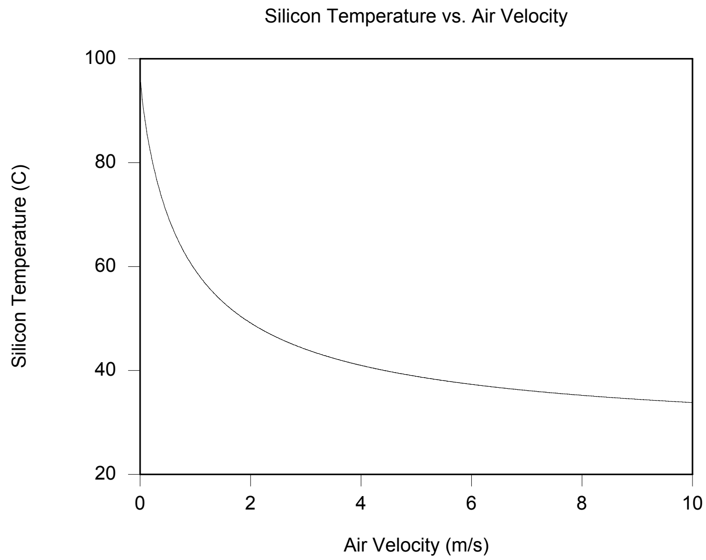
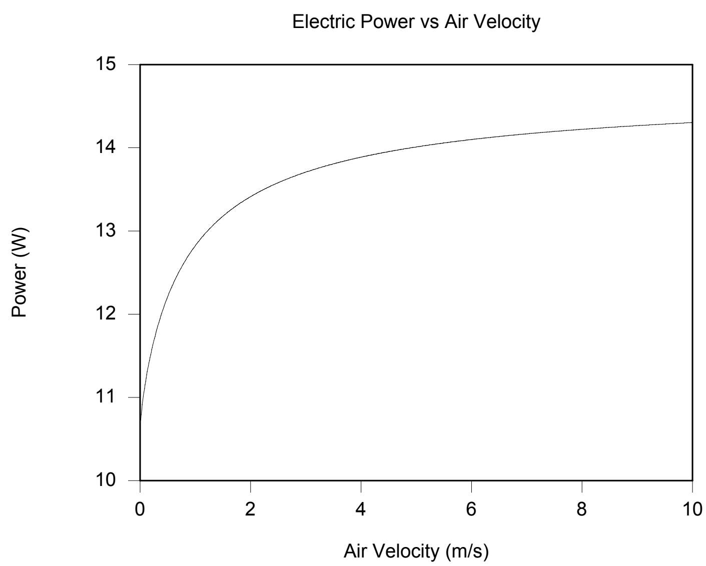
(c) Solving Equations 1 through 4 over the velocity range $0 \le u_m \le 10$ m/s yields the following behavior

Continued…

PROBLEM 7.18 (Cont.)





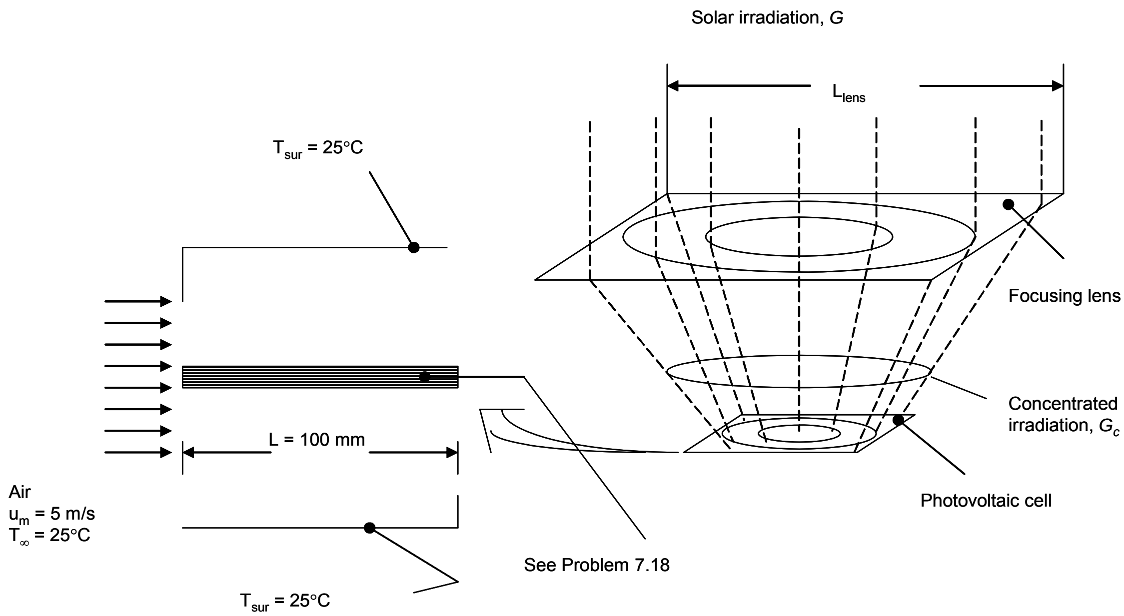
COMMENTS: (1) Changing the orientation of the solar panel to the L = 0.1 m configuration reduces the temperature of the silicon semiconductor significantly. The influence of the orientation on the electric power would be more pronounced for warmer air temperatures. (2) Decreasing the air velocity results in significantly diminished power output. At very low cross flow velocities, natural convection would become significant and would lead to slightly improved power output relative to that predicted here. (3) Film temperatures for Parts (a) and (b) are 31.9 °C and 28.6 °C, respectively. The assumed value of the film temperature is good.

PROBLEM 7.19

KNOWN: Dimensions of a photovoltaic cell, cooling air velocity and temperature, size of concentrating lens, photovoltaic construction and properties.

FIND: (a) The electric power output and silicon temperature of a system consisting of a 400 mm × 400 mm concentrating lens and a 100 mm × 100 mm photovoltaic cell, (b) Variation of the electric power output and silicon temperature for 100 mm ≤ L_{lens} ≤ 600 mm.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional heat transfer, (4) Tripped and turbulent boundary layer, (5) Large surroundings, (6) Negligible contact resistances.

PROPERTIES: Given, Glass: k_g = 1.4 W/m·K, ε_g = 0.90, Adhesive: k_a = 145 W/m·K, Solder, k_s = 50 W/m·K, Aluminum nitride: k_{an} = 120 W/m·K, Table A.4, air (assume T_f = 70°C): k = 0.02948 W/m·K, $\nu = 2.022 \times 10^{-5}$ m^2/s, Pr = 0.701.

ANALYSIS:

(a) We begin by drawing the thermal circuit,

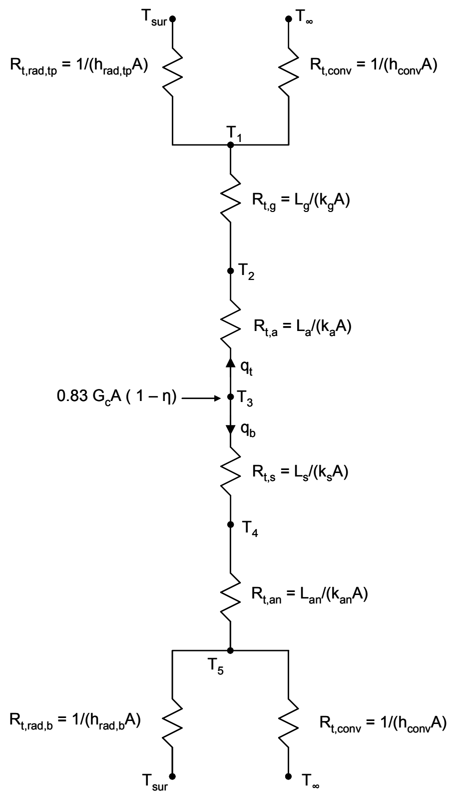
PROBLEM 7.19 (Cont.)



The thermal resistances are

$$R_{t,g} = L_g/(k_g A) = 3 \times 10^{-3} \text{ m} \big/ \left(1.4 \text{ W/m} \cdot \text{K} \times 0.1 \text{ m} \times 0.1 \text{ m}\right) = 0.2143 \text{ K/W}$$

$$R_{t,a} = L_a/(k_a A) = 0.1 \times 10^{-3} \text{ m} \big/ \left(145 \text{ W/m} \cdot \text{K} \times 0.1 \text{ m} \times 0.1 \text{ m}\right) = 6.897 \times 10^{-5} \text{ K/W}$$

$$R_{t,s} = L_s/(k_s A) = 0.1 \times 10^{-3} \text{ m} \big/ \left(50 \text{ W/m} \cdot \text{K} \times 0.1 \text{ m} \times 0.1 \text{ m}\right) = 200 \times 10^{-6} \text{ K/W}$$

$$R_{t,an} = L_{an}/(k_{an} A) = 2 \times 10^{-3} \text{ m} \big/ \left(120 \text{ W/m} \cdot \text{K} \times 0.1 \text{ m} \times 0.1 \text{ m}\right) = 1.67 \times 10^{-3} \text{ K/W}$$

$$h_{rad,tp} = \varepsilon_g \sigma (T_1 + T_{sur})(T_1^2 + T_{sur}^2)$$

$$R_{t,rad,tp} = \frac{1}{0.9 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (T_1 + 298 \text{ K}) \times (T_1^2 + (298 \text{ K})^2)} \quad (1)$$

$$h_{rad,b} = \varepsilon_b \sigma (T_5 + T_{sur})(T_5^2 + T_{sur}^2)$$

$$R_{t,rad,b} = \frac{1}{0.95 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (T_5 + 298 \text{ K}) \times (T_5^2 + (298 \text{ K})^2)} \quad (2)$$

For the top and bottom tripped boundary layers,

$$Re_L = \frac{u_\infty L}{\nu} = \frac{5 \text{ m/s} \times 0.1 \text{ m}}{2.022 \times 10^{-5} \text{ m}^2\text{/s}} = 24.73 \times 10^3$$

From Equation 7.38

Continued…

PROBLEM 7.19 (Cont.)

$$\overline{Nu}_L = 0.037 Re_L^{4/5} Pr^{1/3} = 0.037 \times \left[24.73 \times 10^3\right]^{0.8} \times 0.701^{1/3} = 107.5$$

$$\bar{h} = \overline{Nu}_L k/L = \frac{107.5 \times 0.02948 \text{ W/m} \cdot \text{K}}{0.1 \text{ m}} = 31.69 \text{ W/m}^2 \cdot \text{K}$$

$$R_{t,conv} = 1/\bar{h}A = 1 \big/ (31.69 \text{ W/m}^2 \cdot \text{K} \times 0.1 \text{ m} \times 0.1 \text{ m}) = 3.155 \text{K/W}$$

From the thermal circuit,

$$0.83 G_c A (1 - \eta) = 0.83 G (L_{lens}/L)^2 A(1 - \eta) = q_t + q_b$$

$$0.83 \times 700 \text{ W/m}^2 \times 4^2 \times 0.1 \text{ m} \times 0.1 \text{ m} \times (1 - \eta) = q_t + q_b$$

$$9296 \text{ W} = (q_t + q_b)/(1 - \eta) \qquad (3)$$

where

$$q_t = (T_3 - T_1)/(R_{t,a} + R_{t,g}) = (T_3 - T_1)/0.2144 \text{ K/W} \qquad (4)$$

and

$$q_b = (T_1 - T_{sur}) \big/ R_{t,rad,tp} + (T_1 - T_\infty) \big/ R_{t,conv}$$

$$= (T_1 - 298 \text{ K}) \big/ R_{t,rad,tp} + (T_1 - 298 \text{ K}) \big/ 3.155 \text{ K/W} \qquad (5)$$

Likewise

$$q_b = (T_3 - T_5)/(R_{t,s} + R_{t,an}) = (T_3 - T_5)/1.87 \times 10^{-3} \text{ K/W} \qquad (6)$$

and

$$q_b = (T_5 - T_{sur}) \big/ R_{t,rad,b} + (T_5 - T_\infty) \big/ R_{t,conv}$$

$$= (T_5 - 298 \text{ K}) \big/ R_{t,rad,b} + (T_5 - 298 \text{ K}) \big/ 3.155 \text{ K/W} \qquad (7)$$

The solar-to-electrical conversion efficiency is

$$\eta = 0.28 - 0.001 ^\circ\text{C}^{-1} \times (T_3 - 273) ^\circ\text{C} \qquad (8)$$

Equations (1) through (8) may be solved simultaneously to yield

$$T_{si} = T_3 - 273 = 125.9^\circ\text{C}, \eta = 0.1541, T_1 = 390.9 \text{ K}, T_5 = 398.8 \text{ K},$$

$$R_{t,rad,tp} = 11.78 \text{ K/W}, R_{t,rad,b} = 10.75 \text{ K/W}, q_t = 37.32 \text{ W}, q_b = 41.32 \text{ W}.$$

The electric power produced is

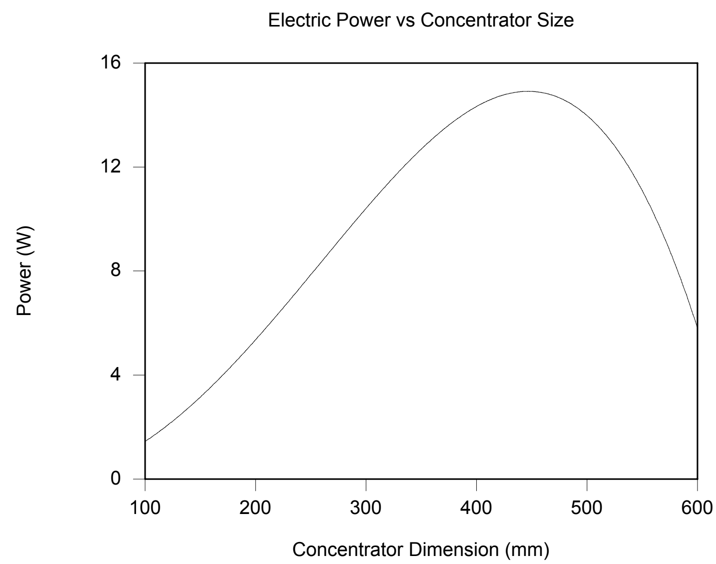
$$P = 0.83 G (L_{lens}/L)^2 A\eta$$

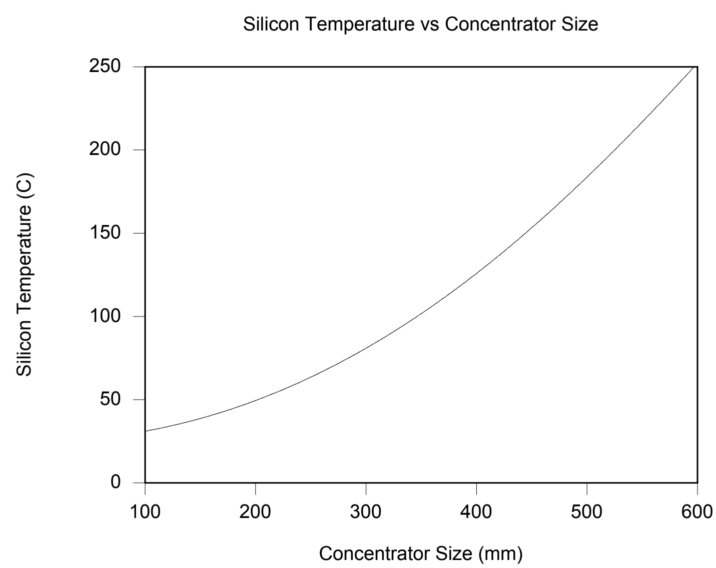
$$= 0.83 \times 700 \text{ W/m}^2 \times 4^2 \times 0.1 \text{ m} \times 0.1 \text{ m} \times 0.1541 = 14.33 \text{ W} \qquad <$$

Continued…

PROBLEM 7.19 (Cont.)

(b) The *IHT* Software may be used to investigate the sensitivity of the silicon temperature and the electric power produced in response to the concentrating lense size. Results are shown below. <





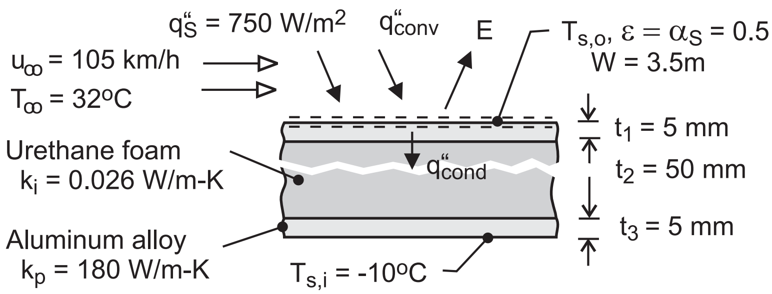
COMMENTS: (1) The electric power output is highly sensitive to the size of the concentrating lens The concentrated irradiation continually increases as the concentrator is made larger until, eventually, the silicon temperature becomes very high and the solar-to-electrical conversion efficiency becomes small. (2) The electric power could be increased if heat sinks and/or liquid cooling could be applied to the solar cell, keeping the silicon temperature low and the conversion efficiency relatively high. (3) The assumed film temperature is a good estimate since $T_{f,tp} = 71.4$ °C and $T_{f,bot} = 75.4$ °C.

PROBLEM 7.20

KNOWN: Material properties, inner surface temperature and dimensions of roof of refrigerated truck compartment. Truck speed and ambient temperature. Solar irradiation.

FIND: (a) Outer surface temperature of roof and rate of heat transfer to compartment, (b) Effect of changing radiative properties of outer surface, (c) Effect of eliminating insulation.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible irradiation from the sky, (2) Turbulent flow over entire outer surface, (3) Average convection coefficient may be used to estimate average surface temperature, (4) Constant properties.

PROPERTIES: *Table A-4*, air (p = 1 atm, $T_f \approx 300K$): $\nu = 15.89 \times 10^{-6}\ m^2/s$, k = 0.0263 W/m·K, Pr = 0.707.

ANALYSIS: (a) From an energy balance for the outer surface,

$$\alpha_S G_S + q''_{conv} - E = q''_{cond} = \frac{T_{s,o} - T_{s,i}}{R''_{tot}}$$

$$\alpha_S G_S + \overline{h}\left(T_\infty - T_{s,o}\right) - \varepsilon\sigma T_{s,o}^4 = \frac{T_{s,o} - T_{s,i}}{2R''_p + R''_i}$$

where $R''_p = \left(t_1 / k_p\right) = 2.78 \times 10^{-5} m^2 \cdot K/W$, $R''_i = \left(t_2 / k_i\right) = 1.923\, m^2 \cdot K/W$, and with $Re_L = u_\infty L/\nu$ $= 29.2\, m/s \times 10m / 15.89 \times 10^{-6} m^2/s = 1.84 \times 10^7$,

$$\overline{h} = \frac{k}{L} 0.037\, Re_L^{4/5} Pr^{1/3} = \frac{0.0263\, W/m \cdot K}{10m} 0.037 \left(1.84 \times 10^7\right)^{4/5} (0.707)^{1/3} = 56.2\, W/m^2 \cdot K$$

Hence,

$$0.5\left(750\, W/m^2 \cdot K\right) + 56.2\, W/m^2 \cdot K\left(305 - T_{s,o}\right) - 0.5 \times 5.67 \times 10^{-8}\, W/m^2 \cdot K^4\, T_{s,o}^4 = \frac{T_{s,o} - 263K}{\left(5.56 \times 10^{-5} + 1.923\right) m^2 \cdot K/W}$$

Solving, we obtain

$$T_{s,o} = 306.8K = 33.8°C$$ <

Hence, the heat load is

$$q = (W \cdot L) q''_{cnd} = (3.5m \times 10m) \frac{(33.8 + 10)°C}{1.923\, m^2 \cdot K/W} = 797\, W$$ <

(b) With the special surface finish $\left(\alpha_S = 0.15,\ \varepsilon = 0.8\right)$,

Continued …

PROBLEM 7.20 (Cont.)

$$T_{s,o} = 300.1\text{K} = 27.1°\text{C}$$ <

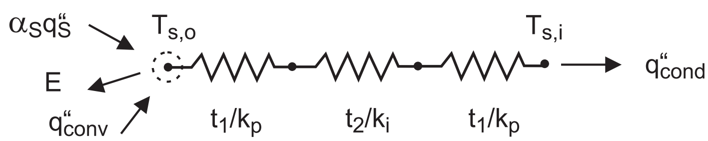
$$q = 675.3\text{W}$$ <

(c) Without the insulation ($t_2 = 0$) and with $\alpha_S = \varepsilon = 0.5$,

$$T_{s,o} = 263.1\text{K} = -9.9°\text{C}$$ <

$$q = 90,630\text{W}$$ <

COMMENTS: (1) Use of the special surface finish reduces the solar input, while increasing radiation emission from the surface. The cumulative effect is to reduce the heat load by 15%. (2) The thermal resistance of the aluminum panels is negligible, and without the insulation, the heat load is *enormous*.

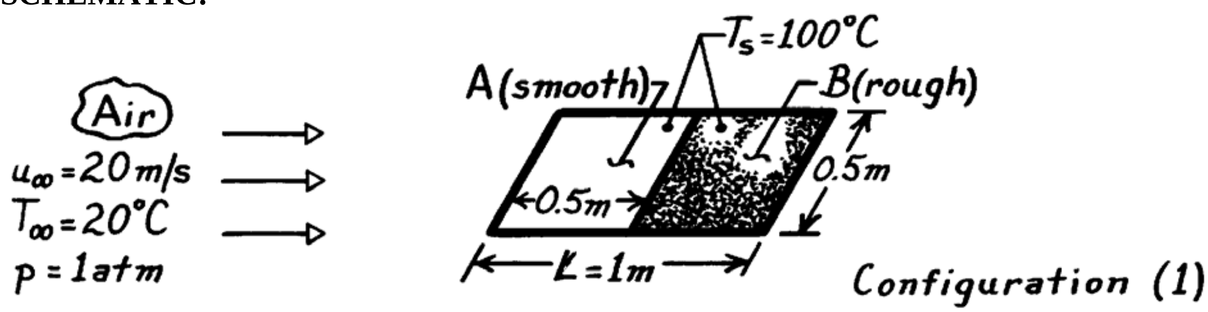


PROBLEM 7.21

KNOWN: Surface characteristics of a flat plate in an air stream.

FIND: Orientation which minimizes convection heat transfer.

SCHEMATIC:



ASSUMPTIONS: (1) Surface B is sufficiently rough to trip the boundary layer when in the upstream position (Configuration 2).

PROPERTIES: *Table A-4*, Air (T_f = 333K, 1 atm): $\nu = 19.2 \times 10^{-6}$ m^2/s, k = 28.7×10^{-3} W/m·K, Pr = 0.7.

ANALYSIS: Since Configuration (2) results in a turbulent boundary layer over the entire surface, the lowest heat transfer is associated with Configuration (1). Find

$$Re_L = \frac{u_\infty L}{\nu} = \frac{20\text{ m/s} \times 1\text{m}}{19.2 \times 10^{-6}\text{m}^2/\text{s}} = 1.04 \times 10^6.$$

Hence in Configuration (1), transition will occur just before the rough surface (x_c = 0.48m). Note that

$$\overline{Nu}_{L,1} = \left[0.037\left(1.04 \times 10^6\right)^{4/5} - 871\right] 0.7^{1/3} = 1366$$

$$\overline{Nu}_{L,2} = 0.037\left(1.04 \times 10^6\right)^{4/5} (0.7)^{1/3} = 2139 > \overline{Nu}_{L,1}.$$

For Configuration (1): $$\frac{\bar{h}_{L,1} L}{k} = \overline{Nu}_{L,1} = 1366.$$

Hence

$$\bar{h}_{L,1} = 1366\left(28.7 \times 10^{-3}\text{W/m} \cdot \text{K}\right)/1\text{m} = 39.2\text{ W/m}^2 \cdot \text{K}$$

and

$$q_1 = \bar{h}_{L,1} A\left(T_s - T_\infty\right) = 39.2\text{ W/m}^2 \cdot \text{K}\left(0.5\text{m} \times 1\text{m}\right)\left(100 - 20\right)\text{K}$$

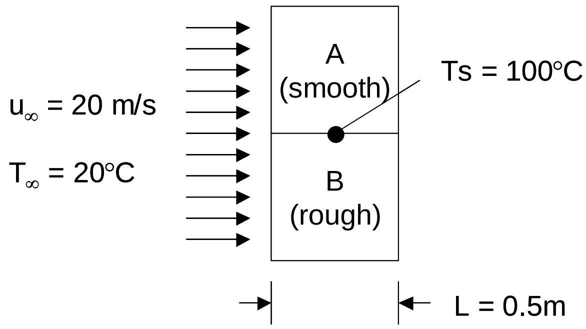
$$q_1 = 1568\text{ W}.$$ <

PROBLEM 7.22

KNOWN: Dimensions and orientation of a flat plate placed in atmospheric airstream, airstream velocity and temperature, plate temperature.

FIND: The average convection coefficient for the entire surface.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Boundary layer on rough plate is tripped at leading edge, (4) Transition occurs at $Re_{x,c}$ = 500,000.

PROPERTIES: *Table A.4*, air (T_f = 60°C = 333K, p = 1 atm): $\nu = 19.24\times10^{-6}$ m²/s, Pr = 0.702, k = 0.0288 W/m·K.

ANALYSIS: For both the smooth and rough sections of the plate,

$$Re_L = \frac{u_\infty L}{\nu} = \frac{20\text{m/s}\times 0.5\text{m}}{19.24\times 10^{-6}\text{m}^2/\text{s}} = 520{,}000$$

Therefore, flow over portion A of the plate is nearly all laminar except near the trailing edge.

For portion A, Eq. 7.38 yields

$$\bar{h}_A = \frac{k}{L}\left[0.037 Re_L^{4/5} - 871\right]Pr^{1/3} = \frac{0.0288\text{W/m}\cdot\text{K}}{0.5\text{m}}\left[0.037\times 520{,}000^{4/5} - 871\right]0.702^{1/3} = 26.2\ \text{W/m}^2\cdot\text{K}$$

For portion B, Eq. 7.38 yields

$$\bar{h}_B = \frac{k}{L}\left[0.037 Re_L^{4/5}\right]Pr^{1/3} = \frac{0.0288\text{W/m}\cdot\text{K}}{0.5\text{m}}\left[0.037\times 520{,}000^{4/5}\right]0.702^{1/3} = 70.8\ \text{W/m}^2\cdot\text{K}$$

Therefore, for the entire plate consisting of half portion A and half portion B,

$$\bar{h} = \frac{\bar{h}_A + \bar{h}_B}{2} = 48.5\ \text{W/m}^2\cdot\text{K}$$ <

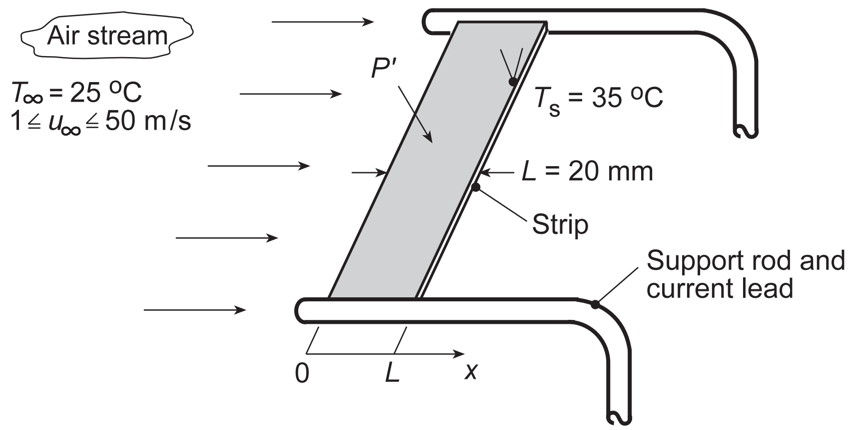
COMMENTS: (1) The value of the average coefficient for orientations 1 and 2 of Problem 7.21 are $\bar{h}_1 = 39.2\ \text{W/m}^2\cdot\text{K}$ and $\bar{h}_2 = 61.4\ \text{W/m}^2\cdot\text{K}$, respectively. The average heat transfer coefficient found here is approximately midway between the values associated with the other two orientations. This is coincidental, since the nature of the flow is very different for the three different orientations. (2) In reality, boundary layer development *cannot* proceed on the smooth and rough parts of the plate independent of the other part of the plate, as implied in the solution above. Rather, there will be an intermediate region that will be characterized by complex flow and heat transfer phenomena. The solution should be viewed as a first approximation of actual heat transfer conditions.

PROBLEM 7.23

KNOWN: Design of an anemometer comprised of a thin metallic strip supported by stiff rods serving as electrodes for passage of heating current. Fine-wire thermocouple on trailing edge of strip.

FIND: (a) Relationship between electrical power dissipation per unit width of the strip in the transverse direction, P' (mW/mm), and airstream velocity u_∞ when maintained at constant strip temperature, T_s; show the relationship graphically; (b) The uncertainty in the airstream velocity if the accuracy with which the strip temperature can be measured and maintained constant is ±0.2°C; (c) Relationship between strip temperature and airstream velocity u_∞ when the strip is provided with a constant power, P' = 30 mW/mm; show the relationship graphically. Also, find the uncertainty in the airstream velocity if the accuracy with which the strip temperature can be measured is ±0.2°C; (d) Compare features associated with each of the operating nodes.

SCHEMATIC:

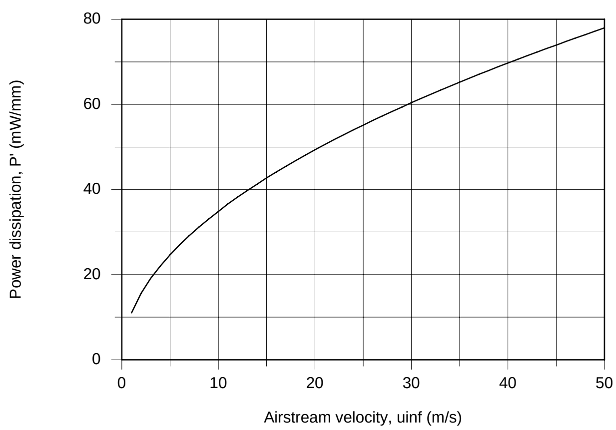


ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Strip has uniform temperature in the midspan region of the strip, (4) Negligible conduction in the transverse direction in the midspan region, and (5) Airstream over strip approximates parallel flow over two sides of a smooth flat plate.

ANALYSIS: (a) In the midspan region of uniform temperature T_s with no conduction in the transverse direction, all the dissipated electrical power is transferred by convection to the airstream,

$$P' = 2\bar{h}_L L\left(T_s - T_\infty\right) \qquad (1)$$

where P' is the power per unit width (transverse direction). Using the *IHT Correlation Tool* for *External Flow-Flat Plate* the power as a function of airstream velocity was determined and is plotted below. The IHT tool uses the flat plate correlation, Eq. 7.30 since the flow is laminar over this velocity range.



Continued...

PROBLEM 7.23 (Cont.)

(b) By differentiation of Eq. (1), the relative uncertainties of the convection coefficient and strip temperature are, assuming the power remains constant,

$$\frac{\Delta \bar{h}_L}{\bar{h}} = -\frac{\Delta T_s}{T_s - T_\infty} \qquad (2)$$

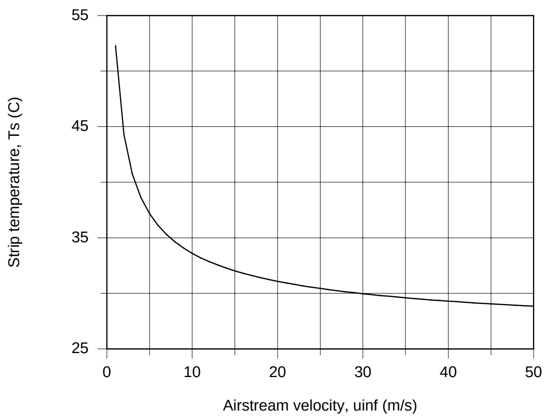
Since the flow was laminar for the range of airstream velocities, Eq. 7.30,

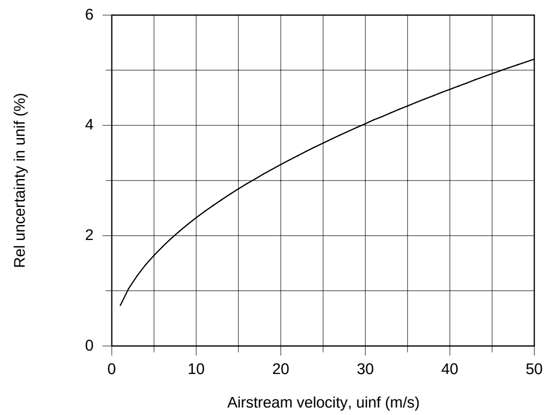
$$\bar{h}_L \sim u_\infty^{1/2} \qquad \text{or} \qquad \frac{\Delta \bar{h}_L}{\bar{h}_L} = 0.5\frac{\Delta u_\infty}{u_\infty} \qquad (3)$$

Hence, the relative uncertainty in the air velocity due to uncertainty in T_s, $\Delta T_s = \pm 0.2^\circ C$

$$\frac{\Delta u_\infty}{u_\infty} = 2\frac{\Delta T_s}{T_s - T_\infty} = 2\frac{\pm 0.2^\circ C}{(35-25)^\circ C} = \pm 4\% \qquad (4)<$$

(c) Using the IHT workspace setting $P' = 30$ mW/mm, the strip temperature T_s as a function of the airstream velocity was determined and plotted. Note that the slope of the T_s vs. u_∞ curve is steep for low velocities and relatively flat for high velocities. That is, the technique is more sensitive at lower velocities. Using Eq. (4), but with T_s dependent upon u_∞, the relative uncertainty in u_∞ can be determined.





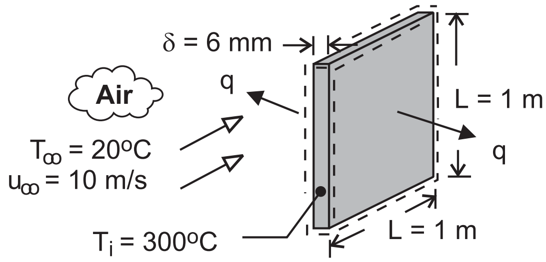
(d) For the constant power mode of operation, part (a), the uncertainty in u_∞ due to uncertainty in temperature measurement was found as 4%, independent of the magnitude u_∞. For the constant-temperature mode of operation, the uncertainty in u_∞ is less than 4% for velocities less than 30 m/s, with a value of 1% around 2 m/s. However, in the upper velocity range, the error increases to 5%.

PROBLEM 7.24

KNOWN: Plate dimensions and initial temperature. Velocity and temperature of air in parallel flow over plates.

FIND: Initial rate of heat transfer from plate. Rate of change of plate temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible radiation, (2) Negligible effect of conveyor velocity on boundary layer development, (3) Plates are isothermal, (4) Negligible heat transfer from sides of plate, (5) $Re_{x,c} = 5 \times 10^5$, (6) Constant properties.

PROPERTIES: *Table A-1*, AISI 1010 steel (573K): k_p = 49.2 W/m·K, c = 549 J/kg·K, ρ = 7832 kg/m^3. *Table A-4*, Air (p = 1 atm, T_f = 433K): ν = 30.4 × 10^{-6} m^2/s, k = 0.0361 W/m·K, Pr = 0.688.

ANALYSIS: The initial rate of heat transfer from a plate is

$$q = 2\,\bar{h}\,A_s\left(T_i - T_\infty\right) = 2\,\bar{h}\,L^2\left(T_i - T_\infty\right)$$

With $Re_L = u_\infty L/\nu = 10\,m/s \times 1m / 30.4\times10^{-6} m^2/s = 3.29\times10^5$, flow is laminar over the entire surface and

$$\overline{Nu}_L = 0.664\,Re_L^{1/2}\,Pr^{1/3} = 0.664\left(3.29\times10^5\right)^{1/2}\left(0.688\right)^{1/3} = 336$$

$$\bar{h} = \left(k/L\right)\overline{Nu}_L = \left(0.0361\,W/m\cdot K/1m\right)336 = 12.1\,W/m^2\cdot K$$

Hence,

$$q = 2\times12.1\,W/m^2\cdot K\left(1m\right)^2\left(300-20\right)°C = 6780\,W$$ <

Performing an energy balance at an instant of time for a control surface about the plate, $-\dot{E}_{out} = \dot{E}_{st}$, we obtain,

$$\rho\,\delta L^2 c\left.\frac{dT}{dt}\right|_i = -\bar{h}\,2L^2\left(T_i - T_\infty\right)$$

$$\left.\frac{dT}{dt}\right|_i = -\frac{2\left(12.1\,W/m^2\cdot K\right)\left(300-20\right)°C}{7832\;kg/m^3\times0.006m\times549\,J/kg\cdot K} = -0.26°C/s$$ <

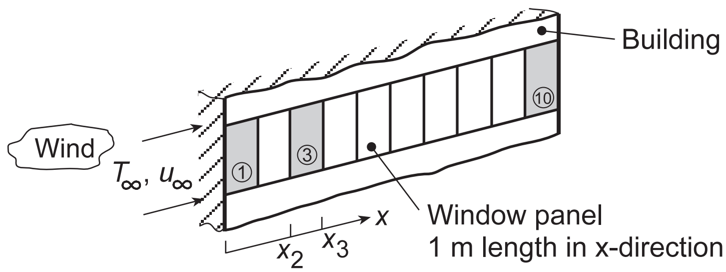
COMMENTS: (1) With $Bi = \bar{h}\left(\delta/2\right)/k_p = 7.4\times10^{-4}$, use of the lumped capacitance method is appropriate. (2) Despite the large plate temperature and the small convection coefficient, if adjoining plates are in close proximity, radiation exchange with the surroundings will be small and the assumption of negligible radiation is justifiable.

PROBLEM 7.25

KNOWN: Prevailing wind with prescribed speed blows past ten window panels, each of 1-m length, on a penthouse tower.

FIND: (a) Average convection coefficient for the first, third and tenth window panels when the wind speed is 5 m/s; evaluate thermophysical properties at 300 K, but determine suitability when ambient air temperature is in the range $-15 \le T_\infty \le 38°C$; (b) Compute and plot the average coefficients for the same panels with wind speeds for the range $5 \le u_\infty \le 100$ km/h; explain features and relative magnitudes.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Wind over panels approximates parallel flow over a smooth flat plate, and (4) Transition Reynolds number is $Re_{s,c} = 5 \times 10^5$.

PROPERTIES: *Table A.4*, Air (T_f = 300 K, 1 atm): $\nu = 15.89 \times 10^{-5}$ m²/s, $k = 26.3 \times 10^{-3}$ W/m·K, Pr = 0.707.

ANALYSIS: (a) The average convection coefficients for the first, third and tenth panels are

$$\bar{h}_1 \qquad \bar{h}_{2-3} = \frac{\bar{h}_3 x_3 - \bar{h}_2 x_2}{x_3 - x_2} \qquad \bar{h}_{9-10} = \frac{\bar{h}_{10} x_{10} - \bar{h}_9 x_9}{x_{10} - x_9} \qquad (1,2,3)$$

where $\bar{h}_2 = \bar{h}_2(x_2)$, etc. If $Re_{x,c} = 5 \times 10^5$, with properties evaluated at T_f = 300 K, transition occurs at

$$x_c = \frac{\nu}{u_\infty} Re_{x,c} = \frac{15.89 \times 10^{-6}\,m^2/s}{5\,m/s} \times 5 \times 10^5 = 1.59\,m$$

The flow over the first panel is laminar, and $\bar{h}_1$ can be estimated using Eq. (7.30).

$$\overline{Nu}_{x1} = \frac{\bar{h}_1 x_1}{k} = 0.664\,Re_x^{1/2}\,Pr^{1/3}$$

$$\bar{h}_1 = (0.0263\,W/m\cdot K \times 0.664/1m)\left(5\,m/s \times 1m/15.89 \times 10^{-6}\,m^2/s\right)^{1/2}(0.707)^{1/3} = 8.73\,W/m^2\cdot K \quad <$$

The flow over the third and tenth panels is mixed, and $\bar{h}_2$, $\bar{h}_3$, $\bar{h}_9$ and $\bar{h}_{10}$ can be estimated using Eq. (7.41). For the third panel with x_3 = 3 m and x_2 = 2 m,

$$\overline{Nu}_{x3} = \frac{\bar{h}_3 x_3}{k} = \left(0.037\,Re_x^{4/5} - 871\right)Pr^{1/3}$$

$$\bar{h}_3 = (0.0263\,W/m\cdot K/3m)$$
$$\times\left[0.037\left(5\,m/s \times 3m/15.89 \times 10^{-6}\,m^2/s\right)^{4/5} - 871\right](0.707)^{1/3} = 10.6\,W/m^2\cdot K$$

Continued...

$$\overline{h}_2 = (0.0263\,W/m\cdot K/2m) \times\left[0.037\left(5\,m/s\times 2m/15.89\times10^{-6}\,m^2/s\right)^{4/5} - 871\right](0.707)^{1/3} = 8.68\,W/m^2\cdot K$$

From Eq. (2),

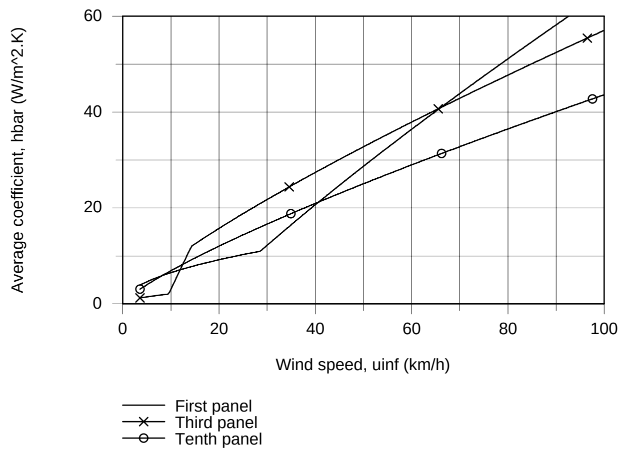
$$\overline{h}_{2-3} = \frac{10.61\,W/m^2\cdot K\times 3m - 8.68\,W/m^2\cdot K\times 2m}{(3-2)m} = 14.5\,W/m^2\cdot K \qquad <$$

Following the same procedure for the tenth panel, find $\overline{h}_{10}$ = 11.64 W/m²·K and $\overline{h}_9$ = 11.71 W/m²·K, and

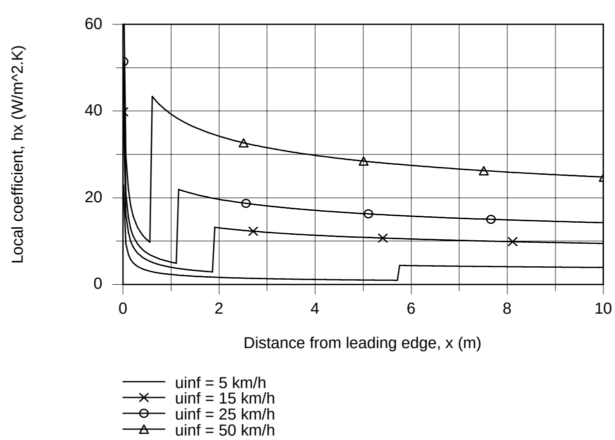
$$\overline{h}_{9-10} = 11.1\,W/m^2\cdot K \qquad <$$

Assuming that the window panel temperature will always be close to room temperature, T_s = 23°C = 296 K. If T_∞ ranges from -15 to 38°C, the film temperature, $T_f = (T_s + T_\infty)/2$, will vary from 275 to 310 K. We'll explore the effect of T_f subsequently.

(b) Using the *IHT Tool*, *Correlations*, *External Flow*, *Flat Plate*, results were obtained for the average coefficients $\overline{h}$. Using Eqs. (2) and (3), average coefficients for the panels as a function of wind speed were computed and plotted.



COMMENTS: (1) The behavior of the panel average coefficients as a function of wind speed can be explained from the behavior of the local coefficient as a function of distance for difference velocities as plotted below.



Continued...

PROBLEM 7.25 (Cont.)

For low wind speeds, transition occurs near the mid-panel, making $\bar{h}_1$ and $\bar{h}_{9-10}$ nearly equal and very high because of leading-edge and turbulence effects, respectively. As the wind speed increases, transition occurs closer to the leading edge. Notice how $\bar{h}_{2-3}$ increases rather abruptly, subsequently becoming greater than $\bar{h}_{9-10}$. The abrupt increase in $\bar{h}_1$ around 30 km/h is a consequence of transition occurring with x < 1m.

(2) Using the IHT code developed for the foregoing analysis with u_∞ = 5 m/s, the effect of T_f is tabulated below

T_f (K)	275	300	310
$\bar{h}_1$ ($W/m^2 \cdot K$)	8.72	8.73	8.70
$\bar{h}_{2-3}$ ($W/m^2 \cdot K$)	15.1	14.5	14.2
$\bar{h}_{9-10}$ ($W/m^2 \cdot K$)	11.6	11.1	10.8

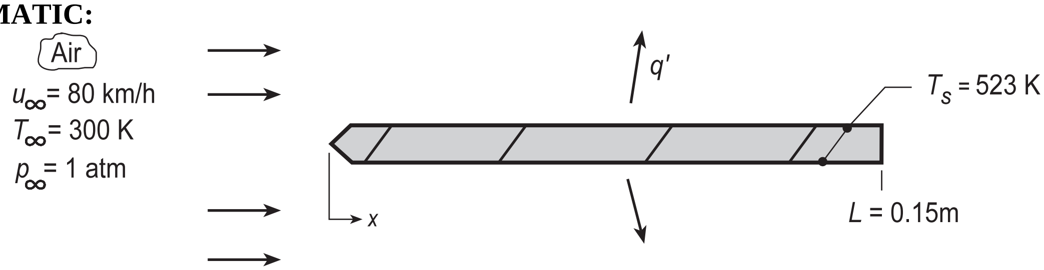
The overall effect of T_f on estimates for the average panel coefficient is slight, less than 5%.

PROBLEM 7.26

KNOWN: Length and surface temperature of a rectangular fin.

FIND: (a) Heat removal per unit width, q', when air at a prescribed temperature and velocity is in parallel, turbulent flow over the fin, and (b) Calculate and plot q' for motorcycle speeds ranging from 10 to 100 km/h.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible radiation, (3) Turbulent flow over entire surface.

PROPERTIES: *Table A.4*, Air (412 K, 1 atm): $\nu = 27.85 \times 10^{-6}$ m²/s, k = 0.0346 W/m·K, Pr = 0.69.

ANALYSIS: (a) The heat loss per unit width is

$$q' = 2\times\left[\overline{h}_L L\left(T_s - T_\infty\right)\right]$$

where $\overline{h}$ is obtained from the correlation, Eq. 7.38 but with turbulent flow over the entire surface,

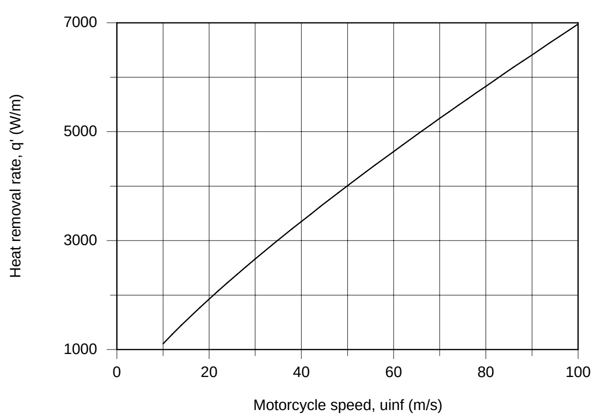
$$\overline{Nu}_L = 0.037\,Re_L^{4/5}\,Pr^{1/3} = 0.037\left[\frac{80\,km/h\times1000\,m/km\times1/3600\,h/s\times0.15\,m}{27.85\times10^{-6}\,m^2/s}\right]^{4/5}(0.69)^{1/3} = 378$$

Hence,

$$\overline{h}_L = \frac{k}{L}\overline{Nu}_L = \frac{0.0346\,W/m\cdot K}{0.15\,m}378 = 87\,W/m^2\cdot K$$

$$q' = 2\times\left[87\,W/m^2\cdot K\times0.15\,m\left(523-300\right)K\right] = 5826\,W/m.$$ <

(b) Using the foregoing equations in the IHT Workspace, q' as a function of speed was calculated and is plotted as shown.



COMMENTS: (1) Radiation emission from the fin is not negligible. With an assumed emissivity of ε = 1, the rate of emission per unit width at 80 km/h would be $q' = \left(\sigma T_s^4\right)2L = 1273$ W/m. If the fin received negligible radiation from its surroundings, its loss by radiation would then be approximately 20% of that by convection.

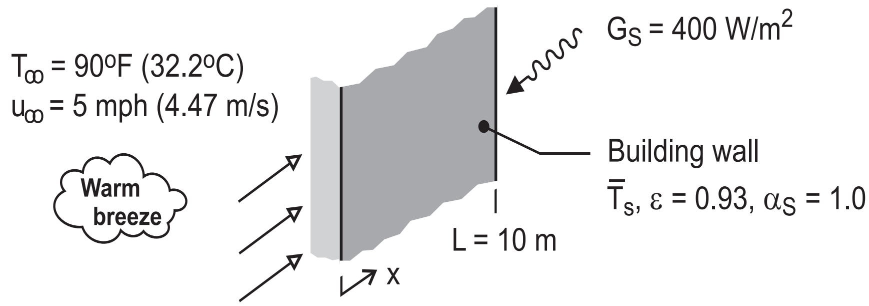
(2) From the correlation and heat rate expression, it follows that $q' \sim u_\infty^{4/5}$. That is, q' vs. u_∞ is nearly linear as evident from the above plot.

PROBLEM 7.27

KNOWN: Wall of a metal building experiences a 10 mph (4.47 m/s) breeze with air temperature of 90°F (32.2°C) and solar insolation of 400 W/m^2. The length of the wall in the wind direction is 10 m and the emissivity is 0.93.

FIND: Estimate the average wall temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) The solar absorptivity of the wall is unity, (3) Sky irradiation is negligible, (4) Wall is isothermal at the average temperature T_s, (5) Flow is fully turbulent over the wall, and (6) Negligible heat transfer into the building.

PROPERTIES: *Table A-4*, Air (assume T_f = 305 K, 1 atm): ν = 16.27 × 10^6 m^2/s, k = 0.02658 W/m·K, Pr = 0.707.

ANALYSIS: Perform an energy balance on the wall surface considering convection, absorbed irradiation and emission. On a per unit width basis,

$$\dot{E}'_{in} - \dot{E}'_{out} = 0$$

$$-q'_{cv} + \left(\alpha_S G_S - E_s\right) L = 0$$

$$-\overline{h}_L\, L\left(T_s - T_\infty\right) + \left(\alpha_S G_S - \varepsilon\sigma T_s^4\right) L = 0 \qquad (1)$$

The average convection coefficient is estimated using Eq. 7.41 assuming fully turbulent flow over the length of the wall in the direction of the breeze.

$$\overline{Nu}_L = \frac{\overline{h}_L\, L}{k} = 0.037\ Re_L^{4/5}\, Pr^{1/3} \qquad (2)$$

$$Re_L = u_\infty L/\nu = 4.47\,m/s \times 10\,m / 16.27\times10^{-6}\,m^2/s = 2.748\times10^6$$

$$\overline{h}_L = \left(0.02658\ W/m\cdot K/10\,m\right)\times 0.037\left(2.748\times10^6\right)^{4/5}\left(0.707\right)^{1/3} = 12.4\ W/m^2\cdot K$$

Substituting numerical values into Eq. (1), find T_s.

$$-12.4\ W/m^2 \times 10\,m\left[T_s - \left(32.2 + 273\right)\right]K$$

$$+\left[1.0\times 400\ W/m^2 - 0.93\times5.67\times10^{-8}\,W/m^2\cdot K^4 T_s^4\right]\times 10\,m = 0$$

$$T_s = 302.2\ K = 29°C$$ <

COMMENTS: (1) The properties for the correlation should be evaluated at $T_f = (T_s + T_\infty)/2$ = 304 K. The assumption of 305 K was reasonable.

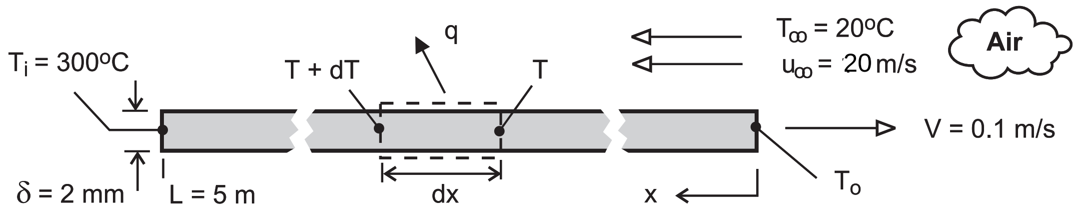
(2) Is the heat transfer by the emission process significant? Would application of a low emissive coating be effective in reducing the wall temperature, assuming α_S remained unchanged? Or, should a low solar absorbing coating be considered?

PROBLEM 7.28

KNOWN: Velocity, initial temperature, and dimensions of aluminum strip on a production line. Velocity and temperature of air in counter flow over top surface of strip.

FIND: (a) Differential equation governing temperature distribution along the strip and expression for outlet temperature, (b) Value of outlet temperature for prescribed conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible variation of sheet temperature across its thickness, (2) Negligible effect of conduction along length (x) of sheet, (3) Negligible radiation, (4) Turbulent flow over entire top surface, (5) Negligible effect of sheet velocity on boundary layer development, (6) Negligible heat transfer from bottom surface and sides, (7) Constant properties.

PROPERTIES: *Table A-1*, Aluminum, 2024-T6 $\left(\overline{T}_{AL} \approx 500\text{K}\right)$: $\rho = 2770\,\text{kg/m}^3$, $c_p = 983\,\text{J/kg}\cdot\text{K}$, k=186 W/m·K. *Table A-4*, Air $\left(p = 1\,\text{atm},\ T_f \approx 400\text{K}\right)$: $\nu = 26.4\times10^{-6}\,\text{m}^2/\text{s}$, $k = 0.0338\,\text{W/m}\cdot\text{K}$, $\text{Pr} = 0.69$

ANALYSIS: (a) Applying conservation of energy to a stationary control surface, through which the sheet moves, steady-state conditions exist and $\dot{E}_{in} - \dot{E}_{out} = 0.$ Hence, with *inflow* due to *advection* and outflow due to *advection* and *convection*,

$$\rho V A_c c_p (T + dT) - \rho V A_c c_p T - dq = 0$$

$$+\rho V \delta W c_p dT - h_x (dx \cdot W)(T - T_\infty) = 0$$

$$\frac{dT}{dx} = +\frac{h_x}{\rho V \delta c_p}(T - T_\infty) \qquad (1) \quad <$$

Alternatively, if the control surface is fixed to the sheet, conditions are transient and the energy balance is of the form, $-\dot{E}_{out} = \dot{E}_{st}$, or

$$-h_x (dx \cdot W)(T - T_\infty) = \rho(dx \cdot W \cdot \delta) c_p \frac{dT}{dt}$$

$$\frac{dT}{dt} = -\frac{h_x}{\rho \delta c_p}(T - T_\infty)$$

Dividing the left- and right-hand sides of the equation by dx/dt and dx/dt = - V, respectively, equation (1) is obtained. The equation may be integrated from x = 0 to x = L to obtain

$$\int_{T_o}^{T_i} \frac{dT}{T - T_\infty} = \frac{L}{\rho V \delta c_p}\left[\frac{1}{L}\int_0^L h_x\, dx\right]$$

Continued …

PROBLEM 7.28 (Cont.)

where $h_x = (k/x) 0.0296\, Re_x^{4/5} Pr^{1/3}$ and the bracketed term on the right-hand side of the equation reduces to $\bar{h}_L = (k/L) 0.037\, Re_L^{4/5} Pr^{1/3}$.

Hence,

$$\ln\left(\frac{T_i - T_\infty}{T_o - T_\infty}\right) = \frac{L\,\bar{h}_L}{\rho V \delta c_p}$$

$$\frac{T_o - T_\infty}{T_i - T_\infty} = \exp\left(-\frac{L\,\bar{h}_L}{\rho V \delta c_p}\right)$$ <

(b) For the prescribed conditions, $Re_L \approx u_\infty L/\nu = 20\,m/s \times 5m / 26.4\times10^{-6} m^2/s = 3.79\times10^6$ and

$$\bar{h}_L = \left(\frac{0.0338\,W/m\cdot K}{5m}\right) 0.037\left(3.79\times10^6\right)^{4/5}(0.69)^{1/3} = 40.5\,W/m^2\cdot K$$

$$T_o = 20°C + (280°C)\exp\left(-\frac{5m \times 40.5\,W/m^2\cdot K}{2770\,kg/m^3 \times 0.1\,m/s \times 0.002m \times 983\,J/kg\cdot K}\right) = 213°C$$ <

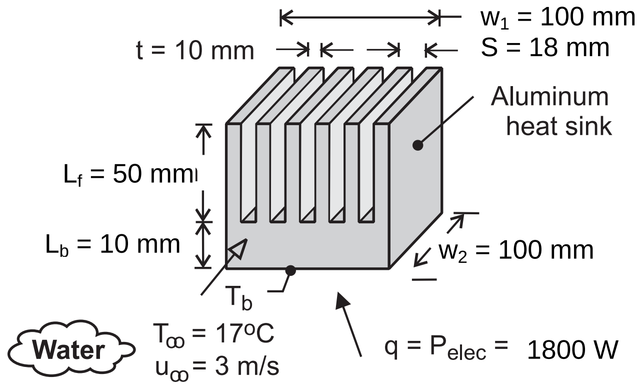
COMMENTS: (1) With $T_o = 213°C$, $\bar{T}_{Al} = 530K$ and $T_f = 411K$ are close to values used to determine the material properties, and iteration is not needed. (2) For a representative emissivity of $\varepsilon = 0.2$ and $T_{sur} = T_\infty$, the maximum value of the radiation coefficient is $h_r = \varepsilon\sigma(T_i + T_{sur})\left(T_i^2 + T_{sur}^2\right) = 4.1\,W/m^2\cdot K << \bar{h}_L$. Hence, the assumption of negligible radiation is appropriate.

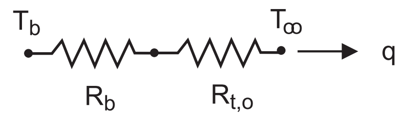
PROBLEM 7.29

KNOWN: Dimensions of aluminum heat sink. Temperature and velocity of coolant (water) flow through the heat sink. Power dissipation of electronic package attached to the heat sink.

FIND: Base temperature of heat sink.

SCHEMATIC:





ASSUMPTIONS: (1) Average convection coefficient associated with flow over fin surfaces may be approximated as that for a flat plate in parallel flow, (2) All of the electric power is dissipated by the heat sink, (3) Transition Reynolds number of $Re_{x,c} = 5 \times 10^5$, (4) Constant properties. (5) Water temperature is nearly constant as it flows through the array.

PROPERTIES: Given. Aluminum: $k_{hs} = 180$ W/m·K. Water: $k_w = 0.62$ W/m·K, $\nu = 7.73 \times 10^{-7}$ m^2/s, Pr = 5.2.

ANALYSIS: From the thermal circuit,

$$q = P_{elec} = \frac{T_b - T_\infty}{R_b + R_{t,o}}$$

where $R_b = L_b / k_{hs}(w_1 \times w_2) = 0.01\ m/180\ W/m \cdot K(0.10\ m)^2 = 5.56 \times 10^{-3}\ K/W$ and, from Eqs. 3.107 and 3.108,

$$R_{t,o} = \left\{\bar{h} A_t \left[1 - \frac{NA_f}{A_t}(1 - \eta_f)\right]\right\}^{-1}$$

The fin and total surface area of the array are $A_f = 2w_2(L_f + t/2) = 0.2\ m(0.055\ m) = 0.011\ m^2$ and $A_t = NA_f + A_b = NA_f + (N-1)(S-t)w_2 = 6\left(0.011\ m^2\right) + 5(0.008\ m)0.1\ m = (0.066 + 0.004) = 0.070\ m^2$.

With $Re_{w_2} = u_\infty w_2/\nu = 3\,m/s \times 0.10\ m/7.73 \times 10^{-7}\ m^2/s = 3.88 \times 10^5$, laminar flow may be assumed over the entire surface. Hence

$$\bar{h} = \left(\frac{k_w}{w_2}\right) 0.664\, Re_{w_2}^{1/2}\, Pr^{1/3} = \left(\frac{0.62\ W/m \cdot K}{0.10\ m}\right) 0.664 \left(3.88 \times 10^5\right)^{1/2} (5.2)^{1/3} = 4443\ W/m^2 \cdot K$$

With $m = \left(2\bar{h}/k_{hs}t\right)^{1/2} = \left(2 \times 4443\ W/m^2 \cdot K/180\ W/m \cdot K \times 0.01\ m\right)^{1/2} = 70.3\,m^{-1}$, $mL_c = 70.3\,m^{-1}$ $(0.055\ m) = 3.86$ and $\tanh mL_c = 0.9991$, Eq. 3.94 yields

$$\eta_f = \frac{\tanh mL_c}{mL_c} = \frac{0.9991}{3.86} = 0.259$$

Continued …

PROBLEM 7.29 (Cont.)

Hence,

$$R_{t,o} = \left\{ 4443\,W/m^2 \cdot K \times 0.070\,m^2 \left[1 - \frac{0.066\,m^2}{0.070\,m^2} (1 - 0.259) \right] \right\}^{-1} = 0.0107\ K/W$$ <

and

$$T_b = T_\infty + P_{elec}\left(R_b + R_{t,o}\right) = 17°C + 1800\,W\left(5.56 \times 10^{-3} + 0.0107\right) K/W = 46.2°C$$ <

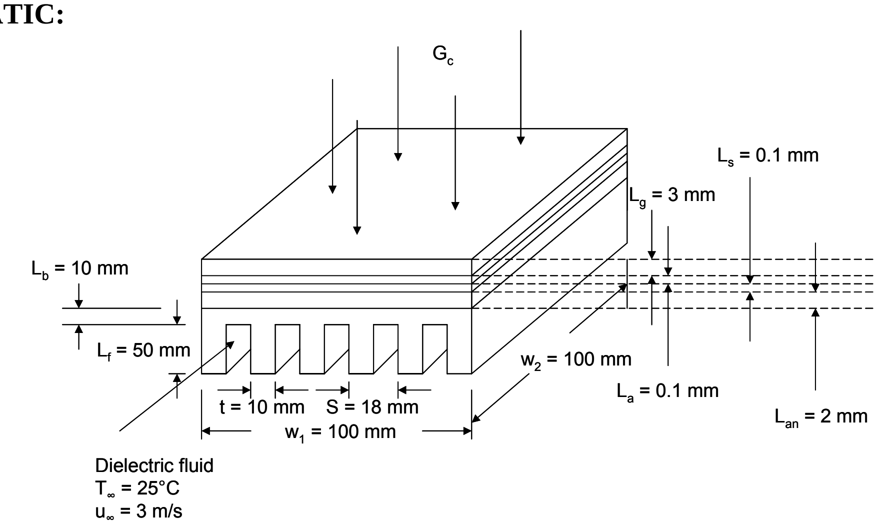
COMMENTS: (1) The boundary layer thickness at the trailing edge of the fin is $\delta = 5w_2 / \left(Re_{w_2}\right)^{1/2} = 0.80\ mm << (S - t)$. Hence, the assumption of parallel flow over a flat plate is reasonable. (2) If a finned heat sink is not employed and heat transfer is simply by convection from the $w_2 \times w_2$ base surface, the corresponding convection resistance would be 0.0225 K/W, which is only twice the resistance associated with the fin array. The small enhancement by the array is attributable to the large value of $\overline{h}$ and the correspondingly small value of η_f. Were a fluid such as air or a dielectric liquid used as the coolant, the much smaller thermal conductivity would yield a smaller $\overline{h}$, a larger η_f and hence a larger effectiveness for the array. (3) The water outlet temperature may be calculated based the energy balance, $q = \dot{m}\, c_p\, (T_{m,o} - T_{m,i})$ or $T_{m,o}$ = 17°C + 1800 W/(5 × 0.008m × 0.05m × 3 m/s × 995 kg/m^3 × 4178 J/kg·K) = 17.07°C where there are N = 5 channels. (The density and specific heat are evaluated at Pr = 5.2.) The assumption of constant water mean temperature is excellent. (4) *If* the increase in the water temperature was significant, an approach described in Chapter 11 would be needed to analyze the problem. See Problem 11.90.

PROBLEM 7.30

KNOWN: Dimensions of a photovoltaic cell, material and dimensions of a finned heat sink, solar irradiation and dimensions of concentrating lens, velocity and temperature of dielectric liquid.

FIND: (a) Electric power produced and silicon temperature for a square concentrating lens with the heat sink in place, (b) Electric power and silicon temperature without the heat sink, (c) Electric power and silicon temperature for 100 mm ≤ L_{lens} ≤ 3000 mm.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional heat transfer, (4) Average convection coefficient associated with flow over fin surfaces may be approximated as that for a flat plate in parallel flow, (5) Transition Reynolds number of $Re_{x,c} = 5 \times 10^5$, (6) Negligible convection off of the top of the solar cell, (7), No radiation to or through the dielectric liquid, (8) Negligible increase in dielectric fluid temperature as if flows through the array.

PROPERTIES: Given: Aluminum: k_{hs} = 180 W/m·K, Dielectric liquid: k_d = 0.064 W/m·K, $\nu = 10^{-6}$ m²/s, ρ = 1400 kg/m³, c_p = 1300 J/kg·K, Pr = 25, Glass: k_g = 1.4 W/m·K, Adhesive: , k_a = 145 W/m·K, Solder: k_s = 50 W/m·K, Aluminum Nitride: k_{an} = 120 W/m·K.

ANALYSIS: (a) The base resistance is

$$R_b = L_b/k_{hs}(w_1 \times w_2) = \frac{0.01\text{m}}{180\text{ W/m}\cdot\text{K}(0.10\text{m})^2} = 5.56 \times 10^{-3}\text{ K/W}$$

and, from Equations 3.107 and 3.108

$$R_{t,o} = \left\{\bar{h}A_t\left[1 - \frac{NA_f}{A_t}(1 - \eta_f)\right]\right\}^{-1}$$

The fin and total surface areas of the array are

$A_f = 2w_2(L_f + t/2) = 0.20\text{m} \times (0.055\text{m}) = 0.0110\text{ m}^2$ and

$$A_t = NA_f + A_b = NA_f + (N - 1)(S - t)w_2$$

$$= 6(0.0110\text{ m}^2) + 5(0.008\text{ m})(0.100\text{ m}) = 0.0660\text{ m}^2 + 0.0040\text{ m}^2 = 0.071\text{ m}^2$$

Continued…

PROBLEM 7.30 (Cont.)

with $Re_{w_2} = u_\infty w_2/\nu = 3\ m/s \times 0.10\ m/10^{-6}\ m^2/s = 3.00\times10^5$, laminar flow may be assumed over the entire surface. Hence

$$\bar{h} = \left(\frac{k_w}{w_2}\right) 0.664\ Re_{w_2}^{1/2} Pr^{1/3}$$

$$= \left(\frac{0.064\ W/m\cdot K}{0.10\ m}\right) 0.664\ (3.00\times10^5)^{1/2}(25)^{1/3} = 681\ W/m^2\cdot K$$

with $m = \left(2\bar{h}/k_{hs}t\right)^{1/2} = \left[362\ W/m^2 / (180\ W/m\cdot K\times0.01\ m)\right]^{1/2} = 27.50\ m^{-1}$

$mL_c = 27.50\ m^{-1}(0.055\ m) = 1.51$ and $\tanh mL_c = 0.907$ Equation 3.94 yields

$$\eta_f = \frac{\tanh mL_c}{mL_c} = \frac{0.907}{1.51} = 0.600$$

Hence,

$$R_{t,o} = \left\{681\ W/m^2\cdot K\times0.070\ m^2\left[1 - \frac{0.066\ m^2}{0.070\ m^2}(0.400)\right]\right\}^{-1} = 33.70\times10^{-3}\ K/W$$

The conduction resistances are

$$R_{t,g} = L_g/k_gA = 3\times10^{-3}\ m/(1.4\ W/m\cdot K\times0.1\ m\times0.1\ m) = 0.2143\ K/W$$

$$R_{t,a} = L_a/k_aA = 0.1\times10^{-3}\ m/(145\ W/m\cdot K\times0.1\ m\times0.1\ m) = 6.897\times10^{-5}\ K/W$$

$$R_{t,s} = L_s/k_sA = 0.1\times10^{-3}\ m/(50\ W/m\cdot K\times0.1\ m\times0.1\ m) = 200\times10^{-6}\ K/W$$

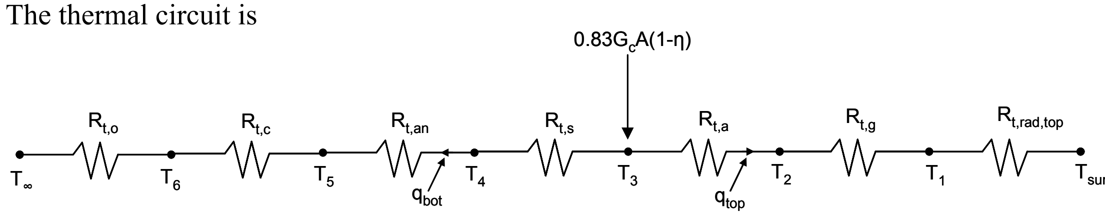
$$R_{t,an} = L_{an}/k_{an}A = 2\times10^{-3}\ m/(120\ W/m\cdot K\times0.1\ m\times0.1\ m) = 1.67\times10^{-3}\ K/W$$

$$R_{t,c} = R''_{t,c}/A = 0.5\times10^{-4}\ m^2\cdot K/W/(0.1\ m\times0.1\ m) = 5.0\times10^{-3}\ K/W$$

$$h_{rad,top} = \varepsilon_g\sigma\,(T_1 + T_{sur})(T_1^2 + T_{sur}^2)$$

$$R_{t,rad,top} = 1/0.9\times5.67\times10^{-8}\ W/m^2\cdot K^4\times(T_1 + 298\ K)\times(T_1^2 + (298\ K)^2) \qquad (1)$$

The thermal circuit is



Continued…

PROBLEM 7.30 (Cont.)

where $G_c = G(L_{lens}/w_1)^2$

From the thermal circuit,

$$0.83G\,(L_{lens}/w_1)^2(w_1 \times w_2)(1 - \eta) = q_{top} + q_{bot}$$

$$0.83 \times 700\ W/m^2(4)^2(0.1\ m \times 0.1\ m)(1 - \eta) = q_{top} - q_{bot}$$

$$92.96\ W(1 - \eta) = q_{top} + q_{bot} \qquad (2)$$

$$q_{top} = (T_3 - T_{sur})\Big/(R_{t,a} + R_{t,g} + R_{t,rad,top})$$

$$= (T_{si} - 298\ K)\Big/\left(6.897 \times 10^{-5}\ K/W + 0.2143\ K/W + R_{t,rad,top}\right)$$

$$= (T_{si} - 298\ K)\Big/(0.2143\ K/W + R_{t,rad,top}) \qquad (3)$$

$$q_{bot} = (T_3 - T_\infty)\Big/(R_{t,o} + R_{t,c} + R_{t,an} + R_{t,s})$$

$$= (T_{si} - 298\ K)\Big/\left(33.70 \times 10^{-3}\ K/W + 5.0 \times 10^{-3}\ K/W + 1.67 \times 10^{-3}\ K/W + 0.20 \times 10^{-3}\ K/W\right)$$

$$= (T_{si} - 298\ K)\Big/(40.57 \times 10^{-3}\ K/W) \qquad (4)$$

From the problem statement

$$\eta = 0.28 - 0.001°C^{-1}(T_{si} - 273)°C \qquad (5)$$

Solving Equations (1) through (5) simultaneously yields

$$T_{si} = 28.2°C,\ \ \eta = 0.252$$ <

The electric power is

$$P = 0.83G(L_{lens}/w_1)^2(w_1 \times w_2)(\eta) \qquad (6)$$

$$P = 0.83 \times 700\ W/m^2(4)^2(0.1\ m \times 0.1\ m)(0.252) = 23.4\ W$$ <

(b) Substituting L_{lens} = 1500 mm in Equations 2 and 6 yields

$$T_{si} = 72.6°C,\ P = 271\ W$$ <

with the heat sink in place. For no heat sink we also substitute

$$R_{t,c} = 0 \text{ and } R_{t,o} = R_{t,conv} = 1/\overline{h}w_1^2 = 1/681 W/m^2\cdot K(0.1m)^2 = 146.8 \times 10^{-3}\ K/W$$

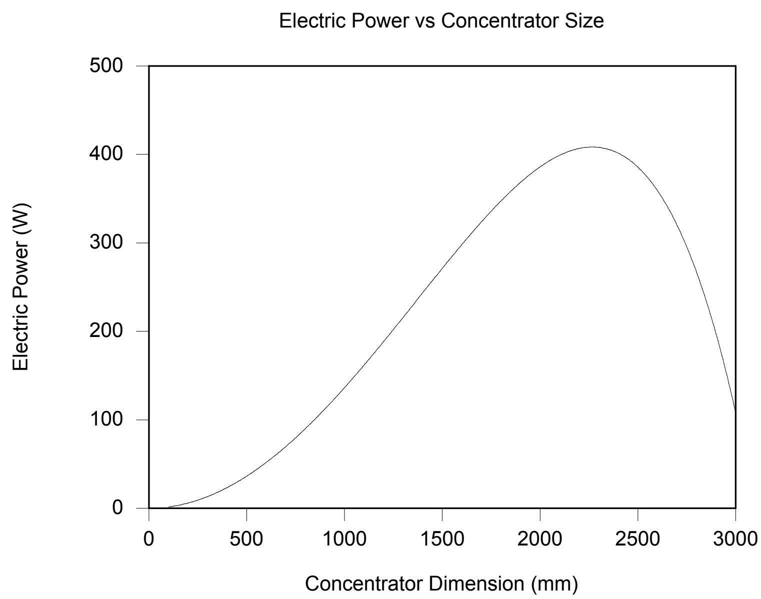
into Equation 4 and solving Equations (1) through (5) simultaneously yields

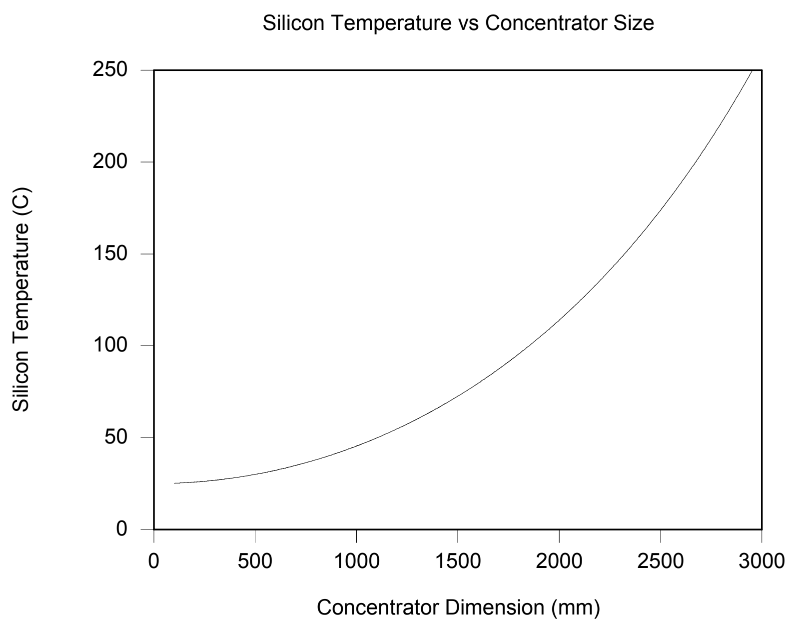
Continued…

PROBLEM 7.30 (Cont.)

T_{si} = 200°C, P = 105 W <

(c) The variation of the silicon temperature and electric power with the heat sink in place is shown in the accompanying graphs.





Continued…

PROBLEM 7.30 (Cont.)

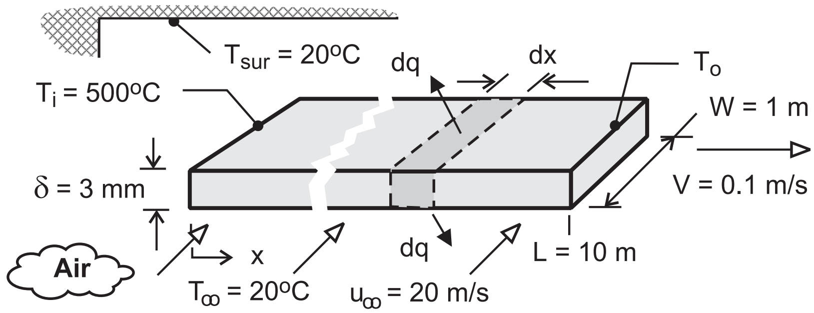
COMMENTS: (1) In Problem 7.19, we see that, for air cooling and L_{lens} = 400 mm, T_{si} = 126 °C, P = 14.3 W. Use of liquid cooling increases the electrical power output to 23.4 W, or 64 percent. In Problem 7.19 we see the maximum power output to be about 15 W. With liquid cooling and the heat sink, maximum power output increases to about 420 W, or 2800%. (2) The electric power is highly sensitive to the size of the concentrator. Initially, the power output increases as the concentrated irradiation increases, but as the silicon temperature increases the efficiency drops, driving the power output down. (3) The boundary layer thickness at the trailing edge of the fin is $\delta = 5w_2/\mathrm{Re}_{w_2}^{1/2}$ = 0.91 mm << (S – t). Also, since Pr > 1, $\delta_t < \delta$. Hence, the assumption of parallel flow over a flat plate is reasonable. (4) The dielectric fluid outlet temperature may be calculated based the energy balance, $q_{bot} = (T_{si} - 298\text{ K})/(40.57 \times 10^{-3}\text{ K/W})$ = 79 W = $\dot{m} c_p (T_{m,o} - T_{m,i})$ or $T_{m,o}$ = 25°C + 79 W/(5 × 0.008m × 0.05m × 3 m/s × 1400 kg/m^3 × 1300 J/kg·K) = 25.007°C where there are N = 5 channels. The assumption of constant dielectric mean temperature is excellent. (5) *If* the increase in the dielectric fluid temperature was significant, an approach described in Chapter 11 would be needed to analyze the problem. (6) Solar irradiation values can be nearly 1100 W/m^2 in clear environments. How do you think the maximum electric power will change when the solar irradiation is increased? You may want to re-work the solution to the problem to find the surprising result.

PROBLEM 7.31

KNOWN: Velocity, initial temperature, properties and dimensions of steel strip on a production line. Velocity and temperature of air in cross flow over top and bottom surfaces of strip. Temperature of surroundings.

FIND: (a) Differential equation governing temperature distribution along the strip, (b) Exact solution for negligible radiation and corresponding value of outlet temperature for prescribed conditions, (c) Effect of radiation on outlet temperature, and parametric effect of sheet velocity on temperature distribution.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible variation of sheet temperature across its width and thickness, (2) Negligible effect of conduction along length (x) of sheet, (3) Constant properties, (4) Radiation exchange between small surface (both sides of sheet) and large surroundings, (5) Turbulent flow over top and bottom surfaces of sheet, (6) Motion of sheet has a negligible effect on the convection coefficient, ($V << u_\infty$), (7) Negligible heat transfer from sides of sheet.

PROPERTIES: Prescribed. Steel: $\rho = 7850\,kg/m^3, c_p = 620\,J/kg\cdot K,\ \varepsilon = 0.70$. Air: k = 0.044 W/m·K, $\nu = 4.5\times10^{-5} m^2/s$, Pr = 0.68.

ANALYSIS: (a) Applying conservation of energy to a stationary differential control surface, through which the sheet passes, conditions are steady and $\dot{E}_{in} - \dot{E}_{out} = 0$. Hence, with *inflow* due to *advection* and *outflow* due to *advection*, *convection* and *radiation*

$$\rho V A_c c_p T - \rho V A_c c_p (T + dT) - 2\,dq = 0$$

$$-\rho V \delta W c_p dT - 2(W dx)\left[\bar{h}_W (T - T_\infty) + \varepsilon\sigma\left(T^4 - T_{sur}^4\right)\right] = 0$$

$$\frac{dT}{dx} = -\frac{2}{\rho V \delta c_p}\left[\bar{h}_W (T - T_\infty) + \varepsilon\sigma\left(T^4 - T_{sur}^4\right)\right] \qquad (1) \quad <$$

Alternatively, if the control surface is fixed to the sheet, conditions are transient and the energy balance is of the form, $-\dot{E}_{out} = \dot{E}_{st}$, or

$$-2(W dx)\left[\bar{h}_W (T - T_\infty) + \varepsilon\sigma\left(T^4 - T_{sur}^4\right)\right] = \rho (W \delta\, dx) c_p \frac{dT}{dt}$$

$$\frac{dT}{dt} = -\frac{2}{\rho \delta c_p}\left[\bar{h}_W (T - T_\infty) + \varepsilon\sigma\left(T^4 - T_{sur}^4\right)\right]$$

Dividing the left- and right-hand sides of the equation by dx/dt and V = dx/dt, respectively, Eq. (1) is obtained.

(b) Neglecting radiation, separating variables and integrating, Eq. (1) becomes

$$\int_{T_i}^{T} \frac{dT}{T - T_\infty} = -\frac{2\bar{h}_W}{\rho V \delta c_p}\int_0^x dx$$

Continued …

PROBLEM 7.31 (Cont.)

$$\ln\left(\frac{T - T_\infty}{T_i - T_\infty}\right) = -\frac{2\bar{h}_W x}{\rho V \delta c_p}$$

$$T = T_\infty + \left(T_i - T_\infty\right)\exp\left(-\frac{2\bar{h}_W x}{\rho V \delta c_p}\right) \qquad (2) \quad <$$

With $Re_W = u_\infty W/\nu = 20\,m/s \times 1m / 4\times10^{-5} m^2/s = 5\times10^5$, the correlation for turbulent flow over a flat plate yields

$$\overline{Nu}_W = 0.037\,Re_W^{4/5}\,Pr^{1/3} = 0.037\left(5\times10^5\right)^{4/5}\left(0.68\right)^{1/3} = 1179$$

$$\bar{h}_W = \frac{k}{W}\overline{Nu}_W = \frac{0.044\,W/m\cdot K}{1m}1179 = 51.9\,W/m^2\cdot K$$

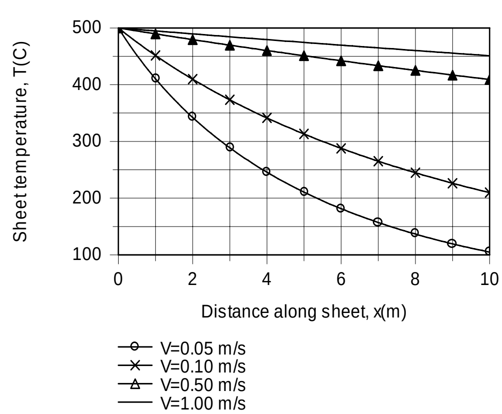
Hence, applying Eq. (2) at x = L = 10m,

$$T_o = 20°C + \left(480°C\right)\exp\left(-\frac{2\times51.9\,W/m^2\cdot K\times10m}{7850\,kg/m^3\times0.1\,m/s\times0.003m\times620\,J/kg\cdot K}\right) = 256°C \quad <$$

(c) Using the DER function of IHT, Eq. (1) may be numerically integrated from x = 0 to x = L = 10m to obtain

$$T_o = 210°C \quad <$$

Contrasting this result with that of Part (b), it is clear that radiation makes a discernable contribution to cooling of the sheet. IHT was also used to determine the effect of the sheet velocity on the temperature distribution.



The sheet velocity has a significant influence on the temperature distribution. The temperature decay decreases with increasing V due to the increasing effect of advection on energy transfer in the x direction.

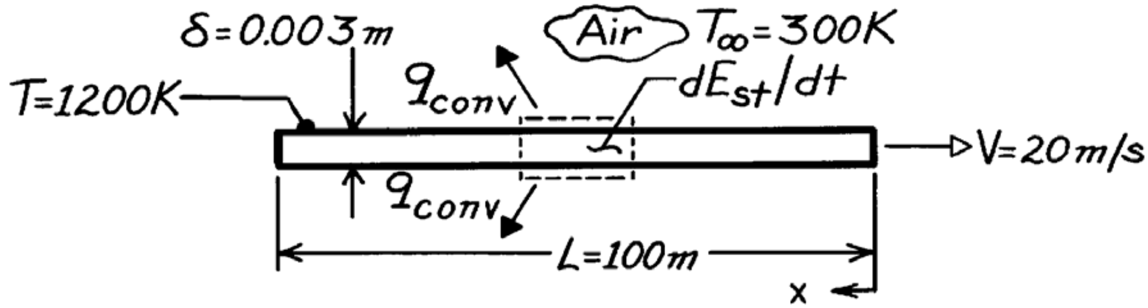
COMMENTS: (1) A critical parameter in the production process is the *coiling temperature*, that is, the temperature at which the wire may be safely coiled for subsequent storage or shipment. The larger the production rate (V), the longer the cooling distance needed to achieve a desired coiling temperature. (2) Cooling may be enhanced by increasing the cross stream velocity u_∞.

PROBLEM 7.32

KNOWN: Length, thickness, speed and temperature of steel strip.

FIND: Rate of change of strip temperature 1 m from leading edge and at trailing edge. Location of minimum cooling rate.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Negligible radiation, (3) Negligible longitudinal conduction in strip, (4) Critical Reynolds number is 5×10^5.

PROPERTIES: Steel (given): $\rho = 7900\ \text{kg/m}^3$, $c_p = 640\ \text{J/kg·K}$. *Table A-4*, Air $\left(\overline{T} = 750\text{K, 1 atm}\right)$: $\nu = 76.4 \times 10^{-6}\ \text{m}^2/\text{s}$, $k = 0.0549\ \text{W/m·K}$, $Pr = 0.702$.

ANALYSIS: Performing an energy balance for a control mass of unit surface area A_s riding with the strip,

$$-\dot{E}_{out} = dE_{st}/dt$$

$$-2h_x A_s \left(T - T_\infty\right) = \rho\delta A_s c_p \left(dT/dt\right)$$

$$dT/dt = \frac{-2h_x\left(T - T_\infty\right)}{\rho\delta c_p} = -\frac{2\left(900\text{K}\right)h_x}{7900\ \text{kg/m}^3\left(0.003\ \text{m}\right)640\ \text{J/kg}\cdot\text{K}} = -0.119h_x\left(\text{K/s}\right).$$

At x = 1 m, $\quad Re_x = \dfrac{Vx}{\nu} = \dfrac{20\ \text{m/s}\left(1\text{m}\right)}{76.4\times10^{-6}\ \text{m}^2/\text{s}} = 2.62\times10^5 < Re_{x,c}$. Hence,

$$h_x = \left(k/x\right)0.332Re_x^{1/2}Pr^{1/3} = \frac{0.0549\ \text{W/m}\cdot\text{K}}{1\ \text{m}}\left(0.332\right)\left(2.62\times10^5\right)^{1/2}\left(0.702\right)^{1/3} = 8.29\text{W/m}^2\cdot\text{K}$$

and at x = 1m, $\quad dT/dt = -0.987$ K/s. <

At the trailing edge, $Re_x = 2.62\times10^7 > Re_{x,c}$. Hence

$$h_x = \left(k/x\right)0.0296Re_x^{4/5}Pr^{1/3} = \frac{0.0549\ \text{W/m}\cdot\text{K}}{100\ \text{m}}\left(0.0296\right)\left(2.62\times10^7\right)^{4/5}\left(0.702\right)^{1/3} = 12.4\text{W/m}^2\cdot\text{K}$$

and at x = 100 m, $\quad dT/dt = -1.47$ K/s. <

The minimum cooling rate occurs just before transition; hence, for $Re_{x,c} = 5\times10^5$

$$x_c = 5\times10^5\left(\nu/V\right) = \frac{5\times10^5\times76.4\times10^{-6}\text{m}^2/\text{s}}{20\ \text{m/s}} = 1.91\ \text{m}$$ <

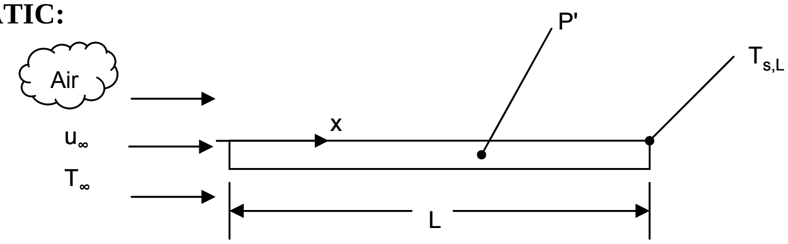
COMMENTS: The cooling rates are very low and would remain low even if radiation were considered. For this reason, hot strip metals are quenched by water and not by air.

PROBLEM 7.33

KNOWN: Thin metallic strip with thermocouple at trailing edge is used as an anemometer. Laminar flow.

FIND: (a) Calibration equations for constant surface temperature and constant heat flux conditions. (b) Percentage error in using the wrong calibration. (c) Location of thermocouple for which calibration is insensitive to thermal boundary condition.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Boundary layer assumptions hold, (3) Laminar flow, (4) Constant properties.

ANALYSIS:

(a) For constant surface temperature

$$\overline{Nu}_L = 0.664\, Re_L^{1/2}\, Pr^{1/3}$$

Therefore

$$\bar{h}_L = 0.664\, Re_L^{1/2}\, Pr^{1/3} k/L$$

and $\quad P' = 2\bar{h}_L L(T_s - T_\infty) = 2\,(0.664)\,\left(\frac{u_\infty L}{\nu}\right)^{1/2} Pr^{1/3}(T_s - T_\infty)$

Solving for u_∞, the calibration for constant T_s is:

$$u_\infty = \left\{P'/\left[2\,(0.664)\,Pr^{1/3} k\,(T_s - T_\infty)\right]\right\}^2 \left(\frac{\nu}{L}\right) \qquad (1) \quad <$$

For constant heat flux, we consider the local heat transfer coefficient at the end of the strip.

$$Nu_L = 0.453\, Re_L^{1/2}\, Pr^{1/3}$$

$$h_L = 0.453\, Re_L^{1/2}\, Pr^{1/3} k/L$$

Accounting for heat loss from both surfaces,

$$P' = 2q_s'' L$$

The uniform heat flux can be related to the conditions at x = L:

$$q_s'' = h_L (T_{s,L} - T_\infty)$$

Thus

$$P' = 2h_L L(T_{s,L} - T_\infty) = 2\,(0.453)\,\left(\frac{u_\infty L}{\nu}\right)^{1/2} Pr^{1/3}\, k\,(T_{s,L} - T_\infty)$$

Continued…

PROBLEM 7.33 (Cont.)

Solving for u_∞, the calibration for constant q_s'' is:

$$u_\infty = \left\{P'/\left[2\,(0.453)\,Pr^{1/3}k(T_{s,L} - T_\infty)\right]\right\}^2 \left(\frac{\nu}{L}\right) \qquad (2)$$ <

(b) Since the true situation is uniform heat flux, the true velocity is found from Equation (2). However the predicted velocity is incorrectly calculated from Equation (1). Thus

$$\frac{u_{\infty,\text{pred.}}}{u_{\infty,\text{true}}} = \left(\frac{0.453}{0.664}\right)^2 = 0.47$$ <

The velocity is underpredicted by more than half, or 53%.

(c) For constant surface heat flux, the local surface temperature is given by

$$T_{s,q}(x) - T_\infty = q_s''/h_x = \frac{P'/2L}{0.453\,Re_x^{1/2}\,Pr^{1/3}k/x}$$

where the q subscript on T_s indicates that it is for the constant heat flux case. This should be equal to the surface temperature for the constant T_s case, namely

$$T_{s,T} - T_\infty = P'/2L\bar{h}_L = \frac{P'/2L}{0.664\,Re_L^{1/2}\,Pr^{1/3}k/L}$$

Equating $T_{s,q}$ and $T_{s,T}$ and solving for x yields

$$0.453x^{-1/2} = 0.664L^{-1/2}$$

$$(x/L) = \left(\frac{0.453}{0.664}\right)^2 = 0.47$$ <

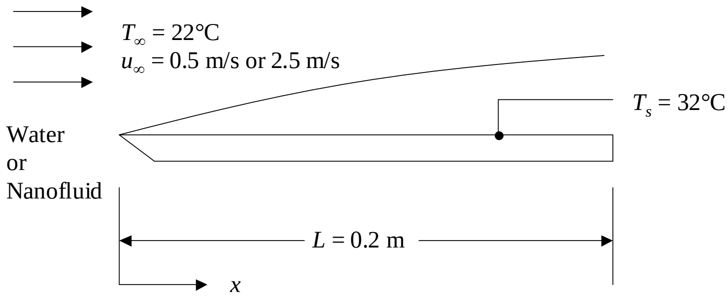
Thus, if the thermocouple is placed approximately at the midpoint of the strip it will be insensitive to the type of thermal boundary condition experienced by the strip.

PROBLEM 7.34

KNOWN: Dimensions of flat plate in parallel flow. Plate and fluid temperatures, fluid velocities.

FIND: Average heat transfer coefficient, convection heat transfer rate, drag force for (a) water flowing at a velocity of 0.5 m/s, (b) nanofluid of Example 2.2 at a velocity of 0.5 m/s, (c) water at a velocity of 2.5 /m/s, (d) nanofluid at a velocity of 2.5 m/s.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, $Re_{x,c} = 5 \times 10^5$.

PROPERTIES: *Table A.4*, water (300 K): ρ_{bf} = 997 kg/m^3, $\nu_{bf} = 857 \times 10^{-9}$ m^2/s, k_{bf} = 0.613 W/m·K, Pr_{bf} = 5.83. Example 2.2, nanofluid (300 K): ρ_{nf} = 1146 kg/m^3, $\mu_{nf} = 962 \times 10^{-6}$ m^2/s, $\nu_{nf} = \mu_{nf}/\rho_{nf} = 839 \times 10^{-9}$ m^2/s, k_{nf} = 0.705 W/m·K, $\alpha_{nf} = 171 \times 10^{-9}$ m^2/s $Pr_{nf} = \nu_{nf}/\alpha_{nf} = 4.91$.

ANALYSIS: (a) For water flowing over the plate at u_m = 0.5 m/s,

$$Re_L = \frac{u_\infty L}{\nu_{bf}} = \frac{0.5\text{m/s} \times 0.2\text{m}}{857 \times 10^{-9}\,\text{m}^2/\text{s}} = 117 \times 10^3$$

Since $Re_L < Re_{x,c}$ the flow is laminar and Eq. 7.30 yields

$$\bar{h}_L = \frac{k_{bf}}{L}\left[0.664 Re_L^{1/2}\right] Pr_{bf}^{1/3} = \frac{0.613\text{W/m}\cdot\text{K}}{0.2\text{m}}\left[0.664 \times 117{,}000^{1/2}\right] 5.83^{1/3} = 1253 \text{ W/m}^2\text{K}$$ <

and the convection heat transfer rate from the top of the plate is

$$q = wL\bar{h}_L(T_s - T_\infty) = 1\text{m} \times 0.2\text{m} \times 1253\text{W/m}^2 \cdot \text{K} \times (32 - 22)°\text{C} = 2500\text{W} = 2.51 \text{ kW}$$ <

The drag force on the plate is

$$F = \bar{\tau}_{s,L} wL = \frac{\bar{C}_f \rho_{bf} u_\infty^2}{2} wL$$

$$= \frac{1.328 \rho_{bf} u_\infty^2}{2\sqrt{Re_L}} wL = \frac{1.328 \times 997 \text{ kg/m}^3 \times (0.5 \text{ m/s})^2}{2\sqrt{117 \times 10^3}} \times 1 \text{ m} \times 0.2 \text{ m}$$

$$= 0.097 \text{ N}$$ <

where Equation 7.29 has been used to determine the average friction coefficient.

Continued…

PROBLEM 7.34 (Cont.)

(b) For the nanofluid flowing over the plate at u_m = 0.5 m/s,

$$Re_L = \frac{u_\infty L}{\nu_{\text{nf}}} = \frac{0.5\text{m/s} \times 0.2\text{m}}{839 \times 10^{-9}\text{m}^2/\text{s}} = 119 \times 10^3$$

The flow is laminar and Eq. 7.30 yields

$$\overline{h}_L = \frac{k_{\text{nf}}}{L}\left[0.664 Re_L^{1/2}\right] Pr_{\text{nf}}^{1/3} = \frac{0.705\text{W/m}\cdot\text{K}}{0.2\text{m}}\left[0.664 \times 119{,}000^{1/2}\right] 4.91^{1/3} = 1372\ \text{W/m}^2\cdot\text{K}$$ <

and the convection heat transfer rate from the top of the plate is

$$q = wL\overline{h}_L(T_s - T_\infty) = 1\text{m} \times 0.2\text{m} \times 1372\text{W/m}^2\cdot\text{K}(32-22)°\text{C} = 2740\text{W} = 2.74\ \text{kW}$$ <

The drag force on the plate is

$$F = \overline{\tau}_{s,L} wL = \frac{\overline{C}_f \rho_{\text{nf}} u_\infty^2}{2} wL$$
$$= \frac{1.328 \rho_{\text{nf}} u_\infty^2}{2\sqrt{Re_L}} wL = \frac{1.328 \times 1146\ \text{kg/m}^3 \times (0.5\ \text{m/s})^2}{2\sqrt{119 \times 10^3}} \times 1\ \text{m} \times 0.2\ \text{m}$$
$$= 0.110\ \text{N}$$ <

(c) For water flowing over the plate at u_m = 2.5 m/s,

$$Re_L = \frac{u_\infty L}{\nu_{\text{bf}}} = \frac{2.5\text{m/s} \times 0.2\text{m}}{857 \times 10^{-9}\text{m}^2/\text{s}} = 5.83 \times 10^5$$

Therefore, the flow at the end of the plate is turbulent and Eq. 7.30 yields

$$\overline{h}_L = \frac{k_{\text{bf}}}{L}\left[0.037 Re_L^{4/5} - 871\right] Pr_{\text{bf}}^{1/3}$$
$$= \frac{0.613\text{W/m}\cdot\text{K}}{0.2\text{m}}\left[0.037(5.83 \times 10^5)^{4/5} - 871\right] 5.83^{1/3} = 3562\ \text{W/m}^2\cdot\text{K}$$ <

and the convection heat transfer rate from the top of the plate is

$$q = wL\overline{h}_L(T_s - T_\infty) = 1\text{m} \times 0.2\text{m} \times 3562\text{W/m}^2\cdot\text{K}(32-22)°\text{C} = 7120\text{W} = 7.12\ \text{kW}$$ <

The drag force on the plate is

Continued…

PROBLEM 7.34 (Cont.)

$$F = \bar{\tau}_{s,L} wL = \bar{C}_f \frac{\rho_{\mathrm{bf}} u_\infty^2}{2} wL$$

$$= \left(0.074 Re_L^{-1/5} - \frac{2 \times 871}{Re_L}\right) \frac{\rho_{\mathrm{bf}} u_\infty^2}{2} wL$$

$$= \left(0.074 \times \left(5.83 \times 10^5\right)^{-1/5} - \frac{2 \times 871}{5.83 \times 10^5}\right) \frac{997\ \mathrm{kg/m^3} \times (2.5\ \mathrm{m})^2}{2} \times 1\ \mathrm{m} \times 0.2\ \mathrm{m}$$

$$= 1.379\ \mathrm{N}$$ <

where Equation 7.40 has been used to determine the average friction coefficient.

(d) For the nanofluid flowing over the plate at u_m = 2.5 m/s, $Re_L = 5.96 \times 10^5$, $\bar{h}_L = 4024\ \mathrm{W/m^2 \cdot K}$, q = 8050 W = 8.05 kW, and F = 1.615 N. <

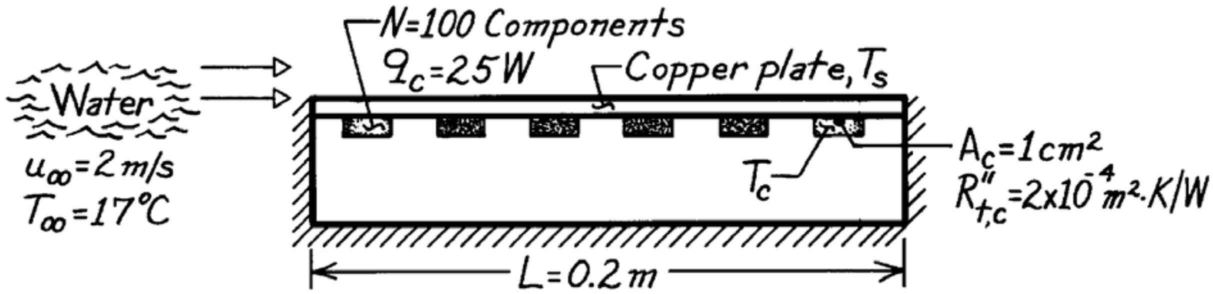
COMMENTS: (1) The convection heat transfer rate is greater for the nanofluid than for the base fluid (water). For the laminar case, the nanofluid convection heat transfer rate is 9.5% larger when the nanofluid is used. For the turbulent flow case the convection heat transfer rate is 13% higher for the nanofluid. The higher efficacy of the nanofluid in the turbulent flow case is associated with its larger Reynolds number, $Re_{L,\mathrm{nf}} > Re_{L,\mathrm{bf}}$. Hence more of the plate experiences turbulent flow when the nanofluid is used. (2) The drag force is always greater when the nanofluid is used. For the laminar flow case, the drag force is 13.6% larger when the nanofluid is used, while for the turbulent flow case the drag force associated with the nanofluid is 17.1% larger than for the base fluid. Larger drag forces are expected due to the larger viscosity associated with the nanofluid. (c) For many cases involving nanofluids, a tradeoff exists between potentially increasing the heat transfer rates, but at a cost of experiencing larger friction losses.

PROBLEM 7.35

KNOWN: Operating power of electrical components attached to one side of copper plate. Contact resistance. Velocity and temperature of water flow on opposite side.

FIND: (a) Plate temperature, (b) Component temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible heat loss from sides and bottom, (4) Turbulent flow throughout.

PROPERTIES: Water (given): $\nu = 0.96 \times 10^{-6}$ m^2/s, k = 0.620 W/m·K, Pr = 5.2.

ANALYSIS: (a) From the convection rate equation,

$$T_s = T_\infty + q/\overline{h}A$$

where q = Nq_c = 2500 W and A = L^2 = 0.04 m^2. The convection coefficient is given by the turbulent flow correlation

$$\overline{h} = \overline{Nu}_L\,(k/L) = 0.037 Re_L^{4/5} Pr^{1/3}(k/L)$$

where

$$Re_L = (u_\infty L/\nu) = (2\text{ m/s} \times 0.2\text{m})/0.96 \times 10^{-6}\text{m}^2/\text{s} = 4.17 \times 10^5$$

and hence

$$\overline{h} = 0.037\left(4.17 \times 10^5\right)^{4/5}(5.2)^{1/3}(0.62\text{ W/m}\cdot\text{K}/0.2\text{ m}) = 6228\text{ W/m}^2\cdot\text{K}.$$

The plate temperature is then

$$T_s = 17^\circ\text{C} + 2500\text{ W}/\left(6228\text{ W/m}^2\cdot\text{K}\right)(0.20\text{ m})^2 = 27^\circ\text{C}. \qquad <$$

(b) For an individual component, a rate equation involving the component's contact resistance can be used to find its temperature,

$$q_c = (T_c - T_s)/R_{t,c} = (T_c - T_s)/\left(R''_{t,c}/A_c\right)$$

$$T_c = T_s + q_c R''_{t,c}/A_c = 27^\circ\text{C} + 25\text{ W}\left(2 \times 10^{-4}\text{ m}^2\cdot\text{K/W}\right)/10^{-4}\text{ m}^2$$

$$T_c = 77^\circ\text{C}. \qquad <$$

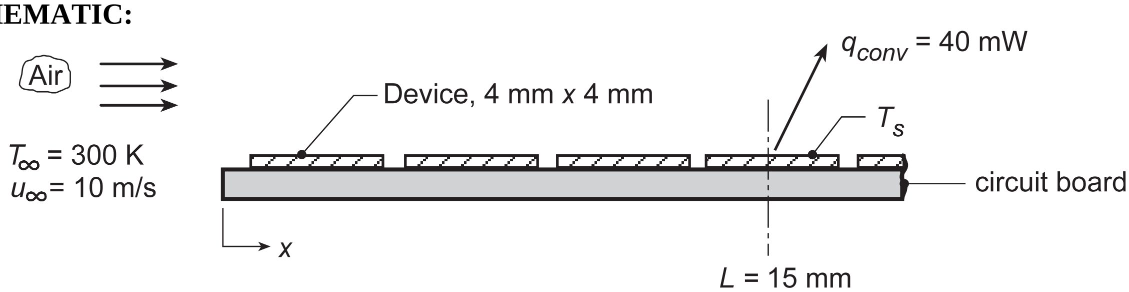
COMMENTS: With $Re_L = 4.17 \times 10^5$, the boundary layer would be laminar over the entire plate without the boundary layer trip, causing T_s and T_c to be appreciably larger.

PROBLEM 7.36

KNOWN: Air at 27°C with velocity of 10 m/s flows turbulently over a series of electronic devices, each having dimensions of 4 mm × 4 mm and dissipating 40 mW.

FIND: (a) Surface temperature T_s of the fourth device located 15 mm from the leading edge, (b) Compute and plot the surface temperatures of the first four devices for the range $5 \le u_\infty \le 15$ m/s, and (c) Minimum free stream velocity u_∞ if the surface temperature of the hottest device is not to exceed 80°C.

SCHEMATIC:



ASSUMPTIONS: (1) Turbulent flow, (2) Heat from devices leaving through top surface by convection only, (3) Device surface is isothermal, and (4) The average coefficient for the devices is equal to the local value at the mid position, i.e. $\bar{h}_4 = h_x(L)$.

PROPERTIES: *Table A.4,* Air (assume T_s = 330 K, $\bar{T} = (T_s + T_\infty)/2$ = 315 K, 1 atm): k = 0.0274 W/m·K, $\nu = 17.40 \times 10^{-6}$ m²/s, $\alpha = 24.7 \times 10^{-6}$ m²/s, Pr = 0.705.

ANALYSIS: (a) From Newton's law of cooling,

$$T_s = T_\infty + q_{conv}/\bar{h}_4 A_s \qquad (1)$$

where $\bar{h}_4$ is the average heat transfer coefficient over the 4th device. Since flow is turbulent, it is reasonable and convenient to assume that

$$\bar{h}_4 = h_x(L = 15\,\text{mm}). \qquad (2)$$

To estimate h_x, use the turbulent correlation evaluating thermophysical properties at $\bar{T}_f$ = 315 K (assume T_s = 330 K),

$$Nu_x = 0.0296\,Re_x^{4/5}\,Pr^{1/3}$$

where

$$Re_x = \frac{u_\infty L}{\nu} = \frac{10\,\text{m/s} \times 0.015\,\text{m}}{17.4 \times 10^{-6}\,\text{m}^2/\text{s}} = 8621$$

giving

$$Nu_x = \frac{h_x L}{k} = 0.0296(8621)^{4/5}(0.705)^{1/3} = 37.1$$

$$\bar{h}_4 = h_x = \frac{Nu_x k}{L} = \frac{37.1 \times 0.0274\,\text{W/m}\cdot\text{K}}{0.015\,\text{m}} = 67.8\,\text{W/m}^2\cdot\text{K}$$

Hence, with A_s = 4 mm × 4 mm, the surface temperature is

$$T_s = 300\,\text{K} + \frac{40 \times 10^{-3}\,\text{W}}{67.8\,\text{W/m}^2\cdot\text{K} \times \left(4 \times 10^{-3}\,\text{m}\right)^2} = 337\,\text{K} = 64^\circ\text{C}. \qquad <$$

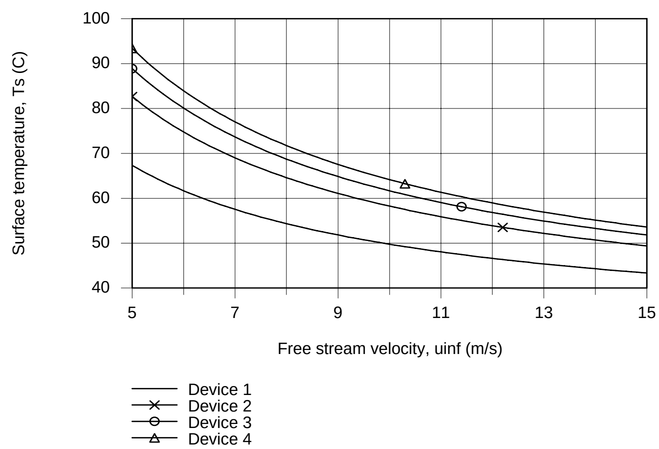
Continued...

PROBLEM 7.36 (Cont.)

(b) The surface temperature for each of the four devices (i = 1, 2, 3 4) follows from Eq. (1),

$$T_{s,i} = T_\infty + q_{conv} / \overline{h}_i A_s \tag{3}$$

For devices 2, 3 and 4, $\overline{h}_i$ is evaluated as the local coefficient at the mid-positions, Eq. (2), x_2 = 6.5 mm, x_3 = 10.75 mm and x_4 = 15 mm. For device 1, $\overline{h}_1$ is the average value 0 to x_1, where evaluated $x_1 = L_1$ = 4.25 mm. Using Eq. (3) in the *IHT Workspace* along with the *Correlations Tool*, *External Flow*, *Local Coefficient* for *Laminar* or *Turbulent Flow*, the surface temperatures $T_{s,i}$ are determined as a function of the free stream velocity.



(c) Using the *Explore* option on the *Plot Window* associated with the IHT code of part (b), the minimum free stream velocity of

$$u_\infty = 6.6 \text{ m/s}$$ <

will maintain device 4, the hottest of the devices, at a temperature $T_{s,4}$ = 80°C.

COMMENTS: (1) Note that the thermophysical properties were evaluated at a reasonable assumed film temperature in part (a).

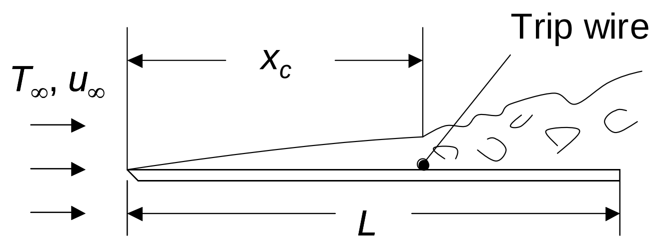
(2) From the $T_{s,i}$ vs. u_∞ plots, note that, as expected, the surface temperatures of the devices increase with distance from the leading edge.

PROBLEM 7.37

KNOWN: Length of isothermal flat plate in parallel flow, *L*.

FIND: Expression for the Reynolds number associated with the location of a trip wire to maximize heat transfer, $Re_{x,c,\text{opt}}$.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties.

ANALYSIS: From Equations 7.38 and 7.39

$$\overline{Nu}_L = \left(0.037\,\text{Re}_L^{4/5} - A\right) Pr^{1/3} \quad \text{where} \quad A = 0.037 Re_{x,c}^{4/5} - 0.664 Re_{x,c}^{1/2} \qquad \text{(1a, b)}$$

To maximize the average Nusselt number, it is necessary to minimize the value of *A*. Taking the derivative of *A* with respect to $Re_{x,c}$ results in

$$\frac{dA}{dRe_{x,c}} = 0.037\left(\frac{4}{5}\right)\left(Re_{x,c}\right)^{-1/5} - 0.664\left(\frac{1}{2}\right)\left(Re_{x,c}\right)^{-1/2}$$

Setting $dA/dRe_{x,c}$ equal to zero yields

$$Re_{x,c,\text{opt}}^{-1/5} Re_{x,c,\text{opt}}^{1/2} = \frac{0.664(1/2)}{0.037(4/5)} = 11.216$$

or $$Re_{x,c,\text{opt}} = 11.216^{(1/0.3)} = 3158$$ <

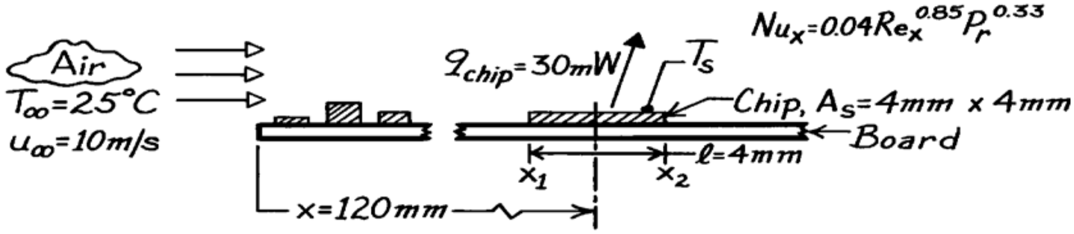
COMMENTS: Substituting $Re_{x,c,\text{opt}} = 3158$ into Equation 1b yields $A_{\text{opt}} = -14$. Since $A = 0$ corresponds to tripping the boundary layer at the leading edge of the plate, and $A = 871$ corresponds to a critical Reynolds number of $Re_{x,c} = 5 \times 10^5$, we know that placing the trip wire at an *x* location corresponding to $Re_{x,c,\text{opt}} = 3158$ must maximize heat transfer from the plate (as opposed to minimizing heat transfer from the plate).

PROBLEM 7.38

KNOWN: Convection correlation for irregular surface due to electronic elements mounted on a circuit board experiencing forced air cooling with prescribed temperature and velocity

FIND: Surface temperature when heat dissipation rate is 30 mW for chip of prescribed area located a specific distance from the leading edge.

SCHEMATIC:



ASSUMPTIONS: (1) Situation approximates parallel flow over a flat plate with prescribed correlation, (2) Heat rate is from top surface of chip.

PROPERTIES: *Table A-4*, Air (assume $T_s \approx 45°C$, then $\bar{T} = (45 + 25)°C/2 \approx 310$ K, 1 atm): k = 0.027 W/m·K, $\nu = 16.90 \times 10^{-6}$ m^2/s, Pr = 0.706.

ANALYSIS: For the chip upper surface, the heat rate is

$$q_{chip} = \bar{h}_{chip} A_s (T_s - T_\infty) \qquad \text{or} \qquad T_s = T_\infty + q_{chip} / \bar{h}_{chip} A_s$$

Assuming the average convection coefficient over the chip length to be equal to the local value at the center of the chip ($x = x_o$), $\bar{h}_{chip} \approx h_x(x_o)$, where

$$Nu_x = 0.04 Re_x^{0.85} Pr^{0.33}$$

$$Nu_x = 0.04\left(10 \text{ m/s} \times 0.120 \text{ m}/16.90 \times 10^{-6} \text{ m}^2/\text{s}\right)^{0.85} (0.706)^{0.33} = 473.4$$

$$h_x = \frac{Nu_x k}{x_o} = \frac{473.4 \times 0.027 \text{ W/m} \cdot \text{K}}{0.120 \text{ m}} = 107 \text{ W/m}^2 \cdot \text{K}$$

Hence,

$$T_s = 25°C + 30 \times 10^{-3} \text{ W}/107 \text{ W/m}^2 \cdot \text{K} \times \left(4 \times 10^{-3} \text{m}\right)^2 = (25 + 17.5)° C = 42.5°C. \quad <$$

COMMENTS: (1) Note that the assumed value of $\bar{T}$ used to evaluate the thermophysical properties was reasonable. (2) We could have evaluated $\bar{h}_{chip}$ by two other approaches. In one case the average coefficient is approximated as the arithmetic mean of local values at the leading and trailing edges of the chip.

$$\bar{h}_{chip} \approx \left[h_{x2}(x_2) + h_{x1}(x_1)\right]/2 = 107 \text{ W/m}^2 \cdot \text{K}.$$

The exact approach is of the form

$$\bar{h}_{chip} \cdot \ell = \bar{h}_{x2} \cdot x_2 - \bar{h}_{x1} \cdot x_1$$

Recognizing that $h_x \sim x^{-0.15}$, it follows that

$$\bar{h}_x = \frac{1}{x}\int_0^x h_x \cdot dx = 1.176 h_x$$

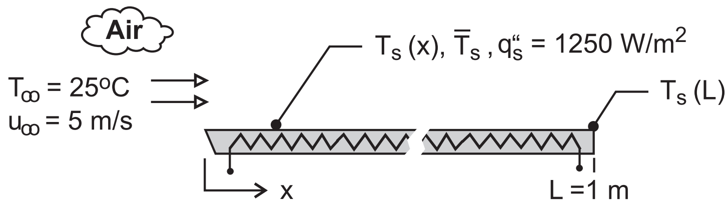
and $\bar{h}_{chip} = 108 \text{ W/m}^2 \cdot \text{K}$. Why do results for the two approximate methods and the exact method compare so favorably?

PROBLEM 7.39

KNOWN: Air at atmospheric pressure and a temperature of 25°C in parallel flow at a velocity of 5 m/s over a 1-m long flat plate with a uniform heat flux of 1250 W/m^2.

FIND: (a) Plate surface temperature, $T_s(L)$, and local convection coefficient, $h_x(L)$, at the trailing edge, x = L, (b) Average temperature of the plate surface, $\overline{T}_s$, (c) Plot the variation of the plate surface temperature, $T_s(x)$, and the convection coefficient, $h_x(x)$, with distance on the same graph; explain key features of these distributions.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Flow is fully turbulent, and (3) Constant properties.

PROPERTIES: *Table A-4*, Air (assume T_f = 325 K, 1 atm): $\nu = 18.76 \times 10^{-6}$ m^2/s; k = 0.0284 W/m·K; Pr = 0.703.

ANALYSIS: (a) At the trailing edge, x = L, the convection rate equation is

$$q''_s = q''_{cv} = h_x(L)\left[T_s(L) - T_\infty\right] \quad (1)$$

where the local convection coefficient, assuming turbulent flow, follows from Eq. 7.46.

$$Nu_x = \frac{h_x x}{k} = 0.0308\ Re_x^{4/5}\,Pr^{1/3} \quad (2)$$

With x = L = 1m, find

$$Re_x = u_\infty L/\nu = 5\ \text{m/s}\times 1\ \text{m}/18.76\times10^{-6}\ \text{m}^2/\text{s} = 2.67\times10^5$$

$$h_x(L) = (0.0284\ \text{W/m}\cdot\text{K}/1\text{m})\times 0.0308\left(2.67\times10^5\right)^{4/5}(0.703)^{1/3} = 17.1\ \text{W/m}^2\cdot\text{K}$$

Substituting numerical values into Eq. (1),

$$T_s(L) = 25°\text{C} + 1250\ \text{W/m}^2/17.1\ \text{W/m}^2\cdot\text{K} = 98.3°\text{C}$$ <

(b) The average surface temperature $\overline{T}_s$ follows from the expression

$$\overline{T}_s - T_\infty = \frac{1}{L}\int_0^L (T_s - T_\infty)\,dx = \frac{q''_s}{L}\int_0^L \frac{x}{k\,Nu_x}\,dx \quad (3)$$

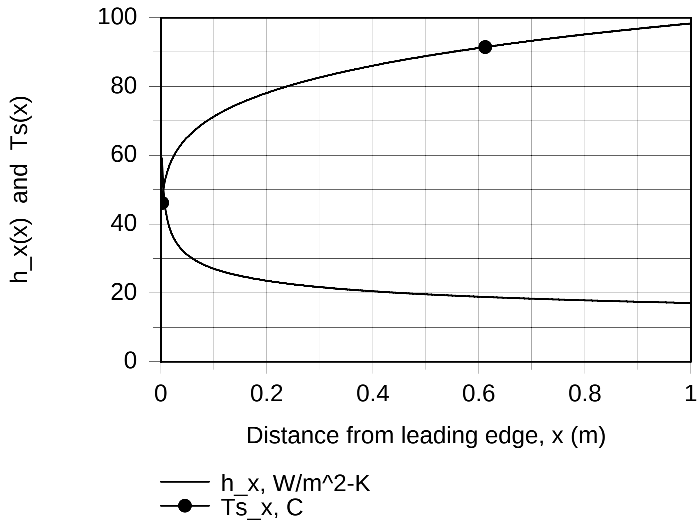
where Nu_x is given by Eq. (2). Using the *Integral* function in *IHT* as described in Comment (3) find

$$\overline{T}_s = 86.1°\text{C}.$$ <

(c) The variation of the plate surface temperature $T_s(x)$ and convection coefficient, $h_x(x)$, shown in the graph are calculated using Eqs. (1) and (2).

Continued …

PROBLEM 7.39 (Cont.)



COMMENTS: (1) The properties for the correlation should be evaluated at $T_f = \left(\overline{T}_s + T_\infty\right)/2$. From the foregoing analyses, T_f = (86.1 + 25)°/2 = 55.5°C = 329 K. Hence, the assumed value of 325 K was reasonable.

(2) The IHT code, excluding the input variables and air property functions, used to evaluate the integral of Eq. (3) and generate the graphs in part (c) is shown below.

```
/* Programming note:  when using the INTEGRAL function, the value of the independent variable
must not be specified as an input variable.  If done so, this error message will appear:
"Redefinition of a constant variable." */

// Turbulent flow correlation, Eq. 7.45, local values
Nu_x = 0.0308 * Re_x^0.8 * Pr^0.333
Nu_x = h_x * x / k
Re_x = uinf * x / nu

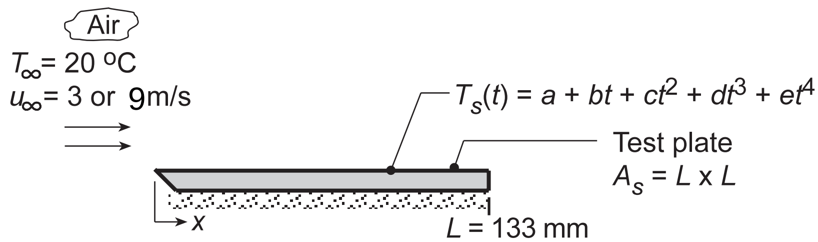
// Plate temperatures
// Local
Ts_x = Tinf + q''s / h_x
// Average
Ts_avg - Tinf = q''s / L * INTEGRAL (y,x)
delT_avg = Ts_avg - Tinf
y = x / (k * Nu_x)
```

PROBLEM 7.40

KNOWN: Experimental apparatus providing nearly uniform airstream over a flat *test plate*. Temperature history of the pre-heated plate for airstream velocities of 3 and 9 m/s were fitted to a fourth-order polynomial.

FIND: (a) Convection coefficient for the two cases assuming the plate behaves as a spacewise isothermal object and (b) Coefficients C and m for a correlation of the form $\overline{Nu}_L = C\,Re^m\,Pr^{1/3}$; compare result with a standard-plate correlation and comment on the goodness of the comparison; explain any differences.

SCHEMATIC:



u_∞ (m/s)	3	9
Δt (s)	300	160
a (°C)	56.87	57.00
b (°C/s)	-0.1472	-0.2641
c (°C/s^2)	3×10^{-4}	9×10^{-4}
d (°C/s^3)	-4×10^{-7}	-2×10^{-6}
e (°C/s^4)	2×10^{-10}	1×10^{-9}

ASSUMPTIONS: (1) Airstream over the *test plate* approximates parallel flow over a flat plate, (2) Plate is spacewise isothermal, (3) Negligible radiation exchange between plate and surroundings, (4) Constant properties, and (5) Negligible heat loss from the bottom surface or edges of the test plate.

PROPERTIES: *Table A.4*, Air ($T_f = (T_s + T_\infty)/2 \approx 310$ K, 1atm): $k_a = 0.0269$ W/m·K, $\nu = 1.669 \times 10^{-5}$ m^2/s, Pr = 0.706. Test plate (Given): $\rho = 2770$ kg/m^3, $c_p = 875$ J/kg·K, k = 177 W/m·K.

ANALYSIS: (a) Using the lumped-capacitance method, the energy balance on the plate is

$$-\bar{h}_L A_s\left[T_s(t) - T_\infty\right] = \rho V c_p \frac{dT}{dt} \qquad (1)$$

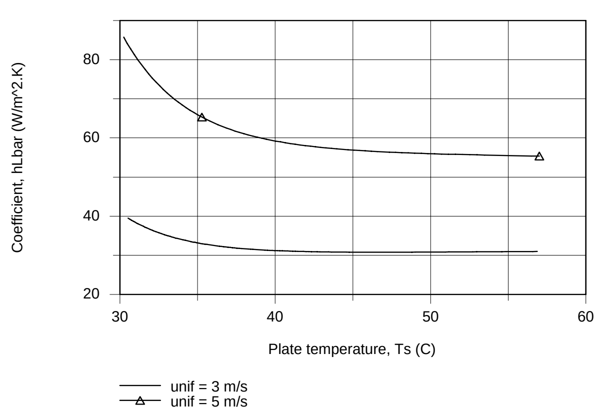
and the average convection coefficient can be determined from the temperature history, $T_s(t)$,

$$\bar{h}_L = \frac{\rho V c_p}{A_s}\frac{(dT/dt)}{T_s(t) - T_\infty} \qquad (2)$$

where the temperature-time derivative is

$$\frac{dT_s}{dt} = b + 2ct + 3dt^2 + 4et^3 \qquad (3)$$

The temperature time history plotted below shows the experimental behavior of the observed data.



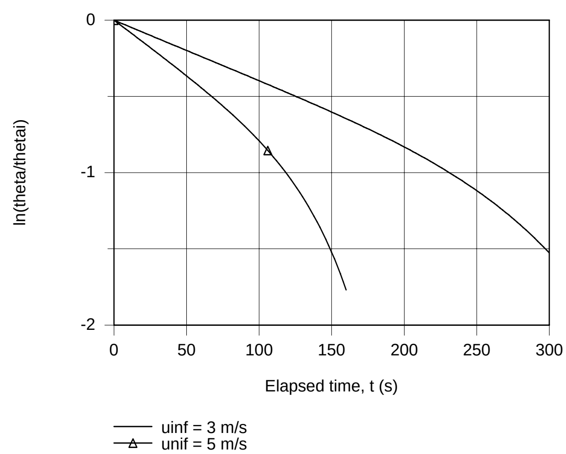
Continued...

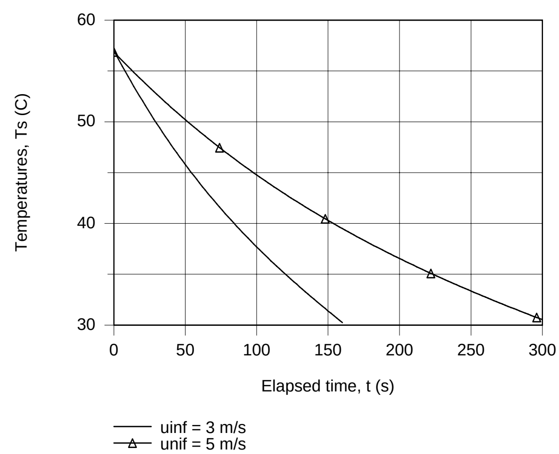
PROBLEM 7.40 (Cont.)

Consider now the integrated form of the energy balance, Eq. (5.6), expressed as

$$\ln\frac{T_s(t)-T_\infty}{T_i-T_\infty}=-\left(\frac{\overline{h}_L A_s}{\rho V c}\right)t \qquad (4)$$

If we were to plot the LHS vs t, the slope of the curve would be proportional to $\overline{h}_L$. Using IHT, plots were generated of $\overline{h}_L$ vs. T_s, Eq. (1), and $\ln\left[\left(T_s(t)-T_\infty\right)/\left(T_i-T_\infty\right)\right]$ vs. t, Eq. (4). From the latter plot, recognize that the regions where the slope is constant corresponds to early times (≤ 100s when u_∞ = 3 m/s and ≤ 50s when u_∞ = 5 m/s).





Selecting two elapsed times at which to evaluate $\overline{h}_L$, the following results were obtained

u_∞ (m/s)	t (s)	T_s (t), (°C)	$\overline{h}_L$ ($W/m^2\cdot K$)	$\overline{Nu}_L$	Re_L
3	100	44.77	30.81	152.4	2.39×10^4
9	50	45.80	56.7	280.4	7.17×10^4

where the dimensionless parameters are evaluated as

$$\overline{Nu}_L=\frac{\overline{h}_L L}{k_a} \qquad Re_L=\frac{u_\infty L}{\nu} \qquad (5,6)$$

where k_a, ν are thermophysical properties of the airstream.

(b) Using the above pairs of $\overline{Nu}_L$ and Re_L, C and m in the correlation can be evaluated,

$$\overline{Nu}_L = C\,Re_L^m\,Pr^{1/3} \qquad (7)$$

$$152.4 = C(2.39\times10^4)^m(0.706)^{1/3}$$

$$280.4 = C(7.17\times10^4)^m(0.706)^{1/3}$$

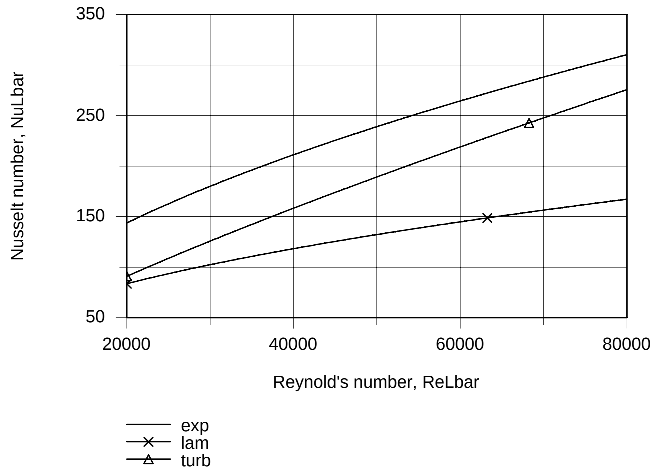
Solving, find

C = 0.633 m = 0.555 (8,9) <

Continued...

PROBLEM 7.40 (Cont.)

The plot below compares the experimental correlation (C = 0.633, m = 0.555) with those for laminar flow (C = 0.664, m = 0.5) and fully turbulent flow (C = 0.037, m = 0.8). The experimental correlation yields $\overline{Nu}_L$ values which are 25% higher than for the correlation. The most likely explanation for this unexpected trend is that the airstream reaching the plate is not parallel, but with a slight impingement effect and/or the flow is very highly turbulent at the leading edge.



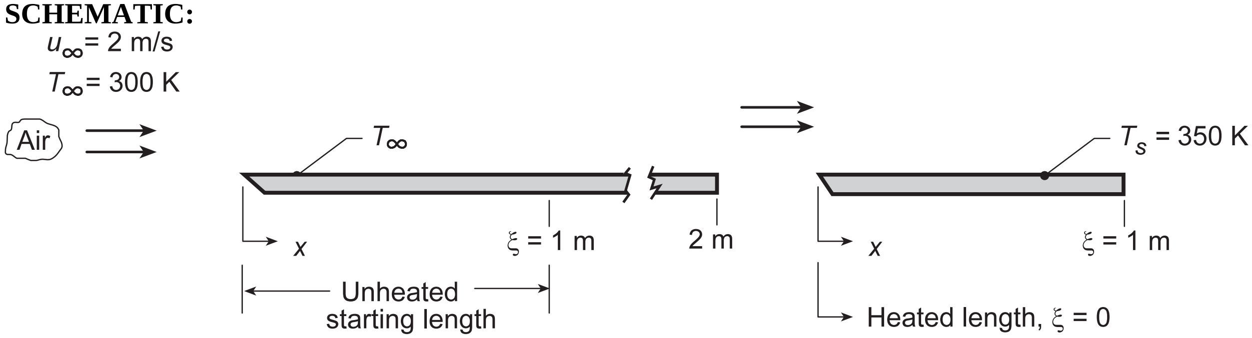
COMMENTS: (1) A more extensive analysis of the experimental observations would involve determining $\overline{Nu}_L$ for the full range of elapsed time (rather than at two selected times) and using a fitting routine to determine values for C and m.

PROBLEM 7.41

KNOWN: Conditions for airflow over isothermal plate with optional unheated starting length.

FIND: (a) local coefficient, h_x, at leading and trailing edges with and without an unheated starting length, ξ = 1 m.

SCHEMATIC:



PROPERTIES: *Table A.4*, Air (T_f = 325 K, 1 atm): $\nu = 18.4 \times 10^{-6}$ m²/s, Pr = 0.703, k = 0.0282 W/m·K.

ANALYSIS: (a) The Reynolds number at ξ = 1 m is

$$Re_\xi = \frac{u_\infty \xi}{\nu} = \frac{2\,\text{m/s} \times 1\text{m}}{18.4\times10^{-6}\,\text{m}^2/\text{s}} = 1.087\times10^5$$

If $Re_{x,c} = 5 \times 10^5$, flow is laminar over the entire plate (with or without the starting length). In general,

$$Nu_x = \frac{0.332\,Re_x^{1/2}\,Pr^{1/3}}{\left[1-(\xi/x)^{3/4}\right]^{1/3}} \qquad (1)$$

$$h_x = \frac{\left(0.332k\,Pr^{1/3}\right)Re_x^{1/2}}{x\left[1-(\xi/x)^{3/4}\right]^{1/3}} = 0.00832\,\text{W/m}\cdot\text{K}\frac{Re_x^{1/2}}{x\left[1-(\xi/x)^{3/4}\right]^{1/3}}.$$

With Unheated Starting Length: Leading edge (x = 1 m): $Re_x = Re_\xi$, $\xi/x = 1$, $h_x = \infty$ <

Trailing Edge (x = 2 m): $Re_x = 2\,Re_\xi = 2.17\times10^5$, $\xi/x = 0.5$

$$h_x = 0.00832\,\text{W/m}\cdot\text{K}\frac{\left(2.17\times10^5\right)^{1/2}}{2\,\text{m}\left[1-(0.5)^{3/4}\right]^{1/3}} = 2.61\,\text{W/m}^2\cdot\text{K}$$ <

Without Unheated Starting Length: Leading edge (x = 0): $h_x = \infty$ <

Trailing edge (x = 1 m): $Re_x = 1.087 \times 10^5$

$$h_x = 0.00832\,\text{W/m}\cdot\text{K}\frac{\left(1.087\times10^5\right)^{1/2}}{1\text{m}} = 2.74\,\text{W/m}^2\cdot\text{K}$$ <

(b) The average convection coefficient $\bar{h}_L$ for the two cases in the schematic are, from Eq. 6.14,

Continued...

PROBLEM 7.41 (Cont.)

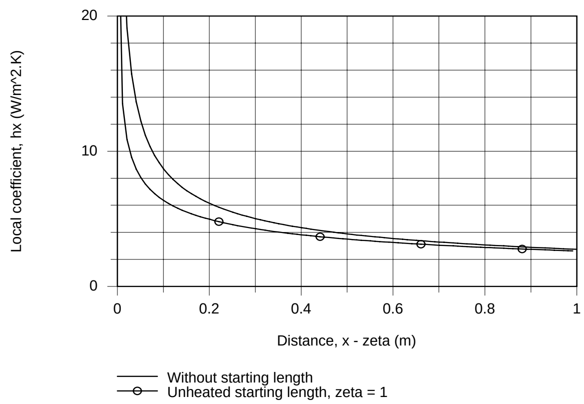
$$\overline{h}_L = \frac{1}{L}\int_0^L h_x(x)\,dx \qquad (2)$$

where L is the x location at the end of the heated section. Substituting Eq. (1) into Eq. (2) and numerically integrating, the results are tabulated below:

ξ (m)	h_x (L)(W/m^2·K)	$\overline{h}_L$ (W/m^2·K)
0	2.74	5.41
1	2.61	4.22

<

(c) The variation of the local convection coefficient over the plate, with and without the unheated starting length, using Eq. (1) is shown below. The abscissa is x - ξ.



COMMENTS: (1) When the velocity and thermal boundary layers grow simultaneously (*without starting length*), we expect the local and average coefficients to be larger than when the velocity boundary layer is thicker (*with starting length*).

(2) When $\xi = 0$, $\overline{h}_L = 2h_L$, when $\xi = 1$, $\overline{h}_L < 2h_L$. From Eq. (7.44), $\overline{h}_L = 4.25\ \mathrm{W/m^2 \cdot K}$.

(3) The numerical integration of Eq. (2) was performed using the INTEGRAL (f,x) operation in IHT as shown in the Workspace below.

```
// Average Coefficient:
hbarL =  1 / (L - zeta ) * INTEGRAL (hx,x)

// Local Coefficient With Unheated Starting Length:
hx  = ( k / x) *  0.332 *  Rex^0.5 * Pr^0.3333 /  ( 1 - (zeta / x)^(3/4) )^(1/3)
Rex = uinf * x / nu

// Properties Tool - Air:
// Air property functions : From Table A.4
// Units: T(K); 1 atm pressure
nu = nu_T("Air",Tf)                 // Kinematic viscosity, m^2/s
k = k_T("Air",Tf)                   // Thermal conductivity, W/m·K
Pr = Pr_T("Air",Tf)                 // Prandtl number
Tf = 325                            // Film temperature, K

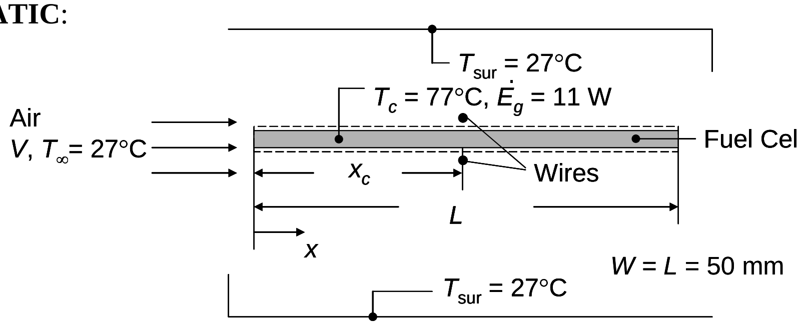
// Assigned Variables:
uinf =  2                           // Airstream velocity, m/s
x = 1                               // Distance from leading edge, m
L = 2                               // Full length of plate, m
zeta = 1                            // Starting length, m
xzeta = x - zeta                    // Difference
```

PROBLEM 7.42

KNOWN: Dimensions of thin fuel cell in parallel flow. Ambient and surroundings temperatures, fuel cell emissivity, desired fuel cell operating temperature. Fuel cell thermal generation rate.

FIND: Minimum velocity needed to sustain desired fuel cell temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible temperature variations inside the fuel cell, (3) Large surroundings, (4) Insulated fuel cell edges, (5) Negligible energy entering or leaving the fuel cell due to gas or liquid flows, (6), Constant properties, (7) Isothermal fuel cell, (8) Trip wire causes laminar-to-turbulent transition.

PROPERTIES: *Table A.4*, air (T_f = (77°C + 27°C)/2 = 52°C = 325K, p = 1 atm): $\nu = 18.4\times10^{-6}$ m²/s, Pr = 0.704, k = 0.0282 W/m·K.

ANALYSIS: An energy balance on the control volume yields $\dot{E}_g = q_{\text{rad}} + q_{cv}$ or

$$q_{cv} = \dot{E}_g - 2LW\varepsilon\sigma(T_c^4 - T_{\text{sur}}^4)$$
$$= 11\text{W} - 2\times(50\times10^{-3}\text{m})^2\times0.85\times5.67\times10^{-8}\text{W/m}^2\cdot\text{K}^4\times\left[(273+77\text{K})^4-(273+27\text{K})^4\right]$$
$$= 9.34\text{W}$$

Applying Newton's law of cooling yields

$$\bar{h} = \frac{q_{cv}}{2LW(T_c - T_\infty)} = \frac{9.34\text{W}}{2\times(50\times10^{-3}\text{m})^2\times(77 - 27)°\text{C}} = 37.4\text{W/m}^2\cdot\text{K}$$

Since the flow may transition at the location of the trip wire, Eqs. (7.38) and (7.39) may be applied, yielding

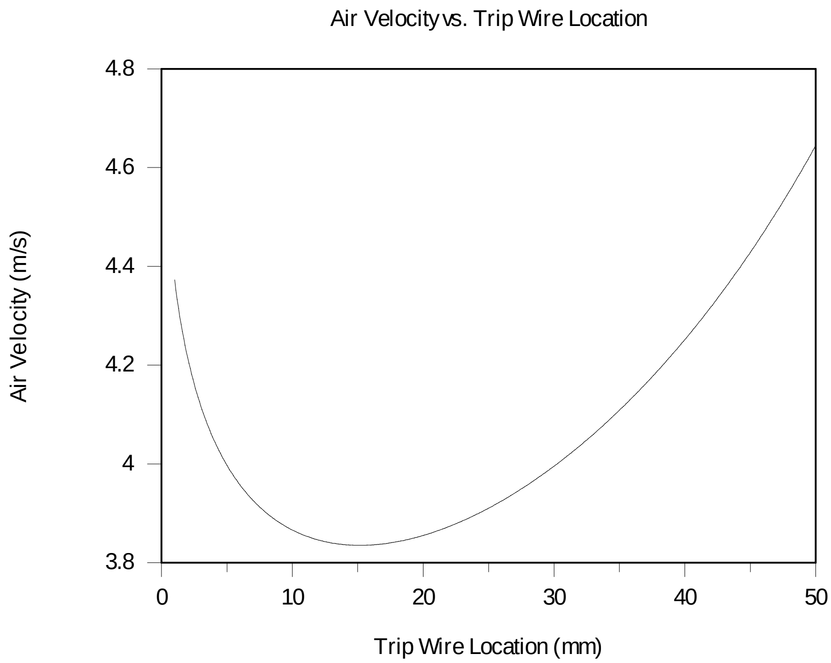
$$\bar{h} = \frac{0.0282\text{W/m}\cdot\text{K}}{0.050\text{m}}\left(0.037Re_L^{4/5} - 0.037Re_{x,c}^{4/5} + 0.664Re_{x,c}^{1/2}\right)0.704^{1/3} = 37.4\ \text{W/m}^2\cdot\text{K}$$

where $Re_L = VL/\nu = V\times0.050\text{m}/18.4\times10^{-6}\text{m}^2/\text{s}$ and $Re_{x,c} = Vx_c/\nu = Vx_c/18.4\times10^{-6}\text{m}^2/\text{s}$

The preceding three equations may be solved for the free stream velocity, V, for various trip wire locations, x_c. The results are shown in the following graph. From the graph, we note that the minimum air velocity is approximately $V_{\min}$ = 3.84 m/s with a trip wire location of x_c = 15 mm. <

Continued…

PROBLEM 7.42 (Cont.)



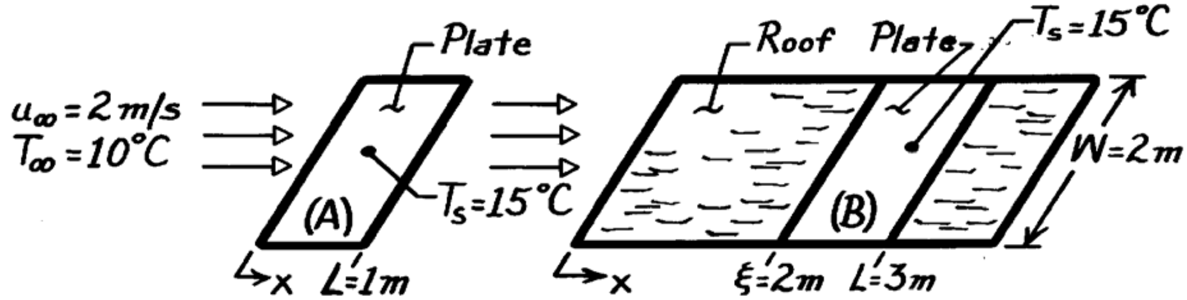
COMMENTS: (1) The optimal trip wire location takes advantage of the very high local Nusselt numbers associated with very thin laminar boundary layers near the leading edge of the fuel cell. Once the local Nusselt numbers within the laminar section begin to decrease, the flow is tripped to take advantage of the increased local Nusselt numbers of turbulent boundary layers. Hence, an optimum trip wire location exists. (2) The *maximum* Reynolds number based upon the fuel cell length and a maximum velocity of approximately V_{max} = 4.65 m/s is $Re_{max,L}$ = 4.65 m/s × 0.050 m/18.4 × 10^{-6} m^2/s = 12,630. This is far below the typical transition Reynolds number of 500,000, and the flow will be laminar if it is not tripped into a turbulent condition. (3) The reduction in the air velocity associated with placement of the trip wires is significant and will result in substantially reduced power requirements to operate the cooling fan.

PROBLEM 7.43

KNOWN: Cover plate dimensions and temperature for flat plate solar collector. Air flow conditions.

FIND: (a) Heat loss with simultaneous velocity and thermal boundary layer development, (b) Heat loss with unheated starting length.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible radiation, (3) Boundary layer is not disturbed by roof-plate interface, (4) $Re_{x,c} = 5\times10^5$.

PROPERTIES: *Table A-4*, Air (T_f = 285.5K, 1 atm): $\nu = 14.6 \times 10^{-6}$ m^2/s, k = 0.0251 W/m·K, Pr = 0.71.

ANALYSIS: (a) The Reynolds number for the plate of L = 1m is

$$Re_L = \frac{u_\infty L}{\nu} = \frac{2\text{ m/s} \times 1\text{m}}{14.6\times10^{-6}\text{ m}^2/\text{s}} = 1.37\times10^5 < Re_{x,c}.$$

For laminar flow

$$\overline{Nu}_L = 0.664\, Re_L^{1/2}\, Pr^{1/3} = 0.664\left(1.37\times10^5\right)^{1/2}(0.71)^{1/3} = 219.2$$

$$q = \frac{k}{L}\overline{Nu}_L A_s\left(T_s - T_\infty\right) = \frac{0.0251\text{ W/m}\cdot\text{K}}{1\text{m}}219.2\left(2\text{m}^2\right)5°\text{C} = 55\text{ W.} \qquad <$$

(b) The Reynolds number for the roof and collector of length L = 3m is

$$Re_L = \frac{2\text{ m/s}\times3\text{m}}{14.6\times10^{-6}\text{ m}^2/\text{s}} = 4.11\times10^5 < Re_{x,c}.$$

Hence, laminar boundary layer conditions exist throughout and the heat rate is

$$q = \int_\xi^L q''\,dA = \left(T_s - T_\infty\right)0.332\left(\frac{u_\infty}{\nu}\right)^{1/2} Pr^{1/3} kW \int_\xi^L \frac{x^{-1/2}dx}{\left[1-\left(\xi/x\right)^{3/4}\right]^{1/3}}$$

$$q = \left(5°\text{C}\right)0.332\left(\frac{2\text{ m/s}}{14.6\times10^{-6}\text{ m}^2/\text{s}}\right)^{1/2}(0.71)^{1/3}\, 0.0251\frac{\text{W}}{\text{m}\cdot\text{K}}2\text{m}\int_\xi^L \frac{x^{-1/2}dx}{\left[1-\left(\xi/x\right)^{3/4}\right]^{1/3}}$$

Using a numerical technique to evaluate the integral,

$$q = 27.50\int_2^3 \frac{x^{-1/2}dx}{\left[1-\left(2.0/x\right)^{3/4}\right]^{1/3}} = 27.50\times1.417 = 39\text{ W} \qquad <$$

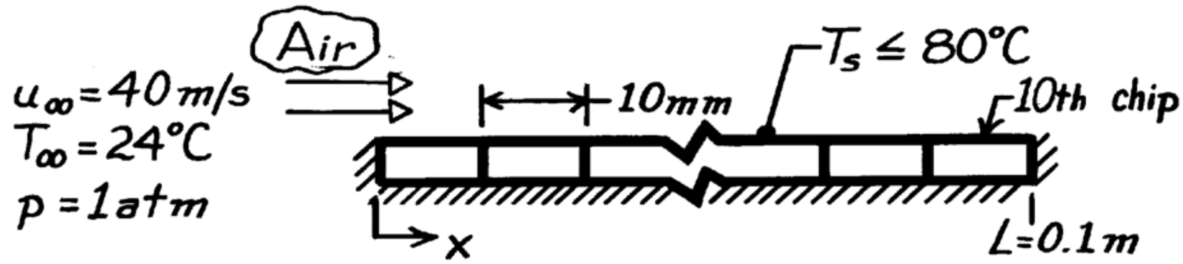
COMMENTS: Values of $\overline{h}$ with and without the unheated starting length are 3.9 and 5.5 W/m^2·K. Prior development of the velocity boundary layer decreases $\overline{h}$.

PROBLEM 7.44

KNOWN: Surface dimensions for an array of 10 silicon chips. Maximum allowable chip temperature. Air flow conditions.

FIND: Maximum allowable chip electrical power (a) without and (b) with a turbulence promoter at the leading edge.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Film temperature of 52°C, (3) Negligible radiation, (4) Negligible heat loss through insulation, (5) Uniform heat flux at chip interface with air, (6) $Re_{x,c} = 5\times10^5$.

PROPERTIES: *Table A-4*, Air (T_f = 325K, 1 atm): $\nu = 18.4 \times 10^{-6}\ m^2/s$, k = 0.0282 W/m·K, Pr = 0.703.

ANALYSIS: $Re_L = u_\infty L/\nu = 40\ m/s\times0.1\ m/18.4\times10^{-6}\ m^2/s = 2.174\times10^5$. Hence, flow is laminar over all chips without the promoter.

(a) For *laminar flow*, the minimum h_x exists on the last chip. Approximating the average coefficient for Chip 10 as the local coefficient at x = 95 mm, $\bar{h}_{10} = h_{x=0.095m}$.

$$\bar{h}_{10} = 0.453\frac{k}{x}Re_x^{1/2}Pr^{1/3}$$

$$Re_x = \frac{u_\infty x}{\nu} = \frac{40\ m/s\times0.095\ m}{18.4\times10^{-6}\ m^2/s} = 2.065\times10^5$$

$$\bar{h}_{10} = 0.453\frac{0.0282\ W/m\cdot K}{0.095}\left(2.065\times10^5\right)^{1/2}(0.703)^{1/3} = 54.3 W/m^2\cdot K$$

$$q_{10} = \bar{h}_{10}A\left(T_s - T_\infty\right) = 54.3\frac{W}{m^2\cdot K}(0.01\ m)^2(80-24)^\circ C = 0.30\ W.$$

Hence, if all chips are to dissipate the same power and T_s is not to exceed 80°C.

$$q_{max} = 0.30\ W. \quad <$$

(b) For *turbulent flow*,

$$\bar{h}_{10} = 0.0308\frac{k}{x}Re_x^{4/5}Pr^{1/3} = 0.0308\frac{0.0282 W/m\cdot K}{0.095\ m}\left(2.065\times10^5\right)^{4/5}(0.703)^{1/3} = 145 W/m^2\cdot K$$

$$q_{10} = \bar{h}_{10}A\left(T_s - T_\infty\right) = 145\frac{W}{m^2\cdot K}(0.01\ m)^2(80-24)^\circ C = 0.81\ W.$$

Hence, $$q_{max} = 0.81\ W. \quad <$$

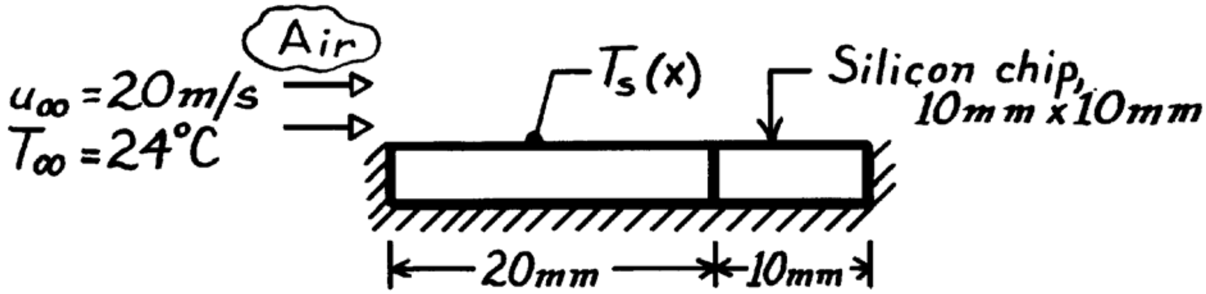
COMMENTS: It is far better to orient array normal to the air flow. Since $\bar{h}_1 > \bar{h}_{10}$, more heat could be dissipated per chip, and the same heat could be dissipated from each chip.

PROBLEM 7.45

KNOWN: Dimensions and maximum allowable temperature of a silicon chip. Air flow conditions.

FIND: Maximum allowable power with or without unheated starting length.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) $T_f = 52°C$, (3) Negligible radiation, (4) Negligible heat loss through insulation, (5) Uniform heat flux at chip-air interface, (6) $Re_{x,c} = 5 \times 10^5$.

PROPERTIES: *Table A-4*, Air (T_f = 325K, 1 atm): $\nu = 18.41 \times 10^{-6}$ m^2/s, k = 0.0282 W/m·K, Pr = 0.703.

ANALYSIS: For uniform heat flux, maximum T_s corresponds to minimum h_x. Without unheated starting length,

$$Re_L = \frac{u_\infty L}{\nu} = \frac{20 \text{ m/s} \times 0.01 \text{ m}}{18.41 \times 10^{-6} \text{ m}^2/\text{s}} = 10,864.$$

With the unheated starting length, L = 0.03 m, Re_L = 32,591. Hence, the flow is laminar in both cases and the minimum h_x occurs at the trailing edge (x = L).

Without unheated starting length,

$$h_L = \frac{k}{L} 0.453 Re_L^{1/2} Pr^{1/3} = \frac{0.0282 \text{ W/m} \cdot \text{K}}{0.01 \text{ m}} 0.453 (10,864)^{1/2} (0.703)^{1/3}$$

$$h_L = 118 \text{ W/m}^2 \cdot \text{K}$$

$$q''(L) = h_L (T_s - T_\infty) = 118 \text{ W/m}^2 \cdot \text{K} (80 - 24)^\circ \text{C} = 6630 \text{ W/m}^2$$

$$q_{max} = A_s q'' = \left(10^{-2} \text{m}\right)^2 6630 \text{ W/m}^2 = 0.66 \text{ W}.$$ <

With the unheated starting length,

$$h_L = \frac{k}{L} 0.453 \frac{Re_L^{1/2} Pr^{1/3}}{\left[1 - (\xi/L)^{3/4}\right]^{1/3}} = \frac{0.0282 \text{ W/m} \cdot \text{K}}{0.03 \text{ m}} 0.453 \frac{(32,951)^{1/2} (0.703)^{1/3}}{\left[1 - (0.02/0.03)^{3/4}\right]^{1/3}}$$

$$h_L = 107 \text{ W/m}^2 \cdot \text{K}$$

$$q''(L) = h_L (T_s - T_\infty) = 107 \text{ W/m}^2 \cdot \text{K} \; (80 - 24)^\circ \text{C} = 6013 \text{ W/m}^2$$

$$q_{max} = A_s q'' = 10^{-4} \text{m}^2 \times 6013 \text{ W/m}^2 = 0.60 \text{ W}.$$ <

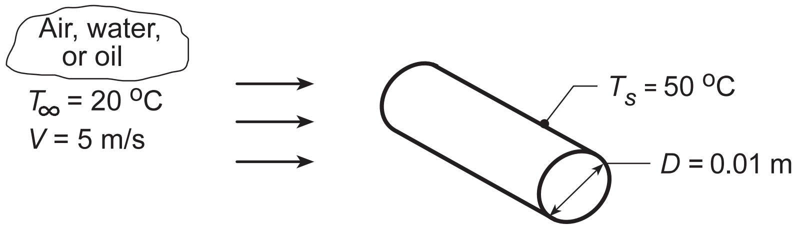
COMMENTS: Prior velocity boundary layer development on the unheated starting section decreases h_x, although the effect diminishes with increasing x.

PROBLEM 7.46

KNOWN: Cylinder diameter and surface temperature. Temperature and velocity of fluids in cross flow.

FIND: (a) Rate of heat transfer per unit length for the fluids: atmospheric air and saturated water, and engine oil, for velocity V = 5 m/s, using the Churchill-Bernstein correlation, and (b) Compute and plot q' as a function of the fluid velocity $0.5 \le V \le 10$ m/s.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform cylinder surface temperature.

