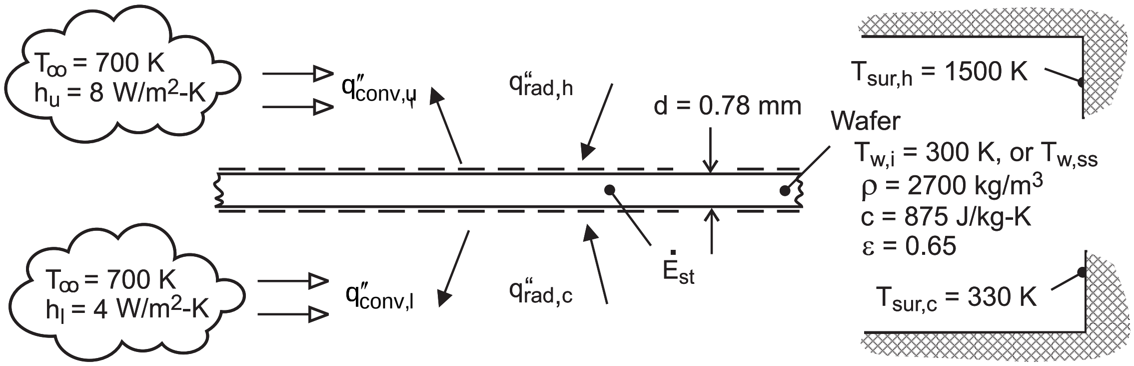
(3) Note how the surface energy balance, Eq. 1.13, is represented schematically. It is essential to show the control surfaces, and then identify the rate processes associated with the surfaces. Make sure the directions (in or out) of the process are consistent with the energy balance equation.

PROBLEM 1.57

KNOWN: Silicon wafer positioned in furnace with top and bottom surfaces exposed to hot and cool zones, respectively.

FIND: (a) Initial rate of change of the wafer temperature corresponding to the wafer temperature $T_{w,i} = 300\,K$, and (b) Steady-state temperature reached if the wafer remains in this position. How significant is convection for this situation? Sketch how you'd expect the wafer temperature to vary as a function of vertical distance.

SCHEMATIC:



ASSUMPTIONS: (1) Wafer temperature is uniform, (2) Transient conditions when wafer is initially positioned, (3) Hot and cool zones have uniform temperatures, (3) Radiation exchange is between small surface (wafer) and large enclosure (chamber, hot or cold zone), and (4) Negligible heat losses from wafer to mounting pin holder.

ANALYSIS: The energy balance on the wafer illustrated in the schematic above includes convection from the upper (u) and lower (l) surfaces with the ambient gas, radiation exchange with the hot- and cool-zone (chamber) surroundings, and the rate of energy storage term for the transient condition.

$$\dot{E}''_{in} - \dot{E}''_{out} = \dot{E}''_{st}$$

$$q''_{rad,h} + q''_{rad,c} - q''_{conv,u} - q''_{conv,l} = \rho c d \frac{dT_w}{dt}$$

$$\varepsilon\sigma\left(T_{sur,h}^4 - T_w^4\right) + \varepsilon\sigma\left(T_{sur,c}^4 - T_w^4\right) - h_u\left(T_w - T_\infty\right) - h_l\left(T_w - T_\infty\right) = \rho c d \frac{dT_w}{dt}$$

(a) For the initial condition, the time rate of temperature change of the wafer is determined using the energy balance above with $T_w = T_{w,i} = 300\,K$,

$$0.65 \times 5.67 \times 10^{-8}\,W/m^2 \cdot K^4 \left(1500^4 - 300^4\right)K^4 + 0.65 \times 5.67 \times 10^{-8}\,W/m^2 \cdot K^4 \left(330^4 - 300^4\right)K^4$$

$$-8\,W/m^2 \cdot K\left(300 - 700\right)K - 4\,W/m^2 \cdot K\left(300 - 700\right)K =$$

$$2700\,kg/m^3 \times 875\,J/kg \cdot K \times 0.00078\,m\left(dT_w/dt\right)_i$$

$$\left(dT_w/dt\right)_i = 104\,K/s$$ <

(b) For the steady-state condition, the energy storage term is zero, and the energy balance can be solved for the steady-state wafer temperature, $T_w = T_{w,ss}$.

Continued …..

PROBLEM 1.57 (Cont.)

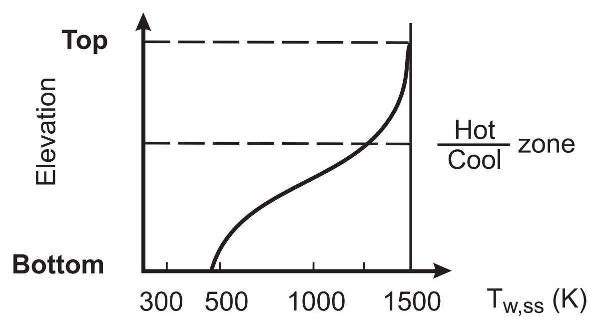
$$0.65\sigma\left(1500^4 - T_{w,ss}^4\right)K^4 + 0.65\sigma\left(330^4 - T_{w,ss}^4\right)K^4$$

$$-8\,W/m^2 \cdot K\left(T_{w,ss} - 700\right)K - 4\,W/m^2 \cdot K\left(T_{w,ss} - 700\right)K = 0$$

$$T_{w,ss} = 1251\,K$$ <

To determine the relative importance of the convection processes, re-solve the energy balance above ignoring those processes to find $\left(dT_w/dt\right)_i = 101\ K/s$ and $T_{w,ss} = 1262\ K$. We conclude that the radiation exchange processes control the initial time rate of temperature change and the steady-state temperature.

If the wafer were elevated above the present operating position, its temperature would increase, since the lower surface would begin to experience radiant exchange with progressively more of the hot zone chamber. Conversely, by lowering the wafer, the upper surface would experience less radiant exchange with the hot zone chamber, and its temperature would decrease. The temperature-distance trend might appear as shown in the sketch.

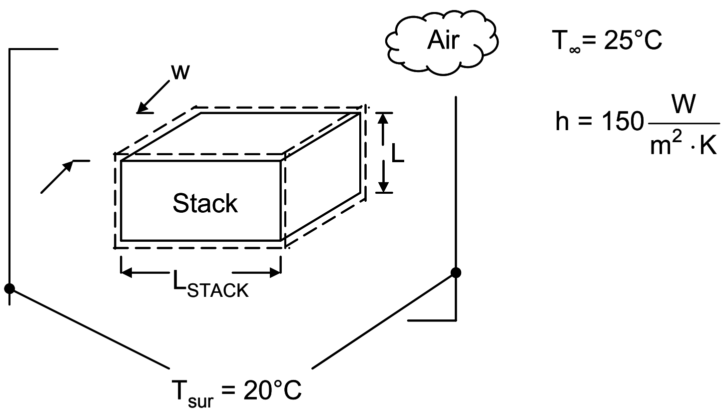


PROBLEM 1.58

KNOWN: Electrolytic membrane dimensions, bipolar plate thicknesses, desired operating temperature and surroundings as well as air temperatures.

FIND: (a) Electrical power produced by stack that is 200 mm in length for bipolar plate thicknesses 1 mm < t_{bp} < 10 mm, (b) Surface temperature of stack for various bipolar plate thicknesses, (c) Identify strategies to promote uniform temperature, identify effect of various air and surroundings temperatures, identify membrane most likely to fail.
.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Large surroundings, (3) Surface emissivity and absorptivity are the same, (4) Negligible energy entering or leaving the control volume due to gas or liquid flows, (5) Negligible energy loss or gain from or to the stack by conduction.

ANALYSIS: The length of the fuel cell is related to the number of membranes and the thickness of the membranes and bipolar plates as follows.

$$L_{stack} = N \times t_m + (N+1) \times t_{bp} = N \times (t_m + t_{bp}) + t_{bp}$$

For t_{bp} = 1 mm, 200×10^{-3} m = N × (0.43×10^{-3} m + 1.0×10^{-3} m) + 1.0×10^{-3} m
or N = 139

For t_{bp}= 10 mm, 200×10^{-3} m = N × (0.43×10^{-3} m + 10×10^{-3} m) + 10×10^{-3} m
or N = 18

(a) For t_{bp} = 1 mm, the electrical power produced by the stack is

$$P = E_{STACK} \times I = N \times E_c \times I = 139 \times 0.6 \text{ V} \times 60 \text{ A} = 5000 \text{ W} = 5 \text{ kW}$$ <

and the thermal energy produced by the stack is

$$\dot{E}_g = N \times \dot{E}_{c,g} = 139 \times 45 \text{ W} = 6,255 \text{ W} = 6.26 \text{ kW}$$ <

Continued…

PROBLEM 1.58 (Cont.)

Proceeding as before for t_{bp} = 10 mm, we find P = 648 W = 0.65 kW; $\dot{E}_g$ = 810 W = 0.81 kW <

(b) An energy balance on the control volume yields

$$\dot{E}_g - \dot{E}_{out} = 0 \quad \text{or} \quad \dot{E}_g - A(q''_{conv} + q''_{rad}) = 0 \tag{1}$$

Substituting Eqs. 1.3a and 1.7 into Eq. (1) yields

$$\dot{E}_g - A[h(T_s - T_\infty) + \varepsilon\sigma(T_s^4 - T_{sur}^4)] = 0$$

where A = 4 × L × w + 2 × H × w

$$= 4 \times 200\times10^{-3}\ \text{m} \times 100\times10^{-3}\text{m} + 2 \times 100\times10^{-3}\ \text{m} \times 100\times10^{-3}\ \text{m} = 0.1\ \text{m}^2$$

For t_{bp} = 1 mm and $\dot{E}_g$ = 6255 W,

$$6255\ \text{W} - 0.1\ \text{m}^2 \times [150\ \frac{\text{W}}{\text{m}^2\cdot\text{K}} \times (T_s - 298)\ \text{K} + 0.88 \times 5.67\times10^{-8}\ \frac{\text{W}}{\text{m}^2\cdot\text{K}^4} \times (T_s^4 - T_{sur}^4)\ \text{K}^4] = 0$$

The preceding equation may be solved to yield

$$T_s = 656\ \text{K} = 383°\text{C}$$

Therefore, for t_{bp} = 1 mm the surface temperature exceeds the maximum allowable operating temperature and the stack must be cooled. <

For t_{bp} = 10 mm and $\dot{E}_g$ = 810 W, T_s = 344 K = 71°C and the stack may need to be heated to operate at T = 80°C. <

(c) To decrease the stack temperature, the emissivity of the surface may be increased, the bipolar plates may be made larger than 100 mm × 100 mm to act as *cooling fins*, internal channels might be machined in the bipolar plates to carry a pumped coolant, and the convection coefficient may be increased by using forced convection from a fan. The stack temperature can be increased by insulating the external surfaces of the stack.

Uniform internal temperatures may be promoted by using materials of high thermal conductivity. The operating temperature of the stack will shift upward as either the surroundings or ambient temperature increases. The membrane that experiences the highest temperature will be most likely to fail. Unfortunately, the highest temperatures are likely to exist near the center of the stack, making stack repair difficult and expensive. <

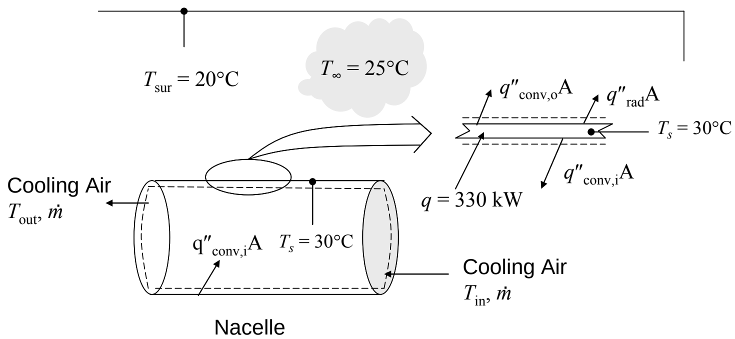
COMMENTS: (1) There is a tradeoff between the power produced by the stack, and the operating temperature of the stack. (2) Manufacture of the bipolar plates becomes difficult, and cooling channels are difficult to incorporate into the design, as the bipolar plates become thinner. (3) If one membrane fails, the entire stack fails since the membranes are connected in series electrically.

PROBLEM 1.59

KNOWN: Total rate of heat transfer leaving nacelle (from Example 1.3). Dimensions and emissivity of the nacelle, ambient and surrounding temperatures, convection heat transfer coefficient exterior to nacelle. Temperature of exiting forced air flow.

FIND: Required mass flow rate of forced air flow.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Large surroundings, (3) Surface of the nacelle that is adjacent to the hub is adiabatic, (4) Forced air exits nacelle at the nacelle surface temperature.

ANALYSIS: The total rate of heat transfer leaving the nacelle is known from Example 1.3 to be $q = 0.33 \times 10^6$ W = 330 kW. Heat is removed from the nacelle by radiation and convection from the exterior surface of the nacelle (q_{rad} and $q_{conv,o}$, respectively), and by convection from the interior surface to the forced flow of air through the nacelle ($q_{conv,i}$). An energy balance on the nacelle based upon the upper-right part of the schematic yields

$$q = q_{rad} + q_{conv,o} + q_{conv,i} = A\left[q''_{rad} + q''_{conv,o}\right] + q_{conv,i}$$

Thus the required rate of heat removal by the forced air is given by

$$q_{conv,i} = q - A\left[q''_{rad} + q''_{conv,o}\right] = q - \left[\pi DL + \frac{\pi D^2}{4}\right]\left[\varepsilon\sigma\left(T_s^4 - T_{sur}^4\right) + h\left(T_s - T_\infty\right)\right]$$

In order to maintain a nacelle surface temperature of T_s = 30°C, the required $q_{conv,i}$ is

$$q_{conv,i} = 330\text{ kW} - \left[\pi \times 3\text{ m} \times 6\text{ m} + \frac{\pi \times (3\text{ m})^2}{4}\right] \times$$
$$\left[0.83 \times 5.67 \times 10^{-8}\text{ W/m}^2\cdot\text{K}^4\left((273+30)^4 - (273+20)^4\right)\text{K}^4 + 35\text{ W/m}^2\cdot\text{K}(30-25)\text{K}\right]$$
$$= 330\text{ kW} - (3\text{ kW} + 11\text{ kW}) = 316\text{ kW}$$

The required mass flow rate of air can be found by applying an energy balance to the air flowing through the nacelle, as shown by the control volume on the lower left of the schematic. From Equation 1.12e:

$$\dot{m} = \frac{q_{conv,i}}{c_p(T_{out} - T_{in})} = \frac{q_{conv,i}}{c_p(T_s - T_\infty)} = \frac{316\text{ kW}}{1007\text{ J/kg}\cdot\text{K}(30-25)\text{K}} = 63\text{ kg/s}$$ <

Continued...

PROBLEM 1.59 (Cont.)

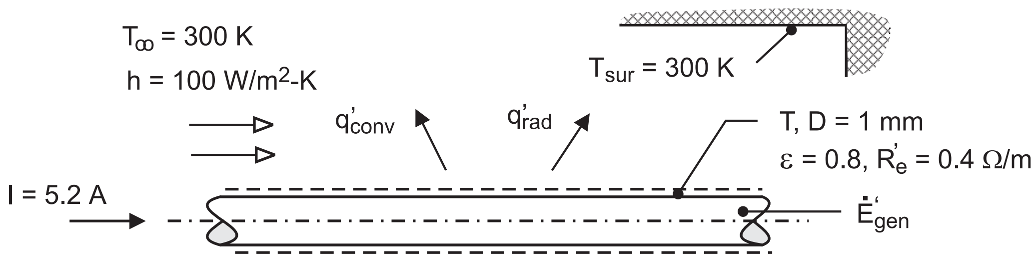
COMMENTS: (1) With the surface temperature lowered to 30°C, the heat lost by radiation and convection from the exterior surface of the nacelle is small, and most of the heat must be removed by convection to the interior forced air flow. (2) The air mass flow rate corresponds to a velocity of around $V = \dot{m} / \rho A_c = \dot{m} / (\rho \pi D^2 / 4) = 7$ m/s, using an air density of 1.1 kg/m^3 and assuming that the air flows through the entire nacelle cross-sectional area. This would lead to uncomfortable working conditions unless the forced air flow were segregated from the working space. (3) The required heat transfer coefficient on the interior surface can be estimated as $h_i = q_{\text{conv,i}}/(\pi DL(T_s - T_\infty)) =$ 1100 W/m^2·K. In Chapter 8, you will learn whether this heat transfer coefficient can be achieved under the given conditions.

PROBLEM 1.60

KNOWN: Rod of prescribed diameter experiencing electrical dissipation from passage of electrical current and convection under different air velocity conditions. See Example 1.4.

FIND: Rod temperature as a function of the electrical current for $0 \le I \le 10$ A with convection coefficients of 50, 100 and 250 W/m^2·K. Will variations in the surface emissivity have a significant effect on the rod temperature?

SCHEMATIC:



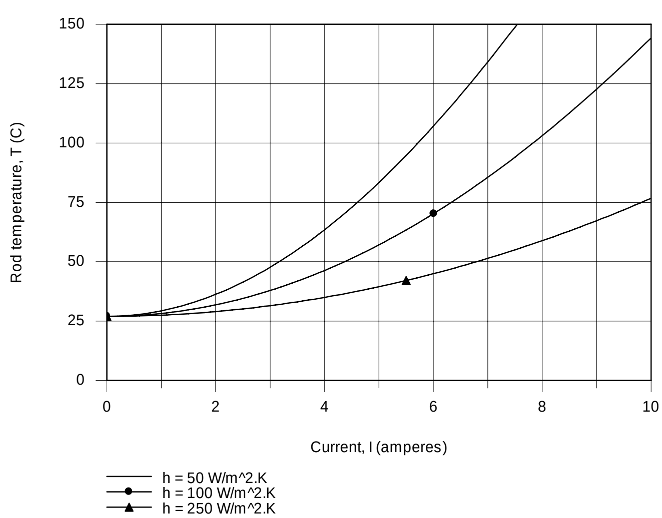
ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform rod temperature, (3) Radiation exchange between the outer surface of the rod and the surroundings is between a small surface and large enclosure.

ANALYSIS: The energy balance on the rod for steady-state conditions has the form,

$$q'_{conv} + q'_{rad} = \dot{E}'_{gen}$$

$$\pi Dh\left(T - T_\infty\right) + \pi D\varepsilon\sigma\left(T^4 - T_{sur}^4\right) = I^2 R'_e$$

Using this equation in the Workspace of IHT, the rod temperature is calculated and plotted as a function of current for selected convection coefficients.



COMMENTS: (1) For forced convection over the cylinder, the convection heat transfer coefficient is dependent upon air velocity approximately as $h \sim V^{0.6}$. Hence, to achieve a 5-fold change in the convection coefficient (from 50 to 250 W/m^2·K), the air velocity must be changed by a factor of nearly 15.

Continued …..

PROBLEM 1.60 (Cont.)

(2) For the condition of I = 4 A with h = 50 W/m^2·K with T = 63.5°C, the convection and radiation exchange rates per unit length are, respectively, $q'_{conv} = 5.7\ W/m$ and $q'_{rad} = 0.67\ W/m$. We conclude that convection is the dominant heat transfer mode and that changes in surface emissivity could have only a minor effect. Will this also be the case if h = 100 or 250 W/m^2·K?

(3) What would happen to the rod temperature if there was a "loss of coolant" condition where the air flow would cease?

(4) The Workspace for the IHT program to calculate the heat losses and perform the parametric analysis to generate the graph is shown below. It is good practice to provide commentary with the code making your solution logic clear, and to summarize the results. It is also good practice to show plots in *customary* units, that is, the units used to prescribe the problem. As such the graph of the rod temperature is shown above with Celsius units, even though the calculations require temperatures in kelvins.

```
// Energy balance; from Ex. 1.4, Comment 1
-q'cv - q'rad + Edot'g = 0
q'cv = pi*D*h*(T - Tinf)
q'rad = pi*D*eps*sigma*(T^4 - Tsur^4)

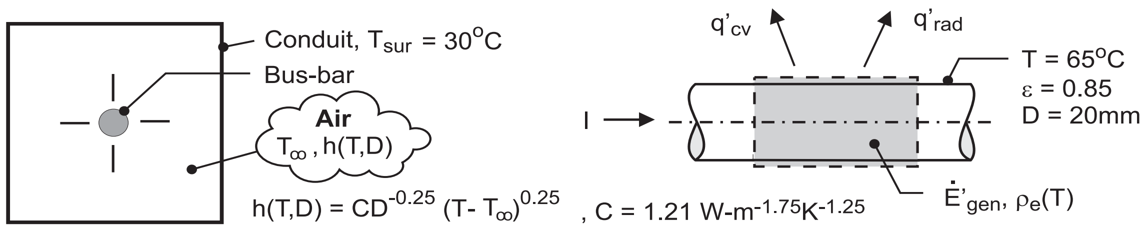
PROBLEM 1.61

KNOWN: Long bus bar of prescribed diameter and ambient air and surroundings temperatures. Relations for the electrical resistivity and free convection coefficient as a function of temperature.

FIND: (a) Current carrying capacity of the bus bar if its surface temperature is not to exceed 65°C; compare relative importance of convection and radiation exchange heat rates, and (b) Show graphically the operating temperature of the bus bar as a function of current for the range 100 ≤ I ≤ 5000 A for bus-bar diameters of 10, 20 and 40 mm. Plot the ratio of the heat transfer by convection to the total heat transfer for these conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Bus bar and conduit are very long, (3) Uniform bus-bar temperature, (4) Radiation exchange between the outer surface of the bus bar and the conduit is between a small surface and a large enclosure.

PROPERTIES: Bus-bar material, $\rho_e = \rho_{e,o}\left[1+\alpha\left(T-T_o\right)\right]$, $\rho_{e,o} = 0.0171\mu\Omega\cdot m$, $T_o = 25°C$, $\alpha = 0.00396\,K^{-1}$.

ANALYSIS: An energy balance on the bus-bar for a unit length as shown in the schematic above has the form

$$\dot{E}'_{in} - \dot{E}'_{out} + \dot{E}'_{gen} = 0$$

$$-q'_{rad} - q'_{conv} + I^2 R'_e = 0$$

$$-\varepsilon\pi D\sigma\left(T^4 - T_{sur}^4\right) - h\pi D\left(T - T_\infty\right) + I^2\rho_e / A_c = 0$$

where $R'_e = \rho_e / A_c$ and $A_c = \pi D^2/4$. Using the relations for $\rho_e(T)$ and $h(T,D)$, and substituting numerical values with T = 65°C, find

$$q'_{rad} = 0.85\pi\left(0.020m\right)\times 5.67\times 10^{-8}\,W/m^2\cdot K^4\left(\left[65+273\right]^4 - \left[30+273\right]^4\right)K^4 = 14.0\,W/m$$ <

$$q'_{conv} = 7.83\,W/m^2\cdot K\;\pi\left(0.020m\right)\left(65-30\right)K = 17.2\,W/m$$ <

where $h = 1.21 W\cdot m^{-1.75}\cdot K^{-1.25}\left(0.020m\right)^{-0.25}\left(65-30\right)^{0.25} = 7.83\,W/m^2\cdot K$

$$I^2R'_e = I^2\left(198.2\times 10^{-6}\,\Omega\cdot m\right)/\pi\left(0.020\right)^2 m^2/4 = 6.31\times 10^{-5} I^2\;W/m$$

where $\rho_e = 0.0171\times 10^{-6}\,\Omega\cdot m\left[1 + 0.00396\,K^{-1}\left(65-25\right)K\right] = 198.2\,\mu\Omega\cdot m$

The maximum allowable current capacity and the ratio of the convection to total heat transfer rate are

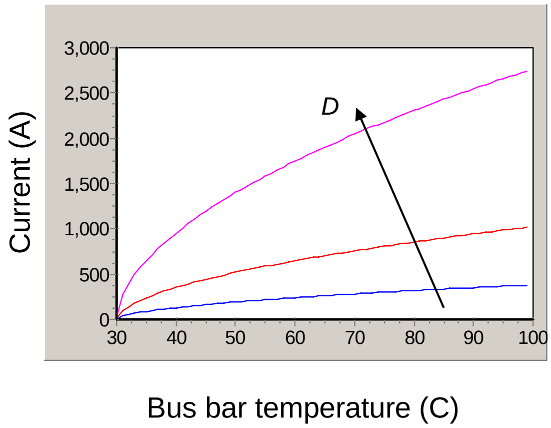
$$I = 700\,A \qquad q'_{cv}/\left(q'_{cv}+q'_{rad}\right) = q'_{cv}/q'_{tot} = 0.55$$ <

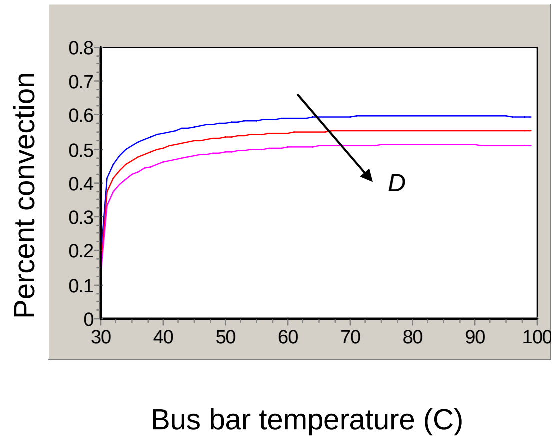
For this operating condition, convection heat transfer is 55% of the total heat transfer.

(b) Using these equations in the Workspace of IHT, the bus-bar operating temperature is calculated and plotted as a function of the current for the range 100 ≤ I ≤ 5000 A for diameters of 10, 20 and 40 mm. Also shown below is the corresponding graph of the ratio (expressed in percentage units) of the heat transfer by convection to the total heat transfer, q'_{cv}/q'_{tot}.

Continued …..

PROBLEM 1.61 (Cont.)





COMMENTS: (1) The trade-off between current-carrying capacity, operating temperature and bar diameter is shown in the first graph. If the surface temperature is not to exceed 65°C, the maximum current capacities for the 10, 20 and 40-mm diameter bus bars are 260, 700, and 1900 A, respectively.

(2) From the second graph with q'_{cv} / q'_{tot} vs. T, note that the convection heat transfer rate is typically comparable to the radiation heat transfer rate. Since the convection heat transfer increases with decreasing diameter, the convection transfer rate is relatively smaller for the larger diameter bus bars.

(3) The Workspace for the IHT program to perform the parametric analysis and generate the graphs is shown below. It is good practice to provide commentary with the code making your solution logic clear, and to summarize the results.

```
//Temperature Information (Celsius unless otherwise indicated)
Ts = 65
TsK = Ts + 273
Tsur = 30
TsurK = Tsur + 273
Tinf = 30

//Radiation (Stefan-Boltzmann constant and emissivity)
sigma = 5.67*10^-8
eps = 0.85

//Three bus bar diameters (m)
D1 = 10/1000
D2 = 20/1000
D3 = 40/1000

//Electrical resistivity (Ohm-m)
rhoe = (0.0171*10^-6) *(1 + 0.00396*(Ts - 25))

//Radiation per unit length (W/m)
qradp1 = eps*sigma*pi*D1*(TsK^4 - TsurK^4)
qradp2 = eps*sigma*pi*D2*(TsK^4 - TsurK^4)
qradp3 = eps*sigma*pi*D3*(TsK^4 - TsurK^4)

//Free convection coefficients (W/m^2K)
h1 = 1.21*(D1^-0.25)*(Ts - Tinf)^0.25
h2 = 1.21*(D2^-0.25)*(Ts - Tinf)^0.25
h3 = 1.21*(D3^-0.25)*(Ts - Tinf)^0.25
```

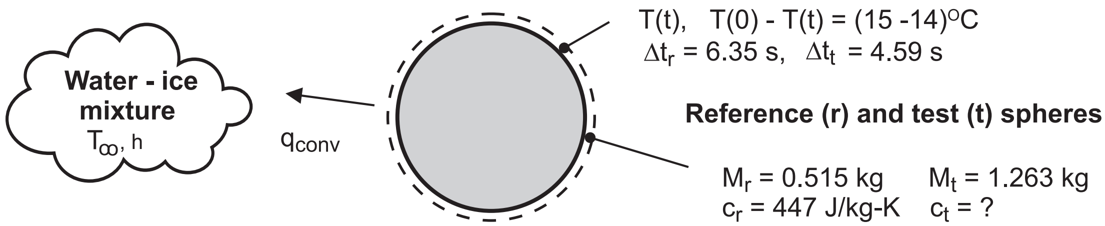
rat3 = qconvp3/(qconvp3 + qradp3)
```

PROBLEM 1.62

KNOWN: Elapsed times corresponding to a temperature change from 15 to 14°C for a reference sphere and test sphere of unknown composition suddenly immersed in a stirred water-ice mixture. Mass and specific heat of reference sphere.

FIND: Specific heat of the test sphere of known mass.

SCHEMATIC:



ASSUMPTIONS: (1) Spheres are of equal diameter, (2) Spheres experience temperature change from 15 to 14°C, (3) Spheres experience same convection heat transfer rate when the time rates of surface temperature are observed, (4) At any time, the temperatures of the spheres are uniform, (5) Negligible heat loss through the thermocouple wires.

PROPERTIES: Reference-grade sphere material: c_r = 447 J/kg K.

ANALYSIS: Apply the conservation of energy requirement at an instant of time, Equation 1.12c, after a sphere has been immersed in the ice-water mixture at T_∞.

$$\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st}$$

$$-q_{conv} = Mc\frac{dT}{dt}$$

where $q_{conv} = h\,A_s\left(T - T_\infty\right)$. Since the temperatures of the spheres are uniform, the change in energy storage term can be represented with the time rate of temperature change, dT/dt. The convection heat rates are equal at this instant of time, and hence the change in energy storage terms for the reference (r) and test (t) spheres must be equal.

$$M_r\ c_r\ \left.\frac{dT}{dt}\right)_r = M_t\ c_t\ \left.\frac{dT}{dt}\right)_t$$

Approximating the instantaneous differential change, dT/dt, by the difference change over a short period of time, $\Delta T/\Delta t$, the specific heat of the test sphere can be calculated.

$$0.515\text{ kg}\times 447\text{ J/kg}\cdot\text{K}\ \frac{(15-14)\text{K}}{6.35\text{s}} = 1.263\text{kg}\times c_t \times \frac{(15-14)\text{K}}{4.59\text{s}}$$

$$c_t = 132\text{ J/kg}\cdot\text{K}$$ <

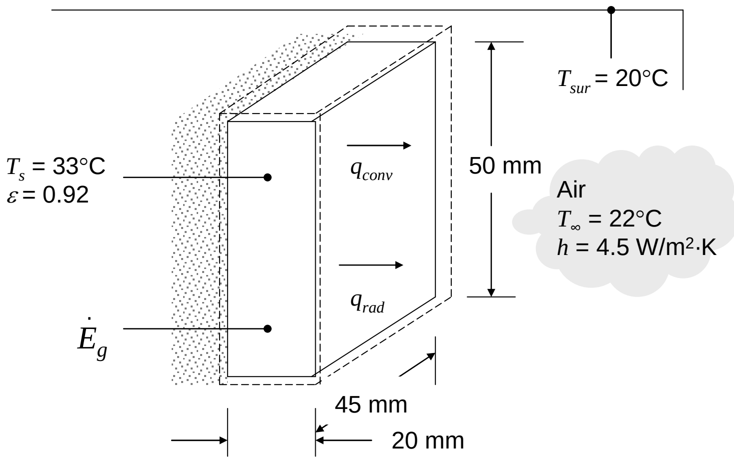
COMMENTS: Why was it important to perform the experiments with the reference and test spheres over the same temperature range (from 15 to 14°C)? Why does the analysis require that the spheres have uniform temperatures at all times?

PROBLEM 1.63

KNOWN: Dimensions and emissivity of a cell phone charger. Surface temperature when plugged in. Temperature of air and surroundings. Convection heat transfer coefficient. Cost of electricity.

FIND: Daily cost of leaving the charger plugged in when not in use.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Convection and radiation are from five exposed surfaces of charger, (3) Large surroundings, (4) Negligible heat transfer from back of charger to wall and outlet.

ANALYSIS: At steady-state, an energy balance on the charger gives $\dot{E}_{\text{in}} + \dot{E}_g = 0$, where $\dot{E}_g$ represents the conversion from electrical to thermal energy. The exposed area is A = (50 mm × 45 mm) + 2(50 mm × 20 mm) + 2(45 mm × 20 mm) = 6050 mm^2. Thus,

$$\dot{E}_g = (q_{\text{conv}} + q_{\text{rad}}) = hA(T_s - T_\infty) + \varepsilon\sigma A(T_s^4 - T_{\text{sur}}^4)$$

$$= \left[4.5\ \text{W/m}^2\cdot\text{K}(33°\text{C} - 22°\text{C}) + 0.92 \times 5.67 \times 10^{-8}\ \text{W/m}^2\cdot\text{K}^4\left((306\ \text{K})^4 - (293\ \text{K})^4\right)\right] \times 6050 \times 10^{-6}\ \text{m}^2$$

$$= 0.74\ \text{W}$$

This is the total rate of electricity used while the charger is plugged in. The daily cost of electricity is

Cost = 0.74 W × \$0.18/kW·h × 1 kW/1000 W × 24 h/day = \$0.0032/day <

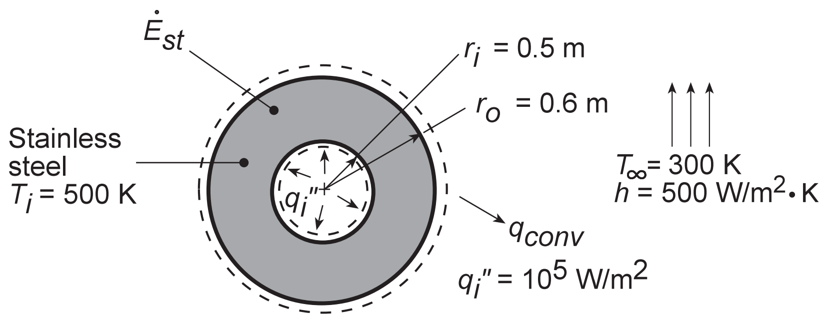
COMMENTS: (1) The radiation and convection heat fluxes are 73 W/m^2 and 50 W/m^2, respectively. Therefore, both modes of heat transfer are important. (2) The cost of leaving the charger plugged in when not in use is small.

PROBLEM 1.64

KNOWN: Inner surface heating and new environmental conditions associated with a spherical shell of prescribed dimensions and material.

FIND: (a) Governing equation for variation of wall temperature with time. Initial rate of temperature change, (b) Steady-state wall temperature, (c) Effect of convection coefficient on canister temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible temperature gradients in wall, (2) Constant properties, (3) Uniform, time-independent heat flux at inner surface.

PROPERTIES: *Table A.1*, Stainless Steel, AISI 302: $\rho = 8055\ \text{kg/m}^3$, $c_p = 535\ \text{J/kg·K}$.

ANALYSIS: (a) Performing an energy balance on the shell at an instant of time, $\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st}$. Identifying relevant processes and solving for dT/dt,

$$q_i''\left(4\pi r_i^2\right) - h\left(4\pi r_o^2\right)\left(T - T_\infty\right) = \rho \frac{4}{3}\pi\left(r_o^3 - r_i^3\right)c_p \frac{dT}{dt}$$

$$\frac{dT}{dt} = \frac{3}{\rho c_p\left(r_o^3 - r_i^3\right)}\left[q_i'' r_i^2 - h r_o^2\left(T - T_\infty\right)\right].$$

Substituting numerical values for the initial condition, find

$$\left.\frac{dT}{dt}\right)_i = \frac{3\left[10^5 \frac{W}{m^2}(0.5m)^2 - 500\frac{W}{m^2\cdot K}(0.6m)^2(500-300)K\right]}{8055\frac{kg}{m^3}510\frac{J}{kg\cdot K}\left[(0.6)^3 - (0.5)^3\right]m^3}$$

$$\left.\frac{dT}{dt}\right)_i = -0.084\ \text{K/s}.$$ <

(b) Under steady-state conditions with $\dot{E}_{st} = 0$, it follows that

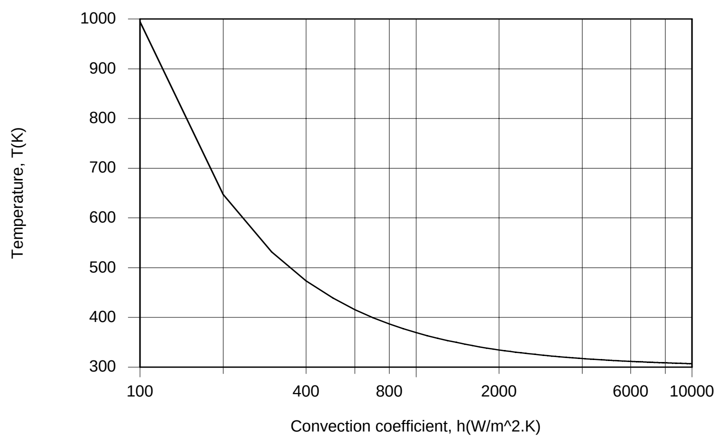
$$q_i''\left(4\pi r_i^2\right) = h\left(4\pi r_o^2\right)\left(T - T_\infty\right)$$

$$T = T_\infty + \frac{q_i''}{h}\left(\frac{r_i}{r_o}\right)^2 = 300K + \frac{10^5\ W/m^2}{500 W/m^2\cdot K}\left(\frac{0.5m}{0.6m}\right)^2 = 439K$$ <

Continued …..

PROBLEM 1.64 (Cont.)

(c) Parametric calculations were performed using the IHT *First Law Model* for an *Isothermal Hollow Sphere*. As shown below, there is a sharp increase in temperature with decreasing values of h < 1000 $W/m^2\cdot K$. For T > 380 K, boiling will occur at the canister surface, and for T > 410 K a condition known as film boiling (Chapter 10) will occur. The condition corresponds to a precipitous reduction in h and increase in T.



Although the canister remains well below the melting point of stainless steel for h = 100 $W/m^2\cdot K$, boiling should be avoided, in which case the convection coefficient should be maintained at h > 1000 $W/m^2\cdot K$.

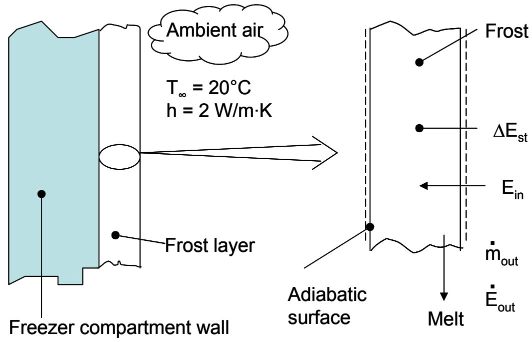
COMMENTS: The governing equation of part (a) is a first order, nonhomogenous differential equation with constant coefficients. Its solution is $\theta = (S/R)\left(1 - e^{-Rt}\right) + \theta_i e^{-Rt}$, where $\theta \equiv T - T_\infty$, $S \equiv 3q_i'' r_i^2 / \rho c_p \left(r_o^3 - r_i^3\right)$, $R = 3hr_o^2/\rho c_p \left(r_o^3 - r_i^3\right)$. Note results for $t \to \infty$ and for S = 0.

PROBLEM 1.65

KNOWN: Frost formation of 2-mm thickness on a freezer compartment. Surface exposed to convection process with ambient air.

FIND: Time required for the frost to melt, t_m.

SCHEMATIC:



ASSUMPTIONS: (1) Frost is isothermal at the fusion temperature, T_f, (2) The water melt falls away from the exposed surface, (3) Frost exchanges radiation with surrounding frost, so net radiation exchange is negligible, and (4) Backside surface of frost formation is adiabatic.

PROPERTIES: Frost, $\rho_f = 770\ kg/m^3$, $h_{sf} = 334\ kJ/kg$.

ANALYSIS: The time t_m required to melt a 2-mm thick frost layer may be determined by applying a mass balance and an energy balance (Eq 1.12b) over the differential time interval dt to a control volume around the frost layer.

$$dm_{st} = -\dot{m}_{out} dt \qquad dE_{st} = \left(\dot{E}_{in} - \dot{E}_{out}\right) dt \qquad (1a,b)$$

With h_f as the enthalpy of the melt and h_s as the enthalpy of frost, we have

$$dE_{st} = dm_{st} h_s \qquad \dot{E}_{out} dt = \dot{m}_{out} h_f dt \qquad (2a,b)$$

Combining Eqs. (1a) and (2a,b), Eq. (1b) becomes (with $h_{sf} = h_f - h_S$)

$$\dot{m}_{out} h_{sf} dt = \dot{E}_{in} dt = q''_{conv} A_s dt$$

Integrating both sides of the equation with respect to time, find

$$\rho_f A_s h_{sf} x_o = h A_s \left(T_\infty - T_f\right) t_m$$

$$t_m = \frac{\rho_f h_{sf} x_o}{h\left(T_\infty - T_f\right)}$$

$$t_m = \frac{700\ kg/m^3 \times 334 \times 10^3\ J/kg \times 0.002m}{2\ W/m^2 \cdot K\left(20-0\right)K} = 11{,}690\ s = 3.2\ hour \qquad <$$

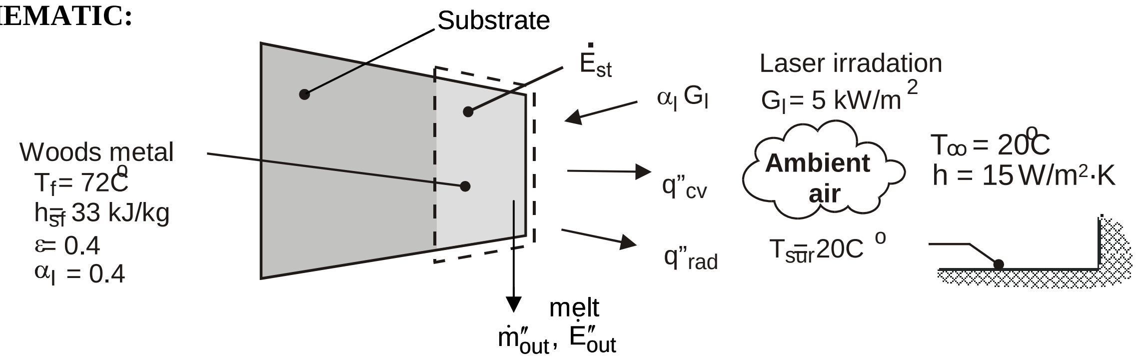
COMMENTS: (1) The energy balance could be formulated intuitively by recognizing that the total heat *in* by convection during the time interval $t_m \left(q''_{conv} \cdot t_m\right)$ must be equal to the total latent energy for melting the frost layer $\left(\rho x_o h_{sf}\right)$. This equality is directly comparable to the derived expression above for t_m.

PROBLEM 1.66

KNOWN: Vertical slab of Woods metal initially at its fusion temperature, T_f, joined to a substrate. Exposed surface is irradiated with laser source, $G_\ell (W/m^2)$.

FIND: Instantaneous rate of melting per unit area, $\dot{m}''_m$ (kg/s·m²), and the material removed in a period of 2 s, (a) Neglecting heat transfer from the irradiated surface by convection and radiation exchange, and (b) Allowing for convection and radiation exchange.

SCHEMATIC:



ASSUMPTIONS: (1) Woods metal slab is isothermal at the fusion temperature, T_f, and (2) The melt runs off the irradiated surface.

ANALYSIS: (a) The instantaneous rate of melting per unit area may be determined by applying a mass balance and an energy balance (Equation 1.12c) on the metal slab at an instant of time neglecting convection and radiation exchange from the irradiated surface.

$$\dot{m}''_{st} = \dot{m}''_{in} - \dot{m}''_{out} \qquad \dot{E}''_{in} - \dot{E}''_{out} = \dot{E}''_{st} \tag{1a,b}$$

With h_f as the enthalpy of the melt and h_s as the enthalpy of the solid, we have

$$\dot{E}''_{st} = \dot{m}''_{st} h_s \qquad \dot{E}''_{out} = \dot{m}''_{out} h_f \tag{2a,b}$$

Combining Equations (1a) and (2a,b), Equation (1b) becomes (with $h_{sf} = h_f - h_s$)

$$\dot{m}''_{out} h_{sf} = \dot{E}''_{in} = \alpha_l G_l$$

Thus the rate of melting is

$$\dot{m}''_{out} = \alpha_l G_l / h_{sf} = 0.4 \times 5000\,W/m^2 \big/ 33{,}000\,J/kg = 60.6 \times 10^{-3}\,kg/s \times m^2 \qquad <$$

The material removed in a 2s period per unit area is

$$M''_{2s} = \dot{m}''_{out} \times \Delta t = 121\,g/m^2 \qquad <$$

(b) The energy balance considering convection and radiation exchange with the surroundings yields

$$\dot{m}''_{out} h_{sf} = \alpha_l G_l - q''_{cv} - q''_{rad}$$

$$q''_{cv} = h\left(T_f - T_\infty\right) = 15\,W/m^2\cdot K\left(72 - 20\right)K = 780\ W/m^2$$

$$q''_{rad} = \varepsilon\sigma\left(T_f^4 - T_\infty^4\right) = 0.4 \times 5.67 \times 10^{-8}\,W/m^2\cdot K\left(\left[72 + 273\right]^4 - \left[20 + 273\right]^4\right)K^4 = 154\,W/m^2$$

$$\dot{m}''_{out} = 32.3 \times 10^{-3}\,kg/s\cdot m^2 \qquad M_{2s} = 64\,g/m^2 \qquad <$$

COMMENTS: (1) The effects of heat transfer by convection and radiation reduce the estimate for the material removal rate by a factor of two. The heat transfer by convection is nearly 5 times larger than by radiation exchange.

Continued…

PROBLEM 1.66 (Cont.)

(2) Suppose the work piece were horizontal, rather than vertical, and the melt puddled on the surface rather than ran off. How would this affect the analysis?

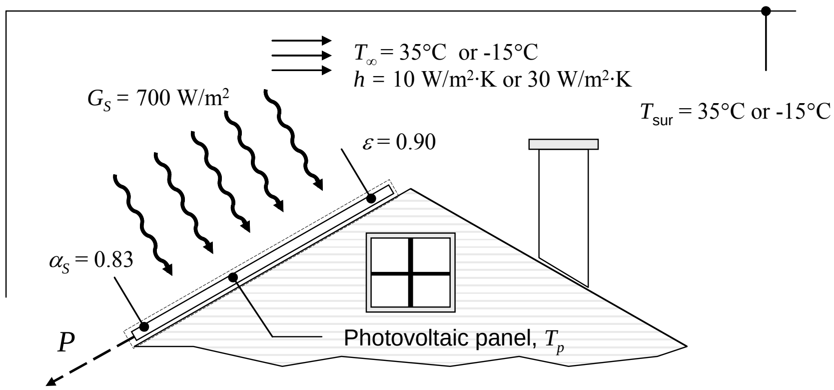
(3) Lasers are common heating sources for metals processing, including the present application of melting (heat transfer with phase change), as well as for heating work pieces during milling and turning (laser-assisted machining).

PROBLEM 1.67

KNOWN: Dimensions, emissivity, and solar absorptivity of solar photovoltaic panel. Solar irradiation, air and surroundings temperature, and convection coefficient. Expression for conversion efficiency.

FIND: Electrical power output on (a) a still summer day, and (b) a breezy winter day.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Lower surface of solar panel is insulated, (3) Radiation from the environment can be treated as radiation from large surroundings, with $\alpha = \varepsilon$.

ANALYSIS: Recognize that there is conversion from thermal to electrical energy, therefore there is a negative generation term equal to the electrical power. Performing an energy balance on the solar panel gives

$$\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_g = 0$$

$$q_{\text{rad}} - q_{\text{conv}} - P = 0$$

$$\left[\alpha_S G_S - \varepsilon\sigma(T_s^4 - T_{\text{sur}}^4)\right]A - hA(T_s - T_\infty) - \eta\alpha_S G_S A = 0$$

Dividing by A, and substituting the expression for η as a function of T_p yields

$$\left[\alpha_S G_S - \varepsilon\sigma(T_p^4 - T_{\text{sur}}^4)\right] - h(T_p - T_\infty) - (0.553 - 0.001T_p)\alpha_S G_S = 0$$

(a) Substituting the parameter values for a summer day:

$$0.83 \times 700\text{ W/m}^2 - 0.90 \times 5.67 \times 10^{-8}\text{ W/m}^2\cdot\text{K}^4(T_p^4 - (308\text{ K})^4) - 10\text{ W/m}^2\cdot\text{K}(T_p - 308\text{ K})$$

$$-(0.553 - 0.001T_p) \times 0.83 \times 700\text{ W/m}^2 = 0$$

$$3799\text{ W/m}^2 - 5.1 \times 10^{-8}\text{ W/m}^2\cdot\text{K}^4 T_p^4 - 9.42\text{ W/m}^2\cdot\text{K}\ T_p = 0$$

Solving this equation for T_p using IHT or other software results in T_p = 335 K. The electrical power can then be found from

$$P = \eta\alpha_S G_S A = (0.553 - 0.001T_p)\alpha_S G_S A$$

$$= (0.553 - 0.001\text{ K}^{-1} \times 335\text{ K}) \times 0.83 \times 700\text{ W/m}^2 \times 8\text{ m}^2 = 1010\text{ W}$$ <

(b) Repeating the calculation for the winter conditions yields T_p = 270 K, P = 1310 W. <

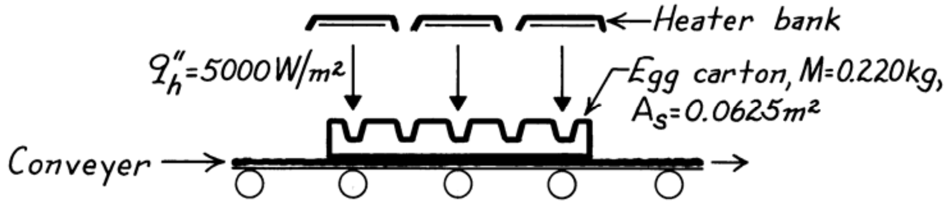
COMMENTS: (1) The conversion efficiency for most photovoltaic materials is higher at lower temperatures. Therefore, for the same solar irradiation, more electrical power is generated in winter conditions. (2) The total solar energy generated would generally be less in the winter due to lower irradiation values and a shorter day.

PROBLEM 1.68

KNOWN: Hot formed paper egg carton of prescribed mass, surface area, and water content exposed to infrared heater providing known radiant flux.

FIND: Whether water content can be reduced by 10% of the total mass during the 18s period carton is on conveyor.

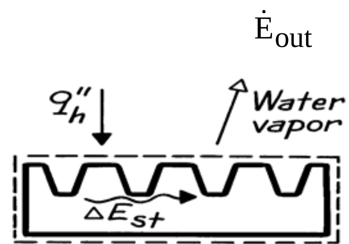
SCHEMATIC:



ASSUMPTIONS: (1) All the radiant flux from the heater bank causes evaporation of water, (2) Negligible heat loss from carton by convection and radiation, (3) Negligible mass loss occurs from bottom side.

PROPERTIES: Water (given): $h_{fg} = 2400$ kJ/kg.

ANALYSIS: Define a control surface about the carton, and write conservation of mass and energy for an interval of time, Δt,



$$\Delta m_{st} = -\dot{m}_{out}\Delta t \qquad \Delta E_{st} = \left(\dot{E}_{in} - \dot{E}_{out}\right)\Delta t \qquad (1a,b)$$

With h_f as the enthalpy of the liquid water and h_g as the enthalpy of water vapor, we have

$$\Delta E_{st} = \Delta m_{st} h_f \qquad \dot{E}_{out}\Delta t = \dot{m}_{out} h_g \Delta t \qquad (2a,b)$$

Combining Equations (1a) and (2a,b), Equation (1b) becomes (with $h_{fg} = h_g - h_f$)

$$\dot{m}_{out} h_{fg}\Delta t = \dot{E}_{in}\Delta t = q_h'' A_s \Delta t$$

where q_h'' is the absorbed radiant heat flux from the heater. Hence,

$$\Delta m = \dot{m}_{out}\Delta t = q_h'' A_s \Delta t / h_{fg} = 5000\ W/m^2 \times 0.0625\ m^2 \times 18\ s / 2400\ kJ/kg = 0.00234\ kg$$

The chief engineer's requirement was to remove 10% of the water content, or

$$\Delta M_{req} = M \times 0.10 = 0.220\ kg \times 0.10 = 0.022\ kg$$

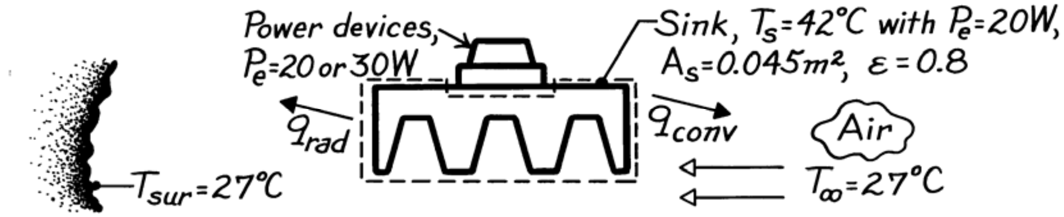
which is nearly an order of magnitude larger than the evaporative loss. Considering heat losses by convection and radiation, the actual water removal from the carton will be less than ΔM. Hence, the purchase should not be recommended, since the desired water removal cannot be achieved. $<$

PROBLEM 1.69

KNOWN: Average heat sink temperature when total dissipation is 20 W with prescribed air and surroundings temperature, sink surface area and emissivity.

FIND: Sink temperature when dissipation is 30 W.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) All dissipated power in devices is transferred to the sink, (3) Sink is isothermal, (4) Surroundings and air temperature remain the same for both power levels, (5) Convection coefficient is the same for both power levels, (6) Heat sink is a small surface within a large enclosure, the surroundings.

ANALYSIS: Define a control volume around the heat sink. Power dissipated within the devices is transferred into the sink, while the sink loses heat to the ambient air and surroundings by convection and radiation exchange, respectively.

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$P_e - hA_s\left(T_s - T_\infty\right) - A_s\varepsilon\sigma\left(T_s^4 - T_{sur}^4\right) = 0. \qquad (1)$$

Consider the situation when P_e = 20 W for which T_s = 42°C; find the value of h.

$$h = \left[P_e / A_s - \varepsilon\sigma\left(T_s^4 - T_{sur}^4\right)\right] / \left(T_s - T_\infty\right)$$

$$h = \left[20\ \text{W}/0.045\ \text{m}^2 - 0.8 \times 5.67 \times 10^{-8}\ \text{W/m}^2 \cdot \text{K}^4 \left(315^4 - 300^4\right)\text{K}^4\right] / \left(315 - 300\right)\text{K}$$

$$h = 24.4\ \text{W/m}^2 \cdot \text{K}.$$

For the situation when P_e = 30 W, using this value for h with Eq. (1), obtain

$$30\ \text{W} - 24.4\ \text{W/m}^2 \cdot \text{K} \times 0.045\ \text{m}^2 \left(T_s - 300\right)\text{K}$$

$$-0.045\ \text{m}^2 \times 0.8 \times 5.67 \times 10^{-8}\ \text{W/m}^2 \cdot \text{K}^4 \left(T_s^4 - 300^4\right)\text{K}^4 = 0$$

$$30 = 1.098\left(T_s - 300\right) + 2.041 \times 10^{-9}\left(T_s^4 - 300^4\right).$$

By trial-and-error, find

$$T_s \approx 322\ \text{K} = 49^\circ\text{C}. \qquad <$$

COMMENTS: (1) It is good practice to express all temperatures in kelvin units when using energy balances involving radiation exchange.

(2) Note that we have assumed A_s is the same for the convection and radiation processes. Since not all portions of the fins are completely exposed to the surroundings, $A_{s,rad}$ is less than $A_{s,conv} = A_s$.

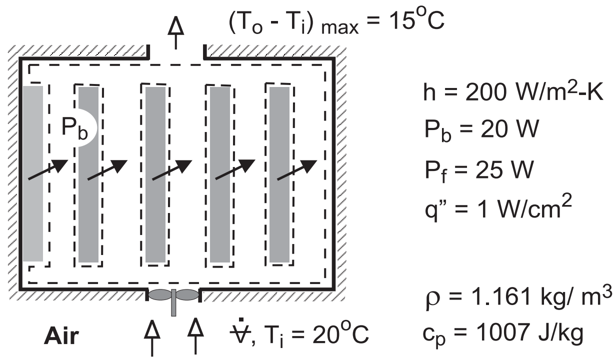
(3) Is the assumption that the heat sink is isothermal reasonable?

PROBLEM 1.70

KNOWN: Number and power dissipation of PCBs in a computer console. Convection coefficient associated with heat transfer from individual components in a board. Inlet temperature of cooling air and fan power requirement. Maximum allowable temperature rise of air. Heat flux from component most susceptible to thermal failure.

FIND: (a) Minimum allowable volumetric flow rate of air, (b) Preferred location and corresponding surface temperature of most thermally sensitive component.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Constant air properties, (3) Negligible potential and kinetic energy changes of air flow, (4) Negligible heat transfer from console to ambient air, (5) Uniform convection coefficient for all components.

ANALYSIS: (a) For a control surface about the air space in the console, conservation of energy for an open system, Equation (1.12d), reduces to

$$\dot{m}\left(u_t + pv\right)_{in} - \dot{m}\left(u_t + pv\right)_{out} + q - \dot{W} = 0$$

where $u_t + pv = i$, $q = 5P_b$, and $\dot{W} = -P_f$. Hence, with $\dot{m}\left(i_{in} - i_{out}\right) = \dot{m}c_p\left(T_{in} - T_{out}\right)$,

$$\dot{m}c_p\left(T_{out} - T_{in}\right) = 5\,P_b + P_f$$

For a maximum allowable temperature rise of 15°C, the required mass flow rate is

$$\dot{m} = \frac{5\,P_b + P_f}{c_p\left(T_{out} - T_{in}\right)} = \frac{5\times 20\text{ W} + 25\text{ W}}{1007\text{ J/kg}\cdot\text{K}\left(15\ ^\circ\text{C}\right)} = 8.28\times 10^{-3}\,\text{kg/s}$$

The corresponding volumetric flow rate is

$$\forall = \frac{\dot{m}}{\rho} = \frac{8.28\times 10^{-3}\,\text{kg/s}}{1.161\text{ kg/m}^3} = 7.13\times 10^{-3}\,\text{m}^3/\text{s}$$ <

(b) The component which is most susceptible to thermal failure should be mounted at the bottom of one of the PCBs, where the air is coolest. From the corresponding form of Newton's law of cooling, $q'' = h\left(T_s - T_{in}\right)$, the surface temperature is

$$T_s = T_{in} + \frac{q''}{h} = 20^\circ\text{C} + \frac{1\times 10^4\ \text{W/m}^2}{200\text{ W/m}^2\cdot\text{K}} = 70^\circ\text{C}$$ <

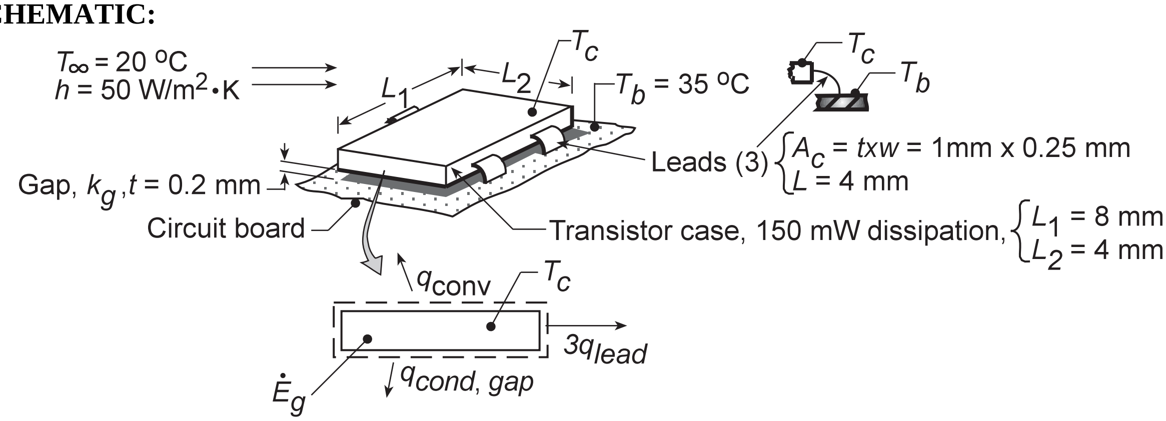
COMMENTS: (1) Although the mass flow rate is invariant, the volumetric flow rate increases as the air is heated in its passage through the console, causing a reduction in the density. However, for the prescribed temperature rise, the change in ρ, and hence the effect on $\dot{\forall}$, is small. (2) If the thermally sensitive component were located at the top of a PCB, it would be exposed to warmer air (T_o = 35°C) and the surface temperature would be T_s = 85°C.

PROBLEM 1.71

KNOWN: Surface-mount transistor with prescribed dissipation and convection cooling conditions.

FIND: (a) Case temperature for mounting arrangement with air-gap and conductive paste between case and circuit board, (b) Consider options for increasing $\dot{E}_g$, subject to the constraint that T_c = 40°C.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Transistor case is isothermal, (3) Upper surface experiences convection; negligible losses from edges, (4) Leads provide conduction path between case and board, (5) Negligible radiation, (6) Negligible energy generation in leads due to current flow, (7) Negligible convection from surface of leads.

PROPERTIES: (Given): Air, $k_{g,a}$ = 0.0263 W/m·K; Paste, $k_{g,p}$ = 0.12 W/m·K; Metal leads, k_ℓ = 25 W/m·K.

ANALYSIS: (a) Define the transistor as the system and identify modes of heat transfer.

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = \Delta\dot{E}_{st} = 0$$

$$-q_{conv} - q_{cond,gap} - 3q_{lead} + \dot{E}_g = 0$$

$$-hA_s\left(T_c - T_\infty\right) - k_g A_s \frac{T_c - T_b}{t} - 3k_\ell A_c \frac{T_c - T_b}{L} + \dot{E}_g = 0$$

where $A_s = L_1 \times L_2$ = 4 × 8 mm² = 32 × 10⁻⁶ m² and A_c = t × w = 0.25 × 1 mm² = 25 × 10⁻⁸ m².

Rearranging and solving for T_c,

$$T_c = \left\{hA_s T_\infty + \left[k_g A_s/t + 3\left(k_\ell A_c/L\right)\right]T_b + \dot{E}_g\right\} / \left[hA_s + k_g A_s/t + 3\left(k_\ell A_c/L\right)\right]$$

Substituting numerical values, with the *air-gap condition* ($k_{g,a}$ = 0.0263 W/m·K)

$$T_c = \left\{50\,\text{W/m}^2\cdot\text{K} \times 32\times10^{-6}\,\text{m}^2 \times 20^\circ\text{C} + \left[\left(0.0263\,\text{W/m}\cdot\text{K} \times 32\times10^{-6}\,\text{m}^2/0.2\times10^{-3}\,\text{m}\right)\right.\right.$$

$$\left.\left. +3\left(25\,\text{W/m}\cdot\text{K} \times 25\times10^{-8}\,\text{m}^2/4\times10^{-3}\,\text{m}\right)\right]35^\circ\text{C}\right\} / \left[1.600\times10^{-3} + 4.208\times10^{-3} + 4.688\times10^{-3}\right]\text{W/K}$$

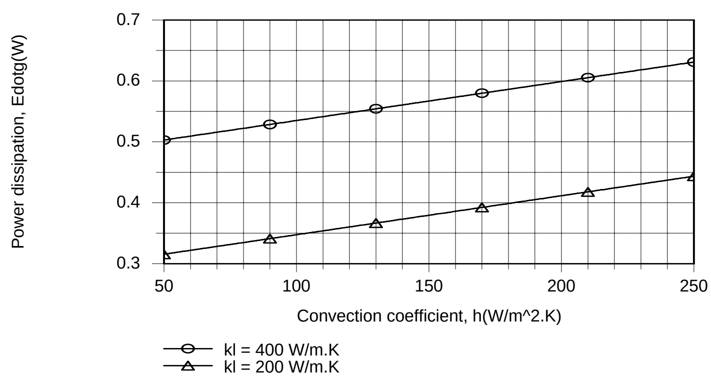
$$T_c = 47.0^\circ\text{C}.$$ <

Continued...

PROBLEM 1.71 (Cont.)

With the *paste condition* ($k_{g,p}$ = 0.12 W/m·K), T_c = 39.9°C. As expected, the effect of the conductive paste is to improve the coupling between the circuit board and the case. Hence, T_c decreases.

(b) Using the keyboard to enter model equations into the workspace, IHT has been used to perform the desired calculations. For values of k_ℓ = 200 and 400 W/m·K and convection coefficients in the range from 50 to 250 W/m^2·K, the energy balance equation may be used to compute the power dissipation for a maximum allowable case temperature of 40°C.



As indicated by the energy balance, the power dissipation increases linearly with increasing h, as well as with increasing k_ℓ. For h = 250 W/m^2·K (enhanced air cooling) and k_ℓ = 400 W/m·K (copper leads), the transistor may dissipate up to 0.63 W.

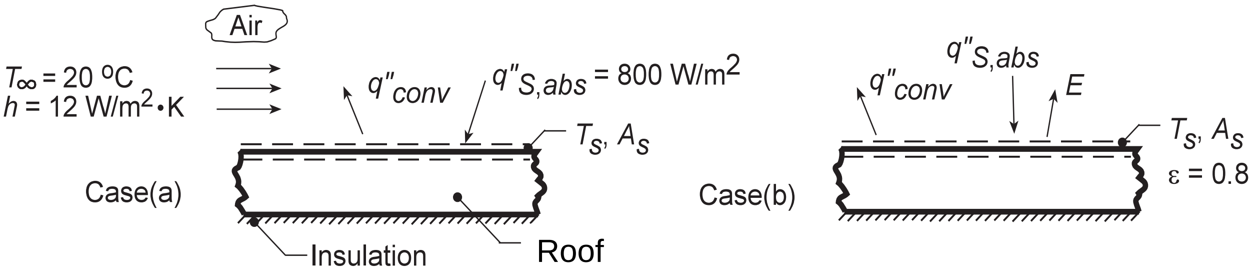
COMMENTS: Additional benefits may be derived by increasing heat transfer across the gap separating the case from the board, perhaps by inserting a highly conductive material in the gap.

PROBLEM 1.72

KNOWN: Top surface of car roof absorbs solar flux, $q''_{S,abs}$, and experiences for case (a): convection with air at T_∞ and for case (b): the same convection process and radiation emission from the roof.

FIND: Temperature of the roof, T_s, for the two cases. Effect of airflow on roof temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat transfer to auto interior, (3) Negligible radiation from atmosphere.

ANALYSIS: (a) Apply an energy balance to the control surfaces shown on the schematic. For an instant of time, $\dot{E}_{in} - \dot{E}_{out} = 0$. Neglecting radiation emission, the relevant processes are convection between the plate and the air, q''_{conv}, and the absorbed solar flux, $q''_{S,abs}$. Considering the roof to have an area A_S,

$$q''_{S,abs} \cdot A_S - hA_S\left(T_S - T_\infty\right) = 0$$

$$T_S = T_\infty + q''_{S,abs}/h$$

$$T_S = 20^\circ C + \frac{800 W/m^2}{12 W/m^2 \cdot K} = 20^\circ C + 66.7^\circ C = 86.7^\circ C$$ <

(b) With radiation emission from the surface, the energy balance has the form

$$q''_{S,abs} \cdot A_S - q_{conv} - E \cdot A_S = 0$$

$$q''_{S,abs} A_S - hA_S\left(T_S - T_\infty\right) - \varepsilon A_S \sigma T_S^4 = 0.$$

Substituting numerical values, with temperature in absolute units (K),

$$800\frac{W}{m^2} - 12\frac{W}{m^2 \cdot K}\left(T_S - 293K\right) - 0.8 \times 5.67 \times 10^{-8}\frac{W}{m^2 \cdot K^4} T_S^4 = 0$$

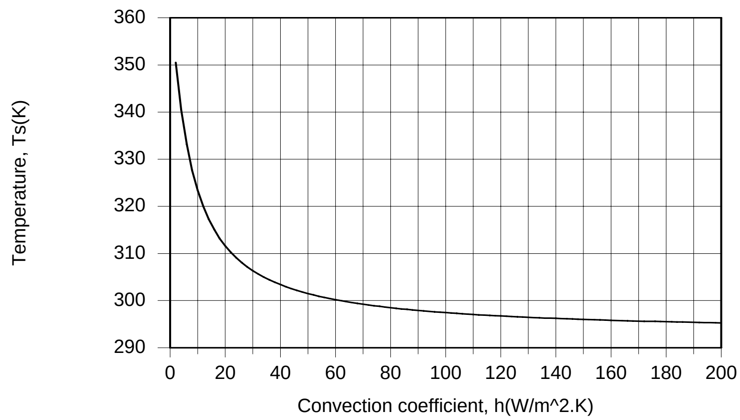
$$12 T_S + 4.536 \times 10^{-8} T_S^4 = 4316$$

It follows that T_s = 320 K = 47°C. <

Continued...

PROBLEM 1.72 (Cont.)

(c) Parametric calculations were performed using the IHT *First Law Model* for an *Isothermal Plane Wall*. As shown below, the roof temperature depends strongly on the velocity of the auto relative to the ambient air. For a convection coefficient of h = 40 W/m^2·K, which would be typical for a velocity of 55 mph, the roof temperature would exceed the ambient temperature by less than 10°C.



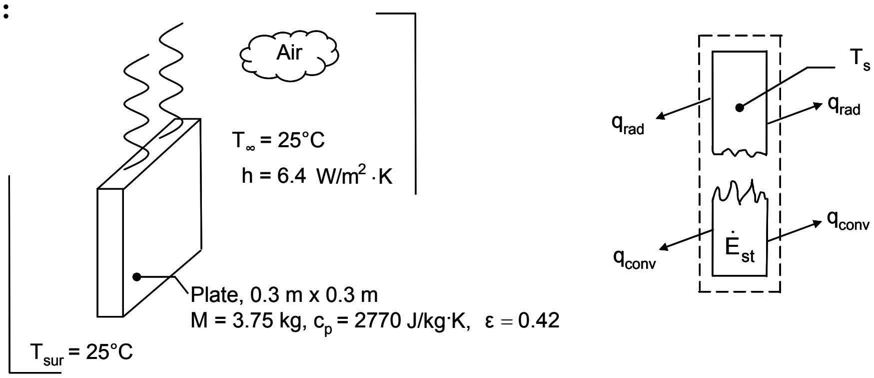
COMMENTS: By considering radiation emission, T_s decreases, as expected. Note the manner in which q''_{conv} is formulated using Newton's law of cooling; since q''_{conv} is shown leaving the control surface, the rate equation must be $h\left(T_s - T_\infty\right)$ and not $h\left(T_\infty - T_s\right)$.

PROBLEM 1.73

KNOWN: Hot plate suspended in a room, plate temperature, room temperature and surroundings temperature, convection coefficient and plate emissivity, mass and specific heat of the plate.

FIND: (a) The time rate of change of the plate temperature, and (b) Heat loss by convection and heat loss by radiation.

SCHEMATIC:



ASSUMPTIONS: (1) Plate is isothermal and at uniform temperature, (2) Large surroundings, (3) Negligible heat loss through suspension wires.

ANALYSIS: For a control volume about the plate, the conservation of energy requirement is

$$\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st} \tag{1}$$

where $\dot{E}_{st} = Mc_p \dfrac{dT}{dt}$ (2)

and $\dot{E}_{in} - \dot{E}_{out} = \varepsilon A\sigma(T_{sur}^4 - T_s^4) + hA(T_\infty - T_s)$ (3)

Combining Eqs. (1) through (3) yields $\dfrac{dT}{dt} = \dfrac{A[\varepsilon\sigma(T_{sur}^4 - T_s^4) + h(T_\infty - T_s)]}{Mc_p}$

Noting that $T_{sur} = 25^oC + 273\ K = 298\ K$ and $T_s = 225^oC + 273\ K = 498\ K$,

$$\frac{dT}{dt} = \frac{\{2\times0.3\ m\times0.3\ m[0.42\times5.67\times10^{-8}\ \frac{W}{m^2\cdot K^4}\times(498^4-298^4)\ K^4]+6.4\frac{W}{m^2\cdot K}\times(25^oC-225^oC)\}}{3.75\ kg\times2770\ \frac{J}{kg\cdot K}}$$

$= -0.044$ K/s <

The heat loss by radiation is the first term in the numerator of the preceding expression and is

$q_{rad} = 230$ W <

The heat loss by convection is the second term in the preceding expression and is

$q_{conv} = 230$ W <

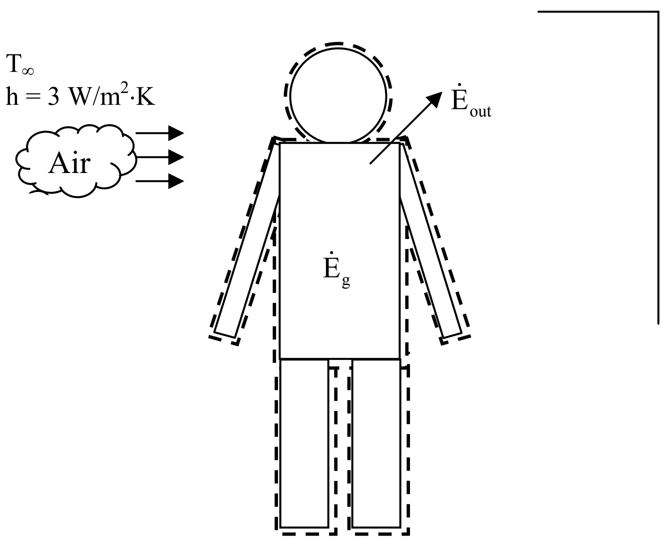
COMMENTS: (1) Note the importance of using kelvins when working with radiation heat transfer. (2) The temperature difference in Newton's law of cooling may be expressed in either kelvins or degrees Celsius. (3) Radiation and convection losses are of the same magnitude. This is typical of many natural convection systems involving gases such as air.

PROBLEM 1.74

KNOWN: Daily thermal energy generation, surface area, temperature of the environment, and heat transfer coefficient.

FIND: (a) Skin temperature when the temperature of the environment is 20ºC, and (b) Rate of perspiration to maintain skin temperature of 33ºC when the temperature of the environment is 33ºC.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Thermal energy is generated at a constant rate throughout the day, (3) Air and surrounding walls are at same temperature, (4) Skin temperature is uniform, (5) Bathing suit has no effect on heat loss from body, (6) Heat loss is by convection and radiation to the environment, and by perspiration in Part 2. (Heat loss due to respiration, excretion of waste, etc., is negligible.), (7) Large surroundings.

PROPERTIES: Table A.11, skin: ε = 0.95, Table A.6, water (306 K): $\rho = 994\ kg/m^3$, $h_{fg} = 2421$ kJ/kg.

ANALYSIS:
(a) The rate of energy generation is:

$$\dot{E}_g = 2000\times 10^3\ \text{cal/day}\big/(0.239\ \text{cal/J}\ \times\ 86{,}400\ \text{s/day}) = 96.9\ \text{W}$$

Under steady-state conditions, an energy balance on the human body yields:

$$\dot{E}_g - \dot{E}_{out} = 0$$

Thus $\dot{E}_{out} = q = 96.9$ W. Energy outflow is due to convection and net radiation from the surface to the environment, Equations 1.3a and 1.7, respectively.

$$\dot{E}_{out} = hA(T_s - T_\infty) + \varepsilon\sigma A(T_s^4 - T_{sur}^4)$$

Substituting numerical values

Continued…

PROBLEM 1.74 (Cont.)

$$96.9\ \text{W} = 3\ \text{W/m}^2\cdot\text{K}\times 1.8\ \text{m}^2\times(T_s - 293\ \text{K})$$
$$+\ 0.95\times 5.67\times 10^{-8}\ \text{W/m}^2\cdot\text{K}^4\times 1.8\ \text{m}^2\times(T_s^4 - (293\ \text{K})^4)$$

and solving either by trial-and-error or using *IHT* or other equation solver, we obtain

$$T_s = 299\ \text{K} = 26^\circ\text{C} \quad <$$

Since the comfortable range of skin temperature is typically 32 – 35ºC, we usually wear clothing warmer than a bathing suit when the temperature of the environment is 20ºC.

(b) If the skin temperature is 33ºC when the temperature of the environment is 33ºC, there will be no heat loss due to convection or radiation. Thus, all the energy generated must be removed due to perspiration:

$$\dot{E}_{out} = \dot{m}h_{fg}$$

We find:

$$\dot{m} = \dot{E}_{out}/h_{fg} = 96.9\ \text{W}/2421\ \text{kJ/kg} = 4.0\times 10^{-5}\ \text{kg/s}$$

This is the perspiration rate in mass per unit time. The volumetric rate is:

$$\dot{\forall} = \dot{m}/\rho = 4.0\times 10^{-5}\ \text{kg/s} / 994\ \text{kg/m}^3 = 4.0\times 10^{-8}\ \text{m}^3\text{/s} = 4.0\times 10^{-5}\ \ell\text{/s} \quad <$$

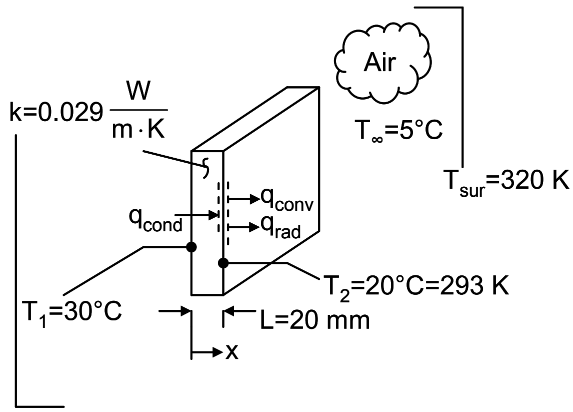
COMMENTS: (1) In Part 1, heat losses due to convection and radiation are 32.4 W and 60.4 W, respectively. Thus, it would not have been reasonable to neglect radiation. Care must be taken to include radiation when the heat transfer coefficient is small, even if the problem statement does not give any indication of its importance. (2) The rate of thermal energy generation is not constant throughout the day; it adjusts to maintain a constant core temperature. Thus, the energy generation rate may decrease when the temperature of the environment goes up, or increase (for example, by shivering) when the temperature of the environment is low. (3) The skin temperature is not uniform over the entire body. For example, the extremities are usually cooler. Skin temperature also adjusts in response to changes in the environment. As the temperature of the environment increases, more blood flow will be directed near the surface of the skin to increase its temperature, thereby increasing heat loss. (4) If the perspiration rate found in Part 2 was maintained for eight hours, the person would lose 1.2 liters of liquid. This demonstrates the importance of consuming sufficient amounts of liquid in warm weather.

PROBLEM 1.75

KNOWN: Thermal conductivity, thickness and temperature difference across a sheet of rigid extruded insulation. Cold wall temperature, surroundings temperature, ambient temperature and emissivity.

FIND: (a) The value of the convection heat transfer coefficient on the cold wall side in units of $W/m^2{\cdot}°C$ or $W/m^2{\cdot}K$, and, (b) The cold wall surface temperature for emissivities over the range $0.05 \le \varepsilon \le 0.95$ for a hot wall temperature of $T_1 = 30$ °C.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in the x-direction, (2) Steady-state conditions, (c) Constant properties, (4) Large surroundings.

ANALYSIS:
(a) An energy balance on the control surface shown in the schematic yields

$$\dot{E}_{in} = \dot{E}_{out} \quad \text{or} \quad q_{cond} = q_{conv} + q_{rad}$$

Substituting from Fourier's law, Newton's law of cooling, and Eq. 1.7 yields

$$k\,\frac{T_1 - T_2}{L} = h(T_2 - T_\infty) + \varepsilon\sigma(T_2^4 - T_{sur}^4) \tag{1}$$

or

$$h = \frac{1}{(T_2 - T_\infty)}\left[k\frac{T_1 - T_2}{L} - \varepsilon\sigma(T_2^4 - T_{sur}^4)\right]$$

Substituting values,

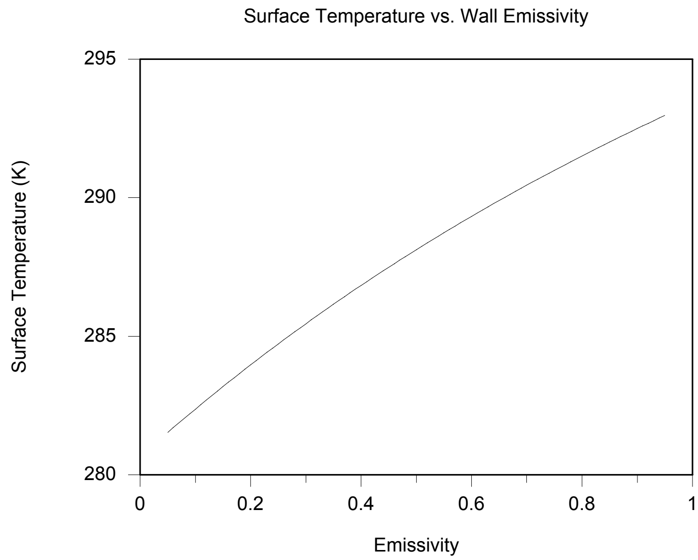
$$h = \frac{1}{(20-5)^{o}C}\left[0.029\frac{W}{m\cdot K}\times\frac{(30-20)^{o}C}{0.02\ m} - 0.95\times 5.67\times 10^{-8}\frac{W}{m^2\cdot K^4}(293^4 - 320^4)\ K^4\right]$$

$$h = 12.2\,\frac{W}{m^2\cdot K}$$ <

Continued...

PROBLEM 1.75 (Cont.)

(b) Equation (1) may be solved iteratively to find T_2 for any emissivity ε. *IHT* was used for this purpose, yielding the following.



COMMENTS: (1) Note that as the wall emissivity increases, the surface temperature increases since the surroundings temperature is relatively hot. (2) The *IHT* code used in part (b) is shown below. (3) It is a good habit to work in temperature units of kelvins when radiation heat transfer is included in the solution of the problem.

```
//Problem 1.75

h = 12.2  //W/m^2·K (convection coefficient)
L = 0.02  //m (sheet thickness)
k = 0.029 //W/m·K (thermal conductivity)
T1 = 30 + 273 //K (hot wall temperature)
Tsur = 320 //K (surroundings temperature)
sigma = 5.67*10^-8 //W/m^2·K^4 (Stefan -Boltzmann constant)
Tinf = 5 + 273 //K (ambient temperature)
e = 0.95 //emissivity

//Equation (1) is

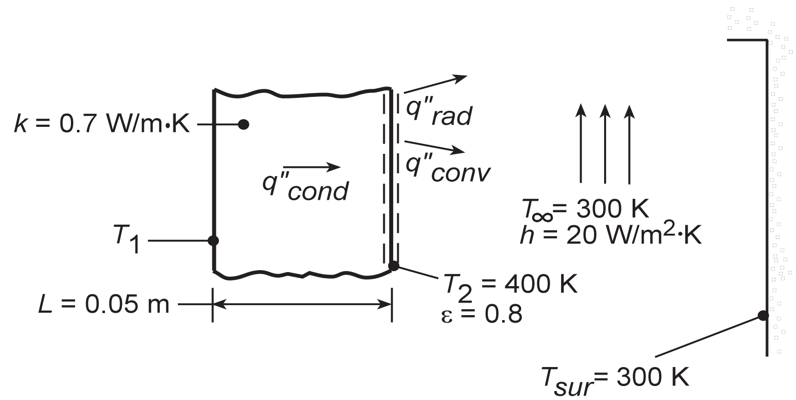
k*(T1-T2)/L = h*(T2-Tinf) + e*sigma*(T2^4 - Tsur^4)
```

PROBLEM 1.76

KNOWN: Thickness and thermal conductivity, k, of an oven wall. Temperature and emissivity, ε, of front surface. Temperature and convection coefficient, h, of air. Temperature of large surroundings.

FIND: (a) Temperature of back surface, (b) Effect of variations in k, h and ε.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction, (3) Radiation exchange with large surroundings.

ANALYSIS: (a) Applying an energy balance, Eq. 1.13 to the front surface and substituting the appropriate rate equations, Eqs. 1.2, 1.3a and 1.7, find

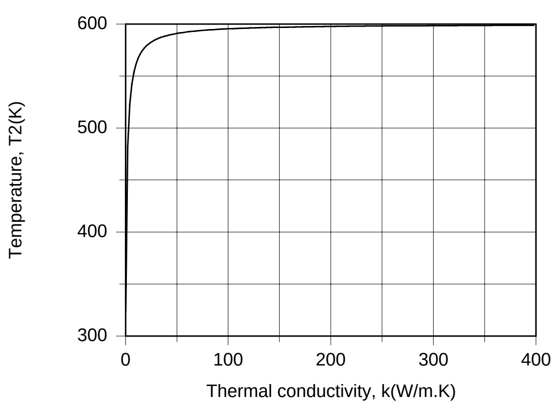
$$k\frac{T_1 - T_2}{L} = h\left(T_2 - T_\infty\right) + \varepsilon\sigma\left(T_2^4 - T_{sur}^4\right).$$

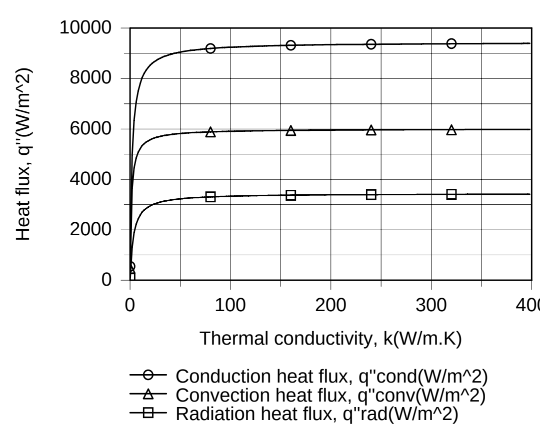
Substituting numerical values, find

$$T_1 - T_2 = \frac{0.05\,\text{m}}{0.7\,\text{W/m}\cdot\text{K}}\left[20\frac{\text{W}}{\text{m}^2\cdot\text{K}}100\,\text{K} + 0.8\times5.67\times10^{-8}\frac{\text{W}}{\text{m}^2\cdot\text{K}^4}\left[\left(400\,\text{K}\right)^4 - \left(300\,\text{K}\right)^4\right]\right] = 200\,\text{K}.$$

Since T_2 = 400 K, it follows that T_1 = 600 K. <

(b) Parametric effects may be evaluated by using the IHT *First Law* Model for a *Nonisothermal Plane* Wall. Changes in k strongly influence conditions for k < 20 W/m·K, but have a negligible effect for larger values, as T_2 approaches T_1 and the heat fluxes approach the corresponding limiting values



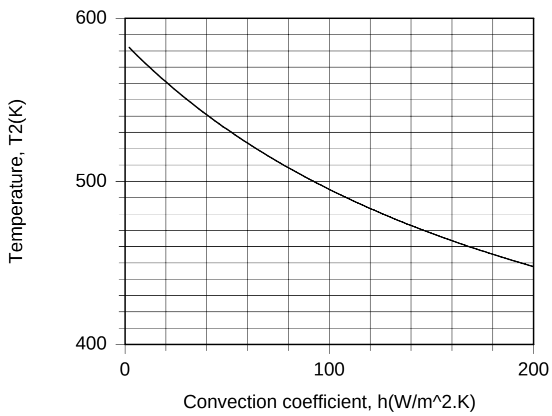


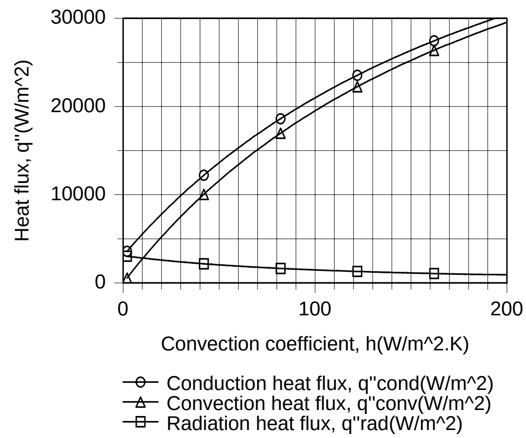
Continued…

PROBLEM 1.76 (Cont.)

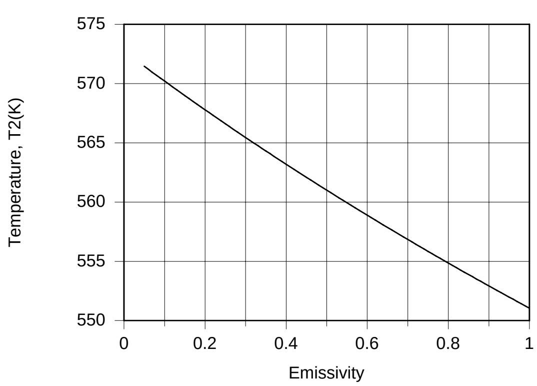
The implication is that, for k > 20 W/m·K, heat transfer by conduction in the wall is extremely efficient relative to heat transfer by convection and radiation, which become the *limiting* heat transfer processes. Larger fluxes could be obtained by increasing ε and h and/or by decreasing T_∞ and T_{sur}.

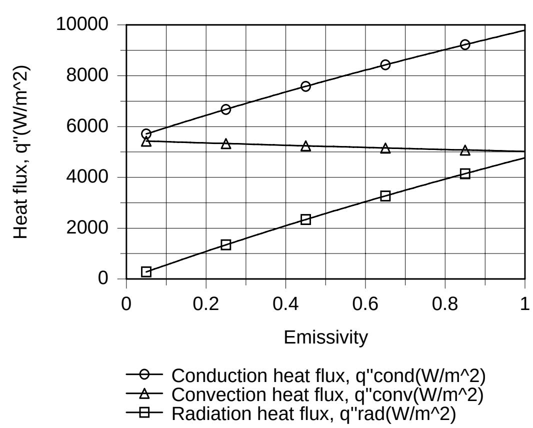
With increasing h, the front surface is cooled more effectively (T_2 decreases), and although q''_{rad} decreases, the reduction is exceeded by the increase in q''_{conv}. With a reduction in T_2 and fixed values of k and L, q''_{cond} must also increase.





The surface temperature also decreases with increasing ε, and the increase in q''_{rad} exceeds the reduction in q''_{conv}, allowing q''_{cond} to increase with ε.





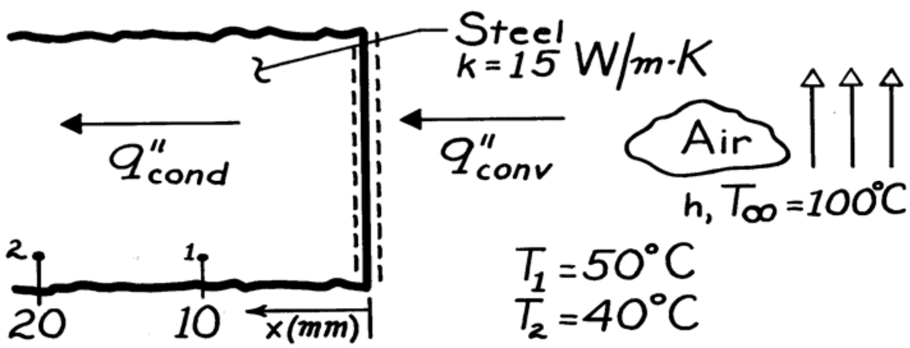
COMMENTS: Conservation of energy, of course, dictates that irrespective of the prescribed conditions, $q''_{cond} = q''_{conv} + q''_{rad}$.

PROBLEM 1.77

KNOWN: Temperatures at 10 mm and 20 mm from the surface and in the adjoining airflow for a thick stainless steel casting.

FIND: Surface convection coefficient, h.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction in the x-direction, (3) Constant properties, (4) Negligible generation.

ANALYSIS: From a surface energy balance, it follows that

$$q''_{cond} = q''_{conv}$$

where the convection rate equation has the form

$$q''_{conv} = h\left(T_\infty - T_0\right),$$

and q''_{cond} can be evaluated from the temperatures prescribed at surfaces 1 and 2. That is, from Fourier's law,

$$q''_{cond} = k\frac{T_1 - T_2}{x_2 - x_1}$$

$$q''_{cond} = 15\frac{W}{m\cdot K}\frac{\left(50-40\right)^\circ C}{\left(20\text{-}10\right)\times 10^{-3} m} = 15,000\ W/m^2.$$

Since the temperature gradient in the solid must be linear for the prescribed conditions, it follows that

$$T_o = 60°C.$$

Hence, the convection coefficient is

$$h = \frac{q''_{cond}}{T_\infty - T_0}$$

$$h = \frac{15,000\ W/m^2}{40^\circ C} = 375\ W/m^2\cdot K.$$ <

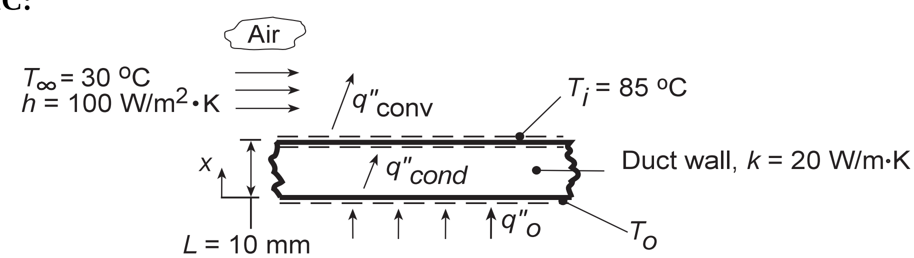
COMMENTS: The accuracy of this procedure for measuring h depends strongly on the validity of the assumed conditions.

PROBLEM 1.78

KNOWN: Duct wall of prescribed thickness and thermal conductivity experiences prescribed heat flux q''_o at outer surface and convection at inner surface with known heat transfer coefficient.

FIND: (a) Heat flux at outer surface required to maintain inner surface of duct at T_i = 85°C, (b) Temperature of outer surface, T_o, (c) Effect of h on T_o and q''_o.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in wall, (3) Constant properties, (4) Backside of heater perfectly insulated, (5) Negligible radiation.

ANALYSIS: (a) By performing an energy balance on the wall, recognize that $q''_o = q''_{cond}$. From an energy balance on the top surface, it follows that $q''_{cond} = q''_{conv} = q''_o$. Hence, using the convection rate equation,

$$q''_o = q''_{conv} = h\left(T_i - T_\infty\right) = 100\,W/m^2 \cdot K\left(85 - 30\right)^\circ C = 5500\,W/m^2. \quad <$$

(b) Considering the duct wall and applying Fourier's Law,

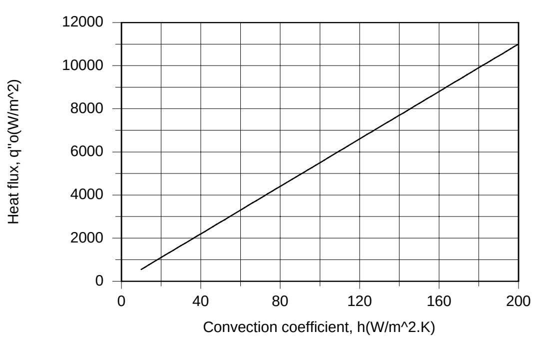
$$q''_o = k\frac{\Delta T}{\Delta X} = k\frac{T_o - T_i}{L}$$

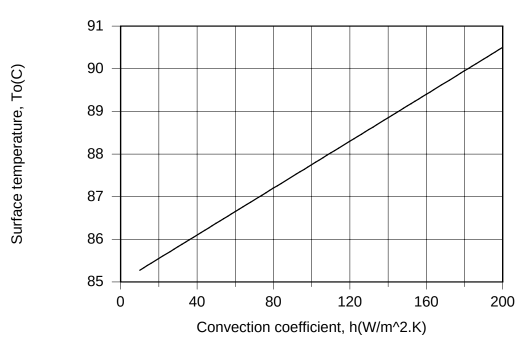
$$T_o = T_i + \frac{q''_o L}{k} = 85^\circ C + \frac{5500\,W/m^2 \times 0.010\,m}{20\,W/m\cdot K} = \left(85 + 2.8\right)^\circ C = 87.8^\circ C. \quad <$$

(c) For T_i = 85°C, the desired results may be obtained by simultaneously solving the energy balance equations

$$q''_o = k\frac{T_o - T_i}{L} \qquad \text{and} \qquad k\frac{T_o - T_i}{L} = h\left(T_i - T_\infty\right)$$

Using the IHT *First Law* Model for a *Nonisothermal Plane Wall*, the following results are obtained.





Since q''_{conv} increases linearly with increasing h, the applied heat flux q''_o and q''_{cond} must also increase. An increase in q''_{cond}, which, with fixed k, T_i and L, necessitates an increase in T_o.

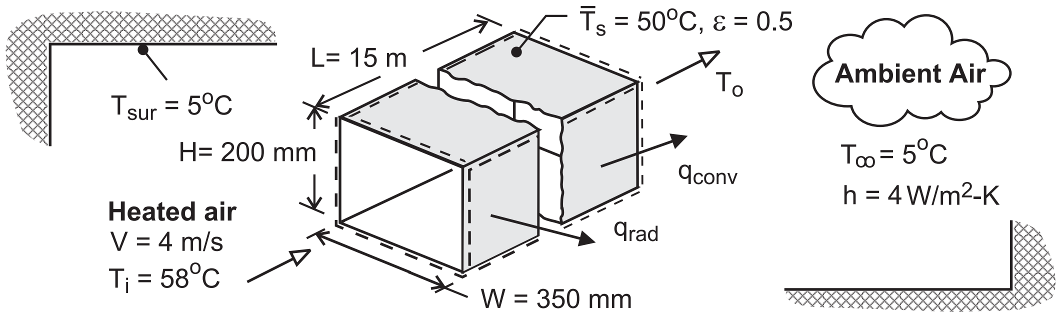
COMMENTS: The temperature difference across the wall is small, amounting to a maximum value of $\left(T_o - T_i\right)$ = 5.5°C for h = 200 W/m²·K. If the wall were thinner (L < 10 mm) or made from a material with higher conductivity (k > 20 W/m·K), this difference would be reduced.

PROBLEM 1.79

KNOWN: Dimensions, average surface temperature and emissivity of heating duct. Duct air inlet temperature and velocity. Temperature of ambient air and surroundings. Convection coefficient.

FIND: (a) Heat loss from duct, (b) Air outlet temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Constant air properties, (3) Negligible potential and kinetic energy changes of air flow, (4) Radiation exchange between a small surface and a large enclosure.

ANALYSIS: (a) Heat transfer from the surface of the duct to the ambient air and the surroundings is given by Eq. (1.10)

$$q = hA_s\left(T_s - T_\infty\right) + \varepsilon A_s \sigma\left(T_s^4 - T_{sur}^4\right)$$

where A_s = L (2W + 2H) = 15 m (0.7 m + 0.5 m) = 16.5 m^2. Hence,

$$q = 4\ \text{W/m}^2\cdot\text{K}\times 16.5\ \text{m}^2\left(45^\circ\text{C}\right) + 0.5\times 16.5\ \text{m}^2\times 5.67\times 10^{-8}\ \text{W/m}^2\cdot\text{K}^4\left(323^4 - 278^4\right)\text{K}^4$$

$$q = q_{conv} + q_{rad} = 2970\ \text{W} + 2298\ \text{W} = 5268\ \text{W} \qquad <$$

(b) With i = u + pv, $\dot{W}$ = 0 and the third assumption, Eq. (1.12d) yields,

$$\dot{m}\left(i_i - i_o\right) = \dot{m}c_p\left(T_i - T_o\right) = q$$

where the sign on q has been reversed to reflect the fact that heat transfer is *from* the system.
With $\dot{m} = \rho V A_c = 1.10\ \text{kg/m}^3 \times 4\ \text{m/s}\left(0.35\text{m}\times 0.20\text{m}\right) = 0.308\ \text{kg/s},$ the outlet temperature is

$$T_o = T_i - \frac{q}{\dot{m}c_p} = 58^\circ\text{C} - \frac{5268\ \text{W}}{0.308\ \text{kg/s}\times 1008\ \text{J/kg}\cdot\text{K}} = 41^\circ\text{C} \qquad <$$

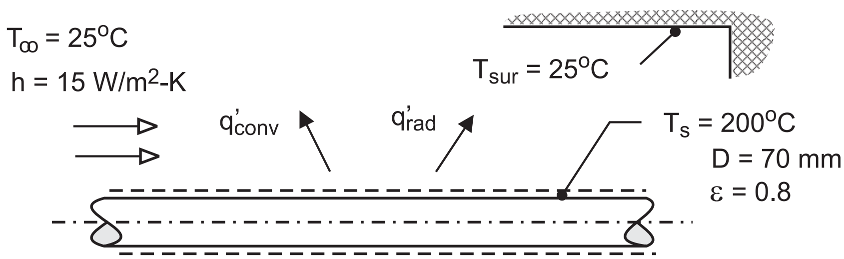
COMMENTS: The temperature drop of the air is large and unacceptable, unless the intent is to use the duct to heat the basement. If not, the duct should be insulated to insure maximum delivery of thermal energy to the intended space(s).

PROBLEM 1.80

KNOWN: Uninsulated pipe of prescribed diameter, emissivity, and surface temperature in a room with fixed wall and air temperatures. See Example 1.2.

FIND: (a) Which option to reduce heat loss to the room is more effective: reduce by a factor of two the convection coefficient (from 15 to 7.5 $W/m^2 \cdot K$) or the emissivity (from 0.8 to 0.4) and (b) Show graphically the heat loss as a function of the convection coefficient for the range $5 \le h \le 20$ $W/m^2 \cdot K$ for emissivities of 0.2, 0.4 and 0.8. Comment on the relative efficacy of reducing heat losses associated with the convection and radiation processes.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Radiation exchange between pipe and the room is between a small surface in a much larger enclosure, (3) The surface emissivity and absorptivity are equal, and (4) Restriction of the air flow does not alter the radiation exchange process between the pipe and the room.

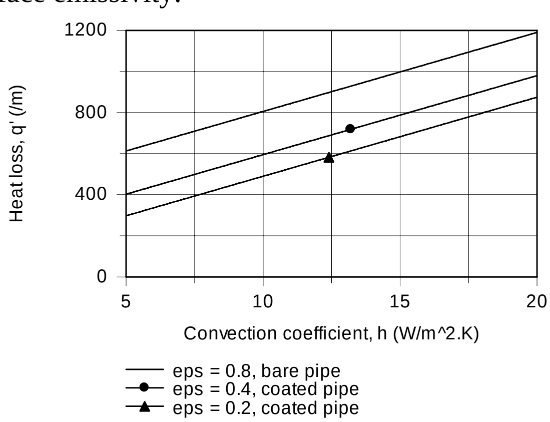
ANALYSIS: (a) The heat rate from the pipe to the room per unit length is

$$q' = q'/L = q'_{conv} + q'_{rad} = h(\pi D)(T_s - T_\infty) + \varepsilon(\pi D)\sigma\left(T_s^4 - T_{sur}^4\right)$$

Substituting numerical values for the two options, the resulting heat rates are calculated and compared with those for the conditions of Example 1.2. We conclude that both options are comparably effective.

Conditions	$h\left(W/m^2 \cdot K\right)$	ε	$q'(W/m)$
Base case, Example 1.2	15	0.8	998
Reducing h by factor of 2	7.5	0.8	788
Reducing ε by factor of 2	15	0.4	709

(b) Using IHT, the heat loss can be calculated as a function of the convection coefficient for selected values of the surface emissivity.



Continued ...

PROBLEM 1.80 (Cont.)

COMMENTS: (1) In Example 1.2, Comment 3, we read that the heat rates by convection and radiation exchange were comparable for the base case conditions (577 vs. 421 W/m). It follows that reducing the key transport parameter (h or ε) by a factor of two yields comparable reductions in the heat loss. Coating the pipe to reduce the emissivity might be the more practical option as it may be difficult to control air movement.

(2) For this pipe size and thermal conditions (T_s and T_∞), the minimum possible convection coefficient is approximately 7.5 $W/m^2 \cdot K$, corresponding to free convection heat transfer to quiescent ambient air. Larger values of h are a consequence of forced air flow conditions.

(3) The Workspace for the IHT program to calculate the heat loss and generate the graph for the heat loss as a function of the convection coefficient for selected emissivities is shown below. It is good practice to provide commentary with the code making your solution logic clear, and to summarize the results.

```
// Heat loss per unit pipe length; rate equation from Ex. 1.2
q' = q'cv + q'rad
q'cv = pi*D*h*(Ts - Tinf)
q'rad = pi*D*eps*sigma*(Ts^4 - Tsur^4)
sigma = 5.67e-8

// Input parameters
D = 0.07
Ts_C = 200        // Representing temperatures in Celsius units using _C subscripting
Ts = Ts_C +273
Tinf_C = 25
Tinf = Tinf_C + 273
h = 15            // For graph, sweep over range from 5 to 20
Tsur_C = 25
Tsur = Tsur_C + 273
eps = 0.8
//eps = 0.4       // Values of emissivity for parameter study
//eps = 0.2

/* Base case results

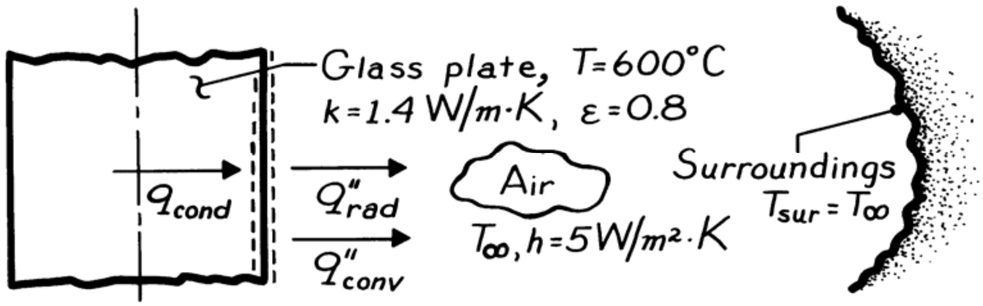
```

PROBLEM 1.81

KNOWN: Conditions associated with surface cooling of plate glass which is initially at 600°C. Maximum allowable temperature gradient in the glass.

FIND: Lowest allowable air temperature, T_∞.

SCHEMATIC:



ASSUMPTIONS: (1) Surface of glass exchanges radiation with large surroundings at $T_{sur} = T_\infty$, (2) One-dimensional conduction in the x-direction.

ANALYSIS: The maximum temperature gradient will exist at the surface of the glass and at the instant that cooling is initiated. From the surface energy balance, Eq. 1.13, and the rate equations, Eqs. 1.1, 1.3a and 1.7, it follows that

$$-k\frac{dT}{dx} - h\left(T_s - T_\infty\right) - \varepsilon\sigma\left(T_s^4 - T_{sur}^4\right) = 0$$

or, with $(dT/dx)_{max}$ = -15°C/mm = -15,000°C/m and $T_{sur} = T_\infty$,

$$-1.4\frac{W}{m\cdot K}\left[-15,000\frac{\circ C}{m}\right] = 5\frac{W}{m^2\cdot K}\left(873 - T_\infty\right)K$$

$$+0.8\times 5.67\times 10^{-8}\frac{W}{m^2\cdot K^4}\left[873^4 - T_\infty^4\right]K^4.$$

T_∞ may be obtained from a trial-and-error solution, from which it follows that, for T_∞ = 618K,

$$21{,}000\frac{W}{m^2} \approx 1275\frac{W}{m^2} + 19{,}730\frac{W}{m^2}.$$

Hence the lowest allowable air temperature is

$$T_\infty \approx 618K = 345^\circ C.$$ <

COMMENTS: (1) Initially, cooling is determined primarily by radiation effects.

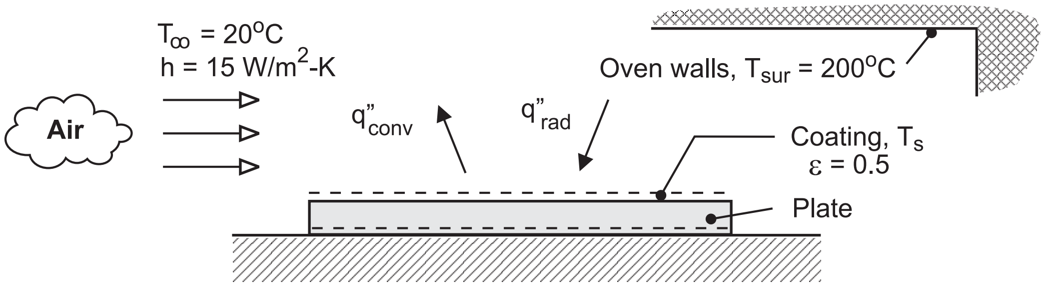
(2) For fixed T_∞, the surface *temperature gradient* would *decrease* with *increasing* time into the cooling process. Accordingly, T_∞ could be decreasing with increasing time and still keep within the maximum allowable temperature gradient.

PROBLEM 1.82

KNOWN: Hot-wall oven, in lieu of infrared lamps, with temperature T_{sur} = 200°C for heating a coated plate to the cure temperature. See Example 1.9.

FIND: (a) The plate temperature T_s for prescribed convection conditions and coating emissivity, and (b) Calculate and plot T_s as a function of T_{sur} for the range $150 \le T_{sur} \le 250$°C for ambient air temperatures of 20, 40 and 60°C; identify conditions for which acceptable curing temperatures between 100 and 110°C may be maintained.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat loss from back surface of plate, (3) Plate is small object in large isothermal surroundings (hot oven walls).

ANALYSIS: (a) The temperature of the plate can be determined from an energy balance on the plate, considering radiation exchange with the hot oven walls and convection with the ambient air.

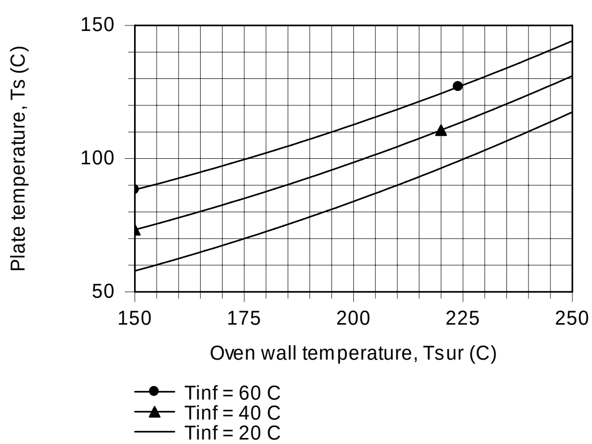
$$\dot{E}''_{in} - \dot{E}''_{out} = 0 \qquad \text{or} \qquad q''_{rad} - q''_{conv} = 0$$

$$\varepsilon\sigma\left(T_{sur}^4 - T_s^4\right) - h\left(T_s - T_\infty\right) = 0$$

$$0.5 \times 5.67 \times 10^{-8}\,\text{W/m}^2 \cdot \text{K}^4\left([200+273]^4 - T_s^4\right)\text{K}^4 - 15\,\text{W/m}^2 \cdot \text{K}\left(T_s - [20+273]\right)\text{K} = 0$$

$$T_s = 357\ \text{K} = 84°\text{C}$$ <

(b) Using the energy balance relation in the Workspace of IHT, the plate temperature can be calculated and plotted as a function of oven wall temperature for selected ambient air temperatures.



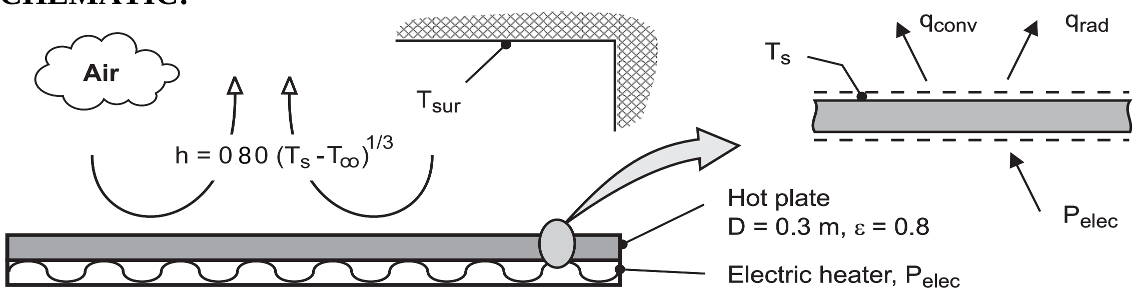
COMMENTS: From the graph, acceptable cure temperatures between 100 and 110°C can be maintained for these conditions: with T_∞ = 20°C when $225 \le T_{sur} \le 240$°C; with T_∞ = 40°C when $205 \le T_{sur} \le 220$°C; and with T_∞ = 60°C when $175 \le T_{sur} \le 195$°C.

PROBLEM 1.83

KNOWN: Surface temperature, diameter and emissivity of a hot plate. Temperature of surroundings and ambient air. Expression for convection coefficient.

FIND: (a) Operating power for prescribed surface temperature, (b) Effect of surface temperature on power requirement and on the relative contributions of radiation and convection to heat transfer from the surface.

SCHEMATIC:



ASSUMPTIONS: (1) Plate is of uniform surface temperature, (2) Walls of room are large relative to plate, (3) Negligible heat loss from bottom or sides of plate.

ANALYSIS: (a) From an energy balance on the hot plate, $P_{elec} = q_{conv} + q_{rad} = A_p \left(q''_{conv} + q''_{rad}\right)$.

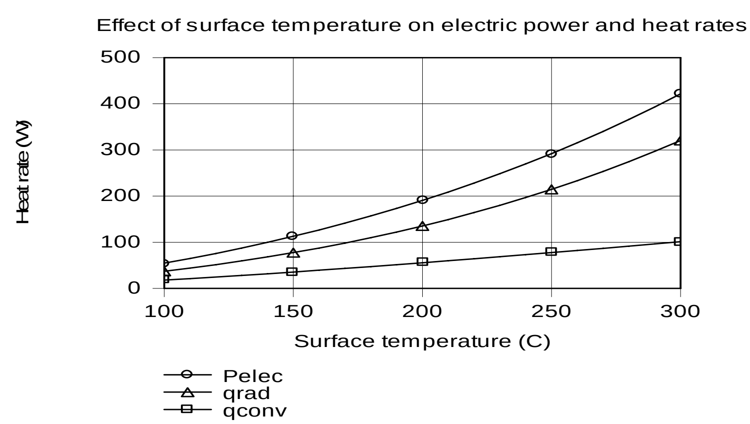
Substituting for the area of the plate and from Eqs. (1.3a) and (1.7), with $h = 0.80\,(T_s - T_\infty)^{1/3}$, it follows that

$$P_{elec} = \left(\pi D^2/4\right)\left[0.80\left(T_s - T_\infty\right)^{4/3} + \varepsilon\sigma\left(T_s^4 - T_{sur}^4\right)\right]$$

$$P_{elec} = \pi\left(0.3\text{m}\right)^2/4\left[0.80\left(175\right)^{4/3} + 0.8\times 5.67\times 10^{-8}\left(473^4 - 298^4\right)\right]\ \text{W/m}^2$$

$$P_{elec} = 0.0707\ \text{m}^2\left[783\ \text{W/m}^2 + 1913\ \text{W/m}^2\right] = 55.4\ \text{W} + 135.2\ \text{W} = 190.6\ \text{W}$$ <

(b) As shown graphically, both the radiation and convection heat rates, and hence the requisite electric power, increase with increasing surface temperature.



However, because of its dependence on the fourth power of the surface temperature, the increase in radiation is more pronounced. The significant relative effect of radiation is due to the small convection coefficients characteristic of natural convection, with $3.37 \le h \le 5.2\ \text{W/m}^2\cdot\text{K}$ for $100 \le T_s < 300°\text{C}$.

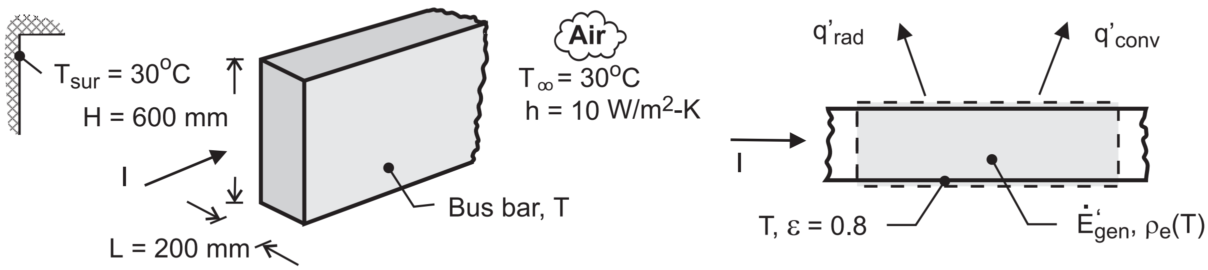
COMMENTS: Radiation losses could be reduced by applying a low emissivity coating to the surface, which would have to maintain its integrity over the range of operating temperatures.

PROBLEM 1.84

KNOWN: Long bus bar of rectangular cross-section and ambient air and surroundings temperatures. Relation for the electrical resistivity as a function of temperature.

FIND: (a) Temperature of the bar with a current of 60,000 A, and (b) Compute and plot the operating temperature of the bus bar as a function of the convection coefficient for the range $10 \le h \le 100$ $W/m^2 \cdot K$. Minimum convection coefficient required to maintain a safe-operating temperature below 120°C. Will increasing the emissivity significantly affect this result?

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Bus bar is long, (3) Uniform bus-bar temperature, (3) Radiation exchange between the outer surface of the bus bar and its surroundings is between a small surface and a large enclosure.

PROPERTIES: Bus-bar material, $\rho_e = \rho_{e,o}\left[1+\alpha\left(T-T_o\right)\right]$, $\rho_{e,o} = 0.0828\,\mu\Omega\cdot m$, $T_o = 25°C$, $\alpha = 0.0040\,K^{-1}$.

ANALYSIS: (a) An energy balance on the bus-bar for a unit length as shown in the schematic above has the form

$$\dot{E}'_{in} - \dot{E}'_{out} + \dot{E}'_{gen} = 0 \qquad -q'_{rad} - q'_{conv} + I^2 R'_e = 0$$

$$-\varepsilon P \sigma\left(T^4 - T_{sur}^4\right) - hP\left(T - T_\infty\right) + I^2 \rho_e / A_c = 0$$

where $P = 2(H+W)$, $R'_e = \rho_e / A_c$ and $A_c = H \times W$. Substituting numerical values,

$$-0.8 \times 2(0.600+0.200)\,m \times 5.67\times10^{-8}\,W/m^2\cdot K^4\left(T^4 - [30+273]^4\right)K^4$$

$$-10\,W/m^2\cdot K \times 2(0.600+0.200)\,m\left(T - [30+273]\right)K$$

$$+(60,000\,A)^2\left\{0.0828\times10^{-6}\,\Omega\cdot m\left[1+0.0040\,K^{-1}\left(T-[25+273]\right)K\right]\right\}/(0.600\times0.200)\,m^2 = 0$$

Solving for the bus-bar temperature, find $\qquad T = 426\ K = 153°C.$ <

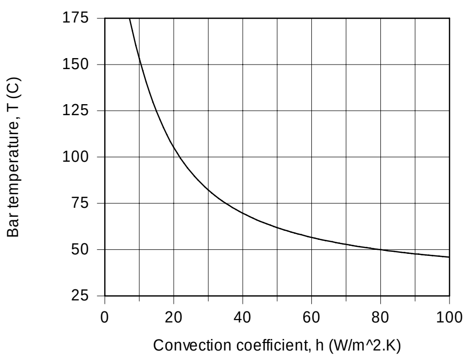
(b) Using the energy balance relation in the Workspace of IHT, the bus-bar operating temperature is calculated as a function of the convection coefficient for the range $10 \le h \le 100\ W/m^2\cdot K$. From this graph we can determine that to maintain a safe operating temperature below 120°C, the minimum convection coefficient required is

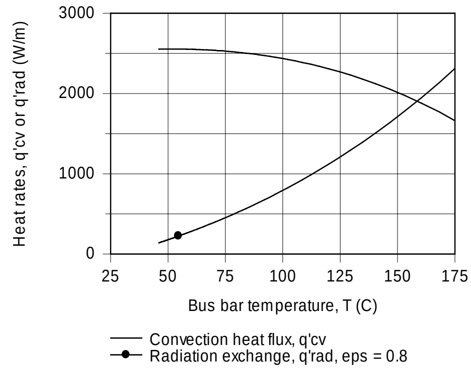
$$h_{min} = 16\ W/m^2\cdot K.$$ <

Continued …

PROBLEM 1.84 (Cont.)

Using the same equations, we can calculate and plot the heat transfer rates by convection and radiation as a function of the bus-bar temperature.





Note that convection is the dominant mode for low bus-bar temperatures; that is, for low current flow. As the bus-bar temperature increases toward the safe-operating limit (120°C), convection and radiation exchange heat transfer rates become comparable. Notice that the relative importance of the radiation exchange rate increases with increasing bus-bar temperature.

COMMENTS: (1) It follows from the second graph that increasing the surface emissivity will be only significant at higher temperatures, especially beyond the safe-operating limit.

(2) The Workspace for the IHT program to perform the parametric analysis and generate the graphs is shown below. It is good practice to provide commentary with the code making your solution logic clear, and to summarize the results.

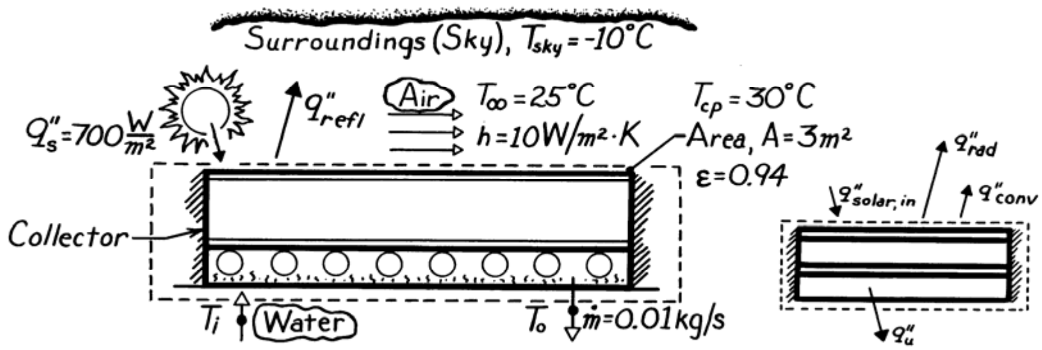
PROBLEM 1.85

KNOWN: Solar collector designed to heat water operating under prescribed solar irradiation and loss conditions.

FIND: (a) Useful heat collected per unit area of the collector, q''_u, (b) Temperature rise of the water flow, $T_o - T_i$, and (c) Collector efficiency.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) No heat losses out sides or back of collector, (3) Collector area is small compared to sky surroundings.

PROPERTIES: *Table A.6*, Water (300K): c_p = 4179 J/kg·K.

ANALYSIS: (a) Defining the collector as the control volume and writing the conservation of energy requirement on a per unit area basis, find that

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = \dot{E}_{st}.$$

Identifying processes as per above right sketch,

$$q''_{solar} - q''_{rad} - q''_{conv} - q''_u = 0$$

where $q''_{solar} = 0.9\ q''_s$; that is, 90% of the solar flux is absorbed in the collector (Eq. 1.6). Using the appropriate rate equations, the useful heat rate per unit area is

$$q''_u = 0.9\ q''_s - \varepsilon\sigma\left(T_{cp}^4 - T_{sky}^4\right) - h\left(T_s - T_\infty\right)$$

$$q''_u = 0.9 \times 700\frac{W}{m^2} - 0.94 \times 5.67 \times 10^{-8}\frac{W}{m^2 \cdot K^4}\left(303^4 - 263^4\right)K^4 - 10\frac{W}{m^2 \cdot K}\left(30-25\right)^\circ C$$

$$q''_u = 630\ W/m^2 - 194\ W/m^2 - 50\ W/m^2 = 386\ W/m^2. \qquad <$$

(b) The total useful heat collected is $q''_u \cdot A$. Defining a control volume about the water tubing, the useful heat causes an enthalpy change of the flowing water. That is,

$$q''_u \cdot A = \dot{m}c_p\left(T_i - T_o\right) \qquad \text{or}$$

$$\left(T_i - T_o\right) = 386\ W/m^2 \times 3m^2 / 0.01kg/s \times 4179J/kg \cdot K = 27.7^\circ C. \qquad <$$

(c) The efficiency is $\eta = q''_u / q''_S = \left(386\ W/m^2\right)/\left(700\ W/m^2\right) = 0.55$ or 55%. $\qquad <$

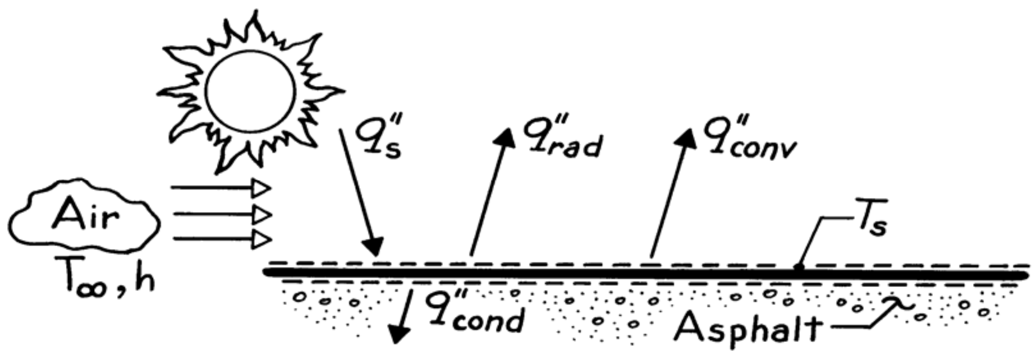
COMMENTS: Note how the sky has been treated as large surroundings at a uniform temperature T_{sky}.

PROBLEM 1.86(a)

KNOWN: Solar radiation is incident on an asphalt paving.

FIND: Relevant heat transfer processes.

SCHEMATIC:



The relevant processes shown on the schematic include:

q''_S Incident solar radiation, a large portion of which $q''_{S,abs}$, is absorbed by the asphalt surface,

q''_{rad} Radiation emitted by the surface to the air,

q''_{conv} Convection heat transfer from the surface to the air, and

q''_{cond} Conduction heat transfer from the surface into the asphalt.

Applying the surface energy balance, Eq. 1.13,

$$q''_{S,abs} - q''_{rad} - q''_{conv} = q''_{cond}.$$

COMMENTS: (1) q''_{cond} and q''_{conv} could be evaluated from Eqs. 1.1 and 1.3, respectively.

(2) It has been assumed that the pavement surface temperature is higher than that of the underlying pavement and the air, in which case heat transfer by conduction and convection are from the surface.

(3) For simplicity, radiation incident on the pavement due to atmospheric emission has been ignored (see Section 12.8 for a discussion). Eq. 1.6 may then be used for the absorbed solar irradiation and Eq. 1.5 may be used to obtain the emitted radiation q''_{rad}.

(4) With the rate equations, the energy balance becomes

$$q''_{S,abs} - \varepsilon\,\sigma\,T_S^4 - h\left(T_S - T_\infty\right) = -k\left.\frac{dT}{dx}\right]_S .$$

PROBLEM 1.86(b)

KNOWN: Physical mechanism for microwave heating.

FIND: Comparison of (a) cooking in a microwave oven with a conventional radiant or convection oven and (b) a microwave clothes dryer with a conventional dryer.

(a) Microwave cooking occurs as a result of volumetric thermal energy generation *throughout* the food, without heating of the food container or the oven wall. Conventional cooking relies on radiant heat transfer from the oven walls and/or convection heat transfer from the air space to the surface of the food and subsequent heat transfer by conduction to the core of the food. Microwave cooking is more efficient and is achieved in less time.

(b) In a microwave dryer, the microwave radiation would heat the water, but not the fabric, directly (the fabric would be heated indirectly by energy transfer from the water). By heating the water, energy would go directly into evaporation, unlike a conventional dryer where the walls and air are first heated electrically or by a gas heater, and thermal energy is subsequently transferred to the wet clothes. The microwave dryer would still require a rotating drum and air flow to remove the water vapor, but is able to operate more efficiently and at lower temperatures.

PROBLEM 1.86 (c)

KNOWN: Water storage tank initial temperature, water initial pressure and temperature, storage tank configuration.

FIND: Identify heat transfer processes that will promote freezing of water. Determine effect of insulation thickness. Determine effect of wall thickness and tank material. Determine effect of transfer tubing material. Discuss optimal tank shape, and effect of applying thin aluminum foil to the outside of the tank.

SCHEMATIC:

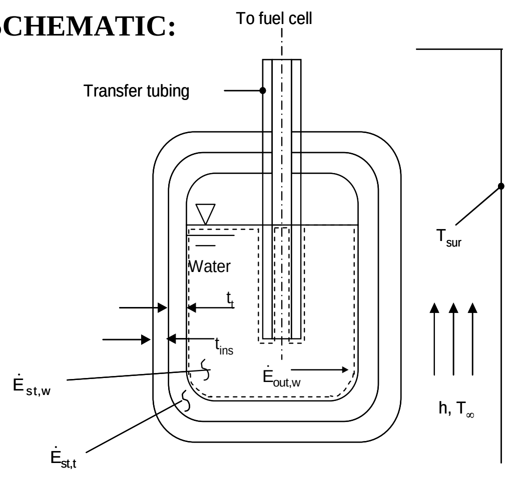


Figure 1 Rapid Response.

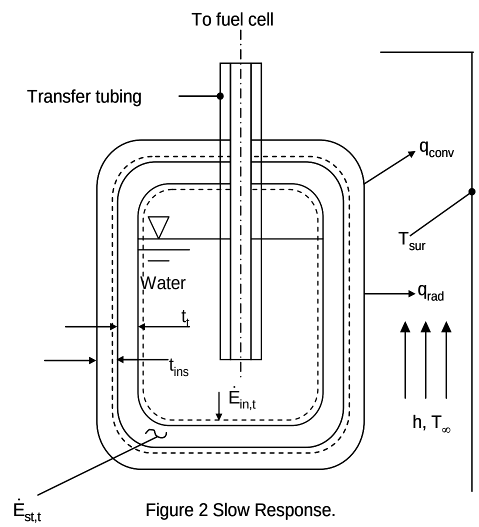

Figure 2 Slow Response.

ANALYSIS: The thermal response of the water may be analyzed by dividing the cooling process into two parts.

<u>Part One. Water and Tank Rapid Response.</u>
We expect the mass of water to be greater than the mass of the tank. From experience, we would not expect the water to completely freeze immediately after filling the tank. Assuming negligible heat transfer through the insulation or transfer tubing during this initial rapid water cooling period, no heat transfer to the air above the water, and assuming isothermal water and tank behavior at any instant in time, an energy balance on a control volume surrounding the water would yield

$$\dot{E}_{st,w} = -\dot{E}_{out,w} \quad (1)$$

An energy balance on a control volume surrounding the tank would yield

$$\dot{E}_{in,t} = \dot{E}_{st,t} \quad (2)$$

where $\dot{E}_{out,w} = \dot{E}_{in,t}$ (3)

Combining Eqs. (1) – (3) yields

Continued…

PROBLEM 1.86 (c) (Cont.)

$$\dot{E}_{st,w} = -\dot{E}_{st,t} = M_w c_{p,w} \cdot (\overline{T} - T_{i,w}) = M_t c_{p,t} \cdot (T_{i,t} - \overline{T}) \qquad (4)$$

where $\overline{T}$ is the average temperature of the water and tank after the initial filling process. For $M_w c_{p,w} >> M_t c_{p,t}$, $\overline{T} \approx T_{i,w}$, thus confirming our expectation.

<u>Part Two. Slow Water Cooling.</u>

The heat transfer processes that would promote water freezing include:

-heat transfer through the insulation to the cold air

-heat loss by conduction upward through the wall of the transfer tubing <

As the insulation thickness, t_{ins}, is increased, Fourier's law indicates that heat losses from the water are decreased, slowing the rate at which the water cools. <

As the tank wall thickness, t_t, is increased, the tank wall mass increases. This, along with increasing the tank wall specific heat, will serve to reduce the average temperature, $\overline{T}$, to a lower value, as evident by inspecting Eq. (4). This effect, based on the first law of thermodynamics, would decrease the time needed to cool the water to the freezing temperature. As the tank wall thickness is increased, however, heat losses by conduction through the tank wall would decrease as seen by inspection of Fourier's law, slowing the cooling process. As the tank wall thermal conductivity is reduced, this will also decrease the cooling rate of the water. Therefore, the effect of the tank wall thickness could increase *or* decrease the water cooling rate. As the thermal conductivity of the transfer tubing is increased, heat losses from the water upward through the tube wall will increase. This suggests that use of plastic for the transfer tubing would slow the cooling of the water. <

To slow the cooling process, a large water mass to surface area is desired. The mass is proportional to the volume of water in the tank, while the heat loss from the tank by convection to the cold air and radiation to the surroundings is proportional to the surface area of the tank. A spherical tank maximizes the volume-to-area ratio, reducing the rate at which the water temperature drops, and would help prevent freezing. <

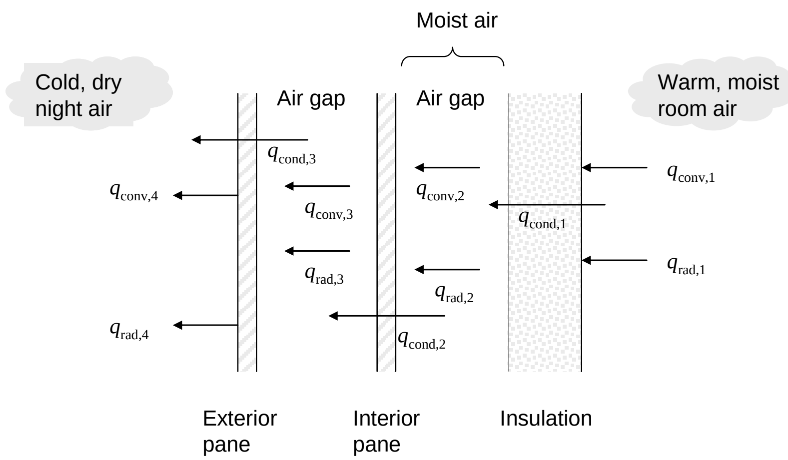
Heat losses will occur by convection and radiation at the exposed tank area. The radiation loss, according to Eq. 1.7, is proportional to the emissivity of the surface. Aluminum foil is a low emissivity material, and therefore a wrap of foil would slow the water cooling process. The aluminum foil is very thin and has a high thermal conductivity, therefore by Fourier's law, there would be a very small temperature drop across the thickness of the foil and would not impact the cooling rate. <

PROBLEM 1.86(d)

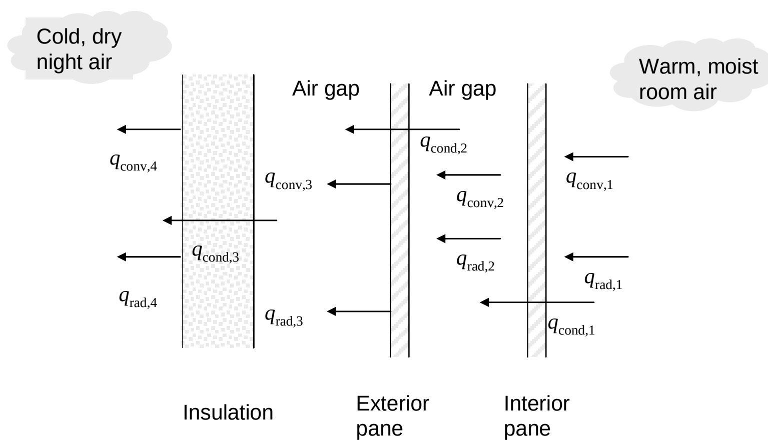
KNOWN: Double-pane windows with foamed insulation inside or outside. Cold, dry air outside and warm, moist air inside.

FIND: Identify heat transfer processes. Which configuration is preferred to avoid condensation?

SCHEMATIC:



Insulation on inside of window.



I

Insulation on outside of window.

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer through window and insulation.

ANALYSIS: With the insulation on the inside, heat is transferred from the warm room air to the insulation by convection ($q_{conv,1}$) and from the warm interior surfaces of the room by radiation ($q_{rad,1}$). Heat is then conducted through the insulation ($q_{cond,1}$). From there, heat is transferred across the air gap between the insulation and the window by free convection ($q_{conv,2}$) and radiation ($q_{rad,2}$). Heat is transferred through the first glass pane by conduction ($q_{cond,2}$). Heat transfer across the air gap between the window panes occurs by free convection ($q_{conv,3}$) and radiation ($q_{rad,3}$). Heat is then transferred through the second glass pane by conduction ($q_{cond,3}$). From there, heat is transferred to the cold air by convection ($q_{conv,4}$) and to the cold surroundings by radiation ($q_{rad,4}$). The same mechanisms occur with the insulation on the outside of the window, just in a different order.

Continued...

PROBLEM 1.86(d) (Cont.)

Condensation may occur on any surface that is exposed to moist air if the surface temperature is below the dewpoint temperature. Condensation causes an additional heat transfer mechanism because when water vapor condenses it releases the enthalpy of vaporization ($q_{condense}$), which heats the surface on which condensation is occurring. For example, if condensation occurs on the inside surface of the window, this will increase the temperature of that surface and the rate of heat transfer through that window pane. The condensation heat transfer processes are not shown on the schematics.

We know that condensation does not occur on the window's interior pane when there is no insulation in place. If insulation were to be placed on the outside of the window, it will increase the temperature difference between the outside air and the window panes, increasing the window pane temperatures. Therefore condensation will still not occur. <

If the insulation is placed on the inside of the window, it will increase the temperature difference between the warm room air and the window's interior pane. Both the inner surface of the window and the side of the insulation facing the window may experience temperatures below the dewpoint temperature. Because the insulation is loosely-fitting, moist air infiltrates the gap between the insulation and the inner window pane, and condensation may occur. Liquid water may accumulate and cause water damage. To avoid condensation and associated water damage, the insulation should be placed on the outside of the window. <

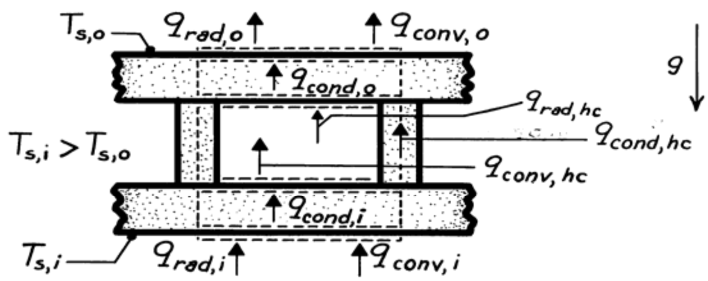
COMMENTS: (1) The potential water damage is *not* caused by window leakage. Any condensation problem would be exacerbated by adding more insulation to the inside of the window. (2) The potential for condensation damage would be reduced by lowering the humidity in the room, at the risk of increasing discomfort and the potential for illness. (3) Moisture may infiltrate through the insulation. Even tightly-fitting, improperly placed insulation can lead to condensation and water damage. (4) Adding the insulation to the exterior of the window will reduce the possibility of water damage due to condensation, but it cannot be easily removed to enjoy a bright winter day.

PROBLEM 1.86(e)

KNOWN: Geometry of a composite insulation consisting of a honeycomb core.

FIND: Relevant heat transfer processes.

SCHEMATIC:



The above schematic represents the cross section of a single honeycomb cell and surface slabs. Assumed direction of gravity field is downward. Assuming that the bottom (inner) surface temperature exceeds the top (outer) surface temperature $\left(T_{s,i} > T_{s,o}\right)$, heat transfer is in the direction shown.

Heat may be transferred to the inner surface by convection and radiation, whereupon it is transferred through the composite by

$q_{cond,i}$	Conduction through the inner solid slab,
$q_{conv,hc}$	Free convection through the cellular airspace,
$q_{cond,hc}$	Conduction through the honeycomb wall,
$q_{rad,hc}$	Radiation between the honeycomb surfaces, and
$q_{cond,o}$	Conduction through the outer solid slab.

Heat may then be transferred from the outer surface by convection and radiation. Note that for a single cell under steady state conditions,

$$q_{rad,i} + q_{conv,i} = q_{cond,i} = q_{conv,hc} + q_{cond,hc}$$

$$+q_{rad,hc} = q_{cond,o} = q_{rad,o} + q_{conv,o}.$$

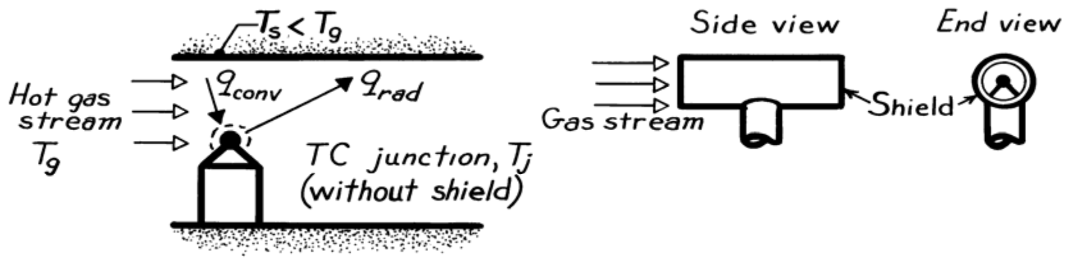
COMMENTS: Performance would be enhanced by using materials of low thermal conductivity, k, and emissivity, ε. Evacuating the airspace would enhance performance by eliminating heat transfer due to free convection.

PROBLEM 1.86(f)

KNOWN: A thermocouple junction is used, with or without a radiation shield, to measure the temperature of a gas flowing through a channel. The wall of the channel is at a temperature much less than that of the gas.

FIND: (a) Relevant heat transfer processes, (b) Temperature of junction relative to that of gas, (c) Effect of radiation shield.

SCHEMATIC:



ASSUMPTIONS: (1) Junction is small relative to channel walls, (2) Steady-state conditions, (3) Negligible heat transfer by conduction through the thermocouple leads.

ANALYSIS: (a) The relevant heat transfer processes are:

q_{rad} Net radiation transfer from the junction to the walls, and

q_{conv} Convection transfer from the gas to the junction.

(b) From a surface energy balance on the junction,

$$q_{conv} = q_{rad}$$

or from Eqs. 1.3a and 1.7,

$$h\,A\left(T_g - T_j\right) = \varepsilon\,A\,\sigma\left(T_j^4 - T_s^4\right).$$

To satisfy this equality, it follows that

$$T_s < T_j < T_g.$$

That is, the junction assumes a temperature between that of the channel wall and the gas, thereby sensing a temperature which is less than that of the gas.

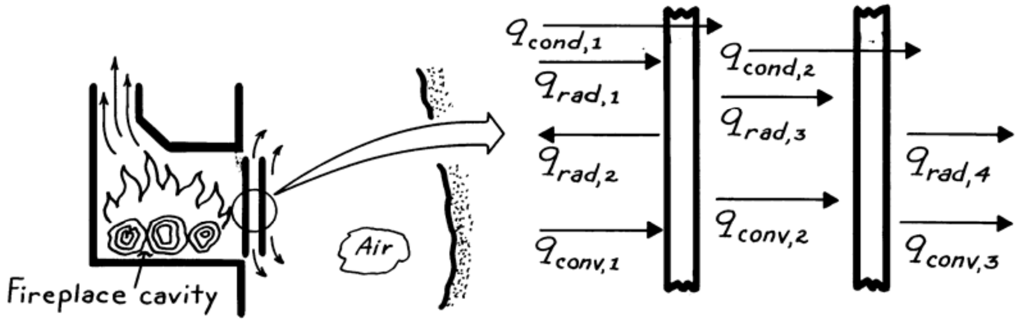
(c) The measurement error $\left(T_g - T_j\right)$ is reduced by using a radiation shield as shown in the schematic. The junction now exchanges radiation with the shield, whose temperature must exceed that of the channel wall. The radiation loss from the junction is therefore reduced, and its temperature more closely approaches that of the gas.

PROBLEM 1.86(g)

KNOWN: Fireplace cavity is separated from room air by two glass plates, open at both ends.

FIND: Relevant heat transfer processes.

SCHEMATIC:



The relevant heat transfer processes associated with the double-glazed, glass fire screen are:

$q_{rad,1}$	Radiation from flames and cavity wall, portions of which are absorbed and transmitted by the two panes,
$q_{rad,2}$	Emission from inner surface of inner pane to cavity,
$q_{rad,3}$	Net radiation exchange between outer surface of inner pane and inner surface of outer pane,
$q_{rad,4}$	Net radiation exchange between outer surface of outer pane and walls of room,
$q_{conv,1}$	Convection between cavity gases and inner pane,
q_{conv2}	Convection across air space between panes,
$q_{conv,3}$	Convection from outer surface to room air,
$q_{cond,1}$	Conduction across inner pane, and
$q_{cond,2}$	Conduction across outer pane.

COMMENTS: (1) Much of the luminous portion of the flame radiation is transmitted to the room interior.

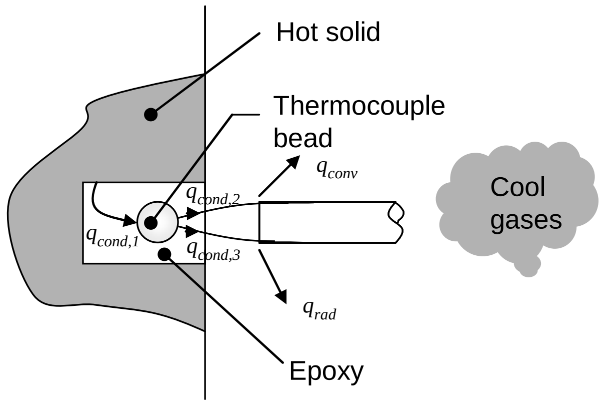
(2) All convection processes are buoyancy driven (free convection).

PROBLEM 1.86(h)

KNOWN: Thermocouple junction held in small hole in solid material by epoxy. Solid is hotter than surroundings.

FIND: Identify heat transfer processes. Will thermocouple junction sense temperature less than, equal to, or greater than solid temperature? How will thermal conductivity of epoxy affect junction temperature?

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions.

ANALYSIS: Heat is transferred from the solid material through the epoxy to the thermocouple junction by conduction, $q_{cond,1}$. Heat is also transferred from the junction along the thermocouple wires and their sheathing by conduction ($q_{cond,2}$ and $q_{cond,3}$), and from there to the surroundings by convection (q_{conv}) and radiation (q_{rad}). Thus, the junction is heated by the solid and cooled by the surroundings, and its temperature will be between the solid temperature and the temperature of the cool gases.

The junction temperature will be less than the solid temperature. <

Under steady-state conditions, the rate at which heat is transferred to the junction from the solid material must equal the rate at which heat is transferred from the junction to the cool gases and surroundings. If we think of this heat transfer rate as fixed, then Equation 1.2 shows that a higher thermal conductivity for the epoxy will result in a smaller temperature difference across the epoxy. This leads to the thermocouple sensing a temperature that is closer to the solid temperature.

Higher thermal conductivity of epoxy leads to the thermocouple temperature being closer to the solid temperature. <

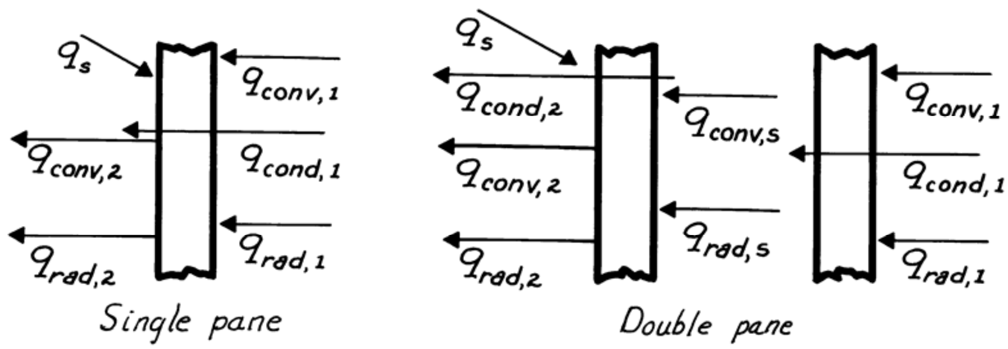
COMMENTS: (1) High thermal conductivity epoxies are formulated specifically for the purpose of affixing thermocouples. Their thermal conductivity is increased by adding small particles of high thermal conductivity materials such as silver. (2) Different types of thermocouple wires are available. To further reduce temperature differences between the solid and the thermocouple junction, small diameter thermocouple wires of relatively low thermal conductivity, such as chromel and alumel, are preferred. (3) Because thermocouple wires are made of different metals, in general $q_{cond,2} \neq q_{cond,3}$.

PROBLEM 1.87(a)

KNOWN: Room air is separated from ambient air by one or two glass panes.

FIND: Relevant heat transfer processes.

SCHEMATIC:



The relevant processes associated with single (above left schematic) and double (above right schematic) glass panes include.

$q_{conv,1}$ Convection from room air to inner surface of first pane,

$q_{rad,1}$ Net radiation exchange between room walls and inner surface of first pane,

$q_{cond,1}$ Conduction through first pane,

$q_{conv,s}$ Convection across airspace between panes,

$q_{rad,s}$ Net radiation exchange between outer surface of first pane and inner surface of second pane (across airspace),

$q_{cond,2}$ Conduction through a second pane,

$q_{conv,2}$ Convection from outer surface of single (or second) pane to ambient air,

$q_{rad,2}$ Net radiation exchange between outer surface of single (or second) pane and surroundings such as the ground, and

q_S Incident solar radiation during day; fraction transmitted to room is smaller for double pane.

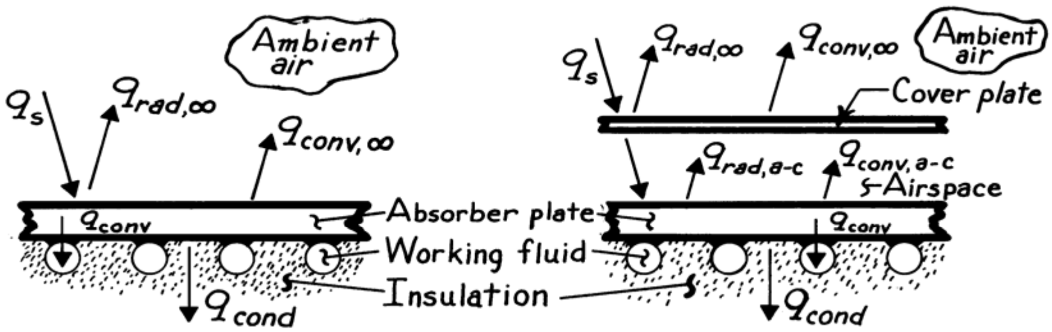
COMMENTS: Heat loss from the room is significantly reduced by the double pane construction.

PROBLEM 1.87(b)

KNOWN: Configuration of a flat plate solar collector.

FIND: Relevant heat transfer processes with and without a cover plate.

SCHEMATIC:



The relevant processes without (above left schematic) and with (above right schematic) include:

q_S	Incident solar radiation, a large portion of which is absorbed by the absorber plate. Reduced with use of cover plate (primarily due to reflection off cover plate).
$q_{rad,\infty}$	Net radiation exchange between absorber plate or cover plate and surroundings,
$q_{conv,\infty}$	Convection from absorber plate or cover plate to ambient air,
$q_{rad,a-c}$	Net radiation exchange between absorber and cover plates,
$q_{conv,a-c}$	Convection heat transfer across airspace between absorber and cover plates,
q_{cond}	Conduction through insulation, and
q_{conv}	Convection to working fluid.

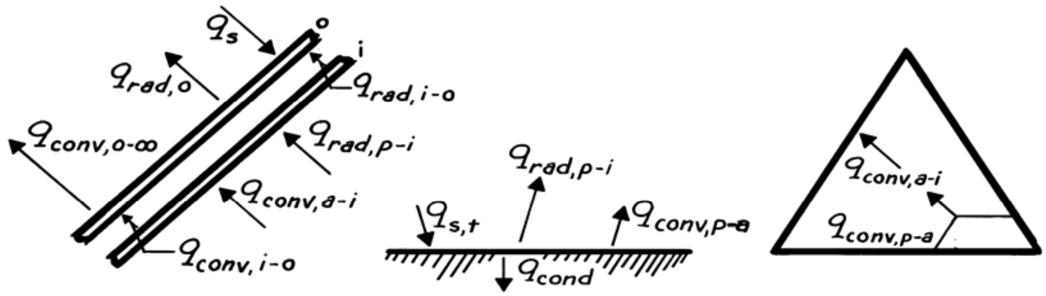
COMMENTS: The cover plate acts to significantly reduce heat losses by convection and radiation from the absorber plate to the surroundings.

PROBLEM 1.87(c)

KNOWN: Configuration of a solar collector used to heat air for agricultural applications.

FIND: Relevant heat transfer processes.

SCHEMATIC:



Assume the temperature of the absorber plates exceeds the ambient air temperature. At the *cover plates*, the relevant processes are:

$q_{conv,a-i}$	Convection from inside air to inner surface,
$q_{rad,p-i}$	Net radiation transfer from absorber plates to inner surface,
$q_{conv,i-o}$	Convection across airspace between covers,
$q_{rad,i-o}$	Net radiation transfer from inner to outer cover,
$q_{conv,o-\infty}$	Convection from outer cover to ambient air,
$q_{rad,o}$	Net radiation transfer from outer cover to surroundings, and
q_S	Incident solar radiation.

Additional processes relevant to the *absorber plates* and *airspace* are:

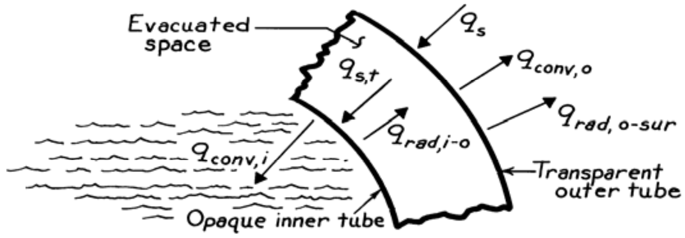
$q_{S,t}$	Solar radiation transmitted by cover plates,
$q_{conv,p-a}$	Convection from absorber plates to inside air, and
q_{cond}	Conduction through insulation.

PROBLEM 1.87(d)

KNOWN: Features of an evacuated tube solar collector.

FIND: Relevant heat transfer processes for one of the tubes.

SCHEMATIC:



The relevant heat transfer processes for one of the evacuated tube solar collectors includes:

q_S	Incident solar radiation including contribution due to reflection off panel (most is transmitted),
$q_{conv,o}$	Convection heat transfer from outer surface to ambient air,
$q_{rad,o-sur}$	Net rate of radiation heat exchange between outer surface of outer tube and the surroundings, including the panel,
$q_{S,t}$	Solar radiation transmitted through outer tube and incident on inner tube (most is absorbed),
$q_{rad,i-o}$	Net rate of radiation heat exchange between outer surface of inner tube and inner surface of outer tube, and
$q_{conv,i}$	Convection heat transfer to working fluid.

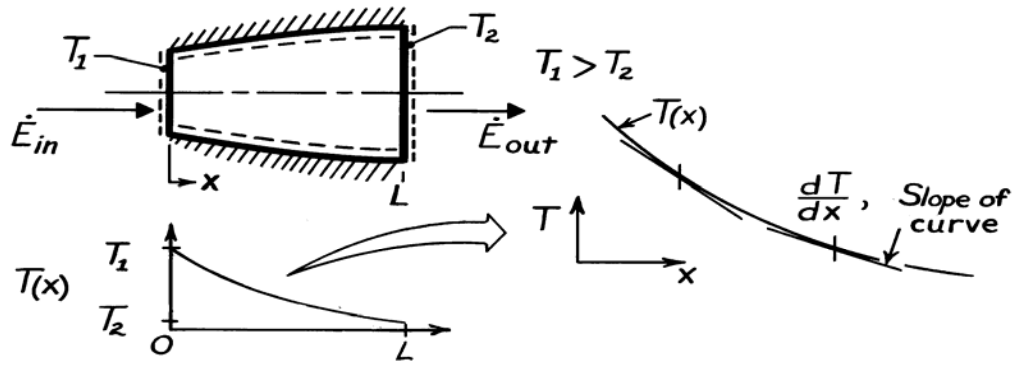
There is also conduction heat transfer through the inner and outer tube walls. If the walls are thin, the temperature drop across the walls will be small.

PROBLEM 2.1

KNOWN: Steady-state, one-dimensional heat conduction through an axisymmetric shape.

FIND: Sketch temperature distribution and explain shape of curve.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, one-dimensional conduction, (2) Constant properties, (3) No internal heat generation.

ANALYSIS: Performing an energy balance on the object according to Eq. 1.12c, $\dot{E}_{in} - \dot{E}_{out} = 0$, it follows that

$$\dot{E}_{in} - \dot{E}_{out} = q_x$$

and that $q_x \neq q_x(x)$. That is, the heat rate within the object is everywhere constant. From Fourier's law,

$$q_x = -kA_x \frac{dT}{dx},$$

and since q_x and k are both constants, it follows that

$$A_x \frac{dT}{dx} = \text{Constant.}$$

That is, the product of the cross-sectional area normal to the heat rate and temperature gradient remains a constant and independent of distance x. It follows that since A_x increases with x, then dT/dx must decrease with increasing x. Hence, the temperature distribution appears as shown above.

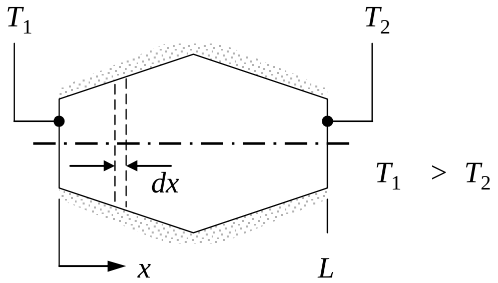
COMMENTS: (1) Be sure to recognize that dT/dx is the slope of the temperature distribution. (2) What would the distribution be when $T_2 > T_1$? (3) How does the heat flux, q''_x, vary with distance?

PROBLEM 2.2

KNOWN: Axisymmetric object with varying cross-sectional area and different temperatures at its two ends, insulated on its sides.

FIND: Shapes of heat flux distribution and temperature distribution.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction, (3) Constant properties, (4) Adiabatic sides, (5) No internal heat generation. (6) Surface temperatures T_1 and T_2 are fixed.

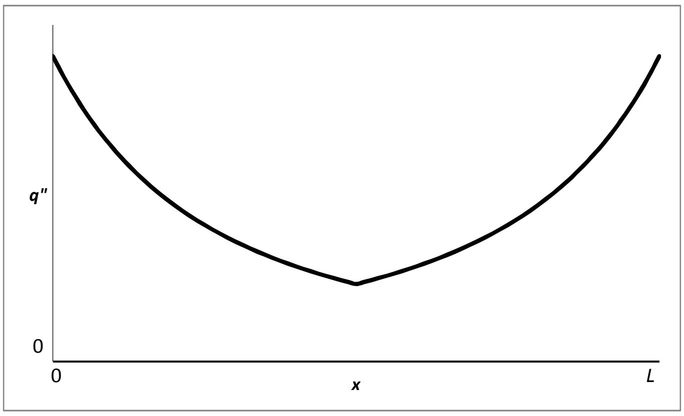
ANALYSIS: For the prescribed conditions, it follows from conservation of energy, Eq. 1.12c, that for a differential control volume, $\dot{E}_{in} = \dot{E}_{out}$ or $q_x = q_{x+dx}$. Hence

$$q_x \text{ is independent of x.}$$

Therefore

$$q_x = q''_x A_c = \text{constant} \tag{1}$$

where A_c is the cross-sectional area perpendicular to the x-direction. Therefore the heat flux must be inversely proportional to the cross-sectional area. The radius of the object first increases and then decreases linearly with x, so the cross-sectional area increases and then decreases as x^2. The resulting heat flux distribution is sketched below.



Continued…

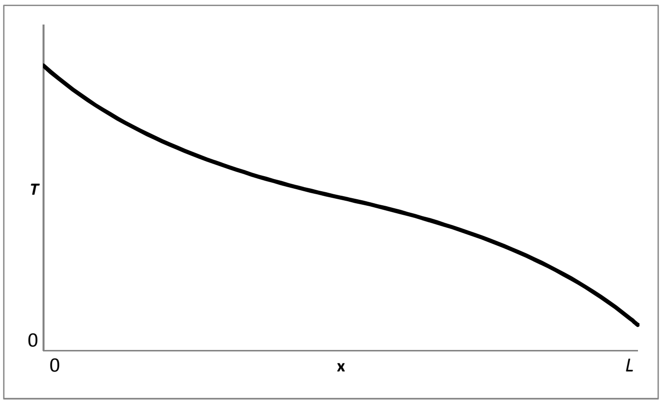
PROBLEM 2.2 (Cont.)

To find the temperature distribution, we can use Fourier's law:

$$q''_x = -k\frac{dT}{dx} \qquad (2)$$

Therefore the temperature gradient is negative and its magnitude is proportional to the heat flux. The temperature decreases most rapidly where the heat flux is largest and more slowly where the heat flux is smaller.

Based on the heat flux plot above we can prepare the sketch of the temperature distribution below.



The temperature distribution is independent of the thermal conductivity. The heat rate and local heat fluxes are both proportional to the thermal conductivity of the material.

<

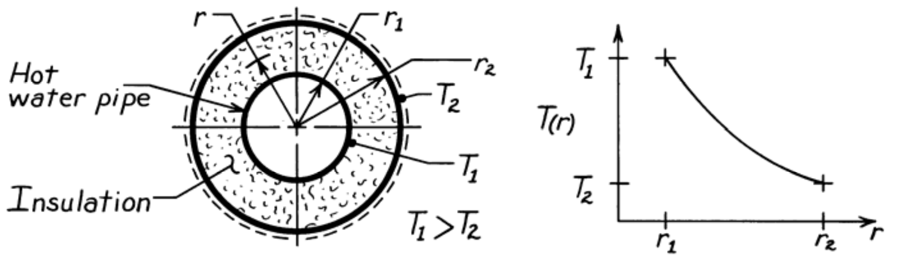
COMMENTS: If the heat rate was fixed the temperature difference, $T_1 - T_2$, would be inversely proportional to the thermal conductivity. The temperature distribution would be of the same shape, but local temperatures T(x) would vary as the thermal conductivity is adjusted.

PROBLEM 2.3

KNOWN: Hot water pipe covered with thick layer of insulation.

FIND: Sketch temperature distribution and give brief explanation to justify shape.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional (radial) conduction, (3) No internal heat generation, (4) Insulation has uniform properties independent of temperature and position.

ANALYSIS: Fourier's law, Eq. 2.1, for this one-dimensional (cylindrical) radial system has the form

$$q_r = -kA_r \frac{dT}{dr} = -k(2\pi r\ell)\frac{dT}{dr}$$

where $A_r = 2\pi r\ell$ and ℓ is the axial length of the pipe-insulation system. Recognize that for steady-state conditions with no internal heat generation, an energy balance on the system requires $\dot{E}_{in} = \dot{E}_{out}$ since $\dot{E}_g = \dot{E}_{st} = 0.$ Hence

$$q_r = \text{Constant.}$$

That is, q_r is independent of radius (r). Since the thermal conductivity is also constant, it follows that

$$r\left[\frac{dT}{dr}\right] = \text{Constant.}$$

This relation requires that the product of the radial temperature gradient, dT/dr, and the radius, r, remains constant throughout the insulation. For our situation, the temperature distribution must appear as shown in the sketch.

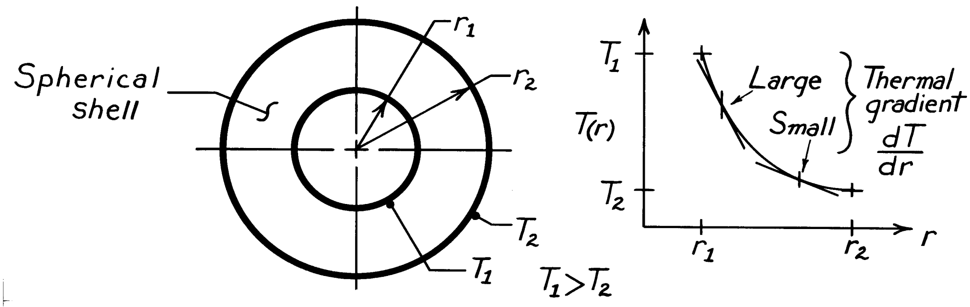
COMMENTS: (1) Note that, while q_r is a constant and independent of r, q''_r is not a constant. How does $q''_r(r)$ vary with r? (2) Recognize that the radial temperature gradient, dT/dr, decreases with increasing radius.

PROBLEM 2.4

KNOWN: A spherical shell with prescribed geometry and surface temperatures.

FIND: Sketch temperature distribution and explain shape of the curve.

SCHEMATIC:



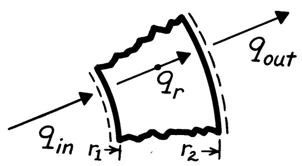
ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in radial (spherical coordinates) direction, (3) No internal generation, (4) Constant properties.

ANALYSIS: Fourier's law, Eq. 2.1, for this one-dimensional, radial (spherical coordinate) system has the form

$$q_r = -k\,A_r \frac{dT}{dr} = -k\left(4\pi r^2\right)\frac{dT}{dr}$$

where A_r is the surface area of a sphere. For steady-state conditions, an energy balance on the system yields $\dot{E}_{in} = \dot{E}_{out}$, since $\dot{E}_g = \dot{E}_{st} = 0$. Hence,

$$q_{in} = q_{out} = q_r \neq q_r(r).$$



That is, q_r is a constant, independent of the radial coordinate. Since the thermal conductivity is constant, it follows that

$$r^2\left[\frac{dT}{dr}\right] = \text{Constant.}$$

This relation requires that the product of the radial temperature gradient, dT/dr, and the radius squared, r^2, remains constant throughout the shell. Hence, the temperature distribution appears as shown in the sketch.

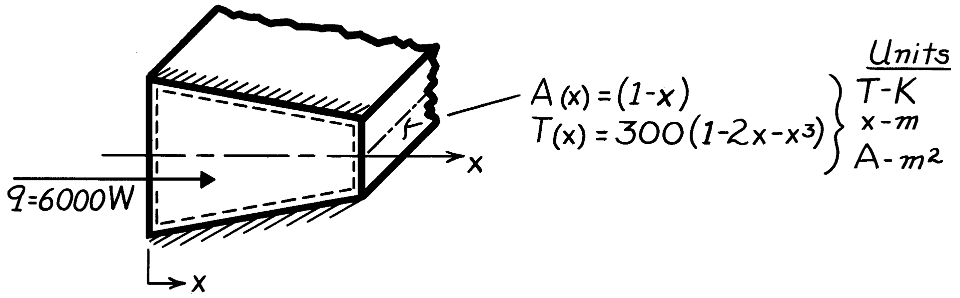
COMMENTS: Note that, for the above conditions, $q_r \neq q_r(r)$; that is, q_r is everywhere constant. How does q_r'' vary as a function of radius?

PROBLEM 2.5

KNOWN: Symmetric shape with prescribed variation in cross-sectional area, temperature distribution and heat rate.

FIND: Expression for the thermal conductivity, k.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in x-direction, (3) No internal heat generation.

ANALYSIS: Applying the energy balance, Eq. 1.12c, to the system, it follows that, since $\dot{E}_{in} = \dot{E}_{out}$,

$$q_x = \text{Constant} \neq f(x).$$

Using Fourier's law, Eq. 2.1, with appropriate expressions for A_x and T, yields

$$q_x = -k\, A_x \frac{dT}{dx}$$

$$6000\text{W} = -k \cdot (1\text{-x})\text{m}^2 \cdot \frac{d}{dx}\left[300\left(1 - 2x\text{-}x^3\right)\right]\frac{\text{K}}{\text{m}}.$$

Solving for k and recognizing its units are W/m·K,

$$k = \frac{-6000}{(1\text{-x})\left[300\left(-2-3x^2\right)\right]} = \frac{20}{(1-x)\left(2+3x^2\right)}.$$ <

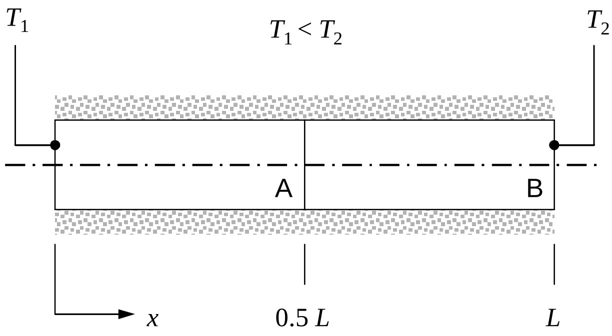
COMMENTS: (1) At x = 0, k = 10W/m·K and k → ∞ as x → 1. (2) Recognize that the 1-D assumption is an approximation which becomes more inappropriate as the area change with x, and hence two-dimensional effects, become more pronounced.

PROBLEM 2.6

KNOWN: Rod consisting of two materials with same lengths. Ratio of thermal conductivities.

FIND: Sketch temperature and heat flux distributions.

SCHEMATIC:

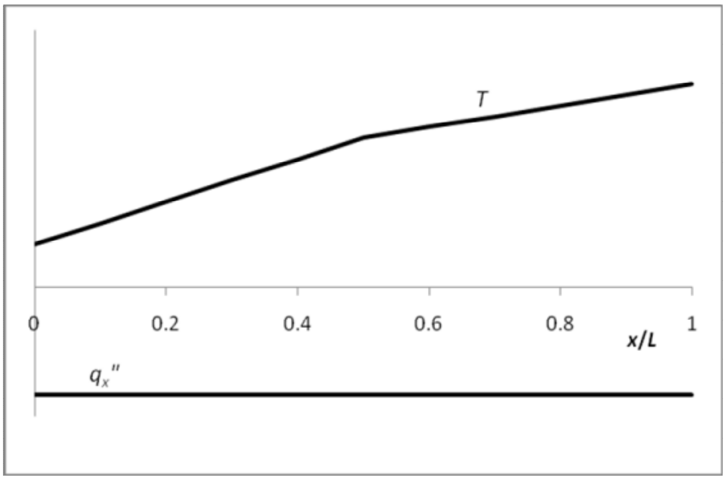


ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (3) No internal generation.

ANALYSIS: From Equation 2.19 for steady-state, one-dimensional conduction with constant properties and no internal heat generation,

$$\frac{\partial}{\partial x}\left(k\frac{\partial T}{\partial x}\right)=0 \quad \text{or} \quad \frac{\partial q_x''}{\partial x}=0$$

From these equations we know that heat flux is constant and the temperature gradient is inversely proportional to k. Thus, with $k_A = 0.5k_B$, we can sketch the temperature and heat flux distributions as shown below:



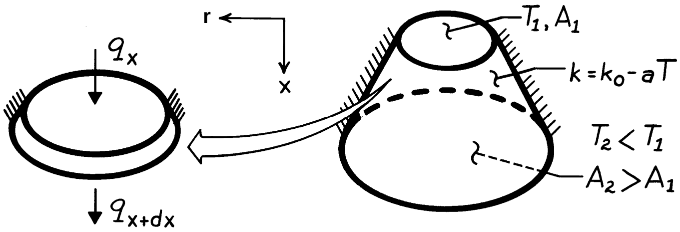
COMMENTS: (1) Note the discontinuity in the slope of the temperature distribution at $x/L = 0.5$. The constant heat flux is in the negative x-direction. (2) A discontinuity in the temperature distribution may occur at x/L = 0.5 due the joining of dissimilar materials. We shall address *thermal contact resistances* in Chapter 3.

PROBLEM 2.7

KNOWN: End-face temperatures and temperature dependence of k for a truncated cone.

FIND: Variation with axial distance along the cone of q_x, q_x'', k, and dT / dx.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in x (negligible temperature gradients in the r direction), (2) Steady-state conditions, (3) Adiabatic sides, (4) No internal heat generation.

ANALYSIS: For the prescribed conditions, it follows from conservation of energy, Eq. 1.12c, that for a differential control volume, $\dot{E}_{in} = \dot{E}_{out}$ or $q_x = q_{x+dx}$. Hence

q_x is independent of x.

Since A(x) *increases* with *increasing* x, it follows that $q_x'' = q_x / A(x)$ *decreases* with *increasing* x. Since T *decreases* with *increasing* x, k *increases* with *increasing* x. Hence, from Fourier's law,

$$q_x'' = -k \frac{dT}{dx},$$

it follows that | dT/dx | *decreases* with increasing x.

COMMENT: How is the analysis changed if the coefficient a has a negative value?

PROBLEM 2.8

KNOWN: Temperature dependence of the thermal conductivity, k(T), for heat transfer through a plane wall.

FIND: Effect of k(T) on temperature distribution, T(x).

ASSUMPTIONS: (1) One-dimensional conduction, (2) Steady-state conditions, (3) No internal heat generation.

ANALYSIS: From Fourier's law and the form of k(T),

$$q''_x = -k\,\frac{dT}{dx} = -\left(k_o + aT\right)\frac{dT}{dx}. \qquad (1)$$

The shape of the temperature distribution may be inferred from knowledge of $d^2T/dx^2 = d(dT/dx)/dx$. Since q''_x is independent of x for the prescribed conditions,

$$\frac{dq''_x}{dx} = -\frac{d}{dx}\left[\left(k_o + aT\right)\frac{dT}{dx}\right] = 0$$

$$-\left(k_o + aT\right)\frac{d^2T}{dx^2} - a\left[\frac{dT}{dx}\right]^2 = 0.$$

Hence,

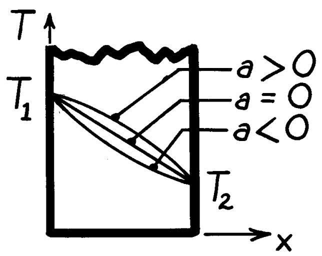
$$\frac{d^2T}{dx^2} = \frac{-a}{k_o + aT}\left[\frac{dT}{dx}\right]^2 \qquad \text{where} \begin{cases} k_o + aT = k > 0 \\ \left[\dfrac{dT}{dx}\right]^2 > 0 \end{cases}$$

from which it follows that for

$a > 0$: $d^2T/dx^2 < 0$

$a = 0$: $d^2T/dx^2 = 0$

$a < 0$: $d^2T/dx^2 > 0$.



COMMENTS: The shape of the distribution could also be inferred from Eq. (1). Since T decreases with increasing x,

$a > 0$: k decreases with increasing x => | dT/dx | increases with increasing x

$a = 0$: $k = k_o$ => dT/dx is constant

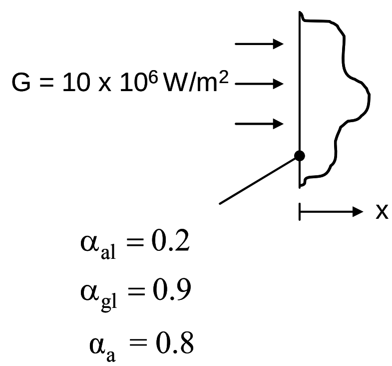
$a < 0$: k increases with increasing x => | dT/dx | decreases with increasing x.

PROBLEM 2.9

KNOWN: Irradiation and absorptivity of aluminum, glass and aerogel.

FIND: Ability of the protective barrier to withstand the irradiation in terms of the temperature gradients that develop in response to the irradiation.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in the x-direction, (2) Constant properties, (c) Negligible emission and convection from the exposed surface.

PROPERTIES: Table A.1, pure aluminum (300 K): k_{al} = 238 W/m·K. Table A.3, glass (300 K): k_{gl} = 1.4 W/m·K.

ANALYSIS: From Eqs. 1.6 and 2.32

$$-k\left.\frac{\partial T}{\partial x}\right|_{x=0} = q_s'' = G_{abs} = \alpha G$$

or

$$\left.\frac{\partial T}{\partial x}\right|_{x=0} = -\frac{\alpha G}{k}$$

The temperature gradients at x = 0 for the three materials are: <

Material	$\partial T / \partial x\|_{x=0}$ (K/m)
aluminum	8.4×10^3
glass	6.4×10^6
aerogel	1.6×10^9

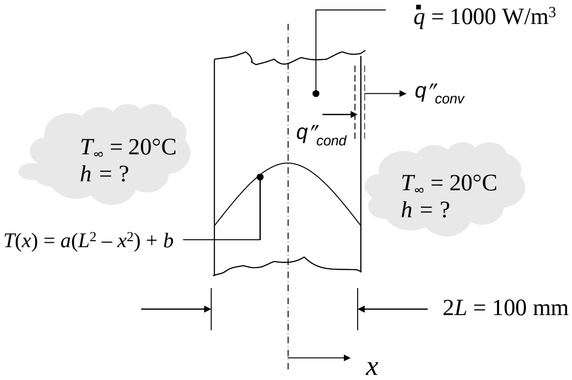
COMMENT: It is unlikely that the aerogel barrier can sustain the thermal stresses associated with the large temperature gradient. Low thermal conductivity solids are prone to large temperature gradients, and are often brittle.

PROBLEM 2.10

KNOWN: Wall thickness. Thermal energy generation rate. Temperature distribution. Ambient fluid temperature.

FIND: Thermal conductivity. Convection heat transfer coefficient.

SCHEMATIC:



ASSUMPTIONS: (1) Steady state, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible radiation.

ANALYSIS: Under the specified conditions, the heat equation, Equation 2.21, reduces to

$$\frac{d^2T}{dx^2} + \frac{\dot{q}}{k} = 0$$

With the given temperature distribution, $d^2T/dx^2 = -2a$. Therefore, solving for k gives

$$k = \frac{\dot{q}}{2a} = \frac{1000 \text{ W/m}^3}{2 \times 10°\text{C/m}^2} = 50 \text{ W/m} \cdot \text{K} \qquad <$$

The convection heat transfer coefficient can be found by applying the boundary condition at $x = L$ (or at $x = -L$),

$$-k\left.\frac{dT}{dx}\right|_{x=L} = h\left[T(L) - T_\infty\right]$$

Therefore

$$h = \frac{-k\left.\dfrac{dT}{dx}\right|_{x=L}}{\left[T(L) - T_\infty\right]} = \frac{2kaL}{b - T_\infty} = \frac{2 \times 50 \text{ W/m} \cdot \text{K} \times 10°\text{C/m}^2 \times 0.05 \text{ m}}{30°\text{C} - 20°\text{C}} = 5 \text{ W/m}^2 \cdot \text{K} \qquad <$$

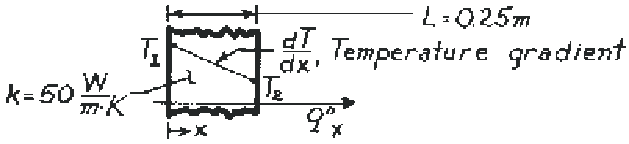
COMMENTS: (1) In Chapter 3, you will learn how to determine the temperature distribution. (2) The heat transfer coefficient could also have been found from an energy balance on the wall. With $\dot{E}_{\text{in}} - \dot{E}_{\text{out}} + \dot{E}_g = 0$, we find $-2hA[T(L) - T_\infty] + 2\dot{q}LA = 0$. This yields the same result for h.

PROBLEM 2.11

KNOWN: One-dimensional system with prescribed thermal conductivity and thickness.

FIND: Unknowns for various temperature conditions and sketch distribution.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) No internal heat generation, (4) Constant properties.

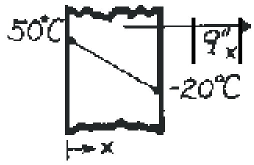
ANALYSIS: The rate equation and temperature gradient for this system are

$$q''_x = -k\frac{dT}{dx} \qquad \text{and} \qquad \frac{dT}{dx} = \frac{T_2 - T_1}{L}. \qquad (1,2)$$

Using Eqs. (1) and (2), the unknown quantities for each case can be determined.

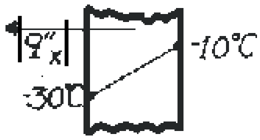
(a) $$\frac{dT}{dx} = \frac{(-20-50)\,K}{0.25\,m} = -280\ K/m$$

$$q''_x = -50\frac{W}{m\cdot K}\times\left[-280\frac{K}{m}\right] = 14.0\ kW/m^2.$$ <



(b) $$\frac{dT}{dx} = \frac{(-10-(-30))\,K}{0.25\,m} = 80\ K/m$$

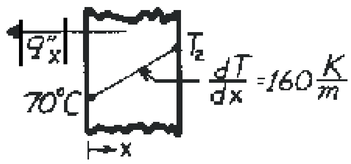
$$q''_x = -50\frac{W}{m\cdot K}\times\left[80\frac{K}{m}\right] = -4.0\ kW/m^2.$$ <



(c) $$q''_x = -50\frac{W}{m\cdot K}\times\left[160\frac{K}{m}\right] = -8.0\ kW/m^2$$

$$T_2 = L\cdot\frac{dT}{dx} + T_1 = 0.25\,m\times\left[160\frac{K}{m}\right] + 70^\circ C.$$

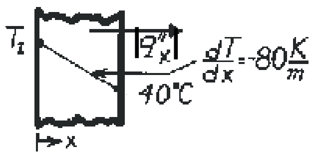
$$T_2 = 110^\circ C.$$ <



(d) $$q''_x = -50\frac{W}{m\cdot K}\times\left[-80\frac{K}{m}\right] = 4.0\ kW/m^2$$

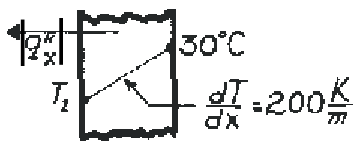
$$T_1 = T_2 - L\cdot\frac{dT}{dx} = 40^\circ C - 0.25\,m\left[-80\frac{K}{m}\right]$$

$$T_1 = 60^\circ C.$$ <



(e) $$q''_x = -50\frac{W}{m\cdot K}\times\left[200\frac{K}{m}\right] = -10.0\ kW/m^2$$

$$T_1 = T_2 - L\cdot\frac{dT}{dx} = 30^\circ C - 0.25\,m\left[200\frac{K}{m}\right] = -20^\circ C.$$ <

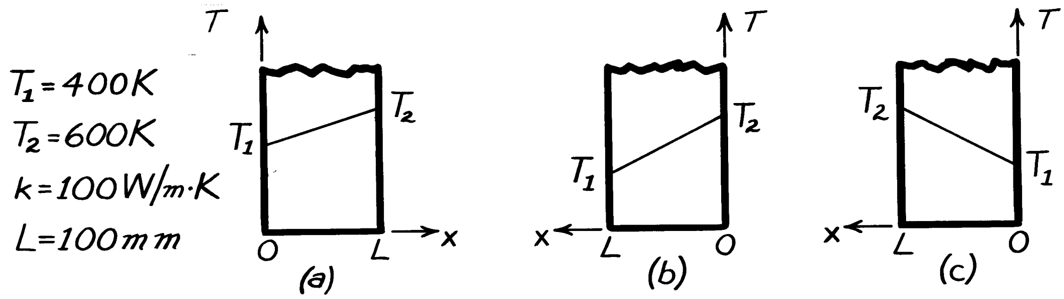


PROBLEM 2.12

KNOWN: Plane wall with prescribed thermal conductivity, thickness, and surface temperatures.

FIND: Heat flux, q''_x, and temperature gradient, dT/dx, for the three different coordinate systems shown.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional heat flow, (2) Steady-state conditions, (3) No internal generation, (4) Constant properties.

ANALYSIS: The rate equation for conduction heat transfer is

$$q''_x = -k\frac{dT}{dx}, \quad (1)$$

where the temperature gradient is constant throughout the wall and of the form

$$\frac{dT}{dx} = \frac{T(L) - T(0)}{L}. \quad (2)$$

Substituting numerical values, find the temperature gradients,

(a) $$\frac{dT}{dx} = \frac{T_2 - T_1}{L} = \frac{(600 - 400)K}{0.100m} = 2000 \text{ K/m}$$ <

(b) $$\frac{dT}{dx} = \frac{T_1 - T_2}{L} = \frac{(400 - 600)K}{0.100m} = -2000 \text{ K/m}$$ <

(c) $$\frac{dT}{dx} = \frac{T_2 - T_1}{L} = \frac{(600 - 400)K}{0.100m} = 2000 \text{ K/m.}$$ <

The heat rates, using Eq. (1) with k = 100 W/m·K, are

(a) $$q''_x = -100\frac{W}{m \cdot K} \times 2000 \text{ K/m=-200 kW/m}^2$$ <

(b) $$q''_x = -100\frac{W}{m \cdot K}(-2000 \text{ K/m)=+200 kW/m}^2$$ <

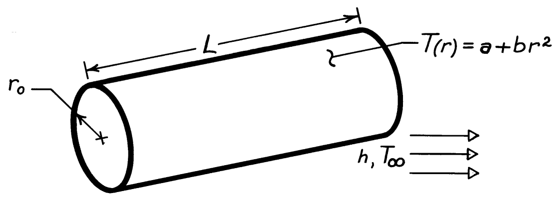
(c) $$q''_x = -100\frac{W}{m \cdot K} \times 2000 \text{ K / m = -200 kW / m}^2$$ <

PROBLEM 2.13

KNOWN: Temperature distribution in solid cylinder and convection coefficient at cylinder surface.

FIND: Expressions for heat rate at cylinder surface and fluid temperature.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, radial conduction, (2) Steady-state conditions, (3) Constant properties.

ANALYSIS: The heat rate from Fourier's law for the radial (cylindrical) system has the form

$$q_r = -kA_r \frac{dT}{dr}.$$

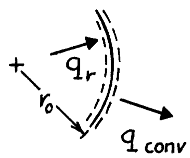
Substituting for the temperature distribution, $T(r) = a + br^2$,

$$q_r = -k(2\pi rL)\ 2br = -4\pi kbLr^2.$$

At the outer surface ($r = r_o$), the conduction heat rate is

$$q_{r=r_o} = -4\pi kbLr_o^2. \qquad <$$

From a surface energy balance at $r = r_o$,



$$q_{r=r_o} = q_{conv} = h(2\pi r_o L)\ \left[T(r_o) - T_\infty\right],$$

Substituting for $q_{r=r_o}$ and solving for T_∞,

$$T_\infty = T(r_o) + \frac{2kbr_o}{h}$$

$$T_\infty = a + br_o^2 + \frac{2kbr_o}{h}$$

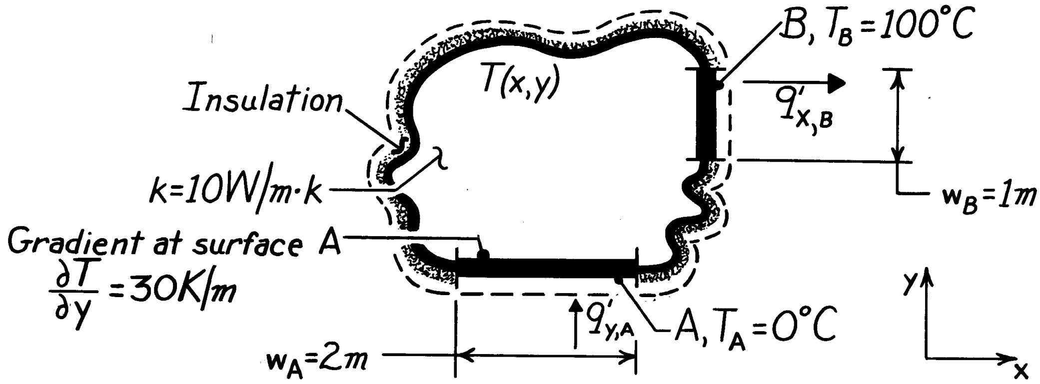
$$T_\infty = a + br_o\left[r_o + \frac{2k}{h}\right]. \qquad <$$

PROBLEM 2.14

KNOWN: Two-dimensional body with specified thermal conductivity and two isothermal surfaces of prescribed temperatures; one surface, A, has a prescribed temperature gradient.

FIND: Temperature gradients, $\partial T/\partial x$ and $\partial T/\partial y$, at the surface B.

SCHEMATIC:



ASSUMPTIONS: (1) Two-dimensional conduction, (2) Steady-state conditions, (3) No heat generation, (4) Constant properties.

ANALYSIS: At the surface A, the temperature gradient in the x-direction must be zero. That is, $(\partial T/\partial x)_A = 0$. This follows from the requirement that the heat flux vector must be normal to an isothermal surface. The heat rate at the surface A is given by Fourier's law written as

$$q'_{y,A} = -k \cdot w_A \left.\frac{\partial T}{\partial y}\right]_A = -10\frac{W}{m \cdot K} \times 2m \times 30\frac{K}{m} = -600 W/m.$$

On the surface B, it follows that

$$(\partial T/\partial y)_B = 0$$ <

in order to satisfy the requirement that the heat flux vector be normal to the isothermal surface B. Using the conservation of energy requirement, Eq. 1.12c, on the body, find

$$q'_{y,A} - q'_{x,B} = 0 \qquad \text{or} \qquad q'_{x,B} = q'_{y,A}.$$

Note that,

$$q'_{x,B} = -k \cdot w_B \left.\frac{\partial T}{\partial x}\right]_B$$

and hence

$$(\partial T/\partial x)_B = \frac{-q'_{y,A}}{k \cdot w_B} = \frac{-(-600 \text{ W/m})}{10 \text{ W/m} \cdot \text{K} \times 1\text{m}} = 60 \text{ K/m}.$$ <

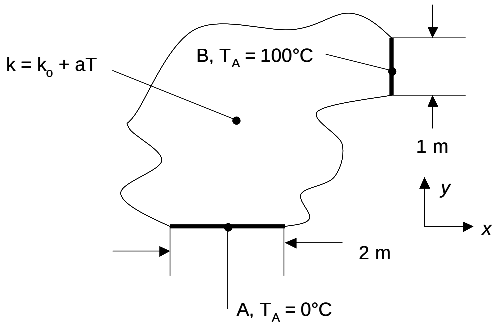
COMMENTS: Note that, in using the conservation requirement, $q'_{in} = +q'_{y,A}$ and $q'_{out} = +q'_{x,B}$.

PROBLEM 2.15

KNOWN: Temperature, size and orientation of Surfaces A and B in a two-dimensional geometry. Thermal conductivity dependence on temperature.

FIND: Temperature gradient $\partial T/\partial y$ at surface A.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) No volumetric generation, (3) Two-dimensional conduction.

ANALYSIS: At Surface A, $k_A = k_o + aT_A$ = 10 W/m·K – 10^{-3} W/m·K^2 × 273 K = 9.73 W/m·K while at Surface B, $k_B = k_o + aT_B$ = 10 W/m·K – 10^{-3} W/m·K^2 × 373 K = 9.63 W/m·K. For steady-state conditions, $\dot{E}_{in} = \dot{E}_{out}$ which may be written in terms of Fourier's law as

$$-k_B \left.\frac{\partial T}{\partial x}\right|_B A_B = -k_A \left.\frac{\partial T}{\partial y}\right|_A A_A$$

or

$$\left.\frac{\partial T}{\partial y}\right|_A = \left.\frac{\partial T}{\partial x}\right|_B \frac{k_B A_B}{k_A A_A} = 30\text{K/m} \times \frac{9.63}{9.73} \times \frac{1}{2} = 14.85 \text{ K/m}$$ <

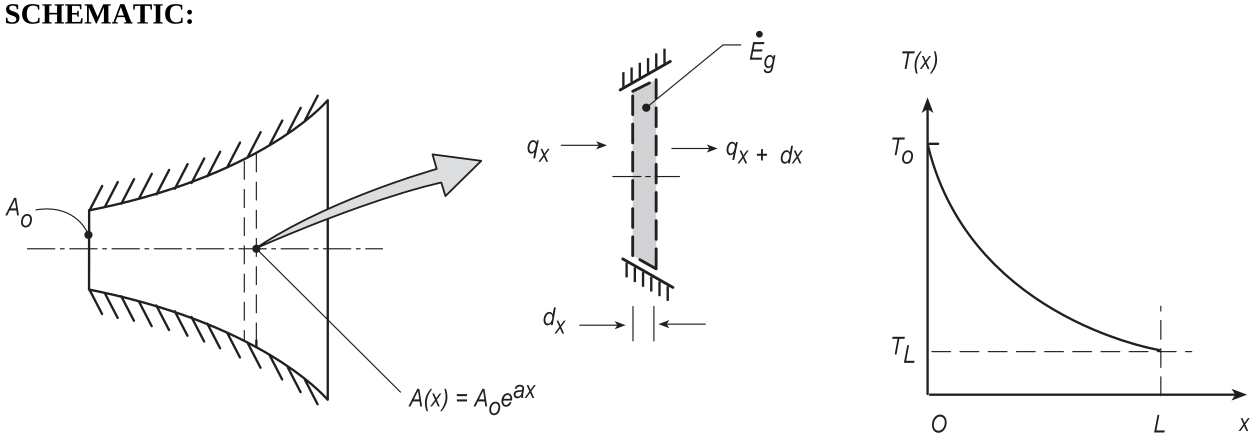
COMMENTS: (1) If the thermal conductivity is not temperature-dependent, then the temperature gradient at A is 15 K/m. (2) Surfaces A and B are both isothermal. Hence, $\partial T/\partial x|_A = \partial T/\partial y|_B = 0$.

PROBLEM 2.16

KNOWN: A rod of constant thermal conductivity k and variable cross-sectional area $A_x(x) = A_o e^{ax}$ where A_o and a are constants.

FIND: (a) Expression for the conduction heat rate, $q_x(x)$; use this expression to determine the temperature distribution, T(x); and sketch of the temperature distribution, (b) Considering the presence of volumetric heat generation rate, $\dot{q} = \dot{q}_o \exp(-ax)$, obtain an expression for $q_x(x)$ when the left face, x = 0, is well insulated.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in the rod, (2) Constant properties, (3) Steady-state conditions.

ANALYSIS: Perform an energy balance on the control volume, A(x)·dx,

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = 0$$

$$q_x - q_{x+dx} + \dot{q} \cdot A(x) \cdot dx = 0$$

The conduction heat rate terms can be expressed as a Taylor series and substituting expressions for $\dot{q}$ and A(x),

$$-\frac{d}{dx}(q_x) + \dot{q}_o \exp(-ax) \cdot A_o \exp(ax) = 0 \quad (1)$$

$$q_x = -k \cdot A(x) \frac{dT}{dx} \quad (2)$$

(a) With no internal generation, $\dot{q}_o = 0$, and from Eq. (1) find

$$-\frac{d}{dx}(q_x) = 0$$ <

indicating that the heat rate is constant with x. By combining Eqs. (1) and (2)

$$-\frac{d}{dx}\left(-k \cdot A(x) \frac{dT}{dx}\right) = 0 \quad \text{or} \quad A(x) \cdot \frac{dT}{dx} = C_1 \quad (3)$$ <

Continued...

PROBLEM 2.16 (Cont.)

That is, the product of the cross-sectional area and the temperature gradient is a constant, independent of x. Hence, with T(0) > T(L), the temperature distribution is exponential, and as shown in the sketch above. Separating variables and integrating Eq. (3), the general form for the temperature distribution can be determined,

$$A_o \exp(ax) \cdot \frac{dT}{dx} = C_1$$

$$dT = C_1 A_o^{-1} \exp(-ax)\, dx$$

$$T(x) = -C_1 A_o a \exp(-ax) + C_2 \quad <$$

We could use the two temperature boundary conditions, $T_o = T(0)$ and $T_L = T(L)$, to evaluate C_1 and C_2 and, hence, obtain the temperature distribution in terms of T_o and T_L.

(b) With the internal generation, from Eq. (1),

$$-\frac{d}{dx}(q_x) + \dot{q}_o A_o = 0 \qquad \text{or} \qquad q_x = \dot{q}_o A_o x \quad <$$

That is, the heat rate increases linearly with x.

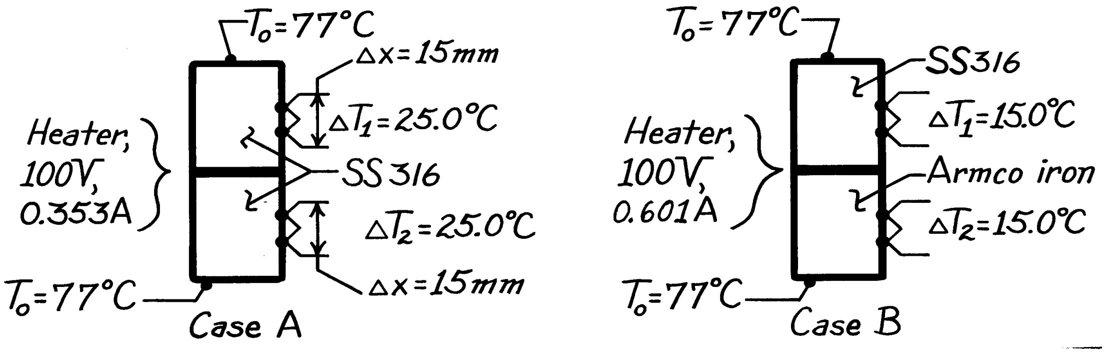
COMMENTS: In part (b), you could determine the temperature distribution using Fourier's law and knowledge of the heat rate dependence upon the x-coordinate. Give it a try!

PROBLEM 2.17

KNOWN: Electrical heater sandwiched between two identical cylindrical (30 mm dia. × 60 mm length) samples whose opposite ends contact plates maintained at T_o.

FIND: (a) Thermal conductivity of SS316 samples for the prescribed conditions (A) and their average temperature, (b) Thermal conductivity of Armco iron sample for the prescribed conditions (B), (c) Comment on advantages of experimental arrangement, lateral heat losses, and conditions for which $\Delta T_1 \neq \Delta T_2$.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional heat transfer in samples, (2) Steady-state conditions, (3) Negligible contact resistance between materials.

PROPERTIES: *Table A.2,* Stainless steel 316 $\left(\bar{T}=400\text{ K}\right)$: $k_{ss} = 15.2\text{ W/m}\cdot\text{K}$; Armco iron $\left(\bar{T}=380\text{ K}\right)$: $k_{iron} = 67.2\text{ W/m}\cdot\text{K}$.

ANALYSIS: (a) For Case A recognize that half the heater power will pass through each of the samples which are presumed identical. Apply Fourier's law to a sample

$$q = kA_c\frac{\Delta T}{\Delta x}$$

$$k = \frac{q\Delta x}{A_c\Delta T} = \frac{0.5(100\text{V}\times 0.353\text{A})\times 0.015\text{ m}}{\pi(0.030\text{ m})^2/4\times 25.0^\circ\text{C}} = 15.0\text{ W/m}\cdot\text{K}. \quad <$$

The total temperature drop across the length of the sample is $\Delta T_1(L/\Delta x)$ = 25°C (60 mm/15 mm) = 100°C. Hence, the heater temperature is T_h = 177°C. Thus the average temperature of the sample is

$$\bar{T} = (T_o + T_h)/2 = 127^\circ\text{C} = 400\text{ K}. \quad <$$

We compare the calculated value of k with the tabulated value (see above) at 400 K and note the good agreement.

(b) For Case B, we assume that the thermal conductivity of the SS316 sample is the same as that found in Part (a). The heat rate through the Armco iron sample is

Continued …..

PROBLEM 2.17 (Cont.)

$$q_{iron} = q_{heater} - q_{ss} = 100\text{V} \times 0.601\text{A} - 15.0\ \text{W/m}\cdot\text{K} \times \frac{\pi\left(0.030\ \text{m}\right)^2}{4} \times \frac{15.0^\circ\text{C}}{0.015\ \text{m}}$$
$$q_{iron} = \left(60.1 - 10.6\right)\text{W} = 49.5\ \text{W}$$

where

$$q_{ss} = k_{ss} A_c \Delta T_2 / \Delta x_2.$$

Applying Fourier's law to the iron sample,

$$k_{iron} = \frac{q_{iron}\Delta x_2}{A_c \Delta T_2} = \frac{49.5\ \text{W} \times 0.015\ \text{m}}{\pi\left(0.030\ \text{m}\right)^2 / 4 \times 15.0^\circ\text{C}} = 70.0\ \text{W/m}\cdot\text{K}.$$ <

The total drop across the iron sample is 15°C(60/15) = 60°C; the heater temperature is (77 + 60)°C = 137°C. Hence the average temperature of the iron sample is

$$\bar{T} = \left(137 + 77\right)^\circ \text{C}/2 = 107^\circ\text{C} = 380\ \text{K}.$$ <

We compare the computed value of k with the tabulated value (see above) at 380 K and note the good agreement.

(c) The principal advantage of having two identical samples is the assurance that all the electrical power dissipated in the heater will appear as equivalent heat flows through the samples. With only one sample, heat can flow from the backside of the heater even though insulated.

Heat leakage out the lateral surfaces of the cylindrically shaped samples will become significant when the sample thermal conductivity is comparable to that of the insulating material. Hence, the method is suitable for metallics, but must be used with caution on nonmetallic materials.

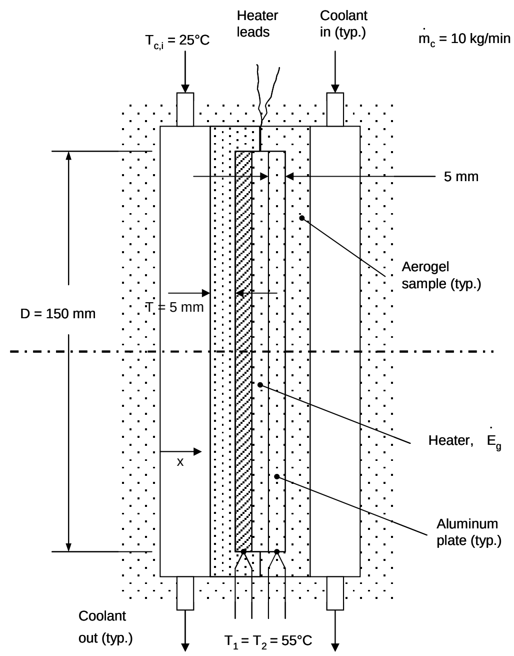
For any combination of materials in the upper and lower position, we expect $\Delta T_1 = \Delta T_2$. However, if the insulation were improperly applied along the lateral surfaces, it is possible that heat leakage will occur, causing $\Delta T_1 \neq \Delta T_2$.

PROBLEM 2.18

KNOWN: Geometry and steady-state conditions used to measure the thermal conductivity of an aerogel sheet.

FIND: (a) Reason the apparatus of Problem 2.17 cannot be used, (b) Thermal conductivity of the aerogel, (c) Temperature difference across the aluminum sheets, and (d) Outlet temperature of the coolant.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional heat transfer.

PROPERTIES: Table A.1, pure aluminum [$T = (T_1 + T_{c,i})/2$ = 40°C = 313 K]: k_{al} = 239 W/m·K. Table A.6, liquid water (25°C = 298 K): c_p = 4180 J/kg·K.

ANALYSIS:

(a) The apparatus of Problem 2.17 cannot be used because it operates under the assumption that the heat transfer is one-dimensional in the axial direction. Since the aerogel is expected to have an extremely small thermal conductivity, the insulation used in Problem 2.17 will likely have a higher thermal conductivity than aerogel. Radial heat losses would be significant, invalidating any measured results.

(b) The electrical power is

$$\dot{E}_g = V(I) = 10\text{V} \times 0.125\text{ A} = 1.25\text{ W}$$

Continued…

PROBLEM 2.18 (Cont.)

The conduction heat rate through each aerogel plate is

$$q = \frac{\dot{E}_g}{2} = -k_a A \frac{dT}{dx} = -k_a\left(\frac{\pi D^2}{4}\right)\left(\frac{T_c - T_l}{t}\right)$$

or

$$k_a = \frac{2\dot{E}_g t}{\pi D^2 (T_l - T_c)} = \frac{2 \times 1.25 \text{ W} \times 0.005 \text{ m}}{\pi \times (0.15 \text{ m})^2 \times (55 - 25)°\text{C}} = 5.9\times10^{-3} \frac{\text{W}}{\text{m}\cdot\text{K}}$$ <

(c) The conduction heat flux through each aluminum plate is the same as through the aerogel. Hence,

$$-k_a \frac{(T_c - T_l)}{t} = -k_{al} \frac{\Delta T_{al}}{t}$$

or

$$\Delta T_{al} = \frac{k_a}{k_{al}}(T_l - T_c) = \frac{5.9\times10^{-3} \text{ W/m}\cdot\text{K}}{239 \text{ W/m}\cdot\text{K}} \times 30°\text{C} = 0.74\times10^{-3} °\text{C}$$ <

The temperature difference across the aluminum plate is negligible. Therefore it is not important to know the location where the thermocouples are attached.

(d) An energy balance on the water yields

$$\dot{E}_g = \dot{m}c_p(T_{c,o} - T_{c,i})$$

or

$$T_{c,o} = T_{c,i} + \frac{\dot{E}_g}{\dot{m}c_p}$$

$$= 25°\text{C} + \frac{1.25 \text{ W}}{1 \text{ kg/min} \times \frac{1}{60} \text{ min/s} \times 4180 \text{ J/kg}\cdot\text{K}} = 25.02°\text{C}$$ <

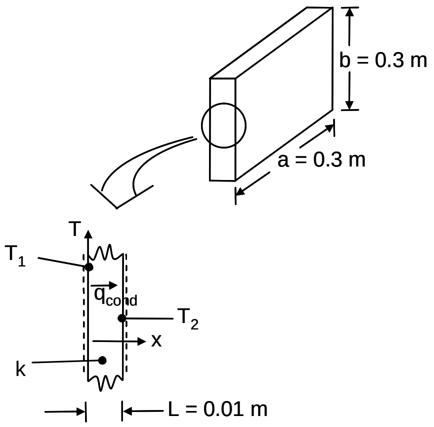
COMMENTS: (1) For all practical purposes the aluminum plates may be considered to be isothermal. (2) The coolant may be considered to be isothermal.

PROBLEM 2.19

KNOWN: Dimensions of and temperature difference across an aircraft window. Window materials and cost of energy.

FIND: Heat loss through one window and cost of heating for 130 windows on 8-hour trip.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in the x-direction, (3) Constant properties.

PROPERTIES: Table A.3, soda lime glass (300 K): k_{gl} = 1.4 W/m·K.

ANALYSIS: From Eq. 2.1,

$$q_x = -kA\frac{dT}{dx} = k\,a\,b\frac{(T_1 - T_2)}{L}$$

For glass,

$$q_{x,g} = 1.4\frac{W}{m \cdot K} \times 0.3\text{ m} \times 0.3\text{ m} \times \left[\frac{80°C}{0.01m}\right] = 1010\text{ W} \quad <$$

The cost associated with heat loss through N windows at a rate of R = \$1/kW·h over a t = 8 h flight time is

$$C_g = Nq_{x,g}Rt = 130 \times 1010\text{ W} \times 1\frac{\$}{kW \cdot h} \times 8\text{ h} \times \frac{1kW}{1000W} = \$1050 \quad <$$

Repeating the calculation for the polycarbonate yields

$$q_{x,p} = 151\text{ W},\ C_p = \$157 \quad <$$

while for aerogel,

$$q_{x,a} = 10.1\text{ W},\ C_a = \$10 \quad <$$

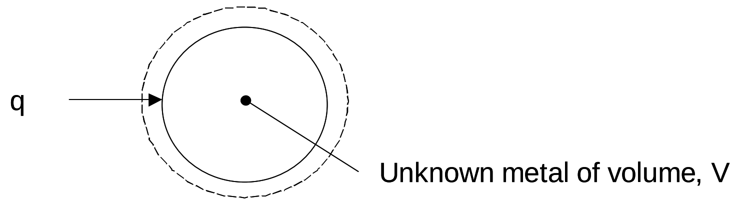
COMMENT: Polycarbonate provides significant savings relative to glass. It is also lighter (ρ_p = 1200 kg/m^3) relative to glass (ρ_g = 2500 kg/m^3). The aerogel offers the best thermal performance and is very light (ρ_a = 2 kg/m^3) but would be relatively expensive.

PROBLEM 2.20

KNOWN: Volume of unknown metal of high thermal conductivity. Known heating rate.

FIND: (a) Differential equation that may be used to determine the temperature response of the metal to heating. (b) If the model can be used to identify the metal, based upon matching the predicted and measured thermal responses.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible spatial temperature gradients, (2) Constant properties.

PROPERTIES: Table A.1 (T = 300 K): Aluminum; ρ = 2702 kg/m^3, c_p = 903 J/kg·K, Gold; ρ = 19300 kg/m^3, c_p = 129 J/kg·K, Silver; ρ = 10500 kg/m^3, c_p = 235 J/kg·K.

ANALYSIS: (a) An energy balance on the control volume yields $\dot{E}_{st} = \dot{E}_{in}$ which may be written

$$\rho V c_p \frac{dT}{dt} = q \quad \text{or} \quad \frac{dT}{dt} = \frac{q}{\rho V c_p} = \frac{q}{V}\frac{1}{\rho c_p}$$

The thermal response, dT/dt, may be measured. Alternatively, the expression may be integrated to find $T(t)$ given the initial temperature, volume, heat rate, and product of the density and specific heat.

(b) For a known metal volume, V, the thermal response to constant heating is determined by the product of the density and specific heat, ρc_p. This product is listed below for each of the three candidate materials.

Material	ρ (kg/m^3)	c_p (J/kg·K)	ρc_p (J/m^3·K)
Aluminum	2702	903	2.44×10^6
Gold	19300	129	2.49×10^6
Silver	10500	235	2.47×10^6

Because the product of the densities and specific heats are so similar for these four candidate materials, in general this approach cannot be used to distinguish which material is being heated. $<$

COMMENTS: (1) By neglecting spatial temperature gradients, the proposed approach is based only on thermodynamics principles. Therefore, it is limited in its usefulness relative to alternative schemes discussed in the text such as in Problem 2.23. (2) For many metals, the product of the density and specific heat lies within a relatively narrow band.

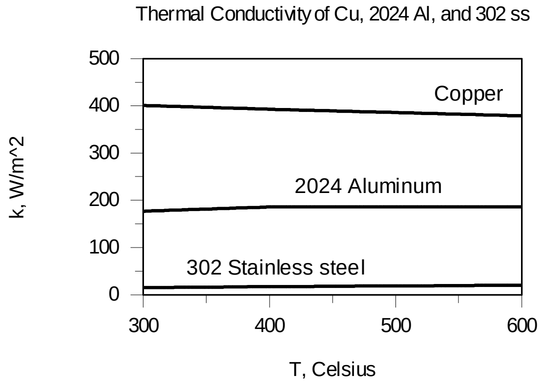
PROBLEM 2.21

KNOWN: Temperatures of various materials.

FIND: (a) Graph of thermal conductivity, *k*, versus temperature, *T*, for pure copper, 2024 aluminum and AISI 302 stainless steel for $300 \leq T \leq 600$ K, (b) Graph of thermal conductivity, *k*, for helium and air over the range $300 \leq T \leq 800$ K, (c) Graph of kinematic viscosity, ν, for engine oil, ethylene glycol, and liquid water for $300 \leq T \leq 360$ K, (d) Graph of thermal conductivity, *k*, versus volume fraction, φ, of a water-Al_2O_3 nanofluid for $0 \leq \varphi \leq 0.08$ and $T = 300$ K. Comment on the trends for each case.

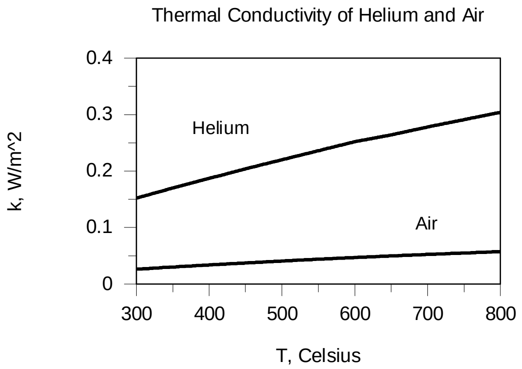
ASSUMPTION: (1) Constant nanoparticle properties.

ANALYSIS: (a) Using the *IHT* workspace of Comment 1 yields



Note the large difference between the thermal conductivities of these metals. Copper conducts thermal energy effectively, while stainless steels are relatively poor thermal conductors. Also note that, depending on the metal, the thermal conductivity increases (2024 Aluminum and 302 Stainless Steel) or decreases (Copper) with temperature.

(b) Using the *IHT* workspace of Comment 2 yields

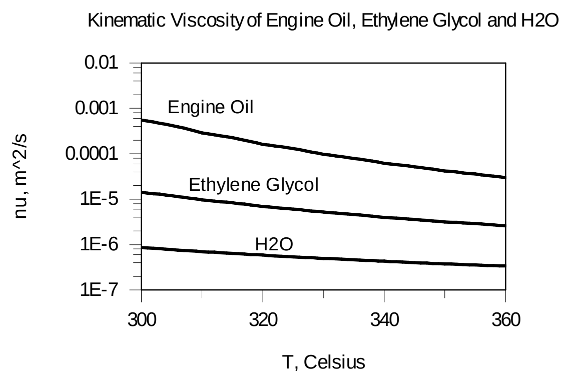


Note the high thermal conductivity of helium relative to that of air. As such, He is sometimes used as a coolant. The thermal conductivity of both gases increases with temperature, as expected from inspection of Figure 2.8.

Continued…

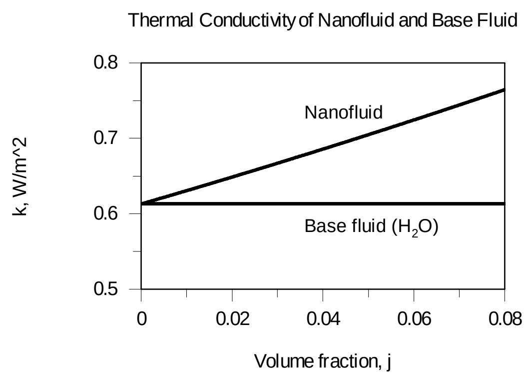
PROBLEM 2.21 (Cont.)

(c) Using the *IHT* workspace of Comment 3 yields



The kinematic viscosities vary by three orders of magnitude between the various liquids. For each case the kinematic viscosity decreases with temperature.

(d) Using the *IHT* workspace of Comment 4 yields



Note the increase in the thermal conductivity of the nanofluid with addition of more nanoparticles. The solid phase usually has a higher thermal conductivity than the liquid phase, as noted in Figures 2.5 and 2.9, respectively.

COMMENTS: (1) The *IHT* workspace for part (a) is as follows.

```
// Copper (pure) property functions : From Table A.1
// Units: T(K)
kCu = k_T("Copper",T)                        // Thermal conductivity,W/m·K

// Aluminum 2024 property functions : From Table A.1
// Units: T(K)
kAl = k_T("Aluminum 2024",T)                 // Thermal conductivity,W/m·K

// Stainless steel-AISI 302 property functions : From Table A.1
// Units: T(K)
kss = k_T("Stainless Steel-AISI 302",T)      // Thermal conductivity,W/m·K

T = 300                                      // Temperature, K
```

Continued…

PROBLEM 2.21 (Cont.)

(2) The *IHT* workspace for part (b) follows.

```
// Helium property functions : From Table A.4
// Units: T(K)
kHe = k_T("Helium",T)                      // Thermal conductivity, W/m·K

// Air property functions : From Table A.4
// Units: T(K); 1 atm pressure
kAir = k_T("Air",T)                        // Thermal conductivity, W/m·K

T = 300                                    // Temperature, K
```

(3) The *IHT* workspace for part (c) follows.

```
// Engine Oil property functions : From Table A.5
// Units: T(K)
nuOil = nu_T("Engine Oil",T)               // Kinematic viscosity, m^2/s

// Ethylene glycol property functions : From Table A.5
// Units: T(K)
nuEG = nu_T("Ethylene Glycol",T)           // Kinematic viscosity, m^2/s

// Water property functions :T dependence, From Table A.6
// Units: T(K), p(bars);
xH2O =0                                    // Quality (0=sat liquid or 1=sat vapor)
nuH2O = nu_Tx("Water",T,xH2O)              // Kinematic viscosity, m^2/s

T = 300                                    // Temperature, K
```

(4) The *IHT* workspace for part (d) follows.

```
// Water property functions :T dependence, From Table A.6
// Units: T(K), p(bars);
xH2O =0                                    // Quality (0=sat liquid or 1=sat vapor)
kH2O = k_Tx("Water",T,xH2O)                // Thermal conductivity, W/m·K
kbf = kH2O
T = 300

j = 0.01                                   // Volume fraction of nanoparticles

//Particle Properties

knf = (num/den)*kbf
num = kp + 2*kbf-2*j*(kbf - kp)
den = kp + 2*kbf + j*(kbf - kp)
```

PROBLEM 2.22

KNOWN: Ideal gas behavior for air, hydrogen and carbon dioxide.

FIND: The thermal conductivity of each gas at 300 K. Compare calculated values to values from Table A.4.

ASSUMPTIONS: (1) Ideal gas behavior.

PROPERTIES: Table A.4 (T = 300 K): Air; c_p = 1007 J/kg·K, k = 0.0263 W/m·K, Hydrogen; c_p = 14,310 J/kg·K, k = 0.183 W/m·K, Carbon dioxide; c_p = 851 J/kg·K, k = 0.0166 W/m·K. Figure 2.8: Air; $\mathcal{M}$ = 28.97 kg/kmol, d = 0.372 × 10^{-9} m, Hydrogen; $\mathcal{M}$ = 2.018 kg/kmol, d = 0.274 × 10^{-9} m, Carbon Dioxide; $\mathcal{M}$ = 44.01 kg/kmol, d = 0.464 × 10^{-9} m.

ANALYSIS: For <u>air</u>, the ideal gas constant, specific heat at constant volume, and ratio of specific heats are:

$$R = \frac{\mathcal{R}}{\mathcal{M}} = \frac{8.315 \text{ kJ/kmol}\cdot\text{K}}{28.97 \text{ kg/kmol}} = 0.287 \ \frac{\text{kJ}}{\text{kg}\cdot\text{K}};$$

$$c_v = c_p - R = 1.007\frac{\text{kJ}}{\text{kg}\cdot\text{K}} - 0.287\frac{\text{kJ}}{\text{kg}\cdot\text{K}} = 0.720\frac{\text{kJ}}{\text{kg}\cdot\text{K}}; \quad \gamma = \frac{c_p}{c_v} = \frac{1.007}{0.720} = 1.399$$

From Equation 2.12

$$k = \frac{9\gamma - 5}{4}\frac{c_v}{\pi d^2}\sqrt{\frac{\mathcal{M}k_B T}{\mathcal{N}\pi}}$$

$$= \frac{9\times1.399 - 5}{4} \times \frac{720 \text{ J/kg}\cdot\text{K}}{\pi\left(0.372\times10^{-9}\text{m}\right)^2}\sqrt{\frac{28.97 \text{ kg/kmol}\times1.381\times10^{-23} \text{ J/K} \times 300 \text{ K}}{\pi \times 6.024 \times 10^{23} \text{ mol}^{-1}\times1000 \text{ mol/kmol}}}$$

$$= 0.025\frac{\text{W}}{\text{m}\cdot\text{K}} \qquad <$$

The thermal conductivity of air at T = 300 K is 0.0263 W/m·K. Hence, the computed value is within 5 % of the reported value.

For <u>hydrogen</u>, the ideal gas constant, specific heat at constant volume, and ratio of specific heats are:

$$R = \frac{\mathcal{R}}{\mathcal{M}} = \frac{8.315 \text{ kJ/kmol}\cdot\text{K}}{2.018 \text{ kg/kmol}} = 4.120 \ \frac{\text{kJ}}{\text{kg}\cdot\text{K}};$$

$$c_v = c_p - R = 14.31\frac{\text{kJ}}{\text{kg}\cdot\text{K}} - 4.120\frac{\text{kJ}}{\text{kg}\cdot\text{K}} = 10.19\frac{\text{kJ}}{\text{kg}\cdot\text{K}}; \quad \gamma = \frac{c_p}{c_v} = \frac{14.31}{10.19} = 1.404$$

Equation 2.12 may be used to calculate

$$k = 0.173 \ \frac{\text{W}}{\text{m}\cdot\text{K}} \qquad <$$

Continued...

PROBLEM 2.22 (Cont.)

The thermal conductivity of hydrogen at T = 300 K is 0.183 W/m·K. Hence, the computed value is within 6 % of the reported value.

For carbon dioxide, the ideal gas constant, specific heat at constant volume, and ratio of specific heats are:

$$R = \frac{\mathcal{R}}{\mathcal{M}} = \frac{8.315 \text{ kJ/kmol} \cdot \text{K}}{44.01 \text{ kg/kmol}} = 0.189 \ \frac{\text{kJ}}{\text{kg} \cdot \text{K}};$$

$$c_v = c_p - R = 0.851 \frac{\text{kJ}}{\text{kg} \cdot \text{K}} - 0.189 \frac{\text{kJ}}{\text{kg} \cdot \text{K}} = 0.662 \frac{\text{kJ}}{\text{kg} \cdot \text{K}}; \quad \gamma = \frac{c_p}{c_v} = \frac{0.851}{0.662} = 1.285$$

Equation 2.12 may be used to calculate

$$k = 0.0158 \ \frac{\text{W}}{\text{m} \cdot \text{K}} \qquad <$$

The thermal conductivity of carbon dioxide at T = 300 K is 0.0166 W/m·K. Hence, the computed value is within 5 % of the reported value.

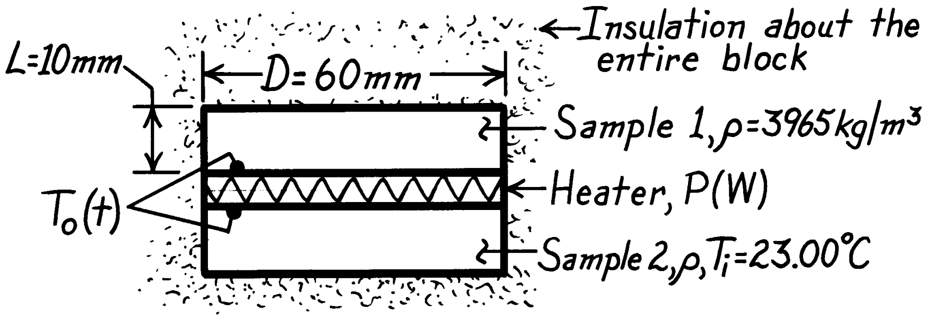
COMMENTS: The preceding analysis may be used to *estimate* the thermal conductivity at various temperatures. However, the analysis is not valid for extreme temperatures or pressures. For example, (1) the thermal conductivity is predicted to be independent of the pressure of the gas. As pure vacuum conditions are approached, the thermal conductivity will suddenly drop to zero, and the preceding analysis is no longer valid. Also, (2) for temperatures considerably higher or lower than normally-encountered room temperatures, the agreement between the predicted and actual thermal conductivities can be poor. For example, for carbon dioxide at T = 600 K, the predicted thermal conductivity is k = 0.0223 W/m·K, while the actual (tabular) value is k = 0.0407 W/m·K. For extreme temperatures, thermal correction factors must be included in the predictions of the thermal conductivity.

PROBLEM 2.23

KNOWN: Identical samples of prescribed diameter, length and density initially at a uniform temperature T_i, sandwich an electric heater which provides a uniform heat flux q''_o for a period of time Δt_o. Conditions shortly after energizing and a long time after de-energizing heater are prescribed.

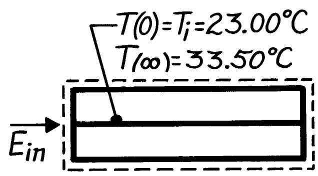
FIND: Specific heat and thermal conductivity of the test sample material. From these properties, identify type of material using Table A.1 or A.2.

SCHEMATIC:



ASSUMPTIONS: (1) One dimensional heat transfer in samples, (2) Constant properties, (3) Negligible heat loss through insulation, (4) Negligible heater mass.

ANALYSIS: Consider a control volume about the samples and heater, and apply conservation of energy over the time interval from t = 0 to ∞



$$E_{in} - E_{out} = \Delta E = E_f - E_i$$

$$P\Delta t_o - 0 = Mc_p\left[T(\infty) - T_i\right]$$

where energy inflow is prescribed by the power condition and the final temperature T_f is known. Solving for c_p,

$$c_p = \frac{P\Delta t_o}{M\left[T(\infty) - T_i\right]} = \frac{15\ \text{W} \times 120\ \text{s}}{2 \times 3965\ \text{kg/m}^3\left(\pi \times 0.060^2/4\right)\text{m}^2 \times 0.010\ \text{m}\left[33.50\text{-}23.00\right]^\circ\text{C}}$$

$$c_p = 765\ \text{J/kg}\cdot\text{K}$$ <

where $M = \rho V = 2\rho(\pi D^2/4)L$ is the mass of both samples. The transient thermal response of the heater is given by

Continued …..

PROBLEM 2.23 (Cont.)

$$T_o(t) - T_i = 2q_o''\left[\frac{t}{\pi\rho c_p k}\right]^{1/2}$$

$$k = \frac{t}{\pi\rho c_p}\left[\frac{2q_o''}{T_o(t) - T_i}\right]^2$$

$$k = \frac{30\ \text{s}}{\pi \times 3965\ \text{kg/m}^3 \times 765\ \text{J/kg}\cdot\text{K}}\left[\frac{2 \times 2653\ \text{W/m}^2}{(24.57 - 23.00)^\circ\text{C}}\right]^2 = 36.0\ \text{W/m}\cdot\text{K}$$ <

where

$$q_o'' = \frac{P}{2A_s} = \frac{P}{2\left(\pi D^2/4\right)} = \frac{15\ \text{W}}{2\left(\pi \times 0.060^2/4\right)\text{m}^2} = 2653\ \text{W/m}^2.$$

With the following properties now known,

$\rho = 3965\ \text{kg/m}^3$ $\quad c_p = 765\ \text{J/kg}\cdot\text{K}$ $\quad k = 36\ \text{W/m}\cdot\text{K}$

entries in Table A.1 are scanned to determine whether these values are typical of a metallic material. Consider the following,

- metallics with low ρ generally have higher thermal conductivities,
- specific heats of both types of materials are of similar magnitude,
- the low k value of the sample is typical of poor metallic conductors which generally have much higher specific heats,
- more than likely, the material is nonmetallic.

From Table A.2, the second entry, polycrystalline aluminum oxide, has properties at 300 K corresponding to those found for the samples. <

PROBLEM 2.24

KNOWN: Five materials at 300 K.

FIND: Heat capacity, ρc_p. Which material has highest thermal energy storage per unit volume. Which has lowest cost per unit heat capacity.

ASSUMPTIONS: Constant properties.

PROPERTIES: *Table A.3*, Common brick (T = 300 K): ρ = 1920 kg/m^3, c_p = 835 J/kg·K. *Table A.1*, Plain carbon steel (T = 300 K): ρ = 7854 kg/m^3, c_p = 434 J/kg·K. *Table A.5*, Engine oil (T = 300 K): ρ = 884.1 kg/m^3, c_p = 1909 J/kg·K. *Table A.6*, Water (T = 300 K): $\rho = 1/v_f$ = 997 kg/m^3, c_p = 4179 J/kg·K. *Table A.3*, Soil (T = 300 K): ρ = 2050 kg/m^3, c_p = 1840 J/kg·K.

ANALYSIS: The values of heat capacity, ρc_p, are tabulated below.

Material	Common brick	Plain carbon steel	Engine oil	Water	Soil
Heat Capacity (kJ/m^3·K)	1603	3409	1688	4166	3772

<

Thermal energy storage refers to either sensible or latent energy. The change in sensible energy per unit volume due to a temperature change ΔT is equal to $\rho c_p \Delta T$. Thus, for a given temperature change, the heat capacity values in the table above indicate the relative amount of sensible energy that can be stored in the material.

Of the materials considered, water has the largest capacity for sensible energy storage. <

Various materials also have the potential for latent energy storage due to either a solid-liquid or liquid-vapor phase change. Taking water as an example, the latent heat of fusion is 333.7 kJ/kg. With a density of $\rho \approx$ 1000 kg/m^3 at 0°C, the latent energy per unit volume associated with the solid-liquid phase transition is 333,700 kJ/m^3. This corresponds to an 80°C temperature change in the liquid phase. The latent heat of vaporization for water is very large, 2257 kJ/kg, but it is generally inconvenient to use a liquid-vapor phase change for thermal energy storage because of the large volume change.

The two materials with the largest heat capacity are also inexpensive. The consumer price of soil is around \$15 per cubic meter, or around \$4 per MJ/K. The consumer price of water is around \$0.40 per cubic meter, or around \$0.10 per MJ/K. In a commercial application, soil could probably be obtained much more inexpensively.

Therefore we conclude that water has the lowest cost per unit heat capacity of the materials considered. <

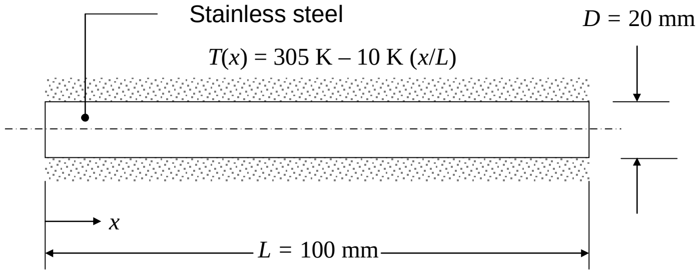
COMMENTS: (1) Many materials used for latent thermal energy storage are characterized by relatively low thermal conductivities. Therefore, although the materials may be attractive from the thermodynamics point of view, it can be difficult to deliver energy to the solid-liquid or liquid-vapor interface because of the poor thermal conductivity of the material. Hence, many latent thermal energy storage applications are severely hampered by heat transfer limitations. (2) Most liquids and solids have a heat capacity which is in a fairly narrow range of around 1000 – 4000 kJ/m^3·K. Gases have heat capacities that are orders of magnitude smaller.

PROBLEM 2.25

KNOWN: Diameter, length, and mass of stainless steel rod, insulated on its exterior surface other than ends. Temperature distribution.

FIND: Heat flux.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in x-direction, (3) Constant properties.

ANALYSIS: The heat flux can be found from Fourier's law,

$$q''_x = -k\frac{dT}{dx}$$

Table A.1 gives values for the thermal conductivity of stainless steels, however we are not told which type of stainless steel the rod is made of, and the thermal conductivity varies between them. We do know the mass of the rod, and can use this to calculate its density:

$$\rho = \frac{M}{V} = \frac{M}{\pi D^2 L/4} = \frac{0.248\text{ kg}}{\pi \times (0.02\text{ m})^2 \times 0.1\text{ m}/4} = 7894\text{ kg/m}^3$$

From Table A.1, it appears that the material is AISI 304 stainless steel. The temperature of the rod varies from 295 K to 305 K. Evaluating the thermal conductivity at 300 K, k = 14.9 W/m·K. Thus,

$$q''_x = -k\frac{dT}{dx} = -k(-b/L) = 14.9\text{ W/m}\cdot\text{K} \times 10\text{ K}/0.1\text{ m} = 1490\text{ W/m}^2 \qquad <$$

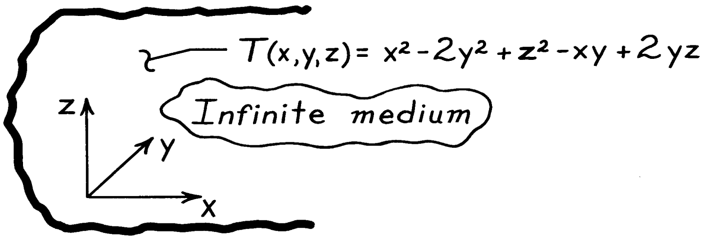
COMMENTS: If the temperature of the rod varies significantly along its length, the thermal conductivity will vary along the rod as much or more than the variation in thermal conductivities between the different stainless steels.

PROBLEM 2.26

KNOWN: Temperature distribution, T(x,y,z), within an infinite, homogeneous body at a given instant of time.

FIND: Regions where the temperature changes with time.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties of infinite medium and (2) No internal heat generation.

ANALYSIS: The temperature distribution throughout the medium, at any instant of time, must satisfy the heat equation. For the three-dimensional cartesian coordinate system, with constant properties and no internal heat generation, the heat equation, Eq. 2.21, has the form

$$\frac{\partial^2 T}{\partial x^2}+\frac{\partial^2 T}{\partial y^2}+\frac{\partial^2 T}{\partial z^2}=\frac{1}{\alpha}\frac{\partial T}{\partial t}. \qquad (1)$$

If T(x,y,z) satisfies this relation, conservation of energy is satisfied at every point in the medium. Substituting T(x,y,z) into the Eq. (1), first find the gradients, $\partial T/\partial x$, $\partial T/\partial y$, and $\partial T/\partial z$.

$$\frac{\partial}{\partial x}(2x\text{-}y)+\frac{\partial}{\partial y}(-4y\text{-}x+2z)+\frac{\partial}{\partial z}(2z+2y)=\frac{1}{\alpha}\frac{\partial T}{\partial t}.$$

Performing the differentiations,

$$2-4+2=\frac{1}{\alpha}\frac{\partial T}{\partial t}.$$

Hence,

$$\frac{\partial T}{\partial t}=0$$

which implies that, at the prescribed instant, the temperature is everywhere independent of time. <

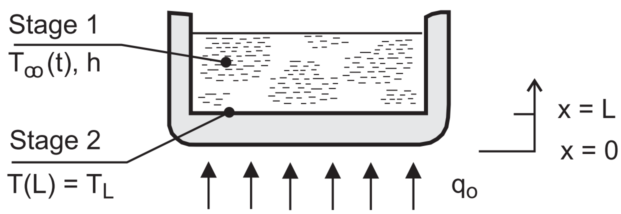
COMMENTS: Since we do not know the initial and boundary conditions, we cannot determine the temperature distribution, T(x,y,z), at any future time. We can only determine that, for this special instant of time, the temperature will not change.

PROBLEM 2.27

KNOWN: Diameter D, thickness L and initial temperature T_i of pan. Heat rate from stove to bottom of pan. Convection coefficient h and variation of water temperature $T_\infty(t)$ during Stage 1. Temperature T_L of pan surface in contact with water during Stage 2.

FIND: Form of heat equation and boundary conditions associated with the two stages.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in pan bottom, (2) Heat transfer from stove is uniformly distributed over surface of pan in contact with the stove, (3) Constant properties.

ANALYSIS:

Stage 1

Heat Equation: $$\frac{\partial^2 T}{\partial x^2} = \frac{1}{\alpha}\frac{\partial T}{\partial t}$$

Boundary Conditions: $$-k\left.\frac{\partial T}{\partial x}\right|_{x=0} = q_o'' = \frac{q_o}{\left(\pi D^2/4\right)}$$

$$-k\left.\frac{\partial T}{\partial x}\right|_{x=L} = h\left[T(L,t) - T_\infty(t)\right]$$

Initial Condition: $T(x,0) = T_i$

Stage 2

Heat Equation: $$\frac{d^2 T}{dx^2} = 0$$

Boundary Conditions: $$-k\left.\frac{dT}{dx}\right|_{x=0} = q_o''$$

$$T(L) = T_L$$

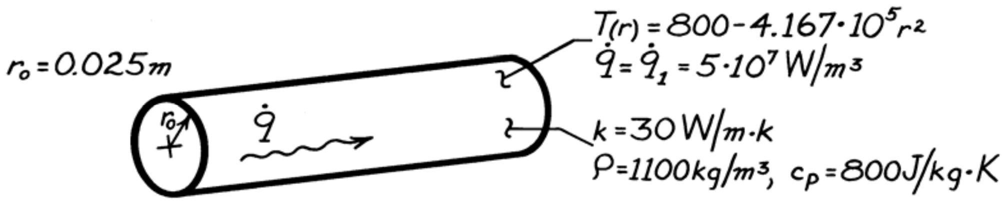
COMMENTS: Stage 1 is a transient process for which $T_\infty(t)$ must be determined separately. As a first approximation, it could be estimated by neglecting changes in thermal energy storage by the pan bottom and assuming that all of the heat transferred from the stove acted to increase thermal energy storage within the water. Hence, with $q \approx Mc_p\, dT_\infty/dt$, where M and c_p are the mass and specific heat of the water in the pan, $T_\infty(t) \approx (q/Mc_p)\, t$.

PROBLEM 2.28

KNOWN: Steady-state temperature distribution in a cylindrical rod having uniform heat generation of $\dot{q}_1 = 5 \times 10^7 \text{ W/m}^3$.

FIND: (a) Steady-state centerline and surface heat transfer rates per unit length, q'_r. (b) Initial time rate of change of the centerline and surface temperatures in response to a change in the generation rate from $\dot{q}_1$ to $\dot{q}_2 = 10^8 \text{ W/m}^3$.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in the r direction, (2) Uniform generation, and (3) Steady-state for $\dot{q}_1 = 5 \times 10^7 \text{ W/m}^3$.

ANALYSIS: (a) From the rate equations for cylindrical coordinates,

$$q''_r = -k \frac{\partial T}{\partial r} \qquad q = -kA_r \frac{\partial T}{\partial r}.$$

Hence,

$$q_r = -k(2\pi r L) \frac{\partial T}{\partial r}$$

or

$$q'_r = -2\pi k r \frac{\partial T}{\partial r} \qquad (1)$$

where $\partial T/\partial r$ may be evaluated from the prescribed temperature distribution, T(r).

At r = 0, the gradient is $(\partial T/\partial r) = 0$. Hence, from Equation (1) the heat rate is

$$q'_r(0) = 0.$$ <

At $r = r_o$, the temperature gradient is

$$\left.\frac{\partial T}{\partial r}\right]_{r=r_o} = -2\left[4.167 \times 10^5 \frac{K}{m^2}\right](r_o) = -2\left(4.167 \times 10^5\right)(0.025m)$$

$$\left.\frac{\partial T}{\partial r}\right]_{r=r_o} = -0.208 \times 10^5 \text{ K/m}.$$

Continued …..

PROBLEM 2.28 (Cont.)

Hence, the heat rate at the outer surface ($r = r_o$) per unit length is

$$q'_r(r_o) = -2\pi[30\ \text{W/m}\cdot\text{K}](0.025\text{m})\left[-0.208\times10^5\ \text{K/m}\right]$$

$$q'_r(r_o) = 0.980\times10^5\ \text{W/m}.$$ <

(b) Transient (time-dependent) conditions will exist when the generation is changed, and for the prescribed assumptions, the temperature is determined by the following form of the heat equation, Equation 2.26

$$\frac{1}{r}\frac{\partial}{\partial r}\left[kr\frac{\partial T}{\partial r}\right] + \dot{q}_2 = \rho c_p \frac{\partial T}{\partial t}$$

Hence

$$\frac{\partial T}{\partial t} = \frac{1}{\rho c_p}\left[\frac{1}{r}\frac{\partial}{\partial r}\left[kr\frac{\partial T}{\partial r}\right] + \dot{q}_2\right].$$

However, initially (at t = 0), the temperature distribution is given by the prescribed form, $T(r) = 800 - 4.167\times10^5 r^2$, and

$$\frac{1}{r}\frac{\partial}{\partial r}\left[kr\frac{\partial T}{\partial r}\right] = \frac{k}{r}\frac{\partial}{\partial r}\left[r\left(-8.334\times10^5\cdot r\right)\right]$$

$$= \frac{k}{r}\left(-16.668\times10^5\cdot r\right)$$

$$= 30\ \text{W/m}\cdot\text{K}\left[-16.668\times10^5\ \text{K/m}^2\right]$$

$$= -5\times10^7\ \text{W/m}^3\ \left(\text{the original } \dot{q}=\dot{q}_1\right).$$

Hence, everywhere in the wall,

$$\frac{\partial T}{\partial t} = \frac{1}{1100\ \text{kg/m}^3\times800\ \text{J/kg}\cdot\text{K}}\left[-5\times10^7 + 10^8\right]\ \text{W/m}^3$$

or

$$\frac{\partial T}{\partial t} = 56.82\ \text{K/s}.$$ <

COMMENTS: (1) The value of ($\partial T/\partial t$) will decrease with increasing time, until a new steady-state condition is reached and once again ($\partial T/\partial t$) = 0. (2) By applying the energy conservation requirement, Equation 1.12c, to a unit length of the rod for the steady-state condition, $\dot{E}'_{in} - E'_{out} + \dot{E}'_{gen} = 0$.

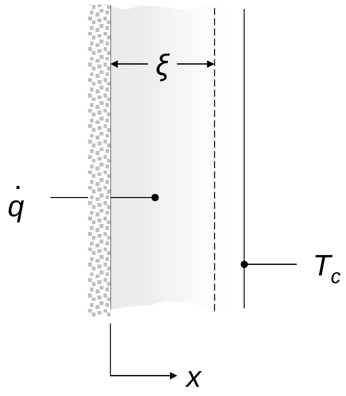
Hence $q'_r(0) - q'_r(r_o) = -\dot{q}_1\left(\pi r_o^2\right)$.

PROBLEM 2.29

KNOWN: Plane wall with constant properties and uniform volumetric energy generation. Insulated left face and isothermal right face.

FIND: (a) Expression for the heat flux distribution based upon the heat equation. (b) Expression for the heat flux distribution based upon a finite control volume.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Uniform volumetric generation, (4) One-dimensional conduction.

ANALYSIS: (a) The appropriate form of the heat equation is Eq. 2.19 which may be written as

$$\frac{d^2T}{dx^2} = \frac{d}{dx}\left(\frac{dT}{dx}\right) = -\frac{\dot{q}}{k}$$

The heat equation may be integrated once to yield

$$\frac{dT}{dx} = -\frac{\dot{q}}{k}x + C_1 \quad \text{and, since } \left.\frac{dT}{dx}\right|_{x=0} = 0,\ C_1 = 0. \text{ Therefore, } -k\frac{dT}{dx} = q''(x) = -\dot{q}x$$ <

(b) For the finite control volume, $\dot{E}_g = \dot{E}_{\text{out}}$, and for a unit cross-sectional area,

$$\dot{q}(\xi) = -k\left.\frac{dT}{dx}\right|_{x=\xi} \quad \text{which may be re-arranged to yield } -k\frac{dT}{dx} = q''(x) = -\dot{q}\xi = -\dot{q}x$$ <

The expressions for the local heat flux are identical.

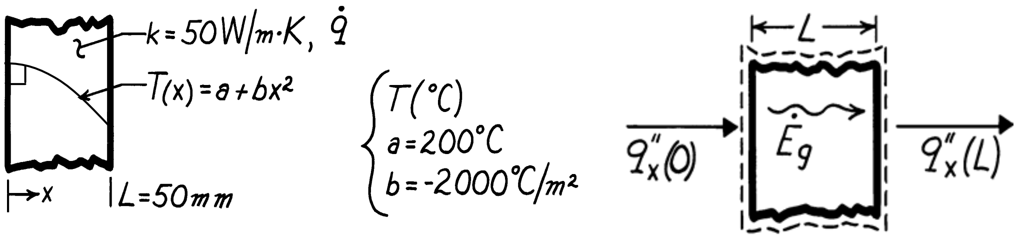
COMMENTS: (1) Although the two methods yield identical results, as they must, the heat equation is more general and can be used to determine temperature and heat flux distributions in more complex situations. (2) The value of the right face temperature is not needed to solve the problem. Is the value of T_c needed to determine the temperature distribution?

PROBLEM 2.30

KNOWN: Temperature distribution in a one-dimensional wall with prescribed thickness and thermal conductivity.

FIND: (a) The heat generation rate, $\dot{q}$, in the wall, (b) Heat fluxes at the wall faces and relation to $\dot{q}$.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat flow, (3) Constant properties.

ANALYSIS: (a) The appropriate form of the heat equation for steady-state, one-dimensional conditions with constant properties is Eq. 2.21 re-written as

$$\dot{q}=-k\frac{d}{dx}\left[\frac{dT}{dx}\right]$$

Substituting the prescribed temperature distribution,

$$\dot{q}=-k\frac{d}{dx}\left[\frac{d}{dx}\left(a+bx^2\right)\right]=-k\frac{d}{dx}\left[2bx\right]=-2bk$$

$$\dot{q}=-2\left(-2000^\circ\text{C/m}^2\right)\times 50\ \text{W/m}\cdot\text{K}=2.0\times 10^5\ \text{W/m}^3. \qquad <$$

(b) The heat fluxes at the wall faces can be evaluated from Fourier's law,

$$q''_x(x)=-k\left.\frac{dT}{dx}\right]_x.$$

Using the temperature distribution T(x) to evaluate the gradient, find

$$q''_x(x)=-k\frac{d}{dx}\left[a+bx^2\right]=-2kbx.$$

The fluxes at x = 0 and x = L are then

$$q''_x(0)=0 \qquad <$$

$$q''_x(L)=-2kbL=-2\times 50\text{W/m}\cdot\text{K}\left(-2000^\circ\text{C/m}^2\right)\times 0.050\text{m}$$

$$q''_x(L)=10,000\ \text{W/m}^2. \qquad <$$

COMMENTS: From an overall energy balance on the wall, it follows that, for a unit area,

$$\dot{E}_{in}-\dot{E}_{out}+\dot{E}_g=0 \qquad q''_x(0)-q''_x(L)+\dot{q}L=0$$

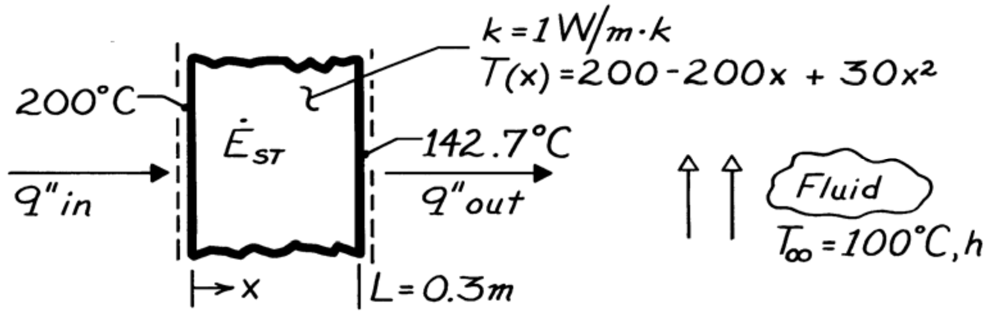
$$\dot{q}=\frac{q''_x(L)-q''_x(0)}{L}=\frac{10,000\ \text{W/m}^2-0}{0.050\text{m}}=2.0\times 10^5\text{W/m}^3.$$

PROBLEM 2.31

KNOWN: Wall thickness, thermal conductivity, temperature distribution, and fluid temperature.

FIND: (a) Surface heat rates and rate of change of wall energy storage per unit area, and (b) Convection coefficient.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in x, (2) Constant k.

ANALYSIS: (a) From Fourier's law,

$$q''_x = -k\frac{\partial T}{\partial x} = (200 - 60x)\cdot k$$

$$q''_{in} = q''_{x=0} = 200\frac{^\circ C}{m}\times 1\frac{W}{m\cdot K} = 200\ W/m^2$$ <

$$q''_{out} = q''_{x=L} = (200 - 60\times 0.3)^\circ C/m\ \times\ 1\ W/m\cdot K = 182\ W/m^2.$$ <

Applying an energy balance to a control volume about the wall, Eq. 1.12c,

$$\dot{E}''_{in} - \dot{E}''_{out} = \dot{E}''_{st}$$

$$\dot{E}''_{st} = q''_{in} - q''_{out} = 18\ W/m^2.$$ <

(b) Applying a surface energy balance at x = L,

$$q''_{out} = h\left[T(L) - T_\infty\right]$$

$$h = \frac{q''_{out}}{T(L) - T_\infty} = \frac{182\ W/m^2}{(142.7\text{-}100)^\circ C}$$

$$h = 4.3\ W/m^2\cdot K.$$ <

COMMENTS: (1) From the heat equation,

$$(\partial T/\partial t) = (k/\rho c_p)\ \partial^2 T/\partial x^2 = 60(k/\rho c_p),$$

it follows that the temperature is increasing with time at every point in the wall.

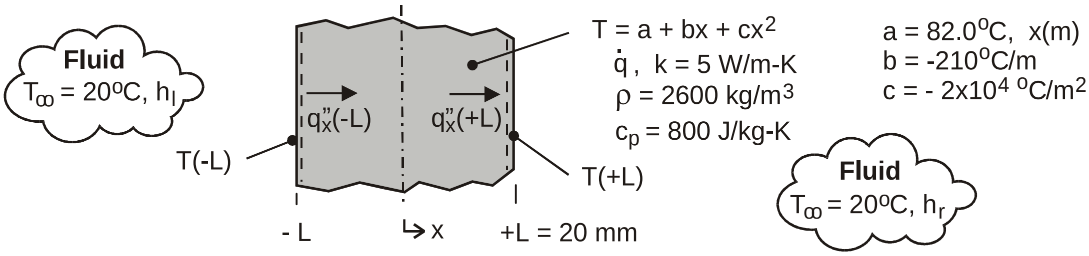
(2) The value of h is small and is typical of free convection in a gas.

PROBLEM 2.32

KNOWN: Analytical expression for the steady-state temperature distribution of a plane wall experiencing uniform volumetric heat generation $\dot{q}$ while convection occurs at both of its surfaces.

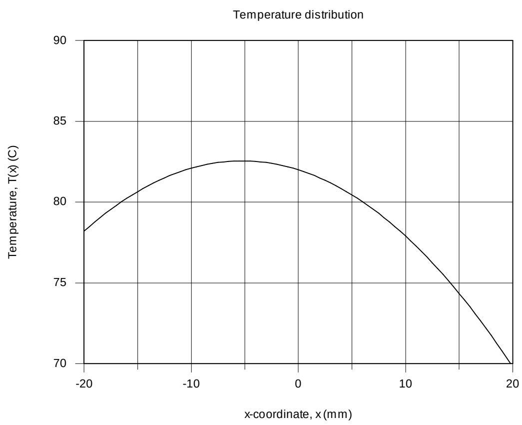
FIND: (a) Sketch the temperature distribution, T(x), and identify significant physical features, (b) Determine $\dot{q}$, (c) Determine the surface heat fluxes, $q''_x(-L)$ and $q''_x(+L)$; how are these fluxes related to the generation rate; (d) Calculate the convection coefficients at the surfaces x = L and x = +L, (e) Obtain an expression for the heat flux distribution, $q''_x(x)$; explain significant features of the distribution; (f) If the source of heat generation is suddenly deactivated ($\dot{q}$ = 0), what is the rate of change of energy stored at this instant; (g) Determine the temperature that the wall will reach eventually with $\dot{q} = 0$; determine the energy that must be removed by the fluid per unit area of the wall to reach this state.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform volumetric heat generation, (3) Constant properties.

ANALYSIS: (a) Using the analytical expression in the Workspace of IHT, the temperature distribution appears as shown below. The significant features include (1) parabolic shape, (2) maximum does not occur at the mid-plane, T(-5.25 mm) = 83.3°C, (3) the gradient at the x = +L surface is greater than at x = -L. Find also that T(-L) = 78.2°C and T(+L) = 69.8°C for use in part (d).



(b) Substituting the temperature distribution expression into the appropriate form of the heat diffusion equation, Eq. 2.21, the rate of volumetric heat generation can be determined.

$$\frac{d}{dx}\left(\frac{dT}{dx}\right)+\frac{\dot{q}}{k}=0 \qquad \text{where} \qquad T(x)=a+bx+cx^2$$

$$\frac{d}{dx}(0+b+2cx)+\frac{\dot{q}}{k}=(0+2c)+\frac{\dot{q}}{k}=0$$

Continued …..

$$\dot{q} = -2ck = -2\left(-2\times10^4 \,°C/m^2\right)5\,W/m\cdot K = 2\times10^5\,W/m^3 \qquad <$$

(c) The heat fluxes at the two boundaries can be determined using Fourier's law and the temperature distribution expression.

$$q''_x(x) = -k\frac{dT}{dx} \qquad \text{where} \qquad T(x) = a + bx + cx^2$$

$$q''_x(-L) = -k\left[0 + b + 2cx\right]_{x=-L} = -\left[b - 2cL\right]k$$

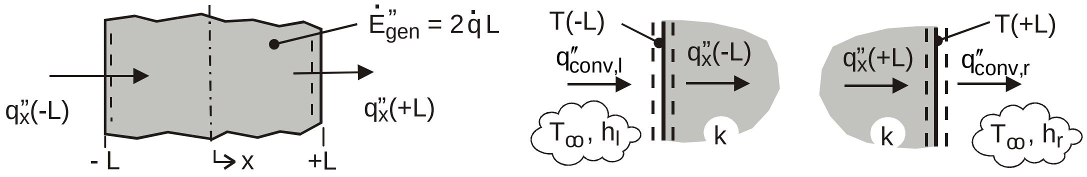
$$q''_x(-L) = -\left[-210°C/m - 2\left(-2\times10^4 °C/m^2\right)0.020m\right]\times5\,W/m\cdot K = -2950\,W/m^2 \qquad <$$

$$q''_x(+L) = -\left(b + 2cL\right)k = +5050\,W/m^2 \qquad <$$

From an overall energy balance on the wall as shown in the sketch below, $\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = 0$,

$$+q''_x(-L) - q''_x(+L) + 2\dot{q}L \overset{?}{=} 0 \quad \text{or} \quad -2950\,W/m^2 - 5050\,W/m^2 + 8000\,W/m^2 = 0$$

where $2\dot{q}L = 2\times2\times10^5\,W/m^3\times0.020\,m = 8000\,W/m^2$, so the equality is satisfied



Part (c) Overall energy balance   Part (d) Surface energy balances

(d) The convection coefficients, h_l and h_r, for the left- and right-hand boundaries (x = -L and x= +L, respectively), can be determined from the convection heat fluxes that are equal to the conduction fluxes at the boundaries. See the surface energy balances in the sketch above. See also part (a) result for T(-L) and T(+L).

$$q''_{conv,\ell} = q''_x(-L)$$

$$h_l\left[T_\infty - T(-L)\right] = h_l\left[20 - 78.2\right]K = -2950\,W/m^2 \qquad h_l = 51\,W/m^2\cdot K \qquad <$$

$$q''_{conv,r} = q''_x(+L)$$

$$h_r\left[T(+L) - T_\infty\right] = h_r\left[69.8 - 20\right]K = +5050\,W/m^2 \qquad h_r = 101\,W/m^2\cdot K \qquad <$$

(e) The expression for the heat flux distribution can be obtained from Fourier's law with the temperature distribution

$$q''_x(x) = -k\frac{dT}{dx} = -k\left[0 + b + 2cx\right]$$

$$q''_x(x) = -5\,W/m\cdot K\left[-210°C/m + 2\left(-2\times10^4 °C/m^2\right)\right]x = 1050 + 2\times10^5 x \qquad <$$

Continued …..

PROBLEM 2.32 (Cont.)

The distribution is linear with the x-coordinate. The maximum temperature will occur at the location where $q''_x(x_{max}) = 0$,

$$x_{max} = -\frac{1050\,W/m^2}{2\times10^5\ W/m^3} = -5.25\times10^{-3}m = -5.25\,mm$$ <

(f) If the source of the heat generation is suddenly deactivated so that $\dot{q} = 0$, the appropriate form of the heat diffusion equation for the ensuing transient conduction is

$$k\frac{\partial}{\partial x}\left(\frac{\partial T}{\partial x}\right) = \rho c_p \frac{\partial T}{\partial t}$$

At the instant this occurs, the temperature distribution is still T(x) = a + bx + cx^2. The right-hand term represents the rate of energy storage per unit volume,

$$\dot{E}''_{st} = k\frac{\partial}{\partial x}[0 + b + 2cx] = k[0 + 2c] = 5\,W/m\cdot K\times 2\left(-2\times10^4 {}^\circ C/m^2\right) = -2\times10^5\,W/m^3$$ <

(g) With no heat generation, the wall will eventually ($t \to \infty$) come to equilibrium with the fluid, $T(x,\infty) = T_\infty = 20°C$. To determine the energy that must be removed from the wall to reach this state, apply the conservation of energy requirement over an interval basis, Eq. 1.12b. The "initial" state is that corresponding to the steady-state temperature distribution, T_i, and the "final" state has $T_f = 20°C$. We've used T_∞ as the reference condition for the energy terms.

$$E''_{in} - E''_{out} = \Delta E''_{st} = E''_f - E''_i \qquad \text{with} \quad E''_{in} = 0.$$

$$E''_{out} = c_p \int_{-L}^{+L} \left(T_i - T_\infty\right) dx$$

$$E''_{out} = \rho c_p \int_{-L}^{+L}\left[a + bx + cx^2 - T_\infty\right]dx = \rho c_p\left[ax + bx^2/2 + cx^3/3 - T_\infty x\right]_{-L}^{+L}$$

$$E''_{out} = \rho c_p\left[2aL + 0 + 2cL^3/3 - 2T_\infty L\right]$$

$$E''_{out} = 2600\,kg/m^3\times800\,J/kg\cdot K\left[2\times82°C\times0.020m + 2\left(-2\times10^4 {}^\circ C/m^2\right)\right.$$
$$\left.(0.020m)^3/3 - 2(20°C)0.020m\right]$$

$$E''_{out} = 4.94\times10^6\,J/m^2$$ <

COMMENTS: (1) In part (a), note that the temperature gradient is larger at x = + L than at x = - L. This is consistent with the results of part (c) in which the conduction heat fluxes are evaluated.

Continued …..

PROBLEM 2.32 (Cont.)

(2) In evaluating the conduction heat fluxes, $q''_x(x)$, it is important to recognize that this flux is in the positive x-direction. See how this convention is used in formulating the energy balance in part (c).

(3) It is good practice to represent energy balances with a schematic, clearly defining the system or surface, showing the CV or CS with dashed lines, and labeling the processes. Review again the features in the schematics for the energy balances of parts (c & d).

(4) Re-writing the heat diffusion equation introduced in part (b) as

$$-\frac{d}{dx}\left(-k\frac{dT}{dx}\right)+\dot{q}=0$$

recognize that the term in parenthesis is the heat flux. From the differential equation, note that if the differential of this term is a constant $(\dot{q}/k)$, then the term must be a linear function of the x-coordinate. This agrees with the analysis of part (e).

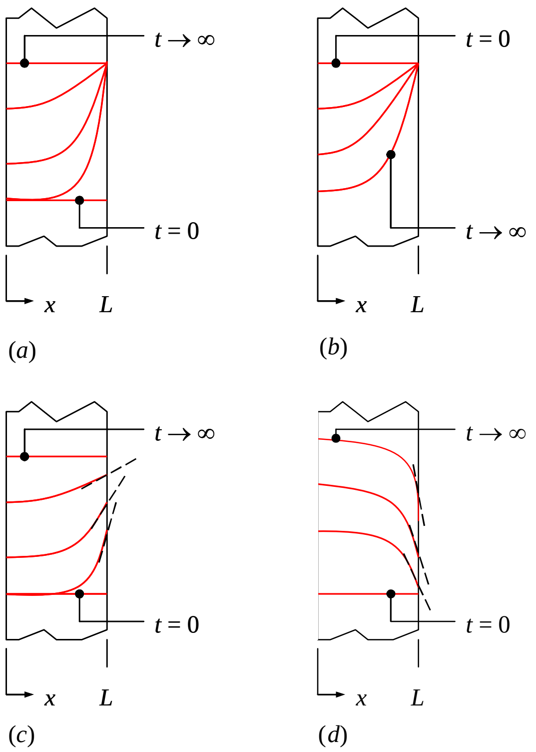
(5) In part (f), we evaluated $\dot{E}_{st}$, the rate of energy change stored in the wall at the instant the volumetric heat generation was deactivated. Did you notice that $\dot{E}_{st} = -2\times10^5\ W/m^3$ is the same value of the deactivated $\dot{q}$? How do you explain this?

PROBLEM 2.33

KNOWN: Transient temperature distributions in a plane wall.

FIND: Appropriate forms of heat equation, initial condition, and boundary conditions.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Negligible radiation.

ANALYSIS: The general form of the heat equation in Cartesian coordinates for constant k is Equation 2.21. For one-dimensional conduction it reduces to

$$\frac{\partial^2 T}{\partial x^2} + \frac{\dot{q}}{k} = \frac{1}{\alpha}\frac{\partial T}{\partial t}$$

At steady state this becomes

$$\frac{d^2 T}{dx^2} + \frac{\dot{q}}{k} = 0$$

If there is no thermal energy generation the steady-state temperature distribution is linear (or could be constant). If there is uniform thermal energy generation the steady-state temperature distribution must be parabolic.

Continued…

PROBLEM 2.33 (Cont.)

In case (*a*), the steady-state temperature distribution is constant, therefore there must not be any thermal energy generation. The heat equation is

$$\frac{\partial^2 T}{\partial x^2} = \frac{1}{\alpha}\frac{\partial T}{\partial t}$$ <

The initial temperature is uniform throughout the solid, thus the initial condition is

$$T(x,0) = T_i$$ <

At $x = 0$, the slope of the temperature distribution is zero at all times, therefore the heat flux is zero (insulated condition). The boundary condition is

$$\left.\frac{\partial T}{\partial x}\right|_{x=0} = 0$$ <

At $x = L$, the temperature is the same for all $t > 0$. Therefore the surface temperature is constant:

$$T(L,t) = T_s$$ <

For case (*b*), the steady-state temperature distribution is not linear and appears to be parabolic, therefore there is thermal energy generation. The heat equation is

$$\frac{\partial^2 T}{\partial x^2} + \frac{\dot{q}}{k} = \frac{1}{\alpha}\frac{\partial T}{\partial t}$$ <

The initial temperature is uniform, the temperature gradient at $x = 0$ is zero, and the temperature at $x = L$ is equal to the initial temperature for all $t > 0$, therefore the initial and boundary conditions are

$$T(x,0) = T_i, \quad \left.\frac{\partial T}{\partial x}\right|_{x=0} = 0, \quad T(L,t) = T_i$$ <

With the left side insulated and the right side maintained at the initial temperature, the cause of the decreasing temperature must be a negative value of thermal energy generation.

In case (*c*), the steady-state temperature distribution is constant, therefore there is no thermal energy generation. The heat equation is

$$\frac{\partial^2 T}{\partial x^2} = \frac{1}{\alpha}\frac{\partial T}{\partial t}$$ <

Continued…

PROBLEM 2.33 (Cont.)

The initial temperature is uniform throughout the solid. At $x = 0$, the slope of the temperature distribution is zero at all times. Therefore the initial condition and boundary condition at $x = 0$ are

$$T(x,0) = T_i, \quad \left.\frac{\partial T}{\partial x}\right|_{x=0} = 0$$ <

At $x = L$, neither the temperature nor the temperature gradient are constant for all time. Instead, the temperature gradient is decreasing with time as the temperature approaches the steady-state temperature. This corresponds to a convection heat transfer boundary condition. As the surface temperature approaches the fluid temperature, the heat flux at the surface decreases. The boundary condition is:

$$-k\left.\frac{\partial T}{\partial x}\right|_{x=L} = h\left[T(L,t) - T_\infty\right]$$ <

The fluid temperature, T_∞, must be higher than the initial solid temperature to cause the solid temperature to increase.

For case (*d*), the steady-state temperature distribution is not linear and appears to be parabolic, therefore there is thermal energy generation. The heat equation is

$$\frac{\partial^2 T}{\partial x^2} + \frac{\dot{q}}{k} = \frac{1}{\alpha}\frac{\partial T}{\partial t}$$ <

Since the temperature is increasing with time and it is *not* due to heat conduction due to a high surface temperature, the energy generation must be positive.

The initial temperature is uniform and the temperature gradient at $x = 0$ is zero. The boundary condition at $x = L$ is convection. The temperature gradient and heat flux at the surface are *increasing* with time as the thermal energy generation causes the temperature to rise further and further above the fluid temperature. The initial and boundary conditions are:

$$T(x,0) = T_i, \quad \left.\frac{\partial T}{\partial x}\right|_{x=0} = 0, \quad -k\left.\frac{\partial T}{\partial x}\right|_{x=L} = h\left[T(L,t) - T_\infty\right]$$ <

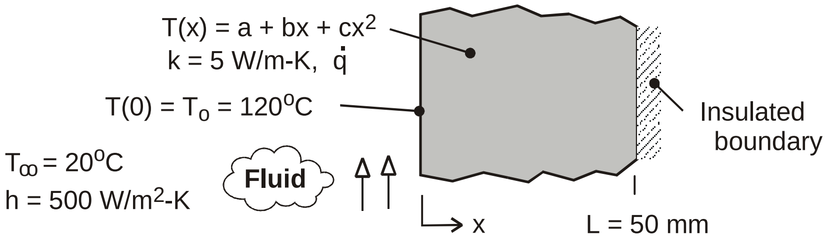
COMMENTS: 1. You will learn to solve for the temperature distribution in transient conduction in Chapter 5. 2. Case (b) might correspond to a situation involving a spatially-uniform endothermic chemical reaction. Such situations, although they can occur, are not common.

PROBLEM 2.34

KNOWN: Steady-state conduction with uniform internal energy generation in a plane wall; temperature distribution has quadratic form. Surface at x=0 is prescribed and boundary at x = L is insulated.

FIND: (a) Calculate the internal energy generation rate, $\dot{q}$, by applying an overall energy balance to the wall, (b) Determine the coefficients a, b, and c, by applying the boundary conditions to the prescribed form of the temperature distribution; plot the temperature distribution and label as Case 1, (c) Determine new values for a, b, and c for conditions when the convection coefficient is halved, and the generation rate remains unchanged; plot the temperature distribution and label as Case 2; (d) Determine new values for a, b, and c for conditions when the generation rate is doubled, and the convection coefficient remains unchanged (h = 500 W/m^2·K); plot the temperature distribution and label as Case 3.

SCHEMATIC:



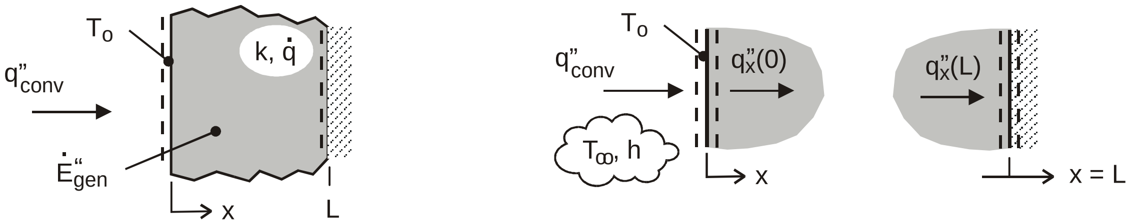
ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction with constant properties and uniform internal generation, and (3) Boundary at x = L is adiabatic.

ANALYSIS: (a) The internal energy generation rate can be calculated from an overall energy balance on the wall as shown in the schematic below.

$$\dot{E}''_{in} - \dot{E}''_{out} + \dot{E}''_{gen} = 0 \qquad \text{where} \qquad \dot{E}''_{in} = q''_{conv}$$

$$h\left(T_\infty - T_o\right) + \dot{q}\,L = 0 \tag{1}$$

$$\dot{q} = -h\left(T_\infty - T_o\right)/L = -500\,\text{W/m}^2\cdot\text{K}\left(20-120\right)°\text{C}/0.050\ \text{m} = 1.0\times10^6\ \text{W/m}^3 \quad <$$



(a) Overall energy balance **(b) Surface energy balances**

(b) The coefficients of the temperature distribution, T(x) = a + bx + cx^2, can be evaluated by applying the boundary conditions at x = 0 and x = L. See Table 2.2 for representation of the boundary conditions, and the schematic above for the relevant surface energy balances.

Boundary condition at x = 0, convection surface condition

$$\dot{E}''_{in} - \dot{E}''_{out} = q''_{conv} - q''_x\left(0\right) = 0 \qquad \text{where} \qquad q''_x\left(0\right) = -k\left.\frac{dT}{dx}\right|_{x=0}$$

$$h\left(T_\infty - T_o\right) - \left[-k\left(0 + b + 2cx\right)_{x=0}\right] = 0$$

Continued ...

PROBLEM 2.34 (Cont.)

$$b = -h(T_\infty - T_o)/k = -500\,W/m^2 \cdot K(20-120)°C/5\,W/m\cdot K = 1.0\times10^4\,K/m \qquad (2)$$ <

Boundary condition at x = L, adiabatic or insulated surface

$$\dot{E}_{in} - \dot{E}_{out} = -q''_x(L) = 0 \text{ where } \qquad q''_x(L) = -k\left.\frac{dT}{dx}\right|_{x=L}$$

$$k[0+b+2cx]_{x=L} = 0 \qquad (3)$$

$$c = -b/2L = -1.0\times10^4\,K/m/(2\times0.050m) = -1.0\times10^5\,K/m^2$$ <

Since the surface temperature at x = 0 is known, $T(0) = T_o = 120°C$, find

$$T(0) = 120°C = a + b\cdot0 + c\cdot0 \qquad \text{or} \qquad a = 120°C \qquad (4)$$ <

Using the foregoing coefficients with the expression for T(x) in the Workspace of IHT, the temperature distribution can be determined and is plotted as Case 1 in the graph below.

(c) Consider Case 2 when the convection coefficient is halved, $h_2 = h/2 = 250\ W/m^2\cdot K$, $\dot{q} = 1\times10^6$ W/m^3 and other parameters remain unchanged except that $T_o \neq 120°C$. We can determine a, b, and c for the temperature distribution expression by repeating the analyses of parts (a) and (b).

Overall energy balance on the wall, see Eqs. (1,4)

$$a = T_o = \dot{q}L/h + T_\infty = 1\times10^6\,W/m^3\times0.050m/250\,W/m^2\cdot K + 20°C = 220°C$$ <

Surface energy balance at x = 0, see Eq. (2)

$$b = -h(T_\infty - T_o)/k = -250\,W/m^2\cdot K(20-220)°C/5\,W/m\cdot K = 1.0\times10^4\,K/m$$ <

Surface energy balance at x = L, see Eq. (3)

$$c = -b/2L = -1.0\times10^4\,K/m/(2\times0.050m) = -1.0\times10^5\,K/m^2$$ <

The new temperature distribution, T_2 (x), is plotted as Case 2 below.

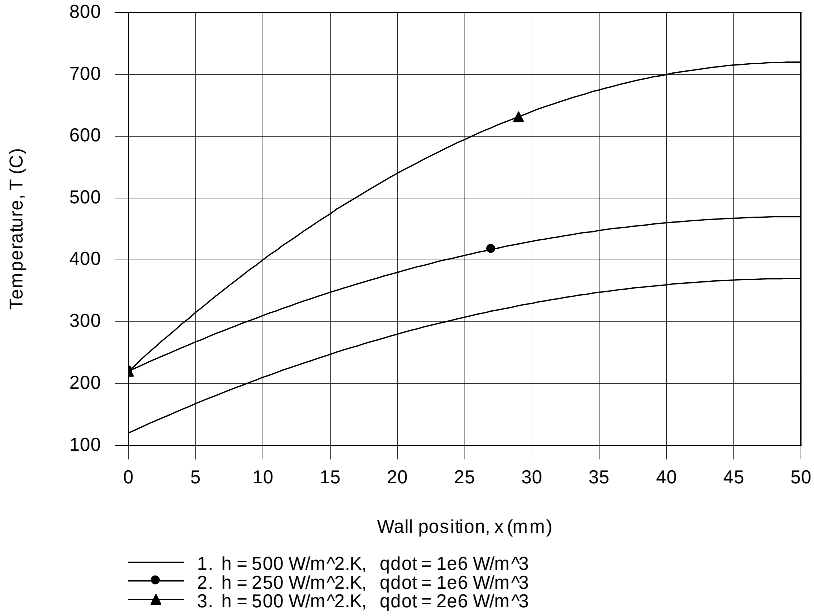
(d) Consider Case 3 when the internal energy volumetric generation rate is doubled, $\dot{q}_3 = 2\dot{q} = 2\times10^6\,W/m^3$, $h = 500\ W/m^2\cdot K$, and other parameters remain unchanged except that $T_o \neq 120°C$. Following the same analysis as part (c), the coefficients for the new temperature distribution, T (x), are

$$a = 220°C \qquad b = 2\times10^4\,K/m \; c = -2\times10^5\,K/m^2$$ <

and the distribution is plotted as Case 3 below.

Continued …

PROBLEM 2.34 (Cont.)



COMMENTS: Note the following features in the family of temperature distributions plotted above. The temperature gradients at x = L are zero since the boundary is insulated (adiabatic) for all cases. The shapes of the distributions are all quadratic, with the maximum temperatures at the insulated boundary.

By halving the convection coefficient for Case 2, we expect the surface temperature T_o to increase relative to the Case 1 value, since the same heat flux is removed from the wall $(\dot{q}L)$ but the convection resistance has increased.

By doubling the generation rate for Case 3, we expect the surface temperature T_o to increase relative to the Case 1 value, since double the amount of heat flux is removed from the wall $(2\dot{q}L)$.

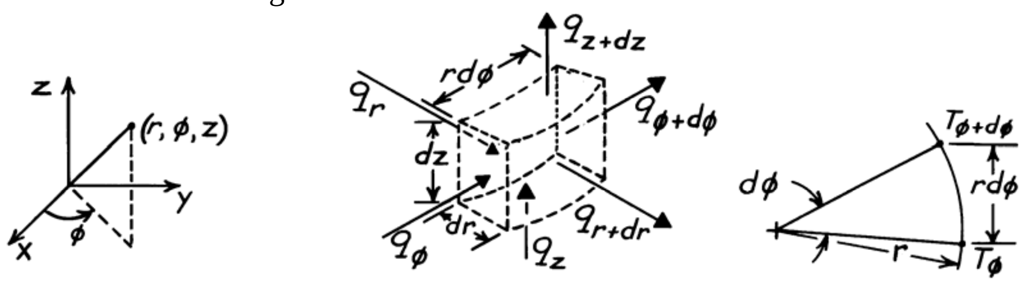
Can you explain why T_o is the same for Cases 2 and 3, yet the insulated boundary temperatures are quite different? Can you explain the relative magnitudes of T(L) for the three cases?

PROBLEM 2.35

KNOWN: Three-dimensional system – described by cylindrical coordinates (r,ϕ,z) – experiences transient conduction and internal heat generation.

FIND: Heat diffusion equation.

SCHEMATIC: See also Fig. 2.12.



ASSUMPTIONS: (1) Homogeneous medium.

ANALYSIS: Consider the differential control volume identified above having a volume given as V = dr·rdϕ·dz. From the conservation of energy requirement,

$$q_r - q_{r+dr} + q_\phi - q_{\phi+d\phi} + q_z - q_{z+dz} + \dot{E}_g = \dot{E}_{st}. \qquad (1)$$

The generation and storage terms, both representing volumetric phenomena, are

$$\dot{E}_g = \dot{q}V = \dot{q}\left(dr \cdot rd\phi \cdot dz\right) \qquad \dot{E}_g = \rho V c \partial T/\partial t = \rho\left(dr \cdot rd\phi \cdot dz\right) c\, \partial T/\partial t. \qquad (2,3)$$

Using a Taylor series expansion, we can write

$$q_{r+dr} = q_r + \frac{\partial}{\partial r}\left(q_r\right)dr, \quad q_{\phi+d\phi} = q_\phi + \frac{\partial}{\partial \phi}\left(q_\phi\right)d\phi, \quad q_{z+dz} = q_z + \frac{\partial}{\partial z}\left(q_z\right)dz. \qquad (4,5,6)$$

Using Fourier's law, the expressions for the conduction heat rates are

$$q_r = -kA_r \partial T/\partial r = -k\left(rd\phi \cdot dz\right)\partial T/\partial r \qquad (7)$$

$$q_\phi = -kA_\phi \partial T/r\partial\phi = -k\left(dr \cdot dz\right)\partial T/r\partial\phi \qquad (8)$$

$$q_z = -kA_z \partial T/\partial z = -k\left(dr \cdot rd\phi\right)\partial T/\partial z. \qquad (9)$$

Note from the above, right schematic that the gradient in the ϕ-direction is ∂T/r∂ϕ and not ∂T/∂ϕ. Substituting Eqs. (2), (3) and (4), (5), (6) into Eq. (1),

$$-\frac{\partial}{\partial r}\left(q_r\right)dr - \frac{\partial}{\partial\phi}\left(q_\phi\right)d\phi - \frac{\partial}{\partial z}\left(q_z\right)dz + \dot{q}\, dr \cdot rd\phi \cdot dz = \rho\left(dr \cdot rd\phi \cdot dz\right)c\frac{\partial T}{\partial t}. \qquad (10)$$

Substituting Eqs. (7), (8) and (9) for the conduction rates, find

$$-\frac{\partial}{\partial r}\left[-k\left(rd\phi \cdot dz\right)\frac{\partial T}{\partial r}\right]dr - \frac{\partial}{\partial \phi}\left[-k\left(drdz\right)\frac{\partial T}{r\partial\phi}\right]d\phi - \frac{\partial}{\partial z}\left[-k\left(dr \cdot rd\phi\right)\frac{\partial T}{\partial z}\right]dz$$

$$+\dot{q}\, dr \cdot rd\phi \cdot dz = \rho\left(dr \cdot rd\phi \cdot dz\right)c\frac{\partial T}{\partial t}. \qquad (11)$$

Dividing Eq. (11) by the volume of the CV, Eq. 2.26 is obtained.

$$\frac{1}{r}\frac{\partial}{\partial r}\left[kr\frac{\partial T}{\partial r}\right] + \frac{1}{r^2}\frac{\partial}{\partial\phi}\left[k\frac{\partial T}{\partial\phi}\right] + \frac{\partial}{\partial z}\left[k\frac{\partial T}{\partial z}\right] + \dot{q} = \rho c\frac{\partial T}{\partial t}$$

<

PROBLEM 2.36

KNOWN: Three-dimensional system – described by spherical coordinates (r,ϕ,θ) – experiences transient conduction and internal heat generation.

FIND: Heat diffusion equation.

SCHEMATIC: See Figure 2.13.

ASSUMPTIONS: (1) Homogeneous medium.

ANALYSIS: The differential control volume is V = dr·rsinθdϕ·rdθ, and the conduction terms are identified in Figure 2.13. Conservation of energy requires

$$q_r - q_{r+dr} + q_\phi - q_{\phi+d\phi} + q_\theta - q_{\theta+d\theta} + \dot{E}_g = \dot{E}_{st}. \qquad (1)$$

The generation and storage terms, both representing volumetric phenomena, are

$$\dot{E}_g = \dot{q}V = \dot{q}\left[dr \cdot r\sin\theta d\phi \cdot rd\theta\right] \qquad \dot{E}_{st} = \rho Vc\frac{\partial T}{\partial t} = \rho\left[dr \cdot r\sin\theta d\phi \cdot rd\theta\right]c\frac{\partial T}{\partial t}. \qquad (2,3)$$

Using a Taylor series expansion, we can write

$$q_{r+dr} = q_r + \frac{\partial}{\partial r}(q_r)dr, \quad q_{\phi+d\phi} = q_\phi + \frac{\partial}{\partial\phi}(q_\phi)d\phi, \quad q_{\theta+d\theta} = q_\theta + \frac{\partial}{\partial\theta}(q_\theta)d\theta. \qquad (4,5,6)$$

From Fourier's law, the conduction heat rates have the following forms.

$$q_r = -kA_r\partial T/\partial r = -k\left[r\sin\theta d\phi \cdot rd\theta\right]\partial T/\partial r \qquad (7)$$

$$q_\phi = -kA_\phi\partial T/r\sin\theta\partial\phi = -k\left[dr \cdot rd\theta\right]\partial T/r\sin\theta\partial\phi \qquad (8)$$

$$q_\theta = -kA_\theta\partial T/r\partial\theta = -k\left[dr \cdot r\sin\theta d\phi\right]\partial T/r\partial\theta. \qquad (9)$$

Substituting Eqs. (2), (3) and (4), (5), (6) into Eq. (1), the energy balance becomes

$$-\frac{\partial}{\partial r}(q_r)dr - \frac{\partial}{\partial\phi}(q_\phi)d\phi - \frac{\partial}{\partial\theta}(q_\theta)d\theta + \dot{q}\left[dr \cdot r\sin\theta d\phi \cdot rd\theta\right] = \rho\left[dr \cdot r\sin\theta d\phi \cdot rd\theta\right]c\frac{\partial T}{\partial t} \qquad (10)$$

Substituting Eqs. (7), (8) and (9) for the conduction rates, find

$$-\frac{\partial}{\partial r}\left[-k\left[r\sin\theta d\phi \cdot rd\theta\right]\frac{\partial T}{\partial r}\right]dr - \frac{\partial}{\partial\phi}\left[-k\left[dr \cdot rd\theta\right]\frac{\partial T}{r\sin\theta\partial\phi}\right]d\phi$$

$$-\frac{\partial}{\partial\theta}\left[-k\left[dr \cdot r\sin\theta d\phi\right]\frac{\partial T}{r\partial\theta}\right]d\theta + \dot{q}\left[dr \cdot r\sin\theta d\phi \cdot rd\theta\right] = \rho\left[dr \cdot r\sin\theta d\phi \cdot rd\theta\right]c\frac{\partial T}{\partial t} \qquad (11)$$

Dividing Eq. (11) by the volume of the control volume, V, Eq. 2.29 is obtained.

$$\frac{1}{r^2}\frac{\partial}{\partial r}\left[kr^2\frac{\partial T}{\partial r}\right] + \frac{1}{r^2\sin^2\theta}\frac{\partial}{\partial\phi}\left[k\frac{\partial T}{\partial\phi}\right] + \frac{1}{r^2\sin\theta}\frac{\partial}{\partial\theta}\left[k\sin\theta\frac{\partial T}{\partial\theta}\right] + \dot{q} = \rho c\frac{\partial T}{\partial t}. \qquad <$$

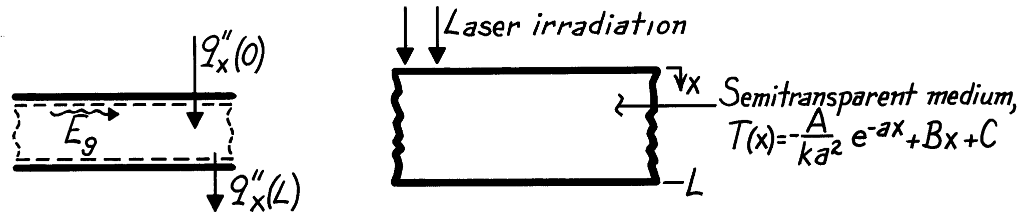
COMMENTS: Note how the temperature gradients in Eqs. (7) - (9) are formulated. The numerator is always ∂T while the denominator is the dimension of the control volume in the specified coordinate direction.

PROBLEM 2.37

KNOWN: Temperature distribution in a semi-transparent medium subjected to radiative flux.

FIND: (a) Expressions for the heat flux at the front and rear surfaces, (b) Heat generation rate $\dot{q}(x)$, (c) Expression for absorbed radiation per unit surface area in terms of A, a, B, C, L, and k.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in medium, (3) Constant properties, (4) All laser irradiation is absorbed and can be characterized by an internal volumetric heat generation term $\dot{q}(x)$.

ANALYSIS: (a) Knowing the temperature distribution, the surface heat fluxes are found using Fourier's law,

$$q''_x = -k\left[\frac{dT}{dx}\right] = -k\left[-\frac{A}{ka^2}(-a)e^{-ax} + B\right]$$

Front Surface, x=0: $$q''_x(0) = -k\left[+\frac{A}{ka}\cdot 1 + B\right] = -\left[\frac{A}{a} + kB\right]$$ <

Rear Surface, x=L: $$q''_x(L) = -k\left[+\frac{A}{ka}e^{-aL} + B\right] = -\left[\frac{A}{a}e^{-aL} + kB\right].$$ <

(b) The heat diffusion equation for the medium is

$$\frac{d}{dx}\left(\frac{dT}{dx}\right) + \frac{\dot{q}}{k} = 0 \quad \text{or} \quad \dot{q} = -k\frac{d}{dx}\left(\frac{dT}{dx}\right)$$

$$\dot{q}(x) = -k\frac{d}{dx}\left[+\frac{A}{ka}e^{-ax} + B\right] = Ae^{-ax}.$$ <

(c) Performing an energy balance on the medium,

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = 0$$

recognize that $\dot{E}_g$ represents the absorbed irradiation. On a unit area basis

$$\dot{E}''_g = -\dot{E}''_{in} + \dot{E}''_{out} = -q''_x(0) + q''_x(L) = +\frac{A}{a}\left(1 - e^{-aL}\right).$$ <

Alternatively, evaluate $\dot{E}''_g$ by integration over the volume of the medium,

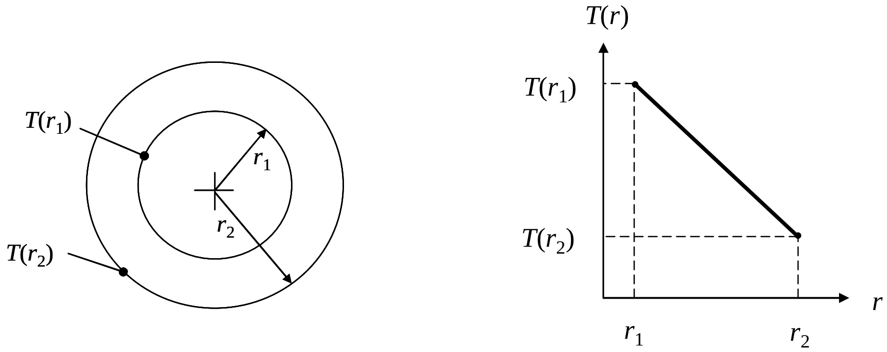
$$\dot{E}''_g = \int_0^L \dot{q}(x)dx = \int_0^L Ae^{-ax}dx = -\frac{A}{a}\left[e^{-ax}\right]_0^L = \frac{A}{a}\left(1 - e^{-aL}\right).$$

PROBLEM 2.38

KNOWN: Cylindrical shell under steady-state conditions with no energy generation.

FIND: Under what conditions is a linear temperature distribution possible.

SCHEMATIC:



ASSUMPTIONS: (1) Steady state conditions. (2) One-dimensional conduction. (3) No internal energy generation.

ANALYSIS: Under the stated conditions, the heat equation in cylindrical coordinates, Equation 2.26, reduces to

$$\frac{d}{dr}\left(kr\frac{dT}{dr}\right) = 0$$

If the temperature distribution is a linear function of r, then the temperature gradient is constant, and this equation becomes

$$\frac{d}{dr}(kr) = 0$$

which implies kr = constant, or $k \sim 1/r$. The only way there could be a linear temperature distribution in the cylindrical shell is if the thermal conductivity were to vary inversely with r. <

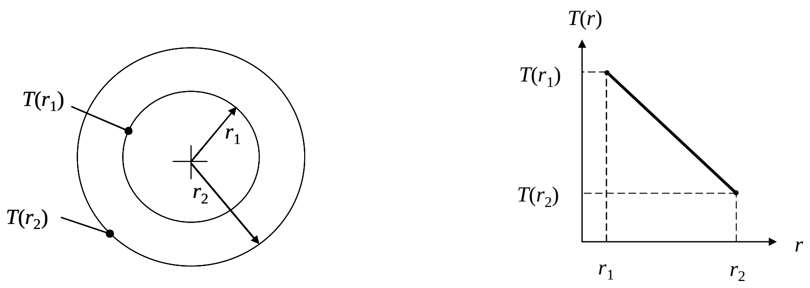
COMMENTS: It is unlikely to encounter or even create a material for which k varies inversely with the cylindrical radial coordinate r. Assuming linear temperature distributions in radial systems is nearly always both fundamentally incorrect and physically implausible.

PROBLEM 2.39

KNOWN: Spherical shell under steady-state conditions with no energy generation.

FIND: Under what conditions is a linear temperature distribution possible.

SCHEMATIC:



ASSUMPTIONS: (1) Steady state, (2) One-dimensional, (3) No heat generation.

ANALYSIS: Under the stated conditions, the heat equation in spherical coordinates, Equation 2.29, reduces to

$$\frac{d}{dr}\left(kr^2\frac{dT}{dr}\right) = 0$$

If the temperature distribution is a linear function of r, then the temperature gradient is constant, and this equation becomes

$$\frac{d}{dr}\left(kr^2\right) = 0$$

which implies kr^2 = constant, or $k \sim 1/r^2$. The only way there could be a linear temperature distribution in the spherical shell is if the thermal conductivity were to vary inversely with r^2. $<$

COMMENTS: It is unlikely to encounter or even create a material for which k varies inversely with the spherical radial coordinate r in the manner necessary to develop a linear temperature distribution. Assuming linear temperature distributions in radial systems is nearly always both fundamentally incorrect and physically implausible.

PROBLEM 2.40

KNOWN: Steady-state temperature distribution in a one-dimensional wall of thermal conductivity, $T(x) = Ax^3 + Bx^2 + Cx + D$.

FIND: Expressions for the heat generation rate in the wall and the heat fluxes at the two wall faces (x = 0,L).

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat flow, (3) Homogeneous medium.

ANALYSIS: The appropriate form of the heat diffusion equation for these conditions is

$$\frac{d^2T}{dx^2} + \frac{\dot{q}}{k} = 0 \quad \text{or} \quad \dot{q} = -k\frac{d^2T}{dx^2}.$$

Hence, the generation rate is

$$\dot{q} = -k\frac{d}{dx}\left[\frac{dT}{dx}\right] = -k\frac{d}{dx}\left[3Ax^2 + 2Bx + C + 0\right]$$

$$\dot{q} = -k\left[6Ax + 2B\right] \qquad <$$

which is linear with the coordinate x. The heat fluxes at the wall faces can be evaluated from Fourier's law,

$$q''_x = -k\frac{dT}{dx} = -k\left[3Ax^2 + 2Bx + C\right]$$

using the expression for the temperature gradient derived above. Hence, the heat fluxes are:

Surface x=0:

$$q''_x(0) = -kC \qquad <$$

Surface x=L:

$$q''_x(L) = -k\left[3AL^2 + 2BL + C\right]. \qquad <$$

COMMENTS: (1) From an overall energy balance on the wall, find

$$\dot{E}''_{in} - \dot{E}''_{out} + \dot{E}''_g = 0$$
$$q''_x(0) - q''_x(L) + \dot{E}''_g = (-kC) - (-k)\left[3AL^2 + 2BL + C\right] + \dot{E}''_g = 0$$
$$\dot{E}''_g = -3AkL^2 - 2BkL.$$

From integration of the volumetric heat rate, we can also find $\dot{E}''_g$ as

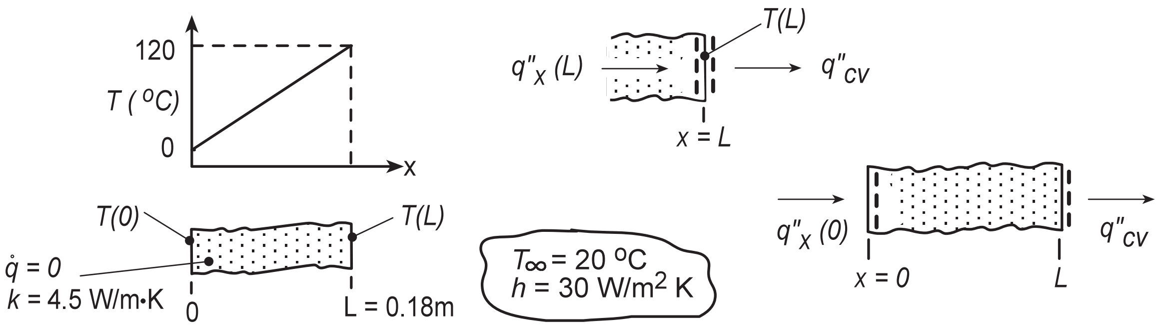
$$\dot{E}''_g = \int_0^L \dot{q}(x)dx = \int_0^L -k\left[6Ax + 2B\right]dx = -k\left[3Ax^2 + 2Bx\right]_0^L$$
$$\dot{E}''_g = -3AkL^2 - 2BkL.$$

PROBLEM 2.41

KNOWN: Plane wall with no internal energy generation.

FIND: Determine whether the prescribed temperature distribution is possible; explain your reasoning. With the temperatures T(0) = 0°C and T_∞ = 20°C fixed, compute and plot the temperature T(L) as a function of the convection coefficient for the range $10 \le h \le 100\ W/m^2 \cdot K$.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) No internal energy generation, (3) Constant properties, (4) No radiation exchange at the surface x = L, and (5) Steady-state conditions.

ANALYSIS: (a) Is the prescribed temperature distribution possible? If so, the energy balance at the surface x = L as shown above in the Schematic, must be satisfied.

$$\dot{E}_{in} - \dot{E}_{out} = 0 \qquad q''_x(L) - q''_{cv} = 0 \qquad (1,2)$$

where the conduction and convection heat fluxes are, respectively,

$$q''_x(L) = -k\left.\frac{dT}{dx}\right)_{x=L} = -k\frac{T(L)-T(0)}{L} = -4.5\,W/m\cdot K \times (120-0)^\circ C/0.18\,m = -3000\,W/m^2$$

$$q''_{cv} = h\left[T(L) - T_\infty\right] = 30\,W/m^2\cdot K \times (120-20)^\circ C = 3000\,W/m^2$$

Substituting the heat flux values into Eq. (2), find (-3000) - (3000) ≠ 0 and therefore, the temperature distribution is not possible.

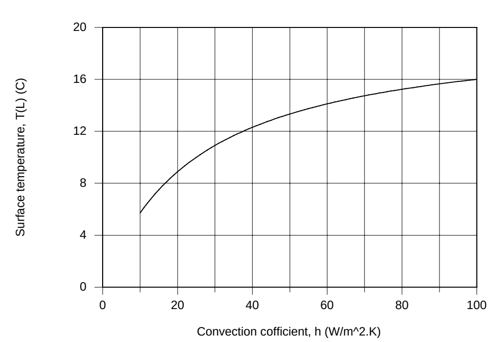
(b) With T(0) = 0°C and T_∞ = 20°C, the temperature at the surface x = L, T(L), can be determined from an overall energy balance on the wall as shown above in the schematic,

$$\dot{E}_{in} - \dot{E}_{out} = 0 \qquad q''_x(0) - q''_{cv} = 0 \qquad -k\frac{T(L)-T(0)}{L} - h\left[T(L) - T_\infty\right] = 0$$

$$-4.5\,W/m\cdot K\left[T(L) - 0^\circ C\right]/0.18\,m - 30\,W/m^2\cdot K\left[T(L) - 20^\circ C\right] = 0$$

$$T(L) = 10.9^\circ C$$ <

Using this same analysis, T(L) as a function of the convection coefficient can be determined and plotted. We don't expect T(L) to be linearly dependent upon h. Note that as h increases to larger values, T(L) approaches T_∞. To what value will T(L) approach as h decreases?

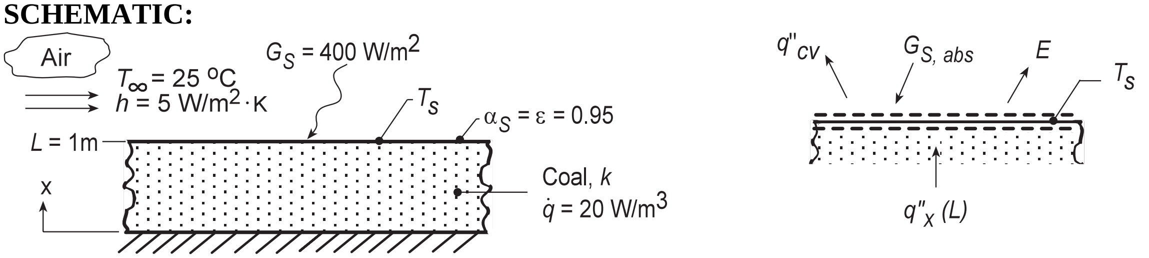


PROBLEM 2.42

KNOWN: Coal pile of prescribed depth experiencing uniform volumetric generation with convection, absorbed irradiation and emission on its upper surface.

FIND: (a) The appropriate form of the heat diffusion equation (HDE) and whether the prescribed temperature distribution satisfies this HDE; conditions at the bottom of the pile, x = 0; sketch of the temperature distribution with labeling of key features; (b) Expression for the conduction heat rate at the location x = L; expression for the surface temperature T_s based upon a surface energy balance at x = L; evaluate T_S and T(0) for the prescribed conditions; (c) Based upon typical daily averages for G_S and h, compute and plot T_S and T(0) for (1) h = 5 $W/m^2 \cdot K$ with $50 \le G_S \le 500\ W/m^2$, (2) G_S = 400 W/m^2 with $5 \le h \le 50\ W/m^2 \cdot K$.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Uniform volumetric heat generation, (3) Constant properties, (4) Negligible irradiation from the surroundings, and (5) Steady-state conditions.

PROPERTIES: *Table A.3*, Coal (300K): k = 0.26 W/m.K

ANALYSIS: (a) For one-dimensional, steady-state conduction with uniform volumetric heat generation and constant properties the heat diffusion equation (HDE) follows from Eq. 2.22,

$$\frac{d}{dx}\left(\frac{dT}{dx}\right)+\frac{\dot{q}}{k}=0 \qquad (1)$$ <

Substituting the temperature distribution into the HDE, Eq. (1),

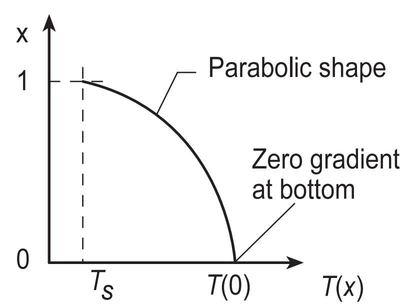
$$T(x)=T_S+\frac{\dot{q}L^2}{2k}\left(1-\frac{x^2}{L^2}\right) \qquad \frac{d}{dx}\left[0+\frac{\dot{q}L^2}{2k}\left(0-\frac{2x}{L^2}\right)\right]+\frac{\dot{q}}{k}?=?0 \qquad (2,3)$$

we find that it does indeed satisfy the HDE for all values of x. <

From Eq. (2), note that the temperature distribution must be quadratic, with maximum value at x = 0. At x = 0, the heat flux is

$$q''_x(0)=-k\left.\frac{dT}{dx}\right)_{x=0}=-k\left[0+\frac{\dot{q}L^2}{2k}\left(0-\frac{2x}{L^2}\right)\right]_{x=0}=0$$

so that the gradient at x = 0 is zero. Hence, the bottom is insulated.



(b) From an overall energy balance on the pile, the conduction heat flux at the surface must be

$$q''_x(L)=\dot{E}''_g=\dot{q}L$$ <

Continued...

PROBLEM 2.42 (Cont.)

From a surface energy balance per unit area shown in the schematic above,

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = 0 \qquad q''_x(L) - q''_{conv} + G_{S,abs} - E = 0$$

$$\dot{q}L - h\left(T_S - T_\infty\right) + 0.95G_S - \varepsilon\sigma T_S^4 = 0 \qquad (4)$$

$$20\,W/m^3 \times 1\,m - 5\,W/m^2\cdot K\left(T_S - 298\,K\right) + 0.95 \times 400\,W/m^2 - 0.95 \times 5.67 \times 10^{-8}\,W/m^2\cdot K^4 T_S^4 = 0$$

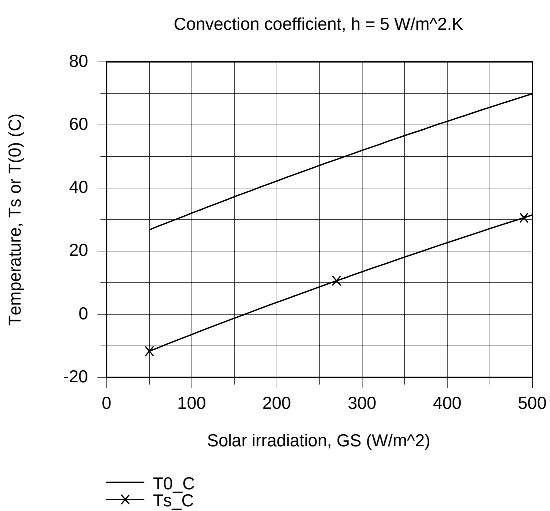
$$T_S = 295.7\,K = 22.7°C$$ <

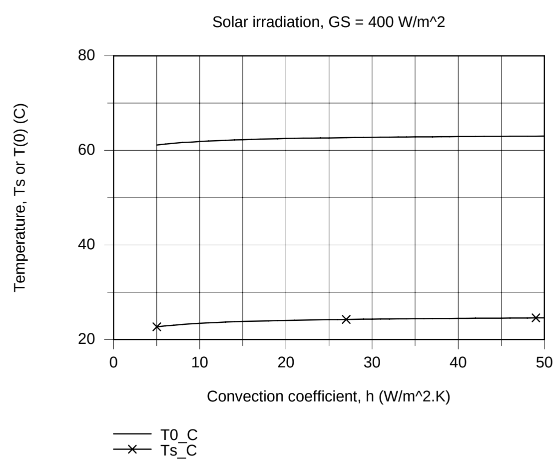
From Eq. (2) with x = 0, find

$$T(0) = T_S + \frac{\dot{q}L^2}{2k} = 22.7°C + \frac{20\,W/m^3 \times (1m)^2}{2 \times 0.26\,W/m\cdot K} = 61.1°C \qquad (5)$$ <

where the thermal conductivity for coal was obtained from Table A.3.

(c) Two plots are generated using Eq. (4) and (5) for T_s and T(0), respectively; (1) with h = 5 W/m^2·K for $50 \le G_S \le 500$ W/m^2 and (2) with G_S = 400 W/m^2 for $5 \le h \le 50$ W/m^2·K.





From the T vs. h plot with G_S = 400 W/m^2, note that the convection coefficient does not have a major influence on the surface or bottom coal pile temperatures. From the T vs. G_S plot with h = 5 W/m^2·K, note that the solar irradiation has a very significant effect on the temperatures. The fact that T_s is less than the ambient air temperature, T_∞, and, in the case of very low values of G_S, below freezing, is a consequence of the large magnitude of the emissive power E.

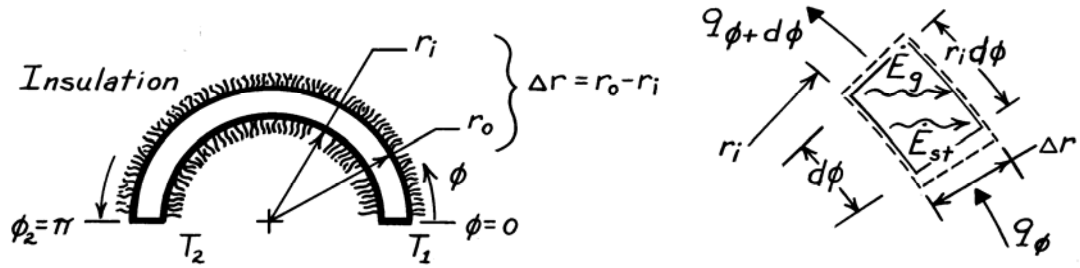
COMMENTS: In our analysis we ignored irradiation from the sky, an environmental radiation effect you'll consider in Chapter 12. Treated as large isothermal surroundings, $G_{sky} = \sigma T_{sky}^4$ where T_{sky} = -30°C for very clear conditions and nearly air temperature for cloudy conditions. For low G_S conditions we should consider G_{sky}, the effect of which will be to predict higher values for T_s and T(0).

PROBLEM 2.43

KNOWN: Cylindrical system with negligible temperature variation in the r,z directions.

FIND: (a) Heat equation beginning with a properly defined control volume, (b) Temperature distribution $T(\phi)$ for steady-state conditions with no internal heat generation and constant properties, (c) Heat rate for Part (b) conditions.

SCHEMATIC:



ASSUMPTIONS: (1) T is independent of r,z, (2) $\Delta r = (r_o - r_i) << r_i$.

ANALYSIS: (a) Define the control volume as $V = r_i d\phi \cdot \Delta r \cdot L$ where L is length normal to page. Apply the conservation of energy requirement, Eq. 1.12c,

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = \dot{E}_{st} \qquad q_\phi - q_{\phi+d\phi} + \dot{q}V = \rho V c \frac{\partial T}{\partial t} \qquad (1,2)$$

where $$q_\phi = -k(\Delta r \cdot L)\frac{\partial T}{r_i \partial \phi} \qquad q_{\phi+d\phi} = q_\phi + \frac{\partial}{\partial \phi}(q_\phi)d\phi. \qquad (3,4)$$

Eqs. (3) and (4) follow from Fourier's law, Eq. 2.1, and from Eq. 2.25, respectively. Combining Eqs. (3) and (4) with Eq. (2) and canceling like terms, find

$$\frac{1}{r_i^2}\frac{\partial}{\partial \phi}\left(k\frac{\partial T}{\partial \phi}\right) + \dot{q} = \rho c \frac{\partial T}{\partial t}. \qquad (5)$$ <

Since temperature is independent of r and z, this form agrees with Eq. 2.26.

(b) For steady-state conditions with $\dot{q} = 0$, the heat equation, (5), becomes

$$\frac{d}{d\phi}\left[k\frac{dT}{d\phi}\right] = 0. \qquad (6)$$

With constant properties, it follows that $dT/d\phi$ is constant which implies $T(\phi)$ is linear in ϕ. That is,

$$\frac{dT}{d\phi} = \frac{T_2 - T_1}{\phi_2 - \phi_1} = +\frac{1}{\pi}(T_2 - T_1) \quad \text{or} \quad T(\phi) = T_1 + \frac{1}{\pi}(T_2 - T_1)\phi. \qquad (7,8)$$ <

(c) The heat rate for the conditions of Part (b) follows from Fourier's law, Eq. (3), using the temperature gradient of Eq. (7). That is,

$$q_\phi = -k(\Delta r \cdot L)\frac{1}{r_i}\left[+\frac{1}{\pi}(T_2 - T_1)\right] = -k\left[\frac{r_o - r_i}{\pi r_i}\right]L(T_2 - T_1). \qquad (9)$$ <

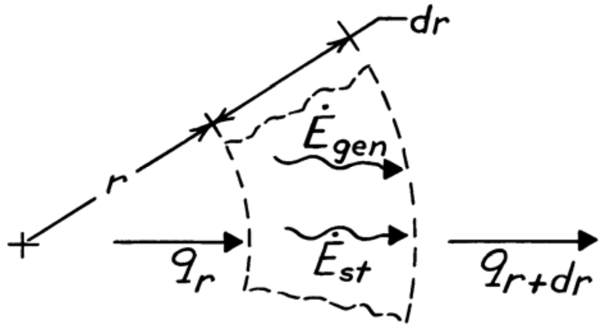
COMMENTS: Note the expression for the temperature gradient in Fourier's law, Eq. (3), is $\partial T / r_i \partial \phi$ not $\partial T / \partial \phi$. For the conditions of Parts (b) and (c), note that q_ϕ is independent of ϕ; this is first indicated by Eq. (6) and confirmed by Eq. (9).

PROBLEM 2.44

KNOWN: Heat diffusion with internal heat generation for one-dimensional cylindrical, radial coordinate system.

FIND: Heat diffusion equation.

SCHEMATIC:



ASSUMPTIONS: (1) Homogeneous medium.

ANALYSIS: Control volume has volume, $V = A_r \cdot dr = 2\pi r \cdot dr \cdot 1$, with unit thickness normal to page. Using the conservation of energy requirement, Eq. 1.12c,

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = \dot{E}_{st}$$

$$q_r - q_{r+dr} + \dot{q}V = \rho V c_p \frac{\partial T}{\partial t}.$$

Fourier's law, Eq. 2.1, for this one-dimensional coordinate system is

$$q_r = -kA_r \frac{\partial T}{\partial r} = -k \times 2\pi r \cdot 1 \times \frac{\partial T}{\partial r}.$$

At the outer surface, r + dr, the conduction rate is

$$q_{r+dr} = q_r + \frac{\partial}{\partial r}(q_r)dr = q_r + \frac{\partial}{\partial r}\left[-k \cdot 2\pi r \cdot \frac{\partial T}{\partial r}\right]dr.$$

Hence, the energy balance becomes

$$q_r - \left[q_r + \frac{\partial}{\partial r}\left[-k2\pi r \frac{\partial T}{\partial r}\right]dr\right] + \dot{q} \cdot 2\pi r dr = \rho \cdot 2\pi r dr \cdot c_p \frac{\partial T}{\partial t}$$

Dividing by the factor 2πr dr, we obtain

$$\frac{1}{r}\frac{\partial}{\partial r}\left[kr\frac{\partial T}{\partial r}\right] + \dot{q} = \rho c_p \frac{\partial T}{\partial t}.$$ <

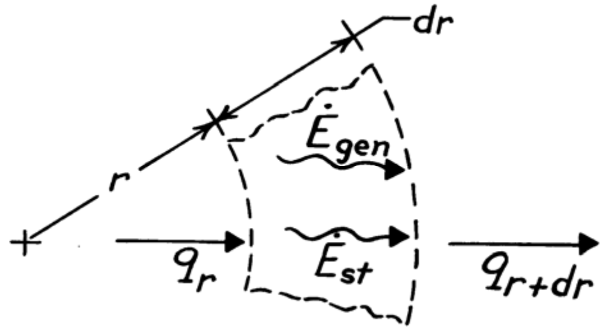
COMMENTS: (1) Note how the result compares with Eq. 2.26 when the terms for the ϕ,z coordinates are eliminated. (2) Recognize that we did not require $\dot{q}$ and k to be independent of r.

PROBLEM 2.45

KNOWN: Heat diffusion with internal heat generation for one-dimensional spherical, radial coordinate system.

FIND: Heat diffusion equation.

SCHEMATIC:



ASSUMPTIONS: (1) Homogeneous medium.

ANALYSIS: Control volume has the volume, $V = A_r \cdot dr = 4\pi r^2 dr$. Using the conservation of energy requirement, Eq. 1.12c,

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = \dot{E}_{st}$$

$$q_r - q_{r+dr} + \dot{q}V = \rho V c_p \frac{\partial T}{\partial t}.$$

Fourier's law, Eq. 2.1, for this coordinate system has the form

$$q_r = -kA_r \frac{\partial T}{\partial r} = -k \cdot 4\pi r^2 \cdot \frac{\partial T}{\partial r}.$$

At the outer surface, r + dr, the conduction rate is

$$q_{r+dr} = q_r + \frac{\partial}{\partial r}(q_r)dr = q_r + \frac{\partial}{\partial r}\left[-k \cdot 4\pi r^2 \cdot \frac{\partial T}{\partial r}\right]dr.$$

Hence, the energy balance becomes

$$q_r - \left[q_r + \frac{\partial}{\partial r}\left[-k \cdot 4\pi r^2 \cdot \frac{\partial T}{\partial r}\right]dr\right] + \dot{q} \cdot 4\pi r^2 dr = \rho \cdot 4\pi r^2 dr \cdot c_p \frac{\partial T}{\partial t}.$$

Dividing by the factor $4\pi r^2 dr$, we obtain

$$\frac{1}{r^2}\frac{\partial}{\partial r}\left[kr^2 \frac{\partial T}{\partial r}\right] + \dot{q} = \rho c_p \frac{\partial T}{\partial t}.$$ <

COMMENTS: (1) Note how the result compares with Eq. 2.29 when the terms for the θ,ϕ directions are eliminated.

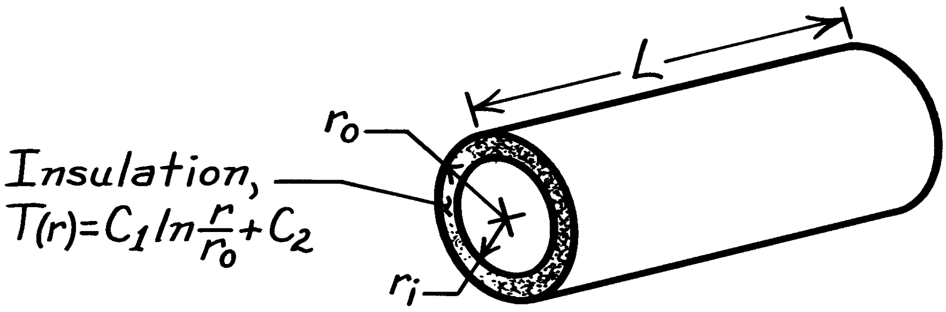
(2) Recognize that we did not require $\dot{q}$ and k to be independent of the coordinate r.

PROBLEM 2.46

KNOWN: Temperature distribution in steam pipe insulation.

FIND: Whether conditions are steady-state or transient. Manner in which heat flux and heat rate vary with radius.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in r, (2) Constant properties.

ANALYSIS: From Equation 2.26, the heat equation reduces to

$$\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial T}{\partial r}\right) = \frac{1}{\alpha}\frac{\partial T}{\partial t}.$$

Substituting for T(r),

$$\frac{1}{\alpha}\frac{\partial T}{\partial t} = \frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{C_1}{r}\right) = 0.$$

Hence, steady-state conditions exist. <

From Equation 2.23, the radial component of the heat flux is

$$q_r'' = -k\frac{\partial T}{\partial r} = -k\frac{C_1}{r}.$$

Hence, q_r'' decreases with increasing $r\left(q_r''\alpha 1/r\right)$. <

At any radial location, the heat rate is

$$q_r = 2\pi r L q_r'' = -2\pi k C_1 L$$

Hence, q_r is independent of r. <

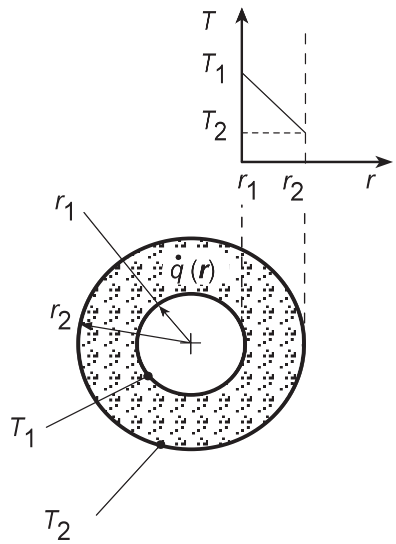
COMMENTS: The requirement that q_r is invariant with r is consistent with the energy conservation requirement. If q_r is constant, the flux must vary inversely with the area perpendicular to the direction of heat flow. Hence, q_r'' varies inversely with r.

PROBLEM 2.47

KNOWN: Inner and outer radii and surface temperatures of a long circular tube with internal energy generation.

FIND: Conditions for which a linear radial temperature distribution may be maintained.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, steady-state conduction, (2) Constant properties.

ANALYSIS: For the assumed conditions, Eq. 2.26 reduces to

$$\frac{k}{r}\frac{d}{dr}\left(r\frac{dT}{dr}\right)+\dot{q}=0$$

If $\dot{q}$ = 0 or $\dot{q}$ = constant, it is clearly impossible to have a linear radial temperature distribution. However, we may use the heat equation to infer a special form of $\dot{q}$ (r) for which dT/dr is a constant (call it C_1). It follows that

$$\frac{k}{r}\frac{d}{dr}\left(r\,C_1\right)+\dot{q}=0$$

$$\dot{q}=-\frac{C_1 k}{r} \qquad <$$

where $C_1 = (T_2 - T_1)/(r_2 - r_1)$. Hence, if the generation rate varies inversely with radial location, the radial temperature distribution is linear.

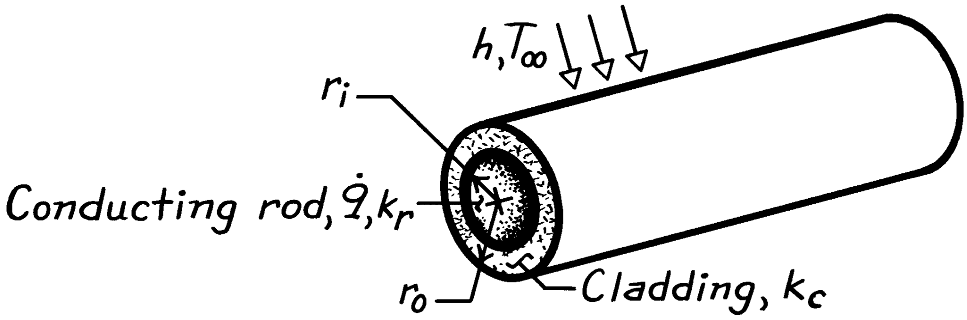
COMMENTS: Conditions for which $\dot{q} \propto (1/r)$ would be unusual.

PROBLEM 2.48

KNOWN: Radii and thermal conductivity of conducting rod and cladding material. Volumetric rate of thermal energy generation in the rod. Convection conditions at outer surface.

FIND: Heat equations and boundary conditions for rod and cladding.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in r, (3) Constant properties.

ANALYSIS: From Equation 2.26, the appropriate forms of the heat equation are

Conducting Rod:

$$\frac{k_r}{r}\frac{d}{dr}\left(r\frac{dT_r}{dr}\right)+\dot{q}=0$$ <

Cladding:

$$\frac{d}{dr}\left(r\frac{dT_c}{dr}\right)=0.$$ <

Appropriate boundary conditions are:

(a) $dT_r / dr|_{r=0} = 0$ <

(b) $T_r(r_i) = T_c(r_i)$ <

(c) $k_r \frac{dT_r}{dr}|_{r_i} = k_c \frac{dT_c}{dr}|_{r_i}$ <

(d) $-k_c \frac{dT_c}{dr}|_{r_o} = h\left[T_c(r_o) - T_\infty\right]$ <

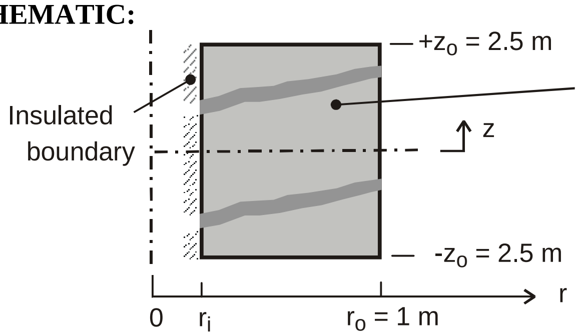
COMMENTS: Condition (a) corresponds to symmetry at the centerline, while the interface conditions at $r = r_i$ (b,c) correspond to requirements of thermal equilibrium and conservation of energy. Condition (d) results from conservation of energy at the outer surface. Note that contact resistance at the interface between the rod and cladding has been neglected.

PROBLEM 2.49

KNOWN: Steady-state temperature distribution for hollow cylindrical solid with volumetric heat generation.

FIND: (a) Determine the inner radius of the cylinder, r_i, (b) Obtain an expression for the volumetric rate of heat generation, $\dot{q}$, (c) Determine the axial distribution of the heat flux at the outer surface, $q''_r(r_o, z)$, and the heat rate at this outer surface; is the heat rate *in* or *out* of the cylinder; (d) Determine the radial distribution of the heat flux at the end faces of the cylinder, $q''_z(r, +z_o)$ and $q''_z(r, -z_o)$, and the corresponding heat rates; are the heat rates *in* or *out* of the cylinder; (e) Determine the relationship of the surface heat rates to the heat generation rate; is an overall energy balance satisfied?

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction with constant properties and volumetric heat generation.

ANALYSIS: (a) Since the inner boundary, r = r_i, is adiabatic, then $q''_r(r_i, z) = 0$. Hence the temperature gradient in the r-direction must be zero.

$$\left.\frac{\partial T}{\partial r}\right)_{r_i} = 0 + 2br_i + c/r_i + 0 = 0$$

$$r_i = +\left(-\frac{c}{2b}\right)^{1/2} = \left(-\frac{-12°C}{2 \times 150°C/m^2}\right)^{1/2} = 0.2 \text{ m} \qquad <$$

(b) To determine $\dot{q}$, substitute the temperature distribution into the heat diffusion equation, Eq. 2.26, for two-dimensional (r,z), steady-state conduction

$$\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial T}{\partial r}\right) + \frac{\partial}{\partial z}\left(\frac{\partial T}{\partial z}\right) + \frac{\dot{q}}{k} = 0$$

$$\frac{1}{r}\frac{\partial}{\partial r}\left(r\left[0 + 2br + c/r + 0\right]\right) + \frac{\partial}{\partial z}\left(0 + 0 + 0 + 2dz\right) + \frac{\dot{q}}{k} = 0$$

$$\frac{1}{r}\left[4br + 0\right] + 2d + \frac{\dot{q}}{k} = 0$$

$$\dot{q} = -k\left[4b + 2d\right] = -16\,W/m \cdot K\left[4 \times 150°C/m^2 + 2\left(-300°C/m^2\right)\right] = 0\,W/m^3 \qquad <$$

(c) The heat flux and the heat rate at the outer surface, r = r_o, may be calculated using Fourier's law.

$$q''_r(r_o, z) = -k\left.\frac{\partial T}{\partial r}\right)_{r_o} = -k\left[0 + 2br_o + c/r_o + 0\right]$$

Continued …

PROBLEM 2.49 (Cont.)

$$q_r''(r_{o,}z) = -16\,\text{W/m}\cdot\text{K}\left[2\times150°\text{C/m}^2\times1\text{ m} - 12°\text{C}/1\text{ m}\right] = -4608\,\text{W/m}^2$$ <

$$q_r(r_o) = A_r\,q_r''(r_{o,}z) \qquad \text{where} \qquad A_r = 2\pi r_o\,(2z_o)$$

$$q_r(r_o) = -4\pi\times1\text{ m}\times2.5\text{ m}\times4608\,\text{W/m}^2 = -144{,}765\,\text{W}$$ <

Note that the sign of the heat flux and heat rate in the positive r-direction is negative, and hence the heat flow is *into* the cylinder.

(d) The heat fluxes and the heat rates at end faces, z = + z_o and – z_o, may be calculated using Fourier's law. The direction of the heat rate *in* or *out* of the end face is determined by the sign of the heat flux in the positive z-direction.

At the upper end face, z = + z_o: <

$$q_z''(r,+z_o) = -k\left.\frac{\partial T}{\partial z}\right)_{z_o} = -k\left[0+0+0+2dz_o\right]$$

$$q_z''(r,+z_o) = -16\,\text{W/m}\cdot\text{K}\times2\left(-300°\text{C/m}^2\right)2.5\text{ m} = +24{,}000\,\text{W/m}^2$$ <

$$q_z(+z_o) = A_z\,q_z''(r,+z_o) \qquad \text{where} \qquad A_z = \pi\left(r_o^2 - r_i^2\right)$$

$$q_z(+z_o) = \pi\left(1^2 - 0.2^2\right)\text{m}^2\times24{,}000\,\text{W/m}^2 = +72{,}382\,\text{W}$$ <

Thus, heat flows out of the cylinder.

At the lower end face, z = - z_o: <

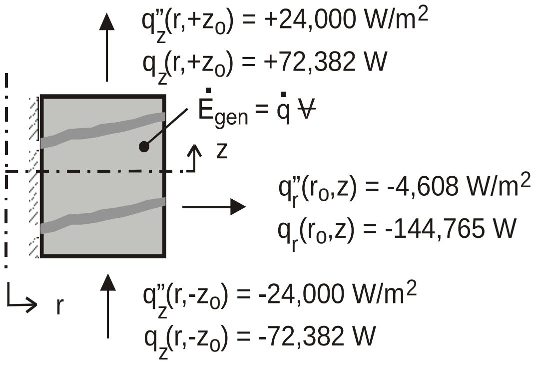
$$q_z''(r,-z_o) = -k\left.\frac{\partial T}{\partial z}\right)_{-z_o} = -k\left[0+0+0+2d(-z_o)\right]$$

$$q_z''(r,-z_o) = -16\,\text{W/m}^2\cdot\text{K}\times2\left(-300°\text{C/m}\right)\left(-2.5\text{ m}\right) = -24{,}000\,\text{W/m}^2$$ <

$$q_z(-z_o) = -72{,}382\,\text{W}$$ <

Again, heat flows out of the cylinder.

(e) The heat rates from the surfaces and the volumetric heat generation can be related through an overall energy balance on the cylinder as shown in the sketch.



Continued…

PROBLEM 2.49 (Cont.)

$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = 0$ where $\dot{E}_{gen} = \dot{q}\forall = 0$

$\dot{E}_{in} = -q_r(r_o) = -(-144,765\,W) = +144,765\,W$ <

$\dot{E}_{out} = +q_z(z_o) - q_z(-z_o) = [72,382 - (-72,382)]\,W = +144,764\,W$ <

The overall energy balance is satisfied.

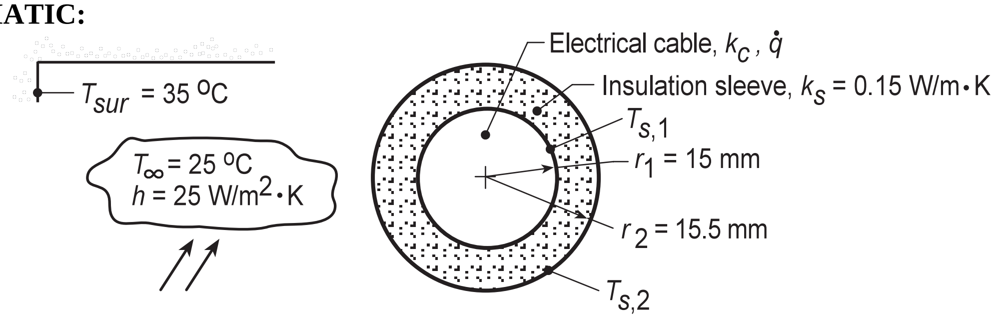
COMMENTS: When using Fourier's law, the heat flux q''_z denotes the heat flux in the positive z-direction. At a boundary, the sign of the numerical value will determine whether heat is flowing into or out of the boundary.

PROBLEM 2.50

KNOWN: An electric cable with an insulating sleeve experiences convection with adjoining air and radiation exchange with large surroundings.

FIND: (a) Verify that prescribed temperature distributions for the cable and insulating sleeve satisfy their appropriate heat diffusion equations; sketch temperature distributions labeling key features; (b) Applying Fourier's law, verify the conduction heat rate expression for the sleeve, q'_r, in terms of $T_{s,1}$ and $T_{s,2}$; apply a surface energy balance to the cable to obtain an alternative expression for q'_r in terms of $\dot{q}$ and r_1; (c) Apply surface energy balance around the outer surface of the sleeve to obtain an expression for which $T_{s,2}$ can be evaluated; (d) Determine $T_{s,1}$, $T_{s,2}$, and T_o for the specified geometry and operating conditions; and (e) Plot $T_{s,1}$, $T_{s,2}$, and T_o as a function of the outer radius for the range $15.5 \le r_2 \le 20$ mm.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, radial conduction, (2) Uniform volumetric heat generation in cable, (3) Negligible thermal contact resistance between the cable and sleeve, (4) Constant properties in cable and sleeve, (5) Surroundings large compared to the sleeve, and (6) Steady-state conditions.

ANALYSIS: (a) The appropriate forms of the heat diffusion equation (HDE) for the insulation and cable are identified. The temperature distributions are valid if they satisfy the relevant HDE.

Insulation: The temperature distribution is given as

$$T(r) = T_{s,2} + \left(T_{s,1} - T_{s,2}\right)\frac{\ln(r/r_2)}{\ln(r_1/r_2)} \tag{1}$$

and the appropriate HDE (radial coordinates, SS, $\dot{q}$ = 0), Eq. 2.26,

$$\frac{d}{dr}\left(r\frac{dT}{dr}\right) = 0$$

$$\frac{d}{dr}\left(r\left[0 + \left(T_{s,1} - T_{s,2}\right)\frac{1/r}{\ln(r_1/r_2)}\right]\right) = \frac{d}{dr}\left(\frac{T_{s,1} - T_{s,2}}{\ln(r_1/r_2)}\right) = 0$$

Hence, the temperature distribution satisfies the HDE. <

Continued...

PROBLEM 2.50 (Cont.)

Cable: The temperature distribution is given as

$$T(r) = T_{s,1} + \frac{\dot{q}r_1^2}{4k_c}\left(1 - \frac{r^2}{r_1^2}\right) \qquad (2)$$

and the appropriate HDE (radial coordinates, SS, $\dot{q}$ uniform), Eq. 2.26,

$$\frac{1}{r}\frac{d}{dr}\left(r\frac{dT}{dr}\right) + \frac{\dot{q}}{k_c} = 0$$

$$\frac{1}{r}\frac{d}{dr}\left(r\left[0 + \frac{\dot{q}r_1^2}{4k_c}\left(0 - \frac{2r}{r_1^2}\right)\right]\right) + \frac{\dot{q}}{k_c} = 0$$

$$\frac{1}{r}\frac{d}{dr}\left(-\frac{\dot{q}r_1^2}{4k_c}\frac{2r^2}{r_1^2}\right) + \frac{\dot{q}}{k_c} = 0$$

$$\frac{1}{r}\left(-\frac{\dot{q}r_1^2}{4k_c}\frac{4r}{r_1^2}\right) + \frac{\dot{q}}{k_c} = 0$$

Hence the temperature distribution satisfies the HDE. <

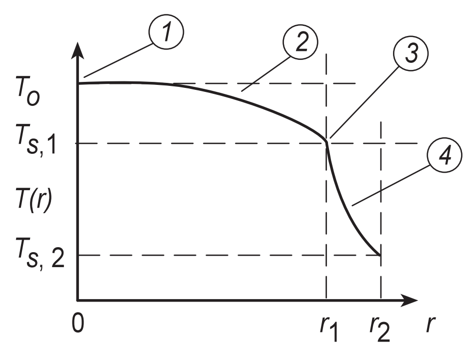
The temperature distributions in the cable, $0 \le r \le r_1$, and sleeve, $r_1 \le r \le r_2$, and their key features are as follows:

(1) Zero gradient, symmetry condition,

(2) Increasing gradient with increasing radius, r, because of $\dot{q}$,

(3) Discontinuous gradient of T(r) across cable-sleeve interface because of different thermal conductivities,

(4) Decreasing gradient with increasing radius, r, since heat rate is constant.



(b) Using Fourier's law for the radial-cylindrical coordinate, the heat rate through the *insulation* (sleeve) per unit length is

$$q'_r = -kA'_r\frac{dT}{dr} = -k2\pi r\frac{dT}{dr}$$ <

and substituting for the temperature distribution, Eq. (1),

$$q'_r = -k_s 2\pi r\left[0 + \left(T_{s,1} - T_{s,2}\right)\frac{1/r}{\ln(r_1/r_2)}\right] = 2\pi k_s\frac{\left(T_{s,1} - T_{s,2}\right)}{\ln(r_2/r_1)} \qquad (3)$$ <

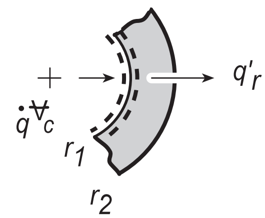
Applying an energy balance to a control surface placed around the cable,

Continued...

PROBLEM 2.50 (Cont.)

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$\dot{q}\forall_c - q'_r = 0$$



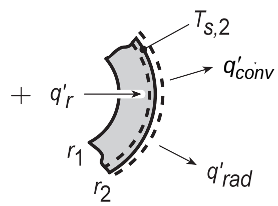
where $\dot{q}\forall_c$ represents the dissipated electrical power in the cable

$$\dot{q}\left(\pi r_1^2\right) - q'_r = 0 \qquad \text{or} \qquad q'_r = \pi \dot{q} r_1^2 \qquad (4) <$$

(c) Applying an energy balance to a control surface placed around the outer surface of the sleeve,

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$q'_r - q'_{conv} - q'_{rad} = 0$$



$$\pi \dot{q} r_1^2 - h\left(2\pi r_2\right)\left(T_{s,2} - T_\infty\right) - \varepsilon\left(2\pi r_2\right)\sigma\left(T_{s,2}^4 - T_{sur}^4\right) = 0 \qquad (5) <$$

This relation can be used to determine $T_{s,2}$ in terms of the variables $\dot{q}$, r_1, r_2, h, T_∞, ε and T_{sur}.

(d) Consider a cable-sleeve system with the following prescribed conditions:

r_1 = 15 mm	k_c = 200 W/m·K	h = 25 W/m^2·K	ε = 0.9
r_2 = 15.5 mm	k_s = 0.15 W/m·K	T_∞ = 25°C	T_{sur} = 35°C

For 250 A with R'_e = 0.005 Ω/m, the volumetric heat generation rate is

$$\dot{q} = I^2 R'_e / \forall_c = I^2 R'_e \Big/ \left(\pi r_1^2\right)$$

$$\dot{q} = (250\,\text{A})^2 \times 0.005\,\Omega/\text{m} \Big/ \left(\pi \times 0.015^2\,\text{m}^2\right) = 4.42 \times 10^5\ \text{W/m}^3$$

Substituting numerical values in appropriate equations, we can evaluate $T_{s,1}$, $T_{s,2}$ and T_o.

Sleeve outer surface temperature, $T_{s,2}$: Using Eq. (5),

$$\pi \times 4.42 \times 10^5\ \text{W/m}^3 \times (0.015\text{m})^2 - 25\ \text{W/m}^2 \cdot \text{K} \times (2\pi \times 0.0155\text{m})\left(T_{s,2} - 298\text{K}\right)$$
$$-0.9 \times (2\pi \times 0.0155\text{m}) \times 5.67 \times 10^{-8}\ \text{W/m}^2 \cdot \text{K}^4 \left(T_{s,2}^4 - 308^4\right)\text{K}^4 = 0$$

$$T_{s,2} = 395\,\text{K} = 122^\circ\text{C} \qquad <$$

Sleeve-cable interface temperature, $T_{s,1}$: Using Eqs. (3) and (4), with $T_{s,2}$ = 395 K,

Continued...

PROBLEM 2.50 (Cont.)

$$\pi \dot{q} r_1^2 = 2\pi k_s \frac{\left(T_{s,1} - T_{s,2}\right)}{\ln\left(r_2/r_1\right)}$$

$$\pi \times 4.42\times10^5\ W/m^3 \times \left(0.015\,m\right)^2 = 2\pi\times0.15\,W/m\cdot K\,\frac{\left(T_{s,1} - 395\,K\right)}{\ln\left(15.5/15.0\right)}$$

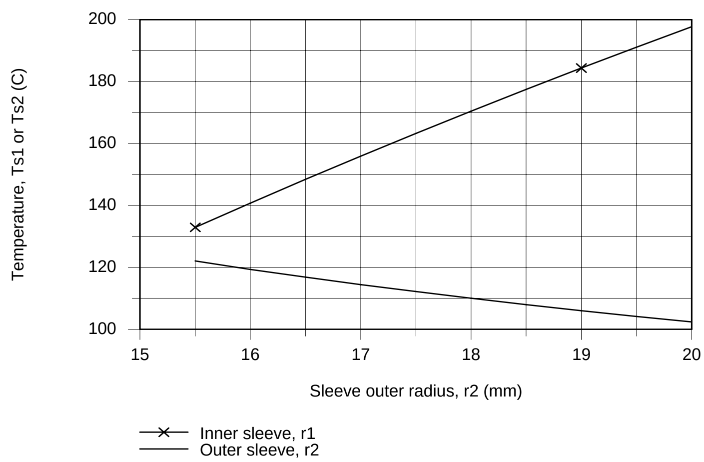
$$T_{s,1} = 406\,K = 133^\circ C$$ <

Cable centerline temperature, T_o: Using Eq. (2) with $T_{s,1}$ = 133°C,

$$T_o = T(0) = T_{s,1} + \frac{\dot{q} r_1^2}{4k_c}$$

$$T_o = 133^\circ C + 4.42\times10^5\ W/m^3 \times \left(0.015\,m\right)^2 \Big/ \left(4\times200\,W/m\cdot K\right) = 133.1^\circ C$$ <

(e) With all other conditions remaining the same, the relations of part (d) can be used to calculate T_o, $T_{s,1}$ and $T_{s,2}$ as a function of the sleeve outer radius r_2 for the range $15.5 \le r_2 \le 20$ mm.



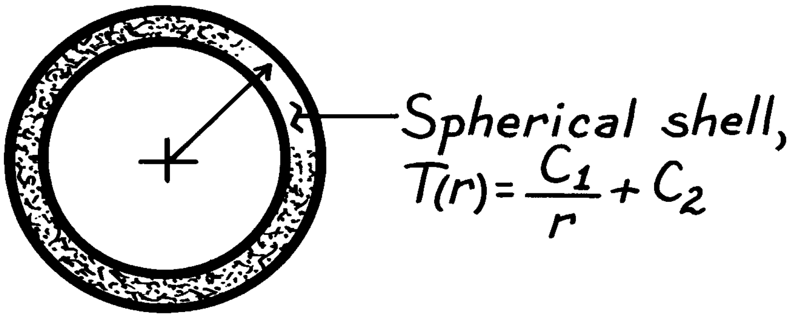
On the plot above T_o would show the same behavior as $T_{s,1}$ since the temperature rise between cable center and its surface is 0.12°C. With increasing r_2, we expect $T_{s,2}$ to decrease since the heat flux decreases with increasing r_2. We expect $T_{s,1}$ to increase with increasing r_2 since the thermal resistance of the sleeve increases.

PROBLEM 2.51

KNOWN: Temperature distribution in a spherical shell.

FIND: Whether conditions are steady-state or transient. Manner in which heat flux and heat rate vary with radius.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in r, (2) Constant properties.

ANALYSIS: From Equation 2.29, the heat equation reduces to

$$\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{\partial T}{\partial r}\right)=\frac{1}{\alpha}\frac{\partial T}{\partial t}.$$

Substituting for T(r),

$$\frac{1}{\alpha}\frac{\partial T}{\partial t}=-\frac{1}{r^2}\frac{\partial}{\partial r}\left(r^2\frac{C_1}{r^2}\right)=0.$$

Hence, steady-state conditions exist. <

From Equation 2.28, the radial component of the heat flux is

$$q''_r=-k\frac{\partial T}{\partial r}=k\frac{C_1}{r^2}.$$

Hence, q''_r decreases with increasing $r^2\left(q''_r \propto 1/r^2\right)$. <

At any radial location, the heat rate is

$$q_r=4\pi r^2 q''_r=4\pi k C_1.$$

Hence, q_r is independent of r. <

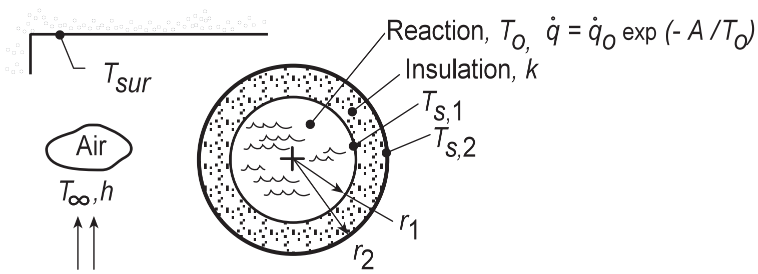
COMMENTS: The fact that q_r is independent of r is consistent with the energy conservation requirement. If q_r is constant, the flux must vary inversely with the area perpendicular to the direction of heat flow. Hence, q''_r varies inversely with r^2.

PROBLEM 2.52

KNOWN: Spherical container with an exothermic reaction enclosed by an insulating material whose outer surface experiences convection with adjoining air and radiation exchange with large surroundings.

FIND: (a) Verify that the prescribed temperature distribution for the insulation satisfies the appropriate form of the heat diffusion equation; sketch the temperature distribution and label key features; (b) Applying Fourier's law, verify the conduction heat rate expression for the insulation layer, q_r, in terms of $T_{s,1}$ and $T_{s,2}$; apply a surface energy balance to the container and obtain an alternative expression for q_r in terms of $\dot{q}$ and r_1; (c) Apply a surface energy balance around the outer surface of the insulation to obtain an expression to evaluate $T_{s,2}$; (d) Determine $T_{s,2}$ for the specified geometry and operating conditions; (e) Compute and plot the variation of $T_{s,2}$ as a function of the outer radius for the range $201 \le r_2 \le 210$ mm; explore approaches for reducing $T_{s,2} \le$ 45°C to eliminate potential risk for burn injuries to personnel.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, radial spherical conduction, (2) Isothermal reaction in container so that $T_o = T_{s,1}$, (2) Negligible thermal contact resistance between the container and insulation, (3) Constant properties in the insulation, (4) Surroundings large compared to the insulated vessel, and (5) Steady-state conditions.

ANALYSIS: The appropriate form of the heat diffusion equation (HDE) for the insulation follows from Eq. 2.29,

$$\frac{1}{r^2}\frac{d}{dr}\left(r^2\frac{dT}{dr}\right) = 0 \qquad (1) \quad <$$

The temperature distribution is given as

$$T(r) = T_{s,1} - \left(T_{s,1} - T_{s,2}\right)\left[\frac{1-(r_1/r)}{1-(r_1/r_2)}\right] \qquad (2)$$

Substitute T(r) into the HDE to see if it is satisfied:

$$\frac{1}{r^2}\frac{d}{dr}\left(r^2\left[0-\left(T_{s,1}-T_{s,2}\right)\frac{0+\left(r_1/r^2\right)}{1-(r_1/r_2)}\right]\right) = 0$$

$$\frac{1}{r^2}\frac{d}{dr}\left(+\left(T_{s,1}-T_{s,2}\right)\frac{r_1}{1-(r_1/r_2)}\right) = 0 \quad <$$

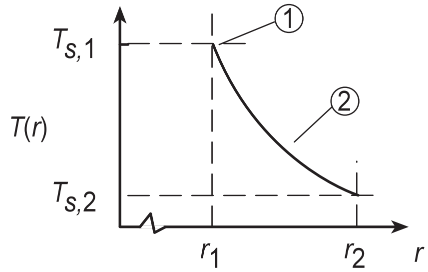
and since the expression in parenthesis is independent of r, T(r) does indeed satisfy the HDE. The temperature distribution in the insulation and its key features are as follows:

Continued...

PROBLEM 2.52 (Cont.)

(1) $T_{s,1} > T_{s,2}$

(2) Decreasing gradient with increasing radius, r, since the heat rate is constant through the insulation.



(b) Using Fourier's law for the radial-spherical coordinate, the heat rate through the insulation is

$$q_r = -kA_r \frac{dT}{dr} = -k\left(4\pi r^2\right)\frac{dT}{dr}$$ <

and substituting for the temperature distribution, Eq. (2),

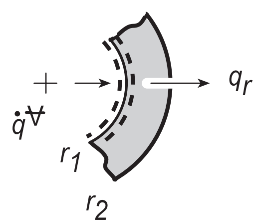
$$q_r = -4k\pi r^2 \left[0 - \left(T_{s,1} - T_{s,2}\right)\frac{0 + \left(r_1/r^2\right)}{1 - \left(r_1/r_2\right)}\right]$$

$$q_r = \frac{4\pi k\left(T_{s,1} - T_{s,2}\right)}{\left(1/r_1\right) - \left(1/r_2\right)} \quad (3)$$ <

Applying an energy balance to a control surface about the container at r = r_1,

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$\dot{q}\forall - q_r = 0$$



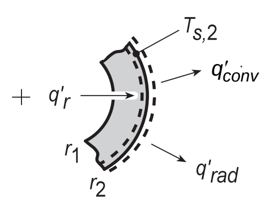
where $\dot{q}\forall$ represents the generated heat in the container,

$$q_r = (4/3)\pi r_1^3 \dot{q} \quad (4)$$ <

(c) Applying an energy balance to a control surface placed around the outer surface of the insulation,

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$q_r - q_{conv} - q_{rad} = 0$$



$$q_r - hA_s\left(T_{s,2} - T_\infty\right) - \varepsilon A_s \sigma\left(T_{s,2}^4 - T_{sur}^4\right) = 0 \quad (5)$$ <

Continued...

PROBLEM 2.52 (Cont.)

where

$$A_s = 4\pi r_2^2 \tag{6}$$

These relations can be used to determine $T_{s,2}$ in terms of the variables $\dot{q}$, r_1, r_2, h, T_∞, ε and T_{sur}.

(d) Consider the reactor system operating under the following conditions:

r_1 = 200 mm	h = 5 W/m^2·K	ε = 0.9
r_2 = 208 mm	T_∞ = 25°C	T_{sur} = 35°C
k = 0.05 W/m·K		

The heat generated by the exothermic reaction provides for a volumetric heat generation rate,

$$\dot{q} = \dot{q}_o \exp(-A/T_o) \qquad q_o = 5000\,\text{W/m}^3 \qquad A = 75\,\text{K} \tag{7}$$

where the temperature of the reaction is that of the inner surface of the insulation, $T_o = T_{s,1}$. The following system of equations will determine the operating conditions for the reactor.

Conduction rate equation, insulation, Eq. (3),

$$q_r = \frac{4\pi \times 0.05\,\text{W/m}\cdot\text{K}\left(T_{s,1} - T_{s,2}\right)}{\left(1/0.200\,\text{m} - 1/0.208\,\text{m}\right)} \tag{8}$$

Heat generated in the reactor, Eqs. (4) and (7),

$$q_r = 4/3\,\pi\,(0.200\,\text{m})^3\,\dot{q} \tag{9}$$

$$\dot{q} = 5000\,\text{W/m}^3 \exp\left(-75\,\text{K}/T_{s,1}\right) \tag{10}$$

Surface energy balance, insulation, Eqs. (5) and (6),

$$q_r - 5\,\text{W/m}^2\cdot\text{K}\,A_s\left(T_{s,2} - 298\,\text{K}\right) - 0.9 A_s\, 5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left(T_{s,2}^4 - (308\,\text{K})^4\right) = 0 \tag{11}$$

$$A_s = 4\pi\,(0.208\,\text{m})^2 \tag{12}$$

Solving these equations simultaneously, find that

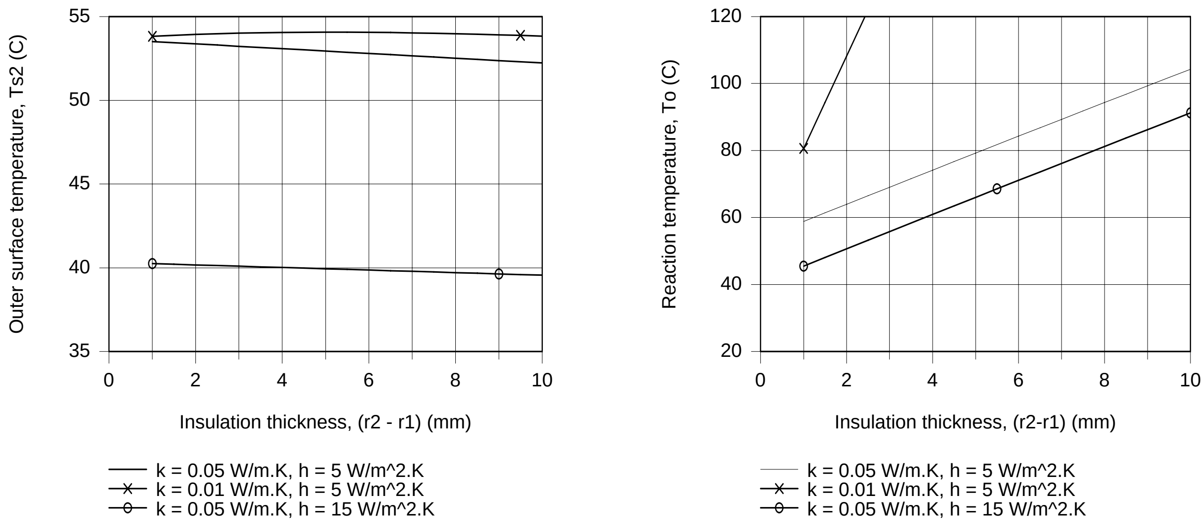
$$T_{s,1} = 94.3^\circ\text{C} \qquad T_{s,2} = 52.5^\circ\text{C}$$ <

That is, the reactor will be operating at $T_o = T_{s,1}$ = 94.3°C, very close to the desired 95°C operating condition.

(e) Using the above system of equations, Eqs. (8)-(12), we have explored the effects of changes in the convection coefficient, h, and the insulation thermal conductivity, k, as a function of insulation thickness, $t = r_2 - r_1$.

Continued...

PROBLEM 2.52 (Cont.)



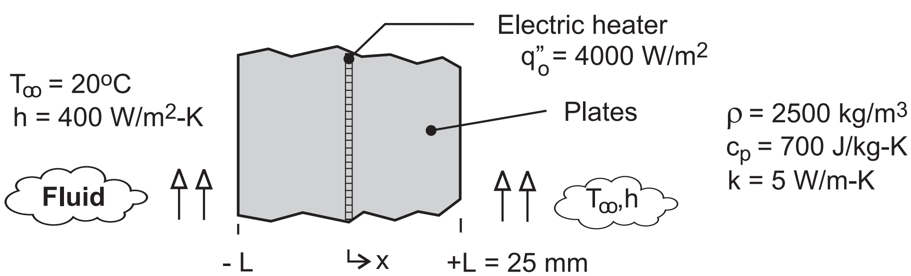
In the $T_{s,2}$ vs. $(r_2 - r_1)$ plot, note that decreasing the thermal conductivity from 0.05 to 0.01 W/m·K slightly increases $T_{s,2}$ while increasing the convection coefficient from 5 to 15 $W/m^2 \cdot K$ markedly decreases $T_{s,2}$. Insulation thickness only has a minor effect on $T_{s,2}$ for either option. In the T_o vs. $(r_2 - r_1)$ plot, note that, for all the options, the effect of increased insulation is to increase the reaction temperature. With k = 0.01 W/m·K, the reaction temperature increases beyond 95°C with less than 2 mm insulation. For the case with h = 15 $W/m^2 \cdot K$, the reaction temperature begins to approach 95°C with insulation thickness around 10 mm. We conclude that by selecting the proper insulation thickness and controlling the convection coefficient, the reaction could be operated around 95°C such that the outer surface temperature would not exceed 45°C.

PROBLEM 2.53

KNOWN: Thin electrical heater dissipating 4000 W/m^2 sandwiched between two 25-mm thick plates whose surfaces experience convection.

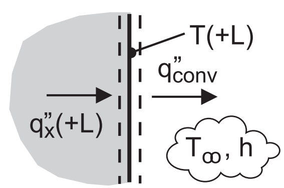
FIND: (a) On T-x coordinates, sketch the steady-state temperature distribution for $-L \le x \le +L$; calculate values for the surfaces x = L and the mid-point, x = 0; label this distribution as Case 1 and explain key features; (b) Case 2: sudden loss of coolant causing existence of adiabatic condition on the x = +L surface; sketch temperature distribution on same T-x coordinates as part (a) and calculate values for x = 0, ± L; explain key features; (c) Case 3: further loss of coolant and existence of adiabatic condition on the x = - L surface; situation goes undetected for 15 minutes at which time power to the heater is deactivated; determine the eventual ($t \to \infty$) uniform, steady-state temperature distribution; sketch temperature distribution on same T-x coordinates as parts (a,b); and (d) On T-t coordinates, sketch the temperature-time history at the plate locations x = 0, ± L during the transient period between the steady-state distributions for Case 2 and Case 3; at what location and when will the temperature in the system achieve a maximum value?

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) No internal volumetric generation in plates, and (3) Negligible thermal resistance between the heater surfaces and the plates.

ANALYSIS: (a) Since the system is symmetrical, the heater power results in equal conduction fluxes through the plates. By applying a surface energy balance on the surface x = +L as shown in the schematic, determine the temperatures at the mid-point, x = 0, and the exposed surface, x + L.



$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$q''_x(+L) - q''_{conv} = 0 \qquad \text{where} \qquad q''_x(+L) = q''_o / 2$$

$$q''_o / 2 - h\left[T(+L) - T_\infty\right] = 0$$

$$T_1(+L) = q''_o / 2h + T_\infty = 4000\,W/m^2 / \left(2 \times 400\,W/m^2 \cdot K\right) + 20°C = 25°C \qquad <$$

From Fourier's law for the conduction flux through the plate, find T(0).

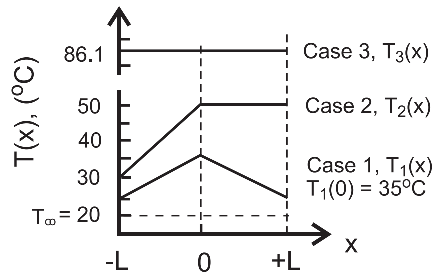
$$q''_x = q''_o / 2 = k\left[T(0) - T(+L)\right]/L$$

$$T_1(0) = T_1(+L) + q''_o L / 2k = 25°C + 4000\,W/m^2 \cdot K \times 0.025m / \left(2 \times 5\,W/m \cdot K\right) = 35°C \qquad <$$

The temperature distribution is shown on the T-x coordinates below and labeled Case 1. The key features of the distribution are its symmetry about the heater plane and its linear dependence with distance.

Continued …

PROBLEM 2.53 (Cont.)



(b) Case 2: sudden loss of coolant with the existence of an adiabatic condition on surface x = +L. For this situation, all the heater power will be conducted to the coolant through the left-hand plate. From a surface energy balance and application of Fourier's law as done for part (a), find

$$T_2(-L) = q_o''/h + T_\infty = 4000\,W/m^2/400\,W/m^2\cdot K + 20°C = 30°C$$ <

$$T_2(0) = T_2(-L) + q_o''L/k = 30°C + 4000\,W/m^2 \times 0.025\ m/5\,W/m\cdot K = 50°C$$ <

The temperature distribution is shown on the T-x coordinates above and labeled Case 2. The distribution is linear in the left-hand plate, with the maximum value at the mid-point. Since no heat flows through the right-hand plate, the gradient must zero and this plate is at the maximum temperature as well. The maximum temperature is higher than for Case 1 because the heat flux through the left-hand plate has increased two-fold.

(c) Case 3: sudden loss of coolant occurs at the x = -L surface also. For this situation, there is no heat transfer out of either plate, so that for a 15-minute period, Δt_o, the heater dissipates 4000 W/m^2 and then is deactivated. To determine the eventual, uniform steady-state temperature distribution, apply the conservation of energy requirement on a time-interval basis, Eq. 1.12b. The initial condition corresponds to the temperature distribution of Case 2, and the final condition will be a uniform, elevated temperature $T_f = T_3$ representing Case 3. We have used T_∞ as the reference condition for the energy terms.

$$E_{in}'' - E_{out}'' + E_{gen}'' = \Delta E_{st}'' = E_f'' - E_i'' \tag{1}$$

Note that $E_{in}'' - E_{out}'' = 0$, and the dissipated electrical energy is

$$E_{gen}'' = q_o''\Delta t_o = 4000\,W/m^2(15\times 60)s = 3.600\times 10^6\ J/m^2 \tag{2}$$

For the final condition,

$$E_f'' = \rho c(2L)[T_f - T_\infty] = 2500\,kg/m^3 \times 700\,J/kg\cdot K(2\times 0.025m)[T_f - 20]°C$$
$$E_f'' = 8.75\times 10^4[T_f - 20]\,J/m^2 \tag{3}$$

where $T_f = T_3$, the final uniform temperature, Case 3. For the initial condition,

$$E_i'' = \rho c\int_{-L}^{+L}[T_2(x) - T_\infty]dx = \rho c\left\{\int_{-L}^{0}[T_2(x) - T_\infty]dx + \int_0^{+L}[T_2(0) - T_\infty]dx\right\} \tag{4}$$

where $T_2(x)$ is linear for $-L \le x \le 0$ and constant at $T_2(0)$ for $0 \le x \le +L$.

$$T_2(x) = T_2(0) + [T_2(0) - T_2(L)]x/L \qquad -L \le x \le 0$$

$$T_2(x) = 50°C + [50 - 30]°Cx/0.025m$$

$$T_2(x) = 50°C + 800x \tag{5}$$

Substituting for $T_2(x)$, Eq. (5), into Eq. (4)

Continued …

$$E_i'' = \rho c \left\{ \int_{-L}^{0} \left[50 + 800x - T_\infty\right] dx + \left[T_2(0) - T_\infty\right] L \right\}$$

$$E_i'' = \rho c \left\{ \left[50x + 400x^2 - T_\infty x\right]_{-L}^{0} + \left[T_2(0) - T_\infty\right] L \right\}$$

$$E_i'' = \rho c \left\{ -\left[-50L + 400L^2 + T_\infty L\right] + \left[T_2(0) - T_\infty\right] L \right\}$$

$$E_i'' = \rho c L \left\{ +50 - 400L - T_\infty + T_2(0) - T_\infty \right\}$$

$$E_i'' = 2500\,\text{kg/m}^3 \times 700\,\text{J/kg}\cdot\text{K} \times 0.025\ \text{m} \left\{ +50 - 400 \times 0.025 - 20 + 50 - 20 \right\} \text{K}$$

$$E_i'' = 2.188 \times 10^6\ \text{J/m}^2 \qquad (6)$$

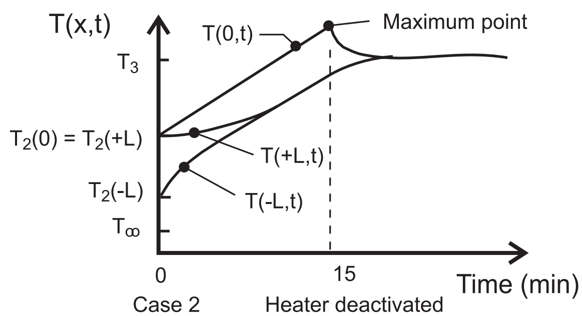
Returning to the energy balance, Eq. (1), and substituting Eqs. (2), (3) and (6), find $T_f = T_3$.

$$3.600 \times 10^6\ \text{J/m}^2 = 8.75 \times 10^4 \left[T_3 - 20\right] - 2.188 \times 10^6\ \text{J/m}^2$$

$$T_3 = (66.1 + 20)^\circ\text{C} = 86.1^\circ\text{C}$$ <

The temperature distribution is shown on the T-x coordinates above and labeled Case 3. The distribution is uniform, and considerably higher than the maximum value for Case 2.