PROPERTIES: *Table A.4*, Air (T_f = 308 K, 1 atm): $\nu = 16.69 \times 10^{-6}$ m²/s, k = 0.0269 W/m·K, Pr = 0.706; *Table A.6*, Saturated Water (T_f = 308 K): ρ = 994 kg/m³, $\mu = 725 \times 10^{-6}$ N·s/m², k = 0.625 W/m·K, Pr = 4.85; *Table A.5*, Engine Oil (T_f = 308 K): $\nu = 340 \times 10^{-6}$ m²/s, k = 0.145 W/m·K, Pr = 4000.

ANALYSIS: (a) For each fluid, calculate the Reynolds number and use the Churchill-Bernstein correlation, Eq. 7.54,

$$\overline{Nu}_D = \frac{\bar{h}D}{k} = 0.3 + \frac{0.62\,Re_D^{1/2}\,Pr^{1/3}}{\left[1+(0.4/Pr)^{2/3}\right]^{1/4}}\left[1+\left(\frac{Re_D}{282,000}\right)^{5/8}\right]^{4/5}$$

Fluid: Atmospheric Air

$$Re_D = \frac{VD}{\nu} = \frac{(5\,m/s)\,0.01\,m}{16.69\times10^{-6}\,m^2/s} = 2996$$

$$\overline{Nu}_D = 0.3 + \frac{0.62(2996)^{1/2}(0.706)^{1/3}}{\left[1+(0.4/0.706)^{2/3}\right]^{1/4}}\left[1+\left(\frac{2996}{282,000}\right)^{5/8}\right]^{4/5} = 28.1$$

$$\bar{h} = \frac{k}{D}\overline{Nu}_D = \frac{0.0269\,W/m\cdot K}{0.01\,m}28.1 = 75.5\,W/m^2\cdot K$$

$$q' = \bar{h}\pi D(T_s - T_\infty) = 75.5\,W/m^2\cdot K\,\pi(0.01\,m)(50-20)^\circ C = 71.1\,W/m$$ <

Fluid: Saturated Water

$$Re_D = \frac{VD}{\nu} = \frac{(5\,m/s)\,0.01\,m}{725\times10^{-6}\,N\cdot s/m^2/994\,kg/m^3} = 68,552$$

$$\overline{Nu}_D = 0.3 + \frac{0.62(68,552)^{1/2}(4.85)^{1/3}}{\left[1+(0.4/4.85)^{2/3}\right]^{1/4}}\left[1+\left(\frac{68,552}{282,000}\right)^{5/8}\right]^{4/5} = 347$$

Continued...

PROBLEM 7.46 (Cont.)

$$\bar{h} = \frac{k}{D}\overline{Nu}_D = \frac{0.625\,W/m\cdot K}{0.01\,m}347 = 21{,}690\,W/m^2\cdot K \qquad q' = 20{,}438\,W/m$$ <

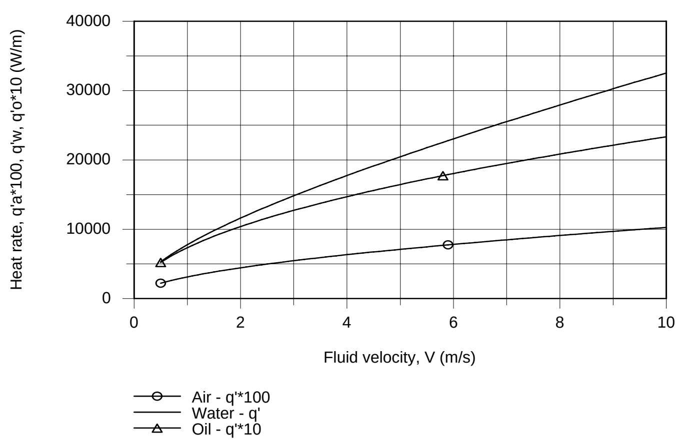
Fluid: Engine Oil

$$Re_D = \frac{VD}{\nu} = \frac{(5\,m/s)\,0.01\,m}{340\times10^{-6}\,m^2/s} = 147$$

$$\overline{Nu}_D = 0.3 + \frac{0.62(147)^{1/2}(4000)^{1/3}}{\left[1+(0.4/4000)^{2/3}\right]^{1/4}}\left[1+\left(\frac{147}{282{,}000}\right)^{5/8}\right]^{4/5} = 120$$

$$\bar{h} = \frac{k}{D}\overline{Nu}_D = \frac{0.145\,W/m\cdot K}{0.01\,m}120 = 1740\,W/m^2\cdot K \qquad q' = 1639\,W/m$$ <

(b) Using the *IHT Correlations Tool*, *External Flow*, *Cylinder*, along with the *Properties Tool* for each of the fluids, the heat rates, q', were calculated for the range $0.5 \le V \le 10$ m/s. Note the q' scale multipliers for the air and oil fluids which permit easy comparison of the three curves.



COMMENTS: (1) Note the inapplicability of the Zukauskas relation, Eq. 7.53, since $Pr_{oil} > 500$.

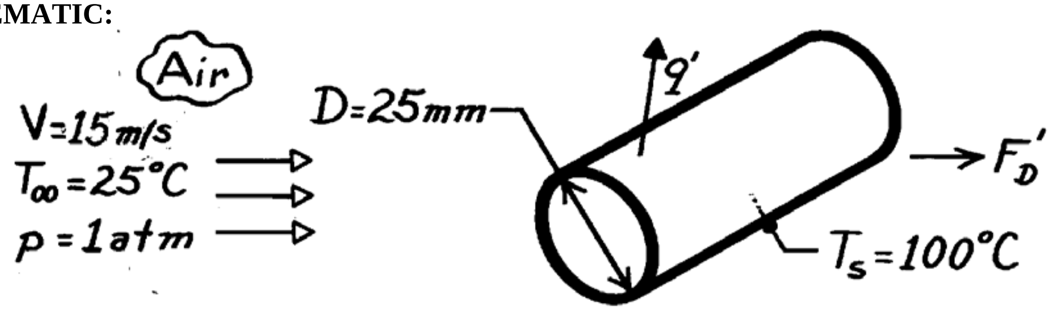
(2) In the plot above, recognize that the heat rate for the water is more than 10 times that with oil and 300 times that with air. How do changes in the velocity affect the heat rates for each of the fluids?

PROBLEM 7.47

KNOWN: Conditions associated with air in cross flow over a pipe.

FIND: (a) Drag force per unit length of pipe, (b) Heat transfer per unit length of pipe.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform cylinder surface temperature, (3) Negligible radiation effects.

PROPERTIES: *Table A-4*, Air (T_f = 335 K, 1 atm): $\nu = 19.31 \times 10^{-6}$ m^2/s, ρ = 1.048 kg/m^3, k = 0.0288 W/m·K, Pr = 0.702.

ANALYSIS: (a) From the definition of the drag coefficient with A_f = DL, find

$$F_D = C_D A_f \frac{\rho V^2}{2}$$

$$F_D' = C_D D \frac{\rho V^2}{2}.$$

With

$$Re_D = \frac{VD}{\nu} = \frac{15 \text{ m/s} \times (0.025 \text{ m})}{19.31 \times 10^{-6} \text{ m}^2/\text{s}} = 1.942 \times 10^4$$

from Fig. 7.9, $C_D \approx 1.1$. Hence

$$F_D' = 1.1(0.025 \text{ m})\ 1.048 \text{ kg/m}^3\ (15 \text{ m/s})^2/2 = 3.24 \text{ N/m}.$$ <

(b) Using Hilpert's relation, with C = 0.193 and m = 0.618 from Table 7.2,

$$\bar{h} = \frac{k}{D} C\, Re_D^m\, Pr^{1/3} = \frac{0.0288 \text{ W/m} \cdot \text{K}}{0.025 \text{ m}} \times 0.193 \left(1.942 \times 10^4\right)^{0.618} (0.702)^{1/3}$$

$$\bar{h} = 88 \text{ W/m}^2 \cdot \text{K}.$$

Hence, the heat rate per unit length is

$$q' = \bar{h}(\pi D)(T_s - T_\infty) = 88 \text{ W/m}^2 \cdot \text{K}(\pi \times 0.025 \text{ m})(100 - 25)^\circ \text{C} = 520 \text{ W/m}.$$ <

COMMENTS: Using the Zukauskas correlation and evaluating properties at T_∞ ($\nu = 15.71 \times 10^{-6}$ m^2/s, k = 0.0261 W/m·K, Pr = 0.707), but with Pr_s = 0.695 at T_s,

$$\bar{h} = \frac{0.0261}{0.025} 0.26 \left(\frac{15 \times 0.025}{15.71 \times 10^{-6}}\right)^{0.6} (0.707)^{0.37} (0.707/0.695)^{1/4} = 102 \text{ W/m}^2 \cdot \text{K}.$$

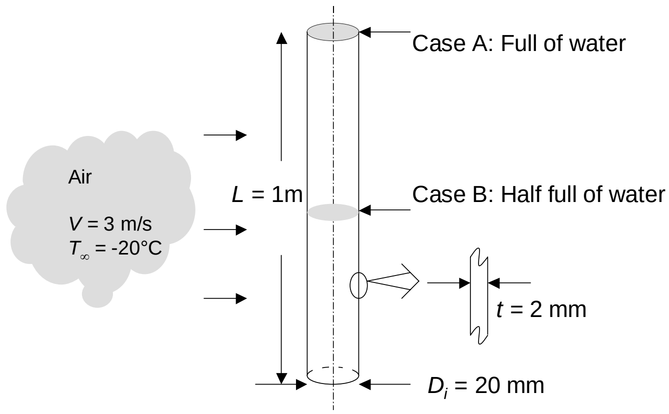
This result agrees with that obtained from Hilpert's relation to within the uncertainty normally associated with convection correlations.

PROBLEM 7.48

KNOWN: Dimensions of a vertical copper tube experiencing crossflow. Air velocity and temperature, water temperature inside the tube.

FIND: (a) The heat loss per unit mass from the water (W/kg) when the pipe is full. (b) The heat loss from the water (W/kg) when the pipe is half full.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Tube behaves as an infinite fin, (4) Water is well-mixed, (5) One-dimensional heat transfer, (6) Inside copper wall temperature at water temperature, (7) Negligible heat transfer to/from the gas above the liquid water, (8) Negligible radiation.

PROPERTIES: *Table A.4*, air assumed: (T_f = (0°C - 20°C)/2 = -10°C ≈ 263K, p = 1 atm): ν = 12.6×10^{-6} m^2/s, Pr = 0.717, k = 0.0233 W/m·K. Table A.1, copper: (T = 300 K): k_{CU} = 401 W/m·K. Table A.6, water (T = 273 K), ρ = 1000 kg/m^3.

ANALYSIS: For either case, the average convection coefficient about the tube must be evaluated. The Reynolds number, based upon the outer diameter D_o = 20 mm + 4 mm = 24 mm is $Re_D = VD_o/\nu$ = 3 m/s × 24 × 10^{-3} m/12.6 × 10^{-6} m^2/s = 5714. Using Eq. 7.54, the average heat transfer coefficient about the exterior of the tube is

$$h = \frac{0.0233\,\text{W/m}\cdot\text{K}}{24\times10^{-3}\,\text{m}}\left\{0.3 + \frac{0.62\left(5714^{1/2}\right)0.717^{1/3}}{\left[1+(0.4/0.717)^{2/3}\right]^{1/4}}\left[1+\left(\frac{5714}{282{,}000}\right)^{5/8}\right]^{4/5}\right\} = 38.56\ \text{W/m}^2\cdot\text{K}$$

(a) From Eq. 3.34 heat loss from the water is

$$q = 1\text{m}\times\frac{\left(0-(-20)°\text{C}\right)}{\dfrac{\ln(24/20)}{2\pi\times401\text{W/m}\cdot\text{K}}+\dfrac{1}{\pi\times24\times10^{-3}\text{m}\times38.56\text{W/m}^2\cdot\text{K}}} = 58\text{W}$$

while the mass of water is $M = \pi(D_i^2/4)L\rho = \pi\times(20\times10^{-3}\text{m})^2/4\times1\text{m}\times1000\text{kg/m}^3$ = 0.314 kg. Hence, the heat loss per unit mass of water is

$$q_M = q/M = 58\ \text{W}/0.314\ \text{kg} = 185\ \text{W/kg}.$$ <

Continued…

PROBLEM 7.48 (Cont.)

(b) When the tube is half full, the upper half of the tube will act as a fin. The total heat loss per unit mass will be $q_M = q_{M1} + q_{M2}$ where q_{M1} is the radial heat loss that is the same as in part (a) and q_{M2} is the heat loss to the upper half of the copper tubing, which serves as a fin. From part (a) q_{M1} = 185 W/kg. Assuming an infinite fin and recognizing that the cross-sectional area is associated with the inner and outer diameters of the tubing,

$$q_{M2} = \sqrt{hPkA_c}\,\theta_b / M$$

$$= \sqrt{38.56\,\mathrm{W/m^2\cdot K} \times \pi \times 24\times10^{-3}\,\mathrm{m} \times 401\,\mathrm{W/m\cdot K} \times \pi\left((24\times10^{-3}\,\mathrm{m})^2 - (20\times10^{-3}\,\mathrm{m})^2\right)/4}$$

$$\times\left(0-(-20)\right)°\mathrm{C}/0.157\,\mathrm{kg}$$

$$= 51.3\ \mathrm{W/kg}$$

Therefore, q_M = 185 W/kg + 51.3 W/kg = 236 W/kg <

COMMENTS: (1) The fin effect is significant, and the water in the half-full tube will freeze before the water in the full tube. (2) The temperature distribution in the copper tubing above the water level in the half-full tubing is $\theta/\theta_b = \exp^{-mx}$ where x is a local coordinate with origin at the water level. For this problem,

$$m = \sqrt{hP/kA_c} = \sqrt{4hD_o / k(D_o^2 - D_i^2)}$$

$$= \sqrt{4\times 38.56\,\mathrm{W/m^2\cdot K}\times 24\times10^{-3}\,\mathrm{m} / 401\,\mathrm{W/m\cdot K}\left((24\times10^{-3}\,\mathrm{m})^2 - (20\times10^{-3}\,\mathrm{m})^2\right)} = 7.24\ \mathrm{m^{-1}}.$$

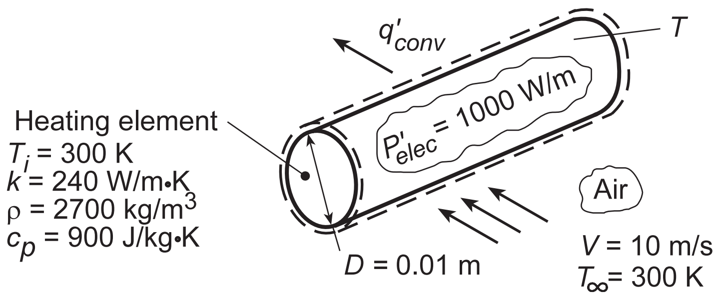
Therefore, over a 0.5 m length above the water surface for part (b), the temperature decreases to $T(x = 0.5\ \mathrm{m}) = -20°\mathrm{C} + (20°\mathrm{C})\exp(-7.24\mathrm{m}^{-1}\times0.5\mathrm{m}) = -19.5°\mathrm{C}$. The assumption of an infinitely long fin is reasonable.

PROBLEM 7.49

KNOWN: Initial temperature, power dissipation, diameter, and properties of heating element. Velocity and temperature of air in cross flow.

FIND: (a) Steady-state temperature, (b) Time to come within 10°C of steady-state temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Uniform heater temperature, (2) Negligible radiation.

PROPERTIES: *Table A.4*, air (assume $T_f \approx 450$ K): $\nu = 32.39 \times 10^{-6}$ m^2/s, k = 0.0373 W/m·K, Pr = 0.686.

ANALYSIS: (a) Performing an energy balance for steady-state conditions, we obtain

$$q'_{conv} = \bar{h}(\pi D)(T - T_\infty) = P'_{elec} = 1000\,\text{W/m}$$

With

$$Re_D = \frac{VD}{\nu} = \frac{(10\,\text{m/s})\,0.01\,\text{m}}{32.39 \times 10^{-6}\,\text{m}^2/\text{s}} = 3,087$$

the Churchill and Bernstein correlation, Eq. 7.54, yields

$$\overline{Nu}_D = 0.3 + \frac{0.62\,Re_D^{1/2}\,Pr^{1/3}}{\left[1+(0.4/Pr)^{2/3}\right]^{1/4}}\left[1+\left(\frac{Re_D}{282,000}\right)^{5/8}\right]^{4/5}$$

$$\overline{Nu}_D = 0.3 + \frac{0.62(3087)^{1/2}(0.686)^{1/3}}{\left[1+(0.4/0.686)^{2/3}\right]^{1/4}}\left[1+\left(\frac{3087}{282,000}\right)^{5/8}\right]^{4/5} = 28.2$$

$$\bar{h} = \frac{k}{D}\overline{Nu}_D = \frac{0.0373\,\text{W/m}\cdot\text{K}}{0.010\,\text{m}}\,28.2 = 105.2\,\text{W/m}^2\cdot\text{K}$$

Hence, the steady-state temperature is

$$T = T_\infty + \frac{P'_{elec}}{\pi D \bar{h}} = 300\,\text{K} + \frac{1000\,\text{W/m}}{\pi(0.01\,\text{m})105.2\,\text{W/m}^2\cdot\text{K}} = 603\,\text{K} \quad <$$

(b) With Bi = $\bar{h}r_o/k$ = 105.2 W/m^2·K(0.005 m)/240 W/m·K = 0.0022, a lumped capacitance analysis may be performed. The time response of the heater is given by Eq. 5.25, which, for $T_i = T_\infty$, reduces to

$$T = T_\infty + (b/a)\left[1 - \exp(-at)\right]$$

Continued...

PROBLEM 7.49 (Cont.)

where a = $4\bar{h}/D\rho c_p = \left(4\times105.2\,W/m^2\cdot K\right)/\left(0.01m\times2700\,kg/m^3\times900\,J/kg\cdot K\right)$ = 0.0173 s^{-1} and b/a = $P'_{elec}/\pi D\bar{h} = 1000\,W/m\Big/\pi\left(0.01m\times105.2\,W/m^2\cdot K\right)$ = 302.6 K. Hence,

$$\left[1-\exp\left(-0.0173t\right)\right]=\frac{\left(593-300\right)K}{302.6\,K}=0.968$$

$t \approx 200s$ <

COMMENTS: (1) For T = 603 K and a representative emissivity of ε = 0.8, net radiation exchange between the heater and surroundings at $T_{sur} = T_\infty$ = 300 K would be $q'_{rad} = \varepsilon\sigma\left(\pi D\right)\left(T^4 - T_{sur}^4\right)$ = 0.8 × 5.67 × 10^{-8} $W/m^2\cdot K^4$ (π × 0.01 m)(603^4 - 300^4)K^4 = 177 W/m. Hence, although small, radiation exchange is not negligible. The effects of radiation are considered in Problem 7.50.

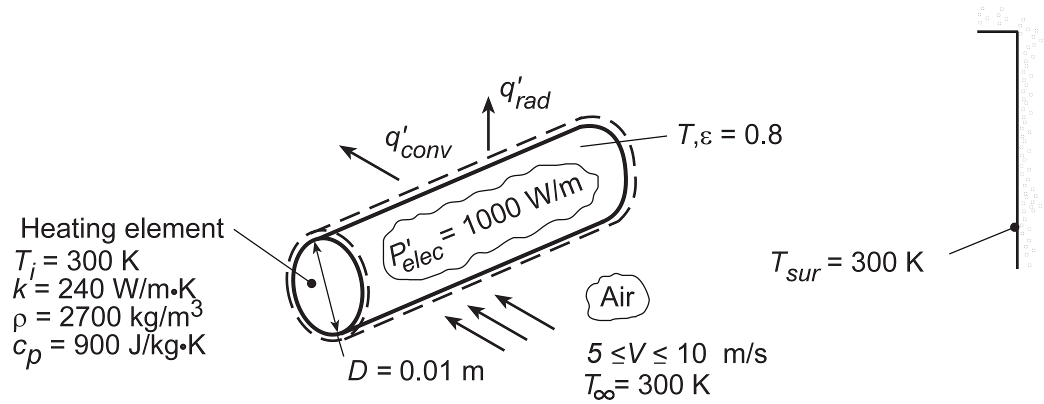
(2) The assumed value of T_f is very close to the actual value, rendering the selected air properties accurate.

PROBLEM 7.50

KNOWN: Initial temperature, power dissipation, diameter, and properties of a heating element. Velocity and temperature of air in cross flow. Temperature of surroundings.

FIND: (a) Steady-state temperature, (b) Time to come within 10°C of steady-state temperature, (c) Variation of power dissipation required to maintain a fixed heater temperature of 275°C over a range of velocities.

SCHEMATIC:



ASSUMPTIONS: Uniform heater surface temperature.

ANALYSIS: (a) Performing an energy balance for steady-state conditions, we obtain

$$q'_{conv} + q'_{rad} = P'_{elec}$$

$$\bar{h}(\pi D)(T - T_\infty) + \varepsilon\sigma(\pi D)\left(T^4 - T_{sur}^4\right) = P'_{elec}$$

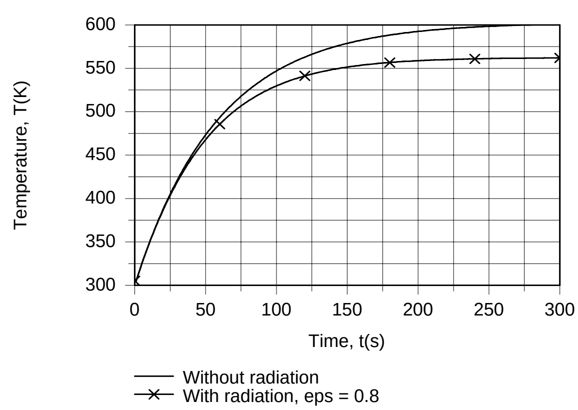
$$(\pi \times 0.01\,m)\left[\bar{h}(T - 300)K + 0.8\left(5.67 \times 10^{-8}\, W/m^2 \cdot K^4\right)\left(T^4 - 300^4\right)K^4\right] = 1000\, W/m$$

Using the *IHT Energy Balance Model* for an *Isothermal Solid Cylinder* with the *Correlations* Tool Pad for a *Cylinder* in *Crossflow* and the *Properties* Tool Pad for Air, we obtain

$T = 562.4\ K$ <

where $\bar{h} = 105.4\, W/m^2 \cdot K$, $h_r = 15.9\, W/m^2 \cdot K$, $q'_{conv} = 868.8\, W/m$, and $q'_{rad} = 131.2\, W/m$.

(b) With Bi = $\left(\bar{h} + h_r\right) r_o / k$ = (121.3 W/m^2·K)0.005 m/240 W/m·K = 0.0025, the transient behavior may be analyzed using the lumped capacitance method. Using the *IHT Lumped Capacitance Model* to perform the numerical integration, the following temperature histories were obtained.

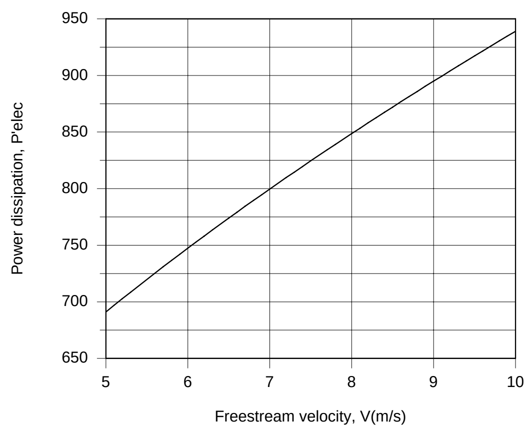


Continued...

PROBLEM 7.50 (Cont.)

The agreement between predictions with and without radiation for t < 50s implies negligible radiation. However, as the heater temperature increases with time, radiation becomes significant, yielding a reduced heater temperature. Steady-state temperatures correspond to 562.4 K and 602.8 K, with and without radiation, respectively. The time required for the heater to reach 552.4 K (with radiation) is t ≈ 155s.

(c) If the heater temperature is to be maintained at a fixed value in the face of velocity excursions, provision must be made for adjusting the heater power. Using the *Explore* and *Graph* options of IHT with the model of part (a), the following results were obtained.



For T = 275°C = 548 K, the controller would compensate for velocity reductions from 10 to 5 m/s by reducing the power from approximately 935 to 690 W/m.

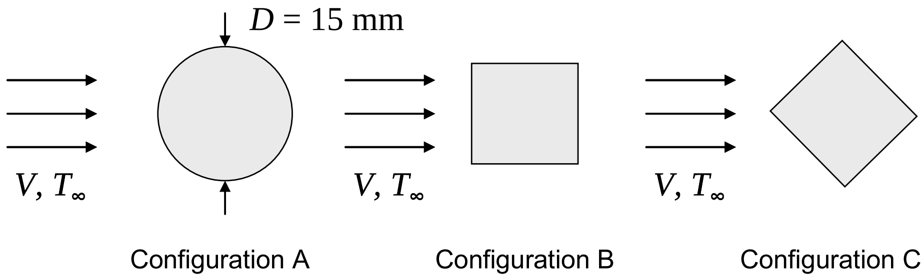
COMMENTS: Although convection heat transfer substantially exceeds radiation heat transfer, radiation is not negligible and should be included in the analysis. If it is neglected, T = 603 K would be predicted for P'_{elec} = 1000 W/m, in contrast to 562 K from the results of part (a).

PROBLEM 7.51

KNOWN: Geometry and dimensions of three pin fins. Velocity and temperature of air in cross flow.

FIND: Which fin has the largest heat transfer rate.

SCHEMATIC:



V = 10 m/s for all cases

ASSUMPTIONS: (1) Steady-state, (2) Constant properties, (3) Fins can be treated as infinitely long, (4) Presence of fin base doesn't affect heat transfer coefficients.

PROPERTIES: *Table A-4* Air (T = 350 K): $\nu_a = 20.92 \times 10^{-6}$ m^2/s

ANALYSIS: For infinitely long fins, the fin heat transfer rate is given by Equation 3.85:

$$q_f = \sqrt{\bar{h}PkA_c}\,\theta_b$$

In every case, the heat transfer coefficient is found from a correlation of the form, $\overline{Nu}_D = CRe_D^m Pr^{1/3}$, thus

$$q_f = \sqrt{\frac{k_a}{D} CRe_D^m Pr_a^{1/3} PkA_c}\,\theta_b$$

where subscript a refers to air properties. Since each fin has the same cross-sectional area, the parameters that vary from one configuration to another are D, C, Re_D, m, and P. Thus, it is sufficient to examine the combination parameter $CRe_D^m P / D$ to determine which fin has the largest heat transfer rate.

The cross-sectional area of the circular cylinder is $A_c = \pi D^2/4$. Thus the dimension of the square, D_s, is $D_s = A_c^{1/2} = \pi^{1/2} D / 2 = \pi^{1/2}(15 \text{ mm}) / 2 = 13.3 \text{ mm}$. The dimension of the diamond is the same, however D_d is defined differently. Referring to Table 7.3, $D_d = 2^{1/2} D_s = 2^{1/2}(13.3 \text{ mm}) = 18.8 \text{ mm}$. The perimeters are $P_c = \pi D$ = 47.1 mm for the circular cylinder and $P_s = P_d = 4D_s$ = 53.2 mm for both the square and diamond configurations.

The Reynolds number can be calculated from $Re = VD/\nu_a$, then C and m can be found from Tables 7.2 and 7.3 for the different configurations. The results are tabulated below for all three configurations. A line has been included to represent the heat transfer coefficient, which is proportional to CRe_D^m / D.

Continued…

PROBLEM 7.51 (Cont.)

	Configuration A (circular)	Configuration B (square)	Configuration C (diamond)
D (mm)	15	13.3	18.8
P (mm)	47.1	53.2	53.2
$Re_D = VD/\nu_a$	7,170	6,358	8,987
C	0.193	0.158	0.304
m	0.618	0.66	0.59
CRe_D^m / D (m^{-1}) ~ h	3106	3846	3478
$CRe_D^m P / D \sim q_f$	146	205	185

For fins of equal mass, the square fin configuration has the largest heat transfer rate. <

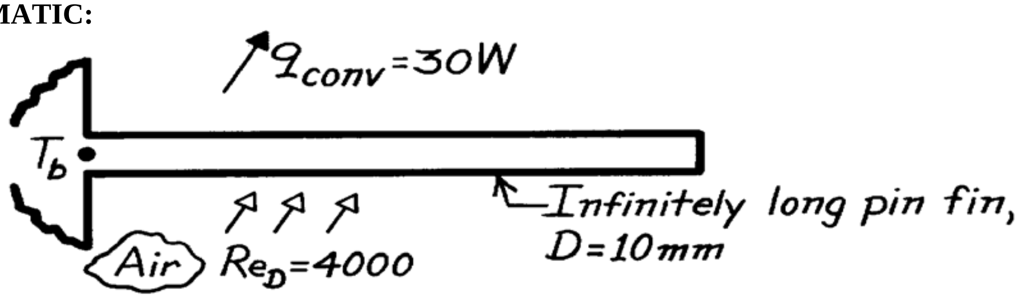
COMMENTS: (1) For the same cross-sectional area, the square and diamond configurations have larger perimeters than the circular cylinder, which contributes to the larger heat transfer rate. (2) For the same cross-sectional area, the square and diamond configurations have larger heat transfer coefficients, which also contributes to the larger heat transfer rates.

PROBLEM 7.52

KNOWN: Pin fin of 10 mm diameter dissipates 30 W by forced convection in cross-flow of air with $Re_D = 4000$.

FIND: Fin heat rate if diameter is doubled while all conditions remain the same.

SCHEMATIC:



ASSUMPTIONS: (1) Pin behaves as infinitely long fin, (2) Conditions of flow, as well as base and air temperatures, remain the same for both situations, (3) Negligible radiation heat transfer.

ANALYSIS: For an infinitely long pin fin, the fin heat rate is

$$q_f = q_{conv} = \left(\overline{h}PkA_c\right)^{1/2} \theta_b$$

where $P = \pi D$ and $A_c = \pi D^2/4$. Hence,

$$q_{conv} \sim \left(\overline{h} \cdot D \cdot D^2\right)^{1/2}.$$

For forced convection cross-flow over a cylinder, an appropriate correlation for estimating the dependence of $\overline{h}$ on the diameter is

$$\overline{Nu}_D = \frac{\overline{h}D}{k} = CRe_D^m\ Pr^{1/3} = C\left(\frac{VD}{\nu}\right)^m Pr^{1/3}.$$

From Table 7.2 for $Re_D = 4000$, find m = 0.466 and

$$\overline{h} \sim D^{-1}(D)^{0.466} = D^{-0.534}.$$

It follows that

$$q_{conv} \sim \left(D^{-0.534} \cdot D \cdot D^2\right)^{1/2} = D^{1.23}.$$

Hence, with $q_1 \rightarrow D_1$ (10 mm) and $q_2 \rightarrow D_2$ (20 mm), find

$$q_2 = q_1\left(\frac{D_2}{D_1}\right)^{1.23} = 30\ W\left(\frac{20}{10}\right)^{1.23} = 70.4\ W. \qquad <$$

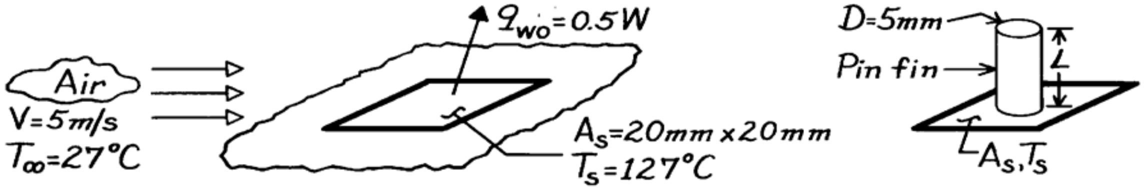
COMMENTS: The effect of doubling the diameter, with all other conditions remaining the same, is to increase the fin heat rate by a factor of 2.35. The effect is nearly linear, with enhancements due to the increase in surface and cross-sectional areas ($D^{1.5}$) exceeding the attenuation due to a decrease in the heat transfer coefficient ($D^{-0.267}$). Note that, with increasing Reynolds number, the exponent m increases and there is greater heat transfer enhancement due to increasing the diameter.

PROBLEM 7.53

KNOWN: Pin fin installed on a surface with prescribed heat rate and temperature.

FIND: (a) Maximum heat removal rate possible, (b) Length of the fin, (c) Effectiveness, ε_f, (d) Percentage increase in heat rate from surface due to fin.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Conditions over A_s are uniform for both situations, (3) Conditions over fin length are uniform, (4) Flow over pin fin approximates cross-flow.

PROPERTIES: *Table A-4*, Air ($T_f = (T_\infty + T_s)/2 = (27 + 127)°C/2 = 350$ K): $\nu = 20.92 \times 10^{-6}$ m^2/s, $k = 30.0 \times 10^{-3}$ W/m·K, Pr = 0.700. *Table A-1*, SS AISI304 ($\overline{T} = T_f = 350$ K): k = 15.8 W/m·K.

ANALYSIS: (a) Maximum heat rate from fin occurs when fin is infinitely long,

$$q_f = M = \left(\overline{h}PkA_c\right)^{1/2}\theta_b \qquad (1)$$

from Eq. 3.85. Estimate convection heat transfer coefficient for cross-flow over cylinder,

$$Re_D = \frac{VD}{\nu} = 5\ \text{m/s} \times 0.005\ \text{m}/20.92\times10^{-6}\text{m}^2/\text{s} = 1195.$$

Using the Hilpert correlation, Eq. 7.52, with Table 7.2,find

$$\overline{h} = \frac{k}{D}CRe_D^m Pr = (0.030\text{W/m}\cdot\text{K}/0.005\text{m})0.683(1195)^{0.466}(0.700)^{1/3} = 98.9\text{W/m}^2\cdot\text{K}$$

From Eq. (1), with $P = \pi D$, $A_c = \pi D^2/4$, and $\theta_b = T_s - T_\infty$, find

$$q_f = \left(98.9\ \text{W/m}^2\cdot\text{K}\times\pi(0.005\ \text{m})\times15.8\ \text{W/m}\cdot\text{K}\times\pi(0.005\ \text{m})^2/4\right)^{1/2}(127-27)\text{K} = 2.20\ \text{W}. \qquad <$$

(b) From Example 3.9, $L \approx L_\infty = 2.65(kA_c/hP)^{1/2}$. Hence,

$$L \approx L_\infty = 2.65\left[15.8\ \text{W/m}\cdot\text{K}\times\pi(0.005\ \text{m})^2/4/98.9\ \text{W/m}^2\cdot\text{K}\times\pi(0.005\ \text{m})\right]^{1/2} = 37.4\ \text{mm}. \qquad <$$

(c) From Eq. 3.86, with h_s used for the base area A_s, the effectiveness is

$$\varepsilon_f = \frac{q_f}{h_s A_{c,b}\theta_b} = \frac{q_f}{q_{wo}}\frac{A_s}{A_{c,b}} = \frac{2.2\ \text{W}}{0.5\ \text{W}}\cdot\frac{(0.020\times0.020)\text{m}^2}{\pi(0.005\ \text{m})^2/4} = 89.6 \qquad <$$

where $\qquad h_s = q_{wo}/A_s\theta_b.$

(d) The percentage increase in heat rate with the installed fin (w) is

$$\frac{q_w - q_{wo}}{q_{wo}}\times100 = \left(\left[q_f + h_s\left(A_s - \pi D^2/4\right)\left(T_s - T_\infty\right)\right] - q_{wo}\right)\times100/q_{wo}$$

$$\Delta q/q = \left\{\left[2.2\ \text{W} + 12.5\ \text{W/m}^2\cdot\text{K}\left([0.02\ \text{m}]^2 - (\pi/4)(0.005\ \text{m})^2\right)100\ \text{K} - 0.5\ \text{W}\right\}\times100/0.5\ \text{W}\right.$$

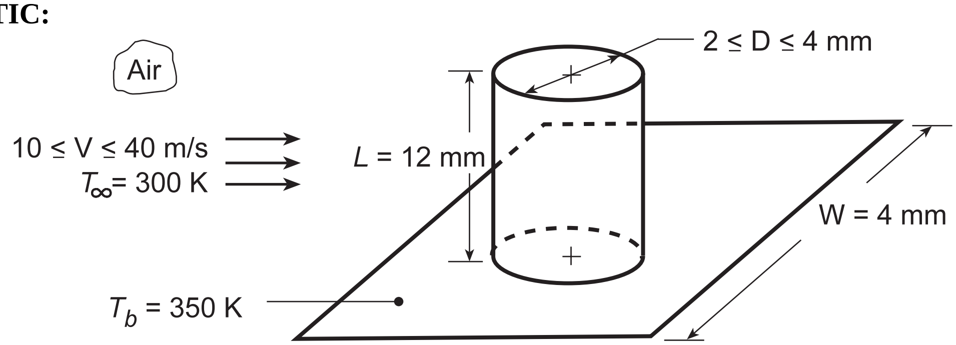
$$\Delta q/q = 435\%. \qquad <$$

PROBLEM 7.54

KNOWN: Dimensions of chip and pin fin. Chip temperature. Free stream velocity and temperature of air coolant.

FIND: (a) Average pin convection coefficient, (b) Pin heat transfer rate, (c) Total heat rate, (d) Effect of velocity and pin diameter on total heat rate.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in pin, (3) Constant properties, (4) Convection coefficients on pin surface (tip and side) and chip surface correspond to single cylinder in cross flow, (5) Negligible radiation.

PROPERTIES: *Table A.1*, Copper (350 K): k = 399 W/m·K; *Table A.4*, Air ($T_f \approx$325 K, 1 atm): ν = 18.41 × 10^{-6} m^2/s, k = 0.0282 W/m·K, Pr = 0.704.

ANALYSIS: (a) With V = 10 m/s and D = 0.002 m,

$$Re_D = \frac{VD}{\nu} = \frac{10\,m/s \times 0.002\,m}{18.41 \times 10^{-6}\,m^2/s} = 1087$$

Using the Churchill and Bernstein correlations, Eq. (7.54),

$$\overline{Nu}_D = 0.3 + \frac{0.62\,Re_D^{1/2}\,Pr^{1/3}}{\left[1+(0.4/Pr)^{2/3}\right]^{1/4}}\left[1+\left(\frac{Re_D}{282,000}\right)^{5/8}\right]^{4/5} = 16.7$$

$$\bar{h} = \left(\overline{Nu}_D k/D\right) = \left(16.7 \times 0.0282\,W/m\cdot K/0.002\,m\right) = 235\,W/m^2\cdot K$$ <

(b) For the fin with tip convection and

$$M = \left(\bar{h}\pi D k \pi D^2/4\right)^{1/2}\theta_b = (\pi/2)\left[235\,W/m^2\cdot K\,(0.002\,m)^3\,399\,W/m\cdot K\right]^{1/2} 50\,K = 2.15\,W$$

$$m = \left(\bar{h}P/kA_c\right)^{1/2} = \left(4 \times 235\,W/m^2\cdot K/399\,W/m\cdot K \times 0.002\,m\right)^{1/2} = 34.3\,m^{-1}$$

$$mL = 34.3\,m^{-1}(0.012\,m) = 0.412$$

$$\left(\bar{h}/mk\right) = \left(235\,W/m^2\cdot K/34.3\,m^{-1} \times 399\,W/m\cdot K\right) = 0.0172.$$

The fin heat rate is

$$q_f = M\frac{\sinh mL + \left(\bar{h}/mk\right)\cosh mL}{\cosh mL + \left(\bar{h}/mk\right)\sinh mL} = 0.868\,W\,.$$ <

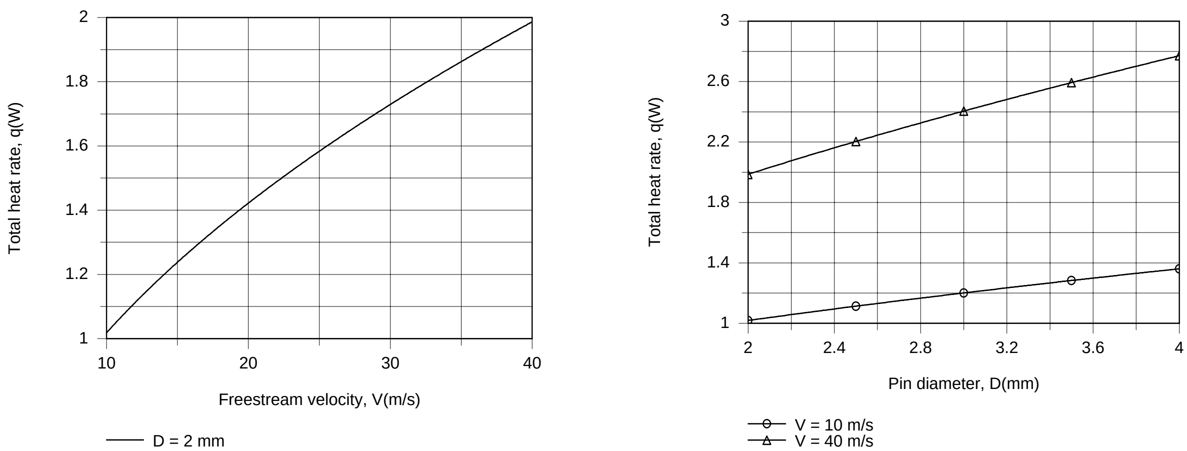
Continued...

PROBLEM 7.54 (Cont.)

(c) The total heat rate is that from the base and through the fin,

$$q = q_b + q_f = \bar{h}\left(W^2 - \pi D^2/4\right)\theta_b + q_f = (0.151 + 0.868)\,W = 1.019\,W\,. \qquad <$$

(d) Using the IHT Extended Surface Model for a Pin Fin with the Correlations Tool Pad for a Cylinder in crossflow and Properties Tool Pad for Air, the following results were generated.



Clearly, there is significant benefit associated with increasing V which increases the convection coefficient and the total heat rate. Although the convection coefficient decreases with increasing D, the increase in the total heat transfer surface area is sufficient to yield an increase in q with increasing D. The maximum heat rate is q = 2.77 W for V = 40 m/s and D = 4 mm.

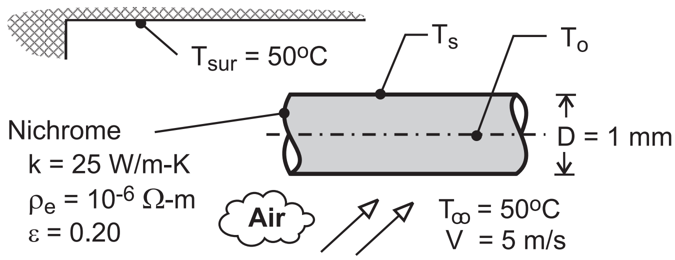
COMMENTS: Radiation effects should be negligible, although tip and base convection coefficients will differ from those calculated in parts (a) and (d).

PROBLEM 7.55

KNOWN: Diameter, resistivity, thermal conductivity and emissivity of Nichrome wire. Electrical current. Temperature of air flow and surroundings. Velocity of air flow.

FIND: (a) Surface and centerline temperatures of the wire, (b) Effect of flow velocity and electric current on temperatures.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Radiation exchange with large surroundings, (3) Constant Nichrome properties, (4) Uniform surface temperature.

PROPERTIES: Prescribed, Nichrome: k = 25 W/m·K, $\rho_e = 10^{-6}\,\Omega\cdot m$, $\varepsilon = 0.2$. *Table A-4*, air $\left(T_f \approx 800K: k_a = 0.057\,W/m\cdot K,\ \nu = 8.5\times10^{-5} m^2/s,\ Pr = 0.71\right)$.

ANALYSIS: (a) The surface temperature may be obtained from Eq. 3.60, with $\bar{h} = \bar{h}_c + h_r$ and $\dot{q} = I^2 R_e/\forall = I^2\rho_e/A_c^2 = I^2\rho_e/\left(\pi D^2/4\right)^2 = 1.013\times10^9\ W/m^3$.

$$T_s = T_\infty + \frac{\dot{q}(D/2)}{2\left(\bar{h}_c + h_r\right)} \qquad (1)$$

The convection coefficient is obtained from the Churchill and Bernstein correlation

$$\bar{h}_c = \frac{k_a}{D}\left\{0.3 + \frac{0.62\,Re_D^{1/2}\,Pr^{1/3}}{\left[1+(0.4/Pr)^{2/3}\right]^{1/4}}\left[1+\left(\frac{Re_D}{282{,}000}\right)^{5/8}\right]^{4/5}\right\} = 230\,W/m^2\cdot K$$

where $Re_D = VD/\nu = 58.8$, and the radiation coefficient is obtained from Eq. 1.9

$$h_r = \varepsilon\sigma\left(T_s + T_{sur}\right)\left(T_s^2 + T_{sur}^2\right) \qquad (2)$$

From an iterative solution of Eqs. (1) and (2), we obtain

$$T_s \approx 1285K = 1012°C$$ <

From Eq. 3.58, the centerline temperature is

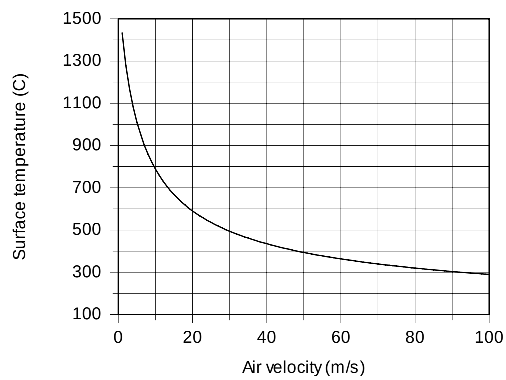
$$T_o = \frac{\dot{q}(D/2)^2}{4k} + T_s = \frac{1.013\times10^9\,W/m^3\,(0.0005m)^2}{100\,W/m\cdot K} + 1012°C \approx 1014°C$$ <

The centerline temperature is only approximately 2°C larger than the surface temperature, and the wire may be assumed to be isothermal.

Continued …

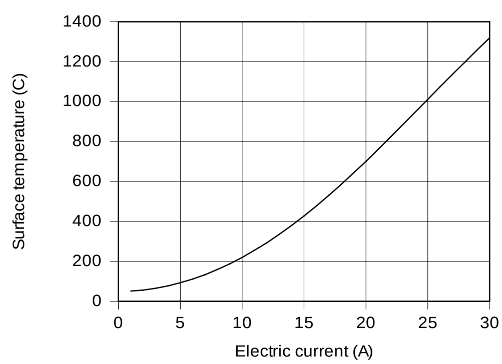
PROBLEM 7.55 (Cont.)

(b) Over the range $1 \le V < 100$ m/s for I = 25A, $\bar{h}_c$ varies from approximately $114\,W/m^2 \cdot K$ to $1050\,W/m^2 \cdot K$, while h_r varies from approximately $69\,W/m^2 \cdot K$ to $4\,W/m^2 \cdot K$. The effect on the surface temperature is shown below.



Maximum and minimum values of $T_s = 1433°C$ and $T_s = 290°C$ are associated with the smallest and largest velocities respectively, while the difference between the centerline and surface temperatures remains at $(T_o - T_s) \approx 2°C$.

For V = 5 m/s, the effect on T_s of varying the current over the range from 1 to 30A is shown below.



From a value of $T_s \approx 52°C$ at 1A, T_s increases to 1320°C at 30A. Over this range the temperature difference $(T_o - T_s)$ increases from approximately 0.01°C to 3°C.

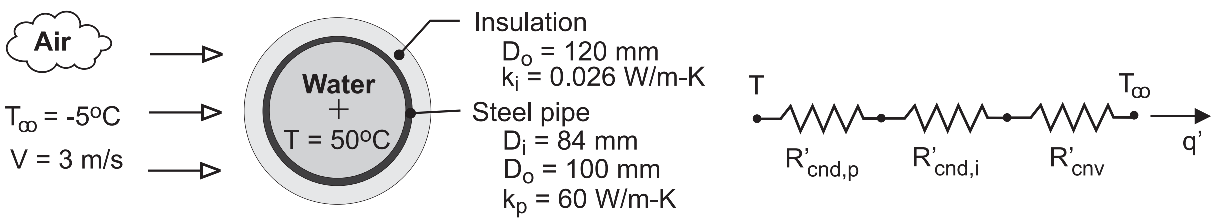
COMMENTS: (1) The radiation coefficient for the conditions of Part (a) is $h_r = 32\,W/m^2 \cdot K$, which is approximately 1/8 of the total coefficient $\bar{h}$. Hence, except for small values of V less than approximately 5 m/s, radiation is negligible compared with convection. (2) The small wire diameter and large thermal conductivity are responsible for maintaining nearly isothermal conditions within the wire. (3) The calculations of Part (b) were performed using the IHT solver with the function $T_f = T_{fluid\_avg}(T_s, T_{inf})$ used to account for the effect of temperature on the air properties.

PROBLEM 7.56

KNOWN: Diameter, thickness and thermal conductivity of steel pipe. Temperature of water flow in pipe. Temperature and velocity of air in cross flow over pipe. Cost of producing hot water.

FIND: (a) Cost of daily heat loss from an uninsulated pipe, (b) Savings associated with insulating the pipe.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Negligible convection resistance for water flow, (3) Negligible contact resistance between insulation and pipe, (4) Negligible radiation.

PROPERTIES: *Table A-4*, air $(p = 1\,\text{atm},\ T_f \approx 300\text{K})$: $k_a = 0.0263\,\text{W/m}\cdot\text{K}$, $\nu = 15.89\times10^{-6}\,\text{m}^2/\text{s}$, $\text{Pr} = 0.707$.

ANALYSIS: (a) With $\text{Re}_D = VD_o/\nu = 3\,\text{m/s}\times0.1\text{m}/15.89\times10^{-6}\,\text{m}^2/\text{s} = 18,880$, application of the Churchill-Bernstein correlation yields

$$\overline{\text{Nu}}_D = 0.3 + \frac{0.62(18,800)^{1/2}(0.707)^{1/3}}{\left[1+(0.4/0.707)^{2/3}\right]^{1/4}}\left[1+\left(\frac{18,880}{282,000}\right)^{5/8}\right]^{4/5} = 76.6$$

$$\bar{h} = \frac{k_a}{D_o}\overline{\text{NU}}_D = \frac{0.0263\,\text{W/m}\cdot\text{K}}{0.1\text{m}}76.6 = 20.1\,\text{W/m}^2\cdot\text{K}$$

Without the insulation, the total thermal resistance and heat loss per length of pipe are then

$$R'_{tot(wo)} = \frac{\ln(D_o/D_i)}{2\pi k_p} + \frac{1}{\pi D_o\bar{h}} = \frac{\ln(100/84)}{2\pi\times60\,\text{W/m}\cdot\text{K}} + \frac{1}{\pi(0.1\text{m})20.1\,\text{W/m}^2\cdot\text{K}}$$

$$= \left(4.63\times10^{-4} + 0.158\right)\text{m}\cdot\text{K/W} = 0.159\,\text{m}\cdot\text{K/W}$$

$$q'_{wo} = \frac{T - T_\infty}{R'_{tot(wo)}} = \frac{55°\text{C}}{0.159\,\text{m}\cdot\text{K/W}} = 346\,\text{W/m} = 0.346\,\text{kW/m}$$

The corresponding daily energy loss is

$$Q'_{wo} = 0.346\,\text{kW/m}\times24\,\text{h/d} = 8.3\,\text{kW}\cdot\text{h/m}\cdot\text{d}$$

and the associated cost is

$$C'_{wo} = (8.3\,\text{kW}\cdot\text{h/m}\cdot\text{d})(\$0.05/\text{kW}\cdot\text{h}) = \$0.415/\text{m}\cdot\text{d}$$ <

(b) The conduction resistance of the insulation is

Continued …

PROBLEM 7.56 (Cont.)

$$R'_{cnd} = \frac{\ln(D_o/D_i)}{2\pi k_i} = \frac{\ln(120/100)}{2\pi(0.026\,W/m\cdot K)} = 1.116\,m\cdot K/W$$

Using the Churchill-Bernstein correlation with an outside diameter of $D_o = 0.12m$, $Re_D = 22,660$, $\overline{Nu}_D = 83.9$ and $\overline{h} = 18.4\,W/m^2\cdot K$. The convection resistance is then

$$R'_{cnv} = \frac{1}{\pi D_o \overline{h}} = \frac{1}{\pi(0.12m)18.4\,W/m^2\cdot K} = 0.144\,m\cdot K/W$$

and the total resistance is

$$R'_{tot(w)} = \left(4.63\times10^{-4} + 1.116 + 0.144\right)m\cdot K/W = 1.261\,m\cdot K/W$$

The heat loss and cost are then

$$q'_w = \frac{T - T_\infty}{R'_{tot(w)}} = \frac{55°C}{1.261\,m\cdot K/W} = 43.6\,W/m = 0.0436\,kW/m$$

$$C'_w = 0.0436\,kW/m \times 24h/d \times \$0.05/kW\cdot h = \$0.052/m\cdot d$$

The daily savings is then

$$S' = C'_{wo} - C'_w = \$0.363/m\cdot d$$ <

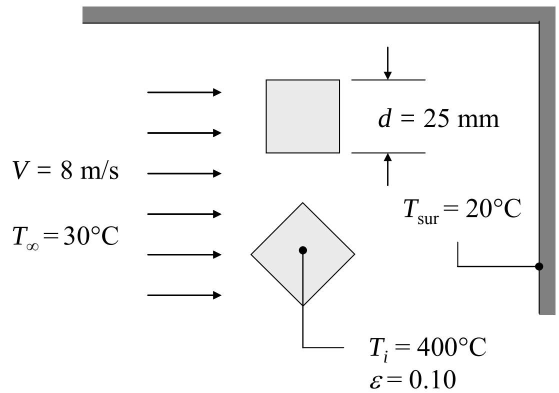
COMMENTS: (1) The savings are significant, and the pipe should be insulated. (2) Assuming a negligible temperature drop across the pipe wall, a pipe emissivity of $\varepsilon_p = 0.6$ and surroundings at $T_{sur} = 268K$, the radiation coefficient associated with the uninsulated pipe is $h_r = \varepsilon\sigma(T + T_{sur})(T^2 + T_{sur}^2) = 0.6\times 5.67\times10^{-8}\,W/m^2\cdot K^4\,(591K)\,(323^2 + 268^2)K^2 = 3.5\,W/m^2\cdot K$. Accordingly, radiation increases the heat loss estimate of Part (a) by approximately 17%.

PROBLEM 7.57

KNOWN: Dimension and initial temperature of long aluminum rods of square cross-section. Velocity and temperature of air in cross flow. Rod emissivity and surroundings temperature.

FIND: Which orientation of the rod relative to the cross flow should be used to minimize the time needed for the rods to reach a temperature of 60°C. Required cooling time for preferred configuration.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties.

PROPERTIES: *Table A-4*, Air (T = 400 K): $\nu = 26.41 \times 10^{-6}$ m²/s, k = 0.0338 W/m·K, Pr = 0.690. *Table A-1*, Pure aluminum (T = 500 K): ρ_s = 2702 kg/m³, $c_{p,s}$ = 991 J/kg·K, k_s = 235 W/m·K.

ANALYSIS: The heat transfer coefficient can be calculated from Equation 7.52, with the dimension D defined differently for the two configurations, as shown in Table 7.3. When the air flows perpendicular to a face of the rod,

$D = d$ = 0.025 m, $Re_D = VD/\nu$ = 8 m/s × 0.025 m/26.41 × 10^{-6} m²/s = 7573, and from Table 7.3, C = 0.158 and m = 0.66. Thus,

$$\overline{h} = \frac{k}{D} C Re_D^m Pr^{1/3} = \frac{0.0338 \text{ W/m}\cdot\text{K}}{0.025 \text{ m}} 0.158(7573)^{0.66}(0.69)^{1/3} = 68.6 \text{ W/m}^2\cdot\text{K}$$

When the rod is rotated so that it presents an edge to the flow, $D = 2^{1/2}d = 2^{1/2} \times 0.025$ m = 0.0354 m, $Re_D = VD/\nu$ = 8 m/s × 0.0354 m/26.41 × 10^{-6} m²/s = 10,710, and from Table 7.3, C = 0.304 and m = 0.59. Thus,

$$\overline{h} = \frac{k}{D} C Re_D^m Pr^{1/3} = \frac{0.0338 \text{ W/m}\cdot\text{K}}{0.0354 \text{ m}} 0.304(10,710)^{0.59}(0.69)^{1/3} = 61.2 \text{ W/m}^2\cdot\text{K}$$

Radiation will affect both rods in the same way, therefore the rod with the larger value of convection heat transfer coefficient will cool faster. The rod should be oriented with a face perpendicular to the flow in order to minimize the cooling time. <

The importance of radiation can be estimated by calculating the radiation heat flux at the initial time, $q''_{\text{rad}} = \varepsilon\sigma\left(T_s^4 - T_{\text{sur}}^4\right) = 0.1 \times 5.67 \times 10^{-8} \text{ W/m}^2\cdot\text{K}^4 \times \left[(673 \text{ K})^4 - (293 \text{ K})^4\right] = 1120 \text{ W/m}^2$. The initial convection heat transfer flux is $q''_{\text{conv}} = \overline{h}(T_s - T_\infty) = 68.6 \text{ W/m}^2\cdot\text{K} \times (400°\text{C} - 30°\text{C}) = 25,380 \text{ W/m}^2$. Since the radiation heat transfer rate is only around 4% initially, and will decrease in relative importance with time, radiation can be neglected in a calculation of the cooling time.

Continued…

PROBLEM 7.57 (Cont.)

The cooling process can be modeled using the lumped capacitance approximation, provided the Biot number is small. Using a characteristic length of $L = V/A_s = d/4 = 0.00625$ m, the Biot number is

$$Bi = \frac{\bar{h}L}{k} = \frac{68.6\ \text{W/m}^2\cdot\text{K} \times 0.00625\ \text{m}}{235\ \text{W/m}\cdot\text{K}} = 0.0018$$

Therefore, the lumped capacitance approximation is valid and the cooling time is given by Equation 5.5,

$$t = \frac{\rho Vc}{hA_s}\ln\frac{\theta_i}{\theta} = \frac{\rho dc}{4\bar{h}}\ln\frac{T_i - T_\infty}{T - T_\infty} = \frac{2702\ \text{kg/m}^3 \times 0.025\ \text{m} \times 991\ \text{J/kg}\cdot\text{K}}{4 \times 68.6\ \text{W/m}^2\cdot\text{K}}\ln\left(\frac{400-30}{60-30}\right) = 613\ \text{s} \quad <$$

COMMENTS: *IHT* was used to solve this problem including the effect of radiation. The required cooling time, including radiation, is 601 s. Inclusion of radiation has a minor effect on the cooling time, as expected.

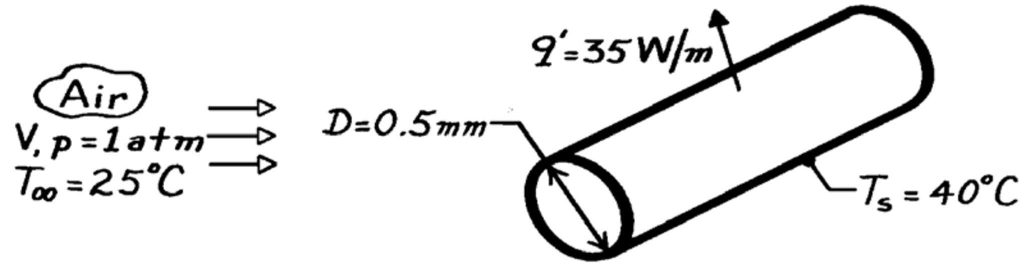
.

PROBLEM 7.58

KNOWN: Temperature and heat dissipation in a wire of diameter D.

FIND: (a) Expression for flow velocity over wire, (b) Velocity of airstream for prescribed conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform wire temperature, (3) Negligible radiation.

PROPERTIES: *Table A-4*, Air (T_∞ = 298 K, 1 atm): $\nu = 15.8 \times 10^{-6}\ m^2/s$, k = 0.0262 W/m·K, Pr = 0.71; (T_s = 313 K, 1 atm): Pr = 0.705.

ANALYSIS: (a) The rate of heat transfer per unit cylinder length is

$$q' = (q/L) = \bar{h}(\pi D)\ (T_s - T_\infty)$$

where, from the Zhukauskas relation, with $Pr \approx Pr_s$,

$$\bar{h} = \frac{k}{D} C\, Re_D^m\ Pr^n = \frac{k}{D}\ C\left(\frac{VD}{\nu}\right)^m Pr^n$$

Hence,

$$V = \left[\frac{q'}{(k/D) C\, Pr^n (\pi D)\ (T_s - T_\infty)}\right]^{1/m}\left(\frac{\nu}{D}\right). \qquad <$$

(b) Assuming ($10^3 < Re_D < 2 \times 10^5$), C = 0.26, m = 0.6 from Table 7.4. Hence,

$$V = \left[\frac{35\ W/m}{0.0262\ W/m\cdot K \times 0.26 (0.71)^{0.37}\ \pi (40-25)^\circ C}\right]^{1/0.6}\left(\frac{15.8\times10^{-6} m^2/s}{5\times10^{-4} m}\right)$$

$$V = 97\ m/s. \qquad <$$

To verify the assumption of the Reynolds number range, calculate

$$Re_D = \frac{VD}{\nu} = \frac{97\ m/s\ \left(5\times10^{-4} m\right)}{15.8\times10^{-6} m^2/s} = 3074.$$

Hence the assumption was correct.

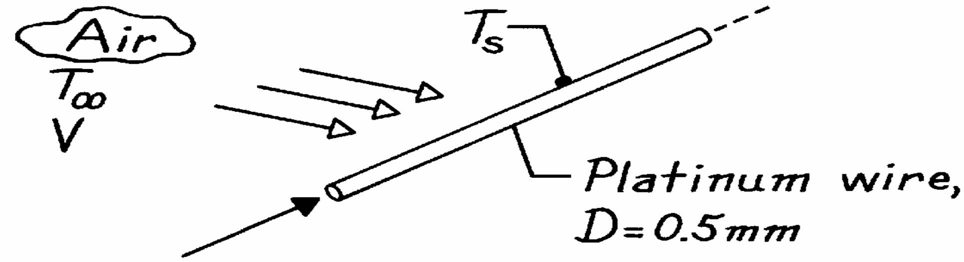
COMMENTS: The major uncertainty associated with using this method to determine V is that associated with use of the correlation for $\overline{Nu}_D$.

PROBLEM 7.59

KNOWN: Platinum wire maintained at a constant temperature in an airstream to be used for determining air velocity changes.

FIND: (a) Relationship between fractional changes in current to maintain constant wire temperature and fractional changes in air velocity and (b) Current required when air velocity is 10 m/s.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Cross-flow of air on wire with $40 < Re_D < 1000$, (3) Radiation effects negligible, (4) Wire is isothermal.

PROPERTIES: Platinum wire (given): Electrical resistivity, $\rho_e = 17.1 \times 10^{-5}$ Ohm·m; *Table A-4*, Air (T_∞ = 27°C = 300 K, 1 atm): $\nu = 15.89 \times 10^{-6}$ m^2/s, k = 0.0263 W/m·K, Pr = 0.707; (T_s = 77°C = 350 K, 1 atm): Pr_s = 0.700.

ANALYSIS: (a) From an energy balance on a unit length of the platinum wire,

$$q'_{elec} - q'_{conv} = I^2 R'_e - \bar{h} P (T_s - T_\infty) = 0 \qquad (1)$$

where the electrical resistance per unit length is $R'_e = \rho_e / A_c$, $P = \pi D$, and $A_c = \pi D^2/4$. Hence,

$$I = \left[\frac{\bar{h} P A_c}{\rho_e}(T_s - T_\infty)\right]^{1/2} = \left[\frac{\pi^2 \bar{h} D^3}{4\rho_e}(T_s - T_\infty)\right]^{1/2} \qquad (2)$$

For the range $40 < Re_D < 1000$, using the Zhukauskas correlation for cross-flow over a cylinder with C = 0.51 and m = 0.5,

$$\overline{Nu}_D = \frac{\bar{h} D}{k} = 0.51\, Re_D^{0.5}\, Pr^{0.37}\left(\frac{Pr}{Pr_s}\right)^{1/4} = 0.51\left(\frac{VD}{\nu}\right)^{0.5} Pr^{0.37}\left(\frac{Pr}{Pr_s}\right)^{1/4} \qquad (3)$$

note that $\bar{h} \sim V^{0.5}$, which, when substituted into Eq. (2) yields

$$I \sim \bar{h}^{1/2} = \left(V^{0.5}\right)^{1/2} = V^{1/4}.$$

Differentiating the proportionality and dividing the result by the proportionality, it follows that

$$\frac{\Delta I}{I} \approx \frac{1}{4}\frac{\Delta V}{V}. \qquad (4)$$ <

(b) For air at T_∞ = 27°C and V = 10 m/s, the current required to maintain the wire of D = 0.5 mm at T_s = 77°C follows from Eq. (2) with $\bar{h}$ evaluated by Eq. (3)

Continued …

PROBLEM 7.59 (Cont.)

$$\bar{h} = \frac{0.0263\ \text{W/m}\cdot\text{K}}{0.0005\ \text{m}} \times 0.51\left(\frac{10\ \text{m/s}\times 0.0005\ \text{m}}{15.89\times 10^{-6}\ \text{m}^2/\text{s}}\right)^{0.5}(0.707)^{0.37}\left(\frac{0.707}{0.700}\right)^{1/4}$$

$$\bar{h} = 420\ \text{W/m}^2\cdot\text{K}$$

where $Re_D = 315$. Hence the required current is

$$I = \left[\frac{\pi^2 \times 420\ \text{W/m}^2\cdot\text{K}(0.0005\ \text{m})^3}{4\times 17.1\times 10^{-5}\,\Omega\cdot\text{m}}(77-27)\text{K}\right]^{1/2} = 195\ \text{mA}. \qquad (5)$$

COMMENTS: (1) To measure 1% fractional velocity change, a 0.25% fractional change in current must be measured according to Eq. (4). From Eq. (5), this implies that $\Delta I = 0.0025I = 0.0025 \times 195$ mA = 488 μA. An electronic circuit with such measurement sensitivity requires care in its design.

(2) Instruments built on this principle to measure air velocities are called *hot-wire anemometers*. Generally, the wire diameters are much smaller (3 to 30 μm vs 500 μm of this problem) in order to have faster response times.

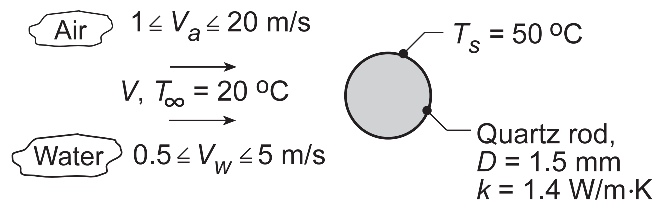
(3) What effect would the presence of radiation exchange between the wire and its surroundings have?

PROBLEM 7.60

KNOWN: Hot film sensor on a quartz rod maintained at T_s = 50°C.

FIND: (a) Compute and plot the convection coefficient as a function of velocity for water, $0.5 \le V_w \le 5$ m/s, and air, $1 \le V_a \le 20$ m/s with T_∞ = 20°C and (b) Suitability of using the hot film sensor for the two fluids based upon Biot number considerations.

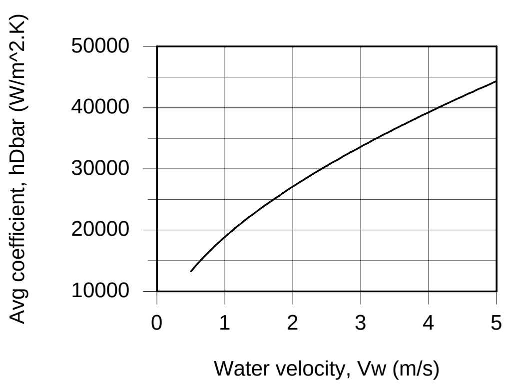
SCHEMATIC:

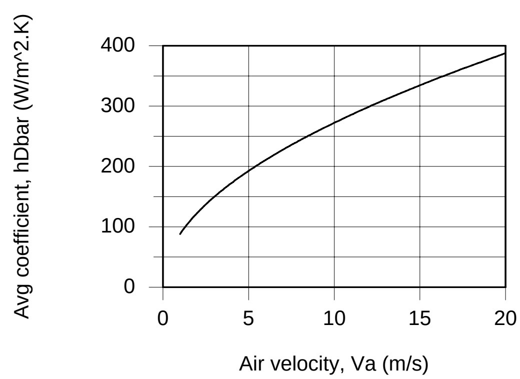


ASSUMPTIONS: (1) Cross-flow over a smooth cylinder, (2) Steady-state conditions, (3) Uniform surface temperature.

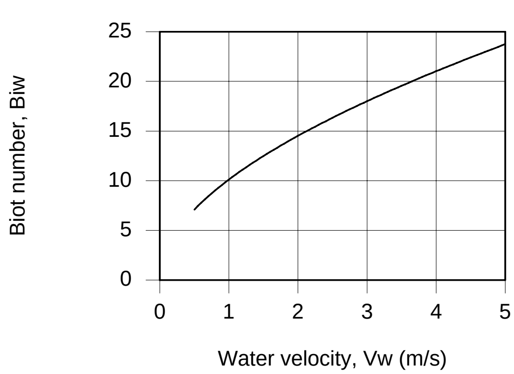
PROPERTIES: *Table A.6*, Water (T_f = 308 K, sat liquid); *Table A.4*, Air (T_f = 308 K, 1 atm).

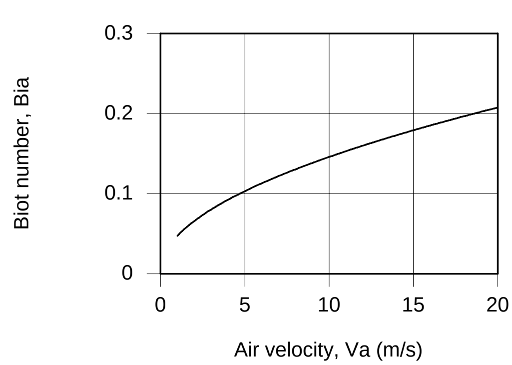
ANALYSIS: (a) Using the *IHT Tool*, *Correlations*, *Cylinder*, along with the *Properties Tool* for *Air* and *Water*, results were obtained for the convection coefficients as a function of velocity.





(b) The Biot number, hD/2k, is the ratio of the internal to external thermal resistances. When Bi >> 1, the thin film is thermally coupled well to the fluid. When Bi ≤ 1, significant power from the heater is dissipated axially by conduction in the rod. The Biot numbers for the fluids as a function of velocity are shown below.





We conclude that the sensor is well suited for use with water, but not so for use with air.

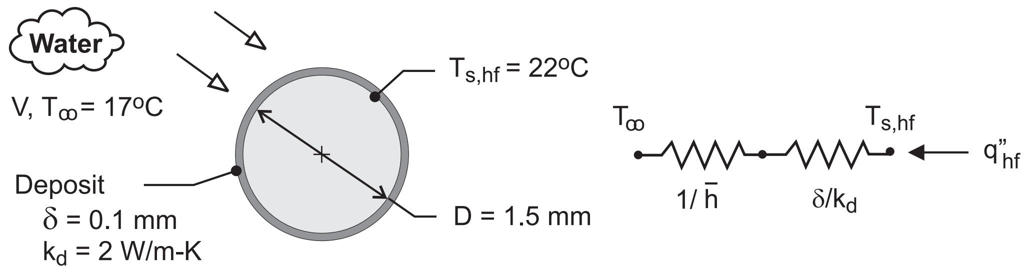
/* Solve, Explore and Graph:  After solving, separate Explore sweeps for 1 <= Va <= 20 and
0.5 <= Vw <= 5 m/s were performed saving results in different Data Sets.  Four separate
plot windows were generated.  */
```

PROBLEM 7.61

KNOWN: Diameter, temperature and heat flux of a hot-film sensor. Fluid temperature. Thickness and thermal conductivity of deposit.

FIND: (a) Fluid velocity, (b) Heat flux if sensor is coated by a deposit.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Constant properties, (3) Thickness of hot film sensor is negligible, (4) Applicability of Churchill-Bernstein correlation for uniform surface heat flux, (5) $Re_D << 282,000$, (6) Deposit may be approximated as a plane layer.

PROPERTIES: *Table A-6*, water $\left(T_f = 292.5\text{K}\right): k = 0.602\ \text{W/m}\cdot\text{K},\ \nu = 1.02\times10^{-6}\text{m}^2/\text{s},\ Pr = 7.09.$

ANALYSIS: (a) With $Re_D << 282,000$ and $\bar{h} = q''_{hf}/\left(T_{s,hf} - T_\infty\right)$, Eq. (7.54) reduces to

$$\overline{Nu}_D = \frac{q''_{hf}D}{k\left(T_{s,hf} - T_\infty\right)} \approx 0.3 + \frac{0.62\,Re_D^{1/2}\,Pr^{1/3}}{\left[1+\left(0.4/Pr\right)^{2/3}\right]^{1/4}} \tag{1}$$

Substituting for D, $\left(T_{s,hf} - T_\infty\right)$, k and Pr,

$$4.98\times10^{-4}q''_{hf} \approx 0.3 + 1.15\,Re_D^{1/2}$$

or, with $Re_D^{1/2} = \left(D/\nu\right)^{1/2}V^{1/2} = 38.3\,V^{1/2}$,

$$4.98\times10^{-4}q''_{hf} \approx 0.3 + 44.1\,V^{1/2} \tag{2}$$

Substituting for q''_{hf},

$$V = 0.20\,\text{m/s}$$ <

(b) For a fixed value of $T_{s,hf}$, the thermal resistance of the deposit reduces q''_{hf}. From the thermal circuit.

$$q''_{hf} = \frac{T_{s,hf} - T_\infty}{\left(1/\bar{h}\right) + \left(\delta/k_d\right)}$$

Using Eq. (1) to evaluate $\bar{h}$,

Continued …

PROBLEM 7.61 (Cont.)

$$\bar{h} \approx \frac{k}{(D+\delta)}\left\{0.3+\frac{0.62\,Re_D^{1/2}\,Pr^{1/3}}{\left[1+(0.4/Pr)^{2/3}\right]^{1/4}}\right\}$$

where, with V = 0.20 m/s, $Re_D = V(D+\delta)/\nu = 314$, we obtain

$$\bar{h} \approx \frac{0.602\,W/m\cdot K}{0.0016m}\{20.7\} = 7,780\,W/m^2\cdot K$$

Hence, $$q''_{hf} = \frac{5°C}{\left(1.285\times10^{-4}+0.5\times10^{-4}\right)m^2\cdot K/W} = 2.80\times10^4\,W/m^2$$ <

With the foregoing heat flux applied to the sensor and use of the model for Part (a), the sensor would indicate a velocity predicted from Eq. (2), or

$$V = \left[\left(4.98\times10^{-4}\times2.80\times10^4-0.3\right)/44.1\right]^2 = 0.096\,m/s$$

The error in the velocity measurement is therefore

$$\%\,Error \equiv \frac{V_{(a)}-V_{(b)}}{V_{(a)}}(100\%) = \frac{0.20-0.096}{0.20}\times100 = 52\%$$ <

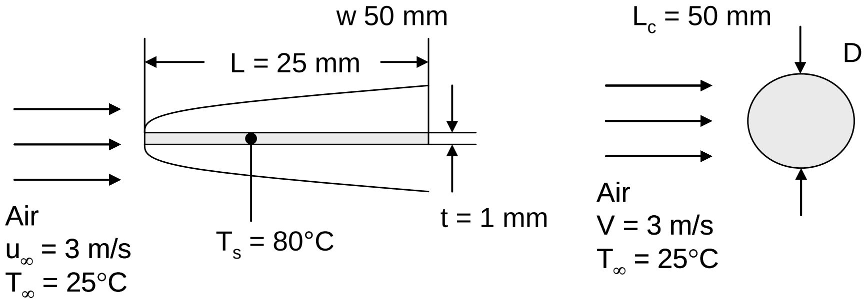
COMMENTS: (1) The accuracy of the hot-film sensor is strongly influenced by the deposit, and in any such application it is important to maintain a clean surface. (2) The Reynolds numbers are much less than 282,000 and assumption 5 is valid.

PROBLEM 7.62

KNOWN: Dimensions of a flat plate in parallel flow. Plate and air temperatures and air velocity. Dimensions of a horizontal cylinder.

FIND: Convective heat loss from top and bottom of the flat plate and from the cylinder.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties.

PROPERTIES: *Table A.4*, air (T_f = (80°C + 25°C)/2 = 52.5°C ≈ 325K, p = 1 atm): $\nu = 18.4\times10^{-6}$ m²/s, Pr = 0.704, k = 0.0282 W/m·K.

ANALYSIS: For the plate,

$$Re_L = \frac{u_\infty L}{\nu} = \frac{3\text{m/s}\times 25\times10^{-3}\text{m}}{18.4\times10^{-6}\text{m}^2/\text{s}} = 4076$$

Therefore, the flow is laminar and Eq. 7.30 yields

$$\overline{h} = \frac{k}{L}\left[0.664 Re_L^{1/2}\right]Pr^{1/3} = \frac{0.0282\text{W/m}\cdot\text{K}}{25\times10^{-3}\text{m}}\left[0.664\times4076^{1/2}\right]0.704^{1/3} = 42.5\ \text{W/m}^2\cdot\text{K}$$

and the convective heat transfer rate from the top and bottom of the flat plate is

$$q = 2wLh(T_s - T_\infty) = 2\times50\times10^{-3}\text{m}\times25\times10^{-3}\text{m}\times42.5\text{W/m}^2\cdot\text{K}(80-25)°\text{C} = 5.84\text{W}$$ <

For the cylinder, $D = \sqrt{\frac{4}{\pi}tL} = \sqrt{\frac{4}{\pi}\times1\times10^{-3}\text{m}\times25\times10^{-3}\text{m}} = 0.00564\text{m} = 5.64\text{mm}$ and

$$Re_D = \frac{VD}{\nu} = \frac{3\text{m/s}\times5.64\times10^{-3}\text{m}}{18.4\times10^{-6}\text{m}^2/\text{s}} = 920$$

Equation 7.54 yields

$$\overline{Nu}_D = 0.3 + \frac{0.62 Re_D^{1/2}Pr^{1/3}}{\left[1+(0.4/Pr)^{2/3}\right]^{1/4}}\left[1+\left(\frac{Re_D}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62\times920^{1/2}0.704^{1/3}}{\left[1+(0.4/0.704)^{2/3}\right]^{1/4}}\left[1+\left(\frac{920}{282{,}000}\right)^{5/8}\right]^{4/5} = 15.3$$

Continued…

PROBLEM 7.62 (Cont.)

and $$\bar{h} = \frac{\overline{Nu}_D k}{D} = \frac{15.3 \times 0.0282 \mathrm{W/m \cdot K}}{5.64 \times 10^{-3} \mathrm{m}} = 76.5 \mathrm{W/m^2 \cdot K}$$

Therefore, the heat transfer rate from the cylinder is,

$$q = \pi D L_c \bar{h}(T_s - T_\infty) = \pi \times 5.64 \times 10^{-3} \mathrm{m} \times 50 \times 10^{-3} \mathrm{m} \times 76.52 \mathrm{W/m^2 \cdot K}(80 - 25)°C = 3.73 \mathrm{W}$$ <

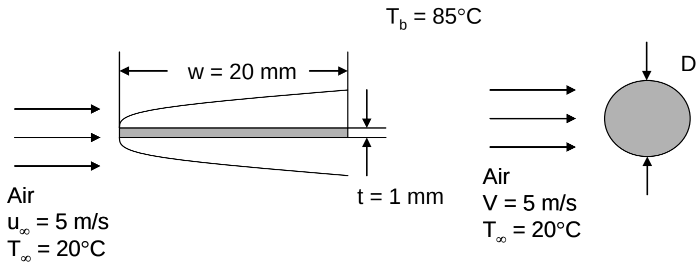
COMMENTS: (1) The heat transfer coefficient associated with the cylinder is 80% greater than that associated with the flat plate. However, for the same volume, the exposed surface area of the cylinder is 65% smaller than that of the flat plate, resulting in an overall smaller heat transfer rate for the cylinder. (2) A trial-and-error solution reveals that a larger cylinder of diameter *D* = 13.6 mm is necessary to transfer the same amount of energy by convection as the flat plate.

PROBLEM 7.63

KNOWN: Dimensions of a rectangular fin in parallel flow. Circular pin fin of same cross-sectional area.

FIND: (a) Fin heat transfer rate for both fins. (b) Diameter of cylindrical fin needed to produce the same fin heat transfer rate as for the rectangular fin.

SCHEMATIC:



Cross-sectional views of the rectangular fin (left) and the cylindrical fin (right). T_b = 85°C.

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Infinite fins, (4) Uniform heat transfer coefficients, equal to the average values.

PROPERTIES: *Table A.4*, air (T_f = (85°C + 20°C)/2 = 52.5°C ≈ 325K, p = 1 atm): $\nu = 18.4\times10^{-6}$ m^2/s, Pr = 0.704, k = 0.0282 W/m·K.

ANALYSIS: (a) For the rectangular fin,

$$Re_w = \frac{u_\infty w}{\nu} = \frac{5\text{m/s}\times20\times10^{-3}\text{m}}{18.4\times10^{-6}\text{m}^2/\text{s}} = 5435$$

Therefore, the flow is laminar and Eq. 7.30 yields

$$\bar{h} = \frac{k}{w}\left[0.664 Re_w^{1/2}\right]Pr^{1/3} = \frac{0.0282\text{W/m}\cdot\text{K}}{20\times10^{-3}\text{m}}\left[0.664\times5435^{1/2}\right]0.704^{1/3} = 61.4\ \text{W/m}^2\cdot\text{K}$$

The periphery of the fin is $P = 2(w + t) = 2\times(20\times10^{-3}\text{ m} + 1\times10^{-3}\text{ m}) = 42\times10^{-3}$ m and the cross-sectional area is $A_c = wt = 20\times10^{-3}\text{ m}\times1\times10^{-3}\text{ m} = 20\times10^{-6}\text{ m}^2$. Evaluating the fin parameter M yields

$$M = \sqrt{hPkA_c}\,\theta_b = \sqrt{61.4\text{W/m}^2\cdot\text{K}\times42\times10^{-3}\text{m}\times237\text{W/m}\cdot\text{K}\times20\times10^{-6}\text{m}}\times(85-20)°\text{C} = 7.19\text{W}$$

For an infinite fin,

$$q_f = M = 7.19\text{ W}$$ <

For the cylindrical fin, $D = \sqrt{\frac{4}{\pi}tw} = \sqrt{\frac{4}{\pi}\times1\times10^{-3}\text{m}\times20\times10^{-3}\text{m}} = 0.00505\text{m} = 5.05\text{mm}$ and

$$Re_D = \frac{VD}{\nu} = \frac{5\text{m/s}\times5.05\times10^{-3}\text{m}}{18.4\times10^{-6}\text{m}^2/\text{s}} = 1372$$

Continued…

PROBLEM 7.63 (Cont.)

Equation 7.54 yields

$$\overline{Nu}_D = 0.3 + \frac{0.62 Re_D^{1/2} Pr^{1/3}}{\left[1 + (0.4/Pr)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{Re_D}{282,000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62 \times 1372^{1/2} 0.704^{1/3}}{\left[1 + (0.4/0.704)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{1372}{282,000}\right)^{5/8}\right]^{4/5} = 18.7$$

and $\bar{h} = \dfrac{\overline{Nu}_D k}{D} = \dfrac{18.7 \times 0.0282 \text{W/m} \cdot \text{K}}{5.05 \times 10^{-3} \text{m}} = 104.4 \text{W/m}^2 \cdot \text{K}$

The periphery of the fin is $P = \pi D = \pi \times 5.05 \times 10^{-3}$ m = 15.9×10^{-3} m and the cross-sectional area is A_c = = 20×10^{-6} m^2. Evaluating the fin parameter M yields

$$M = \sqrt{hPkA_c}\theta_b = \sqrt{104.4 \text{W/m}^2 \cdot \text{K} \times 15.9 \times 10^{-3} \text{m} \times 237 \text{W/m} \cdot \text{K} \times 20 \times 10^{-6} \text{m}} \times (85 - 20)°\text{C} = 5.77 \text{W}$$

For an infinite fin,

$$q_f = M = 5.77 \text{ W}$$ <

The rectangular fin heat rate is 25% greater than that of the cylindrical fin. <

(b) A trial-and-error solution shows that a cylinder diameter of D = 6.02 mm is necessary to transfer the same amount of heat as the rectangular fin. <

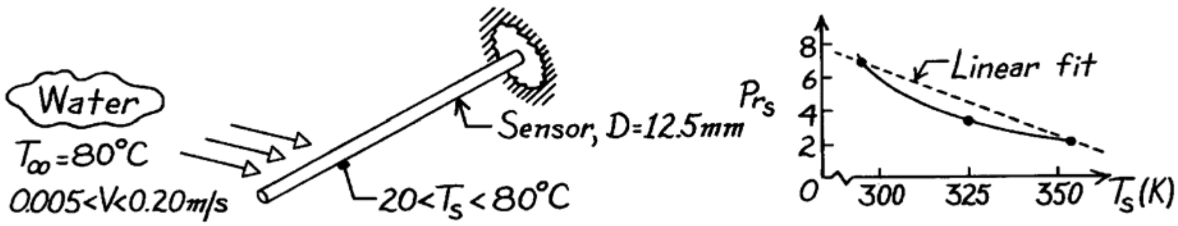
COMMENTS: (1) The Reynolds number and heat transfer coefficient associated with part (b) are 1636 and 96.0 W/m^2·K, respectively. (2) The ratio of the mass of the cylinder in part (b) to that of the cylinder in part (a) is $r = (D_b^2 / D_a^2) = (6.02/5.05)^2 = 1.42$. Good thermal design, such as use of the rectangular fin rather than the cylindrical fin, can help conserve both natural resources and energy that is used to produce the aluminum.

PROBLEM 7.64

KNOWN: Temperature sensor of 12.5 mm diameter experiences cross-flow of water at 80°C and velocity, $0.005 < V < 0.20$ m/s. Sensor temperature may vary over the range $20 < T_s < 80°C$.

FIND: Expression for convection heat transfer coefficient as a function of T_s and V.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Sensor-water flow approximates a cylinder in cross-flow, (3) Prandtl number varies linearly with temperature over the range of interest.

PROPERTIES: *Table A-6*, Sat. water (T_∞ = 80°C = 353 K): k = 0.670 W/m·K, $\nu = \mu v_f = 352 \times 10^{-6}$ N·s/m^2 × 1.029 × 10^{-3} m^3/kg = 3.621 × 10^{-7} m^2/s; Pr_s values for $20 \le T_s \le 80°C$:

T (K)	293	300	325	350	353
Pr	7.00	5.83	3.42	2.29	2.20

ANALYSIS: Using the Zhukauskus correlation for the range $40 < Re_D < 4000$ with C = 0.51 and m = 0.5,

$$\overline{Nu}_D = \frac{\bar{h}D}{k} = 0.51 Re_D^{0.5} Pr^{0.37}\left(\frac{Pr}{Pr_s}\right)^{1/4}.$$

with $Re_D = VD/\nu$, the thermophysical properties of interest are k, ν and Pr, which are evaluated at T_∞ = 80°C, and Pr_s which varies markedly with T_s for the range $20 < T_s < 80°C$. Assuming Pr_s to vary linearly with T_s and using the extreme values to find the relation,

$$Pr_s = 7.00 + \frac{(2.20 - 7.00)}{(353 - 293)K}(T_s - 293)K = 7.00 - 0.0800(T_s - 293)$$

where the units of T_s are [K]. Substituting numerical values, find

$$\bar{h}(T_s) = \frac{0.670 \text{ W/m}\cdot\text{K}}{0.0125 \text{ m}} 0.51\left(\frac{V \times 0.0125 \text{ m}}{3.621 \times 10^{-7} \text{ m}^2/\text{s}}\right)^{0.5}(2.20)^{0.37}\left(\frac{2.20}{7.00 - 0.080(T_s - 293)}\right)^{1/4}$$

$$\bar{h}(T_s) = 6800 V^{0.5}\left[3.182 - 0.0364(T_s - 293)\right]^{-1/4}.$$ <

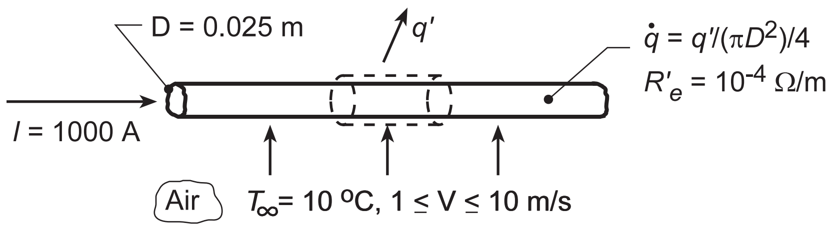
COMMENTS: (1) From the Pr_s vs T_s graph above, a linear fit is seen to be poor for this temperature range. However, because the Pr_s dependence is to the ¼ power, the discrepancy may be acceptable.

PROBLEM 7.65

KNOWN: Diameter, electrical resistance and current for a high tension line. Velocity and temperature of ambient air.

FIND: (a) Surface and (b) Centerline temperatures of the wire, (c) Effect of air velocity on surface temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional radial conduction.

PROPERTIES: *Table A.4*, Air ($T_f \approx 300$ K, 1 atm): $\nu = 15.89 \times 10^{-6}$ m²/s, k = 0.0263 W/m·K, Pr = 0.707; *Table A.1*, Copper (T ≈ 300 K): k = 400 W/m·K.

ANALYSIS: (a) Applying conservation of energy to a control volume of unit length,

$$\dot{E}'_g = I^2 R'_e = q' = \bar{h}\pi D\left(T_s - T_\infty\right)$$

With

$$Re_D = \frac{VD}{\nu} = \frac{10\,\mathrm{m/s}\left(0.025\,\mathrm{m}\right)}{15.89\times10^{-6}\,\mathrm{m^2/s}} = 15,733$$

the Churchill and Bernstein correlation, yields

$$\overline{Nu}_D = 0.3 + \frac{0.62\,Re_D^{1/2}\,Pr^{1/3}}{\left[1+\left(0.4/Pr\right)^{2/3}\right]^{1/4}}\left[1+\left(\frac{Re_D}{282,000}\right)^{5/8}\right]^{4/5} = 69.0$$

Hence,

$$\bar{h} = \overline{Nu}_D\,\frac{k}{D} = 69.0\,\frac{0.0263\,\mathrm{W/m\cdot K}}{0.025\,\mathrm{m}} = 72.6\,\mathrm{W/m^2\cdot K}$$

and

$$T_s = T_\infty + \frac{I^2 R'_e}{\bar{h}\pi D} = 10^\circ\mathrm{C} + \frac{\left(1000\,\mathrm{A}\right)^2 10^{-4}\,\Omega/\mathrm{m}}{\left(72.6\,\mathrm{W/m^2\cdot K}\right)\pi\left(0.025\,\mathrm{m}\right)} = 10^\circ\mathrm{C} + 17.6^\circ\mathrm{C} = 27.6^\circ\mathrm{C} \quad <$$

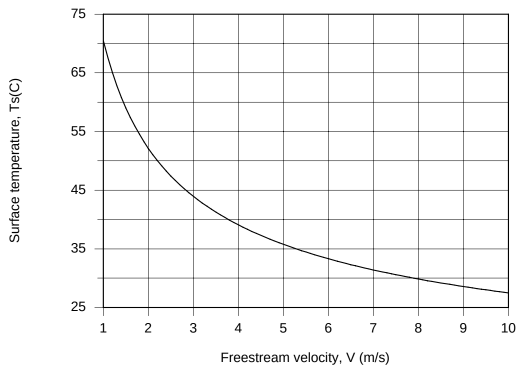
(b) With $\dot{q} = \dot{E}'_g \big/ \left(\pi D^2/4\right) = 4\left(1000\,\mathrm{A}\right)^2\left(10^{-4}\,\Omega/\mathrm{m}\right)\big/\pi\left(0.025\,\mathrm{m}\right)^2 = 2.04\times10^5\,\mathrm{W/m^3}$, Equation 3.58 yields

$$T(0) = \frac{\dot{q}r_o^2}{4k} + T_s = \frac{2.041\times10^5\,\mathrm{W/m^3}\left(0.0125\,\mathrm{m}\right)^2}{1600\,\mathrm{W/m\cdot K}} + 27.6^\circ\mathrm{C} = 0.02^\circ\mathrm{C} + 27.6^\circ\mathrm{C} \approx 27.6^\circ\mathrm{C} \quad <$$

Continued...

PROBLEM 7.65 (Cont.)

(c) The effect of V on the surface temperature was determined using the *Correlations* and *Properties* Tool Pads of IHT.



The effect is significant, with a surface temperature of $T_s \approx 70°C$ corresponding to V = 1 m/s. For velocities of 1 and 10 m/s, respectively, convection coefficients are 21.1 and 72.8 $W/m^2 \cdot K$ and film temperatures are 313.2 and 291.7 K.

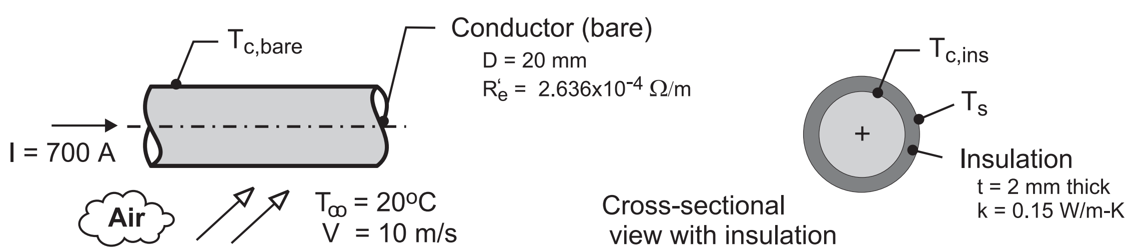
COMMENTS: The small values of $\dot{q}$ and r_o and the large value of k render the wire approximately isothermal.

PROBLEM 7.66

KNOWN: Aluminum transmission line with a diameter of 20 mm having an electrical resistance of $R' = 2.636\times10^{-4}$ ohm/m carrying a current of 700 A subjected to severe cross winds. To reduce potential fire hazard when adjacent lines make contact and spark, insulation is to be applied.

FIND: (a) The bare conductor temperature when the air temperature is 20°C and the line is subjected to cross flow with a velocity of 10 m/s; (b) The conductor temperature for the same conditions, but with an insulation covering of 2 mm thickness and thermal conductivity of 0.15 W/m·K; and (c) Plot the conductor temperatures of the bare and insulated conductors for wind velocities in the range of 2 to 20 m/s. Comment on the features of the curves and the effect that wind velocity has on the conductor operating temperatures.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform surface temperatures, (3) Negligible solar irradiation and radiation exchange, and (4) Constant properties.

PROPERTIES: *Table A-4*, Air ($T_f = (T_s + T_\infty)/2$, 1 atm): evaluated using the *IHT Properties* library with a *Correlation* function; see Comment 2.

ANALYSIS: (a) For the *bare* conductor the energy balance per unit length is

$$\dot{E}'_{in} - \dot{E}'_{out} + \dot{E}'_{gen} = 0$$

$$0 - q'_{cv} + \dot{q}\,A_c = 0 \tag{1}$$

where the cross-sectional area of the conductor is $A_c = \pi D^2/4$ and the generation rate is

$$\dot{q} = I^2 R'_e / A_c = (700\,\text{A})^2 \times 2.636\times10^{-4}\,\Omega/\text{m} \Big/ \left(\pi(0.020\,\text{m})^2/4\right) \tag{2}$$

$$\dot{q} = 4.111\times10^5\ \text{W/m}^3$$

The convection rate equation can be expressed as

$$q'_{cv} = \left(T_{c,bare} - T_\infty\right)/R'_t \qquad\qquad R'_t = 1/\left(\bar{h}_D \times \pi D\right) \tag{3,4}$$

and the convection coefficient is estimated using the Churchill-Bernstein correlation, Eq. 7.54, with $Re_D = VD/\nu$,

$$\overline{Nu}_L = \frac{\bar{h}_D D}{k} = 0.3 + \frac{0.62\,Re_D^{1/2}\,Pr^{1/3}}{\left[1+(0.4/Pr)^{2/3}\right]^{1/4}}\left[1+\left(\frac{Re_D}{282{,}000}\right)^{5/8}\right]^{4/5} \tag{4}$$

(b) For the conductor *with insulation* thickness t = 2 mm, the energy balance per unit length is

$$\dot{E}'_{in} - \dot{E}'_{out} + \dot{E}'_{gen} = 0$$

$$0 - \left(T_{c,ins} - T_\infty\right)/R'_t + I^2 R'_e / A_c = 0 \tag{5}$$

Continued …

PROBLEM 7.66 (Cont.)

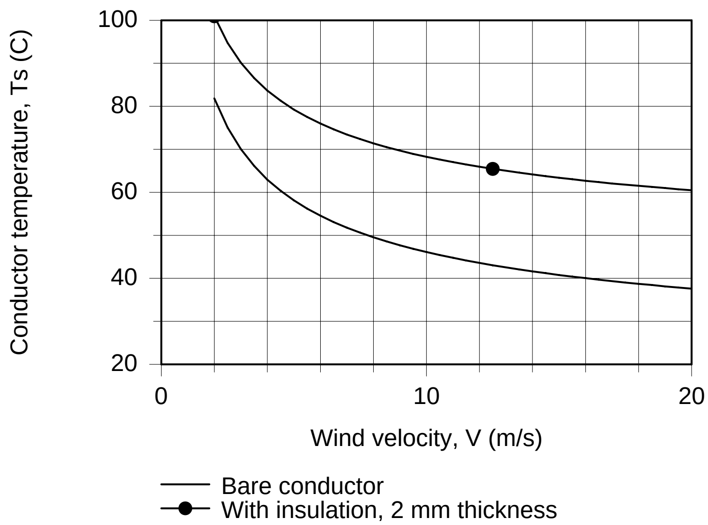
where R'_t is the sum of the insulation conduction and convection process thermal resistances,

$$R'_t = \ell n\left[\left(D+2t\right)/D\right]/\left(2\pi k\right)+1/\left[\bar{h}_{D+2t}\pi\left(D+2t\right)\right] \tag{6}$$

The results of the analysis using *IHT* are tabulated below.

Condition	V (m/s)	D (mm)	Re_D	$\overline{Nu}_D$	$\bar{h}_D$ ($W/m^2 \cdot K$)	R'_t (m·K/W)	T_c (°C)
bare	10	20	1.214×10^4	59.6	79.6	0.1998	45.8
insulated	10	24	1.468×10^4	66.3	73.6	0.3736	68.3

(c) Using the *IHT* code with the foregoing relations, the conductor temperatures $T_{c,base}$ and $T_{c,ins}$ for the bare and insulated conditions are calculated and plotted for the wind velocity range of 2 to 20 m/s.



COMMENTS: (1) The effect of the 2-mm thickness insulation is to increase the conductor operating temperature by (68.3 – 46.1)°C = 22°C. While we didn't account for an increase in the electrical resistivity with increasing temperature, the adverse effect is to increase the I^2R loss, which represents a loss of revenue to the power provider. From the graph, note that the conductor temperature increases markedly with decreasing wind velocity, and the effect of insulation is still around +20°C.

(2) Because of the tediousness of hand calculations required in using the convection correlation without fore-knowledge of T_f at which to evaluate properties, we used the *IHT Correlation* function treating T_f as one of the unknowns in the system of equations. Salient portions of the *IHT* code and property values are provided below.

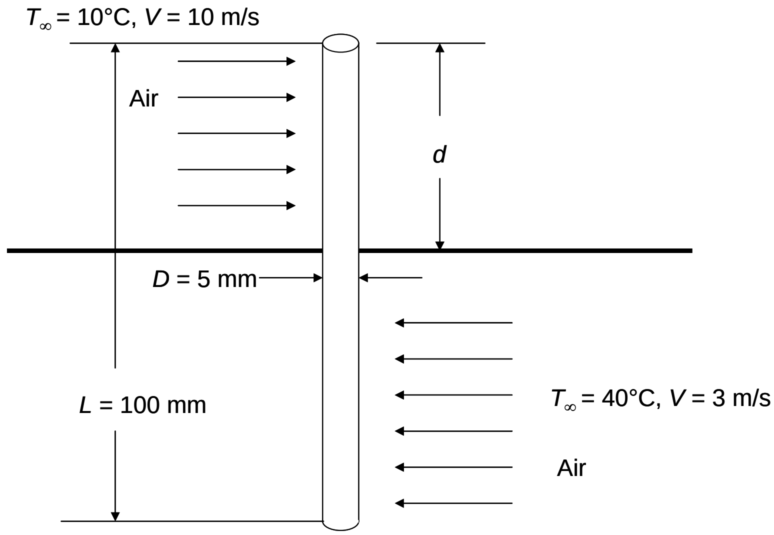
(3) Is the temperature gradient within the conductor significant?

PROBLEM 7.67

KNOWN: Velocities and temperatures of two air streams separated by a wall. Dimensions of an aluminum pin fin inserted through the wall. Distance it extends into the upper fluid.

FIND: (a) Heat transfer rate between the fluids via the pin fin, when it extends 50 mm into the upper fluid. (b) Heat transfer rate as a function of the distance it extends into the upper fluid.

SCHEMATIC:



ASSUMPTIONS: (1) Velocity is uniform – decreased velocity near wall can be neglected, (2) For the purpose of evaluating properties, the fin temperature is equal to the average of the two fluid temperatures, $T_s = 25°C$.

PROPERTIES: Table A-4, Air 1 ($T_{f1} = 17.5°C \cong 290.5$ K): $\nu_1 = 1.504 \times 10^{-5}$ m^2/s, $k_1 = 0.02554$ W/m·K, $Pr_1 = 0.710$. Air 2 ($T_{f2} = 32.5°C \cong 305.5$ K): $\nu_2 = 1.644 \times 10^{-5}$ m^2/s, $k_2 = 0.02671$ W/m·K, $Pr_2 = 0.706$. Table A-1, Aluminum 2024 ($T_s = 25°C \approx 300$ K): k = 177 W/m·K.

ANALYSIS:

(a) The heat transfer coefficients between the air and the fin are analyzed as flow past a cylinder using the Churchhill-Bernstein correlation:

$$Re_{D1} = \frac{V_1 D}{\nu_1} = \frac{10\text{ m/s} \times 0.005\text{ m}}{1.504 \times 10^{-5}\text{m}^2/\text{s}} = 3320$$

$$Re_{D2} = \frac{V_2 D}{\nu_2} = \frac{3\text{ m/s} \times 0.005\text{ m}}{1.644 \times 10^{-5}\text{m}^2/\text{s}} = 912.$$

From Equation 7.54,

$$Nu_{D1} = 0.3 + \frac{0.62\, Re_{D1}^{1/2}\, Pr^{1/3}}{\left[1 + (0.4/Pr_1)^{2/3}\right]^{1/4}}\left[1 + \left(\frac{Re_{D1}}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62 \times (3320)^{1/2} \times (0.710)^{1/3}}{\left[1 + (0.4/0.710)^{2/3}\right]^{1/4}}\left[1 + \left(\frac{3320}{282{,}000}\right)^{5/8}\right]^{4/5} = 29.7$$

and $$h_1 = \frac{Nu_{D1} k_1}{D} = \frac{29.7 \times 0.02554\text{ W/m}\cdot\text{K}}{0.005\text{ m}} = 152\text{ W/m}^2\cdot\text{K}$$

Continued…

PROBLEM 7.67 (Cont.)

Similarly, $Nu_{D2} = 15.3$, $h_2 = 81.5\ W/m^2{\cdot}K$.

Next we analyze heat transfer along the rod as if it were two fins joined at their base – the location where the fin passes through the wall. Thus, using the corrected fin length approach, Equation 3.88,

$$q_1 = M_1 \tanh m_1 L_{c1}$$
$$q_2 = M_2 \tanh m_2 L_{c2}$$

where

$$M_i = \sqrt{h_i P k A_c}\,\theta_{bi} = \sqrt{h_i D k \frac{\pi D}{2}}\,(T_b - T_{\infty i})$$
$$m_i = \sqrt{h_i P / k A_c} = 2\sqrt{h_i / kD}$$

and $L_{ci} = L_i + D/4$. In this expression, $L_1 = d$ and $L_2 = L - d$. Finally, since heat leaving one rod enters the other,

$$q_1 = -q_2$$
$$\sqrt{h_1 D k \frac{\pi D}{2}}\,(T_b - T_{\infty 1}) \tanh m_1 L_{c1} = -\sqrt{h_2 D k \frac{\pi D}{2}}\,(T_b - T_{\infty 2}) \tanh m_2 L_{c2}$$

Solving for T_b:

$$T_b = \frac{\sqrt{h_1}\ T_{\infty 1}\ \tanh(m_1 L_{c1}) + \sqrt{h_2}\ T_{\infty 2}\ \tanh(m_2 L_{c2})}{\sqrt{h1}\ \tanh(m_1 L_{c1}) + \sqrt{h_2}\ \tanh(m_2 L_{c2})} \qquad (1)$$

We calculate

$$m_1 = 2\sqrt{h_1/kD} = 2\sqrt{152\ W/m^2\cdot K/(177\ W/m\cdot K \times 0.005\ m)} = 26.2\ m^{-1}$$

and similarly, $m_2 = 19.2\ m^{-1}$. Also, $L_{c1} = L_{c2} = d + D/4 = 0.05\ m + 0.005\ m/4 = 0.05125\ m$.

Thus

$$T_b = \left[\sqrt{152\ W/m^2\cdot K} \times 10°C \times \tanh(26.2\ m^{-1} \times 0.05125\ m) + \sqrt{81.5\ W/m^2\cdot K} \times 40°C \times \tanh(19.2\ m^{-1} \times 0.05125\ m)\right] \Big/ \left[\sqrt{152\ W/m^2\cdot K} \times \tanh(26.2\ m^{-1} \times 0.05125\ m) + \sqrt{81.5\ W/m^2\cdot K} \times \tanh(19.2\ m^{-1} \times 0.05125\ m)\right] = 21.6°C$$

Finally

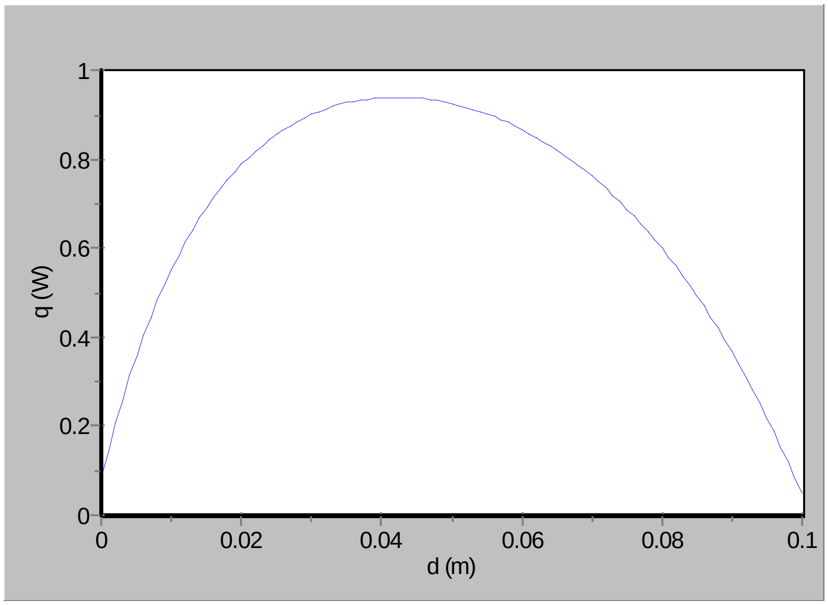
$$q = q_1 = -q_2 = \sqrt{h_1 D k \frac{\pi D}{2}}\,(T_b - T_{\infty 1}) \tanh(m_1 L_{c1}) \qquad (2)$$
$$= \sqrt{152\ W/m^2\cdot K \times 0.005\ m \times 177\ W/m\cdot K \times \frac{\pi(0.005\ m)}{2}} \times (21.6°C - 10°C) \tanh(26.2\ m^{-1} \times 0.05125\ m)$$
$$= 0.924\ W$$

<

Continued…

PROBLEM 7.67 (Cont.)

(b) With $L_{c1} = d + D/4$ and $L_{c2} = L - d + D/4$, we vary d in the range $0 \le d \le 0.1$ m and solve Equations (1) and (2). The results for q are plotted below.



We see that there is an optimal insertion distance, $d \cong 40$ mm. A longer fin length (≈ 60 mm) is needed in fluid 2 to compensate for its smaller heat transfer coefficient.

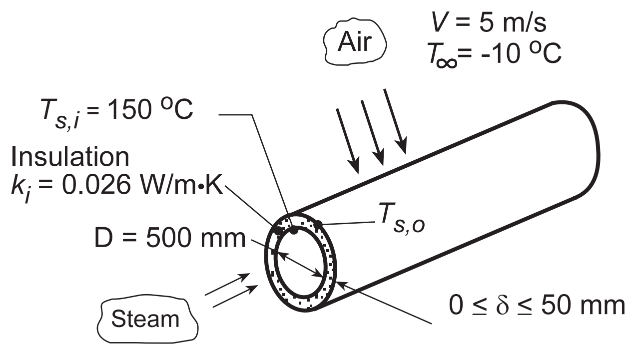
COMMENTS: It is of interest to compare the heat transfer between the two fluids via the fin to the heat transfer through the wall. In Chapter 8 we will see how to calculate heat transfer coefficients for flow in a channel. Assuming that the channel widths are both approximately 50 mm, the heat transfer coefficients between the fluid and the wall are roughly 40 $W/m^2 \cdot K$ and 10 $W/m^2 \cdot K$ for the faster and slower streams, respectively. Then $q'' = \dfrac{T_2 - T_1}{1/h_1 + 1/h_2} \cong 240\ W/m^2$. A wall area of $4 \times 10^{-3}\ m^2$, for example a 60 mm-square area, would be required to transfer the same amount of heat as the fin (in part a), 0.924 W.

PROBLEM 7.68

KNOWN: Diameter and surface temperature of an uninsulated steam pipe. Velocity and temperature of air in cross flow.

FIND: (a) Heat loss per unit length, (b) Effect of insulation thickness on heat loss.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform surface temperature, (3) Negligible radiation.

PROPERTIES: *Table A.4*, Air ($T_f \approx 350$ K, 1 atm): $\nu = 20.9 \times 10^{-6}$ m^2/s, k = 0.030 W/m·K, Pr = 0.70.

ANALYSIS: (a) Without the insulation, the heat loss per unit length is

$$q' = \bar{h}\pi D\left(T_{s,i} - T_\infty\right)$$

where $\bar{h}$ may be obtained from the Churchill-Bernstein relation. With

$$Re_D = \frac{VD}{\nu} = \frac{5\,m/s \times 0.5\,m}{20.9 \times 10^{-6}\,m^2/s} = 1.196 \times 10^5$$

$$\overline{Nu}_D = 0.3 + \frac{0.62\,Re_D^{1/2}\,Pr^{1/3}}{\left[1+(0.4/Pr)^{2/3}\right]^{1/4}}\left[1+\left(\frac{Re_D}{282,000}\right)^{5/8}\right]^{4/5} = 242$$

$$\bar{h} = \overline{Nu}_D\frac{k}{D} = 242\frac{0.030\,W/m\cdot K}{0.5\,m} = 14.5\,W/m^2\cdot K$$

The heat rate is then

$$q' = 14.5\,W/m^2\cdot K\,\pi(0.5\,m)(150-(-10))^\circ C = 3644\,W/m.$$ <

(b) With the insulation, the heat loss may be expressed as

$$q' = U_i\pi D\left(T_{s,i} - T_\infty\right)$$

where, from Eq. 3.36,

$$U_i = \left[\frac{(D/2)}{k_i}\ln\bar{r} + \frac{1}{\bar{r}\bar{h}}\right]^{-1}$$

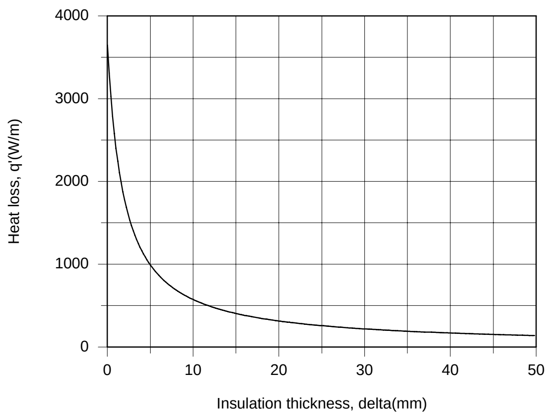
and $\bar{r} \equiv (D/2+\delta)/(D/2)$. The outer diameter, $D_o = D + 2\delta$, as well as the film temperature, $T_f = (T_{s,o} + T_\infty)/2$, must now be used to evaluate the convection coefficient, where

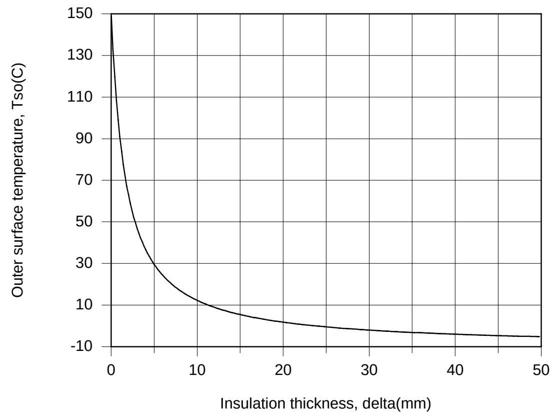
Continued...

PROBLEM 7.68 (Cont.)

$$\frac{T_{s,i} - T_{s,o}}{T_{s,i} - T_\infty} = \frac{R'_{cond}}{R'_{tot}} = \frac{\left(\ln \bar{r}\right)/k_i}{\left(\ln \bar{r}\right)/k_i + 1/\left(D/2\right)\bar{r}\bar{h}}$$

Using the IHT *Correlations* and *Properties* Tool Pads to evaluate $\bar{h}$, the following results were obtained.





The insulation is extremely effective, with a thickness of only 10 mm yielding a 7-fold reduction in heat loss and decreasing the outer surface temperature from 150 to 10°C. For δ = 50 mm, U_i = 0.56 $W/m^2 \cdot K$, q' = 140 W/m and $T_{s,o}$ = -5.2°C.

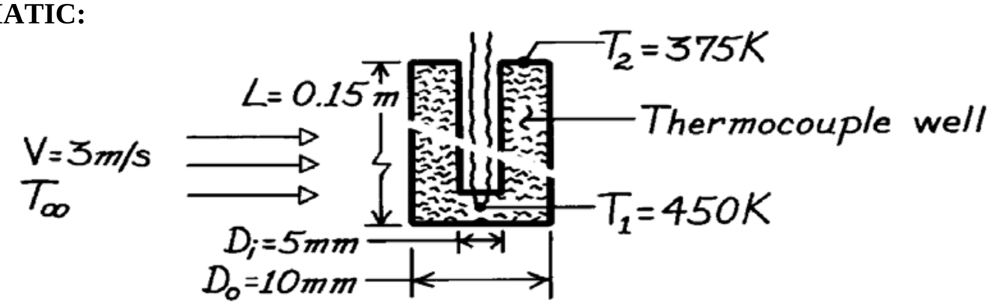
COMMENTS: The dominant contribution to the total thermal resistance is made by the insulation.

PROBLEM 7.69

KNOWN: Dimensions and thermal conductivity of a thermocouple well. Temperatures at well tip and base. Air velocity.

FIND: Air temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional conduction along well, (4) Uniform convection coefficient, (5) Negligible radiation.

PROPERTIES: Steel (given): k = 35 W/m·K; Air (given): $\rho = 0.774$ kg/m^3, $\mu = 251 \times 10^{-7}$ N·s/m^2, k = 0.0373 W/m·K, Pr = 0.686.

ANALYSIS: Applying Equation 3.75 at the well tip (x = L), where T = T_1,

$$\frac{T_1 - T_\infty}{T_2 - T_\infty} = \left[\cosh mL + \left(\bar{h}/mk\right)\sinh mL\right]^{-1}$$

$$m = \left(\bar{h}P/kA_c\right)^{1/2} \qquad P = \pi D_o = \pi\left(0.010\ \text{m}\right) = 0.0314\ \text{m}$$

$$A_c = (\pi/4)\left(D_o^2 - D_i^2\right) = (\pi/4)\left(0.010^2 - 0.005^2\right)\text{m}^2 = 5.89 \times 10^{-5}\ \text{m}^2.$$

With $$Re_D = \frac{\rho V D}{\mu} = \frac{0.774\ \text{kg/m}^3 (3\text{m/s}) 0.01\ \text{m}}{251 \times 10^{-7}\ \text{N}\cdot\text{s/m}^2} = 925$$

C = 0.51, m = 0.5, n = 0.37 and the Zhukauskas correlation yields

$$\overline{Nu}_D = 0.51 Re_D^{0.5} Pr^{0.37}\left(Pr/Pr_s\right)^{1/4} \approx 0.51(925)^{0.5}(0.686)^{0.37} \times 1 = 13.5$$

$$\bar{h} = \overline{Nu}_D \frac{k}{D_o} = 13.5 \frac{0.0373\ \text{W/m}\cdot\text{K}}{0.01\ \text{m}} = 50.4\ \text{W/m}^2\cdot\text{K}.$$

Hence

$$m = \left[\frac{\left(50.4\ \text{W/m}^2\cdot\text{K}\right)0.0314\ \text{m}}{\left(35\ \text{W/m}\cdot\text{K}\right)5.89 \times 10^{-5}\ \text{m}^2}\right]^{1/2} = 27.7\ \text{m}^{-1} \qquad mL = \left(27.7\ \text{m}^{-1}\right)0.15\ \text{m} = 4.15.$$

With

$$\left(\bar{h}/mk\right) = \left(50.4\ \text{W/m}^2\cdot\text{K}\right)/\left(27.7\ \text{m}^{-1}\right)\left(35\ \text{W/m}\cdot\text{K}\right) = 0.0519$$

find $$\frac{T_1 - T_\infty}{T_2 - T_\infty} = \left[31.9 + (0.0519)31.8\right]^{-1} = 0.0298 \qquad T_\infty = 452.2\ \text{K}.$$ <

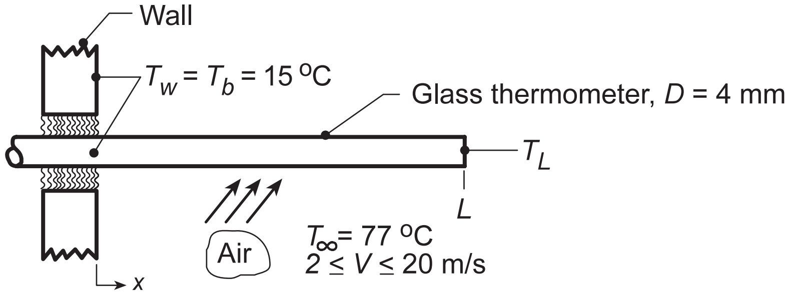
COMMENTS: Heat conduction along the wall to the base at 375 K is balanced by convection from the air.

PROBLEM 7.70

KNOWN: Mercury-in-glass thermometer mounted on duct wall used to measure air temperature.

FIND: (a) Relationship for the immersion error, $\Delta T_i = T(L) - T_\infty$ as a function of air velocity, thermometer diameter and length, (b) Length of insertion if ΔT_i is not to exceed 0.25°C when the air velocity is 10 m/s, (c) For the length of part (b), calculate and plot ΔT_i as a function of air velocity for 2 to 20 m/s, and (d) For a given insertion length, will ΔT_i increase or decrease with thermometer diameter increase; is ΔT_i more sensitive to diameter or velocity changes?

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Thermometer approximates a one-dimensional (glass) fin with an *adiabatic* tip, (3) Convection coefficient is uniform over length of thermometer.

PROPERTIES: *Table A.3*, Glass (300 K): k_g = 1.4 W/m·K; *Table A.4*, Air (T_f = (15 + 77)°C/2 ≈ 320 K, 1 atm): k = 0.0278 W/m·K, $\nu = 17.90 \times 10^{-6}$ m/s^2, Pr = 0.704.

ANALYSIS: (a) From the analysis of a one-dimensional fin, see Table 3.4,

$$\frac{T_L - T_\infty}{T_b - T_\infty} = \frac{1}{\cosh(mL)} \qquad m^2 = \frac{\bar{h}P}{k_g A_c} = \frac{4\bar{h}}{k_g D} \tag{1}$$

where P = πD and $A_c = \pi D^2/4$. Hence, the immersion error is

$$\Delta T_i = T(L) - T_\infty = (T_b - T_\infty)/\cosh(mL). \tag{2}$$

Using the Hilpert correlation for the circular cylinder in cross flow,

$$\bar{h} = \frac{k}{D} C\, Re_D^m\, Pr^{1/3} = \frac{k}{D} C \left(\frac{VD}{\nu}\right)^m Pr^{1/3} = \frac{k\, Pr^{1/3}}{\nu^m} \cdot C \cdot V^m \cdot D^{m-1} \tag{3}$$

$$\bar{h} = N \cdot V^m \cdot D^{m-1} \qquad \text{where} \qquad N = \frac{k\, Pr^{1/3}}{\nu^m} C \tag{4,5}$$

Substituting into Eq. (2), the immersion error is

$$\Delta T_i(V, D, L) = (T_b - T_\infty)/\cosh\left\{\left[(4/k_g) N \cdot V^m \cdot D^{m-2}\right]^{1/2} L\right\} \tag{6}$$ <

where k_g is the thermal conductivity of the glass thermometer.

(b) When the air velocity is 10 m/s, find

$$Re_D = \frac{VD}{\nu} = \frac{10\,m/s \times 0.004\,m}{17.9 \times 10^{-6}\,m/s^2} = 2235$$

Continued...

PROBLEM 7.70 (Cont.)

with C = 0.683 and m = 0.466 from Table 7.2 for the range 40 < Re_D < 4000. From Eqs. (5) and (6),

$$N = \frac{0.0278\,W/m\cdot K\,(0.704)^{1/3}}{\left(17.9\times10^{-6}\,m/s^2\right)^{0.466}}\times 0.683 = 2.753$$

$$\Delta T_i = (15-77)K/\cosh\left\{\left[\frac{4}{1.4\,W/m\cdot K}\times 2.753(10\,m/s)^{0.466}(0.004\,m)^{0.466-2}\right]^{1/2} L\right\}$$

and when ΔT_i = -0.25°C, find

L = 18.7 mm <

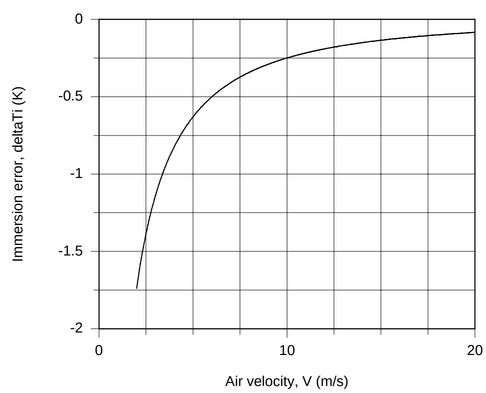
(c) For the air velocity range 2 to 20 m/s, find 447 ≤ Re_D ≤ 4470 for which the previous values of C and m of the Hilpert correlation are appropriate. Hence, the immersion error for an insertion length of L = 18.7 mm, part (b), find

$$\Delta T_i = (15-77)K/\cosh\left\{\left[\frac{4}{1.4\,W/m\cdot K}\times 2.753\times V^{0.466}(0.004\,m)-1.534\right]^{1/2} 0.0187\right\}$$

$$\Delta T_i = -62^\circ C/\cosh\left(3.629V^{0.233}\right)$$ <

where the units of V are [m/s]. Entering the above equation into the IHT Workspace the plot shown below was generated.

V(m/s)	ΔT_i (°C)
2	-1.74
5	-0.63
10	-0.25
15	-0.14
20	-0.08



(d) For a given insertion length, the immersion error will *increase* if the diameter of the thermometer were *increased*. This follows from Eq. (6) written as

$$\Delta T_i \sim 1/\cosh\left(A\cdot D^{(m-2)/2}\right) \qquad (7)$$

where A is a constant depending on variables other than D. For a given insertion length and air velocity, from Eq. (6)

$$\Delta T_i \sim 1/\cosh\left(B\cdot V^{m/2}\right) \qquad (8)$$

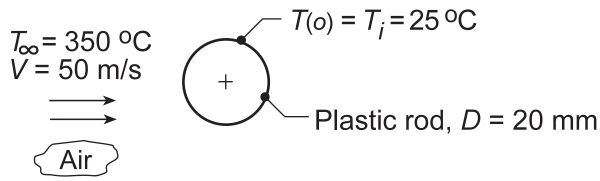
where B is a constant. From Eq. (7) we see ΔT_i relates to change in *diameter* as $D^{-0.767}$ and to change in *velocity* as $V^{0.233}$. That is, to reduce the immersion error decrease D and increase V (both cause $\bar{h}$ to increase!). Based upon the exponents of each parameter, however, diameter change is the more influential.

PROBLEM 7.71

KNOWN: Long coated plastic, 20-mm diameter rod, initially at a uniform temperature of $T_i = 25°C$, is suddenly exposed to the cross-flow of air at $T_\infty = 350°C$ and V = 50 m/s.

FIND: (a) Time for the surface of the rod to reach 175°C, the temperature above which the special coating cures, and (b) Compute and plot the time-to-reach 175°C as a function of air velocity for 5 ≤ V ≤ 50 m/s.

SCHEMATIC:



ASSUMPTIONS: (a) One-dimensional, transient conduction in the rod, (2) Constant properties, and (3) Evaluate thermophysical properties at $T_f = [(T_s + T_i)/2 + T_\infty]/2$ = [(175 + 25)/2 + 350]°C/2 = 225°C = 500 K.

PROPERTIES: Rod (Given): $\rho = 2200\ kg/m^3$, c = 800 J/kg·K, k = 1 W/m·K, $\alpha = k/\rho c = 5.68 \times 10^{-7}\ m^2/s$; *Table A.4*, Air ($T_f \approx 500$ K, 1 atm): $\nu = 38.79 \times 10^{-6}\ m^2/s$, k = 0.0407 W/m·K, Pr = 0.684.

ANALYSIS: (a) To determine whether the lumped capacitance method is valid, determine the Biot number

$$Bi_{lc} = \frac{\bar{h}(r_o/2)}{k} \qquad (1)$$

The convection coefficient can be estimated using the Churchill-Bernstein correlation, Eq. 7.54,

$$\overline{Nu}_D = \frac{\bar{h}D}{k} = 0.3 + \frac{0.62\,Re_D^{1/2}\,Pr^{1/3}}{\left[1+(0.4/Pr)^{2/3}\right]^{1/4}}\left[1+\left(\frac{Re_D}{282,000}\right)^{5/8}\right]^{4/5}$$

$$Re_D = \frac{VD}{\nu} = 50\,m/s \times 0.020\,m \big/ 38.79\times10^{-6}\,m^2/s = 25,780$$

$$\bar{h} = \frac{0.0407\,W/m\cdot K}{0.020\,m}\left\{0.3 + \frac{0.62(25,780)^{1/2}(0.684)^{1/3}}{\left[1+(0.4/0.684)^{2/3}\right]^{1/4}}\left[1+\left(\frac{25,780}{282,000}\right)^{5/8}\right]^{4/5}\right\} = 184\ W/m^2\cdot K \quad (2)$$

Substituting for $\bar{h}$ from Eq. (2) into Eq. (1), find

$$Bi_{lc} = 184\,W/m^2\cdot K\,(0.010\,m/2)/1\,W/m\cdot K = 0.92 \qquad >> 0.1$$

Hence, the lumped capacitance method is inappropriate. Using the one-term series approximation, Eqs. 5.52 with Table 5.1,

$$\theta^* = C_1 \exp\left(-\zeta_1^2 Fo\right) J_o\left(\zeta_1 r^*\right) \qquad r^* = r/r_o = 1$$

$$\theta^* = \frac{T(r_o,t)-T_\infty}{T_i - T_\infty} = \frac{(175-350)^\circ C}{(25-350)^\circ C} = 0.54$$

$$Bi = \bar{h}r_o/k = 1.84 \qquad \zeta_1 = 1.546\ rad \qquad C_1 = 1.318$$

Continued...

PROBLEM 7.71 (Cont.)

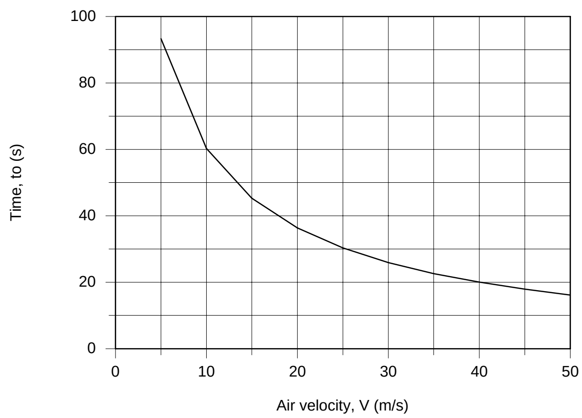
$0.54 = 1.318\exp[-(1.546\text{rad})^2 Fo]J_o(1.546 \times 1)$

Using Table B.4 to evaluate $J_o(1.546) = 0.4859$, find Fo = 0.0725 where

$$Fo = \frac{\alpha t_o}{r_o^2} = \frac{5.68\times10^{-7}\,m^2/s\times t_o}{(0.010\,m)^2} = 5.68\times10^{-3} t_o \quad (6)$$

$$t_o = 12.8s$$ <

(b) Using the *IHT Model*, *Transient Conduction*, *Cylinder*, and the *Tool*, *Correlations*, *External Flow*, *Cylinder*, results for the time-to-reach a surface temperature of 175°C as a function of air velocity V are plotted below.



COMMENTS: (1) Using the *IHT Tool*, *Correlations*, *External Flow*, *Cylinder*, the effect of the film temperature T_f on the estimated convection coefficient with V = 50 m/s can be readily evaluated.

T_f (K)	460	500	623
$\bar{h}$ ($W/m^2 \cdot K$)	187	184	176

At early times, $\bar{h}$ = 184 $W/m^2 \cdot K$ is a good estimate, while as the cylinder temperature approaches the airsteam temperature, the effect starts to be noticeable (10% decrease).

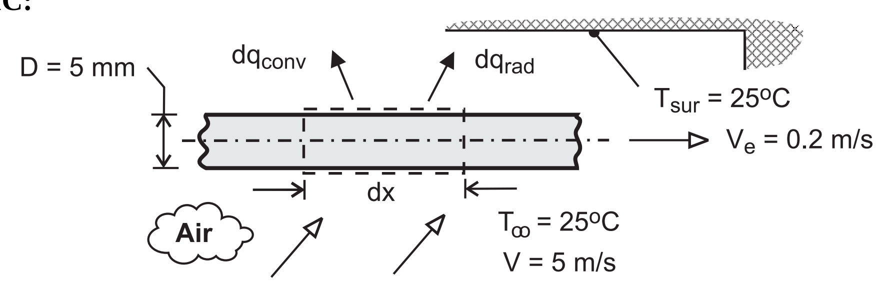
(2) The IHT analysis performed for part (b) was developed in two parts. Using a known value for $\bar{h}$, the *Transient Conduction, Cylinder Model* was tested. Separately, the *Correlation Tools* was assembled and tested. Then, the two files were merged to give the workspace for determining the time-to-reach 175°C as a function of velocity V.

PROBLEM 7.72

KNOWN: Velocity, diameter, initial temperature and properties of extruded wire. Temperature and velocity of air. Temperature of surroundings.

FIND: (a) Differential equation for temperature distribution T(x), (b) Exact solution for negligible radiation and corresponding value of temperature at prescribed length of wire, (c) Effect of radiation on temperature of wire at prescribed length. Effect of wire velocity and emissivity on temperature distribution.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible variation of wire temperature in radial direction, (2) Negligible effect of axial conduction along the wire, (3) Constant properties, (4) Radiation exchange between small surface and large enclosure, (5) Motion of wire has a negligible effect on the convection coefficient ($V_e << V$).

PROPERTIES: Prescribed. Copper: $\rho = 8900\,kg/m^3$, $c_p = 400\,J/kg\cdot K$, $\varepsilon = 0.55$. Air: $k = 0.037\,W/m\cdot K$, $\nu = 3\times10^{-5}\,m^2/s$, $Pr = 0.69$.

ANALYSIS: (a) Applying conservation of energy to a stationary control surface, through which the wire moves, steady-state conditions exist and $\dot{E}_{in} - \dot{E}_{out} = 0$. Hence, with *inflow* due to *advection* and *outflow* due to *advection*, *convection* and *radiation*,

$$\rho V_e A_c c_p T - \rho V_e A_c c_p (T + dT) - dq_{conv} - dq_{rad} = 0$$

$$-\rho V_e \left(\pi D^2/4\right) c_p dT - \pi D dx\left[\bar{h}(T - T_\infty) + \varepsilon\sigma\left(T^4 - T_{sur}^4\right)\right] = 0$$

$$\frac{dT}{dx} = -\frac{4}{\rho V_e D c_p}\left[\bar{h}(T - T_\infty) + \varepsilon\sigma\left(T^4 - T_{sur}^4\right)\right] \qquad (1) \quad <$$

Alternatively, if the control surface is fixed to the wire, conditions are transient and the energy balance is of the form, $-\dot{E}_{out} = \dot{E}_{st}$, or

$$-\pi D\,dx\left[\bar{h}(T - T_\infty) + \varepsilon\sigma\left(T^4 - T_{sur}^4\right)\right] = \rho\left(\frac{\pi D^2}{4}dx\right)c_p \frac{dT}{dt}$$

$$\frac{dT}{dt} = -\frac{4}{\rho D c_p}\left[\bar{h}(T - T_\infty) + \varepsilon\sigma\left(T^4 - T_{sur}^4\right)\right]$$

Dividing the left- and right-hand sides of the equation by dx/dt and $V_e = dx/dt$, respectively, Eq. (1) is obtained.

(b) Neglecting radiation, separating variables and integrating, Eq. (1) becomes

$$\int_{T_i}^{T} \frac{dT}{T - T_\infty} = -\frac{4\bar{h}}{\rho V_e D c_p}\int_0^x dx$$

Continued …

$$\ln\left(\frac{T - T_\infty}{T_i - T_\infty}\right) = -\frac{4\bar{h}\,x}{\rho V_e\, D\, c_p}$$

$$T = T_\infty + \left(T_i - T_\infty\right)\exp\left(-\frac{4\bar{h}x}{\rho V_e\, D\, c_p}\right) \qquad (2)$$ <

With $Re_D = VD/\nu = 5\,m/s \times 0.005\,m / 3\times10^{-5} m^2/s = 833$, the Churchill-Bernstein correlation yields

$$\overline{Nu}_D = 0.3 + \frac{0.62(833)^{1/2}(0.69)^{1/3}}{\left[1+(0.4/0.69)^{2/3}\right]^{1/4}}\left[1+\left(\frac{833}{282,000}\right)^{5/8}\right]^{4/5} = 14.4$$

$$\bar{h} = \frac{k}{D}\overline{Nu}_D = \frac{0.037\,W/m\cdot K}{0.005m}14.4 = 107\,W/m^2\cdot K$$

Hence, applying Eq. (2) at x = L,

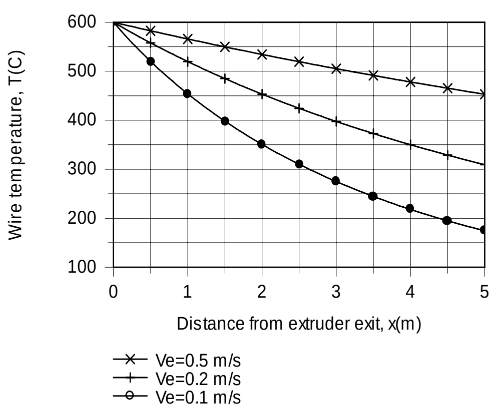
$$T_o = 25°C + (575°C)\exp\left(-\frac{4\times107\,W/m^2\cdot K\times5m}{8900\,kg/m^3\times0.2\,m/s\times0.005m\times400\,J/kg\cdot K}\right)$$

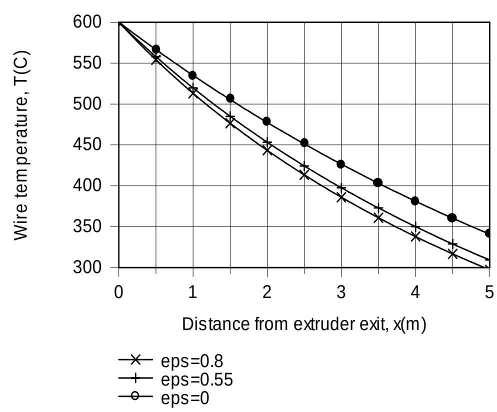
$$T_o = 340°C$$ <

(c) Using the DER function of IHT, Eq. (1) may be numerically integrated from x = 0 to x = L = 5.0m to obtain

$$T_o = 309°C$$ <

Hence, radiation makes a discernable contribution to cooling of the wire. IHT was also used to obtain the following distributions.





The speed with which the wire is drawn from the extruder has a significant influence on the temperature distribution. The temperature decay decreases with increasing V_e due to the increasing effect of advection on energy transfer in the x direction. The effect of the surface emissivity is less pronounced, although, as expected, the temperature decay becomes more pronounced with increasing ε.

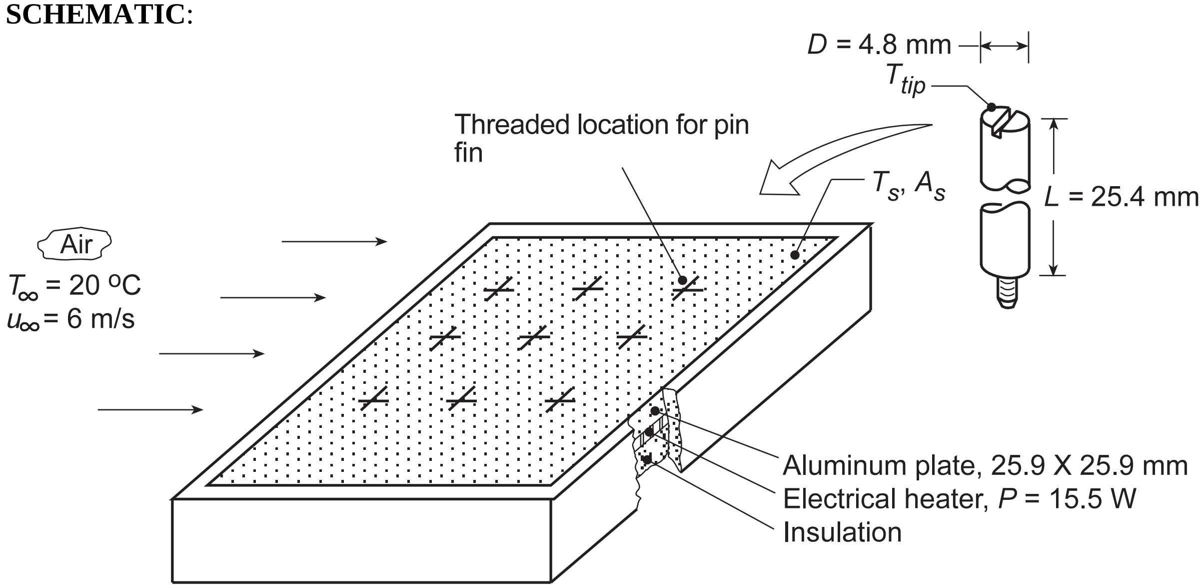
COMMENTS: (1) A critical parameter in wire extrusion processes is the *coiling temperature*, that is, the temperature at which the wire may be safely coiled for subsequent storage or shipment. The larger the production rate (V_e), the longer the cooling distance needed to achieve a desired coiling temperature. (2) Cooling may be enhanced by increasing the cross-flow velocity, and the specific effect of V may also be explored.

PROBLEM 7.73

KNOWN: Experimental apparatus comprised of a flat plate subjected to an airstream in parallel flow. Electrical patch heater on backside dissipates 15.5 W for all conditions. Pin fins fabricated from brass with prescribed diameter and length can be firmly attached to the plate. Fin tip and base temperatures observed for five different configurations (N, number of fins).

FIND: (a) The thermal resistance between the plate and airstream for the five configurations, (b) Model of the plate-fin system using appropriate convection correlations to predict the thermal resistances for the five configurations; compare predictions and observations; explain differences, and (b) Predict thermal resistances when the airstream velocity is doubled.

SCHEMATIC:



Experimental observations:

N	T_{tip} (°C)	T_s (°C)
0	--	70.2
1	40.6	67.4
2	39.5	64.7
5	36.4	57.4
8	34.2	52.1

ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible effect of flow interactions between pins, (3) Negligible radiation exchange with surroundings, (4) All heater power is transferred to airstream, and (5) Constant properties.

PROPERTIES: *Table A.4*, Air (T_f = 310 K, 1 atm): k = 0.0270 W/m·K, $\nu = 1.69 \times 10^{-5}$ m^2/s, Pr = 0.706; *Table A.1*, Brass (T = 300 K): k = 110 W/m·K.

ANALYSIS: (a) The thermal resistance between the plate and the airstream is defined as

$$R_{tot} = \frac{T_s - T_\infty}{q} \qquad (1)$$

The heat rate is 15.5 W for all configurations and using T_s values from the above table with T_∞ = 20°C, find

Continued...

PROBLEM 7.73 (Cont.)

N	0	1	2	5	8
R_{tot} (K/W)	3.24	3.06	2.88	2.41	2.07

<

(b) The thermal resistance of the plate-fin system can be expressed as

$$R_{tot} = \left[1/R_{base} + N/R_{fin}\right]^{-1} \quad (2)$$

where the thermal resistance of the exposed portion of the base, A_b, is

$$R_{base} = \frac{1}{\bar{h}_b A_b} \quad (3)$$

$$A_b = A_s - NA_c \quad (4)$$

where A_c is the cross-sectional area of a fin and A_s is the plate surface area. Approximating the airstream over the plate as parallel flow over a plate, use the *IHT Correlation Tool*, *External Flow*, *Flat Plate* assuming the flow is turbulated by the leading edge, to find

$$\bar{h}_b = 51\,W/m^2 \cdot K.$$

From the experimental observation with no fins (N = 0), the convection coefficient was measured as

$$\bar{h}_{b,cxp} = \frac{q}{A_s(T_s - T_\infty)} = \frac{15.5\,W}{(0.0259\,m)^2(70.2 - 20)^\circ C} = 460\,W/m^2 \cdot K$$

Since the predicted coefficient is nearly an order of magnitude lower, we chose to use the experimental value in our subsequent analyses to predict overall system thermal resistance.

Approximating the airstream over a pin fin as cross-flow over a cylinder, use the *IHT Correlation Tool*, *External Flow*, *Cylinder* to find

$$\bar{h}_{fin} = 118\,W/m^2 \cdot K.$$

Using the *IHT Extended Surface Model* for the *Rectangular Pin Fin* (*Temperature Distribution and Heat Rate*) with a convection tip condition, the following fin thermal resistance was found as

$$R_{fin} = 25.4\,K/W$$

Using the foregoing values for R_{fin} and $\bar{h}_b$, the thermal resistances of the plate-fin system are tabulated below.

N	0	1	2	4	8
R_{base} (K/W)	3.241	3.331	3.426	3.746	4.133
R_{fin} (K/W)	--	25.4	12.7	5.08	3.18
R_{tot} (K/W)	3.24	2.95	2.70	2.16	1.80

<

By comparison with the experimental results of part (a), note that we assured agreement for the N = 0 condition by using the measured rather than estimated (correlation) convection coefficient. The predicted thermal resistances are systematically lower than the experimental values, with the worst case (N = 8) being 13% lower.

Continued...

PROBLEM 7.73 (Cont.)

(c) The effect of doubling the velocity, from u_∞ = 6 to 12 m/s, will cause the fin convection coefficient to increase from $\overline{h}_{fin}$ = 118 to 169 W/m^2·K. For the base convection coefficient, we'll assume the flow is fully turbulent so that $\overline{h} \sim (u_\infty)^{0.8}$ according to Eq. 7.38, hence

$$\overline{h}_b(12\,m/s) = \overline{h}_b(6\,m/s)\left(\frac{12}{6}\right)^{0.8} = 460\,W/m^2\cdot K(2)^{0.8} = 800\,W/m^2\cdot K$$

Using the same procedure as above, find

N	0	1	2	4	8
R_{base} (K/W)	1.863	1.915	1.970	2.154	2.376
R_{fin} (K/W)	--	18.96	9.480	4.740	2.370
R_{tot} (K/W)	1.86	1.74	1.63	1.48	1.19

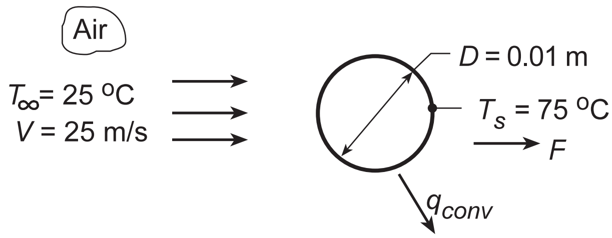
The effect of doubling the airstream velocity is to reduce the thermal resistance by approximately 35%.

PROBLEM 7.74

KNOWN: Temperature and velocity of air flow over a sphere of prescribed surface temperature and diameter.

FIND: (a) Drag force, (b) Heat transfer rate with air velocity of 25 m/s; and (c) Compute and plot the heat rate as a function of air velocity for the range $1 \le V \le 25$ m/s.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform surface temperature, (3) Negligible radiation exchange with surroundings.

PROPERTIES: *Table A.4*, Air (T_∞ = 298 K, 1 atm): $\mu = 184 \times 10^{-7}$ N·s/m^2; $\nu = 15.71 \times 10^{-6}$ m^2/s, k = 0.0261 W/m·K, Pr = 0.71; (T_s = 348 K): $\mu = 208 \times 10^{-7}$ N·s/m^2; (T_f = 323 K): $\nu = 18.2 \times 10^{-6}$ m^2/s, ρ = 1.085 kg/m^3.

ANALYSIS: (a) Working with properties evaluated at T_f

$$Re_D = \frac{VD}{\nu} = \frac{25\,m/s\left(0.01m\right)}{18.2\times10^{-6}\,m^2/s} = 1.37\times10^4$$

and from Fig. 7.9, find $C_D \approx 0.4$. Hence

$$F_D = C_D\left(\pi D^2/4\right)\left(\rho V^2/2\right) = 0.4(\pi/4)(0.01m)^2\,1.085\,kg/m^3\,(25\,m/s)^2/2 = 0.011\,N \quad <$$

(b) With

$$Re_D = \frac{VD}{\nu} = \frac{25\,m/s\left(0.01m\right)}{15.71\times10^{-6}\,m^2/s} = 1.59\times10^4$$

it follows from the Whitaker relation that

$$\overline{Nu}_D = 2 + \left[0.4\,Re_D^{1/2} + 0.06\,Re_D^{2/3}\right]Pr^{0.4}\left(\frac{\mu}{\mu_s}\right)^{1/4}$$

$$\overline{Nu}_D = 2 + \left[0.4\left(1.59\times10^4\right)^{1/2} + 0.06\left(1.59\times10^4\right)^{2/3}\right](0.71)^{0.4}\left(\frac{184}{208}\right)^{1/4} = 76.7$$

Hence, the convection coefficient and convection heat rate are

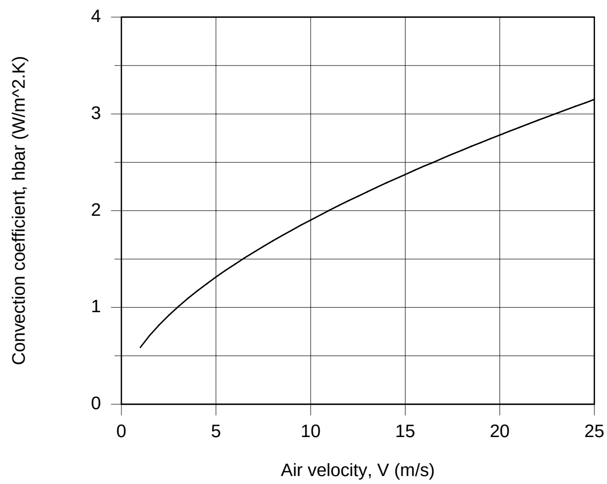
$$\bar{h} = \overline{Nu}_D\frac{k}{D} = 76.7\frac{0.0261\,W/m\cdot K}{0.01m} = 200\,W/m^2\cdot K$$

$$q = \bar{h}\pi D^2\left(T_s - T_\infty\right) = 200\,W/m^2\cdot K\times\pi\left(0.01m\right)^2\left(75-25\right)^\circ C = 3.14\,W \quad <$$

Continued...

PROBLEM 7.74 (Cont.)

(c) Using the *IHT Correlation Tool*, *External Flow*, *Sphere*, the average coefficient and heat rate were calculated and are plotted below.



COMMENTS: (1) A copy of the IHT Workspace used to generate the above plot is shown below.

```

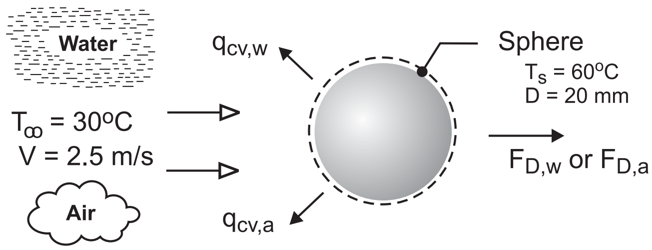
PROBLEM 7.75

KNOWN: Sphere with a diameter of 20 mm and a surface temperature of 60°C that is immersed in a fluid at a temperature of 30°C with a velocity of 2.5 m/s.

FIND: The drag force and the heat rate when the fluid is (a) water and (b) air at atmospheric pressure. Explain why the results for the two fluids are so different.

SCHEMATIC:



ASSUMPTIONS: (1) Flow over a smooth sphere, (2) Constant properties.

PROPERTIES: *Table A-6*, Water (T_∞ = 30°C = 303 K): $\mu = 8.034 \times 10^{-4}$ N·s/m^2, $\nu = 8.068 \times 10^{-7}$ m^2/s, k = 0.6172 W/m·K, Pr = 5.45; Water (T_s = 333 K): $\mu_s = 4.674 \times 10^{-4}$ N·s/m^2; *Table A-4*, Air (T_∞ = 30°C = 303 K, 1 atm): $\mu = 1.86 \times 10^{-5}$ N·s/m^2, $\nu = 1.619 \times 10^{-5}$ m^2/s, k = 0.0265 W/m·K, Pr = 0.707; Air (T_∞ = 333 K): $\mu_s = 2.002 \times 10^{-5}$ N·s/m^2.

ANALYSIS: The drag force, F_o, for the sphere is determined from the drag coefficient, Eq. 7.50,

$$C_D = \frac{F_D}{A_f\left(\rho V^2/2\right)}$$

where $A_f = \pi D^2/4$ is the frontal area. C_D is a function of the Reynolds number $Re_D = VD/\nu$ as represented in Figure 7.9. For the convection rate equation**,**

$$q = \overline{h}_D A_s\left(T_s - T_\infty\right)$$

where $A_s = \pi D^2$ is the surface area and the convection coefficient is estimated using the Whitaker correlation, Eq. 7.56,

$$\overline{Nu}_D = 2 + \left[0.4 Re_D^{1/2} + 0.06 Re_D^{2/3}\right] Pr^{0.4}\left(\mu/\mu_s\right)^{1/4}$$

where all properties except μ_s are evaluated at T_∞. For convenience we will evaluate properties required for the drag force at T_∞. The results of the analyses for the two fluids are tabulated below.

Fluid	Re_D	C_D	F_D (N)	$\overline{Nu}_D$	$\overline{h}_D\left(W/m^2\cdot K\right)$	q(W)
water	6.198×10^4	0.5	0.489	439	13,540	510
air	3.088×10^3	0.4	0.452×10^{-3}	31.9	42.3	1.59

The frontal and surface areas, respectively, are $A_f = 3.142 \times 10^{-4}$ m^2 and $A_s = 1.257 \times 10^{-3}$ m^2.

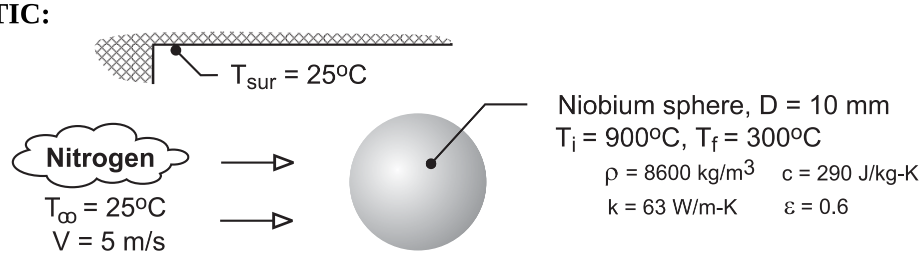
COMMENTS: The Reynolds number is the ratio of inertia to viscous forces. We associate higher viscous shear and heat transfer with larger Reynolds numbers. The drag force also depends upon the fluid density, which further explains why F_D for water is much larger, by a factor of 1000, than for air. Nu_D is dependent upon Re_D^n where n is 1/2 to 2/3, and represents the dimensionless temperature gradient at the surface. Since the thermal conductivity of water is nearly 20 times that of air, we expect a significant difference between $\overline{h}_D$ and q for the two fluids.

PROBLEM 7.76

KNOWN: Diameter, properties and initial temperature of niobium sphere. Velocity and temperature of nitrogen. Temperature of surroundings.

FIND: (a) Time for sphere to cool to prescribed temperature if radiation is neglected, (b) Cooling time if radiation is considered. Effect of flow velocity.

SCHEMATIC:



ASSUMPTIONS: (1) Lumped capacitance method is valid, (2) Constant properties, (3) Radiation exchange with large surroundings.

PROPERTIES: *Table A-4*, nitrogen $(T_\infty = 298\text{K})$: $\mu = 177\times10^{-7}\ \text{N}\cdot\text{s/m}^2$, $\nu = 15.7\times10^{-6}\ \text{m}^2/\text{s}$, $k = 0.0257\ \text{W/m}\cdot\text{K}$, $\text{Pr} = 0.716$. *Table A-4*, nitrogen $(\overline{T}_s = 873\text{K})$: $\mu_s = 368\times10^{-7}\ \text{N}\cdot\text{s/m}^2$.

ANALYSIS: (a) Neglecting radiation, the cooling time may be determined from Eq. (5.5),

$$t = \frac{\rho\left(\pi D^3/6\right)c}{\overline{h}\pi D^2}\ln\frac{\theta_i}{\theta} = \frac{\rho c D}{6\overline{h}}\ln\frac{T_i - T_\infty}{T_f - T_\infty}$$

The convection coefficient is obtained from the Whitaker correlation with $Re_D = VD/\nu$ $= 5\ \text{m/s}\times0.01\text{m}/15.7\times10^{-6}\ \text{m}^2/\text{s} = 3185$. Hence,

$$\overline{Nu}_D = \left(\overline{h}D/k\right) = 2 + \left(0.4\,Re_D^{1/2} + 0.06\,Re_D^{2/3}\right)Pr^{0.4}\left(\mu/\mu_s\right)^{1/4}$$

$$\overline{h} = \frac{0.0257\ \text{W/m}\cdot\text{K}}{0.01\text{m}}\left\{2 + \left[0.4(3185)^{1/2} + 0.06(3185)^{2/3}\right](0.716)^{0.4}\left(\frac{177}{368}\right)^{0.25}\right\} = 71.8\ \text{W/m}^2\cdot\text{K}$$

$$t = \frac{8600\ \text{kg/m}^3\times290\ \text{J/kg}\cdot\text{K}\times0.01\text{m}}{6\times71.8\ \text{W/m}^2\cdot\text{K}}\ln\frac{(900-25)}{(300-25)} = 67\,\text{s}$$ <

(b) If the effect of radiation is considered, the cooling time can be obtained by integrating Eq. (5.15). With $A_s/V = \pi D^2/\left(\pi D^3/6\right) = 6/D$, the appropriate form of the equation is

$$\frac{dT}{dt} = -\frac{6}{\rho c D}\left[\overline{h}\left(T - T_\infty\right) + \varepsilon\sigma\left(T^4 - T_{sur}^4\right)\right]$$

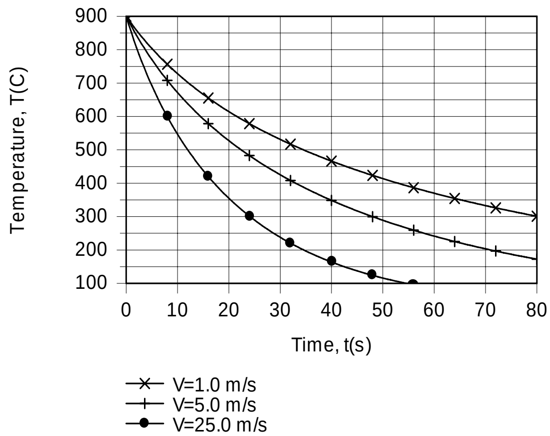
Using the DER function of IHT to integrate this equation over the limits from $T_i = 1173\,\text{K}$ to $T_f = 573\,\text{K}$, we obtain

$$t = 48\,\text{s}$$ <

Continued …

PROBLEM 7.76 (Cont.)

For V = 1.0 and 25.0 m/s, the cooling times are t ≈ 80 and 24 s, respectively. Temperature histories for the three velocities are shown below.



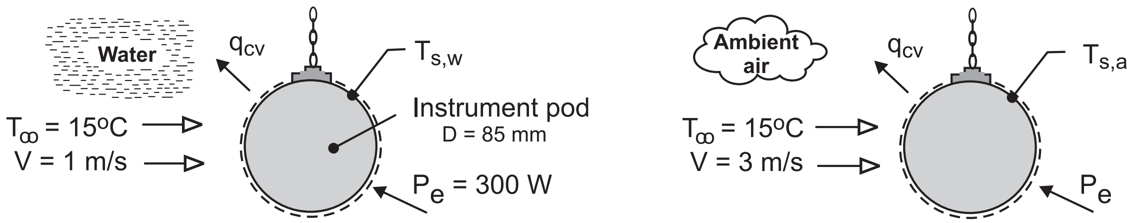
COMMENTS: The cooling time is significantly affected by the flow velocity.

PROBLEM 7.77

KNOWN: An underwater instrument pod having a spherical shape with a diameter of 85 mm dissipating 300 W.

FIND: Estimate the surface temperature of the pod for these conditions: (a) when submersed in a bay where the water temperature is 15°C and the current is 1 m/s, and (b) after being hauled out of the water *without deactivating the power* and suspended in the ambient where the air temperature is 15°C and the wind speed is 3 m/s.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Flow over a smooth sphere, (3) Uniform surface temperatures, (4) Negligible radiation heat transfer for air (a) condition, and (5) Constant properties.

PROPERTIES: *Table A-6*, Water (T_∞ = 15°C = 288 K): μ = 0.001053 N·s/m^2, ν = 1.139 × 10^{-6} m^2/s, k = 0.5948 W/m·K, Pr = 8.06; *Table A-4*, Air (T_∞ = 288 K, 1 atm): μ = 1.788 × 10^{-5} N·s/m^2, ν = 1.482 × 10^{-5} m^2/s, k = 0.02534 W/m·K, Pr = 0.710 ; Air (T_s = 945 K): μ_s = 4.099 × 10^{-5} N·s/m^2.

ANALYSIS: The energy balance for the submersed-in-water (w) and suspended-in-air (a) conditions are represented in the schematics above and have the form

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = -q_{cv} + P_e = 0 \qquad (1)$$

$$-\bar{h}_D A_s \left(T_s - T_\infty\right) + P_e = 0$$

where $A_s = \pi D^2$ and $\bar{h}_D$ is estimated using the Whitaker correlation, Eq. 7.56,

$$\overline{Nu}_D = 2 + \left[0.4 Re_D^{1/2} + 0.06 Re_D^{2/3}\right] Pr^{0.4} \left(\mu / \mu_s\right)^{1/4} \qquad (2)$$

where all properties except μ_s are evaluated at T_∞. The results are tabulated below.

Condition	Re_D	$\overline{Nu}_D$	$\bar{h}_D$ (W/m^2·K)	T_s (°C)
(w) water	7.465 × 10^4	499	3491	18.8
(a) air	1.72 × 10^4	67.5	20.1	672

COMMENTS: (1) While submerged and dissipating 300 W, the pod is safely operating at a temperature slightly above that of the water. When hauled from the water and suspended in air, the pod temperature increases to a destruction temperature (672°C). The pod gets smoked!

(2) The assumption that $\mu/\mu_s \approx 1$ is appropriate for the water (w) condition. For the air (a) condition, μ/μ_s = 0.436 and the final term of the correlation is significant. Recognize that radiation exchange with the surroundings for the air condition should be considered for an improved estimate.

Continued …

PROBLEM 7.77 (Cont.)

(3) Why such a difference in T_s for the water (w) and air (a) conditions? From the results table note that the Re_D, Nu_D, and $\overline{h}_D$ are, respectively, 4x, 7x and 170x times larger for water compared to air. Water, because of its thermophysical properties which drive the magnitude of $\overline{h}_D$, is a much better coolant than air for similar flow conditions.

```
/* Comment:  Because Ts is much larger than Tinf for the in-air operation, the ratio of mu / mus
exceeds the limits for the correlation.  Hence, a warning message comes with the IHT solution.  */

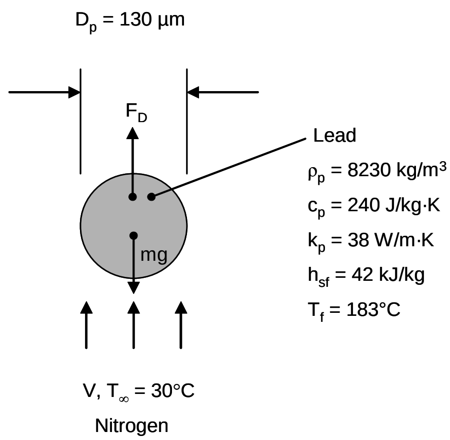
PROBLEM 7.78

KNOWN: Method to manufacture small diameter lead solder balls. Properties of D = 130 μm diameter particles ejected into nitrogen gas at V = 2 m/s. Nitrogen temperature and pressure, initial particle temperature. Piezoelectric device oscillation frequency.

FIND: (a) Terminal velocity of the droplets and distance traveled when a droplet completely solidifies, (b) Separation distance between droplets and pot size needed to produce solder balls continuously for one week.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible radiation heat transfer, (2) lumped capacitance thermal response.

PROPERTIES: Table A.4, Nitrogen: ($T_f \approx (T_i + T_\infty)/2$ = (225°C + 30 °C)/2 = 127.5 °C ≈ 400 K): ρ = 0.8425 kg/m^3, $\nu = 26.16 \times 10^{-6}$ m^2/s. ($\overline{T}_s$ = (225°C + 183°C)/2 = 205°C = 477 K: $\mu_s = 248 \times 10^{-7}$ N·s/m^2. (T_∞ = 30°C = 303 K): ρ = 1.1233 kg/m^3, $\nu = 15.86 \times 10^{-6}$ m^2/s, k = 0.0259 W/m·K, $\mu = 178 \times 10^{-7}$ N·s/m^2, Pr = 0.716.

ANALYSIS:

(a) A force balance on the particle yields

$$F_D = mg = \pi\left(D_p/2\right)^2 C_D\rho_f V^2/2 = \frac{4}{3}\pi\left(D_p/2\right)^3\rho_p g$$

Which may be rearranged to yield

$$C_D = \frac{4}{3} D_p\left(\rho_p/\rho_f\right)g/V^2$$

$$C_D = \frac{4}{3} \times 130 \times 10^{-6}\text{ m} \times (8230/0.8425) \times 9.8\text{ m/s}^2/V^2$$

$$C_D = (16.59\text{m}^2/\text{s}^2)/V^2 \qquad (1)$$

and

Continued…

PROBLEM 7.78 (Cont.)

$$Re_D = \frac{VD_p}{\nu} = V \times 130 \times 10^{-6}\ m/26.16 \times 10^{-6}\ m^2/s$$

$$Re_D = (4.97 s/m) \times V \qquad (2)$$

Equations 1 and 2 may be solved for C_D and Re_D for any value of V. The resulting values of C_D and Re_D must be consistent with the results of Figure 7.9.

A trial-and-error solution yields $V = 2.03$ m/s, $C_D = 4.03$, $Re_D = 10.09$ from solution of Equations 1 and 2. From Figure 7.9, at $Re_D = 10$, $C_D = 4$. Therefore $V \approx 2$ m/s. <

We note that the terminal velocity is identical to the injection velocity. Hence, the particles travel at constant velocity. The particle cooling process occurs in two steps.

<u>Step One:</u> Particle cooling to $T_f = 183°C$.
With nitrogen properties evaluated at $T_\infty = 30°C$, the Reynolds number is

$$Re_D = \frac{2\ m/s \times 130 \times 10^{-6}\ m}{15.86 \times 10^{-6}\ m^2/s} = 16.39$$

The Whitaker correlation yields

$$\overline{Nu}_D = 2 + \left[0.4\sqrt{16.39} + 0.06 \times 16.39^{2/3}\right] \times 0.716^{0.4} \times \left(\frac{178}{248}\right)^{1/4} = 3.62$$

Therefore

$$\overline{h}_D = \overline{Nu}_D k/D_p = 3.62 \times 0.0259\ W/m \cdot K/130 \times 10^{-6}\ m = 721\ W/m^2 \cdot K$$

Using Equation 5.6 with $A_s = 4\pi(D/2)^2 = 4 \times \pi \times (130 \times 10^{-6}\ m/2)^2 = 53.1 \times 10^{-9}\ m^2$,

$\forall = (4/3)\ \pi\ (D/2)^3 = (4/3) \times \pi \times (130 \times 10^{-6}\ m/2)^3 = 1.15 \times 10^{-12}\ m^3$,

$$\frac{T - T_\infty}{T_i - T_\infty} = \frac{183 - 30}{225 - 30} = 0.785 = \exp\left[-\left(\frac{721\ W/m^2 \cdot K \times 53.1 \times 10^{-9}\ m^2}{8230\ kg/m^3 \times 1.15 \times 10^{-12}\ m^3 \times 240\ J/kg \cdot K}\right) \times t_1\right]$$

from which

$$t_1 = 14.3 \times 10^{-3}\ s$$

<u>Step Two:</u> Particle solidification at $T_f = 183°C$.
An energy balance on the particle during solidification yields

$$\dot{E}_{st} + \dot{E}_{out} = 0$$

or

$$-\forall \rho_p h_{sf} - hA_s(T_f - T_\infty)t_2$$

or

$$t_2 = \frac{1.15 \times 10^{-12}\ m^3 \times 8230\ kg/m^3 \times 42{,}000\ J/kg}{721\ W/m^2 \cdot K \times 53.1 \times 10^{-9}\ m^2 \times (183 - 30)°C} = 67.6 \times 10^{-3}\ s$$

Therefore, the time to completely solidify is

Continued…

PROBLEM 7.78 (Cont.)

$T = t_1 + t_2 = 14.3 \times 10^{-3}$ s + 67.6×10^{-3} s = 82×10^{-3} s

and the distance traveled is L = 2m/s × 0.082s = 0.163 m <

(b) The distance that one particle travels is

$$L = (2\text{ m/s}) / (1800\text{ s}^{-1}) = 1.11\text{ mm}$$ <

The required pot size for one week of operation is

$$\forall_{pot} = 1.15 \times 10^{-12}\ \text{m}^3/\text{particle} \times 1800\ \text{particles/s} \times 7\ \text{days} \times 24\ \text{h/day} \times 3600\ \text{s/h}$$

$$\forall_{pot} = 1.25 \times 10^{-3}\ \text{m}^3$$ <

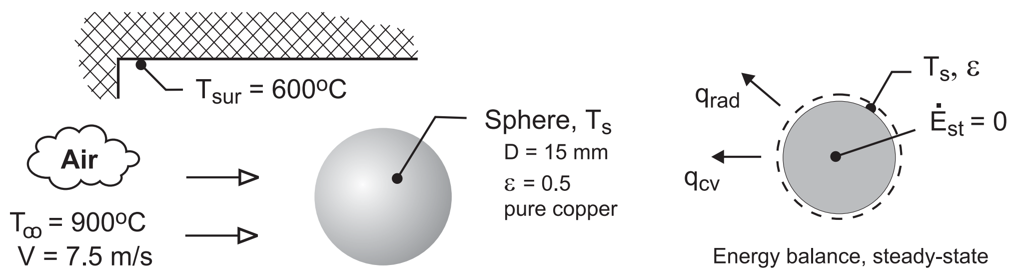
COMMENTS: (1) The Biot number associated with the cooling of the particle is $Bi = h(D_p/6)/k_p$ = 721 W/m^2·K × (130 × 10^{-6} m/s)/(38 W/m·K) = 0.0004 << 0.1. Therefore, the lumped capacitance assumption is valid. (2) The maximum possible radiation heat transfer coefficient is associated with the initial particle temperature and an emissivity of unity. Assuming a surroundings temperature of 30°C = 303 K, we find a radiation heat transfer coefficient of h_r = 5.67 × 10^{-8} W/m^2·K^4 × (498 + 303) K × (498^2 + 303^2) K^2 = 15 W/m^2·K. Therefore, radiation heat transfer is negligible. (3) The terminal velocity of the very small spherical particle is relatively low. This is because the surface area to weight ratio of a sphere is inversely proportional to the sphere diameter. As the sphere becomes small, drag forces become relatively large at relatively low velocities.

PROBLEM 7.79

KNOWN: A spherical workpiece of pure copper with a diameter of 15 mm and emissivity of 0.5 is suspended in a large furnace with walls at a uniform temperature of 600°C. The air flow over the workpiece has a temperature of 900°C with a velocity of 7.5 m/s.

FIND: (a) The steady-state temperature of the workpiece; (b) Estimate the time required for the workpiece to reach within 5°C of the steady-state temperature if its initial, uniform temperature is 25°C; (c) Estimate the steady-state temperature of the workpiece if the air velocity is doubled with all other conditions remaining the same; also, determine the time required for the workpiece to reach within 5°C of this value. Plot on the same graph the workpiece temperature histories for the two air velocity conditions**.**

SCHEMATIC:



ASSUMPTIONS: (1) Flow over a smooth sphere, (2) Sphere behaves as spacewise isothermal object; lumped capacitance method is valid, (3) Sphere is small object in large, isothermal surroundings, and (4) Constant properties.

PROPERTIES: *Table A-4*, Air (T_∞ = 1173 K, 1 atm): $\mu = 4.665 \times 10^{-5}$ N·s/m^2, $\nu = 0.0001572$ m^2/s, k = 0.075 W/m·K, Pr = 0.728; Air (T_s = 1010 K, 1 atm): $\mu_s = 4.268 \times 10^{-5}$ N·s/m^2.

ANALYSIS: (a) The steady-state temperature is determined from the energy balance on the sphere as represented in the schematic above.

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = 0 \qquad -q_{cv} - q_{rad} + 0 = 0$$

$$-\overline{h}_D A_s \left(T_s - T_\infty\right) - \varepsilon A_s \sigma \left(T_s^4 - T_{sur}^4\right) = 0 \qquad (1)$$

where $A_s = \pi D^2/4$. The convection coefficient can be estimated using the Whitaker correlation, Eq. 7.56, where all properties except μ_s are evaluated at T_∞. Assume T_s = 737°C = 1010 K to evaluate μ_s.

$$\overline{Nu}_D = 2 + \left[0.4\, Re_D^{1/2} + 0.06\, Re_D^{2/3}\right] Pr^{0.4} \left(\mu / \mu_s\right)^{1/4} \qquad (2)$$

See the table below for results of the correlation calculations. From the energy balance, canceling out A_s, with numerical values, find T_s.

$$-79.8\ W/m^2 \cdot K\left(T_s - 1173\right)K - 0.5 \times 5.67 \times 10^{-8} W/m^2 \cdot K^4 \left(T_s^4 - 873^4\right)K^4 = 0$$

$$T_s = 1010\ K = 737°C. \qquad <$$

(b) The time required for the sphere initially at T_i = 25°C to reach within 5°C of the steady-state temperature can be determined from the energy balance for the transient condition.

Continued …

PROBLEM 7.79 (Cont.)

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = \dot{E}_{st}$$

$$-\overline{h}_D A_s \left(T_s - T_\infty\right) - \varepsilon A_s \sigma \left(T_s^4 - T_{sur}^4\right) = \rho c \left(\pi D^3 / 6\right) \frac{dT}{dt} \qquad (3)$$

Recognize that $\overline{h}_D$ is not constant, but depends upon $T_s(t)$. Using *IHT* to perform the integration, evaluate $\overline{h}_D$, and provide pure copper properties ρ and c as a function of T_s, the time t_o for $T(t_o)$ = (737 – 5)°C = 732°C is

$$t_o = 274 \text{ s}$$ <

See Comments 1 and 2 for details on the *IHT* calculation method.

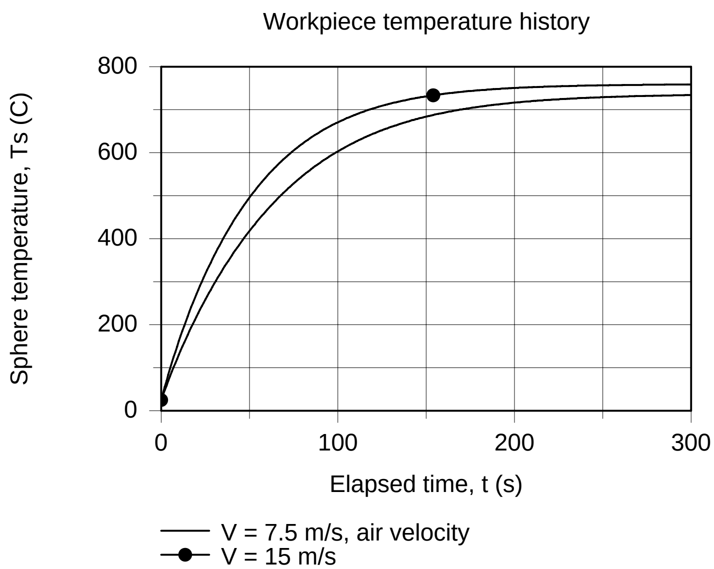
(c) Use Eq. (1) and (2) to find the steady-state temperature when the air velocity is doubled, V = 2 × 7.5 ms = 15 m/s. The results are tabulated below along with those from part (a).

Part	V (m/s)	Re_D	$\overline{Nu}_D$	$\overline{h}_D$ (W/m^2·K)	T_s (°C)
a	7.5	715.6	15.96	79.8	737
b	15	1431	22.42	112.1	760

As expected, increasing the air velocity will cause the sphere temperature to increase toward T_∞. Note that $\overline{h}_D$ increases by a factor of 1.4 as the air velocity is doubled. From correlation Eq. (2) note that $\overline{h}_D$ is approximately proportional to V^n where n is in the range 1/2 to 2/3. Using the *IHT* code for the lumped capacitance analysis, the time for $T(t_o)$ = (760 – 5)°C = 755°C is

$$t_o = 230 \text{ s}$$ <

The temperature histories for the two air velocity conditions are calculated using the foregoing transient analyses in the *IHT* workspace.



Continued …

PROBLEM 7.79 (Cont.)

COMMENTS: **(**1) The portion of the *IHT* code for performing the energy balance and evaluating the convection correlation function using the properties function follows.

```
// Convection correlation, sphere
NuDbar = NuL_bar_EF_SP(ReD,Pr,mu,mus)     // Eq 7.56
NuDbar = hbar * D / k
ReD = V * D / nu
/* All properties except mus are evaluated at Tinf. */
/*  Correlation description: External flow (EF) over a sphere (SP), average coefficient,
3.5<ReD<7.6x10^4, 0.71<Pr<380, 1.0<(mu/mus)<3.2, Whitaker correlation, Eq 7.56. See Table 7.9.  */

// Energy balance, steady-state temperature
-hbar * As * (Ts - Tinf) - eps * sigma * (Ts^4 - Tsur^4) * As = 0
As = pi * D^2
sigma = 5.67e-8

// Air property functions : From Table A.4
// Units: T(K); 1 atm pressure
mu = mu_T("Air",Tinf)         // Viscosity,  N·s/m^2
mus = mu_T("Air",Ts)          // Viscosity,  N·s/m^2
nu = nu_T("Air",Tinf)         // Kinematic viscosity, m^2/s
k = k_T("Air",Tinf)           // Thermal conductivity, W/m·K
Pr = Pr_T("Air",Tinf)         // Prandtl number

// Input variables
D = 0.015
eps = 0.5
V = 7.5
Tinf = 900 + 273
Tsur = 600 + 273
```

(2) Two modifications can be made to the code above to perform the lumped capacitance method for the transient analysis: (a) include the storage term in the energy balance and (b) provide the properties function for copper. The initial condition, T_i = 288 K, is entered as the initial condition when the solver performs the integration.

```
// Energy balance, steady-state; equilibrium temperature
-hbar * As * (Ts - Tinf) - eps * sigma * (Ts^4 - Tfur^4) * As = M * ccu * der(Ts,t)
As = pi * D^2
sigma = 5.67e-8
M = rhocu * pi * D^3 / 6