(d) The temperature-time history at the plate locations x = 0, ± L during the transient period between the distributions for Case 2 and Case 3 are shown on the T-t coordinates below.



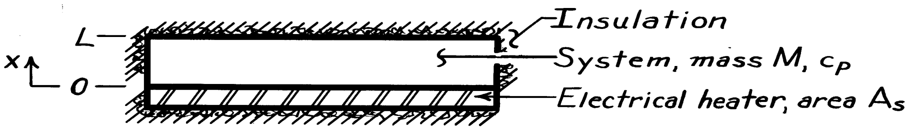
Note the temperatures for the locations at time t = 0 corresponding to the instant when the surface x = - L becomes adiabatic. These temperatures correspond to the distribution for Case 2. The heater remains energized for yet another 15 minutes and then is deactivated. The midpoint temperature, T(0,t), is always the hottest location and the maximum value slightly exceeds the final temperature T_3.

PROBLEM 2.54

KNOWN: One-dimensional system, initially at a uniform temperature T_i, is suddenly exposed to a uniform heat flux at one boundary, while the other boundary is insulated.

FIND: (a) Proper form of heat equation and boundary and initial conditions, (b) Temperature distributions for following conditions: initial condition ($t \le 0$), and several times after heater is energized; will a steady-state condition be reached; (c) Heat flux at x = 0, L/2, L as a function of time; (d) Expression for uniform temperature, T_f, reached after heater has been switched off following an elapsed time, t_e, with the heater on.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) No internal heat generation, (3) Constant properties.

ANALYSIS: (a) The appropriate form of the heat equation follows from Eq. 2.21. Also, the appropriate boundary and initial conditions are:

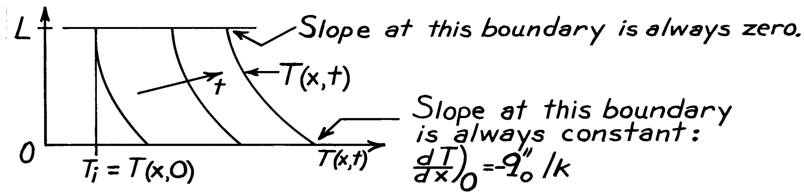
Initial condition: $T(x,0) = T_i$ Uniform temperature

$$\frac{\partial^2 T}{\partial x^2} = \frac{1}{\alpha}\frac{\partial T}{\partial t}$$

Boundary conditions: $x = 0$ $\quad q_o'' = -k\partial T/\partial x)_0$

$x = L$ $\quad \partial T/\partial x)_L = 0$

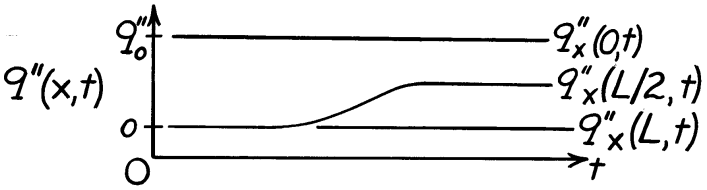
(b) The temperature distributions are as follows:



<

No steady-state condition will be reached since $\dot{E}_{in} = \dot{E}_{st}$ and $\dot{E}_{in}$ is constant.

(c)The heat flux as a function of time for positions x = 0, L/2 and L is as follows:



<

(d) If the heater is energized until $t = t_e$ and then switched off, the system will eventually reach a uniform temperature, T_f. Perform an energy balance on the system, Eq. 1.12b, for an interval of time $\Delta t = t_e$,

$$E_{in} = E_{st} \qquad E_{in} = Q_{in} = \int_0^{t_e} q_o'' A_s dt = q_o'' A_s t_e \qquad E_{st} = Mc\left(T_f - T_i\right)$$

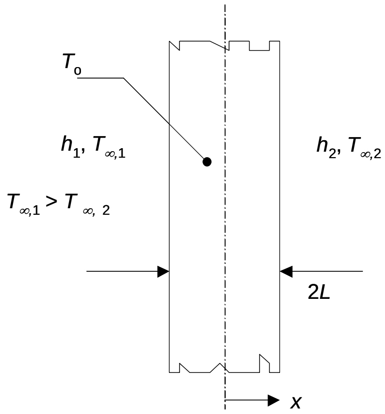
It follows that $\quad q_o'' A_s t_e = Mc\left(T_f - T_i\right) \quad$ or $\quad T_f = T_i + \dfrac{q_o'' A_s t_e}{Mc}.$ <

PROBLEM 2.55

KNOWN: Dimensions of one-dimensional plane wall, initial and boundary conditions.

FIND: (a) Differential equation, boundary and initial conditions used to determine $T(x,t)$, (b) Sketch of the temperature distributions for the initial condition, the steady-state condition, and for two intermediate times, (c) Sketch of the heat flux $q_x''(x,t)$ at the planes $x = 0$, $-L$, and $+L$, (d) Sketch of the temperature distributions for the initial condition, the steady-state condition, and for two intermediate times for h_1 twice the previous value, (e) Sketch of the heat flux $q_x''(x,t)$ at the planes $x = 0$, $-L$, and $+L$ for h_1 twice the previous value.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional heat transfer, (2) Constant properties, (3) No internal generation.

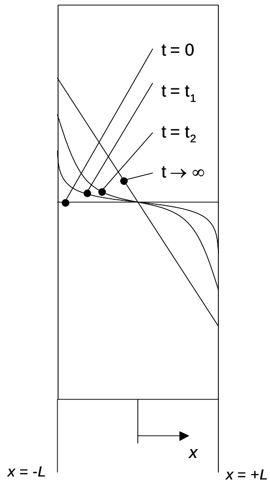
ANALYSIS: The differential equation may be found by simplifying the heat equation, Equation 2.21. The simplification yields

$$\frac{\partial^2 T}{\partial x^2} = \frac{1}{\alpha}\frac{\partial T}{\partial t}$$

The initial and boundary conditions are:

$$T(x,t=0) = T_o\,;\; -k\left.\frac{\partial T}{\partial x}\right|_{x=-L} = h_1\left[T_{\infty,1} - T(x=-L,t)\right];\, -k\left.\frac{\partial T}{\partial x}\right|_{x=+L} = h_2\left[T(x=+L,t) - T_{\infty,2}\right]$$

(b) The temperature distributions are shown in the sketch below.



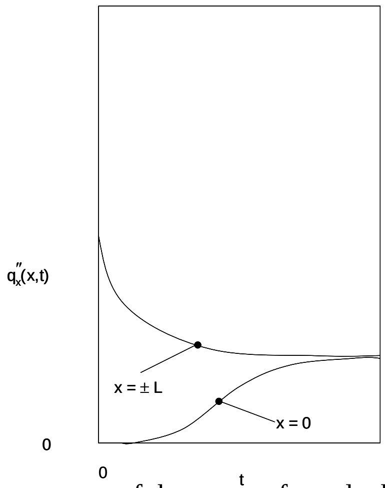
Continued…

PROBLEM 2.55

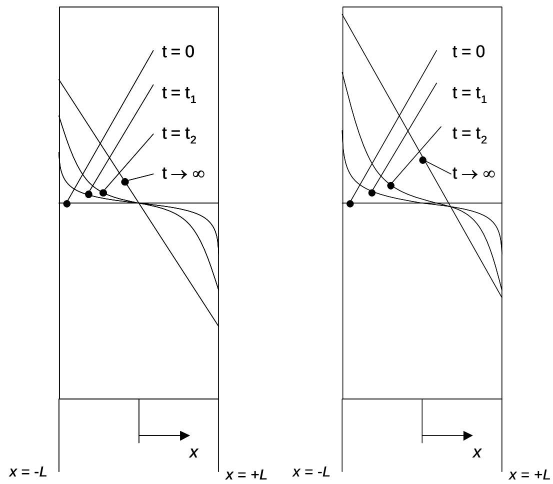
The temperature is uniform at the initial time, as required by the initial condition listed in part (a). Note the temperature gradients at the exposed surfaces are large at early times and decrease in magnitude as the convective heat flux is reduced, as required by the boundary conditions listed in part (a). The steady-state temperature distribution is linear. At the steady state,

$$-k\frac{dT}{dx} = h_1\left[T_{\infty,1} - T(x=-L)\right] = h_2\left[T(x=+L) - T_{\infty,2}\right]$$

(c) At any time, the heat fluxes at $x = \pm L$ are identical. The initial heat flux value is $q''_x(x = \pm L) =$ $h_1[T_{\infty,1} - T_o] = h_2[T_o - T_{\infty,2}]$. As time progresses, thermal effects propagate to $x = 0$, resulting in a uniform heat flux distribution throughout the wall thickness.



(d) A comparison of the transient response of the system for a doubled value of h_1 is shown in the RHS sketch below. Note that for all but the initial time, temperatures throughout the wall are higher relative to the case associated with the original value of h_1 (LHS). At intermediate times, temperature gradients at x = -L are larger than temperature gradients at x = +L due to the larger convection heat transfer coefficient at the left surface.



h_1 $2h_1$

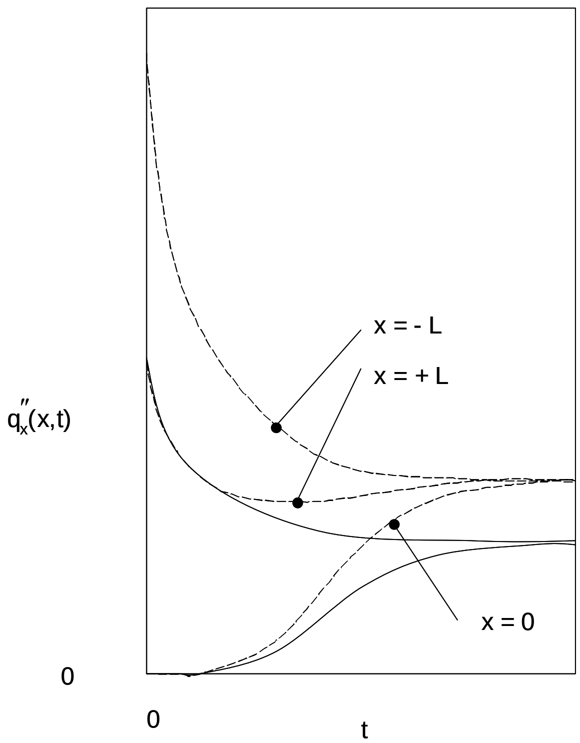
Continued…

PROBLEM 2.55

(e) The heat flux histories are shown in the plot below as dashed lines. The results for part (c) are replicated as solid lines. Note that at the initial time, the heat flux at the left face is doubled relative to part (c) because the heat transfer coefficient is doubled. The heat flux at the initial time for the right face is the same as in part (c). The heat fluxes at the three planes asymptotically approach the steady-state value given by

$$-k\frac{dT}{dx} = 2h_1\left[T_{\infty,1} - T(x=-L)\right] = h_2\left[T(x=+L) - T_{\infty,2}\right]$$

Note that the overall heat flux is *not* doubled at the steady state since the temperature at the right face ($T(x = \pm L)$) is greater for the case of the doubled LHS heat transfer coefficient, h_1.

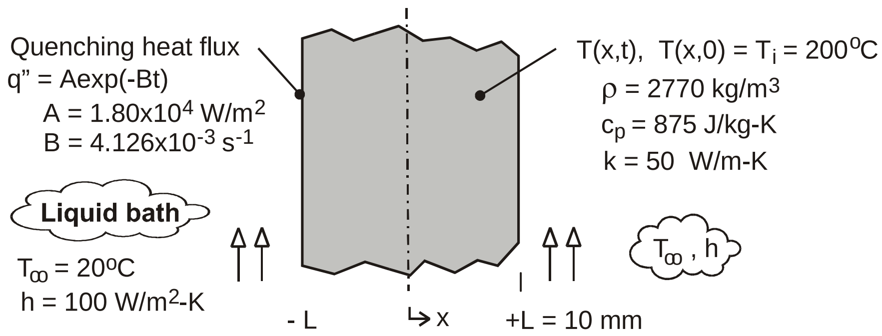


PROBLEM 2.56

KNOWN: Plate of thickness 2L, initially at a uniform temperature of $T_i = 200°C$, is suddenly quenched in a liquid bath of $T_\infty = 20°C$ with a convection coefficient of 100 $W/m^2 \cdot K$.

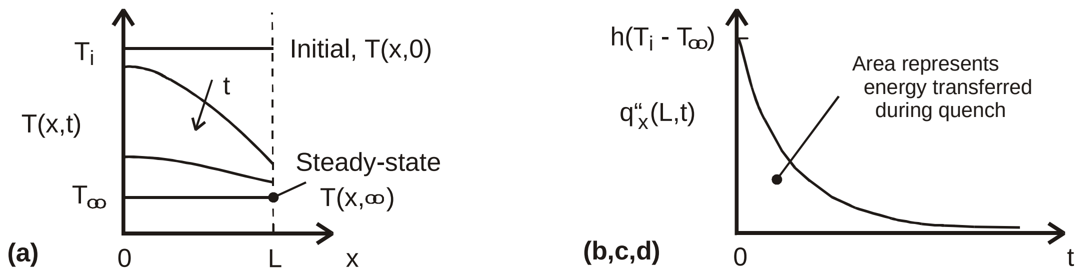
FIND: (a) On T-x coordinates, sketch the temperature distributions for the initial condition ($t \le 0$), the steady-state condition ($t \to \infty$), and two intermediate times; (b) On $q''_x - t$ coordinates, sketch the variation with time of the heat flux at x = L, (c) Determine the heat flux at x = L and for t = 0; what is the temperature gradient for this condition; (d) By performing an energy balance on the plate, determine the amount of energy per unit surface area of the plate (J/m^2) that is transferred to the bath over the time required to reach steady-state conditions; and (e) Determine the energy transferred to the bath during the quenching process using the exponential-decay relation for the surface heat flux.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, and (3) No internal heat generation.

ANALYSIS: (a) The temperature distributions are shown in the sketch below.



(b) The heat flux at the surface x = L, $q''_x(L,t)$, is initially a maximum value, and decreases with increasing time as shown in the sketch above.

(c) The heat flux at the surface x = L at time t = 0, $q''_x(L,0)$, is equal to the convection heat flux with the surface temperature as $T(L,0) = T_i$.

$$q''_x(L,0) = q''_{conv}(t=0) = h(T_i - T_\infty) = 100\,W/m^2 \cdot K(200-20)°C = 18.0\,kW/m^2 \qquad <$$

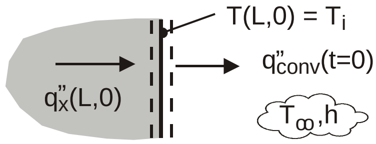
From a surface energy balance as shown in the sketch considering the conduction and convection fluxes at the surface, the temperature gradient can be calculated.

Continued …

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$q''_x(L,0) - q''_{conv}(t=0) = 0 \qquad \text{with} \quad q''_x(L,0) = -k\left.\frac{\partial T}{\partial x}\right)_{x=L}$$

$$\left.\frac{\partial T}{\partial x}\right)_{L,0} = -q''_{conv}(t=0)/k = -18\times10^3\,W/m^2/50\,W/m\cdot K = -360\,K/m$$ <



(d) The energy transferred from the plate to the bath over the time required to reach steady-state conditions can be determined from an energy balance on a time interval basis, Eq. 1.12b. For the initial state, the plate has a uniform temperature T_i; for the final state, the plate is at the temperature of the bath, T_∞.

$$E''_{in} - E''_{out} = \Delta E''_{st} = E''_f - E''_i \qquad \text{with} \qquad E''_{in} = 0,$$

$$-E''_{out} = \rho c_p (2L)\left[T_\infty - T_i\right]$$

$$E''_{out} = -2770\,kg/m^3 \times 875\,J/kg\cdot K\left(2\times0.010\ m\right)\left[20-200\right]K = +8.73\times10^6\,J/m^2$$ <

(e) The energy transfer from the plate to the bath during the quenching process can be evaluated from knowledge of the surface heat flux as a function of time. The area under the curve in the $q''_x(L,t)$ vs. time plot (see schematic above) represents the energy transferred during the quench process.

$$E''_{out} = 2\int_{t=0}^{\infty} q''_x(L,t)\,dt = 2\int_{t=0}^{\infty} Ae^{-Bt}dt$$

$$E''_{out} = 2A\left[-\frac{1}{B}e^{-Bt}\right]_0^{\infty} = 2A\left[-\frac{1}{B}(0-1)\right] = 2A/B$$

$$E''_{out} = 2\times1.80\times10^4\,W/m^2/4.126\times10^{-3}s^{-1} = 8.73\times10^6\,J/m^2$$ <

COMMENTS: (1) Can you identify and explain the important features in the temperature distributions of part (a)?

(2) The maximum heat flux from the plate occurs at the instant the quench process begins and is equal to the convection heat flux. At this instant, the gradient in the plate at the surface is a maximum. If the gradient is too large, excessive thermal stresses could be induced and cracking could occur.

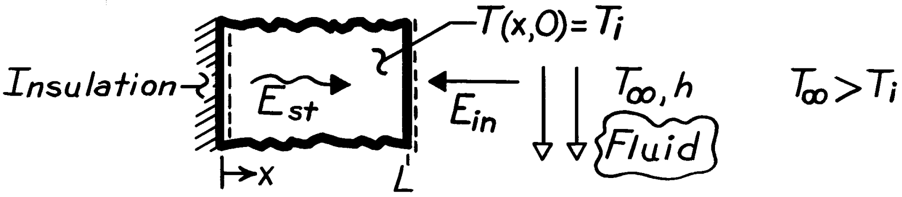
(3) In this thermodynamic analysis, we were able to determine the energy transferred during the quenching process. We cannot determine the rate at which cooling of the plate occurs without solving the heat diffusion equation.

PROBLEM 2.57

KNOWN: Plane wall, initially at a uniform temperature, is suddenly exposed to convective heating.

FIND: (a) Differential equation and initial and boundary conditions which may be used to find the temperature distribution, T(x,t); (b) Sketch T(x,t) for these conditions: initial ($t \le 0$), steady-state, $t \to \infty$, and two intermediate times; (c) Sketch heat fluxes as a function of time for surface locations; (d) Expression for total energy transferred to wall per unit volume (J/m^3).

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) No internal heat generation.

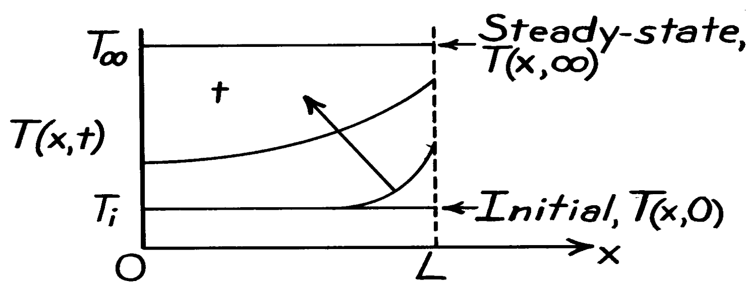
ANALYSIS: (a) For one-dimensional conduction with constant properties, the heat equation has the form,

$$\frac{\partial^2 T}{\partial x^2} = \frac{1}{\alpha}\frac{\partial T}{\partial t}$$

and the conditions are:

$$\begin{cases} \text{Initial, } t \le 0: & T(x,0) = T_i & \text{uniform} \\ \text{Boundaries:} \quad x=0 & \partial T/\partial x)_0 = 0 & \text{adiabatic} \\ \quad x=L & -k\partial T/\partial x)_L = h\left[T(L,t) - T_\infty\right] & \text{convection} \end{cases}$$

(b) The temperature distributions are shown on the sketch.

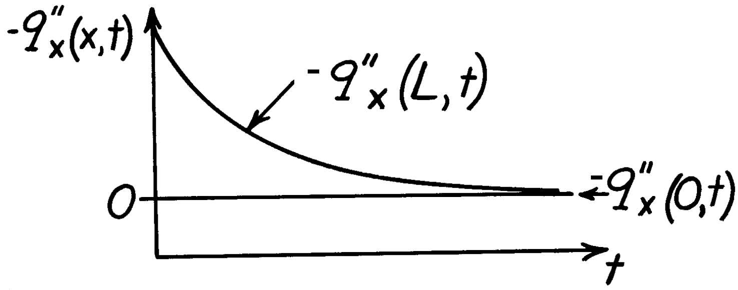


Note that the gradient at x = 0 is always zero, since this boundary is adiabatic. Note also that the gradient at x = L decreases with time.

(c) The heat flux, $q''_x(x,t)$, as a function of time, is shown on the sketch for the surfaces x = 0 and x = L.

Continued …

PROBLEM 2.57 (Cont.)



For the surface at $x = 0$, $q''_x(0,t) = 0$ since it is adiabatic. At x = L and t = 0, $q''_x(L,0)$ is a maximum (in magnitude)

$$\left|q''_x(L,0)\right| = h\left|T(L,0) - T_\infty\right|$$

where T(L,0) = T_i. The temperature difference, and hence the flux, decreases with time.

(d) The total energy transferred to the wall may be expressed as

$$E_{in} = \int_0^\infty q''_{conv} A_s dt$$
$$E_{in} = hA_s \int_0^\infty \left(T_\infty - T(L,t)\right)dt$$

Dividing both sides by A_sL, the energy transferred per unit volume is

$$\frac{E_{in}}{V} = \frac{h}{L}\int_0^\infty \left[T_\infty - T(L,t)\right]dt \qquad \left[J/m^3\right]$$

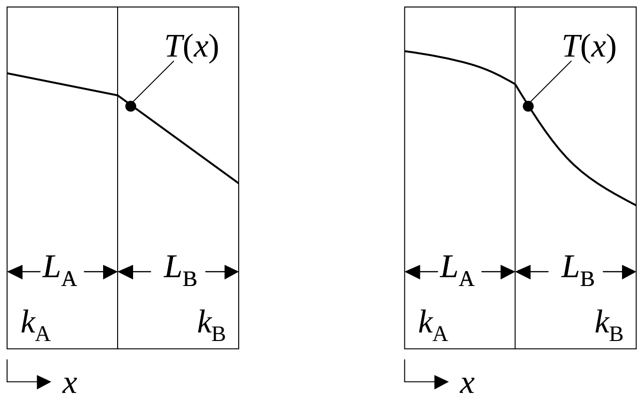
COMMENTS: Note that the heat flux at x = L is into the wall and is hence in the negative x direction.

PROBLEM 2.58

KNOWN: Qualitative temperature distributions in two cases.

FIND: For each of two cases, determine which material (A or B) has the higher thermal conductivity, how the thermal conductivity varies with temperature, description of the heat flux distribution through the composite wall, effect of simultaneously doubling the wall thickness and thermal conductivity.

SCHEMATIC:



Case 1. Case 2.

ASSUMPTIONS: (1) Steady-state, one-dimensional conditions, (2) Negligible contact resistances, (3) No internal energy generation.

ANALYSIS: Under steady-state conditions with no internal generation, the conservation of energy requirement dictates that the heat flux through the wall must be constant. <

For Materials A and B, Fourier's law is written $q''_A = -k_A \frac{dT_A}{dx} = q''_B = -k_B \frac{dT_B}{dx}$. Therefore,

$$\frac{k_A}{k_B} = \frac{dT_B/dx}{dT_A/dx} > 1 \quad \text{and} \quad k_B < k_A \text{ for both cases.}$$ <

Since the heat flux through the wall is constant, Fourier's law dictates that lower thermal conductivity material must exist where temperature gradients are larger. For Case 1, the temperature distributions are linear. Therefore, the temperature gradient is constant in each material, and the thermal conductivity of each material must not vary significantly with temperature. For Case 2, Material A, the temperature gradient is larger at lower temperatures. Hence, for Material A the thermal conductivity increases with increasing material temperature. For Case 2, Material B, the temperature gradient is smaller at lower temperatures. Hence, for Material B the thermal conductivity decreases with increases in material temperature. <

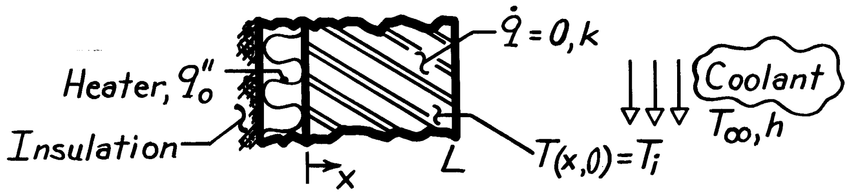
COMMENTS: If you were given information regarding the relative values of the thermal conductivities and how the thermal conductivities vary with temperature in each material, you should be able to sketch the temperature distributions provided in the problem statement.

PROBLEM 2.59

KNOWN: Plane wall, initially at a uniform temperature T_i, is suddenly exposed to convection with a fluid at T_∞ at one surface, while the other surface is exposed to a constant heat flux q_o''.

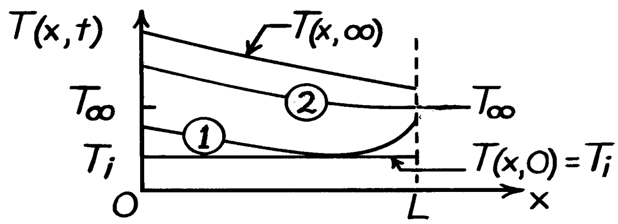
FIND: (a) Temperature distributions, T(x,t), for initial, steady-state and two intermediate times, (b) Corresponding heat fluxes on $q_x'' - x$ coordinates, (c) Heat flux at locations x = 0 and x = L as a function of time, (d) Expression for the steady-state temperature of the heater, T(0,∞), in terms of q_o'', T_∞, k, h and L.

SCHEMATIC:



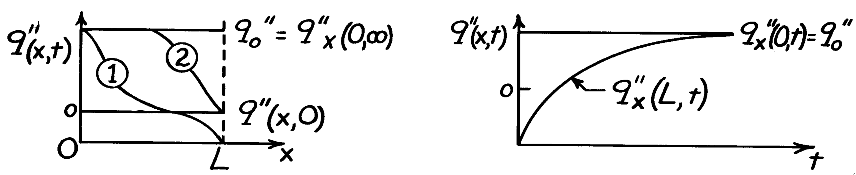
ASSUMPTIONS: (1) One-dimensional conduction, (2) No heat generation, (3) Constant properties.

ANALYSIS: (a) For $T_i < T_\infty$, the temperature distributions are



Note the constant gradient at x = 0 since $q_x''(0) = q_o''$.

(b) The heat flux distribution, $q_x''(x,t)$, is determined from knowledge of the temperature gradients, evident from Part (a), and Fourier's law.

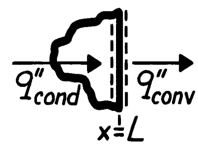


(c) On $q_x''(x,t) - t$ coordinates, the heat fluxes at the boundaries are shown above.

(d) Perform a surface energy balance at x = L and an energy balance on the wall:

$$q''_{cond} = q''_{conv} = h\left[T(L,\infty) - T_\infty\right] \quad (1), \qquad q''_{cond} = q_o''. \quad (2)$$

For the wall, under steady-state conditions, Fourier's law gives



$$q_o'' = -k\frac{dT}{dx} = k\frac{T(0,\infty) - T(L,\infty)}{L}. \quad (3)$$

Combine Eqs. (1), (2), (3) to find:

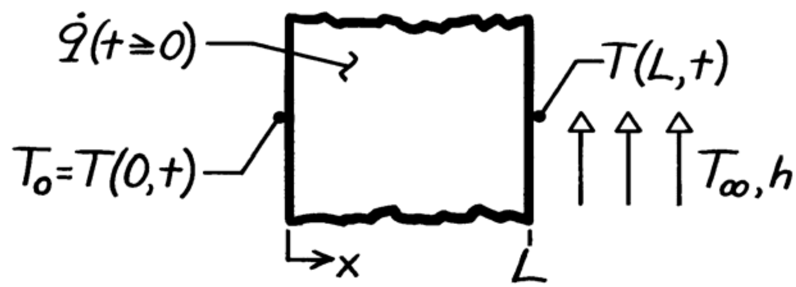
$$T(0,\infty) = T_\infty + \frac{q_o''}{1/h + L/k}.$$

PROBLEM 2.60

KNOWN: Plane wall, initially at a uniform temperature T_o, has one surface (x = L) suddenly exposed to a convection process ($T_\infty > T_o$,h), while the other surface (x = 0) is maintained at T_o. Also, wall experiences uniform volumetric heating $\dot{q}$ such that the maximum steady-state temperature will exceed T_∞.

FIND: (a) Sketch temperature distribution (T vs. x) for following conditions: initial ($t \le 0$), steady-state ($t \to \infty$), and two intermediate times; also show distribution when there is no heat flow at the x = L boundary, (b) Sketch the heat flux $\left(q''_x \text{ vs. } t\right)$ at the boundaries x = 0 and L.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Uniform volumetric generation, (4) $T_o < T_\infty$ and $\dot{q}$ large enough that $T(x,\infty) > T_\infty$ for some x.

ANALYSIS: (a) The initial and boundary conditions for the wall can be written as

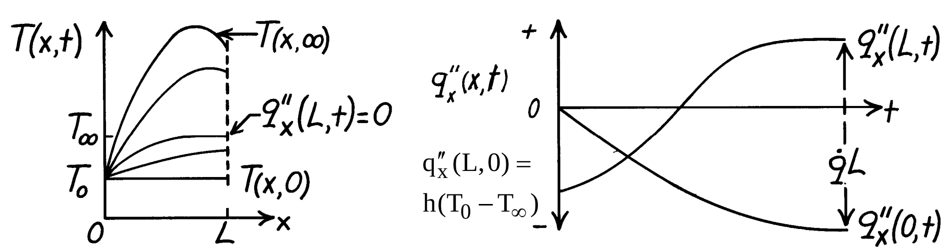
Initial (t ≤ 0): $T(x,0) = T_o$ Uniform temperature

Boundary: $x = 0 \quad T(0,t) = T_o$ Constant temperature

$$x = L \qquad -k\left.\frac{\partial T}{\partial x}\right)_{x=L} = h\left[T(L,t) - T_\infty\right]$$ Convection process.

The temperature distributions are shown on the T-x coordinates below. Note the special condition when the heat flux at (x = L) is zero.

(b) The heat flux as a function of time at the boundaries, $q''_x(0,t)$ and $q''_x(L,t)$, can be inferred from the temperature distributions using Fourier's law.



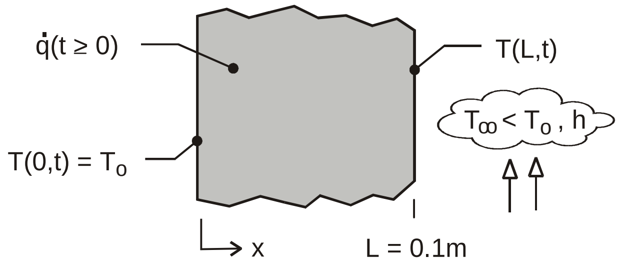
COMMENTS: Since $T(x,\infty) > T_\infty$ for some x and $T_\infty > T_o$, heat transfer at both boundaries must be out of the wall at steady state. From an overall energy balance at steady state, $+q''_x(L,\infty) - q''_x(0,\infty) = \dot{q}L.$

PROBLEM 2.61

KNOWN: Plane wall, initially at a uniform temperature T_o, has one surface (x = L) suddenly exposed to a convection process ($T_\infty < T_o$, h), while the other surface (x = 0) is maintained at T_o. Also, wall experiences uniform volumetric heating $\dot{q}$ such that the maximum steady-state temperature will exceed T_∞.

FIND: (a) Sketch temperature distribution (T vs. x) for following conditions: initial ($t \le 0$), steady-state ($t \to \infty$), and two intermediate times; identify key features of the distributions, (b) Sketch the heat flux $\left(q''_x \text{ vs. } t\right)$ at the boundaries x = 0 and L; identify key features of the distributions.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Uniform volumetric generation, (4) $T_\infty < T_o$ and $\dot{q}$ large enough that $T(x,\infty) > T_o$.

ANALYSIS: (a) The initial and boundary conditions for the wall can be written as

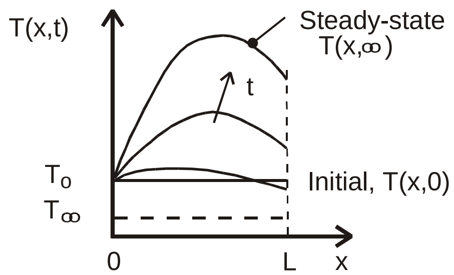
Initial ($t \le 0$): $T(x,0) = T_o$ Uniform temperature

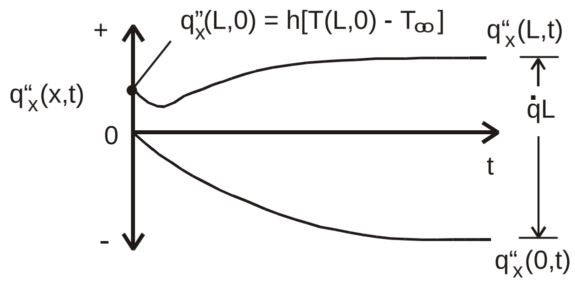
Boundary: $x = 0 \quad T(0,t) = T_o$ Constant temperature

$$x = L \qquad -k\left.\frac{\partial T}{\partial x}\right)_{x=L} = h\left[T(L,t) - T_\infty\right]$$ Convection process.

The temperature distributions are shown on the T-x coordinates below. Note that the maximum temperature occurs under steady-state conditions not at the midplane, but to the right toward the surface experiencing convection. The temperature gradients at x = L increase for t > 0 since the convection heat rate from the surface increases as the surface temperature increases.

(b) The heat flux as a function of time at the boundaries, $q''_x(0,t)$ and $q''_x(L,t)$, can be inferred from the temperature distributions using Fourier's law. At the surface x = L, the convection heat flux at t = 0 is $q''_x(L,0) = h(T_o - T_\infty)$. Because the surface temperature dips slightly at early times, the convection heat flux decreases slightly, and then increases until the steady-state condition is reached. For the steady-state condition, heat transfer at both boundaries must be out of the wall. It follows from an overall energy balance on the wall that $+q''_x(0,\infty) - q''_x(L,\infty) + \dot{q}L = 0$.



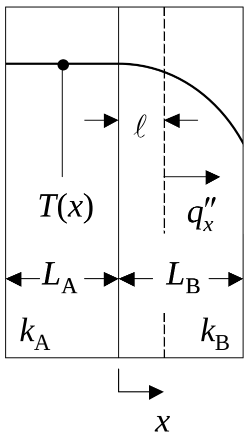


PROBLEM 2.62

KNOWN: Qualitative temperature distribution in a composite wall with one material experiencing uniform volumetric energy generation.

FIND: Which material experiences uniform volumetric generation. The boundary condition at $x = -L_A$. Temperature distribution if the thermal conductivity of Material A is doubled. Temperature distribution if the thermal conductivity of Material B is doubled. Whether a contact resistance exists at the interface between the two materials. Sketch the heat flux distribution $q_x''(x)$ through the composite wall.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, one-dimensional conditions, (2) Constant properties.

ANALYSIS: Consider a control volume with the LHS control surface at the interface between the two materials and the RHS control surface located at an arbitrary location within Material B, as shown in the schematic. For this control volume, conservation of energy and Fourier's law may be combined to yield, for uniform volumetric generation in Material B,

$$\dot{q}(\ell) = q_x'' = -k\left.\frac{dT}{dx}\right|_{x=\ell} \quad \text{or} \quad \left.\frac{dT}{dx}\right|_{x=\ell} \propto \ell \qquad (1)$$

The temperature distribution of the problem reflects the preceding proportionality between the temperature gradient and the distance ℓ, and it is appropriate to assume that uniform volumetric generation occurs in Material B but not in Material A. <

The boundary condition at $x = -L_A$ is associated with perfectly insulated conditions,

$$0 = q_x''(x = -L_A) = -k\left.\frac{dT}{dx}\right|_{x=-L_A} \quad \text{or} \quad \left.\frac{dT}{dx}\right|_{x=-L_A} = 0$$ <

The temperature distribution in Material A corresponds to $q_{x,A}'' = 0$, and is independent of its thermal conductivity. <

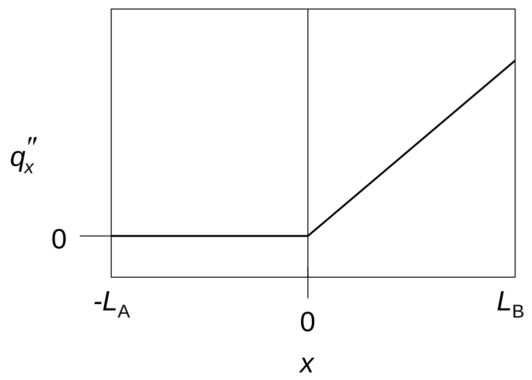
Continued...

PROBLEM 2.62 (Cont.)

If the volumetric energy generation rate, $\dot{q}$, is unchanged, Equation (1) requires that the temperature gradient everywhere in Material B will be reduced by half if the thermal conductivity of Material B is doubled. Hence, the difference between the minimum and maximum temperatures in the composite wall would be reduced by half. <

Since there is no volumetric energy generation in Material A, and since the surface at $x = -L_A$ is insulated, there can be no conduction of energy into or out of Material A at the LHS of the control volume previously described. Hence, if a contact resistance exists at the interface between Materials A and B, it would not induce any temperature drop across the interface since there is no heat transfer across the interface. Therefore, based on the temperature distribution given in the problem statement, it is impossible to conclude whether a contact resistance exists or not at the interface between Materials A and B. <

Considering Eq. 1, it follows that the heat flux distribution throughout the composite wall is as shown in the sketch below.



<

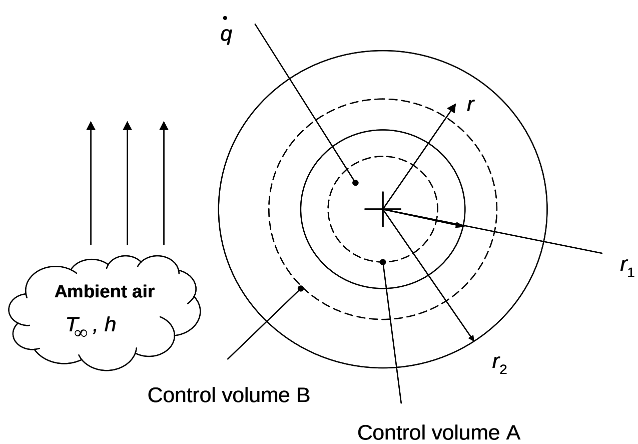
COMMENTS: If you were given information regarding which material experiences internal energy generation, the boundary condition at $x = -L_A$, the thermal conductivities of both materials, and the value of the contact resistance, you should be able to sketch the temperature and heat flux distributions.

PROBLEM 2.63

KNOWN: Size and thermal conductivities of a spherical particle encased by a spherical shell.

FIND: (a) Relationship between dT/dr and r for $0 \le r \le r_1$, (b) Relationship between dT/dr and r for $r_1 \le r \le r_2$, (c) Sketch of T(r) over the range $0 \le r \le r_2$.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional heat transfer.

ANALYSIS:

(a) The conservation of energy principle, applied to control volume A, results in

$$\dot{E}_{in} + \dot{E}_g - \dot{E}_{out} = \dot{E}_{st} \qquad (1)$$

where $\dot{E}_g = \dot{q}\forall = \dot{q}\frac{4}{3}\pi r^3$ (2)

since $\dot{E}_{st} = 0$

$$\dot{E}_{in} - \dot{E}_{out} = q_r''A = -(-k_1\frac{dT}{dr})(4\pi r^2) \qquad (3)$$

Substituting Eqs. (2) and (3) in Eq. (1) yields

$$\dot{q}\frac{4}{3}\pi r^3 + k_1\frac{dT}{dr}(4\pi r^2) = 0$$

or

$$\frac{dT}{dr} = -\frac{\dot{q}}{3}\frac{r}{k_1}$$ <

Continued…

PROBLEM 2.63 (Cont.)

(b) For $r > r_1$, the radial heat rate is constant and is

$$\dot{E}_g = q_r = \dot{q}\forall_1 = \dot{q}\frac{4}{3}\pi r_1^3 \quad (4)$$

$$\dot{E}_{in} - \dot{E}_{out} = q_r''A = -(-k_2\frac{dT}{dr})4\pi r^2 \quad (5)$$

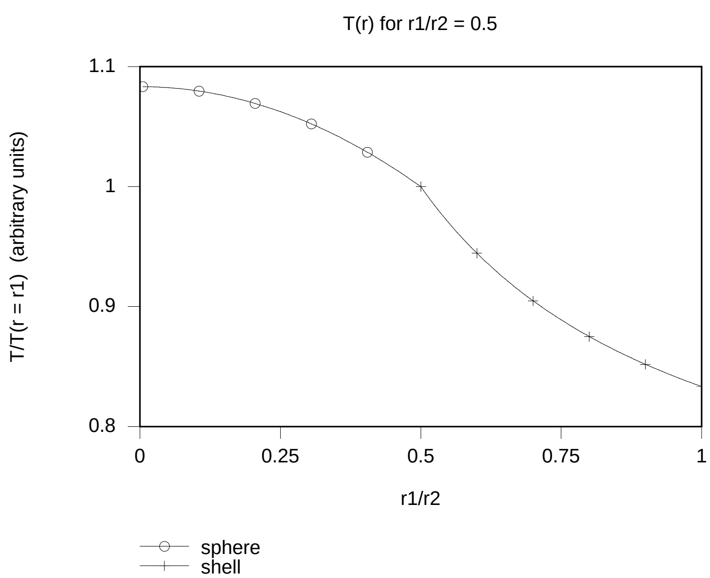
Substituting Eqs. (4) and (5) into Eq. (1) yields

$$k_2\frac{dT}{dr}4\pi r^2 + \dot{q}\frac{4}{3}\pi r_1^3 = 0$$

or

$$\frac{dT}{dr} = -\frac{\dot{q}r_1^3}{3k_2 r^2}$$ <

(c) The temperature distribution on T-r coordinates is



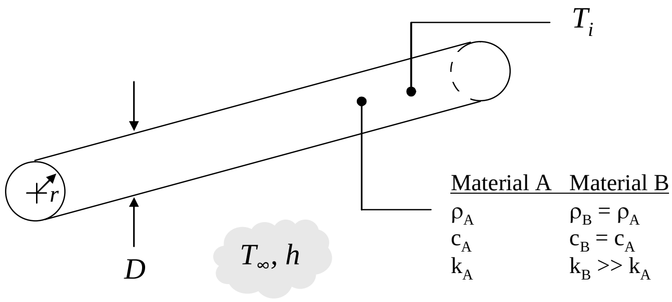
COMMENTS: (1) Note the non-linear temperature distributions in both the particle and the shell. (2) The temperature gradient at r = 0 is zero. (3) The discontinuous slope of T(r) at r_1/r_2 = 0.5 is a result of $k_1 = 2k_2$.

PROBLEM 2.64

KNOWN: Long cylindrical rod with uniform initial temperature immersed in liquid at a lower temperature.

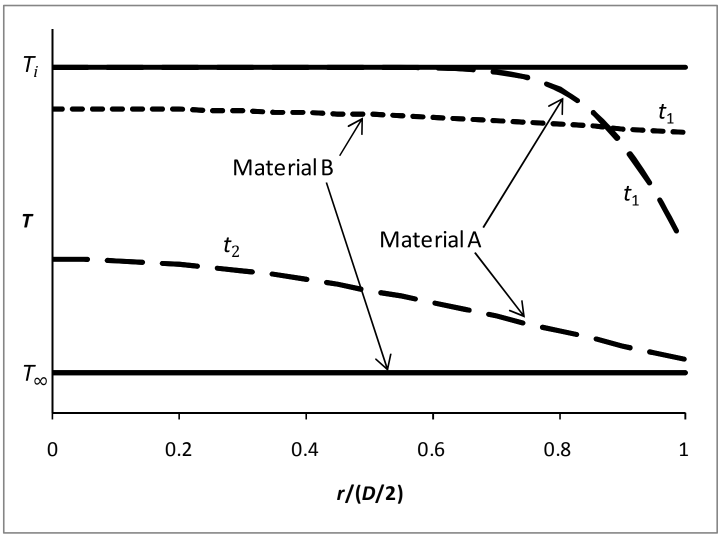
FIND: Sketch temperature distribution at initial time, steady state, and two intermediate times for two rods with different thermal conductivities. State boundary conditions at centerline and surface.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in radial direction, (2) Constant properties, (3) Fluid temperature remains constant, (4) Convection heat transfer coefficient is constant.

ANALYSIS: Referring to the figure below, first consider Material A of moderate thermal conductivity. Initially, the rod temperature is uniform at T_i. When the rod is first exposed to the liquid, heat is transferred from the rod to the fluid due to convection, causing the surface temperature to decrease. The resulting temperature gradient in the rod causes heat to conduct radially outward, and the temperature further inside the rod decreases as well. Toward the beginning of this process, the temperature near the center of the rod is still very close to the initial temperature (see Material A, t_1). As time increases, the temperature everywhere in the rod decreases (see Material A, t_2). Eventually, at steady state, the rod temperature reaches the fluid temperature, T_∞.



<

Continued…

PROBLEM 2.64 (Cont.)

The boundary condition at the rod surface expresses a balance between heat reaching the surface by conduction and heat leaving the surface by convection:

$$-k\left.\frac{\partial T}{\partial r}\right|_{D/2} = h\left[T(D/2,t) - T_\infty\right] \qquad (1)$$ <

From this, it can be seen that the temperature gradient at the surface is negative and its magnitude decreases with time as the surface temperature approaches the fluid temperature. This is shown for the two intermediate times for Material A.

Next compare Material A to Material B having a very large thermal conductivity. At time $t = 0$ when both rods have the same temperature T_i, it can be seen from the right hand side of Equation (1) that the heat flux is the same for both materials. Energy is being removed from both rods at the same rate. However, because of the large thermal conductivity of material B, its temperature gradient is smaller and its temperature tends to be nearly uniform, as shown in the figure for Material B, t_1. Its temperature is higher at the surface and lower in the center as compared to Material A. Because its surface temperature stays higher for longer, the heat flux leaving the rod is larger, and overall it cools faster. At time t_2, when Material A's surface temperature is close to T_∞, but it is still warm in the center, Material B has already reached steady state.

The rod with the higher thermal conductivity reaches steady state sooner. <

The boundary condition at $r = 0$ expresses radial symmetry:

$$\left.\frac{\partial T}{\partial r}\right|_0 = 0$$ <

The boundary condition at $r = D/2$ was given in Equation (1).

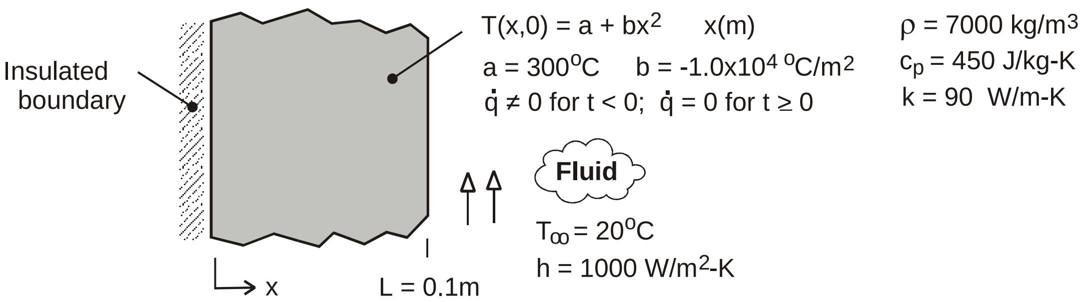
COMMENTS: The problem of transient conduction in a cylinder will be solved in Chapter 5.

PROBLEM 2.65

KNOWN: Temperature distribution in a plane wall of thickness L experiencing uniform volumetric heating $\dot{q}$ having one surface (x = 0) insulated and the other exposed to a convection process characterized by T_∞ and h. Suddenly the volumetric heat generation is deactivated while convection continues to occur.

FIND: (a) Determine the magnitude of the volumetric energy generation rate associated with the initial condition, (b) On T-x coordinates, sketch the temperature distributions for the initial condition ($T \le 0$), the steady-state condition ($t \to \infty$), and two intermediate times; (c) On q''_x - t coordinates, sketch the variation with time of the heat flux at the boundary exposed to the convection process, $q''_x(L,t)$; calculate the corresponding value of the heat flux at t = 0; and (d) Determine the amount of energy removed from the wall per unit area (J/m^2) by the fluid stream as the wall cools from its initial to steady-state condition.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, and (3) Uniform internal volumetric heat generation for t < 0.

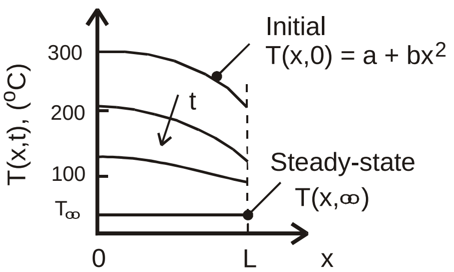
ANALYSIS: (a) The volumetric heating rate can be determined by substituting the temperature distribution for the initial condition into the appropriate form of the heat diffusion equation.

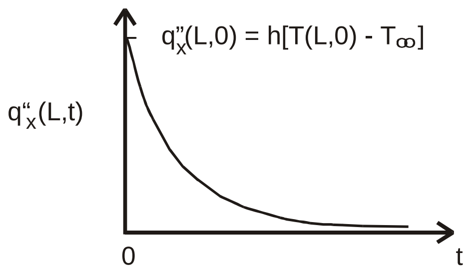
$$\frac{d}{dx}\left(\frac{dT}{dx}\right)+\frac{\dot{q}}{k}=0 \qquad \text{where} \qquad T(x,0)=a+bx^2$$

$$\frac{d}{dx}(0+2bx)+\frac{\dot{q}}{k}=0=2b+\frac{\dot{q}}{k}=0$$

$$\dot{q}=-2kb=-2\times 90\,\mathrm{W/m\cdot K}\left(-1.0\times 10^{4\circ}\mathrm{C/m^2}\right)=1.8\times 10^6\ \mathrm{W/m^3}$$ <

(b) The temperature distributions are shown in the sketch below.





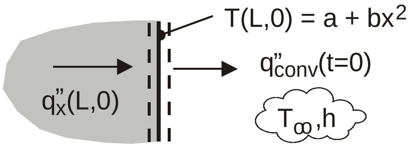
Continued …

PROBLEM 2.65 (Cont.)

(c) The heat flux at the exposed surface x = L, $q''_x(L,0)$, is initially a maximum value and decreases with increasing time as shown in the sketch above. The heat flux at t = 0 is equal to the convection heat flux with the surface temperature T(L,0). See the surface energy balance represented in the schematic.

$$q''_x(L,0) = q''_{conv}(t=0) = h\left(T(L,0) - T_\infty\right) = 1000\,W/m^2 \cdot K\,(200-20)°C = 1.80 \times 10^5\,W/m^2 \quad <$$

where $T(L,0) = a + bL^2 = 300°C - 1.0 \times 10^4 °C/m^2\,(0.1m)^2 = 200°C.$



(d) The energy removed from the wall to the fluid as it cools from its initial to steady-state condition can be determined from an energy balance on a time interval basis, Eq. 1.12b. For the initial state, the wall has the temperature distribution $T(x,0) = a + bx^2$; for the final state, the wall is at the temperature of the fluid, $T_f = T_\infty$. We have used T_∞ as the reference condition for the energy terms.

$$E''_{in} - E''_{out} = \Delta E''_{st} = E''_f - E''_i \qquad \text{with} \qquad E''_{in} = 0$$

$$E''_{out} = \rho c_p \int_{x=0}^{x=L} \left[T(x,0) - T_\infty\right] dx$$

$$E''_{out} = \rho c_p \int_{x=0}^{x=L} \left[a + bx^2 - T_\infty\right] dx = \rho c_p \left[ax + bx^3/3 - T_\infty x\right]_0^L$$

$$E''_{out} = 7000\,kg/m^3 \times 450\,J/kg \cdot K \left[300 \times 0.1 - 1.0 \times 10^4 (0.1)^3/3 - 20 \times 0.1\right] K \cdot m$$

$$E''_{out} = 7.77 \times 10^7\,J/m^2 \quad <$$

COMMENTS: (1) In the temperature distributions of part (a), note these features: initial condition has quadratic form with zero gradient at the adiabatic boundary; for the steady-state condition, the wall has reached the temperature of the fluid; for all distributions, the gradient at the adiabatic boundary is zero; and, the gradient at the exposed boundary decreases with increasing time.

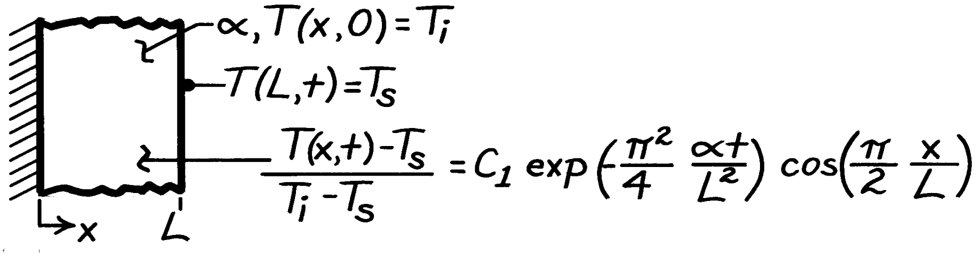
(2) In this thermodynamic analysis, we were able to determine the energy transferred during the cooling process. However, we cannot determine the rate at which cooling of the wall occurs without solving the heat diffusion equation.

PROBLEM 2.66

KNOWN: Temperature as a function of position and time in a plane wall suddenly subjected to a change in surface temperature, while the other surface is insulated.

FIND: (a) Validate the temperature distribution, (b) Heat fluxes at x = 0 and x = L, (c) Sketch of temperature distribution at selected times and surface heat flux variation with time, (d) Effect of thermal diffusivity on system response.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in x, (2) Constant properties.

ANALYSIS: (a) To be valid, the temperature distribution must satisfy the appropriate forms of the heat equation and boundary conditions. Substituting the distribution into Equation 2.21, it follows that

$$\frac{\partial^2 T}{\partial x^2}=\frac{1}{\alpha}\frac{\partial T}{\partial t}$$

$$-C_1\left(T_i-T_s\right)\exp\left(-\frac{\pi^2}{4}\frac{\alpha t}{L^2}\right)\left(\frac{\pi}{2L}\right)^2\cos\left(\frac{\pi}{2}\frac{x}{L}\right)$$

$$=-\frac{C_1}{\alpha}\left(T_i-T_s\right)\left(\frac{\pi^2}{4}\frac{\alpha}{L^2}\right)\exp\left(-\frac{\pi^2}{4}\frac{\alpha t}{L^2}\right)\cos\left(\frac{\pi}{2}\frac{x}{L}\right). \qquad <$$

Hence, the heat equation is satisfied. Applying boundary conditions at x = 0 and x = L, it follows that

$$\frac{\partial T}{\partial x}\Big|_{x=0}=-\frac{C_1\pi}{2L}\left(T_i-T_s\right)\exp\left(-\frac{\pi^2}{4}\frac{\alpha t}{L^2}\right)\sin\left(\frac{\pi}{2}\frac{x}{L}\right)\Big|_{x=0}=0 \qquad <$$

and

$$T\left(L,t\right)=T_s+C_1\left(T_i-T_s\right)\exp\left(-\frac{\pi^2}{4}\frac{\alpha t}{L^2}\right)\cos\left(\frac{\pi}{2}\frac{x}{L}\right)\Big|_{x=L}=T_s. \qquad <$$

Hence, the boundary conditions are also satisfied.

(b) The heat flux has the form

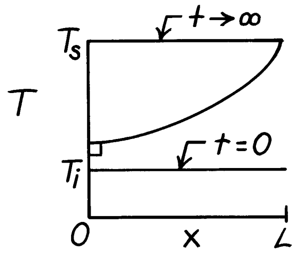
$$q''_x=-k\frac{\partial T}{\partial x}=+\frac{kC_1\pi}{2L}\left(T_i-T_s\right)\exp\left(-\frac{\pi^2}{4}\frac{\alpha t}{L^2}\right)\sin\left(\frac{\pi}{2}\frac{x}{L}\right).$$

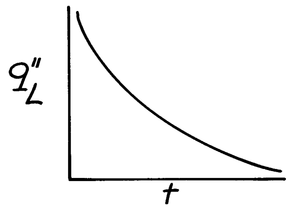
Continued …

Hence, $q''_x(0) = 0,$ <

$$q''_x(L) = +\frac{kC_1\pi}{2L}(T_i - T_s)\exp\left(-\frac{\pi^2}{4}\frac{\alpha t}{L^2}\right).$$ <

(c) The temperature distribution and surface heat flux variations are:





(d) For materials A and B of different α,

$$\frac{[T(x,t) - T_s]_A}{[T(x,t) - T_s]_B} = \exp\left[-\frac{\pi^2}{4L^2}(\alpha_A - \alpha_B)t\right]$$

Hence, if $\alpha_A > \alpha_B$, $T(x,t) \to T_s$ more rapidly for Material A. If $\alpha_A < \alpha_B$, $T(x,t) \to T_s$ more rapidly for Material B. <

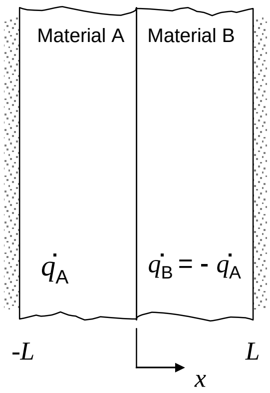
COMMENTS: Note that the prescribed function for T(x,t) does not reduce to T_i for $t \to 0$. For times at or close to zero, the function is not a valid solution of the problem. At such times, the solution for T(x,t) must include additional terms. The solution is considered in Section 5.5.1 of the text.

PROBLEM 2.67

KNOWN: Thickness of composite plane wall consisting of material A in left half and material B in right half. Exothermic reaction in material A and endothermic reaction in material B, with equal and opposite heat generation rates. External surfaces are insulated.

FIND: Sketch temperature and heat flux distributions for three thermal conductivity ratios, k_A/k_B.

SCHEMATIC:

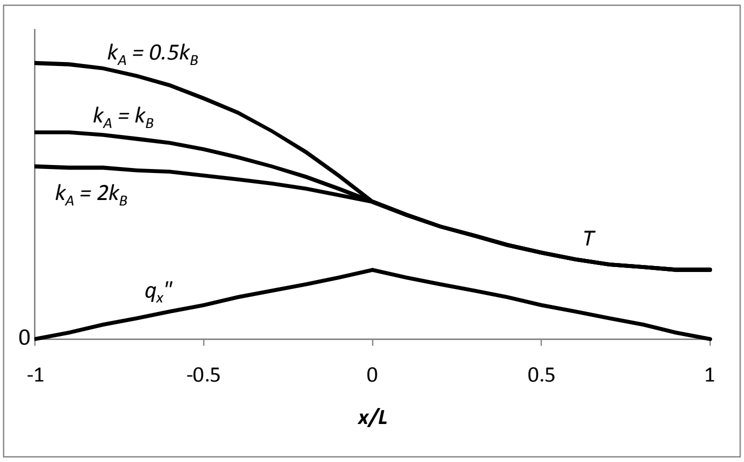


ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties.

ANALYSIS: From Equation 2.19 for steady-state, one-dimensional conduction, we find

$$\frac{\partial}{\partial x}\left(k\frac{\partial T}{\partial x}\right) = -\dot{q} \quad \text{or} \quad \frac{\partial q_x''}{\partial x} = \dot{q}$$

From the second equation, with uniform heat generation rate, we see that q_x'' varies linearly with x, and its slope is $+\dot{q}_A$ in material A and $-\dot{q}_A$ in material B. Furthermore, since the wall is insulated on both exterior surfaces, the heat flux must be zero at $x = \pm L$. Thus, the heat flux is as shown in the graph below and does not depend on the thermal conductivities. The heat generated in the left half is conducting to the right and accumulating as it goes. Once it reaches the centerline, it begins to be consumed by the exothermic reaction and drops to zero at $x = L$.



Continued…

PROBLEM 2.67 (Cont.)

Since $q''_x = -k\dfrac{\partial T}{\partial x}$, the temperature gradient is negative everywhere, and its magnitude is greatest where the heat flux is greatest. Thus the slope of the temperature distribution is zero at $x = -L$, it becomes more negative as it reaches the center, and then becomes flatter again until it reaches a slope of zero at $x = L$. When $k_A = k_B$, the temperature distribution has equal and opposite slopes on either side of the centerline. If k_B is held fixed and k_A is varied, the results are as shown in the plot above. Since the temperature gradient is inversely proportional to the thermal conductivity, it is steeper in the region that has the smaller thermal conductivity. Physically, when thermal conductivity is larger, heat conducts more readily and causes the temperature to become more uniform.

If $\dot{q}_B = -2\dot{q}_A$, an energy balance on the wall gives:

$$\frac{dE_{st}}{dt} = \dot{E}_{in} - \dot{E}_{out} + \dot{E}_g$$

$$\frac{dE_{st}}{dt} = \dot{E}_g = (\dot{q}_A + \dot{q}_B)V = -\dot{q}_A V$$

where V is the volume. Since dE_{st}/dt is non-zero, the wall cannot be at steady-state. With the exothermic reaction greater than the endothermic reaction, the wall will continuously decrease in temperature. <

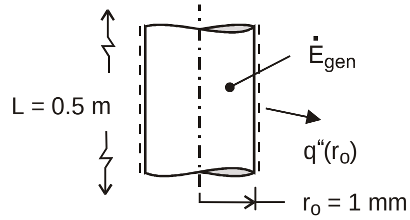
COMMENTS: (1) Given the information in the problem statement, it is not possible to calculate actual temperatures. There are an infinite number of correct solutions regarding temperature *values*, but only one correct solution regarding the *shape* of the temperature distribution. (2) Chemical reactions would cease if the temperature became too small. It would not be possible to continually cool the wall for the case when, initially, $\dot{q}_B = -2\dot{q}_A$.

PROBLEM 2.68

KNOWN: Radius and length of coiled wire in hair dryer. Electric power dissipation in the wire, and temperature and convection coefficient associated with air flow over the wire.

FIND: (a) Form of heat equation and conditions governing transient, thermal behavior of wire during start-up, (b) Volumetric rate of thermal energy generation in the wire, (c) Sketch of temperature distribution at selected times during start-up, (d) Variation with time of heat flux at r = 0 and r = r_o.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, radial conduction, (2) Constant properties, (3) Uniform volumetric heating, (4) Negligible radiation from surface of wire.

ANALYSIS: (a) The general form of the heat equation for cylindrical coordinates is given by Eq. 2.26. For one-dimensional, radial conduction and constant properties, the equation reduces to

$$\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial T}{\partial r}\right)+\frac{\dot{q}}{k}=\frac{\rho c_p}{k}\frac{\partial T}{\partial t}=\frac{1}{\alpha}\frac{\partial T}{\partial t}$$ <

The initial condition is $T(r,0)=T_i$ <

The boundary conditions are: $\partial T/\partial r|_{r=0}=0$ <

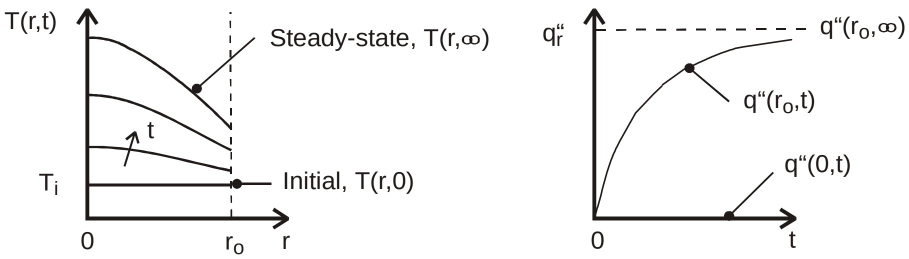
$$-k\left.\frac{\partial T}{\partial r}\right|_{r=r_o}=h\left[T(r_o,t)-T_\infty\right]$$ <

(b) The volumetric rate of thermal energy generation is

$$\dot{q}=\frac{\dot{E}_g}{\forall}=\frac{P_{elec}}{\pi r_o^2 L}=\frac{500\ \text{W}}{\pi(0.001\text{m})^2(0.5\text{m})}=3.18\times10^8\ \text{W/m}^3$$ <

Under steady-state conditions, all of the thermal energy generated within the wire is transferred to the air by convection. Performing an energy balance for a control surface about the wire, $-\dot{E}_{out}+\dot{E}_g=0$, it follows that $-2\pi r_o L\ q''(r_o, t\to\infty)+P_{elec}=0$. Hence,

$$q''(r_o, t\to\infty)=\frac{P_{elec}}{2\pi r_o L}=\frac{500\ \text{W}}{2\pi(0.001\text{m})0.5\text{m}}=1.59\times10^5\ \text{W/m}^2$$ <



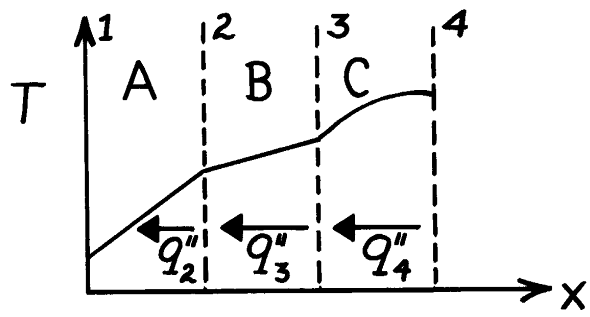
COMMENTS: The symmetry condition at r = 0 imposes the requirement that $\partial T/\partial r|_{r=0}=0$, and hence $q''(0,t)=0$ throughout the process. The temperature at r_o, and hence the convection heat flux, increases steadily during the start-up, and since conduction to the surface must be balanced by convection from the surface at all times, $\left|\partial T/\partial r\right|_{r=r_o}$ also increases during the start-up.

PROBLEM 2.69

KNOWN: Temperature distribution in a composite wall.

FIND: (a) Relative magnitudes of interfacial heat fluxes, (b) Relative magnitudes of thermal conductivities, and (c) Heat flux as a function of distance x.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties.

ANALYSIS: (a) For the prescribed conditions (one-dimensional, steady-state, constant k), the parabolic temperature distribution in C implies the existence of heat generation. Hence, since dT/dx *increases* with *decreasing* x, the heat flux in C *increases* with *decreasing* x. Hence,

$$q''_3 > q''_4$$

However, the linear temperature distributions in A and B indicate no generation, in which case

$$q''_2 = q''_3$$

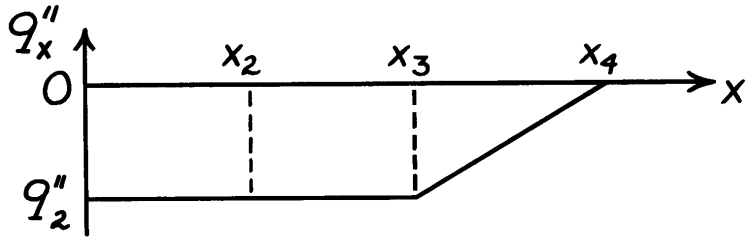
(b) Since conservation of energy requires that $q''_{3,B} = q''_{3,C}$ and $dT/dx)_B < dT/dx)_C$, it follows from Fourier's law that

$$k_B > k_C.$$

Similarly, since $q''_{2,A} = q''_{2,B}$ and $dT/dx)_A > dT/dx)_B$, it follows that

$$k_A < k_B.$$

(c) It follows that the flux distribution appears as shown below.



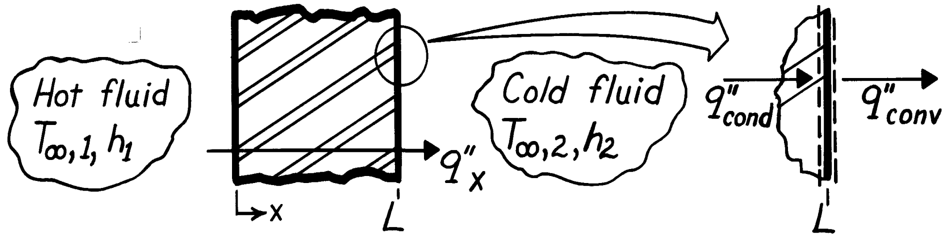
COMMENTS: Note that, with $dT/dx)_{4,C} = 0$, the interface at 4 is adiabatic.

PROBLEM 3.1

KNOWN: One-dimensional, plane wall separating hot and cold fluids at $T_{\infty,1}$ and $T_{\infty,2}$, respectively.

FIND: Temperature distribution, T(x), and heat flux, q''_x, in terms of $T_{\infty,1}$, $T_{\infty,2}$, h_1, h_2, k and L.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Steady-state conditions, (3) Constant properties, (4) Negligible radiation, (5) No generation.

ANALYSIS: For the foregoing conditions, the general solution to the heat diffusion equation is of the form, Equation 3.2,

$$T(x) = C_1 x + C_2. \qquad (1)$$

The constants of integration, C_1 and C_2, are determined by using surface energy balance conditions at x = 0 and x = L, Equation 2.34, and as illustrated above,

$$-k\frac{dT}{dt}\bigg]_{x=0} = h_1\left[T_{\infty,1} - T(0)\right] \qquad -k\frac{dT}{dx}\bigg]_{x=L} = h_2\left[T(L) - T_{\infty,2}\right]. \qquad (2,3)$$

For the boundary condition at x = 0, Equation (2), use Equation (1) to find

$$-k(C_1 + 0) = h_1\left[T_{\infty,1} - (C_1 \cdot 0 + C_2)\right] \qquad (4)$$

and for the boundary condition at x = L to find

$$-k(C_1 + 0) = h_2\left[(C_1 L + C_2) - T_{\infty,2}\right]. \qquad (5)$$

Multiply Eq. (4) by h_2 and Eq. (5) by h_1, and add the equations to obtain C_1. Then substitute C_1 into Eq. (4) to obtain C_2. The results are

$$C_1 = -\frac{(T_{\infty,1} - T_{\infty,2})}{k\left[\frac{1}{h_1} + \frac{1}{h_2} + \frac{L}{k}\right]} \qquad C_2 = -\frac{(T_{\infty,1} - T_{\infty,2})}{h_1\left[\frac{1}{h_1} + \frac{1}{h_2} + \frac{L}{k}\right]} + T_{\infty,1}$$

$$T(x) = -\frac{(T_{\infty,1} - T_{\infty,2})}{\left[\frac{1}{h_1} + \frac{1}{h_2} + \frac{L}{k}\right]}\left[\frac{x}{k} + \frac{1}{h_1}\right] + T_{\infty,1}. \qquad <$$

From Fourier's law, the heat flux is a constant and of the form

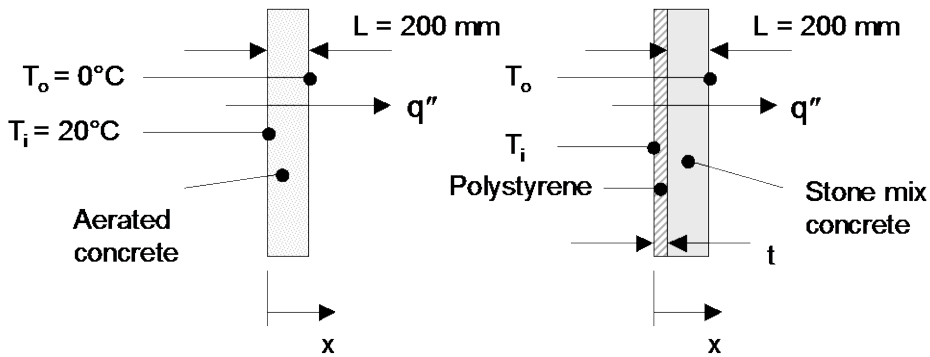
$$q''_x = -k\frac{dT}{dx} = -k\,C_1 = +\frac{(T_{\infty,1} - T_{\infty,2})}{\left[\frac{1}{h_1} + \frac{1}{h_2} + \frac{L}{k}\right]}. \qquad <$$

PROBLEM 3.2

KNOWN: Thickness of basement wall. Inner and outer wall temperatures. Thermal conductivity of aerated concrete.

FIND: Thickness of polystyrene insulation needed to reduce heat flux through the stone mix concrete wall to that of the aerated concrete wall. Lost annual rental income associated with specification of the stone mix concrete wall.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, one-dimensional conduction, (2) Constant properties, (3) Negligible contact resistance.

PROPERTIES: *Table A.3*, Stone mix concrete (300 K): k_{sm} = 1.4 W/m·K; Rigid extruded polystyrene sheet (285 K, ρ = 35 kg/m^3): k_{ps} = 0.027 W/m·K. Aerated concrete: k_{ac} = 0.15 W/m·K (given).

ANALYSIS: The heat flux through the aerated concrete is

$$q'' = k_{ac}(T_i - T_o)/L = 0.15 \text{ W/m}\cdot\text{K} \times (20°\text{C} - 0°\text{C})/0.20 \text{ m} = 15 \text{ W/m}^2 \qquad (1)$$

The heat flux through the stone mix concrete and polystyrene sheet composite wall is

$$q'' = 15 \text{ W/m}^2 = \frac{T_i - T_o}{(t/k_{ps}) + (L/k_{sm})} = \frac{(20°\text{C} - 0°\text{C})}{(t/0.027 \text{ W/m}\cdot\text{K}) + (0.200 \text{ m}/1.4 \text{ W/m}\cdot\text{K})} \qquad (2)$$

Hence, t = 0.032 m = 32 mm. <

The floor space occupied by the polystyrene insulation is A = 0.032 m × (20 m + 30 m) × 2 = 3.2 m^2. The lost annual revenue associated with specification of the stone mix concrete is ΔR = \$50/m^2/month × 12 months/year × 3.2 m^2 = \$1920 per year. <

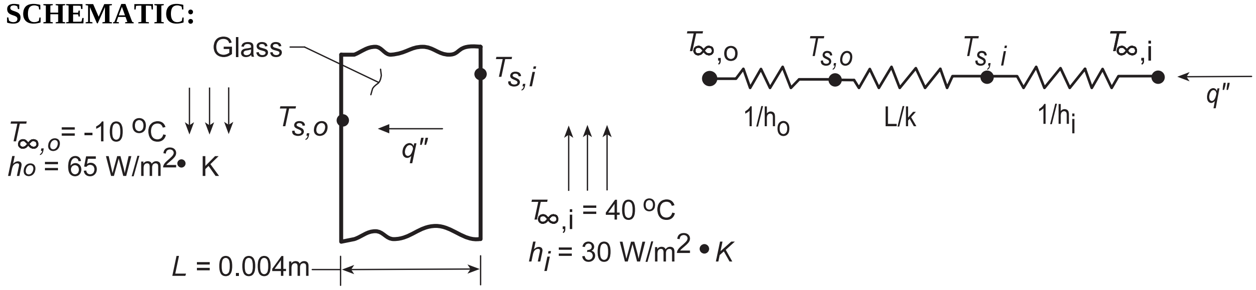
COMMENTS: (1) Inclusion of the thermal contact resistance will reduce the value of the required insulation thickness. (2) A careful economic analysis would account for the difference in cost of the two materials. However, additional costs associated with specification of the stone mix concrete are labor costs for installation of the insulation, and the cost of the insulation itself. Additional costs for the aerated concrete wall are labor costs for constructing the wall of aerated concrete blocks. (3) Lightweight aerated concrete blocks are fabricated of recycled fly ash, a byproduct of coal combustion. The low thermal conductivity is due to small air bubbles that are entrapped within the solid matrix.

PROBLEM 3.3

KNOWN: Temperatures and convection coefficients associated with air at the inner and outer surfaces of a rear window.

FIND: (a) Inner and outer window surface temperatures, $T_{s,i}$ and $T_{s,o}$, and (b) $T_{s,i}$ and $T_{s,o}$ as a function of the outside air temperature $T_{\infty,o}$ and for selected values of outer convection coefficient, h_o.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Negligible radiation effects, (4) Constant properties.

PROPERTIES: *Table A-3*, Glass (300 K): k = 1.4 W/m·K.

ANALYSIS: (a) The heat flux may be obtained from Eqs. 3.11 and 3.12,

$$q'' = \frac{T_{\infty,i} - T_{\infty,o}}{\dfrac{1}{h_o} + \dfrac{L}{k} + \dfrac{1}{h_i}} = \frac{40^\circ C - \left(-10^\circ C\right)}{\dfrac{1}{65\,W/m^2\cdot K} + \dfrac{0.004\,m}{1.4\,W/m\cdot K} + \dfrac{1}{30\,W/m^2\cdot K}}$$

$$q'' = \frac{50^\circ C}{\left(0.0154 + 0.0029 + 0.0333\right)m^2\cdot K/W} = 969\,W/m^2 .$$

Hence, with $q'' = h_i\left(T_{\infty,i} - T_{\infty,o}\right)$, the inner surface temperature is

$$T_{s,i} = T_{\infty,i} - \frac{q''}{h_i} = 40^\circ C - \frac{969\,W/m^2}{30\,W/m^2\cdot K} = 7.7^\circ C$$ <

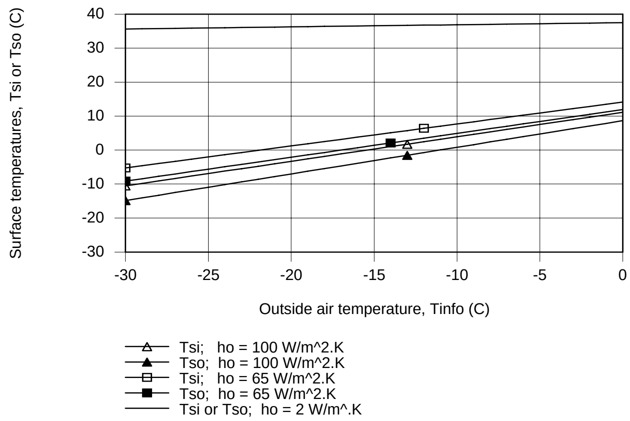
Similarly for the outer surface temperature with $q'' = h_o\left(T_{s,o} - T_{\infty,o}\right)$ find

$$T_{s,o} = T_{\infty,o} + \frac{q''}{h_o} = -10^\circ C + \frac{969\,W/m^2}{65\,W/m^2\cdot K} = 4.9^\circ C$$ <

(b) Using the same analysis, $T_{s,i}$ and $T_{s,o}$ have been computed and plotted as a function of the outside air temperature, $T_{\infty,o}$, for outer convection coefficients of h_o = 2, 65, and 100 W/m^2·K. As expected, $T_{s,i}$ and $T_{s,o}$ are linear with changes in the outside air temperature. The difference between $T_{s,i}$ and $T_{s,o}$ increases with increasing convection coefficient, since the heat flux through the window likewise increases. This difference is larger at lower outside air temperatures for the same reason. Note that with h_o = 2 W/m^2·K, $T_{s,i}$ - $T_{s,o}$, is too small to show on the plot.

Continued …

PROBLEM 3.3 (Cont.)

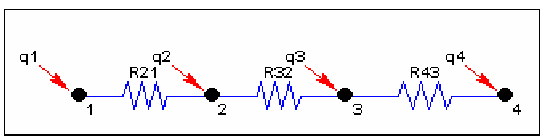


COMMENTS: (1) The largest resistance is that associated with convection at the inner surface. The values of $T_{s,i}$ and $T_{s,o}$ could be increased by increasing the value of h_i.

(2) The *IHT Thermal Resistance Network Model* was used to create a model of the window and generate the above plot. The Workspace is shown below.

// Thermal Resistance Network Model:

// The Network:



```
// Heat rates into node j,qij, through thermal resistance Rij
q21 = (T2 - T1) / R21
q32 = (T3 - T2) / R32
q43 = (T4 - T3) / R43

// Nodal energy balances
q1 + q21 = 0
q2 - q21 + q32 = 0
q3 - q32 + q43 = 0
q4 - q43 = 0

/* Assigned variables list: deselect the qi, Rij and Ti which are unknowns; set qi = 0 for embedded nodal points
at which there is no external source of heat. */
T1 =  Tinfo          // Outside air temperature, C
//q1 =               // Heat rate, W
T2 =  Tso            // Outer surface temperature, C
q2 =  0              // Heat rate, W; node 2, no external heat source
T3 =  Tsi            // Inner surface temperature, C
q3 =  0              // Heat rate, W; node 2, no external heat source
T4 = Tinfi           // Inside air temperature, C
//q4 =               // Heat rate, W
```

// Thermal Resistances:

```
R21 =  1 / ( ho * As )      // Convection thermal resistance, K/W; outer surface
R32 =  L / ( k * As )       // Conduction thermal resistance, K/W; glass
R43 =  1 / ( hi * As )      // Convection thermal resistance, K/W; inner surface
```

// Other Assigned Variables:

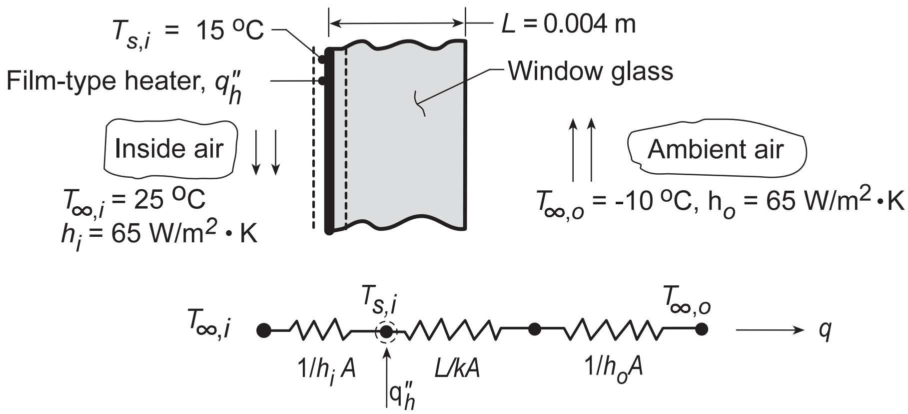
```
Tinfo = -10          // Outside air temperature, C
ho = 65              // Convection coefficient, W/m^2.K; outer surface
L = 0.004            // Thickness, m; glass
k = 1.4              // Thermal conductivity, W/m.K; glass
Tinfi = 40           // Inside air temperature, C
hi = 30              // Convection coefficient, W/m^2.K; inner surface
As = 1               // Cross-sectional area, m^2; unit area
```

PROBLEM 3.4

KNOWN: Desired inner surface temperature of rear window with prescribed inside and outside air conditions.

FIND: (a) Heater power per unit area required to maintain the desired temperature, and (b) Compute and plot the electrical power requirement as a function of $T_{\infty,o}$ for the range -30 ≤ $T_{\infty,o}$ ≤ 0°C with h_o of 2, 20, 65 and 100 W/m^2·K. Comment on heater operation needs for low h_o. If h ~ V^n, where V is the vehicle speed and n is a positive exponent, how does the vehicle speed affect the need for heater operation?

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Uniform heater flux, q''_h, (4) Constant properties, (5) Negligible radiation effects, (6) Negligible film resistance.

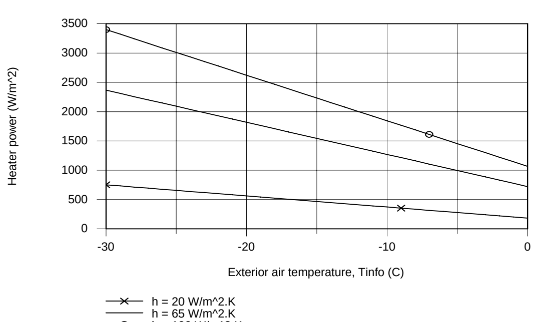
PROPERTIES: *Table A-3*, Glass (300 K): k = 1.4 W/m·K.

ANALYSIS: (a) From an energy balance at the inner surface and the thermal circuit, it follows that for a unit surface area,

$$\frac{T_{\infty,i}-T_{s,i}}{1/h_i}+q''_h=\frac{T_{s,i}-T_{\infty,o}}{L/k+1/h_o} \quad \text{and that} \quad q''_h=\frac{T_{s,i}-T_{\infty,o}}{L/k+1/h_o}-\frac{T_{\infty,i}-T_{s,i}}{1/h_i}$$

$$q''_h=\frac{15^\circ\text{C}-\left(-10^\circ\text{C}\right)}{\dfrac{0.004\,\text{m}}{1.4\,\text{W/m}\cdot\text{K}}+\dfrac{1}{65\,\text{W/m}^2\cdot\text{K}}}-\frac{25^\circ\text{C}-15^\circ\text{C}}{\dfrac{1}{10\,\text{W/m}^2\cdot\text{K}}}=\left(1370-100\right)\text{W/m}^2=1270\,\text{W/m}^2$$ <

(b) The heater electrical power requirement as a function of the exterior air temperature for different exterior convection coefficients is shown in the plot. When h_o = 2 W/m^2·K, the heater is unecessary, since the glass is maintained at 15°C by the interior air. If h ~ V^n, we conclude that, with higher vehicle speeds, the exterior convection will increase, requiring increased heat power to maintain the 15°C condition.



COMMENTS: With q''_h = 0, the inner surface temperature with $T_{\infty,o}$ = -10°C would be given by

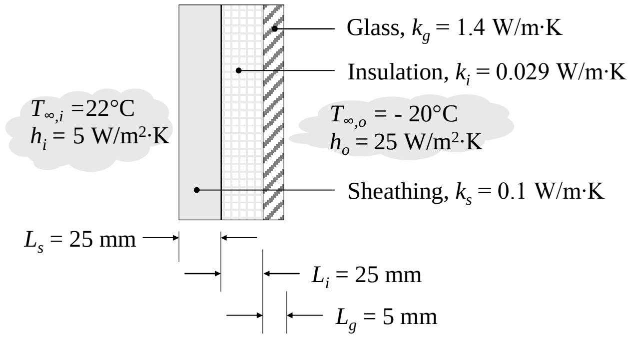
$$\frac{T_{\infty,i}-T_{s,i}}{T_{\infty,i}-T_{\infty,o}}=\frac{1/h_i}{1/h_i+L/k+1/h_o}=\frac{0.10}{0.118}=0.846, \qquad \text{or} \qquad T_{s,i}=25^\circ\text{C}-0.846\left(35^\circ\text{C}\right)=-4.6^\circ\text{C}.$$

PROBLEM 3.5

KNOWN: Thermal conductivities and thicknesses of original wall, insulation layer, and glass layer. Interior and exterior air temperatures and convection heat transfer coefficients.

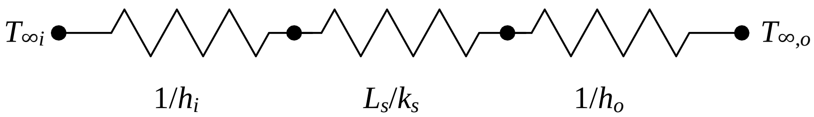
FIND: Heat flux through original and retrofitted walls.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Steady-state conditions, (3) Constant properties, (4) Negligible contact resistances.

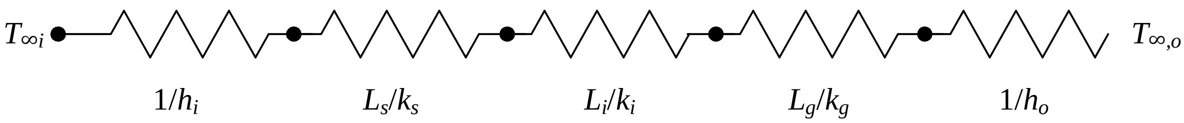
ANALYSIS: The original wall with convection inside and outside can be represented by the following thermal resistance network, where the resistances are each for a unit area:



Thus the heat flux can be expressed as

$$q'' = \frac{T_{\infty,i} - T_{\infty,o}}{\frac{1}{h_i} + \frac{L_s}{k_s} + \frac{1}{h_o}} = \frac{22°\text{C} - (-20°\text{C})}{\frac{1}{5\ \text{W/m}^2\cdot\text{K}} + \frac{0.025\ \text{m}}{0.1\ \text{W/m}\cdot\text{K}} + \frac{1}{25\ \text{W/m}^2\cdot\text{K}}} = 85.7\ \text{W/m}^2$$ <

The retrofitted wall has three layers. The thermal circuit can be represented as follows:



Thus the heat flux can be expressed as

$$q'' = \frac{T_{\infty,i} - T_{\infty,o}}{\frac{1}{h_i} + \frac{L_s}{k_s} + \frac{L_i}{k_i} + \frac{L_g}{k_g} + \frac{1}{h_o}}$$

$$= \frac{22°\text{C} - (-20°\text{C})}{\frac{1}{5\ \text{W/m}^2\cdot\text{K}} + \frac{0.025\ \text{m}}{0.1\ \text{W/m}\cdot\text{K}} + \frac{0.025\ \text{m}}{0.029\ \text{W/m}\cdot\text{K}} + \frac{0.005\ \text{m}}{1.4\ \text{W/m}\cdot\text{K}} + \frac{1}{25\ \text{W/m}^2\cdot\text{K}}} = 31.0\ \text{W/m}^2$$ <

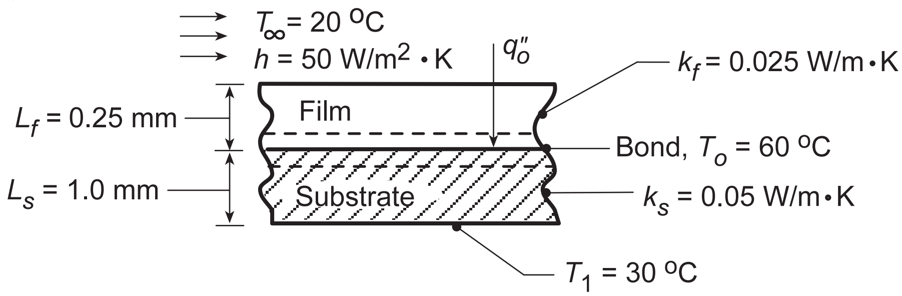
COMMENTS: The heat flux has been reduced to approximately one-third of the original value because of the increased resistance, which is mainly due to the insulation layer.

PROBLEM 3.6

KNOWN: Curing of a transparent film by radiant heating with substrate and film surface subjected to known thermal conditions.

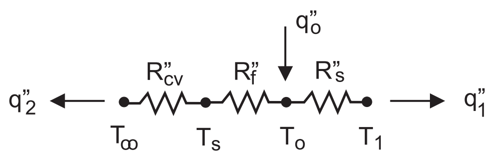
FIND: (a) Thermal circuit for this situation, (b) Radiant heat flux, q''_o (W/m^2), to maintain bond at curing temperature, T_o, (c) Compute and plot q''_o as a function of the film thickness for $0 \le L_f \le 1$ mm, and (d) If the film is not transparent, determine q''_o required to achieve bonding; plot results as a function of L_f.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat flow, (3) All the radiant heat flux q''_o is absorbed at the bond, (4) Negligible contact resistance.

ANALYSIS: (a) The thermal circuit for this situation is shown at the right. Note that terms are written on a per unit area basis.



(b) Using this circuit and performing an energy balance on the film-substrate interface,

$$q''_o = q''_1 + q''_2 \qquad\qquad q''_o = \frac{T_o - T_\infty}{R''_{cv} + R''_f} + \frac{T_o - T_1}{R''_s}$$

where the thermal resistances are

$$R''_{cv} = 1/h = 1/50\,\mathrm{W/m^2 \cdot K} = 0.020\,\mathrm{m^2 \cdot K/W}$$

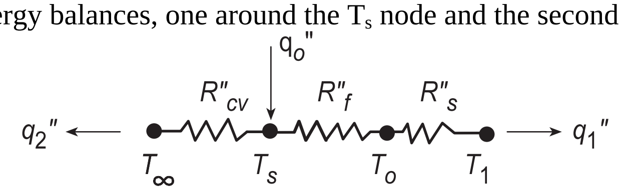
$$R''_f = L_f/k_f = 0.00025\,\mathrm{m}/0.025\,\mathrm{W/m \cdot K} = 0.010\,\mathrm{m^2 \cdot K/W}$$

$$R''_s = L_s/k_s = 0.001\,\mathrm{m}/0.05\,\mathrm{W/m \cdot K} = 0.020\,\mathrm{m^2 \cdot K/W}$$

$$q''_o = \frac{(60-20)^\circ\mathrm{C}}{[0.020+0.010]\,\mathrm{m^2 \cdot K/W}} + \frac{(60-30)^\circ\mathrm{C}}{0.020\,\mathrm{m^2 \cdot K/W}} = (1333+1500)\,\mathrm{W/m^2} = 2833\,\mathrm{W/m^2} \quad <$$

(c) For the transparent film, the radiant flux required to achieve bonding as a function of film thickness L_f is shown in the plot below.

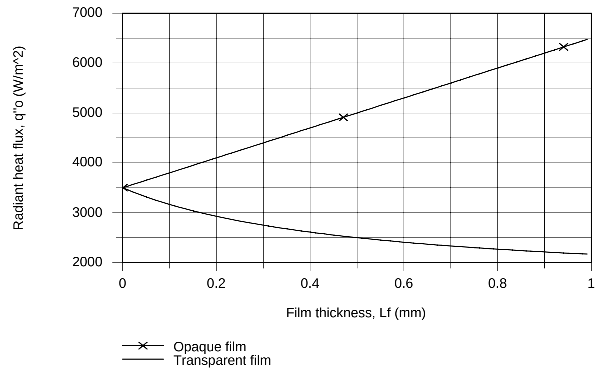
(d) If the film is opaque (not transparent), the thermal circuit is shown below. In order to find q''_o, it is necessary to write two energy balances, one around the T_s node and the second about the T_o node.



.
The results of the analysis are plotted below.

Continued...

PROBLEM 3.6 (Cont.)

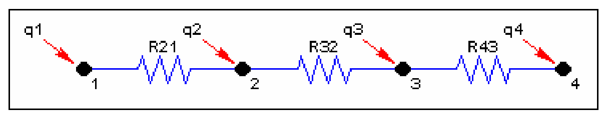


COMMENTS: (1) When the film is transparent, the radiant flux is absorbed on the bond. The flux required decreases with increasing film thickness. Physically, how do you explain this? Why is the relationship not linear?

(2) When the film is opaque, the radiant flux is absorbed on the surface, and the flux required increases with increasing thickness of the film. Physically, how do you explain this? Why is the relationship linear?

(3) The IHT Thermal Resistance Network Model was used to create a model of the film-substrate system and generate the above plot. The Workspace is shown below.

// Thermal Resistance Network Model:
// The Network:



```
// Heat rates into node j,qij, through thermal resistance Rij
q21 = (T2 - T1) / R21
q32 = (T3 - T2) / R32
q43 = (T4 - T3) / R43

// Nodal energy balances
q1 + q21 = 0
q2 - q21 + q32 = 0
q3 - q32 + q43 = 0
q4 - q43 = 0

/* Assigned variables list: deselect the qi, Rij and Ti which are unknowns; set qi = 0 for embedded nodal points
at which there is no external source of heat. */
T1 = Tinf          // Ambient air temperature, C
//q1 =             // Heat rate, W; film side
T2 = Ts            // Film surface temperature, C
q2 = 0             // Radiant flux, W/m^2; zero for part (a)
T3 = To            // Bond temperature, C
q3 = qo            // Radiant flux, W/m^2; part (a)
T4 = Tsub          // Substrate temperature, C
//q4 =             // Heat rate, W; substrate side

// Thermal Resistances:
R21 =  1 / ( h * As )          // Convection resistance, K/W
R32 =  Lf / (kf * As)          // Conduction resistance, K/W; film
R43 =  Ls / (ks * As)// Conduction resistance, K/W; substrate

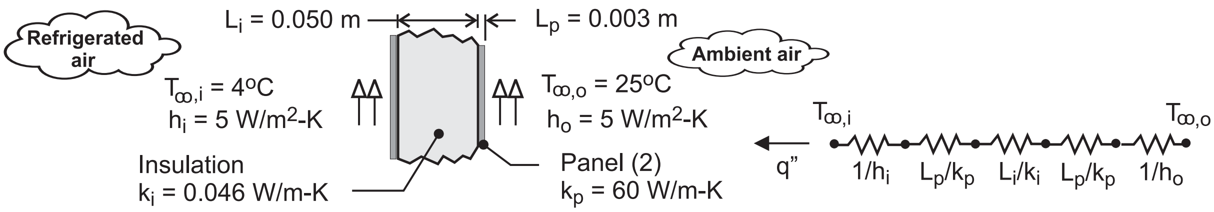
// Other Assigned Variables:
Tinf = 20          // Ambient air temperature, C
h = 50             // Convection coefficient, W/m^2.K
Lf = 0.00025       // Thickness, m; film
kf = 0.025         // Thermal conductivity, W/m.K; film
To = 60            // Cure temperature, C
Ls = 0.001         // Thickness, m; substrate
ks = 0.05          // Thermal conductivity, W/m.K; substrate
Tsub = 30// Substrate temperature, C
As = 1             // Cross-sectional area, m^2; unit area
```

PROBLEM 3.7

KNOWN: Thicknesses and thermal conductivities of refrigerator wall materials. Inner and outer air temperatures and convection coefficients.

FIND: Heat gain per surface area.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional heat transfer, (2) Steady-state conditions, (3) Negligible contact resistance, (4) Negligible radiation, (5) Constant properties.

ANALYSIS: From the thermal circuit, the heat gain per unit surface area is

$$q'' = \frac{T_{\infty,o} - T_{\infty,i}}{(1/h_i) + (L_p/k_p) + (L_i/k_i) + (L_p/k_p) + (1/h_o)}$$

$$q'' = \frac{(25-4)^\circ C}{2(1/5\,W/m^2\cdot K) + 2(0.003m/60\,W/m\cdot K) + (0.050m/0.046\,W/m\cdot K)}$$

$$q'' = \frac{21^\circ C}{(0.4 + 0.0001 + 1.087)m^2\cdot K/W} = 14.1\,W/m^2$$ <

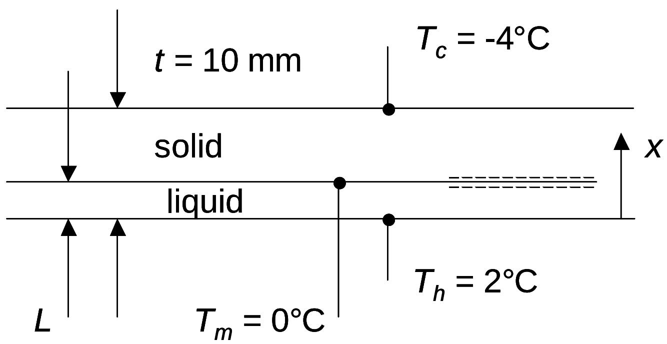
COMMENTS: Although the contribution of the panels to the total thermal resistance is negligible, that due to convection is not inconsequential and is comparable to the thermal resistance of the insulation.

PROBLEM 3.8

KNOWN: Top and bottom temperatures applied to a water layer of known thickness.

FIND: Steady-state location of the solid-liquid interface.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible radiation, (4) Negligible convection in the liquid.

PROPERTIES: Table A.6, liquid water (T = 273 K): k_f = 0.569 W/m·K; Table A.3, ice (T = 0 K), k_s = 1.88 W/m·K.

ANALYSIS: An energy balance at the control surface shown in the schematic yields

$$k_f (T_h - T_m)/L = k_s (T_m - T_c)/(t - L)$$

or

$$L = \frac{t}{\left(\dfrac{k_s (T_m - T_c)}{k_f (T_h - T_m)} + 1\right)} = \frac{10 \times 10^{-3}\text{m}}{\left(\dfrac{1.88\text{W/m}\cdot\text{K}(0°\text{C} - (-4°\text{C})}{0.569\text{W/m}\cdot\text{K}(2°\text{C} - 0°\text{C})} + 1\right)} = 1.31 \times 10^{-3}\text{m} = 1.31 \text{ mm} \quad <$$

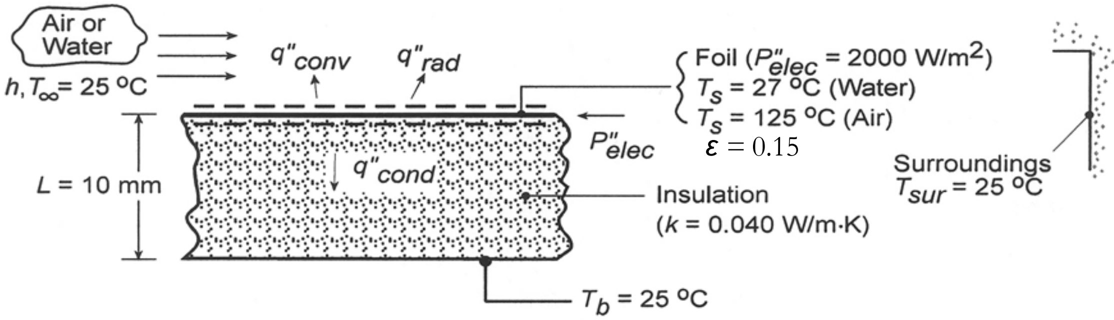
COMMENTS: (1) Liquid water is opaque to thermal radiation, but ice is semi-transparent. A more detailed analysis would account for the effects of radiation. (2) Free convection in the liquid is negligible because the density of liquid water at T_h = 2°C is greater than the density at T_m = 0°C. Water is one of only several liquids that experiences such a *density inversion*.

PROBLEM 3.9

KNOWN: Design and operating conditions of a heat flux gage.

FIND: (a) Convection coefficient for water flow (T_s = 27°C) and error associated with neglecting conduction in the insulation, (b) Convection coefficient for air flow (T_s = 125°C) and error associated with neglecting conduction and radiation, (c) Effect of convection coefficient on error associated with neglecting conduction for T_s = 27°C.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction, (3) Constant k.

ANALYSIS: (a) The electric power dissipation is balanced by convection to the water and conduction through the insulation. An energy balance applied to a control surface about the foil therefore yields

$$P''_{elec} = q''_{conv} + q''_{cond} = h\left(T_s - T_\infty\right) + k\left(T_s - T_b\right)\big/L$$

Hence,

$$h = \frac{P''_{elec} - k\left(T_s - T_b\right)/L}{T_s - T_\infty} = \frac{2000\,W\big/m^2 - 0.04\,W/m\cdot K\left(2\,K\right)\big/0.01\,m}{2\,K}$$

$$h = \frac{\left(2000-8\right)W\big/m^2}{2\,K} = 996\,W\big/m^2\cdot K$$ <

If conduction is neglected, a value of h = 1000 W/m^2·K is obtained, with an attendant error of (1000 - 996)/996 = 0.40%

(b) In air, energy may also be transferred from the foil surface by radiation, and the energy balance yields

$$P''_{elec} = q''_{conv} + q''_{rad} + q''_{cond} = h\left(T_s - T_\infty\right) + \varepsilon\sigma\left(T_s^4 - T_{sur}^4\right) + k\left(T_s - T_b\right)\Big/L$$

Hence,

$$h = \frac{P''_{elec} - \varepsilon\sigma\left(T_s^4 - T_{sur}^4\right) - k\left(T_s - T_\infty\right)\Big/L}{T_s - T_\infty}$$

$$= \frac{2000\,W\big/m^2 - 0.15\times5.67\times10^{-8}\,W\big/m^2\cdot K^4\left(398^4 - 298^4\right)K^4 - 0.04\,W/m\cdot K\,(100\,K)/0.01\,m}{100\,K}$$

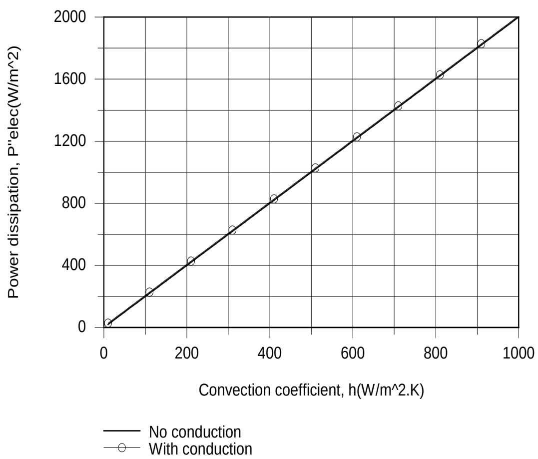
$$= \frac{\left(2000-146-400\right)W\big/m^2}{100\,K} = 14.5\,W\big/m^2\cdot K$$ <

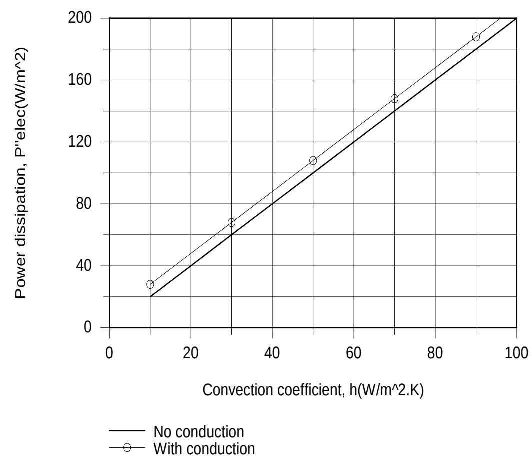
Continued...

PROBLEM 3.9 (Cont.)

If conduction, radiation, or conduction and radiation are neglected, the corresponding values of h and the percentage errors are 18.5 W/m^2·K (27.6%), 16 W/m^2·K (10.3%), and 20 W/m^2·K (37.9%).

(c) For a fixed value of T_s = 27°C, the conduction loss remains at q''_{cond} = 8 W/m^2, which is also the fixed difference between P''_{elec} and q''_{conv}. Although this difference is not clearly shown in the plot for 10 ≤ h ≤ 1000 W/m^2·K, it is revealed in the subplot for 10 ≤ 100 W/m^2·K.





Errors associated with neglecting conduction decrease with increasing h from values which are significant for small h (h < 100 W/m^2·K) to values which are negligible for large h.

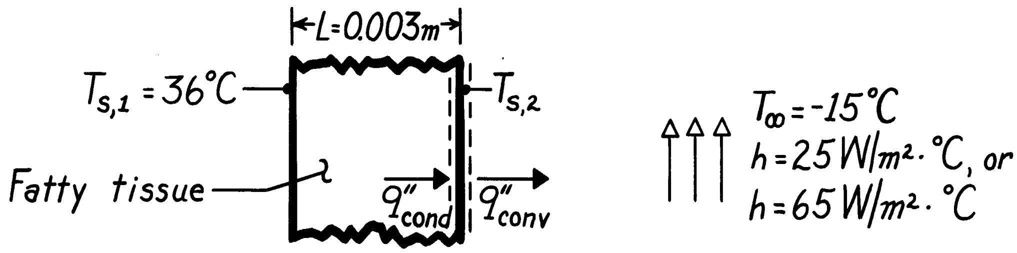
COMMENTS: In liquids (large h), it is an excellent approximation to neglect conduction and assume that all of the dissipated power is transferred to the fluid.

PROBLEM 3.10

KNOWN: A layer of fatty tissue with fixed inside temperature can experience different outside convection conditions.

FIND: (a) Ratio of heat loss for different convection conditions, (b) Outer surface temperature for different convection conditions, and (c) Temperature of still air which achieves same cooling as moving air (*wind chill* effect).

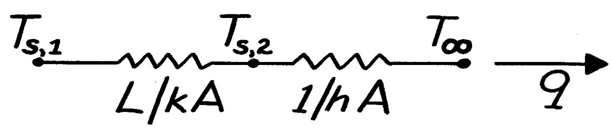
SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction through a plane wall, (2) Steady-state conditions, (3) Homogeneous medium with constant properties, (4) No internal heat generation (metabolic effects are negligible), (5) Negligible radiation effects.

PROPERTIES: *Table A-3*, Tissue, fat layer: k = 0.2 W/m·K.

ANALYSIS: The thermal circuit for this situation is



Hence, the heat rate is

$$q = \frac{T_{s,1} - T_\infty}{R_{tot}} = \frac{T_{s,1} - T_\infty}{L/kA + 1/hA}.$$

Therefore,

$$\frac{q''_{calm}}{q''_{windy}} = \frac{\left[\frac{L}{k} + \frac{1}{h}\right]_{windy}}{\left[\frac{L}{k} + \frac{1}{h}\right]_{calm}}.$$

Applying a surface energy balance to the outer surface, it also follows that

$$q''_{cond} = q''_{conv}.$$

Continued …

PROBLEM 3.10 (Cont.)

Hence,

$$\frac{k}{L}\left(T_{s,1}-T_{s,2}\right)=h\left(T_{s,2}-T_{\infty}\right)$$

$$T_{s,2}=\frac{T_{\infty}+\dfrac{k}{hL}T_{s,1}}{1+\dfrac{k}{hL}}.$$

To determine the wind chill effect, we must determine the heat loss for the windy day and use it to evaluate the hypothetical ambient air temperature, T'_{∞}, which would provide the same heat loss on a calm day, Hence,

$$q''=\frac{T_{s,1}-T_{\infty}}{\left[\dfrac{L}{k}+\dfrac{1}{h}\right]_{windy}}=\frac{T_{s,1}-T'_{\infty}}{\left[\dfrac{L}{k}+\dfrac{1}{h}\right]_{calm}}$$

From these relations, we can now find the results sought:

(a)

$$\frac{q''_{calm}}{q''_{windy}}=\frac{\dfrac{0.003\text{ m}}{0.2\text{ W/m}\cdot\text{K}}+\dfrac{1}{65\text{ W/m}^2\cdot\text{K}}}{\dfrac{0.003\text{ m}}{0.2\text{ W/m}\cdot\text{K}}+\dfrac{1}{25\text{ W/m}^2\cdot\text{K}}}=\frac{0.015+0.0154}{0.015+0.04}$$

$$\frac{q''_{calm}}{q''_{windy}}=0.553$$ <

(b)

$$T_{s,2}\Big]_{calm}=\frac{-15^\circ\text{C}+\dfrac{0.2\text{ W/m}\cdot\text{K}}{\left(25\text{ W/m}^2\cdot\text{K}\right)\left(0.003\text{ m}\right)}36^\circ\text{C}}{1+\dfrac{0.2\text{ W/m}\cdot\text{K}}{\left(25\text{ W/m}^2\cdot\text{K}\right)\left(0.003\text{ m}\right)}}=22.1^\circ\text{C}$$ <

$$T_{s,2}\Big]_{windy}=\frac{-15^\circ\text{C}+\dfrac{0.2\text{ W/m}\cdot\text{K}}{\left(65\text{ W/m}^2\cdot\text{K}\right)\left(0.003\text{m}\right)}36^\circ\text{C}}{1+\dfrac{0.2\text{ W/m}\cdot\text{K}}{\left(65\text{ W/m}^2\cdot\text{K}\right)\left(0.003\text{m}\right)}}=10.8^\circ\text{C}$$ <

(c)

$$T'_{\infty}=36^\circ\text{C}-\left(36+15\right)^\circ\text{C}\frac{\left(0.003/0.2+1/25\right)}{\left(0.003/0.2+1/65\right)}=-56.3^\circ\text{C}$$ <

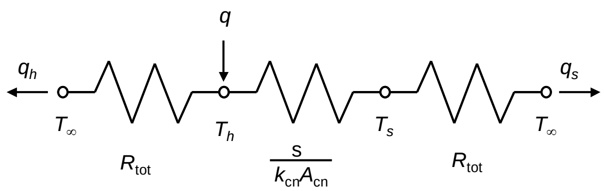
COMMENTS: The wind chill effect is equivalent to a decrease of $T_{s,2}$ by 11.3°C and increase in the heat loss by a factor of $(0.553)^{-1} = 1.81$.

PROBLEM 3.11

KNOWN: Temperature of the heating island and sensing island, as well as the surrounding silicon nitride wafer temperature of Example 3.4.

FIND: The thermal conductivity of the carbon nanotube, k_{cn}, for the conditions of the problem statement and T_h = 332.6 K, without evaluating the thermal resistances of the supports.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional heat transfer, (4) Isothermal heating and sensing islands, (5) Negligible radiation and convection effects.

ANALYSIS: We begin by defining an *excess temperature*, $\theta \equiv T - T_\infty$ and modifying the thermal circuit as shown in the schematic. In the modified circuit, the total thermal resistance, R_{tot}, represents the combined effects of the two beams that support either the heated island or the sensing island.

From the modified thermal circuit, it is evident that an expression for R_{tot} can be derived as

$$q = q_h + q_s = \frac{T_h - T_\infty}{R_{tot}} + \frac{T_s - T_\infty}{R_{tot}} = \frac{\theta_h + \theta_s}{R_{tot}} \quad \text{or} \quad R_{tot} = \frac{\theta_h + \theta_s}{q}$$

For conduction through the supporting beams of the heated island, and through the carbon nanotube, we may write

$$q = q_h + q_s = \frac{T_h - T_\infty}{R_{tot}} + \frac{T_h - T_s}{s/(k_{cn}A_{cn})} = \frac{\theta_h}{R_{tot}} + \frac{\theta_h - \theta_s}{s/(k_{cn}A_{cn})}$$

Substituting the expression for R_{tot} into the preceding equation, and rearranging the resulting expression yields

$$k_{cn} = \left[1 - \frac{\theta_h}{\theta_h + \theta_s}\right]\left[\frac{1}{\theta_h - \theta_s}\right]\frac{sq}{A_{cn}} = \left[1 - \frac{32.6\text{ K}}{32.6\text{ K} + 8.4\text{ K}}\right]\left[\frac{1}{32.6\text{ K} - 8.4\text{ K}}\right]\frac{5\times10^{-6}\text{ m}\times11.3\times10^{-6}\text{ W}}{1.54\times10^{-16}\text{ m}^2}$$

$$= 3113\text{ W/m}\cdot\text{K}$$ <

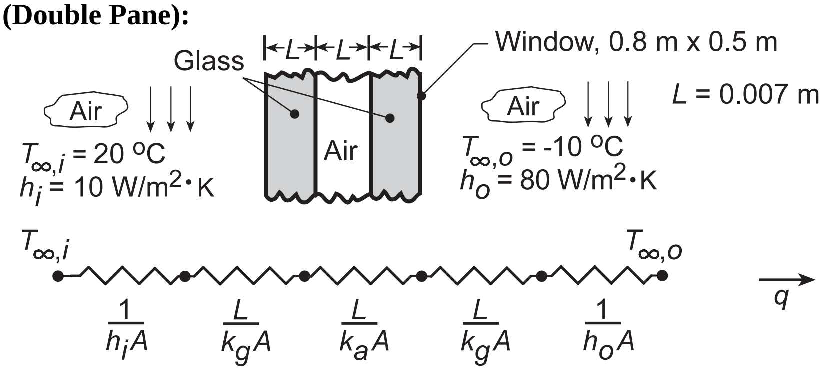
COMMENTS: (1) The analysis is simplified if the heating island temperature is known. (2) This solution is independent of the thermal resistance posed by the support beams, making the measured thermal conductivity of the carbon nanotube less susceptible to experimental error.

PROBLEM 3.12

KNOWN: Dimensions of a thermopane window. Room and ambient air conditions.

FIND: (a) Heat loss through window, (b) Effect of variation in outside convection coefficient for double and triple pane construction.

SCHEMATIC (Double Pane):



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Constant properties, (4) Neglect radiation effects, (5) Air between glass is stagnant.

PROPERTIES: *Table A-3*, Glass (300 K): k_g = 1.4 W/m·K; *Table A-4*, Air (T = 278 K): k_a = 0.0245 W/m·K.

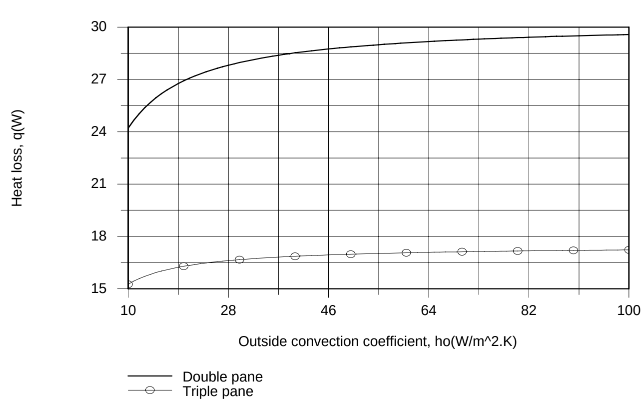
ANALYSIS: (a) From the thermal circuit, the heat loss is

$$q = \frac{T_{\infty,i} - T_{\infty,o}}{\frac{1}{A}\left(\frac{1}{h_i} + \frac{L}{k_g} + \frac{L}{k_a} + \frac{L}{k_g} + \frac{1}{h_o}\right)}$$

$$q = \frac{20^\circ\text{C} - \left(-10^\circ\text{C}\right)}{\left(\frac{1}{0.4\,\text{m}^2}\right)\left(\frac{1}{10\,\text{W/m}^2\cdot\text{K}} + \frac{0.007\,\text{m}}{1.4\,\text{W/m}\cdot\text{K}} + \frac{0.007\,\text{m}}{0.0245\,\text{W/m}\cdot\text{K}} + \frac{0.007\,\text{m}}{1.4\,\text{W/m}\cdot\text{K}} + \frac{1}{80\,\text{W/m}^2\cdot\text{K}}\right)}$$

$$q = \frac{30^\circ\text{C}}{\left(0.25 + 0.0125 + 0.715 + 0.0125 + 0.03125\right)\text{K/W}} = \frac{30^\circ\text{C}}{1.021\,\text{K/W}} = 29.4\ \text{W}$$ <

(b) For the triple pane window, the additional pane and airspace increase the total resistance from 1.021 K/W to 1.749 K/W, thereby reducing the heat loss from 29.4 to 17.2 W. The effect of h_o on the heat loss is plotted as follows.



Continued...

PROBLEM 3.12 (Cont.)

Changes in h_o influence the heat loss at small values of h_o, for which the outside convection resistance is not negligible relative to the total resistance. However, the resistance becomes negligible with increasing h_o, particularly for the triple pane window, and changes in h_o have little effect on the heat loss.

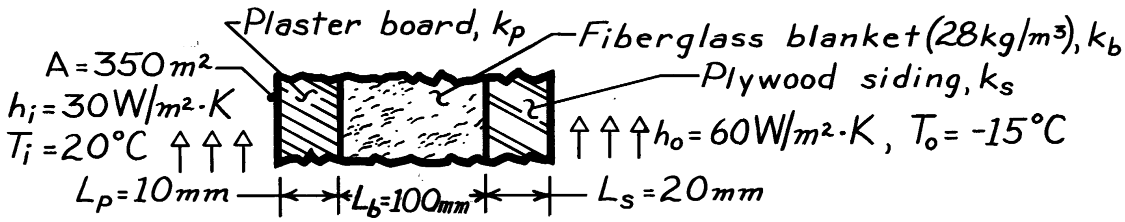
COMMENTS: (1) The largest contribution to the thermal resistance is due to conduction across the enclosed air. Note that this air could be in motion due to free convection currents. If the corresponding convection coefficient exceeded 3.5 $W/m^2 \cdot K$, the thermal resistance would be less than that predicted by assuming conduction across stagnant air, thereby increasing the heat loss.
(2) Determination of the radiation heat loss is complex and will be addressed in Chapters 12 and 13. Radiation would increase the heat loss between the room and outside air, but on a sunny day, solar radiation transmitted through the window would contribute to heating the room.

PROBLEM 3.13

KNOWN: Composite wall of a house with prescribed convection processes at inner and outer surfaces.

FIND: (a) Expression for thermal resistance of house wall, R_{tot}; (b) Total heat loss, q(W); (c) Effect on heat loss due to increase in outside heat transfer convection coefficient, h_o; and (d) Controlling resistance for heat loss from house.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Steady-state conditions, (3) Negligible contact resistance.

PROPERTIES: *Table A-3*, $\left(\overline{T} = (T_i + T_o)/2 = (20-15)^\circ C/2 = 2.5^\circ C \approx 300K\right)$: Fiberglass blanket, 28 kg/m^3, k_b = 0.038 W/m·K; Plywood siding, k_s = 0.12 W/m·K; Plasterboard, k_p = 0.17 W/m·K.

ANALYSIS: (a) The expression for the total thermal resistance of the house wall follows from Eq. 3.18.

$$R_{tot} = \frac{1}{h_i A} + \frac{L_p}{k_p A} + \frac{L_b}{k_b A} + \frac{L_s}{k_s A} + \frac{1}{h_o A}.$$ <

(b) The total heat loss through the house wall is

$$q = \Delta T / R_{tot} = (T_i - T_o)/R_{tot}.$$

Substituting numerical values, find

$$R_{tot} = \frac{1}{30 W/m^2 \cdot K \times 350 m^2} + \frac{0.01m}{0.17 W/m \cdot K \times 350 m^2} + \frac{0.10m}{0.038 W/m \cdot K \times 350 m^2}$$
$$+ \frac{0.02m}{0.12 W/m \cdot K \times 350 m^2} + \frac{1}{60 W/m^2 \cdot K \times 350 m^2}$$
$$R_{tot} = [9.52 + 16.8 + 752 + 47.6 + 4.76] \times 10^{-5}\ ^\circ C/W = 831 \times 10^{-5}\ ^\circ C/W$$

The heat loss is then,

$$q = [20-(-15)]^\circ C / 831 \times 10^{-5}\ ^\circ C/W = 4.21\ kW.$$ <

(c) If h_o changes from 60 to 300 W/m^2·K, $R_o = 1/h_o A$ changes from 4.76 × 10^{-5} °C/W to 0.95 × 10^{-5} °C/W. This reduces R_{tot} to 826 × 10^{-5} °C/W, which is a 0.6% decrease and hence a 0.6% increase in q.

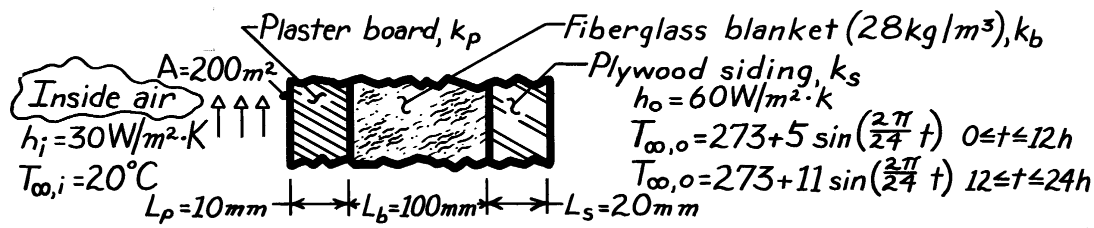
(d) From the expression for R_{tot} in part (b), note that the insulation resistance, $L_b/k_b A$, is 752/830 ≈ 90% of the total resistance. Hence, this material layer controls the resistance of the wall. From part (c) note that a 5-fold decrease in the outer convection resistance due to an increase in the wind velocity has a negligible effect on the heat loss.

PROBLEM 3.14

KNOWN: Composite wall of a house with prescribed convection processes at inner and outer surfaces.

FIND: Daily heat loss for prescribed diurnal variation in ambient air temperature.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, steady-state conduction (negligible change in wall thermal energy storage over 24h period), (2) Negligible contact resistance.

PROPERTIES: *Table A-3*, T ≈ 300 K: Fiberglas blanket (28 kg/m^3), k_b = 0.038 W/m·K; Plywood, k_s = 0.12 W/m·K; Plasterboard, k_p = 0.17 W/m·K.

ANALYSIS: The heat loss may be approximated as $Q = \int_0^{24h} \frac{T_{\infty,i} - T_{\infty,o}}{R_{tot}} dt$ where

$$R_{tot} = \frac{1}{A}\left[\frac{1}{h_i} + \frac{L_p}{k_p} + \frac{L_b}{k_b} + \frac{L_s}{k_s} + \frac{1}{h_o}\right]$$

$$R_{tot} = \frac{1}{200m^2}\left[\frac{1}{30\ W/m^2 \cdot K} + \frac{0.01m}{0.17\ W/m \cdot K} + \frac{0.1m}{0.038\ W/m \cdot K} + \frac{0.02m}{0.12\ W/m \cdot K} + \frac{1}{60\ W/m^2 \cdot K}\right]$$

$$R_{tot} = 0.01454\ K/W.$$

Hence the heat rate is

$$Q = \frac{1}{R_{tot}}\left\{\int_0^{12h}\left[293 - \left[273 + 5\sin\frac{2\pi}{24}t\right]\right]dt + \int_{12}^{24h}\left[293 - \left[273 + 11\sin\frac{2\pi}{24}t\right]\right]dt\right\}$$

$$Q = 68.8\frac{W}{K}\left\{\left[20t + 5\left[\frac{24}{2\pi}\right]\cos\frac{2\pi t}{24}\right]\Bigg|_0^{12} + \left[20t + 11\left[\frac{24}{2\pi}\right]\cos\frac{2\pi t}{24}\right]\Bigg|_{12}^{24}\right\} K \cdot h$$

$$Q = 68.8\left\{\left[240 + \frac{60}{\pi}(-1-1)\right] + \left[480 - 240 + \frac{132}{\pi}(1+1)\right]\right\} W \cdot h$$

$$Q = 68.8\ \{480\text{-}38.2\text{+}84.03\}\ W \cdot h$$

$$Q = 36.18\ kW \cdot h = 1.302 \times 10^8 J.$$ <

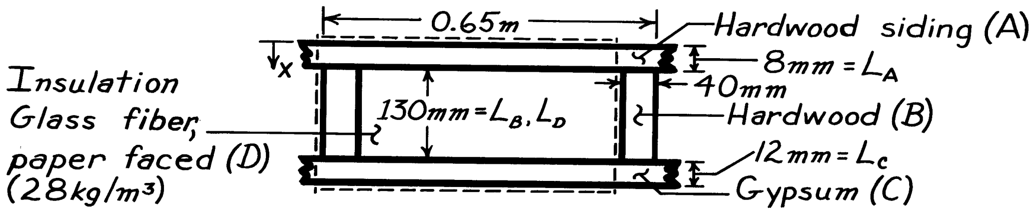
COMMENTS: From knowledge of the fuel cost, the total daily heating bill could be determined. For example, at a cost of 0.18$/kW·h, the heating bill would be $6.52/day.

PROBLEM 3.15

KNOWN: Dimensions and materials associated with a composite wall (2.5m × 6.5m, 10 studs each 2.5m high).

FIND: Wall thermal resistance.

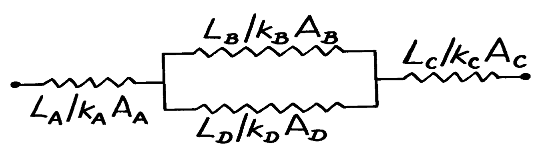
SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Temperature of composite depends only on x (surfaces normal to x are isothermal), (3) Constant properties, (4) Negligible contact resistance.

PROPERTIES: *Table A-3* (T ≈ 300K): Hardwood siding, k_A = 0.094 W/m·K; Hardwood, k_B = 0.16 W/m·K; Gypsum, k_C = 0.17 W/m·K; Insulation (glass fiber paper faced, 28 kg/m^3), k_D = 0.038 W/m·K.

ANALYSIS: Using the isothermal surface assumption, the thermal circuit associated with a single unit (enclosed by dashed lines) of the wall is



$$\left(L_A/k_AA_A\right) = \frac{0.008\text{m}}{0.094\text{ W/m}\cdot\text{K}\left(0.65\text{m}\times 2.5\text{m}\right)} = 0.0524\text{ K/W}$$

$$\left(L_B/k_BA_B\right) = \frac{0.13\text{m}}{0.16\text{ W/m}\cdot\text{K}\left(0.04\text{m}\times 2.5\text{m}\right)} = 8.125\text{ K/W}$$

$$\left(L_D/k_DA_D\right) = \frac{0.13\text{m}}{0.038\text{ W/m}\cdot\text{K}\left(0.61\text{m}\times 2.5\text{m}\right)} = 2.243\text{ K/W}$$

$$\left(L_C/k_CA_C\right) = \frac{0.012\text{m}}{0.17\text{ W/m}\cdot\text{K}\left(0.65\text{m}\times 2.5\text{m}\right)} = 0.0434\text{ K/W.}$$

The equivalent resistance of the core is

$$R_{eq} = \left(1/R_B + 1/R_D\right)^{-1} = \left(1/8.125 + 1/2.243\right)^{-1} = 1.758\text{ K/W}$$

and the total unit resistance is

$$R_{tot,1} = R_A + R_{eq} + R_C = 1.854\text{ K/W.}$$

With 10 such units in parallel, the total wall resistance is

$$R_{tot} = \left(10\times 1/R_{tot,1}\right)^{-1} = 0.1854\text{ K/W.}$$ <

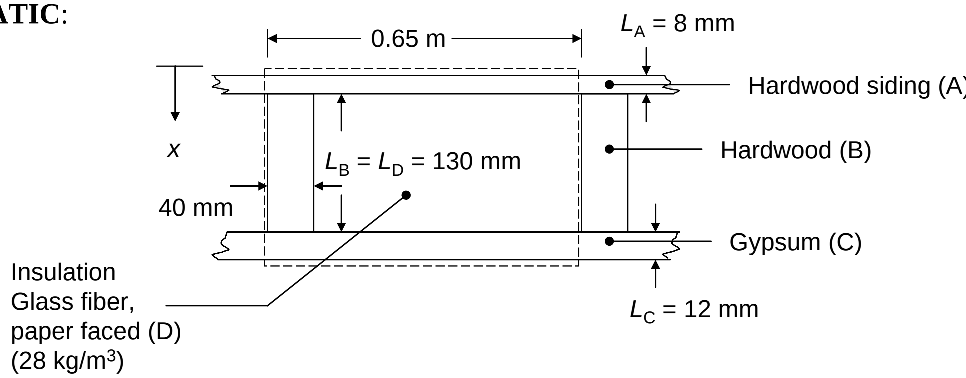
COMMENTS: If surfaces parallel to the heat flow direction are assumed adiabatic, the thermal circuit and the value of R_{tot} will differ.

PROBLEM 3.16

KNOWN: Dimensions and materials associated with a composite wall (2.5 m × 6.5 m, 10 studs each 2.5 m high).

FIND: Wall thermal resistance.

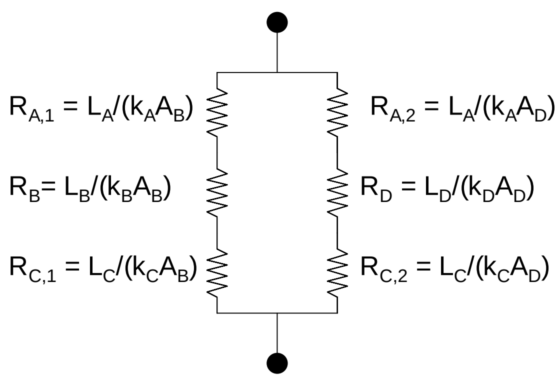
SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, one-dimensional conditions, (2) Planes parallel to *x* are adiabatic, (3) Constant properties, (4) Negligible contact resistance.

PROPERTIES: Table A-3 ($T \approx 300$ K): Hardwood siding, k_A = 0.094 W/m·K; Hardwood, k_B = 0.16 W/m·K; Gypsum, k_C = 0.17 W/m·K; Insulation (glass fiber paper faced, 28 kg/m^3), k_D = 0.038 W/m·K.

ANALYSIS: Using the adiabatic surface assumption, the thermal circuit associated with a single unit (enclosed by dashed lines) of the wall is as shown to the right. The various resistances are



$$R_{A,1} = (L_A/k_A A_B) = \frac{0.008\text{ m}}{0.094\text{ W/m}\cdot\text{K}\ (0.04\text{ m} \times 2.5\text{ m})} = 0.8511\text{ K/W}$$

$$R_B = (L_B/k_B A_B) = \frac{0.13\text{ m}}{0.16\text{ W/m}\cdot\text{K}\ (0.04\text{ m} \times 2.5\text{ m})} = 8.125\text{ K/W}$$

$$R_{C,1} = (L_C/k_C A_B) = \frac{0.012\text{ m}}{0.17\text{ W/m}\cdot\text{K}\ (0.04\text{ m} \times 2.5\text{ m})} = 0.7059\text{ K/W}$$

$$R_{A,2} = (L_A/k_A A_D) = \frac{0.008\text{ m}}{0.094\text{ W/m}\cdot\text{K}\ (0.61\text{ m} \times 2.5\text{ m})} = 0.0558\text{ K/W}$$

$$R_D = (L_D/k_D A_D) = \frac{0.13\text{ m}}{0.038\text{ W/m}\cdot\text{K}\ (0.61\text{ m} \times 2.5\text{ m})} = 2.243\text{ K/W}$$

$$R_{C,2} = (L_C/k_C A_D) = \frac{0.012\text{ m}}{0.17\text{ W/m}\cdot\text{K}\ (0.61\text{ m} \times 2.5\text{ m})} = 0.0463\text{ K/W}$$

Continued…

PROBLEM 3.16 (Cont.)

The total unit resistance is

$$R_{tot,1} = \left(\frac{1}{R_{A,1}+R_B+R_{C,1}} + \frac{1}{R_{A,2}+R_D+R_{C,2}}\right)^{-1} = \left(\frac{1}{0.8511+8.125+0.7059} + \frac{1}{0.0558+2.243+0.0463}\right)^{-1}$$

$= 1.888$ K/W

With 10 such units in parallel, the total wall resistance is $R_{tot} = (10 \times 1/R_{tot,1})^{-1} = 0.1888$ K/W. <

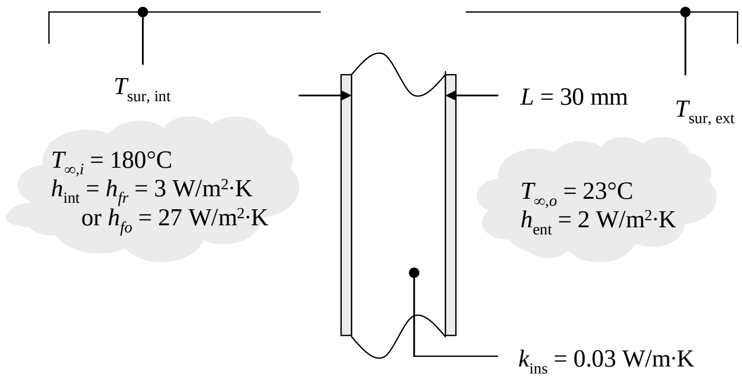
COMMENTS: (1) Contact resistance will increase the overall wall resistance relative to that calculated here. (2) The total wall resistance assuming isothermal surfaces normal to the *x* direction is 0.1854 K/W, which is within 2 % of the value found in this solution.

PROBLEM 3.17

KNOWN: Thickness and thermal conductivity of oven wall insulation. Exterior air temperature and convection heat transfer coefficient. Interior air temperature and convection heat transfer coefficients under free and forced convection conditions.

FIND: Heat flux through oven walls under free and forced convection conditions. Impact of forced convection on heat loss. Effect of radiation.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction through walls, (3) Thermal resistance of sheet metal layers is negligible, (4) Interior and exterior radiation is to large surroundings at the air temperatures, (5) Emissivity is approximately 1.0, (6) Negligible contact resistances.

ANALYSIS: Neglecting radiation, the heat flux through the oven wall can be calculated from Equations 3.11 and 3.12 on a per unit area basis.

$$q''_x = (T_{\infty,\text{int}} - T_{\infty,\text{ext}}) / R''_{\text{tot}}$$

where

$$R''_{\text{tot}} = \frac{1}{h_{\text{int}}} + \frac{L}{k_{\text{ins}}} + \frac{1}{h_{\text{ext}}}$$

When forced convection is disabled inside the oven, we have $h_{\text{int}} = h_{fr}$ and

$$R''_{\text{tot}} = \frac{1}{h_{\text{int}}} + \frac{L}{k_{\text{ins}}} + \frac{1}{h_{\text{ext}}} = \frac{1}{3\text{ W/m}^2\cdot\text{K}} + \frac{0.03\text{ m}}{0.03\text{ W/m}\cdot\text{K}} + \frac{1}{2\text{ W/m}^2\cdot\text{K}}$$
$$= 0.33\text{ m}^2\cdot\text{K/W} + 1\text{ m}^2\cdot\text{K/W} + 0.5\text{ m}^2\cdot\text{K/W} = 1.83\text{ m}^2\cdot\text{K/W}$$

Therefore

$$q''_x = (T_{\infty,\text{int}} - T_{\infty,\text{ext}}) / R''_{\text{tot}} = (180°\text{C} - 23°\text{C}) / 1.83\text{ m}^2\cdot\text{K/W} = 85.6\text{ W/m}^2$$ <

When forced convection is activated inside the oven, we have $h_{\text{int}} = h_{fo}$ and

Continued…

$$R''_{\text{tot}} = \frac{1}{h_{\text{int}}} + \frac{L}{k_{\text{ins}}} + \frac{1}{h_{\text{ext}}} = \frac{1}{27 \text{ W/m}^2 \cdot \text{K}} + \frac{0.03 \text{ m}}{0.03 \text{ W/m} \cdot \text{K}} + \frac{1}{2 \text{ W/m}^2 \cdot \text{K}}$$
$$= 0.037 \text{ m}^2 \cdot \text{K/W} + 1 \text{ m}^2 \cdot \text{K/W} + 0.5 \text{ m}^2 \cdot \text{K/W} = 1.537 \text{ m}^2 \cdot \text{K/W}$$

and

$$q''_x = (T_{\infty,\text{int}} - T_{\infty,\text{ext}}) / R''_{\text{tot}} = (180°\text{C} - 23°\text{C}) / 1.537 \text{ m}^2 \cdot \text{K/W} = 102 \text{ W/m}^2$$ <

Operation in forced convection mode increases oven heat loss by around 19%. Although h_{int} increases by a factor of 9, other thermal resistances tend to dominate the total thermal resistance. <

Radiation at both the inner and outer oven surfaces can be accounted for by combining convection and radiation heat transfer in parallel. This results in a total heat transfer coefficient at each surface that is the sum of the convection and radiation heat transfer coefficients, see Example 3.1. Therefore, the total thermal resistance can be expressed as

$$R''_{\text{tot}} = \frac{1}{h_{\text{int}} + h_{r,\text{int}}} + \frac{L}{k_{\text{ins}}} + \frac{1}{h_{\text{ext}} + h_{r,\text{ext}}}$$

The radiation heat transfer coefficient is given by Equation 1.9 and can be approximated as

$$h_r \approx 4\varepsilon\sigma\overline{T}^3$$

where $\overline{T} = (T_s + T_{\text{sur}})/2$. We do not know the oven surface temperatures and will approximate both surface temperatures as the average of the interior and exterior air temperatures, $T_s = (T_{\infty,\text{int}} + T_{\infty,\text{ext}})/2$ = 101.5°C ≈ 375 K. Thus, $\overline{T}_{\text{int}} = 414$ K and $\overline{T}_{\text{ext}} = 335.5$ K. Assuming the emissivity of both surfaces is $\varepsilon \approx 1$, we find $h_{r,\text{int}} \approx 16 \text{ W/m}^2 \cdot \text{K}$ and $h_{r,\text{ext}} \approx 8.6 \text{ W/m}^2 \cdot \text{K}$. Thus, under free convection conditions,

$$R''_{\text{tot}} = \frac{1}{(3+16) \text{ W/m}^2 \cdot \text{K}} + 1 \text{ m}^2 \cdot \text{K/W} + \frac{1}{(2+8.6) \text{ W/m}^2 \cdot \text{K}}$$
$$= (0.053 + 1 + 0.094)\text{m}^2 \cdot \text{K/W} = 1.17 \text{ m}^2 \cdot \text{K/W}$$

and under forced convection conditions,

$$R''_{\text{tot}} = \frac{1}{(27+16) \text{ W/m}^2 \cdot \text{K}} + 1 \text{ m}^2 \cdot \text{K/W} + 0.094 \text{ m}^2 \cdot \text{K/W}$$
$$= (0.023 + 1 + 0.094)\text{m}^2 \cdot \text{K/W} = 1.12 \text{ m}^2 \cdot \text{K/W}$$

When radiation is accounted for, the internal and external heat transfer resistances become small compared to the thermal resistance of the insulation, and there is little difference between the total thermal resistance with or without forced convection inside the oven. <

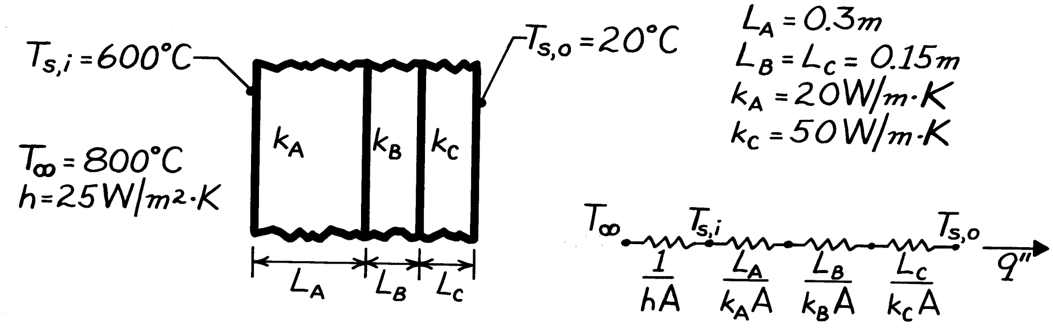
COMMENTS: The radiation heat flux can be calculated more accurately by solving for the oven interior and exterior surface temperatures, however without knowledge of the surface emissivity there is no reason to be so precise.

PROBLEM 3.18

KNOWN: Thicknesses of three materials which form a composite wall and thermal conductivities of two of the materials. Inner and outer surface temperatures of the composite; also, temperature and convection coefficient associated with adjoining gas.

FIND: Value of unknown thermal conductivity, k_B.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible contact resistance, (5) Negligible radiation effects.

ANALYSIS: Referring to the thermal circuit, the heat flux may be expressed as

$$q'' = \frac{T_{s,i} - T_{s,o}}{\frac{L_A}{k_A} + \frac{L_B}{k_B} + \frac{L_C}{k_C}} = \frac{(600-20)^\circ C}{\frac{0.3\ m}{20\ W/m\cdot K} + \frac{0.15\ m}{k_B} + \frac{0.15\ m}{50\ W/m\cdot K}}$$

$$q'' = \frac{580}{0.018 + 0.15/k_B} W/m^2. \quad (1)$$

The heat flux may be obtained from

$$q'' = h\left(T_\infty - T_{s,i}\right) = 25\ W/m^2\cdot K\,(800\text{-}600)^\circ C \quad (2)$$

$$q'' = 5000\ W/m^2.$$

Substituting for the heat flux from Eq. (2) into Eq. (1), find

$$\frac{0.15}{k_B} = \frac{580}{q''} - 0.018 = \frac{580}{5000} - 0.018 = 0.098$$

$$k_B = 1.53\ W/m\cdot K. \quad <$$

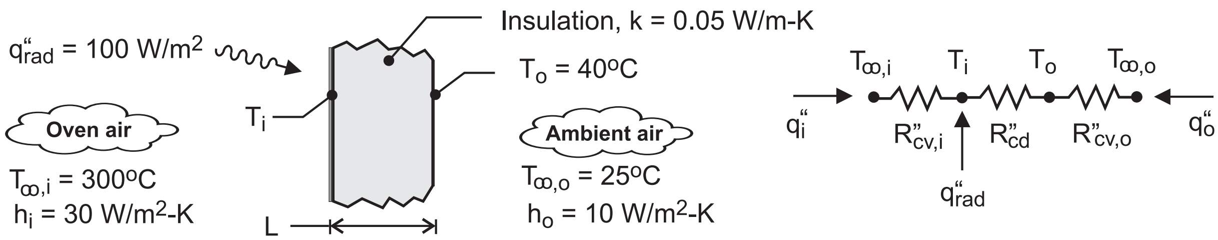
COMMENTS: Radiation effects are likely to have a significant influence on the net heat flux at the inner surface of the oven.

PROBLEM 3.19

KNOWN: Drying oven wall having material with known thermal conductivity sandwiched between thin metal sheets. Radiation and convection conditions prescribed on inner surface; convection conditions on outer surface.

FIND: (a) Thermal circuit representing wall and processes and (b) Insulation thickness required to maintain outer wall surface at $T_o = 40°C$.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in wall, (3) Thermal resistance of metal sheets negligible,(4) Negligible contact resistance.

ANALYSIS: (a) The thermal circuit is shown above. Note labels for the temperatures, thermal resistances and the relevant heat fluxes.

(b) Perform energy balances on the i- and o- nodes finding

$$\frac{T_{\infty,i} - T_i}{R''_{cv,i}} + \frac{T_o - T_i}{R''_{cd}} + q''_{rad} = 0 \quad (1)$$

$$\frac{T_i - T_o}{R''_{cd}} + \frac{T_{\infty,o} - T_o}{R''_{cv,o}} = 0 \quad (2)$$

where the thermal resistances are

$$R''_{cv,i} = 1/h_i = 0.0333\ m^2 \cdot K/W \quad (3)$$

$$R''_{cd} = L/k = L/0.05\ m^2 \cdot K/W \quad (4)$$

$$R''_{cv,o} = 1/h_o = 0.100\ m^2 \cdot K/W \quad (5)$$

Substituting numerical values, and solving Eqs. (1) and (2) simultaneously, find

$$L = 86\ mm$$ <

COMMENTS: (1) The temperature at the inner surface can be found from an energy balance on the i-node using the value found for L.

$$\frac{T_{\infty,i} - T_i}{R''_{cv,o}} + \frac{T_{\infty,o} - T_i}{R''_{cd} + R''_{cv,i}} + q''_{rad} = 0 \qquad T_i = 298.3°C$$

It follows that T_i is close to $T_{\infty,i}$ since the wall represents the dominant resistance of the system.

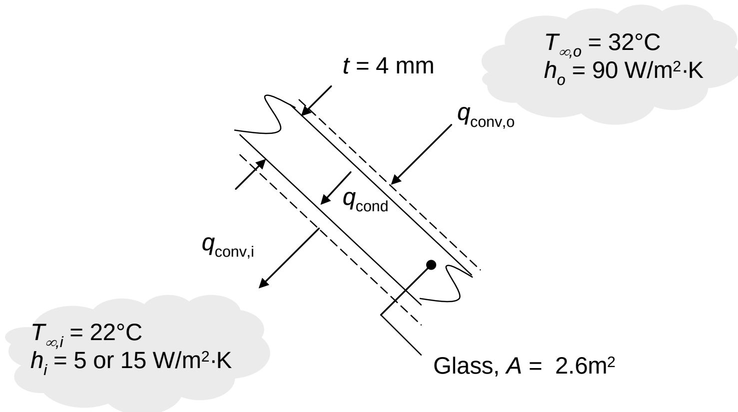
(2) Verify that $q''_i = 50\ W/m^2$ and $q''_o = -150\ W/m^2$. Is the overall energy balance on the system satisfied?

PROBLEM 3.20

KNOWN: Window surface area and thickness, inside and outside heat transfer coefficients, outside and passenger compartment temperatures.

FIND: Heat loss through the windows for high and low inside heat transfer coefficients.

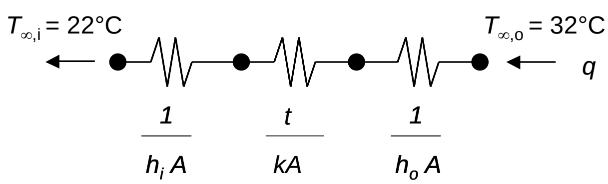
SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, one-dimensional conduction. (2) Constant properties. (3) Negligible radiation.

PROPERTIES: Table A.3, glass (T = 300 K): k = 1.4 W/m·K.

ANALYSIS: The thermal circuit is



from which the heat transfer rate through the windows for h_i = 15 W/m^2·K is

$$q = \frac{T_{\infty,o} - T_{\infty,i}}{\left(\frac{1}{h_i A} + \frac{t}{kA} + \frac{1}{h_o A}\right)}$$

$$= \frac{(32-22)°\text{C}}{\left(\frac{1}{15\ \text{W/m}^2\cdot\text{K}\times 2.6\ \text{m}^2} + \frac{4\times10^{-3}\ \text{m}}{1.4\ \text{W/m}\cdot\text{K}\times 2.6\ \text{m}^2} + \frac{1}{90\ \text{W/m}^2\cdot\text{K}\times 2.6\text{m}^2}\right)}$$

$$= 333\ \text{W}$$ <

Repeating the calculation for h_i = 5 W/m^2·K yields q = 121 W <

Continued…

PROBLEM 3.20 (Cont.)

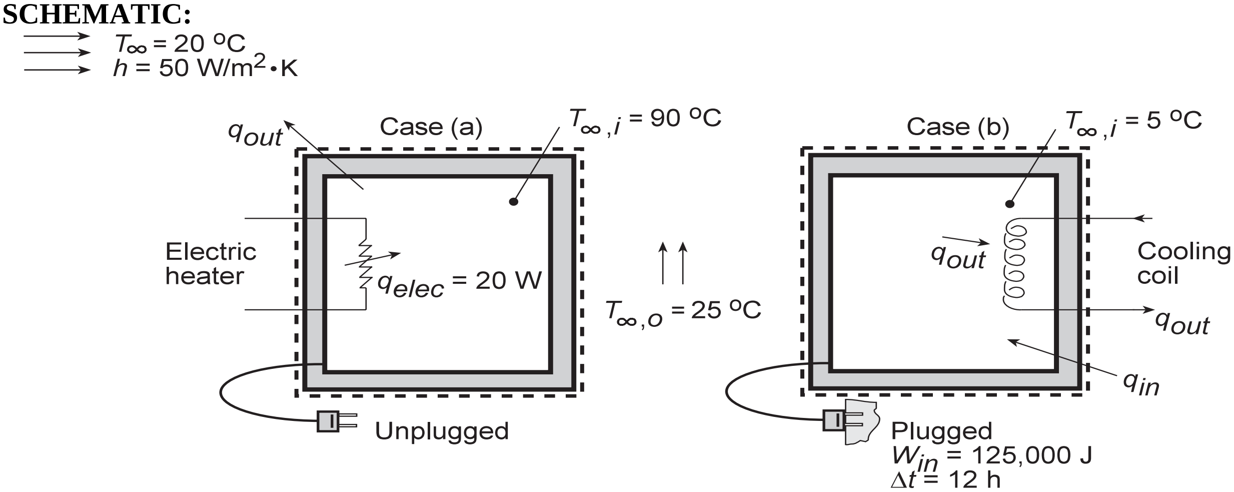
COMMENTS: (1) Assuming an air conditioner COP of 3, controlling the airflow in the passenger cabin to reduce the interior convection heat transfer coefficient will reduce the power consumed by the air conditioner by ΔP = (333 W – 121 W)/3 = 71 W. (2) A smaller air conditioner can be utilized with the lower interior heat transfer coefficient. This will both (a) reduce the cost of the air conditioner and (b) reduce the amount of refrigerant in the air conditioning unit. Reduction in the amount of refrigerant used will also reduce the level of refrigerant that might leak from the system, potentially reducing greenhouse gas emissions. (3) The individual resistance values are $R_{conv,i}$ = 0.026 K/W, R_{cond} = 0.0011 K/W, and $R_{conv,o}$ = 0.0043 K/W for h_i = 15 W/m^2·K.

PROBLEM 3.21

KNOWN: Conditions associated with maintaining heated and cooled conditions within a refrigerator compartment.

FIND: Coefficient of performance (COP).

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state operating conditions, (2) Negligible radiation, (3) Compartment completely sealed from ambient air.

ANALYSIS: The Case (a) experiment is performed to determine the overall thermal resistance to heat transfer between the interior of the refrigerator and the ambient air. Applying an energy balance to a control surface about the refrigerator, it follows from Eq. 1.12b that, at any instant,

$$\dot{E}_g - \dot{E}_{out} = 0$$

Hence,

$$q_{elec} - q_{out} = 0$$

where $q_{out} = \left(T_{\infty,i} - T_{\infty,o}\right)/R_t$. It follows that

$$R_t = \frac{T_{\infty,i} - T_{\infty,o}}{q_{elec}} = \frac{(90-25)^\circ C}{20\,W} = 3.25^\circ C/W$$

For Case (b), heat transfer from the ambient air to the compartment (the heat load) is balanced by heat transfer to the refrigerant ($q_{in} = q_{out}$). Hence, the thermal energy transferred from the refrigerator over the 12 hour period is

$$Q_{out} = q_{out}\Delta t = q_{in}\Delta t = \frac{T_{\infty,i} - T_{\infty,o}}{R_t}\Delta t$$

$$Q_{out} = \frac{(25-5)^\circ C}{3.25^\circ C/W}\left(12\,h \times 3600\,s/h\right) = 266,000\,J$$

The coefficient of performance (COP) is therefore

$$COP = \frac{Q_{out}}{W_{in}} = \frac{266,000}{125,000} = 2.13$$ <

COMMENTS: The ideal (Carnot) COP is

$$COP)_{ideal} = \frac{T_c}{T_h - T_c} = \frac{278\,K}{(298-278)\,K} = 13.9$$

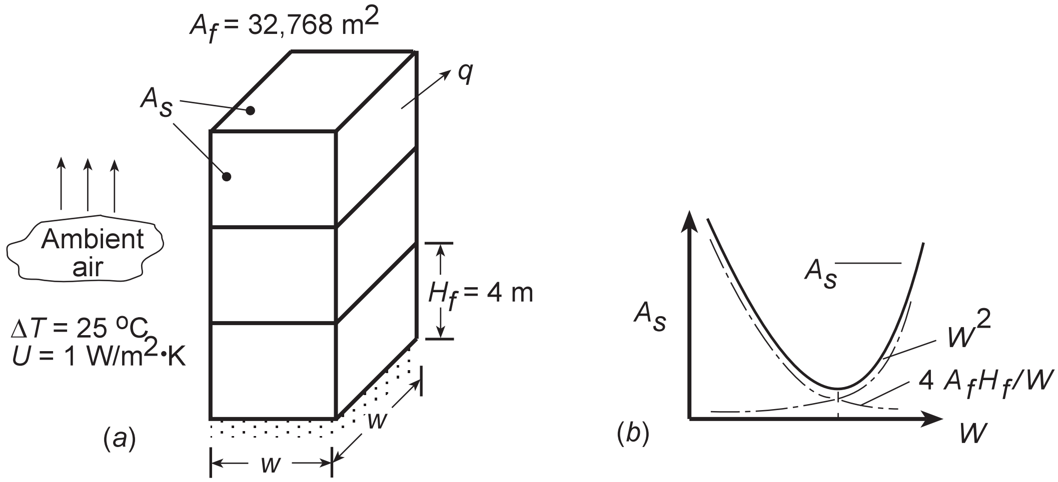
and the system is operating well below its peak possible performance.

PROBLEM 3.22

KNOWN: Total floor space and vertical distance between floors for a square, flat roof building.

FIND: (a) Expression for width of building which minimizes heat loss, (b) Width and number of floors which minimize heat loss for a prescribed floor space and distance between floors. Corresponding heat loss, percent heat loss reduction from 2 floors.

SCHEMATIC:



ASSUMPTIONS: Negligible heat loss to ground.

ANALYSIS: (a) To minimize the heat loss q, the exterior surface area, A_s, must be minimized. From Fig. (a)

$$A_s = W^2 + 4WH = W^2 + 4WN_f H_f$$

where

$$N_f = A_f / W^2$$

Hence,

$$A_s = W^2 + 4WA_f H_f / W^2 = W^2 + 4A_f H_f / W$$

The optimum value of W corresponds to

$$\frac{dA_s}{dW} = 2W - \frac{4A_f H_f}{W^2} = 0$$

or

$$W_{op} = (2A_f H_f)^{1/3}$$ <

The competing effects of W on the areas of the roof and sidewalls, and hence the basis for an optimum, is shown schematically in Fig. (b).

(b) For A_f = 32,768 m^2 and H_f = 4 m,

$$W_{op} = \left(2 \times 32,768\,\text{m}^2 \times 4\,\text{m}\right)^{1/3} = 64\,\text{m}$$ <

Continued …

PROBLEM 3.22 (Cont.)

Hence,

$$N_f = \frac{A_f}{W^2} = \frac{32,768\,m^2}{(64\,m)^2} = 8$$ <

and

$$q = UA_s\Delta T = 1\,W/m^2\cdot K\left[(64\,m)^2 + \frac{4\times 32,768\,m^2\times 4\,m}{64\,m}\right]25^\circ C = 307,200\,W$$ <

For $N_f = 2$,

$$W = (A_f/N_f)^{1/2} = (32,768\ m^2/2)^{1/2} = 128\ m$$

$$q = 1\,W/m^2\cdot K\left[(128\,m)^2 + \frac{4\times 32,768\,m^2\times 4\,m}{128\,m}\right]25^\circ C = 512,000\,W$$

% reduction in q = (512,000 - 307,200)/512,000 = 40% <

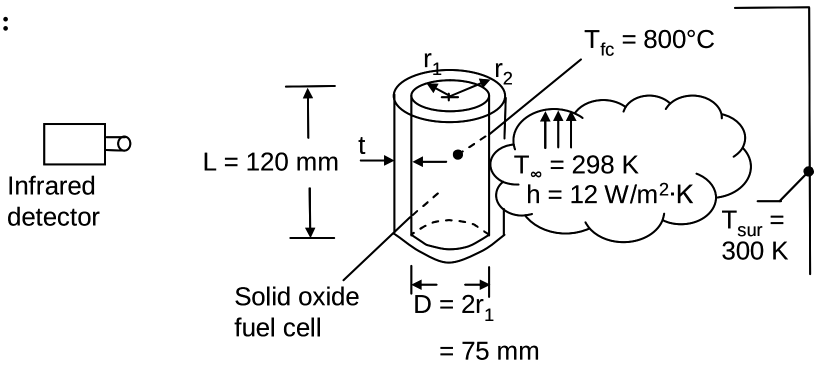
COMMENTS: Even the minimum heat loss is excessive and could be reduced by reducing U.

PROBLEM 3.23

KNOWN: Dimensions and temperature of a canister containing a solid oxide fuel cell. Surroundings and ambient temperature.

FIND: (a) Required insulation thickness to keep the equivalent blackbody temperature below 305 K, (b) Canister surface temperature for four cases, (c) Heat flux through the cylindrical walls for four cases.

SCHEMATIC:

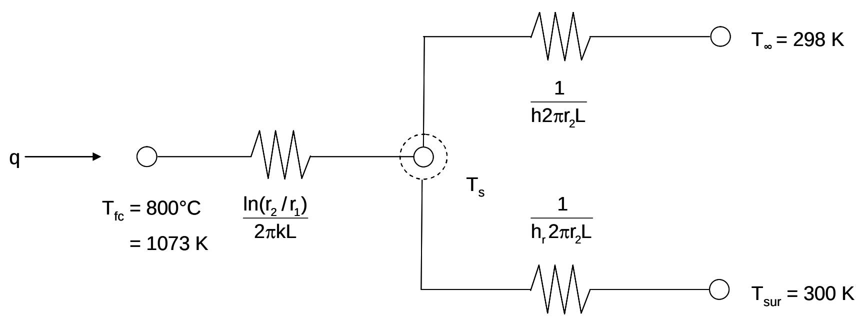


ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional heat transfer, (4) Large surroundings.

ANALYSIS: The maximum allowable surface temperature may be found by relating the actual and inferred surface temperatures through the relation

$$E_s = E_b = \varepsilon_s \sigma T_s^4 = \sigma T_b^4 \quad \text{or} \quad T_s = (T_b^4/\varepsilon_s)^{1/4} \tag{1}$$

The thermal circuit is



where, from Eq. 1.9,

$$h_r = \varepsilon_s \sigma (T_s + T_{sur})(T_s^2 + T_{sur}^2) \tag{2}$$

Summing currents at the T_s node yields

Continued…

PROBLEM 3.23 (Cont.)

$$\frac{T_{fc} - T_s}{\left[\frac{\ln(r_2 / r_1)}{2\pi kL}\right]} = \frac{T_s - T_\infty}{\left[\frac{1}{h2\pi r_2 L}\right]} + \frac{T_s - T_{sur}}{\left[\frac{1}{h_r 2\pi r_2 L}\right]} \qquad (3)$$

where

$$q = \frac{T_{fc} - T_s}{\left[\frac{\ln(r_2 / r_1)}{2\pi / L}\right]} L \qquad (4)$$

Noting that the insulation thickness is $t = r_2 - r_1$, solving Eqs. (2) and (3) simultaneously, and then solving Eq. (4) yields the following results.

ε_s	k (W/m·K)	t(m)	T_s(K)	q(W)
0.08	0.09	0.0875	573.5	135
0.9	0.09	0.963	313.1	33.75
0.08	0.006	0.0008	573.5	108.4
0.9	0.006	0.015	313.1	10.2

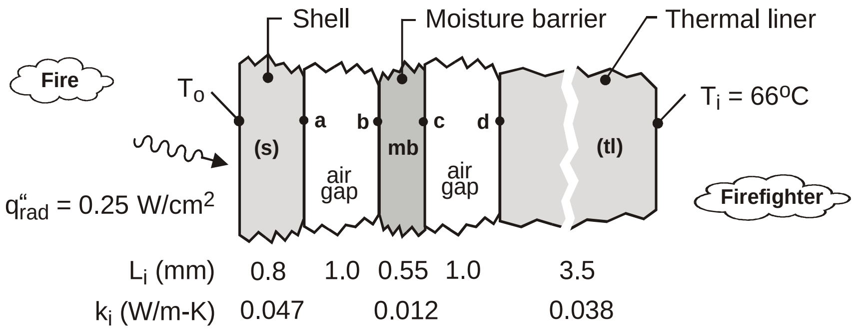
COMMENTS: (1) Use of the low emissivity surface allows surface temperatures to be high without the fuel cell being detected. (2) The high surface temperature is not safe to the touch. (3) The low thermal conductivity of the aerogel allows the use of a small insulation thickness relative to the calcium silicate. (4) Small heat losses and low surface temperatures are desired. The ε_s = 0.9, k = 0.006 case offers the best performance, and the surface need not be kept in a polished condition to avoid detection.

PROBLEM 3.24

KNOWN: Representative dimensions and thermal conductivities for the layers of fire-fighter's protective clothing, a turnout coat.

FIND: (a) Thermal circuit representing the turnout coat; tabulate thermal resistances of the layers and processes; and (b) For a prescribed radiant heat flux on the fire-side surface and temperature of $T_i = 60°C$ at the inner surface, calculate the fire-side surface temperature, T_o.

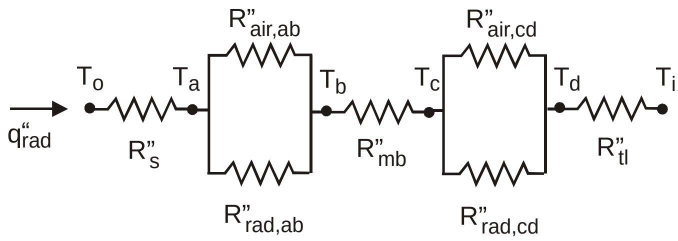
SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction through the layers, (3) Heat is transferred by conduction and radiation exchange across the stagnant air gaps, (3) Constant properties.

PROPERTIES: *Table A-4*, Air (470 K, 1 atm): $k_{ab} = k_{cd} = 0.0387$ W/m·K.

ANALYSIS: (a) The thermal circuit is shown with labels for the temperatures and thermal resistances.



The conduction thermal resistances have the form $R''_{cd} = L/k$ while the radiation thermal resistances across the air gaps have the form

$$R''_{rad} = \frac{1}{h_{rad}} = \frac{1}{4\sigma T_{avg}^3}$$

The linearized radiation coefficient follows from Eqs. 1.8 and 1.9 with ε = 1 where T_{avg} represents the average temperature of the surfaces comprising the gap

$$h_{rad} = \sigma\left(T_1 + T_2\right)\left(T_1^2 + T_2^2\right) \approx 4\sigma T_{avg}^3$$

For the radiation thermal resistances tabulated below, we used $T_{avg} = 470$ K.

Continued …

PROBLEM 3.24 (Cont.)

	Shell (s)	Air gap (a-b)	Barrier (mb)	Air gap (c-d)	Liner (tl)	*Total* (tot)
$R''_{cd}\left(m^2 \cdot K/W\right)$	0.01702	0.0222	0.04583	0.0222	0.0921	--
$R''_{rad}\left(m^2 \cdot K/W\right)$	--	0.04246	--	0.04246	--	--
$R''_{gap}\left(m^2 \cdot K/W\right)$	--	0.0146	--	0.0146	--	--
R''_{total}	--	--	--	--	--	0.1842

From the thermal circuit, the resistance across the gap for the conduction and radiation processes is

$$\frac{1}{R''_{gap}} = \frac{1}{R''_{cd}} + \frac{1}{R''_{rad}}$$

and the total thermal resistance of the turn coat is

$$R''_{tot} = R''_{cd,s} + R''_{gap,a-b} + R''_{cd,mb} + R''_{gap,c-d} + R''_{cd,tl}$$

(b) If the heat flux through the coat is 0.25 W/cm^2, the fire-side surface temperature T_o can be calculated from the rate equation written in terms of the overall thermal resistance.

$$q'' = \left(T_o - T_i\right)/R''_{tot}$$

$$T_o = 66°C + 0.25\ W/cm^2 \times \left(10^2 cm/m\right)^2 \times 0.1842\ m^2 \cdot K/W$$

$$T_o = 526°C$$ <

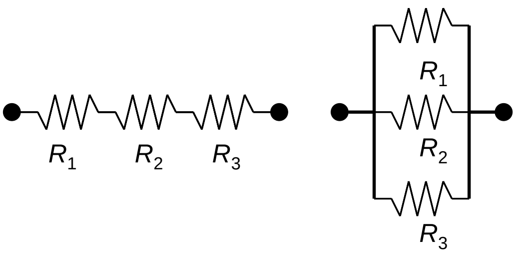
COMMENTS: (1) From the tabulated results, note that the thermal resistance of the moisture barrier (mb) is nearly 3 times larger than that for the shell or air gap layers. The thermal liner has the greatest thermal resistance. (2) The air gap conduction and radiation resistances were calculated based upon the average temperature of 570 K. This value was determined by setting $T_{avg} = (T_o + T_i)/2$ and solving the equation set using *IHT* with $k_{air} = k_{air}(T_{avg})$.

PROBLEM 3.25

KNOWN: Values of three individual thermal conduction resistances.

FIND: Which conduction resistance should be reduced by half in order to most effectively reduce the total conduction resistance.

SCHEMATIC:



Case A Case B

ASSUMPTIONS: (1) Steady-state, one-dimensional conduction, (2) Constant properties.

ANALYSIS: We begin with the series resistance network, Case A. The total thermal resistances associated with the nominal values of the individual thermal resistances, as well as for situations where the nominal resistance values are reduced by 50%, are presented in the table below.

Case A	R_1 (K/W)	R_2 (K/W)	R_3 (K/W)	R_{tot} (K/W)	
Nominal	1	2	4	7	
	0.5	2	4	6.5	
	1	1	4	6	
	1	2	2	5	<

The reduction in the total thermal resistance is greatest if the value of R_3 is reduced from 4 to 2 K/W.

Case B	R_1 (K/W)	R_2 (K/W)	R_3 (K/W)	R_{tot} (K/W)	
Nominal	1	2	4	0.5714	
	0.5	2	4	0.3636	<
	1	1	4	0.4444	
	1	2	2	0.5000	

For the resistances in parallel, the reduction in the total thermal resistance is greatest if the value of R_1 is reduced from 1 to 0.5 K/W.

Hence, it is not possible to make a recommendation to the chief engineer as to which resistance should be targeted for reduction without first knowing how the resistances are placed within the resistance network.

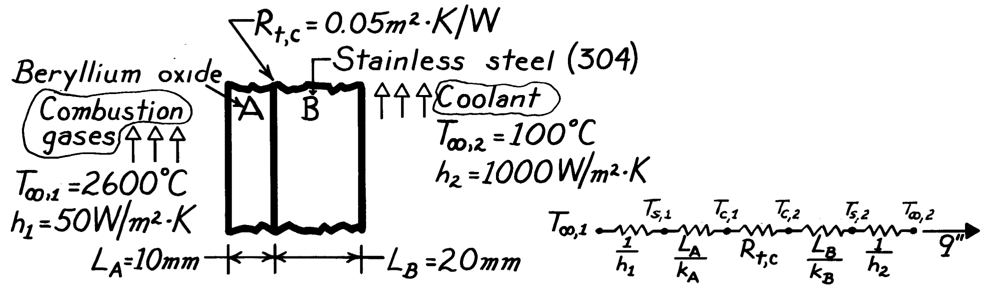
COMMENTS: A common and serious mistake is to assume that the largest thermal resistance dominates the thermal resistance network. Although this is sometimes the case, careful analysis will often reveal quicker, and less expensive alternatives to either reduce or increase the total thermal resistance.

PROBLEM 3.26

KNOWN: Materials and dimensions of a composite wall separating a combustion gas from a liquid coolant.

FIND: (a) Heat loss per unit area, and (b) Temperature distribution.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional heat transfer, (2) Steady-state conditions, (3) Constant properties, (4) Negligible radiation effects.

PROPERTIES: *Table A-1*, St. St. (304) $\left(\overline{T} \approx 1000K\right)$: k = 25.4 W/m·K; *Table A-2*, Beryllium Oxide (T ≈ 1500K): k = 21.5 W/m·K.

ANALYSIS: (a) The desired heat flux may be expressed as

$$q'' = \frac{T_{\infty,1} - T_{\infty,2}}{\frac{1}{h_1} + \frac{L_A}{k_A} + R_{t,c} + \frac{L_B}{k_B} + \frac{1}{h_2}} = \frac{(2600 - 100)^{\circ} C}{\left[\frac{1}{50} + \frac{0.01}{21.5} + 0.05 + \frac{0.02}{25.4} + \frac{1}{1000}\right] \frac{m^2.K}{W}}$$

$$q'' = 34{,}600 \text{ W/m}^2.$$ <

(b) The composite surface temperatures may be obtained by applying appropriate rate equations. From the fact that $q'' = h_1 \left(T_{\infty,1} - T_{s,1}\right)$, it follows that

$$T_{s,1} = T_{\infty,1} - \frac{q''}{h_1} = 2600^{\circ} C - \frac{34{,}600 \text{ W/m}^2}{50 \text{ W/m}^2 \cdot K} = 1908^{\circ} C.$$

With $q'' = \left(k_A / L_A\right)\left(T_{s,1} - T_{c,1}\right)$, it also follows that

$$T_{c,1} = T_{s,1} - \frac{L_A q''}{k_A} = 1908^{\circ} C - \frac{0.01 m \times 34{,}600 \text{ W/m}^2}{21.5 \text{ W/m} \cdot K} = 1892^{\circ} C.$$

Similarly, with $q'' = \left(T_{c,1} - T_{c,2}\right) / R_{t,c}$

$$T_{c,2} = T_{c,1} - R_{t,c} q'' = 1892^{\circ} C - 0.05 \frac{m^2 \cdot K}{W} \times 34{,}600 \frac{W}{m^2} = 162^{\circ} C$$

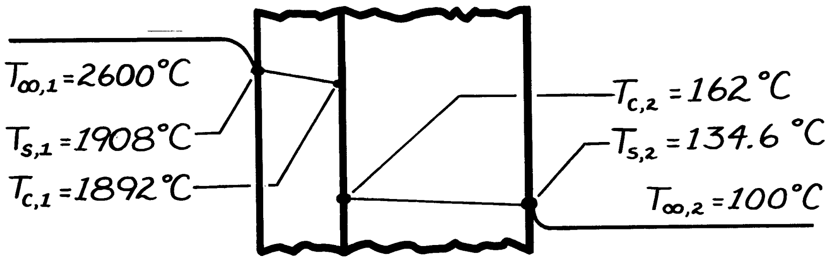
Continued …

PROBLEM 3.26 (Cont.)

and with $q'' = (k_B / L_B)(T_{c,2} - T_{s,2})$,

$$T_{s,2} = T_{c,2} - \frac{L_B q''}{k_B} = 162^\circ C - \frac{0.02m \times 34{,}600\ W/m^2}{25.4\ W/m \cdot K} = 134.6^\circ C.$$

The temperature distribution is therefore of the following form:



<

COMMENTS: (1) The calculations may be checked by recomputing q'' from

$$q'' = h_2 (T_{s,2} - T_{\infty,2}) = 1000 W/m^2 \cdot K (134.6\text{-}100)^\circ C = 34{,}600 W/m^2$$

(2) The initial *estimates* of the mean material temperatures are in error, particularly for the stainless steel. For improved accuracy the calculations should be repeated using k values corresponding to T ≈ 1900°C for the oxide and T ≈ 115°C for the steel.

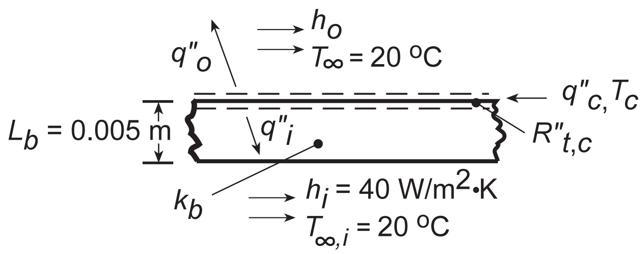
(3) The major contributions to the total resistance are made by the combustion gas boundary layer and the contact, where the temperature drops are largest.

PROBLEM 3.27

KNOWN: Operating conditions for a board mounted chip.

FIND: (a) Equivalent thermal circuit, (b) Chip temperature, (c) Maximum allowable heat dissipation for dielectric liquid (h_o = 1000 W/m^2·K) and air (h_o = 100 W/m^2·K). Effect of changes in circuit board temperature and contact resistance.

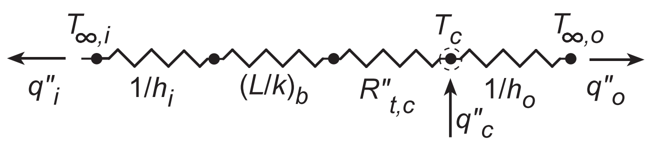
SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Negligible chip thermal resistance, (4) Negligible radiation, (5) Constant properties.

PROPERTIES: *Table A-2*, Aluminum oxide (polycrystalline, 358 K): k_b = 32.4 W/m·K.

ANALYSIS: (a)



(b) Applying conservation of energy to a control surface about the chip $\left(\dot{E}_{in} - \dot{E}_{out} = 0\right)$,

$$q''_c - q''_i - q''_o = 0$$

$$q''_c = \frac{T_c - T_{\infty,i}}{1/h_i + (L/k)_b + R''_{t,c}} + \frac{T_c - T_{\infty,o}}{1/h_o}$$

With $q''_c = 3\times10^4\ \mathrm{W/m^2}$, h_o = 1000 W/m^2·K, k_b = 1 W/m·K and $R''_{t,c} = 10^{-4}\ \mathrm{m^2\cdot K/W}$,

$$3\times10^4\ \mathrm{W/m^2} = \frac{T_c - 20^\circ\mathrm{C}}{\left(1/40 + 0.005/1 + 10^{-4}\right)\mathrm{m^2\cdot K/W}} + \frac{T_c - 20^\circ\mathrm{C}}{(1/1000)\ \mathrm{m^2\cdot K/W}}$$

$$3\times10^4\ \mathrm{W/m^2} = \left(33.2T_c - 664 + 1000T_c - 20{,}000\right)\mathrm{W/m^2\cdot K}$$

$1033T_c = 50{,}664$

$T_c = 49°C.$ <

(c) For T_c = 85°C and h_o = 1000 W/m^2·K, the foregoing energy balance yields

$$q''_c = 67{,}160\ \mathrm{W/m^2}$$ <

with q''_o = 65,000 W/m^2 and q''_i = 2160 W/m^2. Replacing the dielectric with air (h_o = 100 W/m^2·K), the following results are obtained for different combinations of k_b and $R''_{t,c}$.

Continued...

PROBLEM 3.27 (Cont.)

k_b (W/m·K)	$R''_{t,c}$ (m^2·K/W)	q''_i (W/m^2)	q''_o (W/m^2)	q''_c (W/m^2)
1	10^{-4}	2159	6500	8659
32.4	10^{-4}	2574	6500	9074
1	10^{-5}	2166	6500	8666
32.4	10^{-5}	2583	6500	9083

<

COMMENTS: 1. For the conditions of part (b), the total internal resistance is 0.0301 m^2·K/W, while the outer resistance is 0.001 m^2·K/W. Hence

$$\frac{q''_o}{q''_i} = \frac{\left(T_c - T_{\infty,o}\right)/R''_o}{\left(T_c - T_{\infty,i}\right)/R''_i} = \frac{0.0301}{0.001} = 30.$$

and only approximately 3% of the heat is dissipated through the board.

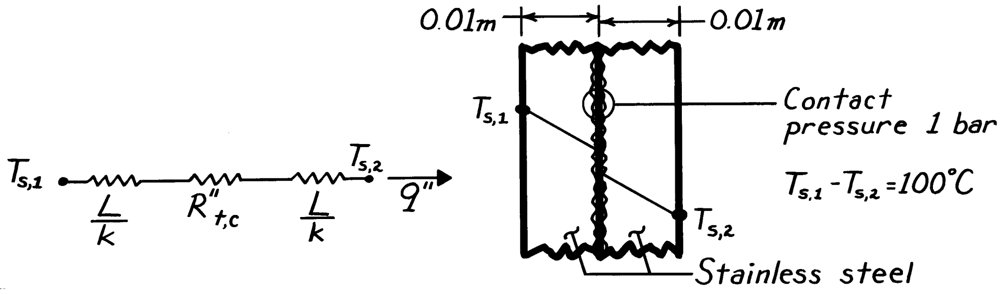
2. With h_o = 100 W/m^2·K, the outer resistance increases to 0.01 m^2·K/W, in which case $q''_o/q''_i = R''_i/R''_o$ = 0.0301/0.01 = 3.1 and now almost 25% of the heat is dissipated through the board. Hence, although measures to reduce R''_i would have a negligible effect on q''_c for the liquid coolant, some improvement may be gained for air-cooled conditions. As shown in the table of part (b), use of an aluminum oxide board increase q''_i by 19% (from 2159 to 2574 W/m^2) by reducing R''_i from 0.0301 to 0.0253 m^2·K/W. Because the initial contact resistance ($R''_{t,c} = 10^{-4} m^2 \cdot K/W$) is already much less than R''_i, any reduction in its value would have a negligible effect on q''_i. The largest gain would be realized by increasing h_i, since the inside convection resistance makes the dominant contribution to the total internal resistance.

PROBLEM 3.28

KNOWN: Thickness, overall temperature difference, and pressure for two stainless steel plates.

FIND: (a) Heat flux and (b) Contact plane temperature drop.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional heat transfer, (2) Steady-state conditions, (3) Constant properties.

PROPERTIES: *Table A-1*, Stainless Steel (T ≈ 400K): k = 16.6 W/m·K.

ANALYSIS: (a) With $R''_{t,c} \approx 15\times10^{-4}\ m^2\cdot K/W$ from Table 3.1 and

$$\frac{L}{k} = \frac{0.01m}{16.6\ W/m\cdot K} = 6.02\times10^{-4} m^2\cdot K/W,$$

it follows that

$$R''_{tot} = 2(L/k) + R''_{t,c} \approx 27\times10^{-4} m^2\cdot K/W;$$

hence

$$q'' = \frac{\Delta T}{R''_{tot}} = \frac{100°C}{27\times10^{-4} m^2\cdot K/W} = 3.70\times10^4 W/m^2.$$ <

(b) From the thermal circuit,

$$\frac{\Delta T_c}{T_{s,1} - T_{s,2}} = \frac{R''_{t,c}}{R''_{tot}} = \frac{15\times10^{-4} m^2\cdot K/W}{27\times10^{-4} m^2\cdot K/W} = 0.556.$$

Hence,

$$\Delta T_c = 0.556\left(T_{s,1} - T_{s,2}\right) = 0.556\left(100°C\right) = 55.6°C.$$ <

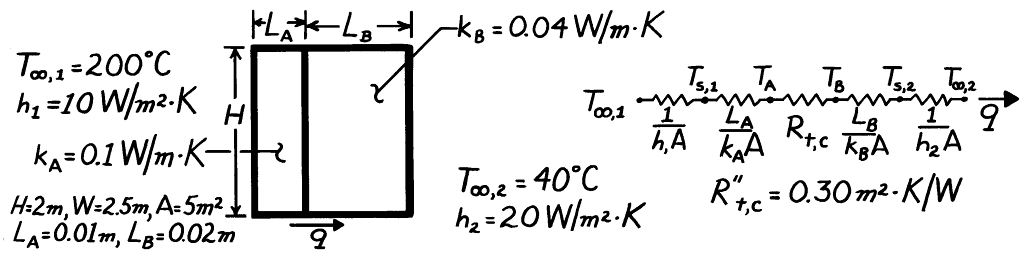
COMMENTS: The contact resistance is significant relative to the conduction resistances. The value of $R''_{t,c}$ would diminish, however, with increasing pressure. Note that there is considerable uncertainty in the answer since the thermal contact resistance can take on a wide range of values.

PROBLEM 3.29

KNOWN: Temperatures and convection coefficients associated with fluids at inner and outer surfaces of a composite wall. Contact resistance, dimensions, and thermal conductivities associated with wall materials.

FIND: (a) Rate of heat transfer through the wall, (b) Temperature distribution.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Negligible radiation, (4) Constant properties.

ANALYSIS: (a) Calculate the total resistance to find the heat rate,

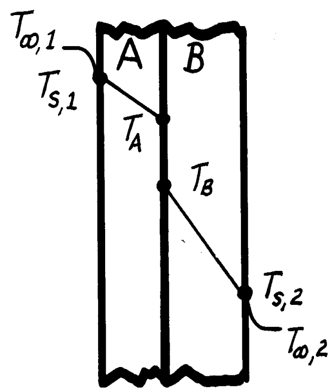
$$R_{tot} = \frac{1}{h_1 A} + \frac{L_A}{k_A A} + R_{t,c} + \frac{L_B}{k_B A} + \frac{1}{h_2 A}$$

$$R_{tot} = \left[\frac{1}{10\times5} + \frac{0.01}{0.1\times5} + \frac{0.3}{5} + \frac{0.02}{0.04\times5} + \frac{1}{20\times5}\right]\frac{K}{W}$$

$$R_{tot} = \left[0.02 + 0.02 + 0.06 + 0.10 + 0.01\right]\frac{K}{W} = 0.21\frac{K}{W}$$

$$q = \frac{T_{\infty,1} - T_{\infty,2}}{R_{tot}} = \frac{(200-40)^\circ C}{0.21\ K/W} = 762\ W. \qquad <$$

(b) It follows that



$$T_{s,1} = T_{\infty,1} - \frac{q}{h_1 A} = 200^\circ C - \frac{762\ W}{50\ W/K} = 184.8^\circ C$$

$$T_A = T_{s,1} - \frac{qL_A}{k_A A} = 184.8^\circ C - \frac{762 W \times 0.01 m}{0.1\frac{W}{m\cdot K}\times 5 m^2} = 169.6^\circ C$$

$$T_B = T_A - qR_{t,c} = 169.6^\circ C - 762 W \times 0.06\frac{K}{W} = 123.8^\circ C$$

$$T_{s,2} = T_B - \frac{qL_B}{k_B A} = 123.8^\circ C - \frac{762 W \times 0.02 m}{0.04\frac{W}{m\cdot K}\times 5 m^2} = 47.6^\circ C$$

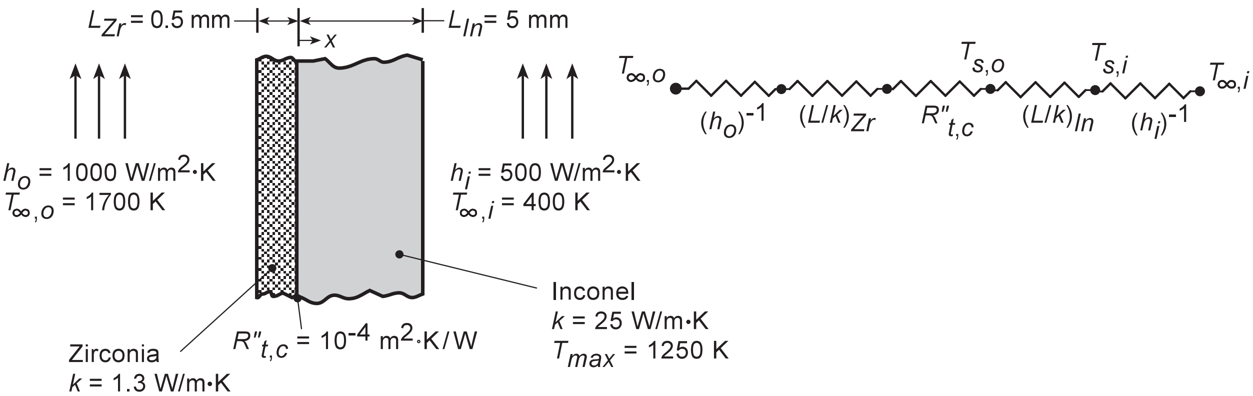
$$T_{\infty,2} = T_{s,2} - \frac{q}{h_2 A} = 47.6^\circ C - \frac{762 W}{100 W/K} = 40^\circ C$$

PROBLEM 3.30

KNOWN: Outer and inner surface convection conditions associated with zirconia-coated, Inconel turbine blade. Thicknesses, thermal conductivities, and interfacial resistance of the blade materials. Maximum allowable temperature of Inconel.

FIND: Whether blade operates below maximum temperature. Temperature distribution in blade, with and without the TBC.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, steady-state conduction in a composite plane wall, (2) Constant properties, (3) Negligible radiation.

ANALYSIS: For a unit area, the total thermal resistance with the TBC is

$$R''_{tot,w} = h_o^{-1} + (L/k)_{Zr} + R''_{t,c} + (L/k)_{In} + h_i^{-1}$$

$$R''_{tot,w} = \left(10^{-3} + 3.85\times10^{-4} + 10^{-4} + 2\times10^{-4} + 2\times10^{-3}\right) m^2\cdot K/W = 3.69\times10^{-3} m^2\cdot K/W$$

With a heat flux of

$$q''_w = \frac{T_{\infty,o} - T_{\infty,i}}{R''_{tot,w}} = \frac{1300\,K}{3.69\times10^{-3}\,m^2\cdot K/W} = 3.52\times10^5\,W/m^2$$

the inner and outer surface temperatures of the Inconel are

$$T_{s,i(w)} = T_{\infty,i} + \left(q''_w/h_i\right) = 400\,K + \left(3.52\times10^5\,W/m^2 / 500\,W/m^2\cdot K\right) = 1104\,K$$

$$T_{s,o(w)} = T_{\infty,i} + \left[(1/h_i) + (L/k)_{In}\right]q''_w = 400\,K + \left(2\times10^{-3} + 2\times10^{-4}\right)m^2\cdot K/W\left(3.52\times10^5\,W/m^2\right) = 1174\,K$$

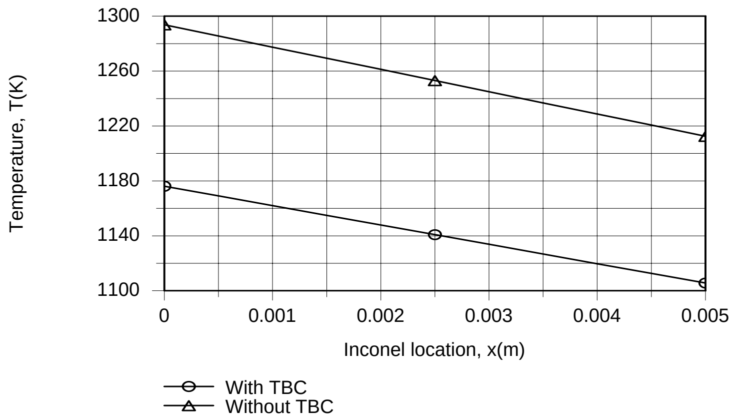
Without the TBC, $R''_{tot,wo} = h_o^{-1} + (L/k)_{In} + h_i^{-1} = 3.20\times10^{-3}\,m^2\cdot K/W$, and $q''_{wo} = \left(T_{\infty,o} - T_{\infty,i}\right)/R''_{tot,wo}$ = (1300 K)/3.20×10^{-3} m²·K/W = 4.06×10^5 W/m². The inner and outer surface temperatures of the Inconel are then

$$T_{s,i(wo)} = T_{\infty,i} + \left(q''_{wo}/h_i\right) = 400\,K + \left(4.06\times10^5\,W/m^2 / 500\,W/m^2\cdot K\right) = 1212\,K$$

$$T_{s,o(wo)} = T_{\infty,i} + \left[(1/h_i) + (L/k)_{In}\right]q''_{wo} = 400\,K + \left(2\times10^{-3} + 2\times10^{-4}\right)m^2\cdot K/W\left(4.06\times10^5\,W/m^2\right) = 1293\,K$$

Continued...

PROBLEM 3.30 (Cont.)



Use of the TBC facilitates operation of the Inconel below T_{max} = 1250 K.

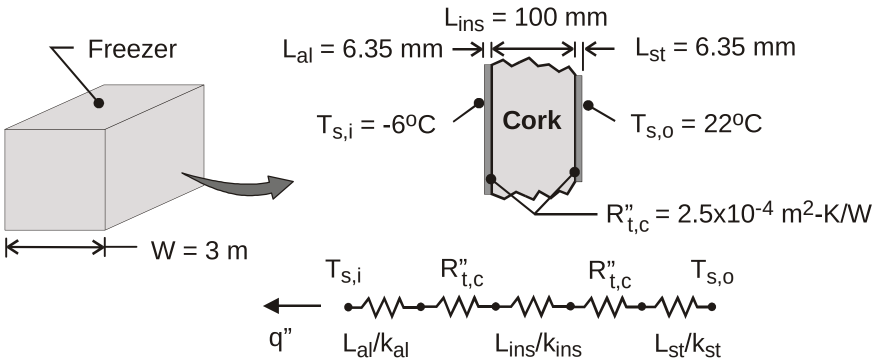
COMMENTS: Since the durability of the TBC decreases with increasing temperature, which increases with increasing thickness, limits to the thickness are associated with reliability considerations.

PROBLEM 3.31

KNOWN: Size and surface temperatures of a cubical freezer. Materials, thicknesses and interface resistances of freezer wall.

FIND: Cooling load.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction, (3) Constant properties.

PROPERTIES: *Table A-1*, Aluminum 2024 (~267K): k_{al} = 173 W/m·K. *Table A-1*, Carbon steel AISI 1010 (~295K): k_{st} = 64 W/m·K. *Table A-3* (~300K): k_{ins} = 0.039 W/m·K.

ANALYSIS: For a unit wall surface area, the total thermal resistance of the composite wall is

$$R''_{tot} = \frac{L_{al}}{k_{al}} + R''_{t,c} + \frac{L_{ins}}{k_{ins}} + R''_{t,c} + \frac{L_{st}}{k_{st}}$$

$$R''_{tot} = \frac{0.00635\text{m}}{173\ \text{W/m}\cdot\text{K}} + 2.5\times10^{-4}\,\frac{\text{m}^2\cdot\text{K}}{\text{W}} + \frac{0.100\text{m}}{0.039\ \text{W/m}\cdot\text{K}} + 2.5\times10^{-4}\,\frac{\text{m}^2\cdot\text{K}}{\text{W}} + \frac{0.00635\text{m}}{64\ \text{W/m}\cdot\text{K}}$$

$$R''_{tot} = \left(3.7\times10^{-5} + 2.5\times10^{-4} + 2.56 + 2.5\times10^{-4} + 9.9\times10^{-5}\right)\text{m}^2\cdot\text{K/W} = 2.56\ \text{m}^2\cdot\text{K/W}$$

Hence, the heat flux is

$$q'' = \frac{T_{s,o} - T_{s,i}}{R''_{tot}} = \frac{\left[22-(-6)\right]^\circ\text{C}}{2.56\ \text{m}^2\cdot\text{K/W}} = 10.9\ \frac{\text{W}}{\text{m}^2}$$

and the cooling load is

$$q = A_s\,q'' = 6\,W^2\,q'' = 54\text{m}^2 \times 10.9\ \text{W/m}^2 = 590\,\text{W}$$ <

COMMENT: Thermal resistances associated with the cladding and the adhesive joints are negligible compared to that of the insulation.

PROBLEM 3.32

KNOWN: Operating conditions, measured temperatures and heat input, and theoretical thermal conductivity of a carbon nanotube.

FIND: (a) Thermal contact resistance between the carbon nanotube and the heating and sensing islands, (b) Fraction of total thermal resistance between the heating and sensing islands due to thermal contact resistance for 5 μm ≤ s ≤ 20 μm.

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional heat transfer, (4) Isothermal heating and sensing islands, (5) Negligible radiation and convection heat transfer.

PROPERTIES: $k_{cn,T} = 5000$ W/m·K

ANALYSIS:

(a) The total thermal resistance between the heated and sensing island is

$$R_{t,tot} = \frac{s}{k_{cn,T}A_{cn}} + 2R_{t,c}$$

The value of this total resistance is the same as the one posed in Example 3.4 with $k_{cn} = 3113$ W/m·K and $R_{t,c} = 0$ or

$$\frac{s}{k_{cn,T}A_{cn}} + 2R_{t,c} = \frac{s}{k_{cn}A_{cn}}$$

for which

$$R_{t,c} = \frac{s}{2A_{cn}}\left[\frac{1}{k_{cn}} - \frac{1}{k_{cn,T}}\right] = \frac{5 \times 10^{-6}\ \text{m}}{2 \times 1.54 \times 10^{-16}\ \text{m}^2} \times \left[\frac{1}{3113\ \text{W/m}\cdot\text{K}} - \frac{1}{5000\ \text{W/m}\cdot\text{K}}\right]$$

$$= 1.97 \times 10^6\ \text{K/W}$$ <

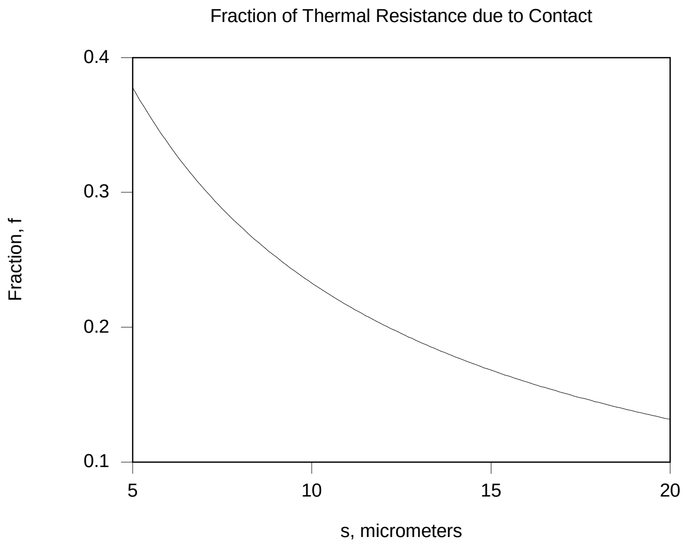
(b) The fraction of the total resistance due to the thermal contact resistance is

$$f = \frac{2R_{t,c}}{2R_{t,c} + \left[\dfrac{s}{k_{cn,T}A_{cn}}\right]} = \frac{2 \times 1.97 \times 10^6\ \text{K/W}}{2 \times 1.97 \times 10^6\ \text{K/W} + \left[\dfrac{s}{5000\ \text{W/m}\cdot\text{K} \times 1.54 \times 10^{-16}\ \text{m}^2}\right]}$$

As evident in the plot below, the fraction of the total thermal resistance due to thermal contact decreases from 0.38 at s = 5 μm to 0.13 at s = 20 μm.

Continued…

PROBLEM 3.32 (Cont.)



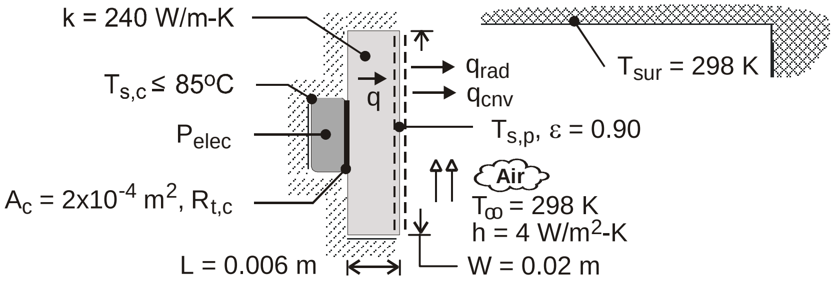
COMMENT: To desensitize the experiment to uncertainty due to the unknown thermal contact resistance values, a large separation distance between the islands is desired. As the separation distance becomes large, however, the surface area of the carbon nanotube increases and surface heat losses by radiation may invalidate the assumption of a linear temperature distribution along the length of the nanotube. An optimal separation distance exists that will minimize the undesirable effects of the thermal contact resistances and radiation loss from the surface of the nanotube.

PROBLEM 3.33

KNOWN: Dimensions, thermal conductivity and emissivity of base plate. Temperature and convection coefficient of adjoining air. Temperature of surroundings. Maximum allowable temperature of transistor case. Case-plate interface conditions.

FIND: (a) Maximum allowable power dissipation for an air-filled interface, (b) Effect of convection coefficient on maximum allowable power dissipation.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Negligible heat transfer from the enclosure, to the surroundings. (3) One-dimensional conduction in the base plate, (4) Radiation exchange at surface of base plate is with large surroundings, (5) Constant thermal conductivity.

PROPERTIES: Aluminum-aluminum interface, air-filled, 10 μm roughness, 10^5 N/m^2 contact pressure (Table 3.1): $R''_{t,c} = 2.75\times10^{-4}\ m^2\cdot K/W$.

ANALYSIS: (a) With all of the heat dissipation transferred through the base plate,

$$P_{elec} = q = \frac{T_{s,c} - T_\infty}{R_{tot}} \qquad (1)$$

where $R_{tot} = R_{t,c} + R_{cnd} + \left[(1/R_{cnv}) + (1/R_{rad})\right]^{-1}$

$$R_{tot} = \frac{R''_{t,c}}{A_c} + \frac{L}{kW^2} + \frac{1}{W^2}\left(\frac{1}{h+h_r}\right) \qquad (2)$$

and $$h_r = \varepsilon\sigma\left(T_{s,p} + T_{sur}\right)\left(T_{s,p}^2 + T_{sur}^2\right) \qquad (3)$$

To obtain $T_{s,p}$, the following energy balance must be performed on the plate surface,

$$q = \frac{T_{s,c} - T_{s,p}}{R_{t,c} + R_{cnd}} = q_{cnv} + q_{rad} = hW^2\left(T_{s,p} - T_\infty\right) + h_r W^2\left(T_{s,p} - T_{sur}\right) \qquad (4)$$

With $R_{t,c}$ = 2.75 × 10^{-4} m^2·K/W/2×10^{-4} m^2 = 1.375 K/W, R_{cnd} = 0.006 m/(240 W/m·K × 4 × 10^{-4} m^2) = 0.0625 K/W, and the prescribed values of h, W, $T_\infty = T_{sur}$ and ε, Eq. (4) yields a surface temperature of $T_{s,p}$ = 357.6 K = 84.6°C and a power dissipation of

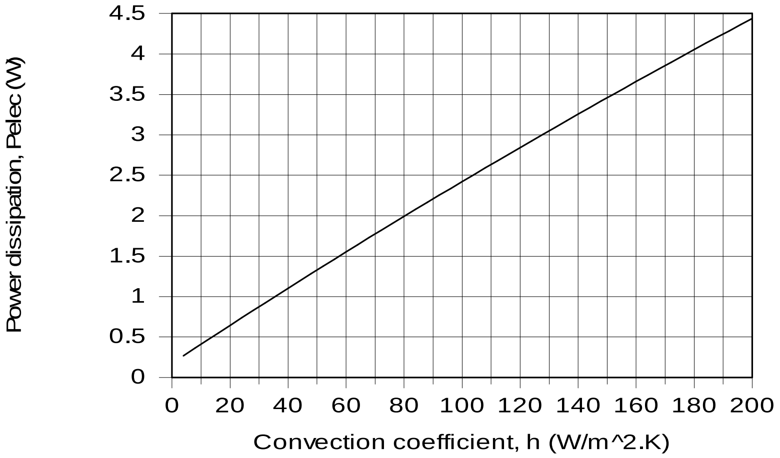
Continued …

PROBLEM 3.33 (Cont.)

$$P_{elec} = q = 0.268 \text{ W}$$ <

The convection and radiation resistances are R_{cnv} = 625 K/W and R_{rad} = 345 K/W, where h_r = 7.25 $W/m^2 \cdot K$.

(b) With the major contribution to the total resistance made by convection, significant benefit may be derived by increasing the value of h.



For h = 200 $W/m^2 \cdot K$, R_{cnv} = 12.5 K/W and $T_{s,p}$ = 351.6 K, yielding R_{rad} = 355 K/W. The effect of radiation is then negligible.

COMMENTS: (1) The plate conduction resistance is negligible, and even for h = 200 $W/m^2 \cdot K$, the contact resistance is small relative to the convection resistance. However, $R_{t,c}$ could be rendered negligible by using indium foil, instead of an air gap, at the interface. From Table 3.1, $R''_{t,c} = 0.07 \times 10^{-4} \text{ m}^2 \cdot \text{K/W}$, in which case $R_{t,c}$ = 0.035 m·K/W.

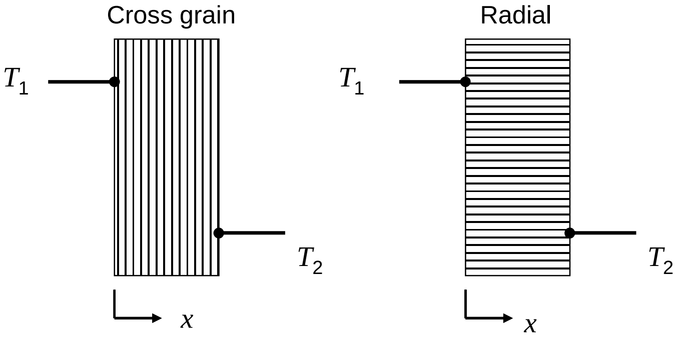
(2) Because $A_c < W^2$, heat transfer by conduction in the plate is actually two-dimensional, rendering the conduction resistance even smaller.

PROBLEM 3.34

KNOWN: Oak wood with a grain structure. Grains are highly porous and the wood is dry.

FIND: Fraction of oak cross-section that appears as being grained.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, one-dimensional conduction, (2) Constant properties, (3) Thermal conductivity of highly porous grain is that of air.

PROPERTIES: *Table A.3*, Oak, cross grain (300 K): k_{cross} = 0.17 W/m·K; Oak, radial (300 K): k_{rad} = 0.19 W/m·K. *Table A.4*, Air (300 K): k_{air} = 0.0263 W/m·K.

ANALYSIS: The cross grain condition is characterized by the lowest effective thermal conductivity. Therefore,

$$k_{\text{cross}} = k_{\min} = 0.17 \text{W/m} \cdot \text{K} = \frac{1}{(1-\varepsilon)/k_s + \varepsilon / k_f} = \frac{1}{(1-\varepsilon)/k_s + \varepsilon / 0.0263 \text{ W/m} \cdot \text{K}} \quad (1)$$

Likewise, the radial condition exhibits the highest effective thermal conductivity. Hence,

$$k_{\text{rad}} = k_{\max} = 0.19 \text{W/m} \cdot \text{K} = \varepsilon k_f + (1-\varepsilon)k_s = \varepsilon \times 0.0263 \text{ W/m} \cdot \text{K} + (1-\varepsilon)k_s \quad (2)$$

The preceding two equations may be solved simultaneously to determine the two unknowns, k_s and ε, yielding

$$\varepsilon = 0.022$$ <

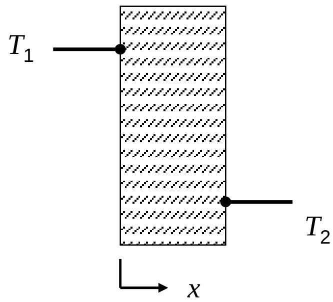
COMMENTS: (1) The predicted value of the solid thermal conductivity is k_s = 0.1937 W/m·K. (2) The predicted value of ε is rather low. In reality, the thermal conductivity of the grain is greater than that of air. Doubling the value of k_f to 0.0526 W/m·K yields ε = 0.061, which is consistent with estimates of ε for oak.

PROBLEM 3.35

KNOWN: Density of glass fiber insulation.

FIND: Maximum and minimum possible values of the effective thermal conductivity of the insulation at T = 300 K, and comparison with the value listed in Table A.3.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Negligible radiation, (3) Atmospheric pressure.

PROPERTIES: *Table A.3,* Glass (plate): k_{gl} = 1.4 W/m·K, ρ_{gl} = 2500 kg/m^3.Glass fiber batt (paper faced, ρ_{ins} = 28 kg/m^3) k_{ins} = 0.038 W/m·K. *Table A.4,* Air (300 K): k_{air} = 0.0263 W/m·K, ρ_{air} = 1.1614 kg/m^3. Given: ρ_{ins} = 28 kg/m^3.

ANALYSIS: The density of the glass fiber insulation may be related to the density of the air and glass phases, and the volume fraction, ε, as follows.

$$\rho_{\text{ins}} = \varepsilon\rho_{\text{air}} + (1-\varepsilon)\rho_{\text{gl}}$$

Therefore,

$$\varepsilon = \frac{\rho_{\text{gl}} - \rho_{\text{ins}}}{\rho_{\text{gl}} - \rho_{\text{air}}} = \frac{2500 - 28}{2500 - 1.164} = 0.989$$

The minimum effective thermal conductivity is

$$k_{\text{eff,min}} = \frac{1}{(1-\varepsilon)/k_{\text{glass}} + \varepsilon/k_{\text{air}}} = \frac{1}{(1-0.989)/1.4 \text{ W/m}\cdot\text{K} + 0.989/0.0263 \text{ W/m}\cdot\text{K}}$$
$$= 0.0265 \text{ W/m}\cdot\text{K}$$ <

The maximum effective thermal conductivity is

$$k_{\text{eff,max}} = \varepsilon k_f + (1-\varepsilon)k_s = 0.989 \times 0.0263 \text{ W/m}\cdot\text{K} + (1-0.989) \times 1.4 \text{ W/m}\cdot\text{K}$$
$$= 0.0414 \text{ W/m}\cdot\text{K}$$ <

As expected, the predicted minimum and maximum effective thermal conductivities bracket the actual effective thermal conductivity of k_{ins} = 0.038 W/m·K. <

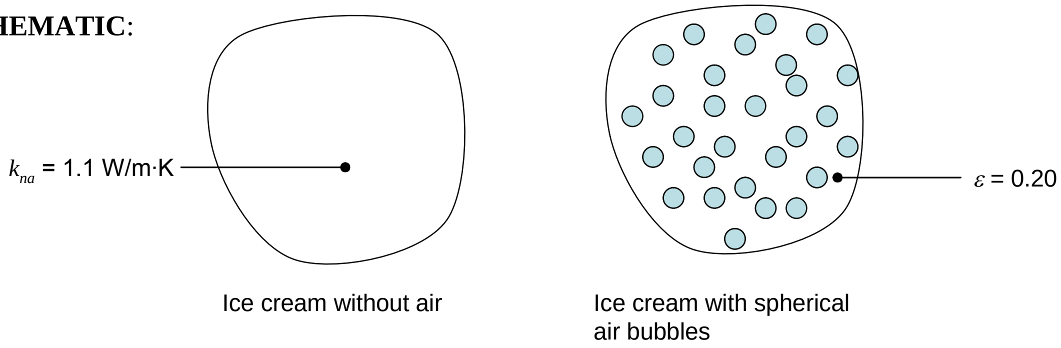
COMMENT: Radiation internal to the glass fiber batting may be significant. If so, this will reduce the insulating capability of the matt.

PROBLEM 3.36

KNOWN: Thermal conductivity of ice cream containing no air at T = -20°C. Shape and volume fraction of air bubbles.

FIND: The thermal conductivity of commercial ice cream characterized by ε = 0.20 at T = -20°C.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Spherical air bubbles.

PROPERTIES: *Table A.4*, Air (300 K): k_{air} = 0.0225 W/m·K.

ANALYSIS: Maxwell's expression for the effective thermal conductivity may be used, with $k_f = k_{air}$ and $k_s = k_{na}$. Hence,

$$k_{eff} = \left[\frac{k_f + 2k_s - 2\varepsilon\left(k_s - k_f\right)}{k_f + 2k_s + \varepsilon\left(k_s - k_f\right)}\right]k_s$$

$$= \left[\frac{0.0225\text{ W/m}\cdot\text{K} + 2\times 1.1\text{ W/m}\cdot\text{K} - 2\times 0.2\times\left(1.1\text{ W/m}\cdot\text{K} - 0.0225\text{ W/m}\cdot\text{K}\right)}{0.0225\text{ W/m}\cdot\text{K} + 2\times 1.1\text{ W/m}\cdot\text{K} + 0.2\times\left(1.1\text{ W/m}\cdot\text{K} - 0.0225\text{ W/m}\cdot\text{K}\right)}\right]\times 1.1\text{ W/m}\cdot\text{K}$$

$= 0.81$ W/m·K <

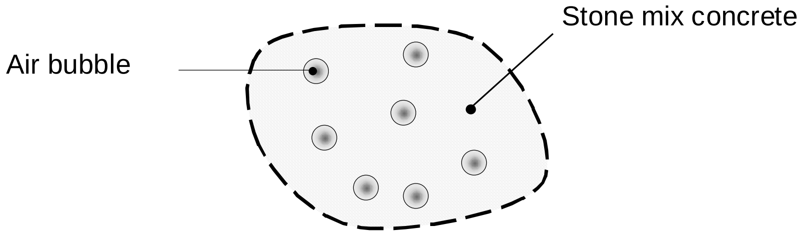
COMMENTS: (1) The reduction in the effective thermal conductivity due to the presence of the air bubbles is 26%. (2) The predicted thermal conductivity is in good agreement with measured values. Furthermore, Maxwell's equation accurately predicts the measured thermal conductivity of ice cream over the range $0 \leq \varepsilon \leq 0.5$. The thermal conductivity as well as additional thermophysical properties of ice cream containing spherical air bubbles (called *overrun* ice cream) are available in Cogne, Andrieu, Laurent, Besson and Noequet, "Experimental Data and Modelling of Thermal Properties of Ice Cream," *Journal of Food Engineering*, Vol. 58, p, 331, 2003.

PROBLEM 3.37

KNOWN: Volume fraction of air in stone mix concrete, forming a lightweight aggregate concrete.

FIND: Values of the lightweight aggregate's thermal conductivity, density and specific heat.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties.

PROPERTIES: Table A.3 (T = 300 K): Stone mix concrete; k_s = 1.4 W/m·K, ρ_s= 2300 kg/m^3, $c_{p,s}$ = 880 J/kg·K. Table A.4 (T = 300 K): Air; k_f = 0.0263 W/m·K, ρ_f = 1.1614 kg/m^3, $c_{p,f}$ = 1007 J/kg·K.

ANALYSIS: Maxwell's expression for the effective thermal conductivity may be used. Hence,

$$k_{\text{eff},a} = \left[\frac{k_f + 2k_s - 2\varepsilon\left(k_s - k_f\right)}{k_f + 2k_s + \varepsilon\left(k_s - k_f\right)}\right]k_s$$

$$= \left[\frac{0.0263 \text{ W/m}\cdot\text{K} + 2\times 1.4 \text{ W/m}\cdot\text{K} - 2\times 0.35\times\left(1.4 \text{ W/m}\cdot\text{K} - 0.0263 \text{ W/m}\cdot\text{K}\right)}{0.0263 \text{ W/m}\cdot\text{K} + 2\times 1.4 \text{ W/m}\cdot\text{K} + 0.35\times\left(1.4 \text{ W/m}\cdot\text{K} - 0.0263 \text{ W/m}\cdot\text{K}\right)}\right]\times 1.4 \text{ W/m}\cdot\text{K}$$

= 0.789 W/m·K $\quad <$

Considering the control volume shown in the schematic to be of unit volume, we note that by conservation of mass, $\rho_a = \rho_s(1 - \varepsilon) + \rho_f\varepsilon$ = 2300 kg/m^3 × (1 – 0.35) + 1.1614 kg/m^3 × 0.35 = 1495 kg/m^3. $\quad <$

Similarly, by conservation of energy for the unit volume, $\rho_a c_{p,a}$ = 1495 kg/m^3 × $c_{p,a} = \rho_s c_{p,s}(1 - \varepsilon) + \rho_f c_{p,f}\,\varepsilon$ = 2300 kg/m^3 × 880 J/kg·K × (1 – 0.35) + 1.1614 kg/m^3 × 1007 J/kg·K × 0.35 = 1.32 × 10^6 J/K.
Therefore, $c_{p,a}$ = 1.32 × 10^6 J/K/1495 kg/m^3 = 880 J/kg·K $\quad <$

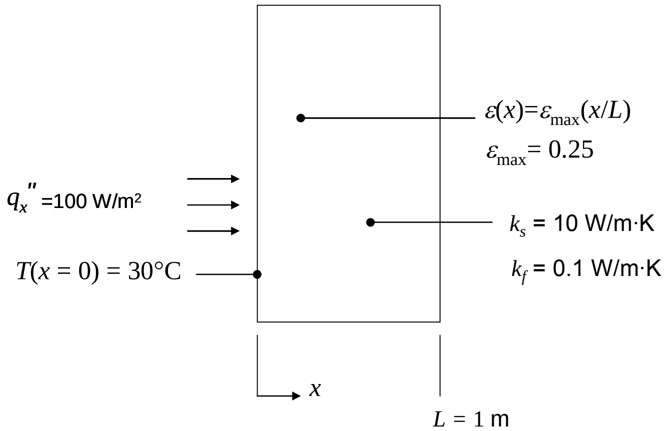
COMMENT: The thermal conductivity and density are reduced significantly relative to the stone mix concrete values.

PROBLEM 3.38

KNOWN: Porosity distribution in a one-dimensional plane wall, $\varepsilon(x)$, thermal conductivities of solid and fluid, wall thickness, temperature at $x = 0$, and heat flux.

FIND: Plot of the temperature distribution using the expressions for the maximum and minimum effective thermal conductivities, Maxwell's expression, and for the constant property case; $k_{eff}(x) = k_s$.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties within the two phases, (2) Negligible radiation, (3) No thermal energy generation, (4) Steady state, one-dimensional heat transfer.

PROPERTIES: *Given*: k_s = 10 W/m·K, k_f = 0.1 W/m·K.

ANALYSIS: Fourier's law may be expressed as

$$\frac{dT}{dx} = -\frac{q_x''}{k_{eff}} \tag{1}$$

We note that the heat flux is constant. The effective thermal conductivity may be evaluated from the various formulae as follows.

Maximum effective thermal conductivity:

$$k_{eff} = k_{eff,max} = \varepsilon k_f + (1-\varepsilon)k_s \tag{2}$$

Minimum effective thermal conductivity:

$$k_{eff} = k_{eff,min} = \frac{1}{(1-\varepsilon)/k_s + \varepsilon/k_f} \tag{3}$$

Maxwell's expression:

$$k_{eff} = k_{eff,Max} = \left[\frac{k_f + 2k_s - 2\varepsilon(k_s - k_f)}{k_f + 2k_s + \varepsilon(k_s - k_f)}\right]k_s \tag{4}$$

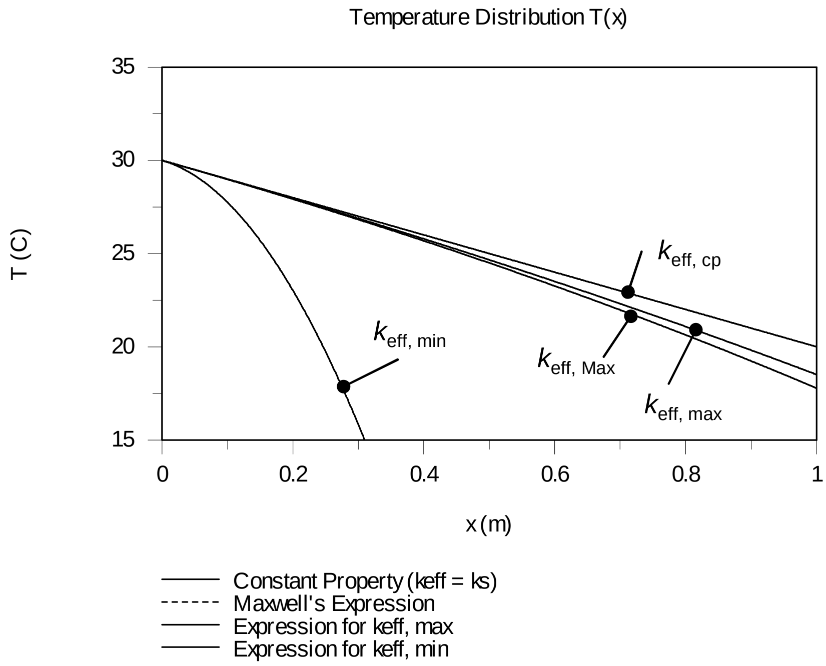
Continued...

PROBLEM 3.38 (Cont.)

No dispersed phase:

$$k_{\text{eff}} = k_s \tag{5}$$

Equations 2, 3, 4, or 5 may be substituted into Equation 1 and the expression may be integrated numerically using a commercial code. IHT was used to generate the following temperature distributions.



The constant property solution exhibits a linear temperature distribution.

The introduction of the low thermal conductivity matter within the medium decreases its effective thermal conductivity. From Equation (1), the temperature gradient must become larger in order to sustain the imposed heat flux as the effective thermal conductivity decreases. The increased temperature gradients are evident in the plot.

Predictions using Maxwell's expression, and the expression for the maximum effective thermal conductivity are in relatively good agreement. This is because Maxwell's expression describes conduction within a porous medium that is characterized by a contiguous solid phase; thermal energy can be transferred across the entire thickness of the plane wall within the solid phase only. The concept of a contiguous solid phase is also embedded in the assumptions that were made in deriving the expression for $k_{\text{eff,max}}$. In contrast, the predictions using the expression for the minimum effective thermal conductivity are not consistent with the other predictions. In deriving the expression for $k_{\text{eff,min}}$, it is assumed that thermal energy *must* be transferred through the low thermal conductivity fluid phase as it propagates through the porous wall. The non-contiguous solid phase associated with the minimum thermal conductivity expression manifests itself as very large temperature gradients through the plane wall.

Continued...

PROBLEM 3.38 (Cont.)

COMMENTS: (1) It is important to be cognizant of the morphology of the porous medium before selecting the appropriate expression for the effective thermal conductivity. (2) The IHT code is shown below.

```
//Input phase properties, dimensions, thermal boundary condition, and porosity parameter.

ks = 10             //W/mK
kf = 0.1            //W/mK
L = 1               //m
emax = 0.25         //dimensionless
qflux = 100         //W/m^2
T1 = 30             //Degrees C
eps = emax*(x/L)

//Constant Property Solution
Der(Tcp,x) = -qflux/ks

//Minimum Effective Thermal Conductivity Solution
Der(Tmin,x) = -qflux/keffmin
keffmin = 1/dena
dena=(1-eps)/ks + eps/kf

//Maximum Effective Thermal Conductivity Solution
Der(Tmax,x) = -qflux/keffmax
keffmax = eps*kf + (1 - eps)*ks

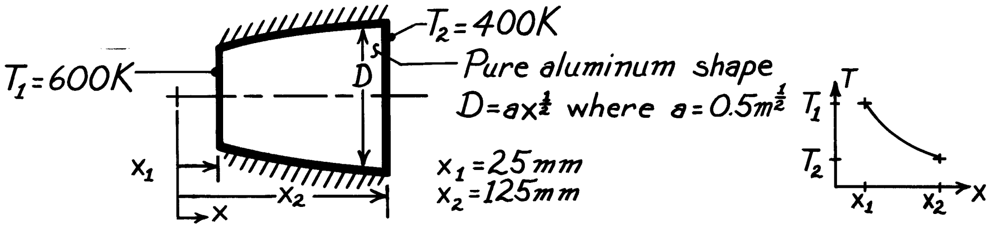
//Maxwell's Expression
Der(TMax,x) = -qflux/keffMax
keffMax = ks*num/denb
num = kf+2*ks-2*eps*(ks-kf)
denb = kf+2*ks+eps*(ks-kf)
```

PROBLEM 3.39

KNOWN: Conduction in a conical section with prescribed diameter, D, as a function of x in the form $D = ax^{1/2}$.

FIND: (a) Temperature distribution, T(x), (b) Heat transfer rate, q_x.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in x-direction, (3) No internal heat generation, (4) Constant properties.

PROPERTIES: *Table A-1*, Pure Aluminum (500K): k= 236 W/m·K.

ANALYSIS: (a) Based upon the assumptions, and following the same methodology of Example 3.4, q_x is a constant independent of x. Accordingly,

$$q_x = -kA\frac{dT}{dx} = -k\left[\pi\left(ax^{1/2}\right)^2/4\right]\frac{dT}{dx} \tag{1}$$

using $A = \pi D^2/4$ where $D = ax^{1/2}$. Separating variables and identifying limits,

$$\frac{4q_x}{\pi a^2 k}\int_{x_1}^{x}\frac{dx}{x} = -\int_{T_1}^{T} dT. \tag{2}$$

Integrating and solving for T(x) and then for T_2,

$$T(x) = T_1 - \frac{4q_x}{\pi a^2 k}\ln\frac{x}{x_1} \qquad T_2 = T_1 - \frac{4q_x}{\pi a^2 k}\ln\frac{x_2}{x_1}. \tag{3,4}$$

Solving Eq. (4) for q_x and then substituting into Eq. (3) gives the results,

$$q_x = -\frac{\pi}{4}a^2k\left(T_1 - T_2\right)/1n\left(x_1/x_2\right) \tag{5}$$

$$T(x) = T_1 + \left(T_1 - T_2\right)\frac{\ln\left(x/x_1\right)}{\ln\left(x_1/x_2\right)}.$$ <

From Eq. (1) note that (dT/dx)·x = Constant. It follows that T(x) has the distribution shown above.

(b) The heat rate follows from Eq. (5),

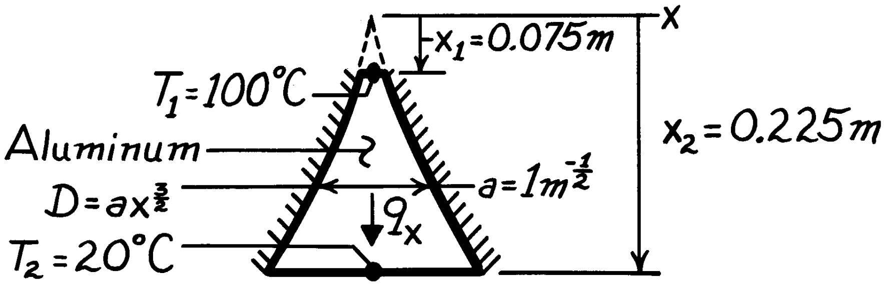
$$q_x = \frac{\pi}{4}\times 0.5^2 m \times 236\frac{W}{m\cdot K}\left(600-400\right)K/\ln\frac{25}{125} = 5.76kW.$$ <

PROBLEM 3.40

KNOWN: Geometry and surface conditions of a truncated solid cone.

FIND: (a) Temperature distribution, (b) Rate of heat transfer across the cone.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in x, (3) Constant properties.

PROPERTIES: *Table A-1*, Aluminum (333K): k = 238 W/m·K.

ANALYSIS: (a) From Fourier's law, Eq. 2.1, with $A=\pi D^2/4=\left(\pi a^2/4\right)x^3$, it follows that

$$\frac{4q_x dx}{\pi a^2 x^3}=-kdT.$$

Hence, since q_x is independent of x,

$$\frac{4q_x}{\pi a^2}\int_{x_1}^{x}\frac{dx}{x^3}=-k\int_{T_1}^{T} dT$$

or

$$\frac{4q_x}{\pi a^2}\left[-\frac{1}{2x^2}\right]\Bigg|_{x_1}^{x}=-k\left(T-T_1\right).$$

Hence

$$T=T_1+\frac{2q_x}{\pi a^2 k}\left[\frac{1}{x^2}-\frac{1}{x_1^2}\right].$$ <

(b) From the foregoing expression, it also follows that

$$q_x=\frac{\pi a^2 k}{2}\frac{T_2-T_1}{\left[1/x_2^2-1/x_1^2\right]}$$

$$q_x=\frac{\pi\left(1m^{-1}\right)238\text{ W/m}\cdot\text{K}}{2}\times\frac{(20-100)^\circ\text{C}}{\left[(0.225)^{-2}-(0.075)^{-2}\right]m^{-2}}$$

$$q_x=189\text{ W}.$$ <

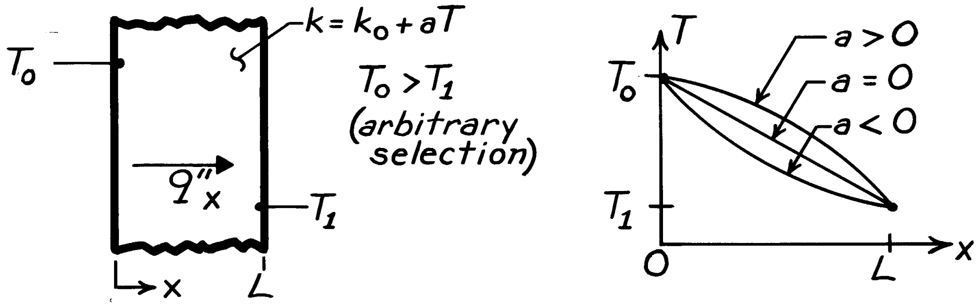
COMMENTS: The foregoing results are approximate due to use of a one-dimensional model in treating what is inherently a two-dimensional problem.

PROBLEM 3.41

KNOWN: Temperature dependence of the thermal conductivity, k.

FIND: Heat flux and form of temperature distribution for a plane wall.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction through a plane wall, (2) Steady-state conditions, (3) No internal heat generation.

ANALYSIS: For the assumed conditions, q_x and A(x) are constant and Eq. 3.26 gives

$$q''_x \int_0^L dx = -\int_{T_o}^{T_1} (k_o + aT)dT$$

$$q''_x = \frac{1}{L}\left[k_o(T_o - T_1) + \frac{a}{2}\left(T_o^2 - T_1^2\right)\right].$$

From Fourier's law,

$$q''_x = -(k_o + aT)\ dT/dx.$$

Hence, since the product of (k_o+aT) and dT/dx) is constant, decreasing T with increasing x implies,

a > 0: decreasing (k_o+aT) and increasing |dT/dx| with increasing x

a = 0: k = k_o => constant (dT/dx)

a < 0: increasing (k_o+aT) and decreasing |dT/dx| with increasing x.

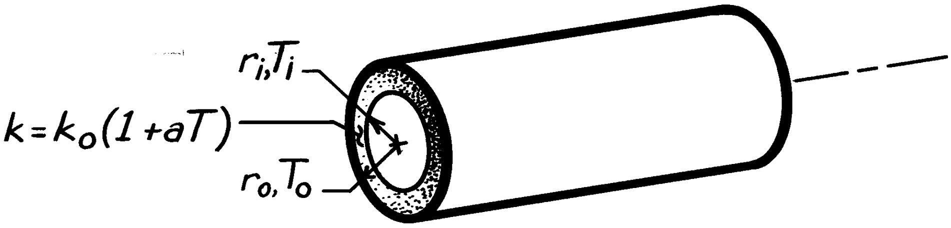
The temperature distributions appear as shown in the above sketch.

PROBLEM 3.42

KNOWN: Temperature dependence of tube wall thermal conductivity.

FIND: Expressions for heat transfer per unit length and tube wall thermal (conduction) resistance.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial conduction, (3) No internal heat generation.

ANALYSIS: From Eq. 3.29, the appropriate form of Fourier's law is

$$q_r = -kA_r \frac{dT}{dr} = -k(2\pi\, rL)\frac{dT}{dr}$$
$$q'_r = -2\pi\, kr\frac{dT}{dr}$$
$$q'_r = -2\pi\, rk_o(1+aT)\frac{dT}{dr}.$$

Separating variables,

$$-\frac{q'_r}{2\pi}\frac{dr}{r} = k_o(1+aT)dT$$

and integrating across the wall, find

$$-\frac{q'_r}{2\pi}\int_{r_i}^{r_o}\frac{dr}{r} = k_o\int_{T_i}^{T_o}(1+aT)dT$$
$$-\frac{q'_r}{2\pi}\ln\frac{r_o}{r_i} = k_o\left[T + \frac{aT^2}{2}\right]\Bigg|_{T_i}^{T_o}$$
$$-\frac{q'_r}{2\pi}\ln\frac{r_o}{r_i} = k_o\left[(T_o - T_i) + \frac{a}{2}\left(T_o^2 - T_i^2\right)\right]$$

$$q'_r = -2\pi k_o\left[1+\frac{a}{2}(T_o + T_i)\right]\frac{(T_o - T_i)}{\ln(r_o/r_i)}. \qquad <$$

It follows that the overall thermal resistance per unit length is

$$R'_t = \frac{T_i - T_o}{q'_r} = \frac{\ln(r_o/r_i)}{2\pi k_o\left[1+\frac{a}{2}(T_o + T_i)\right]}. \qquad <$$

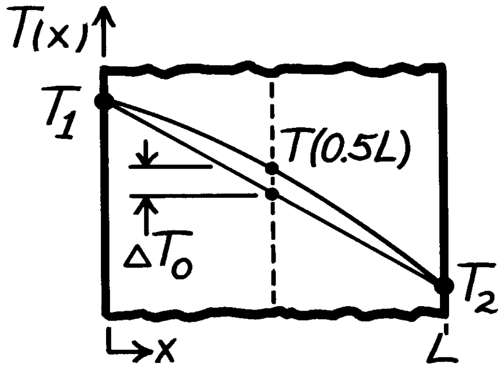
COMMENT: Note the necessity of the stated assumptions to treating q'_r as independent of r.

PROBLEM 3.43

KNOWN: Steady-state temperature distribution of convex shape for material with $k = k_o(1 + \alpha T)$ where α is a constant and the mid-point temperature is ΔT_o higher than expected for a linear temperature distribution.

FIND: Relationship to evaluate α in terms of ΔT_o and T_1, T_2 (the temperatures at the boundaries).

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) No internal heat generation, (4) α is positive and constant.

ANALYSIS: At any location in the wall, Fourier's law has the form

$$q''_x = -k_o\left(1+\alpha\, T\right)\frac{dT}{dx}. \qquad (1)$$

Since q''_x is a constant, we can separate Eq. (1), identify appropriate integration limits, and integrate to obtain

$$\int_0^L q''_x dx = -\int_{T_1}^{T_2} k_o\left(1+\alpha\, T\right)dT \qquad (2)$$

$$q''_x = -\frac{k_o}{L}\left[\left(T_2+\frac{\alpha\, T_2^2}{2}\right)-\left(T_1+\frac{\alpha T_1^2}{2}\right)\right]. \qquad (3)$$

We could perform the same integration, but with the upper limits at x = L/2, to obtain

$$q''_x = -\frac{2k_o}{L}\left[\left(T_{L/2}+\frac{\alpha T_{L/2}^2}{2}\right)-\left(T_1+\frac{\alpha\, T_1^2}{2}\right)\right] \qquad (4)$$

where

$$T_{L/2} = T\left(L/2\right) = \frac{T_1+T_2}{2}+\Delta T_o. \qquad (5)$$

Setting Eq. (3) equal to Eq. (4), substituting from Eq. (5) for $T_{L/2}$, and solving for α, it follows that

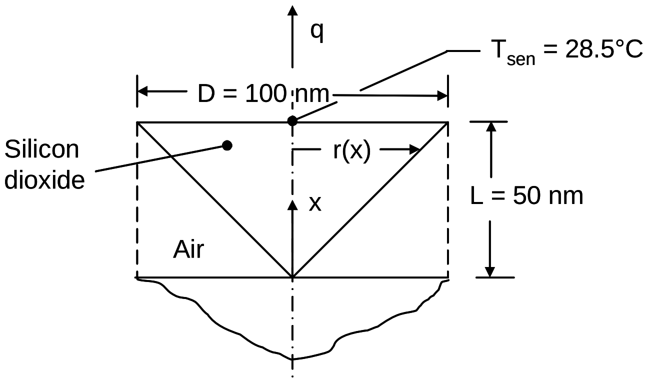
$$\alpha = \frac{2\Delta T_o}{\left(T_2^2+T_1^2\right)/2-\left[\left(T_1+T_2\right)/2+\Delta T_o\right]^2}. \qquad <$$

PROBLEM 3.44

KNOWN: Construction and dimensions of a device to measure the temperature of a surface. Ambient and sensing temperatures, and thermal resistance between the sensing element and the pivot point.

FIND: (a) Thermal resistance between the surface temperature and the sensing temperature, (b) Surface temperature for T_{sen} = 28.5°C.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Negligible nanoscale effects, (4) Constant properties.

PROPERTIES: Table A.2, polycrystalline silicon dioxide (300 K): k = 1.38 W/m·K. Table A.4, air (300 K): k = 0.0263 W/m·K.

ANALYSIS:

(a) At any x location, heat transfer in the x-direction occurs by conduction in the air as well as conduction in the probe. Applying Fourier's law,

$$q_x = -k_a A_a \frac{dT}{dx} - k_p A_p \frac{dT}{dx} \tag{1}$$

Since the probe radius is r = Dx/2L, the probe area is

$$A_p = \frac{\pi D^2}{4L^2} x^2 \quad \text{and} \quad A_a = \frac{\pi D^2}{4} - A_p = \frac{\pi D^2}{4}\left[1 - \frac{x^2}{L^2}\right] \qquad \text{(2a, 2b)}$$

Substituting Eqs. (2a) and (2b) into Eq. (1) yields

$$q_x = -\frac{\pi D^2}{4L^2}\left[k_a (L^2 - x^2) + k_p x^2\right]\frac{dT}{dx}$$

Separating variables and integrating,

Continued…

PROBLEM 3.44 (Cont.)

$$q_x \int_{x=0}^{L} \frac{dx}{k_a(L^2 - x^2) + k_p x^2} = -\frac{\pi D^2}{4L^2} \int_{T=T_{surf}}^{T_{sen}} dT = -\frac{\pi D^2}{4L^2}\left(T_{sen} - T_{surf}\right)$$

Therefore, the thermal resistance associated with the probe is

$$R_{sen} = \frac{(T_{surf} - T_{sen})}{q_x} = \frac{4L^2}{\pi D^2} \int_{x=0}^{L} \frac{dx}{k_a L^2 + (k_p - k_a)x^2}$$

Carrying out the integration yields

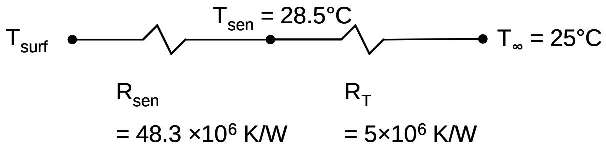
$$R_{sen} = \frac{4L^2}{\pi D^2} \frac{1}{\sqrt{k_a(k_p - k_a)}} \tan^{-1}\sqrt{\frac{k_p - k_a}{k_a}}$$

Substituting values gives

$$R_{sen} = \frac{4 \times 50 \times 10^{-9}\ \text{m}}{\pi \times (100 \times 10^{-9}\ \text{m})^2} \times \frac{1}{\sqrt{0.0263\ \text{W/m}\cdot\text{K} \times (1.38 - 0.0263)\ \text{W/m}\cdot\text{K}}}$$

$$\times \tan^{-1}\sqrt{\frac{(1.38 - 0.0263)\ \text{W/m}\cdot\text{K}}{0.0263\ \text{W/m}\cdot\text{K}}} = 48.3 \times 10^6\ \text{K/W}$$ <

(b) The thermal circuit is



Hence,

$$\frac{(T_{surf} - T_{sen})}{R_{sen}} = \frac{(T_{sen} - T_\infty)}{R_T}$$

$$T_{surf} = (T_{sen} - T_\infty)\frac{R_{sen}}{R_T} + T_{sen} = (28.5 - 25)°\text{C} \times \frac{48.3 \times 10^6\ \text{K/W}}{5 \times 10^6\ \text{K/W}} + 28.5°\text{C}$$

$$T_{surf} = 62.3°\text{C}$$ <

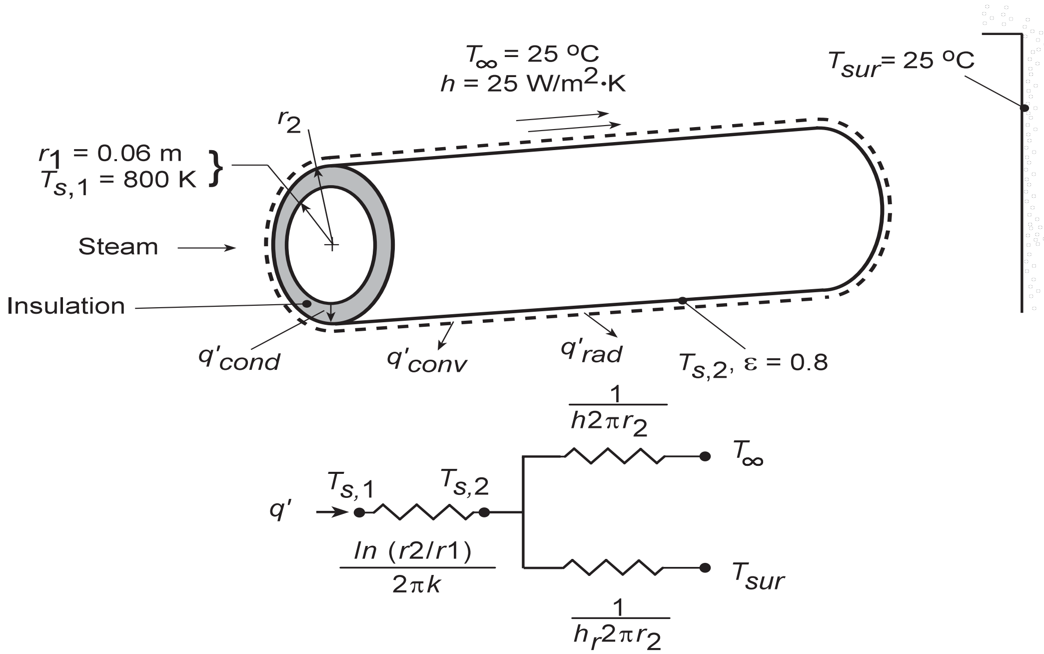
COMMENT: Heat transfer within the probe region will not be one-dimensional and modification of heat transfer due to nanoscale effects may be important. However, the probe may be calibrated by measuring the surface temperature of a large isothermal object.

PROBLEM 3.45

KNOWN: Thickness and inner surface temperature of calcium silicate insulation on a steam pipe. Convection and radiation conditions at outer surface.

FIND: (a) Heat loss per unit pipe length for prescribed insulation thickness and outer surface temperature. (b) Heat loss and radial temperature distribution as a function of insulation thickness.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties.

PROPERTIES: *Table A-3*, Calcium Silicate (T = 645 K): k = 0.089 W/m·K.

ANALYSIS: (a) From Eq. 3.32 with $T_{s,2}$ = 490 K, the heat rate per unit length is

$$q' = q_r/L = \frac{2\pi k\left(T_{s,1} - T_{s,2}\right)}{\ln\left(r_2/r_1\right)}$$

$$q' = \frac{2\pi\left(0.089\,\text{W/m}\cdot\text{K}\right)\left(800-490\right)\text{K}}{\ln\left(0.08\,\text{m}/0.06\,\text{m}\right)}$$

$$q' = 603\,\text{W/m}\,.$$ <

(b) Performing an energy for a control surface around the outer surface of the insulation, it follows that

$$q'_{cond} = q'_{conv} + q'_{rad}$$

$$\frac{T_{s,1} - T_{s,2}}{\ln\left(r_2/r_1\right)/2\pi k} = \frac{T_{s,2} - T_\infty}{1/\left(2\pi r_2 h\right)} + \frac{T_{s,2} - T_{sur}}{1/\left(2\pi r_2 h_r\right)}$$

where $h_r = \varepsilon\sigma\left(T_{s,2} + T_{sur}\right)\left(T_{s,2}^2 + T_{sur}^2\right)$. Solving this equation for $T_{s,2}$, the heat rate may be determined from

$$q' = 2\pi r_2\left[h\left(T_{s,2} - T_\infty\right) + h_r\left(T_{s,2} - T_{sur}\right)\right]$$

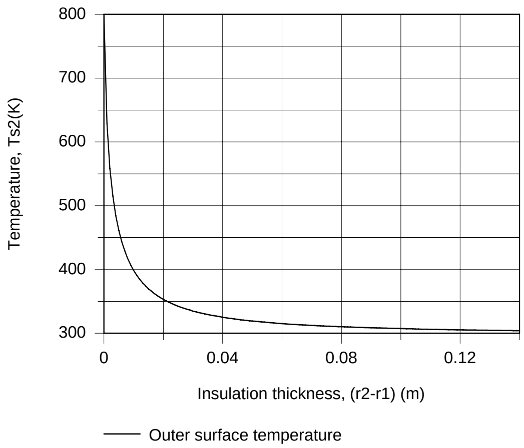
Continued...

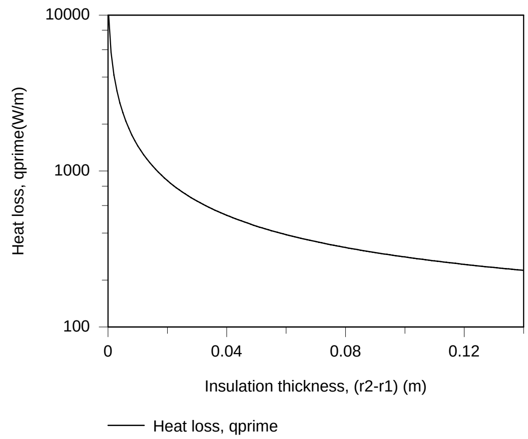
PROBLEM 3.45 (Cont.)

and from Eq. 3.31 the temperature distribution is

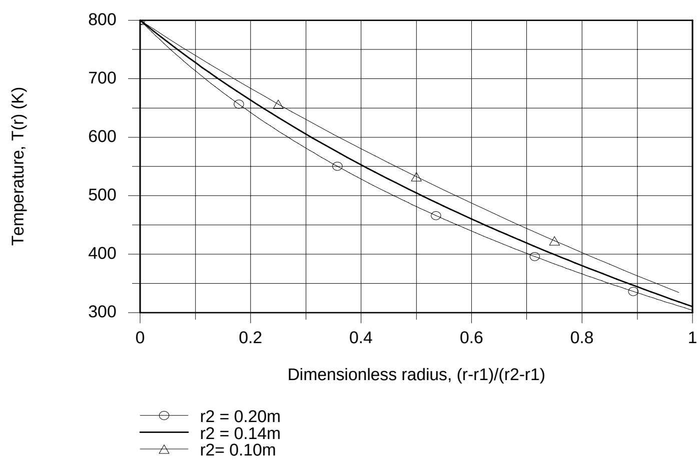
$$T(r) = \frac{T_{s,1} - T_{s,2}}{\ln(r_1/r_2)} \ln\left(\frac{r}{r_2}\right) + T_{s,2}$$

As shown below, the outer surface temperature of the insulation $T_{s,2}$ and the heat loss q' decay precipitously with increasing insulation thickness from values of $T_{s,2} = T_{s,1} = 800$ K and $q' = 11,600$ W/m, respectively, at $r_2 = r_1$ (no insulation).





When plotted as a function of a dimensionless radius, $(r - r_1)/(r_2 - r_1)$, the temperature decay becomes more pronounced with increasing r_2.



Note that $T(r_2) = T_{s,2}$ increases with decreasing r_2 and a linear temperature distribution is approached as r_2 approaches r_1.

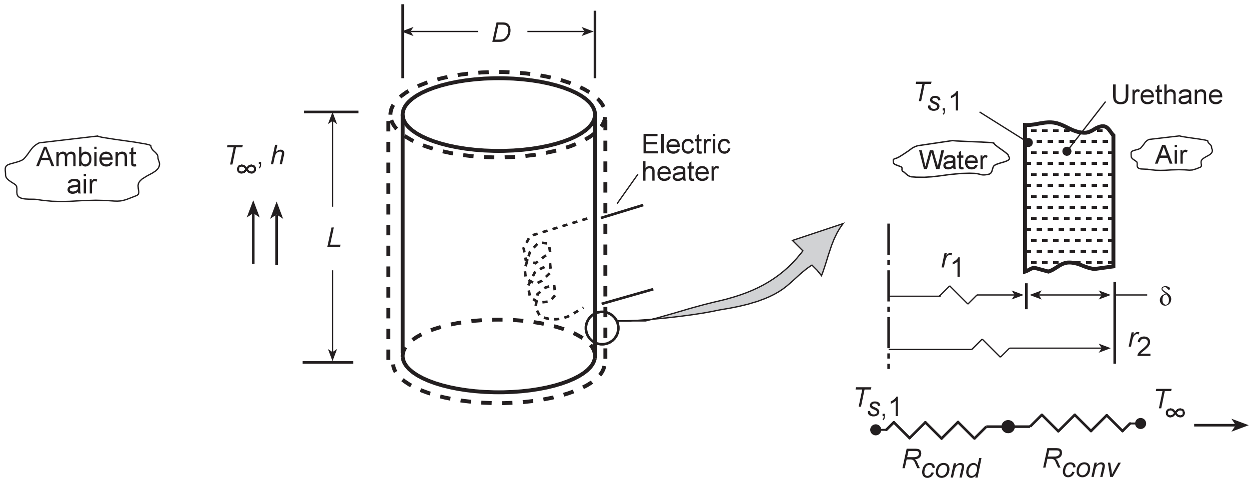
COMMENTS: An insulation layer thickness of 20 mm is sufficient to maintain the outer surface temperature and heat rate below 350 K and 1000 W/m, respectively.

PROBLEM 3.46

KNOWN: Temperature and volume of hot water heater. Nature of heater insulating material. Ambient air temperature and convection coefficient. Unit cost of electric power.

FIND: Heater dimensions and insulation thickness for which annual cost of heat loss is less than \$50.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, steady-state conduction through side and end walls, (2) Conduction resistance dominated by insulation, (3) Inner surface temperature is approximately that of the water ($T_{s,1}$ = 55°C), (4) Constant properties, (5) Negligible radiation due to low emissivity foil covering on insulation.

PROPERTIES: *Table A.3*, Urethane Foam (T = 300 K): k = 0.026 W/m·K.

ANALYSIS: To minimize heat loss, tank dimensions which minimize the total surface area, $A_{s,t}$, should be selected. With $L = 4\forall/\pi D^2$, $A_{s,t} = \pi DL + 2\left(\pi D^2/4\right) = 4\forall/D + \pi D^2/2$, and the tank diameter for which $A_{s,t}$ is an extremum is determined from the requirement

$$dA_{s,t}/dD = -4\forall/D^2 + \pi D = 0$$

It follows that

$$D = \left(4\forall/\pi\right)^{1/3} \qquad \text{and} \qquad L = \left(4\forall/\pi\right)^{1/3}$$

With $d^2A_{s,t}/dD^2 = 8\forall/D^3 + \pi > 0$, the foregoing conditions yield the desired minimum in $A_{s,t}$. Hence, for $\forall$ = 100 gal × 0.00379 m³/gal = 0.379 m³,

$$D_{op} = L_{op} = 0.784\,\text{m}$$ <

For an annual cost of heat loss of \$50 and a unit electric power cost of \$0.18/kWh

$$Q_{annual} = \$50.00/\$0.18/\text{kWh} = 278\ \text{kWh}$$

The energy loss rate is therefore

$$q = Q_{annual}/(\text{hours per year}) = 278\times10^3\,\text{W}\cdot\text{h}/[(365\,\text{days})(24\ \text{h/day})] = 31.7\,\text{W}$$

Continued...

PROBLEM 3.46 (Cont.)

The total heat loss through the side and end walls is

$$q = \frac{T_{s,1} - T_\infty}{\dfrac{\ln(r_2/r_1)}{2\pi k L_{op}} + \dfrac{1}{h 2\pi r_2 L_{op}}} + \frac{2\left(T_{s,1} - T_\infty\right)}{\dfrac{\delta}{k\left(\pi D_{op}^2/4\right)} + \dfrac{1}{h\left(\pi D_{op}^2/4\right)}}$$

With $r_1 = D_{op}/2 = 0.392$ m and $r_2 = r_1 + \delta$, everything is known except for the insulation thickness, δ.

$$q = 31.7\ \text{W} = \frac{(55-20)^\circ \text{C}}{\dfrac{\ln((0.392+\delta)/0.392)}{2\pi(0.026\ \text{W/m}\cdot\text{K})0.784\ \text{m}} + \dfrac{1}{\left(2\ \text{W/m}^2\cdot\text{K}\right)2\pi(0.392\ \text{m}+\delta)0.784\ \text{m}}}$$

$$+ \frac{2(55-20)^\circ \text{C}}{\dfrac{\delta}{(0.026\ \text{W/m}\cdot\text{K})\pi(0.784\ \text{m})^2/4} + \dfrac{1}{\left(2\ \text{W/m}^2\cdot\text{K}\right)\pi(0.784\ \text{m})^2/4}}$$

Solving by trial and error yields an insulation thickness of

$\delta = 68$ mm <

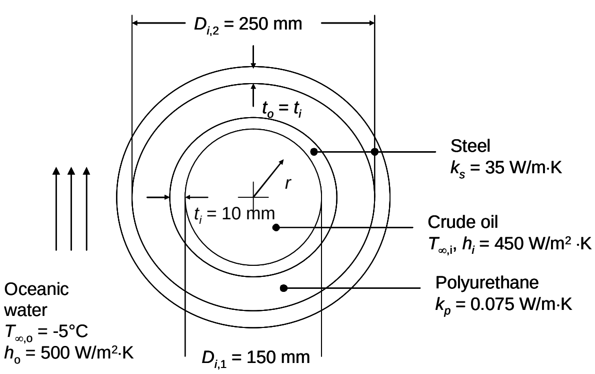
COMMENTS: Cylindrical containers of aspect ratio L/D = 1 are seldom used because of floor space constraints. Choosing L/D = 2, $\forall = \pi D^3/2$ and $D = (2\forall/\pi)^{1/3} = 0.623$ m. Hence, L = 1.245 m, r_1 = 0.312m and r_2 = 0.337 m. It follows that q = 34 W and C = \$53.62. The 7% increase in the annual cost of the heat loss is small, providing little justification for using the optimal heater dimensions.

PROBLEM 3.47

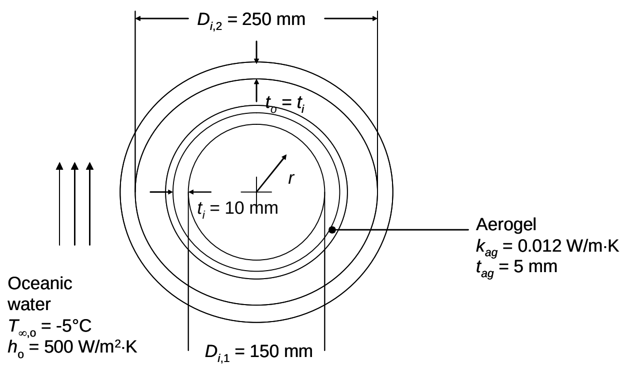
KNOWN: Dimensions of components of a pipe-in-pipe device. Thermal conductivity of materials, inner and outer heat transfer coefficients, outer fluid temperature.

FIND: (a) Maximum crude oil temperature to not exceed allowable service temperature of polyurethane. (b) Maximum crude oil temperature to not exceed allowable service temperature of polyurethane after insertion of aerogel layer.

SCHEMATIC:



Without Aerogel

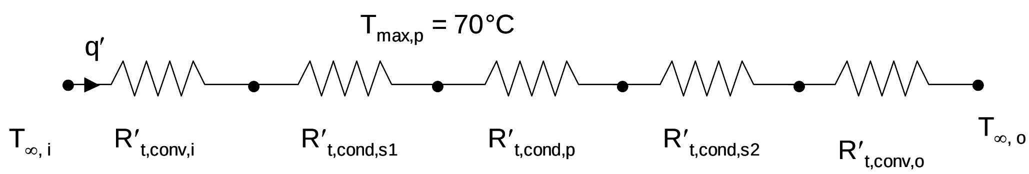


With Aerogel

ASSUMPTIONS: (1) Steady-state, one-dimensional conditions, (2) Negligible contact resistances, (3) Constant properties.

PROPERTIES: *Given*, Steel: k = 35 W/m·K; polyurethane: k = 0.075 W/m·K; aerogel: k = 0.012 W/m·K.

ANALYSIS: (a) The thermal resistance network for the case without the aerogel is shown below. The maximum polyurethane temperature occus at its inner surface.



Equating the heat rate per unit length of tubing from the crude oil to the inner surface of the polyurethane with the heat rate from the inner surface of the polyurethane to the oceanic waters yields

$$q' = \frac{T_{\infty,i} - T_{\max,p}}{R'_{t,\text{conv},i} + R'_{t,\text{cond},s1}} = \frac{T_{\max,p} - T_{\infty,o}}{R'_{t,\text{cond},p} + R'_{t,\text{cond},s2} + R'_{t,\text{conv},o}}$$

which may be rearranged to give

$$T_{\infty,i} = \frac{(T_{\max,p} - T_{\infty,o})(R'_{t,\text{conv},i} + R'_{t,\text{cond},s1})}{(R'_{t,\text{cond},p} + R'_{t,\text{cond},s2} + R'_{t,\text{conv},o})} + T_{\max,p} \qquad (1)$$

Continued…

PROBLEM 3.47 (Cont.)

The various thermal resistances are evaluated as follows.

$$R'_{t,\text{conv},i} = \frac{1}{450\text{W}/\text{m}^2\cdot\text{K}\times\pi\times 0.150\text{m}} = 4.716\times10^{-3}\,\frac{\text{m}\cdot\text{K}}{\text{W}} \;\;;\;\; R'_{t,\text{cond},s1} = \frac{\ln\left[(150+20)/150\right]}{2\times\pi\times 35\text{W/m}\cdot\text{K}} = 569.2\times10^{-6}\,\frac{\text{m}\cdot\text{K}}{\text{W}}$$

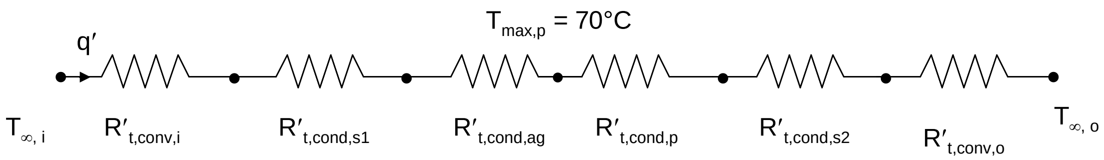
$$R'_{t,\text{cond},p} = \frac{\ln\left[250/(150+20)\right]}{2\times\pi\times 0.075\text{W/m}\cdot\text{K}} = 818.4\times10^{-3}\,\frac{\text{m}\cdot\text{K}}{\text{W}} \;\;;\;\; R'_{t,\text{cond},s2} = \frac{\ln\left[(250+20)/250\right]}{2\times\pi\times 35\text{W/m}\cdot\text{K}} = 350.0\times10^{-6}\,\frac{\text{m}\cdot\text{K}}{\text{W}}$$

$$R'_{t,\text{conv},o} = \frac{1}{500\text{W/m}^2\cdot\text{K}\times\pi\times 0.270\text{m}} = 2.358\times10^{-3}\,\frac{\text{m}\cdot\text{K}}{\text{W}}$$

Substituting into Equation (1) yields

$$T_{\infty,i} = \frac{\left[70°\text{C}-(-5°\text{C})\right](4.716\times10^{-3}\,\frac{\text{m}\cdot\text{K}}{\text{W}}+569.2\times10^{-6}\,\frac{\text{m}\cdot\text{K}}{\text{W}})}{(818.4\times10^{-3}\,\frac{\text{m}\cdot\text{K}}{\text{W}}+350\times10^{-6}\,\frac{\text{m}\cdot\text{K}}{\text{W}}+2.358\times10^{-3}\,\frac{\text{m}\cdot\text{K}}{\text{W}})} + 70°\text{C} = 70.5°\text{C} \qquad <$$

(b) The thermal resistance network for the case with the aerogel is shown below.



The thermal resistance values are as before, except the conduction resistance per unit length in the polyurethane is decreased, since its thickness is reduced relative to part (a). In addition, the conduction resistance for the aerogel must be evaluated. These two resistances are:

$$R'_{t,\text{conv},ag} = \frac{\ln\left[(150+20+10)/(150+20)\right]}{2\times\pi\times 0.012\text{W/m}\cdot\text{K}} = 758\times10^{-3}\,\frac{\text{m}\cdot\text{K}}{\text{W}} \;\;;\;\; R'_{t,\text{cond},p} = \frac{\ln\left[250/180\right]}{2\times\pi\times 0.075\text{W/m}\cdot\text{K}} = 697\times10^{-3}\,\frac{\text{m}\cdot\text{K}}{\text{W}}$$

Incorporating the aerogel resistance, Equation (1) becomes

$$T_{\infty,i} = \frac{(T_{\max,p}-T_{\infty,o})(R'_{t,\text{conv},i}+R'_{t,\text{cond},s1}+R'_{t,\text{cond},ag})}{(R'_{t,\text{cond},p}+R'_{t,\text{cond},s2}+R'_{t,\text{conv},o})} + T_{\max,p}$$

Substituting values yields

Continued…

PROBLEM 3.47 (Cont.)

$$T_{\infty,i} = \frac{\left[70°\text{C} - (-5°\text{C})\right](4.716\times10^{-3}\,\frac{\text{m}\cdot\text{K}}{\text{W}} + 569.2\times10^{-6}\,\frac{\text{m}\cdot\text{K}}{\text{W}} + 758\times10^{-3}\,\frac{\text{m}\cdot\text{K}}{\text{W}})}{(697\times10^{-3}\,\frac{\text{m}\cdot\text{K}}{\text{W}} + 350\times10^{-6}\,\frac{\text{m}\cdot\text{K}}{\text{W}} + 2.358\times10^{-3}\,\frac{\text{m}\cdot\text{K}}{\text{W}})} + 70°\text{C}$$

$= 151.8°\text{C}$ <

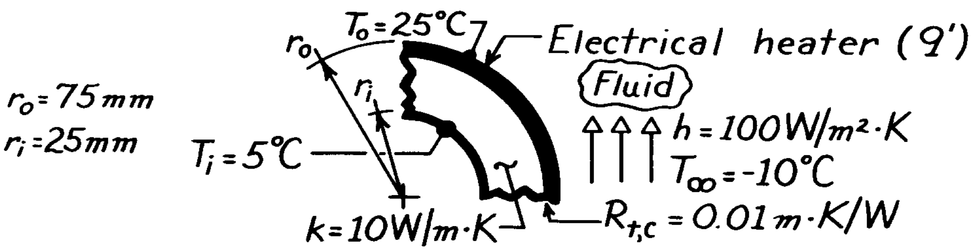
COMMENTS: Assuming the dynamic viscosity of crude oil is similar to that of engine oil, we may evaluate the viscosity of the oil at the two maximum operating temperatures. From Table A-5 at T = 70.5°C = 343 K, μ = 0.046 N·s/m^2. At T = 151.8°C = 425 K, μ = 0.517 N·s/m^2. The viscosity of the oil with the aerogel insulation is 0.046/0.517 = 0.09, or only 9% of the viscosity of the oil without the aerogel. Savings in pumping costs and/or increases in oil production rates could be realized with use of the aerogel pipe-in-pipe concept.

PROBLEM 3.48

KNOWN: Inner and outer radii of a tube wall which is heated electrically at its outer surface and is exposed to a fluid of prescribed h and T_∞. Thermal contact resistance between heater and tube wall and wall inner surface temperature.

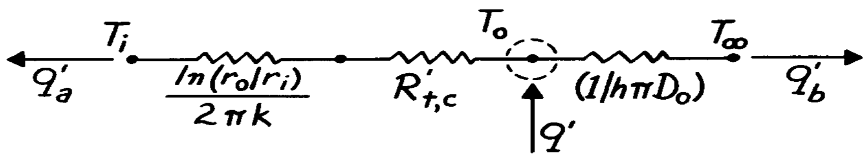
FIND: Heater power per unit length required to maintain a heater temperature of 25°C.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible temperature drop across heater.

ANALYSIS: The thermal circuit has the form



Applying an energy balance to a control surface about the heater,

$$q' = q'_a + q'_b$$

$$q' = \frac{T_o - T_i}{\dfrac{\ln(r_o/r_i)}{2\pi k} + R'_{t,c}} + \frac{T_o - T_\infty}{(1/h\pi D_o)}$$

$$q' = \frac{(25\text{-}5)^\circ C}{\dfrac{\ln(75\text{mm}/25\text{mm})}{2\pi \times 10\ \text{W/m}\cdot\text{K}} + 0.01\dfrac{\text{m}\cdot\text{K}}{\text{W}}} + \frac{[25-(-10)]^\circ C}{\left[1/\left(100\ \text{W/m}^2\cdot\text{K} \times \pi \times 0.15\text{m}\right)\right]}$$

$$q' = (728 + 1649)\ \text{W/m}$$

$$q' = 2377\ \text{W/m}.$$ <

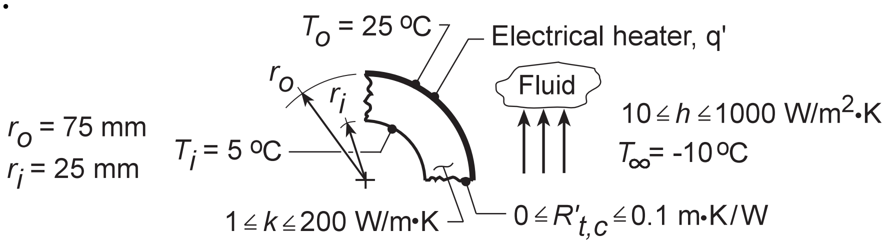
COMMENTS: The conduction, contact and convection resistances are 0.0175, 0.01 and 0.021 m ·K/W, respectively,

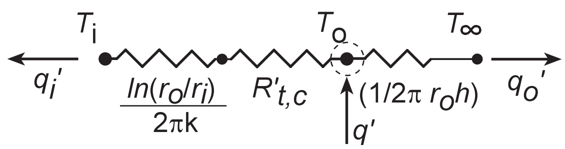
PROBLEM 3.49

KNOWN: Inner and outer radii of a tube wall which is heated electrically at its outer surface. Inner and outer wall temperatures. Temperature of fluid adjoining outer wall.

FIND: Effect of wall thermal conductivity, thermal contact resistance, and convection coefficient on total heater power and heat rates to outer fluid and inner surface.

SCHEMATIC:





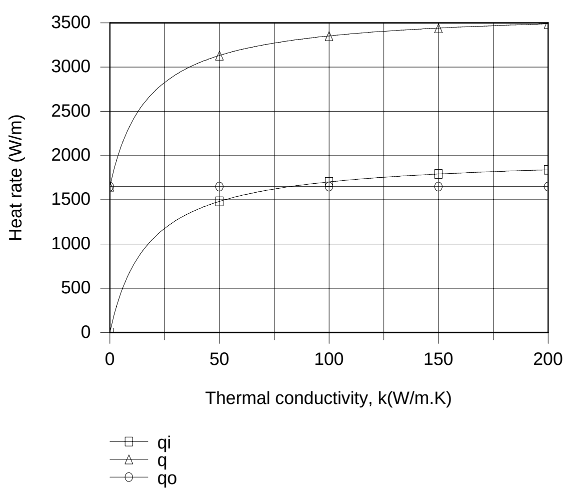
ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible temperature drop across heater, (5) Negligible radiation.

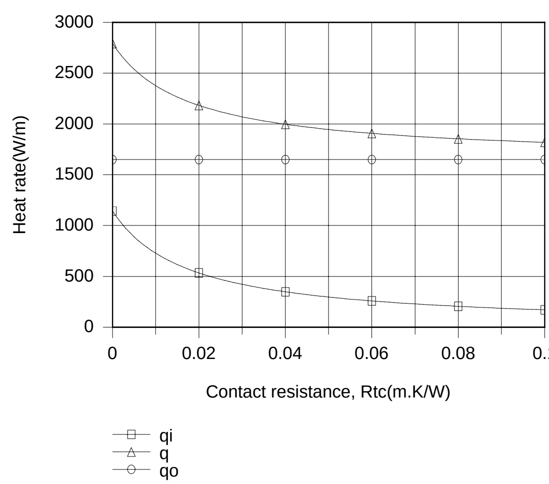
ANALYSIS: Applying an energy balance to a control surface about the heater,

$$q' = q_i' + q_o'$$

$$q' = \frac{T_o - T_i}{\frac{\ln(r_o/r_i)}{2\pi k} + R'_{t,c}} + \frac{T_o - T_\infty}{(1/2\pi r_o h)}$$

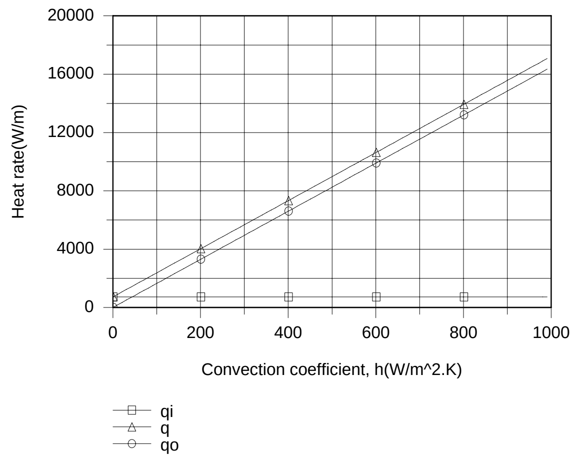
Selecting nominal values of k = 10 W/m·K, $R'_{t,c}$ = 0.01 m·K/W and h = 100 W/m^2·K, the following parametric variations are obtained





Continued...

PROBLEM 3.49 (Cont.)



For a prescribed value of h, q'_o is fixed, while q'_i, and hence q', increase and decrease, respectively, with increasing k and $R'_{t,c}$. These trends are attributable to the effects of k and $R'_{t,c}$ on the total (conduction plus contact) resistance separating the heater from the inner surface. For fixed k and $R'_{t,c}$, q'_i is fixed, while q'_o, and hence q', increase with increasing h due to a reduction in the convection resistance.

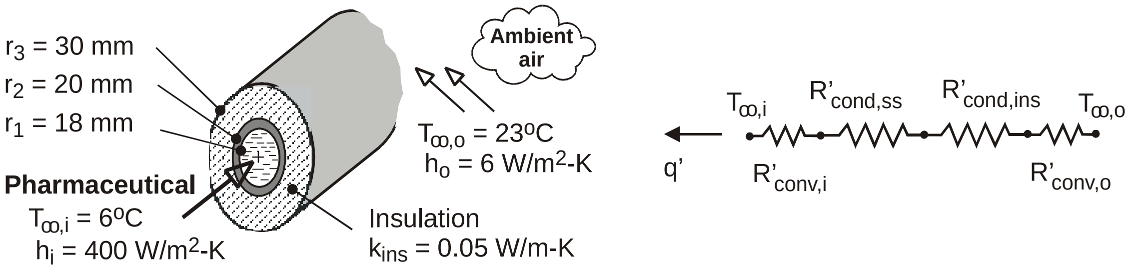
COMMENTS: For the prescribed nominal values of k, $R'_{t,c}$ and h, the electric power requirement is q' = 2377 W/m. To maintain the prescribed heater temperature, q' would increase with any changes which reduce the conduction, contact and/or convection resistances.

PROBLEM 3.50

KNOWN: Wall thickness and diameter of stainless steel tube. Inner and outer fluid temperatures and convection coefficients.

FIND: (a) Heat gain per unit length of tube, (b) Effect of adding a 10 mm thick layer of insulation to outer surface of tube.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial conduction, (3) Constant properties, (4) Negligible contact resistance between tube and insulation, (5) Negligible effect of radiation.

PROPERTIES: *Table A-1*, Ss 304 (~280K): k_{st} = 14.2 W/m·K.

ANALYSIS: (a) Without the insulation, the total thermal resistance per unit length is

$$R'_{tot} = R'_{conv,i} + R'_{cond,st} + R'_{conv,o} = \frac{1}{2\pi r_1 h_i} + \frac{\ln(r_2/r_i)}{2\pi k_{st}} + \frac{1}{2\pi r_2 h_o}$$

$$R'_{tot} = \frac{1}{2\pi(0.018\text{m})400\ \text{W/m}^2\cdot\text{K}} + \frac{\ln(20/18)}{2\pi(14.2\ \text{W/m}\cdot\text{K})} + \frac{1}{2\pi(0.020\text{m})6\ \text{W/m}^2\cdot\text{K}}$$

$$R'_{tot} = \left(0.0221 + 1.18\times10^{-3} + 1.33\right)\text{m}\cdot\text{K/W} = 1.35\ \text{m}\cdot\text{K/W}$$

The heat gain per unit length is then

$$q' = \frac{T_{\infty,o} - T_{\infty,i}}{R'_{tot}} = \frac{(23-6)°\text{C}}{1.35\,\text{m}\cdot\text{K/W}} = 12.6\ \text{W/m}$$ <

(b) With the insulation, the total resistance per unit length is now $R'_{tot} = R'_{conv,i} + R'_{cond,st} + R'_{cond,ins} + R'_{conv,o}$, where $R'_{conv,i}$ and $R'_{cond,st}$ remain the same. The thermal resistance of the insulation is

$$R'_{cond,ins} = \frac{\ln(r_3/r_2)}{2\pi k_{ins}} = \frac{\ln(30/20)}{2\pi(0.05\ \text{W/m}\cdot\text{K})} = 1.29\ \text{m}\cdot\text{K/W}$$

and the outer convection resistance is now

$$R'_{conv,o} = \frac{1}{2\pi r_3 h_o} = \frac{1}{2\pi(0.03\text{m})6\ \text{W/m}^2\cdot\text{K}} = 0.88\ \text{m}\cdot\text{K/W}$$

The total resistance is now

$$R'_{tot} = \left(0.0221 + 1.18\times10^{-3} + 1.29 + 0.88\right)\text{m}\cdot\text{K/W} = 2.20\,\text{m}\cdot\text{K/W}$$

Continued …

and the heat gain per unit length is

$$q' = \frac{T_{\infty,o} - T_{\infty,i}}{R'_{tot}} = \frac{17°C}{2.20\ m \cdot K/W} = 7.7\ W/m$$

COMMENTS: (1) The validity of assuming negligible radiation may be assessed for the worst case condition corresponding to the bare tube. Assuming a tube outer surface temperature of $T_s = T_{\infty,i}$ = 279K, large surroundings at $T_{sur} = T_{\infty,o}$ = 296K, and an emissivity of ε = 0.7 (Table A-11), the heat gain due to net radiation exchange with the surroundings is $q'_{rad} = \varepsilon\sigma\left(2\pi r_2\right)\left(T_{sur}^4 - T_s^4\right) = 8.1\ W/m.$ Hence, the net rate of heat transfer by radiation to the tube surface is comparable to that by convection, and the assumption of negligible radiation is inappropriate.

(2) If heat transfer from the air is by natural convection, the value of h_o with the insulation would actually be less than the value for the bare tube, thereby further reducing the heat gain. Use of the insulation would also increase the outer surface temperature, thereby reducing net radiation transfer from the surroundings.

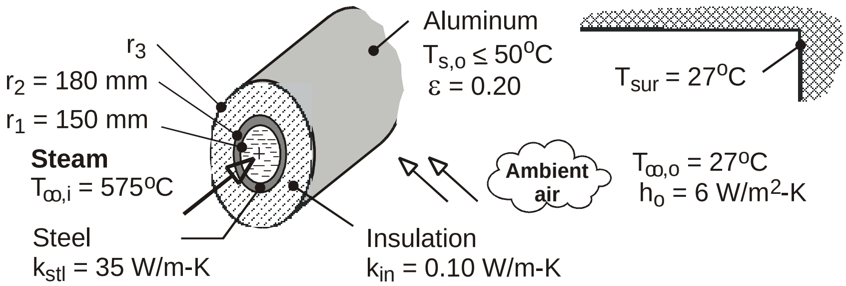
(3) The critical radius is $r_{cr} = k_{ins}/h \approx 8$ mm < r_2. Hence, as indicated by the calculations, heat transfer is reduced by the insulation.

PROBLEM 3.51

KNOWN: Diameter, wall thickness and thermal conductivity of steel tubes. Temperature of steam flowing through the tubes. Thermal conductivity of insulation and emissivity of aluminum sheath. Temperature of ambient air and surroundings. Convection coefficient at outer surface and maximum allowable surface temperature.

FIND: (a) Minimum required insulation thickness ($r_3 - r_2$) and corresponding heat loss per unit length, (b) Effect of insulation thickness on outer surface temperature and heat loss.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) One-dimensional radial conduction, (3) Negligible contact resistances at the material interfaces, (4) Negligible steam side convection resistance ($T_{\infty,i} = T_{s,i}$), (5) Negligible conduction resistance for aluminum sheath, (6) Constant properties, (7) Large surroundings.

ANALYSIS: (a) To determine the insulation thickness, an energy balance must be performed at the outer surface, where $q' = q'_{conv,o} + q'_{rad}$. With $q'_{conv,o} = 2\pi r_3 h_o \left(T_{s,o} - T_{\infty,o}\right)$, $q'_{rad} = 2\pi r_3 \ \varepsilon\sigma \left(T_{s,o}^4 - T_{sur}^4\right)$, $q' = \left(T_{s,i} - T_{s,o}\right)/\left(R'_{cond,st} + R'_{cond,ins}\right)$, $R'_{cond,st} = \ell n\left(r_2/r_1\right)/2\pi k_{st}$, and $R'_{cond,ins} = \ell n\left(r_3/r_2\right)/2\pi k_{ins}$, it follows that

$$\frac{2\pi\left(T_{s,i} - T_{s,o}\right)}{\dfrac{\ell n\left(r_2/r_1\right)}{k_{st}} + \dfrac{\ell n\left(r_3/r_2\right)}{k_{ins}}} = 2\pi r_3\left[h_o\left(T_{s,o} - T_{\infty,o}\right) + \varepsilon\sigma\left(T_{s,o}^4 - T_{sur}^4\right)\right]$$

$$\frac{2\pi\left(848 - 323\right)\text{K}}{\dfrac{\ell n\left(0.18/0.15\right)}{35\text{ W/m}\cdot\text{K}} + \dfrac{\ell n\left(r_3/0.18\right)}{0.10\text{ W/m}\cdot\text{K}}} = 2\pi r_3\left[6\text{ W/m}^2\cdot\text{K}\left(323 - 300\right)\text{K} + 0.20 \times 5.67 \times 10^{-8}\text{ W/m}^2\cdot\text{K}^4\left(323^4 - 300^4\right)\text{K}^4\right]$$

A trial-and-error solution yields $r_3 = 0.394$ m = 394 mm, in which case the insulation thickness is

$$t_{ins} = r_3 - r_2 = 214\,\text{mm}$$ <

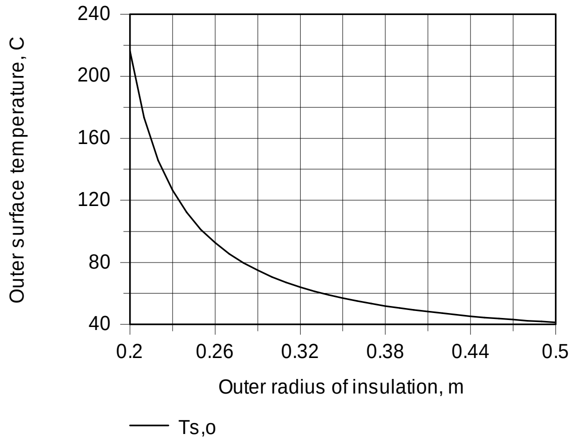
The heat rate is then

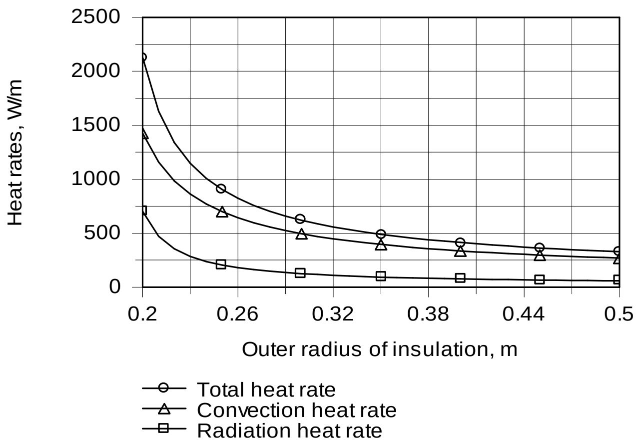
$$q' = \frac{2\pi\left(848 - 323\right)\text{K}}{\dfrac{\ell n\left(0.18/0.15\right)}{35\,\text{W/m}\cdot\text{K}} + \dfrac{\ell n\left(0.394/0.18\right)}{0.10\,\text{W/m}\cdot\text{K}}} = 420\,\text{W/m}$$ <

(b) The effects of r_3 on $T_{s,o}$ and q' have been computed and are shown below.

Continued …

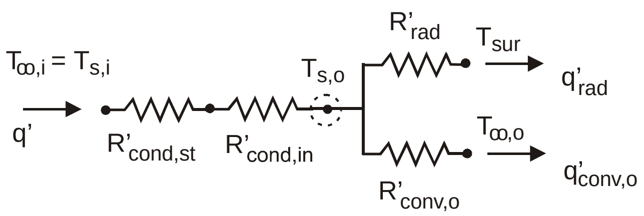
PROBLEM 3.51 (Cont.)





Beyond $r_3 \approx 0.40$ m, there are rapidly diminishing benefits associated with increasing the insulation thickness.

COMMENTS: Note that the thermal resistance of the insulation is much larger than that for the tube wall. For the conditions of Part (a), the radiation coefficient is $h_r = 1.37$ W/m, and the heat loss by radiation is less than 25% of that due to natural convection $\left(q'_{rad} = 78\,W/m,\ q'_{conv,o} = 342\ W/m\right)$.

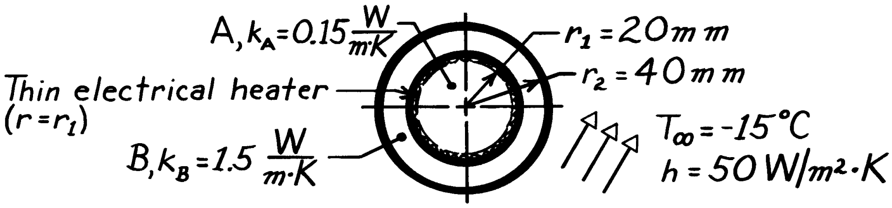


PROBLEM 3.52

KNOWN: Thin electrical heater fitted between two concentric cylinders, the outer surface of which experiences convection.

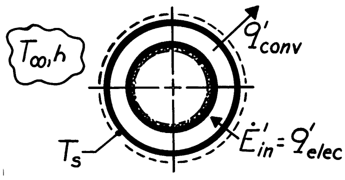
FIND: (a) Electrical power required to maintain outer surface at a specified temperature, (b) Temperature at the center.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, radial conduction, (2) Steady-state conditions, (3) Heater element has negligible thickness, (4) Negligible contact resistance between cylinders and heater, (5) Constant properties, (6) No generation.

ANALYSIS: (a) Perform an energy balance on the composite system to determine the power required to maintain $T(r_2) = T_s = 5°C$.



$$\dot{E}'_{in} - \dot{E}'_{out} + \dot{E}_{gen} = \dot{E}_{st}$$

$$+q'_{elec} - q'_{conv} = 0.$$

Using Newton's law of cooling,

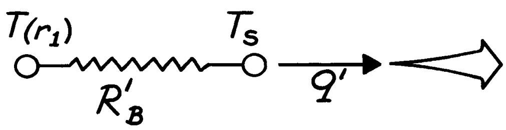
$$q'_{elec} = q'_{conv} = h \cdot 2\pi\ r_2 \left(T_s - T_\infty\right)$$

$$q'_{elec} = 50 \frac{W}{m^2 \cdot K} \times 2\pi \left(0.040 m\right) \left[5 - (-15)\right]^\circ C = 251\ W/m.$$ <

(b) From a control volume about Cylinder A, we recognize that the cylinder must be isothermal, that is,

$$T(0) = T(r_1).$$

Represent Cylinder B by a thermal circuit:



$$q' = \frac{T(r_1) - T_s}{R'_B}$$

For the cylinder, from Eq. 3.28,

$$R'_B = \ln r_2 / r_1 / 2\pi\ k_B$$

giving

$$T(r_1) = T_s + q'R'_B = 5^\circ C + 251 \frac{W}{m} \frac{\ln 40/20}{2\pi \times 1.5\ W/m \cdot K} = 23.5^\circ C$$

Hence, $T(0) = T(r_1) = 23.5°C$. <

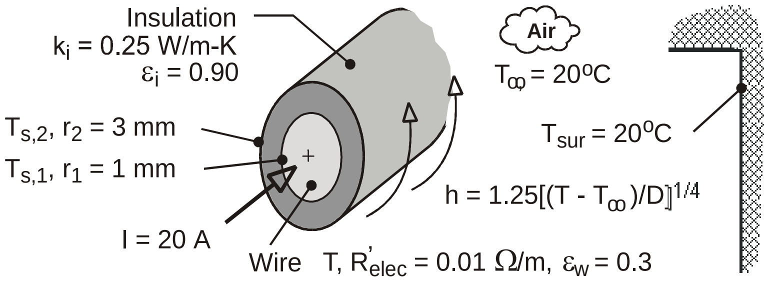
Note that k_A has no influence on the temperature T(0).

PROBLEM 3.53

KNOWN: Electric current and resistance of wire. Wire diameter and emissivity. Thickness, emissivity and thermal conductivity of coating. Temperature of ambient air and surroundings. Expression for heat transfer coefficient at surface of the wire or coating.

FIND: (a) Heat generation per unit length and volume of wire, (b) Temperature of uninsulated wire, (c) Inner and outer surface temperatures of insulation, including the effect of insulation thickness.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) One-dimensional radial conduction through insulation, (3) Constant properties, (4) Negligible contact resistance between insulation and wire, (5) Negligible radial temperature gradients in wire, (6) Large surroundings.

ANALYSIS: (a) The rates of energy generation per unit length and volume are, respectively,

$$\dot{E}'_g = I^2 R'_{elec} = (20\,A)^2 (0.01\Omega/m) = 4\ W/m \qquad <$$

$$\dot{q} = \dot{E}'_g / A_c = 4\dot{E}'_g / \pi D^2 = 16\,W/m/\pi(0.002m)^2 = 1.27\times10^6\ W/m^3 \qquad <$$

(b) Without the insulation, an energy balance at the surface of the wire yields

$$\dot{E}'_g = q' = q'_{conv} + q'_{rad} = \pi D h (T - T_\infty) + \pi D \varepsilon_w \sigma \left(T^4 - T_{sur}^4\right)$$

where $h = 1.25[(T - T_\infty)/D]^{1/4}$. Substituting,

$$4\,W/m = 1.25\pi(0.002m)^{3/4}(T-293)^{5/4} + \pi(0.002m)0.3\times5.67\times10^{-8}\,W/m^2\cdot K^4\left(T^4 - 293^4\right)K^4$$

and a trial-and-error solution yields

$$T = 331\,K = 58°C \qquad <$$

(c) Performing an energy balance at the outer surface,

$$\dot{E}'_g = q' = q'_{conv} + q'_{rad} = \pi D h \left(T_{s,2} - T_\infty\right) + \pi D \varepsilon_i \sigma \left(T_{s,2}^4 - T_{sur}^4\right)$$

$$4\,W/m = 1.25\pi(0.006m)^{3/4}\left(T_{s,2}-293\right)^{5/4} + \pi(0.006m)0.9\times5.67\times10^{-8}\,W/m^2\cdot K^4\left(T_{s,2}^4 - 293^4\right)K^4$$

and an iterative solution yields the following value of the surface temperature

$$T_{s,2} = 307.8\,K = 34.8°C \qquad <$$

The inner surface temperature may then be obtained from the following expression for heat transfer by conduction in the insulation.

Continued …

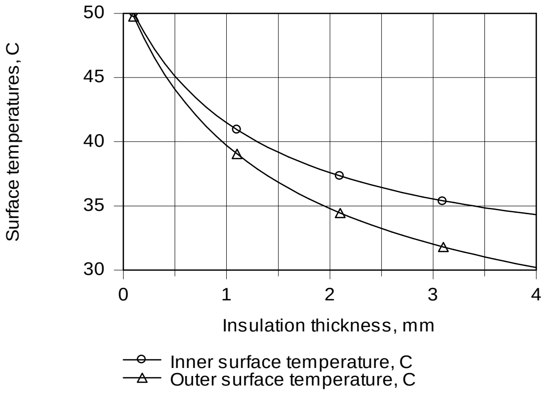
PROBLEM 3.53 (Cont.)

$$q' = \frac{T_{s,i} - T_{s,2}}{R'_{cond}} = \frac{T_{s,i} - T_{s,2}}{\ell n(r_2 / r_1) / 2\pi k_i}$$

$$4\,W = \frac{2\pi(0.25\,W/m \cdot K)(T_{s,i} - 307.8\,K)}{\ell n(3)}$$

$$T_{s,i} = 310.6\,K = 37.6°C$$ <

As shown below, the effect of increasing the insulation thickness is to *reduce*, not increase, the surface temperatures.



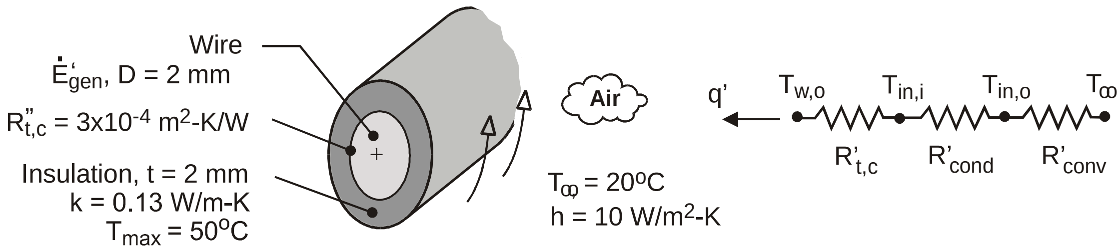
This behavior is due to a reduction in the total resistance to heat transfer with increasing r_2. Although the convection, h, and radiation, $h_r = \varepsilon\sigma(T_{s,2} + T_{sur})(T_{s,2}^2 + T_{sur}^2)$, coefficients decrease with increasing r_2, the corresponding increase in the surface area is more than sufficient to provide for a reduction in the total resistance. Even for an insulation thickness of t = 4 mm, $h = h + h_r = (7.1 + 5.4)$ $W/m^2 \cdot K = 12.5\ W/m^2 \cdot K$, and $r_{cr} = k/h = 0.25\ W/m \cdot K/12.5\ W/m^2 \cdot K = 0.020m = 20\ mm > r_2 = 5\ mm$. The outer radius of the insulation is therefore well below the critical radius.

PROBLEM 3.54

KNOWN: Diameter of electrical wire. Thickness and thermal conductivity of rubberized sheath. Contact resistance between sheath and wire. Convection coefficient and ambient air temperature. Maximum allowable sheath temperature.

FIND: Maximum allowable power dissipation per unit length of wire. Critical radius of insulation.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) One-dimensional radial conduction through insulation, (3) Constant properties, (4) Negligible radiation exchange with surroundings.

ANALYSIS: The maximum insulation temperature corresponds to its inner surface and is independent of the contact resistance. From the thermal circuit, we may write

$$\dot{E}'_g = q' = \frac{T_{in,i} - T_\infty}{R'_{cond} + R'_{conv}} = \frac{T_{in,i} - T_\infty}{\left[\ell n\left(r_{in,o}/r_{in,i}\right)/2\pi k\right] + \left(1/2\pi r_{in,o} h\right)}$$

where $r_{in,i} = D/2 = 0.001\text{m}$, $r_{in,o} = r_{in,i} + t = 0.003\text{m}$, and $T_{in,i} = T_{max} = 50°\text{C}$ yields the maximum allowable power dissipation. Hence,

$$\dot{E}'_{g,max} = \frac{(50-20)°\text{C}}{\dfrac{\ell n 3}{2\pi \times 0.13\,\text{W/m}\cdot\text{K}} + \dfrac{1}{2\pi\,(0.003\text{m})10\,\text{W/m}^2\cdot\text{K}}} = \frac{30°\text{C}}{(1.35+5.31)\,\text{m}\cdot\text{K/W}} = 4.51\,\text{W/m}$$ <

The critical insulation radius is also unaffected by the contact resistance and is given by

$$r_{cr} = \frac{k}{h} = \frac{0.13\,\text{W/m}\cdot\text{K}}{10\,\text{W/m}^2\cdot\text{K}} = 0.013\text{m} = 13\,\text{mm}$$ <

Hence, $r_{in,o} < r_{cr}$ and $\dot{E}'_{g,max}$ could be increased by increasing $r_{in,o}$ up to a value of 13 mm (t = 12 mm).

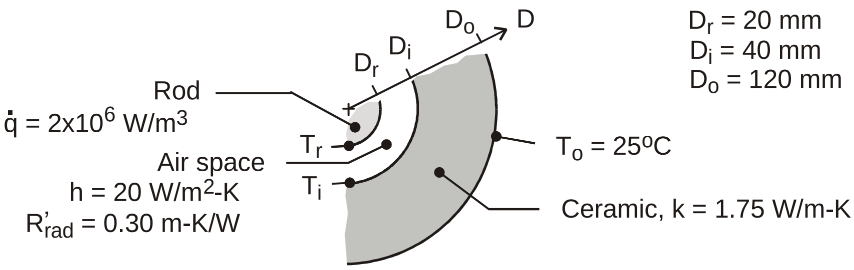
COMMENTS: The contact resistance affects the temperature of the wire, and for $q' = \dot{E}'_{g,max} = 4.51\,\text{W/m}$, the outer surface temperature of the wire is $T_{w,o} = T_{in,i} + q' R'_{t,c} = 50°\text{C} + (4.51\,\text{W/m})\left(3\times10^{-4}\,\text{m}^2\cdot\text{K/W}\right)/\pi\,(0.002\text{m}) = 50.2°\text{C}$. Hence, the temperature change across the contact resistance is negligible.

PROBLEM 3.55

KNOWN: Long rod experiencing uniform volumetric generation of thermal energy, $\dot{q}$, concentric with a hollow ceramic cylinder creating an enclosure filled with air. Thermal resistance per unit length due to radiation exchange between enclosure surfaces is R'_{rad}. The free convection coefficient for the enclosure surfaces is h = 20 W/m^2·K.

FIND: (a) Thermal circuit of the system that can be used to calculate the surface temperature of the rod, T_r; label all temperatures, heat rates and thermal resistances; evaluate the thermal resistances; and (b) Calculate the surface temperature of the rod.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional, radial conduction through the hollow cylinder, (3) The enclosure surfaces experience free convection and radiation exchange.

ANALYSIS: (a) The thermal circuit is shown below. Note labels for the temperatures, thermal resistances and the relevant heat fluxes.

Enclosure, radiation exchange (given):

$$R'_{rad} = 0.30\ \text{m}\cdot\text{K/W}$$

Enclosure, free convection:

$$R'_{cv,rod} = \frac{1}{h\pi D_r} = \frac{1}{20\ \text{W/m}^2\cdot\text{K}\times\pi\times0.020\text{m}} = 0.80\ \text{m}\cdot\text{K/W}$$

$$R'_{cv,cer} = \frac{1}{h\pi D_i} = \frac{1}{20\ \text{W/m}^2\cdot\text{K}\times\pi\times0.040\text{m}} = 0.40\ \text{m}\cdot\text{K/W}$$

Ceramic cylinder, conduction:

$$R'_{cd} = \frac{\ell n\left(D_o/D_i\right)}{2\pi k} = \frac{\ell n\left(0.120/0.040\right)}{2\pi\times1.75\ \text{W/m}\cdot\text{K}} = 0.10\ \text{m}\cdot\text{K/W}$$

The thermal resistance between the enclosure surfaces (r-i) due to convection and radiation exchange is

$$\frac{1}{R'_{enc}} = \frac{1}{R'_{rad}} + \frac{1}{R'_{cv,rod}+R'_{cv,cer}}$$

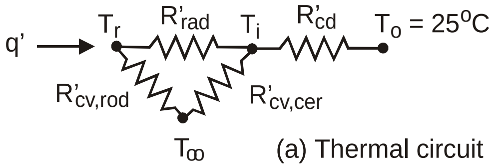
$$R'_{enc} = \left[\frac{1}{0.30}+\frac{1}{0.80+0.40}\right]^{-1}\text{m}\cdot\text{K/W} = 0.24\ \text{m}\cdot\text{K/W}$$

The total resistance between the rod surface (r) and the outer surface of the cylinder (o) is

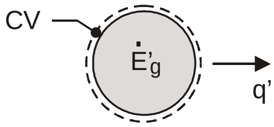
$$R'_{tot} = R'_{enc}+R'_{cd} = \left(0.24+0.1\right)\text{m}\cdot\text{K/W} = 0.34\ \text{m}\cdot\text{K/W}$$

Continued …

PROBLEM 3.55 (Cont.)



(a) Thermal circuit



(b) Overall energy balance on rod

(b) From an energy balance on the rod (see schematic) find T_r.

$$\dot{E}'_{in} - \dot{E}'_{out} + \dot{E}'_{gen} = 0$$

$$-q + \dot{q}\forall = 0$$

$$-\left(T_r - T_i\right)/R'_{tot} + \dot{q}\left(\pi D_r^2/4\right) = 0$$

$$-\left(T_r - 25\right)\text{K}/0.34\ \text{m}\cdot\text{K/W} + 2\times10^6\,\text{W/m}^3\left(\pi\times0.020\text{m}^2/4\right) = 0$$

$$T_r = 239°\text{C}$$ <

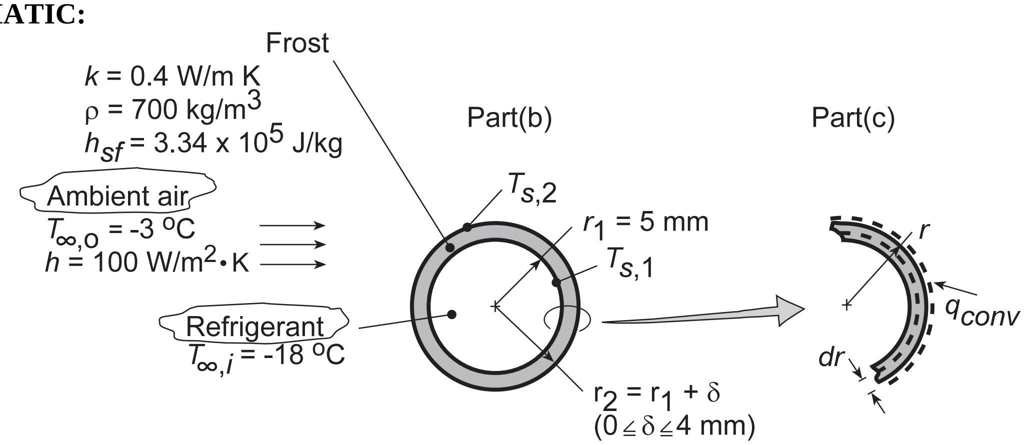
COMMENTS: In evaluating the convection resistance of the air space, it was necessary to define an average air temperature (T_∞) and consider the convection coefficients for each of the space surfaces. As you'll learn later in Chapter 9, correlations are available for directly estimating the convection coefficient (h_{enc}) for the enclosure so that $q_{cv} = h_{enc}\,(T_r - T_i)$.

PROBLEM 3.56

KNOWN: Tube diameter and refrigerant temperature for evaporator of a refrigerant system. Convection coefficient and temperature of outside air.

FIND: (a) Rate of heat extraction without frost formation, (b) Effect of frost formation on heat rate, (c) Time required for a 2 mm thick frost layer to melt in ambient air for which h = 2 $W/m^2 \cdot K$ and T_∞ = 20°C.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, steady-state conditions, (2) Negligible convection resistance for refrigerant flow $\left(T_{\infty,i} = T_{s,1}\right)$, (3) Negligible tube wall conduction resistance, (4) Negligible radiation exchange at outer surface.

ANALYSIS: (a) The cooling capacity in the defrosted condition (δ = 0) corresponds to the rate of heat extraction from the airflow. Hence,

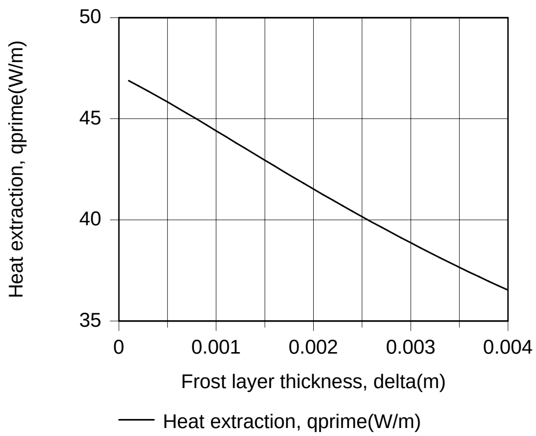
$$q' = h2\pi r_1\left(T_{\infty,o} - T_{s,1}\right) = 100\,W/m^2 \cdot K\left(2\pi \times 0.005\,m\right)\left(-3+18\right)^\circ C$$

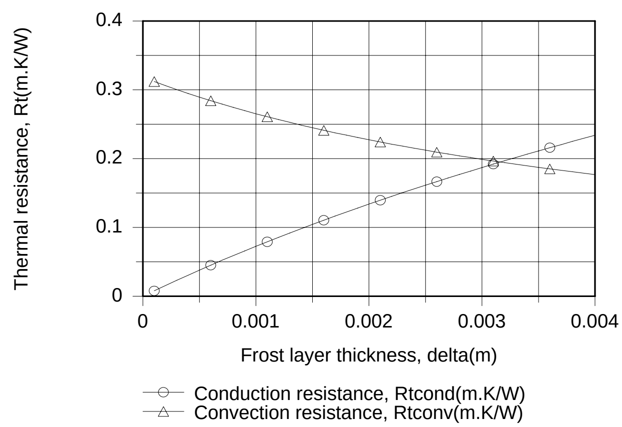
$$q' = 47.1\,W/m$$ <

(b) With the frost layer, there is an additional (conduction) resistance to heat transfer, and the extraction rate is

$$q' = \frac{T_{\infty,o} - T_{s,1}}{R'_{conv} + R'_{cond}} = \frac{T_{\infty,o} - T_{s,1}}{1/\left(h2\pi r_2\right) + \ln\left(r_2/r_1\right)/2\pi k}$$

For $5 \le r_2 \le 9$ mm and k = 0.4 W/m·K, this expression yields





Continued...

PROBLEM 3.56 (Cont.)

The heat extraction, and hence the performance of the evaporator coil, decreases with increasing frost layer thickness due to an increase in the total resistance to heat transfer. Although the convection resistance decreases with increasing δ, the reduction is exceeded by the increase in the conduction resistance.

(c) The time t_m required to melt a 2 mm thick frost layer may be determined by applying an energy balance, Eq. 1.12c, over the differential time interval dt and to a differential control volume extending inward from the surface of the layer.

$$\dot{E}_{in} dt = dE_{st} = dU_{lat}$$

$$h(2\pi rL)(T_{\infty,o} - T_f)dt = -h_{sf}\rho d\forall = -h_{sf}\rho(2\pi rL)dr$$

$$h(T_{\infty,o} - T_f)\int_0^{t_m} dt = -\rho h_{sf}\int_{r_2}^{r_1} dr$$

$$t_m = \frac{\rho h_{sf}(r_2 - r_1)}{h(T_{\infty,o} - T_f)} = \frac{700\,kg/m^3\left(3.34\times10^5\,J/kg\right)(0.002\,m)}{2\,W/m^2\cdot K(20-0)^\circ C}$$

$$t_m = 11,690\,s = 3.25\,h$$ <

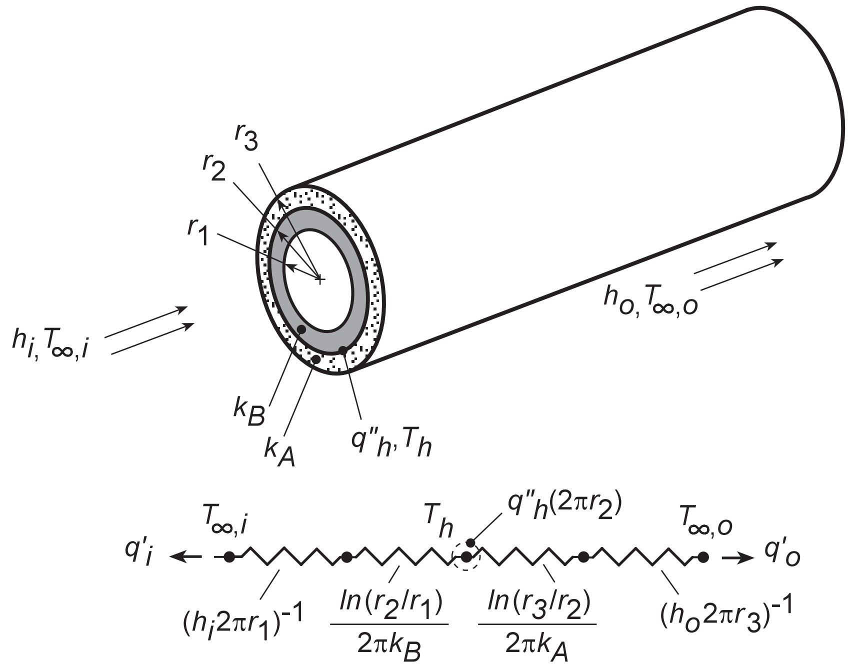
COMMENTS: The tube radius r_1 exceeds the critical radius $r_{cr} = k/h = 0.4\ W/m\cdot K/100\ W/m^2\cdot K = 0.004$ m, in which case any frost formation will reduce the performance of the coil.

PROBLEM 3.57

KNOWN: Conditions associated with a composite wall and a thin electric heater.

FIND: (a) Equivalent thermal circuit, (b) Expression for heater temperature, (c) Ratio of outer and inner heat flows and conditions for which ratio is minimized.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, steady-state conduction, (2) Constant properties, (3) Isothermal heater, (4) Negligible contact resistance(s).

ANALYSIS: (a) On the basis of a unit axial length, the circuit, thermal resistances, and heat rates are as shown in the schematic.

(b) Performing an energy balance for the heater, $\dot{E}_{in} = \dot{E}_{out}$, it follows that

$$q''_h(2\pi r_2) = q'_i + q'_o = \frac{T_h - T_{\infty,i}}{(h_i 2\pi r_1)^{-1} + \dfrac{\ln(r_2/r_1)}{2\pi k_B}} + \frac{T_h - T_{\infty,o}}{(h_o 2\pi r_3)^{-1} + \dfrac{\ln(r_3/r_2)}{2\pi k_A}} \quad <$$

(c) From the circuit,

$$\frac{q'_o}{q'_i} = \frac{(T_h - T_{\infty,o})}{(T_h - T_{\infty,i})} \times \frac{(h_i 2\pi r_1)^{-1} + \dfrac{\ln(r_2/r_1)}{2\pi k_B}}{(h_o 2\pi r_3)^{-1} + \dfrac{\ln(r_3/r_2)}{2\pi k_A}} \quad <$$

To reduce q'_o/q'_i, one could increase k_B, h_i, and r_3/r_2, while reducing k_A, h_o and r_2/r_1.

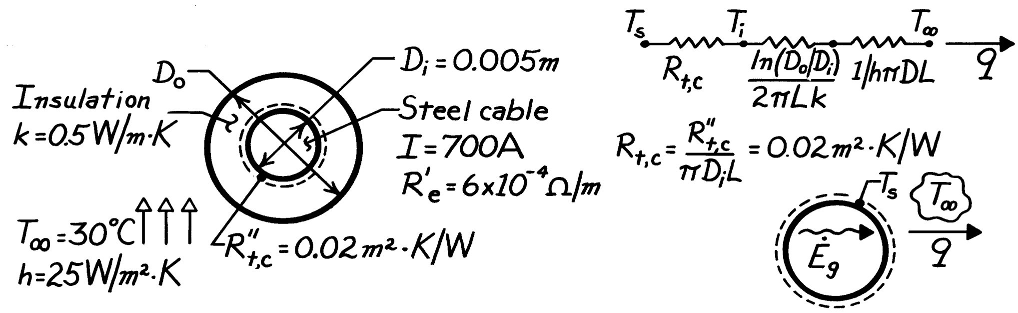
COMMENTS: Contact resistances between the heater and materials A and B could be important.

PROBLEM 3.58

KNOWN: Electric current flow, resistance, diameter and environmental conditions associated with a cable.

FIND: (a) Surface temperature of bare cable, (b) Cable surface and insulation temperatures for a thin coating of insulation, (c) Insulation thickness which provides the lowest value of the maximum insulation temperature. Corresponding value of this temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in r, (3) Constant properties.

ANALYSIS: (a) The rate at which heat is transferred to the surroundings is fixed by the rate of heat generation in the cable. Performing an energy balance for a control surface about the cable, it follows that $\dot{E}_g = q$ or, for the bare cable, $I^2 R'_e L = h(\pi D_i L)(T_s - T_\infty)$. With $q' = I^2 R'_e = (700\text{A})^2 \left(6\times10^{-4}\Omega/\text{m}\right) = 294$ W/m, it follows that

$$T_s = T_\infty + \frac{q'}{h\pi D_i} = 30^\circ\text{C} + \frac{294 \text{ W/m}}{\left(25 \text{ W/m}^2\cdot\text{K}\right)\pi(0.005\text{m})}$$

$$T_s = 778.7^\circ\text{C}.$$ <

(b) With a thin coating of insulation, there exist contact and convection resistances to heat transfer from the cable. The heat transfer rate is determined by heating within the cable, however, and therefore remains the same.

$$q = \frac{T_s - T_\infty}{R_{t,c} + \dfrac{1}{h\pi D_i L}} = \frac{T_s - T_\infty}{\dfrac{R''_{t,c}}{\pi D_i L} + \dfrac{1}{h\pi D_i L}}$$

$$q' = \frac{\pi D_i (T_s - T_\infty)}{R''_{t,c} + 1/h}$$

and solving for the surface temperature, find

$$T_s = \frac{q'}{\pi D_i}\left[R''_{t,c} + \frac{1}{h}\right] + T_\infty = \frac{294 \text{ W/m}}{\pi(0.005\text{m})}\left[0.02\frac{\text{m}^2\cdot\text{K}}{\text{W}} + 0.04\frac{\text{m}^2\cdot\text{K}}{\text{W}}\right] + 30^\circ\text{C}$$

$$T_s = 1153^\circ\text{C}.$$ <

Continued …

PROBLEM 3.58 (Cont.)

The insulation temperature is then obtained from

$$q = \frac{T_s - T_i}{R_{t,c}}$$

or

$$T_i = T_s - qR_{t,c} = 1153^\circ C - q\frac{R''_{t,c}}{\pi D_i L} = 1153^\circ C - \frac{294\frac{W}{m} \times 0.02\frac{m^2 \cdot K}{W}}{\pi (0.005m)}$$

$$T_i = 778.7^\circ C. \qquad <$$

(c) The maximum insulation temperature could be reduced by reducing the resistance to heat transfer from the outer surface of the insulation. Such a reduction is possible if $D_i < D_{cr}$. From Example 3.6,

$$r_{cr} = \frac{k}{h} = \frac{0.5 \text{ W/m} \cdot \text{K}}{25 \text{ W/m}^2 \cdot \text{K}} = 0.02\text{m}.$$

Hence, $D_{cr} = 0.04m > D_i = 0.005m$. To minimize the maximum temperature, which exists at the inner surface of the insulation, add insulation in the amount

$$t = \frac{D_o - D_i}{2} = \frac{D_{cr} - D_i}{2} = \frac{(0.04 - 0.005)m}{2}$$

$$t = 0.0175\text{m}. \qquad <$$

The cable surface temperature may then be obtained from

$$q' = \frac{T_s - T_\infty}{\frac{R''_{t,c}}{\pi D_i} + \frac{\ln(D_{cr}/D_i)}{2\pi k} + \frac{1}{h\pi D_{cr}}} = \frac{T_s - 30^\circ C}{\frac{0.02 \text{ m}^2 \cdot \text{K/W}}{\pi (0.005\text{m})} + \frac{\ln(0.04/0.005)}{2\pi (0.5 \text{ W/m} \cdot \text{K})} + \frac{1}{25\frac{W}{m^2 \cdot K}\pi (0.04\text{m})}}$$

Hence,

$$294\frac{W}{m} = \frac{T_s - 30^\circ C}{(1.27 + 0.66 + 0.32)\text{m} \cdot \text{K/W}} = \frac{T_s - 30^\circ C}{2.25 \text{ m} \cdot \text{K/W}}$$

$$T_s = 692.5^\circ C$$

Recognizing that $q = (T_s - T_i)/R_{t,c}$, find

$$T_i = T_s - qR_{t,c} = T_s - q\frac{R''_{t,c}}{\pi D_i L} = 692.5^\circ C - \frac{294\frac{W}{m} \times 0.02\frac{m^2 \cdot K}{W}}{\pi (0.005m)}$$

$$T_i = 318.2^\circ C. \qquad <$$

COMMENTS: Use of the critical insulation thickness in lieu of a thin coating has the effect of reducing the maximum insulation temperature from 778.7°C to 318.2°C. Use of the critical insulation thickness also reduces the cable surface temperature to 692.5°C from 778.7°C with no insulation or from 1153°C with a thin coating.

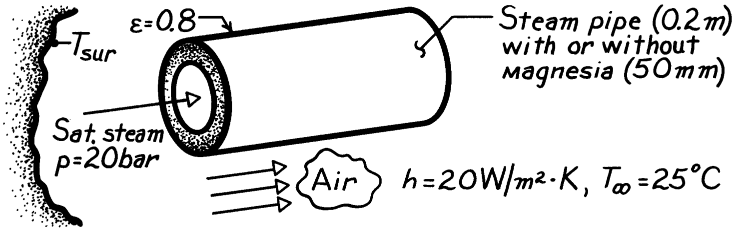
PROBLEM 3.59

KNOWN: Saturated steam conditions in a pipe with prescribed surroundings.

FIND: (a) Heat loss per unit length from bare pipe and from insulated pipe, (b) Pay back period for insulation.

SCHEMATIC:

Steam Costs:
 \$4 for 10^9 J
Insulation Cost:
 \$100 per meter
Operation time:
 7500 h/yr



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Constant properties, (4) Negligible pipe wall resistance, (5) Negligible steam side convection resistance (pipe inner surface temperature is equal to steam temperature), (6) Negligible contact resistance, (7) $T_{sur} = T_\infty$.

PROPERTIES: *Table A-6*, Saturated water (p = 20 bar): $T_{sat} = T_s = 486K$; *Table A-3*, Magnesia, 85% (T ≈ 392K): k = 0.058 W/m·K.

ANALYSIS: (a) Without the insulation, the heat loss may be expressed in terms of radiation and convection rates,

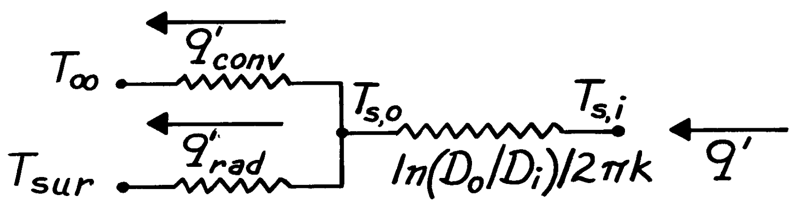
$$q' = \varepsilon\pi D\sigma\left(T_s^4 - T_{sur}^4\right) + h(\pi D)(T_s - T_\infty)$$

$$q' = 0.8\pi(0.2m)5.67\times10^{-8}\frac{W}{m^2\cdot K^4}\left(486^4 - 298^4\right)K^4$$

$$+20\frac{W}{m^2\cdot K}(\pi\times0.2m)\ (486\text{-}298)K$$

$$q' = (1365+2362)\,W/m = 3727\ W/m.$$ <

With the insulation, the thermal circuit is of the form



Continued …

PROBLEM 3.59 (Cont.)

From an energy balance at the outer surface of the insulation,

$$q'_{cond} = q'_{conv} + q'_{rad}$$

$$\frac{T_{s,i} - T_{s,o}}{\ln(D_o / D_i)/2\pi\ k} = h\pi\ D_o\left(T_{s,o} - T_\infty\right) + \varepsilon\sigma\pi\ D_o\left(T_{s,o}^4 - T_{sur}^4\right)$$

$$\frac{\left(486 - T_{s,o}\right)K}{\dfrac{\ln(0.3m/0.2m)}{2\pi(0.058\ W/m\cdot K)}} = 20\frac{W}{m^2\cdot K}\pi(0.3m)\left(T_{s,o} - 298K\right)$$

$$+0.8\times 5.67\times 10^{-8}\frac{W}{m^2\cdot K^4}\pi(0.3m)\left(T_{s,o}^4 - 298^4\right)K^4.$$

By trial and error, we obtain

$$T_{s,o} \approx 305K$$

in which case

$$q' = \frac{(486\text{-}305)K}{\dfrac{\ln(0.3m/0.2m)}{2\pi(0.055\ W/m\cdot K)}} = 163\ W/m.$$ <

(b) The yearly energy savings per unit length of pipe due to use of the insulation is

$$\frac{\text{Savings}}{\text{Yr}\cdot\text{m}} = \frac{\text{Energy Savings}}{\text{Yr.}}\times\frac{\text{Cost}}{\text{Energy}}$$

$$\frac{\text{Savings}}{\text{Yr}\cdot\text{m}} = (3727 - 163)\frac{J}{s\cdot m}\times 3600\frac{s}{h}\times 7500\frac{h}{Yr}\times\frac{\$4}{10^9\,J}$$

$$\frac{\text{Savings}}{\text{Yr}\cdot\text{m}} = \$385/\text{Yr}\cdot\text{m}.$$

The pay back period is then

$$\text{Pay Back Period} = \frac{\text{Insulation Costs}}{\text{Savings/Yr.}\cdot\text{m}} = \frac{\$100/m}{\$385/\text{Yr}\cdot m}$$

Pay Back Period = 0.26 Yr = 3.1 mo. <

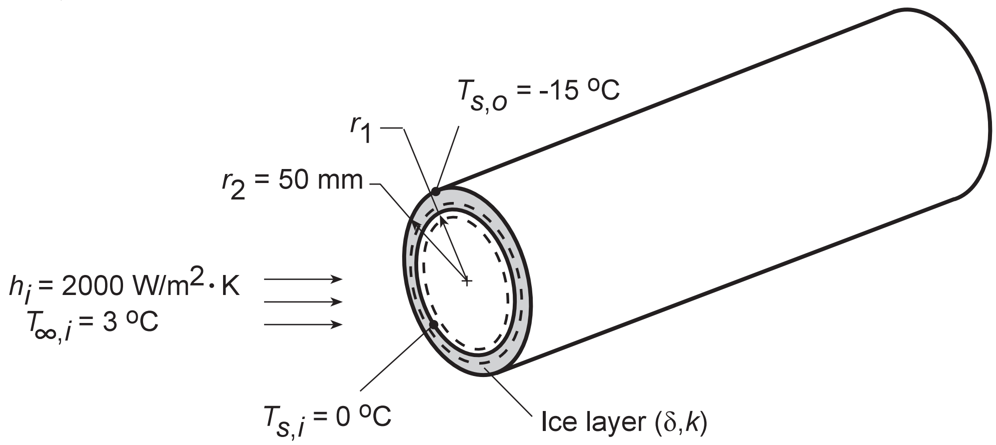
COMMENTS: Such a low pay back period is more than sufficient to justify investing in the insulation.

PROBLEM 3.60

KNOWN: Pipe wall temperature and convection conditions associated with water flow through the pipe and ice layer formation on the inner surface.

FIND: Ice layer thickness δ.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, steady-state conduction, (2) Negligible pipe wall thermal resistance, (3) negligible ice/wall contact resistance, (4) Constant k.

PROPERTIES: *Table A.3*, Ice (T = 265 K): k ≈ 1.94 W/m·K.

ANALYSIS: Performing an energy balance for a control surface about the ice/water interface, it follows that, for a unit length of pipe,

$$q'_{conv} = q'_{cond}$$

$$h_i\left(2\pi r_1\right)\left(T_{\infty,i} - T_{s,i}\right) = \frac{T_{s,i} - T_{s,o}}{\ln\left(r_2/r_1\right)/2\pi k}$$

Dividing both sides of the equation by r_2,

$$\frac{\ln\left(r_2/r_1\right)}{\left(r_2/r_1\right)} = \frac{k}{h_i r_2} \times \frac{T_{s,i} - T_{s,o}}{T_{\infty,i} - T_{s,i}} = \frac{1.94\,W/m\cdot K}{\left(2000\,W/m^2\cdot K\right)\left(0.05\,m\right)} \times \frac{15^\circ C}{3^\circ C} = 0.097$$

The equation is satisfied by $r_2/r_1 = 1.114$, in which case $r_1 = 0.050\ m/1.114 = 0.045\ m$, and the ice layer thickness is

$$\delta = r_2 - r_1 = 0.005\,m = 5\,mm$$ <

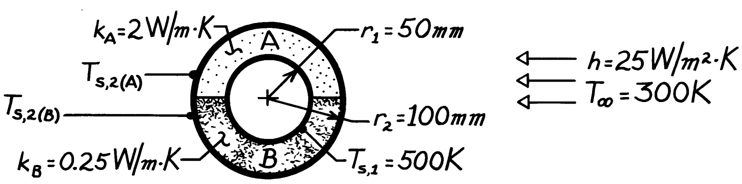
COMMENTS: With no flow, $h_i \to 0$, in which case $r_1 \to 0$ and complete blockage could occur. The pipe should be insulated.

PROBLEM 3.61

KNOWN: Inner surface temperature of insulation blanket comprised of two semi-cylindrical shells of different materials. Ambient air conditions.

FIND: (a) Equivalent thermal circuit, (b) Total heat loss and material outer surface temperatures.

SCHEMATIC:



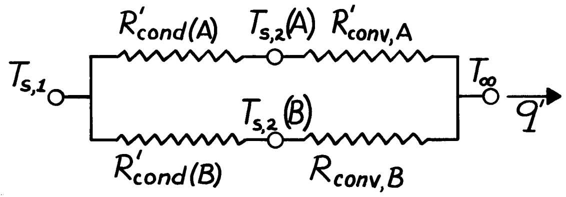
ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional, radial conduction, (3) Infinite contact resistance between materials, (4) Constant properties.

ANALYSIS: (a) The thermal circuit is,

$$R'_{conv,A} = R'_{conv,B} = 1/\pi\, r_2 h$$

$$R'_{cond(A)} = \frac{\ln(r_2/r_1)}{\pi\, k_A}$$

$$R'_{cond(\mathbf{B})} = \frac{\ln(r_2/r_i)}{\pi\, k_B}$$



<

The conduction resistances follow from Section 3.3.1 and Eq. 3.33. Each resistance is larger by a factor of 2 than the result of Eq. 3.28 due to the reduced area.

(b) Evaluating the thermal resistances and the heat rate $(q' = q'_A + q'_B)$,

$$R'_{conv} = \left(\pi \times 0.1\text{m} \times 25\ \text{W/m}^2\cdot\text{K}\right)^{-1} = 0.1273\ \text{m}\cdot\text{K/W}$$

$$R'_{cond(A)} = \frac{\ln(0.1\text{m}/0.05\text{m})}{\pi \times 2\ \text{W/m}\cdot\text{K}} = 0.1103\ \text{m}\cdot\text{K/W} \quad R'_{cond(B)} = 8\ R'_{cond(A)} = 0.8825\ \text{m}\cdot\text{K/W}$$

$$q' = \frac{T_{s,1} - T_\infty}{R'_{cond(A)} + R'_{conv}} + \frac{T_{s,1} - T_\infty}{R'_{cond(B)} + R'_{conv}}$$

$$q' = \frac{(500-300)\text{K}}{(0.1103+0.1273)\text{m}\cdot\text{K/W}} + \frac{(500-300)\text{K}}{(0.8825+0.1273)\text{m}\cdot\text{K/W}} = (842 + 198)\text{W/m} = 1040\ \text{W/m}.$$ <

Hence, the temperatures are

$$T_{s,2(A)} = T_{s,1} - q'_A R'_{cond(A)} = 500\text{K} - 842\frac{\text{W}}{\text{m}} \times 0.1103\frac{\text{m}\cdot\text{K}}{\text{W}} = 407\text{K}$$ <

$$T_{s,2(B)} = T_{s,1} - q'_B R'_{cond(B)} = 500\text{K} - 198\frac{\text{W}}{\text{m}} \times 0.8825\frac{\text{m}\cdot\text{K}}{\text{W}} = 325\text{K}.$$ <

COMMENTS: The total heat loss can also be computed from $q' = (T_{s,1} - T_\infty)/R_{equiv}$,

where $R_{equiv} = \left[\left(R'_{cond(A)} + R'_{conv,A}\right)^{-1} + \left(R'_{cond(B)} + R'_{conv,B}\right)^{-1}\right]^{-1} = 0.1923\ \text{m}\cdot\text{K/W}.$

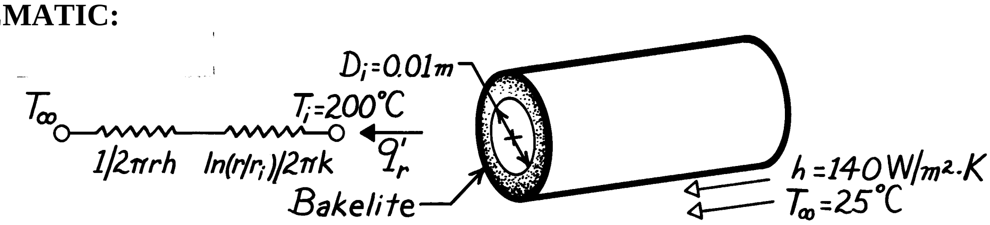
Hence $q' = (500-300)\text{K}/0.1923\ \text{m}\cdot\text{K/W} = 1040\ \text{W/m}.$

PROBLEM 3.62

KNOWN: Surface temperature of a circular rod coated with Bakelite and adjoining fluid conditions.

FIND: (a) Critical insulation radius, (b) Heat transfer per unit length for bare rod and for insulation at critical radius, (c) Insulation thickness needed for 25% heat rate reduction.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in r, (3) Constant properties, (4) Negligible radiation and contact resistance.

PROPERTIES: *Table A-3*, Bakelite (300K): k = 1.4 W/m·K.

ANALYSIS: (a) From Example 3.6, the critical radius is

$$r_{cr} = \frac{k}{h} = \frac{1.4\ \text{W/m}\cdot\text{K}}{140\ \text{W/m}^2\cdot\text{K}} = 0.01\text{m}. \qquad <$$

(b) For the bare rod,

$$q' = h(\pi\ D_i)\ (T_i - T_\infty)$$

$$q' = 140\frac{\text{W}}{\text{m}^2\cdot\text{K}}(\pi\times 0.01\text{m})\ (200-25)^\circ\text{C} = 770\ \text{W/m} \qquad <$$

For the critical insulation thickness,

$$q' = \frac{T_i - T_\infty}{\dfrac{1}{2\pi\ r_{cr}h} + \dfrac{\ln(r_{cr}/r_i)}{2\pi\ k}} = \frac{(200-25)^\circ\text{C}}{\dfrac{1}{2\pi\times(0.01\text{m})\times 140\ \text{W/m}^2\cdot\text{K}} + \dfrac{\ln(0.01\text{m}/0.005\text{m})}{2\pi\times 1.4\ \text{W/m}\cdot\text{K}}}$$

$$q' = \frac{175^\circ\text{C}}{(0.1137+0.0788)\ \text{m}\cdot\text{K/W}} = 909\ \text{W/m} \qquad <$$

(c) The insulation thickness needed to reduce the heat rate to 577 W/m is obtained from

$$q' = \frac{T_i - T_\infty}{\dfrac{1}{2\pi\ rh} + \dfrac{\ln(r/r_i)}{2\pi\ k}} = \frac{(200-25)^\circ\text{C}}{\dfrac{1}{2\pi(r)140\ \text{W/m}^2\cdot\text{K}} + \dfrac{\ln(r/0.005\text{m})}{2\pi\times 1.4\ \text{W/m}\cdot\text{K}}} = 577\frac{\text{W}}{\text{m}}$$

From a trial-and-error solution, find

$$r \approx 0.06\ \text{m}.$$

The desired insulation thickness is then

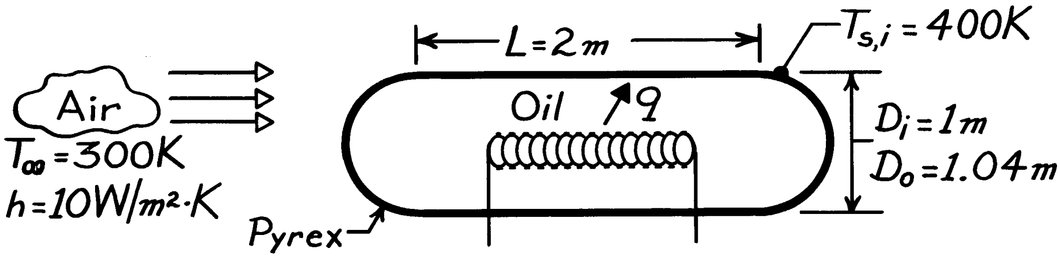
$$\delta = (r - r_i) \approx (0.06 - 0.005)\text{m} = 55\ \text{mm}. \qquad <$$

PROBLEM 3.63

KNOWN: Geometry of an oil storage tank. Temperature of stored oil and environmental conditions.

FIND: Heater power required to maintain a prescribed inner surface temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in radial direction, (3) Constant properties, (4) Negligible radiation.

PROPERTIES: *Table A-3*, Pyrex (300K): k = 1.4 W/m·K.

ANALYSIS: The rate at which heat must be supplied is equal to the loss through the cylindrical and hemispherical sections. Hence,

$$q = q_{cyl} + 2q_{hemi} = q_{cyl} + q_{spher}$$

or, from Eqs. 3.33 and 3.41,

$$q = \frac{T_{s,i} - T_\infty}{\frac{\ln(D_o/D_i)}{2\pi\, Lk} + \frac{1}{\pi\, D_o L h}} + \frac{T_{s,i} - T_\infty}{\frac{1}{2\pi\, k}\left[\frac{1}{D_i} - \frac{1}{D_o}\right] + \frac{1}{\pi D_o^2 h}}$$

$$q = \frac{(400-300)\text{K}}{\frac{\ln 1.04}{2\pi(2\text{m})1.4\ \text{W/m}\cdot\text{K}} + \frac{1}{\pi(1.04\text{m})2\text{m}\left(10\ \text{W/m}^2\cdot\text{K}\right)}}$$

$$+ \frac{(400-300)\text{K}}{\frac{1}{2\pi(1.4\ \text{W/m}\cdot\text{K})}(1-0.962)\text{m}^{-1} + \frac{1}{\pi(1.04\text{m})^2\, 10\ \text{W/m}^2\cdot\text{K}}}$$

$$q = \frac{100\text{K}}{2.23\times10^{-3}\ \text{K/W} + 15.30\times10^{-3}\ \text{K/W}} + \frac{100\text{K}}{4.32\times10^{-3}\ \text{K/W} + 29.43\times10^{-3}}$$

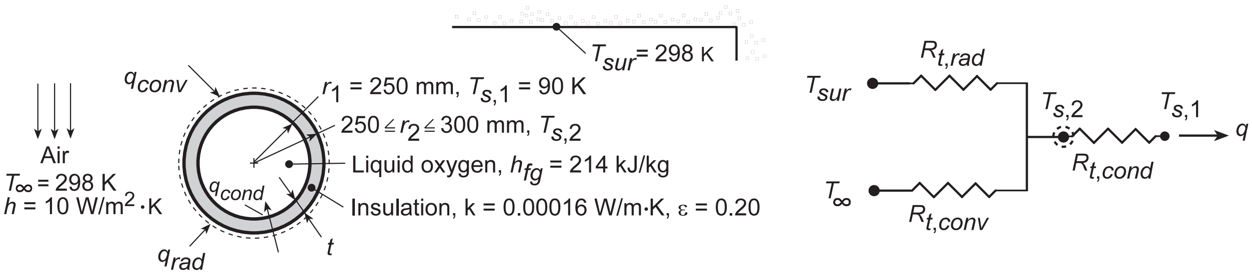
q = 5705W + 2963W = 8668W. <

PROBLEM 3.64

KNOWN: Diameter of a spherical container used to store liquid oxygen and properties of insulating material. Environmental conditions.

FIND: (a) Reduction in evaporative oxygen loss associated with a prescribed insulation thickness, (b) Effect of insulation thickness on evaporation rate.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, one-dimensional conduction, (2) Negligible conduction resistance of container wall and contact resistance between wall and insulation, (3) Container wall at boiling point of liquid oxygen.

ANALYSIS: (a) Applying an energy balance to a control surface about the insulation, $\dot{E}_{in} - \dot{E}_{out} = 0$, it follows that $q_{conv} + q_{rad} = q_{cond} = q$. Hence,

$$\frac{T_\infty - T_{s,2}}{R_{t,conv}} + \frac{T_{sur} - T_{s,2}}{R_{t,rad}} = \frac{T_{s,2} - T_{s,1}}{R_{t,cond}} = q \qquad (1)$$

where $R_{t,conv} = \left(4\pi r_2^2 h\right)^{-1}$, $R_{t,rad} = \left(4\pi r_2^2 h_r\right)^{-1}$, $R_{t,cond} = (1/4\pi k)\left[(1/r_1) - (1/r_2)\right]$, and, from Eq. 1.9, the radiation coefficient is $h_r = \varepsilon\sigma\left(T_{s,2} + T_{sur}\right)\left(T_{s,2}^2 + T_{sur}^2\right)$. With t = 10 mm ($r_2$ = 260 mm), ε = 0.2 and $T_\infty = T_{sur}$ = 298 K, an iterative solution of the energy balance equation yields $T_{s,2} \approx 297.7$ K, where $R_{t,conv}$ = 0.118 K/W, $R_{t,rad}$ = 0.982 K/W and $R_{t,cond}$ = 76.5 K/W. With the insulation, it follows that the heat gain is

$$q_w \approx 2.72 \text{ W}$$

Without the insulation, the heat gain is

$$q_{wo} = \frac{T_\infty - T_{s,1}}{R_{t,conv}} + \frac{T_{sur} - T_{s,1}}{R_{t,rad}}$$

where, with $r_2 = r_1$, $T_{s,1}$ = 90 K, $R_{t,conv}$ = 0.127 K/W and $R_{t,rad}$ = 3.14 K/W. Hence,

$$q_{wo} = 1702 \text{ W}$$

With the oxygen mass evaporation rate given by $\dot{m} = q/h_{fg}$, the percent reduction in evaporated oxygen is

$$\% \text{ Reduction} = \frac{\dot{m}_{wo} - \dot{m}_w}{\dot{m}_{wo}} \times 100\% = \frac{q_{wo} - q_w}{q_{wo}} \times 100\%$$

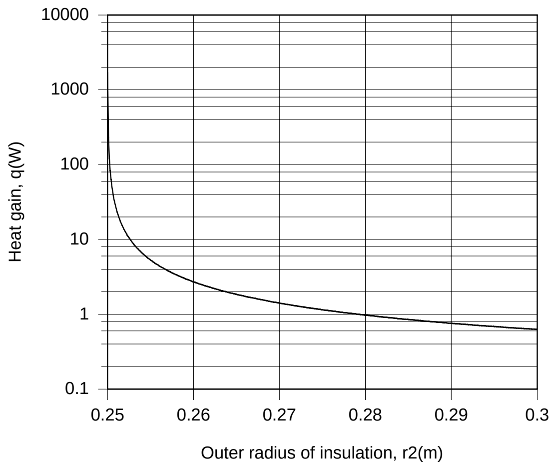
Hence,

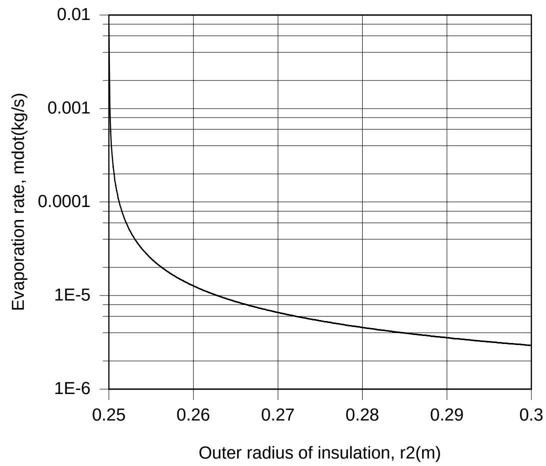
$$\% \text{ Reduction} = \frac{(1702 - 2.7)\text{ W}}{1702 \text{ W}} \times 100\% = 99.8\% \qquad <$$

Continued...

PROBLEM 3.64 (Cont.)

(b) Using Equation (1) to compute $T_{s,2}$ and q as a function of r_2, the corresponding evaporation rate, $\dot{m} = q/h_{fg}$, may be determined. Variations of q and $\dot{m}$ with r_2 are plotted as follows.





Because of its extremely low thermal conductivity, significant benefits are associated with using even a thin layer of insulation. Nearly three-order magnitude reductions in q and $\dot{m}$ are achieved with $r_2 = 0.26$ m. With increasing r_2, q and $\dot{m}$ decrease from values of 1702 W and 8×10^{-3} kg/s at $r_2 = 0.25$ m to 0.627 W and 2.9×10^{-6} kg/s at $r_2 = 0.30$ m.

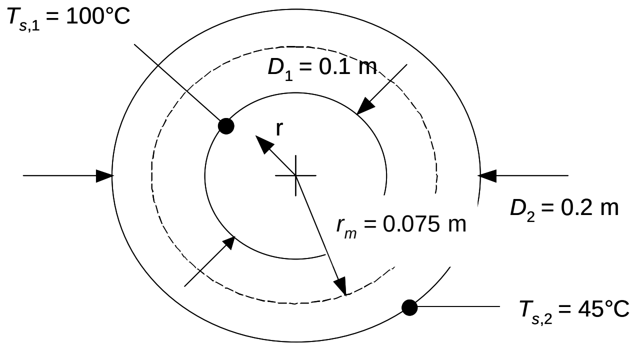
COMMENTS: Laminated metallic-foil/glass-mat insulations are extremely effective and corresponding conduction resistances are typically much larger than those normally associated with surface convection and radiation.

PROBLEM 3.65

KNOWN: Dimensions and surface temperatures of a glass or aluminum spherical shell.

FIND: (a) Mid-point temperature within the shell for a glass shell, (b) Mid-point temperature within the shell for an aluminum shell.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional heat transfer, (4) No internal energy generation within the shell.

ANALYSIS: (a) The conduction heat rate into the dashed control surface must equal the conduction heat rate out of the dashed control surface. Hence, from Eq. 3.40

$$q_r = \frac{4\pi k\left(T_{s,1} - T(r_m)\right)}{(1/r_1) - (1/r_m)} = \frac{4\pi k\left(T(r_m) - T_{s,2}\right)}{(1/r_m) - (1/r_2)}$$

or,

$$T(r_m) = \frac{1}{\left(\dfrac{1}{(1/r_m) - (1/r_2)}\right) + \left(\dfrac{1}{(1/r_1) - (1/r_m)}\right)}\left(\frac{T_{s,1}}{(1/r_1) - (1/r_m)} + \frac{T_{s,2}}{(1/r_m) - (1/r_2)}\right)$$

$$= \frac{1}{\left(\dfrac{1}{(1/0.075\text{m}) - (1/0.1\text{m})}\right) + \left(\dfrac{1}{(1/0.05\text{m}) - (1/0.075\text{m})}\right)} \times$$

$$\left(\frac{100°\text{C}}{(1/0.05\text{m}) - (1/0.075\text{m})} + \frac{45°\text{C}}{(1/0.075\text{m}) - (1/0.1\text{m})}\right)$$

$= 63.3°\text{C}$ <

(b) The temperature distribution is independent of the shell material. Hence, $T(r_m) = 63.3°\text{C}$ <

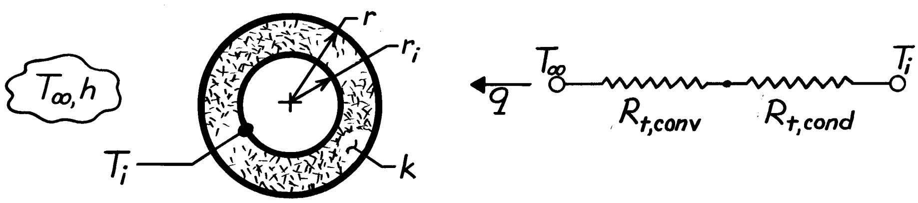
COMMENTS: (1) The temperature distribution is not linear. Assuming a linear distribution would be a serious error. (2) The conduction heat rate through the sphere will be much higher for the aluminum shell since the thermal conductivity of aluminum is much greater than that of glass.

PROBLEM 3.66

KNOWN: Sphere of radius r_i, covered with insulation whose outer surface is exposed to a convection process.

FIND: Critical insulation radius, r_{cr}.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial (spherical) conduction, (3) Constant properties, (4) Negligible radiation at surface.

ANALYSIS: The heat rate follows from the thermal circuit shown in the schematic,

$$q = \left(T_i - T_\infty\right) / R_{tot}$$

where $R_{tot} = R_{t,conv} + R_{t,cond}$ and

$$R_{t,conv} = \frac{1}{hA_s} = \frac{1}{4\pi\ hr^2} \qquad (3.9)$$

$$R_{t,cond} = \frac{1}{4\pi\ k}\left[\frac{1}{r_i} - \frac{1}{r}\right] \qquad (3.36)$$

If q is a maximum or minimum, we need to find the condition for which

$$\frac{d\,R_{tot}}{dr} = 0.$$

It follows that

$$\frac{d}{dr}\left[\frac{1}{4\pi k}\left[\frac{1}{r_i} - \frac{1}{r}\right] + \frac{1}{4\pi\ hr^2}\right] = \left[+\frac{1}{4\pi\ k}\frac{1}{r^2} - \frac{1}{2\pi\ h}\frac{1}{r^3}\right] = 0$$

giving

$$r_{cr} = 2\frac{k}{h}$$

The second derivative, evaluated at $r = r_{cr}$, is

$$\frac{d}{dr}\left[\frac{dR_{tot}}{dr}\right] = -\frac{1}{2\pi\ k}\ \frac{1}{r^3} + \frac{3}{2\pi\ h}\ \frac{1}{r^4}\Bigg]_{r=r_{cr}}$$

$$= \frac{1}{\left(2k/h\right)^3}\left\{-\frac{1}{2\pi\ k} + \frac{3}{2\pi\ h}\frac{1}{2k/h}\right\} = \frac{1}{\left(2k/h\right)^3}\frac{1}{2\pi\ k}\left\{-1 + \frac{3}{2}\right\} > 0$$

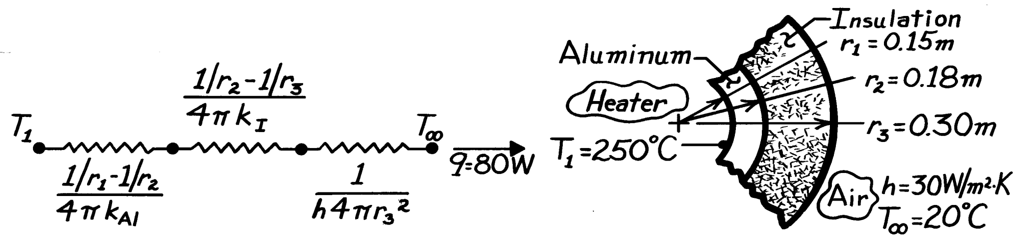
Hence, it follows no optimum R_{tot} exists. We refer to this condition as the critical insulation radius. See Example 3.6 which considers this situation for a cylindrical system.

PROBLEM 3.67

KNOWN: Thickness of hollow aluminum sphere and insulation layer. Heat rate and inner surface temperature. Ambient air temperature and convection coefficient.

FIND: Thermal conductivity of insulation.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial conduction, (3) Constant properties, (4) Negligible contact resistance, (5) Negligible radiation exchange at outer surface.

PROPERTIES: *Table A-1*, Aluminum (523K): k ≈ 230 W/m·K.

ANALYSIS: From the thermal circuit,

$$q=\frac{T_1-T_\infty}{R_{tot}}=\frac{T_1-T_\infty}{\frac{1/r_1-1/r_2}{4\pi\ k_{A1}}+\frac{1/r_2-1/r_3}{4\pi\ k_I}+\frac{1}{h4\pi\ r_3^2}}$$

$$q=\frac{(250-20)^\circ\,C}{\left[\frac{1/0.15-1/0.18}{4\pi(230)}+\frac{1/0.18-1/0.30}{4\pi\ k_I}+\frac{1}{30(4\pi)(0.3)^2}\right]\frac{K}{W}}=80\ W$$

or

$$3.84\times10^{-4}+\frac{0.177}{k_I}+0.0029=\frac{230}{80}=2.875.$$

Solving for the unknown thermal conductivity, find

$$k_I = 0.062\ W/m\cdot K.$$ <

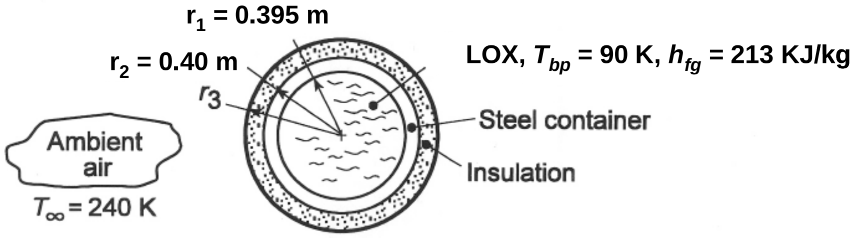
COMMENTS: The dominant contribution to the total thermal resistance is made by the insulation. Hence uncertainties in knowledge of h or k_{A1} have a negligible effect on the accuracy of the k_I measurement.

PROBLEM 3.68

KNOWN: Dimensions of spherical, stainless steel liquid oxygen (LOX) storage container. Boiling point and latent heat of fusion of LOX. Environmental temperature.

FIND: Thermal isolation system which maintains boil-off below 1 kg/day.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, steady-state conditions, (2) Negligible thermal resistances associated with internal and external convection, conduction in the container wall, and contact between wall and insulation, (3) Negligible radiation at exterior surface (due to low emissivity insulation selected), (4) Constant insulation thermal conductivity.

PROPERTIES: *Table A.1*, 304 Stainless steel (T = 100 K): k_s = 9.2 W/m·K; *Table A.3*, Reflective, aluminum foil-glass paper insulation (T = 150 K): k_i = 0.000017 W/m·K (see choice of insulation below).

ANALYSIS: The heat gain associated with a loss of 1 kg/day is

$$q = \dot{m}h_{fg} = \frac{1\,\text{kg/day}}{86,400\,\text{s/day}}\left(2.13\times10^5\ \text{J/kg}\right) = 2.47\,\text{W}$$

With an overall temperature difference of $\left(T_\infty - T_{bp}\right)$ = 150 K, the corresponding total thermal resistance is

$$R_{tot} = \frac{\Delta T}{q} = \frac{150\,\text{K}}{2.47\,\text{W}} = 60.7\,\text{K/W}$$

The conduction resistance of the steel wall is

$$R_{t,cond,s} = \frac{1}{4\pi k_s}\left(\frac{1}{r_1} - \frac{1}{r_2}\right) = \frac{1}{4\pi\left(9.2\,\text{W/m}\cdot\text{K}\right)}\left(\frac{1}{0.395\,\text{m}} - \frac{1}{0.40\,\text{m}}\right) = 2.7\times10^{-4}\ \text{K/W}$$

With a typical combined radiation and convection heat transfer coefficient of h = 10 W/m^2·K, the resistance between the surface and the environment can be estimated as

$$R_{conv,rad} = \frac{1}{hA_s} = \frac{1}{10\ \text{W/m}^2\cdot\text{K}\times4\pi\left(0.40\,\text{m}\right)^2} = 0.05\,\text{K/W}$$

It is clear that these resistances are insufficient, and reliance must be placed on the insulation. A special insulation of very low thermal conductivity should be selected. The best choice is a highly reflective foil/glass matted insulation which was developed for cryogenic applications. It follows that

$$R_{t,cond,i} = 60.7\,\text{K/W} = \frac{1}{4\pi k_i}\left(\frac{1}{r_2} - \frac{1}{r_3}\right) = \frac{1}{4\pi\left(0.000017\,\text{W/m}\cdot\text{K}\right)}\left(\frac{1}{0.40\,\text{m}} - \frac{1}{r_3}\right)$$

which yields r_3 = 0.4021 m. The minimum insulation thickness is therefore $\delta = (r_3 - r_2)$ = 2.1 mm.

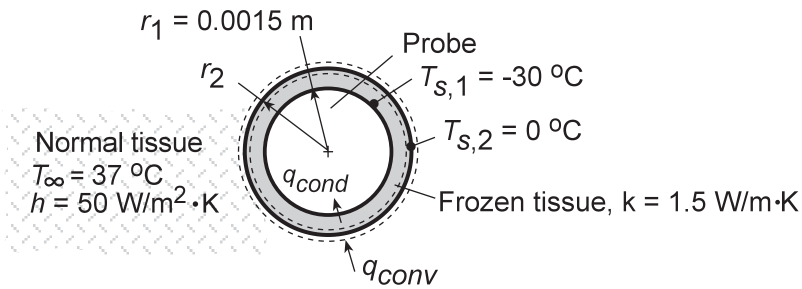
COMMENTS: The heat loss could be reduced well below the maximum allowable by adding more insulation. Also, in view of weight restrictions associated with launching space vehicles, consideration should be given to fabricating the LOX container from a lighter material.

PROBLEM 3.69

KNOWN: Diameter and surface temperature of a spherical cryoprobe. Temperature of surrounding tissue and effective convection coefficient at interface between frozen and normal tissue.

FIND: Thickness of frozen tissue layer.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, steady-state conditions, (2) Negligible contact resistance between probe and frozen tissue, (3) Constant properties, (4) Negligible perfusion effects.

ANALYSIS: Performing an energy balance for a control surface about the phase front, it follows that

$$q_{conv} - q_{cond} = 0$$

Hence,

$$h\left(4\pi r_2^2\right)\left(T_\infty - T_{s,2}\right) = \frac{T_{s,2} - T_{s,1}}{\left[\left(1/r_1\right) - \left(1/r_2\right)\right]/4\pi k}$$

$$r_2^2\left[\left(1/r_1\right) - \left(1/r_2\right)\right] = \frac{k}{h}\frac{\left(T_{s,2} - T_{s,1}\right)}{\left(T_\infty - T_{s,2}\right)}$$

$$\left(\frac{r_2}{r_1}\right)\left[\left(\frac{r_2}{r_1}\right) - 1\right] = \frac{k}{hr_1}\frac{\left(T_{s,2} - T_{s,1}\right)}{\left(T_\infty - T_{s,2}\right)} = \frac{1.5\,W/m\cdot K}{\left(50\,W/m^2\cdot K\right)\left(0.0015\,m\right)}\left(\frac{30}{37}\right)$$

$$\left(\frac{r_2}{r_1}\right)\left[\left(\frac{r_2}{r_1}\right) - 1\right] = 16.2$$

$$\left(r_2/r_1\right) = 4.56$$

It follows that r_2 = 6.84 mm and the thickness of the frozen tissue is

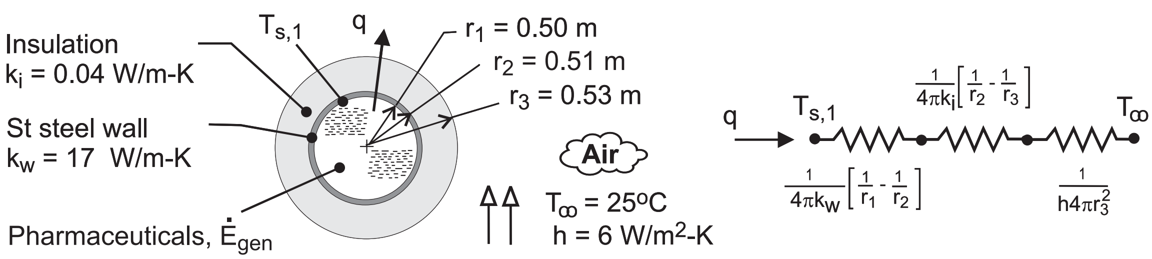
$$\delta = r_2 - r_1 = 5.34\,mm$$ <

PROBLEM 3.70

KNOWN: Inner diameter, wall thickness and thermal conductivity of spherical vessel containing heat generating medium. Inner surface temperature without insulation. Thickness and thermal conductivity of insulation. Ambient air temperature and convection coefficient.

FIND: (a) Thermal energy generated within vessel, (b) Inner surface temperature of vessel with insulation.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) One-dimensional, radial conduction, (3) Constant properties, (4) Negligible contact resistance, (5) Neglect radiation due to relatively low emissivity of stainless steel in part (a). In part (b), insulation resistance dominates.

ANALYSIS: (a) From an energy balance performed at an instant for a control surface about the pharmaceuticals, $\dot{E}_g = q$, in which case, without the insulation

$$\dot{E}_g = q = \frac{T_{s,1} - T_\infty}{\frac{1}{4\pi k_w}\left(\frac{1}{r_1} - \frac{1}{r_2}\right) + \frac{1}{4\pi r_2^2 h}} = \frac{(50-25)°C}{\frac{1}{4\pi(17\,W/m\cdot K)}\left(\frac{1}{0.50m} - \frac{1}{0.51m}\right) + \frac{1}{4\pi(0.51m)^2\,6\,W/m^2\cdot K}}$$

$$\dot{E}_g = q = \frac{25°C}{\left(1.84\times10^{-4} + 5.10\times10^{-2}\right)K/W} = 489\,W$$ <

(b) With the insulation,

$$T_{s,1} = T_\infty + q\left[\frac{1}{4\pi k_w}\left(\frac{1}{r_1} - \frac{1}{r_2}\right) + \frac{1}{4\pi k_i}\left(\frac{1}{r_2} - \frac{1}{r_3}\right) + \frac{1}{4\pi r_3^2 h}\right]$$

$$T_{s,1} = 25°C + 489\,W\left[1.84\times10^{-4} + \frac{1}{4\pi(0.04)}\left(\frac{1}{0.51} - \frac{1}{0.53}\right) + \frac{1}{4\pi(0.53)^2\,6}\right]\frac{K}{W}$$

$$T_{s,1} = 25°C + 489\,W\left[1.84\times10^{-4} + 0.147 + 0.047\right]\frac{K}{W} = 120°C$$ <

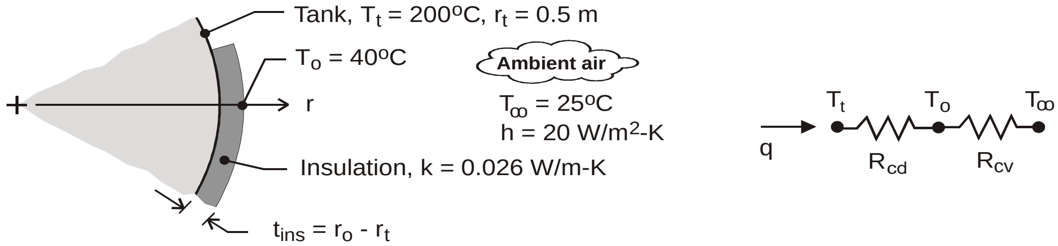
COMMENTS: The thermal resistance associated with the vessel wall is negligible, and without the insulation the dominant resistance is due to convection. The thermal resistance of the insulation is approximately three times that due to convection. Radiation may not be negligible, and would have the effect of increasing the heat loss rate (for fixed inner surface temperature) or decreasing the inner surface temperature (for fixed heat loss rate).

PROBLEM 3.71

KNOWN: Spherical tank of 1-m diameter containing an exothermic reaction and is at 200°C when the ambient air is at 25°C. Convection coefficient on outer surface is 20 $W/m^2 \cdot K$.

FIND: Determine the thickness of urethane foam required to reduce the exterior temperature to 40°C. Determine the percentage reduction in the heat rate achieved using the insulation.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional, radial (spherical) conduction through the insulation, (3) Convection coefficient is the same for bare and insulated exterior surface, and (4) Negligible radiation exchange between the insulation outer surface and the ambient surroundings, (5) Negligible contact resistances.

PROPERTIES: *Table A-3*, urethane, rigid foam (300 K): k = 0.026 W/m·K.