// Copper (pure) property functions : From Table A.1
// Units: T(K)
rhocu = rho_300K("Copper")             // Density, kg/m^3
kcu = k_T("Copper",Ts)       // Thermal conductivity,W/m·K
ccu = cp_T("Copper",Ts)      // Specific heat, J/kg·K
```

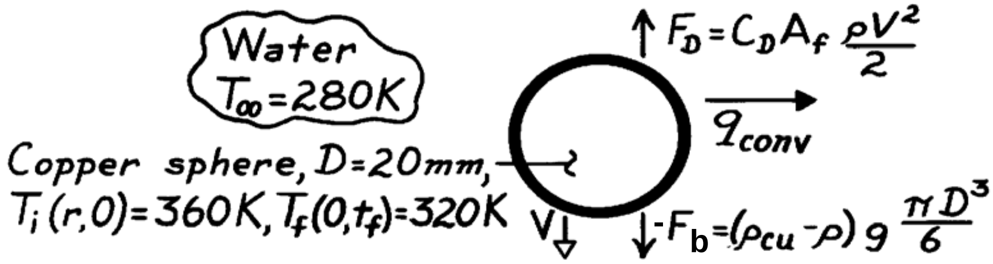
(3) Show that the lumped capacitance method is valid for this application.

PROBLEM 7.80

KNOWN: Diameter and initial and final temperatures of copper spheres quenched in a water bath.

FIND: (a) Terminal velocity in the bath, (b) Tank height.

SCHEMATIC:



ASSUMPTIONS: (1) Sphere descends at terminal velocity, (2) Uniform, but time varying surface, temperature.

PROPERTIES: *Table A-1*, Copper (350K): ρ = 8933 kg/m^3, k = 398 W/m·K, c_p = 387 J/kg·K; *Table A-6*, Water (T_∞ = 280 K): ρ = 1000 kg/m^3, $\mu = 1422 \times 10^{-6}$ N·s/m^2, k = 0.582 W/m·K, Pr = 10.26; ($T_s \approx$ 340 K): $\mu_s = 420 \times 10^{-5}$ N·s/m^2.

ANALYSIS: A force balance gives $C_D\left(\pi D^2/4\right) \rho V^2/2 = \left(\rho_{cu} - \rho\right)\ g\ \pi D^3/6$,

$$C_D\ V^2 = \frac{4D}{3}\frac{\rho_{cu} - \rho}{\rho} g = \frac{4\times 0.02\ \text{m}}{3}\cdot\frac{8933-1000}{1000} 9.8\ \text{m/s}^2 = 2.07\ \text{m}^2/\text{s}^2.$$

An iterative solution is needed, where C_D is obtained from Figure 7.9 with $Re_D = VD/\nu$ = 0.02 m V/1.42 × 10^{-6} m^2/s = 14,085 V (m/s). Convergence is achieved with

$$V \approx 2.1\ \text{m/s}$$ <

for which Re_D = 29,580 and $C_D \approx$ 0.46. Using the Whitaker expression

$$\overline{Nu}_D = 2 + \left(0.4\times 29{,}850^{1/2} + 0.06\times 29{,}850^{2/3}\right)\ (10.26)^{0.4}\left(1422/420\right)^{1/4} = 439$$

$$\bar{h} = \overline{Nu}_D\ k/D = 439\times 0.582\ \text{W/m}\cdot\text{K}/0.02\ \text{m} = 12{,}775\ \text{W/m}^2\cdot\text{K}.$$

To determine applicability of lumped capacitance method, find $Bi = \bar{h}\left(r_o/3\right)/k_{cu} = 12{,}775$ $\text{W/m}^2\cdot\text{K}\ \left(0.01\ \text{m}/3\right)/398\text{W/m}\cdot\text{K} = 0.11.$ Applicability is marginal. Using Eq. 5.53c,

$\theta_o^* = C_1 \exp(-\xi_1^2 Fo)$ and from Table 5.1 at $B_i = \bar{h}\ r_o/k$ = 0.32, C_1 = 1.0937, ξ_1 = 0.9472. Substituting into the preceding equation yields

$$0.5 = 1.0937 \exp(-0.94722\ Fo) \text{ from which}$$

$$Fo = 0.87 = \alpha t_f/r_o^2$$

With $\alpha_{cu} = k/\rho c_p$ = 398 W/m·K/(8933 kg/m^3) (387 J/kg·K) = 1.15 × 10^{-4} m^2/s, find

$$t_f = 0.87\ \left(0.01\ \text{m}\right)^2/1.15\times 10^{-4}\text{m}^2/\text{s} = 0.76\ \text{s}.$$

Required tank height is

$$H = t_f\cdot V = 0.76\ \text{s}\times 2.1\ \text{m/s} = 1.6\ \text{m}.$$ <

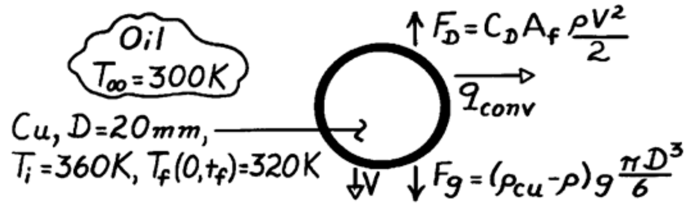
COMMENTS: Note that the terminal velocity is not reached immediately. Reduced V implies reduced $\bar{h}$ and increased t_f. The Fourier number, Fo, is greater than 0.2. Hence, use of Eq. 5.53c is justified.

PROBLEM 7.81

KNOWN: Diameter and initial and final temperatures of copper spheres quenched in an oil bath.

FIND: (a) Terminal velocity in bath, (b) Bath height.

SCHEMATIC:



ASSUMPTIONS: (1) Sphere descends at terminal velocity, (2) Uniform, but time varying, surface temperature.

PROPERTIES: *Table A-1*, Copper (350K): ρ_{cu} =8933 kg/m^3, k = 398 W/m·K, c_p = 387 J/kg·K; *Table A-5*, Oil (T_∞ = 300K): ρ = 884 kg/m^3, μ = 0.486 N·s/m^2, k = 0.145 W/m·K, Pr = 6400; ($T_s \approx$ 340K): μ = 0.0531 N·s/m^2.

ANALYSIS: (a) Force balance gives $C_D\left(\pi D^2/4\right)\rho V^2/2 = \left(\rho_{cu} - \rho\right)\, g\, \pi D^3/6$,

$$C_D\ V^2 = \frac{4D}{3}\frac{\rho_{cu} - \rho}{\rho}\ g = \frac{4 \times 0.02\ \text{m}}{3}\frac{8933 - 884}{884} 9.8\frac{\text{m}}{\text{s}^2} = 2.38\text{m}^2/\text{s}^2.$$

An iterative solution is needed, where C_D is obtained from Fig. 7.9 with

$$Re_D = \frac{VD}{\nu} = \frac{0.02\ \text{m}\ (V)}{(0.486/884)\ \text{m}^2/\text{s}} = 36.4\ V(\text{m/s}).$$

Convergence is achieved for $V \approx 1.1$ m/s <

for which Re_D = 40 and $C_D \approx$ 1.97. Using the Whitaker expression

$$\overline{Nu}_D = 2 + \left(0.4\ Re_D^{1/2} + 0.06\ Re_D^{2/3}\right) Pr^{0.4} \left(\mu/\mu_s\right)^{1/4}$$

$$\overline{Nu}_D = 2 + \left(0.4 \times 40^{1/2} + 0.06 \times 40^{2/3}\right)\ (6400)^{0.4} \left(0.486/0.0531\right)^{1/4} = 189.2$$

$$\bar{h} = \overline{Nu}_D\ k/D = 189.2 \times 0.145/0.02 = 1357\ \text{W/m}^2 \cdot \text{K}.$$

To determine applicability of the lumped capacitance method, find $Bi = \bar{h}\left(r_o/3\right)/k_{cu}$ = $1357\ \text{W/m}^2 \cdot \text{K}\ \left(0.01\ \text{m/3}\right)/398\ \text{W/m} \cdot \text{K} = 0.011$. Hence lumped capacitance method can be used; from Eq. 5.5,

$$t_f = \frac{(\rho\ c)_{cu}\ \pi D^3/6}{\bar{h}\ \pi D^2} \ell n \frac{T_i - T_\infty}{T_f - T_\infty}$$

$$t_f = \frac{8933\ \text{kg/m}^3 \times 387\ \text{J/kg} \cdot \text{K}}{1357\ \text{W/m}^2 \cdot \text{K}} \frac{0.02\ \text{m}}{6} \ell n \frac{60}{20} = 9.33\ \text{s}.$$

Required tank height is $H = t_f \cdot V$ = 9.33 s × 1.1 m/s = 10.3 m. <

COMMENTS: (1) Whitaker correlation has been used well beyond its limits (Pr >> 380). Hence estimate of $\bar{h}$ is uncertain. (2) Since terminal velocity is not reached immediately,

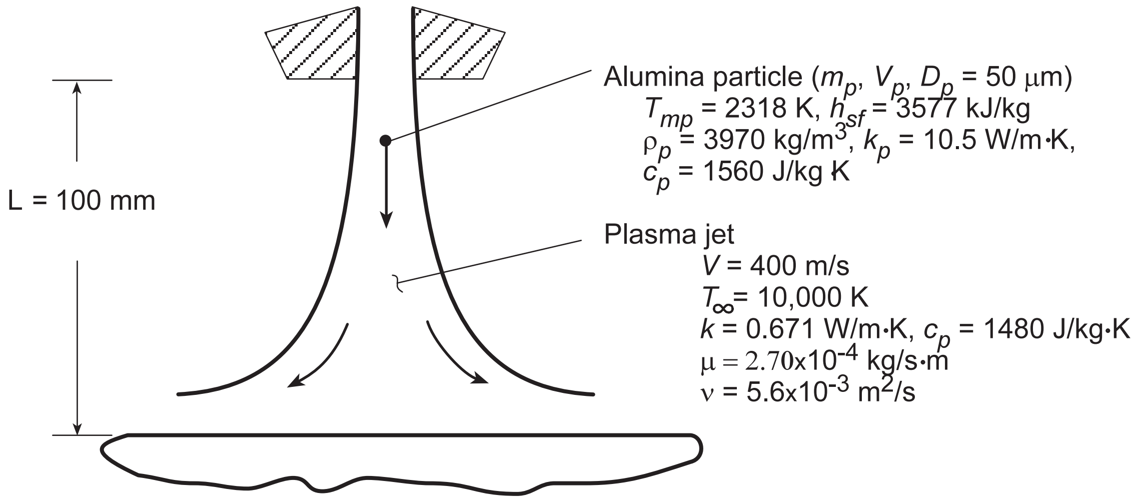
$\bar{h} < 1357\ \text{W/m}^2 \cdot \text{K}$ and $t_f > 9.33$ s.

PROBLEM 7.82

KNOWN: Velocity of plasma jet and initial particle velocity in a plasma spray coating process. Distance from particle injection to impact.

FIND: (a) Particle velocity and distance of travel as a function of time. Time-in-flight and particle impact velocity, (b) Convection heat transfer coefficient and time required to heat particle to melting point and to subsequently melt it.

SCHEMATIC:



ASSUMPTIONS: (1) Applicability of Stokes' law, (2) Constant particle and plasma properties, (3) Negligible influence of viscosity ratio in Whitaker correlation, (4) Negligible radiation effects, (5) Validity of lumped capacitance approximation.

ANALYSIS: (a) From Eqs. 7.50 and 7.55,

$$C_D \equiv \frac{F_D}{A_f\left(\rho\bar{V}^2/2\right)} = \frac{24}{Re_D} = \frac{24}{\rho\bar{V}D_p/\mu}$$

where $\bar{V} \equiv V - V_p$ is the relative velocity and $A_f = \pi D_p^2/4$. Hence, the drag force on the particle is

$$F_D = 3\pi\mu D_p\bar{V} = m_p\left(dV_p/dt\right) = -m_p\left(d\bar{V}/dt\right)$$

Separating variables and integrating from the nozzle exit, where $V_p = 0$, $\bar{V} = V$ and t = 0,

$$\int_V^{\bar{V}}\frac{d\bar{V}}{V} = -\frac{3\pi\mu D_p}{m_p}\int_0^t dt$$

$$\ln\frac{\bar{V}}{V} = -\frac{3\pi\mu D_p t}{m_p}$$

$$\bar{V} = V\exp\left(-3\pi\mu D_p t/m_p\right) = V - V_p$$

Hence,

$$V_p(t) = V\left[1 - \exp\left(-3\pi\mu D_p t/m_p\right)\right]$$ <

With $V_p = dx_p/dt$, it follows that

$$\int_o^L dx_p = \int_o^{t_f} V\left[1 - \exp\left(-3\pi\mu D_p t/m_p\right)\right]dt$$

Continued...

PROBLEM 7.82 (Cont.)

$$L = Vt_f - \frac{Vm_p}{3\pi\mu D_p}\left[1-\exp\left(-3\pi\mu D_p t_f / m_p\right)\right]$$ <

Substituting the prescribed values of D_p, L, V and the material properties, the foregoing equations yield

$$V_p = 166.7\,\text{m/s} \qquad t_f = 0.0011\,\text{s}$$ <

(b) Assuming an average value of $\bar{V}$ = 315 m/s, the Reynolds number is

$$Re_D = \frac{315\,\text{m/s}\times 50\times 10^{-6}\,\text{m}}{5.6\times 10^{-3}\,\text{m}^2/\text{s}} = 2.81$$

From the Whitaker correlation,

$$\overline{Nu}_D = 2 + \left(0.4\,Re_D^{1/2} + 0.06\,Re_D^{2/3}\right)Pr^{0.4}$$

$$\overline{Nu}_D = 2 + \left(0.4\times 2.81^{1/2} + 0.06\times 2.81^{2/3}\right)(0.60)^{0.4} = 2.64$$

$$\bar{h} = 2.64k/D_p = 2.64(0.671\,\text{W/m}\cdot\text{K})/50\times 10^{-6}\,\text{m} = 35,400\,\text{W/m}^2\cdot\text{K}$$ <

The two-step melting process involves (i) the time t_1 to heat the particle to its melting point and (ii) the time t_2 required to achieve complete melting. Hence, $t_m = t_1 + t_2$, where from Eq. 5.5,

$$t_1 = \frac{\rho_p D_p c_p}{6\bar{h}}\ln\frac{T_i - T_\infty}{T_{mp} - T_\infty}$$

$$t_1 = \frac{3970\,\text{kg/m}^3\left(50\times 10^{-6}\,\text{m}\right)1560\,\text{J/kg}\cdot\text{K}}{6\left(35,400\,\text{W/m}^2\cdot\text{K}\right)}\ln\frac{(300-10,000)}{(2318-10,000)} = 3.4\times 10^{-4}\,\text{s}$$

Performing an energy balance for the second step, we obtain

$$\int_{t_1}^{t_m} q_{conv}\,dt = \Delta E_{st} = \rho_p \forall h_{sf}$$

Hence,

$$t_2 = \frac{\rho_p D_p}{6\bar{h}}\frac{h_{sf}}{\left(T_\infty - T_{mp}\right)} = \frac{3970\,\text{kg/m}^3\left(50\times 10^{-6}\,\text{m}\right)}{6\left(35,400\,\text{W/m}^2\cdot\text{K}\right)}\times\frac{3.577\times 10^6\,\text{J/kg}}{(10,000-2318)\,\text{K}} = 4.4\times 10^{-4}\,\text{s}$$

Hence,

$$t_m = \left(3.4\times 10^{-4} + 4.4\times 10^{-4}\right)\text{s} = 7.8\times 10^{-4}\,\text{s}$$ <

and the prescribed value of L is sufficient to insure complete melting before impact.

COMMENTS: (1) Since Bi = $\left(\bar{h}\,r_p/3\right)/k_p \approx 0.03$, use of the lumped capacitance approach is appropriate.

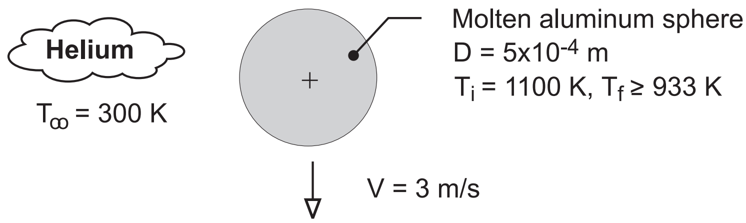
(2) With Re_D = 2.81, conditions are slightly outside the ranges associated with Stokes' law.

PROBLEM 7.83

KNOWN: Diameter, velocity, initial temperature and melting point of molten aluminum droplets. Temperature of helium atmosphere.

FIND: Maximum allowable separation between droplet injector and substrate.

SCHEMATIC:



ASSUMPTIONS: (1) Lumped capacitance approximation is valid, (2) Constant properties, (3) Negligible radiation.

PROPERTIES: *Table A-4*, Helium $(T_\infty = 300K): \nu = 122 \times 10^{-6} m^2/s,\ \mu = 199 \times 10^{-7}\ N \cdot s/m^2$, $k = 0.152\ W/m \cdot K,\ Pr = 0.68$. Helium $(T_s \approx 1000K): \mu_s = 446 \times 10^{-7}\ N \cdot s/m^2$. Given, Aluminum: $\rho = 2500\ kg/m^3,\ c = 1200\ J/kg \cdot K,\ k = 200\ W/m \cdot K$.

ANALYSIS: With $Re_D = VD/\nu = 3\ m/s\left(5 \times 10^{-4}\ m\right)/122 \times 10^{-6}\ m^2/s = 12.3$, the Whitaker correlation yields

$$\bar{h} = \frac{k}{D}\left[2 + \left(0.4\, Re_D^{1/2} + 0.06\, Re_D^{2/3}\right) Pr^{0.4} \left(\mu/\mu_s\right)^{1/4}\right]$$

$$\bar{h} = \frac{0.152\ W/m \cdot K}{0.0005m}\left\{2 + \left[0.4(12.3)^{1/2} + 0.06(12.3)^{2/3}\right](0.68)^{0.4}\left(\frac{199}{446}\right)^{1/4}\right\} = 975\ W/m^2 \cdot K$$

The *time-of-flight* for the droplet to cool from 1100K to 933K may be obtained from Eq. 5.5.

$$t = \frac{\rho \forall c}{\bar{h} A_s} \ln\frac{\theta_i}{\theta} = \frac{\rho c D}{6\bar{h}} \ln\frac{T_i - T_\infty}{T_f - T_\infty}$$

$$t = \frac{\left(2500\ kg/m^3\right) 1200\ J/kg \cdot K\,(0.0005m)}{6 \times 975\ W/m^2 \cdot K} \ln\left(\frac{800}{633}\right) = 0.06\,s$$

The maximum separation is therefore

$$L = V \times t = 3\,m/s \times 0.06\,s = 0.18m = 180\ mm$$ <

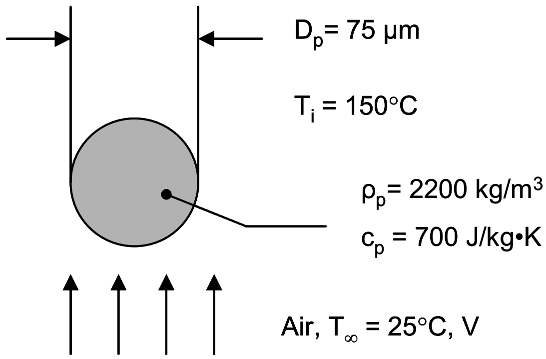
COMMENTS: (1) With $Bi = \bar{h}(D/6)/k = 4 \times 10^{-4}$, the lumped capacitance approximation is excellent. (2) With the surroundings assumed to be at $T_{sur} = T_\infty$ and a representative emissivity of ε = 0.1 for molten aluminum, $h_r \le \varepsilon\sigma\left(T_i + T_\infty\right)\left(T_i^2 + T_\infty^2\right) \approx 10\ W/m^2 \cdot K << \bar{h} = 975\ W/m^2 \cdot K$. Hence, radiation is, in fact, negligible. (3) Note that, for liquid metals especially, surfaces can quickly become oxidized. The oxidation layer restricts surface motion and the droplet can behave like a solid sphere. Thus we have used the Whitaker correlation in lieu of the Ranz-Marshall correlation.

PROBLEM 7.84

KNOWN: Method to manufacture small diameter droplets. Properties of D = 75 μm diameter particles ejected into air. Air temperature and pressure, initial particle temperature. Desired temperature of drop upon impact of a substrate.

FIND: (a) Terminal velocity of the droplets, (b) Separation distance between droplet injection location and substrate so that the droplets impact the substrate at T_2 = 120 °C.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible radiation heat transfer, (2) lumped capacitance thermal response, (3) Negligible microscale heat transfer effects.

PROPERTIES: Table A.4, air: ($T_f \approx [(T_i + T_2)/2 + T_\infty]/2$) = [(150 °C + 120 °C)/2 + 25 °C]/2 = 80 °C ≈ 353 K): ρ = 0.9876 kg/m³, ν = 21.25 × 10⁻⁶ m²/s, k = 0.03023 W/m·K, Pr = 0.6994. ($\overline{T}_s$ = (150 °C + 120 °C)/2 = 135 °C = 408 K: μ_s = 2.334 × 10⁻⁵ N·s/m². (T_∞ = 25 °C = 298 K): ν = 15.71 × 10⁻⁶ m²/s, k = 0.02614 W/m·K, μ = 1.836 × 10⁻⁵ N·s/m², Pr = 0.7075.

ANALYSIS:

(a) A force balance on the particle yields

$$\forall \rho_p g = C_D A_f (\rho V^2/2) \quad (1)$$

where $\forall = \frac{4}{3}\pi(D_p/2)^3 = \frac{4}{3} \times \pi \times (75 \times 10^{-6}\ \text{m}/2)^3 = 220.9 \times 10^{-15}\ \text{m}^3$

$$A_f = \pi(D_p/2)^2 = \pi \times (75 \times 10^{-6}\ \text{m}/2)^2 = 4.42 \times 10^{-9}\ \text{m}^2$$

We also know

$$Re_D = \frac{VD_p}{\nu} = \frac{V \times 75 \times 10^{-6}\ \text{m}}{21.25 \times 10^{-6}\ \text{m}^2/\text{s}} = 3.53(\text{s/m}) \times V \quad (2)$$

The correct velocity will yield values of C_D and Re_D that are consistent with Figure 7.9. A trial-and-error solution yields (using properties at $\overline{T}_f$)

$V \approx 0.30$ m/s, $Re_D = 1.06$, $C_D = 24.2$ (C_D from Figure 7.8 ≈ 25) <

(b) Using the Whitaker correlation with properties evaluated at T_∞,

$Re_D = 0.3\ \text{m/s} \times 75 \times 10^{-6}\ \text{m}/1.571 \times 10^{-5}\ \text{m}^2/\text{s} = 1.43$

Therefore,

Continued…

PROBLEM 7.84 (Cont.)

$$\overline{Nu}_D = 2 + \left[0.4\sqrt{1.43} + 0.06 \times 1.43^{2/3}\right] \times 0.7075^{0.4} \times \left(\frac{1.836}{2.334}\right)^{1/4} = 2.45$$

$$\overline{h}_D = \overline{Nu}_D k/D_p = 2.45 \times 0.02614 \text{ W/m} \cdot \text{K}/75 \times 10^{-6} \text{ m} = 854 \text{ W/m}^2 \cdot \text{K}$$

Using Equation 5.6 with $A_s = 4 \times \pi \times (75 \times 10^{-6} \text{ m}/2)^2 = 17.7 \times 10^{-9} \text{ m}^2$,

$$\frac{T_2 - T_\infty}{T_i - T_\infty} = \frac{120 - 25}{150 - 25} = 0.76 = \exp\left[-\left(\frac{854 \text{ W/m}^2 \cdot \text{K} \times 17.7 \times 10^{-9} \text{ m}^2}{2200 \text{ kg/m}^3 \times 220.9 \times 10^{-15} \text{ m}^3 \times 700 \text{ J/kg} \cdot \text{K}}\right) \times t\right]$$

yielding $t = 6.20 \times 10^{-3}$ s = 6.2 ms. The separation distance, L, is therefore

$L = 0.30 \text{ m/s} \times 6.2 \times 10^{-3} \text{ s} = 1.86 \times 10^{-3} \text{ m} = 1.86 \text{ mm}$ <

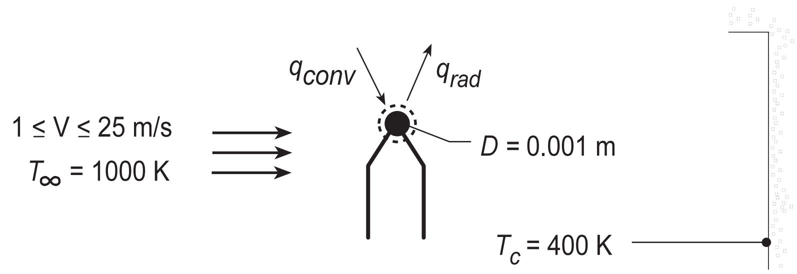
COMMENTS: (1) The maximum possible radiation heat transfer coefficient is associated with the initial particle temperature and an emissivity of unity. Assuming a surroundings temperature of 25 °C = 298 K, we find a radiation heat transfer coefficient of $h_r = 5.67 \times 10^{-8} \text{ W/m}^2{\cdot}\text{K}^4 \times (423 + 298) \text{ K} \times (423^2 + 298^2) \text{ K}^2 = 11 \text{ W/m}^2{\cdot}\text{K}$. Therefore, radiation heat transfer is negligible. (2) The terminal velocity of the very small spherical particle is very low. This is because the surface area to weight ratio of a sphere is inversely proportional to the sphere diameter. As the sphere becomes small, drag forces become relatively large at relatively low velocities. (3) The Whitaker correlation has been extrapolated outside of its recommended range of application. However, we know that the limiting value of the average Nusselt number is two. (4) The sphere is very small and the density of the sphere is relatively low. The lumped capacitance assumption is likely to be valid.

PROBLEM 7.85

KNOWN: Velocity and temperature of combustion gases. Diameter and emissivity of thermocouple junction. Combustor temperature.

FIND: (a) Time to achieve 98% of maximum thermocouple temperature rise, (b) Steady-state thermocouple temperature, (c) Effect of gas velocity and thermocouple emissivity on measurement error.

SCHEMATIC:



ASSUMPTIONS: (1) Validity of lumped capacitance analysis, (2) Constant properties, (3) Negligible conduction through lead wires, (4) Radiation exchange between small surface and a large enclosure (parts b and c).

PROPERTIES: Thermocouple (given): $0.1 \le \varepsilon \le 1.0$, k = 100 W/m·K, c = 385 J/kg·K, ρ = 8920 kg/m^3; Gases (given): k = 0.05 W/m·K, $\nu = 50 \times 10^{-6}$ m^2/s, Pr = 0.69.

ANALYSIS: (a) If the lumped capacitance analysis may be used, it follows from Equation 5.5 that

$$t = \frac{\rho V c}{\bar{h} A_s} \ln \frac{T_i - T_\infty}{T - T_\infty} = \frac{D \rho c}{6 \bar{h}} \ln(50).$$

Neglecting the viscosity ratio correlation for variable property effects, use of V = 5 m/s with the Whitaker correlation yields

$$\overline{Nu}_D = (\bar{h}D/k) = 2 + \left(0.4\,Re_D^{1/2} + 0.06\,Re_D^{2/3}\right) Pr^{0.4} \qquad Re_D = \frac{VD}{\nu} = \frac{5\,m/s(0.001\,m)}{50 \times 10^{-6}\,m^2/s} = 100$$

$$\bar{h} = \frac{0.05\,W/m \cdot K}{0.001m}\left[2 + \left(0.4(100)^{1/2} + 0.06(100)^{2/3}\right)(0.69)^{0.4}\right] = 328\,W/m^2 \cdot K$$

Since Bi = $\bar{h}(r_o/3)/k$ = 5.5 × 10^{-4}, the lumped capacitance method may be used. Hence,

$$t = \frac{0.001m\left(8920\,kg/m^3\right)385\,J/kg \cdot K}{6 \times 328\,W/m^2 \cdot K} \ln(50) = 6.83s \qquad <$$

(b) Performing an energy balance on the junction and evaluating radiation exchange, $q_{conv} = q_{rad}$. Hence, with ε = 0.5,

$$\bar{h} A_s (T_\infty - T) = \varepsilon A_s \sigma \left(T^4 - T_c^4\right)$$

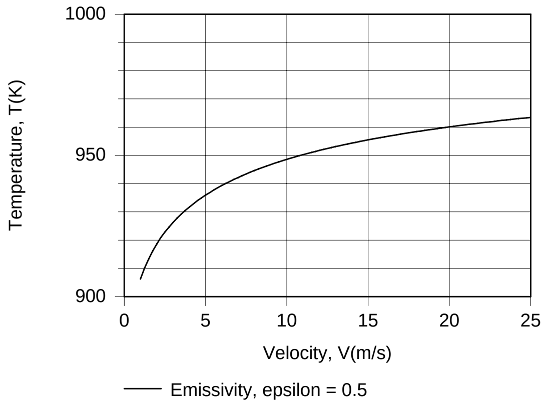
$$(1000 - T)K = \frac{0.5 \times 5.67 \times 10^{-8}\,W/m^2 \cdot K^4}{328\,W/m^2 \cdot K}\left[T^4 - (400)^4\right]K^4.$$

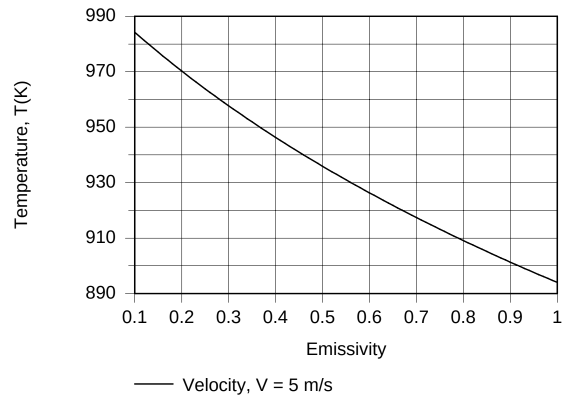
T = 936 K <

(c) Using the *IHT First Law Model* for a *Solid Sphere* with the appropriate *Correlation* for external flow from the Tool Pad, parametric calculations were performed to determine the effects of V and ε_g, and the following results were obtained.

Continued...

PROBLEM 7.85 (Cont.)





Since the temperature recorded by the thermocouple junction increases with increasing V and decreasing ε, the measurement error, T_∞ - T, decreases with increasing V and decreasing ε. The error is due to net radiative transfer from the junction (which depresses T) and hence should decrease with decreasing ε. For a prescribed heat loss, the temperature difference (T_∞ - T) decreases with decreasing convection resistance, and hence with increasing h(V).

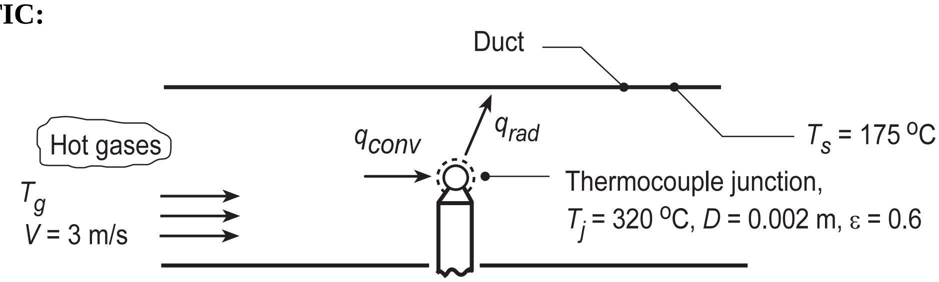
COMMENTS: To infer the actual gas temperature (1000 K) from the measured result (936 K), correction would have to be made for radiation exchange with the cold surroundings.

PROBLEM 7.86

KNOWN: Diameter, emissivity and temperature of a thermocouple junction exposed to hot gases flowing through a duct of prescribed surface temperature.

FIND: (a) Relative magnitudes of gas and thermocouple temperatures if the duct surface temperature is less than the gas temperature, (b) Gas temperature for prescribed conditions, (c) Effect of Velocity and emissivity on measurement error.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Junction is diffuse-gray, (3) Duct forms a large enclosure about the junction, (4) Negligible heat transfer by conduction through the thermocouple leads, (5) Gas properties are those of atmospheric air.

PROPERTIES: *Table A-4*, Air ($T_g \approx 650$ K, 1 atm): $\nu = 60.21 \times 10^{-6}$ m²/s, k = 0.0497 W/m·K, Pr = 0.690, $\mu = 322.5 \times 10^{-7}$ N·s/m²; Air (T_j = 593 K, 1 atm): $\mu = 304 \times 10^{-7}$ N·s/m².

ANALYSIS: (a) From an energy balance on the thermocouple junction, $\underset{(g\to j)}{q_{conv}} = \underset{(j\to s)}{q_{rad}}$. Hence,

$$\bar{h}A\left(T_g - T_j\right) = \varepsilon\sigma A\left(T_j^4 - T_s^4\right) \qquad \text{or} \qquad T_g - T_j = \frac{\varepsilon}{\bar{h}}\sigma\left(T_j^4 - T_s^4\right).$$

If $T_s < T_j$, it follows that $T_j < T_g$. <

(b) Neglecting the variable property correction, $(\mu/\mu_s)^{1/4} = (322.5/304)^{1/4} = 1.01 \approx 1.00$, and using

$$Re_D = \frac{VD}{\nu} = \frac{3\,m/s\,(0.002\,m)}{60.21\times10^{-6}\,m^2/s} = 100$$

the Whitaker correlation for a sphere gives

$$\bar{h} = \frac{0.0497\,W/m\cdot K}{0.002\,m}\left\{2 + \left[0.4(100)^{1/2} + 0.06(100)^{2/3}\right](0.69)^{0.4}\right\} = 163\,W/m^2\cdot K.$$

Hence

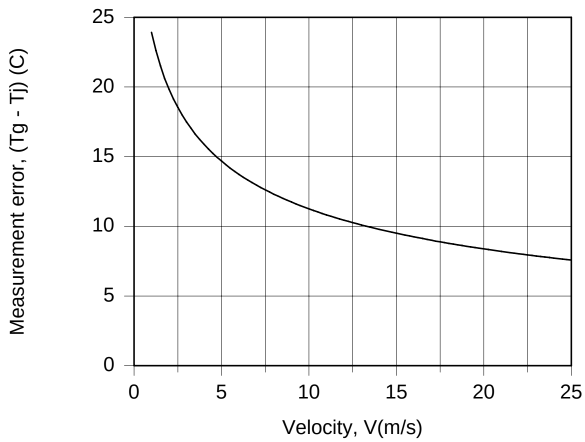
$$\left(T_g - 593\,K\right) = \frac{0.6}{163\,W/m^2\cdot K}5.67\times10^{-8}\,W/m^2\cdot K^4\left[(593\,K)^4 - (448\,K)^4\right] = 17\,K$$

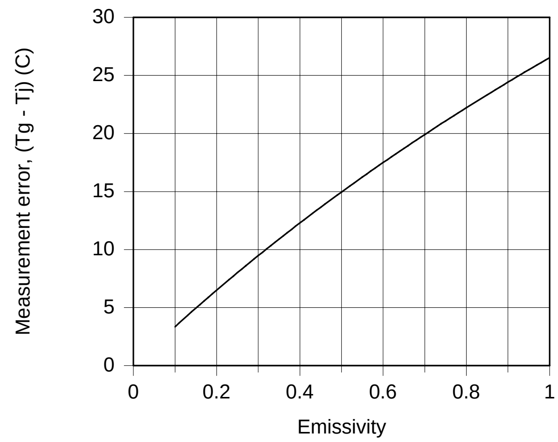
$$T_g = 610\,K = 337^\circ C.$$ <

(c) With T_g fixed at 610 K, the IHT *First Law* Model was used with the *Correlations* and *Properties* Tool Pads to compute the measurement error as a function of V and ε.

Continued...

PROBLEM 7.86 (Cont.)





Since the convection resistance decreases with increasing V, the junction temperature will approach the gas temperature and the measurement error will decrease. Since the depression in the junction temperature is due to radiation losses from the junction to the duct wall, a reduction in ε will reduce the measurement error.

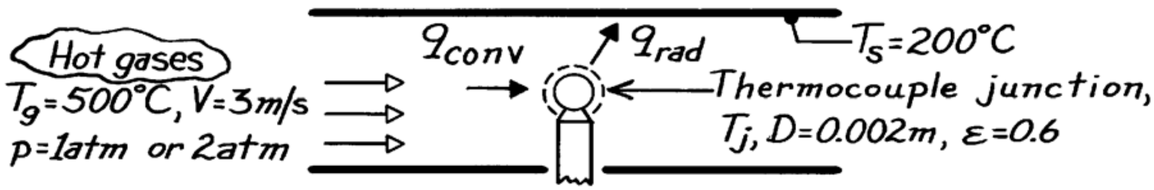
COMMENTS: In part (b), calculations could be improved by evaluating properties at 610 K (instead of 650 K).

PROBLEM 7.87

KNOWN: Diameter and emissivity of a thermocouple junction exposed to hot gases of prescribed velocity and temperature flowing through a duct of prescribed surface temperature.

FIND: (a) Thermocouple reading for gas at atmospheric pressure, (b) Thermocouple reading when gas pressure is doubled.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Junction is diffuse-gray, (3) Duct forms a large enclosure about junction, (4) Negligible heat loss by conduction through thermocouple leads, (5) Gas properties are those of air, (6) Perfect gas behavior.

PROPERTIES: *Table A-4,* Air (T_g = 773 K, 1 atm): $\nu = 80.5 \times 10^{-6}$ m^2/s, k = 0.0561 W/m·K, Pr = 0.705.

ANALYSIS: (a) Performing an energy balance on the junction

$$\underset{(g\to j)}{q_{conv}} = \underset{(j\to s)}{q_{rad}}$$

$$\bar{h}A\left(T_g - T_j\right) = \varepsilon\sigma A\left(T_j^4 - T_s^4\right).$$

Neglecting the variable property correction, $(\mu/\mu_s)^{1/4}$, and using

$$Re_D = \frac{VD}{\nu} = \frac{3\text{ m/s}\times 0.002\text{ m}}{80.5\times10^{-6}\text{ m}^2/\text{s}} = 74.5$$

the Whitaker correlation for a sphere gives,

$$\bar{h} = \frac{0.0561\text{ W/m}\cdot\text{K}}{0.002\text{ m}}\left\{2+\left[0.4(74.5)^{1/2}+0.06(74.5)^{2/3}\right](0.705)^{0.4}\right\} = 166\text{ W/m}^2\cdot\text{K}.$$

$$166\left(773 - T_j\right) = 0.6\times5.67\times10^{-8}\left[T_j^4 - (473)^4\right]$$

and from a trial-and-error solution,

$$T_j \approx 726\text{ K.}$$ <

(b) Assuming all properties other than ν to remain constant with a change in pressure, ↑ p by 2 will ↓ ν by 2 and hence ↑ Re_D by 2, giving Re_D = 149. Hence

$$\bar{h} = \frac{0.0561}{0.002}\left\{2+\left[0.4(149)^{1/2}+0.06(149)^{2/3}\right](0.705)^{0.4}\right\} = 216\text{ W/m}^2\cdot\text{K}.$$

$$216\left(773 - T_j\right) = 0.6\times5.67\times10^{-8}\left[T_j^4 - (473)^4\right]$$

and from a trial-and-error solution

$$T_j \approx 735\text{ K.}$$ <

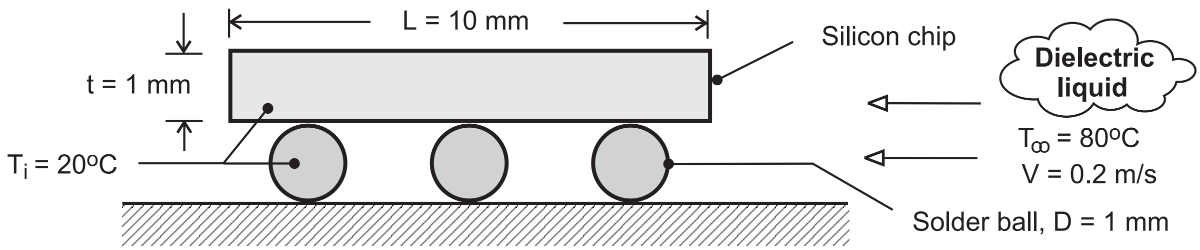
COMMENTS: The thermocouple error will ↓ with ↑ h, which ↑ with ↑p.

PROBLEM 7.88

KNOWN: Initial temperature, dimensions and properties of chip and solder connectors. Velocity, temperature and properties of liquid.

FIND: (a) Ratio of time constants (chip-to-solder), (b) Chip-to-solder temperature difference after 0.25s of heating.

SCHEMATIC:



ASSUMPTIONS: (1) Solder balls and chips are spatially isothermal, (2) Negligible heat transfer from sides of chip, (3) Top and bottom surfaces of chip act as flat plates in turbulent parallel flow, (4) Heat transfer from solder balls may be approximated as that from an isolated sphere, (5) Constant properties.

PROPERTIES: Given. Dielectric liquid: $k = 0.064\,W/m\cdot K$, $\nu = 10^{-6}\,m^2/s$, $Pr = 25$; Silicon chip: $k = 150\,W/m\cdot K$, $\rho = 2300\,kg/m^3$, $c_p = 700\,J/kg\cdot K$; Solder ball: $k = 40\,W/m\cdot K$, $\rho = 10,000\,kg/m^3$, $c_p = 150\,J/kg\cdot K$.

ANALYSIS: (a) From Eq. 5.7, the thermal time constant is $\tau_t = \left(\rho \forall c / \bar{h} A_s\right)$. Hence,

$$\frac{\tau_{t,ch}}{\tau_{t,sld}} = \frac{(\rho c)_{ch}\left(L^2 t\right)}{2\bar{h}_{ch}L^2}\,\frac{\bar{h}_{sld}\left(\pi D^2\right)}{(\rho c)_{sld}\left(\pi D^3/6\right)} = 3\frac{t}{D}\,\frac{(\rho c)_{ch}}{(\rho c)_{sld}}\,\frac{\bar{h}_{sld}}{\bar{h}_{ch}}$$

The convection coefficient for the chip may be obtained from Eq. 7.38 with A = 0, with $Re_L = VL/\nu = 0.2\,m/s \times 0.01m/10^{-6}\,m^2/s = 2000.$

$$\bar{h}_{ch} = \frac{0.064\,W/m\cdot K}{0.01m}(0.037)(2000)^{4/5}(25)^{1/3} = 302\,W/m^2\cdot K$$

The convection coefficient for the solder may be obtained from Eq. 7.56, with $Re_D = VD/\nu = 0.2\,m/s \times 0.001m/10^{-6}\,m^2/s = 200.$ Neglecting the effect of the viscosity ratio,

$$\bar{h}_{sld} = \frac{0.064\,W/m\cdot K}{0.001m}\left\{2 + \left[0.4(200)^{1/2} + 0.06(200)^{2/3}\right](25)^{0.4}\right\} = 1916\,W/m^2\cdot K$$

Hence, $$\frac{\tau_{t,ch}}{\tau_{t,sld}} = 3\left(\frac{2300\,kg/m^3 \times 700\,J/kg\cdot K}{10,000\,kg/m^3 \times 150\,J/kg\cdot K}\right)\frac{1916\,W/m^2\cdot K}{302\,W/m^2\cdot K} = 20.4$$ <

Hence, the solder responds much more quickly to the convective heating.

(b) From Eq. 5.6, the chip-to-solder temperature difference may be expressed as

Continued …

PROBLEM 7.88 (Cont.)

$$T_{ch} - T_{sld} = (T_i - T_\infty)\left\{\exp\left[-\left(\frac{2\bar{h}}{\rho c t}\right)_{ch} t\right] - \exp\left[-\left(\frac{6\bar{h}}{\rho c D}\right)_{sld} t\right]\right\}$$

$$T_{ch} - T_{sld} = 60°C\left\{\exp\left[-\frac{604\,W/m^2\cdot K}{1610\,J/m^2\cdot K}0.25\,s\right] - \exp\left[-\frac{11,496\,W/m^2\cdot K}{1500\,J/m^2\cdot K}0.25\,s\right]\right\}$$

$$T_{ch} - T_{sld} = 60°C\{0.910 - 0.147\} = 45.8°C$$ <

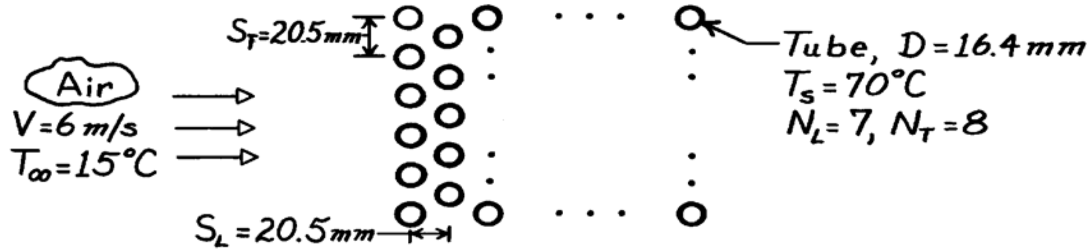
COMMENTS: (1) The foregoing process is used to subject soldered chip connections (a major reliability issue) to rapid and intense thermal stresses. (2) Some heat transfer by conduction will occur between the chip and solder balls, thereby reducing the temperature difference and thermal stress. (3) Constriction of flow between the chip and substrate will reduce $\bar{h}_{sld}$, as well as $\bar{h}_{ch}$ at the lower surface of the chip, relative to values predicted by the correlations. The corresponding time constants would be increased accordingly. (4) With $Bi_{ch} = \bar{h}_{ch}(t/2)/k_{chip} = 0.001 << 1$ and $Bi_{sld} = \bar{h}_{sld}(D/6)/k_{sld} = 0.008 << 1$, the lumped capacitance analysis is appropriate for both components.

PROBLEM 7.89

KNOWN: Conditions associated with Example 7.7, but with reduced longitudinal and transverse pitches.

FIND: (a) Air side convection coefficient, (b) Tube bundle pressure drop, (c) Heat rate.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform tube surface temperature, (3) Negligible radiation and incompressible flow.

PROPERTIES: *Table A-4*, Atmospheric air (T_∞ = 288 K): $\rho = 1.217\ kg/m^3$, $\nu = 14.82 \times 10^{-6}\ m^2/s$, k = 0.0253 W/m·K, Pr = 0.71, c_p = 100.7 J/kg·K; (T_s = 343 K): Pr = 0.701.

ANALYSIS: (a) From the tube pitches, find

$$S_D = \left[S_L^2 + (S_T/2)^2\right]^{1/2} = \left[(20.5)^2 + (10.25)^2\right]^{1/2} = 22.91\ \text{mm}$$

$$(S_T + D)/2 = (20.5 + 16.4)/2 = 18.45\ \text{mm}.$$

Hence, the maximum velocity occurs on the transverse plane, and

$$V_{max} = \frac{S_T}{S_T - D} V = \frac{20.5\ \text{mm}}{(20.5 - 16.4)\ \text{mm}} 6\ \text{m/s} = 30\ \text{m/s}.$$

With $$Re_{D,max} = \frac{V_{max} D}{\nu} = \frac{30\ \text{m/s}(0.0164\ \text{m})}{14.82 \times 10^{-6}\ \text{m}^2/\text{s}} = 3.32 \times 10^4$$

and $(S_T/S_L) = 1 < 2$, it follows from Table 7.5 that

$C_1 = 0.35 \qquad m = 0.60.$

Hence, from the Zukauskas correlation and Table 7.6 (C_2 = 0.95),

$$\overline{Nu}_D = (0.95)0.35\, Re_{D,max}^{0.6}\, Pr^{0.36} (Pr/Pr_s)^{1/4}$$

$$\overline{Nu}_D = (0.95)0.35\left(3.32 \times 10^4\right)^{0.6} (0.71)^{0.36} (0.71/0.701)^{1/4} = 152$$

$$\bar{h} = \overline{Nu}_D \frac{k}{D} = 152 \times \frac{0.0253\ \text{W/m}\cdot\text{K}}{0.0164\ \text{m}} = 234\ \text{W/m}^2\cdot\text{K}.$$ <

(b) From the Zukauskas relation

$$\Delta p = N_L \chi \left(\frac{\rho V_{max}^2}{2}\right) f.$$

With $Re_{D,max} = 3.32 \times 10^4$, $P_T = (S_T/D) = 1.25$ and $(P_T/P_L) = 1$, it follows from Fig. 7.15 that

$\chi \approx 1.02 \qquad f \approx 0.38.$

Continued …

PROBLEM 7.89 (Cont.)

Hence

$$\Delta p = 7 \times 1.02 \frac{1.217\ \text{kg/m}^3 (30\ \text{m/s})^2}{2} 0.38 = 1490\ \text{N/m}^2$$

$$\Delta p = 0.0149\ \text{bar}. \qquad <$$

(c) The air outlet temperature is obtained from

$$T_s - T_o = (T_s - T_i)\exp\left(-\frac{\pi D N \bar{h}}{\rho V N_t S_t c_p}\right)$$

$$T_s - T_o = 55^\circ\text{C} \exp\left(\frac{-\pi(0.0164\ \text{m})56(234\ \text{W/m}^2 \cdot \text{K})}{1.217\ \text{kg/m}^3 \times 6\ \text{m/s} \times 8 \times 0.0205\ \text{m} \times 1007\ \text{J/kg} \cdot \text{K}}\right)$$

$$T_s - T_o = 31.4^\circ\text{C}$$

$$T_o = 38.5^\circ\text{C}. \qquad <$$

The log mean temperature difference is

$$\Delta T_{\ell m} = \frac{\Delta T_i - \Delta T_o}{\ell n(\Delta T_i / \Delta T_o)} = \frac{(55 - 31.4)^\circ\ \text{C}}{\ell n(55/31.4)} = 42.1^\circ\text{C}$$

$$q' = N\bar{h}\pi D \Delta T_{\ell m} = 56(234\ \text{W/m}^2 \cdot \text{K})\pi(0.0164\ \text{m})\ 42.1^\circ\text{C}$$

$$q' = 28.4\ \text{kW/m}. \qquad <$$

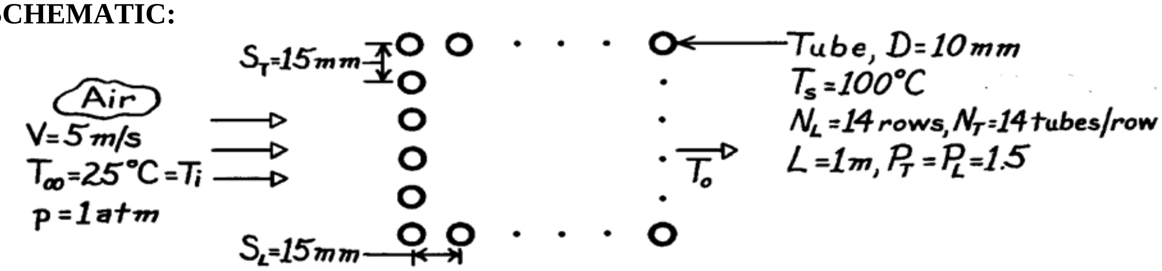
COMMENTS: Making the tube bank more compact has the desired effect of increasing the convection coefficient and therefore the heat transfer rate. However, it has the adverse effect of increasing the pressure drop and hence the fan power requirement. Note that the convection coefficient increases by a factor of (234/135.6) = 1.73, while the pressure drop increases by a factor of (1490/246) = 6.1. This disparity is a consequence of the fact that $\bar{h} \sim V_{max}^{0.6}$, while $\Delta p \sim V_{max}^2$. Hence any increase in V_{max}, which would result from a more closely spaced arrangement, would more adversely affect Δp than favorably affect $\bar{h}$.

PROBLEM 7.90

KNOWN: Surface temperature and geometry of a tube bank. Velocity and temperature of air in cross flow.

FIND: (a) Total heat transfer, (b) Air flow pressure drop.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible radiation and incompressible flow, (3) Uniform surface temperature.

PROPERTIES: *Table A-4*, Atmospheric air (T_∞ = 298 K): $\nu = 15.8 \times 10^{-6}\ m^2/s$, k = 0.0263 W/m·K, Pr = 0.707, c_p = 1007 J/kg·K, ρ = 1.17 kg/m^3; (T_s = 373 K): Pr = 0.695.

ANALYSIS: (a) The total heat transfer rate is

$$q = \bar{h} N \pi D L \frac{(T_s - T_i) - (T_s - T_o)}{\ell n\left[(T_s - T_i)/(T_s - T_o)\right]} = \bar{h} N \pi D L\, \Delta T_{\ell m}.$$

With $V_{max} = \frac{S_T}{S_T - D} V = \frac{15\ mm}{5\ mm} 5\ m/s = 15\ m/s$, $Re_{D,max} = \frac{15\ m/s(0.01\ m)}{15.8 \times 10^{-6}\ m^2/s} = 9494$. Tables 7.5 and 7.6 give C_1 = 0.27, m = 0.63 and $C_2 \approx 0.99$. Hence, from the Zukauskas correlation

$$\overline{Nu}_D = 0.99 \times 0.27(9494)^{0.63}(0.707)^{0.36}(0.707/0.695)^{1/4} = 75.9$$

$$\bar{h} = \overline{Nu}_D\ k/D = 75.9 \times 0.0263\ W/m \cdot K/0.01\ m = 200\ W/m^2 \cdot K$$

$$T_s - T_o = (T_s - T_i)\exp\left(-\frac{\pi D N \bar{h}}{\rho V N_T S_T c_p}\right) = 75^\circ C \exp\left(-\frac{\pi \times 0.01\ m \times 196 \times 200\ W/m^2 \cdot K}{1.17\ kg/m^3 \times 5\ m/s \times 14 \times 0.015\ m \times 1007\ J/kg \cdot K}\right)$$

$$T_s - T_o = 27.7^\circ C.$$

Hence

$$q = 200\ W/m^2 \cdot K \times 196\pi(0.01\ m)\ 1\ m \frac{75^\circ C - 27.7^\circ C}{\ell n(75/27.7)} = 58.5\ kW.$$ <

(b) With $Re_{D,max}$ = 9494, $(P_T - 1)/(P_L - 1)$ = 1, Fig. 7.14 yields f ≈ 0.32 and χ = 1. Hence,

$$\Delta p = N\chi\left(\rho V_{max}^2/2\right) f = 14 \times 1\left(\frac{1.17\ kg/m^3 (15\ m/s)^2}{2}\right) 0.32$$

$$\Delta p = 590\ N/m^2 = 5.9 \times 10^{-3}\ bar.$$

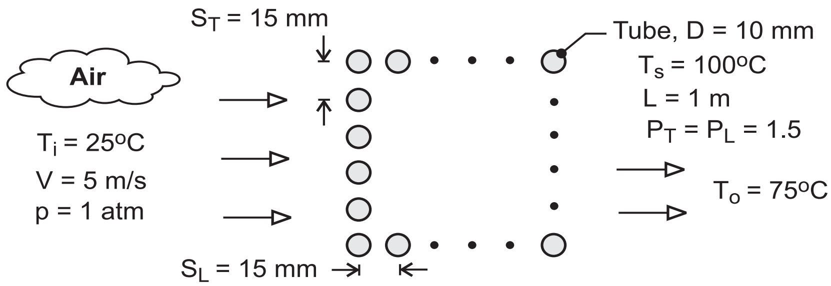
COMMENTS: The heat transfer rate would have been substantially overestimated (93.3 kW) if the inlet temperature difference ($T_s - T_i$) had been used in lieu of the log-mean temperature difference.

PROBLEM 7.91

KNOWN: Surface temperature and geometry of a tube bank. Inlet velocity and inlet and outlet temperatures of air in cross flow over the tubes.

FIND: Number of tube rows needed to achieve the prescribed outlet temperature and corresponding pressure of drop of air.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Negligible temperature drop across tube wall and uniform outer surface temperature, (3) Constant properties, (4) $C_2 \approx 1$, (5) Negligible radiation and incompressible flow.

PROPERTIES: *Table A-4*, Atmospheric air. $\left(\overline{T} = \left(T_i + T_o\right)/2 = 323K\right)$: $\rho = 1.085\,kg/m^3$, $c_p = 1007\,J/kg\cdot K$, $\nu = 18.2\times10^{-6}m^2/s$, $k = 0.028\,W/m\cdot K$, $Pr = 0.707$; $\left(T_i = 298K\right)$: $\rho = 1.17\,kg/m^3$; $\left(T_s = 373K\right)$: $Pr_s = 0.695$.

ANALYSIS: The temperature difference $\left(T_s - T\right)$ decreases exponentially in the flow direction, and at the outlet

$$\frac{T_s - T_o}{T_s - T_i} = \exp\left(-\frac{\pi D N_L \overline{h}}{\rho V S_T c_p}\right)$$

where $N_L = N/N_T$. Hence,

$$N_L = -\frac{\rho V S_T c_p}{\pi D \overline{h}} \ell n\left(\frac{T_s - T_o}{T_s - T_i}\right) \qquad (1)$$

With $V_{max} = \left[S_T/\left(S_T - D\right)\right]V = 15\,m/s$, $Re_{D,max} = V_{max}D/\nu = 8240$. Hence, with $S_T/S_L = 1 > 0.7$, $C_1 = 0.27$ and m = 0.63 from Table 7.5, and the Zukauskas correlation yields

$$\overline{Nu}_D = C_1 C_2 Re_{D,max}^m Pr^{0.36}\left(\frac{Pr}{Pr_s}\right)^{1/4} = 0.27\times1\left(8240\right)^{0.63}\left(0.707\right)^{0.36}\left(0.707/0.695\right)^{1/4} = 70.1$$

$$\overline{h} = \frac{k}{D}\overline{Nu}_D = \frac{0.028\,W/m\cdot K}{0.01m}70.1 = 196.3\,W/m^2\cdot K$$

Hence,
$$N_L = -\frac{1.17\,kg/m^3\left(5\,m/s\right)0.015m\left(1007\,J/kg\cdot K\right)}{\pi\left(0.01m\right)196.3\,W/m^2\cdot K}\ell n\left(\frac{25}{75}\right) = 15.7$$

and 16 tube rows should be used $\qquad N_L = 16 \qquad$ <

With $Re_{D,max} = 8240$, $P_L = 1.5$ and $\left(P_T - 1\right)/\left(P_L - 1\right) = 1$, $f \approx 0.35$ and $\chi = 1$ from Fig. 7.14. Hence,

$$\Delta p \approx N_L \chi\left(\frac{\rho V_{max}^2}{2}\right)f = 16\left[\frac{1.085\,kg/m^3\times\left(15\,m/s\right)^2}{2}\right]0.35 = 684\,N/m^2$$ <

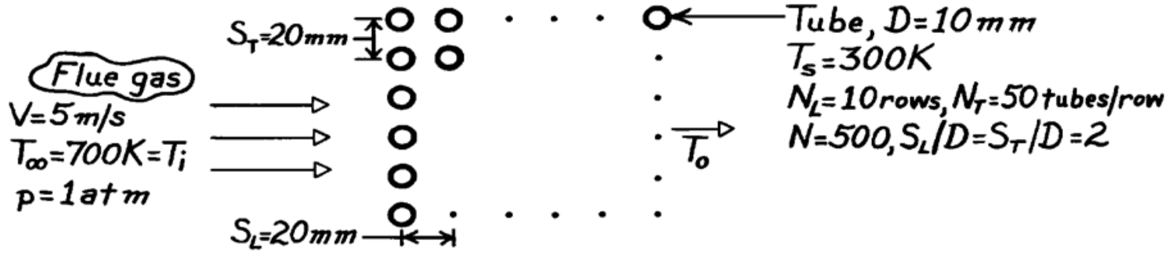
COMMENTS: (1) With $C_2 = 0.99$ for $N_L = 16$ from Table 7.8, assumption 4 is appropriate. (2) Note use of the density evaluated at $T_i = 298K$ in Eq. (1).

PROBLEM 7.92

KNOWN: Geometry, surface temperature, and air flow conditions associated with a tube bank.

FIND: Rate of heat transfer per unit length.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible radiation effects and incompressible flow, (3) Gas properties are approximately those of air.

PROPERTIES: *Table A-4*, Air (300K, 1 atm): Pr = 0.707; *Table A-4*, Air (700K, 1 atm): $\nu = 68.1 \times 10^{-6}\ m^2/s$, k = 0.0524 W/m·K, Pr = 0.695, $\rho = 0.498\ kg/m^3$, c_p = 1075 J/kg·K.

ANALYSIS: The rate of heat transfer per unit length of tubes is

$$q' = \bar{h} N \pi D\, \Delta T_{\ell m} = \bar{h} N \pi D \frac{(T_s - T_i) - (T_s - T_o)}{\ell n\left[(T_s - T_i)/(T_s - T_o)\right]}.$$

With $V_{max} = \frac{S_T}{S_T - D} V = \frac{20}{10}\ 5\ m/s = 10\ m/s$, $Re_{D,max} = \frac{V_{max} D}{\nu} = \frac{10\ m/s \times 0.01\ m}{68.1 \times 10^{-6}\ m^2/s} = 1468.$

Tables 7.5 and 7.6 give $C_1 = 0.27$, m = 0.63 and $C_2 = 0.97$. Hence from the Zukauskas correlation,

$$\overline{Nu}_D = C_1 C_2 Re_{D,max}^m Pr^{0.36} (Pr/Pr_s)^{1/4} = 0.26(1468)^{0.63}(0.695)^{0.36}(0.695/0.707)^{1/4}$$

$$\overline{Nu}_D = 22.4 \qquad \bar{h} = \frac{k}{D}\overline{Nu}_D = 0.0524\ W/m \cdot K \times 22.4/0.01\ m = 117\ W/m^2 \cdot K.$$

Hence,

$$(T_s - T_o) = (T_s - T_i)\exp\left(-\frac{\pi D N \bar{h}}{\rho V N_T S_T c_p}\right) = -400K\ \exp\left(-\frac{\pi \times 0.01\ m \times 500 \times 117\ W/m^2 \cdot K}{0.498\ kg/m^3 (5\ m/s) 50 (0.02\ m) 1075 J/kg \cdot K}\right)$$

$$T_s - T_o = -201.3K$$

and the heat rate is

$$q' = \left(117\ W/m^2 \cdot K\right) 500\pi (0.01\ m) \frac{(-400 + 201.3) K}{\ell n\left[(-400)/(-201.3)\right]} = -532\ kW/m \qquad <$$

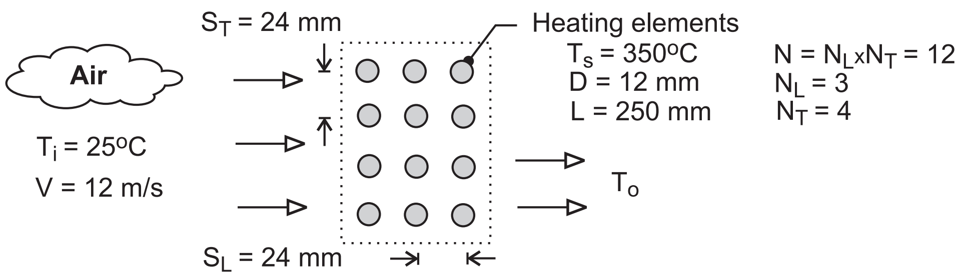
COMMENTS: (1) There is a significant decrease in the gas temperature as it passes through the tube bank. Hence, the heat rate would have been substantially overestimated (- 768 kW) if the inlet temperature difference had been used in lieu of the log-mean temperature difference. (2) The negative sign implies heat transfer to the water. (3) If the temperature of the water increases substantially, the assumption of uniform T_s becomes poor. The extent to which the water temperature increases depends on the water flow rate.

PROBLEM 7.93

KNOWN: An air duct heater consists of an aligned arrangement of electrical heating elements with $S_L = S_T = 24$ mm, $N_L = 3$ and $N_T = 4$. Atmospheric air with an upstream velocity of 12 m/s and temperature of 25°C moves in cross flow over the elements with a diameter of 12 mm and length of 250 mm maintained at a surface temperature of 350°C.

FIND: (a) The total heat transfer to the air and the temperature of the air leaving the duct heater, (b) The pressure drop across the element bank and the fan power requirement, (c) Compare the average convection coefficient obtained in part (a) with the value for an isolated (single) element; explain the relative difference between the results; (d) What effect would increasing the longitudinal and transverse pitches to 30 mm have on the exit temperature of the air, the total heat rate, and the pressure drop?

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible radiation effects, (3) Negligible effect of change in air temperature across tube bank on air properties.

PROPERTIES: *Table A-4*, Air (T_i = 298, 1 atm): $\rho = 1.171$ kg/m^3, $c_p = 1007$ J/kg·K; Air ($T_m = (T_i + T_o)/2 = 309$ K, 1 atm): $\rho = 1.130$ kg/m^3, $c_p = 1007$ J/kg·K, $\mu = 1.89 \times 10^{-5}$ N·s/m^2, k = 0.02699 W/m·K, Pr = 0.7057; Air (T_s = 623 K, 1 atm): $Pr_s = 0.687$; Air ($T_f = (T_i + T_o)/2 = 461$ K, 1 atm): $\nu = 3.373 \times 10^{-5}$ m^2/s, k = 0.03801 W/m·K, Pr = 0.686.

ANALYSIS: (a) The total heat transfer to the air is determined from the rate equation

$$q = N\left(\bar{h}_D \pi D \Delta T_{\ell m}\right) \tag{1}$$

where the log mean temperature difference is

$$\Delta T_{\ell m} = \frac{T_s - T_i}{T_s - T_o} \Big/ \ln \frac{\left(T_s - T_i\right)}{\left(T_s - T_o\right)} \tag{2}$$

and from the overall energy balance,

$$\frac{T_s - T_o}{T_s - T_i} = \exp\left(\frac{\pi D N \bar{h}_D}{\rho V N_T S_T c_p}\right) \tag{3}$$

The properties ρ and c_p in Eq. (3) are evaluated at the inlet temperature T_i. The average convection coefficient using the Zukauskus correlation,

$$\overline{Nu}_D = \frac{\bar{h}_D}{k} = C\ Re_{D,max}^m\ Pr^{0.36}\left(Pr/Pr_s\right)^{1/4} \tag{4}$$

where $C_1 = 0.27$, m = 0.63 are determined from Table 7.5 for the *aligned* configuration with $S_T/S_L = 1 > 0.7$ and $10^3 < Re_{D,max} \le 10^5$. All properties except Pr_s are evaluated at the arithmetic mean temperature $T_m = (T_i + T_o)/2$. The maximum Reynolds number is

Continued …

PROBLEM 7.93 (Cont.)

$$Re_{D,max} = \rho V_{max} D / \mu \tag{5}$$

where for the *aligned* arrangement, the maximum velocity occurs at the transverse plane

$$V_{max} = \frac{S_T}{S_T - D} V \tag{6}$$

The results of the analyses for $S_T = S_L = 24$ mm are tabulated below.

V_{max} (m/s)	$Re_{D,max}$	$\overline{Nu}_D$	$\overline{h}_D$ ($W/m^2 \cdot K$)	$\Delta T_{\ell m}$ (°C)	q (W)	T_o (°C)	
24	1.723×104	96.2	216	314	7671	47.6	<

(b) The pressure drop across the tube bundle is

$$\Delta p = N_L \chi \left(\rho V_{max}^2 / 2 \right) f \tag{7}$$

where the friction factor, f, and correction factor, χ, are determined from Fig. 7.14 using $Re_{D,max} = 1.723 \times 10^4$,

f = 0.2 $\qquad$ χ = 1

Substituting numerical values,

$$\Delta p = 3 \times 1 \left[1.171 \text{ kg/m}^3 \times (24 \text{ m/s})^2 / 2 \right] \times 0.2$$

$$\Delta p = 195 \text{ N/m}^2$$ <

The fan power requirement is

$$P = \forall \Delta p = V\, N_T S_T L \Delta p \tag{8}$$

$$P = 12 \text{ m/s} \times 4 \times 0.024 \text{ m} \times 0.250 \text{ m} \times 195 \text{ N/m}^2$$

$$P = 56 \text{ W}$$ <

where ∀ is the volumetric flow rate. For this calculation, ρ in Eq. (7) was evaluated at T_m.

(c) For a single element in cross flow, the average convection coefficient can be estimated using the Churchill-Bernstein correlation,

$$\overline{Nu}_D = \frac{\overline{h}_D D}{k} = 0.3 + \frac{0.62\, Re_D^{1/2} Pr^{1/3}}{\left[1 + (0.4/Pr)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{Re_D}{282,000}\right)^{5/8}\right]^{4/5} \tag{9}$$

where all properties are evaluated at the film temperature, $T_f = (T_i + T_o)/2$. The results of the calculations are

$$Re_D = 4269 \qquad \overline{Nu}_{D,1} = 33.4 \qquad \overline{h}_{D,1} = 106 \text{ W/m}^2 \cdot \text{K}$$ <

Continued …

PROBLEM 7.93 (Cont.)

For the isolated element, $\bar{h}_{D,1} = 106\ W/m^2 \cdot K$, compared to the average value for the array, $\bar{h}_D = 216\ W/m^2 \cdot K$. Because the first row of the array acts as a turbulence grid, the heat transfer coefficient for the second and third rows will be larger than for the first row. Here, the array value is twice that for the isolated element.

(d) The effect of increasing the longitudinal and transverse pitches to 30 mm, should be to reduce the outlet temperature, heat rate, and pressure drop. The effect can be explained by recognizing that the maximum Reynolds number will be decreased, which in turn will result in lower values for the convection coefficient and pressure drop. Repeating the calculations of part (a) for $S_L = S_T = 30$ mm, find

V_{max} (m/s)	$Re_{D,max}$	$\overline{Nu}_D$	$\bar{h}_D$ ($W/m^2 \cdot K$)	$\Delta T_{\ell m}$ (°C)	q (W)	T_o (°C)
12	1.46×10^4	86.7	193	317	6925	41.3

and part (b) for the pressure drop and fan power, find

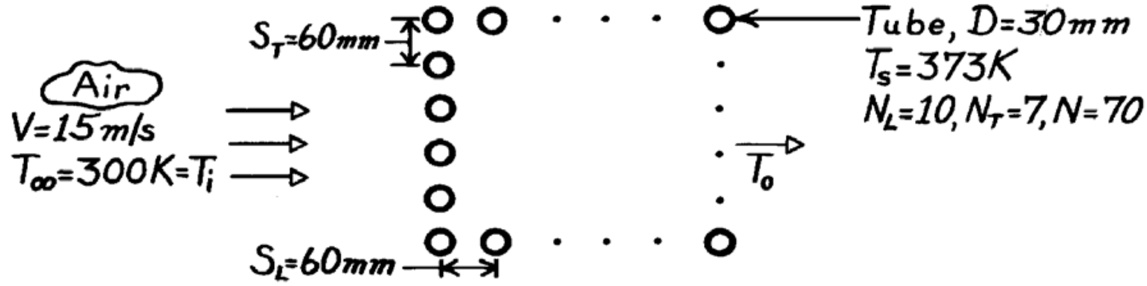
$$f = 0.18 \qquad \chi = 1 \qquad \Delta p = 122\ N/m^2 \qquad P = 44\ W$$

PROBLEM 7.94

KNOWN: Surface temperature and geometry of a tube bank. Velocity and temperature of air in cross-flow.

FIND: (a) Air outlet temperature, (b) Pressure drop and fan power requirements.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible radiation, (3) Air pressure is approximately one atmosphere, (4) Uniform surface temperature.

PROPERTIES: *Table A-4,* Air (300 K, 1 atm): $\rho = 1.1614\ \text{kg/m}^3$, $c_p = 1007$ J/kg·K, $\nu = 15.89 \times 10^{-6}\ \text{m}^2\text{/s}$, k = 0.0263 W/m·K, Pr = 0.707; (373K): Pr = 0.695.

ANALYSIS: (a) The air temperature increases exponentially, with

$$T_o = T_s - (T_s - T_i)\exp\left(-\frac{\pi D N \bar{h}}{\rho V N_T S_T c_p}\right).$$

With $V_{max} = \frac{S_T}{S_T - D} V = \frac{60}{30} 15 \frac{m}{s} = 30 \frac{m}{s}$; $Re_{D,max} = \frac{30\ m/s \times 0.03\ m}{15.89 \times 10^{-6}\ m^2/s} = 56,639.$

Tables 7.5 and 7.6 give $C_1 = 0.27$, m = 0.63 and $C_2 = 0.97$. Hence from the Zukauskas correlation,

$$\overline{Nu}_D = 0.27(0.97)(56,639)^{0.63}(0.707)^{0.36}(0.707/0.695)^{1/4} = 229$$

$$\bar{h} = \overline{Nu}_D k/D = 229 \times 0.0263\ \text{W/m}\cdot\text{K}/0.03\ \text{m} = 201\ \text{W/m}^2\cdot\text{K}.$$

Hence,

$$T_o = 373\text{K} - (373 - 300)\text{K}\exp\left(-\frac{\pi \times 0.03\ \text{m} \times 70 \times 201\ \text{W/m}^2\cdot\text{K}}{1.1614\ \text{kg/m}^3 \times 15\ \text{m/s} \times 7 \times 0.06\ \text{m} \times 1007\ \text{J/kg}\cdot\text{K}}\right)$$

$$T_o = 373\text{K} - 73\text{K} \times 0.835 = 312\text{K} = 39^\circ\text{C}. \qquad <$$

(b) With $Re_{D,max} = 5.66 \times 10^4$, $P_L = 2$, $(P_T - 1)/(P_L - 1) = 1$, Fig. 7.14 yields $f \approx 0.19$ and $\chi = 1$. Hence,

$$\Delta p = N_L \chi \left(\frac{\rho V_{max}^2}{2}\right) f = 10\left(\frac{1.1614\ \text{kg/m}^3 \times (30\ \text{m/s})^2}{2}\right) 0.19 = 993\ \text{N/m}^2 = 0.00993\ \text{bar}. \qquad <$$

The fan power requirement is

$$P = \dot{m}_a \Delta p/\rho = \rho V N_T S_T L\ \Delta p/\rho = 15\ \text{m/s} \times 7 \times 0.06\ \text{m} \times 1\text{m} \times 993\ \text{N/m}^2 = 6.26\ \text{kW}. \qquad <$$

COMMENTS: The heat rate is

$$q = \dot{m}_a c_p (T_o - T_i) = \rho V N_T S_T L\ c_p (T_o - T_i)$$

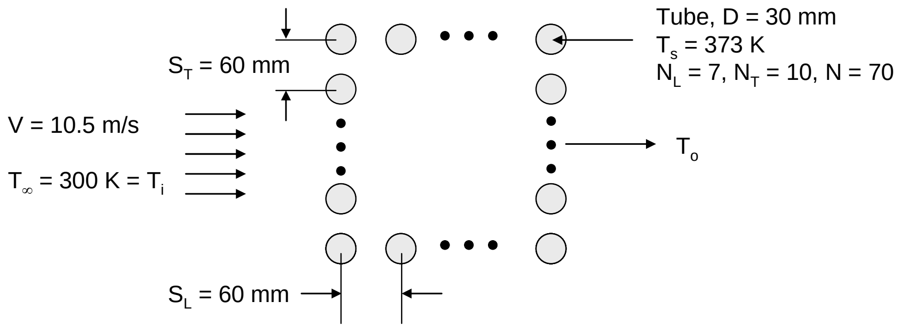
$$q = 1.1614\ \text{kg/m}^3 \times 15\ \text{m/s} \times 7 \times 0.06\text{m} \times 1\text{m} \times 1007\ \text{J/kg}\cdot\text{K}\ (312 - 300)\text{K} = 88.4\ \text{kW}.$$

PROBLEM 7.95

KNOWN: Surface temperature and geometry of tube bank. Velocity and temperature of air in cross-flow.

FIND: (a) Air outlet temperature, (b) Pressure drop and fan power requirements.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible radiation, (3) Air pressure approximately one atmosphere, (4) Uniform surface temperature.

PROPERTIES: *Table A.4*, air (300K, 1 atm): $\nu = 15.89\times10^{-6}$ m^2/s, $Pr = 0.707$, $k = 0.0263$ W/m·K, $\rho = 1.1614$ kg/m^3, $c_p = 1007$ J/kg·K; (373 K): $Pr_s = 0.695$.

ANALYSIS: (a) The outlet air temperature may be found from

$$T_o = T_s - (T_s - T_i)\exp\left(-\frac{\pi D N \bar{h}}{\rho V N_T S_T c_p}\right)$$

With $V_{\max} = \dfrac{S_T}{S_T - D}V = \dfrac{60}{30}\times10.5\text{m/s} = 21\text{m/s}$; $\quad \text{Re}_{D,\max} = \dfrac{21\text{m/s}\times0.03\text{m}}{15.89\times10^{-6}\text{m}^2\text{/s}} = 39{,}648$

Tables 7.5 and 7.6 give $C_1 = 0.27$, $m = 0.63$ and $C_2 = 0.95$. From the Zukauskas correlation,

$$\overline{Nu}_D = 0.27\times0.95\times39{,}648^{0.63}(0.707)^{0.36}(0.707/0.695)^{1/4} = 179.3$$

$$\bar{h} = \overline{Nu}_D k/D = 179.3\times0.0263\text{W/m}\cdot\text{K}/0.03\text{m} = 157\text{W/m}^2\cdot\text{K}$$

and therefore,

$$T_o = 373\text{K} - 73\text{K}\exp\left(-\frac{\pi\times0.03\text{m}\times70\times157\text{W/m}^2\cdot\text{K}}{1.1614\text{kg/m}^3\times10.5\text{m/s}\times10\times0.06\text{m}\times1007\text{J/kg}\cdot\text{K}}\right)$$

$$= 373\text{K} - 73\text{K}\times0.869 = 310\text{K} = 37°\text{C}$$ <

(b) With $Re_{D,max} = 39{,}648$, $P_L = P_T = 2$, $(P_T - 1)/(P_L - 1) = 1$, Fig. 7.14 yields $f \approx 0.20$ and $\chi = 1$. Therefore,

$$\Delta p = N_L\chi\left(\frac{\rho V_{\max}^2}{2}\right)f = 7\left(\frac{1.1614\text{kg/m}^3\times(21\text{m/s})^2}{2}\right)0.20 = 359\text{N/m}^2$$

and the fan power requirement is

Continued…

PROBLEM 7.95 (Cont.)

$$P = \dot{m}_a \Delta p / \rho = V N_T S_T L \Delta p = 10.5\text{m/s} \times 10 \times 0.06\text{m} \times 1\text{m} \times 359\text{N/m}^2 = 2.26\text{kW}$$ <

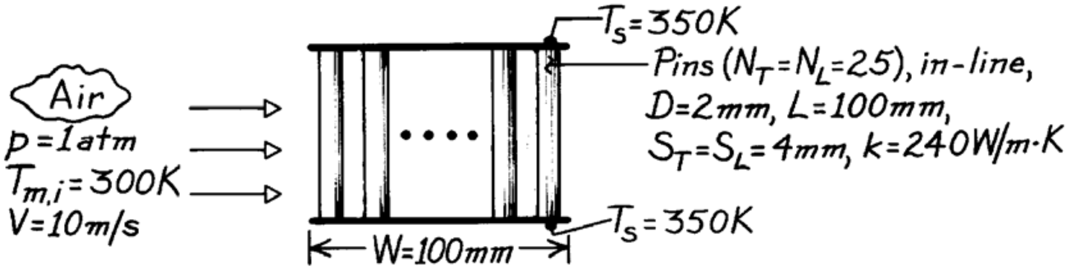
COMMENTS: Note that the mass flow rate here is the same as in Problem 7.94. In Problem 7.94, for $N_L = 7$ and $N_T = 10$, the outlet temperature, pressure drop, and fan power requirements are T_o = 39°C, Δp = 993 N/m^2, and P = 6.26 kW, respectively. Placing the tube bundle with fewer tubes in the streamwise direction ($N_L/N_T < 1$) results in a higher overall heat transfer rate (lower air outlet temperature) since the downstream tubes experience a larger temperature difference between the tube wall and the flowing air. In addition, a significantly lower pressure drop and pumping power is needed. However, the cross-sectional area of the duct within which the tube bundle is placed must be increased, and therefore capital cost of installation would be higher, for the $N_L/N_T < 1$ case.

PROBLEM 7.96

KNOWN: Characteristics of pin fin array used to enhance cooling of electronic components. Velocity and temperature of coolant air.

FIND: (a) Average convection coefficient for array, (b) Total heat rate and air outlet temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible radiation, (3) One-dimensional conduction in pins, (4) Uniform plate temperature, (5) Plates have a negligible effect on flow over pins, (6) Uniform convection coefficient over all surfaces, corresponding to average coefficient for flow over a tube bank.

PROPERTIES: Air (300 K, 1 atm): $\rho = 1.1614\ \text{kg/m}^3$, Pr = 0.707, $c_p = 1007$ J/kg·K, $\mu = 184.6 \times 10^{-7}$ kg/s·m, k = 0.0263 W/m·K. Aluminum (given): k = 240 W/m·K.

ANALYSIS: (a) From the Zukauskas relation

$$\overline{Nu}_D = C\,Re_{D,\max}^m\,Pr^{0.36}\left(Pr_\infty / Pr_s\right)^{1/4}$$

$$\left(Pr_\infty / Pr_s\right)^{1/4} \approx 1 \qquad V_{\max} = \frac{S_T}{S_T - D} V = \frac{4}{4-2} 10\ \text{m/s} = 20\ \text{m/s}$$

$$Re_{D,\max} = \frac{1.164\ \text{kg/m}^3 \times 20\ \text{m/s} \times 0.002\ \text{m}}{184.6 \times 10^{-7}\ \text{kg/s}\cdot\text{m}} = 2517$$

From Table 7.5 find $C_1 = 0.27$ and m = 0.63, hence

$$\overline{Nu}_D = 0.27(2517)^{0.63}(0.707)^{0.36} = 33.1$$

$$\bar{h} = \overline{Nu}_D \frac{k}{D} = 33.1 \times \frac{0.0263\ \text{W/m}\cdot\text{K}}{0.002\ \text{m}} = 435\ \text{W/m}^2\cdot\text{K}. \qquad <$$

(b) If T_s = 350 K is taken to be the temperature of all of the heat transfer surfaces, correction must be made for the actual temperature drop along the pins. This is done by introducing the overall surface efficiency η_o and replacing $\bar{h}A$ by $\bar{h}A_t\eta_o$. Hence, to obtain the air outlet temperature, we use

$$\frac{T_s - T_o}{T_s - T_i} = \exp\left(-\frac{\bar{h}A_t\eta_o}{\dot{m}c_p}\right)$$

where

Continued …

PROBLEM 7.96 (Cont.)

$$A_t = N(\pi DL) + 2W^2 - 2N(\pi D^2/4)$$

$$A_t = 625(\pi \times 0.002\ \text{m} \times 0.1\ \text{m}) + 2(0.1\ \text{m})^2 - 2 \times 625\pi(0.002\ \text{m})^2/4 = 0.409\ \text{m}^2$$

Also $\eta_o = 1 - \frac{A_f}{A_t}(1-\eta_f)$ where η_f is given by Eq. (3.91). With symmetry about the midplane of the pin, q_f = M tanh (mL/2). Hence

$$\eta_f = \frac{q}{q_{max}} = \frac{\left(\bar{h}\pi Dk\pi D^2/4\right)^{1/2}\theta_b \tanh(mL/2)}{\bar{h}\pi D(L/2)\theta_b} = \frac{\tanh(mL/2)}{\left(\bar{h}/kD\right)^{1/2} L}$$

or, with $m = \left[\bar{h}\pi D/\left(k\pi D^2/4\right)\right]^{1/2} = 2\left(\bar{h}/kD\right)^{1/2}$,

$$\eta_f = \frac{\tanh(mL/2)}{mL/2}$$

$$m = 2\left(\frac{435\ \text{W/m}^2\cdot\text{K}}{240\ \text{W/m}\cdot\text{K} \times 0.002\ \text{m}}\right)^{1/2} = 60.2\ \text{m}^{-1}$$

$$mL/2 = 60.2\ \text{m}^{-1} \times 0.05\ \text{m} = 3.01 \quad \text{and} \quad \tanh(mL/2) = 0.995$$

$$\eta_f = \frac{0.995}{3.01} = 0.331.$$

Hence, $\eta_o = 1 - \frac{625 \times \pi(0.002\ \text{m})(0.1\ \text{m})}{0.409\ \text{m}^2}(1-0.331) = 0.357$

$$\dot{m} = \rho VLN_T S_T = 1.1614\ \text{kg/m}^3(10\ \text{m/s})0.1\ \text{m}(25)(0.004\ \text{m}) = 0.116\ \text{kg/s}.$$

Now evaluating the air outlet temperature,

$$\frac{T_s - T_o}{T_s - T_i} = \exp\left(-\frac{435\ \text{W/m}^2\cdot\text{K} \times 0.409\ \text{m}^2 \times 0.357}{0.116\ \text{kg/s} \times 1007\ \text{J/kg}\cdot\text{K}}\right) = 0.581$$

$$T_o = T_s - 0.581(T_s - T_i) = 350\ \text{K} - 0.581(50\ \text{K})$$

$$T_o = 321\ \text{K}. \quad <$$

The total heat rate is

$$q = \dot{m}c_p(T_o - T_i) = 0.116\ \text{kg/s}(1007\ \text{J/kg}\cdot\text{K})21\ \text{K} = 2453\ \text{W}. \quad <$$

COMMENTS: (1) The average surface heat flux which can be dissipated by the electronic components is $q/2W^2$ = 122,650 W/m^2, or 12.3 W/cm^2. (2) To check the numerical results, compute

$$\Delta T_{\ell m} = \frac{\Delta T_o - \Delta T_i}{\ln(\Delta T_o/\Delta T_i)} = \frac{29\ \text{K} - 50\ \text{K}}{\ln(29/50)} = 38.6\ \text{K}$$

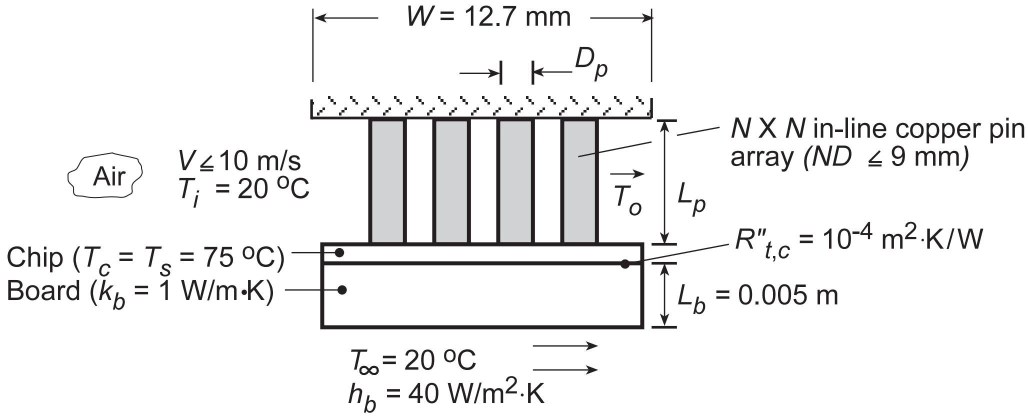
Hence $q = \bar{h}A_t\eta_o\Delta T_{\ell m} = 435\ \text{W/m}^2\cdot\text{K} \times 0.409\ \text{m}^2 \times 0.357 \times 38.6\ \text{K} = 2449\ \text{W}.$

PROBLEM 7.97

KNOWN: Dimensions and properties of chip, board and pin fin assembly. Convection conditions for chip and board surface. Maximum allowable chip temperature.

FIND: Effect of design and operating conditions on maximum chip power dissipation.

SCHEMATIC:



ASSUMPTIONS: (1) Uniform chip temperature, (2) One-dimensional conduction in pins, (3) Insulated pin tips, (4) Negligible radiation, (5) Uniform convection coefficient over pin and base surfaces.

PROPERTIES: *Table A.1*, copper ($T \approx 340$ K): $k_p = 397$ W/m·K. *Table A.4*, air: properties evaluated using IHT *Properties* Tool Pad.

ANALYSIS: The chip heat rate may be expressed as

$$q_c = \frac{A_c\left(T_c - T_\infty\right)}{\left[R''_{t,c} + \left(L_b/k_b\right) + \left(1/h_b\right)\right]} + q_t$$

where $A_c = W^2$ and q_t is the total heat rate for the fin array. This heat rate must account for the variation of the air temperature across the array. Hence, the appropriate driving potential is $\Delta T_{1m} = \left[\left(T_c - T_i\right) - \left(T_c - T_o\right)\right] / \ln\left[\left(T_c - T_i\right)/\left(T_c - T_o\right)\right]$. However, the total surface area must account for the finite pin length and the exposed base (prime) surface. Hence, from Eqs. 3.106 and 3.107, with ΔT_{lm} replacing θ_b,

$$q_t = \overline{h} A_t \eta_o \Delta T_{lm}$$

where $A_t = N^2 A_f + A_b$, $A_b = A_c - N^2 A_{p,c}$, $A_{p,c} = \pi D_p^2/4$ and

$$\eta_o = 1 - \frac{N^2 A_f}{A_t}\left(1 - \eta_f\right)$$

For an adiabatic tip, Eq. 3.100 yields

$$\eta_f = \frac{\tanh mL_p}{mL_p}$$

where $m = \left(4\overline{h}/k_p D_p\right)^{1/2}$. The air outlet temperature is given by the expression

$$\frac{T_c - T_o}{T_c - T_i} = \exp\left(-\frac{\overline{h} A_t \eta_o}{\dot{m} c_p}\right)$$

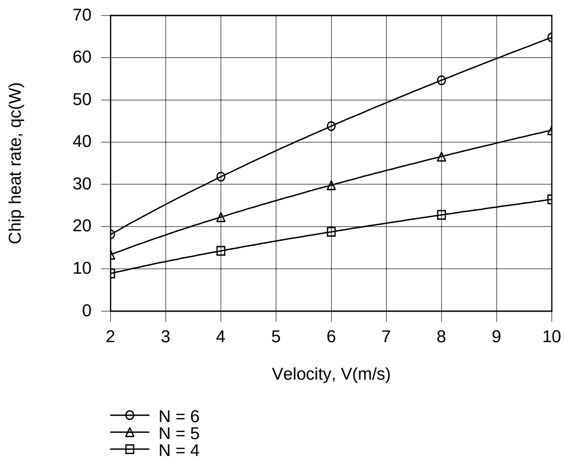
Continued...

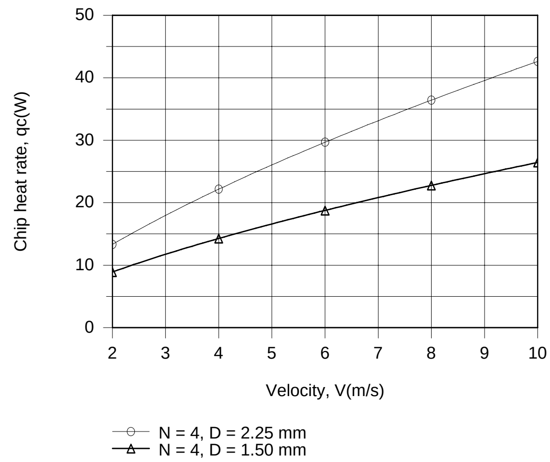
PROBLEM 7.97 (Cont.)

where $\dot{m} = \rho VWL_p$ and $\overline{h}$ is obtained from the Zukauskas correlation,

$$\overline{Nu}_D = C_1 C_2 \, Re_{D,max}^m \, Pr^{0.36} \left(Pr/Pr_s\right)^{1/4}$$

The foregoing model, including the convection correlation, was entered from the keyboard into the workspace of IHT and used with the *Properties* Tool Pad to perform the following parametric calculations.





Remaining within the limit $ND_p \leq 9$ mm, there is clearly considerable benefit associated with increasing N from 4 to 6 for $D_p = 1.5$ mm or with increasing D_p from 1.5 to 2.25 mm for N = 4. However, the best configuration corresponds to N = 6 and $D_p = 1.5$ mm (a larger number of smaller diameter pins), for which both A_t and $\overline{h}$ are approximately 50% and 20% larger than values associated with N = 4 and D_p = 2.25 mm. The peak heat rate is $q_c = 64.5$ W for V = 10 m/s, N = 6, and $D_p = 1.5$ mm.

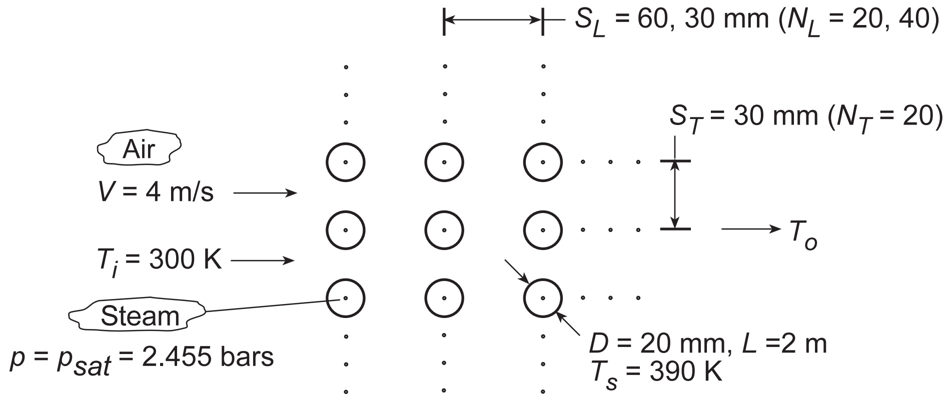
COMMENTS: (1) The heat rate through the board is only $q_b = 0.295$ W and hence a negligible portion of the total heat rate. (2) Values of C = 0.27 and m = 0.63 were used for the entire range of conditions. However, $Re_{D,max}$ was less than 1000 in the mid to low range of V, for which the correlation was therefore used outside its prescribed limits and the results are somewhat approximate. (3) Using the IHT solver, the model was implemented in three stages, beginning with (i) the correlation and the Properties Tool Pad and sequentially adding (ii) expressions for q_t and $(T_c - T_o)/(T_c - T_i)$ without η_o, and (iii) inclusion of η_o in the model. Results computed from one calculation were loaded as initial guesses for the next calculation.

PROBLEM 7.98

KNOWN: Tube geometry and flow conditions for steam condenser. Surface temperature and pressure of saturated steam.

FIND: (a) Coolant outlet temperature, (b) Heat and condensation rates, (c) Effects of reducing longitudinal pitch and change in velocity.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Negligible radiation, (3) Negligible effect of temperature change on air properties, (parts a and b), (4) Applicability of convection correlation outside designated range.

PROPERTIES: *Table A.4*, air (T_i = 300 K): ρ = 1.16 kg/m^3, c_p = 1007 J/kg·K, ν = 15.89 × 10^{-6} m^2/s, k = 0.0263 W/m·K, Pr = 0.707. (T_s = 390 K): Pr = 0.692. *Table A.6*, saturated water at 2.455 bars: h_{fg} = 2.183 × 10^6 J/kg.

ANALYSIS: (a) From Section 7.6,

$$T_o = T_s - \left(T_s - T_i\right)\exp\left(-\frac{\pi D N \bar{h}}{\rho V N_T S_T c_p}\right)$$

With

$$V_{max} = \frac{S_T}{S_T - D}V = \frac{30}{10}4\,m/s = 12\,m/s$$

$$Re_{D,max} = \frac{V_{max}D}{\nu} = \frac{12\,m/s\left(0.02\,m\right)}{15.89\times10^{-6}\,m^2/s} = 15{,}104$$

Using the Zhukauskas correlation outside its designated range $\left(S_T/S_L = 0.5\right)$, Table 7.5 yields C_1 = 0.27 and m = 0.63. Hence, with C_2 = 1,

$$\overline{Nu}_D = C_1 Re_{D,max}^m Pr^{0.36}\left(Pr/Pr_s\right)^{1/4} = 0.27\left(15{,}104\right)^{0.63}\left(0.707\right)^{0.36}\left(\frac{0.707}{0.692}\right)^{1/4} = 103$$

$$\bar{h} = \overline{Nu}_D\left(k/D\right) = 103\left(0.0263\,W/m\cdot K/0.02\,m\right) = 135\,W/m^2\cdot K$$

$$T_o = 390\,K - \left(90\,K\right)\exp\left[-\frac{\pi\left(0.02\,m\right)400\left(135\,W/m^2\cdot K\right)}{1.16\,kg/m^3\left(4\,m/s\right)20\left(0.03\,m\right)1007\,J/kg\cdot K}\right] = 363\,K \quad <$$

(b) With q = q' L,

Continued...

PROBLEM 7.98 (Cont.)

$$q = N\left(\bar{h}\pi DL\Delta T_{lm}\right)$$

where

$$\Delta T_{lm} = \frac{(T_s - T_i) - (T_s - T_o)}{\ln\left(\frac{T_s - T_i}{T_s - T_o}\right)} = \frac{(90-27)\,K}{\ln\left(\frac{90}{27}\right)} = 52.3\,K$$

Hence $q = 400\left(135\,W/m^2 \cdot K\right)\pi(0.02\,m)\,2\,m\,(52.3\,K) = 355\,kW$ <

The condensation rate is

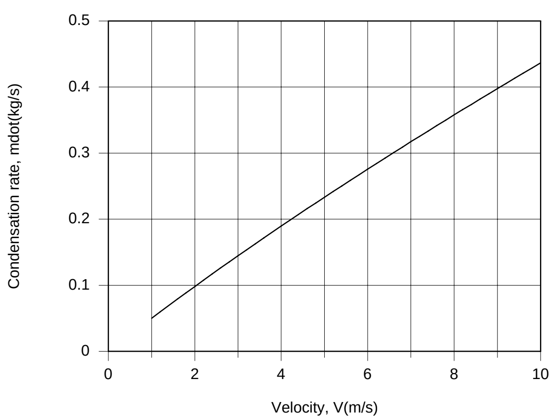
$$\dot{m}_{cond} = \frac{q}{h_{fg}} = \frac{3.55 \times 10^5\,W}{2.183 \times 10^6\,J/kg} = 0.163\,kg/s$$ <

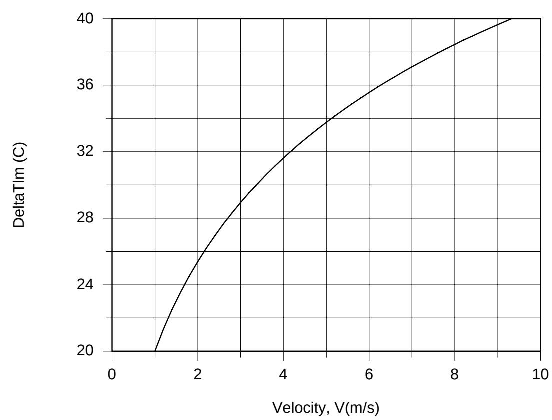
(c) For S_L = 0.03 m, N_L = 40 and N = 800, using IHT with the foregoing model and the Properties Tool Pad to evaluate air properties at $(T_i + T_o)/2$, we obtain

$$T_o = 383.6\,K, \quad \Delta T_{lm} = 31.6\,C, \quad q = 414\,kW, \quad \dot{m}_{cond} = 0.190\,kg/s$$ <

As expected, q and $\dot{m}_{cond}$ increase with increasing N_L. However, due to a corresponding increase in T_o, and hence a reduction in ΔT_{lm}, the increase is not commensurate with the two-fold increase in surface area for the tube bank.

The effect of velocity is shown below.





The heat rate, and hence condensation rate, is strongly affected by velocity, because in addition to increasing $\bar{h}$, an increase in V decreases T_o, and hence increases ΔT_{lm}.

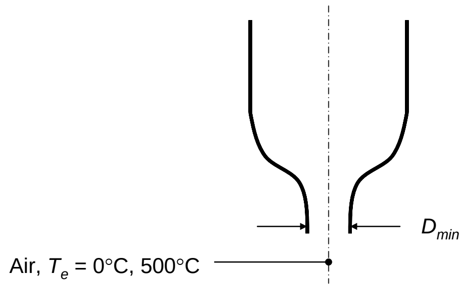
COMMENTS: (1) The calculations of part (a) should be repeated with air properties evaluated at $(T_i + T_o)/2$. (2) the condensation rate could be increased significantly by using a water-cooled (larger $\bar{h}$), rather than an air-cooled, condenser.

PROBLEM 7.99

KNOWN: Temperature of single round air jet.

FIND: Minimum jet diameter for which Equation 7.71 can be applied.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Constant properties, (3) Air is ideal gas, (4) Flow is incompressible for $Ma < 0.3$.

PROPERTIES: *Table A-4*, Air (T = 273 K): c_p = 1006.5 J/kg·K, $\nu = 13.5 \times 10^{-6}$ m²/s; (T = 773 K): c_p = 1092.5 J/kg·K, $\nu = 80.3 \times 10^{-6}$ m²/s.

ANALYSIS: (a) Equation 7.71 is restricted to the Reynolds range:

$$2000 \le Re \le 400{,}000$$

With $Re = VD/\nu$, this restricts VD, but does not limit D directly. Therefore there must be another constraint, namely the flow must be incompressible, which is valid for $Ma = V/a < 0.3$, where a is the speed of sound. The Mach number constraint implies $V < 0.3a$, which in turn means that $Re < 0.3aD/\nu$. Incorporating the lower Reynolds number limit provides a minimum bound on D, namely

$$2000 \le Re < \frac{0.3aD}{\nu}$$

$$D \ge 2000\frac{\nu}{0.3a}$$

Also, the gas constant for air is $R \equiv \mathcal{R}/\mathcal{M}$ = 8315 J/kmol·K/28.97 kg/kmol = 287 J/kg.

(a) At T = 273 K, $c_v \equiv c_p - R = 1006.5\ \text{J/kg}\cdot\text{K} - 287\ \text{J/kg}\cdot\text{K} = 719.5\ \text{J/kg}\cdot\text{K}$. The ratio of specific heats is therefore $\gamma = c_p/c_v$ = 1006.5 J/kg·K/719.5 J/kg·K = 1.40 and the speed of sound is $a = \sqrt{\gamma RT} = \sqrt{1.40 \times 287\ \text{J/kg}\cdot\text{K} \times 273\ \text{K}} = 331\ \text{m/s}$. Hence the minimum diameter jet is given by

$$D \ge 2000\frac{13.5\times10^{-6}\ \text{m}^2/\text{s}}{0.3\times331\ \text{m/s}} = 2.7\times10^{-4}\ \text{m} = 0.27\ \text{mm} \qquad <$$

(b) For T = 773 K, $c_v \equiv c_p - R = 1092.5\ \text{J/kg}\cdot\text{K} - 287\ \text{J/kg}\cdot\text{K} = 805.5\ \text{J/kg}\cdot\text{K}$. The ratio of specific heats is therefore $\gamma = c_p/c_v$ = 1092.5 J/kg·K/805.5 J/kg·K = 1.36 and the speed of sound is $a = \sqrt{\gamma RT} = \sqrt{1.36 \times 287\ \text{J/kg}\cdot\text{K} \times 773\ \text{K}} = 549\ \text{m/s}$. Hence the minimum diameter jet is given by

$$D \ge 2000\frac{80.3\times10^{-6}\ \text{m}^2/\text{s}}{0.3\times549\ \text{m/s}} = 0.00098\ \text{m} = 0.98\ \text{mm} \qquad <$$

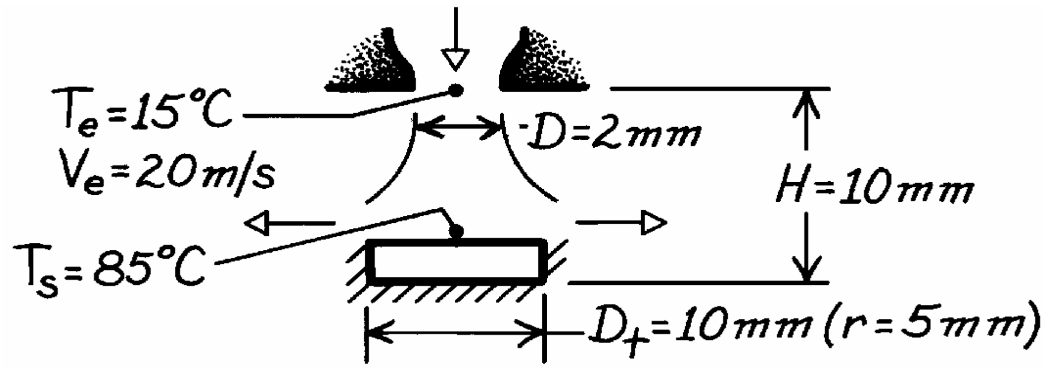
COMMENTS: If jet diameters smaller than these limits are to be used, alternative approaches would need to be taken to estimate the corresponding convection heat transfer rates.

PROBLEM 7.100

KNOWN: Geometry of air jet impingement on a transistor. Jet temperature and velocity. Maximum allowable transistor temperature.

FIND: Maximum allowable operating power.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Isothermal surface, (3) Bell-shaped nozzle, (4) All of the transistor power is dissipated to the jet.

PROPERTIES: *Table A-4*, Air (T_f = 323 K, 1 atm): $\nu = 18.2 \times 10^{-6}$ m^2/s, k = 0.028 W/m·K, Pr = 0.704.

ANALYSIS: The maximum power or heat transfer rate by convection is

$$P_{max} = q_{max} = \bar{h}\left(\pi D_t^2/4\right)\left(T_s - T_e\right)_{max}.$$

For a single round nozzle,

$$\frac{\overline{Nu}}{Pr^{0.42}} = G\left(A_r, H/D\right)F_1\left(Re\right)$$

where $A_r = D^2/4r^2 = 0.04$ and

$$G = ZA_r^{1/2}\frac{1-2.2A_r^{1/2}}{1+0.2(H/D-6)A_r^{1/2}} = 2(0.04)^{1/2}\frac{1-2.2(0.04)^{1/2}}{1+0.2(5-6)(0.04)^{1/2}} = 0.233$$

With

$$Re = \frac{V_e D}{\nu} = \frac{\left(20\text{ m/s}\right)0.002\text{ m}}{18.2\times10^{-6}\text{ m}^2/\text{s}} = 2198$$

$$F_1 = 2Re^{1/2}\left(1+0.005Re^{0.55}\right)^{1/2} = 2\left(2198\right)^{1/2}\left[1+0.005\left(2198\right)^{0.55}\right]^{1/2} = 108.7$$

Hence $\bar{h} = \frac{k}{D}GF_1 Pr^{0.42} = \frac{0.028\text{ W/m}\cdot\text{K}}{0.002\text{ m}}\left(0.233\right)\left(108.7\right)\left(0.704\right)^{0.42} = 306\text{ W/m}^2\cdot\text{K}$

Hence $P_{max} = \left(306\text{ W/m}^2\cdot\text{K}\right)\left(\pi/4\right)\left(0.01\text{ m}\right)^2\left(70^\circ\text{C}\right) = 1.68\text{ W}.$ <

COMMENTS: (1) All conditions required for use of the correlation are satisfied.

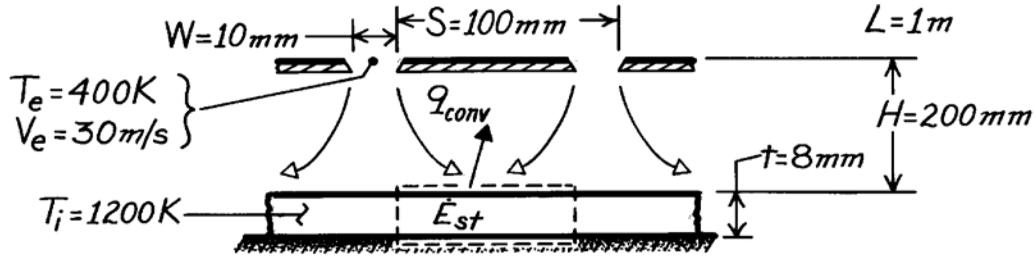
(2) Power dissipation may be enhanced by allowing for heat loss through the side and base of the transistor.

PROBLEM 7.101

KNOWN: Dimensions of heated plate and slot jet array. Jet exit temperature and velocity. Initial plate temperature.

FIND: Initial plate cooling rate.

SCHEMATIC:



ASSUMPTIONS: (a) Negligible variation in h along plate, (b) Negligible heat loss from back surface of plate, (c) Negligible radiation from front surface of plate.

PROPERTIES: *Table A-1*, AISI 304 Stainless steel (1200 K): k = 28.0 W/m·K, c_p = 640 J/kg·K, ρ = 7900 kg/m^3; *Table A-4*, Air ($\overline{T}_f$ = 800 K): ν = 84.9 × 10^{-6} m^2/s, k = 0.0573 W/m·K, Pr = 0.709.

ANALYSIS: Performing an energy balance on a control surface about the plate,

$$-q_{conv} = -\overline{h}A_s\left(T_i - T_e\right) = \dot{E}_{st} = \rho\left(A_s t\right)c_p\left(dT/dt\right)_i \qquad \left.\frac{dT}{dt}\right)_i = -\frac{\overline{h}\left(T_i - T_e\right)}{\rho\, c_p t}.$$

For an array of slot nozzles,

$$\frac{\overline{Nu}}{Pr^{0.42}} = \frac{2}{3}A_{r,o}^{3/4}\left[\frac{2Re}{A_r / A_{r,o} + A_{r,o} / A_r}\right]^{2/3}$$

where A_r = W/S = 0.1

$$A_{r,o} = \left\{60 + 4\left[\left(H/2W\right) - 2\right]^2\right\}^{-1/2} = \left\{60 + 4\left(64\right)\right\}^{-1/2} = 0.0563$$

$$Re = \frac{V_e\left(2W\right)}{\nu} = \frac{30\text{ m/s}\left(0.02\text{ m}\right)}{84.9\times10^{-6}\text{ m}^2/\text{s}} = 7067$$

$$\overline{h} = \frac{0.0573\text{ W/m}\cdot\text{K}}{0.02\text{ m}}\frac{2}{3}\left(0.0563\right)^{3/4}\left[\frac{2\times7067}{1.776 + 0.563}\right]^{2/3} = 73.2\text{ W/m}^2\cdot\text{K}.$$

Hence,

$$\left.\frac{dT}{dt}\right)_i = -\frac{73.2\text{ W/m}^2\cdot\text{K}\left(800\text{ K}\right)}{\left(7900\text{ kg/m}^3\right)\left(640\text{ J/kg}\cdot\text{K}\right)\left(0.008\text{ m}\right)} = 1.45\text{ K/s}. \qquad <$$

COMMENTS: (1) Bi = $\overline{h}t/k$ = (73.2 W/m^2·K) (0.008 m)/28 W/m·K = 0.02 and use of the lumped capacitance method is justified.

(2) Radiation may be significant.

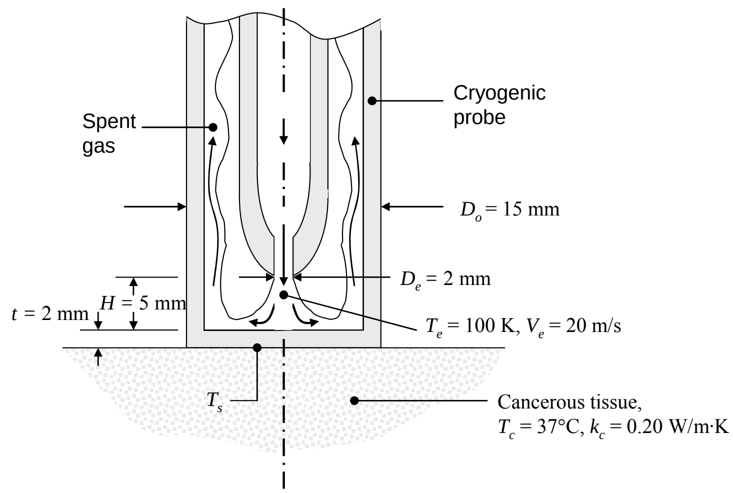
(3) Conditions required for use of the correlation are satisfied.

PROBLEM 7.102

KNOWN: Dimensions and material of a cryogenic probe. Temperature and velocity of nitrogen at jet exit. Cancerous tissue thermal conductivity and temperature far from the probe.

FIND: (a) Skin surface temperature under probe.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible contact resistance between skin and probe, (4) Incompressible flow, (5) Due to wall confinement, jet can be modeled as if it were one in an array.

PROPERTIES: *Table A-4*, Nitrogen ($T \approx 100$ K): $k = 9.58 \times 10^{-3}$ W/m·K, $\nu = 2.00 \times 10^{-6}$ m^2/s, Pr = 0.768. *Table A-1,* AISI 302 Stainless Steel ($T \approx$ 300 K): k_p = 15.1 W/m·K.

ANALYSIS: (a) The Reynolds number is

$$Re = \frac{V_e D}{\nu} = \frac{20 \text{ m/s} \times 0.002 \text{ m}}{2.00 \times 10^{-6} \text{ m}^2/\text{s}} = 2 \times 10^4$$

The jet behaves as if it were in a staggered array, with the probe walls behaving as if they were the symmetry planes between jets (see Figure 7.18*c*). Thus $S = D_o - 2t$ = 11 mm and

$$A_r = \pi D_e^2 / 2\sqrt{3}S^2 = \pi(0.002 \text{ m})^2 / 2\sqrt{3}(0.011 \text{ m})^2 = 0.030 \text{ m}^2$$

Furthermore, H/D_e = 2.5. Based on all of these values, the correlation for an array of round nozzles is valid. From Equations 7.72 and 7.74,

$$G = 2A_r^{1/2} \frac{1 - 2.2A_r^{1/2}}{1 + 0.2(H/D_e - 6)A_r^{1/2}} = 2(0.030 \text{ m}^2)^{1/2} \frac{1 - 2.2(0.030 \text{ m}^2)^{1/2}}{1 + 0.2(2.5 - 6)(0.030 \text{ m}^2)^{1/2}} = 0.244$$

$$K = \left[1 + \left(\frac{H/D_e}{0.6/A_r^{1/2}}\right)^6\right]^{-0.05} = \left[1 + \left(\frac{2.5}{0.6/(0.030 \text{ m})^{1/2}}\right)^6\right]^{-0.05} = 0.993$$

Thus from Equation 7.73,

Continued...

PROBLEM 7.102 (Cont.)

$$\overline{Nu} = 0.5KGRe^{2/3}Pr^{0.42} = 0.5 \times 0.993 \times 0.244 \times (2 \times 10^4)^{2/3}(0.768)^{0.42} = 79.9$$

and

$$\overline{h} = \overline{Nu}k / D_e = 79.9 \times 9.58 \times 10^{-3} \text{ W/m} \cdot \text{K} / 0.002 \text{ m} = 383 \text{ W/m}^2 \cdot \text{K}$$

Next, consider the heat transfer from the cancerous tissue at T_c to the probe surface, through the probe wall, and from the wall to the jet. The heat transfer rate can be written by considering a sum of thermal resistances, as follows:

$$q = \frac{T_c - T_e}{R_c + R_p + R_{\text{jet}}}$$

In this expression,

R_c is the resistance associated with the semi-infinite cancerous tissue having a disk of diameter D_o at temperature T_s, as in Table 4.1, Case 10:

$$R_c = 1/2D_o k_c = 1/(2 \times 0.015 \text{ m} \times 0.2 \text{ W/m·K}) = 167 \text{ K/W}$$

R_p represents conduction through the probe wall:

$$R_p = t/(k_p \pi D_o^2/4) = 0.002 \text{ m} \times 4/(15.1 \text{ W/m·K} \times \pi \times 0.015^2 \text{ m}^2) = 0.750 \text{ K/W}$$

$$R_{\text{jet}} = 1/(\overline{h}\ \pi D_o^2/4) = 4/(383 \text{ W/m}^2\text{·K} \times \pi \times 0.015^2 \text{ m}^2) = 14.8 \text{ K/W}$$

The heat transfer rate is

$$q = \frac{(310 - 100)\text{K}}{(167 + 0.75 + 14.8)\text{K / W}} = 1.15 \text{ W}$$

and $q = (T_c - T_s)/R_c$, so that

$$T_s = T_c - qR_c = 310 \text{ K} - 1.15 \text{ W} \times 167 \text{K / W} = 118 \text{ K}$$ <

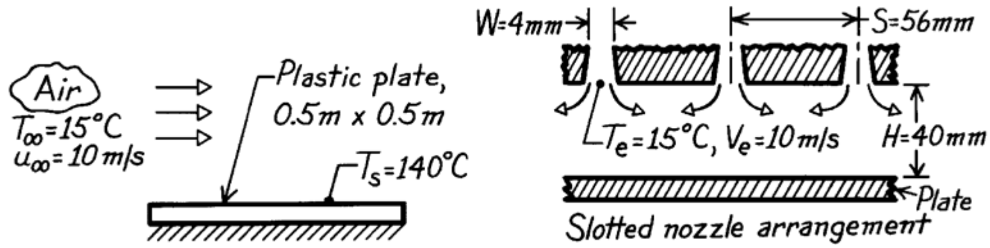
COMMENTS: (1) The assumption of incompressible flow can be checked as follows. For nitrogen, the gas constant is $R \equiv \mathcal{R}/\mathcal{M}$ = 8315 J/kmol·K/28 kg/kmol = 297 J/kg. At 100 K, $c_v = c_p - R = 1070 \text{ J / kg} \cdot \text{K} - 297 \text{ J / kg} \cdot \text{K} = 773 \text{ J / kg} \cdot \text{K}$. The ratio of specific heats is therefore $\gamma = c_p/c_v$ = 1070 J/kg·K/773 J/kg·K = 1.38 and the speed of sound is $a = \sqrt{1.38 \times 297 \text{ J/kg} \cdot \text{K} \times 100 \text{ K}}$ = 203 m/s. Hence the Mach number is $Ma = V/a$ = 20 m/s/203 m/s = 0.1, and the flow may be treated as incompressible.

PROBLEM 7.103

KNOWN: Air at 10 m/s and 15°C is available for cooling hot plastic plate. An array of slotted nozzles with prescribed width, pitch and nozzle-to-plate separation.

FIND: (a) Improvement in cooling rate achieved using the slotted nozzle arrangement in place of turbulent air in parallel flow over the plate, (b) Change in heat rates if air velocities were doubled, (c) Air mass rate requirement for the slotted nozzle arrangement.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) For parallel flow over plate, flow is turbulent, (3) Negligible radiation effects.

PROPERTIES: *Table A-4*, Air (T_f = (140 + 15)°C/2 = 350 K, 1 atm): $\rho = 0.995\ kg/m^3$, $\nu = 20.92 \times 10^{-6}\ m^2/s$, $k = 30.3 \times 10^{-3}$ W/m·K, Pr = 0.700.

ANALYSIS: (a) For turbulent flow over the *plate* of length L with

$$Re_L = \frac{u_\infty L}{\nu} = \frac{10\ m/s \times 0.5\ m}{20.92 \times 10^{-6}\ m^2/s} = 2.390 \times 10^5$$

using the turbulent flow correlation, find

$$\overline{Nu}_L = \frac{\bar{h}L}{k} = 0.037 Re_L^{4/5} Pr^{1/3} = 0.037\left(2.390 \times 10^5\right)^{4/5}(0.700)^{1/3} = 659.6$$

$$\bar{h} = \overline{Nu}_L k/L = 659.6 \times 0.030\ W/m \cdot K/0.5\ m = 39.6\ W/m^2 \cdot K.$$

For an array of *slot nozzles*,

$$\overline{Nu} = \frac{\bar{h}D}{k} = \frac{2}{3}A_{r,o}^{3/4}\left[\frac{2Re}{A_r/A_{r,o} + A_{r,o}/A_r}\right]^{2/3} Pr^{0.42}$$

where $$Re = \frac{V_e D_h}{\nu} = \frac{10\ m/s\left(2 \times 0.004\ m\right)}{20.92 \times 10^{-6}\ m^2/s} = 3824$$

$$A_{r,o} = \left\{60 + 4\left[\left(H/2W\right) - 2\right]^2\right\}^{-1/2} = \left\{60 + 4\left[40/2 \times 4 - 2\right]^2\right\}^{-1/2} = 0.1021$$

$$A_r = W/S = 4\ mm/56\ mm = 0.0714$$

$$\overline{Nu} = \frac{2}{3}(0.1021)^{3/4}\left[\frac{2 \times 3824}{0.0714/0.1021 + 0.1021/0.0714}\right]^{2/3}(0.700)^{0.42} = 24.3$$

$$\bar{h} = \overline{Nu}k/D_h = 24.3 \times 0.030\ W/m \cdot K/2 \times 0.004\ m = 91.1\ W/m^2 \cdot K.$$

Continued …

The improvement in heat rate with the slot nozzles (sn) over the flat plate (fp) is

$$\frac{q''_{sn}}{q''_{fp}} = \frac{\bar{h}_{sn}}{\bar{h}_{fp}} = \frac{91.1\ \mathrm{W/m^2 \cdot K}}{39.6\ \mathrm{W/m^2 \cdot K}} = 2.3. \qquad <$$

(b) If the air velocities were doubled for each arrangement in part (a), the heat transfer coefficients are affected as

$$\bar{h}_{sn} \sim Re^{2/3} \qquad \bar{h}_{fp} \sim Re^{4/5}.$$

Hence

$$\frac{\bar{h}_{sn}}{\bar{h}_{fp}} = 2.3\left(\frac{2^{2/3}}{2^{4/5}}\right) = 2.1. \qquad <$$

That is, comparative advantage of the slot nozzle over the flat plate decreases with increasing velocity.

(c) The mass rate of air flow through the array of slot nozzles is

$$\dot{m} = \rho N A_{c,e} = 0.995\mathrm{kg/m^3} \times 9\ (0.5\ \mathrm{m} \times 0.004\ \mathrm{m})10\mathrm{m/s} = 0.179\mathrm{kg/s}$$

where the number of slots is determined as

$$N \approx L/S = 0.5\mathrm{m}/0.056\ \mathrm{m} = 8.9 \approx 9. \qquad <$$

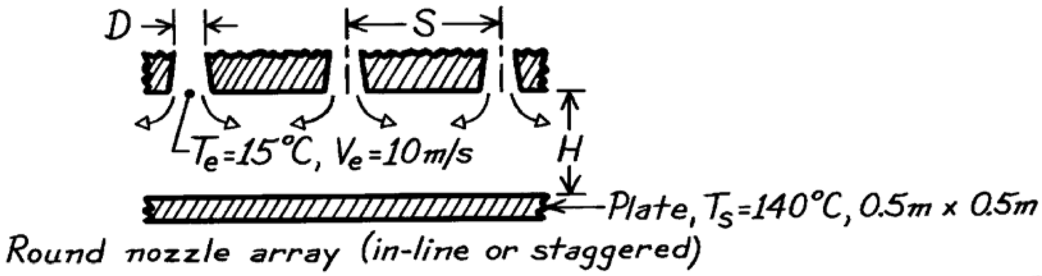
COMMENTS: Note, for the slot nozzle, the hydraulic diameter is $D_h = 2W$ and the relative nozzle area $(A_{c,e}/A_{cell})$ is $A_r = W/S$.

PROBLEM 7.104

KNOWN: Air jet velocity and temperature of 10 m/s and 15°C, respectively, for cooling hot plastic plate..

FIND: Design of optimal round nozzle array. Compare cooling rate with results for a slot nozzle array and flow over a flat plate. Discuss features associated with these three methods relevant to selecting one for this application.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible radiation effects.

PROPERTIES: *Table A-4*, Air (T_f = (140 + 15)°C/2 = 350 K, 1 atm): ρ = 0.995 kg/m^3, ν = 20.92 × 10^{-6} m^2/s, k = 30.0 × 10^{-3} W/m·K, Pr = 0.700.

ANALYSIS: To design an *optimal array* of round nozzles, we require that $D_{h,op} \approx 0.2H$ and $S_{op} \approx 1.4H$. Choose H = 40 mm, the nozzle-to-plate separation, hence

$$D_{h,op} = D = 0.2 \times 40 \text{ mm} = 8 \text{ mm} \qquad S_{op} = 1.4 \times 40 \text{ mm} = 56 \text{ mm}.$$

For an array of round nozzles,

$$\overline{Nu} = K(A_r, H/D) \cdot G(A_r, H/D) \cdot F_2(Re) \cdot Pr^{0.42}$$

where for an *in-line* array, see Fig. 7.18,

$$A_r = \frac{\pi D^2}{4S^2} = \frac{\pi (8 \text{ mm})^2}{4(56 \text{ mm})^2} = 0.0160$$

$$K = \left[1 + \left(\frac{H/D}{0.6/A_r^{1/2}}\right)^6\right]^{-0.05} = \left[1 + \left(\frac{40/8}{0.6/0.0160^{1/2}}\right)^6\right]^{-0.05} = 0.9577$$

$$G = 2A_r^{1/2}\frac{1 - 2.2A_r}{1 + 0.2(H/D - 6)A_r^{1/2}} = 2 \times 0.0160^{1/2}\frac{1 - 2.2 \times 0.0160}{1 + 0.2(40/8 - 6)0.0160^{1/2}}$$

$$G = 0.2504$$

$$F_2 = 0.5Re^{2/3} = 0.5\left(\frac{10 \text{ m/s} \times 0.008 \text{ m}}{20.92 \times 10^{-6} \text{ m}^2/\text{s}}\right)^{2/3} = 122.2.$$

The average heat transfer coefficient for the *optimal in-line* (op, il) array of round nozzles is,

$$\bar{h}_{op,il} = \overline{Nu}\, k/D_{h,op} = \frac{0.030 \text{ W/m} \cdot \text{K}}{0.008 \text{ m}} \times 0.9577 \times 0.2504 \times 122.2(0.700)^{0.42}$$

$$\bar{h}_{op,il} = 94.6 \text{ W/m}^2 \cdot \text{K}.$$

Continued …

PROBLEM 7.104 (Cont.)

If an *optimal staggered* (op,s) array were used, see Fig. 7.18, with

$$A_r = \frac{\pi D^2}{2(3)^{1/2} S^2} = \frac{\pi \times (8\text{ mm})^2}{2(3)^{1/2}(56\text{ mm})^2} = 0.0185$$

find K = 0.9447, G = 0.2632, F_2 = 122.2 and $\bar{h}_{op,s} = 100.0\ \text{W/m}^2 \cdot \text{K}$.

Using the previous results for *parallel flow* (pf) and the *slot nozzle* (sn) array, the heat rates, which are proportional to the average convection coefficients, can be compared.

Arrangement	Flat plate (fp)	Slot nozzle (sn)	Optimal round nozzle (op) In-line (il)	Staggered (s)
$\bar{h}$, $\text{W/m}^2 \cdot \text{K}$	39.6	91.1	94.6	100.0
$\bar{h}/h_{fp}$	1.0	2.30	2.39	2.53
$\dot{m}$, kg/s	---	0.199	0.040	0.046

For these flow conditions, we conclude that there is only slightly improved performance associated with using the round nozzles. As expected, the *staggered* array is better than the *in-line* arrangement, since the former has a higher area ratio (A_r). The air flow requirements for the round nozzle arrays are

$$\dot{m} = \rho N A_{c,e} V_e = \rho \left(A_s / A_{cell}\right) A_{c,e} V_e = \rho A_r A_s\ V_e$$

where N = A_s/A_{cell} is the number of nozzles and A_s is the area of the plate to be cooled. Substituting numerical values, find

$$\dot{m}_{op,il} = 0.995\ \text{kg/m}^3 \times 0.0160 \left(0.5 \times 0.5\ \text{m}^2\right) \times 10\ \text{m/s} = 0.040\ \text{kg/s}$$

$$\dot{m}_{op,s} = 0.995\ \text{kg/m}^3 \times 0.0185 \left(0.5 \times 0.5\ \text{m}^2\right) \times 10\ \text{m/s} = 0.046\ \text{kg/s.}$$

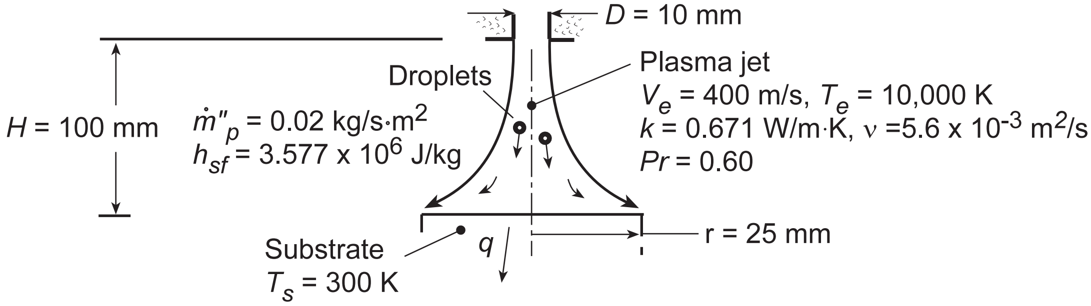
For this application, selection of a nozzle arrangement should be based upon air flow requirements (round nozzles have considerable advantage) and costs associated with fabrication of the arrays (slot nozzle may be easier to form from sheet metal).

PROBLEM 7.105

KNOWN: Exit diameter of plasma generator and radius of jet impingement surface. Temperature and velocity of plasma jet. Temperature of impingement surface. Droplet deposition rate.

FIND: Rate of heat transfer to substrate due to convection and release of latent heat.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible radiation, (3) Negligible sensible energy change due to cooling of droplets to T_s.

ANALYSIS: The total heat rate to the substrate is due to convection from the jet and release of the latent heat of fusion due to solidification, $q = q_{conv} + q_{lat}$. With $Re = V_eD/\nu = (400\text{ m/s})0.01\text{ m}/5.6 \times 10^{-3}\text{ m}^2\text{/s} = 714$, $A_r = D^2/4r^2 = 0.04$, and $H/D = 10$, $F_1 = 2Re^{1/2}(1 + 0.005\, Re^{0.55})^{1/2} = 58.2$ and $G = 2A_r^{1/2}(1-2.2A_r^{1/2})/\left[1+0.2(H/D-6)A_r^{1/2}\right] = 0.193$, the correlation for a single round nozzle (Section 7.7) yields

$$\overline{Nu} = GF_1\, Pr^{0.42} = 0.193(58.2)\left(0.60^{0.42}\right) = 9.07$$

$$\bar{h} = \overline{Nu}(k/D) = 9.07(0.671\,W/m\cdot K/0.01\,m) = 609\,W/m^2\cdot K$$

Hence,

$$q = \bar{h}A_s\left(T_e - T_s\right) = 609\,W/m^2\cdot K \times \pi(0.025\,m)^2(10,000-300)K = 11,600\,W \qquad <$$

The release of latent heat is

$$q_{lat} = A_s\dot{m}''_p h_{sf} = \pi(0.025\,m)^2\left(0.02\,kg/s\cdot m^2\right)3.577\times 10^6\,J/kg = 140\,W \qquad <$$

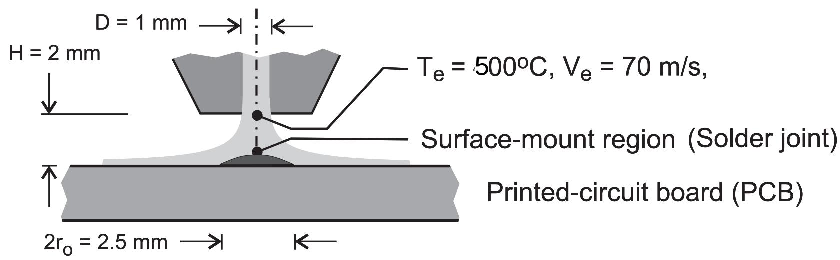
COMMENTS: (1) The large plasma temperature renders heat transfer due to droplet deposition negligible compared to convection from the plasma. (2) Note that Re = 714 is outside the range of applicability of the correlation, which has therefore been used as an approximation to actual conditions.

PROBLEM 7.106

KNOWN: A round nozzle with a diameter of 1 mm located a distance of 2 mm from the surface mount area with a diameter of 2.5 mm; air jet has a velocity of 70 m/s and a temperature of 500°C.

FIND: (a) Estimate the average convection coefficient over the area of the surface mount, (b) Estimate the time required for the surface mount region on the PCB, modeled as a semi-infinite medium initially at 25°C, to reach 183°C; (c) Calculate and plot the surface temperature of the surface mount region for air jet temperatures of 500, 600 and 700°C as a function time for $0 \le t \le 150$ s. Comment on the outcome of your study, the appropriateness of the assumptions, and the feasibility of using the jet for a soldering application.

SCHEMATIC:



ASSUMPTIONS: (1) Air jet is a single round nozzle, (2) Uniform temperature over the PCB surface, and (3) Surface mount region can be modeled as a one-dimensional semiinfinite medium.

PROPERTIES: *Table A-4*, Air (T_f = 536 K, 1 atm): $\nu = 4.36 \times 10^{-5}$ m^2/s, k = .0497 W/m·K, Pr = 0.6833; Solder (given): ρ = 8333 kg/m^3, c_p = 188 J/kg·K, and k = 51 W/m·K; eutectic temperature, T_{sol} = 183°C; PCB (given): glass transition temperature, T_{gl} = 250°C.

ANALYSIS: For a single round nozzle, from the correlation of Eqs. 7.71 and 7.72, estimate the convection coefficient,

$$\frac{\overline{Nu}}{Pr^{0.42}} = G\left(\frac{r}{D}, \frac{H}{D}\right) F_1(Re) \qquad \overline{Nu} = \frac{\bar{h}D}{k} \tag{1,2}$$

where

$$F_1 = 2 Re^{1/2}\left(1 + 0.005\, Re^{0.55}\right)^{1/2} \tag{3}$$

$$G = 2\, A_r^{1/2} \frac{1 - 2.2\, A_r^{1/2}}{1 + 0.2(H/D - 6) A_r^{1/2}} \tag{4}$$

$$A_r = D^2 / 4r_o^2 \tag{5}$$

The Reynolds number is based on the jet diameter and velocity at the nozzle,

$$Re_D = V_e D / \nu \tag{6}$$

and r_o is the radius of the region over which the average coefficient is being evaluated. The thermophysical properties are evaluated at the film temperature, $T_f = (T_e + T_i)/2$. The results of the calculation are tabulated below.

Continued …

PROBLEM 7.106 (Cont.)

Re	F_1	G	A_r	$\overline{Nu}$	$\overline{h}$ (W/m^2·K)
1605	91.01	0.1412	0.16	10.95	470.5

<

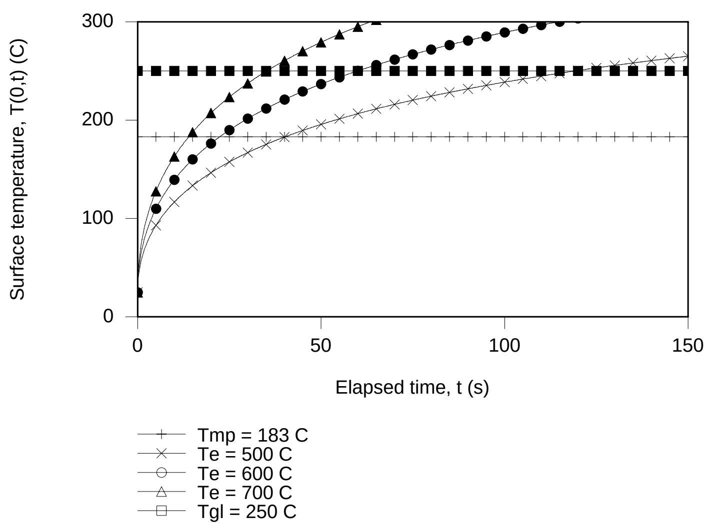
Consider the surface mount region as a semi-infinite medium, with solder properties, initially at a uniform temperature of 25°C, that experiences sudden exposure to the convection process with the air jet at a temperature T_∞ = 500°C and the convection coefficient as found in part (a). The surface temperature, T(0,t), is determined from Case 3, Fig. 5.7 and Eq. 5.63,

$$\frac{T(0,t)-T_i}{T_\infty - T_i} = 1 - \exp\left(\frac{h^2 \alpha t}{k^2}\right) \times \operatorname{erfc}\left(\frac{h(\alpha t)^{1/2}}{k}\right) \tag{7}$$

where $\alpha = k/\rho c_p$. With T_i = 25°C and $T_\infty = T_e$, by trial-and-error, or by using the appropriate *IHT* model, find

$$T(0,t_o) = 183°C \qquad t_o = 40.1 \text{ s}$$ <

(c) Using the foregoing relations in *IHT*, the surface temperature T(0,t) is calculated and plotted for jet air temperatures of 400, 500 and 600°C for 0 ≤ t ≤ 40 s.



The effect of increasing the jet air temperature is to reduce the time for the surface temperature to reach the solder temperature of 183°C. With the 700°C air jet, it takes about 14 s to reach the solder temperature, and the glass transition temperature is achieved in 35 s. The analysis represents a first-order model giving approximate results only. While the estimates for the average convection coefficients are reasonable, modeling the surface mount region as a semi-infinite medium is an over simplification. The region is of limited extent on the PCB, which is thin and also a poor approximation to an infinite medium. However, the model has provided insight into the conditions under which an air jet could be used for a soldering operation.

COMMENTS: (1) Note that for our application, the round nozzle correlation of part (a) exceeds the ranges of validity.

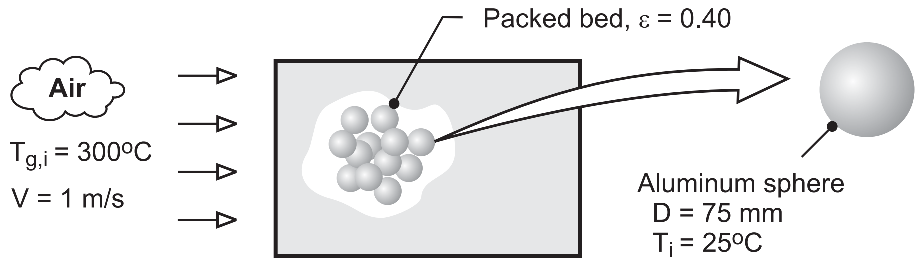
(2) The jet convection coefficient is not strongly dependent upon the air temperature. Values for 500, 600, and 700°C, respectively, are 464, 471, and 458 W/m^2·K.

PROBLEM 7.107

KNOWN: Diameter and properties of aluminum spheres used in packed bed. Porosity of bed and velocity and temperature of inlet air.

FIND: Time for sphere to acquire 90% of maximum possible thermal energy.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat transfer to or from a sphere by radiation or conduction due to contact with other spheres, (2) Validity of lumped capacitance method, (3) Constant properties.

PROPERTIES: Prescribed, Aluminum: $\rho = 2700\,\text{kg/m}^3$, $c = 950\,\text{J/kg}\cdot\text{K}$, $k = 240\,\text{W/m}\cdot\text{K}$. *Table A-4*, Air (573K): $\rho_a = 0.609\,\text{kg/m}^3$, $c_{p,a} = 1045\,\text{J/kg}\cdot\text{K}$, $\nu = 48.8\times10^{-6}\,\text{m}^2/\text{s}$, $k_a = 0.0453\,\text{W/m}\cdot\text{K}$, $\text{Pr} = 0.684$.

ANALYSIS: From Eqs. 5.7 and 5.8a, achievement of 90% of the maximum possible thermal energy storage corresponds to

$$\frac{Q}{\rho c \forall \theta_i} = 0.9 = 1 - \exp\left(-\frac{t}{\tau_t}\right) = 1 - \exp\left(-\frac{\overline{h} A_s t}{\rho \forall c}\right)$$

where the convection coefficient is given by

$$\varepsilon\, j_H = \varepsilon\, \overline{\text{St}}\,\text{Pr}^{2/3} = \varepsilon \frac{\overline{h}}{\rho_a V c_{p,a}} \text{Pr}^{2/3} = 2.06\,\text{Re}_D^{-0.575}$$

With $\text{Re}_D = VD/\nu = 1\,\text{m/s}\times 0.075\text{m}/48.8\times10^{-6}\,\text{m}^2/\text{s} = 1537$,

$$\overline{h} = \frac{2.06\times 0.609\,\text{kg/m}^3 \times 1\,\text{m/s}\times 1045\,\text{J/kg}\cdot\text{K}}{0.4(0.684)^{2/3}(1537)^{0.575}} = 62.1\,\text{W/m}^2\cdot\text{K}$$

Hence, with $A_s/\forall = 6/D$,

$$t = -\frac{\rho c D}{6\overline{h}}\ln(0.1) = \frac{2700\,\text{kg/m}^3\times 950\,\text{J/kg}\cdot\text{K}\times 0.075\text{m}\times 2.30}{6\times 62.1\,\text{W/m}^2\cdot\text{K}} = 1189\,\text{s}$$ <

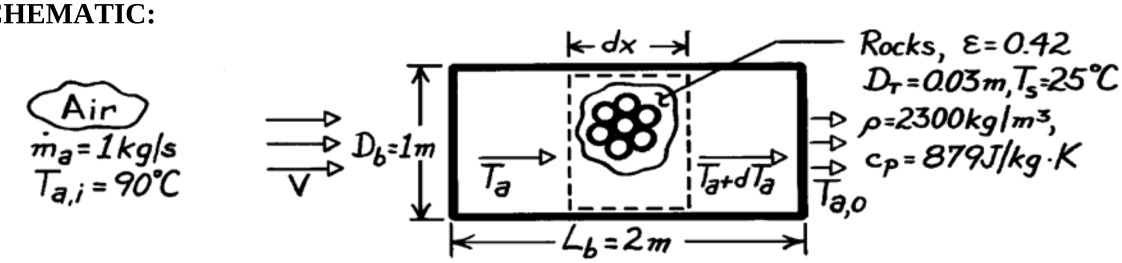
COMMENTS: (1) With $\text{Bi} = \overline{h}(D/6)/k = 0.003$, the spheres are spatially isothermal and the lumped capacitance approximation is excellent. (2) Before the packed bed becomes fully charged, the temperature of the air decreases as it passes through the bed. Hence, the time required for a sphere to reach a prescribed state of thermal energy storage increases with increasing distance from the bed inlet.

PROBLEM 7.108

KNOWN: Overall dimensions of a packed bed of rocks. Rock diameter and thermophysical properties. Initial temperature of rock and bed porosity. Flow rate and upstream temperature of atmospheric air passing through the pile.

FIND: Rate of heat transfer to pile.

SCHEMATIC:



ASSUMPTIONS: (1) Rocks are spherical and at a uniform temperature, (2) Steady-state conditions.

PROPERTIES: *Table A-4*, Atmospheric air (T_∞ = 363K): $\nu = 22.35 \times 10^{-6}$ m^2/s, k = 0.031 W/m·K, Pr = 0.70, $\rho = 0.963$ kg/m^3, c_p = 1010 J/kg·K.

ANALYSIS: The heat transfer rate may be expressed as $q = \bar{h}A_{p,t}\Delta T_{\ell m}$ where the total surface area of the rocks is

$$A_{p,t} = V_r \frac{\pi D_r^2}{\pi D_r^3/6} = (1-\varepsilon)\left(\frac{\pi D_b^2}{4} L_b\right)\frac{6}{D_r} = (1-0.42)\left(\pi(1\text{ m})^2 \times 2\text{ m}/4\right)6/0.03\text{ m} = 182.2\text{ m}^2.$$

The upstream velocity and Reynolds number are

$$V = \frac{\dot{m}_a}{\rho\pi D_b^2/4} = \frac{4\times 1\text{ kg/s}}{\left(0.963\text{ kg/m}^3\right)\pi\ 1\text{m}^2} = 1.32\text{ m/s} \quad Re_D = \frac{VD_r}{\nu} = \frac{1.32\text{ m/s}\times 0.03\text{ m}}{22.35\times 10^{-6}\text{ m}^2/\text{s}} = 1772.$$

From Section 7.8, it follows that

$$\varepsilon \bar{j}_H = \varepsilon \bar{St}Pr^{2/3} = \varepsilon \frac{\bar{h}}{\rho V c_p} Pr^{2/3} = 2.06\ Re_D^{-0.575}$$

$$\bar{h} = \frac{2.06}{\varepsilon}\rho V c_p Re_D^{-0.575} Pr^{-2/3}$$

$$\bar{h} = \frac{2.06}{0.42} 0.963\text{ kg/m}^3 \times 1.32\text{ m/s} \times 1010\text{J/kg}\cdot\text{K}\,(1772)^{-0.575}(0.70)^{-2/3} = 108\text{ W/m}^2\cdot\text{K}.$$

The appropriate form of the mean temperature difference, $\Delta T_{\ell m}$, may be obtained by performing an energy balance on a differential control volume about the rock. That is,

$$\dot{m}_a\ c_p\ T_a - \dot{m}_a\ c_p\left(T_a + dT_a\right) - dq_r = 0$$

where $dq_r = \bar{h}A'_{p,t}dx\left(T_a - T_s\right)$ and $A'_{p,t}$ is the rock surface area per unit length of bed. Hence

$$\dot{m}_a\ c_p\ dT_a = -\bar{h}A'_{p,t}dx\left(T_a - T_s\right) \qquad \frac{d\,T_a}{dx} = -\frac{\bar{h}A'_{p,t}}{\dot{m}_a\ c_p}\left(T_a - T_s\right).$$

Continued …

PROBLEM 7.108 (Cont.)

Integrating between inlet and outlet, it follows that

$$\ell n\left(T_a - T_s\right)\Big|_i^o = -\frac{\bar{h}A'_{p,t}}{\dot{m}_a\ c_p}L_b = -\frac{\bar{h}A_{p,t}}{\dot{m}_a\ cp} \qquad \ell n\frac{T_{a,o}-T_s}{T_{a,i}-T_s} = -\frac{\bar{h}A_{p,t}}{\dot{m}_a\ c_p}.$$

With $q = \dot{m}_a\ c_p\left(T_{a,i} - T_{a,o}\right) = \dot{m}_a\ c_p\left[\left(T_{a,i} - T_s\right) - \left(T_{a,o} - T_s\right)\right]$

it follows that

$$q = \bar{h}A_{p,t}\frac{\left(T_{a,i}-T_s\right)-\left(T_{a,o}-T_s\right)}{\ell n\left[\left(T_{a,i}-T_s\right)/\left(T_{a,o}-T_s\right)\right]} = \bar{h}A_{p,t}\Delta T_{\ell m}$$

where $$\Delta T_{lm} = \frac{\left(T_{a,i}-T_s\right)-\left(T_{a,o}-T_s\right)}{\ln\left[\left(T_{a,i}-T_s\right)/\left(T_{a,o}-T_s\right)\right]}.$$

The air outlet temperature may be obtained from the requirement

$$\frac{T_{a,o}-T_s}{T_{a,i}-T_s} = \exp\left(-\frac{\bar{h}A_{p,t}}{\dot{m}_a\ c_p}\right) = \exp\left(-\frac{108\text{W/m}^2\cdot\text{K}\times 182.2\ \text{m}^2}{1\ \text{kg/s}\times 1010\ \text{J/kg}\cdot\text{K}}\right) = 3.46\times 10^{-9}$$

$$T_{a,o} = 25^\circ\text{C} + 65^\circ\text{C}\left(3.46\times 10^{-9}\right) = 25^\circ\text{C} + 2.25\times 10^{-7}\ ^\circ\text{C}$$

$$T_{a,o} \approx T_s = 25^\circ\text{C}.$$

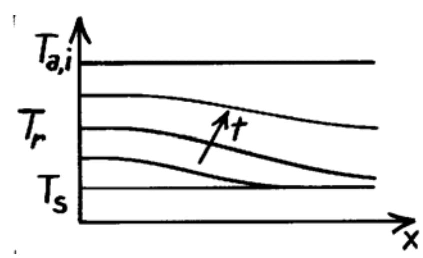
Hence $$\Delta T_{\ell m} = \frac{65^\circ\text{C} - 2.25\times 10^{-7}\ ^\circ\text{C}}{\ell n\left(65^\circ\text{C}/2.25\times 10^{-7}\ ^\circ\text{C}\right)} = 3.34^\circ\text{C}$$

and $$q = 108\text{W/m}^2\cdot\text{K}\left(182.2\ \text{m}^2\right)3.34^\circ\text{C} = 65.7\ \text{kW}.$$ <

COMMENTS: (1) The above result may be checked from the requirement that q =
$\dot{m}_a\ c_p\left(T_{a,i} - T_{a,o}\right) = 1\ \text{kg/s}\times 1010\ \text{J/kg}\cdot\text{K}\times 65^\circ\text{C} = 65.7\ \text{kW}.$

(2) The heat rate would be *grossly* overpredicted by using a rate equation of the form
$q = \bar{h}A_{p,t}\left(T_{a,i} - T_s\right)$.

(3) The foregoing results are reasonable during the early stages of the heating process; however q would decrease with increasing time as the temperature of the rock increases. The axial temperature distribution of the rock in the pile would be as shown for different times.

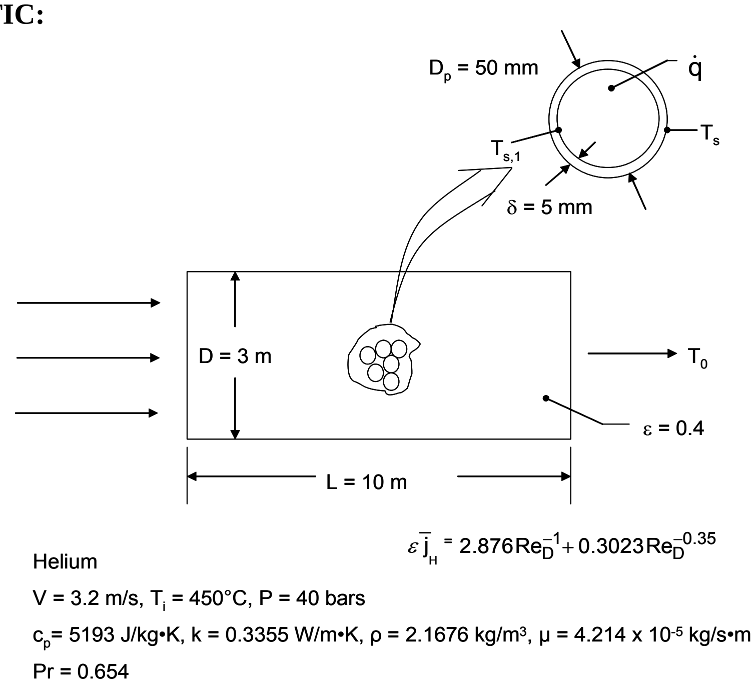


PROBLEM 7.109

KNOWN: Dimensions of a pebble bed nuclear reactor. Dimensions of core and cladding of pellets. Porosity of the reactor and helium properties, inlet temperature, and upstream velocity. Graphite properties. Correlation for convective heat transfer from the spherical pellets in the packed bed.

FIND: (a) Mean helium outlet temperature and amount of thermal energy generated per pellet for an overall thermal energy transfer rate of q = 125 MW, (b) Maximum internal temperature of the hottest pellet.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible radiation heat transfer, (2) One-dimensional heat transfer, (3) Uniform volumetric thermal generation inside the core, (4) Negligible contact resistance between core and cladding.

ANALYSIS:

(a) From the simplified steady-flow thermal energy equation of Chapter 1 we may write

$$q = \dot{m}c_p(T_o - T_i) = \rho AVc_p(T_o - T_i)$$

Thus

$$T_o = T_i + q/\rho AVc_p$$

$$= 450°\text{C} + 125 \times 10^6 \text{ W}\Big/\left(2.1676 \text{ kg/m}^3 \times \pi \times (0.3 \text{ m}/2)^2 \times 3.2 \text{ m/s} \times 5193 \text{ J/k}\cdot\text{K}\right)$$

$$T_o = 941°\text{C}$$ <

The number of pellets in the chamber is

Continued….

PROBLEM 7.109 (Cont.)

$$N = (1 - \varepsilon)(\pi)(D/2)^2 \times L \Big/ \frac{4}{3}\pi\left[\left(D_p + 2\delta\right)/2\right]^3$$

$$N = (1 - 0.4) \times (1.5\text{m})^2 \times 10\text{ m} \Big/ \left(\frac{4}{3} \times \left[\left(50 \times 10^{-3}\text{ m} + 10 \times 10^{-3}\text{ m}\right)/2\right]^3\right)$$

$$N = 375{,}000$$

The energy generated per pellet is

$$\dot{E}_g = q/N = 125 \times 10^6\text{ W}/375{,}000 = 333\text{ W}$$ <

(b) The Reynolds number based on the pellet diameter is

$$Re_D = \frac{\rho V(D_p + 2\delta)}{\mu} = \frac{2.1676\text{ kg/m}^3 \times 3.2\text{ m/s} \times (50 \times 10^{-6}\text{ m} + 10 \times 10^{-6}\text{ m})}{4.214 \times 10^{-5}\text{ kg/s}\cdot\text{m}}$$

$$Re_D = 9876$$

From the problem statement we know

$$\varepsilon \bar{j}_H = \varepsilon \frac{\bar{h}}{\rho V c_p} Pr^{2/3} = \frac{2.876}{Re_D} + \frac{0.3023}{Re_D^{0.35}}$$

or

$$\bar{h} = \frac{\rho V c_p}{\varepsilon Pr^{2/3}}\left[\frac{2.876}{Re_D} + \frac{0.3023}{Re_D^{0.35}}\right]$$

$$\bar{h} = \frac{2.1676\text{ kg/m}^3 \times 3.2\text{ m/s} \times 5193\text{ J/kg}\cdot\text{K}}{0.4 \times (0.654)^{2/3}} \times \left[\frac{2.876}{9876} + \frac{0.3023}{9876^{0.35}}\right] = 1480\text{ W/m}^2\cdot\text{K}$$

A sphere at the exit of the chamber will be adjacent to the highest helium temperature and will be, in turn, the hottest. An energy balance about the single sphere yields

$$q = \bar{h}A(T_s - T_\infty) \quad \text{or} \quad T_s = T_\infty + \frac{q}{\bar{h}A} = T_o + \frac{\dot{E}_g}{\bar{h}\pi(D_p + 2\delta)^2}$$

$$T_s = 941°\text{C} + \frac{333\text{ W}}{1480\text{ W/m}^2\cdot\text{K} \times \pi \times (50 \times 10^{-3}\text{ m} + 10 \times 10^{-3}\text{ m})^2}$$

$$T_s = 960.9°\text{C}$$

The temperature at the inner surface of the cladding may be found using Equation 3.40

$$q_r = \frac{4\pi k(T_{s,1} - T_s)}{\dfrac{1}{(D_p/2)} - \dfrac{1}{(D_p/2 + \delta)}}$$

$$T_{s,1} = T_s + q\left[\frac{1}{(D_p/2)} - \frac{1}{(D_p/2 + \delta)}\right] \Big/ 4\pi k$$

Continued….

PROBLEM 7.109 (Cont.)

$$T_{s,1} = 960.9°C + 333\ W \times \left[\frac{1}{25 \times 10^{-3}\ m} - \frac{1}{(25 \times 10^{-3}\ m + 5 \times 10^{-3}\ m)}\right] \Big/ (4\pi \times 2 W/m \cdot K)$$

$$T_{s,1} = 1049.2°C$$

The maximum temperature occurs at the center of the sphere at the exit plane. Beginning with the heat equation for the pellet, find

$$\frac{d}{dr}\left(r^2 \frac{dT}{dr}\right) = -\frac{\dot{q}}{k} r^2$$

$$r^2 \frac{dT}{dr} = -\frac{\dot{q}}{3k} r^3 + C_1$$

$$T(r) = -\frac{\dot{q}}{6k} r^2 - \frac{C_1}{r} + C_2$$

Applying boundary conditions,

$$\text{at } r = 0, \quad dT/dr\big|_{r=0} = 0 \rightarrow C_1 = 0$$

$$\text{at } r = r_p = D_p/2, \quad T(r_p) = T_{s,1} \rightarrow C_2 = T_{s,1} + \frac{\dot{q}}{6k} r_p^2$$

$$T(r) = T_{s,1} + \frac{\dot{q}}{6k}(r_p^2 - r^2)$$

$$T(0) = T_{s,1} + \frac{\dot{q} D_p^2}{24k}$$

For $\dot{q} = \dot{E}_g/\forall = \dot{E}_g \Big/ \left[\frac{4}{3}\pi(D_p/2)^3\right]$

$$\dot{q} = 333 W \Big/ \left[\frac{4}{3} \times \pi \times (50 \times 10^{-3}\ m/2)^3\right]$$

$$\dot{q} = 5.09 \times 10^6\ W/m^3$$

$$T(o) = 1049.2°C + \frac{5.09 \times 10^6\ W/m^3 \times (50 \times 10^{-3}\ m)^2}{24 \times 2\ W/m \cdot K} = 1314°C$$ <

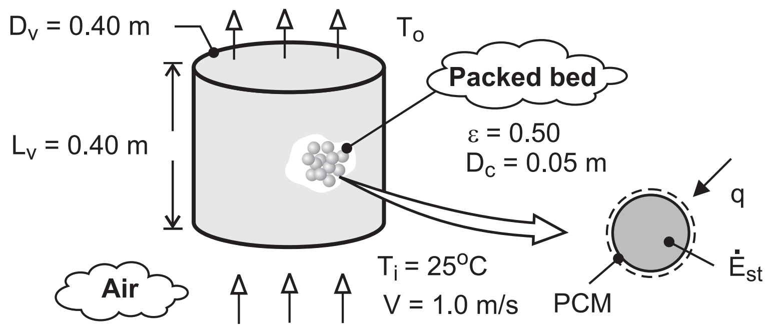
COMMENTS: (1) The maximum temperature is below the temperature associated with reduction in the thermal energy generation. (2) Helium is an excellent choice for the working fluid due to its high thermal conductivity and extremely small *nuclear cross section* (Helium does not absorb gamma radiation. Therefore the helium that exists the chamber can be fed directly to a turbine as opposed to transferring thermal energy from the helium to a second working fluid.)

PROBLEM 7.110

KNOWN: Diameter and properties of phase-change material. Dimensions of cylindrical vessel and porosity of packed bed. Inlet temperature and velocity of air.

FIND: (a) Outlet temperature of air and rate of melting, (b) Effect of inlet velocity and capsule diameter on outlet temperature, (c) Location at which complete melting of PCM is first to occur and subsequent variation of outlet temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible thickness (and thermal resistance) of capsule shell, (2) All capsules are at T_{mp}, (3) Constant properties, (4) Negligible heat transfer from surroundings to vessel.

PROPERTIES: Prescribed, PCM: $T_{mp} = 4°C$, $\rho = 1200\,kg/m^3$, $h_{sf} = 165\,kJ/kg$. *Table A-4*, Air $\left(\text{Assume } (T_i + T_o)/2 = 17°C = 290K\right)$: $\rho_a = 1.208\,kg/m^3$, $c_p = 1007\,J/kg\cdot K$, $\nu = 15.00\times10^{-6}\,m^2/s$, Pr = 0.71.

ANALYSIS: (a) For a packed bed the outlet temperature is given by

$$T_o = T_{mp} - \left(T_{mp} - T_i\right)\exp\left(-\frac{\overline{h}A_{p,t}}{\rho_a V A_{c,b} c_p}\right)$$

where $A_{c,b} = \pi D_v^2/4 = \pi(0.40m)^2/4 = 0.126m^2$ and $A_{p,t} = (1-\varepsilon)(\forall_v/\forall_c)\left(\pi D_c^2\right) = (1-\varepsilon)$ $\left(1.5\pi L_v D_v^2/D_c\right) = 0.5\left(1.5\pi\times0.4m^3/0.05m\right) = 3.02m^2$. With $Re_D = VD_c/\nu = 1\,m/s\times0.05m/15.00$ $\times10^{-6}\,m^2/s = 3333$, the convection correlation for a packed bed yields

$$\varepsilon\overline{j}_H = \varepsilon\overline{St}\,Pr^{2/3} = \varepsilon\frac{\overline{h}}{\rho_a V\,c_p}Pr^{2/3} = 2.06\,Re_D^{-0.575}$$

$$\overline{h} = \frac{2.06\,\rho_a V\,c_p}{\varepsilon Pr^{2/3}Re_D^{0.575}} = \frac{2.06\times1.208\,kg/m^3\times1\,m/s\times1007\,J/kg\cdot K}{0.5(0.71)^{2/3}(3333)^{0.575}} = 59.4\,W/m^2\cdot K$$

Hence, $$T_o = 4°C + (21°C)\exp\left(-\frac{59.4\,W/m^2\cdot K\times3.02\,m^2}{1.208\,kg/m^3\times1\,m/s\times0.126\,m^2\times1007\,J/kg\cdot K}\right) = 10.5°C$$ <

The rate at which PCM in the vessel changes from the solid to liquid state, $\dot{M}(kg/s)$, may be obtained from an energy balance that equates the total rate of heat transfer to the capsules to the rate of increase in latent energy of the PCM. That is

$$q = \frac{d}{dt}\left(M\,h_{sf}\right) = h_{sf}\,\dot{M}$$

Continued …

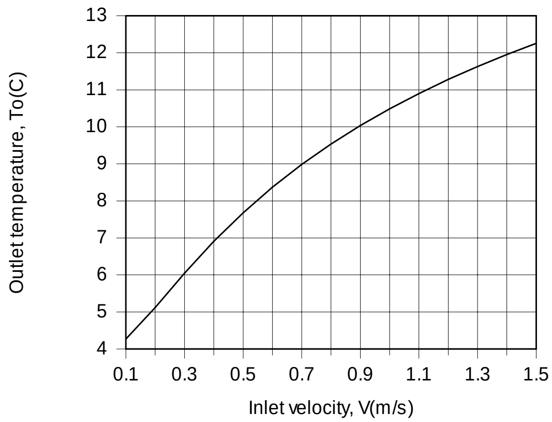
PROBLEM 7.110 (Cont.)

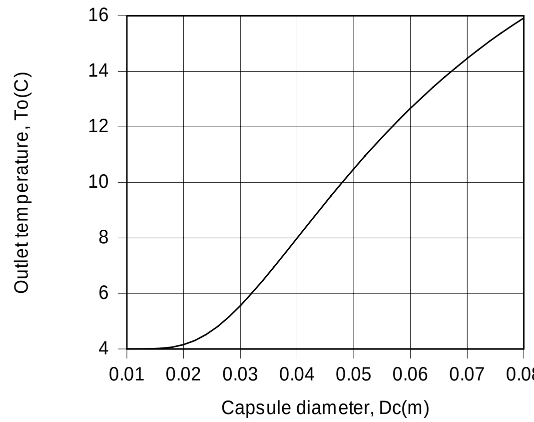
where M is the total mass of PCM and

$$q = -\overline{h} A_{p,t} \frac{(T_{mp} - T_i) - (T_{mp} - T_o)}{\ell n\left(\frac{T_{mp} - T_i}{T_{mp} - T_o}\right)} = -59.4\,W/m^2 \cdot K \times 3.02\,m^2 \frac{-14.5°C}{\ell n\left(\frac{-21}{-6.5}\right)} = 2220\,W$$

Hence, $\dot{M} = q / h_{sf} = 2220\,W / 165{,}000\,J/kg = 0.0134\,kg/s$ <

(b) The effect of the inlet velocity and capsule diameter are shown below.





Despite the reduction in $\overline{h}$ with decreasing V, the reduction in the mass flow rate of air through the vessel and the corresponding increase in the residence time of air in the vessel allow it to more closely achieve thermal equilibrium with the capsules before it leaves the vessel. Hence, T_o decreases with decreasing V, approaching T_{mp} in the limit $V \rightarrow 0$. Of course, the production of chilled air in kg/s decreases accordingly. With decreasing capsule diameter, there is an increase in the number of capsules in the vessel and in the total surface area $A_{p,t}$ for heat transfer from the air. Hence, the heat rate increases with decreasing D_c and the outlet temperature of the air decreases.

(c) Because the temperature of the air decreases as it moves through the vessel, heat rates to the capsules are largest and smallest at the entrance and exit, respectively, of the vessel. Hence, complete melting will first occur in capsules at the entrance. After complete melting begins to occur in the capsules, progressing downstream with increasing time, heat transfer from the air will increase the temperatures of the capsules, thereby decreasing the heat rate. With decreasing heat rate, the outlet temperature will increase, approaching the inlet temperature after melting has occurred in all capsules and they achieve thermal equilibrium with the inlet air.

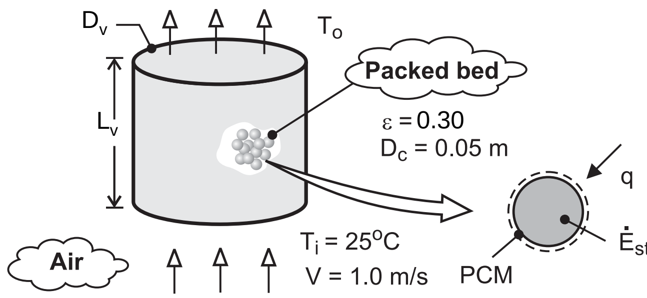
COMMENTS: (1) The estimate of To used to evaluate the properties of air was good, and iteration of the solution is not necessary. (2) The total mass of phase change material in the vessel is $M = N_c \rho \forall_c = [(1-\varepsilon)\forall_v / \forall_c]\rho \forall_c = (1-\varepsilon)\rho L_v (\pi D_v^2 / 4) = (\pi/4) 0.5 \times 1200\,kg/m^3 (0.4m)^3 = 30.2\,kg$. At the maximum possible melting rate of $\dot{M} = 0.0134\,kg/s$, it would therefore take 2250s = 37.5 min to melt all of the PCM in the vessel. Why would it, in fact, take longer to melt all of the PCM?

PROBLEM 7.111

KNOWN: Diameter and properties of phase-change material. Dimensions of cylindrical vessel and porosity of packed bed. Inlet temperature and velocity of air.

FIND: (a) Outlet temperature of air and rate of melting for ε = 0.3 and length reduced to compensate, (b) Outlet temperature of air and rate of melting for ε = 0.3 and diameter reduced to compensate. Which geometry is preferred.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible thickness (and thermal resistance) of capsule shell, (2) All capsules are at T_{mp}, (3) Constant properties, (4) Negligible heat transfer from surroundings to vessel.

PROPERTIES: Prescribed, PCM: $T_{mp} = 4°C$, $\rho = 1200\ kg/m^3$, $h_{sf} = 165\ kJ/kg$. *Table A-4*, Air $\left(\text{Assume } (T_i + T_o)/2 = 17°C = 290K\right)$: $\rho_a = 1.208\ kg/m^3$, $c_p = 1007\ J/kg\cdot K$, $\nu = 15.00\times10^{-6} m^2/s$, Pr = 0.71.

ANALYSIS: (a) The new length of the vessel is determined from the fact that the same mass, or volume, of capsules is now compressed to give a porosity of 0.3 instead of 0.5. We can relate the total capsule volume, $\forall_c$, to the vessel volume, $\forall_v = \pi D_v^2 L_v$, as follows.

$$\forall_c = (1-\varepsilon_{old})\forall_{v,old} = (1-\varepsilon_{new})\forall_{v,new} \qquad (1)$$

Thus,

$$L_{v,new} = \frac{(1-\varepsilon_{old})}{(1-\varepsilon_{new})} L_{v,old} = \frac{0.5}{0.7} 0.4\ m = 0.286\ m$$

For a packed bed the outlet temperature is given by

$$T_o = T_{mp} - (T_{mp} - T_i)\exp\left(-\frac{\bar{h} A_{p,t}}{\rho_a V A_{c,b} c_p}\right) \qquad (2)$$

where $A_{c,b} = \pi D_v^2/4 = \pi(0.40\ m)^2/4 = 0.126\ m^2$ and $A_{p,t} = (1-\varepsilon)(\forall_v/\forall_c)(\pi D_c^2) = (1-\varepsilon)$ $(1.5\pi L_v D_v^2 / D_c) = 0.7(1.5\pi \times 0.286\ m \times 0.4^2\ m^2 / 0.05\ m) = 3.02\ m^2$. With $Re_D = VD_c/\nu =$ $1\ m/s \times 0.05 m / 15.00 \times 10^{-6} m^2/s = 3333$, the convection correlation for a packed bed yields

Continued …

PROBLEM 7.111 (Cont.)

$$\varepsilon \bar{j}_H = \varepsilon \overline{St}\ Pr^{2/3} = \varepsilon \frac{\bar{h}}{\rho_a V\ c_p} Pr^{2/3} = 2.06\ Re_D^{-0.575}$$

$$\bar{h} = \frac{2.06 \rho_a V\ c_p}{\varepsilon\, Pr^{2/3}\, Re_D^{0.575}} = \frac{2.06 \times 1.208\,kg/m^3 \times 1\,m/s \times 1007\,J/kg\cdot K}{0.3(0.71)^{2/3}(3333)^{0.575}} = 99.0\,W/m^2\cdot K$$

Hence, $$T_o = 4°C + (21°C)\exp\left(-\frac{99.0\,W/m^2\cdot K \times 3.02\,m^2}{1.208\,kg/m^3 \times 1\,m/s \times 0.126\,m^2 \times 1007\,J/kg\cdot K}\right) = 7.0°C$$ <

The rate at which PCM in the vessel changes from the solid to liquid state, $\dot{M}(kg/s)$, may be obtained from an energy balance that equates the total rate of heat transfer to the capsules to the rate of increase in latent energy of the PCM. That is

$$q = \frac{d}{dt}(M\,h_{sf}) = h_{sf}\,\dot{M}$$

where M is the total mass of PCM and

$$q = -\bar{h}\,A_{p,t}\frac{(T_{mp} - T_i) - (T_{mp} - T_o)}{\ell n\left(\frac{T_{mp} - T_i}{T_{mp} - T_o}\right)} = -99.0\,W/m^2\cdot K \times 3.02\,m^2\,\frac{-18°C}{\ell n\left(\frac{-21}{-3.0}\right)} = 2770\,W$$

Hence, $$\dot{M} = q/h_{sf} = 2770\,W/165{,}000\,J/kg = 0.0168\,kg/s$$ <

(b)The new vessel diameter is found from Eq. (1) to be

$$D_{v,new} = \sqrt{\frac{(1-\varepsilon_{old})}{(1-\varepsilon_{new})}} D_{v,old} = \sqrt{\frac{0.5}{0.7}}\,0.4\ m = 0.338\ m$$

Since the mass flow rate of air is unchanged, the velocity must be increased to compensate for the reduced diameter, thus

$$V_{new} = V_{old}D^2_{v,old}/D^2_{v,new} = 1\ m/s(0.4\ m/0.338\ m)^2 = 1.40\ m/s$$

Repeating all of the calculations, we find

$A_{c,b} = \pi D_v^2/4 = \pi(0.338\ m)^2/4 = 0.0897\ m^2$, $A_{p,t} = 3.02\ m^2$ (unchanged), $Re_D = 4667$, $\bar{h} = 114\,W/m^2\cdot K$, and

$$T_o = 6.2°C$$ <

Continued …

PROBLEM 7.111 (Cont.)

Then $q = 2870\,\mathrm{W}$ and

$$\dot{M} = 0.0173\,\mathrm{kg/s}$$ <

This configuration results in a lower air outlet temperature and an increased PCM melting rate. <

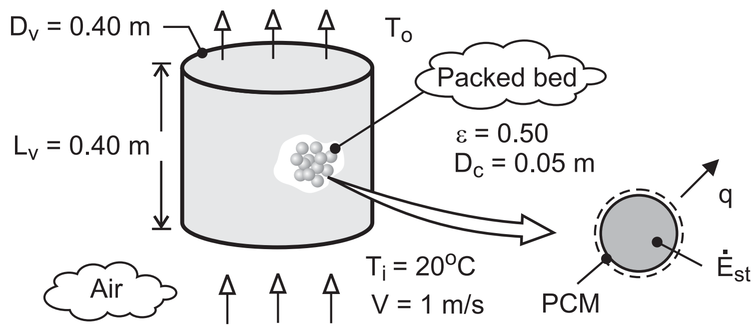
COMMENTS: (1) The estimate of T_o used to evaluate the properties of air was reasonably good, and iteration of the solution is not necessary. (2) Compared to Problem 7.110 which had $\varepsilon = 0.5$, both of these configurations yield a higher heat transfer coefficient and result in a lower outlet temperature and are therefore preferable from the heat transfer point-of-view. However, a more thorough design would also consider the pressure drop and pumping power requirements for the various configurations. Which configuration do you expect to have the lowest pumping power requirement? (3) By reducing the vessel diameter in part (b), the velocity and Reynolds number increase, thereby increasing the heat transfer coefficient. This yields a lower outlet temperature compared to part (a).

PROBLEM 7.112

KNOWN: Diameter and properties of phase-change material. Dimensions of cylindrical vessel and porosity of packed bed. Inlet temperature and velocity of air.

FIND: (a) Outlet temperature of air and rate of freezing, (b) Effect of inlet velocity and capsule diameter on outlet temperature, (c) Location at which complete melting of PCM is first to occur and subsequent variation of outlet temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible thickness (and thermal resistance) of capsule shell, (2) All capsules are at T_{mp}, (3) Constant properties, (4) Negligible heat transfer from vessel to surroundings.

PROPERTIES: Prescribed, PCM: $T_{mp} = 50°C$, $\rho = 900\,kg/m^3$, $h_{sf} = 200\,kJ/kg$. *Table A-4*, Air (Assume $(T_i + T_o)/2 = 30°C = 303K$): $\rho_a = 1.151\,kg/m^3$, $c_p = 1007\,J/kg\cdot K$, $\nu = 16.2\times10^{-6}\,m^2/s$, $Pr = 0.707$.

ANALYSIS: (a) For a packed bed the outlet temperature is given by

$$T_o = T_{mp} - \left(T_{mp} - T_i\right)\exp\left(-\frac{\overline{h}\,A_{p,t}}{\rho_a V A_{c,b}\, c_p}\right)$$

where $A_{c,b} = \pi D_v^2/4 = 0.126\,m^2$ and $A_{p,t} = (1-\varepsilon)(\forall_v/\forall_c)\pi D_c^2 = 3.02\,m^2$. With $Re_D = VD_c/\nu = 3086$, the convection correlation for a packed bed yields

$$\varepsilon\,\overline{j}_H = \varepsilon\overline{St}\,Pr^{2/3} = \varepsilon\frac{\overline{h}}{\rho_a V c_p}Pr^{2/3} = 2.06\,Re_D^{-0.575}$$

$$\overline{h} = \frac{2.06\,\rho_a V c_p}{\varepsilon\, Pr^{2/3}\, Re_D^{0.575}} = \frac{2.06\times1.151\,kg/m^3\times1\,m/s\times1007\,J/kg\cdot K}{0.5(0.707)^{2/3}(3086)^{0.575}} = 59.1\,W/m^2\cdot K$$

Hence,

$$T_o = 50°C - (30°C)\exp\left(-\frac{59.1\,W/m^2\cdot K\times3.02\,m^2}{1.151\,kg/m^3\times1\,m/s\times0.126\,m^2\times1007\,J/kg\cdot K}\right) = 41.2°C \quad <$$

The rate at which PCM in the vessel solidifies, $\dot{M}(kg/s)$, may be obtained from an energy balance that equates the total rate of heat transfer from the capsules to the rate at which the latent energy of the PCM decreases. That is,

$$q = \frac{d}{dt}\left(M\,h_{s,f}\right) = h_{sf}\,\dot{M}$$

where M is the total mass of PCM and

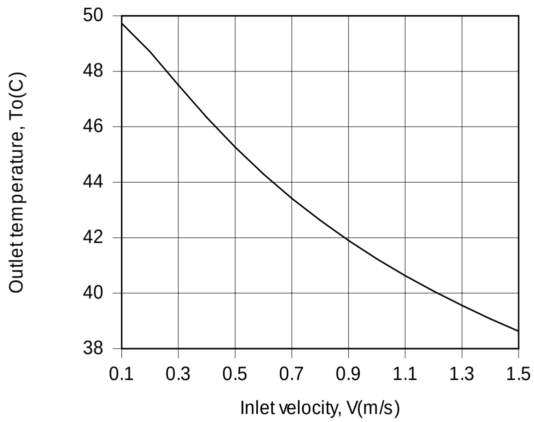
Continued …

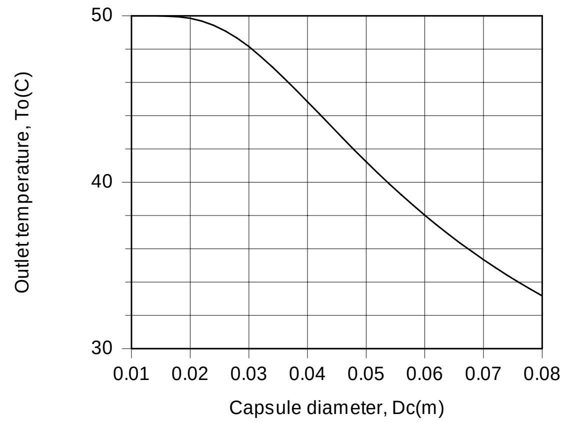
PROBLEM 7.112 (Cont.)

$$q = \overline{h} A_{p,t} \frac{(T_{mp} - T_i) - (T_{mp} - T_o)}{\ell n\left(\frac{T_{mp} - T_i}{T_{mp} - T_o}\right)} = 59.1\,W/m^2 \cdot K \times 3.02\,m^2 \frac{21.2°C}{\ell n\left(\frac{30}{8.8}\right)} = 3085\,W$$

Hence, $\dot{M} = q/h_{sf} = 3085\,W/200,000\,J/kg = 0.0154\,kg/s$ <

(b) The effect of V and D_c are shown below





Despite the reduction in $\overline{h}$ with decreasing V, the reduction in the mass flow rate of air in the vessel and the corresponding increase in the residence time of air in the vessel allow it to more closely reach thermal equilibrium with the capsules before it leaves the vessel. Hence, T_o increases with decreasing V, approaching T_{mp} in the limit $V \rightarrow 0$. Of course, the production of warm air in kg/s decreases accordingly. With decreasing capsule diameter, there is an increase in the number of capsules in the vessel and in the total surface area $A_{p,t}$ for heat transfer to the air. Hence, the heat rate and the air outlet temperature increase with decreasing D_c.

(c) Because the air temperature increases as it moves through the vessel, heat rates from the capsules are largest and smallest at the entrance and exit, respectively, of the vessel. Hence, complete freezing will first occur in capsules at the entrance. After complete freezing begins to occur in the capsules, progressing downstream with increasing time, heat transfer to the air will decrease the temperatures of the capsules, thereby decreasing the heat rate. With decreasing heat rate, the outlet temperature will decrease, approaching the inlet temperature after freezing has occurred in all capsules and they achieve thermal equilibrium with the inlet air.

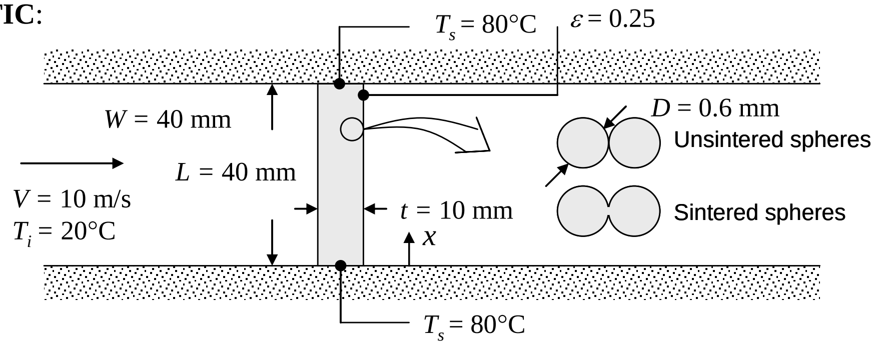
COMMENTS: (1) The estimate of T_o used to evaluate the properties of air was good, and iteration of the solution is not necessary. (2) The total mass of phase change material in the vessel is $M = N_c \rho \forall_c$ $= [(1-\varepsilon)\forall_v / \forall_c]\rho \forall_c = (1-\varepsilon)\rho L_v \left(\pi D_v^2/4\right) = 22.6\,kg$. At the maximum possible melting rate of $\dot{M} = 0.0154\,kg/s$, it would therefore take 1470s = 24.5 min to freeze all of the PCM in the vessel. Why would it, in fact, take longer to freeze all of the PCM?

PROBLEM 7.113

KNOWN: Dimensions, particle diameter, and porosity of bronze foam sheet. Temperature of upper and lower surfaces of foam. Velocity and inlet temperature of air flowing through foam.

FIND: (a) Convection heat transfer rate to air assuming foam is at uniform temperature T_s. Whether actual heat transfer rate would be greater, less, or the same. (b) Convection heat transfer rate to air treating foam as an extended surface with one-dimensional conduction in the *x*-direction. Whether actual heat transfer rate would be greater, less, or the same. Effective perimeter and effective thermal conductivity of the foam.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional heat transfer, (3) Constant properties, (4) Foam behaves as packed bed in part (a), (5) Foam behaves as extended surface in part (b), (6) Negligible radiation transfer.

PROPERTIES: *Table A-1*, Commercial bronze ($T \approx$ 325 K): k_b = 52 W/m·K. *Table A-4*, Air ($T \approx$ 325 K): ρ = 1.0782 kg/m^3, c_p = 1008 J/kg·K, k = 0.0282 W/m·K, $\nu = 18.41 \times 10^{-6}$ m^2/s, Pr = 0.704.

ANALYSIS: (a) The heat transfer coefficient can be found from Equation 7.81:

$$\varepsilon \bar{j}_H = \varepsilon \frac{\bar{h}}{\rho c_p V} Pr^{2/3} = 2.06 Re_D^{-0.575}$$

where $Re_D = VD/\nu = 10 \text{ m/s} \times 0.0006 \text{ m}/18.41 \times 10^{-6} \text{ m}^2\text{/s} = 326$

$$\bar{h} = \frac{2.06 \rho c_p V}{\varepsilon} Re_D^{-0.575} Pr^{-2/3}$$

$$= \frac{2.06 \times 1.0782 \text{ kg/m}^3 \times 1008 \text{ J/kg} \cdot \text{K} \times 10 \text{ m/s}}{0.25} (326)^{-0.575} (0.704)^{-2/3} = 4060 \text{ W/m}^2 \cdot \text{K}$$

The surface area can be found as follows, where N = number of particles:

$V_p = N\pi D^3/6 = (1-\varepsilon)V_{\text{tot}} = (1-\varepsilon)WtL$ and

$$A_{p,t} = N\pi D^2 = 6(1-\varepsilon)WtL/D = = \frac{6 \times 0.75 \times 0.04 \text{ m} \times 0.01 \text{ m} \times 0.04 \text{ m}}{0.0006 \text{ m}} = 0.12 \text{ m}^2$$

The outlet air temperature is given by Equation 7.83:

$$T_o = T_s - (T_s - T_i)\exp\left(\frac{-\bar{h}A_{p,t}}{\rho V A_{c,b} c_p}\right)$$

Continued...

PROBLEM 7.113 (Cont.)

$$= 80°\text{C} - 60°\text{C}\exp\left(\frac{-4060\ \text{W/m}^2\cdot\text{K}\times 0.12\ \text{m}^2}{1.0782\ \text{kg/m}^3\times 10\ \text{m/s}\times(0.04\ \text{m})^2\times 1008\ \text{J/kg}\cdot\text{K}}\right) = 80°\text{C}$$

From Equation 7.82, or equivalently from an energy balance on the air,

$$q = \dot{m}c_p(T_o - T_i) = \rho V A_{c,b} c_p (T_o - T_i)$$
$$= 1.0782\ \text{kg/m}^3\times 10\ \text{m/s}\times(0.04\ \text{m})^2\times 1008\ \text{J/kg}\cdot\text{K}\times(80-20)°\text{C} = 1043\ \text{W} \qquad <$$

We would expect the actual convection heat transfer rate to be less because the foam has a conduction resistance and there are temperature gradients in the foam, primarily in the *x*-direction. Thus, near the center of the cross-section, the foam temperature will be reduced and so will the heat transfer rate.

(b) For a slice of the foam of length dx, the surface area of foam in contact with the air is $dA_s = A_{p,t}dx/L$. Thus,

$$dq_{\text{conv}} = \frac{\bar{h}A_{p,t}dx}{L}(T(x) - T_\infty)$$

By analogy with $dq_{\text{conv}} = hPdx(T(x) - T_\infty)$ for a solid fin, we find

$$P_{\text{eff}} = \frac{A_{p,t}}{L} = \frac{0.12\ \text{m}^2}{0.04\ \text{m}} = 3.0\ \text{m} \qquad <$$

From Equation 3.25 with $k_s = k_b$,

$$k_{\text{eff}} = \left[\frac{k_f + 2k_b - 2\varepsilon(k_b - k_f)}{k_f + 2k_b + \varepsilon(k_b - k_f)}\right]k_b$$
$$= \left[\frac{(0.0282 + 2\times 52 - 2\times 0.25\times(52 - 0.0282))\text{W/m}\cdot\text{K}}{(0.0282 + 2\times 52 + 0.25\times(52 - 0.0282))\text{W/m}\cdot\text{K}}\right]\times 52\ \text{W/m}\cdot\text{K} = 34.7\ \text{W/m}\cdot\text{K} \qquad <$$

Due to symmetry, the foam sheet can be treated as a fin of length $L/2$ with an insulated fin tip. From Equation 3.81,

$$q_f = 2\sqrt{\bar{h}P_{\text{eff}}k_{\text{eff}}A_{c,f}}(T_s - T_i)\tanh(mL/2)$$

where the factor of 2 accounts for both halves of the foam, each of length $L/2$, $A_{c,f}$ is the fin cross-sectional area, $A_{c,f} = Wt = 0.04\ \text{m} \times 0.01\ \text{m} = 4 \times 10^{-4}\ \text{m}^2$, and

$$m = \sqrt{\bar{h}P_{\text{eff}}/k_{\text{eff}}A_{c,f}} = \sqrt{4060\ \text{W/m}^2\cdot\text{K}\times 3\ \text{m}/(34.7\ \text{W/m}\cdot\text{K}\times 4\times 10^{-4}\ \text{m}^2)} = 937\ \text{m}^{-1}$$

Continued...

PROBLEM 7.113 (Cont.)

Thus,

$$q_f = 2\sqrt{4060\ \text{W/m}^2\cdot\text{K} \times 3\ \text{m} \times 34.7\ \text{W/m}\cdot\text{K} \times 4\times10^{-4}\ \text{m}^2}\,(80 - 20)^\circ\text{C}\tanh(933\ \text{m}^{-1}\times 0.02\ \text{m})$$

$$= 1560\ \text{W}$$ $<$

We would expect the actual rate of heat transfer to be less because the air temperature increases as it flows through the foam. This is not accounted for in the extended surface analysis, and if it were to be accounted for, we would have a smaller driving overall temperature difference through most of the foam, reducing q_f. $<$

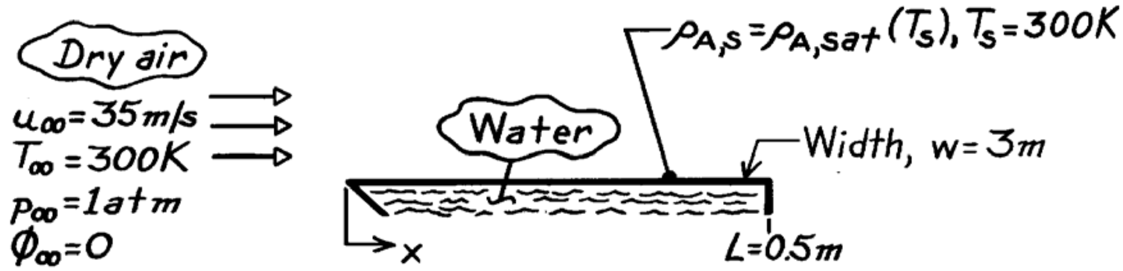
COMMENTS: (1) The results *suggest* that the foam might be an effective heat transfer medium. The heat transfer rates are quite high. However, the actual heat transfer rate will be lower than calculated here because of the *simultaneous* conduction resistance in the foam *and* increase in the air temperature as it passes through the foam. (2) In Problem 11.93, this problem is solved accounting for both the variation of air temperature in the flow direction and the variation of foam temperature in the *x*-direction. By accounting for both effects, you will learn that the heat transfer rates calculated here significantly overestimate the actual heat transfer rate.

PROBLEM 7.114

KNOWN: Flow of air over a flat, smooth wet plate.

FIND: (a) Average mass transfer coefficient, $\overline{h}_m$, (b) Water vapor mass loss rate, n_A (kg/s).

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Heat-mass transfer analogy applies, (3) $Re_{x,c} = 5 \times 10^5$.

PROPERTIES: *Table A-4*, Air (300K): $\nu = 15.89 \times 10^{-6}$ m^2/s, Pr = 0.707; *Table A-8*, Water vapor-air (300K, 1 atm): $D_{AB} = 0.26 \times 10^{-4}$ m^2/s, $Sc = \nu/D_{AB} = 0.611$; *Table A-6*, Water vapor (300K): $\rho_{A,sat} = 1/v_g = 0.0256$ kg/m^3.

ANALYSIS: (a) The Reynolds number for the plate, x = L, is

$$Re_L = \frac{u_\infty L}{\nu} = \frac{35\text{ m/s} \times 0.5\text{ m}}{15.89 \times 10^{-6}\text{ m}^2/\text{s}} = 1.10 \times 10^6.$$

Hence flow is mixed and the appropriate flat plate convection correlation is given by Eq. 7.41,

$$\overline{Sh}_L = \frac{\overline{h}_m L}{D_{AB}} = \left(0.037\, Re_L^{4/5} - 871\right) Sc^{1/3} = \left(0.037\left[1.10 \times 10^6\right]^{0.8} - 871\right) 0.611^{0.33}$$

giving

$$\overline{Sh}_L = 1399 \qquad \overline{h}_m = \frac{1399 \times 0.26 \times 10^{-4}\text{ m}^2/\text{s}}{0.5\text{ m}} = 0.0728\text{ m/s}. \qquad <$$

(b) The evaporative mass loss rate is

$$n_A = \overline{h}_m A_s \left(\rho_{A,s} - \rho_{A,\infty}\right)$$

where $A_s = L \cdot w$, $\rho_{A,\infty} = 0$ (dry air) and $\rho_{A,s} = \rho_{A,sat}$. Hence,

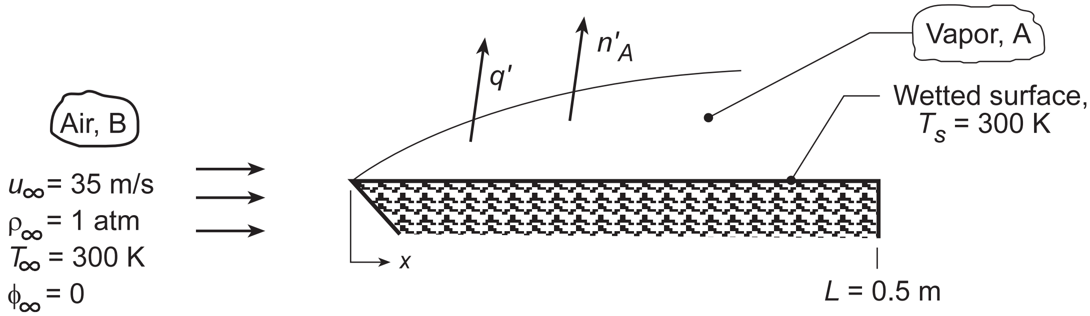
$$n_A = 0.0728\text{ m/s} \times (0.5 \times 3)\text{ m}^2\ (0.0256 - 0)\text{ kg/m}^3 = 0.0028\text{ kg/s}. \qquad <$$

PROBLEM 7.115

KNOWN: Air flow conditions over a wetted flat plate of known length and temperature.

FIND: (a) Heat loss and evaporation rate, per unit plate width, q' and n'_A, respectively, (b) Compute and plot q' and n'_A for a range of water temperatures $300 \le T_s \le 350$ K with air velocities of 10, 20 and 35 m/s, and (c) Water temperature T_s at which the heat loss will be zero for the air velocities and temperatures of part (b).

SCHEMATIC:



ASSUMPTIONS: (1) Heat and mass transfer analogy is applicable, (2) Constant properties, (3) $Re_{x,c} = 5 \times 10^5$.

PROPERTIES: *Table A.4*, Air (T = 300 K, 1 atm): $\nu = 15.89 \times 10^{-6}$ m²/s; *Table A.6*, Water (300 K): $v_g = 39.13$ m³/kg, $h_{fg} = 2438$ kJ/kg; *Table A.8*, Water-air (298 K, 1 atm): $D_{AB} = 0.26 \times 10^{-4}$ m²/s, Sc = 0.61.

ANALYSIS: (a) The heat loss from the plate is due only to the transfer of latent heat. Per unit width of the plate,

$$q' = n'_A h_{fg} \qquad (1)$$

$$n'_A = \bar{h}_m L\left[\rho_{A,sat}(T_s) - \rho_{A,\infty}\right] = \bar{h}_m L \rho_{A,sat}(T_s) \qquad (2)$$

With

$$Re_L = \frac{u_\infty L}{\nu} = \frac{35\,m/s \times 0.5\,m}{15.89 \times 10^{-6}\,m^2/s} = 1.10 \times 10^6$$

mixed boundary layer condition exists and the appropriate correlation is Eq. 7.41 with A = 871,

$$\overline{Sh}_L = \left(0.037\,Re_L^{4/5} - 871\right)Sc^{1/3} = \left[0.037\left(1.10 \times 10^6\right)^{4/5} - 871\right](0.61)^{1/3} \qquad (3)$$

giving $\overline{Sh}_L$ = 1398 and

$$\bar{h}_m = \overline{Sh}_L \frac{D_{AB}}{L} = 1398 \frac{0.26 \times 10^{-4}\,m^2/s}{0.5\,m} = 0.0727\,m/s\,.$$

with $\rho_{A,sat}(T_s) = v_g^{-1} = 0.0256\,kg/m^3$,

$$n'_A = 0.0727\,m/s(0.5\,m)\left(0.0256\,kg/m^3\right) = 9.29 \times 10^{-4}\,kg/s \cdot m \qquad <$$

Hence, the evaporative heat loss per unit plate width is

$$q' = n'_A h_{fg} = 9.29 \times 10^{-4}\,kg/s \cdot m\left(2.438 \times 10^6\,J/kg\right) = 2265\,W/m \qquad <$$

Continued...

PROBLEM 7.115 (Cont.)

Heat would have to be applied to the plate in the amount of 2265 W/m to maintain its temperature at 300 K with the evaporative heat loss.

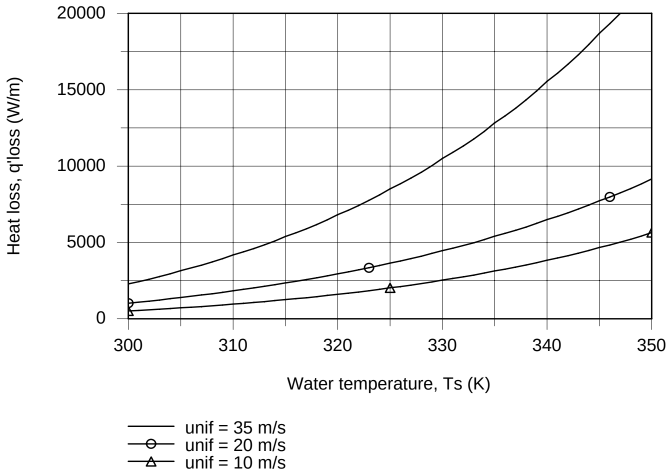
(b) When T_s and T_∞ are different, convection heat transfer will also occur, and the heat loss from the water surface is

$$q'_{loss} = q'_{conv} + q'_{evap} = \overline{h}L\left(T_s - T_\infty\right) + n'_A h_{fg} \tag{4}$$

Invoking the heat-mass analogy, Eq. 6.60 with n = 1/3,

$$\overline{h}/\overline{h}_m = \rho c\left(\alpha/D_{AB}\right)^{2/3} \tag{5}$$

where $\overline{h}_m$ and n'_A are evaluated using Eqs. (3) and (2), respectively. Using the foregoing relations in the *IHT Workspace*, but evaluating $\overline{h}$ (rather than $\overline{h}_m$) with the *Correlations Tool*, *External Flow*, for the *Average* coefficient for *Laminar* or *Mixed Flow*, q'_{loss} was evaluated as a function of u_∞ with T_∞ = 300 K.



(c) To determine the water temperature T_s at which the heat loss is zero, the foregoing IHT model was run with q'_{loss} = 0 with the result that, for all velocities,

T_s = 281 K $\quad <$

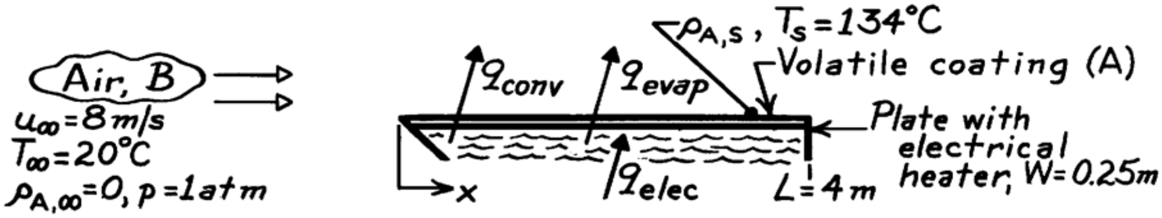
COMMENTS: Why is the result for part (c) independent of the air velocity?

PROBLEM 7.116

KNOWN: Flow over a heated flat plate coated with a volatile substance.

FIND: Electric power required to maintain surface at $T_s = 134°C$.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Heat-mass transfer analogy is applicable, (3) Transition occurs at $Re_{xc} = 5 \times 10^5$, (4) Perfect gas behavior of vapor A, (5) Upstream air is dry, $\rho_{A,\infty} = 0$.

PROPERTIES: *Table A-4*, Air (T_f = (134 + 20)°C/2 = 350 K, 1 atm): $\nu = 20.92 \times 10^{-6}$ m²/s, k = 0.030 W/m·K, Pr = 0.700; Substance A (given): $\mathcal{M}_A$ = 150 kg/kmol, $p_{A,sat}$ (134°C) = 0.12 atm, $D_{AB} = 7.75 \times 10^{-7}$ m²/s, $h_{fg} = 5.44 \times 10^6$ J/kg.

ANALYSIS: From an overall energy balance on the plate, the power required to maintain T_s is

$$q_{elec} = q_{conv} + q_{evap} = \bar{h}_L A_s \left(T_s - T_\infty\right) + \bar{h}_{m,L} A_s \left(\rho_{A,s} - \rho_{A,\infty}\right) h_{fg}. \quad (1)$$

To estimate $\bar{h}_L$, first determine Re_L,

$$Re_L = u_\infty L/\nu = 8 \text{ m/s} \times 4 \text{ m}/20.92 \times 10^{-6} \text{ m}^2/\text{s} = 1.530 \times 10^6.$$

Hence the flow is mixed and the appropriate correlation:

$$\overline{Nu}_L = \bar{h}_L L/k = \left(0.037 Re_L^{4/5} - 871\right) Pr^{1/3}$$

$$\bar{h}_L = \left(0.030 \text{ W/m}\cdot\text{K}/4\text{m}\right) \left(0.037\left(1.530 \times 10^6\right)^{4/5} - 871\right) \left(0.700\right)^{1/3} = 16.0 \text{ W/m}^2\cdot\text{K}.$$

To estimate $\bar{h}_{m,L}$, invoke the heat-mass analogy, with $Sc = \nu_B/D_{AB}$,

$$\bar{h}_{m,L} = \bar{h}_L \frac{D_{AB}}{k}\left(\frac{Sc}{Pr}\right)^{1/3} = 16.0 \frac{\text{W}}{\text{m}^2\cdot\text{K}} \left(\frac{7.75 \times 10^{-7} \text{m}^2/\text{s}}{0.030 \text{ W/m}\cdot\text{K}}\right) \left(\frac{20.92 \times 10^{-6} \text{m}^2/\text{s}}{7.75 \times 10^{-7} \text{m}^2/\text{s}} / 0.700\right)^{1/3} = 0.00140 \frac{\text{m}}{\text{s}}.$$

The density of species A at the surface, $\rho_{A,s}(T_s)$, follows from the perfect gas law,

$$\rho_{A,s} = p_{A,s} / \frac{\Re}{\mathcal{M}_A} T_s = 0.12 \text{ atm} / \frac{8.205 \times 10^{-2} \text{m}^3 \cdot \text{atm/kmol}\cdot\text{K}}{150 \text{ kg/kmol}} \cdot \left(134 + 273\right) \text{K} = 0.539 \frac{\text{kg}}{\text{m}^3}.$$

Using values calculated for $\bar{h}_L$, $\bar{h}_{m,L}$ and $\rho_{A,s}$ in Eq. (1), find

$$q_{elec} = \left(4\text{m} \times 0.25\text{m}\right) \left[16.0 \frac{\text{W}}{\text{m}^2\cdot\text{K}} \left(134 - 20\right)^\circ \text{C} + 0.00140 \frac{\text{m}}{\text{s}} \left(0.539 - 0\right) \frac{\text{kg}}{\text{m}^3} \times 5.44 \times 10^6 \frac{\text{J}}{\text{kg}}\right]$$

$$q_{elec} = 1.0 \text{ m}^2 \left[1{,}824 + 4{,}105\right] \text{ W/m}^2 = 5.93 \text{ kW}. \quad <$$

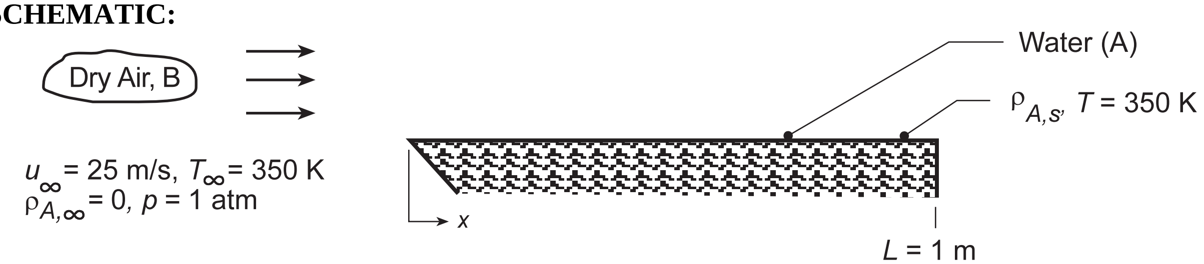
COMMENTS: For these conditions, nearly 70% of the heat loss is by evaporation.

PROBLEM 7.117

KNOWN: Flow of dry air over a water-saturated plate for prescribed flow conditions and mixed temperature.

FIND: (a) Mass rate of evaporation per unit plate width, $n''_A\,(kg/s\cdot m)$, and (b) Calculate and plot n'_A as a function of velocity for the range $1 \le u_\infty \le 25$ m/s for air and water temperatures of $T_s = T_\infty = 300$, 325, and 350 K.

SCHEMATIC:



ASSUMPTIONS: (1) Water surface is smooth, (2) Heat and mass transfer analogy is applicable, (3) $Re_{x,c} = 5 \times 10^5$.

PROPERTIES: *Table A.6*, Water vapor (T_s = 350 K, 1 atm): $\rho_{A,s} = 1/v_g = 1/3.846\ m^3/kg = 0.2600\ kg/m^3$; *Table A.4*, Air ($T_f = T_\infty$ = 350 K, 1 atm): $\nu = 20.92 \times 10^{-6}\ m^2/s$, $\alpha = 29.9 \times 10^{-6}\ m^2/s$; *Table A.8*, Air-water ($T_f = T_\infty$ = 350 K, 1 atm): $D_{AB} = 0.26 \times 10^{-4}\ m^2/s\ (350\ K/298\ K)^{3/2} = 0.331 \times 10^{-4}\ m^2/s$.

ANALYSIS: (a) Determine the nature of the air flow by calculating Re_L. With L = 1 m,

$$Re_L = \frac{u_\infty L}{\nu} = \frac{25\,m/s \times 1\,m}{20.92 \times 10^{-6}\,m^2/s} = 1.195 \times 10^6. \quad (1)$$

Since $Re_L > 5 \times 10^5$, it follows that the flow is mixed, and with Eq. 7.41 with A = 871, using $Sc = \nu/D_{AB}$,

$$\overline{Sh}_L = \frac{\bar{h}_m L}{D_{AB}} = \left(0.037\,Re_L^{4/5} - 871\right)Sc^{1/3}. \quad (2)$$

$$\overline{Sh}_L = \left(0.037\left[1.195 \times 10^6\right]^{4/5} - 871\right)\left(\frac{20.92 \times 10^{-6}\,m^2/s}{0.331 \times 10^{-4}\,m^2/s}\right)^{1/3} = 1563$$

The average mass transfer coefficient for the entire plate is

$$\bar{h}_m = \overline{Sh}_L \frac{D_{AB}}{L} = 1563 \frac{0.331 \times 10^{-4}\,m^2/s}{1\,m} = 0.0517\,m/s.$$

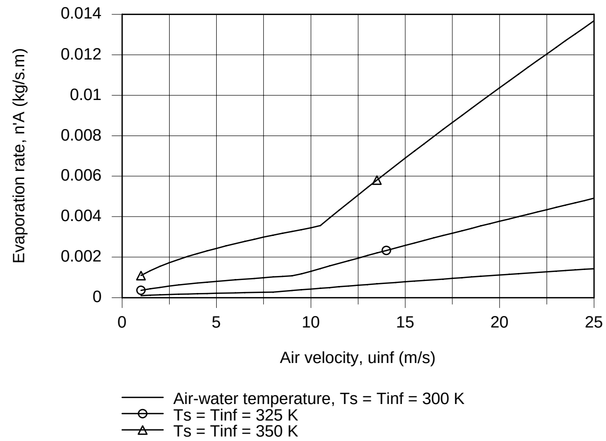
The mass rate of water evaporation per unit plate width is

$$n'_A = \bar{h}_m L\left(\rho_{A,s} - \rho_{A,\infty}\right) = 0.0517\,m/s \times 1\,m\,(0.260 - 0)\,kg/m^3 = 0.0135\,kg/s\cdot m \quad <$$

(b) Using Eq. (1) and (3) in the IHT Workspace with the *Correlations Tool*, *External Flow*, *Flat Plate*, *Average* coefficient for *Laminar* or *Mixed Flow*, replacing heat transfer with mass transfer parameters, the evaporation rate as a function of a velocity for selected air-water velocities was calculated and is plotted below.

Continued...

PROBLEM 7.117 (Cont.)



COMMENTS: (1) Note carefully the use of the heat-mass transfer analogy, recognizing that air is species B.

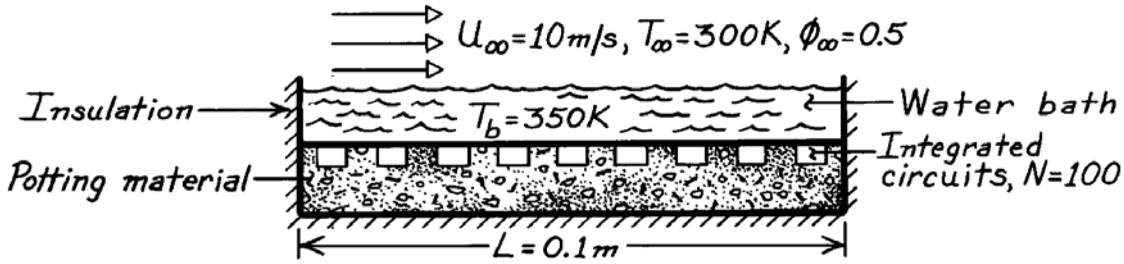
(2) How do you explain the abrupt slope changes in the evaporation rate as a function of velocity in the above plot?

PROBLEM 7.118

KNOWN: Temperature of water bath used to dissipate heat from 100 integrated circuits. Air flow conditions.

FIND: Heat dissipation per circuit.

SCHEMATIC:



ASSUMPTIONS: (1) Heat and mass transfer analogy is applicable, (2) Vapor may be approximated as a perfect gas, (3) Turbulent boundary layer over entire surface, (4) All heat loss is across air-water interface.

PROPERTIES: *Table A-4*, Air (325 K, 1 atm): $\nu = 18.4 \times 10^{-6}\ m^2/s$, k = 0.0282 W/m·K, Pr = 0.704; *Table A-8*, Air-vapor (325 K, 1 atm): $D_{AB} = 0.26 \times 10^{-4}\ m^2/s(325/298)^{3/2} = 0.296 \times 10^{-4}\ m^2/s$, $Sc = \nu/D_{AB} = 0.622$; *Table A-6*, Saturated water vapor (T_b = 350 K): $\rho_g = 0.260\ kg/m^3$, $h_{fg} = 2.32 \times 10^6$ J/kg; (T_∞ = 300 K): $\rho_g = 0.026\ kg/m^3$.

ANALYSIS: The heat rate is

$$q_1 = \frac{q}{N} = \frac{L^2}{N}\left[q'' + n''_A h_{fg}\left(T_b\right)\right].$$

Evaluate the heat and mass transfer convection coefficients with

$$Re_L = \frac{u_\infty L}{\nu} = \frac{10\ m/s \times 0.1\ m}{18.4 \times 10^{-6}\ m^2/s} = 54,348$$

$$\bar{h} = (k/L)0.037 Re_L^{4/5} Pr^{1/3} = (0.0282\ W/m \cdot K/0.1\ m)0.037(54,348)^{4/5}(0.704)^{1/3} = 57\ W/m^2 \cdot K$$

$$\bar{h}_m = (D_{AB}/L)0.037 Re_L^{4/5} Sc^{1/3} = \left(0.296 \times 10^{-4}\ m^2/s/0.1\ m\right)0.037(54,348)^{4/5}(0.622)^{1/3} = 0.0574\ m/s.$$

The convection heat transfer rate is

$$q'' = \bar{h}\left(T_b - T_\infty\right) = 57\ W/m^2 \cdot K(350 - 300)K = 2850\ W/m^2$$

and the evaporative cooling rate is

$$n''_A h_{fg} = \bar{h}_m\left[\rho_{A,sat}\left(T_b\right) - \phi_\infty \rho_{A,sat}\left(T_\infty\right)\right] h_{fg}\left(T_b\right)$$

$$n''_A h_{fg} = 0.0574\ m/s[0.260 - 0.5 \times 0.026]kg/m^3 \times 2.32 \times 10^6\ J/kg = 32,890\ W/m^2$$

Hence

$$q_1 = \frac{(0.1\ m)^2}{100}(2850 + 32,890)W/m^2 = 3.57\ W.$$ <

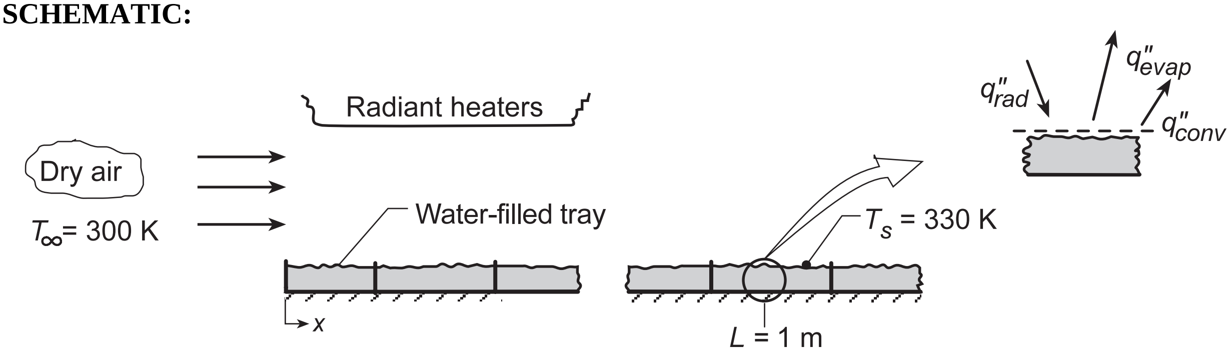
COMMENTS: Heat loss due to evaporative cooling is approximately an order of magnitude larger than that due to the convection of sensible energy.

PROBLEM 7.119

KNOWN: Dry air flows at 300 K over water-filled trays, each 222 mm long, with velocity of 15 m/s while radiant heaters maintain the surface temperature at 330 K.

FIND: (a) Evaporative flux (kg/s·m^2) at a distance 1 m from leading edge, (b) Radiant flux at this distance required to maintain water temperature at 330 K, (c) Evaporation rate from the tray at location L = 1 m, n'_A (kg/s·m) and (d) Irradiation which should be applied to each of the first four trays such that their rates are identical to that found in part (c).

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Heat-mass transfer analogy applicable, (3) Water vapor behaves as perfect gas, (4) All incident radiant power absorbed by water, (5) Critical Reynolds number is 5×10^5.

PROPERTIES: *Table A.4*, Air (T_f = 315 K, 1 atm): $\nu = 17.40 \times 10^{-6}$ m^2/s, k = 0.0274 W/m·K, Pr = 0.705; *Table A.8*, Water vapor-air (T_f = 315 K): $D_{AB} = 0.26 \times 10^{-4}$ m^2/s $(315/298)^{3/2} = 0.28 \times 10^{-4}$ m^2/s, Sc = ν/D_{AB} = 0.616; *Table A.6*, Saturated water vapor (T_s = 330 K): $\rho_{A,sat} = 1/v_g = 0.1134$ kg/m^3, h_{fg} = 2366 kJ/kg.

ANALYSIS: (a) The evaporative flux of water vapor (A) at location x is

$$\dot{n}''_{A,x} = h_{m,x}\left(\rho_{A,s} - \rho_{A,\infty}\right) = h_{m,x}\left[\rho_{A,sat}\left(T_s\right) - \phi_\infty \rho_{A,sat}\left(T_\infty\right)\right] \qquad (1)$$

Evaluate Re_x to determine the nature of the flow and then select the proper correlation.

$$Re_x = \frac{u_\infty x}{\nu} = 15\,\text{m/s} \times 1\,\text{m} \Big/ 17.40 \times 10^{-6}\,\text{m}^2/\text{s} = 8.621 \times 10^5 .$$

Hence, the flow is turbulent, and invoking the heat-mass analogy with Eq. 7.37,

$$Sh_x = \frac{h_m x}{D_{AB}} = 0.0296\, Re_x^{4/5}\, Sc^{1/3}$$

$$h_m = \frac{0.28 \times 10^{-4}\,\text{m}^2/\text{s}}{1\text{m}} \times 0.0296\left(8.621 \times 10^5\right)^{4/5}\left(0.616\right)^{1/3} = 3.952 \times 10^{-2}\,\text{m/s}.$$

Hence, the evaporative flux at x = 1 m is

$$\dot{n}''_{A,x} = 3.952 \times 10^{-2}\,\text{m/s}\left(0.1134\,\text{kg/m}^3 - 0\right) = 4.48 \times 10^{-3}\,\text{kg/s}\cdot\text{m}^2 \qquad (2) <$$

(b) From an energy balance on the differential element at x = 1 m,

$$q''_{rad} = q''_{conv} + q''_{evap} = h_x\left(T_s - T_\infty\right) + \dot{n}''_{A,x} h_{fg} \qquad (3)$$

Continued...

PROBLEM 7.119 (Cont.)

To estimate h_x, invoke the heat-mass analogy using the correlation, Eq. 7.37,

$$Nu_x / Sh_x = (Pr/Sc)^{1/3} \qquad \text{or} \qquad h_x = h_{m,x}\, k/D_{AB}\,(Pr/Sc)^{1/3} \tag{4}$$

$$h_x = 3.95\times10^{-2}\ kg/s\cdot m^2\left(0.0274\ W/m\cdot K/0.28\times10^{-4}\ m^2/s\right)(0.705/0.616)^{1/3} = 40.45\ W/m^2\cdot K$$

Hence, the required radiant flux is

$$q''_{rad} = 40.45\ W/m^2\cdot K(330-300)K + 4.48\times10^{-3}\ kg/s\cdot m^2\times 2366\times10^3\ J/kg$$

$$q''_{rad} = 1,214\ W/m^2 + 10,600\ W/m^2 = 11,813\ W/m^2$$ <

(c) The flow is turbulent over tray 5 having its mid-length at x = 1 m, so that it is reasonable to assume,

$$\bar{h}_5 \approx h_x(1m) \tag{5}$$

so that the evaporation rate can be determined from the evaporative flux as,

$$n'_A = n''_{A,x}\Delta L = 4.48\times10^{-3}\ kg/s\cdot m^2\times 0.222\ m = 9.95\times10^{-4}\ kg/s\cdot m$$ <

(d) For tray 5, following the form of Eq. (3), the energy balance is

$$q''_{rad,5}\Delta L = \bar{h}_5\Delta L\left(T_{s,5}-T_\infty\right) + n'_{A,5}h_{fg} \tag{6}$$

and the evaporation rate for the tray is

$$n'_{A,5} = \bar{h}_{m,5}\Delta L\left(\rho_{A,s}-0\right) \tag{7}$$

While $\bar{h}_5$ and $\bar{h}_{m,5}$ represent tray averages, Eq. (4) is still applicable. Using the *IHT Correlation Tool*, *External Flow*, *Average* coefficient for *Laminar*, or *Mixed Flow*, $\bar{h}_5$ is evaluated as

$$\bar{h}_5 = \left[\bar{h}_x(1.10\,m)L_5 - \bar{h}_x(0.880\,m)L_4\right]/\Delta L \tag{8}$$

where $\Delta L = L_5 - L_4 = 0.22$ m. The same relations can be applied to trays 2, 3 and 4. For tray 1, $\bar{h}_1 = \bar{h}(0.22\ m)\cdot L_1$, where $L_1 = \Delta L$. With Eqs. (3, 6, 7 and 8) in the IHT Workspace, along with the *Correlations* and *Properties Tools*, the following results were obtained with the requirement that the evaporation rate for each tray is equal at $n'_{A,5} = 10.01\times10^{-4}$ kg/s·m.

Tray	1	2	3	4	5
T_s	342.7	357	348.1	329	330
q''_{rad}	11,920	11,150	11,400	11,950	11,920

COMMENTS: (1) Note carefully at which temperatures the thermophysical properties are evaluated.

(2) Recognize that in part (d), if we require equal evaporation rates for each tray, $n'_{A,5}$, the water temperature, T_s, and radiant flux, q''_{rad}, for each tray must be different since the convection coefficients $\bar{h}_x$ and $\bar{h}_{m,x}$ are different for each of the trays. How do you explain the changes in T_s? Which tray has the highest $\bar{h}$? The lowest $\bar{h}$?

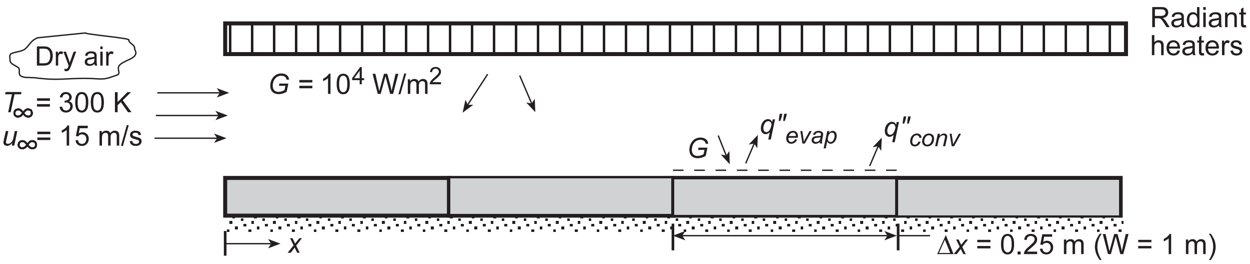
(3) For tray 5, using Eq. (5) we found $\bar{h}_5 = 40.45\ W/m^2\cdot K$; using the more accurate formulation, Eq. (8), the result is $40.49\ W/m^2\cdot K$. If the flow were laminar or mixed over the tray, Eq. (5) would be inappropriate.

PROBLEM 7.120

KNOWN: Irradiation on sequential water-filled trays of prescribed length and width. Temperature and velocity of airflow over the trays.

FIND: Rate of water loss from first, third and fourth trays and temperature of water in each tray.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform irradiation of each container, (3) Complete absorption of irradiation by water, (4) Negligible heat transfer between containers and from bottom of containers, (5) Validity of heat-mass transfer analogy, (6) Applicability of convection correlations for an isothermal surface, (7) $Re_{x,c} = 5 \times 10^5$.

PROPERTIES: *Table A.4*, air (1 atm, *assume* T_f = 315 K): $\nu = 17.4 \times 10^{-6}$ m^2/s, k = 0.0274 W/m·K, Pr = 0.705. *Table A.8*, vapor/air (1 atm, 315 K): $D_{AB} = 0.26 \times 10^{-4}$ m^2/s $(315/298)^{3/2} = 0.28 \times 10^{-4}$ m^2/s, Sc = ν/D_{AB} = 0.616.

ANALYSIS: The temperature of each tray is determined by a balance between the absorbed radiation and the convection and evaporative losses. Hence,

$$G = q''_{conv} + q''_{evap} = \bar{h}\left(T_s - T_\infty\right) + \bar{h}_m \rho_{A,sat} h_{fg}$$

where, assuming an exponent of n = 1/3, the heat-mass transfer analogy yields

$$\bar{h}_m = \left(D_{AB}/k\right)\left(Sc/Pr\right)^{1/3}\bar{h} = \left(0.26\times10^{-4}\ \mathrm{m^2/s}/0.0274\ \mathrm{W/m\cdot K}\right)\left(0.616/0.705\right)^{1/3}\bar{h} = \left(9.07\times10^{-4}\ \mathrm{m^3\cdot K/W\cdot s}\right)\bar{h}$$

Hence,

$$G = \bar{h}\left[\left(T_s - T_\infty\right) + 9.07\times10^{-4}\rho_{A,sat}h_{fg}\right]$$

With $Re_N = u_\infty N\Delta x/\nu = 15$ m/s(N × 0.25 m)/17.4 × 10^{-6} m^2/s = (2.155×10^5)N, the flow is laminar for N = 1,2 with transition to turbulence occurring for N = 3.

For tray 1,

$$\bar{h} = \left(k/\Delta x\right)0.664\,Re_1^{1/2}\,Pr^{1/3}$$
$$= \left(0.0274\ \mathrm{W/m\cdot K}/0.25\ \mathrm{m}\right)0.664\left(2.155\times10^5\right)^{1/2}\left(0.705\right)^{1/3} = 30.1\ \mathrm{W/m^2\cdot K}$$

For tray 4, with x = 0.875 m (N = 7/2),

$$\bar{h}_4 \approx \left(k/x\right)0.0296\,Re_{7/2}^{4/5}\,Pr^{1/3}$$
$$= \left(0.0274\ \mathrm{W/m\cdot K}/0.875\ \mathrm{m}\right)0.0296\left(7.543\times10^5\right)^{4/5}\left(0.705\right)^{1/3} = 41.5\ \mathrm{W/m^2\cdot K}$$

Continued...

PROBLEM 7.120 (Cont.)

For tray 3, $\bar{h}_3 = \left(\bar{h}_{1-3}L_3 - \bar{h}_{1-2}L_2\right)/\Delta x$, where

$$\bar{h}_{1-3}L_3 = k\left(0.037\,Re_3^{4/5} - 871\right)Pr^{1/3}$$
$$= 0.0274\,W/m\cdot K\left(0.037\times 44,510 - 871\right)(0.705)^{1/3} = 18.9\,W/m\cdot K$$

$$\bar{h}_{1-2}L_2 = k\left(0.664\,Re_2^{1/2}\,Pr^{1/3}\right)$$
$$= 0.0274\,W/m\cdot K\left(0.664\times 656.5\right)(0.705)^{1/3} = 10.6\,W/m\cdot K$$

$$\bar{h}_3 = (18.9 - 10.6)\,W/m\cdot K/0.25\,m = 33.1\,W/m^2\cdot K$$

For tray 1, the energy balance yields

$$10^4\,W/m^2 = 30.1\,W/m^2\cdot K\left[\left(T_s - T_\infty\right) + 9.07\times 10^{-4}\rho_{A,sat}h_{fg}\right]$$

Since $\rho_{A,sat}$ depends strongly on T_s, the solution to this equation must be obtained by trial-and-error, with $\rho_{A,sat}$ (and h_{fg}) determined from Table A.6. The solution yields

$$T_{s,1} \approx 334.7\,K$$ <

Similarly, for trays 3 and 4

$$T_{s,3} \approx 332.8\,K \qquad T_{s,4} \approx 327.1\,K$$ <

The evaporation rate for tray N is

$$\dot{m}_{evap} = \bar{h}_m\rho_{A,sat}\left(W\Delta x\right) = 2.27\times 10^{-4}\bar{h}\rho_{A,sat}$$

from which it follows that

$$\dot{m}_{evap,1} \approx 9.5\times 10^{-4}\,kg/s, \qquad \dot{m}_{evap,3} \approx 9.5\times 10^{-4}\,kg/s, \qquad \dot{m}_{evap,4} \approx 9.3\times 10^{-4}\,kg/s$$ <

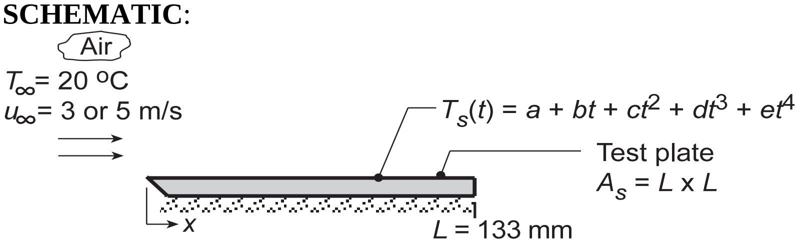
COMMENTS: (1) The largest convection coefficient is associated with the tray for which the entire flow is turbulent. (2) The temperature of the water varies inversely with the average convection coefficient for its tray.

PROBLEM 7.121

KNOWN: Apparatus as described in Problem 7.40 providing a nearly uniform airstream over a flat *test plate* to experimentally determine the heat and mass transfer coefficients. Temperature history of the pre-heated plate for airstream velocities of 3 and 9 m/s were fitted to a fourth-order polynomial for determining the heat transfer coefficient. Water mass loss observations from a water-saturated paper over the plate and its surface temperature for determining the heat transfer coefficient.

FIND: (a) From the temperature-time history, determine the heat transfer coefficients and evaluate the constants C and m for a correlation of the form $\overline{Nu}_L = C\,Re^m\,Pr^{1/3}$; compare results with a standard-plate correlation and comment on the goodness of the comparison; explain any differences; (b) From the water mass loss observations, determine the mass transfer coefficients for the two flow conditions; evaluate the constants C and m for a correlation of the form $\overline{Sh}_L = C\,Re^m\,Sc^{1/3}$; and (c) Using the heat-mass analogy, compare the experimental results with each other and against standard correlations; comment on the goodness of the comparison; explain any differences.

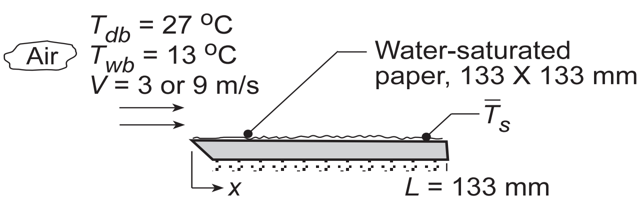
SCHEMATIC:



(a) Heat transfer experiment

Temperature Observations

u_∞ (m/s)	3	9
Δt (s)	300	160
a (°C)	56.87	57.00
b (°C/s)	-0.1472	-0.2641
c (°C/s²)	3×10^{-4}	9×10^{-4}
d (°C/s³)	-4×10^{-7}	-2×10^{-6}
e (°C/s⁴)	2×10^{-10}	1×10^{-9}



(b) Mass transfer experiment

Mass Loss Observations

V (m/s)	$\overline{T}_s$ (°C)	m (t) (g)	m (t + Δt) (g)	Δt (s)
3	15.3	55.62	54.45	475
9	16.0	55.60	54.50	240

ASSUMPTIONS: (1) Airstream over the test plate approximates parallel flow over a flat plate, (2) Plate is spacewise isothermal, (3) Negligible radiation exchange between plate and surroundings, (4) Constant properties, and (5) Negligible heat loss from the bottom surface or edges of the test plate.

PROPERTIES: *Heat transfer coefficient*, *Table A.4*, Air ($T_f = \left(\overline{T}_s + T_\infty\right)/2$ = 310 K, 1 atm): k_a = 0.0269 W/m·K, ν = 1.669 × 10^{-5} m²/s, Pr = 0.706. *Test plate* (*Given*): ρ = 2770 kg/m³, c_p = 875 J/kg·K, k = 177 W/m·K. *Mass transfer coefficient*: *Table A.6*, Water vapor ($\overline{T}_s$ = 15.3°C = 288.3 K): $\rho_{A,sat} = 1/v_g$ = 79.81 m³/kg = 0.01253 kg/m³; *Table A.6*, Water vapor ($\overline{T}_s$ = 16.0°C = 289 K): $\rho_{A,sat}$ = 0.01322 kg/m³; *Table A.6*, Water vapor (T_{inf} = 27°C = 300 K): $\rho_{A,sat}$ = 0.02556 kg/m³; *Table A.8*, Water vapor-air [T_f = $\left(\overline{T}_s + T_\infty\right)/2$ ≈ 295 K]: D_{AB} = 0.26 × 10^{-4} m²/s $(295/298)^{1.5}$ = 0.256 × 10^{-4} m²/s.

ANALYSIS: (a) Using the lumped-capacitance method, the energy balance on the plate is

$$-\overline{h}_L A_s \left[T_s(t) - T_\infty\right] = \rho V c_p \frac{dT}{dt} \qquad (1)$$

Continued...

PROBLEM 7.121 (Cont.)

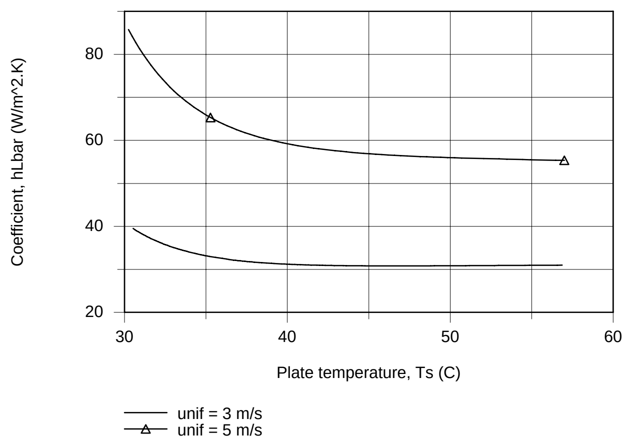
and the average convection coefficient can be determined from the temperature history, $T_s(t)$,

$$\bar{h}_L = \frac{\rho V c_p}{A_s} \frac{(dT/dt)}{T_s(t) - T_\infty} \tag{2}$$

where the temperature-time derivative is

$$\frac{dT_s}{dt} = b + 2ct + 3dt^2 + 4et^3 \tag{3}$$

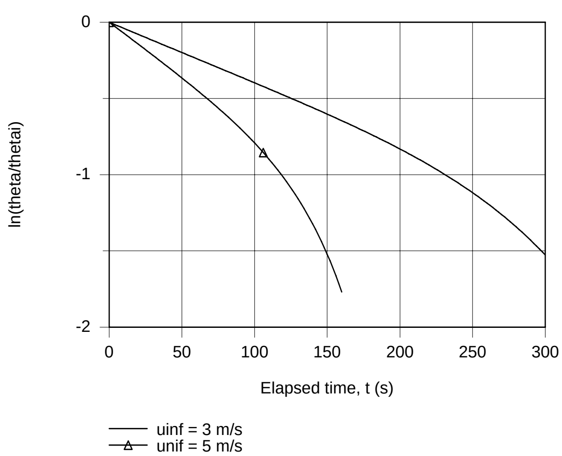
The temperature time history plotted below shows the experimental behavior of the observed data.

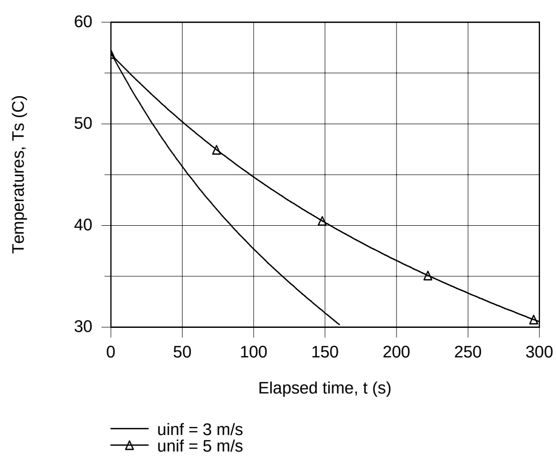


Consider now the integrated form of the energy balance, Eq. (5.6), expressed as

$$\ln \frac{T_s(t) - T_\infty}{T_i - T_\infty} = -\left(\frac{\bar{h}_L A_s}{\rho V c}\right) t \tag{4}$$

If we were to plot the LHS vs t, the slope of the curve would be proportional to $\bar{h}_L$. Using IHT, plots were generated of $\bar{h}_L$ vs. T_s, Eq. (1), and $\ln\left[\left(T_s(t) - T_\infty\right)/\left(T_i - T_\infty\right)\right]$ vs. t, Eq. (4). From the latter plot, recognize that the regions where the slope is constant corresponds to early times (≤ 100s when u_∞ = 3 m/s and ≤ 50s when u_∞ = 5 m/s).





Continued...

PROBLEM 7.121 (Cont.)

Selecting two elapsed times at which to evaluate $\overline{h}_L$, the following results were obtained

u_∞ (m/s)	t (s)	T_s (t), (°C)	$\overline{h}_L$ (W/m^2·K)	$\overline{Nu}_L$	Re_L
3	100	44.77	30.81	152.4	2.39×10^4
9	50	45.80	56.7	280.4	7.17×10^4

where the dimensionless parameters are evaluated as

$$\overline{Nu}_L = \frac{\overline{h}_L L}{k_a} \qquad Re_L = \frac{u_\infty L}{\nu} \qquad (5,6)$$

where k_a, ν are thermophysical properties of the airstream.

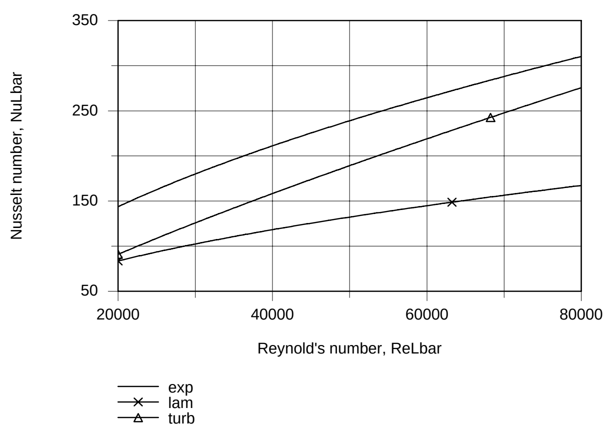
(b) Using the above pairs of $\overline{Nu}_L$ and Re_L, C and m in the correlation can be evaluated,

$$\overline{Nu}_L = C\, Re_L^m\, Pr^{1/3} \qquad (7)$$

$$152.4 = C(2.39 \times 10^4)^m(0.706)^{1/3} \qquad 280.4 = C(7.17 \times 10^4)^m(0.706)^{1/3}$$

Solving, find C = 0.633 m = 0.555 (8,9) <

The plot below compares the experimental correlation (C = 0.633, m = 0.555) with those for laminar flow (C = 0.664, m = 0.5) and fully turbulent flow (C = 0.037, m = 0.8). The experimental correlation yields $\overline{Nu}_L$ values which are 25% higher than for the correlation. The most likely explanation for this unexpected trend is that the airstream reaching the plate is not parallel, but with a slight impingement effect and/or the flow is very highly turbulent at the leading edge.



(b) From the convection mass transfer rate equation,

$$n_A = \overline{h}_{m,L} A_s \left(\rho_{A,s} - \rho_{A,\infty}\right) \qquad (10)$$

where the evaporation rate can be determined from the paper mass and time interval observations,

$$n_A = \left[m\left(t + \Delta t\right) - m\left(t\right)\right]/\Delta t \qquad (11)$$

and the species densities, $\rho_{A,s}$ and $\rho_{A,\infty}$, correspond to $\rho_{A,sat}\left(\overline{T}_s\right)$ and $\phi_\infty \rho_{A,sat}\left(T_\infty\right)$, respectively.

Using the ASHRAE psychrometric chart (1 atm) with T_{wb} = 13°C and T_{db} = 27°C, find the relative humidity as ϕ_∞ = 0.17. The correlation dimensionless parameters are evaluated as

$$\overline{Sh}_L = \frac{\overline{h}_{m,L} L}{D_{AB}} \qquad Re_L = \frac{u_\infty L}{\nu} \qquad Sc = \frac{\nu}{D_{AB}} \qquad (12,13,14)$$

Continued...

PROBLEM 7.121 (Cont.)

where all the properties are evaluated at $T_f = \left(\overline{T}_s + T_\infty\right)/2$. The results of the analyses are summarized in the following table.

u_∞	n_A	$\overline{h}_{m,L}$	$\overline{Sh}_L$	Re_L	Sc
(m/s)	kg/s	(m/s)			
3	2.463×10^{-6}	0.0168	87.58	2.594×10^4	0.603
9	4.583×10^{-6}	0.0288	150	7.767×10^4	0.603

Using the two sets of tabulated values for $\overline{Sh}_L$, Re_L and Sc and the standard correlation of the form,

$$\overline{Sh}_L = C\,Re_L^m\,Sc^{1/3} \tag{15}$$

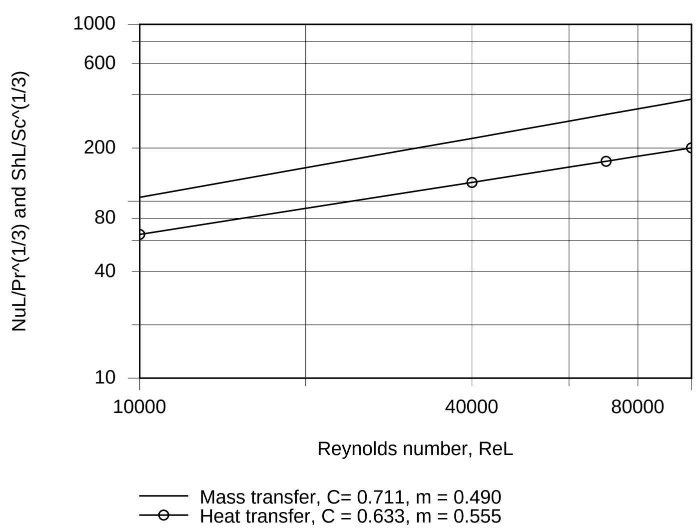
$$87.58 = C\left(2.594\times10^4\right)^m (0.603)^{1/3} \qquad 150 = C\left(7.767\times10^4\right)^m (0.603)^{1/3}$$

solve simultaneously to find C = 0.711 m = 0.490 (16,17)

From the heat-mass analogy, we expect the constants C and m in Eq. (7) for heat transfer and in Eq. (13) for mass transfer to be the same. From the two experiments, we found

	C	m
Heat transfer	0.633	0.555
Mass transfer	0.711	0.490

In the plot below, the parameters $\overline{Sh}_L/Sc^{1/3}$ or $\overline{Nu}_L/Pr^{1/3}$ are plotted against Re_L using Eq. (15) or (7). Note that the curves are nearly parallel on the log-log axes since their "m" constants are of similar value. The mass transfer results are, however, nearly 50% higher than those for heat transfer. We have no way to explain this systematic difference without more information on the apparatus, observation procedures and repeated observations. However, overall the results support the general form of the heat-mass analogy.

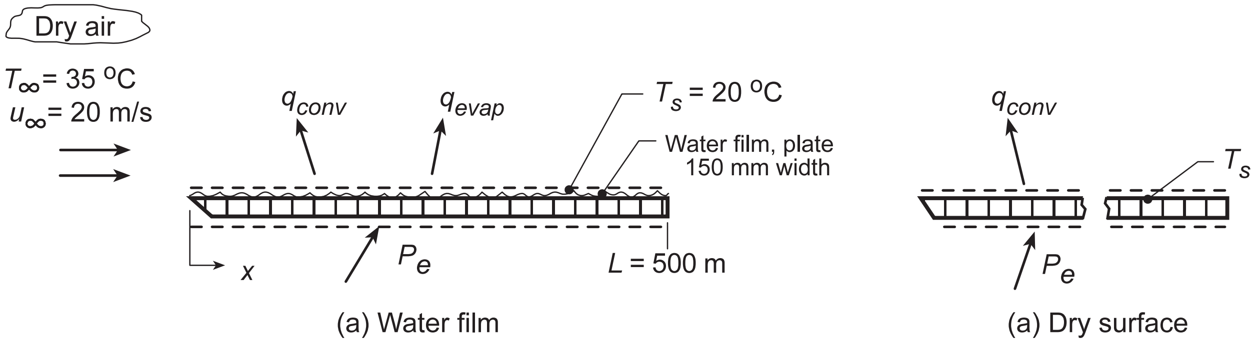


PROBLEM 7.122

KNOWN: Dry air at prescribed temperature and velocity flowing over a wetted plate of length 500 mm and width 150 mm. Imbedded electrical heater maintains the surface at T_s = 20°C.

FIND: (a) Water evaporation rate (kg/h) and electrical power P_e (W) required to maintain steady-state conditions, and (b) The temperature of the plate after all the water has evaporated, for the same airstream conditions and heater power of part (a).

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties and (3) Heat-mass transfer analogy is applicable.

PROPERTIES: *Table A.4*, Air ($T_f = (T_s + T_\infty)/2$ = 300 K, 1 atm): ρ = 1.16 kg/m^3, c_p = 1007 J/kg·K, k = 0.0263 W/m·K, ν = 15.94 × 10^{-6} m^2/s, α = 2.257 × 10^{-5} m^2/s, *Table A.6*, Water (T_s = 20°C = 293 K): $\rho_{A,s} = 1/v_g$ = 1/59.04 = 0.0169 kg/m^3, h_{fg} = 2454 kJ/K; *Table A.8*, Water-air (T_f = 300 K): D_{AB} = 0.26 × 10^{-4} m^2/s.

ANALYSIS: (a) Perform an energy balance on the plate,

$$\dot{E}_{in} - \dot{E}_{out} = 0 \qquad P_e - q_{conv} - q_{evap} = 0 \tag{1}$$

where the convection and evaporation rate equations are,

$$q_{conv} = \bar{h}_L A_s (T_s - T_\infty) \tag{2}$$

$$q_{evap} = n_A h_{fg} = \bar{h}_m A_s (\rho_{A,s} - \rho_{A,\infty}) h_{fg} \tag{3}$$

The Reynolds number for the plate length L is

$$Re_L = \frac{u_\infty L}{\nu} = \frac{20\,m/s \times 0.50\,m}{15.94 \times 10^{-6}\,m^2/s} = 6.274 \times 10^5$$

so that the flow is mixed and Eq. 7.38 is appropriate to estimate $\bar{h}_L$,

$$\overline{Nu}_L = \frac{\bar{h}_L L}{k} = \left(0.037\,Re_D^{4/5} - 871\right) Pr^{1/3}$$

$$\bar{h}_L = \frac{0.0263\,W/m \cdot K}{0.5\,m}\left(0.037\left[6.274 \times 10^5\right]^{4/5} - 871\right)(0.707)^{1/3} = 34.5\,W/m^2 \cdot K$$

Invoking the heat-mass analogy, Chapter 6, with n = 1/3

$$\frac{\bar{h}_L}{\bar{h}_m} = \rho c_p \left(\frac{\alpha}{D_{AB}}\right)^{-2/3} = 1.16\,kg/m^3 \times 1007\,J/kg \cdot K \left(\frac{2.257 \times 10^{-5}\,m^2/s}{0.26 \times 10^{-4}\,m^2/s}\right)^{-2/3} = 1284\,J/m^3 \cdot K$$

Continued...

PROBLEM 7.122 (Cont.)

$$\overline{h}_m = 34.5\,\text{W/m}^2\cdot\text{K}\big/1284\,\text{J/m}^3\cdot\text{K} = 0.0269\,\text{m/s}$$

Substituting numerical values, the energy balance, Eq. (1), with A_s = 0.5 m × 0.15 m = 0.075 m^2,

$$P_e - 34.5\,\text{W/m}^2\cdot\text{K}\times 0.075\,\text{m}^2\,(20-35)\,\text{K}$$
$$-0.0269\,\text{m/s}\times 0.075\,\text{m}^2\,(0.0169-0)\,\text{kg/m}^3\times 2454\times 10^3\,\text{J/kg}\cdot\text{K} = 0$$

$$P_e = -38.8\,\text{W} + 83.7 = 44.9\,\text{W}$$ <

The evaporation rate is

$$n_A = \overline{h}_m A_s\left(\rho_{A,s} - \rho_{A,\infty}\right) = 0.0269\,\text{m/s}\times 0.075\,\text{m}^2\times 0.0169\,\text{kg/m}^3\times 3600\,\text{s/h} = 0.123\,\text{kg/h}$$ <

(b) When the plate is dry, the energy balance is

$$P_e = \overline{h}_L A_s\left(T_s - T_\infty\right)$$

and with P_e and $\overline{h}_L$ as determined in part (a),

$$T_s = T_\infty + P_e/\overline{h}_L A_s = 35^\circ\text{C} + 44.9\,\text{W}\big/34.5\,\text{W/m}^2\cdot\text{K}\times 0.075\,\text{m}^2 = 52.3^\circ\text{C}$$ <

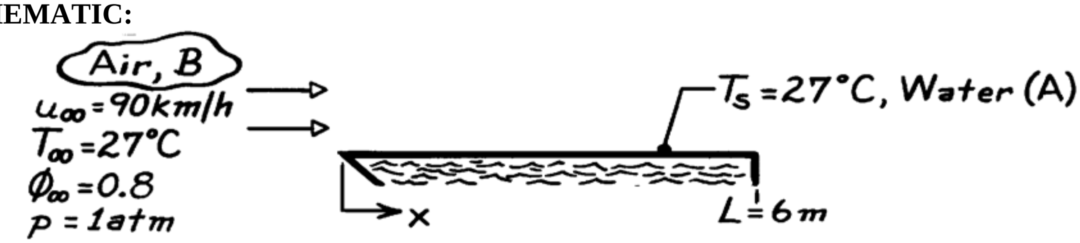
COMMENTS: Using *IHT Correlations Tool*, *External Flow*, *Flat Plate*, the calculation of part (b) was performed using the proper film temperature, T_f = 318 K, to find $\overline{h}_L$ = 32.7 W/m^2·K and T_s = 53.3°C.

PROBLEM 7.123

KNOWN: Convection mass transfer with turbulent flow over a flat plate (van roof).

FIND: (a) Location on van that will dry last, (b) Evaporation rate at trailing edge, $kg/s\cdot m^2$.

SCHEMATIC:



ASSUMPTIONS: (1) Turbulent flow over entire plate (van top), (2) Heat-mass transfer analogy is applicable, (3) Perfect gas behavior for water vapor (A).

PROPERTIES: *Table A-4*, Air (300 K, 1 atm): $\nu = 15.89 \times 10^{-6}\ m^2/s$, k = 0.0263 W/m·K, Pr = 0.707; *Table A-8*, Air-water vapor (25°C): $D_{AB} = 0.26 \times 10^{-4}\ m^2/s$; *Table A-6*, Saturated water vapor (300K): $\rho_{A,sat} = v_g^{-1} = 0.0256\ kg/m^3$.

ANALYSIS: (a) The mass transfer coefficient, $h_m(x)$, will be largest at x = 0 and smallest at x = L for turbulent flow conditions. Hence, the trailing edge will dry last.

(b) The evaporation rate on a per unit area basis, at the trailing edge where x = L, is given by the rate equation,

$$n''_A = h_{m,L}\ \left(\rho_{A,s} - \rho_{A,\infty}\right) = h_{m,L}\ \rho_{A,sat}\left(1 - \phi_\infty\right)$$

For turbulent flow the appropriate correlation for estimating $h_{m,L}$ is of the form

$$Sh_x = h_{m,x}x/D_{AB} = 0.0296\ Re_x^{4/5}\ Sc^{1/3}.$$

Substituting numerical values,

$$Re_L = \frac{u_\infty L}{\nu_B} = \frac{90 \times 10^3\ m/h}{3600\ s/h} \times 6m/15.89 \times 10^{-6}\ m^2/s = 9.44 \times 10^6$$

$$Sc = \frac{\nu_B}{D_{AB}} = 15.89 \times 10^{-6}\ m^2/s/0.26 \times 10^{-4}\ m^2/s = 0.611$$

$$h_{m,L} = \left(0.26 \times 10^{-4}\ m^2/s/6m\right) \times 0.0296\ \left(9.44 \times 10^6\right)^{4/5}(0.611)^{1/3} = 0.0414\ m/s.$$

Hence, the evaporation flux (rate per unit area) is

$$n''_A = 0.0414\ m/s \times 0.0256\ kg/m^3\ (1 - 0.8) = 2.12 \times 10^{-4}\ kg/s \cdot m^2.$$ <

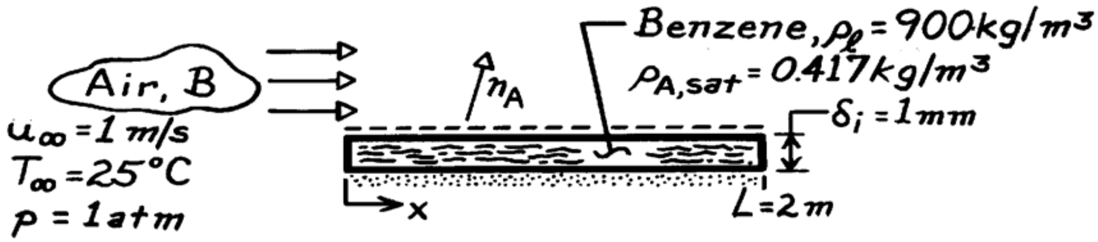
COMMENTS: Recognize how the heat-mass analogy is utilized and the appropriate correlation selected from Table 7.7.

PROBLEM 7.124

KNOWN: Length and thickness of a layer of benzene. Velocity and temperature of air in parallel flow over the layer.

FIND: Time required for complete evaporation.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Smooth liquid surface and negligible free-stream turbulence, (3) Heat and mass transfer analogy is applicable, (4) Negligible benzene vapor concentration in free-stream air, (5) Isothermal conditions at 25°C.

PROPERTIES: *Table A-4*, Air (25°C, 1 atm): $\nu = 15.7 \times 10^{-6}$ m^2/s; *Table A-8*, Benzene-air, (25°C, 1 atm): $D_{AB} = 0.88 \times 10^{-5}$ m^2/s, Sc = 1.78.

ANALYSIS: Applying conservation of mass to a control volume about the liquid,

$$\frac{dM}{dt} = \frac{d(\rho_\ell V)}{dt} = -n_A.$$

For a unit width, V = L·δ. Hence

$$\rho_\ell L \frac{d\delta}{dt} = -n'_A = -\bar{h}_m L\left(\rho_{A,sat} - \rho_{A,\infty}\right)$$

and integrating

$$\int_{\delta_i}^{0} d\delta = -\frac{\bar{h}_m}{\rho_\ell}\rho_{A,sat} \int_0^t dt$$

$$t = \frac{\delta_i \ \rho_\ell}{\bar{h}_m \rho_{A,sat}}.$$

With $Re_L = \dfrac{u_\infty L}{\nu} = \dfrac{1 \text{ m/s} \times 2 \text{ m}}{15.7 \times 10^{-6} \text{ m}^2/\text{s}} = 1.27 \times 10^5,$

the flow is laminar throughout and from Eq. 7.31,

$$\bar{h}_m = \frac{D_{AB}}{L} 0.664\, Re_L^{1/2} Sc^{1/3} = \frac{0.88 \times 10^{-5} \text{ m}^2/\text{s}}{2 \text{ m}} \times 0.664 \left(1.27 \times 10^5\right)^{1/2} (1.78)^{1/3}$$

$$\bar{h}_m = 1.26 \times 10^{-3} \text{ m/s}$$

and

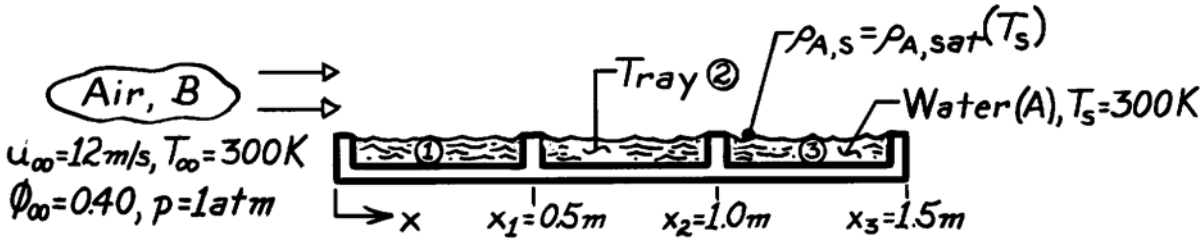
$$t = \frac{0.001 \text{ m}\left(900 \text{ kg/m}^3\right)}{\left(1.26 \times 10^{-3} \text{ m/s}\right)\left(0.417 \text{ kg/m}^3\right)} = 1713 \text{ s} = 28.6 \text{ min.}$$ <

PROBLEM 7.125

KNOWN: Parallel air flow over a series of water-filled trays.

FIND: Power required to maintain each of the first three trays at 300K.

SCHEMATIC:



ASSUMPTIONS: (a) Steady-state conditions, (2) Heat-mass transfer analogy applicable, (3) Perfect gas behavior for water vapor, (4) $Re_{x,c} = 5 \times 10^5$.

PROPERTIES: *Table A-4*, Air (300 K, 1 atm): $\nu = \nu_B = 15.89 \times 10^{-6}\ m^2/s$; *Table A-8*, Water vapor-air (300K): $D_{AB} = 0.26 \times 10^{-4}\ m^2/s$, $Sc = \nu_B/D_{AB} = 0.611$; *Table A-6*, Saturated water vapor (300K): $\rho_{A,sat} = v_g^{-1} = 0.02556\ kg/m^3$, $h_{fg} = 2438\ kJ/kg$.

ANALYSIS: Since $T_s = T_\infty$, there is no convective heat transfer, hence,

$$q_{tray} = \dot{m}_{tray} h_{fg} = \overline{h}_m \cdot A_s \cdot \rho_{A,sat}\left(1-\phi_\infty\right) h_{fg} \qquad (1)$$

where

$\phi_\infty \equiv \rho_{A,\infty} / \rho_{A,sat}$ and $\rho_{A,s} = \rho_{A,sat}\left(T_s\right)$. Calculate the Reynolds number at x_3,

$$Re_{x3} = u_\infty x_3 / \nu_B = 12\ m/s \times 1.5 m / 15.89 \times 10^{-6}\ m^2/s = 1.133 \times 10^6$$

finding that transition occurs at x = 0.662 m, a location on tray 2. The average mass transfer coefficients $\overline{h}_m$ and heat rates for each tray are as follows:

Tray 1: The flow is laminar and the appropriate correlation for $\overline{h}_{m,1}$ and heat rate are

$$\overline{Sh}_{x1} = \overline{h}_{m,1} x_1 / D_{AB} = 0.664\ Re_{x1}^{1/2}\ Sc^{1/3}$$

$$\overline{h}_{m,1} = \left(0.26 \times 10^{-4}\ m^2/s/0.5\ m\right) \times 0.664 \left(\frac{12\ m/s \times 0.5\ m}{15.89 \times 10^{-6}\ m^2/s}\right)^{1/2} (0.611)^{1/3} = 1.800 \times 10^{-2}\ m/s$$

$$q_1' = 1.800 \times 10^{-2}\ m/s \times 0.5\ m \times 0.02556\ kg/m^3\ \left(1-0.40\right) \times 2438 \times 10^3\ J/kg = 337\ W/m. \qquad <$$

Tray 2: Since transition occurs over the span of tray 2, the rate equation has the form

$$q_2' = \left[x_2 \overline{h}_{m,0-2} - x_1 \overline{h}_{m,0-1}\right] \rho_{A,sat}\left(1-\phi_\infty\right) h_{fg}. \qquad (2)$$

Continued ….

PROBLEM 7.125 (Cont.)

Note that $\overline{h}_{m,0-1} = \overline{h}_{m,1}$ from above and that $\overline{h}_{m,0-2}$ is evaluated using the correlation

$$\overline{Sh}_x = \left(0.037\ Re_x^{4/5} - 871\right)\ Sc^{1/3}$$

$$\overline{h}_{m,0-2} = 2.193 \times 10^{-2}\ \text{m/s} \qquad q'_2 = 483\ \text{W/m.}$$ <

Tray 3: The rate equation is of the same form as Eq. (2). Alternatively, an approximation can be used,

$$q'_3 = h_m(\overline{x})\ (x_3 - x_2)\ \rho_{A,sat}\ (1 - \phi_\infty)\ h_{fg}$$

where $h_m(\overline{x})$ is the *local* value at the midspan, $\overline{x} = (x_2 + x_3)/2$. Using

$$Sh_x = 0.0296\ Re_x^{4/5}\ Sc^{1/3}$$

and substituting numerical values, find

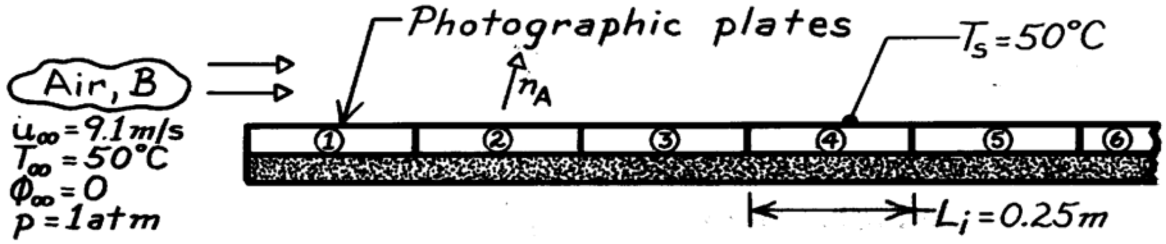
$$h_{m(\overline{x})} = 3.148 \times 10^{-2}\ \text{m/s} \qquad q'_3 = 589\ \text{W/m.}$$ <

PROBLEM 7.126

KNOWN: Air and surface conditions for a drying process in which photographic plates are aligned in the direction of the air flow.

FIND: (a) Variation of local mass transfer convection coefficient, (b) Drying rate for fastest drying plate, (c) Heat addition needed to maintain the plate temperature.

SCHEMATIC:



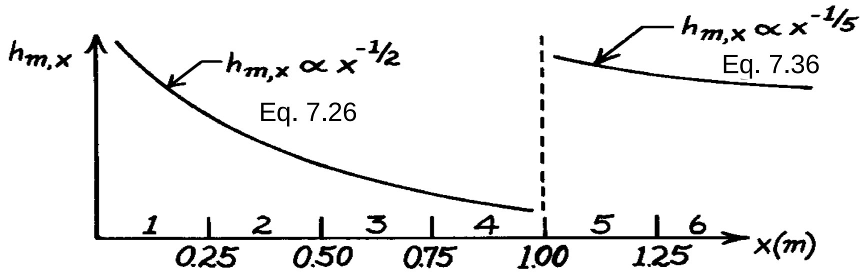
ASSUMPTIONS: (1) Heat and mass transfer analogy is applicable, (2) Critical Reynolds number is $Re_{x.c} = 5 \times 10^5$, (3) Radiation effects are negligible.

PROPERTIES: *Table A-4*, Air (50°C = 323K): $\nu = 18.2 \times 10^{-6}$ m^2/s; *Table A-6*, Water vapor (50°C = 323K): $\rho_{A,sat} = 0.082$ kg/m^3, $h_{fg} = 2383$ kJ/kg; *Table A-8*, Water vapor-air (25°C = 298K) $D_{AB} = 0.26 \times 10^{-4}$ m^2/s; since $D_{AB} \propto T^{3/2}$, D_{AB}(50°C = 323K) = 0.26×10^{-4} $(323/298)^{3/2} = 0.29 \times 10^{-4}$ m^2/s, Sc = $\nu/D_{AB} = 0.62$.

ANALYSIS: (a) With $Re_{x,c} = u_\infty x_c/\nu = 5 \times 10^5$, the point of transition is

$$x_c = \frac{5\times10^5 \left(18.2\times10^{-6}\ \text{m}^2/\text{s}\right)}{9.1\ \text{m/s}} = 1\ \text{m}$$

and the variation of the local mass transfer coefficient is as shown below



<

(b) The largest evaporation will be associated with either the first plate or the fifth plate. For the *first* plate,

$$n_{A,1} = \overline{h}_{m,1} A_{s,1} \left(\rho_{A,s} - \rho_{A,\infty}\right)$$

where $\rho_{A,\infty} = 0$ since the upstream air is dry. Since the boundary layer is laminar over the entire plate, with

$$Re_{x,1} = (9.1\ \text{m/s})\ (0.25\ \text{m})/\left(18.2\times10^{-6}\ \text{m}^2/\text{s}\right) = 1.25\times10^5$$

Continued …

PROBLEM 7.126 (Cont.)

Eq. 7.31 may be used to obtain

$$\bar{h}_{m,1} = \left(\frac{D_{AB}}{x_1}\right) 0.664\ Re_{x,1}^{1/2}\ Sc^{1/3} = \left(\frac{0.29\times10^{-4}\ m^2/s}{0.25\ m}\right) 0.664\ \left(1.25\times10^5\right)^{1/2}\left(0.62\right)^{1/3}$$

$\bar{h}_{m,1} = 0.0232$ m/s.

Hence $\quad n_{A,1} = 0.0232\text{m/s}\left(0.25\ \text{m}\times1\ \text{m}\right)\ \left(0.082\text{kg/m}^3\right) = 4.72\times10^{-4}\ \text{kg/s}\cdot\text{m}.$

For the *fifth* plate,

$$n_{A,5} = n_{A,0-5} - n_{A,0-4} = \left[\left(\bar{h}_m A_s\right)_{0-5} - \left(\bar{h}_m A_s\right)_{0-4}\right]\ \left(\rho_{A,s} - \rho_{A,\infty}\right).$$

With $Re_{x,5} = 6.25 \times 10^5$, Eq. 7.41 gives

$$\bar{h}_{m,0-5} = \left(\frac{D_{AB}}{x_5}\right)\left[0.037\ Re_{x,5}^{4/5} - 871\right]\ Sc^{1/3}$$

$$\bar{h}_{m,0-5} = \left(\frac{0.29\times10^{-4}\ m^2/s}{1.25\ m}\right)\left[0.037\left(6.25\times10^5\right)^{4/5} - 871\right]\ \left(0.62\right)^{1/3}$$

$$\bar{h}_{m,0-5} = 0.0145\ \text{m/s}.$$

With $Re_{x,4} = 5 \times 10^5$, Eq. 7.31 gives

$$\bar{h}_{m,0-4} = \left(\frac{D_{AB}}{x_4}\right) 0.664\ Re_{x,4}^{1/4}\ Sc^{1/3}$$

$$\bar{h}_{m,0-4} = \left(\frac{0.29\times10^{-4}\ m^2/s}{1\ m}\right)\left[0.664\ \left(5\times10^5\right)^{1/2}\ \ \left(0.62\right)^{1/3}\right]$$

$$\bar{h}_{m,0-4} = 0.0116\ \text{m/s}.$$

Hence,

$$n_{A,5} = \left[0.0145\text{m/s}\times1.25\ \text{m}\times1\ \text{m} - 0.0116\text{m/s}\times1\ \text{m}\times1\ \text{m}\right]\ \left(0.082\text{kg/m}^3\right)$$

$$n_{A,5} = 5.35\times10^{-4}\ \text{kg/s}\cdot\text{m}. \qquad <$$

Hence the evaporation rate is largest for Plate 5.

(c) Heat would have to be supplied to each plate at a rate which is equal to the evaporative cooling rate in order to maintain the prescribed temperature. Hence

$$q_5 = n_{A,5} h_{fg} = 5.35\times10^{-4}\text{kg/s}\cdot\text{m}\times2.383\times10^6\ \text{J/kg} = 1.275\ \text{kW/m}. \qquad <$$

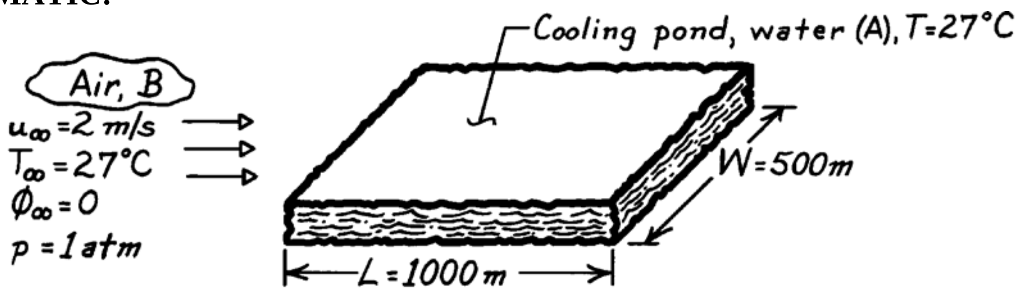
COMMENTS: The large value of q_5 is a consequence of the significant evaporative cooling effect.

PROBLEM 7.127

KNOWN: Dimensions and temperature of a cooling pond. Conditions of air flow.

FIND: Daily make-up water requirement.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Turbulent boundary layer over the entire surface, (3) Heat and mass transfer analogy is applicable.

PROPERTIES: *Table A-4*, Air (T = 300K, 1 atm): $\nu = 15.89 \times 10^{-6}$ m^2/s, k = 0.0263 W/m·K, Pr = 0.707; *Table A-6*, Water vapor (300K): $\rho_{A,sat} = v_g^{-1} = 0.0256$ kg/m^3; *Table A-8,* Water vapor-air (300K): $D_{AB} = 0.26 \times 10^{-4}$ m^2/s, Sc = ν/D_{AB} = 0.61.

ANALYSIS: The make-up water requirement must equal the daily water loss due to evaporation,

$$\Delta M = \dot{m}_{evap}\Delta t = \bar{h}_m (W \cdot L) \left[\rho_{A,sat}(T_s) - \phi_\infty \rho_{A,sat}(T_\infty)\right] \cdot \Delta t.$$

From Eq. 7.41 with A = 0, $\overline{Sh}_L = 0.037\ Re_L^{4/5}\ Sc^{1/3}$, with

$$Re_L = \frac{u_\infty L}{\nu} = \frac{2\text{ m/s} \times 1000\text{ m}}{15.89 \times 10^{-6}\text{ m}^2/\text{s}} = 1.26 \times 10^8$$

$$\overline{Sh}_L = 0.037\left(1.26 \times 10^8\right)^{4/5}(0.61)^{1/3} = 9.48 \times 10^4$$

$$\bar{h}_{m,L} = \frac{D_{AB}\overline{Sh}_L}{L} = \frac{0.26 \times 10^{-4}\text{ m}^2/\text{s} \times 9.48 \times 10^4}{1000\text{ m}}$$

$$\bar{h}_{m,L} = 2.47 \times 10^{-3}\text{ m/s}.$$

Hence, the make-up water requirement is

$$\Delta M = 2.47 \times 10^{-3}\text{ m/s}\ (500\text{ m} \times 1000\text{ m})\ 0.0256\text{ kg/m}^3 (24\text{h} \times 3600\text{ s/h})$$

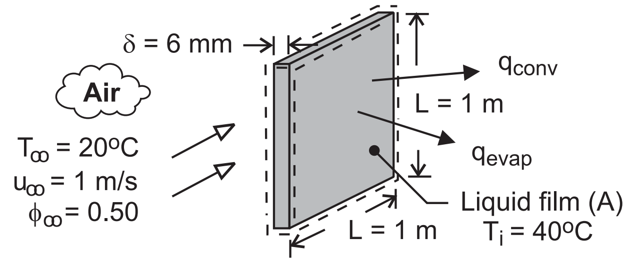
$$\Delta M = 2.73 \times 10^6\text{ kg/day.}$$ <

PROBLEM 7.128

KNOWN: Dimensions and initial temperature of plate covered by liquid film. Properties of liquid. Velocity and temperature of air flow over the plates.

FIND: Initial rate of heat transfer from plate and rate of change of plate temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible effect of conveyor velocity on boundary layer development, (2) Plates are isothermal and at same temperature as liquid film, (3) Negligible heat transfer from sides of plate, (4) Smooth air-liquid interface, (5) Applicability of heat/mass transfer analogy, (6) Negligible solvent vapor in free stream, (7) $Re_{x,c} = 5 \times 10^5$, (8) Constant properties.

PROPERTIES: *Table A-1*, AISI 1010 steel (313K): c = 441 J/kg·K, $\rho = 7832\,kg/m^3$. *Table A-4*, Air (p = 1 atm, T_f = 303K): $\nu = 16.2 \times 10^{-6} m^2/s$, $k = 0.0265\,W/m \cdot K$, $Pr = 0.707$. Prescribed: Solvent: $\rho_{A,sat} = 0.75\,kg/m^3$, $D_{AB} = 10^{-5} m^2/s$, $h_{fg} = 9 \times 10^5\,J/kg$.

SOLUTION: The initial rate of heat transfer from the plate is due to both convection and evaporation.

$$q = q_{conv} + q_{evap} = \bar{h} A_s (T_i - T_\infty) + n_A h_{fg} = \bar{h} A_s (T_i - T_\infty) + \bar{h}_m A_s \rho_{A,sat} h_{fg}$$

With $Re_L = u_\infty L/\nu = 1\,m/s \times 1m / 16.2 \times 10^{-6} m^2/s = 6.17 \times 10^4$, flow is laminar over the entire surface. Hence,

$$\overline{Nu}_L = 0.664 Re_L^{1/2} Pr^{1/3} = 0.664 \left(6.17 \times 10^4\right)^{1/2} (0.707)^{1/3} = 147$$

$$\bar{h} = (k/L)\overline{Nu}_L = (0.0265\,W/m \cdot K/1m)147 = 3.9\,W/m^2 \cdot K$$

Also, with $Sc = \nu / D_{AB} = 16.2 \times 10^{-6} m^2/s / 10^{-5} m^2/s = 1.62$,

$$\overline{Sh}_L = 0.664 Re_L^{1/2} Sc^{1/3} = 0.664 \left(6.17 \times 10^4\right)^{1/2} (1.62)^{1/3} = 194$$

$$\bar{h}_m = (D_{AB}/L)\overline{Sh}_L = \left(10^{-5} m^2/s/1m\right)194 = 0.00194\,m/s$$

Hence, with $A_s = 2\,L^2 = 2\,m^2$,

$$q = 2\,m^2 \left[3.9\,W/m^2 \cdot K(20°C) + 0.00194\,m/s \times 0.75\,kg/m^3 \times 9 \times 10^5\,J/kg\right] = 156\,W + 2619\,W = 2775\,W \quad <$$

Performing an energy balance at an instant of time for a control surface about the plate, $-\dot{E}_{out} = \dot{E}_{st}$, we obtain (Eq. 5.2),

$$\left.\frac{dT}{dt}\right|_i = -\frac{q}{\rho \delta L^2 c} = -\frac{2775\,W}{7832\,kg/m^3 \times 0.006m (1m)^2\, 441 J/kg \cdot K} = -0.13°C/s \quad <$$

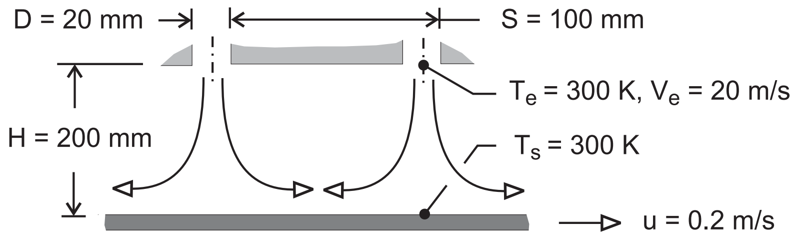
COMMENTS: (1) Heat transfer by evaporation exceeds that due to convection by more than an order of magnitude, (2) The total heat rate is small enough to render the lumped capacitance approximation excellent.

PROBLEM 7.129

KNOWN: Dimensions of round jet array. Jet exit velocity and temperature. Temperature of paper.

FIND: Drying rate per unit surface area.

SCHEMATIC:



ASSUMPTIONS: (1) Applicability of heat and mass transfer analogy. (2) Paper motion has a negligible effect on convection ($u << V_e$), (3) Air is dry.

PROPERTIES: *Table A-4*, Air (300K, 1 atm): $\nu = 15.89 \times 10^{-6}\ m^2/s$; *Table A-6*, Saturated water (300K): $\rho_{A,sat} = v_g^{-1} = 0.0256\ kg/m^3$; *Table A-8*, water vapor-air (300K): $D_{AB} = 0.26 \times 10^{-4} m^2/s$, Sc = 0.61.

ANALYSIS: The average mass evaporation flux is

$$n''_A = \overline{h}_m \left(\rho_{A,s} - \rho_{A,e}\right) = \overline{h}_m\, \rho_{A,s}$$

For an array of round nozzles,

$$\overline{Sh} = 0.5\, K\, G\, Re^{2/3}\, Sc^{0.42}$$

where $Re = V_e D/\nu = 20\ m/s \times 0.02 m/15.89 \times 10^{-6} m^2/s = 25,170$ and, with H/D = 10 and $A_r = \pi D^2/4S^2 = 0.0314$,

$$K = \left[1 + \left(\frac{H/D}{0.6/A_r^{1/2}}\right)^6\right]^{-0.05} = \left[1 + \left(\frac{10}{3.39}\right)^6\right]^{-0.05} = 0.723$$

$$G = 2 A_r^{1/2} \frac{1 - 2.2 A_r^{1/2}}{1 + 0.2(H/D - 6) A_r^{1/2}} = 0.354 \frac{1 - 0.390}{1 + 0.2(4) 0.177} = 0.189$$

Hence,

$$\overline{h}_m = \frac{D_{AB}}{D}\overline{Sh} = \frac{0.26 \times 10^{-4} m^2/s}{0.02m}\left[0.5 \times 0.723 \times 0.189 (25,170)^{2/3} (0.61)^{0.42}\right] = 0.062\ m/s$$

The average evaporative flux is then

$$n''_A = 0.062\ m/s \left(0.0256\ kg/m^3\right) = 0.0016\ kg/s \cdot m^2 \qquad <$$

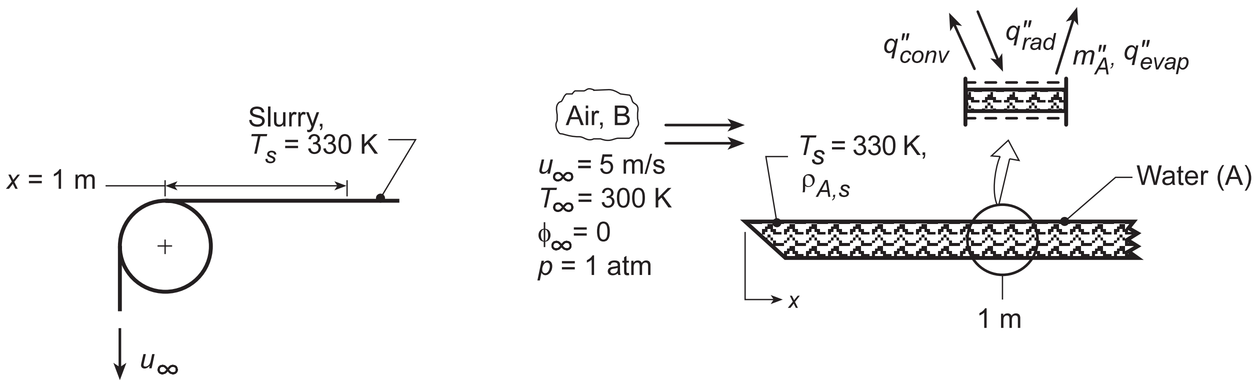
COMMENTS: Note that, for maximum evaporation, the ratio D/H = 0.1 is less than the optimum of $\left.D/H\right)_{op} \approx 0.2$, as is S/H = 0.5 less than $\left.S/H\right)_{op} \approx 1.4$. If H is reduced by a factor of 2 and S is increased by 40%, a near optimal condition could be achieved.

PROBLEM 7.130

KNOWN: Paper mill process using radiant heat for drying.

FIND: (a) Evaporative flux at a distance 1 m from roll edge; corresponding irradiation, G (W/m^2), required to maintain surface at T_s = 300 K, and (b) Compute and plot variations of $h_{m,x}(x)$, N''_A (x), and G(x) for the range $0 \le x \le 1$ m when the velocity and temperature are increased to 10 m/s and 340 K, respectively.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Heat-mass transfer analogy, (3) Paper slurry (water-fiber mixture) has water properties, (4) Water vapor behaves as perfect gas, (5) All irradiation absorbed by slurry, (6) Negligible emission from the slurry, (7) $Re_{x,c} = 5 \times 10^5$.

PROPERTIES: *Table A.4*, Air (T_f = 315 K, 1 atm): $\nu = 17.40 \times 10^{-6}$ m^2/s, k = 0.0274 W/m·K, Pr = 0.705; *Table A.8*, Water vapor-air (T_f = 315 K): $D_{AB} = 0.26 \times 10^{-4}$ m^2/s $(315/298)^{3/2} = 0.28 \times 10^{-4}$ m^2/s, $Sc = \nu_B/D_{AB} = 0.616$; *Table A.6*, Saturated water vapor (T_s = 330 K): $\rho_{A,sat} = 1/v_g = 0.1134$ kg/m^3, h_{fg} = 2366 kJ/kg.

ANALYSIS: (a) Recognize that the drying process can be modeled as flow over a flat plate with heat and mass transfer. For a unit area at x = 1 m,

$$n''_{A,x} = h_{m,x}\left(\rho_{A,s} - \rho_{A,\infty}\right) = h_{m,x}\left[\rho_{A,sat}\left(T_s\right) - \phi_\infty \rho_{A,sat}\left(T_\infty\right)\right] \quad (1)$$

Evaluate Re_x to determine the nature of flow, select a correlation to estimate $h_{m,x}$,

$$Re_x = u_\infty x/\nu_B = (5\,m/s \times 1\,m)\big/(17.40 \times 10^{-6}\,m^2/s) = 2.874 \times 10^5 .$$

Since $Re_x < 5 \times 10^5$, the flow is laminar. Invoking the heat-mass analogy,

$$Sh_x = \frac{h_{m,x} x}{D_{AB}} = 0.332\, Re_x^{1/2}\, Sc^{1/3} \quad (2)$$

$$h_{m,x} = \left(0.28 \times 10^{-4}\,m^2/s/1\,m\right) \times 0.332\left(2.874 \times 10^5\right)^{1/2}(0.616)^{1/3} = 4.24 \times 10^{-3}\,m/s .$$

Hence, the evaporative flux at x = 1 m is

$$n''_{A,x} = 4.24 \times 10^{-3}\,m/s\left(0.1134\,kg/m^3 - 0\right) = 4.81 \times 10^{-4}\,kg/s \cdot m^2 \quad <$$

From an energy balance on the differential element at x = 1 m (see above),

$$G = q''_{conv} + q''_{evap} = h_x\left(T_s - T_\infty\right) + n''_{A,x} h_{fg} . \quad (3)$$

Continued...

PROBLEM 7.130 (Cont.)

To estimate h_x, invoke the heat-mass transfer analogy using the correlation of Eq. (2),

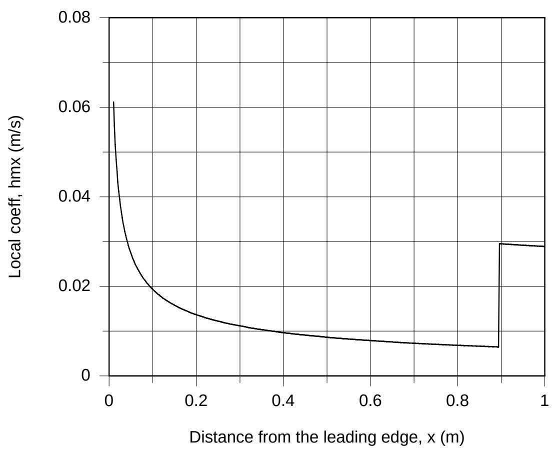
$$h_x = h_{m,x} \frac{k}{D_{AB}} \left(\frac{Pr}{Sc}\right)^{1/3} = 4.24\times10^{-3}\,m/s \left(\frac{0.0274\,W/m\cdot K}{0.28\times10^{-4}\,m^2/s}\right)\left(\frac{0.705}{0.616}\right)^{1/3} = 4.34\,W/m^2\cdot K \qquad (4)$$

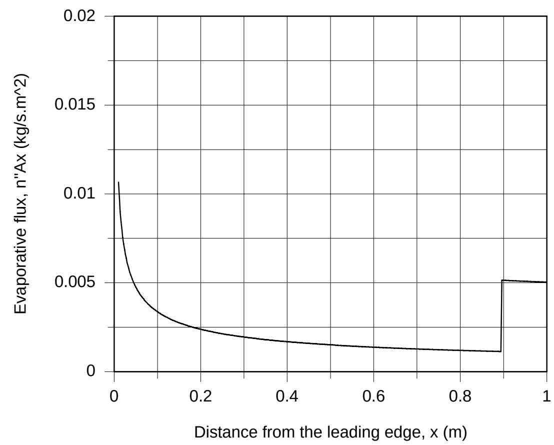
Hence, from Eq. (3), the radiant power required to maintain the slurry at T_s = 330 K is

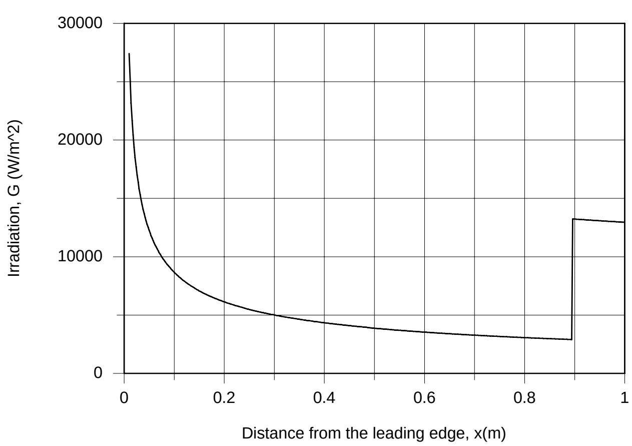
$$G = 4.34\,W/m^2\cdot K(330-300)K + 4.81\times10^{-4}\,kg/s\cdot m^2 \times 2366\times10^3\,J/kg$$

$$G = (130+1138)\,W/m^2 = 1268\,W/m^2 .$$ <

(b) Equations (1), (3) and (4) were entered into the *IHT Workspace*. The *Correlations Tool*, *External Flow*, *Local* coefficients for *Laminar* or *Turbulent Flow* was used to estimate the heat transfer convection coefficient. The results for $h_{m,x}(x)$, $n''_{A,x}(x)$ and G(x) were evaluated, and are plotted below for T_s = 340 K and u_∞ = 10 m/s.







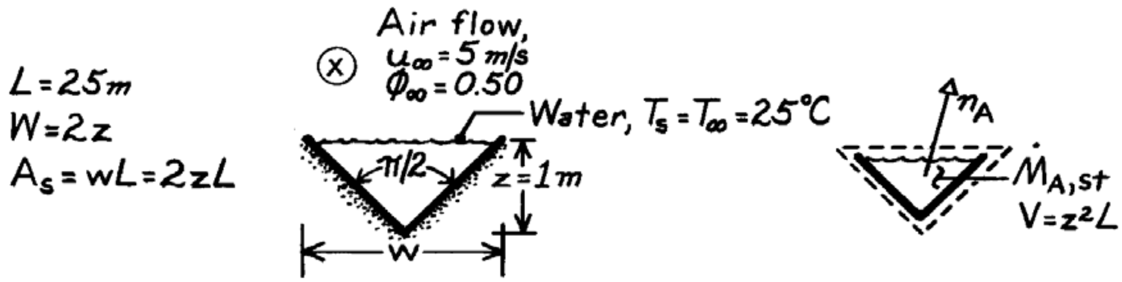
COMMENTS: (1) The abrupt change in the parameter plots occurs at the transition, x_c = 0.9 m.

PROBLEM 7.131

KNOWN: Geometry and air flow conditions for a water storage channel.

FIND: (a) Evaporation rate, (b) Expression for rate of change of water layer depth and time required for complete evaporation.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Smooth water surface and negligible free stream turbulence, (3) Heat and mass transfer analogy is applicable, (4) $Re_{x,c} = 5 \times 10^5$, (5) Perfect gas behavior for water vapor.

PROPERTIES: *Table A-4* Air (25°C = 298K): $\nu = 15.71 \times 10^{-6}$ m^2/s; *Table A-6*, Water (25°C = 298K): $\rho_{A,sat} = v_g^{-1} = 0.0226$ kg/m^3, $\rho_f = v_f^{-1} = 997$ kg/m^3; *Table A-8*, Water vapor-air (25°C = 298K): $D_{AB} = 0.26 \times 10^{-4}$ m^2/s, $Sc = \nu/D_{AB} = 0.60$.

ANALYSIS: (a) The evaporation rate is $n_A = \bar{h}_m A_s \left(\rho_{A,sat} - \rho_{A,\infty}\right) = \bar{h}_m \left(w \times L\right) \rho_{A,sat} \left(1 - \phi_\infty\right)$. With

$$Re_L = u_\infty L/\nu = 5\text{ m/s} \times 25\text{ m}/15.71 \times 10^{-6}\text{ m}^2/\text{s} = 7.96 \times 10^6$$

Eq. 7.42 yields $\overline{Sh}_L = \left[0.037\left(7.96 \times 10^6\right)^{4/5} - 871\right]\left(0.6\right)^{1/3} = 9616$

$$\bar{h}_m = 9616\ D_{AB}/L = 9616 \times 0.26 \times 10^{-4}\text{ m}^2/\text{s}/\left(25\text{ m}\right) = 0.010\text{ m/s.}$$

With w = 2z = 2m,

$$n_A = 0.01\text{ m/s}\ \left(2\text{m} \times 25\text{m}\right) 0.0226\text{ kg/m}^3 \left(0.5\right) = 0.00565\text{ kg/s} = 20.3\text{ kg/h.}$$ <

(b) Performing a mass balance on a control volume about the water,

$$-n_A = \dot{m}_{A,st} = \frac{d}{dt}\left(\rho_f V\right) \qquad -\bar{h}_m \left(2\,z\,L\right)\ \rho_{A,sat} \left(1 - \phi_\infty\right) = \frac{d}{dt}\left(\rho_f\ z^2 L\right)$$

$$\frac{dz}{dt} = -\bar{h}_m \frac{\rho_{A.sat}}{\rho_f}\left(1 - \phi_\infty\right).$$

Integrating, $\int_z^0 dz = -\bar{h}_m \dfrac{\rho_{A,sat}}{\rho_f}\left(1 - \phi_\infty\right) \int_0^t dt$

$$t = \frac{z\,\rho_f}{\bar{h}_m \rho_{A,sat}} \frac{1}{1 - \phi_\infty} = \frac{1\text{ m} \times 997\text{ kg/m}^3}{0.01\text{ m/s} \times 0.0226\text{ kg/m}^3\ \left(1 - 0.5\right)} = 8.82 \times 10^6\text{ s} = 2451\text{ h} = 102\text{ d.}$$ <

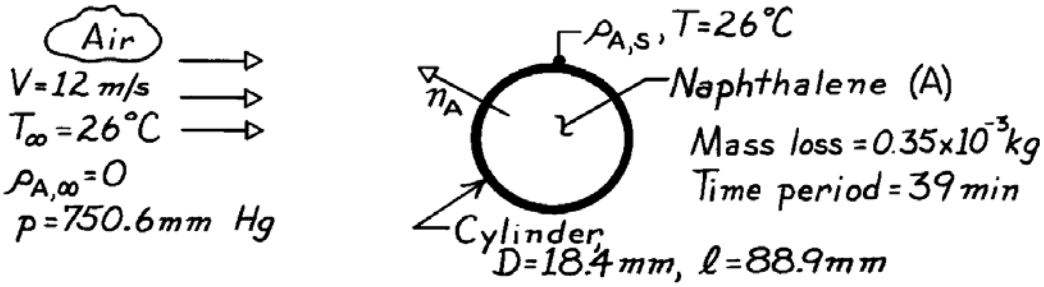
COMMENTS: Although the evaporation rate decreases with increasing time due to decreasing A_s, dz/dt remains constant and the water depth decreases linearly.

PROBLEM 7.132

KNOWN: Mass change for a given time period of a solid naphthalene cylinder subjected to cross flow of air for prescribed conditions.

FIND: (a) Mass transfer coefficient, $\overline{h}_m$, based upon experimental observations and (b) $\overline{h}_m$ based upon appropriate correlation.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible naphthalene vapor in free stream, (3) Heat-mass transfer analogy applies.

PROPERTIES: *Table A-4*, Air (299K, 1 atm): $\nu = 15.80 \times 10^{-6}\ m^2/s$; *Table A-6*, Naphthalene vapor-air (298K, 1 atm): $D_{AB} = 0.62 \times 10^{-5}\ m^2/s$; Naphthalene (given): $\mathcal{M} = 128.16$ kg/kmol, $p_{sat} = p \times 10^E$ where $E = 8.67 - (3766/T)$ with p[bar] and T[K].

ANALYSIS: (a) The rate equation for the sublimation of naphthalene vapor from the solid naphthalene can be written in terms of the mass transfer coefficient.

$$\overline{h}_m = \frac{n_A}{A_s\left(\rho_{A,s} - \rho_{A,\infty}\right)} \tag{1}$$

where $A_s = \pi D\ell$. From the mass loss and time observations

$$n_A = \frac{\Delta m}{\Delta t} = \frac{0.35 \times 10^{-3}\text{kg}}{39 \times 60\ \text{s}} = 1.50 \times 10^{-7}\ \text{kg/s}.$$

The saturation density of the vapor at the solid surface, $\rho_{A,s}$, can be determined from the perfect gas relation,

$$\rho_{A,s} = C_{A,s}M_A = \frac{p_{sat}(T_s)}{(\Re/\mathcal{M}_A)T_s}. \tag{2}$$

The saturation pressure, p_{sat}, is given by

$$p_{sat} = p \times 10^E \tag{3}$$

where $E = 8.67 - (3766/T) = 8.67 - (3766/299\text{K}) = -3.925$

$$p = 750.6\ \text{mm Hg} \times \frac{1\ \text{N/m}^2}{2.953 \times 10^{-4}\text{in Hg}} \times \frac{1\ \text{in}}{25.4\ \text{mm}} \times \frac{1\ \text{bar}}{1 \times 10^5\ \text{N/m}^2} = 1.001\ \text{bar}$$

or $\quad p_{sat} = 1.001\ \text{bar} \times 10^{-3.925} = 1.190 \times 10^{-4}\text{bar}.$

Continued …

PROBLEM 7.132 (Cont.)

Substituting into Eq. (2),

$$\rho_{A,s} = 1.190\times10^{-4}\text{bar}/\frac{8.314\times10^{-2}\ \text{m}^3\cdot\text{bar/kmol}\cdot\text{K}}{128.16\ \text{kg/kmol}}\times 299\text{K} = 6.135\times10^{-4}\text{kg/m}^3.$$

Using the parameters required for Eq. (1), the mass transfer coefficient is

$$\overline{h}_m = \frac{1.50\times10^{-7}\,\text{kg/s}}{\pi\left(18.4\times10^{-3}\text{m}\right)\ \left(88.9\times10^{-3}\text{m}\right)}\left[6.135\times10^{-4} - 0\right]\ \text{kg/m}^3$$

$$\overline{h}_m = 4.76\times10^{-2}\,\text{m/s}.$$ <

(b) Invoking the heat-mass transfer analogy and assuming a Prandtl number ratio of unity, Eq. 7.53 can be used to estimate $\overline{h}_m$,

$$\overline{Sh}_D = \frac{\overline{h}_m D}{D_{AB}} = C\ Re_D^m\ Sc^n.$$

With

$$Re_D = \frac{VD}{\nu} = 12\ \text{m/s}\left(18.4\times10^{-3}\right)\text{m}/15.80\times10^{-6}\text{m}^2/\text{s} = 13{,}975$$

it follows from Table 7.4 that C = 0.26 and m = 0.6. With

$$Sc = \nu/D_{AB} = 15.80\times10^{-6}\text{m}^2/\text{s}/0.62\times10^{-5}\text{m}^2/\text{s} = 2.55$$

n = 0.37 and

$$\overline{Sh}_D = 0.26(13{,}975)^{0.6}(2.55)^{0.37} = 112.9$$

and

$$\overline{h}_m = \overline{Sh}_D\ \frac{D_{AB}}{D} = 112.9\times\frac{0.62\times10^{-5}\ \text{m}^2/\text{s}}{18.4\times10^{-3}\ \text{m}} = 3.80\times10^{-2}\ \text{m/s}.$$ <

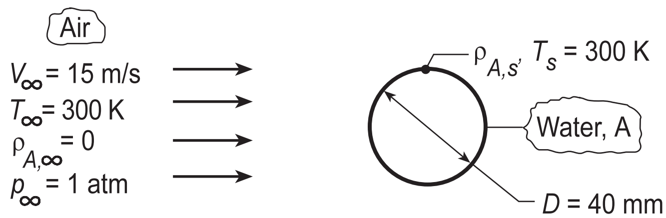
COMMENTS: The result from the correlation is 20% less than the experimental result. This may be considered reasonable in view of the uncertainties associated with the observations and the approximate nature of the correlation.

PROBLEM 7.133

KNOWN: Flow of dry air over a cylindrical medium saturated with water.

FIND: (a) Mass rate of water vapor evaporated per unit length n'_A, when water-air is at 300 K, (b) Briefly explain change in mass rate if temperatures are at 325 K.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Heat-mass transfer analogy.

PROPERTIES: *Table A.4*, Air (300 K, 1 atm): $\nu = 15.89 \times 10^{-6}$ m^2/s, Pr = 0.707; Air (325 K, 1 atm): $\nu = 18.41 \times 10^{-6}$ m^2/s, Pr = 0.703; *Table A.8*, Water vapor-air (300 K): $D_{AB} = 0.26 \times 10^{-4}$ m^2/s; *Table A.6*, Water vapor (300 K, 1 atm): $\rho_{A,sat} = (v_g)^{-1} = (39.13\ m^3/kg)^{-1} = 0.0256\ kg/m^3$; Water vapor (325 K, 1 atm): $\rho_{A,sat} = (v_g)^{-1} = (11.06\ m^3/kg)^{-1} = 0.0904\ kg/m^3$.

ANALYSIS: (a) For cross-flow over a cylinder, Eq. 7.52,

$$\overline{Sh}_D = C\,Re^m\,Sc^{1/3} \tag{1}$$

where m,n are taken from Table 7.2. Calculate the Reynolds number, $Re_D = VD/\nu$ = 15 m/s × 0.04 m/15.89 × 10^{-6} m^2/s = 37,760. With C = 0.193, m = 0.618, and $Sc \equiv \nu/D_{AB}$,

$$\overline{Sh}_D = \frac{\overline{h}_m D}{D_{AB}} = 0.193(37,760)^{0.618}\left[15.89\times10^{-6}\ m^2/s \big/ 0.26\times10^{-4}\ m^2/s\right]^{1/3} = 110.4 \tag{2}$$

$$\overline{h}_m = \overline{Sh}_D\,D_{AB}/D = 110.4\times0.26\times10^{-4}\ m^2/s/0.04\ m = 0.0717\ m/s$$

The evaporation rate, with $A_s = \pi D\cdot\ell$, is

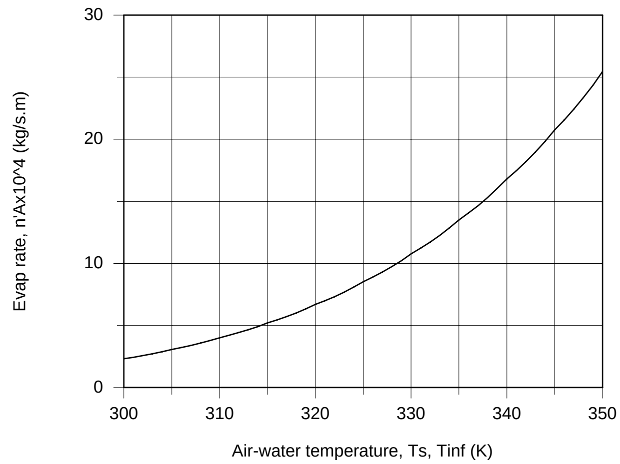
$$n_A = \overline{h}_m A_s\left(\rho_{A,s}-\rho_{A,\infty}\right) \qquad n'_A = n_A/\ell = \overline{h}_m \pi D\left(\rho_{A,s}-\rho_{A,\infty}\right) \tag{3}$$

$$n'_A = 0.0717\ m/s(\pi\times0.04\ m)(0.0256-0)\ kg/m^3 = 2.31\times10^{-4}\ kg/s\cdot m \qquad <$$

(b) The foregoing equations were entered into the *IHT Workspace*, and using the *Properties Tools* for air and water vapor thermophysical properties, the evaporation rate n'_A was calculated as a function of air-water temperatures ($T_s = T_{inf}$).

Continued...

PROBLEM 7.133 (Cont.)



As expected, the evaporation rate increased with increasing temperature markedly. For a 50 K increase, the evaporation rate increased by a factor of approximately 12.

COMMENTS: (1) What parameters cause this high sensitivity of n'_A to T_s? From the IHT analysis, we observed only modest changes in D_{AB} (0.26 to 0.33×10^{-4} m^2/s) and $\overline{h}_m$ (0.07273 to 0.0779 m/s) over the range 300 to 350 K. The density of water vapor, $\rho_{A,s}$, however, is highly temperature dependent as can be seen by examining the steam tables, Table A.6. Find $\rho_{A,s}$ (300 K) = 0.02556 kg/m^3 while $\rho_{A,s}$ (350 K) = 0.260 kg/m^3, which accounts for more than a factor of 10 change.

(2) A copy of the IHT Workspace used to perform the analysis is shown below.