ANALYSIS: (a) The heat transfer situation for the heat rate from the tank can be represented by the thermal circuit shown above. The heat rate from the tank is

$$q = \frac{T_t - T_\infty}{R_{cd} + R_{cv}}$$

where the thermal resistances associated with conduction within the insulation (Eq. 3.41) and convection for the exterior surface, respectively, are

$$R_{cd} = \frac{\left(1/r_t - 1/r_o\right)}{4\pi k} = \frac{\left(1/0.5 - 1/r_o\right)}{4\pi \times 0.026\ W/m \cdot K} = \frac{\left(1/0.5 - 1/r_o\right)}{0.3267} K/W$$

$$R_{cv} = \frac{1}{hA_s} = \frac{1}{4\pi h r_o^2} = \frac{1}{4\pi \times 20\ W/m^2 \cdot K \times r_o^2} = 3.979 \times 10^{-3} r_o^{-2} K/W$$

To determine the required insulation thickness so that T_o = 40°C, perform an energy balance on the o-node.

$$\frac{T_t - T_o}{R_{cd}} + \frac{T_\infty - T_o}{R_{cv}} = 0$$

$$\frac{(200-40)K}{\left(1/0.5 - 1/r_o\right)/0.3267\ K/W} + \frac{(25-40)K}{3.979 \times 10^{-3} r_o^2\ K/W} = 0$$

$$r_o = 0.5135\ m \qquad t = r_o - r_i = (0.5135 - 0.5000)\ m = 13.5\ mm$$ <

From the rate equation, for the bare and insulated surfaces, respectively,

$$q_o = \frac{T_t - T_\infty}{1/4\pi h r_t^2} = \frac{(200-25)K}{0.01592\ K/W} = 10.99\ kW$$

$$q_{ins} = \frac{T_t - T_\infty}{R_{cd} + R_{cv}} = \frac{(200-25)}{(0.161 + 0.01592)K/W} = 0.994\ kW$$

Hence, the percentage reduction in heat loss achieved with the insulation is,

$$\frac{q_{ins} - q_o}{q_o} \times 100 = -\frac{0.994 - 10.99}{10.99} \times 100 = 91\%$$ <

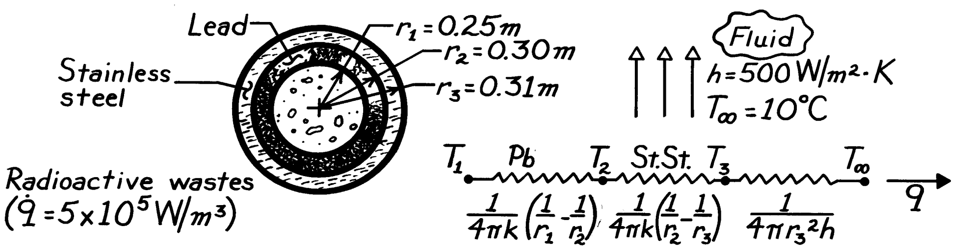
COMMENTS: (1) Contact resistances will reduce the required insulation thickness. (2) Radiation may be shown to be negligible by considering the case of ε = 1.

PROBLEM 3.72

KNOWN: Dimensions and materials used for composite spherical shell. Heat generation associated with stored material.

FIND: Inner surface temperature, T_1, of lead (proposal is flawed if this temperature exceeds the melting point).

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Steady-state conditions, (3) Constant properties at 300K, (4) Negligible contact resistance.

PROPERTIES: *Table A-1*, Lead: k = 35.3 W/m·K, MP = 601K; St.St.: 15.1 W/m·K.

ANALYSIS: From the thermal circuit, it follows that

$$q = \frac{T_1 - T_\infty}{R_{tot}} = \dot{q}\left[\frac{4}{3}\pi\ r_1^3\right]$$

Evaluate the thermal resistances,

$$R_{Pb} = \left[1/\left(4\pi \times 35.3\ \text{W/m}\cdot\text{K}\right)\right]\ \left[\frac{1}{0.25\text{m}} - \frac{1}{0.30\text{m}}\right] = 0.00150\ \text{K/W}$$

$$R_{St.St.} = \left[1/\left(4\pi \times 15.1\ \text{W/m}\cdot\text{K}\right)\right]\ \left[\frac{1}{0.30\text{m}} - \frac{1}{0.31\text{m}}\right] = 0.000567\ \text{K/W}$$

$$R_{conv} = \left[1/\left(4\pi \times 0.31^2\,\text{m}^2 \times 500\ \text{W/m}^2\cdot\text{K}\right)\right] = 0.00166\ \text{K/W}$$

$$R_{tot} = 0.00372\ \text{K/W}.$$

The heat rate is $q = 5\times10^5\ \text{W/m}^3\left(4\pi/3\right)\left(0.25\text{m}\right)^3 = 32,725\ \text{W}$. The inner surface temperature is

$$T_1 = T_\infty + R_{tot}\ q = 283\text{K} + 0.00372\text{K/W}\left(32{,}725\ \text{W}\right)$$

$$T_1 = 405\ \text{K} < \text{MP} = 601\text{K}.$$ <

Hence, from the thermal standpoint, the proposal is adequate.

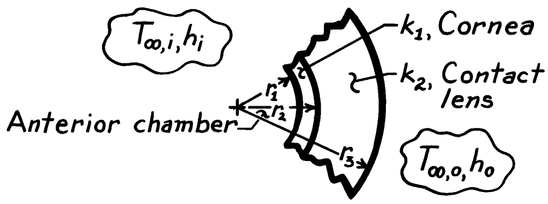
COMMENTS: In fabrication, attention should be given to maintaining a good thermal contact. A protective outer coating should be applied to prevent long term corrosion of the stainless steel.

PROBLEM 3.73

KNOWN: Representation of the eye with a contact lens as a composite spherical system subjected to convection processes at the boundaries.

FIND: (a) Thermal circuits with and without contact lens in place, (b) Heat loss from anterior chamber for both cases, and (c) Implications of the heat loss calculations.

SCHEMATIC:

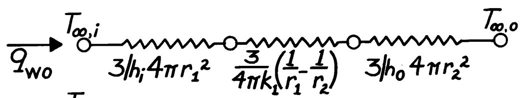


r_1=10.2mm k_1=0.35 W/m·K
r_2=12.7mm k_2=0.80 W/m·K
r_3=16.5mm
$T_{\infty,i}$=37°C h_i=12 W/m^2·K
$T_{\infty,o}$=21°C h_o=6 W/m^2·K

ASSUMPTIONS: (1) Steady-state conditions, (2) Eye is represented as 1/3 sphere, (3) Convection coefficient, h_o, unchanged with or without lens present, (4) Negligible contact resistance.

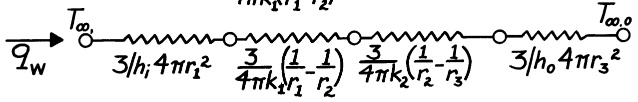
ANALYSIS: (a) Using Eqs. 3.9 and 3.41 to express the resistance terms, the thermal circuits are:

Without lens:



<

With lens:



<

(b) The heat losses for both cases can be determined as $q = (T_{\infty,i} - T_{\infty,o})/R_t$, where R_t is the thermal resistance from the above circuits.

Without lens:
$$R_{t,wo} = \frac{3}{12\text{W/m}^2 \cdot \text{K} 4\pi \left(10.2\times10^{-3}\text{m}\right)^2} + \frac{3}{4\pi \times 0.35 \text{ W/m}\cdot\text{K}}\left[\frac{1}{10.2} - \frac{1}{12.7}\right]\frac{1}{10^{-3}}\text{m}$$

$$+\frac{3}{6 \text{ W/m}^2 \cdot \text{K} 4\pi\left(12.7\times10^{-3}\text{m}\right)^2} = 191.2 \text{ K/W} + 13.2 \text{ K/W} + 246.7 \text{ K/W} = 451.1 \text{ K/W}$$

With lens:
$$R_{t,w} = 191.2 \text{ K/W} + 13.2 \text{ K/W} + \frac{3}{4\pi\times0.80 \text{ W/m}\cdot\text{K}}\left[\frac{1}{12.7}-\frac{1}{16.5}\right]\frac{1}{10^{-3}}\text{m}$$

$$+\frac{3}{6\text{W/m}^2\cdot\text{K}4\pi\left(16.5\times10^{-3}\text{m}\right)^2} = 191.2 \text{ K/W} + 13.2 \text{ K/W} + 5.41 \text{ K/W} + 146.2 \text{ K/W} = 356.0 \text{ K/W}$$

Hence the heat loss rates from the anterior chamber are

Without lens: $q_{wo} = (37-21)^\circ \text{C}/451.1 \text{ K/W} = 35.5\text{mW}$ <

With lens: $q_w = (37-21)^\circ \text{C}/356.0 \text{ K/W} = 44.9\text{mW}$ <

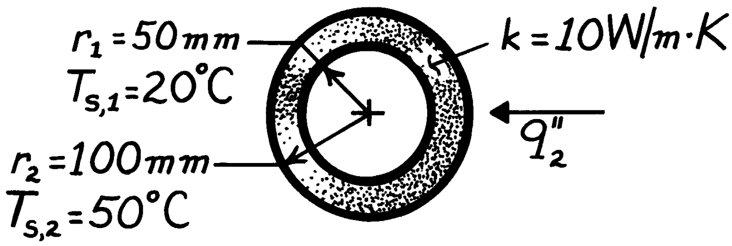
(c) The heat loss from the anterior chamber increases by approximately 20% when the contact lens is in place, implying that the outer radius, r_3, is less than the critical radius.

PROBLEM 3.74

KNOWN: Thermal conductivity and inner and outer radii of a hollow sphere subjected to a uniform heat flux at its outer surface and maintained at a uniform temperature on the inner surface.

FIND: (a) Expression for radial temperature distribution, (b) Heat flux required to maintain prescribed surface temperatures.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial conduction, (3) No generation, (4) Constant properties.

ANALYSIS: (a) For the assumptions, the temperature distribution may be obtained by integrating Fourier's law, Eq. 3.38. That is,

$$\frac{q_r}{4\pi}\int_{r_1}^{r}\frac{dr}{r^2} = -k\int_{T_{s,1}}^{T} dT \quad \text{or} \quad -\frac{q_r}{4\pi}\frac{1}{r}\Bigg|_{r_1}^{r} = -k\left(T - T_{s,1}\right).$$

Hence,

$$T(r) = T_{s,1} + \frac{q_r}{4\pi\, k}\left[\frac{1}{r} - \frac{1}{r_1}\right]$$

or, with $q''_2 \equiv q_r / 4\pi\, r_2^2$,

$$T(r) = T_{s,1} + \frac{q''_2 r_2^2}{k}\left[\frac{1}{r} - \frac{1}{r_1}\right]$$ <

(b) Applying the above result at r_2,

$$q''_2 = \frac{k\left(T_{s,2} - T_{s,1}\right)}{r_2^2\left[\frac{1}{r_2} - \frac{1}{r_1}\right]} = \frac{10\ \text{W/m}\cdot\text{K}\ (50-20)^\circ\text{C}}{(0.1\text{m})^2\left[\frac{1}{0.1} - \frac{1}{0.05}\right]\frac{1}{\text{m}}} = -3000\ \text{W/m}^2.$$ <

COMMENTS: (1) The desired temperature distribution could also be obtained by solving the appropriate form of the heat equation,

$$\frac{d}{dr}\left[r^2\frac{dT}{dr}\right] = 0$$

and applying the boundary conditions $T(r_1) = T_{s,1}$ and $-k\frac{dT}{dr}\Big]_{r_2} = q''_2$.

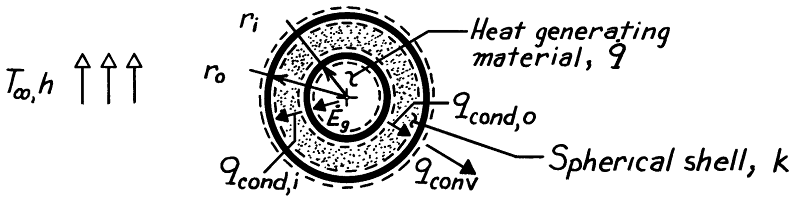
(2) The negative sign on q''_2 implies heat transfer in the negative r direction.

PROBLEM 3.75

KNOWN: Volumetric heat generation occurring within the cavity of a spherical shell of prescribed dimensions. Convection conditions at outer surface.

FIND: Expression for steady-state temperature distribution in shell.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Steady-state conditions, (3) Constant properties, (4) Uniform generation within the shell cavity, (5) Negligible radiation.

ANALYSIS: For the prescribed conditions, the appropriate form of the heat equation is

$$\frac{d}{dr}\left[r^2\frac{dT}{dr}\right]=0$$

Integrate twice to obtain,

$$r^2\frac{dT}{dr}=C_1 \qquad \text{and} \qquad T=-\frac{C_1}{r}+C_2. \tag{1,2}$$

The boundary conditions may be obtained from energy balances at the inner and outer surfaces. At the inner surface (r_i),

$$\dot{E}_g=\dot{q}\left(4/3\pi\ r_i^3\right)=q_{cond,i}=-k\left(4\pi\ r_i^2\right)dT/dr)_{r_i} \qquad dT/dr|_{r_i}=-\dot{q}r_i/3k. \tag{3}$$

At the outer surface (r_o),

$$q_{cond,o}=-k4\pi\ r_o^2\ dT/dr)_{r_o}=q_{conv}=h4\pi\ r_o^2\left[T\left(r_o\right)-T_\infty\right]$$

$$dT/dr|_{r_o}=-\left(h/k\right)\ \left[T\left(r_o\right)-T_\infty\right]. \tag{4}$$

From Eqs. (1) and (3), $C_1=-\dot{q}r_i^3/3k$. From Eqs. (1), (2) and (4)

$$-\frac{\dot{q}r_i^3}{3kr_o^2}=-\left[\frac{h}{k}\right]\left[\frac{\dot{q}r_i^3}{3r_o k}+C_2-T_\infty\right]$$

$$C_2=\frac{\dot{q}r_i^3}{3hr_o^2}-\frac{\dot{q}r_i^3}{3r_o k}+T_\infty.$$

Hence, the temperature distribution is

$$T=\frac{\dot{q}r_i^3}{3k}\left[\frac{1}{r}-\frac{1}{r_o}\right]+\frac{\dot{q}r_i^3}{3hr_o^2}+T_\infty.$$ <

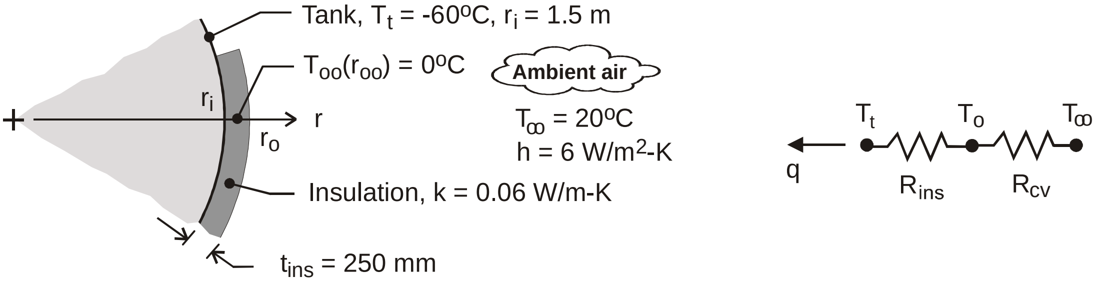
COMMENTS: Note that $\dot{E}_g=q_{cond,i}=q_{cond,o}=q_{conv}$.

PROBLEM 3.76

KNOWN: Spherical tank of 3-m diameter containing LP gas at -60°C with 250 mm thickness of insulation having thermal conductivity of 0.06 W/m·K. Ambient air temperature and convection coefficient on the outer surface are 20°C and 6 $W/m^2 \cdot K$, respectively.

FIND: (a) Determine the radial position in the insulation at which the temperature is 0°C and (b) If the insulation is pervious to moisture, what conclusions can be reached about ice formation? What effect will ice formation have on the heat gain? How can this situation be avoided?

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional, radial (spherical) conduction through the insulation, and (3) Negligible radiation exchange between the insulation outer surface and the ambient surroundings, (4) Inner surface of insulation at T_t.

ANALYSIS: (a) The heat transfer situation can be represented by the thermal circuit shown above. The heat gain to the tank is

$$q = \frac{T_\infty - T_t}{R_{ins} + R_{cv}} = \frac{\left[20 - (-60)\right]K}{\left(0.1263 + 4.33 \times 10^{-3}\right)K/W} = 612.4\ W$$

where the thermal resistances for the insulation (see Table 3.3) and the convection process on the outer surface are, respectively,

$$R_{ins} = \frac{1/r_i - 1/r_o}{4\pi k} = \frac{(1/1.50 - 1/1.75)m^{-1}}{4\pi \times 0.06\ W/m \cdot K} = 0.1263\ K/W$$

$$R_{cv} = \frac{1}{hA_s} = \frac{1}{h 4\pi r_o^2} = \frac{1}{6\ W/m^2 \cdot K \times 4\pi (1.75\ m)^2} = 4.33 \times 10^{-3} K/W$$

To determine the location within the insulation where $T_{oo}(r_{oo})$ = 0°C, use the conduction rate equation, Eq. 3.41,

$$q = \frac{4\pi k \left(T_{oo} - T_t\right)}{\left(1/r_i - 1/r_{oo}\right)} \qquad r_{oo} = \left[\frac{1}{r_i} - \frac{4\pi k \left(T_{oo} - T_t\right)}{q}\right]^{-1}$$

and substituting numerical values, find

$$r_{oo} = \left[\frac{1}{1.5\ m} - \frac{4\pi \times 0.06\ W/m \cdot K\left(0 - (-60)\right)K}{612.4\ W}\right]^{-1} = 1.687\ m$$ <

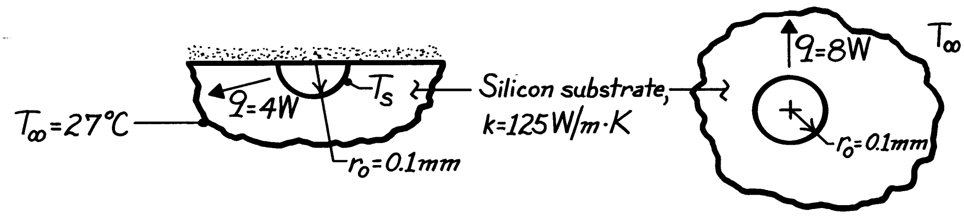
(b) With r_{oo} = 1.687 m, we'd expect the region of the insulation $r_i \le r \le r_{oo}$ to be filled with ice formations if the insulation is pervious to water vapor. The effect of the ice formation is to substantially increase the heat gain since k_{ice} is nearly twice that of k_{ins}, and the ice region is of thickness (1.687 – 1.50)m = 187 mm. To avoid ice formation, a vapor barrier should be installed at a radius larger than r_{oo}.

PROBLEM 3.77

KNOWN: Radius and heat dissipation of a hemispherical source embedded in a substrate of prescribed thermal conductivity. Source and substrate boundary conditions.

FIND: Substrate temperature distribution and surface temperature of heat source.

SCHEMATIC:



ASSUMPTIONS: (1) Top surface is adiabatic. Hence, hemispherical source in semi-infinite medium is equivalent to spherical source in infinite medium (with q = 8 W) and heat transfer is one-dimensional in the radial direction, (2) Steady-state conditions, (3) Constant properties, (4) No generation.

ANALYSIS: Heat equation reduces to

$$\frac{1}{r^2}\frac{d}{dr}\left(r^2\frac{dT}{dr}\right)=0 \qquad r^2 dT/dr=C_1$$

$$T(r)=-C_1/r+C_2.$$

Boundary conditions:

$$T(\infty)=T_\infty \qquad T(r_o)=T_s$$

Hence, $C_2 = T_\infty$ and

$$T_s=-C_1/r_o+T_\infty \quad \text{and} \quad C_1=r_o\left(T_\infty-T_s\right).$$

The temperature distribution has the form

$$T(r)=T_\infty+\left(T_s-T_\infty\right)r_o/r$$ <

and the heat rate is

$$q=-kAdT/dr=-k2\pi\, r^2\left[-\left(T_s-T_\infty\right)r_o/r^2\right]=k2\pi\, r_o\left(T_s-T_\infty\right)$$

It follows that

$$T_s-T_\infty=\frac{q}{k2\pi\, r_o}=\frac{4\text{ W}}{125\text{ W/m}\cdot\text{K}\; 2\pi\left(10^{-4}\text{ m}\right)}=50.9^\circ\text{C}$$

$$T_s=77.9^\circ\text{C}.$$ <

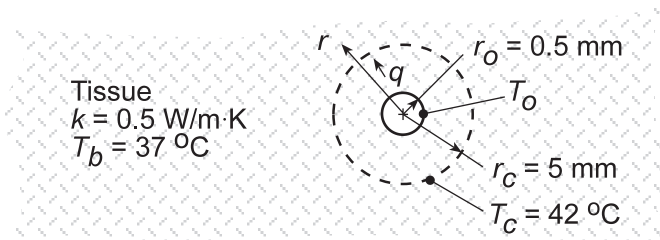
COMMENTS: For the semi-infinite (or infinite) medium approximation to be valid, the substrate dimensions must be much larger than those of the transistor.

PROBLEM 3.78

KNOWN: Critical and normal tissue temperatures. Radius of spherical heat source and radius of tissue to be maintained above the critical temperature. Tissue thermal conductivity.

FIND: General expression for radial temperature distribution in tissue. Heat rate required to maintain prescribed thermal conditions.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, steady-state conduction, (2) Constant k, (3) Negligible contact resistance.

ANALYSIS: The appropriate form of the heat equation is

$$\frac{1}{r^2}\frac{d}{dr}\left(r\frac{dT}{dr}\right)=0$$

Integrating twice,

$$\frac{dT}{dr}=\frac{C_1}{r^2}$$

$$T(r)=-\frac{C_1}{r}+C_2$$

Since $T \to T_b$ as $r \to \infty$, $C_2 = T_b$. At $r = r_o$, $q = -k\left(4\pi r_o^2\right)dT/dr|_{r_o} = -4\pi k r_o^2\, C_1/r_o^2 = -4\pi k C_1$.

Hence, $C_1 = -q/4\pi k$ and the temperature distribution is

$$T(r)=\frac{q}{4\pi kr}+T_b$$ <

It follows that

$$q=4\pi kr\left[T(r)-T_b\right]$$

Applying this result at $r = r_c$,

$$q=4\pi\left(0.5\,W/m\cdot K\right)\left(0.005\,m\right)\left(42-37\right)^{\circ}C=0.157\,W$$ <

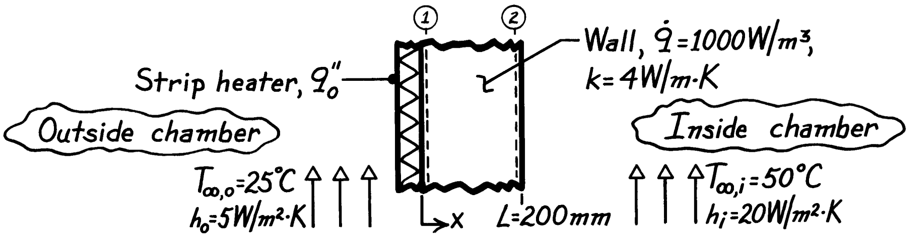
COMMENTS: At $r_o = 0.0005$ m, $T(r_o) = \left[q/\left(4\pi k r_o\right)\right]+T_b = 87°C$. Proximity of this temperature to the boiling point of water suggests the need to operate at a lower power dissipation level.

PROBLEM 3.79

KNOWN: Wall of thermal conductivity k and thickness L with uniform generation $\dot{q}$; strip heater with uniform heat flux q''_o; prescribed inside and outside air conditions (h_i, $T_{\infty,i}$, h_o, $T_{\infty,o}$).

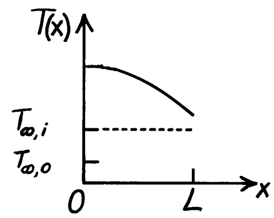
FIND: (a) Sketch temperature distribution in wall if none of the heat generated within the wall is lost to the outside air, (b) Temperatures at the wall boundaries T(0) and T(L) for the prescribed condition, (c) Value of q''_o required to maintain this condition, (d) Temperature of the outer surface, T(L), if $\dot{q}$=0 but q''_o corresponds to the value calculated in (c).

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Uniform volumetric generation, (4) Constant properties.

ANALYSIS: (a) If none of the heat generated within the wall is lost to the *outside* of the chamber, the gradient at x = 0 must be zero. Since $\dot{q}$ is uniform, the temperature distribution is parabolic, with $T(L) > T_{\infty,i}$.



(b) To find temperatures at the boundaries of wall, begin with the general solution to the appropriate form of the heat equation (Eq.3.40).

$$T(x) = -\frac{\dot{q}}{2k}x^2 + C_1x + C_2 \quad (1)$$

From the first boundary condition,

$$\left.\frac{dT}{dx}\right|_{x=o} = 0 \quad \rightarrow \quad C_1 = 0. \quad (2)$$

Two approaches are possible using different forms for the second boundary condition.

Approach No. 1: With boundary condition $\rightarrow$ $T(0) = T_1$

$$T(x) = -\frac{\dot{q}}{2k}x^2 + T_1 \quad (3)$$

To find T_1, perform an overall energy balance on the wall

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = 0$$

$$-h\left[T(L) - T_{\infty,i}\right] + \dot{q}L = 0 \qquad T(L) = T_2 = T_{\infty,i} + \frac{\dot{q}L}{h} \quad (4)$$

Continued …

PROBLEM 3.79 (Cont.)

and from Eq. (3) with x = L and T(L) = T_2,

$$T(L) = -\frac{\dot{q}}{2k}L^2 + T_1 \quad \text{or} \quad T_1 = T_2 + \frac{\dot{q}}{2k}L^2 = T_{\infty,i} + \frac{\dot{q}L}{h} + \frac{\dot{q}L^2}{2k} \tag{5,6}$$

Substituting numerical values into Eqs. (4) and (6), find

$$T_2 = 50^\circ\text{C}+1000\ \text{W/m}^3 \times 0.200\ \text{m}/20\ \text{W/m}^2\cdot\text{K}=50^\circ\text{C}+10^\circ\text{C}=60^\circ\text{C}$$ <

$$T_1 = 60^\circ\text{C}+1000\ \text{W/m}^3 \times (0.200\ \text{m})^2 / 2\times 4\ \text{W/m}\cdot\text{K}=65^\circ\text{C}.$$ <

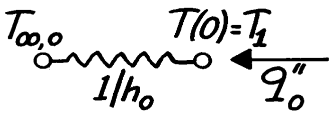
Approach No. 2: Using the boundary condition

$$-k\frac{dT}{dx}\bigg|_{x=L} = h\left[T(L) - T_{\infty,i}\right]$$

yields the following temperature distribution which can be evaluated at x = 0,L for the required temperatures,

$$T(x) = -\frac{\dot{q}}{2k}\left(x^2 - L^2\right) + \frac{\dot{q}L}{h} + T_{\infty,i}.$$

(c) The value of q''_o when T(0) = T_1 = 65°C follows from the circuit

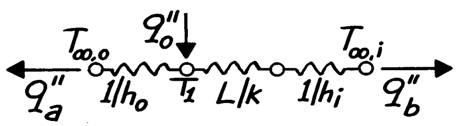


$$q''_o = \frac{T_1 - T_{\infty,o}}{1/h_o}$$

$$q''_o = 5\ \text{W/m}^2\cdot\text{K}\,(65\text{-}25)^\circ\,\text{C}=200\ \text{W/m}^2.$$ <

(d) With $\dot{q}=0$, the situation is represented by the thermal circuit shown. Hence,

$$q''_o = q''_a + q''_b$$



$$q''_o = \frac{T_1 - T_{\infty,o}}{1/h_o} + \frac{T_1 - T_{\infty,i}}{L/k+1/h_i}$$

which yields

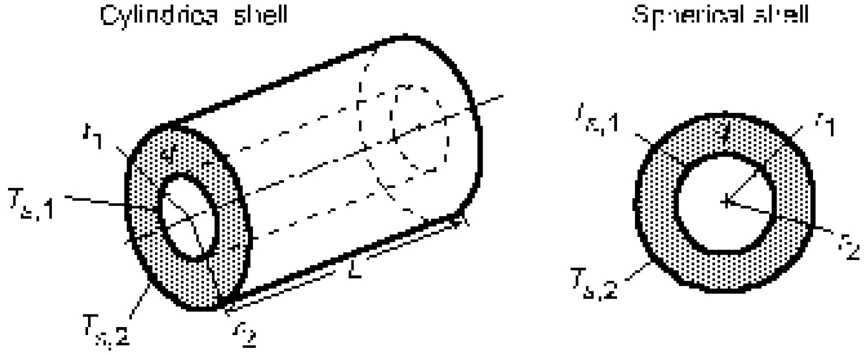
$$T_1 = 55^\circ\text{C}.$$ <

PROBLEM 3.80

KNOWN: Cylindrical and spherical shells with uniform heat generation and surface temperatures.

FIND: Radial distributions of temperature, heat flux and heat rate.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, steady-state conduction, (2) Uniform heat generation, (3) Constant k.

ANALYSIS: (a) For the *cylindrical shell*, the appropriate form of the heat equation is

$$\frac{1}{r}\frac{d}{dr}\left(r\frac{dT}{dr}\right)+\frac{\dot{q}}{k}=0$$

The general solution is

$$T(r)=-\frac{\dot{q}}{4k}r^2+C_1\ln r+C_2$$

Applying the boundary conditions, it follows that

$$T(r_1)=T_{s,1}=-\frac{\dot{q}}{4k}r_1^2+C_1\ln r_1+C_2$$

$$T(r_2)=T_{s,2}=-\frac{\dot{q}}{4k}r_2^2+C_1\ln r_2+C_2$$

which may be solved for

$$C_1=\left[(\dot{q}/4k)\left(r_2^2-r_1^2\right)+\left(T_{s,2}-T_{s,1}\right)\right]\Big/\ln(r_2/r_1)$$

$$C_2=T_{s,2}+(\dot{q}/4k)r_2^2-C_1\ln r_2$$

Hence,

$$T(r)=T_{s,2}+(\dot{q}/4k)\left(r_2^2-r^2\right)+\left[(\dot{q}/4k)\left(r_2^2-r_1^2\right)+\left(T_{s,2}-T_{s,1}\right)\right]\frac{\ln(r/r_2)}{\ln(r_2/r_1)}$$ <

With $q''=-k\,dT/dr$, the heat flux distribution is

$$q''(r)=\frac{\dot{q}}{2}r-\frac{k\left[(\dot{q}/4k)\left(r_2^2-r_1^2\right)+\left(T_{s,2}-T_{s,1}\right)\right]}{r\ln(r_2/r_1)}$$ <

Continued...

PROBLEM 3.80 (Cont.)

Similarly, with q = q'' A(r) = q'' (2πrL), the heat rate distribution is

$$q(r) = \pi L \dot{q} r^2 - \frac{2\pi Lk\left[(\dot{q}/4k)\left(r_2^2 - r_1^2\right) + \left(T_{s,2} - T_{s,1}\right)\right]}{\ln(r_2/r_1)}$$ <

(b) For the *spherical shell*, the heat equation and general solution are

$$\frac{1}{r^2}\frac{d}{dr}\left(r^2 \frac{dT}{dr}\right) + \frac{\dot{q}}{k} = 0$$

$$T(r) = -(\dot{q}/6k)r^2 - C_1/r + C_2$$

Applying the boundary conditions, it follows that

$$T(r_1) = T_{s,1} = -(\dot{q}/6k)r_1^2 - C_1/r_1 + C_2$$

$$T(r_2) = T_{s,2} = -(\dot{q}/6k)r_2^2 - C_1/r_2 + C_2$$

Hence,

$$C_1 = \left[(\dot{q}/6k)\left(r_2^2 - r_1^2\right) + \left(T_{s,2} - T_{s,1}\right)\right] \Big/ \left[(1/r_1) - (1/r_2)\right]$$

$$C_2 = T_{s,2} + (\dot{q}/6k)r_2^2 + C_1/r_2$$

and

$$T(r) = T_{s,2} + (\dot{q}/6k)\left(r_2^2 - r^2\right) - \left[(\dot{q}/6k)\left(r_2^2 - r_1^2\right) + \left(T_{s,2} - T_{s,1}\right)\right]\frac{(1/r) - (1/r_2)}{(1/r_1) - (1/r_2)}$$ <

With q''(r) = - k dT/dr, the heat flux distribution is

$$q''(r) = \frac{\dot{q}}{3}r - \frac{\left[(\dot{q}/6)\left(r_2^2 - r_1^2\right) + k\left(T_{s,2} - T_{s,1}\right)\right]}{(1/r_1) - (1/r_2)}\frac{1}{r^2}$$ <

and, with q = $q''\left(4\pi r^2\right)$, the heat rate distribution is

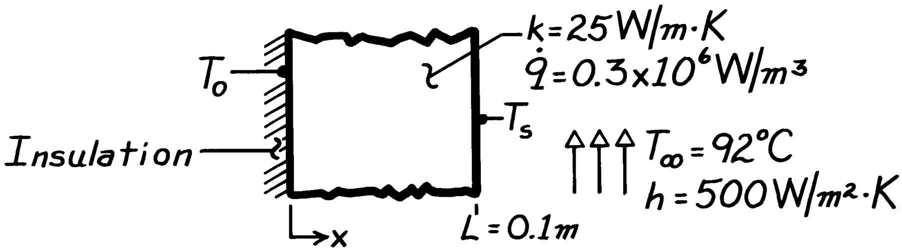
$$q(r) = \frac{4\pi\dot{q}}{3}r^3 - \frac{4\pi\left[(\dot{q}/6)\left(r_2^2 - r_1^2\right) + k\left(T_{s,2} - T_{s,1}\right)\right]}{(1/r_1) - (1/r_2)}$$ <

PROBLEM 3.81

KNOWN: Plane wall with internal heat generation which is insulated at the inner surface and subjected to a convection process at the outer surface.

FIND: Maximum temperature in the wall.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction with uniform volumetric heat generation, (3) Inner surface is adiabatic.

ANALYSIS: The temperature at the inner surface is given by Eq. 3.48 and is the maximum temperature within the wall,

$$T_o = \dot{q}L^2/2k + T_s.$$

The outer surface temperature follows from Eq. 3.51,

$$T_s = T_\infty + \dot{q}L/h$$

$$T_s = 92^\circ C + 0.3\times10^6 \frac{W}{m^3}\times 0.1m/500 W/m^2\cdot K = 92^\circ C + 60^\circ C = 152^\circ C.$$

It follows that

$$T_o = 0.3\times10^6 W/m^3 \times (0.1m)^2/2\times 25 W/m\cdot K + 152^\circ C$$

$$T_o = 60^\circ C + 152^\circ C = 212^\circ C.$$ <

COMMENTS: The heat flux leaving the wall can be determined from knowledge of h, T_s and T_∞ using Newton's law of cooling.

$$q''_{conv} = h(T_s - T_\infty) = 500 W/m^2\cdot K(152-92)^\circ C = 30 kW/m^2.$$

This same result can be determined from an energy balance on the entire wall, which has the form

$$\dot{E}_g - \dot{E}_{out} = 0$$

where

$$\dot{E}_g = \dot{q}AL \qquad \text{and} \qquad \dot{E}_{out} = q''_{conv}\cdot A.$$

Hence,

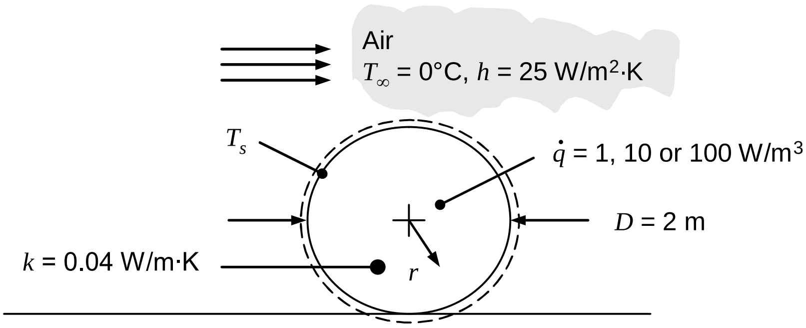
$$q''_{conv} = \dot{q}L = 0.3\times10^6 W/m^3 \times 0.1m = 30 kW/m^2.$$

PROBLEM 3.82

KNOWN: Diameter, thermal conductivity and microbial energy generation rate in cylindrical hay bales. Ambient conditions.

FIND: The maximum hay temperature for $\dot{q}$ = 1, 10, and 100 W/m^3.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional heat transfer (4) Uniform volumetric generation, (5) Negligible radiation, (6) Negligible conduction to or from the ground.

PROPERTIES: k = 0.04 W/m·K (given).

ANALYSIS: The surface temperature of the dry hay is (Eq. 3.60)

$$T_s = T_\infty + \frac{\dot{q}r_o}{2h} = 0°\text{C} + \frac{1\text{W/m}^3 \times 1\text{m}}{2 \times 25\text{W/m}^2 \cdot \text{K}} = 0.02°\text{C}$$ <

whereas T_s = 0.2°C and 2.0°C for the moist and wet hay, respectively. <

The maximum hay temperature occurs at the centerline, r = 0. From Eq. 3.58, for the dry hay,

$$T_{\max} = \frac{\dot{q}r_o^2}{4k} + T_s = \frac{1\text{W/m}^3 \times (1\text{m})^2}{4 \times 0.04\ \text{W/m} \cdot \text{K}} + 0.02°\text{C} = 6.27°\text{C}$$ <

whereas $T_{\max}$ = 62.7°C and 627°C for the moist and wet hay, respectively. <

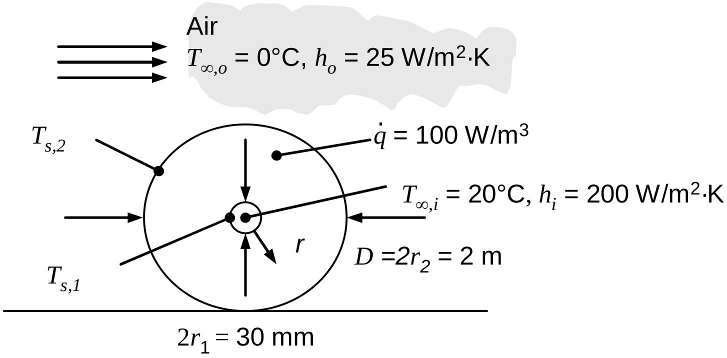
COMMENTS: (1) The hay begins to lose its nutritional value at temperatures exceeding 50°C. Therefore the center of the moist hay bale will lose some of its nutritional value. (2) The center of the wet hay bale can experience very high temperatures without combusting due to lack of oxygen internal to the hay bale. However, when the farmer breaks the bale apart for feeding, oxygen is suddenly supplied to the hot hay and combustion may occur. (3) The outer surface of the hay bale differs by only 2°C from the dry to the wet condition, while the centerline temperature differs by over 600 degrees. The farmer cannot anticipate the potential for starting a fire by touching the outer surface of the hay bale. (4) See Opuku, Tabil, Crerar and Shaw, "Thermal Conductivity and Thermal Diffusivity of Timothy Hay," *Canadian Biosystems Engineering*, Vol. 48, pp. 3.1 - 3.6, 2006 for hay property information.

PROBLEM 3.83

KNOWN: Diameter, thermal conductivity and microbial energy generation rate in cylindrical hay bales. Thin-walled tube diameter and insertion location. Temperature of flowing water and convective heat transfer coefficient inside the tube. Ambient conditions.

FIND: (a) Steady-state heat transfer to the water per unit length of tube, (b) Plot of the radial temperature distribution, $T(r)$, in the hay (c) Plot of the heat transfer to the water per unit length of tube for bale diameters of 0.2 m ≤ D ≤ 2 m for $\dot{q}$ = 100 W/m^3.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional heat transfer (4) Uniform volumetric generation, (5) Negligible radiation, (6) Negligible conduction to or from the ground.

PROPERTIES: k = 0.04 W/m·K (given).

ANALYSIS: (a) The temperature distribution is found by utilizing the general solution given by Eq. 3.56 with mixed boundary conditions applied at r_1 and r_2. Specifically,

$$\text{at } r_1: \quad -k\left.\frac{dT}{dr}\right|_{r=r_1} = h_i\left[T_{\infty,i} - T_{s,1}\right] \qquad \text{at } r_2: -k\left.\frac{dT}{dr}\right|_{r=r_2} = h_o\left[T_{s,2} - T_{\infty,o}\right]$$

The solutions are given by Eqs. C.16, C.17, and C.2.

From Eq. C.16,

$$h_{\infty,i}(T_{\infty,i} - T_{s,1}) = 200\text{ W/m}^2\cdot\text{K}\times(20°\text{C} - \text{T}_{s,1})$$

$$= \frac{\dot{q}r_1}{2} - \frac{k\left[\frac{\dot{q}r_2^2}{4k}\left(1 - \frac{r_1^2}{r_2^2}\right) + \left(T_{s,2} - T_{s,1}\right)\right]}{r_1\ln(r_2/r_1)}$$

$$= \frac{100\text{W/m}^3\times 15\times 10^{-3}\text{m}}{2} - \frac{0.04\text{W/m}\cdot\text{K}\left[\frac{100\text{W/m}^3(1\text{m})^2}{4\times 0.04\text{W/m}\cdot\text{K}}\left(1 - \frac{(15\times 10^{-3}\text{m})^2}{(1\text{m})^2}\right) + \left(T_{s,2} - T_{s,1}\right)\right]}{15\times 10^{-3}\text{m}\times\ln(1000/15)} \quad (1)$$

Continued…

PROBLEM 3.83 (Cont.)

From Eq. C.17,

$$h_{\infty,o}(T_{s,2} - T_{\infty,o}) = 25\ \text{W/m}^2 \cdot \text{K} \times (T_{s,2} - 0°C)$$

$$= \frac{\dot{q}r_2}{2} - \frac{k\left[\frac{\dot{q}r_2^2}{4k}\left(1 - \frac{r_1^2}{r_2^2}\right) + \left(T_{s,2} - T_{s,1}\right)\right]}{r\,2\ln(r_2/r_1)}$$

$$= \frac{100\text{W/m}^3 \times 1\text{m}}{2} - \frac{0.04\text{W/m}\cdot\text{K}\left[\frac{100\text{W/m}^3(1\text{m})^2}{4 \times 0.04\text{W/m}\cdot\text{K}}\left(1 - \frac{(15\times10^{-3}\text{m})^2}{(1\text{m})^2}\right) + \left(T_{s,2} - T_{s,1}\right)\right]}{1\text{m} \times \ln(1000/15)} \quad (2)$$

Equations (1) and (2) may be solved simultaneously to yield $T_{s,1}$ = 21.54°C, $T_{s,2}$ = 1.75°C. The heat transfer to the cold fluid per unit length is

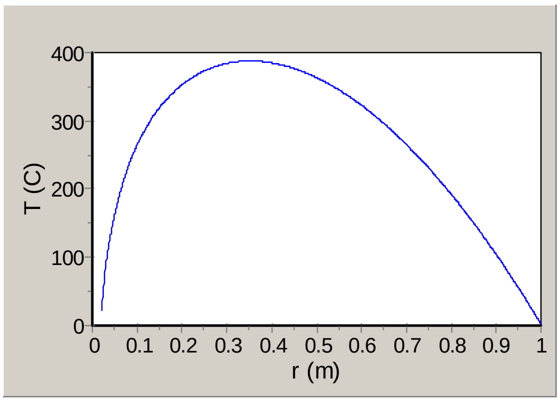
$$q' = h_i(2\pi r_i)(T_{s,i} - T_{\infty,i}) = 200\text{W/m}^2 \cdot \text{K} \times 2 \times \pi \times 15 \times 10^{-3}\text{m} \times (21.54 - 20)°C = 38.7\text{W/m}$$ <

(b) The radial temperature distribution is evaluated from Eq. C.2 and is shown below.

$$T(r) = T_{s,2} + \frac{\dot{q}r_2^2}{4k}\left(1 - \frac{r^2}{r_2^2}\right) - \left[\frac{\dot{q}r_2^2}{4k}\left(1 - \frac{r_1^2}{r_2^2}\right) + \left(T_{s,2} - T_{s,1}\right)\right]\frac{\ln(r_2/r)}{\ln(r_2/r_1)}$$

$$= 1.75°\text{C} + \frac{100\text{W/m}^3 \times (1\text{m})^2}{4 \times 0.04\text{W/m}\cdot\text{K}}\left(1 - \frac{r^2}{(1\text{m})^2}\right) - \left[\frac{100\text{W/m}^3 \times (1\text{m})^2}{4 \times 0.04\text{W/m}\cdot\text{K}}\left(1 - \frac{(15\times10^{-3}\text{m})^2}{(1\text{m})^2}\right) + \left(1.75°\text{C} - 21.54°\text{C}\right)\right]$$

$$\times \frac{\ln(1\text{m}/r)}{\ln(1\text{m}/15\times10^{-3}\text{m})}$$

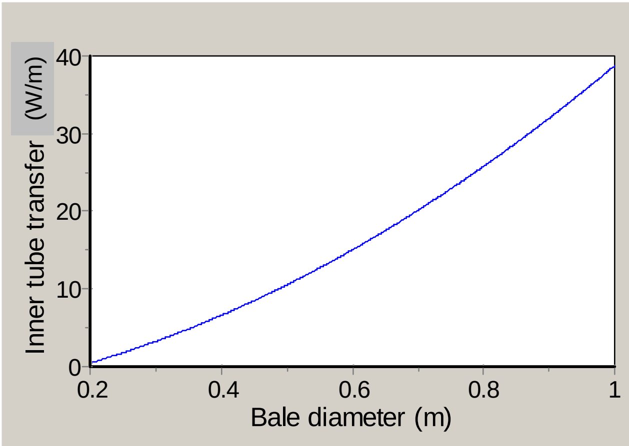


Continued…

PROBLEM 3.83 (Cont.)

Note that the maximum temperature occurs at $r \approx 0.35$ m.

(c) The rate of heat transfer to the cool fluid, per unit length, is shown versus the bale diameter in the plot below.



Note that at very small bale diameters, the heat transfer to the inner tube will become negative. That is, the energy generation in the bale is not sufficient to offset conduction losses from the relatively warm tube liquid to the relatively cold outside air.

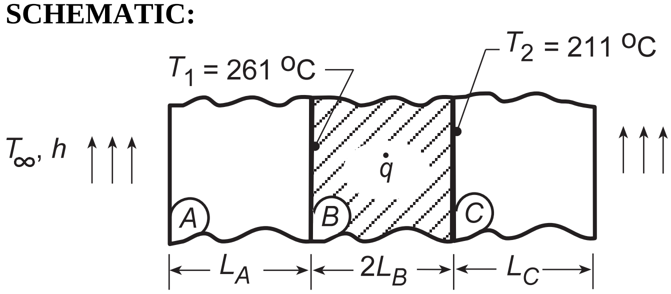
COMMENTS: (1) The energy generated in the bale per unit length is $\dot{E}_g' = \dot{q} \times \pi \times (r_2^2 - r_1^2) = 100\text{W/m}^3 \times \pi \times (1\text{m}^2 - (0.015\text{m})^2) = 314$ W/m. Hence, the heat transfer to the inner tube represents (38.7/314)×100 = 12.3% of the total generated. The remaining 87.6% is lost to the ambient air. (2) The performance could be improved by inserting more tubes, or by stacking the bales in adjacent rows so that heat losses from the exterior surface would be minimized. (3) Evaluation of the two constants appearing in the analytical solution (Eq. 3.56) using the two mixed boundary conditions is very tedious, resulting in a cumbersome expression. Utilization of the results of Appendix C saves considerable time.

PROBLEM 3.84

KNOWN: Composite wall with outer surfaces exposed to convection process.

FIND: (a) Volumetric heat generation and thermal conductivity for material B required for special conditions, (b) Plot of temperature distribution, (c) T_1 and T_2, as well as temperature distributions corresponding to loss of coolant condition where h = 0 on surface A.

SCHEMATIC:



L_A = 30 mm
L_B = 30 mm
L_C = 20 mm
k_A = 25 W/m·K
k_C = 50 W/m·K

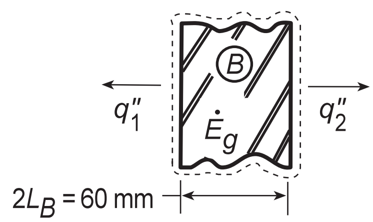
ASSUMPTIONS: (1) Steady-state, one-dimensional heat transfer, (2) Negligible contact resistance at interfaces, (3) Uniform generation in B; zero in A and C.

ANALYSIS: (a) From an energy balance on wall B,

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = \dot{E}_{st}$$

$$-q''_1 - q''_2 + 2\dot{q}L_B = 0$$

$$\dot{q}_B = \left(q''_1 + q''_2\right)/2L_B \,. \qquad (1)$$



To determine the heat fluxes, q''_1 and q''_2, construct thermal circuits for A and C:

$$q''_1 = \left(T_1 - T_\infty\right)/\left(1/h + L_A/k_A\right) \qquad q''_2 = \left(T_2 - T_\infty\right)/\left(L_C/k_C + 1/h\right)$$

$$q''_1 = \left(261 - 25\right)^\circ C \Big/ \left(\frac{1}{1000\,W/m^2\cdot K} + \frac{0.030\,m}{25\,W/m\cdot K}\right) \qquad q''_2 = \left(211 - 25\right)^\circ C \Big/ \left(\frac{0.020\,m}{50\,W/m\cdot K} + \frac{1}{1000\,W/m^2\cdot K}\right)$$

$$q''_1 = 236^\circ C/\left(0.001 + 0.0012\right)m^2\cdot K/W \qquad q''_2 = 186^\circ C/\left(0.0004 + 0.001\right)m^2\cdot K/W$$

$$q''_1 = 107,273\,W/m^2 \qquad q''_2 = 132,857\,W/m^2$$

Using the values for q''_1 and q''_2 in Eq. (1), find

$$\dot{q}_B = \left(106,818 + 132,143\,W/m^2\right)/2\times 0.030\,m = 4.00\times 10^6\,W/m^3 \,.$$ <

To determine k_B, use the general form of the temperature (Eq. 3.40) and heat flux distributions in wall B,

$$T(x) = -\frac{\dot{q}_B}{2k_B}x^2 + C_1 x + C_2 \qquad q''_x(x) = -k_B\left[-\frac{\dot{q}_B}{k_B}x + C_1\right] \qquad (2,3)$$

there are 3 unknowns, C_1, C_2 and k_B, which can be evaluated using three conditions,

Continued...

PROBLEM 3.84 (Cont.)

$$T(-L_B) = T_1 = -\frac{\dot{q}_B}{2k_B}(-L_B)^2 - C_1 L_B + C_2 \qquad \text{where } T_1 = 261°C \qquad (4)$$

$$T(+L_B) = T_2 = -\frac{\dot{q}_B}{2k_B}(+L_B)^2 + C_1 L_B + C_2 \qquad \text{where } T_2 = 211°C \qquad (5)$$

$$q''_x(-L_B) = -q''_1 = -k_B\left[-\frac{\dot{q}_B}{k_B}(-L_B) + C_1\right] \qquad \text{where } q''_1 = 107{,}273 \text{ W/m}^2 \qquad (6)$$

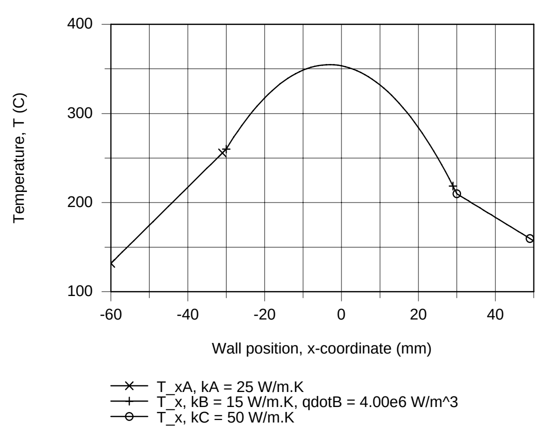
Using IHT to solve Eqs. (4), (5) and (6) simultaneously with $\dot{q}_B = 4.00 \times 10^6$ W/m^3, find

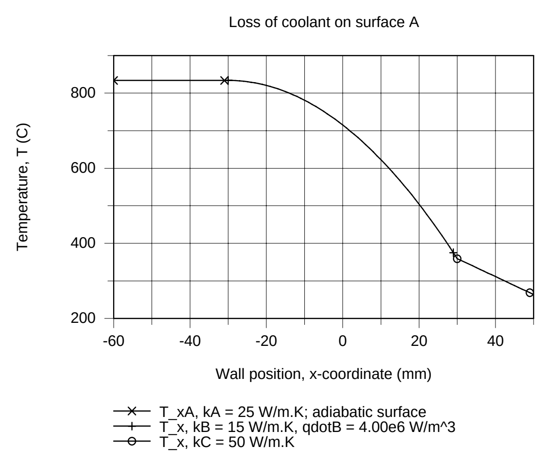
$$k_B = 15.3 \text{ W/m} \cdot \text{K}$$ <

(b) Following the method of analysis in the *IHT Example 3.6, User-Defined Functions*, the temperature distribution is shown in the plot below. The important features are (1) Distribution is quadratic in B, but non-symmetrical; linear in A and C; (2) Because thermal conductivities of the materials are different, discontinuities exist at each interface; (3) By comparison of gradients at x = $-L_B$ and $+L_B$, find $q''_2 > q''_1$.

(c) Using the same method of analysis as for Part (c), the temperature distribution is shown in the plot below when h = 0 on the surface of A. Since the left boundary is adiabatic, material A will be isothermal at T_1. Find

T_1 = 835°C $\qquad$ T_2 = 360°C <



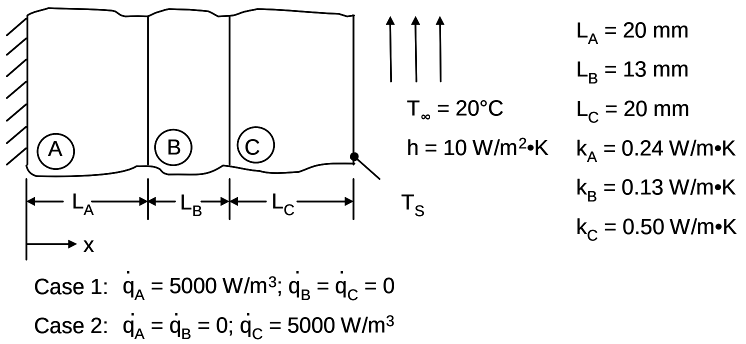


PROBLEM 3.85

KNOWN: Dimensions and properties of a composite wall exposed to convective or insulated conditions.

FIND: (a) Maximum wall temperature for left face insulated and right face convectively cooled, (b) Sketch the steady-state temperature distribution of part (a), (c) Sketch the steady-state temperature distribution with reversed boundary conditions.

SCHEMATIC:



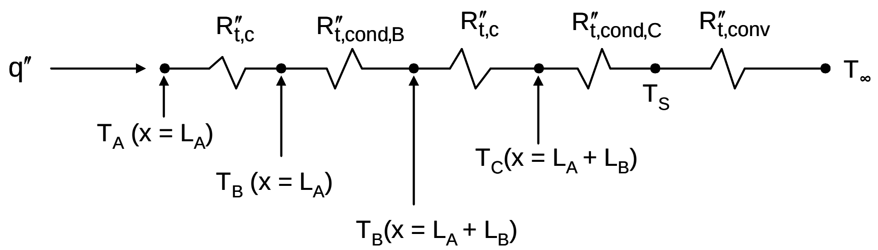
ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Uniform volumetric energy generation.

ANALYSIS:

(a) The heat flux through materials B and C is constant and is

$$q'' = \dot{q}_A (L_A) = 5000\ W/m^3 \times 0.02\ m = 100\ W/m^2$$

The thermal resistance network that spans from $x = L_A$ to the coolant is



The thermal resistances are:

$$R''_{t,c} = 0.01 m^2 \cdot K/w$$

$$R''_{t,cond,B} = \frac{L_B}{k_B} = \frac{0.013\ m}{0.13\ W/m \cdot K} = 0.1\ \frac{m^2 \cdot K}{W}$$

$$R''_{t,cond,C} = \frac{L_C}{k_C} = \frac{0.020\ m}{0.50\ W/m \cdot K} = 0.04\ \frac{m^2 \cdot K}{W}$$

Continued…

PROBLEM 3.85 (Cont.)

$$R''_{t,conv} = \frac{1}{h} = \frac{1}{10\ W/m^2\cdot K} = 0.1\ \frac{m^2\cdot K}{W}$$

The total thermal resistance is

$$R''_{t,tot} = (0.01 + 0.1 + 0.01 + 0.04 + 0.1) = 0.26\ \frac{m^2\cdot K}{W}$$

Therefore,

$$T_A(x{=}L_A) = q''(R''_{t,tot}) + T_\infty = 100\ W/m^2 \times 0.26\ \frac{m^2\cdot K}{W} + 20°C = 46°C$$

The maximum temperature occurs at x = 0 and may be evaluated by using Eq. 3.48 as follows

$$T_A(x{=}0) = T_A(x{=}L_A) + \frac{\dot{q}_A L_A^2}{2k_A} = 46°C + \frac{5000\ W/m^3 \times (0.02\ m)^2}{2 \times 0.24\ W/m\cdot K}$$

$$T_A(x{=}0) = T_{max} = 50.2°C$$ <

(b) To sketch the temperature distribution, we begin by evaluating the temperatures shown in the thermal resistance network. Working from the coolant side,

$$T_s = T_\infty + q''(R''_{t,conv}) = 20°C + 100\ W/m^2 \times 0.1\ m^2\cdot K/W = 30°C$$

$$T_C(x = L_A + L_B) = T_s + q''(R''_{t,cond,C}) = 30°C + 100\ W/m^2 \times 0.04\ m^2\cdot K/W = 34°C$$

$$T_B(x = L_A + L_B) = T_C(x = L_A + L_B) + q''(R''_{t,c}) = 34°C + 100\ W/m^2 \times 0.01\ \frac{m^2\cdot K}{W} = 35°C$$

$$T_B(x = L_A) = T_B(x = L_A + L_B) + q''(R''_{t,cond,B}) = 35°C + 100\ W/m^2 \times 0.1\ m^2\cdot K/W = 45°C$$

and from part (a), $T_A(x = L_A) = 46°C$. The temperature distribution is sketched below.

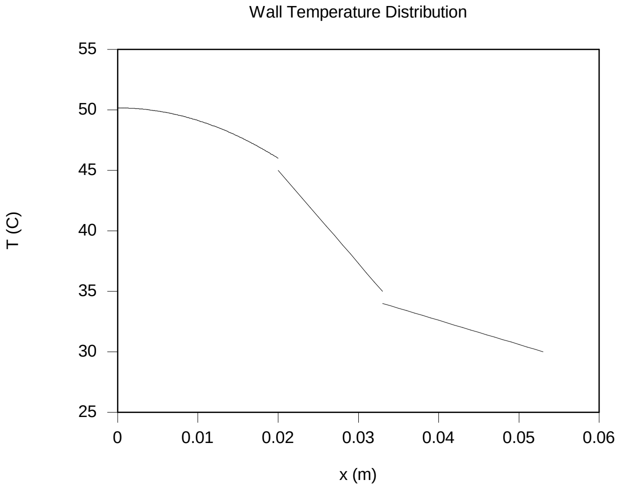
(c) For case 2, the heat flux in the range $0 \le x \le L_A + L_B$ is zero. Hence the boundary at $x = L_A + L_B$ acts as an insulated surface for material C. Therefore, from Eq. 3.43,

$$T_{max} = T_c(x = L_A + L_B) = T_s + \frac{\dot{q}L_C^2}{2k_C} = 30°C + \frac{5000\ W/m^3 \times (0.02m)^2}{2 \times 0.50\ W/m\cdot K} = 32°C$$

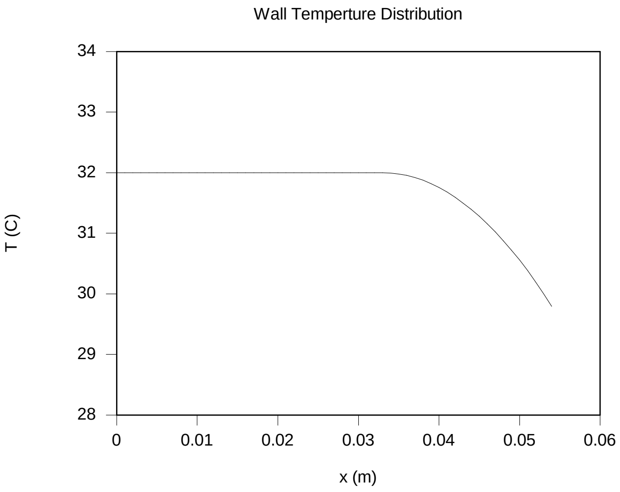
The temperature distribution is sketched below.

Continued…

PROBLEM 3.85 (Cont.)



Case 1 temperature distribution.



Case 2 temperature distribution.

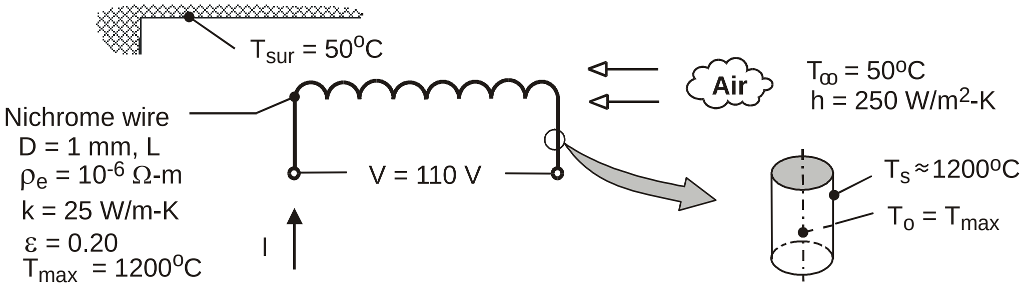
C**OMMENTS:** If the heat flux due to conduction in the x-direction is zero, the temperature gradient, dT/dx, must be zero. This is a direct consequence of Fourier's law, and holds under all conditions.

PROBLEM 3.86

KNOWN: Diameter, resistivity, thermal conductivity, emissivity, voltage, and maximum temperature of heater wire. Convection coefficient and air exit temperature. Temperature of surroundings.

FIND: Maximum operating current, heater length and power rating.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Uniform wire temperature, (3) Constant properties, (4) Radiation exchange with large surroundings.

ANALYSIS: Assuming a uniform wire temperature, $T_{max} = T(r = 0) \equiv T_o \approx T_s$, the maximum volumetric heat generation may be obtained from Eq. (3.60), but with the total heat transfer coefficient, $h_t = h + h_r$, used in lieu of the convection coefficient h. With

$$h_r = \varepsilon\sigma\left(T_s + T_{sur}\right)\left(T_s^2 + T_{sur}^2\right) = 0.20 \times 5.67 \times 10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left(1473 + 323\right)\text{K}\left(1473^2 + 323\right)^2\text{K}^2 = 46.3\,\text{W/m}^2\cdot\text{K}$$

$$h_t = \left(250 + 46.3\right)\text{W/m}^2\cdot\text{K} = 296.3\,\text{W/m}^2\cdot\text{K}$$

$$\dot{q}_{max} = \frac{2h_t}{r_o}\left(T_s - T_\infty\right) = \frac{2\left(296.3\,\text{W/m}^2\cdot\text{K}\right)}{0.0005\text{m}}\left(1150°\text{C}\right) = 1.36 \times 10^9\,\text{W/m}^3$$

Hence, with $\dot{q} = \dfrac{I^2 R_e}{\forall} = \dfrac{I^2\left(\rho_e L/A_c\right)}{LA_c} = \dfrac{I^2\rho_e}{A_c^2} = \dfrac{I^2\rho_e}{\left(\pi D^2/4\right)^2}$

$$I_{max} = \left(\frac{\dot{q}_{max}}{\rho_e}\right)^{1/2}\frac{\pi D^2}{4} = \left(\frac{1.36 \times 10^9\,\text{W/m}^3}{10^{-6}\,\Omega\cdot\text{m}}\right)^{1/2}\frac{\pi\left(0.001\text{m}\right)^2}{4} = 29.0\,\text{A}$$ <

Also, with $\Delta E = I\,R_e = I\,(\rho_e L/A_c)$,

$$L = \frac{\Delta E \cdot A_c}{I_{max}\,\rho_e} = \frac{110\,\text{V}\left[\pi\left(0.001\text{m}\right)^2/4\right]}{29.0\,\text{A}\left(10^{-6}\,\Omega\cdot\text{m}\right)} = 2.98\text{m}$$ <

and the power rating is

$$P_{elec} = \Delta E \cdot I_{max} = 110\,\text{V}\left(29\,\text{A}\right) = 3190\,\text{W} = 3.19\,\text{kW}$$ <

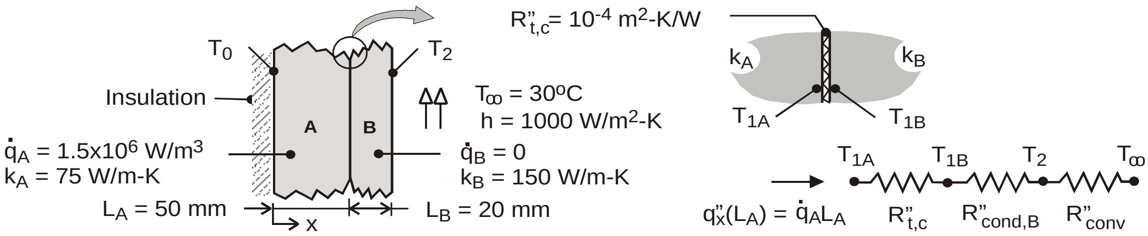
COMMENTS: To assess the validity of assuming a uniform wire temperature, Eq. (3.58) may be used to compute the centerline temperature corresponding to $\dot{q}_{max}$ and a surface temperature of 1200°C. It follows that $T_o = \dfrac{\dot{q}\,r_o^2}{4k} + T_s = \dfrac{1.36 \times 10^9\,\text{W/m}^3\left(0.0005\text{m}\right)^2}{4\left(25\,\text{W/m}\cdot\text{K}\right)} + 1200°\text{C} = 1203°\text{C}$. With only a 3°C temperature difference between the centerline and surface of the wire, the assumption is excellent.

PROBLEM 3.87

KNOWN: Composite wall of materials A and B. Wall of material A has uniform generation, while wall B has no generation. The inner wall of material A is insulated, while the outer surface of material B experiences convection cooling. Thermal contact resistance between the materials is $R''_{t,c} = 10^{-4} m^2 \cdot K/W$. See Example 3.7 that considers the case without contact resistance.

FIND: Compute and plot the temperature distribution in the composite wall.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction with constant properties, and (3) Inner surface of material A is adiabatic.

ANALYSIS: From the analysis of Example 3.8, we know the temperature distribution in material A is parabolic with zero slope at the inner boundary, and that the distribution in material B is linear. At the interface between the two materials, x = L_A, the temperature distribution will show a discontinuity.

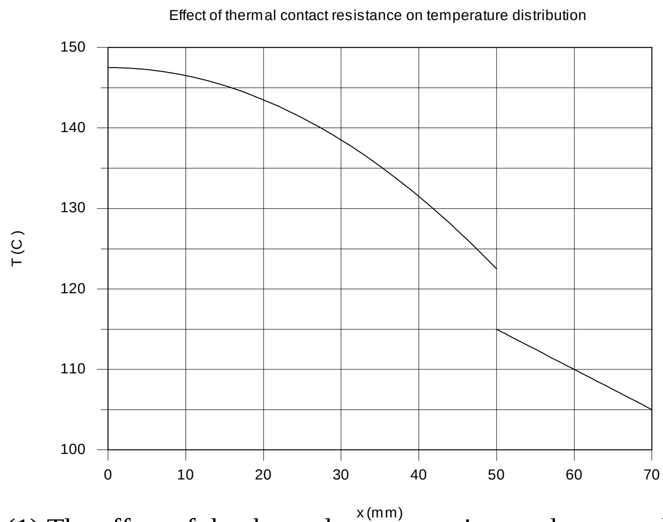
$$T_A(x) = \frac{\dot{q} L_A^2}{2 k_A}\left(1 - \frac{x^2}{L_A^2}\right) + T_{1A} \qquad 0 \le x \le L_A$$

$$T_B(x) = T_{1B} - (T_{1B} - T_2)\frac{x - L_A}{L_B} \qquad L_A \le x \le L_A + L_B$$

Considering the thermal circuit above (see also Example 3.8) including the thermal contact resistance,

$$q'' = \dot{q} L_A = \frac{T_{1A} - T_\infty}{R''_{tot}} = \frac{T_{1B} - T_\infty}{R''_{cond,B} + R''_{conv}} = \frac{T_2 - T_\infty}{R''_{conv}}$$

find $T_A(0)$ = 147.5°C, T_{1A} = 122.5°C, T_{1B} = 115°C, and T_2 = 105°C. Using the foregoing equations in IHT, the temperature distributions for each of the materials can be calculated and are plotted on the graph below.



COMMENTS: (1) The effect of the thermal contact resistance between the materials is to increase the maximum temperature of the system.

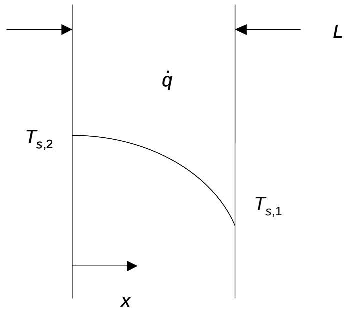
(2) Can you explain why the temperature distribution in the material B is not affected by the presence of the thermal contact resistance at the materials' interface?

PROBLEM 3.88

KNOWN: One dimensional plane wall with uniform thermal energy generation and cold surface temperature $T_{s,1}$.

FIND: (a) Expression for the heat flux to the cold wall and hot surface temperature, (b) Comparison of the heat flux of part (a) with that associated with a plane wall with no energy generation and wall temperatures of $T_{s,1}$ and $T_{s,2}$.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional heat transfer, (4) Uniform volumetric generation.

ANALYSIS: From Eq. (3.46) and the discussion beneath Eq. (3.49) the temperature distribution is

$$T(x) = \frac{\dot{q}L^2}{2k}\left(1 - \frac{x^2}{L^2}\right) + T_{s,1} \qquad (1)$$

(a) Equation (1) may be used to find an expression for the temperature gradient

$$\frac{\mathrm{d}T(x)}{\mathrm{d}x} = \frac{\dot{q}L^2}{2k}\left(-\frac{2x}{L^2}\right) = -\frac{\dot{q}x}{k}$$

Therefore, the heat flux at the cold ($x = L$) surface is

$$q''(x = L) = -k\left.\frac{dT}{dx}\right|_{x=L} = \dot{q}L \qquad <$$

The temperature of the hot surface may be found from Eq. (1) and is

$$T_{s,2} = T(x = 0) = \frac{\dot{q}L^2}{2k} + T_{s,1} \qquad <$$

(b) For the plane wall without energy generation, and with surface temperatures $T_{s,1}$ and $T_{s,2}$,

$$q'' = k\frac{\left(T_{s,2} - T_{s,1}\right)}{L} = k\left(\frac{\frac{\dot{q}L^2}{2k} + T_{s,1} - T_{s,1}}{L}\right) = \frac{\dot{q}L}{2} = \frac{1}{2}q''(x = L) \qquad <$$

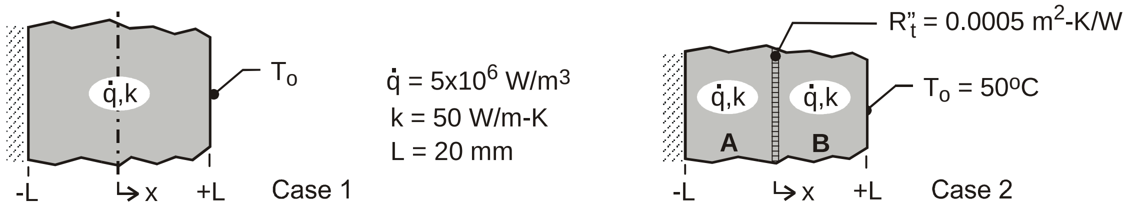
Hence, the heat flux with uniform thermal energy generation is twice that which would be calculated for a plane wall without energy generation based upon the difference between the actual hot and cold surface temperatures.

PROBLEM 3.89

KNOWN: Plane wall of thickness 2L, thermal conductivity k with uniform energy generation $\dot{q}$. For case 1, boundary at x = -L is perfectly insulated, while boundary at x = +L is maintained at T_o = 50°C. For case 2, the boundary conditions are the same, but a thin dielectric strip with thermal resistance $R''_t = 0.0005\ m^2 \cdot K/W$ is inserted at the mid-plane.

FIND: (a) Sketch the temperature distribution for case 1 on T-x coordinates and describe key features; identify and calculate the maximum temperature in the wall, (b) Sketch the temperature distribution for case 2 on the same T-x coordinates and describe the key features; (c) What is the temperature difference between the two walls at x = 0 for case 2? And (d) What is the location of the maximum temperature of the composite wall in case 2; calculate this temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in the plane and composite walls, and (3) Constant properties.

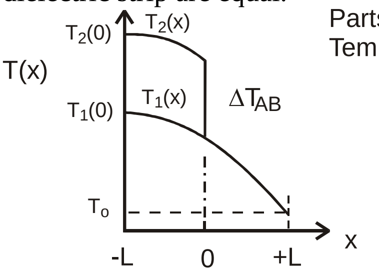
ANALYSIS: (a) For case 1, the temperature distribution, $T_1(x)$ vs. x, is parabolic as shown in the schematic below and the gradient is zero at the insulated boundary, x = -L. From Eq. 3.48 (see discussion after Eq. 3.49),

$$T_1(-L) - T_1(+L) = \frac{\dot{q}(2L)^2}{2k} = \frac{5\times10^6\ W/m^3\,(2\times0.020\ m)^2}{2\times50\ W/m\cdot K} = 80°C$$

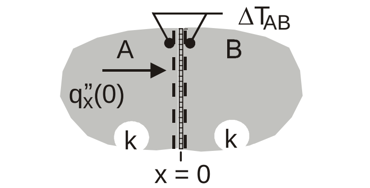
and since $T_1(+L) = T_o$ = 50°C, the maximum temperature occurs at x = -L,

$$T_1(-L) = T_1(+L) + 80°C = 130°C$$

(b) For case 2, the temperature distribution, $T_2(x)$ vs. x, is piece-wise parabolic, with zero gradient at x = -L and a drop across the dielectric strip, ΔT_{AB}. The temperature gradients at either side of the dielectric strip are equal.



Parts (a,b)
Temperature distributions



Part (d) Surface energy balance

(c) For case 2, the temperature drop across the thin dielectric strip follows from the surface energy balance shown above.

$$q''_x(0) = \Delta T_{AB} / R''_t \qquad q''_x(0) = \dot{q}L$$

$$\Delta T_{AB} = R''_t\,\dot{q}L = 0.0005\ m^2\cdot K/W \times 5\times10^6\ W/m^3 \times 0.020\ m = 50°C.$$

(d) For case 2, the maximum temperature in the composite wall occurs at x = -L, with the value,

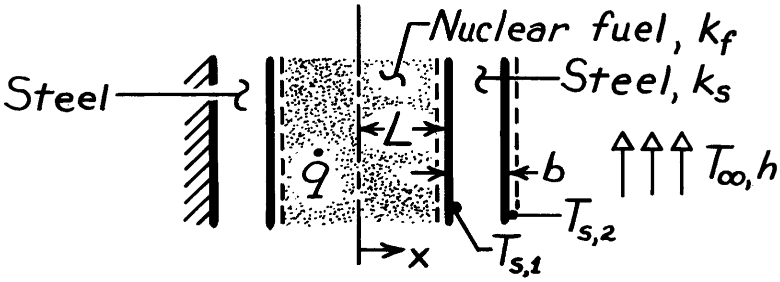
$$T_2(-L) = T_1(-L) + \Delta T_{AB} = 130°C + 50°C = 180°C$$ <

PROBLEM 3.90

KNOWN: Geometry and boundary conditions of a nuclear fuel element.

FIND: (a) Expression for the temperature distribution in the fuel, (b) Form of temperature distribution for the entire system.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional heat transfer, (2) Steady-state conditions, (3) Uniform generation, (4) Constant properties, (5) Negligible contact resistance between fuel and cladding.

ANALYSIS: (a) The general solution to the heat equation, Eq. 3.44,

$$\frac{d^2T}{dx^2} + \frac{\dot{q}}{k_f} = 0 \qquad (-L \le x \le +L)$$

is $\quad T = -\frac{\dot{q}}{2k_f}x^2 + C_1 x + C_2.$

The insulated wall at x = - (L+b) dictates that the heat flux at x = - L is zero (for an energy balance applied to a control volume about the wall, $\dot{E}_{in} = \dot{E}_{out} = 0$). Hence

$$\left.\frac{dT}{dx}\right]_{x=-L} = -\frac{\dot{q}}{k_f}(-L) + C_1 = 0 \qquad \text{or} \qquad C_1 = -\frac{\dot{q}L}{k_f}$$

$$T = -\frac{\dot{q}}{2k_f}x^2 - \frac{\dot{q}L}{k_f}x + C_2. \tag{1}$$

The value of $T_{s,1}$ may be determined from the energy conservation requirement that $\dot{E}_g = q_{cond} = q_{conv}$, or on a unit area basis.

$$\dot{q}(2L) = \frac{k_s}{b}\left(T_{s,1} - T_{s,2}\right) = h\left(T_{s,2} - T_\infty\right).$$

Hence,

$$T_{s,1} = \frac{\dot{q}(2\,Lb)}{k_s} + T_{s,2} \qquad \text{where} \qquad T_{s,2} = \frac{\dot{q}(2L)}{h} + T_\infty$$

$$T_{s,1} = \frac{\dot{q}(2\,Lb)}{k_s} + \frac{\dot{q}(2L)}{h} + T_\infty.$$

Continued …

PROBLEM 3.90 (Cont.)

Hence from Eq. (1),

$$T(L) = T_{s,1} = \frac{\dot{q}(2\,Lb)}{k_s} + \frac{\dot{q}(2\,L)}{h} + T_\infty = -\frac{3}{2}\,\frac{\dot{q}\left(L^2\right)}{k_f} + C_2$$

which yields

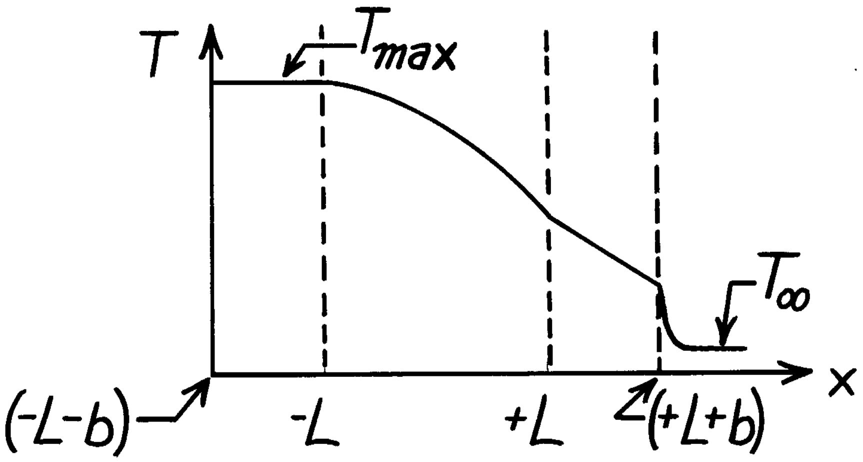
$$C_2 = T_\infty + \dot{q}L\left[\frac{2b}{k_s} + \frac{2}{h} + \frac{3}{2}\,\frac{L}{k_f}\right]$$

Hence, the temperature distribution for $(-L \le x \le +L)$ is

$$T = -\frac{\dot{q}}{2k_f}x^2 - \frac{\dot{q}L}{k_f}x + \dot{q}L\left[\frac{2b}{k_s} + \frac{2}{h} + \frac{3}{2}\,\frac{L}{k_f}\right] + T_\infty$$ <

(b) For the temperature distribution shown below,

$(-L-b) \le x \le -L$: $dT/dx=0,\ T=T_{max}$
$-L \le x \le +L$: $|\,dT/dx\,| \uparrow$ with $\uparrow$ x
$+L \le x \le L+b$: (dT/dx) is const.

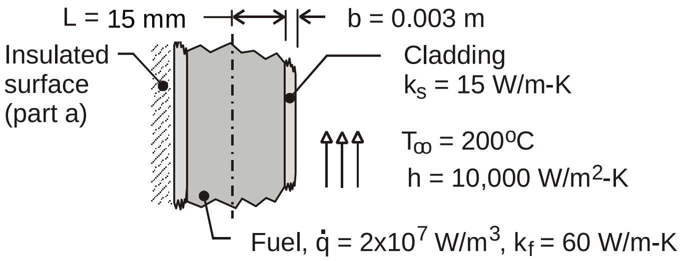


PROBLEM 3.91

KNOWN: Thermal conductivity, heat generation and thickness of fuel element. Thickness and thermal conductivity of cladding. Surface convection conditions.

FIND: (a) Temperature distribution in fuel element with one surface insulated and the other cooled by convection. Largest and smallest temperatures and corresponding locations. (b) Same as part (a) but with equivalent convection conditions at both surfaces, (c) Plot of temperature distributions.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional heat transfer, (2) Steady-state, (3) Uniform generation, (4) Constant properties, (5) Negligible contact resistance.

ANALYSIS: (a) From Eq. C.1,

$$T(x) = \frac{\dot{q}L^2}{2k_f}\left(1 - \frac{x^2}{L^2}\right) + \frac{T_{s,2} - T_{s,1}}{2}\frac{x}{L} + \frac{T_{s,1} + T_{s,2}}{2} \quad (1)$$

With an insulated surface at x = -L, Eq. C.10 yields

$$T_{s,1} - T_{s,2} = \frac{2\dot{q}L^2}{k_f} \quad (2)$$

and with convection at x = L + b, Eq. C.13 yields

$$U\left(T_{s,2} - T_\infty\right) = \dot{q}L - \frac{k_f}{2L}\left(T_{s,2} - T_{s,1}\right)$$

$$T_{s,1} - T_{s,2} = \frac{2LU}{k_f}\left(T_{s,2} - T_\infty\right) - \frac{2\dot{q}L^2}{k_f} \quad (3)$$

where $U^{-1} = h^{-1} + b/k_s$. Subtracting Eq. (2) from Eq. (3),

$$0 = \frac{2LU}{k_f}\left(T_{s,2} - T_\infty\right) - \frac{4\dot{q}L^2}{k_f}$$

$$T_{s,2} = T_\infty + \frac{2\dot{q}L}{U} \quad (4)$$

Continued …

PROBLEM 3.91 (Cont.)

Alternatively, this result could have been found from an energy balance on the wall which equates the generated heat to the heat leaving at L+b,

$$2\dot{q}L = U(T_{s,2} - T_{\infty})$$

Substituting Eq. (4) into Eq. (2)

$$T_{s,1} = T_{\infty} + 2\dot{q}L\left(\frac{L}{k_f} + \frac{1}{U}\right) \qquad (5)$$

Substituting Eqs. (4) and (5) into Eq. (1),

$$T(x) = -\frac{\dot{q}}{2k_f}x^2 - \frac{\dot{q}L}{k_f}x + \dot{q}L\left(\frac{2}{U} + \frac{3}{2}\frac{L}{k_f}\right) + T_{\infty}$$

Or,

$$T(x) = -\frac{\dot{q}}{2k_f}x^2 - \frac{\dot{q}L}{k_f}x + \dot{q}L\left(\frac{2b}{k_s} + \frac{2}{h} + \frac{3}{2}\frac{L}{k_f}\right) + T_{\infty} \qquad (6) <$$

The maximum temperature occurs at x = - L and is

$$T(-L) = 2\dot{q}L\left(\frac{b}{k_s} + \frac{1}{h} + \frac{L}{k_f}\right) + T_{\infty}$$

$$T(-L) = 2 \times 2 \times 10^7\ \text{W/m}^3 \times 0.015\,\text{m}\left(\frac{0.003\text{m}}{15\ \text{W/m}\cdot\text{K}} + \frac{1}{10,000\ \text{W/m}^2\cdot\text{K}} + \frac{0.015\ \text{m}}{60\ \text{W/m}\cdot\text{K}}\right) + 200°\text{C} = 530°\text{C} \qquad <$$

The lowest temperature is at x = + L and is

$$T(+L) = -\frac{3}{2}\frac{\dot{q}L^2}{k_f} + \dot{q}L\left(\frac{2b}{k_s} + \frac{2}{h} + \frac{3}{2}\frac{L}{k_f}\right) + T_{\infty} = 380°\text{C} \qquad <$$

(b) If a convection condition is maintained at x = - L, Eq. C.12 reduces to

$$U(T_{\infty} - T_{s,1}) = -\dot{q}L - \frac{k_f}{2L}(T_{s,2} - T_{s,1})$$

$$T_{s,1} - T_{s,2} = \frac{2LU}{k_f}(T_{s,1} - T_{\infty}) - \frac{2\dot{q}L^2}{k_f} \qquad (7)$$

Subtracting Eq. (7) from Eq. (3),

$$0 = \frac{2LU}{k_f}(T_{s,2} - T_{\infty} - T_{s,1} + T_{\infty}) \qquad \text{or} \qquad T_{s,1} = T_{s,2}$$

Hence, from Eq. (7)

Continued …

PROBLEM 3.91 (Cont.)

$$T_{s,1} = T_{s,2} = \frac{\dot{q}L}{U} + T_\infty = \dot{q}L\left(\frac{1}{h} + \frac{b}{k_s}\right) + T_\infty \qquad (8)$$

Substituting into Eq. (1), the temperature distribution is

$$T(x) = \frac{\dot{q}L^2}{2k_f}\left(1 - \frac{x^2}{L^2}\right) + \dot{q}L\left(\frac{1}{h} + \frac{b}{k_s}\right) + T_\infty \qquad (9) \quad <$$

The maximum temperature is at x = 0 and is

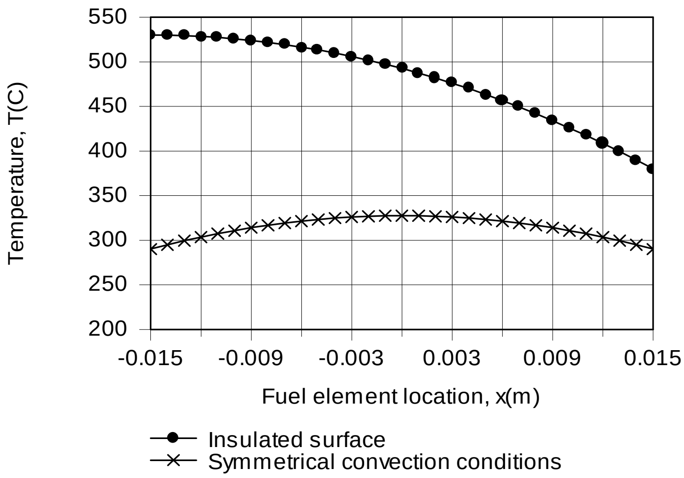
$$T(0) = \frac{2\times10^7\ W/m^3(0.015\,m)^2}{2\times60\ W/m\cdot K} + 2\times10^7\ W/m^3\times0.015\,m\left(\frac{1}{10,000\ W/m^2\cdot K} + \frac{0.003\,m}{15\ W/m\cdot K}\right) + 200°C$$

$$T(0) = 37.5°C + 90°C + 200°C = 327.5°C \quad <$$

The minimum temperature at x = ± L is

$$T_{s,1} = T_{s,2} = 2\times10^7\ W/m^3(0.015\,m)\left(\frac{1}{10,000\ W/m^2\cdot K} + \frac{0.003\,m}{15\ W/m\cdot K}\right) + 200°C = 290°C \quad <$$

(c) The temperature distributions are as shown.



The amount of heat generation is the same for both cases, but the ability to transfer heat from both surfaces for case (b) results in lower temperatures throughout the fuel element.

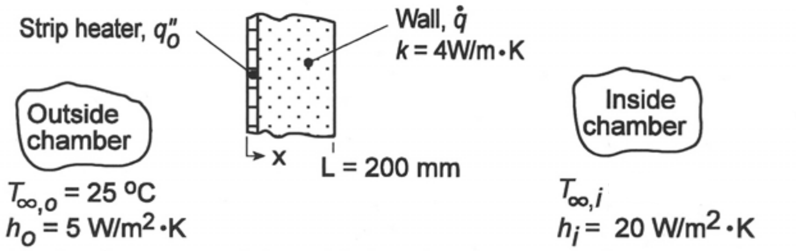
COMMENTS: Note that for case (a), the temperature in the insulated cladding is constant and equivalent to $T_{s,1}$ = 530°C.

PROBLEM 3.92

KNOWN: Wall of thermal conductivity k and thickness L with uniform generation and strip heater with uniform heat flux q''_o; prescribed inside and outside air conditions ($T_{\infty,i}$, h_i, $T_{\infty,o}$, h_o). Strip heater acts to guard against heat losses from the wall to the outside.

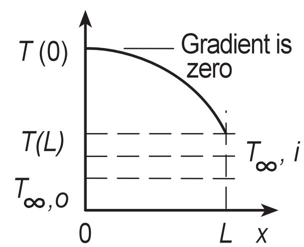
FIND: Compute and plot q''_o and T(0) as a function of $\dot{q}$ for $200 \le \dot{q} \le 2000$ W/m^3 and $T_{\infty,i}$ = 30, 50 and 70°C.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Uniform volumetric generation, (4) Constant properties.

ANALYSIS: If no heat generated within the wall will be lost to the outside of the chamber, the gradient at the position x = 0 must be zero. Since $\dot{q}$ is uniform, the temperature distribution must be parabolic as shown in the sketch.



To determine the required heater flux q''_o as a function of the operation conditions $\dot{q}$ and $T_{\infty,i}$, the analysis begins by considering the temperature distribution in the wall and then surface energy balances at the two wall surfaces. The analysis is organized for easy treatment with equation-solving software.

Temperature distribution in the wall, T(x): The general solution for the temperature distribution in the wall is, Eq. 3.45,

$$T(x) = -\frac{\dot{q}}{2k}x^2 + C_1 x + C_2$$

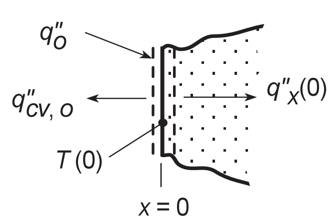
and the guard condition at the outer wall, x = 0, requires that the conduction heat flux be zero. Using Fourier's law,

$$q''_x(0) = -k\left.\frac{dT}{dx}\right|_{x=0} = -kC_1 = 0 \qquad (C_1 = 0) \qquad (1)$$

At the outer wall, x = 0,

$$T(0) = C_2 \qquad (2)$$

Heater energy balance, x = 0:



$$\dot{E}_{in} + \dot{E}_g - \dot{E}_{out} = 0$$

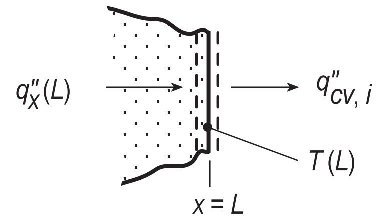
$$0 + q''_o - q''_{cv,o} - q''_x(0) = 0 \qquad (3)$$

$$q''_{cv,o} = h_o\left(T(0) - T_{\infty,o}\right), q''_x(0) = 0 \qquad (4a,b)$$

Continued...

PROBLEM 3.92 (Cont.)

Surface energy balance, x = L:



$$\dot{E}_{in} - \dot{E}_{out} = 0$$

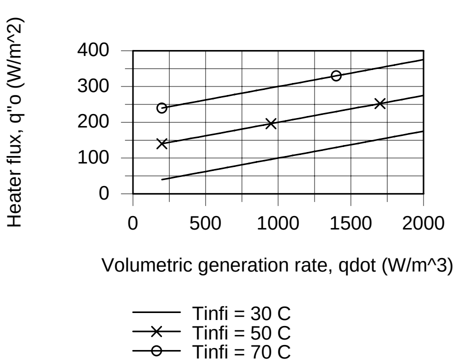
$$q''_x(L) - q''_{cv,i} = 0 \qquad (5)$$

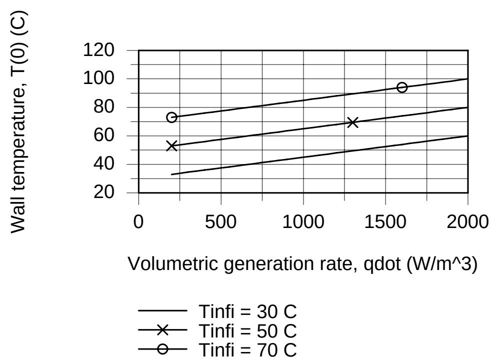
$$q''_x(L) = -k\left.\frac{dT}{dx}\right|_{x=L} = +\dot{q}L \qquad (6)$$

$$q''_{cv,i} = h_i\left[T(L) - T_{\infty,i}\right]$$

$$q''_{cv,i} = h_i\left[-\frac{\dot{q}}{2k}L^2 + T(0) - T_{\infty,i}\right] \qquad (7)$$

Solving Eqs. (3) through (7) simultaneously with appropriate numerical values and performing the parametric analysis, the results are plotted below.





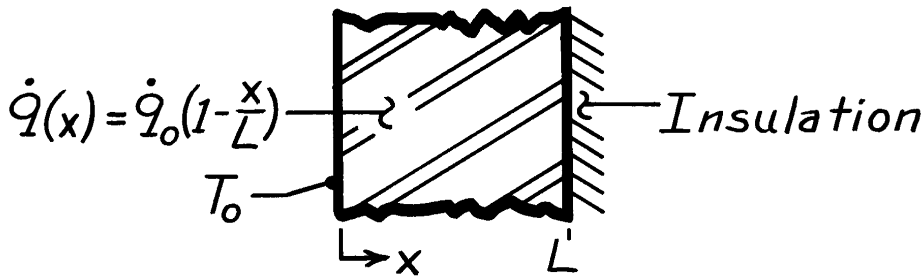
From the first plot, the heater flux q''_o is a linear function of the volumetric generation rate $\dot{q}$. As expected, the higher $\dot{q}$ and $T_{\infty,i}$, the higher the heat flux required to maintain the guard condition ($q''_x(0) = 0$). Notice that for any $\dot{q}$ condition, equal changes in $T_{\infty,i}$ result in equal changes in the required q''_o. The outer wall temperature T(0) is also linearly dependent upon $\dot{q}$. From our knowledge of the temperature distribution, it follows that for any $\dot{q}$ condition, the outer wall temperature T(0) will track changes in $T_{\infty,i}$.

PROBLEM 3.93

KNOWN: Plane wall with prescribed nonuniform volumetric generation having one boundary insulated and the other isothermal.

FIND: Temperature distribution, T(x), in terms of x, L, k, $\dot{q}_o$ and T_o.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in x-direction, (3) Constant properties.

ANALYSIS: The appropriate form the heat diffusion equation is

$$\frac{d}{dx}\left[\frac{dT}{dx}\right]+\frac{\dot{q}}{k}=0.$$

Noting that $\dot{q}=\dot{q}(x)=\dot{q}_o\ (1-x/L)$, substitute for $\dot{q}(x)$ into the above equation, separate variables and then integrate,

$$d\left[\frac{dT}{dx}\right]=-\frac{\dot{q}_o}{k}\left[1-\frac{x}{L}\right]dx \qquad \frac{dT}{dx}=-\frac{\dot{q}_o}{k}\left[x-\frac{x^2}{2L}\right]+C_1.$$

Separate variables and integrate again to obtain the general form of the temperature distribution in the wall,

$$dT=-\frac{\dot{q}_o}{k}\left[x-\frac{x^2}{2L}\right]dx+C_1dx \qquad T(x)=-\frac{\dot{q}_o}{k}\left[\frac{x^2}{2}-\frac{x^3}{6L}\right]+C_1x+C_2.$$

Identify the boundary conditions at x = 0 and x = L to evaluate C_1 and C_2. At x = 0,

$$T(0)=T_o=-\frac{\dot{q}_o}{k}(0-0)+C_1\cdot 0+C_2 \qquad \text{hence, } C_2=T_o$$

At x = L,

$$\left.\frac{dT}{dx}\right]_{x=L}=0=-\frac{\dot{q}_o}{k}\left[L-\frac{L^2}{2L}\right]+C_1 \qquad \text{hence, } C_1=\frac{\dot{q}_oL}{2k}$$

The temperature distribution is

$$T(x)=-\frac{\dot{q}_o}{k}\left[\frac{x^2}{2}-\frac{x^3}{6L}\right]+\frac{\dot{q}_oL}{2k}x+T_o.$$ <

COMMENTS: It is good practice to test the final result for satisfying BCs. The heat flux at x = 0 can be found using Fourier's law or from an overall energy balance

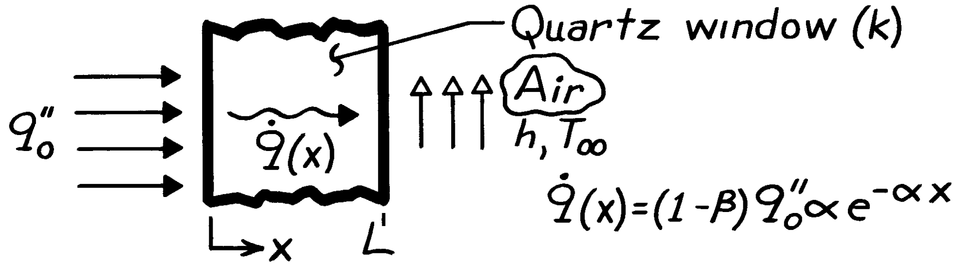
$$\dot{E}_{out}=\dot{E}_g=\int_0^L \dot{q}dV \qquad \text{to obtain} \qquad q''_{out}=\dot{q}_oL/2.$$

PROBLEM 3.94

KNOWN: Distribution of volumetric heating and surface conditions associated with a quartz window.

FIND: Temperature distribution in the quartz.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Negligible radiation emission and convection at inner surface (x = 0) and negligible emission from outer surface, (4) Constant properties.

ANALYSIS: The appropriate form of the heat equation for the quartz is obtained by substituting the prescribed form of $\dot{q}$ into Eq. 3.44.

$$\frac{d^2T}{dx^2} + \frac{\alpha(1-\beta)q''_o}{k} e^{-\alpha x} = 0$$

Integrating,

$$\frac{dT}{dx} = +\frac{(1-\beta)q''_o}{k} e^{-\alpha x} + C_1 \qquad T = -\frac{(1-\beta)}{k\alpha} q''_o e^{-\alpha x} + C_1 x + C_2$$

Boundary Conditions:

$$-k\, dT/dx)_{x=o} = \beta q''_o$$
$$-k\, dT/dx)_{x=L} = h\left[T(L) - T_\infty\right]$$

Hence, at x = 0:

$$-k\left[\frac{(1-\beta)}{k} q''_o + C_1\right] = \beta q''_o$$
$$C_1 = -q''_o / k$$

At x = L:

$$-k\left[\frac{(1-\beta)}{k} q''_o e^{-\alpha L} + C_1\right] = h\left[-\frac{(1-\beta)}{k\alpha} q''_o e^{-\alpha L} + C_1 L + C_2 - T_\infty\right]$$

Substituting for C_1 and solving for C_2,

$$C_2 = \frac{q''_o}{h}\left[1-(1-\beta)e^{-\alpha L}\right] + \frac{q''_o L}{k} + \frac{q''_o(1-\beta)}{k\alpha} e^{-\alpha L} + T_\infty.$$

Hence,

$$T(x) = \frac{(1-\beta)q''_o}{k\alpha}\left[e^{-\alpha L} - e^{-\alpha x}\right] + \frac{q''_o}{k}(L-x) + \frac{q''_o}{h}\left[1-(1-\beta)e^{-\alpha L}\right] + T_\infty. \quad <$$

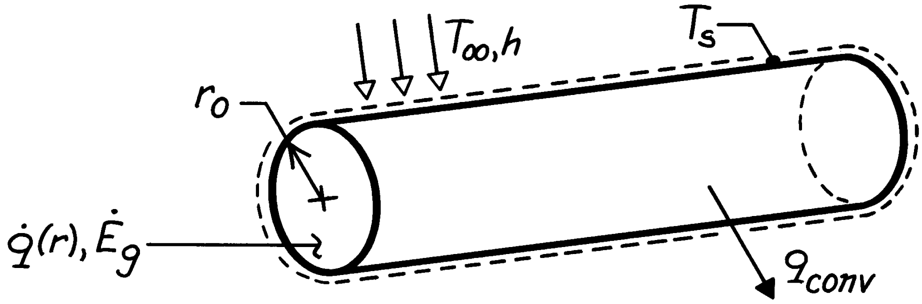
COMMENTS: The temperature distribution depends strongly on the radiative coefficients, α and β. For α → ∞ or β = 1, the heating occurs entirely at x = 0 (no volumetric heating).

PROBLEM 3.95

KNOWN: Radial distribution of heat dissipation in a cylindrical container of radioactive wastes. Surface convection conditions.

FIND: Radial temperature distribution.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible temperature drop across container wall.

ANALYSIS: The appropriate form of the heat equation is

$$\frac{1}{r}\frac{d}{dr}\left(r\frac{dT}{dr}\right) = -\frac{\dot{q}}{k} = -\frac{\dot{q}_o}{k}\left(1-\frac{r^2}{r_o^2}\right)$$

$$r\frac{dT}{dr} = -\frac{\dot{q}_o r^2}{2k} + \frac{\dot{q}_o r^4}{4kr_o^2} + C_1 \qquad T = -\frac{\dot{q}_o r^2}{4k} + \frac{\dot{q}_o r^4}{16kr_o^2} + C_1 \ln r + C_2.$$

From the boundary conditions,

$$\frac{dT}{dr}\Big|_{r=0} = 0 \rightarrow C_1 = 0 \qquad -k\frac{dT}{dr}\Big|_{r=r_o} = h\left[T(r_o) - T_\infty\right]$$

$$+\frac{\dot{q}_o r_o}{2} - \frac{\dot{q}_o r_o}{4} = h\left[-\frac{\dot{q}_o r_o^2}{4k} + \frac{\dot{q}_o r_o^2}{16k} + C_2 - T_\infty\right]$$

$$C_2 = \frac{\dot{q}_o r_o}{4h} + \frac{3\dot{q}_o r_o^2}{16k} + T_\infty.$$

Hence

$$T(r) = T_\infty + \frac{\dot{q}_o r_o}{4h} + \frac{\dot{q}_o r_o^2}{k}\left[\frac{3}{16} - \frac{1}{4}\left(\frac{r}{r_o}\right)^2 + \frac{1}{16}\left(\frac{r}{r_o}\right)^4\right].$$ <

COMMENTS: Applying the above result at r_o yields

$$T_s = T(r_o) = T_\infty + (\dot{q}_o r_o)/4h$$

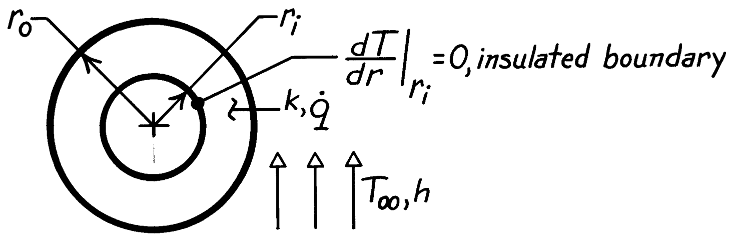
The same result may be obtained by applying an energy balance to a control surface about the container, where $\dot{E}_g = q_{conv}$. The maximum temperature exists at r = 0.

PROBLEM 3.96

KNOWN: Cylindrical shell with uniform volumetric generation is insulated at inner surface and exposed to convection on the outer surface.

FIND: (a) Temperature distribution in the shell in terms of r_i, r_o, $\dot{q}$, h, T_∞ and k, (b) Expression for the heat rate per unit length at the outer radius, $q'(r_o)$.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial (cylindrical) conduction in shell, (3) Uniform generation, (4) Constant properties.

ANALYSIS: (a) The general form of the temperature distribution and boundary conditions are

$$T(r) = -\frac{\dot{q}}{4k}r^2 + C_1 \ln r + C_2$$

at r = r_i: $$\left.\frac{dT}{dr}\right)_{r_i} = 0 = -\frac{\dot{q}}{2k}r_i + C_1\frac{1}{r_i} + 0 \qquad C_1 = \frac{\dot{q}}{2k}r_i^2$$

at r = r_o: $$-k\left.\frac{dT}{dr}\right)_{r_o} = h\left[T(r_o) - T_\infty\right] \qquad \text{surface energy balance}$$

$$-k\left[-\frac{\dot{q}}{2k}r_o + \left(\frac{\dot{q}}{2k}r_i^2 \cdot \frac{1}{r_o}\right)\right] = h\left[-\frac{\dot{q}}{4k}r_o^2 + \left(\frac{\dot{q}}{2k}r_i^2\right)\ln r_o + C_2 - T_\infty\right]$$

$$C_2 = -\frac{\dot{q}r_o}{2h}\left[1 - \left(\frac{r_i}{r_o}\right)^2\right] + \frac{\dot{q}r_o^2}{2k}\left[\frac{1}{2} - \left(\frac{r_i}{r_o}\right)^2 \ln r_o\right] + T_\infty$$

Hence,

$$T(r) = \frac{\dot{q}}{4k}\left(r_o^2 - r^2\right) + \frac{\dot{q}r_i^2}{2k}\ln\left(\frac{r}{r_o}\right) - \frac{\dot{q}r_o}{2h}\left[1 - \left(\frac{r_i}{r_o}\right)^2\right] + T_\infty. \qquad <$$

(b) From an overall energy balance on the shell,

$$q_r'(r_o) = \dot{E}_g' = \dot{q}\pi\left(r_o^2 - r_i^2\right). \qquad <$$

Alternatively, the heat rate may be found using Fourier's law and the temperature distribution,

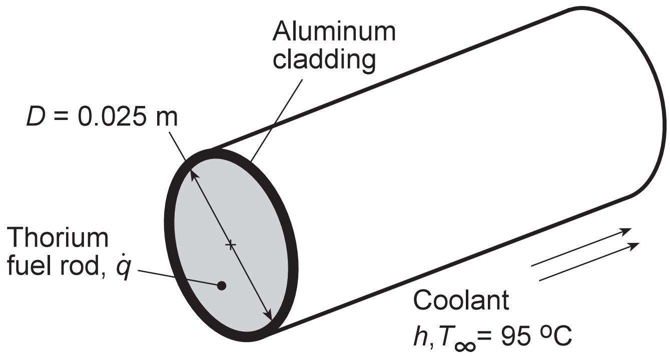
$$q_r'(r) = -k(2\pi\ r_o)\left.\frac{dT}{dr}\right)_{r_o} = -2\pi\ kr_o\left[-\frac{\dot{q}}{2k}r_o + \frac{\dot{q}r_i^2}{2k}\ \frac{1}{r_o} + 0 + 0\right] = \dot{q}\pi\left(r_o^2 - r_i^2\right)$$

PROBLEM 3.97

KNOWN: Energy generation in an aluminum-clad, thorium fuel rod under specified operating conditions.

FIND: (a) Whether prescribed operating conditions are acceptable, (b) Effect of $\dot{q}$ and h on acceptable operating conditions.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in r-direction, (2) Steady-state conditions, (3) Constant properties, (4) Negligible temperature gradients in aluminum and contact resistance between aluminum and thorium.

PROPERTIES: *Table A-1*, Aluminum, pure: M.P. = 933 K; *Table A-1*, Thorium: M.P. = 2023 K, k ≈ 60 W/m·K.

ANALYSIS: (a) System failure would occur if the melting point of either the thorium or the aluminum were exceeded. From Eq. 3.58, the maximum thorium temperature, which exists at r = 0, is

$$T(0) = \frac{\dot{q} r_o^2}{4k} + T_s = T_{Th,max}$$

where, from the energy balance equation, Eq. 3.60, the surface temperature, which is also the aluminum temperature, is

$$T_s = T_\infty + \frac{\dot{q} r_o}{2h} = T_{Al}$$

Hence,

$$T_{Al} = T_s = 95^\circ C + \frac{7\times10^8\ W/m^3 \times 0.0125\,m}{14,000\ W/m^2\cdot K} = 720^\circ C = 993\,K$$

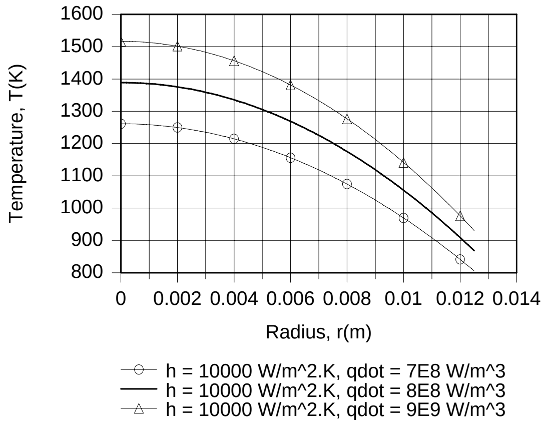
$$T_{Th,max} = \frac{7\times10^8\ W/m^3\,(0.0125m)^2}{4\times60\ W/m\cdot K} + 993\,K = 1449\,K$$ <

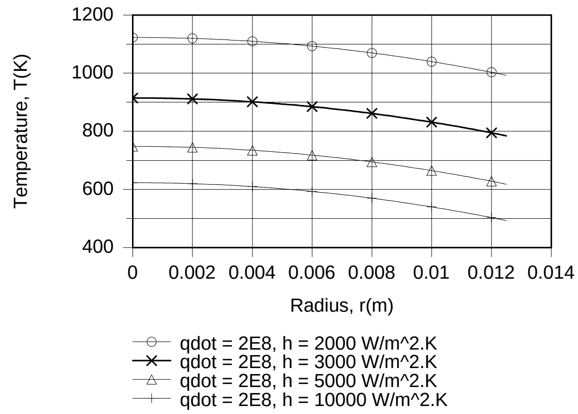
Although $T_{Th,max} < M.P._{Th}$ and the thorium would not melt, $T_{al} > M.P._{Al}$ and the cladding would melt under the proposed operating conditions. The problem could be eliminated by *decreasing* $\dot{q}$ or r_o, *increasing* h or using a cladding material with a higher melting point.

(b) Using the one-dimensional, steady-state conduction model (solid cylinder) of the IHT software, the following radial temperature distributions were obtained for parametric variations in $\dot{q}$ and h.

Continued...

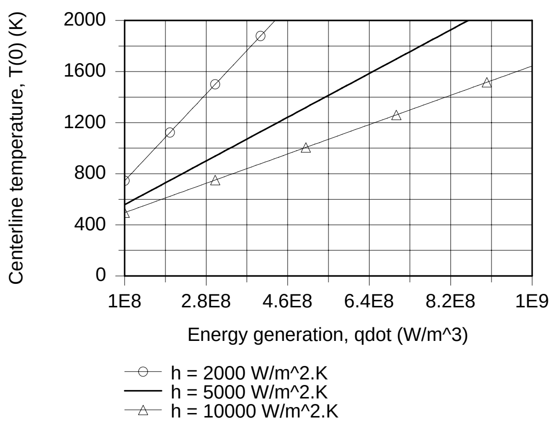
PROBLEM 3.97 (Cont.)

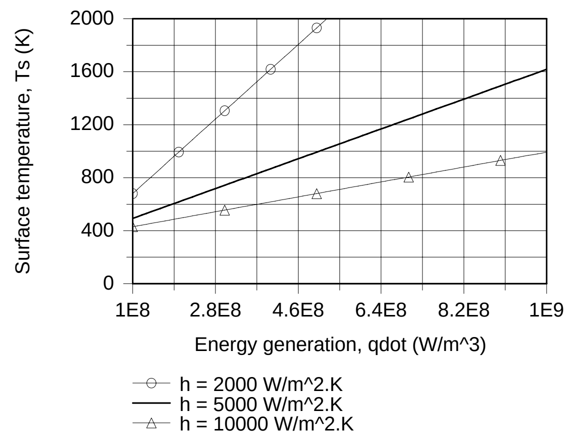




For h = 10,000 $W/m^2 \cdot K$, which represents a reasonable upper limit with water cooling, the temperature of the aluminum would be well below its melting point for $\dot{q} = 7 \times 10^8$ W/m^3, but would be close to the melting point for $\dot{q} = 8 \times 10^8$ W/m^3 and would exceed it for $\dot{q} = 9 \times 10^8$ W/m^3. Hence, under the best of conditions, $\dot{q} \approx 7 \times 10^8$ W/m^3 corresponds to the maximum allowable energy generation. However, if coolant flow conditions are constrained to provide values of h < 10,000 $W/m^2 \cdot K$, volumetric heating would have to be reduced. Even for $\dot{q}$ as low as 2×10^8 W/m^3, operation could not be sustained for h = 2000 $W/m^2 \cdot K$.

The effects of $\dot{q}$ and h on the centerline and surface temperatures are shown below.





For h = 2000 and 5000 $W/m^2 \cdot K$, the melting point of thorium would be approached for $\dot{q} \approx 4.4 \times 10^8$ and 8.5×10^8 W/m^3, respectively. For h = 2000, 5000 and 10,000 $W/m^2 \cdot K$, the melting point of aluminum would be approached for $\dot{q} \approx 1.6 \times 10^8$, 4.3×10^8 and 8.7×10^8 W/m^3. Hence, the envelope of acceptable operating conditions must call for a reduction in $\dot{q}$ with decreasing h, from a maximum of $\dot{q} \approx 7 \times 10^8$ W/m^3 for h = 10,000 $W/m^2 \cdot K$.

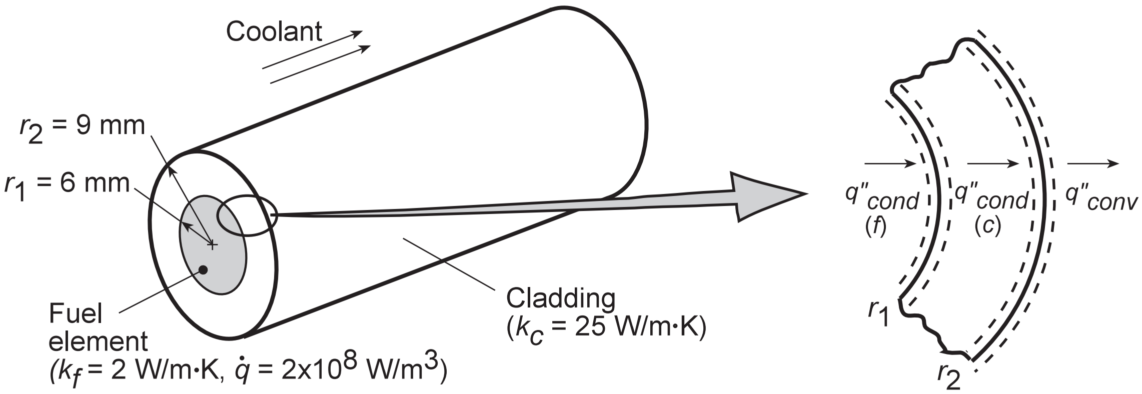
COMMENTS: Note the problem which would arise in the event of a *loss of coolant*, for which case h would *decrease* drastically.

PROBLEM 3.98

KNOWN: Radii and thermal conductivities of reactor fuel element and cladding. Fuel heat generation rate. Temperature and convection coefficient of coolant.

FIND: (a) Expressions for temperature distributions in fuel and cladding, (b) Maximum fuel element temperature for prescribed conditions, (c) Effect of h on temperature distribution.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Negligible contact resistance, (4) Constant properties.

ANALYSIS: (a) From Eqs. 3.54 and 3.28, the heat equations for the fuel (f) and cladding (c) are

$$\frac{1}{r}\frac{d}{dr}\left(r\frac{dT_f}{dr}\right) = -\frac{\dot{q}}{k_f} \qquad (0 \le r \le r_1) \qquad \frac{1}{r}\frac{d}{dr}\left(r\frac{dT_c}{dr}\right) = 0 \qquad (r_1 \le r \le r_2)$$

Hence, integrating both equations twice,

$$\frac{dT_f}{dr} = -\frac{\dot{q}r}{2k_f} + \frac{C_1}{k_f r} \qquad T_f = -\frac{\dot{q}r^2}{4k_f} + \frac{C_1}{k_f}\ln r + C_2 \tag{1,2}$$

$$\frac{dT_c}{dr} = \frac{C_3}{k_c r} \qquad T_c = \frac{C_3}{k_c}\ln r + C_4 \tag{3,4}$$

The corresponding boundary conditions are:

$$dT_f/dr)_{r=0} = 0 \qquad T_f(r_1) = T_c(r_1) \tag{5,6}$$

$$-k_f\frac{dT_f}{dr}\bigg)_{r=r_1} = -k_c\frac{dT_c}{dr}\bigg)_{r=r_1} \qquad -k_c\frac{dT_c}{dr}\bigg)_{r=r_2} = h\left[T_c(r_2) - T_\infty\right] \tag{7,8}$$

Note that Eqs. (7) and (8) are obtained from surface energy balances at r_1 and r_2, respectively. Applying Eq. (5) to Eq. (1), it follows that $C_1 = 0$. Hence,

$$T_f = -\frac{\dot{q}r^2}{4k_f} + C_2 \tag{9}$$

From Eq. (6), it follows that

$$-\frac{\dot{q}r_1^2}{4k_f} + C_2 = \frac{C_3\ln r_1}{k_c} + C_4 \tag{10}$$

Continued...

PROBLEM 3.98 (Cont.)

Also, from Eq. (7),

$$\frac{\dot{q}r_1}{2} = -\frac{C_3}{r_1} \qquad \text{or} \qquad C_3 = -\frac{\dot{q}r_1^2}{2} \tag{11}$$

Finally, from Eq. (8), $-\frac{C_3}{r_2} = h\left[\frac{C_3}{k_c}\ln r_2 + C_4 - T_\infty\right]$ or, substituting for C_3 and solving for C_4

$$C_4 = \frac{\dot{q}r_1^2}{2r_2 h} + \frac{\dot{q}r_1^2}{2k_c}\ln r_2 + T_\infty \tag{12}$$

Substituting Eqs. (11) and (12) into (10), it follows that

$$C_2 = \frac{\dot{q}r_1^2}{4k_f} - \frac{\dot{q}r_1^2 \ln r_1}{2k_c} + \frac{\dot{q}r_1^2}{2r_2 h} + \frac{\dot{q}r_1^2}{2k_c}\ln r_2 + T_\infty$$

$$C_2 = \frac{\dot{q}r_1^2}{4k_f} + \frac{\dot{q}r_1^2}{2k_c}\ln\frac{r_2}{r_1} + \frac{\dot{q}r_1^2}{2r_2 h} + T_\infty \tag{13}$$

Substituting Eq. (13) into (9),

$$T_f = \frac{\dot{q}}{4k_f}\left(r_1^2 - r^2\right) + \frac{\dot{q}r_1^2}{2k_c}\ln\frac{r_2}{r_1} + \frac{\dot{q}r_1^2}{2r_2 h} + T_\infty \tag{14}$$ <

Substituting Eqs. (11) and (12) into (4),

$$T_c = \frac{\dot{q}r_1^2}{2k_c}\ln\frac{r_2}{r} + \frac{\dot{q}r_1^2}{2r_2 h} + T_\infty . \tag{15}$$ <

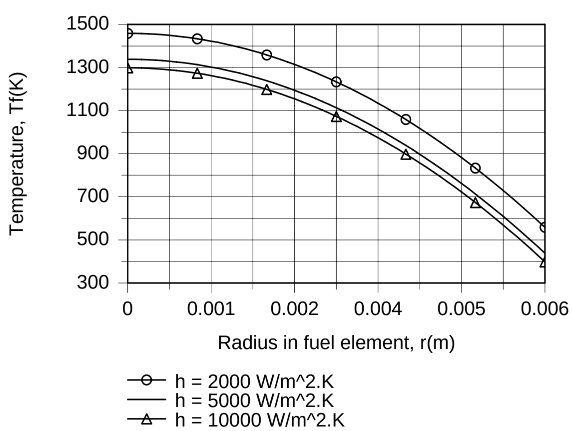
(b) Applying Eq. (14) at r = 0, the maximum fuel temperature for h = 2000 W/m^2·K is

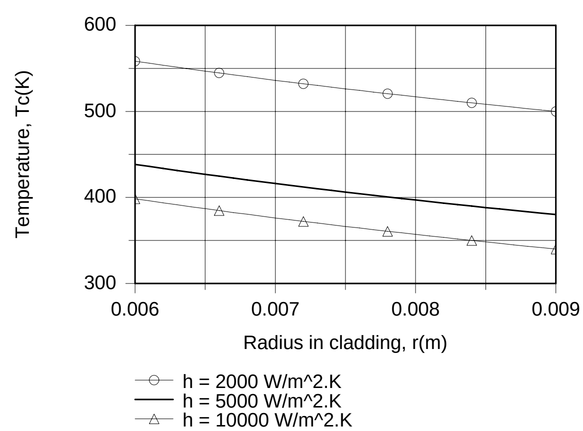
$$T_f(0) = \frac{2\times10^8\ \text{W/m}^3 \times (0.006\ \text{m})^2}{4\times 2\ \text{W/m}\cdot\text{K}} + \frac{2\times10^8\ \text{W/m}^3 \times (0.006\ \text{m})^2}{2\times 25\ \text{W/m}\cdot\text{K}}\ln\frac{0.009\ \text{m}}{0.006\ \text{m}}$$

$$+ \frac{2\times10^8\ \text{W/m}^3 (0.006\ \text{m})^2}{2\times(0.009\ \text{m})2000\ \text{W/m}^2\cdot\text{K}} + 300\ \text{K}$$

$$T_f(0) = (900 + 58.4 + 200 + 300)\ \text{K} = 1458\ \text{K} .$$ <

(c) Temperature distributions for the prescribed values of h are as follows:





Continued...

PROBLEM 3.98 (Cont.)

Clearly, the ability to control the maximum fuel temperature by increasing h is limited, and even for $h \to \infty$, $T_f(0)$ exceeds 1000 K. The overall temperature drop, $T_f(0) - T_\infty$, is influenced principally by the low thermal conductivity of the fuel material.

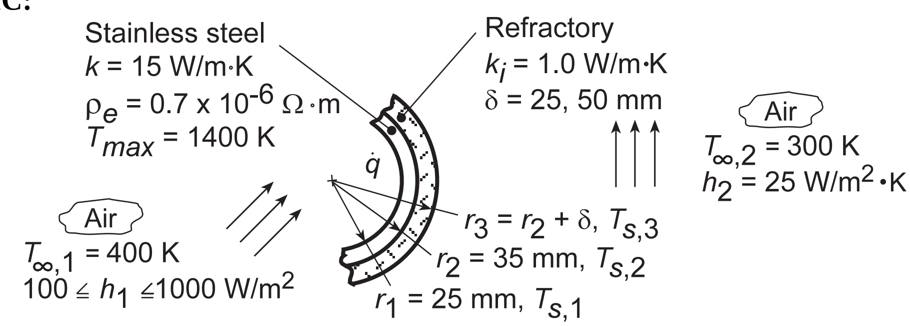
COMMENTS: For the prescribed conditions, Eq. (14) yields, $T_f(0) - T_f(r_1) = \dot{q} r_1^2 / 4k_f = (2\times10^8$ $W/m^3)(0.006\ m)^3/8\ W/m\cdot K = 900\ K$, in which case, with no cladding and $h \to \infty$, $T_f(0) = 1200$ K. To reduce $T_f(0)$ below 1000 K for the prescribed material, it is necessary to reduce $\dot{q}$.

PROBLEM 3.99

KNOWN: Dimensions and properties of tubular heater and external insulation. Internal and external convection conditions. Maximum allowable tube temperature.

FIND: (a) Maximum allowable heater current for adiabatic outer surface, (3) Effect of internal convection coefficient on heater temperature distribution, (c) Extent of heat loss at outer surface.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, steady-state conditions, (2) Constant properties, (3) Uniform heat generation, (4) Negligible radiation at outer surface, (5) Negligible contact resistance.

ANALYSIS: (a) From Eqs. 7 and 10, respectively, of Example 3.8, we know that

$$T_{s,2} - T_{s,1} = \frac{\dot{q}}{2k} r_2^2 \ln\frac{r_2}{r_1} - \frac{\dot{q}}{4k}\left(r_2^2 - r_1^2\right) \qquad (1)$$

and

$$T_{s,1} = T_{\infty,1} + \frac{\dot{q}\left(r_2^2 - r_1^2\right)}{2h_1 r_1} \qquad (2)$$

Hence, eliminating $T_{s,1}$, we obtain

$$T_{s,2} - T_{\infty,1} = \frac{\dot{q} r_2^2}{2k}\left[\ln\frac{r_2}{r_1} - \frac{1}{2}\left(1 - r_1^2/r_2^2\right) + \frac{k}{h_1 r_1}\left(1 - r_1^2/r_2^2\right)\right]$$

Substituting the prescribed conditions ($h_1 = 100\ W/m^2 \cdot K$),

$$T_{s,2} - T_{\infty,1} = 1.237 \times 10^{-4}\left(m^3 \cdot K/W\right)\dot{q}\left(W/m^3\right)$$

Hence, with T_{max} corresponding to $T_{s,2}$, the maximum allowable value of $\dot{q}$ is

$$\dot{q}_{max} = \frac{1400 - 400}{1.237 \times 10^{-4}} = 8.084 \times 10^6\ W/m^3$$

with

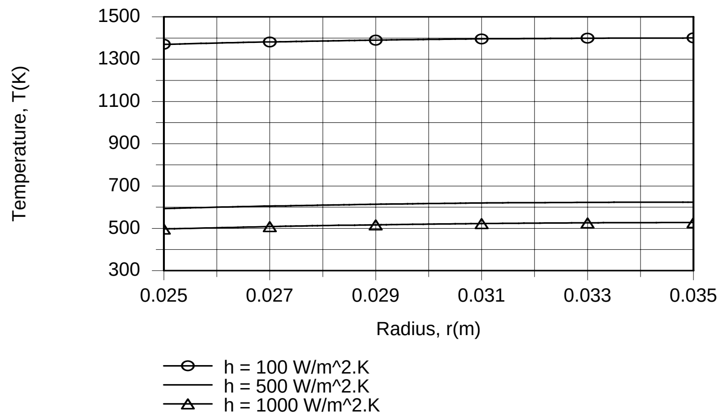
$$\dot{q} = \frac{I^2 R_e}{\forall} = \frac{I^2 \rho_e L/A_c}{LA_c} = \frac{\rho_e I^2}{\left[\pi\left(r_2^2 - r_1^2\right)\right]^2}$$

$$I_{max} = \pi\left(r_2^2 - r_1^2\right)\left(\frac{\dot{q}}{\rho_e}\right)^{1/2} = \pi\left(0.035^2 - 0.025^2\right)m^2\left(\frac{8.084 \times 10^6\ W/m^3}{0.7 \times 10^{-6}\ \Omega \cdot m}\right)^{1/2} = 6406\ A \quad <$$

Continued …

PROBLEM 3.99 (Cont.)

(b) Using the one-dimensional, steady-state conduction model of *IHT* (hollow cylinder; convection at inner surface and adiabatic outer surface), the following temperature distributions were obtained.



The results are consistent with key implications of Eqs. (1) and (2), namely that the value of h_1 has no effect on the temperature drop across the tube ($T_{s,2}$ - $T_{s,1}$ = 30 K, irrespective of h_1), while $T_{s,1}$ decreases with increasing h_1. For h_1 = 100, 500 and 1000 W/m$^2\cdot$K, respectively, the ratio of the temperature drop between the inner surface and the air to the temperature drop across the tube, $(T_{s,1} - T_{\infty,1})/(T_{s,2} - T_{s,1})$, decreases from 970/30 = 32.3 to 194/30 = 6.5 and 97/30 = 3.2. Because the outer surface is insulated, the heat rate to the airflow is fixed by the value of $\dot{q}$ and, irrespective of h_1,

$$q'(r_1) = \pi\left(r_2^2 - r_1^2\right)\dot{q} = -15,240\,\text{W}$$ <

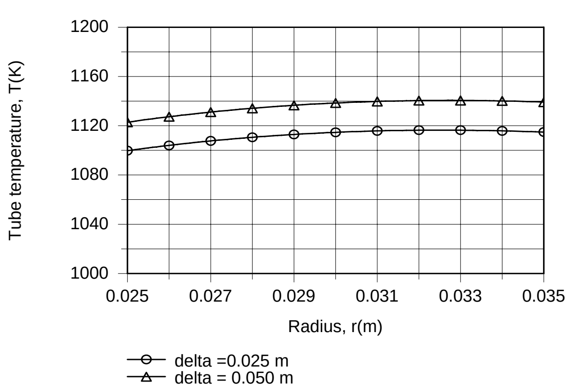
(c) Heat loss from the outer surface of the tube to the surroundings depends on the total thermal resistance

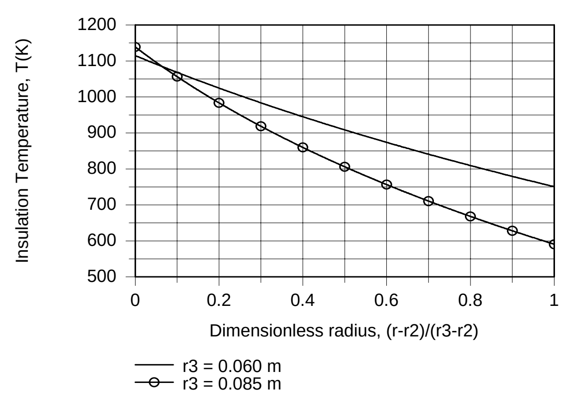
$$R_{tot} = \frac{\ln(r_3/r_2)}{2\pi L k_i} + \frac{1}{2\pi r_3 L h_2}$$

or, for a unit area on surface 2,

$$R''_{tot,2} = (2\pi r_2 L) R_{tot} = \frac{r_2 \ln(r_3/r_2)}{k_i} + \frac{r_2}{r_3 h_2}$$

Again using the capabilities of *IHT* (hollow cylinder; convection at inner surface and heat transfer from outer surface through $R''_{tot,2}$), the following temperature distributions were determined for the tube and insulation.





Continued...

PROBLEM 3.99 (Cont.)

Heat losses through the insulation, $q'(r_2)$, are 4250 and 3890 W/m for δ = 25 and 50 mm, respectively, with corresponding values of $q'(r_1)$ equal to -10,990 and -11,350 W/m. Comparing the tube temperature distributions with those predicted for an adiabatic outer surface, it is evident that the losses reduce tube wall temperatures predicted for the adiabatic surface and also shift the maximum temperature from r = 0.035 m to r ≈ 0.033 m. Although the tube outer and insulation inner surface temperatures, $T_{s,2} = T(r_2)$, increase with increasing insulation thickness, Fig. (c), the insulation outer surface temperature decreases.

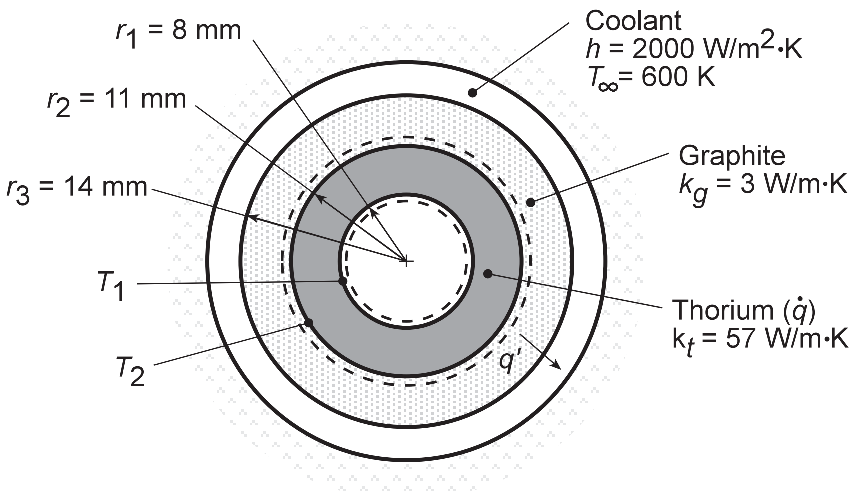
COMMENTS: If the intent is to maximize heat transfer to the airflow, heat losses to the ambient should be reduced by selecting an insulation material with a significantly smaller thermal conductivity.

PROBLEM 3.100

KNOWN: Materials, dimensions, properties and operating conditions of a gas-cooled nuclear reactor.

FIND: (a) Inner and outer surface temperatures of fuel element, (b) Temperature distributions for different heat generation rates and maximum allowable generation rate.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible contact resistance, (5) Negligible radiation.

PROPERTIES: *Table A.1*, Thorium: $T_{mp} \approx 2000$ K; *Table A.2*, Graphite: $T_{mp} \approx 2300$ K.

ANALYSIS: (a) The outer surface temperature of the fuel, T_2, may be determined from the rate equation

$$q' = \frac{T_2 - T_\infty}{R'_{tot}}$$

where

$$R'_{tot} = \frac{\ln(r_3/r_2)}{2\pi k_g} + \frac{1}{2\pi r_3 h} = \frac{\ln(14/11)}{2\pi(3\,\text{W/m}\cdot\text{K})} + \frac{1}{2\pi(0.014\,\text{m})(2000\,\text{W/m}^2\cdot\text{K})} = 0.0185\,\text{m}\cdot\text{K/W}$$

and the heat rate per unit length may be determined by applying an energy balance to a control surface about the fuel element. Since the interior surface of the element is essentially adiabatic, it follows that

$$q' = \dot{q}\pi\left(r_2^2 - r_1^2\right) = 10^8\,\text{W/m}^3 \times \pi\left(0.011^2 - 0.008^2\right)\text{m}^2 = 17,907\,\text{W/m}$$

Hence,

$$T_2 = q'R'_{tot} + T_\infty = 17,907\,\text{W/m}(0.0185\,\text{m}\cdot\text{K/W}) + 600\,\text{K} = 931\,\text{K}$$ <

With zero heat flux at the inner surface of the fuel element, Eq. C.14 yields

$$T_1 = T_2 + \frac{\dot{q}r_2^2}{4k_t}\left(1 - \frac{r_1^2}{r_2^2}\right) - \frac{\dot{q}r_1^2}{2k_t}\ln\left(\frac{r_2}{r_1}\right)$$

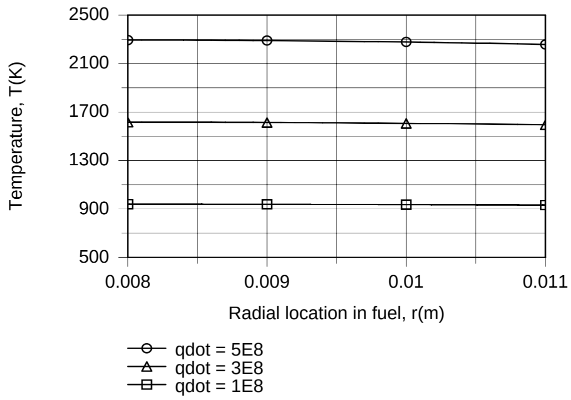
$$T_1 = 931\,\text{K} + \frac{10^8\,\text{W/m}^3(0.011\,\text{m})^2}{4\times 57\,\text{W/m}\cdot\text{K}}\left[1 - \left(\frac{0.008}{0.011}\right)^2\right] - \frac{10^8\,\text{W/m}^3(0.008\,\text{m})^2}{2\times 57\,\text{W/m}\cdot\text{K}}\ln\left(\frac{0.011}{0.008}\right)$$

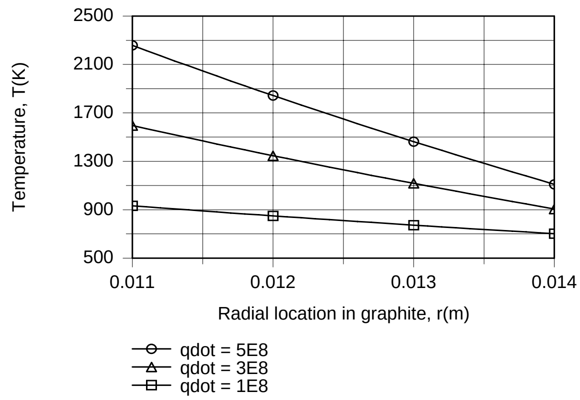
Continued...

PROBLEM 3.100 (Cont.)

$$T_1 = 931\,K + 25\,K - 18\,K = 938\,K$$ <

(b) The temperature distributions may be obtained by using the IHT model for one-dimensional, steady-state conduction in a hollow tube. For the fuel element ($\dot{q} > 0$), an adiabatic surface condition is prescribed at r_1, while heat transfer from the outer surface at r_2 to the coolant is governed by the thermal resistance $R''_{tot,2} = 2\pi r_2 R'_{tot} = 2\pi(0.011\ m)0.0185\ m{\cdot}K/W = 0.00128\ m^2{\cdot}K/W$. For the graphite ($\dot{q} = 0$), the value of T_2 obtained from the foregoing solution is prescribed as an inner boundary condition at r_2, while a convection condition is prescribed at the outer surface (r_3). For $1 \times 10^8 \le \dot{q} \le 5 \times 10^8\ W/m^3$, the following distributions are obtained.





The comparatively large value of k_t yields small temperature variations across the fuel element, while the small value of k_g results in large temperature variations across the graphite. Operation at $\dot{q} = 5 \times 10^8\ W/m^3$ is clearly unacceptable, since the melting points of thorium and graphite are exceeded and approached, respectively. To prevent softening of the materials, which would occur below their melting points, the reactor should not be operated much above $\dot{q} = 3 \times 10^8\ W/m^3$.

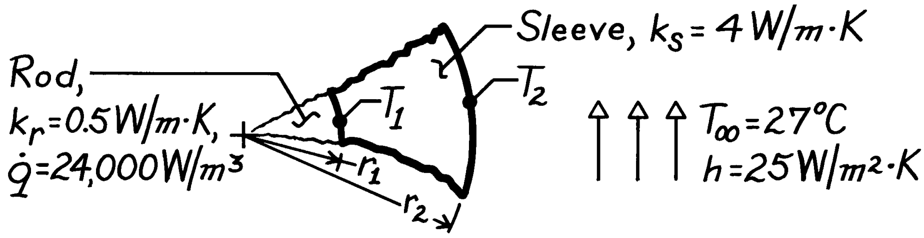
COMMENTS: A contact resistance at the thorium/graphite interface would increase temperatures in the fuel element, thereby reducing the maximum allowable value of $\dot{q}$.

PROBLEM 3.101

KNOWN: Long rod experiencing uniform volumetric generation encapsulated by a circular sleeve exposed to convection.

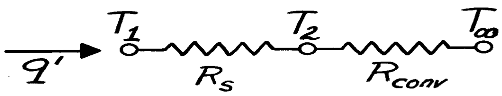
FIND: (a) Temperature at the interface between rod and sleeve and on the outer surface, (b) Temperature at center of rod.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional radial conduction in rod and sleeve, (2) Steady-state conditions, (3) Uniform volumetric generation in rod, (4) Negligible contact resistance between rod and sleeve.

ANALYSIS: (a) Construct a thermal circuit for the sleeve,



where

$$q' = \dot{E}'_{gen} = \dot{q}\pi\, D_1^2/4 = 24,000\ \text{W/m}^3 \times \pi \times (0.20\ \text{m})^2/4 = 754.0\ \text{W/m}$$

$$R'_s = \frac{\ln(r_2/r_1)}{2\pi\, k_s} = \frac{\ln(400/200)}{2\pi \times 4\ \text{W/m}\cdot\text{K}} = 2.758\times10^{-2}\text{m}\cdot\ \text{K/W}$$

$$R_{conv} = \frac{1}{h\pi\, D_2} = \frac{1}{25\ \text{W/m}^2\cdot\text{K}\times\pi\times0.400\ \text{m}} = 3.183\times10^{-2}\text{m}\cdot\ \text{K/W}$$

The rate equation can be written as

$$q' = \frac{T_1 - T_\infty}{R'_s + R'_{conv}} = \frac{T_2 - T_\infty}{R'_{conv}}$$

$$T_1 = T_\infty + q'\left(R'_s + R'_{conv}\right) = 27^\circ\text{C} + 754\ \text{W/m}\left(2.758\times10^{-2} + 3.183\times10^{-2}\right)\text{K/W}\cdot\text{m} = 71.8^\circ\text{C}$$ <

$$T_2 = T_\infty + q'R'_{conv} = 27^\circ\text{C} + 754\ \text{W/m}\times3.183\times10^{-2}\text{m}\cdot\ \text{K/W} = 51.0^\circ\text{C}.$$ <

(b) The temperature at the center of the rod is

$$T(0) = T_o = \frac{\dot{q}r_1^2}{4k_r} + T_1 = \frac{24,000\ \text{W/m}^3\,(0.100\ \text{m})^2}{4\times0.5\ \text{W/m}\cdot\text{K}} + 71.8^\circ\text{C} = 192^\circ\text{C}.$$ <

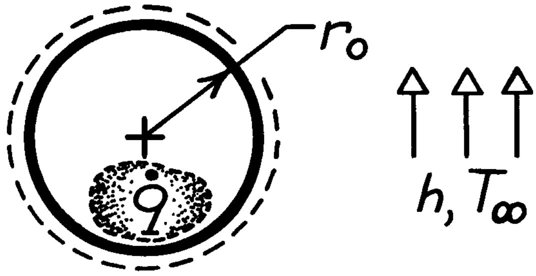
COMMENTS: The thermal resistances due to conduction in the sleeve and convection are comparable. Will increasing the sleeve outer diameter cause the surface temperature T_2 to increase or decrease?

PROBLEM 3.102

KNOWN: Radius, thermal conductivity, heat generation and convection conditions associated with a solid sphere.

FIND: Temperature distribution.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial conduction, (3) Constant properties, (4) Uniform heat generation.

ANALYSIS: Integrating the appropriate form of the heat diffusion equation,

$$\frac{1}{r^2}\frac{d}{dr}\left[kr^2\frac{dT}{dr}\right]+\dot{q}=0 \qquad \text{or} \qquad \frac{d}{dr}\left[r^2\frac{dT}{dr}\right]=-\frac{\dot{q}r^2}{k}$$

$$r^2\frac{dT}{dr}=-\frac{\dot{q}r^3}{3k}+C_1 \qquad \frac{dT}{dr}=-\frac{\dot{q}r}{3k}+\frac{C_1}{r^2}$$

$$T(r)=-\frac{\dot{q}r^2}{6k}-\frac{C_1}{r}+C_2.$$

The boundary conditions are: $\left.\frac{dT}{dr}\right]_{r=0}=0$ hence $C_1=0,$ and

$$-k\left.\frac{dT}{dr}\right]_{r_o}=h\left[T(r_o)-T_\infty\right].$$

Substituting into the second boundary condition ($r = r_o$), find

$$\frac{\dot{q}r_o}{3}=h\left[-\frac{\dot{q}r_o^2}{6k}+C_2-T_\infty\right] \qquad C_2=\frac{\dot{q}r_o}{3h}+\frac{\dot{q}r_o^2}{6k}+T_\infty.$$

The temperature distribution has the form

$$T(r)=\frac{\dot{q}}{6k}\left(r_o^2-r^2\right)+\frac{\dot{q}r_o}{3h}+T_\infty.$$ <

COMMENTS: To verify the above result, obtain $T(r_o) = T_s$,

$$T_s=\frac{\dot{q}r_o}{3h}+T_\infty$$

Applying energy balance to the control volume about the sphere,

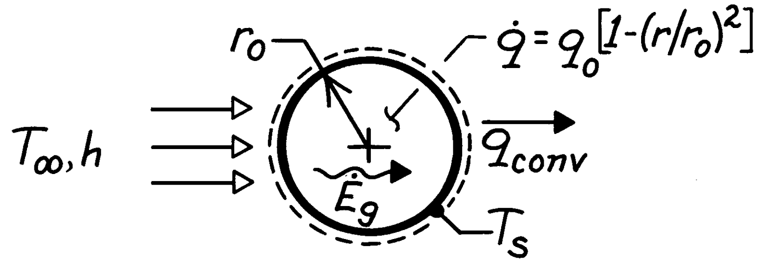
$$\dot{q}\left[\frac{4}{3}\pi\, r_o^3\right]=h4\pi\, r_o^2\left(T_s-T_\infty\right) \qquad \text{find} \qquad T_s=\frac{\dot{q}r_o}{3h}+T_\infty.$$

PROBLEM 3.103

KNOWN: Radial distribution of heat dissipation of a spherical container of radioactive wastes. Surface convection conditions.

FIND: Radial temperature distribution.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible temperature drop across container wall.

ANALYSIS: The appropriate form of the heat equation is

$$\frac{1}{r^2}\frac{d}{dr}\left(r^2\frac{dT}{dr}\right) = -\frac{\dot{q}}{k} = -\frac{\dot{q}_o}{k}\left[1-\left(\frac{r}{r_o}\right)^2\right].$$

Hence
$$r^2\frac{dT}{dr} = -\frac{\dot{q}_o}{k}\left(\frac{r^3}{3}-\frac{r^5}{5r_o^2}\right)+C_1$$

$$T = -\frac{\dot{q}_o}{k}\left(\frac{r^2}{6}-\frac{r^4}{20r_o^2}\right)-\frac{C_1}{r}+C_2.$$

From the boundary conditions,

$$dT/dr|_{r=0} = 0 \quad \text{and} \quad -k\,dT/dr|_{r=r_o} = h\left[T(r_o)-T_\infty\right]$$

it follows that $C_1 = 0$ and

$$\dot{q}_o\left(\frac{r_o}{3}-\frac{r_o}{5}\right) = h\left[-\frac{\dot{q}_o}{k}\left(\frac{r_o^2}{6}-\frac{r_o^2}{20}\right)+C_2-T_\infty\right]$$

$$C_2 = \frac{2r_o\dot{q}_o}{15h}+\frac{7\dot{q}_o r_o^2}{60k}+T_\infty.$$

Hence
$$T(r) = T_\infty+\frac{2r_o\dot{q}_o}{15h}+\frac{\dot{q}r_o^2}{k}\left[\frac{7}{60}-\frac{1}{6}\left(\frac{r}{r_o}\right)^2+\frac{1}{20}\left(\frac{r}{r_o}\right)^4\right].$$ <

COMMENTS: Applying the above result at r_o yields

$$T_s = T(r_o) = T_\infty + \left(2r_o\dot{q}_o/15h\right).$$

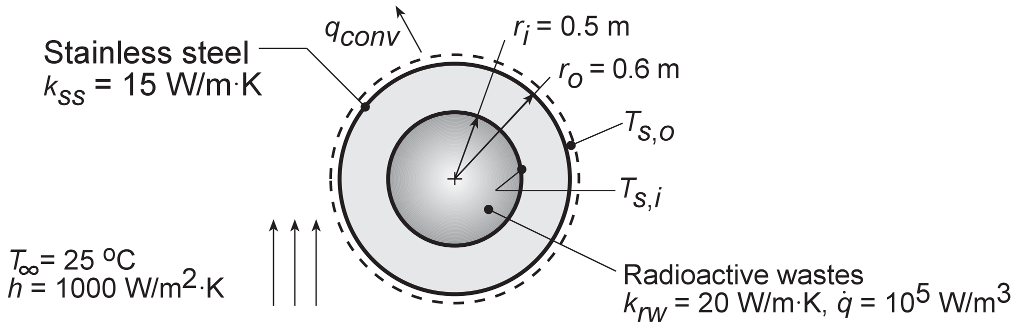
The same result may be obtained by applying an energy balance to a control surface about the container, where $\dot{E}_g = q_{conv}$. The maximum temperature exists at r = 0.

PROBLEM 3.104

KNOWN: Dimensions and thermal conductivity of a spherical container. Thermal conductivity and volumetric energy generation within the container. Outer convection conditions.

FIND: (a) Outer surface temperature, (b) Container inner surface temperature, (c) Temperature distribution within and center temperature of the wastes, (d) Feasibility of operating at twice the energy generation rate.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional radial conduction.

ANALYSIS: (a) For a control volume which includes the container, conservation of energy yields $\dot{E}_g - \dot{E}_{out} = 0$, or $\dot{q}V - q_{conv} = 0$. Hence

$$\dot{q}(4/3)\left(\pi r_i^3\right) = h4\pi r_o^2\left(T_{s,o} - T_\infty\right)$$

and with $\dot{q} = 10^5\ W/m^3$,

$$T_{s,o} = T_\infty + \frac{\dot{q}r_i^3}{3hr_o^2} = 25^\circ C + \frac{10^5\ W/m^2\,(0.5\,m)^3}{3000\,W/m^2\cdot K\,(0.6\,m)^2} = 36.6^\circ C.$$ <

(b) Performing a surface energy balance at the outer surface, $\dot{E}_{in} - \dot{E}_{out} = 0$ or $q_{cond} - q_{conv} = 0$. Hence

$$\frac{4\pi k_{ss}\left(T_{s,i} - T_{s,o}\right)}{(1/r_i) - (1/r_o)} = h4\pi r_o^2\left(T_{s,o} - T_\infty\right)$$

$$T_{s,i} = T_{s,o} + \frac{h}{k_{ss}}\left(\frac{r_o}{r_i} - 1\right)r_o\left(T_{s,o} - T_\infty\right) = 36.6^\circ C + \frac{1000\,W/m^2\cdot K}{15\,W/m\cdot K}(0.2)\,0.6\,m\left(11.6^\circ C\right) = 129.4^\circ C.$$ <

(c) The heat equation in spherical coordinates is

$$k_{rw}\frac{d}{dr}\left(r^2\frac{dT}{dr}\right) + \dot{q}r^2 = 0.$$

Solving,

$$r^2\frac{dT}{dr} = -\frac{\dot{q}r^3}{3k_{rw}} + C_1 \qquad \text{and} \qquad T(r) = -\frac{\dot{q}r^2}{6k_{rw}} - \frac{C_1}{r} + C_2$$

Applying the boundary conditions,

$$\left.\frac{dT}{dr}\right|_{r=0} = 0 \qquad \text{and} \qquad T(r_i) = T_{s,i}$$

$$C_1 = 0 \qquad \text{and} \qquad C_2 = T_{s,i} + \dot{q}r_i^2/6k_{rw}.$$

Continued...

PROBLEM 3.104 (Cont.)

Hence

$$T(r) = T_{s,i} + \frac{\dot{q}}{6k_{rw}}\left(r_i^2 - r^2\right) \qquad <$$

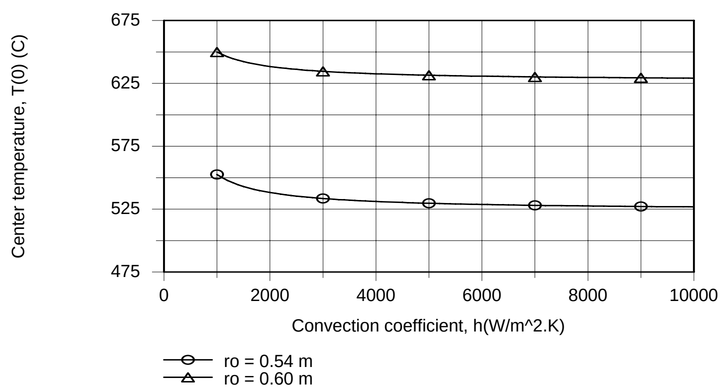
At r = 0,

$$T(0) = T_{s,i} + \frac{\dot{q}r_i^2}{6k_{rw}} = 129.4^\circ C + \frac{10^5\,W/m^3\,(0.5\,m)^2}{6(20\,W/m\cdot K)} = 337.7^\circ C \qquad <$$

(d) The feasibility assessment may be performed by using the IHT model for one-dimensional, steady-state conduction in a solid sphere, with the surface boundary condition prescribed in terms of the total thermal resistance

$$R''_{tot,i} = \left(4\pi r_i^2\right)R_{tot} = R''_{cnd,i} + R''_{cnv,i} = \frac{r_i^2\left[(1/r_i) - (1/r_o)\right]}{k_{ss}} + \frac{1}{h}\left(\frac{r_i}{r_o}\right)^2$$

where, for r_o = 0.6 m and h = 1000 W/m^2·K, $R''_{cnd,i}$ = 5.56 × 10^{-3} m^2·K/W, $R''_{cnv,i}$ = 6.94 × 10^{-4} m^2·K/W, and $R''_{tot,i}$ = 6.25 × 10^{-3} m^2·K/W. Results for the center temperature are shown below.



Clearly, even with r_o = 0.54 m = $r_{o,min}$ and h = 10,000 W/m^2·K (a practical upper limit), T(0) > 475°C and the desired condition can not be met. The corresponding resistances are $R''_{cnd,i}$ = 2.47 × 10^{-3} m^2·K/W, $R''_{cnv,i}$ = 8.57 × 10^{-5} m^2·K/W, and $R''_{tot,i}$ = 2.56 × 10^{-3} m^2·K/W. The conduction resistance remains dominant, and the effect of reducing $R''_{cnv,i}$ by increasing h is small. *The proposed extension is not feasible.*

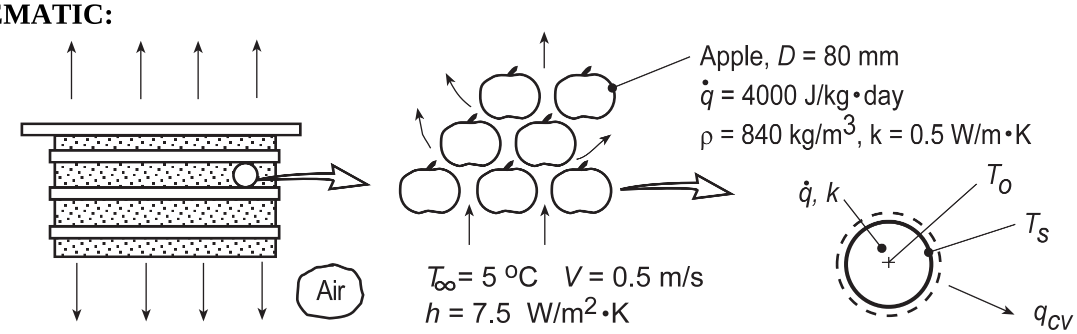
COMMENTS: A value of $\dot{q}$ = 1.79 × 10^5 W/m^3 would allow for operation at T(0) = 475°C with r_o = 0.54 m and h = 10,000 W/m^2·K.

PROBLEM 3.105

KNOWN: Carton of apples, modeled as 80-mm diameter spheres, ventilated with air at 5°C and experiencing internal volumetric heat generation at a rate of 4000 J/kg·day.

FIND: (a) The apple center and surface temperatures when the convection coefficient is 7.5 $W/m^2 \cdot K$, and (b) Compute and plot the apple temperatures as a function of air velocity, V, for the range $0.1 \le V \le 1$ m/s, when the convection coefficient has the form $h = C_1 V^{0.425}$, where $C_1 = 10.1\ W/m^2 \cdot K \cdot (m/s)^{0.425}$.

SCHEMATIC:



ASSUMPTIONS: (1) Apples can be modeled as spheres, (2) Each apple experiences flow of ventilation air at $T_\infty = 5°C$, (3) One-dimensional radial conduction, (4) Constant properties and (5) Uniform heat generation.

ANALYSIS: (a) From Eq. C.24, the temperature distribution in a solid sphere (apple) with uniform generation is

$$T(r) = \frac{\dot{q} r_o^2}{6k}\left(1 - \frac{r^2}{r_o^2}\right) + T_s \qquad (1)$$

To determine T_s, perform an energy balance on the apple as shown in the sketch above, with volume $V = 4/3 \pi r_o^3$,

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = 0 \qquad -q_{cv} + \dot{q}\forall = 0$$

$$-h\left(4\pi r_o^2\right)\left(T_s - T_\infty\right) + \dot{q}\left(4\pi r_o^3/3\right) = 0 \qquad (2)$$

$$-7.5\,W/m^2 \cdot K\left(4\pi \times 0.040^2\,m^2\right)\left(T_s - 5^\circ C\right) + 38.9\,W/m^3\left(4\pi \times 0.040^3\,m^3/3\right) = 0$$

where the volumetric generation rate is

$$\dot{q} = 4000\,J/kg \cdot day$$

$$\dot{q} = 4000\,J/kg \cdot day \times 840\,kg/m^3 \times (1\,day/24\,hr) \times (1\,hr/3600\,s)$$

$$\dot{q} = 38.9\,W/m^3$$

and solving for T_s, find

$$T_s = 5.14^\circ C \qquad <$$

From Eq. (1), at r = 0, with T_s, find

$$T(0) = \frac{38.9\,W/m^3 \times 0.040^2\,m^2}{6 \times 0.5\,W/m \cdot K} + 5.14^\circ C = 0.12^\circ C + 5.14^\circ C = 5.26^\circ C \qquad <$$

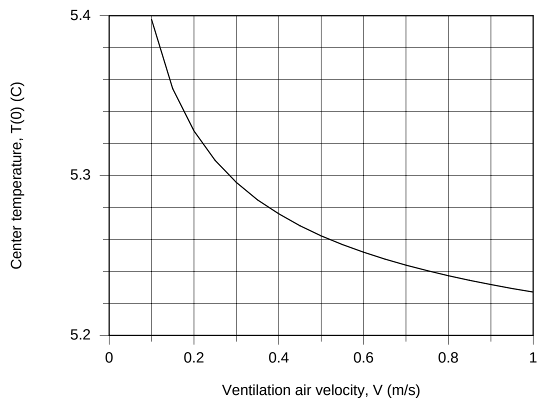
PROBLEM 3.105 (Cont.)

(b) With the convection coefficient depending upon velocity,

$$h = C_1 V^{0.425}$$

with $C_1 = 10.1\ W/m^2 \cdot K \cdot (m/s)^{0.425}$, and using the energy balance of Eq. (2), calculate and plot T_s as a function of ventilation air velocity V. With very low velocities, the center temperature is nearly 0.5°C higher than the air. From our earlier calculation we know that $T(0) - T_s = 0.12°C$ and is independent of V.



COMMENTS: (1) While the temperature within the apple is nearly isothermal, the center temperature will track the ventilation air temperature which will increase as it passes through stacks of cartons.

(2) The *IHT* Workspace used to determine T_s for the base condition and generate the above plot is shown below.

```
// The temperature distribution, Eq (1),
T_r = qdot * ro^2 / (4 * k) * ( 1- r^2/ro^2 )  +  Ts

// Energy balance on the apple, Eq (2)
- qcv + qdot * Vol = 0
Vol = 4 / 3 * pi *  ro ^3

// Convection rate equation:
qcv = h* As * ( Ts - Tinf )
As = 4 * pi * ro^2

// Generation rate:
qdot = qdotm * (1/24) * (1/3600) * rho          // Generation rate, W/m^3; Conversions: days/h and h/sec

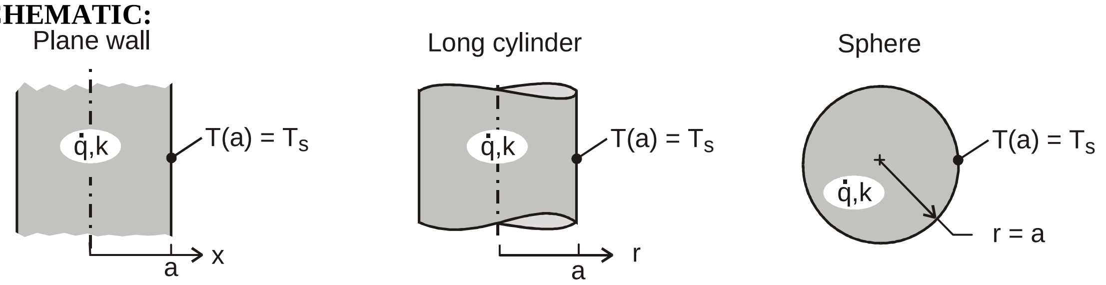
// Assigned variables:
ro = 0.080                  // Radius of apple, m
k = 0.5                     // Thermal conductivity, W/m.K
qdotm = 4000                // Generation rate, J/kg.K
rho = 840                   // Specific heat, J/kg.K
r = 0                       // Center, m; location for T(0)
h =  7.5                    // Convection coefficient, W/m^2.K; base case, V = 0.5 m/s
//h = C1 * V^0.425          // Correlation
//C1 = 10.1
//V = 0.5                   // Air velocity, m/s; range 0.1 to 1 m/s
Tinf = 5                    // Air temperature, C
```

PROBLEM 3.106

KNOWN: Plane wall, long cylinder and sphere, each with characteristic length a, thermal conductivity k and uniform volumetric energy generation rate $\dot{q}$.

FIND: (a) On the same graph, plot the dimensionless temperature, $[T(x \text{ or } r) - T(a)]/[\dot{q}a^2/2k]$, *vs.* the dimensionless characteristic length, x/a or r/a, for each shape; (b) Which shape has the smallest temperature difference between the center and the surface? Explain this behavior by comparing the ratio of the volume-to-surface area; and (c) Which shape would be preferred for use as a nuclear fuel element? Explain why?

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties and (4) Uniform volumetric generation.

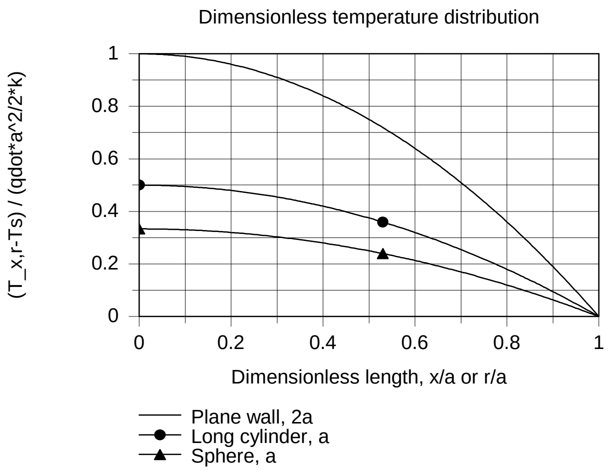
ANALYSIS: (a) For each of the shapes, with $T(a) = T_s$, the dimensionless temperature distributions can be written by inspection from results in Appendix C.3.

Plane wall, Eq. C.22
$$\frac{T(x)-T_s}{\dot{q}a^2/2k} = 1-\left(\frac{x}{a}\right)^2$$

Long cylinder, Eq. C.23
$$\frac{T(r)-T_s}{\dot{q}a^2/2k} = \frac{1}{2}\left[1-\left(\frac{r}{a}\right)^2\right]$$

Sphere, Eq. C.24
$$\frac{T(r)-T_s}{\dot{q}a^2/2k} = \frac{1}{3}\left[1-\left(\frac{r}{a}\right)^2\right]$$

The dimensionless temperature distributions using the foregoing expressions are shown in the graph below.



Continued …

PROBLEM 3.106 (Cont.)

(b) The sphere shape has the smallest temperature difference between the center and surface, T(0) – T(a). The ratio of volume-to-surface-area, $\forall/A_s$, for each of the shapes is

Plane wall $$\frac{\forall}{A_s} = \frac{a(1\times1)}{(1\times1)} = a$$

Long cylinder $$\frac{\forall}{A_s} = \frac{\pi a^2 \times 1}{2\pi a \times 1} = \frac{a}{2}$$

Sphere $$\frac{\forall}{A_s} = \frac{4\pi a^3/3}{4\pi a^2} = \frac{a}{3}$$

The smaller the $\forall/A_s$ ratio, the smaller the temperature difference, T(0) – T(a).

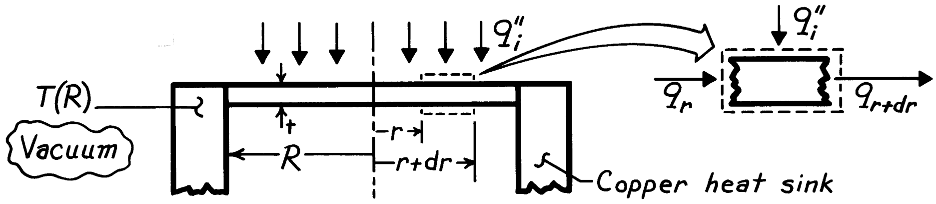
(c) The sphere would be the preferred element shape since, for a given $\forall/A_s$ ratio, which controls the generation and transfer rates, the sphere will operate at the lowest temperature.

PROBLEM 3.107

KNOWN: Radius, thickness, and incident flux for a radiation heat gauge.

FIND: Expression relating incident flux to temperature difference between center and edge of gauge.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in r (negligible temperature drop across foil thickness), (3) Constant properties, (4) Uniform incident flux, (5) Negligible heat loss from foil due to radiation exchange with enclosure wall, (6) Negligible contact resistance between foil and heat sink.

ANALYSIS: Applying energy conservation to a circular ring extending from r to r + dr,

$$q_r + q_i''(2\pi\ rdr) = q_{r+dr}, \qquad q_r = -k(2\pi\ rt)\frac{dT}{dr}, \qquad q_{r+dr} = q_r + \frac{dq_r}{dr}dr.$$

Rearranging, find that

$$q_i''(2\pi\ rdr) = \frac{d}{dr}\left[(-k2\pi\ rt)\frac{dT}{dr}\right]dr$$

$$\frac{d}{dr}\left[r\frac{dT}{dr}\right] = -\frac{q_i''}{kt}r.$$

Integrating,

$$r\frac{dT}{dr} = -\frac{q_i''r^2}{2kt} + C_1 \qquad \text{and} \qquad T(r) = -\frac{q_i''r^2}{4kt} + C_1 \ln r + C_2.$$

With $dT/dr|_{r=0} = 0$, $C_1 = 0$ and with $T(r = R) = T(R)$,

$$T(R) = -\frac{q_i''R^2}{4kt} + C_2 \qquad \text{or} \qquad C_2 = T(R) + \frac{q_i''R^2}{4kt}.$$

Hence, the temperature distribution is

$$T(r) = \frac{q_i''}{4kt}\left(R^2 - r^2\right) + T(R).$$

Applying this result at r = 0, it follows that

$$q_i'' = \frac{4kt}{R^2}\left[T(0) - T(R)\right] = \frac{4kt}{R^2}\Delta T. \qquad <$$

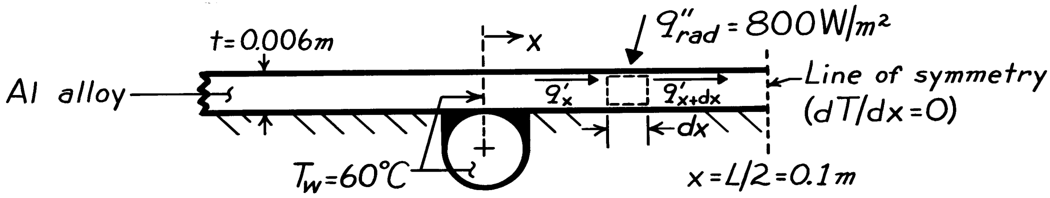
COMMENTS: This technique allows for determination of a radiation flux from measurement of a temperature difference. It becomes inaccurate if emission from the foil becomes significant.

PROBLEM 3.108

KNOWN: Net radiative flux to absorber plate.

FIND: (a) Maximum absorber plate temperature, (b) Rate of energy collected per tube.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional (x) conduction along absorber plate, (3) Uniform radiation absorption at plate surface, (4) Negligible losses by conduction through insulation, (5) Negligible losses by convection at absorber plate surface, (6) Temperature of absorber plate at x = 0 is approximately that of the water.

PROPERTIES: *Table A-1*, Aluminum alloy (2024-T6): k ≈ 180 W/m·K.

ANALYSIS: The absorber plate acts as an extended surface (a conduction-radiation system), and a differential equation which governs its temperature distribution may be obtained by applying Eq.1.11b to a differential control volume. For a unit length of tube

$$q'_x + q''_{rad}(dx) - q'_{x+dx} = 0.$$

With $$q'_{x+dx} = q'_x + \frac{dq'_x}{dx}dx$$

and $$q'_x = -kt\frac{dT}{dx}$$

it follows that,

$$q''_{rad} - \frac{d}{dx}\left[-kt\frac{dT}{dx}\right] = 0$$

$$\frac{d^2T}{dx^2} + \frac{q''_{rad}}{kt} = 0$$

Integrating twice it follows that, the general solution for the temperature distribution has the form,

$$T(x) = -\frac{q''_{rad}}{2kt}x^2 + C_1x + C_2.$$

Continued …

PROBLEM 3.108 (Cont.)

The boundary conditions are:

$$T(0) = T_w \qquad C_2 = T_w$$

$$\left.\frac{dT}{dx}\right]_{x=L/2} = 0 \qquad C_1 = \frac{q''_{rad} L}{2kt}$$

Hence,

$$T(x) = \frac{q''_{rad}}{2kt}\, x(L - x) + T_w.$$

The maximum absorber plate temperature, which is at x = L/2, is therefore

$$T_{max} = T(L/2) = \frac{q''_{rad} L^2}{8kt} + T_w.$$

The rate of energy collection per tube may be obtained by applying Fourier's law at x = 0. That is, energy is transferred to the tubes via conduction through the absorber plate. Hence,

$$q' = 2\left[-k\,t \left.\frac{dT}{dx}\right]_{x=0}\right]$$

where the factor of two arises due to heat transfer from both sides of the tube. Hence,

$$q' = -Lq''_{rad}.$$

Hence $$T_{max} = \frac{800\frac{W}{m^2}(0.2m)^2}{8\left[180\frac{W}{m \cdot K}\right](0.006m)} + 60^\circ C$$

or $$T_{max} = 63.7^\circ C$$ <

and $$q' = -0.2m \times 800\ W/m^2$$

or $$q' = -160\ W/m.$$ <

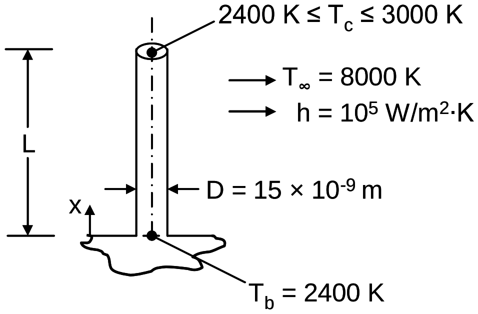
COMMENTS: Convection losses in the typical flat plate collector, which is not evacuated, would reduce the value of q'.

PROBLEM 3.109

KNOWN: Diameter and base temperature of a silicon carbide nanowire, required temperature of the catalyst tip.

FIND: Maximum length of a nanowire that may be grown under specified conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Nanowire stops growing when $T_c = T(x = L) = 3000$ K, (2) Constant properties, (3) One-dimensional heat transfer, (4) Convection from the tip of the nanowire, (5) Nanowire grows very slowly, (6) Negligible impact of nanoscale heat transfer effects.

PROPERTIES: Table A.2, silicon carbide (1500 K): k = 30 W/m·K.

ANALYSIS: The tip of the nanowire is initially at T = 2400 K, and increases in temperature as the nanowire becomes longer. At steady-state, the tip reaches T = 3000 K. The temperature distribution at steady-state is given by Eq. 3.75:

$$\frac{\theta}{\theta_b} = \frac{\cosh m(L - x) + (h/mk)\sinh m(L - x)}{\cosh mL + (h/mk)\sinh mL} \qquad (1)$$

where

$$m = \left(\frac{hP}{kA_c}\right)^{1/2} = \left(\frac{4h}{kD}\right)^{1/2} = \left(\frac{4 \times 10^5 \text{ W/m}^2 \cdot \text{K}}{30 \text{ W/m} \cdot \text{K} \times 15 \times 10^{-9} \text{ m}}\right)^{1/2} = 943 \times 10^3 \text{ m}^{-1}$$

and

$$\frac{h}{mk} = \frac{10^5 \text{ W/m}^2 \cdot \text{K}}{943 \times 10^3 \text{ m}^{-1} \times 30 \text{ W/m} \cdot \text{K}} = 3.53 \times 10^{-3}$$

Equation 1, evaluated at x = L, is

$$\frac{\theta}{\theta_b} = \frac{(3000 - 8000)\text{ K}}{(2400 - 8000)\text{ K}} = 0.893 = \frac{1}{\cosh(943 \times 10^3 \times L) + 3.53 \times 10^{-3}\sinh(943 \times 10^3 \times L)}$$

A trial-and-error solution yields $L = 510 \times 10^{-9}$ m = 510 nm <

Continued…

PROBLEM 3.109 (Cont.)

COMMENTS: (1) The importance of radiation heat transfer may be ascertained by evaluating Eq. 1.9. Assuming large surroundings at a temperature of T_{sur} = 8000 K and an emissivity of unity, the radiation heat transfer coefficient at the fin tip is

$$h_r = \varepsilon\sigma(T(x = L) + T_{sur})\left[T^2(x{=}L) + T_{sur}^2\right]$$
$$= 5.67 \times 10^{-8}\ \text{W/m}^2 \cdot \text{K}^4 \times (3000\ \text{K} + 8000\ \text{K}) \times \left[(3000\ \text{K})^2 + (8000\ \text{K})^2\right] = 4.5 \times 10^4\ \text{W/m}^2 \cdot \text{K}$$

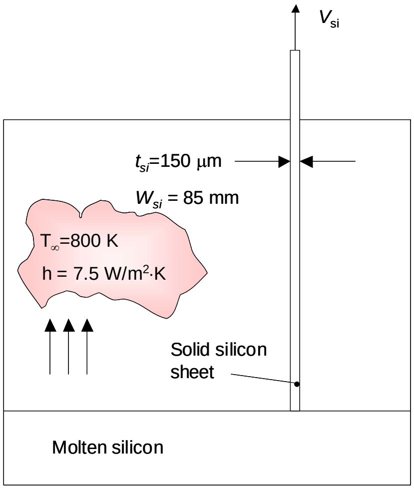
We see that $h_r < h$, but radiation may be important. (2) The thermal conductivity has been evaluated at 1500 K and extrapolated to a much higher temperature. More accurate values of the thermal conductivity, accounting for the high temperature and possible nanoscale heat transfer effects, are desirable. (3) If the nanowire were to grow rapidly, the transient temperature distribution within the nanowire would need to be evaluated.

PROBLEM 3.110

KNOWN: Process for growing thin, photovoltaic grade silicon sheets. Sheet dimensions, ambient temperature and heat transfer coefficient.

FIND: The velocity at which the silicon sheet can be extracted from the pool of molten silicon.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, one-dimensional conditions, (2) Negligible radiation heat transfer, (3) Silicon sheet behaves as an infinite fin, (4) Constant properties, (5) Neglect advection inside the silicon sheet, (6) Neglect the presence of the strings, (7) Molten silicon is isothermal at the melting point (1685 K).

PROPERTIES: *Table A-1*, Silicon ($\overline{T}$ = (1685 K + 800 K)/2 = 1243 K): k = 25.3 W/m·K, ρ = 2330 kg/m^3, h_{sl} = 1.8 × 10^6 J/kg (given).

ANALYSIS: The velocity is expected to be very small. Therefore, heat transfer *within* the silicon sheet may be considered to be by conduction only. In addition, thermal energy is generated due to solidification at the solid-liquid interface, and must be removed by conduction along the silicon sheet. Therefore,

$$\dot{m}h_{sl} = \rho W_{\text{si}} t_{\text{si}} V_{\text{si}} h_{\text{sl}} = q_{\text{cond}} \qquad (1)$$

From Table 3.4 for an infinite fin

$$q_{\text{cond}} = q_f = M = \sqrt{hPkA_c}\,\theta_b = \sqrt{h2(W_{si}+t_{si})kW_{si}t_{si}}\,(T_f - T_\infty) \qquad (2)$$

Combining Equations (1) and (2) yields

$$V_{\text{si}} = \frac{\sqrt{2h(W_{\text{si}}+t_{\text{si}})kW_{\text{si}}t_{\text{si}}}}{\rho W_{\text{si}} t_{\text{si}} h_{\text{sl}}}\left(T_f - T_\infty\right)$$

$$= \frac{\sqrt{2\times 7.5\text{W/m}^2\cdot\text{K}\times(0.085\text{m}+150\times10^{-6}\text{m})\times 25.3\text{W/m}\cdot\text{K}\times 0.085\text{m}\times 150\times10^{-6}\text{m}}}{2330\text{kg/m}^3\times 0.085\text{m}\times 150\times10^{-6}\text{m}\times 1.8\times10^6\text{J/kg}}\left(1685\text{K}-800\text{K}\right)$$

$$= 335\times10^{-6}\text{m/s}\times 1000\text{mm/m}\times 60\text{s/min} = 20.1 \text{ mm/min}$$ <

Continued...

PROBLEM 3.110 (Cont.)

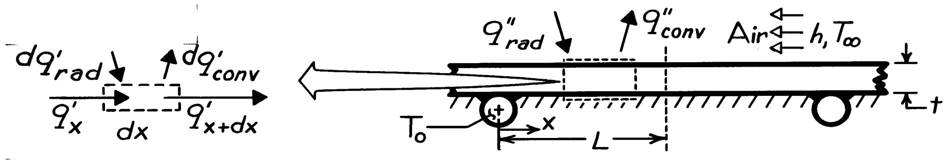
COMMENTS: (1) The rate at which the photovoltaic sheet can be manufactured is limited by heat transfer effects. If the velocity were increased above the value calculated, the solid sheet would be lifted out of the molten pool of silicon, and the manufacturing process would stop. If the velocity were below the value calculated, the solid-liquid interface would begin to propagate downward into the pool, increasing the thickness of the silicon sheet. (2) As the thickness of the photovoltaic sheet is reduced, less silicon is needed to fabricate a solar panel, reducing manufacturing costs, reducing energy consumption in the manufacturing process, and conserving natural resources. Equally important, as the thickness of the sheet is reduced, the velocity at which the sheet can be pulled from the pool of molten silicon can be increased, resulting in production of more photovoltaic surface area per unit time.

PROBLEM 3.111

KNOWN: Surface conditions and thickness of a solar collector absorber plate. Temperature of working fluid.

FIND: (a) Differential equation which governs plate temperature distribution, (b) Form of the temperature distribution.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Adiabatic bottom surface, (4) Uniform radiation flux and convection coefficient at top, (5) Temperature of absorber plate at x = 0 corresponds to that of working fluid.

ANALYSIS: (a) Performing an energy balance on the differential control volume,

$$q'_x + dq'_{rad} = q'_{x+dx} + dq'_{conv}$$

where
$$q'_{x+dx} = q'_x + \left(dq'_x / dx\right)dx$$
$$dq'_{rad} = q''_{rad} \cdot dx$$
$$dq'_{conv} = h\left(T - T_\infty\right) \cdot dx$$

Hence, $$q''_{rad}dx = \left(dq'_x / dx\right)dx + h\left(T - T_\infty\right)dx.$$

From Fourier's law, the conduction heat rate per unit width is

$$q'_x = -k\ t\ dT/dx \qquad \frac{d^2T}{dx^2} - \frac{h}{kT}\left(T - T_\infty\right) + \frac{q''_{rad}}{kt} = 0.$$ <

(b) Defining $\theta = T - T_\infty, d^2T/dx^2 = d^2\theta / dx^2$ and the differential equation becomes,

$$\frac{d^2\theta}{dx^2} - \frac{h}{kt}\theta + \frac{q''_{rad}}{kt} = 0.$$

It is a second-order, differential equation with constant coefficients and a source term, and its general solution is of the form

$$\theta = C_1 e^{+\lambda x} + C_2 e^{-\lambda x} + S/\lambda^2$$

where $\lambda = \left(h/kt\right)^{1/2}$, $\quad S = q''_{rad} / kt.$

Appropriate boundary conditions are:

$$\theta\left(0\right) = T_o - T_\infty \equiv \theta_o, \qquad d\theta/dx|_{x=L} = 0.$$

Hence, $$\theta_o = C_1 + C_2 + S/\lambda^2$$

$$d\theta/dx|_{x=L} = C_1\ \lambda e^{+\lambda L} - C_2\ \lambda e^{-\lambda L} = 0 \qquad C_2 = C_1\ e^{2\lambda L}$$

Hence, $$C_1 = \left(\theta_0 - S/\lambda^2\right) / \left(1 + e^{2\lambda L}\right) \qquad C_2 = \left(\theta_0 - S/\lambda^2\right) / \left(1 + e^{-2\lambda L}\right)$$

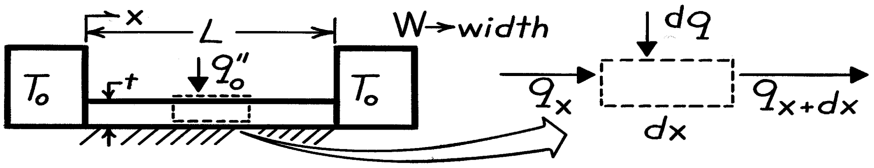
$$\theta = \left(\theta_0 - S/\lambda^2\right)\left[\frac{e^{\lambda x}}{1+e^{2\lambda L}} + \frac{e^{-\lambda x}}{1+e^{-2\lambda L}}\right] + S/\lambda^2.$$ <

PROBLEM 3.112

KNOWN: Dimensions of a plate insulated on its bottom and thermally joined to heat sinks at its ends. Net heat flux at top surface.

FIND: (a) Differential equation which determines temperature distribution in plate, (b) Temperature distribution and heat loss to heat sinks.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction in x (W,L>>t), (3) Constant properties, (4) Uniform surface heat flux, (5) Adiabatic bottom, (6) Negligible contact resistance.

ANALYSIS: (a) Applying conservation of energy to the differential control volume, $q_x + dq = q_{x+dx}$, where $q_{x+dx} = q_x + (dq_x/dx)\,dx$ and $dq = q_o''\,(W\cdot dx)$. Hence, $(dq_x/dx) - q_o''\,W = 0$. From Fourier's law, $q_x = -k(t\cdot W)\,dT/dx$. Hence, the differential equation for the temperature distribution is

$$-\frac{d}{dx}\left[ktW\,\frac{dT}{dx}\right] - q_o''\,W = 0 \qquad \frac{d^2T}{dx^2} + \frac{q_o''}{kt} = 0.$$ <

(b) Integrating twice, the general solution is,

$$T(x) = -\frac{q_o''}{2kt}x^2 + C_1\,x + C_2$$

and appropriate boundary conditions are $T(0) = T_o$, and $T(L) = T_o$. Hence, $T_o = C_2$, and

$$T_o = -\frac{q_o''}{2kt}L^2 + C_1L + C_2 \qquad \text{and} \qquad C_1 = \frac{q_o''L}{2kt}.$$

Hence, the temperature distribution is

$$T(x) = -\frac{q_o''}{2kt}\left(x^2 - Lx\right) + T_o.$$ <

Applying Fourier's law at x = 0, and at x = L,

$$q(0) = -k(Wt)\;dT/dx)_{x=0} = -kWt\left[-\frac{q_o''}{kt}\right]\left[x - \frac{L}{2}\right]\Bigg|_{x=0} = -\frac{q_o''WL}{2}$$

$$q(L) = -k(Wt)dT/dx)_{x=L} = -kWt\left[-\frac{q_o''}{kt}\right]\left[x - \frac{L}{2}\right]\Bigg|_{x=L} = +\frac{q_o''WL}{2}$$

Hence the heat loss from the plates is $q = 2\left(q_o''WL/2\right) = q_o''WL$. <

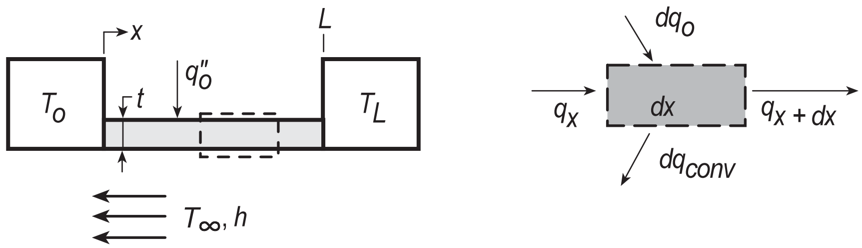
COMMENTS: (1) Note signs associated with q(0) and q(L). (2) Note symmetry about x = L/2. Alternative boundary conditions are $T(0) = T_o$ and $dT/dx)_{x=L/2} = 0$.

PROBLEM 3.113

KNOWN: Dimensions and surface conditions of a plate thermally joined at its ends to heat sinks at different temperatures. Heat flux into top of plate. Convection conditions beneath plate.

FIND: (a) Differential equation which determines temperature distribution in plate, (b) Temperature distribution and an expression for the heat rate from the plate to the sinks, and (c) Compute and plot temperature distribution and heat rates corresponding to changes in different parameters.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in x (W,L >> t), (3) Constant properties, (4) Uniform surface heat flux and convection coefficient, (5) Negligible contact resistance.

ANALYSIS: (a) Applying conservation of energy to the differential control volume

$$q_x + dq_o = q_{x+dx} + dq_{conv}$$

where

$$q_{x+dx} = q_x + \left(dq_x/dx\right)dx \qquad\qquad dq_{conv} = h\left(T - T_\infty\right)\left(W \cdot dx\right)$$

Hence,

$$q_x + q_o''\left(W \cdot dx\right) = q_x + \left(dq_x/dx\right)dx + h\left(T - T_\infty\right)\left(W \cdot dx\right) \qquad\qquad \frac{dq_x}{dx} + hW\left(T - T_\infty\right) = q_o''W .$$

Using Fourier's law, $q_x = -k\left(t \cdot W\right)dT/dx$,

$$-ktW\frac{d^2T}{dx^2} + hW\left(T - T_\infty\right) = q_o''W \qquad\qquad \frac{d^2T}{dx^2} - \frac{h}{kt}\left(T - T_\infty\right) + \frac{q_o''}{kt} = 0 .$$ <

(b) Introducing $\theta \equiv T - T_\infty$, the differential equation becomes

$$\frac{d^2\theta}{dx^2} - \frac{h}{kt}\theta + \frac{q_o''}{kt} = 0 .$$

This differential equation is of second order with constant coefficients and a source term. With $\lambda^2 \equiv h/kt$ and $S \equiv q_o''/kt$, it follows that the general solution is of the form

$$\theta = C_1 e^{+\lambda x} + C_2 e^{-\lambda x} + S/\lambda^2 . \qquad (1)$$

Appropriate boundary conditions are: $\theta(0) = T_o - T_\infty \equiv \theta_o \qquad \theta(L) = T_L - T_\infty \equiv \theta_L \qquad (2,3)$

Substituting the boundary conditions, Eqs. (2,3) into the general solution, Eq. (1),

$$\theta_o = C_1 e^0 + C_2 e^0 + S/\lambda^2 \qquad\qquad \theta_L = C_1 e^{+\lambda L} + C_2 e^{-\lambda L} + S/\lambda^2 \qquad (4,5)$$

To solve for C_2, multiply Eq. (4) by $-e^{+\lambda L}$ and add the result to Eq. (5),

$$-\theta_o e^{+\lambda L} + \theta_L = C_2\left(-e^{+\lambda L} + e^{-\lambda L}\right) + S/\lambda^2\left(-e^{+\lambda L} + 1\right)$$

$$C_2 = \left[\left(\theta_L - \theta_o e^{+\lambda L}\right) - S/\lambda^2\left(-e^{+\lambda L} + 1\right)\right] \Big/ \left(-e^{+\lambda L} + e^{-\lambda L}\right) \qquad (6)$$

Continued...

PROBLEM 3.113 (Cont.)

Substituting for C_2 from Eq. (6) into Eq. (4), find

$$C_1 = \theta_o - \left\{ \left[\left(\theta_L - \theta_o e^{+\lambda L} \right) - S/\lambda^2 \left(-e^{+\lambda L} + 1 \right) \right] \Big/ \left(-e^{+\lambda L} + e^{-\lambda L} \right) \right\} - S/\lambda^2 \qquad (7)$$

Using C_1 and C_2 from Eqs. (6,7) and Eq. (1), the temperature distribution can be expressed as

$$\theta(x) = \left[e^{+\lambda x} - \frac{\sinh(\lambda x)}{\sinh(\lambda L)} e^{+\lambda L} \right] \theta_o + \frac{\sinh(\lambda x)}{\sinh(\lambda L)} \theta_L + \left[-\left(1 - e^{+\lambda L}\right) \frac{\sinh(\lambda x)}{\sinh(\lambda L)} + \left(1 - e^{+\lambda x}\right) \right] \frac{S}{\lambda^2} \qquad (8) <$$

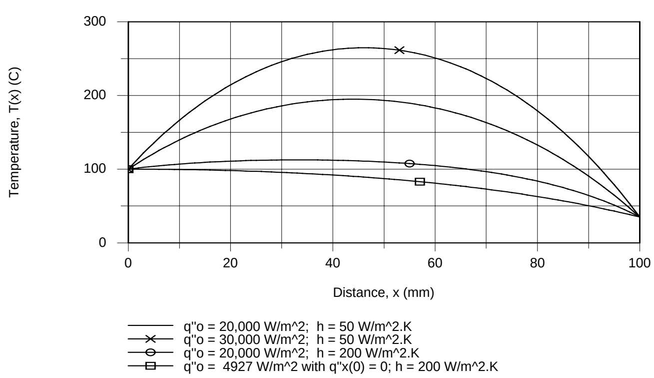
The heat rate from the plate is $q_p = -q_x(0) + q_x(L)$ and using Fourier's law, the conduction heat rates, with $A_c = W \cdot t$, are

$$q_x(0) = -kA_c \left.\frac{d\theta}{dx}\right)_{x=0} = -kA_c \left\{ \left[\lambda e^0 - \frac{e^{\lambda L}}{\sinh(\lambda L)} \lambda \right] \theta_o + \frac{\lambda}{\sinh(\lambda L)} \theta_L + \left[-\frac{1 - e^{+\lambda L}}{\sinh(\lambda L)} \lambda - \lambda \right] \frac{S}{\lambda^2} \right\} \qquad <$$

$$q_x(L) = -kA_c \left.\frac{d\theta}{dx}\right)_{x=L} = -kA_c \left\{ \left[\lambda e^{\lambda L} - \frac{e^{\lambda L}}{\sinh(\lambda L)} \lambda \cosh(\lambda L) \right] \theta_o + \frac{\lambda \cosh(\lambda L)}{\sinh(\lambda L)} \theta_L + \left[-\frac{1 - e^{+\lambda L}}{\sinh(\lambda L)} \lambda \cosh(\lambda L) - \lambda e^{+\lambda L} \right] \frac{S}{\lambda^2} \right\} \qquad <$$

(c) For the prescribed base-case conditions listed below, the temperature distribution (solid line) is shown in the accompanying plot. As expected, the maximum temperature does not occur at the midpoint, but slightly toward the x-origin. The sink heat rates are

$$q''_x(0) = -17.22\,\text{W} \qquad q''_x(L) = 23.62\,\text{W} \qquad <$$



The additional temperature distributions on the plot correspond to changes in the following parameters, with all the remaining parameters unchanged: (i) q''_o = 30,000 W/m^2, (ii) h = 200 $W/m^2 \cdot K$, (iii) the value of q''_o for which $q''_x(0) = 0$ with h = 200 $W/m^2 \cdot K$. The condition for the last curve is q''_o = 4927 W/m^2 for which the temperature gradient at x = 0 is zero.

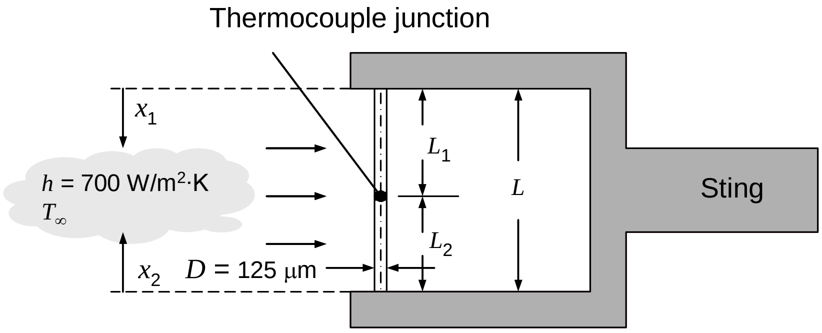
Base case conditions are: q''_o = 20,000 W/m^2, T_o = 100°C, T_L = 35°C, T_∞ = 25°C, k = 25 W/m·K, h = 50 $W/m^2 \cdot K$, L = 100 mm, t = 5 mm, W = 30 mm.

PROBLEM 3.114

KNOWN: Wire diameters associated with a thermocouple junction, value of the convection heat transfer coefficient.

FIND: Minimum wire lengths necessary to ensure the junction temperature is at the gas temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, one-dimensional conditions, (2) Negligible radiation heat transfer, (3) Constant properties, (4) Infinitely long fin behavior.

PROPERTIES: *Table A-1*, Copper ($\bar{T}$ = 300 K): k = 401 W/m·K; Constantan ($\bar{T}$ = 300 K): k = 23 W/m·K; *Given*, Chromel: k = 19 W/m·K; Alumel: k = 29 W/m·K.

ANALYSIS: To ensure the junction temperature is at the gas temperature (that is, the junction temperature is not influenced by the sting temperature) we require the two wires to behave as infinitely long fins. From Example 3.9, Comment 1, the requirement is,

$$L_1 \geq 4.6\left(\frac{k_1 A_c}{hP}\right)^{1/2}; L_2 \geq 4.6\left(\frac{k_2 A_c}{hP}\right)^{1/2}$$

where $L = L_1 + L_2$. With $A_c = \pi D^2/4 = \pi \times (125 \times 10^{-6} \text{m})^2/4 = 12.27 \times 10^{-9} \text{m}^2$ and $P = \pi D = \pi \times 125 \times 10^{-6}$ m $= 393 \times 10^{-6}$ m, we may calculate the following values of L_1, L_2, and L.

Material	L_1 (mm)	L_2 (mm)		
(1) Copper	19.5	-		
(2) Constantan	-	4.70		
$L = L_1 + L_2$			24.2 mm	<
(1) Chromel	4.24	-		
(2) Alumel	-	5.23		
$L = L_1 + L_2$			9.47 mm	<

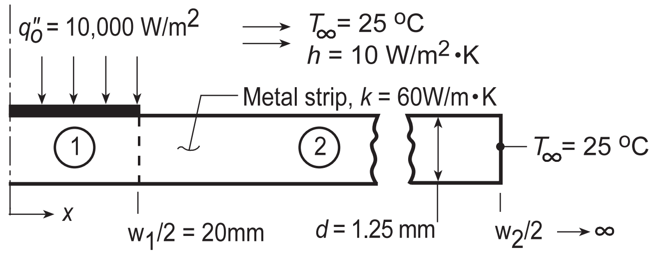
COMMENTS: Use of the chromel-alumel thermocouple junction leads to a substantial reduction in the size of the measurement device, while simultaneously minimizing measurement error associated with conduction along the wires to or from the sting.

PROBLEM 3.115

KNOWN: Thin plastic film being bonded to a metal strip by laser heating method; strip dimensions and thermophysical properties are prescribed as are laser heating flux and convection conditions.

FIND: (a) Expression for temperature distribution for the region with the plastic strip, $-w_1/2 \le x \le w_1/2$, (b) Temperature at the center (x = 0) and the edge of the plastic strip ($x = \pm w_1/2$) when the laser flux is 10,000 W/m^2; (c) Plot the temperature distribution for the strip and point out special features.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in x-direction only, (3) Plastic film has negligible thermal resistance, (4) Upper and lower surfaces have uniform convection coefficients, (5) Edges of metal strip are at air temperature (T_∞), that is, strip behaves as infinite fin so that $w_2 \to \infty$, (6) All the incident laser heating flux q''_o is absorbed by the film, (7) Negligible radiation heat transfer.

PROPERTIES: Metal strip (given): ρ = 7850 kg/m^3, c_p = 435 J/kg·m^3, k = 60 W/m·K.

ANALYSIS: (a) The strip-plastic film arrangement can be modeled as an infinite fin of uniform cross section a portion of which is exposed to the laser heat flux on the upper surface. The general solutions for the two regions of the strip, in terms of $\theta \equiv T(x) - T_\infty$, are

$$0 \le x \le w_1/2 \qquad \theta_1(x) = C_1 e^{+mx} + C_2 e^{-mx} + M/m^2 \tag{1}$$

$$M = q''_o P/2kA_c = q''_o/kd \qquad m = (2h/kd)^{1/2} \tag{2,3}$$

$$w_1/2 \le x \le \infty \qquad \theta_2(x) = C_3 e^{+mx} + C_4 e^{-mx}. \tag{4}$$

Four boundary conditions can be identified to evaluate the constants:

At x = 0: $\dfrac{d\theta_1}{dx}(0) = 0 = C_1 m e^0 - C_2 m e^{-0} + 0 \quad \rightarrow \quad C_1 = C_2$ (5)

At x = w_1/2: $\theta(w_1/2) = \theta_2(w_1/2)$

$$C_1 e^{+mw_1/2} + C_2 e^{-mw_1/2} + M/m^2 = C_3 e^{+mw_1/2} + C_4 e^{-mw_1/2} \tag{6}$$

At x = w_1/2: $d\theta_1(w_1/2)/dx = d\theta_2(w_1/2)/dx$

$$mC_1 e^{+mw_1/2} - mC_2 e^{-mw_1/2} + 0 = mC_3 e^{+mw_1/2} - mC_4 e^{-mw_1/2} \tag{7}$$

At x → ∞: $\theta_2(\infty) = 0 = C_3 e^{\infty} + C_4 e^{-\infty} \quad \rightarrow \quad C_3 = 0$ (8)

With $C_3 = 0$ and $C_1 = C_2$, combine Eqs. (6 and 7) to eliminate C_4 to find

$$C_1 = C_2 = -\frac{M/m^2}{2e^{mw_1/2}}. \tag{9}$$

and using Eq. (6) with Eq. (9) find

$$C_4 = M/m^2 \sinh(mw_1/2) e^{-mx_1/2} \tag{10}$$

Continued...

PROBLEM 3.115 (Cont.)

Hence, the temperature distribution in the region (1) under the plastic film, $0 \le x \le w_1/2$, is

$$\theta_1(x) = -\frac{M/m^2}{2e^{mw_1/2}}\left(e^{+mx} + e^{-mx}\right) + \frac{M}{m^2} = \frac{M}{m^2}\left(1 - e^{-mw_1/2}\cosh mx\right) \qquad (11)$$ <

and for the region (2), $x \ge w_1/2$,

$$\theta_2(x) = \frac{M}{m^2}\sinh\left(mw_1/2\right)e^{-mx} \qquad (12)$$

(b) Substituting numerical values into the temperature distribution expression above, $\theta_1(0)$ and $\theta_1(w_1/2)$ can be determined. First evaluate the following parameters:

$$M = 10,000\,W/m^2 / 60\,W/m\cdot K \times 0.00125\,m = 133,333\,K/m^2$$

$$m = \left(2\times 10\,W/m^2\cdot K / 60\,W/m\cdot K \times 0.00125\,m\right)^{1/2} = 16.33\,m^{-1}$$

Hence, for the midpoint x = 0,

$$\theta_1(0) = \frac{133,333\,K/m^2}{\left(16.33\,m^{-1}\right)^2}\left[1 - \exp\left(-16.33\,m^{-1}\times 0.020\,m\right)\times\cosh(0)\right] = 139.3\,K$$

$$T_1(0) = \theta_1(0) + T_\infty = 139.3\,K + 25^\circ C = 164.3^\circ C.$$ <

For the position $x = w_1/2 = 0.020$ m,

$$\theta_1(w_1/2) = 500.0\left[1 - 0.721\cosh\left(16.33\,m^{-1}\times 0.020\,m\right)\right] = 120.1\,K$$

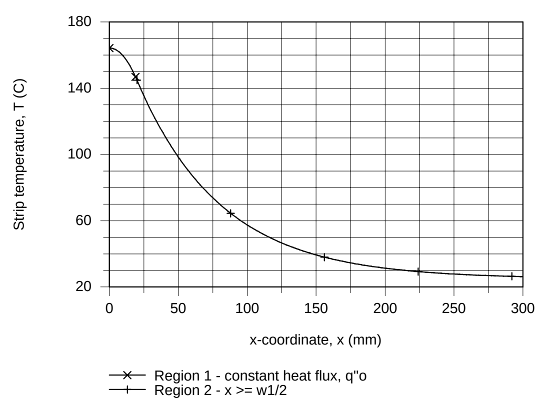
$$T_1(w_1/2) = 120.1\,K + 25^\circ C = 145.1^\circ C.$$ <

(c) The temperature distributions, $\theta_1(x)$ and $\theta_2(x)$, are shown in the plot below. Using IHT, Eqs. (11) and (12) were entered into the workspace and a graph created. The special features are noted:

(1) No gradient at midpoint, x = 0; symmetrical distribution.

(2) No discontinuity of gradient at $w_1/2$ (20 mm).

(3) Temperature excess and gradient approach zero with increasing value of x.



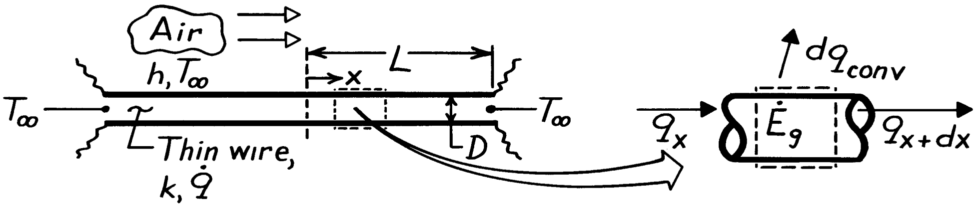
COMMENTS: How wide must the strip be in order to satisfy the infinite fin approximation such that $\theta_2(x \to \infty) = 0$? For x = 200 mm, find θ_2(200 mm) = 6.3°C; this would be a poor approximation. When x = 300 mm, θ_2(300 mm) = 1.2°C; hence when $w_2/2$ = 300 mm, the strip is a reasonable approximation to an infinite fin.

PROBLEM 3.116

KNOWN: Thermal conductivity, diameter and length of a wire which is annealed by passing an electrical current through the wire.

FIND: (a) Steady-state temperature distribution along wire, (b) Maximum wire temperature, (c) Average wire temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction along the wire, (3) Constant properties, (4) Negligible radiation, (5) Uniform convection coefficient h.

ANALYSIS: (a) Applying conservation of energy to a differential control volume,

$$q_x + \dot{E}_g - dq_{conv} - q_{x+dx} = 0$$

$$q_{x+dx} = q_x + \frac{dq_x}{dx}dx \qquad q_x = -k\left(\pi D^2/4\right)dT/dx$$

$$dq_{conv} = h(\pi D\,dx)\;(T - T_\infty) \qquad \dot{E}_g = \dot{q}\left(\pi D^2/4\right)dx.$$

Hence,

$$k\left(\pi D^2/4\right)\frac{d^2T}{dx^2}dx + \dot{q}\left(\pi D^2/4\right)dx - h(\pi D dx)\;(T - T_\infty) = 0$$

or, with $\theta \equiv T - T_\infty$, $$\frac{d^2\theta}{dx^2} - \frac{4h}{kD}\theta + \frac{\dot{q}}{k} = 0$$

The solution (general and particular) to this nonhomogeneous equation is of the form

$$\theta = C_1\,e^{mx} + C_2\,e^{-mx} + \frac{\dot{q}}{km^2}$$

where $m^2 = (4h/kD)$. The boundary conditions are:

$$\left.\frac{d\theta}{dx}\right|_{x=0} = 0 = m\,C_1\,e^0 - mC_2\,e^0 \rightarrow \qquad C_1 = C_2$$

$$\theta(L) = 0 = C_1\left(e^{mL} + e^{-mL}\right) + \frac{\dot{q}}{km^2} \rightarrow \qquad C_1 = \frac{-\dot{q}/km^2}{e^{mL} + e^{-mL}} = C_2$$

Continued...

PROBLEM 3.116 (Cont.)

The temperature distribution has the form

$$T = T_\infty - \frac{\dot{q}}{km^2}\left[\frac{e^{mx}+e^{-mx}}{e^{mL}+e^{-mL}} - 1\right] = T_\infty - \frac{\dot{q}}{km^2}\left[\frac{\cosh mx}{\cosh mL} - 1\right].$$ <

(b) The maximum wire temperature exists at $x = 0$. Hence,

$$T_{\max} = T(x=0) = T_\infty - \frac{\dot{q}}{km^2}\left[\frac{\cosh(0)}{\cosh(mL)} - 1\right] = T_\infty - \frac{\dot{q}}{km^2}\left[\frac{1}{\cosh(mL)} - 1\right]$$ <

(c) The average wire temperature may be obtained by evaluating the expression

$$\overline{T} = \frac{1}{L}\int_{x=0}^{L} T(x)dx = \frac{1}{L}\int_{x=0}^{L}\left[T_\infty - \frac{\dot{q}}{km^2}\left[\frac{\cosh(mx)}{\cosh(mL)} - 1\right]\right]dx$$

$$= T_\infty + \frac{\dot{q}}{km^2} - \tanh(mL)\frac{\dot{q}}{Lkm^3}$$ <

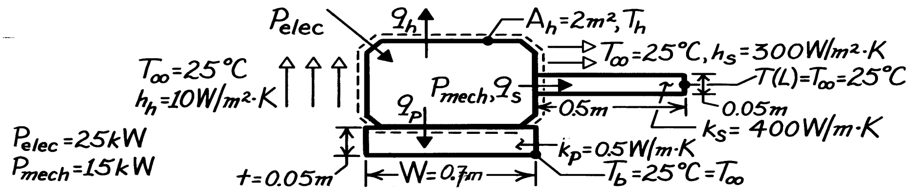
COMMENTS: (1) This process is commonly used to anneal wire and spring products. It is also used for flow measurement based upon the principle that the maximum or average wire temperature varies with the value of *m* and, hence, the convective heat transfer coefficient *h* and, ultimately, the fluid velocity. (2) To check the result of part (a), note that $T(L) = T(-L) = T_\infty$.

PROBLEM 3.117

KNOWN: Electric power input and mechanical power output of a motor. Dimensions of housing, mounting pad and connecting shaft needed for heat transfer calculations. Temperature of ambient air, tip of shaft, and base of pad.

FIND: Housing temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in pad and shaft, (3) Constant properties, (4) Negligible radiation.

ANALYSIS: Conservation of energy yields

$$P_{elec} - P_{mech} - q_h - q_p - q_s = 0$$

$$q_h = h_h A_h (T_h - T_\infty), \quad q_p = k_p W^2 \frac{(T_h - T_\infty)}{t}, \quad q_s = M \frac{\cosh mL - \theta_L/\theta_b}{\sinh mL}$$

$$\theta_L = 0, \quad mL = \left(4h_s L^2/k_s D\right)^{1/2}, \quad M = \left(\frac{\pi^2}{4} D^3 h_s k_s\right)^{1/2} (T_h - T_\infty).$$

Hence
$$q_s = \frac{\left(\left[\pi^2/4\right] D^3 h_s k_s\right)^{1/2} (T_h - T_\infty)}{\tanh\left(4h_s L^2/k_s D\right)^{1/2}}$$

Substituting, and solving for $(T_h - T_\infty)$,

$$T_h - T_\infty = \frac{P_{elec} - P_{mech}}{h_h A_h + k_p W^2/t + \left(\left(\pi^2/4\right) D^3 h_s k_s\right)^{1/2} / \tanh\left(4h_s L^2/k_s D\right)^{1/2}}$$

$$\left(\left(\pi^2/4\right) D^3 h_s k_s\right)^{1/2} = 6.08 \text{ W/K}, \quad \left(4h_s L^2/k_s D\right)^{1/2} = 3.87, \quad \tanh mL = 0.999$$

$$T_h - T_\infty = \frac{(25-15)\times 10^3 \text{ W}}{\left[10\times 2 + 0.5(0.7)^2/0.05 + 6.08/0.999\right] \text{W/K}} = \frac{10^4 \text{ W}}{(20+4.90+6.15)\text{ W/K}}$$

$$T_h - T_\infty = 322.1\text{K} \qquad T_h = 347.1°\text{C}$$ <

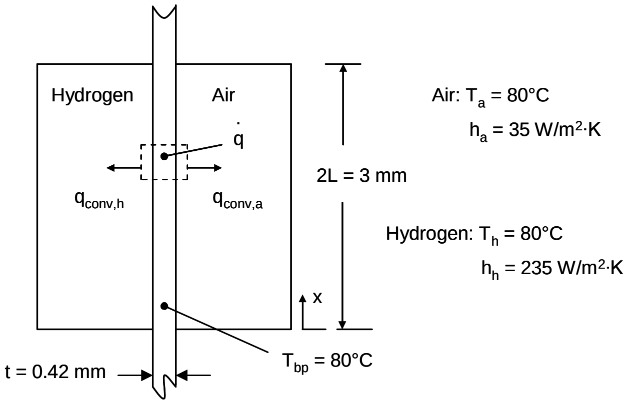
COMMENTS: (1) T_h is large enough to provide significant heat loss by radiation from the housing. Assuming an emissivity of 0.8 and surroundings at 25°C, $q_{rad} = \varepsilon A_h \left(T_h^4 - T_{sur}^4\right) = 4347$ W, which compares with $q_{conv} = hA_h (T_h - T_\infty) = 5390$ W. Radiation has the effect of decreasing T_h. (2) The infinite fin approximation, $q_s = M$, is excellent.

PROBLEM 3.118

KNOWN: Dimensions, convective conditions, bipolar plate, hydrogen and air temperatures within a fuel cell.

FIND: (a) The differential equation governing the membrane temperature distribution, T(x), (b) Solution of the equation of part (a), (c) Temperature distributions associated with carbon nanotube loadings of 0 and 10 volume percent.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Uniform volumetric energy generation, (4) Negligible contact resistance.

ANALYSIS:
(a) Performing an energy balance on the differential control volume,

$$q'_x + dq'_g = q'_{x+dx} + dq'_{conv,a} + dq'_{conv,h} \quad (1)$$
$$q'_{x+dx} = q'_x + (dq'_x/dx)dx$$

where $dq'_g = \dot{q} \cdot t \cdot dx$, $dq'_{conv,a} = h_a(T - T_a)dx$, $dq'_{conv,h} = h_h(T - T_h)dx$

Noting that $T_a = T_h$, Eq, (1) becomes

$$\dot{q} \cdot t \cdot dx = (dq'_x / dx)dx + h_a(T - T_a)dx + h_h(T - T_h)dx = (dq'_x/dx)dx + \left[(h_a + h_h)(T - T_h)\right]dx$$

From Fourier's law,

$$q'_x = - kt\, dT/dx$$

and $$\frac{d^2T}{dx^2} - \frac{1}{k_{eff,x}t}\left[(h_a + h_h)(T - T_a)\right] + \frac{\dot{q}}{k_{eff,x}} = 0$$ <

Continued…

PROBLEM 3.118 (Cont.)

(b) Defining $\theta = T - T_a$ and $\frac{d^2T}{dx^2} = \frac{d^2\theta}{dx^2}$, the differential equation becomes

$$\frac{d^2\theta}{dx^2} - \frac{(h_a + h_h)}{k_{eff,x}t}\theta + \frac{\dot{q}}{k_{eff,x}} = 0$$

This is the second-order, differential equation, and its general solution is of the form

$$\theta = C_1 e^{+\lambda x} + C_2 e^{-\lambda x} + S/\lambda^2$$

where $\lambda = \left(\frac{h_a + h_h}{k_{eff,x}t}\right)^{1/2}$, $S = \frac{\dot{q}}{k_{eff,x}}$

Appropriate boundary conditions are:

$$\theta(0) = T_0 - T_\infty = \theta_0, \quad d\theta/dx)_{x=L} = 0.$$

Hence, $\theta_0 = C_1 + C_2 + S/\lambda^2$

$$d\theta/dx)_{x=L} = C_1\lambda e^{+\lambda L} - C_2\lambda e^{-\lambda L} = 0 \qquad C_2 = C_1 e^{2\lambda L}$$

Hence, $C_1 = \left(\theta_0 - S/\lambda^2\right)/\left(1 + e^{2\lambda L}\right) \qquad C_2 = \left(\theta_0 - S/\lambda^2\right)/\left(1 + e^{-2\lambda L}\right)$

$$\theta = (\theta_0 - S/\lambda^2)\left[\frac{e^{\lambda x}}{1 + e^{2\lambda L}} + \frac{e^{-\lambda x}}{1 + e^{-2\lambda L}}\right] + S/\lambda^2.$$ <

(c) For $h_a = 35\ \text{W/m}^2\cdot\text{K}$, $h_h = 235\ \text{W/m}^2\cdot\text{K}$ and $k_{eff,x} = 0.79\ \text{W/m}\cdot\text{K}$

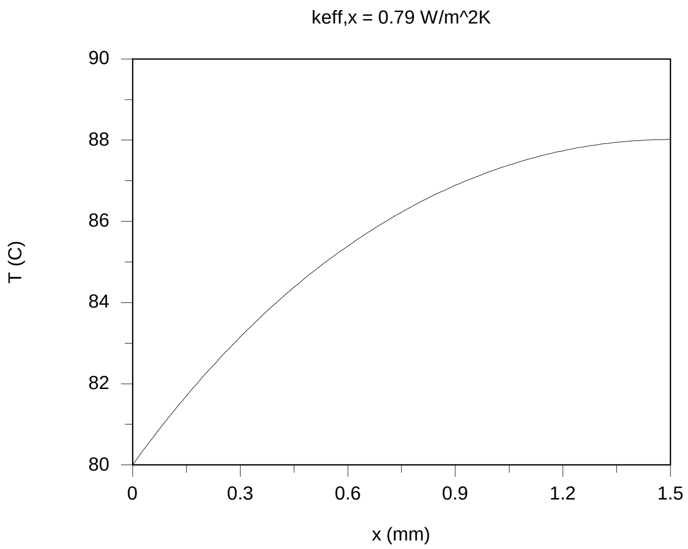
$$\lambda = \left[\frac{35\ \text{W/m}^2\cdot\text{K} + 235\ \text{W/m}^2\cdot\text{K}}{0.79\ \text{W/m}\cdot\text{K} \times 0.42 \times 10^{-3}\ \text{m}}\right]^{1/2} = 902\ \text{m}^{-1}$$

For $\dot{q} = 10 \times 10^6\ \text{W/m}^3$, $S = \frac{10 \times 10^6\ \text{W/m}^3}{0.79\ \text{W/m}\cdot\text{K}} = 12.7 \times 10^6\ \text{K/m}^2$

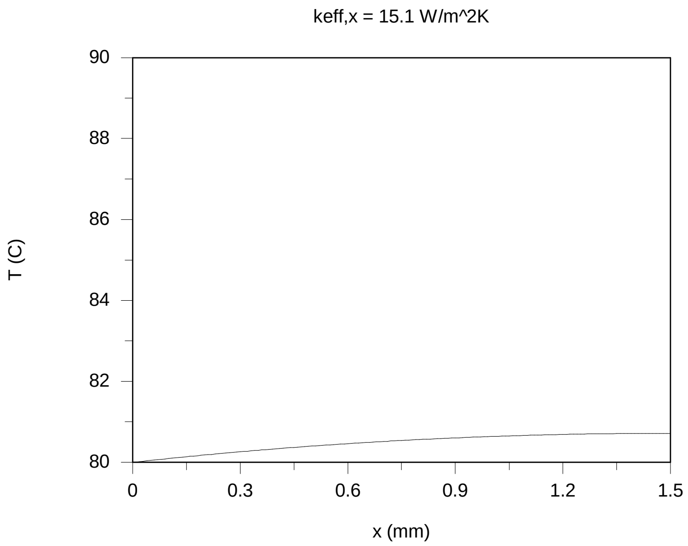
The temperature distribution without, and with carbon nanotube loading, is shown below. <

Continued…

PROBLEM 3.118 (Cont.)



Without carbon nanotube loading.



With carbon nanotube loading.

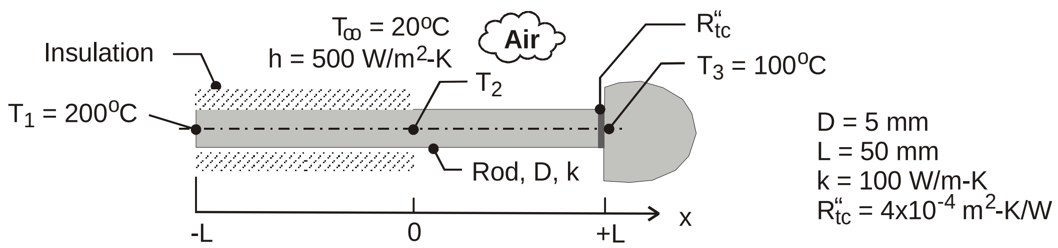
COMMENTS: (1) The carbon nanotubes appear to be effective in reducing the maximum temperature of the membrane. (2) Contact resistances between the bipolar plates and the membrane can be large. Hence, the actual membrane temperature will be higher than indicated with this analysis.

PROBLEM 3.119

KNOWN: Rod (D, k, 2L) that is perfectly insulated over the portion of its length $-L \le x \le 0$ and experiences convection (T_∞, h) over the portion $0 \le x \le +L$. One end is maintained at T_1 and the other is separated from a heat sink at T_3 with an interfacial thermal contact resistance R''_{tc}.

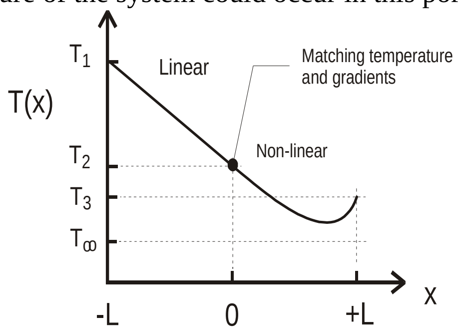
FIND: (a) Sketch the temperature distribution T vs. x and identify key features; assume $T_1 > T_3 > T_2$; (b) Derive an expression for the mid-point temperature T_2 in terms of thermal and geometric parameters of the system, (c) Using numerical values, calculate T_2 and plot the temperature distribution. Describe key features and compare to your sketch of part (a).

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in rod for $-L \le x \le 0$, (3) Rod behaves as one-dimensional extended surface for $0 \le x \le +L$, (4) Constant properties.

ANALYSIS: (a) The sketch for the temperature distribution is shown below. Over the insulated portion of the rod, the temperature distribution is linear. A temperature drop occurs across the thermal contact resistance at x = +L. The distribution over the exposed portion of the rod is non-linear. The minimum temperature of the system could occur in this portion of the rod.



(b) To derive an expression for T_2, begin with the general solution from the conduction analysis for a fin of uniform cross-sectional area, Eq. 3.71.

$$\theta(x) = C_1 e^{mx} + C_2 e^{-mx} \qquad 0 \le x \le +L \tag{1}$$

where $m = (hP/kA_c)^{1/2}$ and $\theta = T(x) - T_\infty$. The arbitrary constants are determined from the boundary conditions.

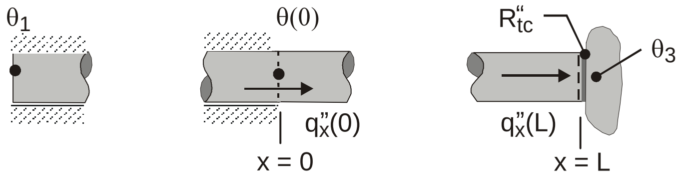
At x = 0, thermal resistance of rod

$$q_x(0) = -kA_c \left.\frac{d\theta}{dx}\right|_{x=0} = kA_c \frac{\theta_1 - \theta(0)}{L} \qquad \theta_1 = T_1 - T_\infty$$

$$-\left[mC_1e^0 - mC_2e^0 \right] = \frac{1}{L}\left[\theta_1 - \left(C_1e^0 + C_2e^0 \right) \right] \tag{2}$$

Continued …

PROBLEM 3.119 (Cont.)



At x=L, thermal contact resistance

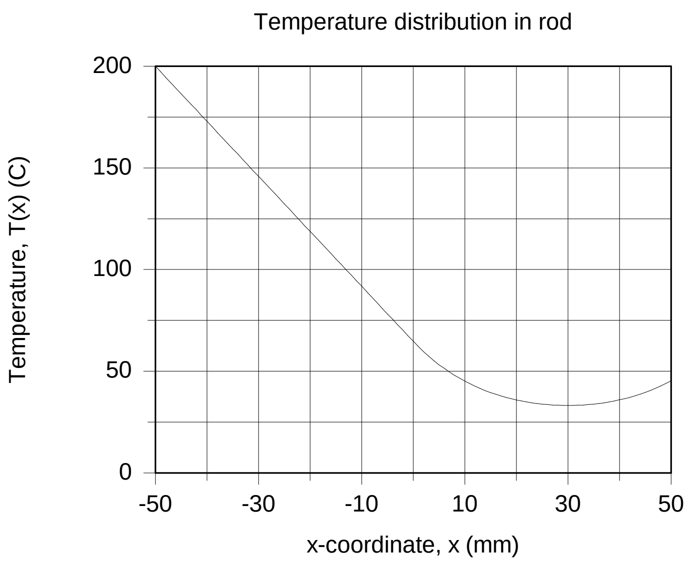
$$q_x(+L) = -kA_c \left.\frac{d\theta}{dx}\right|_{x=L} = \frac{\theta(L)-\theta_3}{R''_{tc}/A_c} \qquad \theta_3 = T_3 - T_\infty$$

$$-k\left[mC_1e^{mL} - mC_2e^{-mL}\right] = \frac{1}{R''_{tc}}\left[C_1e^{mL} + C_2e^{-mL} - \theta_3\right] \tag{3}$$

Eqs. (2) and (3) cannot be rearranged easily to find explicit forms for C_1 and C_2. The constraints will be evaluated numerically in part (c). Knowing C_1 and C_2, Eq. (1) gives

$$\theta_2 = \theta(0) = T_2 - T_\infty = C_1e^0 + C_2e^0 \tag{4}$$

(c) With Eqs. (1-4) in the *IHT Workspace* using numerical values shown in the schematic, find T_2 = 62.1°C. The temperature distribution is shown in the graph below.



COMMENTS: (1) The purpose of asking you to sketch the temperature distribution in part (a) was to give you the opportunity to identify the relevant thermal processes and come to an understanding of the system behavior.

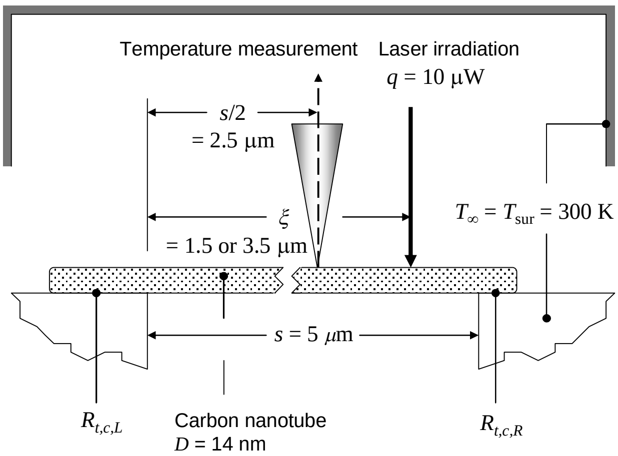
(2) Sketch the temperature distributions for the following conditions and explain their key features: (a) $R''_{tc} = 0$, (b) $R''_{tc} \to \infty$, and (c) the exposed portion of the rod behaves as an infinitely long fin; that is, k is very large.

PROBLEM 3.120

KNOWN: Trench length and nanotube diameter. Laser irradiation of known power at two distinct axial locations. Measured nanotube temperatures at the trench half-width. Nanotube thermal conductivity. Island temperature.

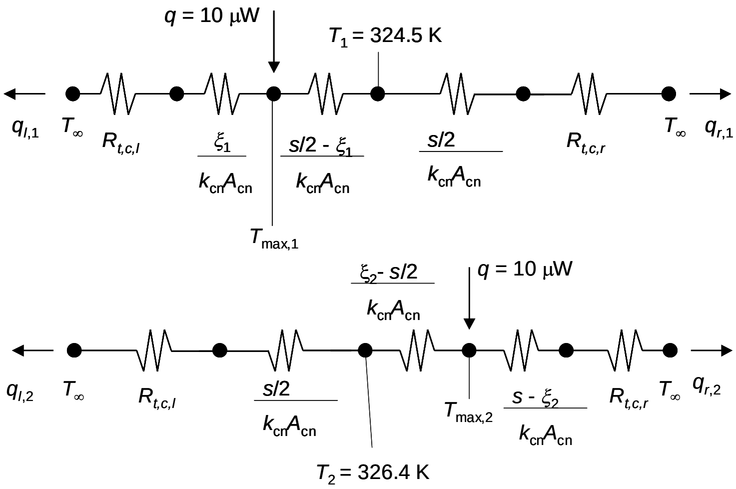
FIND: Thermal contact resistances at the left and right ends of the nanotube.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, one-dimensional conduction. (2) Constant properties. (3) Negligible radiation and convection losses.

ANALYSIS: Thermal circuits may be drawn for the two laser irradiation locations as follows. The top circuit corresponds to irradiation on the left half of the nanotube. The bottom circuit corresponds to irradiation of the right half of the nanotube.



The following equations may be written for irradiation of the left side of the nanotube (top circuit).

$$q = q_{l,1} + q_{r,1} \tag{1}$$

$$q_{l,1} = \frac{T_{max,1} - T_\infty}{R_{t,c,l} + \dfrac{\xi_1}{k_{cn}A_{cn}}} \tag{2}$$

Continued…

PROBLEM 3.120 (Cont.)

$$q_{r,1} = \frac{T_{\max,1} - T_\infty}{\dfrac{s/2 - \xi_1}{k_{cn}A_{cn}} + \dfrac{s/2}{k_{cn}A_{cn}} + R_{t,c,r}} \quad (3)$$

$$q_{r,1} = \frac{T_1 - T_\infty}{\dfrac{s/2}{k_{cn}A_{cn}} + R_{t,c,r}} \quad (4)$$

For irradiation of the right side of the nanotube (bottom circuit),

$$q = q_{l,2} + q_{r,2} \quad (5)$$

$$q_{l,2} = \frac{T_{\max,2} - T_\infty}{\dfrac{s/2}{k_{cn}A_{cn}} + \dfrac{\xi_2 - s/2}{k_{cn}A_{cn}} + R_{t,c,l}} \quad (6)$$

$$q_{l,2} = \frac{T_2 - T_\infty}{\dfrac{s/2}{k_{cn}A_{cn}} + R_{t,c,l}} \quad (7)$$

$$q_{r,2} = \frac{T_{\max,2} - T_\infty}{\dfrac{s - \xi_2}{k_{cn}A_{cn}} + R_{t,c,r}} \quad (8)$$

With k_{cn} = 3100 W/m·K, $A_{cn} = 1.54 \times 10^{-16}$ m^2, ξ_1 = 1.5 μm, T_1 = 324.5 K, ξ_2 = 3.5 μm, and T_2 = 326.4 K, Equations (1) through (8) may be solved simultaneously to yield

$T_{\max,1}$ = 331.0 K, $q_{l,1} = 6.896 \times 10^{-6}$ W, $q_{r,1} = 3.104 \times 10^{-6}$ W
$T_{\max,2}$ = 334.8 K, $q_{l,2} = 4.00 \times 10^{-6}$ W, $q_{r,2} = 6.00 \times 10^{-6}$ W

and

$R_{t,c,l} = 1.35 \times 10^6$ K/W ; $R_{t,c,r} = 2.65 \times 10^6$ K/W <

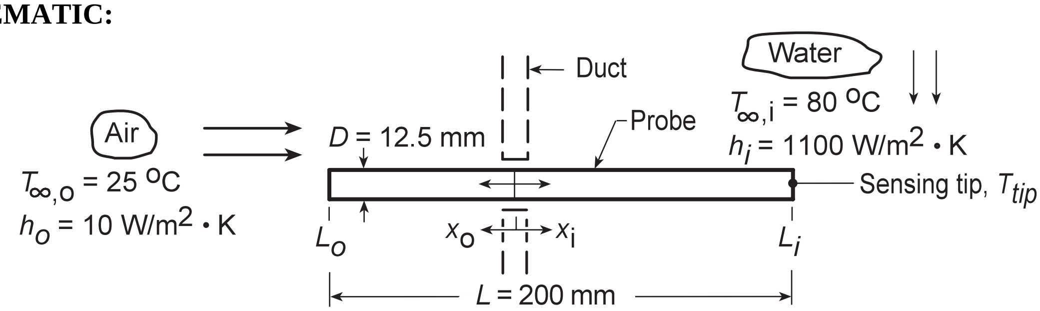
COMMENTS: (1) Assuming large surroundings, the maximum possible radiation loss is associated with blackbody behavior and $T_{\max,1}$. For this situation, $q_{\text{rad,max}} = \sigma\pi Ds(T_{\max,2}^4 - T_{sur}^4) = 5.67 \times 10^{-8}$ W/m^2·K^4 $\times \pi \times 14 \times 10^{-9}$ m $\times 5 \times 10^{-6}$ m $\times (334.8^4 - 300^4)$K^4 $= 55 \times 10^{-10}$ W. This is much less than the laser irradiation. Therefore, radiation heat transfer is negligible. (2) The carbon nanotube is not placed symmetrically between the two islands. It is difficult to place a carbon nanotube with such accuracy.

PROBLEM 3.121

KNOWN: Temperature sensing probe of thermal conductivity k, length L and diameter D is mounted on a duct wall; portion of probe L_i is exposed to water stream at $T_{\infty,i}$ while other end is exposed to ambient air at $T_{\infty,o}$; convection coefficients h_i and h_o are prescribed.

FIND: (a) Expression for the measurement error, $\Delta T_{err} = T_{tip} - T_{\infty,i}$, (b) For prescribed $T_{\infty,i}$ and $T_{\infty,o}$, calculate ΔT_{err} for immersion to total length ratios of 0.225, 0.425, and 0.625, (c) Compute and plot the effects of probe thermal conductivity and water velocity (h_i) on ΔT_{err}.

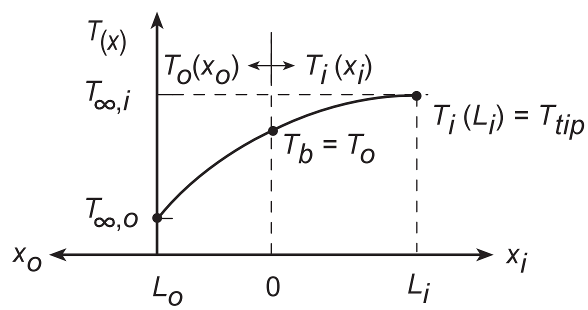
SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in probe, (3) Probe is thermally isolated from the duct, (4) Convection coefficients are uniform over their respective regions.

PROPERTIES: Probe material (given): k = 177 W/m·K.

ANALYSIS: (a) To derive an expression for $\Delta T_{err} = T_{tip} - T_{\infty,i}$, we need to determine the temperature distribution in the immersed length of the probe $T_i(x)$. Consider the probe to consist of two regions: $0 \le x_i \le L_i$, the immersed portion, and $0 \le x_o \le (L - L_i)$, the ambient-air portion where the origin corresponds to the location of the duct wall. Use the results for the temperature distribution and fin heat rate of Case A, Table 3.4:



Temperature distribution in region i:

$$\frac{\theta_i}{\theta_{b,i}} = \frac{T_i(x_i) - T_{\infty,i}}{T_o - T_{\infty,i}} = \frac{\cosh\left(m_i\left(L_i - x_i\right)\right) + \left(h_i/m_i k\right)\sinh\left(L_i - x_i\right)}{\cosh\left(m_i L_i\right) + \left(h_i/m_i k\right)\sinh\left(m_i L_i\right)} \quad (1)$$

and the tip temperature, $T_{tip} = T_i(L_i)$ at $x_i = L_i$, is

$$\frac{T_{tip} - T_{\infty,i}}{T_o - T_{\infty,i}} = A = \frac{\cosh(0) + \left(h_i/m_i k\right)\sinh(0)}{\cosh\left(m_i L_i\right) + \left(h_i/m_i k\right)\sinh\left(m_i L_i\right)} \quad (2)$$

and hence

$$\Delta T_{err} = T_{tip} - T_{\infty,i} = A\left(T_o - T_{\infty,i}\right) \quad (3)$$ <

where T_o is the temperature at $x_i = x_o = 0$ which at present is unknown, but can be found by setting the fin heat rates equal, that is,

$$q_{f,o} = -q_{f,i} \quad (4)$$

Continued...

PROBLEM 3.121 (Cont.)

$$\left(h_o PkA_c\right)^{1/2}\theta_{b,o}\cdot B=-\left(h_i PkA_c\right)^{1/2}\theta_{b,i}\cdot C$$

Solving for T_o, find

$$\frac{\theta_{b,o}}{\theta_{b,i}}=\frac{T_o-T_{\infty,o}}{T_o-T_{\infty,i}}=-\frac{\left(h_i PkA_c\right)^{1/2}C}{\left(h_o PkA_c\right)^{1/2}B}=-\left(\frac{h_i}{h_o}\right)^{1/2}\frac{C}{B}$$

$$T_o=\left[T_{\infty,o}+\left(\frac{h_i}{h_o}\right)^{1/2}\frac{C}{B}T_{\infty,i}\right]\Bigg/\left[1+\left(\frac{h_i}{h_o}\right)^{1/2}\frac{C}{B}\right] \qquad (5)$$

where the constants B and C are,

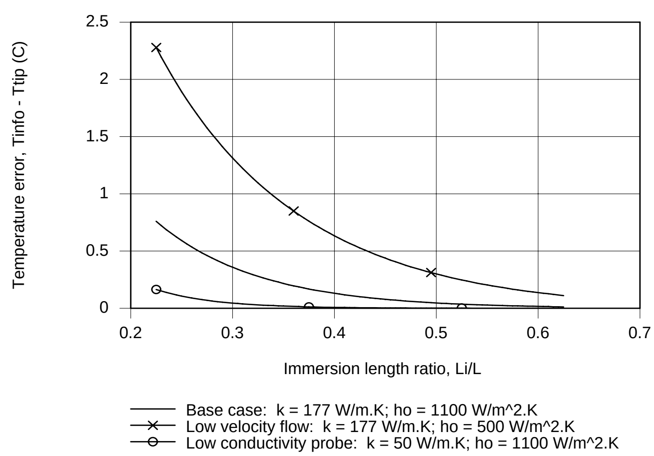
$$B=\frac{\sinh\left(m_o L_o\right)+\left(h_o/m_o k\right)\cosh\left(m_o L_o\right)}{\cosh\left(m_o L_o\right)+\left(h_o/m_o k\right)\sinh\left(m_o L_o\right)} \qquad (6)$$

$$C=\frac{\sinh\left(m_i L_i\right)+\left(h_i/m_i k\right)\cosh\left(m_i L_i\right)}{\cosh\left(m_i L_i\right)+\left(h_i/m_i k\right)\sinh\left(m_i L_i\right)} \qquad (7)$$

(b) To calculate the immersion error for prescribed immersion lengths, L_i/L = 0.225, 0.425 and 0.625, we use Eq. (3) as well as Eqs. (2, 6, 7 and 5) for A, B, C, and T_o, respectively. Results of these calculations are summarized below.

L_i/L	L_o (mm)	L_i (mm)	A	B	C	T_o (°C)	ΔT_{err} (°C)	
0.225	155	45	0.2328	0.5865	0.9731	76.7	-0.76	<
0.425	115	85	0.0396	0.4639	0.992	77.5	-0.10	<
0.625	75	125	0.0067	0.3205	0.9999	78.2	-0.01	<

(c) The probe behaves as a fin having ends exposed to the cool ambient air and the hot ambient water whose temperature is to be measured. As shown above, the probe is more accurate when more of its length is exposed to the water. If the thermal conductivity is *decreased*, heat transfer along the probe length is likewise decreased, the tip temperature will be closer to the water temperature. If the velocity of the water *decreases*, the convection coefficient will decrease, and the difference between the tip and water temperatures will increase.

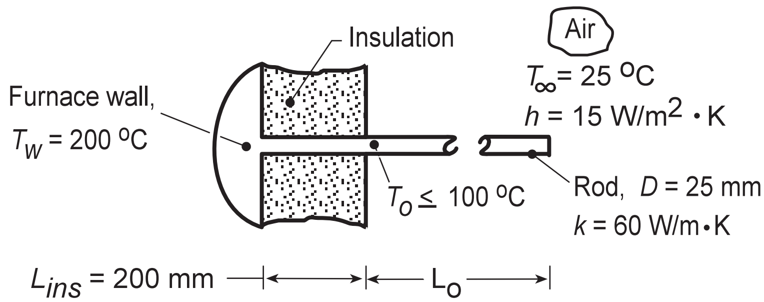


PROBLEM 3.122

KNOWN: Rod protruding normally from a furnace wall covered with insulation of thickness L_{ins} with the length L_o exposed to convection with ambient air.

FIND: (a) An expression for the exposed surface temperature T_o as a function of the prescribed thermal and geometrical parameters. (b) Will a rod of L_o = 100 mm meet the specified operating limit, $T_0 \leq 100°C$? If not, what design parameters would you change?

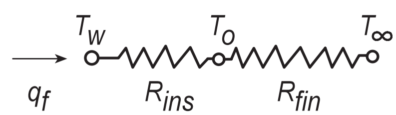
SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in rod, (3) Negligible thermal contact resistance between the rod and hot furnace wall, (4) Insulated section of rod, L_{ins}, experiences no lateral heat losses, (5) Convection coefficient uniform over the exposed portion of the rod, L_o, (6) Adiabatic tip condition for the rod and (7) Negligible radiation exchange between rod and its surroundings.

ANALYSIS: (a) The rod can be modeled as a thermal network comprised of two resistances in series: the portion of the rod, L_{ins}, covered by insulation, R_{ins}, and the portion of the rod, L_o, experiencing convection, and behaving as a fin with an adiabatic tip condition, R_{fin}. For the insulated section:

$$R_{ins} = L_{ins}/kA_c \qquad (1)$$



For the fin, Table 3.4, Case B, Eq. 3.81,

$$R_{fin} = \theta_b/q_f = \frac{1}{(hPkA_c)^{1/2}\tanh(mL_o)} \qquad (2)$$

$$m = (hP/kA_c)^{1/2} \qquad A_c = \pi D^2/4 \qquad P = \pi D \qquad (3,4,5)$$

From the thermal network, by inspection,

$$\frac{T_o - T_\infty}{R_{fin}} = \frac{T_w - T_\infty}{R_{ins} + R_{fin}} \qquad T_o = T_\infty + \frac{R_{fin}}{R_{ins} + R_{fin}}(T_w - T_\infty) \qquad (6)$$ <

(b) Substituting numerical values into Eqs. (1) - (6) with L_o = 200 mm,

$$T_o = 25^\circ C + \frac{6.298}{6.790 + 6.298}(200 - 25)^\circ C = 109^\circ C$$ <

$$R_{ins} = \frac{0.200\,m}{60\,W/m\cdot K \times 4.909\times10^{-4}\,m^2} = 6.790\,K/W \qquad A_c = \pi(0.025\,m)^2/4 = 4.909\times10^{-4}\,m^2$$

$$R_{fin} = 1\Big/\left(0.0347\,W^2/K^2\right)^{1/2}\tanh(6.324\times0.200) = 6.298\,K/W$$

$$(hPkA_c) = \left(15\,W/m^2\cdot K\times\pi(0.025\,m)\times60\,W/m\cdot K\times4.909\times10^{-4}\,m^2\right) = 0.0347\,W^2/K^2$$

Continued...

PROBLEM 3.122 (Cont.)

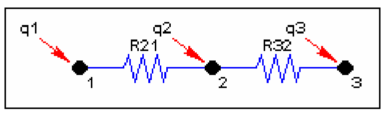
$$m = \left(hP/kA_c\right)^{1/2} = \left(15\,W/m^2\cdot K \times \pi\left(0.025\,m\right)/60\,W/m\cdot K \times 4.909\times10^{-4}\,m^2\right)^{1/2} = 6.324\,m^{-1}$$

Consider the following design changes aimed at reducing $T_o \leq 100°C$. (1) Increasing length of the fin portions: with L_o = 400 and 600 mm, T_o is 102.8°C and 102.3°C, respectively. Hence, increasing L_o will reduce T_o only modestly. (2) Decreasing the thermal conductivity: backsolving the above equation set with T_0 = 100°C, find the required thermal conductivity is k = 14 W/m·K. Hence, we could select a stainless steel alloy; see Table A.1. (3) Increasing the insulation thickness: find that for T_o = 100°C, the required insulation thickness would be L_{ins} = 211 mm. This design solution might be physically and economically unattractive. (4) A very practical solution would be to introduce thermal contact resistance between the rod base and the furnace wall by "tack welding" (rather than a continuous bead around the rod circumference) the rod in two or three places. (5) A less practical solution would be to increase the convection coefficient, since to do so, would require an air handling unit. (6) Using a tube rather than a rod will decrease A_c. For a 3 mm tube wall and 25 mm outside diameter, $A_c = 2.07 \times 10^{-4}\,m^2$, R_{ins} = 16.103 K/W and R_{fin} = 8.61 K/W, yielding T_o = 86°C. (conduction within the air inside the tube is neglected).

COMMENTS: (1) Would replacing the rod by a thick-walled tube provide a practical solution?

(2) The *IHT Thermal Resistance Network Model* and the *Thermal Resistance Tool* for a *fin* with an *adiabatic tip* were used to create a model of the rod. The Workspace is shown below.

// Thermal Resistance Network Model:
// The Network:



```
// Heat rates into node j,qij, through thermal resistance Rij
q21 = (T2 - T1) / R21
q32 = (T3 - T2) / R32

// Nodal energy balances
q1 + q21 = 0
q2 - q21 + q32 = 0
q3 - q32 = 0

/* Assigned variables list: deselect the qi, Rij and Ti which are unknowns; set qi = 0 for embedded nodal
points at which there is no external source of heat. */
T1 = Tw            // Furnace wall temperature, C
//q1 =             // Heat rate, W
T2 = To            // To, beginning of rod exposed length
q2 =  0            // Heat rate, W; node 2; no external heat source
T3 =  Tinf         // Ambient air temperature, C
//q3 =             // Heat rate, W

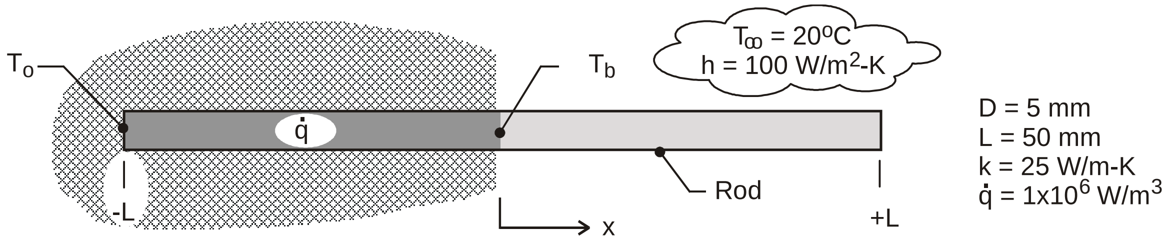
// Thermal Resistances:
// Rod - conduction resistance
R21 =  Lins / (k * Ac)          // Conduction resistance, K/W
Ac = pi * D^2 / 4               // Cross sectional area of rod, m^2
// Thermal Resistance Tools - Fin with Adiabatic Tip:
R32 =  Rfin                     //  Resistance of fin, K/W
/* Thermal resistance of a fin of uniform cross sectional area Ac, perimeter P, length L, and thermal
conductivity k with an adiabatic tip condition experiencing convection with a fluid at Tinf and coefficient h, */
Rfin = 1/ ( tanh (m*Lo) * (h * P * k * Ac ) ^ (1/2) )          // Case B, Table 3.4
m = sqrt(h*P / (k*Ac))
P = pi * D                      // Perimeter, m
// Other Assigned Variables:
Tw = 200           // Furnace wall temperature, C
k = 60             // Rod thermal conductivity, W/m.K
Lins = 0.200       // Insulated length, m
D = 0.025          // Rod diameter, m
h = 15             // Convection coefficient, W/m^2.K
Tinf = 25          // Ambient air temperature,C
Lo = 0.200         // Exposed length, m
```

PROBLEM 3.123

KNOWN: Rod (D, k, 2L) inserted into a perfectly insulating wall, exposing one-half of its length to an airstream (T_∞, h). An electromagnetic field induces a uniform volumetric energy generation $(\dot{q})$ in the imbedded portion.

FIND: (a) Derive an expression for T_b at the base of the exposed half of the rod; the exposed region may be approximated as a very long fin; (b) Derive an expression for T_o at the end of the imbedded half of the rod, and (c) Using numerical values, plot the temperature distribution in the rod and describe its key features. Does the rod behave as a very long fin?

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in imbedded portion of rod, (3) Imbedded portion of rod is perfectly insulated, (4) Exposed portion of rod behaves as an infinitely long fin, and (5) Constant properties.

ANALYSIS: (a) Since the exposed portion of the rod ($0 \le x \le +L$) behaves as an infinite fin, the fin heat rate using Eq. 3.85 is

$$q_x(0) = q_f = M = (hPkA_c)^{1/2}(T_b - T_\infty) \qquad (1)$$

From an energy balance on the imbedded portion of the rod,

$$q_f = \dot{q} A_c L \qquad (2)$$

Combining Eqs. (1) and (2), with $P = \pi D$ and $A_c = \pi D^2/4$, find

$$T_b = T_\infty + q_f (hPkA_c)^{-1/2} = T_\infty + \dot{q} A_c^{1/2} L (hPk)^{-1/2} \qquad (3) \quad <$$

(b) The imbedded portion of the rod ($-L \le x \le 0$) experiences one-dimensional heat transfer with uniform $\dot{q}$. From Eq. 3.48,

$$T_o = \frac{\dot{q}L^2}{2k} + T_b \quad <$$

(c) The temperature distribution T(x) for the rod is piecewise parabolic and exponential,

$$T(x) - T_b = \frac{\dot{q}L^2}{2k}\left(\frac{x}{L}\right)^2 \qquad -L \le x \le 0$$

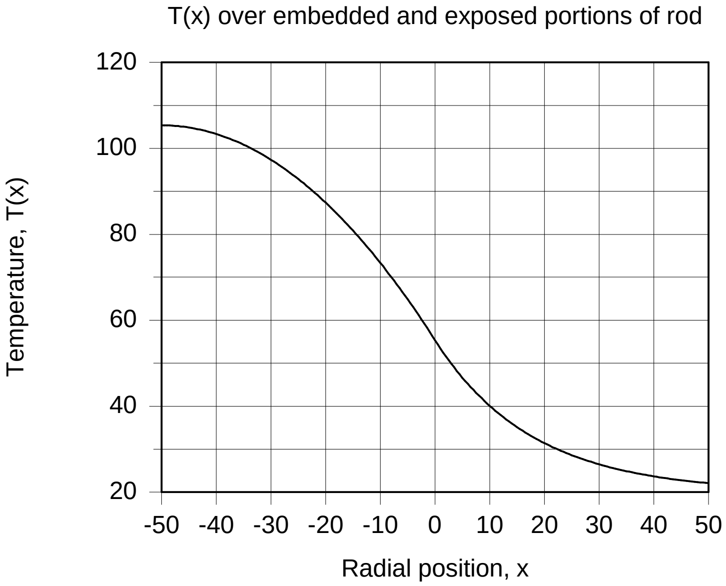
$$\frac{T(x) - T_\infty}{T_b - T_\infty} = \exp(-mx) \qquad 0 \le x \le +L$$

where $m = (hP/kA_c)^{1/2}$.

Continued …

PROBLEM 3.123 (Cont.)

The gradient at x = 0 will be continuous since we used this condition in evaluating T_b. The distribution is shown below with T_o = 105.4°C and T_b = 55.4°C.



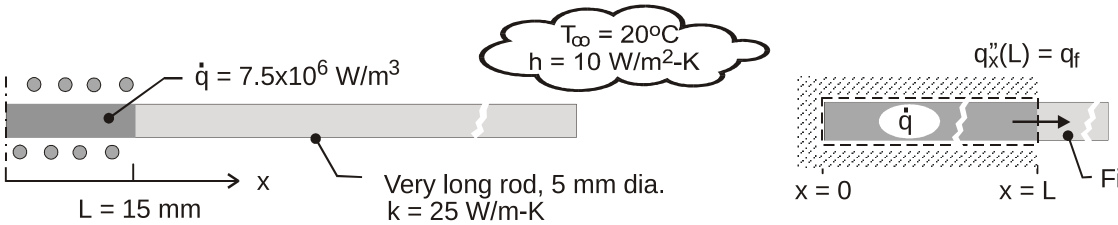
COMMENTS: The assumption that the rod behaves as an infinitely long fin is accurate; we see from the figure above that the temperature approaches the ambient temperature near the end of the rod.

PROBLEM 3.124

KNOWN: Very long rod (D, k) subjected to induction heating experiences uniform volumetric generation $(\dot{q})$ over the center, 30-mm long portion. The unheated portions experience convection (T_∞, h).

FIND: Calculate the temperature of the rod at the mid-point of the heated portion within the coil, T_o, and at the edge of the heated portion, T_b.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction with uniform $\dot{q}$ in portion of rod within the coil; no convection from lateral surface of rod, (3) Exposed portions of rod behave as infinitely long fins, and (4) Constant properties, (5) Neglect radiation.

ANALYSIS: The portion of the rod within the coil, $0 \le x \le +L$, experiences one-dimensional conduction with uniform generation. From Eq. 3.48,

$$T_o = \frac{\dot{q}L^2}{2k} + T_b \tag{1}$$

The portion of the rod beyond the coil, $L \le x \le \infty$, behaves as an infinitely long fin for which the heat rate from Eq. 3.85 is

$$q_f = q_x(L) = \left(hPkA_c\right)^{1/2}\left(T_b - T_\infty\right) \tag{2}$$

where $P = \pi D$ and $A_c = \pi D^2/4$. From an overall energy balance on the imbedded portion of the rod as illustrated in the schematic above, find the heat rate as

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = 0$$

$$-q_f + \dot{q}A_c L = 0$$

$$q_f = \dot{q}A_c L \tag{3}$$

Combining Eqs. (1-3),

$$T_b = T_\infty + \dot{q}A_c^{1/2}L\left(hPk\right)^{-1/2} \tag{4}$$

$$T_o = T_\infty + \frac{\dot{q}L^2}{2k} + \dot{q}A_c^{1/2}L\left(hPk\right)^{-1/2} \tag{5}$$

and substituting numerical values find

$$T_o = 305°C \qquad T_b = 272°C$$ <

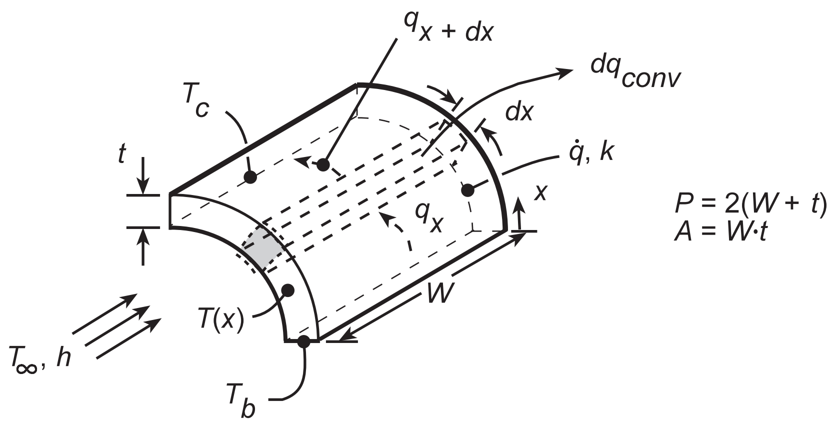
COMMENT: Assuming $\varepsilon = 0.8$ and $T_{sur} = T_\infty = 20°C$, $h_{rad} = 14.6\ W/m^2\cdot K$. Hence, radiation is significant and would serve to substantially reduce both T_o and T_b.

PROBLEM 3.125

KNOWN: Dimensions, end temperatures and volumetric heating of wire leads. Convection coefficient and ambient temperature.

FIND: (a) Equation governing temperature distribution in the leads, (b) Form of the temperature distribution.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction in x, (3) Uniform volumetric heating, (4) Uniform h (both sides), (5) Negligible radiation, (6) Constant properties.

ANALYSIS: (a) Performing an energy balance for the differential control volume,

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = 0 \qquad q_x - q_{x+dx} - dq_{conv} + \dot{q}dV = 0$$

$$-kA_c \frac{dT}{dx} - \left[-kA_c \frac{dT}{dx} - \frac{d}{dx}\left(kA_c \frac{dT}{dx}\right)dx\right] - hPdx\left(T - T_\infty\right) + \dot{q}A_c dx = 0$$

$$\frac{d^2T}{dx^2} - \frac{hP}{kA_c}\left(T - T_\infty\right) + \frac{\dot{q}}{k} = 0 \qquad <$$

(b) With a *reduced temperature* defined as $\Theta \equiv T - T_\infty - \left(\dot{q}A_c/hP\right)$ and $m^2 \equiv hP/kA_c$, the differential equation may be rendered homogeneous, with a general solution and boundary conditions as shown

$$\frac{d^2\Theta}{dx^2} - m^2\Theta = 0 \qquad \Theta(x) = C_1 e^{mx} + C_2 e^{-mx}$$

$$\Theta_b = C_1 + C_2 \qquad \Theta_c = C_1 e^{mL} + C_2 e^{-mL}$$

it follows that

$$C_1 = \frac{\Theta_b e^{-mL} - \Theta_c}{e^{-mL} - e^{mL}} \qquad C_2 = \frac{\Theta_c - \Theta_b e^{mL}}{e^{-mL} - e^{mL}}$$

$$\Theta(x) = \frac{\left(\Theta_b e^{-mL} - \Theta_c\right)e^{mx} + \left(\Theta_c - \Theta_b e^{mL}\right)e^{-mx}}{e^{-mL} - e^{mL}} \qquad <$$

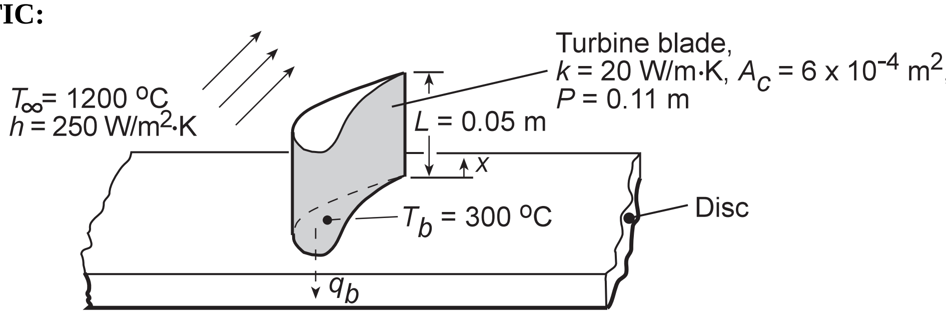
COMMENTS: If $\dot{q}$ is large and h is small, temperatures within the lead may readily exceed the prescribed boundary temperatures.

PROBLEM 3.126

KNOWN: Dimensions and thermal conductivity of a gas turbine blade. Temperature and convection coefficient of gas stream. Temperature of blade base and maximum allowable blade temperature.

FIND: (a) Whether blade operating conditions are acceptable, (b) Heat transfer to blade coolant.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, steady-state conduction in blade, (2) Constant k, (3) Adiabatic blade tip, (4) Negligible radiation.

ANALYSIS: Conditions in the blade are determined by Case B of Table 3.4.

(a) With the maximum temperature existing at x = L, Eq. 3.80 yields

$$\frac{T(L)-T_\infty}{T_b-T_\infty}=\frac{1}{\cosh mL}$$

$$m=\left(hP/kA_c\right)^{1/2}=\left(250\,W/m^2\cdot K\times 0.11\,m/20\,W/m\cdot K\times 6\times 10^{-4}\,m^2\right)^{1/2}$$

$m = 47.87\ m^{-1}$ and $mL = 47.87\ m^{-1} \times 0.05\ m = 2.39$

From Table B.1, cosh mL = 5.51. Hence,

$$T(L)=1200^\circ C+(300-1200)^\circ C/5.51=1037^\circ C$$ <

and the operating conditions are acceptable.

(b) With $M=\left(hPkA_c\right)^{1/2}\Theta_b=\left(250\,W/m^2\cdot K\times 0.11\,m\times 20\,W/m\cdot K\times 6\times 10^{-4}\,m^2\right)^{1/2}\left(-900^\circ C\right)=-517\,W$, Eq. 3.81 and Table B.1 yield

$$q_f=M\tanh mL=-517\,W(0.983)=-508\,W$$

Hence, $q_b=-q_f=508\,W$ <

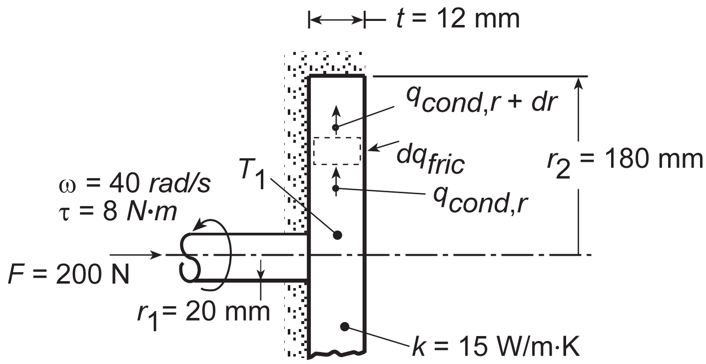
COMMENTS: Radiation losses from the blade surface and convection from the tip will contribute to reducing the blade temperatures.

PROBLEM 3.127

KNOWN: Dimensions of disc/shaft assembly. Applied angular velocity, force, and torque. Thermal conductivity and inner temperature of disc.

FIND: (a) Expression for the friction coefficient μ, (b) Radial temperature distribution in disc, (c) Value of μ for prescribed conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial conduction, (3) Constant k, (4) Uniform disc contact pressure p, (5) All frictional heat dissipation is transferred to shaft from base of disc.

ANALYSIS: (a) The normal force acting on a differential ring extending from r to r+dr on the contact surface of the disc may be expressed as $dF_n = p2\pi r dr$. Hence, the tangential force is $dF_t = \mu p 2\pi r dr$, in which case the torque may be expressed as

$$d\tau = 2\pi\mu p r^2 dr$$

For the entire disc, it follows that

$$\tau = 2\pi\mu p \int_o^{r_2} r^2 dr = \frac{2\pi}{3}\mu p r_2^3$$

where $p = F/\pi r_2^2$. Hence,

$$\mu = \frac{3}{2}\frac{\tau}{F r_2}$$ <

(b) Performing an energy balance on a differential control volume in the disc, it follows that

$$q_{cond,r} + dq_{fric} - q_{cond,r+dr} = 0$$

With $dq_{fric} = \omega d\tau = 2\mu F\omega\left(r^2/r_2^2\right)dr$, $q_{cond,r+dr} = q_{cond,r} + \left(dq_{cond,r}/dr\right)dr$, and

$q_{cond,r} = -k\left(2\pi r t\right)dT/dr$, it follows that

$$2\mu F\omega\left(r^2/r_2^2\right)dr + 2\pi k t\frac{d\left(r dT/dr\right)}{dr}dr = 0$$

or

$$\frac{d\left(r dT/dr\right)}{dr} = -\frac{\mu F\omega}{\pi k t r_2^2}r^2$$

Integrating twice,

Continued...

PROBLEM 3.127 (Cont.)

$$\frac{dT}{dr} = -\frac{\mu F\omega}{3\pi k t r_2^2} r^2 + \frac{C_1}{r}$$

$$T = -\frac{\mu F\omega}{9\pi k t r_2^2} r^3 + C_1 \ell n r + C_2$$

Since the disc is well insulated at $r = r_2$, $dT/dr|_{r_2} = 0$ and

$$C_1 = \frac{\mu F\omega r_2}{3\pi k t}$$

With $T(r_1) = T_1$, it also follows that

$$C_2 = T_1 + \frac{\mu F\omega}{9\pi k t r_2^2} r_1^3 - C_1 \ell n r_1$$

Hence,

$$T(r) = T_1 - \frac{\mu F\omega}{9\pi k t r_2^2}\left(r^3 - r_1^3\right) + \frac{\mu F\omega r_2}{3\pi k t} \ell n \frac{r}{r_1}$$ <

(c) For the prescribed conditions,

$$\mu = \frac{3}{2}\frac{8N \cdot m}{200N(0.18m)} = 0.333$$ <

Since the maximum temperature occurs at $r = r_2$,

$$T_{max} = T(r_2) = T_1 - \frac{\mu F\omega r_2}{9\pi k t}\left[1 - \left(\frac{r_1}{r_2}\right)^3\right] + \frac{\mu F\omega r_2}{3\pi k t} \ell n \left(\frac{r_2}{r_1}\right)$$

With $(\mu F\omega r_2/3\pi k t) = (0.333 \times 200N \times 40 rad/s \times 0.18m/3\pi \times 15 W/m \cdot K \times 0.012m) = 282.7^\circ C$,

$$T_{max} = 80^\circ C - \frac{282.7^\circ C}{3}\left[1 - \left(\frac{0.02}{0.18}\right)^3\right] + 282.7^\circ C \ell n \left(\frac{0.18}{0.02}\right)$$

$$T_{max} = 80^\circ C - 94.1^\circ C + 621.1^\circ C = 607^\circ C$$ <

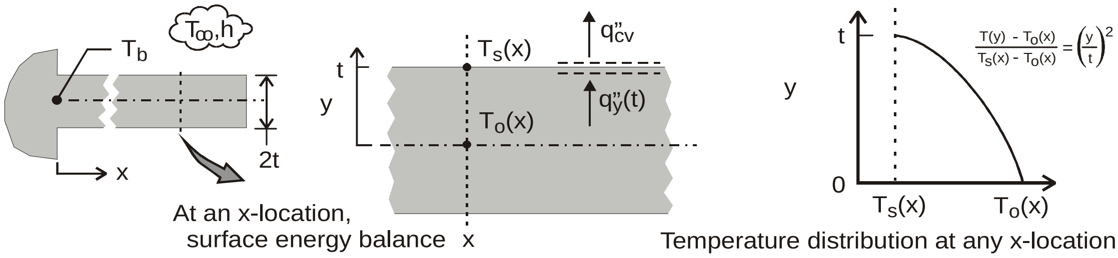
COMMENTS: The maximum temperature is excessive, and the disks should be actively cooled (by convection) at their outer surfaces.

PROBLEM 3.128

KNOWN: Extended surface of rectangular cross-section with heat flow in the longitudinal direction.

FIND: Determine the conditions for which the transverse (y-direction) temperature difference is negligible compared to the temperature difference between the surface and the environment, such that the 1-D analysis of Section 3.6.1 is valid by finding: (a) An expression for the conduction heat flux at the surface, $q_y''(t)$, in terms of T_s and T_o, assuming the transverse temperature distribution is parabolic, (b) An expression for the convection heat flux at the surface for the x-location; equate the two expressions, and identify the parameter that determines the ratio $(T_o - T_s)/(T_s - T_\infty)$; and (c) Developing a criterion for the validity of the 1-D assumption used to model an extended surface.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform convection coefficient and (3) Constant properties.

ANALYSIS: (a) Referring to the schematics above, the conduction heat flux at the surface y = t at any x-location follows from Fourier's law using the parabolic transverse temperature distribution.

$$q_y''(t) = -k\left.\frac{\partial T}{\partial y}\right)_{y=t} = -k\left(\left[T_s(x) - T_o(x)\right]\frac{2y}{t^2}\right)_{y=t} = -\frac{2k}{t}\left[T_s(x) - T_o(x)\right] \qquad (1)$$

(b) The convection heat flux at the surface of any x-location follows from the rate equation

$$q_{cv}'' = h\left[T_s(x) - T_\infty\right] \qquad (2)$$

Performing a surface energy balance as represented schematically above, equating Eqs. (1) and (2) provides

$$q_y''(t) = q_{cv}''$$

$$-\frac{2k}{t}\left[T_s(x) - T_o(x)\right] = h\left[T_s(x) - T_\infty\right]$$

$$\frac{T_s(x) - T_o(x)}{T_s(x) - T_\infty(x)} = -0.5\frac{ht}{k} = -0.5\ \mathrm{Bi} \qquad (3)$$

where Bi = ht/k, the Biot number, represents the ratio of the conduction to the convection thermal resistances,

$$\mathrm{Bi} = \frac{R_{cd}''}{R_{cv}''} = \frac{t/k}{1/h} \qquad (4)$$

(c) The transverse temperature difference $(T_s - T_o)$ will be negligible compared to the temperature difference between the surface and the environment $(T_s - T_\infty)$ when Bi << 1, say, 0.1, an order of magnitude smaller. This is the criterion to validate the one-dimensional assumption used to model extended surfaces.

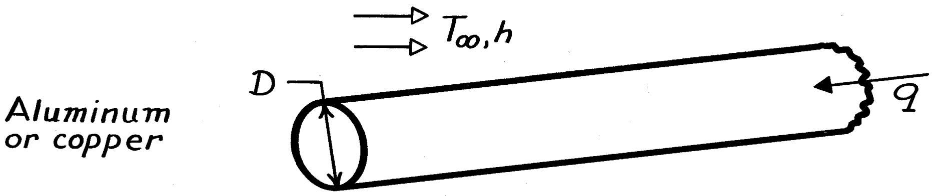
COMMENTS: The coefficient 0.5 in Eq. (3) is a consequence of the parabolic distribution assumption. This distribution represents the simplest polynomial expression that could approximate the real distribution.

PROBLEM 3.129

KNOWN: Long, aluminum cylinder acts as an extended surface.

FIND: (a) Increase in heat transfer if diameter is tripled and (b) Increase in heat transfer if copper is used in place of aluminum.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Uniform convection coefficient, (5) Rod is infinitely long.

PROPERTIES: *Table A-1,* Aluminum (pure): k = 240 W/m·K; *Table A-1,* Copper (pure): k = 400 W/m·K.

ANALYSIS: (a) For an infinitely long fin, the fin heat rate from Table 3.4 is

$$q_f = M = \left(hPkA_c\right)^{1/2}\theta_b$$

$$q_f = \left(h\,\pi\,D\,k\,\pi\,D^2/4\right)^{1/2}\theta_b = \frac{\pi}{2}\left(hk\right)^{1/2}D^{3/2}\ \theta_b.$$

where $P = \pi D$ and $A_c = \pi D^2/4$ for the circular cross-section. Note that $q_f \propto D^{3/2}$. Hence, if the diameter is tripled,

$$\frac{q_{f(3D)}}{q_{f(D)}} = 3^{3/2} = 5.2$$

and there is a 420% increase in heat transfer. <

(b) In changing from aluminum to copper, since $q_f \propto k^{1/2}$, it follows that

$$\frac{q_f\,(Cu)}{q_f\,(A1)} = \left[\frac{k_{Cu}}{k_{A1}}\right]^{1/2} = \left[\frac{400}{240}\right]^{1/2} = 1.29$$

and there is a 29% increase in the heat transfer rate. <

COMMENTS: (1) Because fin effectiveness is enhanced by maximizing $P/A_c = 4/D$, the use of a larger number of small diameter fins is preferred to a single large diameter fin.

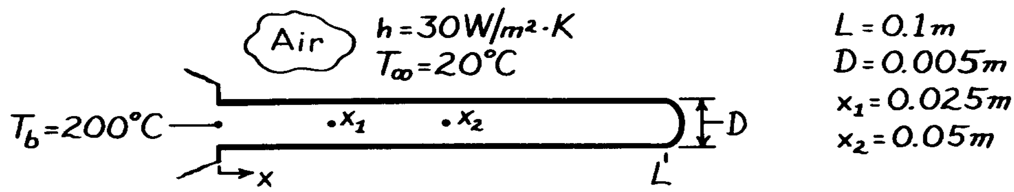
(2) From the standpoint of cost, weight and machinability, aluminum is preferred over copper.

PROBLEM 3.130

KNOWN: Length, diameter, base temperature and environmental conditions associated with a brass rod.

FIND: Temperature at specified distances along the rod.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible radiation, (5) Uniform convection coefficient h.

PROPERTIES: *Table A-1*, Brass $\left(\overline{T} = 110^\circ C\right)$: $k = 133\ W/m \cdot K$.

ANALYSIS: Evaluate first the fin parameter

$$m = \left[\frac{hP}{kA_c}\right]^{1/2} = \left[\frac{h\pi\ D}{k\pi\ D^2/4}\right]^{1/2} = \left[\frac{4h}{kD}\right]^{1/2} = \left[\frac{4 \times 30\ W/m^2 \cdot K}{133\ W/m \cdot K \times 0.005m}\right]^{1/2}$$

$$m = 13.43\ m^{-1}.$$

Hence, m L = (13.43)×0.1 = 1.34 and from the results of Example 3.9, it is advisable not to make the infinite rod approximation. Thus from Table 3.4, the temperature distribution has the form

$$\theta = \frac{\cosh m(L-x) + (h/mk)\sinh m(L-x)}{\cosh mL + (h/mk)\sinh mL}\theta_b$$

Evaluating the hyperbolic functions, cosh mL = 2.04 and sinh mL = 1.78, and the parameter

$$\frac{h}{mk} = \frac{30\ W/m^2 \cdot K}{13.43m^{-1}\ (133\ W/m \cdot K)} = 0.0168,$$

with θ_b = 180°C the temperature distribution has the form

$$\theta = \frac{\cosh m(L-x) + 0.0168\ \sinh m(L-x)}{2.07}\left(180^\circ C\right).$$

The temperatures at the prescribed locations are tabulated below.

x(m)	cosh m(L-x)	sinh m(L-x)	θ	T(°C)	
x_1 = 0.025	1.55	1.19	136.5	156.5	<
x_2 = 0.05	1.24	0.725	108.9	128.9	<
L = 0.10	1.00	0.00	87.0	107.0	<

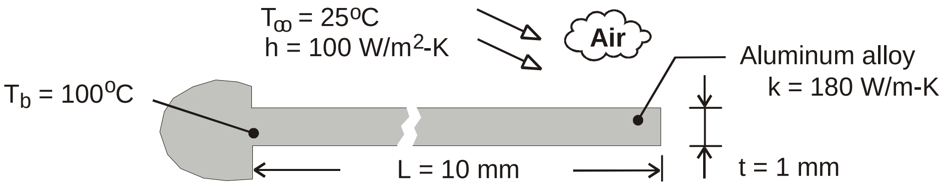
COMMENTS: If the rod were approximated as infinitely long: $T(x_1)$ = 148.7°C, $T(x_2)$ = 112.0°C, and T(L) = 67.0°C. The assumption would therefore result in significant underestimates of the rod temperature.

PROBLEM 3.131

KNOWN: Thickness, length, thermal conductivity, and base temperature of a rectangular fin. Fluid temperature and convection coefficient.

FIND: (a) Heat rate per unit width, efficiency, effectiveness, thermal resistance, and tip temperature for different tip conditions, (b) Effect of convection coefficient and thermal conductivity on the heat rate.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction along fin, (3) Constant properties, (4) Negligible radiation, (5) Uniform convection coefficient, (6) Fin width is much longer than thickness (w >> t).

ANALYSIS: (a) The fin heat transfer rate for Cases A, B and D are given by Eqs. (3.77), (3.81) and (3.85), where $M \approx (2\,hw^2tk)^{1/2}\,(T_b - T_\infty) = (2 \times 100\ W/m^2{\cdot}K \times 0.001m \times 180\ W/m{\cdot}K)^{1/2}\,(75°C)\ w$ = 450 w W, $m \approx (2h/kt)^{1/2} = (200\ W/m^2{\cdot}K/180\ W/m{\cdot}K \times 0.001m)^{1/2} = 33.3m^{-1}$, $mL \approx 33.3m^{-1} \times 0.010m = 0.333$, and $(h/mk) \approx (100\ W/m^2{\cdot}K/33.3m^{-1} \times 180\ W/m{\cdot}K) = 0.0167$. From Table B-1, it follows that sinh mL ≈ 0.340, cosh mL ≈ 1.057, and tanh mL ≈ 0.321. From knowledge of q_f, Eqs. (3.91), (3.86) and (3.88) yield

$$\eta_f \approx \frac{q_f'}{h(2L+t)\theta_b},\quad \varepsilon_f \approx \frac{q_f'}{ht\theta_b},\quad R_{t,f}' = \frac{\theta_b}{q_f'}$$

Case A: From Eq. (3.77), (3.91), (3.86), (3.88) and (3.75),

$$q_f' = \frac{M}{w}\frac{\sinh mL + (h/mk)\cosh mL}{\cosh mL + (h/mk)\sinh mL} = 450\ W/m\,\frac{0.340 + 0.0167 \times 1.057}{1.057 + 0.0167 \times 0.340} = 151\ W/m$$ <

$$\eta_f = \frac{151\ W/m}{100\ W/m^2 \cdot K(0.021m)75°C} = 0.96$$ <

$$\varepsilon_f = \frac{151\ W/m}{100\ W/m^2 \cdot K(0.001m)75°C} = 20.2,\quad R_{t,f}' = \frac{75°C}{151\ W/m} = 0.50\ m \cdot K/W$$ <

$$T(L) = T_\infty + \frac{\theta_b}{\cosh mL + (h/mk)\sinh mL} = 25°C + \frac{75°C}{1.057 + (0.0167)0.340} = 95.6°C$$ <

Case B: From Eqs. (3.81), (3.91), (3.86), (3.88) and (3.80)

$$q_f' = \frac{M}{w}\tanh mL = 450\ W/m(0.321) = 144\ W/m$$ <

$$\eta_f = 0.92,\quad \varepsilon_f = 19.3,\quad R_{t,f}' = 0.52\ m \cdot K/W$$ <

$$T(L) = T_\infty + \frac{\theta_b}{\cosh mL} = 25°C + \frac{75°C}{1.057} = 96.0°C$$ <

Continued …

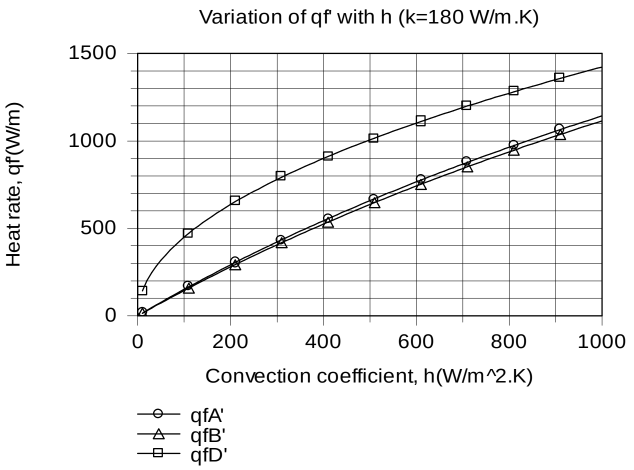
PROBLEM 3.131 (Cont.)

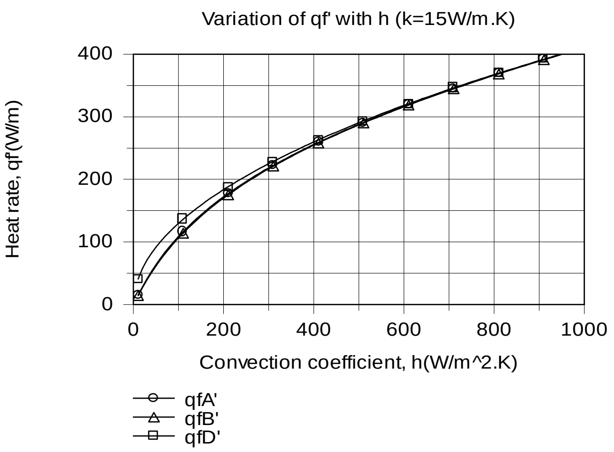
Case D (L → ∞): From Eqs. (3.85), (3.91), (3.86), (3.88) and (3.84)

$$q'_f = \frac{M}{w} = 450\ W/m$$ <

$$\eta_f = 0,\ \varepsilon_f = 60.0,\ R'_{t,f} = 0.167\ m\cdot K/W,\ T(L) = T_\infty = 25°C$$ <

(b) The effect of h on the heat rate is shown below for the aluminum and stainless steel fins.





For both materials, there is little difference between the Case A and B results over the entire range of h. The difference (percentage) increases with decreasing h and increasing k, but even for the worst case condition (h = 10 $W/m^2\cdot K$, k = 180 W/m·K), the heat rate for Case A (15.7 W/m) is only slightly larger than that for Case B (14.9 W/m). For aluminum, the heat rate is significantly over-predicted by the infinite fin approximation over the entire range of h. For stainless steel, it is over-predicted for small values of h, but results for all three cases are within 1% for h > 500 $W/m^2\cdot K$.

COMMENTS: From the results of Part (a), we see there is a slight reduction in performance (smaller values of q'_f, η_f and ε_f, as well as a larger value of $R'_{t,f}$) associated with insulating the tip.

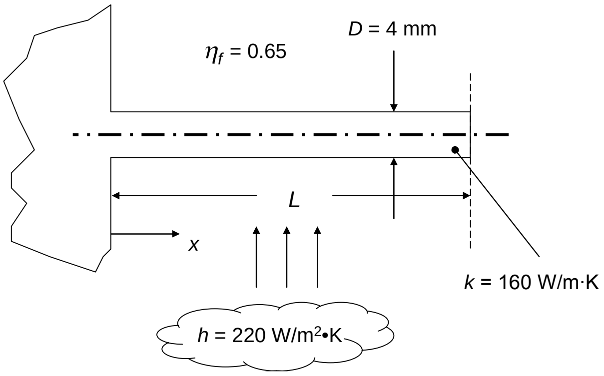
Although η_f = 0 for the infinite fin, q'_f and ε_f are substantially larger than results for L = 10 mm, indicating that performance may be significantly improved by increasing L.

PROBLEM 3.132

KNOWN: Thermal conductivity and diameter of a pin fin. Value of the heat transfer coefficient and fin efficiency.

FIND: (a) Length of fin, (b) Fin effectiveness.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, one-dimensional conditions, (2) Negligible radiation heat transfer, (3) Constant properties, (4) Convection from fin tip.

PROPERTIES: *Given*, Aluminum Alloy: k = 160 W/m·K.

ANALYSIS: For an active fin tip, the efficiency may be expressed in terms of the corrected fin length as:

$$\eta_f = \frac{\tanh(mL_c)}{mL_c}$$

where $m = \sqrt{hP/kA_c} = \sqrt{4h/kD} = \sqrt{4 \times 220\text{W/m}^2 \cdot \text{K} / \left(160\text{W/m} \cdot \text{K} \times 4 \times 10^{-3}\text{m}\right)} = 37.1\text{m}^{-1}$

Hence, $\eta_f = 0.65 = \dfrac{\tanh(37.1\text{m}^{-1} \times L_c)}{37.1\text{m}^{-1} \times L_c}$ which may be solved by trial-and-error (or by using *IHT*) to yield L_c = 0.0362 m = 36.2 mm. The fin length is therefore, $L = L_c - D/4$ = 0.0362 m – 0.004m/4 = 0.0352 m = 35.2 mm. <

The fin effectiveness is:

$$\varepsilon_f = \frac{q_f}{hA_{c,b}\theta_b} = \frac{M\tanh(mL_c)}{hA_{c,b}\theta_b} = \frac{\sqrt{hPkA_{c,b}}\tanh(mL_c)}{hA_{c,b}} = \frac{2}{\sqrt{hD/k}}\tanh(mL_c)$$

$$= \frac{2}{\sqrt{\dfrac{220\text{W/m}^2 \cdot \text{K} \times 4 \times 10^{-3}\text{m}}{160\text{W/m} \cdot \text{K}}}}\tanh(37.1\text{m}^{-1} \times 36.2 \times 10^{-3}\text{m}) = 23.5$$ <

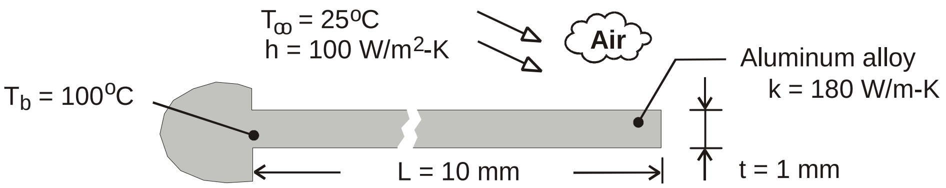
COMMENTS: The values of the fin effectiveness and fin efficiency are independent of the base or fluid temperatures.

PROBLEM 3.133

KNOWN: Thickness, length, thermal conductivity, and base temperature of a rectangular fin. Fluid temperature and convection coefficient.

FIND: (a) Heat rate per unit width, efficiency, effectiveness, thermal resistance, and tip temperature for different tip conditions, (b) Effect of fin length and thermal conductivity on the heat rate.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction along fin, (3) Constant properties, (4) Negligible radiation, (5) Uniform convection coefficient, (6) Fin width is much longer than thickness (w >> t).

ANALYSIS: (a) The fin heat transfer rate for Cases A, B and D are given by Eqs. (3.77), (3.81) and (3.85), where $M \approx (2\,hw^2tk)^{1/2}\,(T_b - T_\infty) = (2 \times 100\ W/m^2\cdot K \times 0.001m \times 180\ W/m\cdot K)^{1/2}\,(75°C)\ w =$ 450 w W, $m \approx (2h/kt)^{1/2} = (200\ W/m^2\cdot K/180\ W/m\cdot K \times 0.001m)^{1/2} = 33.3m^{-1}$, $mL \approx 33.3m^{-1} \times 0.010m = 0.333$, and $(h/mk) \approx (100\ W/m^2\cdot K/33.3m^{-1} \times 180\ W/m\cdot K) = 0.0167$. From Table B-1, it follows that sinh mL ≈ 0.340, cosh mL ≈ 1.057, and tanh mL ≈ 0.321. From knowledge of q_f, Eqs. (3.91), (3.86) and (3.88) yield

$$\eta_f \approx \frac{q_f'}{h(2L+t)\theta_b},\quad \varepsilon_f \approx \frac{q_f'}{ht\,\theta_b},\quad R_{t,f}' = \frac{\theta_b}{q_f'}$$

Case A: From Eq. (3.77), (3.91), (3.86), (3.88) and (3.75),

$$q_f' = \frac{M}{w}\frac{\sinh mL + (h/mk)\cosh mL}{\cosh mL + (h/mk)\sinh mL} = 450\ W/m\,\frac{0.340 + 0.0167 \times 1.057}{1.057 + 0.0167 \times 0.340} = 151\ W/m \qquad <$$

$$\eta_f = \frac{151\ W/m}{100\ W/m^2\cdot K\,(0.021m)\,75°C} = 0.96 \qquad <$$

$$\varepsilon_f = \frac{151\ W/m}{100\ W/m^2\cdot K\,(0.001m)\,75°C} = 20.1,\quad R_{t,f}' = \frac{75°C}{151\ W/m} = 0.50\ m\cdot K/W \qquad <$$

$$T(L) = T_\infty + \frac{\theta_b}{\cosh mL + (h/mk)\sinh mL} = 25°C + \frac{75°C}{1.057 + (0.0167)0.340} = 95.6°C \qquad <$$

Case B: From Eqs. (3.81), (3.91), (3.86), (3.88) and (3.80)

$$q_f' = \frac{M}{w}\tanh mL = 450\ W/m\,(0.321) = 144\ W/m \qquad <$$

$$\eta_f = 0.92,\ \varepsilon_f = 19.2,\ R_{t,f}' = 0.52\ m\cdot K/W \qquad <$$

$$T(L) = T_\infty + \frac{\theta_b}{\cosh mL} = 25°C + \frac{75°C}{1.057} = 96.0°C \qquad <$$

Continued …..

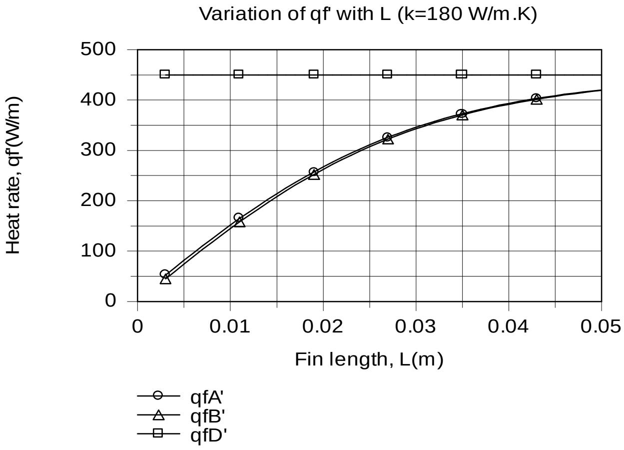
PROBLEM 3.133 (Cont.)

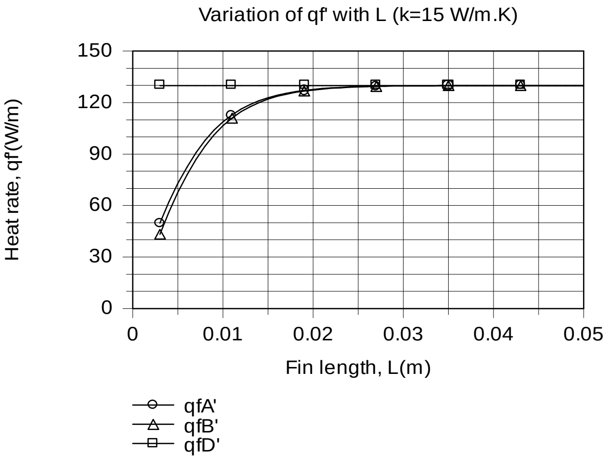
Case D (L $\rightarrow \infty$): From Eqs. (3.85), (3.91), (3.86), (3.88) and (3.84)

$$q'_f = \frac{M}{w} = 450\,\text{W/m}$$ <

$$\eta_f = 0,\ \varepsilon_f = 60.0,\ R'_{t,f} = 0.167\,\text{m}\cdot\text{K/W},\ T(L) = T_\infty = 25°\text{C}$$ <

(b) The effect of L on the heat rate is shown below for the aluminum and stainless steel fins.





For both materials, differences between the Case A and B results diminish with increasing L and are within 1% of each other at L ≈ 27 mm and L ≈ 13 mm for the aluminum and steel, respectively. At L = 3 mm, results differ by 14% and 13% for the aluminum and steel, respectively. The Case A and B results approach those of the infinite fin approximation more quickly for stainless steel due to the larger temperature gradients, |dT/dx|, for the smaller value of k.

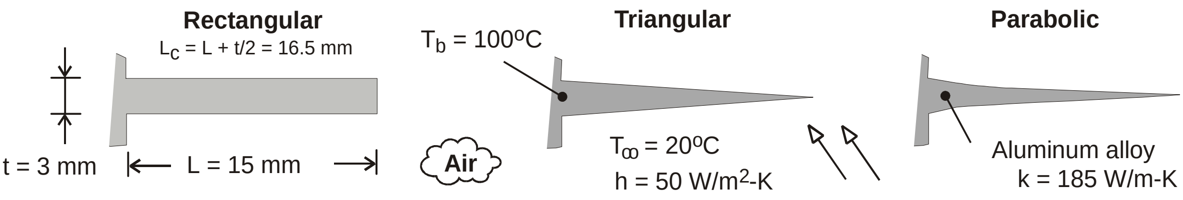
COMMENTS: From the results of Part (a), we see there is a slight reduction in performance (smaller values of q'_f, η_f and ε_f, as well as a larger value of $R'_{t,f}$) associated with insulating the tip. Although $\eta_f = 0$ for the infinite fin, q'_f and ε_f are substantially larger than results for L = 10 mm, indicating that performance may be significantly improved by increasing L.

PROBLEM 3.134

KNOWN: Length, thickness and temperature of straight fins of rectangular, triangular and parabolic profiles. Ambient air temperature and convection coefficient.

FIND: Heat rate per unit width, efficiency and volume of each fin.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible radiation, (5) Uniform convection coefficient.

ANALYSIS: For each fin,

$$q'_f = q'_{max} = \eta_f \, hA'_f \, \theta_b, \qquad V' = A_p$$

where η_f depends on the value of $m = (2h/kt)^{1/2} = (100\ W/m^2\cdot K/185\ W/m\cdot K \times 0.003m)^{1/2} = 13.4m^{-1}$ and the product $mL = 13.4m^{-1} \times 0.015m = 0.201$ or $mL_c = 0.222$. Expressions for η_f, A'_f and A_p are obtained from Table 3-5.

Rectangular Fin:

$$\eta_f = \frac{\tanh\ mL_c}{mL_c} = \frac{0.218}{0.222} = 0.982, \;\; A'_f = 2L_c = 0.033m \quad <$$

$$q' = 0.982\left(50\,W/m^2\cdot K\right)0.033m\left(80°C\right) = 129.6\,W/m, \;\; V' = tL = 4.5\times10^{-5}\ m^2 \quad <$$

Triangular Fin:

$$\eta_f = \frac{1}{mL}\frac{I_1(2mL)}{I_0(2mL)} = \frac{0.205}{(0.201)1.042} = 0.978, \;\; A'_f = 2\left[L^2 + (t/2)^2\right]^{1/2} = 0.030m \quad <$$

$$q' = 0.978\left(50\,W/m^2\cdot K\right)0.030m\left(80°C\right) = 117.3\,W/m, \;\; V' = (t/2)L = 2.25\times10^{-5}m^2 \quad <$$

Parabolic Fin:

$$\eta_f = \frac{2}{\left[4(mL)^2+1\right]^{1/2}+1} = 0.963, \;\; A'_f = \left[C_1L + \left(L^2/t\right)\ln\left(t/L + C_1\right)\right] = 0.030m \quad <$$

$$q'_f = 0.963\left(50\,W/m^2\cdot K\right)0.030m\left(80°C\right) = 115.6\,W/m, \;\; V' = (t/3)L = 1.5\times10^{-5}m^2 \quad <$$

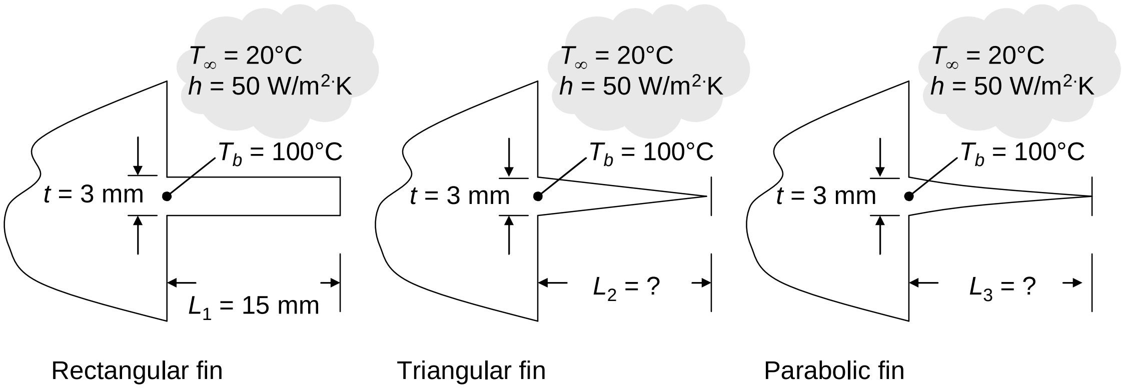
COMMENTS: Although the heat rate is slightly larger (~10%) for the rectangular fin than for the triangular or parabolic fins, the heat rate per unit volume (or mass) is larger and largest for the triangular and parabolic fins, respectively.

PROBLEM 3.135

KNOWN: Thermal conditions, base thickness, thermal conductivity, and length of a straight rectangular fin.

FIND: (a) Length of triangular straight fin needed to produce the same fin heat rate. Ratio of rectangular straight fin mass to triangular straight fin mass. (b) Repeat part (a) for a parabolic straight fin.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, one-dimensional conduction, (2) Constant properties, (3) Negligible radiation.

PROPERTIES: Aluminum 2024: Given: k = 185 W/m·K, Table A.1: ρ = 2770 kg/m^3.

ANALYSIS: For each of the fins, $m = (2h/kt)^{1/2} = (2 \times 50\ \text{W/m}^2\cdot\text{K}/185\ \text{W/m}\cdot\text{K} \times 0.003\ \text{m})^{1/2}$ = 13.42 m^{-1} and, for fins of unit width, $A_{c,b} = tb$ = 0.003 m × 1 m = 0.003 m^2. Combining the definition of the fin effectiveness, $\varepsilon_f = q_f/(hA_{c,b}\theta_b)$ and the fin efficiency, $\eta_f = q_f/hA_f\theta_b$, yields

$$\varepsilon_f = \eta_f A_f / A_{c,b} \qquad (1)$$

Rectangular Fin: From Table 3.5, $L_c = L + t/2$ = 0.015m + 0.003m/2 = 0.0165m, $\eta_f = \tanh mL_c/(mL_c)$ = tanh 13.42m^{-1}× 0.0165m/(13.42m^{-1}× 0.0165m) = 0.9839, $A_f = 2wL_c$ = 2 × 1m × 0.0165m = 0.033m^2. Hence, ε_{f1} = 0.9839 × 0.033m^2/0.003m^2 = 10.83. The mass of the rectangular fin is $M_1 = \rho tL$ = 2770 kg/m^3 × 0.003 m × 0.015 m = 0.125 kg.

(a) *Triangular Fin*: From Table 3.5,

$$A_f = 2w[L_2^2 + (t/2)^2]^{1/2} = 2 \times 1\text{m} \times [L_2^2 + (0.0015\text{m})^2]^{1/2} \qquad (2a)$$
$$\eta_f = I_1(2mL_2)/[mL_2 I_0(2mL_2)] = I_1(2 \times 13.42\text{m}^{-1}L_2)/[\,13.42\text{m}^{-1}L_2 I_0(2\times 13.42\text{m}^{-1}L_2)] \qquad (2b)$$

Equating $\varepsilon_{f2} = \varepsilon_{f1}$ = 10.83, and solving Equations (1) and 2(a, b) simultaneously yields

L_2 = 0.0166m = 16.6mm <

from which $M_2 = \rho(t/2)L_2$ = 2770 kg/m^3 × 0.0015 m × 0.0166 m = 0.069 kg; M_2/M_1 = 0.069kg/0.126kg = 0.55. <

Continued…

PROBLEM 3.135 (Cont.)

(b) *Parabolic Fin*: From Table 3.5,

$$C_1 = [1 + (t/L_3)^2]^{1/2} = [1 + (0.003\text{m}/L_3)^2]^{1/2} \quad (3a)$$
$$A_f = w[C_1L_3 + (L_3^2/t)\ln(t/L_3 + C_1)] = 1\text{m}\times[C_1L_3 + (L_3^2/0.003\text{m})\ln(0.003\text{m}/L_3 + C_1)] \quad (3b)$$
$$\eta_f = 2/\{[4(mL_3)^2 + 1]^{1/2} + 1\} = 2/\{[4(13.42\text{m}^{-1}L_3)^2 + 1]^{1/2} + 1\} \quad (3c)$$

Equating $\varepsilon_{f3} = \varepsilon_{f1} = 10.83$, and solving Equations (1) and 3(a - c) simultaneously yields

$L_3 = 0.0169\text{m} = 16.9\text{mm}$ <

The mass of the parabolic fin is found from

$$M_3 = \rho A_p w = \rho w t L_3/3 = 2770\text{kg/m}^3 \times 1\text{m} \times 0.003\text{m}/3 = 0.0468\text{kg}$$

and $M_3/M_1 = 0.0468\text{kg}/0.126\text{kg} = 0.37$. <

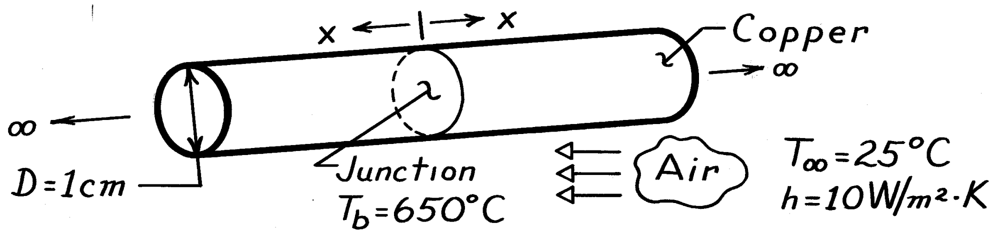
COMMENTS: (1) The lengths of the three fins are all similar. This is because the fin efficiencies are all near unity ($\eta_R = 0.984$, $\eta_T = 0.976$, $\eta_P = 0.953$) yielding fins of almost constant base temperature. (2) Use of triangular and parabolic fins is appropriate when weight savings is important, such as in aerospace applications. (3) Reduction in cost due to reduction in the amount of raw material used is usually offset by higher manufacturing cost for the triangular and parabolic fins.

PROBLEM 3.136

KNOWN: Melting point of solder used to join two long copper rods.

FIND: Minimum power needed to solder the rods.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction along the rods, (3) Constant properties, (4) No internal heat generation, (5) Negligible radiation exchange with surroundings, (6) Uniform h, and (7) Infinitely long rods.

PROPERTIES: *Table A-1:* Copper $\bar{T} = (650 + 25)^\circ C \approx 600K$: $k = 379$ W/m·K.

ANALYSIS: The junction must be maintained at 650°C while energy is transferred by conduction from the junction (along both rods). The minimum power is twice the fin heat rate for an infinitely long fin,

$$q_{min} = 2q_f = 2(hPkA_c)^{1/2}(T_b - T_\infty).$$

Substituting numerical values,

$$q_{min} = 2\left[10\frac{W}{m^2 \cdot K}(\pi \times 0.01m)\left[379\frac{W}{m \cdot K}\right]\frac{\pi}{4}(0.01m)^2\right]^{1/2}(650-25)^\circ C.$$

Therefore,

$$q_{min} = 120.9 \text{ W}.$$ <

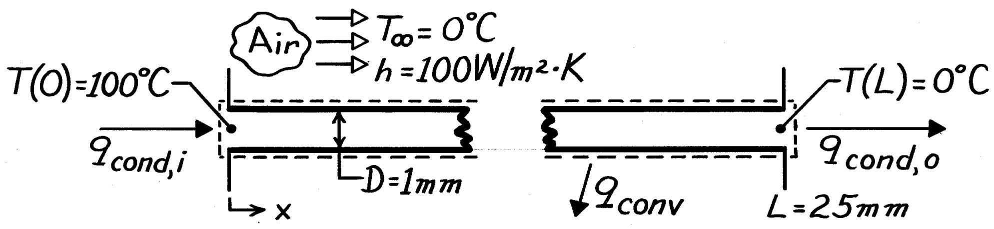
COMMENTS: Radiation losses from the rods may be significant, particularly near the junction, thereby requiring a larger power input to maintain the junction at 650°C.

PROBLEM 3.137

KNOWN: Dimensions and end temperatures of pin fins.

FIND: (a) Heat transfer by convection from a single fin and (b) Total heat transfer from a 1 m^2 surface with fins mounted on 4mm centers.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction along rod, (3) Constant properties, (4) No internal heat generation, (5) Negligible radiation.

PROPERTIES: *Table A-1*, Copper, pure (323K): k ≈ 400 W/m·K.

ANALYSIS: (a) By applying conservation of energy to the fin, it follows that

$$q_{conv} = q_{cond,i} - q_{cond,o}$$

where the conduction rates may be evaluated from knowledge of the temperature distribution. The general solution for the temperature distribution is

$$\theta(x) = C_1\, e^{mx} + C_2\, e^{-mx} \qquad \theta \equiv T - T_\infty.$$

The boundary conditions are $\theta(0) \equiv \theta_o$ = 100°C and $\theta(L)$ = 0. Hence

$$\theta_o = C_1 + C_2$$

$$0 = C_1\, e^{mL} + C_2\, e^{-mL}$$

Therefore, $\qquad C_2 = C_1\, e^{2mL}$

$$C_1 = \frac{\theta_o}{1-e^{2mL}}, \qquad C_2 = -\frac{\theta_o\, e^{2mL}}{1-e^{2mL}}$$

and the temperature distribution has the form

$$\theta = \frac{\theta_o}{1-e^{2mL}}\left[e^{mx} - e^{2mL-mx}\right].$$

The conduction heat rate can be evaluated by Fourier's law,

$$q_{cond} = -kA_c\frac{d\theta}{dx} = -\frac{kA_c\theta_o}{1-e^{2mL}}\, m\left[e^{mx} + e^{2mL-mx}\right]$$

or, with $m = (hP/kA_c)^{1/2}$,

$$q_{cond} = -\frac{\theta_o (hPkA_c)^{1/2}}{1-e^{2mL}}\left[e^{mx} + e^{2mL-mx}\right].$$

Continued …

Hence at x = 0,

$$q_{cond,i} = -\frac{\theta_o \left(hPkA_c\right)^{1/2}}{1-e^{2mL}}\left(1+e^{2mL}\right)$$

at x = L

$$q_{cond,o} = -\frac{\theta_o \left(hPkA_c\right)^{1/2}}{1-e^{2mL}}\left(2e^{mL}\right)$$

Evaluating the fin parameters:

$$m = \left[\frac{hP}{kA_c}\right]^{1/2} = \left[\frac{4h}{kD}\right]^{1/2} = \left[\frac{4\times 100\ W/m^2\cdot K}{400\ W/m\cdot K\times 0.001m}\right]^{1/2} = 31.62\ m^{-1}$$

$$\left(hPkA_c\right)^{1/2} = \left[\frac{\pi^2}{4}D^3hk\right]^{1/2} = \left[\frac{\pi^2}{4}\times\left(0.001m\right)^3\times 100\frac{W}{m^2\cdot K}\times 400\frac{W}{m\cdot K}\right]^{1/2} = 9.93\times 10^{-3}\ \frac{W}{K}$$

$$mL = 31.62\ m^{-1}\times 0.025m = 0.791, \qquad e^{mL} = 2.204, \qquad e^{2mL} = 4.865$$

The conduction heat rates are

$$q_{cond,i} = \frac{-100K\left(9.93\times 10^{-3}\ W/K\right)}{-3.865}\times 5.865 = 1.507\ W$$

$$q_{cond,o} = \frac{-100K\left(9.93\times 10^{-3}\ W/K\right)}{-3.865}\times 4.408 = 1.133\ W$$

and from the conservation relation,

$$q_{conv} = 1.507\ W - 1.133\ W = 0.374\ W.$$ <

(b) The total heat transfer rate is the heat transfer from N = 250×250 = 62,500 rods and the heat transfer from the remaining (bare) surface (A = $1m^2$ - NA_c). Hence,

$$q = N\,q_{cond,i} + hA\theta_o = 62,500\ \left(1.507\ W\right) + 100W/m^2\cdot K\left(0.951\ m^2\right)\ 100K$$

$$q = 9.42\times 10^4\ W + 0.95\times 10^4\ W = 1.037\times 10^5\ W.$$

COMMENTS: (1) The fins, which cover only 5% of the surface area, provide for more than 90% of the heat transfer from the surface.

(2) The fin effectiveness, $\varepsilon \equiv q_{cond,i}/hA_c\theta_o$, is ε = 192, and the fin efficiency, $\eta \equiv \left(q_{conv}/h\pi\ DL\theta_o\right)$, is $\eta = 0.48$.

(3) The temperature distribution, $\theta(x)/\theta_o$, and the conduction term, $q_{cond,i}$, could have been obtained directly from Eqs. 3.82 and 3.83, respectively.

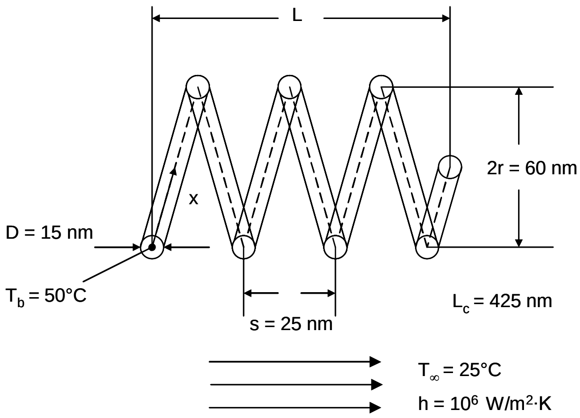
(4) Heat transfer by convection from a single fin could also have been obtained from Eq. 3.78.

PROBLEM 3.138

KNOWN: Dimensions of a nanospring, dependence of pitch upon temperature.

FIND: Actuation distance of the spring in response to heating of its end, accuracy to which the actuation length can be controlled.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Steady-state conditions, (3) One-dimensional heat transfer, (4) Adiabatic tip, (5) Negligible radiation heat transfer, (6) Negligible impact of nanoscale heat transfer effects.

PROPERTIES: Table A.2, silicon carbide (300 K): k = 490 W/m·K.

ANALYSIS: When the nanospring is at T_i = 25°C, the spring length is

$$L_i = \frac{s}{2\pi}\frac{Lc}{\sqrt{r^2 + (S/2\pi)^2}} = \frac{25 \times 10^{-9}\ \text{m}}{2\pi} \times \frac{425 \times 10^{-9}\ \text{m}}{\sqrt{(30 \times 10^{-9}\ \text{m})^2 + \left(25 \times 10^{-9}\ \text{m})/2\pi\right)^2}}$$

$$= 55.9 \times 10^{-9}\ \text{m} = 55.9\ \text{nm}$$

Since the average spring pitch varies linearly with the average temperature, the average pitch of the heated spring is

$$\overline{s} = s_i + \frac{d\overline{s}}{d\overline{T}}(\overline{T} - T_i) \qquad (1)$$

The average excess temperature is

$$\overline{\theta} = \overline{T} - T_\infty = \frac{1}{L_c}\int_{x=0}^{L_c} \theta(x)dx \quad \text{where, from Eq. 3.80,}$$

Continued…

PROBLEM 3.138 (Cont.)

$$\bar{\theta} = \frac{\theta_b}{L_c}\int_{x=0}^{L_c} \frac{\cosh m(L-x)}{\cosh ml}\,dx = -\frac{\theta_b}{mL_c(\cosh mL_c)}\sinh m(L_c - x)\Big|_0^{L_c}$$

$$\bar{\theta} = \frac{\theta_b}{mL_c\ (\cosh mL_c)} \times (0 - \sinh mL_c) = \frac{\theta_b}{mL_c}\tanh(mL_c)$$

For a particular spring,

$$mL_c = \left(\frac{hP}{kA_c}\right)^{1/2} L_c = \left(\frac{4h}{kD}\right)^{1/2} L_c = \left(\frac{4 \times 10^6\ \text{W/m}^2\cdot\text{K}}{490\ \text{W/m}\cdot\text{K} \times 15 \times 10^{-9}\ \text{m}}\right)^{1/2} \times 425 \times 10^{-9}\ \text{m} = 0.314$$

Therefore $\bar{\theta} = \dfrac{(50-25)°\text{C}}{0.314}\tanh(0.314) = 24.2°\text{C}$

and $\quad \bar{T} = \bar{\theta} + T_\infty = 24.2°\text{C} + 25°\text{C} = 49.2°\text{C}$

From Eq. (1),

$$\bar{s} = 25 \times 10^{-9}\ \text{m} + 0.1 \times 10^{-9}\ \text{m/K} \times (49.2 - 25)°\text{C} = 27.4 \times 10^{-9}\ \text{m}$$

Therefore,

$$L_2 = \frac{27.4 \times 10^{-9}\ \text{m}}{2\pi} \times \frac{425 \times 10^{-9}\ \text{m}}{\sqrt{(30 \times 10^{-9}\ \text{m})^2 + (27.4 \times 10^{-9}\ \text{m}/2\pi)^2}} = 61.1 \times 10^{-9}\ \text{m} = 61.1\ \text{nm}$$

and the actuation length is

$$\Delta L = L_2 - L_i = 61.1\ \text{nm} - 55.9\ \text{nm} = 5.2\ \text{nm} \quad <$$

If the base temperature can be controlled to within 1 degree Celsius, the resolution of the actuation length is: $R = \Delta L \times \dfrac{1\ \text{degree C}}{25\ \text{degree C}} = 0.2\ \text{nm}$ <

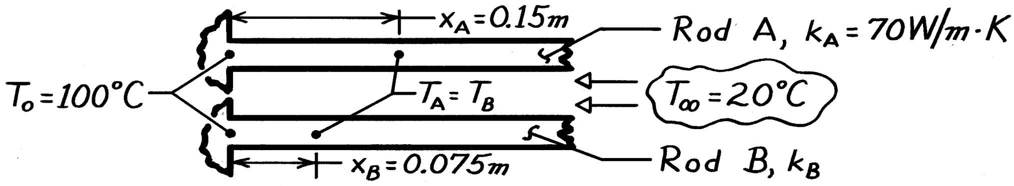
COMMENTS: (1) The actuation distance and its resolution are extremely small. (2) Application of other tip conditions will lead to different predictions of the actuation distance.

PROBLEM 3.139

KNOWN: Positions of equal temperature on two long rods of the same diameter, but different thermal conductivity, which are exposed to the same base temperature and ambient air conditions.

FIND: Thermal conductivity of rod B, k_B.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Rods are infinitely long fins of uniform cross-sectional area, (3) Uniform heat transfer coefficient, (4) Constant properties.

ANALYSIS: The temperature distribution for the infinite fin has the form

$$\frac{\theta}{\theta_b} = \frac{T(x) - T_\infty}{T_o - T_\infty} = e^{-mx} \qquad m = \left[\frac{hP}{kA_c}\right]^{1/2}. \qquad (1,2)$$

For the two positions prescribed, x_A and x_B, it was observed that

$$T_A(x_A) = T_B(x_B) \qquad \text{or} \qquad \theta_A(x_A) = \theta_B(x_B). \qquad (3)$$

Since θ_b is identical for both rods, Eq. (1) with the equality of Eq. (3) requires that

$$m_A x_A = m_B x_B$$

Substituting for m from Eq. (2) gives

$$\left[\frac{hP}{k_A A_c}\right]^{1/2} x_A = \left[\frac{hP}{k_B A_c}\right]^{1/2} x_B.$$

Recognizing that h, P and A_c are identical for each rod and rearranging,

$$k_B = \left[\frac{x_B}{x_A}\right]^2 k_A$$

$$k_B = \left[\frac{0.075\text{m}}{0.15\text{m}}\right]^2 \times 70\ \text{W/m}\cdot\text{K} = 17.5\ \text{W/m}\cdot\text{K}.$$ <

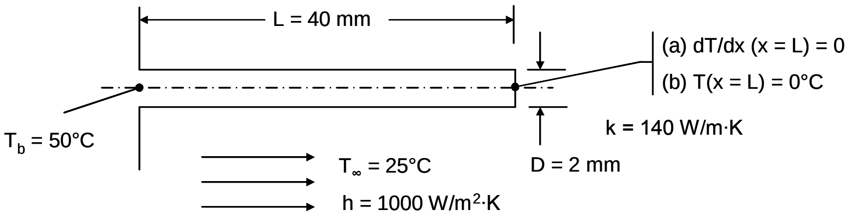
COMMENTS: This approach has been used as a method for determining the thermal conductivity. It has the attractive feature of not requiring power or temperature measurements, assuming of course, a reference material of known thermal conductivity is available.

PROBLEM 3.140

KNOWN: Dimension and length of an aluminum pin fin. Base and ambient temperatures, value of the convection heat transfer coefficient.

FIND: (a) Fin heat transfer rate with an adiabatic tip, (b) Fin heat transfer rate when the fin tip is cooled below the ambient temperature, (c) Temperature distribution along the fin for parts (a) and (b), (d) Fin heat rates for $0 \le h \le 1000\ W/m^2 \cdot K$.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Steady-state conditions, (3) One-dimensional heat transfer, (4) Negligible radiation heat transfer.

ANALYSIS:
(a) The fin heat transfer rate is given by Eq. 3.81; $q_f = M \tanh ml$ where

$$M = \sqrt{hPkA_c}\ \theta_b$$
$$= \sqrt{1000 W/m^2 \cdot K \times \pi \times 2 \times 10^{-3}\ m \times 140\ W/m \cdot K \times \pi \times (2 \times 10^{-3}\ m)^2/4} \times (50 - 25)°C$$
$$= 1.314\ W$$

and

$$m = \sqrt{\frac{hP}{kA_c}} = \sqrt{\frac{1000\ W/m^2 \cdot K \times \pi \times 2 \times 10^{-3}\ m}{140\ W/m^2 \cdot K \times \pi \times (2 \times 10^{-3}\ m)^2/4}} = 119.5\ m^{-1}$$

Therefore, $q_f = 1.314\ W \tanh(119.5\ m^{-1} \times 40 \times 10^{-3}\ m) = 1.314\ W$ <

(b) For the case where T(x = L) = 0°C, the fin heat transfer rate is

$$q_f = M\,\frac{(\cosh ml - \theta_L/\theta_b)}{\sinh ml}$$

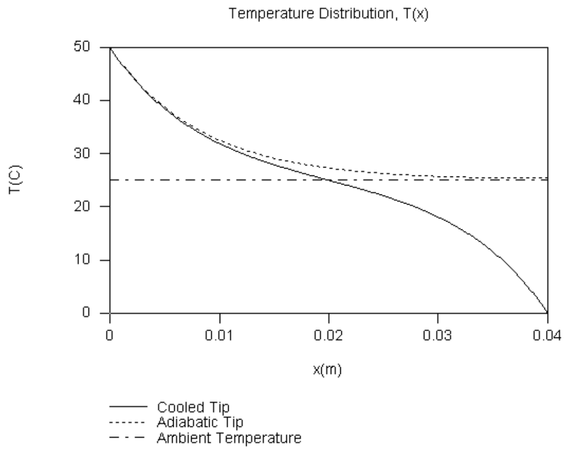
$$= 1.314\ W \times \frac{\cosh(119.5\ m^{-1} \times 40 \times 10^{-3}\ m) - (0 - 25)°C / (50 - 25)°C}{\sinh(119.5\ m^{-1} \times 40 \times 10^{-3}\ m)} = 1.336\ W$$ <

(c) The temperature distributions are found by plotting Eqs. 3.80 and 3.82 over the range $0 \le x \le$ 40 mm. Note, that for the adiabatic tip case, the tip temperature is nearly equal to the

Continued…

PROBLEM 3.140 (Cont.)

ambient temperature. For the cooled tip, the temperature distribution is anti-symmetric about x = ½ L. For the cooled tip case and h = 0, the temperature distribution in the fin would be linear, corresponding to one-dimensional conduction in the fin. <

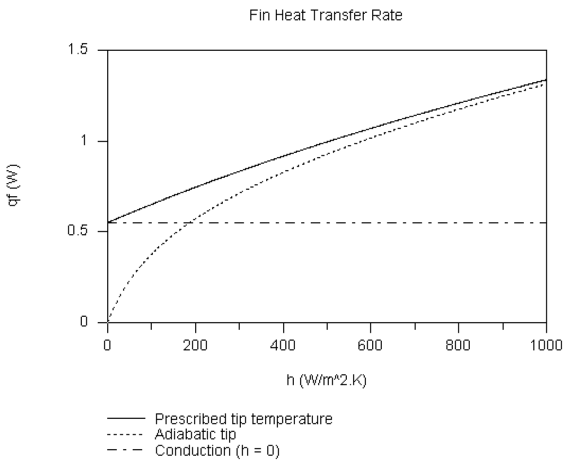


(d) The fin heat rate distributions are shown below. For adiabatic tip and h = 0, $q_f = 0$. For the case of the cooled tip and negligible convection, the fin heat rate is

$$q_f = kA_c(T(x{=}L) - T_b) / L = \left(140\ W/m^2 \cdot K \times \pi \times (2 \times 10^{-3}\ m)^2/ 4\right) \times \left((0 - 50)°C / 40 \times 10^{-3}\ m\right)$$

= 0.549 W.

As the convection coefficient increases, the temperatures at x = ½ L approach T(x = ½ L) = 25°C for both the adiabatic and cooled tip cases, resulting in nearly the same fin heat transfer rates. Equations 3.76 and 3.78 would yield the same result for the cooled tip case since heat lost by convection over the range $0 \le x \le 20$ mm would be exactly offset by the heat gain by convection over the range 20 mm $\le x \le$ 40 mm, and heat loss at x = L by conduction is equal to heat gain at x = 0 by conduction. <

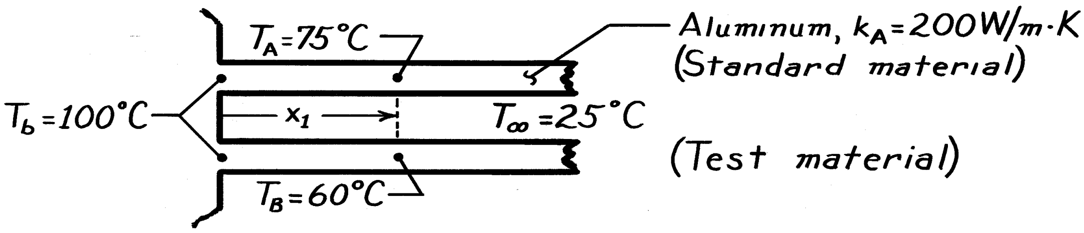


PROBLEM 3.141

KNOWN: Base temperature, ambient fluid conditions, and temperatures at a prescribed distance from the base for two long rods, with one of known thermal conductivity.

FIND: Thermal conductivity of other rod.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction along rods, (3) Constant properties, (4) Negligible radiation, (5) Negligible contact resistance at base, (6) Infinitely long rods, (7) Rods are identical except for their thermal conductivity.

ANALYSIS: With the assumption of infinitely long rods, the temperature distribution is

$$\frac{\theta}{\theta_b} = \frac{T - T_\infty}{T_b - T_\infty} = e^{-mx}$$

or

$$\ln \frac{T - T_\infty}{T_b - T_\infty} = -mx = \left[\frac{hP}{kA}\right]^{1/2} x$$

Hence, for the two rods,

$$\frac{\ln\left[\frac{T_A - T_\infty}{T_b - T_\infty}\right]}{\ln\left[\frac{T_B - T_\infty}{T_b - T_\infty}\right]} = \left[\frac{k_B}{k_A}\right]^{1/2}$$

$$k_B^{1/2} = k_A^{1/2} \frac{\ln\left[\frac{T_A - T_\infty}{T_b - T_\infty}\right]}{\ln\left[\frac{T_B - T_\infty}{T_b - T_\infty}\right]} = (200)^{1/2} \frac{\ln \frac{75-25}{100-25}}{\ln \frac{60-25}{100-25}} = 7.524$$

$$k_B = 56.6 \text{ W/m}\cdot\text{K}.$$ <

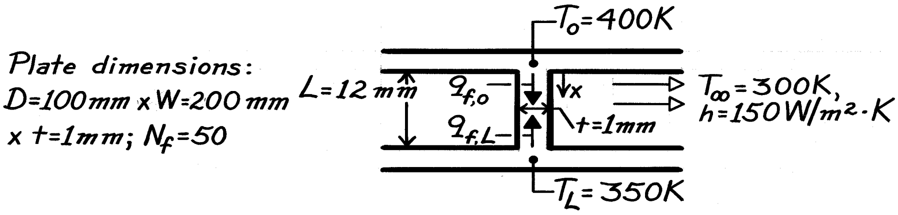
COMMENTS: Providing conditions for the two rods may be maintained nearly identical, the above method provides a convenient means of measuring the thermal conductivity of solids.

PROBLEM 3.142

KNOWN: Arrangement of fins between parallel plates. Temperature and convection coefficient of air flow in finned passages. Maximum allowable plate temperatures.

FIND: (a) Expressions relating fin heat transfer rates to end temperatures, (b) Maximum power dissipation for each plate.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in fins, (3) Constant properties, (4) Negligible radiation, (5) Uniform h, (6) Negligible variation in T_∞, (7) Negligible contact resistance.

PROPERTIES: *Table A.1*, Aluminum (pure), 375 K: k = 240 W/m·K.

ANALYSIS: (a) The general solution for the temperature distribution in a fin is

$$\theta(x) \equiv T(x) - T_\infty = C_1 e^{mx} + C_2 e^{-mx}$$

Boundary conditions: $\theta(0) = \theta_o = T_o - T_\infty, \qquad \theta(L) = \theta_L = T_L - T_\infty.$

Hence $\theta_o = C_1 + C_2 \qquad \theta_L = C_1 e^{mL} + C_2 e^{-mL}$

$$\theta_L = C_1 e^{mL} + (\theta_o - C_1) e^{-mL}$$

$$C_1 = \frac{\theta_L - \theta_o e^{-mL}}{e^{mL} - e^{-mL}} \qquad C_2 = \theta_o - \frac{\theta_L - \theta_o e^{-mL}}{e^{mL} - e^{-mL}} = \frac{\theta_o e^{mL} - \theta_L}{e^{mL} - e^{-mL}}.$$

Hence $$\theta(x) = \frac{\theta_L e^{mx} - \theta_o e^{m(x-L)} + \theta_o e^{m(L-x)} - \theta_L e^{-mx}}{e^{mL} - e^{-mL}}$$

$$\theta(x) = \frac{\theta_o\left[e^{m(L-x)} - e^{-m(L-x)}\right] + \theta_L\left(e^{mx} - e^{-mx}\right)}{e^{mL} - e^{-mL}}$$

$$\theta(x) = \frac{\theta_o \sinh m(L-x) + \theta_L \sinh mx}{\sinh mL}.$$

The fin heat transfer rate is then

$$q_f = -kA_c \frac{dT}{dx} = -kDt\left[-\frac{\theta_o m}{\sinh mL}\cosh m(L-x) + \frac{\theta_L m}{\sinh mL}\cosh mx\right].$$

Hence $$q_{f,o} = kDt\left(\frac{\theta_o m}{\tanh mL} - \frac{\theta_L m}{\sinh mL}\right)$$ <

$$q_{f,L} = kDt\left(\frac{\theta_o m}{\sinh mL} - \frac{\theta_L m}{\tanh mL}\right).$$ <

Continued …

PROBLEM 3.142 (Cont.)

(b) $$m=\left(\frac{hP}{kA_c}\right)^{1/2}=\left(\frac{150\ \text{W/m}^2\cdot\text{K}\left(2\times0.1\ \text{m}+2\times0.001\ \text{m}\right)}{240\ \text{W/m}\cdot\text{K}\times0.1\ \text{m}\times0.001\ \text{m}}\right)^{1/2}=35.5\ \text{m}^{-1}$$

$$mL = 35.5\ \text{m}^{-1}\times0.012\ \text{m} = 0.43$$

$\sinh mL = 0.439$ $\quad\tanh mL = 0.401$ $\quad\theta_o = 100\ \text{K}$ $\quad\theta_L = 50\ \text{K}$

$$q_{f,o} = 240\ \text{W/m}\cdot\text{K}\times0.1\ \text{m}\times0.001\ \text{m}\left(\frac{100\ \text{K}\times35.5\ \text{m}^{-1}}{0.401}-\frac{50\ \text{K}\times35.5\ \text{m}^{-1}}{0.439}\right)$$

$q_{f,o} = 115.4\ \text{W}$ (*from* the top plate)

$$q_{f,L} = 240\ \text{W/m}\cdot\text{K}\times0.1\ \text{m}\times0.001\ \text{m}\left(\frac{100\ \text{K}\times35.5\ \text{m}^{-1}}{0.439}-\frac{50\ \text{K}\times35.5\ \text{m}^{-1}}{0.401}\right)$$

$q_{f,L} = 87.8\ \text{W.}$ (*into* the bottom plate)

Maximum power dissipations are therefore

$$q_{o,max} = N_f q_{f,o} + \left(W - N_f t\right)Dh\theta_o$$

$$q_{o,max} = 50\times115.4\ \text{W}+\left(0.200-50\times0.001\right)\text{m}\times0.1\ \text{m}\times150\ \text{W/m}^2\cdot\text{K}\times100\ \text{K}$$

$$q_{o,max} = 5770\ \text{W}+225\ \text{W} = 5995\ \text{W}$$ <

$$q_{L,max} = -N_f q_{f,L} + \left(W - N_f t\right)Dh\theta_o$$

$$q_{L,max} = -50\times87.8\text{W}+\left(0.200-50\times0.001\right)\text{m}\times0.1\ \text{m}\times150\ \text{W/m}^2\cdot\text{K}\times50\ \text{K}$$

$$q_{L,max} = -4390\ \text{W}+112\text{W} = -4278\ \text{W.}$$ <

COMMENTS: (1) It is of interest to determine the air velocity needed to prevent excessive heating of the air as it passes between the plates. If the air temperature change is restricted to $\Delta T_\infty = 5$ K, its flowrate must be

$$\dot{m}_{air} = \frac{q_{tot}}{c_p\Delta T_\infty} = \frac{1717\ \text{W}}{1007\ \text{J/kg}\cdot\text{K}\times5\ \text{K}} = 0.34\ \text{kg/s.}$$

Its mean velocity is then

$$V_{air} = \frac{\dot{m}_{air}}{\rho_{air}A_c} = \frac{0.34\ \text{kg/s}}{1.16\ \text{kg/m}^3\times0.012\ \text{m}\left(0.2-50\times0.001\right)\text{m}} = 163\ \text{m/s.}$$

Such a velocity would be impossible to maintain. To reduce it to a reasonable value, e.g. 10 m/s, A_c would have to be increased substantially by increasing W (and hence the space between fins) and by increasing L. The present configuration is impractical from the standpoint that 1717 W could not be transferred to air in such a small volume.

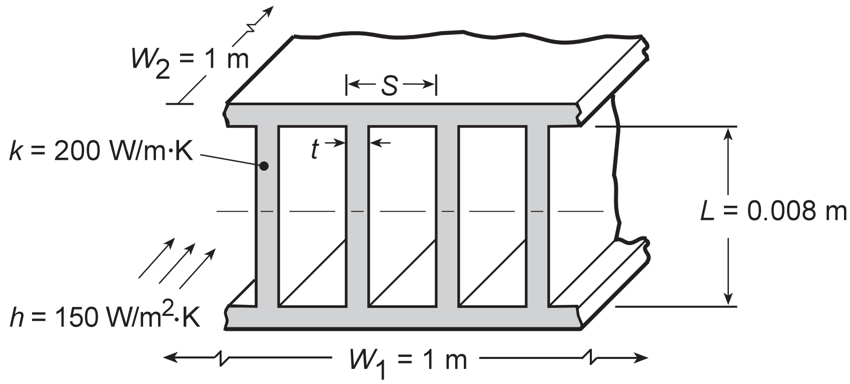
(2) A negative value of $q_{L,max}$ implies that the bottom plate must be cooled externally to maintain the plate at 350 K.

PROBLEM 3.143

KNOWN: Conditions associated with an array of straight rectangular fins.

FIND: Thermal resistance of the array.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Uniform convection coefficient, (3) Symmetry about midplane.

ANALYSIS: (a) Considering a one-half section of the array, the corresponding resistance is

$$R_{t,o} = \left(\eta_o h A_t\right)^{-1}$$

where $A_t = NA_f + A_b$. With S = 4 mm and t = 1 mm, it follows that N = W_1/S = 250, A_f = $2(L/2)W_2 = 0.008\ m^2$, $A_b = W_2(W_1 - Nt) = 0.75\ m^2$, and $A_t = 2.75\ m^2$.
The overall surface efficiency is

$$\eta_o = 1 - \frac{NA_f}{A_t}\left(1 - \eta_f\right)$$

where the fin efficiency is

$$\eta_f = \frac{\tanh m(L/2)}{m(L/2)} \qquad \text{and} \qquad m = \left(\frac{hP}{kA_c}\right)^{1/2} = \left[\frac{h\left(2t + 2W_2\right)}{ktW_2}\right]^{1/2} \approx \left(\frac{2h}{kt}\right)^{1/2} = 38.7 m^{-1}$$

With m(L/2) = 0.155, it follows that η_f = 0.992 and η_o = 0.994. Hence

$$R_{t,o} = \left(0.994 \times 150 W/m^2 \cdot K \times 2.75 m^2\right)^{-1} = 2.44 \times 10^{-3} K/W$$ <

(b) The requirements that t ≥ 0.5 m and (S - t) > 2 mm are based on manufacturing and flow passage restriction constraints. Repeating the foregoing calculations for representative values of t and (S - t), we obtain

S (mm)	N	t (mm)	$R_{t,o}$ (K/W)
2.5	400	0.5	0.00169
3	333	0.5	0.00193
3	333	1	0.00202
4	250	0.5	0.00234
4	250	2	0.00268
5	200	0.5	0.00269
5	200	3	0.00334

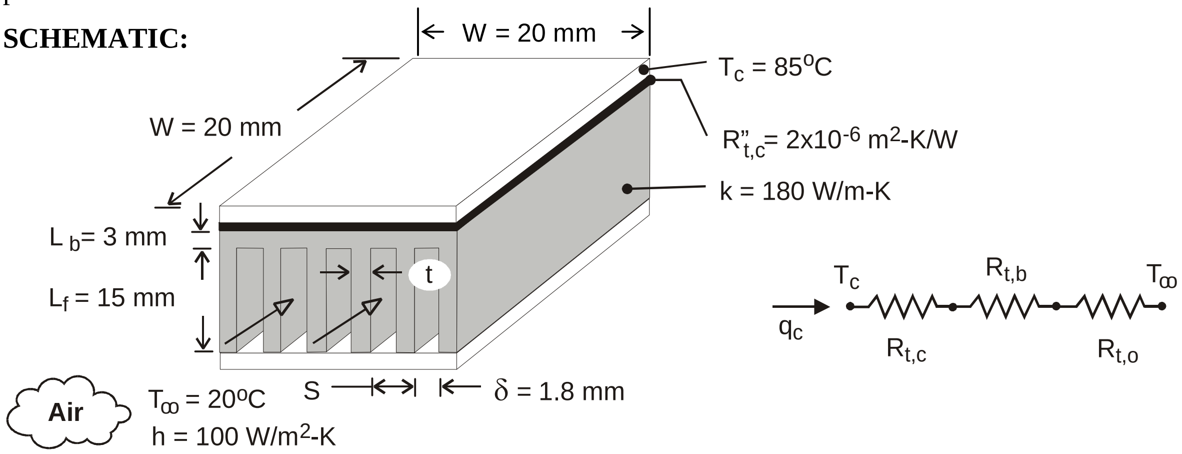
COMMENTS: Clearly, the thermal performance of the fin array improves ($R_{t,o}$ decreases) with increasing N. Because $\eta_f \approx 1$ for the entire range of conditions, there is a slight degradation in performance ($R_{t,o}$ increases) with increasing t and fixed N. The reduced performance is associated with the reduction in surface area of the exposed base. Note that the overall thermal resistance for the entire fin array (top and bottom) is $R_{t,o}/2 = 1.22 \times 10^{-2}$ K/W.

PROBLEM 3.144

KNOWN: Dimensions and maximum allowable temperature of an electronic chip. Thermal contact resistance between chip and heat sink. Dimensions and thermal conductivity of heat sink. Temperature and convection coefficient associated with air flow through the heat sink.

FIND: (a) Maximum allowable chip power for heat sink with prescribed number of fins, fin thickness, and fin pitch, and (b) Effect of fin thickness/number and convection coefficient on performance.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) One-dimensional heat transfer, (3) Isothermal chip, (4) Negligible heat transfer from top surface of chip, (5) Negligible temperature rise for air flow, (6) Uniform convection coefficient associated with air flow through channels and over outer surfaces of heat sink, (7) Negligible radiation.

ANALYSIS: (a) From the thermal circuit,

$$q_c = \frac{T_c - T_\infty}{R_{tot}} = \frac{T_c - T_\infty}{R_{t,c} + R_{t,b} + R_{t,o}}$$

where $R_{t,c} = R''_{t,c}/W^2 = 2\times10^{-6}\,m^2\cdot K/W/(0.02m)^2 = 0.005\ K/W$ and $R_{t,b} = L_b/k\left(W^2\right)$

$= 0.003m/180\ W/m\cdot K\,(0.02m)^2 = 0.042\ K/W$. From Eqs. (3.108), (3.107), and (3.104)

$$R_{t,o} = \frac{1}{\eta_o h A_t}, \qquad \eta_o = 1 - \frac{N A_f}{A_t}(1-\eta_f), \qquad A_t = N A_f + A_b$$

where $A_f = 2WL_f = 2 \times 0.02m \times 0.015m = 6 \times 10^{-4}\ m^2$ and $A_b = W^2 - N(tW) = (0.02m)^2 - 11(0.182 \times 10^{-3}\ m \times 0.02m) = 3.6 \times 10^{-4}\ m^2$. With $mL_f = (2h/kt)^{1/2} L_f = (200\ W/m^2\cdot K/180\ W/m\cdot K \times 0.182 \times 10^{-3} m)^{1/2}\,(0.015m) = 1.17$, $\tanh mL_f = 0.824$ and Eq. (3.92) yields

$$\eta_f = \frac{\tanh mL_f}{mL_f} = \frac{0.824}{1.17} = 0.704$$

It follows that $A_t = 6.96 \times 10^{-3}\ m^2$, $\eta_o = 0.719$, $R_{t,o} = 2.00$ K/W, and

$$q_c = \frac{(85-20)°C}{(0.005+0.042+2.00)K/W} = 31.8\ W$$ <

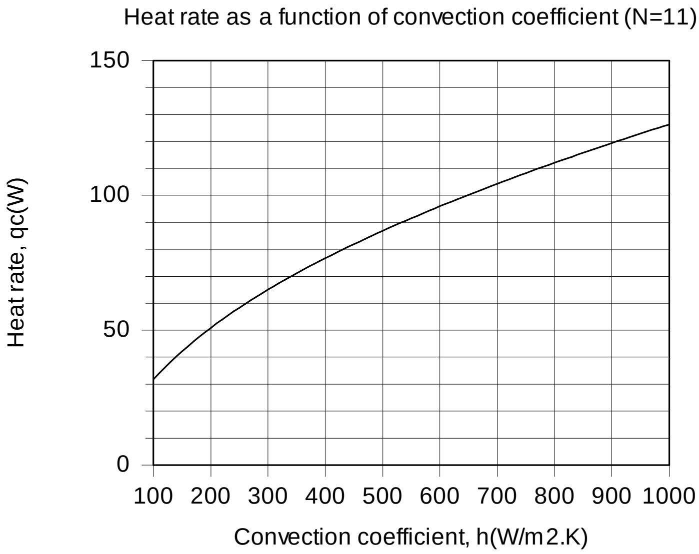
(b) The following results are obtained from parametric calculations performed to explore the effect of decreasing the number of fins and increasing the fin thickness.

Continued …

PROBLEM 3.144 (Cont.)

N	t(mm)	η_f	$R_{t,o}$ (K/W)	q_c (W)	A_t (m^2)
6	1.833	0.957	2.76	23.2	0.00378
7	1.314	0.941	2.40	26.6	0.00442
8	0.925	0.919	2.15	29.7	0.00505
9	0.622	0.885	1.97	32.2	0.00569
10	0.380	0.826	1.89	33.5	0.00632
11	0.182	0.704	2.00	31.8	0.00696

Although η_f (and η_o) increases with decreasing N (increasing t), there is a reduction in A_t which yields a minimum in $R_{t,o}$, and hence a maximum value of q_c, for N = 10. For N = 11, the effect of h on the performance of the heat sink is shown below.



With increasing h from 100 to 1000 $W/m^2\cdot K$, $R_{t,o}$ decreases from 2.00 to 0.47 K/W, despite a decrease in η_f (and η_o) from 0.704 (0.719) to 0.269 (0.309). The corresponding increase in q_c is significant.

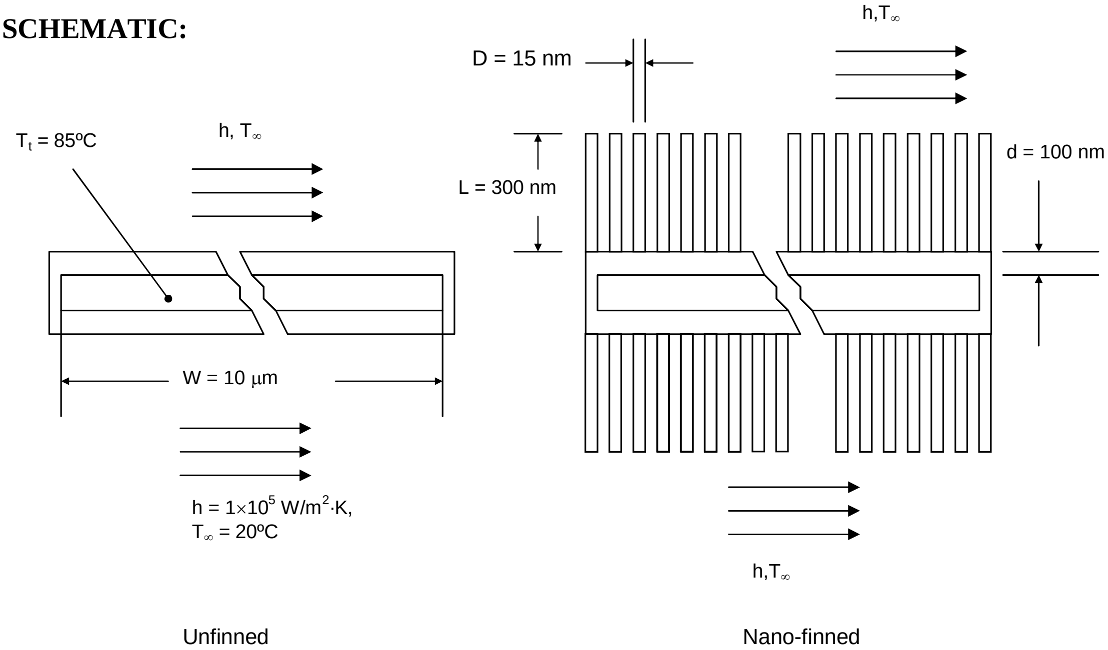
COMMENTS: (1) The heat sink significantly increases the allowable heat dissipation. If it were not used and heat was simply transferred by convection from the surface of the chip with h = 100 $W/m^2\cdot K$, R_{tot} = 2.05 K/W from Part (a) would be replaced by $R_{cnv} = 1/hW^2$ = 25 K/W, yielding q_c = 2.60 W. (2) The air temperature will increase as it flows through the heat sink. Therefore the required air velocity will be greater than determined here. See Problem 11.89.

PROBLEM 3.145

KNOWN: Dimensions of electronics package and finned nano-heat sink. Temperature and heat transfer coefficient of coolant.

FIND: Maximum heat rate to maintain temperature below 85°C for finned and un-finned packages.

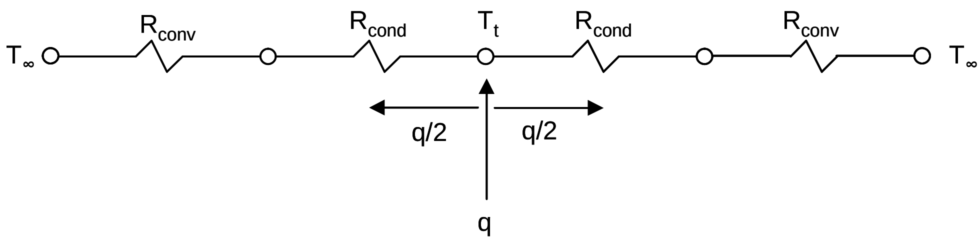
SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Negligible temperature variation across fin thickness, (3) Constant properties, (4) Uniform heat transfer coefficient, (5) Negligible contact resistance, (6) Negligible heat loss from edges of package.

PROPERTIES: Table A.2, Silicon carbide (T ≈ 300 K): k = 490 W/m·K.

ANALYSIS: (a) The thermal circuit for the un-finned package is



where $$R_{cond} = \frac{d}{kA} = \frac{100 \times 10^{-9}\ \text{m}}{490\ \text{W/m} \cdot \text{K} \times (10 \times 10^{-6}\ \text{m})^2} = 2.04\ \text{K/W}$$

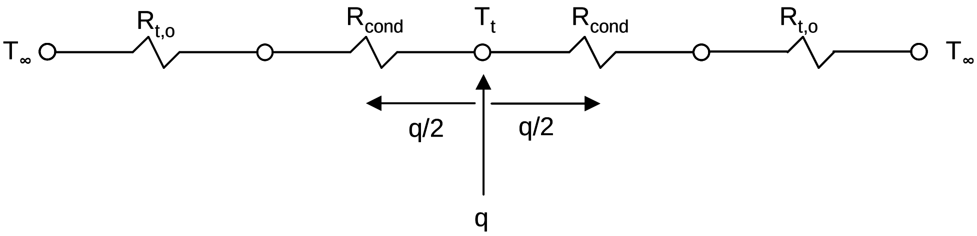
$$R_{conv} = \frac{1}{hA} = \frac{1}{10^5\ \text{W/m}^2 \cdot \text{K} \times (10 \times 10^{-6}\ \text{m})^2} = 1 \times 10^5\ \text{K/W}$$

Thus $$q = 2\frac{(T_t - T_\infty)}{R_{cond} + R_{conv}} = 2\frac{(85°\text{C} - 20°\text{C})}{(2.04 + 10^5)\ \text{K/W}} = 1.30 \times 10^{-3}\ \text{W}$$ <

Continued…

PROBLEM 3.145 (Cont.)

For the finned nano-heat sink, the convection resistance is replaced by a fin array thermal resistance:



From Equations 3.108, 3.107, and 3.104

$$R_{t,o} = \frac{1}{\eta_o h A_t}, \quad \eta_o = 1 - \frac{NA_f}{A_t}(1 - \eta_f), \quad A_t = NA_f + A_b$$

where $A_f = \pi DL_c = \pi D(L + D/4) = \pi \times 15 \times 10^{-9}\text{ m} \times (300 + 15/4) \times 10^{-9}\text{ m} = 1.43 \times 10^{-14}\text{ m}^2$,
$A_b = W^2 - N\pi D^2/4 = (10 \times 10^{-6}\text{ m})^2 - 40{,}000 \times \pi \times (15 \times 10^{-9}\text{ m})^2/4 = 9.29 \times 10^{-11}\text{ m}^2$, and
$A_t = 40{,}000 \times 1.43 \times 10^{-14}\text{ m}^2 + 9.29 \times 10^{-11}\text{ m}^2 = 6.65 \times 10^{-10}\text{ m}^2$. Then with
$mL_c = (4h/kD)^{1/2}L_c = (4 \times 10^5\text{ W/m}^2\cdot\text{K} / 490\text{ W/m}\cdot\text{K} \times 15 \times 10^{-9}\text{ m})^{1/2} \times 304 \times 10^{-9}\text{ m} = 7.09 \times 10^{-2}$,

$$\eta_f = \frac{\tanh(mL_c)}{mL_c} = \frac{\tanh(7.09 \times 10^{-2})}{7.09 \times 10^{-2}} = 0.998$$

It follows that

$$\eta_o = 1 - \frac{40{,}000 \times 1.43 \times 10^{-14}\text{ m}^2}{6.65 \times 10^{-10}\text{ m}^2}(1 - 0.998) = 0.999$$

and

$$R_{t,o} = \frac{1}{0.999 \times 10^5\text{ W/m}^2\cdot\text{K} \times 6.65 \times 10^{-10}\text{ m}^2} = 1.50 \times 10^4\text{ K/W}$$

Therefore

$$q = 2\,\frac{(T_t - T_\infty)}{R_{cond} + R_{t,o}} = 2\,\frac{(85°\text{C} - 20°\text{C})}{2.04\text{ K/W} + 1.50 \times 10^4\text{ K/W}} = 8.64 \times 10^{-3}\text{ W} \qquad <$$

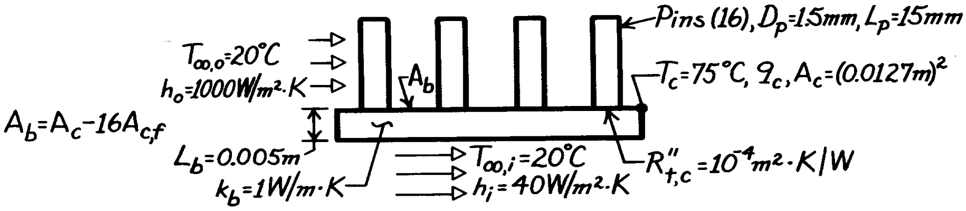
COMMENTS: (1) The conduction resistance of the silicon carbide sheets is negligible. (2) The fins increase the allowable heat rate significantly. (3) We have neglected the contact resistance between the electronics and the silicon carbide sheets. If it dominates, the fins will not be effective in increasing the allowable heat rate. Little is known about contact resistance at the nanoscale.

PROBLEM 3.146

KNOWN: Geometry and cooling arrangement for a chip-circuit board arrangement. Maximum chip temperature.

FIND: (a) Equivalent thermal circuit, (b) Maximum chip heat rate.

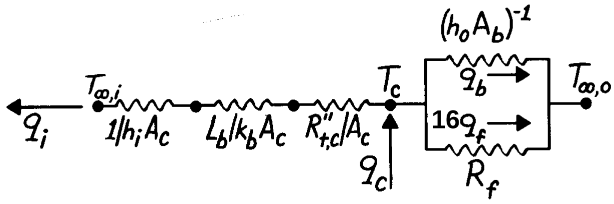
SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer in chip-board assembly, (3) Negligible pin-chip contact resistance, (4) Constant properties, (5) Negligible chip thermal resistance, (6) Uniform chip temperature.

PROPERTIES: *Table A.1*, Copper (300 K): k ≈ 400 W/m·K.

ANALYSIS: (a) The thermal circuit is



$$R_f = \frac{\theta_b}{16q_f} = \frac{\cosh mL + (h_o/mk)\sinh mL}{16\left(h_o PkA_{c,f}\right)^{1/2}\left[\sinh mL + (h_o/mk)\cosh mL\right]}$$

(b) The maximum chip heat rate is

$$q_c = 16q_f + q_b + q_i.$$

Evaluate these parameters

$$m = \left(\frac{h_o P}{kA_{c,f}}\right)^{1/2} = \left(\frac{4h_o}{kD_p}\right)^{1/2} = \left(\frac{4\times 1000\ \text{W/m}^2\cdot\text{K}}{400\ \text{W/m}\cdot\text{K}\times 0.0015\ \text{m}}\right)^{1/2} = 81.7\ \text{m}^{-1}$$

$$mL = \left(81.7\ \text{m}^{-1}\times 0.015\ \text{m}\right) = 1.23, \quad \sinh mL = 1.57, \quad \cosh mL = 1.86$$

$$\left(h_o/mk\right) = \frac{1000\ \text{W/m}^2\cdot\text{K}}{81.7\ \text{m}^{-1}\times 400\ \text{W/m}\cdot\text{K}} = 0.0306$$

$$M = \left(h_o\pi\, D_p k\pi\, D_p^2/4\right)^{1/2}\theta_b$$

$$M = \left[1000\ \text{W/m}^2\cdot\text{K}\left(\pi^2/4\right)(0.0015\ \text{m})^3\,400\ \text{W/m}\cdot\text{K}\right]^{1/2}\left(55^\circ\text{C}\right) = 3.17\ \text{W}.$$

Continued …

PROBLEM 3.146 (Cont.)

The fin heat rate is

$$q_f = M\frac{\sinh mL+(h_o/mk)\cosh mL}{\cosh mL+(h_o/mk)\sinh mL} = 3.17\text{ W}\frac{1.57+0.0306\times 1.86}{1.86+0.0306\times 1.57}$$

$$q_f = 2.703\text{ W.}$$

The heat rate from the chip top by convection is

$$q_b = h_o A_b \theta_b = 1000\text{ W/m}^2\cdot\text{K}\left[(0.0127\text{ m})^2 - (16\pi/4)(0.0015\text{ m})^2\right]55^\circ\text{C}$$

$$q_b = 7.32\text{ W.}$$

The convection heat rate from the board is

$$q_i = \frac{T_c - T_{\infty,i}}{\left(1/h_i + R''_{t,c} + L_b/k_b\right)(1/A_c)} = \frac{(0.0127\text{ m})^2(55^\circ\text{C})}{\left(1/40+10^{-4}+0.005/1\right)\text{m}^2\cdot\text{K/W}}$$

$$q_i = 0.29\text{ W.}$$

Hence, the maximum chip heat rate is

$$q_c = [16(2.703) + 7.32 + 0.29]\text{W} = [43.25 + 7.32 + 0.29]\text{W}$$

$$q_c = 50.9\text{ W.}$$ <

COMMENTS: (1) The fins are extremely effective in enhancing heat transfer from the chip (assuming negligible contact resistance). Their effectiveness is $\varepsilon = q_f / (\pi D_p^2/4) h_o \theta_b = 2.703$ W/0.097 W = 27.8

(2) Without the fins, q_c = 1000 W/m^2·K(0.0127 m)^{2}55°C + 0.29 W = 9.16 W. Hence the fins provide for a (50.9 W/9.16 W) × 100% = 555% enhancement of heat transfer.

(3) With the fins, the chip heat flux is 50.9 W/(0.0127 m)^2 or $q''_c = 3.16\times 10^5\text{ W/m}^2 = 31.6$ W/cm^2.

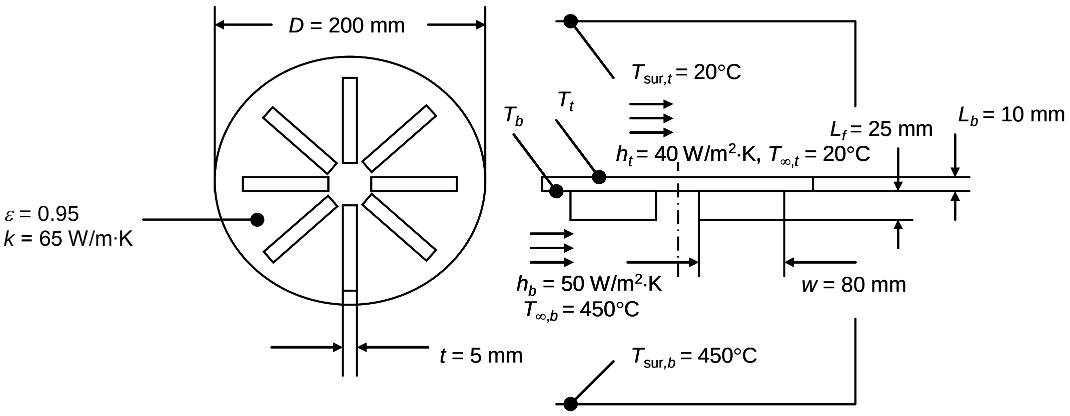
(4) If the infinite fin approximation is made, q_f = M = 3.17 W, and the actual fin heat transfer is overestimated by 17%.

PROBLEM 3.147

KNOWN: Geometry of a cast iron burner with and without fins. Room temperature, combustion temperature, heat transfer coefficient at the top burner surface, heat transfer coefficient at the bottom burner surface, emissivity of burner coating, thermal conductivity of cast iron.

FIND: Temperature of the top burner surface with and without fins.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, one-dimensional conditions, (2) Constant properties, (3) Convection from fin tip, (4) Large surroundings at top and bottom of burner.

PROPERTIES: *Given*, Cast iron: k = 65 W/m·K.

ANALYSIS: Evaluating the radiation heat transfer from the combustion products to the bottom of the burner as $q_{\text{rad},b} = \varepsilon\sigma(\pi D^2/4)(T_{\text{sur},b}^4 - T_b^4)$, the total heat transfer to the bottom of the burner's base is

$$q_b = N\eta_f h_b A_f (T_{\infty,b} - T_b) + h_b A_b (T_{\infty,b} - T_b) + A_t \varepsilon\sigma \left(T_{\text{sur},b}^4 - T_b^4\right) \quad (1)$$

where $A_b = \pi D^2/4 - Ntw = \pi(0.200\text{m})^2/4$ - 8× 0.005 m × 0.080 m = 0.0282 m^2 is the base area without fins and $A_t = \pi D^2/4 = \pi(0.2\text{m})^2/4$ = 0.0314 m^2. The total heat transfer from the top surface is

$$q_t = h_t A_t (T_t - T_{\infty,t}) + A_t \varepsilon\sigma \left(T_t^4 - T_{\text{sur},t}^4\right) \quad (2)$$

One-dimensional conduction through the base of the burner is

$$q_{\text{base}} = \left(kA_t / L_b\right)(T_b - T_t) \quad (3)$$

At steady state, the heat rates must be equal,

$$q_b = q_t; \quad q_{\text{base}} = q_t \quad (4, 5)$$

Continued…

PROBLEM 3.147 (Cont.)

The fin efficiency may be evaluated using Table 3.5. The corrected fin length is $L_c = L_f + t/2$ = 25 mm + 5 mm/2 = 27.5 mm = 27.5 × 10^{-3} m. The fin area is $A_f = 2wL_c$ = 2 × 0.080 m × 27.5 × 10^{-3} m = 0.0044 m^2. The value of m is $m = \sqrt{2h_b / kt} = \sqrt{2 \times 50 \text{W/m}^2 \cdot \text{K} / 65 \text{W/m} \cdot \text{K} \times 5 \times 10^{-3} \text{m}} = 17.54 \text{m}^{-1}$ Finally, the fin efficiency is

$$\eta_f = \frac{\tanh mL_c}{mL_c} = \frac{\tanh(17.54 \text{m}^{-1} \times 27.5 \times 10^{-3} \text{m})}{17.54 \text{m}^{-1} \times 27.5 \times 10^{-3} \text{m}} = 0.93$$

Substituting values listed in the schematic, along with values of the various areas, the fin efficiency, and N = 8 into Eqs. (1) through (5) and solving simultaneously yields

$$T_t = 601.7 \text{ K} = 328.7°\text{C}$$ <

For a burner without fins, Eq. (1) is replaced by

$$q_b = h_b A_t (T_{\infty,b} - T_b) + A_t \varepsilon \sigma \left(T_{\text{sur},b}^4 - T_b^4 \right) \quad (6)$$

Substituting values and solving Eqs. (2) through (6) simultaneously yields

$$T_t = 570.5 \text{ K} = 297.5°\text{C}$$ <

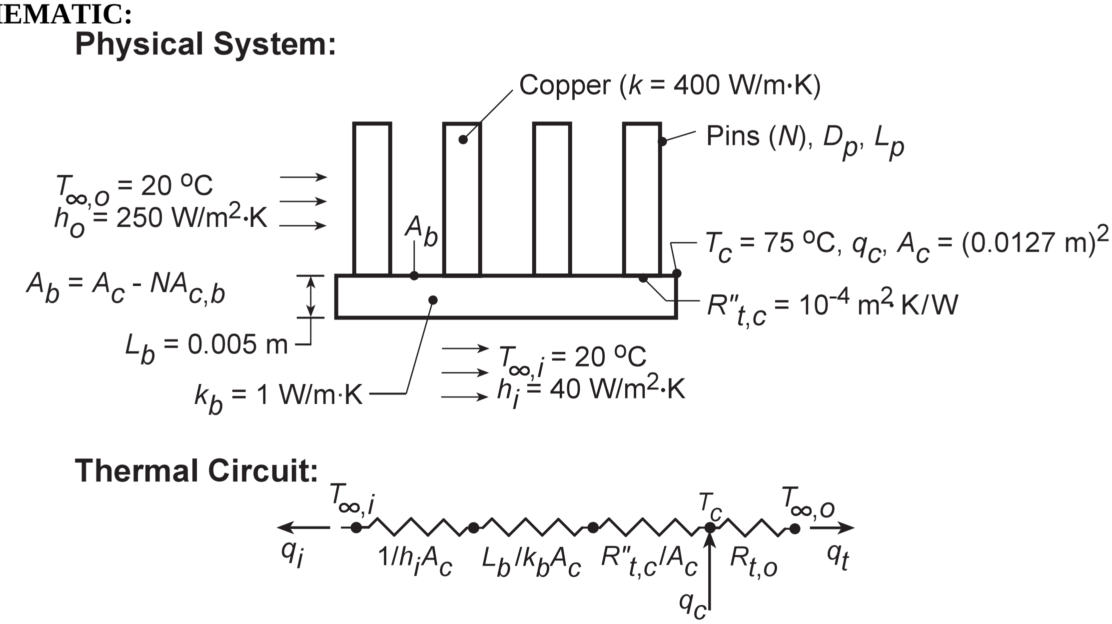
COMMENTS: (1) Adding fins to the bottom of the burner increases the steady-state top temperature by approximately 30 degrees Celsius. (2) The finned burner heat rate is q = 597.2 W, while without fins the heat rate is q = 515.5 W. Hence, the fins increase the heat rate available for cooking. (3) Radiation heat transfer is significant. With fins, radiation accounts for 35% of the heat rate at the top surface and 40% at the bottom surface. Without fins, radiation accounts for 32% at the top surface and 54% at the bottom surface. (4) In general, the treatment of radiation for finned surfaces, such as at the bottom surface of the finned burner is justified, as will be discussed in Chapter 13.

PROBLEM 3.148

KNOWN: Geometry of pin fin array used as heat sink for a computer chip. Array convection and chip substrate conditions.

FIND: Effect of pin diameter, spacing and length on maximum allowable chip power dissipation.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer in chip-board assembly, (3) Negligible pin-chip contact resistance, (4) Constant properties, (5) Negligible chip thermal resistance, (6) Uniform chip temperature.

ANALYSIS: The total power dissipation is $q_c = q_i + q_t$, where

$$q_i = \frac{T_c - T_{\infty,i}}{\left(1/h_i + R''_{t,c} + L_b/k_b\right)/A_c} = 0.3\text{W}$$

and

$$q_t = \frac{T_c - T_{\infty,o}}{R_{t,o}}$$

The resistance of the pin array is

$$R_{t,o} = \left(\eta_o h_o A_t\right)^{-1}$$

where

$$\eta_o = 1 - \frac{NA_f}{A_t}\left(1 - \eta_f\right)$$

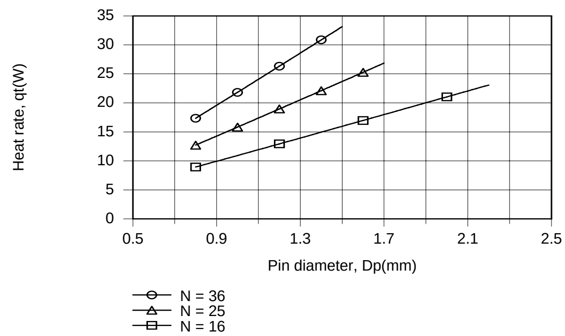
$$A_t = NA_f + A_b$$

$$A_f = \pi D_p L_c = \pi D_p \left(L_p + D_p/4\right)$$

Subject to the constraint that $N^{1/2}D_p \le 9$ mm, the foregoing expressions may be used to compute q_t as a function of D_p for L_p = 15 mm and values of N = 16, 25 and 36. Using the IHT *Performance Calculation, Extended Surface Model* for the *Pin Fin Array*, we obtain

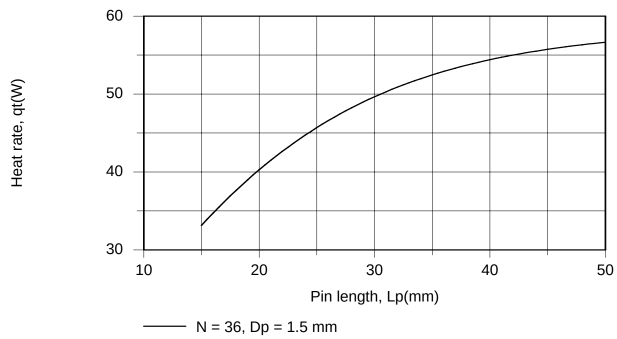
Continued...

PROBLEM 3.148 (Cont.)



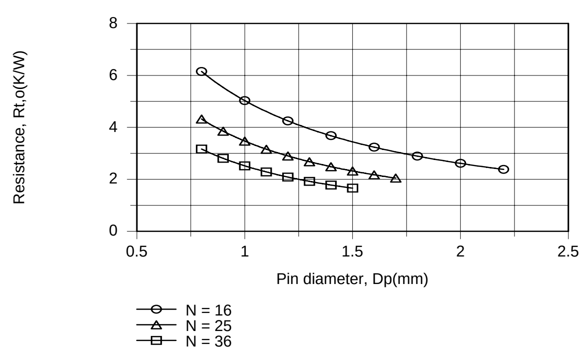
Clearly, it is desirable to maximize the number of pins and the pin diameter, so long as flow passages are not constricted to the point of requiring an excessive pressure drop to maintain the prescribed convection coefficient. The maximum heat rate for the fin array (q_t = 33.1 W) corresponds to N = 36 and D_p = 1.5 mm. Further improvement could be obtained by using N = 49 pins of diameter D_p = 1.286 mm, which yield q_t = 37.7 W.

Exploring the effect of L_p for N = 36 and D_p = 1.5 mm, we obtain



Clearly, there are benefits to increasing L_p, although the effect diminishes due to an attendant reduction in η_f (from η_f = 0.887 for L_p = 15 mm to η_f = 0.471 for L_p = 50 mm). Although a heat dissipation rate of q_t = 56.7 W is obtained for L_p = 50 mm, package volume constraints could preclude such a large fin length.

COMMENTS: By increasing N, D_p and/or L_p, the total surface area of the array, A_t, is increased, thereby reducing the array thermal resistance, $R_{t,o}$. The effects of D_p and N are shown for L_p = 15 mm.

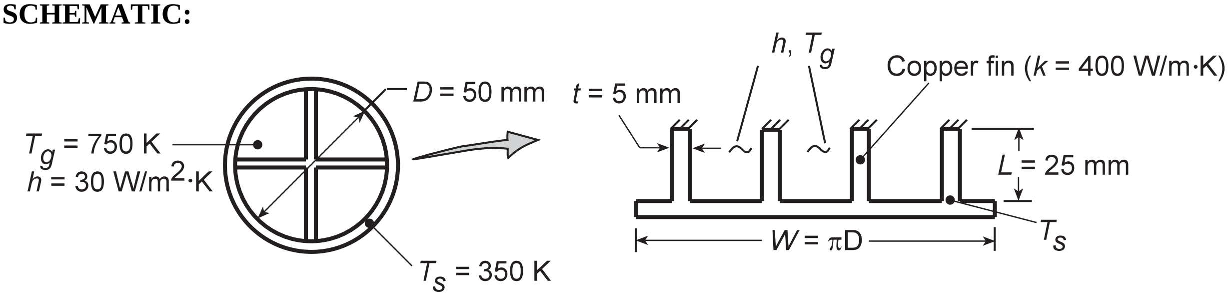


PROBLEM 3.149

KNOWN: Diameter and internal fin configuration of copper tubes submerged in water. Tube wall temperature and temperature and convection coefficient of gas flow through the tube.

FIND: Rate of heat transfer per tube length.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) One-dimensional fin conduction, (3) Constant properties, (4) Negligible radiation, (5) Uniform convection coefficient, (6) Tube wall may be unfolded and represented as a plane wall with four straight, rectangular fins, each with an adiabatic tip (since, by symmetry, there can be no heat flow along the fins where they cross).

ANALYSIS: The rate of heat transfer per unit tube length is:

$$q_t' = \eta_o h A_t' \left(T_g - T_s\right)$$

$$\eta_o = 1 - \frac{NA_f'}{A_t'}\left(1-\eta_f\right)$$

$$NA_f' = 4\times 2L = 8\left(0.025\text{m}\right) = 0.20\text{m}$$

$$A_t' = NA_f' + A_b' = 0.20\text{m} + \left(\pi D - 4t\right) = 0.20\text{m} + \left(\pi\times 0.05\text{m} - 4\times 0.005\text{m}\right) = 0.337\text{m}$$

For an adiabatic fin tip,

$$\eta_f = \frac{q_f}{q_{max}} = \frac{M\tanh mL}{h\left(2L\cdot 1\right)\left(T_g - T_s\right)}$$

$$M = \left[h2\left(1\text{m}+t\right)k\left(1\text{m}\times t\right)\right]^{1/2}\left(T_g - T_s\right) \approx \left[30\,\text{W/m}^2\cdot\text{K}\left(2\text{m}\right)400\,\text{W/m}\cdot\text{K}\left(0.005\text{m}^2\right)\right]^{1/2}\left(400\text{K}\right) = 4382\text{W}$$

$$mL = \left\{\left[h2\left(1\text{m}+t\right)\right]/\left[k\left(1\text{m}\times t\right)\right]\right\}^{1/2} L \approx \left[\frac{30\,\text{W/m}^2\cdot\text{K}\left(2\text{m}\right)}{400\,\text{W/m}\cdot\text{K}\left(0.005\text{m}^2\right)}\right]^{1/2} 0.025\text{m} = 0.137$$

Hence, tanh mL = 0.136, and

$$\eta_f = \frac{4382\text{W}\left(0.136\right)}{30\,\text{W/m}^2\cdot\text{K}\left(0.05\text{m}^2\right)\left(400\text{K}\right)} = \frac{595\text{W}}{600\text{W}} = 0.992$$

$$\eta_o = 1 - \frac{0.20}{0.337}\left(1-0.992\right) = 0.995$$

$$q_t' = 0.995\left(30\,\text{W/m}^2\cdot\text{K}\right)0.337\text{m}\left(400\text{K}\right) = 4025\,\text{W/m}$$

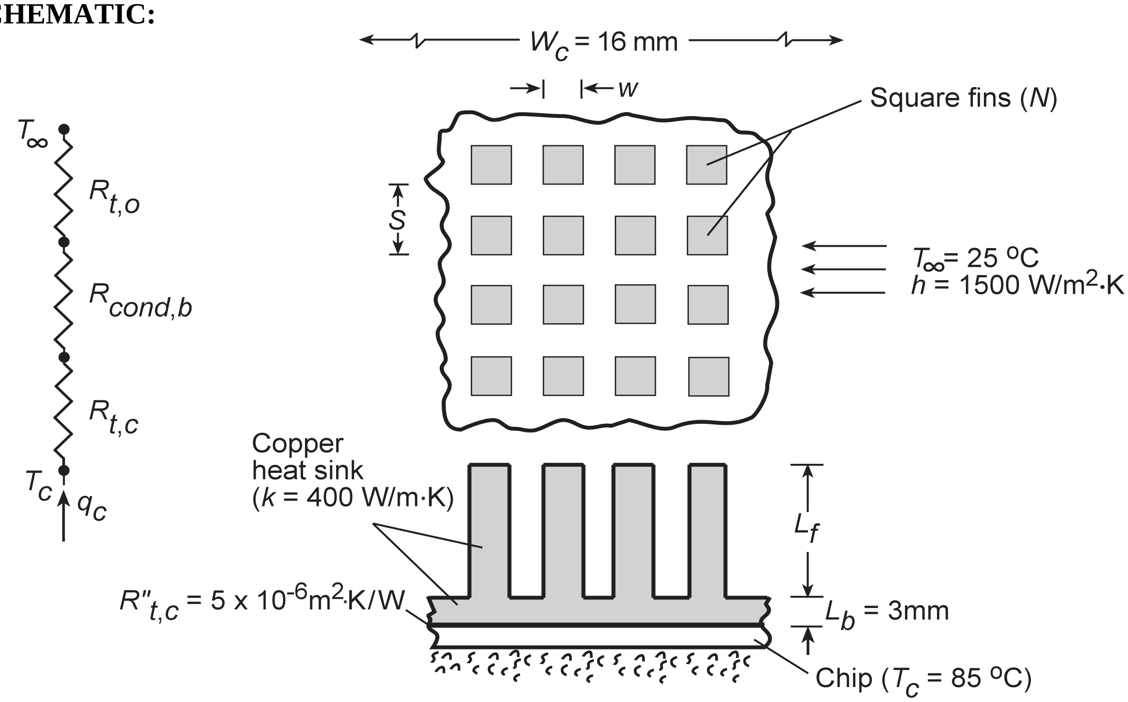
COMMENTS: Alternatively, $q_t' = 4q_f' + h\left(A_t' - A_f'\right)\left(T_g - T_s\right)$. Hence, q' = 4(595 W/m) + 30 W/m^2·K (0.137 m)(400 K) = (2380 + 1644) W/m = 4024 W/m.

PROBLEM 3.150

KNOWN: Copper heat sink dimensions and convection conditions.

FIND: (a) Maximum allowable heat dissipation for a prescribed chip temperature and interfacial chip/heat-sink contact resistance, (b) Effect of fin length and width on heat dissipation.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer in chip-heat sink assembly, (3) Constant k, (4) Negligible chip thermal resistance, (5) Negligible heat transfer from back of chip, (6) Uniform chip temperature.

ANALYSIS: (a) For the prescribed system, the chip power dissipation may be expressed as

$$q_c = \frac{T_c - T_\infty}{R_{t,c} + R_{cond,b} + R_{t,o}}$$

where $R_{t,c} = \dfrac{R''_{t,c}}{W_c^2} = \dfrac{5\times10^{-6}\,m^2\cdot K/W}{(0.016m)^2} = 0.0195\,K/W$

$$R_{cond,b} = \frac{L_b}{kW_c^2} = \frac{0.003m}{400\,W/m\cdot K\,(0.016m)^2} = 0.0293\,K/W$$

The thermal resistance of the fin array is

$$R_{t,o} = (\eta_o h A_t)^{-1}$$

where $\eta_o = 1 - \dfrac{NA_f}{A_t}(1-\eta_f)$

and $A_t = NA_f + A_b = N(4wL_c) + (W_c^2 - Nw^2)$

Continued...

PROBLEM 3.150 (Cont.)

With w = 0.25 mm, S = 0.50 mm, L_f = 6 mm, N = 1024, and $L_c \approx L_f + w/4 = 6.063\times10^{-3}$ m, it follows that $A_f = 6.06\times10^{-6}\,m^2$ and $A_t = 6.40\times10^{-3}\,m^2$. The fin efficiency is

$$\eta_f = \frac{\tanh mL_c}{mL_c}$$

where $m = \left(hP/kA_c\right)^{1/2} = \left(4h/kw\right)^{1/2}$ = 245 m^{-1} and mL_c = 1.49. It follows that η_f = 0.608 and η_o = 0.619, in which case

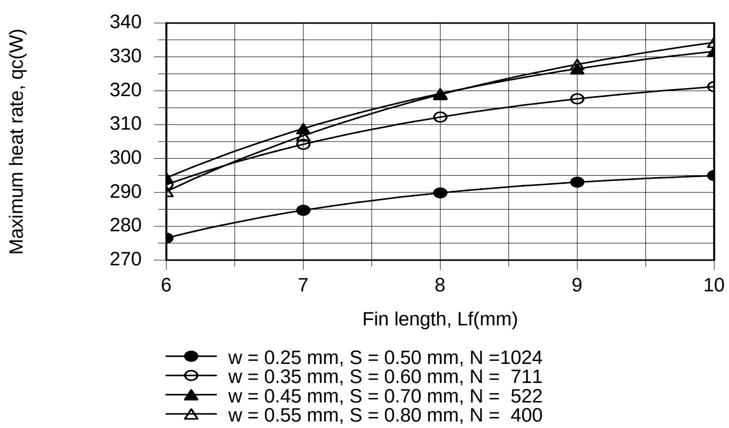
$$R_{t,o} = \left(0.619\times1500\,W/m^2\cdot K\times6.40\times10^{-3}\,m^2\right) = 0.168\,K/W$$

and the maximum allowable heat dissipation is

$$q_c = \frac{(85-25)^\circ C}{(0.0195+0.0293+0.168)\,K/W} = 276W \qquad <$$

(b) The IHT *Performance Calculation, Extended Surface Model* for the *Pin Fin Array* has been used to determine q_c as a function of L_f for four different cases, each of which is characterized by the closest allowable fin spacing of (S - w) = 0.25 mm.

Case	w (mm)	S (mm)	N
A	0.25	0.50	1024
B	0.35	0.60	711
C	0.45	0.70	522
D	0.55	0.80	400



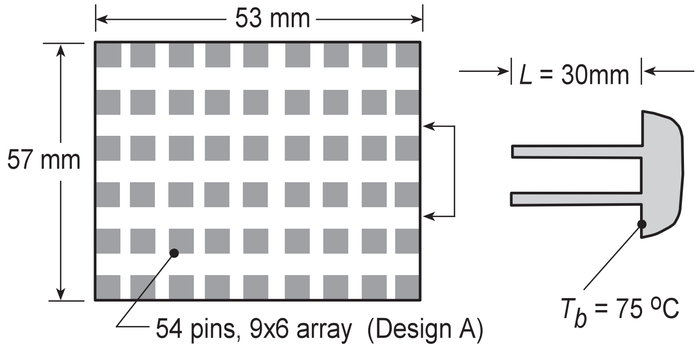
With increasing w and hence decreasing N, there is a reduction in the total area A_t associated with heat transfer from the fin array. However, for Cases A through C, the reduction in A_t is more than balanced by an increase in η_f (and η_o), causing a reduction in $R_{t,o}$ and hence an increase in q_c. As the fin efficiency approaches its limiting value of η_f = 1, reductions in A_t due to increasing w are no longer balanced by increases in η_f, and q_c begins to decrease. Hence there is an optimum value of w, which depends on L_f. For the conditions of this problem, L_f = 10 mm and w = 0.55 mm provide the largest heat dissipation.

Problem 3.151

KNOWN: Two finned heat sinks, Designs A and B, prescribed by the number of fins in the array, N, fin dimensions of square cross-section, w, and length, L, with different convection coefficients, h.

FIND: Determine which fin arrangement is superior. Calculate the heat rate, q_f, efficiency, η_f, and effectiveness, ε_f, of a single fin, as well as, the total heat rate, q_t, and overall efficiency, η_o, of the array. Also, compare the total heat rates per unit volume.

SCHEMATIC:



Design	Fin dimensions Cross section w x w (mm)	Length L (mm)	Number of fins	Convection coefficient (W/m^2·K)
A	3 x 3	30	6 x 9	125
B	1 x 1	7	14 x 17	375

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in fins, (3) Convection coefficient is uniform over fin and prime surfaces, (4) Fin tips experience convection, and (5) Constant properties.

ANALYSIS: Following the treatment of Section 3.6.5, the overall efficiency of the array, Eq. (3.103), is

$$\eta_o = \frac{q_t}{q_{max}} = \frac{q_t}{hA_t\theta_b} \tag{1}$$

where A_t is the total surface area, the sum of the exposed portion of the base (prime area) plus the fin surfaces, Eq. 3.104,

$$A_t = N \cdot A_f + A_b \tag{2}$$

where the surface area of a single fin and the prime area are

$$A_f = 4(L \times w) + w^2 \tag{3}$$

$$A_b = b1 \times b2 - N \cdot A_c \tag{4}$$

Combining Eqs. (1) and (2), the total heat rate for the array is

$$q_t = N\eta_f hA_f\theta_b + hA_b\theta_b \tag{5}$$

where η_f is the efficiency of a single fin. From Table 3.4, Case A, for the tip condition with convection, the single fin efficiency based upon Eq. 3.91,

$$\eta_f = \frac{q_f}{hA_f\theta_b} \tag{6}$$

Continued...

PROBLEM 3.151 (Cont.)

where

$$q_f = M \frac{\sinh(mL) + (h/mk)\cosh(mL)}{\cosh(mL) + (h/mk)\sinh(mL)} \quad (7)$$

$$M = (hPkA_c)^{1/2}\theta_b \qquad m = (hP/kA_c)^{1/2} \qquad P = 4w \qquad A_c = w^2 \quad (8,9,10)$$

The single fin effectiveness, from Eq. 3.86,

$$\varepsilon_f = \frac{q_f}{hA_c\theta_b} \quad (11)$$

Additionally, we want to compare the performance of the designs with respect to the array volume,

$$q_f''' = q_t/\forall = q_t/(b1 \cdot b2 \cdot L) \quad (12)$$

The above analysis was organized for easy treatment with equation-solving software. Solving Eqs. (1) through (11) simultaneously with appropriate numerical values, the results are tabulated below.

Design	q_t (W)	q_f (W)	η_o	η_f	ε_f	q_f''' (W/m^3)
A	113	1.80	0.804	0.779	31.9	1.25×10^6
B	165	0.475	0.909	0.873	25.3	7.81×10^6

COMMENTS: (1) Both designs have good efficiencies and effectiveness. Clearly, Design B is superior because the heat rate is nearly 50% larger than Design A for the same board footprint. Further, the space requirement for Design B is four times less ($\forall = 2.12\times10^{-5}$ vs. 9.06×10^{-5} m^3) and the heat rate per unit volume is 6 times greater.

(2) Design A features 54 fins compared to 238 fins for Design B. Also very significant to the performance comparison is the magnitude of the convection coefficient which is 3 times larger for Design B. Estimating convection coefficients for fin arrays (and tube banks) is discussed in Chapter 7.6. Of concern is how the upstream fins alter the flow past the downstream fins and whether the convection coefficient is uniform over the array.

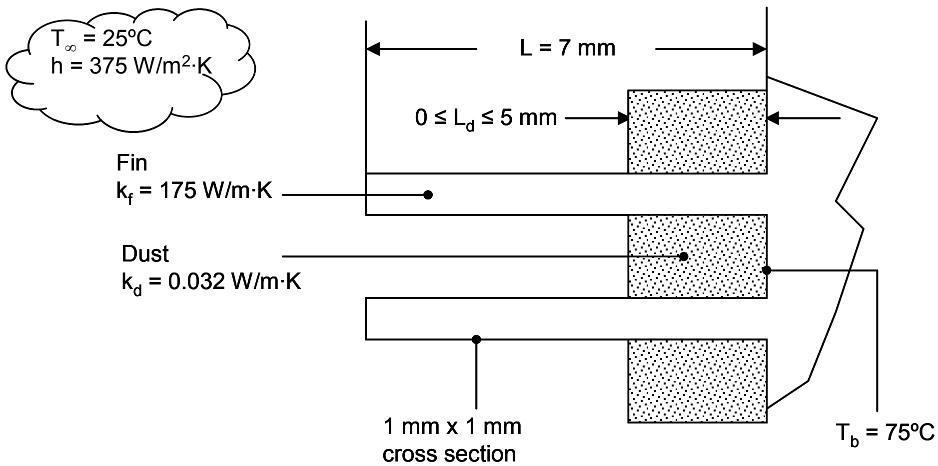
(3) The *IHT Extended Surfaces Model*, for a *Rectangular Pin Fin Array* could have been used to solve this problem.

PROBLEM 3.152

KNOWN: Dimensions of a fin array and dust layer. Aluminum and dust thermal conductivities. Base temperature. Air temperature and heat transfer coefficient.

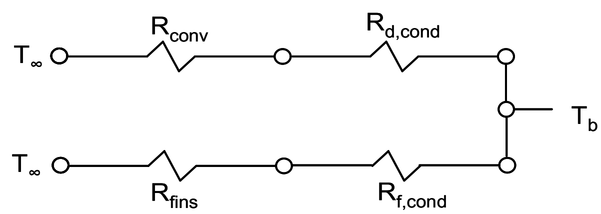
FIND: Allowable heat rate for dust layer thickness in the range of $0 \le L_d \le 5$ mm.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Negligible temperature variation across fin thickness, (3) Constant properties, (4) Uniform heat transfer coefficient, including over fin tips.

ANALYSIS: There are two heat transfer paths, one through the dust and into the air, and the other through the fin. The thermal circuit is



The thermal resistances are given by

$$R_{d,cond} = \frac{L_d}{k_d A_d} = \frac{L_d}{k_d (A_p - NA_c)}$$

where $A_p = 53 \times 10^{-3}$ m $\times 57 \times 10^{-3}$ m $= 3.02 \times 10^{-3}$ m^2, $N = 14 \times 17 = 238$ and $A_c = w^2 = 10^{-6}$ m^2.

$$R_{conv} = \frac{1}{hA_d}, \quad R_{f,cond} = \frac{L_d}{k_f NA_c} \quad \text{and } R_{fins} = \frac{R_{t,f}}{N}$$

where from Equation 3.88

$$R_{t,f} = \frac{\theta_b}{q_f}$$

where q_f is given by Equation 3.77,

$$R_{t,f} = \frac{\cosh(mL_f) + (h / mk_f)\sinh(mL_f)}{\sqrt{4hw^3k}\,(\sinh(mL_f) + (h / mk_f)\cosh(mL_f))}$$

Continued…

PROBLEM 3.152 (Cont.)

Here, $m = (4h / k_f w)^{1/2} = (4 \times 375 \text{ W/m}^2\cdot\text{K} / 175 \text{ W/m}\cdot\text{K} \times 10^{-3} \text{ m})^{1/2} = 92.6 \text{ m}^{-1}$

and $L_f = L - L_d$.

Finally,

$$q = q_{dust} + q_{fin}$$

$$= \frac{T_b - T_\infty}{R_{d,cond} + R_{conv}} + \frac{T_b - T_\infty}{R_{f,cond} + R_{fins}}$$

Performing the calculation for a dust layer thickness of $L_d = 5$ mm yields

$R_{d,cond} = 56.1$ K/W

$R_{conv} = 0.958$ K/W

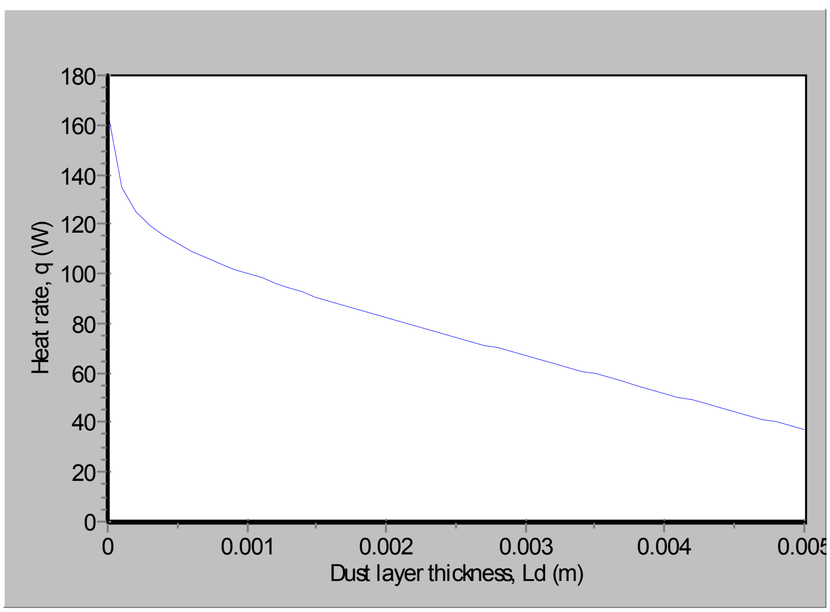
$R_{f,cond} = 0.120$ K/W

$R_{t,f} = 301$ K/W, $R_{fins} = 1.26$ K/W

$$q = \frac{75°C - 25°C}{(56.1 + 0.958)\text{ K/W}} + \frac{75°C - 25°C}{0.120 + 1.26} = 0.876 \text{ W} + 36.1 \text{ W} = 37.0 \text{ W}$$

<

The figure shows the variation of the allowable heat rate as the dust layer thickness varies.



COMMENTS: The figure below shows the two contributions to the heat rate, q_{dust} and q_{fin}. The heat transfer through the dust layer decreases rapidly as the dust layer thickness increases and insulates the surface. The fin heat transfer also decreases with increasing dust layer thickness as more of the fin surface is insulated by the dust.

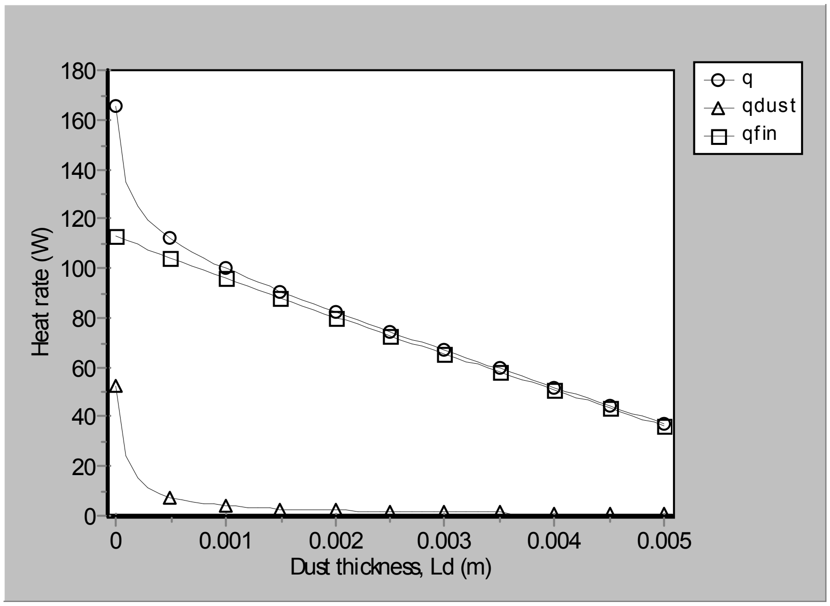
PROBLEM 3.152 (Cont.)

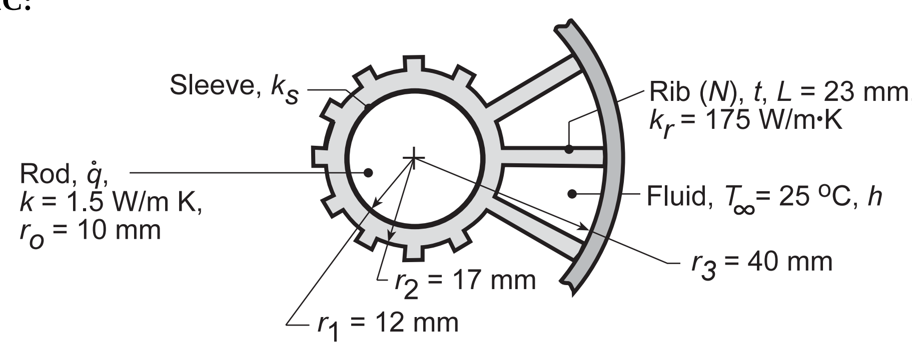


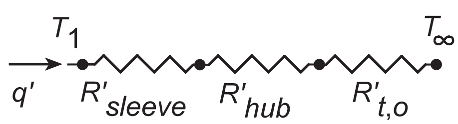
PROBLEM 3.153

KNOWN: Long rod with internal volumetric generation covered by an electrically insulating sleeve and supported with a ribbed spider.

FIND: Combination of convection coefficient, spider design, and sleeve thermal conductivity which enhances volumetric heating subject to a maximum centerline temperature of 100°C.

SCHEMATIC:





ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial heat transfer in rod, sleeve and hub, (3) Negligible interfacial contact resistances, (4) Constant properties, (5) Adiabatic outer surface.

ANALYSIS: The system heat rate per unit length may be expressed as

$$q' = \dot{q}\left(\pi r_o^2\right) = \frac{T_1 - T_\infty}{R'_{sleeve} + R'_{hub} + R'_{t,o}}$$

where

$$R'_{sleeve} = \frac{\ln\left(r_1/r_o\right)}{2\pi k_s}, \quad R'_{hub} = \frac{\ln\left(r_2/r_1\right)}{2\pi k_r} = 3.168\times10^{-4}\,\text{m}\cdot\text{K/W}, \quad R'_{t,o} = \frac{1}{\eta_o h A'_t},$$

$$\eta_o = 1 - \frac{NA'_f}{A'_t}\left(1-\eta_f\right), \qquad A'_f = 2\left(r_3 - r_2\right), \qquad A'_t = NA'_f + \left(2\pi r_3 - Nt\right),$$

$$\eta_f = \frac{\tanh m\left(r_3 - r_2\right)}{m\left(r_3 - r_2\right)}, \qquad m = \left(2h/k_r t\right)^{1/2}.$$

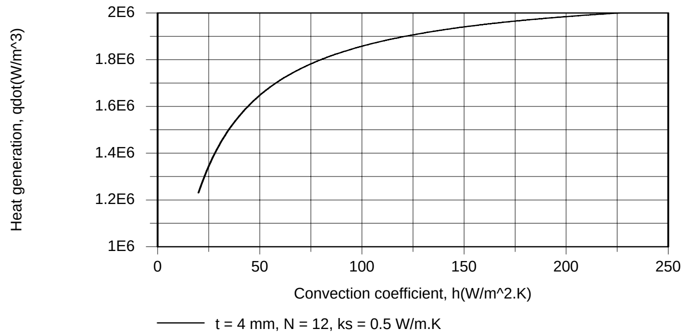
The rod centerline temperature is related to T_1 through

$$T_o = T(0) = T_1 + \frac{\dot{q} r_o^2}{4k}$$

Calculations may be expedited by using the IHT *Performance Calculation, Extended Surface Model* for the *Straight Fin Array*. For base case conditions of k_s = 0.5 W/m·K, h = 20 W/m^2·K, t = 4 mm and N = 12, R'_{sleeve} = 0.0580 m·K/W, $R'_{t,o}$ = 0.0826 m·K/W, η_f = 0.990, q' = 387 W/m, and $\dot{q}$ = 1.23 × 10^6 W/m^3. As shown below, $\dot{q}$ may be increased by increasing h, where h = 250 W/m^2·K represents a reasonable upper limit for airflow. However, a more than 10-fold increase in h yields only a 63% increase in $\dot{q}$.

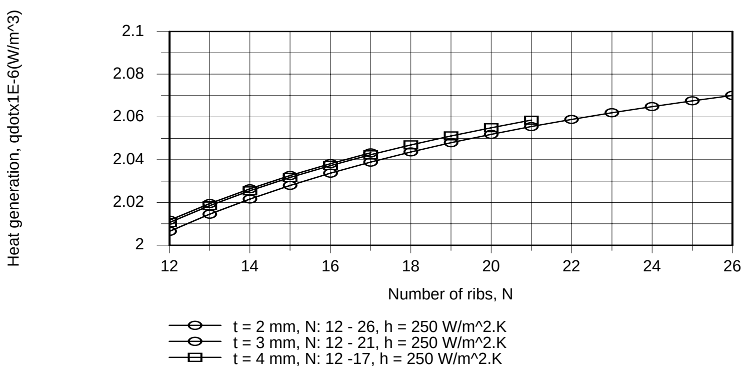
Continued...

PROBLEM 3.153 (Cont.)

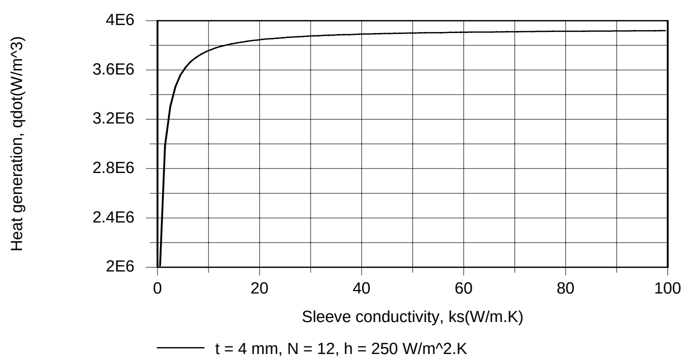


The difficulty is that, by significantly increasing h, the thermal resistance of the fin array is reduced to 0.00727 m·K/W, rendering the sleeve the dominant contributor to the total resistance.

Similar results are obtained when N and t are varied. For values of t = 2, 3 and 4 mm, variations of N in the respective ranges $12 \le N \le 26$, $12 \le N \le 21$ and $12 \le N \le 17$ were considered. The upper limit on N was fixed by requiring that $(S - t) \ge 2$ mm to avoid an excessive resistance to airflow between the ribs. As shown below, the effect of increasing N is small, and there is little difference between results for the three values of t.



In contrast, significant improvement is associated with changing the sleeve material, and it is only necessary to have $k_s \approx 25$ W/m·K (e.g. a boron sleeve) to approach an upper limit to the influence of k_s.



For $h = 250$ W/m^2·K and $k_s = 25$ W/m·K, only a slight improvement is obtained by increasing N. Hence, the recommended conditions are:

$$h = 250\,\mathrm{W/m^2 \cdot K}, \qquad k_s = 25\,\mathrm{W/m \cdot K}, \qquad N = 12, \qquad t = 4\mathrm{mm} \qquad <$$

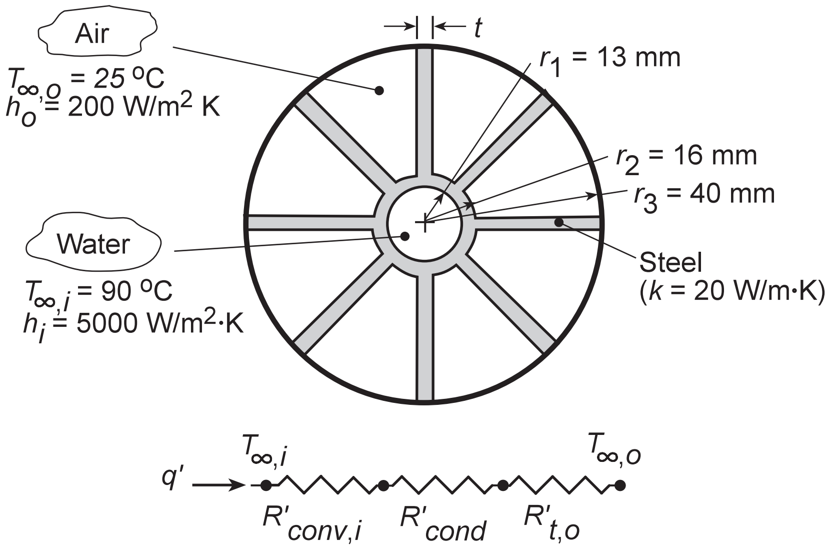
COMMENTS: The upper limit to $\dot{q}$ is reached as the total thermal resistance approaches zero, in which case $T_1 \to T_\infty$. Hence $\dot{q}_{max} = 4k\left(T_o - T_\infty\right)/r_o^2 = 4.5 \times 10^6\,\mathrm{W/m^3}$.

PROBLEM 3.154

KNOWN: Geometrical and convection conditions of internally finned, concentric tube air heater.

FIND: (a) Thermal circuit, (b) Heat rate per unit tube length, (c) Effect of changes in fin array.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer in radial direction, (3) Constant k, (4) Adiabatic outer surface.

ANALYSIS: (a) For the thermal circuit shown schematically,

$$R'_{conv,i} = \left(h_i 2\pi r_1\right)^{-1}, \qquad R'_{cond} = \ln\left(r_2/r_1\right)/2\pi k \text{, and} \qquad R'_{t,o} = \left(\eta_o h_o A'_t\right)^{-1},$$

where

$$\eta_o = 1 - \frac{NA'_f}{A'_t}\left(1-\eta_f\right), \quad A'_f = 2L = 2\left(r_3 - r_2\right), \quad A'_t = NA'_f + \left(2\pi r_2 - Nt\right), \text{ and} \quad \eta_f = \frac{\tanh mL}{mL}.$$

(b) $$q' = \frac{\left(T_{\infty,i} - T_{\infty,o}\right)}{R'_{conv,i} + R'_{cond} + R'_{t,o}}$$

Substituting the known conditions, it follows that

$$R'_{conv,i} = \left(5000\,W/m^2 \cdot K \times 2\pi \times 0.013m\right)^{-1} = 2.45\times10^{-3}\,m\cdot K/W$$

$$R'_{cond} = \ln\left(0.016m/0.013m\right)/2\pi\left(20\,W/m\cdot K\right) = 1.65\times10^{-3}\,m\cdot K/W$$

$$R'_{t,o} = \left(0.575\times 200\,W/m^2\cdot K\times 0.461m\right)^{-1} = 18.86\times10^{-3}\,m\cdot K/W$$

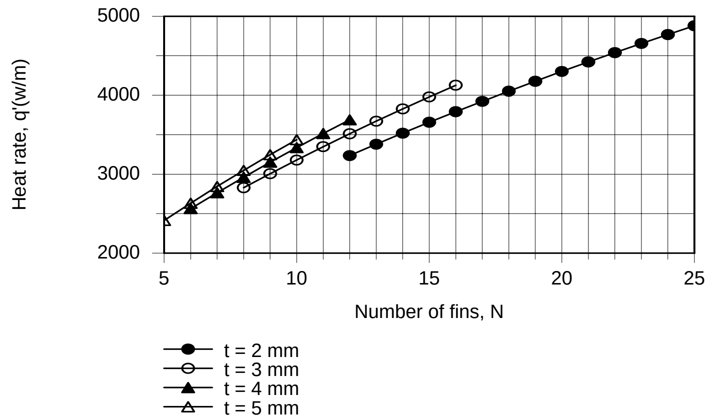
where η_f = 0.490. Hence,

$$q' = \frac{\left(90-25\right)^\circ C}{\left(2.45+1.65+18.86\right)\times10^{-3}\,m\cdot K/W} = 2831\,W/m$$ <

(c) The small value of η_f suggests that some benefit may be gained by increasing t, as well as by increasing N. With the requirement that Nt ≤ 50 mm, we use the IHT *Performance Calculation, Extended Surface Model* for the *Straight Fin Array* to consider the following range of conditions: t = 2 mm, 12 ≤ N ≤ 25; t = 3 mm, 8 ≤ N ≤ 16; t = 4 mm, 6 ≤ N ≤ 12; t = 5 mm, 5 ≤ N ≤ 10. Calculations based on the foregoing model are plotted as follows.

Continued...

PROBLEM 3.154 (Cont.)



By increasing t from 2 to 5 mm, η_f increases from 0.410 to 0.598. Hence, for fixed N, q' increases with increasing t. However, from the standpoint of maximizing q'_t, it is clearly preferable to use the larger number of thinner fins. Hence, subject to the prescribed constraint, we would choose t = 2 mm and N = 25, for which q' = 4880 W/m.

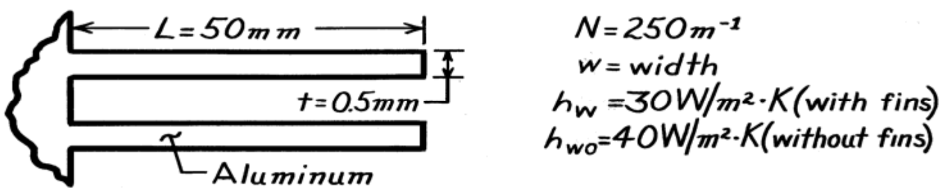
COMMENTS: (1) The air side resistance makes the dominant contribution to the total resistance, and efforts to increase q' by reducing $R'_{t,o}$ are well directed. (2) A fin thickness any smaller than 2 mm would be difficult to manufacture.

PROBLEM 3.155

KNOWN: Dimensions and number of rectangular aluminum fins. Convection coefficient with and without fins.

FIND: Percentage increase in heat transfer resulting from use of fins.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible radiation, (5) Negligible fin contact resistance, (6) Uniform convection coefficient.

PROPERTIES: *Table A-1,* Aluminum, pure: k ≈ 240 W/m·K.

ANALYSIS: Evaluate the fin parameters

$$L_c = L+t/2 = 0.05025\text{m}$$

$$A_p = L_c t = 0.05025\text{m} \times 0.5\times10^{-3}\text{m} = 25.13\times10^{-6}\ \text{m}^2$$

$$L_c^{3/2}\left(h_w / kA_p\right)^{1/2} = \left(0.05025\text{m}\right)^{3/2}\left[\frac{30\ \text{W/m}^2\cdot\text{K}}{240\ \text{W/m}\cdot\text{K}\times25.13\times10^{-6}\text{m}^2}\right]^{1/2}$$

$$L_c^{3/2}\left(h_w / kA_p\right)^{1/2} = 0.794$$

It follows from Fig. 3.19 that $\eta_f \approx 0.72$. Hence,

$$q_f = \eta_f q_{max} = 0.72\ h_w 2wL\ \theta_b$$

$$q_f = 0.72\times30\ \text{W/m}^2\cdot\text{K}\times2\times0.05\text{m}\times\left(w\ \theta_b\right) = 2.16\ \text{W/m}\cdot\text{K}\left(w\ \theta_b\right)$$

With the fins, the heat transfer from the walls is

$$q_w = N\ q_f + \left(1-Nt\right)w\ h_w\ \theta_b$$

$$q_w = 250\times2.16\frac{\text{W}}{\text{m}\cdot\text{K}}\left(w\ \theta_b\right) + \left(1\text{m} - 250\times5\times10^{-4}\text{m}\right)\times30\ \text{W/m}^2\cdot\text{K}\ \left(w\ \theta_b\right)$$

$$q_w = \left(540+26.3\right)\frac{\text{W}}{\text{m}\cdot\text{K}}\left(w\ \theta_b\right) = 566\ w\ \theta_b.$$

Without the fins, $q_{wo} = h_{wo}\ 1\text{m} \times w\ \theta_b = 40\ w\ \theta_b$. Hence the percentage increase in heat transfer is

$$\frac{q_w - q_{wo}}{q_{wo}} = \frac{\left(566-40\right)w\ \theta_b}{40\ w\ \theta_b} = 13.15 = 1315\% \qquad <$$

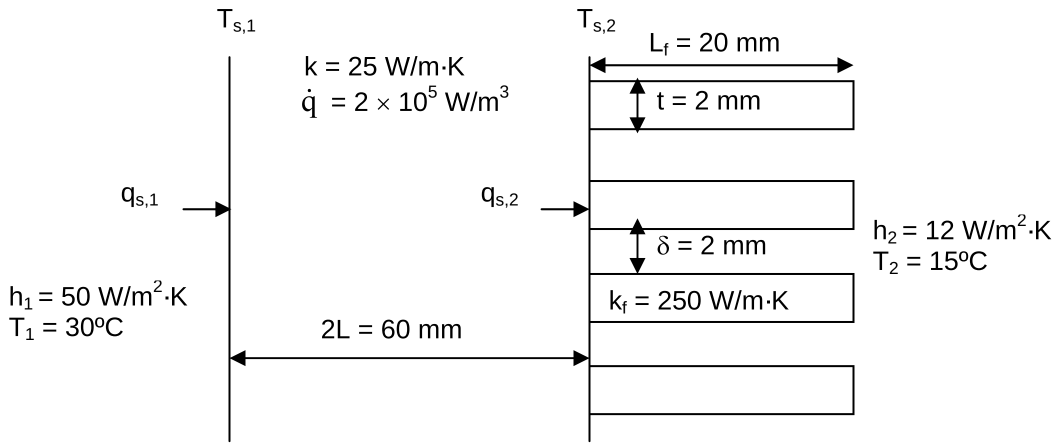
COMMENTS: If the infinite fin approximation is made, it follows that $q_f = (hPkA_c)^{1/2}\ \theta_b = [h_w 2wkwt]^{1/2}\ \theta_b = (30 \times 2 \times 240 \times 5\times10^{-4})^{1/2}\ w\ \theta_b = 2.68\ w\ \theta_b$. Hence, q_f is overestimated.

PROBLEM 3.156

KNOWN: Wall with known heat generation rate, thermal conductivity, and thickness. Dimensions and thermal conductivity of fins. Heat transfer coefficients and environment temperatures.

FIND: Maximum temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Wall surface temperatures are uniform. (3) No contact resistance between fins and wall, (4) Heat transfer from the fin tips can be neglected.

ANALYSIS: The temperature distribution in a wall with uniform volumetric heat generation and specified temperature boundary conditions is, from Equation 3.46

$$T(x) = \frac{\dot{q}L^2}{2k}\left(1 - \frac{x^2}{L^2}\right) + \frac{T_{s,2} - T_{s,1}}{2}\frac{x}{L} + \frac{T_{s,1} + T_{s,2}}{2} \quad (1)$$

The heat transfer rates at the two surfaces, for a wall section of area A, can be found from Fourier's law:

$$q_{s,1} = -kA\left.\frac{dT}{dx}\right|_{x=-L} = -\dot{q}LA - kA\frac{T_{s,2} - T_{s,1}}{2L} \quad (2)$$

$$q_{s,2} = -kA\left.\frac{dT}{dx}\right|_{x=L} = \dot{q}LA - kA\frac{T_{s,2} - T_{s,1}}{2L} \quad (3)$$

We can express these same heat transfer rates alternatively, as follows:

$$q_{s,1} = h_1 A(T_1 - T_{s,1}) \quad (4)$$

$$q_{s,2} = h_2 A_t (T_{s,2} - T_2)\eta_o \quad (5)$$

where η_o is given by Equation 3.107. Equating the two expressions for $q_{s,1}$, Equations (2) and (4), and equating the expressions for $q_{s,2}$, Equations (3) and (5), and solving for $T_{s,1}$ and $T_{s,2}$ yields

Continued…

PROBLEM 3.156 (Cont.)

$$T_{s,1} = \frac{\left(\frac{k}{2L} + h_2\tilde{A}\right)h_1T_1 + \frac{k}{2L}h_2\tilde{A}T_2 + \left(\frac{k}{L} + h_2\tilde{A}\right)\dot{q}L}{\frac{kh_1}{2L} + h_1h_2\tilde{A} + \frac{kh_2\tilde{A}}{2L}}$$

$$T_{s,2} = \frac{\frac{k}{2L}h_1T_1 + \left(\frac{k}{2L} + h_1\right)h_2\tilde{A}T_2 + \left(\frac{k}{L} + h_1\right)\dot{q}L}{\frac{kh_1}{2L} + h_1h_2\tilde{A} + \frac{kh_2\tilde{A}}{2L}}$$

where

$$\tilde{A} = \frac{A_t\eta_o}{A} = \frac{A_t}{A} - \frac{NA_f}{A}\left(1 - \eta_f\right)$$

Performing the calculations:

$$m = \sqrt{\frac{h_2P}{k_fA_c}} = \sqrt{\frac{2h_2}{k_ft}} = \sqrt{\frac{2 \times 12\ \text{W/m}^2\cdot\text{K}}{250\ \text{W/m}\cdot\text{K} \times 0.002\ \text{m}}} = 6.9\ \text{m}^{-1}$$

$$\eta_f = \frac{\tanh\left(mL_f\right)}{mL_f} = \frac{\tanh\left(6.9\ \text{m}^{-1} \times 0.02\ \text{m}\right)}{6.9\ \text{m}^{-1} \times 0.02\ \text{m}} = 0.994$$

$$\frac{NA_f}{A} = \frac{N2wL_f}{(\delta + t)Nw} = \frac{2L_f}{\delta + t} = \frac{2 \times 0.02\ \text{m}}{0.004\ \text{m}} = 10.0$$

$$\frac{A_t}{A} = \frac{NA_f}{A} + \frac{A_b}{A} = \frac{NA_f}{A} + \frac{\delta Nw}{(\delta+t)Nw} = \frac{NA_f}{A} + \frac{\delta}{\delta + t} = 10. + \frac{0.002\ \text{m}}{0.004\ \text{m}} = 10.5$$

$$\tilde{A} = 10.5 - 10.\left(1 - 0.994\right) = 10.4$$

$$h_2\tilde{A} = 12\ \text{W/m}^2\cdot\text{K} \times 10.4 = 125\ \text{W/m}^2\cdot\text{K}$$

$$\frac{k}{2L} = \frac{25\ \text{W/m}\cdot\text{K}}{0.06\ \text{m}} = 417\ \text{W/m}^2\cdot\text{K}$$

Thus

$$T_{s,1} = \left(\begin{array}{l}\left(417+125\right)\ \text{W/m}^2\cdot\text{K}\times 50\ \text{W/m}^2\cdot\text{K}\times 30°\text{C} \\ +\ 417\ \text{W/m}^2\cdot\text{K}\times 125\ \text{W/m}^2\cdot\text{K}\times 15°\text{C} \\ +\left(2\times 417+125\right)\ \text{W/m}^2\cdot\text{K}\times 2\times 10^5\ \text{W/m}^3\times 0.03\ \text{m}\end{array}\right) \Bigg/ \left(\begin{array}{l}(417\times 50 \\ +\ 50\times 125 \\ +\ 417\times 125)\ \left(\text{W/m}^2\cdot\text{K}\right)^2\end{array}\right)$$

Continued…

PROBLEM 3.156 (Cont.)

$$T_{s,1} = 92.7°C$$

Similarly,

$$T_{s,2} = 85.8°C$$

The location of the maximum temperature in the wall can be found by setting the gradient of the temperature (from Equation (1)) to zero:

$$\frac{dT}{dx} = -\frac{\dot{q}x}{k} + \frac{T_{s,2} - T_{s,1}}{2L} = 0$$

Thus, $x_{max} = k\frac{T_{s,2} - T_{s,1}}{2L\dot{q}}$. Substituting this back into the temperature distribution,

$$T_{max} = \frac{\dot{q}L^2}{2k} + \frac{k\left(T_{s,2} - T_{s,1}\right)^2}{8L^2\dot{q}} + \frac{T_{s,1} + T_{s,2}}{2}$$

$$= \frac{2 \times 10^5\ W/m^3 \times (0.03\ m)^2}{2 \times 25\ W/m \cdot K} + \frac{25\ W/m \cdot K\left(85.8°C - 92.7°C\right)^2}{8 \times (0.03\ m)^2 \times 2 \times 10^5\ W/m^3}$$

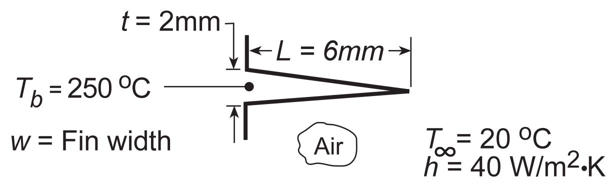
$$+ \frac{92.7°C + 85.8°C}{2} = 93.7°C$$ <

PROBLEM 3.157

KNOWN: Dimensions, base temperature and environmental conditions associated with a triangular, aluminum fin.

FIND: (a) Fin efficiency and effectiveness, (b) Heat dissipation per unit width.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible radiation and base contact resistance, (5) Uniform convection coefficient.

PROPERTIES: *Table A-1*, Aluminum, pure (T ≈ 400 K): k = 240 W/m·K.

ANALYSIS: (a) With $L_c = L = 0.006$ m, find

$$A_p = Lt/2 = (0.006\,m)(0.002\,m)/2 = 6\times10^{-6}\,m^2,$$

$$L_c^{3/2}(h/kA_p)^{1/2} = (0.006\,m)^{3/2}\left(\frac{40\,W/m^2\cdot K}{240\,W/m\cdot K\times 6\times10^{-6}\,m^2}\right)^{1/2} = 0.077$$

and from Fig. 3.19, the fin efficiency is

$$\eta_f \approx 0.99 .$$ <

From Eq. 3.91 and Table 3.5, the fin heat rate is

$$q_f = \eta_f q_{max} = \eta_f hA_{f(tri)}\theta_b = 2\eta_f hw\left[L^2 + (t/2)^2\right]^{1/2}\theta_b .$$

From Eq. 3.86, the fin effectiveness is

$$\varepsilon_f = \frac{q_f}{hA_{c,b}\theta_b} = \frac{2\eta_f hw\left[L^2+(t/2)^2\right]^{1/2}\theta_b}{h(w\cdot t)\theta_b} = \frac{2\eta_f\left[L^2+(t/2)^2\right]^{1/2}}{t}$$

$$\varepsilon_f = \frac{2\times0.99\left[(0.006)^2+(0.002/2)^2\right]^{1/2}\,m}{0.002\,m} = 6.02$$ <

(b) The heat dissipation per unit width is

$$q_f' = (q_f/w) = 2\eta_f h\left[L^2+(t/2)^2\right]^{1/2}\theta_b$$

$$q_f' = 2\times0.99\times40\,W/m^2\cdot K\left[(0.006)^2+(0.002/2)^2\right]^{1/2}\,m\times(250-20)^\circ C = 110.8\,W/m .$$ <

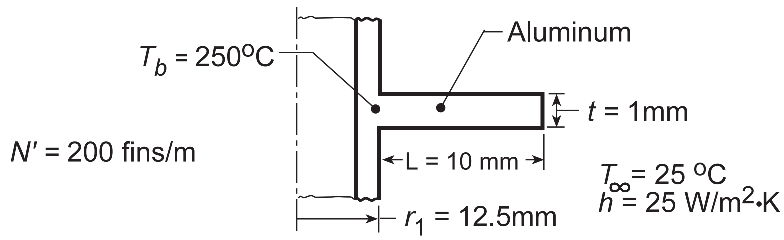
COMMENTS: The parabolic profile is known to provide the maximum heat dissipation per unit fin mass.

PROBLEM 3.158

KNOWN: Dimensions and base temperature of an annular, aluminum fin of rectangular profile. Ambient air conditions.

FIND: (a) Fin heat loss, (b) Heat loss per unit length of tube with 200 fins spaced at 5 mm increments.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible radiation and contact resistance, (5) Uniform convection coefficient.

PROPERTIES: *Table A-1*, Aluminum, pure (T ≈ 400 K): k = 240 W/m·K.

ANALYSIS: (a) The fin parameters for use with Figure 3.20 are

$$r_{2c} = r_2 + t/2 = (12.5\,\text{mm} + 10\,\text{mm}) + 0.5\,\text{mm} = 23\,\text{mm} = 0.023\,\text{m}$$

$$r_{2c}/r_1 = 1.84 \qquad L_c = L + t/2 = 10.5\,\text{mm} = 0.0105\,\text{m}$$

$$A_p = L_c t = 0.0105\,\text{m} \times 0.001\,\text{m} = 1.05 \times 10^{-5}\,\text{m}^2$$

$$L_c^{3/2}\left(h/kA_p\right)^{1/2} = (0.0105\,\text{m})^{3/2}\left(\frac{25\,\text{W/m}^2\cdot\text{K}}{240\,\text{W/m}\cdot\text{K} \times 1.05 \times 10^{-5}\,\text{m}^2}\right)^{1/2} = 0.15\,.$$

Hence, the fin effectiveness is $\eta_f \approx 0.97$, and from Eq. 3.91 and Fig. 3.6, the fin heat rate is

$$q_f = \eta_f q_{max} = \eta_f h A_{f\,(ann)} \theta_b = 2\pi\eta_f h\left(r_{2,c}^2 - r_1^2\right)\theta_b$$

$$q_f = 2\pi \times 0.97 \times 25\,\text{W/m}^2\cdot\text{K} \times \left[(0.023\,\text{m})^2 - (0.0125\,\text{m})^2\right] 225^\circ\text{C} = 12.8\,\text{W}\,. \qquad <$$

(b) Recognizing that there are N = 200 fins per meter length of the tube, the total heat rate considering contributions due to the fin and base (unfinned) surfaces is

$$q' = N' q_f + h(1 - N't)2\pi r_1 \theta_b$$

$$q' = 200\,\text{m}^{-1} \times 12.8\,\text{W} + 25\,\text{W/m}^2\cdot\text{K}\left(1 - 200\,\text{m}^{-1} \times 0.001\,\text{m}\right) \times 2\pi \times (0.0125\,\text{m})\,225^\circ\text{C}$$

$$q' = (2560\,\text{W} + 353\,\text{W})/\text{m} = 2.91\,\text{kW/m}\,. \qquad <$$

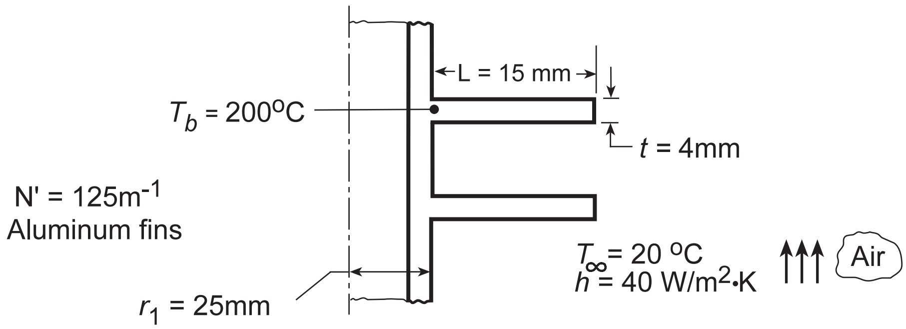
COMMENTS: Note that, while covering only 20% of the tube surface area, the tubes account for more than 85% of the total heat dissipation.

PROBLEM 3.159

KNOWN: Dimensions and base temperature of aluminum fins of rectangular profile. Ambient air conditions.

FIND: (a) Fin efficiency and effectiveness, (b) Rate of heat transfer per unit length of tube.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial conduction in fins, (3) Constant properties, (4) Negligible radiation, (5) Negligible base contact resistance, (6) Uniform convection coefficient.

PROPERTIES: *Table A-1*, Aluminum, pure (T ≈ 400 K): k = 240 W/m·K.

ANALYSIS: (a) The fin parameters for use with Figure 3.20 are

$$r_{2c} = r_2 + t/2 = 40\,\text{mm} + 2\,\text{mm} = 0.042\,\text{m} \qquad L_c = L + t/2 = 15\,\text{mm} + 2\,\text{mm} = 0.017\,\text{m}$$

$$r_{2c}/r_1 = 0.042\,\text{m}/0.025\,\text{m} = 1.68 \qquad A_p = L_c t = 0.017\,\text{m} \times 0.004\,\text{m} = 6.8\times10^{-5}\,\text{m}^2$$

$$L_c^{3/2}\left(h/kA_p\right)^{1/2} = \left(0.017\,\text{m}\right)^{3/2}\left[40\,\text{W/m}^2\cdot\text{K}\big/240\,\text{W/m}\cdot\text{K}\times6.8\times10^{-5}\,\text{m}^2\right]^{1/2} = 0.11$$

The fin efficiency is $\eta_f \approx 0.97$. From Eq. 3.91,

$$q_f = \eta_f q_{max} = \eta_f hA_{f(ann)}\theta_b = 2\pi\eta_f h\left[r_{2c}^2 - r_1^2\right]\theta_b$$

$$q_f = 2\pi\times0.97\times40\,\text{W/m}^2\cdot\text{K}\left[\left(0.042\right)^2 - \left(0.025\right)^2\right]\text{m}^2\times180^\circ\text{C} = 50\,\text{W}$$ <

From Eq. 3.86, the fin effectiveness is

$$\varepsilon_f = \frac{q_f}{hA_{c,b}\theta_b} = \frac{50\,\text{W}}{40\,\text{W/m}^2\cdot\text{K}\;\;2\pi\left(0.025\,\text{m}\right)\left(0.004\,\text{m}\right)180^\circ\text{C}} = 11.05$$ <

(b) The rate of heat transfer per unit length is

$$q' = N'q_f + h\left(1 - N't\right)\left(2\pi r_1\right)\theta_b$$

$$q' = 125\times50\,\text{W/m} + 40\,\text{W/m}^2\cdot\text{K}\left(1 - 125\times0.004\right)\left(2\pi\times0.025\,\text{m}\right)\times180^\circ\text{C}$$

$$q' = \left(6250 + 565\right)\text{W/m} = 6.82\,\text{kW/m}$$ <

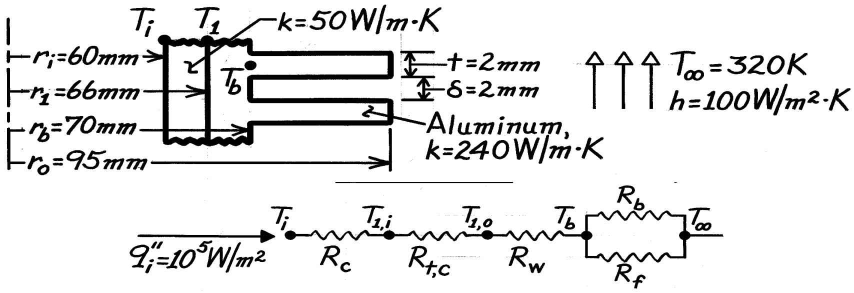
COMMENTS: Note the dominant contribution made by the fins to the total heat transfer.

PROBLEM 3.160

KNOWN: Dimensions and materials of a finned (annular) cylinder wall. Heat flux and ambient air conditions. Contact resistance.

FIND: Surface and interface temperatures (a) without and (b) with an interface contact resistance.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, steady-state conditions, (2) Constant properties, (3) Uniform h over surfaces, (4) Negligible radiation.

ANALYSIS: The analysis may be performed per unit length of cylinder or for a 4 mm long section. The following calculations are based on a unit length. The inner surface temperature may be obtained from

$$q' = \frac{T_i - T_\infty}{R'_{tot}} = q''_i\left(2\pi\ r_i\right) = 10^5\ \text{W/m}^2 \times 2\pi \times 0.06\ \text{m} = 37,700\ \text{W/m}$$

where $R'_{tot} = R'_c + R'_{t,c} + R'_w + R'_{equiv};\quad R'_{equiv} = \left(1/R'_f + 1/R'_b\right)^{-1}.$

R'_c, *Conduction resistance of cylinder wall:*

$$R'_c = \frac{\ln\left(r_1/r_i\right)}{2\pi\ k} = \frac{\ln\left(66/60\right)}{2\pi\left(50\ \text{W/m}\cdot\text{K}\right)} = 3.034\times10^{-4}\ \text{m}\cdot\text{K/W}$$

$R'_{t,c}$, *Contact resistance:*

$$R'_{t,c} = R''_{t,c}/2\pi\ r_1 = 10^{-4}\ \text{m}^2\cdot\text{K/W}/2\pi\times0.066\ \text{m} = 2.411\times10^{-4}\ \text{m}\cdot\text{K/W}$$

R'_w, *Conduction resistance of aluminum base:*

$$R'_w = \frac{\ln\left(r_b/r_1\right)}{2\pi\ k} = \frac{\ln\left(70/66\right)}{2\pi\times240\ \text{W/m}\cdot\text{K}} = 3.902\times10^{-5}\ \text{m}\cdot\text{K/W}$$

R'_b, *Resistance of prime or unfinned surface:*

$$R'_b = \frac{1}{hA'_b} = \frac{1}{100\ \text{W/m}^2\cdot\text{K}\times0.5\times2\pi\left(0.07\ \text{m}\right)} = 454.7\times10^{-4}\ \text{m}\cdot\text{K/W}$$

R'_f, *Resistance of fins:* The fin resistance may be determined from

$$R'_f = \frac{T_b - T_\infty}{q'_f} = \frac{1}{\eta_f\, hA'_f}$$

The fin efficiency may be obtained from Fig. 3.20,

$$r_{2c} = r_o + t/2 = 0.096\ \text{m} \qquad L_c = L + t/2 = 0.026\ \text{m}$$

Continued …

PROBLEM 3.160 (Cont.)

$A_p = L_c t = 5.2\times10^{-5}\ m^2 \qquad r_{2c}/r_1 = 1.45 \qquad L_c^{3/2}\left(h/kA_p\right)^{1/2} = 0.375$

Fig. 3.20 $\rightarrow \eta_f \approx 0.88$.

The total fin surface area per meter length

$$A'_f = 250\left[\pi\left(r_o^2 - r_b^2\right)\times 2\right] = 250\ m^{-1}\left[2\pi\left(0.096^2 - 0.07^2\right)\right]m^2 = 6.78\ m.$$

Hence $\quad R'_f = \left[0.88\times100\ W/m^2\cdot K\times 6.78\ m\right]^{-1} = 16.8\times10^{-4}\ m\cdot K/W$

$$1/R'_{equiv} = \left(1/16.8\times10^{-4} + 1/454.7\times10^{-4}\right)W/m\cdot K = 617.2\ W/m\cdot K$$

$$R'_{equiv} = 16.2\times10^{-4}\ m\cdot K/W.$$

Neglecting the *contact resistance,*

$$R'_{tot} = \left(3.034 + 0.390 + 16.2\right)10^{-4}\ m\cdot K/W = 19.6\times10^{-4}\ m\cdot K/W$$

$$T_i = q'R'_{tot} + T_\infty = 37{,}700\ W/m\times19.6\times10^{-4}\ m\cdot K/W + 320\ K = 393.9\ K \quad <$$

$$T_1 = T_i - q'R'_w = 393.9\ K - 37{,}700\ W/m\times3.034\times10^{-4}\ m\cdot K/W = 382.5\ K \quad <$$

$$T_b = T_1 - q'R'_b = 382.5\ K - 37{,}700\ W/m\times3.902\times10^{-5}\ m\cdot K/W = 381.0\ K. \quad <$$

Including the *contact resistance,*

$$R'_{tot} = \left(19.6\times10^{-4} + 2.411\times10^{-4}\right)m\cdot K/W = 22.0\times10^{-4}\ m\cdot K/W$$

$$T_i = 37{,}700\ W/m\times22.0\times10^{-4}\ m\cdot K/W + 320\ K = 402.9\ K \quad <$$

$$T_{1,i} = 402.9\ K - 37{,}700\ W/m\times3.034\times10^{-4}\ m\cdot K/W = 391.5\ K \quad <$$

$$T_{1,o} = 391.5\ K - 37{,}700\ W/m\times2.411\times10^{-4}\ m\cdot K/W = 382.4\ K \quad <$$

$$T_b = 382.4\ K - 37{,}700\ W/m\times3.902\times10^{-5}\ m\cdot K/W = 380.9\ K. \quad <$$

COMMENTS: (1) The effect of the contact resistance is small.

(2) The effect of including the aluminum fins may be determined by computing T_i without the fins. In this case $R'_{tot} = R'_c + R'_{conv}$, where

$$R'_{conv} = \frac{1}{h2\pi r_1} = \frac{1}{100\ W/m^2\cdot K\ 2\pi\left(0.066\ m\right)} = 241.1\times10^{-4}\ m\cdot K/W.$$

Hence, $R_{tot} = 244.1\times10^{-4}\ m\cdot K/W$, and

$$T_i = q'R'_{tot} + T_\infty = 37{,}700\ W/m\times244.1\times10^{-4}\ m\cdot K/W + 320\ K = 1240\ K.$$

Hence, the fins have a significant effect on reducing the cylinder temperature.

(3) The overall surface efficiency is

$$\eta_o = 1 - \left(A'_f / A'_t\right)\left(1 - \eta_f\right) = 1 - 6.78\ m/7.00\ m\left(1 - 0.88\right) = 0.884.$$

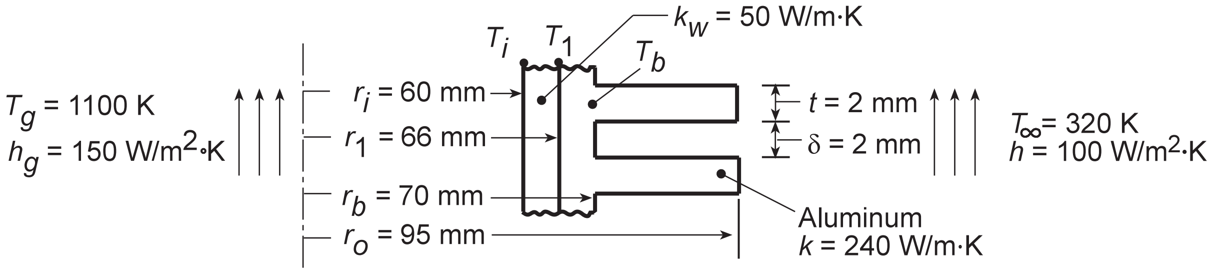
It follows that $q' = \eta_o h_o A'_t \theta_b = 37{,}700\ W/m$, which agrees with the prescribed value.

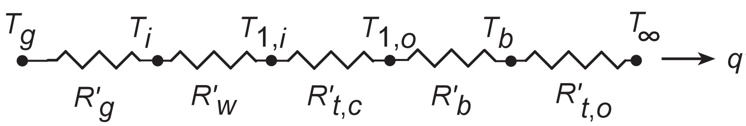
PROBLEM 3.161

KNOWN: Dimensions and materials of a finned (annular) cylinder wall. Combustion gas and ambient air conditions. Contact resistance.

FIND: (a) Heat rate per unit length and surface and interface temperatures, (b) Effect of increasing the fin thickness.

SCHEMATIC:





ASSUMPTIONS: (1) One-dimensional, steady-state conditions, (2) Constant properties, (3) Uniform h over surfaces, (4) Negligible radiation.

ANALYSIS: (a) The heat rate per unit length is

$$q' = \frac{T_g - T_\infty}{R'_{tot}}$$

where $R'_{tot} = R'_g + R'_w + R'_{t,c} + R'_b + R'_{t,o}$, and

$$R'_g = \left(h_g 2\pi r_i\right)^{-1} = \left(150\,W/m^2 \cdot K \times 2\pi \times 0.06m\right)^{-1} = 0.0177 m \cdot K/W,$$

$$R'_w = \frac{\ln\left(r_1/r_i\right)}{2\pi k_w} = \frac{\ln(66/60)}{2\pi\left(50\,W/m \cdot K\right)} = 3.03 \times 10^{-4} m \cdot K/W,$$

$$R'_{t,c} = \left(R''_{t,c}/2\pi r_1\right) = 10^{-4} m^2 \cdot K/W \Big/ 2\pi \times 0.066m = 2.41 \times 10^{-4}\ m \cdot K/W$$

$$R'_b = \frac{\ln\left(r_b/r_1\right)}{2\pi k} = \frac{\ln(70/66)}{2\pi \times 240\,W/m \cdot K} = 3.90 \times 10^{-5} m \cdot K/W,$$

$$R_{t,o} = \left(\eta_o h A'_t\right)^{-1},$$

$$\eta_o = 1 - \frac{N' A_f}{A'_t}\left(1 - \eta_f\right),$$

$$A_f = 2\pi\left(r_{oc}^2 - r_b^2\right)$$

$$A'_t = N' A_f + \left(1 - N' t\right) 2\pi r_b$$

$$\eta_f = \frac{\left(2r_b/m\right)}{\left(r_{oc}^2 - r_b^2\right)} \frac{K_1\left(mr_b\right) I_1\left(mr_{oc}\right) - I_1\left(mr_b\right) K_1\left(mr_{oc}\right)}{I_0\left(mr_1\right) K_1\left(mr_{oc}\right) + K_0\left(mr_b\right) I_1\left(mr_{oc}\right)}$$

$$r_{oc} = r_o + (t/2), \qquad m = \left(2h/kt\right)^{1/2}$$

Continued...

PROBLEM 3.161 (Cont.)

Once the heat rate is determined from the foregoing expressions, the desired interface temperatures may be obtained from

$$T_i = T_g - q'R'_g$$

$$T_{1,i} = T_g - q'\left(R'_g + R'_w\right)$$

$$T_{1,o} = T_g - q'\left(R'_g + R'_w + R'_{t,c}\right)$$

$$T_b = T_g - q'\left(R'_g + R'_w + R'_{t,c} + R'_b\right)$$

For the specified conditions we obtain A'_t = 7.00 m, η_f = 0.902, η_o = 0.906 and $R'_{t,o}$ = 0.00158 m·K/W. It follows that

$$q' = 39,300\,W/m$$ <

$$T_i = 405K, \quad T_{1,i} = 393K, \quad T_{1,o} = 384K, \quad T_b = 382K$$ <

(b) The *Performance Calculation, Extended Surface* Model for the *Circular Fin* Array may be used to assess the effects of fin thickness and spacing. Increasing the fin thickness to t = 3 mm, with δ = 2 mm, reduces the number of fins per unit length to 200. Hence, although the fin efficiency increases (η_f = 0.930), the reduction in the total surface area (A'_t = 5.72 m) yields an increase in the resistance of the fin array ($R'_{t,o}$ = 0.00188 m·K/W), and hence a reduction in the heat rate (q' = 38,700 W/m) and an increase in the interface temperatures (T_i = 415 K, $T_{1,i}$ = 404 K, $T_{1,o}$ = 394 K, and T_b = 393 K).

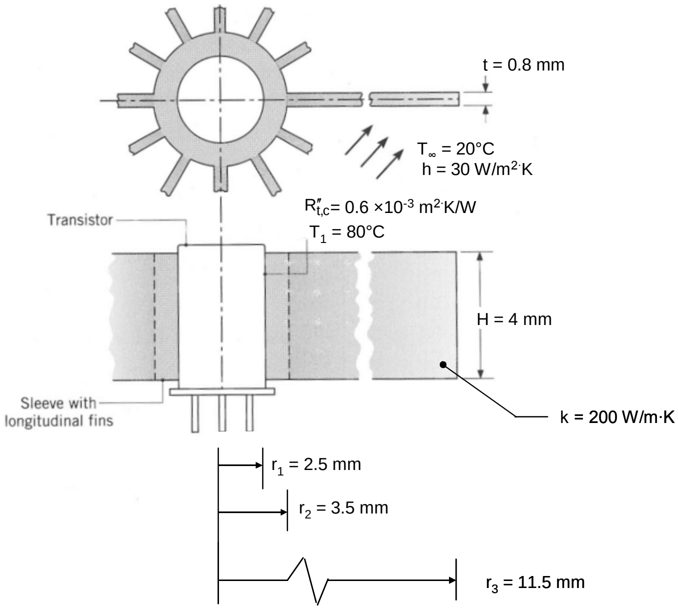
COMMENTS: Because the gas convection resistance exceeds all other resistances by at least an order of magnitude, incremental changes in $R_{t,o}$ will not have a significant effect on q' or the interface temperatures.

PROBLEM 3.162

KNOWN: Dimensions of finned aluminum sleeve inserted over a transistor. Contact resistance between sleeve and transistor. Surface convection conditions and temperature of transistor case.

FIND: (a) Rate of heat transfer from sleeve and (b) Measures for increasing heat dissipation.

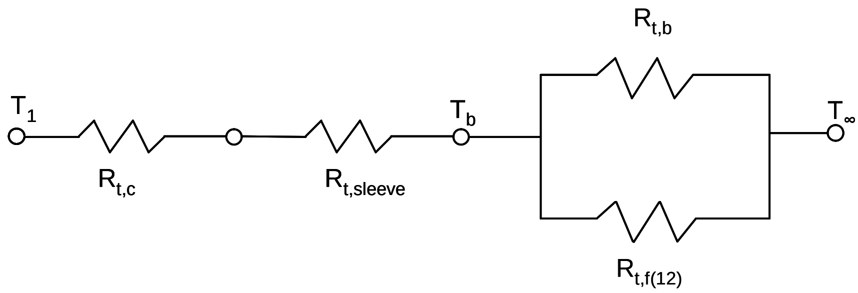
SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat transfer from the top and bottom surfaces of the transistor, (3) One-dimensional radial conduction, (4) Constant properties, (5) Negligible radiation.

ANALYSIS:

(a) The circuit must account for the contact resistance, conduction in the sleeve, convection from the exposed base, and conduction/convection from the fins.



Thermal resistances for the contact joint and sleeve are

$$R_{t,c} = \frac{R''_{t,c}}{2\pi r_1 H} = \frac{0.6 \times 10^{-3}\ \mathrm{m^2 \cdot K/W}}{2\pi(0.0025\ \mathrm{m})(0.004\ \mathrm{m})} = 9.55\ \mathrm{K/W}$$

$$R_{t,sleeve} = \frac{\ln(r_2/r_1)}{2\pi k H} = \frac{\ln(3.5/2.5)}{2\pi(200\ \mathrm{W/m \cdot K})(0.004\ \mathrm{m})} = 0.0669\ \mathrm{K/W}$$

For a single fin, $R_{t,f} = \theta_b / q_f$, where from Table 3.4, with tip convection,

Continued…

PROBLEM 3.162 (Cont.)

$$q_f = (hPkA_c)^{1/2}\theta_b \frac{\sinh(mL) + (h/mk)\cosh(mL)}{\cosh(mL) + (h/mk)\sinh(mL)}$$

with $P = 2(H + t) = 9.6$ mm $= 0.0096$ m and $A_c = t \times H = 3.2 \times 10^{-6}$ m^2,

$$m = \left(\frac{hP}{kA_c}\right)^{1/2} = \left(\frac{30\ \text{W/m}^2\cdot\text{K} \times 0.0096\ \text{m}}{200\ \text{W/m}\cdot\text{K} \times 3.2 \times 10^{-6}\ \text{m}^2}\right)^{1/2} = 21.2\ \text{m}^{-1}$$

$$mL = 21.2\ \text{m}^{-1} \times 0.008\ \text{m} = 0.170$$

$$\frac{h}{mk} = \frac{30\ \text{W/m}^2\cdot\text{K}}{21.2\ \text{m}^{-1} \times 200\ \text{W/m}\cdot\text{K}} = 0.00707$$

and

$$(hPkA_c)^{1/2} = (30\ \text{W/m}^2\cdot\text{K} \times 0.0096\ \text{m} \times 200\ \text{W/m}\cdot\text{K} \times 3.2 \times 10^{-6}\ \text{m}^2)^{1/2} = 0.0136\ \text{W/K}$$

Use of Table B.1 yields, for a single fin

$$R_{t,f} = \frac{1.014 + 0.00707 \times 0.171}{0.0136\ \text{W/K}\ (0.171 + 0.00707 \times 1.014)} = 421\ \text{K/W}$$

Hence, for 12 fins,

$$R_{t,f(12)} = \frac{R_{t,f}}{12} = 35.1\ \text{K/W}$$

For the exposed base,

$$R_{t,b} = \frac{1}{h(2\pi r_2 - 12t)H} = \frac{1}{30\ \text{W/m}^2\cdot\text{K}\ (2\pi \times 0.0035 - 12 \times 0.0008)\text{m} \times 0.004\ \text{m}} = 673\ \text{K/W}$$

With

$$R_{t,o} = \left[(35.1)^{-1} + (673)^{-1}\right]^{-1} = 33.3\ \text{K/W}$$

it follows that

$$R_{tot} = (9.55 + 0.0669 + 33.3)\ \text{K/W} = 43.0\ \text{K/W}$$

and

$$q_t = \frac{T_1 - T_\infty}{R_{tot}} = \frac{(80 - 20)°\text{C}}{43.0\ \text{K/W}} = 1.40\ \text{W} \qquad <$$

(b) With $2\pi r_2 = 0.022$ m and Nt = 0.0096 m, the existing gap between fins is extremely small (0.96 mm). Hence, by increasing N and/or t, it would become even more difficult to maintain satisfactory airflow between the fins, and this option is not particularly attractive.

Because the fin efficiency for the prescribed conditions is close to unity ($\eta_f = (hA_f R_{t,f})^{-1} = 0.992$), there is little advantage to replacing the aluminum with a material of higher thermal conductivity (e.g. Cu

Continued…

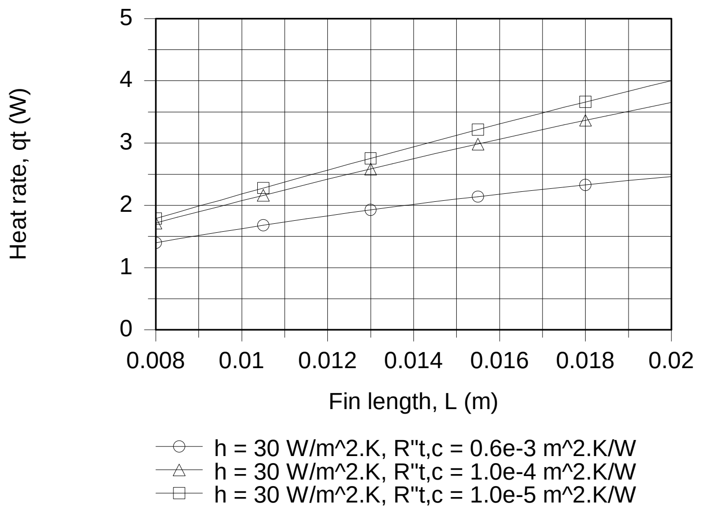
PROBLEM 3.162 (Cont.)

with k ~ 400 W/m·K). However, the large value of η_f suggests that significant benefit could be gained by increasing the fin length, $L = r_3 - r_2$.

It is also evident that the thermal contact resistance is large, and from Table 3.2, it's clear that a significant reduction could be effected by using indium foil or a conducting grease in the contact zone. Specifically, a reduction of $R''_{t,c}$ from 0.6×10^{-3} to 10^{-4} or even 10^{-5} m^2·K/W is certainly feasible.

Table 1.1 suggests that, by increasing the velocity of air flowing over the fins, a larger convection coefficient may be achieved. A value of h = 100 W/m^2·K would not be unreasonable.

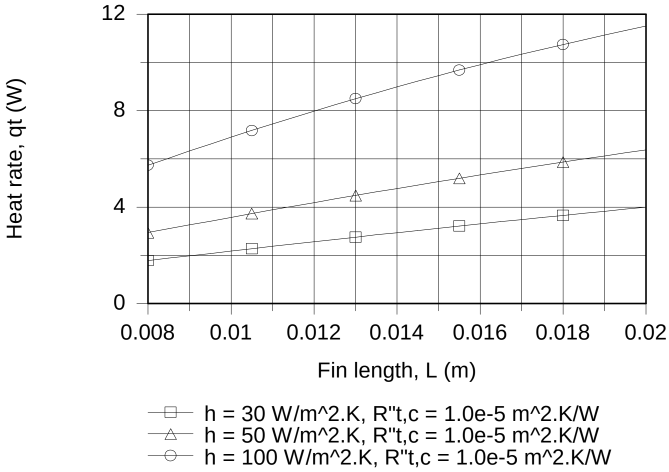
As options for enhancing heat transfer, we therefore enter the foregoing equations into IHT to explore the effect of parameter variations over the ranges $8 \le L \le 20$ mm, $10^{-5} \le R''_{t,c} \le 0.6\times10^{-3}$ m^2·K/W and $30 \le h \le 100$ W/m^2·K. As shown below, there is a significant enhancement in heat transfer associated with reducing $R''_{t,c}$ from 0.6×10^{-3} to 10^{-4} m^2·K/W, for which $R_{t,c}$ decreases from 9.55 to 1.59 K/W. At this value of $R''_{t,c}$, the reduction in $R_{t,o}$ from 33.3 to 14.8 K/W which accompanies an increase in L from 8 to 20 mm becomes significant, yielding a heat rate of q_t = 3.65 W for $R''_{t,c} = 10^{-4}$ m^2·K/W and L = 20 mm. However, since $R_{t,o} >> R_{t,c}$, little benefit is gained by further reducing $R''_{t,c}$ to 10^{-5} m^2·K/W.



To derive benefit from a reduction in $R''_{t,c}$ to 10^{-5} m^2·K/W, an additional reduction in $R_{t,o}$ must be made. This can be achieved by increasing h, and for L = 20 mm and h = 100 W/m^2·K, $R_{t,o}$ = 5.0 K/W. With $R''_{t,c} = 10^{-5}$ m^2·K/W, a value of q_t = 11.5 W may be achieved.

Continued…

PROBLEM 3.162 (Cont.)



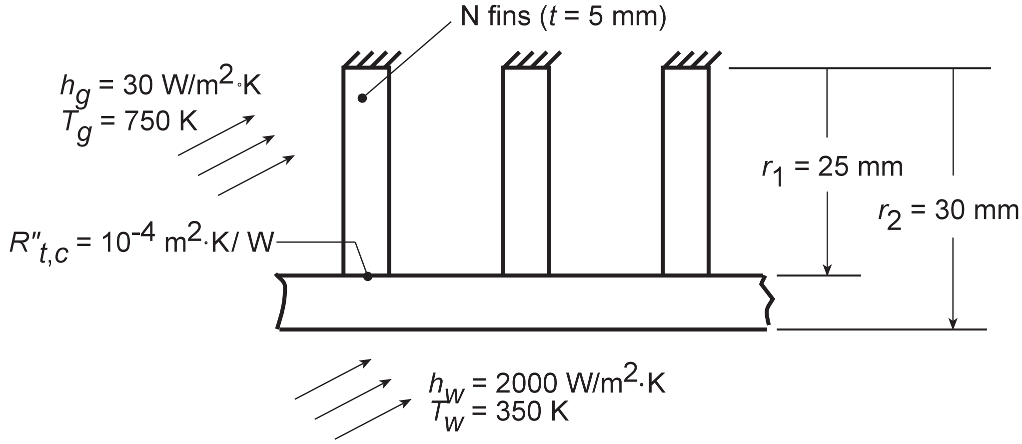
COMMENTS: (1) Without the finned sleeve, the convection resistance of the transistor case is $R_{tran} = (2\pi r_1 Hh)^{-1} = 531$ K/W. Hence there is considerable advantage to using the fins. (2) If an adiabatic fin tip is assumed, tanh(mL) = 0.168 and $R_{t,f} = 437$. Hence the error in the fin resistance is 4% relative to the actual convecting tip. (3) With $\eta_f = 0.992$, Equation 3.102 yields $\eta_o = 0.992$, from which it follows that $R_{t,o} = (\eta_o h A_t)^{-1} = 33.3$ K/W. This result is, of course, identical to that obtained in the foregoing determination of $R_{t,o}$. (4) In assessing options for enhancing heat transfer, the limiting (largest) resistance(s) should be identified and efforts directed at their reduction.

PROBLEM 3.163

KNOWN: Internal and external convection conditions for an internally finned tube. Fin/tube dimensions and contact resistance.

FIND: Heat rate per unit tube length and corresponding effects of the contact resistance, number of fins, and fin/tube material.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Constant properties, (4) Negligible radiation, (5) Uniform convection coefficient on finned surfaces, (6) Tube wall may be unfolded and approximated as a plane surface with N straight rectangular fins.

PROPERTIES: Copper: k = 400 W/m·K; St.St.: k = 20 W/m·K.

ANALYSIS: The heat rate per unit length may be expressed as

$$q' = \frac{T_g - T_w}{R'_{t,o(c)} + R'_{cond} + R'_{conv,o}}$$

where

$$R_{t,o(c)} = \left(\eta_{o(c)} h_g A'_t\right), \quad \eta_{o(c)} = 1 - \frac{NA'_f}{A'_t}\left(1 - \frac{\eta_f}{C_1}\right), \quad C_1 = 1 + \eta_f h_g A'_f \left(R''_{t,c} / A'_{c,b}\right),$$

$$A'_t = NA'_f + \left(2\pi r_1 - Nt\right), \quad A'_f = 2r_1, \quad \eta_f = \tanh mr_1 / mr_1, \quad m = \left(2h_g / kt\right)^{1/2} \quad A'_{c,b} = t,$$

$$R'_{cond} = \frac{\ln\left(r_2 / r_1\right)}{2\pi k}, \quad \text{and} \quad R'_{conv,o} = \left(2\pi r_2 h_w\right)^{-1}.$$

Using the IHT *Performance Calculation, Extended Surface Model* for the *Straight Fin Array*, the following results were obtained. For the *base case*, q' = 3857 W/m, where $R'_{t,o(c)}$ = 0.101 m·K/W, R'_{cond} = 7.25 × 10^{-5} m·K/W and $R'_{conv,o}$ = 0.00265 m·K/W. If the contact resistance is eliminated ($R''_{t,c}$ = 0), q' = 3922 W/m, where $R'_{t,o}$ = 0.0993 m·K/W. If the number of fins is increased to N = 8, q' = 5799 W/m, with $R'_{t,o(c)}$ = 0.063 m·K/W. If the material is changed to stainless steel, q' = 3591 W/m, with $R'_{t,o(c)}$ = 0.107 m·K/W and R'_{cond} = 0.00145 m·K/W.

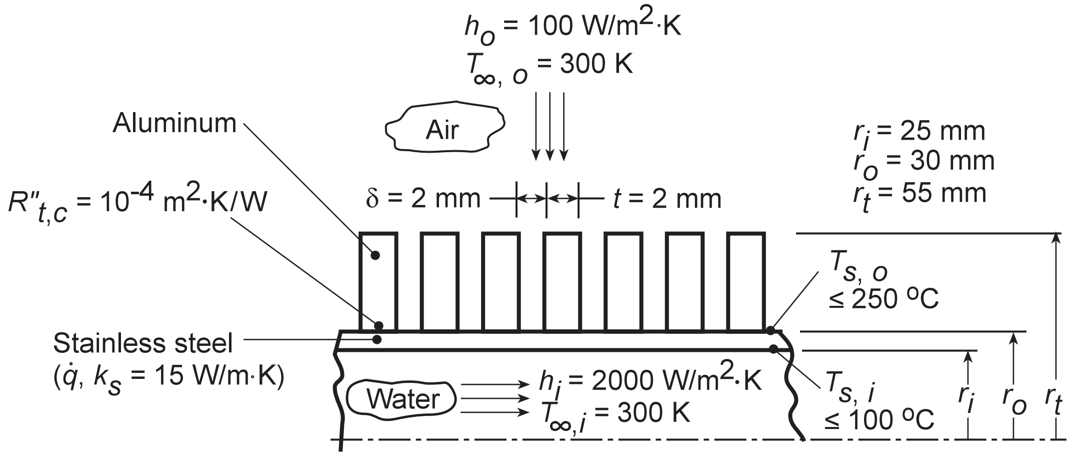
COMMENTS: The small reduction in q' associated with use of stainless steel is perhaps surprising, in view of the large reduction in k. However, because h_g is small, the reduction in k does not significantly reduce the fin efficiency (η_f changes from 0.994 to 0.891). Hence, the heat rate remains large. The influence of k would become more pronounced with increasing h_g.

PROBLEM 3.164

KNOWN: Design and operating conditions of a tubular, air/water heater.

FIND: (a) Expressions for heat rate per unit length at inner and outer surfaces, (b) Expressions for inner and outer surface temperatures, (c) Surface heat rates and temperatures as a function of volumetric heating $\dot{q}$ for prescribed conditions. Upper limit to $\dot{q}$.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Constant properties, (3) One-dimensional heat transfer.

PROPERTIES: Table A-1: Aluminum, T = 300 K, k_a = 237 W/m·K.

ANALYSIS: (a) Applying Equation C.8 to the inner and outer surfaces, it follows that

$$q'(r_i) = \dot{q}\pi r_i^2 - \frac{2\pi k_s}{\ln(r_o/r_i)}\left[\frac{\dot{q}r_o^2}{4k_s}\left(1-\frac{r_i^2}{r_o^2}\right)+\left(T_{s,o}-T_{s,i}\right)\right] \quad <$$

$$q'(r_o) = \dot{q}\pi r_o^2 - \frac{2\pi k_s}{\ln(r_o/r_i)}\left[\frac{\dot{q}r_o^2}{4k_s}\left(1-\frac{r_i^2}{r_o^2}\right)+\left(T_{s,o}-T_{s,i}\right)\right] \quad <$$

(b) From Equations C.16 and C.17, energy balances at the inner and outer surfaces are of the form

$$h_i\left(T_{\infty,i}-T_{s,i}\right) = \frac{\dot{q}r_i}{2} - \frac{k_s\left[\frac{\dot{q}r_o^2}{4k_s}\left(1-\frac{r_i^2}{r_o^2}\right)+\left(T_{s,o}-T_{s,i}\right)\right]}{r_i\ln(r_o/r_i)} \quad <$$

$$U_o\left(T_{s,o}-T_{\infty,o}\right) = \frac{\dot{q}r_o}{2} - \frac{k_s\left[\frac{\dot{q}r_o^2}{4k_s}\left(1-\frac{r_i^2}{r_o^2}\right)+\left(T_{s,o}-T_{s,i}\right)\right]}{r_o\ln(r_o/r_i)} \quad <$$

Accounting for the fin array and the contact resistance, Equation 3.109 may be used to cast the overall heat transfer coefficient U_o in the form

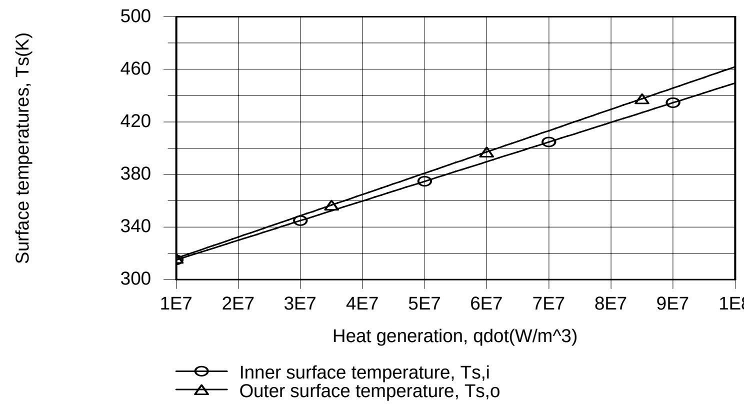
$$U_o = \frac{q'(r_o)}{A'_w\left(T_{s,o}-T_{\infty,o}\right)} = \frac{1}{A'_w R'_{t,o(c)}} = \frac{A'_t}{A'_w}\eta_{o(c)}h_o$$

where $\eta_{o(c)}$ is determined from Equations 3.110a,b and $A'_w = 2\pi r_o$.

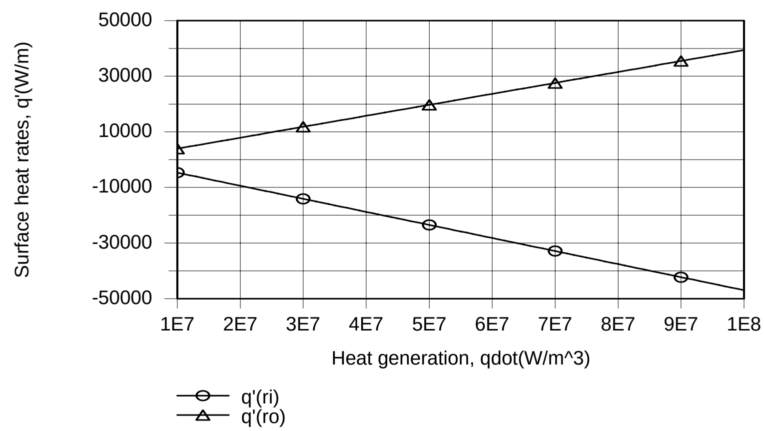
Continued...

PROBLEM 3.164 (Cont.)

(c) For the prescribed conditions and a representative range of $10^7 \le \dot{q} \le 10^8$ W/m^3, use of the relations of part (b) with the capabilities of the IHT *Performance Calculation Extended Surface Model* for a *Circular Fin Array* yields the following graphical results.



It is in this range that the upper limit of $T_{s,i}$ = 373 K is exceeded for $\dot{q}$ = 4.9 × 10^7 W/m^3, while the corresponding value of $T_{s,o}$ = 379 K is well below the prescribed upper limit. The expressions of part (a) yield the following results for the surface heat rates, where heat transfer in the negative r direction corresponds to $q'(r_i)$ < 0.



For $\dot{q}$ = 4.9 × 10^7 W/m^3, $q'(r_i)$ = -2.30 × 10^4 W/m and $q'(r_o)$ = 1.93 × 10^4 W/m.

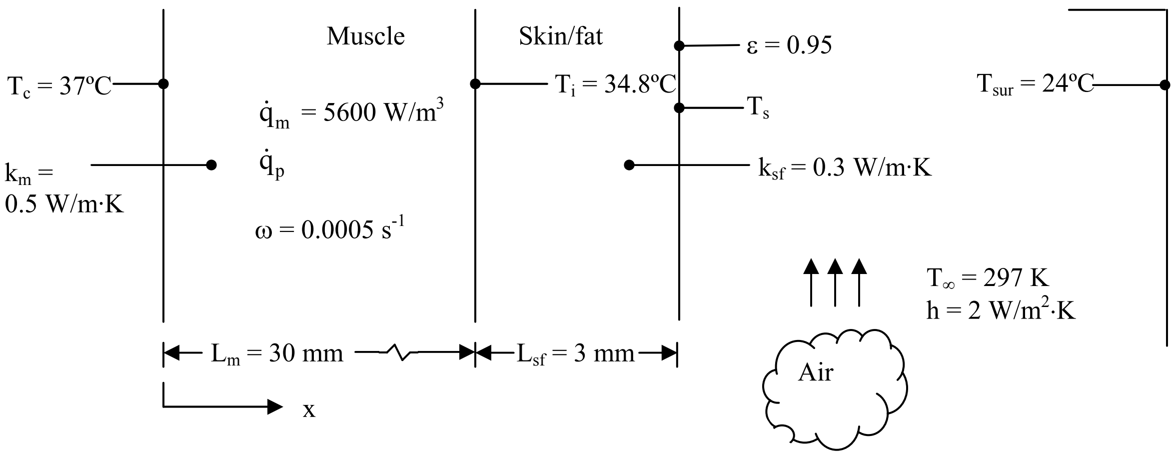
COMMENTS: The foregoing design provides for comparable heat transfer to the air and water streams. This result is a consequence of the nearly equivalent thermal resistances associated with heat transfer from the inner and outer surfaces. Specifically, $R'_{conv,i} = (h_i 2\pi r_i)^{-1}$ = 0.00318 m·K/W is slightly smaller than $R'_{t,o(c)}$ = 0.00411 m·K/W, in which case $|q'(r_i)|$ is slightly larger than $q'(r_o)$, while $T_{s,i}$ is slightly smaller than $T_{s,o}$. Note that the solution must satisfy the energy conservation requirement, $\pi\left(r_o^2 - r_i^2\right)\dot{q} = |q'(r_i)| + q'(r_o)$.

PROBLEM 3.165

KNOWN: Dimensions and thermal conductivities of a muscle layer and a skin/fat layer. Skin emissivity and surface area. Metabolic heat generation rate and perfusion rate within the muscle layer. Core body and arterial temperatures. Blood density and specific heat. Ambient conditions.

FIND: Perspiration rate to maintain same skin temperature as in Example 3.12.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer through the muscle and skin/fat layers, (3) Metabolic heat generation rate, perfusion rate, arterial temperature, blood properties, and thermal conductivities are all uniform, (4) Radiation heat transfer coefficient is known from Example 1.7, (5) Solar radiation is negligible, (6) Conditions are the same everywhere on the torso, limbs, etc., (7) Perspiration on skin has a negligible effect on heat transfer from the skin to the environment, that is, it adds a negligible thermal resistance and doesn't change the emissivity.

ANALYSIS: First we need to find the skin temperature, T_s, for the conditions of Example 3.12, in the air environment. Both q and T_i, the interface temperature between the muscle and the skin/fat layer, are known. The rate of heat transfer across the skin/fat layer is given by

$$q = \frac{k_{sf}A\left(T_i - T_s\right)}{L_{sf}} \tag{1}$$

Thus, the skin temperature is

$$T_s = T_i - \frac{qL_{sf}}{k_{sf}A} = 34.8°\text{C} - \frac{142\ \text{W} \times 0.003\ \text{m}}{0.3\ \text{W/m}\cdot\text{K} \times 1.8\ \text{m}^2} = 34.0°\text{C}$$

Now the heat transfer rate will change because of the increased metabolic heat generation rate. Heat transfer in the muscle layer is governed by Equation 3.114. In Example 3.12, this equation was solved subject to specified temperature boundary conditions, and the rate at which heat leaves the muscle and enters the skin/fat layer was found to be

$$q\big|_{x=L_m} = -k_m A\tilde{m}\theta_c \frac{(\theta_i/\theta_c)\cosh\tilde{m}L_m - 1}{\sinh\tilde{m}L_m} \tag{2}$$

Continued…

PROBLEM 3.165 (Cont.)

This must equal the rate at which heat is transferred across the skin/fat layer, given by Equation (1). Equating Equations 1 and 2 and solving for T_i, recalling that T_i also appears in θ_i, yields

$$T_i = \frac{T_s \sinh\tilde{m}L_m + k_m\tilde{m}\frac{L_{sf}}{k_{sf}}\left[\theta_c + \left(T_a + \frac{\dot{q}_m}{\omega\rho_b c_b}\right)\cosh\tilde{m}L_m\right]}{\sinh\tilde{m}L_m + k_m\tilde{m}\frac{L_{sf}}{k_{sf}}\cosh\tilde{m}L_m}$$

where

$$\tilde{m} = \sqrt{\omega\rho_b c_b/k_m} = \left[0.0005\ \mathrm{s}^{-1} \times 1000\ \mathrm{kg/m^3} \times 3600\ \mathrm{J/kg\cdot K}\big/0.5\ \mathrm{W/m\cdot K}\right]^{1/2} = 60\ \mathrm{m}^{-1}$$

$$\sinh(\tilde{m}L_m) = \sinh(60\ \mathrm{m}^{-1} \times 0.03\ \mathrm{m}) = 2.94\ ; \quad \cosh(\tilde{m}L_m) = \cosh(60\ \mathrm{m}^{-1} \times 0.03\ \mathrm{m}) = 3.11$$

$$\theta_c = T_c - T_a - \frac{\dot{q}_m}{\omega\rho_b c_b} = -\frac{\dot{q}_m}{\omega\rho_b c_b} = -\frac{5600\ \mathrm{W/m^3}}{0.0005\ \mathrm{s}^{-1} \times 1000\ \mathrm{kg/m^3} \times 3600\ \mathrm{J/kg\cdot K}} = -3.11\ \mathrm{K}$$

The excess temperature can be expressed in kelvins or degrees Celsius, since it is a temperature difference. Thus

$$T_i = \frac{34.0°\mathrm{C} \times 2.94 + 0.5\ \mathrm{W/m\cdot K} \times 60\ \mathrm{m}^{-1} \times \frac{0.003\ \mathrm{m}}{0.3\ \mathrm{W/m\cdot K}}\left[-3.11°\mathrm{C} + \left(37°\mathrm{C} + 3.11°\mathrm{C}\right) \times 3.11\right]}{2.94 + 0.5\ \mathrm{W/m\cdot K} \times 60\ \mathrm{m}^{-1} \times \frac{0.003\ \mathrm{m}}{0.3\ \mathrm{W/m\cdot K}} \times 3.11}$$

$$T_i = 35.2°\mathrm{C}$$

and again from Equation (1)

$$q = \frac{k_{sf}A\left(T_i - T_s\right)}{L_{sf}} = \frac{0.3\ \mathrm{W/m\cdot K} \times 1.8\ \mathrm{m}^2(35.2°\mathrm{C} - 34.0°\mathrm{C})}{0.003\ \mathrm{m}} = 222\ \mathrm{W}$$

Since the skin temperature is unchanged from Example 3.12, the rate of heat transfer to the environment by convection and radiation will remain the same, and is therefore still 142 W. The difference of 80 W must be removed from the skin by perspiration, therefore

$$q_{per} = \dot{m}_{per}h_{fg} = 80\ \mathrm{W}$$

Assuming the properties of perspiration are the same as that of water, evaluated at the skin temperature of 307 K, then from Table A.6 h_{fg} = 2421 kJ/kg and ρ = 994 kg/m^3. Thus the volume rate of perspiration is

$$\dot{\forall} = \frac{\dot{m}_{per}}{\rho} = \frac{q_{per}}{\rho h_{fg}} = \frac{80\ \mathrm{W}}{994\ \mathrm{kg/m^3} \times 2421 \times 10^3\ \mathrm{J/kg}} = 3.3 \times 10^{-8}\ \mathrm{m^3/s} = 3.3 \times 10^{-5}\ \ell/\mathrm{s} \quad <$$

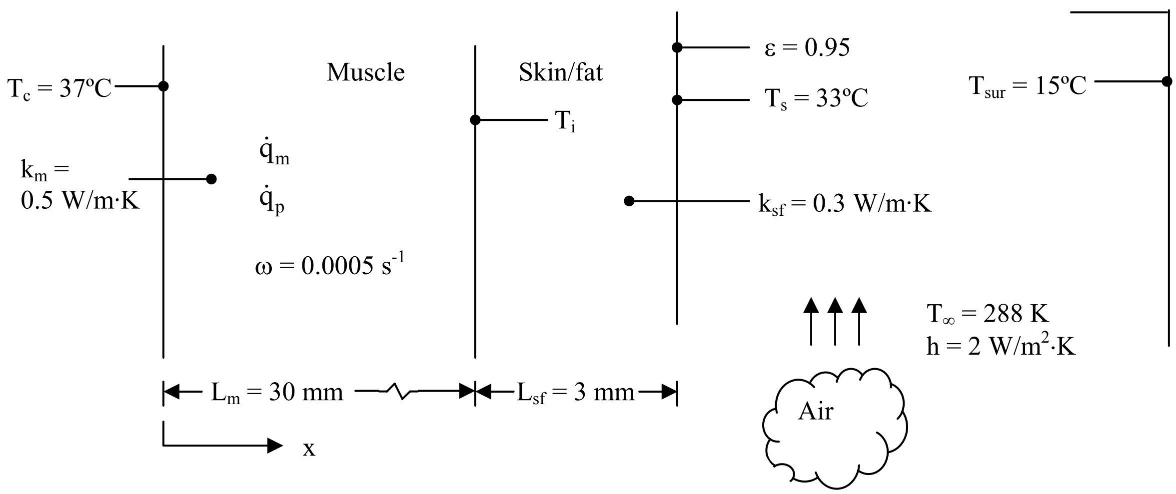
COMMENTS: (1) This is a moderate rate of perspiration. In one hour, it would account for around 0.1 ℓ. (2) In reality, our bodies adjust in many ways to maintain core and skin temperatures. Exercise will likely cause an increase in perfusion rate near the skin surface, to locally elevate the temperature and increase the rate of heat transfer to the environment.

PROBLEM 3.166

KNOWN: Dimensions and thermal conductivities of a muscle layer and a skin/fat layer. Skin emissivity and surface area. Skin temperature. Perfusion rate within the muscle layer. Core body and arterial temperatures. Blood density and specific heat. Ambient conditions.

FIND: Metabolic heat generation rate to maintain skin temperature at 33ºC.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer through the muscle and skin/fat layers, (3) Metabolic heat generation rate, perfusion rate, arterial temperature, blood properties, and thermal conductivities are all uniform, (4) Solar radiation is negligible, (5) Conditions are the same everywhere on the torso, limbs, etc.

ANALYSIS: Since we know the skin temperature and environment temperature, we can find the heat loss rate from the skin surface to the environment:

$$q = hA\,(T_s - T_\infty) + \varepsilon\sigma A(T_s^4 - T_{sur}^4)$$

$$= 2\ \text{W/m}^2\cdot\text{K} \times 1.8\ \text{m}^2(33 - 15)°\text{C} + 0.95 \times 5.67 \times 10^{-8}\ \text{W/m}^2\cdot\text{K}^4 \times 1.8\ \text{m}^2\left(306^4 - 288^4\right)\text{K}^4$$

$$= 248\ \text{W}$$

We can then find T_i, the interface temperature between the skin/fat layer and the muscle layer, by analyzing heat transfer through the skin/fat layer:

$$T_i = T_s + \frac{qL_{sf}}{k_{sf}A} = 33°\text{C} + \frac{248\ \text{W} \times 0.003\ \text{m}}{0.3\ \text{W/m}\cdot\text{K} \times 1.8\ \text{m}^2} = 34.4°\text{C}$$

Heat transfer in the muscle layer is governed by Equation 3.114. In Example 3.12, this equation was solved subject to specified surface temperature boundary conditions, and the rate at which heat leaves the muscle and enters the skin/fat layer was found to be

Continued…

PROBLEM 3.166 (Cont.)

$$q = -k_m A\tilde{m}\frac{\theta_i \cosh\tilde{m}L_m - \theta_c}{\sinh\tilde{m}L_m}$$

This must equal the rate at which heat is transferred across the skin/fat layer, as calculated above. Inserting the definitions of θ_i and θ_c, we can solve for the metabolic heat generation rate:

$$\dot{q}_m = \omega\rho_b c_b \frac{\dfrac{q}{k_m A\tilde{m}}\sinh\tilde{m}L_m + (T_i - T_a)\cosh\tilde{m}L_m + (T_c - T_a)}{\cosh\tilde{m}L_m + 1} \qquad (1)$$

where

$$\tilde{m} = \sqrt{\omega\rho_b c_b/k_m} = \left[0.0005\ s^{-1} \times 1000\ kg/m^3 \times 3600\ J/kg\cdot K \big/ 0.5\ W/m\cdot K\right]^{1/2} = 60\ m^{-1}$$

$$\sinh(\tilde{m}L_m) = \sinh(60\ m^{-1} \times 0.03\ m) = 2.94\ ; \quad \cosh(\tilde{m}L_m) = \cosh(60\ m^{-1} \times 0.03\ m) = 3.11$$

With $T_c = T_a$, Equation (1) yields

$$\dot{q}_m = 0.0005\ s^{-1} \times 1000\ kg/m^3 \times 3600\ J/kg\cdot K$$

$$\times \left[\frac{\dfrac{248\ W}{0.5\ W/m\cdot K \times 1.8\ m^2 \times 60\ m^{-1}} \times 2.94 + (34.4 - 37)°C \times 3.11}{3.11 + 1}\right]$$

$$= 2341\ W/m^3$$ <

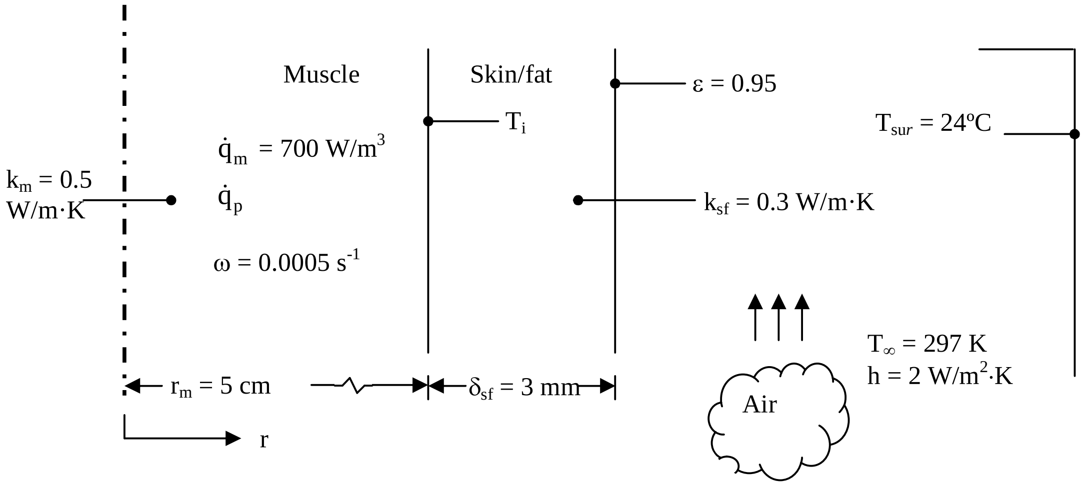
COMMENT: (1) Shivering can increase the metabolic heat generation rate by up to five to six times the resting metabolic rate. The value found here is approximately three times the metabolic heat generation rate given in Example 3.12, so it is well within what can be produced by shivering. (2) In the water environment, even with the original 24ºC water temperature, shivering would be insufficient to maintain a comfortable skin temperature.

PROBLEM 3.167

KNOWN: Dimensions and thermal conductivities of a muscle layer and a skin/fat layer. Metabolic heat generation rate and perfusion rate within the muscle layer. Arterial temperature. Blood density and specific heat. Ambient conditions.

FIND: Heat loss rate from body and temperature at inner surface of the skin/fat layer.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer through the muscle and skin/fat layers, (3) Metabolic heat generation rate, perfusion rate, arterial temperature, blood properties, and thermal conductivities are all uniform, (4) Radiation heat transfer coefficient is known from Example 1.6.

ANALYSIS:

(a) Conduction with heat generation is expressed in radial coordinates by Equation 3.54. With metabolic heat generation and perfusion, this becomes

$$\frac{1}{r}\frac{d}{dr}\left(r\frac{dT}{dr}\right) + \frac{\dot{q}_m + \omega\rho_b c_b (T_a - T)}{k} = 0$$ <

The boundary conditions of symmetry at the centerline and specified temperature at the outer surface of the muscle are expressed as

$$\left.\frac{dT}{dr}\right|_{r=0} = 0, \quad T(r_1) = T_i$$ <

Defining an excess temperature, $\theta \equiv T - T_a - \dot{q}_m/\omega\rho_b c_b$, the differential equation becomes

$$\frac{1}{r}\frac{d}{dr}\left(r\frac{d\theta}{dr}\right) - \tilde{m}^2\theta = 0$$

Continued…

PROBLEM 3.167 (Cont.)

where $\tilde{m}^2 = \omega\rho_b c_b/k$. The general solution to the differential equation is given in Section 3.6.4 as

$$\theta = c_1 I_0(\tilde{m}r) + c_2 K_0(\tilde{m}r)$$

Applying the boundary condition at r = 0 yields

$$\left.\frac{dT}{dr}\right|_{r=0} = \left.\frac{d\theta}{dr}\right|_{r=0} = c_1\tilde{m}I_1(0) - c_2\tilde{m}K_1(0) = 0$$

Since $K_1(0)$ is infinite, we must have $c_2 = 0$. Applying the specified temperature boundary condition at $r = r_1$ yields

$$T(r_1) = T_i,\ \theta(r_1) = T_i - T_a - \frac{\dot{q}_m}{\omega\rho_b c_b} \equiv \theta_i = c_1 I_0(\tilde{m}r_1)$$

Solving for c_1 we now have the complete solution for θ:

$$\theta = \theta_i \frac{I_0(\tilde{m}r)}{I_0(\tilde{m}r_1)} \qquad (1)$$ <

(b) The heat flux at the outer surface of the muscle is given by

$$q_i'' = -k_m \left.\frac{dT}{dr}\right|_{r=r_1} = -k_m \left.\frac{d\theta}{dr}\right|_{r=r_1} = -k_m\theta_i\tilde{m}\frac{I_1(\tilde{m}r_1)}{I_0(\tilde{m}r_1)} \qquad (2)$$

This must be equated to the heat flux through the skin/fat layer and into the environment. In terms of the heat transfer rate per unit length of forearm, q_i', and the total resistance for a unit length, R'_{tot},

$$q_i'' = \frac{q_i'}{2\pi r_1} = \frac{1}{2\pi r_1}\frac{T_i - T_\infty}{R'_{tot}} \qquad (3)$$

As in Example 3.1 and for exposure of the skin to the air, R'_{tot} accounts for conduction through the skin/fat layer in series with heat transfer by convection and radiation, which act in parallel with each other. Here the conduction resistance is for a radial geometry. Thus, it is

$$R'_{tot} = \frac{\ln(r_2/r_1)}{2\pi k_{sf}} + \frac{1}{2\pi r_2}\left(\frac{1}{1/h} + \frac{1}{1/h_r}\right)^{-1} = \frac{\ln(r_2/r_1)}{2\pi k_{sf}} + \frac{1}{2\pi r_2}\left(\frac{1}{h + h_r}\right)$$

Using the values from Example 1.7 for air,

$$R'_{tot} = \frac{\ln(0.053\text{ m}/0.05\text{ m})}{2\times\pi\times 0.3\text{ W/m}\cdot\text{K}} + \frac{1}{2\times\pi\times 0.053\text{ m}}\left(\frac{1}{(2+5.9)\text{ W/m}^2\cdot\text{K}}\right) = 0.41\text{ m}\cdot\text{K/W}$$

Combining Equations 2 and 3 yields

Continued…

PROBLEM 3.167 (Cont.)

$$-k_m \theta_i \tilde{m} \frac{I_1(\tilde{m}r_1)}{I_0(\tilde{m}r_1)} = \frac{1}{2\pi r_1} \frac{T_i - T_\infty}{R'_{tot}}$$

This expression can be solved for T_i, recalling that T_i also appears in θ_i.

$$T_i = \frac{T_\infty I_0(\tilde{m}r_1) + k_m 2\pi r_1 \tilde{m} R'_{tot}\left(T_a + \frac{\dot{q}_m}{\omega \rho_b c_b}\right) I_1(\tilde{m}r_1)}{I_0(\tilde{m}r_1) + k_m 2\pi r_1 \tilde{m} R'_{tot} I_1(\tilde{m}r_1)}$$

where

$$\tilde{m} = \sqrt{\omega \rho_b c_b / k_m} = \left[0.0005\ \text{s}^{-1} \times 1000\ \text{kg/m}^3 \times 3600\ \text{J/kg}\cdot\text{K} \big/ 0.5\ \text{W/m}\cdot\text{K}\right]^{1/2} = 60\ \text{m}^{-1}$$

$$\frac{\dot{q}_m}{\omega \rho_b c_b} = \frac{700\ \text{W/m}^3}{0.0005\ \text{s}^{-1} \times 1000\ \text{kg/m}^3 \times 3600\ \text{J/kg}\cdot\text{K}} = 0.389\ \text{K}$$

and from Table B.5

$$I_0(\tilde{m}r_1) = I_0(60\ \text{m}^{-1} \times 0.05\ \text{m}) = I_0(3) = 4.88; \quad I_1(\tilde{m}r_1) = I_1(60\ \text{m}^{-1} \times 0.05\ \text{m}) = I_1(3) = 3.95$$

Thus,

$$T_i = \left[\left[\begin{matrix} 24°\text{C} \times 4.88 + 0.5\ \text{W/m}\cdot\text{K} \\ \times 2 \times \pi \times 0.05\ \text{m} \times 60\ \text{m}^{-1} \\ \times 0.41\ \text{m}\cdot\text{K/W}(37 + 0.389)°\text{C} \times 3.95 \end{matrix}\right] \Big/ \left[\begin{matrix} 4.88 + 0.5\ \text{W/m}\cdot\text{K} \\ \times 2 \times \pi \times 0.05\ \text{m} \times 60\ \text{m}^{-1} \\ \times 0.41\ \text{m}\cdot\text{K/W} \times 3.95 \end{matrix}\right]\right] = 34.2°\text{C} \quad <$$

(c) The maximum temperature occurs at the centerline of the forearm, r = 0, thus from Equation 1, with $I_0(0) = 1$,

$$T = T_a + \frac{\dot{q}_m}{\omega \rho_b c_b} + \left(T_i - T_a - \frac{\dot{q}_m}{\omega \rho_b c_b}\right) \frac{1}{I_0(\tilde{m}r_1)} \quad <$$

$$= 37°\text{C} + 0.389°\text{C} + (34.2°\text{C} - 37°\text{C} - 0.389°\text{C}) \times \frac{1}{4.88} = 36.7°\text{C}$$

COMMENTS: (1) The maximum temperature is very close to the core body temperature of 37ºC, as would be expected. (2) Pennes [17] conducted an experimental investigation of the temperature distribution in human forearms, by inserting thermocouples into living subjects.

PROBLEM 3.168

KNOWN: Thermoelectric module properties and performance, as given in Example 3.13.

FIND: (a) The thermodynamic efficiency, $\eta_{\text{therm}} \equiv P_{M=1}/q_1$, (b) the figure of merit $Z\overline{T}$ for one module, and the thermoelectric efficiency, η_{TE}. (c) the Carnot efficiency, $\eta_{\text{Carnot}} = 1 - T_2/T_1$, (d) the value of η_{TE} based upon the inappropriate use of $T_{\infty,1}$ and $T_{\infty,2}$ (e) the thermoelectric efficiency based upon the correct usage of T_1 and T_2 in Equation 3.128, and the Carnot efficiency for the case where $h_1 = h_2 \rightarrow \infty$.

ASSUMPTIONS: (1) Steady-state, one-dimensional conduction, (2) Negligible contact resistances, (3) Negligible radiation exchange and gas phase conduction inside the module, (4) Negligible conduction resistance due to metallic contacts and ceramic insulators, (5) The properties of the two semiconductors are identical and $S_p = - S_n$.

ANALYSIS: (a) From Example 3.13 the electrical power per module is $P_{M=1} = P_{\text{tot}}/M$ = 46.9 W/48 = 0.9773 W. The heat input to one module may be evaluated from Equation 3 of the solution to the example problem as

$$q_1 = h_1 W^2 (T_{\infty,1} - T_1) = 40\ \text{W/m}^2\cdot\text{K} \times (0.054\text{m})^2 \times \left[(550+273)\text{K} - (173+273)\text{K}\right] = 43.92\ \text{W}$$

Therefore, the thermodynamic efficiency is $\eta_{\text{therm}} = P_{M=1}/q_1$ = 0.9773 W/43.92 W = 0.022 <

(b) From Equations 3.121 and 3.125 (or 3.122 and 3.126), we note that

$$S_{p-n} = S_{p-n,\text{eff}}/N = 0.1435\ \text{volts/K}/100 = 0.001435\ \text{volts/K}$$

and

$$\rho_{e,s} = \frac{R_{e,\text{eff}} A_s}{2NL} = \frac{4\Omega \times 1.2\times10^{-5}\ \text{m}^2}{2\times100\times2.5\times10^{-3}\ \text{m}} = 9.6\times10^{-5}\ \Omega\cdot\text{m}$$

From Section 3.8, $S = S_p = - S_n$ and for $S_p = - S_n$, $S = S_p = S_{p-n}/2$ = 0.0007175 volts/K,

$$Z = \frac{S^2}{\rho_{e,s} k} = \frac{(0.0007175\ \text{volts/K})^2}{9.6\times10^{-5}\ \Omega\cdot\text{m}\times1.2\ \text{W/m}\cdot\text{K}} = 0.004469\ \text{K}^{-1}$$

For T_1 = 173°C + 273 K = 446 K and T_2 = 134°C + 273 K = 407 K, as determined in the example problem, the average module temperature is $\overline{T} = (T_1 + T_2)/2 = (446\ \text{K} + 407\ \text{K})/2 = 426.5\ \text{K}$. Therefore, the figure of merit is

$$Z\overline{T} = 0.004469\ \text{K}^{-1} \times 426.5\ \text{K} = 1.908.$$ <

The thermoelectric efficiency is therefore,

Continued...

$$\eta_{TE} = \left(1 - \frac{T_2}{T_1}\right) \frac{\sqrt{1 + Z\overline{T}} - 1}{\sqrt{1 + Z\overline{T}} + T_2 / T_1} = \left(1 - \frac{407 \text{ K}}{446 \text{ K}}\right) \frac{\sqrt{1 + 1.908\text{K}^{-1}} - 1}{\sqrt{1 + 1.908\text{K}^{-1}} + 407 \text{ K} / 446 \text{ K}} = 0.024$$ <

We note that the thermodynamic efficiency is less than the thermoelectric efficiency based uo the figure of merit and the surface temperatures of the module. The thermoelectric efficiency is the maximum possible efficiency for the case when the load resistance is optimized.

(c) The Carnot efficiency is η_{Carnot} = 1 - 407K /446 K = 0.087 <

(d) The value of η_{TE} based upon $T_{\infty,1}$ = 550°C + 273 K = 823 K, $T_{\infty,2}$ = 105°C + 273 K = 378 K, and $Z\overline{T} = 0.004469 \text{ K}^{-1} \times 600.5 \text{ K} = 2.684$ is

$$\eta_{TE} = \left(1 - \frac{T_{\infty,2}}{T_{\infty,1}}\right) \frac{\sqrt{1 + Z\overline{T}} - 1}{\sqrt{1 + Z\overline{T}} + T_{\infty,2} / T_{\infty,1}} = \left(1 - \frac{378 \text{ K}}{823 \text{ K}}\right) \frac{\sqrt{1 + 2.684} - 1}{\sqrt{1 + 2.684} + 378 \text{ K} / 823 \text{ K}} = 0.21$$ <

(e) For $h_1 = h_2 \rightarrow \infty$, the surface temperatures of the module are $T_1 = T_{\infty,1}$ = 823 K and $T_2 = T_{\infty,2}$ = 378 K, respectively. Therefore, from part (d) η_{TE} = 0.21. The Carnot efficiency is η_{Carnot} = 1 - 378 K/823 K = 0.54. <

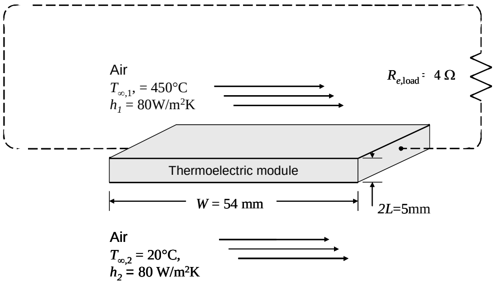
COMMENTS: (1) The conversion efficiency for the thermoelectric modules of Example 3.13 is quite small, approximately 2%. (2) The conversion efficiency can be increased by an order of magnitude (to 21%) by utilizing thermal management approaches that will increase the temperature difference across the module. (c) The incorrect usage of $T_{\infty,1}$ and $T_{\infty,2}$ in the expression for the thermoelectric efficiency as in part (d) provides an efficiency (21%) that far exceeds the Carnot efficiency of 8.7% found in part (c). Hence, use of the incorrect temperatures in the thermoelectric efficiency expression can lead to grossly exaggerated levels of thermodynamic performance that violate the second law of thermodynamics. Reporting the efficiency of a thermoelectric module or thermoelectric material based upon fluid (or surrounding) temperatures is meaningless.

PROBLEM 3.169

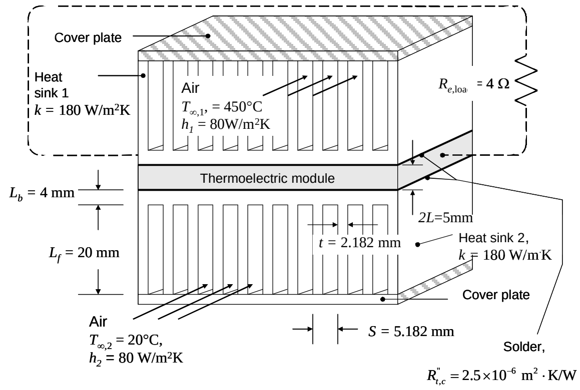
KNOWN: Dimensions of thermoelectric module and heat sinks. Convection conditions, heat sink thermal conductivity, thermoelectric module performance parameters, load electrical resistance. Contact resistance between thermoelectric module and heat sinks.

FIND: (a) Sketch of the equivalent thermal circuit and electrical power generated without the heat sinks. (b) Sketch of the equivalent thermal circuit and electrical power generated with the heat sinks.

SCHEMATIC:



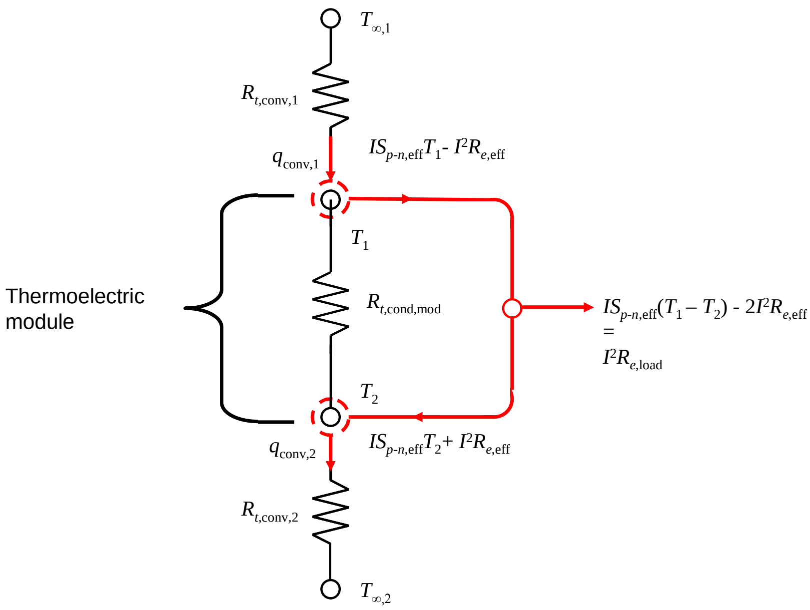
(a)



(b)

ASSUMPTIONS: (1) Steady-state, one-dimensional conduction, (2) Constant properties, (3) Negligible radiation, (4) Adiabatic fin tips for part (b), (5) Convection coefficients same in parts (a) and (b) and the same on the sides of the fin arrays.

ANALYSIS: (a) Without the heat sinks, the equivalent thermal circuit is shown in Figure 3.24*b* as replicated below.



<

Continued…

PROBLEM 3.169 (Cont.)

The analysis can proceed as in Example 3.13. The conduction resistance of one module is the same as in the example, namely

$$R_{t,\text{cond,mod}} = \frac{L}{NA_{c,s}k_s} = \frac{2.5 \times 10^{-3}\ \text{m}}{100 \times 1.2 \times 10^{-5}\ \text{m}^2 \times 1.2\ \text{W/m} \cdot \text{K}} = 1.736\ \text{K/W}$$

From Equations 3.125 and 3.126,

$$q_1 = \frac{1}{R_{t,\text{cond,mod}}}(T_1 - T_2) + IS_{p\text{-}n,\text{eff}}T_1 - I^2R_{e,\text{eff}} = \frac{(T_1 - T_2)}{1.736\ \text{K/W}} + I \times 0.1435\ \text{V/K} \times T_1 - I^2 \times 4\ \Omega \qquad (1)$$

$$q_2 = \frac{1}{R_{t,\text{cond,mod}}}(T_1 - T_2) + IS_{p\text{-}n,\text{eff}}T_2 + I^2R_{e,\text{eff}} = \frac{(T_1 - T_2)}{1.736\ \text{K/W}} + I \times 0.1435\ \text{V/K} \times T_2 + I^2 \times 4\ \Omega \qquad (2)$$

Newton’s law of cooling may be written at each surface as

$$q_1 = h_1W^2(T_{\infty,1} - T_1) = 80\ \text{W/m}^2 \cdot \text{K} \times (0.054\ \text{m})^2 \times \left[(450 + 273)\ \text{K - } T_1\right] \qquad (3)$$

$$q_2 = h_2W^2(T_2 - T_{\infty,2}) = 80\ \text{W/m}^2 \cdot \text{K} \times (0.054\ \text{m})^2 \times \left[T_2 - (20 + 273)\ \text{K}\right] \qquad (4)$$

The electric power produced by a single module, P_N, is equal to the electric power dissipated in the load resistance. Equating the expression for P_N from Equation 3.127 to the electric power dissipated in the load gives

$$P_N = IS_{p\text{-}n,\text{eff}}(T_1 - T_2) - 2I^2R_{e,\text{eff}} = I^2R_{e,\text{load}}$$

$$I \times 0.1435\ \text{V/K} \times (T_1 - T_2) - 2I^2 \times 4\ \Omega = I^2 \times 4\ \Omega \qquad (5)$$

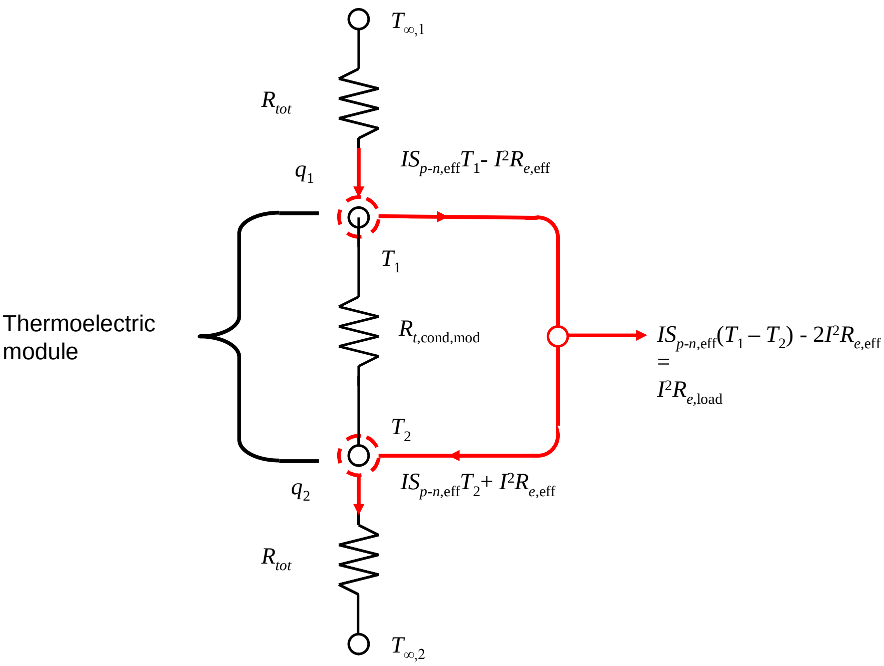
Equations 1 through 5 may be solved simultaneously, for example using IHT, to yield $I = 0.38$ A, and

$$P_N = I^2R_{e,\text{load}} = (0.38\ \text{A})^2 \times 4\ \Omega = 0.59\ \text{W}$$ <

(b) The thermal circuit associated with the thermoelectric module is unchanged, but each convection resistance must be replaced with the total thermal resistance, R_{tot}, associated with the contact resistance, fin array base, and overall resistance of the fin array, as shown below. Also, $q_{\text{conv},1}$ and $q_{\text{conv},2}$ have been replaced with the more general terms q_1 and q_2.

Continued…

PROBLEM 3.169 (Cont.)



The total thermal resistance is given by

$$R_{\text{tot}} = \frac{R''_{t,c}}{W^2} + R_{\text{base}} + R_{t,o} = \frac{R''_{t,c}}{W^2} + \frac{L_b}{kW^2} + \frac{1}{\eta_o hA_t}$$

where Equation 3.108 has been used to express the overall fin resistance. From Equations 3.104, 3.107, and 3.94,

$$\eta_o A_t = A_b + NA_f\eta_f = (N-1)W(S-t) + 2NWL_f \frac{\tanh mL_f}{mL_f}$$

where

$$m = \sqrt{hP/kA_c} = \sqrt{2h/kt} = \sqrt{2\times 80\text{ W/m}^2\cdot\text{K}/(180\text{ W/m}\cdot\text{K}\times 0.002182\text{ m})} = 20.2\text{ m}^{-1}$$

Thus,

$$\eta_o A_t = 10\times 0.054\text{ m}\times 0.003\text{ m} + 2\times 11\times 0.054\text{ m}\times 0.020\text{ m}\frac{\tanh(20.2\text{ m}^{-1}\times 0.02\text{ m})}{20.2\text{ m}^{-1}\times 0.02\text{ m}} = 0.0242\text{ m}^2$$

The total thermal resistance is then

$$R_{\text{tot}} = \frac{2.5\times 10^{-6}\text{ K/W}}{(0.054\text{ m})^2} + \frac{0.004\text{ m}}{180\text{ W/m}\cdot\text{K}(0.054\text{ m})^2} + \frac{1}{0.0242\text{ m}^2\times 80\text{ W/m}^2\cdot\text{K}} = 0.526\text{ K/W}$$

Continued…

PROBLEM 3.169 (Cont.)

The system of equations from part (a) applies here, except that Equations 3 and 4 are replaced by the revised versions

$$q_1 = \frac{T_{\infty,1} - T_1}{R_{\text{tot}}} = \frac{(450 + 273)\text{K} - T_1}{0.526 \text{ K/W}} \tag{3r}$$

$$q_2 = \frac{T_2 - T_{\infty,2}}{R_{\text{tot}}} = \frac{T_2 - (20 + 273)\text{K}}{0.526 \text{ K/W}} \tag{4r}$$

Equations 1, 2, 3r, 4r, and 5 may be solved simultaneously to yield I = 2.04 A, and

$$P_N = I^2 R_{e,\text{load}} = (2.04 \text{ A})^2 \times 4 \ \Omega = 16.7 \text{ W}$$ <

This is 28 times larger than the result of part (a). <

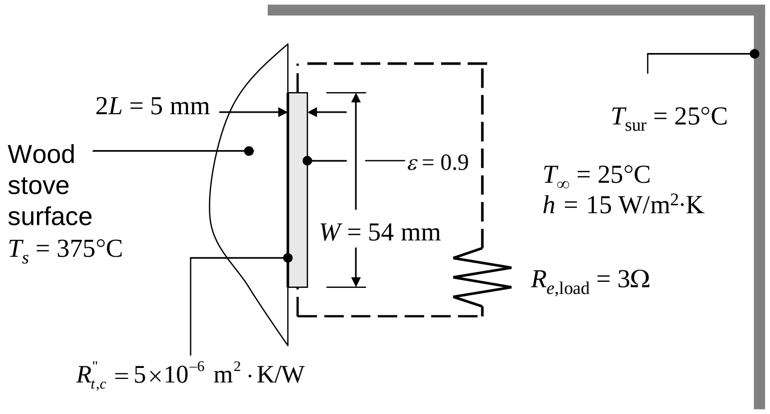
COMMENTS: By adding the two heat sinks to the thermoelectric module, the power produced by the module increases by a factor of 28. Not only does the power depend on the semiconductor properties of the thermoelectric material, but also strongly on the thermal management of the module through, as in this problem, addition of heat sinks.

PROBLEM 3.170

KNOWN: Dimensions of thermoelectric module. Convection conditions, thermoelectric module performance parameters, load electrical resistance, contact resistance between thermoelectric module and stove surface, emissivity of the exposed surface of the thermoelectric module, temperature of surroundings.

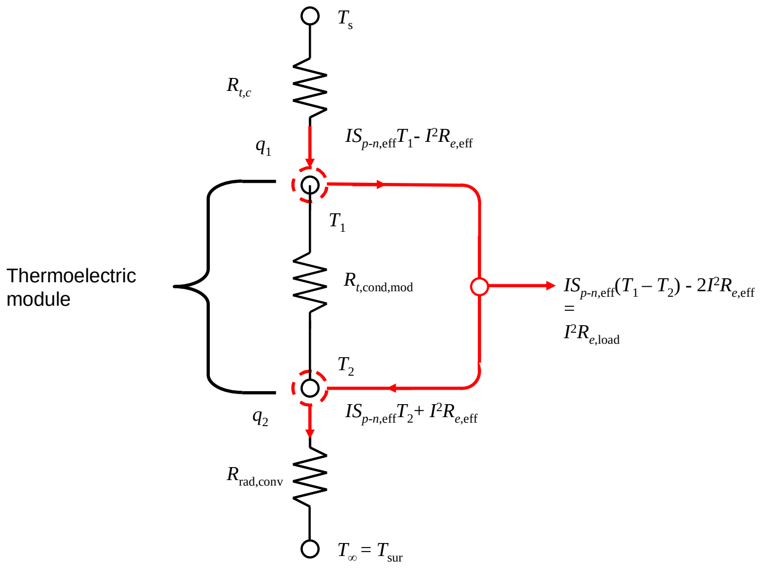
FIND: Sketch of the equivalent thermal circuit and electrical power generated by the module.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, one-dimensional conduction, (2) Constant properties, (3) Large surroundings.

ANALYSIS: The portion of the equivalent thermal circuit that describes the thermoelectric module is the same as shown in Figure 3.24*b*. However, the external thermal resistances are different. The high temperature side of the TEM is exposed to the stove surface through a contact resistance, $R_{t,c}$. The low temperature side exchanges heat with the surroundings through radiation and convection. Since T_∞ = T_{sur}, the radiation and convection thermal resistances can be combined into a single resistance, $R_{rad,conv}$, as shown below. Also, $q_{conv,1}$ and $q_{conv,2}$ have been replaced with the more general terms q_1 and q_2.



<

Continued…

PROBLEM 3.170 (Cont.)

The two external resistances can be calculated as follows:

$$R_{t,c} = R''_{t,c} / W^2 = 5\times10^{-6}\ \text{m}^2\cdot\text{K/W} / (0.054\ \text{m})^2 = 1.71\times10^{-3}\ \text{K/W}$$

$$R_{\text{rad,conv}} = 1/[(h_{\text{conv}} + h_r)W^2]$$

$$h_r = \varepsilon\sigma(T_2 + T_{\text{sur}})(T_2^2 + T_{\text{sur}}^2) \quad (1)$$

The radiation heat transfer coefficient, h_r, depends on the unknown TEM surface temperature, T_2. This can be left as an unknown in solving the simultaneous equations.

The analysis proceeds as in Example 3.13. The conduction resistance of one module is the same as in the example, namely

$$R_{t,\text{cond,mod}} = \frac{L}{NA_{c,s}k_s} = \frac{2.5\times10^{-3}\ \text{m}}{100\times1.2\times10^{-5}\ \text{m}^2\times1.2\ \text{W/m}\cdot\text{K}} = 1.736\ \text{K/W}$$

From Equations 3.125 and 3.126,

$$q_1 = \frac{1}{R_{t,\text{cond,mod}}}(T_1 - T_2) + IS_{p\text{-}n,\text{eff}}T_1 - I^2R_{e,\text{eff}} = \frac{(T_1 - T_2)}{1.736\ \text{K/W}} + I\times0.1435\ \text{V/K}\times T_1 - I^2\times4\ \Omega \quad (2)$$

$$q_2 = \frac{1}{R_{t,\text{cond,mod}}}(T_1 - T_2) + IS_{p\text{-}n,\text{eff}}T_2 + I^2R_{e,\text{eff}} = \frac{(T_1 - T_2)}{1.736\ \text{K/W}} + I\times0.1435\ \text{V/K}\times T_2 + I^2\times4\ \Omega \quad (3)$$

Additional relationships can be written by considering heat transfer through the external resistances.

$$q_1 = (T_s - T_1)/R_{t,c} = \left[(375 + 273)\ \text{K - } T_1\right]/1.71\times10^{-3}\ \text{K/W} \quad (4)$$

$$\begin{aligned} q_2 &= (T_2 - T_\infty)/R_{\text{rad,conv}} = (T_2 - T_\infty)(h + h_r)W^2 \\ &= \left[T_2 - (25 + 273)\ \text{K}\right]\times(15\ \text{W/m}^2\cdot\text{K} + h_r)\times(0.054\ \text{m})^2 \end{aligned} \quad (5)$$

The electric power produced by the single module, P_N, is equal to the electric power dissipated in the load resistance. Equating the expression for P_N from Equation 3.127 to the electric power dissipated in the load gives

$$P_N = IS_{p\text{-}n,\text{eff}}(T_1 - T_2) - 2I^2R_{e,\text{eff}} = I^2R_{e,\text{load}}$$

$$I\times0.1435\ \text{V/K}\times(T_1 - T_2) - 2I^2\times4\ \Omega = I^2\times3\ \Omega \quad (6)$$

Continued…

PROBLEM 3.170 (Cont.)

Equations 1 through 6 may be solved simultaneously, for example using IHT, to yield I = 0.27 A, and

$$P_N = I^2 R_{e,\text{load}} = (0.27\text{ A})^2 \times 3\ \Omega = 0.22\text{ W}$$ <

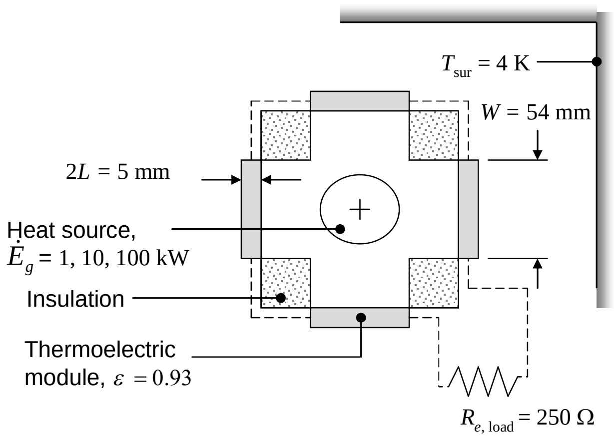
COMMENTS: (1) Radiation is significant. If radiation heat transfer were neglected, the electrical power output would be decreased to 0.036 W. (2) The electrical power output is quite low. The power output could be raised by increasing the temperature difference across the module. For example, the electrical power could be used to rotate a small fan to increase the value of the heat transfer coefficient. If h were to increase to 30 W/m^2·K, for example, the electrical power would increase to 0.40 W. A tradeoff exists between the extra power provided by the fan and the power needed to operate the fan.

PROBLEM 3.171

KNOWN: Thermal energy generation rate. Dimensions of thermoelectric modules and total number of modules. Thermoelectric module performance parameters, load electrical resistance, emissivity of the exposed surface of the thermoelectric modules, deep space temperature.

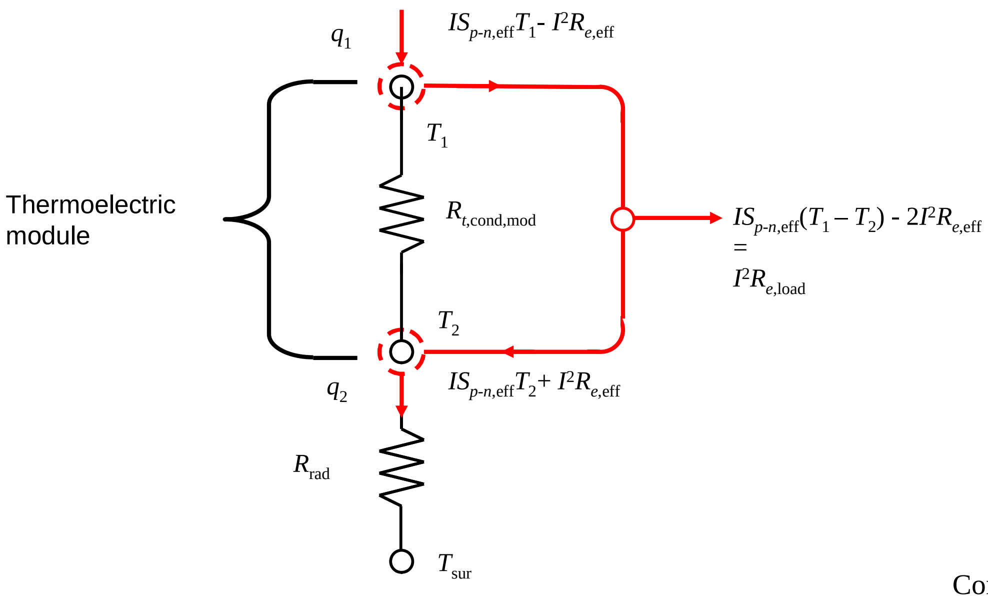
FIND: Electrical power generated by the device. Surface temperatures of the modules.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, one-dimensional conduction, (2) Constant properties, (3) Large surroundings.

ANALYSIS: The portion of the equivalent thermal circuit that describes the thermoelectric module is the same as shown in Figure 3.24*b*. The energy generated in the uranium is known, and under steady-state conditions $q_1 = \dot{E}_g / M$. As a consequence, knowledge of the thermal resistance between the uranium and the inner surface of the TEMs is not needed. The low temperature side of the TEMs exchanges heat with the surroundings through radiation. Thus, the equivalent thermal circuit is as shown below. Note that $q_{conv,1}$ and $q_{conv,2}$ have been replaced with the more general terms q_1 and q_2.



<

Continued…

PROBLEM 3.171 (Cont.)

The analysis proceeds as in Example 3.13. The conduction resistance of one module is the same as in the example, namely

$$R_{t,\text{cond,mod}} = \frac{L}{NA_{c,s}k_s} = \frac{2.5\times 10^{-3}\text{ m}}{100\times 1.2\times 10^{-5}\text{ m}^2\times 1.2\text{ W/m}\cdot\text{K}} = 1.736\text{ K/W}$$

From Equations 3.125 and 3.126,

$$q_1 = \frac{1}{R_{t,\text{cond,mod}}}(T_1 - T_2) + IS_{p\text{-}n,\text{eff}}T_1 - I^2R_{e,\text{eff}} = \frac{(T_1 - T_2)}{1.736\text{ K/W}} + I\times 0.1435\text{ V/K}\times T_1 - I^2\times 4\ \Omega \qquad (1)$$

$$q_2 = \frac{1}{R_{t,\text{cond,mod}}}(T_1 - T_2) + IS_{p\text{-}n,\text{eff}}T_2 + I^2R_{e,\text{eff}} = \frac{(T_1 - T_2)}{1.736\text{ K/W}} + I\times 0.1435\text{ V/K}\times T_2 + I^2\times 4\ \Omega \qquad (2)$$

An additional relationship can be written by considering heat transfer by radiation to deep space.

$$q_2 = h_rW^2(T_2 - T_{\text{sur}}) = h_r\times(0.054\text{ m})^2\times(T_2 - 4\text{ K}) \qquad (3)$$

where

$$h_r = \varepsilon\sigma(T_2 + T_{\text{sur}})(T_2^2 + T_{\text{sur}}^2) = 0.93\times 5.67\times 10^{-8}\text{ W/m}^2\cdot\text{K}\times(T_2 + 4\text{ K})\times(T_2^2 + (4\text{ K})^2) \qquad (4)$$

The radiation heat transfer coefficient, h_r, depends on the unknown TEM surface temperature, T_2. This can be left as an unknown in solving the simultaneous equations.

The electric power produced by all 80 modules, P_{tot}, is equal to the electric power dissipated in the load resistance. Making use of Equation 3.127 and equating the total electrical power generated in the M modules to the electric power dissipated in the load gives

$$P_{\text{tot}} = MP_N = I^2R_{e,\text{load}}$$

$$M\left[IS_{p\text{-}n,\text{eff}}(T_1 - T_2) - 2I^2R_{e,\text{eff}}\right] = I^2R_{e,\text{load}}$$

$$80\left[I\times 0.1435\text{ V/K}\times(T_1 - T_2) - 2I^2\times 4\ \Omega\right] = I^2\times 250\ \Omega \qquad (5)$$

With q_1 known from $q_1 = \dot{E}_g / M$, Equations 1 through 5 can be solved for the five unknowns, T_1, T_2, I, q_2, and h_r. Solving the equations numerically using IHT yields the following results for the three different values of $\dot{E}_g$:

Continued…

PROBLEM 3.171 (Cont.)

$\dot{E}_g$ (kW)	I (A)	P_{tot} (W)	T_2 (K)	$\eta = P_N/q_1$
1	0.10	2.63	534	0.0026
10	0.67	114	947	0.011
100	3.99	3990	1671	0.040

<

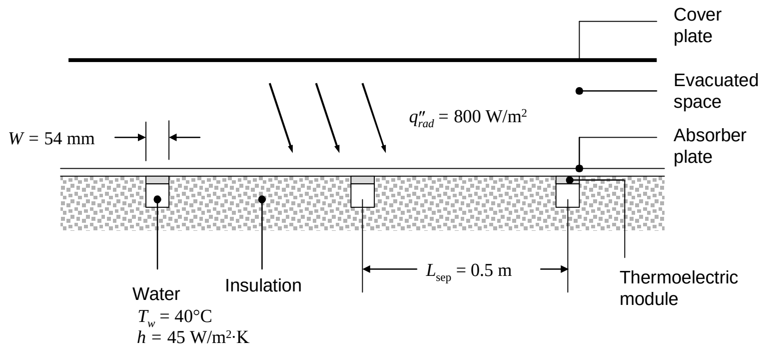
COMMENTS: (1) The temperature for the highest thermal energy generation rate is unacceptably high. (2) The electrical energy generated by the device is relatively high, but the efficiency is quite low. The efficiency increases as a function of the thermal generation rate because of larger temperature differences across the module, which are ΔT = 8, 52, and 310 K for the low, medium and high energy generation rates. (3) Numerical solution of the equations requires a good initial guess. One can be obtained by assuming that the current is zero, resulting in $q_1 = q_2$ and enabling direct calculation of the temperatures due to conduction across the TEM and radiation to the surroundings. (4) In this application, thermal generation can occur continuously for many years, providing reliable electrical power to the satellite over its lifetime. (5) What steps could be taken to increase the electrical power generated for each thermal energy generation rate?

PROBLEM 3.172

KNOWN: Net radiation heat flux on absorber plate. Dimensions of thermoelectric modules, total number of modules, spacing of module rows. Thermoelectric module performance parameters, load electrical resistance. Water temperature and heat transfer coefficient.

FIND: Electrical power produced by one row of thermoelectric modules. Heat transfer rate to water.

SCHEMATIC:

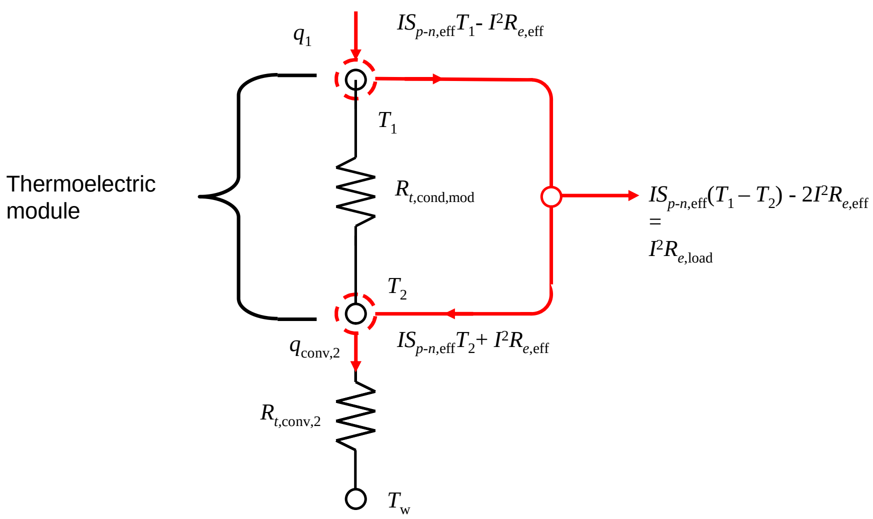


ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible losses through insulation, (4) Negligible losses by convection at absorber plate surface, (5) High thermal conductivity tube wall creates uniform temperature around the tube perimeter, (6) Tubes of square cross section. (7) Water temperature remains at 40°C.

ANALYSIS: The heat absorbed in the absorber plate is known, and under steady-state conditions all of this heat must conduct along the absorber plate and enter the thermoelectric modules, so that the heat associated with one module is given by

$$q_1 = q''_{\text{rad}} L_{\text{sep}} W = 800 \text{ W/m}^2 \times 0.5 \text{ m} \times 0.054 \text{ m} = 21.6 \text{ W}$$

The portion of the equivalent thermal circuit that describes the thermoelectric module is the same as shown in Figure 3.24*b*, see below. The low temperature side of the TEMs exchanges heat with the water through convection. Note that $q_{\text{conv},1}$ has been replaced with the more general term q_1.



Continued…

The analysis proceeds as in Example 3.13. The conduction resistance of one module is the same as in the example, namely

$$R_{t,\text{cond,mod}} = \frac{L}{NA_{c,s}k_s} = \frac{2.5 \times 10^{-3}\ \text{m}}{100 \times 1.2 \times 10^{-5}\ \text{m}^2 \times 1.2\ \text{W/m}\cdot\text{K}} = 1.736\ \text{K/W}$$

From Equations 3.125 and 3.126,

$$q_1 = \frac{1}{R_{t,\text{cond,mod}}}(T_1 - T_2) + IS_{p\text{-}n,\text{eff}}T_1 - I^2R_{e,\text{eff}} = \frac{(T_1 - T_2)}{1.736\ \text{K/W}} + I \times 0.1435\ \text{V/K} \times T_1 - I^2 \times 4\ \Omega \qquad (1)$$

$$q_2 = \frac{1}{R_{t,\text{cond,mod}}}(T_1 - T_2) + IS_{p\text{-}n,\text{eff}}T_2 + I^2R_{e,\text{eff}} = \frac{(T_1 - T_2)}{1.736\ \text{K/W}} + I \times 0.1435\ \text{V/K} \times T_2 + I^2 \times 4\ \Omega \qquad (2)$$

An additional relationship can be written by considering heat transfer by convection to the water. It is assumed that heat exiting the thermoelectric modules conducts around the perimeter of the square tube wall and enters the water uniformly over the entire tube wall area,

$$q_2 = 4hW^2(T_2 - T_w) = 4 \times 45\ \text{W/m}^2\cdot\text{K} \times (0.054\ \text{m})^2 \times (T_2 - (40 + 273)\ \text{K}) \qquad (3)$$

The electric power produced by all $M = 20$ modules, P_{tot}, is equal to the electric power dissipated in the load resistance. Making use of Equation 3.127, and equating the total electrical power generated in the M modules to the electric power dissipated in the load gives

$$P_{\text{tot}} = MP_N = I^2R_{e,\text{load}}$$

$$M\left[IS_{p\text{-}n,\text{eff}}(T_1 - T_2) - 2I^2R_{e,\text{eff}}\right] = I^2R_{e,\text{load}}$$

$$20\left[I \times 0.1435\ \text{V/K} \times (T_1 - T_2) - 2I^2 \times 4\ \Omega\right] = I^2 \times 60\ \Omega \qquad (4)$$

With q_1 known, Equations 1 through 4 can be solved for the four unknowns, T_1, T_2, I, and q_2. Then P_{tot} can be found from $P_{\text{tot}} = I^2R_{e,\text{load}}$. Solving the equations numerically using IHT yields

T_1 = 371 K, T_2 = 354 K, I = 0.22 A, q_2 = 21.5 W, P_N = 0.15 W

These are the values for a single module. For an entire row:

$$q_{1,\text{tot}} = 20q_1 = 432\ \text{W}$$
$$q_{2,\text{tot}} = 20q_2 = 429\ \text{W}$$
$$P_{\text{tot}} = 3\ \text{W}$$

Thus, each row of modules generates 3.0 W of electricity and supplies 429 W to heat water. <

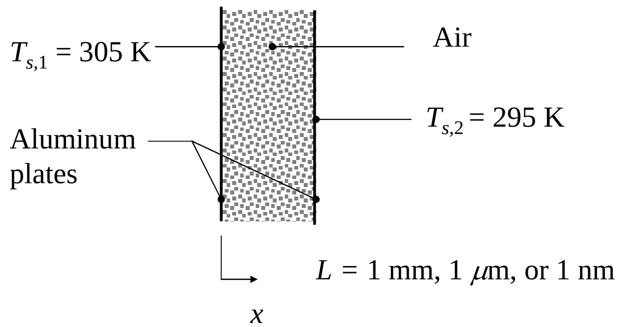
COMMENTS: (1) This technology provides combined hot water and electricity generation and could potentially displace photovoltaics. If hot water is stored in a thermal energy storage unit, it can be used to generate electricity 24 hours per day, exploiting nighttime radiation loss to the cold sky. (2) The heat entering the water will cause the water temperature to increase along a row of modules. This would have to be accounted for in a more accurate analysis. (3) The electrical conversion efficiency is P_{tot}/Mq_1 = 0.0069. This efficiency can be improved significantly with careful thermal design. For example, doubling the tube spacing to L_{sep} = 1 m more than triples the electric power generated to P_{tot} = 10.4 W. Can you explain why?

PROBLEM 3.173

KNOWN: Size and temperatures of parallel aluminum plates. Spacing between the plates. Air between the plates.

FIND: The conduction heat transfer through the air.

SCHEMATIC:



ASSUMPTIONS: (1) Ideal gas behavior.

PROPERTIES: Table A.4 (T = 300 K): Air; c_p = 1007 J/kg·K, k = 0.0263 W/m·K. Figure 2.8: Air; $\mathcal{M}$ = 28.97 kg/kmol, $d = 0.372 \times 10^{-9}$ m.

ANALYSIS: For air, the ideal gas constant, specific heat at constant volume, and ratio of specific heats are:

$$R = \frac{\mathcal{R}}{\mathcal{M}} = \frac{8.315 \text{ kJ/kmol}\cdot\text{K}}{28.97 \text{ kg/kmol}} = 0.287 \ \frac{\text{kJ}}{\text{kg}\cdot\text{K}};$$

$$c_v = c_p - R = 1.007\frac{\text{kJ}}{\text{kg}\cdot\text{K}} - 0.287\frac{\text{kJ}}{\text{kg}\cdot\text{K}} = 0.720\frac{\text{kJ}}{\text{kg}\cdot\text{K}}; \quad \gamma = \frac{c_p}{c_v} = \frac{1.007}{0.720} = 1.399$$

From Equation 2.11 the mean free path of air is

$$\lambda_{\text{mfp}} = \frac{k_B T}{\sqrt{2}\pi d^2 p} = \frac{1.381\times10^{-23} \text{ J/K}\times 300 \text{ K}}{\sqrt{2}\pi\left(0.372 \times 10^{-9} \text{ m}\right)^2\left(1.0133\times10^5 \text{ N/m}^2\right)} = 66.5\times10^{-9} \text{ m} = 66.5 \text{ nm}$$

For L = 1 mm,

$$R_{t,m-m} = \frac{L}{kA} = \frac{1\times10^{-3}\text{m}}{0.0263 \text{ W/m}\cdot\text{K}\times10\times10^{-3}\text{m}\times10\times10^{-3}\text{m}} = 380.2 \text{ K/W}$$

$$R_{t,m-s} = \frac{\lambda_{\text{mfp}}}{kA}\left[\frac{2-\alpha_t}{\alpha_t}\right]\left[\frac{9\gamma-5}{\gamma+1}\right] = \frac{66.5\times10^{-9} \text{ m}}{0.0263 \text{ W/m}\cdot\text{K}\times100\times10^{-6} \text{ m}^2}\left[\frac{2-0.92}{0.92}\right]\left[\frac{9\times1.399-5}{1.399+1}\right]$$

$$= 0.09392 \text{ K/W}$$

Hence, the conduction heat rate is

Continued...

PROBLEM 3.173 (Cont.)

$$q = \frac{T_{s,1} - T_{s,2}}{\left(R_{t,m-m} + R_{t,m-s}\right)} = \frac{305\text{K} - 295\text{K}}{\left(380.2\text{ K/W} + 0.09392\text{ K/W}\right)} = 0.0263\text{ W}$$ <

For L = 1 μm,

$$R_{t,m-m} = \frac{L}{kA} = \frac{1 \times 10^{-6}\text{m}}{0.0263\text{ W/m}\cdot\text{K} \times 10 \times 10^{-3}\text{m} \times 10 \times 10^{-3}\text{m}} = 0.3802\text{ K/W}$$

$$R_{t,m-s} = 0.09392\text{ K/W}$$

Hence, the conduction heat rate is

$$q = \frac{T_{s,1} - T_{s,2}}{\left(R_{t,m-m} + R_{t,m-s}\right)} = \frac{305\text{K} - 295\text{K}}{\left(0.3802\text{ K/W} + 0.09392\text{ K/W}\right)} = 21.09\text{ W}$$ <

For L = 10 nm,

$$R_{t,m-m} = \frac{L}{kA} = \frac{10 \times 10^{-9}\text{m}}{0.0263\text{ W/m}\cdot\text{K} \times 10 \times 10^{-3}\text{m} \times 10 \times 10^{-3}\text{m}} = 0.0038\text{ K/W}$$

$$R_{t,m-s} = 0.09392\text{ K/W}$$

Hence, the conduction heat rate is

$$q = \frac{T_{s,1} - T_{s,2}}{\left(R_{t,m-m} + R_{t,m-s}\right)} = \frac{305\text{K} - 295\text{K}}{\left(0.0038\text{ K/W} + 0.09392\text{ K/W}\right)} = 102.3\text{ W}$$ <

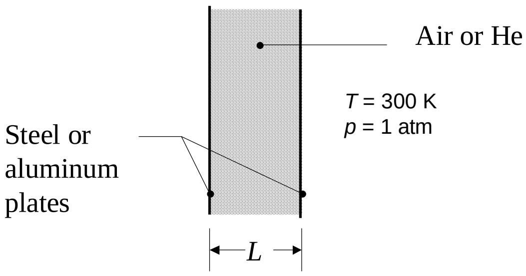
COMMENT: If the molecule-surface collision resistance were to be neglected, the heat rates would be q = 0.0263 W, 26.3 W, and 2632 W for the L = 1 mm, 1 μm and 10 nm plate spacings, respectively. Hence, molecule-surface collisions are negligible for large plate spacings, and dominant at small plate spacings.

PROBLEM 3.174

KNOWN: Air or helium between steel and aluminum parallel plates, respectively. Gas temperature and pressure. Thermal accommodation coefficient values.

FIND: The separation distance, L, above which $R_{t,m-s}/R_{t,m-m}$ is less than 0.01 for (*a*) air and (*b*) helium.

SCHEMATIC:



ASSUMPTIONS: (1) Ideal gas behavior, (2) One-dimensional conduction.

PROPERTIES: Table A.4 (T = 300 K): Air; c_p = 1007 J/kg·K, k = 0.0263 W/m·K. He; c_p = 5193 J/kg·K, k = 0.170 W/m·K Figure 2.8: Air; $\mathcal{M}$ = 28.97 kg/kmol, $d = 0.372 \times 10^{-9}$ m. He; $\mathcal{M}$ = 4.003 kg/kmol, $d = 0.219 \times 10^{-9}$ m.

ANALYSIS:

(*a*) For air, the ideal gas constant, specific heat at constant volume, and ratio of specific heats are:

$$R = \frac{\mathcal{R}}{\mathcal{M}} = \frac{8.315 \text{ kJ/kmol}\cdot\text{K}}{28.97 \text{ kg/kmol}} = 0.287 \ \frac{\text{kJ}}{\text{kg}\cdot\text{K}};$$

$$c_v = c_p - R = 1.007\frac{\text{kJ}}{\text{kg}\cdot\text{K}} - 0.287\frac{\text{kJ}}{\text{kg}\cdot\text{K}} = 0.720\frac{\text{kJ}}{\text{kg}\cdot\text{K}}; \quad \gamma = \frac{c_p}{c_v} = \frac{1.007}{0.720} = 1.399$$

From Equation 2.11 the mean free path of air is

$$\lambda_{\text{mfp}} = \frac{k_B T}{\sqrt{2}\pi d^2 p} = \frac{1.381\times10^{-23} \text{ J/K}\times300 \text{ K}}{\sqrt{2}\pi\left(0.372 \times 10^{-9} \text{ m}\right)^2\left(1.0133\times10^5 \text{ N/m}^2\right)} = 66.5\times10^{-9} \text{ m} = 66.5 \text{ nm}$$

From Section 3.9.1, the plate separation, L, is

$$L = \lambda_{\text{mfp}}\frac{R_{t,m-m}}{R_{t,m-s}}\left[\frac{2-\alpha_t}{\alpha_t}\right]\left[\frac{9\gamma-5}{\gamma+1}\right]$$

$$= 66.5\times10^{-9} \text{ m}\times100\times\left[\frac{2-0.92}{0.92}\right]\left[\frac{9\times1.399-5}{1.399+1}\right] = 2.47\times10^{-5} \text{ m} = 24.7 \ \mu\text{m}$$ <

Continued…

PROBLEM 3.174 (Cont.)

(*b*) For He, the ideal gas constant, specific heat at constant volume, and ratio of specific heats are:

$$R = \frac{\mathcal{R}}{\mathcal{M}} = \frac{8.315 \text{ kJ/kmol} \cdot \text{K}}{4.003 \text{ kg/kmol}} = 2.077 \ \frac{\text{kJ}}{\text{kg} \cdot \text{K}};$$

$$c_v = c_p - R = 5.193\frac{\text{kJ}}{\text{kg} \cdot \text{K}} - 2.077\frac{\text{kJ}}{\text{kg} \cdot \text{K}} = 3.116\frac{\text{kJ}}{\text{kg} \cdot \text{K}}; \ \ \gamma = \frac{c_p}{c_v} = \frac{5.193}{3.116} = 1.667$$

The mean free path is

$$\lambda_{\text{mfp}} = \frac{k_B T}{\sqrt{2}\pi d^2 p} = \frac{1.381 \times 10^{-23} \text{ J/K} \times 300 \text{ K}}{\sqrt{2}\pi \left(0.219 \times 10^{-9} \text{ m}\right)^2 \left(1.0133 \times 10^5 \text{ N/m}^2\right)} = 1.919 \times 10^{-7} \text{ m} = 192 \text{ nm}$$

The plate separation, *L*, is

$$L = \lambda_{\text{mfp}} \frac{R_{t,m-m}}{R_{t,m-s}} \left[\frac{2-\alpha_t}{\alpha_t}\right]\left[\frac{9\gamma - 5}{\gamma + 1}\right]$$

$$= 1.919 \times 10^{-7} \text{ m} \times 100 \times \left[\frac{2-0.02}{0.02}\right]\left[\frac{9 \times 1.667 - 5}{1.667 + 1}\right] = 0.0071 \text{ m} = 7.1 \text{ mm}$$ <

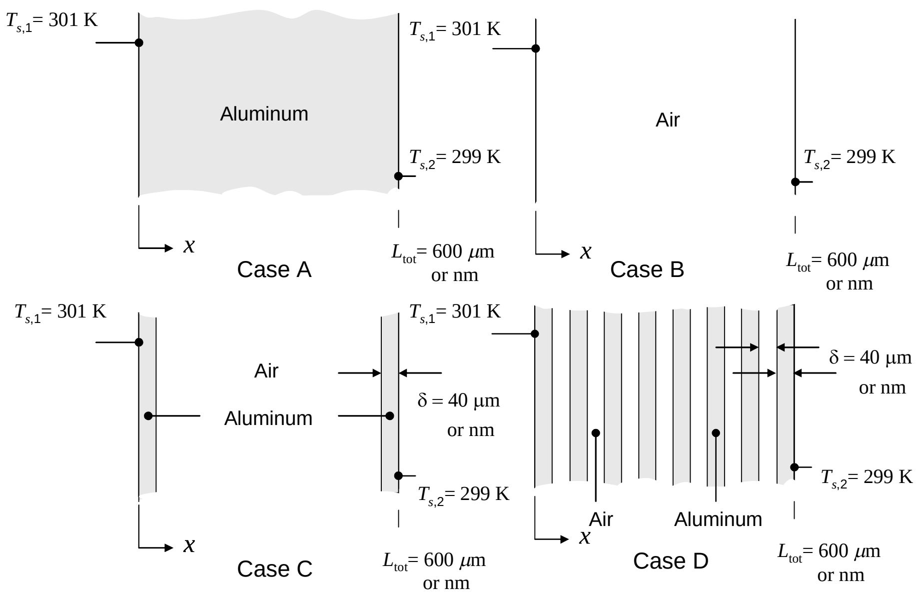
COMMENTS: The critical plate separation associated with helium is 7.1×10^{-3} m/ 24.7×10^{-6} m = 290 times greater than that for air. The thermal resistance associated with molecule-surface interactions can become significant for gases of small molecular diameter and for gas-surface material combinations that have a small thermal accommodation coefficient, even at relatively large plate separation distances (7.1 mm).

PROBLEM 3.175

KNOWN: Thickness of of parallel aluminum plates and air layers. Wall surface temperatures.

FIND: The conduction heat flux through (a) aluminum wall, (b) air layer, (c) air layer contained between two aluminum sheets and (d) composite wall consisting of 8 aluminum sheets and 7 air layers.

SCHEMATIC:



ASSUMPTIONS: (1) Ideal gas behavior. (2) Nanoscale effects within the solid are not important.

PROPERTIES: Table A.4 (T = 300 K): Air; c_p = 1007 J/kg·K, k_{Air} = 0.0263 W/m·K. Figure 2.8: Air; $\mathcal{M}$ = 28.97 kg/kmol, $d = 0.372 \times 10^{-9}$ m. Table A.1 (T = 300 K): Pure Aluminum, k_{Al} = 237 W/m·K.

ANALYSIS:

(a) Case A: Aluminum Wall

For L_{tot} = 600 μm, the heat flux is

$$q_x'' = \frac{k_{Al}\left(T_{s,1} - T_{s,2}\right)}{L_{tot}} = \frac{237 \text{ W/m}\cdot\text{K}\left(301 \text{ K} - 299 \text{ K}\right)}{600 \times 10^{-6} \text{ m}} = 7.9 \times 10^5 \text{ W/m}^2 \qquad <$$

Similarly, for L_{tot} = 600 nm, the heat flux is $q_x'' = 7.9 \times 10^8$ W/m^2 <

Continued...

PROBLEM 3.175 (Cont.)

(b) Case B: Air Layer

For L_{tot} = 600 μm, the heat flux is

$$q_x'' = \frac{k_{Air}\left(T_{s,1} - T_{s,2}\right)}{L_{tot}} = \frac{0.0263 \text{ W/m}\cdot\text{K}\left(301 \text{ K} - 299 \text{ K}\right)}{600 \times 10^{-6} \text{ m}} = 87.7 \text{ W/m}^2$$ <

Similarly, for L_{tot} = 600 nm, the heat flux is q_x'' = 87.7 × 10^3 W/m^2 <

(c) Case C: Air Layer between two Aluminum Sheets

This case involves a resistance due to molecule-molecule interactions, as well as molecule-surface collisions. For air, the ideal gas constant, specific heat at constant volume, and ratio of specific heats are:

$$R = \frac{\mathcal{R}}{\mathcal{M}} = \frac{8.315 \text{ kJ/kmol}\cdot\text{K}}{28.97 \text{ kg/kmol}} = 0.287 \ \frac{\text{kJ}}{\text{kg}\cdot\text{K}};$$

$$c_v = c_p - R = 1.007\frac{\text{kJ}}{\text{kg}\cdot\text{K}} - 0.287\frac{\text{kJ}}{\text{kg}\cdot\text{K}} = 0.720\frac{\text{kJ}}{\text{kg}\cdot\text{K}}; \quad \gamma = \frac{c_p}{c_v} = \frac{1.007}{0.720} = 1.399$$

From Equation 2.11 the mean free path of air is

$$\lambda_{mfp} = \frac{k_B T}{\sqrt{2}\pi d^2 p} = \frac{1.381 \times 10^{-23} \text{ J/K} \times 300 \text{ K}}{\sqrt{2}\pi\left(0.372 \times 10^{-9} \text{ m}\right)^2\left(1.0133 \times 10^5 \text{ N/m}^2\right)} = 66.5 \times 10^{-9} \text{ m} = 66.5 \text{ nm}$$

For L_{tot} = 600 μm, the air layer is $L = L_{tot} - 2\delta$ = 600 μm - 2 × 40 μm = 520 μm thick.

$$R''_{t,m-m} = \frac{L}{k_{Air}} = \frac{520 \times 10^{-6} \text{m}}{0.0263 \text{ W/m}\cdot\text{K}} = 0.0198 \text{ K}\cdot\text{m}^2\text{/W}$$

$$R''_{t,m-s} = \frac{\lambda_{mfp}}{k_{Air}}\left[\frac{2-\alpha_t}{\alpha_t}\right]\left[\frac{9\gamma - 5}{\gamma + 1}\right] = \frac{66.5 \times 10^{-9} \text{ m}}{0.0263 \text{ W/m}\cdot\text{K}}\left[\frac{2-0.92}{0.92}\right]\left[\frac{9 \times 1.399 - 5}{1.399 + 1}\right]$$
$$= 9.39 \times 10^{-6} \text{ K}\cdot\text{m}^2\text{/W}$$

In addition, the aluminum sheets pose a cumulative thermal resistance of

$$R''_{t,cond} = \frac{2\delta}{k_{Al}} = \frac{2 \times 40 \times 10^{-6} \text{ m}}{237 \text{ W/m}\cdot\text{K}} = 3.38 \times 10^{-7} \text{ K}\cdot\text{m}^2\text{/W}$$

Hence, the conduction heat flux is

Continued...

$$q_x'' = \frac{T_{s,1} - T_{s,2}}{\left(R''_{t,m-m} + R''_{t,m-s} + R''_{t,\text{cond}}\right)}$$

$$= \frac{301\text{ K} - 299\text{ K}}{\left(0.0198\text{ K}\cdot\text{m}^2/\text{W} + 9.39\times10^{-6}\text{ K}\cdot\text{m}^2/\text{W} + 3.38\times10^{-7}\text{ K}\cdot\text{m}^2/\text{W}\right)}$$ <

$$= 101\text{ W/m}^2$$

For L_{tot} = 600 nm, the air layer is $L = L_{tot} - 2\delta$ = 600 nm - 2 × 40 nm = 520 nm thick.

$$R''_{t,m-m} = \frac{L}{k_{\text{Air}}} = \frac{520\times10^{-9}\text{m}}{0.0263\text{ W/m}\cdot\text{K}} = 19.8\times10^{-6}\text{ K}\cdot\text{m}^2/\text{W}$$

The aluminum sheets pose a cumulative thermal resistance of

$$R''_{t,\text{cond}} = \frac{2\delta}{k_{\text{Al}}} = \frac{2\times40\times10^{-9}\text{ m}}{237\text{ W/m}\cdot\text{K}} = 3.38\times10^{-10}\text{ K}\cdot\text{m}^2/\text{W}$$

Hence, the conduction heat flux is

$$q_x'' = \frac{T_{s,1} - T_{s,2}}{\left(R''_{t,m-m} + R''_{t,m-s} + R''_{t,\text{cond}}\right)}$$

$$= \frac{301\text{ K} - 299\text{ K}}{\left(19.8\times10^{-6}\text{ K}\cdot\text{m}^2/\text{W} + 9.39\times10^{-6}\text{ K}\cdot\text{m}^2/\text{W} + 3.38\times10^{-10}\text{ K}\cdot\text{m}^2/\text{W}\right)}$$ <

$$= 68.6\times10^{3}\text{ W/m}^2$$

(d) Case D: Seven Air Layers between Eight Aluminum Sheets

This case involves multiple resistances due to molecule-molecule interactions, as well as molecule-surface collisions at multiple surfaces.

For L_{tot} = 600 μm, each air layer is $L = L_{tot}$ × (1/15)= 600 μm × (1/15) = 40 μm thick. Hence, for each air layer

$$R''_{t,m-m} = \frac{L}{k_{\text{Air}}} = \frac{40\times10^{-6}\text{m}}{0.0263\text{ W/m}\cdot\text{K}} = 1.52\times10^{-3}\text{ K}\cdot\text{m}^2/\text{W}$$

In addition, the aluminum sheets pose a cumulative thermal resistance of

$$R''_{t,\text{cond}} = \frac{8\delta}{k_{\text{Al}}} = \frac{8\times40\times10^{-6}\text{ m}}{237\text{ W/m}\cdot\text{K}} = 1.35\times10^{-6}\text{ K}\cdot\text{m}^2/\text{W}$$

Continued...

Problem 3.175 (Cont.)

Hence, the conduction heat flux is

$$q_x'' = \frac{T_{s,1} - T_{s,2}}{\left(7R_{t,m-m}'' + 7R_{t,m-s}'' + R_{t,\text{cond}}''\right)}$$
$$= \frac{301\text{ K} - 299\text{ K}}{\left(7 \times 1.52 \times 10^{-3}\text{ K} \cdot \text{m}^2/\text{W} + 7 \times 9.39 \times 10^{-6}\text{ K} \cdot \text{m}^2/\text{W} + 1.35 \times 10^{-6}\text{ K} \cdot \text{m}^2/\text{W}\right)} \quad <$$
$$= 186.7\text{ W/m}^2$$

For L_{tot} = 600 nm, each air layer is $L = L_{tot} \times (1/15)$= 600 nm × (1/15) = 40 nm thick. Hence, for each air layer

$$R_{t,m-m}'' = \frac{L}{k_{\text{Air}}} = \frac{40 \times 10^{-9}\text{m}}{0.0263\text{ W/m} \cdot \text{K}} = 1.52 \times 10^{-6}\text{ K} \cdot \text{m}^2/\text{W}$$

In addition, the aluminum sheets pose a cumulative thermal resistance of

$$R_{t,\text{cond}}'' = \frac{8\delta}{k_{\text{Al}}} = \frac{8 \times 40 \times 10^{-9}\text{ m}}{237\text{ W/m} \cdot \text{K}} = 1.35 \times 10^{-9}\text{ K} \cdot \text{m}^2/\text{W}$$

Hence, the conduction heat flux is

$$q_x'' = \frac{T_{s,1} - T_{s,2}}{\left(7R_{t,m-m}'' + 7R_{t,m-s}'' + R_{t,\text{cond}}''\right)}$$
$$= \frac{301\text{ K} - 299\text{ K}}{\left(7 \times 1.52 \times 10^{-6}\text{ K} \cdot \text{m}^2/\text{W} + 7 \times 9.39 \times 10^{-6}\text{ K} \cdot \text{m}^2/\text{W} + 1.35 \times 10^{-9}\text{ K} \cdot \text{m}^2/\text{W}\right)} \quad <$$
$$= 26.2 \times 10^3\text{ W/m}^2$$

The predicted heat fluxes are summarized below.

Case	L_{tot} = 600 μm	L_{tot} = 600 nm
A	$q_x'' = 7.9 \times 10^5\text{ W/m}^2 \cdot \text{K}$	$q_x'' = 7.9 \times 10^8\text{ W/m}^2 \cdot \text{K}$
B	$q_x'' = 87.7\text{ W/m}^2 \cdot \text{K}$	$q_x'' = 87.7 \times 10^3\text{ W/m}^2 \cdot \text{K}$
C	$q_x'' = 101\text{ W/m}^2 \cdot \text{K}$	$q_x'' = 68.6 \times 10^3\text{ W/m}^2 \cdot \text{K}$
D	$q_x'' = 186.7\text{ W/m}^2 \cdot \text{K}$	$q_x'' = 26.2 \times 10^3\text{ W/m}^2 \cdot \text{K}$

Continued...

PROBLEM 3.175 (Cont.)

COMMENTS: (1) For the L_{tot} = 600 μm cases, it is readily evident that the highest heat flux corresponds to Case A in which conduction occurs exclusively through the high thermal conductivity aluminum. The lowest heat flux is associated with conduction through the pure air layer (Case B). For the case involving two aluminum sheets (Case C) the heat flux is increased relative to Case B primarily in response to replacing some low thermal conductivity air with high thermal conductivity metal. However, as more aluminum sheets are added, the thermal resistance across the entire layer is reduced, leading to increases in the heat flux for Case D. In each case, the resistance posed by molecule-surface interactions is not significant. Specifically, heat transfer rates for Cases C and D, calculated without accounting for the molecule-surface collisions, are 101 W/m^2 and 187.8 W/m^2, respectively.

(2) For the L_{tot} = 600 nm cases, we again observe that the largest heat flux is associated with conduction exclusively within the aluminum (Case A). *However, consideration of the other three cases reveals nanoscale behavior that would be unexpected from the macroscale point-of-view.* Specifically, Case B involving conduction through pure air is no longer characterized by the lowest heat flux. Rather, we observe that as more sheets of high thermal conductivity metal are added to the composite layer, the heat flux is *reduced*, with the minimum heat flux associated with the most aluminum sheets, Case D. The reduction in the conduction resistance due to the replacement of low thermal conductivity air with high thermal conductivity metal is more than offset with the increase in the total thermal resistance that is associated with molecule-surface interactions at the interfaces between the aluminum sheets and the air. The molecule-surface interactions can have a profound effect on nanoscale heat transfer.

(3) Nanoscale effects could become important in the solid as the thickness of the solid approaches the mean free path. See Table 2.1.

PROBLEM 3.176

KNOWN: Knudsen number, specific heat ratio and thermal accommodation coefficient for an ideal gas and solid surface.

FIND: Expression for the the ratio of the thermal resistance due to molecule-surface collisions to the thermal resistance associated with molecule-molecule collisions, $R_{t,m-s}/R_{t,m-m}$.

ASSUMPTIONS: (1) Ideal gas behavior.

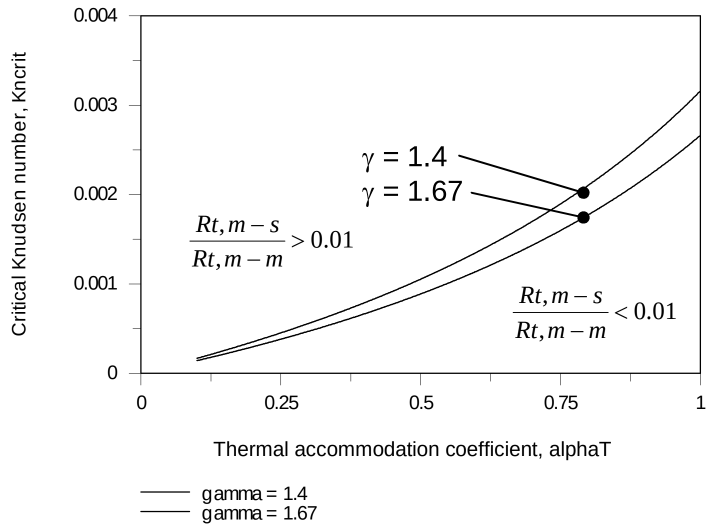
ANALYSIS: The expressions for $R_{t,m-m}$ and $R_{t,m-s}$ are

$$R_{t,m-m} = \frac{L}{kA} \qquad \text{and} \qquad R_{t,m-s} = \frac{\lambda_{\text{mfp}}}{kA}\left[\frac{2-\alpha_t}{\alpha_t}\right]\left[\frac{9\gamma-5}{\gamma+1}\right]$$

therefore,

$$\frac{R_{t,m-s}}{R_{t,m-m}} = \frac{\lambda_{\text{mfp}}}{L}\left[\frac{2-\alpha_t}{\alpha_t}\right]\left[\frac{9\gamma-5}{\gamma+1}\right] = Kn\left[\frac{2-\alpha_t}{\alpha_t}\right]\left[\frac{9\gamma-5}{\gamma+1}\right]$$ <

Associating the critical Knudsen number, Kn_{crit}, with $R_{t,m-s}/R_{t,m-m} = 0.01$, we may plot the value of the critical Knudsen number for $\gamma = 1.4$ and 1.67 over the range $0.01 \le \alpha_t \le 1$ as shown below.



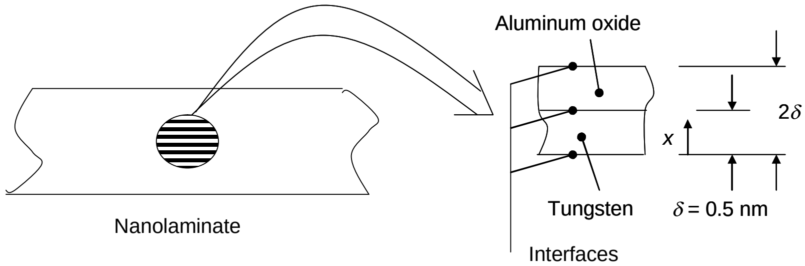
COMMENTS: (1) Relatively large Knudsen numbers are associated with more significant surface-molecule collisions. (2) The critical Knudsen number is relatively insensitive to the specific heat ratio, γ.

PROBLEM 3.177

KNOWN: Thickness of alternating tungsten and aluminum oxide layers, interface thermal resistance, thermal conductivities of tungsten and aluminum oxide thin films.

FIND: (a) Effective thermal conductivity of the nanolaminate. Comparison with bulk thermal conductivities of aluminum oxide and tungsten, (b) Effective thermal conductivity of the nanolaminate using bulk values of the thermal conductivity of aluminum oxide and tungsten.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, one-dimensional conditions, (2) Constant properties.

PROPERTIES: Table A.1, tungsten (300 K): k_T = 174 W/m·K. Table A.2, aluminum oxide (300 K): k_A = 36 W/m·K.

ANALYSIS: (a) Consider a unit cell consisting of one layer of aluminum oxide, one layer of tungsten, and two interfaces of unit cell thickness $2\delta = 1.0$ nm as shown in the schematic. The sum of the thermal resistances is

$$\sum R_t'' = 2(R_{t,i}'') + \frac{\delta}{k_A} + \frac{\delta}{k_T} = 2\times 3.85\times 10^{-9}\,\frac{\text{m}^2\cdot\text{K}}{\text{W}} + \frac{0.5\times 10^{-9}\,\text{m}}{1.65\,\text{W/m}\cdot\text{K}} + \frac{0.5\times 10^{-9}\,\text{m}}{6.10\,\text{W/m}\cdot\text{K}} = 8.08\times 10^{-9}\,\frac{\text{m}^2\cdot\text{K}}{\text{W}}$$

The effective thermal conductivity is

$$k_{eff} = \frac{L}{\sum R_t''} = \frac{2\delta}{\sum R_t''} = \frac{2\times 0.5\times 10^{-9}\,\text{m}}{8.08\times 10^{-9}\,\frac{\text{m}^2\cdot\text{K}}{\text{W}}} = 0.123\,\frac{\text{W}}{\text{m}\cdot\text{K}}$$ <

The value of the effective thermal conductivity is 0.123/174 × 100 = 0.07% that of bulk tungsten and 0.123/36 × 100 = 0.34% that of bulk aluminum oxide.

(b) Repeating part (a) using k_T = 174 W/m·K and k_A = 36 W/m·K yields $k_{eff} = 0.129\,\frac{\text{W}}{\text{m}\cdot\text{K}}$ <

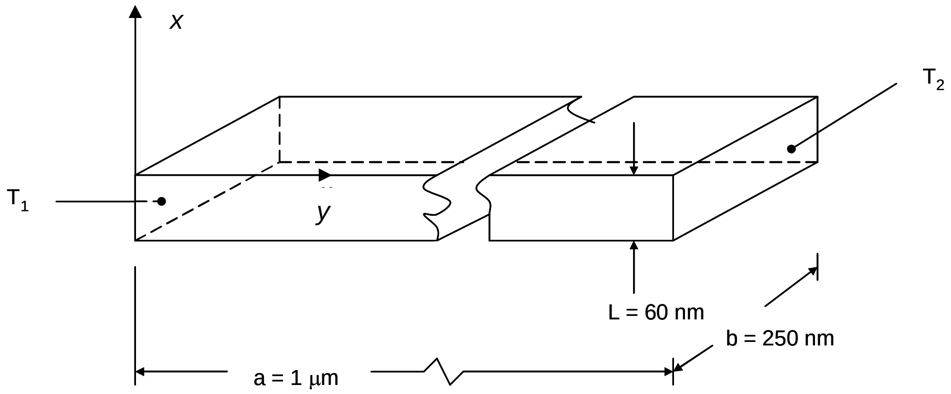
COMMENTS: (1) The effective thermal conductivity is dominated by the interface resistances and is relatively insensitive to the thermal conductivity of the two materials. Although the interface resistance is very small compared to typical contact resistance values (see Table 3.2), by using extremely thin layer thicknesses, many such interfaces may be packed into the laminated structure, resulting in very small values of the effective or bulk thermal conductivity. The material service temperature would be limited to values less than approximately 1000°C, due to the tendency of the material to lose thermal stability at high temperatures and, in turn, lose its nanolaminated structure. (2) See Costescu, Cahill, Fabreguette, Sechrist, and George, "Ultra-Low Thermal Conductivity in W/AL_2O_3 Nanolaminates," *Science*, Vol. 303, pp. 989 – 990, 2004, for additional information.

PROBLEM 3.178

KNOWN: Dimensions of and temperature difference applied across thin gold film.

FIND: (a) Energy conducted along the film, (b) Plot the thermal conductivity along and across the thin dimension of the film, for film thicknesses 30 ≤ L ≤ 140 nm.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in the x- and y-directions, (2) Steady-state conditions, (3) Constant properties, (4) Thermal conductivity not affected by nanoscale effects associated with 250 nm dimension.

PROPERTIES: Table A.1, gold (bulk, 300 K): k = 317 W/m·K.

ANALYSIS:
a) From Fourier's law,

$$q_y = -kA\frac{dT}{dy} = k_y Lb[\frac{T_1 - T_2}{a}] \qquad (1)$$

From Eq. 2.9b,

$$k_y = k\,[1 - 2\lambda_{mfp} / (3\pi L)] \qquad (2)$$

Combining Eqs. (1) and (2), and using the value of λ_{mfp} = 31 nm from Table 2.1 yields

$$q_y = k[1 - 2\lambda_{mfp} / (3\pi L)]Lb[\frac{T_1 - T_2}{a}]$$

$$= 317\frac{W}{m\cdot K} \times [1 - \frac{2\times 31\times 10^{-9}\ m}{3\times\pi\times 60\times 10^{-9}\ m}] \times 60 \times 10^{-9} m \times 250 \times 10^{-9} m \times \frac{20°C}{1 \times 10^{-6}\ m}$$

$$= 85 \times 10^{-6}\ W = 85\ \mu W$$ <

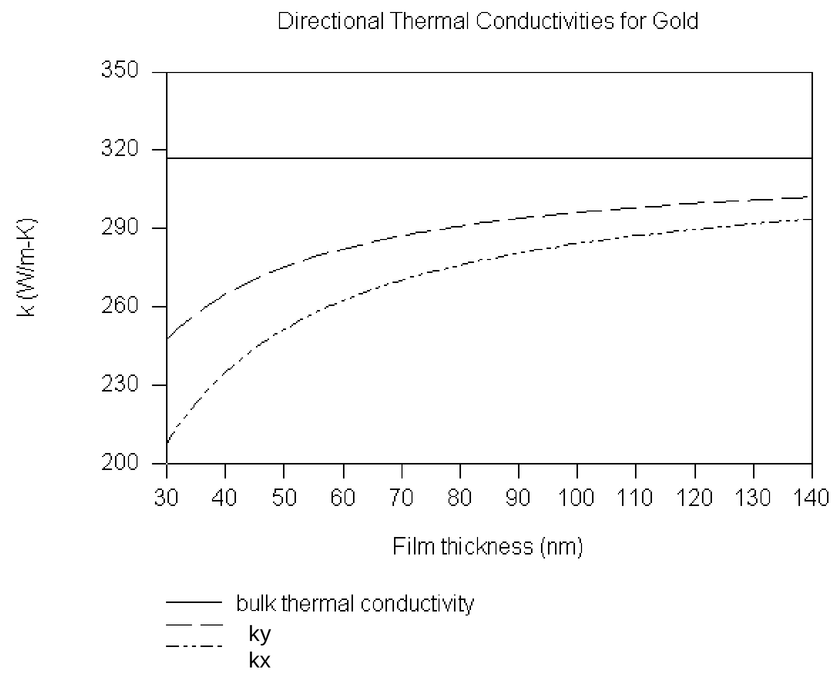
(b) The spanwise thermal conductivity may be found from Eq. 2.9a,

$$k_x = k[1 - \lambda_{mfp} / (3L)] \qquad (3)$$

Continued…

PROBLEM 3.178 (Cont.)

The plot is shown below.



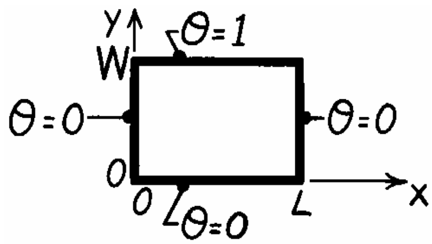
COMMENT: Nanoscale effects become less significant as the thickness of the film is increased.

PROBLEM 4.1

KNOWN: Method of separation of variables for two-dimensional, steady-state conduction.

FIND: Show that negative or zero values of λ^2, the separation constant, result in solutions which cannot satisfy the boundary conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Two-dimensional, steady-state conduction, (2) Constant properties.

ANALYSIS: From Section 4.2, identification of the separation constant λ^2 leads to the two ordinary differential equations, 4.6 and 4.7, having the forms

$$\frac{d^2X}{dx^2}+\lambda^2X=0 \qquad \frac{d^2Y}{dy^2}-\lambda^2Y=0 \tag{1,2}$$

and the temperature distribution is $$\theta(x,y)=X(x)\cdot Y(y). \tag{3}$$

Consider now the situation when $\lambda^2 = 0$. From Eqs. (1), (2), and (3), find that

$$X=C_1+C_2x,\quad Y=C_3+C_4y \quad \text{and} \quad \theta(x,y)=(C_1+C_2x)\ (C_3+C_4y). \tag{4}$$

Evaluate the constants - C_1, C_2, C_3 and C_4 - by substitution of the boundary conditions:

$$\begin{array}{lll} x=0: & \theta(0,y)=(C_1+C_2\cdot 0)(C_3+C_4\cdot y)=0 & C_1=0 \\ y=0: & \theta(x,0)=(0+C_2\cdot x)(C_3+C_4\cdot 0)=0 & C_3=0 \\ x=L: & \theta(L,0)=(0+C_2\cdot L)(0+C_4\cdot y)=0 & C_2=0 \\ y=W: & \theta(x,W)=(0+0\cdot x)(0+C_4\cdot W)=1 & 0\neq 1 \end{array}$$

The last boundary condition leads to an impossibility ($0 \neq 1$). We therefore conclude that a λ^2 value of zero will not result in a form of the temperature distribution which will satisfy the boundary conditions. Consider now the situation when $\lambda^2 < 0$. The solutions to Eqs. (1) and (2) will be

$$X=C_5e^{-\lambda x}+C_6e^{+\lambda x}, \qquad Y=C_7\cos\lambda y+C_8\sin\lambda y \tag{5,6}$$

and $$\theta(x,y)=\left[C_5e^{-\lambda x}+C_6e^{+\lambda x}\right]\ \left[C_7\cos\lambda y+C_8\sin\lambda y\right]. \tag{7}$$

Evaluate the constants for the boundary conditions.

$$\begin{array}{lll} y=0: & \theta(x,0)=\left[C_5e^{-\lambda x}+C_6e^{-\lambda x}\right]\ \left[C_7\cos 0+C_8\sin 0\right]=0 & C_7=0 \\ x=0: & \theta(0,y)=\left[C_5e^{0}+C_6e^{0}\right]\ \left[0+C_8\sin\lambda y\right]=0 & C_8=0 \end{array}$$

If $C_8 = 0$, a trivial solution results or $C_5 = -C_6$.

$$x=L: \quad \theta(L,y)=C_5\left[e^{-xL}-e^{+xL}\right]C_8\sin\lambda y=0.$$

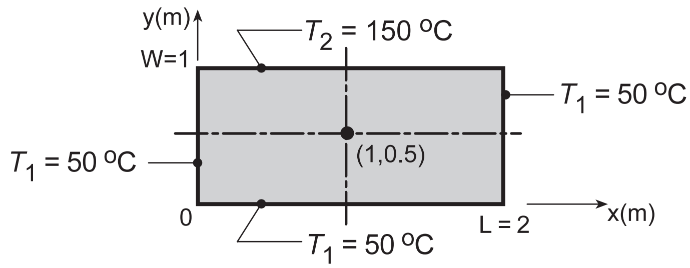
From the last boundary condition, we require C_5 or C_8 is zero; either case leads to a trivial solution with either no x or y dependence.

PROBLEM 4.2

KNOWN: Two-dimensional rectangular plate subjected to prescribed uniform temperature boundary conditions.

FIND: Temperature at the mid-point using the exact solution considering the first five non-zero terms; assess error resulting from using only first three terms. Plot the temperature distributions T(x,0.5) and T(1,y).

SCHEMATIC:



ASSUMPTIONS: (1) Two-dimensional, steady-state conduction, (2) Constant properties.

ANALYSIS: From Section 4.2, the temperature distribution is

$$\theta(x,y) \equiv \frac{T-T_1}{T_2-T_1} = \frac{2}{\pi}\sum_{n=1}^{\theta}\frac{(-1)^{n+1}+1}{n}\sin\left(\frac{n\pi x}{L}\right)\cdot\frac{\sinh(n\pi y/L)}{\sinh(n\pi W/L)}. \qquad (1,4.19)$$

Considering now the point (x,y) = (1.0,0.5) and recognizing x/L = 1/2, y/L = 1/4 and W/L = 1/2,

$$\theta(1,0.5) \equiv \frac{T-T_1}{T_2-T_1} = \frac{2}{\pi}\sum_{n=1}^{\theta}\frac{(-1)^{n+1}+1}{n}\sin\left(\frac{n\pi}{2}\right)\cdot\frac{\sinh(n\pi/4)}{\sinh(n\pi/2)}.$$

When n is even (2, 4, 6 ...), the corresponding term is zero; hence we need only consider n = 1, 3, 5, 7 and 9 as the first five non-zero terms.

$$\theta(1,0.5) = \frac{2}{\pi}\left\{2\sin\left(\frac{\pi}{2}\right)\frac{\sinh(\pi/4)}{\sinh(\pi/2)} + \frac{2}{3}\sin\left(\frac{3\pi}{2}\right)\frac{\sinh(3\pi/4)}{\sinh(3\pi/2)} + \right.$$

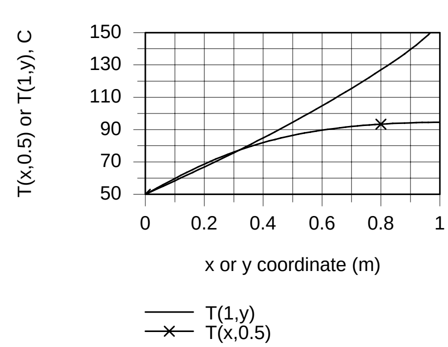
$$\left.\frac{2}{5}\sin\left(\frac{5\pi}{2}\right)\frac{\sinh(5\pi/4)}{\sinh(5\pi/2)} + \frac{2}{7}\sin\left(\frac{7\pi}{2}\right)\frac{\sinh(7\pi/4)}{\sinh(7\pi/2)} + \frac{2}{9}\sin\left(\frac{9\pi}{2}\right)\frac{\sinh(9\pi/4)}{\sinh(9\pi/2)}\right\}$$

$$\theta(1,0.5) = \frac{2}{\pi}[0.755 - 0.063 + 0.008 - 0.001 + 0.000] = 0.445 \qquad (2)$$

$$T(1,0.5) = \theta(1,0.5)(T_2 - T_1) + T_1 = 0.445(150-50) + 50 = 94.5^\circ C.$$ <

If only the first three terms of the series, Eq. (2), are considered, the result will be θ(1,0.5) = 0.46; that is, there is less than a 0.2% effect.

Using Eq. (1), and writing out the first five terms of the series, expressions for θ(x,0.5) or T(x,0.5) and θ(1,y) or T(1,y) were keyboarded into the IHT workspace and evaluated for sweeps over the x or y variable. Note that for T(1,y), that as y → 1, the upper boundary, T(1,1) is greater than 150°C. Upon examination of the magnitudes of terms, it becomes evident that more than 5 terms are required to provide an accurate solution.

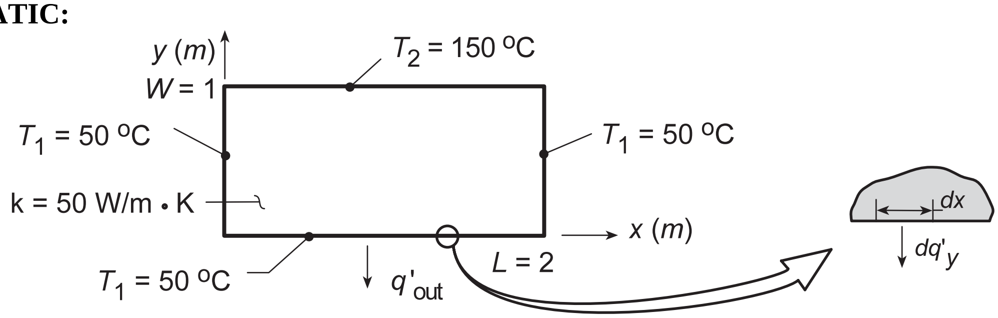


PROBLEM 4.3

KNOWN: Temperature distribution in the two-dimensional rectangular plate of Problem 4.2.

FIND: Expression for the heat rate per unit thickness from the lower surface ($0 \le x \le 2, 0$) and result based on first five non-zero terms of the infinite series.

SCHEMATIC:



ASSUMPTIONS: (1) Two-dimensional, steady-state conduction, (2) Constant properties.

ANALYSIS: The heat rate per unit thickness *from the plate* along the lower surface is

$$q'_{out} = -\int_{x=0}^{x=2} dq'_y(x,0) = -\int_{x=0}^{x=2} -k\left.\frac{\partial T}{\partial y}\right|_{y=0} dx = k(T_2 - T_1)\int_{x=0}^{x=2} \left.\frac{\partial \theta}{\partial y}\right|_{y=0} dx \qquad (1)$$

where from the solution to Problem 4.2,

$$\theta \equiv \frac{T - T_1}{T_2 - T_1} = \frac{2}{\pi}\sum_{n=1}^{\infty}\frac{(-1)^{n+1}+1}{n}\sin\left(\frac{n\pi x}{L}\right)\frac{\sinh(n\pi y/L)}{\sinh(n\pi W/L)}. \qquad (2)$$

Evaluate the gradient of θ from Eq. (2) and substitute into Eq. (1) to obtain

$$q'_{out} = k(T_2 - T_1)\int_{x=0}^{x=2}\frac{2}{\pi}\sum_{n=1}^{\infty}\frac{(-1)^{n+1}+1}{n}\sin\left(\frac{n\pi x}{L}\right)\left.\frac{(n\pi/L)\cosh(n\pi y/L)}{\sinh(n\pi W/L)}\right|_{y=0} dx$$

$$q'_{out} = k(T_2 - T_1)\frac{2}{\pi}\sum_{n=1}^{\infty}\frac{(-1)^{n+1}+1}{n}\frac{1}{\sinh(n\pi W/L)}\left[-\cos\left(\frac{n\pi x}{L}\right)\Big|_{x=0}^{2}\right]$$

$$q'_{out} = k(T_2 - T_1)\frac{2}{\pi}\sum_{n=1}^{\infty}\frac{(-1)^{n+1}+1}{n}\frac{1}{\sinh(n\pi/L)}\left[1-\cos(n\pi)\right] \qquad <$$

To evaluate the first five, non-zero terms, recognize that since cos(nπ) = 1 for n = 2, 4, 6 ..., only the n-odd terms will be non-zero. Hence,

Continued …

PROBLEM 4.3 (Cont.)

$$q'_{out} = 50\,\text{W/m}\cdot\text{K}\,(150-50)^\circ\text{C}\,\frac{2}{\pi}\left\{\frac{(-1)^2+1}{1}\cdot\frac{1}{\sinh(\pi/2)}(2)+\frac{(-1)^4+1}{3}\cdot\frac{1}{\sinh(3\pi/2)}\cdot(2)\right.$$

$$\left.+\frac{(-1)^6+1}{5}\cdot\frac{1}{\sinh(5\pi/2)}(2)+\frac{(-1)^8+1}{7}\cdot\frac{1}{\sinh(7\pi/2)}(2)+\frac{(-1)^{10}+1}{9}\cdot\frac{1}{\sinh(9\pi/2)}(2)\right\}$$

$$q'_{out} = 3.183\,\text{kW/m}\left[1.738+0.024+0.00062+(...)\right] = 5.611\,\text{kW/m}$$ <

COMMENTS: If the foregoing procedure were used to evaluate the heat rate into the upper surface, $q'_{in} = -\int_{x=0}^{x=2} dq'_y(x,W)$, it would follow that

$$q'_{in} = k(T_2 - T_1)\frac{2}{\pi}\sum_{n=1}^{\infty}\frac{(-1)^{n+1}+1}{n}\coth(n\pi/2)\left[1-\cos(n\pi)\right]$$

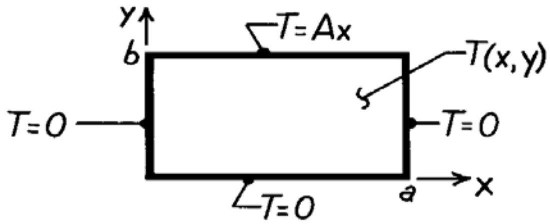
However, with $\coth(n\pi/2) \geq 1$, irrespective of the value of n, and with $\sum_{n=1}^{\infty}\left[(-1)^{n+1}+1\right]\Big/n$ being a divergent series, the complete series does not converge and $q'_{in} \to \infty$. This physically untenable condition results from the temperature discontinuities imposed at the upper left and right corners.

PROBLEM 4.4

KNOWN: Rectangular plate subjected to prescribed boundary conditions.

FIND: Steady-state temperature distribution.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, 2-D conduction, (2) Constant properties.

ANALYSIS: The solution follows the method of Section 4.2. The product solution is

$$T(x,y) = X(x)\cdot Y(y) = \left(C_1\cos\lambda x + C_2\sin\lambda x\right)\left(C_3e^{-\lambda y} + C_4e^{+\lambda y}\right)$$

and the boundary conditions are: T(0,y) = 0, T(a,y) = 0, T(x,0) = 0, T(x.b) = Ax. Applying BC#1, T(0,y) = 0, find $C_1 = 0$. Applying BC#2, T(a,y) = 0, find that $\lambda = n\pi/a$ with n = 1,2,…. Applying BC#3, T(x,0) = 0, find that $C_3 = -C_4$. Hence, the product solution is

$$T(x,y) = X(x)\cdot Y(y) = C_2C_4\ \sin\left[\frac{n\pi}{a}x\right]\ \left(e^{+\lambda y} - e^{-\lambda y}\right).$$

Combining constants and using superposition, find

$$T(x,y) = \sum_{n=1}^{\infty} C_n\ \sin\left[\frac{n\pi x}{a}\right]\sinh\left[\frac{n\pi y}{a}\right].$$

To evaluate C_n and satisfy BC#4, use orthogonal functions with Equation 4.16 to find

$$C_n = \int_0^a Ax\cdot\sin\left[\frac{n\pi x}{a}\right]\cdot dx/\sinh\left[\frac{n\pi b}{a}\right]\int_0^a \sin^2\left[\frac{n\pi x}{a}\right]dx,$$

noting that y = b. The numerator, denominator and C_n, respectively, are:

$$A\int_0^a x\cdot\sin\frac{n\pi x}{a}\cdot dx = A\left[\left[\frac{a}{n\pi}\right]^2\sin\left[\frac{n\pi x}{a}\right] - \frac{ax}{n\pi}\cos\left[\frac{n\pi x}{a}\right]\right]_0^a = \frac{Aa^2}{n\pi}\left[-\cos(n\pi)\right] = \frac{Aa^2}{n\pi}(-1)^{n+1},$$

$$\sinh\left[\frac{n\pi b}{a}\right]\int_0^a \sin^2\frac{n\pi x}{a}\cdot dx = \sinh\left[\frac{n\pi b}{a}\right]\left[\frac{1}{2}x - \frac{a}{4n\pi}\sin\left[\frac{2n\pi x}{a}\right]\right]_0^a = \frac{a}{2}\cdot\sinh\left[\frac{n\pi b}{a}\right],$$

$$C_n = \frac{Aa^2}{n\pi}(-1)^{n+1}/\frac{a}{2}\sinh\left[\frac{n\pi b}{a}\right] = 2Aa\ (-1)^{n+1}/n\pi\ \sinh\left[\frac{n\pi b}{a}\right].$$

Hence, the temperature distribution is

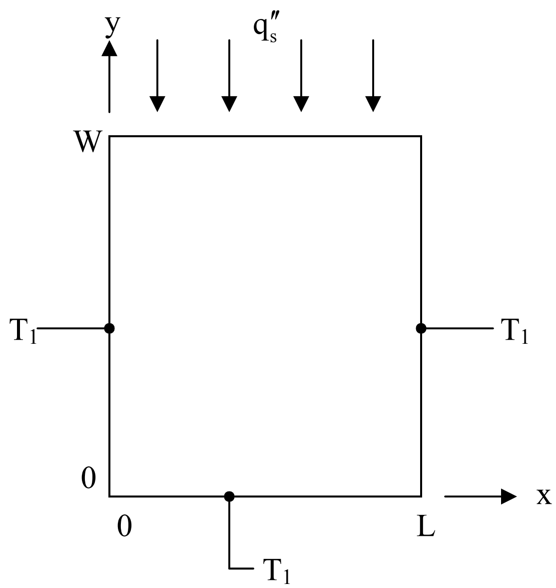
$$T(x,y) = \frac{2\ Aa}{\pi}\sum_{n=1}^{\infty}\frac{(-1)^{n+1}}{n}\cdot\sin\left[\frac{n\pi x}{a}\right]\frac{\sinh\left[\frac{n\pi y}{a}\right]}{\sinh\left[\frac{n\pi b}{a}\right]}.$$ <

PROBLEM 4.5

KNOWN: Boundary conditions on four sides of a rectangular plate.

FIND: Temperature distribution.

SCHEMATIC:



ASSUMPTIONS: (1) Two-dimensional, steady-state conduction, (2) Constant properties.

ANALYSIS: This problem differs from the one solved in Section 4.2 only in the boundary condition at the top surface. Defining $\theta = T - T_\infty$, the differential equation and boundary conditions are

$$\frac{\partial^2\theta}{\partial x^2} + \frac{\partial^2\theta}{\partial y^2} = 0$$

$$\theta(0,y) = 0 \quad \theta(L,y) = 0 \quad \theta(x,0) = 0 \quad k\left.\frac{\partial\theta}{\partial y}\right|_{y=W} = q_s'' \qquad (1a,b,c,d)$$

The solution is identical to that in Section 4.2 through Equation (4.11),

$$\theta = \sum_{n=1}^{\infty} C_n \sin\frac{n\pi x}{L}\sinh\frac{n\pi y}{L} \qquad (2)$$

To determine C_n, we now apply the top surface boundary condition, Equation (1d). Differentiating Equation (2) yields

Continued…

PROBLEM 4.5 (Cont.)

$$\left.\frac{\partial\theta}{\partial y}\right|_{y=W} = \sum_{n=1}^{\infty} C_n \frac{n\pi}{L}\sin\frac{n\pi x}{L}\cosh\frac{n\pi W}{L} \qquad (3)$$

Substituting this into Equation (1d) results in

$$\frac{q_s''}{k} = \sum_{n=1}^{\infty} A_n \sin\frac{n\pi x}{L} \qquad (4)$$

where $A_n = C_n(n\pi/L)\cosh(n\pi W/L)$. The principles expressed in Equations (4.13) through (4.16) still apply, but now with reference to Equation (4) and Equation (4.14), we should choose $f(x) = q_s''/k$, $g_n(x) = \sin\frac{n\pi x}{L}$. Equation (4.16) then becomes

$$A_n = \frac{\frac{q_s''}{k}\int_0^L \sin\frac{n\pi x}{L}dx}{\int_0^L \sin^2\frac{n\pi x}{L}dx} = \frac{q_s''}{k}\frac{2}{\pi}\frac{(-1)^{n+1}+1}{n}$$

Thus

$$C_n = 2\frac{q_s''L}{k}\frac{(-1)^{n+1}+1}{n^2\pi^2\cosh(n\pi W/L)} \qquad (5)$$

The solution is given by Equation (2) with C_n defined by Equation (5).

PROBLEM 4.6

KNOWN: Uniform media of prescribed geometry.

FIND: (a) Shape factor expressions from thermal resistance relations for the plane wall, cylindrical shell and spherical shell, (b) Shape factor expression for the isothermal sphere of diameter D buried in an infinite medium.

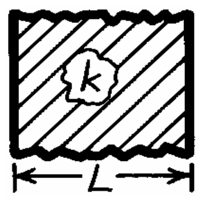
ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform properties.

ANALYSIS: (a) The relationship between the shape factor and thermal resistance of a shape follows from their definitions in terms of heat rates and overall temperature differences.

$$q = kS\Delta T \quad (4.20), \qquad q = \frac{\Delta T}{R_t} \quad (3.19), \qquad S = 1/kR_t \qquad (4.21)$$

Using the thermal resistance relations developed in Chapter 3, their corresponding shape factors are:

Plane wall:



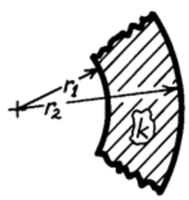
$$R_t = \frac{L}{kA} \qquad S = \frac{A}{L}.$$ <

Cylindrical shell:

$$R_t = \frac{\ln(r_2/r_1)}{2\pi Lk} \qquad S = \frac{2\pi L}{\ln r_2/r_1}.$$ <

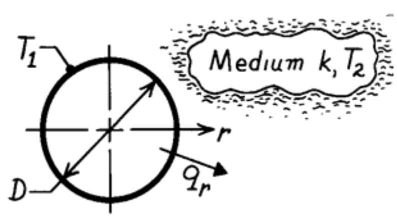
(*L into the page*)

Spherical shell:



$$R_t = \frac{1}{4\pi k}\left[\frac{1}{r_1} - \frac{1}{r_2}\right] \qquad S = \frac{4\pi}{1/r_1 - 1/r_2}.$$ <

(b) The shape factor for the sphere of diameter D in an infinite medium can be derived using the alternative conduction analysis of Section 3.2. For this situation, q_r is a constant and Fourier's law has the form



$$q_r = -k\left(4\pi\, r^2\right)\frac{dT}{dr}.$$

Separate variables, identify limits and integrate.

$$-\frac{q_r}{4\pi k}\int_{D/2}^{\infty}\frac{dr}{r^2} = \int_{T_1}^{T_2} dT \qquad -\frac{q_r}{4\pi k}\left[-\frac{1}{r}\right]_{D/2}^{\infty} = -\frac{q_r}{4\pi k}\left[0 - \frac{2}{D}\right] = \left(T_2 - T_1\right)$$

$$q_r = 4\pi k\left[\frac{D}{2}\right]\left(T_1 - T_2\right) \qquad \text{or} \qquad S = 2\pi D.$$ <

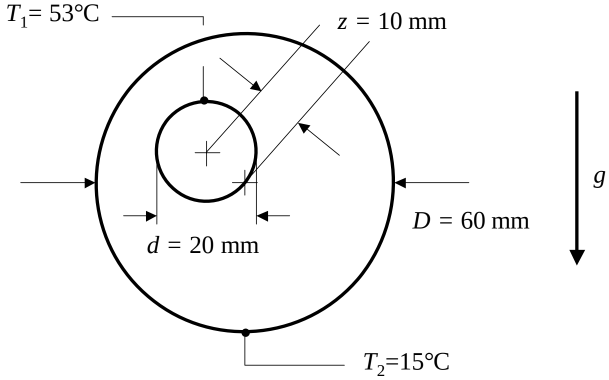
COMMENTS: Note that the result for the buried sphere, $S = 2\pi D$, can be obtained from the expression for the spherical shell with $r_2 = \infty$. Also, the shape factor expression for the "isothermal sphere buried in a semi-infinite medium" presented in Table 4.1 provides the same result with $z \to \infty$.

PROBLEM 4.7

KNOWN: Diameters and temperatures of horizontal circular cylinders. Eccentricity factor. Heat transfer rate per unit length. Fluid thermal conductivity.

FIND: Effective thermal conductivity.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Steady state conditions.

PROPERTIES: Given: k = 0.255 W/m·K.

ANALYSIS: In the absence of free convection the conduction heat transfer per unit length may be found by using the shape factor expression and applying Case 7 of Table 4.1. Hence

$$q'_{cond} = \frac{S}{L}k(T_1 - T_2) = \frac{2\pi k(T_1 - T_2)}{\cosh^{-1}\left(\frac{D^2 + d^2 - 4z^2}{2Dd}\right)} = \frac{2\pi \times 0.255 \text{ W/m}\cdot\text{K}(53-15)°\text{C}}{\cosh^{-1}\left(\frac{(60\times10^{-3}\text{m})^2 + (20\times10^{-3}\text{ m})^2 - 4\times(10\times10^{-3}\text{ m})^2}{2\times60\times10^{-3}\text{ m}\times20\times10^{-3}\text{ m}}\right)}$$

$$= 63.3 \text{ W/m}$$

The free convection heat transfer rate is

$$q'_{conv} = \frac{S}{L}k_{eff}(T_1 - T_2) = 110 \text{ W/m}$$

Therefore the effective thermal conductivity is

$$k_{eff} = k\frac{q_{conv}}{q_{cond}} = 0.255 \text{ W/m}\cdot\text{K}\cdot\frac{110 \text{ W/m}}{63.3 \text{ W/m}} = 0.44 \text{ W/m}\cdot\text{K} \quad <$$

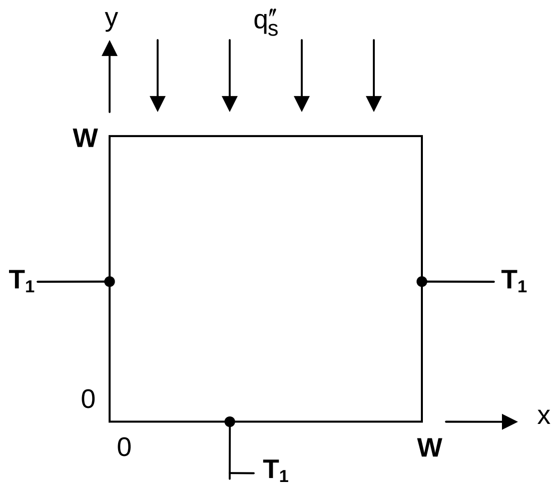
COMMENTS: Buoyancy-induced fluid motion increases the heat transfer rate between the cylinders by 74%.

PROBLEM 4.8

KNOWN: Boundary conditions on four sides of a square plate.

FIND: Expressions for shape factors associated with the *maximum* and *average* top surface temperatures. Values of these shape factors. The maximum and average temperatures for specified conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Two-dimensional, steady-state conduction, (2) Constant properties.

ANALYSIS: We must first find the temperature distribution as in Problem 4.5. Problem 4.5 differs from the problem solved in Section 4.2 only in the boundary condition at the top surface. Defining $\theta = T - T_\infty$, the differential equation and boundary conditions are

$$\frac{\partial^2\theta}{\partial x^2} + \frac{\partial^2\theta}{\partial y^2} = 0$$

$$\theta(0,y) = 0 \quad \theta(L,y) = 0 \quad \theta(x,0) = 0 \quad k\left.\frac{\partial\theta}{\partial y}\right|_{y=W} = q''_s \qquad (1a,b,c,d)$$

The solution is identical to that in Section 4.2 through Equation (4.11),

$$\theta = \sum_{n=1}^{\infty} C_n \sin\frac{n\pi x}{L}\sinh\frac{n\pi y}{L} \qquad (2)$$

To determine C_n, we now apply the top surface boundary condition, Equation (1d). Differentiating Equation (2) yields

$$\left.\frac{\partial\theta}{\partial y}\right|_{y=W} = \sum_{n=1}^{\infty} C_n \frac{n\pi}{L}\sin\frac{n\pi x}{L}\cosh\frac{n\pi W}{L} \qquad (3)$$

Continued …

PROBLEM 4.8 (Cont.)

Substituting this into Equation (1d) results in

$$\frac{q_s''}{k} = \sum_{n=1}^{\infty} A_n \sin\frac{n\pi x}{L} \tag{4}$$

where $A_n = C_n(n\pi/L)\cosh(n\pi W/L)$. The principles expressed in Equations (4.13) through (4.16) still apply, but now with reference to Equation (4) and Equation (4.14), we should choose $f(x) = q_s''/k$, $g_n(x) = \sin\frac{n\pi x}{L}$. Equation (4.16) then becomes

$$A_n = \frac{\frac{q_s''}{k}\int_0^L \sin\frac{n\pi x}{L}dx}{\int_0^L \sin^2\frac{n\pi x}{L}dx} = \frac{q_s''}{k}\frac{2}{\pi}\frac{(-1)^{n+1}+1}{n}$$

Thus

$$C_n = 2\frac{q_s''L}{k}\frac{(-1)^{n+1}+1}{n^2\pi^2\cosh(n\pi W/L)} \tag{5}$$

The solution is given by Equation (2) with C_n defined by Equation (5). We now proceed to evaluate the shape factors.

(a) The maximum top surface temperature occurs at the midpoint of that surface, x = W/2, y = W. From Equation (2) with L = W,

$$\theta(W/2,W) = T_{2,max} - T_1 = \sum_{n=1}^{\infty} C_n \sin\frac{n\pi}{2}\sinh n\pi = \sum_{n\ odd} C_n(-1)^{(n-1)/2}\sinh n\pi$$

where

$$C_n = 2\frac{q_s''W}{k}\frac{(-1)^{n+1}+1}{n^2\pi^2\cosh n\pi}$$

Thus

$$S_{max} = \frac{q_s''Wd}{k(T_{2,max} - T_1)} = \left[\frac{2}{d}\sum_{n\ odd}\frac{(-1)^{n+1}+1}{n^2\pi^2}(-1)^{(n-1)/2}\tanh n\pi\right]^{-1} = \left[\frac{4}{d}\sum_{n\ odd}\frac{(-1)^{(n-1)/2}}{n^2\pi^2}\tanh n\pi\right]^{-1} \quad <$$

where d is the depth of the rectangle into the page.

Continued…

PROBLEM 4.8 (Cont.)

(b) The average top surface temperature is given by

$$\overline{\theta}(y = W) = \overline{T}_2 - T_1 = \sum_{n=1}^{\infty} C_n \frac{1}{W} \int_0^W \sin \frac{n\pi x}{W} dx \sinh n\pi = \sum_{n=1}^{\infty} C_n \frac{1 - (-1)^n}{n\pi} \sinh n\pi$$

Thus

$$\overline{S} = \frac{q_s'' W d}{k(\overline{T}_2 - T_1)} = \left[\frac{2}{d} \sum_{n=1}^{\infty} \frac{[(-1)^{n+1} + 1][1 - (-1)^n]}{n^3 \pi^3} \tanh n\pi \right]^{-1} = \left[\frac{8}{d} \sum_{n \text{ odd}} \frac{1}{n^3 \pi^3} \tanh n\pi \right]^{-1}$$ <

(c) Evaluating the expressions for the shape factors yields

$$\frac{S_{max}}{d} = \left[4 \sum_{n \text{ odd}} \frac{(-1)^{(n-1)/2}}{n^2 \pi^2} \tanh n\pi \right]^{-1} = 2.70$$ <

$$\frac{\overline{S}}{d} = \left[8 \sum_{n \text{ odd}} \frac{1}{n^3 \pi^3} \tanh n\pi \right]^{-1} = 3.70$$ <

The temperatures can then be found from

$$T_{2,max} = T_1 + \frac{q}{S_{max} k} = T_1 + \frac{q_s'' W d}{S_{max} k} = 0°C + \frac{1000 \text{ W/m}^2 \times 0.01 \text{ m}}{2.70 \times 20 \text{ W/m} \cdot \text{K}} = 0.19°C$$ <

$$\overline{T}_2 = T_1 + \frac{q}{\overline{S} k} = T_1 + \frac{q_s'' W d}{\overline{S} k} = 0°C + \frac{1000 \text{ W/m}^2 \times 0.01 \text{ m}}{3.70 \times 20 \text{ W/m} \cdot \text{K}} = 0.14°C$$ <

PROBLEM 4.9

KNOWN: Heat generation in a buried spherical container.

FIND: (a) Outer surface temperature of the container, (b) Representative isotherms and heat flow lines.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Soil is a homogeneous medium with constant properties.

PROPERTIES: *Table A-3,* Soil (300K): k = 0.52 W/m·K.

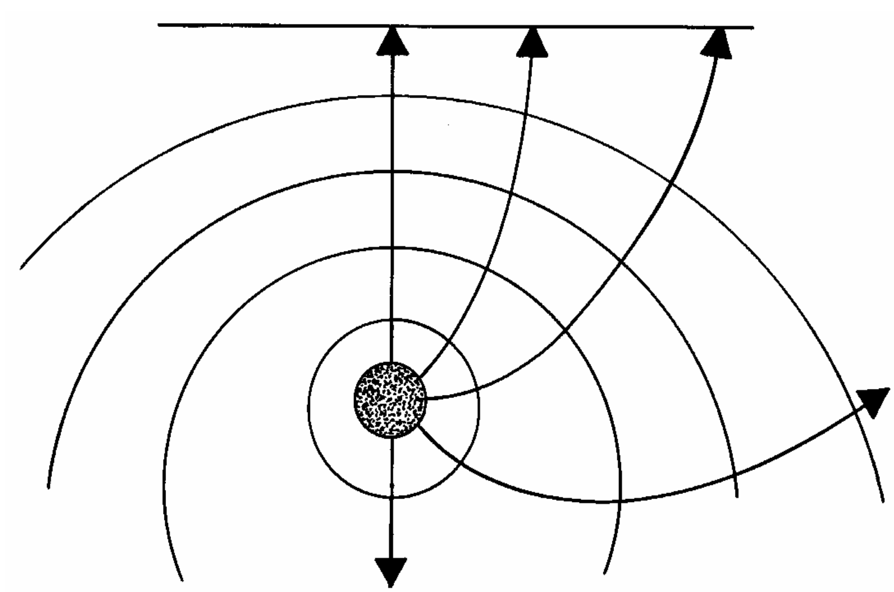
ANALYSIS: (a) From an energy balance on the container, $q = \dot{E}_g$ and from the first entry in Table 4.1,

$$q = \frac{2\pi D}{1 - D/4z} k \left(T_1 - T_2\right).$$

Hence,

$$T_1 = T_2 + \frac{q}{k}\frac{1 - D/4z}{2\pi D} = 20^\circ C + \frac{500\,W}{0.52\,\frac{W}{m \cdot K}} \frac{1 - 2m/40m}{2\pi\left(2m\right)} = 92.7^\circ C$$ <

(b) The isotherms may be viewed as spherical surfaces whose center moves downward with increasing radius. The surface of the soil is an isotherm for which the center is at z = ∞.

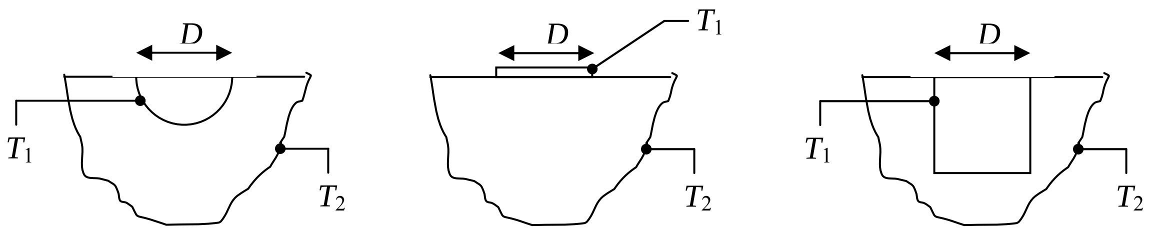


PROBLEM 4.10

KNOWN: Shape of objects at surface of semi-infinite medium.

FIND: Shape factors between object at temperature T_1 and semi-infinite medium at temperature T_2.

SCHEMATIC:



(a) (b) (c)

ASSUMPTIONS: (1) Steady-state, (2) Medium is semi-infinite, (3) Constant properties, (4) Surface of semi-infinite medium is adiabatic.

ANALYSIS: Cases 12 -15 of Table 4.1 all pertain to objects buried in an infinite medium. Since they all possess symmetry about a horizontal plane that bisects the object, they are equivalent to the cases given in this problem for which the horizontal plane is adiabatic. In particular, the heat flux is the same for the cases of this problem as for the cases of Table 4.1. Note, that when we use Table 4.1 to determine the dimensionless conduction heat rate, q_{ss}^*, we must be consistent and use the surface area of the "entire" object of Table 4.1, not the "half" object of this problem. Then

$$q'' = \frac{q}{A_s} = \frac{q_{ss}^* k(T_1 - T_2)}{L_c}$$

where $L_c = (A_s/4\pi)^{1/2}$ and A_s is the area given in Table 4.1

When we calculate the shape factors we must account for the fact that the surface areas and heat transfer rates for the objects of this problem are half as much as for the objects of Table 4.1.

$$S = \frac{q}{k(T_1 - T_2)} = \frac{q'' A_s/2}{k(T_1 - T_2)} = \frac{q_{ss}^* A_s}{2L_c} = \frac{q_{ss}^* (4\pi A_s)^{1/2}}{2}$$

where A_s is still the area in table 4.1 and the 2 in the denominator accounts for the area being halved. Thus, finally,

$$S = q_{ss}^* (\pi A_s)^{1/2}$$

(a) $S = 1 \cdot (\pi \cdot \pi D^2)^{1/2} = \pi D$ <

(b) $S = \dfrac{2\sqrt{2}}{\pi}\left(\pi \cdot \dfrac{\pi D^2}{2}\right)^{1/2} = 2D$ <

This agrees with Table 4.1a, Case 10.

(c) $S = 0.932(\pi \cdot 2D^2)^{1/2} = \sqrt{2\pi}(0.932)D = 2.34D$ <

(d) The height of the "whole object" is d = 2D. Thus

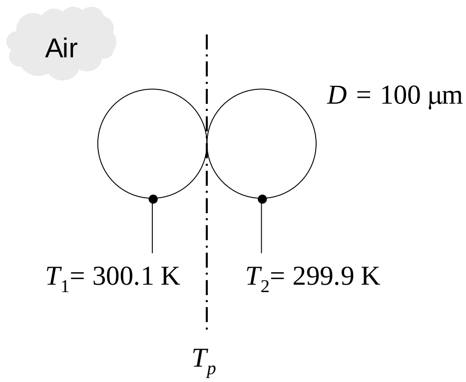
$$S = 0.961\left[\pi\left(2D^2 + 4D \cdot 2D\right)\right]^{1/2} = \sqrt{10\pi}(0.961)D = 5.39D$$ <

PROBLEM 4.11

KNOWN: Diameters and temperatures of spherical particles that are in contact.

FIND: Heat transfer rate.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Isothermal particles.

PROPERTIES: Table A.4, Air (300 K): k = 0.0263 W/m·K.

ANALYSIS: By symmetry, the vertical plane at the particle contact point is at temperature $T_p = (T_1 + T_2)/2$ = 300 K. Therefore, conduction between the particles q_{12} is equal to conduction from particle 1 to the plane, $q_{1p} = Sk(T_1 - T_p)$. The shape factor is that of Case 1 of Table 4.1 evaluated at $z = D/2$ yielding $S = 4\pi D$. Therefore,

$$q_{12} = q_{1p} = 4\pi Dk\left(T_1 - \frac{T_1 + T_2}{2}\right) = 4\pi \times 100 \times 10^{-6}\,\text{m} \times 0.0263\ \text{W/m}\cdot\text{K} \times 0.1\ \text{K} = 3.3\times10^{-6}\ \text{W} = 3.3\mu\text{W}$$ <

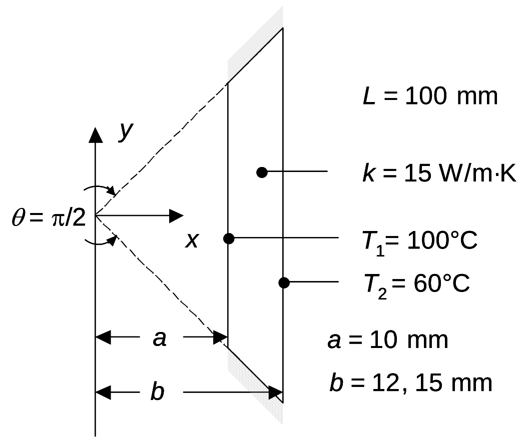
COMMENTS: (1) The air thermal conductivity in the vicinity of the contact point would be reduced by nanoscale effects such as those described in Chapter 2. In applying the shape factor of Case 1 of Table 4.1 to the $z = D/2$ situation we have implicitly assumed that nanoscale effects are negligible. See B. Gebhart, *Heat Conduction and Mass Diffusion*, McGraw-Hill, 1993 for an appropriate treatment of nanoscale phenomena for this geometry. (2) The effective thermal conductivity of porous media composed of high thermal conductivity particles, such as packed metal powder layers, may be estimated by accounting for the particle size and packing distribution and using an analysis such as the one presented here.

PROBLEM 4.12

KNOWN: Dimensions of a two-dimensional object, applied boundary conditions and thermal conductivity.

FIND: (a) Shape factor for the object if the dimensions are a = 10 mm, b = 12 mm. (b) Shape factor for a = 10 mm, b = 15 mm. (c) Shape factor for cases (a) and (b) using the alternative conduction analysis (d) For T_1 = 100°C and T_2 = 60°C, determine the heat transfer rate per unit depth for k = 15 W/m·K for cases (a) and (b).

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties.

PROPERTIES: Given: k = 15 W/m·K.

ANALYSIS: (a) The geometry and applied boundary conditions correspond to Case 11 of Table 4.1(a). Noting that the diagonals of the square channel of Case 11 are adiabats, the shape factor for $b/a = W/w$ = 12/10 = 1.2 is one-fourth the shape factor given in Table 4.1(a),

$$S = 0.25 \times \frac{2\pi L}{0.785 \ln(W/w)} = \frac{2.00L}{\ln(W/w)} = \frac{2.00 \times 0.10\text{m}}{\ln(1.2)} = 1.097 \quad <$$

(b) For $b/a = W/w$ = 15/10 = 1.5,

$$S = 0.25 \times \frac{2\pi L}{0.930 \ln(W/w) - 0.050} = \frac{1.69L}{\ln(W/w) - 0.0534} = \frac{1.69 \times 0.10\text{m}}{\ln(1.5) - 0.0534} = 0.480 \quad <$$

(c) From the one-dimensional alternative conduction analysis with the top surface described by $y = x$ and $A = 2yL$,

$$q_x = -kA\frac{dT}{dx} = -2kLx\frac{dT}{dx}$$

Separating variables and integrating yields

$$\int_{x=a}^{b} \frac{dx}{x} = -\frac{2kL}{q_x}\int_{T_1}^{T_2} dT \quad \text{or} \quad \ln(b/a) = \frac{2kL}{q_x}(T_1 - T_2)$$

Hence, $S_{1\text{-D}} = 2L/[\ln(b/a)]$.

Continued…

PROBLEM 4.12 (Cont.)

For b/a = 1.2, $S_{1\text{-D}}$ = 2 × 0.1m/[ln(1.2)] = 1.097. For b/a = 1.5, $S_{1\text{-D}}$ = 2 × 0.1m/[ln(1.5)] = 0.493. <

As b/a becomes small, the influence of the lateral edges is diminished and one-dimensional conditions are approached. Hence, the shape factor estimated using the one-dimensional alternative conduction solution is nearly the same as for the two-dimensional shape factor for b/a = 1.2. As b/a is increased, the lateral edge effects become more important, and the shape factors obtained by the two methods begin to diverge in value. As two-dimensional conduction in the object becomes more pronounced, the heat transfer rate is decreased relative to that associated with the assumed one-dimensional conditions.

(d) For b/a = 1.2, the heat transfer rate is

$$q = Sk(T_1 - T_2) = 1.097 \times 15\ \mathrm{W/m \cdot K} \times (100 - 60)^\circ\mathrm{C} = 658\ \mathrm{W}$$ <

for b/a = 1.5, the heat transfer rate is

$$q = Sk(T_1 - T_2) = 0.480 \times 15\ \mathrm{W/m \cdot K} \times (100 - 60)^\circ\mathrm{C} = 288\ \mathrm{W}$$ <

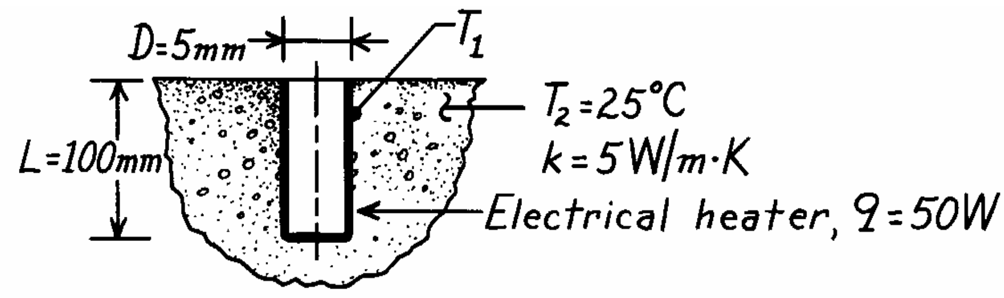
COMMENTS: The heat transfer rate is independent of the individual values of a or b. As either b or a is increased while maintaining a fixed b/a ratio, the cross-sectional area for heat transfer increases, but the increase is offset by increased thickness through which the conduction occurs. The offsetting effects balance one another, and the net result is no change in the heat transfer rate.

PROBLEM 4.13

KNOWN: Electrical heater of cylindrical shape inserted into a hole drilled normal to the surface of a large block of material with prescribed thermal conductivity.

FIND: Temperature reached when heater dissipates 50 W with the block at 25°C.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Block approximates semi-infinite medium with constant properties, (3) Negligible heat loss to surroundings above block surface, (4) Heater can be approximated as isothermal at T_1.

ANALYSIS: The temperature of the heater surface follows from the rate equation written as

$$T_1 = T_2 + q/kS$$

where S can be estimated from the conduction shape factor given in Table 4.1 for a "vertical cylinder in a semi-infinite medium,"

$$S = 2\pi L/\ell n\left(4L/D\right).$$

Substituting numerical values, find

$$S = 2\pi \times 0.1\text{m}/\ell n\left[\frac{4\times 0.1\text{m}}{0.005\text{m}}\right] = 0.143\text{m}.$$

The temperature of the heater is then

$$T_1 = 25°\text{C} + 50\ \text{W}/(5\ \text{W/m·K} \times 0.143\text{m}) = 94.9°\text{C}.$$ <

COMMENTS: (1) Note that the heater has L >> D, which is a requirement of the shape factor expression.

(2) Our calculation presumes there is negligible thermal contact resistance between the heater and the medium. In practice, this would not be the case unless a conducting paste were used.

(3) Since L >> D, assumption (3) is reasonable.

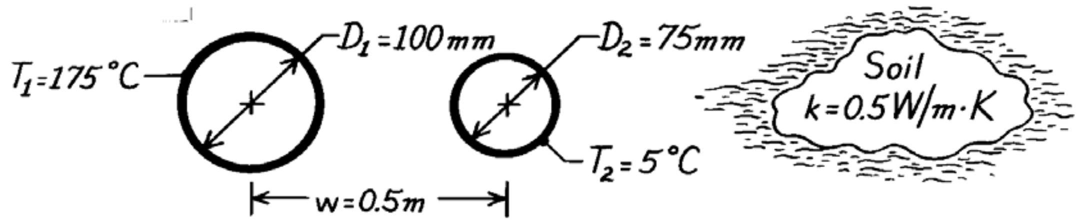
(4) This configuration has been used to determine the thermal conductivity of materials from measurement of q and T_1.

PROBLEM 4.14

KNOWN: Surface temperatures of two parallel pipe lines buried in soil.

FIND: Heat transfer per unit length between the pipe lines.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties, (4) Pipe lines are buried very deeply, approximating burial in an infinite medium, (5) Pipe length >> D_1 or D_2 and w > D_1 or D_2.

ANALYSIS: The heat transfer rate per unit length from the hot pipe to the cool pipe is

$$q' = \frac{q}{L} = \frac{S}{L}k\left(T_1 - T_2\right).$$

The shape factor S for this configuration is given in Table 4.1 as

$$S = \frac{2\pi L}{\cosh^{-1}\left[\dfrac{4w^2 - D_1^2 - D_2^2}{2D_1 D_2}\right]}.$$

Substituting numerical values,

$$\frac{S}{L} = 2\pi / \cosh^{-1}\left[\frac{4\times(0.5\text{m})^2 - (0.1\text{m})^2 - (0.075\text{m})^2}{2\times 0.1\text{m}\times 0.075\text{m}}\right] = 2\pi / \cosh^{-1}(65.63)$$

$$\frac{S}{L} = 2\pi / 4.88 = 1.29.$$

Hence, the heat rate per unit length is

$$q' = 1.29\times 0.5\text{W/m}\cdot\text{K}\left(175-5\right)^\circ\text{C} = 110\ \text{W/m}.$$ <

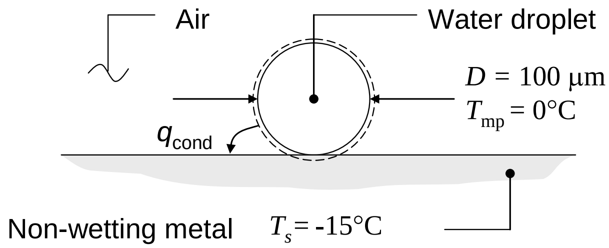
COMMENTS: The heat gain to the cooler pipe line will be larger than 110 W/m if the soil temperature is greater than 5°C. How would you estimate the heat gain if the soil were at 25°C?

PROBLEM 4.15

KNOWN: Dimensions and temperature of water droplet.

FIND: Time for droplet to freeze completely.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Negligible convection and radiation, (3) Isothermal water particle, (4) Semi-infinite medium.

PROPERTIES: Table A.4, Air (265 K): k_a = 0.0235 W/m·K. Table A.6, Liquid water (273 K): ρ_w = 1000 kg/m^3.

ANALYSIS: An energy balance on the droplet yields

$$t = \frac{\Delta E}{q_{\text{cond}}} = \frac{V\rho_w h_{sf}}{Sk(T_{\text{mp}} - T_s)} \tag{1}$$

The shape factor S is that of Case 1 of Table 4.1 with $z = D/2$

$$S = \frac{2\pi D}{1 - D/4z} = 4\pi D \tag{2}$$

Combining Equations (1) and (2) with the expression for the droplet volume $V = \pi D^3/6$ yields

$$t = \frac{D^2 \rho_w h_{sf}}{24 k_a (T_{mp} - T_s)} = \frac{(100 \times 10^{-6}\ \text{m})^2 \times 1000\ \text{kg/m}^3 \times 334{,}000\ \text{J/kg}}{24 \times 0.0235\ \text{W/m}\cdot\text{K} \times 15\ \text{K}} = 0.39\ \text{s}$$ <

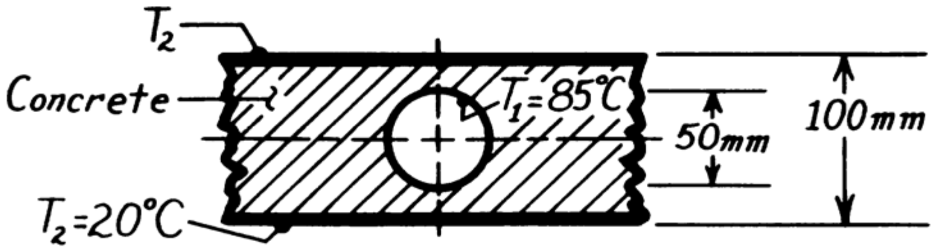
COMMENTS: (1) Solidification might initiate in the lower region of the droplet. The ice that forms would pose an additional conduction resistance between the cold metal surface and the liquid water. This would increase the time needed for the droplet to solidify completely. (2) The air thermal conductivity in the vicinity of the contact point would be reduced by the nanoscale effects described in Chapter 2. In applying this shape factor for the $z = D/2$ case we have implicitly assumed that nanoscale effects are negligible. See B. Gebhart, *Heat Conduction and Mass Diffusion*, McGraw-Hill, 1993.

PROBLEM 4.16

KNOWN: Tube embedded in the center plane of a concrete slab.

FIND: The shape factor and heat transfer rate per unit length using the appropriate tabulated relation,

SCHEMATIC:



ASSUMPTIONS: (1) Two-dimensional conduction, (2) Steady-state conditions, (3) Constant properties, (4) Concrete slab infinitely long in horizontal plane, L >> z.

PROPERTIES: *Table A-3*, Concrete, stone mix (300K): k = 1.4 W/m·K.

ANALYSIS: If we relax the restriction that z >> D/2, the embedded tube-slab system corresponds to the fifth case of Table 4.1. Hence,

$$S = \frac{2\pi L}{\ell n(8z/\pi D)}$$

where L is the length of the system normal to the page, z is the half-thickness of the slab and D is the diameter of the tube. Substituting numerical values, find

$$S = 2\pi L/\ell n(8 \times 50\text{mm}/\pi 50\text{mm}) = 6.72L.$$

Hence, the heat rate per unit length is

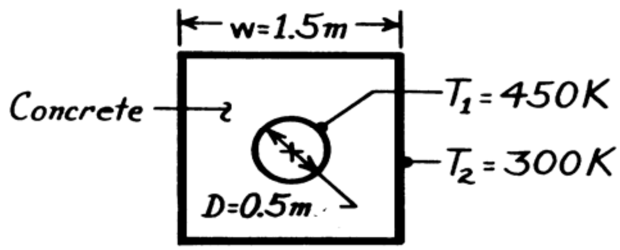
$$q' = \frac{q}{L} = \frac{S}{L} k(T_1 - T_2) = 6.72 \times 1.4 \frac{W}{m \cdot K}(85 - 20)^\circ C = 612 \text{ W}.$$

PROBLEM 4.17

KNOWN: Dimensions and boundary temperatures of a steam pipe embedded in a concrete casing.

FIND: Heat loss per unit length.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible steam side convection resistance, pipe wall resistance and contact resistance (T_1 = 450K), (3) Constant properties.

PROPERTIES: *Table A-3*, Concrete (300K): k = 1.4 W/m·K.

ANALYSIS: The heat rate can be expressed as

$$q = Sk\Delta T_{1\text{-}2} = Sk\left(T_1 - T_2\right)$$

From Table 4.1, the shape factor is

$$S = \frac{2\pi L}{\ell n\left[\frac{1.08\ w}{D}\right]}.$$

Hence,

$$q' = \left[\frac{q}{L}\right] = \frac{2\pi k\left(T_1 - T_2\right)}{\ell n\left[\frac{1.08\ w}{D}\right]}$$

$$q' = \frac{2\pi \times 1.4\text{W/m}\cdot\text{K} \times \left(450 - 300\right)\text{K}}{\ell n\left[\frac{1.08 \times 1.5\text{m}}{0.5\text{m}}\right]} = 1122\ \text{W/m}.$$ <

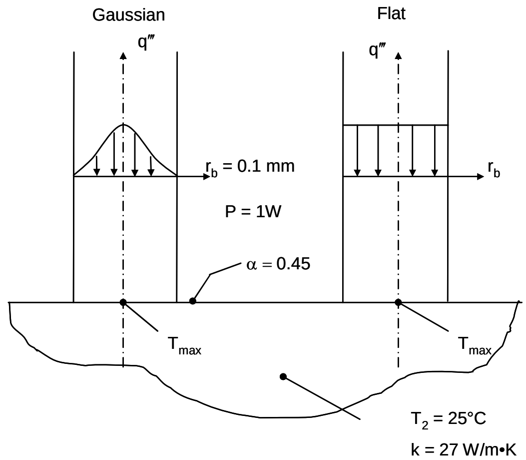
COMMENTS: Having neglected the steam side convection resistance, the pipe wall resistance, and the contact resistance, the foregoing result overestimates the actual heat loss.

PROBLEM 4.18

KNOWN: Power, size and shape of laser beam. Material properties.

FIND: Maximum surface temperature for a Gaussian beam, maximum temperature for a flat beam, and average temperature for a flat beam.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Semi-infinite medium, (4) Negligible heat loss from the top surface.

ANALYSIS: The shape factor is defined in Eq. 4.20 and is $q = Sk\Delta T_{1-2}$ (1)

From the problem statement and Section 4.3, the shape factors for the three cases are:

Beam Shape	Shape Factor	$T_{1,avg}$ or $T_{1,max}$
Gaussian	$2\sqrt{\pi}r_b$	$T_{1,max}$
Flat	πr_b	$T_{1,max}$
Flat	$3\pi^2 r_b/8$	$T_{1,avg}$

For the Gaussian beam, $S_1 = 2\sqrt{\pi} \times 0.1 \times 10^{-3}\text{ m} = 354 \times 10^{-6}\text{ m}$

For the flat beam (max. temperature), $S_2 = \pi \times 0.1 \times 10^{-3}\text{ m} = 314 \times 10^{-6}\text{ m}$

For the flat beam (avg. temperature), $S_3 = (3/8) \times \pi^2 \times 0.1 \times 10^{-3}\text{ m} = 370 \times 10^{-6}\text{ m}$

The temperature at the heated surface for the three cases is evaluated from Eq. (1) as

$$T_1 = T_2 + q/Sk = T_2 + P\alpha/Sk$$

For the Gaussian beam, $T_{1,max} = 25°C + 1\text{ W} \times 0.45 / (354 \times 10^{-6}\text{ m} \times 27\text{ W/m}\cdot\text{K}) = 72.1°C$ <

For the flat beam (T_{max}), $T_{1,max} = 25°C + 1\text{ W} \times 0.45 / (314 \times 10^{-6}\text{ m} \times 27\text{ W/m}\cdot\text{K}) = 78.1°C$ <

For the flat beam (T_{avg}), $T_{1,avg} = 25°C + 1\text{ W} \times 0.45 / (370 \times 10^{-6}\text{ m} \times 27\text{ W/m}\cdot\text{K}) = 70.0°C$ <

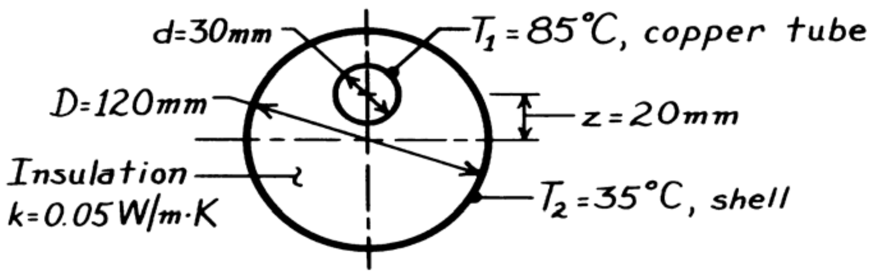
COMMENTS: (1) The maximum temperature occurs at r = 0 for all cases. For the flat beam, the maximum temperature exceeds the average temperature by 78.1 – 70.0 = 8.1 degrees Celsius.

PROBLEM 4.19

KNOWN: Thin-walled copper tube enclosed by an eccentric cylindrical shell; intervening space filled with insulation.

FIND: Heat loss per unit length of tube; compare result with that of a concentric tube-shell arrangement.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Thermal resistances of copper tube wall and outer shell wall are negligible, (4) Two-dimensional conduction in insulation.

ANALYSIS: The heat loss per unit length written in terms of the shape factor S is $q' = k(S/\ell)(T_1 - T_2)$ and from Table 4.1 for this geometry,

$$\frac{S}{\ell} = 2\pi / \cosh^{-1}\left[\frac{D^2 + d^2 - 4z^2}{2Dd}\right].$$

Substituting numerical values, all dimensions in mm,

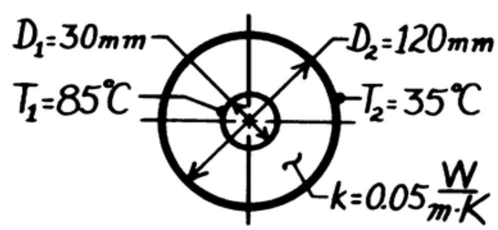
$$\frac{S}{\ell} = 2\pi / \cosh^{-1}\left[\frac{120^2 + 30^2 - 4(20)^2}{2 \times 120 \times 30}\right] = 2\pi / \cosh^{-1}(1.903) = 4.991.$$

Hence, the heat loss is

$$q' = 0.05 \text{W/m} \cdot \text{K} \times 4.991(85 - 35)^\circ \text{C} = 12.5 \text{ W/m}.$$ <

If the copper tube were concentric with the shell, but all other conditions were the same, the heat loss would be

$$q_c' = \frac{2\pi\, k(T_1 - T_2)}{\ell n(D_2 / D_1)}$$



using Eq. 3.27. Substituting numerical values,

$$q_c' = 2\pi \times 0.05 \frac{\text{W}}{\text{m} \cdot \text{K}}(85 - 35)^\circ \text{C}/\ell n\left(120/30\right)$$

$$q_c' = 11.3 \text{ W/m}.$$

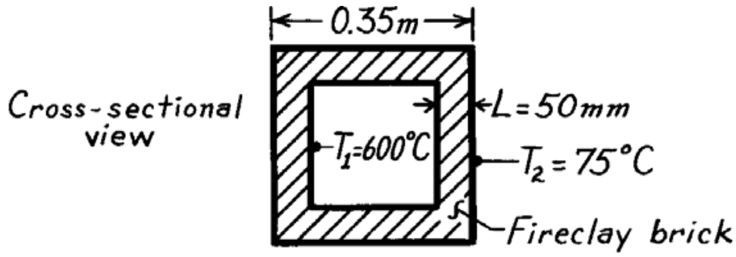
COMMENTS: As expected, the heat loss with the eccentric arrangement is larger than that for the concentric arrangement. The effect of the eccentricity is to increase the heat loss by (12.5 - 11.3)/11.3 ≈ 11%.

PROBLEM 4.20

KNOWN: Cubical furnace, 350 mm external dimensions, with 50 mm thick walls.

FIND: The heat loss, q(W).

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties.

PROPERTIES: *Table A-3,* Fireclay brick $\left(\bar{T} = \left(T_1 + T_2\right)/2 = 610\text{K}\right)$: $k \approx 1.1$ W/m·K.

ANALYSIS: Using relations for the shape factor from Table 4.1,

Plane Walls (6) $\qquad S_W = \dfrac{A}{L} = \dfrac{0.25 \times 0.25\text{m}^2}{0.05\text{m}} = 1.25\text{m}$

Edges (12) $\qquad S_E = 0.54D = 0.54 \times 0.25\text{m} = 0.14\text{m}$

Corners (8) $\qquad S_C = 0.15L = 0.15 \times 0.05\text{m} = 0.008\text{m}.$

The heat rate in terms of the shape factors is

$$q = kS\left(T_1 - T_2\right) = k\left(6S_W + 12S_E + 8S_C\right)\ \left(T_1 - T_2\right)$$

$$q = 1.1\frac{\text{W}}{\text{m}\cdot\text{K}}\left(6\times1.25\text{m}+12\times0.14\text{m}+8\times0.008\text{m}\right)\ \left(600-75\right)^\circ\text{C}$$

$$q = 5.30\ \text{kW}.$$ <

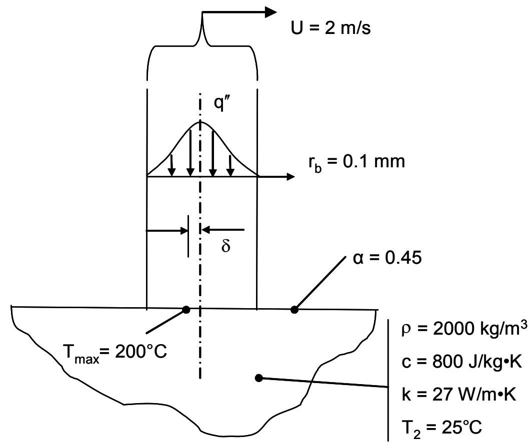
COMMENTS: Note that the restrictions for S_E and S_C have been met.

PROBLEM 4.21

KNOWN: Relation between maximum material temperature and its location, and scanning velocities.

FIND: (a) Required laser power to achieve a desired operating temperature for given material, beam size and velocity, (b) Lag distance separating the center of the beam and the location of maximum temperature, (c) Plot of the required laser power for velocities in the range $0 \le U \le 2$ m/s.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Semi-infinite medium, (4) Negligible heat loss from the top surface.

ANALYSIS: The thermal diffusivity of the materials is

$$\alpha = k/\rho c = 27 \text{ W/m} \cdot \text{K} / (2000 \text{ kg/m}^3 \cdot 800 \text{ J/kg} \cdot \text{K}) = 16.9 \times 10^{-6} \text{ m}^2\text{/s}$$

(a) The Peclet number is

$$Pe = Ur_b / \sqrt{2}\alpha = 2 \text{ m/s} \times 0.0001 \text{ m} / (\sqrt{2} \times 16.9 \times 10^{-6} \text{ m}^2\text{/s}) = 8.38$$

Since this value of the Peclet number is within the range of the correlation provided in the problem statement, the maximum temperature corresponding to a stationary beam delivering the same power would be

$$T_{1,max,U=0} = (1 + 0.301Pe - 0.0108Pe^2)(T_{1,maxU\neq0} - T_2) + T_2$$
$$= (1 + 0.301 \times 8.37 - 0.0108 \times 8.37^2) \times (200 - 25)°C + 25°C$$
$$= 509°C.$$

From Eq. 4.20 and Problem 4.18 we know that (with the symbol $\hat{\alpha}$ now representing the absorptivity, since α is used for thermal diffusivity)

Continued…

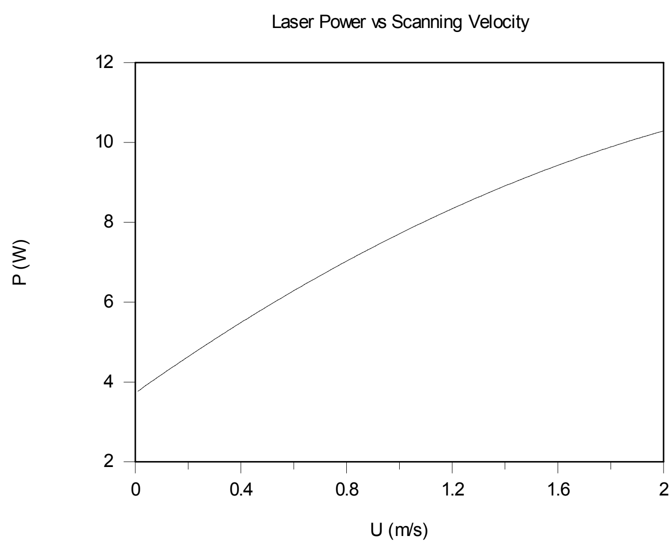
PROBLEM 4.21 (Cont.)

$P = Sk\Delta T_{1\text{-}2} / \hat{\alpha} = 2\sqrt{\pi} r_b k \Delta T_{1\text{-}2}/\hat{\alpha} = 2\sqrt{\pi} \times 0.0001 \text{ m} \times 27 \text{ W/m} \cdot \text{K} \times (509 - 25)°\text{C} / 0.45$
$= 10.3 \text{ W}$ <

(b) The lag distance is

$$\delta = 0.944 \frac{\alpha}{U} Pe^{1.55} = 0.944 \times \frac{16.9 \times 10^{-6} \text{ m}^2/\text{s}}{2 \text{ m/s}} \times 8.37^{1.55} = 0.21 \text{ mm}$$ <

(c) The plot of the required laser power versus scanning velocity is shown below.



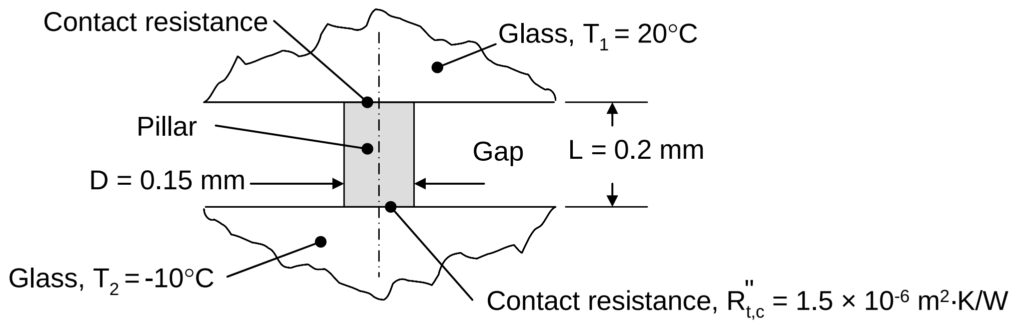
COMMENTS: (1) The required laser power increases as the scanning velocity increases since more material must be heated at higher scanning velocities. (2) The relative motion between the laser beam and the heated material represents an advection process. Advective effects will be dealt with extensively in Chapters 6 through 9.

PROBLEM 4.22

KNOWN: Dimensions of stainless steel pillar and nominal glass temperatures. Contact resistance between pillar and glass.

FIND: Conduction rate through the pillar.

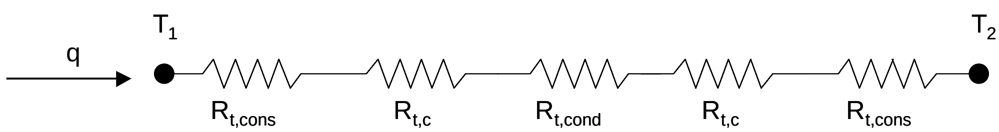
SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible radiation, (4) Two-dimensional conduction, (5) Glass behaves as a semi-infinite medium.

PROPERTIES: Table A.1, AISI 302 stainless steel (300 K): k_p = 15.1 W/m·K. Table A.3, plate glass (300 K): k_g = 1.4 W/m·K.

ANALYSIS: Conduction through the pillar results in a depression of the glass temperature adjacent to the pillar. This is associated with a *constriction resistance* within each glass sheet. Therefore, the resistance network consists of two constriction resistances, two contact resistances, and a conduction resistance through the pillar as shown below.



Using the shape factor for Case 10 of Table 4.1(a) the resistances are:

$$R_{t,\text{cons}} = 1/(Sk_g) = 1/(2Dk_g) = 1/(2 \times 0.15 \times 10^{-3}\text{m} \times 1.4 \text{ W/m}\cdot\text{K}) = 2381 \text{ K/W}$$

$$R_{t,\text{c}} = R''_{t,c}/A_p = 1.5 \times 10^{-6}\text{m}^2\cdot\text{K/W}/\left[\pi \times \left(0.15 \times 10^{-3}\text{m}\right)^2/4\right] = 84.88 \text{ K/W}$$

$$R_{t,\text{cond}} = L/k_p A_p = L/k_p\left(\pi D_p^2/4\right) = 0.2 \times 10^{-3} \text{ m}/\left[15.1 \text{ W/m}\cdot\text{K} \times \pi \times \left(0.15 \times 10^{-3} \text{ m}\right)^2/4\right] = 749.5 \text{ K/W}$$

Therefore, the total resistance is

$$R_{tot} = 2(R_{t,cons} + R_{t,c}) + R_{t,cond} = 2 \times (2381 \text{ K/W} + 84.88 \text{ K/W}) + 749.5 \text{ K/W} = 5681 \text{ K/W}$$

and the conduction through an individual pillar is

$$q = (T_1 - T_2)/R_{tot} = [20 - (-10)°\text{C}]/[5681 \text{ K/W}] = 5.28 \times 10^{-3} \text{ W} = 5.28 \text{ mW}$$ <

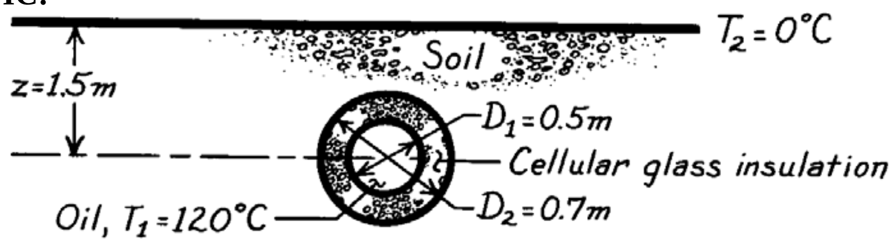
COMMENTS: (1) Constriction of the heat flow within the glass poses the largest resistance to heat transfer. (2) Radiation between the two glass sheets exists, and may be important in determining the overall heat transfer through the window. (3) Extremely high vacuum between the two glass sheets is required to eliminate conduction within the gap. (4) See Manz, Brunner and Wullschleger, "Triple Vacuum Glazing: Heat Transfer and Basic Design Constraints," *Solar Energy*, Vol. 80, pp. 1632-1642, 2006 for more information.

PROBLEM 4.23

KNOWN: Temperature, diameter and burial depth of an insulated pipe.

FIND: Heat loss per unit length of pipe.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction through insulation, two-dimensional through soil, (3) Constant properties, (4) Negligible oil convection and pipe wall conduction resistances.

PROPERTIES: *Table A-3*, Soil (300K): k = 0.52 W/m·K; *Table A-3*, Cellular glass (365K): k = 0.069 W/m·K.

ANALYSIS: The heat rate can be expressed as

$$q = \frac{T_1 - T_2}{R_{tot}}$$

where the thermal resistance is $R_{tot} = R_{ins} + R_{soil}$. From Equation 3.33,

$$R_{ins} = \frac{\ell n\left(D_2 / D_1\right)}{2\pi\ Lk_{ins}} = \frac{\ell n\left(0.7\text{m}/0.5\text{m}\right)}{2\pi\ L \times 0.069\ \text{W/m}\cdot\text{K}} = \frac{0.776\text{m}\cdot\text{K/W}}{L}.$$

From Equation 4.21 and Table 4.1,

$$R_{soil} = \frac{1}{Sk_{soil}} = \frac{\cosh^{-1}\left(2z/D_2\right)}{2\pi\ Lk_{soil}} = \frac{\cosh^{-1}\left(3/0.7\right)}{2\pi \times \left(0.52\ \text{W/m}\cdot\text{K}\right)L} = \frac{0.653}{L}\text{m}\cdot\text{K/W}.$$

Hence,

$$q = \frac{\left(120-0\right)^{\circ}\text{C}}{\frac{1}{L}\left(0.776+0.653\right)\frac{\text{m}\cdot\text{K}}{\text{W}}} = 84\frac{\text{W}}{\text{m}} \times L$$

$$q' = q/L = 84\ \text{W/m}.$$ <

COMMENTS: (1) Contributions of the soil and insulation to the total resistance are approximately the same. The heat loss may be reduced by burying the pipe deeper or adding more insulation.

(2) The convection resistance associated with the oil flow through the pipe may be significant, in which case the foregoing result would overestimate the heat loss. A calculation of this resistance may be based on results presented in Chapter 8.

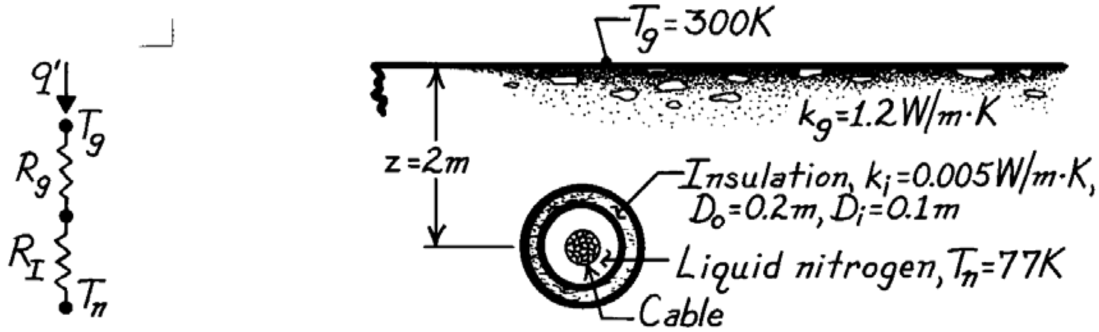
(3) Since z > 3D/2, the shape factor for the soil can also be evaluated from $S = 2\pi L/\ell n(4z/D)$ of Table 4.1, and an equivalent result is obtained.

PROBLEM 4.24

KNOWN: Operating conditions of a buried superconducting cable.

FIND: Required cooling load.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Two-dimensional conduction in soil, (4) One-dimensional conduction in insulation, (5) Pipe inner surface is at liquid nitrogen temperature.

ANALYSIS: The heat rate per unit length is

$$q' = \frac{T_g - T_n}{R'_g + R'_I}$$

$$q' = \frac{T_g - T_n}{\left[k_g\left(2\pi/\ln\left(4z/D_o\right)\right)\right]^{-1} + \ln\left(D_o / D_i\right)/2\pi\ k_i}$$

where Tables 3.3 and 4.1 have been used to evaluate the insulation and ground resistances, respectively. Hence,

$$q' = \frac{\left(300 - 77\right)K}{\left[\left(1.2\ W/m\cdot K\right)\left(2\pi / \ln\left(8/0.2\right)\right)\right]^{-1} + \ln\left(2\right)/2\pi\times 0.005\ W/m\cdot K}$$

$$q' = \frac{223\ K}{\left(0.489+22.064\right)m\cdot K/W}$$

$$q' = 9.9\ W/m.$$ <

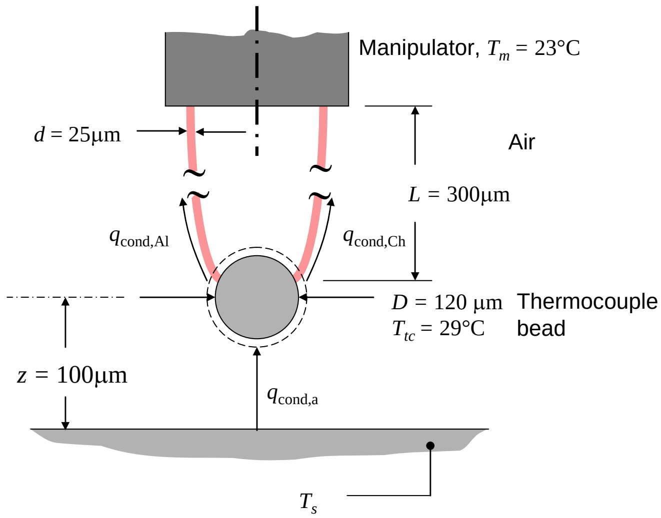
COMMENTS: The heat gain is small and the dominant contribution to the thermal resistance is made by the insulation.

PROBLEM 4.25

KNOWN: Dimensions and temperature of thermocouple bead and wires. Manipulator temperature, distance between bead and surface.

FIND: Surface temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Negligible radiation and convection, (3) Isothermal thermocouple bead, (4) Air behaves as a semi-infinite medium, (5) Steady state conditions.

PROPERTIES: Table A.4, Air (310 K): k_a = 0.027 W/m·K.

ANALYSIS: An energy balance on the thermocouple bead yields

$$q_{\text{cond,air}} = q_{\text{cond,Al}} + q_{\text{cond,Ch}} \qquad (1)$$

where the conduction heat transfer rates through the alumel and chromel wires are denoted as $q_{\text{cond,Al}}$ and $q_{\text{cond.Ch}}$, respectively. Conduction from the surface through the air to the thermocouple bead, $q_{\text{cond,air}}$, may be determined by use of the shape factor $S = (2\pi D)/(1 - D/4z)$of Case 1 of Table 4.1. Therefore, Equation (1) may be written as

$$Sk_a\left(T_s - T_{tc}\right) = k_{\text{Al}}\frac{\pi d^2}{4L}\left(T_{tc} - T_m\right) + k_{\text{Ch}}\frac{\pi d^2}{4L}\left(T_{tc} - T_m\right) \qquad (2)$$

which may be rearranged to yield

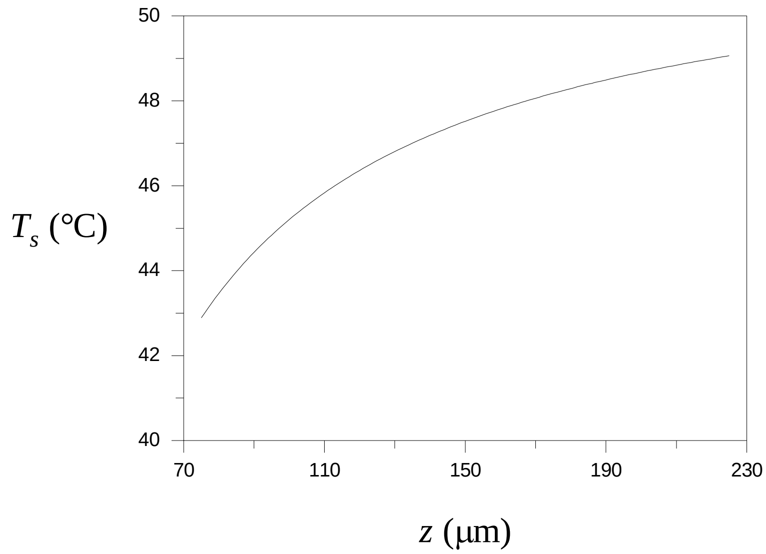
$$T_s = \frac{1 - D/4z}{2Dk_a}\cdot\frac{d^2}{4L}\left[k_{\text{Al}}\left(T_{tc} - T_m\right) + k_{\text{Ch}}\left(T_{tc} - T_m\right)\right] + T_{tc}$$

$$= \frac{1 - 120/\left(4\times 100\right)}{2\times 120\times 10^{-6}\,\text{m}\times 0.027\ \text{W/m}\cdot\text{K}}\cdot\frac{\left(25\times 10^{-6}\ \text{m}\right)^2}{4\times 300\times 10^{-6}\ \text{m}}\left[29\ \text{W/m}\cdot\text{K}\left(29-23\right)°\text{C} + 19\text{W/m}\cdot\text{K}\left(29-23\right)°\text{C}\right] + 29°\text{C}$$

$= 45.2°\text{C}$ <

Continued…

COMMENTS: The required surface temperature to induce the specified thermocouple temperature and its dependence on the separation distance, *z*, is shown below. As expected, the required surface temperature becomes greater as the separation distance increases.

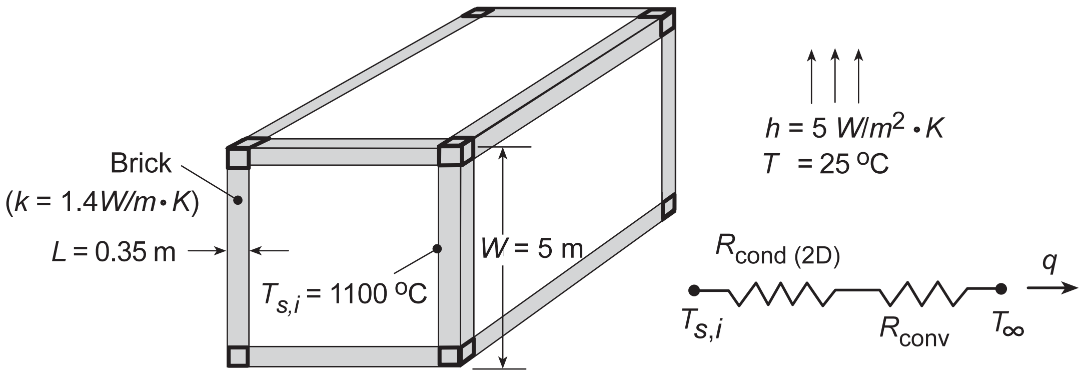


PROBLEM 4.26

KNOWN: Dimensions, thermal conductivity and inner surface temperature of furnace wall. Ambient conditions.

FIND: Heat loss.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Uniform convection coefficient over entire outer surface of container, (3) Negligible radiation losses.

ANALYSIS: From the thermal circuit, the heat loss is

$$q = \frac{T_{s,i} - T_\infty}{R_{cond(2D)} + R_{conv}}$$

where $R_{conv} = 1/hA_{s,o} = 1/6(hW^2) = 1/6[5\ W/m^2 \cdot K(5\ m)^2] = 0.00133\ K/W$. From Equation (4.21), the two-dimensional conduction resistance is

$$R_{cond(2D)} = \frac{1}{Sk}$$

where the shape factor S must include the effects of conduction through the 8 corners, 12 edges and 6 plane walls. Hence, using the relations for Cases 8 and 9 of Table 4.1,

$$S = 8(0.15L) + 12 \times 0.54(W - 2L) + 6A_{s,i}/L$$

where $A_{s,i} = (W - 2L)^2$. Hence,

$$S = [8(0.15 \times 0.35) + 12 \times 0.54(4.30) + 6(52.83)]m$$

$$S = (0.42 + 27.86 + 316.98)m = 345.26m$$

and $R_{cond(2D)} = 1/(345.26\ m \times 1.4\ W/m \cdot K) = 0.00207\ K/W$. Hence

$$q = \frac{(1100 - 25)^\circ C}{(0.00207 + 0.00133)K/W} = 316\,kW$$ <

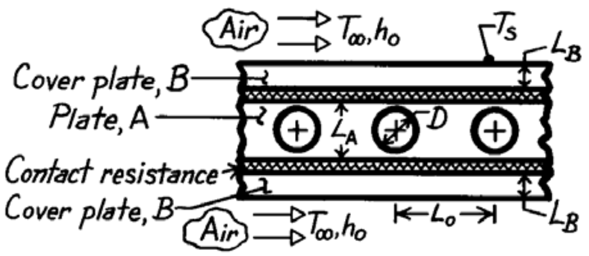
COMMENTS: The heat loss is extremely large and measures should be taken to insulate the furnace. Radiation losses may be significant, leading to larger heat losses.

PROBLEM 4.27

KNOWN: Platen heated by passage of hot fluid in poor thermal contact with cover plates exposed to cooler ambient air.

FIND: (a) Heat rate per unit thickness from each channel, q_i', (b) Surface temperature of cover plate, T_s, (c) q_i' and T_s if lower surface is perfectly insulated, (d) Effect of changing centerline spacing on q_i' and T_s

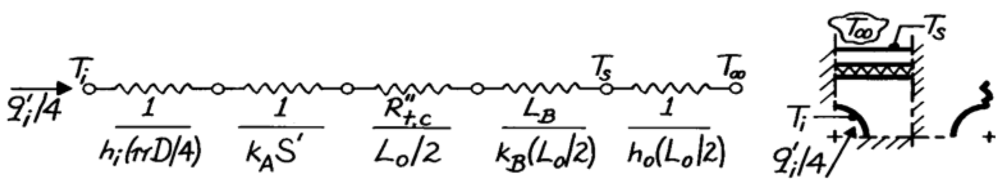
SCHEMATIC:



D=15 mm L_o=60 mm
L_A=30 mm L_B=7.5 mm
T_i=150°C h_i=1000 W/m^2·K
T_∞=25°C h_o=200 W/m^2·K
k_A=20 W/m·K k_B=75 W/m·K
$R''_{t,c} = 2.0\times10^{-4}\,\text{m}^2\cdot\text{K/W}$

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction in platen, but one-dimensional in coverplate, (3) Temperature of interfaces between A and B is uniform, (4) Constant properties.

ANALYSIS: (a) The heat rate per unit thickness from each channel can be determined from the following thermal circuit representing the quarter section shown.



The value for the shape factor is $S' = 1.06$ as determined from the flux plot shown on the next page. Hence, the heat rate is

$$q_i' = 4\left(T_i - T_\infty\right)/R'_{tot} \tag{1}$$

$$R'_{tot} = [1/1000\ \text{W/m}^2\cdot\text{K}\left(\pi 0.015\text{m}/4\right) + 1/20\ \text{W/m}\cdot\text{K}\times1.06$$
$$+2.0\times10^{-4}\text{m}^2\cdot\text{K/W}/\left(0.060\text{m}/2\right) + 0.0075\text{m}/75\ \text{W/m}\cdot\text{K}\left(0.060\text{m}/2\right)$$
$$+1/200\ \text{W/m}^2\cdot\text{K}\left(0.060\text{m}/2\right)]$$

$$R'_{tot} = \left[0.085 + 0.047 + 0.0067 + 0.0033 + 0.1667\right]\text{m}\cdot\text{K/W}$$
$$R'_{tot} = 0.309\ \text{m}\cdot\text{K/W}$$

$$q_i' = 4\left(150 - 25\right)\text{K}/0.309\ \text{m}\cdot\text{K/W} = 1.62\ \text{kW/m}.$$ <

(b) The surface temperature of the cover plate also follows from the thermal circuit as

$$q_i'/4 = \frac{T_s - T_\infty}{1/h_o\left(L_o/2\right)} \tag{2}$$

Continued …

PROBLEM 4.27 (Cont.)

$$T_s = T_\infty + \frac{q_i'}{4}\frac{1}{h_o(L_o/2)} = 25^\circ C + \frac{1.62\ kW}{4} \times 0.167\ m \cdot K/W$$

$$T_s = 25^\circ C + 67.6^\circ C \approx 93^\circ C.$$ <

(c,d) The effect of the centerline spacing on q_i' and T_s can be understood by examining the relative magnitudes of the thermal resistances. The dominant resistance is that due to the ambient air convection process which is inversely related to the spacing L_o. Hence, from Equation (1), the heat rate will increase nearly linearly with an increase in L_o,

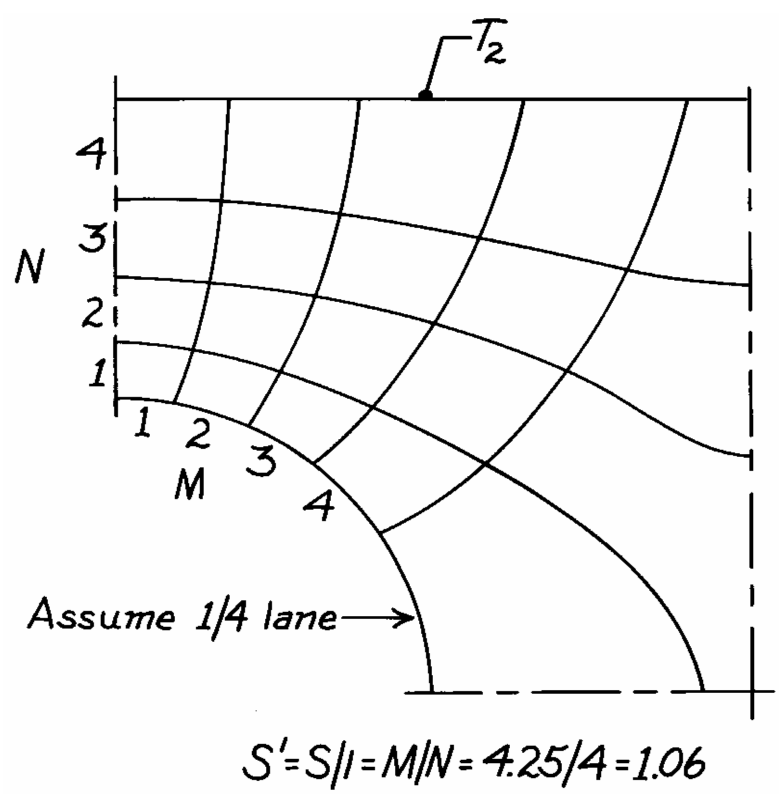
$$q_i' \sim \frac{1}{R_{tot}'} \approx \frac{1}{1/h_o(L_o/2)} \sim L_o.$$

From Eq. (2), find

$$\Delta T = T_s - T_\infty = \frac{q_i'}{4}\frac{1}{h_o(L_o/2)} \sim q_i' \cdot L_o^{-1} \sim L_o \cdot L_o^{-1} \approx 1.$$

Hence we conclude that ΔT will not increase with a change in L_o. Does this seem reasonable? What effect does L_o have on Assumptions (2) and (3)?

If the lower surface were insulated, the heat rate would be decreased nearly by half. This follows again from the fact that the overall resistance is dominated by the surface convection process. The temperature difference, T_s - T_∞, would only increase slightly.

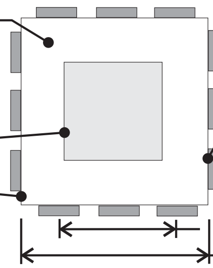


PROBLEM 4.28

KNOWN: Dimensions and surface temperatures of a square channel. Number of chips mounted on outer surface and chip thermal contact resistance.

FIND: Heat dissipation per chip and chip temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady state, (2) Approximately uniform channel inner and outer surface temperatures, (3) Two-dimensional conduction through channel wall (negligible end-wall effects), (4) Constant thermal conductivity.

ANALYSIS: The total heat rate is determined by the two-dimensional conduction resistance of the channel wall, $q = (T_2 - T_1)/R_{t,cond(2D)}$, with the resistance determined by using Equation 4.21 with Case 11 of Table 4.1. For W/w = 1.6 > 1.4

$$R_{t,cond(2D)} = \frac{0.930 \ln(W/w) - 0.050}{2\pi L k} = \frac{0.387}{2\pi(0.160\text{m})240 \text{ W/m}\cdot\text{K}} = 0.00160 \text{ K/W}$$

The heat rate per chip is then

$$q_c = \frac{T_2 - T_1}{N R_{t,cond(2D)}} = \frac{(50-20)°\text{C}}{120(0.0016 \text{ K/W})} = 156.3 \text{ W} \qquad <$$

and, with $q_c = (T_c - T_2)/R_{t,c}$, the chip temperature is

$$T_c = T_2 + R_{t,c}\, q_c = 50°\text{C} + (0.2 \text{ K/W})156.3 \text{ W} = 81.3°\text{C} \qquad <$$

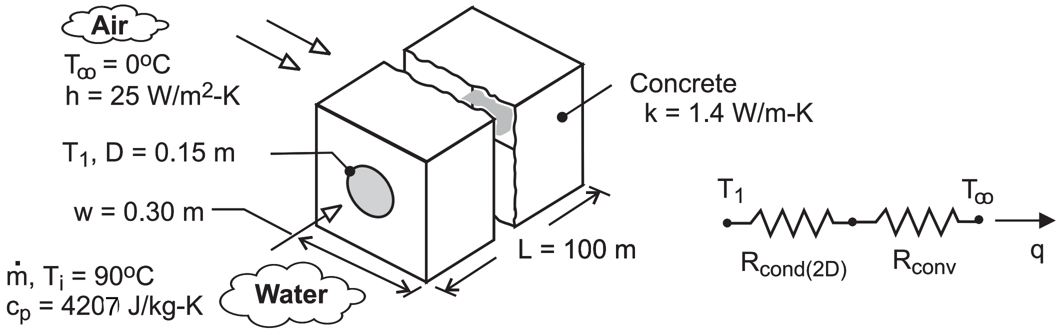
COMMENTS: (1) By acting to *spread* heat flow lines away from a chip, the channel wall provides an excellent *heat sink* for dissipating heat generated by the chip. However, recognize that, in practice, there will be temperature variations on the inner and outer surfaces of the channel, and if the prescribed values of T_1 and T_2 represent minimum and maximum inner and outer surface temperatures, respectively, the rate is overestimated by the foregoing analysis. (2) The shape factor may also be determined by combining the expression for a plane wall with the result of Case 8 (Table 4.1). With $S = [4(wL)/((W-w)/2)] + 4(0.54 L) = 2.479$ m, $R_{t,cond(2D)} = 1/(Sk) = 0.00168$ K/W.

PROBLEM 4.29

KNOWN: Dimensions and thermal conductivity of concrete duct. Convection conditions of ambient air. Inlet temperature of water flow through the duct.

FIND: (a) Heat loss per duct length near inlet, (b) Minimum allowable flow rate corresponding to maximum allowable temperature rise of water.

SCHEMATIC:



ASSUMPTIONS: (1) Steady state, (2) Negligible water-side convection resistance, pipe wall conduction resistance, and pipe/concrete contact resistance (temperature at inner surface of concrete corresponds to that of water), (3) Constant properties, (4) Negligible flow work and kinetic and potential energy changes.

ANALYSIS: (a) From the thermal circuit, the heat loss per unit length near the entrance is

$$q' = \frac{T_i - T_\infty}{R'_{cond(2D)} + R'_{conv}} = \frac{T_i - T_\infty}{\dfrac{\ln(1.08\,w/D)}{2\pi k} + \dfrac{1}{h(4w)}}$$

where $R'_{cond(2D)}$ is obtained by using the shape factor of Case 6 from Table 4.1 with Eq. (4.21). Hence,

$$q' = \frac{(90-0)°C}{\dfrac{\ln(1.08\times 0.3\text{m}/0.15\text{m})}{2\pi(1.4\,\text{W/m}\cdot\text{K})} + \dfrac{1}{25\,\text{W/m}^2\cdot\text{K}(1.2\text{m})}} = \frac{90°C}{(0.0876+0.0333)\text{K}\cdot\text{m/W}} = 745\ \text{W/m}$$ <

(b) From Eq. (1.12d), with $q = q'L$ and $(T_i - T_o) = 5°C$,

$$\dot{m} = \frac{q'L}{u_i - u_o} = \frac{q'L}{c(T_i - T_o)} = \frac{745\,\text{W/m}(100\text{m})}{4207\,\text{J/kg}\cdot\text{K}(5°C)} = 3.54\ \text{kg/s}$$ <

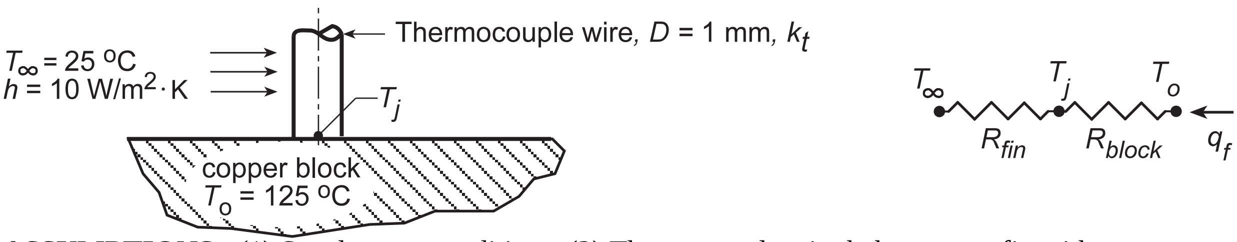
COMMENTS: The small reduction in the temperature of the water as it flows from inlet to outlet induces a slight departure from two-dimensional conditions and a small reduction in the heat rate per unit length. A slightly conservative value (upper estimate) of $\dot{m}$ is therefore obtained in part (b).

PROBLEM 4.30

KNOWN: Long constantan wire butt-welded to a large copper block forming a thermocouple junction on the surface of the block.

FIND: (a) The measurement error (T_j - T_o) for the thermocouple for prescribed conditions, and (b) Compute and plot (T_j - T_o) for h = 5, 10 and 25 W/m^2·K for block thermal conductivity 15 ≤ k ≤ 400 W/m·K. When is it advantageous to use smaller diameter wire?

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Thermocouple wire behaves as a fin with constant heat transfer coefficient, (3) Copper block has uniform temperature, except in the vicinity of the junction.

PROPERTIES: *Table A-1*, Copper (pure, 400 K), k_b = 393 W/m·K; Constantan (350 K), $k_t \approx$ 25 W/m·K.

ANALYSIS: The thermocouple wire behaves as a long fin permitting heat to flow from the surface thereby depressing the sensing junction temperature below that of the block T_o. In the block, heat flows into the circular region of the wire-block interface; the thermal resistance to heat flow within the block is approximated as a disk of diameter D on a semi-infinite medium (k_b, T_o). The thermocouple-block combination can be represented by a thermal circuit as shown above. The thermal resistance of the fin follows from the heat rate expression for an infinite fin, $R_{fin} = (hPk_tA_c)^{-1/2}$.

From Table 4.1, the shape factor for the disk-on-a-semi-infinite medium is given as S = 2D and hence $R_{block} = 1/k_bS = 1/2k_bD$. From the thermal circuit,

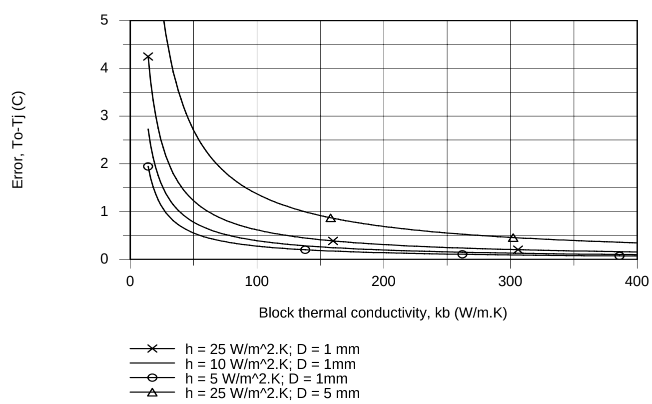
$$T_o - T_j = \frac{R_{block}}{R_{fin} + R_{block}}\left(T_o - T_\infty\right) = \frac{1.27}{1273 + 1.27}\left(125 - 25\right)^\circ C \approx 0.001\left(125 - 25\right)^\circ C = 0.1^\circ C . \quad <$$

with $P = \pi D$ and $A_c = \pi D^2/4$ and the thermal resistances as

$$R_{fin} = \left(10\,W/m^2 \cdot K\,(\pi/4)\,25\,W/m \cdot K \times \left(1 \times 10^{-3}\,m\right)^3\right)^{-1/2} = 1273\,K/W$$

$$R_{block} = (1/2) \times 393\,W/m \cdot K \times 10^{-3}\,m = 1.27\,K/W .$$

(b) We keyed the above equations into the IHT workspace, performed a sweep on k_b for selected values of h and created the plot shown. When the block thermal conductivity is low, the error (T_o - T_j) is larger, increasing with increasing convection coefficient. A smaller diameter wire will be advantageous for low values of k_b and higher values of h.

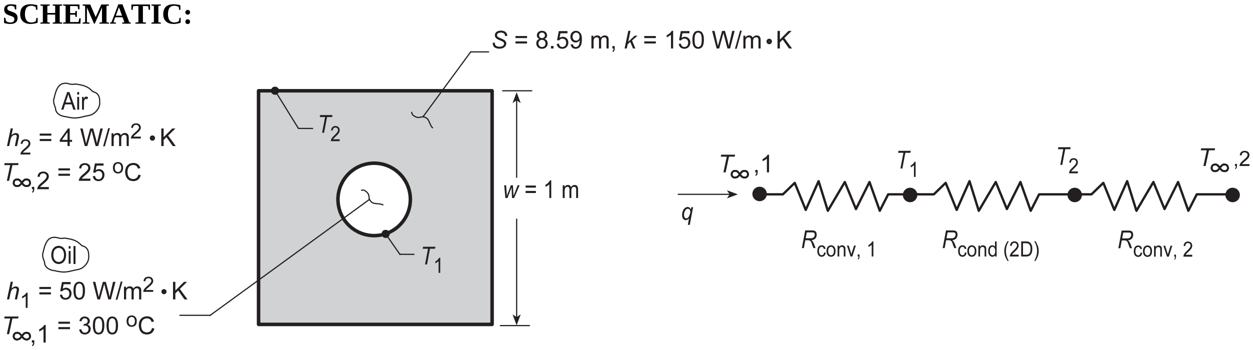


PROBLEM 4.31

KNOWN: Dimensions, shape factor, and thermal conductivity of square rod with drilled interior hole. Interior and exterior convection conditions.

FIND: Heat rate and surface temperatures.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties, (3) Uniform convection coefficients at inner and outer surfaces.

ANALYSIS: The heat loss can be expressed as

$$q = \frac{T_{\infty,1} - T_{\infty,2}}{R_{conv,1} + R_{cond(2D)} + R_{conv,2}}$$

where

$$R_{conv,1} = \left(h_1 \pi D_1 L\right)^{-1} = \left(50\,W/m^2 \cdot K \times \pi \times 0.25\,m \times 2\,m\right)^{-1} = 0.01273\,K/W$$

$$R_{cond(2D)} = \left(Sk\right)^{-1} = \left(8.59\,m \times 150\,W/m \cdot K\right)^{-1} = 0.00078\,K/W$$

$$R_{conv,2} = \left(h_2 \times 4wL\right)^{-1} = \left(4\,W/m^2 \cdot K \times 4\,m \times 1\,m\right)^{-1} = 0.0625\,K/W$$

Hence,

$$q = \frac{\left(300 - 25\right)^{\circ}C}{0.076\,K/W} = 3.62\,kW$$ <

$$T_1 = T_{\infty,1} - qR_{conv,1} = 300^{\circ}C - 46^{\circ}C = 254^{\circ}C$$ <

$$T_2 = T_{\infty,2} + qR_{conv,2} = 25^{\circ}C + 226^{\circ}C = 251^{\circ}C$$ <

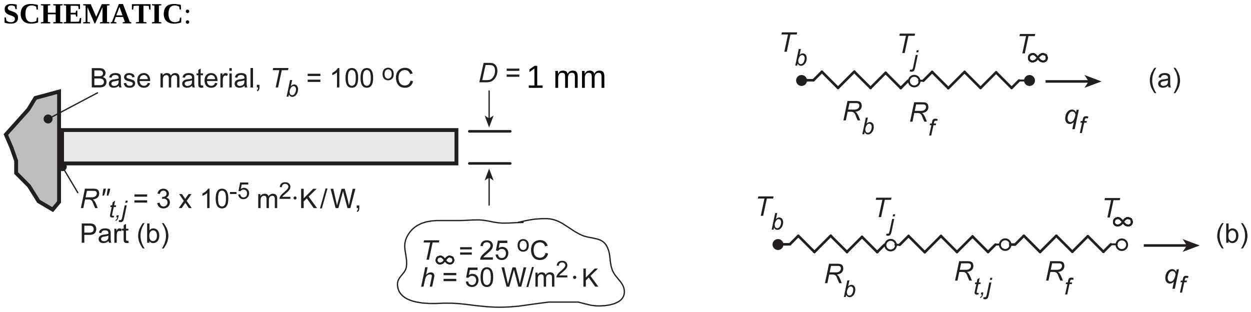
COMMENTS: The largest resistance is associated with convection at the outer surface, and the conduction resistance is much smaller than both convection resistances. Hence, $(T_2 - T_{\infty,2}) > (T_{\infty,1} - T_1) >> (T_1 - T_2)$.

PROBLEM 4.32

KNOWN: Long fin of aluminum alloy with prescribed convection coefficient attached to different base materials (aluminum alloy or stainless steel) with and without thermal contact resistance $R''_{t,j}$ at the junction.

FIND: (a) Heat rate q_f and junction temperature T_j for base materials of aluminum and stainless steel, (b) Repeat calculations considering thermal contact resistance, $R''_{t,j}$, and (c) Plot as a function of h for the range $10 \le h \le 1000$ W/m^2·K for each base material.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Infinite fin.

PROPERTIES: (Given) Aluminum alloy, k = 240 W/m·K, Stainless steel, k = 15 W/m·K.

ANALYSIS: (a,b) From the thermal circuits, the heat rate and junction temperature are

$$q_f = \frac{T_b - T_\infty}{R_{tot}} = \frac{T_b - T_\infty}{R_b + R_{t,j} + R_f} \quad (1)$$

$$T_j = T_\infty + q_f R_f \quad (2)$$

and, with $P = \pi D$ and $A_c = \pi D^2/4$, from Tables 4.1 and 3.4 find

$$R_b = 1/Sk_b = 1/(2Dk_b) = (2 \times 0.005\,\text{m} \times k_b)^{-1}$$

$$R_{t,j} = R''_{t,j}/A_c = 3\times10^{-5}\text{m}^2\cdot\text{K/W}/\left[\pi(0.005\text{m})^2/4\right] = 1.528\,\text{K/W}$$

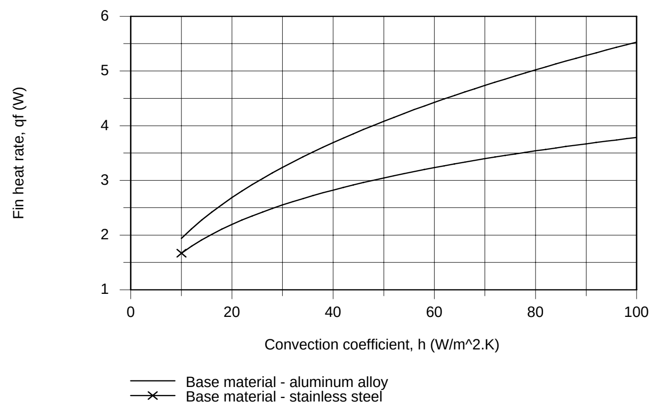
$$R_f = (hPkA_c)^{-1/2} = \left[50\,\text{W/m}^2\cdot\text{K}\,\pi^2(0.005\,\text{m})^3\,240\,\text{W/m}\cdot\text{K}/4\right]^{-1/2} = 16.4\,\text{K/W}$$

		Without $R''_{t,j}$		With $R''_{t,j}$	
Base	R_b (K/W)	q_f (W)	T_j (°C)	q_f (W)	T_j (°C)
Al alloy	0.417	4.46	98.2	4.09	92.1
St. steel	6.667	3.26	78.4	3.05	75.1

(c) We used the *IHT Model for Extended Surfaces, Performance Calculations, Rectangular Pin Fin* to calculate q_f for $10 \le h \le 100$ W/m^2·K by replacing R''_{tc} (thermal resistance at fin base) by the sum of the contact and spreading resistances, $R''_{t,j} + R''_b$.

Continued...

PROBLEM 4.32 (Cont.)



COMMENTS: (1) From part (a), the aluminum alloy base material has negligible effect on the fin heat rate and depresses the base temperature by only 2°C. The effect of the stainless steel base material is substantial, reducing the heat rate by 27% and depressing the junction temperature by 25°C.

(2) The contact resistance reduces the heat rate and increases the temperature depression relatively more with the aluminum alloy base.

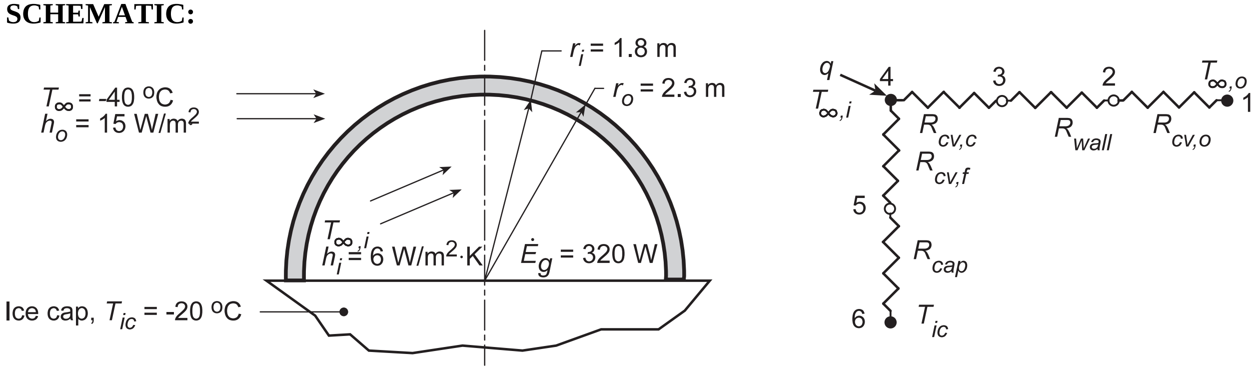
(3) From the plot of q_f vs. h, note that at low values of h, the heat rates are nearly the same for both materials since the fin is the dominant resistance. As h increases, the effect of R''_b becomes more important.

PROBLEM 4.33

KNOWN: Igloo constructed in hemispheric shape sits on ice cap; igloo wall thickness and inside/outside convection coefficients (h_i, h_o) are prescribed.

FIND: (a) Inside air temperature $T_{\infty,i}$ when outside air temperature is $T_{\infty,o}$ = -40°C assuming occupants provide 320 W within igloo, (b) Perform parameter sensitivity analysis to determine which variables have significant effect on T_i.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Convection coefficient is the same on floor and ceiling of igloo, (3) Floor and ceiling are at uniform temperatures, (4) Floor-ice cap resembles disk on semi-infinite medium, (5) One-dimensional conduction through igloo walls.

PROPERTIES: Ice and compacted snow (given): k = 0.15 W/m·K.

ANALYSIS: (a) The thermal circuit representing the heat loss from the igloo to the outside air and through the floor to the ice cap is shown above. The heat loss is

$$q = \frac{T_{\infty,i} - T_{\infty,o}}{R_{cv,c} + R_{wall} + R_{cv,o}} + \frac{T_{\infty,i} - T_{ic}}{R_{cv,f} + R_{cap}}.$$

Convection, ceiling: $$R_{cv,c} = \frac{2}{h_i\left(4\pi r_i^2\right)} = \frac{2}{6\,\text{W/m}^2\cdot\text{K}\times 4\pi\,(1.8\,\text{m})^2} = 0.00819\,\text{K/W}$$

Convection, outside: $$R_{cv,o} = \frac{2}{h_o\left(4\pi r_o^2\right)} = \frac{2}{15\,\text{W/m}^2\cdot\text{K}\times 4\pi\,(2.3\,\text{m})^2} = 0.00201\,\text{K/W}$$

Convection, floor: $$R_{cv,f} = \frac{1}{h_i\left(\pi r_i^2\right)} = \frac{1}{6\,\text{W/m}^2\cdot\text{K}\times \pi\,(1.8\,\text{m})^2} = 0.01637\,\text{K/W}$$

Conduction, wall: $$R_{wall} = 2\left[\frac{1}{4\pi k}\left(\frac{1}{r_i} - \frac{1}{r_o}\right)\right] = 2\left[\frac{1}{4\pi\times 0.15\,\text{W/m}\cdot\text{K}}\left(\frac{1}{1.8} - \frac{1}{2.3}\right)\text{m}\right] = 0.1281\,\text{K/W}$$

Conduction, ice cap: $$R_{cap} = \frac{1}{kS} = \frac{1}{4kr_i} = \frac{1}{4\times 0.15\,\text{W/m}\cdot\text{K}\times 1.8\,\text{m}} = 0.9259\,\text{K/W}$$

where S was determined from the shape factor of Table 4.1. Hence,

$$q = 320\,\text{W} = \frac{T_{\infty,i} - (-40)^\circ\text{C}}{(0.00819 + 0.1281 + 0.00201)\,\text{K/W}} + \frac{T_{\infty,i} - (-20)^\circ\text{C}}{(0.01637 + 0.9259)\,\text{K/W}}$$

$$320\,\text{W} = 7.231(T_{\infty,i} + 40) + 1.06(T_{\infty,i} + 20) \qquad T_{\infty,i} = 1.2^\circ\text{C}. \qquad <$$

Continued...

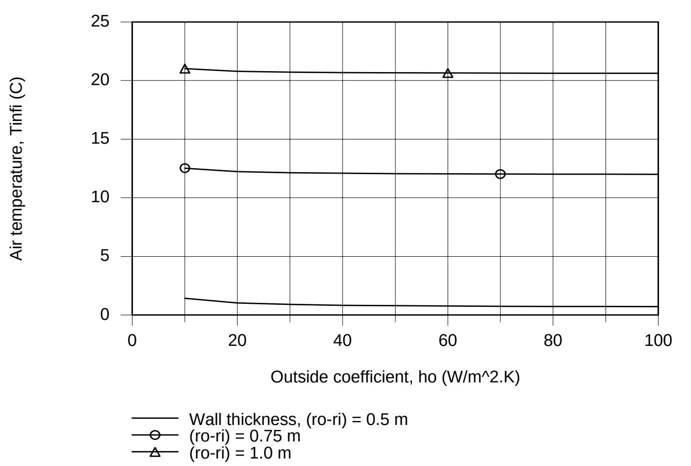
PROBLEM 4.33 (Cont.)

(b) Begin the parameter sensitivity analysis to determine important variables which have a significant influence on the inside air temperature by examining the thermal resistances associated with the processes present in the system and represented by the network.

Process	Symbols		Value (K/W)
Convection, outside	$R_{cv,o}$	R21	0.0020
Conduction, wall	R_{wall}	R32	0.1281
Convection, ceiling	$R_{cv,c}$	R43	0.0082
Convection, floor	$R_{cv,f}$	R54	0.0164
Conduction, ice cap	R_{cap}	R65	0.9259

It follows that the convection resistances are negligible relative to the conduction resistance across the igloo wall. As such, only changes to the wall thickness will have an appreciable effect on the inside air temperature relative to the outside ambient air conditions. We don't want to make the igloo walls thinner and thereby allow the air temperature to dip below freezing for the prescribed environmental conditions.

Using the *IHT Thermal Resistance Network Model*, we used the circuit builder to construct the network and perform the energy balances to obtain the inside air temperature as a function of the outside convection coefficient for selected increased thicknesses of the wall.



COMMENTS: (1) From the plot, we can see that the influence of the outside air velocity which controls the outside convection coefficient h_o is negligible.

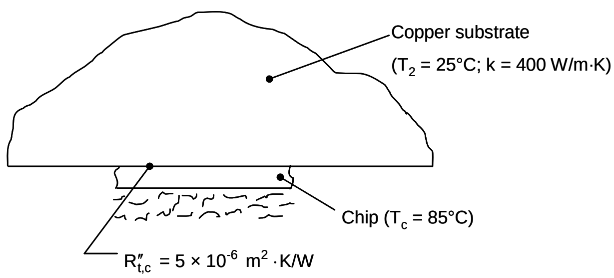
(2) The thickness of the igloo wall is the dominant thermal resistance controlling the inside air temperature.

PROBLEM 4.34

KNOWN: Chip dimensions, contact resistance and substrate material.

FIND: Maximum allowable chip power dissipation.

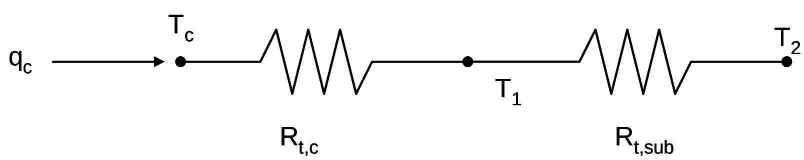
SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible heat transfer from back of chip, (4) Uniform chip temperature, (5) Infinitely large substrate, (6) Negligible heat loss from the exposed surface of the substrate.

PROPERTIES: Table A.1, copper (25 °C): k = 400 W/m·K.

ANALYSIS: For the prescribed system, a thermal circuit may be drawn so that



where T_1 is the temperature of the substrate adjacent to the top of the chip. For an infinitely thin square object in an infinite medium we may apply Case 14 of Table 4.1 ($q_{ss}^* = 0.932$) resulting in

$$q = q_{ss}^* k A_s (T_1 - T_2)/L_c$$

where $L_c = (A_s/4\pi)^{1/2}; \quad A_s = 2W_c^2$

Recognizing that the bottom surfaces of the chip and substrate are insulated, the heat loss to the substrate may be determined by combining the preceding equations and dividing by 2 (to account for no heat losses from the bottom of the chip) resulting in

$$q = (2\pi)^{1/2} q_{ss}^* W_c k (T_1 - T_2) = \frac{1}{R_{t,sub}}(T_1 - T_2)$$

or $$R_{t,sub} = \frac{1}{(2\pi)^{1/2} \times 0.932 \times 0.016 \text{ m} \times 400 \text{ W/m} \cdot \text{K}} = 0.067 \text{ K/W}$$

The thermal contact resistance is

Continued…

PROBLEM 4.34 (Cont.)

$$R_{t,c} = \frac{R''_{t,c}}{W_c^2} = \frac{5 \times 10^{-6}\ m^2 \cdot K/W}{(0.016\ m)^2} = 0.0195\ K/W$$

Therefore, the maximum allowable heat dissipation is

$$q_c = \frac{(85 - 25)°C}{(0.0195 + 0.067)\ K/W} = 694\ W$$ <

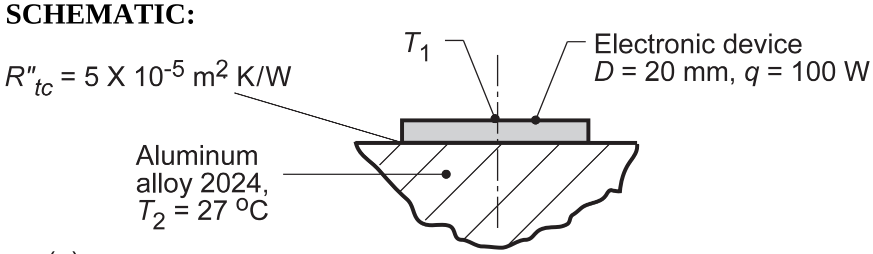
COMMENTS: (1) The copper block provides 694/276 = 2.5 times greater allowable heat dissipation relative to the heat sink of Problem 3.150. (2) Use of a large substrate would not be practical in many applications due to its size and weight. (3) The actual allowable heat dissipation is greater than calculated here because of additional heat losses from the bottom of the block and chip that are not accounted for in the solution.

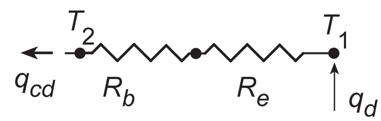
PROBLEM 4.35

KNOWN: Disc-shaped electronic devices dissipating 100 W mounted to aluminum alloy block with prescribed contact resistance.

FIND: (a) Temperature device will reach when block is at 27°C assuming all the power generated by the device is transferred by conduction to the block and (b) For the operating temperature found in part (a), the permissible operating power with a 30-pin fin heat sink.

SCHEMATIC:





(a)

ASSUMPTIONS: (1) Two-dimensional, steady-state conduction, (2) Device is at uniform temperature, T_1, (3) Block behaves as semi-infinite medium.

PROPERTIES: *Table A.1,* Aluminum alloy 2024 (300 K): k = 177 W/m·K.

ANALYSIS: (a) The thermal circuit for the conduction heat flow between the device and the block shown in the schematic where R_e is the thermal contact resistance due to the epoxy-filled interface,

$$R_e = R''_{t,c}/A_c = R''_{t,c}\Big/\left(\pi D^2/4\right)$$

$$R_e = 5\times10^{-5}\ \mathrm{K\cdot m^2/W}\Big/\left(\pi\left(0.020\,\mathrm{m}\right)^2\right)\Big/4 = 0.159\,\mathrm{K/W}$$

The thermal resistance between the device and the block is given in terms of the conduction shape factor, Table 4.1, as

$$R_b = 1/Sk = 1/\left(2Dk\right)$$

$$R_b = 1/\left(2\times0.020\,\mathrm{m}\times177\,\mathrm{W/m\cdot K}\right) = 0.141\,\mathrm{K/W}$$

From the thermal circuit,

$$T_1 = T_2 + q_d\left(R_b + R_e\right)$$

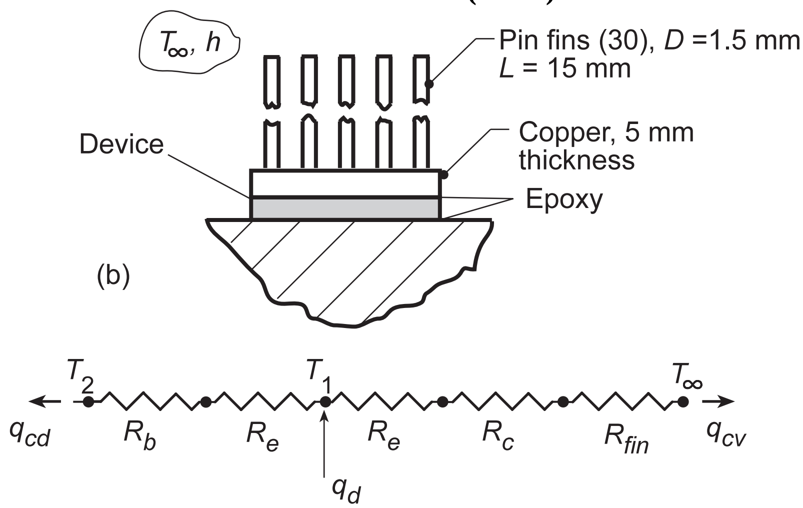
$$T_1 = 27^\circ\mathrm{C} + 100\,\mathrm{W}\left(0.141 + 0.159\right)\mathrm{K/W}$$

$$T_1 = 27^\circ\mathrm{C} + 30^\circ\mathrm{C} = 57^\circ\mathrm{C}$$ <

(b) The schematic below shows the device with the 30-pin fin heat sink with fins and base material of copper (k = 400 W/m·K). The airstream temperature is 27°C and the convection coefficient is 1000 $W/m^2\cdot K$.

Continued...

PROBLEM 4.35 (Cont.)



The thermal circuit for this system has two paths for the device power: to the block by conduction, q_{cd}, and to the ambient air by conduction to the fin array, q_{cv},

$$q_d = \frac{T_1 - T_2}{R_b + R_e} + \frac{T_1 - T_\infty}{R_e + R_c + R_{fin}} \tag{3}$$

where the thermal resistance of the fin base material is

$$R_c = \frac{L_c}{k_c A_c} = \frac{0.005\,\text{m}}{400\,\text{W/m}\cdot\text{K}\left(\pi 0.02^2/4\right)\text{m}^2} = 0.03979\,\text{K/W} \tag{4}$$

and R_{fin} represents the thermal resistance of the fin array (see Section 3.6.5),

$$R_{fin} = R_{t,o} = \frac{1}{\eta_o h A_t} \tag{5, 3.108}$$

$$\eta_o = 1 - \frac{NA_f}{A_t}\left(1 - \eta_f\right) \tag{6, 3.107}$$

where the fin and prime surface area is

$$A_t = NA_f + A_b \tag{3.99}$$

$$A_t = N\left(\pi D_f L\right) + \left[\pi D_d^2/4 - N\left(\pi D_f^2/4\right)\right]$$

where A_f is the fin surface area, D_d is the device diameter and D_f is the fin diameter.

$$A_t = 30\left(\pi \times 0.0015\,\text{m} \times 0.015\,\text{m}\right) + \left[\pi\left(0.020\,\text{m}\right)^2/4 - 30\left(\pi\left(0.0015\,\text{m}\right)^2/4\right)\right]$$

$$A_t = 0.00212\ \text{m}^2 + 0.0002611\ \text{m}^2 = 0.00238\ \text{m}^2$$

Using the *IHT Model*, *Extended Surfaces*, *Performance Calculations*, *Rectangular Pin Fin*, find the fin efficiency as

$$\eta_f = 0.6769 \tag{7}$$

Continued...

PROBLEM 4.35 (Cont.)

Substituting numerical values into Equation (6), find

$$\eta_o = 1 - \frac{30 \times \pi \times 0.0015\,\text{m} \times 0.015\,\text{m}}{0.00238\,\text{m}^2}(1 - 0.6769)$$

$$\eta_o = 0.712$$

and the fin array thermal resistance is

$$R_{fin} = \frac{1}{0.712 \times 1000\,\text{W/m}^2 \cdot \text{K} \times 0.00238\,\text{m}^2} = 0.590\,\text{K/W}$$

Returning to Eq. (3), with T_1 = 57°C from part (a), the permissible heat rate is

$$q_d = \frac{(57-27)^\circ\text{C}}{(0.141+0.159)\,\text{K/W}} + \frac{(57-27)^\circ\text{C}}{(0.159+0.03979+0.590)\,\text{K/W}}$$

$$q_d = 100\,\text{W} + 38\,\text{W} = 138\,\text{W}$$ <

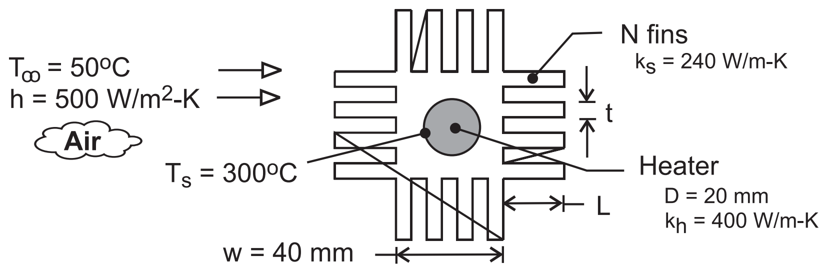
COMMENTS: In calculating the fin efficiency, η_f, using the IHT Model it is not necessary to know the base temperature as η_f depends only upon geometric parameters, thermal conductivity and the convection coefficient.

PROBLEM 4.36

KNOWN: Dimensions and thermal conductivities of a heater and a finned sleeve. Convection conditions on the sleeve surface.

FIND: (a) Heat rate per unit length, (b) Generation rate and centerline temperature of heater, (c) Effect of fin parameters on heat rate.

SCHEMATIC:



ASSUMPTIONS: (1) Steady state, (2) Constant properties, (3) Negligible contact resistance between heater and sleeve, (4) Uniform convection coefficient at outer surfaces of sleeve, (5) Uniform heat generation, (6) Negligible radiation.

ANALYSIS: (a) From the thermal circuit, the desired heat rate is

$$q' = \frac{T_s - T_\infty}{R'_{cond(2D)} + R'_{t,o}} = \frac{T_s - T_\infty}{R'_{tot}}$$

The two-dimensional conduction resistance, may be estimated from Eq. (4.21) and Case 6 of Table 4.2

$$R'_{cond(2D)} = \frac{1}{S' k_s} = \frac{\ln(1.08w/D)}{2\pi k_s} = \frac{\ln(2.16)}{2\pi(240\,W/m\cdot K)} = 5.11\times10^{-4}\,m\cdot K/W$$

The thermal resistance of the fin array is given by Equation (3.103), where η_o and A_t are given by Equations. (3.107) and (3.104) and η_f is given by Equation (3.94). With $L_c = L + t/2 = 0.022$ m, $m = (2h/k_s t)^{1/2} = 32.3\ m^{-1}$ and $mL_c = 0.710$,

$$\eta_f = \frac{\tanh\ mL_c}{mL_c} = \frac{0.61}{0.71} = 0.86$$

$$A'_t = NA'_f + A'_b = N(2L+t) + (4w - Nt) = 0.704m + 0.096m = 0.800m$$

$$\eta_o = 1 - \frac{NA'_f}{A'_t}(1-\eta_f) = 1 - \frac{0.704m}{0.800m}(0.14) = 0.88$$

$$R'_{t,o} = (\eta_o h A'_t)^{-1} = \left(0.88\times500\,W/m^2\cdot K\times0.80m\right)^{-1} = 2.84\times10^{-3} m\cdot K/W$$

$$q' = \frac{(300-50)°C}{\left(5.11\times10^{-4} + 2.84\times10^{-3}\right)m\cdot K/W} = 74,600\,W/m$$ <

Continued…

PROBLEM 4.36 (Cont.)

(b) Equation (3.60) may be used to determine $\dot{q}$, if h is replaced by an overall coefficient based on the surface area of the heater. From Equation (3.37),

$$U_s A_s' = U_s \pi D = \left(R'_{tot}\right)^{-1} = \left(3.35\times10^{-3} \text{m}\cdot\text{K/W}\right)^{-1} = 298\,\text{W/m}\cdot\text{K}$$

$$U_s = 298\,\text{W/m}\cdot\text{K}/(\pi\times0.02\text{m}) = 4750\,\text{W/m}^2\cdot\text{K}$$

$$\dot{q} = 4\,U_s\left(T_s - T_\infty\right)/D = 4\left(4750\,\text{W/m}^2\cdot\text{K}\right)\left(250°\text{C}\right)/0.02\text{m} = 2.38\times10^8\,\text{W/m}^3 \quad <$$

From Equation (3.58) the centerline temperature is

$$T(0) = \frac{\dot{q}(D/2)^2}{4k_h} + T_s = \frac{2.38\times10^8\,\text{W/m}^3\,(0.01\text{m})^2}{4(400\,\text{W/m}\cdot\text{K})} + 300°\text{C} = 315°\text{C} \quad <$$

(c) Subject to the prescribed constraints, the following results have been obtained for parameter variations corresponding to 16 ≤ N ≤ 40, 2 ≤ t ≤ 8 mm and 20 ≤ L ≤ 40 mm.

N	t(mm)	L(mm)	η_f	$q'(\text{W/m})$
16	4	20	0.86	74,400
16	8	20	0.91	77,000
28	4	20	0.86	107,900
32	3	20	0.83	115,200
40	2	20	0.78	127,800
40	2	40	0.51	151,300

Clearly there is little benefit to simply increasing t, since there is no change in A_t' and only a marginal increase in η_f. However, due to an attendant increase in A_t', there is significant benefit to increasing N for fixed t (no change in η_f) and additional benefit in concurrently increasing N while decreasing t. In this case the effect of increasing A_t' exceeds that of decreasing η_f. The same is true for increasing L, although there is an upper limit at which diminishing returns would be reached. The upper limit to L could also be influenced by manufacturing constraints.

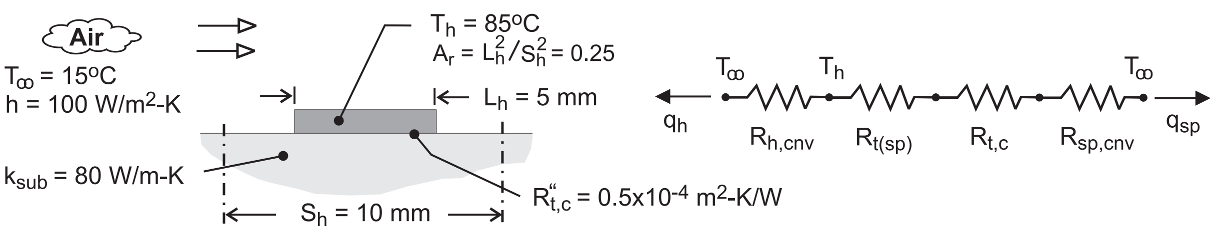
COMMENTS: Without the sleeve, the heat rate would be $q' = \pi Dh\left(T_s - T_\infty\right) = 7850\,\text{W/m}$, which is well below that achieved by using the increased surface area afforded by the sleeve.

PROBLEM 4.37

KNOWN: Dimensions of chip array. Conductivity of substrate. Convection conditions. Contact resistance. Expression for resistance of spreader plate. Maximum chip temperature.

FIND: Maximum chip heat rate.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Constant thermal conductivity, (3) Negligible radiation, (4) All heat transfer is by convection from the chip and the substrate surface (negligible heat transfer from bottom or sides of substrate).

ANALYSIS: From the thermal circuit,

$$q = q_h + q_{sp} = \frac{T_h - T_\infty}{R_{h,cnv}} + \frac{T_h - T_\infty}{R_{t(sp)} + R_{t,c} + R_{sp,cnv}}$$

$$R_{h,cnv} = \left(h\,A_{s,h}\right)^{-1} = \left(hL_h^2\right)^{-1} = \left[100\,W/m^2 \cdot K\left(0.005m\right)^2\right]^{-1} = 400\,K/W$$

$$R_{t(sp)} = \frac{1-1.410\,A_r + 0.344\,A_r^3 + 0.043\,A_r^5 + 0.034\,A_r^7}{4\,k_{sub}\,L_h} = \frac{1-0.353+0.005+0+0}{4\left(80\,W/m\cdot K\right)\left(0.005m\right)} = 0.408\,K/W$$

$$R_{t,c} = \frac{R''_{t,c}}{L_h^2} = \frac{0.5\times10^{-4}m^2\cdot K/W}{\left(0.005m\right)^2} = 2.000\,K/W$$

$$R_{sp,cnv} = \left[h\left(A_{sub} - A_{s,h}\right)\right]^{-1} = \left[100\,W/m^2\cdot K\left((0.010m)^2 - (0.005m)^2\right)\right]^{-1} = 133.3\,K/W$$

$$q = \frac{70°C}{400\,K/W} + \frac{70°C}{\left(0.408+2+133.3\right)K/W} = 0.18\,W + 0.52\,W = 0.70\,W \qquad <$$

COMMENTS: (1) The thermal resistances of the substrate and the chip/substrate interface are much less than the substrate convection resistance. Hence, the heat rate is increased almost in proportion to the additional surface area afforded by the substrate. An increase in the spacing between chips (S_h) would increase q correspondingly.

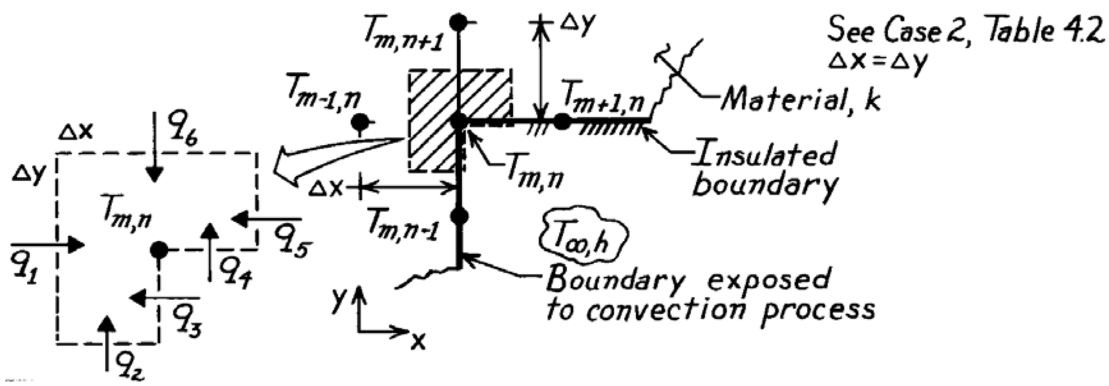
(2) In the limit $A_r \to 0$, $R_{t(sp)}$ reduces to $2\pi^{1/2}k_{sub}D_h$ for a circular heat source and $4k_{sub}L_h$ for a square source.

PROBLEM 4.38

KNOWN: Internal corner of a two-dimensional system with prescribed convection boundary conditions.

FIND: Finite-difference equations for these situations: (a) Horizontal boundary is perfectly insulated and vertical boundary is subjected to a convection process (T_∞,h), (b) Both boundaries are perfectly insulated; compare result with Eq. 4.41.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties, (4) No internal generation.

ANALYSIS: Consider the nodal network shown above and also as Case 2, Table 4.2. Having defined the control volume – the shaded area of unit thickness normal to the page – next identify the heat transfer processes. Finally, perform an energy balance wherein the processes are expressed using appropriate rate equations.

(a) With the horizontal boundary insulated and the vertical boundary subjected to a convection process, the energy balance results in the following finite-difference equation:

$$\dot{E}_{in} - \dot{E}_{out} = 0 \qquad q_1 + q_2 + q_3 + q_4 + q_5 + q_6 = 0$$

$$k(\Delta y \cdot 1)\frac{T_{m-1,n} - T_{m,n}}{\Delta x} + k\left[\frac{\Delta x}{2}\cdot 1\right]\frac{T_{m,n-1} - T_{m,n}}{\Delta y} + h\left[\frac{\Delta y}{2}\cdot 1\right](T_\infty - T_{m,n})$$

$$+0 + k\left[\frac{\Delta y}{2}\cdot 1\right]\frac{T_{m+1,n} - T_{m,n}}{\Delta x} + k(\Delta x \cdot 1)\frac{T_{m,n+1} - T_{m,n}}{\Delta y} = 0.$$

Letting Δx = Δy, and regrouping, find

$$2(T_{m-1,n} + T_{m,n+1}) + (T_{m+1,n} + T_{m,n-1}) + \frac{h\Delta x}{k}T_\infty - \left[6 + \frac{h\Delta x}{k}\right]T_{m,n} = 0. \qquad <$$

(b) With both boundaries insulated, the energy balance would have $q_3 = q_4 = 0$. The same result would be obtained by letting h = 0 in the previous result. Hence,

$$2(T_{m-1,n} + T_{m,n+1}) + (T_{m+1,n} + T_{m,n-1}) - 6\,T_{m,n} = 0. \qquad <$$

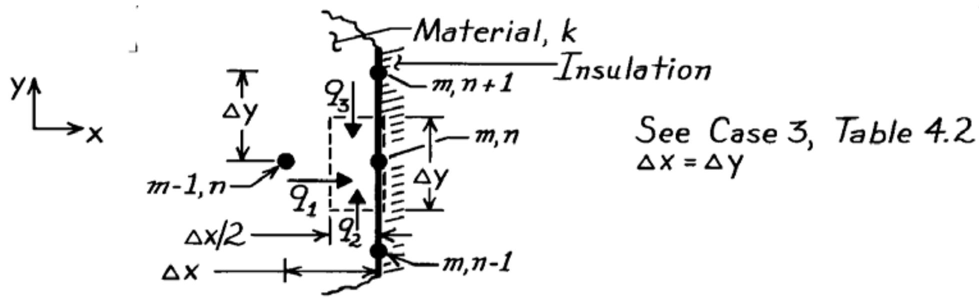
Note that this expression compares exactly with Equation 4.41 when h = 0, which corresponds to insulated boundaries.

PROBLEM 4.39

KNOWN: Plane surface of two-dimensional system.

FIND: The finite-difference equation for nodal point on this boundary when (a) insulated; compare result with Eq. 4.42, and when (b) subjected to a constant heat flux.

SCHEMATIC:



ASSUMPTIONS: (1) Two-dimensional, steady-state conduction with no generation, (2) Constant properties, (3) Boundary is adiabatic.

ANALYSIS: (a) Performing an energy balance on the control volume, (Δx/2)·Δy, and using the conduction rate equation, it follows that

$$\dot{E}_{in} - \dot{E}_{out} = 0 \qquad q_1 + q_2 + q_3 = 0 \qquad (1,2)$$

$$k(\Delta y \cdot 1)\frac{T_{m-1,n} - T_{m,n}}{\Delta x} + k\left[\frac{\Delta x}{2} \cdot 1\right]\frac{T_{m,n-1} - T_{m,n}}{\Delta y} + k\left[\frac{\Delta x}{2} \cdot 1\right]\frac{T_{m,n+1} - T_{m,n}}{\Delta y} = 0. \quad (3)$$

Note that there is no heat rate across the control volume surface at the insulated boundary. Recognizing that Δx =Δy, the above expression reduces to the form

$$2T_{m-1,n} + T_{m,n-1} + T_{m,n+1} - 4T_{m,n} = 0. \qquad (4)$$ <

The Eq. 4.42 of Table 4.2 considers the same configuration but with the boundary subjected to a convection process. That is,

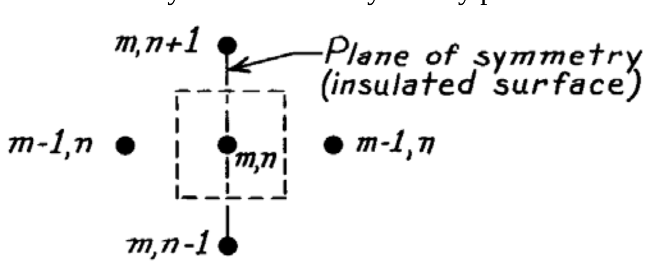
$$\left(2T_{m-1,n} + T_{m,n-1} + T_{m,n+1}\right) + \frac{2h\Delta x}{k}T_\infty - 2\left[\frac{h\Delta x}{k} + 2\right]T_{m,n} = 0. \qquad (5)$$

Note that, if the boundary is insulated, h = 0 and Eq. 4.42 reduces to Eq. (4).

(b) If the surface is exposed to a constant heat flux, q''_o, the energy balance has the form $q_1 + q_2 + q_3 + q''_o \cdot \Delta y = 0$ and the finite difference equation becomes

$$2T_{m-1,n} + T_{m,n-1} + T_{m,n+1} - 4T_{m,n} = -\frac{2q''_o\Delta x}{k}.$$ <

COMMENTS: Equation (4) can be obtained by using the "interior node" finite-difference equation, Eq. 4.29, where the insulated boundary is treated as a symmetry plane as shown below.

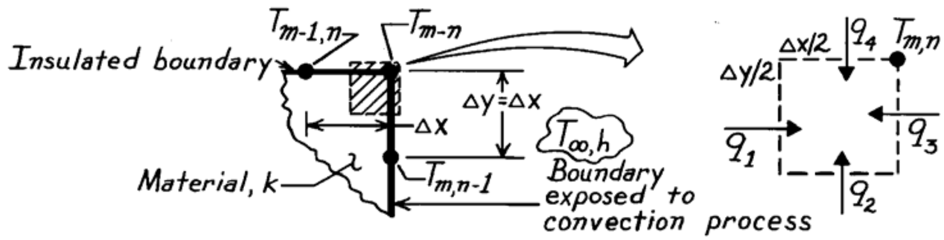


PROBLEM 4.40

KNOWN: External corner of a two-dimensional system whose boundaries are subjected to prescribed conditions.

FIND: Finite-difference equations for these situations: (a) Upper boundary is perfectly insulated and side boundary is subjected to a convection process, (b) Both boundaries are perfectly insulated; compare result with Eq. 4.43.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties, (4) No internal generation.

ANALYSIS: Consider the nodal point configuration shown in the schematic and also as Case 4, Table 4.2. The control volume about the node – shaded area above of unit thickness normal to the page – has dimensions, $(\Delta x/2)(\Delta y/2)\cdot 1$. The heat transfer processes at the surface of the CV are identified as q_1, q_2 ···. Perform an energy balance wherein the processes are expressed using the appropriate rate equations.

(a) With the upper boundary insulated and the side boundary subjected to a convection process, the energy balance has the form

$$\dot{E}_{in} - \dot{E}_{out} = 0 \qquad q_1 + q_2 + q_3 + q_4 = 0 \qquad (1,2)$$

$$k\left[\frac{\Delta y}{2}\cdot 1\right]\frac{T_{m-1,n} - T_{m,n}}{\Delta x} + k\left[\frac{\Delta x}{2}\cdot 1\right]\frac{T_{m,n-1} - T_{m,n}}{\Delta y} + h\left[\frac{\Delta y}{2}\cdot 1\right]\left(T_{\infty} - T_{m,n}\right) + 0 = 0.$$

Letting $\Delta x = \Delta y$, and regrouping, find

$$T_{m,n-1} + T_{m-1,n} + \frac{h\Delta x}{k}T_{\infty} - 2\left[\frac{1}{2}\frac{h\Delta x}{k} + 1\right]T_{m,n} = 0. \qquad (3) <$$

(b) With both boundaries insulated, the energy balance of Eq. (2) would have $q_3 = q_4 = 0$. The same result would be obtained by letting $h = 0$ in the finite-difference equation, Eq. (3). The result is

$$T_{m,n-1} + T_{m-1,n} - 2T_{m,n} = 0. \qquad <$$

Note that this expression is identical to Eq. 4.43 when $h = 0$, in which case both boundaries are insulated.

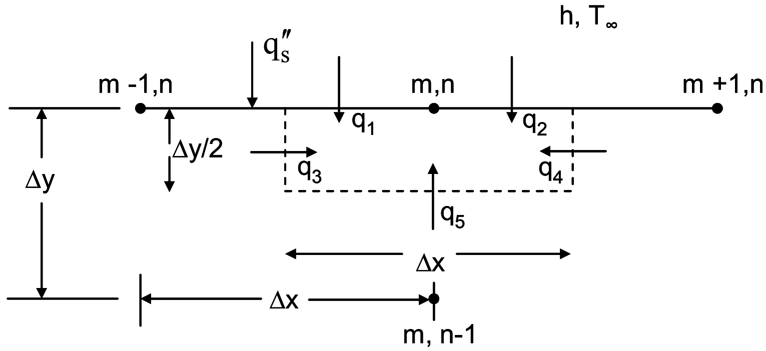
COMMENTS: Note the convenience resulting from formulating the energy balance by *assuming* that all the heat flow is *into the node.*

PROBLEM 4.41

KNOWN: Boundary conditions that change from specified heat flux to convection.

FIND: The finite difference equation for the node at the point where the boundary condition changes.

SCHEMATIC:



ASSUMPTIONS: (1) Two dimensional, steady-state conduction with no generation, (2) Constant properties.

ANALYSIS: Performing an energy balance on the control volume Δx • Δy/2,

$$\dot{E}_{in} - \dot{E}_{out} = 0 \qquad\qquad q_1 + q_2 + q_3 + q_4 + q_5 = 0$$

Expressing q_1 in terms of the specified heat flux, q_2 in terms of the known heat transfer coefficient and environment temperature, and the remaining heat rates using the conduction rate equation,

$$q_1 = q_s'' \frac{\Delta x}{2} \cdot 1$$

$$q_2 = h(T_\infty - T_{m,n}) \frac{\Delta x}{2} \cdot 1$$

$$q_3 = \frac{k(T_{m-1,n} - T_{m,n})}{\Delta x} \frac{\Delta y}{2} \cdot 1$$

$$q_4 = \frac{k(T_{m+1,n} - T_{m,n})}{\Delta x} \frac{\Delta y}{2} \cdot 1$$

$$q_5 = \frac{k(T_{m,n-1} - T_{m,n})}{\Delta y} \Delta x \cdot 1$$

Letting Δx = Δy, substituting these expressions into the energy balance, and rearranging yields

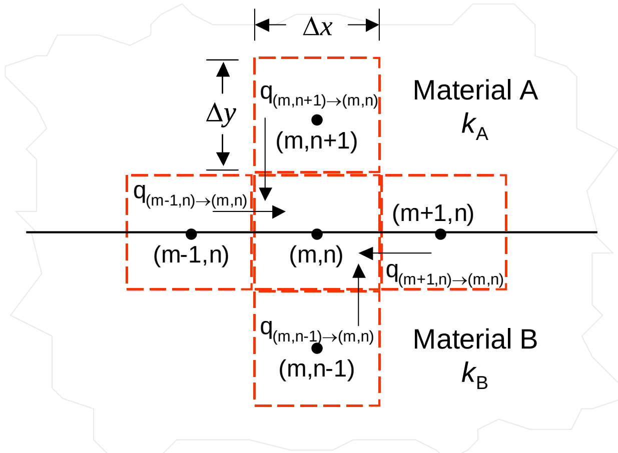
$$T_{m-1,n} + T_{m+1,n} + 2T_{m,n-1} - \left[4 + \frac{h\Delta x}{k}\right] T_{m,n} + \frac{h\Delta x}{k} T_\infty + \frac{q_s''\Delta x}{k} = 0$$ <

PROBLEM 4.42

KNOWN: Control volume and nodal configuration in the vicinity of the interface between two materials.

FIND: Expressions for control surface heat rates. Finite difference equation at node m,n.

SCHEMATIC:



ASSUMPTIONS: Steady-state, two-dimensional heat transfer, no heat generation, negligible contact resistance.

ANALYSIS: Conduction from Node (m,n+1) to Node (m,n) occurs exclusively in Material A. Therefore,

$$q_{(m,n+1)\to(m,n)} = k_A L \frac{\Delta x}{\Delta y}\left[T_{m,n+1} - T_{m,n}\right]$$ <

Likewise for conduction from Node (m,n-1) to Node (m,n),

$$q_{(m,n-1)\to(m,n)} = k_B L \frac{\Delta x}{\Delta y}\left[T_{m,n-1} - T_{m,n}\right]$$ <

Conduction from Node (m-1,n) to Node (m,n) occurs in both Material A and Material B. In Material A,

$$q_{A(m-1,n)\to(m,n)} = k_A L \frac{\Delta y/2}{\Delta x}\left[T_{m-1,n} - T_{m,n}\right]$$

Likewise for conduction in Material B,

$$q_{B(m-1,n)\to(m,n)} = k_B L \frac{\Delta y/2}{\Delta x}\left[T_{m-1,n} - T_{m,n}\right]$$

For both materials,

$$\begin{aligned} q_{(m-1,n)\to(m,n)} &= q_{A(m-1,n)\to(m,n)} + q_{B(m-1,n)\to(m,n)} \\ &= k_A L \frac{\Delta y/2}{\Delta x}\left[T_{m-1,n} - T_{m,n}\right] + k_B L \frac{\Delta y/2}{\Delta x}\left[T_{m-1,n} - T_{m,n}\right] \\ &= \left(k_A + k_B\right) L \frac{\Delta y/2}{\Delta x}\left[T_{m-1,n} - T_{m,n}\right] \end{aligned}$$ <

Similarly for conduction from Node (m+1,n) to (m,n),

$$q_{(m+1,n)\to(m,n)} = \left(k_A + k_B\right) L \frac{\Delta y/2}{\Delta x}\left[T_{m+1,n} - T_{m,n}\right]$$ <

Continued...

PROBLEM 4.42 (Cont.)

An energy balance on node m,n yields

$$q_{(m-1,n)\to(m,n)} + q_{(m+1,n)\to(m,n)} + q_{(m,n-1)\to(m,n)} + q_{(m,n+1)\to(m,n)} = 0$$

or

$$k_A \frac{\Delta x}{\Delta y}\left[T_{m,n+1} - T_{m,n}\right] + k_B \frac{\Delta x}{\Delta y}\left[T_{m,n-1} - T_{m,n}\right] + (k_A + k_B)\frac{\Delta y/2}{\Delta x}\left[T_{m-1,n} + T_{m+1,n} - 2T_{m,n}\right] = 0 \qquad <$$

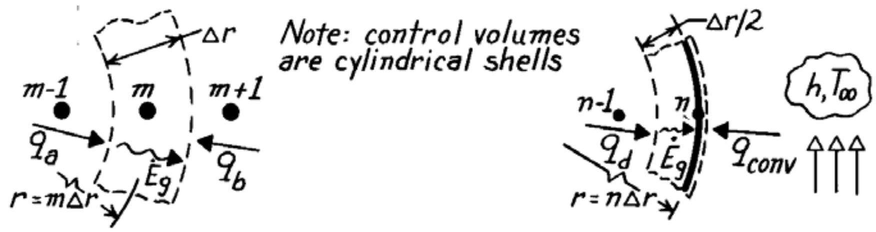
COMMENTS: How would you modify the analysis if the contact resistance is significant?

PROBLEM 4.43

KNOWN: Conduction in a one-dimensional (radial) *cylindrical* coordinate system with volumetric generation.

FIND: Finite-difference equation for (a) Interior node, m, and (b) Surface node, n, with convection.

SCHEMATIC:



(a) Interior node, m (b) Surface node with convection, n

ASSUMPTIONS: (1) Steady-state, one-dimensional (radial) conduction in *cylindrical* coordinates, (2) Constant properties.

ANALYSIS: (a) The network has nodes spaced at equal Δr increments with m = 0 at the center; hence, r = mΔr (or nΔr). The control volume is $V = 2\pi\ r \cdot \Delta r \cdot \ell = 2\pi\left(m\Delta r\right)\Delta r \cdot \ell$. The energy balance is $\dot{E}_{in} + \dot{E}_g = q_a + q_b + \dot{q}V = 0$

$$k\left[2\pi\left[r - \frac{\Delta r}{2}\right]\ell\right]\frac{T_{m-1} - T_m}{\Delta r} + k\left[2\pi\left[r + \frac{\Delta r}{2}\right]\ell\right]\frac{T_{m+1} - T_m}{\Delta r} + \dot{q}\left[2\pi\left(m\Delta r\right)\Delta r\ell\right] = 0.$$

Recognizing that r = mΔr, canceling like terms, and regrouping find

$$\left[m - \frac{1}{2}\right]T_{m-1} + \left[m + \frac{1}{2}\right]T_{m+1} - 2mT_m + \frac{\dot{q}m\Delta r^2}{k} = 0.$$ <

(b) The control volume for the surface node is $V = 2\pi\ r \cdot \left(\Delta r/2\right) \cdot \ell$. The energy balance is $\dot{E}_{in} + \dot{E}_g = q_d + q_{conv} + \dot{q}V = 0$. Use Fourier's law to express q_d and Newton's law of cooling for q_{conv} to obtain

$$k\left[2\pi\left[r - \frac{\Delta r}{2}\right]\ell\right]\frac{T_{n-1} - T_n}{\Delta r} + h\left[2\pi\ r\ell\right]\left(T_\infty - T_n\right) + \dot{q}\left[2\pi\left(n\Delta r\right)\frac{\Delta r}{2}\ell\right] = 0.$$

Let r = nΔr, cancel like terms and regroup to find

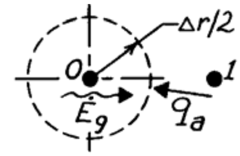
$$\left[n - \frac{1}{2}\right]T_{n-1} - \left[\left[n - \frac{1}{2}\right] + \frac{hn\Delta r}{k}\right]T_n + \frac{\dot{q}n\Delta r^2}{2k} + \frac{hn\Delta r}{k}T_\infty = 0.$$ <

COMMENTS: (1) Note that when m or n becomes very large compared to ½, the finite-difference equation becomes independent of m or n. Then the cylindrical system approximates a rectangular one.

(2) The finite-difference equation for the center node (m = 0) needs to be treated as a special case. The control volume is

$V = \pi\left(\Delta r/2\right)^2 \ell$ and the energy balance is

$$\dot{E}_{in} + \dot{E}_g = q_a + \dot{q}V = k\left[2\pi\left[\frac{\Delta r}{2}\right]\ell\right]\frac{T_1 - T_0}{\Delta r} + \dot{q}\left[\pi\left[\frac{\Delta r}{2}\right]^2\ell\right] = 0.$$



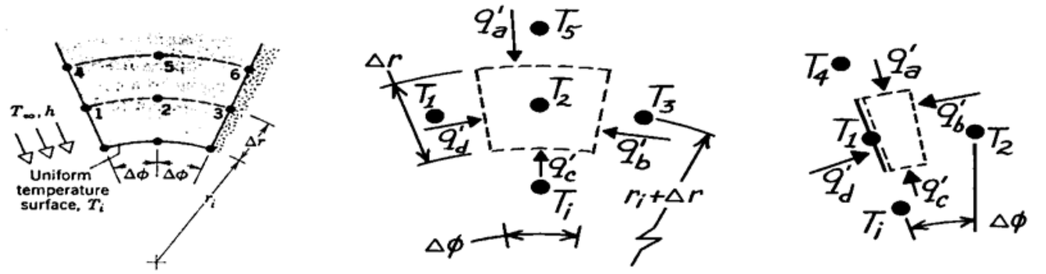
Regrouping, the finite-difference equation is $-T_o + T_1 + \dfrac{\dot{q}\Delta r^2}{4k} = 0.$

PROBLEM 4.44

KNOWN: Two-dimensional cylindrical configuration with prescribed radial (Δr) and angular ($\Delta\phi$) spacings of nodes.

FIND: Finite-difference equations for nodes 2, 3 and 1.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction in cylindrical coordinates (r,ϕ), (3) Constant properties.

ANALYSIS: The method of solution is to define the appropriate control volume for each node, to identify relevant processes and then to perform an energy balance.

(a) Node 2. This is an *interior* node with control volume as shown above. The energy balance is $\dot{E}_{in} = q'_a + q'_b + q'_c + q'_d = 0$. Using Fourier's law for each process, find

$$k\left[\left[r_i + \frac{3}{2}\Delta r\right]\Delta\phi\right]\frac{(T_5 - T_2)}{\Delta r} + k(\Delta r)\frac{(T_3 - T_2)}{(r_i + \Delta r)\Delta\phi} +$$
$$+ k\left[\left[r_i + \frac{1}{2}\Delta r\right]\Delta\phi\right]\frac{(T_i - T_2)}{\Delta r} + k(\Delta r)\frac{(T_1 - T_2)}{(r_i + \Delta r)\Delta\phi} = 0.$$

Canceling terms and regrouping yields,

$$-2\left[(r_i + \Delta r) + \frac{(\Delta r)^2}{(\Delta\phi)^2}\frac{1}{(r_i + \Delta r)}\right]T_2 + \left[r_i + \frac{3}{2}\Delta r\right]T_5 + \frac{(\Delta r)^2}{(r_i + \Delta r)(\Delta\phi)^2}(T_3 + T_1) + \left[r_i + \frac{1}{2}\Delta r\right]T_i = 0.$$

(b) Node 3. The adiabatic surface behaves as a symmetry surface. We can utilize the result of Part (a) to write the finite-difference equation by inspection as

$$-2\left[(r_i + \Delta r) + \frac{(\Delta r)^2}{(\Delta\phi)^2}\frac{1}{(r_i + \Delta r)}\right]T_3 + \left[r_i + \frac{3}{2}\Delta r\right]T_6 + \frac{2(\Delta r)^2}{(r_i + \Delta r)(\Delta\phi)^2}\cdot T_2 + \left[r_i + \frac{1}{2}\Delta r\right]T_i = 0.$$

(c) Node 1. The energy balance is $q'_a + q'_b + q'_c + q'_d = 0$. Substituting,

$$k\left[\left[r_i + \frac{3}{2}\Delta r\right]\frac{\Delta\phi}{2}\right]\frac{(T_4 - T_1)}{\Delta r} + k(\Delta r)\frac{(T_2 - T_1)}{(r_i + \Delta r)\Delta\phi} +$$

$$+k\left[\left[r_i + \frac{1}{2}\Delta r\right]\frac{\Delta\phi}{2}\right]\frac{(T_i - T_1)}{\Delta r} + h(\Delta r)(T_\infty - T_1) = 0 \qquad <$$

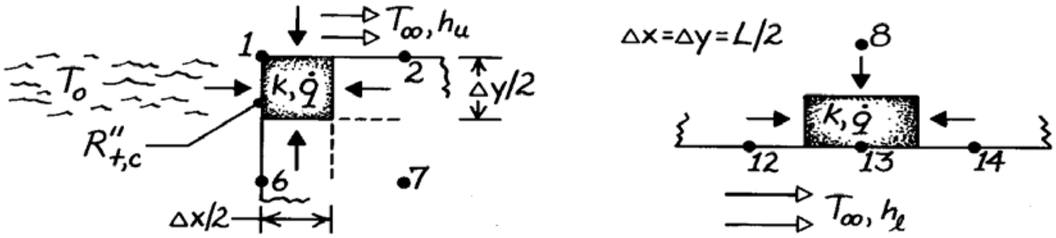
This expression could now be rearranged.