```
// The Mass Transfer Rate Equation:
n'A = hmbar * pi * D * (rhoAs - 0 )       // Eq (3)
n'A_plot = 1e4 * n'A                      // Scale change for plotting

// Mass Transfer Coefficient Correlation:
ShDbar = C * ReD^m * Sc^(1/3)             // Eq (1,2)
ShDbar = hmbar * D / DAB
C = 0.193                       // Table 7.2,  4000 <= ReD <= 40000
m = 0.618
ReD = uinf * D / nu
Sc = nu / DAB

// Properties Tool - Water Vapor:
// Water property functions :T dependence, From Table A.6
// Units: T(K), p(bars);
xs = 1                          // Quality (0=sat liquid or 1=sat vapor)
rhoAs = rho_Tx("Water",Ts,xs)             // Density, kg/m^3

// Properties Tool - Air:

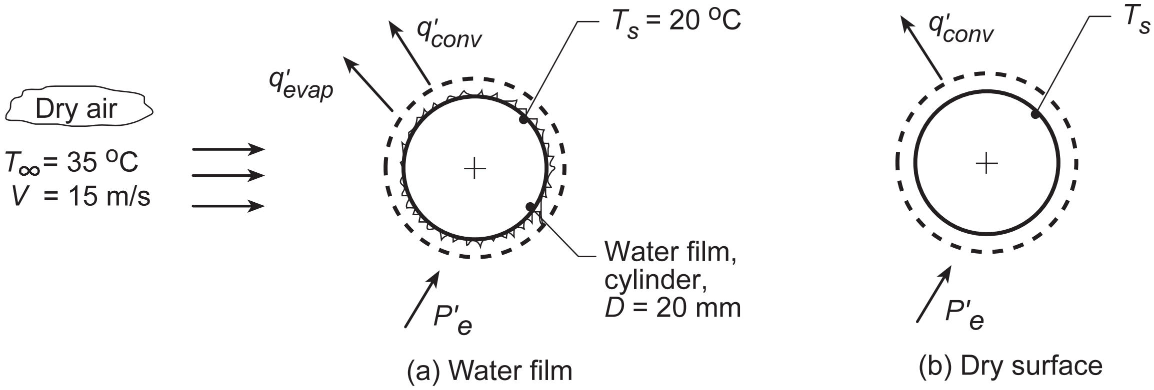
uinf = 15                       // Airstream velocity, m/s
Tinf = Ts                       // Airstream temperature, K
```

PROBLEM 7.134

KNOWN: Dry air at prescribed temperature and velocity flowing over a long, wetted cylinder of diameter 20 mm. Embedded electrical heater maintains the surface at $T_s = 20°C$.

FIND: (a) Water evaporation rate per unit length (kg/h·m) and electrical power per unit length P'_e (W/m) required to maintain steady-state conditions, and (b) The temperature of the cylinder after all the water has evaporated for the same airstream conditions and heater power of part (a).

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties and (3) Heat-mass transfer analogy is applicable.

PROPERTIES: *Table A.4*, Air ($T_f = (T_s + T_\infty)/2$ = 300 K, 1 atm): ρ = 1.16 kg/m^3, c_p = 1007 J/kg·K, k = 0.0263 W/m·K, $\nu = 15.94 \times 10^{-6}$ m^2/s, $\alpha = 2.257 \times 10^{-5}$ m^2/s, Pr = 0.707. *Table A.6*, Water (T_s = 20°C = 293 K): $\rho_{A,s} = 1/v_g$ = 1/59.04 = 0.0169 kg/m^3, h_{fg} = 2454 kJ/K; *Table A.8*, Water-air (T_f = 300 K): $D_{AB} = 0.26 \times 10^{-4}$ m^2/s.

ANALYSIS: (a) Perform an energy balance on the cylinder,

$$\dot{E}_{in} - \dot{E}_{out} = 0 \qquad P'_e - q'_{conv} - q'_{evap} = 0 \qquad (1)$$

where the convection and evaporation rate equations are,

$$q'_{conv} = \overline{h}_D \pi D (T_s - T_\infty) \qquad (2)$$

$$q_{evap} = n_A h_{fg} = \overline{h}_m \pi D \left(\rho_{A,s} - \rho_{A,\infty}\right) h_{fg} \qquad (3)$$

The convection coefficient can be estimated from the Churchill-Bernstein correlation, Eq. 7.54,

$$\overline{Nu}_D = 0.3 + \frac{0.62\, Re_D^{1/2}\, Pr^{1/3}}{\left[1 + (0.4/Pr)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{Re_D}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$Re_D = \frac{VD}{\nu} = \frac{15\,m/s \times 0.020\,m}{15.94 \times 10^{-6}\,m^2/s} = 18{,}821$$

$$\overline{Nu}_D = 0.3 + \frac{0.62 (18{,}821)^{1/2} (0.707)^{1/3}}{\left[1 + (0.4/0.707)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{18{,}821}{282{,}000}\right)^{5/8}\right]^{4/5} = 76.5$$

$$\overline{h}_D = \frac{k}{D} \overline{Nu}_D = \frac{0.0263\,W/m \cdot K}{0.020\,m} \times 76.5 = 101\,W/m^2 \cdot K$$

Continued...

PROBLEM 7.134 (Cont.)

Invoking the heat-mass analogy, Chapter 6, with n = 1/3

$$\frac{\overline{h}_D}{\overline{h}_m} = \rho c_p \left(\frac{\alpha}{D_{AB}}\right)^{2/3} = 1.16\,\text{kg}/\text{m}^3 \times 1007\,\text{J}/\text{kg}\cdot\text{K}\left(\frac{2.257\times10^{-5}\,\text{m}^2/\text{s}}{0.26\times10^{-4}\,\text{m}^2/\text{s}}\right)^{2/3} = 1063\,\text{J}/\text{m}^3\cdot\text{K}$$

$$\overline{h}_m = 101\,\text{W}/\text{m}^2\cdot\text{K}/1063\,\text{J}/\text{m}^3\cdot\text{K} = 0.095\,\text{m/s}$$

Substituting numerical values, the energy balance, Eq. (1),

$$P_e - 101\,\text{W}/\text{m}^2\cdot\text{K}\times\pi\times0.020\,\text{m}(20-35)\,\text{K}$$
$$-0.095\,\text{m/s}\times\pi\times0.020\,\text{m}(0.0169-0)\,\text{kg}/\text{m}^3\times2454\times10^3\,\text{J/kg}\cdot\text{K} = 0$$

$$P_e = -95.1\,\text{W/m} + 247\,\text{W/m} = 152\,\text{W/m}$$ <

The evaporation rate is

$$n_A = \overline{h}_m \pi D\left(\rho_{A,s} - \rho_{A,\infty}\right) = 0.095\,\text{m/s}\,\pi\times0.020\,\text{m}(0.0169-0)\,\text{kg}/\text{m}^3 = 0.362\,\text{kg/h}\cdot\text{m}$$ <

(b) When the cylinder is dry, the energy balance is

$$P'_e = \overline{h}_D \pi D\left(T_s - T_\infty\right)$$

$$T_s = T_\infty + P'_e/\overline{h}_D \pi D = 35^\circ\text{C} + 152\,\text{W/m}\Big/\left(101\,\text{W}/\text{m}^2\cdot\text{K}\,\pi\times0.020\,\text{m}\right) = 58.9^\circ\text{C}$$ <

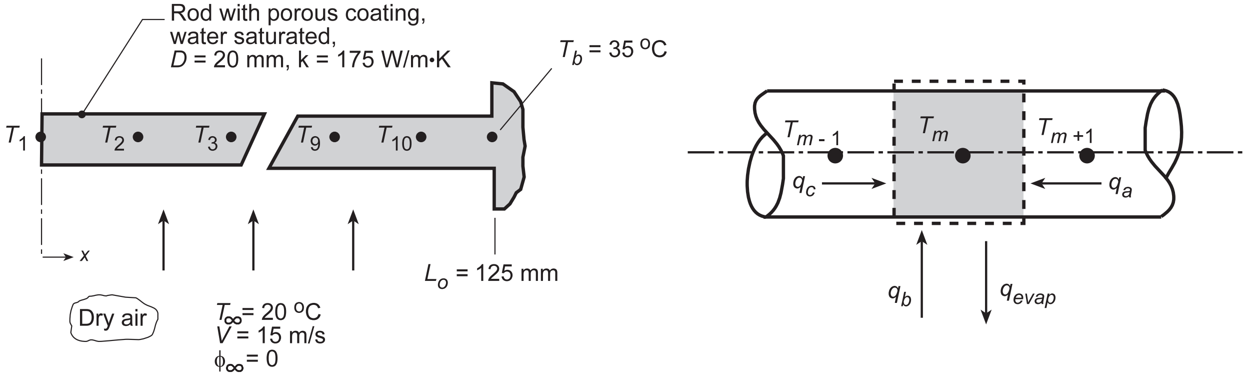
COMMENTS: Using *IHT Correlations Tool*, *External Flow*, *Cylinder*, the calculation of part (b) was performed using the proper film temperature, T_f = 316.8 K, to find $\overline{h}_D$ = 99.4 W/m^2·K and T_s = 52.6°C.

PROBLEM 7.135

KNOWN: Dry air at prescribed temperature and velocity flows over a rod covered with a thin porous coating saturated with water. The ends of the rod are attached to heat sinks maintained at a constant temperature.

FIND: Temperature at the midspan of the rod and evaporation rate from the surface using a steady-state, finite-difference analysis. Validate your code, without the evaporation process, by comparing the temperature distribution with the analytical solution of a fin.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in rod, (3) Constant properties, and (4) Heat-mass transfer analogy is applicable.

PROPERTIES: *Table A.4*, Air ($\overline{T}_f$, see Eq. (2); 1 atm): ρ, c_p, k, α, Pr; *Table A.6*, Water ($T_m = T_{sat,m}$, 1 atm): $\rho_{A,sat} = 1/v_g$, h_{fg}; *Table A.8*, Water Vapor-Air ($\overline{T}_f$, 1 atm): $D_{AB} = D_{AB}(298\text{ K}) \times (\overline{T}_f/298)^{1.5}$.

ANALYSIS: As suggested, the 10-node network shown above represents the half-length of the system. Performing an energy balance on the control volume about the m-th node, the finite-difference equation for the system is derived.

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$q_a - q_{evap} + q_b + q_c = 0$$

$$kA_c \frac{T_{m+1} - T_m}{\Delta x} - n_{A,m} h_{fg,m} + \overline{h} P \Delta x \left(T_\infty - T_m\right) + kA_c \frac{T_{m-1} - T_m}{\Delta x} = 0 \quad (1)$$

where the cross-sectional area and perimeter are $A_c = \pi D^2/4$ and $P = \pi D$, respectively. The average heat transfer coefficient $\overline{h}$ can be evaluated using the Churchill-Bernstein correlation, Eq. 7.54, evaluating thermophysical properties at an average film temperature for the system,

$$\overline{T}_f = \left[\left(T_1 + T_b\right)/2 + T_\infty\right]/2 \quad (2)$$

The evaporation rate from Eq. (1) can be expressed as

$$n_{A,m} = \overline{h}_{D,m} P \Delta x \left(\rho_{A,s,m} - 0\right) \quad (3)$$

where $\overline{h}_{D,m}$ can be determined from the heat-mass analogy, Eq. 6.60, with n = 1/3,

$$\frac{\overline{h}}{\overline{h}_m} = \rho c_p \left(\frac{\alpha}{D_{AB}}\right)^{-2/3} \quad (4)$$

Continued...

PROBLEM 7.135 (Cont.)

where all properties are evaluated at $\overline{T}_f$. The density of water vapor, $\rho_{A,s,m}$, as well as the heat of vaporization, $h_{fg,m}$, must be evaluated at the nodal temperature T_m.

Using the *IHT Correlation Tool*, *External Flow*, *Cylinder*, an estimate of $\overline{h}_D$ = 101 W/m^2·K was obtained with $\overline{T}_f$ = 298.5 K (based upon assumed value of T_1 = 27°C). From the analogy, Eq. (4), find that $\overline{h}_{D,m}$ = 0.0772 m/s. Using the *IHT Workspace*, the finite-difference equations, Eq. (1), were entered and the temperature distribution (K, Case 1) determined as tabulated below. Using this same code with $\overline{h}_{D,m} = 1.0 \times 10^{-10}$ m/s, the temperature distribution (K, Case 2) was obtained. The results compared identically with the analytical solution for a fin with an adiabatic tip using the *IHT Model*, *Extended Surface*, *Rectangular Pin Fin*.

Case	T_1	T_2	T_3	T_4	T_5	T_6	T_7	T_8	T_9	T_{10}	T_b
1	287	287.2	287.6	288.3	289.4	290.9	292.9	295.4	298.6	302.7	308
2	300.3	300.4	300.6	300.9	301.4	302.1	302.8	303.8	305	306.4	308

<

The evaporation rate obtained by summing rates from each nodal element including node b is

$$n_{A,tot} = 1.08 \times 10^{-5}\ \text{kg/s}$$ <

COMMENTS: A copy of the *IHT Workspace* used to perform the above analysis is shown below.

```

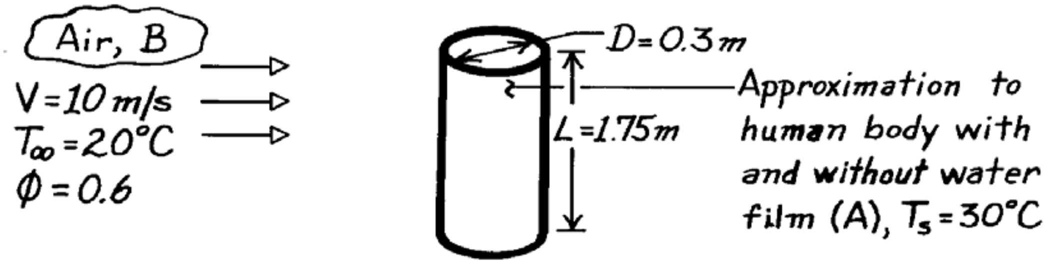
PROBLEM 7.136

KNOWN: The dimensions of a cylinder which approximates the human body.

FIND: (a) Heat loss by forced convection to ambient air, (b) Total heat loss when a water film covers the surface.

SCHEMATIC:



ASSUMPTIONS: (1) Direct contact between skin and air (no clothing), (2) Negligible radiation effects, (3) Heat and mass transfer analogy is applicable, (4) Water vapor is an ideal gas.

PROPERTIES: *Table A-6*, Water (30°C = 303 K): $\rho_{A,sat} = v_g^{-1} = 0.0336\ kg/m^3$, $h_{fg} = 2431$ kJ/kg; Water (20°C = 293K): $\rho_{A,sat} = 0.017\ kg/m^3$; *Table A-4*, Air: ($T_\infty$ = 20°C = 293K): $\nu = 15.27 \times 10^{-6}\ m^2/s$, $k = 25.7 \times 10^{-3}$ W/m·K, Pr = 0.71; *Table A-8*, Water vapor-air (300K): $D_{AB} = 26 \times 10^{-6}\ m^2/s$, $Sc = \nu/D_{AB} = 0.59$.

ANALYSIS: (a) The heat rate is

$$q = \bar{h}(\pi DL)\ (T_s - T_\infty).$$

With

$$Re_D = \frac{VD}{\nu} = \frac{(10\ m/s)\ (0.3\ m)}{15.27\times10^{-6}\ m^2/s} = 1.96\times10^5$$

obtain $\bar{h}$ from Eq. 7.53, where n = 0.37 and, from Table 7.4, C = 0.26 and m = 0.6,

$$\overline{Nu}_D = 0.6\left(1.96\times10^5\right)^{0.6}\ (0.71)^{0.37}\ (0.71/0.71)^{0.25} = 343.$$

Hence $\bar{h} = \overline{Nu}_D\ \dfrac{k}{D} = 343\times\dfrac{25.7\times10^{-3}\ W/m\cdot K}{0.3\ m} = 29.4\ W/m^2\cdot K$

and $q = 29.4\ W/m^2\cdot K\ (\pi\times0.3\ m\times1.75\ m)\ (30-20)^\circ C = 485\ W.$ <

(b) The total heat loss with the water film includes latent, as well as sensible, contributions and may be expressed as

$$q = \bar{h}(\pi DL)\ (T_s - T_\infty) + \dot{n}_A\ h_{fg}$$

where $\dot{n}_A = \bar{h}_m\ (\pi DL)\ \left[\rho_{A,sat}(T_s) - \rho_{A,\infty}\right]$

$$\rho_{A,sat}(T_s) = 0.0336\ kg/m^3 \qquad \rho_{A,\infty} \approx \phi\rho_{A,sat}(T_\infty) = 0.6(0.017) = 0.010\ kg/m^3.$$

Continued …

PROBLEM 7.136 (Cont.)

The convection mass transfer coefficient may be obtained by expressing the mass transfer analog of Eq. 7.53. Neglecting the Pr ratio, the analogous form is

$$\overline{Sh}_D = 0.26\ Re_D^{0.6}\ Sc^{0.37}$$
$$\overline{Sh}_D = 0.26\ \left(1.96\times10^5\right)^{0.6}\left(0.59\right)^{0.37} = 320.$$

Hence

$$\overline{h}_m = 320\frac{D_{AB}}{D} = \frac{320\times0.26\times10^{-4}\ m^2/s}{0.3\ m} = 0.028\ m/s.$$

The evaporation rate is then

$$\dot{n}_A = 0.028 m/s\ \left(\pi\times0.3\ m\times1.75\ m\right)\ \left[0.0336-0.010\right]\ kg/m^3$$
$$\dot{n}_A = 1.09\times10^{-3}\ kg/s.$$

Hence,

$$q = 485\ W + 1.09\times10^{-3} kg/s\times2.431\times10^6\ J/kg$$

$$q = 485\ W + 2650\ W = 3135\ W.$$ <

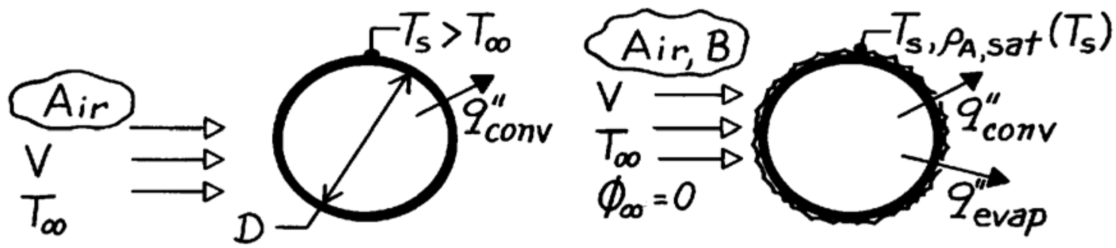
COMMENTS: The evaporative (latent) heat loss dominates over the sensible heat loss. Its effect is often felt when stepping out of a swimming pool or other body of water.

PROBLEM 7.137

KNOWN: Horizontal tube exposed to transverse stream of dry air.

FIND: Equation to determine heat transfer enhancement due to wetting. Evaluate enhancement for prescribed conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Heat-mass transfer analogy applicable, (3) Water vapor behaves as perfect gas.

PROPERTIES: *Table A-4*, Air (310K, 1 atm): $\rho = 1.1281$ kg/m^3, $c_p = 1007.4$ J/kg, $\nu = 16.90 \times 10^{-6}$ m^2/s, Pr = 0.706; *Table A-8*, Air-water vapor mixture (310K): $D_{AB} \approx 0.26 \times 10^{-4}$ m^2/s, Sc = $\nu_B/D_{AB} = 0.650$; *Table A-6*, Saturated water vapor (320K): $\rho_{A,sat} = 1/v_g = 0.07153$ kg/m^3, h_{fg} = 2390 kJ/kg.

ANALYSIS: The enhancement due to wetting can be expressed as the ratio of the wet-to-dry cylinder heat fluxes.

$$\frac{q''_w}{q''_d} = \frac{q''_{conv} + q''_{evap}}{q''_{conv}} = 1 + \frac{q''_{evap}}{q''_{conv}}$$

where

$$q''_{conv} = \bar{h}\left(T_s - T_\infty\right) \qquad q''_{evap} = \dot{m}''_A h_{fg} = \bar{h}_m\left(\rho_{A,s} - \rho_{A,\infty}\right)h_{fg} = \bar{h}_m\,\rho_{A,sat}\,h_{fg}.$$

Invoking the heat-mass transfer analogy, using Eq. 6.60, find

$$\frac{\bar{h}}{\bar{h}_m} = \left(\rho\, c_p\right)_B Le^{1-n} = \left(\rho\, c_p\right)_B \left(Sc/Pr\right)^{2/3}$$

assuming n = 1/3 with $\rho_{A,\infty} = 0$, find

$$\frac{q''_w}{q''_d} = 1 + \left[\left(\rho\, c_p\right)_B \left(Sc/Pr\right)^{2/3}\right]^{-1} \frac{\rho_{A,sat}\, h_{fg}}{\left(T_s - T_\infty\right)}. \qquad <$$

Substituting numerical values, the enhancement is

$$\frac{q''_w}{q''_d} = 1 + \left[\left(1.1281\frac{kg}{m^3} \times 1007.4\frac{J}{kg}\right)\left(\frac{0.650}{0.706}\right)^{2/3}\right]^{-1} \frac{0.07153\ kg/m^3 \times 2390 \times 10^3\ J/kg}{\left(320 - 300\right)K} = 9.0. \qquad <$$

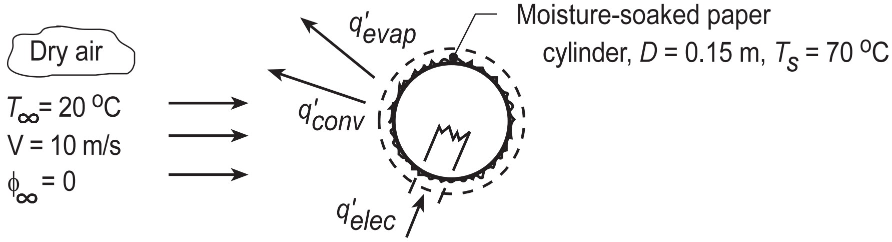
COMMENTS: For the prescribed conditions, the effect of wetting is to enhance the heat transfer by nearly an order of magnitude. Will the enhancement increase or decrease with increasing T_s?

PROBLEM 7.138

KNOWN: Moisture-soaked paper is cylindrical form maintained at given temperature by imbedded heaters. Dry air at prescribed velocity and temperature in cross flow over cylinder.

FIND: (a) Required electrical power and the evaporation rate per unit length, q'_{evap} and n'_A, respectively, and (b) Calculate and plot q' and n'_A as a function of dry air velocity $5 \le V \le 20$ m/s and paper temperatures of 65, 70 and 75°C.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Heat-mass transfer analogy applicable, (3) Negligible radiation effects.

PROPERTIES: *Table A.4*, Air (T_∞ = 20°C = 293 K, 1 atm): ρ = 1.1941 kg/m^3, c_p = 1007 J/kg·K, k = 25.7 × 10^{-3} W/m·K, ν = 15.26 × 10^{-6} m^2/s, Pr = 0.709; (T_s = 70°C = 343 K): Pr_s = 0.701; *Table A.6*, Sat. water vapor (T_s = 70°C = 343 K): $\rho_{A,s} = 1/v_g$ = 0.196 kg/m^3, h_{fg} = 2334 × 10^3 J/kg; *Table A.8*, Air-water vapor mixture ($\bar{T}_f = (T_\infty + T_s)/2$ = 318 K, 1 atm): D_{AB} = 0.26 × 10^{-4} m^2/s(318/298)$^{3/2}$ = 0.29 × 10^{-4} m^2/s.

ANALYSIS: (a) From an energy balance on the cylinder on a per unit length basis,

$$q'_{elec} = q'_{conv} + q'_{evap} \qquad q'_{elec} = \pi D\left[\bar{h}\left(T_s - T_\infty\right) + \bar{h}_m\left(\rho_{A,s} - \rho_{A,\infty}\right)h_{fg}\right] \quad (1)$$

where $\rho_{A,\infty}$ = 0, the freestream air is dry, and $\rho_{A,s} = \rho_{A,sat}(T_s)$. To estimate $\bar{h}$, find

$$Re_D = \frac{VD}{\nu} = \frac{10\,\text{m/s} \times 0.15\,\text{m}}{15.26 \times 10^{-6}\,\text{m}^2/\text{s}} = 98,296 \quad (2)$$

and using the Zhukauskus correlation, from Table 7.4: C = 0.26, m = 0.6, and n = 0.37,

$$\overline{Nu}_D = \frac{\bar{h}D}{k} = 0.26\,Re^{0.6}\,Pr^{0.37}\left(Pr/Pr_s\right)^{0.25} \quad (3)$$

$$\bar{h} = \frac{0.0257\,\text{W/m}\cdot\text{K}}{0.15\,\text{m}} \times 0.26(98,296)^{0.6}(0.709)^{0.37}(0.709/0.701)^{0.25} = 38.9\,\text{W/m}^2\cdot\text{K}.$$

Using the heat-mass analogy with n = 1/3, find

$$\bar{h}/\bar{h}_m = \left(\rho c_p\right)_B (Sc/Pr)^{2/3} = \left(\rho c_p\right)_B \left(\nu/D_{AB}/Pr\right)^{2/3} \quad (4)$$

$$\bar{h}_m = 38.9\,\text{W/m}^2\cdot\text{K}\Big/\left(1.1941\,\text{kg/m}^3 \times 1007\,\text{J/kg}\cdot\text{K}\right)\left[\frac{15.26\times10^{-6}\,\text{m}^2/\text{s}/0.29\times10^{-4}\,\text{m}^2/\text{s}}{0.709}\right]^{2/3}$$

$$\bar{h}_m = 0.03946\,\text{m/s}.$$

Hence, the electric power requirement is

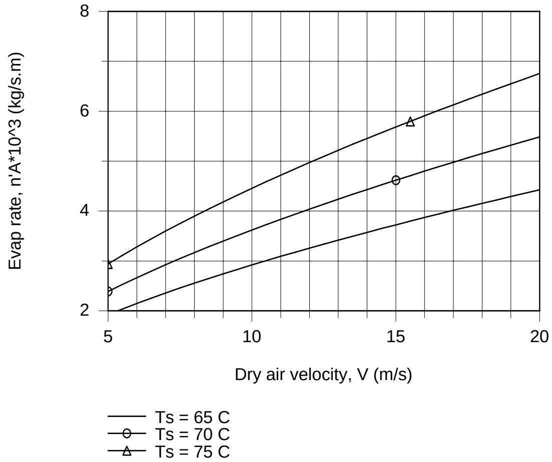
$$q'_{elec} = \pi \times 0.15\,\text{m}\left[38.9\,\text{W/m}^2\cdot\text{K}\left(70-20\right)\text{K} + 0.03946\,\text{m/s}\left(0.196-0\right)\text{kg/m}^3 \times 2334\times10^3\,\text{J/kg}\right]$$

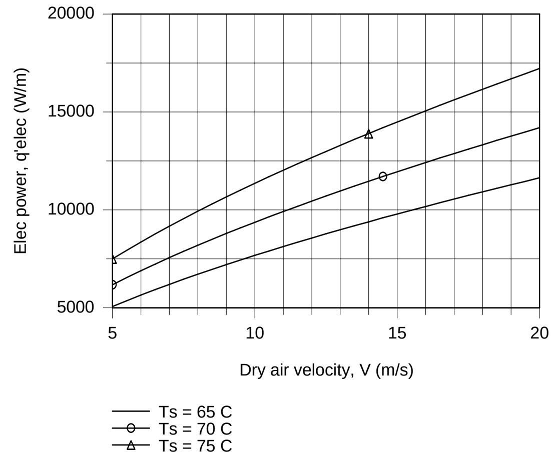
Continued...

PROBLEM 7.138 (Cont.)

$$q'_{elec} = (917 + 8507)\,\text{W/m} = 9424\,\text{W/m} \qquad (5)$$

(b) The foregoing equations were entered into the IHT Workspace, and using the *Properties Tools*, for air and water vapor required thermophysical properties, the required electrical power, q', and evaporation rate, n'_A, were calculated as a function of dry air velocity for selected water temperatures.





COMMENTS: (1) Note at which temperatures the thermophysical properties are evaluated.

(2) From Equation (5), note that the evaporation heat rate far exceeds that due to convection.

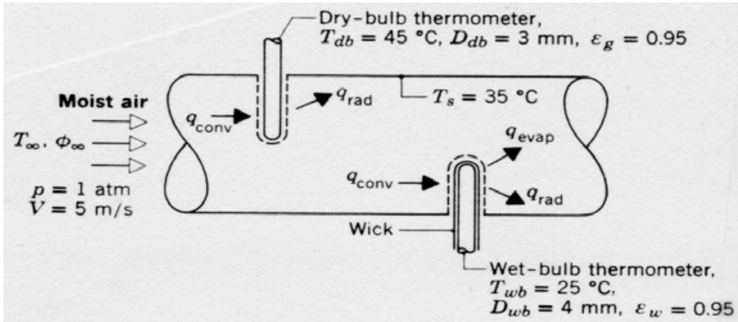
(3) From the plots, note that both q'_{elec} and n'_A are nearly proportional to air velocity, and increase with increasing water temperature.

PROBLEM 7.139

KNOWN: Dry-and wet-bulb temperatures associated with a moist airflow through a large diameter duct of prescribed surface temperature.

FIND: Temperature and relative humidity of airflow.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Conduction along the thermometers is negligible, (3) Duct wall forms a large enclosure about the thermometers.

PROPERTIES: *Table A-4*, Air (318K, 1 atm): $\nu = 17.7 \times 10^{-6}$ m^2/s, k = 0.0276 W/m·K, Pr = 0.70; *Table A-4*, Air (298K, 1 atm): $\nu = 15.7 \times 10^{-6}$ m^2/s, k = 0.0261 W/m·K, Pr = 0.71; *Table A-6*, Saturated water vapor (298K): v_g = 44.3 m^3/kg, h_{fg} = 2442 kJ/kg; Saturated water vapor (318.5K): v_g = 15.5 m^3/kg; *Table A-8*, Water vapor-air (298K): $D_{AB} = 0.26 \times 10^{-4}$ m^2/s, Sc = 0.60.

ANALYSIS: *Dry-bulb Thermometer*: Since $T_{db} > T_s$, there is net radiation transfer from the surface of the dry-bulb thermometer to the duct wall. Hence to maintain steady-state conditions, the thermometer temperature must be less than that of the air ($T_{db} < T_\infty$) to allow for convection heat transfer from the air. Hence, from application of a surface energy balance to the thermometer, $q_{conv} = q_{rad}$, or,

$$\bar{h}A_{db}\left(T_\infty - T_{db}\right) = \varepsilon_g A_{db}\sigma\left(T_{db}^4 - T_s^4\right).$$

The air temperature is then

$$T_\infty = T_{db} + \left(\varepsilon_g \sigma / \bar{h}\right)\left(T_{db}^4 - T_s^4\right) \tag{1}$$

where $\bar{h}$ may be obtained from Eq. 7.53.

Wet-bulb Temperature: The relative humidity may be obtained by performing an energy balance on the wet-bulb thermometer. In this case convection heat transfer to the wick is balanced by evaporative and radiative heat losses from the wick,

$$q_{conv} = q_{evap} + q_{rad} \qquad q_{evap} = n''_A A_{wb} h_{fg} = \bar{h}_m\left[\rho_{A,sat}\left(T_{wb}\right) - \phi_\infty \rho_{A,sat}\left(T_\infty\right)\right]A_{wb}h_{fg}.$$

$$\bar{h}A_{wb}\left(T_\infty - T_{wb}\right) = \bar{h}_m\left[\rho_{A,sat}\left(T_{wb}\right) - \phi_\infty\rho_{A,sat}\left(T_\infty\right)\right]A_{wb}h_{fg} + \varepsilon_w A_{wb}\sigma\left(T_{wb}^4 - T_s^4\right)$$

$$\phi_\infty = \left\{\rho_{A,sat}\left(T_{wb}\right) + \left[\varepsilon_w\sigma\left(T_{wb}^4 - T_s^4\right) - \bar{h}\left(T_\infty - T_{wb}\right)\right]/h_{fg}\bar{h}_m\right\}/\rho_{A,sat}\left(T_\infty\right) \tag{2}$$

where $\bar{h}_m$ may be determined from the mass transfer analog of Eq. 7.53.

Continued …

PROBLEM 7.139 (Cont.)

Convection Calculations: For the prescribed conditions, the Reynolds number associated with the dry-bulb thermometer is

$$Re_{D(db)} = VD_{db}/\nu = 5\text{ m/s}\times 0.003\text{ m}/17.7\times 10^{-6}\text{ m}^2/\text{s} = 847.$$

Approximating the Prandtl number ratio as unity, from Eq. 7.53 and Table 7.4,

$$\overline{Nu}_{D(db)} = CRe_{D(db)}^m Pr^n = 0.51(847)^{0.5}(0.70)^{0.37} = 13.01$$

$$\overline{h} = 13.01\frac{k}{D_{db}} = 13.01\frac{0.0276\text{ W/m}\cdot\text{K}}{0.003\text{ m}} = 120\text{ W/m}^2\cdot\text{K}.$$

From Eq. (1) the air temperature is

$$T_\infty = 45^\circ\text{C} + \frac{0.95\times 5.67\times 10^{-8}\text{W/m}^2\cdot\text{K}^4}{120\text{ W/m}^2\cdot\text{K}}\left(318^4 - 308^4\right)\text{K}^4 = 45^\circ\text{C} + 0.55^\circ\text{C} = 45.6^\circ\text{C}. \qquad <$$

The relative humidity may now be obtained from Eq. (2). The Reynolds number associated with the wet-bulb thermometer is

$$Re_{D(wb)} = VD_{wb}/\nu = 5\text{ m/s}\times 0.004\text{ m}/15.7\times 10^{-6}\text{ m}^2/\text{s} = 1274.$$

From Eq. 7.53 and Table 7.4, it follows that

$$\overline{Nu}_{D(wb)} = 0.26(1274)^{0.6}(0.71)^{0.37} = 16.71$$

$$\overline{h} = 16.71\frac{k}{D_{wb}} = 16.71\frac{0.0261\text{ W/m}\cdot\text{K}}{0.004\text{ m}} = 109\text{ W/m}^2\cdot\text{K}.$$

Using the mass transfer analog of Eq. 7.53, it also follows that

$$\overline{Sh}_{D(wb)} = 0.26Re_{D(wb)}^{0.6}Sc^{0.37} = 0.26(1274)^{0.6}(0.6)^{0.37} = 15.7$$

$$\overline{h}_m = 15.7\frac{D_{AB}}{D_{wb}} = \frac{15.7\times 0.26\times 10^{-4}\text{ m}^2/\text{s}}{0.004\text{ m}} = 0.102\text{ m/s}.$$

Also, $\rho_{A,sat}(T_{wb}) = v_g(298\text{ K})^{-1} = \left(44.3\text{ m}^3/\text{kg}\right)^{-1} = 0.0226\text{ kg/m}^3$

$$\rho_{A,sat}(T_\infty) = v_g(318.5\text{ K})^{-1} = \left(15.5\text{ m}^3/\text{kg}\right)^{-1} = 0.0645\text{ kg/m}^3.$$

Hence the relative humidity is, from Eq. (2)

$$\phi_\infty = \left(0.0226\text{ kg/m}^3 + \frac{\left[0.95\times 5.67\times 10^{-8}\text{W/m}^2\cdot\text{K}^4\left(298^4 - 308^4\right)\text{K}^4 - 109\text{W/m}^2\cdot\text{K}(45.55 - 25)\text{K}\right]}{\left(2.442\times 10^6\text{ J/kg}\right)(0.102\text{ m/s})}\right)/0.0645\text{ kg/m}^3$$

$$\phi_\infty = 0.21 \qquad <$$

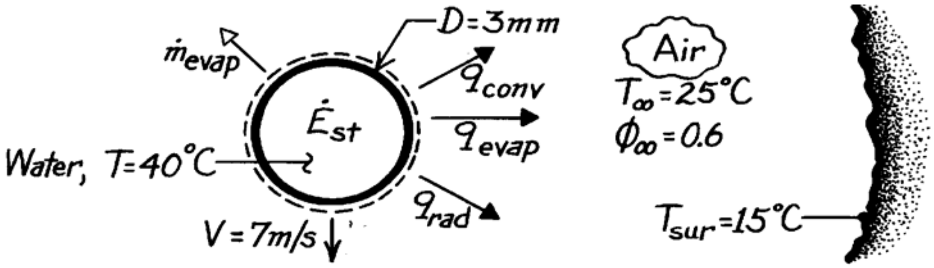
COMMENTS: (1) The effect of radiation exchange between the duct wall and the thermometers is small. For this reason $T_\infty = T_{db}$. (2) The evaporative heat loss is significant due to the small value of ϕ_∞, causing T_{wb} to be significantly less than T_∞.

PROBLEM 7.140

KNOWN: Velocity, diameter and temperature of a spherical droplet. Conditions of surroundings.

FIND: (a) Expressions for droplet evaporation and cooling rates, (b) Evaporation and cooling rates for prescribed conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible temperature gradients in the drop, (2) Heat and mass transfer analogy is applicable, (3) Perfect gas behavior for vapor.

PROPERTIES: *Table A-4*, Air (T_∞ = 298K, 1 atm): $\nu = 15.71 \times 10^{-6}$ m²/s, k = 0.0261 W/m·K, Pr = 0.71; *Table A-6*, Water (T = 40°C): $\rho_{A,sat}$ = 0.050 kg/m³, h_{fg} = 2407 kJ/kg, ρ_ℓ = 992 kg/m³, $c_{p,\ell}$ = 4179 J/kg·K; (T_∞ = 25°C): $\rho_{A,sat}$ = 0.023 kg/m³; *Table A-8*, Water vapor-air (298K): $D_{AB} = 0.26 \times 10^{-4}$ m²/s.

ANALYSIS: (a) The evaporation rate is given by

$$\dot{m}_{evap} = \overline{h}_m A_s\left(\rho_{A,s} - \rho_{A,\infty}\right) = \overline{h}_m \pi D^2\left[\rho_{A,sat}(T) - \phi_\infty \rho_{A,sat}(T_\infty)\right]. \qquad <$$

The cooling rate is obtained from an energy balance performed for a control surface about the droplet,

$$\dot{E}_{st} = -q_{out} = -\left(q_{conv} + q_{rad} + q_{evap}\right)$$

or

$$\frac{d}{dt}\left(\rho_\ell \frac{\pi D^3}{6} c_{p,\ell} T\right) = -A_s\left[\overline{h}\left(T_s - T_\infty\right) + \varepsilon\sigma\left(T_s^4 - T_{sur}^4\right) + \dot{m}''_{evap} h_{fg}\right].$$

With $A_s = \pi D^2$, it follows that

$$\frac{dT}{dt} = -\frac{6}{\rho_\ell c_{p,\ell} D}\left[\overline{h}\left(T_s - T_\infty\right) + \varepsilon\sigma\left(T_s^4 - T_{sur}^4\right) + \dot{m}''_{evap} h_{fg}\right]. \qquad <$$

(b) To obtain $\overline{h}_m$, the mass transfer analog of the Ranz-Marshall correlation gives

$$\overline{Sh}_D = 2 + 0.6 Re_D^{1/2} Sc^{1/3}$$

where

$$Re_D = \frac{VD}{\nu} = \frac{7\text{ m/s} \times 0.003\text{ m}}{15.71 \times 10^{-6}\text{ m}^2/\text{s}} = 1337, \qquad Sc = \frac{\nu}{D_{AB}} = \frac{15.71 \times 10^{-6}}{26 \times 10^{-6}} = 0.60.$$

Continued …

Hence

$$\overline{Sh}_D = 2 + 0.6(1337)^{1/2}(0.6)^{1/3} = 20.5$$

$$\overline{h}_m = \overline{Sh}_D \frac{D_{AB}}{D} = 20.5 \frac{0.26\times10^{-4}\ m^2/s}{0.003\ m} = 0.18\ m/s$$

$$\dot{m}_{evap} = 0.18\ m/s\ \pi(0.003\ m)^2[0.05 - 0.6\times.023]kg/m^3 = 1.82\times10^{-7}\ kg/s. \quad <$$

The evaporative heat flux is then

$$q''_{evap} = \frac{q_{evap}}{A_s} = \frac{\dot{m}_{evap}h_{fg}}{\pi D^2} = \frac{1.82\times10^{-7}\ kg/s\left(2.407\times10^6\ J/kg\right)}{\pi(0.003\ m)^2}$$

$$q''_{evap} = 15,494\ W/m^2.$$

Using the heat transfer correlation, the Nusselt number is

$$\overline{Nu}_D = 2 + 0.6Re_D^{1/2}Pr^{1/3} = 2 + 0.6(1337)^{1/2}(0.71)^{1/3} = 21.58.$$

Hence $$\overline{h} = \overline{Nu}_D \frac{k}{D} = 21.58\frac{0.0261\ W/m\cdot K}{0.003\ m} = 188\ W/m^2\cdot K$$

and the sensible heat flux is

$$q''_{conv} = \overline{h}(T - T_\infty) = 188\ W/m^2\cdot K(40-25)^\circ C$$

$$q''_{conv} = 2815\ W/m^2.$$

The net radiative flux is

$$q''_{rad} = \varepsilon\sigma\left(T^4 - T_{sur}^4\right) = 0.95\times5.67\times10^{-8}\ W/m^2\cdot K^4\left[313^4 - 288^4\right]K^4$$

$$q''_{rad} = 146\ W/m^2\cdot K.$$

Hence $$\frac{dT}{dt} = -\frac{6}{992\ kg/m^3\times4179\ J/kg\cdot K(0.003\ m)}(2815 + 146 + 15,494)\ W/m^2$$

$$\frac{dT}{dt} = -8.9\ K/s. \quad <$$

COMMENTS: (1) Evaporative cooling provides the dominant heat loss from the drop. (2) To test the validity of assuming negligible temperature gradients in the drop, calculate

$$Bi \approx \frac{h_{eff}(r_o/3)}{k_\ell}, \quad \text{where} \quad h_{eff} \equiv \frac{q''_{tot}}{T - T_\infty} = \frac{18,455}{25} = 738\ W/m^2\cdot K.$$

From Table A-6, $k_\ell = 0.631\ W/m\cdot K$, hence

$$Bi \approx \frac{738\ W/m^2\cdot K(0.0005\ m)}{0.631\ W/m\cdot K} = 0.58.$$

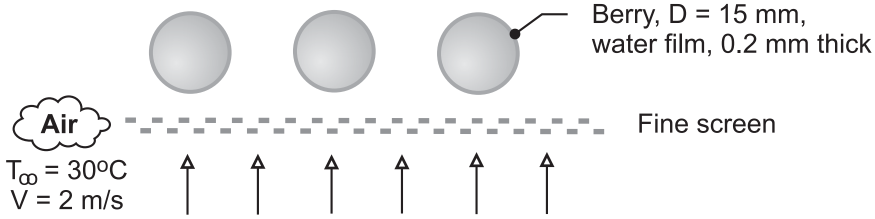
Hence, although suspect, the assumption is not totally unreasonable.

PROBLEM 7.141

KNOWN: Cranberries with an average diameter of 15 mm rolling over a fine screen. Thickness of the water film is 0.2 mm.

FIND: Time required to dry the berries exposed to heated air with a velocity of 2 m/s and temperature of 30°C.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Air stream is dry, (3) Water film on the berries is also at 30°C, (4) Convection process is uniform over the exposed surface, and (5) Heat-mass analogy is applicable.

PROPERTIES: *Table A-6*, Water (T_f = 30°C = 303 K): $\rho_{A,f} = 995.8\ kg/m^3$, $\rho_{A,g}$ = 0.02985 kg/m^3; *Table A-8*, Water-air (T_f = 303 K, 1 atm): $D_{AB} = 0.26 \times 10^{-4}\ m^2/s\ (303/298)^{1.5}$ = $2.67 \times 10^{-5}\ m^2/s$; *Table A-4*, Air ($T_f$ = 303 K, 1 atm): $\mu = \mu_s = 1.86 \times 10^{-5}\ N\cdot s/m^2$, $\nu = 1.619 \times 10^{-5}$ m^2/s, $\alpha = 2.294 \times 10^{-5}\ m^2/s$, k = 0.02652 W/m·K, Pr = 0.707.

ANALYSIS: The evaporation rate of water from the berry surface is given by the rate equation,

$$n = \overline{h}_m A_s \left(\rho_{A,s} - \rho_{A,\infty}\right) \tag{1}$$

where $A_s = \pi D^2$ and $\overline{h}_m$ is determined using the heat-mass analogy, Eq. 6.60,

$$\frac{\overline{h}}{\overline{h}_m} = \frac{k}{D_{AB}} Le^{-n} \tag{2}$$

where $Le = \alpha/D_{AB}$ and typically n = 1/3. The heat transfer coefficient $\overline{h}$ is estimated with the Whitaker correlation, Eq. 7.56,

$$\overline{Nu}_D = \frac{\overline{h}D}{k} = 2 + \left[0.4\ Re_D^{1/2} + 0.06\ Re_D^{2/3}\right] Pr^{0.4} \left(\mu/\mu_s\right)^{1/4} \tag{3}$$

Substituting numerical values, find

$$Re_D = \frac{VD}{\nu} = \frac{2\ m/s \times 0.015\ m}{1.619 \times 10^{-5} m^2/s} = 1853$$

$$Nu_D = 2 + \left[0.4(1853)^{1/2} + 0.06(1853)^{2/3}\right] \times (0.707)^{0.4} \times 1 = 24.9$$

$$\overline{h} = 24.9 \times 0.02652\ W/m\cdot K/0.015\ m = 44.0\ W/m^2\cdot K$$

and using the heat-mass analogy,

$$\overline{h}_m = 44.0\ W/m^2\cdot K \times \left(2.67 \times 10^{-5} m^2/s / 0.02652\ W/m\cdot K\right) \times (0.861)^{1/3}$$

$$\overline{h}_m = 0.0420\ m/s$$

Continued …

where

$$\text{Le} = \alpha / \text{D}_{\text{AB}} = 2.294 \times 10^{-5} \text{m}^2 / \text{s} \big/ 2.667 \times 10^{-5} \text{ m}^2 / \text{s} = 0.861$$

Using Eq. (1), the evaporation rate is

$$\text{n} = 0.0420 \text{ m/s} \times \left(\pi \left(0.015 \text{ m} \right)^2 \right) \left(0.02985 - 0 \right) \text{kg/m}^3 = 8.87 \times 10^{-7} \text{ kg/s}$$

The time, t_o, required to evaporate the water film of thickness $\delta = 0.2$ mm is

$$\text{nt}_o = \text{M}_{\text{film}} = \rho_{\text{A},\ell} \left(\pi \text{D}^2 \right) \delta$$

$$\text{t}_o = 995.8 \text{ kg/m}^3 \left(\pi \times (0.015 \text{ m})^2 \right) \times 0.0002 \text{ m} / 8.87 \times 10^{-7} \text{ kg/s}$$

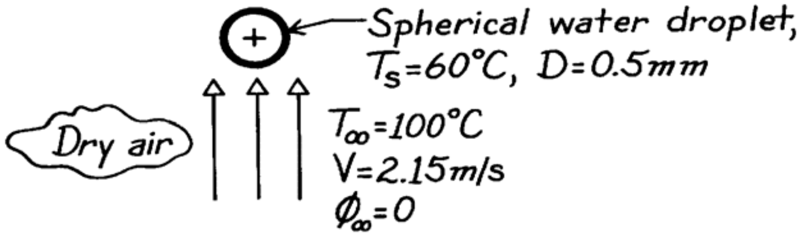
$$\text{t}_o = 159 \text{ s}$$ $<$

PROBLEM 7.142

KNOWN: Spherical droplet at prescribed temperature and velocity falling in still, hotter dry air.

FIND: Instantaneous rate of evaporation.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Heat-mass transfer analogy applicable.

PROPERTIES: *Table A-4*, Air (T_∞ = 100°C = 373K, 1atm): ρ = 0.9380 kg/m^3, c_p = 1011 J/kg·K, k = 0.0317 W/m·K, ν = 23.45 × 10^{-6} m^2/s, Pr = 0.695; *Table A-6*, Sat. water (T_s = 60°C = 333 K): $\rho_\ell = 1/v_\ell$ = 983 kg/m^3, $\rho_{A,s} = 1/v_f$ = 0.129 kg/m^3; *Table A-8*, Air-water vapor mixture (T_∞ = 373K, 1 atm): D_{AB} = 0.267 × 10^{-4} m^2/s (373/298)$^{3/2}$ = 0.36 × 10^{-4} m^2/s.

ANALYSIS: The instantaneous evaporation rate is

$$\dot{n}_A = \bar{h}_m A_s \left(\rho_{A,s} - \rho_{A,\infty}\right)$$

where $A_s = \pi D^2$, $\rho_{A,\infty} = 0$ and $\rho_{A,s} = \rho_{A,sat}(T_s)$. To estimate $\bar{h}_m$ use the Whitaker correlation, written in terms of mass transfer parameters and with $\mu/\mu_s \approx 1$,

$$\overline{Sh}_D = \frac{\bar{h}_m D}{D_{AB}} = 2 + \left(0.4 Re_D^{1/2} + 0.06 Re_D^{2/3}\right) Sc^{0.4}$$

$$\bar{h}_m = \frac{0.36\times10^{-4}\ \text{m}^2/\text{s}}{0.0005\ \text{m}}\left[2 + \left(0.4(45.8)^{1/2} + 0.06(45.8)^{2/3}\right)\times 0.651^{0.4}\right] = 0.355\ \text{m/s}$$

where
$$Re_D = \frac{VD}{\nu} = \frac{2.15\ \text{m/s}\times 0.0005\ \text{m}}{23.45\times10^{-6}\ \text{m}^2/\text{s}} = 45.8$$

$$Sc = \nu/D_{AB} = 23.45\times10^{-6}\ \text{m}^2/\text{s}/0.36\times10^{-4}\ \text{m}^2/\text{s} = 0.651.$$

Hence, the evaporation rate is

$$\dot{n}_A = 0.355\ \text{m/s}\times\pi\left(0.0005\ \text{m}\right)^2\left(0.129-0\right)\text{kg/m}^3 = 3.60\times10^{-8}\ \text{kg/s}.$$ <

COMMENTS: If this evaporation rate were to remain constant with time, the droplet of mass M would be completely evaporated in

$$\Delta t = M/\dot{n}_A = \frac{\rho_\ell\left(\pi D^3/6\right)}{\dot{n}_A} = \frac{983\ \text{kg/m}^3\left(\pi\left(0.0005\ \text{m}\right)^3/6\right)}{3.60\times10^{-8}\ \text{kg/s}} = 1.8\ \text{s}.$$

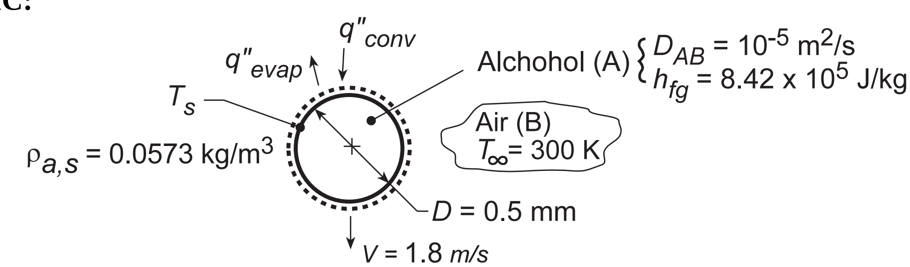
To determine whether the droplet temperature will increase or decrease with time, it is necessary to compare convective heat and evaporation rates. Hence it is not clear whether the time to completely evaporate will be less or greater than 1.8 s.

PROBLEM 7.143

KNOWN: Diameter, velocity and surface vapor concentration of alcohol droplet falling in quiescent air. Latent heat of vaporization and diffusion coefficient. Air temperature.

FIND: Droplet surface temperature

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Applicability of heat and mass transfer analogy, (3) Negligible radiation, (4) Negligible vapor concentration in air ($\rho_{A,\infty}$ = 0).

PROPERTIES: *Table A.4*, air (T_∞ = 300 K): $\nu = 15.89 \times 10^{-6}$ m^2/s, k = 0.0263 W/m·K, Pr = 0.707.

ANALYSIS: Application of a surface energy balance yields

$$q''_{evap} = q''_{conv}$$

$$\bar{h}_m \left(\rho_{A,s} - \rho_{A,\infty}\right) h_{fg} = \bar{h}\left(T_\infty - T_s\right)$$

$$T_s = T_\infty - \frac{\bar{h}_m}{\bar{h}} \rho_{A,s} h_{fg}$$

With $Re_D = VD/\nu = 1.8\,m/s \times 5\times10^{-4}\,m / 15.89\times10^{-6}\,m^2/s$ = 56.6 and Sc = ν/D_{AB} = 1.59, the Ranz-Marshall correlation yields

$$\overline{Nu}_D = 2 + 0.6\,Re_D^{1/2}\,Pr^{1/3} = 2 + 0.6(56.6)^{1/2}(0.707)^{1/3} = 6.02$$

$$\overline{Sh}_D = 2 + 0.6\,Re_D^{1/2}\,Sc^{1/3} = 2 + 0.6(56.6)^{1/2}\left(1.59^{1/3}\right) = 7.27$$

With $\bar{h}_m/\bar{h}$ = $\overline{Sh}_D\left(D_{AB}/D\right) / \overline{Nu}_D\left(k/D\right)$,

$$\frac{\bar{h}_m}{\bar{h}} = \frac{\overline{Sh}_D\left(D_{AB}\right)}{\overline{Nu}_D\left(k\right)} = \frac{7.27\times10^{-5}\,m^2/s}{6.02\times0.0263\,W/m\cdot K} = 4.59\times10^{-4}\,m^3\cdot K/J$$

Hence,

$$T_s = 300\,K - 4.59\times10^{-4}\,m^3\cdot K/J\left(0.0573\,kg/m^3\right)\left(8.42\times10^5\,J/kg\right) = 277.9\,K$$ <

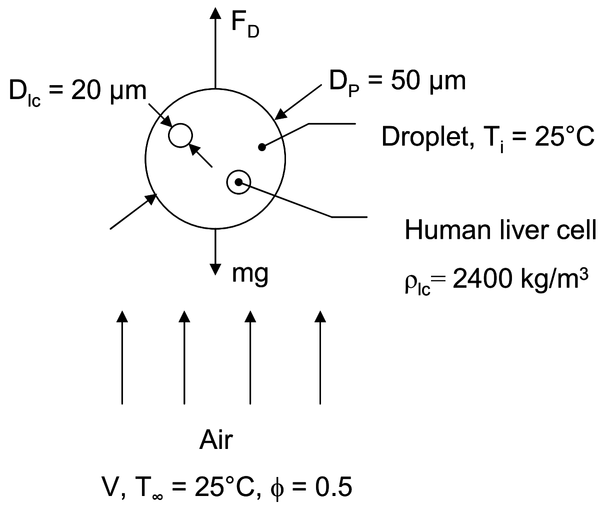
COMMENTS: The large vapor density, $\rho_{A,s}$, renders the *evaporative cooling* effect significant.

PROBLEM 7.144

KNOWN: Diameter and density of liver cells, diameter of droplets.

FIND: (a) Terminal velocity of the droplets when each droplet contains one liver cell, (b) Time of flight of a droplet containing one liver cell if the distance between injector and scaffold is L = 4 mm, (c) Initial evaporation rate from the droplet, (d) Comparison of the mass variation due to evaporation to variation due to liver cell populations ranging from one to five per droplet.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Negligible evaporative cooling, (3) Stokes' law is valid, $C_D = 24/Re_D$, (4) Neglect mass of displaced air in force balance, (5) Evaporation rate is unaffected by change in droplet diameter, (6) Negligible microscale mass transfer effects.

PROPERTIES: Table A.4, air: (T = 25 °C = 298 K): $\rho = 1.171$ kg/m^3, $\nu = 15.71 \times 10^{-6}$ m^2/s, Table A.6, liquid water: (T = 25 °C = 298 K): $\rho = 997.4$ kg/m^3, Table A.6, water vapor: (T = 25 °C = 298 K): $v_g = 44.25$ m^3/kg. Table A.8, water vapor in air: (T = 25 °C = 298 K): $D_{AB} = 0.26 \times 10^{-4}$ m^2/s.

ANALYSIS:

(a) At terminal velocity, the face balance is

$$M_g = C_D A_f (\rho V^2/2) \qquad (1)$$

The mass of the particle, M, is

$$M = \forall_{lc}\rho_{lc} + (\forall_p - \forall_{lc})\rho_p \qquad (2)$$

The volume of the droplet is $\forall_p = \frac{4}{3}\pi \times (25 \times 10^{-6}\text{m})^3 = 6.54 \times 10^{-14}\text{m}^3$ while the volume of a liver cell is $\forall_{lc} = \frac{4}{3}\pi \times (10 \times 10^{-6}\text{m})^3 = 4.12 \times 10^{-15}\text{m}^3$ and the frontal area is

$A_f = \pi \times (25 \times 10^{-6}\text{m})^2 = 1.963 \times 10^{-9}\text{m}^2$.

The mass is therefore

$$M = 4.12 \times 10^{-15}\text{m}^3 \times 2400\text{ kg/m}^3 + (6.54 \times 10^{-14}\text{m}^3 - 4.12 \times 10^{-15}\text{m}^3) \times 997.4\text{ kg/m}^3$$

$$M = 7.10 \times 10^{-11}\text{ kg} \qquad (3)$$

Note that $C_D = 24/Re_D = 24\,\nu/VD_P$ (4)

Continued….

PROBLEM 7.144 (Cont.)

Combining Equations 1, 2 and 3 yields

$$V = \frac{M_g D_p}{12\nu A_f \rho} = \frac{7.10 \times 10^{-11}\text{kg} \times 9.8\ \text{m/s}^2 \times 50 \times 10^{-6}\ \text{m}}{12 \times 15.71 \times 10^{-6}\text{m}^2\text{/s} \times 1.963 \times 10^{-9}\text{m}^2 \times 1.171\ \text{kg/m}^3}$$

$$V = 0.080\ \text{m/s}$$ <

The volume fraction of liver cells in the slurry is

$$f = \forall_{lc}/\forall_p = 4.12 \times 10^{-15}\text{m}^3/6.54 \times 10^{-14}\ \text{m}^3 = 0.063$$ <

(b) The time of flight is

$$t = L/V = 4 \times 10^{-3}\ \text{m} / 0.080\ \text{m/s} = 50 \times 10^{-3}\ \text{s} = 50\ \text{ms}$$ <

(c) With $Sc = \nu/D_{AB} = 1.571 \times 10^{-5}\ \text{m}^2\text{/s} / 0.26 \times 10^{-4}\ \text{m}^2\text{/s} = 0.604$, the heat and mass transfer analogy may be applied to Whitaker's correlation to yield

$$\overline{h}_D = \frac{D_{AB}}{D_p}\left\{2 + \left[0.4\sqrt{Re_D} + 0.06(Re_D)^{2/3}\right]Pr^{0.4}\right\}$$

The Reynolds number is $Re_D = VD_p/\nu = 0.08\ \text{m/s} \times 50 \times 10^{-6}\ \text{m}/15.71 \times 10^{-6}\ \text{m}^2\text{/s} = 0.255$.

Hence,

$$\overline{h}_D = \frac{0.26 \times 10^{-4}\ \text{m}^2\text{/s}}{50 \times 10^{-6}\ \text{m}}\left\{2 + \left[0.4\sqrt{0.255} + 0.06(0.255)^{2/3}\right]0.604^{0.4}\right\}$$

$$\overline{h}_D = 1.14\ \text{m/s}$$

The initial evaporation rate is

$$n_A = \overline{h}_D A(\rho_{A,sat} - \phi\rho_{A,sat})$$

$$n_A = 1.14\ \text{m/s} \times \pi \times (50 \times 10^{-6}\text{m})^2 \times \left[\frac{1}{44.25} - \frac{0.5}{44.25}\right]\frac{\text{kg}}{\text{m}^3} = 1.01 \times 10^{-10}\ \text{kg/s}$$ <

(d) The sensitivity may be estimated by comparing the change in mass due to evaporation to the difference in mass due to liver cell loading.

Evaporation

$$\Delta M = n_A t = 1.01 \times 10^{-10}\ \text{kg/s} \times 50 \times 10^{-3}\text{s} = 5.05 \times 10^{-12}\text{kg}$$ <

Loading

The droplet mass with 3 liver cells is

$$M_3 = 3 \times 4.12 \times 10^{-15}\text{m}^3 \times 2400\ \text{kg/m}^3 + (6.54 \times 10^{-14}\text{m}^3 - 3 \times 4.12 \times 10^{-15}\text{m}^3) \times 997.4\ \text{kg/m}^3$$

$$M_3 = 8.26 \times 10^{-11}\ \text{kg}$$

The change in mass relative to one liver cell in the droplet is

$$\Delta M = M_3 - M_1 = 8.26 \times 10^{-11}\ \text{kg} - 7.10 \times 10^{-11}\ \text{kg} = 1.16 \times 10^{-11}\ \text{kg}$$ <

The change in mass is more sensitive to variations in the number of liver cells than to evaporation.

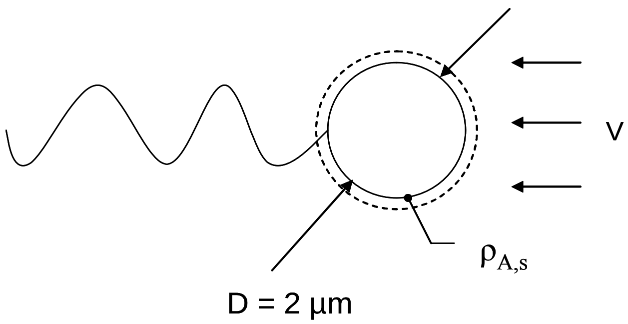
COMMENTS: (1) Inspection of Figure 7.9 shows that Stokes' law is valid at $Re_D = 0.255$.

PROBLEM 7.145

KNOWN: Dimension and approximate shape of E. coli bacterium. Binary diffusivity, nutrient value, propulsion efficiency and concentration difference from free stream water-based solution to bacterium shell.

FIND: Estimate the maximum E. coli speed in body diameters per second.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible capability of bacterium to store energy, (2) Constant properties, (3) Steady-state, (4) Stokes' law is valid, that is $C_D = 24/Re_D$, (5) Negligible microscale mass transfer effects.

PROPERTIES: Table A.6, water (T = 37 °C = 310 K): $\rho = 993$ kg/m^3, $\nu = 6.999 \times 10^{-7}$ m^2/s, Pr = 0.701.

ANALYSIS: For the spherical bacterium shell

$$Re_D = VD/\nu = (V \times 2 \times 10^{-6} m)/(6.999 \times 10^{-7} m^2/s) = 2.858\ (s/m) \times V \qquad (1)$$

The power required to propel the bacterium is

$$P = F_D V = \frac{C_D A_f \rho V^2}{2} V = \frac{C_D \pi D^2 \rho V^3}{8} \qquad (2)$$

assuming $C_D = \dfrac{24}{Re_D} = \dfrac{24}{2.858\ (s/m)\ V}$

We may combine Equations 1 and 2 to yield

$$P = \frac{24}{2.858}\frac{\pi D^2 \rho V^2}{8} = \frac{3}{2.858\ s/m} \times \pi \times (2 \times 10^{-6} m)^2 \times 993\ kg/m^3 \times V^2$$

$$= 13.1 \times 10^{-9}\ Ws^2/m^2 (V)^2$$

For $\eta = 0.5$, the energy to be delivered from the water-based solution to the bacterium is

$$E = P/\eta = 26.2 \times 10^{-9}\ Ws^2/m^2 (V)^2 \qquad (3)$$

The energy supplied to the bacterium is

$$E = \overline{h}_m A \mathcal{N} \Delta C = \overline{h}_m pD^2 \mathcal{N} \Delta C/4$$

$$E = \overline{h}_m \pi (2 \times 10^{-6} m)^2 \times 16{,}000\ kJ/kg \times 860 \times 10^{-12} kg/m^3 / 4$$

Continued…

PROBLEM 7.145 (Cont.)

$$E = 43.23 \times 10^{-18}\ \text{Ws/m} \times \overline{h}_m \qquad (4)$$

Applying the heat and mass transfer analogy to the Whitaker correlation yields

$$\overline{Sh}_D = \frac{\overline{h}_m D}{D_{AB}} = 2 + (0.4\sqrt{Re_D} + 0.06\, Re_D^{2/3})\, Sc^{0.4}\left(\frac{1}{1}\right)$$

where $S_c = \nu/D_{AB} = 6.999 \times 10^{-7}\ \text{m}^2\text{/s}/(0.7 \times 10^{-9}\ \text{m}^2\text{/s}) = 1000$

Therefore

$$\overline{h}_m = \frac{0.7 \times 10^{-9}\ \text{m}^2\text{/s}}{2 \times 10^{-6}\ \text{m}}\left[2 + \left(0.4\sqrt{2.858\ \text{s/m} \times V} + 0.06\left(2.858\ \text{s/m} \times V\right)^{2/3}\right) \times 1000^{0.4}\right] \qquad (5)$$

Combining Equations (3) through (5) and solving for V yields

$$V = 70 \times 10^{-6}\ \text{m/s} = 70\ \mu\text{m/s}$$

or $V = 70\ \mu\text{m/s} \times 1$ body diameter/2 μm = 35 body diameters/s <

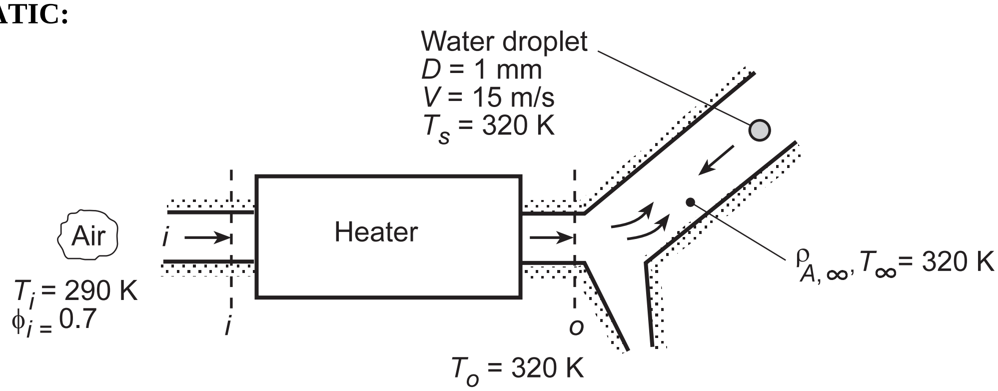
COMMENTS: (1) The maximum Reynolds number is $Re_D = VD/\nu = 70 \times 10^{-6}$ m/s $\times\ 2 \times 10^{-6}$ m/6.999×10^{-7} m^2/s = 200×10^{-6}. The Whitaker correlation is extrapolated outside of its range of application and provides a Sherwood number of 2.093 and a mass transfer coefficient of 732×10^{-6} m/s. Using a Sherwood number of two, one would calculate a mass transfer coefficient of 700×10^{-6} m/s. Using the limiting value of the Sherwood number would change the answer by less than 5%. (2) The small Reynolds number validates the application of Stokes' law. (3) It is hypothesized that the direction of rotation of the flagellum (clockwise or counterclockwise) is driven by the spatial concentration gradient in the solution. The direction of rotation changes with the solutions' nutrient concentration gradient in a manner that consistently "steers" the bacterium into more fertile feeding grounds. (4) The bacterium splits into multiple bacteria when it is stationary. Presumably, the energy needed to split the bacterium is available since no power is needed to propel the E. coli during splitting.

PROBLEM 7.146

KNOWN: Humidity and temperature of air entering heater; temperature of air leaving heater. Diameter, temperature and relative velocity of injected droplets.

FIND: Droplet evaporation rate.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible change in droplet diameter due to evaporation, (2) Negligible cooling of droplet due to evaporation, (3) Applicability of heat/mass transfer analogy, (4) Ideal gas behavior for vapor.

PROPERTIES: *Table A.4*, air ($T_\infty = T_o = 320$ K): $\nu = 17.90 \times 10^{-6}$ m^2/s, k = 0.0278 W/m·K, Pr = 0.705. *Table A.6*, saturated water ($T_i = 290$ K): $p_{sat} = 0.01917$ bars; ($T_o = 320$ K): $p_{sat} = 0.1053$ bars, $v_g = 13.98$ m^3/kg. *Table A.8*, H_2O/air (T = 320 K): $D_{AB} = 0.26 \times 10^{-4}$ m^2/s $(320/298)^{3/2} = 0.289 \times 10^{-4}$ m^2/s.

ANALYSIS: Due to an increase in temperature, the air leaves the heater with a smaller relative humidity. With $\phi_i = 0.7$ and $p_{sat,i} = 0.01917$ bars, the vapor pressure at the heater inlet is $p_i = \phi_i p_{sat,i} = 0.7(0.01917$ bars) = 0.0134 bars. Since the vapor pressure doesn't change with passage through the heater,

$$\phi_o = \frac{p_i}{p_{sat,o}} = \frac{0.0134\,\text{bars}}{0.1053\,\text{bars}} = 0.127$$

The vapor density associated with air flow around the droplets is therefore

$$\rho_{A,\infty} = \phi_o \rho_{A,sat}(T_o) = \phi_o v_g(T_o)^{-1} = 0.127 \times 0.0715\,\text{kg/m}^3 = 0.0091\,\text{kg/m}^3$$

The droplet evaporation rate is

$$\dot{m}_{evap} = \overline{h}_m A_s \left[\rho_{A,sat}(T_s) - \rho_{A,\infty}\right]$$

where $\overline{h}_m$ may be obtained from the mass transfer analog to the Whitaker correlation. With $Re_D = VD/\nu = 15$ m/s $\times$ 0.001 m/17.9 $\times 10^{-6}$ m^2/s = 838, $Sc = \nu/D_{AB} = 17.9 \times 10^{-6}$ m^2/s/28.9 $\times 10^{-6}$ m^2/s = 0.62, and $\mu/\mu_s = 1$,

$$\overline{Sh}_D = 2 + \left(0.4\,Re_D^{1/2} + 0.06\,Re_D^{2/3}\right)Sc^{0.4} = 2 + \left[0.4(838)^{1/2} + 0.06(838)^{2/3}\right](0.62)^{0.4} = 16.0$$

$$\overline{h}_m = \overline{Sh}_D\left(D_{AB}/D\right) = 16\left(0.289 \times 10^{-4}\,\text{m}^2/\text{s}/0.001\,\text{m}\right) = 0.462\,\text{m/s}$$

$$\dot{m}_{evap} = (0.462\,\text{m/s})\pi(0.001\,\text{m})^2(0.0715 - 0.0091)\,\text{kg/m}^3 = 9.06 \times 10^{-8}\,\text{kg/s}$$ <

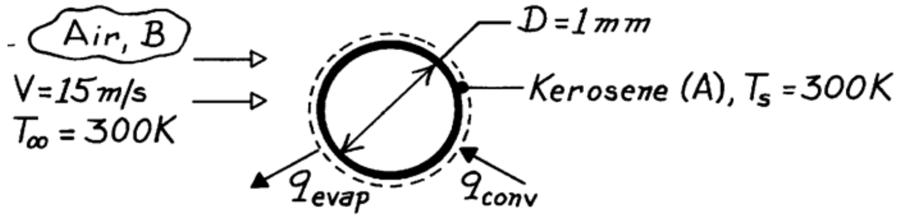
COMMENTS: The energy required for evaporation must be supplied by convection heat transfer from the heated air to the droplet. Hence, in actuality, the droplet temperature T_s must be less than that of the freestream air, T_∞, which in turn will decrease from the value T_o at the heater outlet.

PROBLEM 7.147

KNOWN: Diameter and temperature of sphere wetted with kerosene. Air flow conditions.

FIND: (a) Minimum kerosene flow rate, (b) Air temperature required to maintain wetted surface at 300K.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Sphere mount has a negligible influence on the flow field and hence on $\overline{h}$, (3) Negligible kerosene vapor concentration in free stream.

PROPERTIES: *Table A-4*, Air (300K): $\nu = 15.89 \times 10^{-6}$ m²/s, k = 0.0263 W/m·K, $\rho = 1.161$ kg/m³, Pr = 0.707; Kerosene (given): $\rho_{A,sat} = 0.015$ kg/m³, $h_{fg} = 300$ kJ/kg; Kerosene vapor-air (given): $D_{AB} = 10^{-5}$ m²/s.

ANALYSIS: (a) The kerosene flowrate is $n_A = \overline{h}_m A\left(\rho_{A,sat} - \rho_{A,\infty}\right)$. Using the mass transfer analog of Eq. 7.56 and neglecting the viscosity ratio,

$$\overline{Sh}_D = 2 + \left(0.4\ Re_D^{1/2} + 0.06\ Re_D^{2/3}\right) Sc^{0.4}$$

with $$Re_D = \frac{VD}{\nu} = \frac{15\ m/s \times 0.001\ m}{15.89 \times 10^{-6}\ m^2/s} = 944 \qquad Sc = \frac{\nu}{D_{AB}} = \frac{15.89 \times 10^{-6}}{10 \times 10^{-6}} = 1.59$$

$$\overline{Sh}_D = 2 + \left(0.4 \times 944^{1/2} + 0.06944^{2/3}\right)\ (1.59)^{0.4} = 23.7$$

$$\overline{h}_m = \overline{Sh}_D\ D_{AB}/D = 23.7 \times 10^{-5}\ m^2/s/0.001\ m = 0.237\ m/s$$

$$n_A = 0.237\ m/s\ \pi\left(10^{-3}\ m\right)^2\ 0.015\ kg/m^3 = 1.12 \times 10^{-8}\ kg/s.$$ <

(b) An energy balance on the sphere yields $n_A\ h_{fg} = \overline{h}A\ \left(T_\infty - T_s\right)$. Using the Whitaker correlation and neglecting the viscosity ratio,

$$\overline{Nu}_D = 2 + \left(0.4 \times 944^{1/2} + 0.06 \times 944^{2/3}\right)\ (0.707)^{0.4} = 17.72$$

$$\overline{h} = \overline{Nu}_D k/D = 17.72 \times 0.0263\ W/m \cdot K/0.001\ m = 466\ W/m^2 \cdot K$$

$$T_\infty = T_s + \frac{n_A\ h_{fg}}{\overline{h}\pi D^2} = 300K + \frac{1.12 \times 10^{-8}\ kg/s \times 3 \times 10^5\ J/kg}{466\ W/m^2 \cdot K \times \pi\left(0.001\ m\right)^2}$$

$$T_\infty = 300K + 2.3K = 302.3K$$ <

or $$T_\infty - T_s = 2.3K.$$

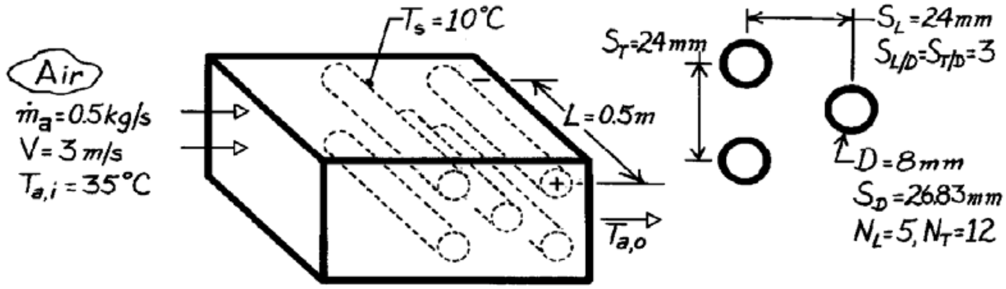
COMMENTS: The small temperature excess (2.3K) is due to comparatively small values of $\rho_{A,sat}$ and h_{fg} for kerosene.

PROBLEM 7.148

KNOWN: Geometry and surface temperature of a tube bank with or without wetted surfaces. Temperature, velocity and flowrate associated with air in cross flow.

FIND: (a) Ratio of air cooling with water film to that without film, (b) Air outlet temperature and specific humidity for prescribed conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Heat and mass transfer analogy is applicable, (3) Air is dry, (4) Heat and mass transfer driving potentials are $T_{a,i} - T_s$ and $\rho_{A,sat}(T_s)$, (5) Vapor has negligible effect on flowrate.

PROPERTIES: *Table A-4*, Air (assume $\bar{T}_a \approx 305\text{K}$): $\rho = 1.1448\ \text{kg/m}^3$, $c_p = 1007\ \text{J/kg·K}$, $\nu = 16.39 \times 10^{-6}\ \text{m}^2/\text{s}$, $k = 0.0267\ \text{W/m·K}$, $Pr = 0.706$, $\alpha = 23.2 \times 10^{-6}\ \text{m}^2/\text{s}$; *Table A-6*, Water vapor ($T_s = 10°C$): $v_g = 111.8\ \text{m}^3/\text{kg}$, $\rho_{A,sat} = 8.94 \times 10^{-3}\ \text{kg/m}^3$, $h_{fg} = 2.478 \times 10^6\ \text{J/kg}$; *Table A-8*, Water vapor-air ($T_f \approx 298\text{K}$): $D_{AB} = 0.26 \times 10^{-4}\ \text{m}^2/\text{s}$, $Sc = (\nu/D_{AB}) = 0.630$.

ANALYSIS: (a) The rate of heat loss from the air may be expressed as

$$q = \dot{m}_a c_{p,a} \left(T_{a,i} - T_{a,o}\right)$$

in which case, the amount of air cooling is

$$\left(T_{a,i} - T_{a,o}\right) = \frac{q}{\dot{m}_a c_{p,a}}. \qquad (1)$$

Without the water film, $q_{wo} \approx \bar{h}A\left(T_{a,i} - T_s\right)$ (2)

With the film,

$$q_w \approx \bar{h}A\left(T_{a,i} - T_s\right) + \dot{m}_{evap}\ h_{fg}$$

$$q_w \approx \bar{h}A\left(T_{a,i} - T_s\right) + \bar{h}_m A\left(\rho_{A,sat} - \rho_{A,\infty}\right)\ h_{fg} \qquad (3)$$

where $\rho_{A,\infty} = 0$. Hence

$$\frac{\left(T_{a,i} - T_{a,o}\right)_w}{\left(T_{a,i} - T_{a,o}\right)_{wo}} \approx 1 + \frac{\bar{h}_m \rho_{A,sat} h_{fg}}{\bar{h}\left(T_{a,i} - T_s\right)}$$

or substituting from Eq. 6.60, with $Le = \alpha/D_{AB}$ and a value of $n = 0.33$,

$$\frac{\left(T_{a,i} - T_{a,o}\right)_w}{\left(T_{a,i} - T_{a,o}\right)_{wo}} \approx 1 + \frac{\left(D_{AB}/\alpha\right)^{0.67}}{\rho\ c_p}\ \frac{\rho_{A,sat}\ h_{fg}}{\left(T_{a,i} - T_s\right)}$$ <

Continued …

PROBLEM 7.148 (Cont.)

For the prescribed conditions,

$$\frac{\left(T_{a,i}-T_{a,o}\right)_{w}}{\left(T_{a,i}-T_{a,o}\right)_{wo}} \approx 1+\frac{\left(\dfrac{0.26\times10^{-4}\,m^2/s}{0.232\times10^{-4}\,m^2/s}\right)^{0.67}}{1.145\ kg/m^3\times1007\ J/kg\cdot K}\times\frac{8.94\times10^{-3}kg/m^3\times2.478\times10^6\,J/kg}{(35-10)^{\circ}\,C}\approx 1.83.$$ <

(b) $T_{a,o}$ may be obtained from Eq. (1), where q is approximated by Eq. (2) or Eq. (3). With S_D = 26.83 mm > (S_T + D)/2 = 16, V_{max} is at the transverse plane. Hence

$$V_{max}=\frac{S_T}{S_T-D}V=\frac{24}{16}\times3 m/s=4.5 m/s \qquad Re_{D,max}=\frac{4.5\ m/s\times0.008\ m}{16.39\times10^{-6}\ m^2/s}=2196.$$

From Tables 7.5 and 7.6, C_1 = 0.35, m = 0.60, C_2 = 0.98 and the Zukauskas relation gives

$$\overline{Nu}_D=0.35(0.98)(2196)^{0.6}(0.706)^{0.36}=30.6$$

where$(Pr/Pr_s)^{1/4}$ is 1.00. Hence

$$\bar{h}=\overline{Nu}_D\ k/D=30.6(0.0267\ W/m\cdot K)/0.008\ m=102\ W/m^2\cdot K.$$

Also $$\bar{h}_m=\bar{h}\frac{(D_{AB}/\alpha)^{0.67}}{\rho\ c_p}=102\frac{W}{m^2\cdot K}\frac{(0.26/0.232)^{0.67}}{1.145\ kg/m^3\times1007\ J/kg\cdot K}=0.0956\ m/s.$$

Hence

$$q_{conv}\approx\bar{h}A\left(T_{a,i}-T_s\right)=102W/m^2\cdot K\times\pi(0.008\ m)0.5\ m\times60(35-10)^{\circ}\,C=1923\ W$$

$$q_{evap}=n_A h_{fg}=\bar{h}_m A\,\rho_{A,sat}\ h_{fg}$$

$$q_{evap}=0.0956\ m/s\times\pi(0.008\ m)0.5\ m\times60\left(8.94\times10^{-3}kg/m^3\right)2.478\times10^6\ J/kg$$

$$q_{evap}\approx1597W.$$

With water film,

$$T_{a,o}=T_{a,i}-\frac{q_{conv}+q_{evap}}{\dot{m}_a\ c_{p,a}}\approx35^{\circ}C-\frac{(1923+1597)W}{0.5\ kg/s\times1007\ J/kg\cdot K}=28.0^{\circ}C.$$ <

The specific humidity of the outlet air is

$$\omega_o=\frac{n_A}{\dot{m}_a}=\frac{\bar{h}_m 60\pi DL\ \rho_{A,sat}}{\dot{m}_a}$$

$$\omega_o=\frac{0.0956\ m/s(60\pi)\ (0.008\ m)0.5\ m\left(8.94\times10^{-3}kg/m^3\right)}{0.5\ kg/s}=0.00129.$$ <

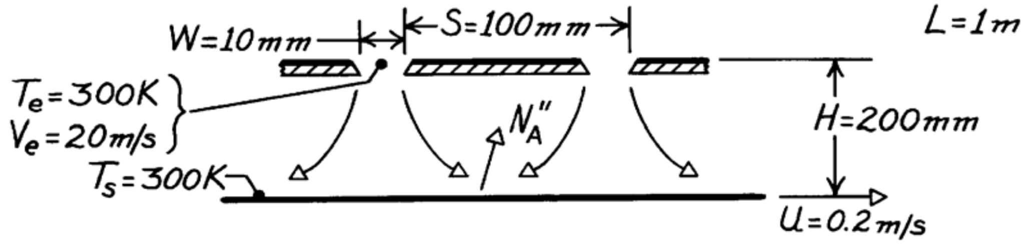
COMMENTS: (1) Enhancement of air cooling by evaporation is significant ($T_{a,o}$ = Ta,i $-q_{conv}/\dot{m}_a\ c_{p,a}\approx31.1^{\circ}C$ without the film). (2) Small value of ω_o justifies neglecting effect of evaporation on $\dot{m}_a$. (3) q_{conv} has been overestimated by using ($T_{a,i}$ - T_s) as the driving potential for convection heat transfer. A more accurate determination involves $\Delta T_{\ell m}$ rather than ($T_{a,i}$ - T_s). (4) Apparently the air properties were evaluated at an appropriate $\overline{T}_a$.

PROBLEM 7.149

KNOWN: Dimensions of slot jet array. Jet exit velocity and temperature. Temperature of paper.

FIND: Drying rate per unit surface area.

SCHEMATIC:



ASSUMPTIONS: (1) Applicability of heat and mass transfer analogy, (2) Paper motion has negligible effect on convection ($U << V_e$).

PROPERTIES: *Table A-4*, Air (300 K, 1 atm): $\nu = 15.89 \times 10^{-6}$ m²/s; *Table A-6*, Saturated water (300 K): $\rho_{A,sat} = v_g^{-1} = 0.0256$ kg/m³; *Table A-8*, Water vapor-air (300 K): $D_{AB} = 0.26 \times 10^{-4}$ m²/s, Sc = 0.61.

ANALYSIS: The mass evaporation flux is

$$n''_A = \overline{h}_m\left(\rho_{A,s} - \rho_{A,e}\right) = \overline{h}_m \rho_{A,sat}$$

For an array of slot nozzles,

$$\frac{\overline{Sh}}{Sc^{0.42}} = \frac{2}{3} A_{r,o}^{3/4}\left(\frac{2\,Re}{A_r / A_{r,o} + A_{r,o} / A_r}\right)^{2/3}$$

where

$$A_r = W/S = 0.1$$

$$A_{r,o} = \left\{60 + 4\left[\left(H/2W\right) - 2\right]^2\right\}^{-1/2} = \left\{60 + 4(64)\right\}^{-1/2} = 0.0563$$

$$Re = \frac{V_e(2W)}{\nu} = \frac{20\text{ m/s}(0.02\text{ m})}{15.89 \times 10^{-6}\text{m}^2/\text{s}} = 25{,}173.$$

Hence

$$\frac{\overline{Sh}}{Sc^{0.42}} = 0.667(0.0563)^{3/4}\left(\frac{50{,}346}{1.776 + 0.563}\right)^{2/3} = 59.6$$

$$\overline{h}_m = \frac{D_{AB}}{2W} 59.6 Sc^{0.42} = \frac{0.26 \times 10^{-4}\text{ m}^2/\text{s}}{0.02\text{ m}} 59.6(0.61)^{0.42} = 0.063\text{ m/s}.$$

The evaporative flux is then

$$n''_A = 0.063\text{ m/s}\left(0.0256\text{ kg/m}^3\right) = 0.0016\text{ kg/s}\cdot\text{m}^2.$$ <

COMMENTS: The mass fraction of water vapor to air leaving the sides of the dryer is $n''_A(S \times L)/\rho_{air} V_e (W \times L) = 7 \times 10^{-4}$. Hence, the assumption of dry air throughout the dryer is reasonable.

PROBLEM 8.1

KNOWN: Flowrate and temperature of water in fully developed flow through a tube of prescribed diameter.

FIND: Maximum velocity and pressure gradient.

SCHEMATIC:

ASSUMPTIONS: (1) Steady-state conditions, (2) Isothermal flow, (3) Horizontal tube.

PROPERTIES: *Table A-6*, Water (300 K): ρ = 998 kg/m^3, μ = 855 × 10^{-6} N·s/m^2.

ANALYSIS: From Eq. 8.6,

$$Re_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 0.01\ \text{kg/s}}{\pi (0.025\text{m})\ 855 \times 10^{-6}\ \text{kg/m} \cdot \text{s}} = 596.$$

Hence the flow is laminar and the velocity profile is given by Eq. 8.15,

$$\frac{u(r)}{u_m} = 2\left[1 - (r/r_o)^2\right].$$

The maximum velocity is therefore at r = 0, the centerline, where

$$u(0) = 2\ u_m.$$

From Eq. 8.5

$$u_m = \frac{\dot{m}}{\rho \pi\ D^2/4} = \frac{4 \times 0.01\ \text{kg/s}}{998\ \text{kg/m}^3 \times \pi (0.025\text{m})^2} = 0.020\ \text{m/s},$$

hence

$$u(0) = 0.041\ \text{m/s}.$$

Combining Eqs. 8.16 and 8.19, the pressure gradient is

$$\frac{dp}{dx} = -\frac{64}{Re_D}\ \frac{\rho u_m^2}{2D}$$

$$\frac{dp}{dx} = -\frac{64}{596} \times \frac{998\ \text{kg/m}^3\ (0.020\ \text{m/s})^2}{2 \times 0.025\ \text{m}} = -0.86\ \text{kg/m}^2 \cdot \text{s}^2$$

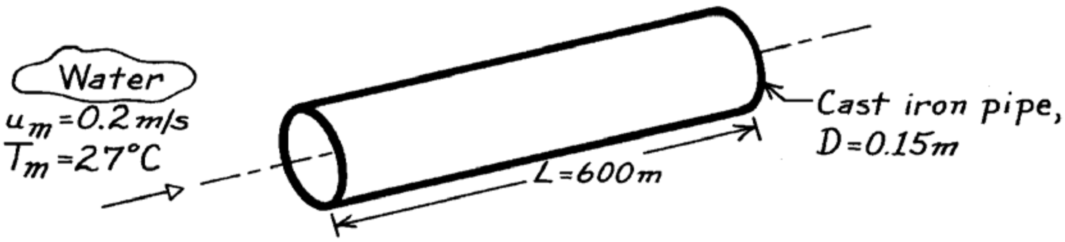
$$\frac{dp}{dx} = -0.86 \text{N/m}^2 \cdot \text{m} = -0.86 \times 10^{-5}\ \text{bar/m}.$$ <

PROBLEM 8.2

KNOWN: Temperature and mean velocity of water flow through a cast iron pipe of prescribed length and diameter.

FIND: Pressure drop.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Fully developed flow, (3) Constant properties.

PROPERTIES: *Table A-6*, Water (300 K): $\rho = 997$ kg/m^3, $\mu = 855 \times 10^{-6}$ N·s/m^2.

ANALYSIS: From Eq. 8.22, the pressure drop is

$$\Delta p = f\frac{\rho u_m^2}{2D}L.$$

With

$$Re_D = \frac{\rho u_m D}{\mu} = \frac{997 \text{ kg/m}^3 \times 0.2 \text{ m/s} \times 0.15 \text{ m}}{855 \times 10^{-6} \text{ N}\cdot\text{s/m}^2} = 3.50 \times 10^4$$

the flow is turbulent and with e = 2.6×10^{-4} m for cast iron (see Fig. 8.3), it follows that e/D = 1.73×10^{-3} and from Eq. 8.20 (or Fig. 8.3)

$$\frac{1}{\sqrt{f}} = -2.0\log\left[\frac{e/D}{3.7} + \frac{2.51}{Re_D\sqrt{f}}\right] \qquad f = 0.027$$

Hence,

$$\Delta p = 0.027\frac{997 \text{ kg/m}^3 (0.2 \text{ m/s})^2}{2 \times 0.15 \text{ m}}(600\text{m})$$

$$\Delta p = 2154 \text{ kg/s}^2 \cdot \text{m} = 2154 \text{ N/m}^2$$

$$\Delta p = 0.0215 \text{ bar.}$$ <

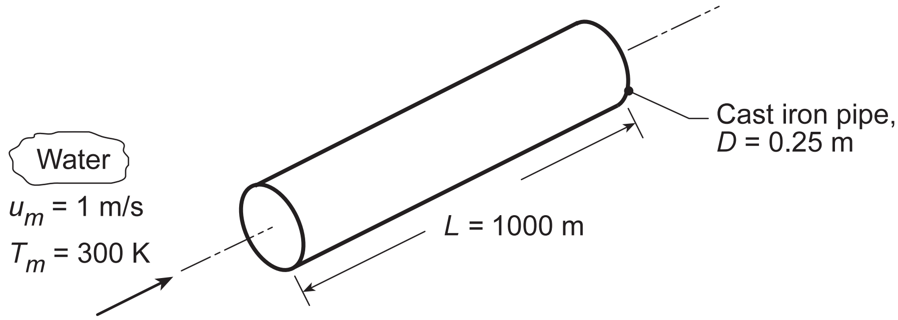
COMMENTS: For the prescribed geometry, L/D = (600/0.15) = 4000 >> $(x_{fd,h}/D)_{turb} \approx 10$, and the assumption of fully developed flow throughout the pipe is justified.

PROBLEM 8.3

KNOWN: Temperature and velocity of water flow in a pipe of prescribed dimensions.

FIND: Pressure drop and pump power requirement for (a) a smooth pipe, (b) a cast iron pipe with a clean surface, and (c) smooth pipe for a range of mean velocities 0.05 to 1.5 m/s.

SCHEMATIC:



ASSUMPTIONS: (1) Steady, fully developed flow.

PROPERTIES: *Table A.6*, Water (300 K): $\rho = 997\ kg/m^3$, $\mu = 855 \times 10^{-6}\ N{\cdot}s/m^2$, $\nu = \mu/\rho = 8.576 \times 10^{-7}\ m^2/s$.

ANALYSIS: From Eq. 8.22a and 8.22b, the pressure drop and pump power requirement are

$$\Delta p = f\,\frac{\rho u_m^2}{2D}L \qquad\qquad P = \Delta p\dot{V} = \Delta p\left(\pi D^2/4\right)u_m \qquad (1,2)$$

The friction factor, f, may be determined from Figure 8.3 or Eq. 8.20 for different relative roughness, e/D, surfaces or from Eq. 8.21 for the smooth condition, $3000 \le Re_D \le 5 \times 10^6$,

$$f = \left(0.790\ln\left(Re_D\right) - 1.64\right)^{-2} \qquad (3)$$

where the Reynolds number is

$$Re_D = \frac{u_m D}{\nu} = \frac{1\,m/s \times 0.25\,m}{8.576\times10^{-7}\ m^2/s} = 2.915\times10^5 \qquad (4)$$

(a) *Smooth surface:* from Eqs. (3), (1) and (2),

$$f = \left(0.790\ln\left(2.915\times10^5\right) - 1.64\right)^{-2} = 0.01451$$

$$\Delta p = 0.01451\left(997\,kg/m^3 \times 1\,m^2/s^2/2\times0.25\,m\right)1000\,m = 2.89\times10^4\ kg/s^2\cdot m\ = 0.289\,bar$$ <

$$P = 2.89\times10^4\ N/m^2\left(\pi\times0.25^2\ m^2/4\right)1\,m/s = 1418\,N\cdot m/s = 1.42\,kW$$ <

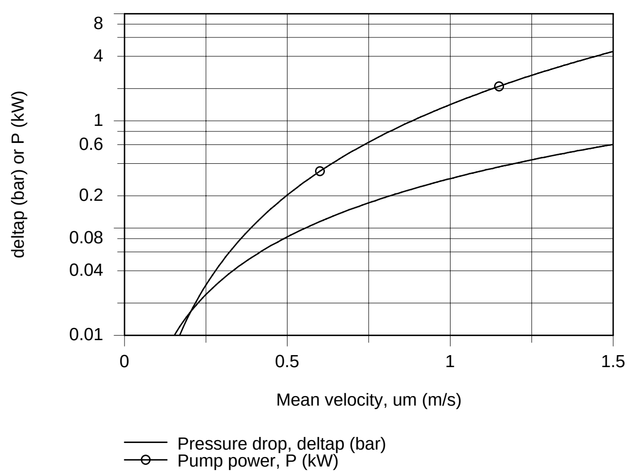
(b) *Cast iron clean surface:* with e = 260 μm, the relative roughness is $e/D = 260 \times 10^{-6}\ m/0.25\ m = 1.04 \times 10^{-3}$. From Figure 8.3 or Eq. 8.20 with $Re_D = 2.92 \times 10^5$, find f = 0.021. Hence,

$\Delta p = 0.402$ bar $\qquad\qquad$ P = 1.97 kW <

(c) *Smooth surface:* Using IHT with the expressions of part (a), the pressure drop and pump power requirement as a function of mean velocity, u_m, for the range $0.05 \le u_m \le 1.5$ m/s are computed and plotted below.

Continued...

PROBLEM 8.3 (Cont.)



The pressure drop is a strong function of the mean velocity. So is the pump power since it is proportional to both Δp and the mean velocity.

COMMENTS: (1) Note that L/D = 4000 >> ($x_{fd,h}$/D) ≈ 10 for turbulent flow and the assumption of fully developed conditions is justified.

(2) Surface fouling results in increased surface roughness and increases operating costs through increasing pump power requirements.

(3) The *IHT Workspace* used to generate the graphical results follows.

```
// Pressure drop:
deltap = f * rho * um^2 * L / ( 2 * D )          // Eq (1); Eq 8.22a
deltap_bar = deltap / 1.00e5                     // Conversion, Pa to bar units
Power = deltap * ( pi * D^2 / 4 ) * um           // Eq (2); Eq 8.22b
Power_kW = Power / 1000                          // Useful for scaling graphical result

// Reynolds number and friction factor:
ReD = um * D / nu                                // Eq (3)
f =  (0.790 * ln (ReD) - 1.64 ) ^ (-2)           // Eq (4); Eq 8.21, smooth surface condition

// Properties Tool - Water:
// Water property functions :T dependence, From Table A.6
// Units: T(K), p(bars);
x = 0                          // Quality (0=sat liquid or 1=sat vapor)
rho = rho_Tx("Water",Tm,x)     // Density, kg/m^3
nu = nu_Tx("Water",Tm,x)       // Kinematic viscosity, m^2/s

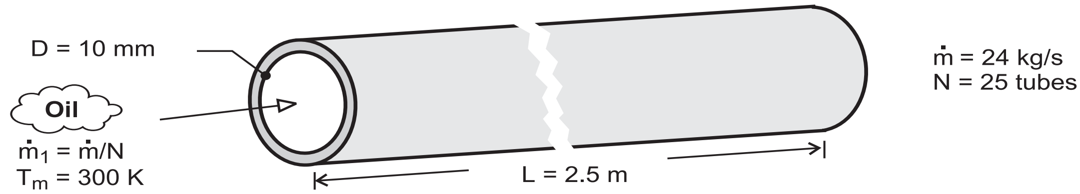
// Assigned variables:
um = 1                         // Mean velocity, m/s
Tm = 300                       // Mean temperature, K
D = 0.25                       // Tube diameter, m
L = 1000                       // Tube length, m
```

PROBLEM 8.4

KNOWN: Number, diameter and length of tubes and flow rate for an engine oil cooler.

FIND: Pressure drop and pump power (a) for flow rate of 24 kg/s and (b) as a function of flow rate for the range $10 \le \dot{m} \le 30$ kg/s.

SCHEMATIC:



ASSUMPTIONS: (1) Fully developed flow throughout the tubes.

PROPERTIES: *Table A.5*, Engine oil (300 K): $\rho = 884$ kg/m^3, $\mu = 0.486$ kg/s·m.

ANALYSIS: (a) Considering flow through a single tube, find

$$Re_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4(24\,\text{kg/s})}{25\pi(0.010\,\text{m})0.486\,\text{kg/s}\cdot\text{m}} = 251.5 \quad (1)$$

Hence, the flow is laminar and from Equation 8.19,

$$f = \frac{64}{Re_D} = \frac{64}{251.5} = 0.2545. \quad (2)$$

With

$$u_m = \frac{\dot{m}_1}{\rho\left(\pi D^2/4\right)} = \frac{(24/25)\,\text{kg/s}(4)}{\left(884\,\text{kg/m}^3\right)\pi(0.010\,\text{m})^2} = 13.8\ \text{m/s} \quad (3)$$

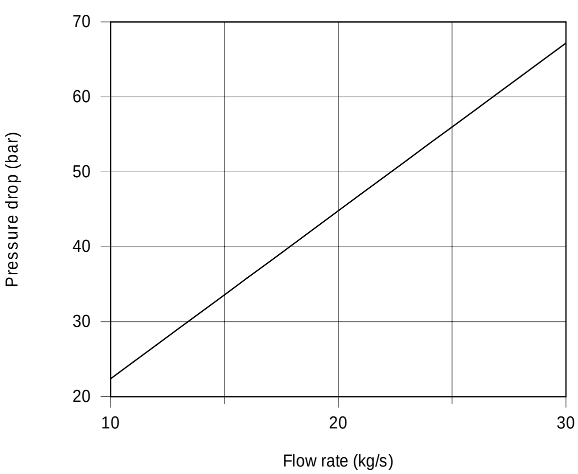
Equation 8.22a yields

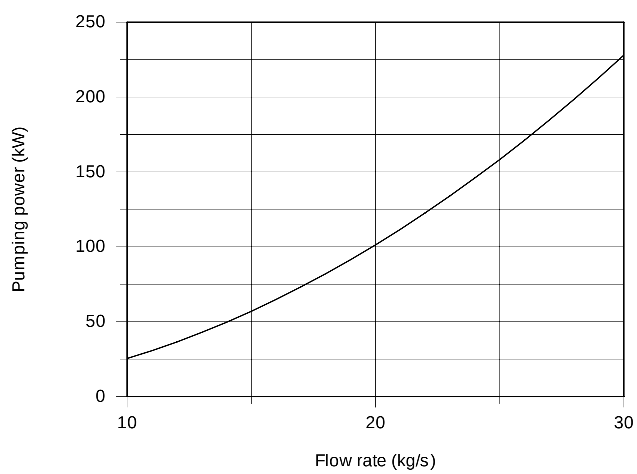
$$\Delta p = f\,\frac{\rho u_m^2}{2D}L = 0.2545\frac{\left(884\,\text{kg/m}^3\right)(13.8\,\text{m/s})^2}{2(0.010\,\text{m})}2.5\,\text{m} = 5.38\times10^6\ \text{N/m}^2 = 53.8\ \text{bar} \quad (4) <$$

The pump power requirement from Equation 8.22b,

$$P = \Delta p \cdot \dot{V} = \Delta p \cdot \frac{\dot{m}}{\rho} = 5.38\times10^6\ \text{N/m}^2\ \frac{24\,\text{kg/s}}{884\,\text{kg/m}^3} = 1.459\times10^5\ \text{N·m/s} = 146\ \text{kW}. \quad (5) <$$

(b) Using IHT with the expressions of part (a), the pressure drop and pump power requirement as a function of flow rate, $\dot{m}$, for the range $10 \le \dot{m} \le 30$ kg/s are computed and plotted below.





Continued...

PROBLEM 8.4 (Cont.)

In the plot above, note that the pressure drop is linear with the flow rate since, from Eq. (2), the friction factor is inversely dependent upon mean velocity. The pump power, however, is quadratic with the flow rate.

COMMENTS: (1) If there is a hydrodynamic entry region, the average friction factor for the entire tube length would exceed the fully developed value, thereby increasing Δp and P.

(2) The *IHT Workspace* used to generate the graphical results follows.

```
/* Results: base case, part (a)

rho = rho_T("Engine Oil",Tm)          // Density, kg/m^3
mu = mu_T("Engine Oil",Tm)            // Viscosity,  N·s/m^2
```

PROBLEM 8.5

KNOWN: The x-momentum equation for fully developed laminar flow in a parallel-plate channel

$$\frac{dp}{dx} = constant = \mu \frac{d^2 u}{dy^2}$$

FIND: Following the same approach as for the circular tube in Section 8.1: (a) Show that the velocity profile, *u(y)*, is parabolic of the form

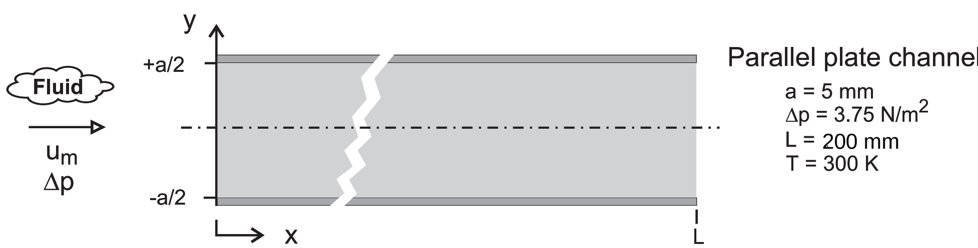
$$u(y) = \frac{3}{2} u_m \left[1 - \frac{y^2}{(a/2)^2} \right]$$

where u_m is the mean velocity expressed as

$$u_m = \frac{a^2}{12\mu}\left(-\frac{dP}{dx} \right)$$

and $-dp/dx = \Delta p/L$ where Δp is the pressure drop across the channel of length L; (b) Write the expression defining the friction factor, f, using the hydraulic diameter as the characteristic length, D_h; What is the hydraulic diameter for the parallel-plate channel? (c) The friction factor is estimated from the expression $f = C/Re_{D_h}$ where C depends upon the flow cross-section as shown in Table 8.1; What is the coefficient C for the parallel-plate channel ($b/a \to \infty$) ? (d) Calculate the mean air velocity and the Reynolds number for air at atmospheric pressure and 300 K in a parallel-plate channel with separation of 5 mm and length of 100 mm subjected to a pressure drop of Δp = 3.75 N/m^2; Is the assumption of fully developed flow reasonable for this application? If not, what effect does this have on the estimate for u_m?

SCHEMATIC:



ASSUMPTIONS: (1) Fully developed laminar flow, (2) Parallel-plate channel, a << b.

PROPERTIES: *Table A-4*, Air (300 K, 1 atm): $\mu = 184.6 \times 10^{-7}$ N·s/m^2, $\nu = 15.89 \times 10^{-6}$ m^2/s.

ANALYSIS: (a) The x-momentum equation for fully developed laminar flow is

$$\mu\left(\frac{d^2u}{dy^2}\right) = \frac{dp}{dx} = \text{constant} \qquad (1)$$

Since the longitudinal pressure gradient is constant, separate variables and integrate twice,

$$\frac{d}{dy}\left(\frac{du}{dy}\right) = \frac{1}{\mu}\left(\frac{dp}{dx}\right) \qquad \frac{du}{dy} = \frac{1}{\mu}\left(\frac{dp}{dx}\right)y + C_1$$

$$u = \frac{1}{2\mu}\left(\frac{dp}{dx}\right)y^2 + C_1 y + C_2$$

Continued …

PROBLEM 8.5 (Cont.)

The integration constants are determined from the boundary conditions,

$$\left.\frac{du}{dy}\right|_{y=0} = 0 \qquad\qquad u(a/2) = 0$$

to find

$$C_1 = 0 \qquad\qquad C_2 = -\frac{1}{2\mu}\left(\frac{dp}{dx}\right)(a/2)^2$$

giving

$$u(y) = -\frac{(a/2)^2}{2\mu}\left(\frac{dp}{dx}\right)\left[1 - \frac{y^2}{(a/2)^2}\right] \qquad (2)$$

The mean velocity is

$$u_m = \frac{2}{a}\int_0^{a/2} u(y)\,dy = -\frac{2}{a}\frac{(a/2)^2}{2\mu}\left(\frac{dp}{dx}\right)\left[y - \frac{y^3/3}{(a/2)^2}\right]_0^{a/2}$$

$$u_m = \frac{a^2}{12\mu}\left(-\frac{dp}{dx}\right) \qquad (3)$$

Substituting Eq. (3) for dp/dx into Eq. (2) find the velocity distribution in terms of the mean velocity

$$u(y) = \frac{3}{2}u_m\left[1 - \frac{y^2}{(a/2)^2}\right] \qquad < \quad (4)$$

(b) The friction factor follows from its definition, Eq. 8.16,

$$f = \frac{-(dp/dx)D_h}{\rho \cdot u_m^2/2} \qquad (5)$$

where the hydraulic diameter for the channel using Eq. 8.66 is

$$D_h = \frac{4 \cdot A_c}{P} = \frac{4(a \times b)}{2(a+b)} = 2a \qquad < \quad (6)$$

since a << b.

(c) Substituting for the pressure gradient, Eq. (3), and rearranging, find using Eq. (6),

$$f = \frac{u_m}{a^2/12\mu}\frac{D_h}{\rho u_m^2/2} = \frac{96}{u_m D_h/\nu} = \frac{96}{Re_{D_h}} \qquad < \quad (7)$$

where the Reynolds number is

$$Re_{D_h} = u_m D_h/\nu \qquad (8)$$

Continued …

PROBLEM 8.5 (Cont.)

This result is in agreement with Table 8.1 for the cross-section with b/a $\rightarrow \infty$ where

$C = 96.$ <

(d) For the conditions shown in the schematic, with air properties evaluated at 300 K, using Eqs. (3) and (8), find

$$u_m = \frac{(0.005\text{m})^2}{12 \times 184.6 \times 10^{-7}\ \text{N}\cdot\text{s/m}^2}\left(\frac{3.75\text{N/m}^2}{0.200\text{m}}\right) = 2.12\text{m/s}$$

$$\text{Re}_D = \frac{2.12\text{m/s} \times 2 \times 0.005\text{m}}{15.89 \times 10^{-6}\ \text{m}^2/\text{s}} = 1332$$

The flow is laminar since $\text{Re}_{Dh} < 2300$, and from Eq. 8.3, the laminar entry length is

$$\left.\left(\frac{x_{fd,h}}{D_h}\right)\right|_{lam} = 0.05\,\text{Re}_{Dh}$$

$$x_{fd,h} = 2 \times 0.005\text{m} \times 0.05 \times 1332 = 0.67\text{m}$$

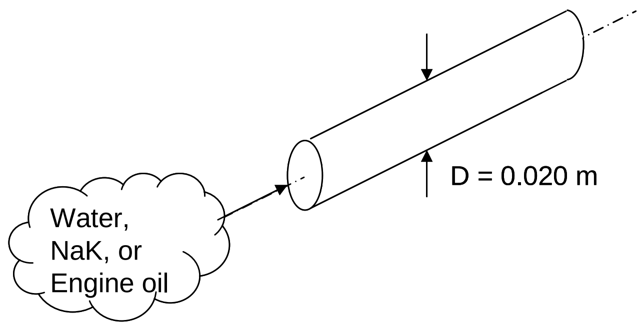
We conclude that the flow is not fully developed, and the friction factor in the entry region will be higher than for fully developed conditions. Hence, for the same pressure drop, the mean velocity will be less than our estimate.

PROBLEM 8.6

KNOWN: Water, engine oil and NaK flowing in a 20 mm diameter tube, temperature of the fluids.

FIND: (a) The mean velocity as well as hydrodynamic and thermal entrance lengths, for a flow rate of 0.01 kg/s and mean temperature of 366 K, (b) The mass flow rate as well as hydrodynamic and thermal entrance lengths for water and oil at a mean velocity of 0.02 m/s at mean temperatures of 300 and 400 K.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties.

PROPERTIES:

Liquid	T(K)	Table	$\rho(kg/m^3)$	$\mu(N \cdot s/m^2)$	$\nu(m^2/s)$	Pr
Water	300	A.6	997	855×10^{-6}	-	5.83
	366	A.6	963	303×10^{-6}	-	1.89
	400	A.6	937	217×10^{-6}	-	1.34
Oil	300	A.5	884	48.6×10^{-2}	-	6400
	366	A.5	844	2.12×10^{-2}	-	338
	400	A.5	825	0.874×10^{-2}	-	152
NaK	366	A.7	849	-	5.797×10^{-7}	0.019

ANALYSIS: (a) The mean velocity is given by

$$u_m = \dot{m}/\rho A_c = 0.01\ \text{kg/s}/\left[\rho\pi(0.020\text{m})^2/4\right] = 31.8\ \text{kg/s}\cdot\text{m}^2/\rho \qquad (1)$$

The Reynolds number is

$$Re_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4 \times 0.01\ \text{kg/s}}{\pi(0.020\ \text{m})\mu} = \frac{0.636\ \text{kg/s}\cdot\text{m}}{\mu} \qquad (2)$$

The hydrodynamic entrance length is

$$x_{fd,h} = 0.05 Re_D D = 0.05 \times \frac{0.636\ \text{kg/s}\cdot\text{m}}{\mu} \times (0.020\ \text{m})$$

$$= \frac{636 \times 10^{-6}\ \text{kg/s}\cdot\text{m}}{\mu} \qquad (3)$$

Continued…

PROBLEM 8.6 (Cont.)

The thermal entrance length is

$$x_{fd,t} = 0.05 Re_D D Pr = x_{fd,h} Pr$$

$$= \frac{636 \times 10^{-6}\ \text{kg/s}\cdot\text{m}}{\mu} Pr \qquad (4)$$

Solving Equations (1), (3) and (4) yields <

Liquid	u_m (m/s)	$x_{fd,h}$ (m)	$x_{fd,t}$ (m)
water	0.033	2.1	3.97
engine oil	0.038	0.030	10.1
NaK	0.037	1.3	0.025

where, for the NaK, μ is found from the definition

$$\mu = \nu\rho = 5.797 \times 10^{-7} \text{m}^2/\text{s} \times 849\ \text{kg/m}^3 = 492 \times 10^{-6} \text{N}\cdot\text{s/m}^2$$

(b) The mass flow rate is given by

$$\dot{m} = \rho A_c u_m = \frac{0.02\ \text{m/s} \times \pi \times (0.020\ \text{m})^2}{4} \rho = 6.28 \times 10^{-6} \frac{\text{m}^3}{\text{s}} \rho \qquad (5)$$

The Reynolds number is

$$Re_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 6.28 \times 10^{-6}\ \text{m}^3/\text{s} \times \rho}{\pi (0.020\ \text{m}) \mu} = 400 \times 10^{-6}\ \text{m}^2/\text{s} \times (\rho/\mu) \qquad (6)$$

The hydrodynamic entrance length is

$$x_{fd,h} = 0.05 Re_D D = 0.05 \times 400 \times 10^{-6}\ \text{m}^2/\text{s} \times 0.02\ \text{m}\ (\rho/\mu)$$

$$x_{fd,h} = 400 \times 10^{-9}\ \text{m}^3/\text{s}\ (\rho/\mu) \qquad (7)$$

The thermal entrance length is

$$x_{fd,t} = x_{fd,h} Pr = 400 \times 10^{-9}\ \text{m}^3/\text{s}\ (\rho/\mu)\ Pr \qquad (8)$$

Solving Equations (5), (7) and (8) yields <

Liquid	T (k)	$\dot{m}$ (kg/s)	$x_{fd,h}$ (m)	$x_{fd,t}$ (m)
Water	300	0.0063	0.464	2.72
Water	400	0.0059	1.72	2.30
Engine Oil	300	0.0056	7.27×10^{-4}	4.65
Engine Oil	400	0.0052	37.7×10^{-3}	5.74

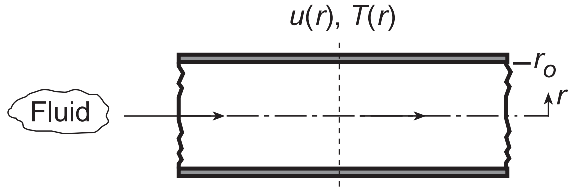
COMMENTS: (1) As the momentum and thermal diffusivities approach similar values ($Pr \rightarrow 1$) $x_{fd,h}/x_{fd,t} \rightarrow 1$. (2) Note the variation of $x_{fd,h}/x_{fd,t}$ with Pr for large and small values of the Prandtl number. (c) The Reynolds number associated with the oil is very small. Buoyancy forces are likely to be significant and may induce secondary fluid motion which, in turn, may increase the convection heat transfer coefficients. We will treat buoyancy effects in Chapter 9.

PROBLEM 8.7

KNOWN: Velocity and temperature profiles for laminar flow in a tube of radius r_o = 10 mm.

FIND: Mean (or bulk) temperature, T_m, at this axial position.

SCHEMATIC:



ASSUMPTIONS: (1) Laminar incompressible flow, (2) Constant properties.

ANALYSIS: The prescribed velocity and temperature profiles, (m/s and K, respectively) are

$$u(r) = 0.1\,[1-(r/r_o)^2] \qquad T(r) = 344.8 + 75.0\,(r/r_o)^2 - 18.8\,(r/r_o)^4 \qquad (1,2)$$

For incompressible flow with constant c_v in a circular tube, from Eq. 8.26, the mean temperature and u_m, the mean velocity, from Eq. 8.8 are, respectively,

$$T_m = \frac{2}{u_m r_o^2}\int_0^{r_o} u(r)\cdot T(r)\cdot r\cdot dr \qquad u_m = \frac{2}{r_o^2}\int_0^{r_o} u(r)\cdot r\cdot dr \qquad (3,4)$$

Substituting the velocity profile, Eq. (1), into Eq. (4) and integrating, find

$$u_m = \frac{2}{r_o^2} r_o^2 \int_0^1 0.1\left[1-(r/r_o)^2\right](r/r_o)\,d(r/r_o) = 2\left\{0.1\left[\frac{1}{2}(r/r_o)^2 - \frac{1}{4}(r/r_o)^4\right]\right\}_0^1 = 0.05\,m/s$$

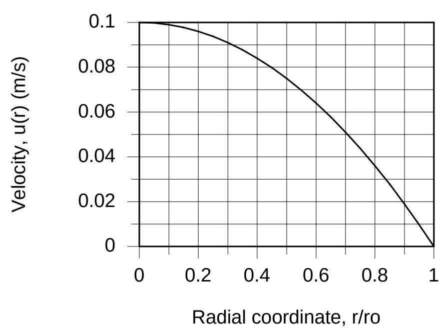
Substituting the profiles and u_m into Eq. (3), find

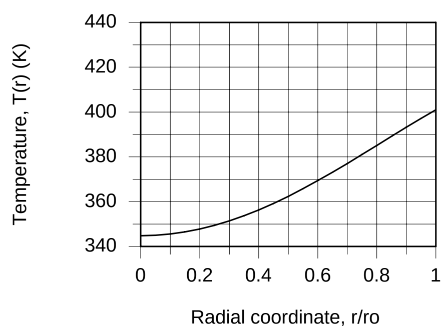
$$T_m = \frac{2}{(0.05\,m/s)r_o^2} r_o^2 \int_0^1 \left\{0.1\left[1-(r/r_o)^2\right]\right\}\left\{344.8 + 75.0(r/r_o)^2 - 18.8(r/r_o)^4\right\}\cdot(r/r_o)\cdot d(r/r_o)$$

$$T_m = 4\int_0^1 \left\{\left[344.8(r/r_o) + 75.0(r/r_o)^3 - 18.8(r/r_o)^5\right] - \left[344.8(r/r_o)^3 + 75.0(r/r_o)^5 - 18.8(r/r_o)^7\right]\right\} d(r/r_o)$$

$$T_m = 4\{[172.40 + 18.75 - 3.13] - [86.20 + 12.50 - 2.35]\} = 367\,K$$ <

The velocity and temperature profiles appear as shown below. Do the values of u_m and T_m found above compare with their respective profiles as you thought? Is the fluid being heated or cooled?



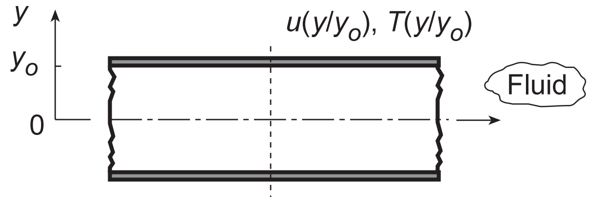


PROBLEM 8.8

KNOWN: Velocity and temperature profiles for laminar flow in a parallel plate channel.

FIND: Mean velocity, u_m, and mean (or bulk) temperature, T_m, at this axial position. Plot the velocity and temperature distributions. Comment on whether values of u_m and T_m appear reasonable.

SCHEMATIC:



ASSUMPTIONS: (1) Laminar incompressible flow, (2) Constant properties.

ANALYSIS: The prescribed velocity and temperature profiles (m/s and °C, respectively) are

$$u(y) = 0.75\left[1-(y/y_o)^2\right] \qquad T(y) = 5.0 + 95.66(y/y_o)^2 - 47.83(y/y_o)^4 \quad (1,2)$$

The mean velocity, u_m, follows from its definition, Eq. 8.7,

$$\dot{m} = \rho A_c u_m = \rho \int_{A_c} u(y) \cdot dA_c$$

where the flow cross-sectional area is $dA_c = 1 \cdot dy$, and $A_c = 2y_o$,

$$u_m = \frac{1}{A_c}\int_{A_c} u(y) \cdot dy = \frac{1}{2y_o}\int_{-y_o}^{+y} u(y) dy \quad (3)$$

$$u_m = \frac{1}{2y_o} \cdot y_o \int_{-1}^{+1} 0.75\left[1-(y/y_o)^2\right] d(y/y_o)$$

$$u_m = 1/2\left\{0.75\left[(y/y_o) - 1/3(y/y_o)^3\right]\right\}_{-1}^{+1}$$

$$u_m = 1/2 \times 0.75\{[1-1/3]-[-1+1/3]\} = 1/2 \times 0.75 \times 4/3 = 2/3 \times 0.75 = 0.50\,\text{m/s}$$ <

The mean temperature, T_m, follows from its definition, Eq. 8.25,

$$\dot{E}_t = \dot{m} c_v T_m \qquad \text{where} \qquad \dot{m} = \rho A_c u_m$$

$$\rho A_c u_m c_p T_m = \rho c_p \int_{A_c} u(y) \cdot T(y) dA_c$$

Hence, substituting velocity and temperature profiles,

$$T_m = \frac{1}{u_m A_c}\int_{-y_o}^{+y_o} u(y) \cdot T(y) dy \quad (4)$$

$$T_m = \frac{1}{(0.5\,\text{m/s})2y_o} y_o \int_{-1}^{+1}\left\{0.75\left[1-(y/y_o)^2\right]\right\}\left\{5.0 + 95.66(y/y_o)^2 - 47.83(y/y_o)^4\right\} d(y/y_o)$$

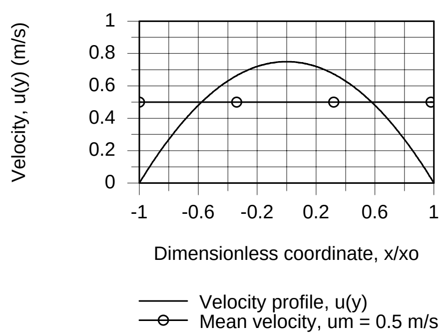
$$T_m = \frac{0.75}{0.5 \times 2}\left\{\left[5(y/y_o) + 31.89(y/y_o)^3 - 9.57(y/y_o)^5\right] - \left[1.67(y/y_o)^3 + 19.13(y/y_o)^5 - 6.83(y/y_o)^7\right]\right\}_{-1}^{+1}$$

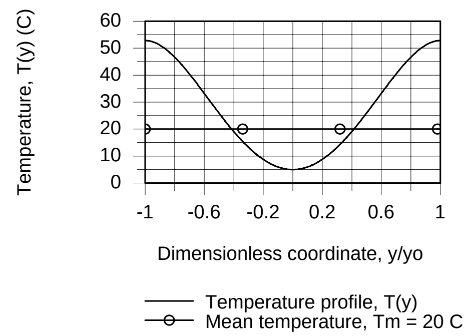
$$T_m = \frac{0.75}{0.5 \times 2}\{[27.32 - 13.97] - [-27.32 - (-13.97)]\} = 20.0^\circ\text{C}$$ <

Continued...

PROBLEM 8.8 (Cont.)

The velocity and temperature profiles along with the u_m and T_m values are plotted below.





For the velocity profile, the mean velocity is 2/3 that of the centerline velocity, $u_m = 2u(0)/3$. Note that the areas above and below the u_m line appear to be equal. Considering the temperature profile, we'd expect the mean temperature to be closer to the centerline temperature since the velocity profile weights the integral toward the centerline.

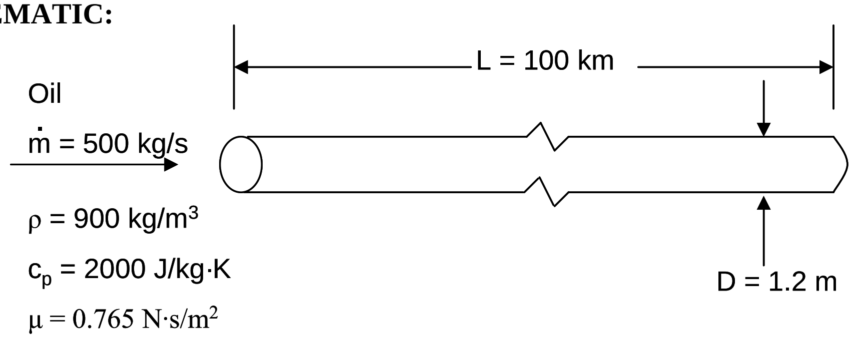
COMMENTS: The integrations required to obtain u_m and T_m, Eqs. (3) and (4), could also be performed using the intrinsic function *INTEGRAL (y,x)* in the *IHT Workspace*.

PROBLEM 8.9

KNOWN: Flow rate and properties of oil flowing in pipe. Dimensions of pipe.

FIND: Pressure drop, flow work, temperature rise caused by flow work.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Incompressible flow, (3) Negligible kinetic and potential energy changes, (4) No work *other than* flow work.

ANALYSIS: We begin by determining whether the flow is laminar or turbulent. From Equation 8.6

$$Re_d = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 500 \text{ kg/s}}{\pi \times 1.2 \text{ m} \times 0.765 \text{ N}\cdot\text{s/m}^2} = 693$$

and the flow is laminar. The friction factor is given by Equation 8.19,

$f = 64/Re_D$

and the pressure drop by Equation 8.22a,

$$\Delta p = f\frac{\rho u_m^2}{2D}(x_2 - x_1) = 32\frac{\rho u_m^2}{DRe_D}L$$

where u_m can be found from $\dot{m} = \rho u_m A_c$:

$$u_m = \frac{\dot{m}}{\rho A_c} = \frac{\dot{m}}{\rho \pi D^2/4} = \frac{4 \times 500 \text{ kg/s}}{900 \text{ kg/m}^3 \times \pi \times (1.2 \text{ m})^2} = 0.491 \text{ m/s}$$

Thus

$$p_{in} - p_{out} = \Delta p = \frac{32 \times 900 \text{ kg/m}^3 \times (0.491 \text{ m/s})^2 \times 100{,}000 \text{ m}}{1.2 \text{ m} \times 693} = 8.4 \times 10^5 \text{ Pa}$$

$$\Delta p = 0.84 \text{ MPa}$$ <

The flow work is then found from its definition (see discussion leading to Equation 1.11d),

$$\dot{W}_{flow} = \frac{\dot{m}}{\rho}(p_{in} - p_{out}) = 500 \text{ kg/s} \times 0.84 \text{ MPa}/900 \text{ kg/m}^3$$

$$= 0.46 \text{ MW}$$ <

Finally, with reference to Equation 1.12d, the portion of the temperature rise due to flow work is given by

$$\dot{m}c_p\Delta T_{flow} = \frac{\dot{m}}{\rho}(p_{in} - p_{out}) = \dot{W}_{flow}$$

$$\Delta T_{flow} = \dot{W}_{flow}/\dot{m}c_p = 0.46 \text{ MW}/(500 \text{ kg/s} \times 2000 \text{ J/kg}\cdot\text{K})$$

$$= 0.46°\text{C}$$ <

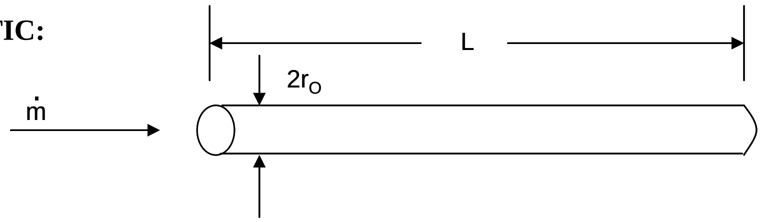
COMMENTS: Despite the long length of pipeline and high viscosity of the oil, which results in a large pressure drop, the temperature rise due to the flow work is quite small.

PROBLEM 8.10

KNOWN: Thermal energy equation describing laminar, fully developed flow in a circular pipe with viscous dissipation.

FIND: (a) Left hand side of equation integrated over the pipe volume, (b) viscous dissipation term integrated over the same volume, (c) temperature rise caused by viscous dissipation.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Laminar, (3) Fully-developed.

ANALYSIS: (a) The thermal energy equation is given as

$$\rho\, c_p\, u\, \frac{\partial T}{\partial x} = \frac{k}{r}\frac{\partial}{\partial r}\left(r\frac{\partial T}{\partial r}\right) + \mu\left(\frac{du}{dr}\right)^2$$

where u is given by Equation 8.15,

$$u = 2\, u_m\left[1 - (r/r_0)^2\right]$$

Integrating the advection term on the left-hand side over a section of the pipe of length L, we have

$$\text{Adv.} = \int_0^L \int_{A_c} \rho\, c_p\, u\, \frac{\partial T}{dx}\, dA_c\, dx$$

$$= \int_0^L \frac{d}{dx}\left[\int_{A_c} \rho\, c_p\, u\, T\, dA_c\right] dx$$

From Equation 8.25, the term in square brackets is $\dot{m} c_p T_m$, thus

$$\text{Adv.} = \int_0^L \dot{m}\, c_p \frac{dT_m}{dx}\, dx = \dot{m}\, c_p\, (T_{m,o} - T_{m,i})$$ <

which coincides with the right-hand side of Equation 8.34.

(b) Integrating the viscous dissipation term, we have

$$\text{Visc. Diss.} = \int_0^L \int_{A_c} \mu\left(\frac{du}{dr}\right)^2 dA_c\, dx$$

$$= \int_0^L 2\,\pi\,\mu \int_0^{r_o} \left(\frac{du}{dr}\right)^2 r\, dr\, dx$$

$$= 2\,\pi\,\mu\, L \int_0^{r_o} 16\, u_m^2 \frac{r^2}{r_o^4}\, r\, dr$$

$$= 32\,\pi\,\mu\, L\, u_m^2 \left.\frac{r^2}{4r_o^4}\right|_0^{r_o} = 8\,\pi\,\mu\, L\, u_m^2$$ <

Continued...

(c) Using the values from Problem 8.9,

$$\dot{m}\, c_p\, \Delta T_{v.d.} = 8\,\pi\,\mu\, L\, u_m^2$$

$$\Delta T_{v.d.} = 8\,\pi\,\mu\, L\, u_m^2 / \dot{m}\, c_p$$

where $u_m = \dot{m}/\rho A_c$. Thus

$$\Delta T_{v.d.} = \frac{8\,\pi\,\mu\, L\, \dot{m}}{\rho^2\, c_p\, A_c^2}$$

$$= \frac{8\pi \times 0.765\ \mathrm{N\cdot s/m^2} \times 100{,}000\ \mathrm{m} \times 500\ \mathrm{kg/s}}{\left[(900\ \mathrm{kg/m^3})^2 \times 2000\ \mathrm{J/kg\cdot K} \times (\pi \times (1.2\ \mathrm{m})^2/4)^2\right]}$$

$$= 0.46°\mathrm{C}$$ <

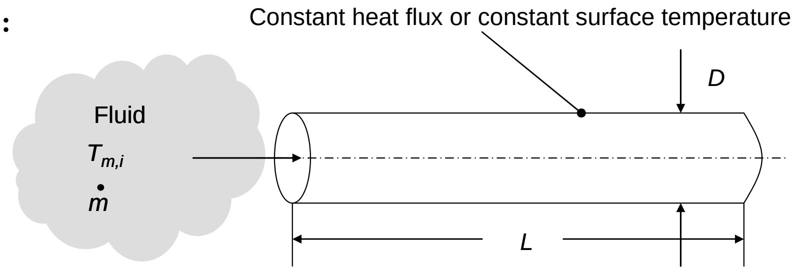
COMMENTS: (1) Even in the case of a long pipe with a highly viscous fluid, the temperature rise due to viscous dissipation is quite small. (2) The temperature rise due to viscous dissipation is identical to the temperature rise due to flow work in Problem 8.9. This is no coincidence. In fully-developed pipe flow, there is a balance between the viscous forces (friction) and the pressure drop needed to overcome them. As a result, viscous dissipation exactly equals the work done by the pressure forces (flow work). Conservation of energy can be expressed in a form that includes flow work (for example, Equation 1.12d) or in a form that includes viscous dissipation (for example, Equation 6.29), and in the case of fully-developed pipe flow they are equal.

PROBLEM 8.11

KNOWN: Mass flow rate in a circular tube, tube length and diameter, thermal conditions.

FIND: (a) Expression for $(T_s(x = L) - T_{m,i})/q$ for constant heat flux conditions, (b) $(T_s - T_{m,i})/q$ for constant surface temperature conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties.

ANALYSIS (a) From Newton's law of cooling,

$$T_s(x = L) - T_m(x = L) = q''/h \tag{1}$$

and from an energy balance on the entire tube,

$$T_m(x = L) = T_{m,i} + q/\dot{m}c_p \tag{2}$$

Combining Eqs. (1) and (2) and noting that $q = q''\pi DL$ yields

$$\frac{T_s(x = L) - T_{m,i}}{q} = \frac{1}{\pi DLh} + \frac{1}{\dot{m}c_p}$$

Substituting the expression for the local Nusselt number, $Nu_D = hD/k$ gives

$$\frac{T_s(x = L) - T_{m,i}}{q} = \frac{1}{Nu_D \pi Lk} + \frac{1}{\dot{m}c_p}$$ <

(b) From Eq. (8.41b)

$$\frac{T_s - T_m(x = L)}{T_s - T_{m,i}} = \exp\left(-\frac{\pi D\bar{h}L}{\dot{m}c_p}\right) \tag{3}$$

Combining Eqs. (2) and (3) yields

$$1 - \frac{q/\dot{m}c_p}{(T_s - T_{m,i})} = \exp\left(-\frac{\pi D\bar{h}L}{\dot{m}c_p}\right)$$

Continued…

PROBLEM 8.11 (Cont.)

which may be rearranged to yield

$$\frac{q}{\left(T_s - T_{m,i}\right)} = \dot{m}c_p\left[1 - \exp\left(-\frac{\pi D\bar{h}L}{\dot{m}c_p}\right)\right]$$

or

$$\frac{(T_s - T_{m,i})}{q} = \frac{1}{\dot{m}c_p\left[1 - \exp\left(-\frac{\pi \overline{Nu}_D kL}{\dot{m}c_p}\right)\right]}$$ <

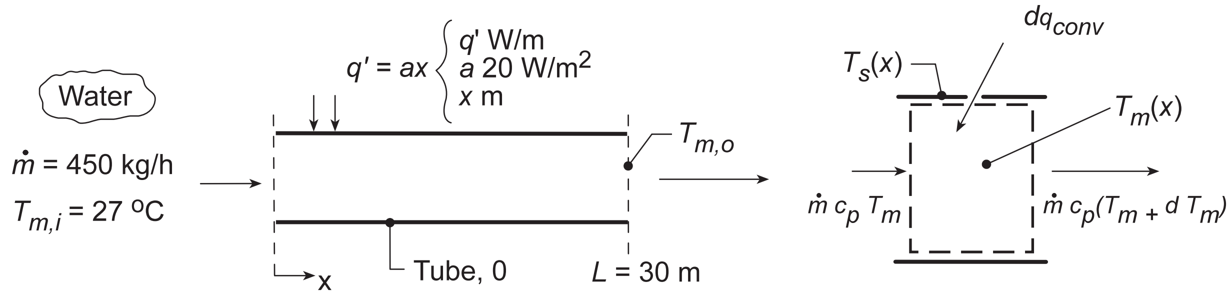
COMMENTS: (1) The ratio on the LHS is a *figure of merit* that, in many applications, is sought to be minimized. (2)The two terms on the RHS of the final expression for the constant heat flux case may be thought of as thermal resistances. The first term on the RHS is a thermal resistance associated with heat transfer between the fluid and the tube wall at the tube exit, and the second term is associated with the increase in temperature between the tube inlet and the tube exit. (3) As the argument of the exponential term increases in magnitude for the constant surface temperature expression, the mean outlet temperature approaches the surface temperature value (see Eq. 3), and the figure of merit expression reduces to Eq. (2).

PROBLEM 8.12

KNOWN: Internal flow with prescribed wall heat flux as a function of distance.

FIND: (a) Beginning with a properly defined differential control volume, the temperature distribution, $T_m(x)$, (b) Outlet temperature, $T_{m,o}$, (c) Sketch $T_m(x)$, and $T_s(x)$ for fully developed *and* developing flow conditions, and (d) Value of uniform wall flux q_s'' (instead of $q_s' = ax$) providing same outlet temperature as found in part (a); sketch $T_m(x)$ and $T_s(x)$ for this heating condition.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Incompressible liquid with negligible viscous dissipation.

PROPERTIES: *Table A.6*, Water (300 K): $c_p = 4.179$ kJ/kg·K.

ANALYSIS: (a) Applying energy conservation to the control volume above,

$$dq_{conv} = \dot{m}c_p dT_m \qquad (1)$$

where $T_m(x)$ is the mean temperature at any cross-section and $dq_{conv} = q' \cdot dx$. Hence,

$$ax = \dot{m}c_p \frac{dT_m}{dx}. \qquad (2)$$

Separating and integrating with proper limits gives

$$a\int_{x=0}^{x} x\,dx = \dot{m}c_p \int_{T_{m,i}}^{T_m(x)} dT_m \qquad T_m(x) = T_{m,i} + \frac{ax^2}{2\dot{m}c_p} \qquad (3,4) <$$

(b) To find the outlet temperature, let x = L, then

$$T_m(L) = T_{m,o} = T_{m,i} + aL^2 / 2\dot{m}c_p. \qquad (5)$$

Solving for $T_{m,o}$, we find

$$T_{m,o} = 27^\circ C + \frac{20\,W/m^2 \left(30\,m^2\right)}{2\left(450\,kg/h/\left(3600\,s/h\right)\right) \times 4179\,J/kg \cdot K} = 27^\circ C + 17.2^\circ C = 44.2^\circ C. \quad <$$

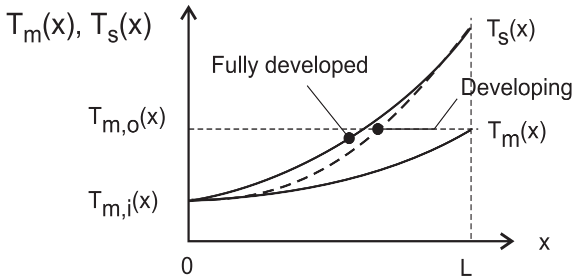
(c) For *linear wall heating*, $q_s' = ax$, the fluid temperature distribution along the length of the tube is quadratic as prescribed by Eq. (4). From the convection rate equation,

$$q_s' = h(x) \cdot \pi D \left(T_s(x) - T_m(x)\right) \qquad (6)$$

For fully developed flow conditions, h(x) = h is a constant; hence, $T_s(x) - T_m(x)$ increases linearly with x. For developing conditions, h(x) will decrease with increasing distance along the tube eventually achieving the fully developed value.

Continued...

PROBLEM 8.12 (Cont.)



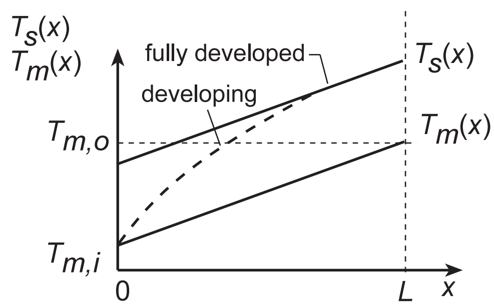
(d) For *uniform wall heat flux heating*, the overall energy balance on the tube yields

$$q = q_s''\pi DL = \dot{m}c_p\left(T_{m,o} - T_{m,i}\right)$$

Requiring that $T_{m,o}$ = 44.2°C from part (a), find

$$q_s'' = \frac{(450/3600)\,\text{kg/s} \times 4179\,\text{J/kg}\cdot\text{K}\,(44.2 - 27)\,\text{K}}{\pi D \times 30\,\text{m}} = 95.3/D\ \text{W/m}^2$$ <

where D is the diameter (m) of the tube which, when specified, would permit determining the required heat flux, q_s''. For uniform heating, Section 8.3.2, we know that $T_m(x)$ will be linear with distance. $T_s(x)$ will also be linear for fully developed conditions and appear as shown below when the flow is developing.



COMMENTS: (1) Note that c_p should be evaluated at T_m = (27 + 44)°C/2 = 309 K.

(2) Why did we show $T_s(0) = T_m(0)$ for both types of history when the flow was developing?

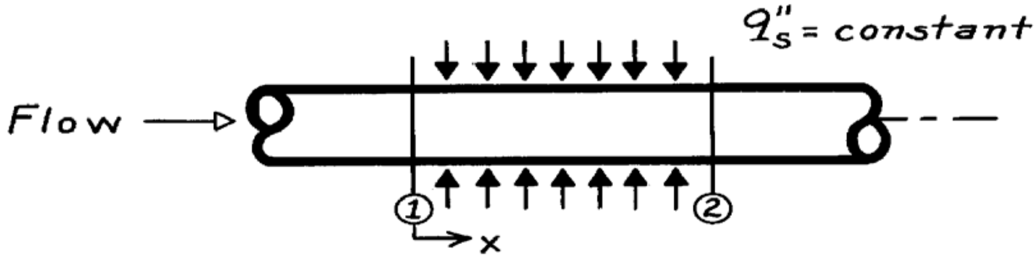
(3) Why must $T_m(x)$ be linear with distance in the case of uniform wall flux heating?

PROBLEM 8.13

KNOWN: Internal flow with constant surface heat flux, q_s''.

FIND: (a) Qualitative temperature distributions, T(x), under developing and fully-developed flow, (b) Exit mean temperature for both situations.

SCHEMATIC:



ASSUMPTIONS: (a) Steady-state conditions, (b) Constant properties, (c) Incompressible flow with negligible viscous dissipation.

ANALYSIS: Based upon the analysis leading to Eq. 8.39, note for the case of constant surface heat flux conditions,

$$\frac{dT_m}{dx} = \text{constant.}$$

Hence, regardless of whether the hydrodynamic or thermal boundary layer is fully developed, it follows that

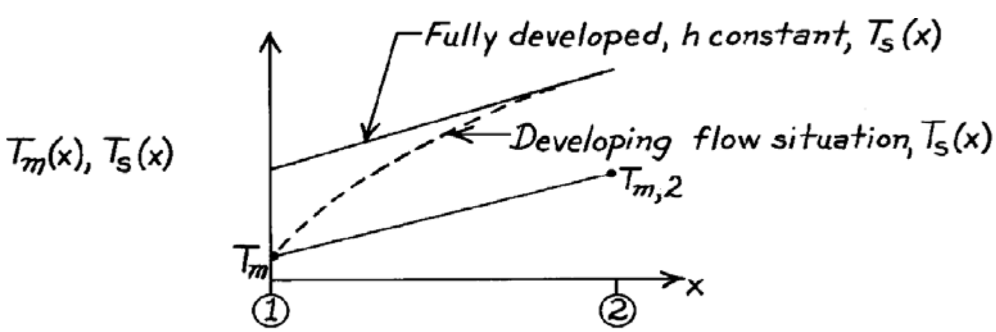
$T_m(x)$ is linear and

$T_{m,2}$ will be the same for all flow conditions. <

The surface heat flux can also be written, using Eq. 8.27, as

$$q_s'' = h\left[T_s(x) - T_m(x)\right].$$

Under fully-developed flow and thermal conditions, $h = h_{fd}$ is a constant. When flow is developing $h > h_{fd}$. Hence, the temperature distributions appear as below.



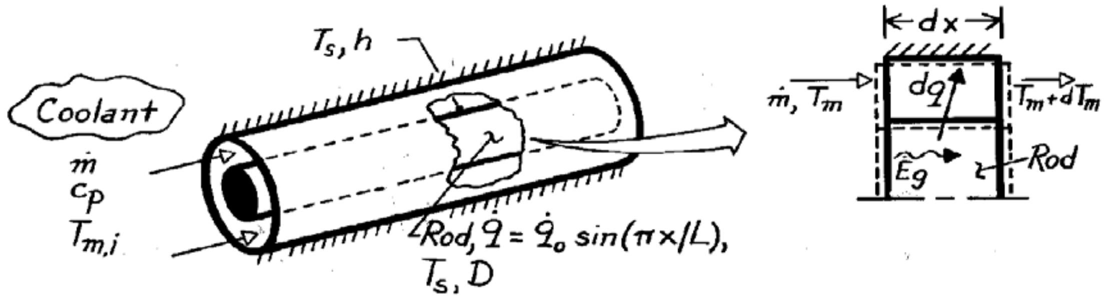
<

PROBLEM 8.14

KNOWN: Geometry and coolant flow conditions associated with a nuclear fuel rod. Axial variation of heat generation within the rod.

FIND: (a) Axial variation of local heat flux and total heat transfer rate, (b) Axial variation of mean coolant temperature, (c) Axial variation of rod surface temperature and location of maximum temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant fluid properties, (3) Uniform surface convection coefficient, (4) Negligible axial conduction in rod and fluid, (5) Incompressible liquid with negligible viscous dissipation, (6) Outer surface is adiabatic.

ANALYSIS: (a) Performing an energy balance for a control volume about the rod,

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = 0 \qquad -dq + \dot{E}_g = 0$$

or

$$-q''(\pi \, D \, dx) + \dot{q}_o \sin(\pi \, x/L)\left(\pi \, D^2/4\right) dx = 0 \qquad q'' = \dot{q}_o (D/4) \sin(\pi \, x/L). \qquad <$$

The total heat transfer rate is then

$$q = \int_0^L q'' \, \pi \, D \, dx = \left(\pi \, D^2/4\right)\dot{q}_o \int_0^L \sin(\pi \, x/L) \, dx$$

$$q = \frac{\pi \, D^2}{4} \, \dot{q}_o \left(-\frac{L}{\pi}\cos\frac{\pi \, x}{L}\right)\Bigg|_0^L = \frac{D^2 \dot{q}_o L}{4}(1+1)$$

$$q = \frac{D^2 L}{2}\dot{q}_o. \qquad (1) \qquad <$$

(b) Performing an energy balance for a control volume about the coolant,

$$\dot{m} \, c_p \, T_m + dq = \dot{m} \, c_p \left(T_m + dT_m\right) = 0.$$

Hence

$$\dot{m} \, c_p \, d\,T_m = dq = (\pi \, D \, dx) \, q''$$

$$\frac{d\,T_m}{dx} = \frac{\pi \, D}{\dot{m} \, c_p} \, \frac{\dot{q}_o D}{4} \, \sin\left(\frac{\pi \, x}{L}\right).$$

Continued …

PROBLEM 8.14 (Cont.)

Integrating,

$$T_m(x) - T_{m,i} = \frac{\pi D^2}{4} \frac{\dot{q}_o}{\dot{m} c_p} \int_0^x \sin \frac{\pi x}{L} dx$$

$$T_m(x) = T_{m,i} + \frac{L D^2}{4} \frac{\dot{q}_o}{\dot{m} c_p} \left[1 - \cos \frac{\pi x}{L}\right] \qquad (2)$$ <

(c) From Newton's law of cooling,

$$q'' = h(T_s - T_m).$$

Hence

$$T_s = \frac{q''}{h} + T_m$$

$$T_s = \frac{\dot{q}_o D}{4h} \sin \frac{\pi x}{L} + T_{m,i} + \frac{LD^2}{4} \frac{\dot{q}_o}{\dot{m} c_p} \left[1 - \cos \frac{\pi x}{L}\right].$$ <

To determine the location of the maximum surface temperature, evaluate

$$\frac{d T_s}{dx} = 0 = \frac{\dot{q}_o D\pi}{4hL} \cos \frac{\pi x}{L} + \frac{LD^2}{4} \frac{\dot{q}_o}{\dot{m} c_p} \frac{\pi}{L} \sin \frac{\pi x}{L}$$

or

$$\frac{1}{hL} \cos \frac{\pi x}{L} + \frac{D}{\dot{m} c_p} \sin \frac{\pi x}{L} = 0.$$

Hence

$$\tan \frac{\pi x}{L} = -\frac{\dot{m} c_p}{D h L}$$

$$x = \frac{L}{\pi} \tan^{-1}\left(-\frac{\dot{m} c_p}{D h L}\right) = x_{max}.$$ <

COMMENTS: Note from Eq. (2) that

$$T_{m,o} = T_m(L) = T_{m,i} + \frac{L D^2 \dot{q}_o}{2 \dot{m} c_p}$$

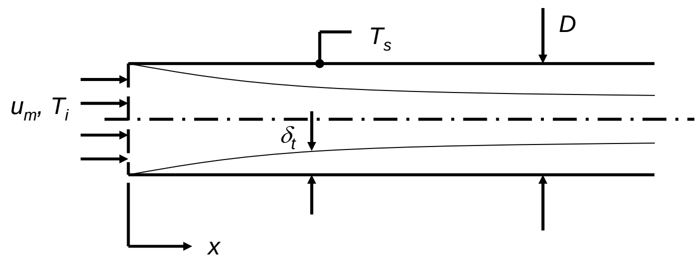
which is equivalent to the result obtained by combining Eq. (1) and Eq. 8.34.

PROBLEM 8.15

KNOWN: Laminar boundary layer development in a tube entrance.

FIND: (a) Expression for Nu_D in terms of Gz_D^{-1} and Pr. Plot of Nu_D versus Gz_D^{-1} for $Pr = 0.7$. (b) Expression for $\overline{Nu}_D$ in terms of Gz_D^{-1} and Pr. Comparison to combined entrance length correlation in the limit of small x.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties. (2) Laminar conditions.

ANALYSIS: (a) From Equation 7.23, the Nusselt number based upon the streamwise coordinate *x* is

$$Nu_x = \frac{hx}{k} = 0.332 Re_x^{1/2} Pr^{1/3} \quad (1)$$

Multiplying both sides of Equation 1 by D/x and substituting $Re_x = Re_D x/D$ yields

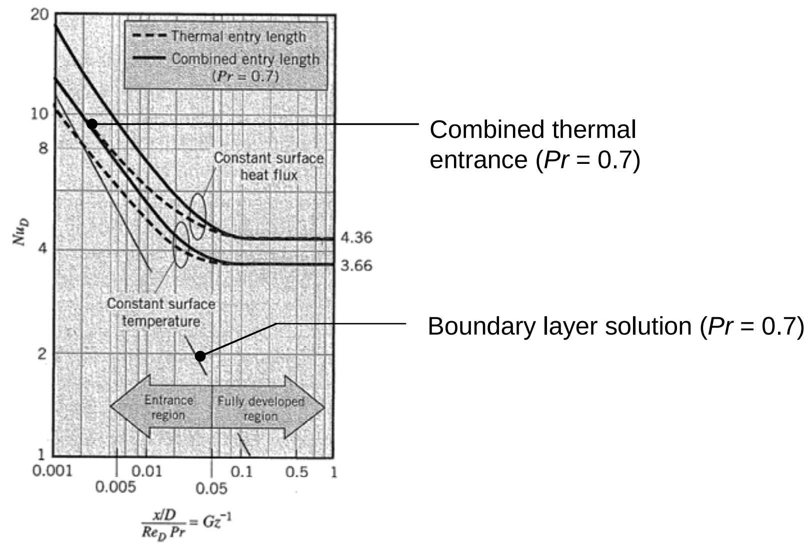
$$Nu_D = \frac{hD}{k} = 0.332\left[Re_x\left(\frac{x}{D}\right)\right]^{1/2}\left[\frac{D}{x}\right]Pr^{1/3} = 0.332\left[Re_x\left(\frac{D}{x}\right)\right]^{1/2} Pr^{1/3} \quad (2)$$

Substituting $Gz_D^{-1} = (x/D)/(Re_D Pr)$ into Equation 2 and noting that $Pr^{1/3} = Pr^{1/2} \cdot Pr^{-1/6}$ yields

$$Nu_D = 0.332\,[Gz_D^{-1}]^{-1/2}\,Pr^{-1/6}$$ <

The expression for the local Nusselt number, Nu_D with $Pr = 0.7$ is plotted below.