PROBLEM 4.45

KNOWN: Heat generation and thermal boundary conditions of bus bar. Finite-difference grid.

FIND: Finite-difference equations for selected nodes.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties.

ANALYSIS: (a) Performing an energy balance on the control volume, (Δx/2)(Δy/2)·1, find the FDE for node 1,

$$\frac{T_o - T_1}{R''_{t,c}/(\Delta y/2)1} + h_u\left(\frac{\Delta x}{2}\cdot 1\right)(T_\infty - T_1) + \frac{k(\Delta y/2\cdot 1)}{\Delta x}(T_2 - T_1)$$
$$+\frac{k(\Delta x/2\cdot 1)}{\Delta y}(T_6 - T_1) + \dot{q}\left[(\Delta x/2)(\Delta y/2)1\right] = 0$$

$$\left(\Delta x/kR''_{t,c}\right)T_o + \left(h_u\Delta x/k\right)T_\infty + T_2 + T_6$$

$$+\dot{q}(\Delta x)^2/2k - \left[\left(\Delta x/kR''_{t,c}\right) + \left(h_u\Delta x/k\right) + 2\right]T_1 = 0. \qquad <$$

(b) Performing an energy balance on the control volume, (Δx)(Δy/2)·1, find the FDE for node 13,

$$h_l(\Delta x\cdot 1)(T_\infty - T_{13}) + (k/\Delta x)(\Delta y/2\cdot 1)(T_{12} - T_{13})$$
$$+(k/\Delta y)(\Delta x\cdot 1)(T_8 - T_{13}) + (k/\Delta x)(\Delta y/2\cdot 1)(T_{14} - T_{13}) + \dot{q}(\Delta x\cdot\Delta y/2\cdot 1) = 0$$

$$\left(h_l\Delta x/k\right)T_\infty + 1/2\left(T_{12} + 2T_8 + T_{14}\right) + \dot{q}(\Delta x)^2/2k - \left(h_l\Delta x/k + 2\right)T_{13} = 0. \qquad <$$

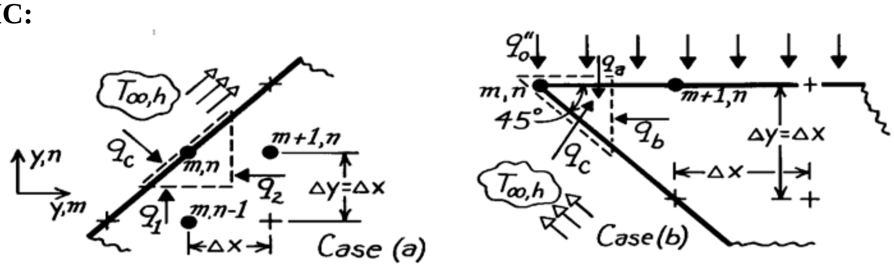
COMMENTS: For fixed T_o and T_∞, the relative amounts of heat transfer to the air and heat sink are determined by the values of h and $R''_{t,c}$.

PROBLEM 4.46

KNOWN: Nodal point configurations corresponding to a diagonal surface boundary subjected to a convection process and to the tip of a machine tool subjected to constant heat flux and convection cooling.

FIND: Finite-difference equations for the node m,n in the two situations shown.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, 2-D conduction, (2) Constant properties.

ANALYSIS: (a) The control volume about node m,n has triangular shape with sides Δx and Δy while the diagonal (surface) length is $\sqrt{2}\ \Delta x$. The heat rates associated with the control volume are due to conduction, q_1 and q_2, and to convection, q_c. Performing an energy balance, find

$$\dot{E}_{in} - \dot{E}_{out} = 0 \qquad q_1 + q_2 + q_c = 0$$

$$k(\Delta x \cdot 1)\frac{T_{m,n-1} - T_{m,n}}{\Delta y} + k(\Delta y \cdot 1)\frac{T_{m+1,n} - T_{m,n}}{\Delta x} + h\left(\sqrt{2}\ \Delta x \cdot 1\right)\left(T_\infty - T_{m,n}\right) = 0.$$

Note that we have considered the solid to have unit depth normal to the page. Recognizing that Δx = Δy, dividing each term by k and regrouping, find

$$T_{m,n-1} + T_{m+1,n} + \sqrt{2}\ \cdot \frac{h\Delta x}{k} T_\infty - \left[2 + \sqrt{2}\ \cdot \frac{h\Delta x}{k}\right] T_{m,n} = 0. \qquad <$$

(b) The control volume about node m,n has triangular shape with sides Δx/2 and Δy/2 while the lower diagonal surface length is $\sqrt{2}(\Delta x/2)$. The heat rates associated with the control volume are due to the constant heat flux, q_a, to conduction, q_b, and to the convection process, q_c. Perform an energy balance,

$$\dot{E}_{in} - \dot{E}_{out} = 0 \qquad q_a + q_b + q_c = 0$$

$$q''_o \cdot \left[\frac{\Delta x}{2} \cdot 1\right] + k \cdot \left[\frac{\Delta y}{2} \cdot 1\right] \frac{T_{m+1,n} - T_{m,n}}{\Delta x} + h \cdot \left[\sqrt{2} \cdot \frac{\Delta x}{2}\right]\left(T_\infty - T_{m,n}\right) = 0.$$

Recognizing that Δx = Δy, dividing each term by k/2 and regrouping, find

$$T_{m+1,n} + \sqrt{2} \cdot \frac{h\Delta x}{k} \cdot T_\infty + q''_o \cdot \frac{\Delta x}{k} - \left(1 + \sqrt{2} \cdot \frac{h\Delta x}{k}\right) T_{m,n} = 0. \qquad <$$

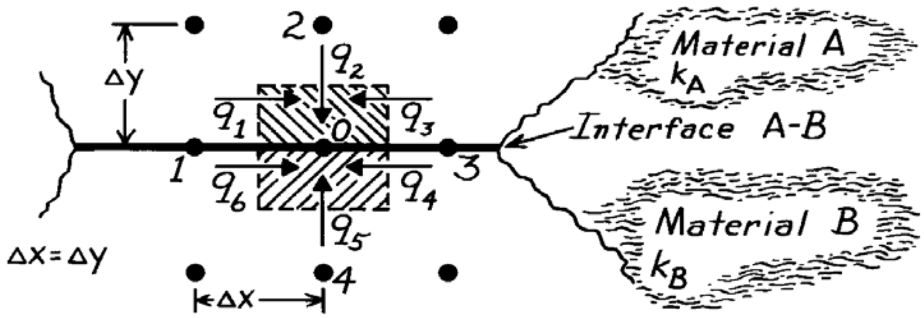
COMMENTS: Note the appearance of the term hΔx/k in both results, which is a dimensionless parameter (the *Biot number*) characterizing the relative effects of convection and conduction.

PROBLEM 4.47

KNOWN: Nodal point on boundary between two materials.

FIND: Finite-difference equation for steady-state conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties, (4) No internal heat generation, (5) Negligible thermal contact resistance at interface.

ANALYSIS: The control volume is defined about nodal point 0 as shown above. The conservation of energy requirement has the form

$$\sum_{i=1}^{6} q_i = q_1 + q_2 + q_3 + q_4 + q_5 + q_6 = 0$$

since all heat rates are shown as *into* the CV. Each heat rate can be written using Fourier's law,

$$k_A \cdot \frac{\Delta y}{2} \cdot \frac{T_1 - T_0}{\Delta x} + k_A \cdot \Delta x \cdot \frac{T_2 - T_0}{\Delta y} + k_A \cdot \frac{\Delta y}{2} \cdot \frac{T_3 - T_0}{\Delta x}$$
$$+ k_B \cdot \frac{\Delta y}{2} \cdot \frac{T_3 - T_0}{\Delta x} + k_B \cdot \Delta x \cdot \frac{T_4 - T_0}{\Delta y} + k_B \cdot \frac{\Delta y}{2} \cdot \frac{T_1 - T_0}{\Delta x} = 0.$$

Recognizing that $\Delta x = \Delta y$ and regrouping gives the relation,

$$-T_0 + \frac{1}{4} T_1 + \frac{k_A}{2(k_A + k_B)} T_2 + \frac{1}{4} T_3 + \frac{k_B}{2(k_A + k_B)} T_4 = 0. \quad <$$

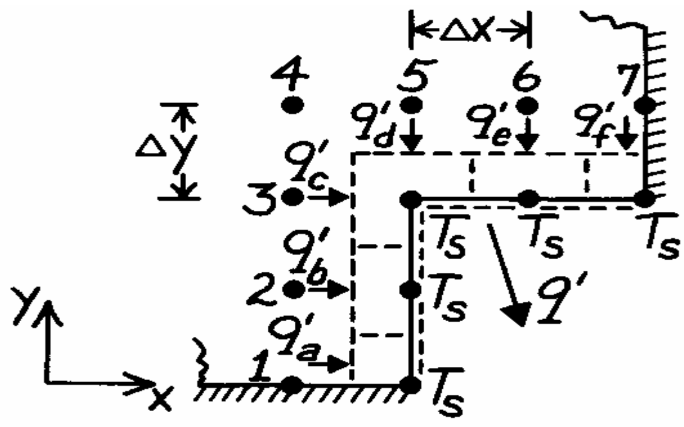
COMMENTS: Note that when $k_A = k_B$, the result agrees with Equation 4.29 which is appropriate for an interior node in a medium of fixed thermal conductivity.

PROBLEM 4.48

KNOWN: Two-dimensional grid for a system with no internal volumetric generation.

FIND: Expression for heat rate per unit length normal to page crossing the isothermal boundary.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional heat transfer, (3) Constant properties.

ANALYSIS: Identify the surface nodes (T_s) and draw control volumes about these nodes. Since there is no heat transfer in the direction parallel to the isothermal surfaces, the heat rate out of the constant temperature surface boundary is

$$q' = q'_a + q'_b + q'_c + q'_d + q'_e + q'_f$$

For each q'_i, use Fourier's law and pay particular attention to the manner in which the cross-sectional area and gradients are specified.

$$q' = k(\Delta y/2)\frac{T_1 - T_s}{\Delta x} + k(\Delta y)\frac{T_2 - T_s}{\Delta x} + k(\Delta y)\frac{T_3 - T_s}{\Delta x}$$
$$+ k(\Delta x)\frac{T_5 - T_s}{\Delta y} + k(\Delta x)\frac{T_6 - T_s}{\Delta y} + k(\Delta x/2)\frac{T_7 - T_s}{\Delta y}$$

Regrouping with $\Delta x = \Delta y$, find

$$q' = k[0.5T_1 + T_2 + T_3 + T_5 + T_6 + 0.5T_7 - 5T_s].$$ <

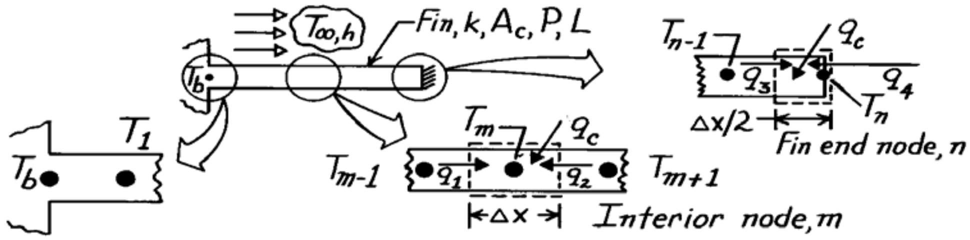
COMMENTS: Looking at the corner node, it is important to recognize the areas associated with q'_c and q'_d (Δy and Δx, respectively).

PROBLEM 4.49

KNOWN: One-dimensional fin of uniform cross section insulated at one end with prescribed base temperature, convection process on surface, and thermal conductivity.

FIND: Finite-difference equation for these nodes: (a) Interior node, m and (b) Node at end of fin, n, where x = L.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction.

ANALYSIS: (a) The control volume about node m is shown in the schematic; the node spacing and control volume length in the x direction are both Δx. The uniform cross-sectional area and fin perimeter are A_c and P, respectively. The heat transfer process on the control surfaces, q_1 and q_2, represent conduction while q_c is the convection heat transfer rate between the fin and ambient fluid. Performing an energy balance, find

$$\dot{E}_{in} - \dot{E}_{out} = 0 \qquad q_1 + q_2 + q_c = 0$$

$$kA_c \frac{T_{m-1} - T_m}{\Delta x} + kA_c \frac{T_{m+1} - T_m}{\Delta x} + hP\Delta x \left(T_\infty - T_m\right) = 0.$$

Multiply the expression by $\Delta x/kA_c$ and regroup to obtain

$$T_{m-1} + T_{m+1} + \frac{hP}{kA_c} \cdot \Delta x^2 T_\infty - \left[2 + \frac{hP}{kA_c} \Delta x^2\right] T_m = 0 \qquad 1<m<n$$ <

Considering now the special node m = 1, then the m-1 node is T_b, the base temperature. The finite-difference equation would be

$$T_b + T_2 + \frac{hP}{kA_c} \Delta x^2 T_\infty - \left[2 + \frac{hP}{kA_c} \Delta x^2\right] T_1 = 0 \qquad m=1$$ <

(b) The control volume of length $\Delta x/2$ about node n is shown in the schematic. Performing an energy balance,

$$\dot{E}_{in} - \dot{E}_{out} = 0 \qquad q_3 + q_4 + q_c = 0$$

$$kA_c \frac{T_{n-1} - T_n}{\Delta x} + 0 + hP \frac{\Delta x}{2} \left(T_\infty - T_n\right) = 0.$$

Note that $q_4 = 0$ since the end (x = L) is insulated. Multiplying by $\Delta x/kA_c$ and regrouping,

$$T_{n-1} + \frac{hP}{kA_c} \cdot \frac{\Delta x^2}{2} T_\infty - \left[\frac{hP}{kA_c} \cdot \frac{\Delta x^2}{2} + 1\right] T_n = 0.$$ <

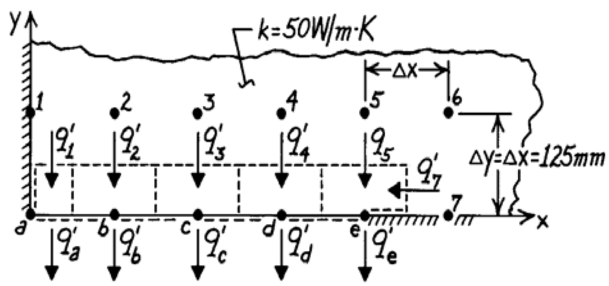
COMMENTS: The value of Δx will be determined by the selection of n; that is, $\Delta x = L/n$. Note that the grouping, hP/kA_c, appears in the finite-difference and differential forms of the energy balance.

PROBLEM 4.50

KNOWN: Two-dimensional network with prescribed nodal temperatures and thermal conductivity of the material.

FIND: Heat rate per unit length normal to page, q'.

SCHEMATIC:



Node	T_i(°C)
1	120.55
2	120.64
3	121.29
4	123.89
5	134.57
6	150.49
7	147.14

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional heat transfer, (3) No internal volumetric generation, (4) Constant properties.

ANALYSIS: Construct control volumes around the nodes on the surface maintained at the uniform temperature T_s and indicate the heat rates. The heat rate per unit length is $q' = q'_a + q'_b + q'_c + q'_d + q'_e$ or in terms of conduction terms between nodes,

$$q' = q'_1 + q'_2 + q'_3 + q'_4 + q'_5 + q'_7.$$

Each of these rates can be written in terms of nodal temperatures and control volume dimensions using Fourier's law,

$$q' = k\cdot\frac{\Delta x}{2}\cdot\frac{T_1 - T_s}{\Delta y} + k\cdot\Delta x\cdot\frac{T_2 - T_s}{\Delta y} + k\cdot\Delta x\frac{T_3 - T_s}{\Delta y} + k\cdot\Delta x\frac{T_4 - T_s}{\Delta y}$$
$$+ k\cdot\Delta x\frac{T_5 - T_s}{\Delta y} + k\cdot\frac{\Delta y}{2}\cdot\frac{T_7 - T_s}{\Delta x}.$$

and since $\Delta x = \Delta y$,

$$q' = k[(1/2)(T_1 - T_s) + (T_2 - T_s) + (T_3 - T_s)$$
$$+ (T_4 - T_s) + (T_5 - T_s) + (1/2)(T_7 - T_s)].$$

Substituting numerical values, find

$$q' = 50\ \text{W/m}\cdot\text{K}[(1/2)(120.55 - 100) + (120.64 - 100) + (121.29 - 100)$$
$$+ (123.89 - 100) + (134.57 - 100) + (1/2)(147.14 - 100)]$$

$$q' = 6711\ \text{W/m}.$$ <

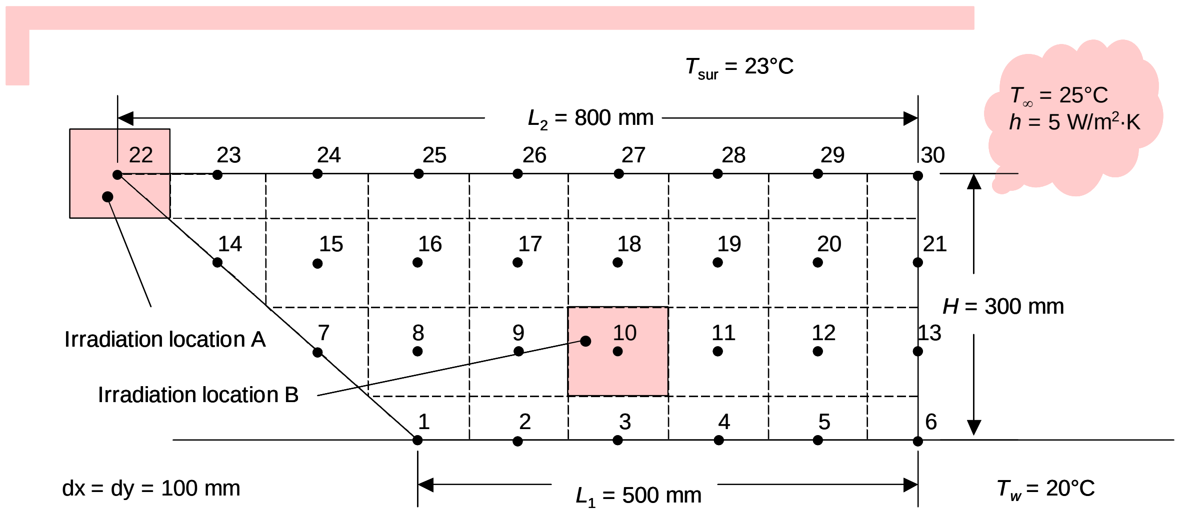
COMMENTS: For nodes a through d, there is no heat transfer into the control volumes in the x-direction. Look carefully at the energy balance for node e, $q'_e = q'_5 + q'_7$, and how q'_5 and q'_7 are evaluated.

PROBLEM 4.51

KNOWN: Dimensions of mockup, absorbed irradiation in 100 mm × 100 mm area, thermal conductivity and emissivity of plywood and stainless steel, temperature of water, ambient air, and surroundings. Convection heat transfer coefficient.

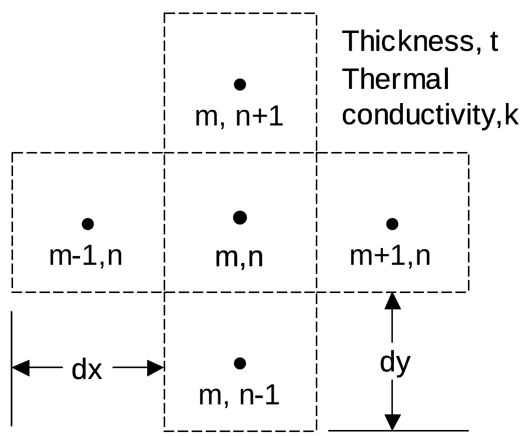
FIND: (a) Maximum steady-state temperature for plywood at locations A and B, (c) Maximum steady-state temperature for stainless steel at locations A and B.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Two-dimensional heat transfer, (4) Uniform irradiation, (5) Large surroundings, (6) Submerged section of mockup at water temperature, (7) Negligible temperature gradients through thickness of mockup.

ANALYSIS: We apply Newton's law of cooling, Fourier's law and Eq. 1.7 to a general control volume within the mockup and apply the following general finite-difference formula. Note that radiation and convective losses occur from both the front and back surfaces of the mockup through an area of $2dxdy$.

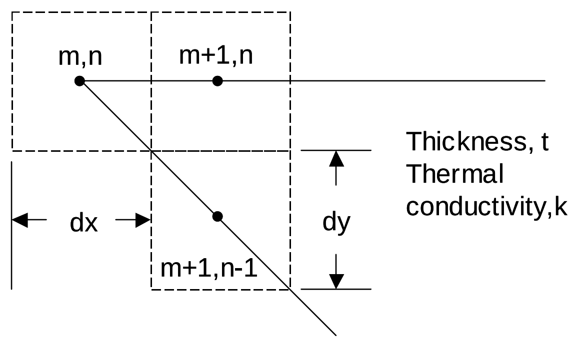


Continued…

PROBLEM 4.51 (Cont.)

$$\frac{k(T_{m-1,n}-T_{m,n})}{dx}(tdy)+\frac{k(T_{m,n+1}-T_{m,n})}{dy}(tdx)+\frac{k(T_{m+1,n}-T_{m,n})}{dx}(tdy)+\frac{k(T_{m,n-1}-T_{m,n})}{dy}(tdx)$$
$$+G_{s,N}(dx\cdot dy)+h(2dx\cdot dy)(T_\infty-T_{m,n})+\varepsilon\sigma(2dx\cdot dy)(T_{sur}^4-T_{m,n}^4)=0$$

Likewise, for the control volume at the tip of the bow,



$$\frac{k(T_{m+1,n}-T_{m,n})}{dx}(tdy/2)+G_{s,N}(dx\cdot dy/8)+h(dx\cdot dy/4)(T_\infty-T_{m,n})+\varepsilon\sigma(dx\cdot dy/4)(T_{sur}^4-T_{m,n}^4)=0$$

Additional finite difference energy balances are included in the IHT code available in Comment (1). The node numbers are keyed to the schematic.

(a) For plywood with k = 0.8 W/m·K and ε = 0.9, the steady-state temperature at location A is T_{22} = 613.6°C. For irradiation at location B, the steady-state temperature is T_{10} = 613.6°C. Therefore, it does not matter where the irradiation is directed. The temperatures are very high and combustion is likely to occur. <

(b) For stainless steel with k = 15 W/m·K and ε = 0.2, the steady-state temperature at location A is T_{22} = 804.7°C. For irradiation at location B, the steady-state temperature is T_{10} = 767.3°C. Therefore, it is preferable to direct the beam to the tip of the bow of the ship (location A). <

COMMENTS: (1) The IHT code is shown below. Note that this version of the code is associated with irradiation at location A for stainless steel. Appropriate modification of the thermal conductivity and emissivity, as well as revision of the energy balances at Nodes 22 and 10 are necessary to simulate the thermal response of stainless steel or irradiation at location B, respectively.

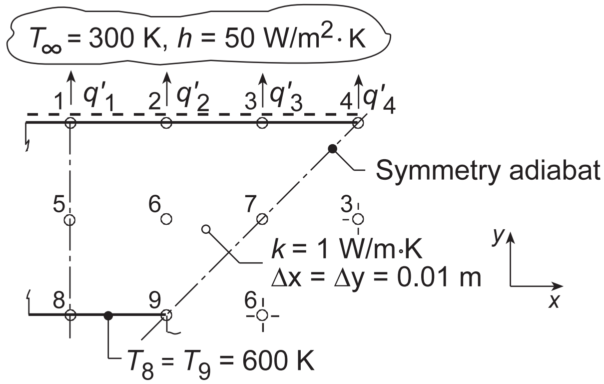
(2) For irradiation at location A of plywood, steady-state temperatures in the vicinity of T_{22} are T_{23} = 42.99°C and T_{14} = 25.62°C. Temperatures at locations far-removed from the irradiation site are at T = 23.97°C. For irradiation at location B, steady-state temperatures in the vicinity of T_{10} are T_{18} = 42.99°C and $T_9 = T_{11}$ = 42.80°C. The thermal conductivity and thickness of the plywood are small, and conduction from the irradiated area to neighboring nodes is negligible. In fact, setting the thermal conductivity to k = 0 W/m·K yields a steady-state temperature of T_{22} = 619.8°C, only a few degrees higher than when conduction is accounted for. (3) For irradiation at location A of stainless steel, steady-state temperatures in the vicinity of T_{22} are T_{23} = 274.9°C and T_{14} = 237.2°C. Temperatures at locations far-removed from the irradiation site are at T = 24.37°C. For irradiation at location B, steady-state temperatures in the vicinity of T_{10} are T_{18} = 233.4°C, T_9 = 202.0°C and T_{11} = 201.6°C. The thermal conductivity and thickness of the stainless steel are sufficiently large so that conduction from the irradiated area to neighboring nodes is significant. Setting the thermal conductivity to k = 0 W/m·K yields a steady-state temperature of T_{22} = 1004°C, significantly higher than when conduction is accounted for.(4) Although conduction losses from the irradiated areas are significant in the stainless steel, relatively high temperatures can be induced because radiation losses are reduced relative to plywood because of the lower emissivity. (5) Stainless steel will have a smaller absorptivity relative to plywood. Many more students would be needed to focus their individual mirrors to induce the absorbed irradiation value given in the problem statement. (6) The preceding analysis is based upon the assumption of two-dimensional heat transfer, implying the edge effects are negligible. However, for Node 22 (location A) the edge surface area is significant and constitutes approximately 30% of the entire exposed surface area. Including edge losses at location A will decrease the temperature of the wood mockup at that location to approximately T_{22} = 527°C while inclusion of edge losses will not affect the predicted temperature at location B. For the stainless steel case, T_{22} = 700°C and the temperature at location B is not affected. Hence, the recommended irradiation location is highly-dependent upon whether edge losses are accounted for.

PROBLEM 4.52

KNOWN: Nodal temperatures from a steady-state, finite-difference analysis for a one-eighth symmetrical section of a square channel.

FIND: (a) Beginning with properly defined control volumes, derive the finite-difference equations for nodes 2, 4 and 7, and determine T_2, T_4 and T_7, and (b) Heat transfer loss per unit length from the channel, q'.

SCHEMATIC:



Node	T(°C)
1	430
3	394
6	492
8,9	600

ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) No internal volumetric generation, (4) Constant properties.

ANALYSIS: (a) Define control volumes about the nodes 2, 4, and 7, taking advantage of symmetry where appropriate and performing energy balances, $\dot{E}_{in} - \dot{E}_{out} = 0$, with Δx = Δy,

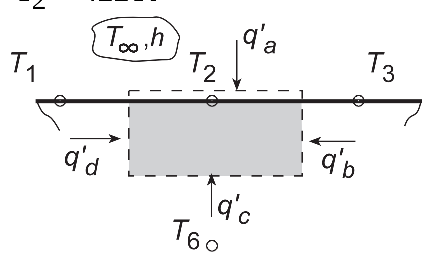
Node 2: $q'_a + q'_b + q'_c + q'_d = 0$

$$h\Delta x\left(T_\infty - T_2\right) + k\left(\Delta y/2\right)\frac{T_3 - T_2}{\Delta x} + k\Delta x\frac{T_6 - T_2}{\Delta y} + k\left(\Delta y/2\right)\frac{T_1 - T_2}{\Delta x} = 0$$

$$T_2 = \left[0.5T_1 + 0.5T_3 + T_6 + \left(h\Delta x/k\right)T_\infty\right] / \left[2 + \left(h\Delta x/k\right)\right]$$

$$T_2 = \left[0.5\times 430 + 0.5\times 394 + 492 + \left(50\,\mathrm{W/m^2\cdot K}\times 0.01\,\mathrm{m}/1\,\mathrm{W/m\cdot K}\right)300\right]\mathrm{K} \Big/ \left[2 + 0.50\right]$$

$$T_2 = 422\,\mathrm{K}$$ <



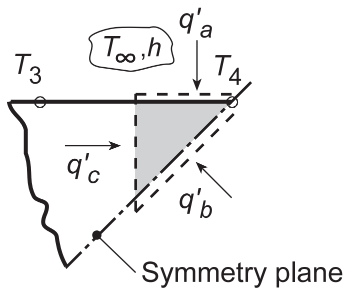
Node 4: $q'_a + q'_b + q'_c = 0$

$$h\left(\Delta x/2\right)\left(T_\infty - T_4\right) + 0 + k\left(\Delta y/2\right)\frac{T_3 - T_4}{\Delta x} = 0$$

$$T_4 = \left[T_3 + \left(h\Delta x/k\right)T_\infty\right] / \left[1 + \left(h\Delta x/k\right)\right]$$

$$T_4 = \left[394 + 0.5\times 300\right]\mathrm{K} / \left[1 + 0.5\right] = 363\,\mathrm{K}$$ <

Continued...



Node 7: From the first schematic, recognizing that the diagonal is a symmetry adiabat, we can treat node 7 as an interior node, hence

$$T_7 = 0.25(T_3 + T_3 + T_6 + T_6) = 0.25(394 + 394 + 492 + 492)\,K = 443\,K \quad <$$

(b) The heat transfer loss from the upper surface can be expressed as the sum of the convection rates from each node as illustrated in the first schematic,

$$q'_{cv} = q'_1 + q'_2 + q'_3 + q'_4$$

$$q'_{cv} = h(\Delta x/2)(T_1 - T_\infty) + h\Delta x(T_2 - T_\infty) + h\Delta x(T_3 - T_\infty) + h(\Delta x/2)(T_4 - T_\infty)$$

$$q'_{cv} = 50\,W/m^2 \cdot K \times 0.01\,m\left[(430-300)/2 + (422-300) + (394-300) + (363-300)/2\right]K$$

$$q'_{cv} = 156\,W/m \quad <$$

COMMENTS: (1) Always look for symmetry conditions which can greatly simplify the writing of the nodal equation as was the case for Node 7.

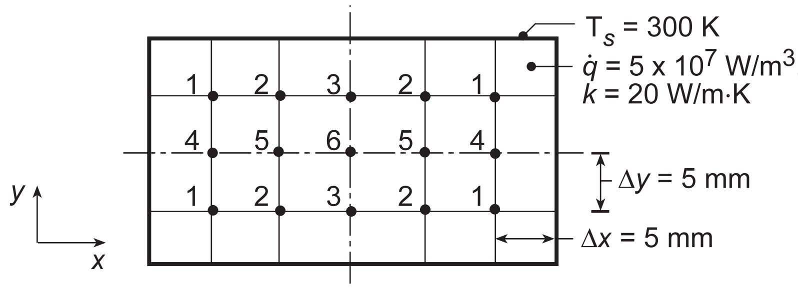
(2) Consider using the *IHT Tool*, *Finite-Difference Equations*, for *Steady-State*, *Two-Dimensional* heat transfer to determine the nodal temperatures T_1 - T_7 when only the boundary conditions T_8, T_9 and (T_∞,h) are specified.

PROBLEM 4.53

KNOWN: Volumetric heat generation in a rectangular rod of uniform surface temperature.

FIND: (a) Temperature distribution in the rod, and (b) With boundary conditions unchanged, heat generation rate causing the midpoint temperature to reach 600 K.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties, (3) Uniform volumetric heat generation.

ANALYSIS: (a) From symmetry it follows that six unknown temperatures must be determined. Since all nodes are interior ones, the finite-difference equations may be obtained from Eq. 4.35 written in the form

$$T_i = 1/4 \sum T_{neighbors} + 1/4\left(\dot{q}\left(\Delta x \Delta y\right)/k\right).$$

With $\dot{q}\left(\Delta x \Delta y\right)/4k$ = 62.5 K, the system of finite-difference equations is

$$T_1 = 0.25\left(T_s + T_2 + T_4 + T_s\right) + 15.625 \quad (1)$$

$$T_2 = 0.25\left(T_s + T_3 + T_5 + T_1\right) + 15.625 \quad (2)$$

$$T_3 = 0.25\left(T_s + T_2 + T_6 + T_2\right) + 15.625 \quad (3)$$

$$T_4 = 0.25\left(T_1 + T_5 + T_1 + T_s\right) + 15.625 \quad (4)$$

$$T_5 = 0.25\left(T_2 + T_6 + T_2 + T_4\right) + 15.625 \quad (5)$$

$$T_6 = 0.25\left(T_3 + T_5 + T_3 + T_5\right) + 15.625 \quad (6)$$

With T_s = 300 K, the set of equations was written directly into the IHT workspace and solved for the nodal temperatures,

T_1	T_2	T_3	T_4	T_5	T_6 (K)
348.6	368.9	374.6	362.4	390.2	398.0

<

(b) With the boundary conditions unchanged, the $\dot{q}$ required for T_6 = 600 K can be found using the same set of equations in the IHT workspace, but with these changes: (1) replace the last term on the RHS (15.625) of Eqs. (1-6) by $\dot{q}$ (ΔxΔy)/4k = $(0.005\text{ m})^2$ $\dot{q}$ /4×20 W/m·K = 3.125×10^{-7} $\dot{q}$ and (2) set T_6 = 600 K. The set of equations has 6 unknown, five nodal temperatures plus $\dot{q}$. Solving find

$$\dot{q} = 1.53 \times 10^8 \text{ W/m}^3$$

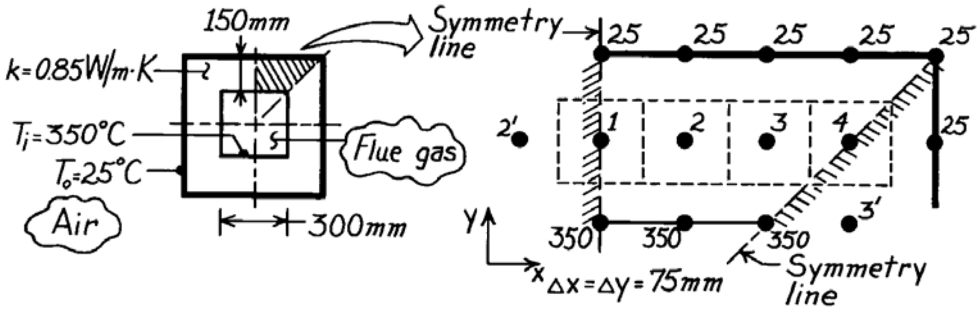
<

PROBLEM 4.54

KNOWN: Flue of square cross section with prescribed geometry, thermal conductivity and inner and outer surface temperatures.

FIND: Heat loss per unit length from the flue, q'.

SCHEMATIC:



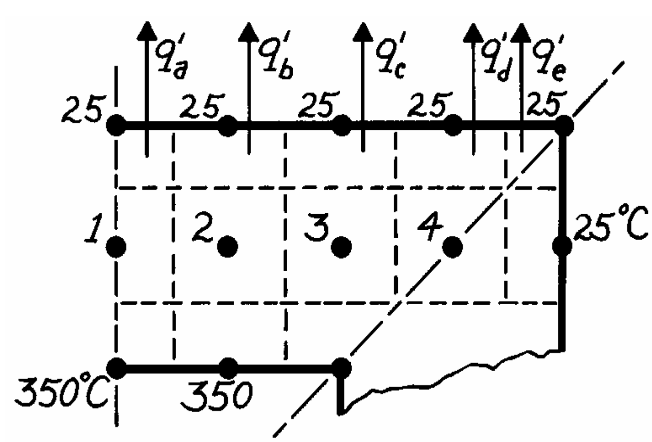
ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties, (3) No internal generation.

ANALYSIS: Taking advantage of symmetry, the nodal network using the suggested 75mm grid spacing is shown above. To obtain the heat rate, we first need to determine the unknown temperatures T_1, T_2, T_3 and T_4. Recognizing that these nodes may be treated as interior nodes, the nodal equations from Eq. 4.29 are

$$(T_2 + 25 + T_2 + 350) - 4T_1 = 0$$
$$(T_1 + 25 + T_3 + 350) - 4T_2 = 0$$
$$(T_2 + 25 + T_4 + 350) - 4T_3 = 0$$
$$(T_3 + 25 + 25 + T_3) - 4T_4 = 0.$$

Simultaneous solution yields $T_1 = 183.9°C$, $T_2 = 180.3°C$, $T_3 = 162.2°C$, $T_4 = 93.6°C$ <

From knowledge of the temperature distribution, the heat rate may be obtained by summing the heat rates across the nodal control volume surfaces, as shown in the sketch.



Continued...

The heat rate leaving the outer surface of this flue section is,

$$q' = q'_a + q'_b + q'_c + q'_d + q'_e$$
$$q' = k\frac{\Delta x}{\Delta y}\left[\frac{1}{2}(T_1 - 25) + (T_2 - 25) + (T_3 - 25) + (T_4 - 25) + 0\right]$$
$$q' = 0.85\frac{W}{m \cdot K}\left[\frac{1}{2}(183.9 - 25) + (180.3 - 25) + (162.2 - 26) + (93.6 - 25)\right]$$
$$q' = 374.5 \text{ W/m.}$$

Since this flue section is 1/8 the total cross section, the total heat loss from the flue is

$$q' = 8 \times 374.5 \text{ W/m} = 3.00 \text{ kW/m.}$$ <

COMMENTS: (1) The heat rate could have been calculated at the inner surface, and from the above sketch has the form

$$q' = k\frac{\Delta x}{\Delta y}\left[\frac{1}{2}(350 - T_1) + (350 - T_2) + (350 - T_3)\right] = 374.5 \text{ W/m.}$$

This result should compare very closely with that found for the outer surface since the conservation of energy requirement must be satisfied in obtaining the nodal temperatures.
(2) The Gauss-Seidel iteration method can be used to find the nodal temperatures. Following the procedures of Appendix D,

$$T_1^k = 0.50\ T_2^{k-1} + 93.75$$
$$T_2^k = 0.25\ T_1^k + 0.25\ T_3^{k-1} + 93.75$$
$$T_3^k = 0.25\ T_2^k + 0.25\ T_4^{k-1} + 93.75$$
$$T_4^k = 0.50\ T_3^k + 12.5.$$

The iteration procedure is implemented in the table on the following page, one row for each iteration k. The initial estimates, for k = 0, are all chosen as (350 + 25)/2 ≈ 185°C. Iteration is continued until the maximum temperature difference is less than 0.2°C, i.e., $\varepsilon < 0.2$°C.

Note that if the system of equations were organized in matrix form, Eq. 4.48, diagonal dominance would exist. Hence there is no need to reorder the equations since the magnitude of the diagonal element is greater than that of other elements in the same row.

k	T_1(°C)	T_2(°C)	T_3(°C)	T_4(°C)	
0	185	185	185	185	← initial estimate
1	186.3	186.6	186.6	105.8	
2	187.1	187.2	167.0	96.0	
3	187.4	182.3	163.3	94.2

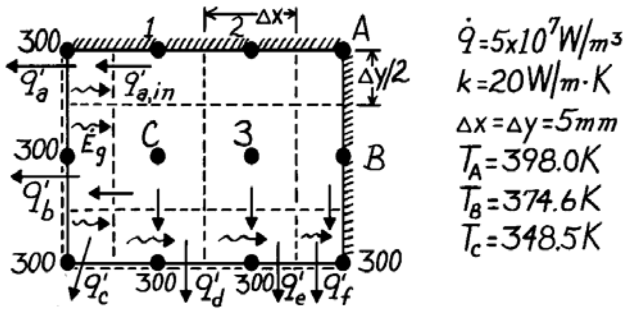
The nodal temperatures are the same as those calculated using the simultaneous solution.

PROBLEM 4.55

KNOWN: Steady-state temperatures (K) at three nodes of a long rectangular bar.

FIND: (a) Temperatures at remaining nodes and (b) heat transfer per unit length from the bar using nodal temperatures; compare with result calculated using knowledge of $\dot{q}$.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, 2-D conduction, (2) Constant properties.

ANALYSIS: (a) The finite-difference equations for the nodes (1,2,3,A,B,C) can be written by inspection using Eq. 4.35 and recognizing that the adiabatic boundary can be represented by a symmetry plane.

$$\sum T_{neighbors} - 4T_i + \dot{q}\Delta x^2 / k = 0 \quad \text{and} \quad \frac{\dot{q}\Delta x^2}{k} = \frac{5\times10^7 \text{ W/m}^3 (0.005\text{m})^2}{20 \text{ W/m}\cdot\text{K}} = 62.5\text{K}.$$

Node A (to find T_2*):* $\quad 2T_2 + 2T_B - 4T_A + \dot{q}\Delta x^2 / k = 0$

$$T_2 = \frac{1}{2}(-2\times374.6 + 4\times398.0 - 62.5)\text{K} = 390.2\text{K} \quad <$$

Node 3 (to find T_3*):* $\quad T_c + T_2 + T_B + 300\text{K} - 4T_3 + \dot{q}\Delta x^2 / k = 0$

$$T_3 = \frac{1}{4}(348.5 + 390.2 + 374.6 + 300 + 62.5)\text{K} = 369.0\text{K} \quad <$$

Node 1 (to find T_1*):* $\quad 300 + 2T_C + T_2 - 4T_1 + \dot{q}\Delta x^2 / k = 0$

$$T_1 = \frac{1}{4}(300 + 2\times348.5 + 390.2 + 62.5) = 362.4\text{K} \quad <$$

(b) The heat rate out of the bar is determined by calculating the heat rate out of each control volume around the 300 K nodes. Consider the node in the upper left-hand corner; from an energy balance

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = 0 \quad \text{or} \quad q'_a = q'_{a,in} + \dot{E}_g \quad \text{where} \quad \dot{E}_g = \dot{q}V.$$

Hence, for the entire bar $\quad q'_{bar} = q'_a + q'_b + q'_c + q'_d + q'_e + q'_f$, or

$$q'_{bar} = \left[k\frac{\Delta y}{2}\frac{T_1 - 300}{\Delta x} + \dot{q}\left[\frac{\Delta x}{2}\cdot\frac{\Delta y}{2}\right]\right]_a + \left[k\Delta y\frac{T_C - 300}{\Delta x} + \dot{q}\left[\frac{\Delta x}{2}\cdot\Delta y\right]\right]_b + \left[\dot{q}\left[\frac{\Delta x}{2}\cdot\frac{\Delta y}{2}\right]\right]_c +$$
$$\left[k\Delta x\frac{T_C - 300}{\Delta y} + \dot{q}\left[\Delta x\cdot\frac{\Delta y}{2}\right]\right]_d + \left[k\Delta x\frac{T_3 - 300}{\Delta y} + \dot{q}\left[\Delta x\cdot\frac{\Delta y}{2}\right]\right]_e + \left[k\frac{\Delta x}{2}\frac{T_B - 300}{\Delta y} + \dot{q}\left[\frac{\Delta x}{2}\cdot\frac{\Delta y}{2}\right]\right]_f.$$

Substituting numerical values, find $q'_{bar} = 7{,}502.5$ W/m. From an overall energy balance on the bar,

$$q'_{bar} = \dot{E}'_g = \dot{q}V/\ell = \dot{q}(3\Delta x\cdot 2\Delta y) = 5\times10^7 \text{ W/m}^3 \times 6(0.005\text{m})^2 = 7{,}500 \text{ W/m.} \quad <$$

As expected, the results of the two methods agree. Why must that be?

PROBLEM 4.56

KNOWN: Dimensions and thermal conductivity distribution within a two-dimensional solid. Applied boundary conditions.

FIND: (a) Spatially-averaged thermal conductivity and heat rate per unit length based upon this value, (b) Heat rate per unit length for case 1 boundary conditions and comparison to estimated heat rate per unit length based upon the spatially-averaged thermal conductivity, (c) Heat rate per unit length for case 2 boundary conditions and comparison to estimated heat rate per unit length based upon the spatially-averaged thermal conductivity.

ASSUMPTIONS: Steady-state, one-dimensional heat transfer.

ANALYSIS: (a) The thermal conductivity varies only in the *x*-direction. Hence,

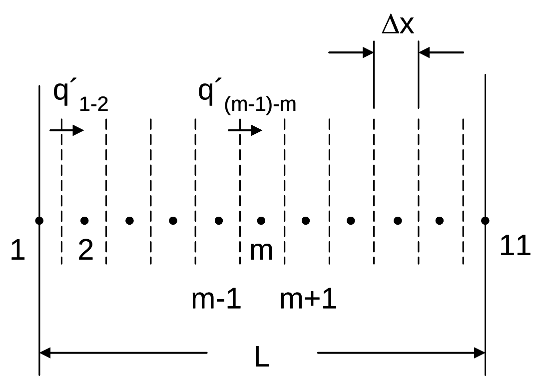
$$\bar{k} = \frac{1}{L}\int_{x=0}^{L} k(x)dx = \frac{1}{L}\int_{x=0}^{L}\left(a + bx^{3/2}\right)dx = a + \frac{2}{5}bL^{3/2}$$

$$= 20\frac{\text{W}}{\text{m}\cdot\text{K}} + \frac{2}{5}\times 7070\frac{\text{W}}{\text{m}^{5/2}\cdot\text{K}}\times(0.02\text{m})^{3/2} = 28\frac{\text{W}}{\text{m}\cdot\text{K}}$$ <

Using this value, the heat rate per unit length is

$$q' = \bar{k}L(\Delta T)/L = 28\frac{\text{W}}{\text{m}\cdot\text{K}}\times 50°\text{C} = 1400\text{W/m}$$ <

(b) The nodal network is shown below. Note that the heat transfer is one-dimensional.



For any control surface, Eq. 4.46 may be combined with Fourier's law and written as

$$q'_{(m-1)-m} = \frac{T_{m-1} - T_m}{R'_{tot}} = \frac{T_{m-1} - T_m}{\left(\dfrac{\Delta x/2}{Lk_{m-1}} + \dfrac{\Delta x/2}{Lk_m}\right)} \quad (1)$$

where the thermal conductivities, k_{m-1} and k_m are evaluated at the left (*m* – 1) and right (*m*) nodes, respectively. At steady state, the heat rate per unit length is constant. Hence, we may write Eqn. (1) for each pair of nodal points from *m* = 1 to *m* = 11 using Δ*x* = 2 mm. The resulting heat rate per unit length is found by solving the 11 simultaneous equations for q′ and the temperatures T_m for $2 \leq m \leq 10$ yielding

$$q' = 1339 \text{ W/m}$$ <

Continued…

PROBLEM 4.56 (Cont.)

The predicted heat rate pure unit length is smaller than that of part (a).

(c) When the applied boundary conditions are changed to those of case 2, we may simply evaluate the heat transfer from the hot surface to the cool surface by evaluating the heat transfer in 11 different lanes and summing the results. For the interior lanes the width is Δx resulting in

$$q_m^{'} = \frac{(\Delta T)k_m}{L}\Delta x \quad \text{for } 2 \le m \le 10$$

where ΔT is the overall temperature difference across the domain. The thermal conductivities are evaluated at the locations of the nodes. For the lanes adjacent to the adiabatic boundaries,

$$q_1^{'} = k_1 \Delta T(\Delta x/2)/L \quad \text{and} \quad q_{11}^{'} k_{11} \Delta T(\Delta x/2)/L$$

and we evaluate the thermal conductivities k_1 and k_{11} at the nodal points, x = 0 and 20 mm, respectively. The heat rate per unit length of the object is

$$q' = \sum_{m=1}^{11} q_m^{'} \quad \text{or} \quad q' = 1401 \text{ W/m}$$ <

The heat rate per unit length is nearly identical to that of part (a).

COMMENTS: (1) The agreement between the results of parts (a) and (c) is expected since $q' = \int_{x=0}^{L} q''(x)dx = \int_{x=0}^{L} \left(k(x)\Delta T/L\right)dx = \bar{k}\left(L/L\right)\Delta T$. The minor difference is due to the evaluation of the thermal conductivity for each lane at the nodal point. The answers would become exactly the same as the spatial resolution of the numerical solution is increased. (2) In part (b) heat transfer is in the x-direction, the same direction in which thermal conductivity varies. This reduces heat transfer rates relative to the value calculated in parts (a) and (c). This is because the resistance expressed in Eq. (1) is composed of two values in series. The total resistance will be dominated by the higher of the two individual resistances. (3) Temperatures calculated for case 1 and heat rates in each lane for case 2 are shown in the table below.

Node or Lane	Temperature, °C (case 1)	Heat rate per unit length, W/m (case 2)
1	100.00	50
2	93.41	103.2

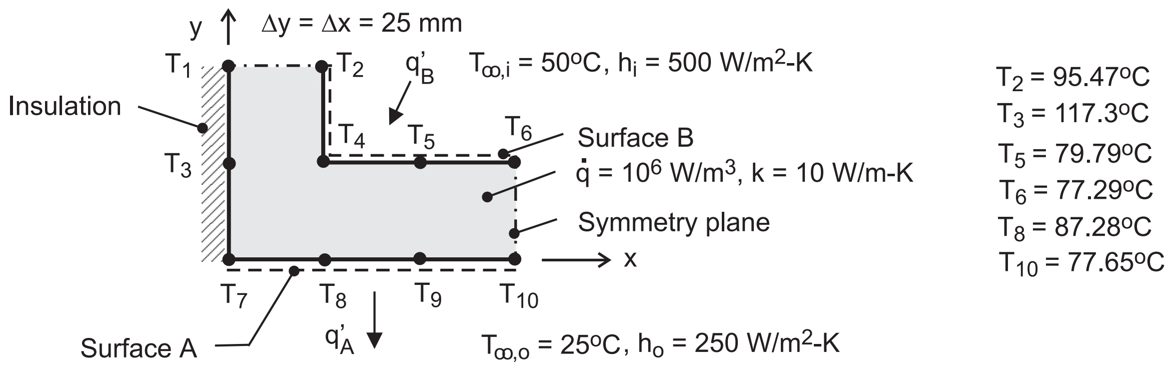
		1401

PROBLEM 4.57

KNOWN: Steady-state temperatures at selected nodal points of the symmetrical section of a flow channel with uniform internal volumetric generation of heat. Inner and outer surfaces of channel experience convection.

FIND: (a) Temperatures at nodes 1, 4, 7, and 9, (b) Heat rate per unit length (W/m) from the outer surface A to the adjacent fluid, (c) Heat rate per unit length (W/m) from the inner fluid to surface B, and (d) Verify that results are consistent with an overall energy balance.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties.

ANALYSIS: (a) The nodal finite-difference equations are obtained from energy balances on control volumes about the nodes shown in the schematics below.

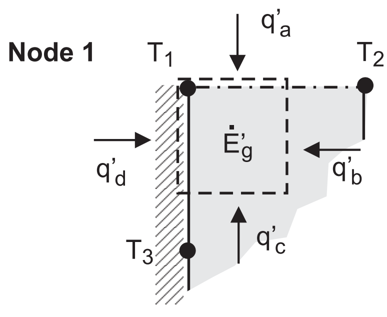
Node 1

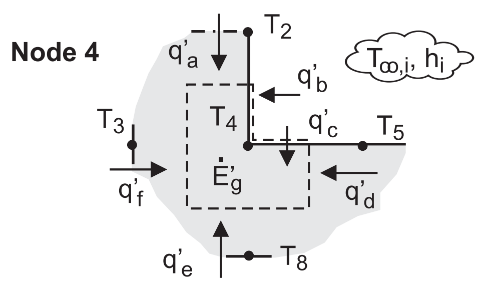
$$q'_a + q'_b + q'_c + q'_d + \dot{E}'_g = 0$$

$$0 + k(\Delta y/2)\frac{T_2 - T_1}{\Delta x} + k(\Delta x/2)\frac{T_3 - T_1}{\Delta y} + 0 + \dot{q}(\Delta x \cdot \Delta y/4) = 0$$

$$T_1 = (T_2 + T_3)/2 + \dot{q}\Delta x^2/4k$$

$$T_1 = (95.47 + 117.3)°C/2 + 10^6\ W/m^3 (25 \times 25)\times 10^{-6}\ m^2/(4 \times 10\ W/m\cdot K) = 122.0°C$$





Node 4

$$q'_a + q'_b + q'_c + q'_d + q'_e + q'_f + \dot{E}'_g = 0$$

$$k(\Delta x/2)\frac{T_2 - T_4}{\Delta y} + h_i(\Delta y/2)(T_{\infty,i} - T_4) + h_i(\Delta x/2)(T_\infty - T_4) +$$

Continued …

PROBLEM 4.57 (Cont.)

$$k(\Delta y/2)\frac{T_5 - T_4}{\Delta x} + k(\Delta x)\frac{T_8 - T_4}{\Delta y} + k(\Delta y)\frac{T_3 - T_4}{\Delta x} + \dot{q}(3\Delta x \cdot \Delta y/4) = 0$$

$$T_4 = \left[T_2 + 2T_3 + T_5 + 2T_8 + 2(h_i \Delta x/k)T_{\infty,i} + \left(3\dot{q}\Delta x^2/2k\right)\right] \Big/ \left[6 + 2(h_i \Delta x/k)\right]$$

$$T_4 = 94.50°C$$ <

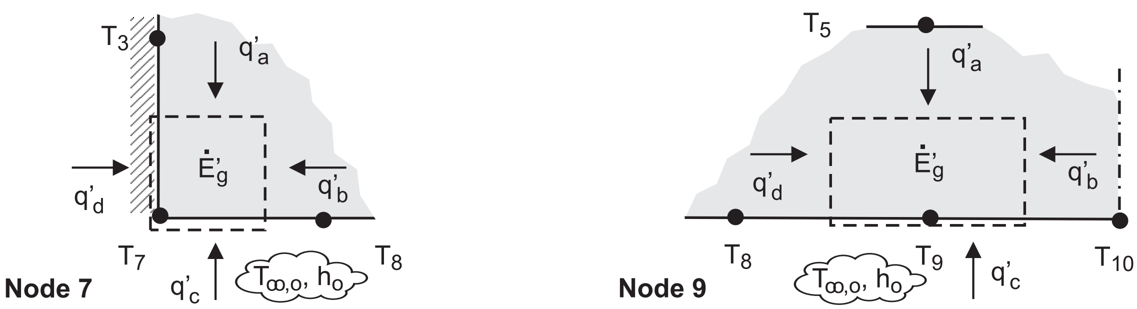
Node 7

$$q'_a + q'_b + q'_c + q'_d + \dot{E}'_g = 0$$

$$k(\Delta x/2)\frac{T_3 - T_7}{\Delta y} + k(\Delta y/2)\frac{T_8 - T_7}{\Delta x} + h_o(\Delta x/2)(T_{\infty,o} - T_7) + 0 + \dot{q}(\Delta x \cdot \Delta y/4) = 0$$

$$T_7 = \left[T_3 + T_8 + (h_o \Delta x/k)T_{\infty,o} + \dot{q}\Delta x^2/2k\right] \Big/ (2 + h_o \Delta x/k)$$

$$T_7 = 95.80°C$$ <



Node 9

$$q'_a + q'_b + q'_c + q'_d + \dot{E}'_g = 0$$

$$k(\Delta x)\frac{T_5 - T_9}{\Delta y} + k(\Delta y/2)\frac{T_{10} - T_9}{\Delta y} + h_o(\Delta x)(T_{\infty,o} - T_9)$$

$$+ k(\Delta y/2)\frac{T_8 - T_9}{\Delta x} + \dot{q}(\Delta x \cdot \Delta y/2) = 0$$

$$T_9 = \left[T_5 + 0.5T_8 + 0.5T_{10} + (h_o \Delta x/k)T_{\infty,o} + \dot{q}\Delta x^2/2k\right] / (2 + h_o \Delta x/k)$$

$$T_9 = 79.67°C$$ <

(b) The heat rate per unit length from the outer surface A to the adjacent fluid, q'_A, is the sum of the convection heat rates from the outer surfaces of nodes 7, 8, 9 and 10.

$$q'_A = h_o\left[(\Delta x/2)(T_7 - T_{\infty,o}) + \Delta x(T_8 - T_{\infty,o}) + \Delta x(T_9 - T_{\infty,o}) + (\Delta x/2)(T_{10} - T_{\infty,o})\right]$$

$$q'_A = 250\ W/m^2 \cdot K\left[(25/2)(95.80 - 25) + 25(87.28 - 25)\right.$$

$$\left. + 25(79.67 - 25) + (25/2)(77.65 - 25)\right] \times 10^{-3} m \cdot K$$

Continued …

$$q'_A = 1117 \text{ W/m} \quad <$$

(c) The heat rate per unit length from the inner fluid to the surface B, q'_B, is the sum of the convection heat rates from the inner surfaces of nodes 2, 4, 5 and 6.

$$q'_B = h_i\left[(\Delta y/2)(T_{\infty,i} - T_2) + (\Delta y/2 + \Delta x/2)(T_{\infty,i} - T_4) + \Delta x(T_{\infty,i} - T_5) + (\Delta x/2)(T_{\infty,i} - T_6)\right]$$

$$q'_B = 500 \text{ W/m}^2\cdot\text{K}\left[(25/2)(50-95.47) + (25/2+25/2)(50-94.50)\right.$$

$$\left.+25(50-79.79) + (25/2)(50-77.29)\right]\times 10^{-3} \text{ m}\cdot\text{K}$$

$$q'_B = -1383 \text{ W/m} \quad <$$

(d) From an overall energy balance on the section, we see that our results are consistent since the conservation of energy requirement is satisfied.

$$\dot{E}'_{in} - \dot{E}'_{out} + \dot{E}'_{gen} = -q'_A + q'_B + \dot{E}'_{gen} = (-1117 - 1383 + 2500)\text{W/m} = 0$$

where $\dot{E}'_{gen} = \dot{q}\forall' = 10^6 \text{ W/m}^3[25\times 50 + 25\times 50]\times 10^{-6} \text{ m}^2 = 2500 \text{ W/m}$

COMMENTS: The nodal finite-difference equations for the four nodes can be obtained by using IHT Tool *Finite-Difference Equations* | *Two-Dimensional* | *Steady-state*. Options are provided to build the FDEs for interior, corner and surface nodal arrangements including convection and internal generation. The IHT code lines for the FDEs are shown below.

```
/* Node 1: interior node; e, w, n, s labeled 2, 2, 3, 3. */
0.0   = fd_2d_int(T1,T2,T2,T3,T3,k,qdot,deltax,deltay)

/* Node 4: internal corner node, e-n orientation; e, w, n, s labeled 5, 3, 2, 8. */
0.0   = fd_2d_ic_en(T4,T5,T3,T2,T8,k,qdot,deltax,deltay,Tinfi,hi,q″a4
q″a4 = 0                    // Applied heat flux, W/m^2; zero flux shown

/* Node 7: plane surface node, s-orientation; e, w, n labeled 8, 8, 3. */
0.0   = fd_2d_psur_s(T7,T8,T8,T3,k,qdot,deltax,deltay,Tinfo,ho,q″a7
q″a7=0                      // Applied heat flux, W/m^2; zero flux shown

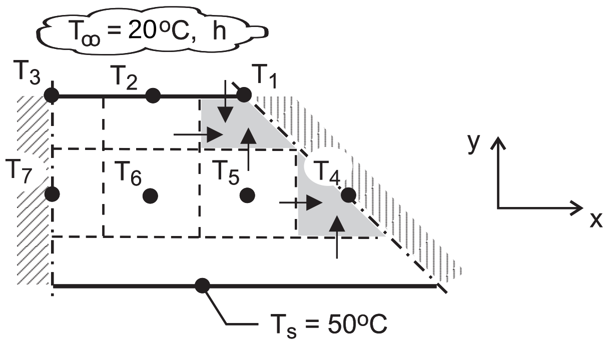
0.0 = fd_2d_psur_s(T9, T10, T8, T5,k,qdot,deltax,deltay,Tinfo,ho,q″a9
q″a9 = 0                    // Applied heat flux, W/m^2; zero flux shown
```

PROBLEM 4.58

KNOWN: Outer surface temperature, inner convection conditions, dimensions and thermal conductivity of a heat sink.

FIND: Nodal temperatures and heat rate per unit length.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Two-dimensional conduction, (3) Uniform outer surface temperature, (4) Constant thermal conductivity.

ANALYSIS: (a) To determine the heat rate, the nodal temperatures must first be computed from the corresponding finite-difference equations. From an energy balance for node 1,

$$h(\Delta x/2\cdot 1)(T_\infty - T_1) + k(\Delta y/2\cdot 1)\frac{T_2 - T_1}{\Delta x} + k(\Delta x\cdot 1)\frac{T_5 - T_1}{\Delta y} = 0$$

$$-\left(3 + \frac{h\Delta x}{k}\right)T_1 + T_2 + 2T_5 + \frac{h\Delta x}{k}T_\infty = 0 \qquad (1)$$

With nodes 2 and 3 corresponding to Case 3 of Table 4.2,

$$T_1 - 2\left(\frac{h\Delta x}{k} + 2\right)T_2 + T_3 + 2T_6 + \frac{2h\Delta x}{k}T_\infty = 0 \qquad (2)$$

$$T_2 - \left(\frac{h\Delta x}{k} + 2\right)T_3 + T_7 + \frac{h\Delta x}{k}T_\infty = 0 \qquad (3)$$

where the symmetry condition is invoked for node 3. Applying an energy balance to node 4, we obtain

$$-2T_4 + T_5 + T_s = 0 \qquad (4)$$

The interior nodes 5, 6 and 7 correspond to Case 1 of Table 4.2. Hence,

$$T_1 + T_4 - 4T_5 + T_6 + T_s = 0 \qquad (5)$$

$$T_2 + T_5 - 4T_6 + T_7 + T_s = 0 \qquad (6)$$

$$T_3 + 2T_6 - 4T_7 + T_s = 0 \qquad (7)$$

where the symmetry condition is invoked for node 7. With $T_s = 50°C$, $T_\infty = 20°C$, and $h\Delta x/k = 5000\ W/m^2\cdot K(0.005m)/240\ W/m\cdot K = 0.1042$, the solution to Eqs. (1) – (7) yields

$$T_1 = 46.61°C,\ T_2 = 45.67°C,\ T_3 = 45.44°C,\ T_4 = 49.23°C$$

$$T_5 = 48.46°C,\ T_6 = 48.00°C,\ T_7 = 47.86°C \qquad <$$

Continued …

PROBLEM 4.58 (Cont.)

The heat rate per unit length of channel may be evaluated by computing convection heat transfer from the inner surface. That is,

$$q' = 8h\left[\Delta x/2\left(T_1 - T_\infty\right) + \Delta x\left(T_2 - T_\infty\right) + \Delta x/2\left(T_3 - T_\infty\right)\right]$$

$$q' = 8 \times 5000\,\text{W/m}^2\cdot\text{K}\left[0.0025\text{m}\left(46.61 - 20\right)°\text{C} + 0.005\text{m}\left(45.67 - 20\right)°\text{C}\right.$$

$$\left. + 0.0025\text{m}\left(45.44 - 20\right)°\text{C}\right] = 10,340\ \text{W/m}$$ <

(b) Since $h = 5000\ \text{W/m}^2\cdot\text{K}$ is at the high end of what can be achieved through forced convection, we consider the effect of reducing h. Representative results are as follows

$h\left(\text{W/m}^2\cdot\text{K}\right)$	$T_1\,(°\text{C})$	$T_2\,(°\text{C})$	$T_3\,(°\text{C})$	$T_4\,(°\text{C})$	$T_5\,(°\text{C})$	$T_6\,(°\text{C})$	$T_7\,(°\text{C})$	$q'\,(\text{W/m})$
200	49.84	49.80	49.79	49.96	49.93	49.91	49.90	477
1000	49.24	49.02	48.97	49.83	49.65	49.55	49.52	2325
2000	48.53	48.11	48.00	49.66	49.33	49.13	49.06	4510
5000	46.61	45.67	45.44	49.23	48.46	48.00	47.86	10,340

There are two resistances to heat transfer between the outer surface of the heat sink and the fluid, that due to conduction in the heat sink, $R_{cond(2D)}$, and that due to convection from its inner surface to the fluid, R_{conv}. With decreasing h, the corresponding increase in R_{conv} reduces heat flow and increases the uniformity of the temperature field in the heat sink. The nearly 5-fold reduction in q' corresponding to the 5-fold reduction in h from 1000 to 200 $\text{W/m}^2\cdot\text{K}$ indicates that the convection resistance is dominant $\left(R_{conv} >> R_{cond(2D)}\right)$.

COMMENTS: To check our finite-difference solution, we could assess its consistency with conservation of energy requirements. For example, an energy balance performed at the inner surface requires a balance between convection from the surface and conduction to the surface, which may be expressed as

$$q' = k\left(\Delta x\cdot 1\right)\frac{\left(T_5 - T_1\right)}{\Delta y} + k\left(\Delta x\cdot 1\right)\frac{T_6 - T_2}{\Delta y} + k\left(\Delta x/2\cdot 1\right)\frac{T_7 - T_3}{\Delta y}$$

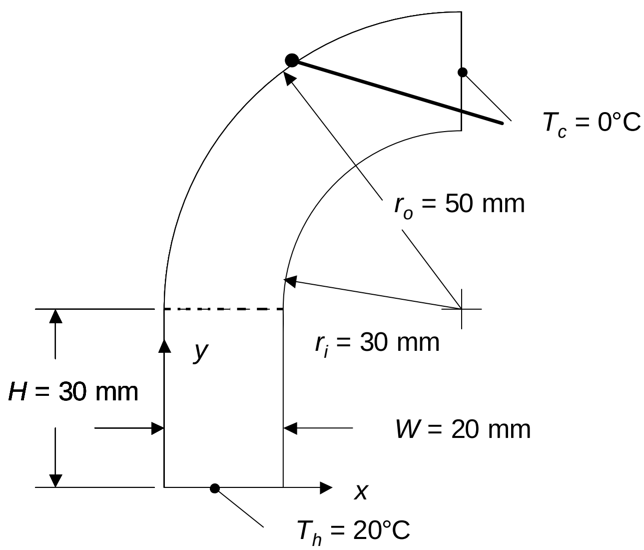
Substituting the temperatures corresponding to $h = 5000\ \text{W/m}^2\cdot\text{K}$, the expression yields $q' = 10,340\,\text{W/m}$, and, as it must be, conservation of energy is precisely satisfied. Results of the analysis may also be checked by using the expression $q' = \left(T_s - T_\infty\right)/\left(R'_{cond(2D)} + R'_{conv}\right)$, where, for $h = 5000\ \text{W/m}^2\cdot\text{K}$, $R'_{conv} = \left(1/4hw\right) = 2.5\times 10^{-3}\text{m}\cdot\text{K/W}$, and from Eq. (4.27) and Case 11 of Table 4.1, $R'_{cond} = \left[0.930\ \ln\left(W/w\right) - 0.05\right]/2\pi k = 3.94\times 10^{-4}\text{m}\cdot\text{K/W}$. Hence, $q' = \left(50 - 20\right)°\text{C}/\left(2.5\times 10^{-3} + 3.94\times 10^{-4}\right)\text{m}\cdot\text{K/W} = 10,370\ \text{W/m}$, and the agreement with the finite-difference solution is excellent. Note that, even for $h = 5000\ \text{W/m}^2\cdot\text{K}$, $R'_{conv} >> R'_{cond(2D)}$.

PROBLEM 4.59

KNOWN: Dimensions of a two-dimensional object with isothermal and adiabatic boundaries.

FIND: Conduction heat transfer rate per unit depth from the hot surface to the cold surface.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) No internal generation, (4) Two-dimensional conduction.

ANALYSIS: We may combine heat fluxes determined from Fourier's law with expressions for the size of the control surfaces of the various control volumes to determine the heat rate per unit depth into each control volume in the discretized domain, which is shown on the next page. Application of conservation of energy for each control volume yields the expression $\dot{E}_{\text{in}} = 0$. Note that energy balances for nodes 10, 11, and 12 are included in both the rectangular and cylindrical sub-domains. These energy balances couple the solutions together.

Rectangular Sub-Domain. For the rectangular sub-domain, application of Fourier's law in Cartesian coordinates along with conservation of energy yields the following finite difference equations.

Nodes 1, 2 and 3: $T_1 = T_2 = T_3 = T_h = 20°C$.

Node 4: $$k\frac{(T_1 - T_4)}{\Delta y}\frac{\Delta x}{2} + k\frac{(T_5 - T_4)}{\Delta x}\Delta y + k\frac{(T_7 - T_4)}{\Delta y}\frac{\Delta x}{2} = 0$$

Node 5: $$k\frac{(T_2 - T_5)}{\Delta y}\Delta x + k\frac{(T_6 - T_5)}{\Delta x}\Delta y + k\frac{(T_8 - T_5)}{\Delta y}\Delta x + k\frac{(T_4 - T_5)}{\Delta x}\Delta y = 0$$

Node 6: $$k\frac{(T_3 - T_6)}{\Delta y}\frac{\Delta x}{2} + k\frac{(T_5 - T_6)}{\Delta x}\Delta y + k\frac{(T_9 - T_6)}{\Delta y}\frac{\Delta x}{2} = 0$$

Node 7: $$k\frac{(T_4 - T_7)}{\Delta y}\frac{\Delta x}{2} + k\frac{(T_8 - T_7)}{\Delta x}\Delta y + k\frac{(T_{10} - T_7)}{\Delta y}\frac{\Delta x}{2} = 0$$

Continued...

Problem 4.59 (Cont.)

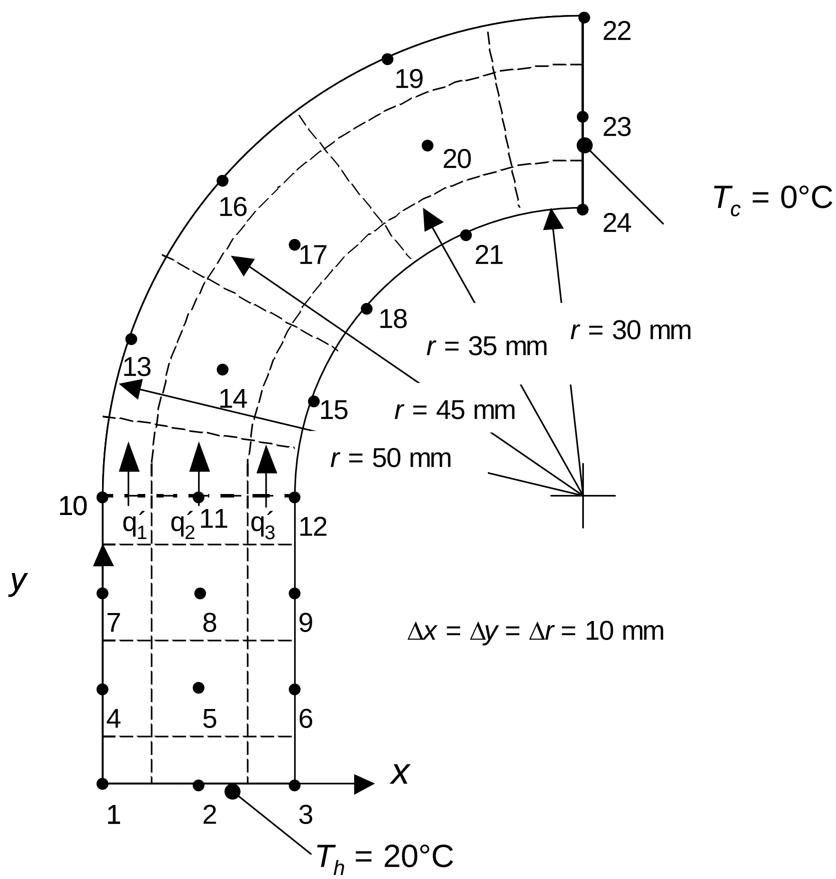
Node 8: $$k\frac{(T_5-T_8)}{\Delta y}\frac{\Delta x}{2}+k\frac{(T_9-T_8)}{\Delta x}\Delta y+k\frac{(T_{11}-T_8)}{\Delta y}\Delta x+k\frac{(T_7-T_8)}{\Delta x}\Delta y=0$$

Node 9: $$k\frac{(T_6-T_9)}{\Delta y}\frac{\Delta x}{2}+k\frac{(T_8-T_9)}{\Delta x}\Delta y+k\frac{(T_{12}-T_9)}{\Delta y}\frac{\Delta x}{2}=0$$

Node 10: $$k\frac{(T_7-T_{10})}{\Delta y}\frac{\Delta x}{2}+k\frac{(T_{11}-T_{10})}{\Delta x}\frac{\Delta y}{2}-q_1^{'}=0$$

Node 11: $$k\frac{(T_8-T_{11})}{\Delta y}\Delta x+k\frac{(T_{10}-T_{11})}{\Delta x}\frac{\Delta y}{2}+k\frac{(T_{12}-T_{11})}{\Delta x}\frac{\Delta y}{2}-q_2^{'}=0$$

Node 12: $$k\frac{(T_9-T_{12})}{\Delta y}\frac{\Delta x}{2}+k\frac{(T_{11}-T_{12})}{\Delta x}\frac{\Delta y}{2}-q_3^{'}=0$$



Continued…

Problem 4.59 (Cont.)

Cylindrical Sub-Domain. We begin by recalling that Fourier's law for the cylindrical coordinate system yields

$$q_r'' = -k\frac{\partial T}{\partial r} \approx -k\frac{\Delta T}{\Delta r}; \quad q_\phi'' = -\frac{k}{r}\frac{\partial T}{\partial \phi} \approx -\frac{k}{r}\frac{\Delta T}{\Delta \phi}$$

and the areas through which conduction occurs in the radial direction increase as the radius increases.

Nodes 10, 13, 16, 19, 22, 23 and 24: $T_{10} = T_{13} = T_{16} = T_{19} = T_{22} = T_{23} = T_{24} = T_c = 0°C$

Node 11: $q_2' + k\frac{(T_{12}-T_{11})}{\Delta r}\cdot 3.5\Delta r\cdot\frac{\Delta\phi}{2} + k\frac{(T_{14}-T_{11})}{4\Delta r\Delta\phi}\cdot\Delta r + k\frac{(T_{10}-T_{11})}{\Delta r}\cdot 4.5\Delta r\cdot\frac{\Delta\phi}{2} = 0$

Node 12: $q_3' + k\frac{(T_{11}-T_{12})}{\Delta r}\cdot 3.5\Delta r\cdot\frac{\Delta\phi}{2} + k\frac{(T_{15}-T_{12})}{3\Delta r\Delta\phi}\cdot\frac{\Delta r}{2} = 0$

Node 14: $k\frac{(T_{11}-T_{14})}{4\Delta r\Delta\phi}\cdot\Delta r + k\frac{(T_{15}-T_{14})}{\Delta r}\cdot 3.5\Delta r\Delta\phi + k\frac{(T_{17}-T_{14})}{4\Delta r\Delta\phi}\Delta r + k\frac{(T_{13}-T_{14})}{\Delta r}\cdot 4.5\Delta r\Delta\phi = 0$

Node 15: $k\frac{(T_{12}-T_{15})}{3\Delta r\Delta\phi}\frac{\Delta r}{2} + k\frac{(T_{14}-T_{15})}{\Delta r}\cdot 3.5\Delta r\Delta\phi + k\frac{(T_{18}-T_{15})}{3\Delta r\Delta\phi}\frac{\Delta r}{2} = 0$

Node 17: $k\frac{(T_{14}-T_{17})}{4\Delta r\Delta\phi}\cdot\Delta r + k\frac{(T_{18}-T_{17})}{\Delta r}\cdot 3.5\Delta r\Delta\phi + k\frac{(T_{20}-T_{17})}{4\Delta r\Delta\phi}\Delta r + k\frac{(T_{16}-T_{17})}{\Delta r}\cdot 4.5\Delta r\Delta\phi = 0$

Node 18: $k\frac{(T_{15}-T_{18})}{3\Delta r\Delta\phi}\frac{\Delta r}{2} + k\frac{(T_{17}-T_{18})}{\Delta r}\cdot 3.5\Delta r\Delta\phi + k\frac{(T_{21}-T_{18})}{3\Delta r\Delta\phi}\frac{\Delta r}{2} = 0$

Node 20: $k\frac{(T_{17}-T_{20})}{4\Delta r\Delta\phi}\Delta r + k\frac{(T_{21}-T_{20})}{\Delta r}\cdot 3.5\Delta r\Delta\phi + k\frac{(T_{23}-T_{20})}{4\Delta r\Delta\phi}\Delta r = 0$

Node 21: $k\frac{(T_{18}-T_{21})}{3\Delta r\Delta\phi}\frac{\Delta r}{2} + k\frac{(T_{20}-T_{21})}{\Delta r}\cdot 3.5\Delta r\Delta\phi + k\frac{(T_{24}-T_{21})}{3\Delta r\Delta\phi}\frac{\Delta r}{2} = 0$

Note that energy balances for nodes 10, 11 and 12 are included in both the rectangular and cylindrical sub-domains. These energy balances couple the solutions for the two sub-domains together.

The preceding finite difference equations may be solved simultaneously with the *IHT* code provided in the Comment yielding the following temperatures and $q' = 114.5$ W/m. <

The nodal temperatures are:

T_1 = 20.00°C	T_2 = 20.00°C	T_3 = 20.00°C	T_4 = 14.11°C	T_5 = 14.29°C	T_6 = 14.41°C
T_7 = 7.86°C	T_8 = 8.66°C	T_9 = 9.03°C	T_{10} = 0.00°C	T_{11} = 3.46°C	T_{12} = 4.40°C
T_{13} = 0.00°C	T_{14} = 1.04°C	T_{15} = 1.59°C	T_{16} = 0.00°C	T_{17} = 0.33°C	T_{18} = 0.54°C
T_{19} = 0.00°C	T_{20} = 0.10°C	T_{21} = 0.16°C	T_{22} = 0.00°C	T_{23} = 0.00°C	T_{24} = 0.00°C

0
//Node 18
(T15 - T18)/3/deltaphi/2 + (T17 - T18)*3.5*deltaphi + (T21 - T18)/3/deltaphi/2 = 0
```

Continued…

Problem 4.59 (Cont.)

```
//Node 19
T19 = Tc
//Node 20
(T17 - T20)/4/deltaphi + (T21 - T20)*3.5*deltaphi + (T23 - T20)/4/deltaphi + (T19 - T20)*4.5*deltaphi =
0
//Node 21
(T18 - T21)/3/deltaphi/2 + (T20 - T21)*3.5*deltaphi + (T24 - T21)/3/deltaphi/2 = 0
//Node 22
T22 = Tc
//Node 23
T23 = Tc
//Node 24
T24 = Tc

qprime = qprime1 + qprime2 + qprime3
```

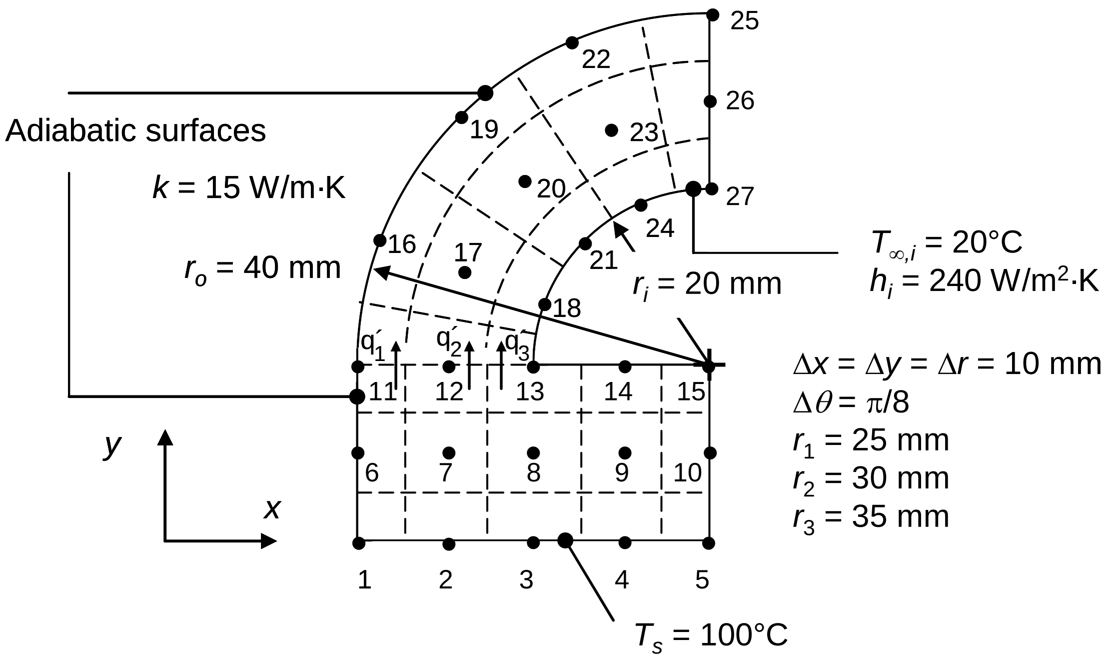
(2) The shape factor for the geometry is $S = \dfrac{q'}{k(Th - Tc)} = \dfrac{114.5\text{ W/m}}{10\text{W/m}\cdot\text{K}\times 20\text{K}} = 0.573$

PROBLEM 4.60

KNOWN: Dimensions of a tube of non-circular cross section that can be broken into rectangular and cylindrical sub-domains. Fluid temperature and heat transfer coefficient, external surface temperature and tube wall thermal conductivity.

FIND: Heat transfer rate per unit length of tube.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) No internal generation, (4) Two-dimensional conduction.

ANALYSIS: We may combine heat fluxes determined from Fourier's law with expressions for the size of the control surfaces of the various control volumes to determine the heat rate per unit depth into each control volume in the discretized domain. Application of conservation of energy for each control volume yields the expression $\dot{E}_{\text{in}} = 0$.

Rectangular Sub-Domain. For the rectangular sub-domain, application of Fourier's law in Cartesian coordinates along with conservation of energy yields the finite difference equations that are listed in the IHT code included in COMMENT (1).

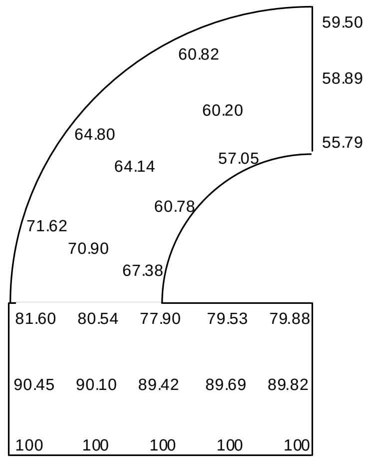
Cylindrical Sub-Domain. For the cylindrical sub-domain, application of Fourier's law in cylindrical coordinates along with conservation of energy yields the finite difference equations that are listed in the IHT code included in COMMENT (1).

Coupling of Domains. Note that energy balances for Nodes 11, 12 and 13 are included in both the rectangular and cylindrical sub-domains. These energy balances couple the two solutions together.

Continued…

PROBLEM 4.60 (Cont.)

The equations are solved simultaneously to yield the following nodal temperatures in degrees Celsius.



The heat transfer rate per unit depth may be expressed as

$$q' = 2\left[\frac{k\Delta x}{\Delta y}\right]\left[(T_1 - T_6)/2 + (T_2 - T_7) + (T_3 - T_8) + (T_4 - T_9) + (T_5 - T_{10})/2\right]$$

$$= 2 \times 15\,\text{W/m}\cdot\text{K} \times \begin{bmatrix} (100 - 90.45)°\text{C}/2 + (100 - 90.10)°\text{C} + \\ (100 - 89.42)°\text{C} + (100 - 89.69)°\text{C} \\ +(100 - 89.82)°\text{C}/2 \end{bmatrix}$$

= 1220 W/m <

COMMENTS: (1) The *IHT* code is listed below. For each control volume, we note that $\dot{E}_{in} = 0$, yielding the energy balances for the rectangular and cylindrical sub-domains.

```

```

(2) For an isothermal tube at T_s = 100°C, the heat transfer per unit length is

$$q' = h(\pi r_i + 2r_i) \times (T_s - T_\infty) = 240 \mathrm{W/m \cdot K} \times (\pi \times 20 \times 10^{-3} \mathrm{m} + 2 \times 20 \times 10^{-3} \mathrm{m}) \times (100 - 20)^\circ\mathrm{C}$$

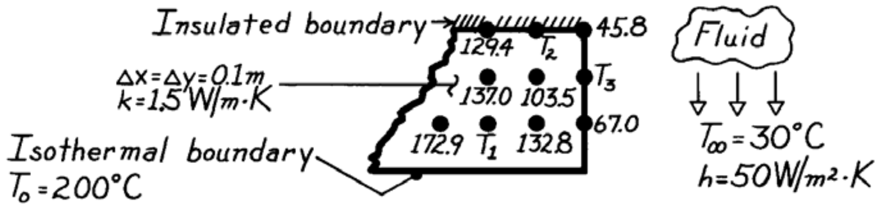
= 1975 W/m. The conduction resistance posed by the tube wall is responsible for decreasing the actual heat transfer rate below this value.

PROBLEM 4.61

KNOWN: Steady-state temperatures (°C) associated with selected nodal points in a two-dimensional system.

FIND: (a) Temperatures at nodes 1, 2 and 3, (b) Heat transfer rate per unit thickness from the system surface to the fluid.

SCHEMATIC:



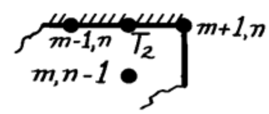
ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties.

ANALYSIS: (a) Using the finite-difference equations for Nodes 1, 2 and 3:

Node 1, Interior node, Eq. 4.29: $T_1 = \frac{1}{4}\cdot\sum T_{neighbors}$

$$T_1 = \frac{1}{4}(172.9 + 137.0 + 132.8 + 200.0)^\circ C = 160.7^\circ C$$ <

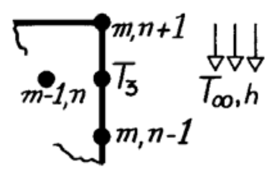
Node 2, Insulated boundary, Eq. 4.46 with h = 0, $T_{m,n} = T_2$



$$T_2 = \frac{1}{4}\left(T_{m-1,n} + T_{m+1,n} + 2T_{m,n-1}\right)$$

$$T_2 = \frac{1}{4}(129.4 + 45.8 + 2\times 103.5)^\circ C = 95.6^\circ C$$ <

Node 3, Plane surface with convection, Eq. 4.42, $T_{m,n} = T_3$



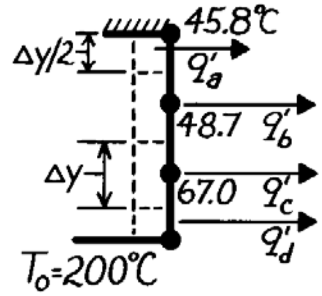
$$2\left[\frac{h\Delta x}{k} + 2\right]T_3 = \left(2T_{m-1,n} + T_{m,n+1} + T_{m,n-1}\right) + \frac{2h\Delta x}{k}T_\infty$$

$$h\Delta x/k = 50 W/m^2\cdot K \times 0.1m/1.5 W/m\cdot K = 3.33$$

$$2(3.33 + 2)T_3 = (2\times 103.5 + 45.8 + 67.0)°C + 2\times 3.33\times 30^\circ C$$

$$T_3 = \frac{1}{10.66}(319.80 + 199.80)°C = 48.7°C$$ <

(b) The heat rate per unit thickness from the surface to the fluid is determined from the sum of the convection rates from each control volume surface.



$$q'_{conv} = q'_a + q'_b + q'_c + q'_d$$

$$q_i = h\Delta y_i\left(T_i - T_\infty\right)$$

$$q'_{conv} = 50\frac{W}{m^2\cdot K}\left[\frac{0.1}{2}m\ (45.8 - 30.0)°C + 0.1m\ (48.7 - 30.0)°C + 0.1m\ (67.0 - 30.0)°C + \frac{0.1m}{2}(200.0 - 30.0)°C\right]$$

$$q'_{conv} = (39.5 + 93.5 + 185.0 + 425)\ W/m = 743\ W/m.$$ <

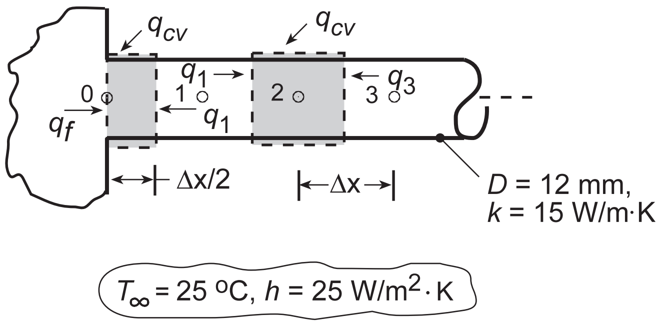
PROBLEM 4.62

KNOWN: Nodal temperatures from a steady-state finite-difference analysis for a cylindrical fin of prescribed diameter, thermal conductivity and convection conditions (T_∞, h).

FIND: (a) The fin heat rate, q_f, and (b) Temperature at node 3, T_3.

SCHEMATIC:

$T_0 = 100.0°C$
$T_1 = 93.4°C$
$T_2 = 89.5°C$



ASSUMPTIONS: (a) The fin heat rate, q_f, is that of conduction at the base plane, x = 0, and can be found from an energy balance on the control volume about node 0, $\dot{E}_{in} - \dot{E}_{out} = 0$,

$$q_f + q_1 + q_{conv} = 0 \qquad \text{or} \qquad q_f = -q_1 - q_{conv}.$$

Writing the appropriate rate equation for q_1 and q_{conv}, with $A_c = \pi D^2/4$ and $P = \pi D$,

$$q_f = -kA_c\frac{T_1 - T_0}{\Delta x} - hP(\Delta x/2)(T_\infty - T_0) = -\frac{\pi k D^2}{4\Delta x}(T_1 - T_0) - (\pi/2)Dh\Delta x(T_\infty - T_0)$$

Substituting numerical values, with Δx = 0.010 m, find

$$q_f = -\frac{\pi \times 15\,\text{W/m}\cdot\text{K}(0.012\,\text{m})^2}{4 \times 0.010\,\text{m}}(93.4 - 100)^\circ\text{C}$$
$$-\frac{\pi}{2} \times 0.012\,\text{m} \times 25\,\text{W/m}^2\cdot\text{K} \times 0.010\,\text{m}(25 - 100)^\circ\text{C}$$

$$q_f = (1.120 + 0.353)\,\text{W} = 1.473\,\text{W}.$$ <

(b) To determine T_3, derive the finite-difference equation for node 3, perform an energy balance on the control volume shown above, $\dot{E}_{in} - \dot{E}_{out} = 0$,

$$q_{cv} + q_3 + q_1 = 0$$

$$hP\Delta x(T_\infty - T_2) + kA_c\frac{T_3 - T_2}{\Delta x} + kA_c\frac{T_1 - T_2}{\Delta x} = 0$$

$$T_3 = -T_1 + 2T_2 - \frac{hP\Delta x^2}{kA_c}[T_\infty - T_2]$$

Substituting numerical values, find

$$T_3 = 89.2^\circ\text{C}$$ <

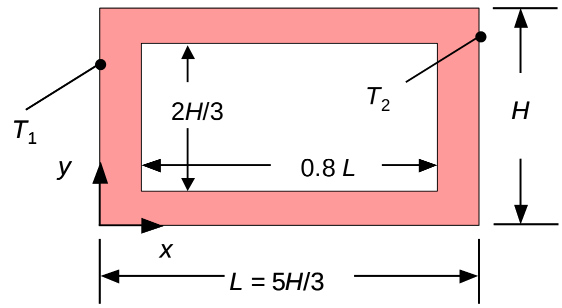
COMMENTS: Note that in part (a), the convection heat rate from the outer surface of the control volume is significant (25%). It would have been a poor approximation to ignore this term.

PROBLEM 4.63

KNOWN: Dimensions of a two-dimensional object with isothermal and adiabatic boundaries.

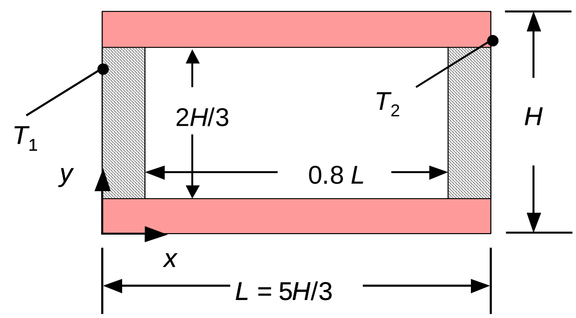
FIND: (a) Estimate of the shape factor using a one-dimensional analysis and (b) estimate of the shape factor using a finite difference method with $\Delta x = \Delta y = 0.05\,L$.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) No internal generation, (4) One-dimensional conduction in part (a), (5) Two-dimensional conduction in part (b).

ANALYSIS: (a) As a first approximation, we ignore conduction in the cross-hatched regions.

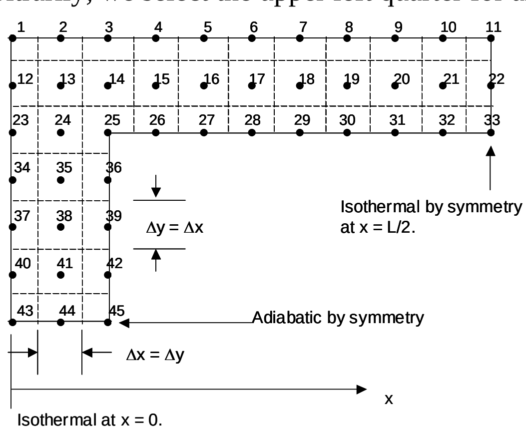


Hence,

$$q' = Sk(T_1 - T_2) \approx (H/3)k(T_1 - T_2)/L = k(T_1 - T_2)/5$$

Therefore, $S \approx 0.20$. <

(b) We begin by taking advantage of the symmetry of the problem. Recognize that the line $y = H/2$ is an adiabat, and the line $x = L/2$ is an isotherm at $T = (T_1 + T_2)/2$. Hence, only one quarter of the domain needs to be modeled. Arbitrarily, we select the upper left quarter for analysis. Note that $\Delta x = \Delta y$.



Continued…

Problem 4.63 (Cont.)

We may use the finite difference equations from the text, or note that for each node, an energy balance can be written for the corresponding control volume. Consider, for example, the control volume about Node 2 for which we may write

$$k \times \frac{\Delta y}{2} \frac{(T_1 - T_2)}{\Delta x} + k \times \frac{\Delta x (T_{13} - T_2)}{\Delta y} + k \times \frac{\Delta y}{2} \frac{(T_3 - T_2)}{\Delta x} = 0$$

or

$$\frac{(T_1 - T_2)}{2} + (T_{13} - T_2) + \frac{(T_3 - T_2)}{2} = 0$$

We let the temperature at $x = 0$ be $T_1 = 1$ and the temperature at $x = L/2$ be $T_2 = 0.5$. The 45 equations are solved simultaneously with the *IHT* code provided in the Comment. The resulting nodal temperatures in the upper left corner are:

1.0000	0.9636	0.9226	0.8737	0.8215	0.7683	0.7147	0.6610	0.6074	0.5537	0.5000
1.0000	0.9659	0.9265	0.8753	0.8220	0.7684	0.7147	0.6611	0.6074	0.5537	0.5000
1.0000	0.9734	0.9423	0.8790	0.8229	0.7686	0.7148	0.6611	0.6074	0.5537	0.5000
1.0000	0.9853	0.9753								
1.0000	0.9923	0.9884								
1.0000	0.9957	0.9938								
1.0000	0.9966	0.9952								

After solving for the temperatures, the heat transfer rate per unit depth may be evaluated at any x location, and for $x = L/2$ it may be expressed as

$$q' = k\left[\frac{\Delta y/2}{\Delta x}(T_{10} - T_{11}) + \frac{\Delta y}{\Delta x}(T_{21} - T_{22}) + \frac{\Delta y/2}{\Delta x}(T_{32} - T_{33})\right] \quad (1)$$

or, in terms of the shape factor,

$$q' = Sk(T_h - T_c) \quad (2)$$

Equating Eqs. (1) and (2) yields the shape factor, $S \approx 0.215$. <

We note that the shape factor calculated with the finite difference approach is only slightly greater than the shape factor based upon the one-dimensional approximation. The good agreement is expected since the major resistance to heat transfer is posed by the top and bottom slender regions that connect the two isothermal boundaries. We also note that temperatures are nearly isothermal in the region $y \approx H/2$ due to the adiabatic interior.

Continued…

Problem 4.63 (Cont.)

COMMENTS: The *IHT* code is listed below. For each control volume, we note that $\dot{E}_{in} = 0$ and $\Delta y = \Delta x$, yielding the following energy balances for all but the isothermal nodes.

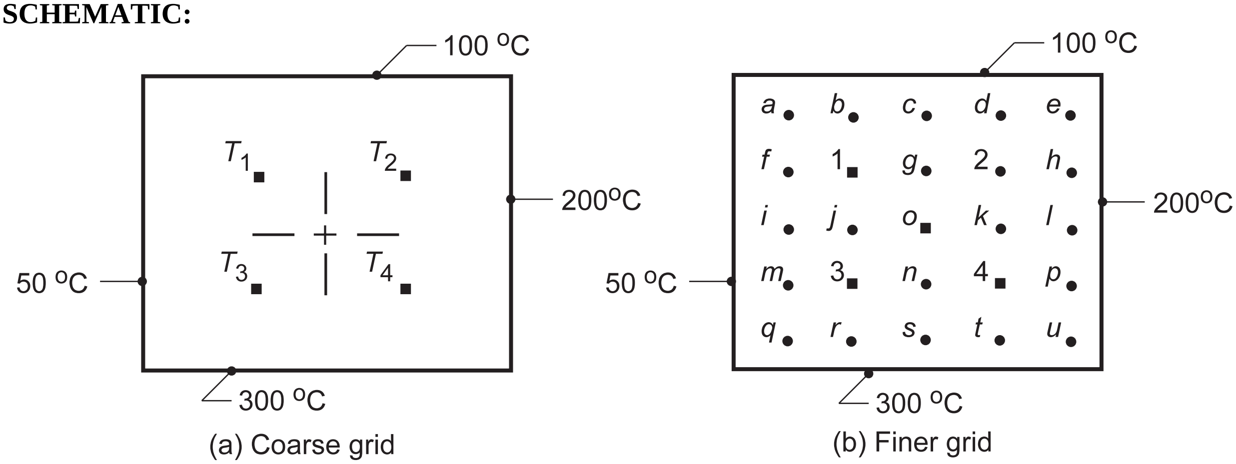
PROBLEM 4.64

KNOWN: Square shape subjected to uniform surface temperature conditions.

FIND: (a) Temperature at the four specified nodes; estimate the midpoint temperature T_o, (b) Reducing the mesh size by a factor of 2, determine the corresponding nodal temperatures and compare results, and (c) For the finer grid, plot the 75, 150, and 250°C isotherms.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties.

ANALYSIS: (a) The finite-difference equation for each node follows from Eq. 4.29 for an interior point written in the form, $T_i = 1/4\sum T_{neighbors}$. Using the Gauss-Seidel iteration method, Section 4.5.2, the finite-difference equations for the four nodes are:

$$T_1^k = 0.25\left(100 + T_2^{k-1} + T_3^{k-1} + 50\right) = 0.25T_2^{k-1} + 0.25T_3^{k-1} + 37.5$$

$$T_2^k = 0.25\left(100 + 200 + T_4^{k-1} + T_1^{k-1}\right) = 0.25T_1^{k-1} + 0.25T_4^{k-1} + 75.0$$

$$T_3^k = 0.25\left(T_1^{k-1} + T_4^{k-1} + 300 + 50\right) = 0.25T_1^{k-1} + 0.25T_4^{k-1} + 87.5$$

$$T_4^k = 0.25\left(T_2^{k-1} + 200 + 300 + T_3^{k-1}\right) = 0.25T_2^{k-1} + 0.25T_3^{k-1} + 125.0$$

The iteration procedure using a hand calculator is implemented in the table below. Initial estimates are entered on the k = 0 row.

k	T_1 (°C)	T_2 (°C)	T_3 (°C)	T_4 (°C)
0	100	150	150	250
1	112.50	165.63	178.13	210.94
2	123.44	158.60	171.10	207.43
3	119.93	156.40	169.34	206.55
4	119.05	156.40	168.90	206.33
5	118.83	156.29	168.79	206.27
6	118.77	156.26	168.76	206.26
7	118.76	156.25	168.76	206.25

<

Continued...

PROBLEM 4.64 (Cont.)

By the seventh iteration, the convergence is approximately 0.01°C. The midpoint temperature can be estimated as

$$T_o = (T_1 + T_2 + T_3 + T_4)/2 = (118.76 + 156.25 + 168.76 + 206.25)^\circ C/4 = 162.5^\circ C$$

(b) Because all the nodes are interior ones, the nodal equations can be written by inspection directly into the IHT workspace and the set of equations solved for the nodal temperatures (°C).

Mesh	T_o	T_1	T_2	T_3	T_4
Coarse	162.5	118.8	156.3	168.8	206.3
Fine	162.5	117.4	156.1	168.9	207.6

The maximum difference for the interior points is 1.4°C (node 1), but the estimate at the center, T_o, is the same, independently of the mesh size. In terms of the boundary surface temperatures,

$$T_o = (50 + 100 + 200 + 300)^\circ C/4 = 162.5^\circ C$$

Why must this be so?

(c) To generate the isotherms, it would be necessary to employ a contour-drawing routine using the tabulated temperature distribution (°C) obtained from the finite-difference solution. Using these values as a guide, try sketching a few isotherms.

-	100	100	100	100	100	-
50	86.0	105.6	119	131.7	151.6	200
50	88.2	117.4	138.7	156.1	174.6	200
50	99.6	137.1	162.5	179.2	190.8	200
50	123.0	168.9	194.9	207.6	209.4	200
50	173.4	220.7	240.6	246.8	239.0	200
-	300	300	300	300	300	-

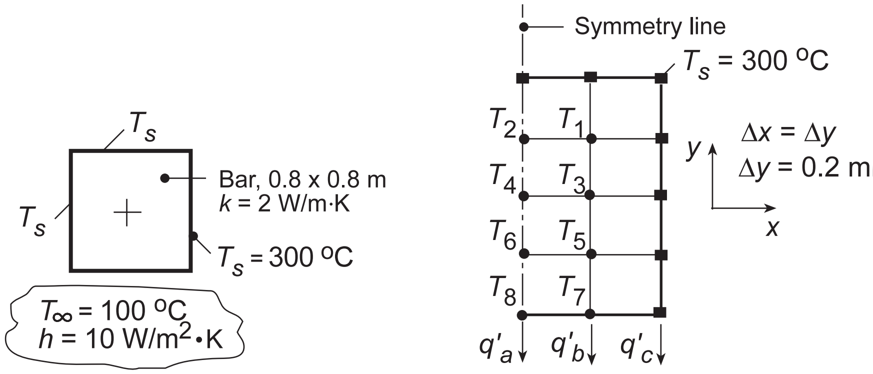
COMMENTS: Recognize that this finite-difference solution is only an approximation to the temperature distribution, since the heat conduction equation has been solved for only four (or 25) discrete points rather than for all points if an analytical solution had been obtained.

PROBLEM 4.65

KNOWN: Long bar of square cross section, three sides of which are maintained at a constant temperature while the fourth side is subjected to a convection process.

FIND: (a) The mid-point temperature and heat transfer rate between the bar and fluid; a numerical technique with grid spacing of 0.2 m is suggested, and (b) Reducing the grid spacing by a factor of 2, find the midpoint temperature and the heat transfer rate. Also, plot temperature distribution across the surface exposed to the fluid.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties.

ANALYSIS: (a) Considering symmetry, the nodal network is shown above. The matrix inversion method of solution will be employed. The finite-difference equations are:

Nodes 1, 3, 5 - Interior nodes, Eq. 4.29; written by inspection.
Nodes 2, 4, 6 - Also can be treated as interior points, considering symmetry.
Nodes 7, 8 - On a plane with convection, Eq. 4.42; noting that $h\Delta x/k$ = $10\ W/m^2\cdot K \times 0.2\ m/2W/m\cdot K = 1$, find

Node 7: $(2T_5 + 300 + T_8) + 2\times1\cdot100 - 2(1+2)T_7 = 0$
Node 8: $(2T_6 + T_7 + T_7) + 2\times1\cdot100 - 2(1+2)T_8 = 0$

The solution matrix [T] can be found using a stock matrix program using the [A] and [C] matrices shown below to obtain the solution matrix [T] (Eq. 4.48). Alternatively, the set of equations could be entered into the IHT workspace and solved for the nodal temperatures.

$$A = \begin{bmatrix} -4 & 1 & 1 & 0 & 0 & 0 & 0 & 0 \\ 2 & -4 & 0 & 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & -4 & 1 & 1 & 0 & 0 & 0 \\ 0 & 1 & 2 & -4 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & -4 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 & 2 & -4 & 0 & 1 \\ 0 & 0 & 0 & 0 & 2 & 0 & -6 & 1 \\ 0 & 0 & 0 & 0 & 0 & 2 & 2 & -6 \end{bmatrix} \quad C = \begin{bmatrix} -600 \\ -300 \\ -300 \\ 0 \\ -300 \\ 0 \\ -500 \\ -200 \end{bmatrix} \quad T = \begin{bmatrix} 292.2 \\ 289.2 \\ 279.7 \\ 272.2 \\ 254.5 \\ 240.1 \\ 198.1 \\ 179.4 \end{bmatrix}$$

From the solution matrix, [T], find the mid-point temperature as

$T_4 = 272.2°C$ <

Continued...

PROBLEM 4.65 (Cont.)

The heat rate by convection between the bar and fluid is given as,

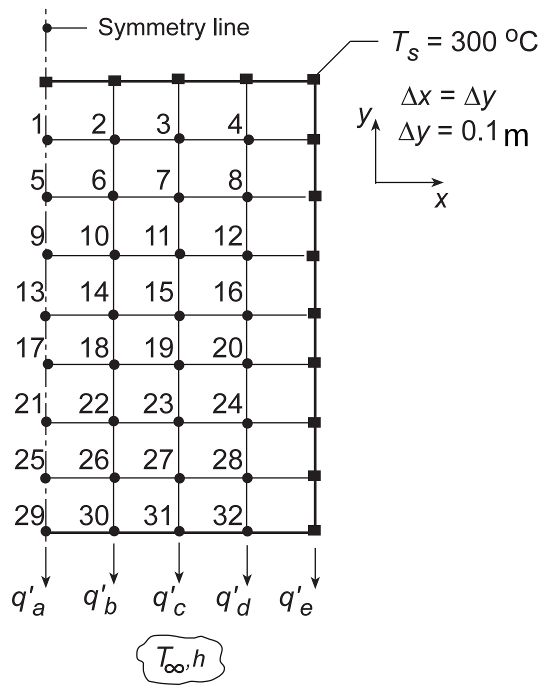
$$q'_{conv} = 2\left(q'_a + q'_b + q'_c\right)$$

$$q'_{conv} = 2\left[h\left(\Delta x/2\right)\left(T_8 - T_\infty\right) + h\left(\Delta x\right)\left(T_7 - T_\infty\right) + h\left(\Delta x/2\right)\left(300 - T_\infty\right)\right]$$

$$q'_{conv} = 2\left[10\,W/m^2 \cdot K \times \left(0.2\,m/2\right)\left[\left(179.4 - 100\right) + 2\left(198.1 - 100\right) + \left(300 - 100\right)\right]K\right]$$

$$q'_{conv} = 952\,W/m\,.$$ <

(b) Reducing the grid spacing by a factor of 2, the nodal arrangement will appear as shown. The finite-difference equation for the interior and centerline nodes were written by inspection and entered into the IHT workspace. The *IHT Finite-Difference Equations Tool* for 2-D, SS conditions, was used to obtain the FDE for the nodes on the exposed surface.



The midpoint temperature T_{13} and heat rate for the finer mesh are

$T_{13} = 271.0°C$ $\quad\quad q' = 834$ W/m <

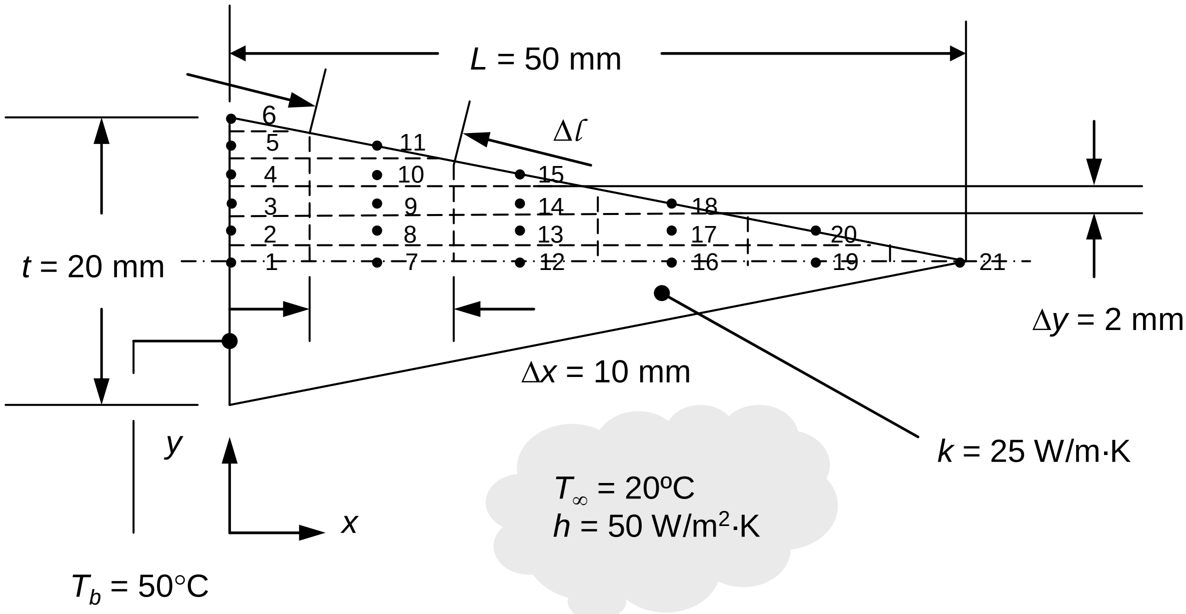
COMMENTS: The midpoint temperatures for the coarse and finer meshes agree closely, $T_4 = 272°C$ vs. $T_{13} = 271.0°C$, respectively. However, the estimate for the heat rate is substantially influenced by the mesh size; $q' = 952$ vs. 834 W/m for the coarse and finer meshes, respectively.

PROBLEM 4.66

KNOWN: Dimensions of a two-dimensional, straight triangular fin. Fin base and ambient temperatures, thermal conductivity and heat transfer coefficient.

FIND: Fin efficiency by using a finite difference solution with specified grid.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) No internal generation, (4) Two-dimensional conduction.

ANALYSIS: We may combine heat fluxes determined from Fourier's law and Newton's law of cooling with expressions for the size of the control surfaces of the various control volumes to determine the heat rate per unit depth into each control volume within the discretized domain. Application of conservation of energy for each control volume yields the expression $\dot{E}_{in} = 0$. Note that $\Delta l = \sqrt{\Delta x^2 + \Delta y^2}$ = 10.198 mm.

Nodes 1, 2, 3, 4, 5 and 6: $T_1 = T_2 = T_3 = T_4 = T_5 = T_6 = T_b = 50°C$.

Node 7: $$\frac{k(T_1 - T_7)(\Delta y/2)}{\Delta x} + \frac{k(T_8 - T_7)\Delta x}{\Delta y} + \frac{k(T_{12} - T_7)(\Delta y/2)}{\Delta x} = 0$$

Node 8: $$\frac{k(T_2 - T_8)(\Delta y)}{\Delta x} + \frac{k(T_7 - T_8)\Delta x}{\Delta y} + \frac{k(T_{13} - T_8)(\Delta y)}{\Delta x} + \frac{k(T_9 - T_8)(\Delta x)}{\Delta y} = 0$$

Node 9: $$\frac{k(T_3 - T_9)(\Delta y)}{\Delta x} + \frac{k(T_8 - T_9)\Delta x}{\Delta y} + \frac{k(T_{14} - T_9)(\Delta y)}{\Delta x} + \frac{k(T_{10} - T_9)(\Delta x)}{\Delta y} = 0$$

Node 10: $$\frac{k(T_4 - T_{10})(\Delta y)}{\Delta x} + \frac{k(T_9 - T_{10})\Delta x}{\Delta y} + \frac{k(T_{15} - T_{10})(\Delta y)}{\Delta x} + \frac{k(T_{11} - T_{10})(\Delta x)}{\Delta y} = 0$$

Node 11: $$\frac{k(T_5 - T_{11})(\Delta y)}{\Delta x} + \frac{k(T_{10} - T_{11})\Delta x}{\Delta y} + h\Delta l(T_\infty - T_{11}) = 0$$

Continued…

PROBLEM 4.66 (Cont.)

Node 12: $$\frac{k(T_7 - T_{12})(\Delta y/2)}{\Delta x} + \frac{k(T_{13} - T_{12})\Delta x}{\Delta y} + \frac{k(T_{16} - T_{12})(\Delta y/2)}{\Delta x} = 0$$

Node 13: $$\frac{k(T_8 - T_{13})(\Delta y)}{\Delta x} + \frac{k(T_{12} - T_{13})\Delta x}{\Delta y} + \frac{k(T_{17} - T_{13})(\Delta y)}{\Delta x} + \frac{k(T_{14} - T_{13})(\Delta x)}{\Delta y} = 0$$

Node 14: $$\frac{k(T_9 - T_{14})(\Delta y)}{\Delta x} + \frac{k(T_{13} - T_{14})\Delta x}{\Delta y} + \frac{k(T_{18} - T_{14})(\Delta y)}{\Delta x} + \frac{k(T_{15} - T_{14})(\Delta x)}{\Delta y} = 0$$

Node 15: $$\frac{k(T_{10} - T_{15})(\Delta y)}{\Delta x} + \frac{k(T_{14} - T_{15})\Delta x}{\Delta y} + h\Delta l(T_\infty - T_{15}) = 0$$

Node 16: $$\frac{k(T_{12} - T_{16})(\Delta y/2)}{\Delta x} + \frac{k(T_{17} - T_{16})\Delta x}{\Delta y} + \frac{k(T_{19} - T_{16})(\Delta y/2)}{\Delta x} = 0$$

Node 17: $$\frac{k(T_{13} - T_{17})(\Delta y)}{\Delta x} + \frac{k(T_{16} - T_{17})\Delta x}{\Delta y} + \frac{k(T_{20} - T_{17})(\Delta y)}{\Delta x} + \frac{k(T_{18} - T_{17})(\Delta x)}{\Delta y} = 0$$

Node 18: $$\frac{k(T_{14} - T_{18})(\Delta y)}{\Delta x} + \frac{k(T_{17} - T_{18})\Delta x}{\Delta y} + h\Delta l(T_\infty - T_{18}) = 0$$

Node 19: $$\frac{k(T_{16} - T_{19})(\Delta y/2)}{\Delta x} + \frac{k(T_{20} - T_{19})\Delta x}{\Delta y} + \frac{k(T_{21} - T_{19})(\Delta y/2)}{\Delta x} = 0$$

Node 20: $$\frac{k(T_{17} - T_{20})(\Delta y)}{\Delta x} + \frac{k(T_{19} - T_{20})\Delta x}{\Delta y} + h\Delta l(T_\infty - T_{20}) = 0$$

Node 21: $$\frac{k(T_{19} - T_{21})(\Delta y/2)}{\Delta x} + h\left(\Delta l/2\right)(T_\infty - T_{21}) = 0$$

The fin heat rate per unit length is evaluated by considering conduction into its base expressed as

$$q_f' = 2\left(k\frac{(T_1 - T_7)(\Delta y/2)}{\Delta x} + k\frac{(T_2 - T_8)(\Delta y)}{\Delta x} + k\frac{(T_3 - T_9)(\Delta y)}{\Delta x} + k\frac{(T_4 - T_{10})(\Delta y)}{\Delta x} + k\frac{(T_5 - T_{11})(\Delta y)}{\Delta x}\right)$$

where the factor of two is due to heat transfer in the bottom half of the fin. The result is $q_f' = 109\ \text{W/m}$. The fin efficiency is evaluated using Eq. 3.91 yielding

$$n_f = \frac{q_f'}{hA_f\theta_b} = \frac{q_f'}{h\left(2\sqrt{L^2 + (t/2)^2}\right)\theta_b} = \frac{109\ \text{W/m}}{50\text{W/m}^2\cdot\text{K}\left(2\sqrt{(50\times10^{-3}\text{m})^2 + (20\times10^{-3}\text{m}/2)^2}\right)30\ \text{K}} = 0.71$$ <

Continued…

PROBLEM 4.66 (Cont.)

From Fig. 3.19 we find $L_c = 50 \times 10^{-3}$ m, $A_p = Lt/2 = (50 \times 10^{-3} \text{ m} \times 20 \times 10^{-3} \text{ m})/2 = 500 \times 10^{-6} \text{ m}^2$. Therefore,

$$L_c^{3/2}\left(\frac{h}{kA_p}\right)^{1/2} = (50\times10^{-3}\text{m})^{3/2}\times\left(\frac{50 \text{ W/m}^2\cdot\text{K}}{25 \text{ W/m}\cdot\text{K}\times500\times10^{-6}\text{m}^2}\right)^{1/2} = 0.707$$

and $n_f \approx 0.78$. The comparison between the calculated value and the value from the figure is reasonable. The difference may be attributed to convective loss from the fin adjacent to the base that is not accounted for in the finite difference solution, as discussed in Comment 3 below, or more generally, to the relatively coarse nodal mesh.

COMMENTS: (1) The nodal temperatures are:

T_6 = 50°C					
T_5 = 50°C	T_{11} = 47.57°C				
T_4 = 50°C	T_{10} = 47.58°C	T_{15} = 45.28°C			
T_3 = 50°C	T_9 = 47.59°C	T_{14} = 45.29°C	T_{18} = 43.10°C		
T_2 = 50°C	T_8 = 47.60°C	T_{13} = 45.30°C	T_{17} = 43.11°C	T_{20} = 41.03°C	
T_1 = 50°C	T_7 = 47.60°C	T_{12} = 45.30°C	T_{16} = 43.11°C	T_{19} = 41.03°C	T_{21} = 39.09°C

Note the nearly uniform cross-sectional temperatures within the fin. Temperatures near the centerline are only slightly warmer than corresponding temperatures at a particular *x*-location nearer to the convectively-cooled fin surface. (2) The *IHT* code is listed below.

//Fin Heat Transfer Rate

qfinhalf = k*(T1 - T7)*dely/2/delx + k*(T2 - T8)*dely/delx + k*(T3 - T9)*dely/delx + k*(T4 - T10)*dely/delx + k*(T5 -
T11)*dely/delx

qfin = 2*qfinhalf
```

(3) The finite difference equations do not account for convective losses from the fin in the exposed region of length $\Delta l / 2$ adjacent to the root of the fin. If this convective loss is estimated to be

$$q'_{est} = 2(\Delta l/2)h(T_6 - T_\infty) = 2\times(10.198\times10^{-3}\text{m})/2\times50\frac{\text{W}}{\text{m}^2\cdot\text{K}}\times(50°C - 20°C) = 15.3\text{ W/m}$$

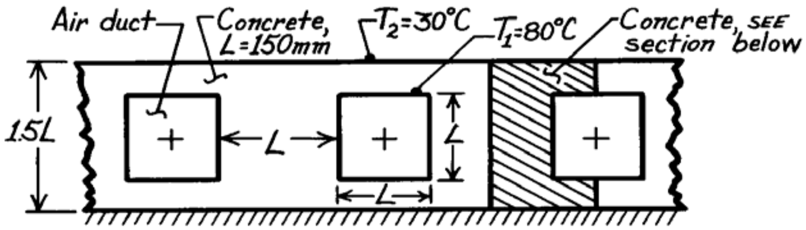
The fin heat transfer rate increases to q'_f = 109 W/m + 15.3 W/m = 124.3 W/m and the fin efficiency increases to n_f = 0.81, slightly greater than the fin efficiency found from Fig. 3.19.

PROBLEM 4.67

KNOWN: Rectangular air ducts having surfaces at 80°C in a concrete slab with an insulated bottom and upper surface maintained at 30°C.

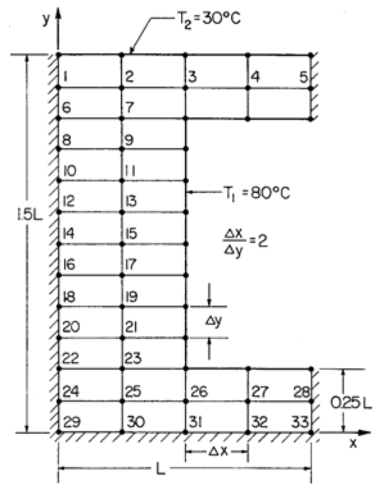
FIND: Heat rate from each duct per unit length of duct, q'.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) No internal volumetric generation, (4) Constant properties.

PROPERTIES: Concrete (given): k = 1.4 W/m·K.



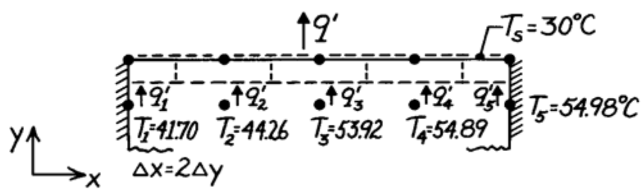
ANALYSIS: Taking advantage of symmetry, the nodal network, using the suggested grid spacing

$$\Delta x = 2\Delta y = 37.50 \text{ mm}$$

$$\Delta y = 0.125L = 18.75 \text{ mm}$$

where L = 150 mm, is shown in the sketch. To evaluate the heat rate, we need the temperatures T_1, T_2, T_3, T_4, and T_5. All the nodes may be treated as interior nodes (considering symmetry for those nodes on insulated boundaries), Eq. 4.29. Use matrix notation, Eq. 4.48, [A][T] = [C], and perform the inversion.

The heat rate per unit length from the prescribed section of the duct follows from an energy balance on the nodes at the top isothermal surface.



$$q' = q_1' + q_2' + q_3' + q_4' + q_5'$$

$$q' = k\left(\Delta x/2\right)\frac{T_1 - T_s}{\Delta y} + k \cdot \Delta x\frac{T_2 - T_s}{\Delta y} + k \cdot \Delta x\frac{T_3 - T_s}{\Delta y} + k \cdot \Delta x\frac{T_4 - T_s}{\Delta y} + k\left(\Delta x/2\right)\frac{T_5 - T_s}{\Delta y}$$

$$q' = k\left[\left(T_1 - T_s\right) + 2\left(T_2 - T_s\right) + 2\left(T_3 - T_s\right) + 2\left(T_4 - T_s\right) + \left(T_5 - T_s\right)\right]$$

$$q' = 1.4 \text{ W/m}\cdot\text{K}\left[\left(41.70 - 30\right) + 2\left(44.26 - 30\right) + 2\left(53.92 - 30\right) + 2\left(54.89 - 30\right) + \left(54.98 - 30\right)\right]$$

$$q' = 228 \text{ W/m.}$$

Since the section analyzed represents one-half of the region about an air duct, the heat loss per unit length for each duct is,

$$q'_{duct} = 2xq' = 456 \text{ W/m.}$$ <

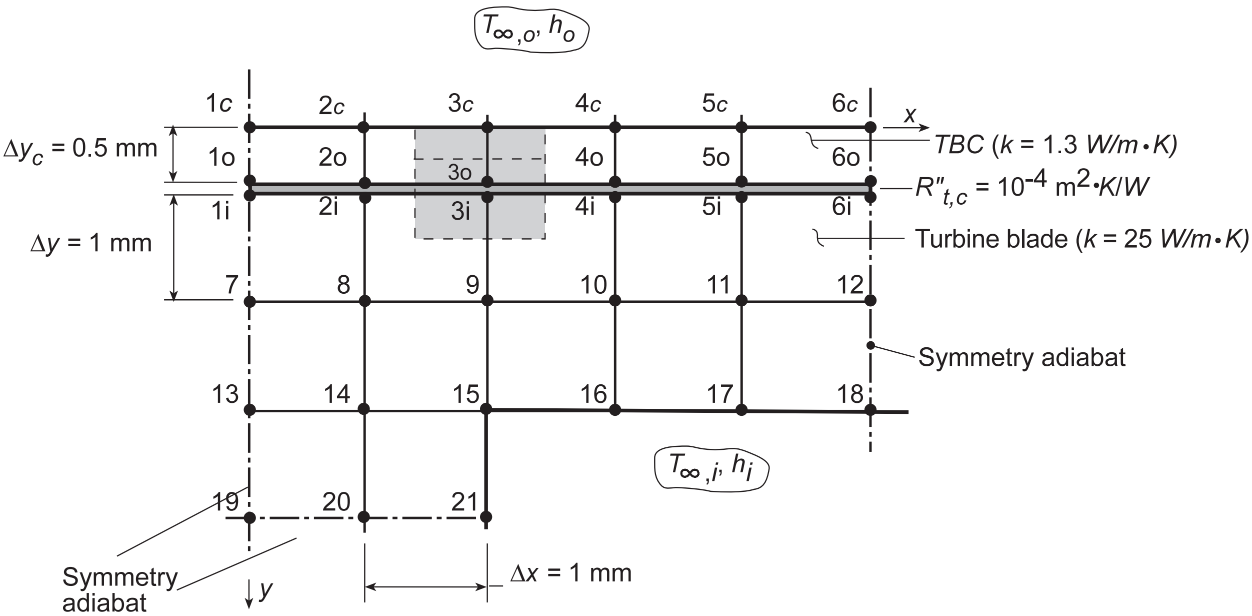
PROBLEM 4.68

KNOWN: Dimensions and operating conditions for a gas turbine blade with embedded channels.

FIND: Effect of applying a zirconia, thermal barrier coating.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties, (3) Negligible radiation.

ANALYSIS: Preserving the nodal network of Example 4.3 and adding surface nodes for the TBC, finite-difference equations previously developed for nodes 7 through 21 are still appropriate, while new equations must be developed for nodes 1c-6c, 1o-6o, and 1i-6i. Considering node 3c as an example, an energy balance yields

$$h_o \Delta x\left(T_{\infty,o} - T_{3c}\right) + \frac{k_c\left(\Delta y_c/2\right)}{\Delta x}\left(T_{2c} - T_{3c}\right) + \frac{k_c\left(\Delta y_c/2\right)}{\Delta x}\left(T_{4c} - T_{3c}\right) + \frac{k_c \Delta x}{\Delta y_c}\left(T_{3o} - T_{3c}\right) = 0$$

or, with Δx = 1 mm and Δy_c = 0.5 mm,

$$0.25\left(T_{2c} + T_{4c}\right) + 2T_{3o} - \left(2.5 + \frac{h_o \Delta x}{k_c}\right)T_{3c} = -\frac{h_o \Delta x}{k_c} T_{\infty,o}$$

Similar expressions may be obtained for the other 5 nodal points on the outer surface of the TBC.

Applying an energy balance to node 3o at the inner surface of the TBC, we obtain

$$\frac{k_c \Delta x}{\Delta y_c}\left(T_{3c} - T_{3o}\right) + \frac{k_c\left(\Delta y_c/2\right)}{\Delta x}\left(T_{2o} - T_{3o}\right) + \frac{k_c\left(\Delta y_c/2\right)}{\Delta x}\left(T_{4o} - T_{3o}\right) + \frac{\Delta x}{R''_{t,c}}\left(T_{3i} - T_{3o}\right) = 0$$

or,

$$2T_{3c} + 0.25\left(T_{2o} + T_{4o}\right) + \frac{\Delta x}{k_c R''_{t,c}} T_{3i} - \left(2.5 + \frac{\Delta x}{k_c R''_{t,c}}\right)T_{3o} = 0$$

Similar expressions may be obtained for the remaining nodal points on the inner surface of the TBC (outer region of the contact resistance).

Continued...

PROBLEM 4.68 (Cont.)

Applying an energy balance to node 3i at the outer surface of the turbine blade, we obtain

$$\frac{\Delta x}{R''_{t,c}}\left(T_{3o}-T_{3i}\right)+\frac{k\left(\Delta y/2\right)}{\Delta x}\left(T_{2i}-T_{3i}\right)+\frac{k\left(\Delta y/2\right)}{\Delta x}\left(T_{4i}-T_{3i}\right)+\frac{k\Delta x}{\Delta y}\left(T_9-T_{3i}\right)=0$$

or,

$$\frac{\Delta x}{kR''_{t,c}}T_{3o}+0.5\left(T_{2,i}+T_{4,i}\right)+T_9-\left(2+\frac{\Delta x}{kR''_{t,c}}\right)T_{3i}=0$$

Similar expressions may be obtained for the remaining nodal points on the inner region of the contact resistance.

The 33 finite-difference equations were entered into the workspace of IHT from the keyboard, and for h_o = 1000 W/m^2·K, $T_{\infty,o}$ = 1700 K, h_i = 200 W/m^2·K and $T_{\infty,i}$ = 400 K, the following temperature field was obtained, where coordinate (x,y) locations are in mm and temperatures are in °C.

y\x	0	1	2	3	4	5
0	1536	1535	1534	1533	1533	1532
0.5	1473	1472	1471	1469	1468	1468
0.5	1456	1456	1454	1452	1451	1451
1.5	1450	1450	1447	1446	1444	1444
2.5	1446	1445	1441	1438	1437	1436
3.5	1445	1443	1438	0	0	0

Note the significant reduction in the turbine blade temperature, as, for example, from a surface temperature of T_1 = 1526 K without the TBC to T_{1i} = 1456 K with the coating. Hence, the coating is serving its intended purpose.

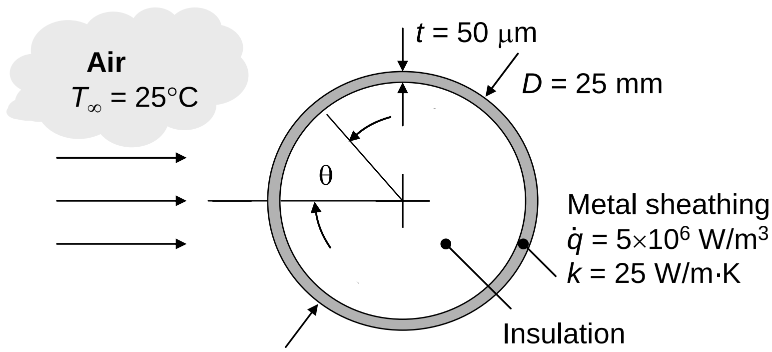
COMMENTS: (1) Significant additional benefits may still be realized by increasing h_i. (2) The foregoing solution may be used to determine the temperature field without the TBC by setting $k_c \to \infty$ and $R''_{t,c} \to 0$.

PROBLEM 4.69

KNOWN: Dimensions of long cylinder, thickness of metal sheathing, volumetric generation rate within the sheathing, thermal conductivity of sheathing and convection heat transfer coefficient dependence upon angle θ.

FIND: (a) Temperature distribution within the thin sheathing neglecting θ-direction conduction heat transfer, (b) temperature distribution in the sheathing accounting for θ-direction conduction heat transfer in the metal.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Uniform internal generation, (4) Metal sheathing is very thin relative to cylinder diameter, (5) One-dimensional conduction, (6) Negligible radiation.

ANALYSIS: (a) Neglecting conduction in the θ-direction in the sheathing, an energy balance at any θ location yields

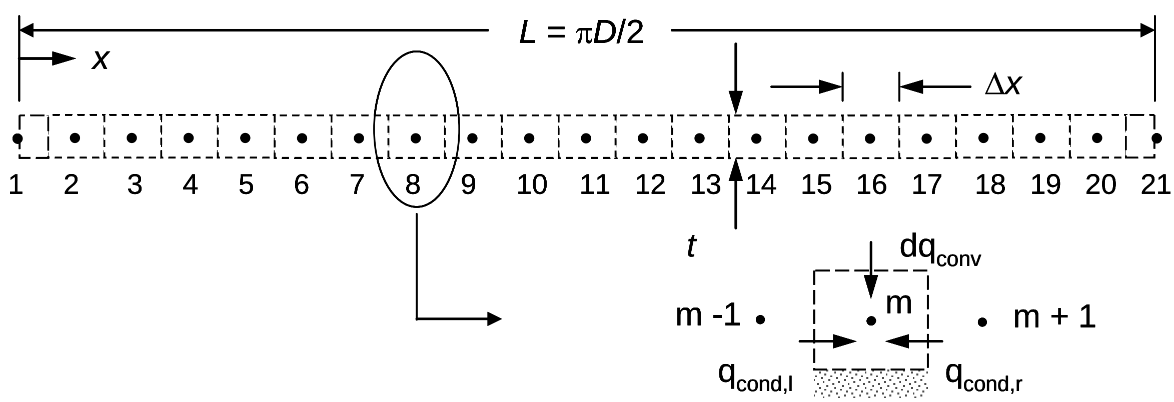
$$\dot{q}t = h(\theta)(T_s - T_\infty) \quad \text{or} \quad T_s = T_\infty + \dot{q}t/h(\theta) \text{ and}$$

$$h(\theta) = 26 + 0.637\theta - 8.92\theta^2 \text{ for } 0 \le \theta < \pi/2; \;\; h(\theta) = 5 \text{ for } \pi/2 \le \theta \le \pi$$

These equations may be solved to yield the temperature distribution that is plotted on the next page where $x = \theta D/2$.

(b) Since the sheathing is thin relative to the cylinder diameter, we may evaluate one-dimensional conduction in the x-direction using the Cartesian coordinate system. The finite difference equations are derived by combining expressions for heat fluxes based upon Fourier's law and Newton's law of cooling, along with conservation of energy for each control volume within the discretized domain. Application of conservation of energy for each control volume yields the expression $\dot{E}_{\text{in}} + \dot{E}_g = 0$.

The discretized domain is shown below.



Continued…

PROBLEM 4.69 (Cont.)

The finite difference equations are as follows.

Node 1:

$$k\frac{(T_2 - T_1)}{\Delta x}t + h(\Delta x/2)(T_\infty - T_1) + \dot{q}(\Delta x/2)t = 0$$

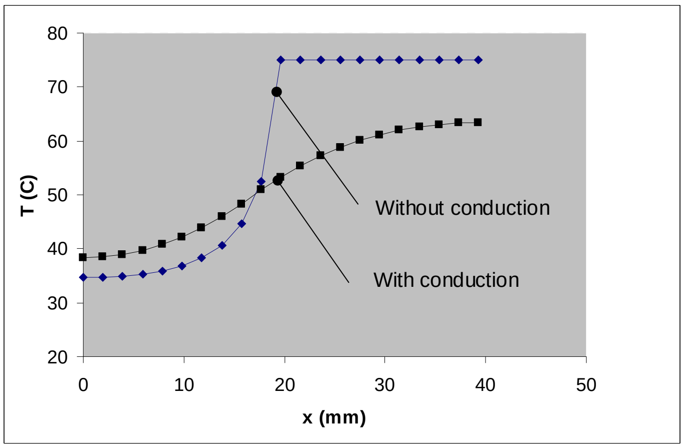
Nodes 2 - 20:

$$k\frac{(T_{m-1} - T_m)}{\Delta x}t + k\frac{(T_{m+1} - T_m)}{\Delta x}t + h(\Delta x)(T_\infty - T_m) + \dot{q}(\Delta x)t = 0$$

Node 21:

$$k\frac{(T_{20} - T_{21})}{\Delta x}t + h(\Delta x/2)(T_\infty - T_{21}) + \dot{q}(\Delta x/2)t = 0$$

The temperature distribution is plotted below.



COMMENTS: (1) Conduction in the θ-direction within the sheathing smears the temperature distribution, increasing the low temperatures on the upstream half of the cylinder and lowering the temperatures on the downstream half of the cylinder. (2) The *IHT* code is listed below.

```

```

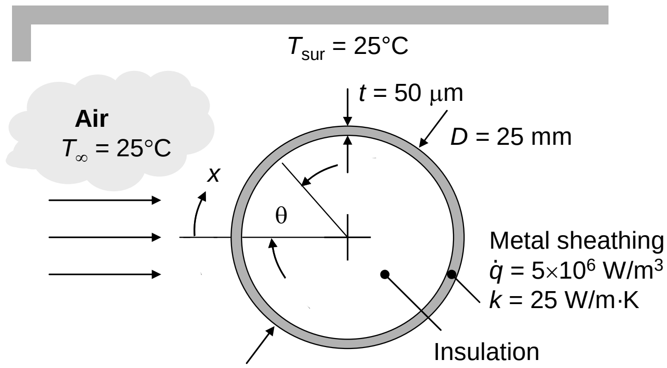
PROBLEM 4.70

KNOWN: Diameter of long cylinder, thickness of metal sheathing, volumetric generation rate within the sheathing, thermal conductivity of sheathing and convection heat transfer coefficient dependence upon angle θ. Emissivity of the sheathing.

FIND: (a) Temperature distribution within the thin sheathing accounting for convection, conduction in the sheathing, and radiation exchange with the surroundings.

SCHEMATIC:

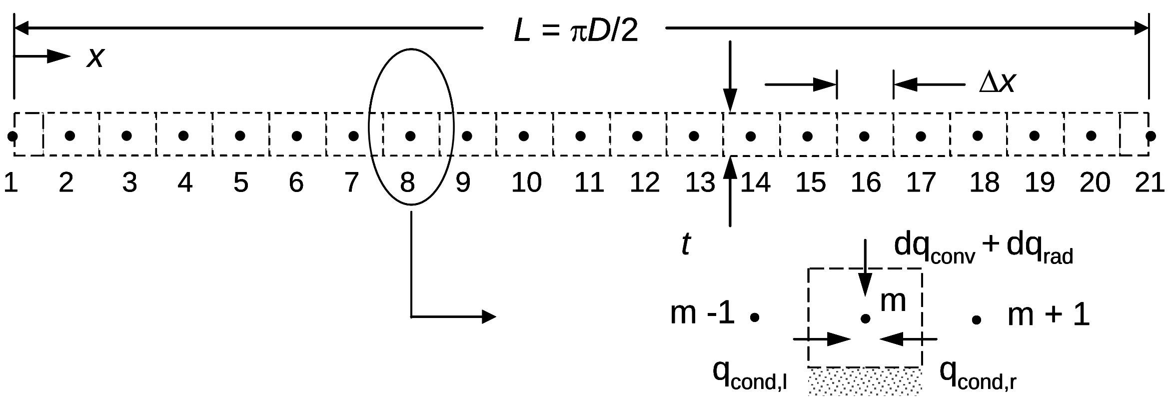


ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Uniform internal generation, (4) Metal sheathing is very thin relative to cylinder diameter, (5) One-dimensional conduction, (6) Large surroundings.

ANALYSIS: From Problem 4.69,

$$h(\theta) = 26 + 0.637\theta - 8.92\theta^2 \text{ for } 0 \le \theta < \pi/2; \;\; h(\theta) = 5 \text{ for } \pi/2 \le \theta \le \pi$$

Since the sheathing is thin relative to the cylinder diameter, we may evaluate one-dimensional conduction in the x-direction using the Cartesian coordinate system. The finite difference equations are derived by combining expressions for heat fluxes determined from Fourier's law, Newton's law of cooling, and Eq. 1.7 along with conservation of energy for each control volume within the discretized domain. Application of conservation of energy for each control volume yields the expression $\dot{E}_{in} + \dot{E}_g = 0$. The discretized domain is shown below.



Energy balances for the control volumes are as follows.

Node 1: $$k\frac{(T_2 - T_1)}{\Delta x}t + h(\Delta x/2)(T_\infty - T_1) + \varepsilon\sigma(\Delta x/2)(T_{sur}^4 - T_1^4) + \dot{q}(\Delta x/2)t = 0$$

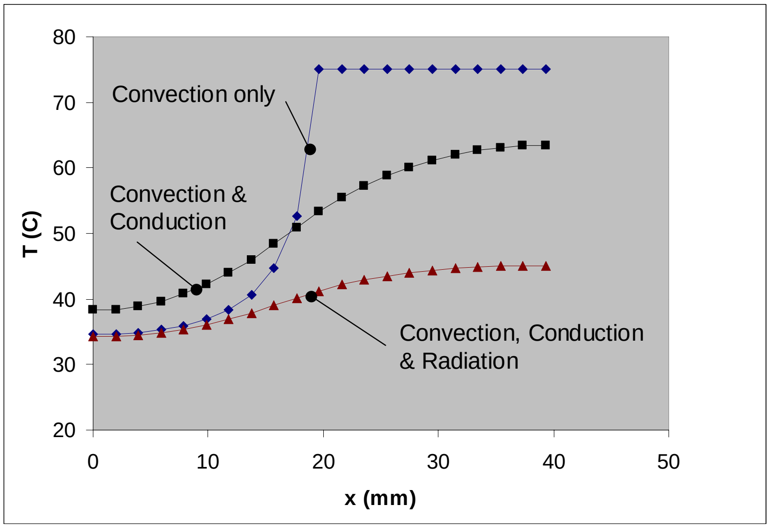
Continued…

PROBLEM 4.70 (Cont.)

Nodes 2 - 20: $k\dfrac{(T_{m-1}-T_m)}{\Delta x}t + k\dfrac{(T_{m+1}-T_m)}{\Delta x}t + h(\Delta x)(T_\infty - T_m) + \varepsilon\sigma(\Delta x)(T_{\text{sur}}^4 - T_m^4) + \dot{q}(\Delta x)t = 0$

Node 21: $k\dfrac{(T_{20}-T_{21})}{\Delta x}t + h(\Delta x/2)(T_\infty - T_{21}) + \varepsilon\sigma(\Delta x/2)(T_{\text{sur}}^4 - T_{21}^4) + \dot{q}(\Delta x/2)t = 0$

The temperature distribution is plotted below.



COMMENTS: (1) Inclusion of radiation in the analysis shows that the resulting temperatures are reduced overall, as expected. The effects of conduction and radiation on local temperatures are comparable. (2) The *IHT* code is listed below.

```
D = 25/1000                 //m

```

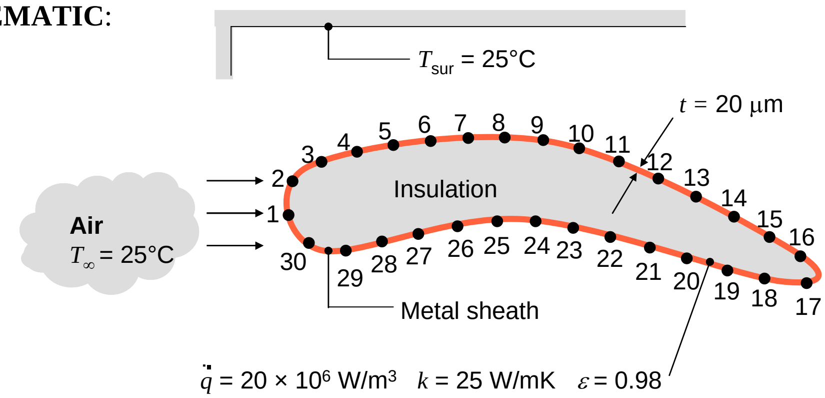
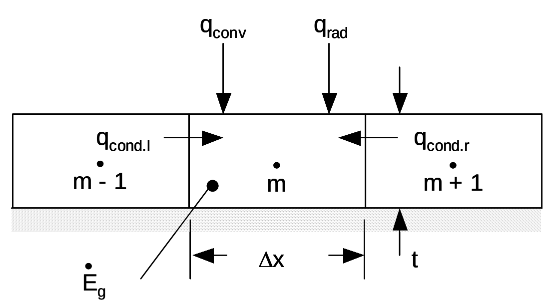
PROBLEM 4.71

KNOWN: Geometry of long airfoil shape, thickness of metal sheathing, volumetric generation rate within the sheathing, thermal conductivity of sheathing, emissivity of the sheathing, and measured temperatures at discrete locations.

FIND: Local convection coefficient at discrete locations accounting for conduction along the sheathing and radiation. Determine effects of conduction and radiation on the calculated convection heat transfer coefficients.

SCHEMATIC:





ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Uniform internal generation, (4) Metal sheathing is very thin relative to cylinder diameter, (5) One-dimensional conduction, (6) Large surroundings.

ANALYSIS: We apply Newton's law of cooling, Fourier's law and Eq. 1.7 to a general control volume about the thin sheathing to find the following general finite-difference formula.

$$q'_{\text{cond,l}} + q'_{\text{cond,r}} + q'_{\text{conv}} + q'_{\text{rad}} + \dot{E}'_{\text{g}} = 0$$

or

$$k\frac{(T_{m-1} - T_m)}{\Delta x}t + k\frac{(T_{m+1} - T_m)}{\Delta x}t + h_m(\Delta x)(T_\infty - T_m) + \varepsilon\sigma(\Delta x)(T_{\text{sur}}^4 - T_m^4) + \dot{q}(\Delta x)t = 0$$

Recognizing that for $m = 1$, $m - 1 = 30$, we may substitute values of T_{m-1}, T_m, and T_{m+1} and $\Delta x = 2$ mm into the preceding formula and solve for h_m. The results for case A (inclusion of convection, conduction and radiation), case B (inclusion of convection and conduction only) and case C (inclusion of convection only) are tabulated below.

Continued…

PROBLEM 4.71 (Cont.)

m	T_m (°C)	$h_{m,A}$ (W/m^2·K)	$h_{m,B}$ (W/m^2·K)	$h_{m,C}$ (W/m^2·K)

27	31.85	*40.08*	46.17	58.39
28	31.51	*31.17*	37.25	61.44
29	29.91	*78.24*	84.27	81.47
30	28.42	141.7	147.7	*117.0*

Note: Maximum predicted values are underlined, while minimum predicted values are *italicized*.

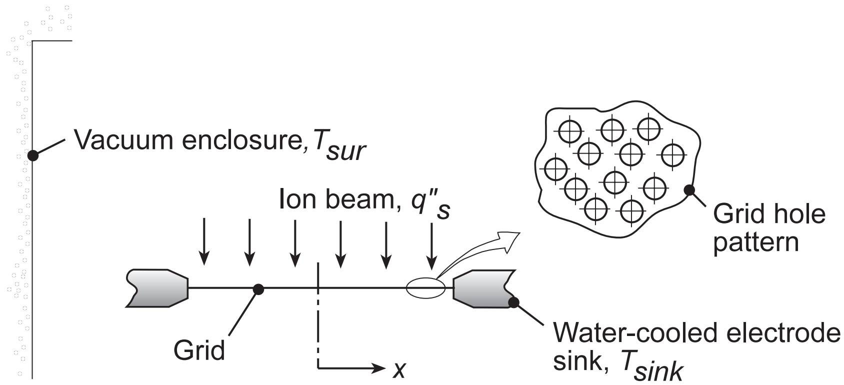
COMMENTS: (1) The heat transfer coefficient distribution is non-uniform. Such non-uniformity is typical of situations involving convection around complex geometries. The largest heat transfer coefficients exist at the leading edge of the object, while the smallest values of h are near the trailing edge. (2) Differences in the measured values of the heat transfer coefficient evolve when different analyses are used to interpret the measured temperatures. (3) Inclusion of radiation in Analysis B always results in lower heat transfer coefficients (relative to Analysis A) since the object is hot relative to the large surroundings.

PROBLEM 4.72

KNOWN: Thin metallic foil of thickness, t, whose edges are thermally coupled to a sink at temperature T_{sink} is exposed on the top surface to an ion beam heat flux, q_s'', and experiences radiation exchange with the vacuum enclosure walls at T_{sur}.

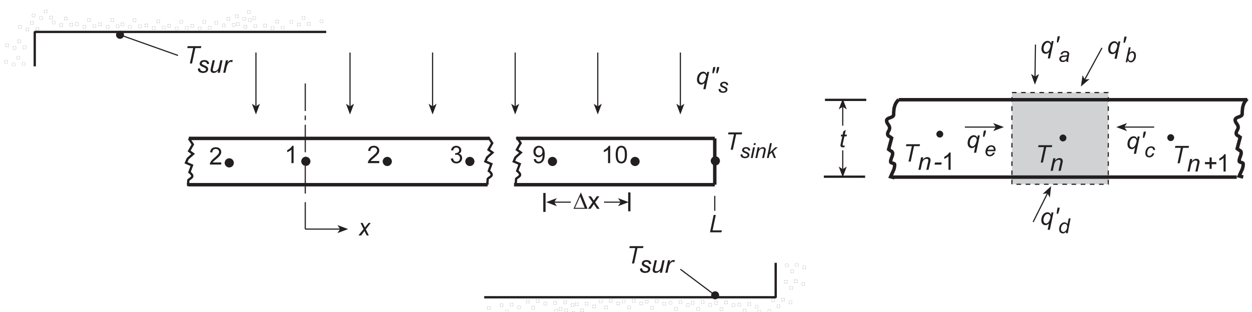
FIND: Temperature distribution across the foil.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, steady-state conduction in the foil, (2) Constant properties, (3) Upper and lower surfaces of foil experience radiation exchange, (4) Foil is of unit length normal to the page.

ANALYSIS: The 10-node network representing the foil is shown below.



From an energy balance on node n, $\dot{E}_{in} - \dot{E}_{out} = 0$, for a unit depth,

$$q'_a + q'_b + q'_c + q'_d + q'_e = 0$$

$$q_s''\Delta x + h_{r,n}\Delta x\left(T_{sur} - T_n\right) + k\left(t\right)\left(T_{n+1} - T_n\right)/\Delta x + h_{r,n}\Delta x\left(T_{sur} - T_n\right) + k\left(t\right)\left(T_{n-1} - T_n\right)/\Delta x = 0 \quad (1)$$

where the linearized radiation coefficient for node n is

$$h_{r,n} = \varepsilon\sigma\left(T_{sur} + T_n\right)\left(T_{sur}^2 + T_n^2\right) \quad (2)$$

Solving Eq. (1) for T_n find,

$$T_n = \left[\left(T_{n+1} + T_{n-1}\right) + \left(2h_{r,n}\Delta x^2/kt\right)T_{sur} + \left(\Delta x^2/kt\right)q_s''\right]\Big/\left[\left(h_{r,n}\Delta x^2/kt\right) + 2\right] \quad (3)$$

which, considering symmetry, applies also to node 1. Using IHT for Eqs. (3) and (2), the set of finite-difference equations was solved for the temperature distribution (K):

T_1	T_2	T_3	T_4	T_5	T_6	T_7	T_8	T_9	T_{10}
374.1	374.0	373.5	372.5	370.9	368.2	363.7	356.6	345.3	327.4

Continued...

PROBLEM 4.72 (Cont.)

COMMENTS: (1) If the temperature gradients were excessive across the foil, it would wrinkle; most likely since its edges are constrained, the foil will bow.

(2) The IHT workspace for the finite-difference analysis follows:

```
// The nodal equations:
T1 = ( (T2 + T2) + A1 * Tsur +  B *q''s ) / ( A1 + 2)

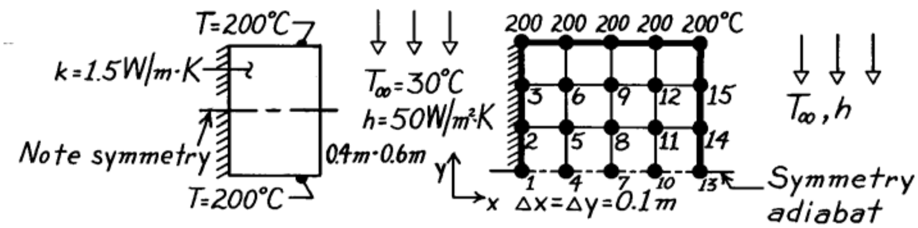
PROBLEM 4.73

KNOWN: Bar of rectangular cross-section subjected to prescribed boundary conditions.

FIND: Using a numerical technique with a grid spacing of 0.1m, determine the temperature distribution and the heat transfer rate from the bar to the fluid.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties.

ANALYSIS: The nodal network has $\Delta x = \Delta y = 0.1\text{m}$. Note the adiabat corresponding to system symmetry. The finite-difference equations for each node can be written using either Eq. 4.29, for interior nodes, or Eq. 4.42, for a plane surface with convection. In the case of adiabatic surfaces, Eq. 4.42 is used with h = 0. Note that

$$\frac{h\Delta x}{k} = \frac{50\text{W/m}^2 \cdot \text{K} \times 0.1\text{m}}{1.5\ \text{W/m} \cdot \text{K}} = 3.333.$$

Node	*Finite-Difference Equations*
1	$-4T_1 + 2T_2 + 2T_4 = 0$
2	$-4T_2 + T_1 + T_3 + 2T_5 = 0$
3	$-4T_3 + 200 + 2T_6 + T_2 = 0$
4	$-4T_4 + T_1 + 2T_5 + T_7 = 0$
5	$-4T_5 + T_2 + T_6 + T_8 + T_4 = 0$
6	$-4T_6 + T_5 + T_3 + 200 + T_9 = 0$
7	$-4T_7 + T_4 + 2T_8 + T_{10} = 0$
8	$-4T_8 + T_7 + T_5 + T_9 + T_{11} = 0$
9	$-4T_9 + T_8 + T_6 + 200 + T_{12} = 0$
10	$-4T_{10} + T_7 + 2T_{11} + T_{13} = 0$
11	$-4T_{11} + T_{10} + T_8 + T_{12} + T_{14} = 0$
12	$-4T_{12} + T_{11} + T_9 + 200 + T_{15} = 0$
13	$2T_{10} + T_{14} + 6.666\times30 - 10.666\ T_{13} = 0$
14	$2T_{11} + T_{13} + T_{15} + 6.666\times30 - 2(3.333+2)T_{14} = 0$
15	$2T_{12} + T_{14} + 200 + 6.666\times30 - 2(3.333+2)\ T_{15} = 0$

Using the matrix inversion method, Section 4.5.2, the above equations can be written in the form [A] [T] = [C] where [A] and [C] are shown on the next page. Using a stock matrix inversion routine, the temperatures [T] are determined.

\end{bmatrix}$$

$$[C]=\begin{bmatrix}0\\0\\-200\\0\\0\\-200\\0\\0\\-200\\0\\0\\-200\\-200\\-200\\-400\end{bmatrix} \qquad [T]=\begin{bmatrix}T_1\\T_2\\T_3\\T_4\\T_5\\T_6\\T_7\\T_8\\T_9\\T_{10}\\T_{11}\\T_{12}\\T_{13}\\T_{14}\\T_{15}\end{bmatrix}=\begin{bmatrix}153.9\\159.7\\176.4\\148.0\\154.4\\172.9\\129.4\\137.0\\160.7\\95.6\\103.5\\132.8\\45.8\\48.7\\67.0\end{bmatrix}\left({}^\circ C\right)$$

Considering symmetry, the heat transfer rate to the fluid is twice the convection rate from the surfaces of the control volumes exposed to the fluid. Using Newton's law of cooling, considering a unit thickness of the bar, find

$$q_{conv}=2\left[h\cdot\frac{\Delta y}{2}\cdot\left(T_{13}-T_\infty\right)+h\cdot\Delta y\cdot\left(T_{14}-T_\infty\right)+h\cdot\Delta y\left(T_{15}-T_\infty\right)+h\cdot\frac{\Delta y}{2}\left(200-T_\infty\right)\right]$$

$$q_{conv}=2h\cdot\Delta y\left[\frac{1}{2}\left(T_{13}-T_\infty\right)+\left(T_{14}-T_\infty\right)+\left(T_{15}-T_\infty\right)+\frac{1}{2}\left(200-T_\infty\right)\right]$$

$$q_{conv}=2\times 50\frac{W}{m^2\cdot K}\times 0.1m\left[\frac{1}{2}\left(45.8-30\right)+\left(48.7-30\right)+\left(67.0-30\right)+\frac{1}{2}\left(200-30\right)\right]$$

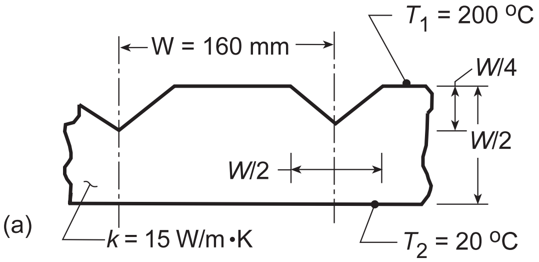
$$q_{conv}=1487\ W/m. \qquad <$$

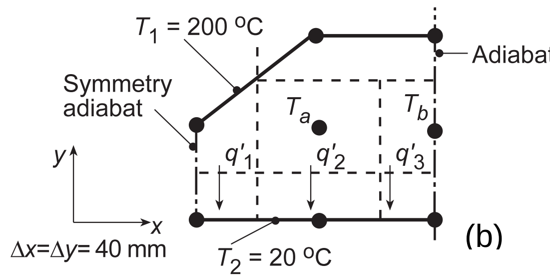
PROBLEM 4.74

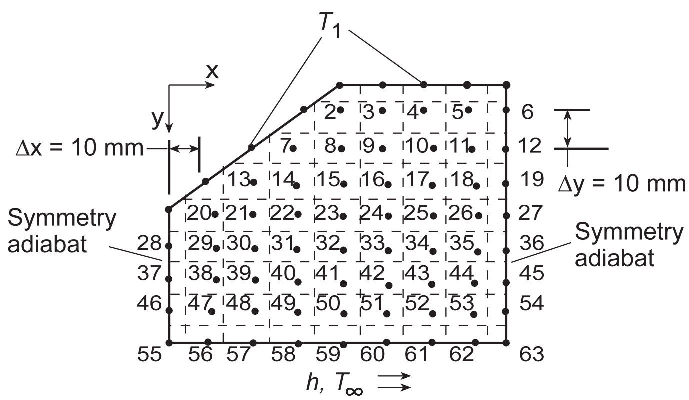
KNOWN: Upper surface and grooves of a plate are maintained at a uniform temperature T_1, while the lower surface is maintained at T_2 or is exposed to a fluid at T_∞.

FIND: (a) Heat rate per width of groove spacing (w) for isothermal top and bottom surfaces using a finite-difference method with Δx = 40 mm, (b) Effect of grid spacing and convection at bottom surface.

SCHEMATIC:







ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties.

ANALYSIS: (a) Using a space increment of Δx = 40 mm, the symmetrical section shown in schematic (b) corresponds to one-half the groove spacing. There exist only two interior nodes for which finite-difference equations must be written.

Node a:
$$4T_a - (T_1 + T_b + T_2 + T_1) = 0$$
$$4T_a - (200 + T_b + 20 + 200) = 0 \qquad \text{or} \qquad 4T_a - T_b = 420 \qquad (1)$$

Node b:
$$4T_b - (T_1 + T_a + T_2 + T_a) = 0$$
$$4T_b - (200 + 2T_a + 20) = 0 \qquad \text{or} \qquad -2T_a + 4T_b = 220 \qquad (2)$$

Multiply Eq. (2) by 2 and add to Eq. (1) to obtain

$7T_b = 860$ or $T_b = 122.9°C$

From Eq. (1),

$4T_a - 122.9 = 420$ or $T_a = (420 + 122.9)/4 = 135.7°C$.

The heat transfer through the symmetrical section is equal to the sum of heat flows through control volumes adjacent to the lower surface. From the schematic,

$$q' = q_1' + q_2' + q_3' = k\left(\frac{\Delta x}{2}\right)\frac{T_1 - T_2}{\Delta y} + k(\Delta x)\frac{T_a - T_2}{\Delta y} + k\left(\frac{\Delta x}{2}\right)\frac{T_b - T_2}{\Delta y}.$$

Continued...

PROBLEM 4.74 (Cont.)

Noting that Δx = Δy, regrouping and substituting numerical values, find

$$q' = k\left[\frac{1}{2}(T_1 - T_2) + (T_a - T_2) + \frac{1}{2}(T_b - T_2)\right]$$

$$q' = 15\,W/m\cdot K\left[\frac{1}{2}(200-20) + (135.7-20) + \frac{1}{2}(122.9-20)\right] = 3.86\,kW/m\,.$$

For the full groove spacing, q'_{total} = 2 × 3.86 kW/m = 7.72 kW/m. <

(b) Using the *Finite-Difference Equations* option from the *Tools* portion of the IHT menu, the following two-dimensional temperature field was computed for the grid shown in schematic (b), where x and y are in mm and the nodal temperatures are in °C. Nodes 2-54 are interior nodes, with those along the symmetry adiabats characterized by $T_{m-1,n} = T_{m+1,n}$, while nodes 55-63 lie on a plane surface.

y\x	0	10	20	30	40	50	60	70	80
0					200	200	200	200	200
10				200	191	186.6	184.3	183.1	182.8
20			200	186.7	177.2	171.2	167.5	165.5	164.8
30		200	182.4	169.5	160.1	153.4	149.0	146.4	145.5
40	200	175.4	160.3	148.9	140.1	133.5	128.7	125.7	124.4
50	141.4	134.3	125.7	118.0	111.6	106.7	103.1	100.9	100.1
60	97.09	94.62	90.27	85.73	81.73	78.51	76.17	74.73	74.24
70	57.69	56.83	55.01	52.95	51.04	49.46	48.31	47.60	47.36
80	20	20	20	20	20	20	20	20	20

The foregoing results were computed for h = 10^7 W/m^2·K (h → ∞) and T_∞ = 20°C, which is tantamount to prescribing an isothermal bottom surface at 20°C. Agreement between corresponding results for the coarse and fine grids is surprisingly good (T_a = 135.7°C ↔ T_{23} = 140.1°C; T_b = 122.9°C ↔ T_{27} = 124.4°C). The heat rate is

$$q' = 2\times k\big[(T_{46}-T_{55})/2 + (T_{47}-T_{56}) + (T_{48}-T_{57}) + (T_{49}-T_{58}) + (T_{50}-T_{59})$$
$$+ (T_{51}-T_{60}) + (T_{52}-T_{61}) + (T_{53}-T_{62}) + (T_{54}-T_{63})/2\big]$$

$$q' = 2\times 15\,W/m\cdot K\big[18.84 + 36.82 + 35.00 + 32.95 + 31.04 + 29.46$$ <

$$+28.31 + 27.6 + 13.68\big]^\circ C = 7.61\,kW/m$$

The agreement with q' = 7.72 kW/m from the coarse grid of part (a) is excellent and a fortuitous consequence of compensating errors. With reductions in the convection coefficient from h → ∞ to h = 1000, 200 and 5 W/m^2·K, the corresponding increase in the thermal resistance reduces the heat rate to values of 6.03, 3.28 and 0.14 kW/m, respectively. With decreasing h, there is an overall increase in nodal temperatures, as, for example, from 191°C to 199.8°C for T_2 and from 20°C to 196.9°C for T_{55}.

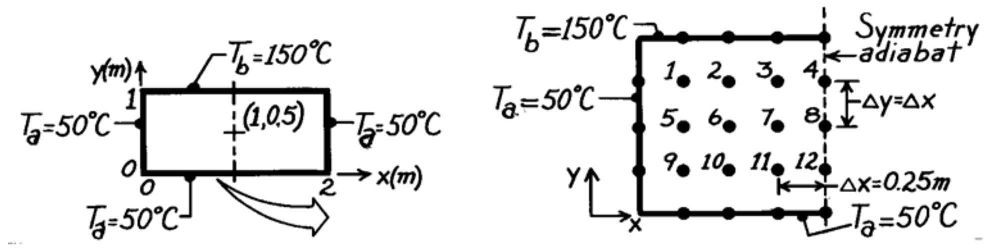
NOTE TO INSTRUCTOR: To reduce computational effort, while achieving the same educational objectives, the problem statement has been changed to allow for convection at the bottom, rather than the top, surface.

PROBLEM 4.75

KNOWN: Rectangular plate subjected to uniform temperature boundaries.

FIND: Temperature at the midpoint using a finite-difference method with space increment of 0.25m

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties.

ANALYSIS: For the nodal network above, 12 finite-difference equations must be written. It follows that node 8 represents the midpoint of the rectangle. Since all nodes are interior nodes, Eq. 4.29 is appropriate and is written in the form

$$4T_m - \sum T_{neighbors} = 0.$$

For nodes on the symmetry adiabat, the neighboring nodes include two symmetrical nodes. Hence, for Node 4, the neighbors are T_b, T_8 and $2T_3$. Because of the simplicity of the finite-difference equations, we may proceed directly to the matrices [A] and [C] – see Eq. 4.48 – and matrix inversion can be used to find the nodal temperatures T_m.

$$A = \begin{bmatrix} -4 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 1 & -4 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & -4 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 2 & -4 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\ 1 & 0 & 0 & 0 & -4 & 1 & 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 1 & -4 & 1 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 1 & -4 & 1 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 & 2 & -4 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & -4 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & -4 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 1 & -4 & 1 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 2 & -4 \end{bmatrix} \quad C = \begin{bmatrix} -200 \\ -150 \\ -150 \\ -150 \\ -50 \\ 0 \\ 0 \\ 0 \\ -100 \\ -50 \\ -50 \\ -50 \end{bmatrix} \quad T = \begin{bmatrix} 96.5 \\ 112.9 \\ 118.9 \\ 120.4 \\ 73.2 \\ 86.2 \\ 92.3 \\ 94.0 \\ 59.9 \\ 65.5 \\ 69.9 \\ 71.0 \end{bmatrix}$$

The temperature at the midpoint (Node 8) is

$$T(1,0.5) = T_8 = 94.0^\circ C.$$ <

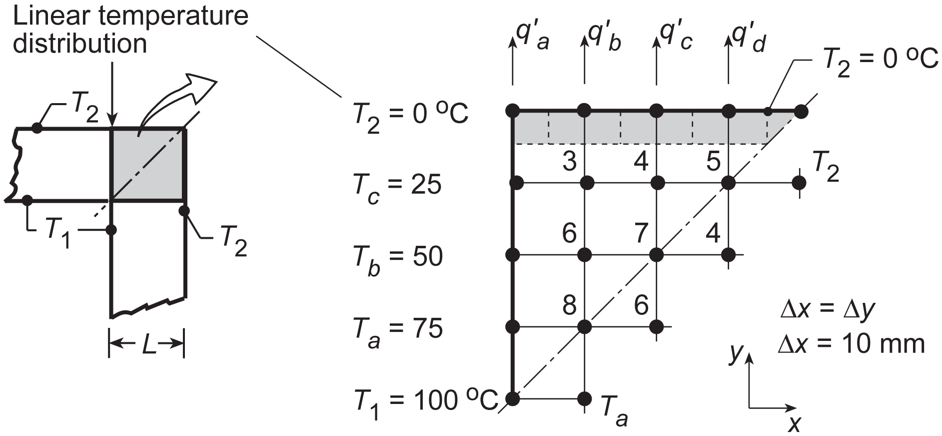
COMMENTS: Using the exact analytical, solution – see Eq. 4.19 and Problem 4.2 – the midpoint temperature is found to be 94.5°C. To improve the accuracy of the finite-difference method, it would be necessary to decrease the nodal mesh size.

PROBLEM 4.76

KNOWN: Edge of adjoining walls (k = 1 W/m·K) represented by symmetrical element bounded by the diagonal symmetry adiabat and a section of the wall thickness over which the temperature distribution is assumed to be linear.

FIND: (a) Temperature distribution, heat rate and shape factor for the edge using the nodal network with = Δx = Δy = 10 mm; compare shape factor result with that from Table 4.1; (b) Assess the validity of assuming linear temperature distributions across sections at various distances from the edge.

SCHEMATIC:



ASSUMPTIONS: (1) Two-dimensional, steady-state conduction, (2) Constant properties, and (3) Linear temperature distribution at specified locations across the section.

ANALYSIS: (a) Taking advantage of symmetry along the adiabat diagonal, all the nodes may be treated as interior nodes. Across the left-hand boundary, the temperature distribution is specified as linear. The finite-difference equations required to determine the temperature distribution, and hence the heat rate, can be written by inspection.

$$T_3 = 0.25(T_2 + T_4 + T_6 + T_c)$$

$$T_4 = 0.25(T_2 + T_5 + T_7 + T_3)$$

$$T_5 = 0.25(T_2 + T_2 + T_4 + T_4)$$

$$T_6 = 0.25(T_3 + T_7 + T_8 + T_b)$$

$$T_7 = 0.25(T_4 + T_4 + T_6 + T_6)$$

$$T_8 = 0.25(T_6 + T_6 + T_a + T_a)$$

The heat rate for both surfaces of the edge is

$$q'_{tot} = 2[q'_a + q'_b + q'_c + q'_d]$$

$$q'_{tot} = 2[k(\Delta x/2)(T_c - T_2)/\Delta y + k\Delta x(T_3 - T_2)/\Delta y + k\Delta x(T_4 - T_2)/\Delta y + k\Delta x(T_5 - T_2)/\Delta x]$$

The shape factor for the full edge is defined as

$$q'_{tot} = kS'(T_1 - T_2)$$

Solving the above equation set in IHT, the temperature (°C) distribution is

Continued...

PROBLEM 4.76 (Cont.)

0	0	0	0	0
25	18.75	12.5	6.25	
50	37.5	25.0		
75	56.25			
100				

<

and the heat rate and shape factor are

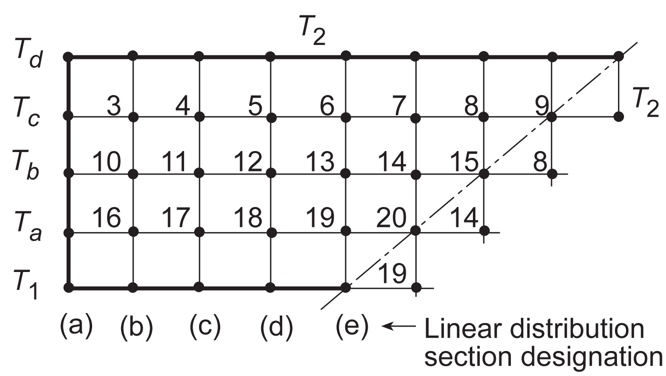
$$q'_{tot} = 100\,W/m \qquad S = 1$$ <

From Table 4.1, the edge shape factor is 0.54, considerably below our estimate from this coarse grid analysis.

(b) The effect of the linear temperature distribution on the shape factor estimate can be explored using a more extensive grid as shown below. The FDE analysis was performed with the linear distribution imposed as the different sections a, b, c, d, e. Following the same approach as above, find

Location of linear distribution	(a)	(b)	(c)	(d)	(e)
Shape factor, S	0.797	0.799	0.809	0.857	1.00

The shape factor estimate decreases as the imposed linear temperature distribution section is located further from the edge. We conclude that assuming the temperature distribution across the section directly at the edge is a poor-one.



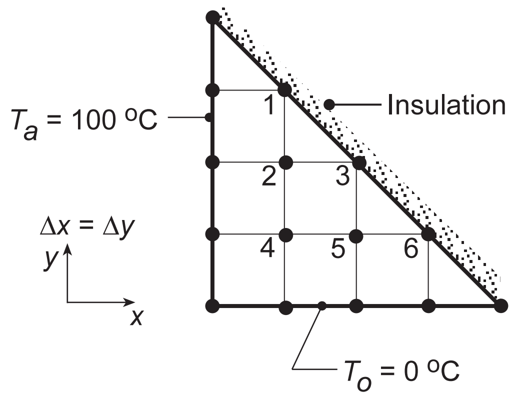
COMMENTS: The grid spacing for this analysis is quite coarse making the estimates in poor agreement with the Table 4.1 result. However, the analysis does show the effect of positioning the linear temperature distribution condition.

PROBLEM 4.77

KNOWN: Long triangular bar insulated on the diagonal while sides are maintained at uniform temperatures T_a and T_b.

FIND: (a) Using a nodal network with five nodes to the side, and beginning with properly defined control volumes, derive the finite-difference equations for the interior and diagonal nodes and obtain the temperature distribution; sketch the 25, 50 and 75°C isotherms and (b) Recognizing that the insulated diagonal surface can be treated as a symmetry line, show that the diagonal nodes can be treated as interior nodes, and write the finite-difference equations by inspection.

SCHEMATIC:

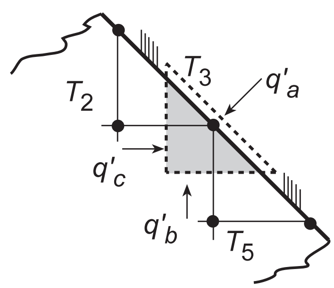


ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional heat transfer, and (3) Constant properties.

ANALYSIS: (a) For the nodal network shown above, nodes 2, 4, and 5 are interior nodes and, since $\Delta x = \Delta y$, the corresponding finite-difference equations are of the form, Equation 4.29,

$$T_j = 1/4 \sum T_{neighbors} \qquad (1)$$

For a node on the adiabatic, diagonal surface, an energy balance, $\dot{E}_{in} - \dot{E}_{out} = 0$, yields



$$q'_a + q'_b + q'_c = 0$$

$$0 + k\Delta x \frac{T_5 - T_3}{\Delta y} + k\Delta y \frac{T_2 - T_3}{\Delta x} = 0$$

$$T_3 = 1/2(T_2 + T_5) \qquad (2)$$

That is, for the diagonal nodes, m,

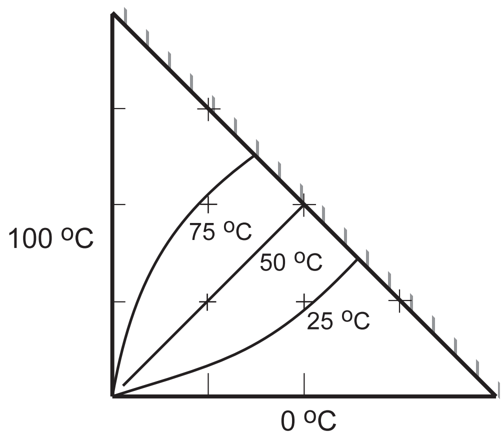
$$T_m = 1/2 \sum T_{neighbors} \qquad (3)$$

To obtain the temperature distributions, enter Eqs. (1, 2, 3) into the IHT workspace and solve for the nodal temperatures (°C), tabulated according to the nodal arrangement:

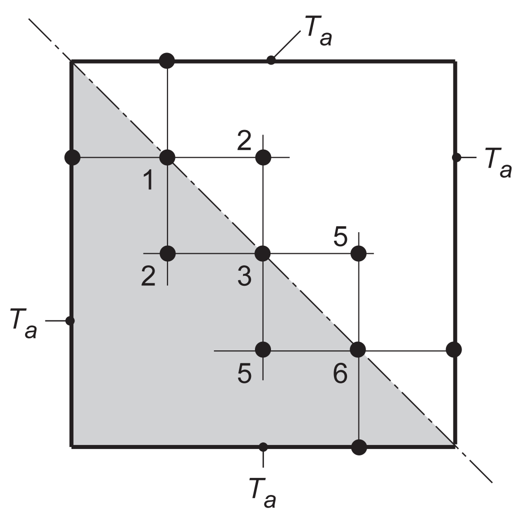
Continued...

–				
100	85.71			
100	71.43	50.00		
100	50.00	28.57	14.29	
–	0	0	0	–

The 25, 50 and 75°C isotherms are sketched below, using an interpolation scheme to scale the isotherms on the triangular bar.



(b) If we consider the insulated surface as a symmetry plane, the nodal network appears as shown. As such, the diagonal nodes can be treated as interior nodes, as Eq. (1) above applies. Recognize the form is the same as that of Eq. (2) or (3).



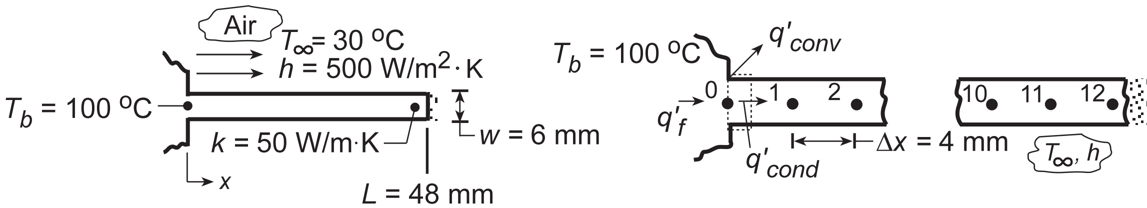
COMMENTS: Always look for symmetry conditions which can greatly simplify the writing of nodal equations. In this situation, the adiabatic surface can be treated as a symmetry plane such that the nodes can be treated as interior nodes, and the finite-difference equations can be written by inspection.

PROBLEM 4.78

KNOWN: Straight fin of uniform cross section with insulated end.

FIND: (a) Temperature distribution using finite-difference method and validity of assuming one-dimensional heat transfer, (b) Fin heat transfer rate and comparison with analytical solution, Eq. 3.81, (c) Effect of convection coefficient on fin temperature distribution and heat rate.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in fin, (3) Constant properties, (4) Uniform film coefficient.

ANALYSIS: (a) From the analysis of Problem 4.50, the finite-difference equations for the nodal arrangement can be directly written. For the nodal spacing Δx = 4 mm, there will be 12 nodes. With l >> w representing the distance normal to the page,

$$\frac{hP}{kA_c}\cdot\Delta x^2 \approx \frac{h\cdot 2\ell}{k\cdot\ell\cdot w}\Delta x^2 = \frac{h\cdot 2}{kw}\Delta x^2 = \frac{500\,\mathrm{W/m^2\cdot K}\times 2}{50\,\mathrm{W/m\cdot K}\times 6\times 10^{-3}\,\mathrm{m}}\left(4\times 10^{-3}\mathrm{mm}\right) = 0.0533$$

Node 1: $100 + T_2 + 0.0533\times 30 - \left(2 + 0.0533\right)T_1 = 0$ or $-2.053T_1 + T_2 = -101.6$

Node n: $T_{n+1} + T_{n-1} + 1.60 - 2.0533T_n = 0$ or $T_{n-1} - 2.053T_n + T_{n-1} = -1.60$

Node 12: $T_{11} + \left(0.0533/2\right)30 - \left(0.0533/2 + 1\right)T_{12} = 0$ or $T_{11} - 1.0267T_{12} = -0.800$

Using matrix notation, Eq. 4.48, where [A] [T] = [C], the A-matrix is tridiagonal and only the non-zero terms are shown below. A matrix inversion routine was used to obtain [T].

Tridiagonal Matrix A						*Column Matrices*		
Nonzero Terms			Values			Node	C	T
	$a_{1,1}$	$a_{1,2}$		-2.053	1	1	-101.6	85.8
$a_{2,1}$	$a_{2,2}$	$a_{2,3}$	1	-2.053	1	2	-1.6	74.5
$a_{3,2}$	$a_{3,3}$	$a_{3,4}$	1	-2.053	1	3	-1.6	65.6
$a_{4,3}$	$a_{4,4}$	$a_{4,5}$	1	-2.053	1	4	-1.6	58.6
$a_{5,4}$	$a_{5,5}$	$a_{5,6}$	1	-2.053	1	5	-1.6	53.1
$a_{6,5}$	$a_{6,6}$	$a_{6,7}$	1	-2.053	1	6	-1.6	48.8
$a_{7,6}$	$a_{7,7}$	$a_{7,8}$	1	-2.053	1	7	-1.6	45.5
$a_{8,7}$	$a_{8,8}$	$a_{8,9}$	1	-2.053	1	8	-1.6	43.0
$a_{9,8}$	$a_{9,9}$	$a_{9,10}$	1	-2.053	1	9	-1.6	41.2
$a_{10,9}$	$a_{10,10}$	$a_{10,11}$	1	-2.053	1	10	-1.6	39.9
$a_{11,10}$	$a_{11,11}$	$a_{11,12}$	1	-2.053	1	11	-1.6	39.2
$a_{12,11}$	$a_{12,12}$	$a_{12,13}$	1	-1.027	1	12	-0.8	38.9

The assumption of one-dimensional heat conduction is justified when Bi ≡ h(w/2)/k < 0.1. Hence, with Bi = 500 W/m²·K(3 × 10⁻³ m)/50 W/m·K = 0.03, the assumption is reasonable.

Continued...

PROBLEM 4.78 (Cont.)

(b) The fin heat rate can be most easily found from an energy balance on the control volume about Node 0,

$$q'_f = q'_1 + q'_{conv} = k \cdot w \frac{T_0 - T_1}{\Delta x} + h\left(2\frac{\Delta x}{2}\right)\left(T_0 - T_\infty\right)$$

$$q'_f = 50\,W/m\cdot K\left(6\times10^{-3}m\right)\frac{\left(100-85.8\right)^\circ C}{4\times10^{-3}m} + 500\,W/m^2\cdot K\left(2\cdot\frac{4\times10^{-3}m}{2}\right)\left(100-30\right)^\circ C$$

$$q'_f = \left(1065+140\right)W/m = 1205\,W/m\,.$$ <

From Eq. 3.81, the fin heat rate is

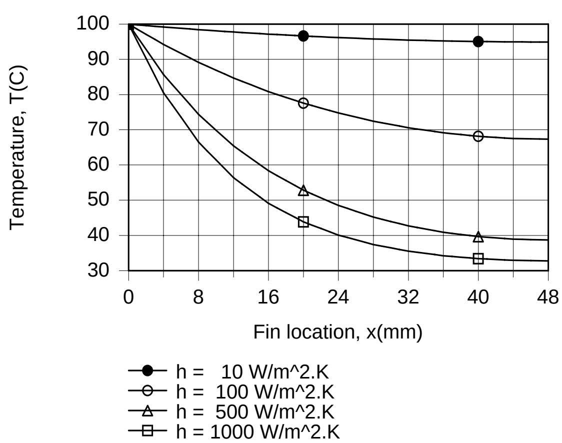
$$q = \left(hPkA_c\right)^{1/2}\cdot\theta_b\cdot\tanh mL\,.$$

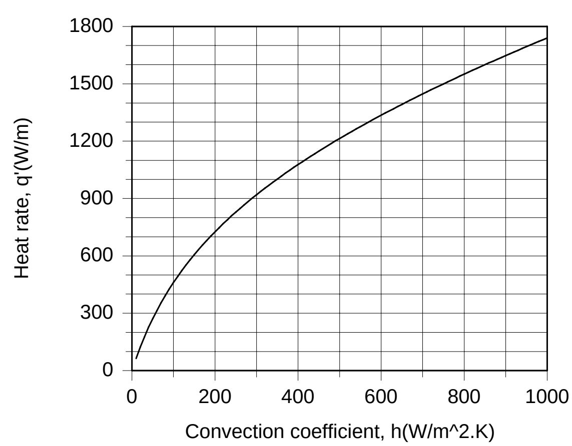
Substituting numerical values with $P = 2(w + \ell) \approx 2\ell$ and $A_c = w\cdot\ell$, $m = (hP/kA_c)^{1/2} = 57.74\ m^{-1}$ and $M = (hPkA_c)^{1/2} = 17.32\,\ell$ W/K. Hence, with $\theta_b = 70°C$,

$$q' = 17.32\,W/K\times70\,K\times\tanh\left(57.44\times0.048\right) = 1203\,W/m$$

and the finite-difference result agrees very well with the exact (analytical) solution.

(c) Using the IHT *Finite-Difference Equations Tool Pad* for *1D, SS* conditions, the fin temperature distribution and heat rate were computed for h = 10, 100, 500 and 1000 W/m^2·K. Results are plotted as follows.





The temperature distributions were obtained by first creating a *Lookup Table* consisting of 4 rows of nodal temperatures corresponding to the 4 values of h and then using the *LOOKUPVAL2* interpolating function with the *Explore* feature of the IHT menu. Specifically, the function T_EVAL = LOOKUPVAL2(t0467, h, x) was entered into the workspace, where t0467 is the file name given to the Lookup Table. For each value of h, *Explore* was used to compute T(x), thereby generating 4 data sets which were placed in the *Browser* and used to generate the plots. The variation of q' with h was simply generated by using the *Explore* feature to solve the finite-difference model equations for values of h incremented by 10 from 10 to 1000 W/m^2·K.

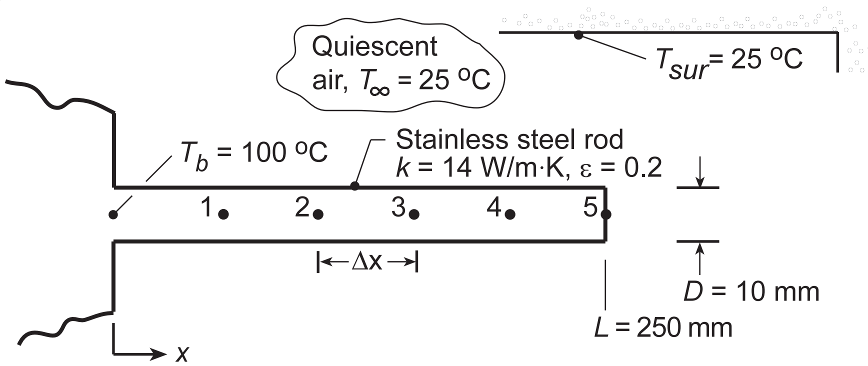
Although q'_f increases with increasing h, the effect of changes in h becomes less pronounced. This trend is a consequence of the reduction in fin temperatures, and hence the fin efficiency, with increasing h. For $10 \le h \le 1000$ W/m^2·K, $0.95 \ge \eta_f \ge 0.24$. Note the nearly isothermal fin for h = 10 W/m^2·K and the pronounced temperature decay for h = 1000 W/m^2·K.

PROBLEM 4.79

KNOWN: Pin fin of 10 mm diameter and length 250 mm with base temperature of 100°C experiencing radiation exchange with the surroundings and free convection with ambient air.

FIND: Temperature distribution using finite-difference method with five nodes. Fin heat rate and relative contributions by convection and radiation.

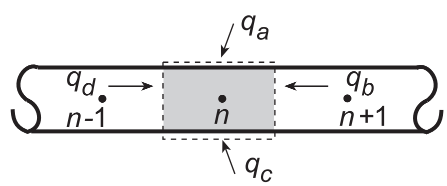
SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in fin, (3) Constant properties, (4) Fin approximates small object in large enclosure, (5) Fin tip experiences convection and radiation, (6) $h_{fc} = 2.89[0.6 + 0.624(T - T_\infty)^{1/6}]^2$.

ANALYSIS: To apply the finite-difference method, define the 5-node system shown above where Δx = L/5. Perform energy balances on the nodes to obtain the finite-difference equations for the nodal temperatures.

Interior node, n = 1, 2, 3 or 4



$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$q_a + q_b + q_c + q_d = 0 \qquad (1)$$

$$h_{r,n}P\Delta x\left(T_{sur} - T_n\right) + kA_c\frac{T_{n+1} - T_n}{\Delta x} + h_{fc,n}P\Delta x\left(T_\infty - T_n\right) + kA_c\frac{T_{n-1} - T_n}{\Delta x} = 0 \qquad (2)$$

where the free convection coefficient is

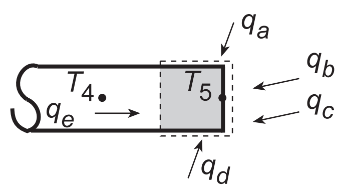
$$h_{fc,n} = 2.89\left[0.6 + 0.624\left(T_n - T_\infty\right)^{1/6}\right]^2 \qquad (3)$$

and the linearized radiation coefficient is

$$h_{r,n} = \varepsilon\sigma\left(T_n + T_{sur}\right)\left(T_n^2 + T_{sur}^2\right) \qquad (4)$$

with $P = \pi D$ and $A_c = \pi D^2/4$. (5,6)

Tip node, n = 5



$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$q_a + q_b + q_c + q_d + q_e = 0$$

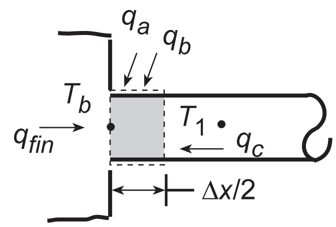
$$h_{r,5}\left(P\Delta x/2\right)\left(T_{sur} - T_5\right) + h_{r,5}A_c\left(T_{sur} - T_5\right) + h_{fc,5}A_c\left(T_\infty - T_5\right)$$
$$+ h_{fc,5}\left(P\Delta x/2\right)\left(T_\infty - T_5\right) + kA_c\frac{T_4 - T_5}{\Delta x} = 0 \qquad (7)$$

Continued...

PROBLEM 4.79 (Cont.)

Knowing the nodal temperatures, the heat rates are evaluated as:

Fin Heat Rate: Perform an energy balance around Node b.



$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$q_a + q_b + q_c + q_{fin} = 0$$

$$h_{r,b}(P\Delta x/2)(T_{sur} - T_b) + h_{fc,b}(P\Delta x/2)(T_\infty - T_b) + kA_c\frac{(T_1 - T_b)}{\Delta x} + q_{fin} = 0 \qquad (8)$$

where $h_{r,b}$ and $h_{fc,b}$ are evaluated at T_b.

Convection Heat Rate: To determine the portion of the heat rate by convection from the fin surface, we need to sum contributions from each node. Using the convection heat rate terms from the foregoing energy balances, for, respectively, node b, nodes 1, 2, 3, 4 and node 5.

$$q_{cv} = -q_b)_b - \sum q_c)_{1-4} - (q_c + q_d)_5 \qquad (9)$$

Radiation Heat Rate: In the same manner,

$$q_{rad} = -q_a)_b - \sum q_b)_{1-4} - (q_a + q_b)_5$$

The above equations were entered into the IHT workspace and the set of equations solved for the nodal temperatures and the heat rates. Summary of key results including the temperature distribution and heat rates is shown below.

Node	b	1	2	3	4	5	Fin
T_j (°C)	100	58.5	40.9	33.1	29.8	28.8	-
q_{cv} (W)	0.603	0.451	0.183	0.081	0.043	0.015	1.375
q_{fin} (W)	-	-	-	-	-	-	1.604
q_{rad} (W)	-	-	-	-	-	-	0.229
h_{cv} (W/m^2·K)	10.1	8.6	7.3	6.4	5.7	5.5	-
h_{rad} (W/m^2·K)	1.5	1.4	1.3	1.3	1.2	1.2	-

<

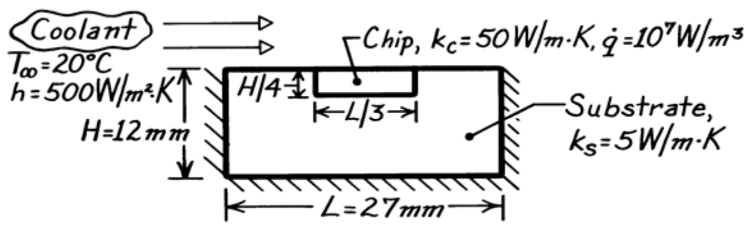
COMMENTS: From the tabulated results, it is evident that free convection is the dominant node. Note that the free convection coefficient varies almost by a factor of two over the length of the fin.

PROBLEM 4.80

KNOWN: Silicon chip mounted in a dielectric substrate. One surface of system is convectively cooled while the remaining surfaces are well insulated.

FIND: Whether maximum temperature in chip will exceed 85°C.

SCHEMATIC:



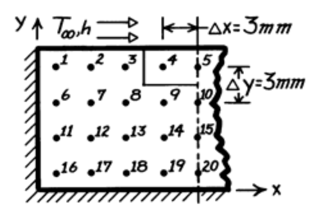
ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Negligible contact resistance between chip and substrate, (4) Upper surface experiences uniform convection coefficient, (5) Other surfaces are perfectly insulated.

ANALYSIS: Performing an energy balance on the chip assuming it is *perfectly insulated from* the substrate, the maximum temperature occurring at the interface with the dielectric substrate will be, according to Eqs. 3.48 and 3.51,

$$T_{max} = \frac{\dot{q}(H/4)^2}{2k_c} + \frac{\dot{q}(H/4)}{h} + T_\infty = \frac{10^7\ \text{W/m}^3(0.003\ \text{m})^2}{2\times 50\ \text{W/m}\cdot\text{K}} + \frac{10^7\ \text{W/m}^3(0.003\ \text{m})}{500\ \text{W/m}^2\cdot\text{K}} + 20^\circ\text{C} = 80.9^\circ\text{C}.$$

Since $T_{max} < 85°C$ for the assumed situation, for the actual two-dimensional situation with the conducting dielectric substrate, the maximum temperature should be less than 80°C.

Using the suggested grid spacing of 3 mm, construct the nodal network and write the finite-difference equation for each of the nodes taking advantage of symmetry of the system. Note that we have chosen to *not* locate nodes on the system surfaces for two reasons: (1) fewer total number of nodes, 20 vs. 25, and (2) Node 5 corresponds to center of chip which is likely the point of maximum temperature. Using these numerical values,



$$\frac{h\Delta x}{k_s} = \frac{500\ \text{W/m}^2\cdot\text{K}\times 0.003\ \text{m}}{5\ \text{W/m}\cdot\text{K}} = 0.30 \qquad \alpha = \frac{2}{(k_s/k_c)+1} = \frac{2}{5/50+1} = 1.818$$

$$\frac{h\Delta x}{k_c} = \frac{500\ \text{W/m}^2\cdot\text{K}\times 0.003\ \text{m}}{5\ \text{W/m}\cdot\text{K}} = 0.030 \qquad \beta = \frac{2}{(k_c/k_s)+1} = \frac{2}{50/5+1} = 0.182$$

$$\frac{\dot{q}\Delta x\Delta y}{k_c} = 1.800 \qquad \gamma = \frac{1}{k_c/k_s+1} = 0.0910$$

find the nodal equations:

Node 1 $\qquad k_s\Delta x\frac{T_6 - T_1}{\Delta y} + k_s\Delta y\frac{T_2 - T_1}{\Delta x} + h\Delta x(T_\infty - T_1) = 0$

Continued …

PROBLEM 4.80 (Cont.)

$$-\left(2+\frac{h\Delta x}{k_s}\right)T_1 + T_2 + T_6 = -\frac{h\Delta x}{k_s}T_\infty \qquad -2.30T_1 + T_2 + T_6 = -6.00 \tag{1}$$

Node 2 $\quad T_1 - 3.3T_2 + T_3 + T_7 = -6.00$ (2)

Node 3

$$k_s\Delta y\frac{T_2 - T_3}{\Delta x} + \frac{T_4 - T_3}{(\Delta x/2)/k_c\Delta y + (\Delta x/2)/k_s\Delta y} + k_s\Delta x\frac{T_8 - T_3}{\Delta y} + h\Delta x\left(T_\infty - T_3\right) = 0$$

$$T_2 - \left(2 + \alpha + \left(h\Delta x/k_s\right)T_3\right) + \alpha T_4 + T_8 = -\left(h\Delta x/k\right)T_\infty$$

$$T_2 - 4.12T_3 + 1.82T_4 + T_8 = -6.00 \tag{3}$$

Node 4

$$\frac{T_3 - T_4}{(\Delta x/2)/k_s\Delta y + (\Delta x/2)/k_c\Delta y} + k_c\Delta y\frac{T_5 - T_4}{\Delta x} + \frac{T_9 - T_4}{(\Delta y/2)/k_s\Delta x + (\Delta y/2)k_c\Delta x}$$

$$+\dot{q}\left(\Delta x\Delta y\right) + h\Delta x\left(T_\infty - T_4\right) = 0$$

$$\beta T_3 - \left(1 + 2\beta + \left[h\Delta x/k_c\right]\right)T_4 + T_5 + \beta T_9 = -\left(h\Delta x/k_c\right)T_\infty - \dot{q}\Delta x\Delta y/k_c$$

$$0.182T_3 - 1.39T_4 + T_5 + 0.182T_9 = -2.40 \tag{4}$$

Node 5

$$k_c\Delta y\frac{T_4 - T_5}{\Delta x} + \frac{T_{10} - T_5}{(\Delta y/2)/k_s\left(\Delta x/2\right) + (\Delta y/2)/k_c\left(\Delta x/2\right)} + h\left(\Delta x/2\right)\left(T_\infty - T_5\right) + \dot{q}\Delta y\left(\Delta x/2\right) = 0$$

$$2T_4 - 2.21T_5 + 0.182T_{10} = -2.40 \tag{5}$$

Nodes 6 and 11

$$k_s\Delta x\left(T_1 - T_6\right)/\Delta y + k_s\Delta y\left(T_7 - T_6\right)/\Delta x + k_s\Delta x\left(T_{11} - T_6\right)/\Delta y = 0$$

$$T_1 - 3T_6 + T_7 + T_{11} = 0 \qquad T_6 - 3T_{11} + T_{12} + T_{16} = 0 \qquad (6,11)$$

Nodes 7, 8, 12, 13, 14 Treat as interior points,

$$T_2 + T_6 - 4T_7 + T_8 + T_{12} = 0 \qquad T_3 + T_7 - 4T_8 + T_9 + T_{13} = 0 \qquad (7,8)$$

$$T_7 + T_{11} - 4T_{12} + T_{13} + T_{17} = 0 \qquad T_8 + T_{12} - 4T_{13} + T_{14} + T_{18} = 0 \qquad (12,13)$$

$$T_9 + T_{13} - 4T_{14} + T_{15} + T_{19} = 0 \tag{14}$$

Node 9

$$k_s\Delta y\frac{T_8 - T_9}{\Delta x} + \frac{T_4 - T_9}{(\Delta y/2)/k_c\Delta x + (\Delta y/2)/k_s\Delta x} + k_s\Delta y\frac{T_{10} - T_9}{\Delta x} + k_s\Delta x\frac{T_{14} - T_9}{\Delta y} = 0$$

$$1.82T_4 + T_8 - 4.82T_9 + T_{10} + T_{14} = 0 \tag{9}$$

Node 10 Using the result of Node 9 and considering symmetry,

$$1.82T_5 + 2T_9 - 4.82T_{10} + T_{15} = 0 \tag{10}$$

Node 15 Interior point considering symmetry $\quad T_{10} + 2T_{14} - 4T_{15} + T_{20} = 0$ (15)

Node 16 By inspection, $\quad T_{11} - 2T_{16} + T_{17} = 0$ (16)

Continued …

PROBLEM 4.80 (Cont.)

Nodes 17, 18, 19, 20

$$T_{12} + T_{16} - 3T_{17} + T_{18} = 0 \qquad T_{13} + T_{17} - 3T_{18} + T_{19} = 0 \qquad (17,18)$$

$$T_{14} + T_{18} - 3T_{19} + T_{20} = 0 \qquad T_{15} + 2T_{19} - 3T_{20} = 0 \qquad (19,20)$$

Using the matrix inversion method, the above system of finite-difference equations is written in matrix notation, Eq. 4.48, [A][T] = [C] where

[A] =

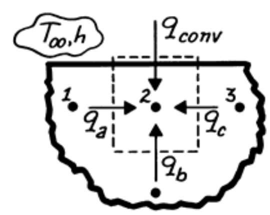
and the temperature distribution (°C), in geometrical representation, is

34.46	36.13	40.41	45.88	46.23
37.13	38.37	40.85	43.80	44.51
38.56	39.38	40.81	42.72	42.78
39.16	39.77	40.76	41.70	42.06

The maximum temperature is T_5 = 46.23°C which is indeed less than 85°C. <

COMMENTS: (1) The convection process for the energy balances of Nodes 1 through 5 were simplified by assuming the node temperature is also that of the surface. Considering Node 2, the energy balance processes for q_a, q_b and q_c are identical (see Eq. (2)); however,



$$q_{conv} = \frac{T_\infty - T_2}{1/h + \Delta y/2k} \approx h\left(T_\infty - T_2\right)$$

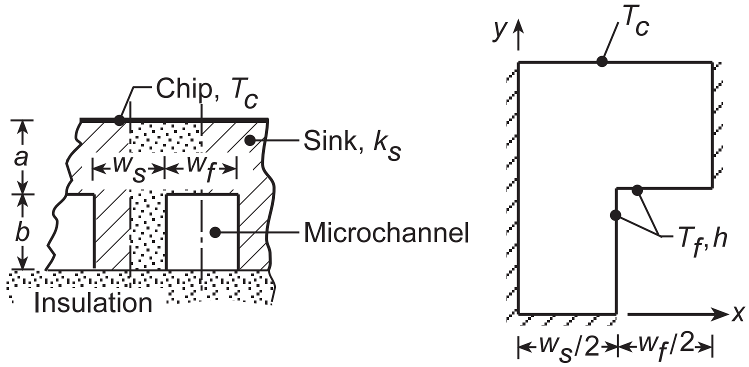
where $h\Delta y/2k = 5\ \text{W/m}^2\cdot\text{K} \times 0.003\ \text{m}/2 \times 50\ \text{W/m}\cdot\text{K} = 1.5\times10^{-4} << 1$. Hence, for this situation, the simplification is justified.

PROBLEM 4.81

KNOWN: Heat sink for cooling computer chips fabricated from copper with microchannels passing fluid with prescribed temperature and convection coefficient.

FIND: (a) Using a square nodal network with 100 μm spatial increment, determine the temperature distribution and the heat rate to the coolant per unit channel length for maximum allowable chip temperature $T_{c,max}$ = 75°C; estimate the thermal resistance betweeen the chip surface and the fluid, $R'_{t,c-f}$ (m·K/W); maximum allowable heat dissipation for a chip that measures 10 x 10 mm on a side; (b) The effect of grid spacing by considering spatial increments of 50 and 25 μm; and (c) Consistent with the requirement that a + b = 400 μm, explore altering the sink dimensions to decrease the thermal resistance.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties, and (3) Convection coefficient is uniform over the microchannel surface and independent of the channel dimensions and shape.

ANALYSIS: (a) The square nodal network with Δx = Δy = 100 μm is shown below. Considering symmetry, the nodes 1, 2, 3, 4, 7, and 9 can be treated as interior nodes and their finite-difference equations representing nodal energy balances can be written by inspection. Using the, *IHT Finite-Difference Equations Tool*, appropriate FDEs for the nodes experiencing surface convection can be obtained. The IHT code along with results is included in the Comments. Having the temperature distribution, the heat rate to the coolant per unit channel length for two symmetrical elements can be obtained by applying Newton's law of cooling to the surface nodes,

$$q'_{cv} = 2\left[h\left(\Delta y/2+\Delta x/2\right)\left(T_5-T_\infty\right)+h\left(\Delta x/2\right)\left(T_6-T_\infty\right)+h\left(\Delta y\right)\left(T_8-T_\infty\right)+h\left(\Delta y/2\right)\left(T_{10}-T_\infty\right)\right]$$

$$q'_{cv} = 2\times 30,000\,\text{W/m}^2\cdot\text{K}\times 100\times 10^{-6}\,\text{m}\left[(74.02-25)+(74.09-25)/2+(73.60-25)+(73.37-25)/2\right]\text{K}$$

$$q'_{cv} = 878\,\text{W/m}$$ <

The thermal resistance between the chip and fluid per unit length for each microchannel is

$$R'_{t,c-f} = \frac{T_c-T_\infty}{q'_{cv}} = \frac{(75-25)^\circ\text{C}}{878\,\text{W/m}} = 5.69\times 10^{-2}\,\text{m}\cdot\text{K/W}$$ <

The maximum allowable heat dissipation for a 10 mm × 10 mm chip is

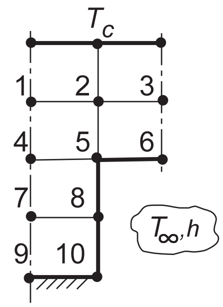
$$P_{chip,max} = q''_c\times A_{chip} = 2.20\times 10^6\,\text{W/m}^2\times(0.01\times 0.01)\,\text{m}^2 = 220\,\text{W}$$ <

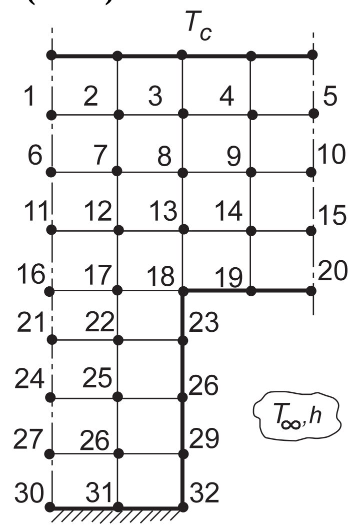
where A_{chip} = 10 mm × 10 mm and the heat flux on the chip surface ($w_f + w_s$) is

$$q''_c = q'_{cv}/\left(w_f+w_s\right) = 878\,\text{W/m}/(200+200)\times 10^{-6}\,\text{m} = 2.20\times 10^6\,\text{W/m}^2$$

Continued...

PROBLEM 4.81 (Cont.)





(b) To investigate the effect of grid spacing, the analysis was repreated with a spatial increment of 50 μm (32 nodes as shown above) with the following results

$$q'_{cv} = 881\,W/m \qquad R'_{t,c-f} = 5.67\times10^{-2}\,m\cdot K/W \qquad <$$

Using a finite-element package with a mesh around 25 μm, we found $R'_{t,c-f} = 5.70\times10^{-2}\,m\cdot K/W$ which suggests the grid spacing effect is not very significant.

(c) Requring that the overall dimensions of the symmetrical element remain unchanged, we explored what effect changes in the microchannel cross-section would have on the overall thermal resistance, $R'_{t,c-f}$. It is important to recognize that the sink conduction path represents the dominant resistance, since for the convection process

$$R'_{t,cv} = 1/A'_s = 1\Big/\left(30,000\,W/m^2\cdot K\times600\times10^{-6}\,m\right) = 5.55\times10^{-2}\,m\cdot K/W$$

where A'_s = (w_f + 2b) = 600 μm.

Using a finite-element package, the thermal resistances per unit length for three additional channel cross-sections were determined and results summarized below.

	Microchannel (μm)		$R'_{t,c-s}\times10^2$
Case	Height	Half-width	(m·K/W)
A	200	100	5.70
B	133	150	6.12
C	300	100	4.29
D	250	150	4.25

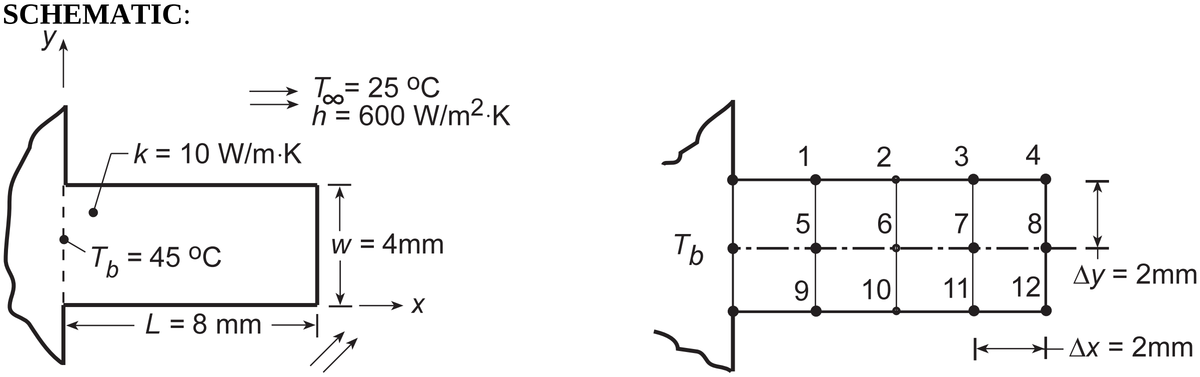
PROBLEM 4.82

KNOWN: Longitudinal rib (k = 10 W/m·K) with rectangular cross-section with length L= 8 mm and width w = 4 mm. Base temperature T_b and convection conditions, T_∞ and h, are prescribed.

FIND: (a) Temperature distribution and fin base heat rate using a finite-difference method with Δx = Δy = 2 mm for a total of 5 × 3 = 15 nodal points and regions; compare results with those obtained assuming one-dimensional heat transfer in rib; and (b) The effect of grid spacing by reducing nodal spacing to Δx = Δy = 1 mm for a total of 9 × 3 = 27 nodal points and regions considering symmetry of the centerline; and (c) A criterion for which the one-dimensional approximation is reasonable; compare the heat rate for the range 1.5 ≤ L/w ≤ 10, keeping L constant, as predicted by the two-dimensional, finite-difference method and the one-dimensional fin analysis.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, and (3) Convection coefficient uniform over rib surfaces, including tip.

ANALYSIS: (a) The rib is represented by a 5 × 3 nodal grid as shown above where the symmetry plane is an adiabatic surface. The *IHT Tool*, *Finite-Difference Equations*, for *Two-Dimensional*, *Steady-State* conditions is used to formulate the nodal equations (see Comment 2 below) which yields the following nodal temperatures (° C)

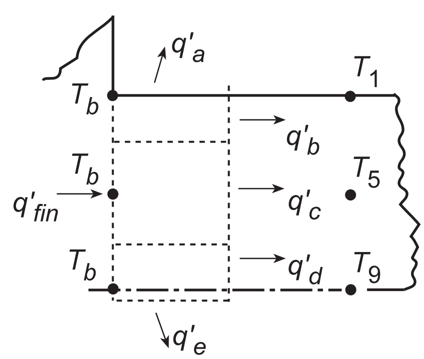
45	39.3	35.7	33.5	32.2
45	40.0	36.4	34.0	32.6
45	39.3	35.7	33.5	32.2

Note that the fin tip temperature is

$$T_{tip} = T_{12} = 32.6^\circ C$$ <

The fin heat rate per unit width normal to the page, q'_{fin}, can be determined from energy balances on the three base nodes as shown in the schematic below.

$$q'_{fin} = q'_a + q'_b + q'_c + q'_d + q'_e$$
$$q'_a = h(\Delta x/2)(T_b - T_\infty)$$
$$q'_b = k(\Delta y/2)(T_b - T_1)/\Delta x$$
$$q'_c = k(\Delta y)(T_b - T_5)/\Delta x$$
$$q'_d = k(\Delta y/2)(T_b - T_9)\Delta x$$
$$q'_3 = h(\Delta x/2)(T_b - T_\infty)$$



Continued...

PROBLEM 4.82 (Cont.)

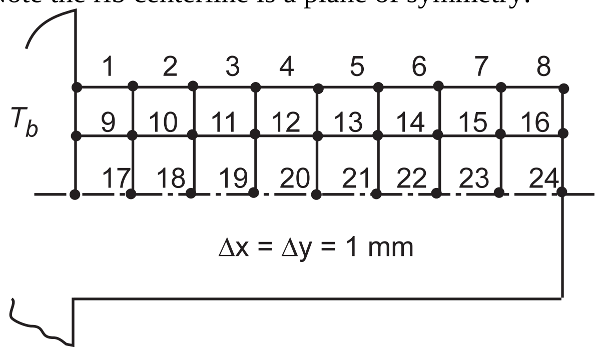
Substituting numerical values, find

$$q'_{fin} = (12.0 + 28.4 + 50.0 + 28.4 + 12.0)\,W/m = 130.8\,W/m$$ <

Using the *IHT Model*, *Extended Surfaces*, *Heat Rate* and *Temperature Distributions* for *Rectangular, Straight Fins*, with convection tip condition, the one-dimensional fin analysis yields

$q'_f = 131\,W/m$ $\qquad T_{tip} = 32.2^\circ C$ <

(b) With Δx = L/8 = 1 mm and Δx = 1 mm, for a total of 9 × 3 = 27 nodal points and regions, the grid appears as shown below. Note the rib centerline is a plane of symmetry.

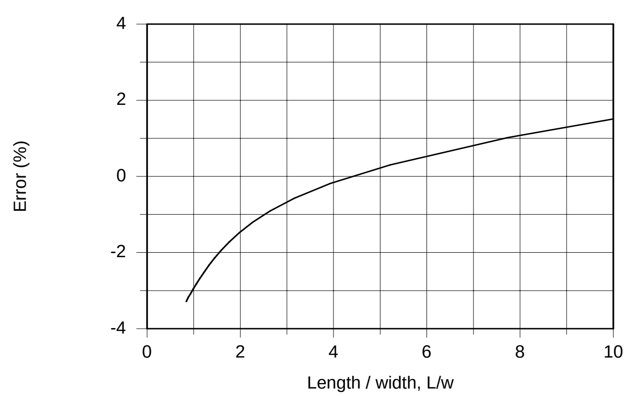


Using the same IHT FDE Tool as above with an appropriate expression for the fin heat rate, Eq. (1), the fin heat rate and tip temperature were determined.

	1-D analysis	2-D analysis (nodes) (5 × 3)	(9 × 3)	
T_{tip} (°C)	32.2	32.6	32.6	<
q'_{fin} (W/m)	131	131	129	<

(c) To determine when the one-dimensional approximation is reasonable, consider a rib of constant length, L = 8 mm, and vary the thickness w for the range 1.5 ≤ L/w ≤ 10. Using the above IHT model for the 27 node grid, the fin heat rates for 1-D, q'_{1d}, and 2-D, q'_{2d}, analysis were determined as a function of w with the error in the approximation evaluated as

$$\text{Error}(\%) = (q'_{2d} - q'_{1d}) \times 100 / q'_{1d}$$



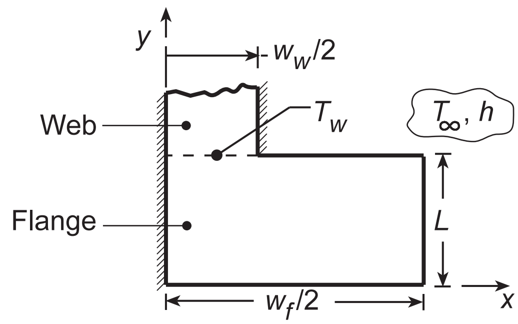
Note that for small L/w, a thick rib, the 1-D approximation is poor. For large L/w, a thin rib which approximates a fin, we would expect the 1-D approximation to become increasingly more satisfactory. The discrepancy at large L/w must be due to discretization error; that is, the grid is too coarse to accurately represent the slender rib.

PROBLEM 4.83

KNOWN: Bottom half of an I-beam exposed to hot furnace gases.

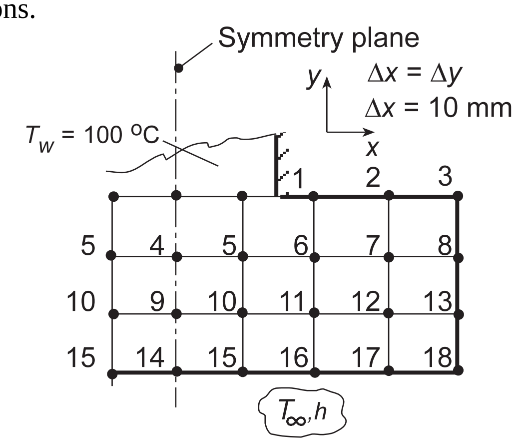
FIND: (a) The heat transfer rate per unit length into the beam using a coarse nodal network (5 × 4) considering the temperature distribution across the web is uniform and (b) Assess the reasonableness of the uniform web-flange interface temperature assumption.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, and (2) Constant properties.

ANALYSIS: (a) The symmetrical section of the I-beam is shown in the Schematic above indicating the web-flange interface temperature is uniform, $T_w = 100°C$. The nodal arrangement to represent this system is shown below. The nodes on the line of symmetry have been shown for convenience in deriving the nodal finite-difference equations.



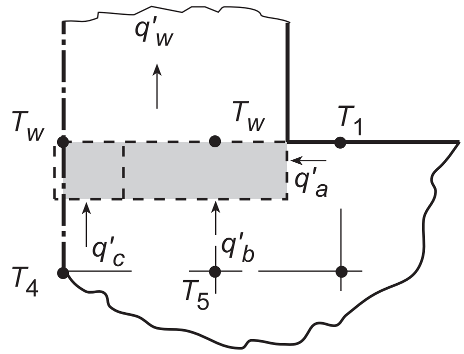
Using the *IHT Finite-Difference Equations Tool*, the set of nodal equations can be readily formulated. The temperature distribution (°C) is tabulated in the same arrangement as the nodal network.

100.00	100.00	215.8	262.9	284.8
166.6	177.1	222.4	255.0	272.0
211.7	219.5	241.9	262.7	274.4
241.4	247.2	262.9	279.3	292.9

The heat rate to the beam can be determined from energy balances about the web-flange interface nodes as shown in the sketch below.

Continued...

PROBLEM 4.83 (Cont.)

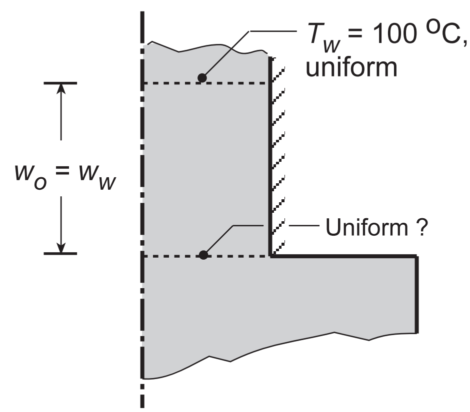


$$q'_w = q'_a + q'_b + q'_c$$

$$q'_w = k(\Delta y/2)\frac{T_1 - T_w}{\Delta x} + k(\Delta x)\frac{T_5 - T_w}{\Delta y} + k(\Delta x/2)\frac{T_4 - T_w}{\Delta y}$$

$$q'_w = 10\,W/m\cdot K\left[(215.8-100)/2 + (177.1-100) + (166.6-100)/2\right]K = 1683\,W/m$$ <

(b) The schematic below poses the question concerning the reasonableness of the uniform temperature assumption at the web-flange interface. From the analysis above, note that T_1 = 215.8°C vs. T_w = 100°C indicating that this assumption is a poor one. This L-shaped section has strong two-dimensional behavior. To illustrate the effect, we performed an analysis with T_w = 100°C located nearly 2 × times further up the web than it is wide. For this situation, the temperature difference at the web-flange interface across the width of the web was nearly 40°C. The steel beam with its low thermal conductivity has substantial internal thermal resistance and given the L-shape, the uniform temperature assumption (T_w) across the web-flange interface is inappropriate.

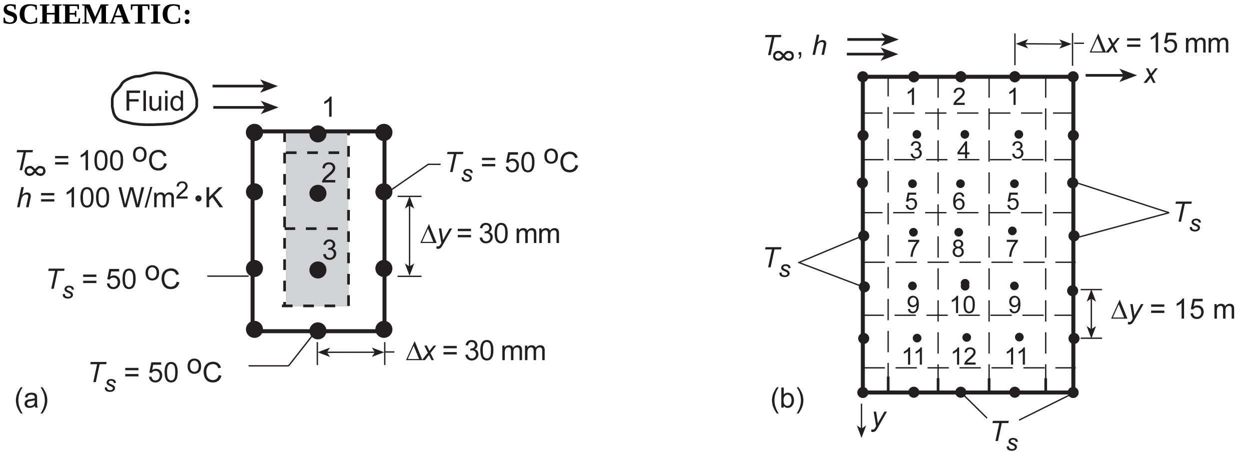


PROBLEM 4.84

KNOWN: Long rectangular bar having one boundary exposed to a convection process (T_∞, h) while the other boundaries are maintained at a constant temperature (T_s).

FIND: (a) Using a grid spacing of 30 mm and the Gauss-Seidel method, determine the nodal temperatures and the heat rate per unit length into the bar from the fluid, (b) Effect of grid spacing and convection coefficient on the temperature field.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties.

ANALYSIS: (a) With the grid spacing Δx = Δy = 30 mm, three nodes are created. Using the finite-difference equations as shown in Table 4.2, but written in the form required of the Gauss-Seidel method (see Appendix D), and with $Bi = h\Delta x/k = 100\ W/m^2\cdot K \times 0.030\ m/1\ W/m\cdot K = 3$, we obtain:

Node 1:
$$T_1 = \frac{1}{(Bi+2)}\left(T_2 + T_s + BiT_\infty\right) = \frac{1}{5}\left(T_2 + 50 + 3\times100\right) = \frac{1}{5}\left(T_2 + 350\right) \quad (1)$$

Node 2:
$$T_2 = \frac{1}{4}\left(T_1 + 2T_s + T_3\right) = \frac{1}{4}\left(T_1 + T_3 + 2\times50\right) = \frac{1}{4}\left(T_1 + T_3 + 100\right) \quad (2)$$

Node 3:
$$T_3 = \frac{1}{4}\left(T_2 + 3T_s\right) = \frac{1}{4}\left(T_2 + 3\times50\right) = \frac{1}{4}\left(T_2 + 150\right) \quad (3)$$

Denoting each nodal temperature with a superscript to indicate iteration step, e.g. T_1^k, calculate values as shown below.

k	T_1	T_2	T_3 (°C)	
0	85	60	55	← initial guess
1	82.00	59.25	52.31	
2	81.85	58.54	52.14	
3	81.71	58.46	52.12	
4	81.69	58.45	52.11	

By the 4th iteration, changes are of order 0.02°C, suggesting that further calculations may not be necessary.

Continued...

PROBLEM 4.84 (Cont.)

In finite-difference form, the heat rate from the fluid to the bar is

$$q'_{conv} = h(\Delta x/2)(T_\infty - T_s) + h\Delta x(T_\infty - T_1) + h(\Delta x/2)(T_\infty - T_s)$$

$$q'_{conv} = h\Delta x(T_\infty - T_s) + h\Delta x(T_\infty - T_1) = h\Delta x\left[(T_\infty - T_s) + (T_\infty - T_1)\right]$$

$$q'_{conv} = 100\,W/m^2 \cdot K \times 0.030\,m\left[(100-50)+(100-81.7)\right]^\circ C = 205\,W/m\,. \quad <$$

(b) Using the *Finite-Difference Equations* option from the *Tools* portion of the IHT menu, the following two-dimensional temperature field was computed for the grid shown in schematic (b), where x and y are in mm and the temperatures are in °C.

y\x	0	15	30	45	60
0	50	80.33	85.16	80.33	50
15	50	63.58	67.73	63.58	50
30	50	56.27	58.58	56.27	50
45	50	52.91	54.07	52.91	50
60	50	51.32	51.86	51.32	50
75	50	50.51	50.72	50.51	50
90	50	50	50	50	50

The improved prediction of the temperature field has a significant influence on the heat rate, where, accounting for the symmetrical conditions,

$$q' = 2h(\Delta x/2)(T_\infty - T_s) + 2h(\Delta x)(T_\infty - T_1) + h(\Delta x)(T_\infty - T_2)$$

$$q' = h(\Delta x)\left[(T_\infty - T_s) + 2(T_\infty - T_1) + (T_\infty - T_2)\right]$$

$$q' = 100\,W/m^2 \cdot K(0.015\,m)\left[50 + 2(19.67) + 14.84\right]^\circ C = 156.3\,W/m \quad <$$

Additional improvements in accuracy could be obtained by reducing the grid spacing to 5 mm, although the requisite number of finite-difference equations would increase from 12 to 108, significantly increasing problem *set-up* time.

An increase in h would increase temperatures everywhere within the bar, particularly at the heated surface, as well as the rate of heat transfer by convection to the surface.

COMMENTS: (1) Using the matrix-inversion method, the exact solution to the system of equations (1, 2, 3) of part (a) is T_1 = 81.70°C, T_2 = 58.44°C, and T_3 = 52.12°C. The fact that only 4 iterations were required to obtain agreement within 0.01°C is due to the close initial guesses.

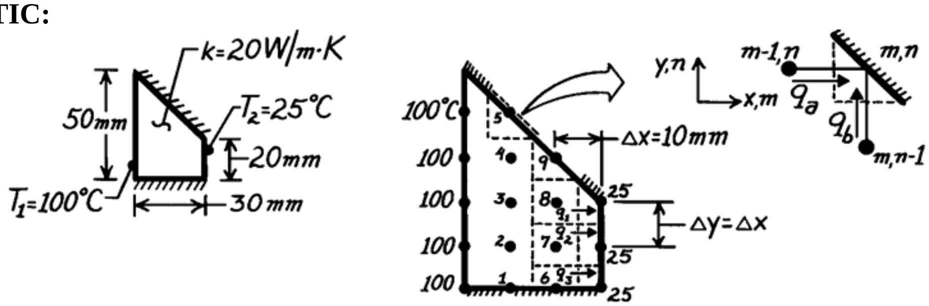
(2) Note that the rate of heat transfer by convection to the top surface of the rod must balance the rate of heat transfer by conduction to the sides and bottom of the rod.

PROBLEM 4.85

KNOWN: Long bar with trapezoidal shape, uniform temperatures on two surfaces, and two insulated surfaces.

FIND: Heat transfer rate per unit length using finite-difference method with space increment of 10mm.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties.

ANALYSIS: The heat rate can be found after the temperature distribution has been determined. Using the nodal network shown above with Δx = 10mm, nine finite-difference equations must be written. Nodes 1-4 and 6-8 are interior nodes and their finite-difference equations can be written directly from Eq. 4.29. For these nodes

$$T_{m,n+1} + T_{m,n-1} + T_{m+1,n} + T_{m-1,n} - 4T_{m,n} = 0 \qquad m = 1-4,\ 6-8. \qquad (1)$$

For nodes 5 and 9 located on the diagonal, insulated boundary, the appropriate finite-difference equation follows from an energy balance on the control volume shown above (upper-right corner of schematic), $\dot{E}_{in} - \dot{E}_{out} = q_a + q_b = 0$

$$k(\Delta y \cdot 1)\frac{T_{m-1,n} - T_{m,n}}{\Delta x} + k(\Delta x \cdot 1)\frac{T_{m,n-1} - T_{m,n}}{\Delta y} = 0.$$

Since Δx = Δy, the finite-difference equation for nodes 5 and 9 is of the form

$$T_{m-1,n} + T_{m,n-1} - 2T_{m,n} = 0 \qquad m = 5,9. \qquad (2)$$

The system of 9 finite-difference equations is first written in the form of Eqs. (1) or (2) and then written in explicit form for use with the Gauss-Seidel iteration method of solution; see Appendix D.

Node	*Finite-difference equation*	*Gauss-Seidel form*
1	$T_2+T_2+T_6+100-4T_1 = 0$	$T_1 = 0.5T_2+0.25T_6+25$
2	$T_3+T_1+T_7+100-4T_2 = 0$	$T_2 = 0.25(T_1+T_3+T_7)+25$
3	$T_4+T_2+T_8+100-4T_3 = 0$	$T_3 = 0.25(T_2+T_4+T_8)+25$
4	$T_5+T_3+T_9+100-4T_4 = 0$	$T_4 = 0.25(T_3+T_5+T_9)+25$
5	$100+T_4-2T_5 = 0$	$T_5 = 0.5T_4+50$
6	$T_7+T_7+25+T_1-4T_6 = 0$	$T_6 = 0.25T_1+0.5T_7+6.25$
7	$T_8+T_6+25+T_2-4T_7 = 0$	$T_7 = 0.25(T_2+T_6+T_8)+6.25$
8	$T_9+T_7+25+T_3-4T_8 = 0$	$T_8 = 0.25(T_3+T_7+T_9)+6.25$
9	$T_4+T_8-2T_9 = 0$	$T_9 = 0.5(T_4+T_8)$

Continued …

PROBLEM 4.85 (Cont.)

The iteration process begins after an initial guess (k = 0) is made. The calculations are shown in the table below.

k	T_1	T_2	T_3	T_4	T_5	T_6	T_7	T_8	T_9(°C)
0	75	75	80	85	90	50	50	60	75
1	75.0	76.3	80.0	86.3	92.5	50.0	52.5	57.5	72.5
2	75.7	76.9	80.0	86.3	93.2	51.3	52.2	57.5	71.9
3	76.3	77.0	80.2	86.3	93.2	51.3	52.7	57.3	71.9
4	76.3	77.3	80.2	86.3	93.2	51.7	52.7	57.5	71.8
5	76.6	77.3	80.3	86.3	93.2	51.7	52.9	57.4	71.9
6	76.6	77.5	80.3	86.4	93.2	51.9	52.9	57.5	71.9

Note that by the sixth iteration the change is less than 0.3°C; hence, we assume the temperature distribution is approximated by the last row of the table.

The heat rate per unit length can be determined by evaluating the heat rates in the x-direction for the control volumes about nodes 6, 7, and 8. From the schematic, find that

$$q' = q'_1 + q'_2 + q'_3$$

$$q' = k\Delta y \frac{T_8 - 25}{\Delta x} + k\Delta y \frac{T_7 - 25}{\Delta x} + k\frac{\Delta y}{2}\ \frac{T_6 - 25}{\Delta x}$$

Recognizing that $\Delta x = \Delta y$ and substituting numerical values, find

$$q' = 20\frac{W}{m \cdot K}\left[(57.5 - 25) + (52.9 - 25) + \frac{1}{2}(51.9 - 25)\right]K$$

$$q' = 1477 \text{ W/m.}$$ <

COMMENTS: (1) Recognize that, while the temperature distribution may have been determined to a reasonable approximation, the uncertainty in the heat rate could be substantial. This follows since the heat rate is based upon a gradient and hence on temperature differences.

(2) Note that the initial guesses (k = 0) for the iteration are within 5°C of the final distribution. The geometry is simple enough that the guess can be very close. In some instances, a flux plot may be helpful and save labor in the calculation.

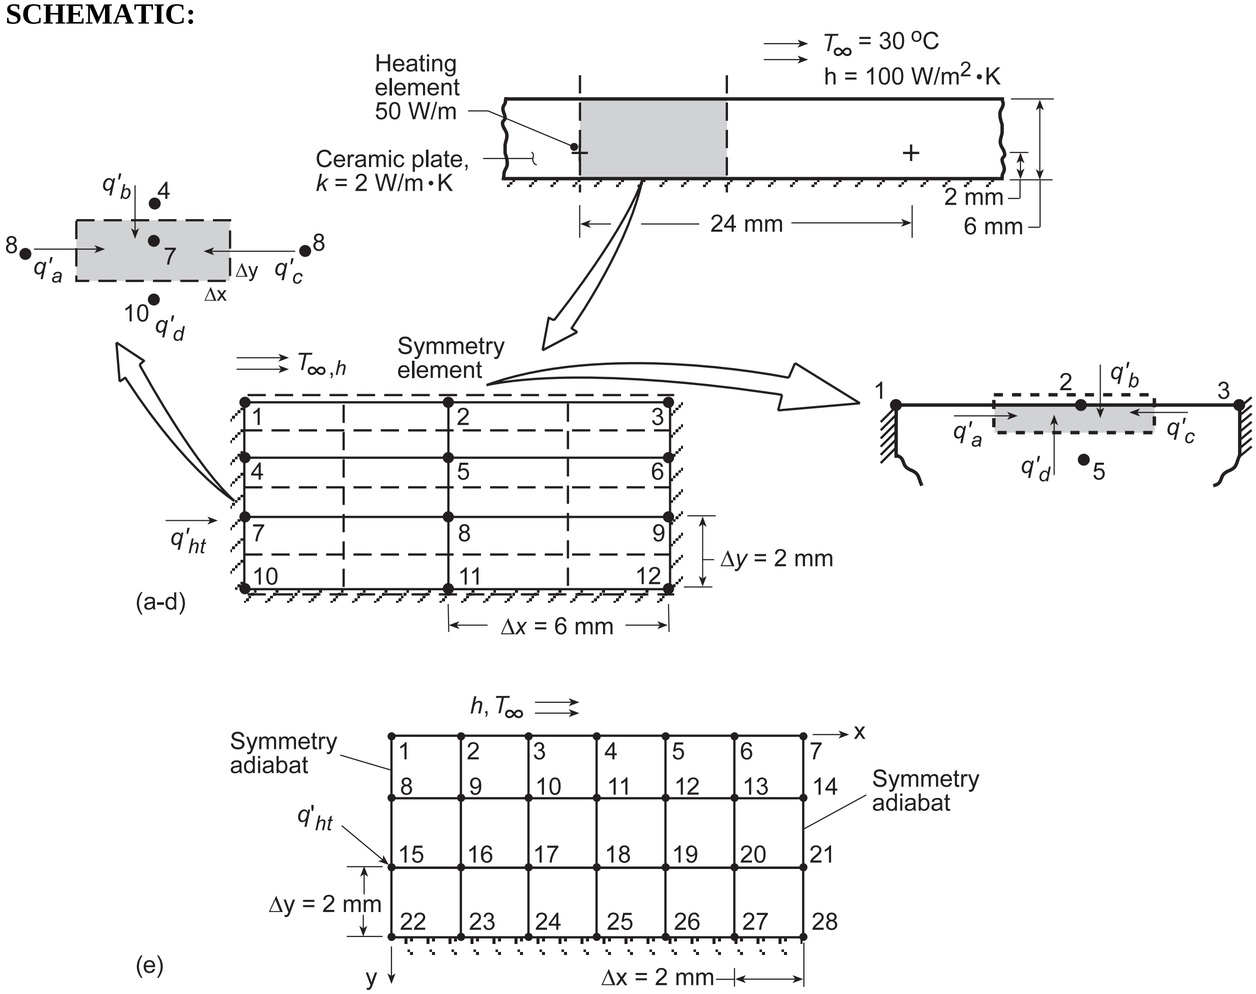
(3) In writing the FDEs, the iteration index (superscript k) was not included to simplify expression of the equations. However, the most recent value of $T_{m,n}$ is always used in the computations. Note that this system of FDEs is diagonally dominant and no rearrangement is required.

PROBLEM 4.86

KNOWN: Electrical heating elements with known dissipation rate embedded in a ceramic plate of known thermal conductivity; lower surface is insulated, while upper surface is exposed to a convection process.

FIND: (a) Temperature distribution within the plate using prescribed grid spacing, (b) Sketch isotherms to illustrate temperature distribution, (c) Heat loss by convection from exposed surface (compare with element dissipation rate), (d) Advantage, if any, in not setting $\Delta x = \Delta y$, (e) Effect of grid size and convection coefficient on the temperature field.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, two-dimensional conduction in ceramic plate, (2) Constant properties, (3) No internal generation, except for Node 7 (or Node 15 for part (e)), (4) Heating element approximates a line source of negligible wire diameter.

ANALYSIS: (a) The prescribed grid for the symmetry element shown above consists of 12 nodal points. Nodes 1-3 are points on a surface experiencing convection; nodes 4-6 and 8-12 are interior nodes. Node 7 is a special case of the interior node having a generation term; because of symmetry, $q'_{ht} = 25$ W/m. The finite-difference equations are derived as follows:

Continued...

PROBLEM 4.86 (Cont.)

Surface Node 2. From an energy balance on the prescribed control volume with $\Delta x/\Delta y = 3$,

$\dot{E}_{in} - \dot{E}_{out} = q'_a + q'_b + q'_c + q'_d = 0;$

$$k\frac{\Delta y}{2}\frac{T_1 - T_2}{\Delta x} + h\Delta x\left(T_\infty - T_2\right) + k\frac{\Delta y}{2}\frac{T_3 - T_2}{\Delta x} + k\Delta x\frac{T_5 - T_2}{\Delta y} = 0\,.$$

Regrouping, find

$$T_2\left(1 + 2N\frac{\Delta x}{\Delta y} + 1 + 2\left(\frac{\Delta x}{\Delta y}\right)^2\right) = T_1 + T_3 + 2\left(\frac{\Delta x}{\Delta y}\right)^2 T_5 + 2N\frac{\Delta x}{\Delta y}T_\infty$$

where $N = h\Delta x/k = 100\ \text{W/m}^2\cdot\text{K} \times 0.006\ \text{m}/2\ \text{W/m}\cdot\text{K} = 0.30\ \text{K}$. Hence, with $T_\infty = 30°\text{C}$,

$$T_2 = 0.04587T_1 + 0.04587T_3 + 0.82569T_5 + 2.4771 \qquad (1)$$

From this FDE, the forms for nodes 1 and 3 can also be deduced.

Interior Node 7. From an energy balance on the prescribed control volume, with $\Delta x/\Delta y = 3$, $\dot{E}'_{in} - \dot{E}'_g = 0$, where $\dot{E}'_g = 2\,q'_{ht}$ and E'_{in} represents the conduction terms. Hence,

$q'_a + q'_b + q'_c + q'_d + 2q'_{ht} = 0$, or

$$k\Delta y\frac{T_8 - T_7}{\Delta x} + k\Delta x\frac{T_4 - T_7}{\Delta y} + k\Delta y\frac{T_8 - T_7}{\Delta x} + k\Delta x\frac{T_{10} - T_7}{\Delta y} + 2q'_{ht} = 0$$

Regrouping,

$$T_7\left[1 + \left(\frac{\Delta x}{\Delta y}\right)^2 + 1 + \left(\frac{\Delta x}{\Delta y}\right)^2\right] = T_8 + \left(\frac{\Delta x}{\Delta y}\right)^2 T_4 + T_8 + \left(\frac{\Delta x}{\Delta y}\right)^2 T_{10} + \frac{2q'_{ht}}{k}\left(\frac{\Delta x}{\Delta y}\right)$$

Recognizing that $\Delta x/\Delta y = 3$, $q'_{ht} = 25$ W/m and $k = 2$ W/m·K, the FDE is

$$T_7 = 0.0500T_8 + 0.4500T_4 + 0.0500T_8 + 0.4500T_{10} + 3.7500 \qquad (2)$$

The FDEs for the remaining nodes may be deduced from this form. Following the procedure described in Appendix D for the Gauss-Seidel method, the system of FDEs has the form:

$$T_1^k = 0.09174T_2^{k-1} + 0.8257T_4^{k-1} + 2.4771$$

$$T_2^k = 0.04587T_1^k + 0.04587T_3^{k-1} + 0.8257T_5^{k-1} + 2.4771$$

$$T_3^k = 0.09174T_2^k + 0.8257T_6^{k-1} + 2.4771$$

$$T_4^k = 0.4500T_1^k + 0.1000T_5^{k-1} + 0.4500T_7^{k-1}$$

$$T_5^k = 0.4500T_2^k + 0.0500T_4^k + 0.0500T_6^{k-1} + 0.4500T_8^{k-1}$$

$$T_6^k = 0.4500T_3^k + 0.1000T_5^k + 0.4500T_9^{k-1}$$

$$T_7^k = 0.4500T_4^k + 0.1000T_8^{k-1} + 0.4500T_{10}^{k-1} + 3.7500$$

$$T_8^k = 0.4500T_5^k + 0.0500T_7^k + 0.0500T_9^{k-1} + 0.4500T_{11}^{k-1}$$

$$T_9^k = 0.4500T_6^k + 0.1000T_8^k + 0.4500T_{12}^{k-1}$$

$$T_{10}^k = 0.9000T_7^k + 0.1000T_{11}^{k-1}$$

$$T_{11}^k = 0.9000T_8^k + 0.0500T_{10}^{k-1} + 0.0500T_{12}^{k-1}$$

$$T_{12}^k = 0.9000T_9^k + 0.1000T_{11}^k$$

Continued …

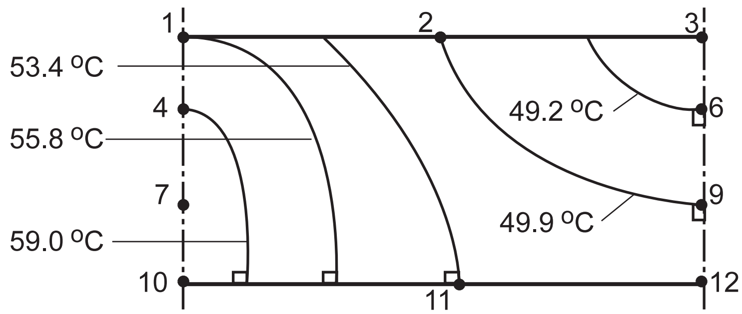
PROBLEM 4.86 (Cont.)

Note the use of the superscript k to denote the level of iteration. Begin the iteration procedure with rational estimates for T_i (k = 0) and prescribe the convergence criterion as $\varepsilon \le 0.1$ K.

k/T_i	1	2	3	4	5	6	7	8	9	10	11	12
0	55.0	50.0	45.0	61.0	54.0	47.0	65.0	56.0	49.0	60.0	55.0	50.0
1	57.4	51.7	46.0	60.4	53.8	48.1	63.5	54.6	49.6	62.7	54.8	50.1
2	57.1	51.6	46.9	59.7	53.2	48.7	64.3	54.3	49.9	63.4	54.5	50.4
∞	55.80	49.93	47.67	59.03	51.72	49.19	63.89	52.98	50.14	62.84	53.35	50.46

The last row with k = ∞ corresponds to the solution obtained by matrix inversion. It appears that at least 20 iterations would be required to satisfy the convergence criterion using the Gauss-Seidel method.

(b) Selected isotherms are shown in the sketch of the nodal network.



Note that the isotherms are normal to the adiabatic surfaces.

(c) The heat loss by convection can be expressed as

$$q'_{conv} = h\left[\frac{1}{2}\Delta x\left(T_1 - T_\infty\right) + \Delta x\left(T_2 - T_\infty\right) + \frac{1}{2}\Delta x\left(T_3 - T_\infty\right)\right]$$

$$q'_{conv} = 100\,\text{W/m}^2\cdot\text{K} \times 0.006\,\text{m}\left[\frac{1}{2}(55.80 - 30) + (49.93 - 30) + \frac{1}{2}(47.67 - 30)\right] = 25.00\,\text{W/m}. \quad <$$

As expected, the heat loss by convection is equal to the heater element dissipation. This follows from the conservation of energy requirement.

(d) For this situation, choosing Δx = 3Δy was advantageous from the standpoint of precision and effort. If we had chosen Δx = Δy = 2 mm, there would have been 28 nodes, doubling the amount of work, but with improved precision.

(e) Examining the effect of grid size by using the *Finite-Difference Equations* option from the *Tools* portion of the IHT Menu, the following temperature field was computed for Δx = Δy = 2 mm, where x and y are in mm and the temperatures are in °C.

y\x	0	2	4	6	8	10	12
0	55.04	53.88	52.03	50.32	49.02	48.24	47.97
2	58.71	56.61	54.17	52.14	50.67	49.80	49.51
4	66.56	59.70	55.90	53.39	51.73	50.77	50.46
6	63.14	59.71	56.33	53.80	52.09	51.11	50.78

Continued …

PROBLEM 4.86 (Cont.)

Agreement with the results of part (a) is excellent, except in proximity to the heating element, where T_{15} = 66.6°C for the fine grid exceeds T_7 = 63.9°C for the coarse grid by 2.7°C.

For h = 10 $W/m^2 \cdot K$, the maximum temperature in the ceramic corresponds to T_{15} = 254°C, and the heater could still be operated at the prescribed power. With h = 10 $W/m^2 \cdot K$, the critical temperature of T_{15} = 400°C would be reached with a heater power of approximately 82 W/m.

COMMENTS: (1) The method used to obtain the rational estimates for T_i (k = 0) in part (a) is as follows. Assume 25 W/m is transferred by convection uniformly over the surface; find $\overline{T}_{surf} \approx 50°C$. Set T_2 = 50°C and recognize that T_1 and T_3 will be higher and lower, respectively. Assume 25 W/m is conducted uniformly to the outer nodes; find $T_5 - T_2 \approx 4°C$. For the remaining nodes, use intuition to guess reasonable values. (2) In selecting grid size (and whether $\Delta x = \Delta y$), one should consider the region of largest temperature gradients. Predicted values of the maximum temperature in the ceramic will be very sensitive to the grid resolution.

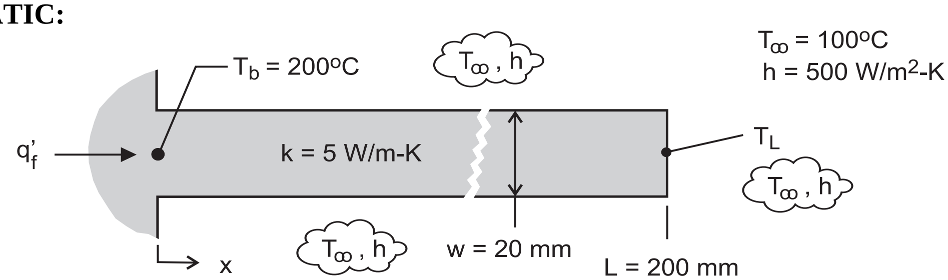
NOTE TO INSTRUCTOR: Although the problem statement calls for calculations with $\Delta x = \Delta y$ = 1 mm, the instructional value and benefit-to-effort ratio are small. Hence, consideration of this grid size is not recommended.

PROBLEM 4.87

KNOWN: Straight fin of uniform cross section with prescribed thermal conditions and geometry; tip condition allows for convection.

FIND: (a) Calculate the fin heat rate, q'_f, and tip temperature, T_L, assuming one-dimensional heat transfer in the fin; calculate the Biot number to determine whether the one-dimensional assumption is valid, (b) Using the finite-element software FEHT, perform a two-dimensional analysis to determine the fin heat rate and the tip temperature; display the isotherms; describe the temperature field and the heat flow pattern inferred from the display, and (c) Validate your FEHT code against the 1-D analytical solution for a fin using a thermal conductivity of 50 and 500 W/m·K.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conduction with constant properties, (2) Negligible radiation exchange, (3) Uniform convection coefficient.

ANALYSIS: (a) Assuming one-dimensional conduction, q'_L and T_L can be determined using Eqs. 3.77 and 3.75, respectively, from Table 3.4, Case A. Alternatively, use the IHT *Model* | *Extended Surfaces* | *Temperature Distribution and Heat Rate* | *Straight Fin* | *Rectangular*. These results are tabulated below and labeled as "1-D." The Biot number for the fin is

$$Bi = \frac{h(t/2)}{k} = \frac{500 \text{ W/m}^2 \cdot \text{K} \, (0.020 \text{ m}/2)}{5 \text{ W/m} \cdot \text{K}} = 1$$

(b, c) The fin can be drawn as a two-dimensional outline in FEHT with convection boundary conditions on the exposed surfaces, and with a uniform temperature on the base. Using a fine mesh (at least 1280 elements), solve for the temperature distribution and use the *View* | *Temperature Contours* command to view the isotherms and the *Heat Flow* command to determine the heat rate into the fin base. The results of the analysis are summarized in the table below.

k (W/m·K)	Bi	Tip temperature, T_L (°C)		Fin heat rate, q'_f (W/m)		Difference* (%)
		1-D	2-D	1-D	2-D	
5	1	100	100	1010	805	20
50	0.1	100.3	100	3194	2990	6.4
500	0.01	123.8	124	9812	9563	2.5

* Difference = $\left(q'_{f,1D} - q'_{f,2D}\right) \times 100 / q'_{f,1D}$

COMMENTS: (1) From part (a), since $Bi = 1 > 0.1$, the internal conduction resistance is not negligible. Therefore significant transverse temperature gradients exist, and the one-dimensional conduction assumption in the fin is a poor one.

Continued …

PROBLEM 4.87 (Cont.)

(2) From the table, with k = 5 W/m·K (Bi = 1), the 2-D fin heat rate obtained from the FEA analysis is 20% lower than that for the 1-D analytical analysis. This is as expected since the 2-D model accounts for transverse thermal resistance to heat flow. Note, however, that analyses predict the same tip temperature, a consequence of the fin approximating an infinitely long fin (mL = 20.2 >> 2.56; see Ex. 3.8 Comments).

(3) For the k = 5 W/m·K case, the FEHT isotherms show considerable curvature in the region near the fin base. For example, at x = 10 and 20 mm, the difference between the centerline and surface temperatures are 15 and 7°C.

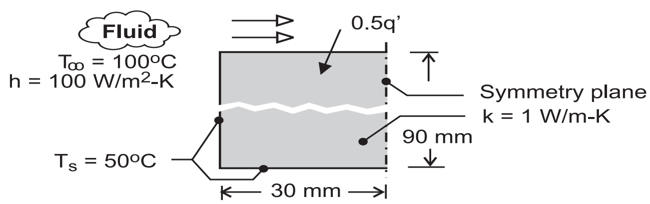
(4) From the table, with increasing thermal conductivity, note that Bi decreases, and the one-dimensional heat transfer assumption becomes more appropriate. The difference for the case when k = 500 W/m·K is mostly due to the approximate manner in which the heat rate is calculated in the FEA software.

PROBLEM 4.88

KNOWN: Long rectangular bar having one boundary exposed to a convection process (T_∞, h) while the other boundaries are maintained at constant temperature T_s.

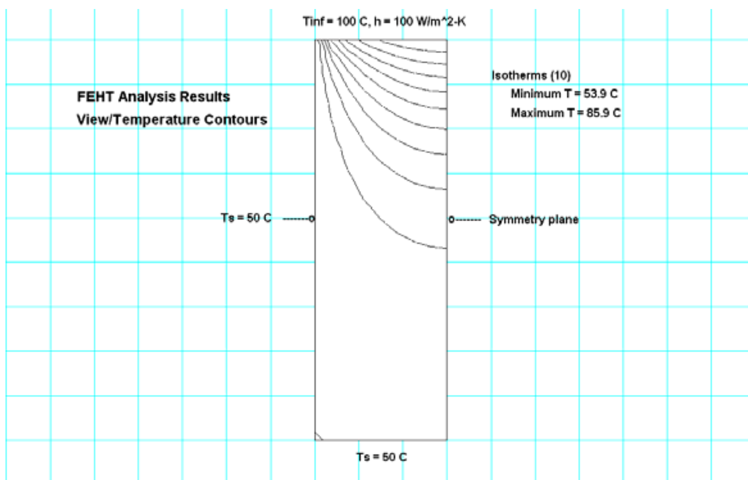
FIND: Using the finite-element method of FEHT, (a) Determine the temperature distribution, plot the isotherms, and identify significant features of the distribution, (b) Calculate the heat rate per unit length (W/m) into the bar from the air stream, and (c) Explore the effect on the heat rate of increasing the convection coefficient by factors of two and three; explain why the change in the heat rate is not proportional to the change in the convection coefficient.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, two dimensional conduction, (2) Constant properties.

ANALYSIS: (a) The symmetrical section shown in the schematic is drawn in FEHT with the specified boundary conditions and material property. The *View | Temperature Contours* command is used to represent ten isotherms (isopotentials) that have minimum and maximum values of 53.9°C and 85.9°C, respectively.



Because of the symmetry boundary condition, the isotherms are normal to the center-plane indicating an adiabatic surface. Note that the temperature change along the upper surface of the bar is substantial (≈ 40°C), whereas the lower half of the bar has less than a 3°C change. That is, the lower half of the bar is largely unaffected by the heat transfer conditions at the upper surface.

(b, c) Using the *View | Heat Flows* command considering the upper surface boundary with selected convection coefficients, the heat rates into the bar from the air stream were calculated.

$h\left(W/m^2\cdot K\right)$	100	200	300
$q'(W/m)$	128	175	206

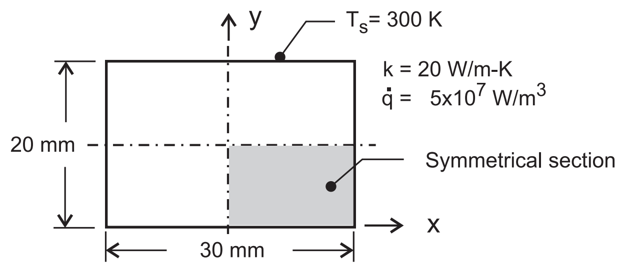
Increasing the convection coefficient by factors of 2 and 3, increases the heat rate by 37% and 61%, respectively. The heat rate from the bar to the air stream is controlled by the thermal resistances of the bar (conduction) and the convection process. Since the conduction resistance is significant, we should not expect the heat rate to change proportionally to the change in convection resistance.

PROBLEM 4.89

KNOWN: Log rod of rectangular cross-section of Problem 4.53 that experiences uniform heat generation while its surfaces are maintained at a fixed temperature. Use the finite-element software FEHT as your analysis tool.

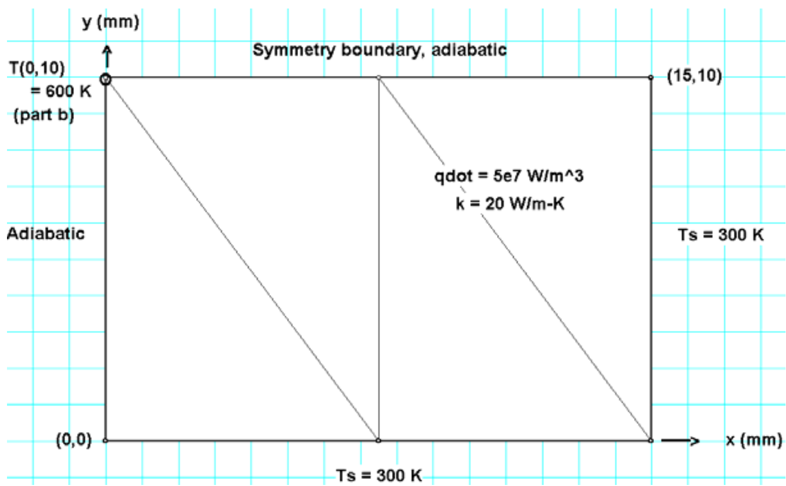
FIND: (a) Represent the temperature distribution with representative isotherms; identify significant features; and (b) Determine what heat generation rate will cause the midpoint to reach 600 K with unchanged boundary conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, and (2) Two-dimensional conduction with constant properties.

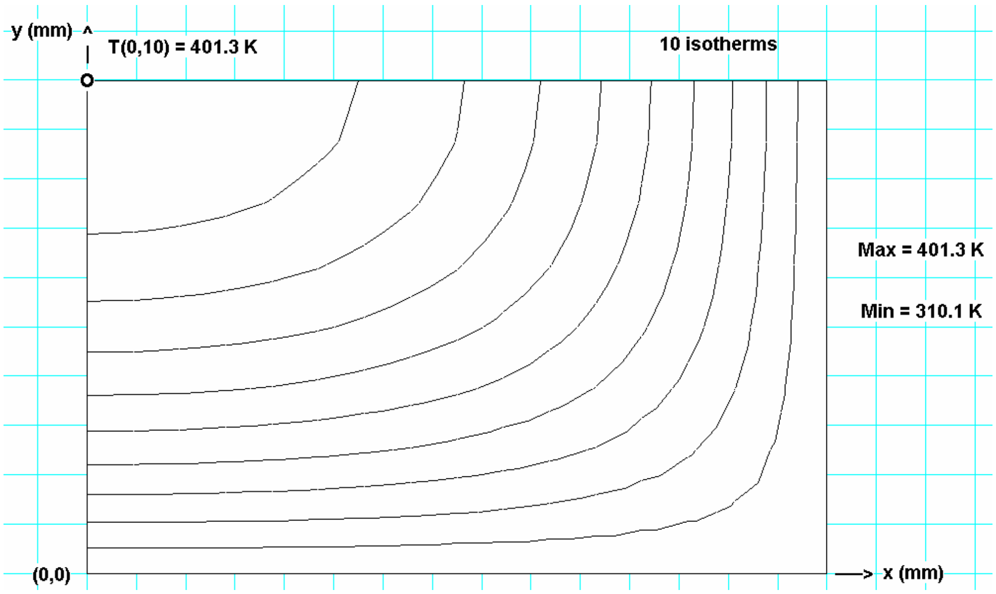
ANALYSIS: (a) Using *FEHT*, do the following: in *Setup*, enter an appropriate scale; *Draw* the outline of the symmetrical section shown in the above schematic; *Specify* the *Boundary Conditions* (zero heat flux or adiabatic along the symmetrical lines, and isothermal on the edges). Also *Specify* the *Material Properties* and *Generation* rate. *Draw* three *Element Lines* as shown on the annotated version of the *FEHT* screen below. To reduce the mesh, hit *Draw/Reduce Mesh* until the desired fineness is achieved (256 elements is a good choice).



Continued …

PROBLEM 4.89 (Cont.)

After hitting *Run*, C*heck* and then *Calculate*, use the *View/Temperature Contours* and select the 10-isopotential option to display the isotherms as shown in an annotated copy of the *FEHT* screen below.



The isotherms are normal to the symmetrical lines as expected since those surfaces are adiabatic. The isotherms, especially near the center, have an elliptical shape. Along the x = 0 axis and the y = 10 mm axis, the temperature gradient is nearly linear. The hottest point is of course the center for which the temperature is

(T(0, 10 mm) = 401.3 K. <

The temperature of this point can be read using the *View/Temperatures* or *View|Tabular Output* command.

(b) To determine the required generation rate so that T(0, 10 mm) = 600 K, it is necessary to re-run the model with several guessed values of $\dot{q}$. After a few trials, find

$$\dot{q} = 1.48 \times 10^8 \ W/m^3$$ <

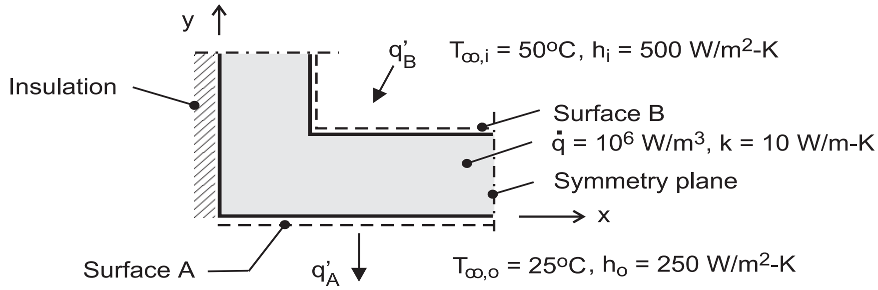
PROBLEM 4.90

KNOWN: Symmetrical section of a flow channel with prescribed values of $\dot{q}$ and k, as well as the surface convection conditions. See Problem 4.57.

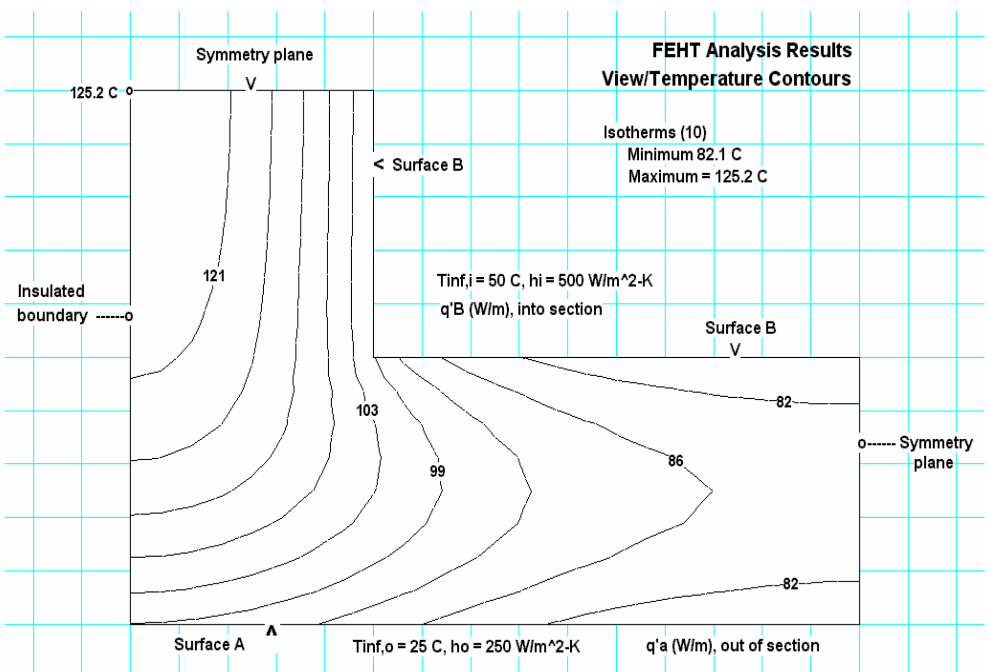
.

FIND: Using the finite-element method of FEHT, (a) Determine the temperature distribution and plot the isotherms; identify the coolest and hottest regions, and the region with steepest gradients; describe the heat flow field, (b) Calculate the heat rate per unit length (W/m) from the outer surface A to the adjacent fluid, (c) Calculate the heat rate per unit length (W/m) to surface B from the inner fluid, and (d) Verify that the results are consistent with an overall energy balance on the section.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties.
ANALYSIS: (a) The symmetrical section shown in the schematic is drawn in FEHT with the specified boundary conditions, material property and generation. The *View | Temperature Contours* command is used to represent ten isotherms (isopotentials) that have minimum and maximum values of 82.1°C and 125.2°C.



The hottest region of the section is the upper vertical leg (left-hand corner). The coolest region is in the lower horizontal leg at the far right-hand boundary. The maximum and minimum section temperatures (125°C and 77°C), respectively, are higher than either adjoining fluid. Remembering that heat flow lines are normal to the isotherms, heat flows from the hottest corner directly to the inner fluid and downward into the lower leg and then flows out surface A and the lower portion of surface B.

Continued …

PROBLEM 4.90 (Cont.)

(b, c) Using the *View* | *Heat Flows* command considering the boundaries for surfaces A and B, the heat rates are:

$$q'_S = 1135\ \text{W/m} \qquad\qquad q'_B = -1365\ \text{W/m}.$$ <

From an energy balance on the section, we note that the results are consistent since conservation of energy is satisfied.

$$\dot{E}'_{in} - \dot{E}'_{out} + \dot{E}_g = 0$$

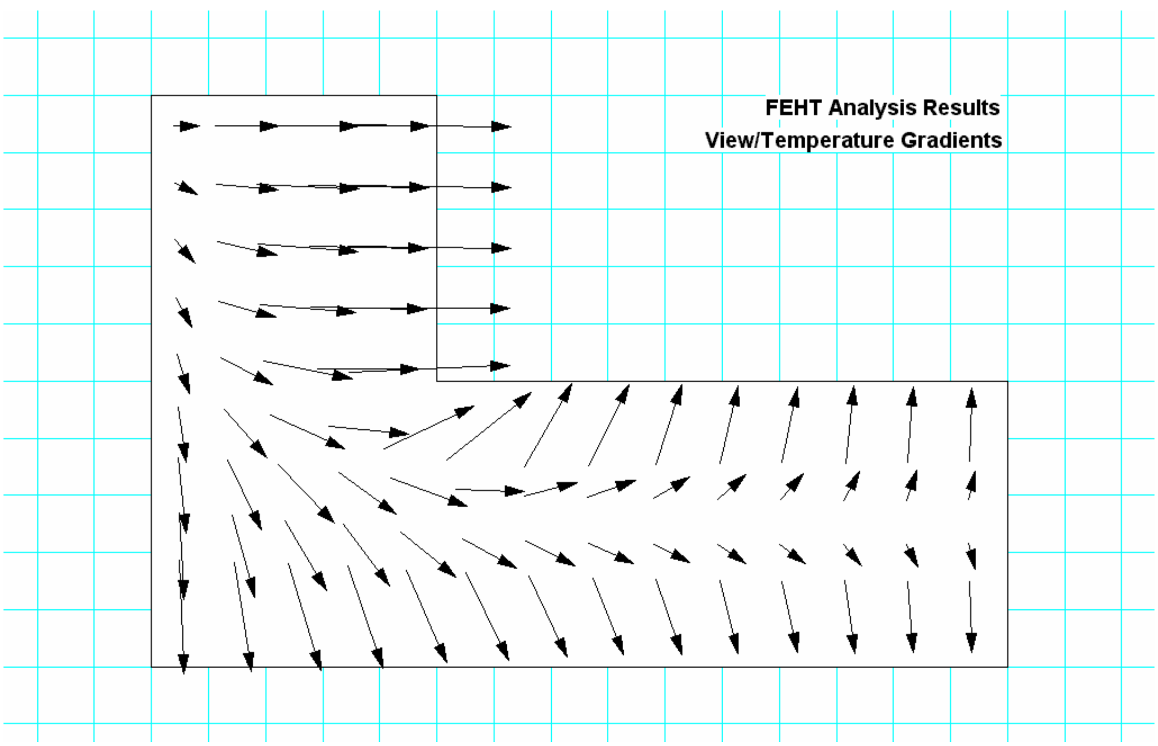
$$-q'_A + q'_B + \dot{q}\forall' = 0$$

$$-1135\ \text{W/m} + \left(-1365\ \text{W/m}\right) + 2500\ \text{W/m} = 0$$ <

where $\dot{q}\forall = 1\times10^6\ \text{W/m}^3 \times \left[25\times50 + 25\times50\right]\times10^{-6}\text{m}^2 = 2500\ \text{W/m}.$

COMMENTS: (1) For background on setting up this problem in FEHT, see the tutorial example of the User's Manual. While the boundary conditions are different, and the internal generation term is to be included, the procedure for performing the analysis is the same.

(2) The heat flow distribution can be visualized using the *View* | *Temperature Gradients* command. The direction and magnitude of the heat flow is represented by the directions and lengths of arrows. Compare the heat flow distribution to the isotherms shown above.

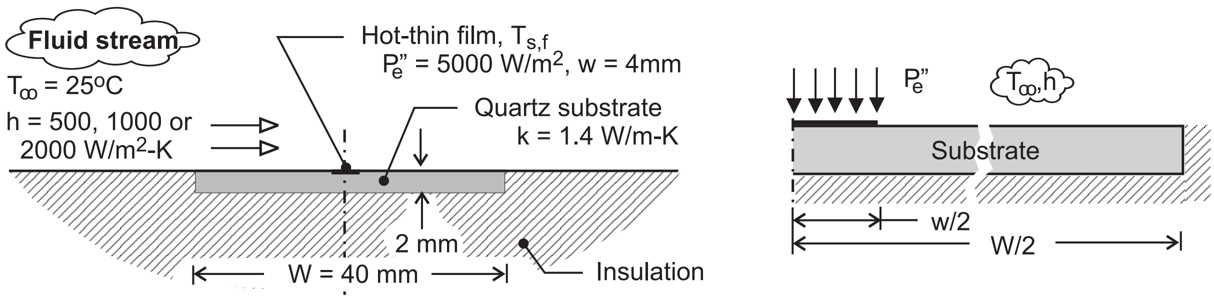


PROBLEM 4.91

KNOWN: Hot-film flux gage for determining the convection coefficient of an adjoining fluid stream by measuring the dissipated electric power, P_e , and the average surface temperature, $T_{s,f}$.

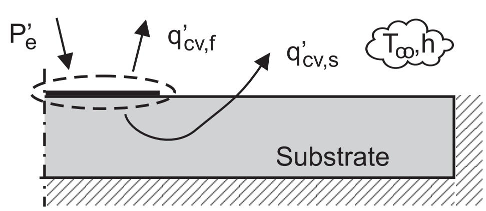
FIND: Using the finite-element method of *FEHT*, determine the fraction of the power dissipation that is conducted into the quartz substrate considering three cases corresponding to convection coefficients of 500, 1000 and 2000 $W/m^2 \cdot K$.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant substrate properties, (3) Uniform convection coefficient over the hot-film and substrate surfaces, (4) Uniform power dissipation over hot film.

ANALYSIS: The symmetrical section shown in the schematic above (right) is drawn into *FEHT* specifying the substrate material property. On the upper surface, a convection boundary condition (T_∞,h) is specified over the full width W/2. Additionally, an applied uniform flux $\left(P_e'', \ W/m^2\right)$ boundary condition is specified for the hot-film region (w/2). The remaining surfaces of the two-dimensional system are specified as adiabatic. In the schematic below, the electrical power dissipation P_e' (W/m) in the hot film is transferred by convection from the film surface, $q'_{cv,f}$, and from the adjacent substrate surface, $q'_{cv,s}$.



The analysis evaluates the fraction, F, of the dissipated electrical power that is conducted into the substrate and convected to the fluid stream,

$$F = q'_{cv,s} / P'_e = 1 - q'_{cv,f} / P'_e$$

where $\quad P'_e = P''_e (w/2) = 5000 \ W/m^2 \times (0.002 \ m) = 10 \ W/m.$

After solving for the temperature distribution, the *View|Heat Flow* command is used to evaluate $q'_{cv,f}$ for the three values of the convection coefficient.

Continued …

PROBLEM 4.91 (Cont.)

Case	$h(W/m^2 \cdot K)$	$q'_{cv,f}\ (W/m)$	F(%)	$T_{s,f}$ (°C)
1	500	5.64	43.6	30.9
2	1000	6.74	32.6	28.6
3	2000	7.70	23.3	27.0

COMMENTS: (1) For the ideal hot-film flux gage, there is negligible heat transfer to the substrate, and the convection coefficient of the air stream is calculated from the measured electrical power, P''_e, the average film temperature (by a thin-film thermocouple), $T_{s,f}$, and the fluid stream temperature, T_∞, as $h = P''_e / \left(T_{s,f} - T_\infty\right)$. The purpose in performing the present analysis is to estimate a correction factor to account for heat transfer to the substrate.

(2) As anticipated, the fraction of the dissipated electrical power conducted into the substrate, F, decreases with increasing convection coefficient. For the case of the largest convection coefficient, F amounts to 25%, making it necessary to develop a reliable, accurate heat transfer model to estimate the applied correction. Further, this condition limits the usefulness of this gage design to flows with high convection coefficients.

(3) A reduction in F, and hence the effect of an applied correction, could be achieved with a substrate material having a lower thermal conductivity than quartz. However, quartz is a common substrate material for fabrication of thin-film heat-flux gages and thermocouples. By what other means could you reduce F?

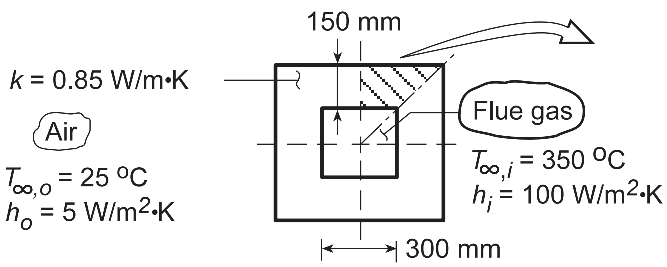
(4) In addition to the tutorial example in the *FEHT* User's Manual, the solved models for Examples 4.3 and 4.4 are useful for developing skills helpful in solving this problem.

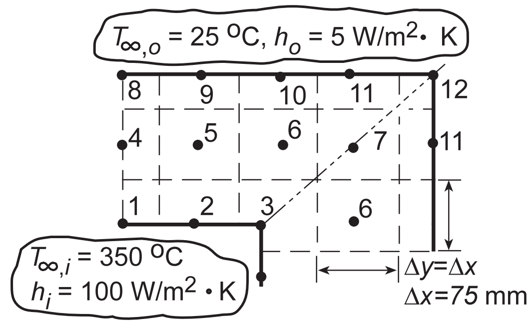
PROBLEM 4.92

KNOWN: Flue of square cross section with prescribed geometry, thermal conductivity and inner and outer surface convective conditions.

FIND: (a) Heat loss per unit length, q', by convection to the air, (b) Effect of grid spacing and convection coefficients on temperature field; show isotherms.

SCHEMATIC:





Schematic (a)

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties.

ANALYSIS: (a) Taking advantage of symmetry, the nodal network for a 75 mm grid spacing is shown in schematic (a). To obtain the heat rate, we need first to determine the temperatures T_i. Recognize that there are four types of nodes: interior (4-7), plane surface with convection (1, 2, 8-11), internal corner with convection (3), and external corner with convection (12). Using the appropriate relations from Table 4.2, the finite-difference equations are

Node		Equation
1	$(2T_4 + T_2 + T_2) + \frac{2h_i\Delta x}{k}T_{\infty,i} - 2\left(\frac{h_i\Delta x}{k} + 2\right)T_1 = 0$	4.42
2	$(2T_5 + T_3 + T_1) + \frac{2h_i\Delta x}{k}T_{\infty,i} - 2\left(\frac{h_i\Delta x}{k} + 2\right)T_2 = 0$	4.42
3	$2(T_6 + T_6) + (T_2 + T_2) + \frac{2h_i\Delta x}{k}T_{\infty,i} - 2\left(3 + \frac{h_i\Delta x}{k}\right)T_3 = 0$	4.41
4	$(T_8 + T_5 + T_1 + T_5) - 4T_4 = 0$	4.29
5	$(T_9 + T_6 + T_2 + T_4) - 4T_5 = 0$	4.29
6	$(T_{10} + T_7 + T_3 + T_5) - 4T_6 = 0$	4.29
7	$(T_{11} + T_{11} + T_6 + T_6) - 4T_7 = 0$	4.29
8	$(2T_4 + T_9 + T_9) + \frac{2h_o\Delta x}{k}T_{\infty,o} - 2\left(\frac{h_o\Delta x}{k} + 2\right)T_8 = 0$	4.42
9	$(2T_5 + T_{10} + T_8) + \frac{2h_o\Delta x}{k}T_{\infty,o} - 2\left(\frac{h_o\Delta x}{k} + 2\right)T_9 = 0$	4.42
10	$(2T_6 + T_{11} + T_9) + \frac{2h_o\Delta x}{k}T_{\infty,o} - 2\left(\frac{h_o\Delta x}{k} + 2\right)T_{10} = 0$	4.42
11	$(2T_7 + T_{12} + T_{10}) + \frac{2h_o\Delta x}{k}T_{\infty,o} - 2\left(\frac{h_o\Delta x}{k} + 2\right)T_{11} = 0$	4.42
12	$(T_{11} + T_{11}) + \frac{2h_o\Delta x}{k}T_{\infty,o} - 2\left(\frac{h_o\Delta x}{k} + 1\right)T_{12} = 0$	4.43

Continued...

PROBLEM 4.92 (Cont.)

Substituting $T_{\infty,o}$ = 350°C, h_o = 100 W/m^2·K, $T_{\infty,i}$ = 25°C, h_i = 5 W/m^2·K, Δx = 0.075 m, and k = 0.85 W/m·K and solving the preceding equations simultaneously using, for example, IHT, yields

T_1 = 340.4°C, T_2 = 339.5°C, T_3 = 329.1°C, T_4 = 256.5°C, T_5 = 251.4°C, T_6 = 231.5°C, T_7 = 182.3°C, T_8 = 182.6°C, T_9 = 178.3°C, T_{10} = 163.1°C, T_{11} = 133.1°C, T_{12} = 100.0°C. <

The heat loss to the outside air for the upper surface (Nodes 8 through 12) is of the form

$$q' = h_o \Delta x \left[\frac{1}{2}\left(T_8 - T_{\infty,o}\right) + \left(T_9 - T_{\infty,o}\right) + \left(T_{10} - T_{\infty,o}\right) + \left(T_{11} - T_{\infty,o}\right) + \frac{1}{2}\left(T_{12} - T_{\infty,o}\right) \right]$$

$$q' = 5\,\mathrm{W/m^2 \cdot K} \times 0.075\,\mathrm{m} \left[\frac{1}{2}(182.6 - 25) + (178.3 - 25) + (163.1 - 25) + (133.1 - 25) + \frac{1}{2}(100.0 - 25) \right] ^\circ\mathrm{C} = 193.4\,\mathrm{W/m}$$

Hence, for the entire flue cross-section, considering symmetry,

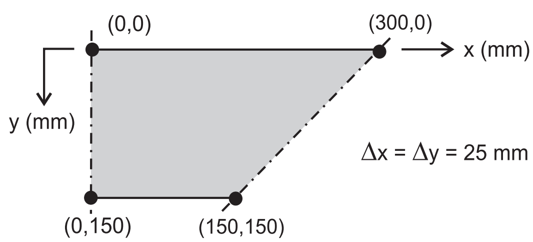
$$q'_{tot} = 8 \times q' = 8 \times 193.4\,\mathrm{W/m} = 1.55\,\mathrm{kW/m}$$ <

The convection heat rate at the inner surface is

$$q'_{tot} = 8 \times h_i \Delta x \left[\frac{1}{2}\left(T_{\infty,i} - T_1\right) + \left(T_{\infty,i} - T_2\right) + \frac{1}{2}\left(T_{\infty,i} - T_3\right) \right] = 1.55\,\mathrm{kW/m}$$

which is the same as the heat loss from the upper surface, as it must be. <

(b) Using the *Finite-Difference Equations* option from the *Tools* portion of the IHT menu, the following two-dimensional temperature field was computed for the grid shown in the schematic below, where x and y are in mm and the temperatures are in °C.

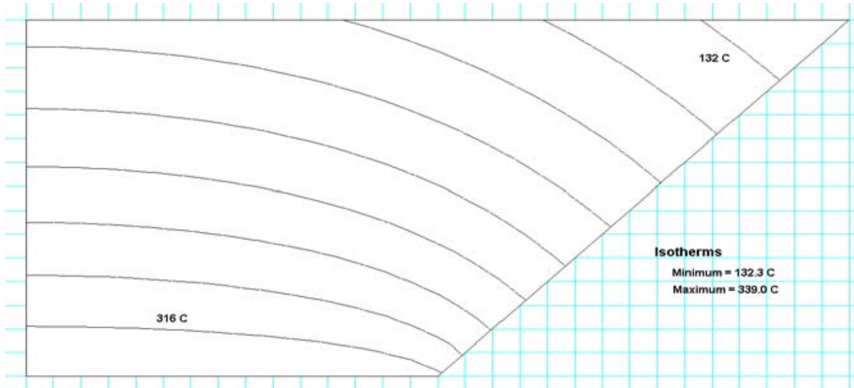


y\x	0	25	50	75	100	125	150	175	200	225	250	275	300
0	180.7	180.2	178.4	175.4	171.1	165.3	158.1	149.6	140.1	129.9	119.4	108.7	98.0
25	204.2	203.6	201.6	198.2	193.3	186.7	178.3	168.4	157.4	145.6	133.4	121.0	
50	228.9	228.3	226.2	222.6	217.2	209.7	200.1	188.4	175.4	161.6	147.5		
75	255.0	254.4	252.4	248.7	243.1	235.0	223.9	209.8	194.1	177.8			
100	282.4	281.8	280.1	276.9	271.6	263.3	250.5	232.8	213.5				
125	310.9	310.5	309.3	307.1	303.2	296.0	282.2	257.5					
150	340.0	340.0	339.6	339.1	337.9	335.3	324.7						

Agreement between the temperature fields for the (a) and (b) grids is good, with the largest differences occurring at the interior and exterior corners. Ten isotherms generated using *FEHT* are shown on the symmetric section below. Note how the heat flow is nearly normal to the flue wall around the mid-section. In the corner regions, the isotherms are curved and we'd expect that grid size might influence the accuracy of the results. Convection heat transfer to the inner surface is

Continued...

PROBLEM 4.92 (Cont.)



$$q' = 8h_i\Delta x\Big[\left(T_{\infty,i} - T_1\right)/2 + \left(T_{\infty,i} - T_2\right) + \left(T_{\infty,i} - T_3\right) + \left(T_{\infty,i} - T_4\right)$$
$$+\left(T_{\infty,i} - T_5\right) + \left(T_{\infty,i} - T_6\right) + \left(T_{\infty,i} - T_7\right)/2\Big] = 1.52\,\text{kW/m}$$

and the agreement with results of the coarse grid is excellent.

The heat rate increases with increasing h_i and h_o, while temperatures in the wall increase and decrease, respectively, with increasing h_i and h_o.

COMMENTS. (1) Gauss-Seidel iteration may be used to solve this system of equations. Following the procedures of Appendix D, the system of equations is rewritten in the proper form. Note that diagonal dominance is present; hence, no re-ordering is necessary.

$$T_1^k = 0.09239T_2^{k-1} + 0.09239T_4^{k-1} + 285.3$$
$$T_2^k = 0.04620T_1^k + 0.04620T_3^{k-1} + 0.09239T_5^{k-1} + 285.3$$
$$T_3^k = 0.08457T_2^k + 0.1692T_6^{k-1} + 261.2$$
$$T_4^k = 0.25T_1^k + 0.50T_5^{k-1} + 0.25T_8^{k-1}$$
$$T_5^k = 0.25T_2^k + 0.25T_4^k + 0.25T_6^{k-1} + 0.25T_9^{k-1}$$
$$T_6^k = 0.25T_3^k + 0.25T_5^k + 0.25T_7^{k-1} + 0.25T_9^{k-1}$$
$$T_7^k = 0.50T_6^k + 0.50T_{11}^{k-1}$$
$$T_8^k = 0.4096T_4^k + 0.4096T_9^{k-1} + 4.52$$
$$T_9^k = 0.4096T_5^k + 0.2048T_8^k + 0.2048T_{10}^{k-1} + 4.52$$
$$T_{10}^k = 0.4096T_6^k + 0.2048T_9^k + 0.2048T_{11}^{k-1} + 4.52$$
$$T_{11}^k = 0.4096T_7^k + 0.2048T_{10}^k + 0.2048T_{12}^{k-1} + 4.52$$
$$T_{12}^k = 0.6939T_{11}^k + 7.65$$

5	339.8	339.2	329.3	254.0	250.5	234.5	183.7	180.6	177.5	164.1	133.8	100.5
6	340.1	339.4	329.7	255.4	251.7	235.7	184.7	181.8	178.5	164.7	134.5	101.0
7	340.3	339.5	329.9	256.4	252.5	236.4	185.5	182.7	179.1	165.6	135.1	101.4

The heat loss to the outside air for the upper surface (Nodes 8 through 12) is of the form

$$q' = h_o \Delta x \left[\frac{1}{2}\left(T_8 - T_{\infty,o}\right) + \left(T_9 - T_{\infty,o}\right) + \left(T_{10} - T_{\infty,o}\right) + \left(T_{11} - T_{\infty,o}\right) + \frac{1}{2}\left(T_{12} - T_{\infty,o}\right) \right]$$

$$q' = 5\,\mathrm{W/m^2 \cdot K} \times 0.075\,\mathrm{m} \left[\frac{1}{2}(182.7 - 25) + (179.1 - 25) + (165.6 - 25) + (135.1 - 25) + \frac{1}{2}(101.4 - 25) \right] {}^\circ\mathrm{C} = 195\,\mathrm{W/m}$$

Hence, for the entire flue cross-section, considering symmetry,

$$q'_{tot} = 8 \times q' = 8 \times 195\,\mathrm{W/m} = 1.57\,\mathrm{kW/m} \qquad <$$

The convection heat rate at the inner surface is

$$q'_{tot} = 8 \times h_i \Delta x \left[\frac{1}{2}\left(T_{\infty,i} - T_1\right) + \left(T_{\infty,i} - T_2\right) + \frac{1}{2}\left(T_{\infty,i} - T_3\right) \right] = 8 \times 190.5\,\mathrm{W/m} = 1.52\,\mathrm{kW/m}$$

which is within 2.5% of the foregoing result. The convection heat rates would be identical when $\varepsilon = 0$.

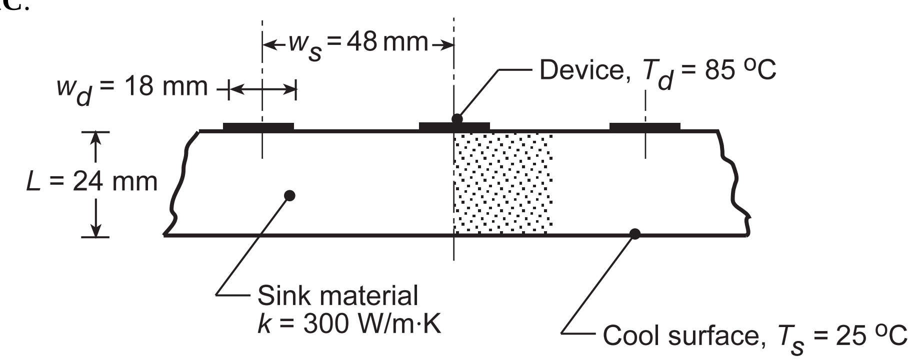
(2) For this problem the Gauss-Seidel iteration method is cumbersome, time-consuming and inaccurate unless many more iterations are included. For relatively small systems of simultaneous equations such as in this problem, enhanced accuracy can usually be obtained with far less effort through use of a numerical solver such as available on many handheld calculators, IHT or some other commercial code.

PROBLEM 4.93

KNOWN: Electronic device cooled by conduction to a heat sink.

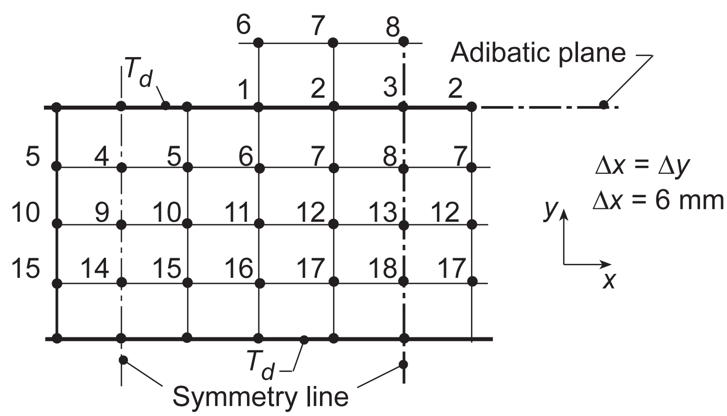
FIND: (a) Beginning with a symmetrical element, find the thermal resistance per unit depth between the device and lower surface of the sink, $R'_{t,d-s}$ (m·K/W) using a coarse (5x5) nodal network, determine $R'_{t,d-s}$; (b) Using nodal networks with finer grid spacings, determine the effect of grid size on the precision of the thermal resistance calculation; (c) Using a fine nodal network, determine the effect of device width on $R'_{t,d-s}$ with w_d/w_s = 0.175, 0.275, 0.375 and 0.475 keeping w_s and L fixed.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties, and (3) No internal generation, (4) Top surface not covered by device is insulated.

ANALYSIS: (a) The coarse 5x5 nodal network is shown in the sketch including the nodes adjacent to the symmetry lines and the adiabatic surface. As such, all the finite-difference equations are interior nodes and can be written by inspection directly onto the IHT workspace. Alternatively, one could use the *IHT Finite-Difference Equations Tool*. The temperature distribution (°C) is tabulated in the same arrangement as the nodal network.



85.00	85.00	62.31	53.26	50.73
65.76	63.85	55.49	50.00	48.20
50.32	49.17	45.80	43.06	42.07
37.18	36.70	35.47	34.37	33.95
25.00	25.00	25.00	25.00	25.00

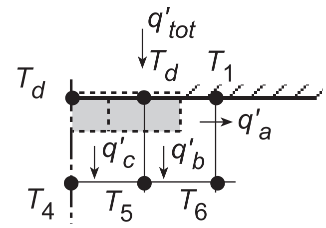
The thermal resistance between the device and sink per unit depth is

$$R'_{t,s-d} = \frac{T_d - T_s}{2q'_{tot}}$$

Continued…

PROBLEM 4.93 (Cont.)

Performing an energy balance on the device nodes, find



$$q'_{tot} = q'_a + q'_b + q'_c$$

$$q'_{tot} = k\left(\Delta y/2\right)\frac{T_d - T_1}{\Delta x} + k\Delta x \frac{T_d - T_5}{\Delta y} + k\left(\Delta x/2\right)\frac{T_d - T_4}{\Delta y}$$

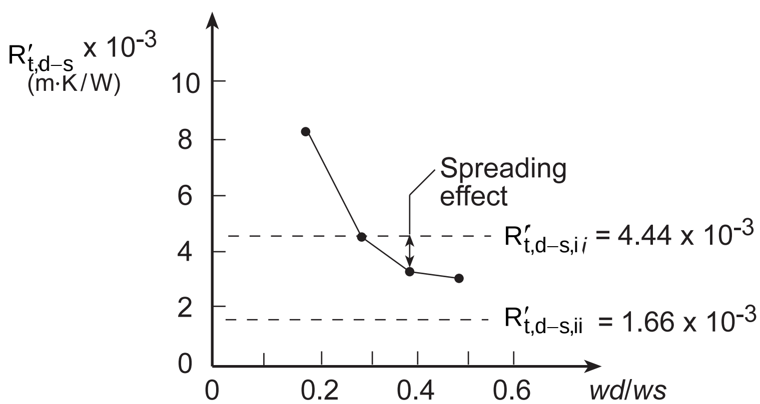
$$q'_{tot} = 300\,\text{W/m}\cdot\text{K}\left[(85-62.31)/2 + (85-63.85) + (85-65.76)/2\right]\text{K} = 1.263\times10^4\ \text{W/m}$$

$$R'_{t,s-d} = \frac{(85-25)\text{K}}{2\times1.263\times10^4\ \text{W/m}} = 2.38\times10^{-3}\text{m}\cdot\text{K/W}$$ <

(b) The effect of grid size on the precision of the thermal resistance estimate should be tested by systematically reducing the nodal spacing Δx and Δy. This is a considerable amount of work even with IHT since the equations need to be individually entered. A more generalized, powerful code would be required which allows for automatically selecting the grid size. Using FEHT, a finite-element package, with eight elements across the device, representing a much finer mesh, we found

$$R'_{t,s-d} = 3.64\times10^{-3}\ \text{m}\cdot\text{K/W}$$

(c) Using the same tool, with the finest mesh, the thermal resistance was found as a function of w_d/w_s with fixed w_s and L.



As expected, as w_d increases, $R'_{t,d-s}$ decreases, and eventually will approach the value for the rectangular domain (ii). The spreading effect is shown for the base case, $w_d/w_s = 0.375$, where the thermal resistance of the sink is less than that for the rectangular domain (i).

COMMENTS: It is useful to compare the results for estimating the thermal resistance in terms of precision requirements and level of effort,

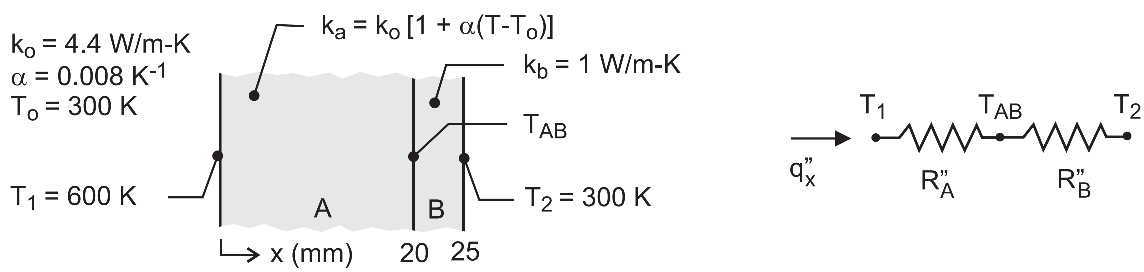
	$R'_{t,d-s} \times 10^3$ (m·K/W)
Rectangular domain (i)	4.44
Flux plot	3.03
Rectangular domain (ii)	1.67
FDE, 5x5 network	2.38
FEA, fine mesh	3.64

PROBLEM 4.94

KNOWN: Plane composite wall with exposed surfaces maintained at fixed temperatures. Material A has temperature-dependent thermal conductivity.

FIND: Heat flux through the wall (a) assuming a uniform thermal conductivity in material A evaluated at the average temperature of the section, and considering the temperature-dependent thermal conductivity of material A using (b) a finite-difference method of solution in IHT with a space increment of 1 mm and (c) the finite-element method of FEHT.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, one-dimensional conduction, (2) No thermal contact resistance between the materials, and (3) No internal generation.

ANALYSIS: (a) From the thermal circuit in the above schematic, the heat flux is

$$q''_x = \frac{T_1 - T_2}{R''_A + R''_B} = \frac{T_{AB} - T_2}{R''_B} \qquad (1, 2)$$

and the thermal resistances of the two sections are

$$R''_A = L_A / k_A \qquad R''_B = L_B / k_B \qquad (3, 4)$$

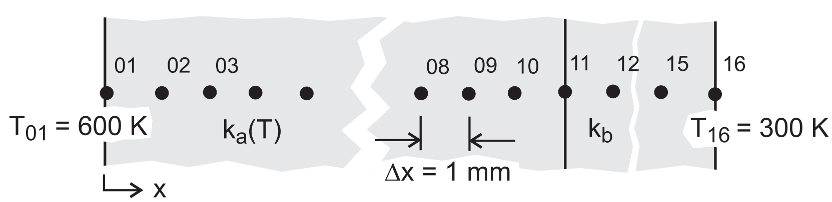
The thermal conductivity of material A is evaluated at the average temperature of the section

$$k_A = k_o \left\{1 + \alpha\left[\left(T_1 + T_{AB}\right)/2 - T_o\right]\right\} \qquad (5)$$

Substituting numerical values and solving the system of equations simultaneously in IHT, find

$$T_{AB} = 563.2 \text{ K} \qquad q''_x = 52.64 \text{ kW/m}^2$$ <

(b) The nodal arrangement for the finite-difference method of solution is shown in the schematic below. FDEs must be written for the internal nodes (02 – 10, 12 – 15) and the A-B interface node (11) considering in section A, the temperature-dependent thermal conductivity.



Interior Nodes, Section A (m = 02, 03 … 10)
Referring to the schematic below, the energy balance on node *m* is written in terms of the heat fluxes at the control surfaces using Fourier's law with the thermal conductivity based upon the average temperature of adjacent nodes. The heat fluxes into node *m* are

Continued …

PROBLEM 4.94 (Cont.)

$$q''_c = k_a(m, m+1)\frac{T_{m+1} - T_m}{\Delta x} \quad (1)$$

$$q''_d = k_a(m-1, m)\frac{T_{m-1} - T_m}{\Delta x} \quad (2)$$

and the FDEs are obtained from the energy balance written as

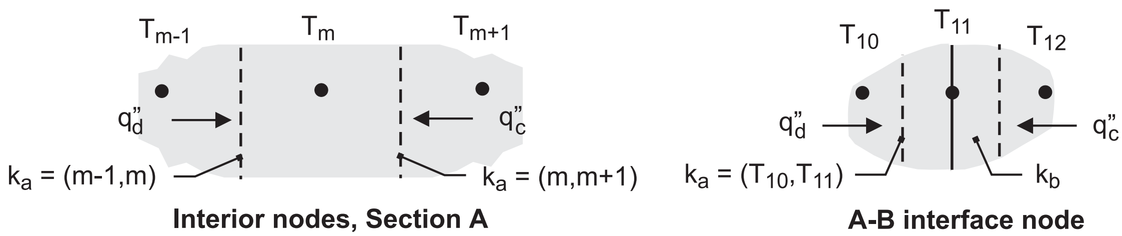
$$q''_c + q''_d = 0 \quad (3)$$

$$k_a(m, m+1)\frac{T_{m+1} - T_m}{\Delta x} + k_a(m-1, m)\frac{T_{m-1} - T_m}{\Delta x} = 0 \quad (4)$$

where the thermal conductivities averaged over the path between the nodes are expressed as

$$k_a(m-1, m) = k_o\left\{1 + \alpha\left[\left(T_{m-1} + T_m\right)/2 - T_o\right]\right\} \quad (5)$$

$$k_a(m, m+1) = k_o\left\{1 + \alpha\left[\left(T_m + T_{m+1}\right)/2 - T_o\right]\right\} \quad (6)$$



A-B Interface Node 11

Referring to the above schematic, the energy balance on the interface node, $q''_c + q''_d = 0$, has the form

$$k_b\frac{T_{12} - T_{11}}{\Delta x} + k_a(10, 11)\frac{T_{10} - T_{11}}{\Delta x} = 0 \quad (7)$$

where the thermal conductivity in the section A path is

$$k(10, 11) = k_o\left\{1 + \left[\left(T_{10} + T_{11}\right)/2 - T_o\right]\right\} \quad (8)$$

Interior Nodes, Section B (n = 12 …15)

Since the thermal conductivity in Section B is uniform, the FDEs have the form

$$T_n = \left(T_{n-1} + T_{n+1}\right)/2 \quad (9)$$

And the heat flux in the x-direction is

$$q''_x = k_b\frac{T_n - T_{n+1}}{\Delta x} \quad (10)$$

Finite-Difference Method of Solution

The foregoing FDE equations for section A nodes (m = 02 to 10), the AB interface node and their respective expressions for the thermal conductivity, k (m, m +1), and for section B nodes are entered into the IHT workspace and solved for the temperature distribution. The heat flux can be evaluated using Eq. (2) or (10). A portion of the IHT code is contained in the Comments, and the results of the analysis are tabulated below.

$T_{11} = T_{AB} = 563.2\ K \qquad q''_x = 52.64\ kW/m^2$ <

Continued …

PROBLEM 4.94 (Cont.)

(c) The finite-element method of FEHT can be used readily to obtain the heat flux considering the temperature-dependent thermal conductivity of section A. Draw the composite wall outline with properly scaled section thicknesses in the x-direction with an arbitrary y-direction dimension. In the *Specify* | *Materials Properties* box for the thermal conductivity, specify k_a as 4.4*[1 + 0.008*(T – 300)] having earlier selected *Set* | *Temperatures in K*. The results of the analysis are

$$T_{AB} = 563 \text{ K} \qquad q''_x = 52.6 \text{ kW/m}^2$$ <

COMMENTS: (1) The results from the three methods of analysis compare very well. Because the thermal conductivity in section A is linear, and moderately dependent on temperature, the simplest method of using an overall section average, part (a), is recommended. This same method is recommended when using tabular data for temperature-dependent properties.

(2) For the finite-difference method of solution, part (b), the heat flux was evaluated at several nodes within section A and in section B with identical results. This is a consequence of the technique for averaging k_a over the path between nodes in computing the heat flux into a node.

(3) To illustrate the use of IHT in solving the finite-difference method of solution, lines of code for representative nodes are shown below.

```
// FDEs – Section A
k01_02 * (T01-T02)/deltax + k02_03 * (T03-T02)/deltax = 0
k01_02 = ko * (1+ alpha * ((T01 + T02)/2 – To))
k02_03 = ko * (1 + alpha * ((T02 + T03)/2 – To))

k02_03 * (T02 – T03)/deltax + k03_04 * (T04 – T03)/deltax = 0
k03_04 = ko * (1 + alpha * ((T03 + T04)/2 – To))

// Interface, node 11
k11 * (T10 –T11)/deltax + kb * (T12 –T11)/deltax =0
k11 = ko * (1 + alpha * ((T10 + T11)/2 – To))

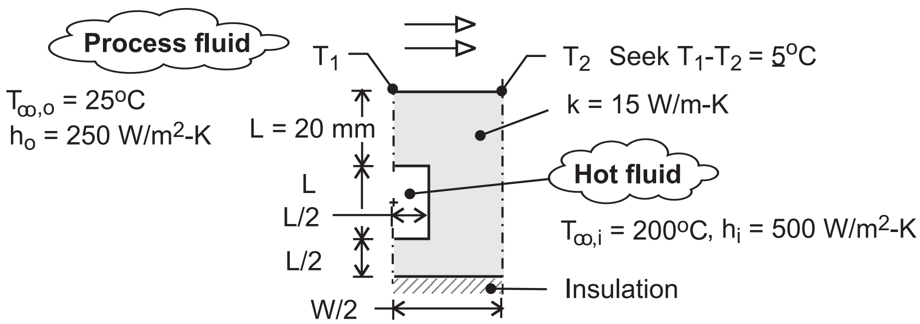
// Section B (using Tools/FDE/One-dimensional/Steady-state)
/* Node 12: interior node; */
0.0 = fd_1d_int(T12, T13, T11, kb, qdot, deltax)
```

PROBLEM 4.95

KNOWN: Upper surface of a platen heated by hot fluid through the flow channels is used to heat a process fluid.

FIND: (a) The maximum allowable spacing, W, between channel centerlines that will provide a uniform temperature requirement of 5°C on the upper surface of the platen, and (b) Heat rate per unit length from the flow channel for this condition.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, two-dimensional conduction with constant properties, and (2) Lower surface of platen is adiabatic.

ANALYSIS: As shown in the schematic above for a symmetrical section of the platen-flow channel arrangement, the temperature uniformity requirement will be met when $T_1 - T_2 = 5°C$. The maximum temperature, T_1, will occur directly over the flow channel centerline, while the minimum surface temperature, T_2, will occur at the mid-span between channel centerlines.

We chose to use FEHT to obtain the temperature distribution and heat rate for guessed values of the channel centerline spacing, W. The following method of solution was used: (1) Make an initial guess value for W; try W = 100 mm, (2) Draw an outline of the symmetrical section, and assign properties and boundary conditions, (3) Make a copy of this file so that in your second trial, you can use the *Draw* | *Move Node* option to modify the section width, W/2, larger or smaller, (4) Draw element lines within the outline to create triangular elements, (5) Use the *Draw* | *Reduce Mesh* command to generate a suitably fine mesh, then solve for the temperature distribution, (6) Use the *View* | *Temperatures* command to determine the temperatures T_1 and T_2, (7) If, $T_1 - T_2 \approx 5°C$, use the *View* | *Heat Flows* command to find the heat rate, otherwise, change the width of the section outline and repeat the analysis. The results of our three trials are tabulated below.

Trial	W (mm)	T_1 (°C)	T_2 (°C)	$T_1 - T_2$ (°C)	q' (W/m)
1	100	108	98	10	--
2	60	119	118	1	--
3	80	113	108	5	1706

COMMENTS: (1) In addition to the tutorial example in the FEHT User's Manual, the solved models for Examples 4.3 and 4.4 of the Text are useful for developing skills in using this problem-solving tool.

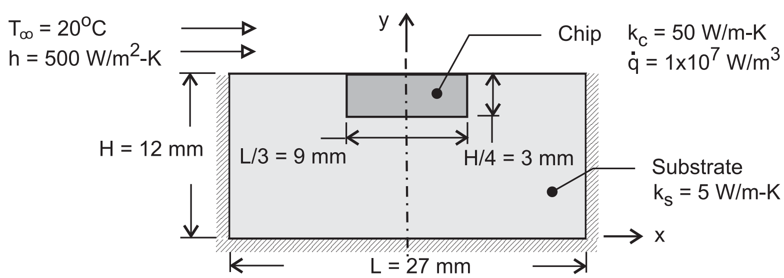
(2) An alternative numerical method of solution would be to create a nodal network, generate the finite-difference equations and solve for the temperature distribution and the heat rate. The FDEs should allow for a non-square grid, $\Delta x \neq \Delta y$, so that different values for W/2 can be accommodated by changing the value of Δx. Even using the IHT tool for building FDEs (*Tools* | *Finite-Difference Equations* | *Steady-State*) this method of solution is very labor intensive because of the large number of nodes required for obtaining good estimates.

PROBLEM 4.96

KNOWN: Silicon chip mounted in a dielectric substrate. One surface of system is convectively cooled, while the remaining surfaces are well insulated. See Problem 4.93. Use the finite-element software *FEHT* as your analysis tool.

FIND: (a) The temperature distribution in the substrate-chip system; does the maximum temperature exceed 85°C?; (b) Volumetric heating rate that will result in a maximum temperature of 85°C; and (c) Effect of reducing thickness of substrate from 12 to 6 mm, keeping all other dimensions unchanged with $\dot{q} = 1\times10^7$ W/m^3; maximum temperature in the system for these conditions, and fraction of the power generated within the chip removed by convection directly from the chip surface.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction in system, and (3) Uniform convection coefficient over upper surface.

ANALYSIS: Using *FEHT*, the symmetrical section is represented in the workspace as two connected regions, chip and substrate. *Draw* first the chip outline; *Specify* the material and generation parameters. Now, *Draw* the outline of the substrate, connecting the nodes of the interfacing surfaces; *Specify* the material parameters for this region. Finally, *Assign* the *Boundary Conditions*: zero heat flux for the symmetry and insulated surfaces, and convection for the upper surface. Draw *Element Lines*, making the triangular elements near the chip and surface smaller than near the lower insulated boundary as shown in a copy of the *FEHT* screen on the next page. Use the *Draw*|*Reduce M*esh command and *Run* the model.

(a) Use the *View*|*Temperature* command to see the nodal temperatures through out the system. As expected, the hottest location is on the centerline of the chip at the bottom surface. At this location, the temperature is

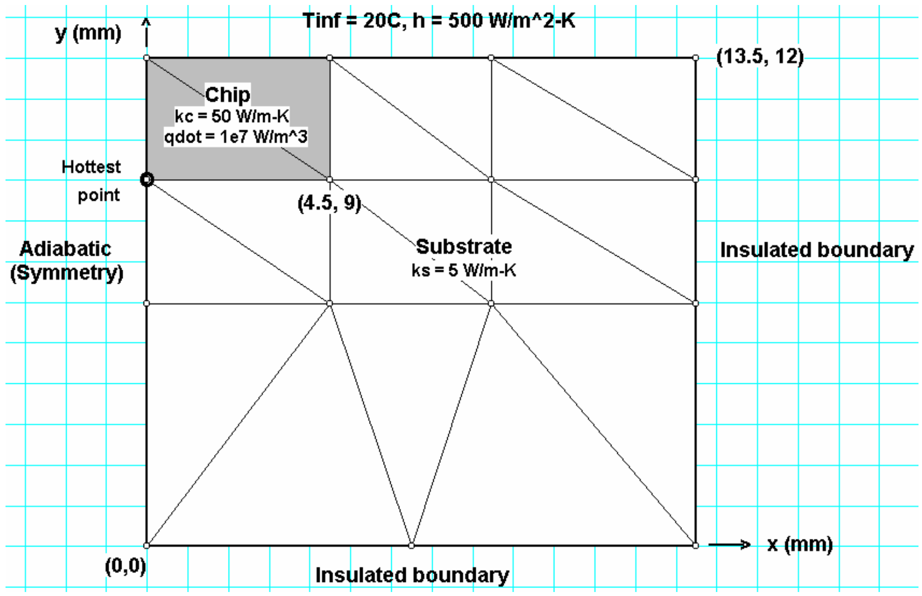
$$T(0, 9\text{ mm}) = 46.7°\text{C}$$ <

(b) Run the model again, with different values of the generation rate until the temperature at this location is T(0, 9 mm) = 85°C, finding

$$\dot{q} = 2.43\times10^7 \text{ W/m}^3$$ <

Continued …

PROBLEM 4.96 (Cont.)



(c) Returning to the model code with the conditions of part (a), reposition the nodes on the lower boundary, as well as the intermediate ones, to represent a substrate that is of 6-mm, rather than 12-mm thickness. Find the maximum temperature as

$$T(0,3\text{ mm}) = 47.5°\text{C} \qquad <$$

Using the *View|Heat Flow* command, click on the adjacent line segments forming the chip surface exposed to the convection process. The heat rate per unit width (normal to the page) is

$$q'_{chip,cv} = 60.26\text{ W/m}$$

The total heat generated within the chip is

$$q'_{tot} = \dot{q}(L/6 \times H/4) = 1\times10^7\text{ W/m}^3 \times (0.0045 \times 0.003)\text{m}^2 = 135\text{ W/m}$$

so that the fraction of the power dissipated by the chip that is convected directly to the coolant stream is

$$F = q'_{chip,cv}/q'_{tot} = 60.26/135 = 45\% \qquad <$$

COMMENTS: (1) Comparing the maximum temperatures for the system with the 12-mm and 6-mm thickness substrates, note that the effect of halving the substrate thickness is to raise the maximum temperature by less than 1°C. The thicker substrate does not provide significantly improved heat removal capability.

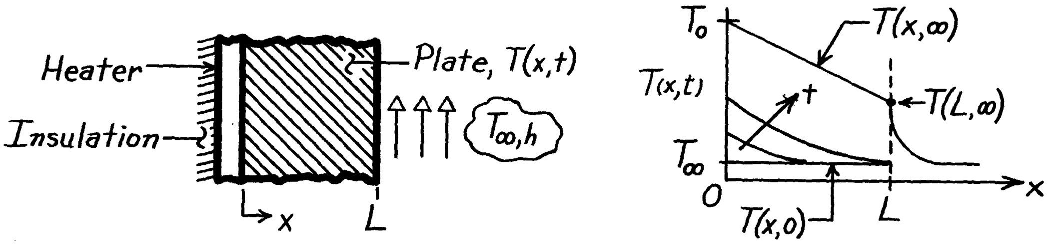
(2) Without running the code for part (b), estimate the magnitude of $\dot{q}$ that would make T(0, 9 mm) = 85°C. Did you get $\dot{q} = 2.43\times10^7$ W/m^3? Why?

PROBLEM 5.1

KNOWN: Electrical heater attached to backside of plate while front surface is exposed to convection process (T_∞,h); initially plate is at a uniform temperature of the ambient air and suddenly heater power is switched on providing a constant q''_o.

FIND: (a) Sketch temperature distribution, T(x,t), (b) Sketch the heat flux at the outer surface, $q''_x(L,t)$ as a function of time.

SCHEMATIC:



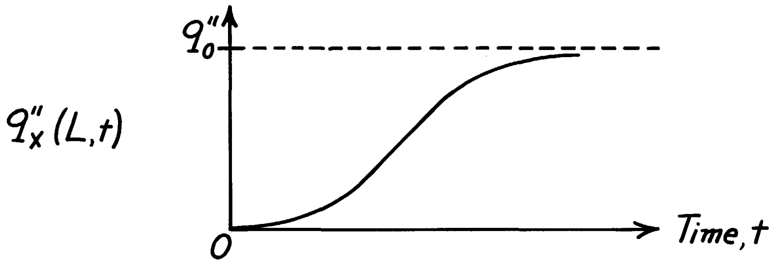
ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Negligible heat loss from heater through insulation.

ANALYSIS: (a) The temperature distributions for four time conditions including the initial distribution, T(x,0), and the steady-state distribution, T(x,∞), are as shown above.

Note that the temperature gradient at x = 0, $-dT/dx)_{x=0}$, for t > 0 will be a constant since the flux, $q''_x(0)$, is a constant. Noting that $T_o = T(0,\infty)$, the steady-state temperature distribution will be linear such that

$$q''_o = k\frac{T_o - T(L,\infty)}{L} = h\left[T(L,\infty) - T_\infty\right].$$

(b) The heat flux at the front surface, x = L, is given by $q''_x(L,t) = -k(dT/dx)_{x=L}$. From the temperature distribution, we can construct the heat flux-time plot.



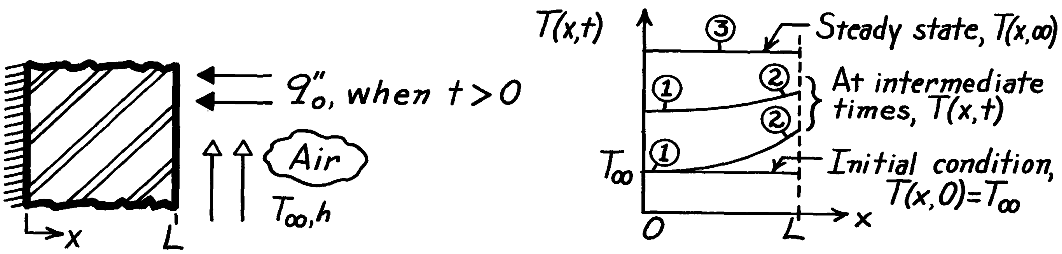
COMMENTS: At early times, the temperature and heat flux at x = L will not change from their initial values. Hence, we show a zero slope for $q''_x(L,t)$ at early times. Eventually, the value of $q''_x(L,t)$ will reach the steady-state value which is q''_o.

PROBLEM 5.2

KNOWN: Plane wall whose inner surface is insulated and outer surface is exposed to an airstream at T_∞. Initially, the wall is at a uniform temperature equal to that of the airstream. Suddenly, a radiant source is switched on applying a uniform flux, q''_o, to the outer surface.

FIND: (a) Sketch temperature distribution on T-x coordinates for initial, steady-state, and two intermediate times, (b) Sketch heat flux at the outer surface, $q''_x(L,t)$, as a function of time.

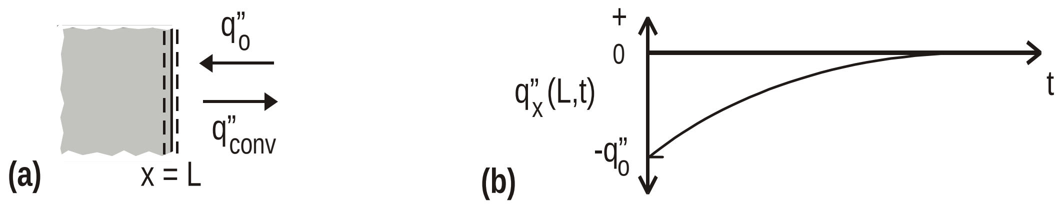
SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) No internal generation, $\dot{E}_g = 0$, (4) Surface at x = 0 is perfectly insulated, (5) All incident radiant power is absorbed and negligible radiation exchange with surroundings.

ANALYSIS: (a) The temperature distributions are shown on the T-x coordinates and labeled accordingly. Note these special features: (1) Gradient at x = 0 is always zero, (2) gradient is more steep at early times and (3) for steady-state conditions, the radiant flux is equal to the convective heat flux (this follows from an energy balance on the CS at x = L),

$q''_o = q''_{conv} = h\left[T(L,\infty) - T_\infty\right]$.



(b) The heat flux at the outer surface, $q''_x(L,t)$, as a function of time appears as shown above.

COMMENTS: The sketches must reflect the initial and boundary conditions:

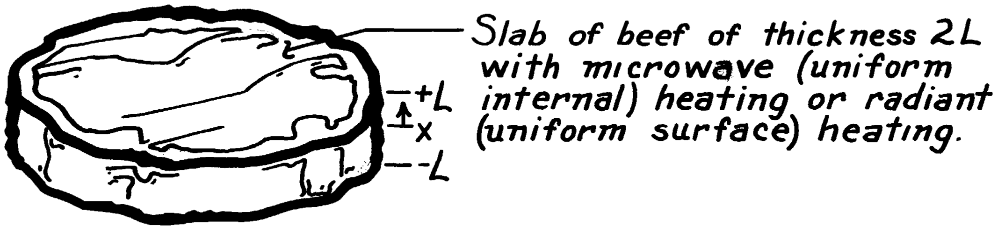
$T(x,0) = T_\infty$	uniform initial temperature.
$-k\dfrac{\partial T}{\partial x}\Big\vert_{x=0} = 0$	insulated at x = 0.
$-k\dfrac{\partial T}{\partial x}\Big\vert_{x=L} = h\left[T(L,t) - T_\infty\right] - q''_o$	surface energy balance at x = L.

PROBLEM 5.3

KNOWN: Microwave and radiant heating conditions for a slab of beef.

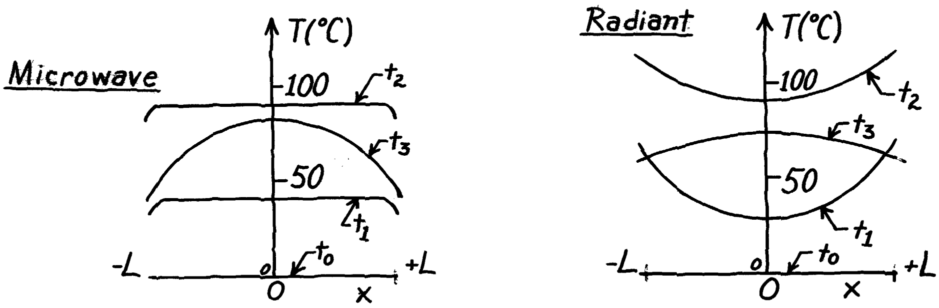
FIND: Sketch temperature distributions at specific times during heating and cooling.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in x, (2) Uniform internal heat generation for microwave, (3) Uniform surface heating for radiant oven, (4) Heat loss from surface of meat to surroundings is negligible during the heating process, (5) Symmetry about midplane.

ANALYSIS:



COMMENTS: (1) With uniform generation and negligible surface heat loss, the temperature distribution remains nearly uniform during *microwave heating.* During the subsequent surface cooling, the maximum temperature is at the midplane.

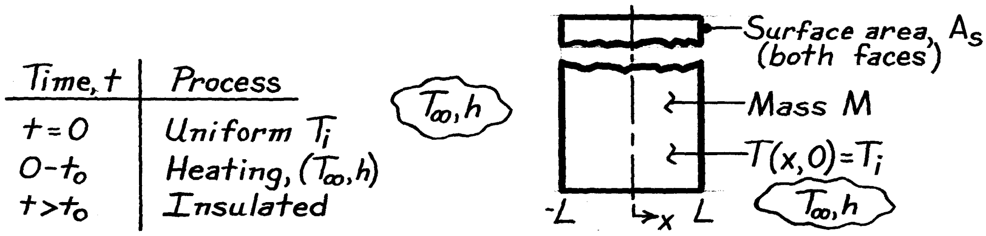
(2) The interior of the meat is heated by conduction from the hotter surfaces during *radiant heating,* and the lowest temperature is at the midplane. The situation is reversed shortly after cooling begins, and the maximum temperature is at the midplane.

PROBLEM 5.4

KNOWN: Plate initially at a uniform temperature T_i is suddenly subjected to convection process (T_∞,h) on both surfaces. After elapsed time t_o, plate is insulated on both surfaces.

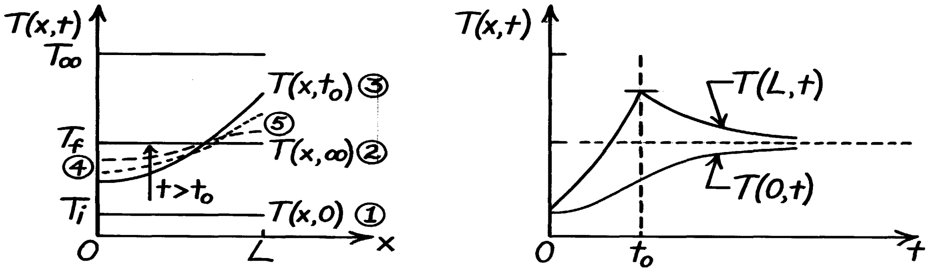
FIND: (a) Assuming Bi >> 1, sketch on T - x coordinates: initial and steady-state ($t \to \infty$) temperature distributions, $T(x,t_o)$ and distributions for two intermediate times $t_o < t < \infty$, (b) Sketch on T - t coordinates midplane and surface temperature histories, (c) Repeat parts (a) and (b) assuming Bi << 1, and (d) Obtain expression for $T(x,\infty) = T_f$ in terms of plate parameters (M,c_p), thermal conditions (T_i, T_∞, h), surface temperature T(L,t) and heating time t_o.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) No internal generation, (4) Plate is perfectly insulated for $t > t_o$, (5) $T(0, t < t_o) < T_\infty$.

ANALYSIS: (a,b) With Bi >> 1, appreciable temperature gradients exist in the plate following exposure to the heating process.



On *T-x* coordinates: (1) initial, uniform temperature, (2) steady-state conditions when $t \to \infty$, (3) distribution at t_o just before plate is covered with insulation, (4) gradients are always zero (symmetry), and (5) when $t > t_o$ (dashed lines) gradients approach zero everywhere.

(c) If Bi << 1, plate is space-wise isothermal (no gradients). On *T-x* coordinates, the temperature distributions are flat; on T-t coordinates, T(L,t) = T(0,t).

(d) The conservation of energy requirement for the interval of time $\Delta t = t_o$ is

$$E_{in} - E_{out} = \Delta E = E_{final} - E_{initial} \qquad 2\int_0^{t_o} hA_s\left[T_\infty - T(L,t)\right]dt - 0 = Mc_p\left(T_f - T_i\right)$$

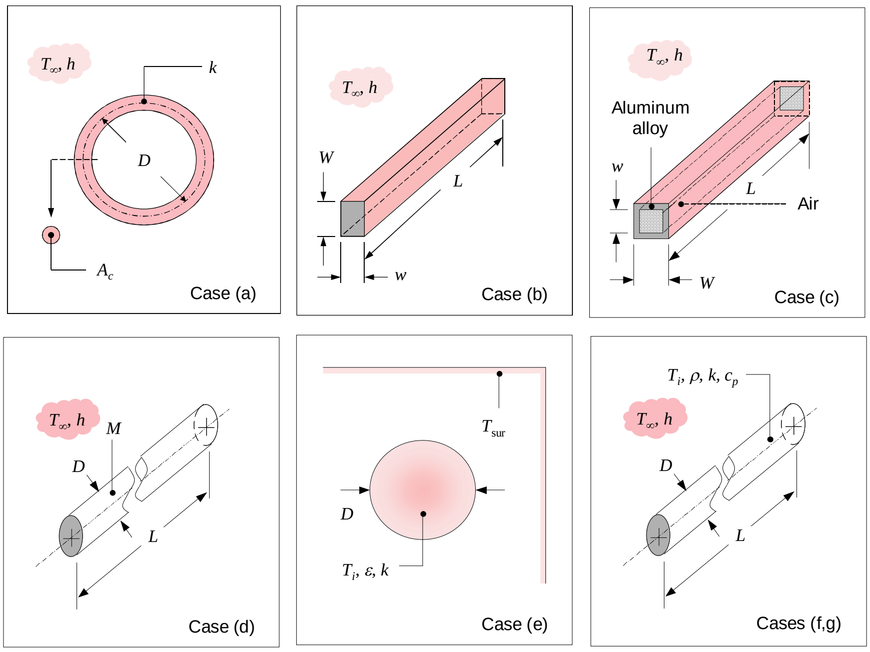
where E_{in} is due to convection heating over the period of time $t = 0 \to t_o$. With knowledge of T(L,t), this expression can be integrated and a value for T_f determined.

PROBLEM 5.5

KNOWN: Geometries of various objects. Material and/or properties. Cases (a) through (d): Convection heat transfer coefficient between object and surrounding fluid. Case (e): Emissivity of sphere, initial temperature, and temperature of surroundings. Cases (f) and (g): Initial temperature, spatially averaged temperature at a later time, and surrounding fluid temperature.

FIND: Characteristic length and Biot number. Validity of lumped capacitance approximation.

SCHEMATIC:



Case (a): D = 50 mm, A_c = 5 mm^2, k = 2.3 W/m·K, h = 50 W/m^2·K.
Case (b): W = 5 mm, w = 3 mm, L = 100 mm, h = 15 W/m^2·K, AISI 304 stainless steel.
Case (c): w = 20 mm, W = 24 mm, h = 37 W/m^2·K (L not specified), 2024 aluminum.
Case (d): L = 300 mm, D = 13 mm, M = 0.328 kg, h = 30 W/m^2·K. stainless steel.
Case (e): D = 12 mm, k = 120 W/m·K, T_{sur} = 20°C, T_i = 100°C, ε = 0.73.
Cases (f,g): D = 20 mm or 200 mm, ρ = 2300 kg/m^3, c_p = 1750 J/kg·K, k = 16 W/m·K, T_∞ = 20°C, T_i = 200°C, T = 100°C at t = 225 s.

ASSUMPTIONS: (1) Constant properties, (2) In case (e), radiation is to large surroundings.

PROPERTIES: *Table A.1*, Stainless steel, AISI 304 (T = 300 K): k = 14.9 W/m·K. Aluminum 2024 (T = 300 K): k = 177 W/m·K.

ANALYSIS: Characteristic lengths can be calculated as $L_{c1} = V/A_s$, or they can be taken conservatively as the dimension corresponding to the maximum spatial temperature difference, L_{c2}. The former definition is more convenient for complex geometries. The lumped capacitance approximation is valid for $Bi = hL_c/k < 0.1$.

(a) The radius of the torus, r_o, can be found from $A_c = \pi r_o^2$. The characteristic lengths are

$$L_{c1} = \frac{V}{A_s} = \frac{A_c \pi D}{2\pi\sqrt{A_c/\pi} \times \pi D} = \frac{1}{2}\sqrt{\frac{A_c}{\pi}} = \frac{1}{2}\sqrt{\frac{5\ \text{mm}^2}{\pi}} = 0.63\ \text{mm} \qquad <$$

Continued…

PROBLEM 5.5 (Cont.)

L_{c2} = Maximum center to surface distance = radius $= \sqrt{A_c / \pi} = \sqrt{5 \text{ mm}^2 / \pi} = 1.26 \text{ mm}$ <

The corresponding Biot numbers are

$$Bi_1 = \frac{hL_{c1}}{k} = \frac{50 \text{ W/m}^2 \cdot \text{K} \times 0.00063 \text{ m}}{2.3 \text{ W/m} \cdot \text{K}} = 0.014$$ <

$$Bi_2 = \frac{hL_{c2}}{k} = \frac{50 \text{ W/m}^2 \cdot \text{K} \times 0.00126 \text{ m}}{2.3 \text{ W/m} \cdot \text{K}} = 0.027$$ <

The lumped capacitance approximation is valid according to either definition. <

(b) For this complex shape, we will calculate only L_{c1}.

$$L_{c1} = \frac{V}{A_s} = \frac{WwL}{2(W+w)L + 2Ww} = \frac{5 \text{ mm} \times 3 \text{ mm} \times 100 \text{ mm}}{2(5 \text{ mm} + 3 \text{ mm}) \times 100 \text{ mm} + 25 \text{ mm} \times 3 \text{ mm}} = 0.90 \text{ mm}$$ <

Notice that the surface area of the ends has been included, and does have a small effect on the result – 0.90 mm versus 0.94 mm if the ends are neglected. The corresponding Biot number is

$$Bi_1 = \frac{hL_{c1}}{k} = \frac{15 \text{ W/m}^2 \cdot \text{K} \times 0.00090 \text{ m}}{14.9 \text{ W/m} \cdot \text{K}} = 0.0009$$ <

The lumped capacitance approximation is valid. <
Furthermore, since the Biot number is very small, the lumped capacitance approximation would certainly still be valid using a more conservative length estimate.

(c) Again, we will only calculate L_{c1}. There will be very little heat transfer to the stagnant air inside the tube, therefore in determining the surface area for convection heat transfer, A_s, only the outer surface area should be included. Thus,

$$L_{c1} = \frac{V}{A_s} = \frac{(W^2 - w^2)L}{4WL} = \frac{(24 \text{ mm})^2 - (20 \text{ mm})^2}{4 \times 24 \text{ mm}} = 1.83 \text{ mm}$$ <

The corresponding Biot number is

$$Bi_1 = \frac{hL_{c1}}{k} = \frac{37 \text{ W/m}^2 \cdot \text{K} \times 0.00183 \text{ m}}{177 \text{ W/m} \cdot \text{K}} = 3.8 \times 10^{-4}$$ <

The lumped capacitance approximation is valid. <
Furthermore, since the Biot number is very small, the lumped capacitance approximation would certainly still be valid using a more conservative length estimate.

Continued…

PROBLEM 5.5 (Cont.)

(d) We are not told which type of stainless steel this is, but we are told its mass, from which we can find its density:

$$\rho = \frac{M}{V} = \frac{M}{\pi D^2 L/4} = \frac{0.328 \text{ kg}}{\pi (0.013 \text{ m})^2 \times 0.3 \text{ m}/4} = 8237 \text{ kg/m}^3$$

This appears to be AISI 316 stainless steel, with a thermal conductivity of k = 13.4 W/m·K at T = 300 K.

The characteristic lengths are

$$L_{c1} = \frac{V}{A_s} = \frac{\pi D^2 L/4}{\pi DL + 2\pi D^2/4} = \frac{DL/4}{L + D/2} = \frac{13 \text{ mm} \times 300 \text{ mm}/4}{300 \text{ mm} + 13 \text{ mm}/2} = 3.18 \text{ mm}$$ <

$$L_{c2} = \text{Maximum center to surface distance} = D/2 = 6.5 \text{ mm}$$ <

Notice that the surface area of the ends has been included in L_{c1}, and does have a small effect on the result. The corresponding Biot numbers are

$$Bi_1 = \frac{hL_{c1}}{k} = \frac{15 \text{ W/m}^2 \cdot \text{K} \times 0.00318 \text{ m}}{13.4 \text{ W/m} \cdot \text{K}} = 0.0036$$ <

$$Bi_2 = \frac{hL_{c2}}{k} = \frac{15 \text{ W/m}^2 \cdot \text{K} \times 0.0065 \text{ m}}{13.4 \text{ W/m} \cdot \text{K}} = 0.0073$$ <

The lumped capacitance approximation is valid according to either definition. <

(e) The characteristic lengths are

$$L_{c1} = \frac{V}{A_s} = \frac{\pi D^3/6}{\pi D^2} = \frac{D}{6} = 2 \text{ mm}$$ <

$$L_{c2} = \text{Maximum center to surface distance} = D/2 = 6 \text{ mm}$$ <

Since heat transfer from the sphere is by radiation, we will calculate the effective radiation heat transfer coefficient (Equation 1.9):

$$\begin{aligned} h_r &= \varepsilon\sigma(T_s + T_{sur})(T_s^2 + T_{sur}^2) \\ &= 0.73 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 [373 \text{ K} + 293 \text{ K}][(373 \text{ K})^2 + (293 \text{ K})^2] = 6.20 \text{ W/m}^2 \cdot \text{K} \end{aligned}$$

Continued…

PROBLEM 5.5 (Cont.)

The surface temperature has been taken as the initial value, to give the largest possible heat transfer coefficient. The Biot numbers are

$$Bi_1 = \frac{h_r L_{c1}}{k} = \frac{6.2 \text{ W/m}^2 \cdot \text{K} \times 0.002 \text{ m}}{120 \text{ W/m} \cdot \text{K}} = 1.0 \times 10^{-4}$$ <

$$Bi_2 = \frac{h_r L_{c2}}{k} = \frac{6.2 \text{ W/m}^2 \cdot \text{K} \times 0.006 \text{ m}}{120 \text{ W/m} \cdot \text{K}} = 3.1 \times 10^{-4}$$ <

The lumped capacitance approximation is valid according to either definition. <

(f) The characteristic lengths are

$$L_{c1} = \frac{V}{A_s} = \frac{\pi D^2 L / 4}{\pi D L} = \frac{D}{4} = 5 \text{ mm}$$ <

$$L_{c2} = \text{Maximum center to surface distance} = D/2 = 10 \text{ mm}$$ <

We are not told the convection heat transfer coefficient, but we do know the fluid temperature and the temperature of the rod initially and at t = 225 s. If we assume that the lumped capacitance approximation is valid, we can determine the heat transfer coefficient from Equation 5.5:

$$h = \frac{\rho V c}{A_s t} \ln\left(\frac{\theta_i}{\theta}\right) = \frac{\rho D c}{4t} \ln\left(\frac{T_i - T_\infty}{T - T_\infty}\right)$$
$$= \frac{2300 \text{ kg/m}^3 \times 0.020 \text{ m} \times 1750 \text{ J/kg} \cdot \text{K}}{4 \times 225 \text{ s}} \ln\left(\frac{200°\text{C} - 20°\text{C}}{100°\text{C} - 20°\text{C}}\right) = 72.5 \text{ W/m}^2 \cdot \text{K}$$

The resulting Biot numbers are:

$$Bi_1 = \frac{h L_{c1}}{k} = \frac{72.5 \text{ W/m}^2 \cdot \text{K} \times 0.005 \text{ m}}{16 \text{ W/m} \cdot \text{K}} = 0.023$$ <

$$Bi_2 = \frac{h L_{c2}}{k} = \frac{72.5 \text{ W/m}^2 \cdot \text{K} \times 0.01 \text{ m}}{16 \text{ W/m} \cdot \text{K}} = 0.045$$ <

The lumped capacitance approximation is valid according to either definition. <
This also means that it was appropriate to use the lumped capacitance approximation to calculate h.

Continued…

PROBLEM 5.5 (Cont.)

(g) With the diameter increased by a factor of ten, so are the characteristic lengths:

$$L_{c1} = \frac{V}{A_s} = \frac{\pi D^2 L/4}{\pi DL} = \frac{D}{4} = 50 \text{ mm}$$ <

$$L_{c2} = \text{Maximum center to surface distance} = D/2 = 100 \text{ mm}$$ <

Once again, we assume that the lumped capacitance approximation is valid to calculate the heat transfer coefficient according to

$$h = \frac{\rho Vc}{A_s t}\ln\left(\frac{\theta_i}{\theta}\right) = \frac{\rho Dc}{4t}\ln\left(\frac{T_i - T_\infty}{T - T_\infty}\right)$$
$$= \frac{2300 \text{ kg/m}^3 \times 0.20 \text{ m} \times 1750 \text{ J/kg}\cdot\text{K}}{4 \times 225 \text{ s}}\ln\left(\frac{200°\text{C} - 20°\text{C}}{100°\text{C} - 20°\text{C}}\right) = 725 \text{ W/m}^2\cdot\text{K}$$

The resulting Biot numbers are:

$$Bi_1 = \frac{hL_{c1}}{k} = \frac{725 \text{ W/m}^2\cdot\text{K} \times 0.05 \text{ m}}{16 \text{ W/m}\cdot\text{K}} = 2.3$$ <

$$Bi_2 = \frac{hL_{c2}}{k} = \frac{725 \text{ W/m}^2\cdot\text{K} \times 0.1 \text{ m}}{16 \text{ W/m}\cdot\text{K}} = 4.5$$ <

The lumped capacitance approximation is *not* valid according to either definition. <
This means that the calculated value of h is incorrect, therefore the above values of the Biot number are incorrect. However, we can still conclude that the Bi number is too large for lumped capacitance to be valid by the following reasoning. If the lumped capacitance approximation were valid, then the calculated h would be correct, and its value would be small enough to result in $Bi < 0.1$. Since the calculated Biot number does not satisfy the criterion to use the lumped capacitance approximation, the initial assumption that the lumped capacitance method is valid must have been false.

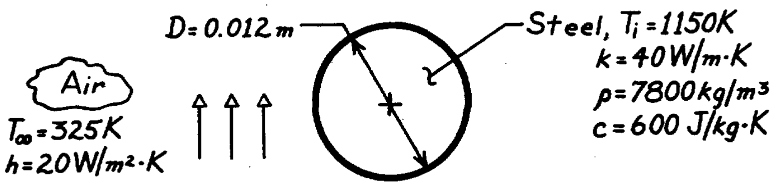
COMMENTS: (1) The determination of whether or not the lumped capacitance approximation can be used is, to some degree, dependent on how much precision is required in a given application. If the Biot number is close to 0.1 and good precision is required, the spatial variation of the temperature should be accounted for. If the geometry is simple, the analytical solutions presented in the text may be appropriate. For complex geometries, a numerical solution is often required, using the finite difference or finite element method. (2) In Case (d), the type of stainless steel is inferred from knowledge of its density. The variation of k among the four stainless steels listed in Table A.1 is on the order of 10%. If the object temperature varies significantly with time, the thermal conductivity may vary by more than 10% as a result. In that case, evaluating k at an appropriate average temperature is at least as important as distinguishing the type of stainless steel.

PROBLEM 5.6

KNOWN: Diameter and initial temperature of steel balls cooling in air.

FIND: Time required to cool to a prescribed temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible radiation effects, (2) Constant properties.

ANALYSIS: Applying Eq. 5.10 to a sphere ($L_c = r_o/3$),

$$Bi = \frac{hL_c}{k} = \frac{h(r_o/3)}{k} = \frac{20\ W/m^2 \cdot K\ (0.002m)}{40\ W/m \cdot K} = 0.001.$$

Hence, the temperature of the steel remains approximately uniform during the cooling process, and the lumped capacitance method may be used. From Eqs. 5.4 and 5.5,

$$t = \frac{\rho V c_p}{hA_s} \ln\frac{T_i - T_\infty}{T - T_\infty} = \frac{\rho\left(\pi D^3/6\right)c_p}{h\pi\ D^2} \ln\frac{T_i - T_\infty}{T - T_\infty}$$

$$t = \frac{7800 kg/m^3 (0.012m) 600 J/kg \cdot K}{6 \times 20\ W/m^2 \cdot K} \ln\frac{1150 - 325}{400 - 325}$$

$$t = 1122\ s\ = 0.312h$$ <

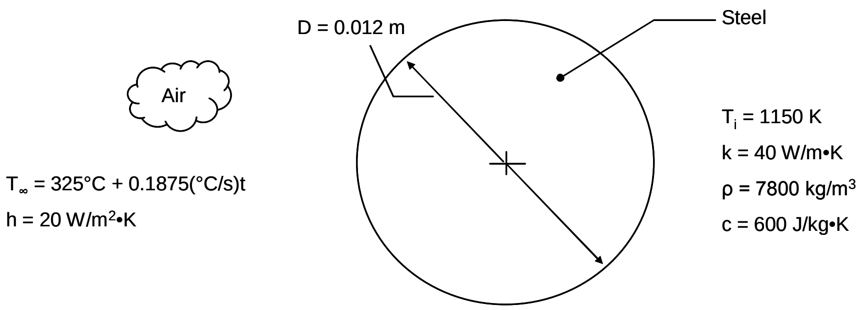
COMMENTS: Due to the large value of T_i, radiation effects are likely to be significant during the early portion of the transient. The effect is to shorten the cooling time.

PROBLEM 5.7

KNOWN: Diameter and initial temperature of steel balls in air. Expression for the air temperature versus time.

FIND: (a) Expression for the sphere temperature, T(t), (b) Graph of T(t) and explanation of special features.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Negligible radiation heat transfer.

PROPERTIES: Given: k = 40 W/m·K, ρ = 7800 kg/m^3, c = 600 J/kg·K.

ANALYSIS:

(a) Applying Equation 5.10 to a sphere ($L_c = r_o/3$),

$$B_i = \frac{hL_c}{k} = \frac{h(r_o/3)}{k} = \frac{20\ \text{W/m}^2\cdot\text{K}\ (0.002\ \text{m})}{40\ \text{W/m}\cdot\text{K}} = 0.001$$

Hence, the temperature of the steel sphere remains approximately uniform during the cooling process. Equation 5.2 is written, with $T_\infty = T_o + at$, as

$$-hA_s(T - T_o - at) = \rho\forall c\frac{dT}{dt}$$

Letting $\theta = T - T_o$, $dT = d\theta$ and $-hA_s(\theta - at) = \rho\forall c\dfrac{d\theta}{dt}$ or $\dfrac{d\theta}{dt} = -C(\theta - at)$ where $C = \dfrac{hA_s}{\rho\forall c}$

The solution may be written as the sum of the homogeneous and particular solutions,

$$\theta = \theta_h + \theta_p \quad \text{where} \quad \theta_h = c_1\exp(-Ct).$$

Assuming $\theta_p = f(t)\theta_h$, we substitute into the differential equation to find

$$\frac{df}{dt} = Cat\exp(Ct)/c_1 \text{ from which } f = a(t - 1/C)\exp(Ct)/c_1.$$

Thus, the complete solution is

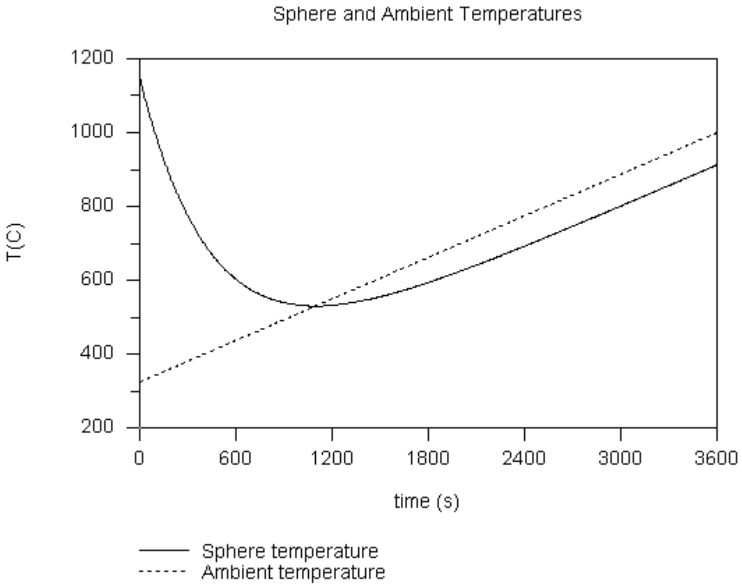
$$\theta = c_1\exp(-Ct) + a(t - 1/C)$$ and applying the initial condition we find

$$T = (T_i - T_o + a/C)\exp(-Ct) + a(t - 1/C) + T_o$$ <

Continued…

PROBLEM 5.7 (Cont.)

(b) The ambient and sphere temperatures for $0 \leq t \leq 3600$ s are shown in the plot below.



Note that:

(1) For small times ($t \leq 600$s) the sphere temperature decreases rapidly,

(2) at $t \approx 1100$ s, $T = T_\infty$ and, from Equation 5.2, $dT/dt = 0$,

(3) at $t \geq 1100$ s, $T < T_\infty$,

(4) at large time, $T - T_\infty$ and dT/dt are constant.

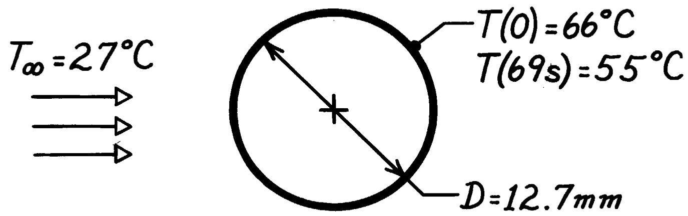
COMMENTS: Unless the air environment of Problem 5.6 is cooled, the air temperature will increase in temperature as energy is transferred from the balls. However, the actual air temperature versus time may not be linear.

PROBLEM 5.8

KNOWN: The temperature-time history of a pure copper sphere in an air stream.

FIND: The heat transfer coefficient between the sphere and the air stream.

SCHEMATIC:



ASSUMPTIONS: (1) Temperature of sphere is spatially uniform, (2) Negligible radiation exchange, (3) Constant properties.

PROPERTIES: *Table A-1*, Pure copper (333K): ρ = 8933 kg/m^3, c_p = 389 J/kg·K, k = 398 W/m·K.

ANALYSIS: The time-temperature history is given by Eq. 5.6 with Eq. 5.7.

$$\frac{\theta(t)}{\theta_i} = \exp\left(-\frac{t}{R_t C_t}\right) \qquad \text{where} \qquad R_t = \frac{1}{hA_s} \qquad A_s = \pi D^2$$

$$C_t = \rho V c_p \qquad V = \frac{\pi D^3}{6}$$

$$\theta = T - T_\infty.$$

Recognize that when t = 69s,

$$\frac{\theta(t)}{\theta_i} = \frac{(55-27)^\circ C}{(66-27)^\circ C} = 0.718 = \exp\left(-\frac{t}{\tau_t}\right) = \exp\left(-\frac{69s}{\tau_t}\right)$$

and solving for τ_t find

$$\tau_t = 208s.$$

Hence,

$$h = \frac{\rho V c_p}{A_s \tau_t} = \frac{8933\ kg/m^3 \left(\pi 0.0127^3\ m^3/6\right) 389 J/kg\cdot K}{\pi 0.0127^2 m^2 \times 208s}$$

$$h = 35.3\ W/m^2 \cdot K.$$ <

COMMENTS: Note that with $L_c = D_o/6$,

$$Bi = \frac{hL_c}{k} = 35.3\ W/m^2 \cdot K \times \frac{0.0127}{6} m/398\ W/m\cdot K = 1.88\times 10^{-4}.$$

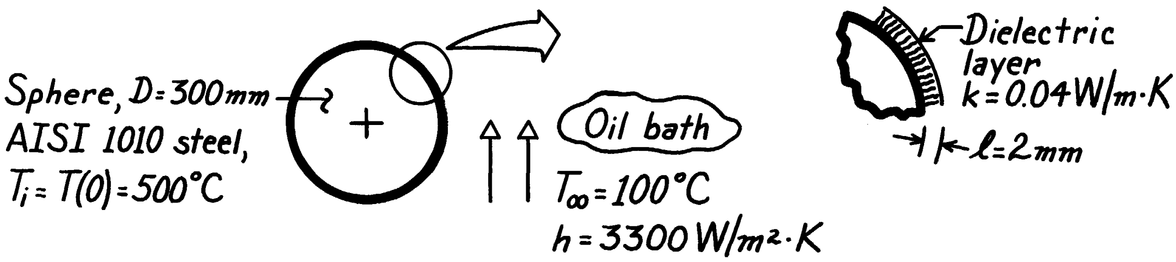
Hence, Bi < 0.1 and the spatially isothermal assumption is reasonable.

PROBLEM 5.9

KNOWN: Solid steel sphere (AISI 1010), coated with dielectric layer of prescribed thickness and thermal conductivity. Coated sphere, initially at uniform temperature, is suddenly quenched in an oil bath.

FIND: Time required for sphere to reach 140°C.

SCHEMATIC:



PROPERTIES: *Table A-1*, AISI 1010 Steel $\left(\overline{T} = [500+140]^\circ C/2 = 320^\circ C \approx 600K\right)$:

$\rho = 7832\ kg/m^3,\ c = 559\ J/kg \cdot K,\ k = 48.8\ W/m \cdot K.$

ASSUMPTIONS: (1) Steel sphere is space-wise isothermal, (2) Dielectric layer has negligible thermal capacitance compared to steel sphere, (3) Layer is thin compared to radius of sphere, (4) Constant properties, (5) Neglect contact resistance between steel and coating.

ANALYSIS: The thermal resistance to heat transfer from the sphere is due to the dielectric layer and the convection coefficient. That is,

$$R'' = \frac{\ell}{k} + \frac{1}{h} = \frac{0.002m}{0.04\ W/m \cdot K} + \frac{1}{3300\ W/m^2 \cdot K} = (0.050 + 0.0003) = 0.0503 \frac{m^2 \cdot K}{W},$$

or in terms of an overall coefficient, $U = 1/R'' = 19.88\ W/m^2 \cdot K$. The effective Biot number is

$$Bi_e = \frac{UL_c}{k} = \frac{U(r_o/3)}{k} = \frac{19.88\ W/m^2 \cdot K \times (0.300/6)m}{48.8\ W/m \cdot K} = 0.0204$$

where the characteristic length is $L_c = r_o/3$ for the sphere. Since $Bi_e < 0.1$, the lumped capacitance approach is applicable. Hence, Eq. 5.5 is appropriate with h replaced by U,

$$t = \frac{\rho c}{U}\left[\frac{V}{A_s}\right] \ln\frac{\theta_i}{\theta_o} = \frac{\rho c}{U}\left[\frac{V}{A_s}\right] \ln\frac{T(0) - T_\infty}{T(t) - T_\infty}.$$

Substituting numerical values with $(V/A_s) = r_o/3 = D/6$,

$$t = \frac{7832\ kg/m^3 \times 559\ J/kg \cdot K}{19.88\ W/m^2 \cdot K}\left[\frac{0.300m}{6}\right] \ln\frac{(500-100)^\circ C}{(140-100)^\circ C}$$

$$t = 25{,}358s = 7.04h.$$ <

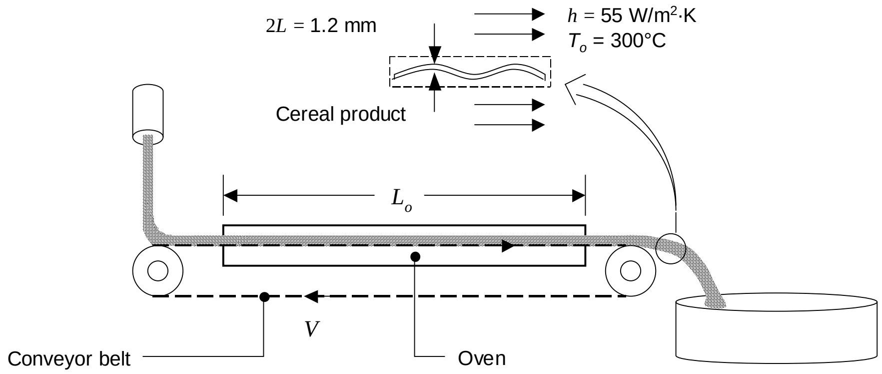
COMMENTS: (1) Note from calculation of R'' that the resistance of the dielectric layer dominates and therefore nearly all the temperature drop occurs across the layer.

PROBLEM 5.10

KNOWN: Thickness and properties of flaked food product. Conveyor length. Initial flake temperature. Ambient temperature and convection heat transfer coefficient. Final product temperature.

FIND: Required conveyor velocities for thick and thin flakes.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties. (2) Lumped capacitance behavior. (3) Negligible radiation heat transfer. (4) Negligible moisture evaporation from product. (5) Negligible conduction between flake and conveyor belt.

PROPERTIES: Flake: ρ = 700 kg/m^3, c_p = 2400 J/kg·K, and k = 0.34 W/m·K.

ANALYSIS: The Biot number is

$$Bi = \frac{hL}{k} = \frac{55\ \text{W/m}^2 \cdot \text{K} \times 0.6 \times 10^{-3}\ \text{m}}{0.34\ \text{W/m} \cdot \text{K}} = 0.098$$

Hence the lumped capacitance assumption is valid. The required heating time is

$$t = \frac{\rho Vc}{hA_s} \ln\frac{\theta_i}{\theta} = \frac{\rho Lc}{h} \ln\frac{\theta_i}{\theta} = \frac{700\ \text{kg/m}^3 \times 0.6 \times 10^{-3}\ \text{m} \times 2400\ \text{J/kg} \cdot \text{K}}{55\ \text{W/m}^2 \cdot \text{K}} \ln\frac{(20-300)}{(220-300)} = 23\ \text{s}$$

Therefore the required conveyor velocity is $V = L_o/t$ = 3m/23s = 0.13 m/s . <

If the flake thickness is reduced to 2L = 1 mm, the lumped capacitance approximation remains valid and the heating time is 19 s. The associated conveyor velocity is 0.16 m/s. <

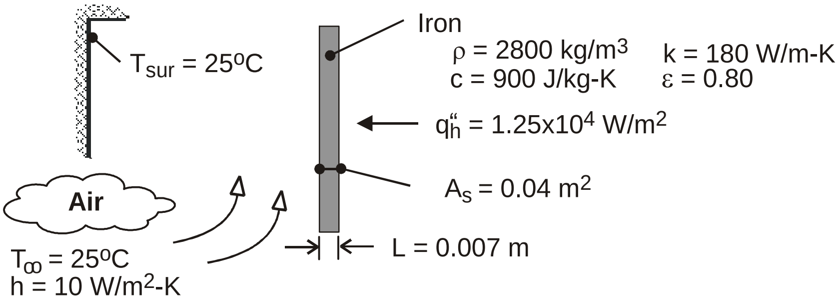
COMMENTS: (1) Assuming large surroundings, a representative value of the radiation heat transfer coefficient is $h_r = \sigma\left(T_i + T_o\right)\left(T_i^2 + T_o^2\right) = 5.67 \times 10^{-8}\ \text{W/m}^2 \cdot \text{K}^4 \left(293 + 573\right)\left(293^2 + 573^2\right)\text{K}^4 = 20.3$ W/m^2·K. Radiation heat transfer would be significant and would serve to increase the product heating rate, increasing the allowable conveyor belt speed. (2) The food product is likely to enter the oven in a moist state. Additional thermal energy would be required to remove the moisture during heating, reducing the rate at which the product temperature increases. (3) The effects noted in Comments 1 and 2 would tend to offset each other. A detailed analysis would be required to assess the impact of radiation and evaporation on the required conveyor velocity.

PROBLEM 5.11

KNOWN: Thickness, surface area, and properties of iron base plate. Heat flux at inner surface. Temperature of surroundings. Temperature and convection coefficient of air at outer surface.

FIND: Time required for plate to reach a temperature of 135°C. Operating efficiency of iron.

SCHEMATIC:



ASSUMPTIONS: (1) Radiation exchange is between a small surface and large surroundings, (2) Convection coefficient is independent of time, (3) Constant properties, (4) Iron is initially at room temperature ($T_i = T_\infty$).

ANALYSIS: Biot numbers may be based on convection heat transfer and/or the maximum heat transfer by radiation, which would occur when the plate reaches the desired temperature (T = 135°C). From Eq. (1.9) the corresponding radiation transfer coefficient is $h_r = \varepsilon\sigma(T + T_{sur})\left(T^2 + T_{sur}^2\right)$ = 0.8 × 5.67 × 10^{-8} $W/m^2 \cdot K^4$ (408 + 298) K (408^2 + 298^2) K^2 = 8.2 $W/m^2 \cdot K$. Hence,

$$Bi = \frac{hL}{k} = \frac{10\,W/m^2 \cdot K(0.007m)}{180\,W/m \cdot K} = 3.9 \times 10^{-4}$$

$$Bi_r = \frac{h_r L}{k} = \frac{8.2\,W/m^2 \cdot K(0.007m)}{180\,W/m \cdot K} = 3.2 \times 10^{-4}$$

With convection and radiation considered independently or collectively, Bi, Bi_r, Bi + Bi_r << 1 and the lumped capacitance analysis may be used.

The energy balance, Eq. (5.15), associated with Figure 5.5 may be applied to this problem. With $\dot{E}g = 0$, the integral form of the equation is

$$T - T_i = \frac{A_s}{\rho Vc}\int_0^t \left[q''_h - h\left(T - T_\infty\right) - \varepsilon\sigma\left(T^4 - T_{sur}^4\right)\right]dt$$

Integrating numerically, we obtain, for T = 135°C,

$$t = 168 \text{ s}$$ <

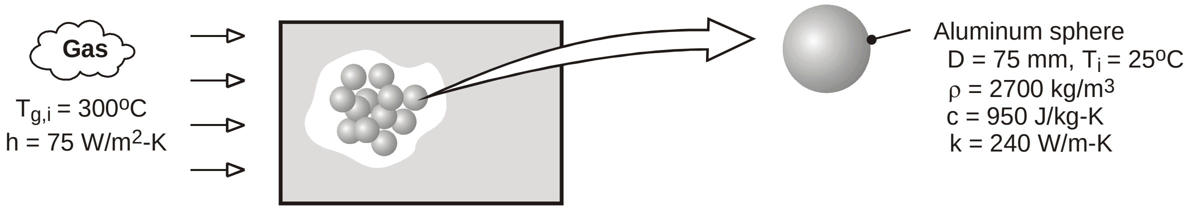
COMMENTS: Note that, if heat transfer is by natural convection, h, like h_r, will vary during the process from a value of 0 at t = 0 to a maximum at t = 168s.

PROBLEM 5.12

KNOWN: Diameter, density, specific heat and thermal conductivity of aluminum spheres used in packed bed thermal energy storage system. Convection coefficient and inlet gas temperature.

FIND: Time required for sphere to acquire 90% of maximum possible thermal energy and the corresponding center temperature. Potential advantage of using copper in lieu of aluminum.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat transfer to or from a sphere by radiation or conduction due to contact with other spheres, (2) Constant properties.

ANALYSIS: To determine whether a lumped capacitance analysis can be used, first compute Bi = $h(r_o/3)/k = 75\ W/m^2\cdot K\ (0.025m)/150\ W/m\cdot K = 0.013 < 0.1$. Hence, the lumped capacitance approximation may be made, and a uniform temperature may be assumed to exist in the sphere at any time. From Eq. 5.8a, achievement of 90% of the maximum possible thermal energy storage corresponds to

$$\frac{Q}{\rho c V \theta_i} = 0.90 = 1 - \exp\left(-t/\tau_t\right)$$

where $\tau_t = \rho Vc/hA_s = \rho Dc/6h = 2700\,kg/m^3 \times 0.075m \times 950\,J/kg\cdot K/6 \times 75\,W/m^2\cdot K = 427s.$ Hence,

$$t = -\tau_t \ln\left(0.1\right) = 427s \times 2.30 = 984s$$ <

From Eq. (5.6), the corresponding temperature at any location in the sphere is

$$T\left(984s\right) = T_{g,i} + \left(T_i - T_{g,i}\right)\exp\left(-6ht/\rho Dc\right)$$

$$T\left(984s\right) = 300°C - 275°C\ \exp\left(-6 \times 75\,W/m^2\cdot K \times 984s/2700\,kg/m^3 \times 0.075m \times 950\,J/kg\cdot K\right)$$

$$T\left(984\right)s = 272.5°C$$ <

Obtaining the density and specific heat of copper from Table A-1, we see that $(\rho c)_{Cu} \approx 8900\ kg/m^3 \times 400\ J/kg\cdot K = 3.56 \times 10^6\ J/m^3\cdot K > (\rho c)_{Al} = 2.57 \times 10^6\ J/m^3\cdot K$. Hence, for an equivalent sphere diameter, the copper can store approximately 38% more thermal energy than the aluminum.

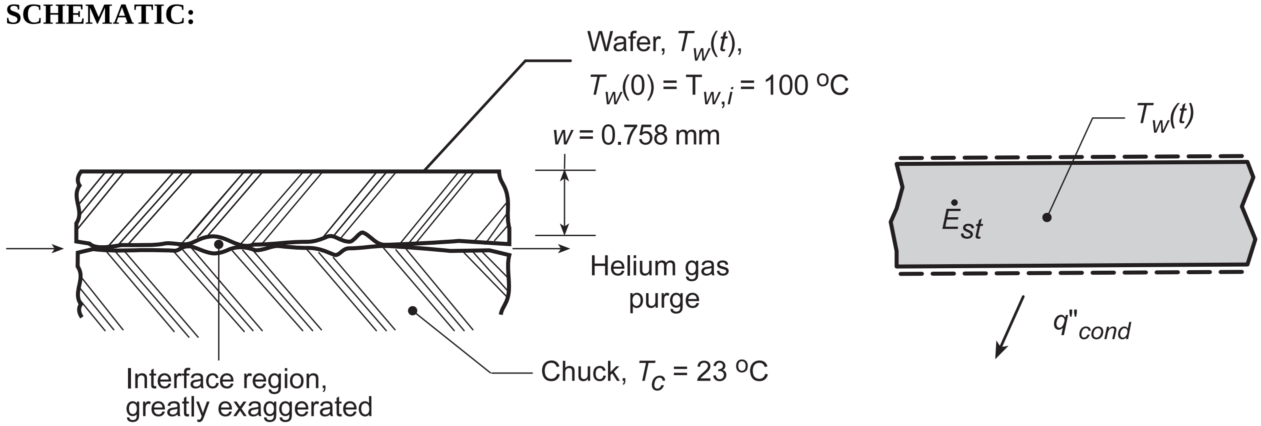
COMMENTS: Before the packed bed becomes fully charged, the temperature of the gas decreases as it passes through the bed. Hence, the time required for a sphere to reach a prescribed state of thermal energy storage increases with increasing distance from the bed inlet.

PROBLEM 5.13

KNOWN: Wafer, initially at 100°C, is suddenly placed on a chuck with uniform and constant temperature, 23°C. Wafer temperature after 15 seconds is observed as 33°C.

FIND: (a) Contact resistance, R''_{tc}, between interface of wafer and chuck through which helium slowly flows, and (b) Whether R''_{tc} will change if air, rather than helium, is the purge gas.

SCHEMATIC:



PROPERTIES: Wafer (silicon, typical values): $\rho = 2700\ kg/m^3$, c = 875 J/kg·K, k = 177 W/m·K.

ASSUMPTIONS: (1) Wafer behaves as a space-wise isothermal object, (2) Negligible heat transfer from wafer top surface, (3) Chuck remains at uniform temperature, (4) Thermal resistance across the interface is due to conduction effects, not convective, (5) Constant properties.

ANALYSIS: (a) Perform an energy balance on the wafer as shown in the Schematic.

$$\dot{E}''_{in} - \dot{E}''_{out} + \dot{E}_g = \dot{E}_{st} \qquad (1)$$

$$-q''_{cond} = \dot{E}''_{st} \qquad (2)$$

$$-\frac{T_w(t) - T_c}{R''_{tc}} = \rho w c \frac{dT_w}{dt} \qquad (3)$$

Separate and integrate Eq. (3)

$$-\int_0^t \frac{dt}{\rho w c R''_{tc}} = \int_{T_{wi}}^{T_w} \frac{dT_w}{T_w - T_c} \qquad (4) \qquad\qquad \frac{T_w(t) - T_c}{T_{wi} - T_c} = \exp\left[-\frac{t}{\rho w c R''_{tc}}\right] \qquad (5)$$

Substituting numerical values for $T_w(15s) = 33°C$,

$$\frac{(33-23)^\circ C}{(100-23)^\circ C} = \exp\left[-\frac{15\,s}{2700\,kg/m^3 \times 0.758\times10^{-3}\,m \times 875\,J/kg\cdot K \times R''_{tc}}\right] \qquad (6)$$

$$R''_{tc} = 0.0041\,m^2\cdot K/W$$ <

(b) R''_{tc} will increase since $k_{air} < k_{helium}$. See Table A.4.

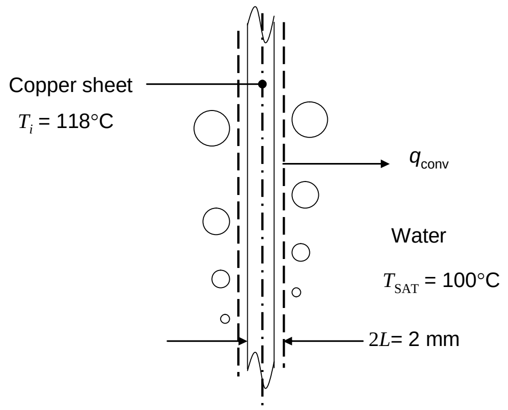
COMMENTS: Note that $Bi = R_{int}/R_{ext} = (w/k)/R''_{tc} = 0.001$. Hence the spacewise isothermal assumption is reasonable.

PROBLEM 5.14

KNOWN: Thickness and initial temperature of copper sheet. Dependence of the convection heat transfer coefficient on sheet temperature.

FIND: Time required to reach sheet temperature of $\overline{T}$ = 102°C.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties. (2) Lumped capacitance behavior.

PROPERTIES: Table A.1, copper (T = 383 K): ρ = 8933 kg/m^3, c = 394 J/kg·K, and k = 394 W/m·K.

ANALYSIS: Since $h = 1010\ \text{W/m}^2\cdot\text{K}^3(T - T_{sat})^2$ the values of C and n in Equation 5.26 are 1010 W/m^2·K^3 and 2, respectively. Equation 5.27 becomes

$$\frac{dT}{dt} = -\frac{CA_{s,c}(T - T_{sat})^3}{\rho Vc} = -\frac{C(T - T_{sat})^3}{L\rho c}$$

or

$$\int_{T_i}^{T}(T - T_{sat})^{-3}dT = -\int_0^t \frac{C}{L\rho c}dt$$

so that

$$\frac{L\rho c}{C}\left[\frac{(T - T_{sat})^{-2}}{2} - \frac{(T_i - T_{sat})^{-2}}{2}\right] = t$$

Substituting values,

$$t = \frac{1\times10^{-3}\ \text{m}\times8933\ \text{kg/m}^3\times394\ \text{J/kg}\cdot\text{K}}{1010\ \text{W/m}^2\cdot\text{K}^3}\left[\frac{(T - 100°\text{C})^{-2}}{2} - \frac{(118°\text{C} - 100°\text{C})^{-2}}{2}\right] \quad (1)$$

For T = 102°C, t = 0.43 s <

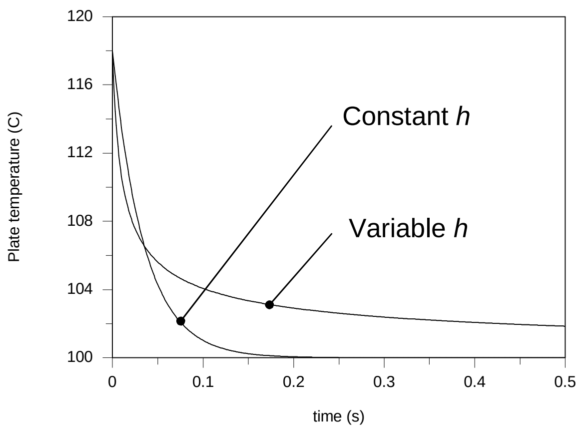
Continued...

PROBLEM 5.14 (Cont.)

The heat transfer coefficient at $\overline{T}$ = 110°C is $\overline{h}$ = 1010 W/m^2·K^3×(10 K)^2 = 101,000 W/m^2·K. Hence, for the case where the heat transfer coefficient is constant Equation 5.6 becomes

$$t = \frac{\rho Lc}{\overline{h}} \ln\left[\frac{T_i - T_{sat}}{T - T_{sat}}\right] = \frac{8933 \text{ kg/m}^3 \times 1\times10^{-3} \text{ m} \times 394 \text{ J/kg}\cdot\text{K}}{101{,}000 \text{ W/m}^2\cdot\text{K}} \ln\left[\frac{118°\text{C} - 100°\text{C}}{T - 100°\text{C}}\right] \quad (2)$$

Equations (1) and (2) may be solved for time-dependence of the plate temperature to yield



The convection heat transfer coefficient is initially relatively high and decays as the temperature difference between the plate and the water decreases. If the convection heat transfer coefficient is evaluated at the average plate temperature, the heat transfer coefficient is initially under-predicted, leading to a slower plate cooling rate at early times. However, the convection coefficient is over-predicted at later times, leading to an unrealistic high cooling rate as evident in the graph.

COMMENTS: (1) The time could also be calculated by solving Equation 5.28.

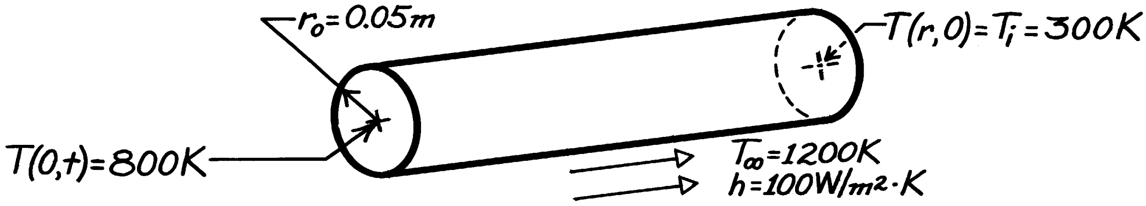
(2) The Biot number based upon the average heat transfer coefficient is $Bi = \frac{\overline{h}L}{k} = \frac{101{,}000\text{W/m}^2\cdot\text{K}\times 1\times10^{-3} \text{ m}}{394 \text{ W/m}\cdot\text{K}} = 0.25$. The lumped capacitance approximation is not valid at early times. However, the trends evident in the comparison of the variable versus constant heat transfer coefficients would also occur if spatial temperature gradients were accounted for.

PROBLEM 5.15

KNOWN: Diameter and radial temperature of AISI 1010 carbon steel shaft. Convection coefficient and temperature of furnace gases.

FIND: Time required for shaft centerline to reach a prescribed temperature.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, radial conduction, (2) Constant properties.

PROPERTIES: AISI 1010 carbon steel, *Table A.1* $(\bar{T} = 550\ K)$: $\rho = 7832\ kg/m^3$, k = 51.2 W/m·K, c = 541 J/kg·K, $\alpha = 1.21\times10^{-5}\ m^2/s$.

ANALYSIS: The Biot number is

$$Bi = \frac{hr_o/2}{k} = \frac{100\ W/m^2 \cdot K(0.05\ m/2)}{51.2\ W/m \cdot K} = 0.0488.$$

Hence, the lumped capacitance method can be applied. From Equation 5.6,

$$\frac{T - T_\infty}{T_i - T_\infty} = \exp\left[-\left(\frac{hAs}{\rho Vc}\right)t\right] = \exp\left[-\frac{4h}{\rho cD}t\right]$$

$$\ln\left(\frac{800-1200}{300-1200}\right) = -0.811 = -\frac{4\times100\ W/m^2 \cdot K}{7832\ kg/m^3(541\ J/kg \cdot K)0.1\ m}t$$

$$t = 859\ s. \qquad <$$

COMMENTS: To check the validity of the foregoing result, use the one-term approximation to the series solution. From Equation 5.52c,

$$\frac{T_o - T_\infty}{T_i - T_\infty} = \frac{-400}{-900} = 0.444 = C_1 \exp\left(-\varsigma_1^2 Fo\right)$$

For Bi = hr_o/k = 0.0976, Table 5.1 yields ς_1 = 0.436 and C_1 = 1.024. Hence

$$\frac{-(0.436)^2\left(1.2\times10^{-5}\ m^2/s\right)}{(0.05\ m)^2}t = \ln(0.434) = -0.835$$

$$t = 915\ s.$$

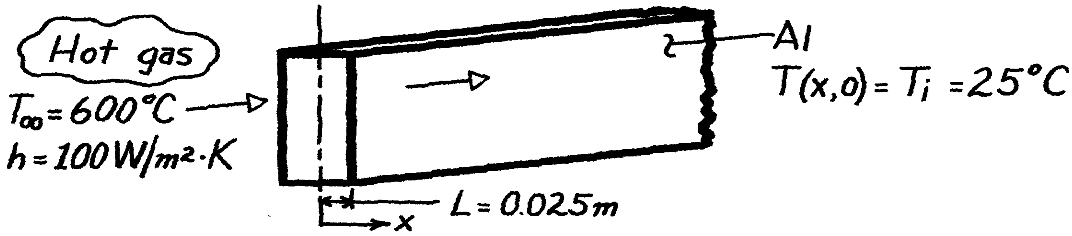
The results agree to within 6%. The lumped capacitance method underestimates the actual time, since the response at the centerline lags that at any other location in the shaft.

PROBLEM 5.16

KNOWN: Configuration, initial temperature and charging conditions of a thermal energy storage unit.

FIND: Time required to achieve 75% of maximum possible energy storage. Temperature of storage medium at this time.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Negligible radiation exchange with surroundings.

PROPERTIES: *Table A-1*, Aluminum, pure $\left(\overline{T} \approx 600K = 327^\circ C\right)$: k = 231 W/m·K, c = 1033 J/kg·K, ρ = 2702 kg/m^3.

ANALYSIS: Recognizing the characteristic length is the half thickness, find

$$Bi = \frac{hL}{k} = \frac{100\ W/m^2 \cdot K \times 0.025m}{231\ W/m \cdot K} = 0.011.$$

Hence, the lumped capacitance method may be used. From Eq. 5.8,

$$Q = (\rho Vc)\theta_i \left[1 - \exp(-t/\tau_t)\right] = -\Delta E_{st} \qquad (1)$$

$$-\Delta E_{st,max} = (\rho Vc)\theta_i. \qquad (2)$$

Dividing Eq. (1) by (2),

$$\Delta E_{st} / \Delta E_{st,max} = 1 - \exp(-t/\tau_{th}) = 0.75.$$

Solving for $\tau_{th} = \frac{\rho Vc}{hA_s} = \frac{\rho Lc}{h} = \frac{2702\ kg/m^3 \times 0.025m \times 1033\ J/kg \cdot K}{100\ W/m^2 \cdot K} = 698s.$

Hence, the required time is

$$-\exp(-t/698s) = -0.25 \qquad or \qquad t = 968s. \qquad <$$

From Eq. 5.6,

$$\frac{T - T_\infty}{T_i - T_\infty} = \exp(-t/\tau_{th})$$

$$T = T_\infty + (T_i - T_\infty)\exp(-t/\tau_{th}) = 600^\circ C - (575^\circ C)\exp(-968/698)$$

$$T = 456^\circ C. \qquad <$$

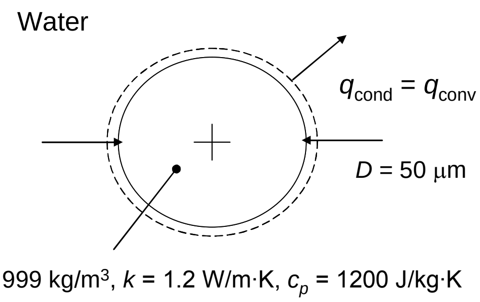
COMMENTS: For the prescribed temperatures, the property temperature dependence is significant and some error is incurred by assuming constant properties. However, selecting properties at 600K was reasonable for this estimate.

PROBLEM 5.17

KNOWN: Diameter and properties of neutrally-buoyant spherical particles.

FIND: Time constant of the particles.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties. (2) Infinite medium. (3) Lumped capacitance behavior.

PROPERTIES: Particle: ρ = 999 kg/m^3, k_p = 1.2 W/m·K, and c_p = 1200 J/kg·K. Table A.6 water (T = 300 K): k = 0.613 W/m·K.

ANALYSIS: Treating heat transfer between the particle and water as conduction, we may use the shape factor corresponding to Case1 of Table 4.1 with $z \to \infty$. Hence

$$S = 2\pi D \tag{1}$$

The surface energy balance may be expressed as

$$q = Sk(T - T_\infty) = hA(T - T_\infty) = h\pi D^2 (T - T_\infty)$$

where h is an effective heat transfer coefficient from which

$$h = \frac{Sk}{\pi D^2} = 2\frac{k}{D} \tag{2}$$

The thermal time constant is

$$\tau_t = \left(\frac{1}{hA_s}\right)\left(\rho V c_p\right) \tag{3}$$

Combining Equations (1) through (3) yields

$$\tau_t = \frac{\rho c D^2}{12k} = \frac{999 \text{ kg/m}^3 \times 1200 \text{ J/kg}\cdot\text{K} \times \left(50 \times 10^{-6} \text{ m}\right)^2}{12 \times 0.613 \text{ W/m}\cdot\text{K}} = 407 \times 10^{-6} \text{ s}$$ <

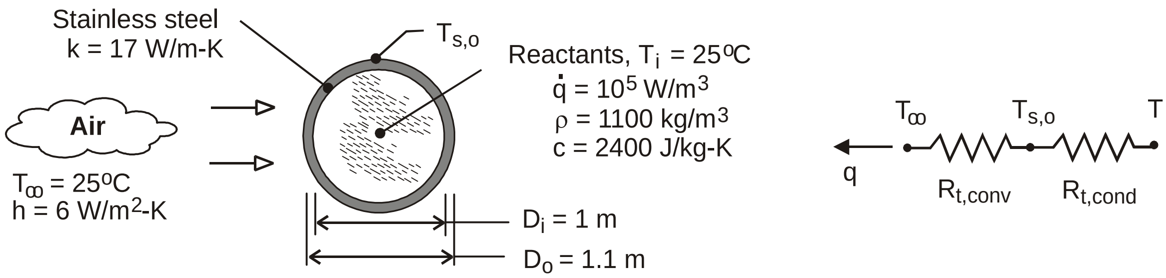
COMMENTS: (1) The Biot number is $Bi = hL_c/k_p = hD/6k_p = k/3k_p$ = 0.613 W/m·K/(3 × 1.2 W/m·K) = 0.17. Lumped capacitance behavior will not exist in the particle and the analysis must be viewed as approximate. (2) Regardless of whether the lumped capacitance approximation is valid, the thermal time constant is relatively small. Hence an assumption that the particle temperature is the same as that of the surrounding water may be valid.

PROBLEM 5.18

KNOWN: Inner diameter and wall thickness of a spherical, stainless steel vessel. Initial temperature, density, specific heat and heat generation rate of reactants in vessel. Convection conditions at outer surface of vessel.

FIND: (a) Temperature of reactants after one hour of reaction time, (b) Effect of convection coefficient on thermal response of reactants.

SCHEMATIC:



ASSUMPTIONS: (1) Temperature of well stirred reactants is uniform at any time and is equal to inner surface temperature of vessel ($T = T_{s,i}$), (2) Thermal capacitance of vessel may be neglected, (3) Negligible radiation exchange with surroundings, (4) Constant properties.

ANALYSIS: (a) Transient thermal conditions within the reactor may be determined from Eq. (5.25), which reduces to the following form for $T_i - T_\infty = 0$.

$$T = T_\infty + (b/a)\left[1 - \exp(-at)\right]$$

where $a = UA/\rho Vc$ and $b = \dot{E}_g/\rho Vc = \dot{q}/\rho c$. From Eq. (3.19) the product of the overall heat transfer coefficient and the surface area is $UA = (R_{cond} + R_{conv})^{-1}$, where from Eqs. (3.41) and (3.9),

$$R_{t,cond} = \frac{1}{2\pi k}\left(\frac{1}{D_i} - \frac{1}{D_o}\right) = \frac{1}{2\pi(17\,W/m\cdot K)}\left(\frac{1}{1.0m} - \frac{1}{1.1m}\right) = 8.51\times 10^{-4}\,K/W$$

$$R_{t,conv} = \frac{1}{hA_o} = \frac{1}{\left(6\,W/m^2\cdot K\right)\pi(1.1m)^2} = 0.0438\,K/W$$

Hence, UA = 22.4 W/K. It follows that, with $V = \pi D_i^3/6$,

$$a = \frac{UA}{\rho Vc} = \frac{6(22.4\,W/K)}{1100\,kg/m^3 \times \pi(1m)^3\,2400\,J/kg\cdot K} = 1.620\times 10^{-5}s^{-1}$$

$$b = \frac{\dot{q}}{\rho c} = \frac{10^4\,W/m^3}{1100\,kg/m^3 \times 2400\,J/kg\cdot K} = 3.788\times 10^{-3}K/s$$

With (b/a) = 233.8°C and t = 18,000s,

$$T = 25°C + 233.8°C\left[1 - \exp\left(-1.62\times 10^{-5}s^{-1}\times 18,000s\right)\right] = 84.1°C$$ <

Neglecting the thermal capacitance of the vessel wall, the heat rate by conduction through the wall is equal to the heat transfer by convection from the outer surface, and from the thermal circuit, we know that

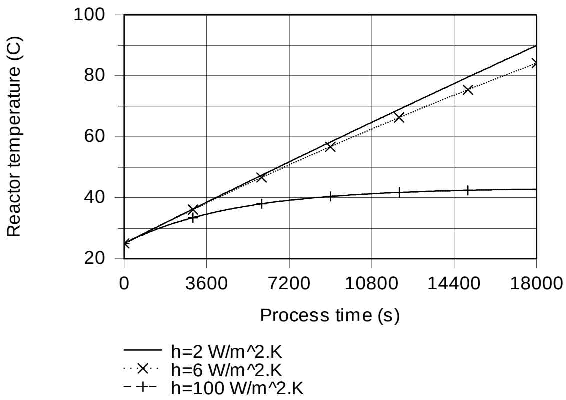
Continued …

PROBLEM 5.18 (Cont.)

$$\frac{T - T_{s,o}}{T_{s,o} - T_\infty} = \frac{R_{t,cond}}{R_{t,conv}} = \frac{8.51\times10^{-4}\,K/W}{0.0438\,K/W} = 0.0194$$

$$T_{s,o} = \frac{T + 0.0194\,T_\infty}{1.0194} = \frac{84.1°C + 0.0194(25°C)}{1.0194} = 83.0°C$$ <

(b) Representative low and high values of h could correspond to 2 $W/m^2 \cdot K$ and 100 $W/m^2 \cdot K$ for free and forced convection, respectively. Calculations based on Eq. (5.25) yield the following temperature histories.



Forced convection is clearly an effective means of reducing the temperature of the reactants and accelerating the approach to steady-state conditions.

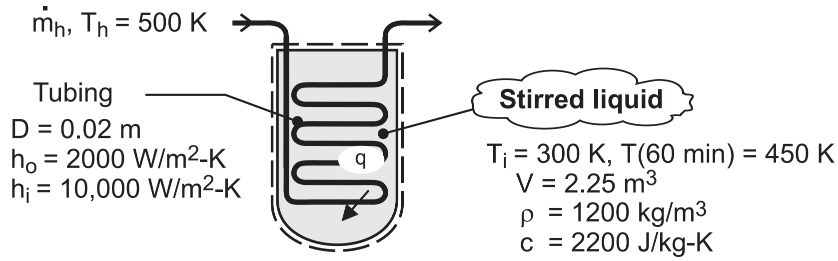
COMMENTS: The validity of neglecting thermal energy storage effects for the vessel may be assessed by contrasting its thermal capacitance with that of the reactants. Selecting values of ρ = 8000 kg/m^3 and c = 475 J/kg·K for stainless steel from Table A-1, the thermal capacitance of the vessel is $C_{t,v} = (\rho Vc)_{st} = 6.57 \times 10^5$ J/K, where $V = (\pi/6)\left(D_o^3 - D_i^3\right)$. With $C_{t,r} = (\rho Vc)_r = 2.64 \times 10^6$ J/K for the reactants, $C_{t,r}/C_{t,v} \approx 4$. Hence, the capacitance of the vessel is not negligible and should be considered in a more refined analysis of the problem.

PROBLEM 5.19

KNOWN: Volume, density and specific heat of chemical in a stirred reactor. Temperature and convection coefficient associated with saturated steam flowing through submerged coil. Tube diameter and outer convection coefficient of coil. Initial and final temperatures of chemical and time span of heating process.

FIND: Required length of submerged tubing. Minimum allowable steam flowrate.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Negligible heat loss from vessel to surroundings, (3) Chemical is isothermal, (4) Negligible work due to stirring, (5) Negligible thermal energy generation (or absorption) due to chemical reactions associated with the batch process, (6) Negligible tube wall conduction resistance, (7) Negligible kinetic energy, potential energy, and flow work changes for steam.

ANALYSIS: Heating of the chemical can be treated as a transient, lumped capacitance problem, wherein heat transfer from the coil is balanced by the increase in thermal energy of the chemical. Hence, conservation of energy yields

$$\frac{dU}{dt} = \rho Vc\frac{dT}{dt} = UA_s\left(T_h - T\right)$$

Integrating, $$\int_{T_i}^{T}\frac{dT}{T_h - T} = \frac{UA_s}{\rho Vc}\int_o^t dt$$

$$-\ln\frac{T_h - T}{T_h - T_i} = \frac{UA_s t}{\rho Vc}$$

$$A_s = -\frac{\rho Vc}{Ut}\ln\frac{T_h - T}{T_h - T_i} \qquad (1)$$

$$U = \left(h_i^{-1} + h_o^{-1}\right)^{-1} = \left[(1/10,000) + (1/2000)\right]^{-1} W/m^2\cdot K$$

$$U = 1670\,W/m^2\cdot K$$

$$A_s = -\frac{\left(1200\,kg/m^3\right)\left(2.25m^3\right)\left(2200\,J/kg\cdot K\right)}{\left(1670\,W/m^2\cdot K\right)\left(3600s\right)}\ln\frac{500-450}{500-300} = 1.37m^2$$

$$L = \frac{A_s}{\pi D} = \frac{1.37m^2}{\pi\left(0.02m\right)} = 21.8m \qquad <$$

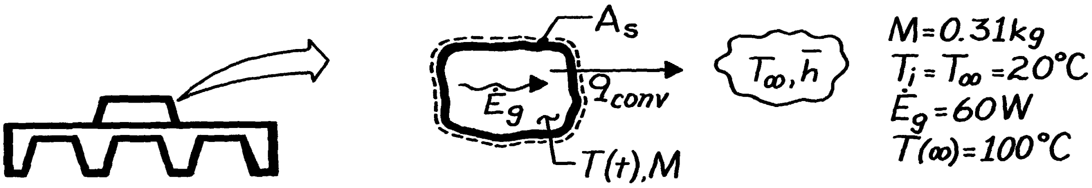
COMMENTS: Eq. (1) could also have been obtained by adapting Eq. (5.5) to the conditions of this problem, with T_∞ and h replaced by T_h and U, respectively.

PROBLEM 5.20

KNOWN: Electronic device on aluminum, finned heat sink modeled as spatially isothermal object with internal generation and convection from its surface.

FIND: (a) Temperature response after device is energized, (b) Temperature rise for prescribed conditions after 5 min.

SCHEMATIC:



ASSUMPTIONS: (1) Spatially isothermal object, (2) Object is primarily aluminum, (3) Initially, object is in equilibrium with surroundings at T_∞.

PROPERTIES: *Table A-1*, Aluminum, pure $\left(\bar{T} = (20+100)^\circ C/2 \approx 333K\right)$: c = 918 J/kg·K.

ANALYSIS: (a) Following the general analysis of Section 5.3, apply the conservation of energy requirement to the object,

$$\dot{E}_{in} + \dot{E}_g - \dot{E}_{out} = \dot{E}_{st} \qquad \dot{E}_g - \bar{h}A_s(T - T_\infty) = Mc\frac{dT}{dt} \tag{1}$$

where T = T(t). Consider now steady-state conditions, in which case the storage term of Eq. (1) is zero. The temperature of the object will be $T(\infty)$ such that

$$\dot{E}_g = \bar{h}A_s(T(\infty) - T_\infty). \tag{2}$$

Substituting for $\dot{E}_g$ using Eq. (2) into Eq. (1), the differential equation is

$$[T(\infty) - T_\infty] - [T - T_\infty] = \frac{Mc}{\bar{h}A_s}\frac{dT}{dt} \qquad \text{or} \qquad \theta = -\frac{Mc}{\bar{h}A_s}\frac{d\theta}{dt} \tag{3,4}$$

with $\theta \equiv T - T(\infty)$ and noting that $d\theta = dT$. Identifying $R_t = 1/\bar{h}A_s$ and $C_t = Mc$, the differential equation is integrated with proper limits,

$$\frac{1}{R_tC_t}\int_0^t dt = -\int_{\theta_i}^{\theta}\frac{d\theta}{\theta} \qquad \text{or} \qquad \frac{\theta}{\theta_i} = \exp\left[-\frac{t}{R_tC_t}\right] \tag{5}$$ <

where $\theta_i = \theta(0) = T_i - T(\infty)$ and T_i is the initial temperature of the object.

(b) Using the information about steady-state conditions and Eq. (2), find first the thermal resistance and capacitance of the system,

$$R_t = \frac{1}{\bar{h}A_s} = \frac{T(\infty) - T_\infty}{\dot{E}_g} = \frac{(100-20)^\circ C}{60\ W} = 1.33\ K/W \qquad C_t = Mc = 0.31\ kg \times 918\ J/kg\cdot K = 285\ J/K.$$

Using Eq. (5), the temperature of the system after 5 minutes is

$$\frac{\theta(5min)}{\theta_i} = \frac{T(5min) - T(\infty)}{T_i - T(\infty)} = \frac{T(5min) - 100^\circ C}{(20-100)^\circ C} = \exp\left[-\frac{5\times 60s}{1.33\ K/W \times 285\ J/K}\right] = 0.453$$

$$T(5min) = 100^\circ C + (20-100)^\circ C \times 0.453 = 63.8^\circ C$$ <

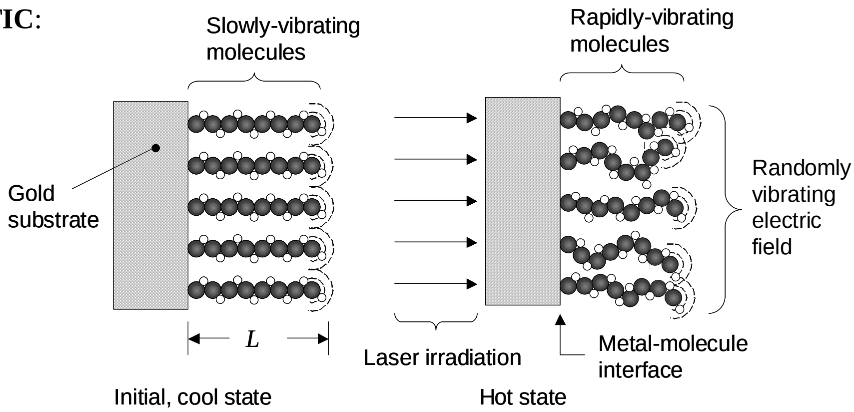
COMMENTS: Eq. 5.24 may be used directly for Part (b) with $a = hA_s/Mc$ and $b = \dot{E}_g/Mc$.

PROBLEM 5.21

KNOWN: Initial length, density and specific heat of self-assembled molecular chains. Time constant of the molecules' vibrational response.

FIND: Value of the contact resistance at the metal-molecule interface.

SCHEMATIC:



ASSUMPTIONS: (1) Molecules lose no thermal energy to surroundings. (2) Lumped capacitance behavior, (3) Constant properties, (4) Vibrational intensity represents temperature at the molecular scale, (5) Cylindrical molecule geometry.

ANALYSIS: From Equation 5.7, $\tau_t = R_{t,c}C_t = R''_{t,c}C_t / A_c$ where $C_t = \rho V c_p = \rho A_c L c_p$ is the lumped thermal capacitance and $R''_{t,c}$ is the thermal contact resistance. Combining the preceding two equations yields

$$R''_{t,c} = \frac{\tau_t}{\rho L c_p} = \frac{5 \times 10^{-12}\text{s}}{180\ \text{kg/m}^3 \times 2\times10^{-9}\ \text{m} \times 3000\ \text{J/kg}\cdot\text{K}} = 4.6 \times 10^{-9}\ \text{m}^2\cdot\text{K/W}$$ <

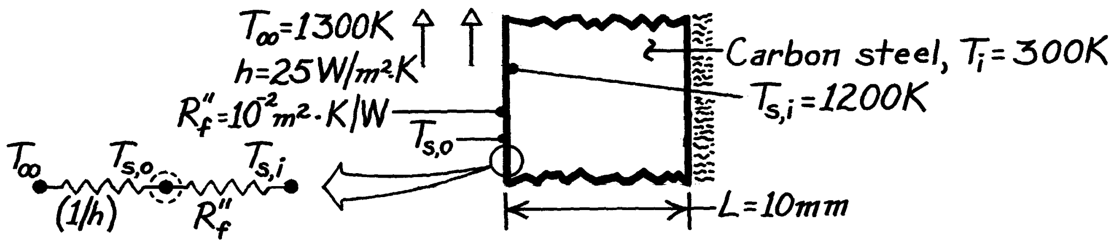
COMMENTS: (1) The contact resistance is very small, compared to values typical of larger systems. Nonetheless, the contact resistance may be larger than the conduction resistance within the moledule or thin gold film. (2) The time response is very fast, as expected at these length scales. This suggests that computational speed using such devices will be correspondingly fast. (3) See Z. Wang, J.A. Carter, A. Lagutchev, Y.K. Koh, N.-H. Seong, D.G. Cahill, and D.D. Dlott, "Ultrafast Flash Thermal Conductance of Molecular Chains," *Science*, Vol. 317, pp. 787-790, 2007, for details.

PROBLEM 5.22

KNOWN: Thickness and properties of furnace wall. Thermal resistance of film on surface of wall exposed to furnace gases. Initial wall temperature.

FIND: (a) Time required for surface of wall to reach a prescribed temperature, (b) Corresponding value of film surface temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Negligible film thermal capacitance, (3) Negligible radiation.

PROPERTIES: Carbon steel (given): ρ = 7850 kg/m^3, c = 430 J/kg·K, k = 60 W/m·K.

ANALYSIS: The overall coefficient for heat transfer from the surface of the steel to the gas is

$$U = \left(R''_{tot}\right)^{-1} = \left(\frac{1}{h} + R''_f\right)^{-1} = \left(\frac{1}{25\ \text{W/m}^2\cdot\text{K}} + 10^{-2}\ \text{m}^2\cdot\text{K/W}\right)^{-1} = 20\ \text{W/m}^2\cdot\text{K}.$$

Hence,

$$Bi = \frac{UL}{k} = \frac{20\ \text{W/m}^2\cdot\text{K}\times 0.01\ \text{m}}{60\ \text{W/m}\cdot\text{K}} = 0.0033$$

and the lumped capacitance method can be used.

(a) It follows that

$$\frac{T - T_\infty}{T_i - T_\infty} = \exp\left(-t/\tau_t\right) = \exp\left(-t/RC\right) = \exp\left(-Ut/\rho Lc\right)$$

$$t = -\frac{\rho Lc}{U}\ln\frac{T - T_\infty}{T_i - T_\infty} = -\frac{7850\ \text{kg/m}^3\left(0.01\ \text{m}\right)430\ \text{J/kg}\cdot\text{K}}{20\ \text{W/m}^2\cdot\text{K}}\ln\frac{1200 - 1300}{300 - 1300}$$

$$t = 3886\text{s} = 1.08\text{h}.$$ <

(b) Performing an energy balance at the outer surface (s,o),

$$h\left(T_\infty - T_{s,o}\right) = \left(T_{s,o} - T_{s,i}\right)/R''_f$$

$$T_{s,o} = \frac{hT_\infty + T_{s,i}/R''_f}{h + \left(1/R''_f\right)} = \frac{25\ \text{W/m}^2\cdot\text{K}\times 1300\ \text{K} + 1200\ \text{K}/10^{-2}\text{m}^2\cdot\text{K/W}}{\left(25 + 100\right)\text{W/m}^2\cdot\text{K}}$$

$$T_{s,o} = 1220\ \text{K}.$$ <

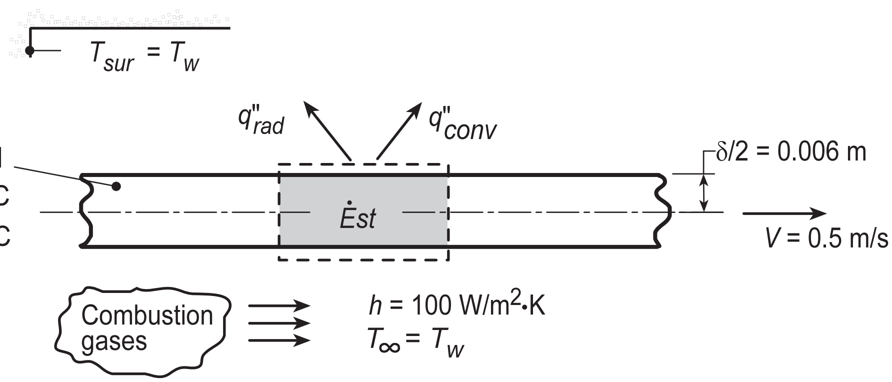
COMMENTS: The film increases τ_t by increasing R_t but not C_t.

PROBLEM 5.23

KNOWN: Thickness and properties of strip steel heated in an annealing process. Furnace operating conditions.

FIND: (a) Time required to heat the strip from 300 to 600°C. Required furnace length for prescribed strip velocity (V = 0.5 m/s), (b) Effect of wall temperature on strip speed, temperature history, and radiation coefficient.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Negligible temperature gradients in transverse direction across strip, (c) Negligible effect of strip conduction in longitudinal direction.

PROPERTIES: Steel: ρ = 7900 kg/m^3, c_p = 640 J/kg·K, k = 30 W/m·K, ε= 0.7.

ANALYSIS: (a) Considering a fixed (control) mass of the moving strip, its temperature variation with time may be obtained from an energy balance which equates the change in energy storage to heat transfer by convection and radiation. If the surface area associated with one side of the control mass is designated as A_s, $A_{s,c} = A_{s,r} = 2A_s$ and $V = \delta A_s$ in Equation 5.15, which reduces to

$$\rho c \delta \frac{dT}{dt} = -2\left[h\left(T - T_\infty\right) + \varepsilon\sigma\left(T^4 - T_{sur}^4\right)\right]$$

or, introducing the radiation coefficient from Equations 1.8 and 1.9 and integrating,

$$T_f - T_i = -\frac{1}{\rho c\left(\delta/2\right)}\int_o^{t_f}\left[h\left(T - T_\infty\right) + h_r\left(T - T_{sur}\right)\right]dt$$

Using the IHT *Lumped Capacitance Model* to integrate numerically with T_i = 573 K, we find that T_f = 873 K corresponds to

$t_f \approx 209s$ <

in which case, the required furnace length is

$$L = Vt_f \approx 0.5\,m/s \times 209\,s \approx 105\,m$$ <

(b) For T_w = 1123 K and 1273 K, the numerical integration yields $t_f \approx$ 102s and 62s respectively. Hence, for L = 105 m , V = L/t_f yields

$$V\left(T_w = 1123K\right) = 1.03\,m/s$$

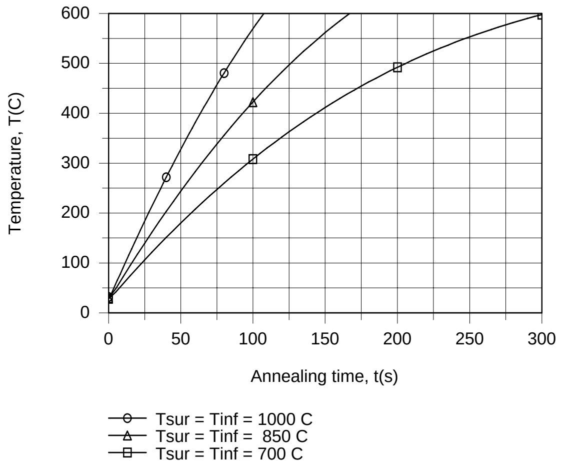
$$V\left(T_w = 1273K\right) = 1.69\,m/s$$ <

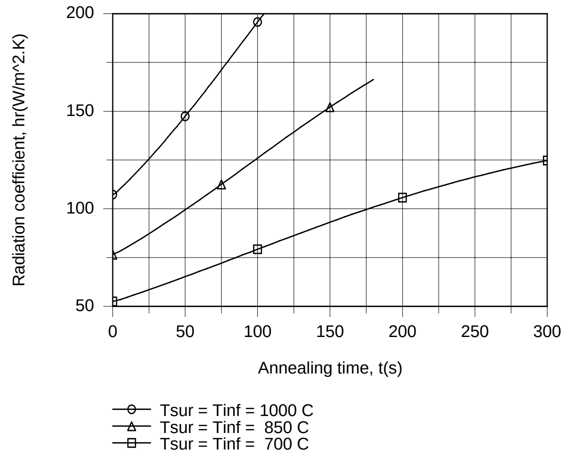
Continued...

PROBLEM 5.23 (Cont.)

which correspond to increased process rates of 106% and 238%, respectively. Clearly, productivity can be enhanced by increasing the furnace environmental temperature, albeit at the expense of increasing energy utilization and operating costs.

If the annealing process extends from 25°C (298 K) to 600°C (873 K), numerical integration yields the following results for the prescribed furnace temperatures.





As expected, the heating rate and time, respectively, increase and decrease significantly with increasing T_w. Although the radiation heat transfer rate decreases with increasing time, the coefficient h_r increases with t as the strip temperature approaches T_w.

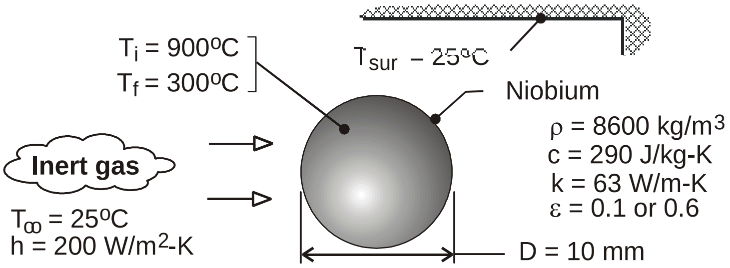
COMMENTS: To check the validity of the lumped capacitance approach, we calculate the Biot number based on a maximum cumulative coefficient of $(h + h_r) \approx 300\ W/m^2 \cdot K$. It follows that $Bi = (h + h_r)(\delta/2)/k = 0.06$ and the assumption is valid.

PROBLEM 5.24

KNOWN: Initial and final temperatures of a niobium sphere. Diameter and properties of the sphere. Temperature of surroundings and/or gas flow, and convection coefficient associated with the flow.

FIND: (a) Time required to cool the sphere exclusively by radiation, (b) Time required to cool the sphere exclusively by convection, (c) Combined effects of radiation and convection.

SCHEMATIC:



ASSUMPTIONS: (1) Uniform temperature at any time, (2) Negligible effect of holding mechanism on heat transfer, (3) Constant properties, (4) Radiation exchange is between a small surface and large surroundings.

ANALYSIS: (a) If cooling is exclusively by radiation, the required time is determined from Eq. (5.18). With $V = \pi D^3/6$, $A_{s,r} = \pi D^2$, and $\varepsilon = 0.1$,

$$t = \frac{8600\ \text{kg/m}^3 (290\,\text{J/kg}\cdot\text{K})0.01\text{m}}{24(0.1)5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4(298\text{K})^3}\left\{\ln\left|\frac{298+573}{298-573}\right| - \ln\left|\frac{298+1173}{298-1173}\right|\right.$$

$$\left. +2\left[\tan^{-1}\left(\frac{573}{298}\right) - \tan^{-1}\left(\frac{1173}{298}\right)\right]\right\}$$

$$t = 6926\text{s}\{1.153 - 0.519 + 2(1.091 - 1.322)\} = 1190\text{s} \qquad (\varepsilon = 0.1)$$ <

If $\varepsilon = 0.6$, cooling is six times faster, in which case,

$$t = 199\text{s} \qquad (\varepsilon = 0.6)$$ <

(b) If cooling is exclusively by convection, Eq. (5.5) yields

$$t = \frac{\rho c D}{6h}\ln\left(\frac{T_i - T_\infty}{T_f - T_\infty}\right) = \frac{8600\ \text{kg/m}^3(290\,\text{J/kg}\cdot\text{K})0.010\text{m}}{1200\,\text{W/m}^2\cdot\text{K}}\ln\left(\frac{875}{275}\right)$$

$$t = 24.1\text{s}$$ <

(c) With both radiation and convection, the temperature history may be obtained from Eq. (5.15).

$$\rho\left(\pi D^3/6\right)c\frac{dT}{dt} = -\pi D^2\left[h(T - T_\infty) + \varepsilon\sigma\left(T^4 - T_{sur}^4\right)\right]$$

Integrating numerically from T_i = 1173 K at t = 0 to T = 573K, we obtain

$$t = 21.0\text{s}$$ <

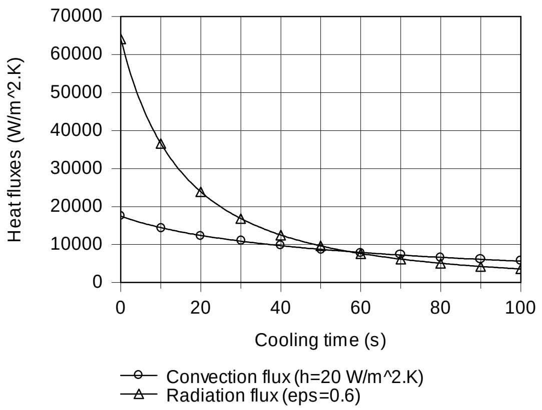
Continued …

PROBLEM 5.24 (Cont.)

Cooling times corresponding to representative changes in ε and h are tabulated as follows

$h(W/m^2\cdot K)$	200	200	20	500
ε	0.6	1.0	0.6	0.6
t(s)	21.0	19.4	102.8	9.1

For values of h representative of forced convection, the influence of radiation is secondary, even for a maximum possible emissivity of 1.0. Hence, to accelerate cooling, it is necessary to increase h. However, if cooling is by natural convection, radiation is significant. For a representative natural convection coefficient of $h = 20\ W/m^2\cdot K$, the radiation flux exceeds the convection flux at the surface of the sphere during early to intermediate stages of the transient.



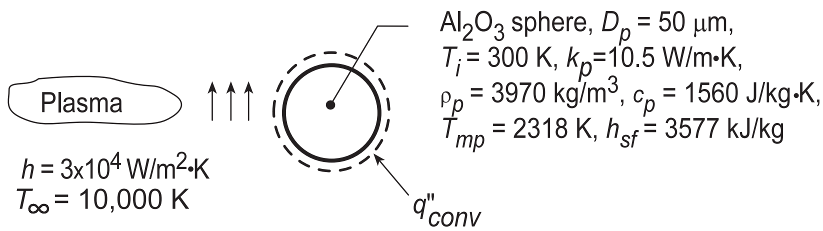
COMMENTS: (1) Even for h as large as $500\ W/m^2\cdot K$, $Bi = h\,(D/6)/k = 500\ W/m^2\cdot K\ (0.01m/6)/63\ W/m\cdot K = 0.013 < 0.1$ and the lumped capacitance model is appropriate. (2) The largest value of h_r corresponds to $T_i = 1173$ K, and for ε = 0.6 Eq. (1.9) yields $h_r = 0.6 \times 5.67 \times 10^{-8}\ W/m^2\cdot K^4\ (1173 + 298)K\ (1173^2 + 298^2)K^2 = 73.3\ W/m^2\cdot K$.

PROBLEM 5.25

KNOWN: Diameter and thermophysical properties of alumina particles. Convection conditions associated with a two-step heating process.

FIND: (a) Time-in-flight (t_{i-f}) required for complete melting, (b) Validity of assuming negligible radiation.

SCHEMATIC:



ASSUMPTIONS: (1) Particle behaves as a lumped capacitance, (2) Negligible radiation, (3) Constant properties.

ANALYSIS: (a) The two-step process involves (i) the time t_1 to heat the particle to its melting point and (ii) the time t_2 required to achieve complete melting. Hence, $t_{i-f} = t_1 + t_2$, where from Eq. (5.5),

$$t_1 = \frac{\rho_p V c_p}{hA_s}\ln\frac{\theta_i}{\theta} = \frac{\rho_p D_p c_p}{6h}\ln\frac{T_i - T_\infty}{T_{mp} - T_\infty}$$

$$t_1 = \frac{3970\,\text{kg/m}^3\left(50\times10^{-6}\,\text{m}\right)1560\,\text{J/kg}\cdot\text{K}}{6\left(30,000\,\text{W/m}^2\cdot\text{K}\right)}\ln\frac{(300-10,000)}{(2318-10,000)} = 4\times10^{-4}\,\text{s}$$

Performing an energy balance for the second step, we obtain

$$\int_{t_1}^{t_1+t_2} q_{conv}dt = \Delta E_{st}$$

where $q_{conv} = hA_s(T_\infty - T_{mp})$ and $\Delta E_{st} = \rho_p V h_{sf}$. Hence,

$$t_2 = \frac{\rho_p D_p}{6h}\frac{h_{sf}}{\left(T_\infty - T_{mp}\right)} = \frac{3970\,\text{kg/m}^3\left(50\times10^{-6}\,\text{m}\right)}{6\left(30,000\,\text{W/m}^2\cdot\text{K}\right)}\times\frac{3.577\times10^6\,\text{J/kg}}{(10,000-2318)\,\text{K}} = 5\times10^{-4}\,\text{s}$$

Hence $t_{i-f} = 9\times10^{-4}\,\text{s} \approx 1\,\text{ms}$ $<$

(b) Contrasting the smallest value of the convection heat flux, $q''_{conv,min} = h\left(T_\infty - T_{mp}\right) = 2.3\times10^8\,\text{W/m}^2$ to the largest radiation flux, $q''_{rad,max} = \varepsilon\sigma\left(T_{mp}^4 - T_{sur}^4\right) = 6.7\times10^5\,\text{W/m}^2$, with $\varepsilon = 0.41$ from Table A.11 for aluminum oxide at 1500 K, and Tsur = 300 K we conclude that radiation is, in fact, negligible.

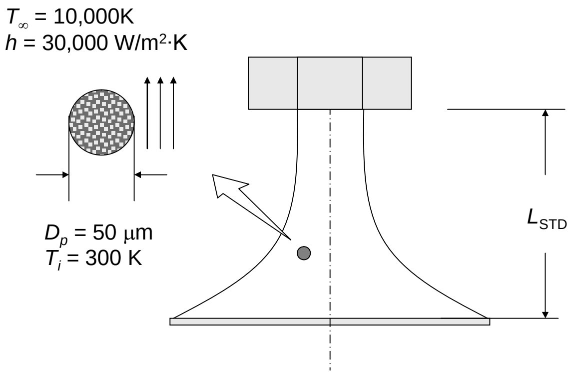
COMMENTS: (1) Since Bi = $(hr_p/3)/k \approx 0.02$, the lumped capacitance assumption is good. (2) In an actual application, the droplet should impact the substrate in a superheated condition ($T > T_{mp}$), which would require a slightly larger t_{i-f}.

PROBLEM 5.26

KNOWN: Diameter and initial temperature of nanostructured ceramic particle. Plasma temperature and convection heat transfer coefficient. Properties and velocity of particles.

FIND: (a) Time-in-flight corresponding to 30% of the particle mass being melted. (b) Time-in-flight corresponding to the particle being 70% melted. (c) Standoff distances between the nozzle and the substrate associated with parts (a) and (b).

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties. (2) Negligible radiation.

PROPERTIES: Given; k = 5 W/m·K, ρ = 3800 kg/m^3, c_p = 1560 J/kg·K, h_{sf} = 3577 kJ/kg, T_{mp} = 2318 K.

ANALYSIS: (a) To determine whether the lumped capacitance assumption is appropriate, the Biot number is calculated as

$$Bi = \frac{h(r_o/3)}{k} = \frac{hD}{6k} = \frac{30{,}000\ \text{W/m}^2\cdot\text{K}\times 50\times 10^{-6}\ \text{m}}{6\times 5\ \text{W/m}\cdot\text{K}} = 0.05$$

Since Bi < 0.1, the lumped capacitance approximation is valid. The particle heating process can be divided into two stages.

<u>Stage 1: Heating to the melting temperature</u>. The time-of-flight for the first stage is found from Equation 5.5.

$$t_1 = \frac{\rho V c}{h A_s}\ln\frac{\theta_i}{\theta} = \frac{\rho D c}{6h}\ln\frac{T_i - T_\infty}{T_{\text{mp}} - T_\infty}$$

$$= \frac{3800\ \text{kg/m}^3\times 50\times 10^{-6}\ \text{m}\times 1560\ \text{J/kg}\cdot\text{K}}{6\times 30{,}000\ \text{W/m}^2\cdot\text{K}}\ln\frac{300\ \text{K} - 10{,}000\ \text{K}}{2318\ \text{K} - 10{,}000\ \text{K}}$$

$$= 0.00038\ \text{s}$$

<u>Stage 2: Melting to 30% liquid</u>. The second stage involves heat transfer to the particle which is isothermal at its melting point temperature. Hence

Continued...

PROBLEM 5.26 (Cont.)

$$t_{2,0.3} = \frac{\Delta E}{q} = \frac{0.3\rho V h_{sf}}{hA_s(T_\infty - T_{mp})} = \frac{0.05\rho D h_{sf}}{h(T_\infty - T_{mp})}$$

$$= \frac{0.05 \times 3800\text{kg/m}^3 \times 50 \times 10^{-6}\text{ m} \times 3577 \times 10^3\text{ J/kg}}{30{,}000\text{W/m}^2 \cdot \text{K} \times \left(10{,}000 - 2318\right)\text{K}} = 0.00015\text{ s}$$

Therefore the required time-of-flight is $t_{tot,0.3} = t_1 + t_{2,\,0.3} = 0.00038\text{ s} + 0.00015\text{ s} = 0.00053\text{ s}$ <

(b) The calculation for the second stage may be repeated for 70% liquid, yielding $t_{2,\,0.7} = 0.00034$ s. Therefore the required time-of-flight is $t_{tot,\,0.7} = t_1 + t_{2,\,0.7} = 0.00038\text{ s} + 0.000341\text{ s} = 0.00072\text{ s}$ <

(c) The required standoff distances are

$$L_{STD,0.3} = Vt_{tot,0.3} = 35\text{ m/s} \times 0.00053\text{ s} = 0.019\text{ m} = 19\text{ mm}$$ <

$$L_{STD,0.7} = Vt_{tot,0.7} = 35\text{ m/s} \times 0.00072\text{ s} = 0.025\text{ m} = 25\text{ mm}$$

COMMENTS: (1) Assuming the particles to have an emissivity of $\varepsilon_p = 0.4$ and radiation is exchanged with surroundings at an assumed temperature of $T_{sur} = 300$ K, the radiation heat transfer coefficient may be found from Equation 1.9 as

$$h_r = \varepsilon_p \sigma (T_{mp} + T_{sur})(T_{mp}^2 + T_{sur}^2) = 0.4 \times 5.67 \times 10^{-8}\frac{\text{W}}{\text{m}^2 \cdot \text{K}^4}\left(2318 + 300\right)\text{K} \times \left(2318\text{K}^2 + 300\text{K}^2\right) = 320$$ W/m²·K.

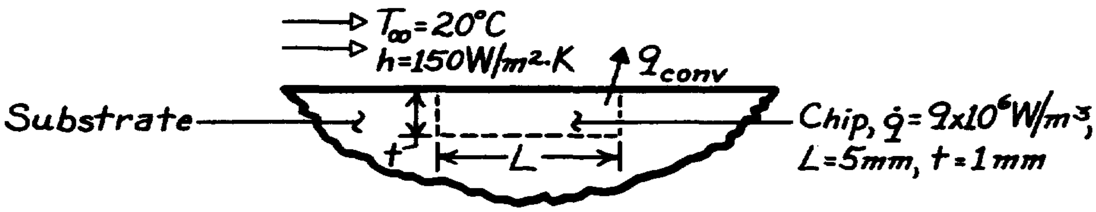
Hence $h_r << h_{conv}$ and radiation heat transfer is negligible. (2) To deliver a partially-molten droplet to the substrate, standoff distances on the order of 20 mm need to be maintained. This is a reasonable requirement. (3) See I. Ahmed and T.L. Bergman, "Simulation of Thermal Plasma Spraying of Partially Molten Ceramics: Effect of Carrier Gas on Particle Deposition and Phase Change Phenomena," *ASME Journal of Heat Transfer*, vol. 123, pp. 188-196, 2001, for more information.

PROBLEM 5.27

KNOWN: Dimensions and operating conditions of an integrated circuit.

FIND: Steady-state temperature and time to come within 1°C of steady-state.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Negligible heat transfer from chip to substrate.

PROPERTIES: Chip material (given): ρ = 2000 kg/m^3, c = 700 J/kg·K.

ANALYSIS: At steady-state, conservation of energy yields

$$-\dot{E}_{out} + \dot{E}_g = 0$$

$$-h\left(L^2\right)\left(T_f - T_\infty\right) + \dot{q}\left(L^2 \cdot t\right) = 0$$

$$T_f = T_\infty + \frac{\dot{q}t}{h}$$

$$T_f = 20^\circ C + \frac{9\times10^6 \text{ W/m}^3 \times 0.001 \text{ m}}{150 \text{ W/m}^2\cdot\text{K}} = 80^\circ C. \qquad <$$

From the general lumped capacitance analysis, Equation 5.15 reduces to

$$\rho\left(L^2\cdot t\right)c\frac{dT}{dt} = \dot{q}\left(L^2\cdot t\right) - h\left(T - T_\infty\right)L^2.$$

With

$$a \equiv \frac{h}{\rho tc} = \frac{150 \text{ W/m}^2\cdot\text{K}}{\left(2000 \text{ kg/m}^3\right)\left(0.001 \text{ m}\right)\left(700 \text{ J/kg}\cdot\text{K}\right)} = 0.107 \text{ s}^{-1}$$

$$b \equiv \frac{\dot{q}}{\rho c} = \frac{9\times10^6 \text{ W/m}^3}{\left(2000 \text{ kg/m}^3\right)\left(700 \text{ J/kg}\cdot\text{K}\right)} = 6.429 \text{ K/s}.$$

From Equation 5.24,

$$\exp(-at) = \frac{T - T_\infty - b/a}{T_i - T_\infty - b/a} = \frac{(79-20-60)\text{K}}{(20-20-60)\text{K}} = 0.01667$$

$$t = -\frac{\ln(0.01667)}{0.107 \text{ s}^{-1}} = 38.3 \text{ s}. \qquad <$$

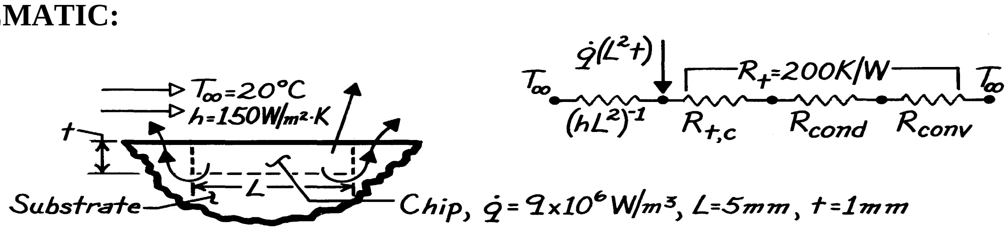
COMMENTS: Due to additional heat transfer from the chip to the substrate, the actual values of T_f and t are less than those which have been computed.

PROBLEM 5.28

KNOWN: Dimensions and operating conditions of an integrated circuit.

FIND: Steady-state temperature and time to come within 1°C of steady-state.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties.

PROPERTIES: Chip material (given): ρ = 2000 kg/m^3, c_p = 700 J/kg·K.

ANALYSIS: The direct and indirect paths for heat transfer from the chip to the coolant are in parallel, and the equivalent resistance is

$$R_{equiv} = \left[hL^2 + R_t^{-1}\right]^{-1} = \left[\left(3.75\times10^{-3} + 5\times10^{-3}\right)\text{W/K}\right]^{-1} = 114.3 \text{ K/W}.$$

The corresponding overall heat transfer coefficient is

$$U = \frac{\left(R_{equiv}\right)^{-1}}{L^2} = \frac{0.00875 \text{ W/K}}{\left(0.005 \text{ m}\right)^2} = 350 \text{ W/m}^2\cdot\text{K}.$$

To obtain the steady-state temperature, apply conservation of energy to a control surface about the chip.

$$-\dot{E}_{out} + \dot{E}_g = 0 \qquad -UL^2\left(T_f - T_\infty\right) + \dot{q}\left(L^2\cdot t\right) = 0$$

$$T_f = T_\infty + \frac{\dot{q}t}{U} = 20^\circ\text{C} + \frac{9\times10^6 \text{ W/m}^3 \times 0.001 \text{ m}}{350 \text{ W/m}^2\cdot\text{K}} = 45.7^\circ\text{C}.$$ <

From the general lumped capacitance analysis, Equation 5.15 yields

$$\rho\left(L^2t\right)c\frac{dT}{dt} = \dot{q}\left(L^2t\right) - U\left(T - T_\infty\right)L^2.$$

With

$$a \equiv \frac{U}{\rho\, tc} = \frac{350 \text{ W/m}^2\cdot\text{K}}{\left(2000 \text{ kg/m}^3\right)\left(0.001 \text{ m}\right)\left(700 \text{ J/kg}\cdot\text{K}\right)} = 0.250 \text{ s}^{-1}$$

$$b = \frac{\dot{q}}{\rho\, c} = \frac{9\times10^6 \text{ W/m}^3}{\left(2000 \text{ kg/m}^3\right)\left(700 \text{ J/kg}\cdot\text{K}\right)} = 6.429 \text{ K/s}$$

Equation 5.24 yields

$$\exp\left(-at\right) = \frac{T - T_\infty - b/a}{T_i - T_\infty - b/a} = \frac{\left(44.7 - 20 - 25.7\right)\text{K}}{\left(20 - 20 - 25.7\right)\text{K}} = 0.0389$$

$$t = -\ln\left(0.0389\right)/0.250 \text{ s}^{-1} = 13.0 \text{ s}.$$ <

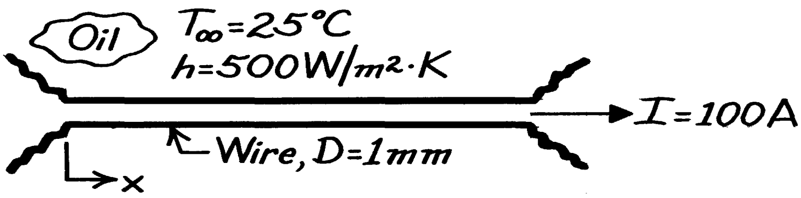
COMMENTS: Heat transfer through the substrate is comparable to that associated with direct convection to the coolant.

PROBLEM 5.29

KNOWN: Diameter, resistance and current flow for a wire. Convection coefficient and temperature of surrounding oil.

FIND: Steady-state temperature of the wire. Time for the wire temperature to come within 1°C of its steady-state value.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Wire temperature is independent of x.

PROPERTIES: Wire (given): $\rho = 8000\ \text{kg/m}^3$, $c_p = 500\ \text{J/kg·K}$, $k = 20\ \text{W/m·K}$, $R'_e = 0.01\ \Omega/\text{m}$.

ANALYSIS: Since

$$Bi = \frac{h(r_o/2)}{k} = \frac{500\ \text{W/m}^2\cdot\text{K}\left(2.5\times10^{-4}\text{m}\right)}{20\ \text{W/m}\cdot\text{K}} = 0.006 < 0.1$$

the lumped capacitance method can be used. The problem has been analyzed in Example 1.4, and without radiation the steady-state temperature is given by

$$\pi\ Dh\left(T - T_\infty\right) = I^2R'_e.$$

Hence

$$T = T_\infty + \frac{I^2R'_e}{\pi\ Dh} = 25^\circ\text{C} + \frac{(100\text{A})^2\ 0.01\Omega/\text{m}}{\pi\left(0.001\ \text{m}\right)500\ \text{W/m}^2\cdot\text{K}} = 88.7^\circ\text{C}. \qquad <$$

With no radiation, the transient thermal response of the wire is governed by the expression (Example 1.4)

$$\frac{dT}{dt} = \frac{I^2R'_e}{\rho c_p\left(\pi D^2/4\right)} - \frac{4h}{\rho\ c_p D}\left(T - T_\infty\right).$$

With $T = T_i = 25°C$ at $t = 0$, the solution is

$$\frac{T - T_\infty - \left(I^2R'_e/\pi\ Dh\right)}{T_i - T_\infty - \left(I^2R'_e/\pi\ Dh\right)} = \exp\left(-\frac{4h}{\rho\ c_p D}t\right).$$

Substituting numerical values, find

$$\frac{87.7 - 25 - 63.7}{25 - 25 - 63.7} = \exp\left(-\frac{4\times500\ \text{W/m}^2\cdot\text{K}}{8000\ \text{kg/m}^3\times500\ \text{J/kg}\cdot\text{K}\times0.001\ \text{m}}t\right)$$

$$t = 8.31\text{s}. \qquad <$$

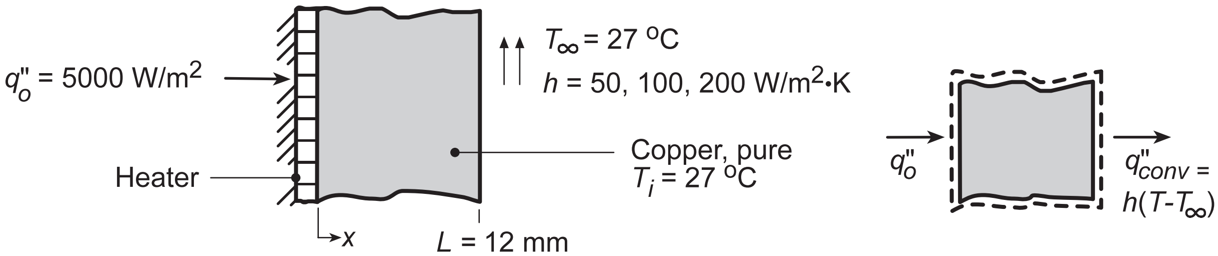
COMMENTS: The time to reach steady state increases with increasing ρ, c_p and D and with decreasing h.

PROBLEM 5.30

KNOWN: Electrical heater attached to backside of plate while front is exposed to a convection process (T_∞, h); initially plate is at uniform temperature T_∞ before heater power is switched on.

FIND: (a) Expression for temperature of plate as a function of time assuming plate is spacewise isothermal, (b) Approximate time to reach steady-state and T(∞) for prescribed T_∞, h and q''_o when wall material is pure copper, (c) Effect of h on thermal response.

SCHEMATIC:



ASSUMPTIONS: (1) Plate behaves as lumped capacitance, (2) Negligible loss out backside of heater, (3) Negligible radiation, (4) Constant properties.

PROPERTIES: *Table A-1*, Copper, pure (350 K): k = 397 W/m·K, c_p = 385 J/kg·K, ρ = 8933 kg/m³.

ANALYSIS: (a) Following the analysis of Section 5.3, the energy conservation requirement for the system is $\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st}$ or $q''_o - h(T - T_\infty) = \rho L c_p \, dT/dt$. Rearranging, and with R''_t = 1/h and C''_t = $\rho L c_p$,

$$T - T_\infty - q''_o/h = -R''_t \cdot C''_t \, dT/dt \quad (1)$$

Defining $\theta(t) \equiv T - T_\infty - q''_o/h$ with dθ = dT, the differential equation is

$$\theta = -R''_t C''_t \frac{d\theta}{dt}. \quad (2)$$

Separating variables and integrating,

$$\int_{\theta_i}^{\theta} \frac{d\theta}{\theta} = -\int_0^t \frac{dt}{R''_t C''_t}$$

it follows that

$$\frac{\theta}{\theta_i} = \exp\left(-\frac{t}{R''_t C''_t}\right) \quad (3) <$$

where $\theta_i = \theta(0) = T_i - T_\infty - (q''_o/h)$ (4)

(b) For h = 50 W/m² ·K, the steady-state temperature can be determined from Eq. (3) with t → ∞; that is,

$$\theta(\infty) = 0 = T(\infty) - T_\infty - q''_o/h \qquad \text{or} \qquad T(\infty) = T_\infty + q''_o/h,$$

giving T(∞) = 27°C + 5000 W/m² /50 W/m²·K = 127°C. To estimate the time to reach steady-state, first determine the thermal time constant of the system,

$$\tau_t = R''_t C''_t = \left(\frac{1}{h}\right)(\rho c_p L) = \left(\frac{1}{50\,W/m^2\cdot K}\right)\left(8933\,kg/m^3 \times 385\,J/kg\cdot K \times 12\times10^{-3}\,m\right) = 825\,s$$

Continued...

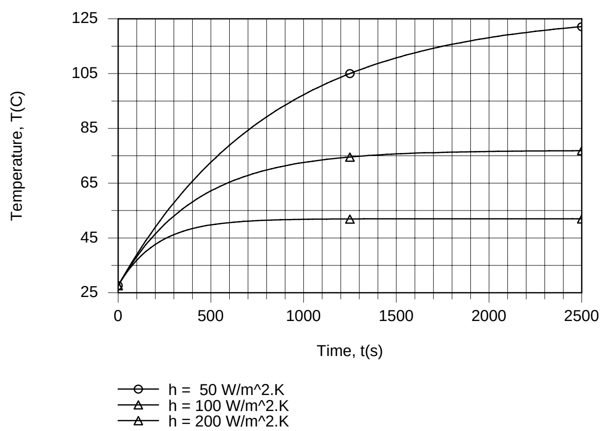
PROBLEM 5.30 (Cont.)

When $t = 3\tau_t = 3\times825s = 2475s$, Eqs. (3) and (4) yield

$$\theta(3\tau_t) = T(3\tau_t) - 27^\circ C - \frac{5000\,W/m^2}{50\,W/m^2\cdot K} = e^{-3}\left[27^\circ C - 27^\circ C - \frac{5000\,W/m^2}{50\,W/m^2\cdot K}\right]$$

$T(3\tau_t) = 122°C$ <

(c) As shown by the following graphical results, which were generated using the IHT *Lumped Capacitance Model*, the steady-state temperature and the time to reach steady-state both decrease with increasing h.



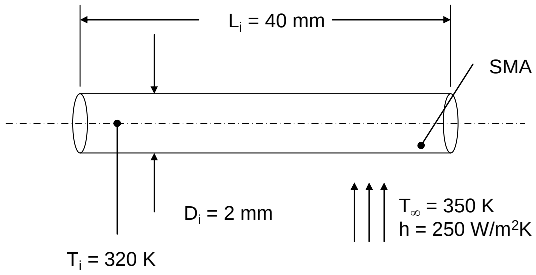
COMMENTS: Note that, even for $h = 200\ W/m^2\cdot K$, $Bi = hL/k << 0.1$ and assumption (1) is reasonable.

PROBLEM 5.31

KNOWN: Initial dimensions and temperature of SMA rod, ambient temperature and convection heat transfer coefficient. Properties of SMA.

FIND: Thermal response of the rod assuming constant and variable specific heats, time for rod temperature to experience 95% of the maximum temperature change.

SCHEMATIC:



ASSUMPTIONS: (1) Lumped capacitance behavior, (2) Effect of change in density and dimensions is negligible, (3) Negligible radiation.

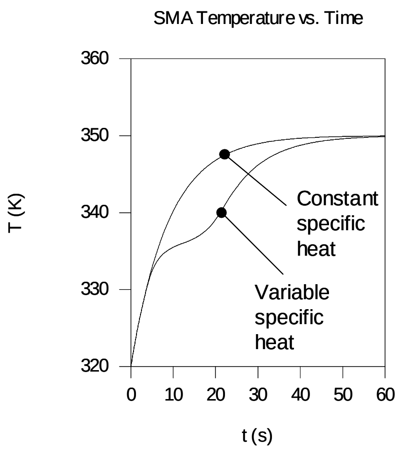
PROPERTIES: *Given*: $c = 500\dfrac{\text{J}}{\text{kg}\cdot\text{K}} + 3630\ \text{J/kg}\cdot\text{K} \times e^{\left(-0.808\text{K}^{-1}\times|T-336\text{K}|\right)}$, ρ = 8900 kg/m^3, k = 23 W/m·K.

ANALYSIS: The Biot number associated with the rod (evaluating dimensions at the initial temperature) is $Bi = h(D_i/4)/k$ = 250 W/m^2·K × 2 × 10^{-3} m/4/23W/m·K = 0.005 << 0.1. Therefore, the lumped capacitance approach is valid. Neglecting the change in the surface area as the rod is heated,

$$\frac{dT}{dt} = -\frac{hA_s(T-T_\infty)}{\rho Vc} = -\frac{4h}{\rho D_i c}(T-T_\infty)$$

$$= -\frac{4\times 250\text{W/m}^2\cdot\text{K}\times(T-T_\infty)}{8900\text{kg/m}^3\times 0.002\text{m}\times\left[500\dfrac{\text{J}}{\text{kg}\cdot\text{K}} + 3630\ \text{J/kg}\cdot\text{K}\times e^{\left(-0.808\text{K}^{-1}\times|T-336\text{K}|\right)}\right]}$$

Because of the absolute value function, the preceding expression is most readily integrated numerically to determine $T(t)$. Based upon an initial temperature of T_i = 320 K, the following results are found using the IHT code included in the Comments.

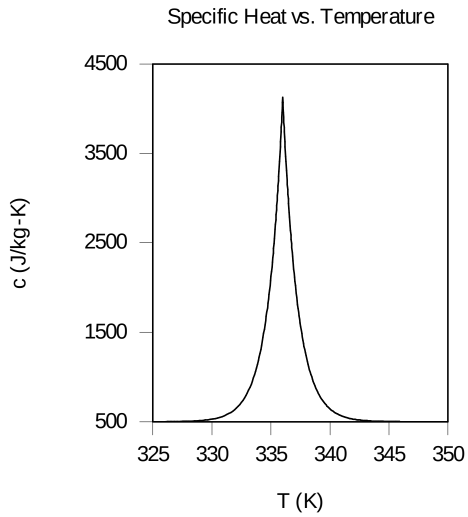


Continued…

PROBLEM 5.31 (Cont.)

Inspection of the predicted response shows the time needed for the rod to experience 95% of its total temperature change (to $T_{95} = T_i + 0.95\times(T_f - T_i) = 320\text{ K} + 0.95 \times (350 - 320)\text{ K} = 348.5\text{ K}$) is 38.2 s and 27.1 s for the variable and constant specific heat cases, respectively. <

COMMENTS: (1) A plot of the specific heat is shown below. The onset of large specific heat values associated with the crystalline transformation slows the thermal response, as evident in the preceding plot. (2) The IHT code is listed below.



```
// Solid Properties and Geometry

rho = 8900                    //kg/m^3
A= pi*D*L                     //m^2
D= 2/1000                     //m
L = 40/1000                   //m
V = L*pi*D*D/4                //m^3
cpnot = 500                   //J/kgK

//Convective Conditions

Tinf = 350                    //K
h = 250                       //W/m^2K

//Variable Property Solution

der(Tvp,t) = h*A*(Tinf - Tvp)/rho/cpstar/V
cpstar = cpnot +( 9*10^3)*0.403*exp(-abs(0.808*(Tair-336)))

//Constant Property Solution

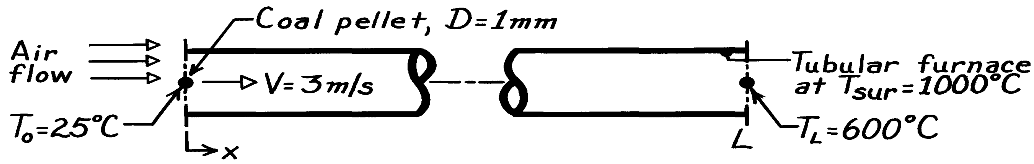
der(Tcp,t) = h*A*(Tinf - Tcp)/rho/cpnot/V
```

PROBLEM 5.32

KNOWN: Spherical coal pellet at 25°C is heated by radiation while flowing through a furnace maintained at 1000°C.

FIND: Length of tube required to heat pellet to 600°C.

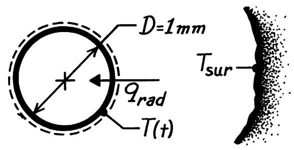
SCHEMATIC:



ASSUMPTIONS: (1) Pellet is suspended in air flow and subjected to only radiative exchange with furnace, (2) Pellet is small compared to furnace surface area, (3) Coal pellet has emissivity, $\varepsilon = 1$.

PROPERTIES: *Table A-3,* Coal $\left(\bar{T} = (600 + 25)\,°C/2 = 585K,\ \text{however, only 300K data available}\right)$: $\rho = 1350\ kg/m^3$, $c_p = 1260$ J/kg·K, k = 0.26 W/m·K.

ANALYSIS: Considering the pellet as spatially isothermal, use the lumped capacitance method of Section 5.3 to find the time required to heat the pellet from $T_o = 25°C$ to $T_L = 600°C$. From an energy balance on the pellet $\dot{E}_{in} = \dot{E}_{st}$ where



$$\dot{E}_{in} = q_{rad} = \sigma A_s \left(T_{sur}^4 - T_s^4\right) \qquad \dot{E}_{st} = \rho \forall c_p \frac{dT}{dt}$$

giving
$$A_s \sigma \left(T_{sur}^4 - T_s^4\right) = \rho \forall c_p \frac{dT}{dt}.$$

Separating variables and integrating with limits shown, the temperature-time relation becomes

$$\frac{A_s \sigma}{\rho \forall c_p} \int_0^t dt = \int_{T_o}^{T_L} \frac{dT}{T_{sur}^4 - T^4}.$$

The integrals are evaluated in Eq. 5.18 giving

$$t = \frac{\rho \forall c_p}{4 A_s \sigma T_{sur}^3} \left\{ \ln\left|\frac{T_{sur} + T}{T_{sur} - T}\right| - \ln\left|\frac{T_{sur} + T_i}{T_{sur} - T_i}\right| + 2\left[\tan^{-1}\left[\frac{T}{T_{sur}}\right] - \tan^{-1}\left[\frac{T_i}{T_{sur}}\right]\right]\right\}.$$

Recognizing that $A_s = \pi D^2$ and $\forall = \pi D^3/6$ or $A_s/\forall = 6/D$ and substituting values,

$$t = \frac{1350\ kg/m^3 (0.001\ m) 1260\ J/kg \cdot K}{24 \times 5.67 \times 10^{-8}\ W/m^2 \cdot K^4 (1273\ K)^3} \left\{ \ln \frac{1273 + 873}{1273 - 873} - \ln \frac{1273 + 298}{1273 - 298} \right.$$

$$\left. + 2\left[\tan^{-1}\left(\frac{873}{1273}\right) - \tan^{-1}\left(\frac{298}{1273}\right)\right]\right\} = 1.18s.$$

Hence, $\qquad L = V \cdot t = 3m/s \times 1.18s = 3.54m.$ <

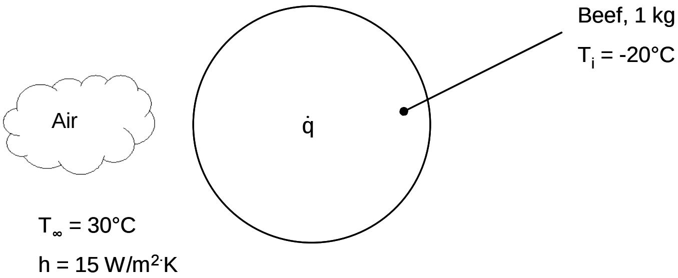
The validity of the lumped capacitance method requires $Bi = h(\forall/A_s)/k < 0.1$. Using Eq. (1.9) for $h = h_r$ and $\forall/A_s = D/6$, find that when T = 600°C, Bi = 0.19; but when T = 25°C, Bi = 0.10. At early times, when the pellet is cooler, the assumption is reasonable but becomes less appropriate as the pellet heats.

PROBLEM 5.33

KNOWN: Mass and initial temperature of frozen ground beef. Temperature and convection coefficient of air. Rate of microwave power absorbed in beef.

FIND: (a) Time for beef to reach 0°C, (b) Time for beef to be heated from liquid at 0°C to 80°C, and (c) Explain nonuniform heating in microwave and reason for low power setting for thawing.

SCHEMATIC:



ASSUMPTIONS: (1) Beef is nearly isothermal, (2) Beef has properties of water (ice or liquid), (3) Radiation is negligible, (4) Constant properties (different for ice and liquid water).

PROPERTIES: Table A.3, Ice (≈ 273 K): ρ = 920 kg/m^3, c = 2040 J/kg·K, Table A.6, Water (≈ 315 K): c = 4179 J/kg·K.

ANALYSIS: (a) We apply conservation of energy to the beef

$$\dot{E}_{in} + \dot{E}_g = \dot{E}_{st}$$

$$hA_s(T_\infty - T) + \dot{q} = mc\frac{dT}{dt} \qquad (1)$$

The initial condition is $T(0) = T_i$. This differential equation can be solved by defining

$$\theta = T - T_\infty - \frac{\dot{q}}{hA_s}$$

Then Eq.(1) becomes $\dfrac{d\theta}{dt} = -\dfrac{hA_s}{mc}\theta$

Separating variables and integrating,

$$\int_{\theta(0)}^{\theta(t)}\frac{d\theta}{\theta} = -\frac{hA_s}{mc}\int_0^t dt$$

$$\ln\left[\frac{\theta(t)}{\theta(0)}\right] = -\frac{hA_s t}{mc}$$

$$\ln\left[\frac{T - T_\infty - \dot{q}/hA_s}{T_i - T_\infty - \dot{q}/hA_s}\right] = -\frac{hA_s t}{mc} \qquad (2)$$

The heat generation rate is given by $\dot{q} = 0.03P = 0.03(1000\text{ W}) = 30\text{ W}$. The radius of the sphere can be found from knowledge of the mass and density:

Continued…

PROBLEM 5.33 (Cont.)

$$m = \rho V = \rho \frac{4}{3}\pi\, r_o^3$$

$$r_o = \left(\frac{3}{4\pi}\frac{m}{\rho}\right)^{1/3} = \left(\frac{3}{4\pi}\frac{1\text{ kg}}{920\text{ kg/m}^3}\right)^{1/3} = 0.0638\text{ m}$$

Thus $A_s = 4\pi r_o^2 = 4\pi(0.0638\text{ m})^2 = 0.0511\text{ m}^2$

Substituting numerical values into Eq.(2), we can find the time at which the temperature reaches 0°C:

$$\ln\left[\frac{0°\text{C} - 30°\text{C} - 30\text{ W}/(15\text{ W/m}^2\cdot\text{K} \times 0.0511\text{ m}^2)}{-20°\text{C} - 30°\text{C} - 30\text{ W}/(15\text{ W/m}^2\cdot\text{K} \times 0.0511\text{ m}^2)}\right] = -\frac{15\text{ W/m}^2\cdot\text{K} \times 0.0511\text{ m}^2}{1\text{ kg} \times 2040\text{ J/kg}\cdot\text{K}}t$$

Thus t = 676 s = 11.3 min <

(b) After all the ice is converted to liquid, the absorbed power is $\dot{q} = 0.95P = 950$ W. The time for the beef to reach 80°C can again be found from Eq.(2):

$$\ln\left[\frac{80°\text{C} - 30°\text{C} - 950\text{ W}/(15\text{ W/m}^2\cdot\text{K} \times 0.0511\text{ m}^2)}{0°\text{C} - 30°\text{C} - 950\text{ W}/(15\text{ W/m}^2\cdot\text{K} \times 0.0511\text{ m}^2)}\right] = -\frac{15\text{ W/m}^2\cdot\text{K} \times 0.0511\text{ m}^2}{1\text{ kg} \times 4179\text{ J/kg}\cdot\text{K}}t$$

Thus t = 355 s = 5.9 min <

(c) Microwave power is more efficiently absorbed in regions of liquid water. Therefore, if food or the microwave irradiation is not homogeneous or uniform, the power will be absorbed nonuniformly, resulting in a nonuniform temperature rise. Thawed regions will absorb more energy per unit volume than frozen regions. If food is of low thermal conductivity, there will be insufficient time for heat conduction to make the temperature more uniform. Use of low power allows more time for conduction to occur.

COMMENTS: (1) The time needed to turn the ice at 0°C into liquid water at 0°C was not calculated. The required energy is $Q = mh_{fg}$ = 1 kg × 2502 kJ/kg = 2502 kJ. The required time depends on how the fraction of microwave power absorbed changes during the thawing process. The minimum possible time would be t_{min} = 2502 kJ/950 W = 2600 s = 44 min. Therefore, the time to thaw is significant.

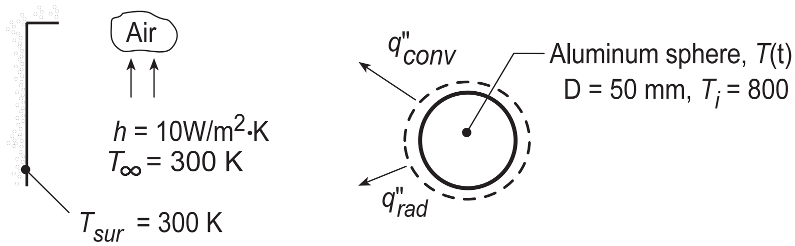
(2) Radiation may not be negligible. It depends on the temperature of the oven walls and the emissivity of the beef. Radiation would contribute to heating the beef.

PROBLEM 5.34

KNOWN: Metal sphere, initially at a uniform temperature T_i, is suddenly removed from a furnace and suspended in a large room and subjected to a convection process (T_∞, h) and to radiation exchange with surroundings, T_{sur}.

FIND: (a) Time it takes for sphere to cool to some temperature T, neglecting radiation exchange, (b) Time it takes for sphere to cool to some temperature t, neglecting convection, (c) Procedure to obtain time required if both convection and radiation are considered, (d) Time to cool an anodized aluminum sphere to 400 K using results of Parts (a), (b) and (c).

SCHEMATIC:



ASSUMPTIONS: (1) Sphere is spacewise isothermal, (2) Constant properties, (3) Constant heat transfer convection coefficient, (4) Sphere is small compared to surroundings.

PROPERTIES: *Table A-1*, Aluminum, pure ($\overline{T}$ = [800 + 400] K/2 = 600 K): $\rho = 2702$ kg/m^3, c = 1033 J/kg·K, k = 231 W/m·K, $\alpha = k/\rho c = 8.276 \times 10^{-5}$ m^2/s; Aluminum, anodized finish: $\varepsilon = 0.75$, polished surface: $\varepsilon = 0.1$.

ANALYSIS: (a) Neglecting radiation, the time to cool is predicted by Eq. 5.5,

$$t = \frac{\rho V c}{h A_s} \ln\frac{\theta_i}{\theta} = \frac{\rho D c}{6h} \ln\frac{T_i - T_\infty}{T - T_\infty} \qquad (1)$$ <

where $V/A_s = (\pi D^3/6)/(\pi D^2) = D/6$ for the sphere.

(b) Neglecting convection, the time to cool is predicted by Eq. 5.18,

$$t = \frac{\rho D c}{24 \varepsilon \sigma T_{sur}^3}\left\{\ln\left|\frac{T_{sur}+T}{T_{sur}-T}\right| - \ln\left|\frac{T_{sur}+T_i}{T_{sur}-T_i}\right| + 2\left[\tan^{-1}\left(\frac{T}{T_{sur}}\right) - \tan^{-1}\left(\frac{T_i}{T_{sur}}\right)\right]\right\} \qquad (2)$$

where $V/A_{s,r} = D/6$ for the sphere.

(c) If convection and radiation exchange are considered, the energy balance requirement results in Eq. 5.15 (with $q_s'' = \dot{E}_g = 0$). Hence

$$\frac{dT}{dt} = \frac{6}{\rho D c}\left[h\left(T - T_\infty\right) + \varepsilon\sigma\left(T^4 - T_{sur}^4\right)\right] \qquad (3)$$ <

where $A_{s(c,r)} = A_s = \pi D^2$ and $V/A_{s(c,r)} = D/6$. This relation must be solved numerically in order to evaluate the time-to-cool.

(d) For the aluminum (pure) sphere with an anodized finish and the prescribed conditions, the times to cool from T_i = 800 K to T = 400 K are:

Continued...

PROBLEM 5.34 (Cont.)

Convection only, Eq. (1)

$$t = \frac{2702\,\text{kg}/\text{m}^3 \times 0.050\,\text{m} \times 1033\,\text{J/kg}\cdot\text{K}}{6 \times 10\,\text{W}/\text{m}^2\cdot\text{K}} \ln\frac{800-300}{400-300} = 3743\text{s} = 1.04\text{h}$$ <

Radiation only, Eq. (2)

$$t = \frac{2702\,\text{kg}/\text{m}^3 \times 0.050\,\text{m} \times 1033\,\text{J/kg}\cdot\text{K}}{24 \times 0.75 \times 5.67 \times 10^{-8}\,\text{W}/\text{m}^2\cdot\text{K}^4 \times (300\,\text{K})^3} \cdot \left\{\left(\ln\frac{400+300}{400-300} - \ln\frac{800+300}{800-300}\right) + 2\left[\tan^{-1}\frac{400}{300} - \tan^{-1}\frac{800}{300}\right]\right\}$$

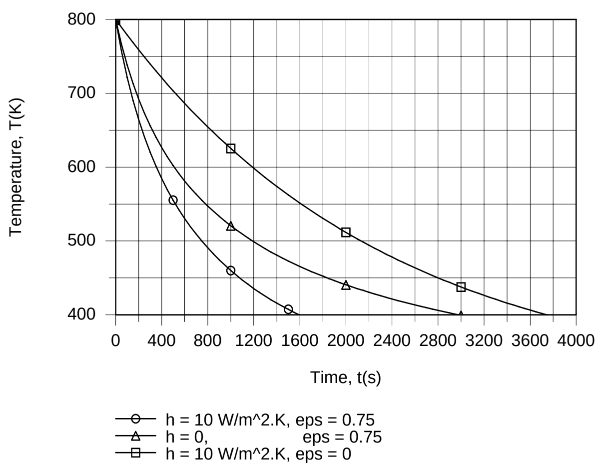
$$t = 5.065 \times 10^3 \left\{1.946 - 0.789 + 2(0.927 - 1.212)\right\} = 2973\text{s} = 0.826\text{h}$$ <

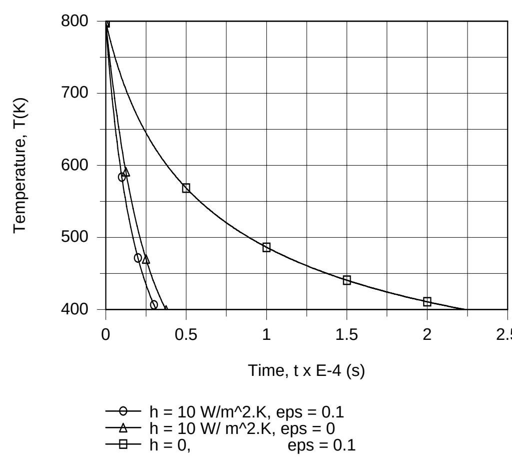
Radiation and convection, Eq. (3)

Using the IHT *Lumped Capacitance Model*, numerical integration yields

$$t \approx 1600\text{s} = 0.444\text{h}$$

In this case, heat loss by radiation exerts the stronger influence, although the effects of convection are by no means negligible. However, if the surface is polished (ε = 0.1), convection clearly dominates. For each surface finish and the three cases, the temperature histories are as follows.





COMMENTS: 1. A summary of the analyses shows the relative importance of the various modes of heat loss:

Active Modes	Time required to cool to 400 K (h)	
	ε = 0.75	ε = 0.1
Convection only	1.040	1.040
Radiation only	0.827	6.194
Both modes	0.444	0.889

2. Note that the spacewise isothermal assumption is justified since Be << 0.1. For the convection-only process,

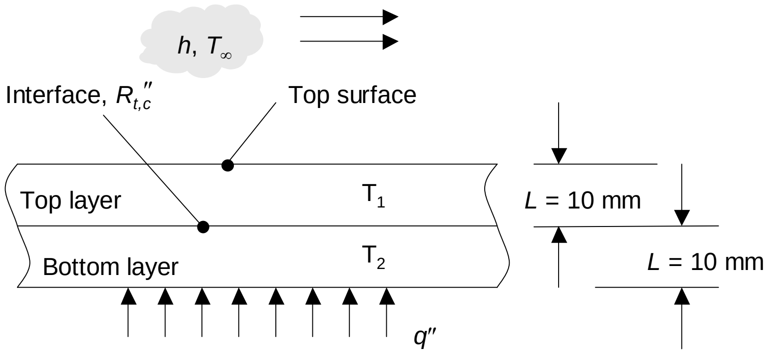
$$Bi = h(r_o/3)/k = 10\ \text{W/m}^2\cdot\text{K}\ (0.025\ \text{m}/3)/231\ \text{W/m}\cdot\text{K} = 3.6 \times 10^{-4}$$

PROBLEM 5.35

KNOWN: Thickness and initial temperatures of two layers of copper and aluminum. Contact resistance at the interface between the layers, applied heat flux, and convective conditions on the upper surface of the top layer.

FIND: (a) Times at which the copper (bottom) and aluminum (top) reach a temperature of T_f = 90°C. (b) Times at which the copper (top) and aluminum (bottom) reach a temperature of T_f = 90°C.

SCHEMATIC:



ASSUMPTIONS: (1) Lumped capacitance behavior, (2) Constant properties, (3) Negligible radiation.

PROPERTIES: Table A.1; copper (T = 300 K): ρ_A = 8933 kg/m^3, c_A = 385 J/kg·K, k_A = 401 W/m·K; aluminum (T = 300 K): ρ_B = 2702 kg/m^3, c_B = 903 J/kg·K, k_B = 237 W/m·K.

ANALYSIS: (a) For copper on the bottom, a modified form of Eq. 5.15 may be applied to both materials, resulting in

Copper: $$q_s'' - \frac{1}{R_{t,c}''}(T_A - T_B) = \rho_A c_A L_A \frac{dT_A}{dt} \tag{1}$$

Aluminum: $$\frac{1}{R_{t,c}''}(T_A - T_B) - h(T_B - T_\infty) = \rho_B c_B L_B \frac{dT_B}{dt} \tag{2}$$

Equations 1 and 2 are coupled differential equations with the initial conditions $T_{i,A} = T_{i,B}$ = 25°C. Hence, a numerical solution is required, yielding $t_{f,A}$ = 34.4 s and $t_{f,B}$ = 44.6 s. <

(b) For copper on the top, modified Eq. 5.15 is written as

Copper: $$\frac{1}{R_{t,c}''}(T_B - T_A) - h\left(T_A - T_\infty\right) = \rho_A c_A L_A \frac{dT_A}{dt}$$

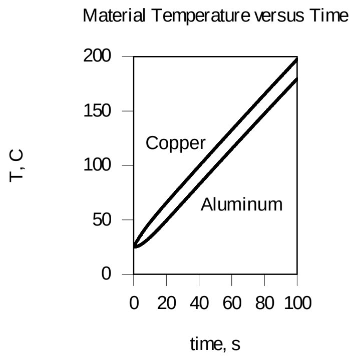
Aluminum: $$q_s'' - \frac{1}{R_{t,c}''}(T_B - T_A) = \rho_B c_B L_B \frac{dT_B}{dt}$$

The numerical solution yields $t_{f,A}$ = 44.6 s and $t_{f,B}$ = 30.4 s. <

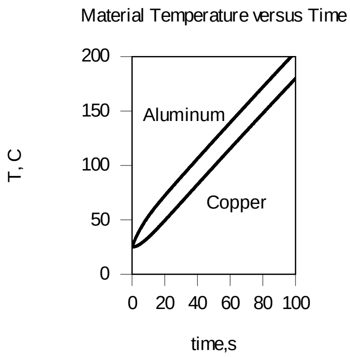
Continued…

PROBLEM 5.35 (Cont.)

COMMENTS: (1) For the aluminum on the top, the Biot number associated with the aluminum is $Bi_B = hL_B/k_B = (40\ W/m^2{\cdot}K \times 10 \times 10^{-3}\ m)/237\ W/m{\cdot}K = 0.0017$. The lumped capacitance approach is valid for the aluminum. For the copper, the contact resistance and the conduction resistance through the top aluminum layer pose thermal resistances in series with the convective resistance. In addition, the thermal conductivity of copper is greater than that of the aluminum, so lumped capacitance behavior is also expected for the copper. For the copper on top, the Biot number for the copper is Bi_A = 0.0010. Lumped capacitance behavior will also exist for this configuration. (2) The thermal responses for the two cases are shown below. Can you explain the differences?



Copper on Bottom



Copper on Top

(3) At t = 44.6 s, the temperature of the copper in part (a) is $T_A(t = 44.6s) = 107.1°C$. At t = 44.6 s, the temperature of the bottom aluminum in part (b) is $T_B = 113.9°C$. Hence, the increase in thermal energy of both materials per unit area during the first 44.6 s of heating for part (a) is $\Delta E_{st}'' = L_A c_A[T_A(t = 44.6\ s) - T_i] + L_B c_B[T_B(t = 44.6\ s) - T_i] = 10 \times 10^{-3}m \times 385\ J/kg{\cdot}K \times [107.1 - 25]°C + 10 \times 10^{-3}m \times 903\ J/kg{\cdot}K \times [90 - 25]°C = 903\ J/m^2$. For part (b) the increase in thermal energy is $\Delta E_{st}'' = = 10 \times 10^{-3}m \times 385\ J/kg{\cdot}K \times [90 - 25]°C + 10 \times 10^{-3}m \times 903\ J/kg{\cdot}K \times [113.9 - 25]°C = 1053\ J/m^2$. The difference between the two values is due to differences in the cumulative convective losses from the top surface for the two configurations. Why are convective heat losses smaller in part (b) than in part (a)? (4) The IHT Code used to solve Equations 1 and 2 is shown below. A time step of Δt = 0.1 s was specified.

```
//Dimensions
LA = 10/1000                //m

//Energy Balance on B
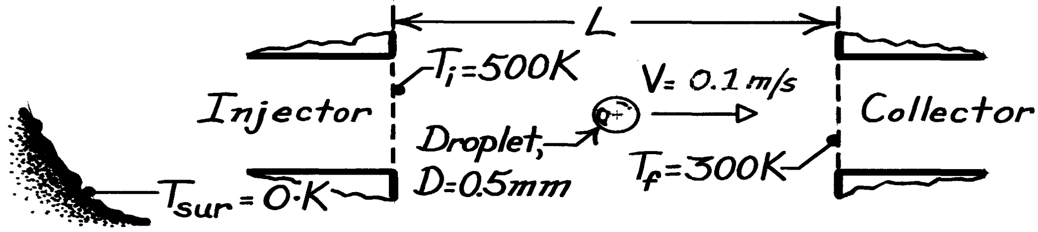
rhoB*LB*cB*Der(TB,t) = qflux - (TB - TA)/Rcont
```

PROBLEM 5.36

KNOWN: Droplet properties, diameter, velocity and initial and final temperatures.

FIND: Travel distance and rejected thermal energy.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Negligible radiation from space.

PROPERTIES: Droplet (given): ρ = 885 kg/m^3, c = 1900 J/kg·K, k = 0.145 W/m·K, ε = 0.95.

ANALYSIS: To assess the suitability of applying the lumped capacitance method, use Equation 1.9 to obtain the maximum radiation coefficient, which corresponds to T = T_i.

$$h_r = \varepsilon\sigma T_i^3 = 0.95\times 5.67\times 10^{-8}\,\text{W/m}^2\cdot\text{K}^4\,(500\text{ K})^3 = 6.73\text{ W/m}^2\cdot\text{K}.$$

Hence

$$Bi_r = \frac{h_r\,(r_o/3)}{k} = \frac{\left(6.73\text{ W/m}^2\cdot\text{K}\right)\left(0.25\times 10^{-3}\text{ m/3}\right)}{0.145\text{ W/m}\cdot\text{K}} = 0.0039$$

and the lumped capacitance method can be used. From Equation 5.19,

$$t = \frac{L}{V} = \frac{\rho c\left(\pi D^3/6\right)}{3\varepsilon\left(\pi D^2\right)\sigma}\left(\frac{1}{T_f^3} - \frac{1}{T_i^3}\right)$$

$$L = \frac{(0.1\text{ m/s})885\text{ kg/m}^3(1900\text{ J/kg}\cdot\text{K})0.5\times 10^{-3}\text{ m}}{18\times 0.95\times 5.67\times 10^{-8}\text{ W/m}^2\cdot\text{K}^4}\left(\frac{1}{300^3} - \frac{1}{500^3}\right)\frac{1}{\text{K}^3}$$

$$L = 2.52\text{ m.}$$ <

The amount of energy rejected by each droplet is equal to the change in its internal energy.

$$E_i - E_f = \rho Vc\left(T_i - T_f\right) = 885\text{ kg/m}^3\pi\frac{\left(5\times 10^{-4}\text{m}\right)^3}{6}1900\text{ J/kg}\cdot\text{K}\left(200\text{ K}\right)$$

$$E_i - E_f = 0.022\text{ J.}$$ <

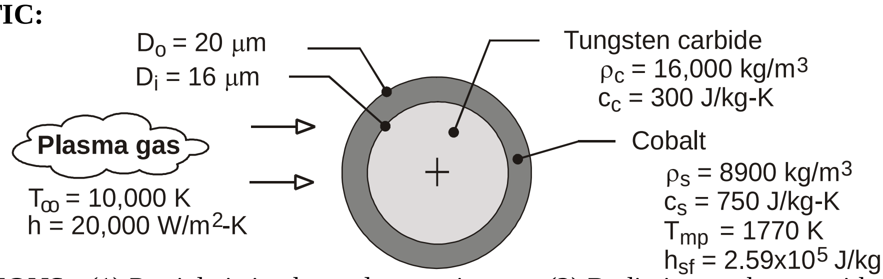
COMMENTS: Because some of the radiation emitted by a droplet will be intercepted by other droplets in the stream, the foregoing analysis overestimates the amount of heat dissipated by radiation to space.

PROBLEM 5.37

KNOWN: Diameters, initial temperature and thermophysical properties of WC and Co in composite particle. Convection coefficient and freestream temperature of plasma gas. Melting point and latent heat of fusion of Co.

FIND: Times required to reach melting and to achieve complete melting of Co.

SCHEMATIC:



ASSUMPTIONS: (1) Particle is isothermal at any instant, (2) Radiation exchange with surroundings is negligible, (3) Negligible contact resistance at interface between WC and Co, (4) Constant properties.

ANALYSIS: From Eq. (5.5), the time required to reach the melting point is

$$t_1 = \frac{(\rho Vc)_{tot}}{h\pi D_o^2} \ln \frac{T_i - T_\infty}{T_{mp} - T_\infty}$$

where the total heat capacity of the composite particle is

$$(\rho Vc)_{tot} = (\rho Vc)_c + (\rho Vc)_s = 16{,}000\,kg/m^3 \left[\pi\left(1.6\times10^{-5}m\right)^3/6\right] 300\,J/kg\cdot K$$

$$+8900\,kg/m^3 \left\{\pi/6\left[\left(2.0\times10^{-5}m\right)^3 - \left(1.6\times10^{-5}m\right)^3\right]\right\} 750\,J/kg\cdot K$$

$$= \left(1.03\times10^{-8} + 1.36\times10^{-8}\right) J/K = 2.39\times10^{-8}\,J/K$$

$$t_1 = \frac{2.39\times10^{-8}\,J/K}{\left(20{,}000\,W/m^2\cdot K\right)\pi\left(2.0\times10^{-5}m\right)^2} \ln\frac{(300-10{,}000)K}{(1770-10{,}000)K} = 1.56\times10^{-4}s \quad <$$

The time required to melt the Co may be obtained by applying the first law, Eq. (1.12b) to a control surface about the particle. It follows that

$$E_{in} = h\pi D_o^2\left(T_\infty - T_{mp}\right)t_2 = \Delta E_{st} = \rho_s(\pi/6)\left(D_o^3 - D_i^3\right)h_{sf}$$

$$t_2 = \frac{8900\,kg/m^3(\pi/6)\left[\left(2\times10^{-5}m\right)^3 - \left(1.6\times10^{-5}m\right)^3\right]2.59\times10^5\,J/kg}{\left(20{,}000\,W/m^2\cdot K\right)\pi\left(2\times10^{-5}m\right)^2(10{,}000-1770)K} = 2.28\times10^{-5}s \quad <$$

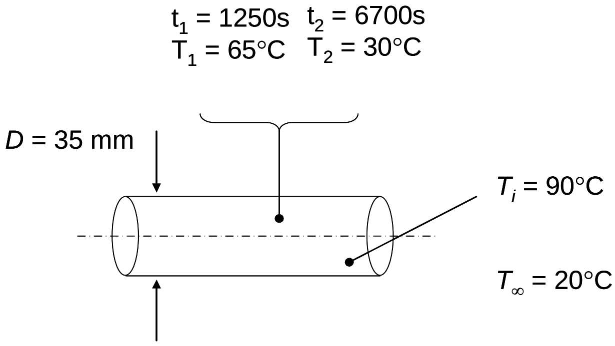
COMMENTS: (1) The largest value of the radiation coefficient corresponds to $h_r = \varepsilon\sigma(T_{mp} + T_{sur})\left(T_{mp}^2 + T_{sur}^2\right)$. For the maximum possible value of ε = 1 and T_{sur} = 300K, h_r = 378 W/m^2·K << h = 20,000 W/m^2·K. Hence, the assumption of negligible radiation exchange is excellent. (2) Despite the large value of h, the small values of D_o and D_i and the large thermal conductivities (~ 40 W/m·K and 70 W/m·K for WC and Co, respectively) render the lumped capacitance approximation a good one. (3) A detailed treatment of plasma heating of a composite powder particle is provided by Demetriou, Lavine and Ghoniem (Proc. 5th ASME/JSME Joint Thermal Engineering Conf., March, 1999).

PROBLEM 5.38

KNOWN: Diameter of highly polished aluminum rod. Temperature of rod initially and at two later times. Room air temperature.

FIND: Values of constants C and n in Equation 5.26. Plot rod temperature vs. time for varying and constant heat transfer coefficients.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Radiation negligible because rod is highly polished, (3) Lumped capacitance approximation is valid.

PROPERTIES: *Table A.1*, Aluminum (T = 328 K): c = 916 J/kg·K, ρ = 2702 kg/m^3, k = 238 W/m·K.

ANALYSIS: If the heat transfer coefficient is given by Equation 5.26, then the temperature as a function of time is given by Equation 5.28:

$$\frac{\theta}{\theta_i} = \left[\frac{nCA_{s,c}\theta_i^n}{\rho Vc}t + 1\right]^{-1/n} \qquad (1)$$

where $\theta = T - T_\infty$ and $A_{s,c}$ is the area exposed to convection, $A_{s,c} = \pi DL$. Since the rod temperature is known at two different times, Equation (1) can be evaluated at these two times, making it possible to solve for the two unknowns, C and n. The two equations are

$$\frac{\theta_1}{\theta_i} = \left[\frac{nCA_{s,c}\theta_i^n}{\rho Vc}t_1 + 1\right]^{-1/n} \qquad \frac{\theta_2}{\theta_i} = \left[\frac{nCA_{s,c}\theta_i^n}{\rho Vc}t_2 + 1\right]^{-1/n} \qquad (2a,b)$$

These equations cannot be explicitly solved for C and n. They can be numerically solved in this form, using IHT or some other software, or they can be further manipulated to solve for the times:

$$t_1 = \left[\left(\frac{\theta_1}{\theta_i}\right)^{-n} - 1\right]\frac{\rho cD}{4nC\theta_i^n} \qquad t_2 = \left[\left(\frac{\theta_2}{\theta_i}\right)^{-n} - 1\right]\frac{\rho cD}{4nC\theta_i^n} \qquad (3a,b)$$

where we have used $V/A_{s,c} = D/4$. Taking the ratio of Equations (3a) and (3b) yields

$$\frac{t_2}{t_1} = \frac{\left(\frac{\theta_2}{\theta_i}\right)^{-n} - 1}{\left(\frac{\theta_1}{\theta_i}\right)^{-n} - 1} \qquad \frac{6700\text{ s}}{1250\text{ s}} = \frac{\left(\frac{30°\text{C} - 20°\text{C}}{90°\text{C} - 20°\text{C}}\right)^{-n} - 1}{\left(\frac{65°\text{C} - 20°\text{C}}{90°\text{C} - 20°\text{C}}\right)^{-n} - 1} \qquad 5.36 = \frac{(0.143)^{-n} - 1}{(0.643)^{-n} - 1} \qquad (4a,b,c)$$

Continued...

PROBLEM 5.38 (Cont.)

This can be iteratively or numerical solved for *n*, to find *n* = 0.25. Then *C* can be determined from Equation (3a) or (3b):

$$C = \left[\left(\frac{\theta_1}{\theta_i}\right)^{-n} - 1\right]\frac{\rho c D}{4n\theta_i^n t_1} = \left[\left(\frac{45°\text{C}}{70°\text{C}}\right)^{-0.25} - 1\right]\frac{2702\ \text{kg/m}^3 \times 916\ \text{J/kg}\cdot\text{K} \times 0.035\ \text{m}}{4 \times 0.25 \times (70°\text{C})^{0.25} \times 1250\ \text{s}} = 2.8\ \text{W/m}^2\cdot\text{K}^{1.25}$$

$$C = 2.8\ \text{W/m}^2\cdot\text{K}^{1.25},\ n = 0.25$$ <

Now that these constants are known, the validity of the lumped capacitance approximation can checked. The maximum heat transfer coefficient occurs at the initial time,

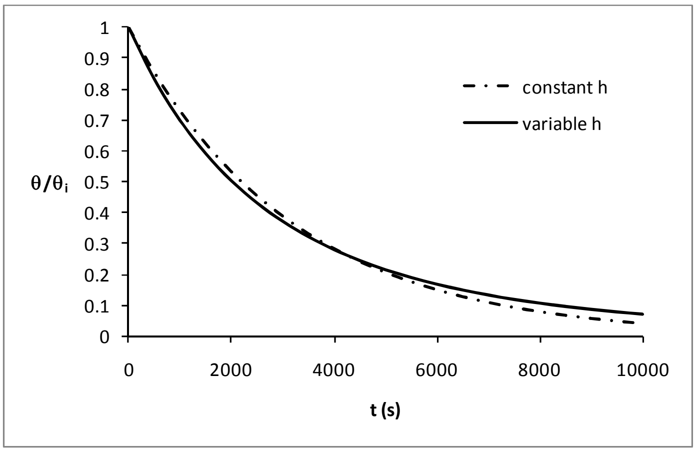
$$h = C(T - T_\infty)^n = 2.8\ \text{W/m}^2\cdot\text{K}^{1.25}\left[(90-20)\text{K}\right]^{0.25} = 8.1\ \text{W/m}^2\cdot\text{K}$$

Thus, using the conservative definition, $Bi = hD/2k = 6 \times 10^{-4}$. The lumped capacitance approximation is valid.

The heat transfer coefficient corresponding to a rod temperature of $\overline{T} = (T_i + T_\infty)/2 = 55°\text{C}$ is

$$h = C(T - T_\infty)^n = 2.8\ \text{W/m}^2\cdot\text{K}^{1.25}\left[(55-20)\text{K}\right]^{0.25} = 6.8\ \text{W/m}^2\cdot\text{K}$$

The plot below shows the rod temperature as a function of time using Equation (1) above for variable heat transfer coefficient, as well as the rod temperature assuming the constant value of $h = 6.8\ \text{W/m}^2\cdot\text{K}$, using text Equation 5.6.



<

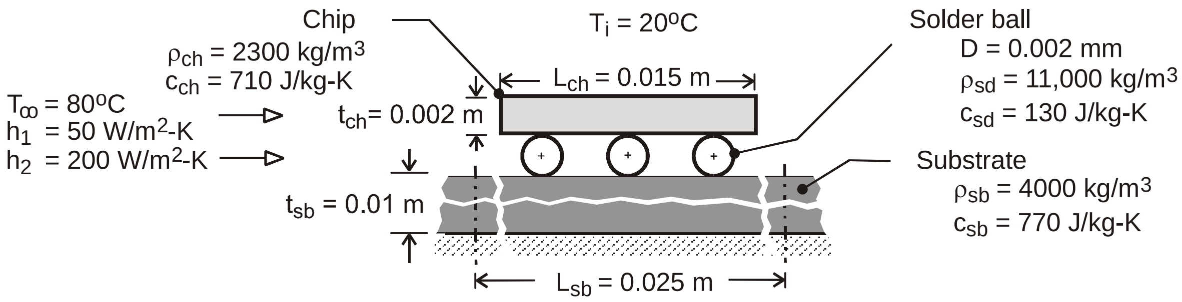
COMMENTS: (1) Since the heat transfer coefficient is temperature difference-dependent (variable *h*), the initial cooling rates are larger when this dependence is accounted for. As the temperature difference decreases, the variable *h* case cools slower relative to the constant *h* case. (2) The discrepancy between the variable and constant heat transfer coefficient cases is not large under these conditions. The difference would be greater if *n* were larger.

PROBLEM 5.39

KNOWN: Dimensions, initial temperature and thermophysical properties of chip, solder and substrate. Temperature and convection coefficient of heating agent.

FIND: (a) Time constants and temperature histories of chip, solder and substrate when heated by an air stream. Time corresponding to maximum stress on a solder ball. (b) Reduction in time associated with using a dielectric liquid to heat the components.

SCHEMATIC:



ASSUMPTIONS: (1) Lumped capacitance analysis is valid for each component, (2) Negligible heat transfer between components, (3) Negligible reduction in surface area due to contact between components, (4) Negligible radiation for heating by air stream, (5) Uniform convection coefficient among components, (6) Constant properties.

ANALYSIS: (a) From Eq. (5.7), $\tau_t = (\rho V c)/hA$

Chip: $V = \left(L_{ch}^2\right)t_{ch} = (0.015\text{m})^2(0.002\text{m}) = 4.50\times10^{-7}\,\text{m}^3, A_s = \left(2L_{ch}^2 + 4L_{ch}t_{ch}\right)$

$$= 2(0.015\text{m})^2 + 4(0.015\text{m})0.002\text{m} = 5.70\times10^{-4}\,\text{m}^2$$

$$\tau_t = \frac{2300\,\text{kg/m}^3 \times 4.50\times10^{-7}\,\text{m}^3 \times 710\,\text{J/kg}\cdot\text{K}}{50\,\text{W/m}^2\cdot\text{K}\times5.70\times10^{-4}\,\text{m}^2} = 25.8\text{s} \quad <$$

Solder: $V = \pi D^3/6 = \pi(0.002\text{m})^3/6 = 4.19\times10^{-9}\,\text{m}^3, A_s = \pi D^2 = \pi(0.002\text{m})^2 = 1.26\times10^{-5}\,\text{m}^2$

$$\tau_t = \frac{11{,}000\,\text{kg/m}^3\times4.19\times10^{-9}\,\text{m}^3\times130\,\text{J/kg}\cdot\text{K}}{50\,\text{W/m}^2\cdot\text{K}\times1.26\times10^{-5}\,\text{m}^2} = 9.5\text{s} \quad <$$

Substrate: $V = \left(L_{sb}^2\,t_{sb}\right) = (0.025\text{m})^2(0.01\text{m}) = 6.25\times10^{-6}\,\text{m}^3, A_s = L_{sb}^2 = (0.025\text{m})^2 = 6.25\times10^{-4}\,\text{m}^2$

$$\tau_t = \frac{4000\,\text{kg/m}^3\times6.25\times10^{-6}\,\text{m}^3\times770\,\text{J/kg}\cdot\text{K}}{50\,\text{W/m}^2\cdot\text{K}\times6.25\times10^{-4}\,\text{m}^2} = 616.0\text{s} \quad <$$

Substituting Eq. (5.7) into (5.5) and recognizing that $(T - T_i)/(T_\infty - T_i) = 1 - (\theta/\theta_i)$, in which case $(T - T_i)/(T_\infty - T_i) = 0.99$ yields $\theta/\theta_i = 0.01$, it follows that the time required for a component to experience 99% of its maximum possible temperature rise is

$$t_{0.99} = \tau\ln(\theta_i/\theta) = \tau\ln(100) = 4.61\tau$$

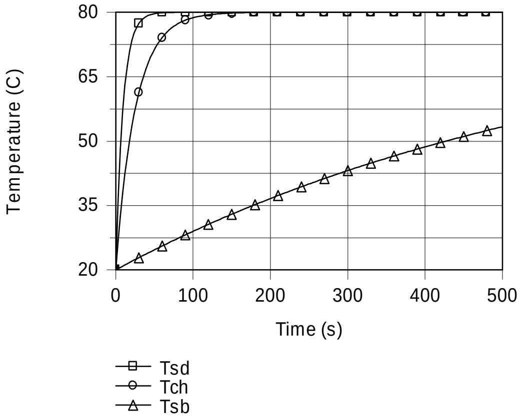
Hence,

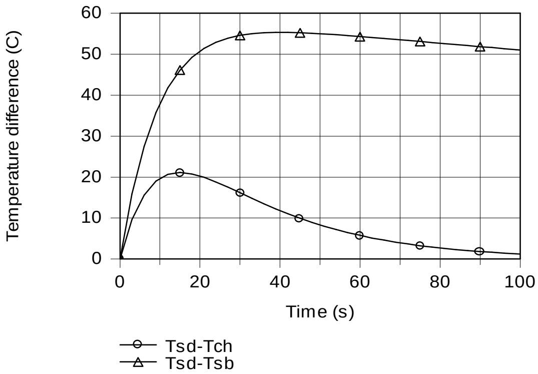
Chip: $t = 118.9\text{s}$, *Solder*: $t = 43.8\text{s}$, *Substrate*: $t = 2840$ $<$

Continued …

PROBLEM 5.39 (Cont.)

Histories of the three components and temperature differences between a solder ball and its adjoining components are shown below.





Commensurate with their time constants, the fastest and slowest responses to heating are associated with the solder and substrate, respectively. Accordingly, the largest temperature difference is between these two components, and it achieves a maximum value of 55°C at

$$t(\text{maximum stress}) \approx 40\text{s}$$ <

(b) With the 4-fold increase in h associated with use of a dielectric liquid to heat the components, the time constants are each reduced by a factor of 4, and the times required to achieve 99% of the maximum temperature rise are

Chip: $t = 29.5\text{s}$, *Solder*: $t = 11.0\text{s}$, *Substrate*: $t = 708\text{s}$ <

The time savings is approximately 75%.

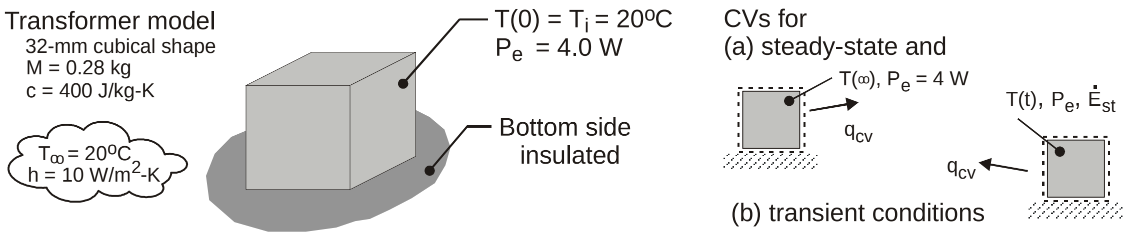
COMMENTS: The foregoing analysis provides only a first, albeit useful, approximation to the heating problem. Several of the assumptions are highly approximate, particularly that of a uniform convection coefficient. The coefficient will vary between components, as well as on the surfaces of the components. Also, because the solder balls are flattened, there will be a reduction in surface area exposed to the fluid for each component, as well as heat transfer between components, which reduces differences between time constants for the components.

PROBLEM 5.40

KNOWN: Electrical transformer of approximate cubical shape, 32 mm to a side, dissipates 4.0 W when operating in ambient air at 20°C with a convection coefficient of 10 W/m^2·K.

FIND: (a) Develop a model for estimating the steady-state temperature of the transformer, T(∞), and evaluate T(∞), for the operating conditions, and (b) Develop a model for estimating the temperature-time history of the transformer if initially the temperature is $T_i = T_\infty$ and suddenly power is applied. Determine the time required to reach within 5°C of its steady-state operating temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Transformer is spatially isothermal object, (2) Initially object is in equilibrium with its surroundings, (3) Bottom surface is adiabatic.

ANALYSIS: (a) Under steady-state conditions, for the control volume shown in the schematic above, the energy balance is

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = 0 \qquad 0 - q_{cv} + P_e = -h A_s\left[T(\infty) - T_\infty\right] + P_e = 0 \qquad (1)$$

where $A_s = 5 \times L^2 = 5 \times 0.032\text{m} \times 0.032\text{m} = 5.12 \times 10^{-3}\ \text{m}^2$, find

$$T(\infty) = T_\infty + P_e / h A_s = 20°\text{C} + 4\,\text{W} / \left(10\ \text{W/m}^2 \cdot \text{K} \times 5.12\times10^{-3}\text{m}^2\right) = 98.1°\text{C} \qquad <$$

(b) Under transient conditions, for the control volume shown above, the energy balance is

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = \dot{E}_{st} \qquad 0 - q_{cv} + P_e = Mc\frac{dT}{dt} \qquad (2)$$

Substitute from Eq. (1) for P_e, separate variables, and define the limits of integration.

$$-h\left[T(t) - T_\infty\right] + h\left[T(\infty) - T_\infty\right] = Mc\frac{dT}{dt}$$

$$-h\left[T(t) - T(\infty)\right] = Mc\frac{d}{dt}\left(T - T(\infty)\right) \qquad \frac{h}{Mc}\int_0^{t_o} dt = -\int_{\theta_i}^{\theta_o} \frac{d\theta}{\theta}$$

where $\theta = T(t) - T(\infty)$; $\theta_i = T_i - T(\infty) = T_\infty - T(\infty)$; and $\theta_o = T(t_o) - T(\infty)$ with t_o as the time when θ_o = - 5°C. Integrating and rearranging find (see Eq. 5.5),

$$t_o = \frac{Mc}{h A_s}\ell n\frac{\theta_i}{\theta_o}$$

$$t_o = \frac{0.28\ \text{kg} \times 400\ \text{J/kg}\cdot\text{K}}{10\ \text{W/m}^2 \cdot \text{K} \times 5.12\times10^{-3}\text{m}^2}\ell n\frac{(20 - 98.1)°\text{C}}{-5°\text{C}} = 1.67\ \text{hour} \qquad <$$

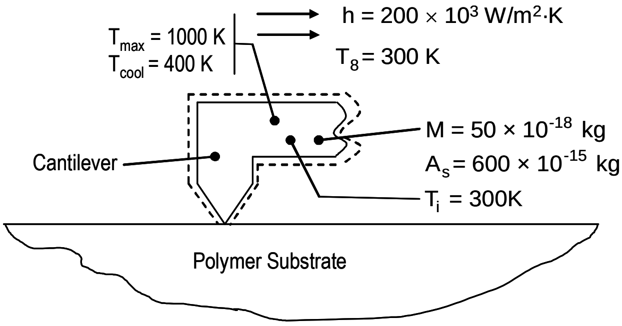
COMMENTS: The spacewise isothermal assumption may not be a gross over simplification since most of the material is copper and iron, and the external resistance by free convection is high. However, by ignoring internal resistance, our estimate for t_o is optimistic.

PROBLEM 5.41

KNOWN: Mass and exposed surface area of a silicon cantilever, convection heat transfer coefficient, initial and ambient temperatures.

FIND: (a) The ohmic heating needed to raise the cantilever temperature from T_i = 300 K to T = 1000 K in $t_h = 1\mu s$, (b) The time required to cool the cantilever from T = 1000 K to T = 400 K, t_c and the thermal processing time ($t_p = t_h + t_c$), (c) The number of bits that can be written onto a 1 mm × 1 mm surface area and time needed to write the data for a processing head equipped with M cantilevers.

SCHEMATIC:



ASSUMPTIONS: (1) Lumped capacitance behavior, (2) Negligible radiation heat transfer, (3) Constant properties, (4) Negligible heat transfer to polymer substrate.

PROPERTIES: Table A.1, silicon ($\overline{T}$ = 650 K): c_p = 878.5 J/kg·K.

ANALYSIS:

(a) From Problem 5.20 we note that

$$\frac{\theta}{\theta_i} = \exp\left(-\frac{t}{RC}\right) \tag{1}$$

where $\theta \equiv T - T(\infty)$ and $T(\infty)$ is the steady-state temperature corresponding to $t \to \infty$;

$\theta_i = T_i - T(\infty)$, $R = \dfrac{1}{hA_s}$, and $C = Mc_p$. For this problem,

$$R = \frac{1}{200 \times 10^3\ \text{W/m}^2 \cdot \text{K} \times 600 \times 10^{-15}\ \text{m}^2} = 8.33 \times 10^6\ \text{K/W}$$

$$C = 50 \times 10^{-18}\ \text{kg} \times 878.5\ \text{J/kg} \cdot \text{K} = 43.9 \times 10^{-15}\ \text{J/K}$$

$$R \times C = 8.33 \times 10^6\ \text{K/W} \times 43.9 \times 10^{-15}\ \text{J/K} = 366 \times 10^{-9}\ \text{s}$$

Therefore, Equation 1 may be evaluated as

Continued…

PROBLEM 5.41 (Cont.)

$$\frac{1000 - T(\infty)}{300 - T(\infty)} = \exp\left(-\frac{1 \times 10^{-6}\ \text{s}}{366 \times 10^{-9}\ \text{s}}\right) = 0.0651$$

hence, $T(\infty) = 1049\text{K}$.

At steady-state, Equation 1.12b yields

$$\dot{E}_g = hA_s(T(\infty) - T_\infty) = 200 \times 10^3\ \text{W/m}^2 \cdot \text{K} \times 600 \times 10^{-15}\ \text{m}^2 (1049 - 300)\ \text{K}$$
$$= 90 \times 10^{-6}\ \text{W} = 90\ \mu\text{W}$$ <

(b) Equation 5.6 may be used. Hence,

$$\frac{\theta}{\theta_i} = \exp\left[-\left(\frac{hA_s}{Mc}\right)t_c\right] \quad \text{where } \theta = T - T_\infty. \text{ Therefore}$$

$$\frac{400 - 300}{1000 - 300} = 0.143 = \exp\left[-\left(\frac{200 \times 10^3\ \text{W/m}^2 \cdot \text{K} \times 600 \times 10^{-15}\ \text{m}^2}{50 \times 10^{-18}\ \text{kg} \times 878.5\ \text{J/kg} \cdot \text{K}}\right)t_c\right]$$

or $t_c = 0.71 \times 10^{-6}\ \text{s} = 0.71\ \mu\text{s}$ <

and $t_p = t_h + t_c = 1.0\ \mu\text{s} + 0.71\ \mu\text{s} = 1.71\ \mu\text{s}$ <

(c) Each bit occupies $A_b = 50 \times 10^{-9}\ \text{m} \times 50 \times 10^{-9}\ \text{m} = 2.5 \times 10^{-15}\ \text{m}^2$

Therefore, the number of bits on a 1 mm × 1 mm substrate is

$$N = \frac{1 \times 10^{-3} \times 1 \times 10^{-3}\ \text{m}^2}{2.5 \times 10^{-15}\ \text{m}^2} = 400 \times 10^6\ \text{bits}$$ <

The total time needed to write the data (t_t) is,

$$t_t = \frac{N \times t_p}{M} = \frac{400 \times 10^6\ \text{bits} \times 1.71 \times 10^{-6}\ \text{s/bit}}{100} = 6.84\ \text{s}$$ <

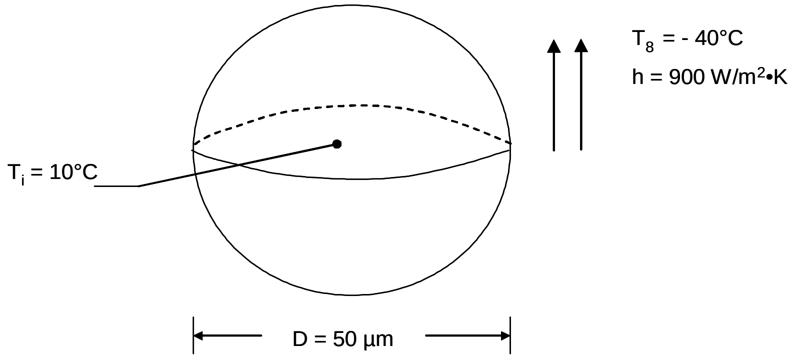
COMMENTS: (1) Lumped thermal capacitance behavior is an excellent approximation for such a small device (2) Each cantilever writes $N/M = 400 \times 10^6$ bits/100 cantilevers = 400×10^4 bits/cantilever. With a separation distance of 50×10^{-9} m, the total distance traveled is 50×10^{-9} m $\times 400 \times 10^4 = 200 \times 10^{-3}$ m = 200 mm. If the head travels at 200 mm/s, it will take 1 second to move the head, providing a total writing and moving time of 6.84 s + 1 s = 7.84 s. The speed of the process is heat transfer-limited.

PROBLEM 5.42

KNOWN: Ambient conditions, initial water droplet temperature and diameter.

FIND: Total time to completely freeze the water droplet for (a) droplet solidification at $T_f = 0°C$ and (b) rapid solidification of the droplet at $T_{f,sc}$.

SCHEMATIC:



ASSUMPTIONS: (1) Isothermal particle, (2) Negligible radiation heat transfer, (3) Constant properties.

PROPERTIES: Table A.6, liquid water (T = 0 °C): c_p = 4217 J/kg·K, k = 0.569 W/m·K, ρ = 1000 kg/m^3. Example 1.6: h_{sf} = 334 kJ/kg.

ANALYSIS: We begin by evaluating the validity of the lumped capacitance method by determining the value of the Biot number.

$$B_i = \frac{hL_c}{k} = \frac{hD/3}{k} = \frac{900\ \text{W/m}^2\cdot\text{K} \times 50 \times 10^{-6}\ \text{m}/3}{0.569\ \text{W/m}\cdot\text{K}} = 0.026 << 0.1$$

Hence, the lumped capacitance approach is valid.

<u>Case A: Equilibrium solidification, $T_f = 0°C$.</u>
The solidification process occurs in two steps. The first step involves cooling the drop to T_f = 0°C while the drop is completely liquid. Hence, Equation 5.6 is used where
$A = \pi D^2 = \pi \times (50 \times 10^{-6}\ \text{m})^2 = 7.85 \times 10^{-9}\ \text{m}^2$ and
$V = 4\pi(D/2)^3/3 = 4 \times \pi \times (50 \times 10^{-6}\ \text{m}/2)^3/3 = 65.4 \times 10^{-15}\ \text{m}^3$. Equation 5.6 may be rearranged to yield

$$t_1 = -\frac{\rho Vc}{hA}\ln\left[\frac{T - T_\infty}{T_i - T_\infty}\right] \qquad (1)$$

$$= -\frac{1000\ \text{kg/m}^3 \times 65.4 \times 10^{-15}\text{m}^3 \times 4217\ \text{J/kg}\cdot\text{K}}{900\ \text{W/m}^2 \times 7.85 \times 10^{-9}\ \text{m}^2} \times \ln\left[\frac{0 - (-40°C)}{10°C - (-40°C)}\right]$$

$t_1 = 8.7 \times 10^{-3}$ s = 8.7 ms

Continued…

PROBLEM 5.42 (Cont.)

The second step involves solidification of the ice, which occurs at $T_f = 0°C$. An energy balance on the droplet yields

$$-E_{out} = \Delta E_{st} \quad \text{or} \quad -hA(T_f - T_\infty)t_2 = \rho V h_{sf}$$

which may be rearranged to provide

$$t_2 = -\frac{\rho V h_{sf}}{hA(T_f - T_\infty)} \tag{2}$$

$$= \frac{1000\ \text{kg/m}^3 \times 65.4 \times 10^{-15}\text{m}^3 \times 334{,}000\ \text{J/kg}}{900\ \text{W/m}^2 \times 7.85 \times 10^{-9}\ \text{m}^2 \times (0°C - (-40)°C)} = 77.3 \times 10^{-3}\ \text{s} = 77.3\ \text{ms}$$

The time needed to cool and solidify the particle is

$$t = t_1 + t_2 = 8.7\ \text{ms} + 77.3\ \text{ms} = 86\ \text{ms}$$ <

<u>Case B: Rapid solidification at $T_{f,sc}$.</u>

Using the expression given in the problem statement, the liquid droplet is supercooled to a temperature of $T_{f,sc}$ prior to freezing.

$$T_{f,sc} = -28 + 1.87\ln(50 \times 10^{-6}\ \text{m}) = -36.6°C$$

The solidification process occurs in multiple steps, the first of which is cooling the particle to $T_{f,sc} = -36.6°C$. Substituting $T = T_{f,sc}$ into Equation 1 yields

$$t_1 = 105 \times 10^{-3}\ \text{s} = 105\ \text{ms}$$

The second step involves rapid solidification of some or all of the supercooled liquid. An energy balance on the particle yields

$$\dot{E}_{st} = 0 = \rho V h_{sf} f = \rho V c(T_f - T_{f,sc}) \tag{3}$$

where f is the fraction of the mass in the droplet that is converted to ice. Solving the preceding equation for f yields

$$f = \frac{c(T_f - T_{f,sc})}{h_{sf}} = \frac{4217\ \text{J/kg}\cdot\text{K} \times (0°C - (-36.6°C))}{334{,}000\ \text{J/kg}} = 0.462$$

Hence, immediately after the rapid solidification, the water droplet is approximately 46% ice and 54% liquid. The time required for the rapid solidification is $t_2 \approx 0$ s.

The third stage of Case B involves the time required to freeze the remaining liquid water, t_3. Equation 2 is modified accordingly to yield

$$t_3 = -\frac{(1-f)\rho V h_{sf}}{hA(T_f - T_\infty)}$$

$$= -\frac{(1 - 0.462) \times 1000\ \text{kg/m}^3 \times 65.4 \times 10^{-15}\text{m}^3 \times 334{,}000\ \text{J/kg}}{900\ \text{W/m}^2 \times 7.85 \times 10^{-9}\ \text{m}^2 \times (0°C - (-40)°C)} = 42 \times 10^{-3}\ \text{s} = 42\ \text{ms}$$

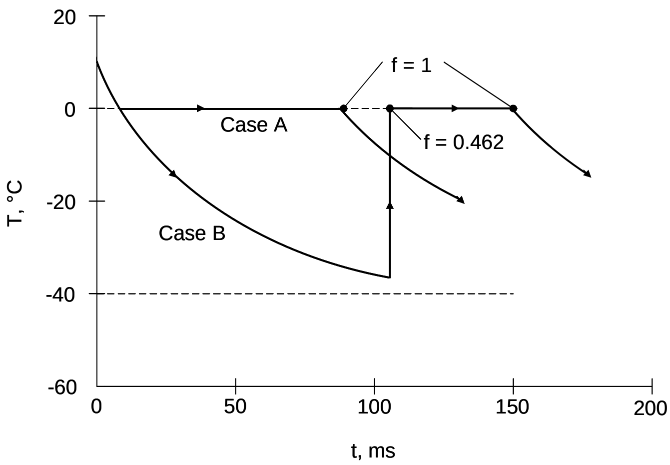
Continued…

PROBLEM 5.42 (Cont.)

The total time to solidify the particle is

$$t = t_1 + t_2 + t_3 = 105 \text{ ms} + 0 + 42 \text{ s} = 147 \text{ ms}$$ <

The temperature histories associated with Case A and Case B are shown in the sketch below.



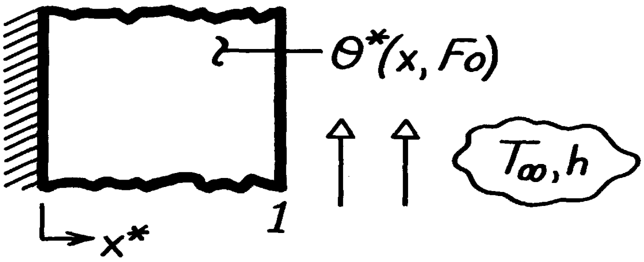
COMMENTS: (1) Equation 3 may be derived by assuming a reference temperature of $T_f = 0$ °C and a liquid reference state. The energy of the particle prior to the rapid solidification is $E_1 = \rho Vc(T_{f,sc} - T_f)$. The energy of the particle after the rapid solidification is $E_2 = -f\rho Vh_{sf} + (1 - f)\rho Vc(T_f - T_f) = -f\rho Vh_{sf}$. Setting $E_1 = E_2$ yields Equation 3. (2) The average temperature of the supercooled particle is significantly lower than the average temperature of the particle of Case A. Hence, the rate at which the supercooled particle of Case B is cooled by the cold air is, on average, much less than the particle of Case A. Since both particles ultimately reach the same state (all ice at T = 0 °C), it takes longer to completely solidify the supercooled particle. (3) For Case A, the ice particle at T = 0 °C will be a solid sphere, sometimes referred to as *sleet*. For Case B, the rapid solidification will result in a *snowflake*.

PROBLEM 5.43

KNOWN: Series solution, Eq. 5.42, for transient conduction in a plane wall with convection.

FIND: Midplane (x*=0) and surface (x*=1) temperatures θ* for Fo=0.1 and 1, using Bi=0.1, 1 and 10 with only the first four eigenvalues. Based upon these results, discuss the validity of the approximate solutions, Eqs. 5.43 and 5.44.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional transient conduction, (2) Constant properties.

ANALYSIS: The series solution, Eq. 5.42a, is of the form,

$$\theta^* = \sum_{n=1}^{\infty} C_n \exp\left(-\zeta_n^2 Fo\right)\cos\left(\zeta_n x^*\right)$$

where the eigenvalues, ζ_n, and the constants, C_n, are from Eqs. 5.39b and 5.39c.

$$\zeta_n \tan \zeta_n = Bi \qquad C_n = 4\sin \zeta_n / \left(2\zeta_n + \sin\left(2\zeta_n\right)\right).$$

The eigenvalues are tabulated in Appendix B.3; note, however, that ζ_1 and C_1 are available from Table 5.1. The values of ζ_n and C_n used to evaluate θ* are as follows:

Bi	ζ_1	C_1	ζ_2	C_2	ζ_3	C_3	ζ_4	C_4
0.1	0.3111	1.0160	3.1731	-0.0197	6.2991	0.0050	9.4354	-0.0022
1	0.8603	1.1191	3.4256	-0.1517	6.4373	0.0466	9.5293	-0.0217
10	1.4289	1.2620	4.3058	-0.3934	7.2281	0.2104	10.2003	-0.1309

Using ζ_n and C_n values, the terms of θ^*, designated as θ_1^*, θ_2^*, θ_3^* and θ_4^*, are as follows:

Fo=0.1

	Bi=0.1		Bi=1.0		Bi=10	
x*	0	1	0	1	0	1
θ_1^*	1.0062	0.9579	1.0393	0.6778	1.0289	0.1455
θ_2^*	-0.0072	0.0072	-0.0469	0.0450	-0.0616	0.0244
θ_3^*	0.0001	0.0001	0.0007	0.0007	0.0011	0.0006
θ_4^*	-2.99×10^{-7}	3.00×10^{-7}	2.47×10^{-6}	2.46×10^{-7}	-3.96×10^{-6}	2.83×10^{-6}
θ^*	0.9991	0.9652	0.9931	0.7235	0.9684	0.1705

Continued …

PROBLEM 5.43 (Cont.)

Fo=1

	Bi=0.1		Bi=1.0		Bi=10	
x*	0	1	0	1	0	1
θ_1^*	0.9223	0.8780	0.5339	0.3482	0.1638	0.0232
θ_2^*	8.35×10^{-7}	8.35×10^{-7}	-1.22×10^{-5}	1.17×10^{-6}	3.49×10^{-9}	1.38×10^{-9}
θ_3^*	7.04×10^{-20}	-	4.70×10^{-20}	-	4.30×10^{-24}	-
θ_4^*	4.77×10^{-42}	-	7.93×10^{-42}	-	8.52×10^{-47}	-
θ^*	0.9223	0.8780	0.5339	0.3482	0.1638	0.0232

The tabulated results for $\theta^* = \theta^*\left(x^*,\ \text{Bi, Fo}\right)$ demonstrate that for Fo=1, the first eigenvalue is sufficient to accurately represent the series. However, for Fo=0.1, three eigenvalues are required for accurate representation.

A more detailed analysis would show that a practical criterion for representation of the series solution by one eigenvalue is Fo > 0.2. For these situations the approximate solutions, Eqs. 5.43 and 5.44, are appropriate. For the midplane, x^*=0, the first two eigenvalues for Fo=0.2 are:

	Fo=0.2	x*=0	
Bi	0.1	1.0	10
θ_1^*	0.9965	0.9651	0.8389
θ_2^*	-0.00226	-0.0145	-0.0096
θ^*	0.9939	0.9506	0.8293
Error,%	+0.26	+1.53	+1.16

The percentage error shown in the last row of the above table is due to the effect of the second term. For Bi = 0.1, neglecting the second term provides an error of 0.26%. For Bi = 1, the error is 1.53%.

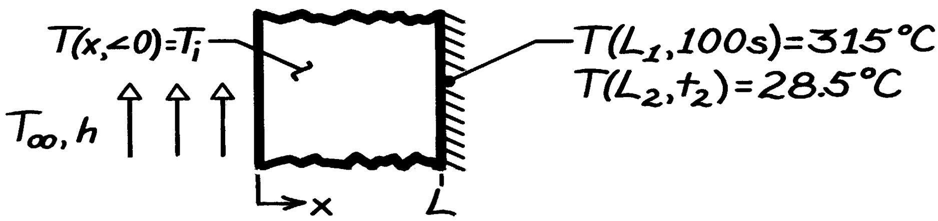
Hence we conclude that the approximate series solutions (with only one eigenvalue) provides systematically high results, but by less than 1.5%, for the Biot number range from 0.1 to 10.

PROBLEM 5.44

KNOWN: One-dimensional wall, initially at a uniform temperature, T_i, is suddenly exposed to a convection process (T_∞, h). For wall #1, the time (t_1 = 100s) required to reach a specified temperature at x = L is prescribed, $T(L_1, t_1)$ = 315°C.

FIND: For wall #2 of different thickness and thermal conditions, the time, t_2, required for $T(L_2, t_2)$ = 28°C.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties.

ANALYSIS: The properties, thickness and thermal conditions for the two walls are:

Wall	L(m)	α(m²/s)	k(W/m·K)	T_i(°C)	T_∞(°C)	h(W/m²·K)
1	0.10	15×10^{-6}	50	300	400	200
2	0.40	25×10^{-6}	100	30	20	100

The dimensionless functional dependence for the one-dimensional, transient temperature distribution, Eq. 5.38, is

$$\theta^* = \frac{T(x,t) - T_\infty}{T_i - T_\infty} = f\left(x^*,\ Bi,\ Fo\right)$$

where

$$x^* = x/L \qquad Bi = hL/k \qquad Fo = \alpha t/L^2.$$

If the parameters x*, Bi, and Fo are the same for both walls, then $\theta_1^* = \theta_2^*$. Evaluate these parameters:

Wall	x*	Bi	Fo	θ*
1	1	0.40	0.150	0.85
2	1	0.40	$1.563\times10^{-4}\ t_2$	0.85

where

$$\theta_1^* = \frac{315 - 400}{300 - 400} = 0.85 \qquad \theta_2^* = \frac{28.5 - 20}{30 - 20} = 0.85.$$

It follows that

$$Fo_2 = Fo_1 \qquad 1.563\times10^{-4} t_2 = 0.150$$

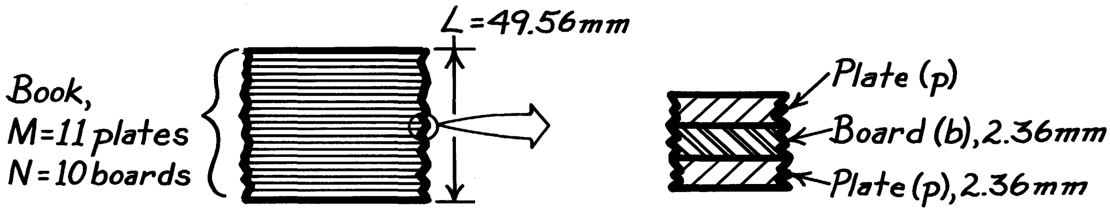
$$t_2 = 960s.$$ <

PROBLEM 5.45

KNOWN: Stack or book comprised of 11 metal plates (p) and 10 boards (b) each of 2.36 mm thickness and prescribed thermophysical properties.

FIND: Effective thermal conductivity, k, and effective thermal capacitance, (ρc_p).

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Negligible contact resistance between plates and boards.

PROPERTIES: Metal plate (p, given): ρ_p = 8000 kg/m^3, $c_{p,p}$ = 480 J/kg·K, k_p = 12 W/m·K; Circuit boards (b, given): ρ_b = 1000 kg/m^3, $c_{p,b}$ = 1500 J/kg·K, k_b = 0.30 W/m·K.

ANALYSIS: The thermal resistance of the book is determined as the sum of the resistance of the boards and plates,

$$R''_{tot} = NR''_b + MR''_p$$

where M,N are the number of plates and boards in the book, respectively, and $R''_i = L_i / k_i$ where L_i and k_i are the thickness and thermal conductivities, respectively.

$$R''_{tot} = M\left(L_p / k_p\right) + N\left(L_b / k_b\right)$$
$$R''_{tot} = 11\left(0.00236 \text{ m}/12 \text{ W/m}\cdot\text{K}\right) + 10\left(0.00236 \text{ m}/0.30 \text{ W/m}\cdot\text{K}\right)$$
$$R''_{tot} = 2.163\times10^{-3} + 7.867\times10^{-2} = 8.083\times10^{-2} \text{ K/W.}$$

The effective thermal conductivity of the book of thickness (10 + 11) 2.36 mm is

$$k = L/R''_{tot} = \frac{0.04956 \text{ m}}{8.083\times10^{-2} \text{ K/W}} = 0.613 \text{ W/m}\cdot\text{K.} \qquad <$$

The thermal capacitance of the stack is

$$C''_{tot} = M\left(\rho_p L_p c_p\right) + N\left(\rho_b L_b c_b\right)$$
$$C''_{tot} = 11\left(8000 \text{ kg/m}^3 \times 0.00236 \text{ m} \times 480 \text{ J/kg}\cdot\text{K}\right) + 10\left(1000 \text{ kg/m}^3 \times 0.00236 \text{ m} \times 1500 \text{ J/kg}\cdot\text{K}\right)$$
$$C''_{tot} = 9.969\times10^4 + 3.540\times10^4 = 1.35\times10^5 \text{ J/m}^2\cdot\text{K.}$$

The effective thermal capacitance of the book is

$$\left(\rho c_p\right) = C''_{tot} / L = 1.351\times10^5 \text{ J/m}^2\cdot\text{K}/0.04956 \text{ m} = 2.726\times10^6 \text{ J/m}^3\cdot\text{K.} \qquad <$$

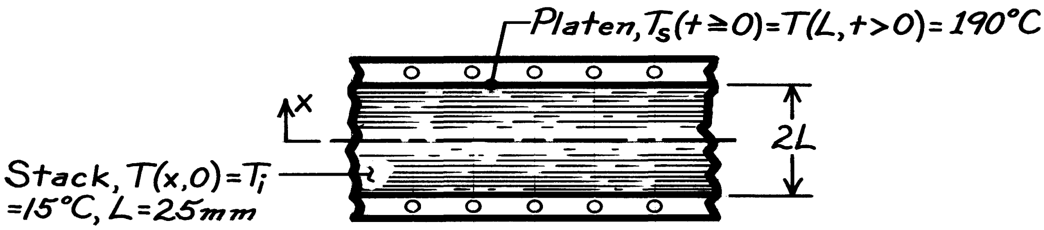
COMMENTS: The results of the analysis allow for representing the stack as a homogeneous medium with *effective* properties: k = 0.613 W/m·K and $\alpha = (k/\rho c_p) = 2.249\times10^{-7}$ m^2/s.

PROBLEM 5.46

KNOWN: Stack of circuit board-pressing plates, initially at a uniform temperature, is subjected by upper/lower platens to a higher temperature.

FIND: (a) Elapsed time, t_e, required for the mid-plane to reach cure temperature when platens are suddenly changed to T_s = 190°C, (b) Energy removal from the stack needed to return its temperature to T_i.

SCHEMATIC:



PROPERTIES: Stack (given): k = 0.613 W/m·K, $\rho c_p = 2.73\times10^6$ J/m^3·K; $\alpha = k/\rho c_p = 2.245\times10^{-7}$ m^2/s.

ANALYSIS: (a) Recognize that sudden application of surface temperature corresponds to $h \to \infty$, or $Bi \to \infty$. With $T_s = T_\infty$,

$$\theta_o^* = \frac{T(0,t)-T_s}{T_i - T_s} = \frac{(170-190)^\circ C}{(15-190)^\circ C} = 0.114.$$

Using Eq. 5.44 with values of $\zeta_1 = 1.5707$ and $C_1 = 1.2733$ for $Bi \to \infty$ (Table 5.1), find Fo

$$\theta_o^* = C_1 \exp\left(-\zeta_1^2 Fo\right)$$

$$Fo = -\frac{1}{\zeta_1^2}\ln\left(\theta_o^*/C_1\right) = -\frac{1}{(1.5707)^2}\ln(0.114/1.2733) = 0.977$$

where Fo = $\alpha t/L^2$,

$$t = \frac{FoL^2}{\alpha} = \frac{0.977\left(25\times10^{-3}\text{ m}\right)^2}{2.245\times10^{-7}\text{ m}^2/\text{s}} = 2.720\times10^3\text{s} = 45.3\text{ min.}$$ <

(b) The energy removal is equivalent to the energy gained by the stack per unit area for the time interval $0 \to t_e$. With Q_o'' corresponding to the maximum amount of energy that could be transferred,

$$Q_o'' = \rho c(2L)(T_i - T_\infty) = 2.73\times10^6\text{ J/m}^3\cdot K\left(2\times25\times10^{-3}\text{ m}\right)(15-190)K = -2.389\times10^7\text{ J/m}^2.$$

Q'' may be determined from Eq. 5.49,

$$\frac{Q''}{Q_o''} = 1 - \frac{\sin\zeta_1}{\zeta_1}\theta_o^* = 1 - \frac{\sin(1.5707\text{ rad})}{1.5707\text{ rad}}\times0.114 = 0.927$$

We conclude that the energy to be removed from the stack per unit area to return it to T_i is

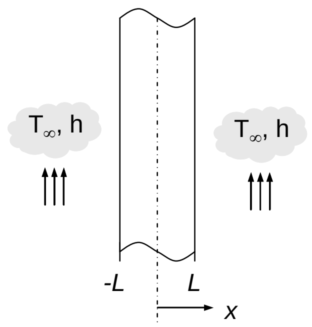
$$Q'' = 0.927Q_o'' = 0.927\times2.389\times10^7\text{ J/m}^2 = 2.21\times10^7\text{ J/m}^2.$$ <

PROBLEM 5.47

KNOWN: One-dimensional convective heating of a plane slab with $Bi = 1$ for a dimensionless time of Fo_1.

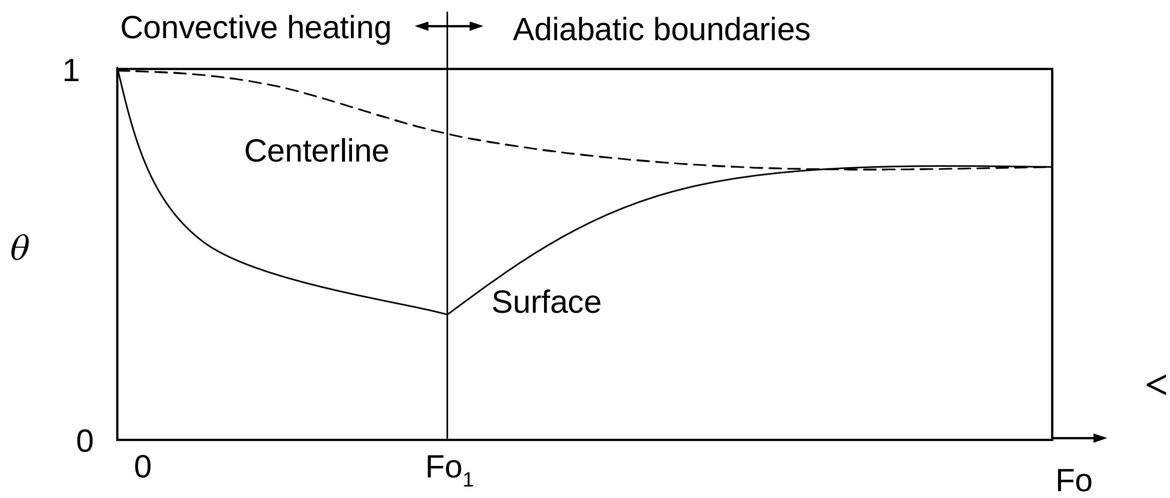
FIND: (a) Sketch of the dimensionless midplane and surface temperatures of the slab as a function of dimensionless time over the range $0 < Fo_1 < Fo < \infty$. Relative value of Fo_2, needed to achieve a steady-state midplane temperature equal to the midplane temperature at Fo_1. (b) Analytical expression for, and value of $\Delta Fo = Fo_2 - Fo_1$ for $Bi = 1$, $Fo_1 > 0.2$, $Fo_2 > 0.2$. (c) Value of ΔFo for $Bi = 0.01$, 0.1, 10, 100 and ∞.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Approximate, one-term solutions are valid.

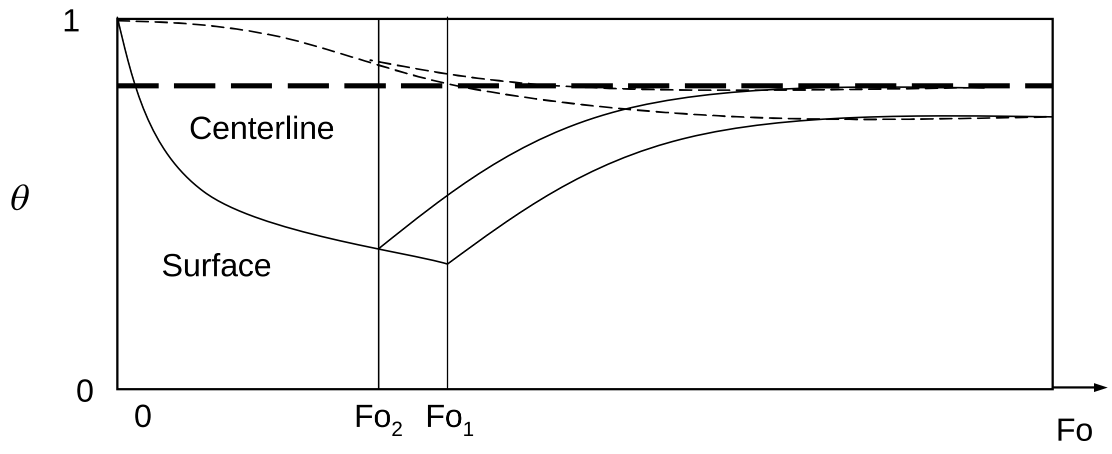
ANALYSIS: (a) A sketch of the dimensionless midplane and surface temperatures is shown below. Note that, at Fo_1, the surface of the slab will be warm (small θ) relative to the midplane since temperature gradients within the slab are significant ($Bi = 1$). At the curtailment of heating (Fo_1), the surface temperature cools rapidly while warm temperatures continue to propagate toward the midplane, slowly heating the midplane until a steady-state, isothermal condition is eventually reached.



Based on the sketch above, one could achieve a steady-state midplane temperature equal to the midplane temperature at Fo_1 by reducing the duration of convective heating to Fo_2, as shown in the sketch below.

Continued…

PROBLEM 5.47 (Cont.)



Hence, $Fo_2 < Fo_1$. <

(b) Using the approximate solutions of Section 5.5.2, and noting that the steady-state temperature of the slab is uniform and related to the energy transferred to the slab,

$$\theta_o^*(Fo_1) = 1 - \frac{Q}{Q_o}(Fo_2)$$

or,

$$1 - \theta_o^*(Fo_1) = \frac{Q}{Q_o}(Fo_1 + \Delta Fo_1) \qquad (1)$$

Substituting Eqs. 5.44 and 5.49 into Eq. (1) yields

$$1 - C_1 \exp(-\zeta_1^2 Fo_1) = 1 - \frac{\sin\zeta_1}{\zeta_1} C_1 \exp\left[-\zeta_1^2 \left(Fo_1 + \Delta Fo\right)\right]$$

which may be simplified to

$$\Delta Fo = -\frac{1}{\zeta_1^2} \ln\left(\frac{\zeta_1}{\sin\zeta_1}\right)$$ <

From Table 5.1, ζ_1 = 0.8603 rad at Bi = 1. Hence,

$$\Delta Fo = -\frac{1}{0.8603^2} \ln\left(\frac{0.8603}{\sin 0.8603}\right) = -0.1709$$ <

(c) The expression for ΔFo may be evaluated for a range of Bi, resulting in the following.

Continued…

PROBLEM 5.47 (Cont.)

Bi	ζ_1	ΔFo
0.01	0.0998	-0.1667
0.1	0.3111	-0.1672
1	0.8603	-0.1709
10	1.4289	-0.1847
100	1.5552	-0.1826
∞	1.5708	-0.1830

<

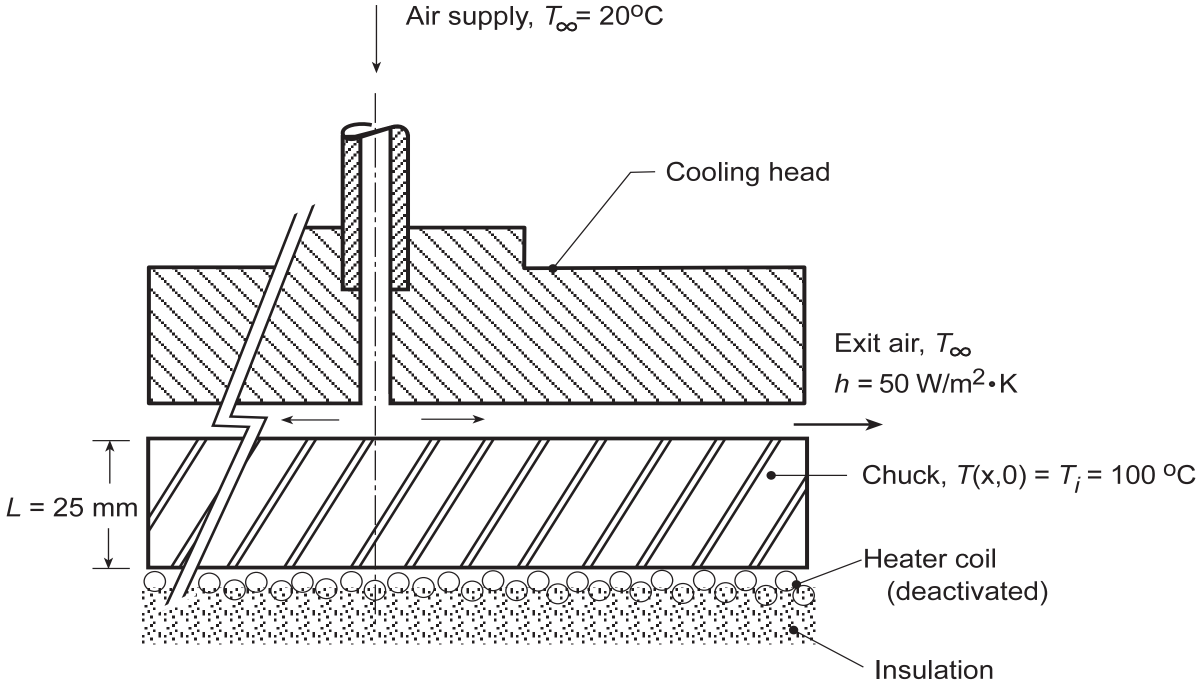
COMMENTS: (1) Note that the dimensionless temperature, $\theta_o^* = C_1 \exp\left(-\zeta_1^2 Fo\right)$, is defined in a manner such that for slab heating, increases in actual temperature correspond to decreases in the dimensionless temperature. (2) The dimensionless time lag, ΔFo, is weakly-dependent on the value of the Biot number and is independent of the heating time. Hence, a general rule-of-thumb is that a time lag of $\Delta Fo \approx$ - 0.17 should be specified in order to achieve an ultimate midplane temperature equal to that predicted at Fo_1 for convective heating or cooling. (3) For applications such as materials or food processing, where a certain minimum midplane temperature is desired, assuming that Fo_1 (as determined by Eq. 5.44 is the appropriate processing or cooking time can result in significant over-heating of the material or food, especially at small Fourier numbers. (4) Significant energy and time savings can be realized by reducing the processing or cooking time from Fo_1 to Fo_2.

PROBLEM 5.48

KNOWN: The chuck of a semiconductor processing tool, initially at a uniform temperature of T_i = 100°C, is cooled on its top surface by supply air at 20°C with a convection coefficient of 50 W/m^2·K.

FIND: (a) Time required for the lower surface to reach 25°C, and (b) Compute and plot the time-to-cool as a function of the convection coefficient for the range 10 ≤ h ≤ 2000 W/m^2·K; comment on the effectiveness of the head design as a method for cooling the chuck.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, transient conduction in the chuck, (2) Lower surface is perfectly insulated, (3) Uniform convection coefficient and air temperature over the upper surface of the chuck, and (4) Constant properties.

PROPERTIES: *Table A.1*, Aluminum alloy 2024 ((25 + 100)°C / 2 = 335 K): ρ = 2770 kg/m^3, c_p = 880 J/kg· K, k = 179 W/m·K.

ANALYSIS: (a) The Biot number for the chuck with h = 50 W/m^2·K is

$$\mathrm{Bi} = \frac{hL}{k} = \frac{50\,\mathrm{W/m^2\cdot K} \times 0.025\,\mathrm{m}}{179\,\mathrm{W/m\cdot K}} = 0.007 \le 0.1 \qquad (1)$$

so that the lumped capacitance method is appropriate. Using Eq. 5.5, with $V/A_s = L$,

$$t = \frac{\rho V c}{h A_s} \ln\frac{\theta_i}{\theta} \qquad \theta = T - T_\infty \qquad \theta_i = T_i - T_\infty$$

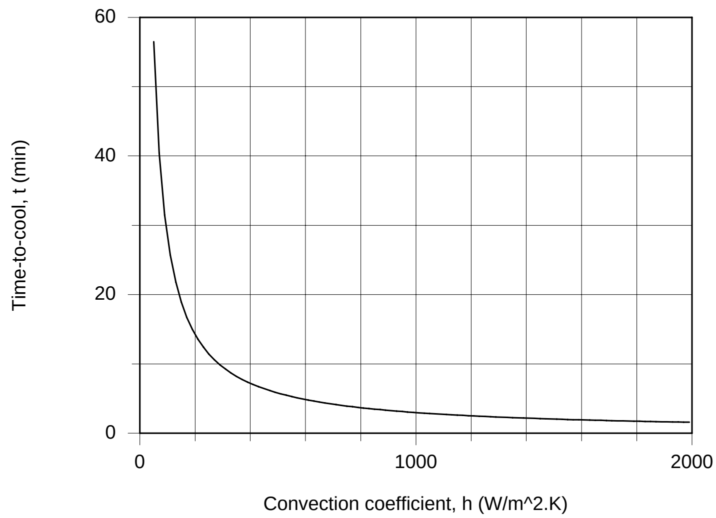
$$t = \left(2770\,\mathrm{kg/m^3} \times 0.025\,\mathrm{m} \times 880\,\mathrm{J/kg\cdot K} \big/ 50\,\mathrm{W/m^2\cdot K}\right) \ln\frac{(100-20)^\circ\mathrm{C}}{(25-20)^\circ\mathrm{C}}$$

$$t = 3379\,\mathrm{s} = 56.3\,\mathrm{min}$$ <

Continued...

PROBLEM 5.48 (Cont.)

(b) When h = 2000 $W/m^2 \cdot K$, using Eq. (1), find Bi = 0.28 > 0.1 so that the series solution, Section 5.5.1, for the plane wall with convection must be used. Using the *IHT Transient Conduction*, *Plane Wall Model*, the time-to-cool was calculated as a function of the convection coefficient. Free convection cooling condition corresponds to $h \approx 10$ $W/m^2 \cdot K$ and the time-to-cool is 282 minutes. With the cooling head design, the time-to-cool can be substantially decreased if the convection coefficient can be increased as shown below.

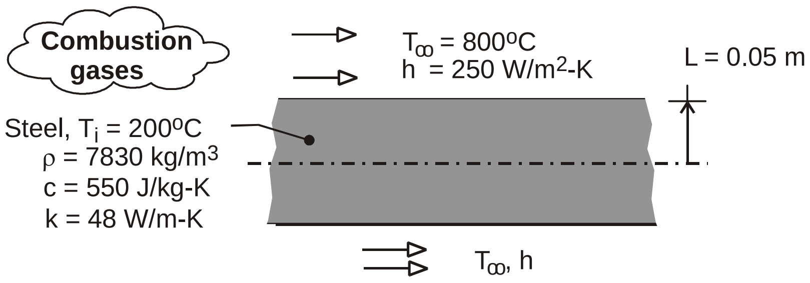


PROBLEM 5.49

KNOWN: Thickness, properties and initial temperature of steel slab. Convection conditions.

FIND: Heating time required to achieve a minimum temperature of 550°C in the slab.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Negligible radiation effects, (3) Constant properties.

ANALYSIS: With a Biot number of hL/k = (250 W/m^2·K × 0.05m)/48 W/m·K = 0.260, a lumped capacitance analysis should not be performed. At any time during heating, the lowest temperature in the slab is at the midplane, and from the one-term approximation to the transient thermal response of a plane wall, Eq. (5.44), we obtain

$$\theta_o^* = \frac{T_o - T_\infty}{T_i - T_\infty} = \frac{(550-800)°C}{(200-800)°C} = 0.417 = C_1 \exp\left(-\zeta_1^2 Fo\right)$$

With $\zeta_1 \approx 0.488$ rad and $C_1 \approx 1.0396$ from Table 5.1 and $\alpha = k/\rho c = 1.115\times10^{-5} m^2/s$,

$$-\zeta_1^2\left(\alpha t / L^2\right) = \ln(0.401) = -0.914$$

$$t = \frac{0.914 L^2}{\zeta_1^2 \alpha} = \frac{0.841(0.05m)^2}{(0.488)^2 1.115\times10^{-5} m^2/s} = 861s$$ <

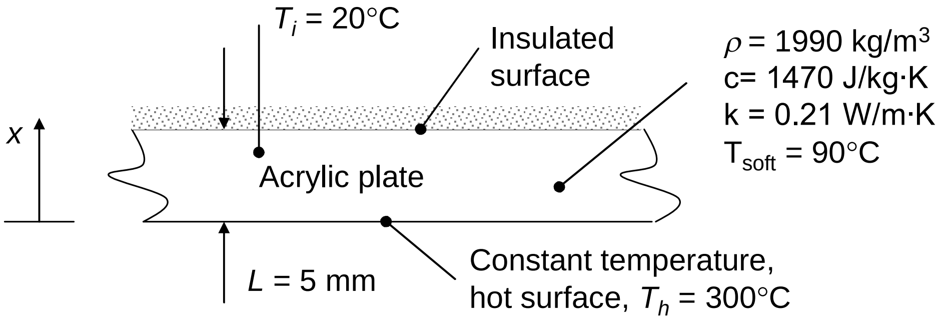
COMMENTS: The surface temperature at t = 861s may be obtained from Eq. (5.43b), where $\theta^* = \theta_o^* \cos\left(\zeta_1 x^*\right) = 0.417\cos(0.488 \text{ rad}) = 0.368$. Hence, $T(L, 792s) \equiv T_s = T_\infty + 0.368(T_i - T_\infty)$ $= 800°C - 221°C = 579°C$. Assuming a surface emissivity of ε = 1 and surroundings that are at $T_{sur} = T_\infty = 800°C$, the radiation heat transfer coefficient corresponding to this surface temperature is $h_r = \varepsilon\sigma(T_s + T_{sur})\left(T_s^2 + T_{sur}^2\right) = 205 \text{ W/m}^2\cdot K$. Since this value is comparable to the convection coefficient, radiation is not negligible and the desired heating will occur well before t = 861s.

PROBLEM 5.50

KNOWN: Thickness and initial temperature of acrylic sheet.

FIND: Time needed to bring the external surface of the acrylic to its softening temperature.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) One-term approximate solution is valid.

PROPERTIES: Acrylic (given): ρ = 1990 kg/m^3, c = 1470 J/kg·K and k = 0.21 W/m·K.

ANALYSIS: For the constant temperature boundary condition, the Biot number is $Bi \to \infty$. Hence, from Table 5.1 for the plane wall, ζ_1 = 1.5708, C_1 = 1.2733. The dimensionless external surface temperature at the time of interest is

$$\theta_o^* = \frac{90°\text{C} - 300°\text{C}}{20°\text{C} - 300°\text{C}} = 0.75 = C_1 \exp(-\zeta_1^2 Fo) = 1.2733 \exp(-1.5708^2 Fo)$$

From which Fo = 0.214. Hence,

$t = FoL^2/\alpha = FoL^2\rho c/k = [0.214 \times (0.005\text{ m})^2 \times 1990\text{ kg/m}^3 \times 1470\text{ J/kg·K}]/0.21\text{ W/m·K} = 74\text{ s}$ <

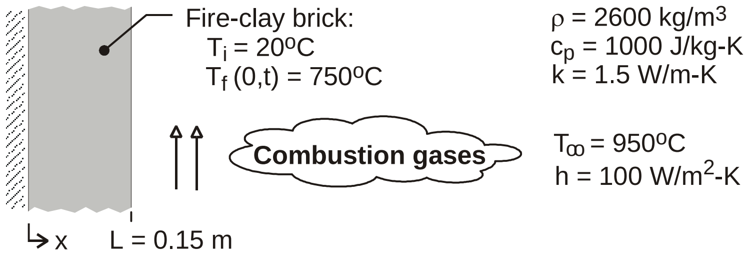
COMMENTS: (1) Since Fo = 0.214 is greater than 0.2, the one-term approximation is valid. (2) A contact resistance would be present at the interface between the acrylic and the substrate. However, as the acrylic softens and deforms locally to make better contact with the substrate, the thermal contact resistance would decrease in value.

PROBLEM 5.51

KNOWN: Thickness, initial temperature and properties of furnace wall. Convection conditions at inner surface.

FIND: Time required for outer surface to reach a prescribed temperature. Corresponding temperature distribution in wall and at intermediate times.

SCHEMATIC:



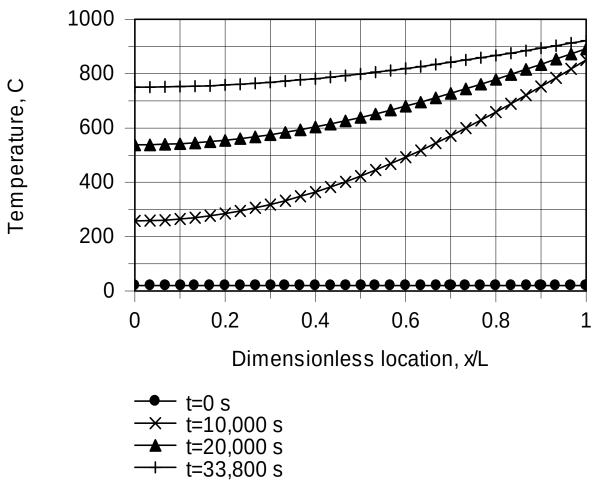
ASSUMPTIONS: (1) One-dimensional conduction in a plane wall, (2) Constant properties, (3) Adiabatic outer surface, (4) Fo > 0.2, (5) Negligible radiation from combustion gases.

ANALYSIS: The wall is equivalent to one-half of a wall of thickness 2L with symmetric convection conditions at its two surfaces. With Bi = hL/k = 100 W/m^2·K × 0.15m/1.5 W/m·K = 10 and Fo > 0.2, the one-term approximation, Eq. 5.44 may be used to compute the desired time, where $\theta_o^* = (T_o - T_\infty)/(T_i - T_\infty) = 0.215$. From Table 5.1, C_1 = 1.262 and ζ_1 = 1.4289. Hence,

$$Fo = -\frac{\ln\left(\theta_o^*/C_1\right)}{\zeta_1^2} = -\frac{\ln(0.215/1.262)}{(1.4289)^2} = 0.867$$

$$t = \frac{Fo\ L^2}{\alpha} = \frac{0.867(0.15m)^2}{\left(1.5\,W/m\cdot K/2600\ kg/m^3 \times 1000\ J/kg\cdot K\right)} = 33{,}800\,s$$ <

The corresponding temperature distribution, as well as distributions at t = 0, 10,000, and 20,000 s are plotted below



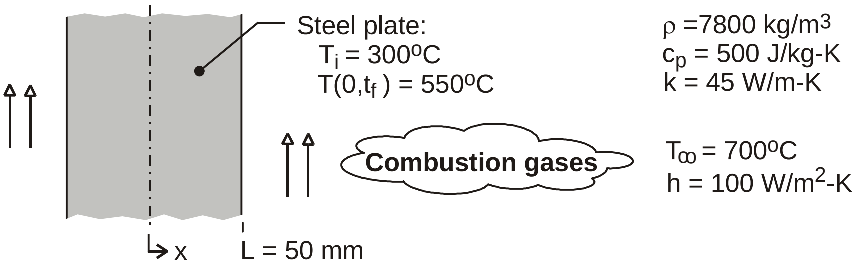
COMMENTS: Because Bi >>1, the temperature at the inner surface of the wall increases much more rapidly than at locations within the wall, where temperature gradients are large. The temperature gradients decrease as the wall approaches a steady-state for which there is a uniform temperature of 950°C.

PROBLEM 5.52

KNOWN: Thickness, initial temperature and properties of steel plate. Convection conditions at both surfaces.

FIND: Time required to achieve a minimum temperature.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in plate, (2) Symmetric heating on both sides, (3) Constant properties, (4) Negligible radiation from gases, (5) Fo > 0.2.

ANALYSIS: The smallest temperature exists at the midplane and, with Bi = hL/k = 500 W/m^2·K × 0.050m/45 W/m·K = 0.556 and Fo > 0.2, may be determined from the one-term approximation of Eq. 5.41. From Table 5.1, $C_1 = 1.076$ and $\zeta_1 = 0.682$. Hence, with $\theta_o^* = (T_o - T_\infty)/(T_i - T_\infty) = 0.375$,

$$\text{Fo} = -\frac{\ln\left(\theta_o^*/C_1\right)}{\zeta_1^2} = -\frac{\ln(0.375/1.076)}{(0.682)^2} = 2.266$$

$$t = \frac{\text{Fo}\ L^2}{\alpha} = \frac{2.266(0.05\text{m})^2}{\left(45\,\text{W/m}\cdot\text{K}/7800\ \text{kg/m}^3 \times 500\ \text{J/kg}\cdot\text{K}\right)} = 491\text{s}$$ <

COMMENTS: From Eq. 5.43b, the corresponding surface temperature is

$$T_s = T_\infty + (T_i - T_\infty)\theta_o^* \cos(\zeta_1) = 700°\text{C} - 400°\text{C} \times 0.375 \times 0.776 = 584°\text{C}$$

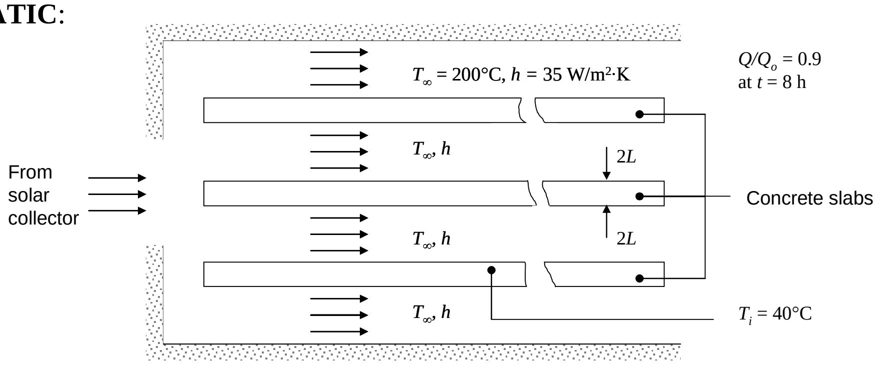
Because Bi is not much larger than 0.1, temperature gradients in the steel are moderate.

PROBLEM 5.53

KNOWN: Initial temperature of concrete slabs. Air temperature and convection heat transfer coefficient.

FIND: Slab thickness required so that $Q/Q_o = 0.90$ for $t = 8$ h.

SCHEMATIC:



ASSUMPTIONS: (1) Properties at 300 K are satisfactory at higher temperature, (2) One-dimensional conduction, (3) Constant convection heat transfer coefficient, (4) Negligible radiation because each concrete slab is surrounded by others at the same temperature.

PROPERTIES: *Table A.3*, Concrete (stone mix) (T = 300 K): $\rho = 2300$ kg/m^3, $c = 880$ J/kg·K, k = 1.4 W/m·K.

ANALYSIS: Without knowing the thickness, we cannot determine in advance whether the lumped capacitance approximation is valid. Considering the small thermal conductivity of concrete, we might anticipate that the Biot number will not be small. Considering the long time period, we may anticipate that the Fourier number is large. Therefore, we will begin by using the first-term approximation of the series solution and check its validity later. From Equation 5.49

$$\frac{Q}{Q_o} = 1 - \frac{\sin\zeta_1}{\zeta_1}\theta_o^* = 0.9 \qquad (1)$$

where from Equation 5.44

$$\theta_o^* = C_1 \exp\left(-\zeta_1^2 Fo\right) \qquad (2)$$

In these equations, C_1 and ζ_1 are functions of Bi:

$$\zeta_1 \tan\zeta_1 = Bi\,, \qquad C_1 = \frac{4\sin\zeta_1}{2\zeta_1 + \sin(2\zeta_1)} \qquad (3,4)$$

where ζ_1 is the smallest root of Equation (3). Both Bi and Fo are unknown because L is unknown. They are given by

$$Bi = \frac{hL}{k}\,, \qquad Fo = \frac{\alpha t}{L^2} \qquad (5,6)$$

Continued…

PROBLEM 5.53 (Cont.)

where $\alpha = k/\rho c = 6.92 \times 10^{-7}$ W/m^2·K. These six simultaneous equations can be solved iteratively. One approach is to guess a value for ζ_1, from which C_1 can be calculated from Equation (4). Equation (1) can be used to find the required value of θ_o^*. Then Equation (2) can be used to determine *Fo* and a new value of *L* can be determined from Equation (6). Finally, *Bi* can be calculated from Equation (5) and a new value of ζ_1 can be found from Equation (3). Beginning this approach with a guessed value of $\zeta_1 = 1$, the iterations proceed as follows:

Guess:	$\zeta_1 = 1$
Equation (4):	$C_1 = 1.16$
Equation (1):	$\theta_o^* = 0.119$
Equation (2):	$Fo = 2.28$
Equation (6):	$L = 0.0936$ m
Equation (5):	$Bi = 2.34$
Equation (3):	$\zeta_1 = 1.1231$

Repeating with the new value of ζ_1 and iterating until *L* converges to two significant digits, we find

$$L = 0.11 \text{ m}$$ <

with $Bi = 2.7$, $Fo = 1.7$. Thus the lumped capacitance approximation is not appropriate, and the first-term approximation is valid.

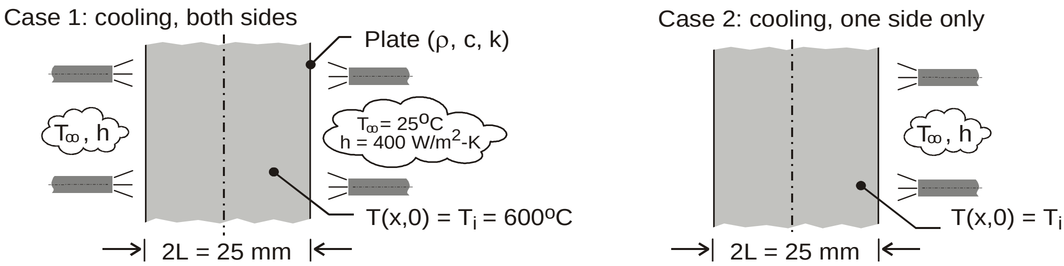
COMMENTS: This hand-solution is time-consuming, especially since Equation (3) must itself be solved iteratively. A much faster approach would be to solve these six equations simultaneously using IHT or other software.

PROBLEM 5.54

KNOWN: Plate of thickness 2L = 25 mm at a uniform temperature of 600°C is removed from a hot pressing operation. Case 1, cooled on both sides; case 2, cooled on one side only.

FIND: (a) Calculate and plot on one graph the temperature histories for cases 1 and 2 for a 500-second cooling period; use the *IHT* software; Compare times required for the maximum temperature in the plate to reach 100°C; and (b) For both cases, calculate and plot on one graph, the variation with time of the maximum temperature difference in the plate; Comment on the relative magnitudes of the temperature gradients within the plate as a function of time.

SCHEMATIC:



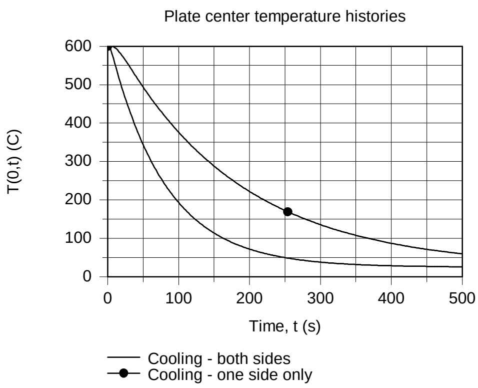
ASSUMPTIONS: (1) One-dimensional conduction in the plate, (2) Constant properties, and (3) For case 2, with cooling on one side only, the other side is adiabatic.

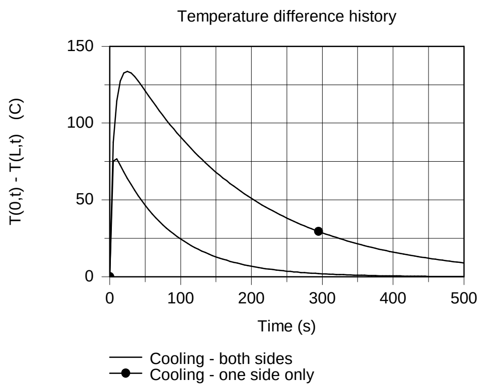
PROPERTIES: Plate (*given*): $\rho = 3000\ kg/m^3$, c = 750 J/kg·K, k = 15 W/m·K.

ANALYSIS: (a) From *IHT*, call up *Plane Wall, Transient Conduction* from the *Models* menu. For case 1, the plate thickness is 25 mm; for case 2, the plate thickness is 50 mm. The plate center (x = 0) temperature histories are shown in the graph below. The times required for the center temperatures to reach 100°C are

$t_1 = 164$ s $\qquad\qquad t_2 = 367$ s $\qquad\qquad$ <

(b) The plot of T(0, t) – T(1, t), which represents the maximum temperature difference in the plate during the cooling process, is shown below.





COMMENTS: (1) From the plate center-temperature history graph, note that it takes more than twice as long for the maximum temperature to reach 100°C with cooling on only one side.

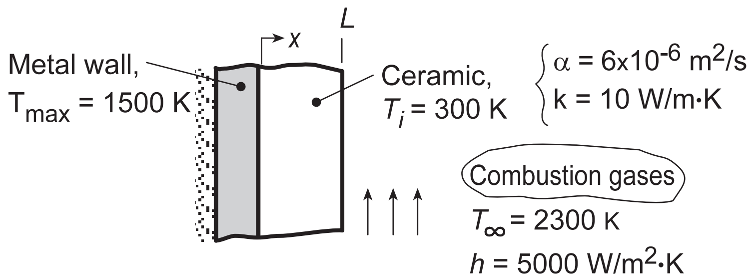
(2) From the maximum temperature-difference graph, as expected, cooling from one side creates a larger maximum temperature difference during the cooling process. The effect could cause microstructure differences, which could adversely affect the mechanical properties within the plate.

PROBLEM 5.55

KNOWN: Properties and thickness L of ceramic coating on rocket nozzle wall. Convection conditions. Initial temperature and maximum allowable wall temperature.

FIND: (a) Maximum allowable engine operating time, t_{max}, for L = 10 mm, (b) Coating inner and outer surface temperature histories for L = 10 and 40 mm.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in a plane wall, (2) Constant properties, (3) Negligible thermal capacitance of metal wall and heat loss through back surface, (4) Negligible contact resistance at wall/ceramic interface, (5) Negligible radiation.

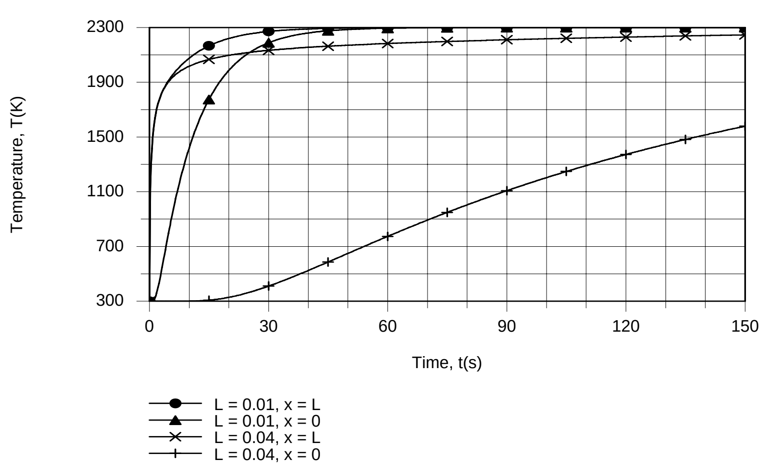
ANALYSIS: (a) Subject to assumptions (3) and (4), the maximum wall temperature corresponds to the ceramic temperature at x = 0. Hence, for the ceramic, we wish to determine the time t_{max} at which T(0,t) = $T_o(t)$ = 1500 K. With Bi = hL/k = 5000 W/m^2·K(0.01 m)/10 W/m·K = 5, the lumped capacitance method cannot be used. Assuming Fo > 0.2, obtaining ζ_1 = 1.3138 and C_1 = 1.2402 from Table 5.1, and evaluating $\theta_o^* = (T_o - T_\infty)/(T_i - T_\infty)$ = 0.4, Equation 5.44 yields

$$Fo = -\frac{\ln\left(\theta_o^*/C_1\right)}{\zeta_1^2} = -\frac{\ln(0.4/1.2402)}{(1.3138)^2} = 0.656$$

confirming the assumption of Fo > 0.2. Hence,

$$t_{max} = \frac{Fo\left(L^2\right)}{\alpha} = \frac{0.656(0.01\,m)^2}{6\times10^{-6}\,m^2/s} = 10.9\,s$$ <

(b) Using the IHT *Lumped Capacitance Model* for a *Plane Wall*, the inner and outer surface temperature histories were computed and are as follows:



Continued...

PROBLEM 5.55 (Cont.)

The increase in the inner (x = 0) surface temperature lags that of the outer surface, but within t ≈ 45s both temperatures are within a few degrees of the gas temperature for L = 0.01 m. For L = 0.04 m, the increased thermal capacitance of the ceramic slows the approach to steady-state conditions. The thermal response of the inner surface significantly lags that of the outer surface, and it is not until t ≈ 137s that the inner surface reaches 1500 K. At this time there is still a significant temperature difference across the ceramic, with $T(L,t_{max}) = 2240$ K.

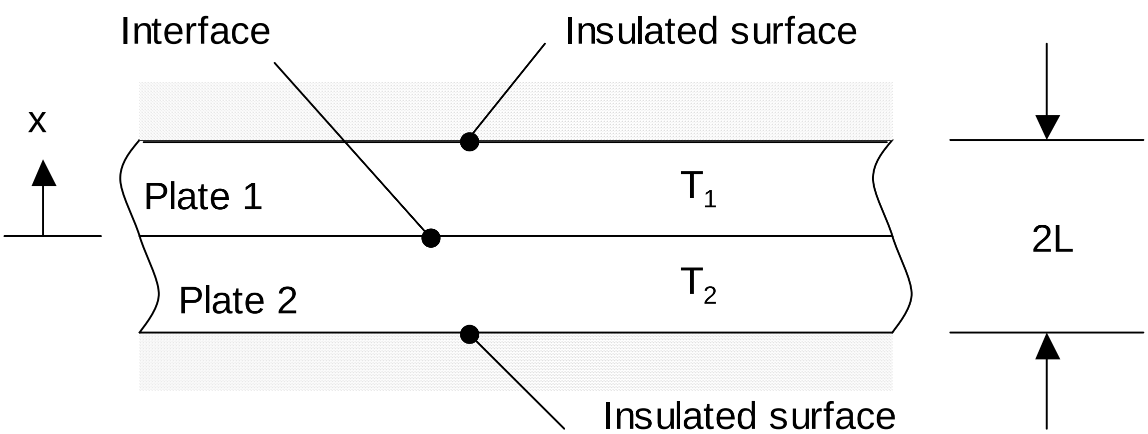
COMMENTS: The allowable engine operating time increases with increasing thermal capacitance of the ceramic and hence with increasing L.

PROBLEM 5.56

KNOWN: Thickness and initial temperatures of two plates of the same material.

FIND: (a) Steady-state dimensionless temperatures of the two plates, $T^*_{ss,1}$ and $T^*_{ss,2}$, as well as the interface temperature, T^*_{int}, (b) Expression for the effective dimensionless overall heat transfer coefficient for the two-plate system, $U^*_{eff,2} \equiv q^*/\left(\overline{T}^*_2 - \overline{T}^*_1\right)$ for $Fo > 0.2$.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Negligible thermal contact resistance.

ANALYSIS: (a) Since the two plates are of the same thickness and have the same properties, both plates will reach a steady-state temperature that is the average of T_1 and T_2. In terms of the dimensionless temperature, $T^*(Fo) \equiv (T - T_1)/(T_2 - T_1)$, this implies that $T^*_{ss,1} = T^*_{ss,2} = 0.5$. <

Accounting for the symmetry about $x = 0$, the dimensionless interface temperature will be $T^*_{int} = 0.5$ at any time. <

(b) Taking advantage of the geometrical symmetry about $x = 0$, we may simplify the problem by analyzing just one of the plates, accounting for one adiabatic surface and a second surface being held at a constant temperature. For the constant temperature boundary condition, $Bi = hL/k \to \infty$ and from Table 5.1 $\zeta_1 = \pi/2$, $C_1 = 1.2733$. Equations 5.44 and 5.49 may be combined to yield

$$\frac{Q}{Q_o} = 1 - \frac{\sin\zeta_1}{\zeta_1} C_1 \exp(-\zeta_1^2 Fo) \qquad (1)$$

The spatially-averaged dimensionless temperature for one plate is

Continued...

PROBLEM 5.56 (Cont.)

$$\overline{\theta^*} = \frac{1}{V}\int \frac{T(x,t) - T_{\text{int}}}{T_i - T_{\text{int}}} dV$$

where T_{int} is the interface temperature. From Eq. 5.46b, $\overline{\theta^*} = 1 - Q/Q_o$. (2)

From Eq. (1),

$$\frac{d(Q/Q_o)}{dFo} = q^* = 2C_1\left(\sin\zeta_1\right)\exp(-\zeta_1^2 Fo)$$

and from Eq. (2)

$$\overline{\theta^*} = \frac{C_1 \sin\zeta_1}{\zeta_1}\exp(-\zeta_1^2 Fo)$$

Therefore, for one plate, $U^*_{\text{eff},1} = \frac{d(Q/Qo)}{dFo}\Big/\overline{\theta^*} = 2\zeta_1 = \pi$

The dimensionless temperature difference for the two-plate system is $T_2^* - T_1^* = 2\overline{\theta^*}$.

Hence, for the two-plane system, $U^*_{\text{eff}} = U^*_{\text{eff},2}/2 = U^*_{\text{eff},1}/2 = \pi/2$. <

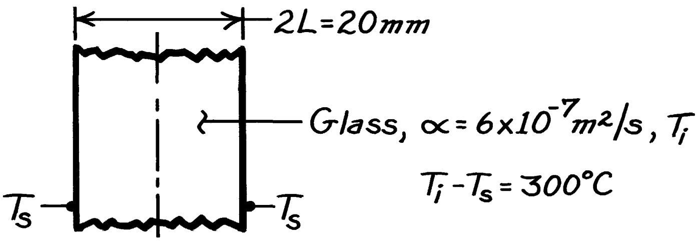
COMMENTS: (1) For this case, the heat transfer rate between the two plates is proportional to the difference in the average temperatures of the plates. If $Fo < 0.2$, it may be shown that U^*_{eff} is initially infinite and decreases with time. This behavior becomes evident if one considers the situation immediately after the plates make contact when the heat transfer between the plates is very large, but the average plate temperatures have not been affected significantly by the heat transfer in the vicinity of the interface. (2) A proportionality between the dimensionless heat transfer rate and the difference in the average dimensionless plate temperatures also exists at large *Fo*, even if the plates are not identical.

PROBLEM 5.57

KNOWN: Initial temperature, thickness and thermal diffusivity of glass plate. Prescribed surface temperature.

FIND: (a) Time to achieve 50% reduction in midplane temperature, (b) Maximum temperature gradient at that time.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties.

ANALYSIS: Prescribed surface temperature is analogous to $h \to \infty$ and $T_\infty = T_s$. Hence, Bi = ∞. Assume validity of one-term approximation to series solution for T (x,t).

(a) At the midplane,

$$\theta_o^* = \frac{T_o - T_s}{T_i - T_s} = 0.50 = C_1 \exp\left(-\zeta_1^2 Fo\right)$$

$$\zeta_1 \tan\zeta_1 = Bi = \infty \to \zeta_1 = \pi/2.$$

Hence

$$C_1 = \frac{4\sin\zeta_1}{2\zeta_1 + \sin(2\zeta_1)} = \frac{4}{\pi} = 1.273$$

$$Fo = -\frac{\ln\left(\theta_o^*/C_1\right)}{\zeta_1^2} = 0.379$$

$$t = \frac{FoL^2}{\alpha} = \frac{0.379(0.01\text{ m})^2}{6\times10^{-7}\text{ m}^2/\text{s}} = 63\text{ s.}$$ <

(b) With $\theta^* = C_1 \exp\left(-\zeta_1^2 Fo\right)\cos\zeta_1 x^*$

$$\frac{\partial T}{\partial x} = \frac{(T_i - T_s)}{L}\frac{\partial\theta^*}{\partial x^*} = -\frac{(T_i - T_s)}{L}\zeta_1 C_1 \exp\left(-\zeta_1^2 Fo\right)\sin\zeta_1 x^*$$

$$\partial T/\partial x\Big|_{max} = \partial T/\partial x\Big|_{x^*=1} = -\frac{300^\circ\text{C}}{0.01\text{ m}}\,\frac{\pi}{2}0.5 = -2.36\times10^4\ ^\circ\text{C/m.}$$ <

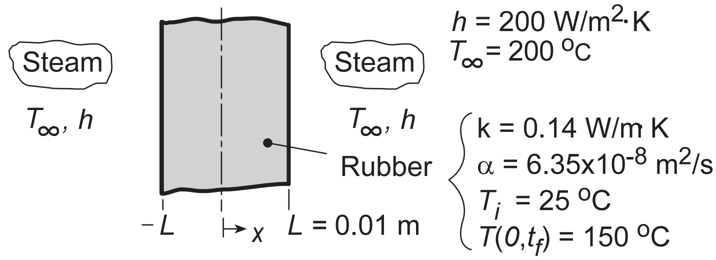
COMMENTS: Validity of one-term approximation is confirmed by Fo > 0.2.

PROBLEM 5.58

KNOWN: Thickness and properties of rubber tire. Convection heating conditions. Initial and final midplane temperature.

FIND: (a) Time to reach final midplane temperature. (b) Effect of accelerated heating.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in a plane wall, (2) Constant properties, (3) Negligible radiation.

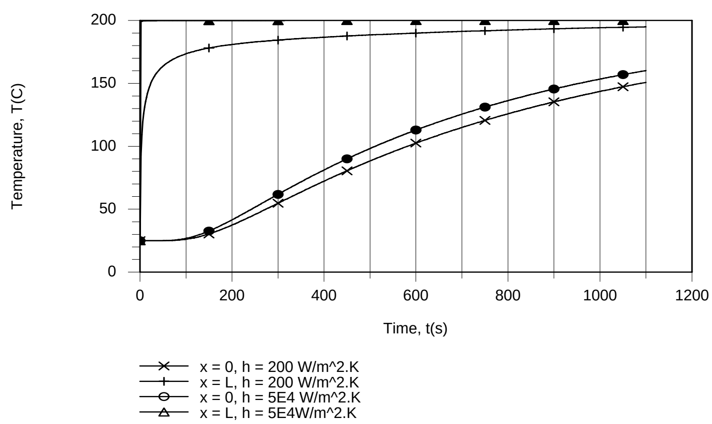
ANALYSIS: (a) With Bi = hL/k = 200 W/m^2·K(0.01 m)/0.14 W/m·K = 14.3, the lumped capacitance method is clearly inappropriate. Assuming Fo > 0.2, Eq. (5.44) may be used with C_1 = 1.265 and $\zeta_1 \approx$ 1.458 rad from Table 5.1 to obtain

$$\theta_o^* = \frac{T_o - T_\infty}{T_i - T_\infty} = C_1 \exp\left(-\zeta_1^2 Fo\right) = 1.265 \exp\left(-2.126\, Fo\right)$$

With $\theta_o^* = \left(T_o - T_\infty\right)/\left(T_i - T_\infty\right)$ = (-50)/(-175) = 0.286, $Fo = -\ln\left(0.286/1.265\right)/2.126 = 0.70 = \alpha t_f / L^2$

$$t_f = \frac{0.7\left(0.01\text{m}\right)^2}{6.35\times10^{-8}\,\text{m}^2/\text{s}} = 1100\,\text{s}$$ <

(b) The desired temperature histories were generated using the IHT *Transient Conduction Model* for a *Plane Wall*, with h = 5 × 10^4 W/m^2·K used to approximate imposition of a surface temperature of 200°C.



The fact that imposition of a constant surface temperature (h → ∞) does not significantly accelerate the heating process should not be surprising. For h = 200 W/m^2·K, the Biot number is already quite large (Bi = 14.3), and limits to the heating rate are principally due to conduction in the rubber and not to convection at the surface. Any increase in h only serves to reduce what is already a small component of the total thermal resistance.

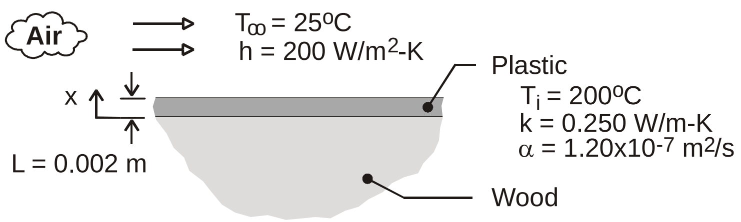
COMMENTS: The heating rate could be accelerated by increasing the steam temperature, but an upper limit would be associated with avoiding thermal damage to the rubber.

PROBLEM 5.59

KNOWN: Thickness, initial temperature and properties of plastic coating. Safe-to-touch temperature. Convection coefficient and air temperature.

FIND: Time for surface to reach safe-to-touch temperature. Corresponding temperature at plastic/wood interface.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in coating, (2) Negligible radiation, (3) Constant properties, (4) Negligible heat of reaction, (5) Negligible heat transfer across plastic/wood interface.

ANALYSIS: With Bi = hL/k = 200 W/m^2·K × 0.002m/0.25 W/m·K = 1.6 > 0.1, the lumped capacitance method may not be used. Applying the approximate solution of Eq. 5.43a, with C_1 = 1.155 and ζ_1 = 0.990 from Table 5.1,

$$\theta_s^* = \frac{T_s - T_\infty}{T_i - T_\infty} = \frac{(42-25)°C}{(200-25)°C} = 0.0971 = C_1 \exp\left(-\zeta_1^2 Fo\right)\cos\left(\zeta_1 x^*\right) = 1.155\exp(-0.980\,Fo)\cos(0.99)$$

Hence, for $x^* = 1$,

$$Fo = -\ln\left(\frac{0.0971}{1.155\cos(0.99)}\right)/(0.99)^2 = 1.914$$

$$t = \frac{Fo\,L^2}{\alpha} = \frac{1.914(0.002m)^2}{1.20\times10^{-7}\,m^2/s} = 63.8\,s$$ <

From Eq. 5.44, the corresponding interface temperature is

$$T_o = T_\infty + (T_i - T_\infty)\exp\left(-\zeta_1^2 Fo\right) = 25°C + 175°C\exp(-0.98\times1.914) = 51.8°C$$ <

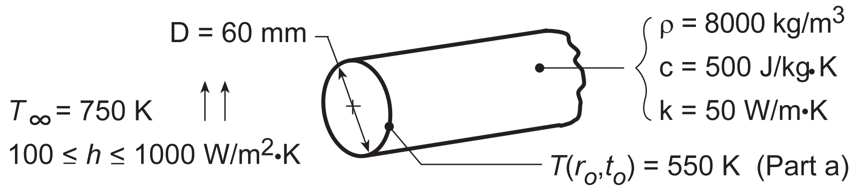
COMMENTS: By neglecting conduction into the wood and radiation from the surface, the cooling time is overpredicted and is therefore a conservative estimate. However, if energy generation due to solidification of polymer were significant, the cooling time would be longer.

PROBLEM 5.60

KNOWN: Long rod with prescribed diameter and properties, initially at a uniform temperature, is heated in a forced convection furnace maintained at 750 K with a convection coefficient of h = 1000 W/m^2·K.

FIND: (a) The corresponding center temperature of the rod, $T(0, t_o)$, when the surface temperature $T(r_o, t_o)$ is measured as 550 K, (b) Effect of h on centerline temperature history.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, radial conduction in rod, (2) Constant properties, (3) Rod, when initially placed in furnace, had a uniform (but unknown) temperature, (4) Fo ≥ 0.2.

ANALYSIS: (a) Since the rod was initially at a uniform temperature and Fo ≥ 0.2, the approximate solution for the infinite cylinder is appropriate. From Eq. 5.52b,

$$\theta^*\left(r^*, Fo\right) = \theta_o^*(Fo) J_0\left(\zeta_1 r^*\right) \quad (1)$$

where, for $r^* = 1$, the dimensionless temperatures are, from Eq. 5.34,

$$\theta^*(1, Fo) = \frac{T(r_o, t_o) - T_\infty}{T_i - T_\infty} \qquad \theta_o^*(Fo) = \frac{T(0, t_o) - T_\infty}{T_i - T_\infty} \quad (2,3)$$

Combining Eqs. (2) and (3) with Eq. (1) and rearranging,

$$\frac{T(r_o, t_o) - T_\infty}{T_i - T_\infty} = \frac{T(0, t_o) - T_\infty}{T_i - T_\infty} J_0(\zeta_1 \cdot 1)$$

$$T(0, t_o) = T_\infty + \frac{1}{J_0(\zeta_1)}\left[T(r_o, t_o) - T_\infty\right] \quad (4)$$

The eigenvalue, ζ_1 = 1.0185 rad, follows from Table 5.1 for the Biot number

$$Bi = \frac{hr_o}{k} = \frac{1000\, W/m^2 \cdot K\,(0.060\, m/2)}{50\, W/m \cdot K} = 0.60\,.$$

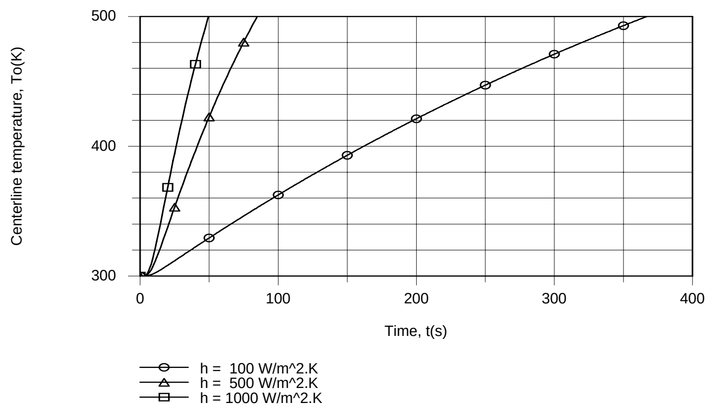
From Table B-4, with ζ_1 = 1.0185 rad, $J_0(1.0185) = 0.7568$. Hence, from Eq. (4)

$$T(0, t_o) = 750\, K + \frac{1}{0.7568}[550 - 750]\, K = 486\, K \quad <$$

(b) Using the IHT *Transient Conduction Model* for a *Cylinder*, the following temperature histories were generated.

Continued...

PROBLEM 5.60 (Cont.)



The times required to reach a centerline temperature of 500 K are 367, 85 and 51s, respectively, for h = 100, 500 and 1000 $W/m^2 \cdot K$. The corresponding values of the Biot number are 0.06, 0.30 and 0.60. Hence, even for h = 1000 $W/m^2 \cdot K$, the convection resistance is not negligible relative to the conduction resistance and significant reductions in the heating time could still be effected by increasing h to values considerably in excess of 1000 $W/m^2 \cdot K$.

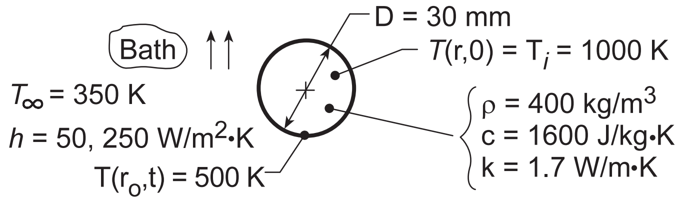
COMMENTS: For Part (a), recognize why it is not necessary to know T_i or the time t_o. We require that $Fo \geq 0.2$, which for this sphere corresponds to $t \geq 14s$. For this situation, the time dependence of the surface and center are the same.

PROBLEM 5.61

KNOWN: A long cylinder, initially at a uniform temperature, is suddenly quenched in a large oil bath.

FIND: (a) Time required for the surface to reach 500 K, (b) Effect of convection coefficient on surface temperature history.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Constant properties, (3) Fo > 0.2.

ANALYSIS: (a) Check first whether lumped capacitance method is applicable. For h = 50 W/m^2·K,

$$Bi_c = \frac{hL_c}{k} = \frac{h(r_o/2)}{k} = \frac{50\,W/m^2 \cdot K(0.015\,m/2)}{1.7\,W/m \cdot K} = 0.221.$$

Since $Bi_c > 0.1$, method is not suited. Using the approximate series solution for the infinite cylinder,

$$\theta^*(r^*, Fo) = C_1 \exp\left(-\zeta_1^2 Fo\right) \times J_0\left(\zeta_1 r^*\right) \quad (1)$$

Solving for Fo and setting $r^* = 1$, find

$$Fo = -\frac{1}{\zeta_1^2} \ln\left[\frac{\theta^*}{C_1 J_0(\zeta_1)}\right]$$

where $\theta^* = (1, Fo) = \dfrac{T(r_o, t_o) - T_\infty}{T_i - T_\infty} = \dfrac{(500-350)K}{(1000-350)K} = 0.231$.

From Table 5.1, with Bi = 0.441, find $\zeta_1 = 0.8882$ rad and $C_1 = 1.1019$. From Table B.4, find $J_0(\zeta_1) = 0.8121$. Substituting numerical values into Eq. (2),

$$Fo = -\frac{1}{(0.8882)^2} \ln[0.231/1.1019 \times 0.8121] = 1.72.$$

From the definition of the Fourier number, $Fo = \alpha t / r_o^2$, and $\alpha = k/\rho c$,

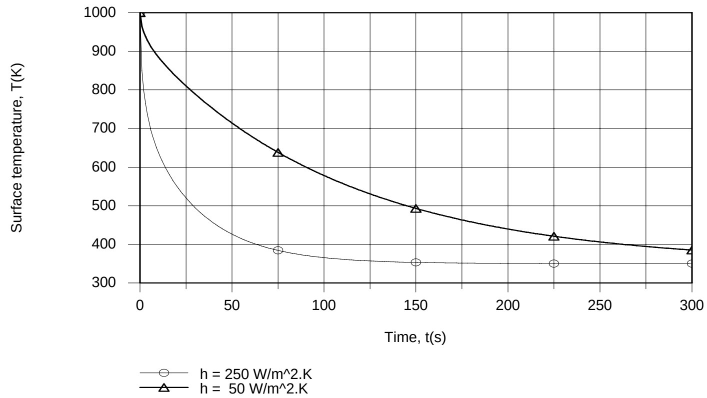
$$t = Fo\frac{r_o^2}{\alpha} = Fo \cdot r_o^2 \frac{\rho c}{k}$$

$$t = 1.72(0.015\,m)^2 \times 400\,kg/m^3 \times 1600\,J/kg \cdot K/1.7\,W/m \cdot K = 145s. \quad <$$

(b) Using the IHT *Transient Conduction Model* for a *Cylinder*, the following surface temperature histories were obtained.

Continued...

PROBLEM 5.61 (Cont.)



Increasing the convection coefficient by a factor of 5 has a significant effect on the surface temperature, greatly accelerating its approach to the oil temperature. However, even with h = 250 W/m^2·K, Bi = 1.1 and the convection resistance remains significant. Hence, in the interest of accelerated cooling, additional benefit could be achieved by further increasing the value of h.

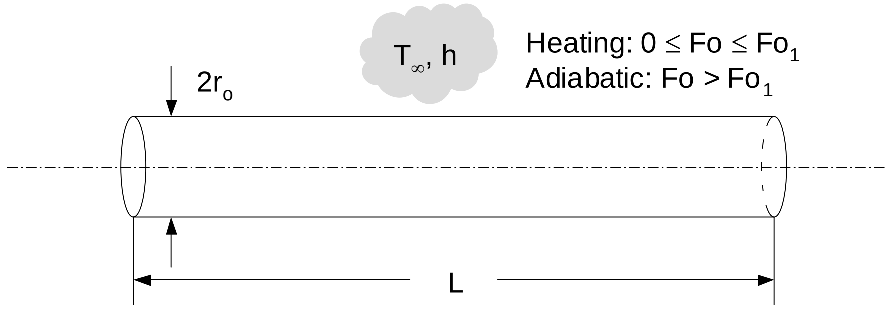
COMMENTS: For Part (a), note that, since Fo = 1.72 > 0.2, the approximate series solution is appropriate.

PROBLEM 5.62

KNOWN: One-dimensional convective heating of an L/r_o = 20 cylinder with Bi = 1 for a dimensionless time of Fo_1.

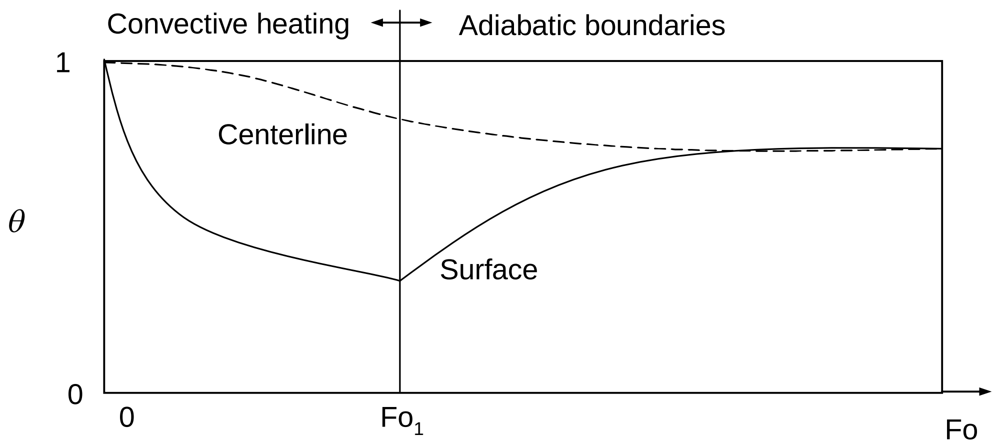
FIND: (a) Sketch of the dimensionless centerline and surface temperatures of the cylinder as a function of dimensionless time over the range $0 < Fo_1 < Fo < \infty$. Relative value of Fo_2 needed to achieve a steady-state centerline temperature equal to the centerline temperature at Fo_1. (b) Analytical expression for, and value of $\Delta Fo = Fo_2 - Fo_1$ for $Bi = 1$, $Fo_1 > 0.2$, $Fo_2 > 0.2$. (c) Value of ΔFo for Bi = 0.01, 0.1, 10, 100 and ∞.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Approximate, one-term solutions are valid.

ANALYSIS: (a) A sketch of the dimensionless centerline and surface temperatures is shown below. Note that, at Fo_1, the surface of the cylinder will be warm (smaller θ) relative to the centerline since temperature gradients within the cylinder are significant (Bi = 1). At the curtailment of heating (Fo_1), the surface temperature cools rapidly while warm temperatures continue to propagate toward the centerline, slowly heating the centerline until a steady-state, isothermal condition is eventually reached.

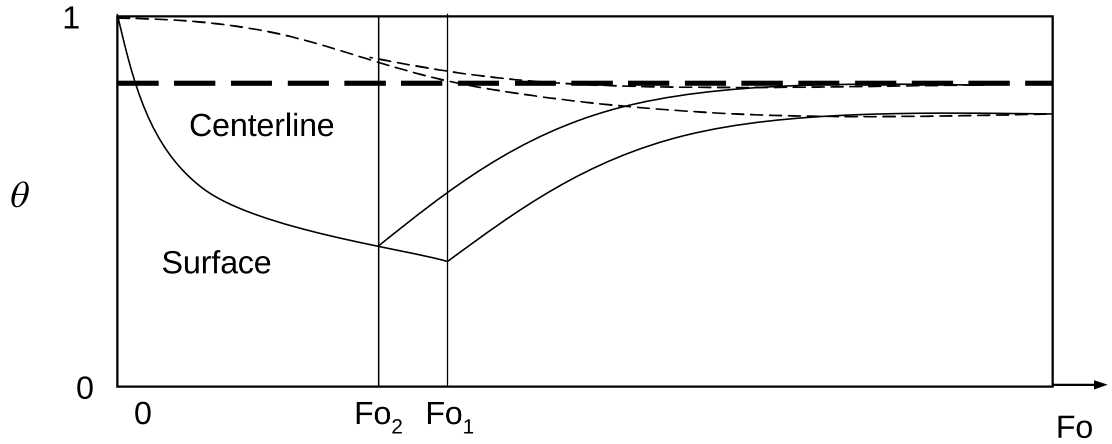


<

Based on the sketch above, one could achieve a steady-state centerline temperature equal to the centerline temperature at Fo_1 by reducing the duration of convective heating to Fo_2, as shown in the sketch below.

Continued…

PROBLEM 5.62 (Cont.)



Hence, $Fo_2 < Fo_1$. <

(b) Using the approximate solutions of Sections 5.6.2 and 5.6.3, and noting that the steady-state temperature of the cylinder is uniform and related to the energy transferred to the cylinder,

$$\theta_o^*(Fo_1) = 1 - \frac{Q}{Q_o}(Fo_2)$$

or,

$$1 - \theta_o^*(Fo_1) = \frac{Q}{Q_o}(Fo_1 + \Delta Fo_1) \tag{1}$$

Substituting Eqs. 5.52c and 5.54 into Eq. (1) yields

$$1 - C_1 \exp(-\zeta_1^2 Fo_1) = 1 - \frac{2C_1 \exp(-\zeta_1^2(Fo_1 + \Delta Fo))}{\zeta_1} J_1(\zeta_1)$$

which may be simplified to

$$\Delta Fo = -\frac{1}{\zeta_1^2} \ln\left(\frac{\zeta_1}{2J_1(\zeta_1)}\right)$$ <

From Table 5.1, ζ_1 = 1.2558 rad at Bi = 1, and from Table B.4, $J_1(\zeta_1)$ = 0.512. Hence,

$$\Delta Fo = -\frac{1}{1.2558^2} \ln\left(\frac{1.2558}{2J_1(1.2558)}\right) = -\frac{1}{1.2558^2} \ln\left(\frac{1.2558}{2 \times 0.512}\right) = -0.1294$$ <

(c) The expression for ΔFo may be evaluated for a range of Bi, resulting in the following.

<

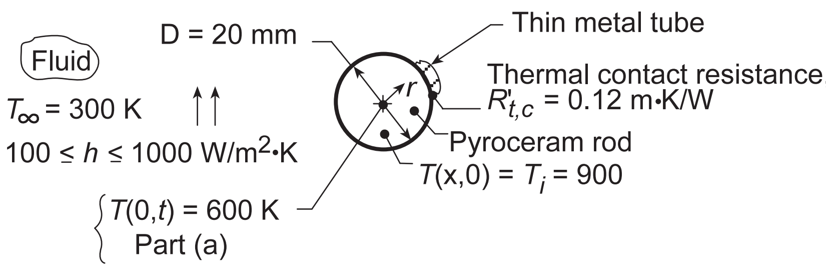
COMMENTS: (1) Note that the dimensionless temperature, $\theta_o^* = C_1 \exp\left(-\zeta_1^2 Fo\right)$, is defined in a manner such that for cylinder heating, increases in actual temperature correspond to decreases in the dimensionless temperature. (2) The dimensionless time lag, ΔFo, is weakly-dependent on the value of the Biot number and is independent of the heating time. Hence, a general rule-of-thumb is that a time lag of $\Delta Fo \approx$ - 0.13 should be specified in order to achieve an ultimate centerline temperature equal to that predicted at Fo_1 for convective heating or cooling. (3) For applications such as materials or food processing, where a certain minimum centerline temperature is desired, assuming that Fo_1 (as determined by Eq. 5.52c is the appropriate processing or cooking time can result in significant over-heating of the material or food, especially at small Fourier numbers. (4) Significant energy and time savings can be realized by reducing the processing or cooking time from Fo_1 to Fo_2.

PROBLEM 5.63

KNOWN: Long pyroceram rod, initially at a uniform temperature of 900 K, and clad with a thin metallic tube giving rise to a thermal contact resistance, is suddenly cooled by convection.

FIND: (a) Time required for rod centerline to reach 600 K, (b) Effect of convection coefficient on cooling rate.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Thermal resistance and capacitance of metal tube are negligible, (3) Constant properties, (4) Fo ≥ 0.2.

PROPERTIES: *Table A-2*, Pyroceram ($\overline{T}$ = (600 + 900)K/2 = 750 K): ρ = 2600 kg/m^3, c = 1100 J/kg·K, k = 3.13 W/m·K.

ANALYSIS: (a) The thermal contact and convection resistances can be combined to give an overall heat transfer coefficient. Note that $R'_{t,c}$ [m·K/W] is expressed per unit length for the outer surface. Hence, for h = 100 W/m^2·K,

$$U = \frac{1}{1/h + R'_{t,c}(\pi D)} = \frac{1}{1/100\,\text{W/m}^2\cdot\text{K} + 0.12\,\text{m}\cdot\text{K/W}(\pi\times 0.020\,\text{m})} = 57.0\,\text{W/m}^2\cdot\text{K}.$$

Using the approximate series solution, Eq. 5.52c, the Fourier number can be expressed as

$$Fo = -\left(1/\zeta_1^2\right)\ln\left(\theta_o^*/C_1\right).$$

From Table 5.1, find ζ_1 = 0.5884 rad and C_1 = 1.0441 for

$$Bi = Ur_o/k = 57.0\,\text{W/m}^2\cdot\text{K}\,(0.020\,\text{m}/2)/3.13\,\text{W/m}\cdot\text{K} = 0.182.$$

The dimensionless temperature is

$$\theta_o^*(0, Fo) = \frac{T(0,t) - T_\infty}{T_i - T_\infty} = \frac{(600-300)\,K}{(900-300)\,K} = 0.5.$$

Substituting numerical values to find Fo and then the time t,

$$Fo = \frac{-1}{(0.5884)^2}\ln\frac{0.5}{1.0441} = 2.127$$

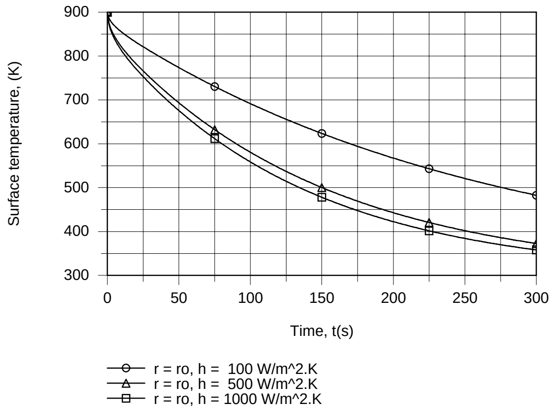
$$t = Fo\frac{r_o^2}{\alpha} = Fo\cdot r_o^2\frac{\rho c}{k}$$

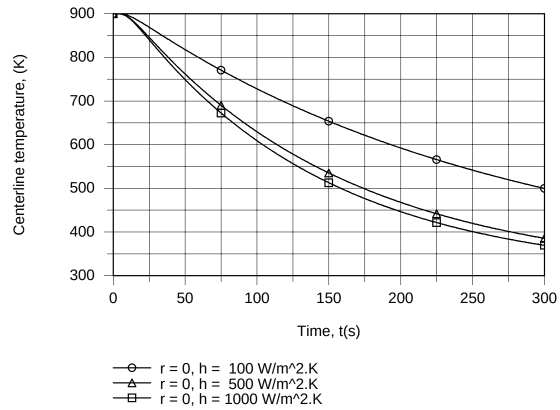
$$t = 2.127(0.020\,\text{m}/2)^2\,2600\,\text{kg/m}^3\times 1100\,\text{J/kg}\cdot\text{K}/3.13\,\text{W/m}\cdot\text{K} = 194\text{s}.$$ <

(b) The following temperature histories were generated using the IHT *Transient conduction Model* for a *Cylinder*.

Continued...

PROBLEM 5.63 (Cont.)





While enhanced cooling is achieved by increasing h from 100 to 500 $W/m^2 \cdot K$, there is little benefit associated with increasing h from 500 to 1000 $W/m^2 \cdot K$. The reason is that for h much above 500 $W/m^2 \cdot K$, the contact resistance becomes the dominant contribution to the total resistance between the fluid and the rod, rendering the effect of further reductions in the convection resistance negligible. Note that, for h = 100, 500 and 1000 $W/m^2 \cdot K$, the corresponding values of U are 57.0, 104.8 and 117.1 $W/m^2 \cdot K$, respectively.

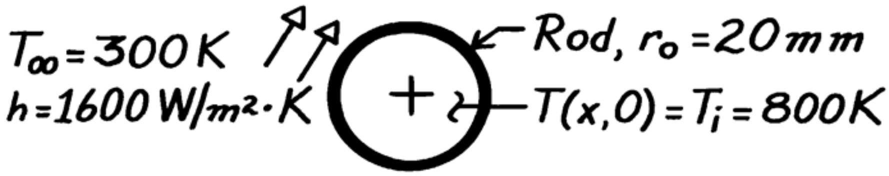
COMMENTS: For Part (a), note that, since Fo = 2.127 > 0.2, Assumption (4) is satisfied.

PROBLEM 5.64

KNOWN: Sapphire rod, initially at a uniform temperature of 800 K is suddenly cooled by a convection process; after 35 s, the rod is wrapped in insulation.

FIND: Temperature rod reaches after a long time following the insulation wrap.

SCHEMATIC:



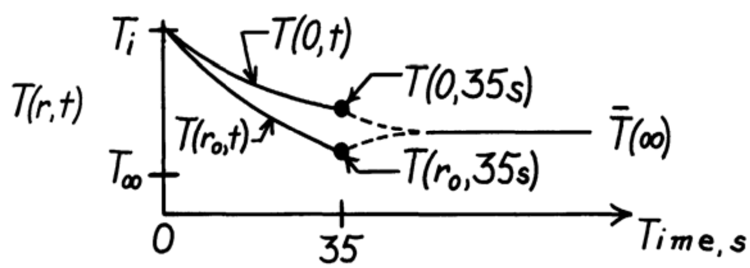
ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Constant properties, (3) No heat losses from the rod when insulation is applied.

PROPERTIES: *Table A-2*, Aluminum oxide, sapphire (550K): $\rho = 3970$ kg/m^3, c = 1068 J/kg·K, k = 22.3 W/m·K, $\alpha = 5.259\times10^{-6}$ m^2/s.

ANALYSIS: First calculate the Biot number with $L_c = r_o/2$,

$$Bi = \frac{h\,L_c}{k} = \frac{h\,(r_o/2)}{k} = \frac{1600\ \text{W/m}^2\cdot\text{K}(0.020\ \text{m}/2)}{22.3\ \text{W/m}\cdot\text{K}} = 0.72.$$

Since Bi > 0.1, the rod cannot be approximated as a lumped capacitance system. The temperature distribution during the cooling process, $0 \le t \le 35$ s, and for the time following the application of insulation, t > 35 s, will appear as



Eventually ($t \to \infty$), the temperature of the rod will be uniform at $\bar{T}(\infty)$.

We begin by determining the energy transferred from the rod at t = 35 s. We have

$$Bi = \frac{hr_o}{k} = \frac{1600\ \text{W/m}^2\cdot\text{K}\times 0.020\ \text{m}}{22.3\ \text{W/m}\cdot\text{K}} = 1.43$$

$$Fo = \alpha t/r_o^2 = 5.259\times10^{-6}\ \text{m}^2/\text{s}\times 35\ \text{s}/(0.02\ \text{m})^2 = 0.46$$

Since Fo > 0.2, we can use the one-term approximation. From Table 5.1, $\zeta_1 = 1.4036$ rad, $C_1 = 1.2636$. Then from Equation 5.49c,

$$\theta_0^* = C_1 \exp(-\zeta_1^2 Fo) = 1.2636 \exp(-1.4036^2 \times 0.46) = 0.5105$$

and from Equation 5.54

Continued…

PROBLEM 5.64 (Cont.)

$$\frac{Q}{Q_o} = 1 - \frac{2\theta_o^*}{\zeta_1} J_1(\zeta_1) = 1 - \frac{2 \times 0.5105}{1.4036} 0.5425 = 0.605$$

where $J_1(\zeta_1)$ was found from App. B.4. Since the rod is well insulated after t = 35 s, the energy transferred from the rod remains unchanged. To find $\overline{T}(\infty)$, write the conservation of energy requirement for the rod on a *time interval* basis, $E_{in} - E_{out} = \Delta E \equiv E_{final} - E_{initial}$. Using the nomenclature of Section 5.5.3 and basing energy relative to T_∞, the energy balance becomes

$$-Q = \rho\, cV\left(\overline{T}(\infty) - T_\infty\right) - Q_o$$

where $Q_o = \rho cV(T_i - T_\infty)$. Dividing through by Q_o and solving for $\overline{T}(\infty)$, find

$$\overline{T}(\infty) = T_\infty + \left(T_i - T_\infty\right)\left(1 - Q/Q_o\right).$$

Hence,

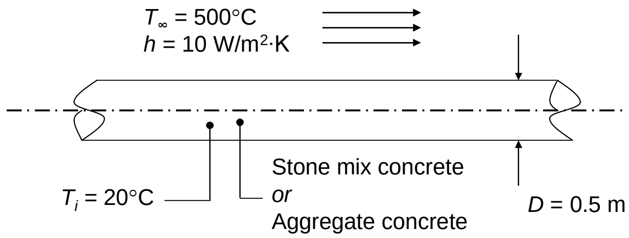
$$\overline{T}(\infty) = 300\text{K} + (800 - 300)\text{K}\ (1\text{-}0.408) = 596\text{ K}.$$ <

PROBLEM 5.65

KNOWN: Dimensions and initial temperature of stone mix concrete beam. Ambient temperature and convection heat transfer coefficient. Properties of aggregate beam.

FIND: Centerline temperature after t = 6 hours for each beam.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties. (2) Negligible radiation. (3) Beam is an infinite cylinder.

PROPERTIES: Table A.3: Stone mix concrete; k = 1.4 W/m·K, ρ = 2300 kg/m^3, c_p = 880 J/kg·K. Problem statement: Aggregate concrete: k = 0.789 W/m·K, ρ = 1495 kg/m^3, c_p = 880 J/kg·K.

ANALYSIS: (a) To determine whether spatial effects are important, the Biot number is calculated in the conservative fashion

$$Bi = \frac{hr_o}{k} = \frac{hD}{2k} = \frac{10\ \text{W/m}^2\cdot\text{K}\times 0.5\ \text{m}}{2\times 1.4\ \text{W/m}\cdot\text{K}} = 1.78$$

The dimensionless time is

$$Fo = \frac{\alpha t}{r_o^2} = \frac{4kt}{\rho c D^2} = \frac{4\times 1.4\ \text{W/m}\cdot\text{K}\times 6\text{h}\times 60\text{min/h}\times 60\text{s/min}}{2300\ \text{kg/m}^3\times 880\ \text{J/kg}\cdot\text{K}\times(0.5\ \text{m})^2} = 0.24$$

Since Bi > 0.1, spatial effects are important. Because Fo > 0.2, the approximate solution of Section 5.6 is valid. From Table 5.1 ζ_1 = 1.52 and C_1 = 1.31. Therefore,

$$\begin{aligned}T &= (T_i - T_\infty)C_1\exp(-\zeta_1^2 Fo) + T_\infty \\ &= (20°\text{C} - 500°\text{C})\times 1.31\times\exp(-1.52^2\times 0.24) + 500°\text{C} \\ &= 139°\text{C}\end{aligned}$$

<

(b) The preceding calculations may be repeated for the aggregate concrete, yielding

Bi = 3.17, Fo = 0.21, ζ_1 = 1.81, C_1 = 1.43, T = 155°C <

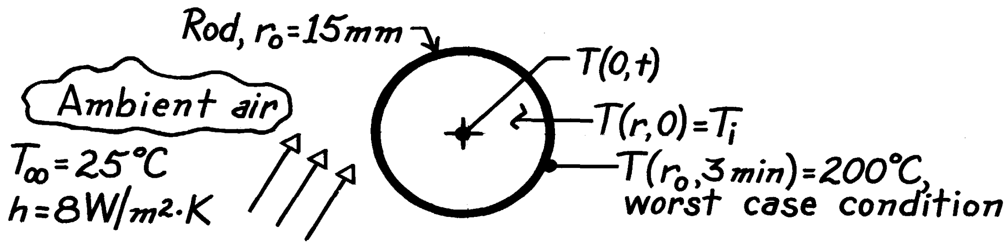
COMMENTS: (1) Because both its thermal conductivity and density are small relative to the stone mix beam, the thermal diffusivity of the aggregate beam is approximately the same as that of the stone mix beam. Hence the Fourier numbers associated with the two materials are approximately equal. (2) Aggregate concrete is often preferred over a more dense concrete for fire protection purposes.

PROBLEM 5.66

KNOWN: Long plastic rod of diameter D heated uniformly in an oven to T_i and then allowed to convectively cool in ambient air (T_∞, h) for a 3 minute period. Minimum temperature of rod should not be less than 200°C and the maximum-minimum temperature within the rod should not exceed 10°C.

FIND: Initial uniform temperature T_i to which rod should be heated. Whether the 10°C internal temperature difference is exceeded.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Constant properties, (3) Uniform and constant convection coefficients.

PROPERTIES: Plastic rod (given): k = 0.3 W/m·K, ρc_p = 1040 kJ/m^3·K.

ANALYSIS: For the worst case condition, the rod cools for 3 minutes and its outer surface is at least 200°C in order that the subsequent pressing operation will be satisfactory. Hence,

$$Bi = \frac{hr_o}{k} = \frac{8\ W/m^2 \cdot K \times 0.015\ m}{0.3\ W/m \cdot K} = 0.40$$

$$Fo = \frac{\alpha\, t}{r_o^2} = \frac{k}{\rho\, c_p} \cdot \frac{t}{r_o^2} = \frac{0.3\ W/m \cdot K}{1040 \times 10^3\ J/m^3 \cdot K} \times \frac{3 \times 60 s}{(0.015\ m)^2} = 0.2308.$$

Using Eq. 5.52a and $\zeta_1 = 0.8516$ rad and C_1 = 1.0932 from Table 5.1,

$$\theta^* = \frac{T(r_o,t) - T_\infty}{T_i - T_\infty} = C_1 J_0\left(\zeta_1 r_o^*\right) \exp\left(-\zeta_1^2 Fo\right).$$

With $r_o^* = 1$, from Table B.4, $J_0(\zeta_1 \times 1) = J_0(0.8516) = 0.8263$, giving

$$\frac{200 - 25}{T_i - 25} = 1.0932 \times 0.8263 \exp\left(-0.8516^2 \times 0.2308\right) \qquad T_i = 254^\circ C. \qquad <$$

At this time (3 minutes) what is the difference between the center and surface temperatures of the rod? From Eq. 5.52b,

$$\frac{\theta^*}{\theta_o} = \frac{T(r_o,t) - T_\infty}{T(0,t) - T_\infty} = \frac{200 - 25}{T(0,t) - 25} = J_0\left(\zeta_1 r_o^*\right) = 0.8263$$

which gives T(0,t) = 237°C. Hence,

$$\Delta T = T(0{,}180s) - T(r_o{,}180s) = (237 - 200)^\circ C = 37^\circ C. \qquad <$$

Hence, the desired max-min temperature difference sought (10°C) is not achieved.

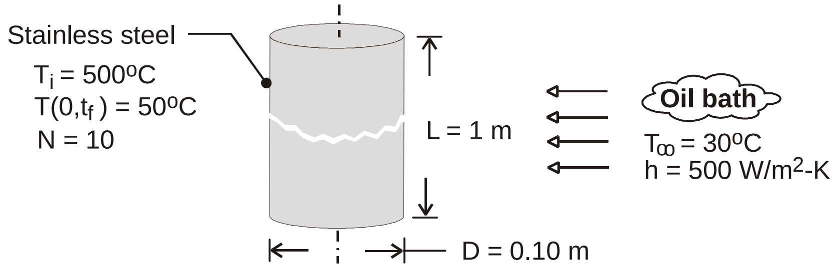
COMMENTS: ΔT could be reduced by decreasing the cooling rate; however, h can not be made much smaller. Two solutions are (a) increase ambient air temperature and (b) non-uniformly heat rod in oven by controlling its residence time.

PROBLEM 5.67

KNOWN: Diameter and initial temperature of roller bearings. Temperature of oil bath and convection coefficient. Final centerline temperature. Number of bearings processed per hour.

FIND: Time required to reach centerline temperature. Cooling load.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, radial conduction in rod, (2) Constant properties.

PROPERTIES: *Table A.1*, St. St. 304 $\left(\overline{T} = 548\,K\right)$: ρ=7900 kg/m^3, k = 19.0 W/m·K, c_p = 546 J/kg·K, α = 4.40 × 10^{-6} m^2/s.

ANALYSIS: With Bi = h (r_o/2)/k = 0.658, the lumped capacitance method can not be used. From the one-term approximation of Eq. 5.52c for the centerline temperature,

$$\theta_o^* = \frac{T_o - T_\infty}{T_i - T_\infty} = \frac{50-30}{500-30} = 0.0426 = C_1 \exp\left(-\zeta_1^2 Fo\right) = 1.1382 \exp\left[-\left(0.9287\right)^2 Fo\right]$$

where, for Bi = hr_o/k = 1.316, C_1 = 1.2486 and ζ_1 = 1.3643 from Table 5.1.

$$Fo = -\ell n\left(0.0341\right)/1.86 = 1.82$$

$$t_f = Fo\, r_o^2/\alpha = 1.82\left(0.05\,m\right)^2/4.40\times10^{-6} = 1031\,s = 17\,min$$ <

From Eqs. 5.47 and 5.54, the energy extracted from a single rod is

$$Q = \rho c V\left(T_i - T_\infty\right)\left[1 - \frac{2\theta_o^*}{\zeta_1} J_1\left(\zeta_1\right)\right]$$

With J_1 (1.3643) = 0.535 from Table B.4,

$$Q = 7900\,kg/m^3 \times 546\,J/kg\cdot K\left[\pi\left(0.05\,m\right)^2 1m\right]470\,K\left[1 - \frac{0.0852\times0.535}{1.3643}\right] = 1.54\times10^7\ J$$

The nominal cooling load is

$$\overline{q} = \frac{N\,Q}{t_f} = \frac{10\times1.54\times10^7\ J}{1031s} = 1.49\times10^5\,W = 149\ kW$$ <

COMMENTS: For a centerline temperature of 50°C, Eq. 5.52b yields a surface temperature of

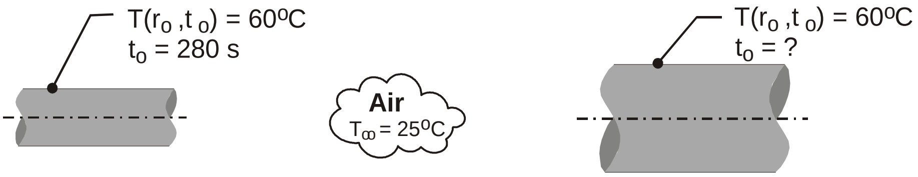
$$T\left(r_o, t\right) = T_\infty + \left(T_i - T_\infty\right)\theta_o^*\ J_o\left(\zeta_1\right) = 30°C + 470°C \times 0.0426 \times 0.586 = 41.7°C$$

PROBLEM 5.68

KNOWN: Long rods of 40 mm- and 80-mm diameter at a uniform temperature of 400°C in a curing oven, are removed and cooled by forced convection with air at 25°C. The 40-mm diameter rod takes 280 s to reach a *safe-to-handle* temperature of 60°C.

FIND: Time it takes for a 80-mm diameter rod to cool to the same safe-to-handle temperature. Comment on the result? Did you anticipate this outcome?

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional radial (cylindrical) conduction in the rods, (2) Constant properties, and (3) Convection coefficient same value for both rods.

PROPERTIES: Rod (*given*): $\rho = 2500$ kg/m^3, c = 900 J/kg·K, k = 15 W/m·K.

ANALYSIS: Not knowing the convection coefficient, the Biot number cannot be calculated to determine whether the rods behave as spacewise isothermal objects. Using the relations from Section 5.6, Radial Systems with Convection, for the infinite cylinder, Eq. 5.52, evaluate $Fo = \alpha t / r_o^2$, and knowing $T(r_o, t_o)$, a trial-and-error solution is required to find $Bi = h r_o/k$ and hence, h. Using the *IHT Transient Conduction* model for the *Cylinder*, the following results are readily calculated for the 40-mm rod. With $t_o = 280$ s,

$$Fo = 4.667 \qquad Bi = 0.264 \qquad h = 197.7\ W/m^2 \cdot K$$

For the 80-mm rod, with the foregoing value for h, with $T(r_o, t_o) = 60°C$, find

$$Bi = 0.528 \qquad Fo = 2.413 \qquad t_o = 579\ s$$ <

COMMENTS: (1) The time-to-cool, t_o, for the 80-mm rod is slightly more than twice that for the 40-mm rod. Did you anticipate this result? Did you believe the times would be proportional to the diameter squared?

(2) The simplest approach to explaining the relationship between t_o and the diameter follows from the lumped capacitance analysis, Eq. 5.13, where for the same θ/θ_i, we expect $Bi \cdot Fo_o$ to be a constant. That is,

$$\frac{h \cdot r_o}{k} \times \frac{\alpha t_o}{r_o^2} = C$$

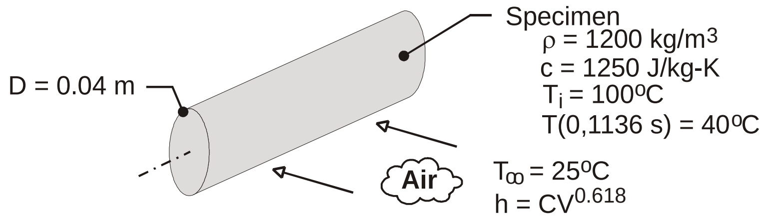
yielding $t_o \sim r_o$ (not r_o^2).

PROBLEM 5.69

KNOWN: Initial temperature, density, specific heat and diameter of cylindrical rod. Convection coefficient and temperature of air flow. Time for centerline to reach a prescribed temperature. Dependence of convection coefficient on flow velocity.

FIND: (a) Thermal conductivity of material, (b) Effect of velocity and centerline temperature and temperature histories for selected velocities.

SCHEMATIC:



ASSUMPTIONS: (1) Lumped capacitance analysis can not be used but one-term approximation for an infinite cylinder is appropriate, (2) One-dimensional conduction in r, (3) Constant properties, (4) Negligible radiation, (5) Negligible effect of thermocouple hole on conduction.

ANALYSIS: (a) With $\theta_o^* = [T_o(0,1136s) - T_\infty]/(T_i - T_\infty) = (40 - 25)/(100 - 25) = 0.20$, Eq. 5.52c yields

$$Fo = \frac{\alpha t}{r_o^2} = \frac{k\ t}{\rho c_p r_o^2} = \frac{k(1136\,s)}{1200\ kg/m^3 \times 1250\,J/kg \cdot K \times (0.02\,m)^2} = -\ln(0.2/C_1)/\zeta_1^2 \qquad (1)$$

Because C_1 and ζ_1 depend on $Bi = hr_o/k$, a trial-and-error procedure must be used. For example, a value of k may be assumed and used to calculate Bi, which may then be used to obtain C_1 and ζ_1 from Table 5.1. Substituting C_1 and ζ_1 into Eq. (1), k may be computed and compared with the assumed value. Iteration continues until satisfactory convergence is obtained, with

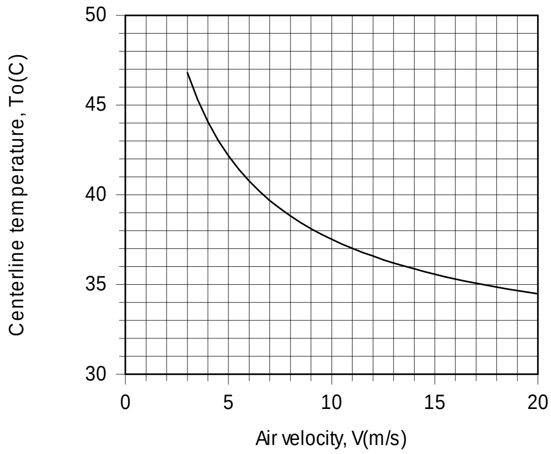
$$k \approx 0.30\ W/m \cdot K$$ <

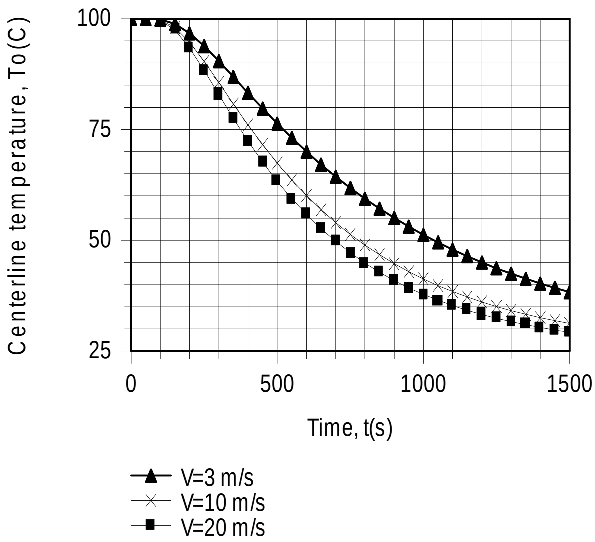
and, hence, Bi = 3.67, $C_1 = 1.45$, $\zeta_1 = 1.87$ and Fo = 0.568. For the above value of k, $-\ln(0.2/C_1)/\zeta_1^2 = 0.567$, which equals the Fourier number, as prescribed by Eq. (1).

(b) With $h = 55\ W/m^2 \cdot K$ for V = 6.8 m/s, $h = CV^{0.618}$ yields a value of $C = 16.8\ W \cdot s^{0.618}/m^{2.618} \cdot K$. The desired variations of the centerline temperature with velocity (for t = 1136 s) and time (for V = 3, 10 and 20 m/s) are as follows:

Continued …..

PROBLEM 5.69 (Cont.)





With increasing V from 3 to 20 m/s, h increases from 33 to 107 $W/m^2 \cdot K$, and the enhanced cooling reduces the centerline temperature at the prescribed time. The accelerated cooling associated with increasing V is also revealed by the temperature histories, and the time required to achieve thermal equilibrium between the air and the cylinder decreases with increasing V.

COMMENTS: (1) For the smallest value of h = 33 $W/m^2 \cdot K$, $Bi \equiv h\,(r_o/2)/k = 1.1 >> 0.1$, and use of the lumped capacitance method is clearly inappropriate.

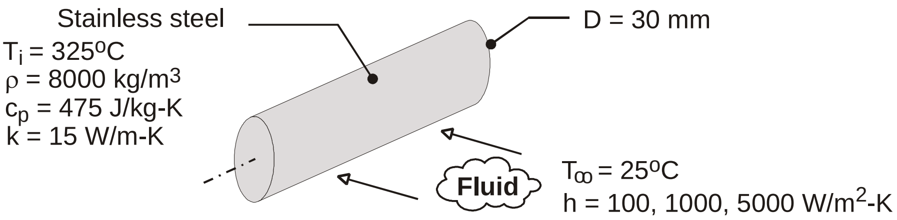
(2) The *IHT* Transient Conduction Model for a cylinder was used to perform the calculations of Part (b). Because the model is based on the exact solution, Eq. 5.50a, it is accurate for values of Fo < 0.2, as well as Fo > 0.2. Although in principle, the model may be used to calculate the thermal conductivity for the conditions of Part (a), convergence is elusive and may only be achieved if the initial guesses are close to the correct results.

PROBLEM 5.70

KNOWN: Diameter, initial temperature and properties of stainless steel rod. Temperature and convection coefficient of coolant.

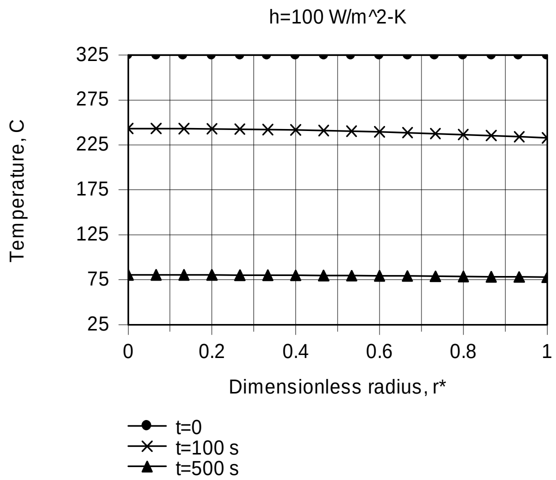
FIND: Temperature distributions for prescribed convection coefficients and times.

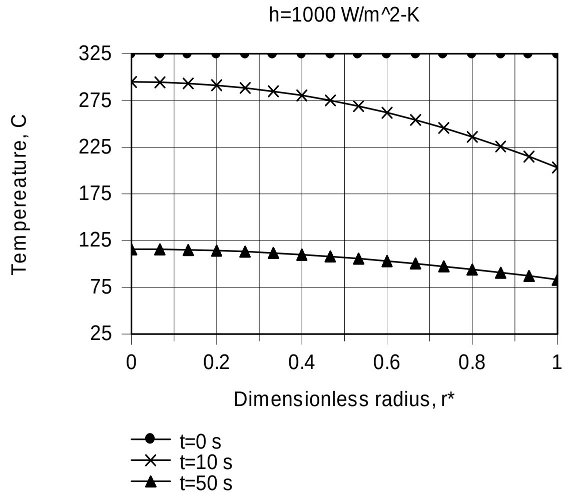
SCHEMATIC:



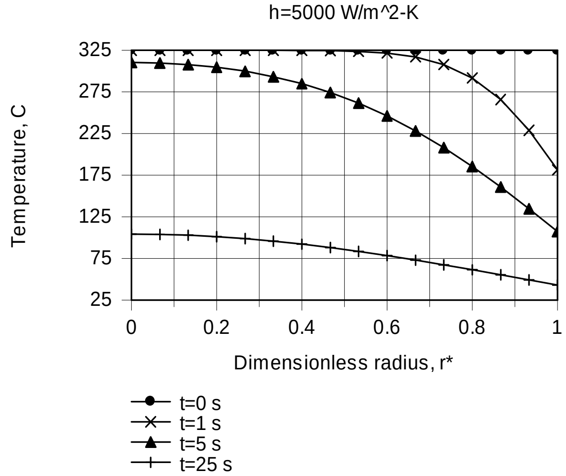
ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Constant properties.

ANALYSIS: The *IHT* model is based on the exact solution to the heat equation, Eq. 5.50. The results are plotted as follows





For h = 100 W/m^2·K, Bi = hr_o/k = 0.1, and as expected, the temperature distribution is nearly uniform throughout the rod. For h = 1000 W/m^2·K (Bi = 1), temperature variations within the rod are not negligible. In this case the centerline-to-surface temperature difference is comparable to the surface-to-fluid temperature difference. For h = 5000 W/m^2·K (Bi = 5), temperature variations within the rod are large and $[T(0,t) - T(r_o,t)]$ is substantially larger than $[T(r_o,t) - T_\infty]$.



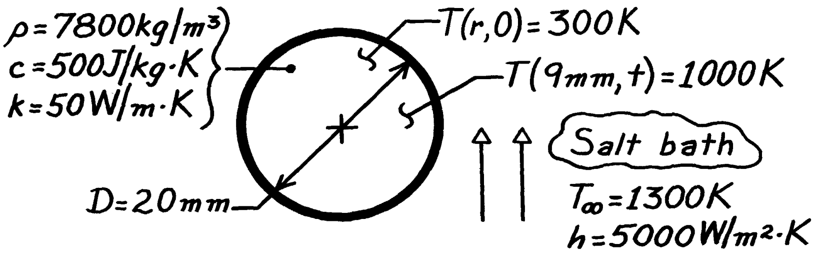
COMMENTS: With increasing Bi, conduction within the rod, and not convection from the surface, becomes the limiting process for heat loss.

PROBLEM 5.71

KNOWN: A ball bearing is suddenly immersed in a molten salt bath; heat treatment to harden occurs at locations with T > 1000 K.

FIND: Time required to harden outer layer of 1mm.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Constant properties, (3) Fo ≥ 0.2.

ANALYSIS: Since any location within the ball whose temperature exceeds 1000 K will be hardened, the problem is to find the time when the location r = 9 mm reaches 1000 K. Then a 1 mm outer layer will be hardened. Begin by finding the Biot number.

$$\mathrm{Bi} = \frac{h\,r_o}{k} = \frac{5000\ \mathrm{W/m^2 \cdot K}\left(0.020\ \mathrm{m}/2\right)}{50\ \mathrm{W/m \cdot K}} = 1.00.$$

Using the one-term approximate solution for a sphere, find

$$\mathrm{Fo} = -\frac{1}{\zeta_1^2}\ln\left[\theta^* / C_1 \frac{1}{\zeta_1 r^*}\sin\left(\zeta_1 r^*\right)\right].$$

From Table 5.1 with Bi = 1.00, for the sphere find $\zeta_1 = 1.5708$ rad and C_1 = 1.2732. With r* = r/r_o = (9 mm/10 mm) = 0.9, substitute numerical values.

$$\mathrm{Fo} = \frac{-1}{(1.5708)^2}\ln\left[\frac{(1000-1300)\,\mathrm{K}}{(300-1300)\,\mathrm{K}}/1.2732\frac{1}{1.5708\times 0.9}\sin\left(1.5708\times 0.9\ \mathrm{rad}\right)\right] = 0.441.$$

From the definition of the Fourier number with α = k/ρc,

$$t = \mathrm{Fo}\frac{r_o^2}{\alpha} = \mathrm{Fo}\cdot r_o^2\frac{\rho\,c}{k} = 0.441\times\left[\frac{0.020\ \mathrm{m}}{2}\right]^2 7800\frac{\mathrm{kg}}{\mathrm{m^3}}\times 500\frac{\mathrm{J}}{\mathrm{kg\cdot K}}/50\ \mathrm{W/m\cdot K} = 3.4\ \mathrm{s}. \quad <$$

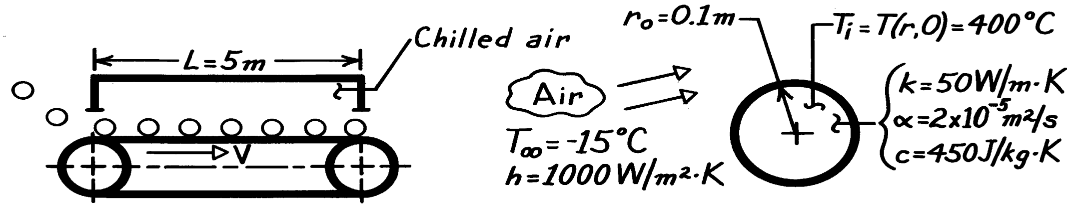
COMMENTS: (1) Note the very short time required to harden the ball. At this time it can be easily shown the center temperature is T(0, 3.4 s) = 871 K.

PROBLEM 5.72

KNOWN: Steel ball bearings at an initial, uniform temperature are to be cooled by convection while passing through a refrigerated chamber; bearings are to be cooled to a temperature such that 70% of the thermal energy is removed.

FIND: Residence time of the balls in the 5 m-long chamber and recommended drive velocity for the conveyor.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible conduction between ball and conveyor surface, (2) Negligible radiation exchange with surroundings, (3) Constant properties, (4) Uniform convection coefficient over ball's surface.

ANALYSIS: The Biot number for the lumped capacitance analysis is

$$Bi \equiv \frac{hL_c}{k} = \frac{h(r_o/3)}{k} = \frac{1000\ W/m^2 \cdot K\ (0.1m/3)}{50\ W/m \cdot K} = 0.67.$$

Since Bi > 0.1, lumped capacitance analysis is not appropriate. We assume that the one-term approximation to the exact solution is valid and check later. The Biot number for the exact solution is

$$Bi = \frac{hr_o}{k} = \frac{1000\ W/m^2 \cdot K \times 0.1m}{50\ W/m \cdot K} = 2.0,$$

From Table 5.1, ζ_1 = 2.0288, C_1 = 1.4793. From Equation 5.55, with Q/Q_o = 0.70, we can solve for θ_o^*:

$$\theta_o^* = \left(1 - \frac{Q}{Q_o}\right)\frac{\zeta_1^3}{3\left[\sin(\zeta_1) - \zeta_1\cos(\zeta_1)\right]} = (1-0.7)\frac{2.0288^3}{3\left[\sin(2.0288) - 2.0288\cos(2.0288)\right]} = 0.465$$

From Eq. 5.53c, we can solve for Fo:

$$Fo = -\frac{1}{\zeta_1^2}\ln\left(\theta_o^*/C_1\right) = -\frac{1}{2.0288^2}\ln\left(0.465/1.4793\right) = 0.281$$

Note that the one-term approximation is indeed valid, since Fo > 0.2. Then

$$t = Fo\frac{r_o^2}{\alpha} = 0.281\frac{(0.1\ m)^2}{2 \times 10^{-5} m^2/s} = 140\ s$$

The velocity of the conveyor is expressed in terms of the length L and residence time t. Hence

$$V = \frac{L}{t} = \frac{5\ m}{140\ s} = 0.036\ m/s = 36\ mm/s.$$ <

COMMENTS: Referring to Equation 5.10, note that for a sphere, the characteristic length is

$$L_c = V/A_s = \frac{4}{3}\pi\ r_o^3/4\pi\ r_o^2 = \frac{r_o}{3}.$$

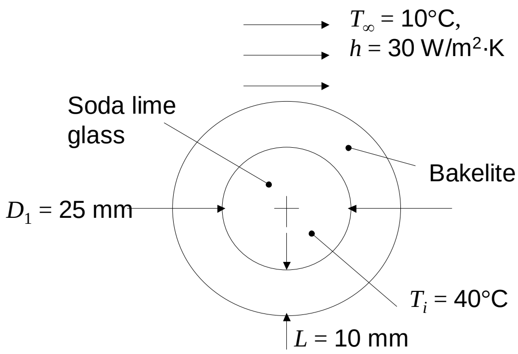
However, when using the exact solution or one-term approximation, note that Bi ≡ h r_o/k.

PROBLEM 5.73

KNOWN: Glass sphere diameter and bakelite shell thickness. Initial solid temperature, fluid temperature, convection heat transfer coefficient, and heating time.

FIND: Center temperature of glass sphere after specified heating time.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Negligible contact resistance.

PROPERTIES: Table A.3, soda lime glass (T = 25°C), ρ = 2500 kg/m^3, k = 1.4 W/m·K, c_p = 750 J/kg·K. Table A.3, bakelite (T = 25°C), ρ = 1300 kg/m^3, k = 1.4 W/m·K, c_p = 1465 J/kg·K.

ANALYSIS: The thermal diffusivities of the bakelite and glass are

$$\alpha_b = \frac{k}{\rho c_p} = \frac{1.4\ \text{W/m}\cdot\text{K}}{1300\ \text{kg/m}^3 \times 1465\ \text{J/kg}\cdot\text{K}} = 735\times10^{-9}\ \text{m}^2/\text{s}$$

$$\alpha_g = \frac{k}{\rho c_p} = \frac{1.4\ \text{W/m}\cdot\text{K}}{2500\ \text{kg/m}^3 \times 750\ \text{J/kg}\cdot\text{K}} = 747\times10^{-9}\ \text{m}^2/\text{s}$$

Since $a_b \approx \alpha_g$, it is reasonable to assign a uniform thermal diffusivity of $\alpha = 740 \times 10^{-9}$ m^2/s to the composite sphere. Since $k_b = k_g$ and the thermal contact resistance between the glass and bakelite is negligible, we may treat the composite sphere as a single sphere of diameter $D = D_1 + 2L$ = 25 mm + 20 mm = 45 mm with uniform properties. The Biot number for the single sphere is

$$Bi = \frac{h(D/6)}{k} = \frac{30\text{W/m}^2\cdot\text{K}\times(45\times10^{-3}\text{m}/6)}{1.4\ \text{W/m}\cdot\text{K}} = 0.16$$

Therefore the lumped capacitance approximation is not valid. The Fourier number is

$$Fo = \frac{\alpha t}{(D/2)^2} = \frac{740\times10^{-9}\ \text{m}^2/\text{s}\times 200\text{s}}{(45\times10^{-3}\ \text{m}/2)^2} = 0.291$$

Since Fo > 0.2, the single term approximation is valid. From Table 5.1 with $Bi = h(D/2)/k$ = 30 W/m^2·K × (45 × 10^{-3} m/2)/1.4W/m·K = 0.482, ζ_1= 1.145, C_1 = 1.139. Hence

$$\theta_o^* = \frac{T - T_\infty}{T_i - T_\infty} = C_1\exp(-\xi_1 Fo) = 1.139\exp(-1.145\times0.291) = 0.817$$

Continued…

PROBLEM 5.73 (Cont.)

Therefore, $T = 0.817\times(40 - 10°C) + 10°C = 34.5°C$ <

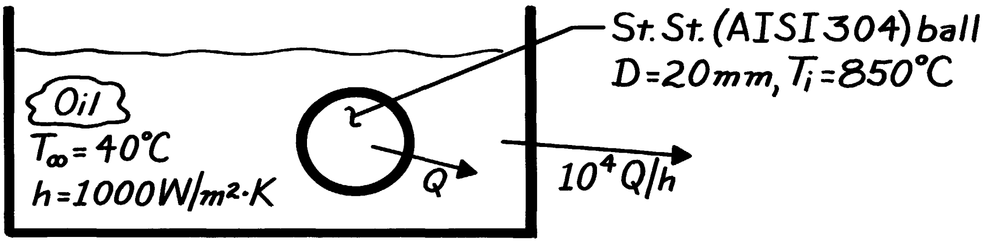
COMMENTS: (1) If the thermal diffusivities and thermal conductivities of the bakelite and soda lime glass were of sufficiently different value, or the thermal contact resistance was not negligible, a more detailed analytical or numerical solution would be required. (2) The Biot number used in conjunction with Table 5.1 is based upon the sphere radius.

PROBLEM 5.74

KNOWN: Diameter and initial temperature of ball bearings to be quenched in an oil bath.

FIND: (a) Time required for surface to cool to 100°C and the corresponding center temperature, (b) Oil bath cooling requirements.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional radial conduction in ball bearings, (2) Constant properties.

PROPERTIES: *Table A-1,* St. St., AISI 304, (T ≈ 500°C): k = 22.2 W/m·K, c_p = 579 J/kg·K, ρ = 7900 kg/m^3, α = 4.85×10^{-6} m^2/s.

ANALYSIS: (a) To determine whether use of the lumped capacitance method is suitable, first compute

$$Bi = \frac{h(r_o/3)}{k} = \frac{1000\ W/m^2 \cdot K(0.010\ m/3)}{22.2\ W/m \cdot K} = 0.15.$$

We conclude that, although the lumped capacitance method could be used as a first approximation, the exact solution should be used in the interest of improving accuracy. We assume that the one-term approximation is valid and check later. Hence, with

$$Bi = \frac{hr_o}{k} = \frac{1000\ W/m^2 \cdot K(0.01\ m)}{22.2\ W/m \cdot K} = 0.450$$

from Table 5.1, ζ_1 = 1.1092, C_1 = 1.1301. Then

$$\theta^*(r^* = 1, Fo) = \frac{T(r_o, t) - T_\infty}{T_i - T_\infty} = \frac{100°C - 40°C}{850°C - 40°C} = 0.0741$$

and Equation 5.53b can be solved for θ_o^*:

$$\theta_o^* = \theta^* \zeta_1 r^* / \sin(\zeta_1 r^*) = 0.0741 \times 1.1092 \times 1/\sin(1.1092) = 0.0918$$

Then Equation 5.53c can be solved for Fo:

$$Fo = -\frac{1}{\zeta_1^2}\ln\left(\theta_o^*/C_1\right) = -\frac{1}{1.1092^2}\ln\left(0.0918/1.1301\right) = 2.04$$

$$t = \frac{r_o^2 Fo}{\alpha} = \frac{(0.01\ m)^2(2.04)}{4.85 \times 10^{-6} m^2/s} = 42\ s.$$ <

Note that the one-term approximation is accurate, since Fo > 0.2.

Continued …

PROBLEM 5.74 (Cont.)

Also,

$$\theta_o = T_o - T_\infty = 0.0918(T_i - T_\infty) = 0.0918(850 - 40) = 74^\circ C$$

$$T_o = 114^\circ C$$ <

(b) Equation 5.55 can be used to calculate the heat loss from a single ball:

$$\frac{Q}{Q_o} = 1 - \frac{3\theta_o^*}{\zeta_1^3}[\sin(\zeta_1) - \zeta_1 \cos(\zeta_1)] = 1 - \frac{3 \times 0.0918}{1.1092^3}[\sin(1.1092) - 1.1092 \cos(1.1092)] = 0.919$$

Hence, from Equation 5.47,

$$Q = 0.919\ \rho c_p V(T_i - T_\infty)$$

$$Q = 0.919 \times 7900\ \text{kg/m}^3 \times 579\ \text{J/kg}\cdot\text{K} \times \frac{\pi}{6}(0.02\ \text{m})^3 \times 810^\circ C$$

$$Q = 1.43 \times 10^4\ \text{J}$$

is the amount of energy transferred from a single ball during the cooling process. Hence, the oil bath cooling rate must be

$$q = 10^4 Q/3600\ \text{s}$$

$$q = 4 \times 10^4 \text{W} = 40\ \text{kW}.$$ <

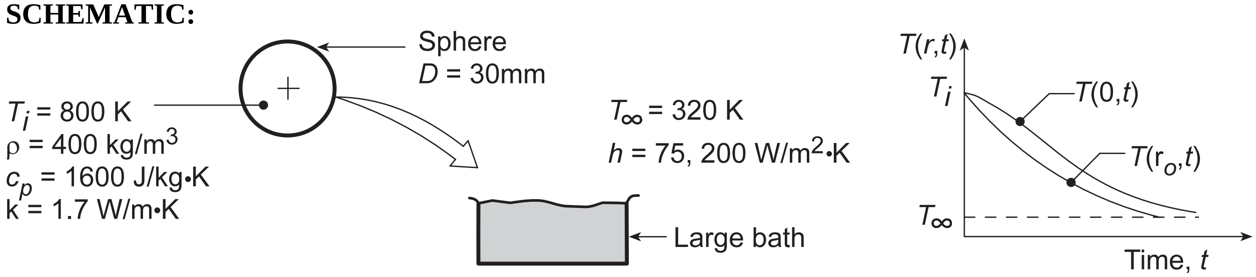
COMMENTS: If the lumped capacitance method is used, the cooling time, obtained from Equation 5.5, would be t = 39.7 s, where the ball is assumed to be uniformly cooled to 100°C. This result, and the fact that $T_o - T(r_o) = 15^\circ C$ at the conclusion, suggests that use of the lumped capacitance method would have been reasonable.

PROBLEM 5.75

KNOWN: Sphere quenching in a constant temperature bath.

FIND: (a) Plot T(0,t) and T(r_o,t) as function of time, (b) Time required for surface to reach 415 K, t', (c) Heat flux when T(r_o, t') = 415 K, (d) Energy lost by sphere in cooling to T(r_o, t') = 415 K, (e) Steady-state temperature reached after sphere is insulated at t = t', (f) Effect of h on center and surface temperature histories.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Constant properties, (3) Uniform initial temperature.

ANALYSIS: (a) Calculate Biot number to determine if sphere behaves as spatially isothermal object,

$$Bi = \frac{hL_c}{k} = \frac{h(r_o/3)}{k} = \frac{75\,W/m^2\cdot K(0.015\ m/3)}{1.7\,W/m\cdot K} = 0.22\,.$$

Hence, temperature gradients exist in the sphere and T(r,t) vs. t appears as shown above.

(b) The exact solution may be used to find t' when T(r_o, t') = 415 K. We assume that the one-term approximation is valid and check later. Hence, with

$$Bi = \frac{hr_o}{k} = \frac{75\ W/m^2\cdot K(0.015\ m)}{1.7\ W/m\cdot K} = 0.662$$

from Table 5.1, ζ_1 = 1.3188, C_1 = 1.1877. Then

$$\theta^*(r^*=1, Fo) = \frac{T(r_o,t)-T_\infty}{T_i-T_\infty} = \frac{415°C-320°C}{800°C-320°C} = 0.1979$$

and Equation 5.53b can be solved for θ_o^*:

$$\theta_o^* = \theta^*\zeta_1 r^*/\sin(\zeta_1 r^*) = 0.1979\times1.3188\times1/\sin(1.3188) = 0.2695$$

Then Equation 5.53c can be solved for Fo:

$$Fo = -\frac{1}{\zeta_1^2}\ln\left(\theta_o^*/C_1\right) = -\frac{1}{1.3188^2}\ln\left(0.2695/1.1877\right) = 0.853$$

$$t' = Fo\frac{r_o^2}{\alpha} = Fo\cdot\frac{\rho c_p}{k}\cdot r_o^2 = 0.853\frac{400\,kg/m^3\times1600\,J/kg\cdot K}{1.7\,W/m\cdot K}\times(0.015\,m)^2 = 72\ s$$ <

Note that the one-term approximation is accurate, since Fo > 0.2.

Continued...

(c) The heat flux at the outer surface at time t' is given by Newton's law of cooling

$$q'' = h\left[T\left(r_o, t'\right) - T_\infty\right] = 75\,\text{W}/\text{m}^2\cdot\text{K}\left[415 - 320\right]\text{K} = 7125\,\text{W}/\text{m}^2. \qquad <$$

The manner in which q'' is calculated indicates that energy is leaving the sphere.

(d) The energy lost by the sphere during the cooling process from t = 0 to t' can be determined from Equation 5.55:

$$\frac{Q}{Q_o} = 1 - \frac{3\theta_o^*}{\zeta_1^3}\left[\sin(\zeta_1) - \zeta_1\cos(\zeta_1)\right] = 1 - \frac{3\times 0.2695}{1.3188^3}\left[\sin(1.3188) - 1.3188\cos(1.3188)\right] = 0.775$$

The energy loss by the sphere with V = $(\pi D^3)/6$ is therefore, from Equation 5.47,

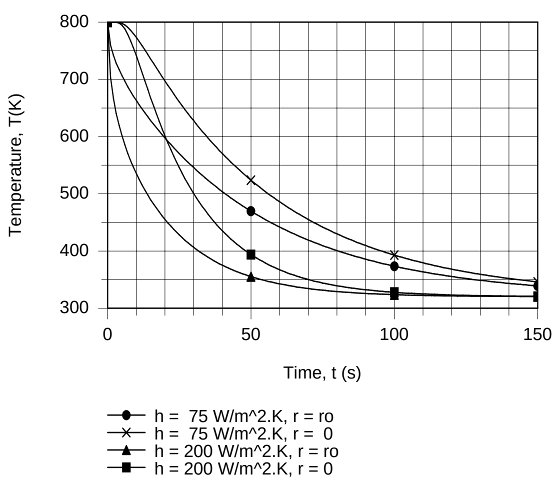
$$Q = 0.775 Q_o = 0.775\rho\left(\pi D^3/6\right)c_p\left(T_i - T_\infty\right)$$

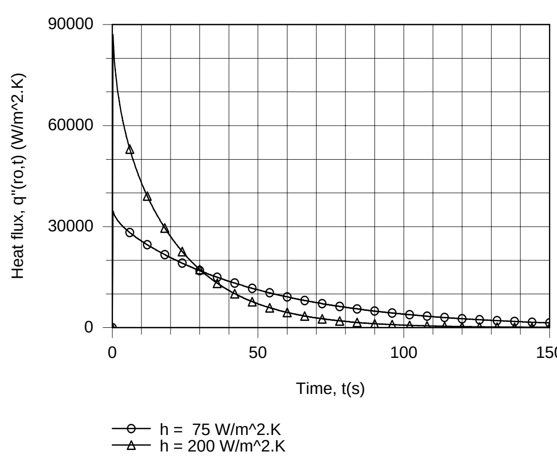
$$Q = 0.775\times 400\,\text{kg}/\text{m}^3\left(\pi\left[0.030\,\text{m}\right]^3/6\right)1600\,\text{J/kg}\cdot\text{K}\left(800 - 320\right)\text{K} = 3364\,\text{J} \qquad <$$

(e) If at time t' the surface of the sphere is perfectly insulated, eventually the temperature of the sphere will be uniform at T(∞). Applying conservation of energy to the sphere over a *time interval*, $E_{in} - E_{out} = \Delta E \equiv E_{final} - E_{initial}$. Hence, $-Q = \rho cV[T(\infty) - T_\infty] - Q_o$, where $Q_o \equiv \rho cV[T_i - T_\infty]$. Dividing by Q_o and regrouping, we obtain

$$T(\infty) = T_\infty + \left(1 - Q/Q_o\right)\left(T_i - T_\infty\right) = 320\,\text{K} + \left(1 - 0.775\right)\left(800 - 320\right)\text{K} = 428\,\text{K} \qquad <$$

(f) Using the IHT *Transient Conduction Model* for a *Sphere*, the following graphical results were generated.





The quenching process is clearly accelerated by increasing h from 75 to 200 W/m^2·K and is virtually completed by t ≈ 100s for the larger value of h. Note that, for both values of h, the temperature difference $[T(0,t) - T(r_o,t)]$ decreases with increasing t. Although the surface heat flux for h = 200 W/m^2·K is initially larger than that for h = 75 W/m^2·K, the more rapid decline in $T(r_o,t)$ causes it to become smaller at t ≈ 30s.

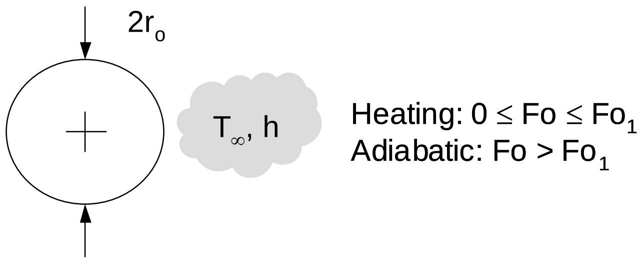
COMMENTS: Using the *Transient Conduction/Sphere* model in *IHT* based upon multiple-term series solution, the following results were obtained: t' = 72.1 s; Q/Q_o = 0.7745, and T(∞) = 428 K.

PROBLEM 5.76

KNOWN: One-dimensional convective heating of sphere of radius r_o, with $Bi = 1$ for a dimensionless time of Fo_1.

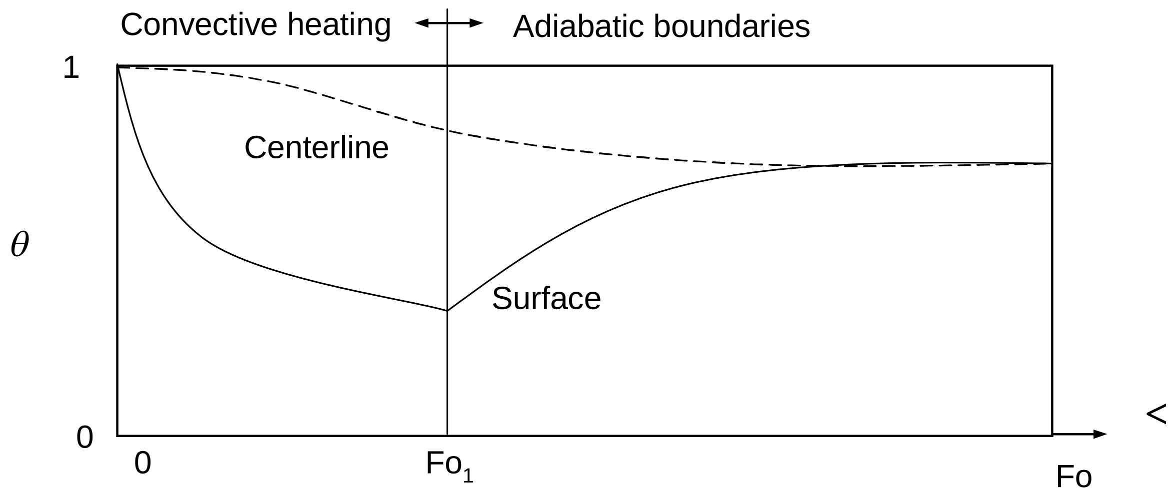
FIND: (a) Sketch of the dimensionless center and surface temperatures of the sphere as a function of dimensionless time over the range $0 < Fo_1 < Fo < \infty$. Relative value of Fo_2 needed to achieve a steady-state center temperature equal to the center temperature at Fo_1. (b) Analytical expression for, and value of $\Delta Fo = Fo_2 - Fo_1$ for $Bi = 1$, $Fo_1 > 0.2$, $Fo_2 > 0.2$. (c) Value of ΔFo for $Bi = 0.01$, 0.1, 10, 100 and ∞.

SCHEMATIC:



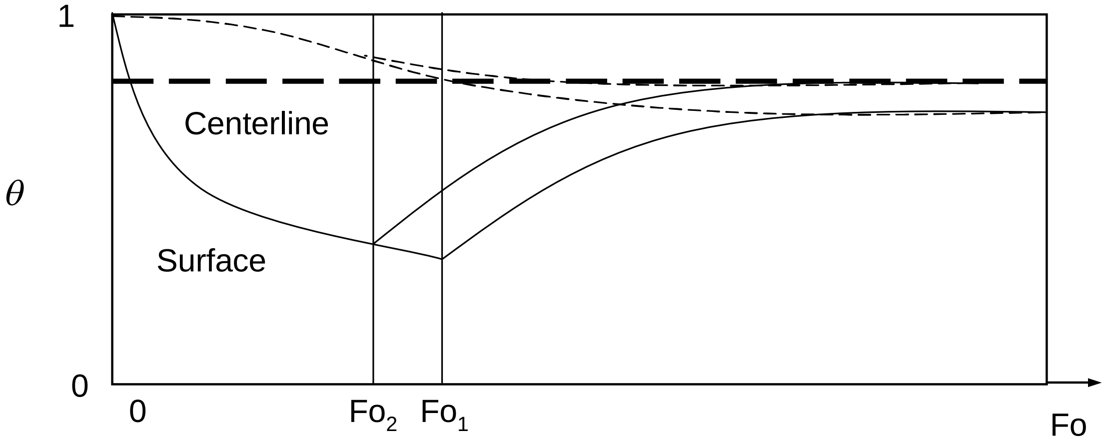
ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Approximate, one-term solutions are valid.

ANALYSIS: (a) A sketch of the dimensionless center and surface temperatures is shown below. Note that, at Fo_1, the surface of the sphere will be warm (smaller θ) relative to its center since temperature gradients within the sphere are significant ($Bi = 1$). At the curtailment of heating (Fo_1), the surface temperature cools rapidly while warm temperatures continue to propagate toward the center, slowly heating the center until a steady-state, isothermal condition is eventually reached.



Based on the sketch above, one could achieve a steady-state center temperature equal to the center temperature at Fo_1 by reducing the duration of convective heating to Fo_2, as shown in the sketch below.

Continued…



Hence, $Fo_2 < Fo_1$. <

(b) Using the approximate solutions of Sections 5.6.2 and 5.6.3, and noting that the steady-state temperature of the sphere is uniform and related to the energy transferred to the sphere,

$$\theta_o^*(Fo_1) = 1 - \frac{Q}{Q_o}(Fo_2)$$

or,

$$1 - \theta_o^*(Fo_1) = \frac{Q}{Q_o}(Fo_1 + \Delta Fo_1) \qquad (1)$$

Substituting Eqs. 5.53c and 5.55 into Eq. (1) yields

$$1 - C_1 \exp(-\zeta_1^2 Fo_1) = 1 - \frac{3C_1 \exp(-\zeta_1^2(Fo_1 + \Delta Fo))}{\zeta_1^3}\left[\sin(\zeta_1) - \zeta_1 \cos(\zeta_1)\right]$$

which may be simplified to

$$\Delta Fo = -\frac{1}{\zeta_1^2}\ln\left(\frac{\zeta_1^3}{3\left[\sin(\zeta_1) - \zeta_1\cos(\zeta_1)\right]}\right)$$ <

From Table 5.1, ζ_1 = 1.5708 rad at Bi = 1. Hence,

$$\Delta Fo = -\frac{1}{1.5708^2}\ln\left(\frac{1.5708^3}{3\left[\sin(1.5708) - 1.5708\cos(1.5708)\right]}\right) = \text{-0.1038}$$ <

(c) The expression for ΔFo may be evaluated for a range of Bi, resulting in the following.

Continued…

PROBLEM 5.76 (Cont.)

Bi	ζ_1	ΔFo
0.01	0.1730	-0.1000
0.1	0.5423	-0.1004
1	1.5708	-0.1038
10	2.8363	-0.1154
100	3.1102	-0.1200
∞	3.1415	-0.1207

<

COMMENTS: (1) Note that the dimensionless temperature, $\theta_o^* = C_1 \exp\left(-\zeta_1^2 Fo\right)$, is defined in a manner such that for sphere heating, increases in actual temperature correspond to decreases in the dimensionless temperature. (2) The dimensionless time lag, ΔFo, is weakly-dependent on the value of the Biot number and is independent of the heating time. Hence, a general rule-of-thumb is that a time lag of $\Delta Fo \approx -0.11$ should be specified in order to achieve an ultimate center temperature equal to that predicted at Fo_1 for convective heating or cooling. (3) For applications such as materials or food processing, where a certain minimum center temperature is desired, assuming that Fo_1 (as determined by Eq. 5.52c) is the appropriate processing or cooking time can result in significant over-heating of the material or food, especially at small Fourier numbers. (4) Significant energy and time savings can be realized by reducing the processing or cooking time from Fo_1 to Fo_2.

PROBLEM 5.77

KNOWN: Two spheres, A and B, initially at uniform temperatures of 800 K and simultaneously quenched in large, constant temperature baths each maintained at 320 K; properties of the spheres and convection coefficients.

FIND: (a) Show in a qualitative manner, on T-t coordinates, temperatures at the center and the outer surface for each sphere; explain features of the curves; (b) Time required for the outer surface of each sphere to reach 415 K, (c) Energy gained by each bath during process of cooling spheres to a surface temperature of 415 K.

SCHEMATIC:

	Sphere A	Sphere B
r_o (mm)	150	15
ρ (kg/m^3)	1600	400
c (J/kg·K)	400	1600
k (W/m·K)	170	1.7
h (W/m^2·K)	5	50

ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Uniform properties, (3) Constant convection coefficient.

ANALYSIS: (a) From knowledge of the Biot number and the thermal time constant, it is possible to qualitatively represent the temperature distributions. From Equation 5.10, with $L_c = r_o/3$, find

$$Bi_A = \frac{5\ W/m^2\cdot K(0.150\ m/3)}{170\ W/m\cdot K} = 1.47\times10^{-3}$$

$$Bi = \frac{h(r_o/3)}{k}$$

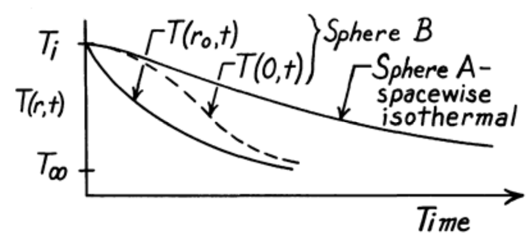
$$Bi_B = \frac{50\ W/m^2\cdot K(0.015\ m/3)}{1.7\ W/m\cdot K} = 0.147$$

The thermal time constant for a lumped capacitance system from Equation 5.7 is

$$\tau = \left[\frac{1}{hA_s}\right](\rho Vc) \qquad \tau_A = \frac{1600\ kg/m^3\times(0.150\ m)400\ J/kg\cdot K}{3\times5\ W/m^2\cdot K} = 6400\ s$$

$$\tau = \frac{\rho\, r_o\, c}{3h} \qquad \tau_B = \frac{400\ kg/m^3\times(0.015\ m)1600\ J/kg\cdot K}{3\times50\ W/m^2\cdot K} = 64\ s$$

When Bi << 0.1, the sphere will cool in a spacewise isothermal manner (Sphere A). For sphere B, Bi > 0.1, hence gradients will be important. Note that the thermal time constant of A is much larger than for B; hence, A will cool much slower. See sketch for these features.



(b) Recognizing that $Bi_A < 0.1$, Sphere A can be treated as spacewise isothermal and analyzed using the lumped capacitance method. From Equation 5.6 and 5.7, with T = 415 K

$$\frac{\theta}{\theta_i} = \frac{T - T_\infty}{T_i - T_\infty} = \exp(-t/\tau)$$

Continued …

PROBLEM 5.77 (Cont.)

$$t_A = -\tau_A\left[\ln\frac{T-T_\infty}{T_i-T_\infty}\right] = -6400\ s\left[\ln\frac{415-320}{800-320}\right] = 10,367\ s = 2.88\ h.$$ <

Note that since the sphere is nearly isothermal, the surface and inner temperatures are approximately the same.

Since $Bi_B > 0.1$, *Sphere B* must be treated by the exact method of solution. We assume that the one-term approximation is valid and check later. Hence, with

$$Bi_B = \frac{hr_o}{k} = \frac{50\ W/m^2\cdot K(0.015\ m)}{1.7\ W/m\cdot K} = 0.441$$

from Table 5.1, $\zeta_1 = 1.0992$, $C_1 = 1.1278$. Then

$$\theta^*(r^*=1, Fo) = \frac{T(r_o,t)-T_\infty}{T_i-T_\infty} = \frac{415°C-320°C}{800°C-320°C} = 0.1979$$

and Equation 5.53b can be solved for θ_o^*:

$$\theta_o^* = \theta^*\zeta_1 r^*/\sin(\zeta_1 r^*) = 0.1979\times1.0992\times1/\sin(1.0992) = 0.2442$$

Then Equation 5.53c can be solved for Fo:

$$Fo = -\frac{1}{\zeta_1^2}\ln\left(\theta_o^*/C_1\right) = -\frac{1}{1.0992^2}\ln\left(0.2442/1.1278\right) = 1.266$$

$$t_B = Fo\frac{r_o^2}{\alpha} = Fo\cdot\frac{\rho c_p}{k}\cdot r_o^2 = 1.266\frac{400\ kg/m^3\times1600\ J/kg\cdot K}{1.7\ W/m\cdot K}\times(0.015\ m)^2 = 107\ s$$ <

Note that the one-term approximation is accurate, since Fo > 0.2.

(c) To determine the energy change by the spheres during the cooling process, apply the conservation of energy requirement on a time interval basis.

Sphere A:

$$E_{in} - E_{out} = \Delta E \qquad -Q_A = \Delta E = E(t) - E(0).$$

$$Q_A = \rho\, cV\left[T(t)-T_i\right] = 1600\ kg/m^3\times400\ J/kg\cdot K\times(4/3)\pi(0.150\ m)^3\left[415-800\right]K$$

$$Q_A = 3.483\times10^6\ J.$$ <

Note that this simple expression is a consequence of the spacewise isothermal behavior.

Sphere B: $E_{in} - E_{out} = \Delta E \qquad -Q_B = E(t) - E(0).$

For the nonisothermal sphere, Equation 5.55 can be used to evaluate Q_B.

$$\frac{Q_B}{Q_o} = 1 - \frac{3\theta_o^*}{\zeta_1^3}\left[\sin(\zeta_1) - \zeta_1\cos(\zeta_1)\right] = 1 - \frac{3\times0.2442}{1.0992^3}\left[\sin(1.0992) - 1.0992\cos(1.0992)\right] = 0.784$$

The energy transfer from the sphere during the cooling process, using Equation 5.47, is

$$Q_B = 0.784\ Q_o = 0.784\left[\rho\, cV\left(T_i - T_\infty\right)\right]$$

$$Q_B = 0.784\times400\ kg/m^3\times1600\ J/kg\cdot K(4/3)\pi(0.015\ m)^3(800-320)K = 3405\ J$$ <

COMMENTS: In summary:

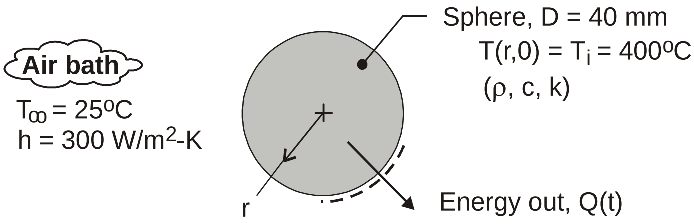
Sphere	$Bi = hr_o/k$	$\tau(s)$	t(s)	Q(J)
A	4.41×10^{-3}	6400	10,370	3.48×10^6
B	0.44	64	107	3405

PROBLEM 5.78

KNOWN: Spheres of 40-mm diameter heated to a uniform temperature of 400°C are suddenly removed from an oven and placed in a forced-air bath operating at 25°C with a convection coefficient of 300 $W/m^2 \cdot K$.

FIND: (a) Time the spheres must remain in the bath for 80% of the thermal energy to be removed, and (b) Uniform temperature the spheres will reach when removed from the bath at this condition and placed in a carton that prevents further heat loss.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional radial conduction in the spheres, (2) Constant properties, and (3) No heat loss from sphere after removed from the bath and placed into the packing carton.

PROPERTIES: Sphere (*given*): ρ = 3000 kg/m^3, c = 850 J/kg·K, k = 15 W/m·K.

ANALYSIS: (a) From Eq. 5.55, the fraction of thermal energy removed during the time interval $\Delta t = t_o$ is

$$\frac{Q}{Q_o} = 1 - 3\theta_o^* / \zeta_1^3 \left[\sin(\zeta_1) - \zeta_1 \cos(\zeta_1) \right] \tag{1}$$

where $Q/Q_o = 0.8$. The Biot number is

$$Bi = hr_o / k = 300\ W/m^2 \cdot K \times 0.020\,m / 15\ W/m \cdot K = 0.40$$

and for the one-term series approximation, from Table 5.1,

$$\zeta_1 = 1.0528\ rad \qquad\qquad C_1 = 1.1164 \tag{2}$$

The dimensionless temperature θ_o^*, follows from Eq. 5.53b.

$$\theta_o^* = C_1 \exp\left(-\zeta_1^2 Fo\right) \tag{3}$$

where $Fo = \alpha\, t_o / r_o^2$. Substituting Eq. (3) into Eq. (1), solve for Fo and t_o.

$$\frac{Q}{Q_o} = 1 - 3\, C_1 \exp\left(-\zeta_1^2 Fo\right) / \zeta_1^3 \left[\sin(\zeta_1) - \zeta_1 \cos(\zeta_1) \right] \tag{4}$$

$$Fo = 1.45 \qquad\qquad t_o = 98.6\ s$$ <

(b) Performing an overall energy balance on the sphere during the interval of time $t_o \le t \le \infty$,

$$E_{in} - E_{out} = \Delta E = E_f - E_i = 0 \tag{5}$$

where E_i represents the thermal energy in the sphere at t_o,

$$E_i = (1-0.8)Q_o = (1-0.8)\,\rho c V (T_i - T_\infty) \tag{6}$$

and E_f represents the thermal energy in the sphere at $t = \infty$,

$$E_f = \rho c V \left(T_{avg} - T_\infty\right) \tag{7}$$

Combining the relations, find the average temperature

$$\rho c V\left[\left(T_{avg} - T_\infty\right) - (1-0.8)\left(T_i - T_\infty\right)\right] = 0$$

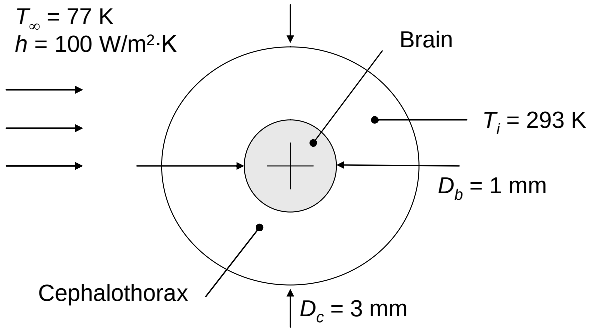
$$T_{avg} = 100°C$$ <

PROBLEM 5.79

KNOWN: Dimensions and initial temperature of spider brain and cephalothorax. Ambient temperature and heat transfer coefficient.

FIND: Time required for brain to begin freezing.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties. (2) Negligible effect of ice formation.

PROPERTIES: Table A.6, water (T = 283 K): ρ = 1000 kg/m^3, c = 4193 J/kg·K, and k = 0.587 W/m·K.

ANALYSIS: To determine whether spatial effects are important, the Biot number is calculated in the conservative fashion

$$Bi = \frac{hr_o}{k} = \frac{hD_c}{2k} = \frac{100 \text{ W/m}^2 \cdot \text{K} \times 3 \times 10^{-3} \text{ m}}{2 \times 0.587 \text{ W/m} \cdot \text{K}} = 0.25$$

Spatial effects are important and the lumped capacitance approximation is not valid. From Table 5.1 ζ_1 = 0.8447, C_1 = 1.0737. The brain begins to freeze when the temperature at D_b = 1 mm reaches the freezing temperature, T = 0°C.

Assuming validity of the approximate solution, Equation 5.53a may be rearranged to yield

$$Fo = -\frac{1}{\zeta_1^2} \ln\left(\frac{\theta^* \zeta_1 r^*}{C_1 \sin(\zeta_1 r^*)} \right)$$

where $$\theta^* = \frac{T - T_\infty}{T_i - T_\infty} = \frac{273 \text{ K} - 77 \text{ K}}{293 \text{ K} - 77 \text{ K}} = 0.907 \quad \text{and} \quad r^* = \frac{D_b}{D_c} = \frac{1 \text{ mm}}{3 \text{ mm}} = 1/3$$

Hence

$$Fo = \frac{\alpha t}{(D_c/2)^2} = \frac{1}{0.8447^2} \ln\left(\frac{0.907 \times 0.8447/3}{1.0737 \sin(0.8447/3)} \right) = 0.22$$

Continued...

PROBLEM 5.79 (Cont.)

Since *Fo* > 0.2 the approximate solution is valid and the time required for the brain to begin to freeze is

$$t = \frac{Fo\rho c(D_c/2)^2}{k} = \frac{0.22 \times 1000\ \text{kg/m}^3 \times 4193\ \text{J/kg}\cdot\text{K} \times (3\times10^{-3}\ \text{m/2})^2}{0.587\ \text{W/m}\cdot\text{K}} = 3.5\ \text{s} \quad <$$

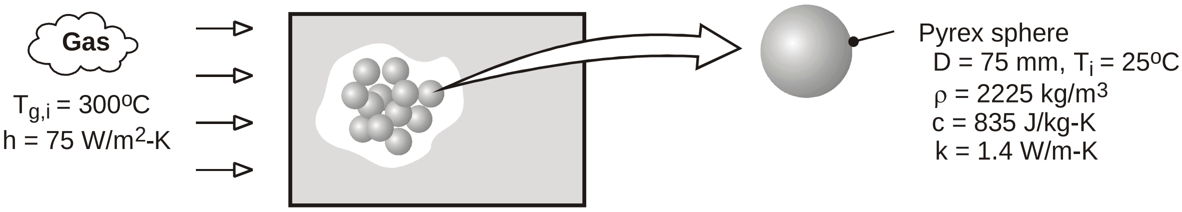
COMMENTS: (1) Solidification of the cephalothorax shell will lengthen the time needed to freeze the spider's brain. (2) The spider's brain begins to freeze 3.5 seconds after being exposed to the liquid nitrogen. It may be the case that the spider no longer remembers the frightening scene in the video when its brain freezes.

PROBLEM 5.80

KNOWN: Diameter, density, specific heat and thermal conductivity of Pyrex spheres in packed bed thermal energy storage system. Convection coefficient and inlet gas temperature.

FIND: Time required for sphere to acquire 90% of maximum possible thermal energy and the corresponding center temperature.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional radial conduction in sphere, (2) Negligible heat transfer to or from a sphere by radiation or conduction due to contact with adjoining spheres, (3) Constant properties.

ANALYSIS: With Bi ≡ $h(r_o/3)/k = 75\ W/m^2\cdot K\ (0.0125m)/1.4\ W/m\cdot K = 0.67$, the approximate solution for one-dimensional transient conduction in a sphere is used to obtain the desired results. We first use Eq. (5.55) to obtain θ_o^*.

$$\theta_o^* = \frac{\zeta_1^3}{3\left[\sin(\zeta_1) - \zeta_1 \cos(\zeta_1)\right]}\left(1 - \frac{Q}{Q_o}\right)$$

With Bi ≡ $hr_o/k = 2.01$, $\zeta_1 \approx 2.03$ and $C_1 \approx 1.48$ from Table 5.1. Hence,

$$\theta_o^* = \frac{0.1(2.03)^3}{3\left[0.896 - 2.03(-0.443)\right]} = \frac{0.837}{5.386} = 0.155$$

The center temperature is therefore

$$T_o = T_{g,i} + 0.155\left(T_i - T_{g,i}\right) = 300°C - 42.7°C = 257.3°C$$ <

From Eq. (5.53c), the corresponding time is

$$t = -\frac{r_o^2}{\alpha \zeta_1^2} \ln\left(\frac{\theta_o^*}{C_1}\right)$$

where $\alpha = k/\rho c = 1.4\ W/m\cdot K / \left(2225\ kg/m^3 \times 835\ J/kg\cdot K\right) = 7.54 \times 10^{-7}\ m^2/s$.

$$t = -\frac{(0.0375m)^2 \ln(0.155/1.48)}{7.54 \times 10^{-7}\ m^2/s\ (2.03)^2} = 1{,}020s$$ <

COMMENTS: The surface temperature at the time of interest may be obtained from Eq. (5.53b). With $r^* = 1$,

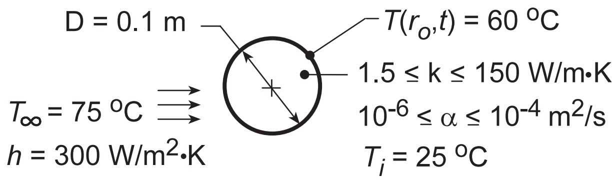
$$T_s = T_{g,i} + \left(T_i - T_{g,i}\right)\frac{\theta_o^* \sin(\zeta_1)}{\zeta_1} = 300°C - 275°C\left(\frac{0.155 \times 0.896}{2.03}\right) = 280.9°C$$ <

PROBLEM 5.81

KNOWN: Initial temperature and properties of a solid sphere. Surface temperature after immersion in a fluid of prescribed temperature and convection coefficient.

FIND: (a) Time to reach surface temperature, (b) Effect of thermal diffusivity and conductivity on thermal response.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, radial conduction, (2) Constant properties.

ANALYSIS: (a) For k = 15 W/m·K, the Biot number is

$$\mathrm{Bi} = \frac{h(r_o/3)}{k} = \frac{300\,\mathrm{W/m^2\cdot K}\,(0.05\,\mathrm{m}/3)}{15\,\mathrm{W/m\cdot K}} = 0.333.$$

Hence, the lumped capacitance method cannot be used. From Equation 5.53a,

$$\frac{T - T_\infty}{T_i - T_\infty} = C_1 \exp\left(-\zeta_1^2 \mathrm{Fo}\right) \frac{\sin\left(\zeta_1 r^*\right)}{\zeta_1 r^*}.$$

At the surface, $r^* = 1$. From Table 5.1, for Bi = 1.0, $\zeta_1 = 1.5708$ rad and $C_1 = 1.2732$. Hence,

$$\frac{60-75}{25-75} = 0.30 = 1.2732 \exp\left(-1.5708^2 \mathrm{Fo}\right) \frac{\sin 90^\circ}{1.5708}$$

$$\exp(-2.467\mathrm{Fo}) = 0.370$$

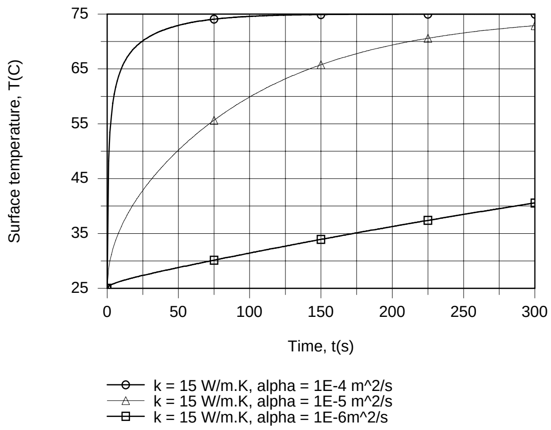
$$\mathrm{Fo} = \frac{\alpha t}{r_o^2} = 0.403$$

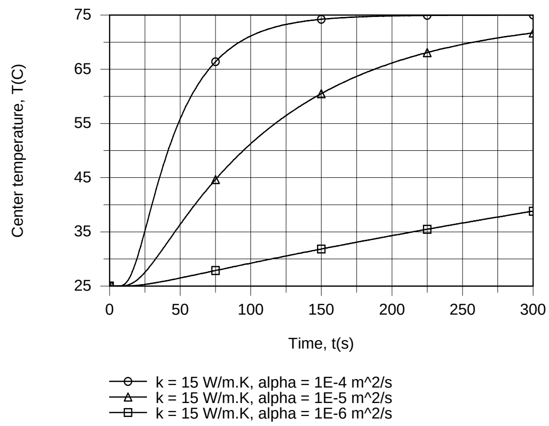
$$t = 0.403 \frac{r_o^2}{\alpha} = 0.403 \frac{(0.05\,\mathrm{m})^2}{10^{-5}\,\mathrm{m^2/s}} = 100\mathrm{s}$$ <

(b) Using the IHT *Transient Conduction Model* for a *Sphere* to perform the parametric calculations, the effect of α is plotted for k = 15 W/m·K.

Continued...

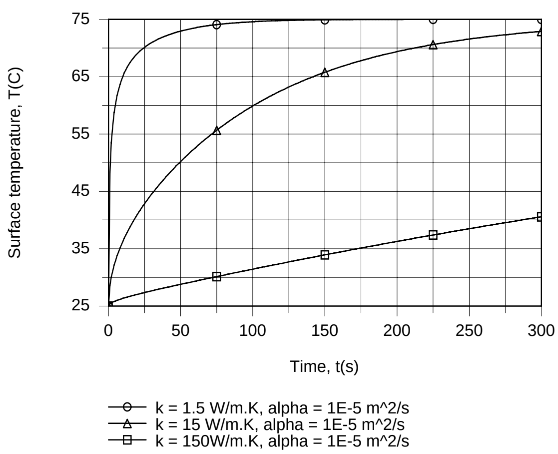
PROBLEM 5.81 (Cont.)

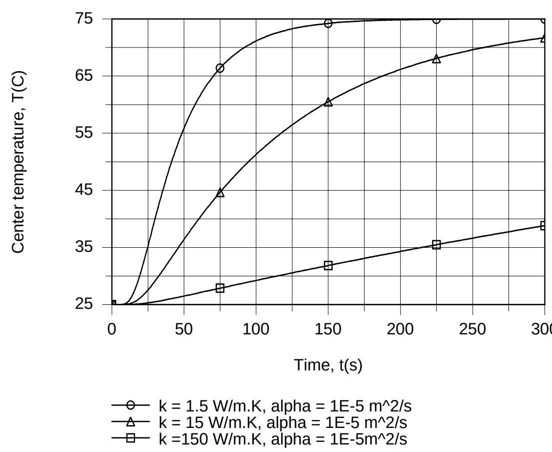




For fixed k and increasing α, there is a reduction in the thermal capacity (ρc_p) of the material, and hence the amount of thermal energy which must be added to increase the temperature. With increasing α, the material therefore responds more quickly to a change in the thermal environment, with the response at the center lagging that of the surface.

The effect of k is plotted for $\alpha = 10^{-5}$ m^2/s.





With increasing k for fixed alpha, there is a corresponding increase in ρc_p, and the material therefore responds more slowly to a thermal change in its surroundings. The thermal response of the center lags that of the surface, with temperature differences, $T(r_o,t) - T(0,t)$, during early stages of solidification increasing with decreasing k.

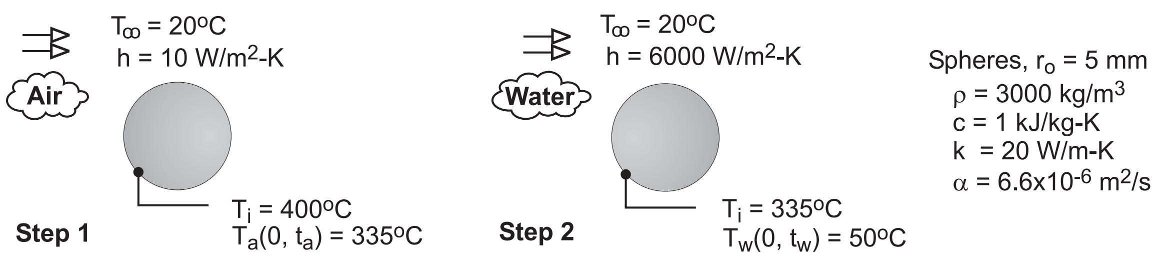
COMMENTS: Use of this technique to determine h from measurement of $T(r_o)$ at a prescribed t requires an iterative solution of the governing equations.

PROBLEM 5.82

KNOWN: Temperature requirements for cooling the spherical material of Example 5.6 in air and in a water bath.

FIND: (a) For step 1, the time required for the center temperature to reach T(0,t) = 335°C while cooling in air at 20°C with h = 10 $W/m^2 \cdot K$; find the Biot number; do you expect radial gradients to be appreciable?; compare results with hand calculations in Example 5.6; (b) For step 2, time required for the center temperature to reach T(0,t) = 50°C while cooling in water bath at 20°C with h = 6000 $W/m^2 \cdot K$; and (c) For step 2, calculate and plot the temperature history, T(x,t) vs. t, for the center and surface of the sphere; explain features; when do you expect the temperature gradients in the sphere to the largest? Use the IHT *Models* | *Transient Conduction* | *Sphere* model as your solution tool.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in the radial direction, (2) Constant properties.

ANALYSIS: The IHT model represents the series solution for the sphere providing the temperatures evaluated at (r,t). A selected portion of the IHT code used to obtain results is shown in the Comments.

(a) Using the IHT model with step 1 conditions, the time required for $T(0,t_a)$ = T_xt = 335°C with r = 0 and the Biot number are:

$$t_a = 94.2 \text{ s} \qquad\qquad Bi = 0.0025 \qquad <$$

Radial temperature gradients will not be appreciable since Bi = 0.0025 << 0.1. The sphere behaves as space-wise isothermal object for the air-cooling process. The result is identical to the lumped-capacitance analysis result of the Text example.

(b) Using the IHT model with step 2 conditions, the time required for $T(0,t_w)$ = T_xt = 50°C with r = 0 and T_i = 335°C is

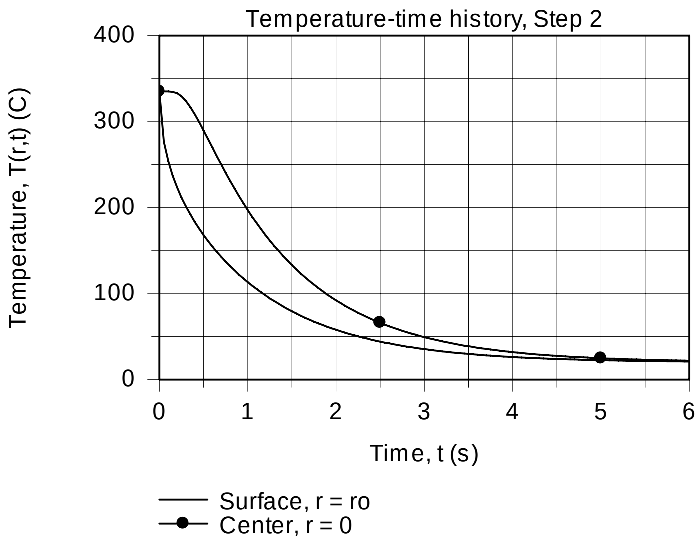
$$t_w = 3.0 \text{ s} \qquad <$$

Radial temperature gradients will be appreciable, since Bi = 1.5 >> 0.1. The sphere does not behave as a space-wise isothermal object for the water-cooling process.

(c) For the step 2 cooling process, the temperature histories for the center and surface of the sphere are calculated using the IHT model.

Continued …

PROBLEM 5.82 (Cont.)



At early times, the difference between the center and surface temperature is appreciable. It is in this time region that thermal stresses will be a maximum, and if large enough, can cause fracture. Within 6 seconds, the sphere has a uniform temperature equal to that of the water bath.

COMMENTS: Selected portions of the IHT sphere model codes for steps 1 and 2 are shown below.

```
/* Results, for part (a), step 1,  air cooling; clearly negligible gradient
Bi          Fo      t       T_xt    Ti      r       ro
0.0025      25.13   94.22   335     400     0       0.005  */

// Models | Transient Conduction | Sphere - Step 1, Air cooling
// The temperature distribution T(r,t) is
T_xt = T_xt_trans("Sphere",rstar,Fo,Bi,Ti,Tinf)    //
T_xt = 335            // Surface temperature

/* Results, for part (b), step 2, water cooling; Ti = 335 C
Bi      Fo      t       T_xt    Ti      r       ro
1.5     0.7936  2.976   50      335     0       0.005  */

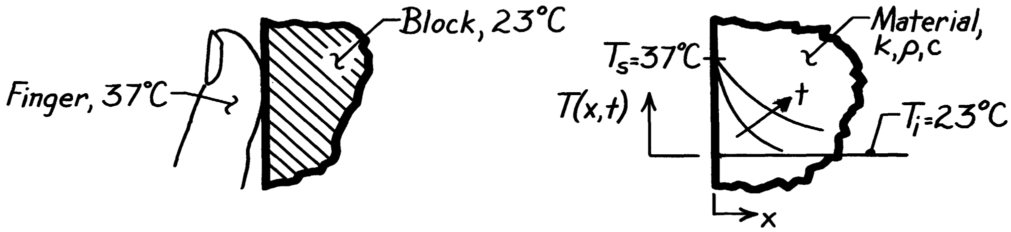
// Models | Transient Conduction | Sphere - Step 2, Water cooling
// The temperature distribution T(r,t) is
T_xt = T_xt_trans("Sphere",rstar,Fo,Bi,Ti,Tinf)    //
//T_xt = 335            // Surface temperature from Step 1; initial temperature for Step 2
T_xt = 50               // Center temperature, end of Step 2
```

PROBLEM 5.83

KNOWN: Two large blocks of different materials – like copper and concrete – at room temperature, 23°C.

FIND: Which block will feel cooler to the touch?

SCHEMATIC:



ASSUMPTIONS: (1) Blocks can be treated as semi-infinite solid, (2) Hand or finger temperature is 37°C.

PROPERTIES: *Table A-1*, Copper (300K): ρ = 8933 kg/m^3, c = 385 J/kg·K, k = 401 W/m·K; *Table A-3*, Concrete, stone mix (300K): ρ = 2300 kg/m^3, c = 880 J/kg·K, k = 1.4 W/m·K.

ANALYSIS: Considering the block as a semi-infinite solid, the heat transfer situation corresponds to a sudden change in surface temperature, Case 1, Figure 5.7. The sensation of coolness is related to the heat flow from the hand or finger to the block. From Eq. 5.61, the surface heat flux is

$$q''_s(t) = k(T_s - T_i)/(\pi\alpha\, t)^{1/2} \qquad (1)$$

or

$$q''_s(t) \sim (k\rho\, c)^{1/2} \qquad \text{since} \quad \alpha = k/\rho\, c. \qquad (2)$$

Hence for the same temperature difference, $T_s - T_i$, and elapsed time, it follows that the heat fluxes for the two materials are related as

$$\frac{q''_{s,copper}}{q''_{s,concrete}} = \frac{(k\rho\, c)^{1/2}_{copper}}{(k\rho\, c)^{1/2}_{concrete}} = \frac{\left[401\dfrac{W}{m\cdot K}\times 8933\dfrac{kg}{m^3}\times 385\dfrac{J}{kg\cdot K}\right]^{1/2}}{\left[1.4\dfrac{W}{m\cdot K}\times 2300\dfrac{kg}{m^3}\times 880\dfrac{J}{kg\cdot K}\right]^{1/2}} = 22.1$$

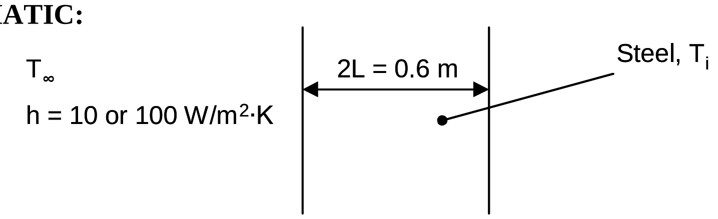
Hence, the heat flux to the copper block is more than 20 times larger than to the concrete block. The *copper* block will therefore feel noticeably cooler than the concrete one.

PROBLEM 5.84

KNOWN: Thickness and properties of plane wall. Convection coefficient.

FIND: (a) Nondimensional temperature for six different cases using four methods and (b) Explain the conditions for which the three approximate methods are good approximations of the exact solution.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties.

PROPERTIES: Steel (given): k = 30 W/m·K, ρ = 7900 kg/m^3, c = 640 J/kg·K.

ANALYSIS:
(a) We perform the calculations for h = 10 W/m^2·K, t = 2.5 min.

Exact Solution
From Equation 5.42a, evaluated at the surface x* = 1,

$$\theta_s^* = \frac{T_s - T_\infty}{T_i - T_\infty} = \sum_{n=1}^{\infty} C_n \exp(-\zeta_n^2 Fo)\cos(\zeta_n)$$

For t = 2.5 min,

$$Fo = \frac{\alpha t}{L^2} = \frac{k}{\rho c}\frac{t}{L^2}$$

$$= \frac{30\ \text{W/m}\cdot\text{K}}{7900\ \dfrac{\text{kg}}{\text{m}^3} \times 640\ \dfrac{\text{J}}{\text{kg}\cdot\text{K}}} \times \frac{(2.5 \times 60)\ \text{s}}{(0.3\ \text{m})^2} = 0.0099$$

We also calculate Bi = hL/k = 10 W/m^2·K × 0.3 m/30 W/m·K = 0.10. The first four values of ζ_n are found in Table B.3, and the corresponding values of C_n can be calculated from Equation 5.39b, $C_n = 4\sin\zeta_n / [2\zeta_n + \sin(2\zeta_n)]$. Then the first four terms in Equation 5.42a can be calculated as well. The results are tabulated below.

n	ζ_n	C_n	$C_n \exp(-\zeta_n^2 Fo)\cos(\zeta_n)$
1	0.3111	1.016	0.9664
2	3.1731	-0.0197	0.0178
3	6.2991	0.0050	0.0034
4	9.4354	-0.0022	0.0009
			$\theta_s^* = 0.989$

Continued…

PROBLEM 5.84 (Cont.)

We can see that the fourth term is small, so to a good approximation the exact solution can be found by summing the first four terms, as shown in the table. Thus

$$\theta^*_{s,exact} = 0.989$$ <

First Term
From the above table,

$$\theta^*_{s,1\text{-term}} = 0.966$$ <

Lumped Capacitance
From Equation 5.6,

$$\theta^*_{lump} = \exp\left[-\frac{hA_s}{\rho Vc}t\right] = \exp\left[-\frac{ht}{\rho Lc}\right]$$

$$= \exp\left[-\frac{10\ \text{W/m}^2\cdot\text{K}\times(2.5\times 60)\ \text{s}}{7900\ \text{kg/m}^3\times 0.3\ \text{m}\times 640\ \text{J/kg}\cdot\text{K}}\right] = 0.999$$

Semi-Infinite Solid
We use Equation 5.63 with x measured from the surface, that is x = 0.

$$\theta^*_{s,semi} = \frac{T_s - T_\infty}{T_i - T_\infty} = 1 - \frac{T_s - T_i}{T_\infty - T_i}$$

$$= 1 - \text{erfc}(0) + \exp\left(\frac{h^2\alpha t}{k^2}\right)\text{erfc}\left(\frac{h\sqrt{\alpha t}}{k}\right)$$

$$= 1 - 1 + \exp(Bi^2\ Fo)\ \text{erfc}(Bi\ Fo^{1/2})$$

$$= \exp(0.10^2 \times 0.0099)\ \text{erfc}(0.10\times(0.0099)^{1/2})$$

$$= 1.0001 \times 0.989 = 0.989$$ <

where the error function was evaluated from Table B.2.

Repeating the calculation for the other five cases, the following table can be compiled:

Method	*Bi* = 0.1			*Bi* = 1		
	Fo = 0.01	*Fo* = 0.1	*Fo* = 1.0	*Fo* = 0.01	*Fo* = 0.1	*Fo* = 1.0
Exact	0.99	0.97	0.88	0.90	0.72	0.35
First-term	0.97	0.96	0.88	0.72	0.68	0.35
Lumped	1.00	0.99	0.90	0.99	0.90	0.37
Semi-inf.	0.99	0.97	0.90	0.90	0.72	0.43

(b) (i) The first term solution is a good approximation to the exact solution for Fo > 0.2. As seen in the above table, for Fo = 1.0, the first term solution is correct to two significant digits.

Continued…

PROBLEM 5.84 (Cont.)

(ii) The lumped capacitance solution is a good approximation to the exact solution for Bi < 0.1. In the above table, the lumped capacitance solution is quite accurate for Bi = 0.1, but not for Bi = 1.0.

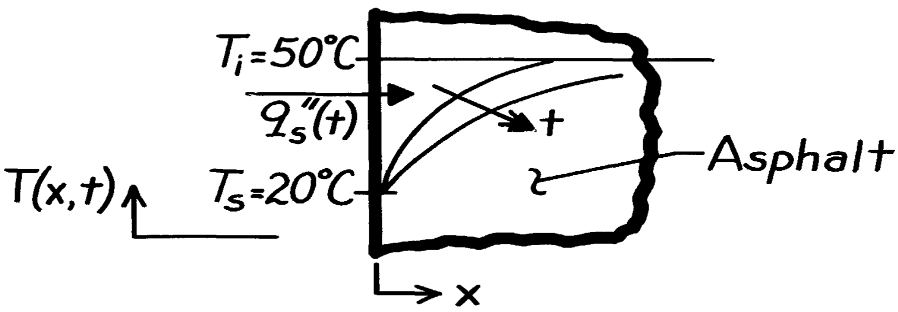
(iii) The semi-infinite solid solution is a good approximation to the exact solution for the smaller values of Fourier, since for small t or α, or for large L, the heat doesn't penetrate through the wall and it can be treated as semi-infinite.

PROBLEM 5.85

KNOWN: Asphalt pavement, initially at 50°C, is suddenly exposed to a rainstorm reducing the surface temperature to 20°C.

FIND: Total amount of energy removed (J/m^2) from the pavement for a 30 minute period.

SCHEMATIC:



ASSUMPTIONS: (1) Asphalt pavement can be treated as a semi-infinite solid, (2) Effect of rainstorm is to suddenly reduce the surface temperature to 20°C and is maintained at that level for the period of interest.

PROPERTIES: *Table A-3*, Asphalt (300K): ρ = 2115 kg/m^3, c = 920 J/kg·K, k = 0.062 W/m·K.

ANALYSIS: This solution corresponds to Case 1, Figure 5.7, and the surface heat flux is given by Eq. 5.61 as

$$q_s''(t) = k(T_s - T_i)/(\pi\alpha\ t)^{1/2} \qquad (1)$$

The energy into the pavement over a period of time is the integral of the surface heat flux expressed as

$$Q'' = \int_0^t q_s''(t)\,dt. \qquad (2)$$

Note that $q_s''(t)$ is into the solid and, hence, Q represents energy into the solid. Substituting Eq. (1) for $q_s''(t)$ into Eq. (2) and integrating find

$$Q'' = k(T_s - T_i)/(\pi\alpha)^{1/2}\int_0^t t^{-1/2}dt = \frac{k(T_s - T_i)}{(\pi\alpha)^{1/2}} \times 2\ t^{1/2}. \qquad (3)$$

Substituting numerical values into Eq. (3) with

$$\alpha = \frac{k}{\rho\ c} = \frac{0.062\ \text{W/m}\cdot\text{K}}{2115\ \text{kg/m}^3 \times 920\ \text{J/kg}\cdot\text{K}} = 3.18\times10^{-8}\text{m}^2/\text{s}$$

find that for the 30 minute period,

$$Q'' = \frac{0.062\ \text{W/m}\cdot\text{K}\ (20-50)\text{K}}{\left(\pi\times3.18\times10^{-8}\text{m}^2/\text{s}\right)^{1/2}} \times 2(30\times60\text{s})^{1/2} = -4.99\times10^5\ \text{J/m}^2.$$ <

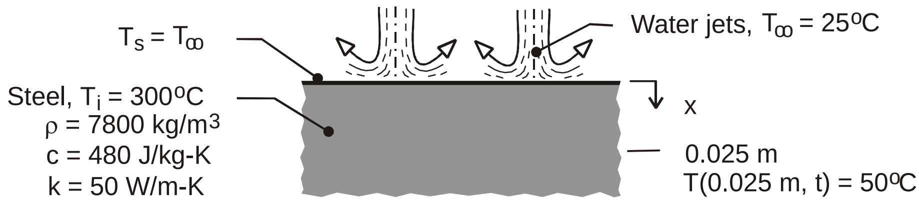
COMMENTS: Note that the sign for Q'' is negative implying that energy is removed from the solid.

PROBLEM 5.86

KNOWN: Thermophysical properties and initial temperature of thick steel plate. Temperature of water jets used for convection cooling at one surface.

FIND: Time required to cool prescribed interior location to a prescribed temperature.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in slab, (2) Validity of semi-infinite medium approximation, (3) Negligible thermal resistance between water jets and slab surface ($T_s = T_\infty$), (4) Constant properties.

ANALYSIS: The desired cooling time may be obtained from Eq. (5.60). With T(0.025m, t) = 50°C,

$$\frac{T(x,t)-T_s}{T_i - T_s} = \frac{(50-25)°C}{(300-25)°C} = 0.0909 = \text{erf}\left(\frac{x}{2\sqrt{\alpha t}}\right)$$

$$\frac{x}{2\sqrt{\alpha t}} = 0.0807$$

$$t = \frac{x^2}{(0.0807)^2\, 4\alpha} = \frac{(0.025\text{m})^2}{0.0261\left(1.34\times10^{-5}\text{m}^2/\text{s}\right)} = 1793\text{s}$$ <

where $\alpha = k/\rho c = 50$ W/m·K/(7800 kg/m^3 × 480 J/kg·K) = 1.34 × 10^{-5} m^2/s.

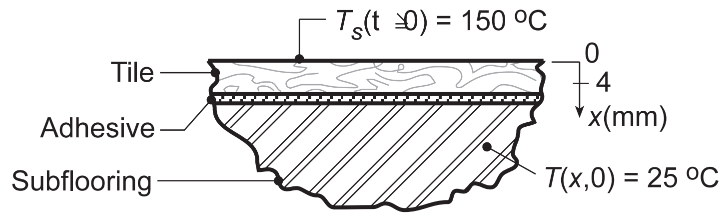
COMMENTS: (1) Large values of the convection coefficient (h ~ 10^4 W/m^2·K) are associated with water jet impingement, and it is reasonable to assume that the surface is immediately quenched to the temperature of the water. (2) The surface heat flux may be determined from Eq. (5.61). In principle, the flux is infinite at t = 0 and decays as $t^{1/2}$.

PROBLEM 5.87

KNOWN: Tile-iron, 254 mm to a side, at 150°C is suddenly brought into contact with tile over a subflooring material initially at T_i = 25°C with prescribed thermophysical properties. Tile adhesive softens in 2 minutes at 50°C, but deteriorates above 120°C.

FIND: (a) Time required to lift a tile after being heated by the tile-iron and whether adhesive temperature exceeds 120°C, (2) How much energy has been removed from the tile-iron during the time it has taken to lift the tile.

SCHEMATIC:



ASSUMPTIONS: (1) Tile and subflooring have same thermophysical properties, (2) Thickness of adhesive is negligible compared to that of tile, (3) Tile-subflooring behaves as semi-infinite solid experiencing one-dimensional transient conduction.

PROPERTIES: Tile-subflooring (given): k = 0.15 W/m·K, $\rho c_p = 1.5 \times 10^6$ J/m³·K, $\alpha = k/\rho c_p = 1.00 \times 10^{-7}$ m²/s.

ANALYSIS: (a) The tile-subflooring can be approximated as a semi-infinite solid, initially at a uniform temperature T_i = 25°C, experiencing a sudden change in surface temperature $T_s = T(0,t)$ = 150°C. This corresponds to Case 1, Figure 5.7. The time required to heat the adhesive (x_o = 4 mm) to 50°C follows from Eq. 5.60

$$\frac{T(x_o,t_o)-T_s}{T_i-T_s} = \text{erf}\left(\frac{x_o}{2(\alpha t_o)^{1/2}}\right)$$

$$\frac{50-150}{25-150} = \text{erf}\left(\frac{0.004\,\text{m}}{2\left(1.00\times10^{-7}\,\text{m}^2/\text{s}\times t_o\right)^{1/2}}\right)$$

$$0.80 = \text{erf}\left(6.325 t_o^{-1/2}\right)$$

t_o = 48.7s = 0.81 min

using error function values from Table B.2. Since the softening time, Δt_s, for the adhesive is 2 minutes, the time to lift the tile is

$$t_\ell = t_o + \Delta t_s = (0.81+2.0)\,\text{min} = 2.81\,\text{min}.$$ <

To determine whether the adhesive temperature has exceeded 120°C, calculate its temperature at t_ℓ = 2.81 min; that is, find $T(x_o, t_\ell)$

$$\frac{T(x_o,t_\ell)-150}{25-150} = \text{erf}\left(\frac{0.004\,\text{m}}{2\left(1.0\times10^{-7}\,\text{m}^2/\text{s}\times 2.81\times 60\text{s}\right)^{1/2}}\right)$$

Continued...

$$T\left(x_o, t_\ell\right) - 150 = -125\,\text{erf}\left(0.4880\right) = -125 \times 0.5098$$

$$T\left(x_o, t_\ell\right) = 86^\circ\text{C}$$ <

Since $T(x_o, t_\ell) < 120°C$, the adhesive will not deteriorate.

(b) The energy required to heat a tile to the lift-off condition is

$$Q = \int_0^{t_\ell} q''_x\left(0, t\right) \cdot A_s dt\,.$$

Using Eq. 5.61 for the surface heat flux $q''_s(t) = q''_x(0,t)$, find

$$Q = \int_0^{t_\ell} \frac{k\left(T_s - T_i\right)}{\left(\pi\alpha\right)^{1/2}} A_s \frac{dt}{t^{1/2}} = \frac{2k\left(T_s - T_i\right)}{\left(\pi\alpha\right)^{1/2}} A_s t_\ell^{1/2}$$

$$Q = \frac{2 \times 0.15\,\text{W/m}\cdot\text{K}\left(150 - 25\right)^\circ\text{C}}{\left(\pi \times 1.00 \times 10^{-7}\,\text{m}^2/\text{s}\right)^{1/2}} \times \left(0.254\,\text{m}\right)^2 \times \left(2.81 \times 60\text{s}\right)^{1/2} = 56\,\text{kJ}$$ <

COMMENTS: (1) Increasing the tile-iron temperature would decrease the time required to soften the adhesive, but the risk of burning the adhesive increases.

(2) From the energy calculation of part (b) we can estimate the size of an electrical heater, if operating continuously during the 2.81 min period, to maintain the tile-iron at a near constant temperature. The power required is

$$P = Q/t_\ell = 56\,\text{kJ}/2.81 \times 60\text{s} = 330\,\text{W}\,.$$

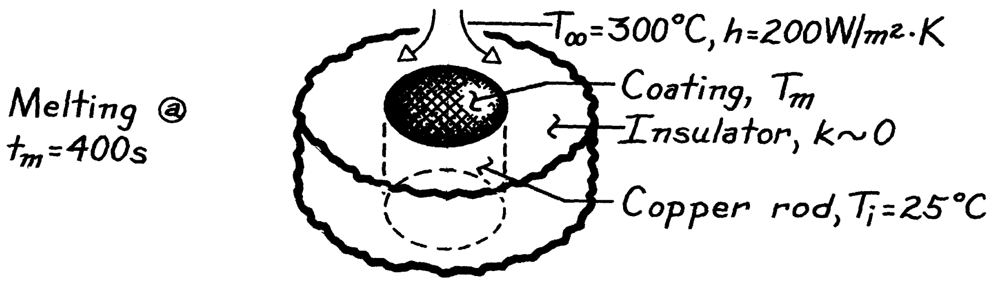
Of course a much larger electrical heater would be required to initially heat the tile-iron up to the operating temperature in a reasonable period of time.

PROBLEM 5.88

KNOWN: Procedure for measuring convection heat transfer coefficient, which involves melting of a surface coating.

FIND: Melting point of coating for prescribed conditions.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in solid rod (negligible losses to insulation), (2) Rod approximated as semi-infinite medium, (3) Negligible surface radiation, (4) Constant properties, (5) Negligible thermal resistance of coating.

PROPERTIES: Copper rod (Given): k = 400 W/m·K, $\alpha = 10^{-4}$ m^2/s.

ANALYSIS: Problem corresponds to transient conduction in a semi-infinite solid. Thermal response is given by

$$\frac{T(x,t)-T_i}{T_\infty - T_i} = \text{erfc}\left(\frac{x}{2(\alpha t)^{1/2}}\right) - \left[\exp\left(\frac{hx}{k}+\frac{h^2\alpha t}{k^2}\right)\right]\left[\text{erfc}\left(\frac{x}{2(\alpha t)^{1/2}}+\frac{h(\alpha t)^{1/2}}{k}\right)\right].$$

For x = 0, erfc(0) = 1 and T(x,t) = T(0,t) = T_s. Hence

$$\frac{T_s - T_i}{T_\infty - T_i} = 1 - \exp\left(\frac{h^2\alpha t}{k^2}\right)\text{erfc}\left(\frac{h(\alpha t)^{1/2}}{k}\right)$$

with

$$\frac{h(\alpha t_m)^{1/2}}{k} = \frac{200\text{ W/m}^2\cdot\text{K}\left(10^{-4}\text{m}^2/\text{s}\times 400\text{ s}\right)^{1/2}}{400\text{ W/m}\cdot\text{K}} = 0.1$$

$$T_s = T_m = T_i + (T_\infty - T_i)\left[1-\exp(0.01)\text{erfc}(0.1)\right]$$

$$T_s = 25^\circ\text{C} + 275^\circ\text{C}\left[1\text{-}1.01\times 0.888\right] = 53.5^\circ\text{C}.$$ <

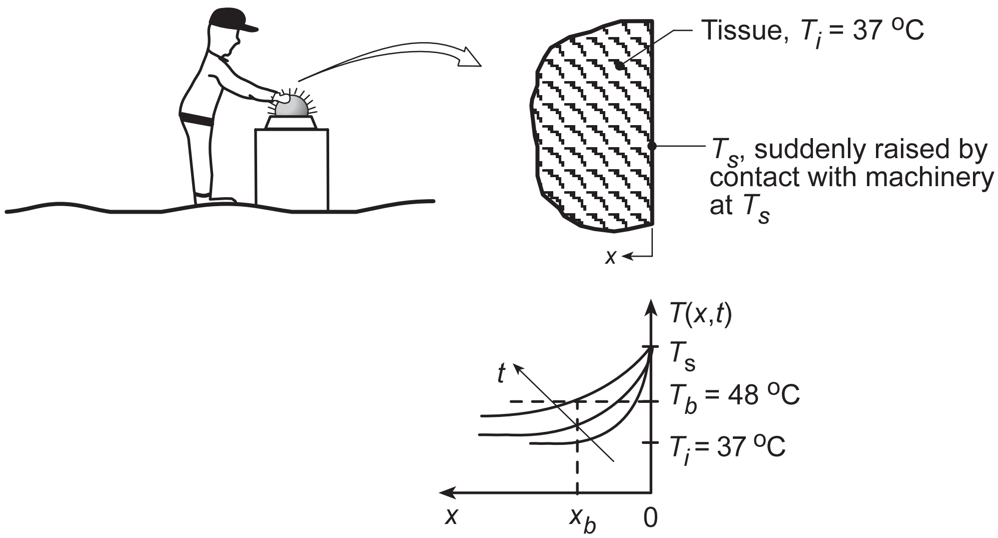
COMMENTS: Use of the procedure to evaluate h from measurement of t_m necessitates iterative calculations.

PROBLEM 5.89

KNOWN: Irreversible thermal injury (cell damage) occurs in living tissue maintained at T ≥ 48°C for a duration Δt ≥ 10s.

FIND: (a) Extent of damage for 10 seconds of contact with machinery in the temperature range 50 to 100°C, (b) Temperature histories at selected locations in tissue (x = 0.5, 1, 5 mm) for a machinery temperature of 100°C.

SCHEMATIC:



ASSUMPTIONS: (1) Portion of worker's body modeled as semi-infinite medium, initially at a uniform temperature, 37°C, (2) Tissue properties are constant and equivalent to those of water at 37°C, (3) Negligible contact resistance.

PROPERTIES: *Table A-6*, Water, liquid (T = 37°C = 310 K): $\rho = 1/v_f = 993.1\ kg/m^3$, c = 4178 J/kg·K, k = 0.628 W/m·K, $\alpha = k/\rho c = 1.513 \times 10^{-7}\ m^2/s$.

ANALYSIS: (a) For a given surface temperature -- suddenly applied -- the analysis is directed toward finding the skin depth x_b for which the tissue will be at T_b ≥ 48°C for more than 10s? From Eq. 5.60,

$$\frac{T(x_b,t)-T_s}{T_i-T_s} = \text{erf}\left[x_b/2(\alpha t)^{1/2}\right] = \text{erf}[\eta].$$

For the two values of T_s, the left-hand side of the equation is

$$T_s = 100^\circ C: \quad \frac{(48-100)^\circ C}{(37-100)^\circ C} = 0.825 \qquad\qquad T_s = 50^\circ C: \quad \frac{(48-50)^\circ C}{(37-50)^\circ C} = 0.154$$

The burn depth is

$$x_b = [w]2(\alpha t)^{1/2} = [w]2\left(1.513\times10^{-7}\ m^2/s\times t\right)^{1/2} = 7.779\times10^{-4}[w]t^{1/2}.$$

Continued...

PROBLEM 5.89 (Cont.)

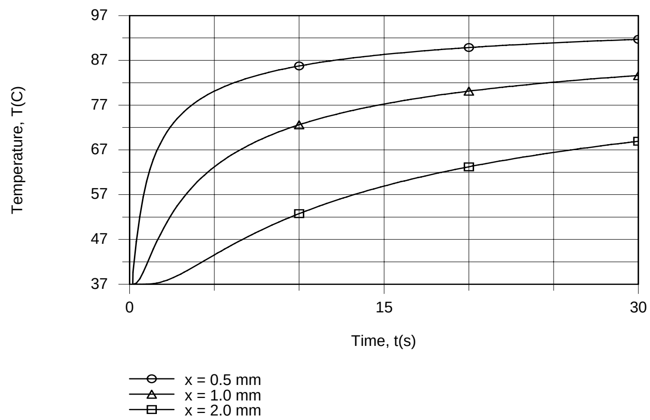
Using Table B.2 to evaluate the error function and letting t = 10s, find x_b as

$T_s = 100°C$: $x_b = 7.779 \times 10^{-4}\,[0.96](10s)^{1/2} = 2.362 \times 10^{3}\text{ m} = 2.36\text{ mm}$ <

$T_s = 50°C$: $x_b = 7.779 \times 10^{-4}\,[0.137](10s)^{1/2} = 3.37 \times 10^{3}\text{ m} = 0.34\text{ mm}$ <

Recognize that tissue at this depth, x_b, has not been damaged, but will become so if T_s is maintained for the next 10s. We conclude that, for $T_s = 50°C$, only superficial damage will occur for a contact period of 20s.

(b) Temperature histories at the prescribed locations are as follows.



The critical temperature of 48°C is reached within approximately 1s at x = 0.5 mm and within 7s at x = 2 mm.

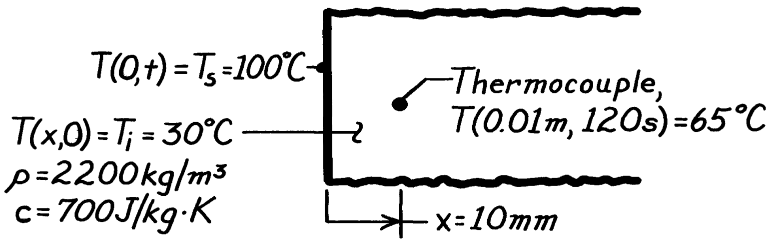
COMMENTS: Note that the burn depth x_b increases as $t^{1/2}$.

PROBLEM 5.90

KNOWN: Thermocouple location in thick slab. Initial temperature. Thermocouple measurement two minutes after one surface is brought to temperature of boiling water.

FIND: Thermal conductivity of slab material.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in x, (2) Slab is semi-infinite medium, (3) Constant properties.

PROPERTIES: Slab material (given): $\rho = 2200\ \text{kg/m}^3$, $c = 700\ \text{J/kg}\cdot\text{K}$.

ANALYSIS: For the semi-infinite medium from Eq. 5.60,

$$\frac{T(x,t)-T_s}{T_i-T_s} = \text{erf}\left[\frac{x}{2(\alpha\ t)^{1/2}}\right]$$

$$\frac{65-100}{30-100} = \text{erf}\left[\frac{0.01\text{m}}{2(\alpha\times 120\text{s})^{1/2}}\right]$$

$$\text{erf}\left[\frac{0.01\text{m}}{2(\alpha\times 120\text{s})^{1/2}}\right] = 0.5.$$

From Appendix B, find for erf w = 0.5 that w = 0.477; hence,

$$\frac{0.01\text{m}}{2(\alpha\times 120\text{s})^{1/2}} = 0.477$$

$$(\alpha\times 120)^{1/2} = 0.0105$$

$$\alpha = 9.156\times 10^{-7}\ \text{m}^2/\text{s}.$$

It follows that since $\alpha = k/\rho c$,

$$k = \alpha\rho\ c$$

$$k = 9.156\times 10^{-7}\ \text{m}^2/\text{s}\times 2200\ \text{kg/m}^3\times 700\ \text{J/kg}\cdot\text{K}$$

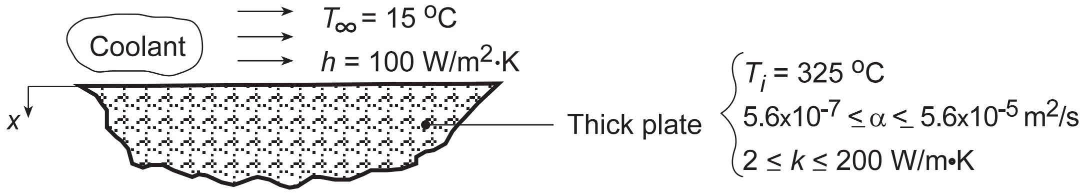
$$k = 1.41\ \text{W/m}\cdot\text{K}.$$ <

PROBLEM 5.91

KNOWN: Very thick plate, initially at a uniform temperature, T_i, is suddenly exposed to a surface convection cooling process (T_∞,h).

FIND: (a) Temperatures at the surface and 45 mm depth after 3 minutes, (b) Effect of thermal diffusivity and conductivity on temperature histories at x = 0, 0.045 m.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Plate approximates semi-infinite medium, (3) Constant properties, (4) Negligible radiation.

ANALYSIS: (a) The temperature distribution for a semi-infinite solid with surface convection is given by Eq. 5.63.

$$\frac{T(x,t)-T_i}{T_\infty - T_i} = \text{erfc}\left(\frac{x}{2(\alpha t)^{1/2}}\right) - \left[\exp\left(\frac{hx}{k}+\frac{h^2\alpha t}{k^2}\right)\right]\left[\text{erfc}\left(\frac{x}{2(\alpha t)^{1/2}}+\frac{h(\alpha t)^{1/2}}{k}\right)\right].$$

At the surface, x = 0, and for t = 3 min = 180s,

$$\frac{T(0,180\text{s})-325^\circ\text{C}}{(15-325)^\circ\text{C}} = \text{erfc}(0) - \left[\exp\left(0+\frac{100^2\ \text{W}^2/\text{m}^4\text{K}^2 \times 5.6\times10^{-6}\ \text{m}^2/\text{s}\times180\text{s}}{(20\ \text{W/m}\cdot\text{K})^2}\right)\right]$$

$$\times\left[\text{erfc}\left(0+\frac{100\ \text{W/m}^2\cdot\text{K}\left(5.6\times10^{-6}\ \text{m}^2/\text{s}\times180\text{s}\right)^{1/2}}{20\ \text{W/m}\cdot\text{K}}\right)\right]$$

$$= 1-\left[\exp(0.02520)\right]\times\left[\text{erfc}(0.159)\right] = 1-1.02552\times(1-0.178)$$

$$T(0,180\text{s}) = 325^\circ\text{C} - (15-325)^\circ\text{C}\cdot(1-1.0255\times0.822)$$

$$T(0,180\text{s}) = 325^\circ\text{C} - 49.3^\circ\text{C} = 276^\circ\text{C}\ .$$ <

At the depth x = 0.045 m, with t = 180s,

$$\frac{T(0.045\text{m},180\text{s})-325^\circ\text{C}}{(15-325)^\circ\text{C}} = \text{erfc}\left(\frac{0.045\ \text{m}}{2\left(5.6\times10^{-6}\ \text{m}^2/\text{s}\times180\text{s}\right)^{1/2}}\right) - \left[\exp\left(\frac{100\ \text{W/m}^2\cdot\text{K}\times0.045\ \text{m}}{20\ \text{W/m}\cdot\text{K}}+0.02520\right)\right]$$

$$\times\left[\text{erfc}\left(\frac{0.045\ \text{m}}{2\left(5.6\times10^{-6}\ \text{m}^2/\text{s}\times180\text{s}\right)^{1/2}}+0.159\right)\right]$$

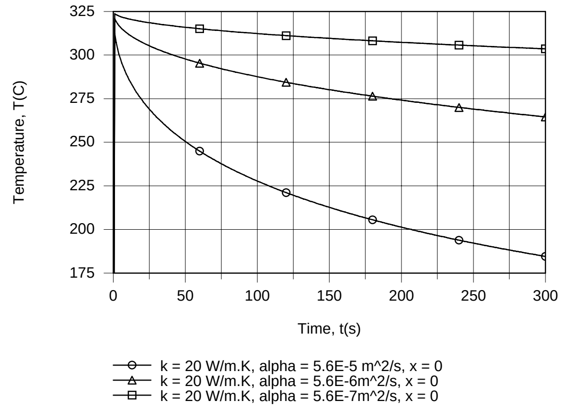
$$= \text{erfc}(0.7087)+\left[\exp(0.225+0.0252)\right]\times\left[\text{erfc}(0.7087+0.159)\right].$$

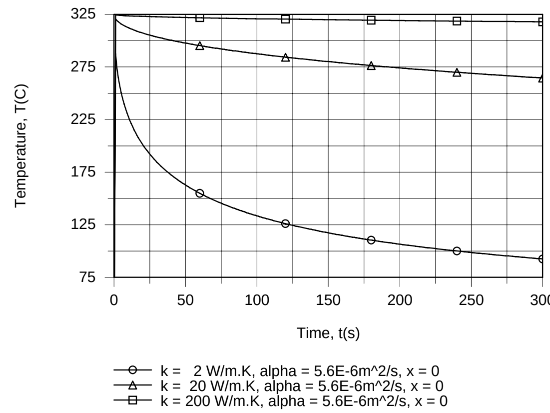
$$T(0.045\text{m},180\text{s}) = 325^\circ\text{C} + (15-325)^\circ\text{C}\left[(1-0.684)-1.284(1-0.780)\right] = 315^\circ\text{C}$$ <

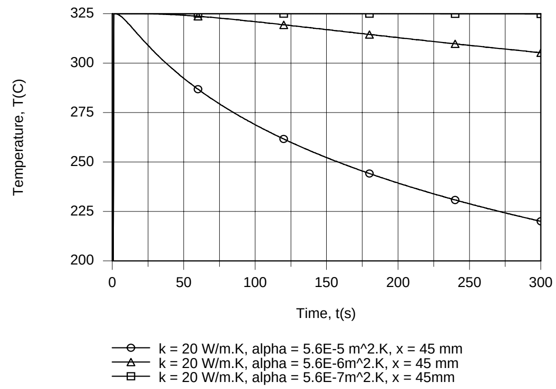
Continued...

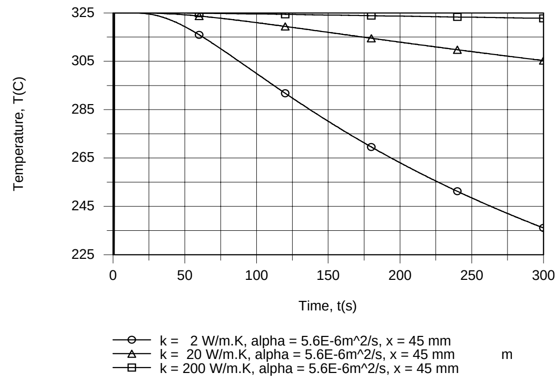
PROBLEM 5.91 (Cont.)

(b) The IHT *Transient Conduction Model* for a *Semi-Infinite Solid* was used to generate temperature histories, and for the two locations the effects of varying α and k are as follows.









For fixed k, increasing alpha corresponds to a reduction in the thermal capacitance per unit volume (ρc_p) of the material and hence to a more pronounced reduction in temperature at both surface and interior locations. Similarly, for fixed α, decreasing k corresponds to a reduction in ρc_p and hence to a more pronounced decay in temperature.

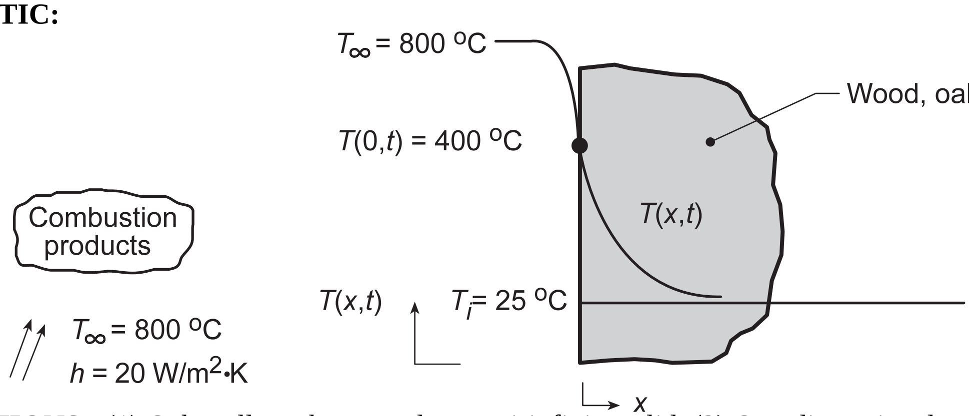
COMMENTS: In part (a) recognize that Fig. 5.8 could also be used to determine the required temperatures.

PROBLEM 5.92

KNOWN: Thick oak wall, initially at a uniform temperature of 25°C, is suddenly exposed to combustion products at 800°C with a convection coefficient of 20 $W/m^2 \cdot K$.

FIND: (a) Time of exposure required for the surface to reach an ignition temperature of 400°C, (b) Temperature distribution at time t = 325s.

SCHEMATIC:



ASSUMPTIONS: (1) Oak wall can be treated as semi-infinite solid, (2) One-dimensional conduction, (3) Constant properties, (4) Negligible radiation.

PROPERTIES: *Table A-3*, Oak, cross grain (300 K): ρ = 545 kg/m^3, c = 2385 J/kg·K, k = 0.17 W/m·K, $\alpha = k/\rho c$ = 0.17 W/m·K/545 $kg/m^3 \times$ 2385 J/kg·K = 1.31 × 10^{-7} m^2/s.

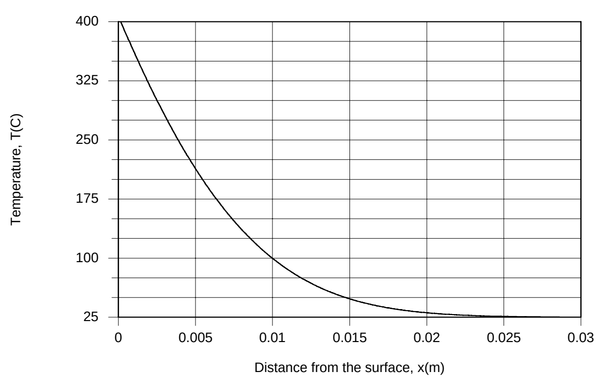
ANALYSIS: (a) This situation corresponds to Case 3 of Figure 5.7. The temperature distribution is given by Eq. 5.63 or by Figure 5.8. Using the figure with

$$\frac{T(0,t)-T_i}{T_\infty - T_i} = \frac{400-25}{800-25} = 0.48 \qquad \text{and} \qquad \frac{x}{2(\alpha t)^{1/2}} = 0$$

we obtain $h(\alpha t)^{1/2}/k \approx 0.75$, in which case $t \approx (0.75k/h\alpha^{1/2})^2$. Hence,

$$t \approx \left(0.75 \times 0.17\,\mathrm{W/m \cdot K} \Big/ 20\,\mathrm{W/m^2 \cdot K}\left(1.31\times10^{-7}\,\mathrm{m^2/s}\right)^{1/2}\right)^2 = 310\mathrm{s}$$ <

(b) Using the IHT *Transient Conduction Model* for a *Semi-infinite Solid*, the following temperature distribution was generated for t = 325s.



The temperature decay would become more pronounced with decreasing α (decreasing k, increasing ρc_p) and in this case the penetration depth of the heating process corresponds to x ≈ 0.025 m at 325s.

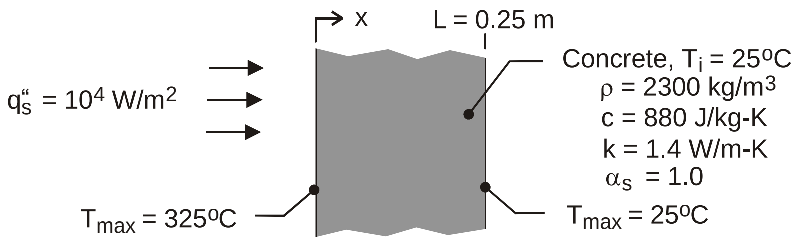
COMMENTS: The result of part (a) indicates that, after approximately 5 minutes, the surface of the wall will ignite and combustion will ensue. Once combustion has started, the present model is no longer appropriate.

PROBLEM 5.93

KNOWN: Thickness, initial temperature and thermophysical properties of concrete firewall. Incident radiant flux and duration of radiant heating. Maximum allowable surface temperatures at the end of heating.

FIND: If maximum allowable temperatures are exceeded.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in wall, (2) Validity of semi-infinite medium approximation, (3) Negligible convection and radiative exchange with the surroundings at the irradiated surface, (4) Negligible heat transfer from the back surface, (5) Constant properties.

ANALYSIS: The thermal response of the wall is described by Eq. (5.62)

$$T(x,t) = T_i + \frac{2\,q_o''(\alpha t/\pi)^{1/2}}{k}\exp\left(\frac{-x^2}{4\alpha t}\right) - \frac{q_o'' x}{k}\,\mathrm{erfc}\left(\frac{x}{2\sqrt{\alpha t}}\right)$$

where, $\alpha = k/\rho c_p = 6.92\times10^{-7}\,m^2/s$ and for $t = 30\ min = 1800s,\ 2q_o''(\alpha t/\pi)^{1/2}/k = 284.5\,K$. Hence, at x = 0,

$$T(0, 30\ min) = 25°C + 284.5°C = 309.5°C < 325°C$$ <

At $x = 0.25m,\ (-x^2/4\alpha t) = -12.54,\ q_o'' x/k = 1,786K,$ and $x/2(\alpha t)^{1/2} = 3.54.$ Hence,

$$T(0.25m,\ 30\,min) = 25°C + 284.5°C\left(3.58\times10^{-6}\right) - 1786°C\times(\sim 0) \approx 25°C$$ <

Both requirements are met.

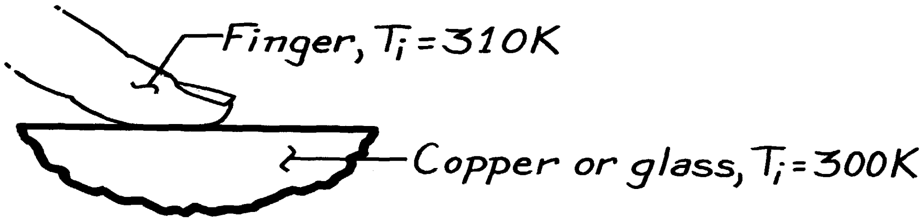
COMMENTS: The foregoing analysis is conservative since heat transfer at the irradiated surface due to convection and net radiation exchange with the environment have been neglected. If the emissivity of the surface and the temperature of the surroundings are assumed to be ε = 1 and T_{sur} = 298K, radiation exchange at T_s = 309.5°C would be $q''_{rad} = \varepsilon\sigma\left(T_s^4 - T_{sur}^4\right) = 6,080\ W/m^2\cdot K$, which is significant (~ 60% of the prescribed radiation).

PROBLEM 5.94

KNOWN: Initial temperature of copper and glass plates. Initial temperature and properties of finger.

FIND: Whether copper or glass feels cooler to touch.

SCHEMATIC:



ASSUMPTIONS: (1) The finger and the plate behave as semi-infinite solids, (2) Constant properties, (3) Negligible contact resistance.

PROPERTIES: Skin (given): ρ = 1000 kg/m^3, c = 4180 J/kg·K, k = 0.625 W/m·K; *Table A-1* (T = 300K), Copper: ρ = 8933 kg/m^3, c = 385 J/kg·K, k = 401 W/m·K; *Table A-3* (T = 300K), Glass: ρ = 2500 kg/m^3, c = 750 J/kg·K, k = 1.4 W/m·K.

ANALYSIS: Which material feels cooler depends upon the contact temperature T_s given by Equation 5.66. For the three materials of interest,

$$(k\rho\, c)^{1/2}_{skin} = (0.625\times1000\times4180)^{1/2} = 1,616\ \text{J/m}^2\cdot\text{K}\cdot\text{s}^{1/2}$$
$$(k\rho\, c)^{1/2}_{cu} = (401\times8933\times385)^{1/2} = 37,137\ \text{J/m}^2\cdot\text{K}\cdot\text{s}^{1/2}$$
$$(k\rho\, c)^{1/2}_{glass} = (1.4\times2500\times750)^{1/2} = 1,620\ \text{J/m}^2\cdot\text{K}\cdot\text{s}^{1/2}.$$

Since $(k\rho\, c)^{1/2}_{cu} >> (k\rho\, c)^{1/2}_{glass}$, the copper will feel much cooler to the touch. From Equation 5.66,

$$T_s = \frac{(k\rho\, c)^{1/2}_A T_{A,i} + (k\rho\, c)^{1/2}_B T_{B,i}}{(k\rho\, c)^{1/2}_A + (k\rho\, c)^{1/2}_B}$$

$$T_{s(cu)} = \frac{1,616(310) + 37,137(300)}{1,616 + 37,137} = 300.4\ \text{K} \qquad <$$

$$T_{s(glass)} = \frac{1,616(310) + 1,620(300)}{1,616 + 1,620} = 305.0\ \text{K}. \qquad <$$

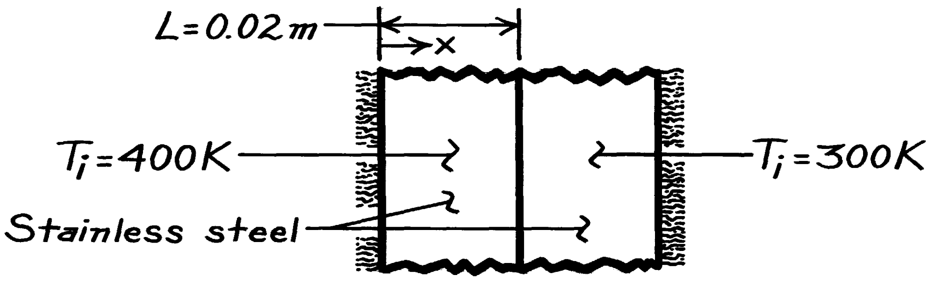
COMMENTS: The extent to which a material's temperature is affected by a change in its thermal environment is inversely proportional to $(k\rho c)^{1/2}$. Large k implies an ability to *spread* the effect by conduction; large ρc implies a large capacity for thermal energy *storage*.

PROBLEM 5.95

KNOWN: Initial temperatures, properties, and thickness of two plates, each insulated on one surface.

FIND: Temperature on insulated surface of one plate at a prescribed time after they are pressed together.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Negligible contact resistance.

PROPERTIES: Stainless steel (given): $\rho = 8000$ kg/m^3, c = 500 J/kg·K, k = 15 W/m·K.

ANALYSIS: At the instant that contact is made, the plates behave as semi-infinite slabs and, since the (ρkc) product is the same for the two plates, Equation 5.66 yields a surface temperature of

$$T_s = 350\text{K}.$$

The interface will remain at this temperature, even after thermal effects penetrate to the insulated surfaces. The transient response of the hot wall may therefore be calculated from Equations 5.43 and 5.44. At the insulated surface ($x^* = 0$), Equation 5.43 yields

$$\frac{T_o - T_s}{T_i - T_s} = C_1 \exp\left(-\zeta_1^2 \text{Fo}\right)$$

where, in principle, $h \to \infty$ and $T_\infty \to T_s$. From Equation 5.42c, Bi $\to \infty$ yields ζ_1 = 1.5707, and from Equation 5.42b

$$C_1 = \frac{4\sin\zeta_1}{2\zeta_1 + \sin(2\zeta_1)} = 1.273$$

Also, $$\text{Fo} = \frac{\alpha t}{L^2} = \frac{3.75\times10^{-6}\text{m}^2/\text{s}(60\text{s})}{(0.02\text{ m})^2} = 0.563.$$

Hence, $$\frac{T_o - 350}{400 - 350} = 1.273\exp\left(-1.5707^2 \times 0.563\right) = 0.318$$

$$T_o = 365.9\text{ K}.$$ <

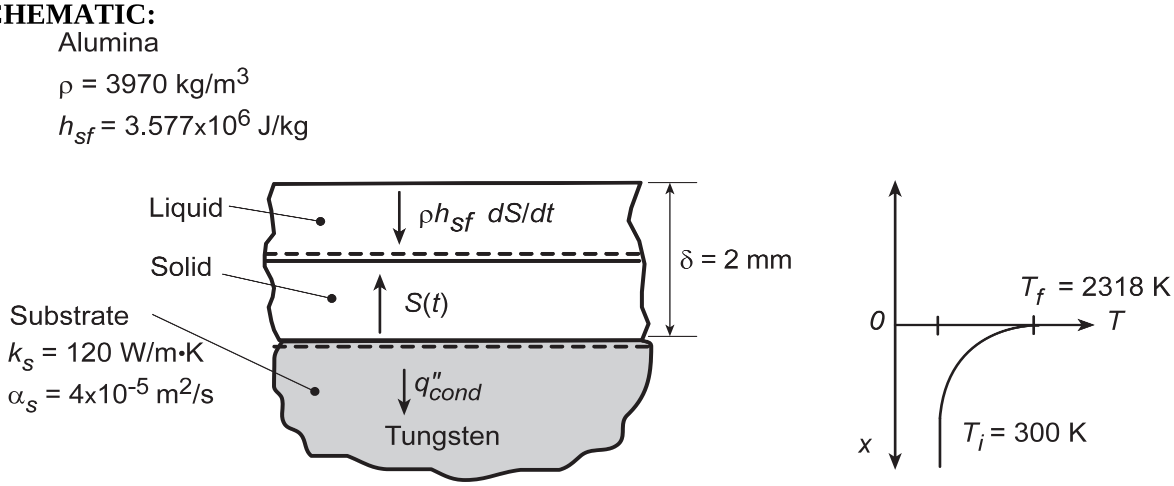
COMMENTS: Since Fo > 0.2, the one-term approximation is appropriate.

PROBLEM 5.96

KNOWN: Thickness and properties of liquid coating deposited on a metal substrate. Initial temperature and properties of substrate.

FIND: (a) Expression for time required to completely solidify the liquid, (b) Time required to solidify an alumina coating.

SCHEMATIC:



ASSUMPTIONS: (1) Substrate may be approximated as a semi-infinite medium in which there is one-dimensional conduction, (2) Solid and liquid alumina layers remain at fusion temperature throughout solidification (negligible resistance to heat transfer by conduction through solid), (3) Negligible contact resistance at the coating/substrate interface, (4) Negligible solidification contraction, (5) Constant properties.

ANALYSIS: (a) Performing an energy balance on the solid layer, whose thickness S increases with t, the latent heat released at the solid/liquid interface must be balanced by the rate of heat conduction into the solid. Hence, per unit surface area,

$$\rho h_{sf}\frac{dS}{dt} = q''_{cond} \quad \text{where, from Eq. 5.61,} \quad q''_{cond} = k\left(T_f - T_i\right)\big/\left(\pi\alpha t\right)^{1/2}. \text{ It follows that}$$

$$\rho h_{sf}\frac{dS}{dt} = \frac{k_s\left(T_f - T_i\right)}{\left(\pi\alpha_s t\right)^{1/2}}$$

$$\int_o^{\delta} dS = \frac{k_s\left(T_f - T_i\right)}{\rho h_{sf}\left(\pi\alpha_s\right)^{1/2}}\int_o^t \frac{dt}{t^{1/2}}$$

$$\delta = \frac{2k_s}{\left(\pi\alpha_s\right)^{1/2}}\left(\frac{T_f - T_i}{\rho h_{sf}}\right)t^{1/2}$$

$$t = \frac{\pi\alpha_s}{4k_s^2}\left(\frac{\delta\rho h_{sf}}{T_f - T_i}\right)^2 \qquad <$$

(b) For the prescribed conditions,

$$t = \frac{\pi\left(4\times10^{-5}\,\text{m}^2/\text{s}\right)}{4\left(120\,\text{W/m}\cdot\text{K}\right)^2}\left(\frac{0.002\,\text{m}\times3970\,\text{kg/m}^3\times3.577\times10^6\,\text{J/kg}}{2018\,\text{K}}\right)^2 = 0.43 \qquad <$$

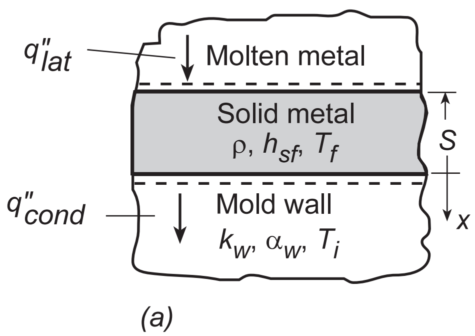
COMMENTS: If solidification occurs over a short time resulting in a change of the solid's microstructure (relative to slow solidification), it is termed *rapid solidification*. See Problem 5.42.

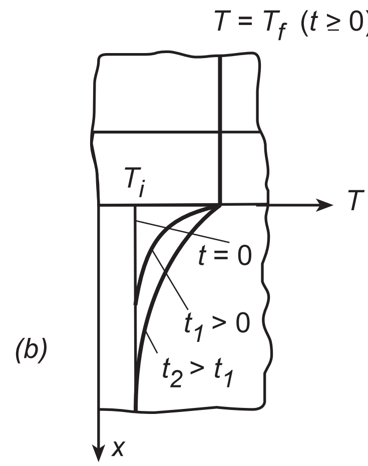
PROBLEM 5.97

KNOWN: Properties of mold wall and a solidifying metal.

FIND: (a) Temperature distribution in mold wall at selected times, (b) Expression for variation of solid layer thickness.

SCHEMATIC:





ASSUMPTIONS: (1) Mold wall may be approximated as a semi-infinite medium in which there is one-dimensional conduction, (2) Solid and liquid metal layers remain at fusion temperature throughout solidification (negligible resistance to heat transfer by conduction through solid), (3) Negligible contact resistance at mold/metal interface, (4) Constant properties.

ANALYSIS: (a) As shown in schematic (b), the temperature remains nearly uniform in the metal (at T_f) throughout the process, while both the temperature and temperature penetration increase with time in the mold wall.

(b) Performing an energy balance for a control surface about the solid layer, the latent energy released due to solidification at the solid/liquid interface is balanced by heat conduction into the solid, $q''_{lat} = q''_{cond}$, where $q''_{lat} = \rho h_{sf}\, dS/dt$ and q''_{cond} is given by Eq. 5.61. Hence,

$$\rho h_{sf} \frac{dS}{dt} = \frac{k_w (T_f - T_i)}{(\pi \alpha_w t)^{1/2}}$$

$$\int_o^S dS = \frac{k_w (T_f - T_i)}{\rho h_{sf} (\pi \alpha_w)^{1/2}} \int_o^t \frac{dt}{t^{1/2}}$$

$$S = \frac{2k_w (T_f - T_i)}{\rho h_{sf} (\pi \alpha_w)^{1/2}} t^{1/2}$$ <

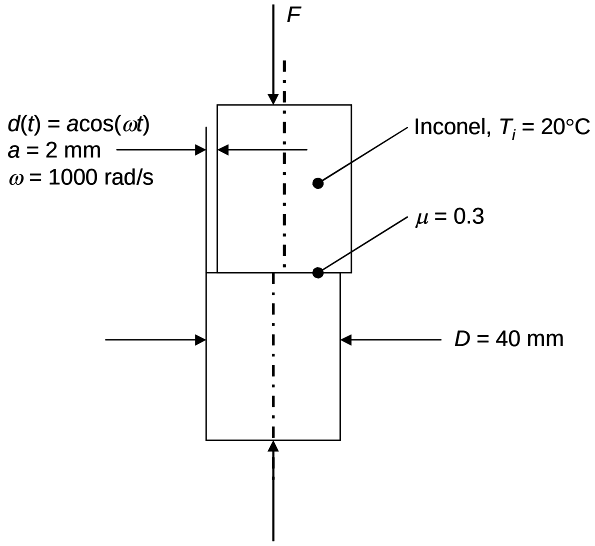
COMMENTS: The analysis of part (b) would only apply until the temperature field penetrates to the exterior surface of the mold wall, at which point, it may no longer be approximated as a semi-infinite medium.

PROBLEM 5.98

KNOWN: Diameter and initial temperature of two Inconel rods. Amplitude and frequency of motion of upper rod. Coefficient of friction.

FIND: Compressive force required to bring rod to melting point in 3 seconds.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss from surfaces of rods, (2) Rods are effectively semi-infinite, (3) Frictional heat generation can be treated as constant in time, (4) Constant properties.

PROPERTIES: Table A.1, Inconel X-750: T_m = 1665 K, $\overline{T} = (T_i + T_m)/2$ = (293 +1665)/2 = 979 K, k = 23.6 W/m·K, c_p = 618 J/kg·K, ρ = 8510 kg/m^3, $\alpha = k/\rho c_p = 4.49 \times 10^{-6}$ m^2/s.

ANALYSIS: We begin by expressing the frictional heat flux in terms of the unknown compressive force, F_n.

$$q'' = -\frac{\vec{F}_t \cdot \vec{V}}{A} = \frac{|\mu F_n V|}{A} = \frac{|\mu F_n|}{A}\frac{dd}{dt} = \frac{|\mu F_n|}{A} a\omega |\sin \omega t|$$

In the above equation, use has been made of the fact that the frictional force always opposes the direction of motion, therefore $\vec{F}_t \cdot \vec{V} = -|F_t V|$. The average value of the heat flux is found by integrating over one period of |sin ωt|, namely π/ω:

$$\overline{q}''_s = \frac{\omega}{\pi}\int_0^{\frac{\pi}{\omega}} \frac{\mu F_n a\omega}{A}|\sin \omega t| dt = -\frac{1}{\pi}\frac{\mu F_n a\omega}{A}\cos \omega t\Big|_0^{\frac{\pi}{\omega}} = \frac{2\mu F_n a\omega}{\pi A} \qquad (1)$$

Continued…

PROBLEM 5.98 (Cont.)

Note that $A = \pi D^2/2$, because heat conducts in both directions. We can find the surface temperature from Eq. 5.62 for the temperature distribution in a semi-infinite solid with uniform surface heat flux. Evaluating that equation at x = 0 yields

$$T_s - T_i = \frac{2\bar{q}''_s(\alpha t/\pi)^{1/2}}{k} \tag{2}$$

With T_s equal to the melting temperature, we can solve for $\bar{q}''_s$:

$$\begin{aligned}\bar{q}''_s &= \frac{k(T_s - T_i)}{2}\left(\frac{\pi}{\alpha t}\right)^{1/2} \\ &= \frac{23.6\ \text{W/m}\cdot\text{K}(1665\ \text{K} - 293\ \text{K})}{2}\left(\frac{\pi}{4.49\times10^{-6}\ \text{m}^2/\text{s}\times 3\ \text{s}}\right)^{1/2} \\ &= 7.82\times10^6\ \text{W/m}^2\end{aligned}$$

Then we can solve for F_n from Eq. (1):

$$F_n = \frac{\bar{q}''_s \pi A}{2\mu a\omega} = \frac{7.82\times10^6\ \text{W/m}^2 \times \pi\times\pi\times(0.04\ \text{m})^2/2}{2\times0.3\times0.002\ \text{m}\times1000\ \text{rad/s}} = 51.4\ \text{kN}$$ <

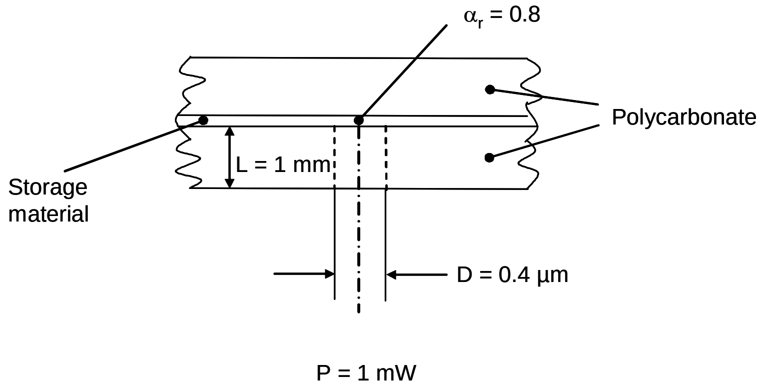
Comments: If the displacement were to be large, the heat transfer would no longer be one-dimensional.

PROBLEM 5.99

KNOWN: Thickness and properties of DVD disk. Laser spot size and power.

FIND: Time needed to raise the storage material from 300 K to 1000 K.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible contact resistances at the interfaces, (2) Infinite medium, (3) Polycarbonate is transparent to laser irradiation, (4) Polycarbonate is opaque to radiation from the heated spot, (5) Spatially-uniform laser power, (6) Motion of disk does not affect the thermal response, (7) Infinitely thin storage material, (8) Negligible nanoscale heat transfer effects.

PROPERTIES: Polycarbonate (given): k = 0.21 W/m·K, ρ = 1200 kg/m^3, c_p = 1260 J/kg·K. Storage material (given): α_r = 0.8

ANALYSIS: The heat transferred from the irradiated storage material is

$$q = \alpha_r P \quad (1)$$

From Case 13 of Table 4.1,

$$A_s = \pi D^2/2 \quad (2)$$

From Table 5.2b for Fo < 0.2,

$$q^*(Fo) = \frac{q_s'' L_c}{k(T_s - T_i)} = \frac{1}{2}\sqrt{\frac{\pi}{Fo}} + \frac{\pi}{4} \quad (3a)$$

From Table 5.2b for Fo ≥ 0.2

$$q^*(Fo) = \frac{q_s'' L_c}{k(T_s - T_i)} = \frac{0.77}{\sqrt{Fo}} + \frac{2\sqrt{2}}{\pi} \quad (3b)$$

where $L_c = (A_s/4\pi)^{1/2} = D/\sqrt{8}$; $q_s'' = \dfrac{q}{A_s}$ (4)

and $Fo = \alpha t/L_c^2 = 8\alpha t/D^2$ (5)

with $\alpha = k/\rho c = 0.21\ \text{W/m}\cdot\text{K}/(1200\ \text{kg/m}^3 \times 1260\ \text{J/kg}\cdot\text{K}) = 139 \times 10^{-9}\ \text{m}^2/\text{s}$,

Continued…

PROBLEM 5.99 (Cont.)

and $$\frac{q_s'' L_c}{k(T_s - T_c)} = \frac{2P\alpha_r}{\pi D\sqrt{8}k(T_s - T_i)}$$

$$= \frac{2 \times 1 \times 10^{-3}\ \text{W} \times 0.8}{\pi \times 0.4 \times 10^{-6} \times \sqrt{8} \times 0.21\ \text{W/m}\cdot\text{K} \times (1000 - 300)\ \text{K}} = 3.0623$$

Equations (3a) and (3b) yield

For Fo < 0.2, Fo = 0.151
For Fo ≥ 0.2, Fo = 0.127

Therefore, Fo = 0.151 <

From Equation (5),

$$t = \frac{\text{Fo}D^2}{8\alpha} = \frac{0.151 \times (0.4 \times 10^{-6}\ \text{m})^2}{8 \times 139 \times 10^{-9}\ \text{m}^2/\text{s}} = 21.8 \times 10^{-9}\ \text{s} = 21.8\ \text{ns}$$ <

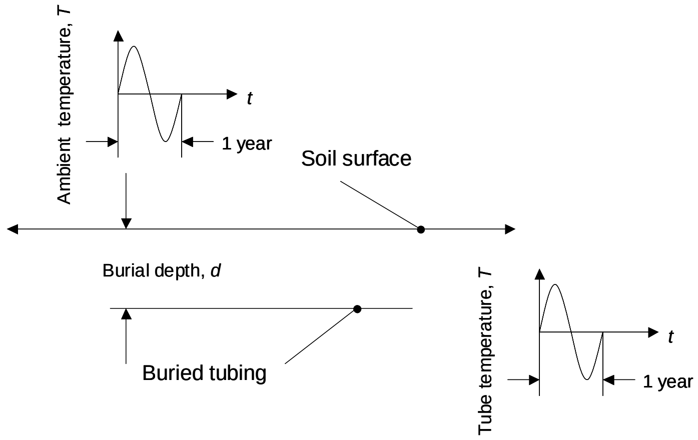
COMMENTS: The actual heating rate will be slightly longer due to the finite thickness of the storage medium.

PROBLEM 5.100

KNOWN: Closely-spaced buried tubing, annual temperature variation.

FIND: Depth associated with the soil behaving as an infinite medium.

SCHEMATIC:



ASSUMPTIONS: (1) Periodic conditions, (2) Constant properties, (3) One-dimensional heat transfer (closely-spaced tubing), (4) Diurnal variation in ambient temperature is small relative to its annual variation.

PROPERTIES: *Table A.3*: Soil (300 K): ρ = 2050 kg/m^3, k = 0.52 W/m·K, c_p = 1840 J/kg·K.

ANALYSIS: Since soil heating and cooling is associated with annual changes in both the ambient and buried tubing temperatures, the burial depth, d, must be larger than twice the penetration depth associated with periodic heating of the soil. Or,

$$d = 2\delta_p = 2 \times 4\sqrt{\alpha/\omega} = 8\sqrt{k/(\rho c_p \omega)}$$

The heating frequency is $\omega = 2\pi/t_p = 2\pi/(1\text{ yr} \times 365\text{ days/yr} \times 24\text{ h/day} \times 60\text{ min/h} \times 60\text{ s/min}) = 200 \times 10^{-9}\text{ s}^{-1}$. Therefore, the required burial depth is

$$d = 8\sqrt{0.52\text{W/m}^2 \cdot \text{K}/\left(2050\text{kg/m}^3 \times 1840\text{ J/kg} \cdot \text{K} \times 200 \times 10^{-9}\text{s}^{-1}\right)} = 6.6\text{ m}$$ <

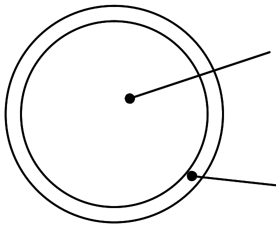
COMMENTS: The installation cost increases as the burial depth increases. A tradeoff exists between the installation cost and the attainment of constant soil temperature conditions.

PROBLEM 5.101

KNOWN: Mass and initial temperatures of frozen ground beef. Rate of microwave power absorbed in packaging material.

FIND: Time for beef adjacent to packaging to reach 0°C.

SCHEMATIC:



ASSUMPTIONS: (1) Beef has properties of ice, (2) Radiation and convection to environment are neglected, (3) Constant properties, (4) Packaging material has negligible heat capacity.

PROPERTIES: Table A.3, Ice (≈ 273 K): ρ = 920 kg/m^3, c = 2040 J/kg·K, k = 1.88 W/m·K.

ANALYSIS: Neglecting radiation and convection losses, all the power absorbed in the packaging material conducts into the beef. The surface heat flux is

$$q_s'' = \frac{\dot{q}}{A_s} = \frac{0.5P}{4\pi R^2}$$

The radius of the sphere can be found from knowledge of the mass and density:

$$m = \rho V = \rho \frac{4}{3}\pi r_o^3$$

$$R = \left(\frac{3}{4\pi}\frac{m}{\rho}\right)^{1/3} = \left(\frac{3}{4\pi}\frac{1\text{ kg}}{920\text{ kg/m}^3}\right)^{1/3} = 0.0638\text{ m}$$

Thus

$$q_s'' = \frac{0.5(1000\text{ W})}{4\pi\times(0.0638\text{ m})^2} = 9780\text{ W/m}^2$$

For a constant surface heat flux, the relationship in Table 5.2b, Interior Cases, sphere, can be used. We begin by calculating q* for T_s = 0°C.

$$q^* = \frac{q_s'' r_o}{k(T_s - T_i)} = \frac{9780\text{ W/m}^2 \times 0.0638\text{ m}}{1.88\text{ W/m}\cdot\text{K}(0°\text{C} - (-20°\text{C}))} = 16.6$$

We proceed to solve for Fo. Assuming that Fo < 0.2, we have

$$q^* \cong \frac{1}{2}\sqrt{\frac{\pi}{\text{Fo}}} - \frac{\pi}{4}$$

Continued…

PROBLEM 5.101 (Cont.)

$$Fo = \pi\left[2(q^* + \frac{\pi}{4})\right]^{-2} = 0.0026$$

Since this is less than 0.2, our assumption was correct. Finally we can solve for the time:

$$t = Fo\, r_o^2/\alpha = Fo\, r_o^2 \rho c/k$$
$$= (0.0026 \times (0.0638\ m)^2 \times 920\ kg/m^3 \times 2040\ J/kg\cdot K)/(1.88\ W/m\cdot K)$$
$$= 10.6\ s$$ $<$

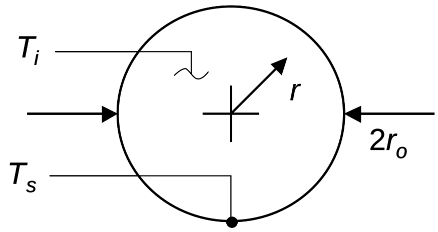
COMMENTS: At the minimum surface temperature of -20°C, with T_∞ = 30°C and h = 15 W/m^2·K from Problem 5.33, the convection heat flux is 750 W/m^2, which is less than 8% of the microwave heat flux. The radiation heat flux would likely be less, depending on the temperature of the oven walls.

PROBLEM 5.102

KNOWN: Cylinder with constant surface temperature.

FIND: Expression for Q/Q_o as a function of $Fo = \alpha t/r_o^2$.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Validity of the approximate solution of Table 5.2a.

ANALYSIS: From Table 5.2a for $Fo < 0.2$,

$$q^* = \frac{q_s'' r_o}{k(T_s - T_i)} = \frac{1}{\sqrt{\pi Fo}} - 0.50 - 0.65Fo \quad ; \quad Fo = \frac{\alpha t}{r_o^2}$$

Substituting the expression for Fo into the first equation yields

$$q_s'' = \frac{k(T_s - T_i)}{r_o}\left[\frac{r_o}{\sqrt{\pi\alpha}} t^{-1/2} - 0.50 - 0.65\frac{\alpha t}{r_o^2}\right]$$

We desire an expression for Q/Q_o. Hence,

$$\frac{Q}{Q_o} = \frac{Q'}{Q_o'} = \frac{2\pi r_o \int_{t=0}^{t} q_s'' dt}{\pi r_o^2 \rho c(T_s - T_i)} = \frac{2\alpha}{r_o^2}\int_{t=0}^{t}\left(\frac{r_o}{\sqrt{\pi\alpha}} t^{-1/2} - 0.50 - 0.65\frac{\alpha t}{r_o^2}\right)dt$$

or

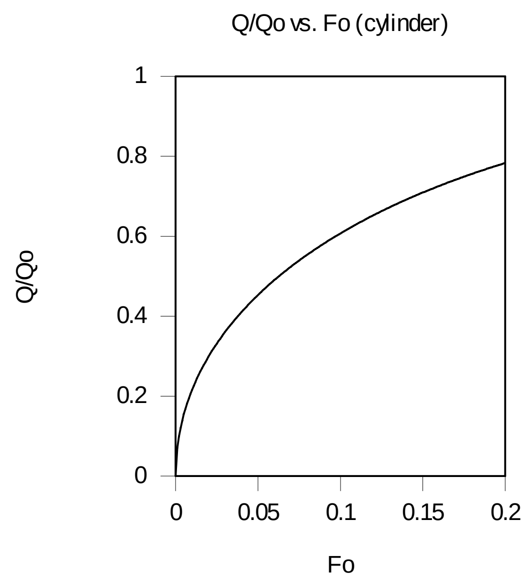
$$\frac{Q}{Q_o} = \frac{2\alpha t}{r_o^2}\left[2\frac{r_o}{\sqrt{\pi\alpha t}} - 0.50 - 0.325\frac{\alpha t}{r_o^2}\right]$$

$$= \frac{4}{\sqrt{\pi}}\sqrt{Fo} - Fo - 0.65Fo^2$$ <

COMMENTS: (1) A plot of Q/Q_o versus Fo is shown below. (2) The exact solution for Q/Q_o involves many terms that would need to be evaluated in the infinite series expression. (2) See Lavine and Bergman, "Small and Large Time Solutions for Surface Temperature, Surface Heat Flux, and Energy Input in Transient, One-Dimensional Conduction in Simple Geometries," *ASME Journal of Heat Transfer*, Vol 130, pp. 101302-1 to 101302-8, 2008 for details.

Continued…

PROBLEM 5.102 (Cont.)

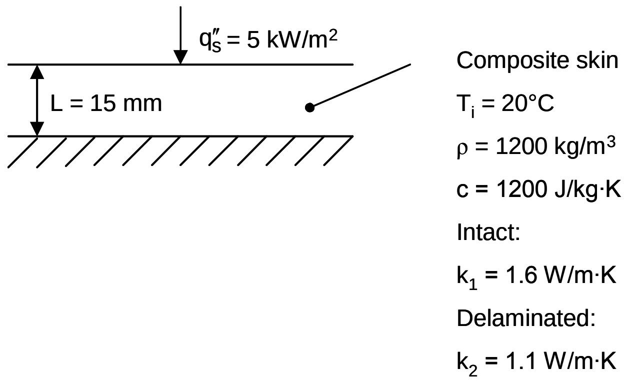


PROBLEM 5.103

KNOWN: Thickness and initial temperature of composite skin. Properties of material when intact and when delaminated. Imposed surface heat flux.

FIND: Surface temperature of (a) intact material and (b) delaminated material, after 10 and 100 seconds.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional heat conduction, (2) Bottom surface adiabatic, (3) Constant and uniform properties, (4) Negligible convection and radiation losses.

ANALYSIS:
(a) The situation is equivalent to a plane wall of thickness 2L with heat flux at both surfaces. We use Table 5.2b, Interior Cases, Plane Wall of thickness 2L. We first calculate Fo for the intact case at t = 10 s.

$$Fo = \frac{\alpha t}{L^2} = \frac{k_1 t}{\rho c L^2}$$

$$= \frac{1.6\ \text{W/m}\cdot\text{K} \times 10\ \text{s}}{1200\ \text{kg/m}^3 \times 1200\ \text{J/kg}\cdot\text{K} \times (0.015\ \text{m})^2}$$

$$= 0.0494$$

Since Fo < 0.2,

$$q^* \cong \frac{1}{2}\sqrt{\frac{\pi}{Fo}} = \frac{1}{2}\sqrt{\frac{\pi}{0.0494}} = 3.99$$

Thus

$$T_{s,1}(10\ \text{s}) = Ti + q_s'' L / k_1 q^*$$

$$= 20°\text{C} + 5000\ \text{W/m}^2 \times 0.015\ \text{m}/(1.6\ \text{W/m}\cdot\text{K} \times 3.99)$$

$$= 31.8°\text{C}$$ <

At t = 100 s, Fo = 0.494 > 0.2, thus

$$q^* \cong \left[Fo + \frac{1}{3}\right]^{-1} = 1.21$$

Continued…

PROBLEM 5.103 (Cont.)

and

$T_{s,1}(100\ s) = Ti + q_s''L/k_1q^*$

$= 20°C + 5000\ W/m^2 \times 0.015\ m/(1.6\ W/m \cdot K \times 1.21)$

$= 58.8°C$ <

(b) Repeating the calculations for $k_2 = 1.1$ W/m·K, we find

$T_{s,2}(10\ s) = 34.2°C$ <

$T_{s,2}(100\ s) = 65.9°C$ <

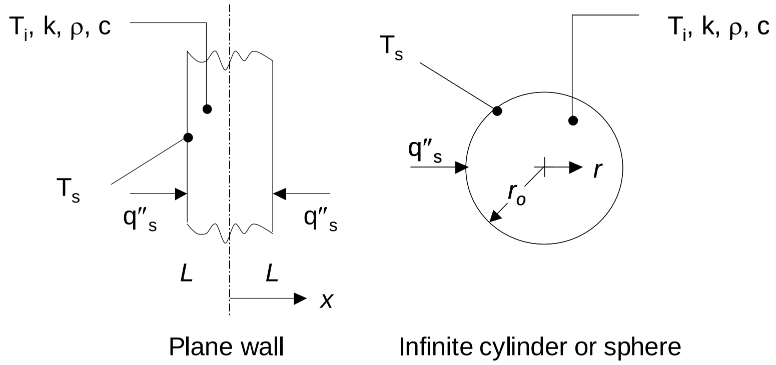
COMMENTS: (1) For t = 10 s, the Fourier number is less than 0.2, and the skin behaves as if it were semi-infinite. However for t = 100 s, the heat has penetrated sufficiently far so that the presence of the insulated bottom surface affects the temperature distribution. The surface temperature is higher than it would be for a semi-infinite solid.
(2) The surface temperatures are sufficiently different for the intact and delaminated cases so that detection is possible. The difference increases with increasing heating time, but if the heating time is too long the elevated temperature will damage the material.
(3) Convection and radiation losses may not be negligible.

PROBLEM 5.104

KNOWN: Plane wall, infinite cylinder and sphere each subjected to a constant surface heat flux.

FIND: The ratio of (i) the actual surface temperature minus the initial temperature, ($T_{s,act} - T_i$), to (ii) the value of this temperature difference associated with lumped capacitance behavior, ($T_{s,lc} - T_i$), for each of the three geometries. Criteria associated with $(T_{s,act} - T_i)/(T_{s,lc} - T_i) \le 1.1$.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) $Fo \ge 0.2$.

ANALYSIS: From Table 5.2b, the approximate solutions for all three geometries may be expressed as

$$\frac{q_s'' L_c}{k(T_{s,act} - T_i)} = \left[a \frac{kt}{\rho c L_c^2} + b \right]^{-1} \tag{1}$$

where $L_c = L$ for the plane wall, and $L_c = r_o$ for the infinite cylinder and the sphere. The constants a and b have the following values.

Geometry	L_c	a	b
Plane wall	L	1	1/3
Infinite cylinder	r_o	2	1/4
Sphere	r_o	3	1/5

For the lumped-capacitance analysis with constant heat flux, we note that in general, $q_s'' A_s t = \rho c V (T_{s,lc} - T_i)$. Substituting expressions for the surface area and volume of each of the three geometries results in the general expression,

$$\left(T_{s,lc} - T_i\right) = a q_s'' t / \rho c L_c \tag{2}$$

where the constant a is the same as in the table above. Solving Eq. (1) for ($T_{s,act} - T_i$) and dividing the resulting expression by Eq. (2) results in

Continued…

PROBLEM C5.104 (Cont.)

$$\frac{\left(T_{s,act}-T_i\right)}{\left(T_{s,lc}-T_i\right)}=\frac{\left[\frac{q_s''L_c}{k}\left(a\frac{k}{\rho c}\frac{t}{L_c^2}+b\right)\right]\rho c L_c}{a q_s'' t}=\frac{1}{aFo}\left[aFo+b\right]=1+\frac{b}{aFo} \tag{3}$$

Therefore, for the plane wall,

$$\frac{\left(T_{s,act}-T_i\right)}{\left(T_{s,lc}-T_i\right)}=1+\frac{b}{aFo}=1+\frac{1}{3Fo}$$ <

for the infinite cylinder,

$$\frac{\left(T_{s,act}-T_i\right)}{\left(T_{s,lc}-T_i\right)}=1+\frac{b}{aFo}=1+\frac{1}{8Fo}$$ <

for the sphere,

$$\frac{\left(T_{s,act}-T_i\right)}{\left(T_{s,lc}-T_i\right)}=1+\frac{b}{aFo}=1+\frac{1}{15Fo}$$ <

The preceding equations may be solved for the Fourier number associated with $(T_{s,\mathrm{act}} - T_i)/(T_{s,lc} - T_i)$ = 1.1, yielding critical Fourier numbers, Fo_c = 3.33, 1.25 and 0.667 for the plane wall, infinite cylinder, and sphere, respectively. Lumped capacitance behavior is exhibited at dimensionless times greater than Fo_c.

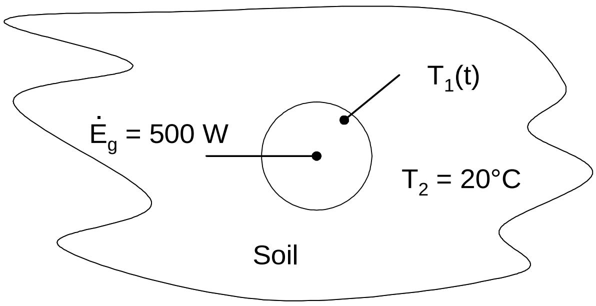
COMMENTS: (1) The calculated values of the Fourier number are each greater than 0.2. Hence, use of the approximate solutions for $Fo \geq 0.2$ is justified. (2) The dimensionless time at which lumped capacitance behavior is reached varies with the geometry.

PROBLEM 5.105

KNOWN: Energy generation rate within a buried spherical container of known size.

FIND: Time needed for the surface of the sphere to come within 10 degrees Celsius of the steady-state temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Infinite medium, (2) Constant properties, (3) Negligible contact resistance between the sphere and the soil.

PROPERTIES: Table A.3, soil (300 K): k = 0.52 W/m·K, ρ = 2050 kg/m^3, c_p = 1840 J/kg·K.

ANALYSIS: The steady-state temperature difference may be obtained from case 12 of Table 4.1 with $L_c = (A_s/4\pi)^{1/2} = (\pi D^2/4\pi)^{1/2} = D/2$

$$q = kA_s(T_{1,ss} - T_2) = 0.52\ \text{W/m}\cdot\text{K} \times \pi \times (2\text{m})^2 \times (T_{1,ss} - T_2) = 500\ \text{W}$$

from which we find

$$T_{1,ss} - T_2 = 76.52°\text{C}$$

Therefore, at the time of interest, $T_1 - T_2$ = 76.52°C - 10°C = 66.52°C
From Table 5.2b, sphere, exterior case,

$$q^*(\text{Fo}) = \frac{q(D/2)}{\pi D^2 k(T_1 - T_2)} = \frac{1}{\left[1 - \exp(\text{Fo})\,\text{erfc}(\text{Fo}^{1/2})\right]}$$

or $$\frac{1}{\left[1 - \exp(\text{Fo})\,\text{erfc}(\text{Fo}^{1/2})\right]} = \frac{500\ \text{W}}{2\pi \times 2\ \text{m} \times 0.52\ \text{W/m}\cdot\text{K} \times 66.52\text{K}} = 1.15$$

Solving for Fo yields Fo = 17.97.
Knowing $\alpha = k/\rho c_p = 0.52\ \text{W/m}\cdot\text{K}\big/(1050\ \text{kg/m}^3 \times 1840\ \text{J/kg}\cdot\text{K}) = 1.379 \times 10^{-7}\ \text{m}^2/\text{s}$

$$t = \frac{\text{Fo} \times (D/2)^2}{\alpha} = \frac{\text{Fo}D^2}{4\alpha} = \frac{17.97 \times (2\ \text{m})^2}{4 \times 1.379 \times 10^{-7}\ \text{m}^2/\text{s}}$$

$$t = 1.303 \times 10^8\ \text{s} \times \frac{1\ \text{day}}{24\ \text{h}} \times \frac{1\ \text{h}}{3600\ \text{s}} \times \frac{1\ \text{year}}{365\ \text{days}} = 4.13\ \text{years}.$$ <

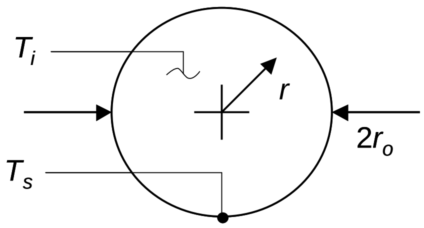
COMMENTS: The time to reach the steady-state is significant. In practice, it is often difficult to ascertain when steady-state is achieved due to the slow thermal response time of many systems.

PROBLEM 5.106

KNOWN: Sphere with constant surface temperature.

FIND: Expression for Q/Q_o as a function of $Fo = \alpha t/r_o^2$.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Validity of the approximate solution of Table 5.2a.

ANALYSIS: From Table 5.2a for $Fo < 0.2$,

$$q^* = \frac{q_s'' r_o}{k(T_s - T_i)} = \frac{1}{\sqrt{\pi Fo}} - 1 \quad ; \quad Fo = \frac{\alpha t}{r_o^2}$$

Substituting the expression for Fo into the first equation yields

$$q_s'' = \frac{k(T_s - T_i)}{r_o}\left[\frac{r_o}{\sqrt{\pi\alpha}} t^{-1/2} - 1\right]$$

We desire an expression for Q/Q_o. Hence,

$$\frac{Q}{Q_o} = \frac{4\pi r_o^2 \int_{t=0}^{t} q_s'' dt}{(4/3)\pi r_o^3 \rho c(T_s - T_i)} = \frac{3\alpha}{r_o^2}\int_{t=0}^{t}\left(\frac{r_o}{\sqrt{\pi\alpha}} t^{-1/2} - 1\right)dt$$

or

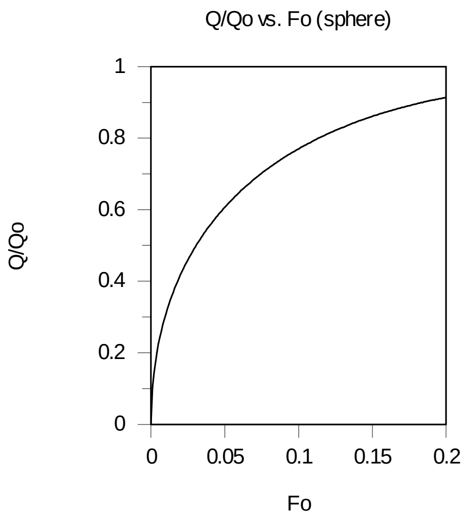
$$\frac{Q}{Q_o} = \frac{3\alpha}{r_o^2}\left[\frac{2r_o}{\sqrt{\pi\alpha}} t^{1/2} - t\right]$$

$$= 3\left[\frac{2}{\sqrt{\pi}}\sqrt{Fo} - Fo\right]$$ <

COMMENTS: (1) A plot of Q/Q_o versus Fo is shown below. (2) The exact solution for Q/Q_o involves many terms that would need to be evaluated in the infinite series expression.

Continued…

PROBLEM 5.106 (Cont.)



PROBLEM 5.107

KNOWN: Desired minimum temperature response of a 3ω measurement.

FIND: Minimum sample thickness that can be measured.

ASSUMPTIONS: (1) Constant properties, (2) Two-dimensional conduction, (3) Semi-infinite medium, (4) Negligible radiation and convection losses from the metal strip and the top surface of the sample.

PROPERTIES: (Example 5.10): k = 1.11 W/m·K, a = 4.37×10^{-7} m^2/s.

ANALYSIS: Equation 5.74 maybe rearranged to yield

$$\omega = 2\exp\left[2\left(C_2 - \frac{\Delta TL\pi k}{\Delta q_s}\right)\right]$$

$$\omega = 2 \times \exp\left[2\left(5.35 - \frac{0.1°C \times 3.5 \times 10^{-3}\ m \times \pi \times 1.11\ W/m\cdot K}{3.5 \times 10^{-3}\ W}\right)\right]$$

$$\omega = 44.2 \times 10^3\ rad/s$$

$$\alpha = 4.37 \times 10^{-7}\ m^2/s$$

Therefore

$$\delta_p = \sqrt{\alpha/\omega} = \sqrt{4.37 \times 10^{-7}\ m^2/s \Big/ 44.2 \times 10^3\ rad/s} = 3.1 \times 10^{-6}\ m = 3.1\ \mu m$$

The minimum sample thickness is therefore 3.1 μm. <

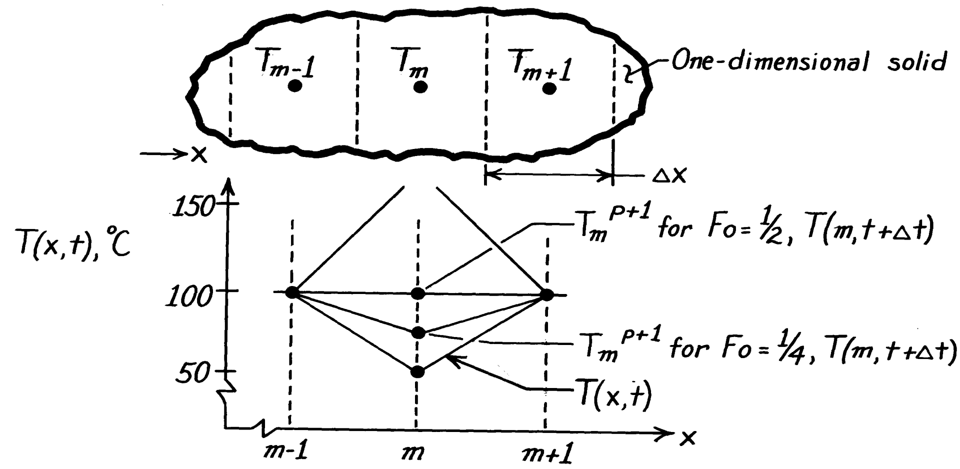
COMMENTS: (1) To ensure the thickness of the sample is adequate, the actual minimum thickness should be greater than the thermal penetration depth. (2) The sample thickness could be increased further by increasing the amplitude of the heating rate, Δq_s. (3) It is commonly desired to measure very thin samples to discern the effect of the top and bottom boundaries of a *thin film* on the conduction heat transfer rate, as depicted in Figure 2.6. As the film becomes thinner, the experimental uncertainties increase.

PROBLEM 5.108

KNOWN: Stability criterion for the explicit method requires that the coefficient of the T_m^p term of the one-dimensional, finite-difference equation be zero or positive.

FIND: For Fo > 1/2, the finite-difference equation will predict values of T_m^{p+1} which violate the Second law of thermodynamics. Consider the prescribed numerical values.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in x, (2) Constant properties, (3) No internal heat generation.

ANALYSIS: The explicit form of the finite-difference equation, Eq. 5.81, for an interior node is

$$T_m^{p+1} = Fo\left(T_{m+1}^p + T_{m-1}^p\right) + (1 - 2\ Fo)T_m^p.$$

The stability criterion requires that the coefficient of T_m^p be zero or greater. That is,

$$(1 - 2\ Fo) \geq 0 \qquad \text{or} \qquad Fo \leq \frac{1}{2}.$$

For the prescribed temperatures, consider situations for which Fo = 1, ½ and ¼ and calculate T_m^{p+1}.

$$Fo = 1 \qquad T_m^{p+1} = 1(100 + 100)^\circ C + (1 - 2\times 1)50^\circ C = 250^\circ C$$
$$Fo = 1/2 \qquad T_m^{p+1} = 1/2(100 + 100)^\circ C + (1 - 2\times 1/2)50^\circ C = 100^\circ C$$
$$Fo = 1/4 \qquad T_m^{p+1} = 1/4(100 + 100)^\circ C + (1 - 2\times 1/4)50^\circ C = 75^\circ C.$$

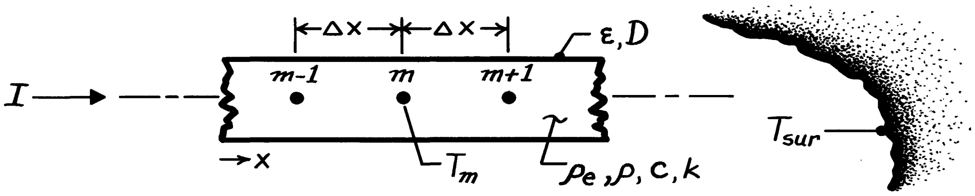
Plotting these distributions above, note that when Fo = 1, T_m^{p+1} is greater than 100°C, while for Fo = ½ and ¼ , $T_m^{p+1} \leq 100^\circ C$. The distribution for Fo = 1 is thermodynamically impossible: heat is flowing into the node during the time period Δt, causing its temperature to rise; yet heat is flowing in the direction of increasing temperature. This is a violation of the Second law. When Fo = ½ or ¼, the node temperature increases during Δt, but the temperature gradients for heat flow are proper. This will be the case when Fo ≤ ½, verifying the stability criterion.

PROBLEM 5.109

KNOWN: Thin rod of diameter D, initially in equilibrium with its surroundings, T_{sur}, suddenly passes a current I; rod is in vacuum enclosure and has prescribed electrical resistivity, ρ_e, and other thermophysical properties.

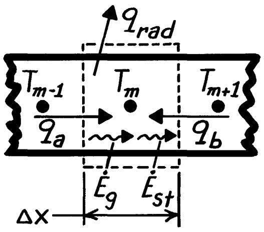
FIND: Transient, finite-difference equation for node m.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, transient conduction in rod, (2) Surroundings are much larger than rod, (3) Properties are constant and evaluated at an average temperature, (4) No convection within vacuum enclosure.

ANALYSIS: The finite-difference equation is derived from the energy conservation requirement on the control volume, $A_c\Delta x$, where $A_c = \pi D^2/4$ and $P = \pi D$. The energy balance has the form



$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = \dot{E}_{st} \qquad q_a + q_b - q_{rad} + I^2R_e = \rho\, cV\frac{T_m^{p+1} - T_m^p}{\Delta t}.$$

where $\dot{E}_g = I^2R_e$ and $R_e = \rho_e\Delta x/A_c$. Using Fourier's law to express the conduction terms, q_a and q_b, and Eq. 1.7 for the radiation exchange term, q_{rad}, find

$$kA_c\frac{T_{m-1}^p - T_m^p}{\Delta x} + kA_c\frac{T_{m+1}^p - T_m^p}{\Delta x} - \varepsilon P\Delta x\sigma\left(T_m^{4,p} - T_{sur}^4\right) + I^2\frac{\rho_e\Delta x}{A_c} = \rho\, cA_c\Delta x\frac{T_m^{p+1} - T_m^p}{\Delta t}.$$

Divide each term by $\rho cA_c\,\Delta x/\Delta t$, solve for T_m^{p+1} and regroup to obtain

$$T_m^{p+1} = \frac{k}{\rho\, c}\cdot\frac{\Delta t}{\Delta x^2}\left(T_{m-1}^p + T_{m+1}^p\right) - \left[2\cdot\frac{k}{\rho\, c}\cdot\frac{\Delta t}{\Delta x^2} - 1\right]T_m^p$$

$$-\frac{\varepsilon P\sigma}{A_c}\cdot\frac{\Delta t}{\rho\, c}\left(T_m^{4,p} - T_{sur}^4\right) + \frac{I^2\rho_e}{A_c^2}\cdot\frac{\Delta t}{\rho\, c}.$$

Recognizing that $Fo = \alpha\,\Delta t/\Delta x^2$, regroup to obtain

$$T_m^{p+1} = Fo\left(T_{m-1}^p + T_{m+1}^p\right) + (1 - 2\,Fo)T_m^p - \frac{\varepsilon P\sigma\Delta x^2}{kA_c}\cdot Fo\left(T_m^{4,p} - T_{sur}^4\right) + \frac{I^2\rho_e\Delta x^2}{kA_c^2}\cdot Fo.$$

The stability criterion is based upon the coefficient of the T_m^p term written as

$$Fo \le 1/2.$$ <

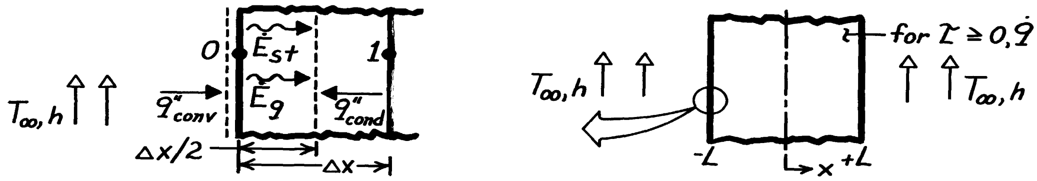
COMMENTS: Note that we have used the forward-difference representation for the time derivative; see Section 5.10.1. This permits convenient treatment of the non-linear radiation exchange term.

PROBLEM 5.110

KNOWN: One-dimensional wall suddenly subjected to uniform volumetric heating and convective surface conditions.

FIND: Finite-difference equation for node at the surface, x = -L.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional transient conduction, (2) Constant properties, (3) Uniform $\dot{q}$.

ANALYSIS: There are two types of finite-difference equations for the *explicit* and *implicit* methods of solution. Using the energy balance approach, both types will be derived.

Explicit Method. Perform an energy balance on the surface node shown above,

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = \dot{E}_{st} \qquad q_{conv} + q_{cond} + \dot{q}V = \rho\, cV \frac{T_o^{p+1} - T_o^p}{\Delta t} \tag{1}$$

$$h(1\cdot 1)\left(T_\infty - T_o^p\right) + k(1\cdot 1)\frac{T_1^p - T_o^p}{\Delta x} + \dot{q}\left[1\cdot 1\cdot\frac{\Delta x}{2}\right] = \rho\, c\left[1\cdot 1\cdot \frac{\Delta x}{2}\right]\frac{T_o^{p+1} - T_o^p}{\Delta t}. \tag{2}$$

For the explicit method, the temperatures on the LHS are evaluated at the *previous* time (p). The RHS provides a *forward*-difference approximation to the time derivative. Divide Eq. (2) by $\rho c\Delta x/2\Delta t$ and solve for T_o^{p+1}.

$$T_o^{p+1} = 2\frac{h\Delta t}{\rho\, c\Delta x}\left(T_\infty - T_o^p\right) + 2\frac{k\Delta t}{\rho\, c\Delta x^2}\left(T_1^p - T_o^p\right) + \dot{q}\frac{\Delta t}{\rho\, c} + T_o^p.$$

Introducing the Fourier and Biot numbers,

$$Fo \equiv (k/\rho\, c)\Delta t/\Delta x^2 \qquad Bi \equiv h\Delta x/k$$

$$T_o^{p+1} = 2\, Fo\left[T_1^p + Bi\cdot T_\infty + \frac{\dot{q}\Delta x^2}{2k}\right] + \left(1 - 2\, Fo - 2\, Fo\cdot Bi\right)T_o^p. \tag{3}$$

The stability criterion requires that the coefficient of T_o^p be positive. That is,

$$\left(1 - 2\, Fo - 2\, Fo\cdot Bi\right) \ge 0 \qquad \text{or} \qquad Fo \le 1/2(1+Bi). \tag{4}$$ <

Implicit Method. Begin as above with an energy balance. In Eq. (2), however, the temperatures on the LHS are evaluated at the *new* (p+1) time. The RHS provides a *backward*-difference approximation to the time derivative.

$$h\left(T_\infty - T_o^{p+1}\right) + k\frac{T_1^{p+1} - T_o^{p+1}}{\Delta x} + \dot{q}\left[\frac{\Delta x}{2}\right] = \rho\, c\left[\frac{\Delta x}{2}\right]\frac{T_o^{p+1} - T_o^p}{\Delta t} \tag{5}$$

$$\left(1 + 2\, Fo(Bi+1)\right)T_o^{p+1} - 2\, Fo\cdot T_1^{p+1} = T_o^p + 2Bi\cdot Fo\cdot T_\infty + Fo\frac{\dot{q}\Delta x^2}{k}. \tag{6}$$ <

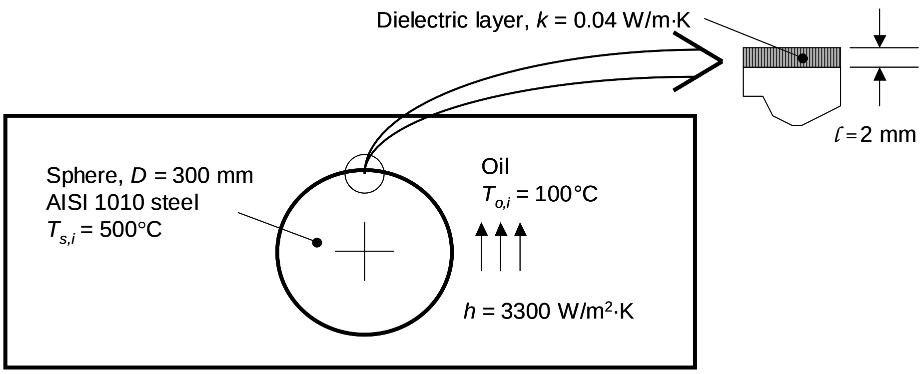
COMMENTS: Compare these results (Eqs. 3, 4 and 6) with the appropriate expression in Table 5.3.

PROBLEM 5.111

KNOWN: Volume of sphere and oil, initial sphere and oil temperatures, convection coefficient, thickness and thermal conductivity of dielectric film coating.

FIND: (a) Steady-state sphere temperature of the sphere, (b) explicit expressions for sphere and oil temperatures and stability requirements, (c) Sphere and oil temperatures after one time step for Δt = 1000, 10,000 and 20,000 s, (d) time needed for the coated sphere to reach 140°C using an implicit finite difference formulation and solution and graph of thermal response of sphere and oil.

SCHEMATIC:



ASSUMPTIONS: (1) Dielectric layer has negligible thermal capacitance compared to steel sphere, (2) Constant properties, (3) Negligible contact resistance between dielectric coating and steel, (4) Oil bath is well-stirred, (5) Oil bath is well-insulated.

PROPERTIES: *Table A-1*, AISI 1010 Steel ($\overline{T} = [500+140]°C/ = 320°C \approx 600$ K): ρ_s = 7832 kg/m^3, c_s = 559 J/kg·K, k_s = 48.8 W/m·K. *Table A-5*, Engine Oil (T = 380 K): ρ_o = 836 kg/m^3, c_o = 2250 J/kg·K.

ANALYSIS: (a) Let U be the overall heat transfer coefficient that combines the effects of convection resistance and conduction resistance associated with the dielectric film. That is, $U = 1/R''$ where $R'' = \ell/k_f + 1/h$ = 0.002m/0.04 W/m·K + 1/3300 W/m^2·K = 0.050 + 0.0003 = 0.0503 m^2·K/W. Therefore, U = 19.88 W/m^2·K. The effective Biot number is

$$Bi_e = \frac{UL_c}{k} = \frac{U(r_o/3)}{k} = \frac{19.88\text{W/m}^2\text{K} \times (0.300\text{m}/6)}{48.8\text{W/m}\cdot\text{K}} = 0.02$$

Since the $Bi_e < 0.1$, a lumped capacitance approach is appropriate for the sphere. Similarly, since the oil is well-mixed, a lumped capacitance approach is appropriate for the oil.

The sphere's volume is $V_s = (4/3)\pi(D/2)^3 = (4/3)\pi(0.300\text{m}/2)^3 = 0.01414\text{m}^3$. The oil volume is V_o = 1 m^3 – 0.01414m^3 = 0.986m^3. Applying energy balances to both the sphere and the oil yields

$$\rho_s c_s V_s (T_{s,i} - T_{ss}) = \rho_o c_o V_o (T_{ss} - T_{o,i}) \qquad (1)$$

Continued…

PROBLEM 5.111 (Cont.)

where T_{ss} is the steady-state temperature of both the oil and the sphere. Rearranging Eq. (1) yields

$$T_{ss} = \frac{\rho_s c_s V_s T_{i,s} + \rho_o c_o V_o T_{o,i}}{(\rho_o c_o V_o + \rho_s c_s V_s)}$$

$$= \frac{7832\text{kg/m}^3 \times 559\text{J/kg}\cdot\text{K} \times 0.01414\text{m}^3 \times 500°\text{C} + 836\text{kg/m}^3 \times 2250\text{J/kg}\cdot\text{K} \times 0.986\text{m}^3 \times 100°\text{C}}{(836\text{kg/m}^3 + 2250\text{J/kg}\cdot\text{K} \times 0.986\text{m}^3 + 7832\text{kg/m}^3 \times 559\text{J/kg}\cdot\text{K} \times 0.01414\text{m}^3)}$$

$= 112.9°\text{C}$ <

(b) Recognizing that the oil temperature varies with time, applying Eqs. 5.2 and 5.77 to the sphere yields

$$T_s^{p+1} = -\frac{UA_s(T_s^p - T_o^p)}{\rho_s c_s V_s}\Delta t + T_s^p \quad (2a)$$

Similarly, applying Eqs. 5.2 and 5.77 to the well-mixed oil leads to the expression

$$T_o^{p+1} = -\frac{UA_s(T_o^p - T_s^p)}{\rho_o c_o V_o}\Delta t + T_o^p \quad (2b)$$

We require the coefficient of T^p to be positive. Thus,

$\Delta t < \frac{\rho c V}{UA_s}$ = 11,000 s for the steel and 330,000 s for the oil. <

(c) Substituting values for the properties, initial temperatures, and volumes into Eqs. (2a) and (2b) for one time step yields the following.

$$T_s^2 = -\frac{19.88\text{W/m}^2\cdot\text{K} \times \pi \times 0.300\text{m}^2 \times (500°\text{C} - 100°\text{C})}{7832\text{ kg/m}^3 \times 559\text{ J/kg}\cdot\text{K} \times 0.01414\text{m}^3}\Delta t + 500°\text{C} = -0.0363°\text{C/s} \times \Delta t + 500°\text{C}$$

$$T_o^2 = -\frac{19.88\text{W/m}^2\cdot\text{K} \times \pi \times 0.300\text{m}^2 \times (100°\text{C} - 500°\text{C})}{836\text{ kg/m}^3 \times 2250\text{ J/kg}\cdot\text{K} \times 0.986\text{m}^3}\Delta t + 100°\text{C} = 1.212 \times 10^{-3}°\text{C/s} \times \Delta t + 100°\text{C}$$

Results for various time steps are:

Δt (s)	T_s^2 (°C)	T_o^2 (°C)
1000	463.7	101.2
10,000	136.7	112.1
20,000	-226.5	124.2

<

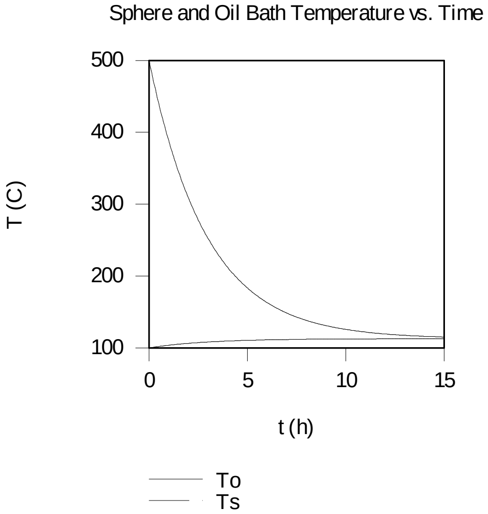
Specification of a time step larger than the stability criterion leads to unrealistic results, as evident in the table above.

Continued…

PROBLEM 5.111 (Cont.)

(d) Using the *IHT* code listed in the Comments, the following response was found for the sphere and oil temperatures as a function of quench time using a time step of Δt = 100s. The time required for the sphere to reach a temperature of 140°C is 28,100 s = 7.81 h <

The time associated with a large oil bath (constant oil temperature) was found in Problem 5.9 using the lumped capacitance method and is t = 25,360 s = 7.04 h. <



COMMENTS: (1) The *IHT* Code is shown below. (2) The bath temperature at 7.81 h is 112°C, which is nearly equal to the oil's steady-state temperature.

```
rhos = 7832                          //kg/m^3

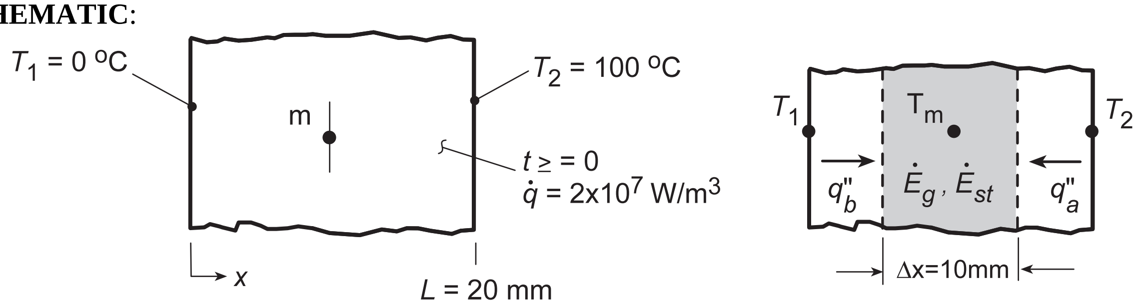
Der(To,t) = -U*As*(To - Ts)/rhoo/co/Vo
```

PROBLEM 5.112

KNOWN: Plane wall, initially having a linear, steady-state temperature distribution with boundaries maintained at $T(0,t) = T_1$ and $T(L,t) = T_2$, suddenly experiences a uniform volumetric heat generation due to the electrical current. Boundary conditions T_1 and T_2 remain fixed with time.

FIND: (a) On T-x coordinates, sketch the temperature distributions for the following cases: initial conditions ($t \le 0$), steady-state conditions ($t \to \infty$) assuming the maximum temperature exceeds T_2, and two intermediate times; label important features; (b) For the three-nodal network shown, derive the finite-difference equation using either the implicit or explicit method; (c) With a time increment of $\Delta t = 5$ s, obtain values of T_m for the first 45s of elapsed time; determine the corresponding heat fluxes at the boundaries; and (d) Determine the effect of mesh size by repeating the foregoing analysis using grids of 5 and 11 nodal points.

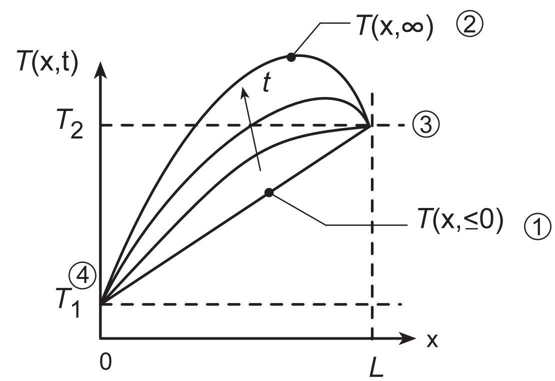
SCHEMATIC:



ASSUMPTIONS: (1) Two-dimensional, transient conduction, (2) Uniform volumetric heat generation for $t \ge 0$, (3) Constant properties.

PROPERTIES: Wall (Given): $\rho = 4000$ kg/m^3, c = 500 J/kg·K, k = 10 W/m·K.

ANALYSIS: (a) The temperature distribution on T-x coordinates for the requested cases are shown below. Note the following key features: (1) linear initial temperature distribution, (2) non-symmetrical parabolic steady-state temperature distribution, (3) gradient at x = L is first positive, then zero and becomes negative, and (4) gradient at x = 0 is always positive.



(b) Performing an energy balance on the control volume about node m above, for unit area, find

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = \dot{E}_{st}$$

$$k(1)\frac{T_2 - T_m}{\Delta x} + k(1)\frac{T_1 - T_m}{\Delta x} + \dot{q}(1)\Delta x = \rho(1)c\Delta x\frac{T_m^{p+1} - T_m^p}{\Delta t}$$

$$Fo\left[T_1 + T_2 - 2T_m\right] + \frac{\dot{q}\Delta t}{\rho c_p} = T_m^{p+1} - T_m^p$$

For the T_m term in brackets, use "p" for explicit and "p+1" for implicit form,

Explicit: $$T_m^{p+1} = Fo\left(T_1^p + T_2^p\right) + (1 - 2Fo)T_m^p + \dot{q}\Delta t/\rho c_p \qquad (1)$$ <

Implicit: $$T_m^{p+1} = \left[Fo\left(T_1^{p+1} + T_2^{p+1}\right) + \dot{q}\,\Delta t/\rho c_p + T_m^p\right]\Big/(1 + 2Fo) \qquad (2)$$ <

Continued...

PROBLEM 5.112 (Cont.)

(c) With a time increment Δt = 5s, the FDEs, Eqs. (1) and (2) become

Explicit: $$T_m^{p+1} = 0.5T_m^p + 75 \qquad (3)$$

Implicit: $$T_m^{p+1} = \left(T_m^p + 75\right)\Big/1.5 \qquad (4)$$

where

$$Fo = \frac{k\Delta t}{\rho c \Delta x^2} = \frac{10\,W/m\cdot K \times 5\,s}{4000\,kg/m^3 \times 500\,J/kg\cdot K\left(0.010\,m\right)^2} = 0.25$$

$$\frac{\dot{q}\Delta t}{\rho c} = \frac{2\times10^7\,W/m^3 \times 5\,s}{4000\,kg/m^3 \times 500\,J/kg\cdot K} = 50\,K$$

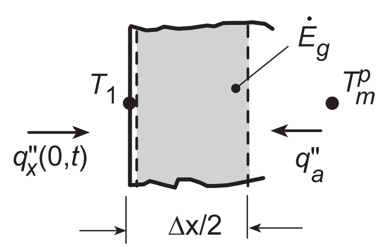
Performing the calculations, the results are tabulated as a function of time,

p	t (s)	T_1 (°C)	T_m (°C) Explicit	T_m (°C) Implicit	T_2 (°C)
0	0	0	50	50	100
1	5	0	100.00	83.33	100
2	10	0	125.00	105.55	100
3	15	0	137.50	120.37	100
4	20	0	143.75	130.25	100
5	25	0	146.88	136.83	100
6	30	0	148.44	141.22	100
7	35	0	149.22	144.15	100
8	40	0	149.61	146.10	100
9	45	0	149.80	147.40	100

<

The heat flux at the boundaries at t = 45s follows from the energy balances on control volumes about the boundary nodes, using the explicit results for T_m^p,

Node 1: $$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = \dot{E}_{st}$$



$$q''_x\left(0,t\right) + k\frac{T_m^p - T_1}{\Delta x} + \dot{q}\left(\Delta x/2\right) = 0$$

$$q''_x\left(0,t\right) = -k\left(T_m^p - T_1\right)\Big/\Delta x - \dot{q}\Delta x/2 \qquad (5)$$

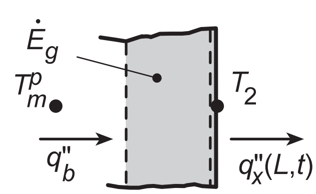
$$q''_x\left(0,45s\right) = -10\,W/m\cdot K\left(149.8-0\right)K/0.010\,m - 2\times10^7\,W/m^3 \times 0.010\,m/2$$

$$q''_x\left(0,45s\right) = -149,800\,W/m^2 - 100,000\,W/m^2 = -249,800\,W/m^2$$

<

Node 2: $$k\frac{T_m^p - T_2}{\Delta x} - q''_x\left(L,t\right) + \dot{q}\left(\Delta x/2\right) = 0$$

$$q''_x\left(L,t\right) = k\left(T_m^p - T_2\right)\Big/\Delta x + \dot{q}\Delta x/2 = 0 \qquad (6)$$



Continued...

PROBLEM 5.112 (Cont.)

$$q''_x(L,t) = 10\,W/m\cdot K(149.80-100)C/0.010\,m + 2\times10^7\,W/m^3\times0.010\,m/2$$

$$q''_x(L,t) = 49,800\,W/m^2 + 100,000\,W/m^2 = +149,800\,W/m^2$$ <

(d) To determine the effect of mesh size, the above analysis was repeated using grids of 5 and 11 nodal points, Δx = 5 and 2 mm, respectively. Using the *IHT Finite-Difference Equation Tool*, the finite-difference equations were obtained and solved for the temperature-time history. Eqs. (5) and (6) were used for the heat flux calculations. The results are tabulated below for t = 45s, where T_m^p (45s) is the center node,

Mesh Size Δx (mm)	T_m^p (45s) (°C)	q''_x (0,45s) kW/m^2	q''_x (L,45s) kW/m^2
10	149.8	-249.8	+149.8
5	149.3	-249.0	+149.0
2	149.4	-249.1	+149.0

COMMENTS: (1) The center temperature and boundary heat fluxes are quite insensitive to mesh size for the condition.

(2) The copy of the IHT workspace for the 5 node grid is shown below.

```
// Mesh size - 5 nodes, deltax = 5 mm
// Nodes a, b(m), and c are interior nodes

// Finite-Difference Equations Tool - nodal

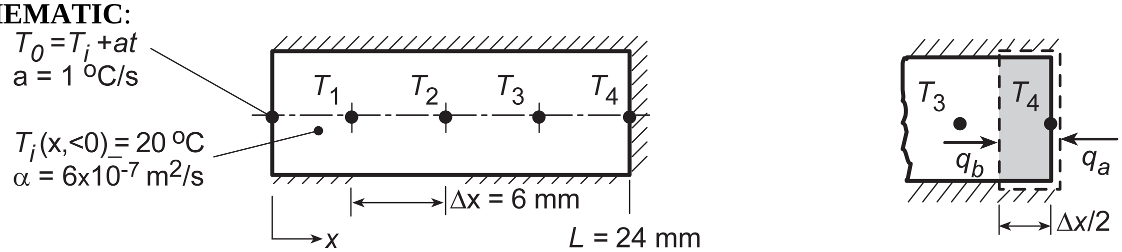
PROBLEM 5.113

KNOWN: Solid cylinder of plastic material ($\alpha = 6 \times 10^{-7}$ m^2/s), initially at uniform temperature of T_i = 20°C, insulated at one end (T_4), while other end experiences heating causing its temperature T_0 to increase linearly with time at a rate of a = 1°C/s.

FIND: (a) Finite-difference equations for the 4 nodes using the explicit method with Fo = 1/2 and (b) Surface temperature T_0 when T_4 = 35°C.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, transient conduction in cylinder, (2) Constant properties, and (3) Lateral and end surfaces perfectly insulated.

ANALYSIS: (a) The finite-difference equations using the *explicit* method for the interior nodes (m = 1, 2, 3) follow from Eq. 5.81 with Fo = 1/2,

$$T_m^{p+1} = Fo\left(T_{m+1}^p + T_{m-1}^p\right) + (1-2Fo)T_m^p = 0.5\left(T_{m+1}^p + T_{m-1}^p\right) \quad (1)$$

From an energy balance on the control volume node 4 as shown above yields with Fo = 1/2

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = \dot{E}_{st} \qquad q_a + q_b + 0 = \rho c V\left(T_4^{p+1} - T_4^p\right)\Big/\Delta t$$

$$0 + k\left(T_3^p - T_4^p\right)\Big/\Delta x = \rho c(\Delta x/2)\left(T_4^{p+1} - T_4^p\right)\Big/\Delta t$$

$$T_4^{p+1} = 2FoT_3^p + (1-2Fo)T_4^p = T_3^p \quad (2)$$

(b) Performing the calculations, the temperature-time history is tabulated below, where $T_0 = T_i + a \cdot t$ where a = 1°C/s and $t = p \cdot \Delta t$ with,

$$Fo = \alpha\Delta t\Big/\Delta x^2 = 0.5 \qquad \Delta t = 0.5(0.006\,m)^2\Big/6\times10^{-7}\,m^2\Big/s = 30s$$

p	t (s)	T_0 (°C)	T_1 (°C)	T_2 (°C)	T_3 (°C)	T_4 (°C)
0	0	20	20	20	20	20
1	30	50	20	20	20	20
2	60	80	35	20	20	20
3	90	110	50	27.5	20	20
4	120	140	68.75	35	23.75	20
5	150	170	87.5	46.25	27.5	23.75
6	180	200	108.1	57.5	35	27.5
7	210	230	-	-	-	35

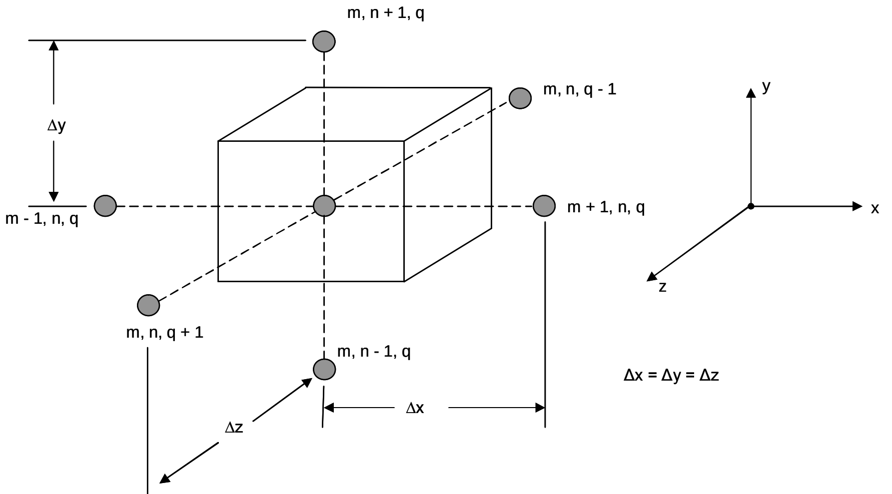
When T_4(210s, p = 7) = 35°C, find T_0(210s) = 230°C. <

PROBLEM 5.114

KNOWN: Three-dimensional, transient conduction.

FIND: Explicit finite difference equation for an interior node, stability criterion.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Equal grid spacing in all three directions, (3) No heat generation.

ANALYSIS: We begin with the three-dimensional form of the transient heat equation, Equation 2.19

$$\frac{1}{\alpha}\frac{\partial T}{\partial t} = \frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} + \frac{\partial^2 T}{\partial z^2}$$

The finite-difference approximation to the time derivative is given by Equation 5.77:

$$\left.\frac{\partial T}{\partial t}\right|_{m,n,q} = \frac{T^{p+1}_{m,n,q} - T^{p}_{m,n,q}}{\Delta t}$$

The spatial derivatives for the x- and y- directions are given by Equations 4.27 and 4.28, with an extra subscript q. By analogy, the z-direction derivative is approximated as

$$\left.\frac{\partial^2 T}{\partial z^2}\right|_{m,n,q} \approx \frac{T_{m,n,q+1} + T_{m,n,q-1} - 2T_{m,n,q}}{(\Delta z)^2}$$

Evaluating the spatial derivatives at time step p for the explicit method, assuming $\Delta x = \Delta y = \Delta z$, yields

Continued…

PROBLEM 5.114 (Cont.)

$$\frac{1}{\alpha}\frac{T^{p+1}_{m,n,q} - T^{p}_{m,n,q}}{\Delta t} = \frac{T^{p}_{m+1,n,q} + T^{p}_{m-1,n,q} - 2T^{p}_{m,n,q}}{(\Delta x)^2}$$
$$+ \frac{T^{p}_{m,n+1,q} + T^{p}_{m,n-1,q} - 2T^{p}_{m,n,q}}{(\Delta x)^2}$$
$$+ \frac{T^{p}_{m,n,q+1} + T^{p}_{m,n,q-1} - 2T^{p}_{m,n,q}}{(\Delta x)^2}$$

Solving for the nodal temperature at time step p+1 results in

$$T^{p+1}_{m,n,q} = Fo(T^{p}_{m+1,n,q} + T^{p}_{m-1,n,q} + T^{p}_{m,n+1,q} + T^{p}_{m,n-1,q} + T^{p}_{m,n,q+1} + T^{p}_{m,n,q-1})$$
$$+ (1 - 6Fo)T^{p}_{m,n,q}$$

where Fo = $\alpha\Delta t/(\Delta x)^2$. <

The stability criterion is determined by the requirement that the coefficient of $T^{p}_{m,n,q} \ge 0$. Thus

$$Fo \le 1/6$$ <

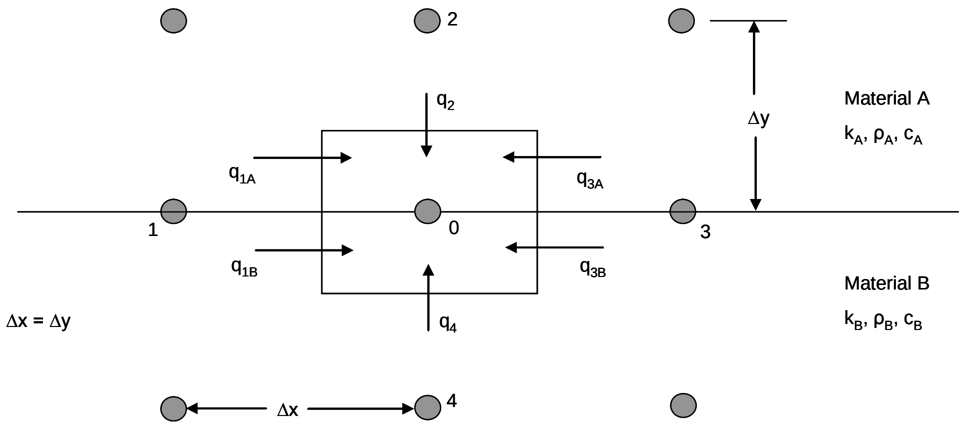
COMMENTS: These results could also have been obtained using the energy balance method applied to a control volume about the interior node.

PROBLEM 5.115

KNOWN: Nodal point located at boundary between two materials A and B.

FIND: Two-dimensional explicit, transient finite difference equation.

SCHEMATIC:



ASSUMPTIONS: (1) Two-dimensional conduction, (2) No heat generation, (3) Constant properties (different in each material).

ANALYSIS: We perform an energy balance on the control volume around node 0.

$$\dot{E}_{in} = \dot{E}_{st}$$

$$q_{1A} + q_{1B} + q_{3A} + q_{3B} + q_2 + q_4 = \dot{E}_{st,A} + \dot{E}_{st,B}$$

Using q_{1A} as an example,

$$q_{1A} = k_A \frac{T_1 - T_0}{\Delta x}\frac{\Delta y}{2} w = k_A (T_1 - T_0) w/2$$

where w is the depth into the page. The quantities q_{1B}, q_{3A}, and q_{3B} can be found similarly. Then q_2 is given by

$$q_2 = k_A \frac{T_2 - T_0}{\Delta y} \Delta x\, w = k_A (T_2 - T_0) w$$

and similarly for q_4.

The storage term $\dot{E}_{st,A}$ is given by

$$\dot{E}_{st,A} = \rho_A\, c_A\, \Delta x \frac{\Delta y}{2} \frac{T_0^{p+1} - T_0^p}{\Delta t}$$

and similarly for $\dot{E}_{st,B}$.

Combining equations yields

Continued….

PROBLEM 5.115 (Cont.)

$$k_A \frac{T_1 - T_0}{2} + k_B \frac{T_1 - T_0}{2} + k_A \frac{T_3 - T_0}{2} + k_B \frac{T_3 - T_0}{2} +$$

$$k_A (T_2 - T_0) + k_B (T_4 - T_0) = (\rho_A c_A + \rho_B c_B) \frac{(\Delta x)^2}{2} \frac{T_0^{p+1} - T_0^p}{\Delta t}$$

Rearranging, we find

$$T_0^{p+1} = \frac{(Fo_A + Fo_B)}{2} (T_1^p + T_3^p) + Fo_A T_2^p + Fo_B T_4^p + \left[1 - 2(Fo_A + Fo_B)\right] T_0^p$$ <

where

$$Fo_A = \frac{2k_A \Delta t}{(\rho_A c_A + \rho_B c_B)(\Delta x)^2}, \quad Fo_B = \frac{2k_B \Delta t}{(\rho_A c_A + \rho_B c_B)(\Delta x)^2}$$

Note, that $Fo_A \neq \alpha_A \Delta t / (\Delta x)^2$.

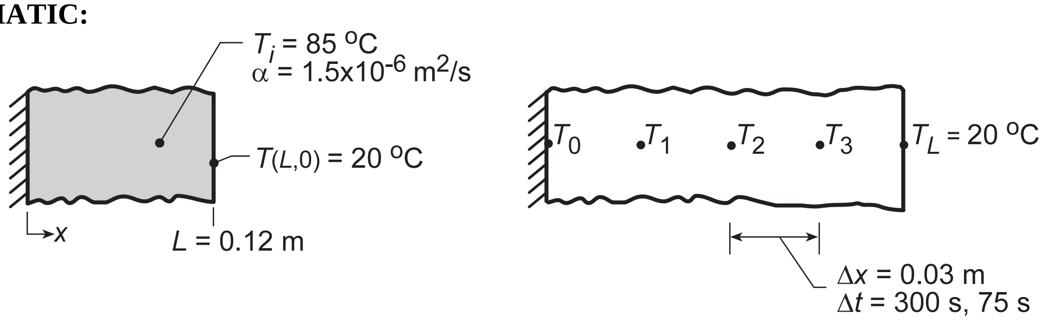
COMMENTS: Note that when the material properties are the same for materials A and B, the result agrees with Equation 5.79.

PROBLEM 5.116

KNOWN: A 0.12 m thick wall, with thermal diffusivity 1.5×10^{-6} m^2/s, initially at a uniform temperature of 85°C, has one face suddenly lowered to 20°C while the other face is perfectly insulated.

FIND: (a) Using the explicit finite-difference method with space and time increments of Δx = 30 mm and Δt = 300s, determine the temperature distribution within the wall 45 min after the change in surface temperature; (b) Effect of Δt on temperature histories of the surfaces and midplane.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional transient conduction, (2) Constant properties.

ANALYSIS: (a) The finite-difference equations for the interior points, nodes 0, 1, 2, and 3, can be determined from Equation 5.81,

$$T_m^{p+1} = Fo\left(T_{m-1}^p + T_{m+1}^p\right) + \left(1 - 2\,Fo\right)T_m^p \qquad (1)$$

with

$$Fo = \alpha \Delta t / \Delta x^2 = 1.5 \times 10^{-6}\, m^2/s \times 300s / (0.03\,m)^2 = 1/2. \qquad (2)$$

Note that the stability criterion, Equation 5.82, Fo ≤ 1/2, is satisfied. Hence, combining Equations (1) and (2), $T_m^{p+1} = 1/2\left(T_{m-1}^p + T_{m+1}^p\right)$ for m = 0, 1, 2, 3. Since the adiabatic plane at x = 0 can be treated as a symmetry plane, $T_{m-1} = T_{m+1}$ for node 0 (m = 0). The finite-difference solution is generated in the table below using $t = p \cdot \Delta t$ = 300 p (s) = 5 p (min).

p	t(min)	T_0	T_1	T_2	T_3	T_L(°C)
0	0	85	85	85	85	20
1		85	85	85	52.5	20
2	10	85	85	68.8	52.5	20
3		85	76.9	68.8	44.4	20
4	20	76.9	76.9	60.7	44.4	20
5		76.9	68.8	60.7	40.4	20
6	30	68.8	68.8	54.6	40.4	20
7		68.8	61.7	54.6	37.3	20
8	40	61.7	61.7	49.5	37.3	20
9	45	61.7	55.6	49.5	34.8	20

<

The temperature distribution can also be determined from the one-term approximation of the exact solution. The insulated surface is equivalent to the midplane of a wall of thickness 2L. Thus,

$$Fo = \frac{\alpha t}{L^2} = \frac{1.5 \times 10^{-6}\, m^2/s \times (45 \times 60)s}{(0.12\,m)^2} = 0.28 \qquad \text{and} \qquad Bi \to \infty.$$

Continued...

PROBLEM 5.116 (Cont.)

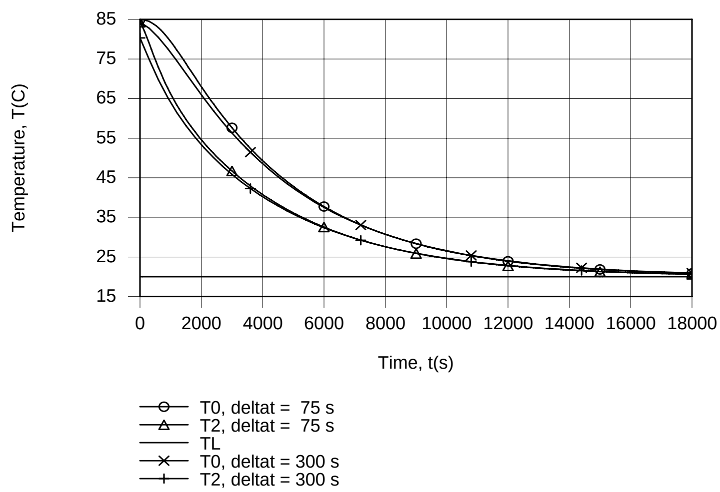
From Table 5.1, ζ_1 = 1.5707, C_1 = 1.2733. Then from Equation 5.44,

$$\theta_o^* = C_1 \exp(-\zeta_1^2 \text{Fo}) = 1.2733 \exp(-1.5707^2 \times 0.28) = 0.64 \quad \text{or}$$

$$T_o = T(0,t) = T_\infty + \theta_o^* (T_i - T_\infty) = 20^\circ\text{C} + 0.64(85-20)^\circ\,\text{C} = 61.5^\circ\text{C}.$$

This value shows excellent agreement with 61.7°C for the finite-difference method.

(b) Using the IHT *Finite-Difference Equation* Tool Pad for *One-Dimensional Transient Conduction*, temperature histories were computed and results are shown for the insulated surface (T0) and the midplane, as well as for the chilled surface (TL).



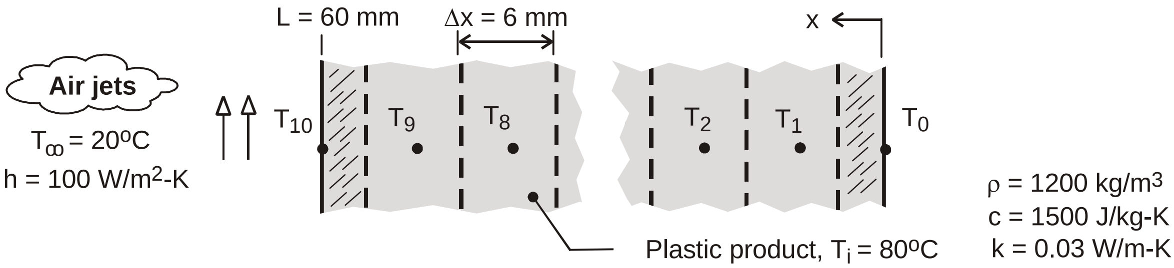
Apart from small differences during early stages of the transient, there is excellent agreement between results obtained for the two time steps. The temperature decay at the insulated surface must, of course, lag that of the midplane.

PROBLEM 5.117

KNOWN: Thickness, initial temperature and thermophysical properties of molded plastic part. Convection conditions at one surface. Other surface insulated.

FIND: Surface temperatures after one hour of cooling.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in product, (2) Negligible radiation, at cooled surface, (3) Negligible heat transfer at insulated surface, (4) Constant properties.

ANALYSIS: Adopting the implicit scheme, the finite-difference equation for the cooled surface node is given by Eq. (5.96), from which it follows that

$$\left(1+2\,\text{Fo}+2\,\text{FoBi}\right)T_{10}^{p+1}-2\text{Fo}\,T_9^{p+1}=2\,\text{FoBi}\,T_\infty+T_{10}^{p}$$

The general form of the finite-difference equation for any interior node (1 to 9) is given by Eq. (5.97),

$$\left(1+2\,\text{Fo}\right)T_m^{p+1}-\text{Fo}\left(T_{m-1}^{p+1}+T_{m+1}^{p+1}\right)=T_m^p$$

The finite-difference equation for the insulated surface node may be obtained by applying the symmetry requirement to Eq. (5.97); that is, $T_{m+1}^p=T_{m-1}^p$. Hence,

$$\left(1+2\,\text{Fo}\right)T_o^{p+1}-2\,\text{Fo}\,T_1^{p+1}=T_o^p$$

For the prescribed conditions, Bi = hΔx/k = 100 W/m^2·K (0.006m)/0.30 W/m·K = 2. If the explicit method were used, the most restrictive stability requirement would be given by Eq. (5.87). Hence, for Fo (1+Bi) ≤ 0.5, Fo ≤ 0.167. With Fo = αΔt/Δx^2 and α = k/ρc = 1.67 ×10^{-7} m^2/s, the corresponding restriction on the time increment would be Δt ≤ 36s. Although no such restriction applies for the implicit method, a value of Δt = 30s is chosen, and the set of 11 finite-difference equations is solved using the *Tools* option designated as *Finite-Difference Equations*, *One-Dimensional*, and *Transient* from the IHT Toolpad. At t = 3600s, the solution yields:

$$T_{10}\left(3600\text{s}\right)=24.1^\circ\text{C}\qquad T_0\left(3600\text{s}\right)=71.5^\circ\text{C}$$ <

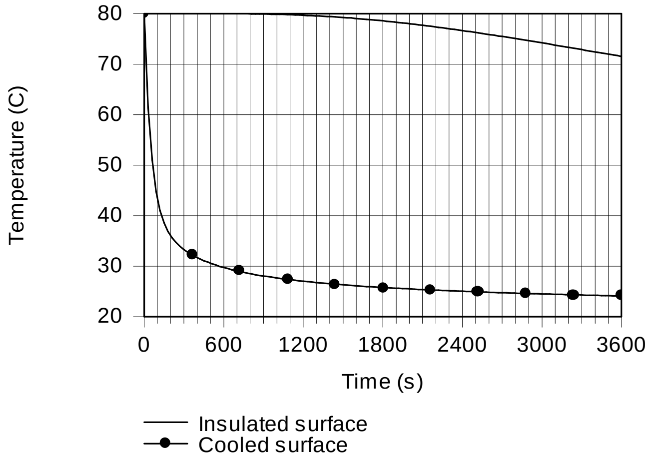
COMMENTS: (1) More accurate results may be obtained from the one-term approximation to the exact solution for one-dimensional, transient conduction in a plane wall. With Bi = hL/k = 20, Table 5.1 yields ζ_1 = 1.496 rad and C_1 = 1.2699. With Fo = αt/L^2 = 0.167, Eq. (5.41) then yields $T_o = T_\infty$ + $(T_i - T_\infty)$ C_1 exp $\left(-\zeta_1^2\text{Fo}\right) = 72.4^\circ\text{C}$, and from Eq. (5.43b), $T_s = T_\infty + (T_i - T_\infty)\cos\left(\zeta_1\right) = 24.5^\circ\text{C}$.

Since the finite-difference results do not change with a reduction in the time step (Δt < 30s), the difference between the numerical and analytical results is attributed to the use of a coarse grid. To improve the accuracy of the numerical results, a smaller value of Δx should be used.

Continued …

PROBLEM 5.117 (Cont.)

(2) Temperature histories for the front and back surface nodes are as shown.



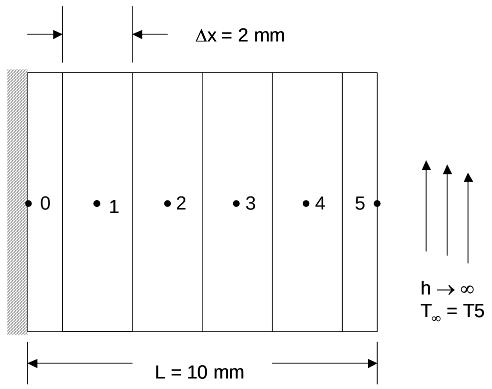
Although the surface temperatures rapidly approaches that of the coolant, there is a significant lag in the thermal response of the back surface. The different responses are attributable to the small value of α and the large value of Bi.

PROBLEM 5.118

KNOWN: Thickness and thermal diffusivity of a plane wall. Initial and boundary conditions.

FIND: (a) Time required for the left face temperature to reach 50% of its maximum possible temperature reduction and (b) Time required for the left face temperature to recover to a 20% temperature reduction when the right face temperature is returned to its initial value.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional heat transfer, (2) Constant properties.

PROPERTIES: Thermal diffusivity, $\alpha = 6 \times 10^{-7}$ m^2/s (given).

ANALYSIS: Using the *IHT Finite-Difference Equation* Tool Pad for *One-Dimensional Transient Conduction*, the following temperatures may be computed using the *IHT* code in the Comments section. Note that for this solution, the conditions at the right face have been incorporated by specifying a very large convection coefficient at the right face so that $T_5 \approx T_\infty$.

(a) For cooling conditions, the initial temperature is arbitrarily set to unity, and $T_\infty = T_{s,r} = 0.5$. If a steady-state solution were achieved, it would correspond to a uniform wall temperature of $T_{ss} = T_{s,r} = 0.5$. Hence we seek to determine the time when $T_0 = (T_i + T_{s,r})/2 = 0.75$. The following representative results are obtained using a time step of $\Delta t = 2$ s.

t(s)	T_0	T_1	T_2	T_3	T_4	T_5	
20	0.952	0.937	0.888	0.798	0.665	0.5	
40	0.852	0.835	0.787	0.710	0.611	0.5	
60	0.765	0.752	0.714	0.656	0.582	0.5	
64	0.750	0.738	0.702	0.647	0.577	0.5	<

(b) For the heating conditions, we set the initial conditions in *IHT* to the temperatures shown at $t = 64$ in the table above. We set $T_\infty = 1$ and monitor the transient response of the system. The following representative results are obtained.

t(s)	T_0	T_1	T_2	T_3	T_4	T_5	
20	0.735	0.741	0.763	0.812	0.893	1.0	
40	0.789	0.798	0.826	0.872	0.932	1.0	
60	0.840	0.848	0.870	0.906	0.950	1.0	
80	0.880	0.886	0.903	0.930	0.963	1.0	
94	0.902	0.907	0.921	0.943	0.970	1.0	<

Continued…

PROBLEM 5.118 (Cont.)

COMMENTS: (1) The *IHT* Code for cooling and heating is shown below. (2) Note the thermal response of T_0 after heating ensues at the right face. The value of T_0 continues to decrease for a short time before it begins to increase in value. Does this make sense to you? (3) Part (a) was solved analytically in Problem 5.57 yielding t = 63 s. The numerical and analytical solutions are in agreement to within an uncertainty associated with the time step of Δt = 2 s.

```
/* Node 0: surface node (w-orientation); transient conditions; e labeled 1. */
rho * cp * der(T0,t) = fd_1d_sur_w(T0,T1,k,qdot,deltax,Tinf,h1,qfla0)

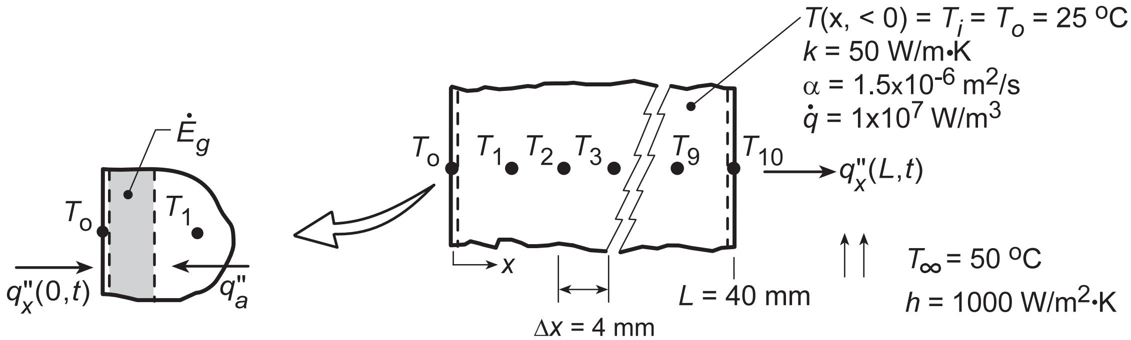
```

PROBLEM 5.119

KNOWN: Plane wall, initially at a uniform temperature $T_o = 25°C$, has one surface (x = L) suddenly exposed to a convection process with $T_\infty = 50°C$ and h = 1000 W/m²·K, while the other surface (x = 0) is maintained at T_o. Also, the wall suddenly experiences uniform volumetric heating with $\dot{q} = 1 \times 10^7$ W/m³. See also Problem 2.60.

FIND: (a) Using spatial and time increments of Δx = 4 mm and Δt = 1s, compute and plot the temperature distributions in the wall for the initial condition, the steady-state condition, and two intermediate times, and (b) On q''_x-t coordinates, plot the heat flux at x = 0 and x = L. At what elapsed time is there zero heat flux at x = L?

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, transient conduction and (2) Constant properties.

ANALYSIS: (a) Using the *IHT Finite-Difference Equations*, *One-Dimensional*, *Transient Tool*, the temperature distributions were obtained and plotted below.

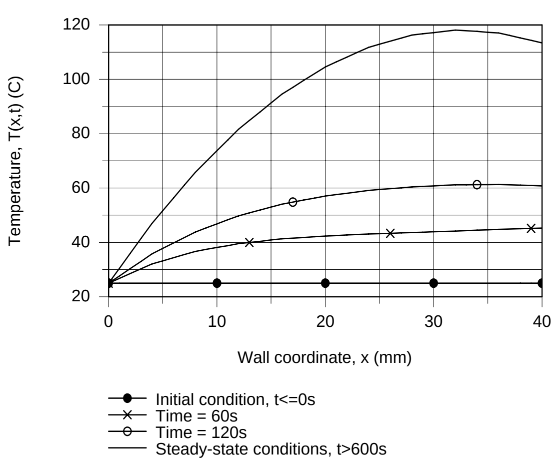
(b) The heat flux, $q''_x(L,t)$, can be expressed in terms of Newton's law of cooling,

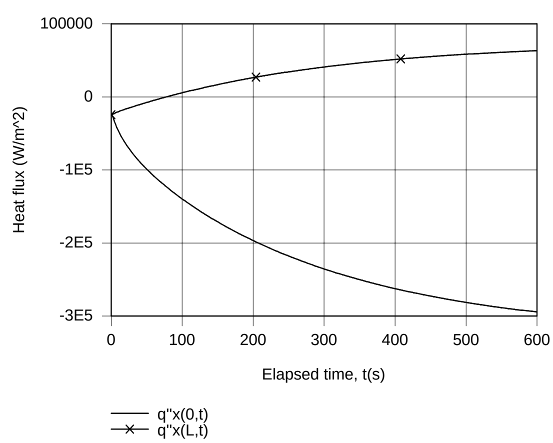
$$q''_x(L,t) = h\left(T_{10}^p - T_\infty\right).$$

From the energy balance on the control volume about node 0 shown above,

$$q''_x(0,t) + \dot{E}_g + q''_a = 0 \qquad\qquad q''_x(0,t) = -\dot{q}(\Delta x/2) - k\left(T_1^p - T_o\right)\Big/\Delta x$$

From knowledge of the temperature distribution, the heat fluxes are computed and plotted.





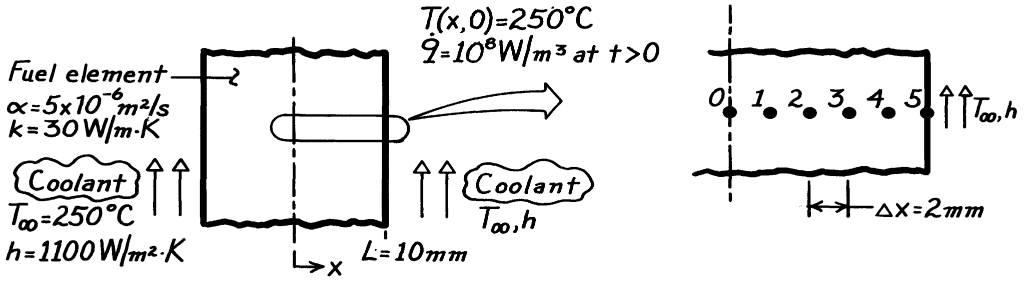
COMMENTS: The steady-state analytical solution has the form of Eq. 3.44 where C_1 = 6500 m-1/°C and C_2 = 25°C. Find $q''_x(0,\infty) = -3.25 \times 10^5\ W/m^2$ and $q''_x(L) = +7.5 \times 10^4\ W/m^2$. Comparing with the graphical results above, we conclude that steady-state conditions are not reached in 600 s.

PROBLEM 5.120

KNOWN: Fuel element of Example 5.11 is initially at a uniform temperature of 250°C with no internal generation; suddenly a uniform generation, $\dot{q} = 10^8 W/m^3$, occurs when the element is inserted into the core while the surfaces experience convection (T_∞,h).

FIND: Temperature distribution 1.5s after element is inserted into the core.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional transient conduction, (2) Constant properties, (3) $\dot{q} = 0$, initially; at t > 0, $\dot{q}$ is uniform.

ANALYSIS: As suggested, the explicit method with a space increment of 2mm will be used. Using the nodal network of Example 5.11, the same finite-difference equations may be used.

Interior nodes, m = 1, 2, 3, 4

$$T_m^{p+1} = Fo\left[T_{m-1}^p + T_{m+1}^p + \frac{\dot{q}(\Delta x)^2}{2}\right] + (1-2\ Fo)T_m^p. \quad (1)$$

Midplane node, m = 0

Same as Eq. (1), but with $T_{m-1}^p = T_{m+1}^p$.

Surface node, m = 5

$$T_5^{p+1} = 2\ Fo\left[T_4^p + Bi \cdot T_\infty + \frac{\dot{q}(\Delta x)^2}{2k}\right] + (1-2Fo-2Bi \cdot Fo)T_5^p. \quad (2)$$

The most restrictive stability criterion is associated with Eq. (2), Fo(1+Bi) ≤ 1/2. Consider the following parameters:

$$Bi = \frac{h\Delta x}{k} = \frac{1100 W/m^2 \cdot K \times (0.002m)}{30 W/m \cdot K} = 0.0733$$

$$Fo \le \frac{1/2}{(1+Bi)} = 0.466$$

$$\Delta t \le \frac{Fo(\Delta x)^2}{\alpha} = 0.466 \frac{(0.002m)^2}{5\times10^{-6} m^2/s} = 0.373s.$$

Continued …

PROBLEM 5.120 (Cont.)

To be well within the stability limit, select Δt = 0.3s, which corresponds to

$$Fo = \frac{\alpha \Delta t}{\Delta x^2} = \frac{5\times10^{-6}m^2/s\times0.3s}{(0.002m)^2} = 0.375$$
$$t = p\Delta t = 0.3p(s).$$

Substituting numerical values with $\dot{q} = 10^8 W/m^3$, the nodal equations become

$$T_0^{p+1} = 0.375\left[2T_1^p + 10^8 W/m^3 (0.002m)^2/30W/m\cdot K\right] + (1-2\times0.375)T_0^p$$

$$T_0^{p+1} = 0.375\left[2T_1^p + 13.33\right] + 0.25\ T_0^p \quad (3)$$

$$T_1^{p+1} = 0.375\left[T_0^p + T_2^p + 13.33\right] + 0.25\ T_1^p \quad (4)$$

$$T_2^{p+1} = 0.375\left[T_1^p + T_3^p + 13.33\right] + 0.25\ T_2^p \quad (5)$$

$$T_3^{p+1} = 0.375\left[T_2^p + T_4^p + 13.33\right] + 0.25\ T_3^p \quad (6)$$

$$T_4^{p+1} = 0.375\left[T_3^p + T_5^p + 13.33\right] + 0.25\ T_4^p \quad (7)$$

$$T_5^{p+1} = 2\times0.375\left[T_4^p + 0.0733\times250 + \frac{13.33}{2}\right] + (1-2\times0.375-2\times0.0733\times0.375)T_5^p$$

$$T_5^{p+1} = 0.750\ \left[T_4^p + 24.99\right] + 0.195\ T_5^p. \quad (8)$$

The initial temperature distribution is T_i = 250°C at all nodes. The marching solution, following the procedure of Example 5.11, is represented in the table below.

p	t(s)	T_0	T_1	T_2	T_3	T_4	T_5(°C)	
0	0	250	250	250	250	250	250	
1	0.3	255.00	255.00	255.00	255.00	255.00	254.99	
2	0.6	260.00	260.00	260.00	260.00	260.00	259.72	
3	0.9	265.00	265.00	265.00	265.00	264.89	264.39	
4	1.2	270.00	270.00	270.00	269.96	269.74	268.97	
5	1.5	275.00	275.00	274.98	274.89	274.53	273.50	<

The desired temperature distribution T(x, 1.5s), corresponds to p = 5.

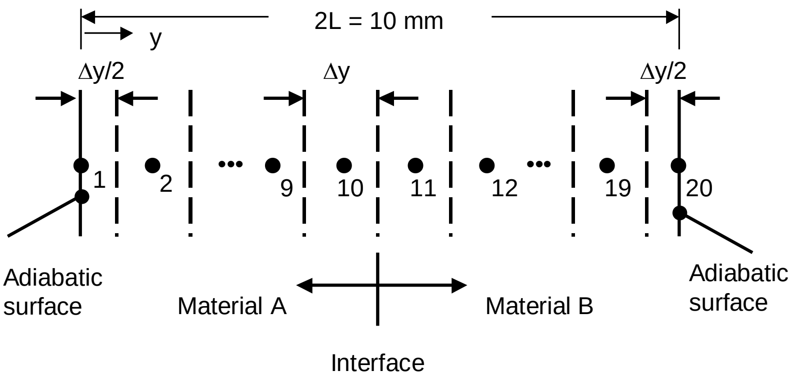
COMMENTS: Note that the nodes near the midplane (0,1) do not feel any effect of the coolant during the first 1.5s time period.

PROBLEM C5.121

KNOWN: Dimensions and properties of acrylic and steel plates. Initial temperatures.

FIND: Time needed to bring external surface of the acrylic to its softening temperature. Plot of the average acrylic and steel plate temperatures and acrylic surface temperature for $0 \le t \le 300$ s.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Negligible contact resistance.

PROPERTIES: Acrylic (given): $\rho_A = 1990$ kg/m^3, $c_A = 1470$ J/kg·K and $k_A = 0.21$ W/m·K. Steel (given): $\rho_B = 7800$ kg/m^3, $c_B = 500$ J/kg·K and $k_B = 45$ W/m·K.

ANALYSIS: We begin by writing energy balances on each of the 20 control volumes using the implicit method,

Node 1:
$$\rho_A c_A \frac{\Delta y}{2}\frac{\left(T_1^{p+1} - T_1^p\right)}{\Delta t} = \frac{k_A\left(T_2^{p+1} - T_1^{p+1}\right)}{\Delta y}$$

Nodes 2 – 9:
$$\rho_A c_A \Delta y \frac{\left(T_n^{p+1} - T_n^p\right)}{\Delta t} = \frac{k_A\left(T_{n-1}^{p+1} - T_n^{p+1}\right)}{\Delta y} + \frac{k_A\left(T_{n+1}^{p+1} - T_n^{p+1}\right)}{\Delta y}$$

Node 10:
$$\rho_A c_A \Delta y \frac{\left(T_{10}^{p+1} - T_{10}^p\right)}{\Delta t} = \frac{k_A\left(T_9^{p+1} - T_{10}^{p+1}\right)}{\Delta y} + \frac{\left(T_{11}^{p+1} - T_{10}^{p+1}\right)}{R_t''}$$

Node 11:
$$\rho_B c_B \Delta y \frac{\left(T_{11}^{p+1} - T_{11}^p\right)}{\Delta t} = \frac{\left(T_{10}^{p+1} - T_{11}^{p+1}\right)}{R_t''} + \frac{k_B\left(T_{12}^{p+1} - T_{11}^{p+1}\right)}{\Delta y}$$

Nodes 12 – 19:
$$\rho_B c_B \Delta y \frac{\left(T_n^{p+1} - T_n^p\right)}{\Delta t} = \frac{k_B\left(T_{n-1}^{p+1} - T_n^{p+1}\right)}{\Delta y} + \frac{k_B\left(T_{n+1}^{p+1} - T_n^{p+1}\right)}{\Delta y}$$

Node 20:
$$\rho_B c_B \frac{\Delta y}{2}\frac{\left(T_{20}^{p+1} - T_{20}^p\right)}{\Delta t} = \frac{k_B\left(T_{19}^{p+1} - T_{20}^{p+1}\right)}{\Delta y}$$

Continued…

PROBLEM 5.121 (Cont.)

where $$R_t'' = \frac{\Delta y/2}{k_A} + \frac{\Delta y/2}{k_B}$$

Also, note that the average temperature of each material may be written as

$$\overline{T} = \frac{1}{L}\int_{y=0}^{L} T(y)dy$$

or, in finite difference form,

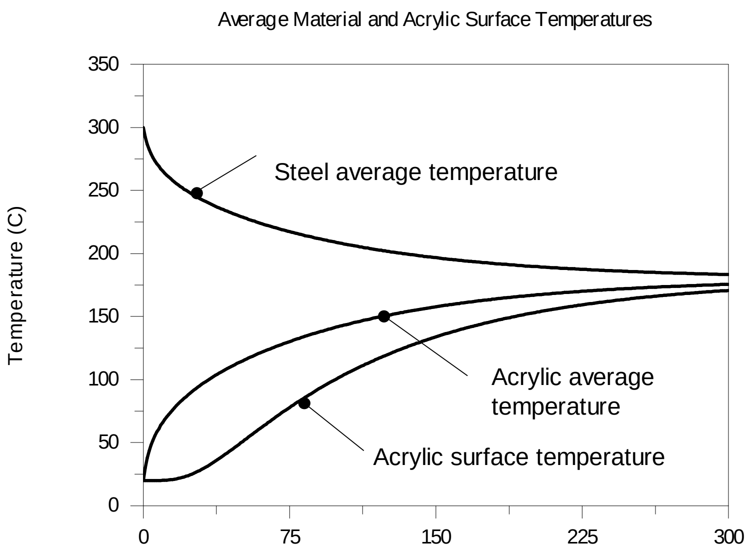
$$\overline{T_A} = \frac{1}{L_A}\left[T_1\frac{\Delta y}{2} + T_2\Delta y + T_3\Delta y + T_4\Delta y + T_5\Delta y + T_6\Delta y + T_7\Delta y + T_8\Delta y + T_9\Delta y + T_{10}\Delta y\right]$$

and

$$\overline{T_B} = \frac{1}{L_B}\left[T_{11}\Delta y + T_{12}\Delta y + T_{13}\Delta y + T_{14}\Delta y + T_{15}\Delta y + T_{16}\Delta y + T_{17}\Delta y + T_{18}\Delta y + T_{19}\Delta y + T_{20}\frac{\Delta y}{2}\right]$$

The preceding equations were solved using IHT code that is listed in the Comments. The spatially-averaged temperatures of the two plates, as well as the external temperature of the acrylic, T_1, are shown in the plot below. <

From the simulation, we also find that the surface of the acrylic reaches T_{soft} = 90°C at t = 87 s. <



COMMENTS: (1) Ultimately, the temperatures of the two plates will reach the same steady-state value. The steady-state temperature may be found by recognizing the energy gained by the acrylic is lost by the steel, $L_Ac_A(T_{ss} - T_{i,A}) = L_Bc_B(T_{i,B} - T_{ss})$ yielding T_{ss} = 180°C, as evident in the plot of the average temperatures. (2) If the surface of the acrylic in contact with the metal is assumed to be of constant temperature and equal to 300°C, the external surface of the acrylic reaches the softening temperature at t = 74 s. (3) The IHT code is shown on the next page.

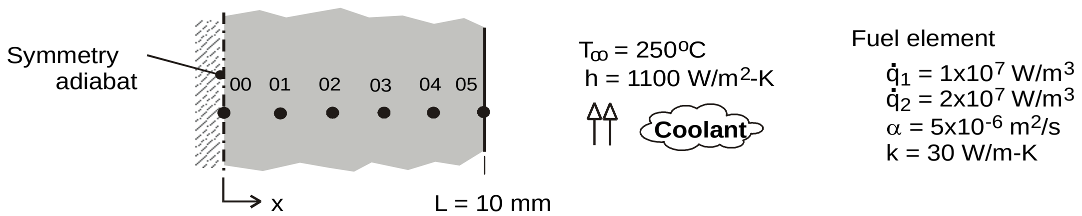
PROBLEM 5.122

KNOWN: Conditions associated with heat generation in a rectangular fuel element with surface cooling. See Example 5.11.

FIND: (a) The temperature distribution 1.5 s after the change in operating power; compare your results with those tabulated in the example, (b) Calculate and plot temperature histories at the mid-plane (00) and surface (05) nodes for $0 \leq t \leq 400$ s; determine the new steady-state temperatures, and approximately how long it will take to reach the new steady-state condition after the step change in operating power. Use the IHT *Tools | Finite-Difference Equations | One-Dimensional | Transient* conduction model builder as your solution tool.

SCHEMATIC:



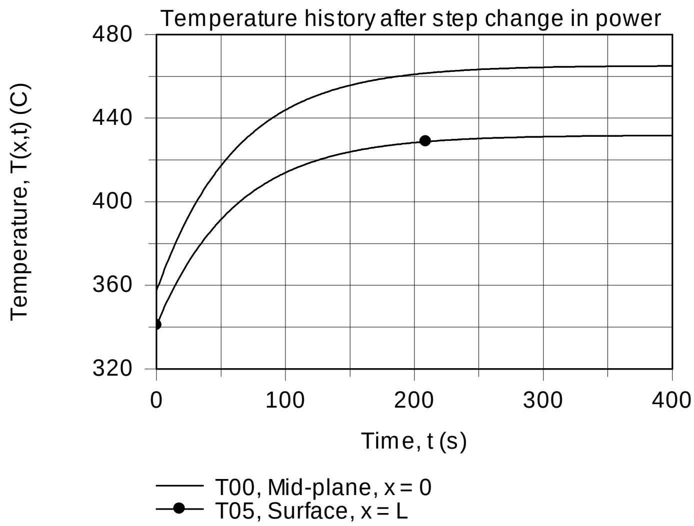
ASSUMPTIONS: (1) One dimensional conduction in the x-direction, (2) Uniform generation, and (3) Constant properties.

ANALYIS: The IHT model builder provides the transient finite-difference equations for the implicit method of solution. Selected portions of the IHT code used to obtain the results tabulated below are shown in the Comments.

(a) Using the IHT code, the temperature distribution (°C) as a function of time (s) up to 1.5 s after the step power change is obtained from the summarized results copied into the workspace

	t	T00	T01	T02	T03	T04	T05
1	0	357.6	356.9	354.9	351.6	346.9	340.9
2	0.3	358.1	357.4	355.4	352.1	347.4	341.4
3	0.6	358.6	357.9	355.9	352.6	347.9	341.9
4	0.9	359.1	358.4	356.4	353.1	348.4	342.3
5	1.2	359.6	358.9	356.9	353.6	348.9	342.8
6	1.5	360.1	359.4	357.4	354.1	349.3	343.2

(b) Using the code, the mid-plane (00) and surface (05) node temperatures are plotted as a function of time.



Continued …

PROBLEM 5.122 (Cont.)

Note that at t ≈ 240 s, the wall has nearly reached the new steady-state condition for which the nodal temperatures (°C) were found as:

T00	T01	T02	T03	T04	T05
465	463.7	459.7	453	443.7	431.7

COMMENTS: (1) Can you validate the new steady-state nodal temperatures from part (b) by comparison against an analytical solution?

(2) Will using a smaller time increment improve the accuracy of the results? Use your code with Δt = 0.15 s to justify your explanation.

(3) Selected portions of the IHT code to obtain the nodal temperature distribution using spatial and time increments of Δx = 2 mm and Δt = 0.3 s, respectively, are shown below. For the solve-integration step, the initial condition for each of the nodes corresponds to the steady-state temperature distribution with $\dot{q}_1$.

```
// Tools | Finite-Difference Equations | One-Dimensional | Transient
/* Node 00: surface node (w-orientation); transient conditions; e labeled 01. */
rho * cp * der(T00,t) = fd_1d_sur_w(T00,T01,k,qdot,deltax,Tinf01,h01,q''a00)
q''a00 = 0        // Applied heat flux, W/m^2; zero flux shown
Tinf01 = 20       // Arbitrary value
h01 = 1e-8        // Causes boundary to behave as adiabatic
/* Node 01: interior node; e and w labeled 02 and 00. */
rho*cp*der(T01,t) = fd_1d_int(T01,T02,T00,k,qdot,deltax)

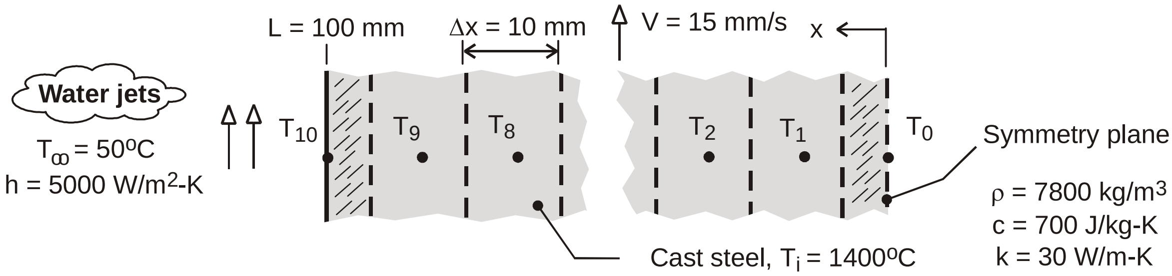
```

PROBLEM 5.123

KNOWN: Thickness, initial temperature, speed and thermophysical properties of steel in a thin-slab continuous casting process. Surface convection conditions.

FIND: Time required to cool the outer surface to a prescribed temperature. Corresponding value of the midplane temperature and length of cooling section.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Negligible radiation at quenched surfaces, (3) Symmetry about the midplane, (4) Constant properties.

ANALYSIS: Adopting the implicit scheme, the finite-difference equation for the cooled surface node is given by Eq. (5.96), from which it follows that

$$(1+2\,\text{Fo}+2\,\text{Fo}\text{Bi})T_{10}^{p+1}-2\,\text{Fo}\,T_9^{p+1}=2\,\text{Fo}\text{Bi}\,T_\infty+T_{10}^{p}$$

The general form of the finite-difference equation for any interior node (1 to 9) is given by Eq. (5.97),

$$(1+2\,\text{Fo})T_m^{p+1}-\text{Fo}\left(T_{m-1}^{p+1}+T_{m+1}^{p+1}\right)=T_m^p$$

The finite-difference equation for the midplane node may be obtained by applying the symmetry requirement to Eq. (5.94); that is, $T_{m+1}^p = T_{m-1}^p$. Hence,

$$(1+2\,\text{Fo})T_0^{p+1}-2\,\text{Fo}\,T_1^{p+1}=T_0^p$$

For the prescribed conditions, Bi = hΔx/k = 5000 $W/m^2 \cdot K$ (0.010m)/30 W/m·K = 1.67. If the explicit method were used, the stability requirement would be given by Eq. (5.87). Hence, for Fo(1 + Bi) ≤ 0.5, Fo ≤ 0.187. With Fo = $\alpha\Delta t/\Delta x^2$ and α = k/ρc = 5.49 × 10^{-6} m^2/s, the corresponding restriction on the time increment would be Δt ≤ 3.40s. Although no such restriction applies for the implicit method, a value of Δt = 1s is chosen, and the set of 11 finite-difference equations is solved using the *Tools* option designated as *Finite-Difference Equations*, *One-Dimensional* and *Transient* from the IHT Toolpad. For T_{10} (t) = 300°C, the solution yields

$$t = 161\text{s}$$ <

Continued …

PROBLEM 5.123 (Cont.)

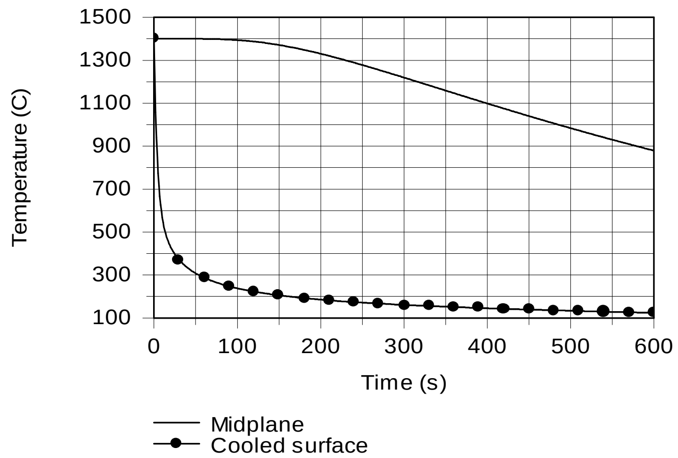
$$T_0(t) = 1364°C$$ <

With a casting speed of V = 15 mm/s, the length of the cooling section is

$$L_{cs} = Vt = 0.015\,m/s(161s) = 2.42m$$ <

COMMENTS: (1) With Fo = $\alpha t/L^2$ = 0.088 < 0.2, the one-term approximation to the exact solution for one-dimensional conduction in a plane wall cannot be used to confirm the foregoing results. However, using the exact solution from the *Models*, *Transient Conduction*, *Plane Wall* Option of IHT, values of T_0 = 1366°C and T_s = 200.7°C are obtained and are in good agreement with the finite-difference predictions. The accuracy of these predictions could still be improved by reducing the value of Δx.

(2) Temperature histories for the surface and midplane nodes are plotted for 0 < t < 600s.



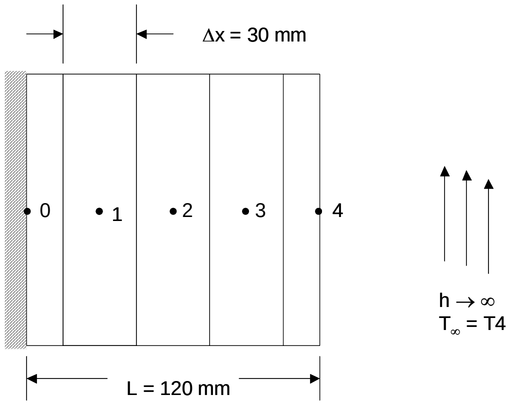
While T_{10} (600s) = 124°C, T_o (600s) has only dropped to 879°C. The much slower thermal response at the midplane is attributable to the small value of α and the large value of Bi = 16.67.

PROBLEM 5.124

KNOWN: Thickness and thermal diffusivity of a plane wall. Initial and boundary conditions.

FIND: (a) Temperature distribution at t = 30 min using an explicit finite difference technique with a time step of 600 s and a space increment of 30 mm. (b) Temperature distribution at t = 30 min using an implicit finite difference technique with a time step of 600 s and a space increment of 30 mm**.**

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional heat transfer, (2) Constant properties.

PROPERTIES: Thermal diffusivity, $\alpha = 1.5 \times 10^{-6}$ m^2/s (given).

ANALYSIS: (a) The finite-difference equations for the interior points, nodes 0, 1, 2 and 3, can be determined from Eq. 5.81,

$$T_m^{p+1} = Fo\left(T_{m-1}^p + T_{m+1}^p\right) + (1-2Fo)T_m^p \qquad (1)$$

The Fourier number is

$$Fo = \alpha\Delta t/\Delta x^2 = 1.5\times10^{-6}\,\text{m}^2/\text{s}\times600\text{s}/(0.03\text{m})^2 = 1 \qquad (2)$$

Note that the stability criterion of Eq. 5.82 is *not* satisfied. Nonetheless, we will combine Eqs. (1) and (2) to yield

$$T_m^{p+1} = T_{m-1}^p + T_{m+1}^p - T_m^p$$

Since the adiabatic surface at x = 0 can be treated as a symmetry plane, we note that $T_{m-1} = T_{m+1}$ for node 0. The finite-difference solution is shown in the table below.

p	t (min)	T_0	T_1	T_2	T_3	$T_4 = T_L$ (°C)
0	0	85	85	85	85	20
1	10	85	85	85	20	20
2	20	85	85	20	85	20
3	30	85	20	150	-45	20

<

Continued…

PROBLEM 5.124 (Cont.)

(b) Note that for this solution, the conditions at the right face have been incorporated by specifying a very large convection coefficient at the right face so that $T_4 \approx T_\infty$. The *IHT* code is shown in the COMMENTS section. The following results were obtained.

p	t (min)	T_0	T_1	T_2	T_3	$T_4 = T_L$ (°C)
0	0	85	85	85	85	20
1	10	82.2	80.9	75.3	60.1	20
2	20	77.3	74.8	66.3	48.8	20
3	30	71.4	68.5	59.1	42.7	20

<

COMMENTS: (1) The *IHT* Code for part (b) is shown at the end of the Comments. (2) Note the thermal response of part (a) is unrealistic. This unrealistic result is expected since the stability criterion is not satisfied. (3) Part (b) was repeated with a smaller time step of Δt = 300 s yielding the following results. Note that these results differ from those associated with the larger time step. Just because the implicit finite-difference method is inherently *stable*, the solutions may still be dependent upon the time step and, as such, are incorrect.

p	t (min)	T_0	T_1	T_2	T_3	$T_4 = T_L$ (°C)
0	0	85	85	85	85	20
1	10	82.8	81.2	74.8	57.5	20
2	20	77.7	74.8	65.3	46.9	20
3	30	71.3	68.1	58.1	41.4	20

```
/* Node 0: surface node (w-orientation); transient conditions; e labeled 1. */

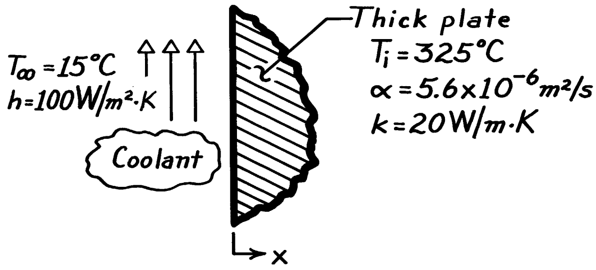
```

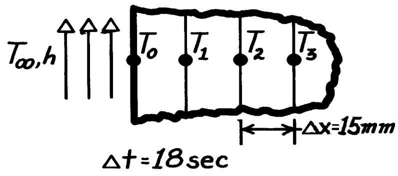
PROBLEM 5.125

KNOWN: Very thick plate, initially at a uniform temperature, T_i, is suddenly exposed to a convection cooling process (T_∞,h).

FIND: Temperatures at the surface and a 45mm depth after 3 minutes using finite-difference method with space and time increments of 15mm and 18s.

SCHEMATIC:





ASSUMPTIONS: (1) One-dimensional transient conduction, (2) Plate approximates semi-infinite medium, (3) Constant properties.

ANALYSIS: The grid network representing the plate is shown above. The finite-difference equation for node 0 is given by Eq. 5.90 for one-dimensional conditions or Eq. 5.85,

$$T_0^{p+1} = 2\,\text{Fo}\left(T_1^p + \text{Bi}\cdot T_\infty\right) + \left(1 - 2\,\text{Fo} - 2\,\text{Bi}\cdot\text{Fo}\right)T_0^p. \tag{1}$$

The numerical values of Fo and Bi are

$$\text{Fo} = \frac{\alpha\Delta t}{\Delta x^2} = \frac{5.6\times10^{-6}\text{m}^2/\text{s}\times18\text{s}}{(0.015\text{m})^2} = 0.448$$

$$\text{Bi} = \frac{h\Delta x}{k} = \frac{100\ \text{W/m}^2\cdot\text{K}\times\left(15\times10^{-3}\text{m}\right)}{20\ \text{W/m}\cdot\text{K}} = 0.075.$$

Recognizing that T_∞ = 15°C, Eq. (1) has the form

$$T_0^{p+1} = 0.0359\ T_0^p + 0.897\ T_1^p + 1.01. \tag{2}$$

It is important to satisfy the stability criterion, Fo (1+Bi) ≤ 1/2. Substituting values, 0.448 (1+0.075) = 0.482 ≤ 1/2, and the criterion is satisfied.

The finite-difference equation for the interior nodes, m = 1, 2…, follows from Eq. 5.78,

$$T_m^{p+1} = \text{Fo}\left(T_{m+1}^p + T_{m-1}^p\right) + \left(1 - 2\text{Fo}\right)T_m^p. \tag{3}$$

Recognizing that the stability criterion, Fo ≤ 1/2, is satisfied with Fo = 0.448,

$$T_m^{p+1} = 0.448\left(T_{m+1}^p + T_{m-1}^p\right) + 0.104T_m^p. \tag{4}$$

Continued …

PROBLEM 5.125 (Cont.)

The time scale is related to p, the number of steps in the calculation procedure, and Δt, the time increment,

$$t = p\Delta t. \tag{5}$$

The finite-difference calculations can now be performed using Eqs. (2) and (4). The results are tabulated below.

p	t(s)	T_0	T_1	T_2	T_3	T_4	T_5	T_6	T_7(K)
0	0	325	325	325	325	325	325	325	325
1	18	304.2	324.7	325	325	325	325	325	325
2	36	303.2	315.3	324.5	325	325	325	325	325
3	54	294.7	313.7	320.3	324.5	325	325	325	325
4	72	293.0	307.8	318.9	322.5	324.5	325	325	325
5	90	287.6	305.8	315.2	321.5	323.5	324.5	325	325
6	108	285.6	301.6	313.5	319.3	322.7	324.0	324.5	325
7	126	281.8	299.5	310.5	317.9	321.4	323.3	324.2	
8	144	279.8	296.2	308.6	315.8	320.4	322.5		
9	162	276.7	294.1	306.0	314.3	319.0			
10	180	274.8	291.3	304.1	312.4				

Hence, find

$$T(0,\ 180s) = T_0^{10} = 275^\circ C \qquad T(45mm,\ 180s) = T_3^{10} = 312^\circ C.$$ <

COMMENTS: (1) The above results can be readily checked against the analytical solution represented in Fig. 5.8 (see also Eq. 5.63). For x = 0 and t = 180s, find

$$\frac{x}{2(\alpha\ t)^{1/2}} = 0$$

$$\frac{h(\alpha\ t)^{1/2}}{k} = \frac{100\ W/m^2\cdot K\left(5.60\times10^{-6} m^2/s\times180s\right)^{1/2}}{20\ W/m\cdot K} = 0.16$$

for which the figure gives

$$\frac{T - T_i}{T_\infty - T_i} = 0.15$$

so that,

$$T(0,\ 180s) = 0.15\left(T_\infty - T_i\right) + T_i = 0.15(15 - 325)^\circ C + 325^\circ C$$

$$T(0,\ 180s) = 278^\circ C.$$

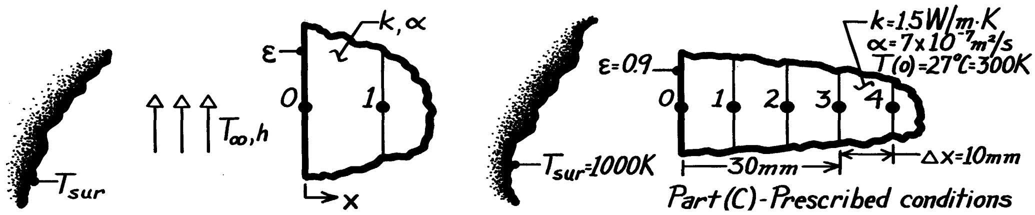
For x = 45mm, the procedure yields T(45mm, 180s) = 316°C. The agreement with the numerical solution is nearly within 1%.

PROBLEM 5.126

KNOWN: Sudden exposure of the surface of a thick slab, initially at a uniform temperature, to convection and to surroundings at a high temperature.

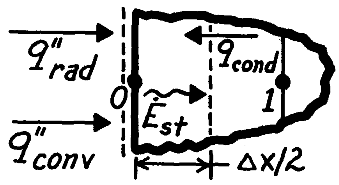
FIND: (a) Explicit, finite-difference equation for the surface node in terms of Fo, Bi, Bi_r, (b) Stability criterion; whether it is more restrictive than that for an interior node and does it change with time, and (c) Temperature at the surface and at 30mm depth for prescribed conditions after 1 minute exposure.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional transient conduction, (2) Thick slab may be approximated as semi-infinite medium, (3) Constant properties, (4) Radiation exchange is between small surface and large surroundings.

ANALYSIS: (a) The explicit form of the FDE for the surface node may be obtained by applying an energy balance to a control volume about the node.



$$\dot{E}''_{in} - \dot{E}''_{out} = q''_{conv} + q''_{rad} + q''_{cond} = \dot{E}''_{st}$$

$$h\left(T_\infty - T_o^p\right) + h_r\left(T_{sur} - T_o^p\right) + k\cdot 1\cdot \frac{T_1^p - T_o^p}{\Delta x}$$

$$= \rho\, c\left[\frac{\Delta x}{2}\cdot 1\right]\frac{T_o^{p+1} - T_o^p}{\Delta t} \qquad (1)$$

where the radiation process has been linearized, Eq. 1.9.

$$h_r = h_r^p\left(T_o^p,\ T_{sur}\right) = \varepsilon\sigma\left(T_o^p + T_{sur}\right)\left(\left[T_0^p\right]^2 + T_{sur}^2\right). \qquad (2)$$

Divide Eq. (1) by $\rho c\Delta x/2\Delta t$ and regroup using these definitions to obtain the FDE:

$$Fo \equiv \left(k/\rho\, c\right)\Delta t/\Delta x^2 \qquad Bi \equiv h\Delta x/k \qquad Bi_r \equiv h_r\Delta x/k \qquad (3,4,5)$$

$$T_o^{p+1} = 2Fo\left(Bi\cdot T_\infty + Bi_r\cdot T_{sur} + T_1^p\right) + \left(1 - 2\ Bi\cdot Fo - 2Bi_r\cdot Fo - 2Fo\right)T_o^p. \qquad (6) <$$

(b) The stability criterion for Eq. (6) requires that the coefficient of T_o^p be positive.

$$1 - 2Fo\left(Bi + Bi_r + 1\right) \geq 0 \qquad \text{or} \qquad Fo \leq 1/2\left(Bi + Bi_r + 1\right). \qquad (7) <$$

The stability criterion for an interior node, Eq. 5.82, is $Fo \leq 1/2$. Since $Bi + Bi_r > 0$, the stability criterion of the surface node is more restrictive. Note that Bi_r is not constant but depends upon h_r which increases with increasing T_o^p (time). Hence, the restriction on Fo increases with increasing T_o^p (time).

Continued …

PROBLEM 5.126 (Cont.)

(c) Consider the prescribed conditions with negligible convection (Bi = 0). The FDEs for the thick slab are:

Surface (0) $$T_o^{p+1} = 2Fo\left(Bi \cdot Fo + Bi_r \cdot T_{sur} + T_1^p\right) + \left(1 - 2Bi \cdot Fo - 2Bi_r \cdot Fo - 2Fo\right)T_o^p \qquad (8)$$

Interior (m≥1) $$T_m^{p+1} = Fo\left(T_{m+1}^p + T_{m-1}^p\right) + \left(1 - 2Fo\right)T_m^p \qquad (9,5,7,3)$$

The stability criterion from Eq. (7) with Bi = 0 is,

$$Fo \le 1/2\left(1 + Bi_r\right) \qquad (10)$$

To proceed with the explicit, marching solution, we need to select a value of Δt (Fo) that will satisfy the stability criterion. A few trial calculations are helpful. A value of Δt = 15s provides Fo = 0.105, and using Eqs. (2) and (5), h_r(300K, 1000K) = 72.3 W/m^2·K and Bi_r = 0.482. From the stability criterion, Eq. (10), find Fo ≤ 0.337. With increasing T_o^p, h_r and Bi_r increase: h_r(800K, 1000K) = 150.6 W/m^2·K, Bi_r = 1.004 and Fo ≤ 0.249. Hence, if $T_o^p < 800K$, $\Delta t = 15s$ or $Fo = 0.105$ satisfies the stability criterion.

Using Δt = 15s or Fo = 0.105 with the FDEs, Eqs. (8) and (9), the results of the solution are tabulated below. Note how h_r^p and Bi_r^p are evaluated at each time increment. Note that t = p·Δt, where Δt = 15s.

p	t(s)	T_o / h_r^p / Bi_r	T1(K)	T_2	T_3	T_4	….
0	0	300 72.3 0.482	300	300	300	300	
1	15	370.867 79.577 0.5305	300	300	300	300	
2	30	426.079 85.984 0.5733	307.441	300	300	300	
3	45	470.256 91.619 0.6108	319.117	300.781	300	300	
4	60	502.289	333.061	302.624	300.082	300	

After 60s(p = 4), T_o(0, 1 min) = 502.3K and T_3(30mm, 1 min) = 300.1K. <

COMMENTS: (1) The form of the FDE representing the surface node agrees with Eq. 5.90 if this equation is reduced to one-dimension.

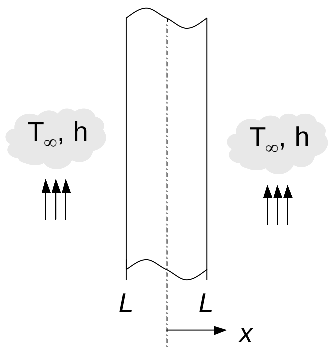
(2) We should recognize that the Δt = 15s time increment represents a coarse step. To improve the accuracy of the solution, a smaller Δt should be chosen.

PROBLEM 5.127

KNOWN: One-dimensional convective heating and cooling of a plane slab with $Bi_1 = 10$ (for Heating Phase 1, beginning at $Fo = 0$ and ending at $Fo = Fo_1 = 0.1$), $Bi_2 = 1$ (for Cooling Phase 2, beginning at $Fo = Fo_1$).

FIND: (a) Dimensionless form of the heat equation, initial and boundary conditions for Phase 1, (b) Dimensionless form of the heat equation, initial and boundary conditions for Phase 2, (c) Finite difference solution for θ_0^* ($x^* = 1$, Fo), θ_0^* ($x^* = 0$, Fo) and θ_0^* ($x^* = 0.5$, Fo) for $Fo_1 = 0.1$ over the range $0 \le Fo \le 0.5$ using $\Delta x^* = 0.1$ and $\Delta Fo = 0.001$, (d) Value of and time associated with the minimum dimensionless temperature at the midplane of the wall.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties.

ANALYSIS: (a) The dimensionless forms of the heat equation, initial and boundary conditions for Phase 1 are given by Eqs. 5.37 through 5.40,

$$\frac{\partial^2\theta^*}{\partial x^{*2}} = \frac{\partial\theta^*}{\partial Fo} \quad ; \quad \theta^*(x^*,0) = 1 \quad ; \quad \left.\frac{\partial\theta^*}{\partial x^*}\right|_{x^*=0} = 0 \quad ; \quad \left.\frac{\partial\theta^*}{\partial x^*}\right|_{x^*=1} = -Bi_1\theta^*(1, Fo)$$ <

where $\theta^* = (T - T_{\infty,1})/(T_i - T_{\infty,1})$, $x^* = x/L$, $Fo = \alpha t/L^2$ and $Bi_1 = h_1L/k$.

(b) For cooling (Phase 2), the dimensionless form of the heat equation and the boundary condition at $x^* = 0$ are unchanged from part (a). However, the initial condition for Phase 2 is the temperature distribution that exists at the conclusion of Phase 1, $\theta^*(x^*, Fo = Fo_1)$ and the boundary condition at $x^* = 1$ is derived beginning with the energy balance at the $x^* = 1$ control surface, < <

$$-k\left.\frac{\partial T}{\partial x}\right|_{x=L} = h_2\left[T(L,t) - T_{\infty,2}\right] = h_2\left[T(L,t) - T_i\right]$$

Substituting the expressions $T = \theta^*(T_i - T_{\infty,1}) + T_{\infty,1}$ and $x = x^*L$ into the preceding equation yields

$$-k\frac{\partial\left[T_{\infty,1} + \theta^*(T_i - T_{\infty,1})\right]}{\partial(x^*L)} = h_2\left[T_{\infty,1} + \theta^*(T_i - T_{\infty,1}) - T_i\right]$$

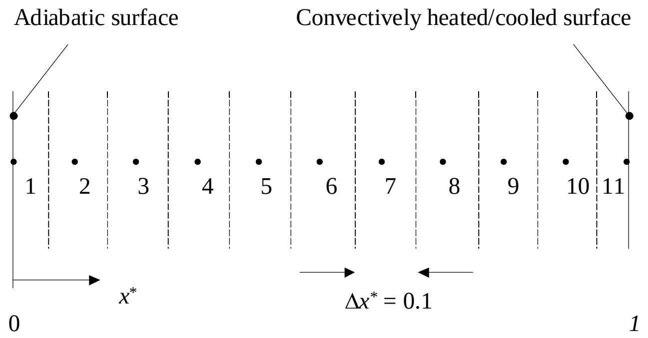
which may be simplified to

Continued…

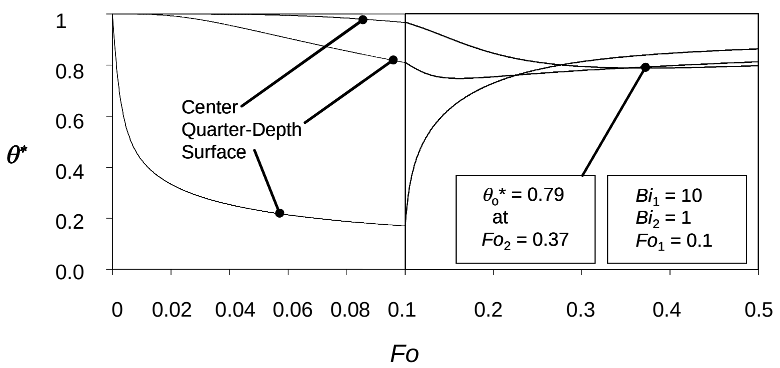
PROBLEM 5.127 (Cont.)

$$\frac{\partial \theta^*}{\partial x^*} = -\frac{h_2 L}{k(T_i - T_{\infty,1})}\left[(T_{\infty,1} - T_i) + \theta^*(T_i - T_{\infty,1})\right]$$
$$= -\frac{h_2 L}{k}\left[\theta^* - 1\right] = Bi_2\left[1 - \theta^*\right]$$ <

(c) The dimensionless form of the energy equation, based upon the discretization shown below, was solved using IHT software. The IHT code is included in the comments.



The thermal response is shown in the graph below.



Note that the surface heats quickly in Phase 1 (θ^* decreases rapidly) while the center midplane temperature changes only slightly over the heating time. The quarter plane (or quarter depth) temperature increases at an intermediate rate during heating. During cooling (Phase 2), the surface cools rapidly, but, as noted during heating, it takes some time for inner regions of the wall to begin changing in temperature in response to the new boundary conditions. Warm temperatures in the inner regions of the wall continue to propagate to the midplane, increasing its temperature until a maximum temperature is reached. The cooling response is slower than the heating response since $Bi_2 < Bi_1$. Ultimately (not shown), the entire wall will return to its initial temperature of $\theta^* = 1$.

(d) The minimum dimensionless temperature at the midplane may be determine by inspecting the predictions of the finite difference model. The minimum midplane temperature is $\theta^* = 0.79$, and occurs at $Fo = Fo_2 = 0.37$, as shown in the figure of part (c).

//(th10 - th11)/dx - Bi2*(th11 - 1) = (dx/2)*der(th11,Fo)
```

Continued…

PROBLEM 5.127 (Cont.)

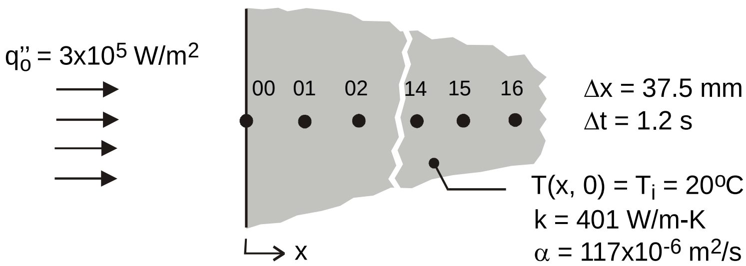
(2) If one is interested in determining the maximum midplane temperature in response to heating, recognize that this maximum value does not occur at the moment heating is stopped. In this problem, the increase in the midplane temperature from the onset of heating to the curtailment of heating is $\Delta\theta^*(x^* = 0, Fo_1 = 0.1) = 0.033$ whereas the maximum change in the midplane temperature is $\Delta\theta^*(x^* = 0, Fo_2 = 0.37) = 0.212$ which is 6 times larger than the increase at Fo_1. Furthermore, maximum midplane temperatures are reached long after heating is stopped and cooling begins ($Fo_2/Fo_1 = 3.7$). (3) The effects illustrated in this problem, specifically the continued heating of inner regions of the wall and the long time delay before maximum wall temperatures are reached after heating has stopped and cooling has begun, are important in many applications including materials processing, food processing and thermal sterilization, and structural response (building collapse) to fire long after the fire is extinguished. (4) See Bergman, "Extreme Midplane Wall Temperatures due to Sequential Heating and Cooling, *ASME Journal of Heat Transfer*, vol. 130, pp. 094503-1 to 094503-4, 2008 for more information.

PROBLEM 5.128

KNOWN: Thick slab of copper, initially at a uniform temperature, is suddenly exposed to a constant net radiant flux at one surface. See Example 5.12.

FIND: (a) The nodal temperatures at nodes 00 and 04 at t = 120 s; that is, T00(0, 120 s) and T04(0.15 m, 120 s); compare results with those given by the exact solution in Comment 1; will a time increment of 0.12 s provide more accurate results?; and, (b) Plot the temperature histories for x = 0, 150 and 600 mm, and explain key features of your results. Use the *IHT Tools | Finite-Difference Equations | One-Dimensional | Transient* conduction model builder to obtain the implicit form of the FDEs for the interior nodes. Use space and time increments of 37.5 mm and 1.2 s, respectively, for a 17-node network. For the surface node 00, use the FDE derived in Section 2 of the Example.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in the x-direction, (2) Slab of thickness 600 mm approximates a semi-infinite medium, and (3) Constant properties.

ANALYSIS: The IHT model builder provides the implicit-method FDEs for the interior nodes, 01 – 15. The +x boundary condition for the node-16 control volume is assumed adiabatic. The FDE for the surface node 00 exposed to the net radiant flux was derived in the Example analysis. Selected portions of the IHT code used to obtain the following results are shown in the Comments.

(a) The 00 and 04 nodal temperatures for t = 120 s are tabulated below using a time increment of Δt = 1.2 s and 0.12 s, and compared with the results given from the exact analytical solution, Eq. 5.62.

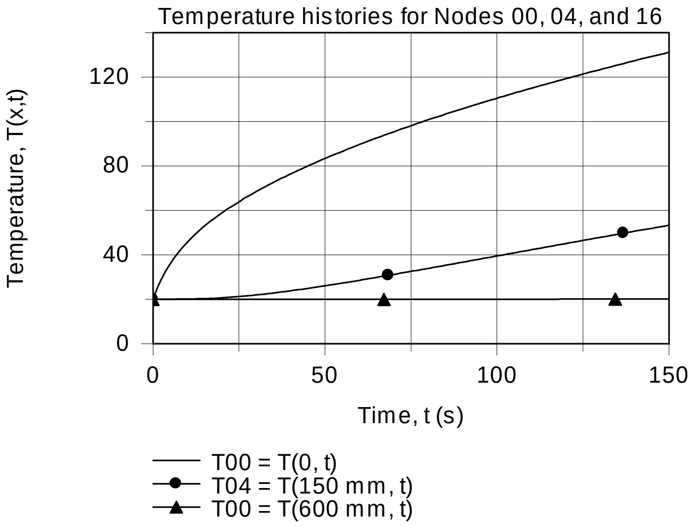
Node	FDE results (°C)		Analytical result (°C)
	Δt = 1.2 s	Δt = 0.12 s	Eq. 5.59
00	119.3	119.4	120.0
04	45.09	45.10	45.4

The numerical FDE-based results with the different time increments agree quite closely with one another. At the surface, the numerical results are nearly 1°C less than the result from the exact analytical solution. This difference represents an error of -1% (-1 °C / (120 – 20) °C x 100). At the x = 150 mm location, the difference is about -0.4 °C, representing an error of –1.5%. For this situation, the smaller time increment (0.12 s) did not provide improved accuracy. To improve the accuracy of the numerical model, it would be necessary to reduce the space increment, in addition to using the smaller time increment.

(b) The temperature histories for x = 0, 150 and 600 mm (nodes 00, 04, and 16) for the range 0 ≤ t ≤ 150 s are as follows.

Continued …

PROBLEM 5.128 (Cont.)



As expected, the surface temperature, T00 = T(0,t), increases markedly at early times. As thermal penetration increases with increasing time, the temperature at the location x = 150 mm, T04 = T(150 mm, t), begins to increase after about 20 s. Note, however, the temperature at the location x = 600 mm, T16 = T(600 mm, t), does not change significantly within the 150 s duration of the applied surface heat flux. Our assumption of treating the +x boundary of the node 16 control volume as adiabatic is justified. A copper plate of 600-mm thickness is a good approximation to a semi-infinite medium at times less than 150 s.

COMMENTS: Selected portions of the *IHT* code with the nodal equations to obtain the temperature distribution are shown below. Note how the FDE for node 00 is written in terms of an energy balance using the *der (T,t)* function. The FDE for node 16 assumes that the "east" boundary is adiabatic.

```
// Finite-difference equation, node 00; from Examples solution derivation; implicit method

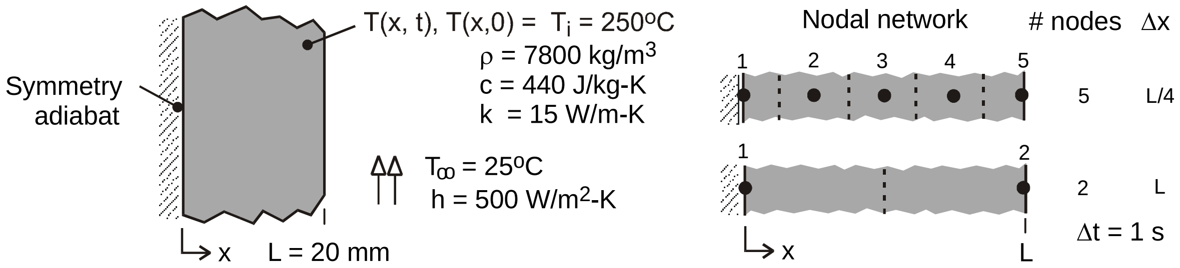
h16 = 1e-8          // Causes boundary to behave as adiabatic
```

PROBLEM 5.129

KNOWN: Plane wall of thickness 2L, initially at a uniform temperature, is suddenly subjected to convection heat transfer.

FIND: The mid-plane, T(0,t), and surface, T(L,t), temperatures at t = 50, 100, 200 and 500 s, using the following methods: (a) the one-term series solution; determine also the Biot number; (b) the lumped capacitance solution; and (c) the two- and 5-node finite-difference numerical solutions. Prepare a table summarizing the results and comment on the relative differences of the predicted temperatures.

SCHEMATIC:



(a) Plane wall, thickness 2L (b) Nodal networks

ASSUMPTIONS: (1) One-dimensional conduction in the x-direction, and (2) Constant properties.

ANALYSIS: (a) The results are tabulated below for the mid-plane and surface temperatures using the one-term approximation to the series solution, Eq. 5.43 and 5.44. The Biot number for the heat transfer process is

$$Bi = h\ L/k = 500\ W/m^2 \cdot K \times 0.020\ m/15\ W/m \cdot K = 0.67$$

Since Bi >> 0.1, we expect an appreciable temperature difference between the mid-plane and surface, as the tabulated results indicate.

(b) The results are tabulated below for the wall temperatures using the lumped capacitance method (LCM) of solution, Eq. 5.6. The LCM neglects the internal conduction resistance and since Bi = 0.67 >> 0.1, we expect this method to predict systematically lower temperatures (faster cooling) at the midplane compared to the one-term approximation.

Solution method/Time(s)	50	100	200	500

(c) The 2- and 5-node nodal networks representing the wall are shown in the schematic above. The implicit form of the finite-difference equations for the mid-plane, interior (if present) and surface nodes can be derived from energy balances on the nodal control volumes. The time-rate of change of the temperature is expressed in terms of the *IHT* integral intrinsic function, *der*(*T*,*t*).

Continued …

PROBLEM 5.129 (Cont.)

Mid-plane node

$$k(T2-T1)/\Delta x = \rho c(\Delta x/2)\cdot der(T1,t)$$

Interior node (5-node network)

$$k(T1-T2)/\Delta x + k(T3-T2)/\Delta x = \rho c\,\Delta x\cdot der(T2,t)$$

Surface node (shown for 5-node network)

$$k(T4-T5)/\Delta x + h(T\inf - T5) = \rho c(\Delta x/2)\cdot der(T5,t)$$

With appropriate values for Δx, the foregoing FDEs were entered into the *IHT* workspace and solved for the temperature distributions as a function of time over the range $0 \le t \le 500$ s using an integration time step of 1 s. Selected portions of the *IHT* codes for each of the models are shown in the Comments. The results of the analysis are summarized in the foregoing table.

COMMENTS: (1) Referring to the table above, we can make the following observations about the relative differences and similarities of the estimated temperatures: (a) The one-term series model estimates are the most reliable, and can serve as the benchmark for the other model results; (b) The LCM model over estimates the rate of cooling, and poorly predicts temperatures since the model neglects the effect of internal resistance and Bi = 0.67 >> 0.1; (c) The 5-node model results are in excellent agreement with those from the one-term series solution; we can infer that the chosen space and time increments are sufficiently small to provide accurate results; and (d) The 2-node model under estimates the rate of cooling for early times when the time-rate of change is high; but for late times, the agreement is improved.

(2) See the *Solver | Intrinsic Functions* section of *IHT|Help* or the *IHT Examples* menu (Example 5.3) for guidance on using the *der(T,t)* function.

(3) Selected portions of the *IHT* code for the 2-node network model are shown below.

```
// Writing the finite-difference equations – 2-node model
//  Node 1
k * (T2 - T1)/ deltax  = rho * cp * (deltax / 2) * der(T1,t)
// Node 2
k * (T1 - T2)/ deltax  + h * (Tinf - T2) = rho * cp * (deltax / 2) * der(T2,t)

// Input parameters
L = 0.020
deltax = L
rho = 7800          // density, kg/m^3
cp =   440          // specific heat, J/kg·K
k = 15              // thermal conductivity, W/m.K
h =   500           // convection coefficient, W/m^2·K
Tinf = 25           // fluid temperature, K
```

(4) Selected portions of the IHT code for the 5-node network model are shown below.

```
// Writing the finite-difference equations – 5-node model
//  Node 1 - midplane
k * (T2 - T1)/ deltax  = rho * cp * (deltax / 2) * der(T1,t)
// Interior nodes
k * (T1 - T2)/ deltax +  k * (T3 - T2 )/ deltax = rho * cp * deltax  * der(T2,t)
k * (T2 - T3)/ deltax +  k * (T4 - T3 )/ deltax = rho * cp * deltax  * der(T3,t)
k * (T3 - T4)/ deltax +  k * (T5 - T4 )/ deltax = rho * cp * deltax  * der(T4,t)
// Node5 - surface
k * (T4 - T5)/ deltax + h * (Tinf - T5) = rho * cp * (deltax / 2) * der(T5,t)

// Input parameters

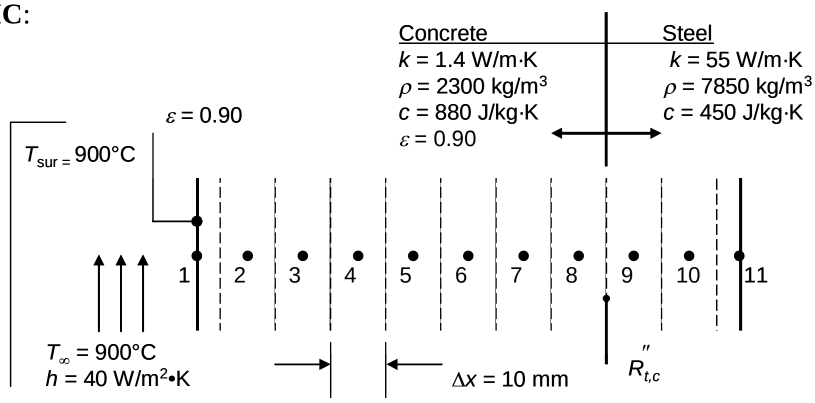
PROBLEM 5.130

KNOWN: Dimensions and properties of a steel-reinforced concrete pillar. Initial, ambient and surroundings temperatures. Values of convection heat transfer coefficient and contact resistance.

FIND: (a) Temperature of the exposed concrete surface and the center of the steel plate at t = 10,000 s without contact resistance, maximum and minimum concrete and steel temperatures for $0 \le t \le$ 10,000 s, (b) same as (a) but with contact resistance, (c) critical times associated with maximum steel temperatures, value of the maximum steel temperature, for cases with and without thermal contact resistance, after the fire is extinguished.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties.

ANALYSIS: We begin by writing energy balances on each of the 11 control volumes, taking advantage of the symmetry of the problem,

Node 1: $$\rho_c c_c \frac{\Delta x}{2}\frac{\left(T_1^{p+1}-T_1^{p}\right)}{\Delta t} = (h+h_r)(T_\infty - T_1^{p+1}) + \frac{k_c(T_2^{p+1}-T_1^{p+1})}{\Delta x}$$

where $$h_r = \varepsilon\sigma\left(T_{\text{sur}} + T_1^{p+1}\right)\left(T_{\text{sur}}^2 + \left[T_1^{p+1}\right]^2\right)$$ and $T_{\text{sur}} = T_\infty$.

Nodes 2 – 7: $$\rho_c c_c \Delta x \frac{\left(T_i^{p+1}-T_i^{p}\right)}{\Delta t} = \frac{k_c(T_{i-1}^{p+1}-T_i^{p+1})}{\Delta x} + \frac{k_c(T_{i+1}^{p+1}-T_i^{p+1})}{\Delta x}$$

Node 8: $$\rho_c c_c \Delta x \frac{\left(T_8^{p+1}-T_8^{p}\right)}{\Delta t} = \frac{(T_9^{p+1}-T_8^{p+1})}{R''_{\text{tot}}} + \frac{k_c(T_7^{p+1}-T_8^{p+1})}{\Delta x}$$

where $$R''_{\text{tot}} = \frac{\Delta x/2}{k_c} + \frac{\Delta x/2}{k_s} + R''_{t,c}$$

Node 9: $$\rho_s c_s \Delta x \frac{\left(T_9^{p+1}-T_9^{p}\right)}{\Delta t} = \frac{(T_8^{p+1}-T_9^{p+1})}{R''_{\text{tot}}} + \frac{k_s(T_{10}^{p+1}-T_9^{p+1})}{\Delta x}$$

Continued…

PROBLEM 5.130 (Cont.)

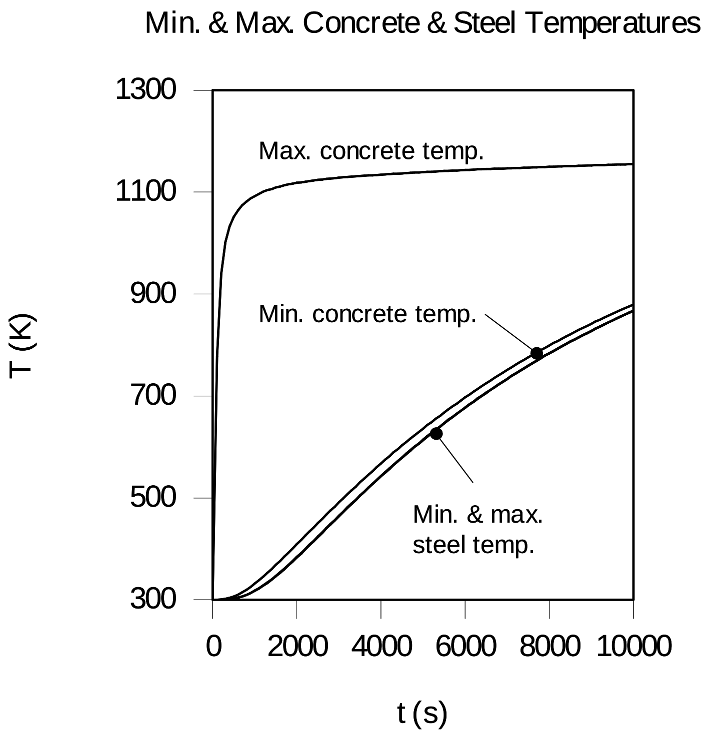
Node 10: $$\rho_s c_s \Delta x \frac{\left(T_{10}^{p+1} - T_{10}^{p}\right)}{\Delta t} = \frac{k_s (T_9^{p+1} - T_{10}^{p+1})}{\Delta x} + \frac{k_s (T_{11}^{p+1} - T_{10}^{p+1})}{\Delta x}$$

Node 11: $$\rho_s c_s \frac{\Delta x}{2} \frac{\left(T_{11}^{p+1} - T_{11}^{p}\right)}{\Delta t} = \frac{k_s (T_{10}^{p+1} - T_{11}^{p+1})}{\Delta x}$$

IHT is used to solve the equations; the IHT code is included in the Comments. Note that the expression $(T_i^{p+1} - T_i^{p})/\Delta t$ in the preceding equations is expressed as der(T_i, t) in the IHT code.

(a) Solving the finite difference equations without the contact resistance results in the following values at t = 10,000 s.

T_1 = 1155 K = 882°C, T_{11} = 867 K = 594°C <



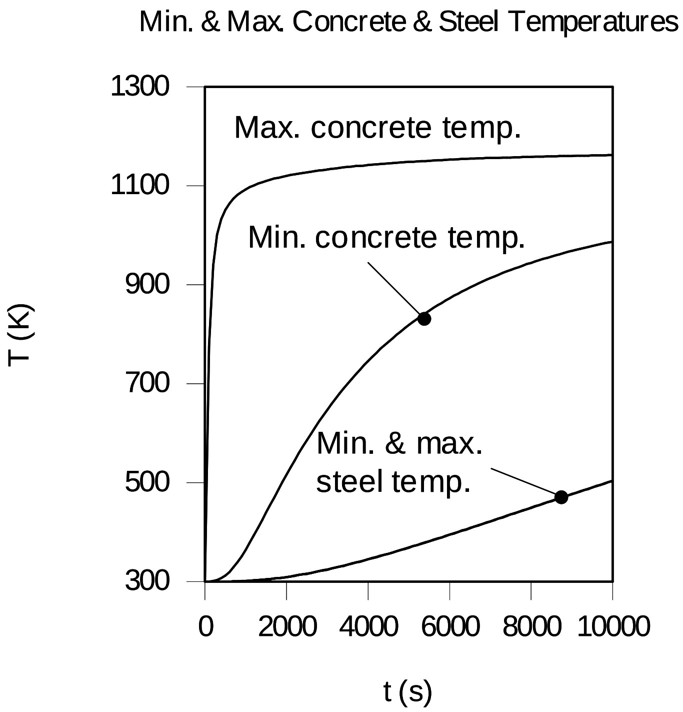
Due to the high thermal conductivity of the steel, the steel is of nearly uniform temperature, with local values varying to within one degree Celsius at any time. There is a large temperature difference between the minimum and maximum concrete temperatures.

(b) Including the contact resistance value of $R''_{t,c}$ = 0.20 $m^2 \cdot K/W$ yields, at t = 10,000 s,

T_1 = 1162 K = 889°C, T_{11} = 504 K = 231°C <

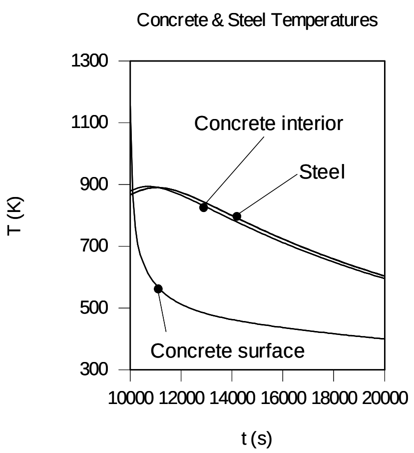
Continued…

PROBLEM 5.130 (Cont.)

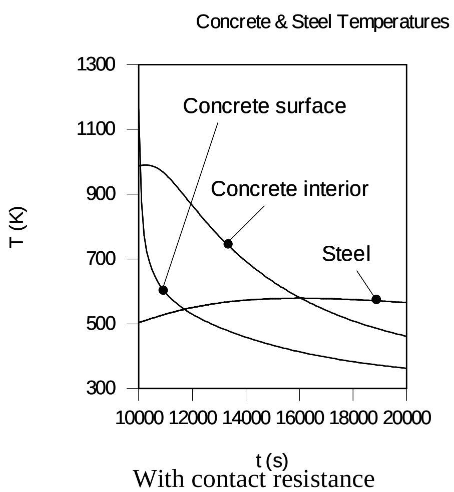


Again, due to the high thermal conductivity of the steel, the steel is isothermal to within one degree Celsius at any time. There is a large temperature difference between the minimum and maximum concrete temperatures. The temperature difference across the contact resistance is significant resulting in much lower steel temperatures than in part (a).

(c) Using the nodal temperatures at t = 10,000s as initial values, the simulation is repeated with T_∞ = T_{sur} = 300K, yielding the following results without and with the thermal contact resistance, respectively. The critical times are $t_{crit,wo}$ = 11,100s with $T_{steel,\ max,\ w}$ = 890.6K = 617.5°C and $t_{crit,w}$ = 16,000s with $T_{steel,\ max,\ w}$ = 578.7K = 305.7°C with the contact resistance. $<$



Without contact resistance



With contact resistance

//Node 11

rhos*cps*(deltax/2)*der(T11,t) =(ks/deltax)*(T10 - T11)
```

(2). The influence of the thermal contact resistance is significant in terms of both the maximum steel temperatures, as well as the critical time at which the maximum steel temperatures occur. (3) With or without the contact resistance, the maximum steel temperatures occur well after the fire is extinguished, as warm temperatures stored within the concrete slowly propagate into the steel plate. Firefighters need to be very cautious entering the building after the fire is extinguished, since structural failure may occur many hours after the fire is extinguished. (3) The minimum concrete temperature is actually equal to the maximum steel temperature in part (a). The difference between the two quantities, evident in the plot, would decrease as the spatial resolution of the simulation is increased. (5) Nodal temperatures (K) at t = 10,000 s are as follows.

Node	1	2	3	4	5	6	7	8	9	10	11
	Without Contact Resistance										
	1155	1108	1063	1019	979	941	908	879	867.4	867.0	866.9
	With Contact Resistance

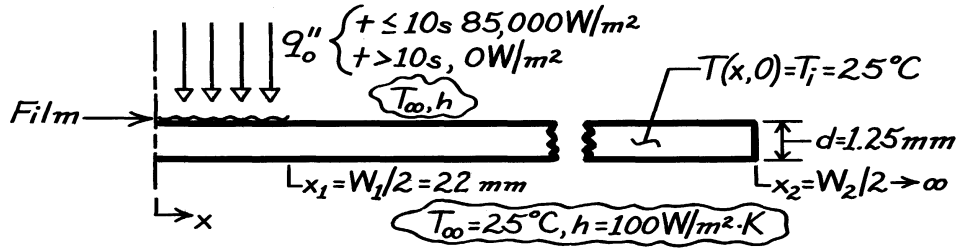
PROBLEM 5.131

KNOWN: Plastic film on metal strip initially at 25°C is heated by a laser (85,000 W/m^2 for Δt_{on} = 10 s), to cure adhesive; convection conditions for ambient air at 25°C with coefficient of 100 W/m^2·K.

FIND: Temperature histories at center and film edge, T(0,t) and T(x_1,t), for 0 ≤ t ≤ 30 s, using an implicit, finite-difference method with Δx = 4mm and Δt = 1 s; determine whether adhesive is cured (T_c ≥ 90°C for Δt_c = 10s) and whether the degradation temperature of 200°C is exceeded.

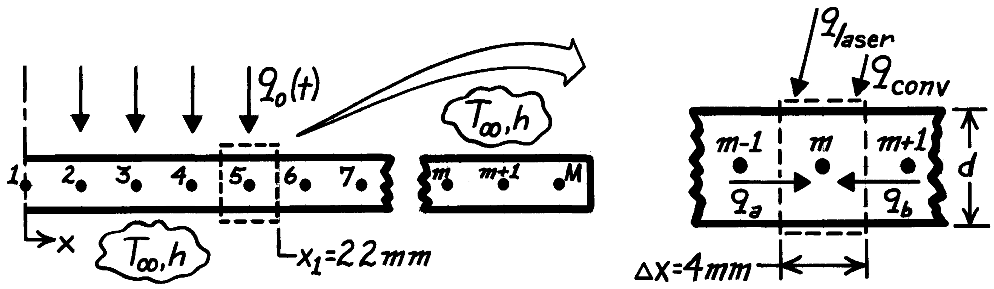
SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Uniform convection coefficient on upper and lower surfaces, (4) Thermal resistance and mass of plastic film are negligible, (5) All incident laser flux is absorbed.

PROPERTIES: Metal strip (given): ρ = 7850 kg/m^3, c_p = 435 J/kg·K, k = 60 W/m·K, α = k/ρc_p = 1.757 × 10^{-5} m^2/s.

ANALYSIS: (a) Using a space increment of Δx = 4mm, set up the nodal network shown below. Note that the film half-length is 22mm (rather than 20mm as in Problem 3.115).



Consider the general control volume and use the conservation of energy requirement to obtain the finite-difference equation.

$$\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st}$$

$$q_a + q_b + q_{laser} + q_{conv} = Mc_p \frac{T_m^{p+1} - T_m^p}{\Delta t}$$

Continued …

PROBLEM 5.131 (Cont.)

$$k(d\cdot 1)\frac{T_{m-1}^{p+1}-T_m^{p+1}}{\Delta x}+k(d\cdot 1)\frac{T_{m+1}^{p+1}-T_m^{p+1}}{\Delta x}$$

$$+q_o''(\Delta x\cdot 1)+2h(\Delta x\cdot 1)\left(T_\infty-T_m^{p+1}\right)=\rho(\Delta x\cdot d\cdot 1)c_p\frac{T_m^{p+1}-T_m^p}{\Delta t}$$

$$T_m^p=(1+2Fo+2Fo\cdot Bi)T_m^{p+1} \quad (1)$$

$$-Fo\left(T_{m+1}^{p+1}+T_{m+1}^{p+1}\right)-2Fo\cdot Bi\cdot T_\infty-Fo\cdot Q$$

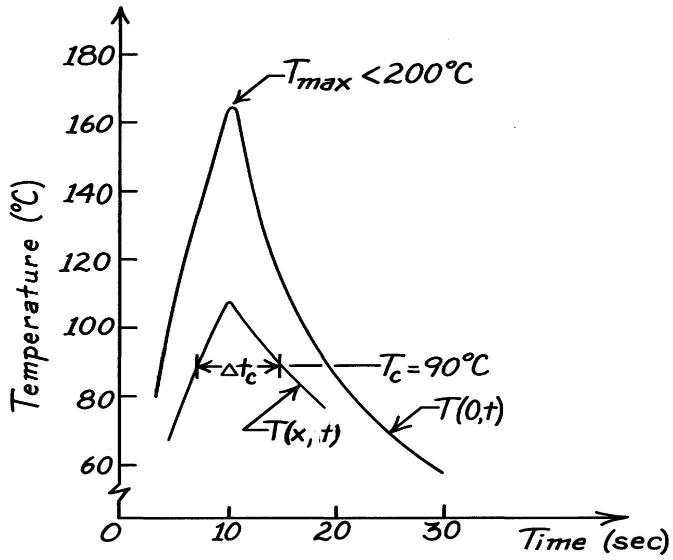
where

$$Fo=\frac{\alpha\Delta t}{\Delta x^2}=\frac{1.757\times10^{-5}m^2/s\times1s}{(0.004\ m)^2}=1.098 \quad (2)$$

$$Bi=\frac{h\left(\Delta x^2/d\right)}{k}=\frac{100\ W/m^2\cdot K\left(0.004^2/0.00125\right)m}{60\ W/m\cdot K}=0.0213 \quad (3)$$

$$Q=\frac{q_o''\left(\Delta x^2/d\right)}{k}=\frac{85,000\ W/m^2\left(0.004^2/0.00125\right)m}{60\ W/m\cdot K}=18.133. \quad (4)$$

The results of the matrix inversion numerical method of solution (Δx = 4mm, Δt = 1s) are shown below. The temperature histories for the center (m = 1) and film edge (m = 5) nodes, T(0,t) and T(x_1,t), respectively, permit determining whether the adhesive has cured (T ≥ 90°C for 10 s).



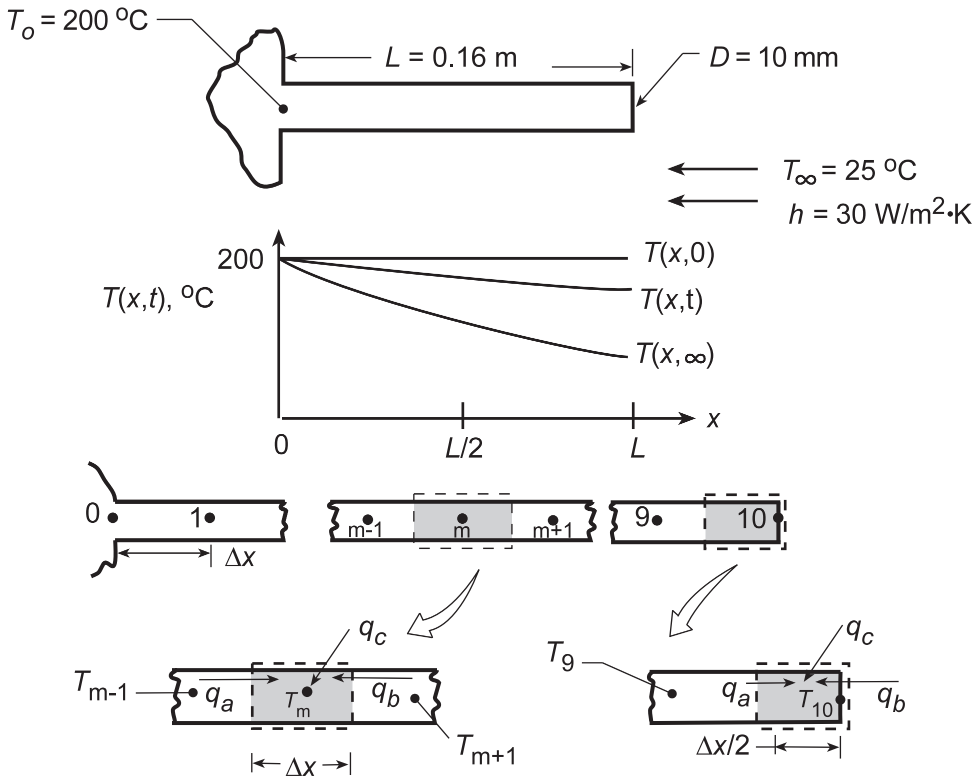
Certainly the center region, T(0,t), is fully cured and furthermore, the degradation temperature (200°C) has not been exceeded. From the T(x_1,t) distribution, note that $\Delta t_c \approx 8$ sec, which is 20% less than the 10 s interval sought. Hence, the laser exposure (now 10 s) should be slightly increased and quite likely, the maximum temperature will not exceed 200°C.

PROBLEM 5.132

KNOWN: Insulated rod of prescribed length and diameter, with one end in a fixture at 200°C, reaches a uniform temperature. Suddenly the insulating sleeve is removed and the rod is subjected to a convection process.

FIND: (a) Time required for the mid-length of the rod to reach 100°C, (b) Temperature history $T(x,t \leq t_1)$, where t_1 is time at which the midlength reaches 50°C. Temperature distribution at 0, 200s, 400s and t_1.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional transient conduction in rod, (2) Uniform h along rod and at end, (3) Negligible radiation exchange between rod and surroundings, (4) Constant properties.

ANALYSIS: (a) Choosing Δx = 0.016 m, the finite-difference equations for the interior and end nodes are obtained.

Interior Point, m:
$$q_a + q_b + q_c = \rho \cdot A_c \Delta x \cdot c_p \cdot \frac{T_m^{p+1} - T_m^p}{\Delta t}$$

$$k \cdot A_c \frac{T_{m-1}^p - T_m^p}{\Delta x} + kA_c \frac{T_{m+1}^p - T_m^p}{\Delta x} + hP\Delta x\left(T_\infty - T_m^p\right) = \rho A_c \Delta x c_p \frac{T_m^{p+1} - T_m^p}{\Delta t}$$

Regrouping,

$$T_m^{p+1} = T_m^p\left(1 - 2Fo - Bi \cdot Fo\right) + Fo\left(T_{m-1}^p + T_{m+1}^p\right) + Bi \cdot FoT_\infty \qquad (1)$$

where

$$Fo = \frac{\alpha \Delta t}{\Delta x^2} \qquad (2) \qquad\qquad Bi = h\left[\Delta x^2 / \left(A_c / P\right)\right] / k. \qquad (3)$$

From Eq. (1), recognize that the stability of the numerical solution will be assured when the first term on the RHS is positive; that is

Continued...

PROBLEM 5.132 (Cont.)

$$\left(1-2Fo-Bi\cdot Fo\right)\geq 0 \qquad \text{or} \qquad Fo\leq 1/\left(2+Bi\right). \tag{4}$$

Nodal Point 1: Consider Eq. (1) for the special case that T_{m-1}^{p} = T_o, which is independent of time. Hence,

$$T_1^{p+1}=T_1^p\left(1-2Fo-Bi\cdot Fo\right)+Fo\left(T_o+T_2^p\right)+Bi\cdot FoT_\infty . \tag{5}$$

End Nodal Point 10: $$q_a+q_b+q_c=\rho\cdot A_c\frac{\Delta x}{2}\cdot c_p\frac{T_{10}^{p+1}-T_{10}^{p}}{\Delta t}$$

$$k\cdot A_c\frac{T_9^p-T_{10}^p}{\Delta x}+hA_c\left(T_\infty-T_{10}^p\right)+hP\frac{\Delta x}{2}\left(T_\infty-T_{10}^p\right)=\rho A_c\frac{\Delta x}{2}c_p\frac{T_{10}^{p+1}-T_{10}^{p}}{\Delta t}$$

Regrouping, $T_{10}^{p+1}=T_{10}^p\left(1-2Fo-2N\cdot Fo-Bi\cdot Fo\right)+2FoT_9^p+T_\infty\left(2N\cdot Fo+Bi\cdot Fo\right)$ (6)

where $N = h\Delta x/k$. (7)

The stability criterion is $Fo \leq 1/2(1 + N + Bi/2)$. (8)

With the finite-difference equations established, we can now proceed with the numerical solution. Having already specified $\Delta x = 0.016$ m, Bi can now be evaluated. Noting that $A_c = \pi D^2/4$ and $P = \pi D$, giving $A_c/P = D/4$, Eq. (3) yields

$$Bi=30\,W/m^2\cdot K\left[\left(0.016\,m\right)^2\Big/\frac{0.010\,m}{4}\right]\Big/14.8\,W/m\cdot K=0.208 \tag{9}$$

From the stability criteria, Eqs. (4) and (8), for the finite-difference equations, it is recognized that Eq. (8) requires the greater value of Fo. Hence

$$Fo=\frac{1}{2}\left(1+0.0324+\frac{0.208}{2}\right)=0.440 \tag{10}$$

where from Eq. (7), $N=\dfrac{30\,W/m^2\cdot K\times 0.016\,m}{14.8\,W/m\cdot K}=0.0324$. (11)

From the definition of Fo, Eq. (2), we obtain the time increment

$$\Delta t=\frac{Fo\left(\Delta x\right)^2}{\alpha}=0.440\left(0.016\,m\right)^2\Big/3.63\times 10^{-6}\,m^2/s=31.1s \tag{12}$$

and the time relation is $t = p\Delta t = 31.1t$. (13)

Using the numerical values for Fo, Bi and N, the finite-difference equations can now be written (°C).

Nodal Point m ($2 \leq m \leq 9$):

$$T_m^{p+1}=T_m^p\left(1-2\times 0.440-0.208\times 0.440\right)+0.440\left(T_{m-1}^p+T_{m+1}^p\right)+0.208\times 0.440\times 25$$

$$T_m^{p+1}=0.029T_m^p+0.440\left(T_{m-1}^p+T_{m+1}^p\right)+2.3 \tag{14}$$

Nodal Point 1:

$$T_1^{p+1}=0.029T_1^p+0.440\left(200+T_2^p\right)+2.3=0.029T_1^p+0.440T_2^p+90.3 \tag{15}$$

Nodal Point 10:

$$T_{10}^{p+1}=0\times T_{10}^p+2\times 0.440T_9^p+25\left(2\times 0.0324\times 0.440+0.208\times 0.440\right)=0.880T_9^p+3.0 \tag{16}$$

Continued...

PROBLEM 5.132 (Cont.)

Using finite-difference equations (14-16) with Eq. (13), the calculations may be performed to obtain

p	t(s)	T_1	T_2	T_3	T_4	T_5	T_6	T_7	T_8	T_9	T_{10}(°C)

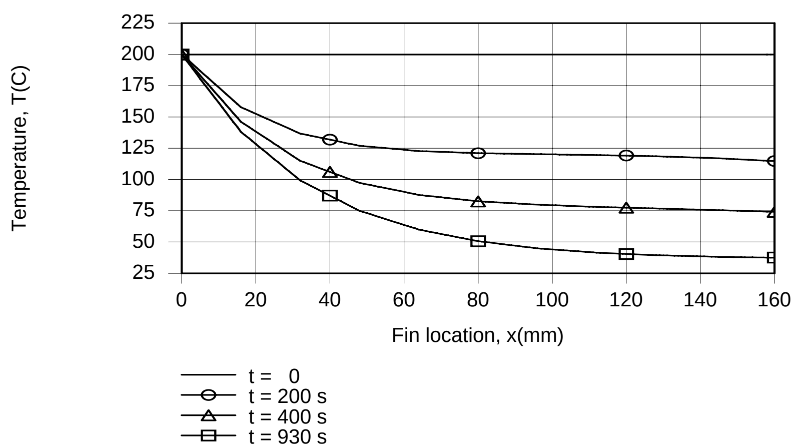
Using linear interpolation between rows 7 and 8, we obtain $T(L/2, 230s) = T_5 \approx 100°C$. <

(b) Using the option concerning *Finite-Difference Equations* for *One-Dimensional Transient Conduction* in *Extended Surfaces* from the IHT Toolpad, the desired temperature histories were computed for $0 \le t \le t_1 = 930s$. A *Lookup Table* involving data for T(x) at t = 0, 200, 400 and 930s was created.

t(s)/x(mm)	0	16	32	48	64	80	96	112	128	144	160
0	200	200	200	200	200	200	200	200	200	200	200
200	200	157.8	136.7	127.0	122.7	121.0	120.2	119.6	118.6	117.1	114.7
400	200	146.2	114.9	97.32	87.7	82.57	79.8	78.14	76.87	75.6	74.13
930	200	138.1	99.23	74.98	59.94	50.67	44.99	41.53	39.44	38.2	37.55

and the *LOOKUPVAL2* interpolating function was used with the *Explore* and *Graph* feature of IHT to create the desired plot.



Temperatures decrease with increasing x and t, and except for early times (t < 200s) and locations in proximity to the fin tip, the magnitude of the temperature gradient, |dT/dx|, decreases with increasing x. The slight increase in |dT/dx| observed for t = 200s and $x \rightarrow 160$ mm is attributable to significant heat loss from the fin tip.

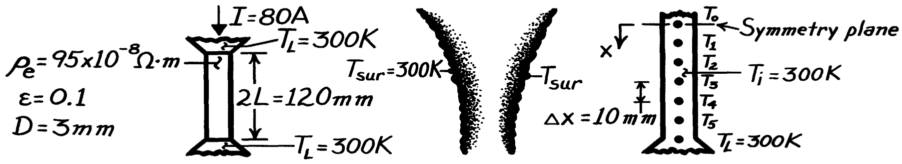
COMMENTS: The steady-state condition may be obtained by extending the finite-difference calculations in time to $t \approx 2650s$ or from Eq. 3.75.

PROBLEM 5.133

KNOWN: Tantalum rod initially at a uniform temperature, 300K, is suddenly subjected to a current flow of 80A; surroundings (vacuum enclosure) and electrodes maintained at 300K.

FIND: (a) Estimate time required for mid-length to reach 1000K, (b) Determine the steady-state temperature distribution and estimate how long it will take to reach steady-state. Use a finite-difference method with a space increment of 10mm.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, transient conduction in rod, (2) Surroundings are much larger than rod, (3) Properties are constant and evaluated at an average temperature.

PROPERTIES: *Table A-1*, Tantalum $\left(\bar{T} = (300+1000)\,K/2 = 650K\right)$: ρ = 16,600 kg/m^3, c = 147 J/kg·K, k = 58.8 W/m·K, and α = k/ρc = 58.8 W/m·K/16,600 kg/m^3 × 147 J/kg·K = 2.410 × 10^{-5}m^2/s.

ANALYSIS: The finite-difference equation is

$$T_m^{p+1} = Fo\left(T_{m-1}^p + T_{m+1}^p\right) + (1-2Fo)T_m^p - \frac{\varepsilon P\sigma\Delta x^2}{kA_c}Fo\left(T_m^{4,p} - T_{sur}^4\right) + \frac{I^2\rho_e\Delta x^2}{kA_c^2}\cdot Fo \qquad (1)$$

where $\quad Fo = \alpha\Delta t/\Delta x^2 \qquad A_c = \pi\ D^2/4 \qquad P = \pi\ D. \qquad (2,3,4)$

From the stability criterion, let Fo = 1/2 and numerically evaluate terms of Eq. (1).

$$T_m^{p+1} = \frac{1}{2}\left(T_{m-1}^p + T_{m+1}^p\right) - \frac{0.1\times 5.67\times 10^{-8}\,W/m^2\cdot K^4\times(0.01m)^2\,4}{58.8\ W/m\cdot K\times(0.003m)}\cdot\frac{1}{2}\left(T_m^{4,p} - [300K]^4\right) + $$
$$+\frac{(80A)^2\times 95\times 10^{-8}\,\Omega\cdot m\,(0.01m)^2}{58.8\ W/m\cdot K\left(\pi[0.003m]^2/4\right)^2}\cdot\frac{1}{2}$$

$$T_m^{p+1} = \frac{1}{2}\left(T_{m-1}^p + T_{m+1}^p\right) - 6.4285\times 10^{-12}T_m^{4,p} + 103.53. \qquad (5)$$

Note that this form applies to nodes 0 through 5. For node 0, $T_{m-1} = T_{m+1} = T_1$. Since Fo = 1/2, using Eq. (2), find that

$$\Delta t = \Delta x^2 Fo/\alpha = (0.01m)^2\times 1/2/2.410\times 10^{-5}m^2/s = 2.07s. \qquad (6)$$

Hence, t = pΔt = 2.07p. (7)

Continued …

PROBLEM 5.133 (Cont.)

(a) To estimate the time required for the mid-length to reach 1000K, that is T_o = 1000K, perform the forward-marching solution beginning with T_i = 300K at p = 0. The solution, as tabulated below, utilizes Eq. (5) for successive values of p. Elapsed time is determined by Eq. (7).

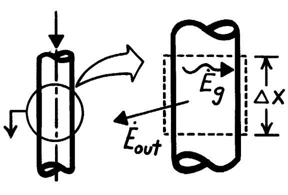
P	t(s)	T_0	T_1	T_2	T_3	T_4	T_5	T_6(°C)
0	0	300	300	300	300	300	300	300
1		403.5	403.5	403.5	403.5	403.5	403.5	300
2		506.9	506.9	506.9	506.9	506.9	455.1	300
3		610.0	610.0	610.0	610.0	584.1	506.7	300
4		712.6	712.6	712.6	699.7	661.1	545.2	300
5	10.4	814.5	814.5	808.0	788.8	724.7	583.5	300
6		915.2	911.9	902.4	867.4	787.9	615.1	300
7		1010.9	1007.9	988.9	945.0	842.3	646.6	300
8		1104.7	1096.8	1073.8	1014.0	896.1	673.6	300
9		1190.9	1183.5	1150.4	1081.7	943.2	700.3	300
10	20.7	1274.1	1261.6	1224.9	1141.5	989.4	723.6	300
11		1348.2	1336.7	1290.6	1199.8	1029.9	746.5	300
12		1419.7	1402.4	1353.9	1250.5	1069.4	766.5	300
13		1479.8	1465.5	1408.4	1299.8	1103.6	786.0	300
14		1542.6	1538.2	1460.9	1341.2	1136.9	802.9	300
15	31.1	1605.3	1569.3	1514.0	1381.6	1164.8	819.3	300

Note that, at p ≈ 6.9 or t = 6.9 × 2.07 = 14.3s, the mid-point temperature is $T_o \approx$ 1000K. <

(b) The steady-state temperature distribution can be obtained by continuing the marching solution until only small changes in T_m are noted. From the table above, note that at p = 15 or t = 31s, the temperature distribution is still changing with time. It is likely that at least 15 more calculation sets are required to see whether steady-state is being approached.

COMMENTS: (1) This problem should be solved with a computer rather than a hand-calculator. For such a situation, it would be appropriate to decrease the spatial increment in order to obtain better estimates of the temperature distribution.

(2) If the rod were very long, the steady-state temperature distribution would be very flat at the mid-length x = 0. Performing an energy balance on the small control volume shown to the right, find



$$\dot{E}_g - \dot{E}_{out} = 0$$

$$I^2 \frac{\rho_e \Delta x}{A_c} - \varepsilon\sigma P \Delta x \left(T_o^4 - T_{sur}^4\right) = 0.$$

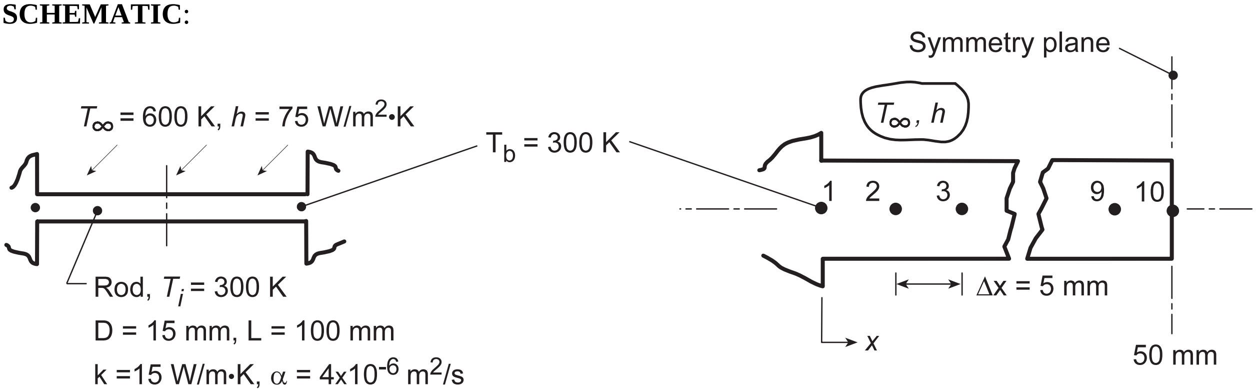
Substituting numerical values, find T_o = 2003K. It is unlikely that the present rod would ever reach this steady-state, maximum temperature. That is, the effect of conduction along the rod will cause the center temperature to be less than this value.

PROBLEM 5.134

KNOWN: Support rod spanning a channel whose walls are maintained at T_b = 300 K. Suddenly the rod is exposed to cross flow of hot gases with T_∞ = 600 K and h = 75 W/m^2·K. After the rod reaches steady-state conditions, the hot gas flow is terminated and the rod cools by free convection and radiation exchange with surroundings.

FIND: (a) Compute and plot the midspan temperature as a function of elapsed heating time; compare the steady-state temperature distribution with results from an analytical model of the rod and (b) Compute the midspan temperature as a function of elapsed cooling time and determine the time required for the rod to reach the safe-to-touch temperature of 315 K.

SCHEMATIC:

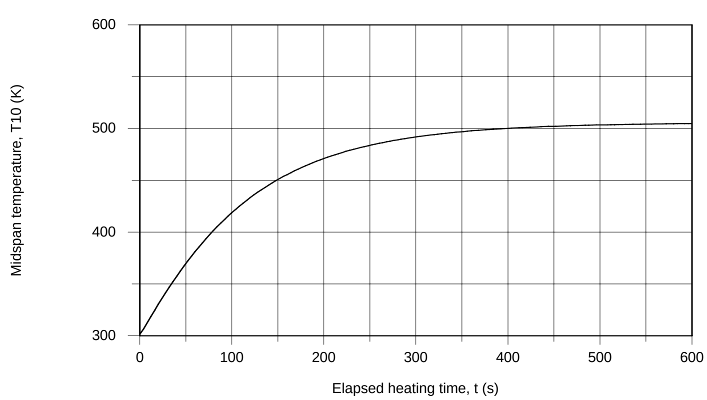


ASSUMPTIONS: (1) One-dimensional, transient conduction in rod, (2) Constant properties, (3) During heating process, uniform convection coefficient over rod, (4) During cooling process, free convection coefficient is of the form h = CΔT^n where C = 4.4 W/m^2·K$^{1.188}$ and n = 0.188, and (5) During cooling process, surroundings are large with respect to the rod.

ANALYSIS: (a) The finite-difference equations for the 10-node mesh shown above can be obtained using the *IHT Finite-Difference Equation, One-Dimensional, Transient Extended Surfaces Tool*. The temperature-time history for the midspan position T_{10} is shown in the plot below. The steady-state temperature distribution for the rod can be determined from Eq. 3.80, Case B, Table 3.4. This case is treated in the *IHT Extended Surfaces Model, Temperature Distribution and Heat Rate, Rectangular Pin Fin*, for the adiabatic tip condition. The following table compares the steady-state temperature distributions for the numerical and analytical methods.

Method	Temperatures (K) vs. Position x (mm)					
	0	10	20	30	40	50
Analytical	300	386.1	443.4	479.5	499.4	505.8
Numerical	300	386.0	443.2	479.3	499.2	505.6

The comparison is excellent indicating that the nodal mesh is sufficiently fine to obtain precise results.



Continued...

PROBLEM 5.134 (Cont.)

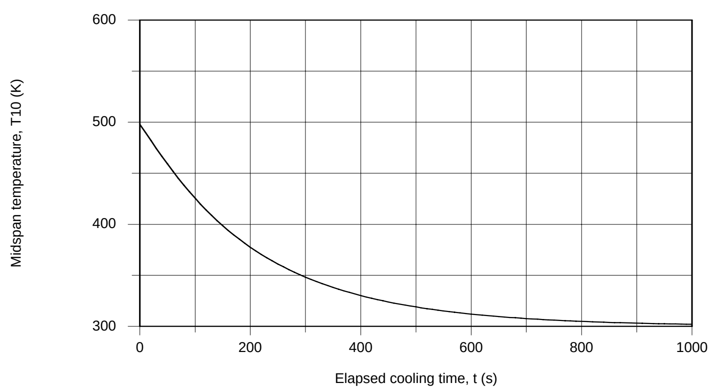
(b) The same finite-difference approach can be used to model the cooling process. In using the IHT tool, the following procedure was used: (1) Set up the FDEs with the convection coefficient expressed as $h_m = h_{fc,m} + h_{r,m}$, the sum of the free convection and linearized radiation coefficients based upon nodal temperature T_m.

$$h_{fc,m} = C\left(T_m^p - T_\infty\right)$$

$$h_{r,m} = \varepsilon\sigma\left(T_m^p + T_{sur}\right)\left(\left(T_m^p\right)^2 + T_{sur}^2\right)$$

(2) For the initial solve, set $h_{fc,m} = h_{r,m} = 5\ \text{W/m}^2\cdot\text{K}$ and solve, (3) Using the solved results as the Initial Guesses for the next solve, allow $h_{fc,m}$ and $h_{r,m}$ to be unknowns. The temperature-time history for the midspan during the cooling process is shown in the plot below. The time to reach the safe-to-touch temperature, $T_{10}^p = 315\,\text{K}$, is

t = 550 s <

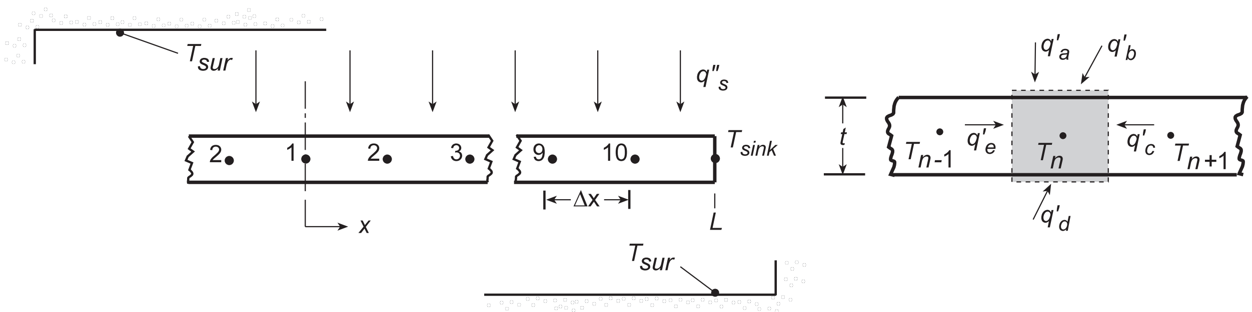


PROBLEM 5.135

KNOWN: Thin metallic foil of thickness, w, whose edges are thermally coupled to a sink at temperature, T_{sink}, initially at a uniform temperature $T_i = T_{sink}$, is suddenly exposed on the top surface to an ion beam heat flux, q''_s, and experiences radiation exchange with the vacuum enclosure walls at T_{sur}. Consider also the situation when the foil is operating under steady-state conditions when suddenly the ion beam is deactivated.

FIND: (a) Compute and plot the midspan temperature-time history during the *heating* process; determine the elapsed time that this point on the foil reaches a temperature within 1 K of the steady-state value, and (b) Compute and plot the midspan temperature-time history during the *cooling* process from steady-state operation; determine the elapsed time that this point on the foil reaches the *safe-to-touch* temperature of 315 K.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, transient conduction in the foil, (2) Constant properties, (3) Upper and lower surfaces of foil experience radiation exchange with the large surroundings, (4) Ion beam incident on upper surface only, (4) Foil is of unit width normal to the page.

ANALYSIS: (a) The finite-difference equations for the 10-node mesh shown above can be obtained using the *IHT Finite-Difference Equation, One-Dimensional, Transient, Extended Surfaces Tool*. In formulating the energy-balance functions, the following steps were taken: (1) the FDE function coefficient h must be identified for each node, e.g., h_1 and (2) coefficient can be represented by the linearized radiation coefficient, e.g., $h_1 = \varepsilon\sigma\left(T_1 + T_{sur}\right)\left(T_1^2 + T_{sur}^2\right)$, (3) set $q''_a = q''_o/2$ since the ion beam is incident on only the top surface of the foil, and (4) when solving, the initial condition corresponds to T_i = 300 K for each node. The temperature-time history of the midspan position is shown below. The time to reach within 1 K of the steady-state temperature (374.1 K) is

$$T_{10}\left(t_h\right) = 373\,\text{K} \qquad t_h = 136\,\text{s} \qquad <$$

(b) The same IHT workspace may be used to obtain the temperature-time history for the cooling process by taking these steps: (1) set $q''_s = 0$, (2) specify the initial conditions as the steady-state temperature (K) distribution tabulated below,

T_1	T_2	T_3	T_4	T_5	T_6	T_7	T_8	T_9	T_{10}
374.1	374.0	373.5	372.5	370.9	368.2	363.7	356.6	345.3	327.4

(3) when performing the integration of the independent time variable, set the start value as 200 s and (4) save the results for the heating process in Data Set A. The temperature-time history for the heating and cooling processes can be made using Data Browser results from the Working and A Data Sets. The time required for the midspan to reach the *safe-to-touch* temperature is

$$T_{10}\left(t_c\right) = 315\,\text{K} \qquad t_c = 73\,\text{s} \qquad <$$

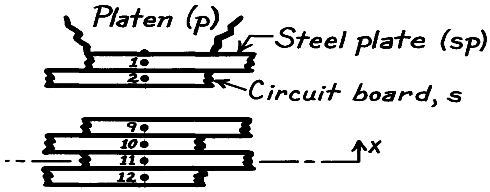
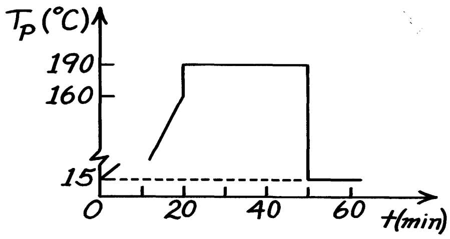
PROBLEM 5.136

KNOWN: Stack or book of steel plates (sp) and circuit boards (b) subjected to a prescribed platen heating schedule $T_p(t)$. See Problem 5.46 for other details of the book.

FIND: (a) Using the implicit numerical method with Δx = 2.36mm and Δt = 60s, find the mid-plane temperature T(0,t) of the book and determine whether curing will occur (> 170°C for 5 minutes), (b) Determine how long it will take T(0,t) to reach 37°C following reduction of the platen temperature to 15°C (at t = 50 minutes), (c) Validate code by using a sudden change of platen temperature from 15 to 190°C and compare with the solution of Problem 5.38.

SCHEMATIC:





ASSUMPTIONS: (1) One-dimensional conduction, (2) Negligible contact resistance between plates, boards and platens.

PROPERTIES: Steel plates (sp, given): ρ_{sp} = 8000 kg/m^3, $c_{p,sp}$ = 480 J/kg·K, k_{sp} = 12 W/m·K; Circuit boards (b, given): ρ_b = 1000 kg/m^3, $c_{p,b}$ = 1500 J/kg·K, k_b = 0.30 W/m·K.

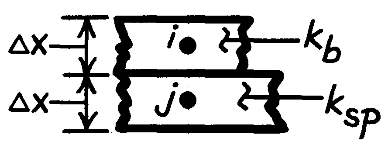
ANALYSIS: (a) Using the suggested space increment Δx = 2.36mm, the model grid spacing treating the steel plates (sp) and circuit boards (b) as discrete elements, we need to derive the nodal equations for the interior nodes (2-11) and the node next to the platen (1). Begin by defining appropriate control volumes and apply the conservation of energy requirement.

Effective thermal conductivity, k_e: Consider an adjacent steel plate-board arrangement. The thermal resistance between the nodes i and j is

$$R''_{ij} = \frac{\Delta x}{k_e} = \frac{\Delta x/2}{k_b} + \frac{\Delta x/2}{k_{sp}}$$

$$k_e = \frac{2}{1/k_{b+} + 1/k_{sp}} = \frac{2}{1/0.3 + 1/12} \text{ W/m}\cdot\text{K}$$

$$k_e = 0.585 \text{ W/m}\cdot\text{K}.$$



Odd-numbered nodes, 3 ≤ m ≤ 11 - steel plates (sp): Treat as interior nodes using Eq. 5.97 with

$$\alpha_{sp} \equiv \frac{k_e}{\rho_{sp} c_{sp}} = \frac{0.585 \text{ W/m}\cdot\text{K}}{8000 \text{ kg/m}^3 \times 480 \text{ J/kg}\cdot\text{K}} = 1.523\times10^{-7} \text{ m}^2/\text{s}$$

$$Fo_m = \frac{\alpha_{sp}\Delta t}{\Delta x^2} = \frac{1.523\times10^{-7} \text{ m}^2/\text{s}\times 60\text{s}}{(0.00236 \text{ m})^2} = 1.641$$

Continued …

PROBLEM 5.136 (Cont.)

to obtain, with m as odd-numbered,

$$\left(1+2\mathrm{Fo}_m\right)T_m^{p+1}-\mathrm{Fo}_m\left(T_{m-1}^{p+1}+T_{m+1}^{p+1}\right)=T_m^p \qquad (1)$$

Even-numbered nodes, 2 ≤ n ≤ 10 - circuit boards (b): Using Eq. 5.97 and evaluating α_b and Fo_n

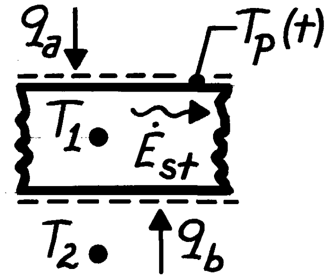
$$\alpha_b=\frac{k_e}{\rho_b c_b}=3.900\times10^{-7}\ \mathrm{m^2/s} \qquad \mathrm{Fo}_n=4.201$$

$$\left(1+2\mathrm{Fo}_n\right)T_n^{p+1}-\mathrm{Fo}_n\left(T_{n-1}^{p+1}+T_{n+1}^{p+1}\right)=T_n^p \qquad (2)$$

Plate next to platen, n = 1 - steel plate (sp): The finite-difference equation for the plate node (n = 1) next to the platen follows from a control volume analysis.

$$\dot{E}_{in}-\dot{E}_{out}=\dot{E}_{st}$$

$$q''_a+q''_b=\rho_{sp}\Delta x c_{sp}\frac{T_1^{p+1}-T_1^p}{\Delta t}$$



where

$$q''_a=k_{sp}\frac{T_p(t)-T_1^{p+1}}{\Delta x/2} \qquad q''_b=k_e\frac{T_2^{p+1}-T_1^{p+1}}{\Delta x}$$

and $T_p(t) = T_p(p)$ is the platen temperature which is changed with time according to the heating schedule. Regrouping find,

$$\left(1+\mathrm{Fo}_m\left(1+\frac{2k_{sp}}{k_e}\right)\right)T_1^{p+1}-\mathrm{Fo}_m T_2^{p+1}-\frac{2k_{sp}}{k_e}\mathrm{Fo}_m T_p(p)=T_1^p \qquad (3)$$

where $2k_{sp}/k_e$ = 2 × 12 W/m·K/0.585 W/m·K = 41.03.

Using the nodal Eqs. (1) -(3), an inversion method of solution was effected and the temperature distributions are shown on the following page.

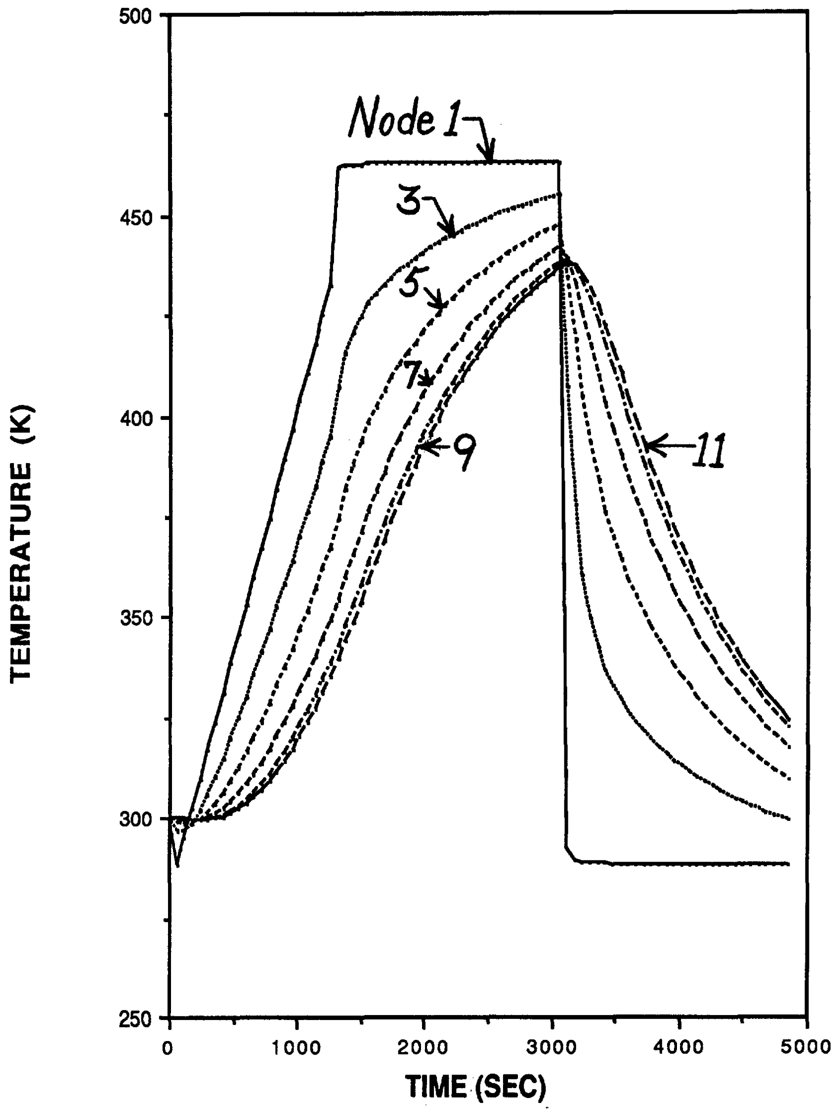
Temperature distributions - discussion: As expected, the temperatures of the nodes near the center of the book considerably lag those nearer the platen. The criterion for cure is T ≥ 170°C = 443 K for Δt_c = 5 min = 300 sec. From the temperature distributions, note that node 10 just reaches 443 K after 50 minutes and will not be cured. It appears that the region about node 5 will be cured.

(b) The time required for the book to reach 37°C = 310 K can likewise be seen from the temperature distribution results. The plates/boards nearest the platen will cool to the safe handling temperature with 1000 s = 16 min, but those near the center of the stack will require in excess of 2000 s = 32 min.

Continued …

PROBLEM 5.136 (Cont.)

(c) It is important when validating computer codes to have the program work a "problem" which has an exact analytical solution. You should select the problem such that all features of the code are tested.

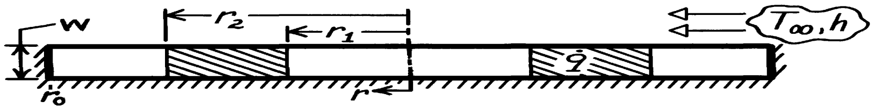


PROBLEM 5.137

KNOWN: Thin, circular-disc subjected to induction heating causing a uniform heat generation in a prescribed region; upper surface exposed to convection process.

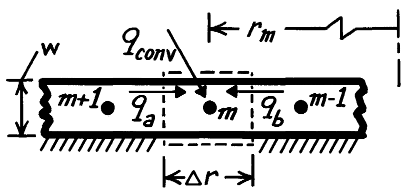
FIND: (a) Transient finite-difference equation for a node in the region subjected to induction heating, (b) Sketch the steady-state temperature distribution on T-r coordinates; identify important features.

SCHEMATIC:



ASSUMPTIONS: (1) Thickness $w << r_o$, such that conduction is one-dimensional in r-direction, (2) In prescribed region, $\dot{q}$ is uniform, (3) Bottom surface of disc is insulated, (4) Constant properties.

ANALYSIS: (a) Consider the nodal point arrangement for the region subjected to induction heating. The size of the control volume is $V = 2\pi\, r_m \cdot \Delta r \cdot w$. The energy conservation requirement for the node m has the form



$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = \dot{E}_{st}$$

with $\quad q_a + q_b + q_{conv} + \dot{q}V = \dot{E}_{st}.$

Recognizing that q_a and q_b are conduction terms and q_{conv} is the convection process,

$$k\left[2\pi\left[r_m - \frac{\Delta r}{2}\right]w\right]\frac{T_{m-1}^p - T_m^p}{\Delta r} + k\left[2\pi\left[r_m + \frac{\Delta r}{2}\right]w\right]\frac{T_{m+1}^p - T_m^p}{\Delta r}$$

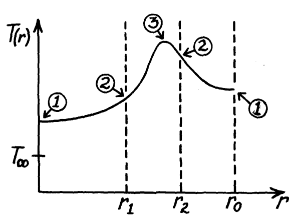
$$+h\left[2\pi\, r_m \cdot \Delta r\right]\left(T_\infty - T_m^p\right) + \dot{q}\left[2\pi\, r_m \cdot \Delta r \cdot w\right] = \rho\, c_p\left[2\pi\, r_m \cdot \Delta r \cdot w\right]\frac{T_m^{p+1} - T_m^p}{\Delta t}.$$

Upon regrouping, the finite-difference equation has the form,

$$T_m^{p+1} = Fo\left[\left[1 - \frac{\Delta r}{2r_m}\right]T_{m-1}^p + \left[1 + \frac{\Delta r}{2r_m}\right]T_{m+1}^p + Bi\left[\frac{\Delta r}{w}\right]T_\infty + \frac{\dot{q}\Delta r^2}{k}\right] + \left[1 - 2Fo - Bi\cdot Fo\left[\frac{\Delta r}{w}\right]\right]T_m^p \qquad <$$

where $\qquad Fo = \alpha\Delta t/\Delta r^2 \qquad Bi = h\Delta r/k.$

(b) The steady-state temperature distribution has these features:



1. Zero gradient at r = 0, r_0
2. No discontinuity at r_1, r_2
3. T_{max} occurs in region $r_1 < r < r_2$

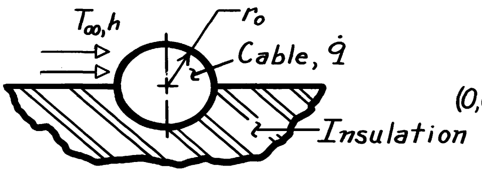
Note also, distribution will not be linear anywhere; distribution is not parabolic in $r_1 < r < r_2$ region.

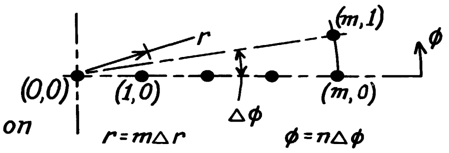
PROBLEM 5.138

KNOWN: An electrical cable experiencing uniform volumetric generation; the lower half is well insulated while the upper half experiences convection.

FIND: (a) Explicit, finite-difference equations for an interior node (m,n), the center node (0,0), and an outer surface node (M,n) for the convective and insulated boundaries, and (b) Stability criterion for each FDE; identify the most restrictive criterion.

SCHEMATIC:





ASSUMPTIONS: (1) Two-dimensional (r,ϕ), transient conduction, (2) Constant properties, (3) Uniform $\dot{q}$.

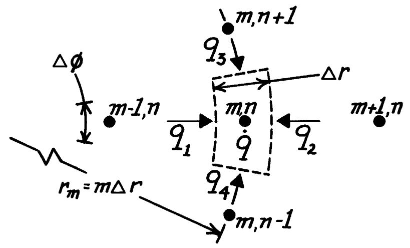
ANALYSIS: The explicit, finite-difference equations may be obtained by applying energy balances to appropriate control volumes about the node of interest. Note the coordinate system defined above where (r,ϕ) → (mΔr, nΔϕ). The stability criterion is determined from the coefficient associated with the node of interest.

Interior Node (m,n). The control volume for an interior node is

$$V = r_m \Delta\phi \cdot \Delta r \cdot \ell$$

(with $r_m = m\Delta r,\ \ell = 1$) where ℓ is the length normal to the page. The conservation of energy requirement is

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = \dot{E}_{st}$$



$$\left(q_1 + q_2\right)_r + \left(q_3 + q_4\right)_\theta + \dot{q}V = \rho\, cV \frac{T_{m,n}^{p+1} - T_{m,n}^{p}}{\Delta t}$$

$$k \cdot \left[m - \frac{1}{2}\right]\Delta r \cdot \Delta\phi \cdot \frac{T_{m-1,n}^{p} - T_{m,n}^{p}}{\Delta r} + k \cdot \left[m + \frac{1}{2}\right]\Delta r \cdot \Delta\phi \cdot \frac{T_{m+1,n}^{p} - T_{m,n}^{p}}{\Delta r} + k \cdot \Delta r \cdot \frac{T_{m,n+1}^{p} - T_{m,n}^{p}}{\left(m\Delta r\right)\Delta\phi}$$

$$+ k \cdot \Delta r \cdot \frac{T_{m,n-1}^{p} - T_{m,n}^{p}}{\left(m\Delta r\right)\Delta\phi} + \dot{q}\left(m\Delta r \cdot \Delta\phi\right) \cdot \Delta r = \rho\, c\left(m\Delta r \cdot \Delta\phi\right) \cdot \Delta r \cdot \frac{T_{m,n}^{p+1} - T_{m,n}^{p}}{\Delta t} \qquad (1)$$

Define the Fourier number as

$$Fo = \frac{k}{\rho\, c} \cdot \frac{\Delta t}{\Delta r^2} = \frac{\alpha \Delta t}{\Delta r^2} \qquad (2)$$

and then regroup the terms of Eq. (1) to obtain the FDE,

$$T_{m,n}^{p+1} = Fo\left\{\frac{m - 1/2}{m} T_{m-1,n}^{p} + \frac{m + 1/2}{m} T_{m+1,n}^{p} + \frac{1}{\left(m\Delta\phi\right)^2}\left(T_{m,n+1}^{p} + T_{m,n-1}^{p}\right) + \frac{\dot{q}}{k}\Delta r^2\right\}$$

$$+ \left\{-Fo\left[2 + \frac{2}{\left(m\Delta\phi\right)^2}\right] + 1\right\} T_{m,n}^{p}. \qquad (3) <$$

Continued …

PROBLEM 5.138 (Cont.)

The stability criterion requires that the last term on the right-hand side in braces be positive. That is, the coefficient of $T_{m,n}^{p}$ must be positive and the stability criterion is

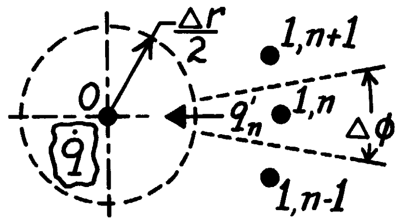
$$Fo \le 1/2\left[1+1/\left(m\Delta\phi\right)^2\right] \tag{4}$$

Note that, for m >> 1/2 and $(m\Delta\phi)^2$ >>1, the FDE takes the form of a 1-D cartesian system.

Center Node (0,0). For the control volume,

$V = \pi\left(\Delta r/2\right)^2 \cdot 1$. The energy balance is

$\dot{E}'_{in} - \dot{E}'_{out} + \dot{E}'_g = \dot{E}'_{st}$ where $\dot{E}'_{in} = \Sigma q'_n$.



$$\sum_{n=0}^{N} k\cdot\left[\frac{\Delta r}{2}\Delta\phi\right]\cdot\frac{T_{1,n}^{p}-T_{o}^{p}}{\Delta r}+\dot{q}\pi\left[\frac{\Delta r}{2}\right]^2$$

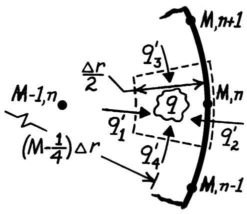
$$=\rho\, c\cdot\pi\left[\frac{\Delta r}{2}\right]^2\frac{T_o^{p+1}-T_o^{p}}{\Delta t} \tag{5}$$

where N = $(2\pi/\Delta\phi)$ - 1, the total number of q_n. Using the definition of Fo, find

$$T_o^{p+1} = 4Fo\left\{\frac{1}{N+1}\sum_{n=0}^{N}T_{1,n}^{p}+\frac{\dot{q}}{4k}\Delta r^2\right\}+\left(1-4Fo\right)T_o^{p}. \quad <$$

By inspection, the stability criterion is Fo ≤ 1/4. (7)

Surface Nodes (M,n). The control volume for the surface node is V = (M - ¼)ΔrΔφ·Δr/2.1. From the energy balance,



$$\dot{E}'_{in} - \dot{E}'_{out} + \dot{E}'_g = \left(q'_1+q'_2\right)_r + \left(q'_3+q'_4\right)_\phi + \dot{q}V = \dot{E}'_{st}$$

$$k\cdot\left(M-1/2\right)\Delta r\cdot\Delta\phi\frac{T_{M-1,n}^{p}-T_{M,n}^{p}}{\Delta r}+h\left(M\Delta r\cdot\Delta\phi\right)\left(T_\infty - T_{M,n}^{p}\right)+k\cdot\frac{\Delta r}{2}\cdot\frac{T_{M,n+1}^{p}-T_{M,n}^{p}}{\left(M\Delta r\right)\Delta\phi}$$

$$+k\cdot\frac{\Delta r}{2}\cdot\frac{T_{M,n-1}^{p}-T_{M,n}^{p}}{\left(M\Delta r\right)\Delta\phi}+\dot{q}\left[\left(M-1/4\right)\Delta r\cdot\Delta\phi\cdot\frac{\Delta r}{2}\right]=\rho\, c\left[\left(M-1/4\right)\Delta r\cdot\Delta\phi\cdot\frac{\Delta r}{2}\right]\frac{T_{M,n}^{p+1}-T_{M,n}^{p}}{\Delta t}.$$

Regrouping and using the definitions for Fo = $\alpha\Delta t/\Delta r^2$ and Bi = $h\Delta r/k$,

$$T_{m,n}^{p+1}=Fo\left\{2\frac{M-1/2}{M-1/4}T_{M-1,n}^{p}+\frac{1}{\left(M-1/4\right)M\left(\Delta\phi\right)^2}\left(T_{M,n+1}^{p}-T_{M,n-1}^{p}\right)+2Bi\cdot T_\infty+\frac{\dot{q}}{k}\Delta r^2\right\}$$

$$+\left\{1-2Fo\left[\frac{M-1/2}{M-1/4}+Bi\cdot\frac{M}{M-1/4}+\frac{1}{\left(M-1/4\right)M\left(\Delta\phi\right)^2}\right]\right\}T_{M,n}^{p}. \tag{8} \quad <$$

The stability criterion is

$$Fo \le \frac{1}{2}\left[\frac{M-1/2}{M-1/4}+Bi\frac{M}{M-1/4}+\frac{1}{\left(M-1/4\right)M\left(\Delta\phi\right)^2}\right]. \tag{9}$$

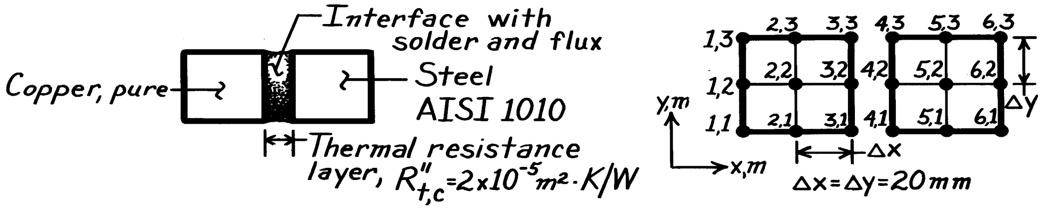
To determine which stability criterion is most restrictive, compare Eqs. (4), (7) and (9). The most restrictive (lowest Fo) has the largest denominator. For small values of m, it is not evident whether Eq. (7) is more restrictive than Eq. (4); Eq. (4) depends upon magnitude of Δφ. Likewise, it is not clear whether Eq. (9) will be more or less restrictive than Eq. (7). Numerical values must be substituted.

PROBLEM 5.139

KNOWN: Initial temperature distribution in two bars that are to be soldered together; interface contact resistance.

FIND: (a) Explicit FDE for $T_{4,2}$ in terms of Fo and $Bi = \Delta x/k\,R''_{t,c}$; stability criterion, (b) $T_{4,2}$ one time step after contact is made if Fo = 0.01 and value of Δt; whether the stability criterion is satisfied.

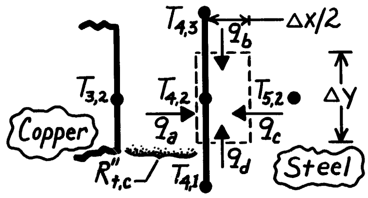
SCHEMATIC:



PROPERTIES: *Table A-1*, Steel, AISI 1010 (1000K): k = 31.3 W/m·K, c = 1168 J/kg·K, ρ = 7832 kh/m^3.

ASSUMPTIONS: (1) Two-dimensional transient conduction, (2) Constant properties, (3) Interfacial solder layer has negligible thickness.

ANALYSIS: (a) From an energy balance on the control volume V = (Δx/2)·Δy·1.



$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = \dot{E}_{st}$$

$$q_a + q_b + q_c + q_d = \rho\, cV \frac{T_{4,2}^{p+1} - T_{4,2}^{p}}{\Delta t}.$$

Note that $q_a = \left(\Delta T/R''_{t,c}\right)A_c$ while the remaining q_i are conduction terms,

$$\frac{1}{R''_{t,c}}\left(T_{3,2}^p - T_{4,2}^p\right)\Delta y + k\left(\Delta x/2\right)\frac{\left(T_{4,3}^p - T_{4,2}^p\right)}{\Delta y} + k\left(\Delta y\right)\frac{\left(T_{5,2}^p - T_{4,2}^p\right)}{\Delta x}$$

$$+ k\left(\Delta x/2\right)\frac{\left(T_{4,1}^p - T_{4,2}^p\right)}{\Delta y} = \rho\, c\left[\left(\Delta x/2\right)\cdot\Delta y\right]\frac{T_{4,2}^{p+1} - T_{4,2}^{p}}{\Delta t}.$$

Defining $Fo \equiv \left(k/\rho\, c\right)\Delta t/\Delta x^2$ and $Bi_c \equiv \Delta y/R''_{t,c}k$, regroup to obtain

$$T_{4,2}^{p+1} = Fo\left(T_{4,3}^p + 2T_{5,2}^p + T_{4,1}^p + 2Bi\, T_{3,2}^p\right) + \left(1 - 4Fo - 2FoBi\right)T_{4,2}^p.$$ <

The stability criterion requires the coefficient of the $T_{4,2}^p$ term be zero or positive,

$$\left(1 - 4Fo - 2FoBi\right) \geq 0 \qquad \text{or} \qquad Fo \leq 1/\left(4 + 2Bi\right)$$ <

(b) For $Fo = 0.01$ and $Bi = 0.020\text{m}/\left(2\times10^{-5}\text{m}^2\cdot\text{K/W}\times31.3\text{W/m}\cdot\text{K}\right) = 31.95$,

$$T_{4,2}^{p+1} = 0.01\left(1000 + 2\times900 + 1000 + 2\times31.95\times700\right)\text{K} + \left(1 - 4\times0.01 - 2\times0.01\times31.95\right)1000\text{K}$$

$$T_{4,2}^{p+1} = 485.30\text{K} + 321.00\text{K} = 806.3\text{K}.$$ <

With Fo = 0.01, the time step is

$$\Delta t = Fo\,\Delta x^2\left(\rho\, c/k\right) = 0.01\left(0.020\text{m}\right)^2\left(7832\text{kg/m}^3\times1168\text{J/kg}\cdot\text{K}/31.3\text{W/m}\cdot\text{K}\right) = 1.17\text{s}.$$ <

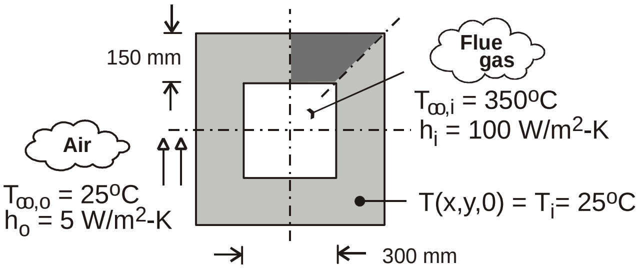
With Bi = 31.95 and Fo = 0.01, the stability criterion, Fo ≤ 0.015, is satisfied. <

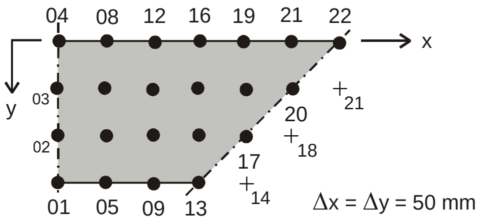
PROBLEM 5.140

KNOWN: Flue of square cross-section, initially at a uniform temperature is suddenly exposed to hot flue gases. See Problem 4.92.

FIND: Temperature distribution in the wall 5, 10, 50 and 100 hours after introduction of gases using the *implicit* finite-difference method.

SCHEMATIC:





ASSUMPTIONS: (1) Two-dimensional transient conduction, (2) Constant properties.

PROPERTIES: Flue (given): k = 0.85 W/m·K, $\alpha = 5.5 \times 10^{-7}$ m^2/s.

ANALYSIS: The network representing the flue cross-sectional area is shown with Δx = Δy = 50mm. Initially all nodes are at T_i = 25°C when suddenly the interior and exterior surfaces are exposed to convection processes, ($T_{\infty,i}$, h_i) and ($T_{\infty,o}$, h_o), respectively Referring to the network above, note that there are four types of nodes: interior (02, 03, 06, 07, 10, 11, 14, 15, 17, 18, 20); plane surfaces with convection (interior – 01, 05, 09); interior corner with convection (13), plane surfaces with convection (exterior – 04, 08, 12, 16, 19, 21); and, exterior corner with convection. The system of finite-difference equations representing the network is obtained using *IHT|Tools|Finite-difference equations|Two-dimensional|Transient*. The *IHT* code is shown in Comment 2 and the results for t = 5, 10, 50 and 100 hour are tabulated below.

Node 17 $$(1+4Fo)T_{17}^{p+1} - Fo\left(T_{18}^{p+1} + T_{14}^{p+1} + T_{18}^{p+1} + T_{14}^{p+1}\right) = T_{17}^{p}$$

Node 13 $$\left[1+4Fo\left[1+\frac{1}{3}Bi_i\right]\right]T_{13}^{p+1} - \frac{2}{3}Fo\left(2T_{14}^{p+1} + T_9 + 2T_{14}^{p+1} + T_9^{p+1}\right) = T_{13}^{p} + \frac{4}{3}Bi_i \cdot Fo \cdot T_{\infty,i}$$

Node 12 $$\left(1+2Fo\left(2+Bi_o\right)\right)T_{12}^{p+1} - Fo\left(2T_{11}^{p+1} + T_{16}^{p+1} + T_8^{p+1}\right) = T_{12}^{p} + 2Bi_o \cdot Fo \cdot T_{\infty,o}$$

Node 22 $$\left(1+4Fo\left(1+Bi_o\right)\right)T_{22}^{p+1} - 2Fo\left(T_{21}^{p+1} + T_{21}^{p+1}\right) = T_{22}^{p} + 4Bi_o \cdot Fo \cdot T_{\infty,o}$$

Numerical values for the relevant parameters are:

$$Fo = \frac{\alpha\Delta t}{\Delta x^2} = \frac{5.5\times10^{-6} m^2/s \times 3600s}{(0.050m)^2} = 7.92000$$

$$Bi_o = \frac{h_o\Delta x}{k} = \frac{5\ W/m^2\cdot K \times 0.050m}{0.85\ W/m\cdot K} = 0.29412$$

$$Bi_i = \frac{h_i\Delta x}{k} = \frac{100\ W/m^2\cdot K \times 0.050m}{0.85\ W/m\cdot K} = 5.88235$$

The system of FDEs can be represented in matrix notation, [A][T] = [C]. The coefficient matrix [A] and terms for the right-hand side matrix [C] are given on the following page.

(3) The results for t = 50 hour, representing the steady-state condition, are shown below, arranged according to the coordinate system.

	Tmn (C)						
x/y (mm)	0	50	100	150	200	250	300
0	181.60	179.50	172.70	160.20	141.80	120.60	98.89
50	229.80	227.30	219.00	202.90	177.50	149.00	
100	282.90	280.80	273.20	172.70	216.20		
150	340.20	339.90	338.20	327.30			

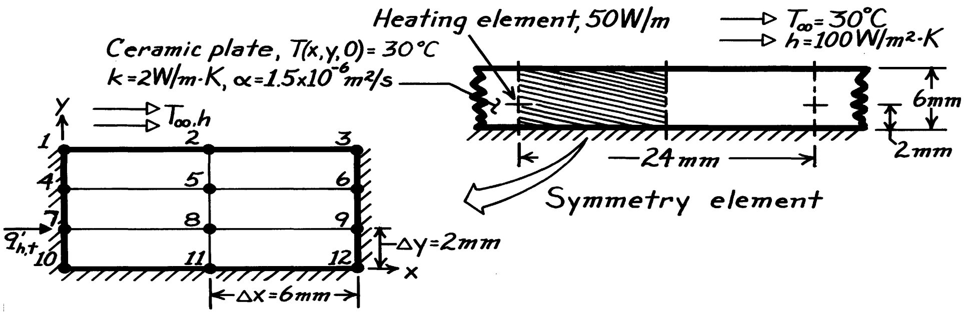
In Problem 4.92, the temperature distribution was determined using the FDEs written for steady-state conditions, but with a finer network, $\Delta x = \Delta y = 25$ mm. By comparison, the results for the coarser network are slightly higher, within a fraction of 1°C, along the mid-section of the flue, but notably higher in the vicinity of inner corner. (For example, node 13 is 2.6°C higher with the coarser mesh.)

PROBLEM 5.141

KNOWN: Electrical heating elements embedded in a ceramic plate as described in Problem 4.86; initially plate is at a uniform temperature and suddenly heaters are energized.

FIND: Time required for the difference between the surface and initial temperatures to reach 95% of the difference for steady-state conditions using the implicit, finite-difference method.

SCHEMATIC:

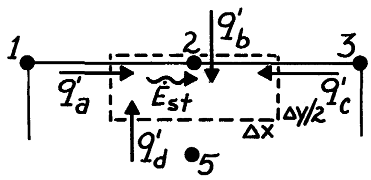


ASSUMPTIONS: (1) Two-dimensional conduction, (2) Constant properties, (3) No internal generation except for Node 7, (4) Heating element approximates a line source; wire diameter is negligible.

ANALYSIS: The grid for the symmetry element above consists of 12 nodes. Nodes 1-3 are points on a surface experiencing convection; nodes 4-12 are interior nodes; node 7 is a special case with internal generation and because of symmetry, q'_{ht} = 25 W/m. Their finite-difference equations are derived as follows

Surface Node 2. From an energy balance on the prescribed control volume with Δx/Δy = 3,

$$\dot{E}_{in} = \dot{E}_{st} = q'_a + q'_b + q'_c + q'_d = \rho\, cV \frac{T_2^{p+1} - T_2^p}{\Delta t}$$



$$k\frac{\Delta y}{2}\frac{T_1^{p+1} - T_2^{p+1}}{\Delta x} + h\Delta x\left(T_\infty - T_2^{p+1}\right)$$

$$+ k\frac{\Delta y}{2}\frac{T_3^{p+1} - T_2^{p+1}}{\Delta x} + k\Delta x\frac{T_5^{p+1} - T_2^{p+1}}{\Delta y} = \rho\, c\left[\Delta x\frac{\Delta y}{2}\right]\frac{T_2^{p+1} - T_2^p}{\Delta t}.$$

Continued …

PROBLEM 5.141 (Cont.)

Divide by k, use the following definitions, and regroup to obtain the finite-difference equations.

$$N \equiv h\Delta x/k = 100\ \text{W/m}^2\cdot\text{K} \times 0.006\text{m}/2\ \text{W/m}\cdot\text{K} = 0.3000 \quad (1)$$

$$Fo \equiv (k/\rho\, c)\Delta t/\Delta x\cdot\Delta y = \alpha\Delta t/\Delta x\cdot\Delta y =$$

$$1.5\times 10^{-6}\text{m}^2/\text{s}\times 1\text{s}/(0.006\times 0.002)\text{m}^2 = 0.1250 \quad (2)$$

$$\frac{1}{2}\left[\frac{\Delta y}{\Delta x}\right]\left(T_1^{p+1}-T_2^{p+1}\right)+N\left(T_\infty - T_2^{p+1}\right)+\frac{1}{2}\left[\frac{\Delta y}{\Delta x}\right]\left(T_3^{p+1}-T_2^{p+1}\right)$$
$$+\left[\frac{\Delta x}{\Delta y}\right]\left(T_5^{p+1}-T_2^{p+1}\right)=\frac{1}{2Fo}\left(T_2^{p+1}-T_2^{p}\right)$$

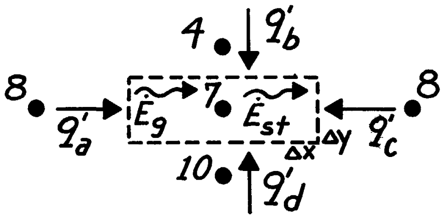
$$\frac{1}{2}\left[\frac{\Delta y}{\Delta x}\right]T_1^{p+1}-\left[\left[\frac{\Delta x}{\Delta y}\right]+N+\left[\frac{\Delta y}{\Delta x}\right]+\frac{1}{2Fo}\right]T_2^{p+1}+\frac{1}{2}\left[\frac{\Delta x}{\Delta y}\right]T_3^{p+1}$$
$$+\left[\frac{\Delta x}{\Delta y}\right]T_5^{p+1}=-NT_\infty-\frac{1}{2Fo}T_2^{p}. \quad (3)$$

Substituting numerical values for Fo and N, and using T_∞ = 30°C and $\Delta x/\Delta y$ = 3, find

$$0.16667T_1^{p+1}-7.63333T_2^{p+1}+0.16667T_3^{p+1}+3.00000T_5^{p+1}=9.0000-4.0000T_2^{p}. \quad (4)$$

By inspection and use of Eq. (3), the FDEs for Nodes 1 and 3 can be inferred.

Interior Node 7. From an energy balance on the prescribed control volume with $\Delta x/\Delta y$ = 3,



$$\dot{E}'_{in}+\dot{E}'_g=\dot{E}'_{st}$$

where $\dot{E}'_g = 2q'_{ht}$ and $\dot{E}'_{in}$ represents the conduction terms $-q'_a+q'_b+q'_c+q'_d$,

$$k\Delta y\frac{T_8^{p+1}-T_7^{p+1}}{\Delta x}+k\Delta x\frac{T_4^{p+1}-T_7^{p+1}}{\Delta y}+k\Delta y\frac{T_8^{p+1}-T_7^{p+1}}{\Delta x}$$
$$+k\Delta x\frac{T_{10}^{p+1}-T_7^{p+1}}{\Delta y}+2q'_{ht}=\rho\, c(\Delta x\cdot\Delta y)\frac{T_7^{p+1}-T_7^{p}}{\Delta t}.$$

Using the definition of Fo, Eq. (2), and regrouping, find

$$\frac{1}{2}\left[\frac{\Delta x}{\Delta y}\right]T_4^{p+1}-\left[\left[\frac{\Delta x}{\Delta y}\right]+\left[\frac{\Delta y}{\Delta x}\right]+\frac{1}{2Fo}\right]T_7^{p+1}$$
$$+\left[\frac{\Delta y}{\Delta x}\right]T_8^{p+1}+\frac{1}{2}\left[\frac{\Delta x}{\Delta y}\right]T_{10}^{p+1}=-\frac{q'_{ht}}{k}-\frac{1}{2Fo}T_7^{p} \quad (5)$$

$$1.50000T_4^{p+1}-7.33333T_7^{p+1}+0.33333T_8^{p+1}+1.50000T_{10}^{p+1}=-12.5000-4.0000T_7^{p}. \quad (6)$$

Continued …

PROBLEM 5.141 (Cont.)

Recognizing the form of Eq. (5), it is a simple matter to infer the FDE for the remaining interior points for which $\dot{q}_{ht} = 0$. In matrix notation [A][T] = [C], the coefficient matrix [A] and RHS matrix [C] are:

THE COEFFICIENT MATRIX, [A] | [C]

												[C]

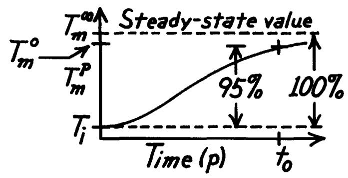
Recall that the problem asks for the time required to reach 95% of the difference for steady-state conditions. This provides information on approximately how long it takes for the plate to come to a steady operating condition. If you worked Problem 4.86, you know the steady-state temperature distribution. Then you can proceed to find the T_m^p values with increasing time until the *first* node reaches the required limit. We should not expect the nodes to reach their limit at the same time.



Not knowing the steady-state temperature distribution, use the implicit FDE in matrix form above to step through time → ∞ to the steady-state solution; that is, proceed to p → 10,20…100 until the solution matrix [T] does not change. The results of the analysis are tabulated below. Column 1 labeled $T_m(\infty)$ is the steady-state distribution. Column 2, $T_m(95\%)$, is the 95% limit being sought as per the graph directly above. The third column is the temperature distribution at t = to = 248s, $T_m(248s)$; at this elapsed time, Node 1 has reached its limit. Can you explain why this node was the first to reach this limit? Which nodes will be the last to reach their limits?

<

$T_m(\infty)$	$T_m(95\%)$	$T_m(248s)$
55.80	54.51	54.51

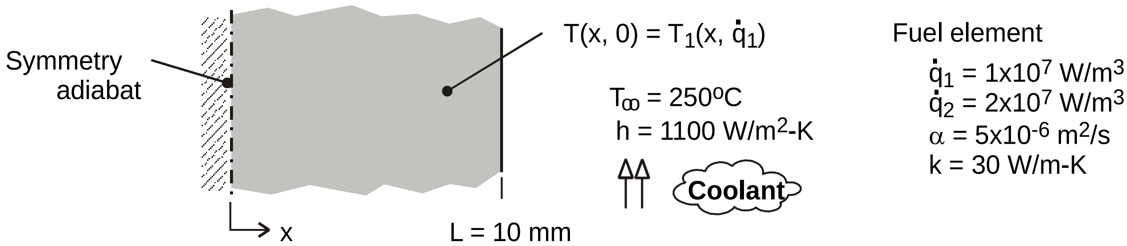
53.35	52.18	51.86
50.46	49.43	48.98

PROBLEM 5.142

KNOWN: Conditions associated with heat generation in a rectangular fuel element with surface cooling. See Example 5.11.

FIND: (a) The temperature distribution 1.5 s after the change in the operating power; compare results with those tabulated in the Example, and (b) Plot the temperature histories at the midplane, x = 0, and the surface, x = L, for $0 \le t \le 400$ s; determine the new steady-state temperatures, and approximately how long it takes to reach this condition. Use the finite-element software *FEHT* as your solution tool.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in the x-direction, (2) Uniform generation, (3) Constant properties.

ANALYSIS: Using *FEHT*, an outline of the fuel element is drawn of thickness 10 mm in the x-direction and arbitrary length in the y-direction. The boundary conditions are specified as follows: on the y-planes and the x = 0 plane, treat as adiabatic; on the x = 10 mm plane, specify the convection option. Specify the material properties and the internal generation with $\dot{q}_1$. In the *Setup* menu, click on *Steady-state*, and then *Run* to obtain the temperature distribution corresponding to the initial temperature distribution, $T_i(x,0) = T(x,\dot{q}_1)$, before the change in operating power to $\dot{q}_2$.

Next, in the *Setup* menu, click on *Transient*; in the *Specify | Internal Generation* box, change the value to $\dot{q}_2$; and in the *Run* command, click on *Continue* (not *Calculate*).

(a) The temperature distribution 1.5 s after the change in operating power from the FEHT analysis and from the FDE analysis in the Example are tabulated below.

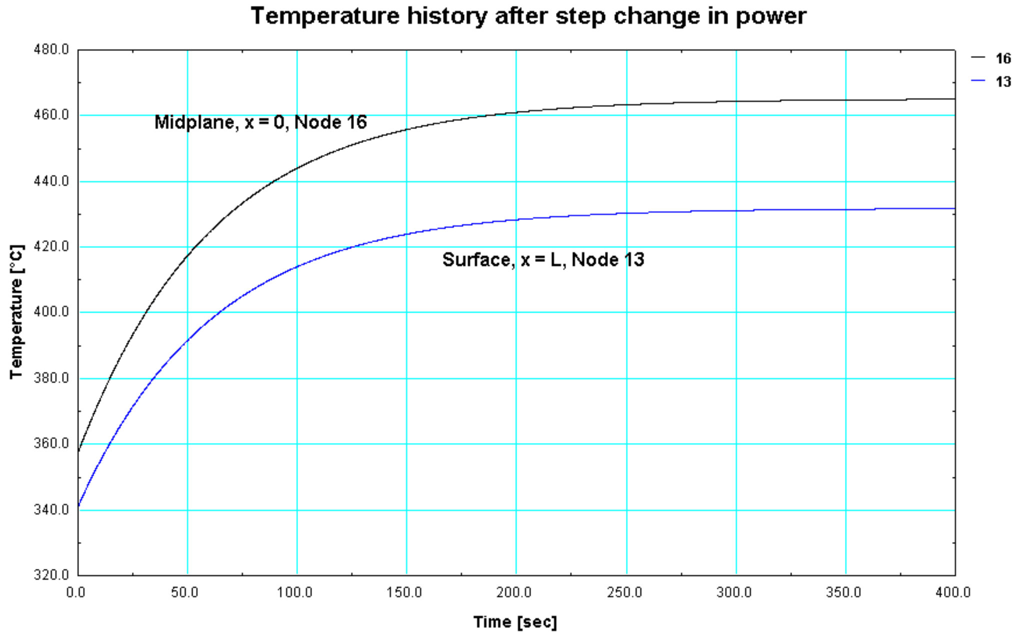
x/L	0	0.2	0.4	0.6	0.8	1.0
T(x/L, 1.5 s)						
FEHT (°C)	360.1	359.4	357.4	354.1	349.3	343.2
FDE (°C)	360.08	359.41	357.41	354.07	349.37	343.27

The mesh spacing for the FEHT analysis was 0.5 mm and the time increment was 0.005 s. For the FDE analyses, the spatial and time increments were 2 mm and 0.3 s. The agreement between the results from the two numerical methods is within 0.1°C.

(b) Using the FEHT code, the temperature histories at the mid-plane (x = 0) and the surface (x = L) are plotted as a function of time.

Continued …

PROBLEM 5.142 (Cont.)



From the distribution, the steady-state condition (based upon 98% change) is approached in 215 s. The steady-state temperature distributions after the step change in power from the FEHT and FDE analysis in the Example are tabulated below. The agreement between the results from the two numerical methods is within 0.1°C

x/L	0	0.2	0.4	0.6	0.8	1.0
$T(x/L, \infty)$						
FEHT (°C)	465.0	463.7	459.6	453.0	443.6	431.7
FDE (°C)	465.15	463.82	459.82	453.15	443.82	431.82

COMMENTS: (1) For background information on the *Continue* option, see the *Run* menu in the *FEHT Help* section. Using the *Run/Calculate* command, the steady-state temperature distribution was determined for the $\dot{q}_1$ operating power. Using the *Run*|*Continue* command (after re-setting the generation to $\dot{q}_2$ and clicking on *Setup* | *Transient*), this steady-state distribution automatically becomes the initial temperature distribution for the $\dot{q}_2$ operating power. This feature allows for conveniently prescribing a non-uniform initial temperature distribution for a transient analysis (rather than specifying values on a node-by-node basis).

(2) Use the *View* | *Tabular Output* command to obtain nodal temperatures to the maximum number of significant figures resulting from the analysis.

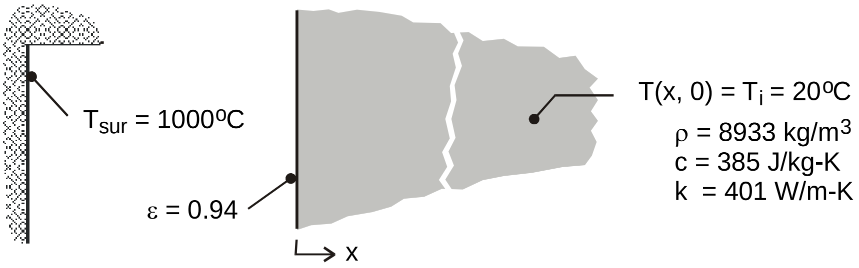
(3) Can you validate the new steady-state nodal temperatures from part (b) (with $\dot{q}_2$, $t \to \infty$) by comparison against an analytical solution?

PROBLEM 5.143

KNOWN: Thick slab of copper as treated in Example 5.12, initially at a uniform temperature, is suddenly exposed to large surroundings at 1000°C (instead of a net radiant flux).

FIND: (a) The temperatures T(0, 120 s) and T(0.15 m, 120s) using the finite-element software *FEHT* for a surface emissivity of 0.94 and (b) Plot the temperature histories for x = 0, 150 and 600 mm, and explain key features of your results.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in the x-direction, (2) Slab of thickness 600 mm approximates a semi-infinite medium, (3) Slab is small object in large, isothermal surroundings.

ANALYSIS: (a) Using FEHT, an outline of the slab is drawn of thickness 600 mm in the x-direction and arbitrary length in the y-direction. Click on *Setup | Temperatures in K*, to enter all temperatures in kelvins. The boundary conditions are specified as follows: on the y-planes and the x = 600 mm plane, treat as adiabatic; on the surface (0,y), select the convection coefficient option, enter the linearized radiation coefficient after Eq. 1.9 written as

0.94 * 5.67e-8 * (T + 1273) * (T^2 + 1273^2)

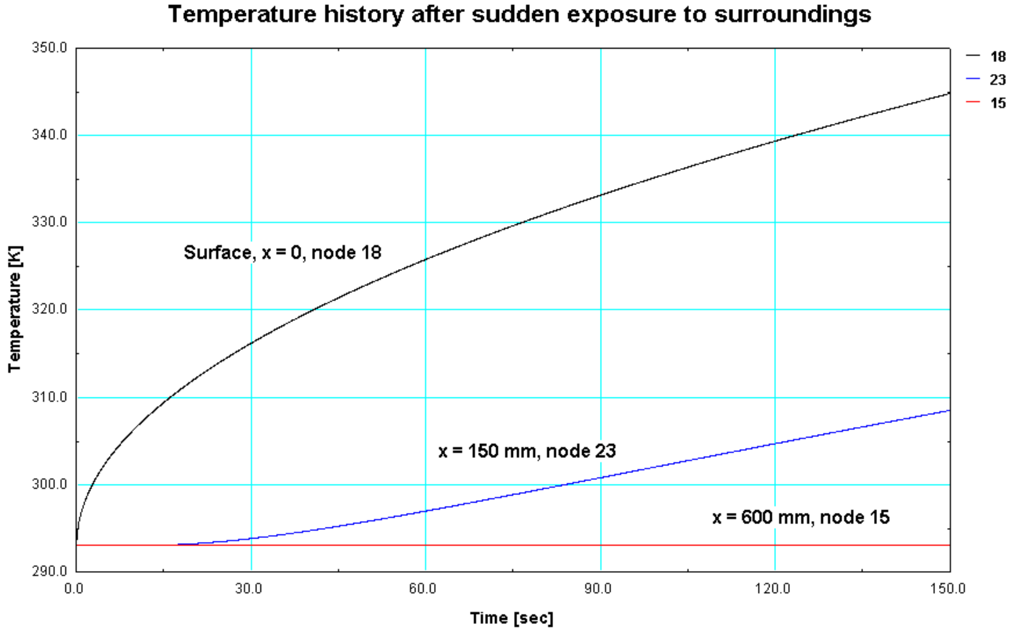
and enter the surroundings temperature, 1273 K, in the fluid temperature box. See the Comments for a view of the input screen. From *View|Temperatures*, find the results:

T(0, 120 s) = 339 K = 66°C   T(150 mm, 120 s) = 305K = 32°C   <

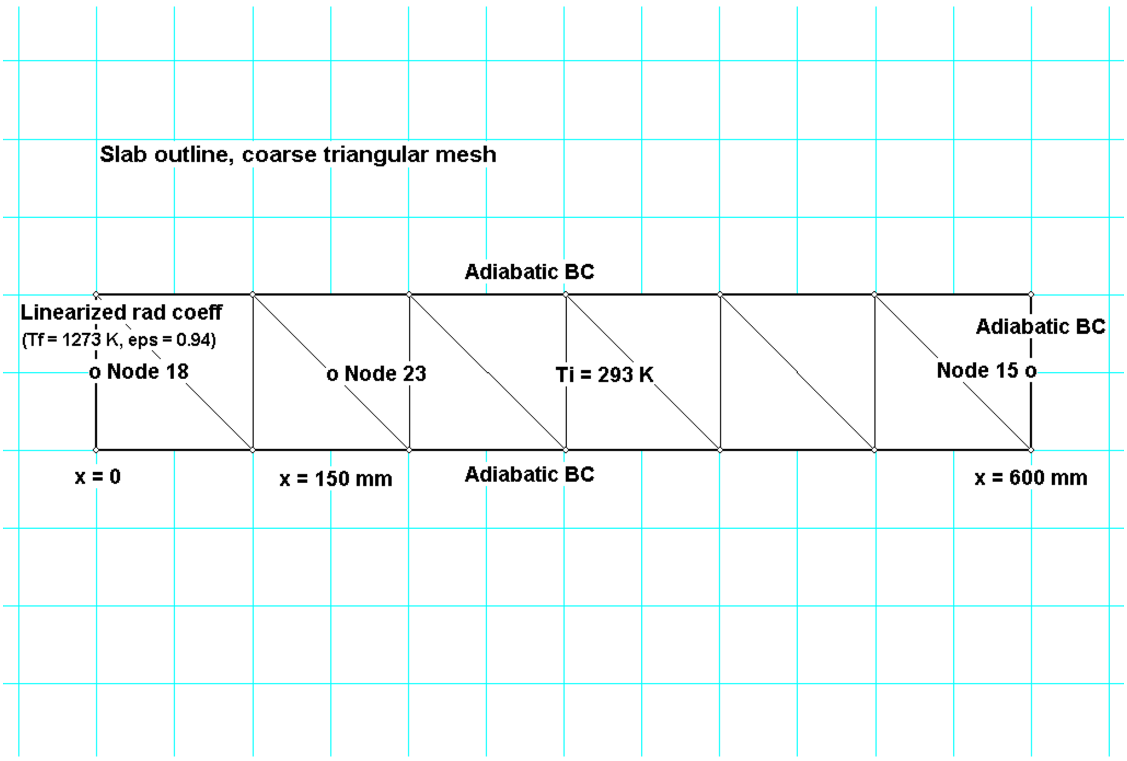
(b) Using the *View | Temperatures* command, the temperature histories for x = 0, 150 and 600 mm (10 mm mesh, Nodes 18, 23 and 15, respectively) are plotted. As expected, the surface temperature increases markedly at early times. As thermal penetration increases with increasing time, the temperature at the location x = 150 mm begins to increase after about 30 s. Note, however, that the temperature at the location x = 600 mm does not change significantly within the 150 s exposure to the hot surroundings. Our assumption of treating the boundary at the x = 600 mm plane as adiabatic is justified. A copper plate of 600 mm is a good approximation to a semi-infinite medium at times less than 150 s.

Continued …

PROBLEM 5.143 (Cont.)



COMMENTS: The annotated *Input* screen shows the outline of the slab, the boundary conditions, and the triangular mesh before using the *Reduce-mesh* option.

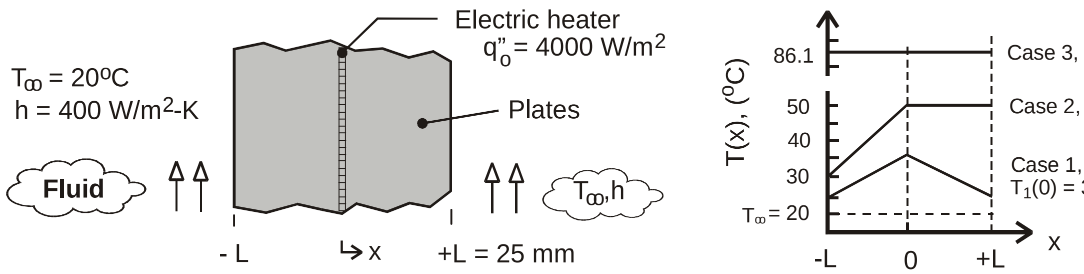


PPROBLEM 5.144

KNOWN: Electric heater sandwiched between two thick plates whose surfaces experience convection. Case 2 corresponds to steady-state operation with a loss of coolant on the x = -L surface. Suddenly, a second loss of coolant condition occurs on the x = +L surface, but the heater remains energized for the next 15 minutes. Case 3 corresponds to the eventual steady-state condition following the second loss of coolant event. See Problem 2.53.

FIND: Calculate and plot the temperature time histories at the plate locations x = 0, ±L during the transient period between steady-state distributions for Case 2 and Case 3 using the finite-element approach with *FEHT* and the finite-difference method of solution with *IHT* (Δx = 5 mm and Δt = 1 s).

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Heater has negligible thickness, and (4) Negligible thermal resistance between the heater surfaces and the plates.

PROPERTIES: Plate material (*given*); ρ = 2500 kg/m^3, c = 700 J/kg·K, k = 5 W/m·K.

ANALYSIS: The temperature distribution for Case 2 shown in the above graph represents the initial condition for the period of time following the second loss of coolant event. The boundary conditions at x = ±L are adiabatic, and the heater flux is maintained at q''_o = 4000 W/m^2 for 0 ≤ t ≤ 15 min.

Using *FEHT*, the heater is represented as a plate of thickness L_h = 0.5 mm with very low thermal capacitance (ρ = 1 kg/m and c = 1 J/kg·K), very high thermal conductivity (k= 10,000 W/m·K), and a uniform volumetric generation rate of $\dot{q} = q''_o / L_h = 4000\ \text{W/m}^2 / 0.0005\ \text{m} = 8.0 \times 10^6$ W/m^3 for 0 ≤ t ≤ 900 s. In the *Specify | Generation* box, the generation was prescribed by the *lookup file* (see *FEHT* Help): 'hfvst',1,2,Time. This *Notepad* file is comprised of four lines, with the values on each line separated by a single tab space:

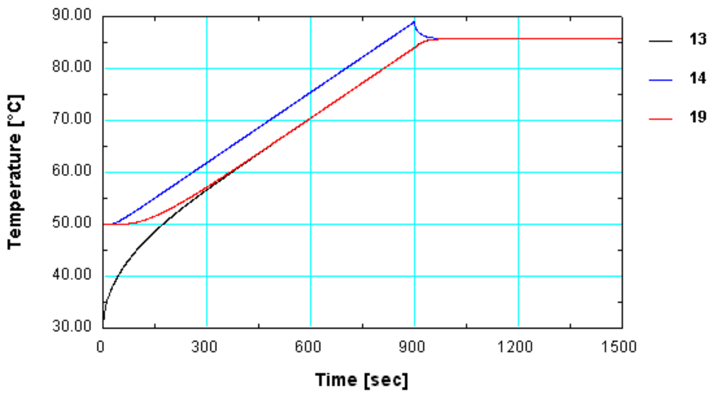
0	8e6
900	8e6
901	0
5000	0

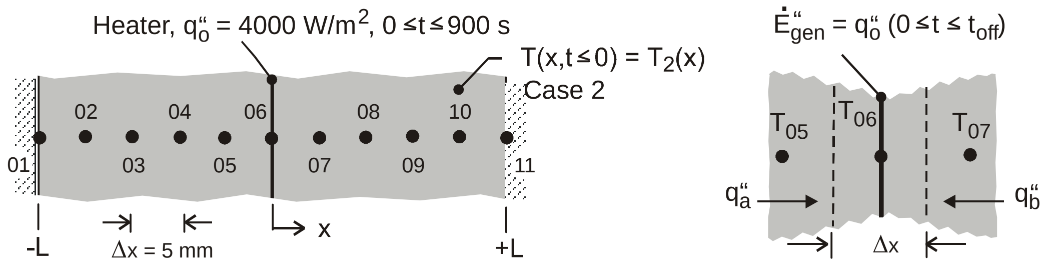
The temperature-time histories are shown in the graph below for the surfaces x = - L (lowest curve, 13) and x = +L (19) and the center point x = 0 (highest curve, 14). The center point experiences the maximum temperature of 89°C at the time the heater is deactivated, t = 900 s.

Continued …

PROBLEM 5.144 (Cont.)

For the finite-difference method of solution, the nodal arrangement for the system is shown below. The *IHT* model builder *Tools* | *Finite-Difference Equations* | *One Dimensional* can be used to obtain the FDEs for the internal nodes (02-04, 07-10) and the adiabatic boundary nodes (01, 11).





Nodal arrangement, FDE solution

Control volume, node 06

For the heater-plate interface node 06, the FDE for the implicit method is derived from an energy balance on the control volume shown in the schematic above.

$$\dot{E}''_{in} - \dot{E}''_{out} + \dot{E}''_{gen} = \dot{E}''_{st}$$

$$q''_a + q''_b + q''_o = \dot{E}''_{st}$$

$$k\frac{T_{05}^{p+1} - T_{06}^{p+1}}{\Delta x} + k\frac{T_{07}^{p+1} - T_{06}^{p+1}}{\Delta x} + q''_o = \rho c \Delta x \frac{T_{06}^{p+1} - T_{06}^{p}}{\Delta t}$$

The *IHT* code representing selected nodes is shown below for the adiabatic boundary node 01, interior node 02, and the heater-plates interface node 06. Note how the foregoing derived finite-difference equation in implicit form is written in the *IHT Workspace*. Note also the use of a *Lookup Table* for representing the heater flux *vs*. time.

```

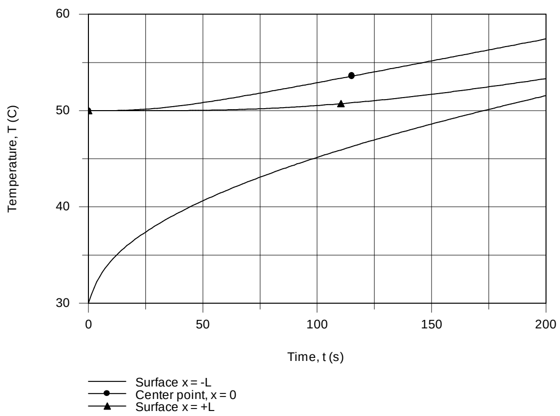
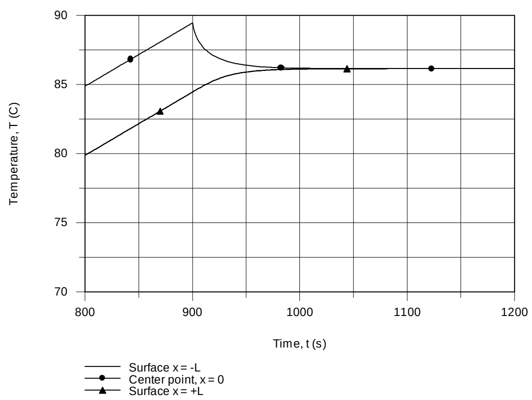
The temperature-time histories using the *IHT* code for the plate locations x = 0, ±L are shown in the graphs below. We chose to show expanded presentations of the histories at early times, just after the second loss of coolant event, t = 0, and around the time the heater is deactivated, t = 900 s.





COMMENTS: (1) The maximum temperature during the transient period is at the center point and occurs at the instant the heater is deactivated, T(0, 900s) = 89°C. After 300 s, note that the two surface temperatures are nearly the same, and never rise above the final steady-state temperature.

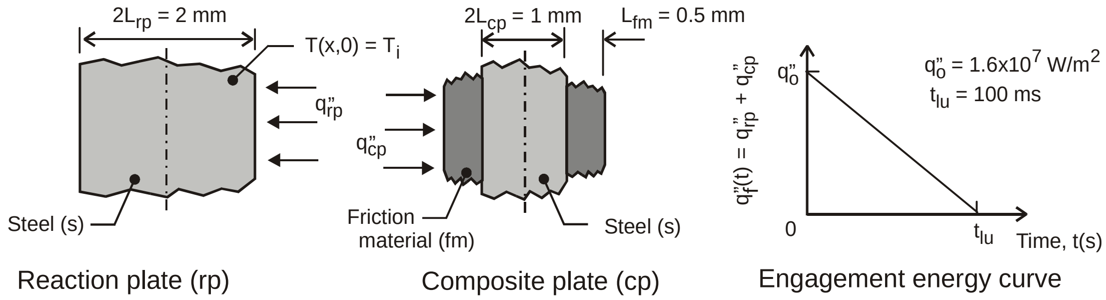
(2) Both the FEHT and IHT methods of solution give identical results. Their steady-state solutions agree with the result of an energy balance on a time interval basis yielding T_{ss} = 86.1°C.

PROBLEM 5.145

KNOWN: Reaction and composite clutch plates, initially at a uniform temperature, T_i = 40°C, are subjected to the frictional-heat flux shown in the engagement energy curve, q''_f vs. t .

FIND: (a) On T-t coordinates, sketch the temperature histories at the mid-plane of the reaction plate, at the interface between the clutch pair, and at the mid-plane of the composite plate; identify key features; (b) Perform an energy balance on the clutch pair over a time interval basis and calculate the steady-state temperature resulting from a clutch engagement; (c) Obtain the temperature histories using the finite-element approach with *FEHT* and the finite-difference method of solution with *IHT* (Δx = 0.1 mm and Δt = 1 ms). Calculate and plot the frictional heat fluxes to the reaction and composite plates, q''_{rp} and q''_{cp}, respectively, as a function of time. Comment on the features of the temperature and frictional-heat flux histories.

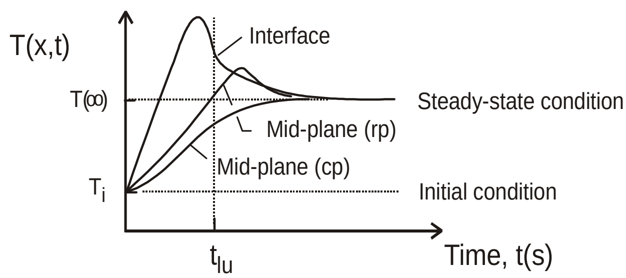
SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Negligible heat transfer to the surroundings.

PROPERTIES: Steel, ρ_s = 7800 kg/m^3, c_s = 500 J/kg·K, k_s = 40 W/m·K; Friction material, ρ_{fm} = 1150 kg/m^3, c_{fm} = 1650 J/kg·K, and k_{fm} = 4 W/m·K.

ANALYSIS: (a) The temperature histories for specified locations in the system are sketched on T-t coordinates below.

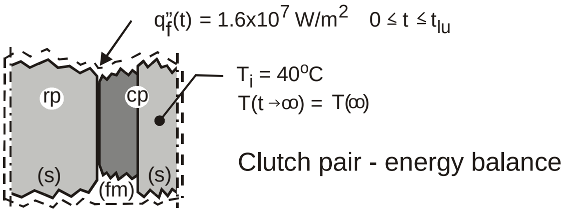


Initially, the temperature at all locations is uniform at T_i. Since there is negligible heat transfer to the surroundings, eventually the system will reach a uniform, steady-state temperature $T(\infty)$. During the engagement period, the interface temperature increases much more rapidly than at the mid-planes of the reaction (rp) and composite (cp) plates. The interface temperature should be the maximum within the system and could occur before lock-up, $t = t_{lu}$.

Continued …

PROBLEM 5.145 (Cont.)

(b) To determine the steady-state temperature following the engagement period, apply the conservation of energy requirement on the clutch pair on a time-interval basis, Eq. 1.12b.



The final and initial states correspond to uniform temperatures of T(∞) and T_i, respectively. The energy input is determined from the engagement energy curve, q''_f vs. t .

$$E''_{in} - E''_{out} + E''_{gen} = \Delta E''_{st} \qquad E''_{in} = E''_{out} = 0$$

$$\int_0^{t_{lu}} q''_f(t)\,dt = E''_f - E''_i = \left[\rho_s c_s \left(L_{rp}/2 + L_{cp}/2\right) + \rho_{fm} c_{fm} L_{fm}\right](T_f - T_i)$$

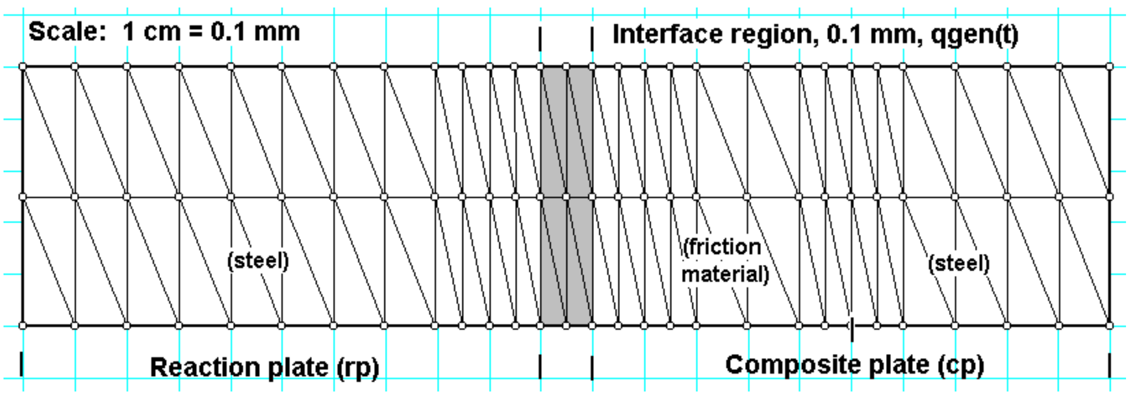
Substituting numerical values, with T_i = 40°C and T_f = T(∞).

$$0.5\ q''_o\ t_{lu} = \left[\rho_s c_s \left(L_{rp}/2 + L_{cp}/2\right) + \rho_{fm} c_{fm} L_{fm}\right]\left(T(\infty) - T_i\right)$$

$$0.5 \times 1.6 \times 10^7\ \mathrm{W/m^2} \times 0.100\ \mathrm{s} = \left[7800\ \mathrm{kg/m^3} \times 500\ \mathrm{J/kg \cdot K}\left(0.001 + 0.0005\right)\mathrm{m}\right.$$
$$\left. +1150\ \mathrm{kg/m^3} \times 1650\ \mathrm{J/kg \cdot K} \times 0.0005\ \mathrm{m}\right]\left(T(\infty) - 40\right)°\mathrm{C}$$

$$T(\infty) = 158°\mathrm{C}$$ <

(c) *Finite-element method of solution, FEHT*. The clutch pair is comprised of the reaction plate (1 mm), an interface region (0.1 mm), and the composite plate (cp) as shown below.



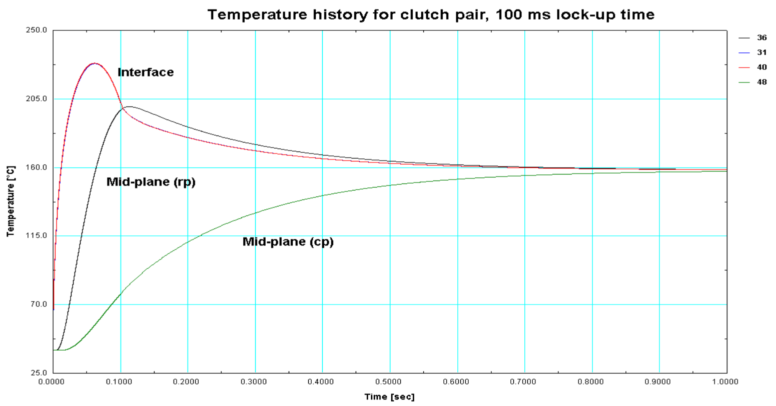
Continued ...

PROBLEM 5.145 (Cont.)

The external boundaries of the system are made adiabatic. The interface region provides the means to represent the frictional heat flux, specified with negligible thermal resistance and capacitance. The generation rate is prescribed as

$$\dot{q} = 1.6 \times 10^{11} (1 - \text{Time}/0.1)\, \text{W/m}^3 \qquad 0 \le \text{Time} \le t_{lu}$$

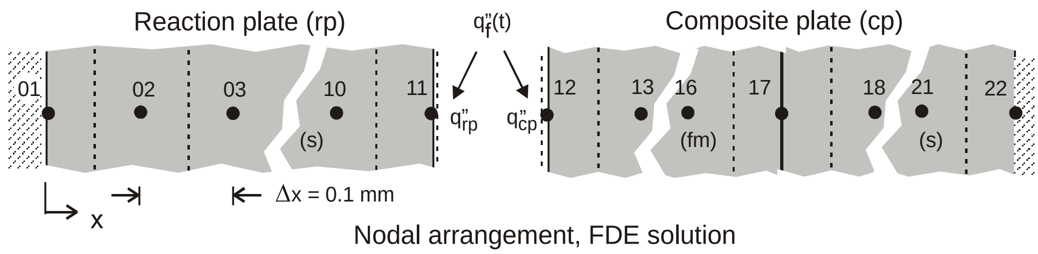
where the first coefficient is evaluated as $q''_o \,/\, 0.1 \times 10^{-3}\,\text{m}$ and the 0.1 mm parameter is the thickness of the region. Using the *Run* command, the integration is performed from 0 to 0.1 s with a time step of 1×10^{-6} s. Then, using the *Specify|Generation* command, the generation rate is set to zero and the *Run|Continue* command is executed. The temperature history is shown below.



(c) *Finite-difference method of solution*, IHT. The nodal arrangement for the clutch pair is shown below with Δx = 0.1 mm and Δt = 1 ms. Nodes 02-10, 13-16 and 18-21 are interior nodes, and their finite-difference equations (FDE) can be called into the *Workspace* using *Tools|Finite Difference Equations|One-Dimenisonal|Transient*. Nodes 01 and 22 represent the mid-planes for the reaction and composite plates, respectively, with adiabatic boundaries. The FDE for node 17 is derived from an energy balance on its control volume (CV) considering different properties in each half of the CV. The FDE for node 11 and 12 are likewise derived using energy balances on their CVs. At the interface, the following conditions must be satisfied

$$T_{11} = T_{12} \qquad\qquad q''_f = q''_{rp} + q''_{cp}$$

The frictional heat flux is represented by a *Lookup Table*, which along with the FDEs, are shown in the *IHT* code listed in Comment 2.

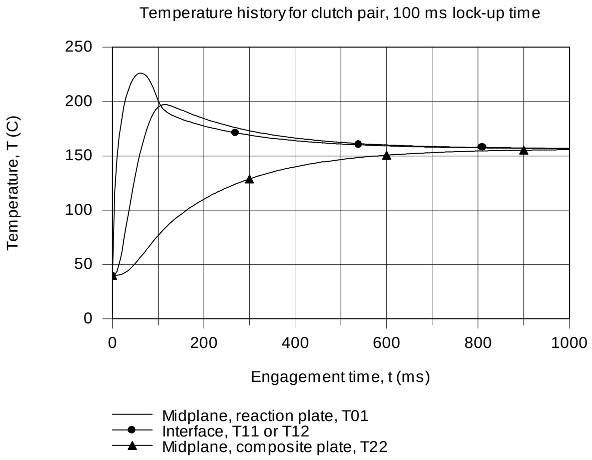


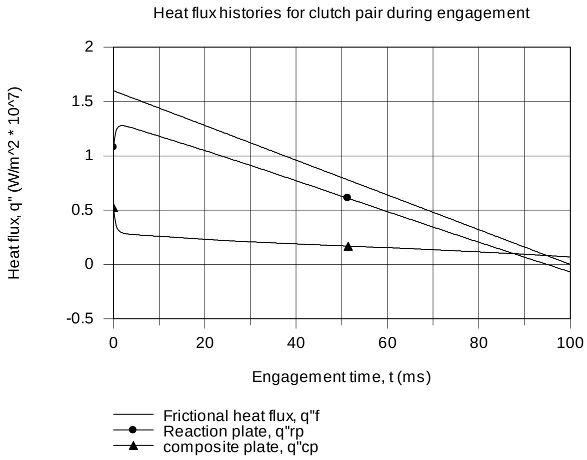
Nodal arrangement, FDE solution

Continued ...

PROBLEM 5.145 (Cont.)

The temperature and heat flux histories are plotted below. The steady-state temperature was found as 156.5° C, which is in reasonable agreement with the energy balance result from part (a).





COMMENTS: (1) The temperature histories resulting from the FEHT and IHT based solutions are in agreement. The interface temperature peaks near 225°C after 75 ms, and begins dropping toward the steady-state condition. The mid-plane of the reaction plate peaks around 100 ms, nearly reaching 200°C. The temperature of the mid-plane of the composite plate increases slowly toward the steady-state condition.

(2) The calculated temperature-time histories for the clutch pair display similar features as expected from our initial sketches on T vs. t coordinates, part a. The maximum temperature for the composite is very high, subjecting the bonded frictional material to high thermal stresses as well as accelerating deterioration. For the reaction steel plate, the temperatures are moderate, but there is a significant gradient that could give rise to thermal stresses and hence, warping. Note that for the composite plate, the steel section is nearly isothermal and is less likely to experience warping.

(2) The *IHT* code representing the FDE for the 22 nodes and the frictional heat flux relation is shown below. Note use of the *Lookup Table* for representing the frictional heat flux *vs*. time boundary condition for nodes 11 and 12.

```
// Nodal equations, reaction plate (steel)

```

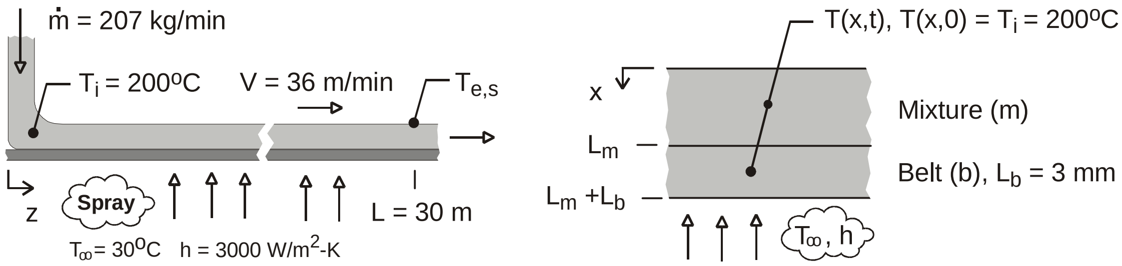
PROBLEM 5.146

KNOWN: A process mixture at 200°C flows at a rate of 207 kg/min onto a 1-m wide conveyor belt traveling with a velocity of 36 m/min. The underside of the belt is cooled by a water spray.

FIND: The surface temperature of the mixture at the end of the conveyor belt, $T_{e,s}$, using (a) *IHT* for writing and solving the FDEs, and (b) *FEHT*. Validate your numerical codes against an appropriate analytical method of solution.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in the x-direction at any z-location, (2) Negligible heat transfer from mixture upper surface to ambient air, and (3) Constant properties.

PROPERTIES: Process mixture (m), $\rho_m = 960$ kg/m^3, $c_m = 1700$ J/kg·K, and $k_m = 1.5$ W/m·K; Conveyor belt (b), $\rho_b = 8000$ kg/ m^3, $c_b = 460$ J/kg·K, and $k_b = 15$ W/m·K.

ANALYSIS: From the conservation of mass requirement, the thickness of the mixture on the conveyor belt can be determined.

$$\dot{m} = \rho_m A_c V \qquad \text{where} \qquad A_c = W L_m$$

$$207\ \text{kg/min} \times 1\ \text{min}/60\,\text{s} = 960\ \text{kg/m}^3 \times 1\,\text{m} \times L_m \times 36\,\text{m/min} \times 1\text{min}/60\,\text{s}$$

$$L_m = 0.0060\,\text{m} = 6\ \text{mm}$$

The time that the mixture is in contact with the steel conveyor belt, referred to as the residence time, is

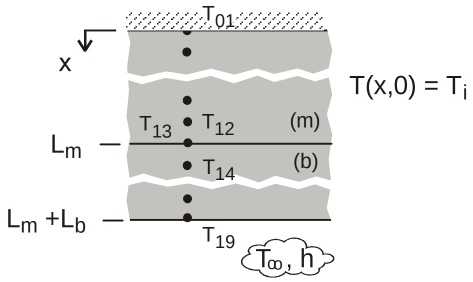
$$t_{res} = L_c / V = 30\ \text{m}/\left(36\ \text{m/min} \times 1\ \text{min}/60\ \text{s}\right) = 50\ \text{s}$$

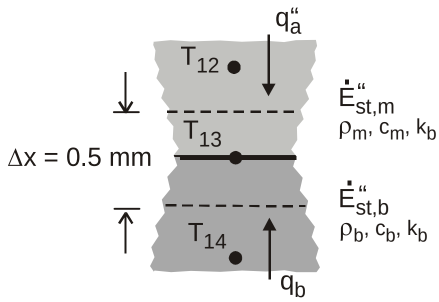
The composite system comprised of the belt, $L_b = 3$ mm, and mixture, $L_m = 6$ mm, as represented in the schematic above, is initially at a uniform temperature $T(x,0) = T_i = 200$°C while at location z = 0, and suddenly is exposed to convection cooling (T_∞, h). We will calculate the mixture upper surface temperature after 50 s, $T(0, t_{res}) = T_{e,s}$.

(a) The nodal arrangement for the composite system is shown in the schematic below. The *IHT* model builder *Tools|Finite-Difference Equations|Transient* can be used to obtain the FDEs for nodes 01-12 and 14-19.

Continued …

PROBLEM 5.146 (Cont.)





For the mixture-belt interface node 13, the FDE for the implicit method is derived from an energy balance on the control volume about the node as shown above.

$$\dot{E}''_{in} - \dot{E}''_{out} = \dot{E}''_{st}$$

$$q''_a + q''_b = \dot{E}''_{st,m} + \dot{E}''_{st,b}$$

$$k_m \frac{T_{12}^{p+1} - T_{13}^{p+1}}{\Delta x} + k_b \frac{T_{14}^{p+1} - T_{13}^{p+1}}{\Delta x} = \left(\rho_m c_m + \rho_b c_b\right)\left(\Delta x / 2\right) \frac{T_{13}^{p+1} - T_{13}^{p}}{\Delta t}$$

IHT code representing selected FDEs, nodes 01, 02, 13 and 19, is shown in Comment 4 below (Δx = 0.5 mm, Δt = 0.1 s). Note how the FDE for node 13 derived above is written in the *Workspace*. From the analysis, find

$T_{e,s} = T(0, 50s) = 54.8°C$ <

(b) Using *FEHT*, the composite system is drawn and the material properties, boundary conditions, and initial temperature are specified. The screen representing the system is shown below in Comment 5 with annotations on key features. From the analysis, find

$T_{e,s} = T(0, 50s) = 54.7°C$ <

COMMENTS: (1) Both numerical methods, *IHT* and *FEHT*, yielded the same result, 55°C. For the safety of plant personnel working in the area of the conveyor exit, the mixture exit temperature should be lower, like 43°C.

(2) By giving both regions of the composite the same properties, the analytical solution for the plane wall with convection, Section 5.5, Eq. 5.43, can be used to validate the *IHT* and *FEHT* codes. Using the *IHT Models|Transient Conduction|Plane Wall* for a 9-mm thickness wall with mixture thermophysical properties, we calculated the temperatures after 50 s for three locations: T(0, 50s) = 91.4°C; T(6 mm, 50s) = 63.6°C; and T(3 mm, 50s) = 91.4°C. The results from the *IHT* and *FEHT* codes agreed exactly.

(3) In view of the high heat removal rate on the belt lower surface, it is reasonable to assume that negligible heat loss is occurring by convection on the top surface of the mixture.

Continued …

PROBLEM 5.146 (Cont.)

(4) The *IHT* code representing selected FDEs, nodes 01, 02, 13 and 19, is shown below. The FDE for node 13 was derived from an energy balance, while the others are written from the *Tools* pad.

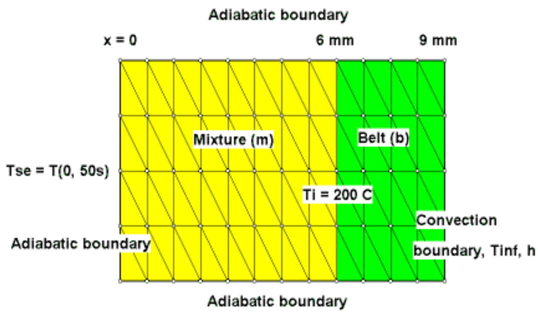
```
// Finite difference equations from Tools, Nodes 01 -12 (mixture) and 14-19 (belt)
/* Node 01: surface node (w-orientation); transient conditions; e labeled 02. */
rhom * cm * der(T01,t) = fd_1d_sur_w(T01,T02,km,qdot,deltax,Tinf01,h01,q''a01)
q''a01 = 0        // Applied heat flux, W/m^2; zero flux shown
qdot = 0
Tinf01 = 20      // Arbitrary value
h01 = 1e-6       // Causes boundary to behave as adiabatic

/* Node 02: interior node; e and w labeled 03 and 01. */
rhom*cm*der(T02,t) = fd_1d_int(T02,T03,T01,km,qdot,deltax)

/* Node 19: surface node (e-orientation); transient conditions; w labeled 18. */
rhob * cb * der(T19,t) = fd_1d_sur_e(T19,T18,kb,qdot,deltax,Tinf19,h19,q''a19)
q''a19 = 0        // Applied heat flux, W/m^2; zero flux shown
Tinf19 = 30
h19 = 3000

// Finite-difference equation from energy balance on CV, Node 13
km*(T12 - T13)/deltax + kb*(T14 - T13)/deltax = (rhom*cm + rhob*cb) *(deltax/2)*der(T13,t)
```

(5) The screen from the *FEHT* analysis is shown below. It is important to use small time steps in the integration at early times. Use the *View|Temperatures* command to find the temperature of the mixture surface at t_{res} = 50 s.

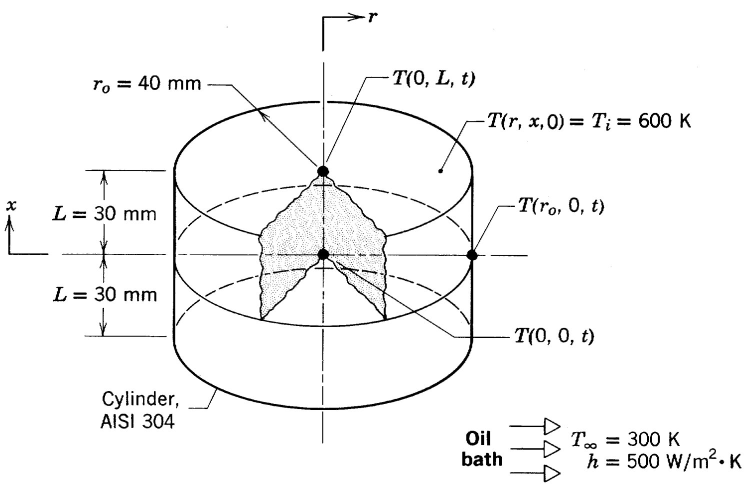


PROBLEM 5.147

KNOWN: Stainless steel cylinder, 80-mm diameter by 60-mm length, initially at 600 K, suddenly quenched in an oil bath at 300 K with h = 500 $W/m^2 \cdot K$. Use the ready-to-solve model in the *Examples* menu of *FEHT* to obtain the following solutions.

FIND: (a) Calculate the temperatures T(r, x ,t) after 3 min: at the cylinder center, T(0, 0, 3 mm), at the center of a circular face, T(0, L, 3 min), and at the midheight of the side, $T(r_o, 0, 3\ min)$; compare your results with those in the example; (b) Calculate and plot temperature histories at the cylinder center, T(0, 0, t), the mid-height of the side, $T(r_o, 0, t)$, for $0 \le t \le 10$ min; use the *View/Temperature vs. Time* command; comment on the gradients and what effect they might have on phase transformations and thermal stresses; (c) Using the results for the total integration time of 10 min, use the *View/Temperature Contours* command; describe the major features of the cooling process shown in this display; create and display a 10-isotherm temperature distribution for t = 3 min; and (d) For the locations of part (a), calculate the temperatures after 3 min if the convection coefficient is doubled (h = 1000 $W/m^2 \cdot K$); for these two conditions, determine how long the cylinder needs to remain in the oil bath to achieve a safe-to touch surface temperature of 316 K. Tabulate and comment on the results of your analysis.

SCHEMATIC:



ASSUMPTIONS: (1) Two-dimensional conduction in r- and x-coordinates, (2) Constant properties.

PROPERTIES: Stainless steel: ρ = 7900 kg/m^3, c = 526 J/kg·K, k = 17.4 W/m·K.

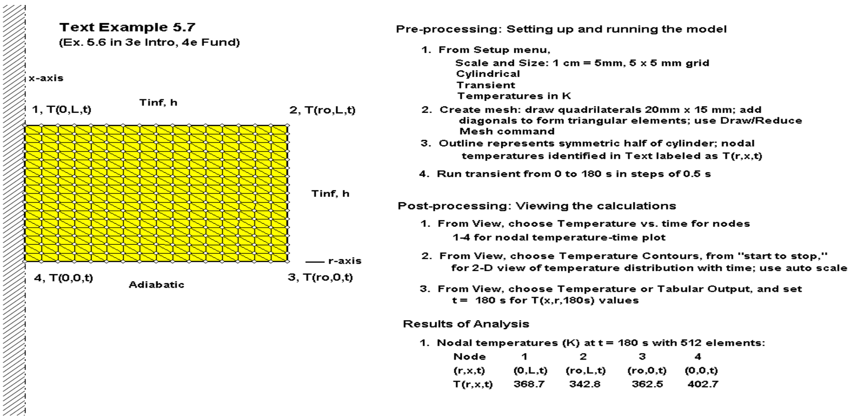
ANALYSIS: (a) The *FEHT ready-to-solve* model is accessed through the *Examples* menu and the annotated *Input* page is shown below. The following steps were used to obtain the solution: (1) Use the *Draw /Reduce Mesh* command three times to create the 512-element mesh; (2) In *Run*, click on *Check*, (3) In *Run*, press *Calculate* and hit *OK* to initiate the solver; and (4) Go to the *View* menu, select *Tabular Output* and read the nodal temperatures 4, 1, and 3 at t = t_o = 180 s. The tabulated results below include those from the n-term series solution used in the *IHT* software.

Continued …

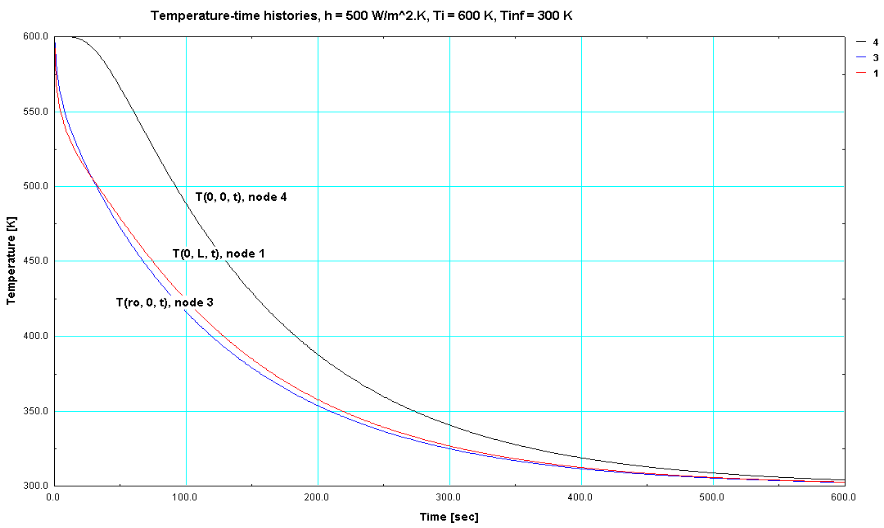
PROBLEM 5.147 (Cont.)

(r, x, t_o)	FEHT node	$T(r, x, t_o)$ (K) *FEHT*	$T(r, x, t_o)$ (K) 1-term series	$T(r, x, t_o)$ (K) n-term series
$0, 0, t_o$	4	402.7	405	402.7
$0, L, t_o$	1	368.7	372	370.5
$ro, 0, t_o$	3	362.5	365	362.4

The *FEHT* results are in excellent agreement with the *IHT* n-term series solutions for the x = 0 plane nodes (4,3), except for the x = L plane node (1).



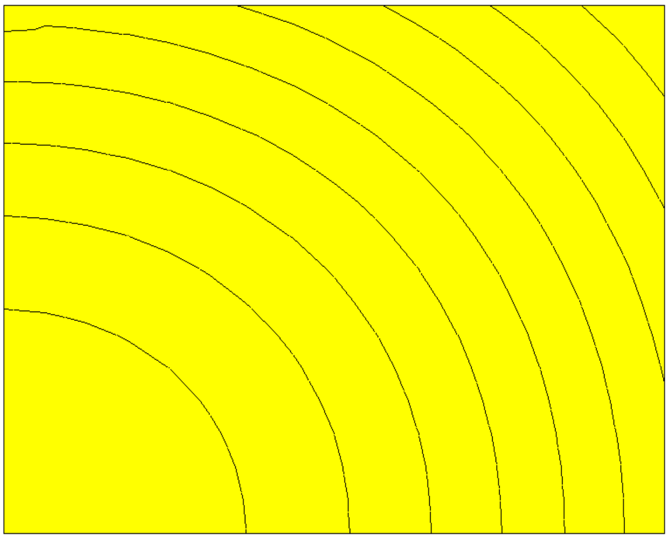
(b) Using the *View Temperature vs. Time* command, the temperature histories for nodes 4, 1, and 3 are plotted in the graph shown below. There is very small temperature difference between the locations on the surface, (node 1; 0, L) and (node 3; r_o, 0). But, the temperature difference between these surface locations and the cylinder center (node 4; 0, 0) is large at early times. Such differences wherein locations cool at considerably different rates could cause variations in microstructure and hence, mechanical properties, as well as induce thermal stresses.



Continued …

PROBLEM 5.147 (Cont.)

(c) Use the *View|Temperature Contours* command with the shaded band option for the isotherm contours. Selecting the *From Start to Stop* time option, see the display of the contours as the cylinder cools during the quench process. The "movie" shows that cooling initiates at the corner (r_o,L,t) and the isotherms quickly become circular and travel toward the center (0,0,t). The 10-isotherm distribution for t = 3 min is shown below.



(d) Using the *FEHT* model with convection coefficients of 500 and 1000 $W/m^2 \cdot K$, the temperatures at $t = t_o = 180$ s for the three locations of part (a) are tabulated below.

	$h = 500\ W/m^2 \cdot K$	$h = 1000\ W/m^2 \cdot K$
$T(0, 0, t_o)$, K	402.7	352.8
$T(0, L, t_o)$, K	368.7	325.8
$T(r_o, 0, t_o)$, K	362.5	322.1

Note that the effect of doubling the convection coefficient is to reduce the temperature at these locations by about 40°C. The time the cylinder needs to remain in the oil bath to achieve the *safe-to-touch* surface temperature of 316 K can be determined by examining the temperature history of the location (node1; 0, L). For the two convection conditions, the results are tabulated below. Doubling the coefficient reduces the cooling process time by 40 %.

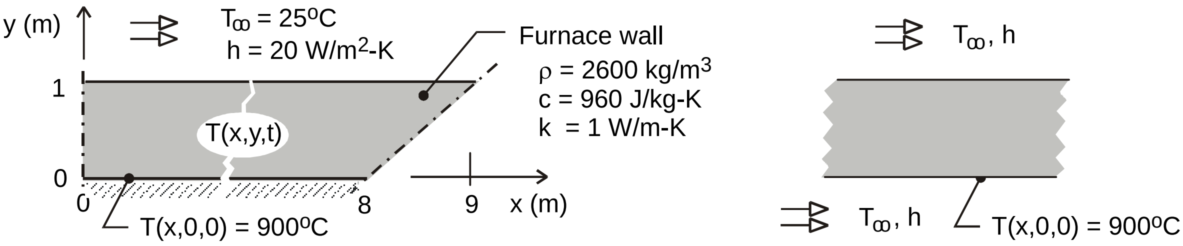
$T(0, L, t_o)$	$h\ (W/m^2 \cdot K)$	t_o (s)
316	500	370
316	1000	219

PROBLEM 5.148

KNOWN: Cubic-shaped furnace, with prescribed operating temperature and convection heat transfer on the exterior surfaces.

FIND: Time required for the furnace to cool to a safe working temperature corresponding to an inner wall temperature of 35°C considering convection cooling on (a) the exterior surfaces and (b) on both the exterior and interior surfaces.

SCHEMATIC:



(a) Adiabatic inner surface **(b) Cooled inner surface**

ASSUMPTIONS: (1) Two-dimensional conduction through the furnace walls and (2) Constant properties.

ANALYSIS: Assuming two-dimensional conduction through the walls and taking advantage of symmetry for the cubical shape, the analysis considers the quarter section shown in the schematic above. For part (a), with no cooling on the interior during the cool-down process, the inner surface boundary condition is adiabatic. For part (b), with cooling on both the exterior and interior, the boundary conditions are prescribed by the convection process. The boundaries through the centerline of the wall and the diagonal through the corner are symmetry planes and considered as adiabatic. We have chosen to use the finite-element software *FEHT* as the solution tool.

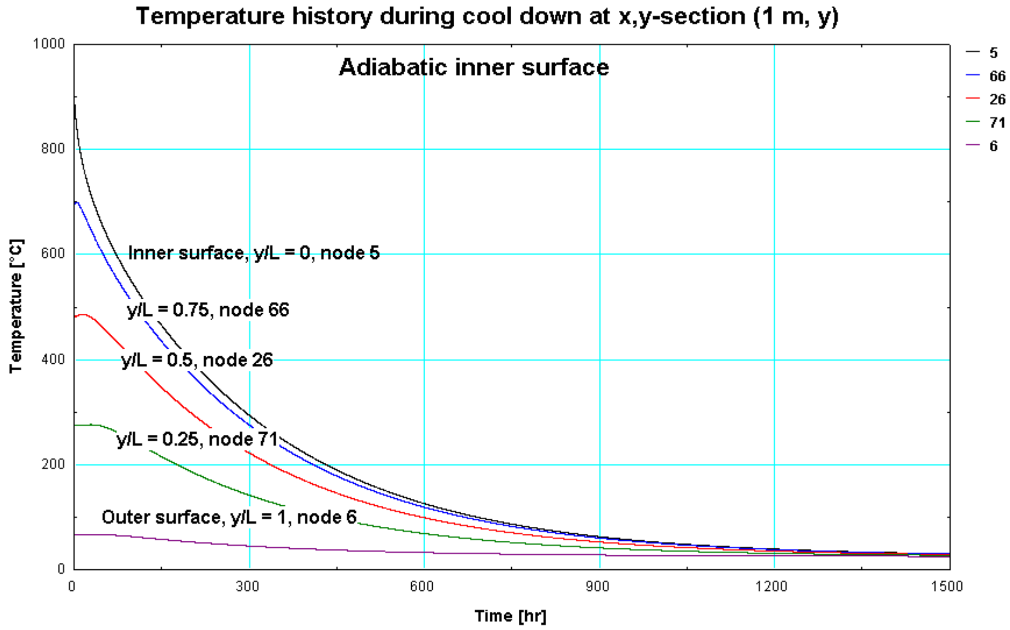
Using *FEHT*, an outline of the symmetrical wall section is drawn, and the material properties are specified. To determine the initial conditions for the cool-down process, we will first find the temperature distribution for steady-state operation. As such, specify the boundary condition for the inner surface as a constant temperature of 900°C; the other boundaries are as earlier described. In the *Setup* menu, click *on Steady-State*, and then *Run* to obtain the steady-state temperature distribution. This distribution represents the initial temperature distribution, T_i (x, y, 0), for the wall at the onset of the cool-down process.

Next, in the *Setup* menu, click on *Transient*; for the nodes on the inner surface, in the *Specify | Boundary Conditions* menu, deselect the *Temperature* box (900°C) and set the *Flux* box to zero for the adiabatic condition (part (a)); and, in the *Run* command, click on *Continue* (not *Calculate*). Be sure to change the integration time scale from *seconds* to *hours*.

Because of the high ratio of wall section width (nearly 8.5 m) to the thickness (1 m), the conduction heat transfer through the section is nearly one-dimensional. We chose the x,y-section 1 m to the right of the centerline (1 m, y) as the location for examining the temperature-time history, and determining the cool-down time for the inner surface to reach the safe working temperature of 35°C.

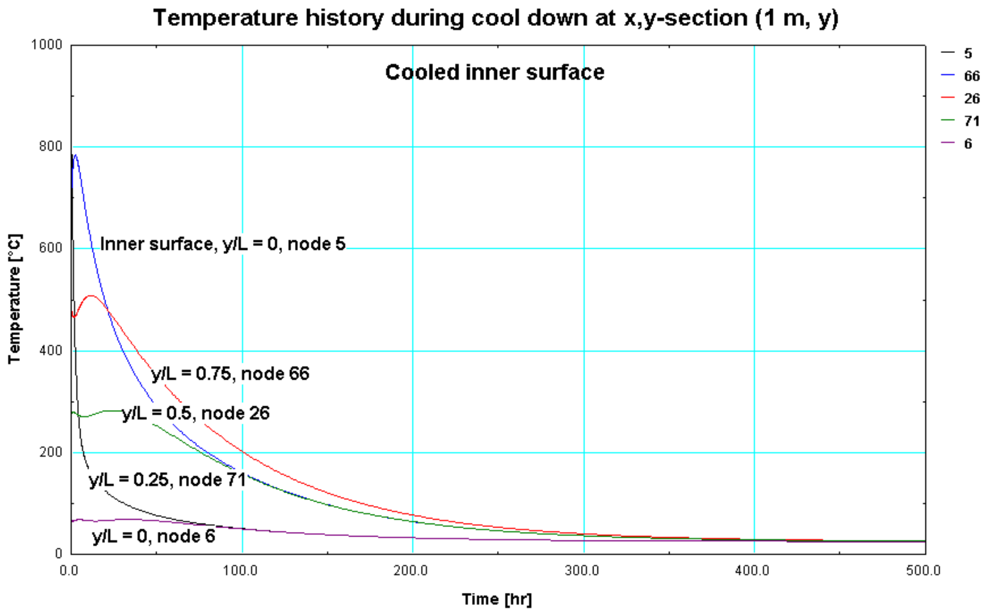
Continued …

PROBLEM 5.148 (Cont.)



Time-to-cool, Part (a), Adiabatic inner surface. From the above temperature history, the cool-down time, t_a, corresponds to the condition when T_a (1 m, 0, t_a) = 35°C. As seen from the history, this location is the last to cool. From the *View | Tabular Output*, find that

$$t_a = 1306 \text{ h} = 54 \text{ days}$$ <



Continued …

PROBLEM 5.148 (Cont.)

Time-to-cool, Part (b), Cooled inner surface. From the above temperature history, note that the center portion of the wall, and not the inner surface, is the last to cool. The inner surface cools to 35°C in approximately 175 h or 7 days. However, if the cooling process on the inner surface were discontinued, its temperature would increase and eventually exceed the desired safe working temperature. To assure the safe condition will be met, estimate the cool down time as, t_b, corresponding to the condition when T_b (1 m, 0.75 m, t_b) = 35°C. From the *View | Tabular Output*, find that

$$t_b = 311\text{ h} = 13\text{ days}$$ <

COMMENTS: (1) Assuming the furnace can be approximated by a two-dimensional symmetrical section greatly simplifies our analysis by not having to deal with three-dimensional corner effects. We justify this assumption on the basis that the corners represent a much shorter heat path than the straight wall section. Considering corner effects would reduce the cool-down time estimates; hence, our analysis provides a conservative estimate.

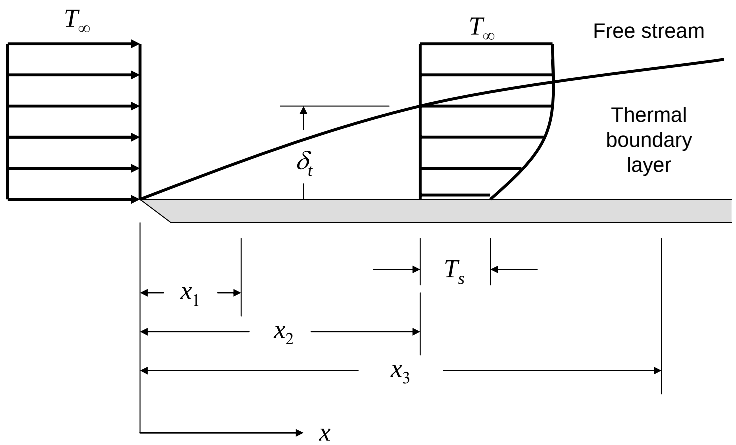
(2) For background information on the *Continue* option, see the *Run* menu in the *FEHT Help* section. Using the *Run | Calculate* command, the steady-state temperature distribution was determined for the normal operating condition of the furnace. Using the *Run | Continue* command (after clicking on *Setup | Transient*), this steady-state distribution automatically becomes the initial temperature distribution for the cool-down transient process. This feature allows for conveniently prescribing a non-uniform initial temperature distribution for a transient analysis (rather than specifying values on a node-by-node basis.

PROBLEM 6.1

KNOWN: Temperature distribution at x_2 in laminar thermal boundary layer.

FIND: (a) Whether plate is being heated or cooled, (b) Temperature distributions at two other x locations. Locations of largest and smallest heat fluxes, (c) Temperature distribution at x_2 for lower and higher free stream velocities. Which velocity condition causes the largest heat flux.

SCHEMATIC:



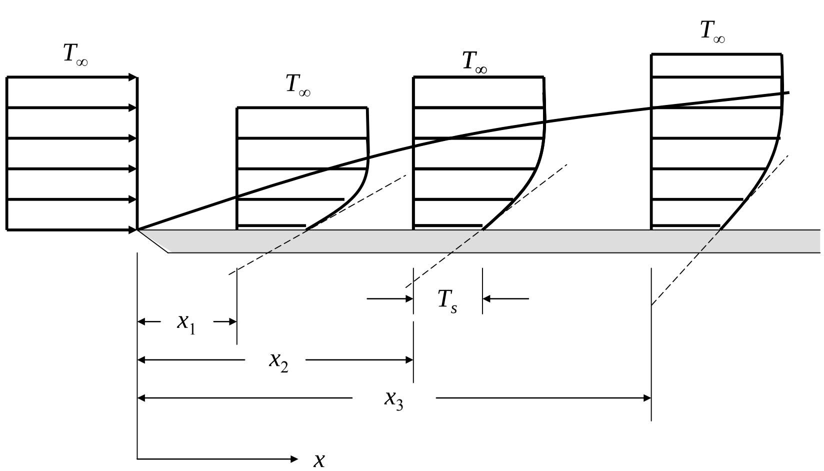
ASSUMPTIONS: (1) Steady-state conditions, (2) Laminar, incompressible flow.

ANALYSIS: (a) Since the sketch indicates that the free stream temperature is greater than the surface temperature, the plate is being heated by the fluid. This is consistent with the fact that the surface heat flux in the positive y-direction is given by Eq. 6.3:

$$q_s'' = -k_f \left.\frac{\partial T}{\partial y}\right|_{y=0}$$

From the sketch, the temperature gradient is positive, therefore the heat flux is negative. The heat transfer is in the negative y-direction, the plate is being heated by the fluid. <

(b) At every location in the boundary layer, the temperature must vary from T_s at the surface to T_∞ in the free stream. This change must occur within the thermal boundary layer thickness, as shown in the sketch below.

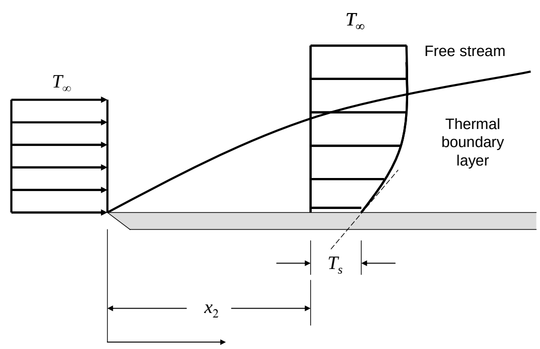


Continued...

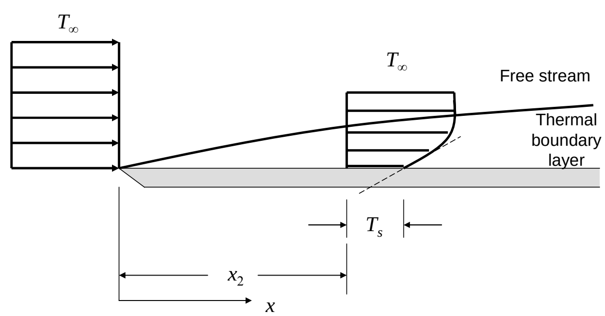
PROBLEM 6.1 (Cont.)

The magnitude of the heat flux is proportional to the temperature gradient at the surface, $\partial T / \partial y|_{y=0}$, which is shown schematically as a dashed line. The temperature gradient is steeper (larger) at x_1 where the thermal boundary layer is thinner and less steep (smaller) at x_3 where the thermal boundary layer is thicker. Therefore, the magnitude of the local heat flux is largest at x_1 and smallest at x_3. <

(c) As the free stream velocity increases the boundary layer becomes thinner. Sketches for a low and high free stream velocity are shown below.



Low freestream velocity case.



High freestream velocity case.

The temperature gradient, shown as the dashed line, is steeper for the higher free stream velocity case. Therefore the higher free stream velocity case has the higher convective heat flux. <

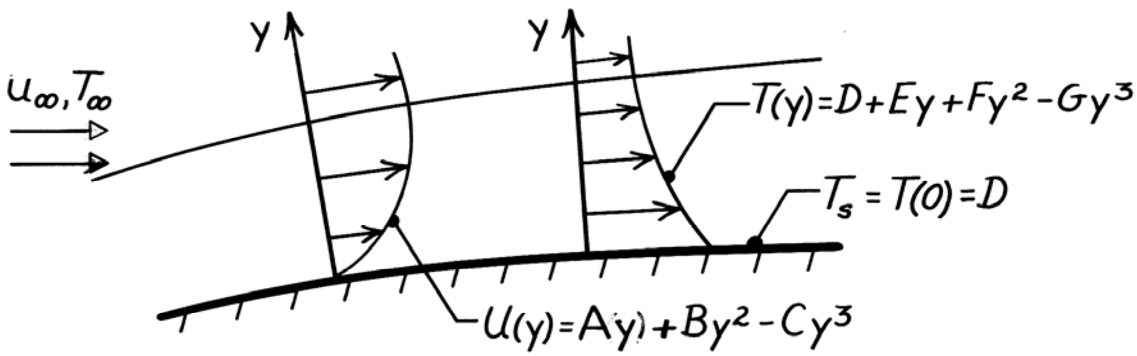
COMMENTS: It is important to understand how the temperature gradient at the surface varies as the thickness of the boundary layer changes.

PROBLEM 6.2

KNOWN: Form of the velocity and temperature profiles for flow over a surface.

FIND: Expressions for the friction and convection coefficients.

SCHEMATIC:



ANALYSIS: The shear stress at the wall is

$$\tau_s = \mu \left.\frac{\partial u}{\partial y}\right]_{y=0} = \mu \left[A + 2By - 3Cy^2\right]_{y=0} = A\mu.$$

Hence, the friction coefficient has the form,

$$C_f = \frac{\tau_s}{\rho u_\infty^2 / 2} = \frac{2A\mu}{\rho u_\infty^2}$$

$$C_f = \frac{2A\nu}{u_\infty^2}. \qquad <$$

The convection coefficient is

$$h = \frac{-k_f \left(\partial T / \partial y\right)_{y=0}}{T_s - T_\infty} = \frac{-k_f \left[E + 2Fy - 3Gy^2\right]_{y=0}}{D - T_\infty}$$

$$h = \frac{-k_f E}{D - T_\infty}. \qquad <$$

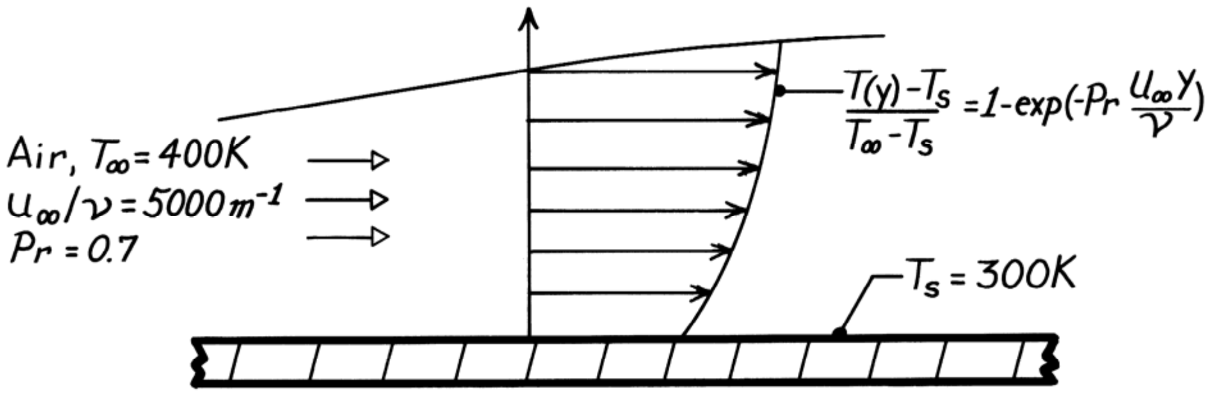
COMMENTS: It is a simple matter to obtain the important surface parameters from knowledge of the corresponding boundary layer profiles. However, it is rarely a simple matter to determine the form of the profile.

PROBLEM 6.3

KNOWN: Boundary layer temperature distribution.

FIND: Surface heat flux.

SCHEMATIC:



PROPERTIES: *Table A-4*, Air (T_s = 300K): k = 0.0263 W/m·K.

ANALYSIS: Applying Fourier's law at y = 0, the heat flux is

$$q''_s = -k\left.\frac{\partial T}{\partial y}\right|_{y=0} = -k\left(T_\infty - T_s\right)\left[\Pr\frac{u_\infty}{\nu}\right]\exp\left[-\Pr\frac{u_\infty y}{\nu}\right]\Bigg|_{y=0}$$

$$q''_s = -k\left(T_\infty - T_s\right)\Pr\frac{u_\infty}{\nu}$$

$$q''_s = -0.0263\ \text{W/m}\cdot\text{K}\left(100\text{K}\right)0.7\times 5000\ \text{1/m}.$$

$$q''_s = -9205\ \text{W/m}^2.$$ <

COMMENTS: (1) Negative flux implies convection heat transfer to the surface.

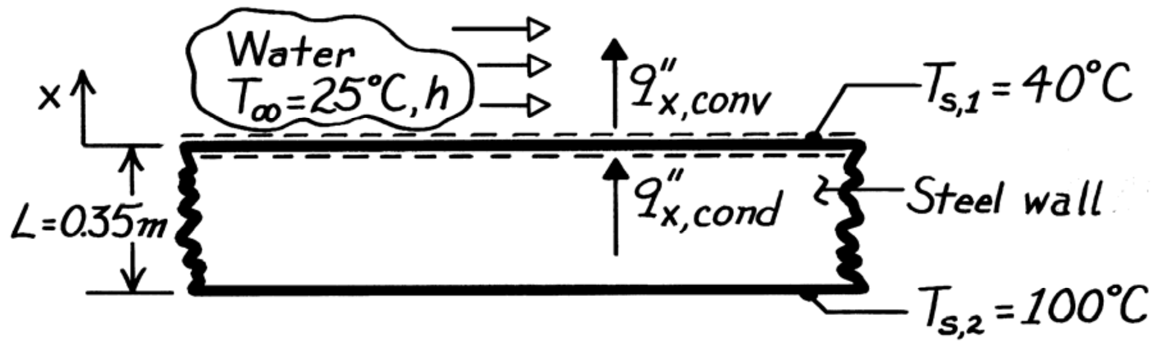
(2) Note use of k at T_s to evaluate q''_s from Fourier's law.

PROBLEM 6.4

KNOWN: Surface temperatures of a steel wall and temperature of water flowing over the wall.

FIND: (a) Convection coefficient, (b) Temperature gradient in wall and in water at wall surface.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer in x, (3) Constant properties.

PROPERTIES: *Table A-1*, Steel Type AISI 1010 (70°C = 343K), k_s = 61.7 W/m·K; *Table A-6*, Water (32.5°C = 305K), k_f = 0.62 W/m·K.

ANALYSIS: (a) Applying an energy balance to the control surface at x = 0, it follows that

$$q''_{x,cond} - q''_{x,conv} = 0$$

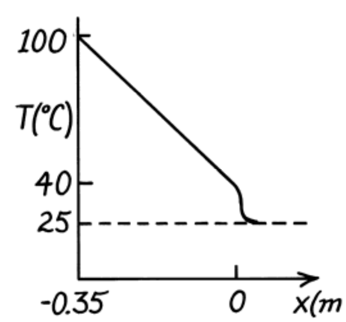
and using the appropriate rate equations,

$$k_s \frac{T_{s,2} - T_{s,1}}{L} = h\left(T_{s,1} - T_\infty\right).$$

Hence,

$$h = \frac{k_s}{L}\frac{T_{s,2} - T_{s,1}}{T_{s,1} - T_\infty} = \frac{61.7\ \text{W/m}\cdot\text{K}}{0.35\text{m}}\frac{60^\circ\text{C}}{15^\circ\text{C}} = 705\ \text{W/m}^2\cdot\text{K}.$$ <

(b) The gradient in the wall at the surface is



$$\left(dT/dx\right)_s = -\frac{T_{s,2} - T_{s,1}}{L} = -\frac{60^\circ\text{C}}{0.35\text{m}} = -171.4^\circ\text{C/m}.$$

In the water at x = 0, the definition of h gives

$$\left(dT/dx\right)_{f,x=0} = -\frac{h}{k_f}\left(T_{s,1} - T_\infty\right)$$

$$\left(dT/dx\right)_{f,x=0} = -\frac{705\ \text{W/m}^2\cdot\text{K}}{0.62\ \text{W/m}\cdot\text{K}}\left(15^\circ\text{C}\right) = -17,056^\circ\text{C/m}.$$ <

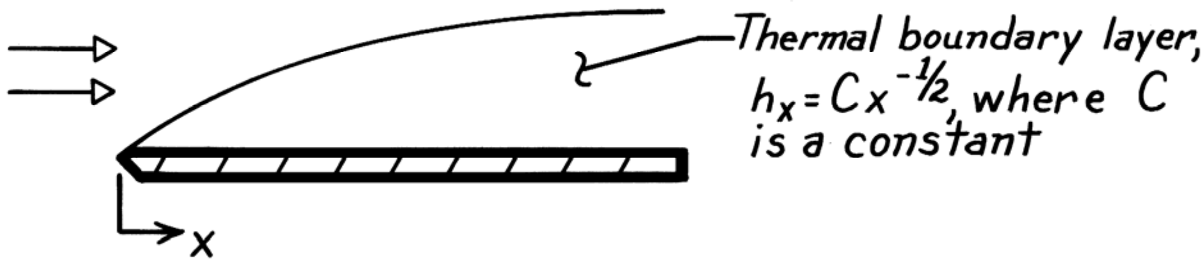
COMMENTS: Note the relative magnitudes of the gradients. Why is there such a large difference?

PROBLEM 6.5

KNOWN: Variation of h_x with x for laminar flow over a flat plate.

FIND: Ratio of average coefficient, $\overline{h}_x$, to local coefficient, h_x, at x.

SCHEMATIC:

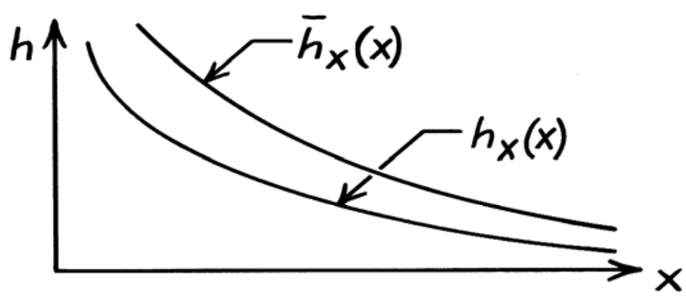


ANALYSIS: The average value of h_x between 0 and x is

$$\overline{h}_x = \frac{1}{x}\int_0^x h_x dx = \frac{C}{x}\int_0^x x^{-1/2} dx$$
$$\overline{h}_x = \frac{C}{x} 2x^{1/2} = 2Cx^{-1/2}$$
$$\overline{h}_x = 2h_x.$$

Hence, $$\frac{\overline{h}_x}{h_x} = 2.$$ <

COMMENTS: Both the local and average coefficients decrease with increasing distance x from the leading edge, as shown in the sketch below.

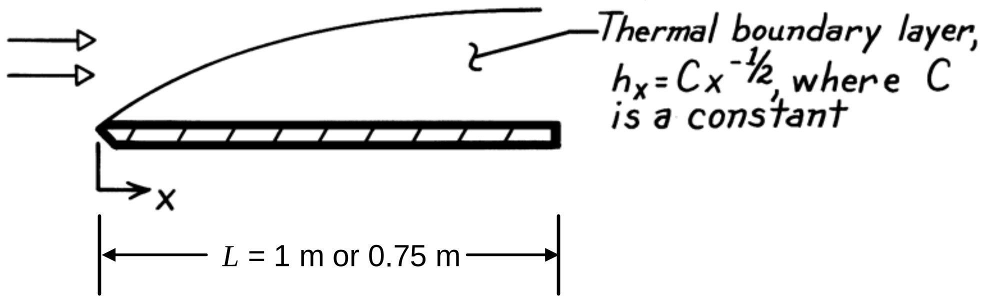


PROBLEM 6.6

KNOWN: Variation of local heat transfer coefficient with *x*. Length of plate.

FIND: Ratio of heat transfer coefficients for flow oriented in short and long directions.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Laminar flow, (3) Incompressible flow.

ANALYSIS: The local heat transfer coefficient varies with *x* according to

$$h_x = Cx^{-1/2}$$

The average heat transfer coefficient over the entire plate is given by Eq. 6.14:

$$\bar{h}_L = \frac{1}{L}\int_0^L h_x dx = \frac{1}{L}\int_0^L Cx^{-1/2} dx = 2CL^{-1/2}$$

Therefore the ratio of average heat transfer coefficients for the two different flow orientations is

$$\frac{\bar{h}_{L,1}}{\bar{h}_{L,2}} = \left(\frac{L_2}{L_1}\right)^{1/2}$$

The average heat transfer coefficient is larger when the flow is oriented in the short direction because local heat transfer coefficients are largest near the leading edge. Therefore the heat transfer rate will be larger when flow is oriented in the short direction. <

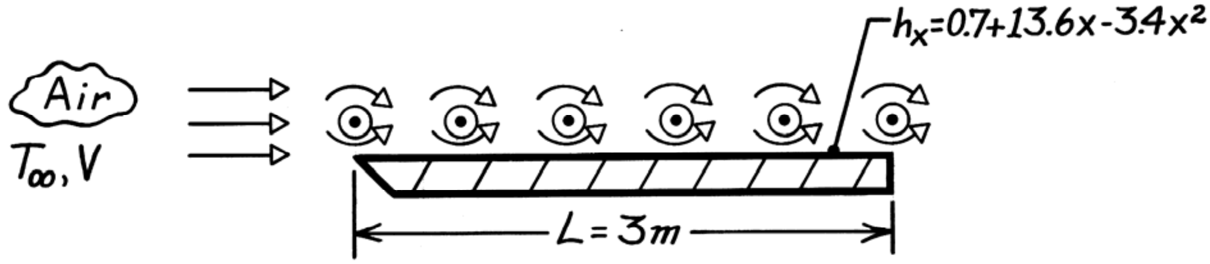
COMMENTS: Many engineering devices that are affected by, or utilize convection heat transfer in their operation incorporate short sections of surfaces in order to take advantage of the high local heat transfer coefficients that exist near the leading edges of such surfaces.

PROBLEM 6.7

KNOWN: Distribution of local convection coefficient for obstructed parallel flow over a flat plate.

FIND: Average heat transfer coefficient and ratio of average to local at the trailing edge.

SCHEMATIC:



ANALYSIS: The average convection coefficient is

$$\bar{h}_L = \frac{1}{L}\int_0^L h_x dx = \frac{1}{L}\int_0^L \left(0.7 + 13.6x - 3.4x^2\right)dx$$

$$\bar{h}_L = \frac{1}{L}\left(0.7L + 6.8L^2 - 1.13L^3\right) = 0.7 + 6.8L - 1.13L^2$$

$$\bar{h}_L = 0.7 + 6.8(3) - 1.13(9) = 10.9\ \text{W/m}^2 \cdot \text{K}. \qquad <$$

The local coefficient at x = 3m is

$$h_L = 0.7 + 13.6(3) - 3.4(9) = 10.9\ \text{W/m}^2 \cdot \text{K}.$$

Hence,

$$\bar{h}_L / h_L = 1.0. \qquad <$$

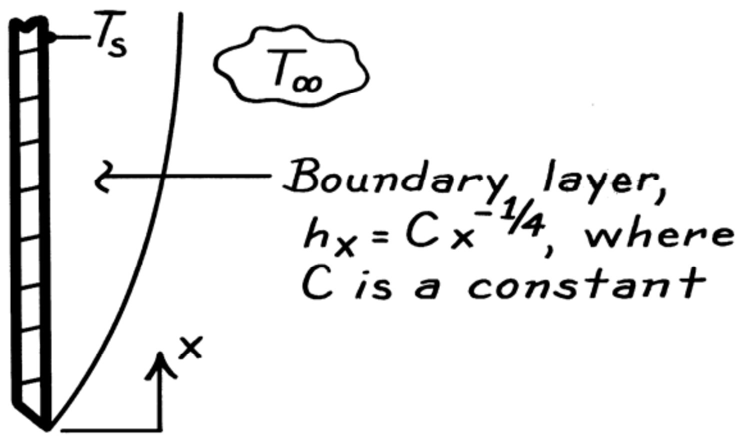
COMMENTS: The result $\bar{h}_L / h_L = 1.0$ is unique to x = 3m and is a consequence of the existence of a maximum for $h_x(x)$. The maximum occurs at x = 2m, where $(dh_x / dx) = 0$ and $\left(d^2h_x / dx^2 < 0.\right)$

PROBLEM 6.8

KNOWN: Variation of local convection coefficient with x for free convection from a vertical heated plate.

FIND: Ratio of average to local convection coefficient.

SCHEMATIC:

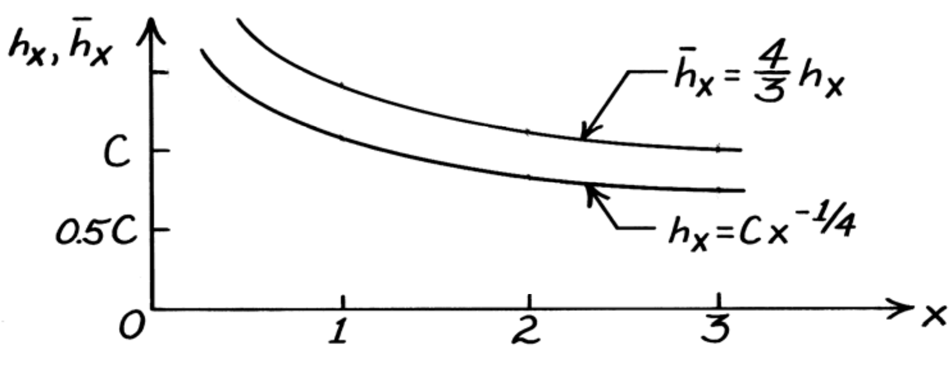


ANALYSIS: The average coefficient from 0 to x is

$$\bar{h}_x = \frac{1}{x}\int_0^x h_x dx = \frac{C}{x}\int_0^x x^{-1/4} dx$$
$$\bar{h}_x = \frac{4}{3}\,\frac{C}{x}x^{3/4} = \frac{4}{3}C\,x^{-1/4} = \frac{4}{3}h_x.$$

Hence,
$$\frac{\bar{h}_x}{h_x} = \frac{4}{3}.$$ <

The variations with distance of the local and average convection coefficients are shown in the sketch.



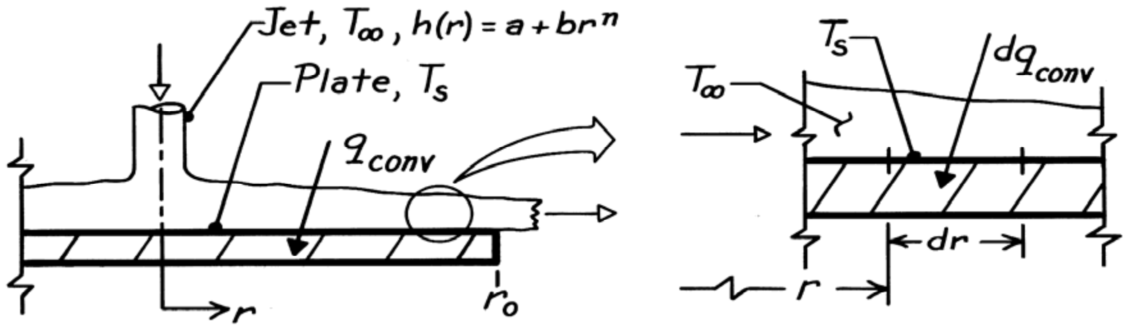
COMMENTS: Note that $\bar{h}_x / h_x = 4/3$ is independent of x. Hence the average coefficient for an entire plate of length L is $\bar{h}_L = \frac{4}{3} h_L$, where h_L is the local coefficient at x = L. Note also that the average *exceeds* the local. Why?

PROBLEM 6.9

KNOWN: Expression for the local heat transfer coefficient of a circular, hot gas jet at T_∞ directed normal to a circular plate at T_s of radius r_o.

FIND: Heat transfer rate to the plate by convection.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Flow is axisymmetric about the plate, (3) For h(r), a and b are constants and n ≠ -2.

ANALYSIS: The convective heat transfer rate to the plate follows from Newton's law of cooling

$$q_{conv} = \int_A dq_{conv} = \int_A h(r) \cdot dA \cdot (T_\infty - T_s).$$

The local heat transfer coefficient is known to have the form,

$$h(r) = a + br^n$$

and the differential area on the plate surface is

$$dA = 2\pi r\, dr.$$

Hence, the heat rate is

$$q_{conv} = \int_0^{r_o} \left(a + br^n\right) \cdot 2\pi\ r\ dr \cdot (T_\infty - T_s)$$

$$q_{conv} = 2\pi (T_\infty - T_s)\left[\frac{a}{2} r^2 + \frac{b}{n+2} r^{n+2}\right]_0^{r_o}$$

$$q_{conv} = 2\pi\left[\frac{a}{2} r_o^2 + \frac{b}{n+2} r_o^{n+2}\right] (T_\infty - T_s). \quad <$$

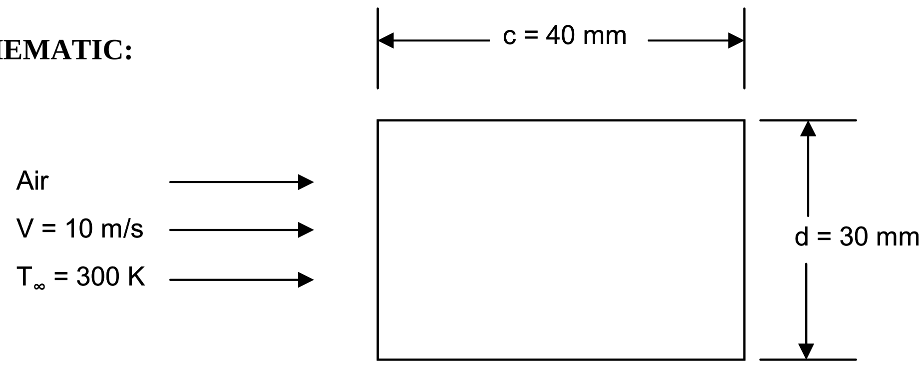
COMMENTS: Note the importance of the requirement, n ≠ -2. Typically, the radius of the jet is much smaller than that of the plate.

PROBLEM 6.10

KNOWN: Expression for face-averaged Nusselt numbers on a cylinder of rectangular cross section. Dimensions of the cylinder.

FIND: Average heat transfer coefficient over the entire cylinder. Plausible explanation for variations in the face-averaged heat transfer coefficients.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties.

PROPERTIES: Table A.4, air (300 K): k = 0.0263 W/m·K, $\nu = 1.589 \times 10^{-5}$ m²/s, Pr = 0.707.

ANALYSIS:
For the square cylinder, c/d = 40 mm/30 mm = 1.33

$$Re_d = \frac{Vd}{\nu} = \frac{10 \text{ m/s} \times 30 \times 10^{-3} \text{ m}}{1.589 \times 10^{-5} \text{ m}^2/\text{s}} = 18{,}880$$

Therefore, for the front face C = 0.674, m = ½. For the sides, C = 0.107, m = 2/3 while for the back C = 0.153, m = 2/3.

Front face:

$$Nu_{d,f} = 0.674 \times 18{,}880^{1/2} \times 0.707^{1/3} = 82.44$$

$$\overline{h}_f = \frac{kNu_d}{d} = \frac{0.0263 \text{ W/m}\cdot\text{K} \times 82.44}{30 \times 10^{-3} \text{ m}} = 72.27 \text{ W/m}^2\cdot\text{K}$$

Side faces:

$$Nu_{d,s} = 0.107 \times 18{,}880^{2/3} \times 0.707^{1/3} = 67.36$$

$$\overline{h}_s = \frac{kNu_{d,s}}{d} = \frac{0.0263 \text{ W/m}\cdot\text{K} \times 67.36}{30 \times 10^{-3} \text{ m}} = 59.05 \text{ W/m}^2\cdot\text{K}$$

Back face:

$$Nu_{d,b} = 0.153 \times 18{,}880^{2/3} \times 0.707^{1/3} = 96.43$$

$$\overline{h}_b = \frac{kNu_{d,b}}{d} = \frac{0.0263 \text{ W/m}\cdot\text{K} \times 96.43}{30 \times 10^{-3} \text{ m}} = 84.54 \text{ W/m}^2\cdot\text{K}$$

Continued…

PROBLEM 6.10 (Cont.)

For the entire square cylinder of unit length,

$$\bar{h} = \frac{\bar{h}_f A_f + 2\bar{h}_s A_s + \bar{h}_b A_b}{A_f + 2A_s + A_b}$$

$$\bar{h} = \frac{\begin{pmatrix} 72.27 \text{ W/m}^2 \cdot \text{K} \times 30 \times 10^{-3} \text{ m} + 2 \times 59.05 \text{ W/m}^2 \cdot \text{K} \times 40 \times 10^{-3} \text{ m} \\ + 84.54 \text{ W/m}^2 \cdot \text{K} \times 30 \times 10^{-3} \text{ m} \end{pmatrix}}{(2 \times 30 \times 10^{-3} \text{m} + 2 \times 40 \times 1^{-3} \text{m})}$$

$$\bar{h} = 67.35 \text{ W/m}^2 \cdot \text{K}$$ <

The face-averaged heat transfer coefficients are largest on the back face and smallest on the side faces. Plausible explanations for the variations of the face-averaged heat transfer coefficients are complex fluid flow patterns including vortex shedding on the back face and development of relatively thick boundary layers along the sides.

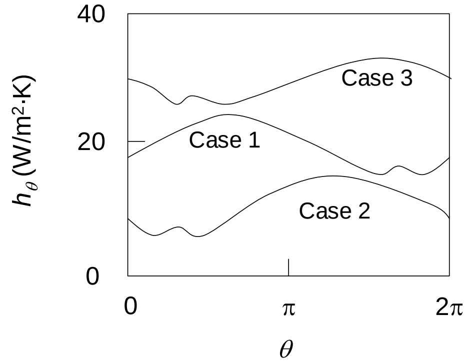
COMMENT: See S.Y. Yoo, J.H. Park, C.H. Chung and M.K. Chung, Journal of Heat Transfer, Vol. 125, pp. 1163-1169, 2003 for details.

PROBLEM 6.11

KNOWN: Variation of local heat transfer coefficient around a circular collector tube.

FIND: (a) Estimate the average heat transfer coefficient, (b) Case with highest collector efficiency.

SCHEMATIC:

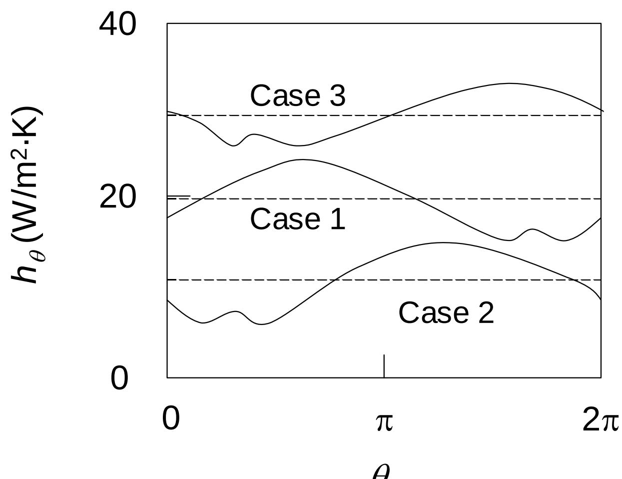


ASSUMPTIONS: Solar irradiation is independent of the reflector orientation.

ANALYSIS: (a) From Eq. 6.13,

$$\bar{h} = \frac{1}{A_s}\int_{A_s} h dA_s = \frac{1}{\pi DL}\int_{\theta=0}^{2\pi} h_\theta (D/2) L d\theta = \frac{1}{2\pi}\int_{\theta=0}^{2\pi} h_\theta d\theta$$

where L is the collector tube length. Hence, the average heat transfer coefficient may be estimated as the average value of the local heat transfer coefficient. Approximate values of the average heat transfer coefficient are shown in the sketch below.



For Case 1, $\bar{h} \approx 20$ W/m^2·K; for Case 2, $\bar{h} \approx 10$ W/m^2·K, for Case 3, $\bar{h} \approx 30$ W/m^2·K <

(b) The collector tube will be hotter than the ambient air. Hence, convective losses from the collector tube will diminish the overall collector efficiency. Therefore, Case 2 will have the highest collector efficiency. <

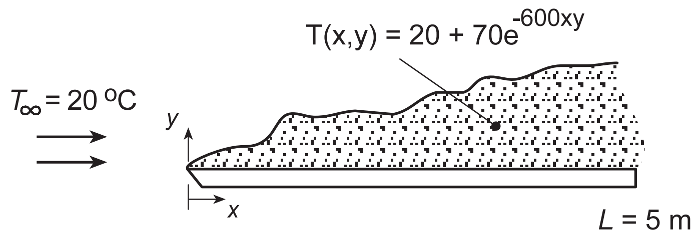
COMMENTS: (1) For case 2, the parabolic reflector partially "shields" the collector tube from the wind, resulting in reduced heat transfer coefficients. The flow adjacent to the tube also experiences a change in direction for case 2, with a large recirculation pattern established behind the reflector. (2) None of the cases experiences symmetrical flow over the collector tube, as would be expected without the reflector in place. (3) See Naeeni and Yaghoubi, "Analysis of Wind Flow Around a Parabolic Collector (2) Heat Transfer from Receiver Tube," *Renewable Energy*, Vol. 32, pp. 1259 – 1272, 2007, for additional discussion.

PROBLEM 6.12

KNOWN: Temperature distribution in boundary layer for air flow over a flat plate.

FIND: Variation of local convection coefficient along the plate and value of average coefficient.

SCHEMATIC:



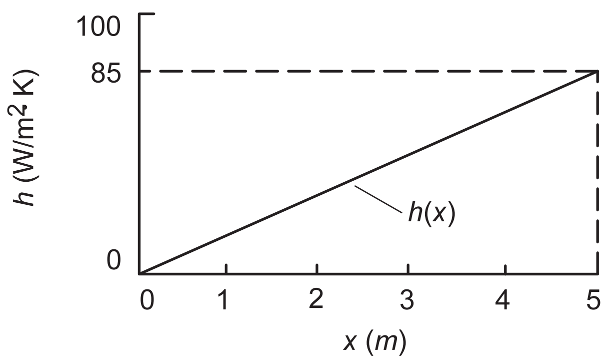
ANALYSIS: From Eq. 6.5,

$$h = -\frac{k\,\partial T/\partial y|_{y=0}}{(T_s - T_\infty)} = +\frac{k(70 \times 600x)}{(T_s - T_\infty)}$$

where $T_s = T(x,0) = 90°C$. Evaluating k at the arithmetic mean of the freestream and surface temperatures, $\bar{T} = (20 + 90)°C/2 = 55°C = 328$ K, Table A.4 yields k = 0.0284 W/m·K. Hence, with $T_s - T_\infty = 70°C = 70$ K,

$$h = \frac{0.0284\,\text{W/m}\cdot\text{K}\,(42,000x)\,\text{K/m}}{70\,\text{K}} = 17x\left(\text{W/m}^2\cdot\text{K}\right)$$ <

and the convection coefficient increases linearly with x.



The average coefficient over the range 0 ≤ x ≤ 5 m is

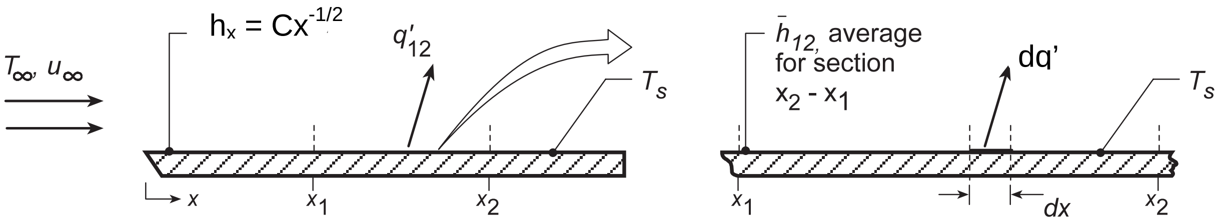
$$\bar{h} = \frac{1}{L}\int_0^L h\,dx = \frac{17}{5}\int_0^5 x\,dx = \frac{17}{5}\frac{x^2}{2}\Big|_0^5 = 42.5\,\text{W/m}^2\cdot\text{K}$$ <

PROBLEM 6.13

KNOWN: Variation of local convection coefficient with distance x from a heated plate with a uniform temperature T_s.

FIND: (a) An expression for the average coefficient $\bar{h}_{12}$ for the section of length (x_2 - x_1) in terms of C, x_1 and x_2, and (b) An expression for $\bar{h}_{12}$ in terms of x_1 and x_2, and the average coefficients $\bar{h}_1$ and $\bar{h}_2$, corresponding to lengths x_1 and x_2, respectively.

SCHEMATIC:



ASSUMPTIONS: (1) Laminar flow over a plate with uniform surface temperature, T_s, and (2) Spatial variation of local coefficient is of the form $h_x = Cx^{-1/2}$, where C is a constant.

ANALYSIS: (a) The heat transfer rate per unit width from a longitudinal section, x_2 - x_1, can be expressed as

$$q'_{12} = \bar{h}_{12}\left(x_2 - x_1\right)\left(T_s - T_\infty\right) \tag{1}$$

where $\bar{h}_{12}$ is the average coefficient for the section of length (x_2 - x_1). The heat rate can also be written in terms of the local coefficient, Eq. (6.11), as

$$q'_{12} = \int_{x_1}^{x_2} h_x dx\left(T_s - T_\infty\right) = \left(T_s - T_\infty\right)\int_{x_1}^{x_2} h_x dx \tag{2}$$

Combining Eq. (1) and (2),

$$\bar{h}_{12} = \frac{1}{\left(x_2 - x_1\right)}\int_{x_1}^{x_2} h_x dx \tag{3}$$

and substituting for the form of the local coefficient, $h_x = Cx^{-1/2}$, find that

$$\bar{h}_{12} = \frac{1}{\left(x_2 - x_1\right)}\int_{x_1}^{x_2} Cx^{-1/2} dx = \frac{C}{x_2 - x_1}\left[\frac{x^{1/2}}{1/2}\right]_{x_1}^{x_2} = 2C\frac{x_2^{1/2} - x_1^{1/2}}{x_2 - x_1} \tag{4}$$ <

(b) The heat rate, given as Eq. (1), can also be expressed as

$$q'_{12} = \bar{h}_2 x_2\left(T_s - T_\infty\right) - \bar{h}_1 x_1\left(T_s - T_\infty\right) \tag{5}$$

which is the difference between the heat rate for the plate over the section (0 - x_2) and over the section (0 - x_1). Combining Eqs. (1) and (5), find,

$$\bar{h}_{12} = \frac{\bar{h}_2 x_2 - \bar{h}_1 x_1}{x_2 - x_1} \tag{6}$$ <

COMMENTS: (1) Note that, from Eq. 6.6,

$$\bar{h}_x = \frac{1}{x}\int_0^x h_x dx = \frac{1}{x}\int_0^x Cx^{-1/2} dx = 2Cx^{-1/2} \tag{7}$$

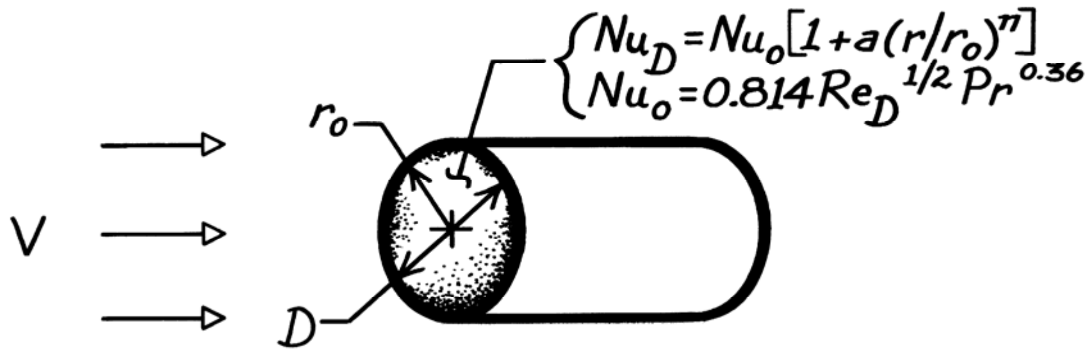
or $\bar{h}_x$ = $2h_x$. Substituting Eq. (7) into Eq. (6), see that the result is the same as Eq. (4).

PROBLEM 6.14

KNOWN: Radial distribution of local convection coefficient for flow normal to a circular disk.

FIND: Expression for average Nusselt number.

SCHEMATIC:



ASSUMPTIONS: Constant properties.

ANALYSIS: The average convection coefficient is

$$\bar{h} = \frac{1}{A_s}\int_{A_s} h dA_s$$

$$\bar{h} = \frac{1}{\pi r_o^2}\int_0^{r_o} \frac{k}{D} Nu_o \left[1 + a\left(r/r_o\right)^n\right] 2\pi\, rdr$$

$$\bar{h} = \frac{kNu_o}{r_o^3}\left[\frac{r^2}{2} + \frac{ar^{n+2}}{(n+2)r_o^n}\right]_0^{r_o}$$

where Nu_o is the Nusselt number at the stagnation point (r = 0). Hence,

$$\overline{Nu}_D = \frac{\bar{h}D}{k} = 2Nu_o\left[\frac{(r/r_o)^2}{2} + \frac{a}{(n+2)}\left(\frac{r}{r_o}\right)^{n+2}\right]_0^{r_o}$$

$$\overline{Nu}_D = Nu_o\left[1 + 2a/(n+2)\right]$$

$$\overline{Nu}_D = \left[1+2a/(n+2)\right]0.814 Re_D^{1/2} Pr^{0.36}.$$ <

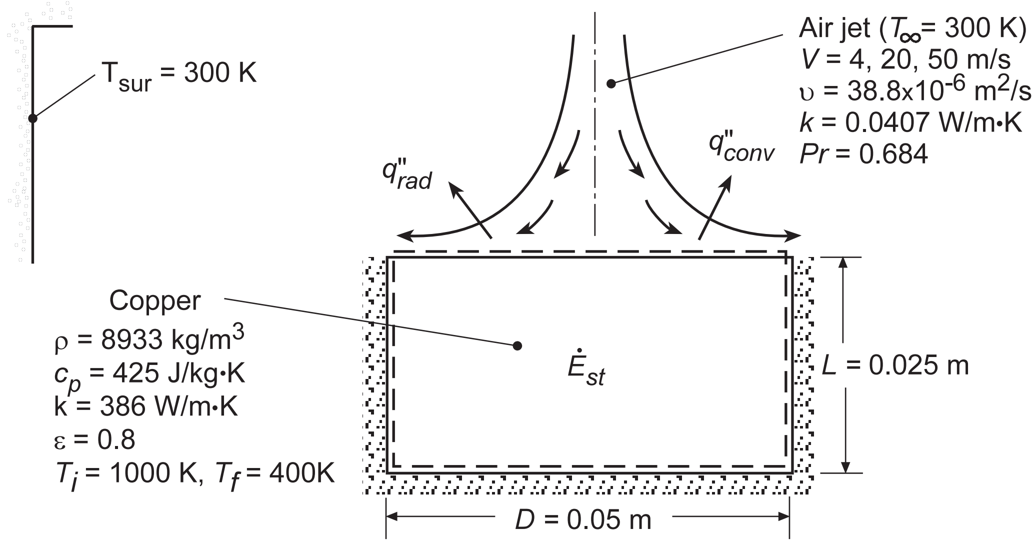
COMMENTS: The increase in h(r) with r may be explained in terms of the sharp turn which the boundary layer flow must make around the edge of the disk. The boundary layer accelerates and its thickness decreases as it makes the turn, causing the local convection coefficient to increase.

PROBLEM 6.15

KNOWN: Convection correlation and temperature of an impinging air jet. Dimensions and initial temperature of a heated copper disk. Properties of the air and copper.

FIND: Effect of jet velocity on temperature decay of disk following jet impingement.

SCHEMATIC:



ASSUMPTIONS: (1) Validity of lumped capacitance analysis, (2) Negligible heat transfer from sides and bottom of disk, (3) Constant properties.

ANALYSIS: Performing an energy balance on the disk, it follows that
$\dot{E}_{st} = \rho V c\, dT/dt = -A_s\left(q''_{conv} + q''_{rad}\right)$. Hence, with V = A_sL,

$$\frac{dT}{dt} = -\frac{\overline{h}\left(T - T_\infty\right) + h_r\left(T - T_{sur}\right)}{\rho c L}$$

where, $h_r = \varepsilon\sigma\left(T + T_{sur}\right)\left(T^2 + T_{sur}^2\right)$ and, from the solution to Problem 6.14,

$$\overline{h} = \frac{k}{D}\overline{Nu}_D = \frac{k}{D}\left(1 + \frac{2a}{n+2}\right)0.814\, Re_D^{1/2}\, Pr^{0.36}$$

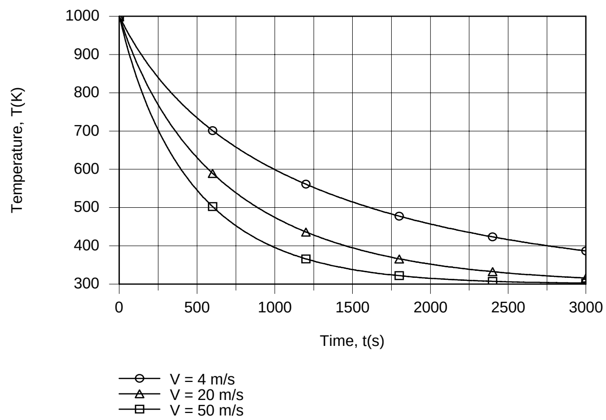
With a = 0.30 and n = 2, it follows that

$$\overline{h} = \left(k/D\right)0.936\, Re_D^{1/2}\, Pr^{0.36}$$

where Re_D = VD/ν. Using the *Lumped Capacitance Model* of IHT, the following temperature histories were determined.

Continued …

PROBLEM 6.15 (Cont.)



The temperature decay becomes more pronounced with increasing V, and a final temperature of 400 K is reached at t = 2760, 1455 and 976s for V = 4, 20 and 50 m/s, respectively.

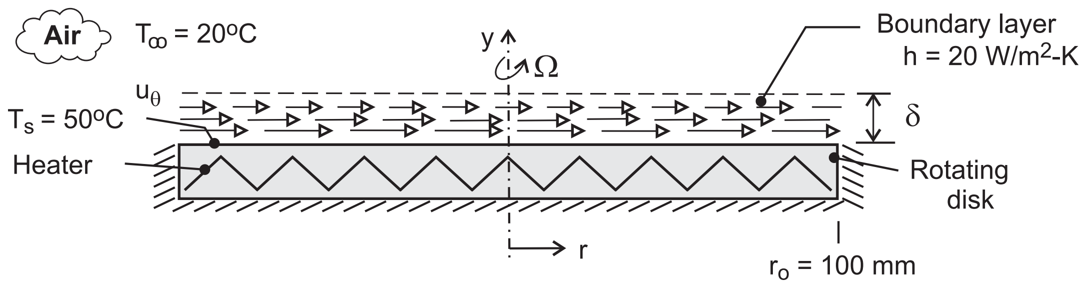
COMMENTS: The maximum Biot number, Bi = $\left(\overline{h}+h_r\right)L/k_{Cu}$, is associated with V = 50 m/s (maximum $\overline{h}$ of 169 $W/m^2\cdot K$) and t = 0 (maximum h_r of 64 $W/m^2\cdot K$), in which case the maximum Biot number is Bi = (233 $W/m^2\cdot K$)(0.025 m)/(386 W/m·K) = 0.015 < 0.1. Hence, the lumped capacitance approximation is valid.

PROBLEM 6.16

KNOWN: Local convection coefficient on rotating disk. Radius and surface temperature of disk. Temperature of stagnant air.

FIND: Local heat flux and total heat rate. Nature of boundary layer.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat transfer from back surface and edge of disk.

ANALYSIS: If the local convection coefficient is independent of radius, the local heat flux at every point on the disk is

$$q'' = h\left(T_s - T_\infty\right) = 20\,W/m^2\cdot K\left(50-20\right)°C = 600\,W/m^2 \quad <$$

Since h is independent of location, $\overline{h} = h = 20\,W/m^2\cdot K$ and the total power requirement is

$$P_{elec} = q = \overline{h}A_s\left(T_s - T_\infty\right) = \overline{h}\pi r_o^2\left(T_s - T_\infty\right)$$

$$P_{elec} = \left(20\,W/m^2\cdot K\right)\pi\left(0.1m\right)^2\left(50-20\right)°C = 18.9\ W \quad <$$

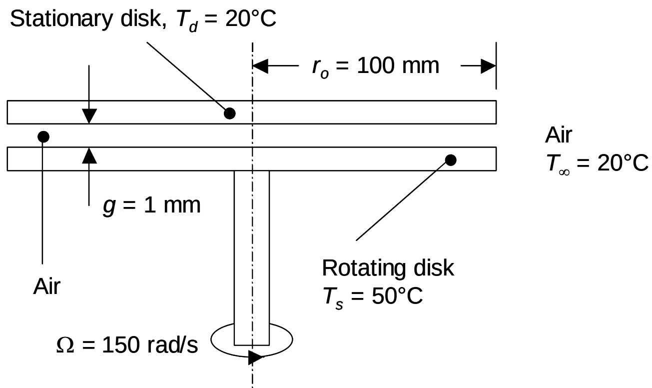
If the convection coefficient is independent of radius, the boundary layer must be of uniform thickness δ. Within the boundary layer, air flow is principally in the circumferential direction. The circumferential velocity component u_θ corresponds to the rotational velocity of the disk at the surface (y = 0) and increases with increasing r ($u_\theta = \Omega r$). The velocity decreases with increasing distance y from the surface, approaching zero at the outer edge of the boundary layer ($y \rightarrow \delta$).

PROBLEM 6.17

KNOWN: Dimensions and temperatures of rotating and stationary disks, air gap spacing between disks, rotational speed. Correlation for the local Nusselt number.

FIND: Value of the average Nusselt number, total heat flux from the disk's top surface, total power requirement. Comment on the nature of the flow between the disks.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible viscous dissipation.

PROPERTIES: *Table A-4*, air ($\overline{T}$ = (50°C + 20°C)/2 = 35°C ≈ 308K): $\nu = 16.69\times10^{-6}$ m^2/s, k = 0.0269 W/m·K.

ANALYSIS: From the problem statement, $Nu_r = \dfrac{h(r)r}{k} = 70\left(1+e^{-140G}\right)Re_{r_o}^{-0.456}Re_r^{0.478}$.

Since $Re_r = \Omega r^2/\nu$, the local heat transfer coefficient is

$$h(r) = k\left[70\left(1+e^{-140G}\right)\left(\frac{\Omega r_o^2}{\nu}\right)^{-0.456}\left(\frac{\Omega}{\nu}\right)^{0.478}\right]r^{-0.044}$$

The average heat transfer coefficient may be evaluated from

$$\overline{h} = \frac{1}{A_s}\int_{A_s} h(r)dA_s = \frac{2\pi k}{\pi r_o^2}\left[70\left(1+e^{-140G}\right)\left(\frac{\Omega r_o^2}{\nu}\right)^{-0.456}\left(\frac{\Omega}{\nu}\right)^{0.478}\right]\int_0^{r_o} r\times r^{-0.044}dr$$

or

$$\overline{h} = \frac{1.022k}{r_o^2}\left[70\left(1+e^{-140G}\right)\left(\frac{\Omega r_o^2}{\nu}\right)^{-0.456}\left(\frac{\Omega}{\nu}\right)^{0.478}\right]r_o^{1.956}$$

Continued…

Substituting values,

$$\bar{h} = \frac{1.022 \times 0.0269\text{W/m}\cdot\text{K}}{(0.100\text{m})^2}$$
$$\times\left[70\left(1+e^{-140\times0.01}\right)\left(\frac{150\text{rad/s}\times\left(0.100\text{m}\right)^2}{16.69\times10^{-6}\text{m}^2/\text{s}}\right)^{-0.456}\left(\frac{150\text{rad/s}}{16.69\times10^{-6}\text{m}^2/\text{s}}\right)^{0.478}\right]\left(0.100\text{m}\right)^{1.956}$$

or

$$\bar{h} = 30.8\ \text{W/m}^2\cdot\text{K} \qquad <$$

The average Nusselt number is

$$\overline{Nu}_D = \bar{h}D/k = 30.8\text{W/m}^2\cdot\text{K}\times0.200\text{m}/0.0269\text{W/m}\cdot\text{K} = 229 \qquad <$$

The heat flux from the top surface of the disk is

$$q'' = \bar{h}(T_s - T_d) = 30.8\text{W/m}^2\cdot\text{K}\times(50-20)°\text{C} = 924\text{W/m}^2 \qquad <$$

Therefore, the total electric power requirement is

$$P = q''A_s = q''\pi r_o^2 = 924\text{W/m}^2\times\pi\times(0.100\text{m})^2 = 29\text{W} \qquad <$$

Note that if only conduction were occurring between the two disks, the heat flux would be

$$q'' = (k/g)(T_s - T_d) = (0.0269\text{W/m}\cdot\text{K}/0.001\text{m})\times(50-20)°\text{C} = 807\text{W/m}^2.$$

The conduction heat flux is slightly less than the calculated quantity with rotation, suggesting that advection in the cross-gap direction is small, and that heat transfer between the disks is dominated by conduction. The laminar flow between the disks is characterized by very small velocities in the cross-gap direction.

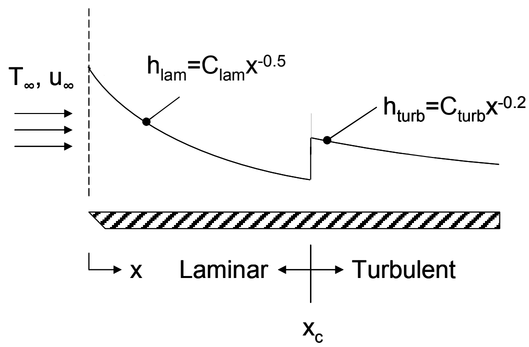
COMMENTS: (1) The slight increase in heat transfer rate is due to edge effects where air can exit or enter the space between the disks, and enhance heat transfer between the disks by mixing. (2) The Reynolds number is $Re_{r_o} = \Omega r_o^2/\nu = 150\text{rad/s}\times\left(0.100\text{m}\right)^2/16.69\times10^{-6}\text{m}^2/\text{s} = 90{,}000$. Transition to turbulent flow begins at a Reynolds number of approximately 180,000 for this configuration. (3) See Pelle and Harmand, "Heat Transfer Measurements in an Opened Rotor-Stator System Air-Gap," *Experimental Thermal and Fluid Science*, 'Vol. 31, pp. 165 – 180, 2007, for more information.

PROBLEM 6.18

KNOWN: Air flow over a flat plate of known length, location of transition from laminar to turbulent flow, value of the critical Reynolds number.

FIND: (a) Free stream velocity with properties evaluated at T = 350 K, (b) Expression for the average convection coefficient, $\bar{h}_{lam}(x)$, as a function of the distance x from the leading edge in the laminar region, (c) Expression for the average convection coefficient $\bar{h}_{turb}(x)$, as a function of the distance x from the leading edge in the turbulent region, (d) Compute and plot the local and average convection coefficients over the entire plate length.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties.

PROPERTIES: Table A.4, air (T = 350 K): k = 0.030 W/m·K, ν = 20.92 × 10^{-6} m^2/s, Pr = 0.700.

ANALYSIS:
(a) Using air properties evaluated at 350 K with x_c = 0.5 m,

$$Re_{x,c} = \frac{u_\infty x_c}{\nu} = 5\times10^5$$

$$u_\infty = 5\times10^5\,\nu/x_c = 5\times10^5\times20.92\times10^{-6}\,m^2/s/0.5\,m = 20.9\,m/s$$ <

(b) From Eq. 6.13, the average coefficient in the laminar region, $0 \le x \le x_c$, is

$$\bar{h}_{lam}(x) = \frac{1}{x}\int_0^x h_{lam}(x)dx = \frac{1}{x}C_{lam}\int_0^x x^{-0.5}dx = \frac{1}{x}C_{lam}x^{0.5} = 2C_{lam}x^{-0.5} = 2h_{lam}(x) \quad (1)$$ <

(c) The average coefficient in the turbulent region, $x_c \le x \le L$, is

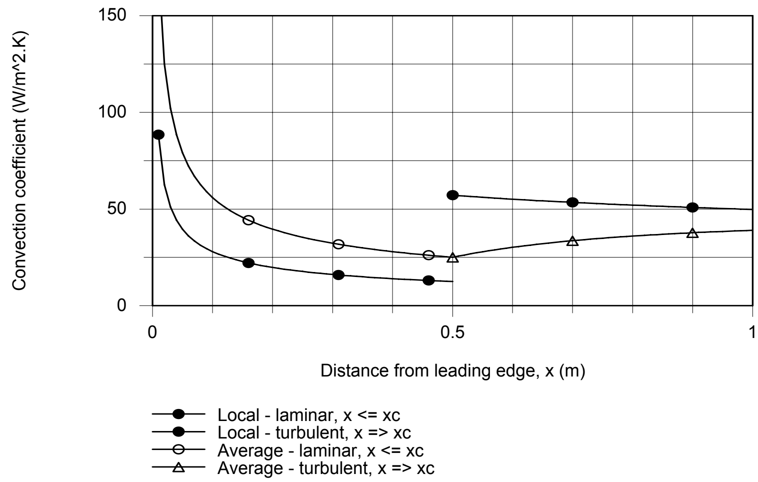
$$\bar{h}_{turb}(x) = \frac{1}{x}\left[\int_0^{x_c} h_{lam}(x)dx + \int_{x_c}^{x} h_{turb}(x)dx\right] = \left[C_{lam}\left.\frac{x^{0.5}}{0.5}\right|_0^{x_c} + C_{turb}\left.\frac{x^{0.8}}{0.8}\right|_{x_c}^{x}\right]$$

Continued…

PROBLEM 6.18 (Cont.)

$$\overline{h}_{turb}(x) = \frac{1}{x}\left[2C_{lam}x_c^{0.5} + 1.25C_{turb}\left(x^{0.8} - x_c^{0.8}\right)\right] \qquad (2) <$$

(d) The local and average coefficients, Eqs. (1) and (2) are plotted below as a function of x for the range $0 \le x \le L$.

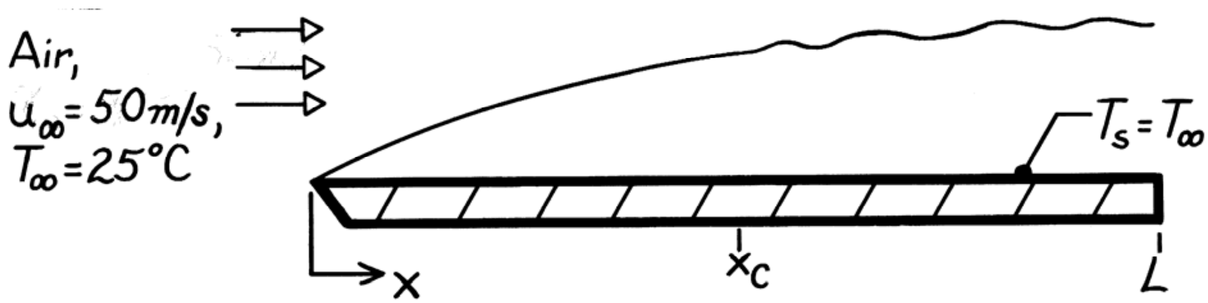


PROBLEM 6.19

KNOWN: Air speed and temperature in a wind tunnel.

FIND: (a) Minimum plate length to achieve a Reynolds number of 10^8, (b) Distance from leading edge at which transition would occur.

SCHEMATIC:



ASSUMPTIONS: (1) Isothermal conditions, $T_s = T_\infty$.

PROPERTIES: *Table A-4*, Air (25°C = 298K): $\nu = 15.71 \times 10^{-6} m^2/s$.

ANALYSIS: (a) The Reynolds number is

$$Re_x = \frac{\rho u_\infty x}{\mu} = \frac{u_\infty x}{\nu}.$$

To achieve a Reynolds number of 1×10^8, the minimum plate length is then

$$L_{min} = \frac{Re_x \nu}{u_\infty} = \frac{1\times10^8\left(15.71\times10^{-6} m^2/s\right)}{50 \text{ m/s}}$$

$$L_{min} = 31.4 \text{ m}.$$ <

(b) For a transition Reynolds number of 5×10^5

$$x_c = \frac{Re_{x,c} \nu}{u_\infty} = \frac{5\times10^5\left(15.71\times10^{-6} m^2/s\right)}{50 \text{ m/s}}$$

$$x_c = 0.157 \text{ m}.$$ <

COMMENTS: Note that

$$\frac{x_c}{L} = \frac{Re_{x,c}}{Re_L}$$

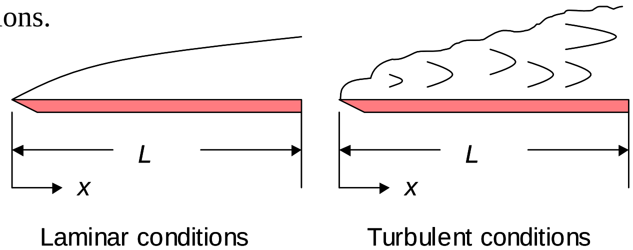
This expression may be used to quickly establish the location of transition from knowledge of $Re_{x,c}$ and Re_L.

PROBLEM 6.20

KNOWN: Flat plate in parallel flow, free stream velocity, expressions for the local heat transfer coefficient under laminar and fully turbulent conditions. Water temperature of 300K.

FIND: Plate length for which the average heat transfer coefficient is the same for laminar and turbulent flow conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible viscous dissipation.

ANALYSIS: For laminar conditions and turbulent conditions,

$$\bar{h}_{\text{lam}} = \frac{1}{L}\int_0^L h_{\text{lam}} dx = 2C_{\text{lam}} L^{-0.5} \quad ; \quad \bar{h}_{\text{turb}} = \frac{1}{L}\int_0^L h_{\text{turb}} dx = 1.25 C_{\text{turb}} L^{-0.2}$$

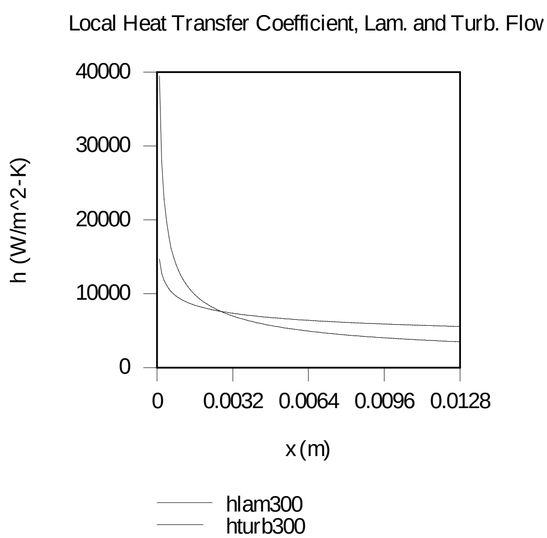
or

$$\frac{\bar{h}_{\text{lam}}}{\bar{h}_{\text{turb}}} = 1 = \frac{2 \times 395 \text{ W/m}^{1.5} \cdot \text{K}}{1.25 \times 2330 \text{ W/m}^{1.8} \cdot \text{K}} L^{-0.30} = \left(0.271\text{m}^{0.30}\right) L^{-0.30}$$

or

$$L = \left(0.271\text{m}^{0.30}\right)^{3.3333} = 0.0128 \text{ m} = 12.8 \text{ mm}$$ <

COMMENTS: (1) A plot of the local laminar and turbulent convection coefficient distributions is shown. The areas under the two curves are identical, reflecting the fact that $\frac{\bar{h}_{\text{lam}}}{\bar{h}_{\text{turb}}} = 1$. (2) A plate shorter than L = 12.8 mm is predicted to provide higher average coefficients under laminar flow conditions, as opposed to when turbulent conditions exist. However, this result may not be reliable because experimental measurement of local heat transfer coefficients is difficult, and the expressions of Example 6.4 may not be of sufficient accuracy to apply to such a short plate. (3) The plate is much shorter than the transition length, x_c = 0.43 m, that was calculated in Example 6.4. Hence, the laminar case is not subjected to a transition to turbulent flow.

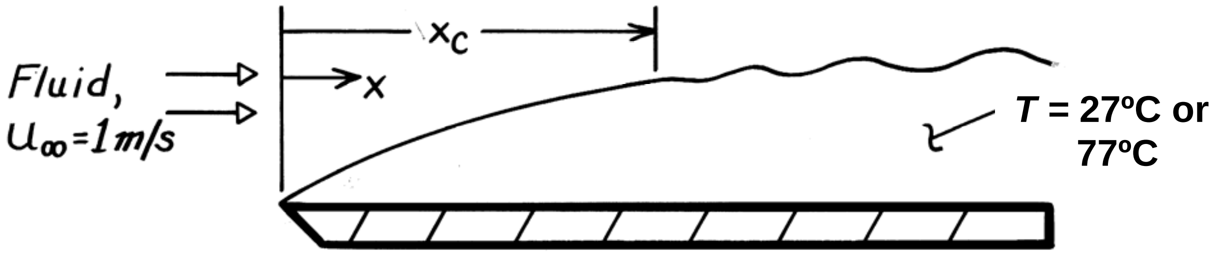


PROBLEM 6.21

KNOWN: Transition Reynolds number. Velocity and temperature of atmospheric air, engine oil, and mercury flow over a flat plate.

FIND: Distance from leading edge at which transition occurs for each fluid.

SCHEMATIC:



ASSUMPTIONS: Transition Reynolds number is $Re_{x,c} = 5 \times 10^5$.

PROPERTIES: For the fluids at T = 300 K and 350 K:

		ν(m²/s)	
Fluid	*Table*	T = 300 K	T = 350 K
Air (1 atm)	A-4	15.89×10^{-6}	20.92×10^{-6}
Engine Oil	A-5	550×10^{-6}	41.7×10^{-6}
Mercury	A-5	0.1125×10^{-6}	0.0976×10^{-6}

ANALYSIS: The point of transition is

$$x_c = Re_{x,c} \frac{\nu}{u_\infty} = \frac{5 \times 10^5}{1 \text{ m/s}} \nu.$$

Substituting appropriate viscosities, find

	x_c(m)	
Fluid	T = 300 K	T = 350 K
Air	7.95	10.5
Oil	275	20.9
Mercury	0.056	0.049

<

COMMENTS: (1) Note the great disparity in transition length for the different fluids. Due to the effect which viscous forces have on attenuating the instabilities which bring about transition, the distance required to achieve transition increases with increasing ν. (2) Note the temperature-dependence of the transition length, in particular for engine oil. (3) As shown in Example 6.4, the variation of the transition location can have a significant effect on the average heat transfer coefficient associated with convection to or from the plate.

PROBLEM 6.22

KNOWN: Pressure dependence of the dynamic viscosity, thermal conductivity and specific heat.

FIND: (a) Variation of the kinematic viscosity and thermal diffusivity with pressure for an incompressible liquid and an ideal gas, (b) Value of the thermal diffusivity of air at 350 K for pressures of 1, 5 and 10 atm, (c) Location where transition occurs for air flow over a flat plate with $T_\infty = 350$ K, p = 1, 5 and 10 atm, and $u_\infty = 2$ m/s.

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Transition at $Re_{x,c} = 5 \times 10^5$, (4) Ideal gas behavior.

PROPERTIES: Table A.4, air (350 K): $\mu = 208.2 \times 10^{-7}$ N·s/m², k = 0.030 W/m·K, $c_p = 1009$ J/kg·K, $\rho = 0.995$ kg/m³.

ANALYSIS:

(a) For an ideal gas

$$p = \rho RT \text{ or } \rho = p/RT \qquad (1)$$

while for an incompressible liquid, ρ = constant (2)

The kinematic viscosity is $\nu = \mu/\rho$ (3)

Therefore, for an ideal gas

$$\nu = \mu RT/p \text{ or } \nu \propto p^{-1} \qquad (4) \quad <$$

and for an incompressible liquid

$$\nu = \mu/\rho \text{ or } \nu \text{ is independent of pressure.} \quad <$$

The thermal diffusivity is

$$\alpha = k/\rho c$$

Therefore, for an ideal gas,

$$\alpha = kRT/pc \quad \text{or} \quad \alpha \propto p^{-1} \qquad (6) \quad <$$

For an incompressible liquid $\alpha = k/\rho c$ or α is independent of pressure <

(b) For T = 350 K, p = 1 atm, the thermal diffusivity of air is

$$\alpha = \frac{0.030 \text{ W/m} \cdot \text{K}}{0.995 \text{ kg/m}^3 \times 1009 \text{ J/kg} \cdot \text{K}} = 29.9 \times 10^{-6} \text{ m}^2\text{/s} \quad <$$

Using Equation 6, at p = 5 atm,

Continued…

$\alpha = 29.9 \times 10^{-6}\ m^2/s/5 = 5.98 \times 10^{-6}\ m^2/s$ <

At p = 10 atm,

$$\alpha = 29.9 \times 10^{-6}\ m^2/s/10 = 2.99 \times 10^{-6}\ m^2/s$$ <

(c) For transition over a flat plate,

$$Re_{x,c} = \frac{x_c u_\infty}{\nu} = 5 \times 10^5$$

Therefore

$$x_c = 5 \times 10^5 (\nu/u_\infty)$$

For $T_\infty = 350$ K, p = 1 atm,

$$\nu = \mu/\rho = 208.2 \times 10^{-7}\ N \cdot s/m^2 \big/ 0.995\ kg/m^3 = 20.92 \times 10^{-6}\ m^2/s$$

Using Equation 4, at p = 5 atm

$$\nu = 20.92 \times 10^{-6}\ m^2/s \big/ 5 = 4.18 \times 10^{-6}\ m^2/s$$

At p = 10 atm,

$$\nu = 20.92 \times 10^{-6}\ m^2/s \big/ 10 = 2.09 \times 10^{-6}\ m^2/s$$

Therefore, at p = 1 atm

$$x_c = 5 \times 10^5 \times 20.92 \times 10^{-6}\ m^2/s/(2 m/s) = 5.23\ m$$ <

At p = 5 atm,

$$x_c = 5 \times 10^5 \times 4.18 \times 10^{-6}\ m^2/s/(2 m/s) = 1.05\ m$$ <

At p = 10 atm

$$x_c = 5 \times 10^5 \times 2.09 \times 10^{-6}\ m^2/s/(2 m/s) = 0.523\ m$$ <

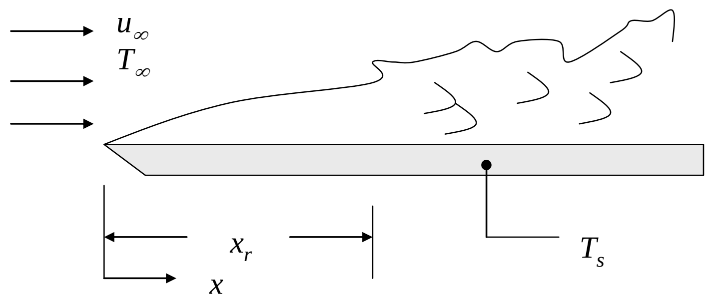
COMMENT: Note the strong dependence of the transition length upon the pressure for the gas (the transition length is independent of pressure for the incompressible liquid).

PROBLEM 6.23

KNOWN: Velocity of water flowing over a flat plate. Length of plate. Variation of local convection coefficient with *x*. Water temperature.

FIND: Average convection coefficient for roughness applied over the range $0 \le x_r \le L$.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Transition occurs at a critical Reynolds number of 5×10^5 for the smooth plate, (4) Incompressible flow.

PROPERTIES: *Table A.6*, Water (T = 300 K): $\rho = v_f^{-1} = 997$ kg/m^3, $\mu = 855 \times 10^{-6}$ N·s/m^2.

ANALYSIS: For roughness applied over the range $0 \le x_r \le x_c = 0.43$ m, transition occurs at x_r. From Eq. 6.14,

$$\bar{h} = \frac{1}{L}\int_0^L h dx = \frac{1}{L}\left[\int_0^{x_r} h_{\text{lam}} dx + \int_{x_r}^{L} h_{\text{turb}} dx\right] = \frac{1}{L}\left[\frac{C_{\text{lam}}}{0.5} x^{0.5}\Big|_0^{x_r} + \frac{C_{\text{turb}}}{0.8} x^{0.8}\Big|_{x_r}^{L}\right]$$

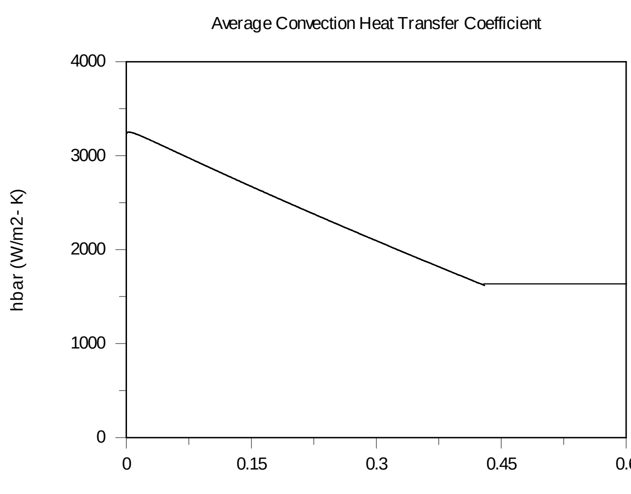
$$= \frac{1}{L}\left[\frac{C_{\text{lam}}}{0.5} x_r^{0.5} + \frac{C_{\text{turb}}}{0.8}\left(L^{0.8} - x_r^{0.8}\right)\right] = \frac{1}{0.6 \text{ m}}\left[\frac{395 \text{ W/m}^{1.5}\cdot\text{K}}{0.5} x_r^{0.5} + \frac{2330 \text{ W/m}^{1.8}\cdot\text{K}}{0.8}\left((0.6 \text{ m})^{0.8} - x_r^{0.8}\right)\right]$$

$$= \frac{1}{0.6 \text{ m}}\left[\frac{395 \text{ W/m}^{1.5}\cdot\text{K}}{0.5} x_r^{0.5} + \frac{2330 \text{ W/m}^{1.8}\cdot\text{K}}{0.8}\left((0.6 \text{ m})^{0.8} - x_r^{0.8}\right)\right]$$

$$= 1317 \text{ W/m}^{2.5}\cdot\text{K} \times x_r^{0.5} + 3226 \text{ W/m}^2\cdot\text{K} - 4854 \text{ W/m}^{2.8}\cdot\text{K} \times x_r^{0.8}$$

Roughness applied over the range $x_r > 0.43$ has no affect on the transition since the transition occurs at $x_c = 0.43$ m for the smooth plate. That is, $\bar{h} = 1620 \text{ W/m}^2\cdot\text{K}$.

This result is plotted below for $0 \le x_r \le 0.6$ m.



<

Continued…

PROBLEM 6.23 (Cont.)

The maximum value of $\overline{h}$ exists when transition occurs very close to the leading edge of the plate, at $x_r = 0.003$ m. It does not occur exactly at the leading edge because the laminar heat transfer coefficient equation yields a slightly higher value than the turbulent heat transfer coefficient equation very near $x = 0$. <

The minimum value of $\overline{h}$ exists when $x_r > x_c = 0.43$ m. <

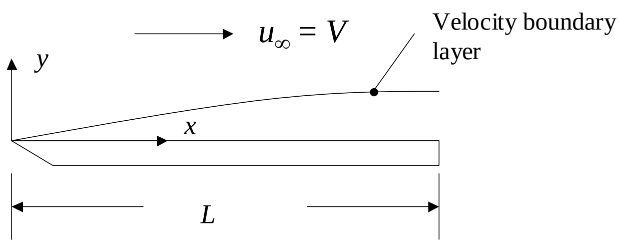
COMMENTS: (1) Turbulent heat transfer coefficients are usually (but not always) larger than laminar heat transfer coefficients. Therefore, tripping the transition to turbulence at or near the leading edge results in enhanced heat transfer. (2) The conclusion that the laminar heat transfer coefficient is slightly higher than the turbulent heat transfer coefficient very near $x = 0$ may not be accurate. Turbulent heat transfer coefficient measurements are usually not performed very close to the leading edge since, in most cases, turbulence develops further downstream. (3) Adding roughness at x locations downstream of where the transition to turbulence would normally occur has no influence on the transition or the average heat transfer rate.

PROBLEM 6.24

KNOWN: Nondimensional form of the *x*-direction velocity boundary layer equation and boundary conditions, expressions for x^*, y^*, u^* and v^*. Laminar, incompressible flow.

FIND: Expressions for (a) the velocity boundary conditions and (b) *x*-momentum equation in dimensional form.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties.

ANALYSIS: (a) From Equation 6.38, the boundary conditions in nondimensional form are

$$u^*(x^*,0) = 0 \quad (1)$$
$$v^*(x^*,0) = 0 \quad (2)$$
$$u^*(x^*,\infty) = \frac{u_\infty(x^*)}{V} \quad (3)$$

Substituting $u^* = \frac{u}{V}$ from Equation 6.32 and $x^* = \frac{x}{L}$ from Equation 6.31 into Equation (1) yields $\frac{u}{V}(x/L,0) = 0$. After multiplying both sides of the resultant equation by *V*, we have $u(x/L, y=0) = 0$.

Hence, the *x*-component of the fluid velocity at any *x* location along the surface is zero. <

Substituting $v^* = v/V$ from Equation 6.32 and $x^* = \frac{x}{L}$ from Equation 6.31 into Equation (2) yields $\frac{v}{V}(x/L,0) = 0$. After multiplying both sides of the equation by *V*, we have $v(x/L, y=0) = 0$.

Hence, the *y*-component of the fluid velocity at any *x* location along the surface is zero. <

The preceding two results are the familiar *zero velocity boundary conditions* that exist at an impenetrable, stationary surface.

Substituting $u^* = \frac{u}{V}$ from Equation 6.32 and $x^* = \frac{x}{L}$ from Equation 6.31 into Equation (3) yields $\frac{u}{V}(x/L,\infty) = \frac{u_\infty(x/L)}{V} = \frac{V}{V} = 1$. After multiplying both sides of the resultant equation by *V*, we have $u(x/L, y \to \infty) = V = u_\infty$. Hence, the *x*-component of the velocity at any *x* location outside of the boundary layer is equal to the free stream value. <

Continued…

PROBLEM 6.24 (Cont.)

(b) Note that $\dfrac{\partial u^*}{\partial x^*} = \dfrac{\partial (u/V)}{\partial (x/L)} = \dfrac{L}{V}\dfrac{\partial u}{\partial x}$. Likewise, $\dfrac{\partial u^*}{\partial y^*} = \dfrac{\partial (u/V)}{\partial (y/L)} = \dfrac{L}{V}\dfrac{\partial u}{\partial y}$ and $\dfrac{\partial^2 u^*}{\partial y^{*2}} = \dfrac{\partial}{\partial y^*}\left(\dfrac{\partial u^*}{\partial y^*}\right) = \dfrac{\partial}{\partial (y/L)}\left(\dfrac{L}{V}\dfrac{\partial u}{\partial y}\right) = \dfrac{L^2}{V}\dfrac{\partial^2 u}{\partial y^2}$. Also, from the definition of p^*, we note that $-\dfrac{\partial p^*}{\partial x^*} = -\dfrac{\partial (p_\infty/\rho V^2)}{\partial (x/L)} = -\dfrac{L}{\rho V^2}\dfrac{\partial p_\infty}{\partial x} = 0$. Substituting the preceding expressions, along with the definition of the Reynolds number, $Re_L = \rho VL/\mu = VL/\nu$ into Equation 6.35 yields

$\dfrac{u}{V}\dfrac{L}{V}\dfrac{\partial u}{\partial x} + \dfrac{v}{V}\dfrac{L}{V}\dfrac{\partial u}{\partial y} = 0 + \dfrac{\nu}{VL}\dfrac{L^2}{V}\dfrac{\partial^2 u}{\partial y^2}$. Multiplying both sides of the preceding equation by $\dfrac{V^2}{L}$ gives

$u\dfrac{\partial u}{\partial x} + v\dfrac{\partial u}{\partial y} = \nu\dfrac{\partial^2 u}{\partial y^2}$ which is identical to Equation 6.28 for the case where $\dfrac{dp_\infty}{dx} = 0$. <

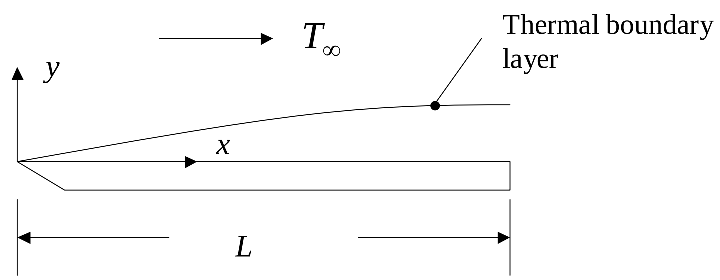
COMMENTS: (1) Equations 6.35 and 6.38 are nondimensional forms of Equations 6.28 and the no-slip boundary conditions. When converted to their nondimensional forms, the equations explicitly illustrate the importance of the Reynolds number in describing the velocity boundary layer. (2) For a flat plate subject to parallel flow, the Reynolds number is usually expressed as $Re_L = u_\infty L/\nu$, since $u_\infty = V$.

PROBLEM 6.25

KNOWN: Nondimensional form of the thermal boundary layer equation and boundary conditions, expressions for x^*, y^*, u^*, v^* and T^*. Laminar, incompressible flow with negligible viscous dissipation.

FIND: Expressions for (a) the thermal boundary conditions and (b) energy equation in dimensional form.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties.

ANALYSIS: (a) From Equation 6.39, the thermal boundary conditions in nondimensional form are

$$T^*(x^*,0) = 0 \qquad (1)$$
$$T^*(x^*,\infty) = 1 \qquad (2)$$

Substituting $T^* = \dfrac{T - T_s}{T_\infty - T_s}$ from Equation 6.33 and $x^* = \dfrac{x}{L}$ from Equation 6.31 into Equation (1) yields $\dfrac{T(x/L,0) - T_s}{T_\infty - T_s} = 0$. After multiplying both sides of the resultant equation by $T_\infty - T_s$, we have $T(x/L, y=0) = T_s$. Hence, the fluid temperature at any x location along the surface is T_s. <

Substituting $T^* = \dfrac{T - T_s}{T_\infty - T_s}$ from Equation 6.33 and $x^* = \dfrac{x}{L}$ from Equation 6.31 into Equation (2) yields $\dfrac{T(x/L, y \to \infty) - T_s}{T_\infty - T_s} = 1$. After multiplying both sides of the equation by $T_\infty - T_s$, we have $T(x/L, y \to \infty) = T_\infty$. Hence, the fluid temperature at any x location outside of the boundary layer is equal to the free stream value. <

(b) Note that $\dfrac{\partial T^*}{\partial x^*} = \dfrac{\partial\left(\dfrac{T - T_s}{T_\infty - T_s}\right)}{\partial(x/L)} = \dfrac{L}{(T_\infty - T_s)}\dfrac{\partial T}{\partial x}$. Likewise, $\dfrac{\partial T^*}{\partial y^*} = \dfrac{\partial\left(\dfrac{T - T_s}{T_\infty - T_s}\right)}{\partial(y/L)} = \dfrac{L}{(T_\infty - T_s)}\dfrac{\partial T}{\partial y}$.

Also, note that $\dfrac{\partial^2 T^*}{\partial y^{*2}} = \dfrac{\partial}{\partial y^*}\left(\dfrac{\partial T^*}{\partial y^*}\right) = \dfrac{L}{(T_\infty - T_s)}\dfrac{\partial}{\partial(y/L)}\dfrac{\partial T}{\partial y} = \dfrac{L^2}{(T_\infty - T_s)}\dfrac{\partial^2 T}{\partial y^2}$. Substituting the preceding expressions, along with $x^* = x/L$, $y^* = y/L$, $Re_L = \dfrac{VL}{\nu}$ and $Pr = \dfrac{\nu}{\alpha}$ into Equation 6.36

Continued…

PROBLEM 6.25 (Cont.)

yields $\frac{u}{V}\frac{L}{(T_\infty - T_s)}\frac{\partial T}{\partial x}+\frac{v}{V}\frac{L}{(T_\infty - T_s)}\frac{\partial T}{\partial y}=\frac{\nu}{VL}\frac{\alpha}{\nu}\frac{L^2}{(T_\infty - T_s)}\frac{\partial^2 T}{\partial y^2}$. Multiplying both sides by $\frac{V(T_\infty - T_s)}{L}$ gives $u\frac{\partial T}{\partial x}+v\frac{\partial T}{\partial y}=\alpha\frac{\partial^2 T}{\partial y^2}$ which is identical to Equation 6.29 when viscous dissipation is negligible. <

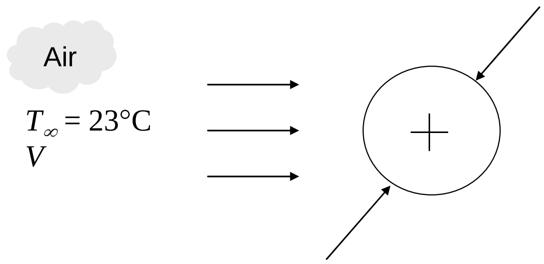
COMMENTS: (1) Equations 6.36 and 6.39 are nondimensional forms of Equations 6.29 and the boundary conditions. When converted to their nondimensional forms, the resulting equations explicitly illustrate the importance of the Reynolds and Prandtl numbers in describing the thermal boundary layer. (2) For a flat plate subject to parallel flow, the Reynolds number is usually expressed as $Re_L = \rho u_\infty L/\mu$, or $u_\infty L/\nu$ since $u_\infty = V$.

PROBLEM 6.26

KNOWN: Critical Reynolds number for a cylinder in cross flow. Critical Mach number.

FIND: Critical cylinder diameter below which, if the flow of air at atmospheric pressure and temperature is turbulent, compressibility effects may be important.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions. (2) Air behaves as an ideal gas.

PROPERTIES: Table A.4, air (T = 300 K): $\mathcal{M}$ = 28.97 kg/kmol, c_p = 1.007 kJ/kg·K, μ = 184.6 × 10^{-7} N·s/m^2.

ANALYSIS: The density of an ideal gas may be found from the equation of state,

$$\rho = \frac{p}{RT}$$

and the speed of sound for an ideal gas is $a = \sqrt{\gamma RT}$.

From the definition of the Mach number, the air velocity may be expressed as

$$V = Ma \cdot a$$

Substituting the preceding equations into the definition of the Reynolds number yields

$$Re_D = \frac{VD}{\nu} = \frac{VD\rho}{\mu} = \frac{Ma\sqrt{\gamma RT}\,Dp}{\mu RT} D = \frac{Ma}{\mu}\sqrt{\frac{\gamma}{RT}}Dp$$

Letting $Re = Re_c$ and $Ma = Ma_c$, the preceding equation can be rearranged to write an expression for the critical cylinder diameter,

$$D_c = \frac{Re_c}{Ma_c}\sqrt{\frac{RT}{\gamma}}\frac{\mu}{p}$$

Before evaluating the critical cylinder diameter, we note that the gas constant for air is

Continued...

PROBLEM 6.26 (Cont.)

$$R = \frac{\mathcal{R}}{\mathcal{M}} = \frac{8315 \text{ J/kmol} \cdot \text{K}}{28.97 \text{ kg/kmol}} = 287 \text{ J/kg} \cdot \text{K}$$

and the specific heat at constant volume, c_v, is

$$c_v = c_p - R = 1007 \text{ J/kg} \cdot \text{K} - 287 \text{ J/kg} \cdot \text{K} = 720 \text{ J/kg} \cdot \text{K}$$

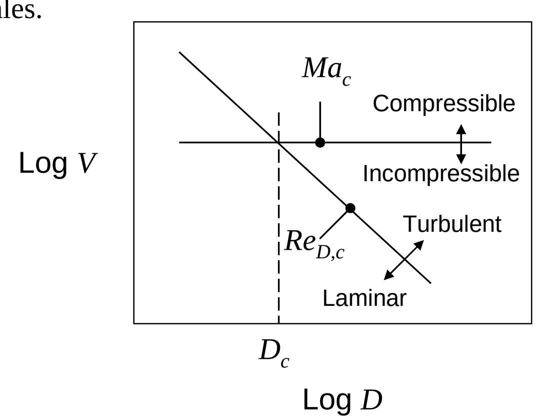
Therefore, the ratio of specific heats for air is

$$\gamma = \frac{c_p}{c_v} = \frac{1007 \text{ J/kg} \cdot \text{K}}{720 \text{ J/kg} \cdot \text{K}} = 1.399$$

For the conditions of the problem, the critical cylinder diameter is

$$D_c = \frac{Re_c}{Ma_c}\sqrt{\frac{RT}{\gamma}}\frac{\mu}{p} = \frac{2 \times 10^5}{0.3}\sqrt{\frac{287 \text{ J/kg} \cdot \text{K} \times 300 \text{ K}}{1.399}} \times \frac{184.6 \times 10^{-7} \text{ N} \cdot \text{s/m}^2}{1.0133 \times 10^5 \text{ N/m}^2} = 0.030 \text{ m} = 30 \text{ mm} \quad <$$

COMMENTS: (1) The expression for the critical Reynolds number ($Re_{D,c} = 2 \times 10^5$) is plotted using *log-log* scales in the figure below. Laminar flow occurs to the left of the sloped line, while turbulent flow occurs to the right of the sloped line. The velocity associated with the critical Mach number is identified by the horizontal line that separates regions of incompressible flow (below the horizontal line) and compressible flow (above the horizontal line). From this plot, it is evident that below the critical cylinder diameter, D_c, if the flow is turbulent, compressibility effects may be important. If the flow is laminar, the flow may or may not be compressible. In general, turbulent flow is difficult to achieve in situations involving small length scales.



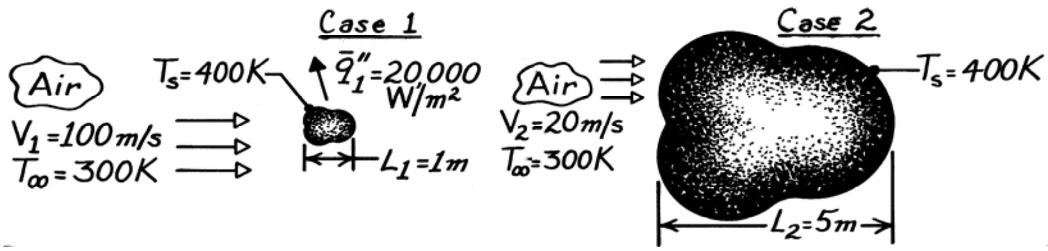
(2) The value of the critical Reynolds number is geometry-dependent. Care must be taken to apply the correct value of the critical Reynolds number in any calculation involving convection heat transfer.

PROBLEM 6.27

KNOWN: Characteristic length, surface temperature and average heat flux for an object placed in an airstream of prescribed temperature and velocity.

FIND: Average convection coefficient if characteristic length of object is increased by a factor of five and air velocity is decreased by a factor of five.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties.

ANALYSIS: For a particular geometry,

$$\overline{Nu}_L = f\left(Re_L, Pr\right).$$

The Reynolds numbers for each case are

Case 1: $$Re_{L,1} = \frac{V_1 L_1}{\nu_1} = \frac{(100\,m/s)1\,m}{\nu_1} = \frac{100\ m^2/s}{\nu_1}$$

Case 2: $$Re_{L,2} = \frac{V_2 L_2}{\nu_2} = \frac{(20\,m/s)5\,m}{\nu_2} = \frac{100\ m^2/s}{\nu_2}.$$

Hence, with $\nu_1 = \nu_2$, $Re_{L,1} = Re_{L,2}$. Since $Pr_1 = Pr_2$, it follows that

$$\overline{Nu}_{L,2} = \overline{Nu}_{L,1}.$$

Hence,

$$\bar{h}_2 L_2 / k_2 = \bar{h}_1 L_1 / k_1$$

$$\bar{h}_2 = \bar{h}_1 \frac{L_1}{L_2} = 0.2\,\bar{h}_1.$$

For *Case 1*, using the rate equation, the convection coefficient is

$$q_1 = \bar{h}_1 A_1 \left(T_s - T_\infty\right)_1$$

$$\bar{h}_1 = \frac{(q_1/A_1)}{\left(T_s - T_\infty\right)_1} = \frac{q''_1}{\left(T_s - T_\infty\right)_1} = \frac{20,000\ W/m^2}{(400-300)K} = 200\ W/m^2\cdot K.$$

Hence, it follows that for *Case 2*

$$\bar{h}_2 = 0.2\times 200\ W/m^2\cdot K = 40\ W/m^2\cdot K.$$ <

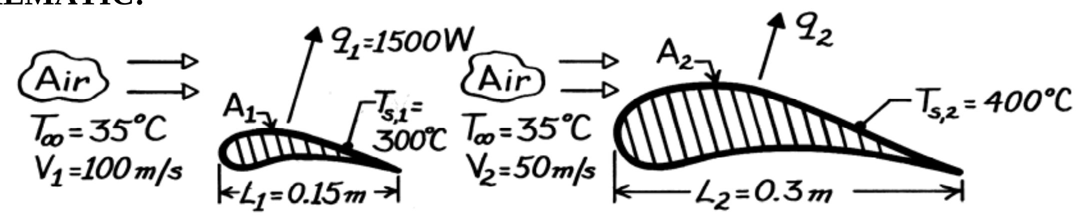
COMMENTS: If $Re_{L,2}$ were *not* equal to $Re_{L,1}$, it would be necessary to know the specific form of $f(Re_L, Pr)$ before $\bar{h}_2$ could be determined.

PROBLEM 6.28

KNOWN: Heat transfer rate from a turbine blade for prescribed operating conditions.

FIND: Heat transfer rate from a larger blade operating under different conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Surface area A is directly proportional to characteristic length L, (4) Negligible radiation, (5) Blade shapes are geometrically similar.

ANALYSIS: For a prescribed geometry,

$$\overline{Nu} = \frac{\bar{h}L}{k} = f\left(Re_L, Pr\right).$$

The Reynolds numbers for the blades are

$$Re_{L,1} = \left(V_1 L_1 / \nu\right) = 15/\nu \qquad Re_{L,2} = \left(V_2 L_2 / \nu\right) = 15/\nu.$$

Hence, with constant properties, $Re_{L,1} = Re_{L,2}$. Also, $Pr_1 = Pr_2$. Therefore,

$$\overline{Nu}_2 = \overline{Nu}_1$$
$$\left(\bar{h}_2 L_2 / k\right) = \left(\bar{h}_1 L_1 / k\right)$$
$$\bar{h}_2 = \frac{L_1}{L_2}\bar{h}_1 = \frac{L_1}{L_2}\frac{q_1}{A_1\left(T_{s,1} - T_\infty\right)}.$$

Hence, the heat rate for the *second blade* is

$$q_2 = \bar{h}_2 A_2\left(T_{s,2} - T_\infty\right) = \frac{L_1}{L_2}\frac{A_2}{A_1}\frac{\left(T_{s,2} - T_\infty\right)}{\left(T_{s,1} - T_\infty\right)}q_1$$
$$q_2 = \frac{T_{s,2} - T_\infty}{T_{s,1} - T_\infty}q_1 = \frac{(400-35)}{(300-35)}(1500\text{ W})$$

$$q_2 = 2066\text{ W}. \qquad <$$

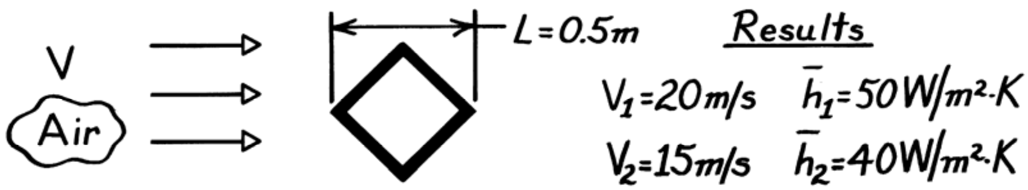
COMMENTS: The slight variation of ν from Case 1 to Case 2 would cause $Re_{L,2}$ to differ from $Re_{L,1}$. However, for the prescribed conditions, this non-constant property effect is small.

PROBLEM 6.29

KNOWN: Experimental measurements of the heat transfer coefficient for a square bar in cross flow.

FIND: (a) $\overline{h}$ for the condition when L = 1m and V = 15m/s, (b) $\overline{h}$ for the condition when L = 1m and V = 30m/s, (c) Effect of defining a side as the characteristic length.

SCHEMATIC:



ASSUMPTIONS: (1) Functional form $\overline{Nu} = CRe^m Pr^n$ applies with C, m, n being constants, (2) Constant properties.

ANALYSIS: (a) For the experiments and the condition L = 1m and V = 15m/s, it follows that Pr as well as C, m, and n are constants. Hence

$$\overline{h}L \propto (VL)^m.$$

Using the experimental results, find m. Substituting values

$$\frac{\overline{h}_1 L_1}{\overline{h}_2 L_2} = \left[\frac{V_1 L_1}{V_2 L_2}\right]^m \qquad \frac{50 \times 0.5}{40 \times 0.5} = \left[\frac{20 \times 0.5}{15 \times 0.5}\right]^m$$

giving m = 0.782. It follows then for L = 1m and V = 15m/s,

$$\overline{h} = \overline{h}_1 \frac{L_1}{L}\left[\frac{V \cdot L}{V_1 \cdot L_1}\right]^m = 50\frac{W}{m^2 \cdot K} \times \frac{0.5}{1.0}\left[\frac{15 \times 1.0}{20 \times 0.5}\right]^{0.782} = 34.3 W/m^2 \cdot K. \qquad <$$

(b) For the condition L = 1m and V = 30m/s, find

$$\overline{h} = \overline{h}_1 \frac{L_1}{L}\left[\frac{V \cdot L}{V_1 \cdot L_1}\right]^m = 50\frac{W}{m^2 \cdot K} \times \frac{0.5}{1.0}\left[\frac{30 \times 1.0}{20 \times 0.5}\right]^{0.782} = 59.0 W/m^2 \cdot K. \qquad <$$

(c) If the characteristic length were chosen as a side rather than the diagonal, the value of C would change. However, the coefficients m and n would not change.

COMMENTS: The foregoing Nusselt number relation is used frequently in heat transfer analysis, providing appropriate scaling for the effects of length, velocity, and fluid properties on the heat transfer coefficient.

PROBLEM 6.30

KNOWN: Form of the Nusselt number correlation for forced convection and fluid properties.

FIND: Expression for figure of merit F_F and values for air, water and a dielectric liquid.

PROPERTIES: Prescribed. Air: k = 0.026 W/m·K, $\nu = 1.6 \times 10^{-5}$ m^2/s, Pr = 0.71. Water: k = 0.600 W/m·K, $\nu = 10^{-6}$ m^2/s, Pr = 5.0. Dielectric liquid: k = 0.064 W/m·K, $\nu = 10^{-6}$ m^2/s, Pr = 25

ANALYSIS: With $Nu_L \sim Re_L^m \, Pr^n$, the convection coefficient may be expressed as

$$h \sim \frac{k}{L}\left(\frac{VL}{\nu}\right)^m Pr^n \sim \frac{V^m}{L^{1-m}}\left(\frac{k\,Pr^n}{\nu^m}\right)$$

The figure of merit is therefore

$$F_F = \frac{k\,Pr^n}{\nu^m} \qquad <$$

and for the three fluids, with m = 0.80 and n = 0.33,

$F_F\left(W \cdot s^{0.8} / m^{2.6} \cdot K\right)$	Air	Water	Dielectric
	167	64,400	11,700

<

Water is clearly the superior heat transfer fluid, while air is the least effective.

COMMENTS: The figure of merit indicates that heat transfer is enhanced by fluids of large k, large Pr and small ν.

PROBLEM 6.31

KNOWN: Form of the Nusselt number correlation for forced convection and fluid properties. Properties of xenon and He-Xe mixture. Temperature and pressure. Expression for specific heat for monatomic gases.

FIND: Figures of merit for air, pure helium, pure xenon, and He-Xe mixture containing 0.75 mole fraction of helium.

PROPERTIES: *Table A-4*, Air (300 K): k = 0.0263 W/m·K, $\nu = 15.89 \times 10^{-6}$ m^2/s, Pr = 0.707. *Table A-4,* Helium (300 K): k = 0.152 W/m·K, $\nu = 122 \times 10^{-6}$ m^2/s, Pr = 0.680. Pure xenon (given): k = 0.006 W/m·K, $\mu = 24.14 \times 10^{-6}$ $N{\cdot}s/m^2$. He-Xe mixture (given): k = 0.0713 W/m·K, $\mu = 25.95 \times 10^{-6}$ $N{\cdot}s/m^2$.

ANALYSIS: With $Nu_L \sim Re_L^m Pr^n$, the convection coefficient may be expressed as

$$h \sim \frac{k}{L}\left(\frac{VL}{\nu}\right)^m Pr^n \sim \frac{V^m}{L^{1-m}}\left(\frac{k\,Pr^n}{\nu^m}\right)$$

The figure of merit is therefore

$$F_F = \frac{k\,Pr^n}{\nu^m} \qquad (1)$$

For xenon and the He-Xe mixture, we must find the density and specific heat. Proceeding for pure xenon:

$$\rho = \frac{P\mathcal{M}}{\Re T} = \frac{1\text{ atm} \times 131.29\text{ kg/kmol}}{8.205 \times 10^{-2}\text{ m}^3 \cdot \text{atm/kmol}\cdot\text{K} \times 300\text{ K}} = 5.33\text{ kg/m}^3$$

$$c_p = \frac{5}{2}\frac{\Re}{\mathcal{M}} = \frac{5}{2}\frac{8.315 \times 10^3\text{ J/kmol}\cdot\text{K}}{131.29\text{ kg/kmol}} = 158\text{ J/kg}$$

Thus $\nu = \mu/\rho = 24.14 \times 10^{-6}$ $N{\cdot}s/m^2$/5.33 kg/m^3 = 4.53×10^{-6} m^2/s and $Pr = \mu c_p/k = 24.14 \times 10^{-6}$ $N{\cdot}s/m^2$ × 158 J/kg/0.006 W/m·K = 0.636.

For the He-Xe mixture, the molecular weight of the mixture can be found from

$$\mathcal{M}_{mix} = 0.75\text{ kmol He/kmol} \times 4.0\text{ kg/kmol He} + 0.25\text{ kmol Xe/kmol} \times 131.29\text{ kg/kmol Xe}$$
$$= 35.82\text{ kg/kmol}$$

from which we can calculate $\rho = 1.46$ kg/m^3, $c_p = 580$ J/kg·K, $\nu = \mu/\rho = 25.95 \times 10^{-6}$ $N{\cdot}s/m^2$/1.46 kg/m^3 = 1.78×10^{-5} m^2/s, and $Pr = \mu c_p/k = 25.95 \times 10^{-6}$ $N{\cdot}s/m^2$ × 580 J/kg/0.0713 W/m·K = 0.211.

Finally, for the four fluids, with m = 0.85 and n = 0.33, we can calculate the figure of merit from Equation (1):

	F_F $(W{\cdot}s^{0.85}/m^{2.7}{\cdot}K)$
Air	281
Helium	284
Xenon	180
He-Xe	465

<

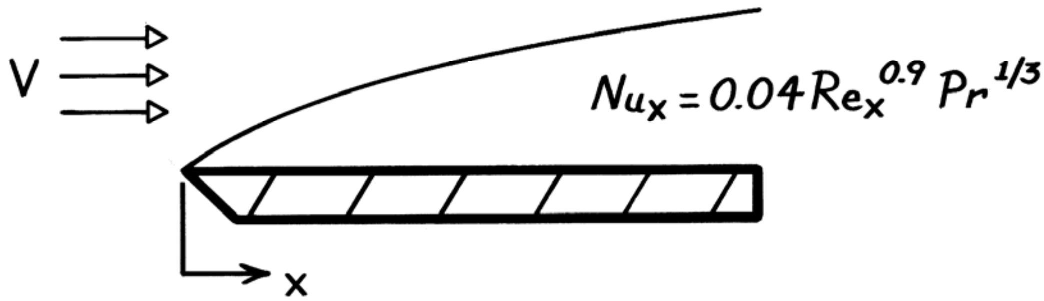
COMMENTS: The effectiveness of the He-Xe mixture is much higher than that of pure He, pure Xe, or air. By blending He and Xe, the high thermal conductivity of helium and the high density of xenon are both exploited in a manner that leads to a high figure of merit.

PROBLEM 6.32

KNOWN: Local Nusselt number correlation for flow over a roughened surface.

FIND: Ratio of average heat transfer coefficient to local coefficient.

SCHEMATIC:



ANALYSIS: The local convection coefficient is obtained from the prescribed correlation,

$$h_x = Nu_x \frac{k}{x} = 0.04 \frac{k}{x} Re_x^{0.9} Pr^{1/3}$$

$$h_x = 0.04\, k \left[\frac{V}{\nu}\right]^{0.9} Pr^{1/3} \frac{x^{0.9}}{x} \equiv C_1 x^{-0.1}.$$

To determine the average heat transfer coefficient for the length zero to x,

$$\overline{h}_x \equiv \frac{1}{x}\int_0^x h_x \, dx = \frac{1}{x} C_1 \int_0^x x^{-0.1} dx$$

$$\overline{h}_x = \frac{C_1}{x}\frac{x^{0.9}}{0.9} = 1.11\, C_1\, x^{-0.1}.$$

Hence, the ratio of the average to local coefficient is

$$\frac{\overline{h}_x}{h_x} = \frac{1.11\, C_1\, x^{-0.1}}{C_1\, x^{-0.1}} = 1.11.$$ <

COMMENTS: Note that $\overline{Nu}_x / Nu_x$ is also equal to 1.11. Note, however, that

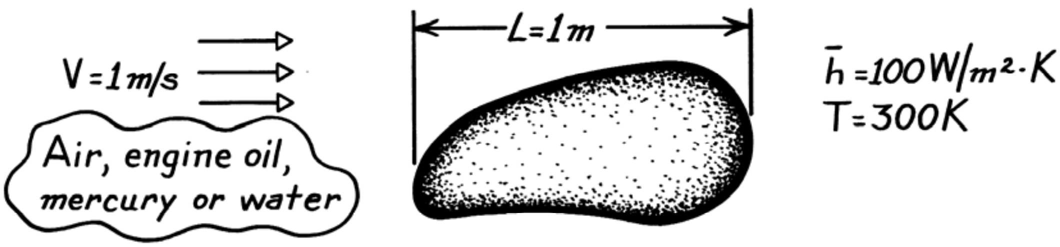
$$\overline{Nu}_x \neq \frac{1}{x}\int_0^x Nu_x \, dx.$$

PROBLEM 6.33

KNOWN: Freestream velocity and average convection heat transfer associated with fluid flow over a surface of prescribed characteristic length.

FIND: Values of $\overline{Nu}_L$, Re_L, Pr, $\bar{j}_H$ for (a) air, (b) engine oil, (c) mercury, (d) water.

SCHEMATIC:



PROPERTIES: For the fluids at 300K:

Fluid	Table	ν(m²/s)	k(W/m·K)	α(m²/s)	Pr
Air	A.4	15.89×10^{-6}	0.0263	22.5×10^{-7}	0.71
Engine Oil	A.5	550×10^{-6}	0.145	0.859×10^{-7}	6400
Mercury	A.5	0.113×10^{-6}	8.54	45.30×10^{-7}	0.025
Water	A.6	0.858×10^{-6}	0.613	1.47×10^{-7}	5.83

ANALYSIS: The appropriate relations required are

$$\overline{Nu}_L = \frac{\bar{h}L}{k} \qquad Re_L = \frac{VL}{\nu} \qquad Pr = \frac{\nu}{\alpha} \qquad j_H = \bar{S}tPr^{2/3} \qquad \bar{S}t = \frac{\overline{Nu}_L}{Re_L\,Pr}$$

Fluid	$\overline{Nu}_L$	Re_L	Pr	$\bar{j}_H$
Air	3802	6.29×10^{4}	0.71	0.068
Engine Oil	690	1.82×10^{3}	6403	0.0204
Mercury	11.7	8.85×10^{6}	0.025	4.52×10^{-6}
Water	163	1.17×10^{6}	5.84	7.74×10^{-5}

<

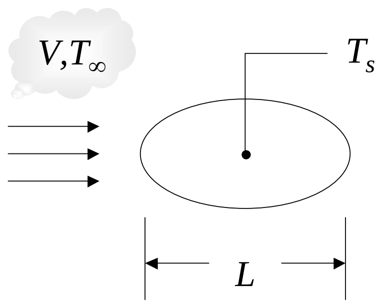
COMMENTS: Note the wide range of Pr associated with the fluids.

PROBLEM 6.34

KNOWN: Base fluid (water) and nanofluid properties. Fixed surface and ambient temperatures, fixed characteristic velocity. Fixed geometry. Form of Nusselt number correlation.

FIND: (a) Prandtl numbers of the base fluid and nanofluid. (b) Ratio of Reynolds numbers of the two fluids and ratio of Nusselt numbers necessary to provide the same convection heat transfer coefficients. (c) Whether the base fluid can provide greater convection heat transfer rates than the nanofluid.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible viscous dissipation.

PROPERTIES: Table A.6 (T = 300 K): Water; k_{bf} = 0.613 W/m·K, ρ_{bf} = 997 kg/m^3, $c_{p,\text{bf}}$ = 4.179 kJ/kg·K, μ_{bf} = 855 × 10^{-6} N·s/m^2. Example 2.2: Nanofluid, k_{nf} = 0.705 W/m·K, ρ_{nf} = 1146 kg/m^3, $c_{p,\text{nf}}$ = 3.587 kJ/kg·K, μ_{nf} = 962 × 10^{-6} N·s/m^2.

ANALYSIS: (a) The Prandtl numbers for the water and nanofluid are:

$$Pr_{\text{bf}} = \frac{\mu_{\text{bf}} c_{p,\text{bf}}}{k_{\text{bf}}} = \frac{855 \times 10^{-6}\,\text{N}\cdot\text{s/m}^2 \times 4179\ \text{J/kg}\cdot\text{K}}{0.613\ \text{W/m}\cdot\text{K}} = 5.83 \qquad <$$

$$Pr_{\text{nf}} = \frac{\mu_{\text{nf}} c_{p,\text{nf}}}{k_{\text{nf}}} = \frac{962 \times 10^{-6}\,\text{N}\cdot\text{s/m}^2 \times 3587\ \text{J/kg}\cdot\text{K}}{0.705\ \text{W/m}\cdot\text{K}} = 4.89 \qquad <$$

(b) For a given velocity and characteristic length,

$$\frac{Re_{\text{nf}}}{Re_{\text{bf}}} = \frac{\rho_{\text{nf}}\mu_{\text{bf}}}{\rho_{\text{bf}}\mu_{\text{nf}}} = \frac{1146\ \text{kg/m}^3 \times 855 \times 10^{-6}\,\text{N}\cdot\text{s/m}^2}{997\ \text{kg/m}^3 \times 962 \times 10^{-6}\,\text{N}\cdot\text{s/m}^2} = 1.022 \qquad <$$

For the same convection heat transfer coefficients,

$$\frac{\bar{h}_{\text{nf}}}{\bar{h}_{\text{bf}}} = 1 = \frac{\overline{Nu}_{\text{nf}} k_{\text{nf}} L_{\text{bf}}}{\overline{Nu}_{\text{bf}} k_{\text{bf}} L_{\text{nf}}} \quad \text{or} \quad \frac{\overline{Nu}_{\text{nf}}}{\overline{Nu}_{\text{bf}}} = \frac{k_{\text{bf}}}{k_{\text{nf}}} = \frac{0.613\ \text{W/m}\cdot\text{K}}{0.705\ \text{W/m}\cdot\text{K}} = 0.870 \qquad <$$

(c) For the base fluid to have a greater convection heat transfer rate would require $\bar{h}_{bf} > \bar{h}_{nf}$, or $\overline{Nu}_{bf} > \frac{1}{0.870}\overline{Nu}_{nf}$. Using the relationship provided in the problem statement,

$C\,\text{Re}_{bf}^{m}\,\text{Pr}_{bf}^{1/3} > \frac{C}{0.870}\text{Re}_{nf}^{n}\,\text{Pr}_{nf}^{1/3}$ which may be rearranged to yield

Continued…

$$\left(\frac{\text{Re}_{nf}}{\text{Re}_{bf}}\right)^{m} < 0.870\left(\frac{\text{Pr}_{bf}}{\text{Pr}_{nf}}\right)^{1/3} = 0.870\left(\frac{5.83}{4.92}\right)^{1/3} = 0.921$$

Since $(Re_{\text{nf}}/Re_{\text{bf}}) > 1$ and $m > 1$, the equation cannot be satisfied. Therefore we conclude that the base fluid would not provide greater convection heat transfer rates than the nanofluid as long as m is positive. <

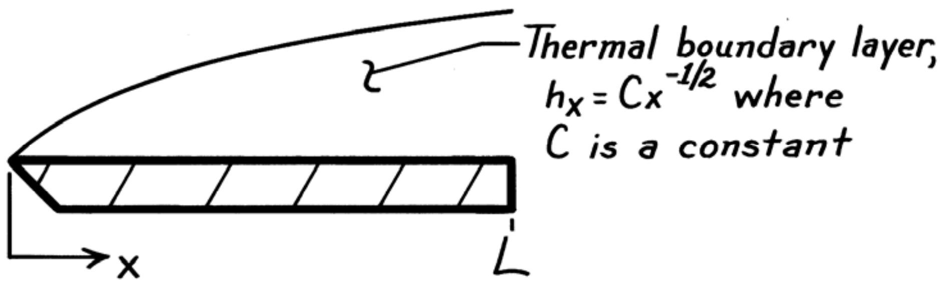
COMMENTS: (1) The conclusion regarding the relative efficacy of the nanofluid to the base fluid is valid only for situations involving unconstrained boundary layers. (2) For internal flow situations, such as will be discussed in Chapter 8, one cannot draw a general conclusion that the nanofluid would outperform the base fluid. In fact, in common instances, the base fluid would outperform the nanofluid.

PROBLEM 6.35

KNOWN: Variation of h_x with x for flow over a flat plate.

FIND: Ratio of average Nusselt number for the entire plate to the local Nusselt number at x = L.

SCHEMATIC:



ANALYSIS: The expressions for the local and average Nusselt numbers are

$$Nu_L = \frac{h_L L}{k} = \frac{\left(CL^{-1/2}\right)L}{k} = \frac{CL^{1/2}}{k}$$

$$\overline{Nu}_L = \frac{\overline{h}_L L}{k}$$

where

$$\overline{h}_L = \frac{1}{L}\int_0^L h_x\, dx = \frac{C}{L}\int_0^L x^{-1/2} dx = \frac{2C}{L} L^{1/2} = 2\, CL^{-1/2}.$$

Hence,

$$\overline{Nu}_L = \frac{2\, CL^{-1/2}(L)}{k} = \frac{2\, CL^{1/2}}{k}$$

and

$$\frac{\overline{Nu}_L}{Nu_L} = 2.$$ <

COMMENTS: Note the manner in which $\overline{Nu}_L$ is defined in terms of $\overline{h}_L$. Also note that

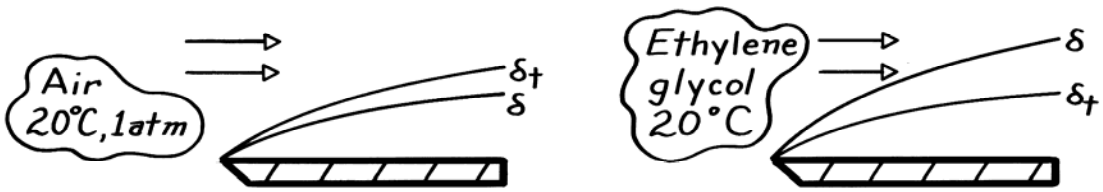
$$\overline{Nu}_L \neq \frac{1}{L}\int_0^L Nu_x\, dx.$$

PROBLEM 6.36

KNOWN: Laminar boundary layer flow of air at 20°C and 1 atm having $\delta_t = 1.13\ \delta$.

FIND: Ratio δ / δ_t when fluid is ethylene glycol for same conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Laminar flow.

PROPERTIES: *Table A-4*, Air (293K, 1 atm): Pr = 0.709; *Table A-5*, Ethylene glycol (293K): Pr = 211.

ANALYSIS: The Prandtl number strongly influences relative growth of the velocity, δ, and thermal, δ_t, boundary layers. For laminar flow, the approximate relationship is given by

$$\mathrm{Pr}^n \approx \frac{\delta}{\delta_t}$$

where n is a positive coefficient. Substituting the values for air

$$(0.709)^n = \frac{1}{1.13}$$

find that n = 0.355. Hence, for ethylene glycol it follows that

$$\frac{\delta}{\delta_t} = \mathrm{Pr}^{0.355} = 211^{0.355} = 6.69. \qquad <$$

COMMENTS: (1) For laminar flow, generally we find n = 0.33. In which case, $\delta / \delta_t = 5.85$.

(2) Recognize the physical importance of $\nu > \alpha$, which gives large values of the Prandtl number, and causes $\delta > \delta_t$.

PROBLEM 6.37

KNOWN: Air, water, engine oil or mercury at 300K in laminar, parallel flow over a flat plate.

FIND: Sketch of velocity and thermal boundary layer thickness.

ASSUMPTIONS: (1) Laminar flow.

PROPERTIES: For the fluids at 300K:

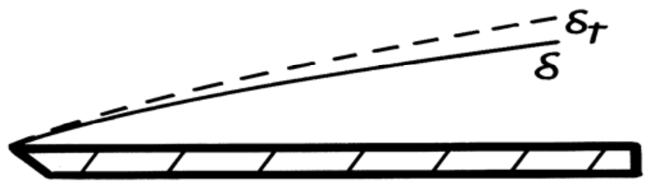
Fluid	Table	Pr
Air	A.4	0.71
Water	A.6	5.83
Engine Oil	A.5	6400
Mercury	A.5	0.025

ANALYSIS: For laminar, boundary layer flow over a flat plate.

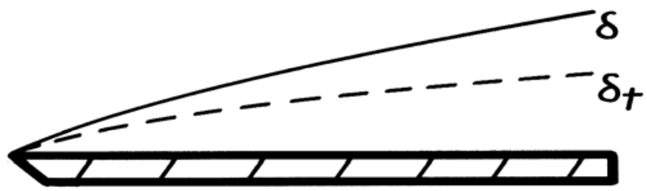
$$\frac{\delta}{\delta_t} \sim Pr^n$$

where n > 0. Hence, the boundary layers appear as shown below.

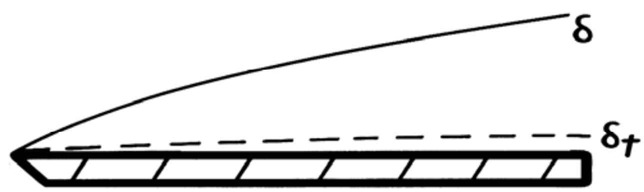
Air:



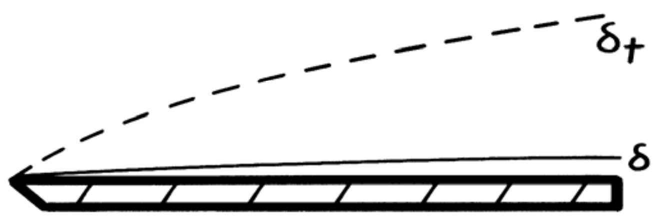
Water:



Engine Oil:



Mercury:



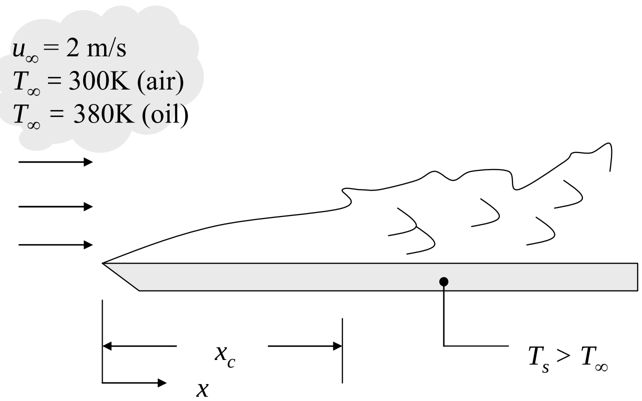
COMMENTS: Although Pr strongly influences relative boundary layer development in laminar flow, its influence is weak for turbulent flow.

PROBLEM 6.38

KNOWN: Flow over a flat plate. Velocity and temperature of two fluids. Variation of boundary layer thickness with *x* for laminar flow.

FIND: (a) Location where transition to turbulence occurs for each fluid, (b) Plot of velocity boundary layer thickness for $0 \le x \le x_c$ for each fluid, (c) Plot of thermal boundary layer thickness over the same range. Which fluid has the largest local temperature gradient at the surface, Nusselt number, and heat transfer coefficient.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Incompressible flow, (3) Transition occurs at a critical Reynolds number of 5×10^5.

PROPERTIES: *Table A.4*, Air (T = 300 K): $\nu = 15.89 \times 10^{-6}$ m^2/s, k = 0.0263 W/m·K, Pr = 0.707. *Table A.5*, Engine Oil (T = 380 K): $\nu = 16.9 \times 10^{-6}$ m^2/s, k = 0.136 W/m·K, Pr = 233.

ANALYSIS: (a) Transition occurs at $Re_{x,c} = u_\infty x/\nu = 5 \times 10^5$. Therefore, for air

$$x_c = 5\times10^5 \frac{\nu}{u_\infty} = 5\times10^5 \frac{15.89\times10^{-6}\ \text{m}^2/\text{s}}{2\ \text{m/s}} = 4.0\ \text{m}$$ <

The value for engine oil is 4.2 m. <

(b) The velocity boundary layer thickness is given by $\dfrac{\delta}{x} = \dfrac{5}{\sqrt{Re_x}}$. Thus, for air

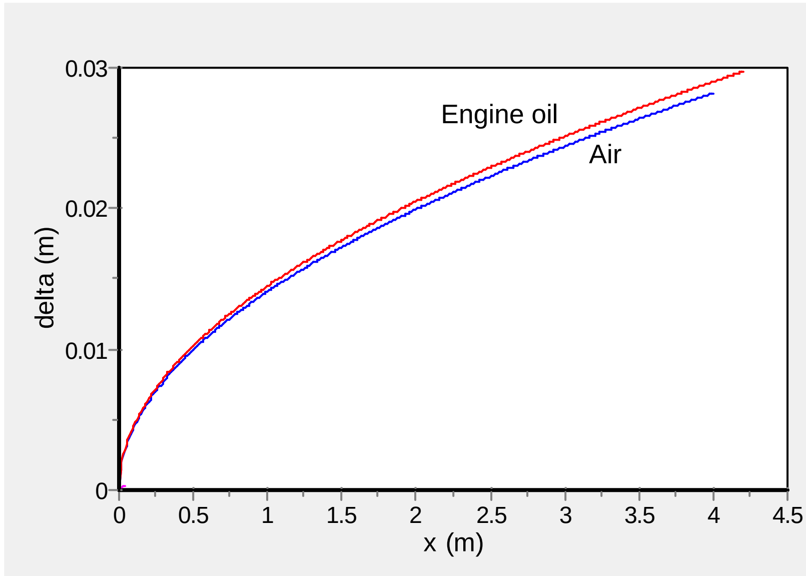
$$\delta = \frac{5x}{\sqrt{Re_x}} = 5\sqrt{x\nu/u_\infty} = 5\sqrt{\frac{15.89\times10^{-6}\ \text{m}^2/\text{s}\times x}{2\ \text{m/s}}} = 0.0141x^{1/2}$$ <

where x and δ are expressed in meters. The corresponding result for engine oil is $\delta = 0.0145x^{1/2}$. <

These results are plotted below.

Continued…

PROBLEM 6.38 (Cont.)



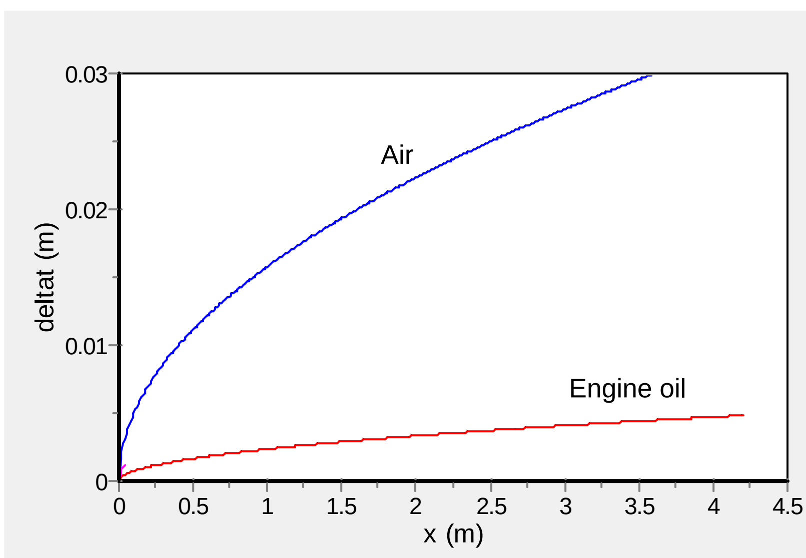
<

(c) From Eq. 6.55 with n = 1/3, $\delta_t = \delta{\cdot}Pr^{-1/3}$. Thus, for air

$$\delta_t = \delta Pr^{-1/3} = 0.0141x^{1/2} \times (0.707)^{-1/3} = 0.0158x^{1/2}$$ <

Similarly for engine oil $\delta_t = 0.00586x^{1/2}$. <

The results for the two fluids are shown below.



<

Continued…

PROBLEM 6.38 (Cont.)

The two fluids are subjected to the same temperature difference between the surface and the free stream. Since the thermal boundary layer thickness is the distance over which the temperature varies from the surface temperature to the free stream temperature, the fluid with the smaller value of δ_t must have a larger temperature gradient, $-\partial T/\partial y|_{y=0}$.

Therefore, engine oil has the larger temperature gradient at the surface. <

The local Nusselt number is given by $Nu = hx/k$, where h is defined in Equation 6.5. Therefore,

$$Nu = \frac{-\partial T/\partial y|_{y=0}}{T_s - T_\infty} x$$

At a given x location, since $T_s - T_\infty$ is the same for both fluids, the fluid with the larger temperature gradient has the larger local Nusselt number.

Engine oil has the larger local Nusselt number. <

The heat transfer coefficient is given by Equation 6.5:

$$h = \frac{-k_f \partial T/\partial y|_{y=0}}{T_s - T_\infty}$$

Since engine oil has a larger temperature gradient *and* a larger thermal conductivity, it is associated with a larger heat transfer coefficient. <

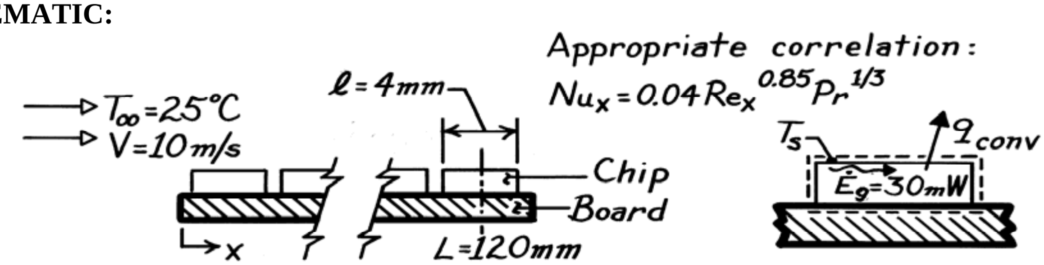
COMMENTS: (1) Since the kinematic viscosity of the two fluids is nearly the same, their local Reynolds numbers, transition locations, and velocity boundary layer thicknesses are comparable. (2) The much higher Prandtl number of the engine oil results in a much thinner thermal boundary layer and consequently a larger temperature gradient at the surface and higher heat transfer coefficient.

PROBLEM 6.39

KNOWN: Expression for the local heat transfer coefficient of air at prescribed velocity and temperature flowing over electronic elements on a circuit board and heat dissipation rate for a 4 × 4 mm chip located 120mm from the leading edge.

FIND: Surface temperature of the chip surface, T_s.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Power dissipated within chip is lost by convection across the upper surface only, (3) Chip surface is isothermal, (4) The average heat transfer coefficient for the chip surface is equivalent to the local value at x = L, (5) Negligible radiation.

PROPERTIES: *Table A-4*, Air (assume T_s = 45°C, T_f = (45 + 25)/2 = 35°C = 308K, 1atm): $\nu = 16.69 \times 10^{-6}\ m^2/s$, $k = 26.9 \times 10^{-3}$ W/m·K, Pr = 0.703.

ANALYSIS: From an energy balance on the chip (see above),

$$q_{conv} = \dot{E}_g = 30W. \tag{1}$$

Newton's law of cooling for the upper chip surface can be written as

$$T_s = T_\infty + q_{conv} / \bar{h}\, A_{chip} \tag{2}$$

where $A_{chip} = \ell^2$. Assume that the *average* heat transfer coefficient $(\bar{h})$ over the chip surface is equivalent to the *local* coefficient evaluated at x = L. That is, $\bar{h}_{chip} \approx h_x(L)$ where the local coefficient can be evaluated from the special correlation for this situation,

$$Nu_x = \frac{h_x x}{k} = 0.04 \left[\frac{Vx}{\nu}\right]^{0.85} Pr^{1/3}$$

and substituting numerical values with x = L, find

$$h_x = 0.04 \frac{k}{L} \left[\frac{VL}{\nu}\right]^{0.85} Pr^{1/3}$$

$$h_x = 0.04 \left[\frac{0.0269\ W/m\cdot K}{0.120\ m}\right] \left[\frac{10\ m/s \times 0.120\ m}{16.69 \times 10^{-6}\ m^2/s}\right]^{0.85} (0.703)^{1/3} = 107\ W/m^2\cdot K.$$

The surface temperature of the chip is from Eq. (2),

$$T_s = 25^\circ C + 30 \times 10^{-3}\ W / \left[107\ W/m^2 \cdot K \times (0.004m)^2\right] = 42.5^\circ C. \quad <$$

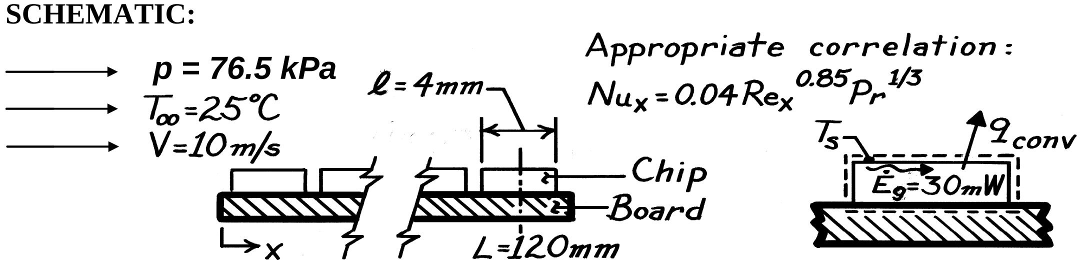
COMMENTS: (1) Note that the estimated value for T_f used to evaluate the air properties was reasonable. (2) Alternatively, we could have evaluated $\bar{h}_{chip}$ by performing the integration of the local value, h(x).

PROBLEM 6.40

KNOWN: Expression for the local heat transfer coefficient of air at prescribed velocity and temperature flowing over electronic elements on a circuit board and heat dissipation rate for a 4 × 4 mm chip located 120 mm from the leading edge. Atmospheric pressure in Mexico City.

FIND: (a) Surface temperature of chip, (b) Air velocity required for chip temperature to be the same at sea level.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Power dissipated in chip is lost bey convection across the upper surface only, (3) Chip surface is isothermal, (4) The average heat transfer coefficient for the chip surface is equivalent to the local value at x = L, (5) Negligible radiation, (6) Ideal gas behavior.

PROPERTIES: Table A.4, air (p = 1 atm, assume T_s = 45 °C, T_f = (45 °C + 25 °C)/2 = 35 °C): k = 0.0269 W/m·K, ν = 16.69 × 10^{-6} m^2/s, Pr = 0.706.

ANALYSIS:

(a) From an energy balance on the chip (see above),

$$q_{conv} = \dot{E}_g = 30\text{W}. \qquad (1)$$

Newton's law of cooling for the upper chip surface can be written as

$$T_s = T_\infty + q_{conv} / \overline{h}\, A_{chip} \qquad (2)$$

where $A_{chip} = \ell^2$. From Assumption 4, $\overline{h}_{chip} \approx h_x(L)$ where the local coefficient can be evaluated from the correlation provided in Problem 6.35.

$$Nu_x = \frac{h_x x}{k} = 0.04\left[\frac{Vx}{\nu}\right]^{0.85} Pr^{1/3} \qquad (3)$$

The kinematic viscosity is

$$\nu = \frac{\mu}{\rho} \qquad (4)$$

while for an ideal gas,

$$\rho = \frac{p}{RT} \qquad (5)$$

Combining Equations 4 and 5 yields

$$\nu \propto p^{-1} \qquad (6)$$

Continued…

PROBLEM 6.40 (Cont.)

The Prandtl number is

$$\Pr = \frac{\nu}{\alpha} = \frac{\mu\rho c}{\rho k} = \frac{\mu c}{k} \qquad (7)$$

which is independent of pressure.

Therefore, at sea level (p = 1 atm)

$$k = 0.0269 \text{ W/m}\cdot\text{K},\ \nu = 16.69 \times 10^{-6} \text{ m}^2\text{/s},\ \Pr = 0.706$$

$$h_x = 0.04\,\frac{k}{L}\left[\frac{VL}{\nu}\right]^{0.85} \Pr^{1/3}$$

$$h_x = 0.04\left[\frac{0.0269 \text{ W/m}\cdot\text{K}}{0.120 \text{ m}}\right]\left[\frac{10 \text{ m/s} \times 0.120 \text{ m}}{16.69 \times 10^{-6} \text{ m}^2\text{/s}}\right]^{0.85} (0.706)^{1/3} = 107 \text{ W/m}^2\cdot\text{K}$$

$$T_s = 25°\text{C} + 30 \times 10^{-3} \text{ W} \Big/ 107 \text{ W/m}^2\cdot\text{K} \times (0.004 \text{ m})^2 = 42.5°\text{C}$$

In Mexico City (p = 76.5 kPa)

$$\nu = 16.69 \times 10^{-6} \text{ m}^2\text{/s} \times \left[\frac{101.3\text{lPa}}{76.5\text{kPa}}\right] = 22.10 \times 10^{-6} \text{ m}^2\text{/s}$$

$$k = 0.0269 \text{ W/m}\cdot\text{K},\quad \Pr = 0.706$$

$$h_x = 0.04\left[\frac{0.0269 \text{ W/m}\cdot\text{K}}{0.120 \text{ m}}\right]\left[\frac{10 \text{ m/s} \times 0.120 \text{ m}}{22.10 \times 10^{-6} \text{ m}^2\text{/s}}\right]^{0.85} (0.706)^{1/3} = 84.5 \text{ W/m}^2\cdot\text{K}$$

$$T_s = 25°\text{C} + 30 \times 10^{-3} \text{ W} \Big/ 84.5 \text{ W/m}^2\cdot\text{K} \times (0.004 \text{ m})^2 = 47.2°\text{C}$$ <

(b) For the same chip temperature, it is required that $h_x = 107$ W/m^2·K. Therefore

$$h_x = 107 \text{ W/m}^2\cdot\text{K} = 0.04\left[\frac{0.0269 \text{ W/m}\times\text{K}}{0.120 \text{ m}}\right]\left[\frac{V \times 0.120 \text{ m}}{22.10 \times 10^{-6} \text{ m}^2\text{/s}}\right]^{0.85} (0.706)^{1/3}$$

From which we may find V = 13.2 m/s <

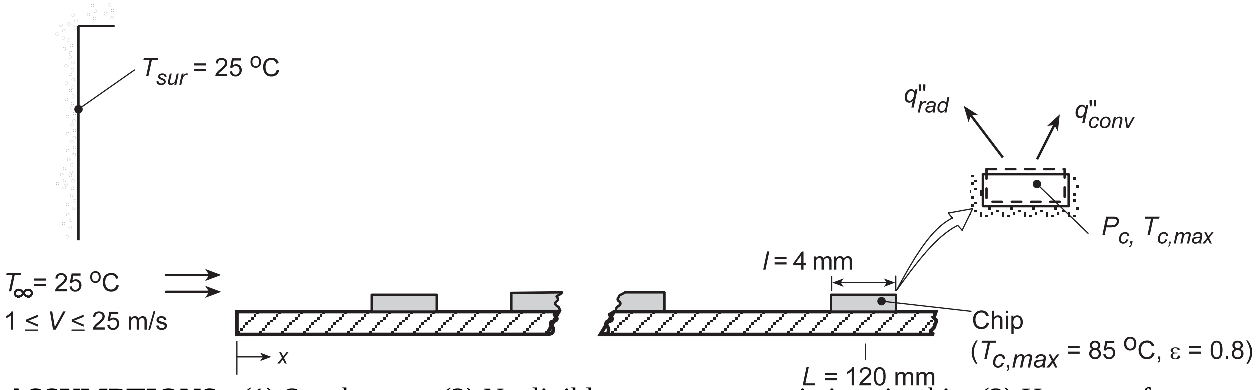
COMMENTS: (1) In Part (a), the chip surface temperature increased from 42.4 °C to 47.2 °C. This is considered to be significant and the electronics packaging engineer needs to consider the effect of large changes in atmospheric pressure on the efficacy of the electronics cooling scheme. (2) Careful consideration needs to be given to the effect changes in the atmospheric pressure on the kinematic viscosity and, in turn, on changes in transition lengths which might affect local convective heat transfer coefficients.

PROBLEM 6.41

KNOWN: Location and dimensions of computer chip on a circuit board. Form of the convection correlation. Maximum allowable chip temperature and surface emissivity. Temperature of cooling air and surroundings.

FIND: Effect of air velocity on maximum power dissipation, first without and then with consideration of radiation effects.

SCHEMATIC:



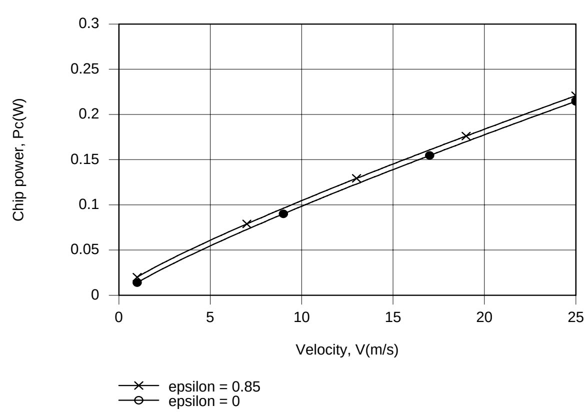
ASSUMPTIONS: (1) Steady-state, (2) Negligible temperature variations in chip, (3) Heat transfer exclusively from the top surface of the chip, (4) The local heat transfer coefficient at x = L provides a good approximation to the average heat transfer coefficient for the chip surface.

PROPERTIES: *Table A.4*, air ($\overline{T} = \left(T_\infty + T_c\right)/2$ = 328 K): $\nu = 18.71 \times 10^{-6}$ m²/s, k = 0.0284 W/m·K, Pr = 0.703.

ANALYSIS: Performing an energy balance for a control surface about the chip, we obtain $P_c = q_{conv} + q_{rad}$, where $q_{conv} = \overline{h}A_s\left(T_c - T_\infty\right)$, $q_{rad} = h_r A_s\left(T_c - T_{sur}\right)$, and $h_r = \varepsilon\sigma\left(T_c + T_{sur}\right)\left(T_c^2 + T_{sur}^2\right)$. With $\overline{h} \approx h_L$, the convection coefficient may be determined from the correlation provided in Problem 6.39 ($Nu_L = 0.04\,Re_L^{0.85}\,Pr^{1/3}$). Hence,

$$P_c = \ell^2\left[0.04\left(k/L\right)Re_L^{0.85}\,Pr^{1/3}\left(T_c - T_\infty\right) + \varepsilon\sigma\left(T_c + T_{sur}\right)\left(T_c^2 + T_{sur}^2\right)\left(T_c - T_{sur}\right)\right]$$

where $Re_L = VL/\nu$. Computing the right side of this expression for ε = 0 and ε = 0.85, we obtain the following results.



Since h_L increases as $V^{0.85}$, the chip power must increase with V in the same manner. Radiation exchange increases P_c by a fixed, but small (6 mW) amount. While h_L varies from 14.5 to 223 W/m²·K over the prescribed velocity range, h_r = 6.5 W/m²·K is a constant, independent of V.

COMMENTS: Alternatively, $\overline{h}$ could have been evaluated by integrating h_x over the range 118 ≤ x ≤ 122 mm to obtain the appropriate average. However, the value would be extremely close to $h_{x=L}$.

PROBLEM 6.42

KNOWN: Form of Nusselt number for flow of air or a dielectric liquid over components of a circuit card.

FIND: Ratios of time constants associated with intermittent heating and cooling. Fluid that provides faster thermal response.

PROPERTIES: Prescribed. Air: k = 0.026 W/m·K, $\nu = 2 \times 10^{-5}$ m^2/s, Pr = 0.71. Dielectric liquid: k = 0.064 W/m·K, $\nu = 10^{-6}$ m^2/s, Pr = 25.

ANALYSIS: From Eq. 5.7, the thermal time constant is

$$\tau_t = \frac{\rho \forall c}{\overline{h} A_s}$$

Since the only variable that changes with the fluid is the convection coefficient, where

$$\overline{h} = \frac{k}{L}\overline{Nu}_L = \frac{k}{L} C\, Re_L^m\, Pr^n = \frac{k}{L} C \left(\frac{VL}{\nu}\right)^m Pr^n$$

the desired ratio reduces to

$$\frac{\tau_{t,air(a)}}{\tau_{t,dielectric(d)}} = \frac{\overline{h}_d}{\overline{h}_a} = \frac{k_d}{k_a}\left(\frac{\nu_a}{\nu_d}\right)^m \left(\frac{Pr_d}{Pr_a}\right)^n$$

$$\frac{\tau_{t,a}}{\tau_{t,d}} = \frac{0.064}{0.026}\left(\frac{2\times10^{-5}}{10^{-6}}\right)^{0.8}\left(\frac{25}{0.71}\right)^{0.33} = 88.6$$

Since its time constant is nearly two orders of magnitude smaller than that of the air, the dielectric liquid is clearly the fluid of choice. <

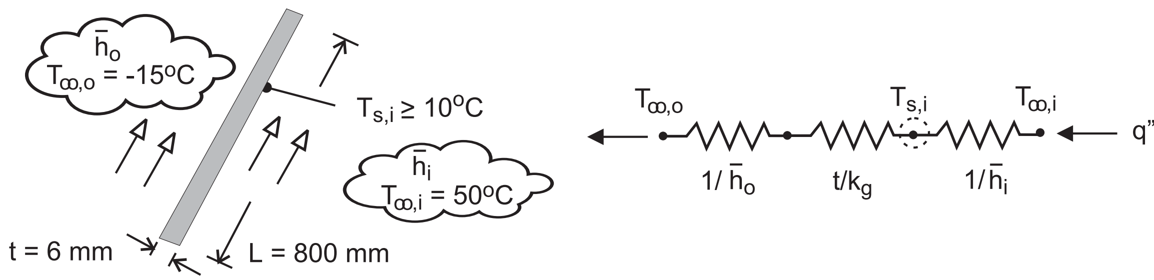
COMMENTS: The accelerated testing procedure suggested by this problem is commonly used to test the durability of electronic packages.

PROBLEM 6.43

KNOWN: Ambient, interior and dewpoint temperatures. Vehicle speed and dimensions of windshield. Heat transfer correlation for external flow.

FIND: Minimum value of convection coefficient needed to prevent condensation on interior surface of windshield.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) One-dimensional heat transfer, (3) Constant properties.

PROPERTIES: *Table A-3*, glass: k_g = 1.4 W/m·K. Prescribed, air: k = 0.023 W/m·K, $\nu = 12.5 \times 10^{-6}$ m^2/s, Pr = 0.70.

ANALYSIS: From the prescribed thermal circuit, conservation of energy yields

$$\frac{T_{\infty,i} - T_{s,i}}{1/\bar{h}_i} = \frac{T_{s,i} - T_{\infty,o}}{t/k_g + 1/\bar{h}_o}$$

where $\bar{h}_o$ may be obtained from the correlation

$$\overline{Nu}_L = \frac{\bar{h}_o L}{k} = 0.030\, Re_L^{0.8}\, Pr^{1/3}$$

With V = (70 mph × 1585 m/mile)/3600 s/h = 30.8 m/s, Re_D = (30.8 m/s × 0.800 m)/12.5 × 10^{-6} m^2/s = 1.97 × 10^6 and

$$\bar{h}_o = \frac{0.023\,W/m\cdot K}{0.800\ m} 0.030\left(1.97\times 10^6\right)^{0.8}(0.70)^{1/3} = 83.1\,W/m^2\cdot K$$

From the energy balance, with $T_{s,i} = T_{dp}$ = 10°C

$$\bar{h}_i = \frac{\left(T_{s,i} - T_{\infty,o}\right)}{\left(T_{\infty,i} - T_{s,i}\right)}\left(\frac{t}{k_g} + \frac{1}{\bar{h}_o}\right)^{-1}$$

$$\bar{h}_i = \frac{(10+15)°C}{(50-10)°C}\left(\frac{0.006\ m}{1.4\,W/m\cdot K} + \frac{1}{83.1\,W/m^2\cdot K}\right)^{-1}$$

$$\bar{h}_i = 38.3\,W/m^2\cdot K$$ <

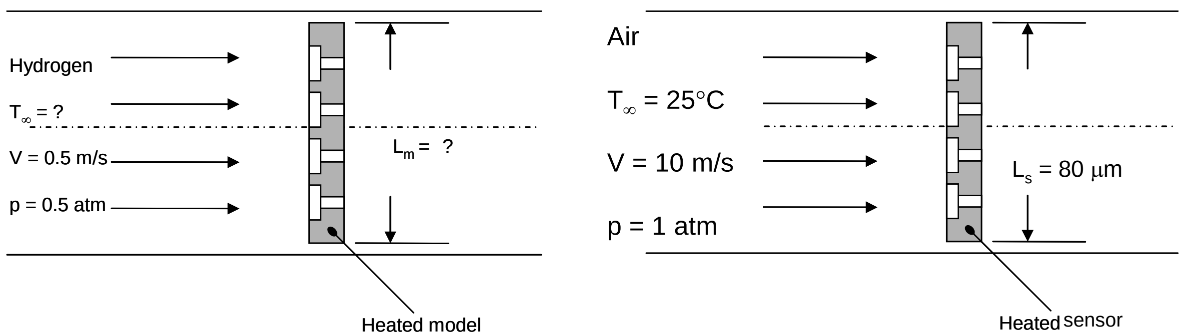
COMMENTS: The output of the fan in the automobile's heater/defroster system must maintain a velocity for flow over the inner surface that is large enough to provide the foregoing value of $\bar{h}_i$. In addition, the output of the heater must be sufficient to maintain the prescribed value of $T_{\infty,i}$ at this velocity.

PROBLEM 6.44

KNOWN: Characteristic length of a microscale chemical detector, free stream velocity and temperature, hydrogen wind tunnel pressure and free stream velocity.

FIND: Model length scale and hydrogen temperature needed for similarity.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible microscale or nanoscale effects, (4) Ideal gas behavior.

PROPERTIES: Table A.4, air (T = 25 °C): $Pr_s = 0.707$, $\nu_s = 15.71 \times 10^{-6}$ m²/s, hydrogen (250 K) $Pr = 0.707$, $\nu = 81.4 \times 10^{-6}$ m²/s.

ANALYSIS: For similarity we require $Re_m = Re_s$ and $Pr_m = Pr_s$. For the sensor,

$$Re_s = \frac{V_s L_s}{\nu_s} = \frac{10 \text{ m/s} \times 80 \times 10^{-6} \text{ m}}{1.571 \times 10^{-5} \text{ m}^2/\text{s}} = 50.93$$

$$Pr_s = 0.707$$

For the model, $Pr_m = Pr_s = 0.707$.

From Table A.4, we note $Pr_s = 0.707$, $\nu = 81.4 \times 10^{-6}$ m²/s at $T_\infty = 250$ K and p = 1 atm. <

The value of the Prandtl number is independent of pressure for an ideal gas. The kinematic viscosity is pressure-dependent. Hence,

$$\nu(\text{at 0.5 atm}) = \frac{\mu}{\rho(\text{at 0.5 atm})} = \frac{\mu}{\rho(\text{at 1.0 atm})} \times \frac{\rho(\text{at 1.0 atm})}{\rho(\text{at 0.5 atm})}$$

For an ideal gas,

$$\nu(\text{at 0.5 atm}) = \nu(\text{at 1.0 atm}) \times \frac{1.0 \text{ atm}}{0.5 \text{ atm}} = 2\nu(\text{at 1.0 atm})$$

Therefore,

$$\nu_m = 81.4 \times 10^{-6} \text{ m}^2/\text{s} \times 2 = 163 \times 10^{-6} \text{ m}^2/\text{s}$$

For similarity,

Continued…

PROBLEM 6.44 (Cont.)

$$Re_m = Re_s = 50.93 = \frac{V_m L_m}{\nu_m} = \frac{0.5\ m/s \times L_m}{163 \times 10^{-6}\ m^2/s}$$

or $\quad L_m = 16.6 \times 10^{-3}\ m = 16.6\ mm$ <

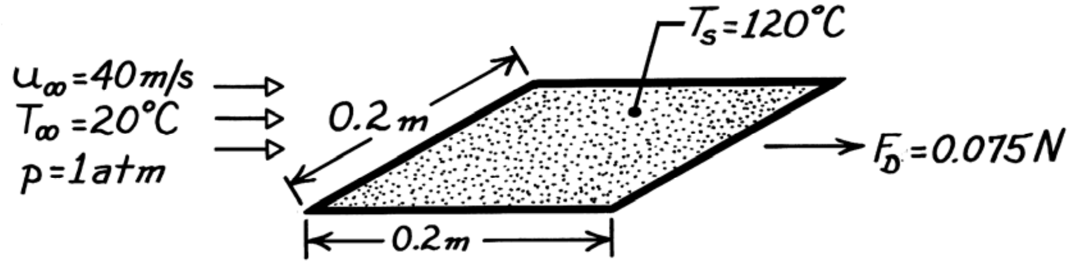
COMMENTS: (1) From Section 2.2.1, we know that the mean free path of air at room conditions is approximately 80 nm. Since L_s is three orders of magnitude greater than the mean free path, the air may be treated as a continuum. (2) Hydrogen can leak from enclosures easily. By keeping the wind tunnel pressure below atmospheric, we avoid possible leakage of flammable hydrogen into the lab. Also, if leaks occur, air must enter the wind tunnel. It is much easier to seal against air leaks than hydrogen leaks. (3) $Pr_m = 0.707$ at 100 K also. However, the operation of the hydrogen wind tunnel at such a low temperature would be much more difficult than at 250 K.

PROBLEM 6.45

KNOWN: Drag force and air flow conditions associated with a flat plate.

FIND: Rate of heat transfer from the plate.

SCHEMATIC:



ASSUMPTIONS: (1) Chilton-Colburn analogy is applicable.

PROPERTIES: *Table A-4,* Air (70°C,1 atm): ρ = 1.018 kg/m^3, c_p = 1009 J/kg·K, Pr = 0.70, $\nu = 20.22 \times 10^{-6} m^2/s$.

ANALYSIS: The rate of heat transfer from the plate is

$$q = 2\bar{h}\left(L^2\right)\left(T_s - T_\infty\right)$$

where $\bar{h}$ may be obtained from the Chilton-Colburn analogy,

$$\bar{j}_H = \frac{\bar{C}_f}{2} = \bar{S}t\, Pr^{2/3} = \frac{\bar{h}}{\rho\, u_\infty\, c_p} Pr^{2/3}$$

$$\frac{\bar{C}_f}{2} = \frac{1}{2}\frac{\bar{\tau}_s}{\rho\, u_\infty^2/2} = \frac{1}{2}\frac{(0.075\text{ N}/2)/(0.2\text{m})^2}{1.018\text{ kg/m}^3(40\text{ m/s})^2/2} = 5.76\times10^{-4}.$$

Hence,

$$\bar{h} = \frac{C_f}{2}\rho\, u_\infty\, c_p\, Pr^{-2/3}$$

$$\bar{h} = 5.76\times10^{-4}\left(1.018\text{kg/m}^3\right)40\text{m/s}\left(1009\text{J/kg}\cdot\text{K}\right)(0.70)^{-2/3}$$

$$\bar{h} = 30\text{ W/m}^2\cdot\text{K}.$$

The heat rate is

$$q = 2\left(30\text{ W/m}^2\cdot\text{K}\right)(0.2\text{m})^2\left(120-20\right)^\circ\text{C}$$

$$q = 240\text{ W}.$$ <

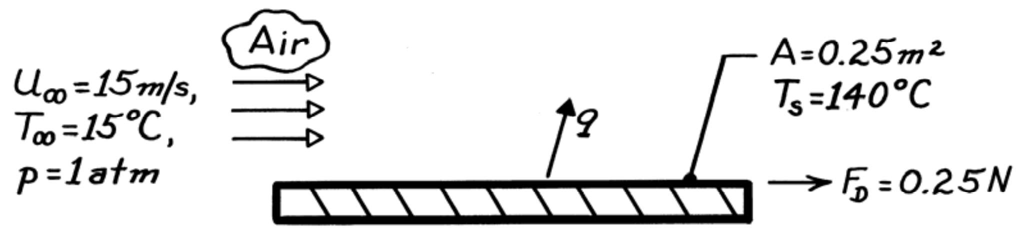
COMMENTS: Although the flow is laminar over the entire surface ($Re_L = u_\infty L/\nu$ = 40 m/s × 0.2m/20.22 × 10^{-6}m^2/s = 4.0 × 10^5), the pressure gradient is zero and the Chilton-Colburn analogy is applicable to *average,* as well as *local,* surface conditions. Note that the only contribution to the drag force is made by the surface shear stress.

PROBLEM 6.46

KNOWN: Air flow conditions and drag force associated with a heater of prescribed surface temperature and area.

FIND: Required heater power.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Reynolds analogy is applicable, (3) Bottom surface is adiabatic.

PROPERTIES: *Table A-4*, Air (T_f = 350K, 1atm): $\rho = 0.995\ kg/m^3$, $c_p = 1009\ J/kg\cdot K$, Pr = 0.700.

ANALYSIS: The average shear stress and friction coefficient are

$$\overline{\tau}_s = \frac{F_D}{A} = \frac{0.25\ N}{0.25\ m^2} = 1\ N/m^2$$

$$\overline{C}_f = \frac{\overline{\tau}_s}{\rho\, u_\infty^2/2} = \frac{1\ N/m^2}{0.995\ kg/m^3 (15 m/s)^2/2} = 8.93\times 10^{-3}.$$

From the Reynolds analogy,

$$\overline{St} = \frac{\overline{h}}{\rho\, u_\infty c_p} = \frac{\overline{C}_f}{2} Pr^{-2/3}.$$

Solving for $\overline{h}$ and substituting numerical values, find

$$\overline{h} = 0.995\ kg/m^3 (15 m/s)\ 1009\ J/kg\cdot K \left(8.93\times 10^{-3}/2\right)\ (0.7)^{-2/3}$$

$$\overline{h} = 85\ W/m^2\cdot K.$$

Hence, the heat rate is

$$q = \overline{h}\, A\, (T_s - T_\infty) = 85 W/m^2\cdot K \left(0.25 m^2\right)\ (140 - 15)^\circ C$$

$$q = 2.66\ kW.$$ <

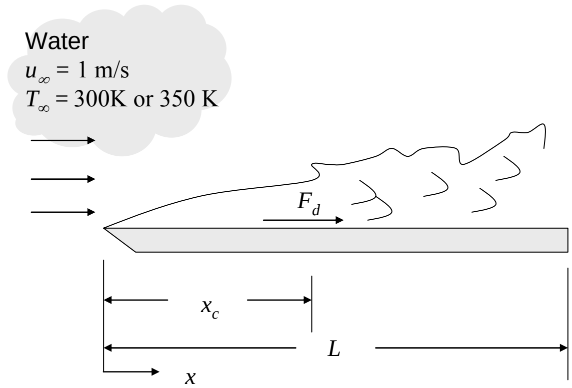
COMMENTS: Due to bottom heat losses, which have been assumed negligible, the actual power requirement would exceed 2.66 kW.

PROBLEM 6.47

KNOWN: Velocity of water flowing over a flat plate. Length and width of plate. Variation of local convection coefficient with x for $T = 300$ K and $T = 350$ K. Locations of turbulence transition.

FIND: Drag force for both water temperatures.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Transition occurs at a critical Reynolds number of 5×10^5, (3) Incompressible flow.

PROPERTIES: *Table A.6*, Water ($T = 300$ K): $\mu = 855 \times 10^{-6}$ N·s/m^2, $k = 0.613$ W/m·K. Water ($T = 350$ K): $\mu = 365 \times 10^{-6}$ N·s/m^2, $k = 0.668$ W/m·K.

ANALYSIS: According to the Reynolds analogy, Eq. 6.66

$$C_f \frac{Re_L}{2} = Nu$$

This relationship holds for the local values of C_f and Nu. The local shear stress can be expressed as

$$\tau_s = C_f \frac{\rho u_\infty^2}{2} = \frac{Nu}{Re_L}\rho u_\infty^2 = \frac{hx}{k}\frac{\rho u_\infty \nu}{L} = \frac{\mu u_\infty}{kL}hx = Bhx$$

where $B = \mu u_\infty/kL$. Therefore, $\tau_{s,\text{lam}} = BC_{\text{lam}}x^{0.5}$ and $\tau_{s,\text{turb}} = BC_{\text{turb}}x^{0.8}$. Now the drag force can be found:

$$F_d = \int_0^L \tau_s dx \cdot W = \left[\int_0^{x_c} BC_{\text{lam}} x^{0.5} dx + \int_{x_c}^L BC_{\text{turb}} x^{0.8} dx\right] W = BW\left[C_{\text{lam}}\frac{x_c^{1.5}}{1.5} + C_{\text{turb}}\left(\frac{L^{1.8}}{1.8} - \frac{x_c^{1.8}}{1.8}\right)\right]$$

At $T = 300$ K,

$$F_d = \frac{855\times10^{-6}\ \text{N}\cdot\text{s/m}^2 \times 1\ \text{m/s}}{0.613\ \text{W/m}\cdot\text{K}\times 0.6\ \text{m}} \times 1\ \text{m}$$
$$\times\left[395\ \text{W/m}^{1.5}\cdot\text{K}\times\frac{(0.43\ \text{m})^{1.5}}{1.5} + 2330\ \text{W/m}^{1.8}\cdot\text{K}\left(\frac{(0.6\ \text{m})^{1.8}}{1.8} - \frac{(0.43\ \text{m})^{1.8}}{1.8}\right)\right]$$

$$F_d = 0.714\ \text{N}$$ <

Continued…

PROBLEM 6.47 (Cont.)

Similarly, at $T = 350$ K with $C_{lam} = 477$ W/m$^{1.5}$·K, $C_{turb} = 3600$ W/m$^{1.8}$·K and $x_c = 0.19$ m,

$$F_d = 0.659 \text{ N}$$ <

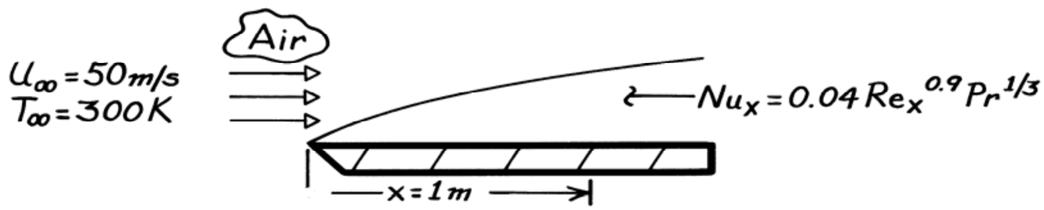
COMMENTS: (1) Even though transition to turbulence occurs earlier for the $T = 350$ K case, the net effect of the much smaller viscosity is a reduction in the drag force. (2) It would be incorrect to apply Reynolds' analogy, Eq. 6.66, directly to the average values of C_f and Nu because of the presence of x in the definition of the Nusselt number. Applying Eq. 6.66 directly to the average values would result in the incorrect values $F_d = 1.36$ and 1.22 N for the 300 K and 350 K cases, respectively.

PROBLEM 6.48

KNOWN: Heat transfer correlation associated with parallel flow over a rough flat plate. Velocity and temperature of air flow over the plate.

FIND: Surface shear stress l m from the leading edge.

SCHEMATIC:



ASSUMPTIONS: (1) Modified Reynolds analogy is applicable, (2) Constant properties.

PROPERTIES: *Table A-4*, Air (300K, 1atm): $\nu = 15.89 \times 10^{-6} m^2/s$, Pr = 0.71, $\rho = 1.16$ kg/m^3.

ANALYSIS: Applying the Chilton-Colburn analogy

$$\frac{C_f}{2} = St_x Pr^{2/3} = \frac{Nu_x}{Re_x Pr} Pr^{2/3} = \frac{0.04\, Re_x^{0.9}\, Pr^{1/3}}{Re_x\, Pr} Pr^{2/3}$$

$$\frac{C_f}{2} = 0.04\, Re_x^{-0.1}$$

where

$$Re_x = \frac{u_\infty x}{\nu} = \frac{50\ m/s \times 1m}{15.89 \times 10^{-6} m^2/s} = 3.15 \times 10^6.$$

Hence, the friction coefficient is

$$C_f = 0.08 \left(3.15 \times 10^6\right)^{-0.1} = 0.0179 = \tau_s / \left(\rho\, u_\infty^2 / 2\right)$$

and the surface shear stress is

$$\tau_s = C_f \left(\rho\, u_\infty^2 / 2\right) = 0.0179 \times 1.16 kg/m^3 \left(50\ m/s\right)^2 / 2$$

$$\tau_s = 25.96\ kg/m \cdot s^2 = 25.96\ N/m^2.$$ <

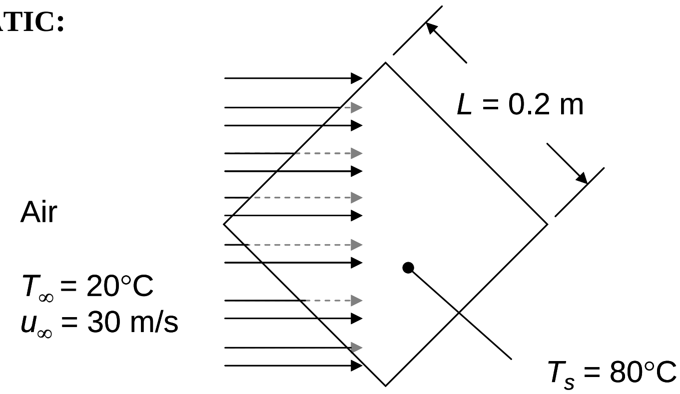
COMMENTS: Note that turbulent flow will exist at the designated location.

PROBLEM 6.49

KNOWN: Dimensions and temperature of a thin, rough plate. Velocity of air flow parallel to plate (at an angle of 45° to a side). Heat transfer rate from plate to air.

FIND: Drag force on plate.

SCHEMATIC:



ASSUMPTIONS: (1) The modified Reynolds analogy holds, (2) Constant properties.

PROPERTIES: Table A-4, Air (50°C = 323 K): c_p = 1008 J/kg·K, Pr = 0.704.

ANALYSIS: The modified Reynolds analogy, Equation 6.70, combined with the definition of the Stanton number, Equation 6.67, yields

$$C_f/2 = (Nu/Re)Pr^{-1/3} \qquad (1)$$

The drag force is related to the friction coefficient according to

$$F_D = \tau_s A_s = C_f \cdot \rho u_\infty^2 A_s / 2 \qquad (2)$$

Combining Equations (1) and (2)

$$F_D = \frac{Nu}{Re} Pr^{-1/3} \rho u_\infty^2 A_s$$

Substituting the definitions of Nu and Re, we find

$$F_D = \frac{hL_c}{k}\frac{\nu}{u_\infty L_c} Pr^{-1/3}\rho u_\infty^2 A_s = \frac{h}{c_p}\frac{\nu}{\alpha} Pr^{-1/3} u_\infty A_s = \frac{h}{c_p} Pr^{2/3} u_\infty A_s$$

Where L_c is a characteristic length used to define Nu and Re. With $hA_s = q/\Delta T$ we have

$$F_D = \frac{q u_\infty Pr^{2/3}}{c_p \Delta T} = \frac{2000\text{ W} \times 30\text{ m/s} \times (0.704)^{2/3}}{1008\text{ J/kg}\cdot\text{K} \times 60\text{ K}} = 0.785\text{ N}$$ <

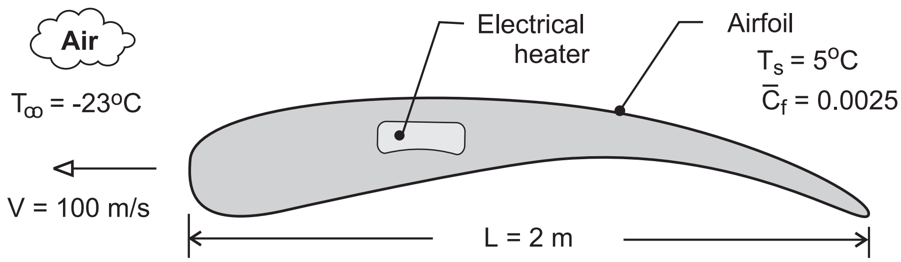
COMMENTS: (1) Heat transfer or friction coefficient correlations for this simple configuration apparently do not exist. (2) Experiments to measure the drag force would be relatively simple to implement and measured drag forces could be used to determine the heat transfer coefficients using the Reynolds analogy. (3) The solution demonstrates advantages associated with working the problem symbolically and only introducing numbers at the end. First, the length scale in Nu and Re did not have to be defined because it cancelled out. Second, the properties k, ν, and ρ also cancelled out.

PROBLEM 6.50

KNOWN: Nominal operating conditions of aircraft and characteristic length and average friction coefficient of wing.

FIND: Average heat flux needed to maintain prescribed surface temperature of wing.

SCHEMATIC:



ASSUMPTIONS: (1) Applicability of modified Reynolds analogy, (2) Constant properties.

PROPERTIES: Prescribed, Air: $\nu = 16.3 \times 10^{-6}$ m^2/s, k = 0.022 W/m·K, Pr = 0.72.

ANALYSIS: The average heat flux that must be maintained over the surface of the air foil is $\overline{q}'' = \overline{h}\left(T_s - T_\infty\right)$, where the average convection coefficient may be obtained from the modified Reynolds analogy.

$$\frac{\overline{C}_f}{2} = St\, Pr^{2/3} = \frac{\overline{Nu}_L}{Re_L\, Pr} Pr^{2/3} = \frac{\overline{Nu}_L}{Re_L\, Pr^{1/3}}$$

Hence, with $Re_L = VL/\nu = 100\,m/s\left(2m\right)/16.3\times10^{-6}\,m^2/s = 1.23\times10^7$,

$$\overline{Nu}_L = \frac{0.0025}{2}\left(1.23\times10^7\right)\left(0.72\right)^{1/3} = 13,780$$

$$\overline{h} = \frac{k}{L}\overline{Nu}_L = \frac{0.022\,W/m\cdot K}{2m}\left(13,780\right) = 152\,W/m^2\cdot K$$

$$\overline{q}'' = 152\,W/m^2\cdot K\left[5-\left(-23\right)\right]°C = 4260\,W/m^2$$ <

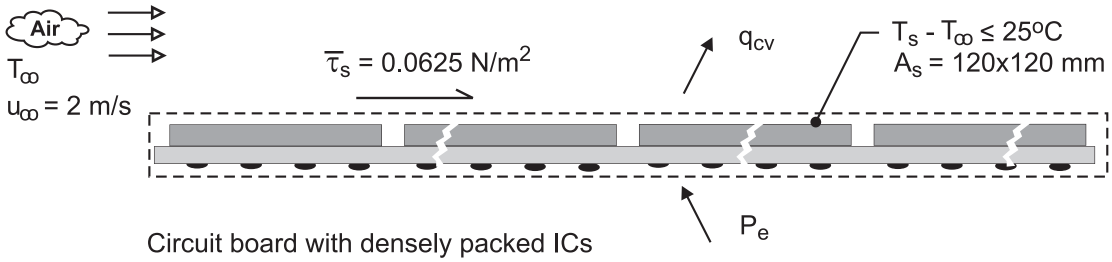
COMMENTS: If the flow is turbulent over the entire airfoil, the modified Reynolds analogy provides a good measure of the relationship between surface friction and heat transfer. The relation becomes more approximate with increasing laminar boundary layer development on the surface and increasing values of the magnitude of the pressure gradient.

PROBLEM 6.51

KNOWN: Average frictional shear stress of $\overline{\tau}_s = 0.0625\ \text{N/m}^2$ on upper surface of circuit board with densely packed integrated circuits (ICs)

FIND: Allowable power dissipation from the upper surface of the board if the average surface temperature of the ICs must not exceed a rise of 25°C above ambient air temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) The modified Reynolds analogy is applicable, (3) Negligible heat transfer from bottom side of the circuit board, and (4) Thermophysical properties required for the analysis evaluated at 300 K,

PROPERTIES: *Table A-4*, Air (T_f = 300 K, 1 atm): $\rho = 1.161\ \text{kg/m}^3$, $c_p = 1007$ J/kg·K, Pr = 0.707.

ANALYSIS: The power dissipation from the circuit board can be calculated from the convection rate equation assuming an excess temperature $(T_s - T_\infty) = 25°C$.

$$q = \overline{h} A_s \left(T_s - T_\infty\right) \qquad (1)$$

The average convection coefficient can be estimated from the Reynolds analogy and the measured average frictional shear stress $\overline{\tau}_s$.

$$\frac{\overline{C}_f}{2} = \overline{St}\ Pr^{2/3} \qquad \overline{C}_f = \frac{\overline{\tau}_s}{\rho\ V^2/2} \qquad \overline{St} = \frac{\overline{h}}{\rho\ V\ c_p} \qquad (2,3,4)$$

With $V = u_\infty$ and substituting numerical values, find $\overline{h}$.

$$\frac{\tau_s}{\rho\ V^2} = \frac{\overline{h}}{\rho\ V c_p} Pr^{2/3}$$

$$\overline{h} = \frac{\overline{\tau}_s\ c_p}{V} Pr^{-2/3}$$

$$\overline{h} = \frac{0.0625\ \text{N/m}^2 \times 1007\ \text{J/kg} \cdot \text{K}}{2\ \text{m/s}} \left(0.707\right)^{-2/3} = 39.7\ \text{W/m}^2 \cdot \text{K}$$

Substituting this result into Eq. (1), the allowable power dissipation is

$$q = 39.7\ \text{W/m}^2 \cdot \text{K} \times \left(0.120 \times 0.120\right) \text{m}^2 \times 25\ \text{K} = 14.3\ \text{W}$$ <

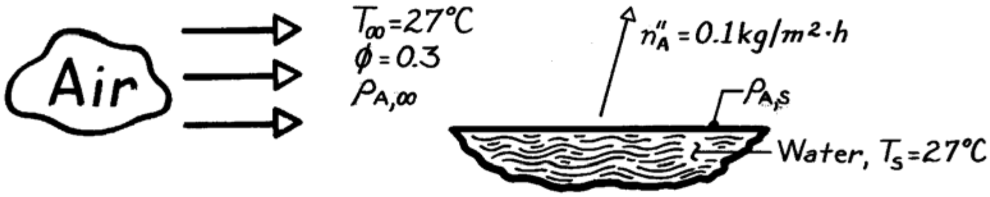
COMMENTS: For this analysis using the modified or Chilton-Colburn analogy, we found C_f = 0.0269 and St = 0.0170. Using the Reynolds analogy, the results are slightly different with $\overline{h} = 31.5\ \text{W/m}^2 \cdot \text{K}$ and q = 11.3 W.

PROBLEM 6.52

KNOWN: Evaporation rate of water from a lake.

FIND: The convection mass transfer coefficient, $\bar{h}_m$.

SCHEMATIC:



ASSUMPTIONS: (1) Equilibrium at water vapor-liquid surface, (2) Isothermal conditions, (3) Perfect gas behavior of water vapor, (4) Air at standard atmospheric pressure.

PROPERTIES: *Table A-6*, Saturated water vapor (300K): $p_{A,sat} = 0.03531$ bar, $\rho_{A,sat} = 1/v_g = 0.02556\ kg/m^3$.

ANALYSIS: The convection mass transfer (evaporation) rate equation can be written in the form

$$\bar{h}_m = \frac{n''_A}{\left(\rho_{A,s} - \rho_{A,\infty}\right)}$$

where

$$\rho_{A,s} = \rho_{A,sat},$$

the saturation density at the temperature of the water and

$$\rho_{A,\infty} = \phi \rho_{A,sat}$$

which follows from the definition of the relative humidity, $\phi = p_A/p_{A,sat}$ and perfect gas behavior. Hence,

$$\bar{h}_m = \frac{n''_A}{\rho_{A,sat}(1-\phi)}$$

and substituting numerical values, find

$$\bar{h}_m = \frac{0.1\ kg/m^2 \cdot h \times 1/3600\ s/h}{0.02556\ kg/m^3 (1-0.3)} = 1.55 \times 10^{-3}\ m/s. \qquad <$$

COMMENTS: (1) From knowledge of $p_{A,sat}$, the perfect gas law could be used to obtain the saturation density.

$$\rho_{A,sat} = \frac{p_{A,sat}\mathcal{M}_A}{\Re T} = \frac{0.03531\ bar \times 18\ kg/kmol}{8.314 \times 10^{-2} m^3 \cdot bar/kmol \cdot K (300K)} = 0.02548\ kg/m^3.$$

This value is within 0.3% of that obtained from Table A-6.

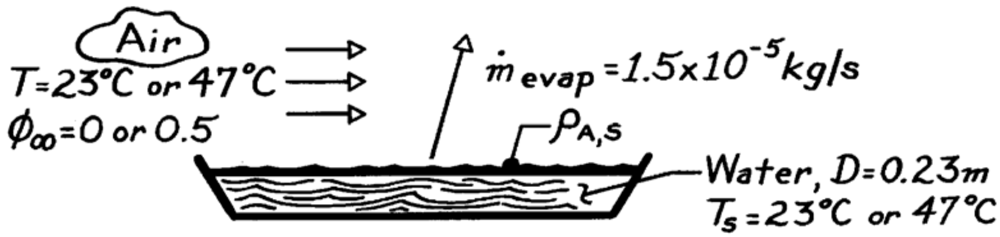
(2) Note that psychrometric charts could also be used to obtain $\rho_{A,sat}$ and $\rho_{A,\infty}$.

PROBLEM 6.53

KNOWN: Evaporation rate from pan of water of prescribed diameter. Water temperature. Air temperature and relative humidity.

FIND: (a) Convection mass transfer coefficient, (b) Evaporation rate for increased relative humidity, (c) Evaporation rate for increased temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Water vapor is saturated at liquid interface and may be approximated as a perfect gas.

PROPERTIES: *Table A-6*, Saturated water vapor (T_s = 296K): $\rho_{A,sat} = v_g^{-1} = (49.4\ m^3/kg)^{-1} =$ 0.0202 kg/m^3; (T_s = 320 K): $\rho_{A,sat} = v_g^{-1} = \left(13.98\ m^3/kg\right)^{-1} = 0.0715\ kg/m^3$.

ANALYSIS: (a) Since evaporation is a convection mass transfer process, the rate equation has the form $\dot{m}_{evap} = \overline{h}_m A\left(\rho_{A,s} - \rho_{A,\infty}\right)$ and the mass transfer coefficient is

$$\overline{h}_m = \frac{\dot{m}_{evap}}{\left(\pi D^2/4\right)\left(\rho_{A,s} - \rho_{A,\infty}\right)} = \frac{1.5\times10^{-5}\,kg/s}{(\pi/4)(0.23\ m)^2\,0.0202\ kg/m^3} = 0.0179\ m/s \quad <$$

with $T_s = T_\infty = 23°C$ and $\phi_\infty = 0$.

(b) If the relative humidity of the ambient air is increased to 50%, the ratio of the evaporation rates is

$$\frac{\dot{m}_{evap}(\phi_\infty = 0.5)}{\dot{m}_{evap}(\phi_\infty = 0)} = \frac{\overline{h}_m A\left[\rho_{A,s}(T_s) - \phi_\infty \rho_{A,s}(T_\infty)\right]}{\overline{h}_m A\,\rho_{A,s}(T_s)} = 1 - \phi_\infty \frac{\rho_{A,s}(T_\infty)}{\rho_{A,s}(T_s)}.$$

Hence, $\dot{m}_{evap}(\phi_\infty = 0.5) = 1.5\times10^{-5}\,kg/s\left[1 - 0.5\frac{0.0202\ kg/m^3}{0.0202\ kg/m^3}\right] = 0.75\times10^{-5}\,kg/s.$

(c) If the temperature of the ambient air is increased from 23°C to 47°C, with $\phi_\infty = 0$ for both cases, the ratio of the evaporation rates is

$$\frac{\dot{m}_{evap}\left(T_s = T_\infty = 47^\circ C\right)}{\dot{m}_{evap}\left(T_s = T_\infty = 23^\circ C\right)} = \frac{\overline{h}_m A\rho_{A,s}\left(47^\circ C\right)}{\overline{h}_m A\rho_{A,s}\left(23^\circ C\right)} = \frac{\rho_{A,s}\left(47^\circ C\right)}{\rho_{A,s}\left(23^\circ C\right)}.$$

Hence, $\dot{m}_{evap}\left(T_s = T_\infty = 47^\circ C\right) = 1.5\times10^{-5}\,kg/s\,\frac{0.0715\ kg/m^3}{0.0202\ kg/m^3} = 5.31\times10^{-5}\,kg/s.$ $<$

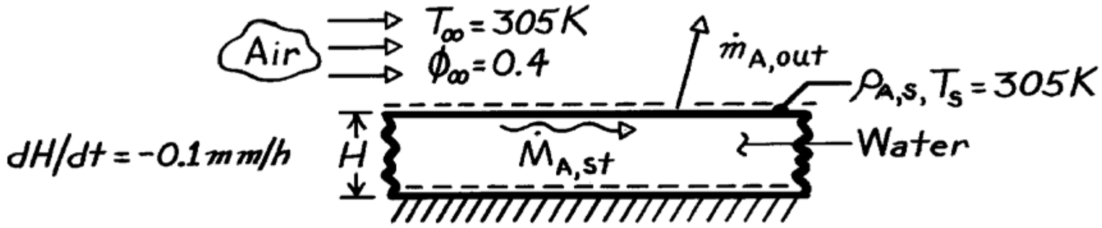
COMMENTS: Note the highly nonlinear dependence of the evaporation rate on the water temperature. For a 24°C rise in $T_s, \dot{m}_{evap}$ increases by 350%.

PROBLEM 6.54

KNOWN: Water temperature and air temperature and relative humidity. Surface recession rate.

FIND: Mass evaporation rate per unit area. Convection mass transfer coefficient.

SCHEMATIC:



ASSUMPTIONS: (1) Water vapor may be approximated as a perfect gas, (2) No water inflow; outflow is only due to evaporation.

PROPERTIES: *Table A-6*, Saturated water: Vapor (305K), $\rho_g = v_g^{-1} = 0.0336$ kg/m^3; Liquid (305K), $\rho_f = v_f^{-1} = 995$ kg/m^3.

ANALYSIS: Applying conservation of species to a control volume about the water,

$$-\dot{M}_{A,out} = \dot{M}_{A,st}$$
$$-\dot{m}''_{evap} A = \frac{d}{dt}(\rho_f V) = \frac{d}{dt}(\rho_f AH) = \rho_f A \frac{dH}{dt}.$$

Substituting numerical values, find

$$\dot{m}''_{evap} = -\rho_f \frac{dH}{dt} = -995\text{kg/m}^3 \left(-10^{-4}\text{m/h}\right) \left(1/3600 \text{ s/h}\right)$$

$$\dot{m}''_{evap} = 2.76 \times 10^{-5} \text{kg/s} \cdot \text{m}^2.$$ <

Because evaporation is a convection mass transfer process, it also follows that

$$\dot{m}''_{evap} = n''_A$$

or in terms of the rate equation,

$$\dot{m}''_{evap} = h_m\left(\rho_{A,s} - \rho_{A,\infty}\right) = h_m\left[\rho_{A,sat}(T_s) - \phi_\infty \rho_{A,sat}(T_\infty)\right]$$
$$\dot{m}''_{evap} = h_m \rho_{A,sat}(305K)\ (1 - \phi_\infty),$$

and solving for the convection mass transfer coefficient,

$$h_m = \frac{\dot{m}''_{evap}}{\rho_{A,sat}(305K)\ (1-\phi_\infty)} = \frac{2.76 \times 10^{-5} \text{kg/s} \cdot \text{m}^2}{0.0336 \text{ kg/m}^3 (1 - 0.4)}$$

$$h_m = 1.37 \times 10^{-3} \text{m/s}.$$ <

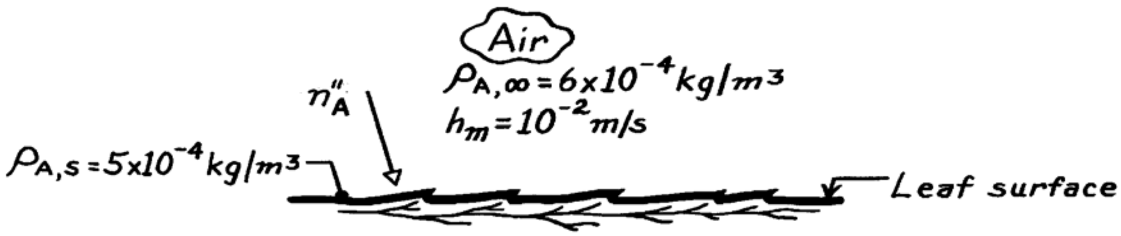
COMMENTS: Conservation of species has been applied in exactly the same way as a conservation of energy. Note the sign convention.

PROBLEM 6.55

KNOWN: CO_2 concentration in air and at the surface of a green leaf. Convection mass transfer coefficient.

FIND: Rate of photosynthesis per unit area of leaf.

SCHEMATIC:



ANALYSIS: Assuming that the CO_2 (species A) is consumed as a reactant in photosynthesis at the same rate that it is transferred across the atmospheric boundary layer, the rate of photosynthesis per unit leaf surface area is given by the rate equation,

$$n''_A = h_m\left(\rho_{A,\infty} - \rho_{A,s}\right).$$

Substituting numerical values, find

$$n''_A = 10^{-2}\,\text{m/s}\left(6\times10^{-4} - 5\times10^{-4}\right)\text{kg/m}^3$$

$$n''_A = 10^{-6}\,\text{kg/s}\cdot\text{m}^2. \qquad <$$

COMMENTS: (1) It is recognized that CO_2 transport is from the air to the leaf, and ($\rho_{A,s}$ - $\rho_{A,\infty}$) in the rate equation has been replaced by ($\rho_{A,\infty}$ - $\rho_{A,s}$).

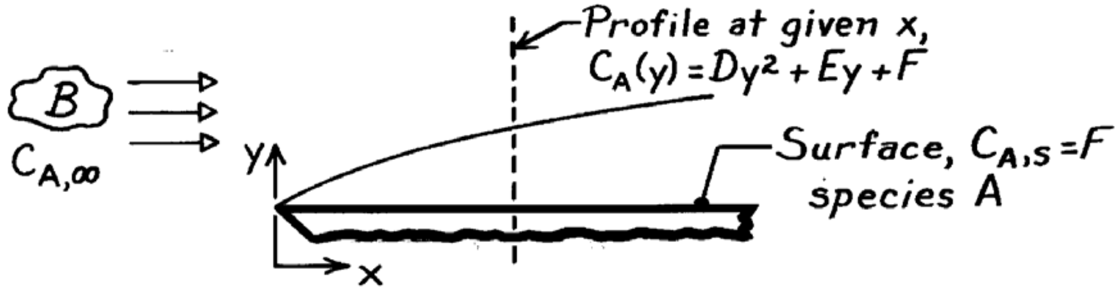
(2) The atmospheric concentration of CO_2 is known to be increasing by approximately 0.3% per year. This increase in $\rho_{A,\infty}$ will have the effect of increasing the photosynthesis rate and hence plant biomass production.

PROBLEM 6.56

KNOWN: Species concentration profile, $C_A(y)$, in a boundary layer at a particular location for flow over a surface.

FIND: Expression for the mass transfer coefficient, h_m, in terms of the profile constants, $C_{A,\infty}$ and D_{AB}. Expression for the molar convection flux, N''_A.

SCHEMATIC:



ASSUMPTIONS: (1) Parameters D, E, and F are constants at any location x, (2) D_{AB}, the mass diffusion coefficient of A through B, is known.

ANALYSIS: The convection mass transfer coefficient is defined in terms of the concentration gradient at the wall,

$$h_m(x) = -D_{AB} \frac{\partial C_A / \partial y|_{y=0}}{(C_{A,s} - C_{A,\infty})}.$$

The gradient at the surface follows from the profile, $C_A(y)$,

$$\left.\frac{\partial C_A}{\partial y}\right|_{y=0} = \left.\frac{\partial}{\partial y}\left(Dy^2 + Ey + F\right)\right|_{y=0} = +E.$$

Hence,

$$h_m(x) = -\frac{D_{AB}E}{(C_{A,s} - C_{A,\infty})} = \frac{-D_{AB}E}{(F - C_{A,\infty})}.$$ <

The molar flux follows from the rate equation,

$$N''_A = h_m(C_{A,s} - C_{A,\infty}) = \frac{-D_{AB}E}{(C_{A,s} - C_{A,\infty})} \cdot (C_{A,s} - C_{A,\infty}).$$

$$N''_A = -D_{AB}E.$$ <

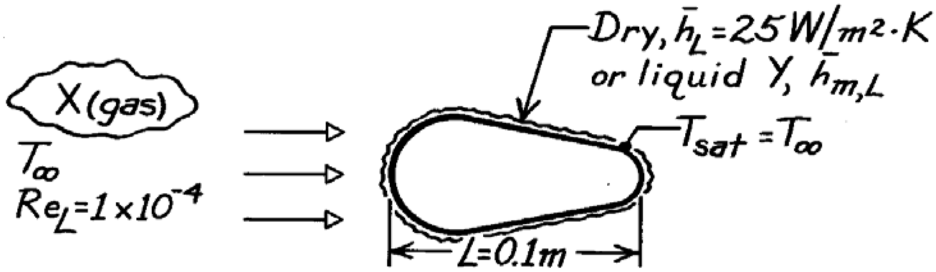
COMMENTS: It is important to recognize that the influence of species B is present in the property D_{AB}. Otherwise, all the parameters relate to species A.

PROBLEM 6.57

KNOWN: Cross flow of gas X over object with prescribed characteristic length L, Reynolds number, and average heat transfer coefficient. Thermophysical properties of gas X, liquid Y, and vapor Y.

FIND: Average mass transfer coefficient for same object when impregnated with liquid Y and subjected to same flow conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Heat and mass transfer analogy is applicable, (2) Vapor Y behaves as perfect gas

PROPERTIES:

(Given)	$\nu(m^2/s)$	k(W/m·K)	$\alpha(m^2/s)$
Gas X	21×10^{-6}	0.030	29×10^{-6}
Liquid Y	3.75×10^{-7}	0.665	1.65×10^{-7}
Vapor Y	4.25×10^{-5}	0.023	4.55×10^{-5}

Mixture of gas X - vapor Y: Sc = 0.72

ANALYSIS: The heat-mass transfer analogy may be written as

$$\overline{Nu}_L = \frac{\bar{h}_L L}{k} = f\left(Re_L,\ Pr\right) \qquad \overline{Sh}_L = \frac{\bar{h}_{m,L} L}{D_{AB}} = f\left(Re_L, Sc\right)$$

The flow conditions are the same for both situations. Check values of Pr and Sc. For Pr, the properties are those for gas X (B).

$$Pr = \frac{\nu_B}{\alpha_B} = \frac{21\times10^{-6} m^2/s}{29\times10^{-6} m^2/s} = 0.72$$

while Sc = 0.72 for the gas X (B) - vapor Y (A) mixture. It follows for this situation

$$\overline{Nu}_L = \frac{\bar{h}_L L}{k} = \overline{Sh}_L = \frac{\bar{h}_{m,L} L}{D_{AB}} \qquad \text{or} \qquad \bar{h}_{m,L} = \bar{h}_L \frac{D_{AB}}{k}.$$

Recognizing that

$$D_{AB} = \nu_B / Sc = 21.6\times10^{-6} m^2/s \Big/ (0.72) = 30.0\times10^{-6} m^2/s$$

and substituting numerical values, find

$$\bar{h}_{m,L} = 25\ W/m^2 \cdot K \times \frac{30.0\times10^{-6} m^2/s}{0.030\ W/m\cdot K} = 0.0250\ m/s. \qquad <$$

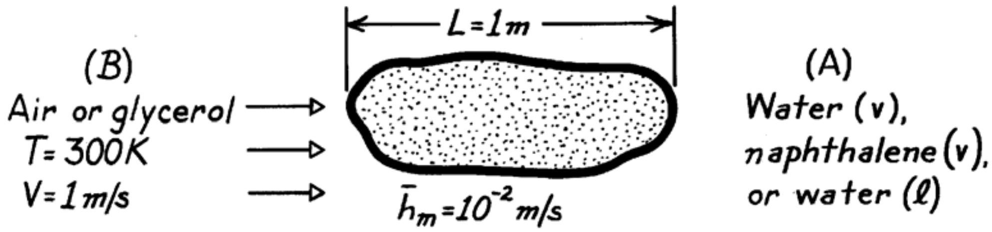
COMMENTS: Note that none of the thermophysical properties of liquid or vapor Y are required for the solution. Only the gas X properties and the Schmidt number (gas X - vapor Y) are required.

PROBLEM 6.58

KNOWN: Free stream velocity and average convection mass transfer coefficient for fluid flow over a surface of prescribed characteristic length.

FIND: Values of $\overline{Sh}_L$, Re_L, Sc and $\overline{j}_m$ for (a) air flow over water, (b) air flow over naphthalene, and (c) warm glycerol over ice.

SCHEMATIC:



PROPERTIES: For the fluids at 300K:

Table	*Fluid(s)*	$\nu(m^2/s)\times10^{-6}$	$D_{AB}(m^2/s)$
A-4	Air	15.89	-
A-5	Glycerin	634	-
A-8	Water vapor - Air	-	0.26×10^{-4}
A-8	Naphthalene - Air	-	0.62×10^{-5}
A-8	Water - Glycerol	-	0.94×10^{-9}

ANALYSIS: (a) *Water (vapor) - Air:*

$$\overline{Sh}_L = \frac{\overline{h}_m L}{D_{AB}} = \frac{(0.01\text{m/s})1\text{m}}{0.26\times10^{-4}\text{m}^2/\text{s}} = 385$$

$$Re_L = \frac{VL}{\nu} = \frac{(1\text{ m/s})1\text{m}}{15.89\times10^{-6}\text{m}^2/\text{s}} = 6.29\times10^4$$

$$Sc = \frac{\nu}{D_{AB}} = \frac{0.16\times10^{-6}\text{m}^2/\text{s}}{0.26\times10^{-6}\text{m}^2/\text{s}} = 0.62$$

$$\overline{j}_m = St_m Sc^{2/3} = \frac{h_m}{V} Sc^{2/3} = \frac{0.01\text{ m/s}}{1\text{ m/s}}(0.62)^{2/3} = 0.0073. \qquad <$$

(b) *Naphthalene (vapor) - Air:*

$$\overline{Sh}_L = 1613 \qquad Re_L = 6.29\times10^4 \qquad Sc = 2.56 \qquad \overline{j}_m = 0.0187. \qquad <$$

(c) *Water (1iquid) - Glycerol:*

$$\overline{Sh}_L = 1.06\times10^7 \qquad Re_L = 1577 \qquad Sc = 6.74\times10^5 \qquad \overline{j}_m = 76.9. \qquad <$$

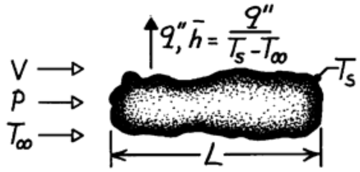
COMMENTS: Note the association of ν with the freestream fluid B.

PROBLEM 6.59

KNOWN: Characteristic length, surface temperature, average heat flux and airstream conditions associated with an object of irregular shape.

FIND: Whether similar behavior exists for alternative conditions, and average convection coefficient for similar cases.

SCHEMATIC:



Case:	1	2	3	4	5
L,m	1	2	2	2	2
V, m/s	100	50	50	50	250
p, atm	1	1	0.2	1	0.2
T∞, K	275	275	275	300	300
Ts, K	325	325	325	300	300
q'', W/m^2	12,000	-	-	-	-
$\bar{h}$, W/m$^2\cdot$K	240	-	-	-	-
$D_{AB}\times10^{+4}$, m^2/s	-	-	-	1.12	1.12

ASSUMPTIONS: (1) Heat and mass transfer analogy is applicable; that is, $f(Re_L,Pr) = f(Re_L,Sc)$, see Eqs. 6.50 and 6.54.

PROPERTIES: *Table A-4,* Air (300K, 1 atm): $\nu_1 = 15.89\times10^{-6}\,m^2/s$, $Pr_1 = 0.71$, $k_1 = 0.0263\ W/m\cdot K$.

ANALYSIS: For Case 1, $h = q''/(T_s - T_\infty) = 12{,}000\ W/m^2/50\ K = 240\ W/m^2\cdot K$.

$$Re_{L,1} = V_1L_1/\nu_1 = (100\ m/s\times1m)/15.89\times10^{-6}\,m^2/s = 6.29\times10^6 \text{ and } Pr_1 = 0.71.$$

Case 2:
$$Re_{L,2} = \frac{V_2L_2}{\nu_2} = \frac{50\ m/s\times2m}{15.89\times10^{-6}m^2/s} = 6.29\times10^6, \qquad Pr_2 = 0.71.$$

From Eq. 6.50 it follows that Case 2 is analogous to Case 1. Hence $\overline{Nu}_2 = \overline{Nu}_1$ and

$$\bar{h}_2 = \frac{\bar{h}_1L_1}{k_1}\frac{k_2}{L_2} = \bar{h}_1\frac{L_1}{L_2} = 240\frac{W}{m^2\cdot K}\frac{1m}{2m} = 120\ W/m^2\cdot K.$$ <

Case 3: With p = 0.2 atm, $\nu_3 = 79.45\times10^{-6}\,m^2/s$ and $Re_{L,3} = \frac{V_3L_3}{\nu_3} = \frac{50\ m/s\times2m}{79.45\times10^{-6}m^2/s} = 1.26\times10^6$, $Pr_3 = 0.71$.

Since $Re_{L,3} \neq Re_{L,1}$, Case 3 is not analogous to Case 1. <

Case 4:
$$Re_{L,4} = Re_{L,1},\ Sc_4 = \frac{\nu_4}{D_{AB,4}} = \frac{15.89\times10^{-6}m^2/s}{1.12\times10^{-4}m^2/s} = 0.142 \neq Pr_1.$$

Hence, Case 4 is not analogous to Case 1. <

Case 5:
$$Re_{L,5} = \frac{V_5L_5}{\nu_5} = \frac{250\ m/s\ \times\ 2m}{79.45\times10^{-6}m^2/s} = 6.29\times10^6 = Re_{L,1}$$

$$Sc_5 = \frac{\nu_5}{D_{AB,5}} = \frac{79.45\times10^{-6}m^2/s}{1.12\times10^{-4}m^2/s} = 0.71 = Pr_1.$$

Hence, conditions are analogous to Case 1, and with $\overline{Sh}_5 = \overline{Nu}_1$,

$$h_{m,5} = h_1\frac{L_1}{L_5}\frac{D_{AB,5}}{k_1} = 240\ \frac{W}{m^2\cdot K}\times\frac{1m}{2m}\times\frac{1.12\times10^{-4}m^2/s}{0.0263\ W/m\cdot K} = 0.51\ m/s.$$ <

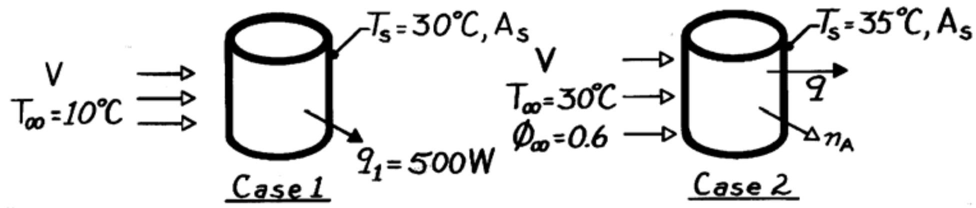
COMMENTS: Note that Pr, k and Sc are independent of pressure, while ν and D_{AB} vary inversely with pressure.

PROBLEM 6.60

KNOWN: Surface temperature and heat loss from a runner's body on a cool, spring day. Surface temperature and ambient air-conditions for a warm summer day.

FIND: (a) Water loss on summer day, (b) Total heat loss on summer day.

SCHEMATIC:



ASSUMPTIONS: (1) Heat and mass transfer analogy is applicable. Hence, from Eqs. 6.50 and 6.54, $f(Re_L,Pr)$ is of same form as $f(Re_L,Sc)$, (2) Negligible surface evaporation for Case 1, (3) Constant properties, (4) Water vapor is saturated for Case 2 surface and may be approximated as a perfect gas.

PROPERTIES: Air (given): $\nu = 1.6\times10^{-5}$ m^2/s, k = 0.026 W/m·K, Pr = 0.70; Water vapor - air (given): $D_{AB} = 2.3\times10^{-5}$ m^2/s; *Table A-6*, Saturated water vapor (T_∞ = 303K): $\rho_{A,sat} = v_g^{-1} = 0.030$ kg/m^3; $(T_s = 308K)$: $\rho_{A,sat} = v_g^{-1} = 0.039$ kg/m^3, $h_{fg} = 2419$ kJ/kg.

ANALYSIS: (a) With $Re_{L,2} = Re_{L,1}$ and $Sc = \nu/D_{AB} = 1.6\times10^{-5} m^2/s / 2.3\times10^{-5} m^2/s = 0.70 = Pr$, it follows that $\overline{Sh}_L = \overline{Nu}_L$. Hence

$$\bar{h}_m L/D_{AB} = \bar{h}L/k$$

$$\bar{h}_m = \bar{h}\frac{D_{AB}}{k} = \frac{q_1}{A_s(T_s - T_\infty)_1}\frac{D_{AB}}{k} = \frac{500\text{ W}}{A_s(20K)}\frac{2.3\times10^{-5}m^2/s}{0.026\text{ W/m}\cdot\text{K}} = \left[\frac{0.0221}{A_s}\right]\text{m/s.}$$

Hence, from the rate equation, with A_s as the wetted surface

$$n_A = \bar{h}_m A_s(\rho_{A,s} - \rho_{A,\infty}) = \left[\frac{0.0221}{A_s}\right]\frac{m}{s}A_s\left[\rho_{A,sat}(T_{s,2}) - \phi_\infty\rho_{A,sat}(T_{\infty,2})\right]$$

$$n_A = 0.0221\text{ m}^3/\text{s}(0.039 - 0.6\times0.030)\text{kg/m}^3 = 4.64\times10^{-4}\text{kg/s.}$$ <

(b) The total heat loss for Case 2 is comprised of sensible and latent contributions, where

$$q_2 = q_{sen} + q_{lat} = \bar{h}A_s(T_{s,2} - T_{\infty,2}) + n_A\ h_{fg}.$$

Hence, with $\bar{h}A_s = q_1/(T_{s,1} - T_{\infty,1}) = 25$ W/K,

$$q_2 = 25\text{ W/K }(35-30)^\circ\text{C} + 4.64\times10^{-4}\text{kg/s}\times2.419\times10^6\text{ J/kg}$$

$$q_2 = 125\text{ W} + 1122\text{ W} = 1247\text{ W.}$$ <

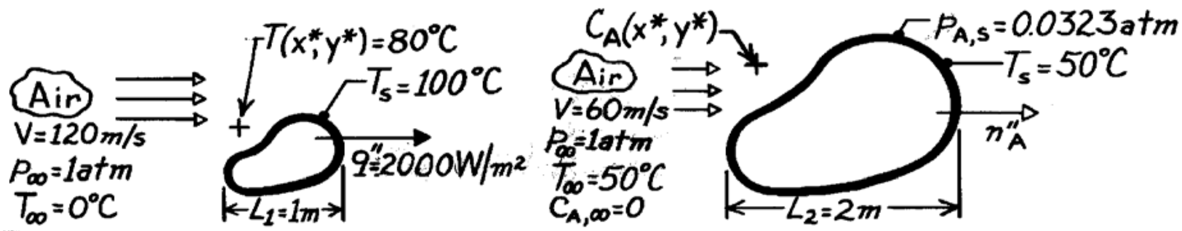
COMMENTS: Note the significance of the evaporative cooling effect.

PROBLEM 6.61

KNOWN: Heat transfer results for an irregularly shaped object.

FIND: (a) The concentration, C_A, and partial pressure, p_A, of vapor in an airstream for a drying process of an object of similar shape, (b) Average mass transfer flux, $n''_A \left(kg/s \cdot m^2\right)$.

SCHEMATIC:



Case 1: Heat Transfer Case 2: Mass Transfer

ASSUMPTIONS: (1) Heat-mass transfer analogy applies, (b) Perfect gas behavior.

PROPERTIES: *Table A-4,* Air (323K, 1 atm): $\nu = 18.20\times10^{-6} m^2/s$, Pr = 0.703, k = 28.0×10^{-3} W/m·K; Plastic vapor (given): $\mathcal{M}_A$ = 82 kg/kmol, $p_{sat}(50°C)$ = 0.0323 atm, $D_{AB} = 2.6\times10^{-5}\ m^2/s$.

ANALYSIS: (a) Calculate Reynolds numbers

$$Re_1 = \frac{V_1 L_1}{\nu} = \frac{120\ m/s\ \times\ 1m}{18.2\ \times\ 10^{-6} m^2/s} = 6.59\times10^6$$

$$Re_2 = \frac{60\ m/s\ \times\ 2m}{18.2\times10^{-6} m^2/s} = 6.59\times10^6.$$

Note that

$$Pr_1 = 0.703 \qquad Sc_2 = \frac{\nu}{D_{AB}} = \frac{18.2\times10^{-6} m^2/s}{2.6\times10^{-5} m^2/s} = 0.700.$$

Since $Re_1 = Re_2$ and $Pr_1 = Sc_2$, the dimensionless solutions to the energy and species equations are identical. That is, from Eqs. 6.47 and 6.51,

$$T^*\left(x^*, y^*\right) = C_A^*\left(x^*, y^*\right)$$

$$\frac{T - T_s}{T_\infty - T_s} = \frac{C_A - C_{A,s}}{C_{A,\infty} - C_{A,s}} \qquad (1)$$

where T^* and C_A^* are defined by Eqs. 6.33 and 6.34, respectively. Now, determine

$$C_{A,s} = \frac{p_{A,sat}}{\Re T} = \left(0.0323\ atm/8.205\times10^{-2} m^3 \cdot atm/kmol\cdot K \times (273+50)K\right)$$

$$C_{A,s} = 1.219\times10^{-3}\ kmol/kg.$$

Continued …

PROBLEM 6.61 (Cont.)

Substituting numerical values in Eq. (1),

$$C_A = C_{A,s} + \left(C_{A,\infty} - C_{A,s}\right)\frac{T - T_s}{T_\infty - T_s}$$

$$C_A = 1.219\times10^{-3}\ \text{kmol/m}^3 + \left(0 - 1.219\times10^{-3}\right)\ \text{kmol/m}^3 \frac{(80-100)^\circ\text{C}}{(0-100)^\circ\text{C}}$$

$$C_A = 0.975\times10^{-3}\ \text{kmol/m}^3. \qquad <$$

The vapor pressure is then

$$p_A = C_A\ \Re T\ =\ 0.0258\ \text{atm}. \qquad <$$

(b) For case 1, $q'' = 2000\ \text{W/m}^2$. The rate equations are

$$q'' = \bar{h}\left(T_s - T_\infty\right) \tag{2}$$

$$n''_A = \bar{h}_m\left(C_{A,s} - C_{A,\infty}\right)\mathcal{M}_A. \tag{3}$$

From the analogy

$$\overline{Nu}_L = \overline{Sh}_L \qquad \rightarrow \qquad \frac{\bar{h}\,L_1}{k} = \frac{\bar{h}_m\ L_2}{D_{AB}} \quad \text{or} \quad \frac{\bar{h}}{\bar{h}_m} = \frac{L_2}{L_1}\ \frac{k}{D_{AB}}. \tag{4}$$

Combining Eqs. (2) - (4),

$$n''_A = q''\frac{\bar{h}_m}{\bar{h}}\ \frac{\left(C_{A,s} - C_{A,\infty}\right)\mathcal{M}_A}{\left(T_s - T_\infty\right)} = q''\frac{L_1 D_{AB}}{L_2 k}\ \frac{\left(C_{A,s} - C_{A,\infty}\right)\mathcal{M}_A}{\left(T_s - T_\infty\right)}$$

which numerically gives

$$n''_A = 2000\ \text{W/m}^2\ \frac{1\text{m}\left(2.6\times10^{-5}\text{m}^2/\text{s}\right)}{2\text{m}\left(28\times10^{-3}\text{W/m}\cdot\text{K}\right)}\ \frac{\left(1.219\times10^{-3} - 0\right)\text{kmol/m}^3\ \left(82\ \text{kg/kmol}\right)}{\left(100\text{-}0\right)\text{K}}$$

$$n''_A = 9.28\times10^{-4}\text{kg/s}\cdot\text{m}^2. \qquad <$$

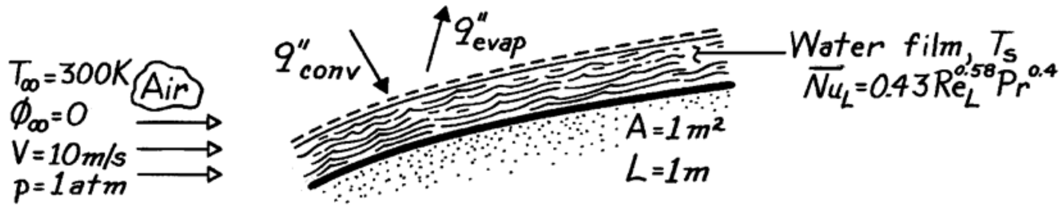
COMMENTS: Recognize that the analogy between heat and mass transfer applies when the conservation equations and boundary conditions are of the same form.

PROBLEM 6.62

KNOWN: Convection heat transfer correlation for flow over a contoured surface.

FIND: (a) Evaporation rate from a water film on the surface, (b) Steady-state film temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (b) Constant properties, (c) Negligible radiation, (d) Heat and mass transfer analogy is applicable.

PROPERTIES: *Table A-4*, Air (300K, 1 atm): k = 0.0263 W/m·K, $\nu = 15.89\times10^{-6}$ m^2/s, Pr = 0.707; *Table A-6*, Water ($T_s \approx 280$K): $v_g = 130.4$ m^3/kg, $h_{fg} = 2485$ kJ/kg; *Table A-8*, Water-air (T ≈ 298K): $D_{AB} = 0.26\times10^{-4}$ m^2/s.

ANALYSIS: (a) The mass evaporation rate is

$$\dot{m}_{evap} = n_A = \bar{h}_m \; A\left[\rho_{A,sat}(T_s) - \phi_\infty \; \rho_{A,sat}(T_\infty)\right] = \bar{h}_m \; A \; \rho_{A,sat}(T_s).$$

From the heat and mass transfer analogy: $\overline{Sh}_L = 0.43 \; Re_L^{0.58} \; Sc^{0.4}$

$$Re_L = \frac{VL}{\nu} = \frac{(10 \text{ m/s}) \; 1\text{m}}{15.89\times10^{-6}\text{m}^2/\text{s}} = 6.29\times10^5 \qquad Sc = \frac{\nu}{D_{AB}} = \frac{15.89\times10^{-6}\text{m}^2/\text{s}}{26\times10^{-6}\text{m}^2/\text{s}} = 0.61$$

$$\overline{Sh}_L = 0.43\left(6.29\times10^5\right)^{0.58}(0.61)^{0.4} = 814$$

$$\bar{h}_m = \frac{D_{AB}}{L}\overline{Sh}_L = \frac{0.26\times10^{-4}\text{m}^2/\text{s}}{1\text{m}}(814) = 0.0212 \text{ m/s}$$

$$\rho_{A,sat}(T_s) = v_g(T_s)^{-1} = 0.0077 \text{ kg/m}^3.$$

Hence, $$\dot{m}_{evap} = 0.0212\text{m/s} \times 1\text{m}^2 \times 0.0077\text{kg/m}^3 = 1.63\times10^{-4}\text{kg/s}.$$ <

(b) From a surface energy balance, $q''_{conv} = q''_{evap}$, or

$$\bar{h}_L(T_\infty - T_s) = \dot{m}''_{evap}h_{fg} \qquad T_s = T_\infty - \frac{\left(\dot{m}''_{evap}h_{fg}\right)}{\bar{h}_L}.$$

With $$\overline{Nu}_L = 0.43\left(6.29\times10^5\right)^{0.58}(0.707)^{0.4} = 864$$

$$\bar{h}_L = \frac{k}{L}\overline{Nu}_L = \frac{0.0263 \text{ W/m}\cdot\text{K}}{1\text{m}}864 = 22.7 \text{ W/m}^2\cdot\text{K}.$$

Hence, $$T_s = 300\text{K} - \frac{1.63\times10^{-4}\text{kg/s}\cdot\text{m}^2\left(2.485\times10^6 \text{ J/kg}\right)}{22.7 \text{ W/m}^2\cdot\text{K}} = 282.2\text{K}.$$ <

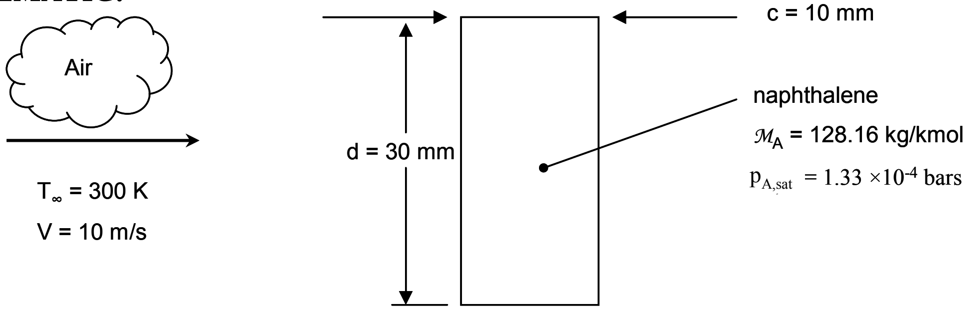
COMMENTS: The saturated vapor density, $\rho_{A,sat}$, is strongly temperature dependent, and if the initial guess of T_s needed for its evaluation differed from the above result by more than a few degrees, the density would have to be evaluated at the new temperature and the calculations repeated.

PROBLEM 6.63

KNOWN: Dimensions of rectangular naphthalene rod. Velocity and temperature of air flow. Molecular weight and saturation pressure of naphthalene.

FIND: Mass loss after 30 minutes.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Mass loss is small, so dimensions remain unchanged, (3) Viscosity of air-naphthalene mixture is approximately that of air.

PROPERTIES: Table A-4, Air (300 K): $\nu = 15.89 \times 10^{-6}$ m^2/s. Table A-8, Naphthalene in air, (300 K): $D_{AB} = 0.62 \times 10^{-5}$ m^2/s, $Sc = \nu/D_{AB} = 2.56$.

ANALYSIS: We will use the heat and mass transfer analogy, with the Nusselt number correlation known from Problem 6.10 to be of the form

$$Nu_d = CRe_d^m Pr^{1/3}$$

Then invoking Equation 6.59,

$$Sh_d = CRe_d^m Sc^{1/3} = h_m d / D_{AB}$$

Now $Re_d = Vd/\nu = 10 \text{ m/s} \times 0.03 \text{ m}/15.89\times10^{-6}\text{m}^2/\text{s} = 18{,}880$. We find the values of C and m from Problem 6.10 with c/d = 0.33, for the front, sides, and back of the rod:

	C	m	Sh_d	h_m(m/s)
front	0.674	1/2	126.7	0.0262
sides	0.153	2/3	148.5	0.0307
back	0.174	2/3	168.8	0.0349

The average mass transfer coefficient is

$$\overline{h_m} = (h_{m,front}d + 2h_{m,side}c + h_{m,back}d)/(2d + 2c)$$

$$= \frac{0.0262 \text{ m/s}\times 0.03 \text{ m} + 2\times 0.0307 \text{ m/s}\times 0.01 \text{ m} + 0.0349 \text{ m/s}\times 0.03 \text{ m}}{2\times 0.03 \text{ m} + 2\times 0.01 \text{ m}}$$

$$= 0.0306 \text{ m/s}$$

Then the mass loss can be found from

$$\Delta m = n_A \Delta t = \overline{h_m} A_{tot} (\rho_{A,s} - \rho_{A,\infty})\Delta t$$

Continued…

PROBLEM 6.63 (Cont.)

Here $\rho_{A,\infty} = 0$ and $\rho_{A,s}$ can be found from the saturation pressure, using the ideal gas law:

$$\rho_{A,s} = \frac{p_{A,sat}}{R_i T_s} = \frac{p_{A,sat}\mathcal{M}_A}{\mathcal{R} T_s}$$

$$= \frac{1.33 \times 10^{-4}\ \text{bar} \times 128.16\ \text{kg/kmol}}{8.314 \times 10^{-2}\ \text{m}^3 \cdot \text{bar/kmol} \cdot \text{K} \times 300\ \text{K}}$$

$$= 6.83 \times 10^{-4}\ \text{kg/m}^3$$

Thus, finally,

$$\Delta m = 0.0306\ \text{m/s} \times (2 \times 0.03\ \text{m} + 2 \times 0.01\ \text{m}) \times 0.5\ \text{m}$$

$$\times (6.83 \times 10^{-4} - 0)\ \text{kg/m}^3 \times 30\ \text{min} \times 60\ \text{s/min}$$

$$= 1.50 \times 10^{-3}\ \text{kg}$$ <

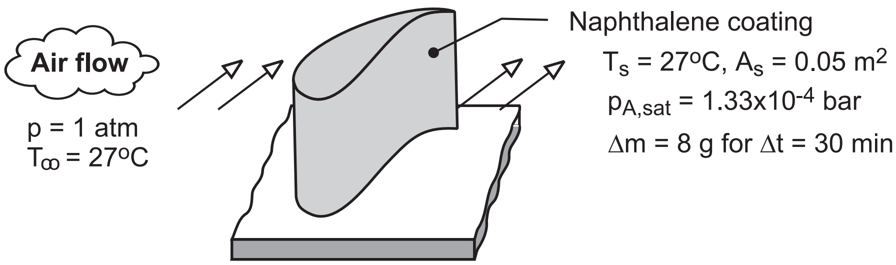
COMMENTS: The average depth of surface recession is given by $\delta = \overline{h_m}(\rho_{A,s} - \rho_{A,\infty})\Delta t/\rho_{A,sol}$ where $\rho_{A,sol}$ is the density of solid naphthalene, $\rho_{A,sol} = 1025\ \text{kg/m}^3$. Thus $\delta = 37\ \mu\text{m}$ and the assumption that the dimensions remain unchanged is good.

PROBLEM 6.64

KNOWN: Surface area and temperature of a coated turbine blade. Temperature and pressure of air flow over the blade. Molecular weight and saturation vapor pressure of the naphthalene coating. Duration of air flow and corresponding mass loss of naphthalene due to sublimation.

FIND: Average convection heat transfer coefficient.

SCHEMATIC:



ASSUMPTIONS: (1) Applicability of heat and mass transfer analogy, (2) Negligible change in A_s due to mass loss, (3) Naphthalene vapor behaves as an ideal gas, (4) Solid/vapor equilibrium at surface of coating, (5) Negligible vapor density in freestream of air flow.

PROPERTIES: *Table A-4*, Air (T = 300K): ρ = 1.161 kg/m^3, c_p = 1007 J/kg·K, $\alpha = 22.5 \times 10^{-6}$ m^2/s. *Table A-8*, Naphthalene vapor/air (T = 300K): $D_{AB} = 0.62 \times 10^{-5}$ m^2/s.

ANALYSIS: From the rate equation for convection mass transfer, the average convection mass transfer coefficient may be expressed as

$$\overline{h}_m = \frac{n_A}{A_s\left(\rho_{A,s} - \rho_{A,\infty}\right)} = \frac{\Delta m / \Delta t}{A_s\ \rho_{A,s}}$$

where

$$\rho_{A,s} = \rho_{A,sat}\left(T_s\right) = \frac{\mathcal{M}_A\ p_{A,sat}}{\Re\, T_s} = \frac{\left(128.16\,\text{kg/kmol}\right)1.33\times10^{-4}\,\text{bar}}{0.08314\,\text{m}^3\cdot\text{bar/kmol}\cdot\text{K}\ \left(300\text{K}\right)} = 6.83\times10^{-4}\,\text{kg/m}^3$$

Hence,

$$\overline{h}_m = \frac{0.008\,\text{kg}/\left(30\,\text{min}\times60\,\text{s/min}\right)}{0.05\text{m}^2\left(6.83\times10^{-4}\,\text{kg/m}^3\right)} = 0.13\,\text{m/s}$$

Using the heat and mass transfer analogy with n = 1/3, we then obtain

$$\overline{h} = \overline{h}_m \rho c_p Le^{2/3} = \overline{h}_m \rho c_p \left(\frac{\alpha}{D_{AB}}\right)^{2/3} = 0.130\,\text{m/s}\left(1.161\,\text{kg/m}^3\right)\times$$

$$1007\,\text{J/kg}\cdot\text{K}\left(22.5\times10^{-6}/0.62\times10^{-5}\right)^{2/3} = 359\,\text{W/m}^2\cdot\text{K} \qquad <$$

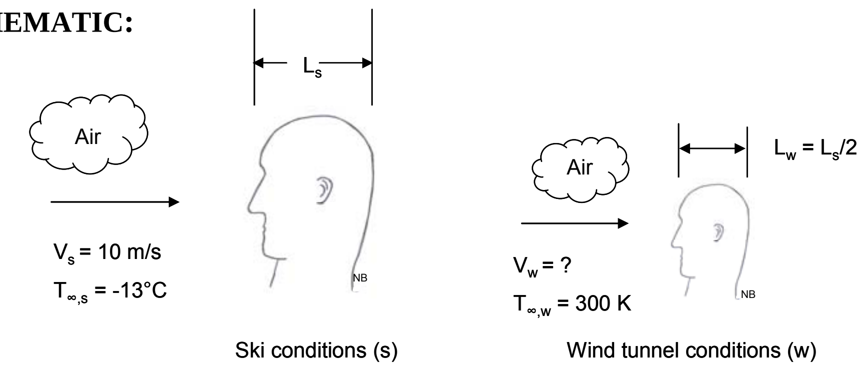
COMMENTS: The naphthalene sublimation technique has been used extensively to determine convection coefficients associated with complex flows and geometries.

PROBLEM 6.65

KNOWN: Half-scale naphthalene model of human head. Velocity and temperature of air flow while skiing. Temperature of air in wind tunnel. Depth of recession after 120 min for three locations. Density of solid naphthalene.

FIND: (a) Required wind tunnel velocity, (b) Heat transfer coefficients for full-scale head in skiing conditions, (c) Explain if uncovered regions would have same heat transfer coefficient when headgear is in place.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Pr and Sc are raised to the one-third power in the heat and mass transfer correlations, (3) The properties of the air-naphthalene mixture are approximately those of air, (4) Properties can be evaluated at T_∞ under the skiing conditions.

PROPERTIES: Table A-4, Air (-13°C = 260 K): $\nu = 12.33 \times 10^{-6}$ m²/s, $k = 23.1 \times 10^{-3}$ W/m·K. Air (300 K): $\rho = 1.161$ kg/m³, $c_p = 1007$ J/kg·K, $\nu = 15.89 \times 10^{-6}$ m²/s, $k = 26.3 \times 10^{-3}$ W/m·K, $\alpha = 22.5 \times 10^{-6}$ m²/s. Table A-8, Naphthalene in air, (300 K): $D_{AB} = 0.62 \times 10^{-5}$ m²/s.

ANALYSIS: (a) In order for the results of the wind tunnel test to be directly applicable to the skiing conditions, the Reynolds numbers must be the same:

$$Re_s = Re_w \qquad V_s L_s / \nu_s = V_w L_w / \nu_w$$

$$V_w = V_s \frac{L_s}{L_w}\frac{\nu_w}{\nu_s} = 10\text{ m/s} \times 2 \times \frac{15.89 \times 10^{-6}\text{ m}^2/\text{s}}{12.33 \times 10^{-6}\text{ m}^2/\text{s}} = 25.8\text{ m/s} \qquad <$$

(b) The mass flux and mass transfer coefficient can be found from knowledge of the recession depth:

$$n''_A = \rho_{A,sol}\delta/\Delta t$$

$$h_m = n''_A/(\rho_{A,s} - \rho_{A,\infty}) = \rho_{A,sol}\delta/(\rho_{A,s} - \rho_{A,\infty})\Delta t$$

where $\rho_{A,\infty} = 0$ and $\rho_{A,s}$ can be found from the saturation pressure and molecular weight (see Problem 6.63) using the ideal gas law.

$$\rho_{A,s} = \frac{\rho_{A,sat}\mathcal{M}_A}{\mathcal{R}T_s} = \frac{1.33 \times 10^{-4}\text{ bars} \times 128.16\text{ kg/kmol}}{8.314 \times 10^{-2}\text{ m}^3 \cdot \text{bar/kmol} \cdot \text{K} \times 300\text{ K}} = 6.83 \times 10^{-4}\text{ kg/m}^3 \qquad <$$

Continued…

PROBLEM 6.65 (Cont.)

Thus, with $\delta_1 = 0.1$ mm,

$$h_{m,1} = 1025\ \text{kg/m}^3 \times 10^{-4}\ \text{m}/(6.83 \times 10^{-4}\ \text{kg/m}^3 \times 120\ \text{min} \times 60\ \text{s/min}) = 2.08 \times 10^{-2}\ \text{m/s}$$

Similarly for the other two locations,

$$h_{m,2} = 6.67 \times 10^{-2}\ \text{m/s}, \quad h_{m,3} = 1.33 \times 10^{-1}\ \text{m/s}$$

The heat transfer coefficients can then be found from the heat and mass transfer analogy as stated in Equation 6.60.

$$h = h_m \rho c_p Le^{1-n}$$

where n = 1/3 and

$$Le = \alpha/D_{AB} = (22.5 \times 10^{-6}\ \text{m}^2/\text{s})/(0.62 \times 10^{-5}\ \text{m}^2/\text{s}) = 3.63$$

Thus at location 1,

$$h_1 = 2.08 \times 10^{-2}\ \text{m/s} \times 1.161\ \text{kg/m}^3 \times 1007\ \text{J/kg}\cdot\text{K} \times (3.63)^{2/3} = 57.4\ \text{W/m}^2\cdot\text{K}$$

And for the other two locations,

$$h_2 = 184\ \text{W/m}^2\cdot\text{K}, \quad h_3 = 368\ \text{W/m}^2\cdot\text{K}$$

These values are for the half-scale model. Since the Reynolds number is the same in the wind tunnel as in the skiing conditions, the local Nusselt numbers are also the same (see Equation 6.49), thus

$$Nu_s = Nu_w \qquad h_s L_s / k_s = h_w L_w / k_w$$

$$h_s = h_w \frac{L_w}{L_s}\frac{k_s}{k_w} = h_w \times 1/2 \times \frac{23.1 \times 10^{-3}\ \text{W/m}\cdot\text{K}}{26.3 \times 10^{-3}\ \text{W/m}\cdot\text{K}}$$

Thus

$$h_{s1} = h_{w1} \times 0.439 = 57.4\ \text{W/m}^2\cdot\text{K} \times 0.439 = 25.2\ \text{W/m}^2\cdot\text{K}$$ <

And similarily

$$h_{s,2} = 80.8\ \text{W/m}^2\cdot\text{K}, \quad h_{s,3} = 162\ \text{W/m}^2\cdot\text{K}$$ <

(c) When the headgear is in place, it will change the geometry of the surface and therefore change the heat transfer coefficients. The regions that are left uncovered will be recessed relative to the rest of the surface. This will probably reduce the local velocity near the surface slightly and reduce the local heat transfer coefficient.

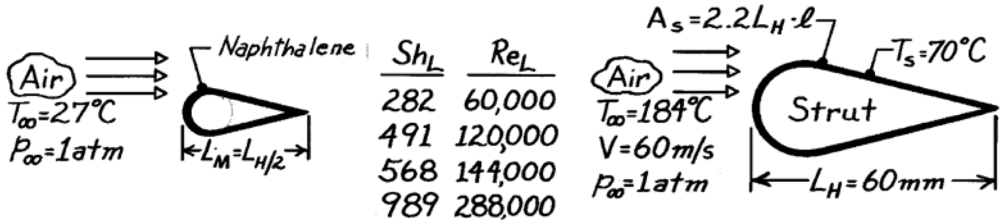
COMMENTS: (1) The properties should be evaluated at the *film temperature*, $T_f = (T_s + T_\infty)/2$. In the wind tunnel the conditions are isothermal, but in the ski conditions they are not. However the surface temperature is unknown and cannot be found without a more complex analysis of heat transfer in the body and the headgear (when present). (2) Heat loss is not the only consideration when designing winter clothing. Comfort is also important and exposed areas could be uncomfortably cold, even though areas with small heat transfer coefficients will be warmer than those with larger coefficients.

PROBLEM 6.66

KNOWN: Mass transfer experimental results on a half-sized model representing an engine strut.

FIND: (a) The coefficients C and m of the correlation $\overline{Sh}_L = CRe_L^m Sc^{1/3}$ for the mass transfer results, (b) Average heat transfer coefficient, $\bar{h}$, for the full-sized strut with prescribed operating conditions, (c) Change in total heat rate if characteristic length L_H is doubled.

SCHEMATIC:



Mass transfer   Heat transfer

ASSUMPTIONS: Analogy exists between heat and mass transfer.

PROPERTIES: *Table A-4*, Air $\left(\bar{T} = (T_\infty + T_s)/2 = 400K, 1\ atm\right)$: $\nu = 26.41\times10^{-6} m^2/s$, k = 0.0338 W/m·K, Pr = 0.690; $\left(\bar{T} = 300K\right)$: $\nu_B = 15.89\times10^{-6}\ m^2/s$; *Table A-8*, Naphthalene-air (300K, 1 atm): $D_{AB} = 0.62\times10^{-5} m^2/s$, $Sc = \nu_B/D_{AB} = 15.89\times10^{-6} m^2/s / 0.62\times10^{-5} m^2/s = 2.56$.

ANALYSIS: (a) The correlation for the mass transfer experimental results is of the form $\overline{Sh}_L = CRe_L^m\ Sc^{1/3}$. The constants C,m may be evaluated from two data sets of $\overline{Sh}_L$ and Re_L; choosing the middle sets (2,3):

$$\frac{\left(\overline{Sh}_L\right)_2}{\left(\overline{Sh}_L\right)_3} = \frac{\left(Re_L\right)_2^m}{\left(Re_L\right)_3^m} \text{ or } m = \frac{\log\left[\overline{Sh}_L)_2/\overline{Sh}_L)_3\right]}{\log\left[Re_L)_2/Re_L)_3\right]} = \frac{\log\left[491/568\right]}{\log\left[120{,}000/144{,}000\right]} = 0.80. \quad <$$

Then, using set 2, find
$$C = \frac{\overline{Sh}_L)_2}{Re_L^m)_2\ Sc^{1/3}} = \frac{491}{(120{,}000)^{0.8}\ 2.56^{1/3}} = 0.031. \quad <$$

(b) For the heat transfer analysis of the strut, the correlation will be of the form $\overline{Nu}_L = \bar{h}_L \cdot L_H/k = 0.031\ Re_L^{0.8} Pr^{1/3}$ where $Re_L = V L_H/\nu$ and the constants C,m were determined in Part (a). Substituting numerical values,

$$\bar{h}_L = \overline{Nu}_L \cdot \frac{k}{L_H} = 0.031\left[\frac{60\ m/s\times0.06\ m}{26.41\times10^{-6} m^2/s}\right]^{0.8} 0.690^{1/3}\frac{0.0338\ W/m\cdot K}{0.06\ m} = 198\ W/m^2\cdot K. \quad <$$

(c) The total heat rate for the strut of characteristic length L_H is $q = \bar{h}\, A_s\left(T_s - T_\infty\right)$, where A_s = 2.2 L_H·l and

$$\bar{h} \sim \overline{Nu}_L \cdot L_H^{-1} \sim RE_L^{0.8}\cdot L_H^{-1} \sim L_H^{0.8}\cdot L_H^{-1} \sim L_H^{-0.2} \quad A_s \sim L_H$$

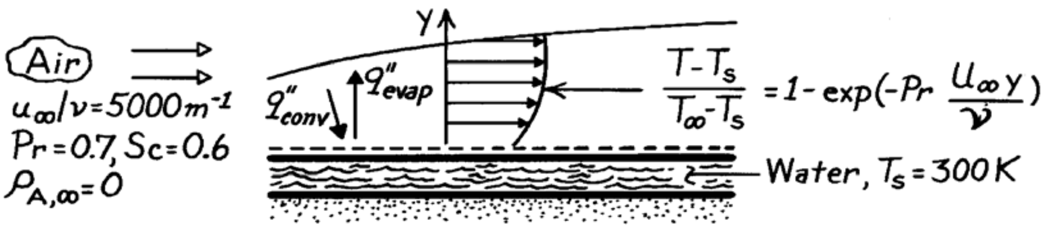
Hence, $q \sim \bar{h}\cdot A_s \sim \left(L_H^{-0.2}\right)\left(L_H\right) \sim L_H^{0.8}$. If the characteristic length were doubled, the heat rate would be increased by a factor of $(2)^{0.8}$ = 1.74. <

PROBLEM 6.67

KNOWN: Boundary layer temperature distribution for flow of dry air over water film.

FIND: Evaporative mass flux and whether net energy transfer is to or from the water.

SCHEMATIC:



ASSUMPTIONS: (1) Heat and mass transfer analogy is applicable, (2) Water is well insulated from below.

PROPERTIES: *Table A-4*, Air (T_s = 300K, 1 atm): k = 0.0263 W/m·K; *Table A-6*, Water vapor (T_s = 300K): $\rho_{A,s} = v_g^{-1} = 0.0256\ \text{kg/m}^3,\ h_{fg} = 2.438\times10^6\ \text{J/kg}$; *Table A-8*, Air-water vapor $(T_s = 300K)$: $D_{AB} = 0.26\times10^{-4}\text{m}^2/\text{s}$.

ANALYSIS: From the heat and mass transfer analogy,

$$\frac{\rho_A - \rho_{A,s}}{\rho_{A,\infty} - \rho_{A,s}} = 1 - \exp\left[-Sc\frac{u_\infty y}{\nu}\right].$$

Using Fick's law at the surface (y = 0), the species flux is

$$n''_A = -D_{AB}\left.\frac{\partial \rho_A}{\partial y}\right|_{y=0} = +\rho_{A,s}\ D_{AB}\ Sc\ \frac{u_\infty}{\nu}$$

$$n''_A = 0.0256\ \text{kg/m}^3 \times 0.26\times10^{-4}\text{m}^2/\text{s} \times (0.6)5000\ \text{m}^{-1} = 2.00\times10^{-3}\ \text{kg/s}\cdot\text{m}^2.$$

The net heat flux to the water has the form

$$q''_{net} = q''_{conv} - q''_{evap} = +k\left.\frac{\partial T}{\partial y}\right|_{y=0} - n''_A\ h_{fg} = k(T_\infty - T_s)\ Pr\ \frac{u_\infty}{\nu} - n''_A\ h_{fg}$$

and substituting numerical values, find

$$q''_{net} = 0.0263\frac{W}{m\cdot K}(100K)\ 0.7 \times 5000\ m^{-1} - 2\times10^{-3}\frac{kg}{s\cdot m^2}\times 2.438\times10^6\ J/kg$$

$$q''_{net} = 9205\ W/m^2 - 4876\ W/m^2 = 4329\ W/m^2.$$

Since $q''_{net} > 0$, the net heat transfer is to the water. <

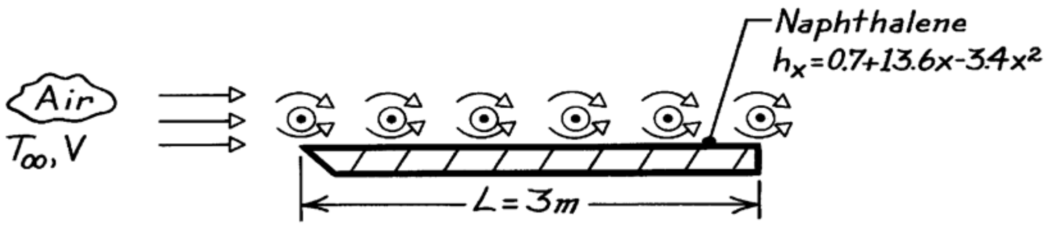
COMMENTS: Note use of properties (D_{AB} and k) evaluated at T_s to determine surface fluxes.

PROBLEM 6.68

KNOWN: Distribution of local convection heat transfer coefficient for obstructed flow over a flat plate with surface and air temperatures of 310K and 290K, respectively.

FIND: Average convection mass transfer coefficient.

SCHEMATIC:



ASSUMPTIONS: Heat and mass transfer analogy is applicable.

PROPERTIES: *Table A-4*, Air $\left(T_f = (T_s + T_\infty)/2 = (310 + 290)K/2 = 300\text{ K, 1 atm}\right)$: $k = 0.0263\text{ W/m}\cdot\text{K}$, $\nu = 15.89\times10^{-6}\text{m}^2/\text{s}$, $Pr = 0.707$. *Table A-8*, Air-napthalene (300K, 1 atm): $D_{AB} = 0.62\times10^{-5}\text{m}^2/\text{s}$, $Sc = \nu/D_{AB} = 2.56$.

ANALYSIS: The average heat transfer coefficient is

$$\bar{h}_L = \frac{1}{L}\int_0^L h_x dx = \frac{1}{L}\int_0^L \left(0.7 + 13.6x - 3.4x^2\right)dx$$

$$\bar{h}_L = 0.7 + 6.8L - 1.13L^2 = 10.9\text{ W/m}^2\cdot\text{K}.$$

Applying the heat and mass transfer analogy with n = 1/3, Equation 6.59 yields

$$\frac{\overline{Nu}_L}{Pr^{1/3}} = \frac{\overline{Sh}_L}{Sc^{1/3}}$$

Hence,

$$\frac{\bar{h}_{m,L}L}{D_{AB}} = \frac{\bar{h}_L L}{k}\frac{Sc^{1/3}}{Pr^{1/3}}$$

$$\bar{h}_{m,L} = \bar{h}_L\frac{D_{AB}}{k}\frac{Sc^{1/3}}{Pr^{1/3}} = 10.9\text{ W/m}^2\cdot\text{K}\frac{0.62\times10^{-5}\text{m}^2/\text{s}}{0.0263\text{ W/m}\cdot\text{K}}\left(\frac{2.56}{0.707}\right)^{1/3}$$

$$\bar{h}_{m,L} = 0.00395\text{ m/s}.$$ <

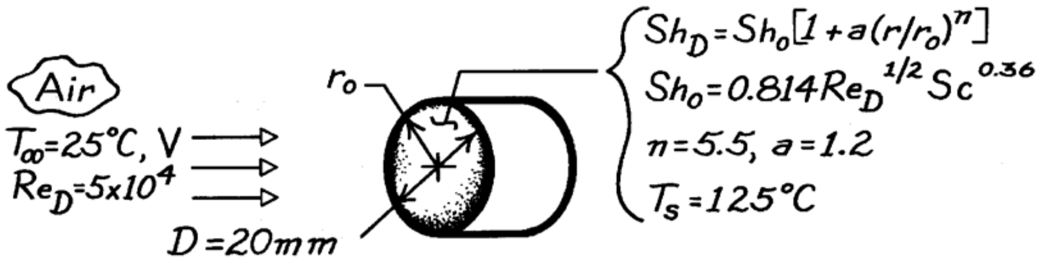
COMMENTS: The napthalene sublimation method provides a useful tool for determining local convection coefficients.

PROBLEM 6.69

KNOWN: Radial distribution of local Sherwood number for uniform flow normal to a circular disk.

FIND: (a) Expression for average Nusselt number. (b) Heat rate for prescribed conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Applicability of heat and mass transfer analogy.

PROPERTIES: *Table A-4*, Air $\left(\bar{T} = 75^\circ C = 348\ K\right)$: k = 0.0299 W/m·K, Pr = 0.70.

ANALYSIS: (a) From the heat and mass transfer analogy, Equation 6.57,

$$\frac{\overline{Nu}_D}{Pr^{0.36}} = \frac{\overline{Sh}_D}{Sc^{0.36}}$$

where

$$\overline{Sh}_D = \frac{1}{A_s}\int_{A_s} Sh_D(r)\,dA_s = \frac{Sh_o}{\pi\, r_o^2} 2\pi \int_0^{r_o}\left[1 + a\left(r/r_o\right)^n\right] r dr$$

$$\overline{Sh}_D = \frac{2Sh_o}{r_o^2}\left[\frac{r^2}{2} + \frac{ar^{n+2}}{(n+2)r_o^n}\right]_0^{r_o} = Sh_o\left[1 + 2a/(n+2)\right]$$

Hence,

$$\overline{Nu}_D = 0.814\left[1 + 2a/(n+2)\right]Re_D^{1/2}Pr^{0.36}.$$ <

(b) The heat rate for these conditions is

$$q = \bar{h}A\left(T_s - T_\infty\right) = 0.814\left[1 + 2a/(n+2)\right]\frac{k}{D}Re_D^{1/2}Pr^{0.36}\frac{\left(\pi\, D^2\right)}{4}\left(T_s - T_\infty\right)$$

$$q = 0.814(1 + 2.4/7.5)\,0.0299\ W/m\cdot K\left(\pi 0.02\ m/4\right)\left(5\times10^4\right)^{1/2}(0.7)^{0.36}\left(100^\circ C\right)$$

$$q = 9.92\ W.$$ <

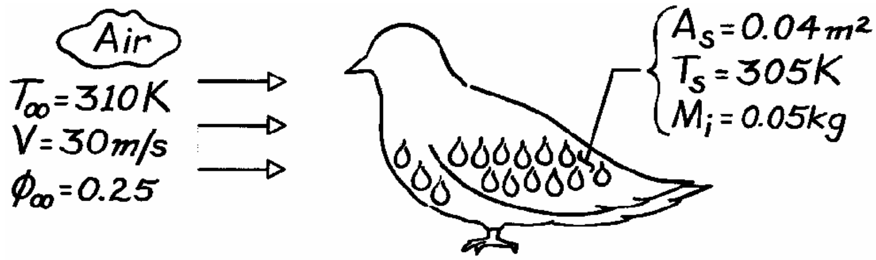
COMMENTS: The increase in h(r) with r may be explained in terms of the sharp turn which the boundary layer flow must make around the edge of the disk. The boundary layer accelerates and its thickness decreases as it makes the turn, causing the local convection coefficient to increase.

PROBLEM 6.70

KNOWN: Convection heat transfer correlation for wetted surface of a sand grouse. Initial water content of surface. Velocity of bird and ambient air conditions.

FIND: Flight distance for depletion of 50% of initial water content.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Vapor behaves as a perfect gas, (3) Constant properties, (4) Applicability of heat and mass transfer analogy.

PROPERTIES: Air (given): $\nu = 16.7\times10^{-6} m^2/s$; Air-water vapor (given): $D_{AB} = 0.26\times10^{-4} m^2/s$; *Table A-6*, Water vapor (T_s = 305 K): v_g = 29.74 m^3/kg; (T_s = 310 K), v_g = 22.93 m^3/kg.

ANALYSIS: The maximum flight distance is

$$X_{max} = Vt_{max}$$

where the time to deplete 50% of the initial water content ΔM is

$$t_{max} = \frac{\Delta M}{\dot{m}_{evap}} = \frac{\Delta M}{\overline{h}_m A_s\left(\rho_{A,s} - \rho_{A,\infty}\right)}.$$

The mass transfer coefficient is

$$\overline{h}_m = \overline{Sh}_L\frac{D_{AB}}{L} = 0.034 Re_L^{4/5} Sc^{1/3}\frac{D_{AB}}{L}$$

$$Sc = \nu/D_{AB} = 0.642, \qquad L = \left(A_s\right)^{1/2} = 0.2 \text{ m}$$

$$Re_L = \frac{VL}{\nu} = \frac{30 \text{ m/s}\times 0.2 \text{ m}}{16.7\times10^{-6} m^2/s} = 3.59\times10^5$$

$$\overline{h}_m = 0.034\left(3.59\times10^5\right)^{4/5}(0.642)^{1/3}\left(0.26\times10^{-4} m^2/s/0.2 \text{ m}\right) = 0.106 \text{ m/s}.$$

Hence,

$$t_{max} = \frac{0.025 \text{ kg}}{0.106 \text{ m/s}\left(0.04 \text{ m}^2\right)\left[(29.74)^{-1} - 0.25(22.93)^{-1}\right]\text{kg/m}^3} = 259 \text{ s}$$

$$X_{max} = 30 \text{ m/s}\left(259 \text{ s}\right) = 7785 \text{ m} = 7.78 \text{ km}. \qquad <$$

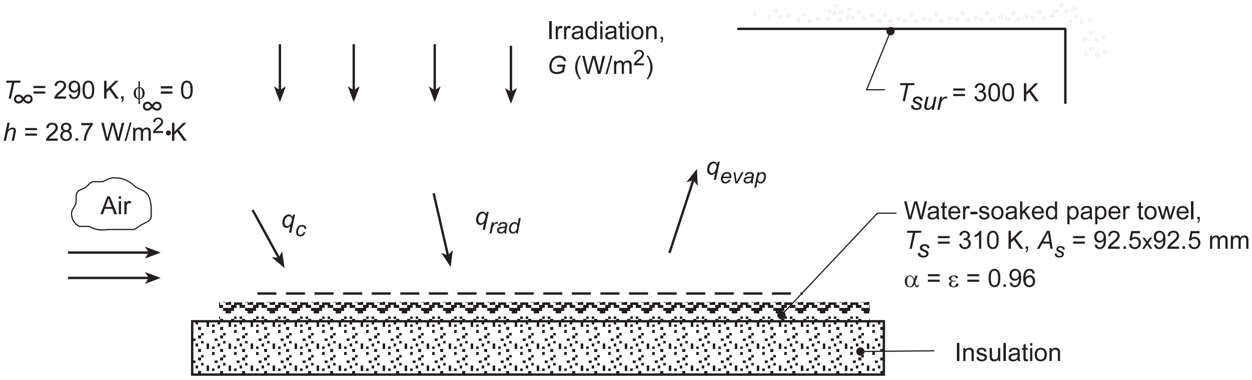
COMMENTS: Evaporative heat loss is balanced by convection heat transfer from air. Hence, $T_s < T_\infty$.

PROBLEM 6.71

KNOWN: Water-soaked paper towel experiences simultaneous heat and mass transfer while subjected to parallel flow of air, irradiation from a radiant lamp bank, and radiation exchange with surroundings. Average convection coefficient estimated as $\overline{h} = 28.7\ W/m^2\cdot K$.

FIND: (a) Rate at which water evaporates from the towel, n_A (kg/s), and (b) The net rate of radiation transfer, q_{rad} (W), to the towel. Determine the irradiation G (W/m^2).

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Vapor behaves as an ideal gas, (3) Constant properties, (4) Towel experiences radiation exchange with the large surroundings as well as irradiation from the lamps, (5) Negligible heat transfer from the bottom side of the towel, and (6) Applicability of the heat-mass transfer analogy.

PROPERTIES: *Table A.4*, Air (T_f = 300 K): $\rho = 1.1614$ kg/m^3, $c_p = 1007$ J/kg·K, $\alpha = 22.5 \times 10^{-6}$ m^2/s; *Table A.6*, Water (310 K): $\rho_{A,s} = \rho_g = 1/v_g = 1/22.93 = 0.0436$ kg/m^3, $h_{fg} = 2414$ kJ/kg.Table A.8, Water-Air (T ≈ 300 K): $D_{AB} = 0.26 \times 10^{-4}$ m^2/s.

ANALYSIS: (a) The evaporation rate from the towel is

$$n_A = \overline{h}_m A_s \left(\rho_{A,s} - \rho_{A,\infty}\right)$$

where $\overline{h}_m$ can be determined from the heat-mass transfer analogy, Eq. 6.60, with n = 1/3,

$$\frac{h}{h_m} = \rho c_p Le^{2/3} = \rho c_p \left(\frac{\alpha}{D_{AB}}\right)^{2/3} = 1.614\,kg/m^3 \times 1007\,J/kg\cdot K \left(\frac{22.5\times10^{-6}}{0.26\times10^{-4}}\right)^{2/3} = 1476\,J/m^3\cdot K$$

$$h_m = 28.7\,W/m^2\cdot K/1476\,J/m^3\cdot K = 0.0194\,m/s$$

The evaporation rate is

$$n_A = 0.0194\,m/s \times (0.0925\times0.0925)\,m^2\,(0.0436-0)\,kg/m^3 = 7.25\times10^{-6}\,kg/s$$ <

(b) Performing an energy balance on the towel considering processes of evaporation, convection and radiation, find

$$\dot{E}_{in} - \dot{E}_{out} = q_{conv} - q_{evap} + q_{rad} = 0$$

$$\overline{h}A_s\left(T_\infty - T_s\right) - n_A h_{fg} + q_{rad} = 0$$

$$q_{rad} = 7.25\times10^{-6}\,kg/s \times 2414\times10^3\,J/kg - 28.7\,W/m^2\,(0.0925\,m)^2\,(290-310)\,K$$

$$q_{rad} = 17.5\,W + 4.91\,W = 22.4\,W$$ <

Continued...

PROBLEM 6.71 (Cont.)

The net radiation heat transfer to the towel is comprised of the absorbed irradiation and the net exchange between the surroundings and the towel,

$$q_{rad} = \alpha G A_s + \varepsilon A_s \sigma \left(T_{sur}^4 - T_s^4 \right)$$

$$22.4\,\text{W} = 0.96G\left(0.0925\,\text{m}\right)^2 + 0.96\times\left(0.0925\,\text{m}\right)^2 5.67\times10^{-8}\,\text{W}/\text{m}^2\cdot\text{K}^4\left(300^4 - 310^4\right)\text{K}^4$$

Solving, find the irradiation from the lamps,

$G = 2791\ \text{W/m}^2$. <

COMMENTS: (1) From the energy balance in Part (b), note that the heat rate by convection is considerably smaller than that by evaporation.

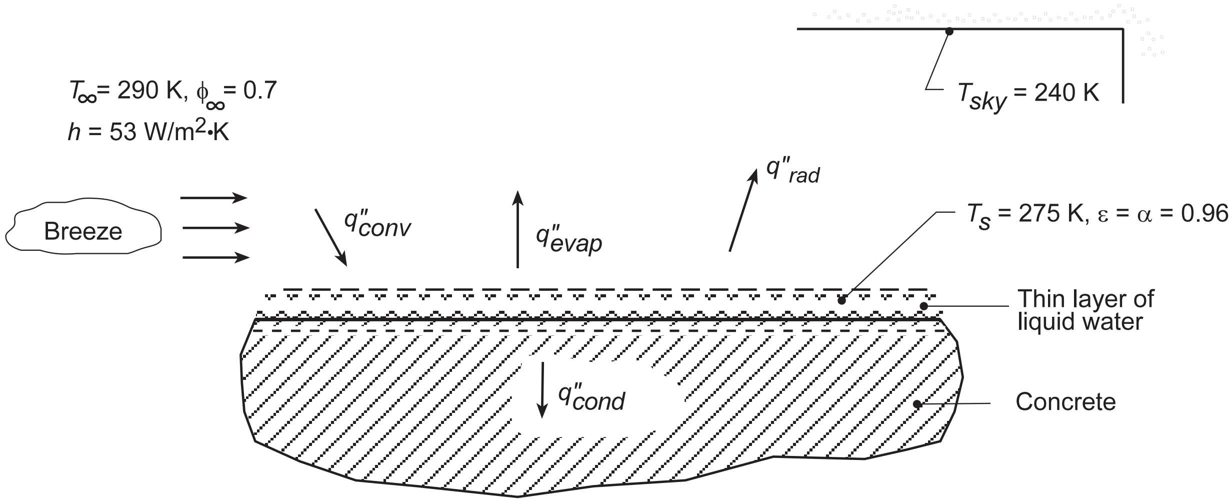
(2) As we'll learn in Chapter 12, the lamp irradiation found in Part (c) is approximately 2 times that of solar irradiation to the earth's surface.

PROBLEM 6.72

KNOWN: Thin layer of water on concrete surface experiences evaporation, convection with ambient air, and radiation exchange with the sky. Average convection coefficient estimated as $\overline{h}$ = 53 W/m²·K.

FIND: (a) Heat fluxes associated with convection, q''_{conv}, evaporation, q''_{evap}, and radiation exchange with the sky, q''_{rad}, (b) Use results to explain why the concrete is wet instead of dry, and (c) Direction of heat flow and the heat flux by conduction into or out of the concrete.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Vapor behaves as an ideal gas, (3) Constant properties, (4) Water surface is small compare to large, isothermal surroundings (sky), and (4) Applicability of the heat-mass transfer analogy.

PROPERTIES: *Table A.4*, Air ($T_f = (T_\infty + T_s)/2$ = 282.5 K): ρ = 1.243 kg/m³, c_p = 1007 J/kg·K, α = 2.019 ×10⁵ m²/s; *Table A.8*, Water-air (T_f = 282.5 K): $D_{AB} = 0.26 \times 10^{-4}$ m²/s $(282.5/298)^{3/2} = 0.24 \times 10^{-4}$ m²/s; *Table A.6*, Water (T_s = 275 K): $\rho_{A,s} = \rho_g = 1/v_g$ = 1/181.7 = 0.0055 kg/m³, h_{fg} = 2497 kJ/kg; *Table A.6*, Water (T_∞ = 290 K): $\rho_{A,s}$ = 1/69.7 = 0.0143 kg/m³.

ANALYSIS: (a) The heat fluxes associated with the processes shown on the schematic are

Convection:

$$q''_{conv} = \overline{h}\left(T_\infty - T_s\right) = 53\,W/m^2 \cdot K\left(290-275\right)K = +795\,W/m^2 \qquad <$$

Radiation Exchange:

$$q''_{rad} = \varepsilon\sigma\left(T_s^4 - T_{sky}^4\right) = 0.96\times5.76\times10^{-8}\,W/m^2\cdot K^4\left(275^4 - 240^4\right)K^4 = +131\,W/m^2 \qquad <$$

Evaporation:

$$q''_{evap} = n''_A h_{fg} = -2.255\times10^{-4}\,kg/s\cdot m^2 \times 2497\times10^3\,J/kg = -563.1\,W/m^2 \qquad <$$

where the evaporation rate *from* the surface is

$$n''_A = \overline{h}_m\left(\rho_{A,s} - \rho_{A,\infty}\right) = 0.050\,m/s\left(0.0055 - 0.7\times0.0143\right)kg/m^3 = -2.255\times10^{-4}\,kg/s\cdot m^2$$

Continued...

PROBLEM 6.72 (Cont.)

and where the mass transfer coefficient is evaluated from the heat-mass transfer analogy, Eq. 6.60, with n = 1/3,

$$\frac{\bar{h}}{\bar{h}_m} = \rho c_p Le^{2/3} = \rho c_p \left(\frac{\alpha}{D_{AB}}\right)^{2/3} = 1.243\,\text{kg}/\text{m}^3 \times 1007\,\text{J/kg}\cdot\text{K}\left(\frac{2.019\times10^{-5}}{0.26\times10^{-4}}\right)^{2/3}$$

$$\frac{\bar{h}}{\bar{h}_m} = 1058\,\text{J}/\text{m}^3\cdot\text{K}$$

$$\bar{h}_m = 53\,\text{W}/\text{m}^2\cdot\text{K}/1058\,\text{J}/\text{m}^3\cdot\text{K} = 0.050\,\text{m/s}$$

(b) From the foregoing evaporation calculations, note that water vapor from the air is condensing on the liquid water layer. That is, vapor is being transported to the surface, explaining why the concrete surface is wet, even without rain.

(c) From an overall energy balance on the water film considering conduction in the concrete as shown in the schematic,

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$q''_{conv} - q''_{evap} - q''_{rad} - q''_{cond} = 0$$

$$q''_{cond} = q''_{conv} - q''_{evap} - q''_{rad}$$

$$q''_{cond} = 1795\,\text{W}/\text{m}^3 - \left(-563.1\,\text{W}/\text{m}^2\right) - \left(+131\,\text{W}/\text{m}^2\right) = 1227\,\text{W}/\text{m}^2 \qquad <$$

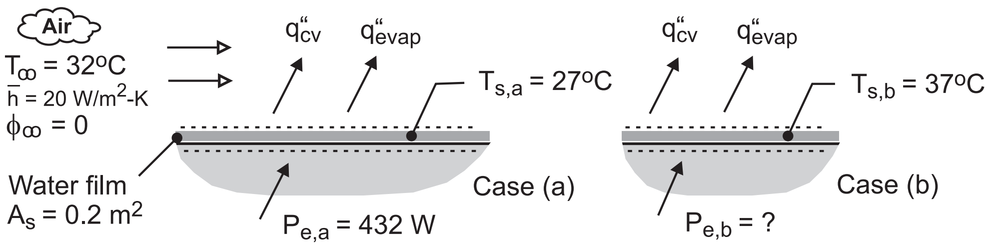
The heat flux by conduction is *into* the concrete.

PROBLEM 6.73

KNOWN: Heater power required to maintain wetted (water) plate at 27°C, and average convection coefficient for specified dry air temperature, case (a).

FIND: Heater power required to maintain the plate at 37°C for the same dry air temperature if the convection coefficients remain unchanged, case (b).

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Convection coefficients unchanged for different plate temperatures, (3) Air stream is dry at atmospheric pressure, and (4) Negligible heat transfer from the bottom side of the plate.

PROPERTIES: *Table A-6*, Water ($T_{s,a}$ = 27°C = 300 K): $\rho_{A,s} = 1/v_g = 0.02556$ kg/m^3, $h_{fg} = 2.438 \times 10^6$ J/kg; Water ($T_{s,b}$ = 37°C = 310 K): $\rho_{A,s} = 1/v_g = 0.04361$ kg/m^3, $h_{fg} = 2.414 \times 10^6$ J/kg.

ANALYSIS: For *case (a)* with T_s = 27°C and P_e = 432 W, perform an energy balance on the plate to determine the mass transfer coefficient h_m.

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$P_{e,a} - \left(q''_{evap} + q''_{cv}\right) A_s = 0$$

Substituting the rate equations and appropriate properties,

$$P_{e,a} - \left[\bar{h}_m \left(\rho_{A,s} - \rho_{A,\infty}\right) h_{fg} + \bar{h}\left(T_{s,a} - T_\infty\right)\right] A_s = 0$$

$$432\ \text{W} - \left[\bar{h}_m \left(0.02556\ \text{kg/m}^3 - 0\right) \times 2.438 \times 10^6\ \text{J/kg} + 20\ \text{W/m}^2 \cdot \text{K}\left(27 - 32\right)\text{K}\right] \times 0.2\ \text{m}^2 = 0$$

where $\rho_{A,s}$ and h_{fg} are evaluated at T_s = 27°C = 300 K. Find,

$$\bar{h}_m = 0.0363\ \text{m/s}$$

For case (b), with T_s = 37°C and the same values for $\bar{h}$ and $\bar{h}_m$, perform an energy balance to determine the heater power required to maintain this condition.

$$P_{e,b} - \left[\bar{h}_m \left(\rho_{A,s} - 0\right) h_{fg} + \bar{h}\left(T_{s,b} - T_\infty\right)\right] A_s = 0$$

$$P_{e,b} - \left[0.0363\ \text{m/s}\left(0.04361 - 0\right)\text{kg/m}^3 \times 2.414 \times 10^6\ \text{J/kg} + 20\ \text{W/m}^2 \cdot \text{K}\left(37 - 32\right)\right] \times 0.2\ \text{m}^2 = 0$$

$$P_{e,b} = 784\ \text{W}$$ <

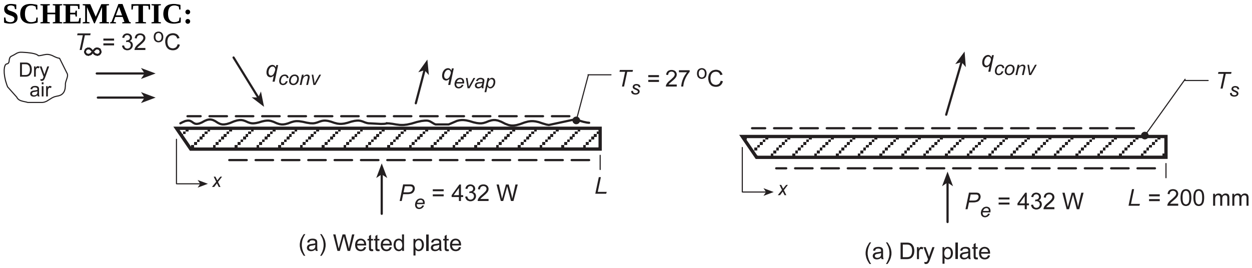
where $\rho_{A,a}$ and h_{fg} are evaluated at T_s = 37°C = 310 K.

PROBLEM 6.74

KNOWN: Dry air at 32°C flows over a wetted plate of width 1 m maintained at a surface temperature of 27°C by an embedded heater supplying 432 W.

FIND: (a) The evaporation rate of water from the plate, n_A (kg/h) and (b) The plate temperature T_s when all the water is evaporated, but the heater power remains the same.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Vapor behaves as an ideal gas, (3) Constant properties, and (4) Applicability of the heat-mass transfer analogy.

PROPERTIES: *Table A.4*, Air (T_f = (32 + 27)°C/2 = 302.5 K): ρ = 1.153 kg/m^3, c_p = 1007 J/kg·K, α = 2.287 ×10^5 m^2/s; *Table A.8*, Water-air ($T_f \approx$ 300 K): D_{AB} = 0.26 × 10^{-4} m^2/s; *Table A.6*, Water (T_s = 27°C = 300 K): $\rho_{A,s} = 1/v_g$ = 1/39.13 = 0.0256 kg/m^3, h_{fg} = 2438 kJ/kg.

ANALYSIS: (a) Perform an energy balance on the wetted plate to obtain the evaporation rate, n_A.

$$\dot{E}_{in} - \dot{E}_{out} = 0 \qquad P_e + q_{conv} - q_{evap} = 0$$

$$P_e + \bar{h}A_s\left(T_\infty - T_s\right) - n_A h_{fg} = 0 \tag{1}$$

In order to find $\bar{h}$, invoke the heat-mass transfer analogy, Eq. (6.60) with n = 1/3,

$$\frac{\bar{h}}{\bar{h}_m} = \rho c_p Le^{2/3} = \rho c_p\left(\frac{\alpha}{D_{AB}}\right)^{2/3} = 1.153\,\text{kg}/\text{m}^3 \times 1007\,\text{J/kg}\cdot\text{K}\left(\frac{2.287\times10^{-5}}{0.26\times10^{-4}}\right)^{2/3} = 1066\,\text{J}/\text{m}^3\cdot\text{K} \tag{2}$$

The evaporation rate equation

$$n_A = \bar{h}_m A_s\left(\rho_{A,s} - \rho_{A,\infty}\right)$$

Substituting Eqs. (2) and (3) into Eq. (1), find $\bar{h}_m$

$$P_e + \left(1066\,\text{J}/\text{m}^3\cdot\text{K}\,\overline{h_m}\right)A_s\left(T_\infty - T_s\right) - \overline{h_m}A_s\left(\rho_{A,s} - \rho_{A,\infty}\right)h_{fg} = 0 \tag{4}$$

$$432\,\text{W} + \left[1066\,\text{J}/\text{m}^3\cdot\text{K}\left(32-27\right)\text{K} - \left(0.0256-0\right)\text{kg}/\text{m}^3 \times 2438\times10^3\,\text{J/kg}\right]\left(0.200\times1\right)\text{m}^2\cdot\overline{h_m} = 0$$

$$432 + [5330 - 62{,}413] \times 0.20\ \overline{h_m} = 0$$

$$\overline{h_m} = 0.0378\text{ m/s}$$

Using Eq. (3), find

$$n_A = 0.0378\,\text{m/s}\left(0.200\times1\right)\text{m}^2\left(0.0256-0\right)\text{kg}/\text{m}^3 = 1.94\times10^{-4}\,\text{kg/s} = 0.70\,\text{kg/h}$$ <

(b) When the plate is dry, all the power must be removed by convection,

$$P_e = q_{conv} = \bar{h}\,A_s(T_s - T_\infty)$$

Assuming $\bar{h}$ is the same as for conditions with the wetted plate,

$$T_s = T_\infty + P_e/\bar{h}\,A_s = T_\infty + P_e/\left(1066\overline{h_m}\right)A_s$$

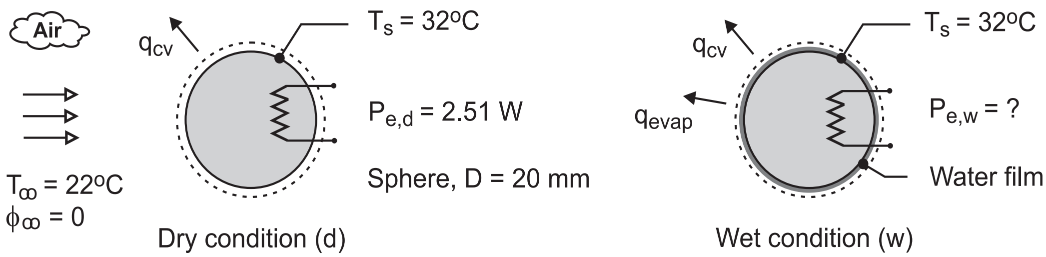
$$T_s = 32^\circ\text{C} + 432\,\text{W}/\left(1066\times0.0378\,\text{W}/\text{m}^2\cdot\text{K}\times0.200\,\text{m}^2\right) = 85.6^\circ\text{C}$$ <

PROBLEM 6.75

KNOWN: Surface temperature of a 20-mm diameter sphere is 32°C when dissipating 2.51 W in a dry air stream at 22°C.

FIND: Power required by the imbedded heater to maintain the sphere at 32°C if its outer surface has a thin porous covering saturated with water for the same dry air temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Heat and mass transfer analogy is applicable, (3) Heat transfer convection coefficient is the same for the dry and wet condition, and (3) Properties of air and the diffusion coefficient of the air-water vapor mixture evaluated at 300 K.

PROPERTIES: *Table A-4*, Air (300 K, 1 atm): ρ = 1.1614 kg/m^3, c_p = 1007 J/kg·K, $\alpha = 22.5 \times 10^{-6}$ m^2/s; *Table A-8,* Water-air mixture (300 K, 1 atm): $D_{A\text{-}B} = 0.26 \times 10^{-4}$ m^2/s; *Table A-4,* Water (305 K, 1 atm): $\rho_{A,s} = 1/v_g = 0.03362$ kg/m^3, $h_{fg} = 2.426 \times 10^6$ J/kg.

ANALYSIS: For the *dry case (d)*, perform an energy balance on the sphere and calculate the heat transfer convection coefficient.

$$\dot{E}_{in} - \dot{E}_{out} = P_{e,d} - q_{cv} = 0 \qquad P_{e,d} - \bar{h} A_s (T_s - T_\infty) = 0$$

$$2.51\ \text{W} - \bar{h}\pi(0.020\ \text{m})^2 \times (32-22)\text{K} = 0 \qquad \bar{h} = 200\ \text{W/m}^2\cdot\text{K}$$

Use the heat-mass analogy, Eq. (6.60) with n = 1/3, to determine $\bar{h}_m$.

$$\frac{\bar{h}}{\bar{h}_m} = \rho c_p \left(\frac{\alpha}{D_{AB}}\right)^{2/3}$$

$$\frac{200\ \text{W/m}^2\cdot\text{K}}{\bar{h}_m} = 1.1614\ \text{kg/m}^3 \times 1007\ \text{J/kg}\cdot\text{K}\left(\frac{22.5\times10^{-6}\text{m}^2/\text{s}}{0.26\times10^{-4}\text{m}^2/\text{s}}\right)^{2/3}$$

$$\bar{h}_m = 0.188\ \text{m/s}$$

For the *wet case* (*w*), perform an energy balance on the wetted sphere using values for $\bar{h}$ and $\bar{h}_m$ to determine the power required to maintain the same surface temperature.

$$\dot{E}_{in} - \dot{E}_{out} = P_{e,w} - q_{cv} - q_{evap} = 0$$

$$P_{e,w} - \left[\bar{h}(T_s - T_\infty) + \bar{h}_m(\rho_{A,s} - \rho_{A,\infty})h_{fg}\right]A_s = 0$$

$$P_{e,w} - \Big[200\ \text{W/m}^2\cdot\text{K}(32-22)\text{K} +$$

$$0.188\ \text{m/s}(0.03362-0)\text{kg/m}^3 \times 2.426\times10^6\text{J/kg}\Big]\pi(0.020\,\text{m})^2 = 0$$

$$P_{e,w} = 21.8\ \text{W}$$ <

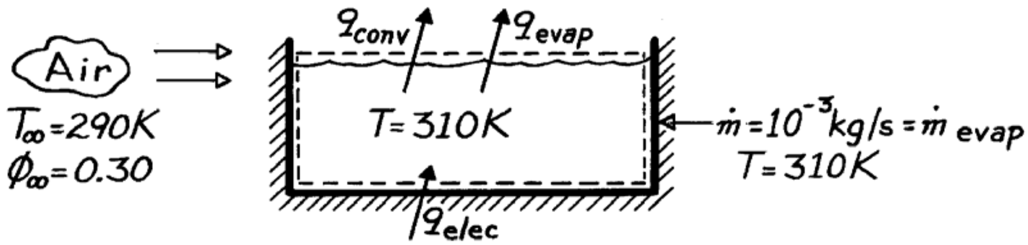
COMMENTS: Note that $\rho_{A,s}$ and h_{fg} for the mass transfer rate equation are evaluated at T_s = 32°C = 305 K, not 300 K. The effect of evaporation is to require nearly 8.5 times more power to maintain the same surface temperature.

PROBLEM 6.76

KNOWN: Operating temperature, ambient air conditions and make-up water requirements for a hot tub.

FIND: Heater power required to maintain prescribed conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Side wall and bottom are adiabatic, (2) Heat and mass transfer analogy is applicable.

PROPERTIES: *Table A-4*, Air $(\bar{T} = 300K, 1\ atm)$: ρ = 1.161 kg/m^3, c_p = 1007 J/kg·K, $\alpha = 22.5\times 10^{-6} m^2/s$; *Table A-6*, Sat. water vapor (T = 310K): h_{fg} = 2414 kJ/kg, $\rho_{A,sat}(T) = 1/v_g = (22.93 m^3/kg)^{-1} = 0.0436\ kg/m^3$; $(T_\infty = 290K)$: $\rho_{A,sat}(T_\infty) = 1/v_g = (69.7\ m^3/kg)^{-1} = 0.0143\ kg/m^3$; *Table A-8*, Air-water vapor (298K): $D_{AB} = 26 \times 10^{-6} m^2/s$.

ANALYSIS: Applying an energy balance to the control volume,

$$q_{elec} = q_{conv} + q_{evap} = \bar{h}\,A\left(T - T_\infty\right) + \dot{m}_{evap}\ h_{fg}\left(T\right).$$

Obtain $\bar{h}\,A$ from Eq. 6.60 with n = 1/3,

$$\frac{\bar{h}}{\bar{h}_m} = \frac{\bar{h}_A}{\bar{h}_m A} = \rho\ c_p Le^{2/3}$$

$$\bar{h}\,A = \bar{h}_m A\,\rho\ c_p Le^{2/3} = \frac{\dot{m}_{evap}}{\rho_{A,sat}\left(T\right) - \phi_\infty\ \rho_{A,sat}\left(T_\infty\right)}\rho\ c_p Le^{2/3}.$$

Substituting numerical values,

$$Le = \alpha/D_{AB} = \left(22.5\times 10^{-6} m^2/s\right)/\,26\times 10^{-6} m^2/s = 0.865$$

$$\bar{h}A = \frac{10^{-3}\ kg/s}{\left[0.0436 - 0.3\times 0.0143\right]\ kg/m^3} 1.161\frac{kg}{m^3}\times 1007\frac{J}{kg\cdot K}\left(0.865\right)^{2/3}$$

$$\bar{h}A = 27.0\ W/K.$$

Hence, the required heater power is

$$q_{elec} = 27.0 W/K\left(310 - 290\right)K + 10^{-3} kg/s \times 2414 kJ/kg \times 1000 J/kJ$$

$$q_{elec} = \left(540 + 2414\right)\ W\ =\ 2954\ W. \qquad <$$

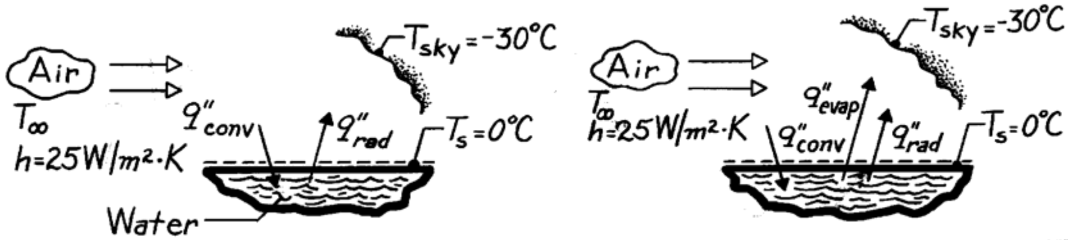
COMMENTS: The evaporative heat loss is dominant.

PROBLEM 6.77

KNOWN: Water freezing under conditions for which the air temperature exceeds 0°C.

FIND: (a) Lowest air temperature, T_∞, before freezing occurs, neglecting evaporation, (b) The mass transfer coefficient, h_m, for the evaporation process, (c) Lowest air temperature, T_∞, before freezing occurs, including evaporation.

SCHEMATIC:



No evaporation With evaporation

ASSUMPTIONS: (1) Steady-state conditions, (2) Water insulated from ground, (3) Water surface has ε = 1, (4) Heat-mass transfer analogy applies, (5) Ambient air is dry.

PROPERTIES: *Table A-4*, Air ($T_f \approx$ 2.5°C ≈ 276K, 1 atm): ρ = 1.2734 kg/m^3, c_p = 1006 J/kg·K, α = 19.3 × 10^{-6}m^2/s; *Table A-6*, Water vapor (273.15K): h_{fg} = 2502 kJ/kg, $\rho_g = 1/v_g$ = 4.847 × 10^{-3}kg/m^3; *Table A-8*, Water vapor - air (298K): $D_{AB} = 0.26\times10^{-4}\,m^2/s$.

ANALYSIS: (a) Neglecting evaporation and performing an energy balance,

$$q''_{conv} - q''_{rad} = 0$$

$$h\left(T_\infty - T_s\right) - \varepsilon\sigma\left(T_s^4 - T_{sky}^4\right) = 0 \quad \text{or} \quad T_\infty = T_s + \left(\varepsilon\sigma/h\right)\left(T_s^4 - T_{sky}^4\right)$$

$$T_\infty = 0^\circ C + \frac{1\times5.667\times10^{-8}\ W/m^2\cdot K^4}{25\ W/m^2\cdot K}\left[\left(0+273\right)^4 - \left(-30+273\right)^4\right] = 4.69^\circ C. \quad <$$

(b) Invoking the heat-mass transfer analogy in the form of Eq. 6.60 with n = 1/3,

$$\frac{h}{h_m} = \rho\ c_p Le^{2/3} \quad \text{or} \quad h_m = h/\rho\ c_p Le^{2/3} \quad \text{where} \quad Le = \alpha/D_{AB}$$

$$h_m = \left(25\ W/m^2\cdot K\right)/1.273\ kg/m^3\left(1006\ J/kg\cdot K\right)\left[\frac{19.3\times10^{-6}m^2/s}{0.26\times10^{-4}m^2/s}\right]^{2/3} = 0.0238\ m/s. \quad <$$

(c) Including evaporation effects and performing an energy balance gives $q''_{conv} - q''_{rad} - q''_{evap} = 0$

where $q''_{evap} = \dot{m}''h_{fg} = h_m\left(\rho_{A,s} - \rho_{A,\infty}\right)h_{fg}$, $\rho_{A,s} = \rho_g$ and $\rho_{A,\infty} = 0$. Hence,

$$T_\infty = T_s + \left(\varepsilon\sigma/h\right)\left(T_s^4 - T_{sky}^4\right) + \left(h_m/h\right)\left(\rho_g - 0\right)h_{fg}$$

$$T_\infty = 4.69^\circ C + \frac{0.0238\ m/s}{25\ W/m^2\cdot K}\times4.847\times10^{-3}kg/m^3\times2.502\times10^6 J/kg$$

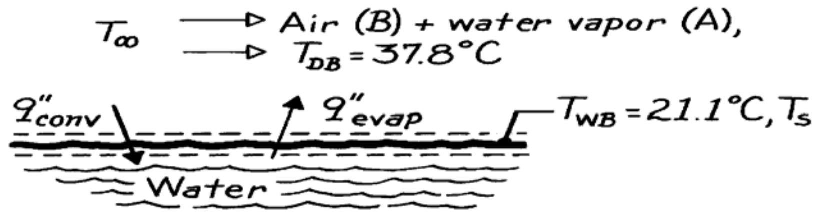
$$T_\infty = 4.69^\circ C + 11.5^\circ C = 16.2^\circ C. \quad <$$

PROBLEM 6.78

KNOWN: Wet-bulb and dry-bulb temperature for water vapor-air mixture.

FIND: (a) Partial pressure, p_A, and relative humidity, ϕ, using Carrier's equation, (b) p_A and ϕ using psychrometric chart, (c) Difference between air stream, T_∞, and wet bulb temperatures based upon evaporative cooling considerations.

SCHEMATIC:



ASSUMPTIONS: (1) Evaporative cooling occurs at interface, (2) Heat-mass transfer analogy applies, (3) Species A and B are perfect gases.

PROPERTIES: *Table A-6*, Water vapor: $p_{A,sat}$ (21.1°C) = 0.02512 bar, $p_{A,sat}$ (37.8°C) = 0.06603 bar, h_{fg} (21.1°C) = 2451 kJ/kg; *Table A-4*, Air ($T_{am} = [T_{WB} + T_{DB}]/2 \cong 300K$, 1 atm): $\alpha = 22.5 \times 10^{-6}$ m^2/s, c_p = 1007 J/kg·K, ρ = 1.15 kg/m^3; *Table A-8*, Air-water vapor (298K): $D_{AB} = 0.26 \times 10^{-4}$ m^2/s.

ANALYSIS: (a) Carrier's equation has the form

$$p_v = p_{gw} - \frac{\left(p - p_{gw}\right)\ \left(T_{DB} - T_{WB}\right)}{1810 - T_{WB}}$$

where p_v = partial pressure of vapor in air stream, bar

p_{gw} = sat. pressure at TWB = 21.1°C, 0.02512 bar

p = total pressure of mixture, 1.033 bar

T_{DB} = dry bulb temperature, 37.8°C

T_{WB} = wet bulb temperature, 21.1°C.

Hence,

$$p_v = 0.02512\text{ bar} - \frac{\left(1.013 - 0.02512\right)\text{bar} \times \left(37.8 - 21.1\right)^\circ\text{C}}{1810 - \left(21.1 + 273.1\right)\text{K}} = 0.0142\text{ bar.}$$

The relative humidity, ϕ, is then

$$\phi \equiv \frac{p_A}{p_{A,sat}} = \frac{p_v}{p_A\left(37.8^\circ\text{C}\right)} = \frac{0.0142\text{ bar}}{0.06603\text{ bar}} = 0.214. \qquad <$$

(b) Using a psychrometric chart

$$\left.\begin{matrix} T_{WB} = 21.1^\circ\text{C} = 70^\circ\text{F} \\ T_{DB} = 37.8^\circ\text{C} = 100^\circ\text{F} \end{matrix}\right\} \qquad \phi \approx 0.225 \qquad <$$

$$p_v = \phi p_{sat} = 0.225 \times 0.06603\text{ bar} = 0.0149\text{ bar.} \qquad <$$

Continued …

(c) An application of the heat-mass transfer analogy is the process of evaporative cooling which occurs when air flows over water. The change in temperature is estimated by Eq. 6.65.

$$T_\infty - T_s = \frac{\mathcal{M}_A \; h_{fg}}{\mathcal{R} \; \rho \, c_p \; L\, e^{2/3}} \left[\frac{p_{A,sat}(T_s)}{T_s} - \frac{p_{A,\infty}}{T_\infty} \right]$$

or

$$(37.8 - 21.1)\text{K} = \frac{(18\text{kg/kmol} \times 2451 \times 10^3\,\text{J/kg})}{8.314 \times 10^{-2}\,\text{m}^3\text{bar/kmol}\cdot\text{K} \times 1.16\,\text{kg/m}^3 \times 1007\,\text{J/kg}\cdot\text{K} \times \left(\dfrac{22.5 \times 10^{-6}\,\text{m}^2/\text{s}}{0.26 \times 10^{-4}\,\text{m}^2/\text{s}} \right)^{2/3}}$$

$$\times \left[\frac{0.02512\,\text{bar}}{(273 + 21.1)\text{K}} + \frac{p_{A,\infty}}{(273 + 37.8)\text{K}} \right]$$

Thus, $p_{A,\infty} = 0.016$ bar

and

$$\phi = p_A/p_{A,sat} = p_v/p_{A,sat} = 0.016 \text{ bar}/0.06603 \text{ bar} = 0.242$$ <

COMMENTS: The following table compares results from the two calculation methods.

	Carrier's Eq.	*Psychrometric Chart*
p_V (bar)	0.0142	0.016
ϕ	0.214	0.242

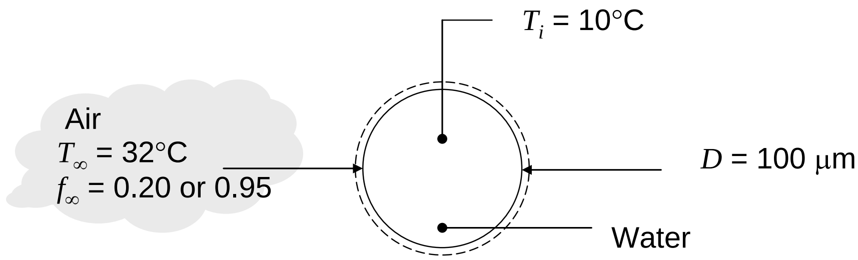
$$\% \text{ Difference: } \frac{0.242 - 0.214}{0.214} \times 100 \;=\; 13.1\%.$$

PROBLEM 6.79

KNOWN: Initial temperature and droplet diameter of water mist. Expression for Nusselt number. Temperature and relative humidity of air stream.

FIND: (a) Initial convection heat transfer rate, evaporative heat loss rate, and rate of change of droplet temperature, (b) Steady-state droplet temperature.

SCHEMATIC:



ASSUMPTIONS: (1) The properties of the air-water vapor mixture can be approximated by pure air properties, (2) Air properties and D_{AB} evaluated at $T_{am} = (T_s + T_\infty)/2$.

PROPERTIES: *Table A-4*, Air (T = 294 K): k = 0.0258 W/m·K; *Table A-8*, H_2O in Air (T = 294 K): $D_{AB} = 0.26 \times 10^{-4}$ m^2/s $(294/298)^{3/2} = 0.255 \times 10^{-4}$ m^2/s; *Table A-6*, Water (T = 283 K): $\rho_{A,sat}(T_s)$ = 1/111.8 m^3/kg = 0.00894 kg/m^3, h_{fg} = 2478 kJ/kg, ρ_w = 1000 kg/m^3, $c_{p,w}$ = 4193 J/kg·K; (T = 305 K): $\rho_{A,sat}(T_\infty)$ = 1/29.74 m^3/kg = 0.0336 kg/m^3.

ANALYSIS: (a) The convection heat transfer coefficient is

$$\bar{h} = \overline{Nu}_D k / D = 2k / D = 2 \times 0.0258 \text{ W/m} \cdot \text{K} / 100 \times 10^{-6} \text{ m} = 516 \text{ W/m}^2 \cdot \text{K}$$

At the initial time, when the droplet temperature is T_i = 10°C, the convection heat transfer rate to the droplet is given by

$$q_{\text{conv}} = \bar{h} A_s (T_\infty - T_i) = 516 \text{ W/m}^2 \cdot \text{K} \times \pi (100 \times 10^{-6} \text{ m})^2 \times (32 - 10)°\text{C} = 357 \times 10^{-6} \text{ W} \quad <$$

Referring to Eq. 6.59, since Nu is independent of Pr, n = 0, and we have

$$Nu = Sh = 2 \qquad \text{or} \qquad \bar{h}_m = 2D_{AB} / D = 2 \times 0.255 \times 10^{-4} \text{ m}^2\text{/s} / 100 \times 10^{-6} \text{ m} = 0.510 \text{ m/s}$$

Thus the rate of evaporative heat loss can be expressed as

$$q_{\text{evap}} = \dot{m}_{\text{evap}} h_{fg} = \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty}) h_{fg}$$

For ϕ_∞ = 0.20, $\rho_{A,\infty} = \phi_\infty \rho_{A,sat}(T_\infty) = 0.2 \times 0.0336$ kg/m^3 = 0.00672 kg/m^3. Thus,

$$\begin{aligned} q_{\text{evap}} &= \dot{m}_{\text{evap}} h_{fg} = \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty}) h_{fg} \\ &= 0.510 \text{ m/s} \times \pi (100 \times 10^{-6} \text{ m})^2 \times (0.00894 - 0.00672) \text{ kg/m}^3 \times 2478 \times 10^3 \text{ J/kg} \\ &= 88.1 \times 10^{-6} \text{ W} \end{aligned} \quad <$$

Continued…

PROBLEM 6.79 (Cont.)

Similarly, for $\phi_\infty = 0.95$, $\rho_{A,\infty} = \phi_\infty \rho_{A,sat}(T_\infty) = 0.95 \times 0.0336\ kg/m^3 = 0.0319\ kg/m^3$

$$q_{evap} = -912 \times 10^{-6}\ \text{W} \qquad <$$

The rate of change of temperature of the droplet can be found from an energy balance on the droplet:

$$\left(\rho c_p V\right)_w \frac{dT}{dt} = q_{conv} - q_{evap}$$

For $\phi_\infty = 0.20$,

$$\frac{dT}{dt} = \frac{q_{conv} - q_{evap}}{\left(\rho c_p V\right)_w} = \frac{(357 - 88.1) \times 10^{-6}\ \text{W}}{1000\ \text{kg/m}^3 \times 4193\ \text{J/kg} \cdot \text{K} \times \pi \times (100 \times 10^{-6}\ \text{m})^3 / 6} = 122\ \text{K/s} \qquad <$$

And for $\phi_\infty = 0.95$,

$$\frac{dT}{dt} = \frac{q_{conv} - q_{evap}}{\left(\rho c_p V\right)_w} = \frac{(357 + 912) \times 10^{-6}\ \text{W}}{1000\ \text{kg/m}^3 \times 4193\ \text{J/kg} \cdot \text{K} \times \pi \times (100 \times 10^{-6}\ \text{m})^3 / 6} = 578\ \text{K/s} \qquad <$$

For $\phi_\infty = 0.20$, the evaporative heat loss is positive; the droplet is evaporating. Convection from the warm air is warming the droplet, while evaporation is cooling it. The net effect is to warm the droplet. For $\phi_\infty = 0.95$, the evaporative heat loss is negative; water from the humid environment is condensing on the droplet. Both convection and condensation cause warming of the droplet, so the rate of temperature increase is higher in this case. Eventually, the droplet will become warm enough so that condensation ceases and evaporation will begin. <

(b) At steady-state, an energy balance requires $q_{conv} = q_{evap}$. Eq. 6.64 applies, with $\overline{h}_m / \overline{h} = D_{AB} / k$. Thus, the following implicit equation must be solved for T_s:

$$T_\infty - T_s = h_{fg} \frac{D_{AB}}{k} [\rho_{A,sat}(T_s) - \rho_{A,\infty}]$$

where the properties D_{AB} and k should be evaluated at $T_{am} = (T_s + T_\infty)/2$, and h_{fg} should be evaluated at T_s. This equation is most easily solved in IHT, which yields

$T_s = 289$ K for $\phi_\infty = 0.20$ <

$T_s = 304$ K for $\phi_\infty = 0.95$ <

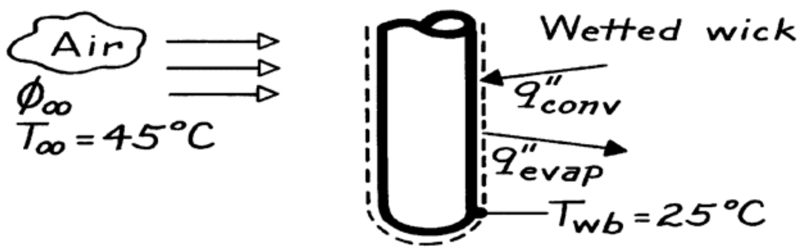
COMMENTS: (1) As expected, the steady-state droplet temperature is lower for the low humidity conditions. (2) The steady-state temperature does not depend on the droplet diameter because the areas for convection and evaporation are the same and the heat and mass transfer coefficients have the same dependence on diameter. (3) Based on the initial rate of temperature increase, it appears that the droplet will take less than 1 s to reach its steady-state temperature. A complete analysis of the transient problem shows that the steady-state temperature is reached in approximately 0.17 and 0.15 s for the $\phi_\infty = 0.20$ and 0.95 cases, respectively. In this time period, the change in diameter of the droplet is less than 1% in both cases. Of course, the droplet will eventually evaporate.

PROBLEM 6.80

KNOWN: Wet and dry bulb temperatures.

FIND: Relative humidity of air.

SCHEMATIC:



ASSUMPTIONS: (1) Perfect gas behavior for vapor, (2) Steady-state conditions, (3) Negligible radiation, (4) Negligible conduction along thermometer.

PROPERTIES: *Table A-4*, Air (308K, 1 atm): $\rho = 1.135$ kg/m^3, $c_p = 1007$ J/kg·K, $\alpha = 23.7 \times 10^{-6}$ m^2/s; *Table A-6*, Saturated water vapor (298K): $v_g = 44.25$ m^3/kg, $h_{fg} = 2443$ kJ/kg; (318K): $v_g = 15.52$ m^3/kg; *Table A-8*, Air-vapor (1 atm, 298K): $D_{AB} = 0.26 \times 10^{-4}$ m^2/s, D_{AB} (308K) = 0.26×10^{-4} m^2/s $\times (308/298)^{3/2} = 0.27 \times 10^{-4}$ m^2/s, Le = $\alpha/D_{AB} = 0.88$.

ANALYSIS: From an energy balance on the wick, Eq. 6.64 follows from Eq. 6.61. Dividing Eq. 6.64 by $\rho_{A,sat}(T_\infty)$,

$$\frac{T_\infty - T_s}{\rho_{A,sat}(T_\infty)} = h_{fg}\left[\frac{h_m}{h}\right]\left[\frac{\rho_{A,sat}(T_s)}{\rho_{A,sat}(T_\infty)} - \frac{\rho_{A,\infty}}{\rho_{A,sat}(T_\infty)}\right].$$

With $\left[\rho_{A,\infty}/\rho_{A,sat}(T_\infty)\right] \approx \phi_\infty$ for a perfect gas and h/h_m given by Eq. 6.60,

$$\phi_\infty = \frac{\rho_{A,sat}(T_s)}{\rho_{A,sat}(T_\infty)} - \frac{\rho\, c_p Le^{2/3}}{\rho_{A,sat}(T_\infty) h_{fg}}(T_\infty - T_s).$$

Using the property values, evaluate

$$\frac{\rho_{A,sat}(T_s)}{\rho_{A,sat}(T_\infty)} = \frac{v_g(T_\infty)}{v_g(T_s)} = \frac{15.52}{44.25} = 0.351$$

$$\rho_{A,sat}(T_\infty) = \left(15.52\ \text{m}^3/\text{kg}\right)^{-1} = 0.064\ \text{kg/m}^3.$$

Hence,

$$\phi_\infty = 0.351 - \frac{1.135\ \text{kg/m}^3\ (1007\ \text{J/kg}\cdot\text{K})(0.88)^{2/3}}{0.064\ \text{kg/m}^3\ \left(2.443\times10^6\ \text{J/kg}\right)}(45-25)\text{K}$$

$$\phi_\infty = 0.351 - 0.133 = 0.218.$$ <

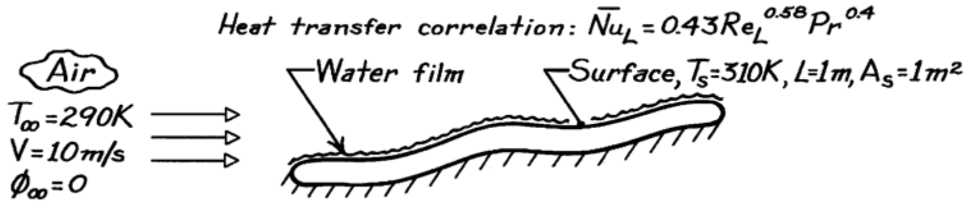
COMMENTS: Note that latent heat must be evaluated at the surface temperature (evaporation occurs at the surface).

PROBLEM 6.81

KNOWN: Heat transfer correlation for a contoured surface heated from below while experiencing air flow across it. Flow conditions and steady-state temperature when surface experiences evaporation from a thin water film.

FIND: (a) Heat transfer coefficient and convection heat rate, (b) Mass transfer coefficient and evaporation rate (kg/h) of the water, (c) Rate at which heat must be supplied to surface for these conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Heat-mass transfer analogy applies, (3) Correlation requires properties evaluated at $T_f = (T_s + T_\infty)/2$.

PROPERTIES: *Table A-4*, Air ($T_f = (T_s + T_\infty)/2 = (290 + 310)K/2 = 300$ K, 1 atm): $\nu = 15.89 \times 10^{-6} m^2/s$, k = 0.0263 W/m·K, Pr = 0.707; *Table A-8*, Air-water mixture (300 K, 1 atm): $D_{AB} = 0.26 \times 10^{-4}\ m^2/s$; *Table A-6*, Sat. water (T_s = 310 K): $\rho_{A,sat} = 1/v_g = 1/22.93\ m^3/kg = 0.04361\ kg/m^3$, h_{fg} = 2414 kJ/kg.

ANALYSIS: (a) To characterize the flow, evaluate Re_L at T_f

$$Re_L = \frac{VL}{\nu} = \frac{10\ m/s \times 1\ m}{15.89 \times 10^{-6} m^2/s} = 6.293 \times 10^5$$

and substituting into the prescribed correlation for this surface, find

$$\overline{Nu}_L = 0.43\left(6.293 \times 10^5\right)^{0.58}(0.707)^{0.4} = 864.1$$

$$\bar{h}_L = \frac{\overline{Nu}_L \cdot k}{L} = \frac{864.1 \times 0.0263\ W/m \cdot K}{1\ m} = 22.7\ W/m^2 \cdot K. \quad <$$

Hence, the convection heat rate is

$$q_{conv} = \bar{h}_L A_s (T_s - T_\infty)$$

$$q_{conv} = 22.7\ W/m^2 \cdot K \times 1\ m^2 (310 - 290) K = 454\ W \quad <$$

(b) Invoking the heat-mass transfer analogy

$$\overline{Sh}_L = \frac{\bar{h}_m L}{D_{AB}} = 0.43 Re_L^{0.58} Sc^{0.4}$$

where

$$Sc = \frac{\nu}{D_{AB}} = \frac{15.89 \times 10^{-6} m^2/s}{0.26 \times 10^{-4} m^2/s} = 0.611$$

and ν is evaluated at T_f. Substituting numerical values, find

Continued …

PROBLEM 6.81 (Cont.)

$$\overline{Sh}_L = 0.43\left(6.293\times10^5\right)^{0.58}(0.611)^{0.4} = 815.2$$

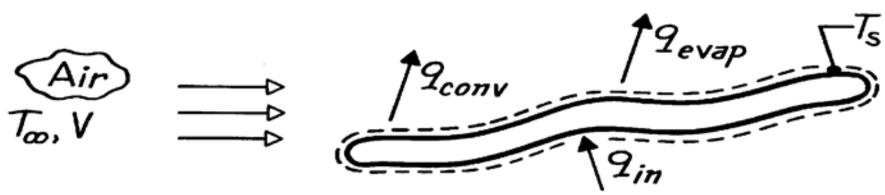
$$\bar{h}_m = \frac{\overline{Sh}_L \cdot D_{AB}}{L} = \frac{815.2\times0.26\times10^{-4}\,m^2/s}{1\ m} = 2.12\times10^{-2}\ m/s. \quad <$$

The evaporation rate, with $\rho_{A,s} = \rho_{A,sat}(T_s)$, is

$$\dot{m} = \bar{h}_m A_s\left(\rho_{A,s} - \rho_{A,\infty}\right)$$
$$\dot{m} = 2.12\times10^{-2}\ m/s\times1\ m^2\,(0.04361\ -\ 0)\,kg/m^3$$

$$\dot{m} = 9.243\times10^{-4} kg/s = 3.32\ kg/h. \quad <$$

(c) The rate at which heat must be supplied to the plate to maintain these conditions follows from an energy balance.



$$\dot{E}_{in} - \dot{E}_{out} = 0$$
$$q_{in} - q_{conv} - q_{evap} = 0$$

where q_{in} is the heat supplied to sustain the losses by convection and evaporation.

$$q_{in} = q_{conv} + q_{evap}$$
$$q_{in} = \bar{h}_L A_s\left(T_s - T_\infty\right) + \dot{m}h_{fg}$$
$$q_{in} = 454\ W\ +\ 9.243\times10^{-4}\ kg/s\times2414\times10^3\ J/kg$$

$$q_{in} = (254 + 2231)\,W = 2685\ W. \quad <$$

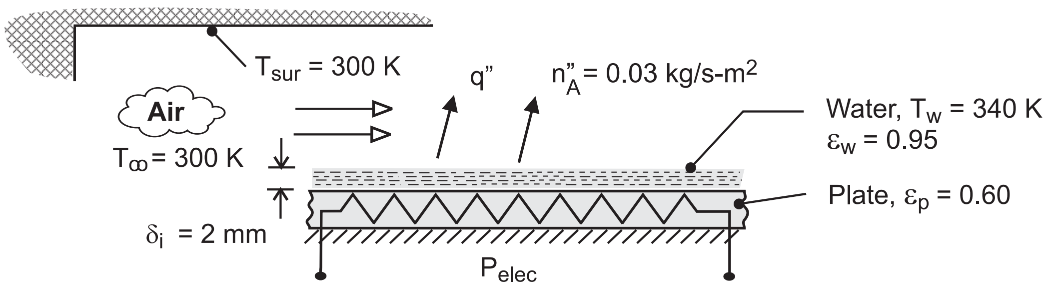
COMMENTS: Note that the loss from the surface by evaporation is nearly 5 times that due to convection.

PROBLEM 6.82

KNOWN: Thickness, temperature and evaporative flux of a water layer. Temperature of air flow and surroundings.

FIND: (a) Convection mass transfer coefficient and time to completely evaporate the water, (b) Convection heat transfer coefficient, (c) Heater power requirement per surface area, (d) Temperature of dry surface if heater power is maintained.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Applicability of heat and mass transfer analogy with n = 1/3, (3) Radiation exchange at surface of water may be approximated as exchange between a small surface and large surroundings, (4) Air is dry ($\rho_{A,\infty} = 0$), (5) Negligible heat transfer from unwetted surface of the plate.

PROPERTIES: *Table A-6*, Water (T_w = 340K): $\rho_f = 979$ kg/m^3, $\rho_{A,sat} = v_g^{-1} = 0.174\,kg/m^3$, $h_{fg} = 2342\,kJ/kg$. Prescribed, Air: $\rho = 1.08$ kg/m^3, c_p = 1008 J/kg·K, k = 0.028 W/m·K. Vapor/Air: $D_{AB} = 0.29 \times 10^{-4}$ m^2/s. Water: $\varepsilon_w = 0.95$. Plate: $\varepsilon_p = 0.60$.

ANALYSIS: (a) The convection mass transfer coefficient may be determined from the rate equation $n''_A = h_m\left(\rho_{A,s} - \rho_{A,\infty}\right)$, where $\rho_{A,s} = \rho_{A,sat}\left(T_w\right)$ and $\rho_{A,\infty} = 0$. Hence,

$$h_m = \frac{n''_A}{\rho_{A,sat}} = \frac{0.03\,kg/s\cdot m^2}{0.174\,kg/m^3} = 0.172\,m/s \qquad <$$

The time required to completely evaporate the water is obtained from a mass balance of the form $-n''_A = \rho_f\, d\delta/dt$, in which case

$$\rho_f \int_{\delta_i}^{0} d\delta = -n''_A \int_0^t dt$$

$$t = \frac{\rho_f \delta_i}{n''_A} = \frac{979\,kg/m^3\left(0.002m\right)}{0.03\,kg/s\cdot m^2} = 65.3s \qquad <$$

(b) With n = 1/3 and Le = $\alpha/D_{AB} = k/\rho c_p D_{AB}$ = 0.028 W/m·K/(1.08 kg/m^3 × 1008 J/kg·K × 0.29 × 10^{-4} m^2/s) = 0.887, the heat and mass transfer analogy yields

$$h = \frac{k\,h_m}{D_{AB}Le^{1/3}} = \frac{0.028\,W/m\cdot K\left(0.172\,m/s\right)}{0.29\times10^{-4}m^2/s\left(0.887\right)^{1/3}} = 173\,W/m^2\cdot K \qquad <$$

The electrical power requirement per unit area corresponds to the rate of heat loss from the water. Hence,

Continued …

PROBLEM 6.82 (Cont.)

$$P''_{elec} = q''_{evap} + q''_{conv} + q''_{rad} = n''_A h_{fg} + h\left(T_w - T_\infty\right) + \varepsilon_w \sigma \left(T_w^4 - T_{sur}^4\right)$$

$$P''_{elec} = 0.03\,\text{kg/s}\cdot\text{m}^2 \left(2.342\times10^6\ \text{J/kg}\right) + 173\,\text{W/m}^2\cdot\text{K}\left(40\text{K}\right) + 0.95\times5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left(340^4 - 300^4\right)$$

$$P''_{elec} = 70{,}260\,\text{W/m}^2 + 6920\,\text{W/m}^2 + 284\,\text{W/m}^2 = 77{,}464\,\text{W/m}^2$$ <

(c) After complete evaporation, the steady-state temperature of the plate is determined from the requirement that

$$P''_{elec} = h\left(T_p - T_\infty\right) + \varepsilon_p \sigma \left(T_p^4 - T_{sur}^4\right)$$

$$77{,}464\,\text{W/m}^2 = 173\,\text{W/m}^2\cdot\text{K}\left(T_p - 300\right) + 0.60\times5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left(T_p^4 - 300^4\right)$$

$$T_p = 702\text{K} = 429°\text{C}$$ <

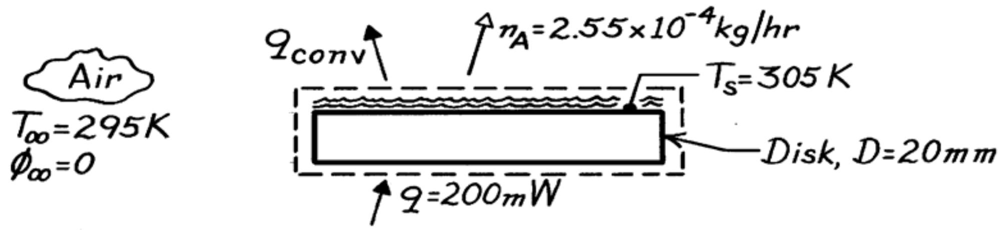
COMMENTS: The evaporative heat flux is the dominant contributor to heat transfer from the water layer, with convection of sensible energy being an order of magnitude smaller and radiation exchange being negligible. Without evaporation (a dry surface), convection dominates and is approximately an order of magnitude larger than radiation.

PROBLEM 6.83

KNOWN: Heater power required to maintain water film at prescribed temperature in dry ambient air and evaporation rate.

FIND: (a) Average mass transfer convection coefficient $\overline{h}_m$, (b) Average heat transfer convection coefficient $\overline{h}$, (c) Whether values of $\overline{h}_m$ and $\overline{h}$ satisfy the heat-mass analogy, and (d) Effect on evaporation rate and disc temperature if relative humidity of the ambient air were increased from 0 to 0.5 but with heater power maintained at the same value.

SCHEMATIC:



ASSUMPTIONS: (1) Water film and disc are at same temperature; (2) Mass and heat transfer coefficient are independent of ambient air relative humidity, (3) Constant properties.

PROPERTIES: *Table A-6*, Saturated water (305 K): v_g = 29.74 m^3/kg, h_{fg} = 2426 × 10^3 J/kg; *Table A-4*, Air $(\overline{T} = 300\text{ K, 1 atm})$: k = 0.0263 W/m·K, α = 22.5 × 10^{-6} m^2/s, *Table A-8,* Air-water vapor (300 K, 1 atm): D_{AB} = 0.26 × 10^{-4} m^2/s.

ANALYSIS: (a) Using the mass transfer convection rate equation,

$$n_A = \overline{h}_m A_s \left(\rho_{A,s} - \rho_{A,\infty}\right) = \overline{h}_m A_s \rho_{A,sat}\left(1 - \phi_\infty\right)$$

and evaluating $\rho_{A,s} = \rho_{A,sat}$ (305 K) = 1/v_g (305 K) with $\phi_\infty \sim \rho_{A,\infty}$ = 0, find

$$\overline{h}_m = \frac{n_A}{A_s\left(\rho_{A,s} - \rho_{A,\infty}\right)}$$

$$\overline{h}_m = \frac{2.55\times10^{-4}\text{ kg/hr}/\left(3600\text{ s/hr}\right)}{\left(\pi\left(0.020\text{ m}\right)^2/4\right)\left(1/29.74 - 0\right)\text{kg/m}^3} = 6.71\times10^{-3}\text{ m/s.}$$ <

(b) Perform an overall energy balance on the disc,

$$q = q_{conv} + q_{evap} = \overline{h}A_s\left(T_s - T_\infty\right) + n_A h_{fg}$$

and substituting numerical values with h_{fg} evaluated at T_s, find $\overline{h}$:

$$200\times10^{-3}\text{ W} = \overline{h}\pi\left(0.020\text{ m}\right)^2/4\left(305-295\right)\text{K} + 7.083\times10^{-8}\text{ kg/s}\times2426\times10^3\text{ J/kg}$$

$$\overline{h} = 8.97\text{ W/m}^2\cdot\text{K.}$$ <

Continued …

PROBLEM 6.83 (Cont.)

(c) The heat-mass transfer analogy, Eq. 6.67, requires that

$$\frac{\bar{h}}{h_m} \stackrel{?}{=} \frac{k}{D_{AB}}\left(\frac{D_{AB}}{\alpha}\right)^{1/3}.$$

Evaluating k and D_{AB} at $\bar{T} = (T_s + T_\infty)/2 = 300$ K and substituting numerical values,

$$\frac{8.97\ \text{W/m}^2\cdot\text{K}}{6.71\times10^{-3}\ \text{m/s}} = 1337 \neq \frac{0.0263\ \text{W/m}\cdot\text{K}}{0.26\times10^{-4}\ \text{m}^2/\text{s}}\left(\frac{0.26\times10^{-4}\ \text{m}^2/\text{s}}{22.5\times10^{-6}\ \text{m}^2/\text{s}}\right)^{1/3} = 1061$$

Since the equality is not satisfied, we conclude that, for this situation, the analogy is only approximately met (≈ 30%).

(d) If $\phi_\infty = 0.5$ instead of 0.0 and q is unchanged, n_A will decrease by nearly a factor of two, as will $n_A h_{fg} = q_{evap}$. Hence, since q_{conv} must increase and $\bar{h}$ remains nearly constant, $T_s - T_\infty$ must increase. Hence, T_s will increase.

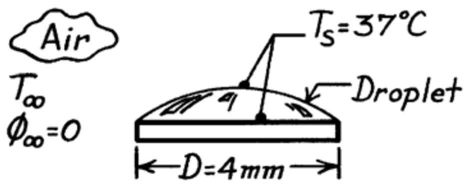
COMMENTS: Note that in part (d), with an increase in T_s, h_{fg} decreases, but only slightly, and $\rho_{A,sat}$ increases. From a trial-and-error solution assuming constant values for $\bar{h}_m$ and h, the disc temperature is 315 K for $\phi_\infty = 0.5$.

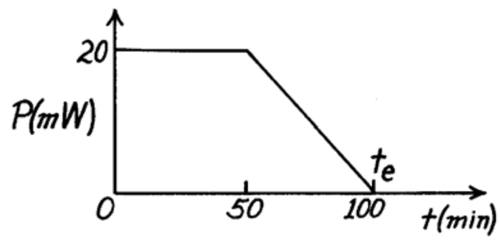
PROBLEM 6.84

KNOWN: Power-time history required to completely evaporate a droplet of fixed diameter maintained at 37°C.

FIND: (a) Average mass transfer convection coefficient when droplet, heater and dry ambient air are at 37°C and (b) Energy required to evaporate droplet if the dry ambient air temperature is 27°C.

SCHEMATIC:





ASSUMPTIONS: (1) Wetted surface area of droplet is of fixed diameter D, (2) Heat-mass transfer analogy is applicable, (3) Heater controlled to operate at constant temperature, T_s = 37°C, (4) Mass of droplet same for part (a) and (b), (5) Mass transfer coefficients for parts (a) and (b) are the same.

PROPERTIES: *Table A-6*, Saturated water (37°C = 310 K): h_{fg} = 2414 kJ/kg, $\rho_{A,sat} = 1/v_g$ = 1/22.93 = 0.04361 kg/m^3; *Table A-8*, Air-water vapor (T_s = 37°C = 310 K, 1 atm): D_{AB} = 0.26×10^{-6} m^2/s(310/298)$^{3/2}$ = 0.276×10^{-6} m^2/s; *Table A-4*, Air ($\bar{T}$ = (27 + 37)°C/2 = 305 K, 1 atm): ρ = 1.1448 kg/m^3, c_p = 1008 J/kg·K, $\nu = 16.39 \times 10^{-6}$ m^2/s, Pr = 0.706.

ANALYSIS: (a) For the isothermal conditions (37°C), the electrical energy Q required to evaporate the droplet during the interval of time $\Delta t = t_e$ follows from the area under the P-t curve above,

$$Q = \int_0^{t_e} Pdt = \left[20\times10^{-3}\ W\times(50\times60)s + 0.5\times20\times10^{-3}\ W(100-50)\times60s\right]$$

$$Q = 90\ J.$$

From an overall energy balance during the interval of time $\Delta t = t_e$, the mass loss due to evaporation is

$$Q = Mh_{fg} \quad \text{or} \quad M = Q/h_{fg}$$

$$M = 90\ J/2414\times10^3\ J/kg = 3.728\times10^{-5}\ kg.$$

To obtain the average mass transfer coefficient, write the rate equation for an interval of time $\Delta t = t_e$,

$$M = \dot{m}\cdot t_e = \bar{h}_m A_s\left(\rho_{A,s} - \rho_{A,\infty}\right)\cdot t_e = \bar{h}_m A_s \rho_{A,s}\left(1-\phi_\infty\right)\cdot t_e$$

Substituting numerical values with $\phi_\infty = 0$, find

$$3.278\times10^{-5}\ kg = \bar{h}_m\left(\pi(0.004\ m)^2/4\right)0.04361\ kg/m^3\times(100\times60)s$$

Continued …

PROBLEM 6.84 (Cont.)

$\overline{h}_m = 0.0113$ m/s. <

(b) The energy required to evaporate the droplet of mass M = 3.728 × 10^{-5} kg follows from an overall energy balance,

$$Q = Mh_{fg} + \overline{h}A_s\left(T_s - T_\infty\right)$$

where $\overline{h}$ is obtained from the heat-mass transfer analogy, Eq. 6.60, using n = 1/3,

$$\frac{\overline{h}}{h_m} = \frac{k}{D_{AB}Le^n} = \rho\, c_p Le^{2/3}$$

where

$$Sc = \frac{\nu}{D_{AB}} = \frac{16.39\times10^{-6}\ m^2/s}{0.276\times10^{-4}\ m^2/s} = 0.594$$

$$Le = \frac{Sc}{Pr} = \frac{0.594}{0.706} = 0.841.$$

Hence,

$$\overline{h} = 0.0113\ m/s\times1.1448\ kg/m^3\times1008\ J/kg\cdot K\left(0.841\right)^{2/3} = 11.62\ W/m^2\cdot K.$$

and the energy requirement is

$$Q = 3.728\times10^{-5}\ kg\times2414\ kJ/kg\ +\ 11.62\ W/m^2\cdot K\left(\pi\left(0.004\ m\right)^2/4\right)\left(37-27\right)^\circ C$$

$$Q\ =\ \left(90.00+0.00145\right)J\ =\ 90\ J.$$ <

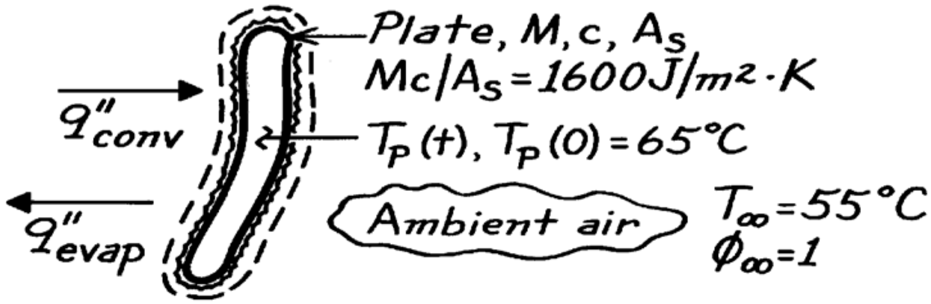
The energy required to meet the convection heat loss is very small compared to that required to sustain the evaporative loss.

PROBLEM 6.85

KNOWN: Initial plate temperature T_p (0) and saturated air temperature (T_∞) in a dishwasher at the start of the dry cycle. Thermal mass per unit area of the plate $Mc/A_s = 1600\ \text{J/m}^2\cdot\text{K}$.

FIND: (a) Differential equation to predict plate temperature as a function of time during the dry cycle and (b) Rate of change in plate temperature at the start of the dry cycle assuming the average convection heat transfer coefficient is 3.5 W/m^2·K.

SCHEMATIC:



ASSUMPTIONS: (1) Plate is spacewise isothermal, (2) Negligible thermal resistance of water film on plate, (3) Heat-mass transfer analogy applies.

PROPERTIES: *Table A-4*, Air ($\bar{T}$ =(55 + 65)°C/2 = 333 K, 1 atm): ρ = 1.0516 kg/m^3, c_p = 1008 J/kg·K, Pr = 0.703, ν = 19.24× 10^{-6} m^2/s; *Table A-6*, Saturated water vapor, (T_s = 65°C = 338 K): $\rho_A = 1/v_g$ = 0.1592 kg/m^3, h_{fg} = 2347 kJ/kg; (T_s = 55°C = 328 K): $\rho_A = 1/v_g$ = 0.1029 kg/m^3; *Table A-8*, Air-water vapor (T_s = 65°C = 338 K, 1 atm): D_{AB} = 0.26 × 10^{-4} m^2/s (338/298)$^{3/2}$ = 0.314 × 10^{-4} m^2/s.

ANALYSIS: (a) Perform an energy balance on a rate basis on the plate,

$$\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st} \qquad q''_{conv} - q''_{evap} = (Mc/A_s)(dT_p/dt).$$

Using the rate equations for the heat and mass transfer fluxes, find

$$\bar{h}\left[T_\infty - T_p(t)\right] - \bar{h}_m\left[\rho_{A,s}(T_s) - \rho_{A,\infty}(T_\infty)\right]h_{fg} = (Mc/A_s)(dT/dt). \qquad <$$

(b) To evaluate the change in plate temperature at t = 0, the start of the drying process when T_p (0) = 65°C and T_∞ = 55°C, evaluate $\bar{h}_m$ from knowledge of $\bar{h} = 3.5\ \text{W/m}^2\cdot\text{K}$ using the heat-mass transfer analogy, Eq. 6.60, with n = 1/3,

$$\frac{\bar{h}}{\bar{h}_m} = \rho\, c_p Le^{2/3} = \rho\, c_p\left(\frac{Sc}{Pr}\right)^{2/3} = \rho\, c_p\left(\frac{\nu/D_{AB}}{Pr}\right)^{2/3}$$

and evaluating thermophysical properties at their appropriate temperatures, find

$$\frac{3.5\ \text{W/m}^2\cdot\text{K}}{\bar{h}_m} = 1.0516\ \text{kg/m}^3 \times 1008\ \text{J/kg}\cdot\text{K}\left(\frac{19.24\times10^{-6}\text{m}^2/\text{s}/0.314\times10^{-4}\text{m}^2/\text{s}}{0.703}\right)^{2/3} \qquad \bar{h}_m = 3.619\times10^{-3}\text{m/s}.$$

Substituting numerical values into the conservation expression of part (a), find

$$3.5\ \text{W/m}^2\cdot\text{K}(55-65)^\circ\text{C} - 3.619\times10^{-3}\text{m/s}(0.1592-0.1029)\text{kg/m}^3\times2347\times10^3\ \text{J/kg} = 1600\ \text{J/m}^2\cdot\text{K}(dT_p/dt)$$

$$dT_p/dt = -[35.0+478.2]\text{W/m}^2\cdot\text{K}/1600\ \text{J/m}^2\cdot\text{K} = -0.32\ \text{K/s}. \qquad <$$

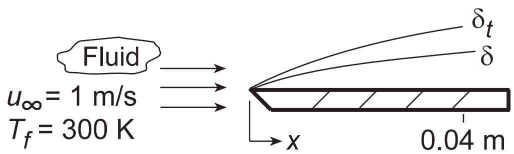
COMMENTS: This rate of temperature change will not be sustained for long, since, as the plate cools, the rate of evaporation (which dominates the cooling process) will diminish.

PROBLEM 7.1

KNOWN: Temperature and velocity of fluids in parallel flow over a flat plate.

FIND: (a) Velocity and thermal boundary layer thicknesses at a prescribed distance from the leading edge, and (b) For each fluid plot the boundary layer thicknesses as a function of distance.

SCHEMATIC:



ASSUMPTIONS: (1) Transition Reynolds number is 5×10^5.

PROPERTIES: *Table A.4*, Air (300 K, 1 atm): $\nu = 15.89 \times 10^{-6}$ m^2/s, Pr = 0.707; *Table A.6*, Water (300 K): $\nu = \mu/\rho = 855 \times 10^{-6}$ N·s/m^2/997 kg/m^3 = 0.858×10^{-6} m^2/s, Pr = 5.83; *Table A.5*, Engine Oil (300 K): $\nu = 550 \times 10^{-6}$ m^2/s, Pr = 6400; *Table A.5*, Mercury (300 K): $\nu = 0.113 \times 10^{-6}$ m^2/s, Pr = 0.0248.

ANALYSIS: (a) If the flow is laminar, the following expressions may be used to compute δ and δ_t, respectively,

$$\delta = \frac{5x}{Re_x^{1/2}} \qquad \delta_t = \frac{\delta}{Pr^{1/3}}$$

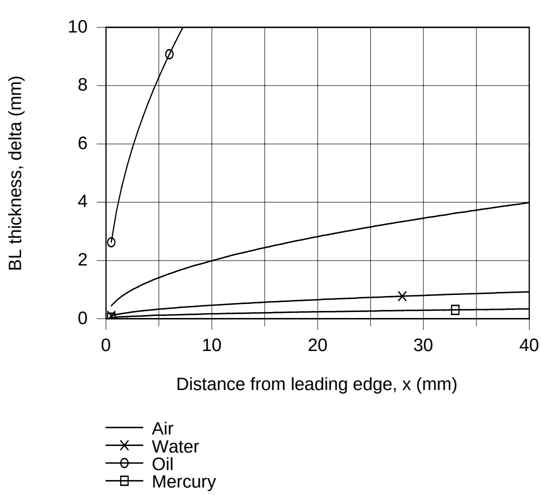
where

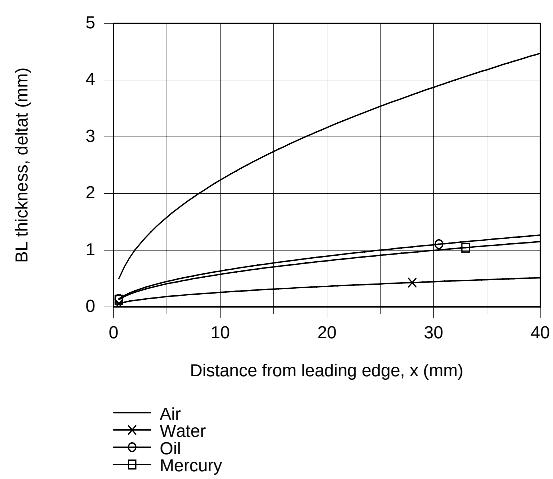
$$Re_x = \frac{u_\infty x}{\nu} = \frac{1\,m/s\,(0.04\,m)}{\nu} = \frac{0.04\,m^2/s}{\nu}$$

Fluid	Re_x	δ (mm)	δ_t (mm)
Air	2517	3.99	4.48
Water	4.66×10^4	0.93	0.52
Oil	72.7	23.5	1.27
Mercury	3.54×10^5	0.34	1.17

<

(b) Using IHT with the foregoing equations, the boundary layer thicknesses are plotted as a function of distance from the leading edge, x.





COMMENTS: (1) Note that $\delta \approx \delta_t$ for air, $\delta > \delta_t$ for water, $\delta >> \delta_t$ for oil, and $\delta < \delta_t$ for mercury. As expected, the boundary layer thicknesses increase with increasing distance from the leading edge.

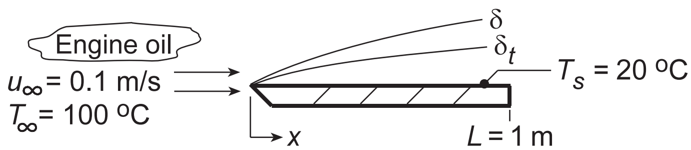
(2) The value of δ_t for mercury should be viewed as a rough approximation since the expression for δ/δ_t was derived subject to the approximation that Pr > 0.6.

PROBLEM 7.2

KNOWN: Temperature and velocity of engine oil. Temperature and length of flat plate.

FIND: (a) Velocity and thermal boundary layer thickness at trailing edge, (b) Heat flux and surface shear stress at trailing edge, (c) Total drag force and heat transfer per unit plate width, and (d) Plot the boundary layer thickness and local values of the shear stress, convection coefficient, and heat flux as a function of x for 0 ≤ x ≤ 1 m.

SCHEMATIC:



ASSUMPTIONS: (1) Critical Reynolds number is 5×10^5, (2) Flow over top and bottom surfaces.

PROPERTIES: *Table A.5*, Engine Oil (T_f = 333 K): $\rho = 864\ kg/m^3$, $\nu = 86.1 \times 10^{-6}\ m^2/s$, k = 0.140 W/m·K, Pr = 1081.

ANALYSIS: (a) Calculate the Reynolds number to determine nature of the flow,

$$Re_L = \frac{u_\infty L}{\nu} = \frac{0.1\,m/s \times 1\,m}{86.1\times 10^{-6}\,m^2/s} = 1161$$

Hence the flow is laminar at x = L. From Eqs. 7.19 and 7.24,

$$\delta = 5L\,Re_L^{-1/2} = 5(1\,m)(1161)^{-1/2} = 0.147\,m \quad <$$

$$\delta_t = \delta\,Pr^{-1/3} = 0.147\,m(1081)^{-1/3} = 0.0143\,m \quad <$$

(b) The local convection coefficient, Eq. 7.23, and heat flux at x = L are

$$h_L = \frac{k}{L}0.332\,Re_L^{1/2}\,Pr^{1/3} = \frac{0.140\,W/m\cdot K}{1m}0.332(1161)^{1/2}(1081)^{1/3} = 16.25\,W/m^2\cdot K$$

$$q''_x = h_L\left(T_s - T_\infty\right) = 16.25\,W/m^2\cdot K\left(20-100\right)^\circ C = -1300\,W/m^2 \quad <$$

Also, the local shear stress is, from Eq. 7.20,

$$\tau_{s,L} = \frac{\rho u_\infty^2}{2}0.664\,Re_L^{-1/2} = \frac{864\,kg/m^3}{2}(0.1\,m/s)^2\,0.664(1161)^{-1/2}$$

$$\tau_{s,L} = 0.0842\,kg/m\cdot s^2 = 0.0842\,N/m^2 \quad <$$

(c) With the drag force per unit width given by $D' = 2L\bar{\tau}_{s,L}$ where the factor of 2 is included to account for both sides of the plate, it follows from Eq. 7.29 that

$$D' = 2L\left(\rho u_\infty^2/2\right)1.328\,Re_L^{-1/2} = (1m)864\,kg/m^3(0.1\,m/s)^2\,1.328(1161)^{-1/2} = 0.337\,N/m \quad <$$

For laminar flow, the average value $\bar{h}_L$ over the distance 0 to L is twice the local value, h_L,

$$\bar{h}_L = 2h_L = 32.5\,W/m^2\cdot K$$

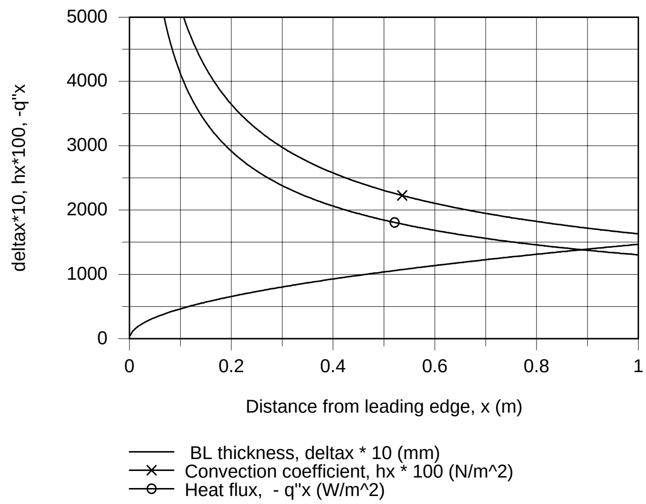
The total heat transfer rate per unit width of the plate is

$$q' = 2L\bar{h}_L\left(T_s - T_\infty\right) = 2(1m)32.5\,W/m^2\cdot K\left(20-100\right)^\circ C = -5200\,W/m \quad <$$

Continued...

PROBLEM 7.2 (Cont.)

(c) Using IHT with the foregoing equations, the boundary layer thickness, and local values of the convection coefficient and heat flux were calculated and plotted as a function of x.



COMMENTS: (1) Note that since Pr >> 1, $\delta >> \delta_t$. That is, for the high Prandtl liquids, the velocity boundary layer will be much thicker than the thermal boundary layer.

(2) A copy of the *IHT Workspace* used to generate the above plot is shown below.

```
// Boundary layer thickness, delta
delta = 5 * x * Rex ^-0.5
delta_mm = delta * 1000
delta_plot = delta_mm * 10          // Scaling parameter for convenience in  plotting

// Convection coefficient and heat flux, q''x
q''x = hx * (Ts - Tinf)
Nux = 0.332 * Rex^0.5 * Pr^(1/3)
Nux = hx * x / k
hx_plot = 100 * hx                  // Scaling parameter for convenience in plotting
q''x_plot = ( -1 ) * q''x           // Scaling parameter for convenience in plotting

// Reynolds number
Rex = uinf * x / nu

// Properties Tool: Engine oil
// Engine Oil property functions : From Table A.5
// Units: T(K)
rho = rho_T("Engine Oil",Tf)        // Density, kg/m^3
cp = cp_T("Engine Oil",Tf)          // Specific heat, J/kg·K
nu = nu_T("Engine Oil",Tf)          // Kinematic viscosity, m^2/s
k = k_T("Engine Oil",Tf)            // Thermal conductivity, W/m·K
Pr = Pr_T("Engine Oil",Tf)          // Prandtl number

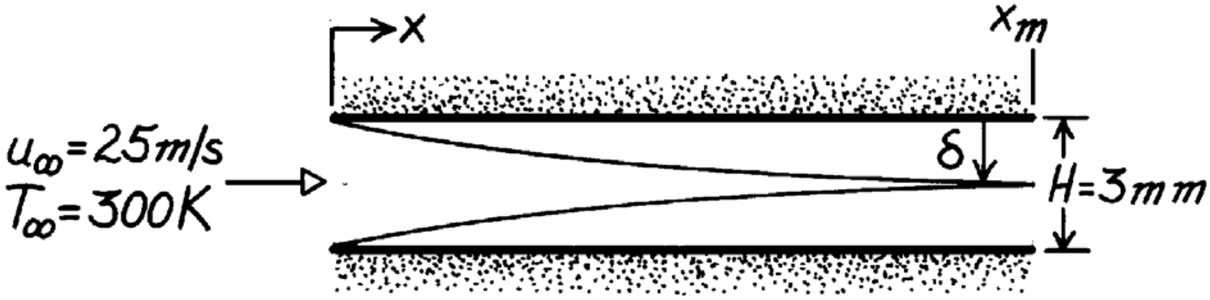
// Assigned variables
Tf = (Ts + Tinf) / 2                // Film temperature, K
Tinf = 100 + 273                    // Freestream temperature, K
Ts = 20 + 273                       // Surface temperature, K
uinf = 0.1                          // Freestream velocity, m/s
x = 1                               // Plate length, m
```

PROBLEM 7.3

KNOWN: Velocity and temperature of air in parallel flow over a flat plate.

FIND: (a) Velocity boundary layer thickness at selected stations. Distance at which boundary layers merge for plates separated by H = 3 mm. (b) Surface shear stress and v(δ) at selected stations.

SCHEMATIC:



ASSUMPTIONS: (1) Steady flow, (2) Boundary layer approximations are valid, (3) Flow is laminar.

PROPERTIES: *Table A-4*, Air (300 K, 1 atm): $\rho = 1.161\ \text{kg/m}^3$, $\nu = 15.89 \times 10^{-6}\ \text{m}^2/\text{s}$.

ANALYSIS: (a) For laminar flow,

$$\delta = \frac{5x}{Re_x^{1/2}} = \frac{5}{(u_\infty/\nu)^{1/2}} x^{1/2} = \frac{5x^{1/2}}{\left(25\ \text{m/s}/15.89\times10^{-6}\ \text{m}^2/\text{s}\right)^{1/2}} = 3.99\times10^{-3}\ x^{1/2}.$$

x (m)	0.001	0.01	0.1
δ (mm)	0.126	0.399	1.262

Boundary layer merger occurs at $x = x_m$ when δ = 1.5 mm. Hence

$$x_m^{1/2} = \frac{0.0015\ \text{m}}{3.99\times10^{-3}\ \text{m}^{1/2}} = 0.376\ \text{m}^{1/2} \qquad x_m = 141\ \text{mm}.$$ <

(b) The shear stress is

$$\tau_{s,x} = 0.664\frac{\rho u_\infty^2/2}{Re_x^{1/2}} = 0.664\frac{\rho u_\infty^2/2}{(u_\infty/\nu)^{1/2} x^{1/2}} = \frac{0.664\times1.161\ \text{kg/m}^3 (25\ \text{m/s})^2/2}{\left(25\ \text{m/s}/15.89\times10^{-6}\ \text{m}^2/\text{s}\right)^{1/2} x^{1/2}} = \frac{0.192}{x^{1/2}}\left(\text{N/m}^2\right).$$

x (m)	0.001	0.01	0.1
$\tau_{s,x}$ (N/m²)	6.07	1.92	0.61

The velocity distribution in the boundary layer is $v = (1/2)\,(\nu u_\infty/x)^{1/2}\,(\eta df/d\eta - f)$. At y = δ, η ≈ 5.0, f ≈ 3.24, df/dη ≈ 0.991.

$$v = \frac{0.5}{x^{1/2}}\left(15.89\times10^{-6}\ \text{m}^2/\text{s}\times25\ \text{m/s}\right)^{1/2}(5.0\times0.991-3.28) = \left(0.0167/x^{1/2}\right)\text{m/s}.$$

x (m)	0.001	0.01	0.1
v (m/s)	0.528	0.167	0.053

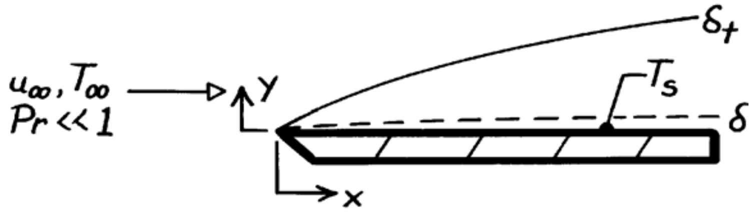
COMMENTS: (1) $v \ll u_\infty$ and $\delta \ll x$ are consistent with BL approximations. Note, $v \to \infty$ as $x \to 0$ and approximations breakdown very close to the leading edge. (2) Since $Re_{x_m} = 2.22\times10^5$, laminar BL model is valid. (3) Above expressions are approximations for flow between parallel plates, since $du_\infty/dx > 0$ and $dp/dx < 0$.

PROBLEM 7.4

KNOWN: Liquid metal in parallel flow over a flat plate.

FIND: An expression for the local Nusselt number.

SCHEMATIC:



ASSUMPTIONS: (1) Steady, incompressible flow, (2) $\delta << \delta_t$, hence $u(y) \approx u_\infty$, (3) Boundary layer approximations are valid, (4) Constant properties.

ANALYSIS: The boundary layer energy equation is

$$u\frac{\partial T}{\partial x} + v\frac{\partial T}{\partial y} = \alpha\frac{\partial^2 T}{\partial y^2}.$$

Assuming $u(y) = u_\infty$, it follows that v = 0 and the energy equation becomes

$$u_\infty\frac{\partial T}{\partial x} = \alpha\frac{\partial^2 T}{\partial y^2} \qquad \text{or} \qquad \frac{\partial T}{\partial x} = \frac{\alpha}{u_\infty}\frac{\partial^2 T}{\partial y^2}.$$

Boundary Conditions: $T(x,0) = T_s$, $T(x,\infty) = T_\infty$.

Initial Condition: $T(0,y) = T_\infty$.

The differential equation is analogous to that for transient one-dimensional conduction in a plane wall, and the conditions are analogous to those of Fig. 5.7, Case (1). Hence the solution is given by Eqs. 5.60 and 5.61. Substituting y for x, x for t, T_∞ for T_i, and α/u_∞ for α, the boundary layer temperature and the surface heat flux become

$$\frac{T(x,y) - T_s}{T_\infty - T_s} = \text{erf}\left[\frac{y}{2(\alpha\, x/u_\infty)^{1/2}}\right]$$

$$q_s'' = \frac{k(T_s - T_\infty)}{(\pi\,\alpha\, x/u_\infty)^{1/2}}.$$

Hence, with $\quad Nu_x \equiv \dfrac{h\,x}{k} = \dfrac{q_s'' x}{(T_s - T_\infty)k}$

find

$$Nu_x = \frac{x}{(\pi\,\alpha\, x/u_\infty)^{1/2}} = \frac{(x u_\infty)^{1/2}}{\pi^{1/2}(k/\rho\, c_p)^{1/2}} = \frac{1}{\pi^{1/2}}\left[\frac{\rho\, u_\infty x}{\mu}\cdot\frac{c_p \mu}{k}\right]^{1/2}$$

$$Nu_x = 0.564\,(Re_x Pr)^{1/2} = 0.564\, Pe^{1/2}$$ <

where Pe = Re · Pr is the Peclet number.

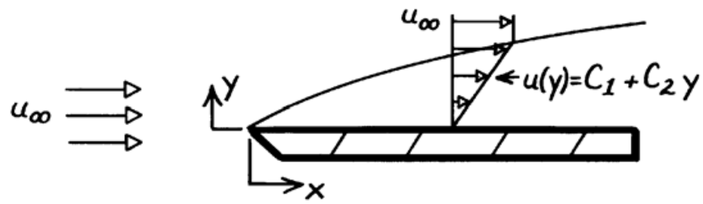
COMMENTS: Because k is very large, axial conduction effects may not be negligible. That is, the $\alpha\, \partial^2 T/\partial x^2$ term of the energy equation may be important.

PROBLEM 7.5

KNOWN: Form of velocity profile for flow over a flat plate.

FIND: (a) Expression for profile in terms of u_∞ and δ, (b) Expression for δ(x), (c) Expression for $C_{f,x}$.

SCHEMATIC:



ASSUMPTIONS: (1) Steady state conditions, (2) Constant properties, (3) Incompressible flow, (4) Boundary layer approximations are valid.

ANALYSIS: (a) From the boundary conditions

$$u(x,0)=0 \rightarrow C_1=0 \qquad \text{and} \qquad u(x,\delta)=u_\infty \rightarrow C_2=u_\infty/\delta.$$

Hence, $\quad u=u_\infty(y/\delta).$ <

(b)From the momentum integral equation for a flat plate

$$\frac{d}{dx}\int_0^\delta (u_\infty-u)u\,dy = \tau_s/\rho$$

$$u_\infty^2\frac{d}{dx}\int_0^\delta\left(1-\frac{u}{u_\infty}\right)\frac{u}{u_\infty}dy = \frac{\mu}{\rho}\left.\frac{\partial u}{\partial y}\right)_{y=0} = \frac{\nu u_\infty}{\delta}$$

$$u_\infty^2\frac{d}{dx}\int_0^\delta\left(1-\frac{y}{\delta}\right)\frac{y}{\delta}dy = \frac{\nu u_\infty}{\delta}$$

$$u_\infty^2\frac{d}{dx}\left[\left(\frac{y^2}{2\delta}-\frac{y^3}{3\delta^2}\right)\Bigg|_0^\delta\right] = \frac{\mu u_\infty}{\delta} \qquad \text{or} \qquad \frac{u_\infty}{6}\frac{d\delta}{dx} = \frac{\nu}{\delta}.$$

Separating and integrating, find

$$\int_0^\delta \delta\,d\delta = \frac{6\nu}{u_\infty}\int_0^x dx \qquad \delta = \left(\frac{12\,\nu x}{u_\infty}\right)^{1/2} = 3.46\,x\left(\frac{\nu}{u_\infty x}\right)^{1/2} = 3.46\,x\,Re_x^{-1/2}.$$ <

(c) The shear stress at the wall is

$$\tau_s=\mu\left.\frac{\partial u}{\partial y}\right)_{y=0}=\mu\frac{u_\infty}{\delta}=\frac{\mu u_\infty}{3.46\,x}Re_x^{1/2}$$

and the friction coefficient is

$$C_{f,x}=\frac{\tau_s}{\rho u_\infty^2/2}=\frac{\mu}{\rho u_\infty x}\frac{2}{3.46}Re_x^{1/2}=0.578\,Re_x^{-1/2}.$$ <

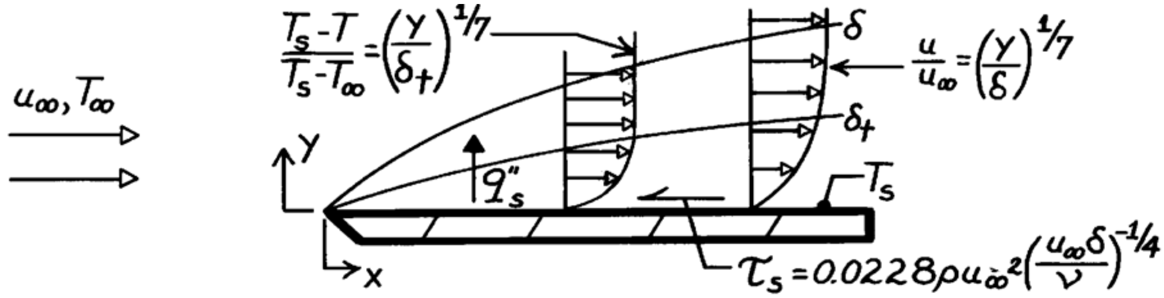
COMMENTS: The foregoing results underpredict those associated with the exact solution $\left(\delta=4.96\,x\,Re_x^{-1/2},\ C_{f,x}=0.664\,Re_x^{-1/2}\right)$ and the cubic profile $\left(\delta=4.64\,x\,Re_x^{-1/2},\right.$ $\left.C_{f,x}=0.646\,Re_x^{-1/2}\right)$.

PROBLEM 7.6

KNOWN: Velocity and temperature profiles and shear stress-boundary layer thickness relation for turbulent flow over a flat plate.

FIND: (a) Expressions for hydrodynamic boundary layer thickness and average friction coefficient, (b) Expressions for local and average Nusselt numbers.

SCHEMATIC:



ASSUMPTIONS: (1) Steady flow, (2) Constant properties, (3) Fully turbulent boundary layer, (4) Incompressible flow, (5) Isothermal plate, (6) Negligible viscous dissipation, (7) $\delta \approx \delta_t$.

ANALYSIS: (a) The momentum integral equation is

$$\rho u_\infty^2 \frac{d}{dx} \int_0^\delta \left(1 - \frac{u}{u_\infty}\right) \frac{u}{u_\infty} dy = \tau_s.$$

Substituting the expression for the wall shear stress

$$\rho u_\infty^2 \frac{d}{dx} \int_0^\delta \left[1 - \left(\frac{y}{\delta}\right)^{1/7}\right] \left(\frac{y}{\delta}\right)^{1/7} dy = 0.0228 \rho u_\infty^2 \left(\frac{u_\infty \delta}{\nu}\right)^{-1/4}$$

$$\frac{d}{dx} \int_0^\delta \left[\left(\frac{y}{\delta}\right)^{1/7} - \left(\frac{y}{\delta}\right)^{2/7}\right] dy = \frac{d}{dx} \left(\frac{7}{8}\frac{y^{8/7}}{\delta^{1/7}} - \frac{7}{9}\frac{y^{9/7}}{\delta^{2/7}}\right) \Big|_0^\delta$$

$$\frac{d}{dx}\left(\frac{7}{8}\delta - \frac{7}{9}\delta\right) = 0.0228 \left(\frac{u_\infty \delta}{\nu}\right)^{-1/4}$$

$$\frac{7}{72}\frac{d\delta}{dx} = 0.0228 \left(\frac{\nu}{u_\infty}\right)^{1/4} \delta^{-1/4} \qquad \frac{7}{72}\int_0^\delta \delta^{1/4} d\delta = 0.0228 \left(\frac{\nu}{u_\infty}\right)^{1/4} \int_0^x dx$$

$$\frac{7}{72} \times \frac{4}{5}\delta^{5/4} = 0.0228\left(\frac{\nu}{u_\infty}\right)^{1/4} x, \qquad \delta = 0.376\left(\frac{\nu}{u_\infty}\right)^{1/5} x^{4/5}, \quad \frac{\delta}{x} = 0.376 Re_x^{-1/5}. \quad <$$

Knowing δ, it follows

$$\tau_s = 0.0228 \rho u_\infty^2 \left(\frac{u_\infty}{\nu}\right)^{-1/4} \left[0.376 \text{ x } Re_x^{-1/5}\right]^{-1/4}$$

$$C_{f,x} = \frac{\tau_s}{\rho u_\infty^2 / 2} = 0.0456 \left[0.376 \frac{u_\infty}{\nu}\left(\frac{u_\infty}{\nu}\right)^{-1/5} \text{x } x^{-1/5}\right]^{-1/4} = 0.0582 Re_x^{-1/5}.$$

Continued …

PROBLEM 7.6 (Cont.)

The average friction coefficient is then

$$\bar{C}_{f,x} = \frac{1}{x}\int_0^x C_{f,x}\,dx = \frac{1}{x}0.0582\left(\frac{u_\infty}{\nu}\right)^{-1/5}\int_0^x x^{-1/5}\,dx$$

$$\bar{C}_{f,x} = \frac{1}{x}0.0582\left(\frac{u_\infty}{\nu}\right)^{-1/5} x^{4/5}\left(\frac{5}{4}\right) = 0.073\,Re_x^{-1/5}.$$ <

(b) The energy integral equation for turbulent flow is

$$\frac{d}{dx}\int_0^{\delta_t} u\left(T_\infty - T\right)dy = \frac{q_s''}{\rho\, c_p} = -\frac{h}{\rho\, c_p}\left(T_s - T_\infty\right).$$

Hence,

$$u_\infty \frac{d}{dx}\int_0^{\delta_t}\frac{u}{u_\infty}\,\frac{T - T_\infty}{T_s - T_\infty}\,dy = u_\infty\frac{d}{dx}\int_0^{\delta_t}\left(y/\delta\right)^{1/7}\left[1-\left(y/\delta_t\right)^{1/7}\right]dy = \frac{h}{\rho\, c_p}$$

$$u_\infty\frac{d}{dx}\left[\frac{7}{8}\,\frac{\delta_t^{8/7}}{\delta^{1/7}} - \frac{7}{9}\,\frac{\delta_t^{8/7}}{\delta^{1/7}}\right] = \frac{h}{\rho\, c_p}$$

or, with $\xi \equiv \delta_t/\delta$,

$$u_\infty\frac{d}{dx}\left[\frac{7}{8}\,\delta\xi^{8/7} - \frac{7}{9}\delta\xi^{8/7}\right] = \frac{h}{\rho\, c_p} \qquad u_\infty\frac{d}{dx}\left[\frac{7}{72}\delta\xi^{8/7}\right] = \frac{h}{\rho\, c_p}.$$

Hence, with $\xi \approx 1$ and $\delta/x = 0.376\,Re_x^{-1/5}$,

$$\frac{7}{72}\,u_\infty\left(0.376\right)\left(\frac{u_\infty}{\nu}\right)^{-1/5}\frac{d\left(x^{4/5}\right)}{dx} = \frac{h}{\rho\, c_p}$$

$$h = 0.0292\,\rho\, c_p u_\infty\,Re_x^{-1/5} = 0.0292\,\frac{k}{x}\,\frac{\nu}{\alpha}\,\frac{u_\infty x}{\nu}\,Re_x^{-1/5}$$

$$Nu_x = \frac{hx}{k} = 0.0292\,Re_x^{4/5}\,Pr.$$ <

Hence,

$$\bar{h}_x = \frac{1}{x}\int_0^x h\,dx = \frac{0.0292\,Pr}{x}\,k\left(\frac{u_\infty}{\nu}\right)^{4/5}\int_0^x x^{-1/5}\,dx = 0.0292\,\frac{k}{x}\,Pr\left(\frac{u_\infty x}{\nu}\right)^{4/5}\frac{5}{4}$$

$$\overline{Nu}_x = \frac{\bar{h}_x x}{k} = 0.037\,Re_x^{4/5}\,Pr.$$ <

COMMENTS: (1) The foregoing results are in excellent agreement with empirical correlations, except that use of $Pr^{1/3}$ instead of Pr, would be more appropriate. This result arose because of the assumption $\delta \approx \delta_t$, which is only valid for $Pr \approx 1$.

(2) Note that the 1/7 profile breaks down at the surface. For example,

$$\left.\frac{\partial\left(u/u_\infty\right)}{\partial\, y}\right)_{y=0} = \frac{1}{7}\,\delta^{-1/7}\,y^{-6/7} = \infty$$

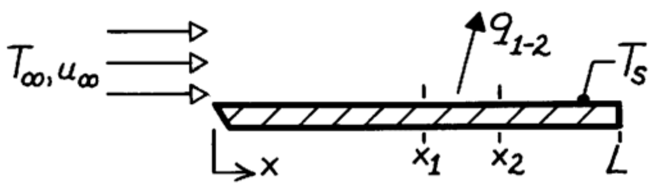
or $\tau_s = \infty$. Despite this unrealistic characteristic of the profile, its use with integral methods provides excellent results.

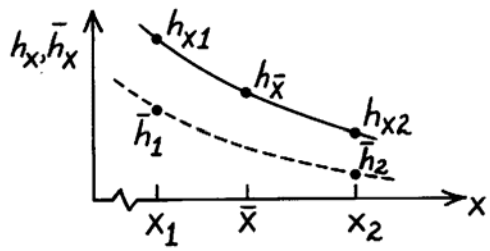
PROBLEM 7.7

KNOWN: Parallel flow over a flat plate and two locations representing a short span x_1 to x_2 where $(x_2 - x_1) << L$.

FIND: Three different expressions for the average heat transfer coefficient over the short span x_1 to x_2, $\overline{h}_{1-2}$.

SCHEMATIC:





ASSUMPTIONS: (1) Parallel flow over a flat plate.

ANALYSIS: The heat rate per unit width for the span can be written as

$$q'_{1-2} = \overline{h}_{1-2}\left(x_2 - x_1\right)\left(T_s - T_\infty\right) \tag{1}$$

where $\overline{h}_{1-2}$ is the average heat transfer coefficient over the span and can be evaluated in either of the following three ways:

(a) *Local coefficient at* $\bar{x} = \left(x_1 + x_2\right)/2$. If the span is very short, it is reasonable to assume that

$$\overline{h}_{1-2} \approx h_{\bar{x}} \quad < \tag{2}$$

where $h_{\bar{x}}$ is the local convection coefficient at the mid-point of the span.

(b) *Local coefficients at x_1 and x_2.* If the span is very short it is reasonable to assume that $\overline{h}_{1-2}$ is the average of the local values at the ends of the span,

$$\overline{h}_{1-2} \approx \left[h_{x1} + h_{x2}\right]/2. \quad < \tag{3}$$

(c) *Average coefficients for x_1 and x_2.* The heat rate for the span can also be written as

$$q'_{1-2} = q'_{0-2} - q'_{0-1} \tag{4}$$

where the rate q_{0-x} denotes the heat rate for the plate over the distance from 0 to x. In terms of heat transfer coefficients, find

$$\overline{h}_{1-2} \cdot \left(x_2 - x_1\right) = \overline{h}_2 \cdot x_2 - \overline{h}_1 \cdot x_1$$

$$\overline{h}_{1-2} = \overline{h}_2 \frac{x_2}{x_2 - x_1} - \overline{h}_1 \frac{x_1}{x_2 - x_1} \quad < \tag{5}$$

where $\overline{h}_1$ and $\overline{h}_2$ are the average coefficients from 0 to x_1 and x_2, respectively.

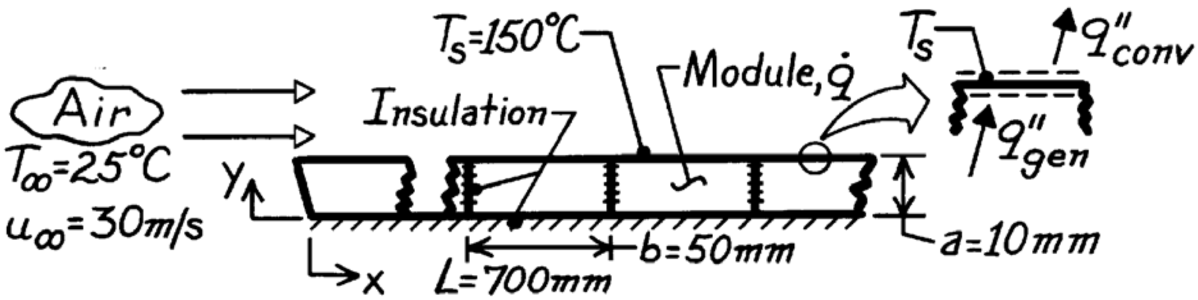
COMMENTS: Eqs. (2) and (3) are approximate and work better when the span is small and the flow is turbulent rather than laminar ($h_x \sim x^{-0.2}$ vs $h_x \sim x^{-0.5}$). Of course, we require that $x_c < x_1, x_2$ or $x_c > x_1, x_2$; that is, the approximations are inappropriate around the transition region. Eq. (5) is an exact relationship, which applies under any conditions.

PROBLEM 7.8

KNOWN: Flat plate comprised of rectangular modules of surface temperature T_s, thickness a and length b cooled by air at 25°C and a velocity of 30 m/s. Prescribed thermophysical properties of the module material.

FIND: (a) Required power generation for the module positioned 700 mm from the leading edge of the plate and (b) Maximum temperature in this module.

SCHEMATIC:



ASSUMPTIONS: (1) Laminar flow at leading edge of plate, (2) Transition Reynolds number of 5 × 10^5, (3) Heat transfer is one-dimensional in y-direction within each module, (4) $\dot{q}$ is uniform within module, (5) Negligible radiation heat transfer.

PROPERTIES: Module material (given): k = 5.2 W/m·K, c_p = 320 J/kg·K, ρ = 2300 kg/m^3; *Table A-4*, Air $\left(\overline{T}_f = (T_s + T_\infty)/2 = 360\text{ K, 1 atm}\right)$: k = 0.0308 W/m·K, ν = 22.02 × 10^{-6} m^2/s, Pr = 0.698.

ANALYSIS: (a) The module power generation follows from an energy balance on the module surface,

$$q''_{conv} = q''_{gen}$$

$$\overline{h}(T_s - T_\infty) = \dot{q} \cdot a \qquad \text{or} \qquad \dot{q} = \frac{\overline{h}(T_s - T_\infty)}{a}.$$

To select a convection correlation for estimating $\overline{h}$, first find the Reynolds numbers at x = L.

$$Re_L = \frac{u_\infty L}{\nu} = \frac{30\text{ m/s} \times 0.70\text{ m}}{22.02 \times 10^{-6}\text{m}^2/\text{s}} = 9.537 \times 10^5.$$

Since the flow is turbulent over the module, the approximation $\overline{h} \approx h_x\ (L + b/2)$ is appropriate, with

$$Re_{L+b/2} = \frac{30\text{ m/s} \times (0.700 + 0.050/2)\text{m}}{22.02 \times 10^{-6}\text{m}^2/\text{s}} = 9.877 \times 10^5.$$

Using the turbulent flow correlation with x = L + b/2 = 0.725 m,

$$Nu_x = \frac{h_x x}{k} = 0.0296 Re_x^{4/5} Pr^{1/3}$$

$$Nu_x = 0.0296\left(9.877 \times 10^5\right)^{4/5}(0.698)^{1/3} = 1640$$

$$\overline{h} \approx h_x = \frac{Nu_x k}{x} = \frac{1640 \times 0.0308\text{ W/m} \cdot \text{K}}{0.725} = 69.7\text{ W/m}^2 \cdot \text{K}.$$

Continued …

PROBLEM 7.8 (Cont.)

Hence,

$$\dot{q} = \frac{69.7\ \text{W/m}^2 \cdot \text{K}(150-25)\text{K}}{0.010\ \text{m}} = 8.713\times10^5\ \text{W/m}^3. \qquad <$$

(b) The maximum temperature within the module occurs at the surface next to the insulation (y = 0). For one-dimensional conduction with thermal energy generation, use Eq. 3.42 to obtain

$$T(0) = \frac{\dot{q}a^2}{2k} + T_s = \frac{8.713\times10^5\ \text{W/m}^3 \times (0.010\ \text{m})^2}{2\times5.2\ \text{W/m}\cdot\text{K}} + 150^\circ\text{C} = 158.4^\circ\text{C}. \qquad <$$

COMMENTS: An alternative approach for estimating the average heat transfer coefficient for the module follows from the relation

$$q_{\text{module}} = q_{0\rightarrow L+b} - q_{0\rightarrow L}$$

$$\bar{h}\cdot b = \bar{h}_{L+b}\cdot(L+b) - \bar{h}_L \cdot L \qquad \text{or} \qquad \bar{h} = \bar{h}_{L+b}\frac{L+b}{b} - \bar{h}_L\frac{L}{b}.$$

Recognizing that laminar and turbulent flow conditions exist, the appropriate correlation is

$$\overline{Nu}_x = \left(0.037 Re_x^{4/5} - 871\right) Pr^{1/3}$$

With x = L + b and x = L, find

$$\bar{h}_{L+b} = 54.79\ \text{W/m}^2\cdot\text{K} \qquad \text{and} \qquad \bar{h}_L = 53.73\ \text{W/m}^2\cdot\text{K}.$$

Hence,

$$\bar{h} = \left[54.79\frac{0.750}{0.050} - 53.73\frac{0.700}{0.05}\right]\ \text{W/m}^2\cdot\text{K} = 69.7\ \text{W/m}^2\cdot\text{K}.$$

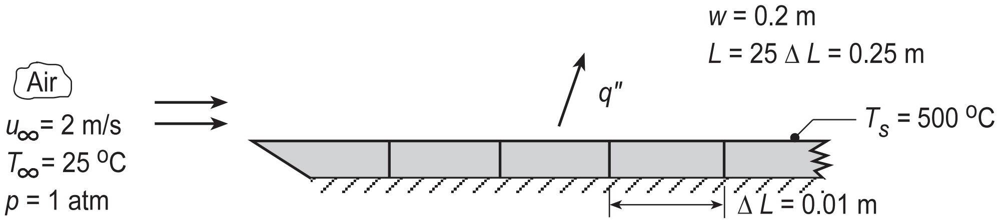
which is in excellent agreement with the approximate result employed in part (a).

PROBLEM 7.9

KNOWN: Dimensions and surface temperature of electrically heated strips. Temperature and velocity of air in parallel flow.

FIND: (a) Rate of convection heat transfer from first, fifth and tenth strips as well as from all the strips, (b) For air velocities of 2, 5 and 10 m/s, determine the convection heat rates for all the locations of part (a), and (c) Repeat the calculations of part (b), but under conditions for which the flow is fully turbulent over the entire array of strips.

SCHEMATIC:



ASSUMPTIONS: (1) Top surface is smooth, (2) Bottom surface is adiabatic, (3) Critical Reynolds number is 5×10^5, (4) Negligible radiation.

PROPERTIES: *Table A.4*, Air (T_f = 535 K, 1 atm): $\nu = 43.54 \times 10^{-6}$ m²/s, k = 0.0429 W/m·K, Pr = 0.683.

ANALYSIS: (a) The location of transition is determined from

$$x_c = 5\times10^5 \frac{\nu}{u_\infty} = 5\times10^5 \frac{43.54\times10^{-6}\,\text{m}^2/\text{s}}{2\,\text{m/s}} = 10.9\,\text{m}$$

Since $x_c >> L = 0.25$ m, the air flow is laminar over the entire heater. For the *first* strip, $q_1 = \bar{h}_1 (\Delta L \times w)(T_s - T_\infty)$ where $\bar{h}_1$ is obtained from

$$\bar{h}_1 = \frac{k}{\Delta L} 0.664\, Re_x^{1/2}\, Pr^{1/3}$$

$$\bar{h}_1 = \frac{0.0429\,\text{W/m}\cdot\text{K}}{0.01\text{m}} \times 0.664 \left(\frac{2\,\text{m/s} \times 0.01\,\text{m}}{43.54\times10^{-6}\,\text{m}^2/\text{s}}\right)^{1/2} (0.683)^{1/3} = 53.8\,\text{W/m}^2\cdot\text{K}$$

$$q_1 = 53.8\,\text{W/m}^2\cdot\text{K}\,(0.01\,\text{m}\times0.2\,\text{m})(500-25)^\circ\text{C} = 51.1\,\text{W}$$ <

For the *fifth* strip, $q_5 = q_{0-5} - q_{0-4}$,

$$q_5 = h_{0-5}(5\Delta L \times w)(T_s - T_\infty) - \bar{h}_{0-4}(4\Delta L \times w)(T_s - T_\infty)$$

$$q_5 = \left(5\bar{h}_{0-5} - 4\bar{h}_{0-4}\right)(\Delta L \times w)(T_s - T_\infty)$$

Hence, with $x_5 = 5\Delta L = 0.05$ m and $x_4 = 4\Delta L = 0.04$ m, it follows that $\bar{h}_{0-5}$ = 24.1 W/m²·K and $\bar{h}_{0-4}$ = 26.9 W/m²·K and

$$q_5 = (5\times24.1 - 4\times26.9)\,\text{W/m}^2\cdot\text{K}\,(0.01\times0.2)\,\text{m}^2\,(500-25)\,\text{K} = 12.2\,\text{W}.$$ <

Similarly, where $\bar{h}_{0-10}$ = 17.00 W/m²·K and $\bar{h}_{0-9}$ = 17.92 W/m²·K.

$$q_{10} = \left(10\bar{h}_{0-10} - 9\bar{h}_{0-9}\right)(\Delta L \times w)(T_s - T_\infty)$$

$$q_{10} = (10\times17.00 - 9\times17.92)\,\text{W/m}^2\cdot\text{K}\,(0.01\times0.2)\,\text{m}^2\,(500-25)\,\text{K} = 8.3\,\text{W}$$ <

Continued...

PROBLEM 7.9 (Cont.)

For the entire heater,

$$\bar{h}_{0-25} = \frac{k}{L} 0.664\, Re_L^{1/2}\, Pr^{1/3} = \frac{0.0429}{0.25} \times 0.664 \left(\frac{2 \times 0.25}{43.54 \times 10^{-6}} \right)^{1/2} (0.683)^{1/3} = 10.75\, W/m^2 \cdot K$$

and the heat rate over all 25 strips is

$$q_{0-25} = \bar{h}_{0-25} (L \times w)(T_s - T_\infty) = 10.75\, W/m^2 \cdot K (0.25 \times 0.2) m^2 (500 - 25)^\circ C = 255.3\, W \quad <$$

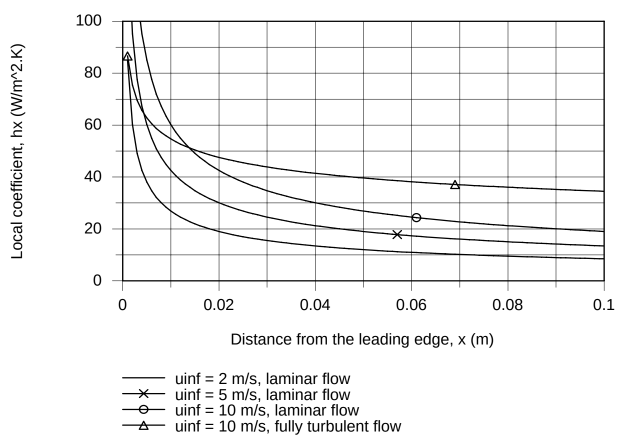
(b,c) Using the *IHT Correlations Tool*, *External Flow*, for *Laminar or Mixed Flow Conditions*, and following the same method of solution as above, the heat rates for the first, fifth, tenth and all the strips were calculated for air velocities of 2, 5 and 10 m/s. To evaluate the heat rates for fully turbulent conditions, the analysis was performed setting $Re_{x,c} = 1 \times 10^{-6}$. The results are tabulated below.

Flow conditions	u_∞ (m/s)	q_1 (W)	q_5 (W)	q_{10} (W)	q_{0-25} (W)
Laminar	2	51.1	12.1	8.3	256
	5	80.9	19.1	13.1	404
	10	114	27.0	18.6	572
Fully turbulent	2	17.9	10.6	9.1	235
	5	37.3	22.1	19.0	490
	10	64.9	38.5	33.1	853

COMMENTS: (1) An alternative approach to evaluating the heat loss from a single strip, for example, strip 5, would take the form $q_5 = \bar{h}_5 (\Delta L \times w)(T_s - T_\infty)$, where $h_5 \approx h_{x=4.5\Delta L}$ or $\bar{h}_5 \approx (h_{x=5\Delta L} + h_{x=4\Delta L})/2$.

(2) From the tabulated results, note that for both flow conditions, the heat rate for each strip and the entire heater, increases with increasing air velocity. For both flow conditions and for any specified velocity, the strip heat rates decrease with increasing distance from the leading edge.

(3) To more fully appreciate the effects due to laminar vs. turbulent flow conditions and air velocity, it is useful to examine the local coefficient as a function of distance from the leading edge. How would you use the results plotted below to explain heat rate behavior evident in the summary table above?

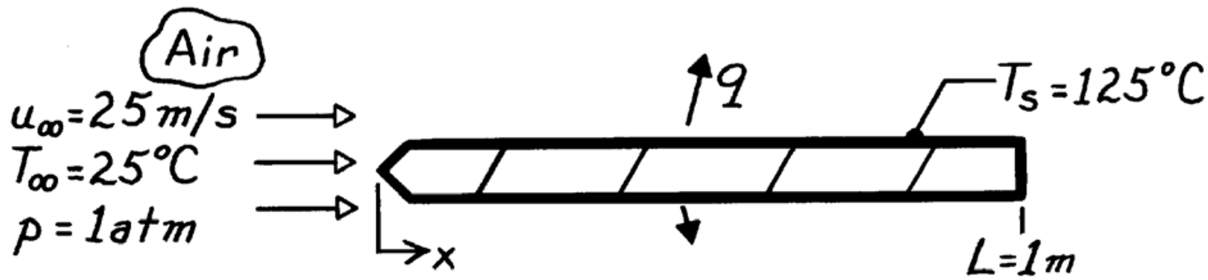


PROBLEM 7.10

KNOWN: Speed and temperature of atmospheric air flowing over a flat plate of prescribed length and temperature.

FIND: Rate of heat transfer corresponding to $Re_{x,c} = 10^5$, 5×10^5 and 10^6.

SCHEMATIC:



ASSUMPTIONS: (1) Flow over top and bottom surfaces.

PROPERTIES: *Table A-4*, Air (T_f = 348K, 1 atm): $\rho = 1.00$ kg/m^3, $\nu = 20.72 \times 10^{-6}$ m^2/s, k = 0.0299 W/m·K, Pr = 0.700.

ANALYSIS: With

$$Re_L = \frac{u_\infty L}{\nu} = \frac{25 \text{ m/s} \times 1\text{m}}{20.72 \times 10^{-6} \text{m}^2/\text{s}} = 1.21 \times 10^6$$

the flow becomes turbulent for each of the three values of $Re_{x,c}$. Hence,

$$\overline{Nu}_L = \left(0.037\, Re_L^{4/5} - A\right) Pr^{1/3}$$
$$A = 0.037\, Re_{x,c}^{4/5} - 0.664\, Re_{x,c}^{1/2}$$

$Re_{x,c}$	10^5	5×10^5	10^6
A	160	871	1671
$\overline{Nu}_L$	2267	1635	926
$\bar{h}_L \left(W/m^2 \cdot K\right)$	67. 8	48.9	27.7
$q' (W/m)$	13,560	9780	5530

where $q' = 2\, \bar{h}_L L \left(T_s - T_\infty\right)$ is the total heat loss per unit width of plate.

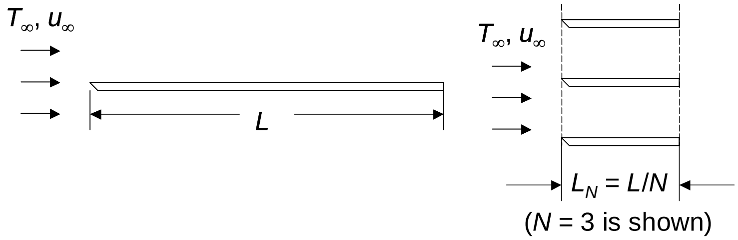
COMMENTS: Note that $\bar{h}_L$ decreases with increasing $Re_{x,c}$, as more of the surface becomes covered with a laminar boundary layer.

PROBLEM 7.11

KNOWN: Length of isothermal flat plate in parallel flow, L.

FIND: Expression for the average heat transfer coefficients for N plates each of length $L_N = L/N$ to the average coefficient for the single plate.

SCHEMATIC:



ASSUMPTIONS: (1) Laminar flow, (2) Constant properties.

ANALYSIS: For the single plate, Equation 7.30 applies

$$\overline{Nu}_L = \frac{\bar{h}_{L,1}L}{k} = 0.664 Re_L^{1/2} Pr^{1/3} \quad \text{or} \quad \bar{h}_{L,1} = (k/L) 0.664 Re_L^{1/2} Pr^{1/3} \tag{1}$$

For the multiple plates,

$$\overline{Nu}_{L,N} = \frac{\bar{h}_{L,N} L_N}{k} = 0.664 Re_{L_N}^{1/2} Pr^{1/3} \quad \text{where} \quad L_N = L/N \quad \text{and} \quad Re_{L_N} = Re_L/N \qquad \text{(2a, b, c)}$$

Combining Equations 2a, 2b and 2c yields

$$\bar{h}_{L,N} = \frac{kN}{L} 0.664 (Re_L/N)^{1/2} Pr^{1/3} \tag{3}$$

Dividing Equation 3 by Equation 1 yields

$$\bar{h}_{L,N} / \bar{h}_{L,1} = N^{1/2}$$ <

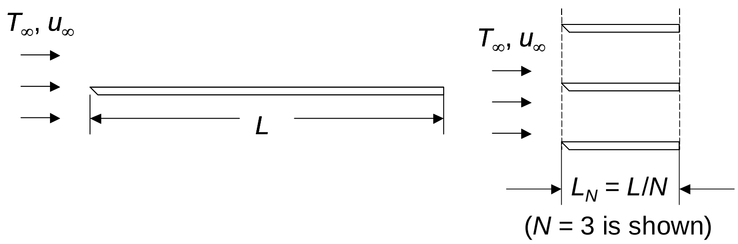
COMMENTS: (1) By breaking the single plate into shorter segments, the average boundary layer thickness is reduced, resulting in an increase of the average heat transfer coefficient. This is an effective strategy for heat transfer *enhancement*. (2) If the boundary layer over the single plate is not completely laminar, breaking it into shorter segments may or may not result in an increase in the average heat transfer coefficient since the turbulent section of the boundary layer over the single plate may be eliminated. (3) The relationship for completely turbulent flow is $\bar{h}_{L_N} / \bar{h}_L = N^{1/5}$, revealing less sensitivity to the plate length than for laminar conditions.

PROBLEM 7.12

KNOWN: Length of isothermal flat plate in parallel flow, L.

FIND: Expression for the average heat transfer coefficients for N plates each of length $L_N = L/N$ to the average heat transfer coefficient for the single plate.

SCHEMATIC:



ASSUMPTIONS: (1) Turbulent flow, (2) Constant properties.

ANALYSIS: Since $Re_{x,c} = 0$, Equation 7.39 yields $A = 0$. Therefore, for the single plate,

$$\overline{Nu}_L = \frac{\bar{h}_{L,1}L}{k} = 0.036 Re_L^{4/5} Pr^{1/3} \quad \text{or} \quad \bar{h}_{L,1} = (k/L) 0.036 Re_L^{4/5} Pr^{1/3} \tag{1}$$

For the multiple plates,

$$\overline{Nu}_{L,N} = \frac{\bar{h}_{L,N} L_N}{k} = 0.037 Re_{L_N}^{4/5} Pr^{1/3} \quad \text{where } L_N = L/N \text{ and } Re_{L_N} = Re_L/N \tag{2a, b, c}$$

Combining Equations 2a, 2b and 2c yields

$$\bar{h}_{L,N} = \frac{kN}{L} 0.037 \left(Re_L/N\right)^{4/5} Pr^{1/3} \tag{3}$$

Dividing Equation 3 by Equation 1 yields

$$\bar{h}_{L,N} / \bar{h}_{L,1} = N^{1/5}$$ <

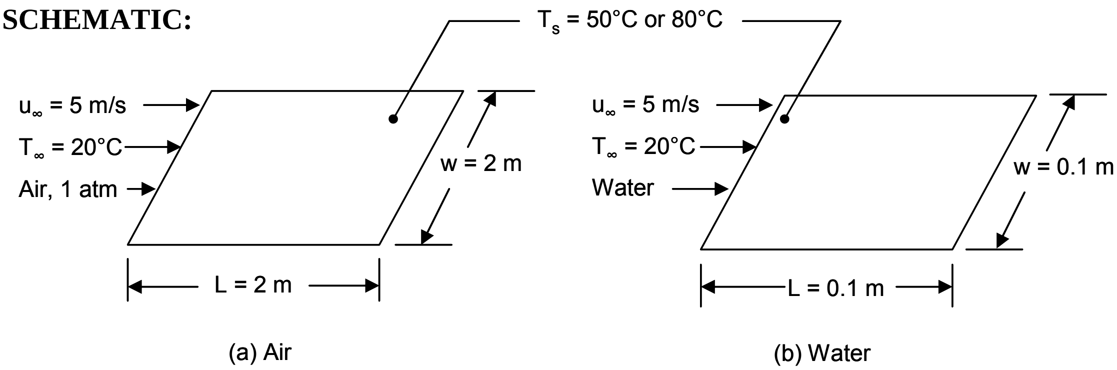
COMMENTS: (1) By breaking the single plate into shorter segments, the average boundary layer thickness is reduced, resulting in a slight increase of the average heat transfer coefficient. Hence, breaking the plate into shorter lengths results in modest heat transfer *enhancement*. (2) The relationship for laminar flow is $\bar{h}_{L,N} / \bar{h}_L = N^{1/2}$, revealing more sensitivity to the plate length for laminar conditions.

PROBLEM 7.13

KNOWN: Dimensions and surface temperatures of a flat plate. Velocity and temperature of air and water flow parallel to the plate.

FIND: (a) Average convective heat transfer coefficient, convective heat transfer rate, and drag force when L = 2 m, w = 2 m. (b) Average convective heat transfer coefficient, convective heat transfer rate, and drag force when L = 0.1 m, w = 0.1 m.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Boundary layer assumptions are valid, (3) Constant properties, (4) Transition Reynolds number is 5×10^5.

PROPERTIES: Using *IHT*, Air (p = 1 atm, T_f = 35°C = 308 K): Pr = 0.706, k = 26.9×10^{-3} W/m·K, $\nu = 1.669 \times 10^{-5}$ m²/s, ρ = 1.135 kg/m³. Air (p = 1 atm, T_f = 50°C = 323 K): Pr = 0.704, k = 28.0×10^{-3} W/m·K, $\nu = 1.82 \times 10^{-5}$ m²/s, ρ = 1.085 kg/m³. Water (T_f = 308 K): Pr = 4.85, k = 0.625 W/m·K, $\nu = 7.291 \times 10^{-7}$ m²/s, ρ = 994 kg/m³. Water (T_f = 323 K): Pr = 3.56, k = 0.643 W/m·K, $\nu = 5.543 \times 10^{-7}$ m²/s, ρ = 988 kg/m³.

ANALYSIS:

(a) We begin by calculating the Reynolds numbers for the two different surface temperatures:

$$Re_{L1} = \frac{u_\infty L}{\nu_1} = \frac{5\text{ m/s} \times 2\text{ m}}{1.669 \times 10^{-5}\text{ m}^2/\text{s}} = 5.99 \times 10^5$$

$$Re_{L2} = \frac{u_\infty L}{\nu_2} = \frac{5\text{ m/s} \times 2\text{ m}}{1.82 \times 10^{-5}\text{ m}^2/\text{s}} = 5.49 \times 10^5$$

Therefore, in both cases the flow is turbulent at the end of the plate and the conditions in the boundary layer are "mixed."

The average drag coefficient can be calculated from Equation 7.40. For the first case,

$$\overline{C}_{f,L1} = 0.074\, Re_{L1}^{-1/5} - 1742\, Re_{L1}^{-1}$$

$$= 0.074(5.99 \times 10^5)^{-1/5} - 1742(5.99 \times 10^5)^{-1} = 2.27 \times 10^{-3}$$

Then

$$F_{D1} = \overline{C}_{f,L1} \frac{1}{2} \rho u_\infty^2 A_s$$

$$= 2.27 \times 10^{-3} \times \frac{1}{2} \times 1.135\text{ kg/m}^3 \times (5\text{ m/s})^2 \times 8\text{ m}^2 = 0.257\text{ N}$$

$$= 0.257\text{ N}$$ <

Continued…

PROBLEM 7.13 (Cont.)

The average Nusselt number is calculated from Equation 7.38, with A = 871 for a transition Reynolds number of 5×10^5.

$$\overline{Nu}_{L1} = (0.037\,Re_L^{4/5} - 871)\,Pr^{1/3}$$
$$= \left[0.037(5.99 \times 10^5)^{4/5} - 871\right](0.706)^{1/3} = 604.$$

Then

$$\bar{h}_{L1} = \overline{Nu}_{L1} k/L = 604 \times 26.9 \times 10^{-3}\ \text{W/m} \cdot \text{K}/2\ \text{m} = 8.13\ \text{W/m}^2 \cdot \text{K} \qquad <$$

and

$$q_1 = \bar{h}_{L1} A_s (T_s - T_\infty) = 8.13\ \text{W/m}^2 \cdot \text{K} \times 8\ \text{m}^2 \times (50°\text{C} - 20°\text{C}) = 1950\ \text{W} \qquad <$$

Similarly for $T_s = 80°C$ we find

$$F_{D2} = 0.227\ \text{N},\ \bar{h}_{L2} = 7.16\ \text{W/m}^2{\cdot}\text{K},\ q_2 = 3440\ \text{W} \qquad <$$

(b) Repeating the calculations for water

$$Re_{L1} = \frac{u_\infty L}{\nu} = \frac{5\ \text{m/s} \times 0.1\ \text{m}}{7.291 \times 10^{-7}\ \text{m}^2/\text{s}} = 6.86 \times 10^5$$

$$Re_{L2} = 9.02 \times 10^5$$

The flow is turbulent at the end of the plate in both cases.

$$\bar{C}_{f,L1} = 0.074(6.86 \times 10^5)^{-1/5} - 1742(6.86 \times 10^5)^{-1} = 2.49 \times 10^{-3}$$

$$F_{D1} = 2.49 \times 10^{-3} \times 1/2 \times 994\ \text{kg/m}^3 \times (5\ \text{m/s})^2 \times 0.02\ \text{m}^2 = 0.620\ \text{N} \qquad <$$

$$\overline{Nu}_L = \left[0.037(6.86 \times 10^5)^{4/5} - 871\right](4.85)^{1/3} = 1450$$

$$\bar{h}_{L1} = 1450 \times 0.625\ \text{W/m} \cdot \text{K}/0.1\ \text{m} = 9050\ \text{W/m}^2 \cdot \text{K} \qquad <$$

$$q_1 = 9050\ \text{W/m}^2 \cdot \text{K} \times 0.02\ \text{m}^2 \times (50°\text{C} - 20°\text{C}) = 5430\ \text{W} \qquad <$$

For the higher surface temperature,

$$F_{D2} = 0.700\ \text{N},\ \bar{h}_{L2} = 12{,}600\ \text{W/m}^2{\cdot}\text{K},\ q_2 = 15{,}100\ \text{W} \qquad <$$

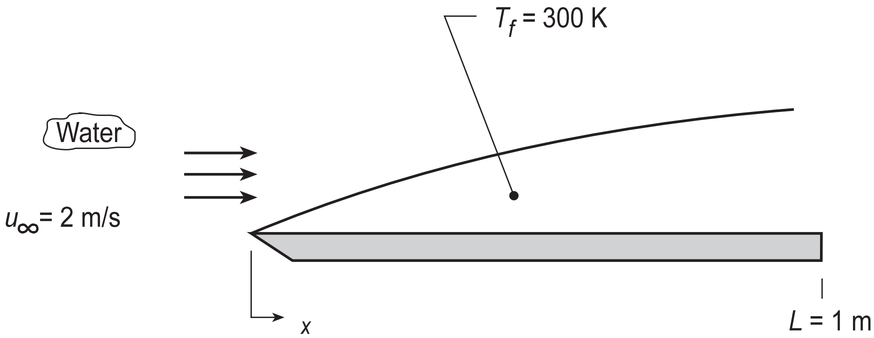
COMMENTS: (1) For air, kinematic viscosity increases with increasing temperature. This decreases the Reynolds number which causes the transition to turbulence to move downstream, thereby decreasing the drag force and average heat transfer coefficient. The heat transfer rate increases for the higher surface temperature, however, because of the greater temperature difference between the surface and air. (2) For water, kinematic viscosity decreases with increasing temperature, causing the opposite trends as for air. The heat transfer rate increases dramatically for the higher surface temperature because of the increases in both the heat transfer coefficient and temperature difference. (3) Even though the water flows over a plate that is 400 times smaller, the drag force and heat transfer rate are larger than for air because of the smaller viscosity and greater density, thermal conductivity, and Prandtl number. The discrepancy is particularly great for the hear transfer rate. (4) The problem highlights the importance of carefully accounting for the temperature dependence of thermal properties.

PROBLEM 7.14

KNOWN: Velocity and temperature of water in parallel flow over a flat plate of 1-m length.

FIND: (a) Calculate and plot the variation of the local convection coefficient, $h_x(x)$, with distance for flow conditions corresponding to transition Reynolds numbers of 5×10^5, 3×10^5 and 0 (fully turbulent), (b) Plot the variation of the average convection coefficient, $\overline{h}_x(x)$, for the three flow conditions of part (a), and (c) Determine the average convection coefficients for the entire plate, $\overline{h}_L$, for the three flow conditions of part (a).

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant surface temperature, and (3) Critical Reynolds depends upon prescribed flow conditions.

PROPERTIES: *Table A.6*, Water (300 K): $\rho = 997$ kg/m^3, $\mu = 855 \times 10^{-6}$ N·s/m^2, $\nu = \mu/\rho = 0.858 \times 10^{-6}$ m^2/s, k = 0.613 W/m·K, Pr = 583.

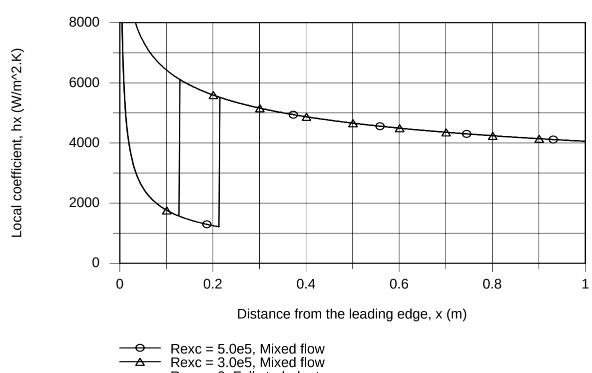
ANALYSIS: (a) The Reynolds number for the plate (L = 1 m) is

$$Re_L = \frac{u_\infty L}{\nu} = \frac{2\,m/s \times 1m}{0.858 \times 10^{-6}\,m^2/s} = 2.33 \times 10^6 .$$

and the boundary layer is mixed with $Re_{x,c} = 5 \times 10^5$,

$$x_c = L\left(Re_{x,c}/Re_L\right) = 1m\frac{5 \times 10^5}{2.33 \times 10^6} = 0.215\,m$$

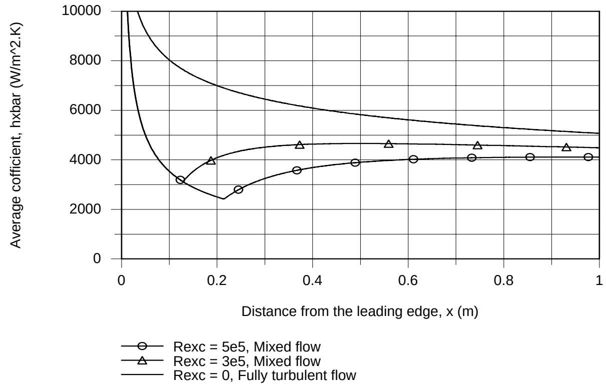
Using the *IHT Correlation Tool*, *External Flow*, *Local* coefficients for *Laminar* or *Turbulent Flow*, $h_x(x)$ was evaluated and plotted with critical Reynolds numbers of 5×10^5, 3.0×10^5 and 0 (fully turbulent). Note the location of the laminar-turbulent transition for the first two flow conditions.



Continued...

PROBLEM 7.14 (Cont.)

(b) Using the *IHT Correlation Tool*, *External Flow*, *Average* coefficient for *Laminar* or *Mixed Flow*, $\overline{h}_x(x)$ was evaluated and plotted for the three flow conditions. Note that the change in $\overline{h}_x(x)$ at the critical length, x_c, is rather gradual, compared to the abrupt change for the local coefficient, $h_x(x)$.



(c) The average convection coefficients for the plate can be determined from the above plot since $\overline{h}_L = \overline{h}_x(L)$. The values for the three flow conditions are

$$\overline{h}_L = 4110, 4490 \text{ and } 5072\, W/m^2 \cdot K$$ <

COMMENTS: A copy of the *IHT Workspace* used to generate the above plot is shown below.

```
/* Method of Solution:  Use the Correlation Tools, External Flow, Flat Plate, for (i) Local, laminar or turbulent
flow and (ii) Average, laminar or mixed flow, to evaluate the local and average convection coefficients as a
function of position on the plate.  In each of these tools, the value of the critical Reynolds number, Rexc, can be
set corresponding to the special flow conditions.   */

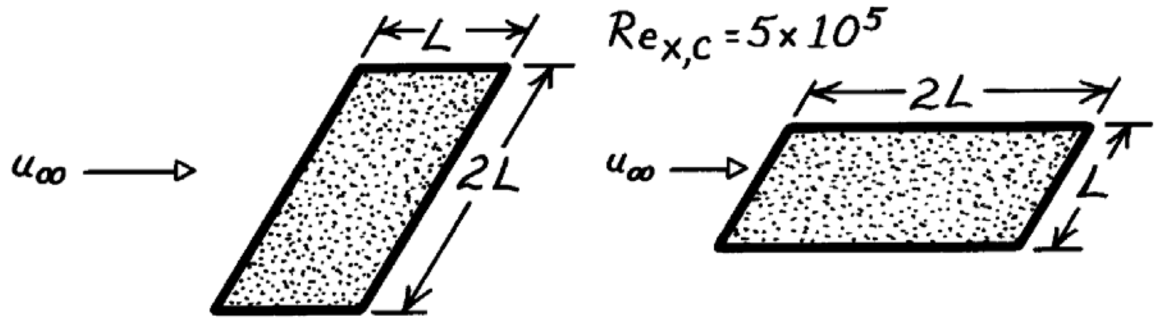
PROBLEM 7.15

KNOWN: Two plates of length L and 2L experience parallel flow with a critical Reynolds number of 5×10^5.

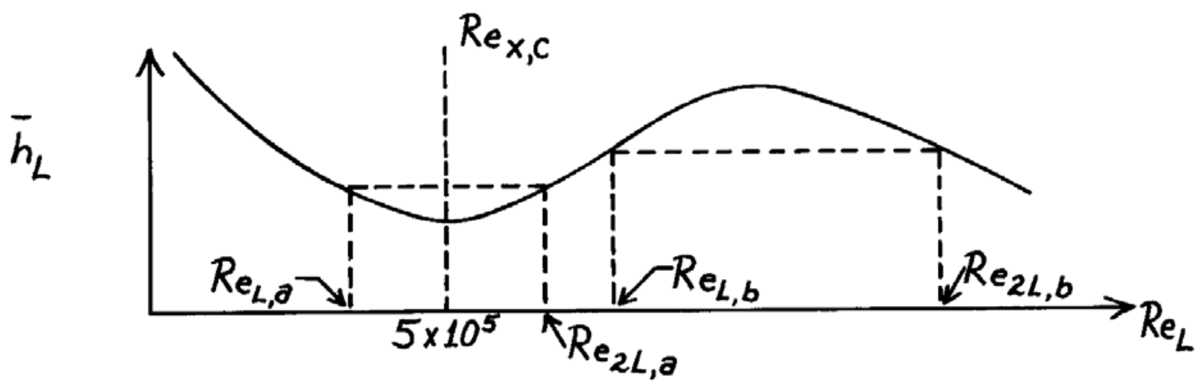
FIND: Reynolds numbers for which the total heat transfer rate is independent of orientation.

SCHEMATIC:



ASSUMPTIONS: (1) Plate temperatures and flow conditions are equivalent.

ANALYSIS: The total heat transfer rate would be the same ($q_L = q_{2L}$), if the convection coefficients were equal, $\bar{h}_L = \bar{h}_{2L}$. Conditions for which such an equality is possible may be inferred from a sketch of $\bar{h}_L$ versus Re_L.



For laminar flow $\left(Re_L < Re_{x,c}\right)$, $\bar{h}_L \; \alpha \; L^{-1/2}$, and for mixed laminar and turbulent flow $\left(Re_L > Re_{x,c}\right)$, $\bar{h}_L = C_1 L^{-1/5} - C_2 L^{-1}$. Hence $\bar{h}_L$ varies with Re_L as shown, and two possibilities are suggested.

Case (a): Laminar flow exists on the shorter plate, while mixed flow conditions exist on the longer plate.

Case (b): Mixed boundary layer conditions exist on both plates.

In both cases, it is required that

$$\bar{h}_L = \bar{h}_{2L} \qquad \text{and} \qquad Re_{2L} = 2\, Re_L.$$

Continued …

Case (a): From expressions for $\overline{h}_L$ in laminar and mixed flow

$$0.664\ \frac{k}{L} Re_L^{1/2}\ Pr^{1/3} = \frac{k}{2L}\left(0.037\ Re_{2L}^{4/5} - 871\right) Pr^{1/3}$$
$$0.664\ Re_L^{1/2} = 0.032\ Re_L^{4/5} - 435.$$

Since $Re_L < 5 \times 10^5$ and $Re_{2L} = 2\ Re_L > 5 \times 10^5$, the required value of Re_L may be narrowed to the range

$$2.5 \times 10^5 \quad < \quad Re_L \quad < \quad 5 \times 10^5.$$

From a trial-and-error solution, it follows that

$$Re_L \approx 3.2 \times 10^5.$$ <

Case (b): For mixed flow on both plates

$$\frac{k}{L}\left(0.037\ Re_L^{4/5} - 871\right)\ Pr^{1/3} = \frac{k}{2L}\left(0.037\ Re_{2L}^{4/5} - 871\right)\ Pr^{1/3}$$

or

$$0.037\ Re_L^{4/5} - 871 = 0.032\ Re_L^{4/5} - 435$$
$$0.005\ Re_L^{4/5} = 436$$

$$Re_L \approx 1.50 \times 10^6.$$ <

COMMENTS: (1) Note that it is impossible to satisfy the requirement that $\overline{h}_L = \overline{h}_{2L}$ if $Re_L < 0.25 \times 10^5$ (laminar flow for both plates).

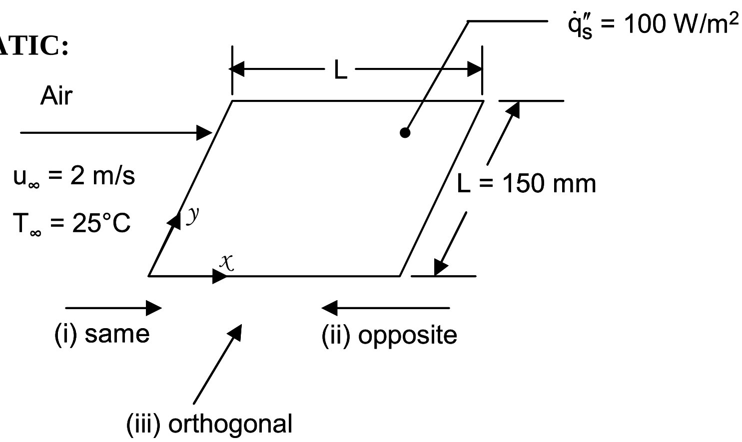
(2) The results are independent of the nature of the fluid.

PROBLEM 7.16

KNOWN: Dimensions of and heat generation rate in thin membrane. Velocity and temperature of air flow parallel to membrane. Air streams above and below membrane are in same, opposite, or orthogonal directions.

FIND: (a) Minimum and maximum local membrane temperatures. Flow configuration that minimizes the membrane temperature. (b) Plot the surface temperature distribution for flow in the same and opposite directions. Find configuration that minimizes spatial temperature gradients.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Boundary layer assumptions hold, (3) Constant properties, (4) Solutions are bounded by constant surface temperature and constant heat flux cases for the opposite and orthogonal flow configurations.

PROPERTIES: Table A-4, Air ($T_f \approx 323$ K): $\nu = 18.20 \times 10^{-6}$ m^2/s, k = 0.0280 W/m·K, Pr = 0.704.

ANALYSIS:

(a) We begin by calculating the Reynolds number

$$Re_L = \frac{u_\infty L}{\nu} = \frac{2 \text{ m/s} \times 0.15 \text{ m}}{18.20 \times 10^{-6} \text{ m}^2/\text{s}} = 1.65 \times 10^4$$

Therefore, the flow is laminar.

<u>(a) Top and bottom flows in same direction.</u>

By symmetry, the heat flux from the membrane to the air is 50 W/m^2 everywhere for the top and bottom air flows. Since the heat flux is uniform, the local Nusselt number is given by Equation 7.45,

$$Nu_x = 0.453\, Re_x^{1/2}\, Pr^{1/3}$$

Thus $h_x = c_q x^{-1/2}$

where

$$c_q = 0.453(u_\infty/\nu)^{1/2}\, Pr^{1/3}\, k$$

$$= 0.453(2 \text{ m/s}/18.2 \times 10^{-6} \text{ m}^2/\text{s})^{1/2} \times (0.704)^{1/3} \times 0.028 \text{ W/m}\cdot\text{K} = 3.74 \text{ W/m}^{3/2}\cdot\text{K}$$

Then $q_s'' = h_x(T_s - T_\infty)$ and $T_s - T_\infty = \dfrac{q_s''}{h_x} = \dfrac{q_s''}{c_q} x^{1/2}$ (1)

Continued…

PROBLEM 7.16 (Cont.)

Clearly the minimum temperature occurs at x = 0 and is

$$T_{min} = T_\infty = 25°C$$ <

The maximum temperature occurs at x = L and is

$$T_{max} = 25°C + 50\ W/m^2 \times (0.15\ m)^{1/2}/3.74\ W/m^{3/2}\cdot K = 30.2°C$$ <

(ii) Top and bottom flows in opposite direction.
The heat flux entering each of the top and bottom flows will no longer be uniform. Near x = 0, where the top flow first encounters the plate, the heat transfer coefficient on the top surface is theoretically infinite, and all the generated heat will enter the top flow. The opposite situation will occur at x = L.

We bound the solution by considering Nusselt number correlations for uniform surface temperature and uniform surface heat flux, Equations 7.23 and 7.45. In both cases, the heat transfer coefficient varies as $x^{-1/2}$, where x is the distance from the leading edge, thus for the top and bottom,

$$h_{x,t} = cx^{-1/2},\quad h_{x,b} = c(L - x)^{-1/2}$$

And all of the generated heat is removed by the top and bottom flows:

$$\dot{q}'' = (h_{x,t} + h_{x,b})(T_s - T_\infty)$$

Thus $$T_s - T_\infty = \frac{\dot{q}''}{h_{x,t} + h_{x,b}} = \frac{\dot{q}''}{c\left[x^{-1/2} + (L - x)^{-1/2}\right]} \qquad (2)$$

The minimum temperature occurs at x = 0 or x = L, and is

$$T_{min} = T_\infty = 25°C$$ <

The maximum temperature occurs where the denominator is minimum:

$$\frac{d}{dx}\left[x^{-1/2} + (L - x)^{-1/2}\right] = 0$$

$$-\frac{1}{2}x^{-3/2} + \frac{1}{2}(L - x)^{-3/2} = 0$$

$$x = L - x$$

$$x = L/2$$

At that location

$$T_{max} = T_\infty + \frac{\dot{q}''}{c2(L/2)^{-1/2}}$$

For uniform surface temperature,

$$c_T = 0.332(u_\infty/\nu)^{1/2}\ Pr^{1/3}\ k$$

$$= 0.332(2\ m/s/18.2 \times 10^{-6} m^2/s)^{1/2} \times (0.704)^{1/3} \times 0.0280\ W/m\cdot K = 2.74\ W/m^{3/2}\cdot K$$

And $$T_{max} = 25°C + \frac{100\ W/m^2}{2.74\ W/m^{3/2}\cdot K \times 2 \times (0.15\ m/2)^{-1/2}} = 30.0°C$$

Continued…

PROBLEM 7.16 (Cont.)

For uniform surface heat flux, we previously found $c_q = 3.74\ W/m^{3/2}\cdot K$, thus, $T_{max} = 28.7°C$.

Therefore, for the opposite flow case, $28.7°C \le T_{max} \le 30.0°C$ <

(iii) Top and bottom flows in orthogonal directions.
Here the heat transfer coefficients are given by

$$h_{x,t} = cx^{-1/2}, \quad h_{y,b} = cy^{-1/2}$$

And $\quad \dot{q}'' = c(x^{-1/2} + y^{-1/2})(T_s - T_\infty)$

So $\quad T_s - T_\infty = \dfrac{\dot{q}''}{c\left(x^{-1/2} + y^{-1/2}\right)}$

The temperature will be minimum along x = 0 or y = 0, where

$$T_{min} = T_\infty = 25°C$$ <

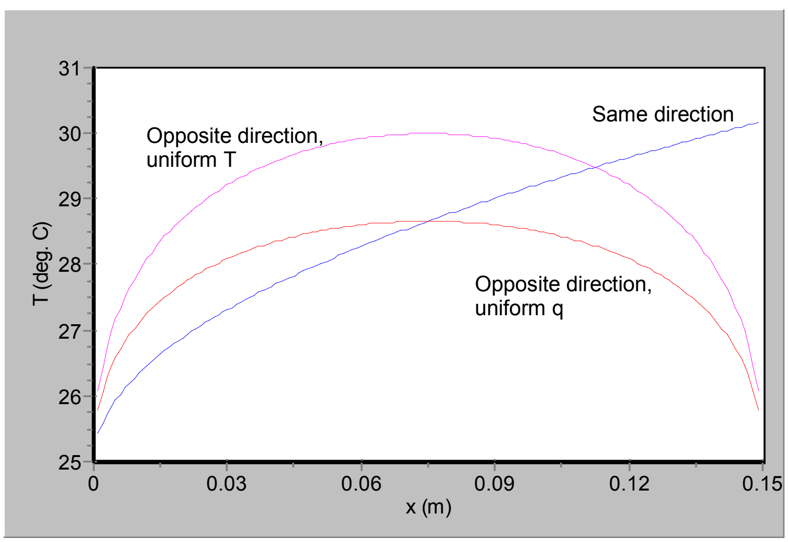
The temperature will be maximum along x = y = L, where

$$T_{max} = T_\infty + \frac{\dot{q}''}{c\,2\,L^{-1/2}}$$

The values of c are the same as previously, therefore we find $30.2°C \le T_{max} \le 32.1°C$ <

The surface temperature is minimized when the air streams are in opposite directions, because a small heat transfer coefficient on the top is paired with a large heat transfer coefficient on the bottom, and vice versa. <

(b) *IHT* was used to plot Equation (1) and (2) for $c = c_T$ or c_q. The result is shown below.



The spatial temperature gradients are somewhat less for the opposite flow case.

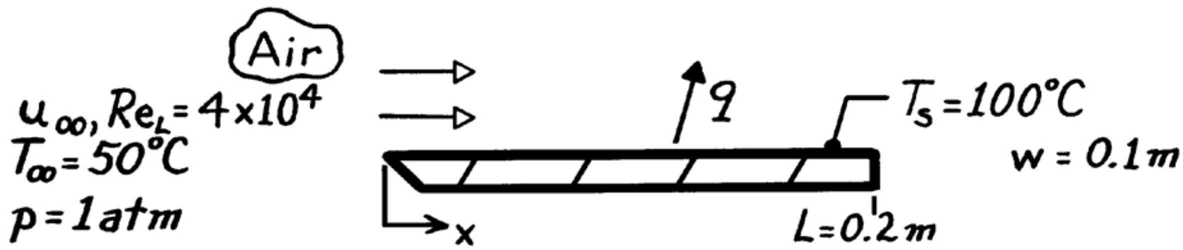
COMMENTS: To correctly treat the convective heat transfer would require a coupled numerical solution of the thermal energy equation for both boundary layers simultaneously.

PROBLEM 7.17

KNOWN: Temperature, pressure and Reynolds number for air flow over a flat plate of uniform surface temperature.

FIND: (a) Rate of heat transfer from the plate, (b) Rate of heat transfer if air velocity is doubled and pressure is increased to 10 atm.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform surface temperature, (3) Negligible radiation, (4) $Re_{x_c} = 5\times10^5$.

PROPERTIES: *Table A-4*, Air (T_f = 348K, 1 atm): k = 0.0299 W/m·K, Pr = 0.70.

ANALYSIS: (a) The heat rate is

$$q = \bar{h}_L (w \times L)\ (T_s - T_\infty).$$

Since the flow is laminar over the entire plate for $Re_L = 4 \times 10^4$, it follows that

$$\overline{Nu}_L = \frac{\bar{h}_L L}{k} = 0.664\ Re_L^{1/2}\ Pr^{1/3} = 0.664(40,000)^{1/2}(0.70)^{1/3} = 117.9.$$

Hence $$\bar{h}_L = 117.9\frac{k}{L} = 117.9\frac{0.0299\ W/m\cdot K}{0.2m} = 17.6\ W/m^2\cdot K$$

and $$q = 17.6\frac{W}{m^2\cdot K}(0.1m\times0.2m)\ (100-50)^\circ C = 17.6\ W.$$ <

(b) With $p_2 = 10\ p_1$, it follows that $\rho_2 = 10\ \rho_1$ and $\nu_2 = \nu_1/10$. Hence

$$Re_{L,2} = \left(\frac{u_\infty L}{\nu}\right)_2 = 2\times10\left(\frac{u_\infty L}{\nu}\right)_1 = 20\ Re_{L,1} = 8\times10^5$$

and mixed boundary layer conditions exist on the plate. Hence

$$\overline{Nu}_L = \frac{\bar{h}_L L}{k} = \left(0.037\ Re_L^{4/5} - 871\right)\ Pr^{1/3} = \left[0.037\times\left(8\times10^5\right)^{4/5} - 871\right]\ (0.70)^{1/3}$$

$$\overline{Nu}_L = 961.$$

Hence, $$\bar{h}_L = 961\frac{0.0299\ W/m\cdot K}{0.2m} = 143.6\ W/m^2\cdot K$$

$$q = 143.6\frac{W}{m^2\cdot K}(0.1m\times0.2m)\ (100-50)^\circ C = 143.6\ W.$$ <

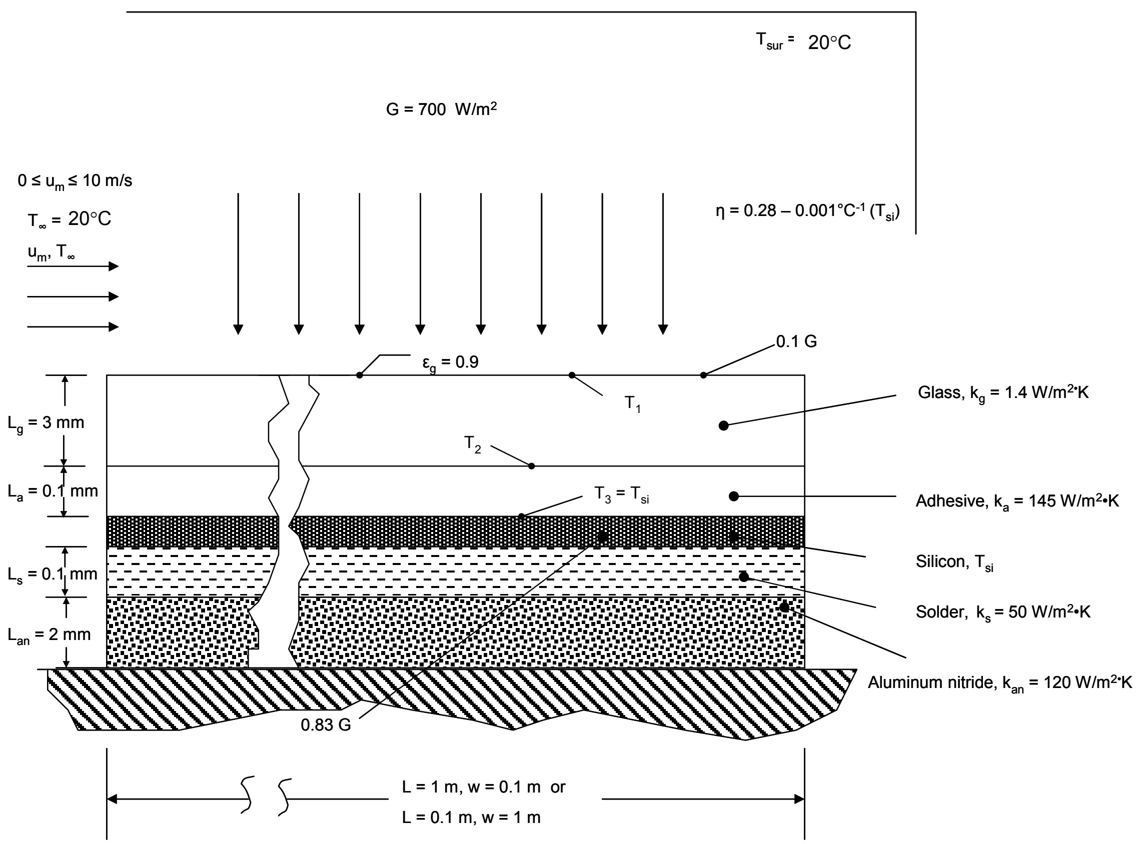
COMMENTS: Note that, in calculating $Re_{L,2}$, ideal gas behavior has been assumed. It has also been assumed that k, μ and Pr are independent of pressure over the range considered.

PROBLEM 7.18

KNOWN: Solar cell material dimensions and properties, solar-to-electrical conversion efficiency dependence on silicon temperature, solar irradiation and location where the irradiation is absorbed, air velocity and temperature.

FIND: (a) Electrical power produced and silicon temperature for a L = 1 m long, w = 0.1 m wide solar cell with G = 700 W/m^2 with tripped boundary layer, (b) Same as Part (a) but with L = 0.1 m, w = 1 m, (c) Plot of the electrical power produced and the silicon temperature for air velocities in the range $0 \le u_m \le 10$ m/s for the L = 0.1 m configuration.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional heat transfer, (4) Tripped and turbulent boundary layer, (5) Large surroundings, (6) Negligible contact resistances.

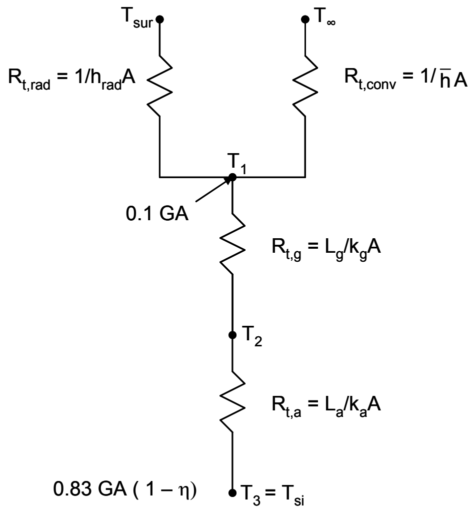
PROPERTIES: Table A.4, air (assume T_f = 308 K, p = 1 atm): k = 0.0269 W/m·K, $\nu = 1.669 \times 10^{-5}$ m^2/s, Pr = 0.706.

ANALYSIS:

(a) We begin by drawing the thermal circuit for the problem, recognizing that there is no heat transfer downward from the thin silicon layer.

Continued…

PROBLEM 7.18 (Cont.)



The thermal resistances are

$$R_{t,g} = L_g/k_g A = 3 \times 10^{-3}\ \text{m}\Big/(1.4\ \text{W/m}\cdot\text{K} \times 1\ \text{m} \times 0.1\ \text{m}) = 21.43 \times 10^{-3}\ \text{K/W}$$

$$R_{t,a} = L_a/k_a A = 0.1 \times 10^{-3}\ \text{m}\Big/(145\ \text{W/m}\cdot\text{K} \times 1\ \text{m} \times 0.1\ \text{m}) = 6.897 \times 10^{-6}\ \text{K/W}$$

$$h_{rad} = \varepsilon_g \sigma (T_1 + T_{sur})(T_1^2 + T_{sur}^2)$$

$$R_{t,rad} = \frac{1}{0.9 \times 5.67 \times 10^{-8}\ \text{W/m}^2\cdot\text{K}^4 \times (T_1 + 295\ \text{K}) \times (T_1^2 + (295\text{K})^2) \times 1\ \text{m} \times 0.1\ \text{m}} \quad (1)$$

For the tripped boundary layer,

$$Re_L = \frac{u_m L}{\nu} = \frac{4\text{m/s} \times 1\text{m}}{1.669 \times 10^{-5}\ \text{m}^2/\text{s}} = 239.7 \times 10^3$$

From Equation 7.38

$$\overline{Nu}_L = 0.037 Re_L^{4/5} Pr^{1/3} = 0.037 \times \left[239.7 \times 10^3\right]^{0.8} \times 0.706^{1/3} = 662.8$$

$$\bar{h} = \overline{Nu}_L k/L = 662.8 \times 0.0269\ \text{W/m}\cdot\text{K/1m} = 17.82\ \text{W/m}^2\cdot\text{K}$$

$$R_{t,conv} = 1/\bar{h}A = \frac{1}{17.82\ \text{W/m}^2\cdot\text{K} \times 1\ \text{m} \times 0.1\ \text{m}} = 561.2 \times 10^{-3}\ \text{K/W}$$

From the thermal circuit,

$$0.83GA\,(1 - \eta) = (T_3 - T_1)/(R_{t,g} + R_{t,a}) \ \text{ or }\ T_3 - T_1 = (R_{t,g} + R_{t,a})\, 0.83GA\,(1 - \eta)$$

$$T_3 - T_1 = (21.43 \times 10^{-3}\ \text{K/W} + 6.897 \times 10^{-6}\ \text{K/W}) \times 0.83 \times 700\ \text{W/m}^2 \times 1\text{m} \times 0.1\text{m} \times (1-\eta)$$

$$T_3 - T_1 = 1.245(1 - \eta) \quad (2)$$

We also note from the thermal circuit,

Continued…

PROBLEM 7.18 (Cont.)

$$0.83GA(1-\eta)+0.1G=(T_1-T_{sur})/R_{t,rad}+(T_1-T_\infty)/R_{t,conv}$$

Since $T_\infty = T_{sur}$

$$0.83GA(1-\eta)+0.1G=(T_1-T_{sur})\left[\frac{1}{R_{t,rad}}+\frac{1}{R_{t,conv}}\right]$$

$$T_1-T_{sur}=\frac{0.83GA(1-\eta)+0.1GA}{\left[1/R_{t,rad}+1/R_{t,conv}\right]}$$

$$T_1-T_{sur}=\frac{0.83\times 700\ \text{W/m}^2\times 1\ \text{m}\times 0.1\ \text{m}\times(1-\eta)+0.1\times 700\ \text{W/m}^2\times 1\ \text{m}\times 0.1\ \text{m}}{\left[1/R_{t,rad}+1.7819\ \text{W/K}\right]}$$

$$T_1-T_{sur}=\frac{58.1\ \text{W}(1-\eta)+7\ \text{W}}{\left[1/R_{t,rad}+1.7819\ \text{W/K}\right]} \qquad (3)$$

where $\eta = 0.28 - 0.001°\text{C}^{-1}\times(T_3-273)°\text{C}$ (4)

Equations (1) – (4) may be solved simultaneously to yield

$\eta = 0.2353$, $T_3 = T_{si} = 44.7°\text{C}$, $T_1 = 43.7°\text{C}$, $R_{t,rad} = 1.71\ \text{K/W}$ <

The electric power is $P = 0.83GA\eta = 0.83\times 700\ \text{W/m}^2\times 1\ \text{m}\times 0.1\ \text{m}\times 0.2353 = 13.67\ \text{W}$ <

(b) For the tripped boundary layer

$$Re_L=\frac{u_m L}{\nu}=\frac{4/\text{ms}\times 0.1\text{m}}{1.669\times 10^{-5}\ \text{m}^2/\text{s}}=239.7\times 10^2$$

From Equation 7.38

$$\overline{Nu}_L=0.037Re^{4/5}Pr^{1/3}=0.037\times\left[239.7\times 10^2\right]^{0.8}\times 0.706^{1/3}=105$$

$$\bar{h}=\overline{Nu}_L k/L=105\times 0.0269\ \text{W/m}\cdot\text{K}/1\text{m}=28.25\ \text{W/m}^2\cdot\text{K}$$

$$R_{t,conv}=1/\bar{h}A=\frac{1}{28.25\ \text{W/m}^2\cdot\text{K}\times 1\ \text{m}\times 0.1\ \text{m}}=354.0\times 10^{-3}\ \text{K/W}$$

Proceeding as in Part (a) we find

$\eta = 0.242$, $T_3 = T_{si} = 38.0°\text{C}$, $T_1 = 37.1°\text{C}$, $R_{t,rad} = 1.768\ \text{K/W}$, $P = 14.06\ \text{W}$ <