Continued...



(b) Equation 7.30 gives the following for the average Nusselt number:

$$\overline{Nu}_x = \frac{\overline{h}_x x}{k} = 0.664 Re_x^{1/2} Pr^{1/3}$$

Following the same steps as in part (a), this can be rewritten as

$$\overline{Nu}_D = 0.664[Gz_D^{-1}]^{-1/2} Pr^{-1/6} \qquad (3)$$

The average Nusselt number for the combined entrance length is given as

$$\overline{Nu}_D = \frac{\dfrac{3.66}{\tanh\left[2.264 Gz_D^{-1/3} + 1.7 Gz_D^{-2/3}\right]} + 0.0499 Gz_D \tanh\left(Gz_D^{-1}\right)}{\tanh\left(2.432 Pr^{1/6} Gz_D^{-1/6}\right)}$$

In the limit of small *x*, Gz_D^{-1} is also small. Furthermore, $Gz_D^{-2/3} << Gz_D^{-1/3}$ Noting that $\tanh(\varepsilon) \rightarrow \varepsilon$ as $\varepsilon \rightarrow 0$, we find

$$\overline{Nu}_D = \frac{\dfrac{3.66}{\tanh\left[2.264 Gz_D^{-1/3} + 1.7 Gz_D^{-2/3}\right]} + 0.0499 Gz_D \tanh\left(Gz_D^{-1}\right)}{\tanh\left(2.432 Pr^{1/6} Gz_D^{-1/6}\right)}$$

$$\rightarrow \frac{\dfrac{3.66}{2.264 Gz_D^{-1/3}} + 0.0499 Gz_D Gz_D^{-1}}{2.432 Pr^{1/6} Gz_D^{-1/6}} \rightarrow \frac{3.66}{2.264 \times 2.432 Gz_D^{-1/6} Gz_D^{-1/3} Pr^{1/6}} = 0.665[Gz_D^{-1}]^{-1/2} Pr^{-1/6}$$

This is in excellent agreement with Eq. (3).

Continued...

PROBLEM 8.15 (Cont.)

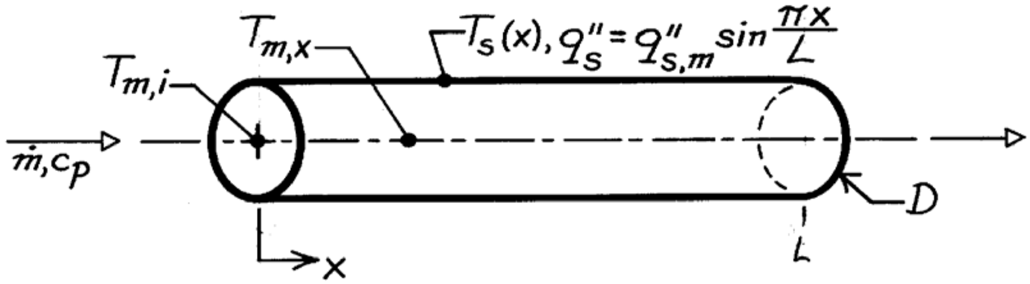
COMMENT: The combined thermal entrance length solution and the boundary layer solution based upon the results of Chapter 7 exhibit asymptotic behavior at small inverse Graetz numbers. Small values of Gz_D^{-1} correspond to the locations where the boundary layer is very thin.

PROBLEM 8.16

KNOWN: Axial variation of surface heat flux for flow through a tube.

FIND: Axial variation of fluid and surface temperatures.

SCHEMATIC:



ASSUMPTIONS: (1) Convection coefficient is independent of x, (2) Applicability of Eq. 8.34.

ANALYSIS: Since Equation 8.37 is applicable,

$$\frac{dT_m}{dx} = \frac{q''_s P}{\dot{m}\, c_p} = \frac{(\pi\, D) q''_{s,m} \sin(\pi\, x/L)}{\dot{m}\, c_p}$$

Separating variables and integrating from x = 0

$$\int_{T_{m,i}}^{T_{m,o}} dT_m = \frac{\pi D q''_{s,m}}{\dot{m}\, c_p} \int_0^x \sin \frac{\pi\, x}{L}\, dx$$

$$T_m(x) - T_{m,i} = -\frac{L D q''_{s,m}}{\dot{m}\, c_p} \cos \frac{\pi\, x}{L} \Big|_0^x$$

$$T_m(x) = T_{m,i} + \frac{L D q''_{s,m}}{\dot{m}\, c_p} (1 - \cos\, \pi x/L).$$ <

From Newton's law of cooling, Eq. 8.27,

$$T_s(x) = (q''_s / h) + T_m(x)$$

$$T_s(x) = \frac{q''_{s,m}}{h} \sin \frac{\pi\, x}{L} + T_{m,i} + \frac{L D q''_{s,m}}{\dot{m}\, c_p} (1 - \cos\, \pi\, x/L).$$ <

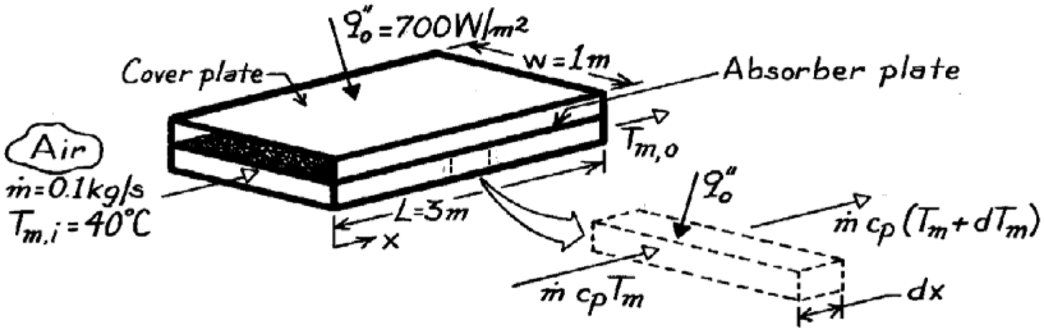
COMMENTS: For the prescribed surface condition, the flow is not fully developed. Hence, the assumption of constant h should be viewed as a first approximation.

PROBLEM 8.17

KNOWN: Surface heat flux for air flow through a rectangular channel.

FIND: (a) Differential equation describing variation in air mean temperature, (b) Air outlet temperature for prescribed conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Ideal gas with negligible viscous dissipation and pressure variation, (2) No heat loss through bottom of channel, (3) Uniform heat flux at top of channel.

PROPERTIES: *Table A-4*, Air (T ≈ 50°C, 1 atm): c_p = 1008 J/kg·K.

ANALYSIS: (a) For the differential control volume about the air,

$$\dot{E}_{in} = \dot{E}_{out}$$

$$\dot{m}\, c_p\, T_m + q''_o\, (w \cdot dx) = \dot{m}\, c_p\, (T_m + d\,T_m)$$

$$\frac{d\,T_m}{dx} = \frac{q''_o \cdot w}{\dot{m}\, c_p}$$

Separating and integrating between the limits of x = 0 and x, find

$$T_m(x) = T_{m,i} + \frac{q''_o (w \cdot x)}{\dot{m}\, c_p}$$

$$T_{m,o} = T_{m,i} + \frac{q''_o (w \cdot L)}{\dot{m}\, c_p}. \qquad <$$

(b) Substituting numerical values, the air outlet temperature is

$$T_{m,o} = 40^\circ C + \frac{\left(700\ W/m^2\right)\ (1 \times 3)\, m^2}{0.1\ kg/s\ \left(1008\ J/kg \cdot K\right)}$$

$$T_{m,o} = 60.8^\circ C. \qquad <$$

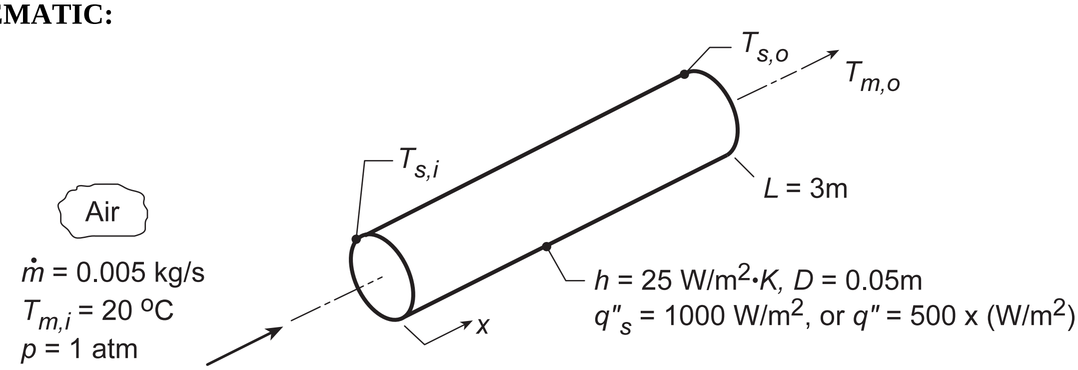
COMMENTS: Due to increasing heat loss with increasing T_m, the net flux q''_o will actually decrease slightly with increasing x.

PROBLEM 8.18

KNOWN: Air inlet conditions and heat transfer coefficient for a circular tube of prescribed geometry. Surface heat flux.

FIND: (a) Tube heat transfer rate, q, air outlet temperature, $T_{m,o}$, and surface inlet and outlet temperatures, $T_{s,i}$ and $T_{s,o}$, for a uniform surface heat flux, q_s''. Air mean and surface temperature distributions. (b) Values of q, $T_{m,o}$, $T_{s,i}$ and $T_{s,o}$ for a linearly varying surface heat flux $q_s'' = 500x$ (m). Air mean and surface temperature distributions, (c) For each type of heating process (a & b), compute and plot the mean fluid and surface temperatures, $T_m(x)$ and $T_s(x)$, respectively, as a function of distance; What is effect of four-fold increase in convection coefficient, and (d) For each type of heating process, heat fluxes required to achieve an outlet temperature of $T_{m,o} = 125°C$; Plot temperatures.

SCHEMATIC:



ASSUMPTIONS: (1) Fully developed conditions in the tube, (2) Applicability of Eq. 8.34, (3) Heat transfer coefficient is the same for both heating conditions.

PROPERTIES: *Table A.4*, Air (for an *assumed* value of $T_{m,o} = 100°C$, $\overline{T}_m = (T_{m,i} + T_{m,o})/2 = 60°C = 333$ K): $c_p = 1.008$ kJ/kg·K.

ANALYSIS: (a) With constant heat flux, from Eq. 8.38,

$$q = q_s''(\pi DL) = 1000\,W/m^2(\pi \times 0.05\,m \times 3\,m) = 471\,W. \quad (1)$$

From the overall energy balance, Eq. 8.34,

$$T_{m,o} = T_{m,i} + \frac{q}{\dot{m}c_p} = 20°C + \frac{471\,W}{0.005\,kg/s \times 1008\,J/kg\cdot K} = 113.5°C \quad (2) <$$

From the convection rate equation, it follows that

$$T_{s,i} = T_{m,i} + \frac{q_s''}{h} = 20°C + \frac{1000\,W/m^2}{25\,W/m^2\cdot K} = 60°C \quad (3) <$$

$$T_{s,o} = T_{m,o} + q_s''/h = 113.5°C + 40°C = 153.5°C \quad <$$

From Eq. 8.39, (dT_m/dx) is a constant, as is (dT_s/dx) for constant h from Eq. 8.30. In the more realistic case for which h decreases with x in the entry region, (dT_m/dx) is still constant but (dT_s/dx) decreases with increasing x. See the plot below.

(b) From Eq. 8.37,

$$\frac{dT_m}{dx} = \frac{500x(\pi D)}{\dot{m}c_p} = \frac{500x\,W/m^2(\pi \times 0.05\,m)}{0.005\,kg/s \times 1008\,J/kg\cdot K} = 15.6x\,K/m. \quad (4)$$

Continued...

PROBLEM 8.18 (Cont.)

Integrating from x = 0 to L it follows that

$$T_{m,o} = T_{m,i} + 15.6\int_0^3 x\,dx = 20^\circ C + 15.6\left.\frac{x^2}{2}\right|_0^3 = 20^\circ C + 70.2^\circ C = 90.2^\circ C. \qquad (5)$$ <

The heat rate is

$$q = \int q_s'' dA_s = 500(\pi \times 0.05\,m)\int_0^3 x\,dx = 78.5\left.\frac{x^2}{2}\right|_0^3 = 353\,W$$ <

From Eq. 8.27 it then follows that

$$T_s = T_m + q_s''/h = T_{m,i} + 15.6\frac{x^2}{2} + \frac{500}{25}x = 20^\circ C + 7.8x^2 + 20x \qquad (6)$$

Hence, at the inlet (x = 0) and outlet (x = L),

$$T_{s,i} = T_{m,i} = 20^\circ C \qquad \text{and} \qquad T_{s,o} = 150.2^\circ C$$ <

Note that (dT_s/dx) and (dT_m/dx) both increase linearly with x, but $(dT_s/dx) > (dT_m/dx)$.

(c) The foregoing relations can be used to determine $T_m(x)$ and $T_s(x)$ for the two heating conditions:

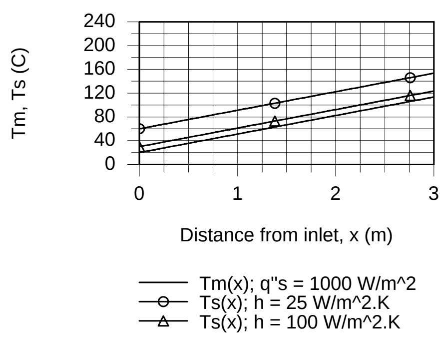
Uniform surface flux, q_s''; Eqs. (1-3),

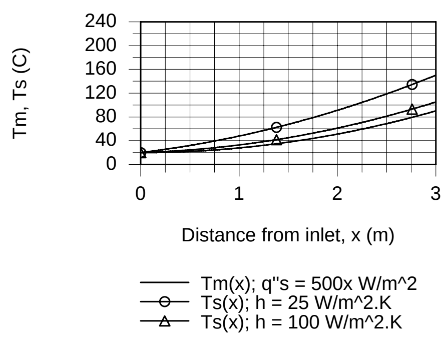
$$T_m(x) = T_{m,i} + q_s''\pi Dx/\dot{m}c_p \qquad T_s(x) = T_m(x) + q_s''/h \qquad (7,8)$$

Linear surface heat flux, $q_s'' = a_o x$, $a_o = 500\ W/m^3$; Eqs. (4-6),

$$T_m(x) = T_{m,i} + \left(a_o\pi D/2\dot{m}c_p\right)x^2 \qquad T_s(x) = T_m(x) + a_o x/h \qquad (9, 10)$$

Using Eqs. (7-10) in IHT, the mean fluid and surface temperatures as a function of distance are evaluated and plotted below. The calculations were repeated with the coefficient increased four-fold, $h = 4 \times 25 = 100\ W/m^2\cdot K$. As expected, the fluid temperature remained unchanged, but the surface temperatures decreased since the thermal resistance between the surface and fluid decreased.





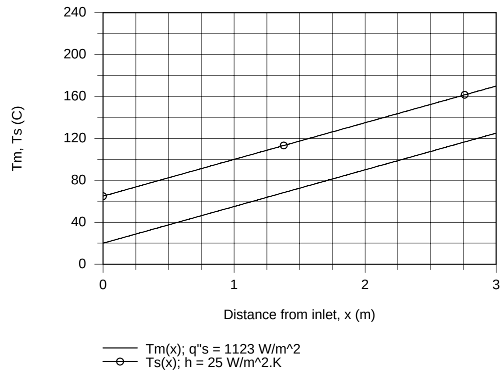
(d) The foregoing set of equations, Eqs. (7-10), in the IHT model can be used to determine the required heat fluxes for the two heating conditions to achieve $T_{m,o} = 125°C$. The results with $h = 25\ W/m^2\cdot K$ are:

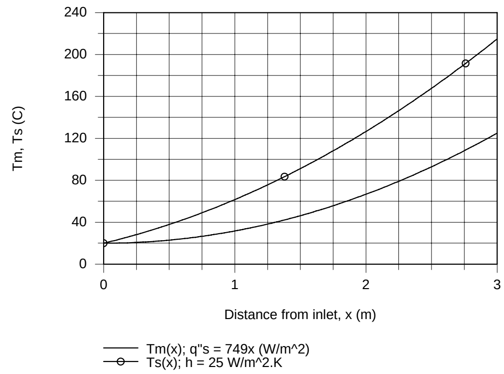
Uniform flux: $q_s'' = 1123\ W/m^2$ *Linear flux:* $q_s'' = 748.7x\ W/m^2$ <

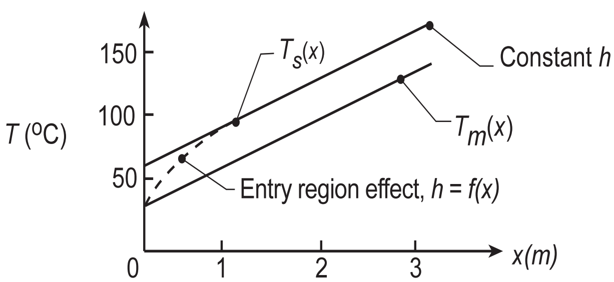
Continued...

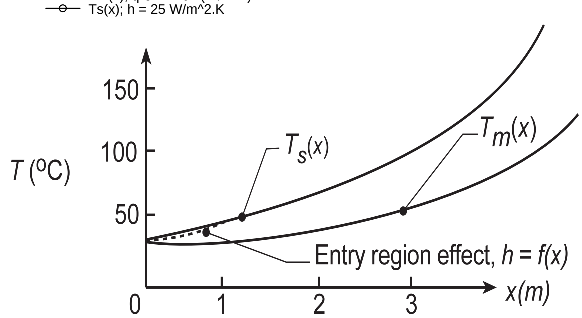
PROBLEM 8.18 (Cont.)

The temperature distributions resulting from these heat fluxes are plotted below. The heat rate for both heating processes is 529 W.









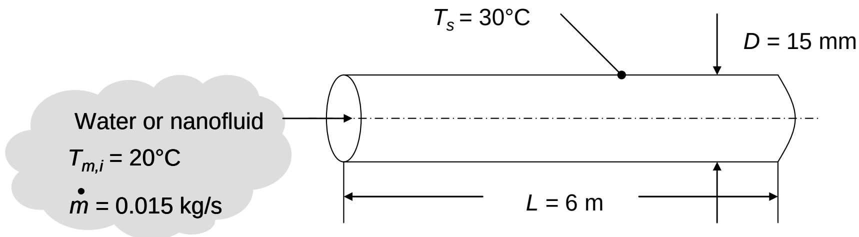
COMMENTS: Note that the assumed value for $T_{m,o}$ (100°C) in determining the specific heat of the air was reasonable.

PROBLEM 8.19

KNOWN: Tube length, diameter and surface temperature. Mass flow rate and inlet temperature of fluid.

FIND: (a) Heat transfer rate if the fluid is water. (b) Heat transfer rate for the nanofluid of Example 2.2.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Negligible viscous dissipation.

PROPERTIES: *Table A.4*, water (300 K): $\mu_{bf} = 855 \times 10^{-6}$ m^2/s, k_{bf} = 0.613 W/m·K, $c_{p,bf}$ = 4179 J/kg·K, Pr_{bf} = 5.83. Example 2.2, nanofluid (300 K): ρ_{nf} = 1146 kg/m^3, $\mu_{nf} = 962 \times 10^{-6}$ m^2/s, $\nu_{nf} = \mu_{nf}/\rho_{nf} = 839 \times 10^{-9}$ m^2/s, k_{nf} = 0.705 W/m·K, $c_{p,nf}$ = 3587 J/kg·K, $\alpha_{nf} = 171 \times 10^{-9}$ m^2/s, $Pr_{nf} = \nu_{nf}/\alpha_{nf}$ = 4.91.

ANALYSIS: (a) The Reynolds number is

$$Re_D = 4\dot{m}/\pi D\mu_{bf} = 4 \times 0.015 \text{ kg/s}/\left[\pi \times 0.015\text{m} \times 855 \times 10^{-6}\text{m}^2/\text{s}\right] = 1489$$

Therefore the flow is laminar. The hydrodynamic and thermal entry lengths are

$$x_{fd,h} = 0.05DRe_D = 0.05 \times 0.015 \text{ m} \times 1489 = 1.12 \text{ m}$$
$$x_{fd,t} = 0.05DRe_D Pr_{bf} = 0.05 \times 0.015 \text{ m} \times 1489 \times 5.83 = 6.51 \text{ m}$$

Since the tube length is L = 6 m, the temperature is still developing. The hydrodynamic entry length is less than the tube length, but perhaps not sufficiently shorter to consider the velocity to be fully developed through the entire tube. With $Pr_{bf} > 5$, the Hausen correlation, Equation 8.57, could be used as an approximation. However the nanofluid Prandtl number is less than 5. To compare the two fluids on an equal basis, we will use the combined entry correlation, Equation 8.58, for both. With $Gz_D = (D/L)Re_D Pr_{bf}$ = (0.015 m/6 m) × 1489 × 5.83 = 21.7, Equation 8.58 is

$$\overline{Nu}_D = \frac{\dfrac{3.66}{\tanh\left[2.264 \times 21.7^{-1/3} + 1.7 \times 21.7^{-2/3}\right]} + 0.0499 \times 21.7 \times \tanh\left(21.7^{-1}\right)}{\tanh\left(2.432 \times 5.83^{1/6} \times 21.7^{-1/6}\right)} = 4.98$$

Therefore $\bar{h} = \overline{Nu}_D k_{bf} / D = 4.98 \times 0.613 \text{ W/m} \cdot \text{K} / 0.015 \text{ m} = 203 \text{ W/m}^2 \cdot \text{K}$. From Equation 8.41b

Continued…

PROBLEM 8.19 (Cont.)

$$T_{m,o} = T_s - (T_s - T_{m,i})\exp\left(-\frac{\pi DL}{\dot{m}c_{p,\mathrm{bf}}}\bar{h}\right)$$

$$= 30°\mathrm{C} - 10°\mathrm{C}\exp\left(-\frac{\pi \times 0.015\ \mathrm{m} \times 6\mathrm{m}}{0.015\ \mathrm{kg/s} \times 4179\ \mathrm{J/kg \cdot K}} 203\ \mathrm{W/m^2 \cdot K}\right) = 26.0°\mathrm{C}$$

Therefore the heat transfer rate to the water is

$$q = \dot{m}c_{p,\mathrm{bf}}(T_{m,o} - T_{m,i}) = 0.015\ \mathrm{kg/s} \times 4179\ \mathrm{J/kg \cdot K} \times (26.0°\mathrm{C} - 20°\mathrm{C}) = 376\ \mathrm{W}$$ <

(b) The preceding calculations may be repeated for the nanofluid. The results are:

$Re_D = 1324$, $x_{fd,h} = 0.99$ m, $x_{fd,t} = 4.87$ m

The combined entry solution is again appropriate. The remaining results are:

$Gz_D = 16.2$, $\overline{Nu}_D = 4.68$ $\bar{h} = 220\ \mathrm{W/m^2 \cdot K}$, $T_{m,o} = 26.9°\mathrm{C}$, and $q = 369$ W <

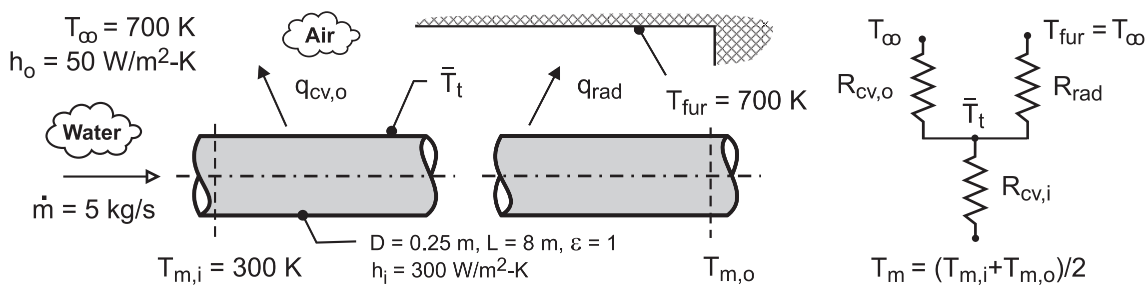
COMMENTS: (1) The nanofluid of Example 2.2 is water containing Al_2O_3 nanoparticles. The thermal conductivity of the nanofluid is 15% greater than that of the base fluid (water). In addition, the convection heat transfer coefficient of the nanofluid is 8% greater than that of the water, and the temperature increase of the nanofluid is 15% higher than for the water. *However, less heat is transferred to the nanofluid than to the water*. This is because the nanofluid suffers from a reduced specific heat relative to the pure water. Any claim that a nanofluid is a better heat transfer medium than its corresponding base fluid because of its larger thermal conductivity is suspect. In this problem, the pure water is the preferred heat transfer fluid if the objective is to maximize the heat transfer rate. In addition, the nanofluid is more costly to produce, and because of its larger viscosity, would suffer from larger pressure drops and higher pumping costs. (2) Use of the Hausen correlation, Equation 8.57 yields q = 366 W and 362 W for the water and nanofluid, respectively. Hence, the predictions of the Hausen correlation are within 3% of the predictions using the correlation of Baehr and Stephan. Use of the Hausen correlation also predicts less heat transfer for the nanofluid than for the pure water.

PROBLEM 8.20

KNOWN: Water at prescribed temperature and flow rate enters a 0.25 m diameter, black thin-walled tube of 8-m length, which passes through a large furnace whose walls and air are at a temperature of $T_{fur} = T_\infty = 700$ K. The convection coefficients for the internal water flow and external furnace air are 300 W/m^2·K and 50 W/m^2·K, respectively.

FIND: (a) An expression for the linearized radiation coefficient for the radiation exchange process between the outer surface of the pipe and the furnace walls; represent the tube by an average temperature and explain how to calculate this value, and (b) determine the outlet temperature of the water, T_o.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions; (2) Tube is small object with large, isothermal surroundings; (3) Furnace air and walls are at the same temperature; (4) Tube is thin-walled with black surface; and (5) Incompressible liquid with negligible viscous dissipation.

PROPERTIES: *Table A-6*, Water ($T_m = (T_{m,i} + T_{m,o})/2 = 304$ K): $c_p = 4178$ J/kg·K.

ANALYSIS: (a) The linearized radiation coefficient follows from Eq. 1.9 with ε = 1,

$$\bar{h}_{rad} = \sigma\left(\bar{T}_t + T_{fur}\right)\left(\bar{T}_t^2 + T_{fur}^2\right)$$

where $\bar{T}_t$ represents the average tube wall surface temperature, which can be evaluated from an energy balance on the tube as represented by the thermal circuit above.

$$T_m = \left(T_{m,i} + T_{m,o}\right)/2$$

$$R_{tot} = R_{cv,i} + \frac{1}{1/R_{cv,o} + 1/R_{rad}}$$

$$\frac{T_m - \bar{T}_t}{R_{cv,i}} = \left(\bar{T}_t - T_{fur}\right)\left(1/R_{cv,o} + 1/R_{rad}\right)$$

The thermal resistances, with $A_s = PL = \pi DL$, are

$$R_{cv,i} = 1/h_i A_s \qquad R_{cv,o} = 1/h_o A_s \qquad R_{rad} = 1/\bar{h}_{rad} A_s$$

(b) The outlet temperature can be calculated using the energy balance relation, Eq. 8.45b, with $T_{fur} = T_\infty$,

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp\left(-\frac{1}{\dot{m}\, c_p\, R_{tot}}\right)$$

where c_p is evaluated at T_m. Using *IHT*, the following results were obtained.

$$R_{cv,i} = 5.31\times10^{-4}\ \text{K/W} \qquad R_{cv,o} = 3.18\times10^{-3}\ \text{K/W} \qquad R_{rad} = 3.96\times10^{-3}\ \text{K/W}$$

$$T_m = 304\ \text{K} \qquad \bar{T}_t = 396\ \text{K} \qquad T_{m,o} = 308\ \text{K}$$ <

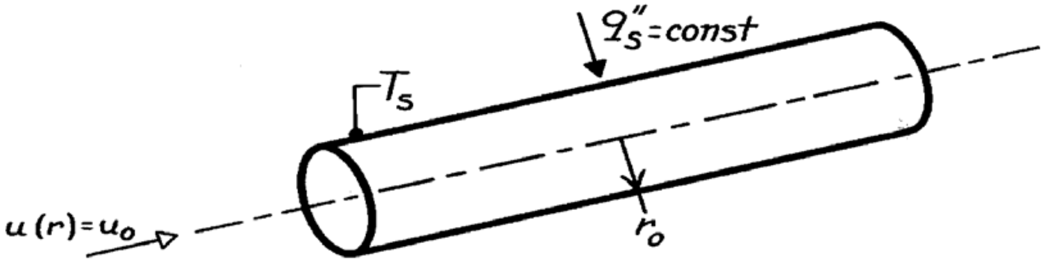
COMMENTS: Since $T_\infty = T_{fur}$, it was possible to use Eq. 8.45b with R_{tot}. How would you write the energy balance relation if $T_\infty \neq T_{fur}$?

PROBLEM 8.21

KNOWN: Laminar, slug flow in a circular tube with uniform surface heat flux.

FIND: Temperature distribution and Nusselt number.

SCHEMATIC:



ASSUMPTIONS: (1) Steady, incompressible flow, with negligible viscous dissipation, (2) Constant properties, (3) Fully developed, laminar flow, (4) Uniform surface heat flux.

ANALYSIS: With v = 0 for fully developed flow and $\partial T/\partial x = dT_m/dx$ = const, from Eqs. 8.32 and 8.39, the energy equation, Eq. 8.48, reduces to

$$u_o \frac{d\,T_m}{dx} = \frac{\alpha}{r}\,\frac{\partial}{\partial r}\left(r\frac{\partial T}{\partial r}\right).$$

Integrating twice, it follows that

$$T(r) = \frac{u_o}{\alpha}\,\frac{d\,T_m}{dx}\,\frac{r^2}{4} + C_1\,\ell n(r) + C_2.$$

Since T(0) must remain finite, $C_1 = 0$. Hence, with $T(r_o) = T_s$

$$C_2 = T_s - \frac{u_o}{\alpha}\,\frac{d\,T_m}{dx}\,\frac{r_o^2}{4} \qquad T(r) = T_s - \frac{u_o}{4\alpha}\,\frac{d\,T_m}{dx}\left(r_o^2 - r^2\right). \qquad <$$

From Eq. 8.26, with $u_m = u_o$,

$$T_m = \frac{2}{r_o^2}\int_0^{r_o} Tr\,dr = \frac{2}{r_o^2}\int_0^{r_o}\left[T_s r - \frac{u_o}{4\alpha}\,\frac{d\,T_m}{dx}\left(r r_o^2 - r^3\right)\right]dr$$

$$T_m = \frac{2}{r_o^2}\left[T_s\,\frac{r_o^2}{2} - \frac{u_o}{4\alpha}\,\frac{d\,T_m}{dx}\left(\frac{r_o^4}{2} - \frac{r_o^4}{4}\right)\right] = T_s - \frac{u_o r_o^2}{8\alpha}\,\frac{d\,T_m}{dx}.$$

From Eq. 8.27 and Fourier's law,

$$h = \frac{q_s''}{T_s - T_m} = \frac{k\frac{\partial T}{\partial r}\Big|_{r_o}}{T_s - T_m}$$

hence,

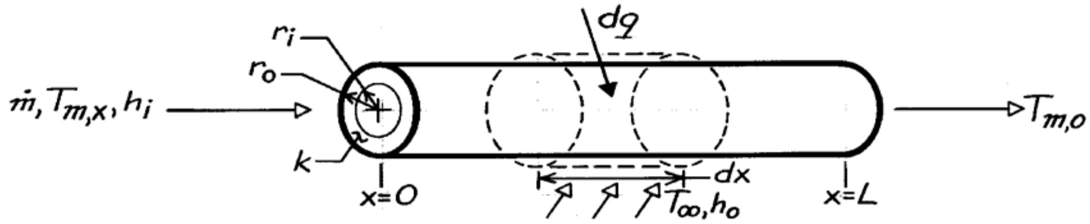
$$h = \frac{k\left(\frac{u_o r_o}{2\alpha}\right)\frac{d\,T_m}{dx}}{\frac{u_o r_o^2}{8\alpha}\,\frac{d\,T_m}{dx}} = \frac{4k}{r_o} = \frac{8k}{D} \qquad \overline{Nu}_D = \frac{hD}{k} = 8. \qquad <$$

PROBLEM 8.22

KNOWN: Heat transfer between fluid flow over a tube and flow through the tube.

FIND: Axial variation of mean temperature for inner flow.

SCHEMATIC:



ASSUMPTIONS: (1) Applicability of Eq. 8.34, (2) Negligible axial conduction, (3) Constant c_p, (4) Uniform T_∞.

ANALYSIS: From Eq. 8.36,

$$dq = \dot{m}\, c_p d\, T_m$$

with

$$dq = U dA\left(T_\infty - T_m\right) = UP\left(T_\infty - T_m\right)dx.$$

The overall heat transfer coefficient may be defined in terms of the inner or outer surface area, with

$$U_i P_i = U_o P_o.$$

For the inner surface, from Eq. 3.36,

$$U_i = \left[\frac{1}{h_i} + \frac{r_i}{k}\ln\frac{r_o}{r_i} + \frac{r_i}{r_o}\frac{1}{h_o}\right]^{-1}.$$

Hence,

$$\frac{d\, T_m}{T_\infty - T_m} = +\frac{UP}{\dot{m}\, c_p}dx$$

or, with $\Delta T \equiv T_\infty - T_m$,

$$\int_{\Delta T_i}^{\Delta T_o} \frac{d\left(\Delta T\right)}{\Delta T} = -\frac{P}{\dot{m}\, c_p} \int_0^L U dx.$$

Hence,

$$\ln\frac{\Delta T_o}{\Delta T_i} = -\frac{PL}{\dot{m}\, c_p}\left(\frac{1}{L}\int_0^L U dx\right)$$

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp\left(-\frac{PL}{\dot{m}\, c_p}\overline{U}\right).$$ <

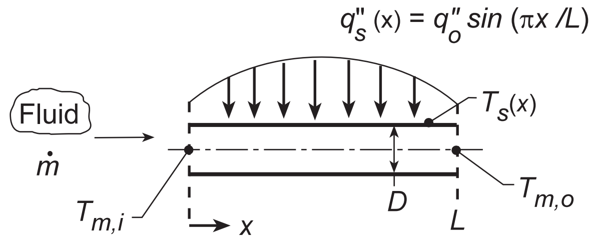
COMMENTS: The development and results parallel those for a constant surface temperature, with $\overline{U}$ and T_∞ replacing $\overline{h}$ and T_s.

PROBLEM 8.23

KNOWN: Thin-walled tube experiences sinusoidal heat flux distribution on the wall.

FIND: (a) Total rate of heat transfer from the tube to the fluid, q, (b) Fluid outlet temperature, $T_{m,o}$, (c) Axial distribution of the wall temperature $T_s(x)$ and (d) Magnitude and position of the highest wall temperature, and (e) For prescribed conditions, calculate and plot the mean fluid and surface temperatures, $T_m(x)$ and $T_s(x)$, respectively, as a function of distance along the tube; identify features of the distributions; explore the effect of ±25% changes in the convection coefficient on the distributions.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Applicability of Eq. 8.34, (3) Turbulent, fully developed flow.

ANALYSIS: (a) The total rate of heat transfer from the tube to the fluid is

$$q = \int_0^L q_s'' P dx = q_o'' \pi D \int_0^D \sin(\pi x/L) dx = q_o'' \pi D (L/\pi) \left[-\cos(\pi x/L)\right]_0^L = 2DLq_o'' \quad (1) <$$

(b) The fluid outlet temperature follows from the overall energy balance with knowledge of the total heat rate,

$$q = \dot{m}c_p (T_{m,o} - T_{m,i}) = 2DLq_o'' \qquad T_{m,o} = T_{m,i} + \left(2DLq_o''/\dot{m}c_p\right) \quad (2) <$$

(c) The axial distribution of the wall temperature can be determined from the rate equation

$$q_s'' = h\left[T_s(x) - T_m(x)\right] \qquad T_{s,x} = T_{m,x}(x) + q_s''/h \quad (3)$$

where, by combining expressions of parts (a) and (b), $T_{m,x}(x)$ is

$$\int_o^x q_s'' P dx = \dot{m}c_p (T_{m,x} - T_{m,i})$$

$$T_{m,x} = T_{m,i} + \frac{q_o'' \pi D}{\dot{m}c_p} \int_0^x \sin(\pi x/L) dx = T_{m,i} + \frac{DLq_o''}{\dot{m}c_p}\left[1 - \cos(\pi x/L)\right] \quad (4)$$

Hence, substituting Eq. (4) into (3), find

$$T_s(x) = T_{m,i} + \frac{DLq_o''}{\dot{m}c_p}\left[1 - \cos(\pi x/L)\right] + \frac{q_o''}{h}\sin(\pi x/L) \quad (5) <$$

(d) To determine the location of the maximum wall temperature x' where $T_x(x') = T_{s,max}$, set

$$\frac{dT_s(x)}{dx} = 0 = \frac{d}{dx}\left\{\frac{DLq_o''}{\dot{m}c_p}\left[1 - \cos(\pi x/L)\right] + \frac{q_o''}{h}\sin(\pi x/L)\right\}$$

$$\frac{DLq_o''}{\dot{m}c_p} \cdot \frac{\pi}{L} \cdot \sin(\pi x'/L) + \frac{q_o''}{h} \cdot \frac{\pi}{L} \cdot \cos(\pi x'/L) = 0 \qquad \tan(\pi x'/L) = -\frac{q_o''/h}{DLq_o''/\dot{m}c_p} = -\frac{\dot{m}c_p}{DLh}$$

Continued...

PROBLEM 8.23 (Cont.)

$$x' = \frac{L}{\pi}\tan^{-1}\left(-\dot{m}c_p/DLh\right) \qquad (6) <$$

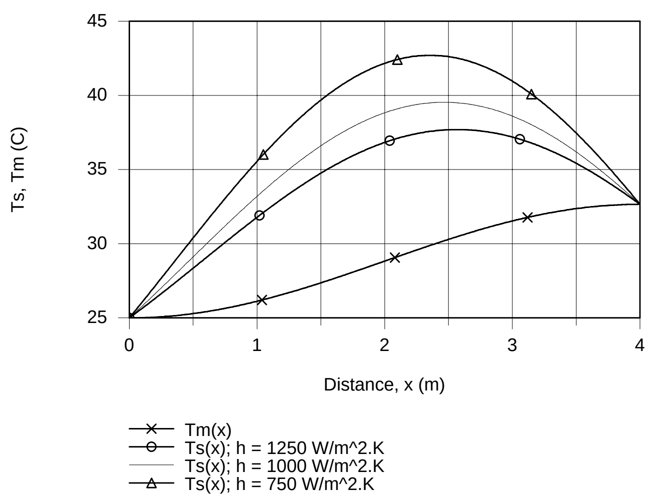
At this location, the wall temperature is

$$T_{s,max} = T_s(x') = T_{m,i} + \frac{DLq''_o}{\dot{m}c_p}\left[1-\cos(\pi x'/L)\right] + \frac{q''_o}{h}\sin(\pi x'/L) \qquad (7) <$$

(e) Consider the prescribed conditions for which to compute and plot $T_m(x)$ and $T_s(x)$,

D = 40 mm	$\dot{m}$ = 0.025 kg/s	h = 1000 W/m^2	q''_o = 10,000 W/m^2
L = 4 m	c_p = 4180 J/kg·K	$T_{m,i}$ = 25°C	

Using Eqs. (4) and (5) in IHT, the results are plotted below.



The effect of a lower convection coefficient is to increase the wall temperature. The position of the maximum temperature, $T_{s,max}$, moves away from the tube exit with decreasing convection coefficient.

COMMENTS: (1) Because the flow is fully developed and turbulent, assuming h is constant along the entire length of the tube is reasonable.

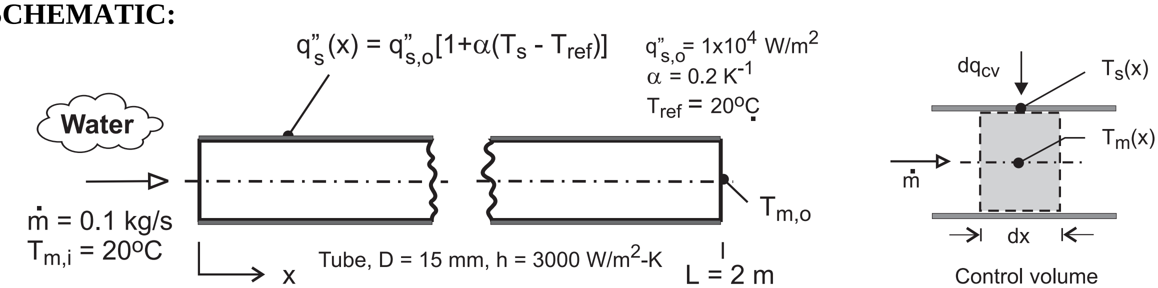
(2) To determine whether the $T_x(x)$ distribution has a maximum (rather than a minimum), you should evaluate $d^2T_s(x)/dx^2$ to show the value is indeed negative.

PROBLEM 8.24

KNOWN: Water is heated in a tube having a wall flux that is dependent upon the wall temperature.

FIND: (a) Beginning with a properly defined differential control volume in the tube, derive expressions that can be used to obtain the temperatures for the water and the wall surface as a function of distance from the inlet, $T_m(x)$ and $T_s(x)$, respectively; (b) Using a numerical integration scheme, calculate and plot the temperature distributions, $T_m(x)$ and $T_s(x)$, on the same graph. Identify and comment on the main features of the distributions; and (c) Calculate the total heat transfer rate to the water.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Fully developed flow and thermal conditions, (3) No losses to the outer surface of the tube, (3) Constant properties, and (4) Incompressible liquid with negligible viscous dissipation .

PROPERTIES: *Table A-6*, Water $\left(\overline{T}_m = \left(T_{m,i} + T_{m,o}\right)/2 = 300\ K\right)$: c_p = 4179 J/kg·K

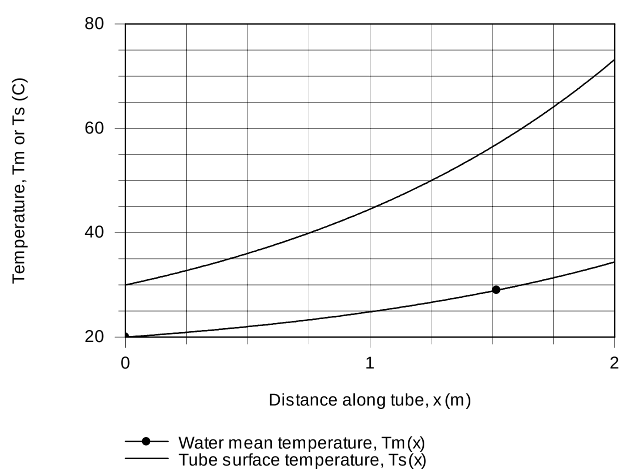
ANALYSIS: (a) The properly defined control volume of perimeter P = πD shown in the above schematic follows from Fig. 8.6. The energy balance on the CV includes advection, convection at the inner tube surface, and the heat flux dissipated in the tube wall. (See Eq. 8.37).

$$\dot{m}\, c_p \frac{dT_m}{dx} = q_s''(x)P = hP\left[T_s(x) - T_m(x)\right] \tag{1,2}$$

where $q_s''(x)$ is dependent upon $T_s(x)$ according to the relation

$$q_s''(x) = q_{s,o}''\left[1 + \alpha\left(T_s(x) - T_{ref}\right)\right] \tag{3}$$

(b) Eqs. (1 and 2) with Eq. (3) can be solved by numerical integration using the Der function in *IHT* as shown in Comment 1. The temperature distributions for the water and wall surface are plotted below.



Continued …

PROBLEM 8.24 (Cont.)

(c) The total heat transfer to the water can be evaluated from an overall energy balance on the water,

$$q = \dot{m}\, c_p \left(T_{m,o} - T_{m,i}\right) \qquad (4)$$

$$q = 0.1\ \text{kg/s} \times 4179\ \text{J/kg}\cdot\text{K}\left(34.4 - 20\right)\text{K} = 6018\ \text{W}$$ <

Alternatively, the heat rate can be evaluated by integration of the heat flux from the tube surface over the length of the tube,

$$q = \int_0^L q_s''(x)\, P dx \qquad (5)$$

where $q_s''(x)$ is given by Eq. (3), and $T_s(x)$ and $T_m(x)$ are determined from the differential form of the energy equation, Eqs. (1) and (2). The result as shown in the *IHT* code below is 6005 W.

COMMENTS: (1) Note that $T_m(x)$ increases with distance greater than linearly, as expected since $q_s''(x)$ does. Also as expected, the difference, $T_s(x) - T_m(x)$, likewise increases with distance greater than linearly.

(2) In the foregoing analysis, c_p is evaluated at the mean fluid temperature $T_m = (T_{m,i} + T_{m,o})/2$.

(3) The *IHT* code representing the foregoing equations to calculate and plot the temperature distribution and to calculate the total heat rate to the water is shown below.

```

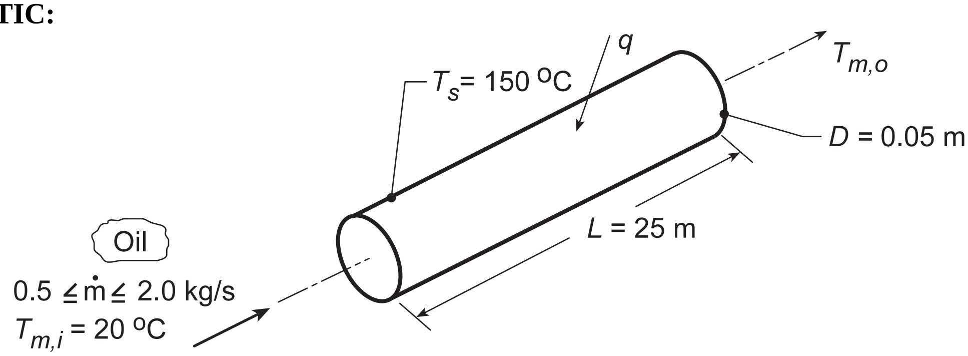
PROBLEM 8.25

KNOWN: Inlet temperature and flowrate of oil flowing through a tube of prescribed surface temperature and geometry.

FIND: (a) Oil outlet temperature and total heat transfer rate, and (b) Effect of flowrate.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible temperature drop across tube wall, (2) Incompressible liquid with negligible viscous dissipation.

PROPERTIES: *Table A.5*, Engine oil (assume $T_{m,o}$ = 140°C, hence $\overline{T}_m$ = 80°C = 353 K): ρ = 852 kg/m^3, ν = 37.5 × 10^{-6} m^2/s, k = 138 × 10^{-3} W/m·K, Pr = 490, μ = ρ·ν = 0.032 kg/m·s, c_p = 2131 J/kg·K.

ANALYSIS: (a) For constant surface temperature the oil outlet temperature may be obtained from Eq. 8.41b. Hence

$$T_{m,o} = T_s - \left(T_s - T_{m,i}\right)\exp\left(-\frac{\pi DL}{\dot{m}c_p}\overline{h}\right)$$

To determine $\overline{h}$, first calculate Re_D from Eq. 8.6,

$$Re_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4(0.5\,kg/s)}{\pi(0.05m)(0.032\,kg/m\cdot s)} = 398$$

Hence the flow is laminar. Moreover, from Eq. 8.23 the thermal entry length is

$$x_{fd,t} \approx 0.05D\,Re_D\,Pr = 0.05(0.05\,m)(398)(490) = 486\,m\,.$$

Since L = 25 m the flow is far from being thermally fully developed. Since Pr > 5, $\overline{h}$ may be determined from Eq. 8.57

$$\overline{Nu}_D = 3.66 + \frac{0.0668Gz_D}{1+0.04Gz_D^{2/3}}\,.$$

With $Gz_D = (D/L)Re_D Pr$ = (0.05/25)398 × 490 = 390, it follows that

$$\overline{Nu}_D = 3.66 + \frac{26}{1+2.14} = 11.95.$$

Hence, $\overline{h} = \overline{Nu}_D\dfrac{k}{D} = 11.95\dfrac{0.138\,W/m\cdot K}{0.05\,m} = 33\,W/m^2\cdot K$ and it follows that

Continued...

PROBLEM 8.25 (Cont.)

$$T_{m,o} = 150^\circ C - \left(150^\circ C - 20^\circ C\right)\exp\left[-\frac{\pi(0.05\,m)(25\,m)}{0.5\,kg/s \times 2131\,J/kg \cdot K} \times 33\,W/m^2 \cdot K\right]$$

$T_{m,o} = 35°C$. <

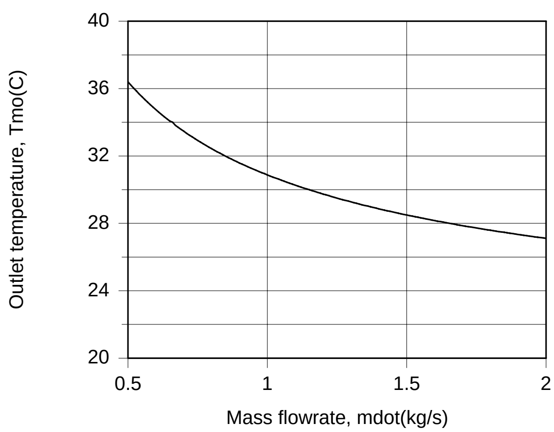
From the overall energy balance, Eq. 8.34, it follows that

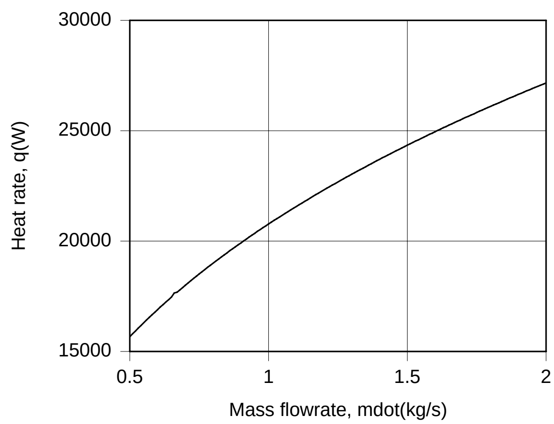
$$q = \dot{m}c_p\left(T_{m,o} - T_{m,i}\right) = 0.5\,kg/s \times 2131\,J/kg \cdot K \times (35 - 20)^\circ C$$

$q = 15,980$ W. <

The value of $T_{m,o}$ has been grossly overestimated in evaluating the properties. The properties should be re-evaluated at $\overline{T}$ = (20 + 35)/2 = 27°C and the calculations repeated. Iteration should continue until satisfactory convergence is achieved between the calculated and assumed values of $T_{m,o}$. Following such a procedure, one would obtain $T_{m,o}$ = 36.4°C, Re_D = 27.8, $\overline{h}$ = 32.8 $W/m^2 \cdot K$, and q = 15,660 W. The small effect of reevaluating the properties is attributed to the compensating effects on Re_D (a large decrease) and Pr (a large increase).

(b) The effect of flowrate on $T_{m,o}$ and q was determined by using the appropriate IHT *Correlations* and *Properties* Toolpads.





The heat rate increases with increasing $\dot{m}$ due to the corresponding increase in Re_D and hence $\overline{h}$. However, the increase is not proportional to $\dot{m}$, causing $\left(T_{m,o} - T_{m,i}\right) = q/\dot{m}c_p$, and hence $T_{m,o}$, to decrease with increasing $\dot{m}$. The maximum heat rate corresponds to the maximum flowrate ($\dot{m}$ = 0.20 kg/s).

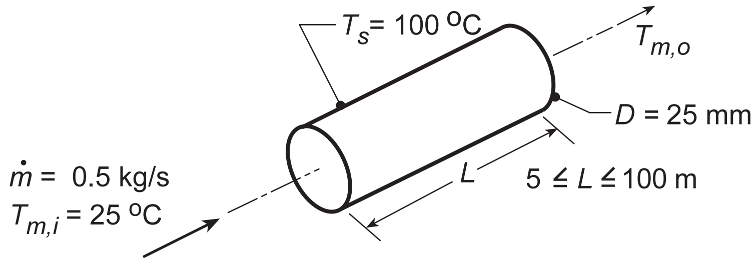
COMMENTS: Note that significant error would be introduced by assuming fully developed thermal conditions and $\overline{Nu}_D$ = 3.66. The flow remains well within the laminar region over the entire range of $\dot{m}$.

PROBLEM 8.26

KNOWN: Inlet temperature and flowrate of oil moving through a tube of prescribed diameter and surface temperature.

FIND: (a) Oil outlet temperature $T_{m,o}$ for two tube lengths, 5 m and 100 m, and log mean and arithmetic mean temperature differences, (b) Effect of L on $T_{m,o}$ and $\overline{Nu}_D$.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Incompressible liquid with negligible viscous dissipation, (3) Constant properties.

PROPERTIES: *Table A.4*, Oil (330 K): c_p = 2035 J/kg·K, μ = 0.0836 N·s/m^2, k = 0.141 W/m·K, Pr = 1205.

ANALYSIS: (a) Using Eqs. 8.41b and 8.6

$$T_{m,o} = T_s - \left(T_s - T_{m,i}\right)\exp\left(-\frac{\pi DL}{\dot{m}c_p}\bar{h}\right)$$

$$Re_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4\times 0.5\,kg/s}{\pi\times 0.025\,m\times 0.0836\,N\cdot s/m^2} = 304.6$$

With $x_{fd,h} = 0.05DRe_D$ = 0.4 m, it is reasonable to assume the flow is hydrodynamically fully developed. However, with $x_{fd,t} = x_{fd,h}Pr$ = 495 m, the flow is thermally developing. Since thermal entry length effects will be significant and Pr > 5, use Eq. 8.57 with Eq. 8.56 for the Graetz number:

$$\bar{h} = \frac{k}{D}\left[3.66 + \frac{0.0688(D/L)Re_D\,Pr}{1+0.04\left[(D/L)Re_D\,Pr\right]^{2/3}}\right] = \frac{0.141\,W/m\cdot K}{0.025\,m}\left[3.66 + \frac{2.45\times 10^4\,D/L}{1+205(D/L)^{2/3}}\right]$$

For L = 5 m, $\bar{h} = 5.64(3.66+17.51) = 119\,W/m^2\cdot K$, hence

$$T_{m,o} = 100^\circ C - \left(75^\circ C\right)\exp\left(-\frac{\pi\times 0.025\,m\times 5\,m\times 119\,W/m^2\cdot K}{0.5\,kg/s\times 2035\,J/kg\cdot K}\right) = 28.4^\circ C \qquad <$$

For L = 100 m, $\bar{h} = 5.64(3.66+3.38) = 40\,W/m^2\cdot K$, $T_{m,o}$ = 44.9°C. <

Also, *for* L = 5 m,

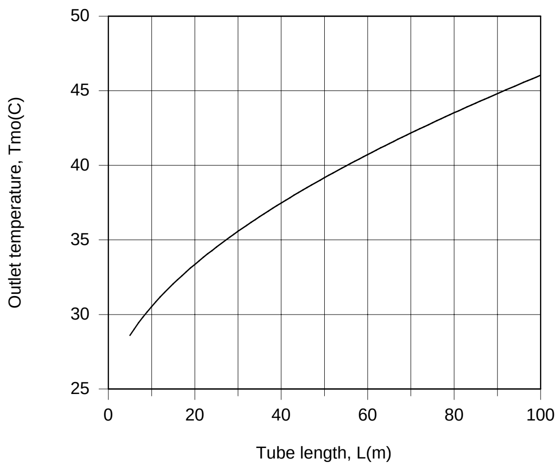
$$\Delta T_{\ell m} = \frac{\Delta T_o - \Delta T_i}{\ell n\left(\Delta T_o/\Delta T_i\right)} = \frac{71.6-75}{\ell n(71.6/75)} = 73.3^\circ C \qquad \Delta T_{am} = \left(\Delta T_o + \Delta T_i\right)/2 = 73.3^\circ C \qquad <$$

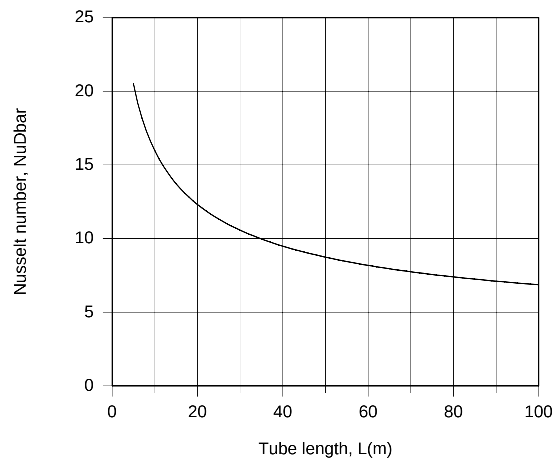
For L = 100 m, $\Delta T_{\ell m} = 64.5^\circ C$, $\Delta T_{am} = 65.1^\circ C$ <

(b) The effect of tube length on the outlet temperature and Nusselt number was determined by using the *Correlations* and *Properties* Toolpads of IHT.

Continued...

PROBLEM 8.26 (Cont.)





The outlet temperature approaches the surface temperature with increasing L, but even for L = 100 m, $T_{m,o}$ is well below T_s. Although $\overline{Nu}_D$ decays with increasing L, it is still well above the fully developed value of $Nu_{D,fd} = 3.66$.

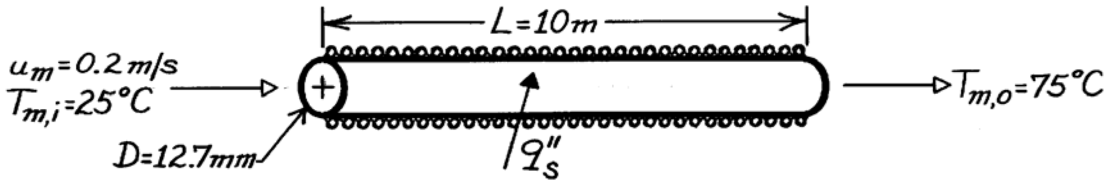
COMMENTS: (1) The average, mean temperature, $\overline{T}_m$ = 330 K, was significantly overestimated in part (a). The accuracy may be improved by evaluating the properties at a lower temperature. (2) Use of ΔT_{am} instead of $\Delta T_{\ell m}$ is reasonable for small to moderate values of $(T_{m,i} - T_{m,o})$. For large values of $(T_{m,i} - T_{m,o})$, $\Delta T_{\ell m}$ should be used.

PROBLEM 8.27

KNOWN: Inlet and outlet temperatures and velocity of fluid flow in tube. Tube diameter and length.

FIND: Surface heat flux and temperatures at x = 0.5 and 10 m.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible heat loss to surroundings, (4) Incompressible liquid with negligible viscous dissipation, (5) Negligible axial conduction.

PROPERTIES: Pharmaceutical (given): $\rho = 1000\ kg/m^3$, $c_p = 4000$ J/kg·K, $\mu = 2 \times 10^{-3}$ kg/s·m, k = 0.80 W/m·K, Pr = 10.

ANALYSIS: With

$$\dot{m} = \rho VA = 1000\ kg/m^3 (0.2\ m/s) \pi (0.0127\ m)^2 / 4 = 0.0253\ kg/s$$

Eq. 8.34 yields

$$q = \dot{m}\ c_p \left(T_{m,o} - T_{m,i}\right) = 0.0253\ kg/s (4000\ J/kg \cdot K) 50\ K = 5060\ W.$$

The required heat flux is then

$$q_s'' = q/A_s = 5060\ W/\pi (0.0127\ m) 10\ m = 12{,}682\ W/m^2. \qquad <$$

With

$$Re_D = \rho VD/\mu = 1000\ kg/m^3 (0.2\ m/s) 0.0127\ m/2 \times 10^{-3}\ kg/s \cdot m = 1270$$

the flow is laminar and Eq. 8.23 yields

$$x_{fd,t} = 0.05 Re_D\, Pr\, D = 0.05(1270)10(0.0127\ m) = 8.06\ m.$$

Hence, with fully developed hydrodynamic and thermal conditions at x = 10 m, Eq. 8.53 yields

$$h(10\ m) = Nu_{D,fd}(k/D) = 4.36(0.80\ W/m \cdot K/0.0127\ m) = 274.6\ W/m^2 \cdot K.$$

Hence, from Newton's law of cooling,

$$T_{s,o} = T_{m,o} + \left(q_s''/h\right) = 75^\circ C + \left(12{,}682\ W/m^2/274.6\ W/m^2 \cdot K\right) = 121^\circ C. \qquad <$$

At x = 0.5 m, $(x/D)/(Re_D Pr) = 0.0031$ and Figure 8.10 yields $Nu_D \approx 8$ for a thermal entry region with uniform surface heat flux. Hence, h(0.5 m) = 503.9 $W/m^2 \cdot K$ and, since T_m increases linearly with x, $T_m(x = 0.5\ m) = T_{m,i} + (T_{m,o} - T_{m,i})(x/L) = 27.5°C$. It follows that

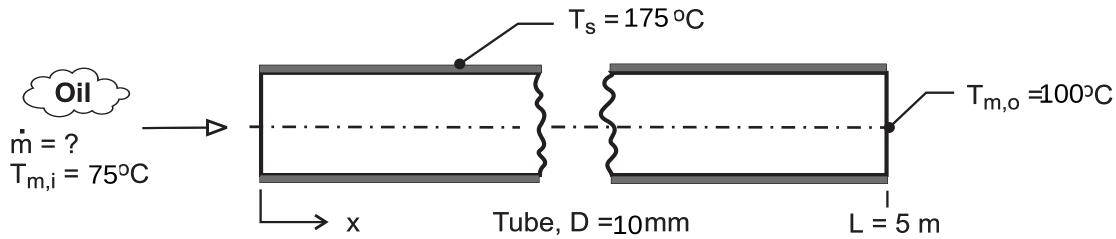
$$T_s(x = 0.5\ m) \approx 27.5^\circ C + \left(12{,}682\ W/m^2/503.9\ W/m^2 \cdot K\right) = 52.7^\circ C. \qquad <$$

PROBLEM 8.28

KNOWN: Oil at 75°C enters a single-tube preheater of 10-mm diameter and 5-m length; tube surface maintained at 175°C by swirling combustion gases.

FIND: Determine the flow rate and heat transfer rate when the outlet temperature is 100°C.

SCHEMATIC:



ASSUMPTIONS: (1) Laminar flow, (2) Tube wall is isothermal, (3) Incompressible liquid with negligible viscous dissipation, (4) Constant properties.

PROPERTIES: *Table A-5*, Engine oil, new ($T_m = (T_{m,i} + T_{m,o})/2 = 361$ K): $\rho = 847.5$ kg/m^3, c_p = 2163 J/kg·K, $\nu = 2.931 \times 10^{-5}$ m^2/s, k = 0.1379 W/m·K, Pr = 390.2, $\mu = 0.0245$.

ANALYSIS: The overall energy balance, Eq. 8.34, and rate equation, Eq. 8.41b, are

$$q = \dot{m} c_p \left(T_{m,o} - T_{m,i}\right) \tag{1}$$

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{PL\bar{h}}{\dot{m} c_p}\right) \tag{2}$$

Not knowing the flow rate $\dot{m}$, the Reynolds number cannot be calculated. Assume that the flow is laminar. Since Pr > 5, the average convection coefficient can be estimated using the Hausen correlation, Eq. 8.57, with Eq. 8.56 for the Graetz number:

$$\overline{Nu}_D = 3.66 + \frac{0.0668(D/L)Re_D Pr}{1 + 0.04\left[(D/L)Re_D Pr\right]^{2/3}} \tag{3}$$

where all properties are evaluated at $T_m = (T_{m,i} + T_{m,o})/2$. The Reynolds number follows from Eq. 8.6,

$$Re_D = 4\dot{m}/\pi D \mu \tag{4}$$

A tedious trial-and-error solution is avoided by using *IHT* to solve the system of equations with the following result:

Re_D	$\overline{Nu}_D$	$\bar{h}_D$ (W/m^2·K)	q(W)	$\dot{m}$ (kg/h)
130	7.25	100	1360	90

<

Note that the flow is laminar, and evaluating $x_{fd,t}$ using Eq. 8.23, find $x_{fd,t}$ = 25 m, so the flow is not thermally fully developed.

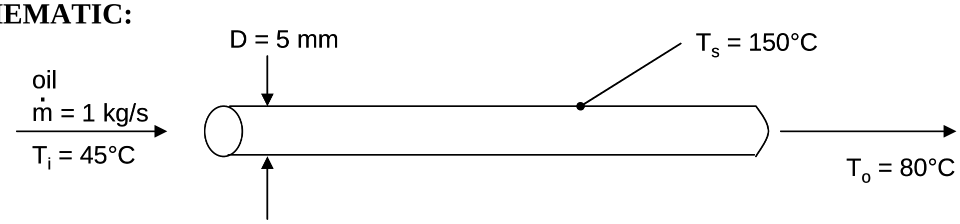
COMMENT: Use of the Baehr and Stephan correlation for the combined entry problem yields the identical values. Hence it may also be used.

PROBLEM 8.29

KNOWN: Oil flow rate. Pipe diameter. Inlet, outlet, and pipe surface temperatures.

FIND: Length of tube required to achieve desired outlet temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Incompressible flow, (3) Negligible viscous dissipation.

PROPERTIES: Table A-5, Engine oil (T_i = 45°C = 318 K): $\mu_i = 16.3 \times 10^{-2}$ N·s/m²; (T_o = 80°C = 353 K): $\mu_o = 3.25 \times 10^{-2}$ N·s/m².

ANALYSIS: We begin by calculating the Reynolds numbers at the inlet and outlet, from Equation 8.6,

$$Re_{Di} = \frac{4\,\dot{m}}{\pi\, D\, \mu_i} = \frac{4 \times 1\text{ kg/s}}{\pi \times 0.005\text{ m} \times 16.3 \times 10^{-2}\text{N} \cdot \text{s/m}^2} = 1560$$

$$Re_{Do} = \frac{4 \times 1\text{ kg/s}}{\pi \times 0.005\text{ m} \times 3.25 \times 10^{-2}\text{N} \cdot \text{s/m}^2} = 7840$$

Therefore the flow is laminar at the inlet and turbulent at the outlet. The transition occurs when Re_D = 2300, that is, where

$$\mu = \frac{4\,\dot{m}}{\pi\, D\, 2300} = \frac{4 \times 1\text{ kg/s}}{\pi \times 0.005\text{ m} \times 2300} = 11.1 \times 10^{-2}\text{N} \cdot \text{s/m}^2$$

From Table A-5, this occurs at a transition temperature of $T_{m,t}$ = 325 K = 52°C. Now we proceed to analyze separately the heat transfer in the laminar and turbulent regions.

<u>Laminar Region.</u> The mean temperature in the laminar region is $\overline{T}_{m1}$ = (45°C + 52°C)/2 = 48.5°C = 321.5 K. The properties are c_{p1} = 1999 J/kg·K, $\mu_1 = 13.2 \times 10^{-2}$ N·s/m², k_1 = 0.143 W/m·K, Pr_1 = 1851. We recalculate the Reynolds number,

$$Re_{D1} = \frac{4\,\dot{m}}{\pi\, D\, \mu_1} = \frac{4 \times 1\text{ kg/s}}{\pi \times 0.005\text{ m} \times 13.2 \times 10^{-2}\text{N} \cdot \text{s/m}^2} = 1930$$

The hydrodynamic and thermal entry lengths are given by

$$x_{fd,h} = 0.05\, Re_{Di}\, D = 0.05 \times 1930 \times 0.005\text{ m} = 0.48\text{ m}$$

$$x_{fd,t} = x_{fd,h} \cdot Pr_i = 0.48\text{ m} \times 1851 = 890\text{ m}$$

Based on this information, we assume the flow is hydrodynamically developed but thermally developing, and use Equations 8.56 and 8.57 for the Nusselt number (with Pr > 5),

$$\overline{Nu}_{D1} = \overline{h}_1 D/k_1 = 3.66 + \frac{0.0668\,(D/L_1)\,Re_{D1}\,Pr_1}{1 + 0.04\left[(D/L_1)\,Re_{D1}\,Pr_1\right]^{2/3}} \qquad (1)$$

where L_1 is the length of the laminar region, which is as yet unknown. We can also use Equation 8.42 for the mean temperature variation:

$$\frac{T_s - T_{m,t}}{T_s - T_i} = \exp\left(-\frac{\pi\, D\, L_1}{\dot{m}\, c_{p1}}\overline{h}_1\right)$$

Continued…

PROBLEM 8.29 (Cont.)

Solving for $\overline{h_1} L_1$, we have

$$\overline{h_1}L_1 = -\frac{\dot{m}c_{p1}}{\pi D}\ln\left(\frac{T_s - T_{m,t}}{T_s - T_i}\right) = -\frac{1\text{ kg/s} \times 1999\text{ J/kg}\cdot\text{K}}{\pi \times 0.005\text{ m}}\ln\left(\frac{150°\text{C} - 52°\text{C}}{150°\text{C} - 45°\text{C}}\right)$$

$$= 8780\text{ W/m}\cdot\text{K} \qquad (2)$$

We can solve by iterating between Equations (1) and (2). Beginning with the estimate $\overline{Nu}_{D1} = 3.66$, we find $\overline{h}_1 = 3.66\ k_1/D = 105\ W/m^2\cdot K$. From Equation (2), $L_1 = 84$ m. Then from Equation (1), $\overline{Nu}_{D1} = 22.3$ and $\overline{h}_1 = 639\ W/m^2\cdot K$. Continuing the iterations, we find $\overline{Nu}_{D1} = 16.9$, $\overline{h}_1 = 484$ $W/m^2\cdot K$, and $L_1 = 18.1$ m.

Turbulent Range. The mean temperature in the turbulent region is $\overline{T}_{m2} = (52°C + 80°C)/2 = 66°C =$ 339 K. The properties are $c_{p2} = 2072$ J/kg·K, $\mu_2 = 5.62 \times 10^{-2}\ N\cdot s/m^2$, $k_2 = 0.139$ W/m·K, $Pr_2 = 834$. Thus

$$Re_{D2} = \frac{4\,\dot{m}}{\pi\,D\,\mu_2} = 4530$$

We assume the flow is fully-developed hydrodynamically and thermally and use Equation 8.62,

$$Nu_{D2} = \frac{(f/8)\,(Re_{D2} - 1000)\,Pr_2}{1 + 12.7\,(f/8)^{1/2}(Pr_2^{2/3} - 1)}$$

where from Equation 8.21,

$$f = (0.790\ln Re_{D2} - 1.64)^{-2} = (0.790\ln(4530) - 1.64)^{-2} = 0.0398$$

Thus

$$Nu_{D2} = \frac{(0.0398/8)\,(4530 - 1000)\,834}{1 + 12.7\,(0.0398/8)^{1/2}(834^{2/3} - 1)} = 184$$

and $h_2 = Nu_{D2}k_2/D = 5120\ W/m^2\cdot K$. Then the required length L_2 can be found from Equation 8.42, expressed between the transition point and the outlet,

$$\frac{T_s - T_o}{T_s - T_{m,t}} = \exp\left(-\frac{\pi\,D\,L_2}{\dot{m}\,c_{p2}}\overline{h}_2\right)$$

$$L_2 = -\frac{\dot{m}\,c_{p2}}{\pi\,D\,h_2}\ln\left(\frac{T_s - T_o}{T_s - T_{m,t}}\right) = -\frac{1\text{ kg/s} \times 2072\text{ J/kg}\cdot\text{K}}{\pi \times 0.005\text{ m} \times 5120\text{ W/m}^2\cdot\text{K}}\ln\left(\frac{150°\text{C} - 80°\text{C}}{150°\text{C} - 52°\text{C}}\right)$$

$$= 8.7\text{ m}$$

The total required length is $L = L_1 + L_2 = 26.8$ m. <

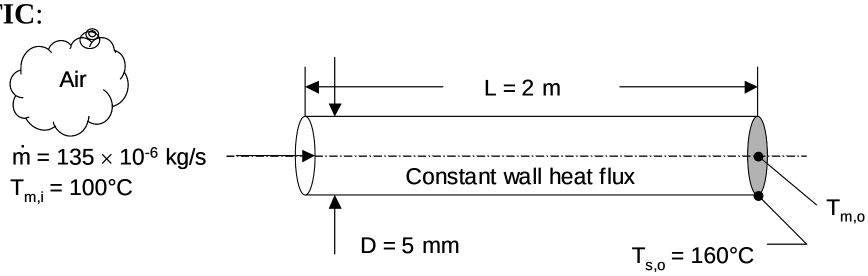
COMMENTS: (1) If we had simply calculated the properties based on the mean temperature of $\overline{T}_m =$ $(45°C + 80°C)/2 = 62.5°C = 335.5$ K, we would have found $Re_D = 3810$. Assuming the flow to be turbulent throughout would have resulted in a higher average Nusselt number, $\overline{Nu}_D = 159$, and correspondingly lower total length, L = 11.9 m. The variation of properties with temperature can be very important for some fluids such as oils. (2) If the oil were being cooled by exposure to a cooler wall, the Reynolds number could decrease from a turbulent to a laminar value. The flow would likely not completely "relaminarize," and the heat transfer in the section for which $Re_D < 2300$ would fall between the values calculated using laminar and turbulent Nusselt number correlations.

PROBLEM 8.30

KNOWN: Diameter and length of tube, air flow rate, air temperature and pressure at the tube inlet. Surface temperature at the tube exit.

FIND: (a) The heat transfer rate of the problem. (b) Conditions at the tube exit for reduced tube length. (c) Conditions at the tube exit for increased air flow rate.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible viscous dissipation.

PROPERTIES: *Table A.4*, Air ($\overline{T}_m \approx 400$ K, p = 1 atm): $\mu = 230.1\times10^{-7}$ N·s/m^2, Pr = 0.690, k = 0.0338 W/m·K, c_p = 1014 J/kg·K.

ANALYSIS: (a) We begin by calculating the Reynolds number

$$Re_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4\times135\times10^{-6}\text{ kg/s}}{\pi\times0.005\text{m}\times230.1\times10^{-7}\text{N}\cdot\text{s/m}^2} = 1494$$

Therefore, the flow is laminar. The hydrodynamic and thermal entrance lengths are

$$x_{fd,h} = 0.05DRe_D = 0.05\times0.005\text{ m}\times1494 = 0.37\text{ m}$$
$$x_{fd,t} = x_{fd,h}Pr = 0.37\text{ m}\times0.690 = 0.26\text{ m}$$

Therefore, the flow is fully-developed at the tube exit. For fully-developed laminar flow with constant heat flux conditions, the Nusselt number is Nu_D = 4.36. Therefore, the local heat transfer coefficient at the tube exit is

$$h = 4.36k/D = 4.36\times0.0338\text{ W/m}\cdot\text{K}/0.005\text{m} = 29.47\text{ W/m}^2\cdot\text{K}$$

Two independent expressions for the heat flux may be written based upon application of Newton's law of cooling at the tube exit and an overall energy balance.

$$q'' = h(T_{s,o} - T_{m,o}) \quad ; \quad q'' = \frac{\dot{m}c_p(T_{m,o} - T_{m,i})}{\pi DL} \qquad (1, 2)$$

Equating Eqs. (1) and (2) yields

Continued…

PROBLEM 8.30 (Cont.)

$$T_{m,o} = \left[hT_{s,o} + \frac{\dot{m}c_p}{\pi DL} T_{m,i} \right] \Bigg/ \left[\frac{\dot{m}c_p}{\pi DL} + h \right]$$

$$= \frac{\left[29.47\text{W/m}^2 \cdot \text{K} \times 160°\text{C} + \dfrac{135 \times 10^{-6}\,\text{kg/s} \times 1014\ \text{J/kg} \cdot \text{K}}{\pi \times 0.005\ \text{m} \times 2\ \text{m}} \times 100°\text{C} \right]}{\left[\dfrac{135 \times 10^{-6}\,\text{kg/s} \times 1014\ \text{J/kg} \cdot \text{K}}{\pi \times 0.005\ \text{m} \times 2\ \text{m}} + 24.97\text{W/m}^2 \cdot \text{K} \right]}$$

$$= 152.3°\text{C}$$

Hence, the heat rate is

$$q = \dot{m}c_p (T_{m,o} - T_{m,i}) = 135 \times 10^{-6}\,\text{kg/s} \times 1014\text{J/kg} \cdot \text{K} \times 52.3°\text{C} = 7.16\ \text{W}$$ <

(b) If L = 0.2 m, conditions at $x = L$ are not fully developed and the value of the heat transfer coefficient at the tube exit would exceed that of part (a).

(c) If the flow rate is increased by an order of magnitude, the Reynolds number will increase to Re_D = 14,940, and the flow will be turbulent at the tube exit. Since L/D = 2 m / 0.005 m = 400, the turbulent flow at the tube exit will also be fully developed. The heat transfer coefficient at the tube exit would exceed that of part (a).

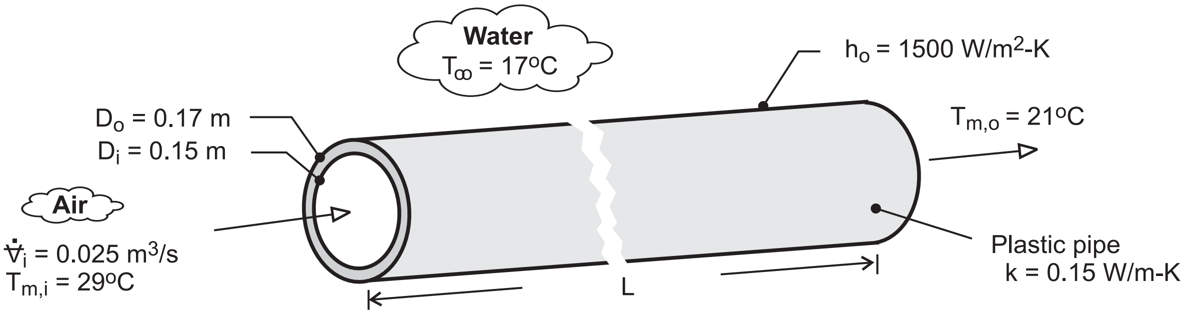
COMMENTS: In part (b), the local heat transfer coefficient would exceed h = 29.47 W/m^2 at the tube exit and could be estimated using Fig. 8.10a. Specifically, for $Gz^{-1} = (x/D)/(Re_D Pr)$ = (0.2 m/ 0.005 m)/(1494 × 0.690) = 0.039, $Nu_D \approx 4.6$. Hence, h = 29.47 W/m^2 × (4.6/4.36) = 31.1 W/m^2·K. In part (c), the local heat transfer coefficient would exceed h = 29.47 W/m^2 and could be evaluated using the Dittus-Boelter correlation. Specifically, $Nu_D = 0.023 \times (14{,}940)^{4/5} 0.690^{0.4} = 43.3$. Hence, h = 29.47 W/m^2 × (43.3/4.36) = 292.7 W/m^2·K. For $T_{s,o}$ to remain the same, the heat rate associated with either part (b) or part (c) would have to exceed that of part (a).

PROBLEM 8.31

KNOWN: Thermal conductivity and inner and outer diameters of plastic pipe. Volumetric flow rate and inlet and outlet temperatures of air flow through pipe. Convection coefficient and temperature of water.

FIND: Pipe length and fan power requirement.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Negligible heat transfer from air in vertical legs of pipe, (3) Ideal gas with negligible viscous dissipation and pressure variation, (4) Smooth interior surface, (5) Constant properties.

PROPERTIES: *Table A-4*, Air ($T_{m,i}$ = 29°C): $\rho_i = 1.155\,kg/m^3$. Air $\left(\overline{T}_m = 25°C\right)$: c_p = 1007 J/kg·K, $\mu = 183.6 \times 10^{-7}$ N·s/m^2, k_a = 0.0261 W/m·K, Pr = 0.707.

ANALYSIS: From Eq. (8.45a)

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp\left(-\frac{\overline{U}A_s}{\dot{m}\,c_p}\right)$$

where, from Eqs. (3.34) and (3.35), $\left(\overline{U}A_s\right)^{-1} = R_{tot} = \frac{1}{\overline{h}_i \pi D_i L} + \frac{\ln\left(D_o/D_i\right)}{2\pi L k} + \frac{1}{h_o \pi D_o L}$

With $\dot{m} = \rho_i \dot{\forall}_i = 0.0289\,kg/s$ and $Re_D = 4\dot{m}/\pi D_i \mu = 13,350$, flow in the pipe is turbulent. Assuming fully developed flow throughout the pipe, and from Eq. (8.60),

$$\overline{h}_i = \frac{k_a}{D_i} 0.023\,Re_D^{4/5}\,Pr^{0.3} = \frac{0.0261\,W/m\cdot K \times 0.023}{0.15m}\left(13,350\right)^{4/5}\left(0.707\right)^{0.3} = 7.20\,W/m^2\cdot K$$

$$\left(\overline{U}A_s\right)^{-1} = \frac{1}{L}\left(\frac{1}{7.21\,W/m^2\cdot K \times \pi \times 0.15m} + \frac{\ln\left(0.17/0.15\right)}{2\pi \times 0.15\,W/m\cdot K} + \frac{1}{1500\,W/m^2\cdot K \times \pi \times 0.17m}\right)$$

$$\overline{U}A_s = \frac{L}{\left(0.294 + 0.133 + 0.001\right)} = 2.335\,L\ \ W/K$$

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \frac{17-21}{17-29} = 0.333 = \exp\left(-\frac{2.335\,L}{0.0289\,kg/s \times 1007\,J/kg\cdot K}\right) = \exp\left(-0.0802L\right)$$

$$L = -\frac{\ln\left(0.333\right)}{0.0802} = 13.7m$$ <

From Eqs. (8.22a) and (8.22b) and with $u_{m,i} = \dot{\forall}_i / \left(\pi D_i^2/4\right) = 1.415\,m/s$, the fan power is

$$P = \left(\Delta p\right)\dot{\forall} \approx f\,\frac{\rho_i u_{m,i}^2}{2\,D_i} L\,\dot{\forall}_i = 0.0291\frac{1.155\,kg/m^3\left(1.415\,m/s\right)^2}{2\left(0.15m\right)} 13.7m \times 0.025\,m^3/s = 0.077\,W$$ <

where $f = (0.790 \ln Re_D - 1.64)^{-2} = 0.0291$ from Eq. (8.21).

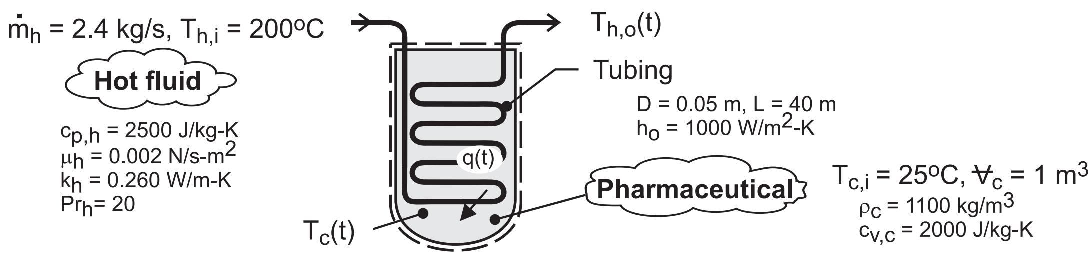
COMMENTS: (1) With L/Di = 91, the assumption of fully developed flow throughout the pipe is justified. (2) The fan power requirement is small, and the process is economical. (3) The resistance to heat transfer associated with convection at the outer surface is negligible.

PROBLEM 8.32

KNOWN: Inlet temperature, flow rate and properties of hot fluid. Initial temperature, volume and properties of pharmaceutical. Heat transfer coefficient at outer surface and dimensions of coil.

FIND: (a) Expressions for $T_c(t)$ and $T_{h,o}(t)$, (b) Plots of $T_c(t)$ and $T_{h,o}(t)$ for prescribed conditions. Effect of flow rate on time for pharmaceutical to reach a prescribed temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Negligible heat loss from vessel to surroundings, (3) Pharmaceutical is isothermal, (4) Negligible work due to stirring, (5) Negligible thermal energy generation (or absorption) due to chemical reactions associated with the batch process, (6) Hot fluid is an incompressible liquid with negligible viscous dissipation, (7) Negligible tube wall conduction resistance.

ANALYSIS: (a) Performing an energy balance for a control surface about the stirred liquid, it follows that

$$\frac{dU_c}{dt} = \frac{d}{dt}\left(\rho_c V_c c_{v,c} T_c\right) = \rho_c V_c c_{v,c} \frac{dT_c}{dt} = q(t) \tag{1}$$

where, $$q(t) = \dot{m}_h c_{p,h}\left(T_{h,i} - T_{h,o}\right) \tag{2}$$

or, $$q(t) = UA_s \Delta T_{\ell m} \tag{3a}$$

where

$$\Delta T_{\ell m} = \frac{\left(T_{h,i} - T_c\right) - \left(T_{h,o} - T_c\right)}{\ell n\left(\dfrac{T_{h,i} - T_c}{T_{h,o} - T_c}\right)} = \frac{\left(T_{h,i} - T_{h,o}\right)}{\ell n\left(\dfrac{T_{h,i} - T_c}{T_{h,o} - T_c}\right)} \tag{3b}$$

Substituting (3b) into (3a) and equating to (2),

$$\dot{m}_h c_{p,h}\left(T_{h,i} - T_{h,o}\right) = UA_s \frac{\left(T_{h,i} - T_{h,o}\right)}{\ell n\left(\dfrac{T_{h,i} - T_c}{T_{h,o} - T_c}\right)}$$

Hence, $$\ell n\left(\frac{T_{h,i} - T_c}{T_{h,o} - T_c}\right) = \frac{UA_s}{\dot{m}_h c_{p,h}}$$

or, $$T_{h,o}(t) = T_c + \left(T_{h,i} - T_c\right)\exp\left(-UA_s / \dot{m}_h c_{p,h}\right) \tag{4}$$ <

Substituting Eqs. (2) and (4) into Eq. (1),

Continued …

PROBLEM 8.32 (Cont.)

$$\rho_c V_c c_{v,c} \frac{dT_c}{dt} = \dot{m}_h c_{p,h}\left[T_{h,i} - T_c - \left(T_{h,i} - T_c\right)\exp\left(-UA_s / \dot{m}_h c_{p,h}\right)\right]$$

$$\frac{dT_c}{dt} = \frac{\dot{m}_h c_{p,h}\left(T_{h,i} - T_c\right)}{\rho_c V_c c_{v,c}}\left[1 - \exp\left(-UA_s / \dot{m}_h c_{p,h}\right)\right]$$

$$-\int_{T_{c,i}}^{T_c(t)} \frac{dT_c}{\left(T_c - T_{h,i}\right)} = \frac{\dot{m}_h c_{p,h}}{\rho_c V_c c_{v,c}}\left[1 - \exp\left(-UA_s / \dot{m}_h c_{p,h}\right)\right]\int_o^t dt$$

$$-\ell n\left(\frac{T_c - T_{h,i}}{T_{c,i} - T_{h,i}}\right) = \frac{\dot{m}_h c_{p,h}}{\rho_c V_c c_{v,c}}\left[1 - \exp\left(-UA_s / \dot{m}_h c_{p,h}\right)\right]t$$

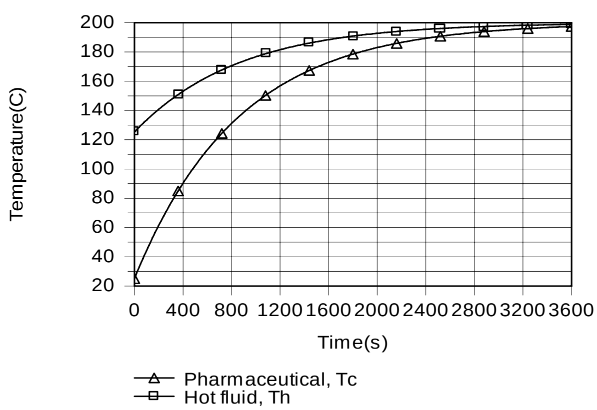
$$T_c(t) = T_{h,i} - \left(T_{h,i} - T_{c,i}\right)\exp\left\{-\frac{\dot{m}_h c_{p,h}\left[1 - \exp\left(-UA_s / \dot{m}_h c_{p,h}\right)\right]t}{\rho_c V_c c_{v,c}}\right\} \qquad (5) \quad <$$

Eq. (5) may be used to determine $T_c(t)$ and the result used with (4) to determine $T_{h,o}(t)$.

(b) To evaluate the temperature histories, the overall heat transfer coefficient, $U = \left(h_o^{-1} + h_i^{-1}\right)^{-1}$, must first be determined. With $Re_D = 4\dot{m} / \pi D\mu = 4 \times 2.4\,kg/s / \pi\left(0.05m\right)0.002\,N \cdot s/m^2 = 30,600$, the flow is turbulent and

$$h_i = \frac{k}{D} Nu_D = \frac{0.260\,W/m \cdot K}{0.05m}\left[0.023\left(30,600\right)^{4/5}\left(20\right)^{0.3}\right] = 1140\,W/m^2 \cdot K$$

Hence, $U = \left[\left(1000\right)^{-1} + \left(1140\right)^{-1}\right]^{-1} W/m^2 \cdot K = 532\,W/m^2 \cdot K$. As shown below, the temperature of the pharmaceuticals increases with time due to heat transfer from the hot fluid, approaching the inlet temperature of the hot fluid (and its maximum possible temperature of 200°C) at t = 3600s.



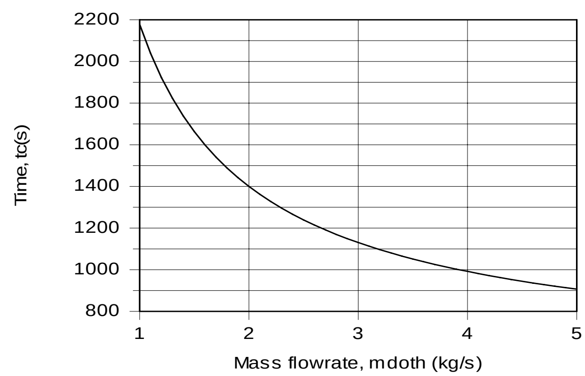
Continued …

PROBLEM 8.32 (Cont.)

With increasing T_c, the rate of heat transfer from the hot fluid decreases (from 4.49×10^5 W at t = 0 to 6760 W at 3600s), in which case $T_{h,o}$ increases (from 125.2°C at t = 0 to 198.9°C at 3600s). The time required for the pharmaceuticals to reach a temperature of T_c = 160°C is

$$t_c = 1266\text{s}$$ <

With increasing $\dot{m}_h$, the overall heat transfer coefficient increases due to increasing h_i and the hot fluid maintains a higher temperature as it flows through the tube. Both effects enhance heat transfer to the pharmaceutical, thereby reducing the time to reach 160°C from 2178s for $\dot{m}_h = 1\,\text{kg/s}$ to 906s at 5 kg/s.



For $1 \le \dot{m}_h \le 5\,\text{kg/s},\ 12{,}700 \le Re_D \le 63{,}700$ and $565 \le h_i \le 2050\,\text{W/m}^2 \cdot \text{K}$.

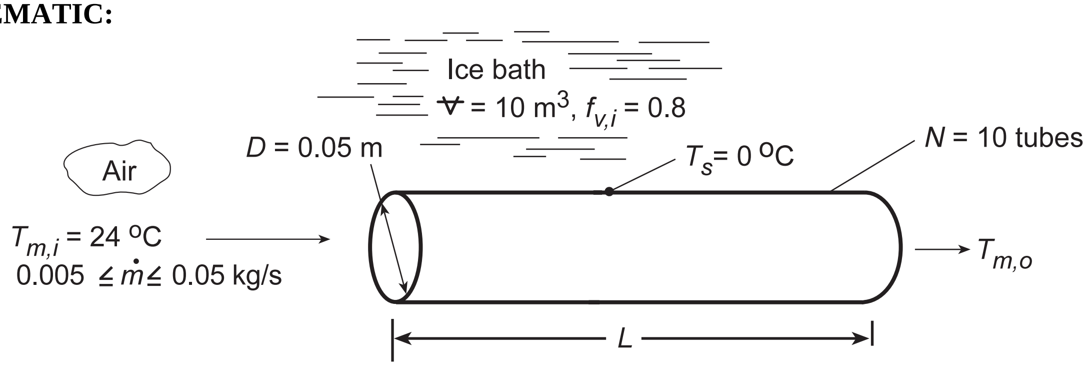
COMMENTS: (1) Although design changes involving the length and diameter of the coil can be used to alter the heating rate, process control parameters are limited to $T_{h,i}$ and $\dot{m}_h$. (2) Coiling the tube can increase the inside heat transfer coefficient, as will be seen in Section 8.7.

PROBLEM 8.33

KNOWN: Diameter and surface temperature of ten tubes in an ice bath. Inlet temperature and flowrate per tube. Volume (∀) of container and initial volume fraction, $f_{v,i}$, of ice.

FIND: (a) Tube length required to achieve a prescribed air outlet temperature $T_{m,o}$ and time to completely melt the ice, (b) Effect of mass flowrate on $T_{m,o}$ and suitable design and operating conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Ideal gas with negligible viscous dissipation and pressure variation, (3) Constant properties, (4) Fully developed flow throughout each tube, (5) Negligible tube wall thermal resistance.

PROPERTIES: *Table A.4*, air (assume $\overline{T}_m$ = 292 K): c_p = 1007 J/kg·K, μ = 180.6 × 10^{-7} N·s/m², k = 0.0257 W/m·K, Pr = 0.709; Ice: ρ = 920 kg/m³, h_{sf} = 3.34 × 10^5 J/kg.

ANALYSIS: (a) With $Re_D = 4\dot{m}/\pi D\mu$ = 4(0.01 kg/s)/π(0.05 m)180.6 × 10^{-7} N·s/m² = 14,100 for $\dot{m}$ = 0.01 kg/s, the flow is turbulent, and from Eq. 8.60,

$$\overline{Nu}_D = Nu_D = 0.023 Re_D^{0.8} Pr^{0.3} = 0.023(14{,}100)^{0.8}(0.709)^{0.3} = 43.3$$

$$\bar{h} = \overline{Nu}_D (k/D) = 43.3(0.0257\,W/m\cdot K/0.05\,m) = 22.2\,W/m^2\cdot K$$

With $T_{m,o}$ = 14°C, the tube length may be obtained from Eq. 8.41b,

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \frac{-14}{-24} = \exp\left(-\frac{\pi D L \bar{h}}{\dot{m} c_p}\right) = \exp\left[-\frac{\pi(0.05\,m)(22.2\,W/m^2\cdot K)L}{0.01\,kg/s(1007\,J/kg\cdot K)}\right]$$

L = 1.56 m $\quad <$

The time required to completely melt the ice may be obtained from an energy balance of the form,

$$(-q)t = f_{v,i}\forall(\rho h_{sf})$$

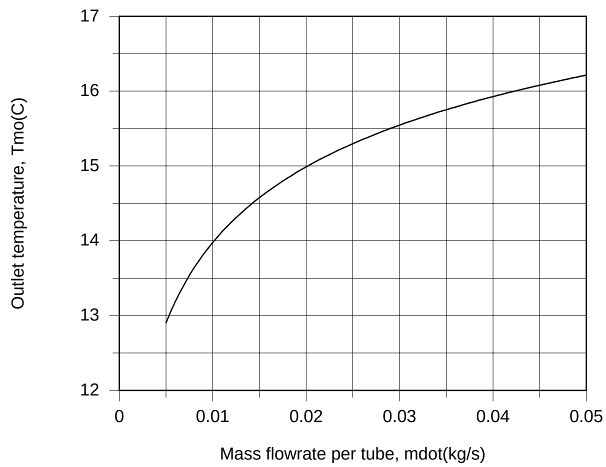
where $q = N\dot{m}c_p(T_{m,i} - T_{m,o}) = 10(0.01\,kg/s)1007\,J/kg\cdot K(10\,K) = 1007\,W$. Hence,

$$t = \frac{0.8(10\,m^3)(920\,kg/m^3)3.34\times10^5\,J/kg}{1007\,W} = 2.44\times10^6\,s = 28.3\,days \quad <$$

(b) Using the appropriate IHT Correlations and Properties Tool Pads, the following results were obtained.

Continued...

PROBLEM 8.33 (Cont.)



Although heat extraction from the air passing through each tube increases with increasing flowrate, the increase is not in proportion to the change in $\dot{m}$ and the temperature difference ($T_{m,i}$ - $T_{m,o}$) decreases. If 0.05 kg/s of air is routed through a single tube, the outlet temperature of $T_{m,o}$ = 16.2°C slightly exceeds the desired value of 16°C. The prescribed value could be achieved by slightly increasing the tube length. However, in the interest of reducing pressure drop requirements, it would be better to operate at a lower flowrate per tube. If, for example, air is routed through four of the tubes at 0.01 kg/s per tube and the discharge is mixed with 0.01 kg/s of the available air at 24°C, the desired result would be achieved.

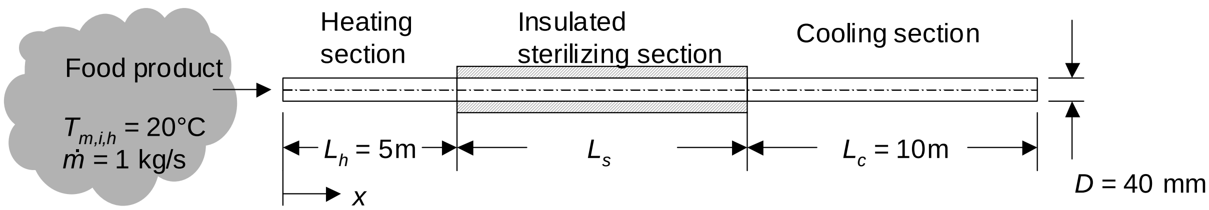
COMMENTS: Since the flow is turbulent and L/D = 31, the assumption of fully developed flow throughout a tube is marginal and the foregoing analysis overestimates the discharge temperature.

PROBLEM 8.34

KNOWN: Initial food temperature and mass flow rate. Length of heating and cooling sections in a food sterilizer. Diameter of sterilizer tube. Time-at-temperature constraint, and constraint on local maximum food temperature.

FIND: (a) Heat flux in the heating section. (b) Maximum local product temperature and its location. (c) Minimum required sterilizing section length. (d) Sketch of the axial distributions of the mean, surface, and centerline food temperatures from entrance to exit of sterilizer.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible viscous dissipation.

PROPERTIES: *Table A.6*, Water ($\overline{T}_m$ = 330 K, p = 1 atm): $\mu = 489\times10^{-6}$ N·s/m^2, Pr = 3.15, k = 0.65 W/m·K, c_p = 4184 J/kg·K, ρ = 984 kg/m^3.

ANALYSIS: (a) An energy balance applied to the heating section yields

$$q = q''A = q''\pi DL_h = \dot{m}c_p(T_{m,o,h} - T_{m,i,h})$$

which may be rearranged to provide the expression

$$q'' = \frac{\dot{m}c_p(T_{m,o,h} - T_{m,i,h})}{\pi DL_h} = \frac{1\text{kg/s}\times 4184\text{J/kg}\cdot\text{K}\times(90-20)°\text{C}}{\pi\times 0.04\text{m}\times 5\text{m}} = 466{,}000\text{W/m}^2 = 466\text{kW/m}^2 \quad <$$

(b) The maximum local product temperature occurs at the tube wall at the end of the heating section. The Reynolds number is

$$Re_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4\times 1\text{kg/s}}{\pi\times 0.04\text{m}\times 489\times10^{-6}\text{N}\cdot\text{s/m}^2} = 65{,}090$$

Hence, the flow is turbulent. Since L_h/D = 5m/0.04m = 125, the flow is fully-developed. Using the Dittus-Boelter correlation,

$$h = \frac{k}{D}\left[0.023Re_D^{4/5}Pr^{0.4}\right] = \frac{0.65\text{W/m}\cdot\text{K}}{0.04\text{m}}\left[0.023\times 65{,}090^{4/5}\times 3.15^{0.4}\right] = 4190\text{W/m}^2\cdot\text{K}$$

From Newton's law of cooling,

$$T_s(x = L_h = 5\text{m}) = T_{m,o,h} + \frac{q''}{h} = 90°\text{C} + \frac{466{,}000\text{W/m}^2}{4190\text{W/m}^2\cdot\text{K}} = 201°\text{C} \quad <$$

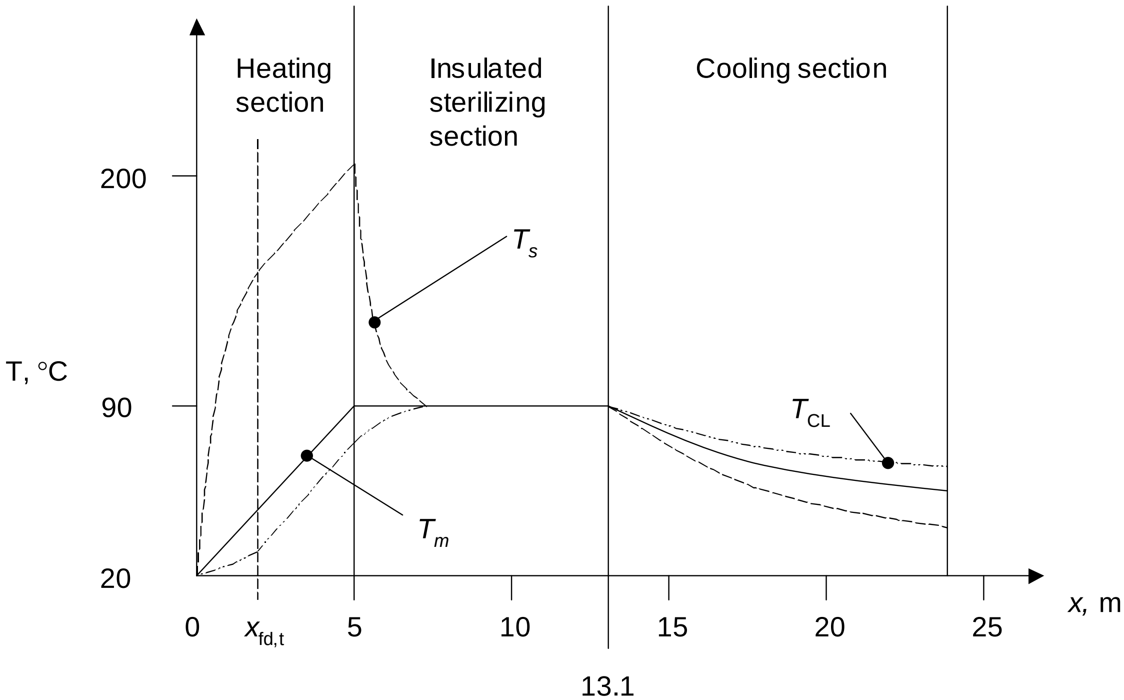
Continued…

The second constraint is satisfied. <

(c) The minimum length of the sterilizing section is

$$L_s = u_m t_s = \frac{4\dot{m}}{\rho \pi D^2} t_s = \frac{4 \times 1 \text{ kg/s}}{984 \text{ kg/m}^3 \times \pi \times (0.04 \text{ m})^2} \times 10 \text{ s} = 8.1\text{m}$$ <

(d) The axial distributions of the mean, surface, and centerline temperatures are shown below.



Important features of the temperature distribution are as follows.

$0 \leq x \leq x_{fd,t}$: Near the tube entrance, the heat transfer coefficient is theoretically infinite, and all three temperatures are nearly the same value.

$x_{fd,t} \leq x \leq L_h$: The flow is fully-developed; the shape of the radial temperature distribution does not change down the tube length. Therefore, the three temperature distributions are parallel.

$L_h \leq x \leq L_h + L_s$: The heat transfer coefficient is zero. However, temperature differences exist in the fluid, with warm temperatures adjacent to the tube wall and cool temperatures near the centerline of the tube. As the flow progresses down the insulated sterilizing section, the temperatures equilibrate by way of diffusion and turbulent mixing. The equilibration takes place over a distance approximately equal to $x_{fd,t}$.

Continued…

PROBLEM 8.34 (Cont.)

$L_h + L_s \leq x \leq L_h + L_s + L_c$: The fluid is cooled. Hence, the warmest temperature fluid is at the centerline, and the coolest fluid is adjacent to the tube wall. Since the fluid is cooled by exposure of the tube to the environment, the cooling rate is expected to be smaller than the heating rate in the heating section. Hence, the radial temperature differences in the cooling section are smaller than the radial temperature differences in the heating section.

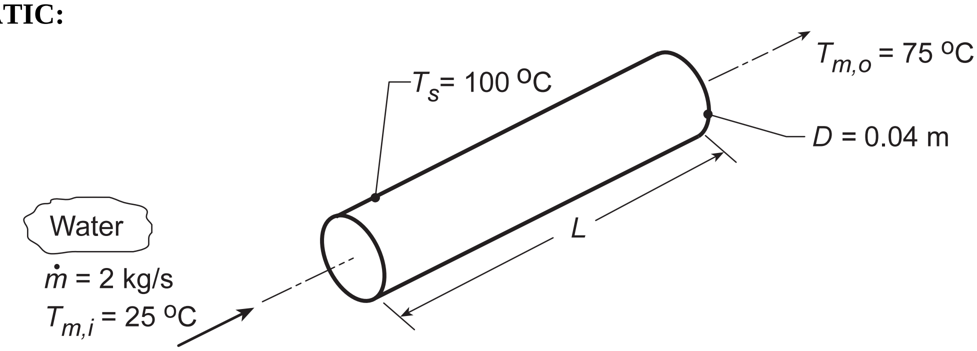
COMMENTS: (1) The velocity of the fluid at the centerline exceeds velocities at any other radial location. Hence, the fluid at the centerline of the tube will not satisfy the time-at-temperature criterion. Therefore, use of a coiled tube or other heat transfer enhancement devices (Section 8.7) would be appropriate in this application. (2) The insulation thickness in the sterilizing section should be much greater than the critical insulation thickness.

PROBLEM 8.35

KNOWN: Flow rate, inlet temperature and desired outlet temperature of water passing through a tube of prescribed diameter and surface temperature.

FIND: (a) Required tube length, L, for prescribed conditions, (b) Required length using tube diameters over the range $30 \le D \le 50$ mm with flow rates $\dot{m}$ = 1, 2 and 3 kg/s; represent this design information graphically, and (c) Pressure gradient as a function of tube diameter for the three flow rates assuming the tube wall is smooth.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Incompressible liquid with negligible viscous dissipation, (3) Constant properties.

PROPERTIES: *Table A.6*, Water ($\overline{T}_m$ = 323 K): c_p = 4181 J/kg·K, $\mu = 547 \times 10^{-6}$ N·s/m^2, k = 0.643 W/m·K, Pr = 3.56.

ANALYSIS: (a) From Eq. 8.6, the Reynolds number is

$$Re_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 2\,kg/s}{\pi (0.04\,m) 547 \times 10^{-6}\,N \cdot s/m^2} = 1.16 \times 10^5. \qquad (1)$$

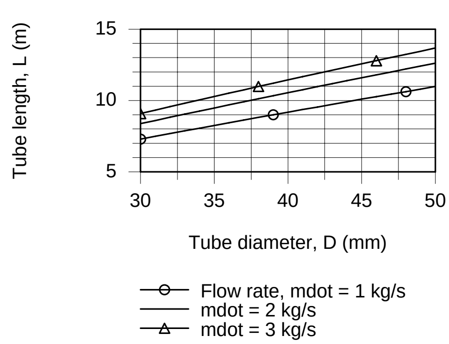
Hence the flow is turbulent, and assuming fully developed conditions throughout the tube, it follows from the Dittus-Boelter correlation, Eq. 8.60,

$$\overline{h} = \frac{k}{D} 0.023\,Re_D^{4/5}\,Pr^{0.4} = \frac{0.643\,W/m \cdot K}{0.04\,m} 0.023 \left(1.16 \times 10^5\right)^{4/5} (3.56)^{0.4} = 6919\,W/m^2 \cdot K \qquad (2)$$

From Eq. 8.41a, we then obtain

$$L = \frac{-\dot{m} c_p \ell n\left(\Delta T_o / \Delta T_i\right)}{\pi D \overline{h}} = -\frac{2\,kg/s\left(4181\,J/kg \cdot K\right) \ell n\left(25^\circ C/75^\circ C\right)}{\pi (0.04\,m) 6919\,W/m^2 \cdot K} = 10.6\,m.$$ <

(b) Using the *IHT Correlations Tool*, *Internal Flow*, for fully developed *Turbulent Flow*, along with appropriate energy balance and rate equations, the required length L as a function of flow rate is computed and plotted on the right.



Continued...

PROBLEM 8.35 (Cont.)

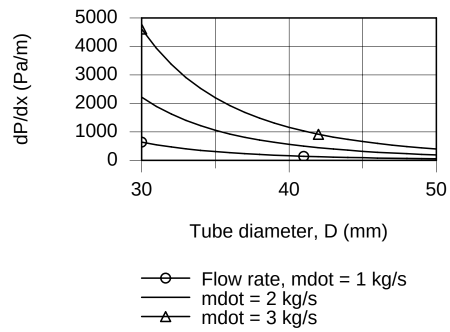
(c) From Eq. 8.22a the pressure drop is

$$\frac{\Delta p}{\Delta x} = f \frac{\rho u_m^2}{2D} \qquad (4)$$

The friction factor, f, for the smooth surface condition, Eq. 8.21 with $3000 \le Re_D \le 5 \times 10^6$, is

$$f = \left(0.790 \ell n\left(Re_D\right) - 1.64\right)^{-2} \qquad (5)$$

Using IHT with these equations and Eq. (1), the pressure gradient as a function of diameter for the selected flow rates is computed and plotted on the right.



COMMENTS: (1) Since L/D = (10.6/0.040) = 265, the assumption of fully developed conditions throughout is justified.

(2) The IHT Workspace used to generate the graphical results are shown below.

```
// Rate Equation Tool - Tube Flow with Constant Surface Temperature:

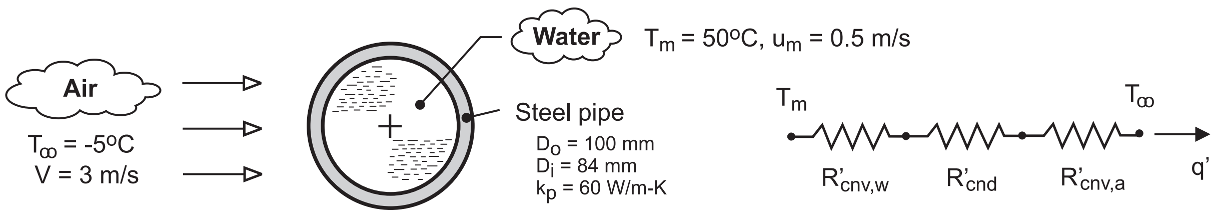
```

PROBLEM 8.36

KNOWN: Diameters and thermal conductivity of steel pipe. Temperature and velocity of water flow in pipe. Temperature and velocity of air in cross flow over pipe. Cost of producing hot water.

FIND: Daily cost of heat loss per unit length of pipe.

SCHEMATIC:



ASSUMPTIONS: (1) Steady state, (2) Constant properties, (3) Negligible radiation from outer surface, (4) Fully-developed flow in pipe.

PROPERTIES: *Table A-4*, air (p = 1 atm, $T_f \approx 300K$): $k_a = 0.0263$ W/m·K, $\nu_a = 15.89 \times 10^{-6}$ m^2/s, $Pr_a = 0.707$. *Table A-6*, water (T_m = 323 K): $\rho_w = 988$ kg/m^3, $\mu_w = 548 \times 10^{-6}$ N·s/m^2, $k_w = 0.643$ W/m·K, $Pr_w = 3.56$.

ANALYSIS: The heat loss per unit length of pipe is

$$q' = \frac{T_m - T_\infty}{R'_{cnv,w} + R'_{cnd} + R'_{cnv,a}} = \frac{T_m - T_\infty}{\left(h_w \pi D_i\right)^{-1} + \dfrac{\ln\left(D_o / D_i\right)}{2\pi k_p} + \left(h_a \pi D_o\right)^{-1}}$$

With $Re_{D,w} = \rho_w u_m D_i / \mu_w = 988\,kg/m^3 \times 0.5\,m/s \times 0.084\,m / 548 \times 10^{-6}\,N\cdot s/m^2 = 75,700$, flow is turbulent, and for fully developed conditions, the Dittus-Boelter correlation yields

$$h_w = \frac{k_w}{D_i} 0.023 Re_{D_w}^{0.8}\ Pr_w^{0.3} = 0.023 \frac{0.643\,W/m\cdot K}{0.084\,m} (75,700)^{0.8} (3.56)^{0.3} = 2060\,W/m^2\cdot K$$

With $Re_{D,a} = VD_o / \nu_a = 3\,m/s \times (0.1m)/15.89 \times 10^{-6} m^2/s = 18,880$, the Churchill-Bernstein correlation yields

$$h_a = \overline{h} = \frac{k_a}{D_o}\left\{0.3 + \frac{0.62 Re_{D,a}^{1/2}\ Pr_a^{1/3}}{\left[1 + \left(0.4/Pr_a\right)^{2/3}\right]^{1/4}}\left[1 + \left(\frac{Re_{D,w}}{282,000}\right)^{5/8}\right]^{4/5}\right\} = 20.1\,W/m^2\cdot K$$

Hence, $$q' = \frac{50°C - (-5°C)}{\left(1.84 \times 10^{-3} + 0.46 \times 10^{-3} + 158.3610^{-3}\right)K/W} = 342\,W/m = 0.342\,kW/m$$

The daily energy loss is then $$Q' = 0.346\,kW/m \times 24\,h/d = 8.22\,kW\cdot h/d\cdot m$$

and the associated cost is $$C' = (8.22\,kW\cdot h/d\cdot m)(\$0.05/kW\cdot h) = \$0.411/m\cdot d$$ <

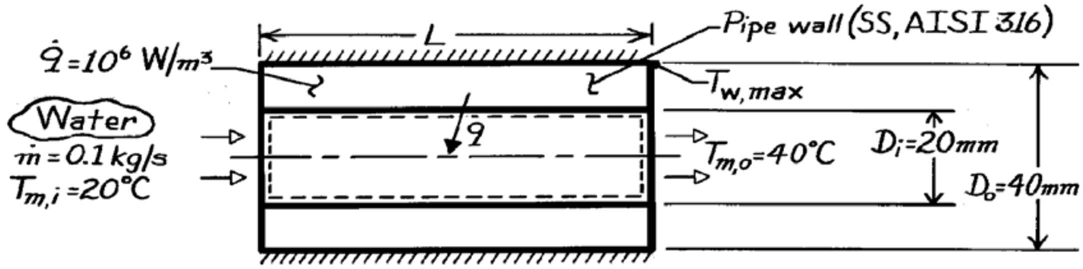
COMMENTS: Because $R'_{cnv,a} >> R'_{cnv,w}$, the convection resistance for the water side of the pipe could have been neglected, with negligible error. The implication is that the temperature of the pipe's inner surface closely approximates that of the water. If $R'_{cnv,w}$ is neglected, the heat loss is $q' = 346\,W/m$.

PROBLEM 8.37

KNOWN: Inner and outer diameter of a steel pipe insulated on the outside and experiencing uniform heat generation. Flow rate and inlet temperature of water flowing through the pipe.

FIND: (a) Pipe length required to achieve desired outlet temperature, (b) Location and value of maximum pipe temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Incompressible liquid with negligible viscous dissipation, (4) One-dimensional radial conduction in pipe wall, (5) Outer surface is adiabatic.

PROPERTIES: *Table A-1*, Stainless steel 316 (T ≈ 400K): k = 15 W/m·K; *Table A-6*, Water $\left(\overline{T}_m = 303K\right)$: c_p = 4178 J/kg·K, k = 0.617 W/m·K, μ = 803 × 10^{-6} N·s/m^2, Pr = 5.45.

ANALYSIS: (a) Performing an energy balance for a control volume about the inner tube, it follows that

$$\dot{m}\, c_p \left(T_{m,o} - T_{m,i}\right) = q = \dot{q}\left(\pi/4\right)\left(D_o^2 - D_i^2\right)L$$

$$L = \frac{\dot{m}\, c_p \left(T_{m,o} - T_{m,i}\right)}{\dot{q}\left(\pi/4\right)\left(D_o^2 - D_i^2\right)} = \frac{(0.1\text{ kg/s})\,4178(\text{J/kg}\cdot\text{K})\,20^\circ\text{C}}{10^6\text{ W/m}^3(\pi/4)\left[(0.04\text{m})^2 - (0.02\text{m})^2\right]}$$

$$L = 8.87\text{m}.$$ <

(b) The maximum wall temperature exists at the pipe exit (x = L) and the insulated surface (r = r_o). From Eq. 3.56, the radial temperature distribution in the wall is of the form

$$T(r) = -\frac{\dot{q}}{4k}r^2 + C_1 \ell n\, r + C_2.$$

Considering the boundary conditions;

$$r = r_o: \quad \left.\frac{dT}{dr}\right)_{r=r_o} = 0 = -\frac{\dot{q}}{2k}\, r_o + \frac{C_1}{r_o} \qquad\qquad C_1 = \frac{\dot{q} r_o^2}{2k}$$

Continued …

PROBLEM 8.37 (Cont.)

$$r = r_i: \quad T(r_i) = T_s = -\frac{\dot{q}}{4k}r_i^2 + \frac{\dot{q}\,r_o^2}{2k}\ln r_i + C_2 \qquad C_2 = \frac{\dot{q}}{4k}r_i^2 - \frac{\dot{q}\,r_o^2}{2k}\ln r_i + T_s.$$

The temperature distribution and the maximum wall temperature ($r = r_o$) are

$$T(r) = -\frac{\dot{q}}{4k}\left(r^2 - r_i^2\right) + \frac{\dot{q}\,r_o^2}{2k}\ln\frac{r}{r_i} + T_s$$

$$T_{w,max} = T(r_o) = -\frac{\dot{q}}{4k}\left(r_o^2 - r_i^2\right) + \frac{\dot{q}\,r_o^2}{2k}\ln\frac{r_o}{r_i} + T_s$$

where T_s, the inner surface temperature of the wall at the exit, follows from

$$q_s'' = \frac{\dot{q}(\pi/4)\left(D_o^2 - D_i^2\right)L}{\pi D_i L} = \frac{\dot{q}\left(D_o^2 - D_i^2\right)}{4D_i} = h\left(T_s - T_{m,o}\right)$$

where h is the local convection coefficient at the exit. With

$$Re_D = \frac{4\dot{m}}{\pi D_i \mu} = \frac{4 \times 0.1\text{ kg/s}}{\pi(0.02\text{m})803\times10^{-6}\text{ N}\cdot\text{s/m}^2} = 7928$$

the flow is turbulent and, with $(L/D_i) = (8.87\text{ m}/0.02\text{m}) = 444 >> (x_{fd}/D) \approx 10$, it is also fully developed. Hence, from the Gnielinski correlation, Eq. 8.62,

$$h = \frac{k}{D_i}\left[\frac{(f/8)(Re_D - 1000)Pr}{1 + 12.7(f/8)^{1/2}(Pr^{2/3} - 1)}\right]$$

$$= \frac{0.617\text{ W/m}\cdot\text{K}}{0.02\text{ m}}\left[\frac{(0.033618)(7928 - 1000)5.45}{1 + 12.7(0.033618)^{1/2}(5.45^{2/3} - 1)}\right] = 1796\text{ W/m}^2\cdot\text{K}$$

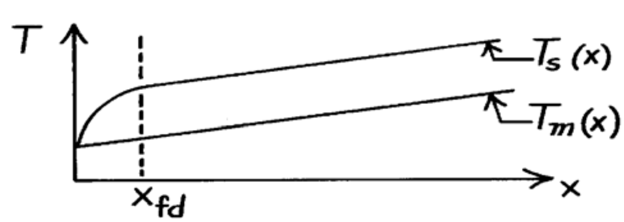
where from Eq. 8.21, $f = (0.790 \ln Re_D - 1.64)^{-2} = 0.0336$. Hence, the inner surface temperature of the wall at the exit is

$$T_s = \frac{\dot{q}\left(D_o^2 - D_i^2\right)}{4hD_i} + T_{m,o} = \frac{10^6\text{ W/m}^3\left[(0.04\text{m})^2 - (0.02\text{m})^2\right]}{4\times1796\text{ W/m}^2\cdot\text{K}(0.02\text{m})} + 40^\circ\text{C} = 48.4^\circ\text{C}$$

and $$T_{w,max} = -\frac{10^6\text{ W/m}^3}{4\times15\text{ W/m}\cdot\text{K}}\left[(0.02\text{m})^2 - (0.01\text{m})^2\right]$$

$$+\frac{10^6\text{ W/m}^3(0.02\text{m})^2}{2\times15\text{ W/m}\cdot\text{K}}\ln\frac{0.02}{0.01} + 48.4^\circ\text{C} = 52.6^\circ\text{C}.$$ <

COMMENTS: The physical situation corresponds to a uniform surface heat flux, and T_m increases linearly with x. In the fully developed region, T_s also increases linearly with x.

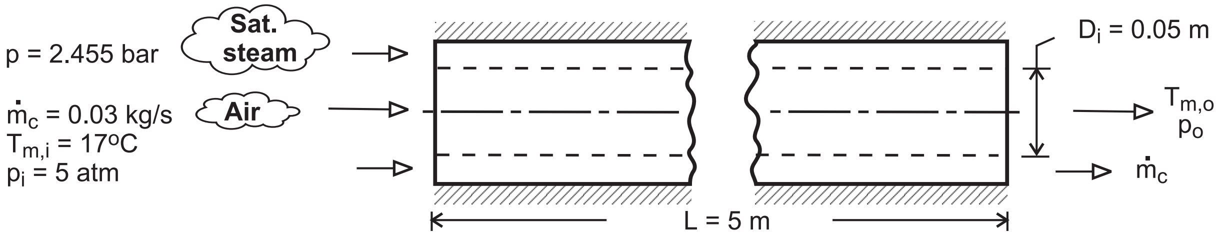


PROBLEM 8.38

KNOWN: Inlet temperature, pressure and flow rate of air. Tube diameter and length. Pressure of saturated steam.

FIND: Outlet temperature and pressure of air. Mass rate of steam condensation.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Outer surface of annulus is adiabatic, (3)Ideal gas with negligible viscous dissipation and pressure variation, (4) Fully-developed flow throughout the tube, (5) Smooth tube surface, (6) Constant properties.

PROPERTIES: *Table A-4*, air $\left(\overline{T}_m \approx 325\,K,\ p = 5\,atm\right)$: $\rho = 5\times\rho(1\,atm) = 5.391\,kg/m^3$, $c_p = 1008\,J/kg\cdot K$, $\mu = 196.4\times10^{-7}\,N\cdot s/m^2$, $k = 0.0281\,W/m\cdot K$, $Pr = 0.703$. *Table A-6*, sat. steam (p = 2.455 bars): T_s = 400 K, h_{fg} = 2183 kJ/kg.

ANALYSIS: With a uniform surface temperature, the air outlet temperature is

$$T_{m,o} = T_s - \left(T_s - T_{m,i}\right)\exp\left(-\frac{\pi D_i L}{\dot{m}\,c_p}\overline{h}\right)$$

With $Re_D = 4\dot{m}/\pi D_i\,\mu = 0.12\,kg/s/\pi(0.05m)196.4\times10^{-7}\,kg/s\cdot m = 38,980$, the flow is turbulent, and the Dittus-Boelter correlation yields

$$\overline{h} \approx h_{fd} = \left(\frac{k}{D_i}\right)0.023\,Re_D^{4/5}\,Pr^{0.4} = \left(\frac{0.0281\,W/m\cdot K}{0.05m}\right)0.023(38,980)^{4/5}(0.703)^{0.4} = 52.8\,W/m^2\cdot K$$

$$T_{m,o} = 127°C - (110°C)\exp\left(-\frac{\pi\times0.05m\times5m\times52.8\,W/m^2\cdot K}{0.03\,kg/s\times1008\,J/kg\cdot K}\right) = 99°C$$ <

The pressure drop is $\Delta p = f\left(\rho u_m^2/2D_i\right)L$, where, with $A_c = \pi D_i^2/4 = 1.963\times10^{-3}m^2$, $u_m = \dot{m}/\rho A_c = 2.83\,m/s$, and with $Re_D = 38,980$, Eq. 8.21 gives f = $[0.790\ln(Re_D) - 1.64]^{-2}$ = 0.022. Hence,

$$\Delta p = 0.022\times5.391\,kg/m^3\,\frac{(2.83\,m/s)^2\,5m}{2\times0.05m} = 47.5\,N/m^2 = 4.7\times10^{-4}atm$$ <

The rate of heat transfer to the air is

$$q = \dot{m}\,c_p\left(T_{m,o} - T_{m,i}\right) = 0.03\,kg/s\times1008\,J/kg\cdot K(82°C) = 2480\,W$$

and the rate of condensation is then

$$\dot{m}_c = \frac{q}{h_{fg}} = \frac{2480\,W}{2.183\times10^6\,J/kg} = 1.14\times10^{-3}kg/s$$ <

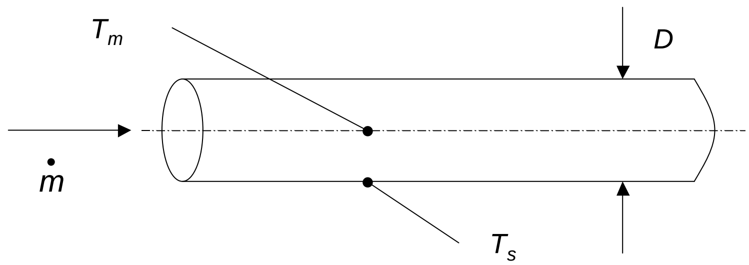
COMMENTS: (1) With $\overline{T}_m = \left(T_{m,i} + T_{m,o}\right)/2 = 331\,K$, the initial estimate of 325 K is reasonable and iteration is not necessary. (2) For a steam flow rate of 0.01 kg/s, approximately 10% of the outflow would be in the form of saturated liquid, (3) With L/D_i = 100, it is reasonable to assume fully developed flow throughout the tube.

PROBLEM 8.39

KNOWN: Fully-developed conditions for laminar or turbulent flow characterized by a fixed mass flow rate. Constant surface temperature conditions with $T_s < T_m$.

FIND: Determine whether a small or large diameter tube will be more effective in minimizing heat loss from the flowing fluid.

SCHEMATIC:



ASSUMPTIONS: (1) Fully-developed, (2) Constant properties, (3) Negligible viscous dissipation.

ANALYSIS: The heat loss rate per unit tube length is

$$q' = \pi D h (T_s - T_m) \quad \text{where} \quad h = Nu_D k / D$$

Combining the preceding equations yields

$$q' = \pi Nu_D k (T_s - T_m) \tag{1}$$

Laminar Conditions

For laminar conditions, $Nu_D = 3.66$. Substituting this expression into Eq. (1) yields

$$q' = 3.66\pi k (T_s - T_m)$$

and the heat loss rate is independent of the tube diameter. <

Turbulent Conditions

For turbulent flow, we may substitute the Dittus-Boelter correlation, $Nu_D = 0.023 Re_D^{4/5} Pr^{0.3}$ with $Re_D = (4\dot{m}/\pi D\mu)$ into Eq. (1) to find

$$q' = \pi(0.023)\left(\frac{4\dot{m}}{\pi\mu}\right)^{4/5} D^{-4/5} Pr^{0.3} k (T_s - T_m)$$

Hence, to minimize the heat loss, a large diameter tube is preferred. <

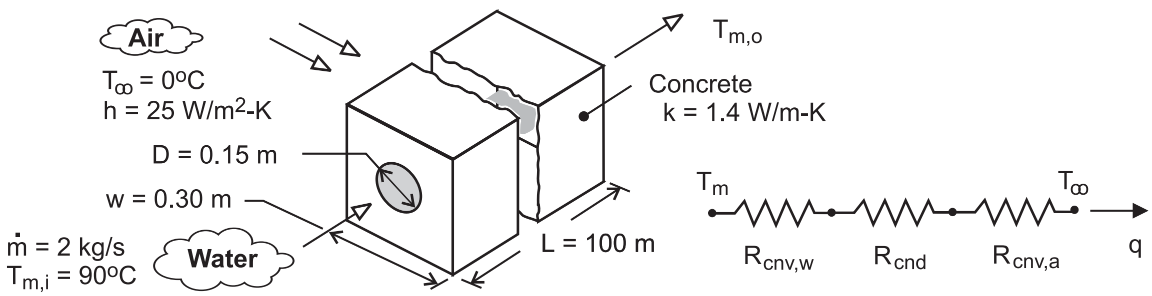
COMMENTS: The large diameter tube will result in reduced heat loss, but will be more expensive relative to a small diameter tube. If the cool surface temperature is induced by heat losses to the environment, a more effective approach to minimize heat loss would be to insulate the exterior of the tube.

PROBLEM 8.40

KNOWN: Dimensions and thermal conductivity of concrete duct. Convection conditions of ambient air. Flow rate and inlet temperature of water flow through duct.

FIND: (a) Outlet temperature, (b) Pressure drop and pump power requirement, (c) Effect of flow rate and pipe diameter on outlet temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Fully developed flow throughout duct, (3) Negligible pipe wall conduction resistance, (4)Water is incompressible liquid with negligible viscous dissipation, (5) Constant properties.

PROPERTIES: *Table A-6*, water $\left(\overline{T}_m \approx 360\,K\right)$: $\rho = 967\,kg/m^3$, $c_p = 4203\,J/kg\cdot K$, $\mu = 324\times10^{-6}$ $N\cdot s/m^2$, $k_w = 0.674\,W/m\cdot K$, $Pr = 2.02$.

ANALYSIS: (a) The outlet temperature is given by

$$T_{m,o} = T_\infty + \left(T_{m,i} - T_\infty\right)\exp\left(-UA/\dot{m}\,c_p\right)$$

where

$$UA = \left(R_{tot}\right)^{-1} = \left(R_{cnv,w} + R_{cnd} + R_{cnv,a}\right)^{-1}$$

From Table 4.1, Case 6,

$$R_{cnd} = \frac{\ln\left(1.08\,w/D\right)}{2\pi kL} = \frac{\ln\left(1.08\times0.30m/0.15m\right)}{2\pi\left(1.4\,W/m\cdot K\right)100m} = 8.75\times10^{-4}\ K/W$$

$$R_{cnv,a} = \left(4\,w\,L\,h\right)^{-1} = \left(4\times0.3m\times100m\times25\,W/m^2\cdot K\right)^{-1} = 3.33\times10^{-4}\,K/W$$

With $Re_D = 4\dot{m}/\pi D\mu = \left(4\times2\,kg/s\right)/\left(\pi\times0.15m\times324\times10^{-6}\,N\cdot s/m^2\right) = 52,400,$

$$\overline{h}_w \approx h_{fd} = \frac{k_w}{D}0.023\,Re_D^{4/5}\,Pr^{0.3} = \frac{0.674\,W/m\cdot K\times0.023}{0.15m}\left(52,400\right)^{4/5}\left(2.02\right)^{0.3} = 761\,W/m^2\cdot K$$

$$R_{cnv,w} = \left(\pi\,D\,L\,\overline{h}_w\right)^{-1} = \left(\pi\times0.15m\times100m\times761\,W/m^2\cdot K\right)^{-1} = 2.79\times10^{-5}\,K/W$$

$$UA = \left[\left(2.79\times10^{-5} + 8.75\times10^{-4} + 3.33\times10^{-4}\right)K/W\right]^{-1} = 809\,W/K$$

$$T_{m,o} = 0°C + 90°C\ \exp\left(-\frac{809\,W/K}{2\,kg/s\times4203\,J/kg\cdot K}\right) = 81.7°C$$ <

Continued …

PROBLEM 8.40 (Cont.)

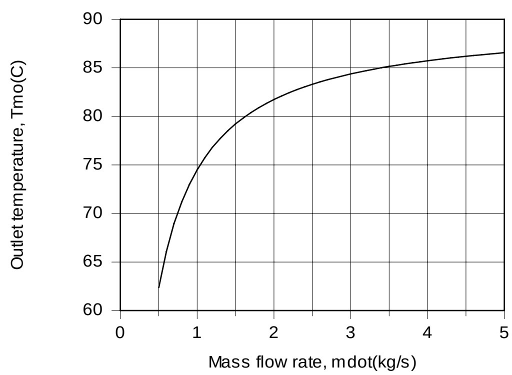
(b) From Eq. 8.21, f = [0.790ln(Re$_D$) – 1.64]$^{-2}$ = 0.0207 and $u_m = \dot{m}/\rho\pi D^2/4 = 0.117\,\text{m/s}$,

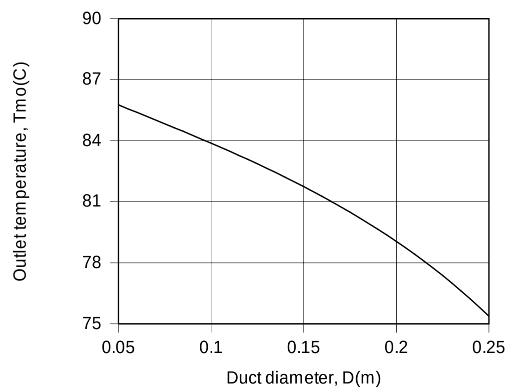
$$\Delta p = f\,\frac{\rho u_m^2}{2D}L = 0.0207\,\frac{967\,\text{kg/m}^3\,(0.117\,\text{m/s})^2}{2\times 0.15\text{m}}100\text{m} = 91\,\text{N/m}^2 = 9.1\times10^{-4}\text{ bars} \quad <$$

With $\dot{\forall} = \dot{m}/\rho = 2.07\times10^{-3}\,\text{m}^3/\text{s}$, the pump power requirement is

$$P = \Delta p\dot{\forall} = \left(91\,\text{N/m}^2\right)2.07\times10^{-3}\,\text{m}^3/\text{s} = 0.19\,\text{W} \quad <$$

(c) The effects of varying the flowrate and duct diameter were assessed using the IHT software, and results are shown below.





Although $R_{cnv,w}$, and hence R_{tot}, decreases with increasing $\dot{m}$, thereby increasing UA, the effect is significantly less than that of $\dot{m}$ to the first power, causing the exponential term, $\exp\left(-UA/\dot{m}\,c_p\right)$, to approach unity and $T_{m,o}$ to approach $T_{m,i}$. The effect can alternatively be attributed to a reduction in the residence time of the water in the pipe (u_m increases with increasing $\dot{m}$ for fixed D). With increasing D for fixed $\dot{m}$ and w, $T_{m,o}$ decreases due to an increase in the residence time, as well as a reduction in the conduction resistance, R_{cnd}.

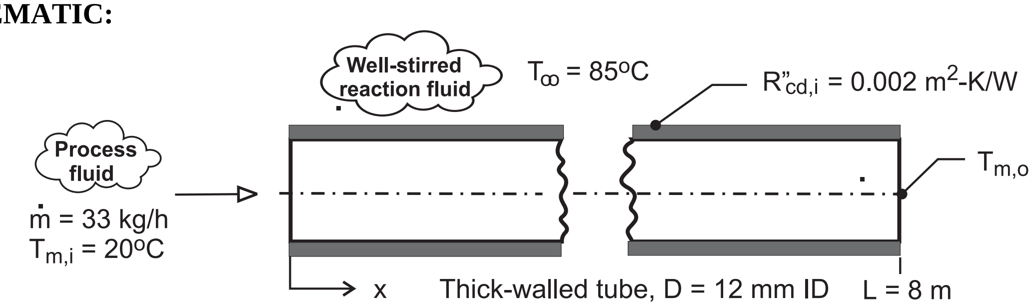
COMMENTS: (1) Use of $\overline{T}_m = 360\,\text{K}$ to evaluate properties of the water for Parts (a) and (b) is reasonable, and iteration is not necessary. (2) The pressure drop and pump power requirement are small.

PROBLEM 8.41

KNOWN: Water flow through a thick-walled tube immersed in a well stirred, hot reaction tank maintained at 85°C; conduction thermal resistance of the tube wall based upon the inner surface area is $R''_{cd} = 0.002\ m^2 \cdot K/W$.

FIND: (a) The outlet temperature of the process fluid, $T_{m,o}$; assume, and then justify, fully developed flow and thermal conditions within the tube; and (b) Do you expect $T_{m,o}$ to increase or decrease if the combined entry condition exists within the tube? Estimate the outlet temperature of the process fluid for this condition.

SCHEMATIC:



ASSUMPTIONS: (1) Flow is fully developed, part (a), (2) Constant properties, (3) Incompressible liquid with negligible viscous dissipation, and (4) Constant wall temperature heating, with $T_s \approx T_\infty$ because of small thermal resistance associated with well-stirred reaction fluid.

PROPERTIES: *Table A-6*, *Water* ($T_m = (T_{m,o} + T_{m,i})/2 = 315$ K): $c_p = 4179$ J/kg·K, $\mu = 6.31 \times 10^{-4}$ N·s/m², k = 0.634 W/m·K, Pr =4.16.

ANALYSIS: (a) The outlet temperature is determined from the rate equation, Eq. 8.45a, written as

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{\overline{U}A_s}{\dot{m}c_p}\right) \tag{1}$$

where the overall coefficient, based upon the inner surface area of the tube is expressed in terms of the convection and conduction thermal resistances,

$$\frac{1}{\overline{U}} = \frac{1}{\overline{h}} + R''_{cd,i} \tag{2}$$

To estimate $\overline{h}$, begin by characterizing the flow

$$Re_D = 4\dot{m}/\pi D\mu \tag{3}$$

$$Re_D = 4(33/3600\ kg/s)/\pi \times 0.012\ m \times 6.31 \times 10^{-4} N \cdot s/m^2 = 1540$$

Consider the flow as laminar, and assuming fully developed conditions, estimate $\overline{h}$ with the correlation of Eq. 8.55,

$$\overline{Nu}_D = \overline{h}D/k = 3.66 \tag{4}$$

$$\overline{h} = 3.66 \times 0.634\ W/m \cdot K/0.012\ m = 193\ W/m^2 \cdot K$$

From Eq. (2),

$$\overline{U} = \left[1/193\ W/m^2 \cdot K + 0.002\ m^2 \cdot K/W\right]^{-1} = 139\ W/m^2 \cdot K$$

and from Eq. (1), with $A_s = \pi DL$, calculate $T_{m,o}$.

Continued …

PROBLEM 8.41 (Cont.)

$$\frac{85-T_{m,o}}{85-20}=\exp\left(-\frac{139\ \mathrm{W/m^2\cdot K}\times\pi\times0.012\ \mathrm{m}\times8\ \mathrm{m}}{33/3600\ \mathrm{kg/s}\times4179\ \mathrm{J/kg\cdot K}}\right)$$

$$T_{m,o}=63°\mathrm{C}$$ <

Fully developed flow and thermal conditions are justified if the tube length is much greater than the fully developed lengths $x_{fd,h}$ and $x_{fd,t}$. From Eqs. 8.3 and 8.23,

$$x_{fd,h}=0.05\ Re_D\ D=0.05\times1540\times0.012\ \mathrm{m}=0.92\ \mathrm{m}$$
$$x_{fd,t}=x_{fd,h}\ Pr=0.92\ \mathrm{m}\times4.16=3.8\ \mathrm{m}$$

That is, while fully developed velocity conditions may be justifiable, the length is only twice that required to reach *thermally* fully developed conditions.

(b) We expect the calculated outlet temperature to be larger if the combined entrance effect exists, since the average heat transfer coefficient would be larger relative to that associated with fully-developed conditions. <

Considering combined entry length conditions, estimate the convection coefficient using the Baehr and Stephan correlation, Eq. 8.58, where from Eq. 8.56, $Gz_D = (D/L)Re_DPr = (0.012\ \mathrm{m}/8\ \mathrm{m}) \times 1540 \times 4.16 = 9.61$:

$$\overline{Nu}_D=\frac{\bar{h}D}{k}=\frac{\dfrac{3.66}{\tanh[2.264Gz_D^{-1/3}+1.7Gz_D^{-2/3}]}+0.0499Gz_D\tanh(Gz_D^{-1})}{\tanh(2.432\,Pr^{1/6}\,Gz_D^{-1/6})} \qquad (5)$$

$$\bar{h}=\frac{0.634\,\mathrm{W/m\cdot K}}{0.012\,\mathrm{m}}\left(\frac{\dfrac{3.66}{\tanh[2.264\times9.61^{-1/3}+1.7\times9.61^{-2/3}]}+0.0499\times9.61\tanh(9.61^{-1})}{\tanh(2.432\times4.16^{1/6}\times9.61^{-1/6})}\right)=225\,\mathrm{W/m^2\cdot K}$$

which is a 17% increase over the fully developed analysis result. Using the foregoing relations, find

$$U=155\ \mathrm{W/m^2\cdot K} \qquad T_{m,o}=65.9°\mathrm{C}$$ <

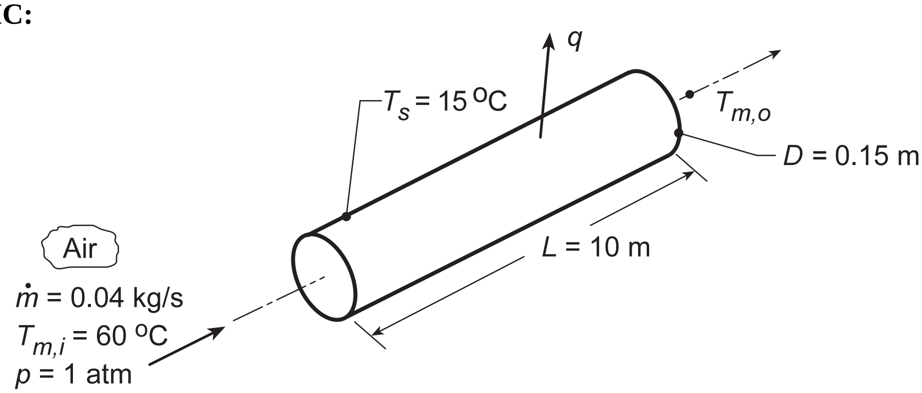
COMMENTS: (1) The thermophysical properties for the fully developed correlation should be evaluated at the mean fluid temperature $T_m = (T_{m,o} + T_{m,i})/2 = 316$ K. This is very close to the assumed value of 315 K. (2) For the Baehr and Stephan correlation, the properties are also evaluated at T_m. (3) For this case where the tube length is about twice $x_{fd,t}$, the average heat transfer coefficient is larger than the fully developed value, as we would expect. (4) The thermal entry length correlation due to Hausen yields $\bar{h}$ = 222 W/m^2·K, close to the combined entry length value. This is not surprising, considering that the Prandtl number of 4.16 is close to meeting the Pr > 5 condition for the Hausen correlation to be valid.

PROBLEM 8.42

KNOWN: Flow rate and temperature of atmospheric air entering a duct of prescribed diameter, length and surface temperature.

FIND: (a) Air outlet temperature and duct heat loss for the prescribed conditions and (b) Calculate and plot q and Δp for the range of diameters, $0.1 \le D \le 0.2$ m, maintaining the total surface area, $A_s = \pi DL$, at the same value as part (a). Explain the trade off between the heat transfer rate and pressure drop.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3)Ideal gas with negligible viscous dissipation and pressure variation, (4) Uniform surface temperature, (5) Fully developed flow conditions.

PROPERTIES: *Table A.4*, Air ($\bar{T}_m \approx 310$ K, 1 atm): $\rho = 1.128$ kg/m^3, $c_p = 1007$ J/kg·K, $\mu = 189 \times 10^{-7}$ N·s/m^2, k = 0.027 W/m·K, Pr = 0.706.

ANALYSIS: (a) With

$$Re_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4\times 0.04\,kg/s}{\pi(0.15\,m)189\times 10^{-7}\,N\cdot s/m^2} = 17,965$$

the flow is turbulent. Assuming fully developed conditions throughout the tube, it follows from the Dittus-Boelter correlation, Eq. 8.60, that

$$\bar{h} = \frac{k}{D}0.023\,Re_D^{4/5}\,Pr^{0.3} = \frac{0.027\,W/m\cdot K}{0.15\,m}0.023(17,965)^{4/5}(0.706)^{0.3} = 9.44\,W/m^2\cdot K\,.$$

Hence, from the energy balance relation, Eq. 8.41b,

$$T_{m,o} = T_s - (T_s - T_{m,i})\exp\left(-\frac{\pi DL}{\dot{m}c_p}\bar{h}\right)$$

$$T_{m,o} = 15^\circ C + 45^\circ C\exp\left(-\frac{\pi(0.15\,m)10\,m(9.44\,W/m^2\cdot K)}{0.04\,kg/s(1007\,J/kg\cdot K)}\right) = 29.9^\circ C$$ <

From the overall energy balance, Eq. 8.34, it follows that

$$q = \dot{m}c_p(T_{m,o} - T_{m,i}) = 0.04\,kg/s\times 1007\,J/kg\cdot K(29.9-60)^\circ C = -1212\,W\,.$$ <

From Eq. 8.22a, the pressure drop is

$$\Delta p = f\frac{\rho u_m^2}{2D}L$$

Continued...

PROBLEM 8.42 (Cont.)

and for the smooth surface conditions, Eq. 8.21 can be used to evaluate the friction factor,

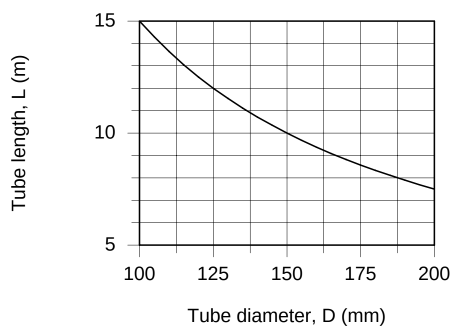
$$f = \left(0.790 \ln\left(Re_D\right) - 1.64\right)^{-2} = \left(0.790 \ln\left(17,965\right) - 1.64\right)^{-2} = 0.0269$$

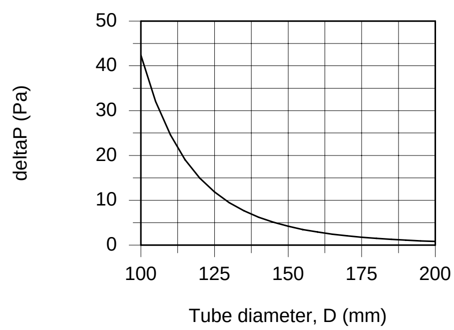
Hence, the pressure drop is

$$\Delta p = 0.0269 \frac{1.128\,kg/m^3 \left(2.0\,m/s\right)^2}{2 \times 0.15\,m} \times 10\,m = 4.03\,N/m^2 \quad <$$

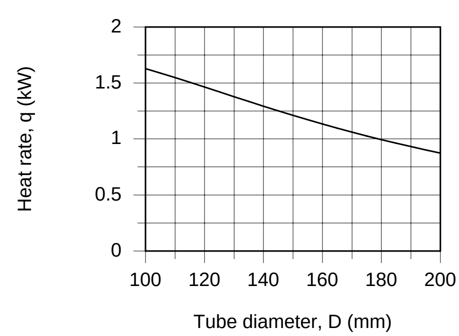
where $u_m = \dot{m}/\rho A_c = 0.04\,kg/s \Big/ 1.128\,kg/m^3 \times \left(\pi 0.15^2\,m^2/4\right) = 2.0\,m/s$.

(b) For the prescribed conditions of part (a), $A_s = \pi DL = \pi(0.15\,m) \times 10\,m = 4.712\,m^2$, using the *IHT Correlations Tool*, *Internal Flow* for fully developed *Turbulent Flow* along with the energy balance equation, rate equation and pressure drop equations used above, the heat rate q and Δp are calculated and plotted below.





From above, as D increases, L decreases so that A_s remains unchanged. The decrease in heat rate with increasing diameter is nearly linear, while the pressure drop decreases markedly. This is the trade off: increased heat rate requires a more significant increase in pressure drop, and hence fan blower power requirements.



COMMENTS: (1) To check the calculations, compute q from Eq. 8.43, where $\Delta T_{\ell m}$ is given by Eq. 8.44. It follows that $\Delta T_{\ell m}$ = -27.1°C and q = -1206 W. The small difference in results may be attributed to round-off error.

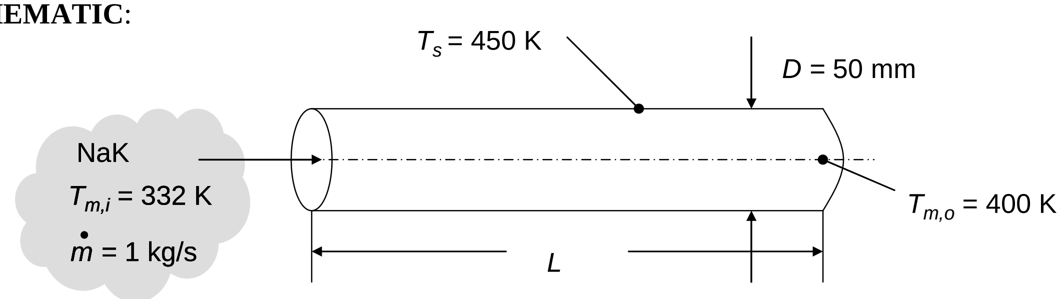
(2) For part (a), a slight improvement in accuracy may be obtained by evaluating the properties at $\overline{T}_m$ = 318 K: $\overline{h}$ = 9.42 W/m^2·K, $T_{m,o}$ = 303 K = 30°C, q = -1211 W, f = 0.0271 and Δp = 4.20 N/m^2.

PROBLEM 8.43

KNOWN: Flow rate of NaK, NaK inlet and outlet temperatures, tube wall temperature, tube diameter.

FIND: Tube length, and local convective flux at the tube exit.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Negligible viscous dissipation, (3) Fully developed flow.

PROPERTIES: *Table A.7* NaK (45%/55%; $\overline{T}_m = (332\text{K} + 400\text{K})/2 = 366\text{K}$): ρ = 887 kg/m^3, k = 25.6 W/m·K, $\nu = 6.52 \times 10^{-7}$ m^2/s, Pr = 0.026, c_p = 1130 J/kg·K.

ANALYSIS: The Reynolds number is

$$Re_D = 4\dot{m}/\pi D\nu\rho = 4\times 1\ \text{kg/s}/\left[\pi\times 0.05\ \text{m}\times 6.52\times 10^{-7}\ \text{m}^2/\text{s}\times 887\ \text{kg/m}^3\right] = 44{,}000$$

and the flow is turbulent. The Peclet number is $Pe_D = Re_D Pr = 44{,}000 \times 0.026 = 1145$. Therefore, we may use Eq. 8.65 if the flow is fully developed. Hence,

$$h = \frac{k}{D}\left(5.0 + 0.025 Pe_D^{0.8}\right) = \frac{25.6\text{W/m}\cdot\text{K}}{0.05\text{m}}\times\left(5.0 + 0.025\times 1145^{0.8}\right) = 6140\text{W/m}^2\cdot\text{K}$$

The required tube length is, from Eq. 8.41a,

$$L = -\frac{\dot{m}c_p}{\pi D h}\ln\frac{\Delta T_o}{\Delta T_i} = -\frac{1\ \text{kg/s}\times 1130\ \text{J/kg}\cdot\text{K}}{\pi\times 0.05\text{m}\times 6140\text{W/m}^2\cdot\text{K}}\ln\left(\frac{50}{118}\right) = 1\ \text{m} \qquad <$$

The local convective heat flux at $x = L = 1$ m is

$$q'' = h(T_s - T_{m,o}) = 6140\text{W/m}^2\cdot\text{K}\times\left(450 - 400\right)\ \text{K} = 30{,}700\ \text{W/m}^2 \qquad <$$

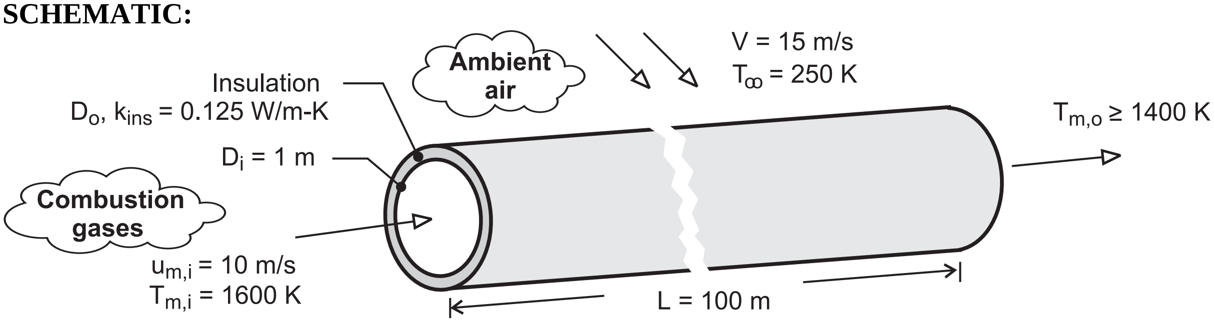
COMMENTS: The dimensionless tube length is L/D = 1m/0.05m = 20. The flow is therefore fully developed, and use of Eq. 8.65 is appropriate.

PROBLEM 8.44

KNOWN: Duct diameter and length. Thermal conductivity of insulation. Gas inlet temperature and velocity and minimum allowable outlet temperature. Temperature and velocity of air in cross flow.

FIND: Minimum allowable insulation thickness.

SCHEMATIC:



ASSUMPTIONS: (1)Combustion gases are ideal with negligible viscous dissipation and pressure variation, (2) Fully developed flow throughout duct, (3) Negligible duct wall conduction resistance, (4) Negligible effect of insulation thickness on outer convection coefficient and thermal resistance, (5) Properties of gas may be approximated as those of air.

PROPERTIES: *Table A-4*, air (p = 1 atm). $T_{m,i}$ = 1600K: (ρ_i = 0.218 kg/m^3). $\overline{T}_m = (T_{m,i} + T_{m,o})/2$ = 1500K: (ρ = 0.232 kg/m^3, c_p = 1230 J/kg·K, $\mu = 557 \times 10^{-7}$ N·s/m^2, k = 0.100 W/m·K, Pr = 0.685). $T_f \approx$ 300K (assumed): $\nu = 15.89 \times 10^{-6}$ m^2/s, k = 0.0263 W/m·K, Pr = 0.707.

ANALYSIS: From Eqs. (8.45a) and (3.19),

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \frac{-1150\,\text{K}}{-1350\,\text{K}} = 0.852 = \exp\left(-\frac{\overline{U}A_s}{\dot{m}\,c_p}\right) = \exp\left(-\frac{1}{R_{tot}\dot{m}\,c_p}\right)$$

Hence, with $\dot{m} = (\rho u_m A_c)_i = 0.218\,\text{kg/m}^3 \times 10\,\text{m/s} \times \pi(1\text{m})^2/4 = 1.712\,\text{kg/s}$,

$$R_{tot} = -\left[\dot{m}\,c_p \ln(0.852)\right]^{-1} = -\left[1.712\,\text{kg/s} \times 1230\,\text{J/kg}\cdot\text{K} \times (-0.160)\right]^{-1} = 2.96 \times 10^{-3}\,\text{K/W}$$

The total thermal resistance is

$$R_{tot} = R_{conv,i} + R_{cond,ins} + R_{conv,o} = (h_i \pi D_i L)^{-1} + \frac{\ln(D_o/D_i)}{2\pi k_{ins} L} + (h_o \pi D_o L)^{-1} \qquad (1)$$

With $Re_{D,i} = 4\dot{m}/\pi D_i \mu = (4 \times 1.712\,\text{kg/s})/\left(\pi \times 1\text{m} \times 557 \times 10^{-7}\,\text{N}\cdot\text{s/m}^2\right) = 39{,}130$, the Dittus-Boelter correlation yields

$$h_i = \left(\frac{k}{D}\right) 0.023\,Re_D^{4/5}\,Pr^{0.3} = \left(\frac{0.100\,\text{W/m}\cdot\text{K}}{1\text{m}}\right) 0.023(39{,}130)^{4/5}(0.685)^{0.3} = 9.69\,\text{W/m}^2\cdot\text{K}$$

The internal resistance is then

$$R_{conv,i} = (h_i \pi D_i L)^{-1} = \left(9.69\,\text{W/m}^2\cdot\text{K} \times \pi \times 1\text{m} \times 100\text{m}\right)^{-1} = 3.28 \times 10^{-4}\,\text{K/W}$$

With $Re_D \approx VD_i/\nu = 15$ m/s × 1m/15.89 × 10^{-6} m^2/s = 9.44 × 10^5, the Churchill-Bernstein correlation yields

Continued …

PROBLEM 8.44 (Cont.)

$$h_o \approx \left(\frac{k}{D}\right)\left\{0.3+\frac{0.62\,Re_D^{1/2}\,Pr^{1/3}}{\left[1+\left(0.4/Pr\right)^{2/3}\right]^{1/4}}\left[1+\left(\frac{Re_D}{282,000}\right)^{5/8}\right]^{4/5}\right\}=30.9\,W/m^2\cdot K$$

$$R_{conv,o} \approx \left(h_o\pi D_i L\right)^{-1}=\left(30.9\,W/m^2\cdot K\times\pi\times 1m\times 100m\right)^{-1}=1.03\times10^{-4}\,K/W$$

Hence, from Eq. (1)

$$\frac{\ln\left(D_o/D_i\right)}{2\pi\,k_{ins}\,L}=\left(2.96\times10^{-3}-3.33\times10^{-4}-1.03\times10^{-4}\right)K/W=2.53\times10^{-3}\,K/W$$

$$D_o = D_i\exp\left(2\pi k_{ins}L\times2.53\times10^{-3}\,K/W\right)=1m\times\exp\left(1.59\times10^{-2}\,K/W\times0.125\,W/m\cdot K\times100m\right)=1.22m$$

Hence, the minimum insulation thickness is

$$t_{min}=\left(D_o-D_i\right)/2=0.11m$$ <

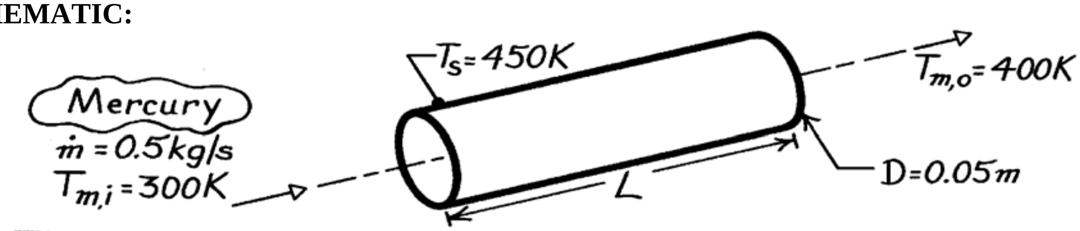
COMMENTS: With D_o = 1.22m, use of D_i = 1m to evaluate the outer convection coefficient and thermal resistance is a reasonable approximation. However, improved accuracy may be obtained by using the calculated value of D_o to determine conditions at the outer surface and iterating on the solution.

PROBLEM 8.45

KNOWN: Flow rate, inlet temperature and desired outlet temperature of liquid mercury flowing through a tube of prescribed diameter and surface temperature.

FIND: Required tube length and error associated with use of a correlation for moderate to large Pr fluids.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3)Incompressible liquid with negligible viscous dissipation, (4) Fully developed flow.

PROPERTIES: *Table A-5*, Mercury $(\overline{T}_m = 350K)$: c_p = 137.7 J/kg·K, $\mu = 0.1309 \times 10^{-2}$ N·s/m^2, k = 9.18 W/m·K, Pr = 0.0196.

ANALYSIS: The Reynolds and Peclet numbers are

$$Re_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4\times 0.5 \text{ kg/s}}{\pi(0.05\text{m})0.1309\times 10^{-2}\text{ N}\cdot\text{s/m}^2} = 9727$$

$$Pe_D = Re_D\ Pr = 9727(0.0196) = 191.$$

Hence, assuming fully developed turbulent flow throughout the tube, it follows from Eq. 8.65 that

$$\overline{h} = \frac{k}{D}\left(5.0 + 0.025\ Pe_D^{0.8}\right) = \frac{9.18\text{ W/m}\cdot\text{K}}{0.05\text{ m}}\left(5.0 + 0.025\times 191^{0.8}\right) = 1224\text{ W/m}^2\cdot\text{K}.$$

From Eq. 8.41a, it follows that

$$L = -\frac{\dot{m}\,c_p}{\pi D\overline{h}}\ln\frac{\Delta T_o}{\Delta T_i} = -\frac{(0.5\text{ kg/s})137.7\text{ J/kg}\cdot\text{K}}{\pi(0.05\text{ m})1224\text{ W/m}^2\cdot\text{K}}\ln\frac{450-400}{450-300} = 0.39\text{ m}. \qquad <$$

If the Dittus-Boelter correlation, Eq. 8.60, is used in place of Eq. 8.65,

$$\overline{h} = \frac{k}{D}0.023\ Re_D^{4/5}\ Pr^{0.4} = \frac{9.18\text{ W/m}^2\cdot\text{K}}{0.05\text{ m}}0.023(9727)^{4/5}(0.0196)^{0.4} = 1358\text{ W/m}^2\cdot\text{K}$$

and the required tube length is

$$L = -\frac{\dot{m}\,c_p}{\pi D\overline{h}}\ln\frac{\Delta T_o}{\Delta T_i} = -\frac{(0.5\text{ kg/s})137.7\text{ J/kg}\cdot\text{K}}{\pi(0.05\text{ m})1358\text{ W/m}^2\cdot\text{K}}\ln\frac{450-400}{450-300} = 0.35\text{ m}. \qquad <$$

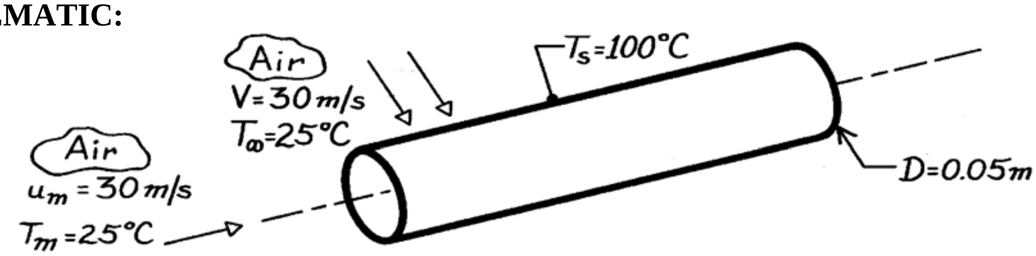
COMMENTS: (1) Such good agreement between results does not occur in general. For example, if $Re_D = 2 \times 10^4$, $\overline{h}$ = 1463 from Eq. 8.65 and 2417 from Eq. 8.60. Large errors are usually associated with using conventional (moderate to large Pr) correlations with liquid metals. (2) The Dittus-Boelter correlation is recommended for $Re_D \gtrsim 10{,}000$, which is not quite satisfied here.

PROBLEM 8.46

KNOWN: Surface temperature and diameter of a tube. Velocity and temperature of air in cross flow. Velocity and temperature of air in fully developed internal flow.

FIND: Convection heat flux associated with the external and internal flows.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform cylinder surface temperature, (3) Fully developed internal flow, (4) For internal flow, air is an ideal gas with negligible viscous dissipation and pressure variations.

PROPERTIES: *Table A-4*, Air (336 K): $\nu = 19.51 \times 10^{-6}$ m^2/s, k = 0.0290 W/m·K, Pr = 0.702.

ANALYSIS: For the *external* and *internal* flows,

$$\mathrm{Re}_D = \frac{VD}{\nu} = \frac{u_m D}{\nu} = \frac{30\text{ m/s} \times 0.05\text{ m}}{19.71 \times 10^{-6}\text{m}^2/\text{s}} = 7.69 \times 10^4.$$

From the Churchill-Bernstein relation for the *external* flow,

$$\overline{\mathrm{Nu}}_D = 0.3 + \frac{0.62\,\mathrm{Re}_D^{1/2}\,\mathrm{Pr}^{1/3}}{\left[1+(0.4/\mathrm{Pr})^{2/3}\right]^{1/4}}\left[1+\left(\frac{\mathrm{Re}_D}{282,000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62(7.69 \times 10^4)^{1/2}\,0.702^{1/3}}{\left[1+(0.4/0.702)^{2/3}\right]^{1/4}}\left[1+\left(\frac{7.69 \times 10^4}{282,000}\right)^{5/8}\right]^{4/5} = 180$$

Hence, the convection coefficient and heat flux are

$$\bar{h} = \frac{k}{D}\overline{\mathrm{Nu}}_D = \frac{0.0290\text{ W/m}\cdot\text{K}}{0.05\text{ m}} \times 180 = 104\text{ W/m}^2\cdot\text{K}$$

$$q'' = h\left(T_s - T_\infty\right) = 104\text{W/m}^2\cdot\text{K}\left(100-25\right)^\circ\text{C} = 7840\text{ W/m}^2.$$ <

Using the Dittus-Boelter correlation, Eq. 8.60, for the *internal* flow, which is turbulent,

$$\overline{\mathrm{Nu}}_D = 0.023\,\mathrm{Re}_D^{4/5}\,\mathrm{Pr}^{0.4} = 0.023\left(7.69 \times 10^4\right)^{4/5}\left(0.702\right)^{0.4} = 162$$

$$\bar{h} = \frac{k}{D}\overline{\mathrm{Nu}}_D = \frac{0.0290\text{ W/m}\cdot\text{K}}{0.05\text{ m}} \times 162 = 94\text{ W/m}^2\cdot\text{K}$$

Continued…

PROBLEM 8.46 (Cont.)

and the heat flux is

$$q'' = h\left(T_s - T_m\right) = 94\ \text{W/m}^2 \cdot \text{K}\left(100 - 25\right)^\circ \text{C} = 7040\ \text{W/m}^2.$$

<

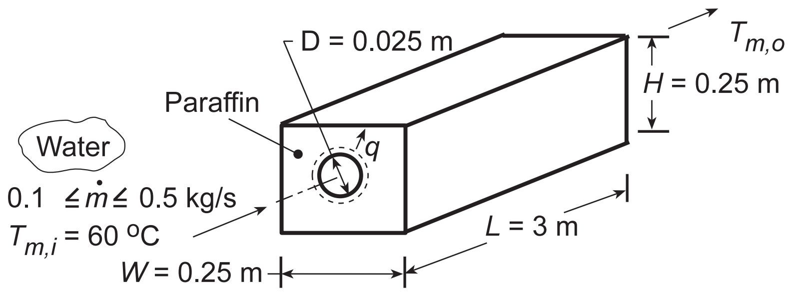
COMMENT: Convection effects associated with the two flow conditions are comparable.

PROBLEM 8.47

KNOWN: Length and diameter of tube submerged in paraffin of prescribed dimensions. Inlet temperature and flow rate of water flowing through tube.

FIND: (a) Outlet temperature, heat rate, and time required for complete melting, and (b) Effect of flowrate on operating conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible KE/PE and flow work changes for water, (2) Constant water properties, (3) Negligible tube wall conduction resistance, (4) Negligible convection resistance in melt ($T_s = T_\infty = T_{mp}$), (5) Fully developed flow, (6) No heat loss to the surroundings.

PROPERTIES: Water (given): c_p = 4.185 kJ/kg·K, k = 0.653 W/m·K, $\mu = 467 \times 10^{-6}$ kg/s·m, Pr = 2.99; Paraffin (given): T_{mp} = 27.4°C, h_{sf} = 244 kJ/kg, ρ = 770 kg/m^3.

ANALYSIS: (a) From Eq. 8.41b, $\dfrac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp\left(-\dfrac{\pi D L \bar{h}}{\dot{m} c_p}\right)$. With $Re_D = \dfrac{4\dot{m}}{\pi D \mu}$ = $\dfrac{4 \times 0.1\,\text{kg/s}}{\pi \times 0.025\,\text{m} \times 467 \times 10^{-6}\,\text{kg/s}\cdot\text{m}}$ = 10,906, the flow is turbulent. Assuming fully developed conditions,

$$h = \frac{Nu_D k}{D} = \frac{k}{D} 0.023 Re_D^{4/5} Pr^{0.3} = \frac{0.653\,\text{W/m}\cdot\text{K}}{0.025\,\text{m}} 0.023 (10,906)^{4/5} (2.99)^{0.3} = 1418\,\text{W/m}^2\cdot\text{K}$$

$$T_{m,o} = 27.4^\circ\text{C} - (27.4 - 60)^\circ\text{C} \exp\left(-\frac{\pi \times 0.025\,\text{m} \times 3\,\text{m}}{0.1\,\text{kg/s} \times 4185\,\text{J/kg}\cdot\text{K}} 1418\,\text{W/m}^2\cdot\text{K}\right) = 42.17^\circ\text{C} \quad <$$

From the overall energy balance,

$$q = \dot{m} c_p (T_{m,i} - T_{m,o}) = 0.1\,\text{kg/s} \times 4185\,\text{J/kg}\cdot\text{K} (60 - 42.17)^\circ\text{C} = 7500\,\text{W} \quad <$$

Applying an energy balance to a control volume about the paraffin, $E_{in} = \Delta E_{st}$, the time t_m required to melt the paraffin is

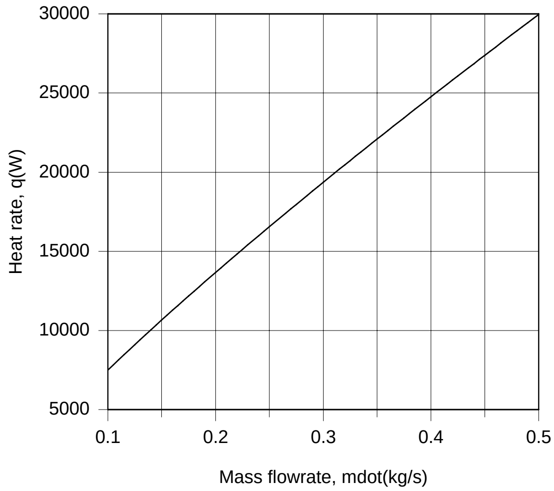
$$q t_m = \rho V h_{sf} = \rho L \left(WH - \pi D^2/4\right) h_{sf}$$

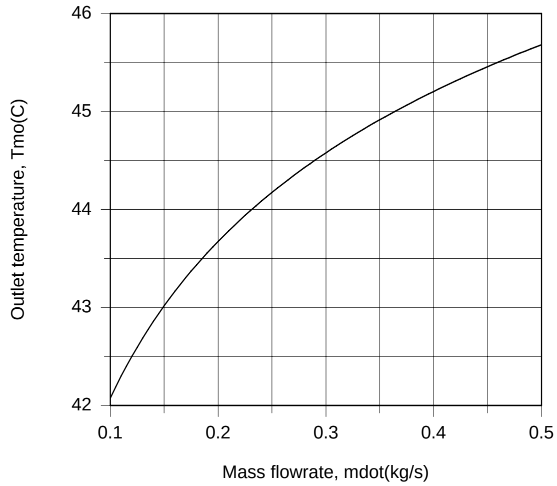
$$t_m = \frac{770\,\text{kg/m}^3 \times 3\,\text{m} \left(0.25 \times 0.25\,\text{m}^2 - \pi (0.025\,\text{m})^2/4\right)}{7500\,\text{W}} 2.44 \times 10^5\,\text{J/kg} = 4660\,\text{s} = 1.29\,\text{h} \quad <$$

Continued...

PROBLEM 8.47 (Cont.)

(b) The effect of $\dot{m}$ on q and $T_{m,o}$ was determined by accessing the *Correlations* Toolpad of IHT, and the results are plotted as follows.





Although q increases with increasing $\dot{m}$ due to the attendant increase in Re_D, and therefore $\overline{h}$, the increase is not linearly proportional to the change in $\dot{m}$. Hence, from the overall energy balance, q = $\dot{m}\,c_p(T_{m,i} - T_{m,o})$, there is a reduction in $(T_{m,i} - T_{m,o})$, which corresponds to an increase in $T_{m,o}$. With the increase in q, there is a reduction in t_m, and for $\dot{m}$ = 0.5 kg/s,

$$t_m = 1167\,s = 0.324\,h$$ <

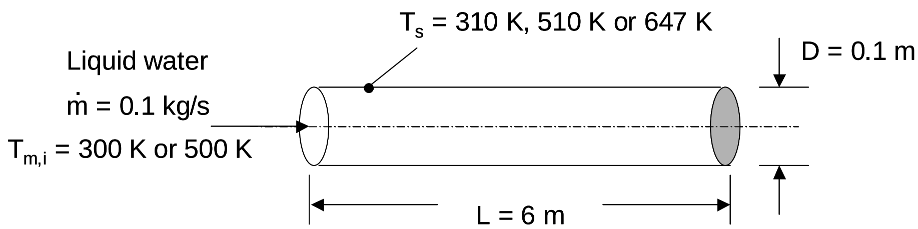
COMMENTS: Heat transfer from the water to the paraffin is also affected by free convection in the melt region around the tube. The effect is to decrease U, increase T_s, and decrease q with increasing time. The actual time to achieve complete melting would exceed values computed in the foregoing analysis.

PROBLEM 8.48

KNOWN: Diameter and length of circular tube, liquid water flow rate, liquid water entrance temperatures and tube surface temperatures.

FIND: Water outlet temperatures for (a) $T_{m,i}$ = 500 K, T_s = 510 K and (b) $T_{m,i}$ = 300 K, T_s = 310 K. (c) Discuss whether the flow is laminar or turbulent for $T_{m,i}$ = 300 K, T_s = 647 K.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties in parts (a) and (b), (3) Negligible viscous dissipation.

PROPERTIES: *Table A.6*, liquid water ($\overline{T}_m$ = 505 K, assumed): $\mu = 115.5\times10^{-6}$ N·s/m², Pr = 0.855, k = 0.635 W/m·K, c_p = 4700 J/kg·K. Liquid water ($\overline{T}_m$ = 305 K, assumed): $\mu = 769\times10^{-6}$ N·s/m², Pr = 5.20, k = 0.620 W/m·K, c_p = 4178 J/kg·K.

ANALYSIS: (a) We begin by calculating the Reynolds number

$$Re_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4\times 0.1\text{ kg/s}}{\pi\times 0.1\text{m}\times 115.5\times 10^{-6}\text{ N}\cdot\text{s/m}^2} = 11{,}014$$

Therefore, the flow is in a fully turbulent condition. Since L/D = 6m/0.1m = 60, we conclude that entrance effects are not important. We may use Dittus-Boelter (Eq. 8.60) to determine the average heat transfer coefficient and the mean outlet temperature may be found from Eq. (8.41b).

$$\overline{h} = \frac{k}{D}\left[0.023Re_D^{4/5}Pr^{0.4}\right] = \frac{0.635\text{W/m}\cdot\text{K}}{0.1\text{m}}\left[0.023\times 11{,}014^{4/5}0.855^{0.4}\right] = 235\text{ W/m}^2\cdot\text{K}$$

$$T_{m,o} = T_s - (T_s - T_{m,i})\exp\left(-\frac{PL}{\dot{m}c_p}\overline{h}\right)$$

$$= 510\text{ K} - 10\text{ K}\times\exp\left(-\frac{\pi\times 0.1\text{ m}\times 6\text{ m}}{0.1\text{ kg/s}\times 4700\text{ J/kg}\cdot\text{K}}235\text{ W/m}^2\cdot\text{K}\right) = 506.1\text{ K}$$ <

(b) The Reynolds number is

$$Re_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4\times 0.1\text{ kg/s}}{\pi\times 0.1\text{m}\times 769\times 10^{-6}\text{ N}\cdot\text{s/m}^2} = 1655$$

Continued…

PROBLEM 8.48 (Cont.)

Therefore, the flow is laminar. The thermal entrance length is $x_{fd,t} = 0.05 \times D \times Re_D \times Pr = 0.05 \times 0.1\text{m} \times 1655 \times 5.20 = 43.0\text{ m} > L$. Therefore, we expect entrance effects to be significant. With $Pr > 5$, we may use Eq. (8.57) with Eq. (8.56) for the Graetz number, to estimate the value of $\bar{h}$.

$$h = \frac{k}{D}\left\{3.66 + \frac{0.0668(D/L)Re_D Pr}{1 + 0.04\left[(D/L)Re_D Pr\right]^{2/3}}\right\}$$

$$= \frac{0.620\text{W/m}\cdot\text{K}}{0.1\text{ m}}\left\{3.66 + \frac{0.0668(0.1\text{ m}/6\text{ m})\times 1655\times 5.20}{1 + 0.04\left[(0.1\text{ m}/6.0\text{ m})\times 1655\times 5.20\right]^{2/3}}\right\} = 51.0\text{ W/m}^2\cdot\text{K}$$

Using Eq. (8.41b)

$$T_{m,o} = T_s - (T_s - T_{m,i})\exp\left(-\frac{PL}{\dot{m}c_p}\bar{h}\right)$$

$$= 310\text{ K} - 10\text{ K}\times\exp\left(-\frac{\pi\times 0.1\text{ m}\times 6\text{ m}}{0.1\text{ kg/s}\times 4178\text{ J/kg}\cdot\text{K}}51\text{ W/m}^2\cdot\text{K}\right) = 302.1\text{ K}$$

<

(c) The temperature variations within the water are very large. Therefore, properties are expected to vary significantly from location to location. Near the entrance of the tube, average temperatures will be low, and the flow is expected to be laminar. However, as the boundary layer regions grow, higher temperatures will exist in a greater portion of the liquid and viscosities may drop to very low values. Hence, the flow may trip into turbulent conditions at a location between the tube entrance and the tube exit. The assumption of constant properties under the conditions of part (c) may not be appropriate.

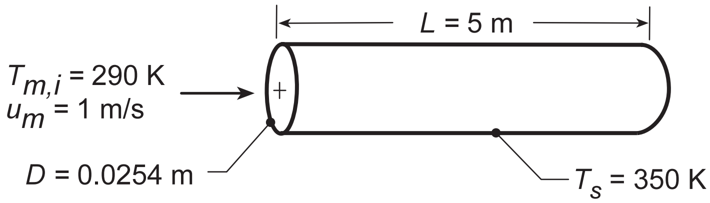
COMMENTS: Even though entrance effects are important for the laminar flow conditions of part (b), the heat transfer coefficient is small relative to that associated with the turbulent conditions of part (a).

PROBLEM 8.49

KNOWN: Diameter, length and surface temperature of condenser tubes. Water velocity and inlet temperature.

FIND: (a) Water outlet temperature evaluating properties at T_m = 300 K, (b) Repeat calculations using properties evaluated at the appropriate temperature, $\overline{T}_m = (T_{m,i} + T_{m,o})/2$, and (c) Coolant mean velocities for the range $4 \le L \le 7$ m which provide the same $T_{m,o}$ as found in part (b).

SCHEMATIC:



ASSUMPTIONS: (1) Negligible tube wall conduction resistance, (2) Incompressible liquid with negligible viscous dissipation.

PROPERTIES: *Table A.6*, Water ($\overline{T}_m$ = 300 K): ρ = 997 kg/m^3, c_p = 4179 J/kg·K, $\mu = 855 \times 10^{-6}$ kg/s·m, k = 0.613 W/m·K, Pr = 5.83.

ANALYSIS: (a) From Equation 8.41b

$$T_{m,o} = T_s - \left(T_s - T_{m,i}\right)\exp\left[-\left(\pi DL/\dot{m}c_p\right)\overline{h}\right].$$

and evaluating properties at $\overline{T}_m$ = 300 K, find

$$Re_D = \frac{\rho u_m D}{\mu} = \frac{997\,kg/m^3\,(1\,m/s)\,0.0254\,m}{855\times10^{-6}\,kg/s\cdot m} = 29,618$$

The flow is turbulent, and since L/D = 197, it is reasonable to assume fully developed flow throughout the tube. Hence, $\overline{h} \approx h_{fd}$. From the Dittus-Boelter equation,

$$Nu_D = 0.023\,Re_D^{4/5}\,Pr^{0.4} = 0.023\left(29,618\right)^{4/5}\left(5.83\right)^{0.4} = 176$$

$$\overline{h} = Nu_D\,(k/D) = 176\left(0.613\,W/m\cdot K/0.0254\,m\right) = 4248\,W/m^2\cdot K.$$

With

$$\dot{m} = \rho u_m\left(\pi D^2/4\right) = (\pi/4)\,997\,kg/m^3\,(1\,m/s)\left(0.0254\,m\right)^2 = 0.505\,kg/s.$$

Equation 8.41b yields

$$T_{m,o} = 350\,K - \left(60\,K\right)\exp\left[-\frac{\pi\left(0.0254\,m\right)5\,m\left(4248\,W/m^2\cdot K\right)}{0.505\,kg/s\left(4179\,J/kg\cdot K\right)}\right] = 323\,K = 50^\circ C$$ <

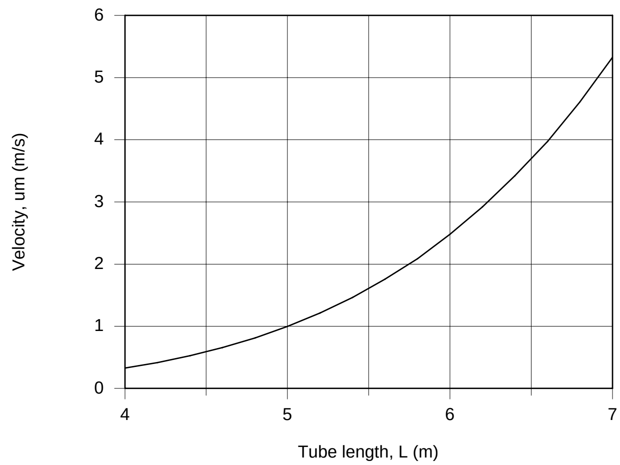
(b) Using the *IHT Correlations Tool*, *Internal Flow*, for fully developed *Turbulent Flow*, along with the energy balance and rate equations above, the calculation of part (a) is repeated with $\overline{T}_m = (T_{m,i} + T_{m,o})/2$ giving these results:

$\overline{T}_m = 307.3\,K$ $\qquad$ $T_{m,o}$ = 51.7°C = 324.7 K <

(c) Using the IHT model developed for the part (b) analysis, the coolant mean velocity, u_m, as a function of tube length L with $T_{m,o}$ = 51.7°C is calculated and the results plotted below.

Continued...

PROBLEM 8.49 (Cont.)



COMMENTS: (1) Using $\overline{T}_m$ = 300 K vs. $\overline{T}_m$ = $(T_{m,i} + T_{m,o})/2$ = 307 K for this application resulted in a difference of $T_{m,o}$ = 50°C vs. $T_{m,o}$ = 51.7°C. While the difference is only 1.7°C, it is good practice to use the proper value for $\overline{T}_m$.

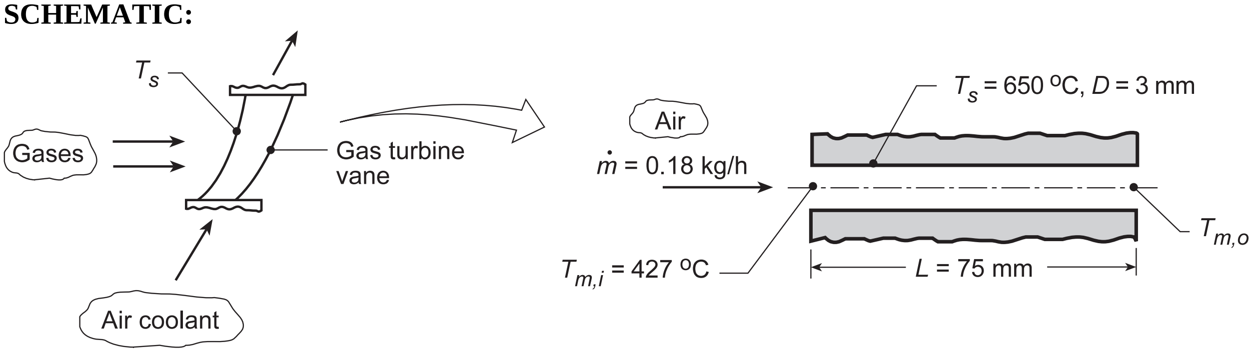
(2) Note that u_m must be increased markedly with increasing length in order that $T_{m,o}$ remain fixed.

PROBLEM 8.50

KNOWN: Gas turbine vane approximated as a tube of prescribed diameter and length maintained at a known surface temperature. Air inlet temperature and flowrate.

FIND: (a) Outlet temperature of the air coolant for the prescribed conditions and (b) Compute and plot the air outlet temperature $T_{m,o}$ as a function of flow rate, $0.1 \le \dot{m} \le 0.6$ kg/h. Compare this result with those for vanes having passage diameters of 2 and 4 mm.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Ideal gas with negligible viscous dissipation and pressure variation.

PROPERTIES: *Table A.4,* Air (assume $\overline{T}_m$ = 780 K, 1 atm): c_p = 1094 J/kg·K, k = 0.0563 W/m·K, μ = 363.7 × 10^{-7} N·s/m^2, Pr = 0.706.

ANALYSIS: (a) For constant wall temperature heating, from Eq. 8.41b,

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{PL\overline{h}}{\dot{m}c_p}\right) \qquad (1)$$

where P = πD. For flow in a circular passage,

$$Re_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 0.18\,\text{kg/h}\left(1/3600\,\text{s/h}\right)}{\pi\left(0.003\,\text{m}\right)363.7 \times 10^{-7}\ \text{N}\cdot\text{s/m}^2} = 584\,. \qquad (2)$$

The flow is laminar, and from Eq. 8.3, $x_{fd,h} = 0.05Re_D D$ = 88 mm. Thus, the flow is in the combined entry length. From Eq. 8.56, $Gz_D = (D/L)Re_D Pr$ = 16.5 and from Eq. 8.58,

$$\overline{Nu}_D = \frac{\overline{h}D}{k} = \frac{\dfrac{3.66}{\tanh[2.264Gz_D^{-1/3} + 1.7Gz_D^{-2/3}]} + 0.0499Gz_D\tanh(Gz_D^{-1})}{\tanh(2.432\,Pr^{1/6}\,Gz_D^{-1/6})} \qquad (3)$$

$$\overline{h} = \frac{0.0563\,\text{W/m}\cdot\text{K}}{0.003\,\text{m}}\left(\frac{\dfrac{3.66}{\tanh[2.264 \times 16.5^{-1/3} + 1.7 \times 16.5^{-2/3}]} + 0.0499 \times 16.5\tanh(16.5^{-1})}{\tanh(2.432 \times 0.706^{1/6} \times 16.5^{-1/6})}\right) = 95.0\,\text{W/m}^2\cdot\text{K}$$

Hence, the air outlet temperature is

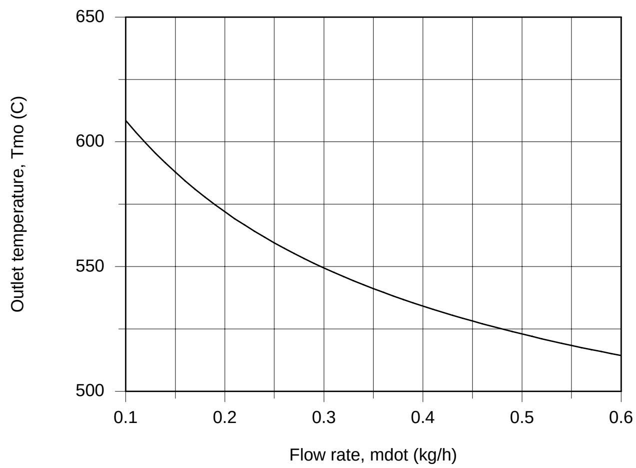
$$\frac{650 - T_{m,o}}{\left(650 - 427\right)^\circ\text{C}} = \exp\left(-\frac{\pi\left(0.003\,\text{m}\right) \times 0.075\,\text{m} \times 95.0\,\text{W/m}^2\cdot\text{K}}{\left(0.18/3600\right)\text{kg/s} \times 1094\ \text{J/kg}\cdot\text{K}}\right)$$

$$T_{m,o} = 585^\circ\text{C}$$ <

Continued...

PROBLEM 8.50 (Cont.)

(b) Using the *IHT Correlations Tool*, *Internal Flow*, for *Laminar Flow* with *combined entry length*, along with the energy balance and rate equations above, the outlet temperature $T_{m,o}$ was calculated as a function of flow rate for diameters of D = 2, 3 and 4 mm. The plot below shows that $T_{m,o}$ decreases strongly with increasing flow rate, but is independent of passage diameter.



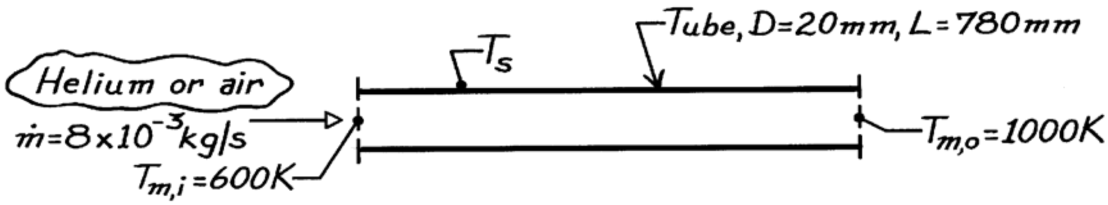
COMMENTS: (1) Based upon the calculation for $T_{m,o}$ = 585°C, $\overline{T}_m$ = 779 K which is in good agreement with our assumption to evaluate the thermophysical properties. (2) Why is $T_{m,o}$ independent of D? Since Re_D varies inversely with D, Gz_D is independent of D, and so is Nu_D. From Eq. (3), note that $\overline{h}$ is inversely proportional to D, $\overline{h} \sim D^{-1}$. From Eq. (1), note that on the right-hand side the product $P \cdot \overline{h}$ will be independent of D. Hence, $T_{m,o}$ will depend only on the mass flow rate. This is, of course, a consequence of the laminar flow condition and will not be the same for turbulent flow.

PROBLEM 8.51

KNOWN: Gas-cooled nuclear reactor tube of 20 mm diameter and 780 mm length with helium heated from 600 K to 1000 K at 8×10^{-3} kg/s.

FIND: (a) Uniform tube wall temperature required to heat the helium, (b) Outlet temperature and required flow rate to achieve same removal rate and wall temperature if the coolant gas is air.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Ideal gas with negligible viscous dissipation and pressure variation, (3) Fully developed conditions.

PROPERTIES: *Table A-4*, Helium $\left(\bar{T}_m = 800\text{K, 1 atm}\right)$: $\rho = 0.06272$ kg/m^3, $c_p = 5193$ J/kg·K, k = 0.304 W/m·K, $\mu = 382 \times 10^{-7}$ N·s/m^2, $\nu = 6.39 \times 10^{-4}$ m^2/s, Pr = 0.654; Air $\left(\bar{T}_m = 800\text{K, 1 atm}\right)$: ρ = 0.4354 kg/m^3, $c_p = 1099$ J/kg·K, k = 57.3×10^{-3} W/m·K, $\nu = 84.93 \times 10^{-6}$ m^2/s, Pr = 0.709.

ANALYSIS: (a) For helium and a constant wall temperature, from Eq. 8.41b,

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{PL\bar{h}}{\dot{m}\, c_p}\right)$$

where P = πD. For the circular tube,

$$Re_D = \frac{4\dot{m}}{\pi\, D\mu} = \frac{4 \times 8 \times 10^{-3}\ \text{kg/s}}{\pi \times 0.020\ \text{m} \times 382 \times 10^{-7}\,\text{N}\cdot\text{s/m}^2} = 1.333 \times 10^4$$

and using the Dittus-Boelter correlation for turbulent, fully developed flow,

$$Nu = 0.023\ Re_D^{4/5}\, Pr^{0.4} = 0.023\left(1.333 \times 10^4\right)^{4/5}\left(0.654\right)^{0.4} = 38.7$$

$$h = Nu \cdot k/D = 38.7 \times 0.304\ \text{W/m}\cdot\text{K}/0.02\ \text{m} = 588\ \text{W/m}^2 \cdot \text{K}.$$

Hence, the surface temperature is

$$\frac{T_s - 1000\ \text{K}}{T_s - 600\ \text{K}} = \exp\left[-\frac{\pi\left(0.020\ \text{m}\right) \times 0.780\ \text{m} \times 588\ \text{W/m}^2 \cdot \text{K}}{8 \times 10^{-3}\ \text{kg/s} \times 5193\ \text{J/kg}\cdot\text{K}}\right] = 0.500$$

$$T_s = 1400\ \text{K}.$$ <

The heat rate with helium coolant is

$$q = \dot{m}\, c_p\left(T_{m,o} - T_{m,i}\right) = 8 \times 10^{-3}\ \text{kg/s} \times 5193\ \text{J/kg}\cdot\text{K}\left(1000 - 600\right)\text{K} = 16.62\ \text{kW}.$$

Continued …

PROBLEM 8.51 (Cont.)

(b) For the same heat removal rate (q) and wall temperature (T_s) with air supplied at $T_{m,i}$, the relevant relations are

$$q = 16{,}620 \text{ W} = \dot{m}_a \, c_p \left(T_{m,o} - T_{m,i}\right) \tag{1}$$

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left[-\frac{PL\bar{h}_a}{\dot{m}_a \, c_p}\right] \tag{2}$$

$$Re = \frac{4\dot{m}_a}{\pi \, D\mu} \qquad \frac{\bar{h}D}{k} = 0.023\, Re_D^{4/5}\, Pr^{0.4} \tag{3,4}$$

where $T_{m,o}$ and $\dot{m}$ are unknown. An iterative solution is required: assume a value of $T_{m,o}$ and find $\dot{m}$ from Eq. (1); use $\dot{m}$ in Eqs. (3) and (4) to find $\bar{h}$ and then Eq. (2) to evaluate $T_{m,o}$; compare results and iterate. Using thermophysical properties of air evaluated at $\bar{T}_m$ = 800K, the above relations, written in the order they would be used in the iteration, become

$$\dot{m}_a = \frac{15.1}{T_{m,o} - 600} \tag{5}$$

$$\bar{h}_a = 5600\dot{m}_a^{4/5} \tag{6}$$

$$T_{m,o} = 1400 \text{ K} - 800 \text{ K} \times \exp\left[-4.459 \times 10^{-5}\left(\bar{h}_a / \dot{m}_a\right)\right] \tag{7}$$

Results of the iterative solution are

Trial	$T_{m,o}$ (K) (Assumed)	$\dot{m}$ (kg/s) Eq. (5)	$\bar{h}_a$ $\left(W/m^2 \cdot K\right)$ Eq. (6)	$T_{m,o}$ (K) Eq. (7)
1	1000	3.781×10^{-2}	407	905
2	950	4.321×10^{-2}	453	899
3	900	5.041×10^{-2}	513	891
4	890	5.215×10^{-2}	527	890

Hence, we find

$$\dot{m}_a = 5.22 \times 10^{-2} \text{ kg/s} \qquad T_{m,o} = 890 \text{ K.}$$ <

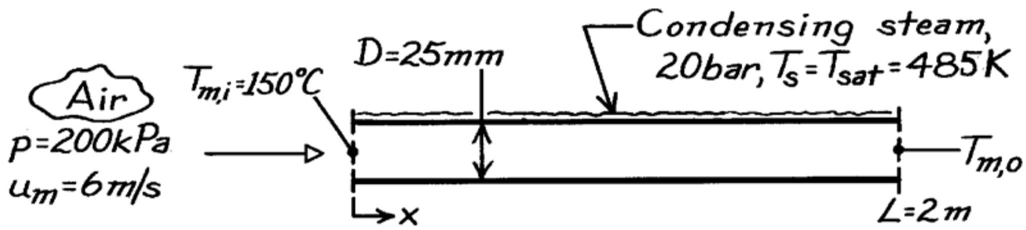
COMMENTS: To achieve the same cooling rate with air, the required mass rate is 6.5 times that obtained with helium.

PROBLEM 8.52

KNOWN: Air at prescribed inlet temperature and mean velocity heated by condensing steam on its outer surface.

FIND: (a) Air outlet temperature, pressure drop and heat transfer rate and (b) Effect on parameters of part (a) if pressure were doubled.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible kinetic and potential energy changes, (3) Thermal resistance of tube wall and condensate film are negligible.

PROPERTIES: *Table A-4*, Air (assume $\overline{T}_m$ = 450 K, 1 atm = 101.3 kPa): ρ = 0.7740 kg/m^3, c_p = 1021 J/kg·K, μ = 250.7 × 10^{-7} N·s/m^2, k = 0.0373 W/m·K, Pr = $\mu c_p/k$ = 0.686. Note that only ρ is pressure dependent; i.e., $\rho \propto p$; *Table A-6*, Saturated water (20 bar): T_{sat} = T_s = 485 K.

ANALYSIS: (a) For constant wall temperature heating, from Eq. 8.41b,

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{PL}{\dot{m}\, c_p}\overline{h}_i\right)$$

where P = πD. For the air flow, find the mass rate and Reynolds number,

$$\dot{m} = \rho A_c u_m = 0.7740 \text{ kg/m}^3 \left(200 \text{ kPa}/101.3 \text{ kPa}\right)\left(\pi\left(0.025 \text{ m}\right)^2/4\right)\times 6 \text{ m/s}$$

$$\dot{m} = 4.501\times 10^{-3} \text{kg/s}.$$

$$Re_D = \frac{4\dot{m}}{\mu\pi D} = \frac{4\times 4.501\times 10^{-3} \text{ kg/s}}{250.7\times 10^{-7} \text{ N}\cdot\text{s/m}^2 \times \pi\left(0.025 \text{ m}\right)} = 9.143\times 10^3.$$

Using the Dittus-Boelter correlation for fully-developed turbulent flow,

$$Nu_D = 0.023 Re^{4/5} Pr^{0.4} = 0.023\left(9.143\times 10^3\right)^{4/5}\left(0.682\right)^{0.4} = 29.12$$

$$h_i = Nu\cdot k/D = 29.12\times 0.0373 \text{ W/m}\cdot\text{K}/0.025 \text{ m} = 43.4 \text{ W/m}^2\cdot\text{K}.$$

Hence, the outlet temperature is

$$\frac{212 - T_{m,o}}{\left(212-150\right)^\circ C} = \exp\left[-\frac{\pi\left(0.025 \text{ m}\right)\times 2 \text{ m}\times 43.4 \text{ W/m}^2\cdot\text{K}}{4.501\times 10^{-3} \text{ kg/s}\times 1021 \text{ J/kg}\cdot\text{K}}\right]$$

$$T_{m,o} = 198^\circ \text{C}.$$ <

Continued …

PROBLEM 8.52 (Cont.)

The pressure drop follows from Eqs. 8.21 and 8.22,

$$f = \left(0.790\ln(Re_D) - 1.64\right)^{-2} = \left(0.790\ln(9.143\times10^3) - 1.64\right)^{-2} = 0.0323$$

$$\Delta p = f\,\frac{\rho u_m^2}{2D}L$$

$$\Delta p = 0.0323\frac{0.7740\ \text{kg/m}^3\left(200/101.3\right)\left(6\ \text{m/s}\right)^2\times 2\ \text{m}}{2\times0.025\ \text{m}} = 71.1\ \text{N/m}^2. \quad <$$

The heat transfer rate is

$$q = \dot{m}\,c_p\left(T_{m,o} - T_{m,i}\right) = 4.501\times10^{-3}\ \text{kg/s}\times1021\ \text{J/kg}\cdot\text{K}\left(198-150\right)\text{K} = 221\ \text{W}. \quad <$$

(b) If the pressure were doubled, we can see from the above relations that $\dot{m} \propto p$ hence

$$\dot{m} = 2\dot{m}_o$$

$$Re_D = 2Re_{D,o},$$

since

$$h_i \propto \left(Re\right)^{4/5} \rightarrow \left(h_i / h_{i,o}\right) = 2^{4/5},$$

$$h_i = 1.74 h_{i,o}.$$

It follows that $T_{m,o}$ = 195°C, so that the effect on temperature is slight. However, the pressure drop increases by the factor 1.68 and the heat rate by the factor 1.88. In summary:

Parameter	p = 200 kPa Part (a)	p = 400 kPa Part (b)	Increase, %
$\dot{m}$, kg/s × 10^3	4.501	9.002	100
h_i, W/m^2·K	43.4	75.6	74
T_{mo} - $T_{m,i}$°C	48	45	-6
Δp, N/m^2	71.1	119	68
q, W	221	415	88

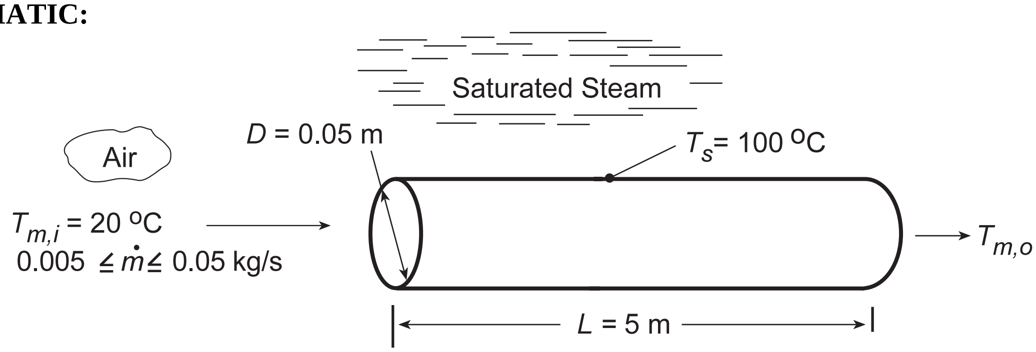
COMMENTS: (1) Note that $\overline{T}_m$ = (198 + 150)°C/2 = 447 K agrees well with the assumed value (450 K) used to evaluate the thermophysical properties.

PROBLEM 8.53

KNOWN: Diameter, length and surface temperature of tubes used to heat ambient air. Flow rate and inlet temperature of air.

FIND: (a) Air outlet temperature and heat rate per tube, (b) Effect of flow rate on outlet temperature. Design and operating conditions suitable for providing 1 kg/s of air at 75°C.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2)Ideal gas with negligible viscous dissipation and pressure variation, (3) Negligible tube wall thermal resistance.

PROPERTIES: *Table A.4*, air (assume $\overline{T}_m$ = 330 K): c_p = 1008 J/kg·K, μ = 198.8 × 10^{-7} N·s/m^2, k = 0.0285 W/m·K, Pr = 0.703.

ANALYSIS: (a) For $\dot{m}$ = 0.01 kg/s, $Re_D = 4\dot{m}/\pi D\mu$ = 0.04 kg/s/π(0.05 m)198.8 × 10^{-7} N·s/m^2 = 12,810. Hence, the flow is turbulent. If fully developed flow is assumed throughout the tube, the Dittus-Boelter correlation may be used to obtain the average Nusselt number.

$$\overline{Nu}_D \approx Nu_D = 0.023 Re_D^{4/5} Pr^{0.4} = 0.023(12,810)^{0.8}(0.703)^{0.4} = 38.6$$

Hence, $\bar{h} = \overline{Nu}_D (k/D) = 38.6(0.0285\,W/m\cdot K/0.05\,m) = 22.0\,W/m^2\cdot K$

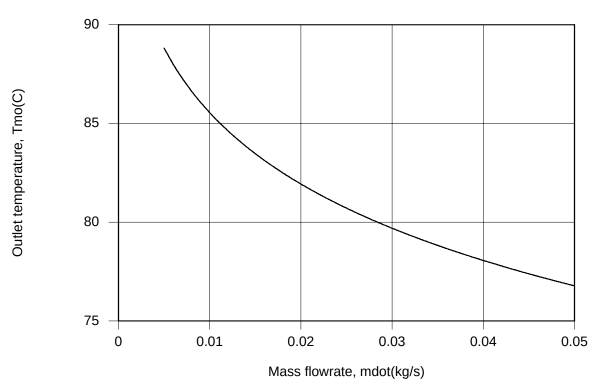
From Eq. 8.41b,

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{\pi DL\bar{h}}{\dot{m}c_p}\right) = \exp\left(-\frac{\pi \times 0.05\,m \times 5\,m \times 22\,W/m^2\cdot K}{0.01\,kg/s \times 1008\,J/kg\cdot K}\right) = 0.180$$

$$T_{m,o} = T_s - 0.180(T_s - T_{m,i}) = 100^\circ C - 0.180(80^\circ C) = 85.6^\circ C$$ <

Hence, $q = \dot{m}c_p(T_{m,o} - T_{m,i}) = 0.01\,kg/s(1008\,J/kg\cdot K)65.6\,K = 661\,W$ <

(b) The effect of flow rate on the outlet temperature was determined by using the IHT *Correlations* and *Properties* Toolpads.



Continued...

PROBLEM 8.53 (Cont.)

Although $\bar{h}$ and hence the heat rate increase with increasing $\dot{m}$, the increase in q is not linearly proportional to the increase in $\dot{m}$ and $T_{m,o}$ decreases with increasing $\dot{m}$.

A flow rate of $\dot{m}$ = 0.05 kg/s is not large enough to provide the desired outlet temperature of 75°C, and to achieve this value, a flow rate of 0.0678 kg/s would be needed. At such a flow rate, N = 1 kg/s/0.0678 kg/s = 14.75 ≈ 15 tubes would be needed to satisfy the process air requirement. Alternatively, a lower flow rate could be supplied to a larger number of tubes and the discharge mixed with ambient air to satisfy the desired conditions. Requirements of this option are that

$$N\dot{m} + \dot{m}_{amb} = 1\,kg/s$$

$$\left(N\dot{m} + \dot{m}_{amb}\right)c_p\left(T_{m,o} - T_{m,i}\right) = 1\,kg/s \times 1008\,J/kg \cdot K\left(75 - 20\right)K = 55,400\,W$$

where $\dot{m}$ is the flow rate per tube. Using a larger number of tubes with a smaller flow rate per tube would reduce flow pressure losses and hence provide for reduced operating costs.

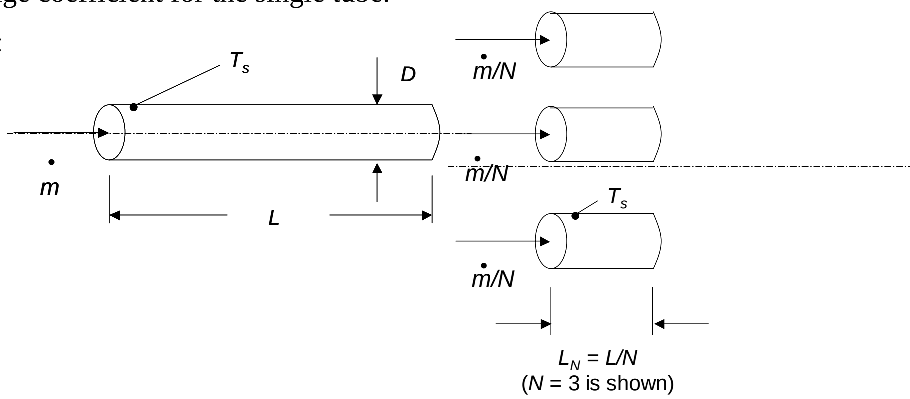
COMMENTS: With L/D = 5 m/0.05 m = 100, the assumption of fully developed conditions throughout the tube is reasonable.

PROBLEM 8.54

KNOWN: Length of a tube with constant surface temperature and a combined entrance length, $L < x_{fd,t}$.

FIND: Expression for the ratio of the average heat transfer coefficient for N tubes each of length $L_N = L/N$ to the average coefficient for the single tube.

SCHEMATIC:



ASSUMPTIONS: (1) Combined entrance conditions, (2) Constant properties, (3) Negligible viscous dissipation.

PROPERTIES: Given: $Pr = 4$.

ANALYSIS: The Nusselt number for the combined entrance problem with $0.1 < Pr < 5$ is given by Equation 8.58 and is seen to be a function of the Graetz number, $Gz_D = DRe_D Pr/L$, and the Prandtl number, Pr. For multiple tubes, each of length $L_N = L/N$ with a flowrate of $\dot{m}_N = \dot{m}/N$, observe that $Re_{D,N} = Re_{D,1}/N$, resulting in

$$Gz_{D,N} = DRe_{D,N}Pr/L_N = DRe_{D,1}Pr/L = Gz_{D,1}$$

Since the Graetz number is unchanged, and Pr has been specified as constant, the Nusselt number is unchanged. With $h = Nu_D k/D$,

$$\overline{h}_{D,N} / \overline{h}_{D,1} = 1$$ <

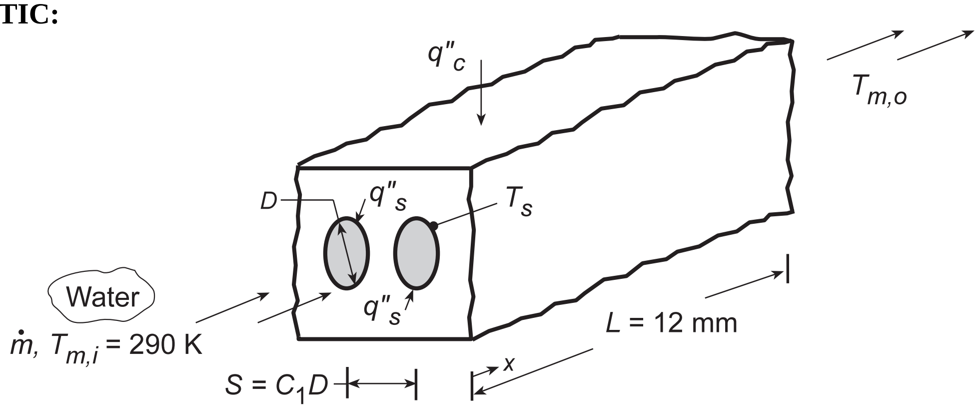
COMMENTS: (1) Breaking the tube into shorter lengths has no impact on the overall heat transfer rate. Shortening the tube will, in general, tend to increase the average heat transfer coefficient, but this effect is offset by reduction of the flow rate in each of the shorter tubes. The scheme would not result in any heat transfer *enhancement*. (2) The same result holds for the thermal entrance problem, since the Nusselt number is also a function only of Gz_D.

PROBLEM 8.55

KNOWN: Configuration of microchannel heat sink.

FIND: (a) Expressions for longitudinal distributions of fluid mean and surface temperatures, (b) Coolant and channel surface temperature distributions for prescribed conditions, (c) Effect of heat sink design and operating conditions on the chip heat flux for a prescribed maximum allowable surface temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2)Incompressible liquid with negligible viscous dissipation, (3) All of the chip power dissipation is transferred to the coolant, with a uniform surface heat flux, q_s'', (4) Laminar, fully developed flow, (5) Constant properties.

PROPERTIES: *Table A.6*, Water (assume $\overline{T}_m = T_{m,i}$ = 290 K): c_p = 4184 J/kg·K, $\mu = 1080 \times 10^{-6}$ N·s/m^2, k = 0.598 W/m·K, Pr = 7.56.

ANALYSIS: (a) The number of channels passing through the heat sink is N = L/S = L/C_1D, and conservation of energy dictates that

$$q_c'' L^2 = N(\pi DL) q_s'' = \pi L^2 q_s''/C_1$$

which yields

$$q_s'' = \frac{C_1 q_c''}{\pi} \qquad (1)$$

With the mass flowrate per channel designated as $\dot{m}_1 = \dot{m}/N$, Eqs. 8.40 and 8.27 yield

$$T_m(x) = T_{m,i} + \frac{q_s'' \pi D}{\dot{m}_1 c_p} x = T_{m,i} + \frac{L q_c''}{\dot{m} c_p} x \qquad (2) <$$

$$T_s(x) = T_m(x) + \frac{q_s''}{h} = T_m(x) + \frac{C_1 q_c''}{\pi h} \qquad (3) <$$

where, for laminar, fully developed flow with uniform q_s'', Eq. 8.53 yields h = 4.36 k/D.

(b) With L = 12 mm, D = 1 mm, C_1 = 2 and $\dot{m}$ = 0.01 kg/s, it follows that S = 2 mm, N = 6 and Re_D = $4\dot{m}_1/\pi D\mu = 4(0.01\,\text{kg/s})/6\pi(0.001\,\text{m})1.08\times10^{-3}\,\text{N}\cdot\text{s/m}^2$ = 1965. Hence, the flow is laminar, as assumed, and h = 4.36(0.598 W/m·K/0.001 m) = 2607 W/m^2·K. From Eqs. (2) and (3) the outlet mean and surface temperatures are

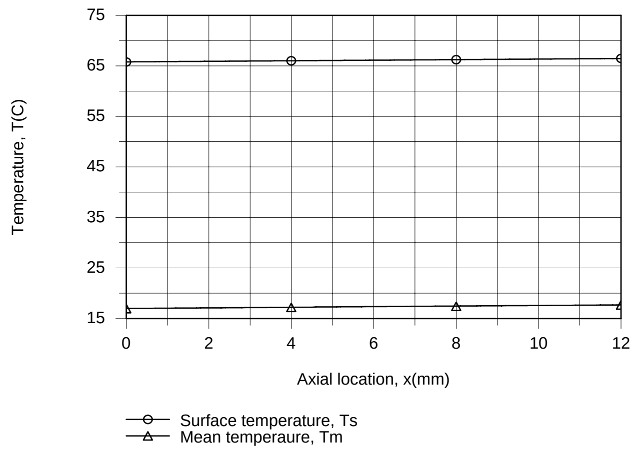
$$T_{m,o} = 290\,\text{K} + \frac{(0.012\,\text{m})^2\, 20\times10^4\,\text{W/m}^2}{0.01\,\text{kg/s}(4184\,\text{J/kg}\cdot\text{K})} = 290.7\,\text{K} = 17.7^\circ\text{C}$$

$$T_{s,o} = T_{m,o} + \frac{2}{\pi} \times \frac{20\times10^4\,\text{W/m}^2}{2607\,\text{W/m}^2\cdot\text{K}} = 339.5\,\text{K} = 66.5^\circ\text{C}$$

Continued...

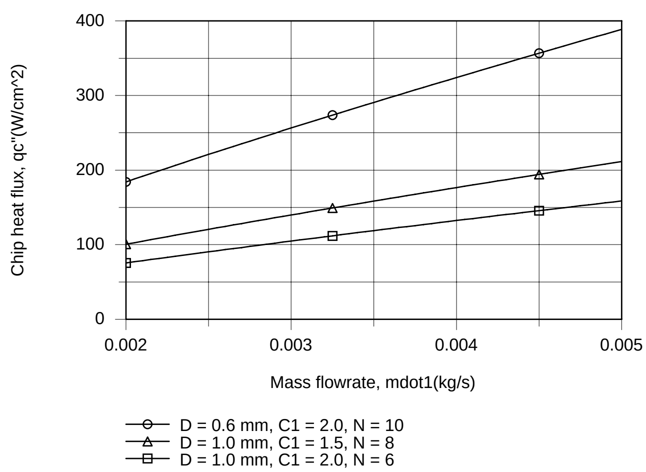
PROBLEM 8.55 (Cont.)

The axial temperature distributions are as follows



The flowrate is sufficiently large (and the convection coefficient sufficiently low) to render the increase in T_m and T_s with increasing x extremely small.

(c) The desired constraint of $T_{s,max} \leq 50°C$ is not met by the foregoing conditions. An obvious and logical approach to achieving improved performance would involve increasing $\dot{m}_1$ such that turbulent flow is maintained in each channel. A value of $\dot{m}_1$ > 0.002 kg/s would provide Re_D > 2300 for D = 0.001. Using Eq. 8.60 with n = 0.4 to evaluate Nu_D and accessing the Correlations Toolpad of IHT to explore the effect of variations in $\dot{m}_1$ for different combinations of D and C_1, the following results were obtained.



We first note that a significant increase in q_c'' may be obtained by operating the channels in turbulent flow. In addition, there is an obvious advantage to reducing C_1, thereby increasing the number of channels for a fixed channel diameter. The biggest enhancement is associated with reducing the channel diameter, which significantly increases the convection coefficient, as well as the number of channels for fixed C_1. For $\dot{m}_1$ = 0.005 kg/s, h increases from 32,400 to 81,600 $W/m^2 \cdot K$ with decreasing D from 1.0 to 0.6 mm. However, for fixed $\dot{m}_1$, the mean velocity in a channel increases with decreasing D and care must be taken to maintain the flow pressure drop within acceptable limits.

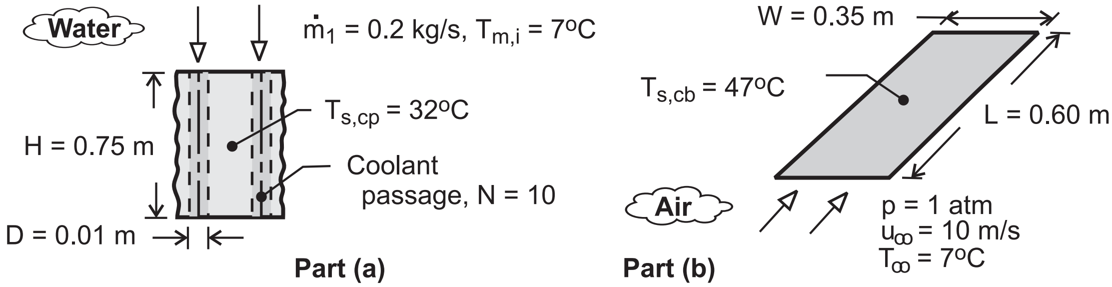
COMMENTS: Although the distribution computed for $T_m(x)$ in part (b) is correct, the distribution for $T_s(x)$ represents an upper limit to actual conditions due to the assumption of fully developed flow throughout the channel.

PROBLEM 8.56

KNOWN: Cold plate geometry and temperature. Inlet temperature and flow rate of water. Number of circuit boards and temperature and velocity of air in parallel flow over boards.

FIND: (a) Heat dissipation by cold plates, (b) Heat dissipation by air flow.

SCHEMATIC:



ASSUMPTIONS: (1) Isothermal cold plate, (2) All heated generated by circuit boards is dissipated by cold plates (Part (a)), (3) Circuit boards may be represented as isothermal at an average surface temperature, (4) Air flow over circuit boards approximates that over a flat plate in parallel flow, (5) Steady operation, (6) Constant properties, (7) Water is incompressible liquid with negligible viscous dissipation.

PROPERTIES: *Table A-6*, Water $(\overline{T}_m \approx 290\text{K})$: c_p = 4184 J/kg·K, $\mu = 1080\times10^{-6}\ \text{N}\cdot\text{s/m}^2$, k=0.598 W/m·K, Pr = 7.56. *Table A-4*, Air (p = 1 atm, T_f = 300K): $\nu = 15.89\times10^{-6}\ \text{m}^2/\text{s}$, k = 0.0263 W/m·K, Pr = 0.707.

ANALYSIS: (a) With $Re_D = 4\dot{m}_1/\pi D\mu = 4\times0.2\,\text{kg/s}/\pi\times0.01\text{m}\times1080\times10^{-6}\ \text{N}\cdot\text{s/m}^2 = 23,600$, the flow is turbulent, and from Eq. (8.60),

$$h = \frac{k}{D}Nu_D = 0.023\frac{k}{D}Re_D^{4/5}Pr^{0.4} = \frac{0.023\times0.598\,\text{W/m}\cdot\text{K}}{0.01\text{m}}(23,600)^{4/5}(7.56)^{0.4} = 9,730\,\text{W/m}^2\cdot\text{K}$$

With H/D = 0.75/0.01 = 75, it is reasonable to assume fully developed flow throughout the tube. Hence, from Eqs. (8.41b) and (8.34)

$$\frac{T_{s,cp}-T_{m,o}}{T_{s,cp}-T_{m,i}} = \exp\left(-\frac{\pi DH}{\dot{m}_1 c_p}h\right) = \exp\left(-\frac{\pi\times0.01\text{m}\times0.75\text{m}\times9730\,\text{W/m}^2\cdot\text{K}}{0.2\,\text{kg/s}\times4184\,\text{J/kg}\cdot\text{K}}\right) = 0.760$$

$$T_{m,o} = T_{s,cp} - 0.76\left(T_{s,cp}-T_{m,i}\right) = 13°\text{C}$$

$$q_1 = \dot{m}_1 c_p\left(T_{m,o}-T_{m,i}\right) = 0.2\,\text{kg/s}\times4184\,\text{J/kg}\cdot\text{K}\times6°\text{C} = 5021\,\text{W}$$

With a total of 2N = 20 passages, the total heat dissipation is

$$q = 2Nq_1 = 20\times5021\,\text{W} = 100\,\text{kW}$$ <

(b) For the air flow, $Re_D = u_\infty L/\nu = 10\,\text{m/s}\times0.60\text{m}/15.89\times10^{-6}\,\text{m}^2\text{s} = 378,000$, and the flow is laminar. From Eq. (7.30),

$$\overline{h} = \frac{k}{L}\overline{Nu}_L = 0.664\frac{k}{L}Re_L^{1/2}Pr^{1/3} = \frac{0.664\times0.0263\,\text{W/m}\cdot\text{K}}{0.60\text{m}}(378,000)^{1/2}(0.707)^{1/3} = 15.9\,\text{W/m}^2\cdot\text{K}$$

Heat dissipation to the air from both sides of 10 circuit boards is then

$$q = 2N_{cb}\overline{h}(WL)\left(T_{s,cb}-T_\infty\right) = 20\times15.9\,\text{W/m}^2\cdot\text{K}\times0.21\text{m}^2\times40°\text{C} = 2,670\,\text{W}$$ <

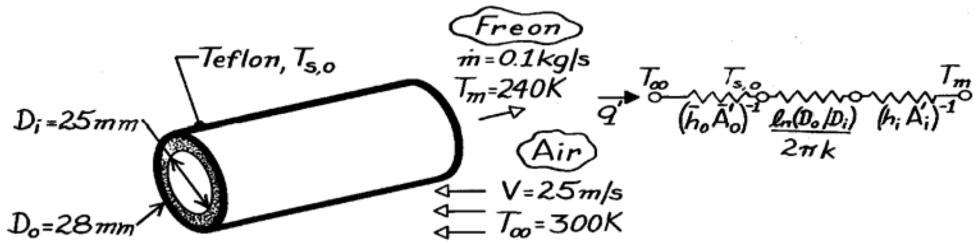
COMMENTS: The cooling capacity of the cold plates far exceeds that of the air flow. However, the challenge would be one of efficiently transferring such a large amount of energy to the cold plates without incurring excessive temperatures on the circuit boards.

PROBLEM 8.57

KNOWN: Flow rate and temperature of Refrigerant-134a passing through a Teflon tube of prescribed inner and outer diameter. Velocity and temperature of air in cross flow over tube.

FIND: Heat transfer per unit tube length.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial conduction, (3) Constant properties, (4) Fully developed flow.

PROPERTIES: *Table A-4*, Air (T = 300 K, 1 atm): $\nu = 15.89 \times 10^{-6}\ m^2/s$, k = 0.0263 W/m·K, Pr = 0.707; *Table A-5*, R-134a (T = 240 K): $\mu = 4.202 \times 10^{-4}\ N\cdot s/m^2$, k = 0.1073 W/m·K, Pr = 5.0; *Table A-3*, Teflon (T ≈ 300 K): k = 0.35 W/m·K.

ANALYSIS: Considering the thermal circuit shown above, the heat rate is

$$q' = \frac{T_\infty - T_m}{\left(1/\overline{h}_o \pi D_o\right) + \left[\ell n\left(D_o / D_i\right)/2\pi k\right] + \left(1/h_i \pi D_i\right)}.$$

$$Re_{D,i} = \frac{4\dot{m}}{\pi D_i \mu} = \frac{0.4\ kg/s}{\pi(0.025m)\ 4.202\times 10^{-4}\ N\cdot s/m^2} = 12,120$$

and the flow is turbulent. Hence, from the Dittus-Boelter correlation

$$h_i = \frac{k}{D_i} 0.023\, Re_{D,i}^{4/5} Pr^{0.4} = \frac{0.1073\ W/m\cdot K}{0.025\ m} 0.023(12,120)^{4/5}(5)^{0.4} = 347\ W/m^2\cdot K.$$

With $$Re_{D,o} = \frac{VD_o}{\nu} = \frac{(25\ m/s)0.028\ m}{15.89\times 10^{-6}\ m^2/s} = 4.405\times 10^4$$

it follows from Eq. 7.53 and Table 7.4 that

$$\overline{h}_o = \frac{k}{D} 0.26\, Re_{D,o}^{0.6}\, Pr^{0.37} = \frac{0.0263\ W/m\cdot K}{0.028\ m} 0.26\left(4.405\times 10^4\right)^{0.6}(0.707)^{0.37} = 131\ W/m^2\cdot K.$$

Hence

$$q' = \frac{T_\infty - T_m}{\left(131\ W/m^2\cdot K\pi 0.028\ m\right)^{-1} + \ell n(28/25)/2\pi(0.350\ W/m\cdot K) + \left(347\ W/m^2\cdot K\pi 0.025\ m\right)^{-1}}$$

$$q' = \frac{(300-240)K}{(0.087+0.052+0.037)\ K\cdot m/W} = 343\ W/m.$$ <

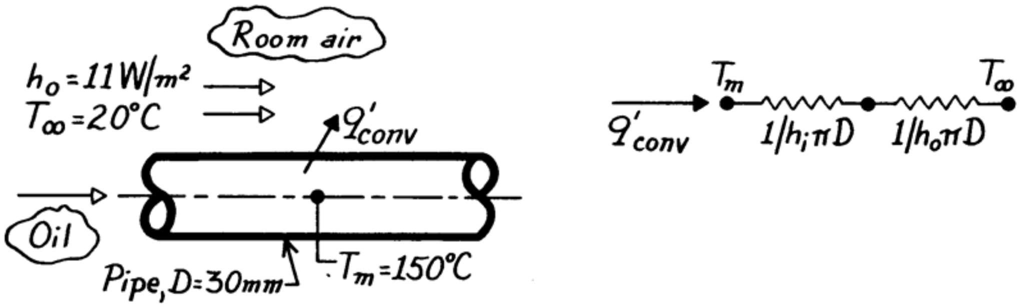
COMMENTS: The three thermal resistances are comparable. Note that $T_{s,o} = T_\infty - q'/h_o\pi D_o$ = 300K - 343 W/m/131 $W/m^2\cdot K$ π 0.028 m = 270 K.

PROBLEM 8.58

KNOWN: Oil flowing slowly through a long, thin-walled pipe suspended in a room.

FIND: Heat loss per unit length of the pipe, q'_{conv}.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Tube wall thermal resistance negligible, (3) Fully developed flow, (4) Radiation exchange between pipe and room negligible.

PROPERTIES: *Table A-5*, Unused engine oil (T_m = 150°C = 423K): k = 0.133 W/m·K.

ANALYSIS: The rate equation, for a unit length of the pipe, can be written as

$$q'_{conv} = \frac{\left(T_m - T_\infty\right)}{R'_t}$$

where the thermal resistance is comprised of two elements,

$$R'_t = \frac{1}{h_i \pi D} + \frac{1}{h_o \pi D} = \frac{1}{\pi D}\left(\frac{1}{h_i} + \frac{1}{h_o}\right).$$

The convection coefficient for internal flow, h_i, must be estimated from an appropriate correlation. From practical considerations, we recognize that the oil flow rate cannot be large enough to achieve turbulent flow conditions. Hence, the flow is *laminar*, and if the pipe is very long, the flow will be *fully developed*. The appropriate correlation is

$$Nu_D = \frac{h_i D}{k} = 3.66$$

$$h_i = Nu_D\ k/D = 3.66 \times 0.133 \frac{W}{m \cdot K} / 0.030\ m = 16.2\ W/m^2 \cdot K.$$

The heat rate per unit length of the pipe is

$$q'_{conv} = \frac{(150-20)^\circ C}{\frac{1}{\pi(0.030m)}\left(\frac{1}{16.2} + \frac{1}{11}\right)\frac{m^2 \cdot K}{W}} = 80.3\ W/m. \qquad <$$

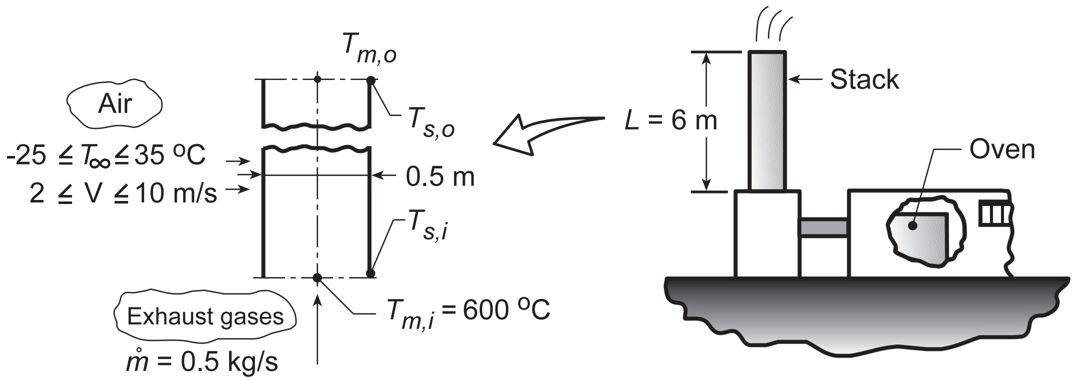
COMMENTS: This problem requires making a judgment that the oil flow will be laminar rather than turbulent. Why is this a reasonable assumption? Recognize that the correlation applies to a constant surface temperature condition.

PROBLEM 8.59

KNOWN: Thin-walled, tall stack discharging exhaust gases from an oven into the environment.

FIND: (a) Outlet gas and stack surface temperatures, $T_{m,o}$ and $T_{s,o}$, and (b) Effect of wind temperature and velocity on $T_{m,o}$.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Wall thermal resistance negligible, (3) Exhaust gas properties approximated as those of atmospheric air, (4) Radiative exchange with surroundings negligible, (5) Ideal gas with negligible viscous dissipation and pressure variation, (6) Fully developed flow, (7) Constant properties.

PROPERTIES: *Table A.4*, air (assume $T_{m,o}$ = 773 K, $\overline{T}_m$ = 823 K, 1 atm): c_p = 1104 J/kg·K, μ = 376.4 × 10^{-7} N·s/m^2, k = 0.0584 W/m·K, Pr = 0.712; *Table A.4*, air (assume T_s = 523 K, T_∞ = 4°C = 277 K, T_f = 400 K, 1 atm): ν = 26.41 × 10^{-6} m^2/s, k = 0.0338 W/m·K, Pr = 0.690.

ANALYSIS: (a) From Eq. 8.45a,

$$T_{m,o} = T_\infty - \left(T_\infty - T_{m,i}\right)\exp\left[-\frac{PL}{\dot{m}c_p}\overline{U}\right] \qquad U = 1\Big/\left(\frac{1}{h_i}+\frac{1}{h_o}\right) \qquad (1,2)$$

where h_i and h_o are average coefficients for internal and external flow, respectively.

Internal flow: With a Reynolds number of

$$Re_{D_i} = \frac{4\dot{m}}{\pi D\mu} = \frac{4\times 0.5\,\text{kg/s}}{\pi\times 0.5\,\text{m}\times 376.4\times 10^{-7}\,\text{N}\cdot\text{s/m}^2} = 33{,}827 \qquad (3)$$

the flow is turbulent. Considering the flow to be fully developed throughout the stack (L/D = 12) and with $T_s < T_m$, the Dittus-Boelter correlation has the form

$$Nu_D = \frac{h_i D}{k} = 0.023\,Re_{D_i}^{4/5}\,Pr^{0.3} \qquad (4)$$

$$h_i = \frac{58.4\times 10^{-3}\,\text{W/m}\cdot\text{K}}{0.5\,\text{m}}\times 0.023(33{,}827)^{4/5}(0.712)^{0.3} = 10.2\,\text{W/m}^2\cdot\text{K}.$$

External flow: Working with the Churchill/Bernstein correlation, the Reynolds and Nusselt numbers are

$$Re_{D_o} = \frac{VD}{\nu} = \frac{5\,\text{m/s}\times 0.5\,\text{m}}{26.41\times 10^{-6}\,\text{m}^2/\text{s}} = 94{,}660 \qquad (5)$$

Continued...

$$\overline{Nu}_D = 0.3 + \frac{0.62\,Re_D^{1/2}\,Pr^{1/3}}{\left[1+(0.4/Pr)^{2/3}\right]^{1/4}}\left[1+\left(\frac{Re_D}{282,000}\right)^{5/8}\right]^{4/5} = 205$$

Hence,

$$h_o = (0.0338\,W/m\cdot K/0.5\,m)\times 205 = 13.9\,W/m^2\cdot K \qquad (6)$$

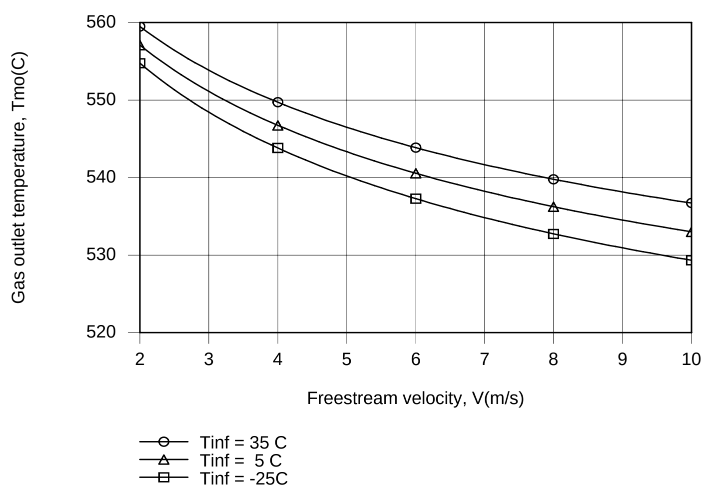
The outlet gas temperature is then

$$T_{m,o} = 4^\circ C - (4-600)^\circ C\exp\left[-\frac{\pi\times 0.5\,m\times 6\,m}{0.5\,kg/s\times 1104\,J/kg\cdot K}\left(\frac{1}{1/10.2+1/13.9}W/m^2\cdot K\right)\right] = 543^\circ C$$ <

The outlet stack surface temperature can be determined from a local surface energy balance of the form, $h_i(T_{m,o} - T_{s,o}) = h_o(T_{s,o} - T_\infty)$, which yields

$$T_{s,o} = \frac{h_i T_{m,o} + h_o T_\infty}{h_i + h_o} = \frac{(10.2\times 543 + 13.9\times 4)\,W/m^2}{(10.2+13.9)\,W/m^2\cdot K} = 232^\circ C$$ <

(b) Using the Correlations and Properties Toolpads of IHT, with a surface temperature of T_s = 523 K assumed solely for the purpose of evaluating properties associated with airflow over the cylinder, the following results were generated.



Due to the elevated temperatures of the gas, the variation in ambient temperature has only a small effect on the gas exit temperature. However, the effect of the freestream velocity is more pronounced. Discharge temperatures of approximately 530 and 560°C would be representative of cold/windy and warm/still atmospheric conditions, respectively.

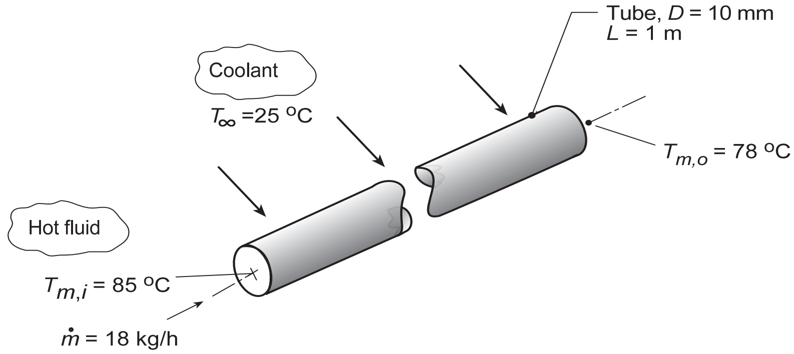
COMMENTS: If there are constituents in the discharge gas flow that condense or precipitate out at temperatures below $T_{s,o}$, this operating condition should be avoided.

PROBLEM 8.60

KNOWN: Hot fluid passing through a thin-walled tube with coolant in cross flow over the tube. Fluid flow rate and inlet and outlet temperatures.

FIND: Outlet temperature, $T_{m,o}$, if the flow rate is increased by a factor of 2 with all other conditions the same.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2)Hot fluid is incompressible with negligible viscous dissipation, (3) Constant properties, (4) Fully developed flow and thermal conditions, (5) Convection coefficients, $\bar{h}_o$ and $\bar{h}_i$, independent of temperature, and (6) Negligible wall thermal resistance.

PROPERTIES: Hot fluid (Given): ρ = 1079 kg/m^3, c_p = 2637 J/kg·K, μ = 0.0034 N·s/m^2, k = 0.261 W/m·K.

ANALYSIS: For conditions prescribed in the Schematic, Eq 8.45a can be used to evaluate the overall convection coefficient with P = πD,

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp\left(-\frac{PL}{\dot{m}_o cp}\bar{U}\right) \quad (1)$$

$$\frac{(25-78)^\circ C}{(25-85)^\circ C} = \exp\left(-\frac{\pi \times 0.010\,m \times 1m}{(18/3600)\,kg/s \times 2637\,J/kg\cdot K}\bar{U}\right)$$

$$U = 52.1\,W/m^2\cdot K$$

The overall coefficient can be expressed in terms of the inside and outside coefficients,

$$U = \left(1/\bar{h}_i + 1/\bar{h}_o\right)^{-1} \quad (2)$$

Characterize the internal flow with the Reynolds number, Eq. 8.6,

$$Re_D = \frac{4\dot{m}_o}{\pi D\mu} = \frac{4\times(18/3600)\,kg/s}{\pi\times 0.010m\times 0.0034\,N\cdot s/m^2} = 187$$

and since the flow is laminar, and assumed to be fully developed, $\bar{h}_i$ will not change when the flow rate is doubled. That is, U = 52.1 W/m$^2\cdot$K when $\dot{m}$ = 2m$_o$. Using Eq. (1) again, but with $T_{m,o}$ unknown,

$$\frac{(25-T_{m,o})^\circ C}{(25-85)^\circ C} = \exp\left(-\frac{\pi\times 0.010\,m\times 1m}{2(18/3600)\,kg/s\times 2637\,J/kg\cdot K}\times 52.1 W/m^2\cdot K\right)$$

$$T_{m,o} = 81.4^\circ C$$ <

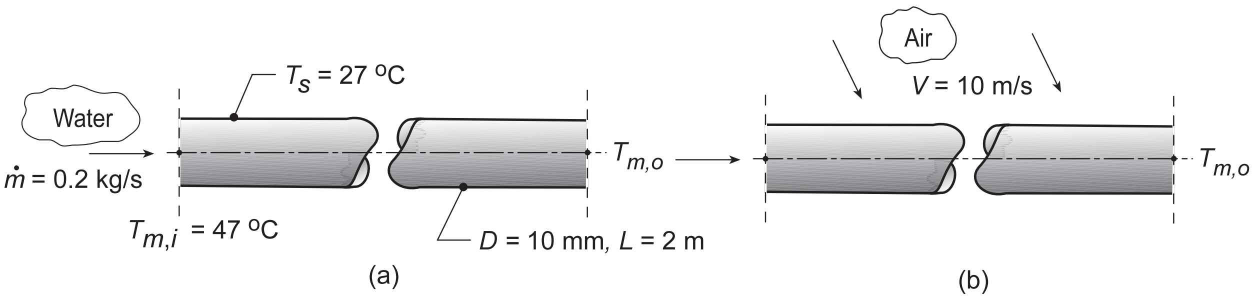
COMMENTS: Examine the assumptions and explain why they were necessary in order to affect the solution.

PROBLEM 8.61

KNOWN: Thin walled tube of prescribed diameter and length. Water inlet temperature and flow rate.

FIND: (a) Outlet temperature of the water when the tube surface is maintained at a uniform temperature $T_s = 27°C$ assuming $\overline{T}_m = 300$ K for evaluating water properties, (b) Outlet temperature of the water when the tube is heated by cross flow of air with V = 10 m/s and $T_\infty = 100°C$ assuming $\overline{T}_f = 350$ K for evaluating air properties, and (c) Outlet temperature of the water for the conditions of part (b) using properly evaluated properties.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Incompressible liquid with negligible viscous dissipation and negligible axial conduction, (3) Fully developed flow and thermal conditions for internal flow, and (4) Negligible tube wall thermal resistance.

PROPERTIES: *Table A.6*, Water ($\overline{T}_m = 300$ K): ρ = 997 kg/m^3, c_p = 4179 J/kg·K, μ = 855 × 10^{-6} N·s/m^2, k = 0.613 W/m·K, Pr = 5.83; *Table A.4*, Air ($\overline{T}_f = 350$ K, 1 atm): ν = 20.92 × 10^{-6} m^2/s, k = 0.030 W/m·K, Pr = 0.700.

ANALYSIS: (a) For the constant wall temperature cooling process, $T_s = 27°C$, the water outlet temperature can be determined from Eq. 8.41b, with P = πD,

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{PL}{\dot{m}c_p}\overline{h}_i\right) \qquad (1)$$

To estimate the convection coefficient, characterize the flow evaluating properties at $\overline{T}_m = 300$ K

$$Re_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4\times 0.2\,\text{kg/s}}{\pi\times 0.010\,\text{m}\times 855\times 10^{-6}\,\text{N}\cdot\text{s/m}^2} = 29{,}783$$

Hence, the flow is turbulent and assuming fully developed (L/D = 200), and using the Dittus-Boelter correlation, Eq. 8.60, find $\overline{h}_i$,

$$Nu_D = \frac{\overline{h}_i D}{k} = 0.023\,Re_D^{0.8}\,Pr^{0.3} \qquad \overline{h}_i = \frac{0.613\,\text{W/m}\cdot\text{K}}{0.010\,\text{m}}0.023(29{,}783)^{0.8}(5.83)^{0.3} = 9080\,\text{W/m}^2\cdot\text{K} \quad (2)$$

Substituting this value for $\overline{h}_i$ into Eq. (1), find

$$\frac{(27 - T_{m,o})}{(27-47)^\circ\text{C}} = \exp\left(-\frac{\pi\times 0.010\,\text{m}\times 2\,\text{m}}{0.2\,\text{kg/s}\times 4179\,\text{J/kg}\cdot\text{K}}\times 9080\,\text{W/m}^2\cdot\text{K}\right) \qquad T_{m,o} = 37.1°C \quad <$$

(b) For the air heating process, $T_\infty = 100°C$, the water outlet temperature follows from Eq. 8.45a,

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp\left(-\frac{\pi DL}{\dot{m}c_p}\overline{U}\right) \qquad (3)$$

Continued...

PROBLEM 8.61 (Cont.)

where the overall coefficient is $\overline{U} = \left(1/\overline{h}_i + 1/\overline{h}_o\right)$ (4)

To estimate $\overline{h}_o$, use the Churchill-Bernstein correlation, Eq. 7.54, for cross flow over a cylinder using properties evaluated at $\overline{T}_f = 350$ K.

$$Re_D = \frac{VD}{\nu} = \frac{10\,m/s \times 0.010\,m}{20.92 \times 10^{-6}\,m^2/s} = 4780 \qquad (5)$$

$$\overline{Nu}_D = 0.3 + \frac{0.62\,Re_D^{1/2}\,Pr^{1/3}}{\left[1+(0.4/Pr)^{2/3}\right]^{1/4}}\left[1+\left(\frac{Re_D}{282{,}000}\right)^{5/8}\right]^{4/5} \qquad (6)$$

$$\overline{Nu}_D = 0.3 + \frac{0.62(4780)^{1/2}(0.700)^{1/3}}{\left[1+(0.4/0.700)^{2/3}\right]^{1/4}}\left[1+\left(\frac{4780}{282{,}000}\right)^{5/8}\right]^{4/5} = 35.76$$

$$\overline{h}_o = \frac{\overline{Nu}_D k}{D} = \frac{0.030\,W/m\cdot K}{0.010\,m} \times 35.76 = 107\,W/m^2\cdot K$$

The value of $\overline{h}_i$ can be recalculated for heating conditions:

$$Nu_D = \frac{\overline{h}_i D}{k} = 0.023\,Re_D^{0.8}\,Pr^{0.4} \qquad \overline{h}_i = \frac{0.613\,W/m\cdot K}{0.010\,m}0.023(29{,}783)^{0.8}(5.83)^{0.4} = 10{,}800\,W/m^2\cdot K$$

Next, find $\overline{U}$ then $T_{m,o}$,

$$\overline{U} = (1/10{,}800 + 1/107)^{-1}\,W/m^2\cdot K = 106\,W/m^2\cdot K$$

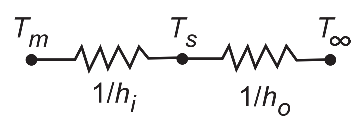
$$\frac{100 - T_{m,o}}{(100-47)^\circ C} = \exp\left(-\frac{\pi \times 0.010\,m \times 2\,m}{0.2\,kg/s \times 4179\,J/kg\cdot K} \times 106\,W/m^2\cdot K\right) \qquad T_{m,o} = 47.4^\circ C \quad <$$

(c) Using the *IHT Correlation Tools* for *Internal Flow* (*Turbulent Flow*) and *External Flow* (over a *Cylinder*) the analyses of part (b) were performed considering the appropriate temperatures to evaluate the thermophysical properties. For internal and external flow, respectively,

$$\overline{T}_m = \left(T_{m,i} + T_{m,o}\right)/2 \qquad \overline{T}_f = \left(\overline{T}_s + T_\infty\right)/2 \qquad (7,8)$$

where the average tube wall temperature is evaluated from the thermal circuit,

$$\frac{\overline{T}_m - \overline{T}_s}{1/\overline{h}_i} = \frac{\overline{T}_s - T_\infty}{1/\overline{h}_o} \qquad (9)$$



The results of the analyses are summarized in the table along with the results from parts (a) and (b),

Condition	$\overline{T}_m$ (K)	$\overline{h}_i$ (W/m²·K)	$\overline{T}_f$ (K)	$\overline{h}_o$ (W/m²·K)	$\overline{U}$ (W/m²·K)	$T_{m,o}$ (°C)
T_s = 27°C	300	9080	---	---	---	37.1°C
T_∞ = 100 °C, T_f = 350°C	300	10,800	350	107	106	47.4°C
Exact solution	320	13,000	347	107.3	106.3	47.4°C

Continued...

PROBLEM 8.61 (Cont.)

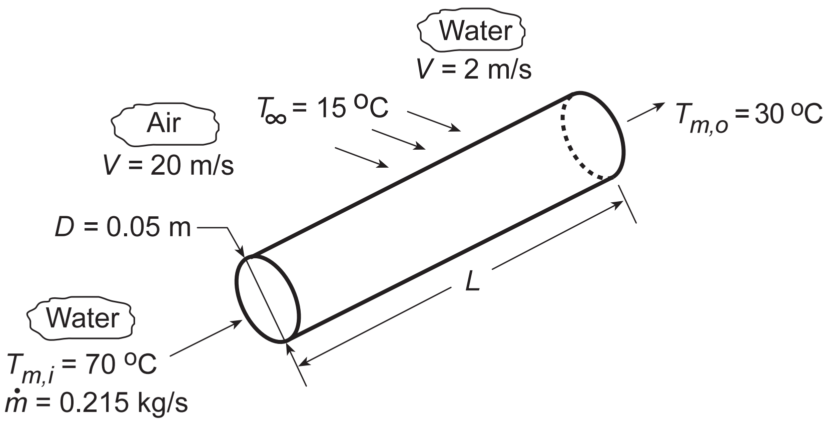
Note that since $\overline{h}_o << \overline{h}_i$, $\overline{U}$ is controlled by the value of $\overline{h}_o$ which was evaluated near 350 K for both parts (b) and (c). Hence, it follows that $T_{m,o}$ is not very sensitive to $\overline{h}_i$ which, as seen above, is sensitive to the value of $\overline{T}_m$.

PROBLEM 8.62

KNOWN: Diameter of tube through which water of prescribed flow rate and inlet and outlet temperatures flows. Temperature of fluid in cross flow over the tube.

FIND: (a) Required tube length for air in cross flow at prescribed velocity, (b) Required tube length for water in cross flow at a prescribed velocity.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Constant properties, (3) Negligible tube wall conduction resistance, (4)Water is incompressible liquid with negligible viscous dissipation.

PROPERTIES: *Table A.6*, water ($\overline{T}_m$ = 50°C = 323 K): c_p = 4181 J/kg·K, $\mu = 548 \times 10^{-6}$ N·s/m^2, k = 0.643 W/m·K, Pr = 3.56. *Table A.4*, air (assume T_f = 300 K): $\nu = 15.89 \times 10^{-6}$ m^2/s, k = 0.0263 W/m·K, Pr = 0.707. *Table A.6*, water (assume T_f = 300 K): $\nu = 0.858 \times 10^{-6}$ m^2/s, k = 0.613 W/m·K, Pr = 5.83.

ANALYSIS: The required heat rate may be determined from the overall energy balance,

$$q = \dot{m}c_p\left(T_{m,i} - T_{m,o}\right) = 0.215\,\text{kg/s}\left(4181\,\text{J/kg}\cdot\text{K}\right)40^\circ\text{C} = 35,960\,\text{W}$$

and the required tube length may be determined from the rate equation, Eq. 8.46a,

$$L = \frac{q}{U\pi D\Delta T_{\ell m}}$$

where

$$\Delta T_{\ell m} = \frac{\left(T_{m,i} - T_\infty\right) - \left(T_{m,o} - T_\infty\right)}{\ell n\left(\dfrac{T_{m,i} - T_\infty}{T_{m,o} - T_\infty}\right)} = 30.8^\circ\text{C} \qquad \text{and} \qquad 1/U = 1/h_i + 1/h_o.$$

With

$$Re_{D_i} = 4\dot{m}/\pi D\mu = 0.860\,\text{kg/s}\Big/\pi\left(0.05\,\text{m}\right)548\times10^{-6}\,\text{N}\cdot\text{s}\big/\text{m}^2 = 9991$$

the flow is turbulent and, assuming fully developed flow throughout the tube, the inside convection coefficient is determined from Eq. 8.62

$$Nu_{D_i} = \frac{(f/8)(Re_{D_i} - 1000)\,Pr}{1 + 12.7(f/8)^{1/2}(Pr^{2/3} - 1)} = \frac{(0.0315/8)(9991-1000)3.56}{1+12.7(0.0315/8)^{1/2}(3.56^{2/3}-1)} = 61.1$$

where f = (0.79 lnRe_{Di} = 1.64)$^{-2}$ = 0.0315

$$h_i = Nu_{D_i}\,k/D = 61.1\left(0.643\,\text{W/m}\cdot\text{K}\right)\big/0.05\,\text{m} = 786\,\text{W}\big/\text{m}^2\cdot\text{K}$$

Continued...

PROBLEM 8.62 (Cont.)

(a) For air in cross flow at 20 m/s, Re_{D_o} = VD/ν = 20 m/s(0.05 m)/15.89 × 10^{-6} m^2/s = 62,933. From the Churchill/Bernstein correlation, it follows that

$$Nu_{D_o} = 0.3 + \frac{0.62 Re_{D_o}^{1/2} Pr^{1/3}}{\left[1+\left(0.4/Pr\right)^{2/3}\right]^{1/4}}\left[1+\left(\frac{Re_{D_o}}{282,000}\right)^{5/8}\right]^{4/5} = 158.7$$

$$h_o = Nu_{D_o} k/D = 158.7\left(0.0263\, W/m\cdot K\right)/0.05\, m = 83.5\, W/m^2\cdot K$$

Hence, U = $\left(1/h_i + 1/h_o\right)^{-1}$ = 75.5 W/m^2·K and

$$L = \frac{35,960\, W}{\left(75.5\, W/m^2\cdot K\right)\pi\left(0.05\, m\right)30.8^\circ C} = 98.5\, m$$ <

(b) For water in cross flow at 2 m/s, Re_{D_o} = 2 m/s(0.05 m)/0.858 × 10^{-6} m^2/s = 116,550, and the correlation yields $Nu_{D_o} = 527.3$. Hence,

$$h_o = Nu_{D_o} k/D = 527.3\left(0.613\, W/m\cdot K\right)/0.05\, m = 6,465\, W/m^2\cdot K$$

U = $\left(1/h_i + 1/h_o\right)^{-1}$ = 701 W/m^2·K

Hence,

$$L = \frac{35,960\, W}{\left(701\, W/m^2\cdot K\right)\pi\left(0.05\, m\right)30.8^\circ C} = 10.6\, m$$ <

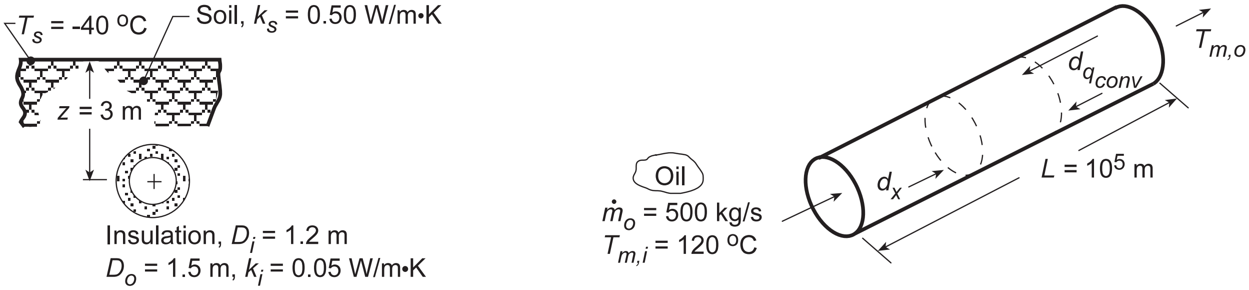
COMMENTS: The foregoing results clearly indicate the superiority of water (relative to air) as a heat transfer fluid. Note the dominant contribution made by the smaller convection coefficient to the value of U in each of the two cases.

PROBLEM 8.63

KNOWN: Length, diameter, insulation characteristics and burial depth of a pipe. Ground surface temperature. Inlet temperature, flow rate and properties of oil flowing through pipe.

FIND: (a) An expression for the oil outlet temperature, (b) Oil outlet temperature and pipe heat transfer rate for prescribed conditions, and (c) Design information for trade off between burial depth of pipe (z) and pipe insulation thickness (t) on the heat loss.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Two-dimensional conduction in soil, (4) Negligible pipe wall thermal resistance, (5) Total resistance to heat loss is independent of x, (6) Oil is incompressible liquid with negligible viscous dissipation.

PROPERTIES: Oil (given): ρ_o = 900 kg/m^3, $c_{p,o}$ = 2000 J/kg·K, $\nu_o = 8.5 \times 10^{-4}$ m^2/s, k_o = 0.140 W/m·K, $Pr_o = 10^4$; Soil (given): k_s = 0.50 W/m·K; Insulation (given): k_i = 0.05 W/m·K.

ANALYSIS: (a) From Eq. 8.36 for a differential control volume in the oil and the rate equation

$$dq_{conv} = \dot{m}_o c_{p,o} dT_m = dq = \left(T_s - T_m\right)/R_{tot} \qquad (1)$$

where the total resistance is expressed as

$$R_{tot} = R_{conv} + R_{cond,i} + R_{cond,s} = \left(\bar{h}\pi D dx\right)^{-1} + \frac{\ln\left(D_o/D_i\right)}{2\pi k_i dx} + \frac{1}{k_s S}$$

$$R_{tot} = \left(\frac{1}{\bar{h}\pi D_i} + \frac{\ln\left(D_o/D_i\right)}{2\pi k_i} + \frac{\cosh^{-1}\left(2z/D_o\right)}{2\pi k_s}\right)/\,dx = R'_{tot}/dx \qquad (2)$$

where, from Table 4.1,

$$S = 2\pi dx \big/ \cosh^{-1}\left(2z/D_o\right) \qquad (3)$$

It follows that

$$\frac{\left(T_s - T_m\right)dx}{R'_{tot}} = \dot{m}_o c_{p,o} dT_m \qquad\qquad \frac{dT_m}{T_s - T_m} = \frac{dx}{\dot{m}_o c_{p,o} R'_{tot}}$$

Integrating between inlet and outlet conditions

$$\int_{T_{m,i}}^{T_{m,o}} \frac{dT_m}{T_m - T_s} = -\int_0^L \frac{dx}{\dot{m}_o c_{p,o} R'_{tot}}.$$

Assuming R'_{tot} to be independent of x and integrating,

$$\frac{T_{m,o} - T_s}{T_{m,i} - T_s} = \exp\left(-\frac{L}{\dot{m}_o c_{p,o} R'_{tot}}\right). \qquad (3) <$$

Continued...

PROBLEM 8.63 (Cont.)

(b) To calculate $T_{m,o}$ for the prescribed conditions, begin by evaluating $\bar{h}$, where

$$Re_D = \frac{4\dot{m}_o}{\pi D_i \rho_o \nu_o} = \frac{4 \times 500\,kg/s}{\pi(1.2\,m)900\,kg/m^3 \times 8.5 \times 10^{-4}\,m^2/s} = 694 \qquad (4)$$

Hence, the flow is laminar, and with $Pr_o > 5$, the Hausen correlation is appropriate,

$$\overline{Nu}_D = 3.66 + \frac{0.0668 Gz_D}{1 + 0.04 Gz_D^{2/3}} \qquad (5)$$

$$Gz_D = (D_i/L) Re_D\,Pr = \left(\frac{1.2}{10^5}\right)(694)10^4 = 83.3 \qquad \overline{Nu}_D = 6.82$$

$$\bar{h} = \frac{k}{D_i} 6.82 = \frac{0.14\,W/m\cdot K}{1.2\,m} 6.82 = 0.80\,W/m^2\cdot K$$

From Eq. (2), the overall thermal resistance is

$$R'_{tot} = \frac{1}{0.8\,W/m^2\cdot K\pi(1.2\,m)} + \frac{\ln(1.5/1.2)}{2\pi(0.05\,W/m\cdot K)} + \frac{\cosh^{-1}(4)}{2\pi(0.5\,W/m\cdot K)}$$

$$R'_{tot} = (0.33 + 0.71 + 0.66)\,K\cdot m/W = 1.70\,K\cdot m/W$$

and the oil outlet temperature can be calculated as

$$\frac{T_{m,o} - T_s}{T_{m,i} - T_s} = \exp\left(-\frac{10^5\,m}{500\,kg/s \times 2000\,J/kg\cdot K \times 1.7\,K\cdot m/W}\right) = 0.943$$

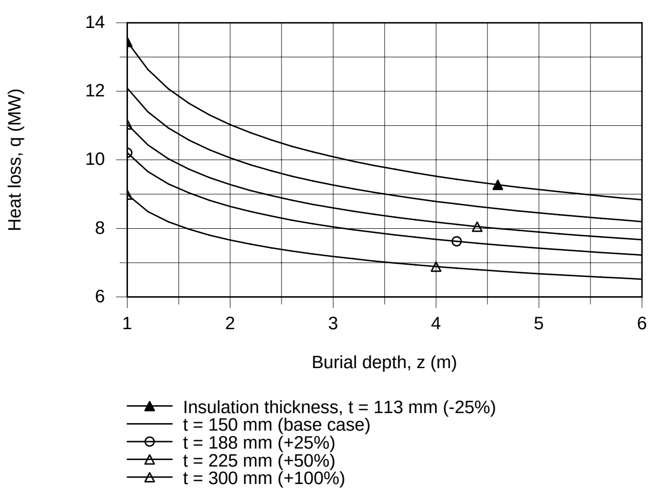
$T_{m,o} = 110.9°C$ <

The total rate of heat transfer *from* the pipeline is then

$$q = \dot{m}_o c_{p,o}\left(T_{m,i} - T_{m,o}\right) \qquad (6)$$

$$q = 500\,kg/s \times 2000\,J/kg\cdot K(120 - 110.9)^\circ C = 9.1 \times 10^6\,W.$$ <

(c) Using the *IHT Workspace* with the foregoing equations, an analysis was performed to determine the heat loss, q, as a function of burial depth for the range, $1 \le z \le 6$ m, for thicknesses of insulation which are -25%, +25%, +50% and 100% that of the base case, $t = r_o - r_1 = 150$ mm.



Continued...

PROBLEM 8.63 (Cont.)

From this information, the operations manager can compare the costs associated with burial depth and insulation thickness with respect to acceptable heat loss.

COMMENTS: (1) Since the thermal entry region is very long, $x_{fd,t} \approx 0.05 D Re_D Pr = 4.16 \times 10^5$ m, h_x will be changing with x throughout the pipe. A more accurate solution would therefore be one in which Eq. (1) is integrated numerically, in a step-by-step fashion. For example, the integration could involve a step width of $\Delta x = 10^3$ m, with h and R'_t evaluated at each step.

(2) The three contributions to the total thermal resistance are comparable.

(3) In IHT 3.0, the inverse hyperbolic cosine function is "invcosh," so the shape factor can be found as:

```
// Shape factor:
S = 2 * pi / invcosh(arg)
arg = 2*z/Do
z = 3
Do = 1.5
```

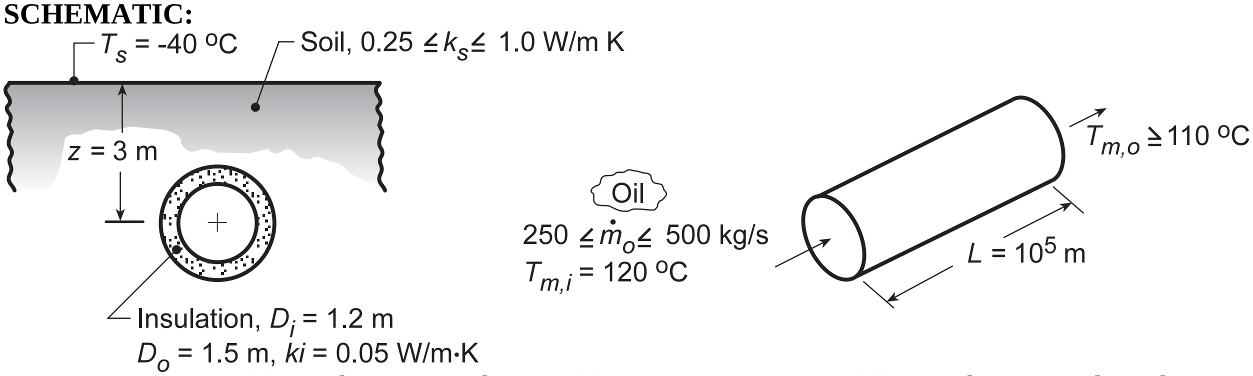
Note that the argument of a function must be calculated separately in IHT. That is, we cannot use invcosh(2*z/Do).

PROBLEM 8.64

KNOWN: Length, diameter, insulation characteristics and burial depth of pipe. Ground surface temperature. Inlet temperature, minimum allowable exit temperature, flow rate and properties of oil flow through pipe.

FIND: Effect of soil thermal conductivity and flowrate on heat rate and outlet temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Two-dimensional conduction in soil, (4) Negligible pipe wall thermal resistance, (5) Total resistance to heat loss is independent of x, (6) Oil is incompressible liquid with negligible viscous dissipation.

PROPERTIES: Oil (given): ρ_o = 900 kg/m^3, $c_{p,o}$ = 2000 J/kg·K, $\nu_o = 8.5 \times 10^{-4}$ m^2/s, k_o = 0.140 W/m·K, $Pr_o = 10^4$.

ANALYSIS: From the analysis of Problem 8.63, the outlet temperature may be computed from the expression

$$\frac{T_{m,o} - T_s}{T_{m,i} - T_s} = \exp\left(-\frac{L}{\dot{m}c_{p,o}R'_{tot}}\right)$$

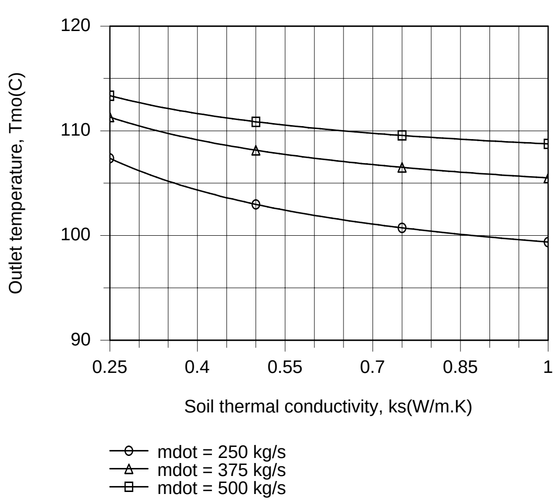
where

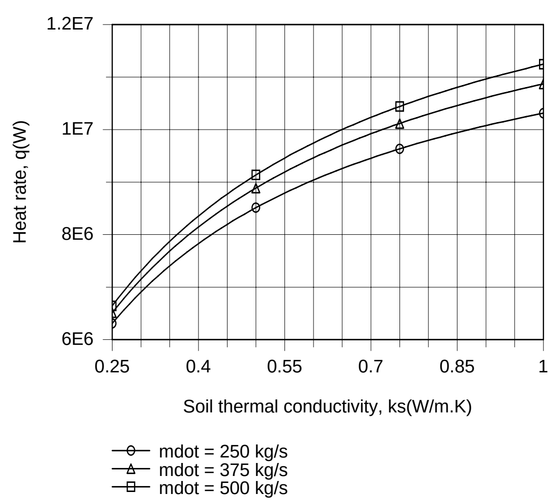
$$R'_{tot} = \frac{1}{\bar{h}\pi D_i} + \frac{\ln(D_o/D_i)}{2\pi k_i} + \frac{\cosh^{-1}(2z/D_o)}{2\pi k_s}$$

and $\bar{h}$ is determined from Eq. 8.57. The heat rate may then be obtained from the overall energy balance

$$q = \dot{m}c_p\left(T_{m,i} - T_{m,o}\right)$$

Using the *Correlations* Toolpad of IHT to perform the parametric calculations, the following results were obtained.





Continued...

PROBLEM 8.64 (Cont.)

Due to a reduction in the thermal conduction resistance of the soil with increasing k_s, there is a corresponding increase in the heat rate q from the pipe and a reduction in the oil outlet temperature. The heat rate also increases with increasing $\dot{m}$ (due to an increase in $\overline{h}$ and hence a decrease in the convection resistance), but the increase lags that of the flow rate, causing the outlet temperature to increase with increasing $\dot{m}$. Conditions for which $T_{m,o} \geq 110°C$ cannot be achieved for $\dot{m}$ = 250 kg/s, but can be achieved for $k_s \leq 0.33$ W/m·K and $k_s \leq 0.65$ W/m·K for $\dot{m}$ = 375 kg/s and 500 kg/s, respectively. The worst case condition corresponds to the smallest value of $\dot{m}$ and the largest value of k_s.

Measures to maintain $T_{m,o} \geq 110°C$ could include increasing the burial depth, increasing the insulation thickness, and/or using an insulation of lower thermal conductivity.

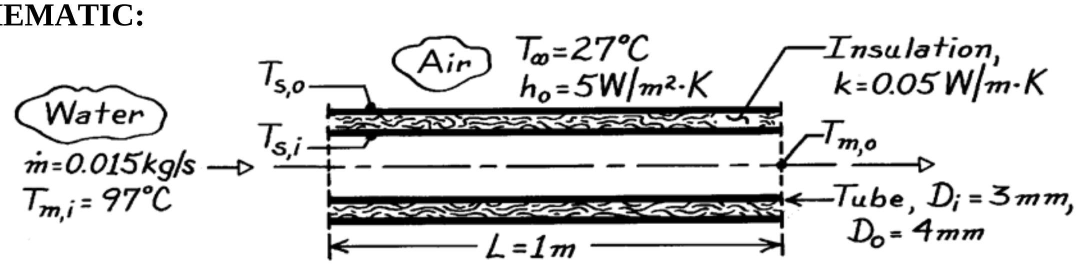
COMMENTS: The thermophysical properties of oil depend strongly on temperature, and a more accurate solution would account for the effect of variations in $\overline{T}_m$ on the properties.

PROBLEM 8.65

KNOWN: Water flow rate and inlet temperature for a thin-walled tube of prescribed length and diameter.

FIND: Water outlet temperature for each of the following conditions: (a) Tube surface maintained at 27°C, (b) Insulation applied and outer surface maintained at 27°C, (c) Insulation applied and outer surface exposed to ambient air at 27°C.

SCHEMATIC:



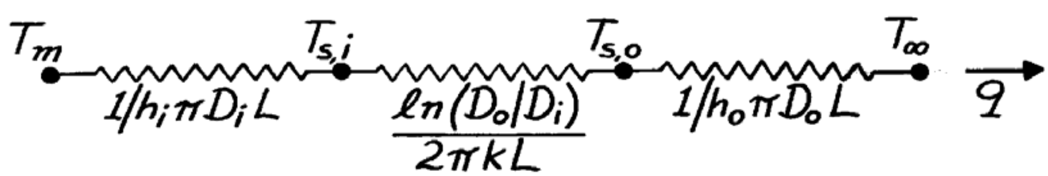
ASSUMPTIONS: (1) Steady-state conditions, (2) Fully developed flow throughout the tube, (3) Negligible tube wall conduction resistance, (4) Negligible contact resistance between tube wall and insulation, (5) Uniform outside convection coefficient.

PROPERTIES: Assume water cools to $T_{m,o}$ = 27°C with no insulation but that cooling is negligible ($T_{m,o}$ = 97°C) with insulation. *Table A-4*, Water $\left(\overline{T}_m = 335\text{K}\right)$: c_p = 4186 J/kg·K, $\mu = 453 \times 10^{-6}$ N·s/m^2, k =0.656 W/m·K, Pr = 2.88; *Table A-4*, Water ($T_{m,i}$ = 370K): c_p = 4214 J/kg·K, $\mu = 289 \times 10^{-6}$ N·s/m^2, k = 0.679 W/m·K, Pr = 1.80.

ANALYSIS: For each of the three cases, heat is transferred from the warm water to a surface (or the air) which is at a fixed temperature (27°C). Accordingly, an expression of the form given by Eq. 8.41b may be used to determine the outlet temperature of the water, so long as the appropriate heat transfer coefficient is used. In particular, each of the cases can be described by Eq. 8.45a.

$$\frac{\Delta T_o}{\Delta T_i} = \exp\left(-\frac{\overline{U}A_s}{\dot{m}\, c_p}\right)$$

Referring to the thermal circuit associated with heat transfer from the water,



and the UA product may be evaluated as

$$\text{UA} = \left(\Sigma R_t\right)^{-1}.$$

(a) For the first case: $T_{s,i} = 27^\circ\text{C}$ $\quad \Delta T_i = T_{m,i} - T_{s,i} = 70^\circ\text{C}$ $\quad \text{UA} = h_i \pi\, D_i L$.

$$\text{Re}_D = \frac{4\dot{m}}{\pi\, D_i \mu} = \frac{4 \times 0.015 \text{ kg/s}}{\pi(0.003\text{m})453 \times 10^{-6} \text{N} \cdot \text{s/m}^2} = 14{,}053.$$

Continued …

PROBLEM 8.65 (Cont.)

From Eq. 8.60,

$$h_i = \frac{k}{D_i} 0.023\, Re_D^{4/5}\, Pr^{0.30} = \frac{0.656\ \text{W/m}\cdot\text{K}}{0.003\text{m}}(0.023)\ (14{,}053)^{4/5}(2.88)^{0.3} = 14,373\ \text{W/m}^2\cdot\text{K}.$$

$$\Delta T_o = \Delta T_i \exp\left(-\frac{h_i \pi D_i L}{\dot{m} c_p}\right) = 70^\circ\text{C}\exp\left(-\frac{14{,}373 \dfrac{\text{W}}{\text{m}^2\cdot\text{K}} \pi \times 0.003\text{m} \times 1\text{m}}{0.015\ \text{kg/s} \times 4186\ \text{J/kg}\cdot\text{K}}\right) = 8.1^\circ\text{C}$$

$$T_{m,o} = \Delta T_o + T_{s,i} = 8.1^\circ\text{C} + 27^\circ\text{C} = 35.1^\circ\text{C}.$$ <

(b) For the second case: $T_{s,o}$ = 27°C with

$$\Delta T_i = T_{m,i} - T_{s,o} = 70^\circ\text{C} \qquad UA = \left[(1/h_i \pi D_i L) + \ell n(D_o / D_i)/2\pi kL\right]^{-1}.$$

With $$Re_D = \frac{4\dot{m}}{\pi D_i \mu} = \frac{4 \times 0.015\ \text{kg/s}}{\pi(0.003\text{m})289 \times 10^{-6}\ \text{N}\cdot\text{s/m}^2} = 22,028$$

$$h_i = \frac{k}{D_i} 0.023\, Re_D^{4/5}\, Pr^{0.3} = \frac{0.679\ \text{W/m}\cdot\text{K}}{0.003\text{m}}(0.023)\ (22{,}028)^{4/5}(1.80)^{0.3} = 18,511\ \text{W/m}^2\cdot\text{K}.$$

It follows that

$$UA = \left[\frac{1}{18{,}511\ \pi \times 0.003} + \frac{\ell n(0.004/0.003)}{2\pi(0.05)}\right]^{-1} = \left[5.73 \times 10^{-3} + 0.916\right]^{-1} = 1.085\ \text{W/K}$$

and the outlet temperature is

$$\Delta T_o = 70^\circ\text{C}\exp\left(-\frac{1.085\ \text{W/K}}{0.015\ \text{kg/s} \times 4214\ \text{J/kg}\cdot\text{K}}\right) = 68.8^\circ\text{C}$$

$$T_{m,o} = \Delta T_o + T_{s,o} = 68.8^\circ\text{C} + 27^\circ\text{C} = 95.8^\circ\text{C}.$$ <

(c) For the third case: T_∞ = 27°C, $\Delta T_i = T_{m,i} - T_\infty$ = 70°C and

$$UA = \left[(1/h_i \pi D_i L) + \ell n(D_o / D_i)/2\pi kL + (1/h_o \pi D_o L)\right]^{-1}$$

$$UA = \left[5.73 \times 10^{-3} + 0.916 + \frac{1}{5\pi(0.004)}\right]^{-1} = \left[5.73 \times 10^{-3} + 0.916 + 15.92\right]^{-1} = 0.0594\ \text{W/K}$$

$$\Delta T_o = 70^\circ\text{C}\exp\left(-\frac{0.0594\ \text{W/K}}{0.015\ \text{kg/s} \times 4214\ \text{J/kg}\cdot\text{K}}\right) = 69.9^\circ\text{C}$$

$$T_{m,o} = \Delta T_o + T_\infty = 69.9^\circ\text{C} + 27^\circ\text{C} = 96.9^\circ\text{C}.$$ <

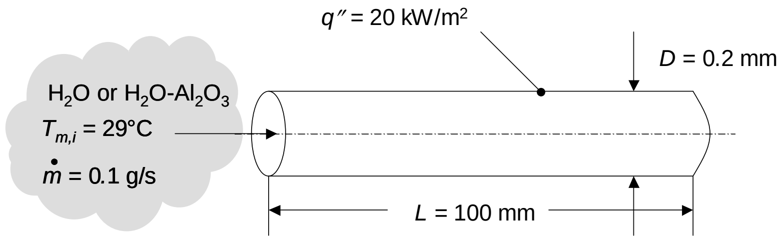
COMMENTS: Note that $R_{conv,o} >> R_{cond,insul} >> R_{conv,i}$,

PROBLEM 8.66

KNOWN: Dimensions of circular tube, applied constant heat flux, inlet temperature, mass flow rate, and expression for nanofluid viscosity.

FIND: Tube wall temperature at the tube exit for pure water and for a water-Al_2O_3 nanofluid.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties.

PROPERTIES: *Table A.4*, water (300 K): $\mu_{\mathrm{bf}} = 855 \times 10^{-6}$ m²/s, $k_{\mathrm{bf}} = 0.613$ W/m·K, $c_{p,\mathrm{bf}} = 4179$ J/kg·K, $Pr_{\mathrm{bf}} = 5.83$. Example 2.2, nanofluid (300 K): $\mu_{\mathrm{nf}} = 962 \times 10^{-6}$ m²/s, $k_{\mathrm{nf}} = 0.705$ W/m·K, $c_{p,\mathrm{nf}} =$ 3587 J/kg·K, $Pr_{\mathrm{nf}} = \mu_{\mathrm{nf}}\, c_{p,\mathrm{nf}}/\, k_{\mathrm{nf}} = 4.91$.

ANALYSIS: The Reynolds number for the pure water is $Re_D = 4\dot{m}/\pi D\mu_{\mathrm{bf}} = \left[4\times(0.1/1000\ \mathrm{kg/s})\right]/\left(\pi\times 0.0002\ \mathrm{m}\times 855\times 10^{-6}\ \mathrm{N\cdot s/m^2}\right) = 745$ and the flow is laminar. Similarly, the Reynolds number for the nanofluid is $Re_{D,\mathrm{nf}} = 662$. The hydrodynamic entrance length for the pure water is $x_{fd,h} = 0.05 Re_D D = 0.05 \times 745 \times 0.2/1000$ m $= 7.45 \times 10^{-3}$ m = 7.45 mm and the flow at the tube exit is hydrodynamically fully developed. Similarly, the hydrodynamic entrance length for the nanofluid is $x_{fd,h,\mathrm{nf}} = 6.62 \times 10^{-3}$ m = 6.62 mm and the flow at the tube exit is also hydrodynamically fully developed. For the pure water, the thermal entrance length is $x_{fd,t} = x_{fd,h}Pr_{\mathrm{bf}} =$ 7.45 mm × 5.83 = 43.4 mm, while for the nanofluid $x_{fd,t,\mathrm{nf}} = x_{fd,h,\mathrm{nf}}Pr_{\mathrm{nf}} = 6.62$ mm × 4.91 = 32.5 mm and the flow is also thermally fully-developed at the tube exit for both fluids.

For constant heat flux conditions, the local Nusselt number in the fully-developed region is $Nu_D =$ 4.36. Therefore, the local heat transfer coefficient at the tube exit is:

Pure fluid: $h_{\mathrm{bf}} = Nu_D k_{\mathrm{bf}}/D = 4.36 \times 0.613$ W/m·K /(0.2/1000m) = = 13,360 W/m²·K.
Nanofluid: $h_{\mathrm{nf}} = Nu_D k_{\mathrm{nf}}/D = 4.36 \times 0.705$ W/m·K /(0.2/1000m) = = 15,370 W/m²·K.

Applying Eq. (8.40) to the pure fluid yields

$$T_{m,o} = T_{m,i} + \frac{q''\pi D}{\dot{m}c_{p,\mathrm{bf}}}L = 29^\circ\mathrm{C} + \frac{20{,}000\ \mathrm{W/m^2}\,\pi(0.2/1000\ \mathrm{m})}{(0.1/1000\ \mathrm{kg/s})\times(4179\ \mathrm{J/kg\cdot K})}0.1\ \mathrm{m} = 29^\circ\mathrm{C} + 3.00^\circ\mathrm{C} = 32.00^\circ\mathrm{C}$$

whereas applying Eq. (8.40) to the nanofluid results in

$$T_{m,o,\mathrm{nf}} = T_{m,i} + \frac{q''\pi D}{\dot{m}c_{p,\mathrm{nf}}}L = 29^\circ\mathrm{C} + \frac{20{,}000\ \mathrm{W/m^2}\,\pi(0.2/1000\ \mathrm{m})}{(0.1/1000\ \mathrm{kg/s})\times(3587\ \mathrm{J/kg\cdot K})}0.1\ \mathrm{m} = 29^\circ\mathrm{C} + 3.50^\circ\mathrm{C} = 32.50^\circ\mathrm{C}$$

Continued…

PROBLEM 8.66 (Cont.)

From Eq. (8.27) the wall temperature at the outlet of the tube carrying the pure water is,

$$T_s(x = L) = T_{m,o} + q''/h_{\text{bf}} = 32.00°\text{C} + 20{,}000\text{W/m}^2 / 13{,}360\ \text{W/m}^2 \cdot \text{K} = 32°\text{C}\ + 1.50°\text{C} = 33.50°\text{C} \quad <$$

Similarly for the nanofluid,

$$T_{s,\text{nf}}(x = L) = T_{m,o,\text{nf}} + q''/h_{\text{nf}} \quad <$$
$$= 32.50°\text{C} + 20{,}000\text{W/m}^2 / 15{,}370\ \text{W/m}^2 \cdot \text{K} = 32.50°\text{C}\ + 1.30°\text{C} = 33.80°\text{C}$$

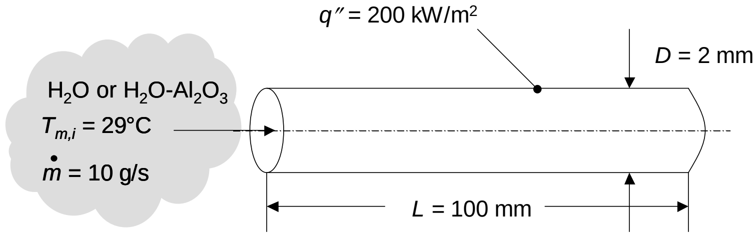
COMMENTS: Although the nanofluid provides a larger thermal conductivity and, in turn, a larger convective heat transfer coefficient relative to the pure water, the wall temperature at the tube outlet with the nanofluid exceeds that of the wall temperature using pure water. This is due to the reduction of the specific heat upon addition of the nanoparticles to the pure water and the associated increase in the outlet mean temperature. Hence, careful consideration of the flow conditions must be made in order to determine whether wall temperatures will decrease or increase with use of the nanofluid.

PROBLEM 8.67

KNOWN: Dimensions of circular tube, applied constant heat flux, inlet temperature, mass flow rate.

FIND: Tube wall temperature at the tube exit for pure water and for a water-Al_2O_3 nanofluid.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties.

PROPERTIES: *Table A.4*, water (300 K): $\mu_{bf} = 855 \times 10^{-6}$ m²/s, $k_{bf} = 0.613$ W/m·K, $c_{p,bf} = 4179$ J/kg·K, $Pr_{bf} = 5.83$. Example 2.2, nanofluid (300 K): $\mu_{nf} = 962 \times 10^{-6}$ m²/s, $k_{nf} = 0.705$ W/m·K, $c_{p,nf} = 3587$ J/kg·K, $Pr_{nf} = 4.91$.

ANALYSIS: The Reynolds number for the pure water is $Re_D = 4\dot{m}/\pi D\mu_{bf} = [4\times(10/1000\text{ kg/s})]/\left(\pi\times 0.002\text{ m}\times 855\times 10^{-6}\text{ N}\cdot\text{s/m}^2\right) = 7450$ and the flow is turbulent. Similarly, the Reynolds number for the nanofluid is $Re_{D,nf} = 6620$. Since $L/D = 100/2 = 50$, the flow is fully-developed at the tube exit for both fluids.

The local Nusselt number is evaluated using the Gnielinski correlation. For pure water, Eq. (8.21) yields, $f_{bf} = (0.790\ln(7450) - 1.64)^{-2} = 0.0342$ while for the nanofluid, $f_{nf} = (0.790\ln(6620) - 1.64)^{-2} = 0.0355$. The Gnielinski correlation yields, for the pure fluid

$$Nu_{D,bf} = \frac{(0.0342/8)(7450-1000)5.83}{1+12.7(0.0342/8)^{1/2}\left(5.83^{2/3}-1\right)} = 56.24$$

while for the nanofluid,

$$Nu_{D,nf} = \frac{(0.0355/8)(6620-1000)4.91}{1+12.7(0.0355/8)^{1/2}\left(4.91^{2/3}-1\right)} = 47.08$$

Hence, $h_{bf} = Nu_{D,bf}k_{bf}/D = 56.24(0.613\text{ W/m}\cdot\text{K})/0.002\text{ m} = 17{,}240\text{ W/m}^2\cdot\text{K}$ and $h_{nf} = Nu_{D,bf}k_{nf}/D = 47.08(0.705\text{ W/m}\cdot\text{K})/0.002\text{ m} = 16{,}600\text{ W/m}^2\cdot\text{K}$.

Applying Eq. (8.40) to the pure fluid yields

$$T_{m,o} = T_{m,i} + \frac{q''\pi D}{\dot{m}c_{p,bf}}L = 29°\text{C} + \frac{200{,}000\text{ W/m}^2\pi(2/1000\text{ m})}{(10/1000\text{ kg/s})\times(4179\text{ J/kg}\cdot\text{K})}0.1\text{ m} = 29°\text{C} + 3.00°\text{C} = 32.00°\text{C}$$

whereas applying Eq. (8.40) to the nanofluid results in

Continued…

PROBLEM 8.67 (Cont.)

$$T_{m,o,\text{nf}} = T_{m,i} + \frac{q''\pi D}{\dot{m}c_{p,\text{nf}}}L = 29°\text{C} + \frac{200,000\ \text{W/m}^2\pi(2/1000\ \text{m})}{(10/1000\ \text{kg/s})\times(3587\ \text{J/kg}\cdot\text{K})}0.1\ \text{m} = 29°\text{C} + 3.50°\text{C} = 32.50°\text{C}$$

From Eq. (8.27) the wall temperature at the outlet of the tube carrying the pure water is,

$$T_s(x = L) = T_{m,o} + q''/h_{\text{bf}}$$

$$= 32.00°\text{C} + 200,000\text{W/m}^2/17,240\ \text{W/m}^2\cdot\text{K} = 32.00°\text{C} + 11.61°\text{C} = 43.61°\text{C}$$ <

Similarly for the nanofluid,

$$T_{s,\text{nf}}(x = L) = T_{m,o,\text{nf}} + q''/h_{\text{nf}}$$

$$= 32.50°\text{C} + 200,000\text{W/m}^2/16,600\ \text{W/m}^2\cdot\text{K} = 32.50°\text{C} + 12.05°\text{C} = 44.55°\text{C}$$ <

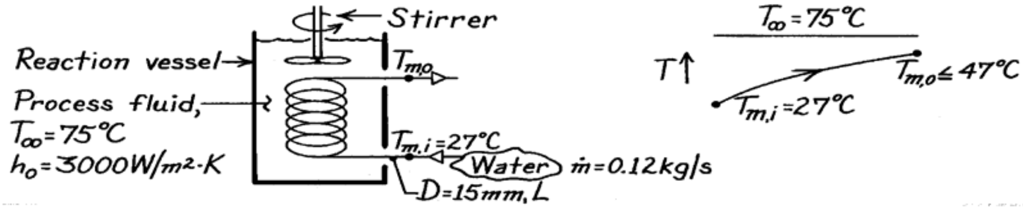
COMMENT: The nanofluid provides a larger thermal conductivity but a smaller convective heat transfer coefficient relative to the pure water. If the objective is to minimize the wall temperature at the outlet of the tube, the nanofluid is *not* the appropriate selection. The wall temperature at the tube outlet may be greater than, less than, or equal to the wall temperature associated with use of pure water, depending on the tube geometry and flow rate.

PROBLEM 8.68

KNOWN: Reaction vessel with process fluid at 75°C cooled by water at 27°C and 0.12 kg/s through 15 mm tube. High convection coefficient on outside of tube (3000 W/m^2·K) created by vigorous stirring.

FIND: (a) Maximum heat transfer rate if outlet temperature of water cannot exceed $T_{m,o}$ = 47°C, and (b) Required tube length.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2)Incompressible liquid with negligible viscous dissipation, (3) Negligible thermal resistance of tube wall.

PROPERTIES: *Table A-6*, Water $\left(\overline{T}_m = (47+27)^\circ C/2 = 310K\right)$: ρ = 1/$v_f$ = 993.1 kg/m^3, c_p = 4178 J/kg·K, μ = 695 × 10^{-6} N·s/m^2, k = 0.628 W/m·K, Pr = 4.62.

ANALYSIS: (a) From an overall energy balance on the tube with $T_{m,o}$ = 47°C,

$$q_{max} = \dot{m}\, c_p \left(T_{m,o} - T_{m,i}\right) = 0.12 \text{ kg/s} \times 4178 \text{ J/kg}\cdot\text{K}\left(47-27\right)^\circ \text{C} = 10{,}027 \text{ W}. \qquad <$$

(b) For the constant surface temperature heating condition, from Eq. 8.45a,

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp\left(-\frac{PL}{\dot{m}\, c_p}\overline{U}\right) \qquad \text{where} \qquad 1/U = 1/\overline{h}_o + 1/\overline{h}_i.$$

For internal flow in the tube, find

$$Re_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4\times 0.12 \text{ kg/s}}{\pi \times 0.015 \text{ m} \times 695\times 10^{-6} \text{N}\cdot\text{s/m}^2} = 14{,}656$$

and the flow is turbulent. Assuming fully developed flow, use the Dittus-Boelter correlation with n = 0.4 (heating),

$$Nu_D = h_i D/k = 0.023 Re_D^{4/5}\, Pr^{0.4}$$

$$h_i = \left[0.628 \text{ W/m}\cdot\text{K}/0.015 \text{ m}\right] \times 0.023\left(14{,}656\right)^{4/5}\left(4.62\right)^{0.4} = 3822 \text{ W/m}^2\cdot\text{K}.$$

Hence, 1/U = [1/3000 + 1/3822] m^2·K/W or U = 1680 W/m^2·K. From the energy balance relation with P = πD, find

$$\frac{\left(75-47\right)^\circ \text{C}}{\left(75-27\right)^\circ \text{C}} = \exp\left(-\frac{\pi\left(0.015 \text{ m}\right) L \times 1680 \text{ W/m}^2\cdot\text{K}}{0.12 \text{ kg/s} \times 4178 \text{ J/kg}\cdot\text{K}}\right) \qquad L = 3.4 \text{ m}. \qquad <$$

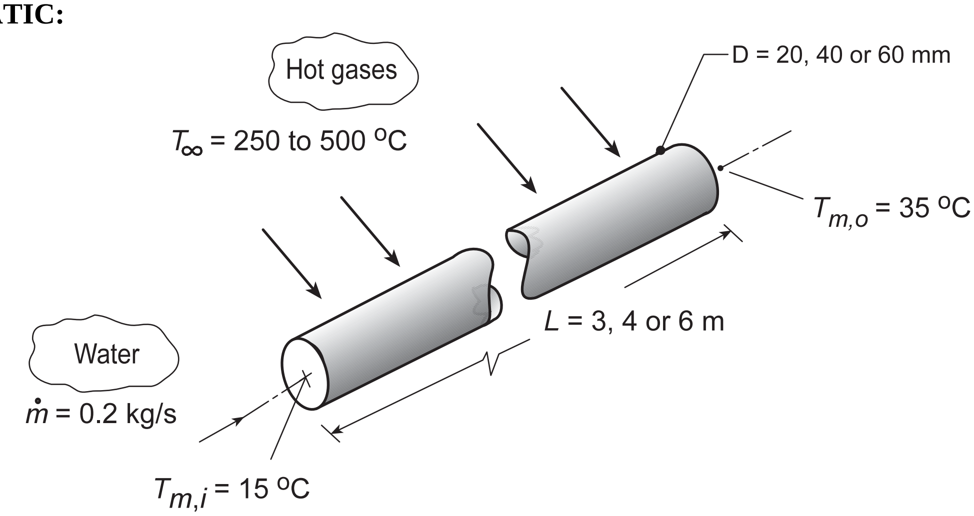
COMMENTS: Note that L/D = 227 and the fully developed flow assumption is appropriate.

PROBLEM 8.69

KNOWN: Water flowing through a tube heated by cross flow of a hot gas. Required to heat water from 15 to 35°C with a flow rate of 0.2 kg/s.

FIND: Design graphs to demonstrate acceptable combinations of tube diameter (D = 20, 30 or 40 mm), tube length (L = 3, 4 or 6 m) and hot gas velocity ($20 \le V \le 40$ m/s) and temperature (T_∞ = 250, 375 or 500°C).

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2)Water is incompressible liquid with negligible viscous dissipation, (3) Fully developed flow and thermal conditions for internal flow, (4) Properties of the hot gas are those of atmospheric air, and (5) Negligible tube wall thermal resistance.

PROPERTIES: *Table A.6*, Water ($\overline{T}_m = (15+35)^\circ C/2 = 298K$); *Table A.4*, Air ($\overline{T}_f = \left(\overline{T}_s + T_\infty\right)/2$, 1 atm).

ANALYSIS: *Method of Analysis*: The tube having internal flow of water with cross flow of hot gas can be analyzed by the energy balance relation, Eq. 8.45a

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp\left(-\frac{(\pi DL)}{\dot{m}c_p}\overline{U}\right) \tag{1}$$

where the overall coefficient $\overline{U}$ is

$$\overline{U} = \left(1/\overline{h}_i + 1/\overline{h}_o\right)^{-1} \tag{2}$$

Estimation of the internal flow coefficient, $\overline{h}_i$: Evaluating water properties at the average mean fluid temperature

$$\overline{T}_m = \left(T_{m,i} + T_{m,o}\right)/2, \tag{3}$$

characterize the flow with the Reynolds number,

$$Re_{D,i} = \frac{4\dot{m}}{(\pi D\mu)} \tag{4}$$

and assuming the flow to be both turbulent and fully developed (L/D > 3m/0.07m = 42), use the Dittus-Boelter correlation, Eq. 8.60, to evaluate $\overline{h}_i$,

Continued...

PROBLEM 8.69 (Cont.)

$$\overline{Nu}_{D,i} = \frac{\overline{h}_i D}{k_i} = 0.023 Re_{D,i}^{0.8} Pr^{0.4} \tag{5}$$

Estimation of the external flow coefficient, $\overline{h}_o$: Evaluating gas (air) properties at the average film temperature

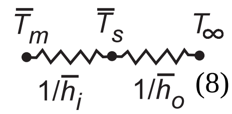
$$\overline{T}_f = \left(\overline{T}_s + T_\infty\right)/2 \tag{6}$$

where $\overline{T}_s$ is the average tube wall temperature (see Eq. (9)), characterize the flow

$$Re_{D,o} = \frac{VD}{\nu} \tag{7}$$

and use the Churchill-Bernstein correlation, Eq. 7.54, for cross-flow over a cylinder,

$$Nu_{D,o} = \frac{\overline{h}_o D}{k_o} = 0.3 + \frac{0.62 Re_{D,o}^{1/2} Pr_o^{1/3}}{\left[1 + \left(0.4/Pr_o\right)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{Re_{D,o}}{282,000}\right)^{5/8}\right]^{4/5} \tag{8}$$



The average tube wall temperature, $\overline{T}_s$, follows from the thermal circuit

$$\frac{\overline{T}_m - \overline{T}_s}{1/\overline{h}_i} = \frac{\overline{T}_s - \overline{T}_\infty}{1/\overline{h}_o} \tag{9}$$

The IHT Workspace: Using the *Correlation Tools* for *Internal Flow* (*Turbulen*t flow), and *External Flow* (*Flow over a Cylinder*) and *Properties* for *Air* and *Water*, along with the appropriate energy balances and rate equations, the heater-tube system can be analyzed.

The Design Strategy: We have chosen to generate the design information in the following manner: for a specified gas temperature, T_∞, plot the required length L (limiting the scale to 3 ≤ L ≤ 6m) as a function of gas velocity V (20 ≤ V ≤ 40 m/s) for tube diameters of D = 20, 30 and 40 mm. Three design graphs corresponding to T_∞ = 250, 375 and 500°C were generated and are shown on the next page.

COMMENTS: (1) The collection of design graphs will allow the contractor to select appropriate combinations of tube D and L and gas stream parameters (T_∞ and V) to achieve the required water heating.

(2) Note from the design graphs that with T_∞ = 250°C, the required heating of the water can be achieved only with a 40-mm diameter by 6 m length tube with gas velocities greater than 32 m/s. This configuration represents a worst case condition of largest tube parameters and highest gas velocity.

(3) Which operating conditions, T_∞ = 375 or 500°C, provides the contractor with more options in selecting combinations of tube parameters and gas velocities? What are the trade-offs in operating at 375 or 500°C? Consider such features as tube life, tubing costs and fan requirements.

(4) The Reynolds numbers for the internal flow are approximately 7,100, 9,460 and 14,200 for the tube diameters of 20, 30 and 40 mm. For the larger tube sizes, the Reynolds numbers are below 10,000, the usual lower limit for turbulent flow. The Gnielinski correlation would be more accurate under these conditions.

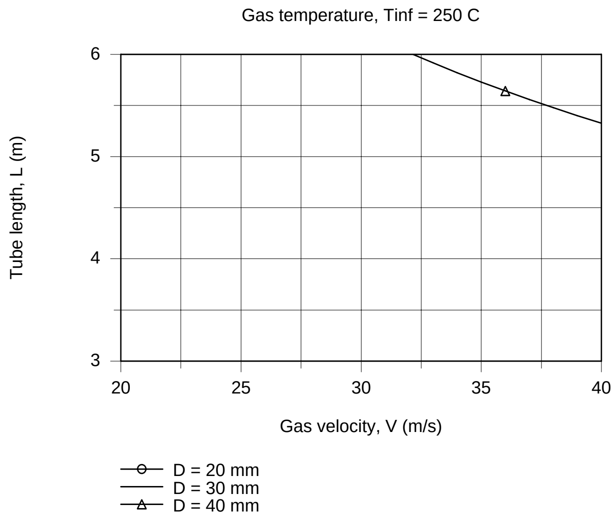
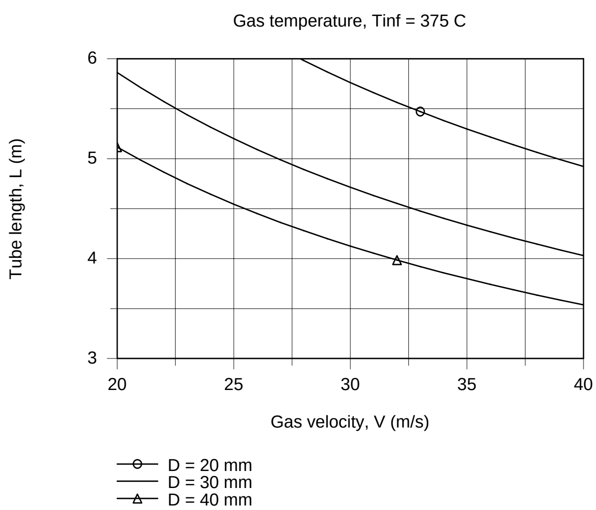
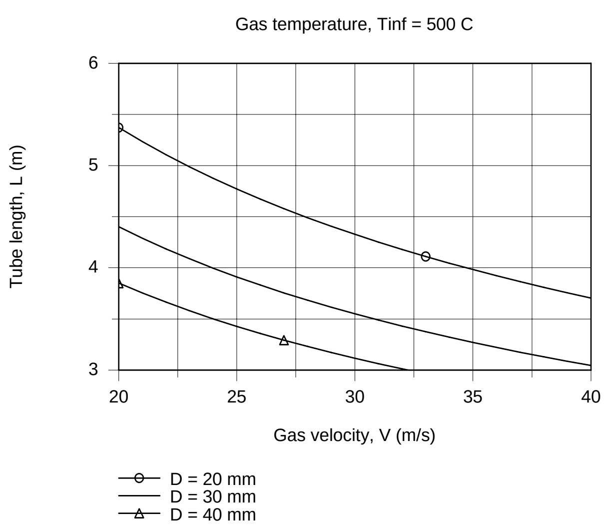
PROBLEM 8.69 (Cont.)





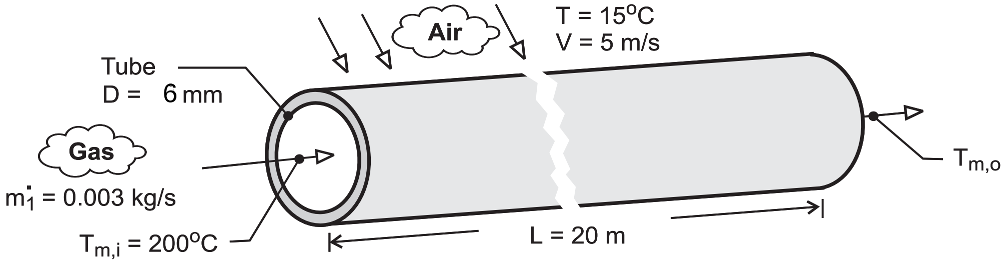


PROBLEM 8.70

KNOWN: Exhaust gases at 200°C and mass rate 0.03 kg/s enter tube of diameter 6 mm and length 20 m. Tube experiences cross-flow of autumn winds at 15°C and 5 m/s.

FIND: Average heat transfer coefficients for (a) exhaust gas inside tube and (b) air flowing across outside of tube, (c) Estimate overall coefficient and exhaust gas temperature at outlet of tube.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Ideal gas with negligible viscous dissipation and pressure variation, (3) Negligible tube wall resistance, (4) Exhaust gas properties are those of air, (5) Negligible radiation effects.

PROPERTIES: *Table A-4*, Air (assume $T_{m,o} \approx 15°C$, hence $\overline{T}_m = 380$ K, 1 atm): $c_p = 1012$ J/kg·K, k = 0.0323 W/m·K, $\mu = 221.6 \times 10^{-7}$ N·s/m^2, Pr = 0.694; Air ($T_\infty = 15°C = 288$ K, 1 atm): k = 0.0253 W/m·K, $\nu = 14.82 \times 10^{-6}$ m^2/s, Pr = 0.710; Air ($\overline{T}_s \approx 90°C = 363$ K, 1 atm): Pr = 0.698.

ANALYSIS: (a) For the *internal flow* through the tube assuming a value for $T_{m,o} = 15°C$, find

$$Re_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4 \times 0.003\ \text{kg/s}}{\pi \times 0.006\ \text{m} \times 221.6 \times 10^{-7}\ \text{N}\cdot\text{s/m}^2} = 2.873 \times 10^4.$$

Hence the flow is turbulent and, since L/D >> 10, fully developed. Using the Dittus-Doelter correlation with n = 0.3,

$$Nu_D = 0.023 Re_D^{0.8} Pr^{0.3} = 0.023\left(2.873 \times 10^4\right)^{0.8} (0.694)^{0.3} = 76.0$$

$$h_i = Nu \cdot k/D = 76.0 \times 0.0323\ \text{W/m}\cdot\text{K}/0.006\ \text{m} = 409\ \text{W/m}^2\cdot\text{K}.$$ <

(b) For *cross-flow* over the circular tube, find using thermophysical properties at T_∞,

$$Re_D = \frac{VD}{\nu} = \frac{5\ \text{m/s} \times 0.006\ \text{m}}{14.82 \times 10^{-6}\ \text{m}^2/\text{s}} = 2024$$

and using the Zukauskus correlation with C = 0.26, m = 0.6, and n = 0.37,

$$Nu_D = C Re_D^m Pr^n \left(Pr/Pr_s\right)^{1/4} = 0.26(2024)^{0.6}\, 0.710^{0.37} (0.710/0.698)^{0.25} = 22.2$$

where Pr_s is evaluated at $\overline{T}_s$. Hence,

$$h_o = Nu_D \cdot k/D = 22.2 \times 0.0253\ \text{W/m}\cdot\text{K}/0.006\ \text{m} = 93.4\ \text{W/m}^2\cdot\text{K}.$$ <

Continued …

(c) Assuming the thermal resistance of the tube wall is negligible,

$$\frac{1}{U} = \frac{1}{h_o} + \frac{1}{h_i} = \left(\frac{1}{93.4} + \frac{1}{409}\right) m^2 \cdot K/W \qquad U = 76.1\ W/m^2 \cdot K.$$ <

The gas outlet temperature can be determined from the expression where P = πD.

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp\left(-\frac{PUL}{\dot{m}\, c_p}\right) = \exp\left(-\frac{\pi \times 0.006\ m \times 76.1\ W/m^2 \cdot K \times 20\ m}{0.003\ kg/s \times 1012\ J/kg \cdot K}\right)$$

$$\frac{15 - T_{m,o}}{(15 - 200)^\circ C} = 7.9 \times 10^{-5}$$

$$T_{m,o} = 15^\circ C.$$ <

COMMENTS: (1) With $T_{m,o}$ = 15°C, find $\overline{T}_m$ = 380 K; hence thermophysical properties for the internal flow correlation were evaluated at a reasonable temperature. Note that the gas is cooled from 200°C to the ambient air temperature, $T_{m,o} = T_\infty$, over the 20-m length!

(2) The average wall surface temperature, $\overline{T}_s$, follows from an energy balance on the wall surface,

$$\frac{\overline{T}_m - \overline{T}_s}{\overline{T}_s - T_{inf}} = \frac{h_i}{h_o}$$

and substituting numerical values, find $\overline{T}_s = 90°C = 363\ K,$ the value we assumed for evaluating Pr_s. Can you draw a thermal circuit to represent this energy balance relation?

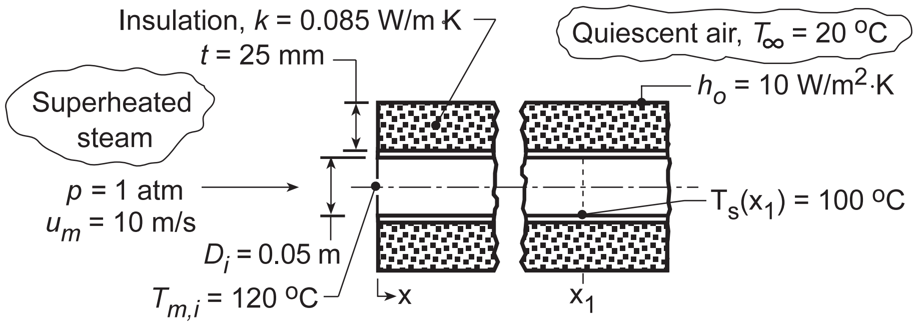
(3) When using the Zukauskus correlation, it is reasonable to evaluate Pr_s at the $\overline{T}_m$ for the first trial. For gases the assumption is a safe one, but for liquids, especially oils, additional trials will be required since the Prandtl number may be strongly dependent upon temperature.

PROBLEM 8.71

KNOWN: Superheated steam passing through thin-walled pipe covered with insulation and suspended in a quiescent air.

FIND: Point along pipe surface where steam will begin condensing (x_1).

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Steam is ideal gas with negligible viscous dissipation and pressure variation, (3) Steam properties may be approximated as those corresponding to saturated conditions.

PROPERTIES: *Table A.6*, Saturated steam ($\bar{T}_m$ = (100 + 120)°C/2 = 110°C ≈ 385 K): $\rho_g = 0.876$ kg/m^3, $c_{p,g}$ = 2080 J/kg·K, $\mu_g = 12.49 \times 10^{-6}$ N·S/m^2, k_g = 0.0258 W/m·K, Pr_g = 1.004.

ANALYSIS: From Eq. 8.45a, where $T_{m,x}$ is the mean temperature at any distance x,

$$\frac{T_\infty - T_{m,x}}{T_\infty - T_{m,i}} = \exp\left(-\frac{Px}{\dot{m}c_p}U\right) \tag{1}$$

The mass flow rate, with $A_c = \pi D^2/4$, is

$$\dot{m} = \rho_g A_c u_m = 0.876\,\text{kg}/\text{m}^3\left(\pi(0.050\,\text{m})^2/4\right)\times 10\,\text{m/s} = 0.0172\,\text{kg/s}$$

and for the internal flow,

$$Re_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4\times 0.0172\,\text{kg/s}}{\pi(0.050\,\text{m})\times 12.49\times 10^{-6}\,\text{N}\cdot\text{s}/\text{m}^2} = 35,068.$$

Assuming the flow is fully developed, the Dittus-Boelter correlation yields

$$Nu_D = \frac{h_i D}{k} = 0.023(35,068)^{4/5}(1.004)^{0.3} = 99.58$$

$$h_i = \frac{0.0258\,\text{W/m}\cdot\text{K}}{0.050\,\text{m}}\times 99.58 = 51.4\,\text{W}/\text{m}^2\cdot\text{K}$$

Hence, from Eq. 3.36, the overall coefficient for the inner surface is

$$U_i = \left[\frac{1}{h_i} + \frac{D_i \ln(D_o/D_i)}{2k} + \frac{D_i}{D_o}\frac{1}{h_o}\right]^{-1} = \left[\frac{1}{51.4} + \frac{(0.050)\ln(0.100/0.050)}{2\times 0.085} + \frac{0.050}{0.100}\frac{1}{10}\right]^{-1}\text{W}/\text{m}^2\cdot\text{K}$$

$$U_i = \left[1.946\times 10^{-2} + 2.039\times 10^{-1} + 5.000\times 10^{-2}\right]^{-1} = 3.66\,\text{W}/\text{m}^2\cdot\text{K}.$$

Continued...

PROBLEM 8.71 (Cont.)

With condensation occurring when the surface temperature reaches 100°C, the corresponding value of T_m may be determined from the local ($x = x_1$) requirement that $U_i(\pi D_i)\left[T_m(x_1) - T_\infty\right] = h_i(\pi D_i)\left[T_m(x_1) - T_s\right]$. Hence,

$$T_m(x_1) = \frac{T_\infty - (h_i/U_i)T_s}{1-(h_i/U_i)} = \frac{20-(51.4/3.66)100^\circ\text{C}}{1-(51.4/3.66)} = 106^\circ\text{C}$$

The distance at which the mean steam temperature is 106°C can then be estimated from Eq. (1), where $P = \pi D_i$ and $U = U_i$,

$$\frac{(20-106)^\circ\text{C}}{(20-120)^\circ\text{C}} = \exp\left(-\frac{\pi(0.050\,\text{m})3.66\,\text{W/m}^2\cdot\text{K}(x_1)}{0.0172\,\text{kg/s}\times 2080\,\text{J/kg}\cdot\text{K}}\right)$$

$x_1 = 9.3$ m <

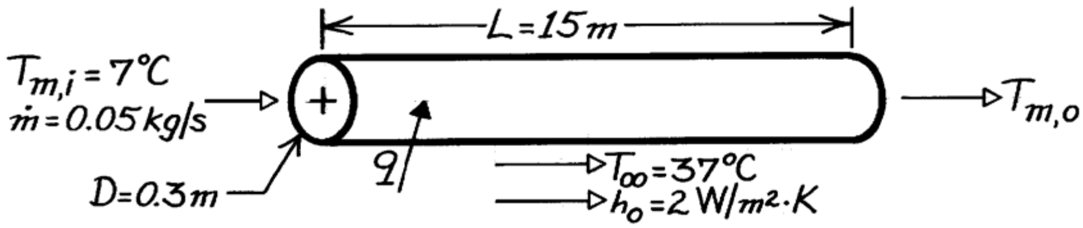
COMMENTS: Note that condensation first occurs at the location for which the surface, and not the mean, temperature reaches 100°C.

PROBLEM 8.72

KNOWN: Length and diameter of air conditioning duct. Inlet temperature of chilled air. Temperature and convection coefficient associated with outer air. Chilled air flowrate.

FIND: Chilled air exit temperature and heat flow rate.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible tube wall conduction resistance, (3) Ideal gas with negligible viscous dissipation, pressure variation, and axial conduction.

PROPERTIES: *Table A-4*, Air (300 K, 1 atm): c_p = 1007 J/kg·K, $\mu = 184.6 \times 10^{-7}$ kg/s·m, k = 0.0263 W/m·K, Pr = 0.707.

ANALYSIS: The exit temperature may be obtained from Eq. 8.45a, where

$$\bar{U} = \left(h_i^{-1} + h_o^{-1}\right)^{-1}$$

With $$\text{Re}_D = \left(4\dot{m}/\pi\,D\mu\right) = \frac{4\left(0.05\text{ kg/s}\right)}{\pi\left(0.3\text{ m}\right)184.6\times10^{-7}\text{ kg/s}\cdot\text{m}} = 11,495$$

the flow is turbulent and, assuming fully developed conditions over the entire length, the Dittus-Boelter correlation yields

$$\text{Nu}_D = 0.023\text{Re}_D^{4/5}\,\text{Pr}^{0.4} = 0.023\left(11,495\right)^{4/5}\left(0.707\right)^{0.4} = 35.5$$

$$h_i = \text{Nu}_D\left(k/D\right) = 35.5\left(0.0263\text{ W/m}\cdot\text{K}/0.3\text{ m}\right) = 3.11\text{ W/m}^2\cdot\text{K}$$

and $$\bar{U} = \left(3.11^{-1} + 2.0^{-1}\right)^{-1}\left(\text{W/m}^2\cdot\text{K}\right) = 1.22\text{ W/m}^2\cdot\text{K}.$$

Eq. 8.45a yields $$T_{m,o} = T_\infty - \left(T_\infty - T_{m,i}\right)\exp\left[-\left(\pi\,DL/\dot{m}\,c_p\right)\bar{U}\right]$$

$$T_{m,o} = 37^\circ\text{C} - 30^\circ\text{C}\exp\left[-\frac{\pi\left(0.3\text{ m}\right)15\text{ m}\left(1.22\text{ W/m}^2\cdot\text{K}\right)}{0.05\text{ kg/s}\left(1007\text{ J/kg}\cdot\text{K}\right)}\right] = 15.7^\circ\text{C}$$ <

and the heat rate is

$$q = \dot{m}\,c_p\left(T_{m,o} - T_{m,i}\right) = 0.05\text{ kg/s}\left(1007\text{ J/kg}\cdot\text{K}\right)\left(8.7^\circ\text{C}\right) = 438\text{ W}.$$ <

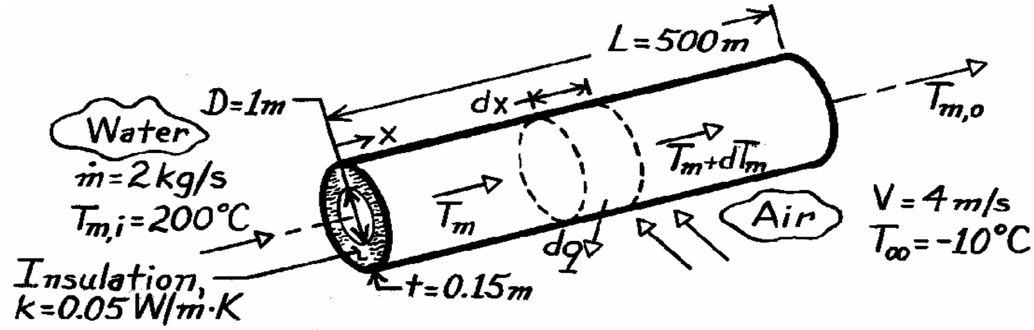
COMMENTS: (1) The temperature rise of the chilled air is excessive, and the outer surface of the duct should be insulated to reduce $\bar{U}$ and thereby $T_{m,o}$ and q. (2) The temperature selected for evaluating air properties was not very accurate. Air properties should be evaluated at $\bar{T}_m = (T_{m,o} + T_{m,i})/2 \approx 285$ K .

PROBLEM 8.73

KNOWN: Flow conditions associated with water passing through a pipe and air flowing over the pipe.

FIND: (a) Differential equation which determines the variation of the mixed-mean temperature of the water, (b) Heat transfer per unit length of pipe at the inlet and outlet temperature of the water.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible temperature drop across the pipe wall, (2) Negligible radiation exchange between outer surface of insulation and surroundings, (3) Fully developed flow throughout pipe, (4) Water is incompressible liquid with negligible viscous dissipation.

PROPERTIES: *Table A-6*, Water ($T_{m,i}$ = 200°C): $c_{p,w}$ = 4500 J/kg·K, μ_w = 134 × 10^{-6} N·s/m^2, k_w = 0.665 W/m·K, Pr_w = 0.91; *Table A-4*, Air (T_∞ = -10°C): ν_a = 12.6 × 10^{-6} m^2/s, k_a = 0.023 W/m·K, Pr_a = 0.71, $Pr_s \approx$ 0.7.

ANALYSIS: (a) Following the development of Section 8.3.1 and applying Eq. 1.12e to a differential element in the water, we obtain

$$dq = -\dot{m}\, c_{p,w}\, dT_m$$

where $$dq = U_i dA_i \left(T_m - T_\infty\right) = U_i \pi\, D\, dx \left(T_m - T_\infty\right).$$

Substituting into the energy balance, it follows that

$$\frac{d\,T_m}{dx} = -\frac{U_i \pi\, D}{\dot{m}\, c_p}\left(T_m - T_\infty\right). \qquad (1)$$ <

The overall heat transfer coefficient based on the inside surface area may be evaluated from Eq. 3.36 which, for the present conditions, reduces to

$$U_i = \frac{1}{\frac{1}{h_i} + \frac{D}{2k}\ell n\left(\frac{D+2t}{D}\right) + \frac{D}{D+2t}\,\frac{1}{h_o}}. \qquad (2)$$

For the *inner water flow*, Eq. 8.6 gives

$$Re_D = \frac{4\,\dot{m}}{\pi\, D \mu_w} = \frac{4 \times 2\text{ kg/s}}{\pi(1\text{ m}) \times 134 \times 10^{-6}\text{ kg/s}\cdot\text{m}} = 19{,}004.$$

Continued …

PROBLEM 8.73 (Cont.)

Hence, the flow is turbulent. With the assumption of fully developed conditions, it follows from Eq. 8.60 that

$$h_i = \frac{k_w}{D} \times 0.023\, Re_D^{4/5}\, Pr_w^{0.3}. \qquad (3)$$

For the *external air flow*

$$Re_D = \frac{V(D+2t)}{\nu} = \frac{4\text{ m/s}(1.3\text{m})}{12.6\times10^{-6}\text{ m}^2/\text{s}} = 4.13\times10^5.$$

Using Eq. 7.53 to obtain the outside convection coefficient,

$$h_o = \frac{k_a}{(D+2t)} \times 0.076\, Re_D^{0.7}\, Pr_a^{0.37}\, (Pr_a/Pr_s)^{1/4}. \qquad (4)$$

(b) The heat transfer per unit length of pipe at the inlet is

$$q' = \pi\, D\, U_i (T_{m,i} - T_\infty). \qquad (5)$$

From Eqs. (3 and 4),

$$h_i = \frac{0.665\text{ W/m}\cdot\text{K}}{1\text{ m}} \times 0.023(19{,}004)^{4/5}\, (0.91)^{0.3} = 39.4\text{ W/m}^2\cdot\text{K}$$

$$h_o = \frac{0.023\text{ W/m}\cdot\text{K}}{(1.3\text{ m})} \times 0.076\left(4.13\times10^5\right)^{0.7} (0.71)^{0.37} (1)^{1/4} = 10.1\text{ W/m}^2\cdot\text{K}.$$

Hence, from Eq. (2)

$$U_i = \left[\frac{1}{39.4\text{ W/m}^2\cdot\text{K}} + \frac{1\text{ m}}{0.1\text{ W/m}\cdot\text{K}}\ell n\left(\frac{1.3}{1}\right) + \frac{1}{1.3}\times\frac{1}{10.1\text{ W/m}^2\cdot\text{K}}\right]^{-1} = 0.37\text{ W/m}^2\cdot\text{K}$$

and from Eq. (5)

$$q' = \pi(1\text{ m})\,\left(0.37\text{ W/m}^2\cdot\text{K}\right)\,(200+10)^\circ\text{C} = 244\text{ W/m}. \qquad <$$

Since U_i is a constant, independent of x, Eq. (1) may be integrated from x = 0 to x = L. The result is Eq. 8.45a.

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp\left(-\frac{\pi\, DL}{\dot{m}\, c_{p,w}} U_i\right) = \exp\left(-\frac{\pi\times1\text{m}\times500\text{m}}{2\text{ kg/s}\times4500\text{ J/kg}\cdot\text{K}}\times0.37\text{ W/m}^2\cdot\text{K}\right)$$

Hence

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = 0.937.$$

$$T_{m,o} = T_\infty + 0.937(T_{m,i} - T_\infty) = 187^\circ\text{C}. \qquad <$$

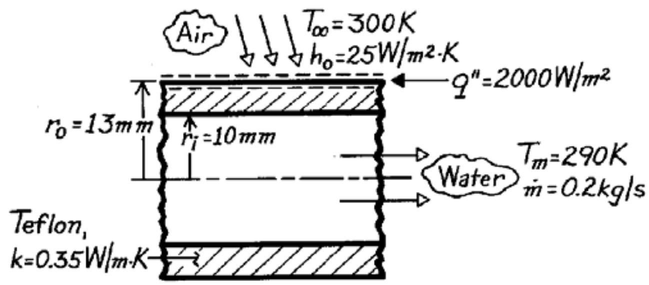
COMMENTS: The largest contribution to the denominator on the right-hand side of Eq. (2) is made by the conduction term (the insulation provides 96% of the total resistance to heat transfer). For this reason the assumption of fully developed conditions throughout the pipe has a negligible effect on the calculations. Since the reduction in T_m is small (13°C), little error is incurred by evaluating all properties of water at $T_{m,i}$.

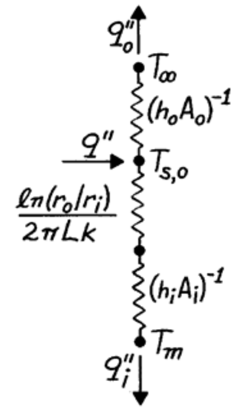
PROBLEM 8.74

KNOWN: Inner and outer radii and thermal conductivity of a Teflon tube. Flowrate and temperature of confined water. Heat flux at outer surface and temperature and convection coefficient of ambient air.

FIND: Fraction of heat transfer to water and temperature of tube outer surface.

SCHEMATIC:





ASSUMPTIONS: (1) Steady-state conditions, (2) Fully-developed flow, (3) One-dimensional conduction, (4) Negligible tape contact and conduction resistances.

PROPERTIES: *Table A-6*, Water (T_m = 290K): μ = 1080 × 10^{-6} kg/s·m, k = 0.598 W/m·K, Pr = 7.56.

ANALYSIS: The outer surface temperature follows from a surface energy balance

$$(2\pi\, r_o L) q'' = \frac{T_{s,o} - T_\infty}{(h_o 2\pi\, r_o L)^{-1}} + \frac{T_{s,o} - T_m}{(\ln(r_o/r_i)/2\pi\, Lk) + (1/2\pi\, r_i L h_i)}$$

$$q'' = h_o(T_{s,o} - T_\infty) + \frac{T_{s,o} - T_m}{(r_o/k)\ln(r_o/r_i) + (r_o/r_i)/h_i}.$$

With $\quad Re_D = 4\,\dot{m}/(\pi\, D\mu) = 4(0.2\text{kg/s})/\left[\pi(0.02\text{ m})1080\times10^{-6}\text{ kg/s}\cdot\text{m}\right] = 11,789$

the flow is turbulent and Eq. 8.60 yields

$$h_i = (k/D_i)\,0.023 Re_D^{4/5} Pr^{0.4} = (0.598\text{ W/m}\cdot\text{K}/0.02\text{ m})(0.023)(11,789)^{4/5}(7.56)^{0.4} = 2792\text{ W/m}^2\cdot\text{K}.$$

Hence

$$2000\text{ W/m}^2 = 25\text{ W/m}^2\cdot\text{K}(T_{s,o} - 300\text{K}) + \frac{T_{s,o} - 290\text{ K}}{(0.013\text{ m}/0.35\text{ W/m}\cdot\text{K})\ln(1.3) + (1.3)/(2792\text{ W/m}^2\cdot\text{K})}$$

and solving for $T_{s,o}$, $\qquad T_{s,o}$ = 308.3 K. $\qquad$ <

The heat flux to the air is

$$q_o'' = h_o(T_{s,o} - T_\infty) = 25\text{ W/m}^2\cdot\text{K}(308.3 - 300)\text{K} = 207.5\text{ W/m}^2.$$

Hence, $\qquad q_i''/q'' = (2000 - 207.5)\text{W/m}^2/2000\text{ W/m}^2 = 0.90.$ $\qquad$ <

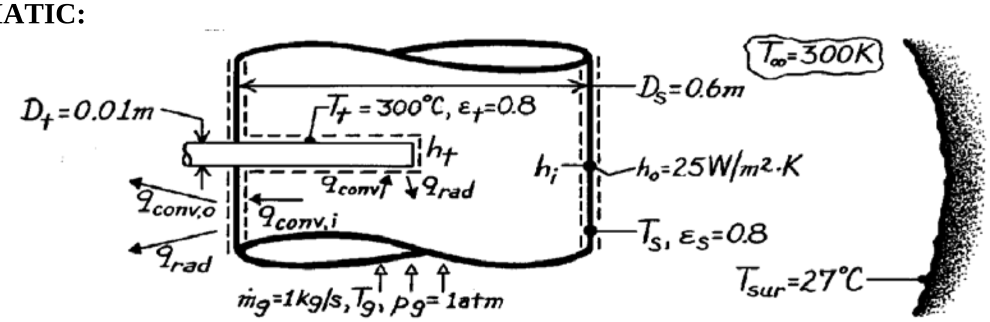
COMMENTS: The resistance to heat transfer by convection to the air substantially exceeds that due to conduction in the teflon and convection in the water. Hence, most of the heat is transferred to the water.

PROBLEM 8.75

KNOWN: Temperature recorded by a thermocouple inserted in a stack containing flue gases with a prescribed flow rate. Diameters and emissivities of thermocouple tube and gas stack. Conditions associated with stack surroundings.

FIND: Equations for predicting thermocouple error and error associated with prescribed conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Flue gas has properties of air at $T_g \approx 327°C$, (3) Stack forms a large enclosure about the thermocouple tube and surroundings form a large enclosure around the stack, (4) Stack surface energy balance is unaffected by heat loss to tube, (5) Gas flow is fully developed, (6) Negligible conduction along thermocouple tube, (7) Stack wall is thin.

PROPERTIES: *Table A-4*, Air ($T_g \approx 600K$, $p_g = 1$ atm): $\rho = 0.58$ kg/m^3, $\mu = 305.8 \times 10^{-7}$ N·s/m^2, $\nu = 52.7\times 10^{-6}$ m^2/s, k = 0.0469 W/m·K, Pr = 0.685.

ANALYSIS: Determination of the thermocouple error necessitates determining the gas temperature T_g and relating it to the thermocouple temperature T_t. From an energy balance applied to a control surface about the thermocouple,

$$q_{conv} = q_{rad} \qquad \text{or} \qquad h_t A_t \left(T_g - T_t\right) = \varepsilon_t \sigma A_t \left(T_t^4 - T_s^4\right).$$

Hence
$$T_g = T_t + \frac{\varepsilon_t \sigma}{h_t}\left(T_t^4 - T_s^4\right). \qquad (1) \quad <$$

However, T_s is unknown and must be determined from an energy balance on the stack wall.

$$q_{conv,i} = q_{conv,o} + q_{rad}$$

$$h_i A_s \left(T_g - T_s\right) = h_o A_s \left(T_s - T_\infty\right) + \varepsilon_s \sigma A_s \left(T_s^4 - T_{sur}^4\right)$$

or
$$T_g = T_s + \frac{h_o}{h_i}\left(T_s - T_\infty\right) + \frac{\varepsilon_s \sigma}{h_i}\left(T_s^4 - T_{sur}^4\right). \qquad (2) \quad <$$

T_g and T_s may be determined by simultaneously solving Eqs. (1) and (2). For the prescribed conditions

$$Re_{Dt} = \frac{\rho V D_t}{\mu} = \frac{\rho\left(\dot m_g / \rho \pi D_s^2 / 4\right) D_t}{\mu} = \frac{4\,\dot m_g D_t}{\pi \mu D_s^2} = \frac{4 \times 1\text{ kg/s} \times 0.01\text{ m}}{\pi \times 305.8 \times 10^{-7}\text{ N}\cdot\text{s/m}^2\ (0.6\text{ m})^2} = 1157.$$

Continued …

PROBLEM 8.75 (Cont.)

Assuming $(Pr/Pr_s) = 1$, it follows from the Zukauskus correlation

$$\overline{Nu}_D = 0.26 Re_{Dt}^{0.6} Pr^{0.37}$$

where C = 0.26 and m = 0.6 from Table 7.4. Hence

$$h_t = \frac{0.0469\ W/m\cdot K}{0.01\ m}(1157)^{0.6}(0.685)^{0.37} \times 0.26 = 73\ W/m^2\cdot K.$$

Hence, from Eq. (1) $\quad T_g = 573\ K + \dfrac{0.8\times 5.67\times 10^{-8}\ W/m^2\cdot K^4}{73\ W/m^2\cdot K}\left(573^4 - T_s^4\right)K^4$

$$T_g = 573\ K + 67\ K - 6.214\times 10^{-10} T_s^4 = 640 - 6.214\times 10^{-10} T_s^4. \qquad (1a)$$

Also, $\quad Re_{Ds} = \dfrac{4\ \dot{m}_g}{\pi\ D_s \mu} = \dfrac{4\times 1\ kg/s}{\pi(0.6\ m)305.8\times 10^{-7}\ N\cdot s/m^2} = 6.94\times 10^4$

and the gas flow is turbulent. Hence from the Dittus-Boelter correlation,

$$h_i = \frac{k}{D_s} 0.023 Re_{Ds}^{4/5} Pr^{0.3} = \frac{0.0469\ W/m\cdot K}{0.6\ m}\times 0.023\left(6.94\times 10^4\right)^{4/5}\times(0.685)^{0.3} = 12\ W/m^2\cdot K.$$

Hence from Eq. (2)

$$T_g = T_s + \frac{25}{12}(T_s - 300\ K) + \frac{0.8\times 5.67\times 10^{-8}\ W/m^2\cdot K^4}{12\ W/m^2\cdot K}\left[T_s^4 - 300^4\right]K^4$$

$$T_g = T_s + 2.083 T_s - 625\ K + 3.78\times 10^{-9} T_s^4 - 30.6\ K = -655.6\ K + 3.083 T_s + 3.78\times 10^{-9} T_s^4. \qquad (2a)$$

Solve Eqs. (1a) and (2a) by trial-and-error. Assume values for T_s and determine T_g from (1a) and (2a). Continue until values of T_g agree.

T_s (K)	T_g (K) $\rightarrow$ (1a)	T_g (K) $\rightarrow$ (2a)
400	624	674
375	628	575
387	626	622
388	626	626

Hence $\qquad T_s = 388\ K,\ T_g = 626\ K$

and the thermocouple error is $\qquad T_g - T_t = 626\ K - 573\ K = 53°C.$ <

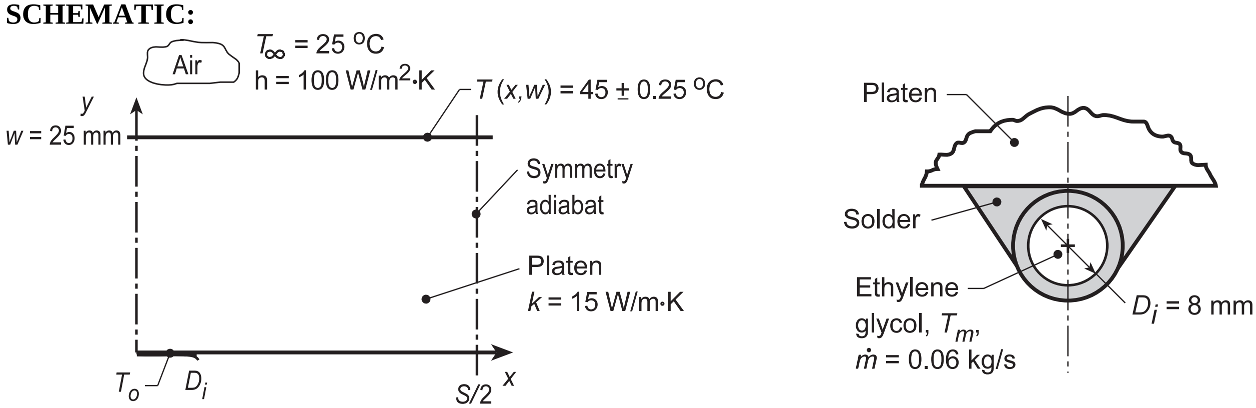
COMMENTS: The thermocouple error results from radiation exchange between the thermocouple tube and the cooler stack wall. Anything done to ↑ T_s would ↓ this error (e.g., ↓ h_o or ↑ T_∞ and T_{sur}). The error also ↓ with ↑ h_t. The error could be reduced by installing a radiation shield around the tube.

PROBLEM 8.76

KNOWN: Platen heated by hot ethylene glycol flowing through tubing arrangement with spacing S soldered to lower surface. Top surface exposed to convection process.

FIND: Tube spacing S and heating fluid temperature T_m which will maintain the top surface at 45 ± 0.25°C.

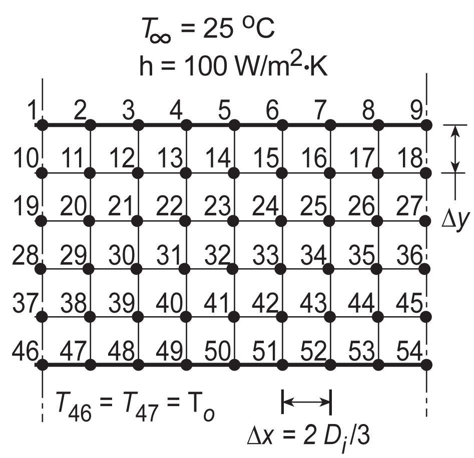
SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions; (2) Lower surface is insulated, all heat transfer from hot fluid is into platen; (3) Copper tube is thick-walled such that interface between solder and platen is isothermal; (4) Fully developed flow conditions in tube.

PROPERTIES: *Table A.4*, Ethylene glycol (T_m = 60°C): μ = 0.00522 N·s/m², k = 0.2603 W/m·K.

ANALYSIS: Begin the analysis by setting up a nodal mesh (9 ×6) to represent the platen experiencing convection on the top surface (T_∞, h) while the two side boundaries are symmetry adiabats. On the lower surface, nodes 46 and 47 represent the isothermal platen-solder interface maintained at T_o by the hot fluid. The remaining nodes (49-54) are insulated on their lower boundary.



The heat rate supplied by the tube to the platen can be expressed as

$$q'_{cv} = 0.5 h_o (\pi D_i)(T_m - T_o) \tag{1}$$

From energy balances about nodes 46 and 47, the heat rate into the platen by conduction can be expressed as

$$q'_{cd} = q'_a + q'_b + q'_c \tag{2}$$

$$q'_a = k(\Delta x/2)(T_{46} - T_{37})/\Delta y \tag{3}$$

Continued...

PROBLEM 8.76 (Cont.)

$$q'_b = k(\Delta x)(T_{47} - T_{38})/\Delta y \qquad (4)$$

$$q'_c = k(\Delta y/2)(T_{47} - T_{48})/\Delta x \qquad (5)$$

and we require that

$$q'_{cd} = q'_{cv} \qquad (6)$$

The convection coefficient for internal flow can be estimated from a correlation assuming fully developed flow. First, characterize the flow with

$$Re_D = \frac{4\dot{m}}{\pi D_i \mu} = \frac{4 \times 0.06\,\text{kg/s}}{\pi(0.008\,\text{m})0.00522\,\text{N}\cdot\text{s/m}^2} = 1829$$

and since it is laminar,

$$Nu_D = \frac{h_o D_i}{k} = 3.66$$

$$h_o = 3.66 \times 0.2603\,\text{W/m}\cdot\text{K}/0.008\,\text{m} = 119.1\,\text{W/m}\cdot\text{K}$$

where properties are evaluated at T_m. Using the *IHT Finite-Difference Tool* for *Two-Dimensional Steady-State Conditions* and the *Properties Tool* for *Ethylene Glycol*, along with the foregoing rate equations and energy balances, Eqs. (1-6), a model was developed to solve for the temperature distribution in the platen. In the solution, we determined what hot fluid temperature was required to maintain T_1 = 45°C. Two trials were run. In the first, the nodal arrangement was as shown above (9 × 6) for which S/2 = (9 - 1)Δx = 42.67 mm with Δx = $2D_i/3$ = 5.33 mm and Δy = w/5 = 5 mm. In the second trial, we repositioned the right-hand symmetry adiabat to pass vertically through the nodes 6-51 so that now the nodal mesh is (6 × 6) and S/2 = (6 - 1)Δx = 26.65 mm with Δx and Δy remaining the same. The results of the trials are tabulated below.

Trial	Mesh	T_1 (°C)	T_6 (°C)	T_9 (°C)	T_m (°C)	q'_{cv} (W/m)
1	9 × 6	45.0	43.5	43.0	105	80.5
2	6 × 6	45.0	44.5	---	85	52.6

From the trial 2 results, the surface temperature uniformity is (T_1 - T_6) = 0.5°C which satisfies the ±0.25°C requirement. So that suitable tube spacing and fluid temperature are

S = 53 mm $\qquad$ T_m = 85°C $\qquad$ <

COMMENTS: (1) Recognize that the grid spacing is quite coarse and good practice demands that we repeat the analysis decreasing the nodal spacing until no further changes are seen in T_m.

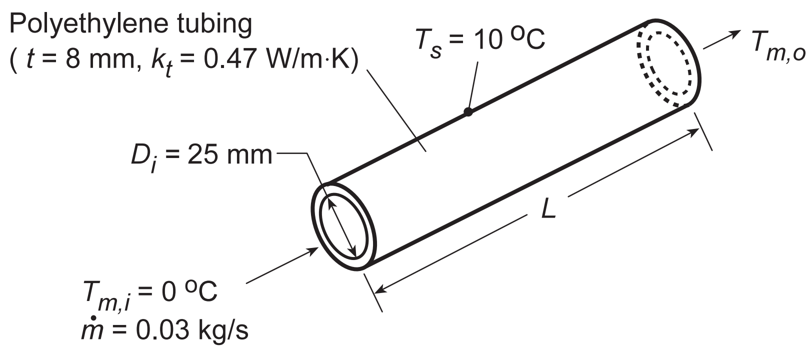
(2) In the first trial, note that T_m = 105°C which of course, is not possible.

PROBLEM 8.77

KNOWN: Features of tubing used in a ground source heat pump. Temperature of surrounding soil. Fluid inlet temperature and flowrate.

FIND: (a) Effect of tube length on outlet temperature, (b) Recommended tube length and the effect of variations in the flowrate.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible conduction resistance in soil, (4) Incompressible liquid with negligible viscous dissipation, (5) Fluid properties correspond to those of water.

PROPERTIES: *Table A.6* (assume $\bar{T}_m$ = 277 K): c_p = 4206 J/kg·K, $\mu = 1560 \times 10^{-6}$ N·s/m^2, k = 0.577 W/m·K, Pr = 11.44.

ANALYSIS: (a) For the prescribed conditions, $Re_D = 4\dot{m}/\pi D_i \mu = 4(0.03\,kg/s)/\pi(0.025\,m)1560 \times 10^{-6}\,N\cdot s/m^2$ = 980 and the flow is laminar. With Pr > 5, Eq. 8.57 may be used to determine the average convection coefficient, with Eq. 8.56 defining the Graetz number:

$$\overline{Nu}_D = 3.66 + \frac{0.0668(D/L)Re_D\,Pr}{1+0.04\left[(D/L)Re_D\,Pr\right]^{2/3}}$$

With T_s used in lieu of T_∞, Eq. 8.45b may be used to determine $T_{m,o}$,

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{L}{\dot{m}c_p R'_{tot}}\right)$$

where R'_{tot} accounts for the convection and tube wall conduction resistances,

$$R'_{tot} = R'_{cnv} + R'_{cnd} = \left(1/\pi D_i \bar{h}\right) + \ln\left(D_o/D_i\right)/2\pi k_t$$

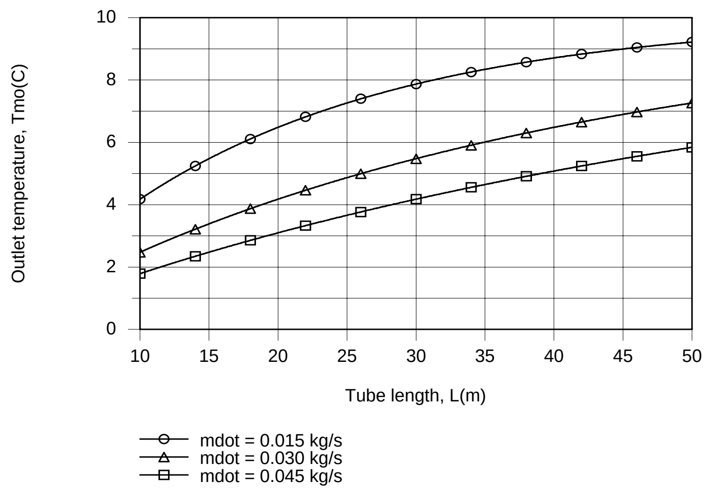
and

$$D_o = D_i + 2t = 41\,mm\,.$$

Using the *Correlations* and *Properties* Toolpads of IHT, the following results were obtained for the effect of the tube length L on $T_{m,o}$.

Continued...

PROBLEM 8.77 (Cont.)



The longer the tube the larger the rate of heat extraction from the soil, and for $\dot{m}$ = 0.030 kg/s, the temperature rise of $\Delta T = (T_{m,o} - T_{m,i}) \approx 7°C$ is well below the maximum possible value of $\Delta T_{max} = 10°C$.

(b) The length should be *at least* 50 m long. If the flowrate were reduced by 50% ($\dot{m}$ = 0.015 kg/s), the corresponding temperature rise would be close to ΔT_{max} and L = 50 m would be close to optimal. However, for the nominal flowrate and a 50% increase from the nominal, the length should exceed 50 m to recover more heat and provide a heat pump inlet temperature which is closer to the maximum possible value.

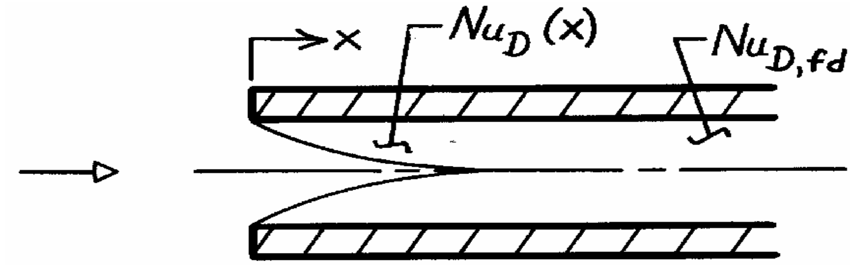
COMMENTS: In practice, the tube surface temperature would be less than 10°C (if the temperature of the soil well removed from the tube were at 10°C), thereby reducing the heat extraction rate and $T_{m,o}$.

PROBLEM 8.78

KNOWN: Effect of entry length on average Nusselt number for turbulent flow in a tube.

FIND: Ratio of average to fully developed Nusselt numbers for prescribed conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Sharp edged inlet, (2) Combined entry region.

ANALYSIS: From Eq. 8.63,

$$\frac{\overline{Nu}_D}{Nu_{D,fd}} = 1 + \frac{C}{(x/D)^m}$$

and with $C = 24Re_D^{-0.23}$ and $m = 0.815 - 2.08\times10^{-6}Re_D$,

$$\frac{\overline{Nu}_D}{Nu_{D,fd}} = 1 + \frac{24Re_D^{-0.23}}{(x/D)^{\left(0.815-2.08\times10^{-6}Re_D\right)}}.$$

It follows that

$\left(\overline{Nu}_D / Nu_{D,fd}\right)$	Re_D	x/D
1.463	10^4	10
1.116	10^4	60
1.420	10^5	10
1.142	10^5	60

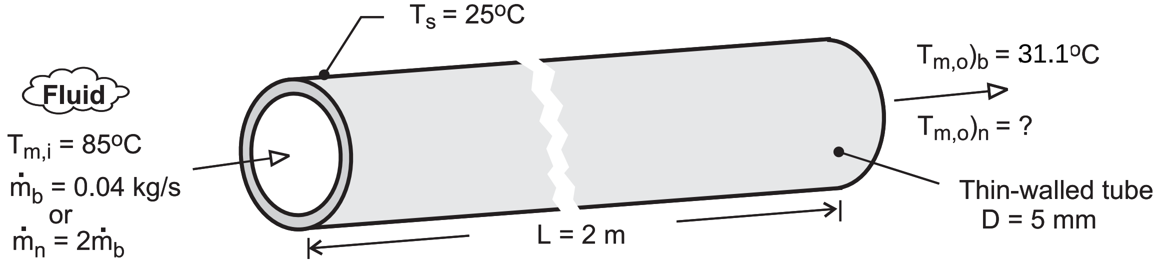
COMMENTS: The assumption $\overline{Nu}_D \approx Nu_{fd}$ for $x/D = 10$ would result in underprediction of $\overline{Nu}_D$ by approximately 45%. The underprediction is only approximately 10% for x/D = 60.

PROBLEM 8.79

KNOWN: Fluid enters a thin-walled tube of 5-mm diameter and 2-m length with a flow rate of 0.04 kg/s and temperature of $T_{m,i}$ = 85°C; tube surface temperature is maintained at T_s = 25°C; and, for this *base* operating condition, the outlet temperature is $T_{m,o}$ = 31.1°C.

FIND: The outlet temperature if the flow rate is doubled?

SCHEMATIC:



ASSUMPTIONS: (1) Flow is fully developed and turbulent, (2) Fluid properties are independent of temperature, (3) Constant surface temperature cooling conditions, (4) Applicability of Eq. 8.34.

ANALYSIS: For the *base* operating condition (b), the rate equation, Eq. 8.41b, with $C = \dot{m} c_p$, the capacity rate, is

$$\frac{T_s - T_{m,o})_b}{T_s - T_{m,i}} = \exp\left(-\frac{PL\,\bar{h}_b}{C_b}\right) \quad (1)$$

Substituting numerical values, with P = πD, find the ratio, $\bar{h}_b / C_b$,

$$\frac{25-31.1}{25-85} = \exp\left[-\pi \times 0.005 \text{ m} \times 2 \text{ m}\left(\bar{h}_b / C_b\right)\right]$$

$$\bar{h}_b / C_b = 72.77 \text{ m}^{-2}$$

For the *new* operating condition (n), the flow rate is doubled, $C_n = 2C_b$, and the convection coefficient scales according to the Dittus-Boelter relation, Eq. 8.60,

$$\bar{h} \propto Re_D^{0.8} \propto \dot{m}^{0.8}$$

$$\bar{h}_n = 2^{0.8}\bar{h}_b \text{ and } \left(\bar{h}_n / C_n\right) = \left(2^{0.8}/2\right)\left(\bar{h}_b / C_b\right) \quad (2)$$

Using the rate equation for the new operating condition, find

$$\frac{T_s - T_{m,o})_n}{T_s - T_{m,i}} = \exp\left(-\frac{PL\,\bar{h}_n}{C_n}\right) = \exp\left[-PL \times 0.871\left(\bar{h}_b / C_b\right)\right] \quad (3)$$

$$\frac{25 - T_{m,o})_n}{25-85} = \exp\left[-\pi \times 0.005 \text{ m} \times 2 \text{ m} \times 0.871 \times 72.77 \text{ m}^{-2}\right]$$

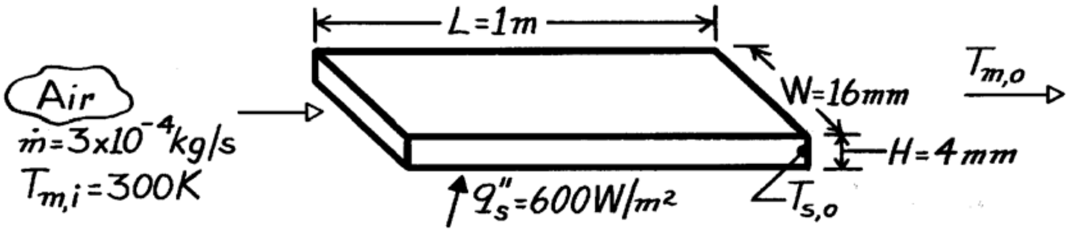
$$T_{m,o})_n = 33.2°C$$ <

PROBLEM 8.80

KNOWN: Flow rate and inlet temperature of air passing through a rectangular duct of prescribed dimensions and surface heat flux.

FIND: Air and duct surface temperatures at outlet.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform surface heat flux, (3) Constant properties, (4) Atmospheric pressure, (3) Fully developed conditions at duct exit, (6) Ideal gas with negligible viscous dissipation and pressure variation.

PROPERTIES: *Table A-4,* Air $\left(\overline{T}_m \approx 300\text{K, 1 atm}\right)$: $c_p = 1007$ J/kg·K, $\mu = 184.6 \times 10^{-7}$ N·s/m^2, k = 0.0263 W/m·K, Pr = 0.707.

ANALYSIS: For this uniform heat flux condition, the heat rate is

$$q = q_s'' \ A_s = q_s'' \left[2(L \times W) + 2(L \times H)\right]$$

$$q = 600 \text{ W/m}^2 \left[2(1\text{m} \times 0.016\text{m}) + 2(1\text{m} \times 0.004\text{m})\right] = 24 \text{ W}.$$

From an overall energy balance

$$T_{m,o} = T_{m,i} + \frac{q}{\dot{m}\, c_p} = 300\text{K} + \frac{24 \text{ W}}{3 \times 10^{-4} \text{ kg/s} \times 1007 \text{ J/kg} \cdot \text{K}} = 379 \text{ K}. \qquad <$$

The surface temperature at the outlet may be determined from Newton's law of cooling, where

$$T_{s,o} = T_{m,o} + q''/h.$$

From Eqs. 8.66 and 8.1

$$D_h = \frac{4\ A_c}{P} = \frac{4(0.016\text{m} \times 0.004\text{m})}{2(0.016\text{m} + 0.004\text{m})} = 0.0064 \text{ m}$$

$$Re_D = \frac{\rho\, u_m\ D_h}{\mu} = \frac{\dot{m}\, D_h}{A_c \mu} = \frac{3 \times 10^{-4} \text{kg/s}(0.0064\text{m})}{64 \times 10^{-6} \text{m}^2 \left(184.6 \times 10^{-7} \text{ N} \cdot \text{s/m}^2\right)} = 1625.$$

Hence the flow is laminar, and from Table 8.1

$$h = \frac{k}{D_h} 5.33 = \frac{0.0263 \text{ W/m} \cdot \text{K}}{0.0064 \text{ m}} 5.33 = 22 \text{ W/m}^2 \cdot \text{K}$$

$$T_{s,o} = 379 \text{ K} + \frac{600 \text{ W/m}^2}{22 \text{ W/m}^2 \cdot \text{K}} = 406 \text{ K}. \qquad <$$

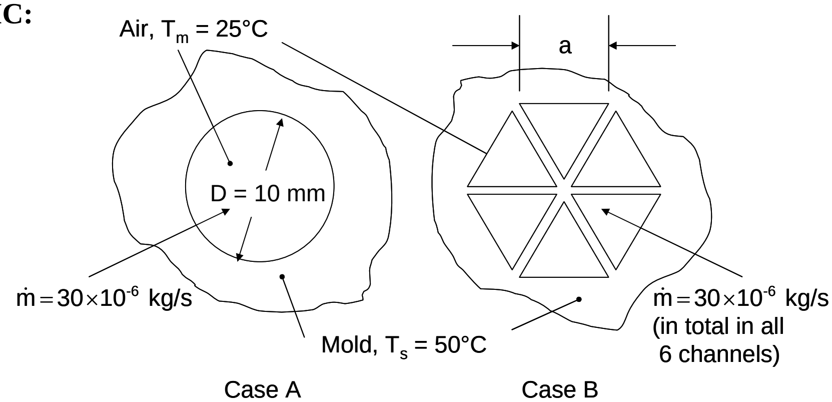
COMMENTS: The calculations should be repeated with properties evaluated at $\overline{T}_m = 340$ K. The change in $T_{m,o}$ would be negligible, and $T_{s,o}$ would decrease slightly.

PROBLEM 8.81

KNOWN: Inlet temperature and mass flow rate of air flow. Geometry and dimensions of channels through a mold. Mold temperature.

FIND: (a) Heat transferred to the air for case A, (b) Heat transferred to the air for case B, and (c) pressure drop for both cases.

SCHEMATIC:



ASSUMPTIONS: (1) Flow is hydrodynamically and thermally fully developed, (2) Mold temperature is uniform. (3) Narrow fins between channels in case B are at the mold temperature.

PROPERTIES: Table A-4, Air (T ≈ 310 K assumed, 1atm): $\rho = 1.128$ kg/m^3, $c_p = 1007$ J/kg·K, $\mu = 189.3 \times 10^{-7}$ N·s/m^2, k = 0.027 W/m·K.

ANALYSIS:

(a) The Reynolds number is

$$Re_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 30 \times 10^{-6} \text{ kg/s}}{\pi \times 0.01 \text{ m} \times 189.3 \times 10^{-7} \text{ N} \cdot \text{s/m}^2} = 202$$

Thus, the flow is laminar. Since it has also been assumed that the flow is fully developed and the mold temperature is uniform, the Nusselt number is

$$Nu_D = 3.66$$

Thus $\quad h = Nu_D k/D = 3.66 \times 0.027 \text{ W/m·K}/0.01 \text{ m} = 9.88 \text{ W/m}^2\text{·K}$.

The outlet temperature can be found from Equation 8.41b,

$$T_{m,o} = T_s + (T_{m,i} - T_s)\exp(-\frac{PL}{\dot{m}c_p}\overline{h})$$

$$= 50°C + (25°C - 50°C)\exp\left(-\frac{\pi \times 0.01 \text{ m} \times 0.1 \text{ m} \times 9.88 \text{ W/m}^2 \cdot \text{K}}{30 \times 10^{-6} \text{ kg/s} \times 1007 \text{ J/kg} \cdot \text{K}}\right)$$

$$= 41.0°C$$

Thus

$$q = \dot{m}c_p(T_{m,o} - T_{m,i}) = 30 \times 10^{-6} \text{ kg/s} \times 1007 \text{ J/kg} \cdot \text{K} \times (41.0°C - 25°C) = 0.485 \text{ W}$$ <

(b) We first determine the dimensions of the triangular channels from the requirement that the total area is the same as case A.

Continued…

PROBLEM 8.81 (Cont.)

$$\pi D^2/4 = 6a^2/2$$

$$a = (\frac{\pi}{12})^{1/2} D = (\frac{\pi}{12})^{1/2} \times 10\text{ mm} = 5.1\text{ mm}$$

and the flowrate in one channel is 5×10^{-6} kg/s.
The hydraulic diameter is $D_h = 4A_c/P = 4(a^2/2)/3a = 2a/3 = 3.4$mm.
The Reynolds number is

$$Re_D = \frac{4\,\dot{m}}{\pi\, D_h\, \mu} = \frac{4 \times 5 \times 10^{-6}\text{ kg/s}}{\pi \times 0.0034\text{ m} \times 189.3 \times 10^{-7}\text{ N}\cdot\text{s/m}^2} = 98.6$$

so the flow is laminar. From Table 8.1, the Nusselt number is $Nu_D = 2.47$, so

$$h = Nu_D k/D_h = 2.47 \times 0.027\text{ W/m}\cdot\text{K}/0.0034\text{ m} = 19.6\text{ W/m}^2\cdot\text{K}.$$

The outlet temperature is

$$T_{m,o} = T_s + (T_{m,i} - T_s)\exp(-\frac{P\,L}{\dot{m}\,c_p}\overline{h})$$

$$= 50°\text{C} + (25°\text{C} - 50°\text{C})\exp\left(-\frac{3 \times 0.0051\text{ m} \times 0.1\text{ m} \times 19.0\text{ W/m}^2\cdot\text{K}}{5 \times 10^{-6}\text{ kg/s} \times 1007\text{ J/kg}\cdot\text{K}}\right)$$

$$= 49.9°\text{C}$$

Then using the total flowrate to account for all six channels,

$$q = \dot{m}c_p(T_{m,o} - T_{m,i}) = 30 \times 10^{-6}\text{ kg/s} \times 1007\text{ J/kg}\cdot\text{K} \times (49.9°\text{C} - 25°\text{C}) = 0.753\text{ W}$$ <

(c) The friction factor for case A is $f = 64/Re_D = 64/202 = 0.317$. The pressure drop is, from Equation 8.22a,

$$\Delta p = f\frac{\rho u_m^2}{2D}L$$

with $u_m = \dot{m}/\rho A_c = 30 \times 10^{-6}\text{ kg/s}/(1.128\text{ kg/m}^3 \times \pi\,(0.01\text{ m})^2/4) = 0.339\text{ m/s}$. Thus

$$\Delta p = 0.317 \times \frac{1.128\text{ kg/m}^3 \times (0.339\text{ m/s})^2}{2 \times 0.01\text{ m}} \times 0.1\text{ m} = 0.205\text{ Pa}$$ <

For Case B, from Table 8.1, $f = 53/Re_D = 53/98.6 = 0.538$, and $u_m = 0.339$ m/s as in Case A. Thus

$$\Delta p = f\frac{\rho u_m^2}{2D_h}L = 0.538 \times \frac{1.128\text{ kg/m}^3 \times (0.339\text{ m/s})^2}{2 \times 0.0034\text{ m}} \times 0.1\text{ m} = 1.02\text{ Pa}$$ <

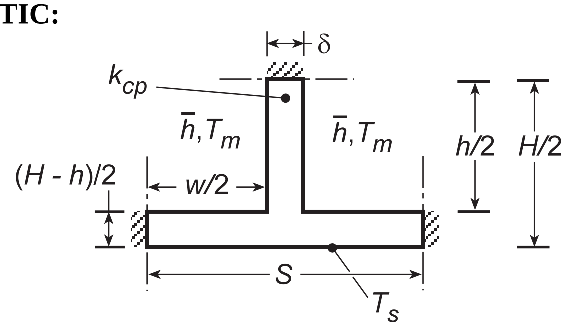
COMMENTS: (1) Segmenting the channel into six smaller sections increases the heat transfer by 55%, but at the expense of almost a five-fold increase in the pressure drop. (2) For the circular duct, the hydrodynamic entry length, is $x_{fd,h} = 0.05\,Re_D\,D = 0.1$ m, so it is not fully developed as assumed. For the triangular duct, $x_{fd,h} = 0.05\,Re_D\,D_h = 0.02$ m, so the assumption is more appropriate. The thermal development length is shorter, since Pr = 0.7.

PROBLEM 8.82

KNOWN: Dimensions, surface temperature and thermal conductivity of a *cold plate*. Velocity, inlet temperature, and properties of coolant.

FIND: (a) Model for determining the heat rate q and outlet temperature, $T_{m,o}$, (b) Values of q and $T_{m,o}$ for prescribed conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Incompressible liquid with negligible viscous dissipation, (3) Constant properties, (4) Symmetry about the midplane (horizontal) of the cold plate and the midplane (vertical) of each cooling channel, (5) Negligible heat transfer at sidewalls of cold plate, (6) One-dimensional conduction from outer surface of cold plate to base surface of channel and within the channel side walls, which act as extended surfaces.

PROPERTIES: Water (prescribed): $\rho = 984\ kg/m^3$, $c_p = 4184\ J/kg \cdot K$, $\mu = 489 \times 10^{-6}\ N \cdot s/m^2$, $k = 0.65\ W/m \cdot K$, $Pr = 3.15$.

ANALYSIS: (a) The outlet temperature, $T_{m,o}$, may be determined from the energy balance prescribed by Eq. 8.45b,

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{1}{\dot{m}_1 c_p R_{tot}}\right)$$

where $\dot{m}_1 = \rho u_m A_c$ is the flowrate for a single channel and R_{tot} is the total resistance to heat transfer between the cold plate surface and the coolant for a particular channel. This resistance may be determined from the symmetrical section shown schematically, which represents one-half of the cell associated with a full channel. With the number of channels (and cells) corresponding to N = W/S, there are 2N = 2(W/S) symmetrical sections, and the total resistance R_{tot} of a cell is one-half that of a symmetrical section. Hence, $R_{tot} = R_{ss}/2$, where the resistance of the symmetrical section includes the effect of conduction through the outer wall of the cold plate and convection from the inner surfaces. Hence,

$$R_{ss} = \frac{(H-h)/2}{k_{cp}(SW)} + \frac{1}{\eta_o \bar{h} A_t}$$

where $A_t = A_f + A_b = 2(h/2 \times W) + (w \times W)$, $\bar{h}$ is the average convection coefficient for the channel flow, and η_o is the overall surface efficiency.

$$\eta_o = 1 - \frac{A_f}{A_t}(1 - \eta_f)$$

Continued...

PROBLEM 8.82 (Cont.)

The efficiency η_f corresponds to that of a straight, rectangular fin with an adiabatic tip, Eq. 3.92, and L_c = w/2. With $D_h = 4A_c/P = 4w^2/4w = w = 0.006\,\text{m}$, $Re_{D_h} = \rho u_m D_h/\mu$ = 984 kg/m^3 × 2 m/s × 0.006 m/489 × 10^{-6} N·s/m^2 = 24,150 and the channel flow is turbulent. Assuming fully-developed flow throughout the channel, the Dittus-Boelter correlation, Eq. 8.60, may therefore be used to evaluate $\bar{h}$, where

$$\overline{Nu}_D \approx Nu_{D,fd} = 0.023 Re_D^{4/5} Pr^{0.4}$$

The total heat rate for the cold plate may be expressed as

$$q = Nq_1 = N\dot{m}_1 c_p \left(T_{m,o} - T_{m,i}\right)$$

(b) For the prescribed conditions,

$$\dot{m}_1 = \rho u_m A_c = 984\,\text{kg/m}^3\,(2\,\text{m/s})(0.006\,\text{m})^2 = 0.0708\,\text{kg/s}$$

$$\overline{Nu}_D = 0.023(24{,}150)^{4/5}(3.15)^{0.4} = 116.8$$

$$\bar{h} = 116.8\,k/D_h = 116.8(0.65\,\text{W/m}\cdot\text{K})/(0.006\,\text{m}) = 12{,}650\,\text{W/m}^2\cdot\text{K}$$

$$A_f = 2(h/2\times W) = 2(0.003\,\text{m}\times 0.1\,\text{m}) = 6\times 10^{-4}\,\text{m}^2$$

$$A_t = A_f + A_b = 6\times 10^{-4}\,\text{m}^2 + (0.006\,\text{m}\times 0.1\,\text{m}) = 1.2\times 10^{-3}\,\text{m}^2$$

With $m = \left(\bar{h}P_f/k_{cp}A_{cf}\right)^{1/2} = \left[\bar{h}(2\delta + 2W)/k_{cp}(\delta W)\right]^{1/2}$ = [12,650 W/m^2·K(0.008 + 0.200)m/400 W/m·K(0.004 × 0.100)m^2]$^{1/2}$ = 128.2 m^{-1}.

$$\eta_f = \frac{\tanh m(h/2)}{m(h/2)} = \frac{\tanh(128.2\times 0.003)}{128.2\times 0.003} = \frac{0.366}{0.385} = 0.952$$

$$\eta_o = 1 - 0.5(1 - 0.952) = 0.976$$

$$R_{ss} = \frac{(0.010 - 0.006)\,\text{m}/2}{400\,\text{W/m}\cdot\text{K}\,(0.01\,\text{m}\times 0.1\,\text{m})} + \frac{1}{0.976\left(12650\,\text{W/m}^2\cdot\text{K}\right)1.2\times 10^{-3}\,\text{m}^2}$$

$$R_{ss} = (0.005 + 0.0675)\,\text{K/W} = 0.0725\,\text{K/W}$$

With $R_{tot} = R_{ss}/2$ = 0.0362 K/W,

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{1}{0.0708\,\text{kg/s}\times 4184\,\text{J/kg}\cdot\text{K}\times 0.0362\,\text{K/W}}\right) = 0.911$$

$$T_{m,o} = T_s - 0.911\left(T_s - T_{m,i}\right) = 360\,\text{K} - 0.911(360 - 300)\,\text{K} = 305.3\,\text{K}$$ <

The total heat rate is

$$q = N\dot{m}_1 c_p\left(T_{m,o} - T_{m,i}\right) = 10\times 0.0708\,\text{kg/s}\times 4184\,\text{J/kg}\cdot\text{K}\,(305.3 - 300)\,\text{K} = 15{,}700\,\text{W}$$ <

COMMENTS: The prescribed properties correspond to a value of $\bar{T}_m$ which significantly exceeds that obtained from the foregoing solution ($\bar{T}_m$ = 302.6 K). Hence, the calculations should be repeated using more appropriate thermophysical properties (see next problem). From Eq. 3.90, the effectiveness of the extended surface is

$$\varepsilon = R_{t,b}/R_{t,f} = \left(\bar{h}\delta W\right)^{-1}/\left(\bar{h}A_f\eta_f\right)^{-1} = \left(A_f\eta_f/\delta W\right) = \left(6\times 10^{-4}\,\text{m}^2\times 0.954\right)/\left(0.004\,\text{m}\times 0.10\,\text{m}\right) = 1.43.$$

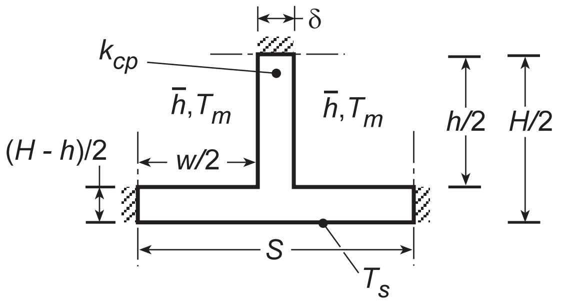
Hence, the ribs are only marginally effective in enhancing heat transfer to the coolant.

PROBLEM 8.83

KNOWN: Geometry, surface temperature and thermal conductivity of a *cold plate*. Velocity and inlet temperature of coolant.

FIND: Effect of channel width on total heat rate.

SCHEMATIC:



δ = 4mm, h = 6 mm
H = 10 mm, W = 100 mm
u_m = 2 m/s, T_{mi} = 300 K
T_s = 360 K
k_{cp} = 400 W/m·K

ASSUMPTIONS: (1) Steady-state conditions, (2) Incompressible liquid with negligible viscous dissipation, (3) Constant properties, (4) Symmetry about midplane (horizontal) of the cold plate and the midplane (vertical) of each channel, (5) Negligible heat transfer at sidewalls of cold plate, (6) One-dimensional conduction from outer surface of cold plate to base surface of channel and within the channel side walls, which act as extended surfaces.

PROPERTIES: Water: Evaluated at $\overline{T}_m$ using the *Properties* Toolpad of IHT.

ANALYSIS: The model developed for the preceding problem was entered into the workspace of IHT, with the Dittus-Boelter equation and exponential relation accessed from the *Correlations* Toolpad and modified to account for the hydraulic diameter and the total resistance to heat transfer. Calculations were performed for

Case 1: w = 96 mm, N = 1, S = W = 100 mm
Case 2: w = 46 mm, N = 2, S = 50 mm
Case 3: w = 21 mm, N = 4, S = 25 mm
Case 4: w = 6 mm, N = 10, S = 10 mm
Case 5: w = 1 mm, N = 20, S = 5 mm

and the results are tabulated as follows.

Case	N	D_h (m)	Re_D	$\bar{h}\left(W/m^2 \cdot K\right)$	$T_{m,o}$ (K)	q (W)
1	1	0.01129	26,920	8783	302.1	10,090
2	2	0.01062	25,310	8892	302.3	10,370
3	4	0.00933	22,340	9142	302.6	10,960
4	10	0.00600	14,630	10,070	304.3	12,950
5	20	0.00171	4760	13,740	317.2	17,160

It is clearly beneficial to increase the number of channels, with the total heat rate increasing by approximately a factor of 5 as N increases from 1 to 20. The heat rate may be increased further by increasing u_m, and hence the flowrate per channel, although an upper limit would be associated with the pressure drop, which would increase with decreasing D_h. Could additional heat transfer enhancement be achieved by altering the thickness δ of the channel walls?

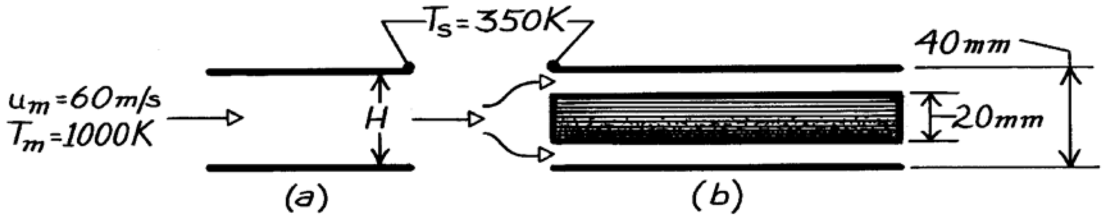
COMMENTS: (1) Note that results obtained for Case 4 differ from those of the preceding problem due to different fluid properties. In this case the properties were evaluated at the actual value of $\overline{T}_m$ = 302.2 K, rather than at an assumed (significantly larger) value. (2) Note that the Dittus-Boelter correlation is applied outside its intended range for the Reynolds number of case 5. The Gnielinski correlation would be preferable.

PROBLEM 8.84

KNOWN: Temperature and velocity of gas flow between parallel plates of prescribed surface temperature and separation. Thickness and location of plate insert.

FIND: Heat flux to the plates (a) without and (b) with the insert.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible radiation, (3) Gas has properties of atmospheric air, (4) Plates are of infinite width W, (5) Fully developed flow.

PROPERTIES: *Table A-4*, Air (1 atm, T_m = 1000 K): $\rho = 0.348$ kg/m^3, $\mu = 424.4 \times 10^{-7}$ kg/s·m, k = 0.0667 W/m·K, Pr = 0.726.

ANALYSIS: (a) Based upon the hydraulic diameter D_h, the Reynolds number is

$$D_h = 4\,A_c/P = 4(H \cdot W)/2(H+W) = 2H = 80\text{ mm}$$

$$Re_{D_h} = \frac{\rho\, u_m\, D_h}{\mu} = \frac{0.348\text{ kg/m}^3(60\text{ m/s})0.08\text{ m}}{424.4\times10^{-7}\text{ kg/s}\cdot\text{m}} = 39,360.$$

Since the flow is fully developed and turbulent, use the Dittus-Boelter correlation,

$$Nu_D = 0.023\,Re_D^{4/5}\,Pr^{0.3} = 0.023(39,360)^{4/5}(0.726)^{0.3} = 99.1$$

$$h = \frac{k}{D_h}Nu_D = \frac{0.0667\text{ W/m}\cdot\text{K}}{0.08\text{ m}}99.1 = 82.6\text{ W/m}^2\cdot\text{K}$$

$$q'' = h(T_m - T_s) = 82.6\text{ W/m}^2\cdot\text{K}(1000-350)\text{K} = 53,700\text{ W/m}^2. \quad <$$

(b) From continuity,

$$\dot{m} = (\rho\, u_m A)_a = (\rho\, u_m A)_b \qquad u_m)_b = u_m)_a\,(\rho A)_a / (\rho A)_b = 60\text{ m/s}(40/20) = 120\text{ m/s}.$$

For each of the resulting channels, D_h = 0.02 m and

$$Re_{D_h} = \frac{\rho\, u_m\, D_h}{\mu} = \frac{0.348\text{ kg/m}^3(120\text{ m/s})0.02\text{ m}}{424.4\times10^{-7}\text{kg/s}\cdot\text{m}} = 19,680.$$

Since the flow is still turbulent,

$$Nu_D = 0.023(19,680)^{4/5}(0.726)^{0.3} = 56.9 \qquad h = \frac{56.9(0.0667\text{ W/m}\cdot\text{K})}{0.02\text{ m}} = 189.8\text{ W/m}^2\cdot\text{K}$$

$$q'' = 189.8\text{ W/m}^2\cdot\text{K}\ (1000-350)\text{K} = 123,400\text{ W/m}^2. \quad <$$

COMMENTS: From the Dittus-Boelter equation,

$$h_b/h_a = (u_{m,b}/u_{m,a})^{0.8}(D_{h,a}/D_{h,b})^{0.2} = (2)^{0.8}(4)^{0.2} = 1.74\times1.32 = 2.30.$$

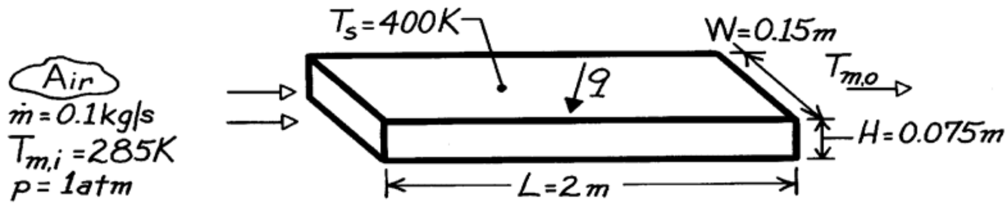
Hence, heat transfer enhancement due to the insert is primarily a result of the increase in u_m and secondarily a result of the decrease in D_h.

PROBLEM 8.85

KNOWN: Temperature, pressure and flow rate of air entering a rectangular duct of prescribed dimensions and surface temperature.

FIND: Air outlet temperature and duct heat transfer rate.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Uniform surface temperature, (4) Fully developed flow throughout, (5) Ideal gas with negligible viscous dissipation and pressure variation.

PROPERTIES: *Table A-4*, Air (assume $T_m \approx 325$K, 1 atm): $c_p = 1008$ J/kg·K, $\mu = 196.4 \times 10^{-7}$ N·s/m^2, k = 0.0282 W/m·K, Pr = 0.707.

ANALYSIS: From Eqs. 8.66 and 8.1,

$$D_h = \frac{4\,A_c}{P} = \frac{4\times(0.15\times0.075)\text{m}^2}{2(0.15+0.075)\text{m}} = 0.10\text{ m}$$

$$Re_D = \frac{\rho\, u_m D_h}{\mu} = \frac{\dot{m}\, D_h}{A_c \mu} = \frac{0.1\text{ kg/s}(0.1\text{m})}{(0.15\text{m}\times0.075\text{m})196.4\times10^{-7}\text{ N}\cdot\text{s/m}^2} = 45,260.$$

Hence the flow is turbulent, and from Eq. 8.60

$$h = \frac{k}{D_h}0.023\,Re_D^{4/5}\,Pr^{0.4} = \frac{0.0282\text{ W/m}\cdot\text{K}}{0.10\text{ m}}0.023(45,260)^{4/5}(0.707)^{0.4} = 30\text{ W/m}^2\cdot\text{K}.$$

From Eq. 8.41b, with P = 2(W + H),

$$T_{m,o} = T_s - (T_s - T_{m,i})\exp\left(-\frac{PL}{\dot{m}\,c_p}\bar{h}\right)$$

$$T_{m,o} = 400\text{ K} - (400-285)\text{K}\exp\left[-\frac{2(0.15\text{m}+0.075\text{m})2\text{m}\left(30\text{W/m}^2\cdot\text{K}\right)}{0.1\text{ kg/s}\times1008\text{ J/kg}\cdot\text{K}}\right]$$

$$T_{m,o} = 312\text{ K}$$ <

and from Eq. 8.34

$$q = \dot{m}\,c_p\left(T_{m,o} - T_{m,i}\right) = 0.1\text{ kg/s}\times1008\text{ J/kg}\cdot\text{K}(312-285)\text{K} = 2724\text{ W}.$$ <

COMMENTS: (1) The calculations may be checked by determining q from Eqs. 8.43 and 8.44. We obtain $\Delta T_{\ell m} = 101^\circ\text{C}$ and q = 2724 W.

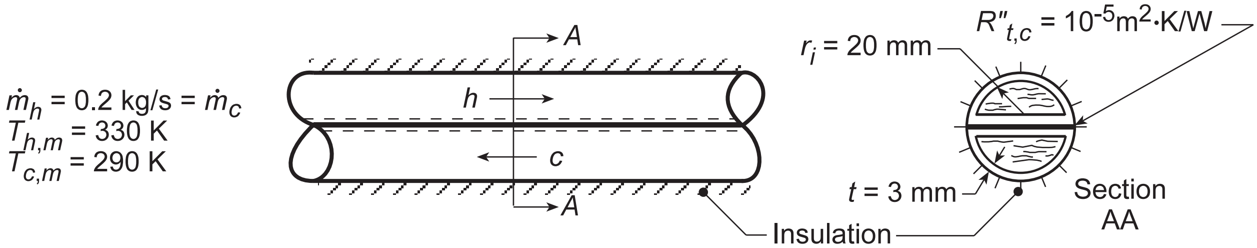
(2) $\bar{T}_m$ has been over-estimated. The calculations should be repeated with properties evaluated at $\bar{T}_m$ = 299 K.

PROBLEM 8.86

KNOWN: Dimensions of semi-circular copper tubes in contact at plane surfaces. Thermal contact resistance. Tube flow conditions.

FIND: (a) Heat rate per unit tube length, and (b) The effect on the heat rate when the fluids are ethylene glycol, the exchanger tube is fabricated from an aluminum alloy, or the exchanger tube thickness is increased.

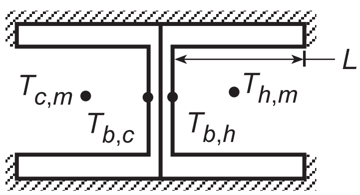
SCHEMATIC:

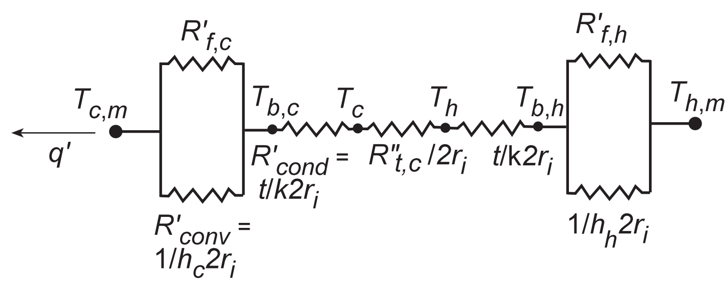


ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Adiabatic outer surface, (4) Fully developed flow, (5) Negligible heat loss to surroundings.

PROPERTIES: *Table A.1*, Copper (T ≈ 300 K): k = 400 W/m·K; Water (given): $\mu = 800 \times 10^{-6}$ kg/s·m, k = 0.625 W/m·K, Pr = 5.35.

ANALYSIS: (a,b) Heat transfer from the hot to cold fluids is *enhanced* by conduction through the semi-circular portions of the tube walls. The walls may be approximated as straight fins with an insulated tip, and the thermal circuit is shown below.





Note that, since each semi-circular surface is insulated on one side, surfaces may be combined to yield a *single* fin of thickness 2t with convection on both sides. Also, due to the equivalent geometry and the assumption of constant properties, there is symmetry on opposite sides of the contact resistance. From the thermal circuit, the heat rate is

$$q' = \frac{T_{h,m} - T_{c,m}}{R'_{tot}} \qquad (1)$$

For flow through the semi-circular tube,

$$Re_D = \frac{\rho u_m D_h}{\mu} = \frac{\dot{m} D_h}{A_c \mu} = \frac{4\dot{m} A_c}{A_c P \mu} = \frac{4\dot{m}}{P\mu} = \frac{4\dot{m}}{(2r_i + \pi r_i)\mu} \qquad (2)$$

$$Re_D = \frac{4 \times 0.2\,\text{kg/s}}{(2+\pi)0.02\,\text{m} \times 800 \times 10^{-6}\,\text{kg/s}\cdot\text{m}} = 9725$$

the flow is turbulent. Using the Gnielinski correlation, since $Re_D < 10{,}000$

$$Nu_D = \frac{(f/8)(Re_D - 1000)\,Pr}{1 + 12.7(f/8)^{1/2}(Pr^{2/3} - 1)} = 69.9 \qquad (3)$$

Continued...

PROBLEM 8.86 (Cont.)

where f = $(0.79\ln(Re_D)-1.64)^{-2} = 0.0317$

$$D_h = \frac{4A_c}{P} = \frac{4\left(\pi r_i^2/2\right)}{(\pi+2)r_i} = \frac{2\pi}{\pi+2}0.02\,m = 0.0244\,m \tag{4}$$

$$h = Nu_D\frac{k}{D_h} = 69.9\frac{0.625}{0.0244} = 1790\,W/m^2\cdot K. \tag{5}$$

Find now values for the thermal resistance of the circuit.

$$R'_{conv} = \frac{1}{2r_i h} = \frac{1}{(0.04\,m)1790\,W/m^2\cdot K} = 0.0140\,m\cdot K/W \tag{6}$$

$$R'_{fin} = \frac{\theta_b}{q'_f} = \frac{1}{\left(hP'kA'_c\right)^{1/2}\tanh\left(hP/kA_c\right)L} \tag{7}$$

$$L = \pi r_i/2 = \pi(0.01\,m) = 0.0314\,m \qquad A_c = 2t\cdot 1\,m = 0.006\,m^2 \qquad P \approx 2.1\text{ m} \tag{8,9,10}$$

$$\left(hP'kA'_c\right)^{1/2} = \left(1790\,W/m^2\cdot K\times 2\,m/m\times 400\,W/m\cdot K\times 0.006\,m^2/s\right)^{1/2} = 92.7\,W/K\cdot m$$

$$\left(hP/kA_c\right)^{1/2}L = \left(1790\,W/m^2\cdot K\times 2\,m/400\,W/m\cdot K\times 0.006\,m^2\right)^{1/2}0.0314\,m = 1.21$$

$$R'_{fin} = \frac{1}{92.7\,W/m\cdot K(0.838)} = 0.0129\,m\cdot K/W \tag{11}$$

$$R'_{cond} = \frac{t}{2kr_i} = \frac{0.003\,m}{2(400\,W/m\cdot K)(0.02\,m)} = 1.875\times 10^{-4}\,m\cdot K/W \tag{12}$$

$$R'_{t,c} = \frac{R''_{t,c}}{2r_i} = \frac{10^{-5}\,m^2\cdot K/W}{2(0.02\,m)} = 2.5\times 10^{-4}\,m\cdot K/W \tag{13}$$

The equivalent resistance of the parallel circuit is

$$R'_{eq} = \left(R'^{-1}_{fin} + R'^{-1}_{conv}\right)^{-1} = (77.6\,W/m\cdot K + 71.5\,W/m\cdot K)^{-1} = 6.70\times 10^{-3}\,m\cdot K/W \tag{14}$$

Hence

$$R'_{tot} = 2\left(R'_{eq} + R'_{cond}\right) + R'_{t,c} \tag{15}$$

$$R'_{tot} = \left[2\left(6.70\times 10^{-3} + 1.875\times 10^{-4}\right) + 2.50\times 10^{-4}\right]m\cdot K/W = 0.0140\,m\cdot K/W$$

$$q' = \frac{(330-290)K}{0.0140\,m\cdot K/W} = 2850\,W/m. \qquad <$$

(c) Using the *IHT Workspace* with the foregoing equations, analyses were performed and the results summarized in the table below. The “Conditions” are described below; the “Change” is relative to the base case condition.

Continued …

PROBLEM 8.86 (Cont.)

Condition*	$R'_{conv} \times 10^4$ (m·K/W)	$R'_{fin} \times 10^4$ (m·K/W)	$R'_{cond} \times 10^4$ (m·K/W)	$R'_{tot} \times 10^4$ (m·K/W)	$R'_{eq} \times 10^4$ (m·K/W)	q' (W/m)	Change (%)
Base case	140	129	1.88	140	67.0	2850	--
Ethylene glycol	6550	4210	1.88	5130	2560	77.9	-97
Aluminum alloy	140	171	4.24	165	76.9	2430	-15
Thicker tube	140	120	2.50	136	64.4	2930	+2.8

*Conditions: change from base case

Base case - water, copper (k = 400 W/m·K), t = 3 mm
Ethylene glycol - ethylene glycol instead of water, Re_D = 727, laminar, Nu_D = 3.66 estimated
Aluminum alloy - alloy (k = 177 W/m·K) instead of copper
Thicker tube - t = 4 mm instead of 3 mm

As expected, using ethylene glycol as the working fluid would decrease the heat rate, especially because the flow becomes laminar. Note that R'_{conv} is the dominate resistance since the convection coefficient is considerably reduced compared to that with water. Using aluminum alloy, rather than copper, as the tube material reduces the heat rate by 14%. Conduction-convection (fin) in the tube wall is important as can be seen by examining the change in R'_{fin} relative to the base condition. Increasing the tube wall thickness for the copper tube exchanger from 3 to 4 mm had only a marginal positive effect on the heat rate.

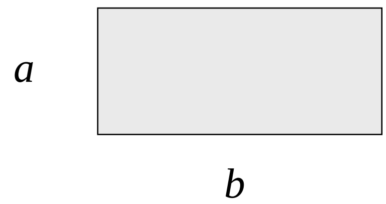
COMMENTS: A more accurate calculation would account for the absence of symmetry about the contact plane. Evaluation of water properties at $T_{h,m}$ = 330 K and $T_{c,m}$ = 290 K yields h_h = 1930 $W/m^2 \cdot K$ and h_c = 1470 $W/m^2 \cdot K$.

PROBLEM 8.87

KNOWN: Rectangular channel with constant surface temperature. Aspect ratio.

FIND: Which aspect ratio channel provides the largest heat transfer rate. Whether this is greater than, equal to, or less than the heat transfer rate for a circular tube.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Incompressible flow, (3) Laminar, (4) Fully-developed.

ANALYSIS: The heat transfer rate is given by $q_s = \dot{m}c_p(T_{m,o} - T_{m,i})$, where from Eq. 8.41b with constant heat transfer coefficient,

$$T_{m,o} - T_{m,i} = (T_s - T_{m,i})\left[1 - \exp\left(-\frac{hPL}{\dot{m}c_p}\right)\right]$$

Thus, the heat transfer rate increases with increasing values of

$$\frac{hPL}{\dot{m}c_p} = \frac{NukPL}{\dot{m}c_p D_h} = \frac{NukP^2L}{4\dot{m}c_p A_c}$$

For fixed mass flow rate and length, and assuming the same properties, the relevant parameter that determines the heat transfer rate is therefore NuP^2/A_c. For a rectangular channel, $P^2/A_c =$ $4(a+b)^2/ab = 4(1+b/a)^2/(b/a)$, whereas for a circular tube, $P^2/A_c = 4\pi$. The table below compares values of NuP^2/A_c for the three different aspect ratio rectangular channels and a circular tube.

b/a	***Nu***	P^2/A_c	NuP^2/A_c
1.0	2.98	16	47.7
1.43	3.08	16.5	50.9
2.0	3.39	18	61.0
Circular tube	3.66	12.6	46.0

The rectangular channel with b/a = 2.0 provides the largest heat transfer rate, which is larger than for a circular tube. <

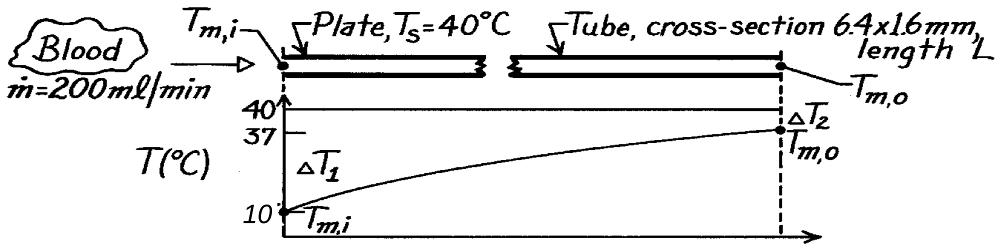
COMMENTS: The Nusselt numbers for the rectangular channel are all less than 3.66 for the circular tube, but their convective heat transfer rates are larger than that of the circular tube because their P^2/A_c values are larger.

PROBLEM 8.88

KNOWN: Heat exchanger to warm blood from a storage temperature 10°C to 37° at 200 ml/min. Tubing has rectangular cross-section 6.4 mm × 1.6 mm sandwiched between plates maintained at 40°C.

FIND: (a) Length of tubing and (b) Assessment of assumptions to indicate whether analysis under- or over-estimates length.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Incompressible liquid with negligible viscous dissipation, (3) Blood flow is fully developed, (4) Blood has properties of water, and (5) Negligible tube wall and contact resistance.

PROPERTIES: *Table A-6*, Water ($\bar{T}_m \approx 300$ K): $c_{p,f} = 4179$ J/kg·K, $\rho_f = 1/v_f = 997$ kg/m^3, $\nu_f = \mu_f v_f = 8.58 \times 10^{-7}$ m^2/s, k = 0.613 W/m·K, Pr = 5.83.

ANALYSIS: (a) From an overall energy balance and the rate equation,

$$q = \dot{m}\, c_p \left(T_{m,o} - T_{m,i}\right) = \bar{h} A_s \Delta T_{LMTD} \qquad (1)$$

where

$$\Delta T_{LMTD} = \frac{\Delta T_1 - \Delta T_2}{\ln\left(\Delta T_1 / \Delta T_2\right)} = \frac{\left(40-15\right)-\left(40-37\right)}{\ln\left(25/3\right)} = 11.7^\circ\text{C}.$$

To estimate $\bar{h}$, find the Reynolds number for the rectangular tube,

$$Re_D = \frac{u_m D_h}{\nu} = \frac{0.326 \text{ m/s} \times 0.00256 \text{ m}}{8.58 \times 10^{-7} \text{m}^2/\text{s}} = 973$$

where

$$D_h = 4\, A_c / P = 4\left(6.4 \text{ mm} \times 1.6 \text{ mm}\right)/2\left(6.4+1.6\right)\text{mm} = 2.56 \text{ mm}$$

$$A_c = \left(6.4 \text{ mm} \times 1.6 \text{ mm}\right) = 1.024 \times 10^{-5} \text{m}^2$$

$$u_m = \dot{m}/\rho A_c = \dot{\forall}/A_c = 200 \text{ m}\ell/60 \text{ s}\left(10^{-6}\text{m}^3/\text{m}\ell\right)/1.024 \times 10^{-5}\text{m}^2 = 0.326 \text{ m/s}.$$

Hence the flow is laminar, but assuming fully developed flow with an isothermal surface from Table 8.1 with b/a = 6.4/1.6 = 4,

$$Nu_D = \frac{hD_h}{k} = 4.44 \qquad h = \frac{4.44 \times 0.613 \text{ W/m}\cdot\text{K}}{0.00256 \text{ m}} = 1063 \text{ W/m}^2\cdot\text{K}.$$

Continued …

PROBLEM 8.88 (Cont.)

From Eq. (1) with

$$A_s = PL = 2(6.4 + 1.6)\times 10^{-3}\,\text{m}\times L = 1.6\times 10^{-2}L$$

$$\dot{m} = \rho A_c u_m = 997\ \text{kg/m}^3 \times 1.024\times 10^{-5}\,\text{m}^2 \times 0.326\ \text{m/s} = 3.328\times 10^{-3}\ \text{kg/s}$$

the length of the rectangular tubing can be found from Eq. (1) as

$$3.328\times 10^{-3}\ \text{kg/s}\times 4179\ \text{J/kg}\cdot\text{K}(37-10)\text{K} = 1063\ \text{W/m}^2\cdot\text{K}\times 1.6\times 10^{-2}\text{Lm}^2\times 11.7\ \text{K}$$

$$L = 1.9\ \text{m}.$$ <

(b) Consider these comments with regard to whether the analysis under- or over-estimates the length,

⇒ With $x_{fd,h} \approx 0.05 D_h Re_D = 0.12$ m and $x_{fd,t} = x_{fd,h} Pr = 0.73$ m, the thermal development may not be negligible and would contribute to increasing heat transfer; the present analysis over predicts the length,

⇒ negligible tube wall resistance - depends upon materials of construction; if plastic, analysis under predicts length,

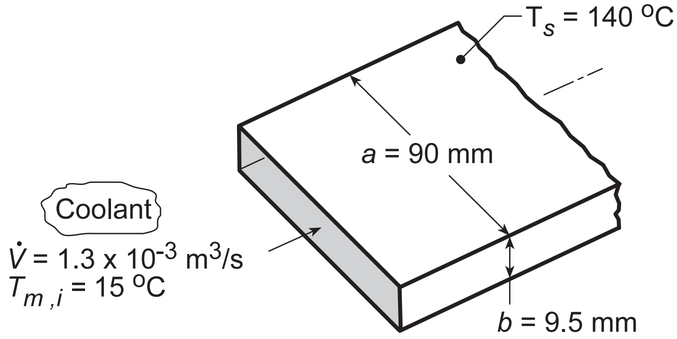
⇒ negligible thermal contact resistance between tube and heating plate - if present, analysis under predicts length.

PROBLEM 8.89

KNOWN: Coolant flowing through a rectangular channel (gallery) within the body of a mold.

FIND: Convection coefficient when the coolant is process water or ethylene glycol.

SCHEMATIC:



ASSUMPTIONS: (1) Gallery can be approximated as a rectangular channel with a uniform surface temperature, (2) Fully developed flow conditions.

PROPERTIES: *Table A.6*, Water ($\overline{T}_m$ = (140 + 15)°C/2 = 350 K): ρ = 974 kg/m^3, μ = 365 × 10^{-6} N·s/m^2, $\nu = \mu/\rho$ = 3.749 × 10^{-7} m^2/s, k = 0.668 W/m·K, Pr = 2.29; *Table A.5*, Ethylene glycol ($\overline{T}_m$ = 350 K): ρ = 1079 kg/m^3, ν = 3.17 × 10^{-6} m^2/s, k = 0.261 W/m·K, Pr = 34.6.

ANALYSIS: The characteristic length of the channel, the hydraulic diameter, Eq. 8.66, is $D_h = 4A_c/P$ where A_c is the cross-sectional flow area and P is the wetted perimeter. For our channel,

$$D_h = \frac{4(a\times b)}{2(a+b)} = \frac{4\times 0.090\,\text{m}\times 0.0095\,\text{m}}{2(0.090+0.0095)\,\text{m}} = 0.0172\,\text{m}$$

For the *water* coolant, from the continuity equation, find the Reynolds number to characterize the flow

$$u_m = \frac{\dot{V}}{A_c} = \frac{1.3\times 10^{-3}\,\text{m}^3/\text{s}}{0.090\,\text{m}\times 0.0095\,\text{m}} = 1.52\,\text{m/s}$$

$$Re_{Dh} = \frac{u_m D_h}{\nu} = \frac{1.52\,\text{m/s}\times 0.0172\,\text{m}}{3.749\times 10^{-7}\,\text{m}^2/\text{s}} = 69,736$$

Since the flow is turbulent, and assuming fully developed conditions, use the Dittus-Boelter correlation, Eq. 8.60, to estimate the convection coefficient,

$$Nu_{Dh} = \frac{hD_h}{k} = 0.023\,Re_{Dh}^{0.8}\,Pr^{0.4} = 0.023(69,736)^{0.8}(2.29)^{0.4} = 240$$

$$h_w = \frac{0.668\,\text{W/m}\cdot\text{K}}{0.0172\,\text{m}}\times 240 = 9326\,\text{W/m}^2\cdot\text{K} \qquad <$$

Repeating the calculations using properties for the *ethylene glycol* coolant, find

$$Re_{Dh} = 8,247 \qquad Nu_{Dh} = 128 \qquad h_{eg} = 1957\,\text{W/m}^2\cdot\text{K} \qquad <$$

Continued...

PROBLEM 8.89 (Cont.)

COMMENTS: (1) The convection coefficient for the *water* coolant is more than 4 times greater than that with the *ethylene glycol* coolant. The corrosion protection afforded by the latter coolant greatly compromises the thermal performance of the gallery. In such situations, it is useful to explore a compromise between corrosion protection and thermal performance by using an aqueous solution of ethylene glycol (50%-50%, for example).

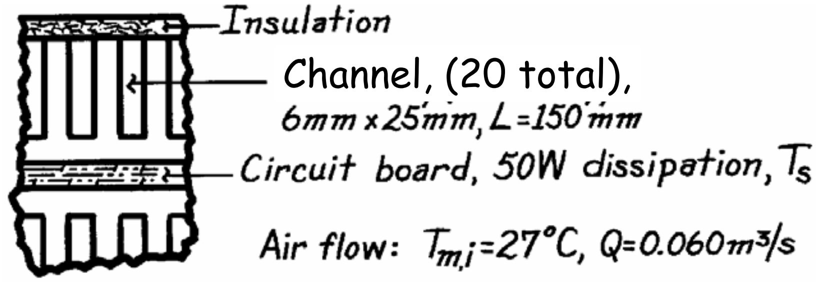
(2) Recognize that for the ethylene glycol coolant calculation the Reynolds number is slightly below the lower limit of applicability of the Dittus-Boelter correlation, and the Gnielinski correlation would be more accurate.

PROBLEM 8.90

KNOWN: Heat sink with 20 passages for air flow removes power dissipation from circuit board.

FIND: Operating temperature of the board and pressure drop across the sink.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Ideal gas with negligible viscous dissipation and pressure variation, (3) Negligible thermal resistance between the circuit boards and air passages, (4) Sink surface and board are isothermal at T_s.

PROPERTIES: *Table A-4*, Air ($\overline{T} \approx 310$ K,1 atm): $\rho = 1.1281$ kg/m^3, $c_p = 1008$ J/kg·K, $\nu = 16.89 \times 10^{-6}$ m^2/s, k = 0.0270 W/m·K, Pr = 0.706.

ANALYSIS: The air outlet temperature follows from Eq. 8.41b,

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{PL\bar{h}}{\dot{m}\,c_p}\right).$$

The mass flow rate for both heat sinks is

$$\dot{m} = \rho\dot{\forall} = 1.1281\text{ kg/m}^3 \times 0.060\text{ m}^3/\text{s} = 6.77\times10^{-2}\text{ kg/s}$$

and the Reynolds number for a rectangular passage is

$$Re_D = \frac{u_m D_h}{\nu}$$

where $D_h = 4A_c/P = 4(6\text{ mm}\times 25\text{ mm})/2(6+25)\text{mm} = 9.68\text{ mm}$

$$u_m = \frac{\dot{m}/20}{\rho A_c} = \frac{6.77\times10^{-2}\text{ kg/s}/20}{1.1281\text{ kg/m}^3(6\times25)\times10^{-6}\text{m}^2} = 20.0\text{ m/s}$$

giving $Re_D = \dfrac{20.0\text{ m/s}\times 9.68\times10^{-3}\text{ m}}{16.89\times10^{-6}\text{ m}^2/\text{s}} = 11,460.$

Assume the flow is turbulent and fully developed and using the Dittus-Boelter correlation find

$$Nu_D = 0.023Re^{4/5}Pr^{0.4} = 0.023(11,460)^{4/5}(0.706)^{0.4} = 35.4$$

$$h = \frac{Nu\cdot k}{D_h} = \frac{35.4\times0.027\text{ W/m}\cdot\text{K}}{0.00968\text{ m}} = 98.6\text{ W/m}^2\cdot\text{K}.$$

Continued …

From an overall energy balance on the sink,

$$q = \dot{m}\, c_p \left(T_{m,o} - T_{m,i}\right) \qquad T_{m,o} = T_{m,i} + q/\dot{m}\, c_p$$

$$T_{m,o} = 27^\circ\text{C} + 50\ \text{W}/6.77\times10^{-2}\ \text{kg/s}\times1008\ \text{J/kg}\cdot\text{K} = 27.73^\circ\text{C}$$

Hence, the operating temperature of the circuit board for these conditions is

$$\frac{T_s - 27.73}{T_s - 27} = \exp\left[-\frac{2\left(6+25\right)\times10^{-3}\ \text{m}\times0.150\text{m}\times98.6\ \text{W/m}^2\cdot\text{K}}{\left(6.77\times10^{-2}\ \text{kg/s}/20\right)\times1008\ \text{J/kg}\cdot\text{K}}\right]$$

$$T_s = 30.1^\circ\text{C}. \qquad <$$

The pressure drop in the rectangular passage for the smooth surface condition follows from Eqs. 8.22 and 8.21

$$\Delta p = f\,\frac{\rho\, u_m^2}{D_h}\,L$$

where

$$f = (0.790\ln(Re_D) - 1.64)^{-2} = 0.032.$$

$$\Delta p = 0.0320\,\frac{1.1281\ \text{kg/m}^3\left(20.0\ \text{m/s}\right)^2}{0.00968\ \text{m}}\times0.150\ \text{m} = 224\ \text{N/m}^2. \qquad <$$

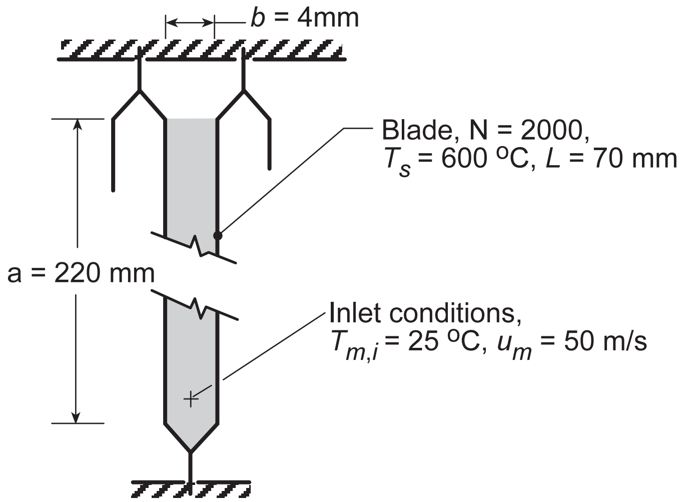
COMMENTS: (1) The analysis has been simplified by assuming the channel is rectangular and all four sides experience heat transfer. Since the insulated surface is a small portion of the total passage surface area, the effect can't be very large. (2) The power required to move the air through the heat sink is $P_{elec} = \dot{\forall}\,\Delta p = 0.060\ \text{m}^3/\text{s} \times 224\ \text{N/m}^2 = 13.4$ W. (3) The assumption $\overline{T} \approx 310$ K for evaluating properties is an overestimate. The calculation could be repeated for $\overline{T} = 300$ K for greater accuracy.

PROBLEM 8.91

KNOWN: Channel formed between metallic blades dissipating heat by internal volumetric generation.

FIND: (a) The heat removal rate per blade for the prescribed thermal conditions and (b) Time required to slow a train of mass 10^6 kg from 120 km/h to 50 km/h.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions for channel blades and air flow, (2) The blades form a channel of rectangular (a × b) cross-section and length L, (3) Ideal gas with negligible viscous dissipation, pressure variation, and axial conduction, and (4) Fully developed flow conditions in the channel.

PROPERTIES: *Table A.4*, Air ($\overline{T}_m \approx 350$ K, 1 atm): ρ = 0.995 kg/m^3, c_p = 1009 J/kg ·K, ν = 20.92 × 10^{-6} m^2/s, k = 0.030 W/m·K, Pr = 0.700.

ANALYSIS: (a) The heat removal rate by the air from a single channel (one blade) follows from an overall energy balance,

$$q = \dot{m}c_p\left(T_{m,o} - T_{m,i}\right) \quad (1)$$

where the outlet temperature can be determined from Eq. 8.41b,

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{PL}{\dot{m}c_p}\overline{h}\right) \quad (2)$$

The hydraulic diameter, D_h, follows from Eq. 8.66,

$$D_h = \frac{4A_c}{P} = \frac{4(a \times b)}{2(a+b)} = \frac{4(0.220 \times 0.004)\,m^2}{2(0.220 + 0.004)\,m} = 0.0079\,m \quad (3)$$

Assuming $\overline{T}_m = 350K$, the Reynolds number is

$$Re_{Dh} = \frac{u_m D_h}{\nu} = \frac{50\,m/s \times 0.0079m}{20.92 \times 10^{-6}\,m^2/s} = 18,779 \quad (4)$$

Using the Dittus-Boelter correlation, Eq. 8.60,

$$Nu_{Dh} = \frac{\overline{h}D_h}{k} = 0.023\,Re_{Dh}^{0.8}\,P_r^{0.4} = 0.023(18,779)^{0.8}(0.700)^{0.4} = 52.37 \quad (5)$$

Continued...

PROBLEM 8.91 (Cont.)

$$\bar{h} = \frac{0.030\,W/m\cdot K}{0.0079m}\times 52.37 = 199\,W\Big/m^2\cdot K$$

Hence, the outlet temperature is

$$\frac{600 - T_{m,o}}{(600-25)^\circ C} = \exp\left(-\frac{2(0.220+0.004)m\times 0.070m}{0.0438\,kg/s\times 1009\,J/kg\cdot K}199\,W\Big/m^2\cdot K\right)$$

$$T_{m,o} = 100.7^\circ C$$

where

$$\dot{m} = \rho A_c u_m = 0.995\ kg/m^3 \times (0.220 \times 0.004)\ m^2 \times 50\ m/s = 0.0438\ kg/s$$

and the rate of heat removal per blade, from Eq. (1), is

$$q = 0.0438\,kg/s\times 1009\,J\Big/kg\cdot K\,(100.7-25)^\circ C = 3.346\,kW$$ <

(b) From an energy balance on the locomotive over an interval of time, Δt, the heat energy transferred to the air stream results in a change in kinetic energy of the train,

$$-E_{out} = \Delta E = KE_f - KE_i \qquad (6)$$

$$-(q\times N)\times \Delta t = \frac{1}{2}M\left(V_f^2 - V_i^2\right)$$

$$-3346\,W/blade\times 2000 blades\times \Delta t(s) = \frac{1}{2}\times 10^6 kg\left[\left(\frac{50,000}{3600}\right)^2 - \left(\frac{120,000}{3600}\right)^2\right]m^2\Big/s^2$$

$$\Delta t = 69s$$ <

COMMENTS: (1) For the channel, L/D_h = 0.070 m/0.0079 m = 8.9 < 10 so that the assumption of fully developed conditions may not be satisfied. Recognize that the flow at the channel entrance may be highly turbulent because of the upstream fan swirl and ducting.

(2) What benefits could be realized by increasing the heat transfer coefficient? Aside from increasing velocity, what design changes would you make to increase h?

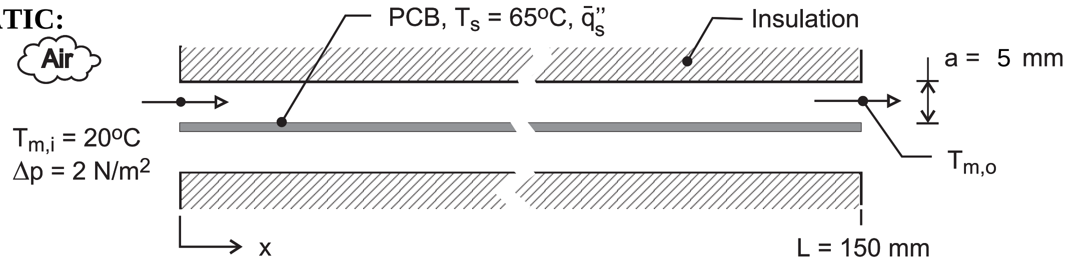
(3) Our assumption for $\overline{T}_m$ = 350 K at which to evaluate properties is reasonable considering T_m = (100.7 + 25)°C/2 = 335 K.

PROBLEM 8.92

KNOWN: Printed-circuit board (PCB) with uniform temperature T_s cooled by laminar, fully developed flow in a parallel-plate channel. The air flow with an inlet temperature of $T_{m,i}$ is driven by a pressure difference, Δp.

FIND: The average heat removal rate per unit area, $\bar{q}''_s \left(W/m^2\right)$, from the PCB.

SCHEMATIC:



ASSUMPTIONS: (1) Laminar, fully developed flow, (2) Upper and lower walls of the channel are insulated and of infinite extent in the transverse direction, (3) PCB has uniform surface temperature, (4) Constant properties, (5) Ideal gas with negligible viscous dissipation.

PROPERTIES: *Table A-4*, Air (T_m = 293 K, 1 atm): ρ = 1.192 kg/m^3, c_p = 1007 J/kg·K, ν = 1.531 × 10^{-5} m^2/s, k = 0.0258 W/m·K, Pr = 0.709.

ANALYSIS: The energy equations for determining the heat rate from one surface of the board are Eqs. 8.34 and 8.41b

$$q = \dot{m} c_p \left(T_{m,o} - T_{m,i}\right) = \bar{q}''_s A_s \tag{1}$$

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{P_h L \bar{h}}{\dot{m} c_p}\right) \tag{2}$$

where A_s = Lw and P = w, since heat transfer is only from one surface, where w is the width in the transverse direction. For the fully developed flow condition, the velocity is estimated from the friction pressure drop relation, Eq. 8.22a,

$$\Delta p = f\left(\rho u_m^2 / 2\right)\left(L / D_h\right) \tag{3}$$

where the hydraulic diameter for the channel cross section is

$$D_h = \frac{4 A_c}{P} = \frac{4(w\,a)}{2(w + a)} = 2a \qquad a << w$$

The friction factor f from Table 8.1 for the cross section b/a = ∞ is

$$f \cdot Re_{Dh} = 96 \tag{4}$$

where the Reynolds number is

$$Re_{Dh} = u_m D_h / \nu \tag{5}$$

Continued …

PROBLEM 8.92 (Cont.)

and the flow rate through one channel is

$$\dot{m} = \rho A_c u_m = \rho(wa)u_m \tag{6}$$

For fully developed laminar flow from Table 8.1.

$$\overline{Nu}_D = \bar{h} D_h / k = 4.86 \tag{7}$$

Substituting Eqs. (4) and (5) into Eq. (3) and solving for u_m yields

$$u_m = \Delta p D_h^2 / 48\nu\rho L = 2\,N/m^2 \times (0.01m)^2 / 48 \times 1.531\times10^{-5} m^2/s \times 1.192 kg/m^3 \times 0.15m = 1.52 m/s$$

$$Re = u_m D_h / \nu = 1.52 m/s \times 0.01m / 1.531\times10^{-5} m^2/s = 994$$

Thus the flow is laminar, as assumed. From Eqs. (6), (7), and (2), $\dot{m}/w = \rho u_m a = 1.192 kg/m^3 \times 1.52$ m/s × 0.005 m = 0.00907 kg/s·m. $\bar{h} = \overline{Nu}_D k / D_h = 4.86 \times 0.0258$ W/m·K/0.01m = 12.5 W/m^2·K. $T_{m,o} = T_s - (T_s - T_{m,i})\exp(-L\bar{h}/(\dot{m}/w)c_p)$ = 65°C - 45°Cexp(-0.15m × 12.5W/m^2·K/0.00907kg/s·m× 1007 J/kg·K) = 28.4°C.

From Eq. (1)

$$q' = \frac{\dot{m}}{w} c_p (T_{m,o} - T_{m,i}) = 0.00907 kg/m\cdot s \times 1007 J/kg\cdot K \times (28.4 - 20)°C = 76.5 W/m$$ <

$$q'' = q'/L = 510 W/m^2$$

COMMENTS: (1) The thermophysical properties of the air are evaluated at the average mean temperature, $\bar{T}_m = (T_{m,i} + T_{m,o})/2$.

(2) The fully developed flow length, $x_{fd,t}$, for the channel follows from Eq. 8.23,

$$x_{fd,t} = D_h \times 0.05 Re_{Dh} Pr$$

$$x_{fd,t} = 2 \times 0.010\ m \times 0.05 \times 7954 \times 0.709 = 5.6\ m$$

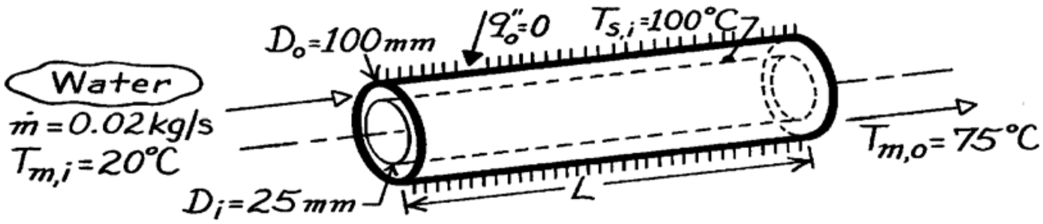
Since L << $x_{fd,t}$, we conclude that the flow is not likely to be fully developed.

PROBLEM 8.93

KNOWN: Surface thermal conditions and diameters associated with a concentric tube annulus. Water flow rate and inlet temperature.

FIND: (a) Length required to achieve desired outlet temperature, (b) Heat flux from inner tube at outlet.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Fully developed conditions throughout, (3) Adiabatic outer surface, (4) Uniform temperature at inner surface, (5) Constant properties, (6) Water is incompressible liquid with negligible viscous dissipation.

PROPERTIES: *Table A-6*, Water $\left(\overline{T}_m = 320\text{K}\right)$: c_p = 4180 J/kg·K, μ = 577 × 10^{-6} N·s/m^2, k = 0.640 W/m·K, Pr = 3.77.

ANALYSIS: (a) From Eq. 8.41a,

$$L = -\frac{\dot{m}\, c_p}{P\overline{h}} \ell n \frac{\Delta T_o}{\Delta T_i} = -\frac{\dot{m}\, c_p}{\pi\, D_i \overline{h}} \ell n \frac{T_s - T_{m,o}}{T_s - T_{m,i}}.$$

With $$Re_D = \frac{\rho\, u_m D_h}{\mu} = \frac{\dot{m}\left(D_o - D_i\right)}{(\pi/4)\left(D_o^2 - D_i^2\right)\mu} = \frac{4\,\dot{m}}{\pi\left(D_o + D_i\right)\mu}$$

$$Re_D = \frac{4 \times 0.02\text{ kg/s}}{\pi\left(0.125\text{m}\right)577 \times 10^{-6}\text{ N}\cdot\text{s/m}^2} = 353$$

the flow is laminar. Hence, from Eq. 8.69 and Table 8.2,

$$\overline{h} = h_i = \frac{k}{D_h}\text{Nu}_i = \frac{0.64\text{ W/m}\cdot\text{K}}{\left(0.100 - 0.025\right)\text{ m}} 7.37 = 63\text{ W/m}^2\cdot\text{K}$$

and $$L = -\frac{0.02\text{ kg/s}\left(4180\text{ J/kg}\cdot\text{K}\right)}{\pi\left(0.025\text{m}\right)63\text{ W/m}^2\cdot\text{K}} \ell n \frac{\left(100-75\right)^\circ\text{C}}{\left(100-20\right)^\circ\text{C}} = 19.7\text{ m.}$$ <

(b) From Eq. 8.67

$$q''_i\left(L\right) = h_i\left(T_{s,i} - T_{m,o}\right) = 63\frac{\text{W}}{\text{m}^2\text{.K}}\left(100-75\right)^\circ\text{C} = 1575\text{ W/m}^2.$$ <

COMMENTS: The total heat rate to the water is

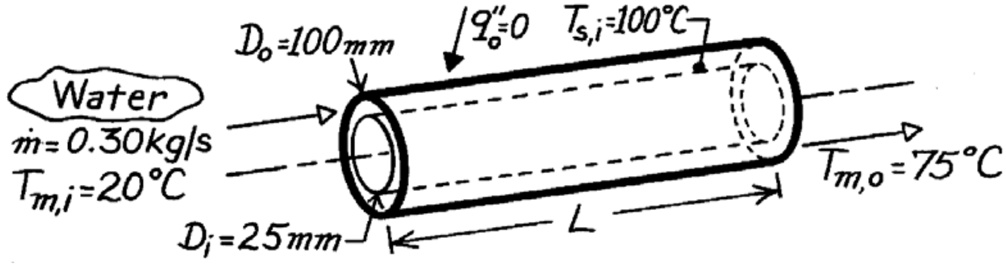
$$q = \dot{m}\, c_p\left(T_{m,o} - T_{m,i}\right) = 0.02\text{ kg/s} \times 4180\text{ J/kg}\cdot\text{K}\left(55^\circ\text{C}\right) = 4598\text{ W.}$$

PROBLEM 8.94

KNOWN: Surface thermal conditions and diameters associated with a concentric tube annulus. Water flow rate and inlet temperature.

FIND: Length required to achieve desired outlet temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Fully developed conditions throughout, (3) Adiabatic outer surface, (4) Uniform temperature at inner surface, (5) Constant properties, (6) Incompressible liquid with negligible viscous dissipation.

PROPERTIES: *Table A-6*, Water $\left(\bar{T}_m = 320\text{K}\right)$: $c_p = 4180$ J/kg·K, $\mu = 577 \times 10^{-6}$ N·s/m^2, k = 0.640 W/m·K, Pr = 3.77.

ANALYSIS: From Eq. 8.41a,

$$L = -\frac{\dot{m}\, c_p}{P\,\bar{h}} \ell n \frac{\Delta T_o}{\Delta T_i} = -\frac{\dot{m}\, c_p}{\pi\, D_i \bar{h}} \ell n \frac{T_s - T_{m,o}}{T_s - T_{m,i}}.$$

With

$$Re_D = \frac{\rho\, u_m D_h}{\mu} = \frac{\dot{m}\,\left(D_o - D_i\right)}{(\pi/4)\,\left(D_o^2 - D_i^2\right)\mu} = \frac{4\,\dot{m}}{\pi\left(D_o + D_i\right)\mu}$$

$$Re_D = \frac{4 \times 0.30 \text{ kg/s}}{\pi\left(0.125\text{m}\right)577 \times 10^{-6}\,\text{N}\cdot\text{s/m}^2} = 5296$$

and the flow is turbulent. Hence, from Eq. 8.60,

$$\bar{h} = \frac{k}{D_h} Nu_D = 0.023 \frac{k}{D_h} Re_D^{4/5}\, Pr^{0.4}$$

$$\bar{h} = 0.023 \frac{0.640 \text{ W/m}\cdot\text{K}}{0.075 \text{ m}} \left(5296\right)^{4/5} \left(3.77\right)^{0.4} = 318 \text{ W/m}^2\cdot\text{K}$$

and hence the required length is

$$L = -\frac{0.30 \text{ kg/s}\left(4180 \text{ J/kg}\cdot\text{K}\right)}{\pi\left(0.025\text{m}\right)\, 318 \text{ W/m}^2\cdot\text{K}} \ell n \frac{\left(100-75\right)^\circ \text{C}}{\left(100-20\right)^\circ \text{C}} = 58.4 \text{ m.}$$ <

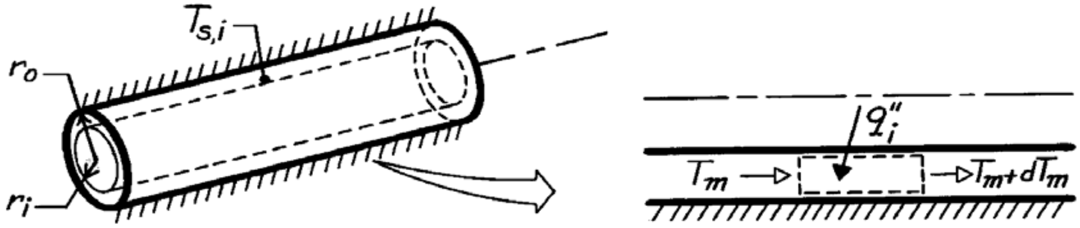
COMMENTS: (1) Increasing $\dot{m}$ by a factor of 15 increases Re_D accordingly, and the flow is turbulent. However, $\bar{h}$ increases by a factor of only 5 from the result of Problem 8.93, in which case the tube length must be a factor of 3 larger than that of Problem 8.93. (2) The Gnielinski correlation would be more accurate than the Dittus-Boelter correlation for the low (but turbulent) conditions suggested by the value of the Reynolds number.

PROBLEM 8.95

KNOWN: Inner and outer tube surface conditions for an annulus.

FIND: (a) Velocity profile, (b) Temperature profile and expression for inner surface Nusselt number.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Laminar, fully developed flow, (3) Uniform heat flux at inner surface, (4) Adiabatic outer surface, (5) Constant properties, (6) Applicability of Eq. 8.34.

ANALYSIS: (a) From Section 8.1.3, the general solution to Eq. 8.12, which also applies to annular flow as represented in Figure 8.11, is

$$u(r) = \frac{1}{\mu}\left(\frac{dp}{dx}\right)\frac{r^2}{4} + C_1 \ell n\, r + C_2.$$

Applying the boundary conditions,

$$u(r_i) = 0 \qquad 0 = \frac{1}{\mu}\left(\frac{dp}{dx}\right)\frac{r_i^2}{4} + C_1 \ell n r_i + C_2$$

$$u(r_o) = 0 \qquad 0 = \frac{1}{\mu}\left(\frac{dp}{dx}\right)\frac{r_o^2}{4} + C_1 \ell n r_o + C_2.$$

Hence,

$$C_1 = \frac{\frac{1}{\mu}\left(\frac{dp}{dx}\right)\left(\frac{r_o^2}{4} - \frac{r_i^2}{4}\right)}{\ell n\, r_i / r_o} \qquad C_2 = -\frac{1}{\mu}\left(\frac{dp}{dx}\right)\frac{r_o^2}{4} - \frac{1}{\mu}\left(\frac{dp}{dx}\right)\left(\frac{r_o^2}{4} - \frac{r_i^2}{4}\right)\frac{\ell n\, r_o}{\ell n\,(r_i / r_o)}$$

and the velocity distribution is

$$u(r) = \frac{1}{\mu}\left(\frac{dp}{dx}\right)\left(\frac{r^2}{4} - \frac{r_o^2}{4}\right) + \frac{1}{\mu}\left(\frac{dp}{dx}\right)\left(\frac{r_o^2}{4} - \frac{r_i^2}{4}\right)\frac{\ell n\, r}{\ell n\,(r_i / r_o)}$$

$$- \frac{1}{\mu}\left(\frac{dp}{dx}\right)\left(\frac{r_o^2}{4} - \frac{r_i^2}{4}\right)\frac{\ell n\, r_o}{\ell n\,(r_i / r_o)}$$

$$u(r) = -\frac{r_o^2}{4\mu}\left(\frac{dp}{dx}\right)\left[1 - (r/r_o)^2 + \frac{(r_i / r_o)^2 - 1}{\ell n\,(r_i / r_o)}\ell n(r/r_o)\right]. \qquad (1)$$ <

(b) For fully developed conditions with uniform surface heat flux,

$$v = 0 \qquad \partial T/\partial x = dT_m / dx = \text{const.}$$

Continued …

PROBLEM 8.95 (Cont.)

Hence, from Eq. 8.48, which also applies for annular flow,

$$\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial T}{\partial r}\right)=\frac{u}{\alpha}\frac{dT_m}{dx}$$

Substituting the velocity distribution, with

$$C_1=-\frac{r_o^2}{4\mu}\left(\frac{dp}{dx}\right) \qquad C_2=\frac{\left(r_i/r_o\right)^2-1}{\ell n\left(r_i/r_o\right)} \qquad (2)$$

it follows that $\frac{1}{r}\frac{\partial}{\partial r}\left(r\frac{\partial T}{\partial r}\right)=\frac{C_1}{\alpha}\frac{dT_m}{dx}\left[1-\left(r/r_o\right)^2+C_2\,\ell n\left(r/r_o\right)\right].$

$$r\frac{\partial T}{\partial r}=\frac{C_1}{\alpha}\frac{dT_m}{dx}\int\left[r-\frac{r^3}{r_o^2}+C_2 r\ell n\frac{r}{r_o}\right]dr+C_3$$

$$\frac{\partial T}{\partial r}=\frac{C_1}{\alpha}\frac{dT_m}{dx}\left[\frac{r}{2}-\frac{r^3}{4r_o^2}+C_2\left(\frac{r}{2}\ell n\frac{r}{r_o}-\frac{r}{4}\right)\right]+\frac{C_3}{r}$$

and the temperature distribution is

$$T(r)=\frac{C_1}{\alpha}\frac{dT_m}{dx}\left[\frac{r^2}{4}-\frac{r^4}{16\,r_o^2}+C_2\left(\frac{r^2}{4}\ell n\frac{r}{r_o}-\frac{r^2}{4}\right)\right]+C_3\,\ell nr+C_4. \qquad (3) <$$

From the requirement that $q_o''=0$, it follows that $\left.\partial T/\partial r\right)_{r_o}=0$. Hence,

$$\frac{C_1}{\alpha}\frac{dT_m}{dx}\left[\frac{r_o}{2}-\frac{r_o}{4}+C_2\left(-\frac{r_o}{4}\right)\right]+\frac{C_3}{r_o}=0$$

$$C_3=\frac{C_1}{\alpha}\frac{dT_m}{dx}\frac{r_o^2}{4}\left(C_2-1\right). \qquad (4) <$$

From the condition that $T(r_i) = T_{s,i}$, it follows that

$$C_4=T_{s,i}-\frac{C_1}{\alpha}\frac{dT_m}{dx}\left[\frac{r_i^2}{4}-\frac{r_i^4}{16\,r_o^2}+C_2\left(\frac{r_i^2}{4}\ell n\frac{r_i}{r_o}-\frac{r_i^2}{4}\right)\right]+C_3\,\ell nr_i. \qquad (5) <$$

From Eqs. 8.67 and 8.69, the inner surface Nusselt number is

$$Nu_i=\frac{h_i\,D_h}{k}=\frac{q_i''\,D_h}{k\left(T_{s,i}-T_m\right)}$$

where $D_h = 2(r_o - r_i)$. To obtain a workable form of Nu_i, the mean temperature T_m must be evaluated. This may be done by substituting Eqs. (1) and (3) into Eq. 8.26 and evaluating u_m by substituting Eq. (1) into Eq. 8.8. Since the integrations are long and tedious, they are not provided.

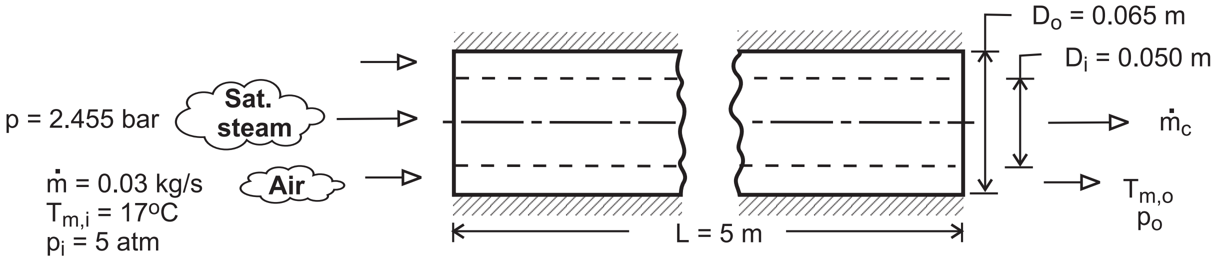
COMMENTS: From an energy balance performed for a differential control volume in the annular region, $dT_m/dx=2r_i q_i''/\rho\,c_p\,u_m\left(r_o^2-r_i^2\right)$.

PROBLEM 8.96

KNOWN: Inlet temperature, pressure and flow rate of air. Annulus length and tube diameters. Pressure of saturated steam.

FIND: Outlet temperature and pressure drop of air. Mass rate of steam condensation.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Outer surface of annulus is adiabatic, (3) Air is ideal gas with negligible viscous dissipation and pressure variation, (4) Fully developed flow throughout annulus, (5) Smooth annulus surfaces, (6) Constant properties.

PROPERTIES: *Table A-4*, air ($\overline{T}_m \approx 325$ K, p = 5 atm): $\rho = 5 \times \rho$ (1 atm) = 5.391 kg/m^3, c_p = 1008 J/kg·K, $\mu = 196.4 \times 10^{-7}$ N·s/m^2, k = 0.0281 W/m·K, Pr = 0.703. *Table A-6*, sat. steam (p = 2.455 bars): T_s = 400 K, h_{fg} = 2183 kJ/kg.

ANALYSIS: With a uniform surface temperature, the air outlet temperature is

$$T_{m,o} = T_s - \left(T_s - T_{m,i}\right)\exp\left(-\frac{\pi D_i L}{\dot{m}\, c_p}\overline{h}\right)$$

With $A_c = \pi\left(D_o^2 - D_i^2\right)/4 = 1.355\times10^{-3}\text{m}^2$, $D_h = D_o - D_i = 0.015\text{m}$ and $Re_D = \rho u_m D_h/\mu$ $= \dot{m}D_h/A_c\mu = 16,900$, the flow is turbulent and the Dittus-Boelter correlation yields

$$\overline{h} \approx h_{fd} = \left(\frac{k}{D_h}\right)0.023\,Re_D^{4/5}\,Pr^{0.4} = \left(\frac{0.0281\,\text{W/m}\cdot\text{K}}{0.015\text{m}}\right)0.023(16,900)^{4/5}(0.703)^{0.4} = 90.3\,\text{W/m}^2\cdot\text{K}$$

$$T_{m,o} = 127°\text{C} - (110°\text{C})\exp\left(-\frac{\pi\times0.05\text{m}\times5\text{m}\times90.3\,\text{W/m}^2\cdot\text{K}}{0.03\,\text{kg/s}\times1008\,\text{J/kg}\cdot\text{K}}\right) = 116.5°\text{C}$$ <

The pressure drop is $\Delta p = f\left(\rho u_m^2/2D_h\right)L$, where, with $u_m = \dot{m}/\rho A_c = 0.03\,\text{kg/s}/$ $\left(5.391\,\text{kg/m}^3\times1.355\times10^{-3}\text{m}^2\right) = 4.11\,\text{m/s}$, and with $Re_D = 16,900$, Eq. 8.21 yields f = [0.790ln(Re_D) – 1.64]$^{-2}$ = 0.027. Hence,

$$\Delta p \approx 0.027\times5.391\,\text{kg/m}^3\frac{(4.11\,\text{m/s})^2\,5\text{m}}{2\times0.015\text{m}} = 415\,\text{N/m}^2 = 4.1\times10^{-3}\text{ atm}$$ <

The rate of heat transfer to the air is

$$q = \dot{m}\,c_p\left(T_{m,o} - T_{m,i}\right) = 0.03\,\text{kg/s}\times1008\,\text{J/kg}\cdot\text{K}\,(99.5°\text{C}) = 3009\,\text{W}$$

and the rate of condensation is then

$$\dot{m}_c = \frac{q}{h_{fg}} = \frac{3009\,\text{W}}{2.183\times10^6\,\text{J/kg}} = 1.38\times10^{-3}\,\text{kg/s}$$ <

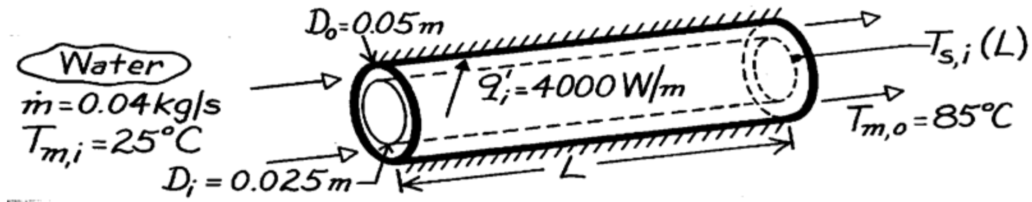
COMMENTS: (1) With $\overline{T}_m = \left(T_{m,i} + T_{m,o}\right)/2 = 340$ K, the initial estimate of 325 K is too low and an iterative solution should be obtained, (2) For a steam flow rate of 0.01 kg/s, approximately 14% of the outflow would be in the form of saturated liquid, (3) With L/D_h = 333, the assumption of fully developed flow throughout the tube is excellent.

PROBLEM 8.97

KNOWN: Dimensions and surface thermal conditions for a concentric tube annulus. Water flow rate and inlet temperature.

FIND: (a) Tube length required to achieve desired outlet temperature, (b) Inner tube surface temperature at outlet.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform heat flux at inner surface, (3) Adiabatic outer surface, (4) Fully developed flow at exit, (5) Constant properties, (6) Incompressible liquid with negligible viscous dissipation.

PROPERTIES: *Table A-6*, Water $\left(\overline{T}_m = 328K\right)$: c_p = 4183 J/kg·K; ($T_{m,o}$ = 358K): μ = 332 × 10^{-6} N·s/m^2, k = 0.673 W/m·K, Pr = 2.07.

ANALYSIS: (a) From the overall energy balance, Eq. 8.34,

$$q = q_i' L = \dot{m}\, c_p \left(T_{m,o} - T_{m,i}\right)$$

$$L = \frac{\dot{m}\, c_p \left(T_{m,o} - T_{m,i}\right)}{q_i'} = \frac{(0.04 \text{ kg/s})4183 \text{ J/kg}\cdot\text{K}(85-25)^\circ\text{C}}{4000 \text{ W/m}} = 2.51 \text{ m}.$$ <

(b) From Eqs. 8.1 and 8.5,

$$Re_D = \frac{\rho\, u_m D_h}{\mu} = \frac{\dot{m}\, D_h}{A_c \mu} = \frac{\dot{m}\left(D_o - D_i\right)}{(\pi/4)\left(D_o^2 - D_i^2\right)\mu} = \frac{4\,\dot{m}}{\pi\left(D_o + D_i\right)\mu}$$

$$Re_D = \frac{4 \times 0.04 \text{ kg/s}}{\pi(0.075 \text{ m})332 \times 10^{-6} \text{kg/s}\cdot\text{m}} = 2045.$$

Hence the flow is laminar, and with $D_i/D_o = 0.5$, it follows from Eq. 8.72 and Table 8.3

$$Nu_i = Nu_{ii} = 6.24$$

$$h_i = 6.24 \frac{k}{D_h} = 6.24 \frac{0.673 \text{ W/m}\cdot\text{K}}{0.025 \text{ m}} = 168 \text{ W/m}^2\cdot\text{K}.$$

From Eq. 8.67,

$$T_{s,i}(L) = T_{m,o} + \frac{q_i''}{h_i} = T_{m,o} + \frac{q_i'/\pi D_i}{h_i}$$

$$T_{s,i}(L) = 85^\circ\text{C} + \frac{4000 \text{ W/m}}{\pi(0.025\text{m})\ 168 \text{ W/m}^2\cdot\text{K}} = 388^\circ\text{C}.$$ <

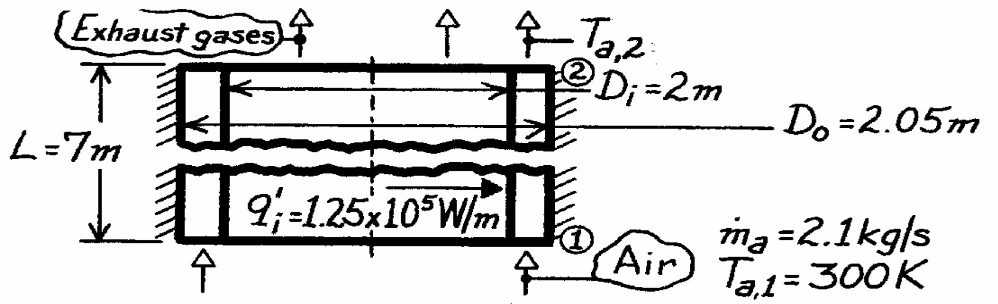
COMMENTS: Unless the water is pressurized, local boiling would occur at the tube surface, causing h_i to be larger.

PROBLEM 8.98

KNOWN: Heat rate per unit length at the inner surface of an annular recuperator of prescribed dimensions. Flow rate and inlet temperature of air passing through annular region.

FIND: (a) Temperature of air leaving the recuperator, (b) Inner pipe temperature at inlet and outlet and outer pipe temperature at inlet.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Uniform heating of recuperator inner surface, (4) Adiabatic outer surface, (5)Air is ideal gas with negligible viscous dissipation and pressure variation, (6) Fully developed air flow throughout.

PROPERTIES: *Table A-4*, Air (given): $c_p = 1030$ J/kg·K, $\mu = 270 \times 10^{-7}$ N·s/m^2, k = 0.041 W/m·K, Pr = 0.68.

ANALYSIS: (a) From an energy balance on the air

$$q_i' \, L = \dot{m}_a \, c_{p,a} \left(T_{a,2} - T_{a,1}\right)$$

$$T_{a,2} = T_{a,1} + \frac{q_i' \, L}{\dot{m}_a \, c_{p,a}} = 300\text{ K} + \frac{1.25 \times 10^5 \text{W/m} \times 7\text{m}}{2.1\text{ kg/s} \times 1030\text{ J/kg} \cdot \text{K}} = 704.5\text{ K.}$$ <

(b) The surface temperatures may be evaluated from Eqs. 8.67 and 8.68 with

$$Re_D = \frac{\rho \, u_m D_h}{\mu} = \frac{\dot{m}_a \, \left(D_o - D_i\right)}{(\pi/4) \, \left(D_o^2 - D_i^2\right)\mu} = \frac{4 \, \dot{m}_a}{\pi\left(D_o + D_i\right)\mu} = \frac{4\left(2.1\text{ kg/s}\right)}{\pi\left(4.05\text{m}\right) \, 270 \times 10^{-7} \text{N} \cdot \text{s/m}^2}$$

$$Re_D = 24{,}452$$

the flow is turbulent and from Eq. 8.60

$$h_i \approx h_o \approx \frac{k}{D_h} 0.023 \, Re_D^{4/5} \, Pr^{0.4} = \frac{0.041\text{ W/m} \cdot \text{K}}{0.05\text{ m}} 0.023\left(24{,}452\right)^{4/5}\left(0.68\right)^{0.4} = 52\text{ W/m}^2 \cdot \text{K.}$$

With $\quad q_i'' = q_i' / \pi \, D_i = 1.25 \times 10^5 \text{W/m}/\pi \times 2\text{m} = 19{,}900\text{ W/m}^2$

Eq. 8.67 gives

$$\left(T_{s,i} - T_m\right) = q_i'' / h_i = 19{,}900\text{ W/m}^2 / 52\text{ W/m}^2 \cdot \text{K} = 383\text{K}$$

$$T_{s,i,1} = 683\text{K} \qquad T_{s,i,2} = 1087\text{K.}$$ <

From Eq. 8.68, with $q_o'' = 0$, $\left(T_{s,o} - T_m\right) = 0$. Hence

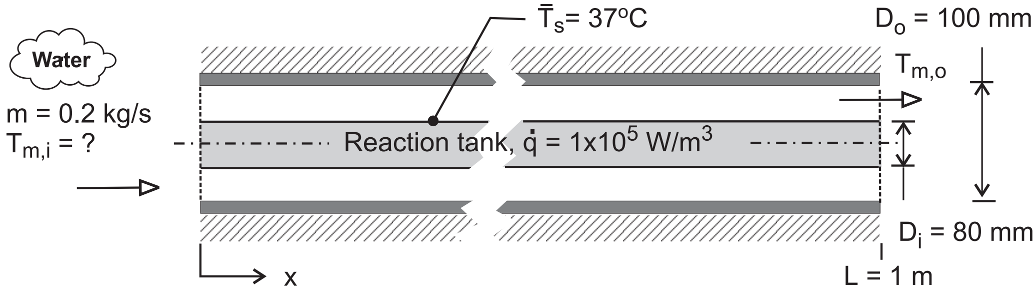
$$T_{s,o,1} = T_{a,1} = 300\text{K.}$$ <

PROBLEM 8.99

KNOWN: A concentric tube arrangement for removing heat generated from a biochemical reaction in a settling tank. Water is supplied to the annular region at rate of 0.2 kg/s.

FIND: (a) The inlet temperature of the supply water that will provide for an average tank surface temperature of 37°C; assume and then justify fully developed flow and thermal conditions; and (b) Sketch the water and surface temperatures along the flow direction for two cases: the fully developed conditions of part (a), and when entrance effects are important. Comment on the features of the temperature distributions, with particular attention to the longitudinal gradient on the tank surface. What change to the system or operating conditions would you make to reduce the gradient?

SCHEMATIC:



ASSUMPTIONS: (1) Fully developed flow and thermal conditions, (2) Inner annulus surface has uniform heat flux, while outer surface is insulated, (3) Constant properties, (4) Incompressible liquid with negligible viscous dissipation.

PROPERTIES: *Table A-6*, Water (T_m = 304 K): ρ = 995.6 kg/m^3, c_p = 4178 J/kg·K, $\nu = 7.987 \times 10^{-7}$ m^2/s, k = 0.618 W/m·K, Pr = 5.39.

ANALYSIS: (a) The overall energy balance on the fluid passing through the concentric tube is

$$q = \dot{m}\, c_p \left(T_{m,i} - T_{m,o}\right) \qquad (1)$$

and from an energy balance on the reaction tank,

$$q = \dot{q}(\pi D_i^2 / 4)/L = 1 \times 10^5 \mathrm{W/m^3} (\pi (0.08\mathrm{m})^2 / 4) \times 1\mathrm{m} = 503\mathrm{W}. \qquad (2)$$

The convection rate equation applied to the inner surface $A_{s,i}$ is

$$q = \overline{h_i} A_{s,i} (\overline{T_s} - \overline{T_m}) = \overline{h_i} \pi D_i L (\overline{T_s} - \overline{T_m}) \qquad (3)$$

where $\overline{T}_s$ is the average inner surface temperature and

$$\overline{T_m} = \left(T_{m,i} + T_{m,o}\right)/2. \qquad (4)$$

To estimate $\overline{h}$, begin by characterizing the flow with

$$Re_{Dh} = u_m D_h / \nu \qquad D_h = D_o - D_i \qquad \dot{m} = \rho A_c u_m$$

where $A_c = \pi\left(D_o^2 - D_i^4\right)/4$. Substituting numerical values find

$$Re_{Dh} = 1779$$

Assuming fully developed conditions for laminar flow through an annulus, it follows from Table 8.3 and Eq. 8.72 with D_i/D_o = 0.8,

$$\overline{Nu}_i = \overline{h}_i D_h / k = 5.58 \qquad \overline{h}_i = 172 \ \mathrm{W/m^2 \cdot K}$$

Continued …

PROBLEM 8.99 (Cont.)

Using Eq. (3) with $\bar{h}_i$, and $\bar{T}_s = 37°C$, and q from Eq. (2), find

$$\overline{T_m} = 25.4°C$$

From Eqs. (1) and (4), calculate

$$T_{m,i} = 25.1°C \qquad T_{m,o} = 25.7°C$$ <

For this annulus, the thermal entry length from Eq. 8.23 is

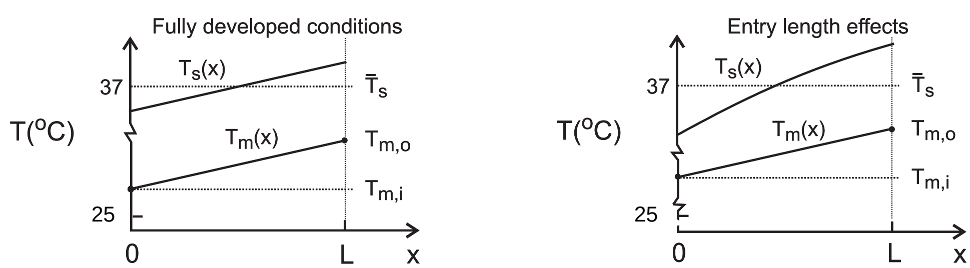
$$x_{fd,t} = D_h \times 0.05\, Re_{Dh}\, Pr$$

$$x_{fd,t} = (0.100 - 0.080)\,m \times 0.05 \times 1779 \times 5.39 = 9.59\ m$$

Since L = 1 m, we conclude that entry length effects are significant, and the fully developed flow assumption is approximate.

(b) Since the fluid is being heated by flow over a surface with uniform heat flux, the mean fluid temperature, $T_m(x)$, will increase linearly with longitudinal distance x. Assuming fully developed conditions, the surface temperature $T_s(x)$ will likewise increase linearly with distance as shown in the schematic below. Note that the longitudinal temperature difference is about 0.6°C, and that the inlet mean temperature is 25.1°C.

Considering now entrance length effects, the convection coefficient is no longer uniform, and will be largest near the entrance, and larger than for the fully developed flow everywhere. Hence, we expect the surface temperature near the entrance to be closer to the mean fluid temperature than elsewhere. We also expect the average mean temperature of the fluid will be higher so that the average surface temperature, $\bar{T}_s$, remains at 37°C. However, the rise in temperature of the fluid ($T_{m,o} - T_{m,i}$) will remain the same, about 0.6°C, since the heat removal rate is the same. Increasing the flow rate will tend to minimize the longitudinal gradient by reducing ($T_{m,o} - T_{m,i}$) and increasing h(x). The graph below illustrates the distinctive features of the fully developed flow and entrance length effects.



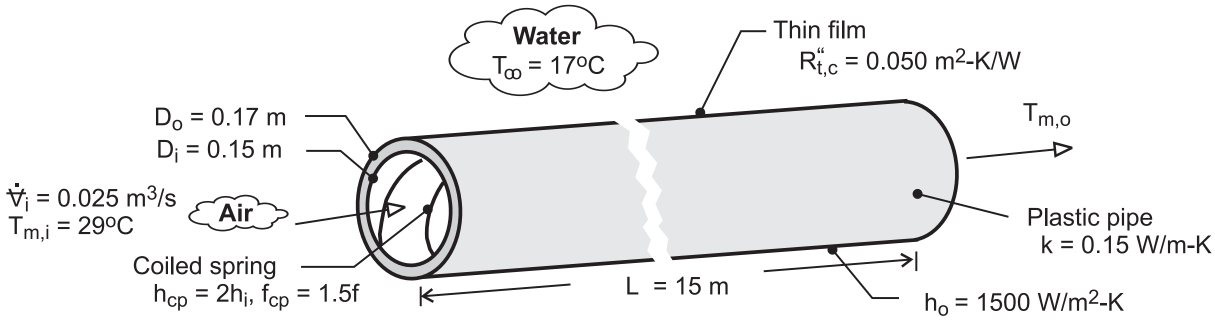
COMMENTS: The thermophysical properties required in the convection correlation and the energy equations should be evaluated at $T_m = (T_{m,i} + T_{m,o})/2 \approx 298$ K.

PROBLEM 8.100

KNOWN: Dimensions and thermal conductivity of plastic pipe. Volumetric flow rate and temperature of inlet air. Enhancement of inner convection coefficient and friction factor associated with coiled spring. Thermal resistance of coating on outer surface.

FIND: (a) Air outlet temperature and fan power requirement without coating and coiled spring, (b) Effect of coiled spring on air outlet temperature and fan power, (c) Effect of coating on outlet temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Negligible heat transfer from air in vertical pipe sections, (3) Air is ideal gas with negligible viscous dissipation and pressure variation, (4) Smooth interior surface without spring, (5) Negligible coating thickness, (6) Constant properties.

PROPERTIES: *Table A-4*, Air ($T_{m,i}$ = 29°C): ρ_i = 1.155 kg/m^3. Air ($\bar{T}_m \approx 25°C$): c_p = 1007 J/kg·K, $\mu = 183.6 \times 10^{-7}$ N·s/m^2, k_a = 0.0261 W/m·K, Pr = 0.707.

ANALYSIS: (a) From Eq. (8.45a),

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp\left(-\frac{\bar{U}A_s}{\dot{m}\,c_p}\right)$$

where, from Eqs. (3.36) and (3.37),

$$\left(\bar{U}A_s\right)^{-1} = R_{tot} = \frac{1}{\bar{h}_i \pi D_i L} + \frac{\ln\left(D_o / D_i\right)}{2\pi L k} + \frac{1}{h_o \pi D_o L}$$

With $\dot{m} = \rho_i \dot{\forall}_i = 0.0289\,\text{kg/s}$ and $Re_D = 4\dot{m}/\pi D_i \mu = 13,350$, the pipe flow is turbulent. With L/D_i = 100, we may assume fully developed flow throughout the pipe, and from Eq. (8.60),

$$\bar{h}_i = \frac{ka}{D_i} 0.023 Re_D^{4/5} Pr^{0.3} = \frac{0.0261\,W/m\cdot K}{0.15m} 0.023(13,350)^{4/5}(0.707)^{0.3} = 7.20\,W/m^2\cdot K$$

Hence, $$R_{tot} = \left(\frac{1}{7.20\times\pi\times0.15\times15} + \frac{\ln(0.17/0.15)}{2\pi\times15\times0.15} + \frac{1}{1500\times\pi\times0.17\times15}\right)\frac{K}{W}$$

$$R_{tot} = (0.0196 + 0.0089 + 0.0001)\,K/W = 0.0286\,K/W$$

Hence, $\bar{U}A_s = R_{tot}^{-1} = 35.0\,W/K$ and

$$T_{m,o} = T_\infty + \left(T_{m,i} - T_\infty\right)\exp\left(-\frac{\bar{U}A_s}{\dot{m}\,c_p}\right) = 17°C + (12°C)\exp\left(-\frac{35.0\,W/K}{0.0289\,kg/s \times 1007\,J/kg\cdot K}\right) = 20.6°C \quad <$$

Continued …

PROBLEM 8.100 (Cont.)

From Eq. (8.21), $f = [0.790\ln(Re_D) - 1.64]^{-2} = 0.0291$. Hence, from Eqs. (8.22a) and (8.22b), with $u_{m,i} = \dot{\forall}_i / A_c = 1.415\,m/s$,

$$P \approx f \frac{\rho_i u_{m,i}^2}{2 D_i} L \dot{\forall}_i = 0.0291 \frac{1.155\,kg/m^3 (1.415\,m/s)^2}{2(0.15m)} 15m \times 0.025\,m^3/s = 0.084\,W$$ <

(b) With $h_{cp} = 2h_i = 14.4\ W/m^2 \cdot K$, the inner convection resistance is reduced from 0.0196 K/W to 0.0098 K/W and hence the total resistance from 0.0286 K/W to 0.0188 K/W. It follows that $\overline{U}A_s = 53.2\,W/K$ and

$$T_{m,o} = 18.9°C$$ <

With $f_{cp} = 1.5f$,

$$P = 0.126\,W$$ <

(c) With the coating of organic matter, there is an additional thermal resistance of the form $R_{t,c} = R''_{t,c} / (\pi D_o L) = (0.05\,m^2 \cdot K/W) / (\pi \times 0.17m \times 15m) = 0.0062\,K/W$. The total resistance is then R_{tot} = 0.0348 K/W and $\overline{U}A_s = 28.7\,W/K$. Hence,

$$T_{m,o} = 21.5°C$$ <

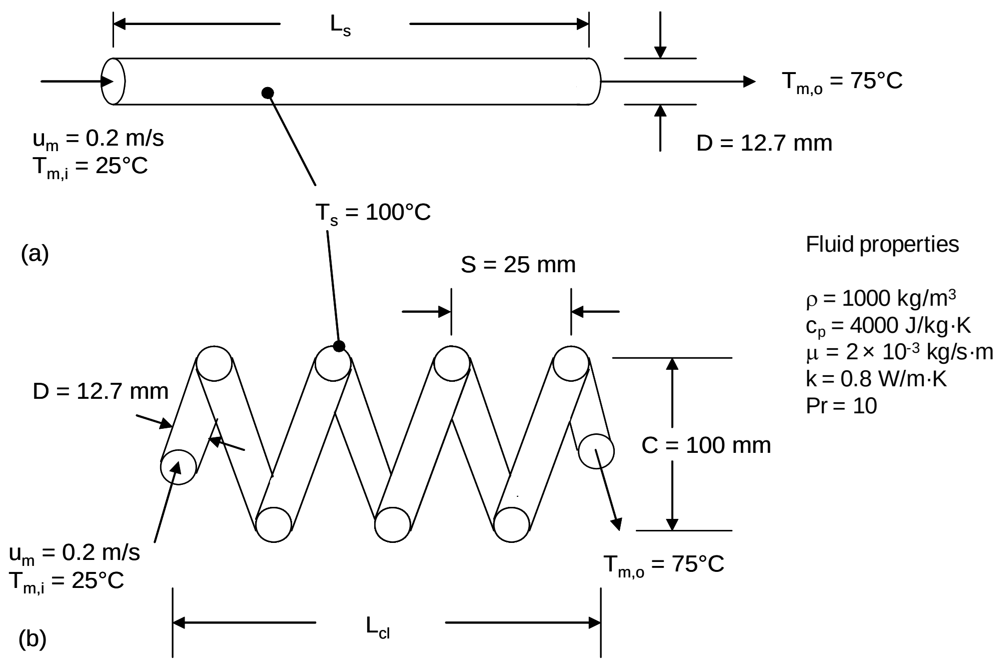
COMMENTS: (1) The fan power requirement is small, and the process is economical, with or without the coiled spring. (2) Heat transfer enhancement associated with the coiled spring is manifested by a 34% reduction in the total thermal resistance and a 1.7°C reduction in the outlet temperature. (3) *Fouling* of the outer surface increases the total resistance by 22% and the outlet temperature by 0.9°C. The penalty is not severe but could be ameliorated by periodic cleaning of the surface.

PROBLEM 8.101

KNOWN: Inlet and desired outlet temperature of a pharmaceutical fluid flowing in a straight tube or coiled tube of known diameter. Inlet velocity and tube surface temperature.

FIND: (a) Length of straight tube needed to achieve the desired outlet temperature, (b) Length of coiled tube to achieve the desired outlet temperature, (c) Pressure drops associated with the straight and coiled tubes, (d) Steam condensation rate.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Incompressible liquid and negligible viscous dissipation, (3) Steady-state conditions, (4) fully developed hydrodynamic conditions at the entrance.

PROPERTIES: Steam (Table A.6): h_{fg} (T = 100°C) = 2257 kJ/kg. Pharmaceutical (given): ρ = 1000 kg/m^3, c_p = 4000 J/kg·K, $\mu = 2 \times 10^{-3}$ kg/s·m, k = 0.80 W/m·K, Pr = 10.

ANALYSIS:

(a) From Problem 8.27, $Re_D = \rho u_m D/\mu = 1270$ and the flow is laminar for both cases. Hence, augmentation is expected to occur in the coiled tube. For the straight tube case a, the Hausen correlation is written as

$$\overline{Nu}_D = \frac{\bar{h}D}{k} = 3.66 + \frac{0.0668 \times (D/L_s)\, Re_D Pr}{1 + 0.04\left[(D/L_s)\, Re_D Pr\right]^{2/3}}$$

which may be rearranged to yield

PROBLEM 8.101 (Cont.)

$$\bar{h} = \frac{k}{D}\left\{3.66 + \frac{0.0668\ (D/L_s)\,Re_D Pr}{1 + 0.04\left[(D/L_s)\ Re_D Pr\right]^{2/3}}\right\}$$

$$\bar{h} = \frac{0.80\ \text{W/mK}}{12.7 \times 10^{-3}\ \text{m}}\left\{3.66 + \frac{0.0668(12.7 \times 10^{-3}\ \text{m}/L_s) \times 1270 \times 10}{1 + 0.04\left[\left(12.7 \times 10^{-3}\ \text{m}/L_s\right) \times 1270 \times 10\right]^{2/3}}\right\} \qquad (1)$$

From Problem 8.27 $\dot{m} = 0.0253$ kg/s and the tube perimeter is
$P = \pi D = \pi \times 12.7 \times 10^{-3}\ \text{m} = 39.9 \times 10^{-3}\ \text{m}$

Equation 8.41b may be written

$$\frac{100°C - 75°C}{100°C - 25°C} = \exp\left(-\frac{39.9 \times 10^{-3}\text{m} \times L_s}{0.0253\ \text{kg/s} \times 4000\ \text{J/kg}\cdot\text{K}} \times \bar{h}\right) \qquad (2)$$

Equations (1) and (2) may be solved simultaneously to yield

$L_s = 9.77$ m, ($\bar{h}$ = 286 W/m^2·K) <

(b) For the coiled tube,

$$Re_D(D/C)^{1/2} = 1270 \times (12.7/100)^{1/2} = 452.6$$

Therefore, C/D = 100/12.7 = 7.87 > 3, Equation 8.77 yields

$$a = \left(1 + \frac{957(C/D)}{Re_D^2 Pr}\right) = \left(1 + \frac{957 \times (100/12.7)}{1270^2 \times 10}\right) = 1.0005$$

$$b = 1 + \frac{0.477}{Pr} = 1 + \frac{0.477}{10} = 1.0477$$

Therefore Equation 8.76 becomes

$$Nu_D = \left[\left(3.66 + \frac{4.343}{1.0005}\right)^3 + 1.158 \times \left(\frac{1270 \times (12.7/100)^{1/2}}{1.0477}\right)^{3/2}\right]^{1/3} = 22.18$$

Therefore,

$$h = Nu_D \frac{k}{D} = 22.18 \times \frac{0.80\ \text{W/m}\cdot\text{K}}{12.7 \times 10^{-3}\ \text{m}} = 1397\ \text{W/m}^2\cdot\text{K}$$

Equation 8.41b may be written

Continued…

PROBLEM 8.101 (Cont.)

$$\frac{100°C - 75°C}{100°C - 25°C} = \exp\left(-\frac{3.99 \times 10^{-3} m \times L_c}{0.0253\ kg/s \times 4000\ J/kg \cdot K} \times 1397\ W/m^2 \cdot K\right)$$

or $L_c = 2.00$ m

The number of coil turns is $N = \frac{L_c}{\pi C} = \frac{2.00\ m}{\pi \times 100 \times 10^{-3}\ m} = 6.4$

The coil length is $L_{cl} = NS = 6.4 \times 25 \times 10^{-3}\ m = 159 \times 10^{-3}\ m = 159\ mm$ <

(c) The flow is hydrodynamically fully-developed in the straight tube. From Equations 8.19 and 8.22a,

$$\Delta p_s = \frac{64}{Re_D}\frac{\rho u_m^2}{2D}L_s = \frac{64}{1270} \times \frac{1000\ kg/m^3 \times (0.2\ m/s)^2}{2 \times 12.7 \times 10^{-3}\ m} \times 9.77\ m = 775\ N/m^2$$ <

For the coiled tube, Equation 8.75b is

$$f = \frac{7.2}{Re_D^{0.5}}(D/C)^{0.25} = \frac{7.2}{1270^{0.5}} \times \left(\frac{12.7}{100}\right)^{0.25} = 0.121$$

$$\Delta p_c = f\frac{\rho u_m^2}{2D}L_c = 0.121 \times \frac{1000\ kg/m^3 \times (0.2\ m/s)^2}{2 \times 12.7 \times 10^{-3}\ m} \times 2.00\ m = 379\ N/m^2$$ <

(d) The steam condensation rate, $\dot{m}_{st}$, is

$$\dot{m}_{st} h_{fg} = \dot{m} c_p (T_{m,o} - T_{m,i}) = u_m \rho A c_p (T_{m,o} - T_{m,i})$$

or

$$\dot{m}_{st} = \frac{0.2\ m/s \times 1000\ kg/m^3 \times \pi \times (12.7 \times 10^{-3}\ m)^2 \times 4000\ J/kg \cdot K \times (75-25)°C}{4 \times 2257 \times 10^3\ J/kg}$$

$$\dot{m}_{st} = 2.25 \times 10^{-3}\ kg/s$$ <

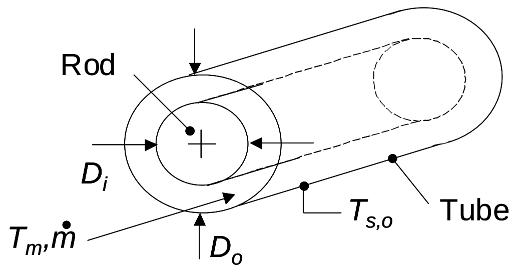
COMMENTS: (1) For the straight tube, $x_{fd,t} = 0.05 Re_D Pr D = 0.05 \times 1270 \times 10 \times 12.7 \times 10^{-3}$ m = 8m. The value of the entrance length for the coiled tube will be 20 to 50 percent shorter than for the straight tube or between approximately 4 and 6 m. The flow in the coiled tube is not fully developed, and actual heat transfer rates will exceed those predicted using Equation 8.76. (2) The coiled tube requires (2/9.77) × 100 = 20 percent of the tube length relative to the straight tube case. (3) The coil length is (0.159/9.77) × 100 = 1.6 percent that of the straight tube. (4) The pressure drop in the coiled tube is (379/775) × 100 = 48 percent that of the straight tube. (5) The coiled tube will induce secondary flow in the pharmaceutical, thereby reducing radial temperature gradients in the liquid.

PROBLEM 8.102

KNOWN: Laminar flow within a tube of diameter D_o. Inner rod diameter, D_i. Mean fluid temperature, T_m, and tube wall temperature, $T_{s,o}$.

FIND: Ratio of heat transfer from the fluid to the tube wall for D_i/D_o = 0, 0.10, 0.25 and 0.50.

SCHEMATIC:



ASSUMPTIONS: (1) Fully developed, laminar flow, (2) Constant properties, (3) Negligible conduction in the rod.

ANALYSIS: A control volume analysis about the inner rod reveals that there is no heat transfer to or from the rod. Hence, it acts as an insulated surface. Equation 8.68 may be written for the tube where, from Equation 8.70 $h_o = Nu_o k/D_h = Nu_o k/(D_o - D_i)$. Hence,

$$q''_o = \frac{Nu_o k\left(T_{s,o} - T_m\right)}{D_o(1 - D_i / D_o)} \quad (1)$$

Without the rod, $D_i/D_o = 0$ and $Nu_o = 3.66$, yielding

$$q''_{o,\text{wo}} = \frac{Nu_o k(T_{s,o} - T_m)}{D_o} = \frac{3.66k(T_{s,o} - T_m)}{D_o} \quad (2)$$

Hence, $$q''_o / q''_{o,\text{wo}} = \frac{Nu_o}{3.66(1 - D_i / D_o)}$$

From Table 8.2,

D_i/D_o	Nu_o	$q''_o / q''_{o,\text{wo}}$
0	3.66	1
0.10	4.11	1.25
0.25	4.23	1.54
0.50	4.43	2.42

<

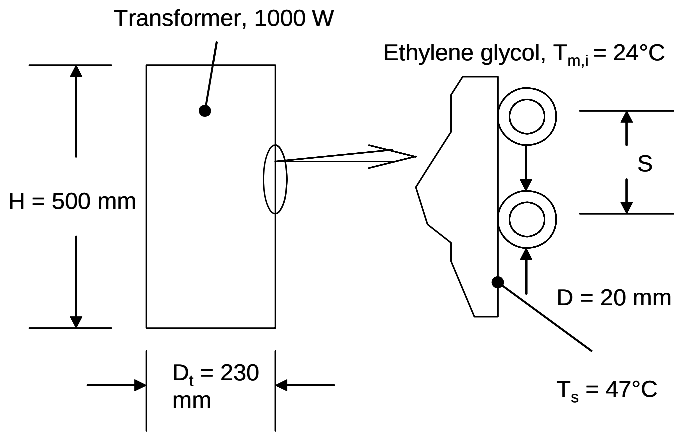
COMMENTS: (1) The proposed scheme enhances the heat transfer between the fluid and the tube wall, (2) The fluid temperature will change as the fluid flows in the axial direction. If the rod is of relatively high thermal conductivity compared to the fluid, the rod will be at a nearly uniform temperature. Hence, the rod could no longer be considered an insulated surface, since it would cool the fluid in upstream locations, and heat the fluid further downstream for the case where the fluid enters the annular region at a temperature higher than that of the tube wall.

PROBLEM 8.103

KNOWN: Tubing with ethylene glycol welded to transformer to remove dissipated power. Maximum allowable coolant temperature rise of 6°C.

FIND: Required coolant flow rate, tube length and lateral spacing of turns.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Incompressible liquid and negligible viscous dissipation, (3) Steady-state conditions, (4) Negligible tube wall thermal resistance, (5) Fully-developed flow, (6) All heat dissipated by transformer is transferred to ethylene glycol.

PROPERTIES: Table A.5, ethylene glycol: ($\overline{T}_m$ = 300 K, assumed): k = 0.252 W/m·K, c_p = 2415 J/kg·K, $\mu_f = 1.57 \times 10^{-2}$ N·s/m^2, Pr = 1151.

ANALYSIS: From an overall energy balance, the required flow rate is

$$q = \dot{m}c_p(T_{m,o} - T_{m,i}) \text{ or } \dot{m} = q/c_p(T_{m,o} - T_{m,i})$$

$$\dot{m} = 1000\ \text{W}/\left(2415\ \text{J/kg}\cdot\text{K} \times 6\text{K}\right)$$

$$\dot{m} = 6.90 \times 10^{-2}\ \text{kg/s}$$ <

From Equation 8.41a the length of tubing may be determined,

$$L = -\frac{\dot{m}c_p}{P\bar{h}}\ln\left(\frac{T_s - T_{m,o}}{T_s - T_{m,i}}\right)$$

where P = πD. For the tube flow, find

$$Re_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4 \times 6.90 \times 10^{-2}\ \text{kg/s}}{\pi \times 0.020\ \text{m} \times 1.57 \times 10^{-2}\ \text{N}\cdot\text{S/m}^2} = 279.8$$

$$C/D = (D_t + D) = 250/20 = 12.5;\ Re_D(D/C)^{1/2} = 279.8 \times (20/250)^{1/2} = 79.1$$

Equation 8.77 yields

Continued…

PROBLEM 8.103 (Cont.)

$$a = \left(1 + \frac{957 \times (250/20)}{(279.8)^2 \times 1151}\right) = 1.0001$$

$$b = 1 + \frac{0.477}{1151} = 1.0004$$

Therefore, Equation 8.76 is

$$Nu_D = \left[\left(3.66 + \frac{4.343}{1.0001}\right)^3 + 1.158\left(\frac{279.8 \times (20/250)^{1/2}}{1.0004}\right)^{3/2}\right]^{1/3}$$

$$= 10.99$$

$$\overline{h} = h = Nu_D \frac{k}{D} = 10.99 \times 252 \times 10^{-3}\ \text{W/m} \cdot \text{K}/20 \times 10^{-3}\text{m} = 138.5\ \text{W/m}^2 \cdot \text{K}$$

Equation 8.41a becomes

$$L = -\frac{6.90 \times 10^{-2}\text{kg/s} \times 2415\ \text{J/kg} \cdot \text{K}}{\pi \times 0.02\ \text{m} \times 138.5\ \text{W/m}^2 \cdot \text{K}} \ln\left(\frac{(47 - 30)°\text{C}}{(47 - 24)°\text{C}}\right) = 5.79\ \text{m}$$ <

The number of turns of the tubing, N, is $N = L/\pi D = 5.79\ \text{m}/\ \pi(0.25\ \text{m}) = 7.37$ and hence the spacing, S, is

$$S = H/N = 500\ \text{mm}/7.37 = 67.8\ \text{mm}$$ <

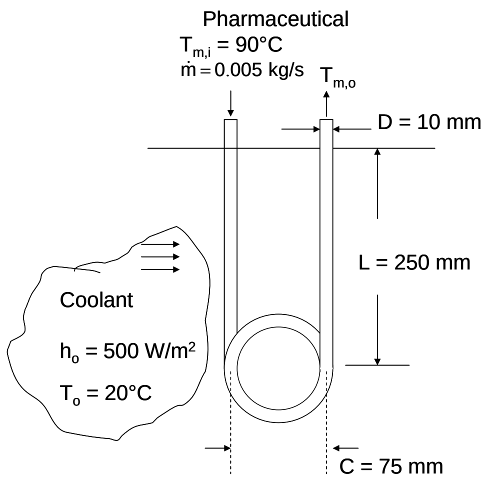
COMMENT: (1) Coiling the tube results in a convective heat transfer coefficient that is 10.99/3.66 = 3 times larger than the fully-developed value for a straight tube. (2) For a straight tube, the thermal entrance length is $x_{fd,t} = 0.05Re_D PrD = 0.05 \times 279.8 \times 1151 \times 0.02\ \text{m} = 322\ \text{m}$. The flow will not be fully-developed, and care must be taken when using the predictions.

PROBLEM 8.104

KNOWN: Geometry and dimensions of a tube with straight and coiled sections. Temperature and convection coefficient of coolant flowing outside the tube. Inlet temperature, mass flow rate, and properties of pharmaceutical fluid in tube.

FIND: (a) Outlet temperature of pharmaceutical, (b) Outlet temperature with inner heat transfer coefficient doubled in straight sections, (c) Effect of left- or right-handed spiral.

SCHEMATIC:



ASSUMPTIONS: (1) Tube wall thermal resistance is negligible. (2) Flow is fully-developed in coiled section. (3) Flow in last straight section is unaffected by swirl introduced in coiled section. (4) Constant properties.

PROPERTIES: Pharmaceutical fluid (given): $\rho = 1200\ \text{kg/m}^3$, $\mu = 4 \times 10^{-3}\ \text{N·s/m}^2$, $c_p = 2000\ \text{J/kg·K}$, $k = 0.5\ \text{W/m·K}$, $Pr = \mu c_p/k = 16$.

ANALYSIS:

(a) The Reynolds number is

$$Re_D = \frac{4\,\dot{m}}{\pi D \mu} = \frac{4 \times 0.005\ \text{kg/s}}{\pi \times 0.01\ \text{m} \times 4 \times 10^{-3}\,\text{N}\cdot\text{s/m}^2} = 159$$

Thus the flow is laminar.

<u>1st Straight Section.</u> The development length in the straight section is

$$x_{fd,h} = 0.05\,Re_D\,D = 0.05 \times 159 \times 0.01\ \text{m} = 0.08\ \text{m}$$

$$x_{fd,t} = x_{fd,h} \cdot Pr = 0.08\ \text{m} \times 16 = 1.3\ \text{m}$$

The flow is thermally developing. With Pr > 5, we can use Equation 8.57 with Equation 8.56,

$$\overline{Nu}_D = 3.66 + \frac{0.0668\,(D/L)\,Re_D\,Pr}{1 + 0.04\left[(D/L)\,Re_D\,Pr\right]^{2/3}} = 7.29$$

Thus $h_i = \overline{Nu}_D k/D = 7.29 \times 0.5\ \text{W/m}\cdot\text{K}/0.01\ \text{m} = 365\ \text{W/m}^2\cdot\text{K}$.

Continued…

PROBLEM 8.104 (Cont.)

The mean temperature at the end of the first straight section can be found from Equation 8.45a,

$$T_{m,o1} = T_\infty + (T_{m,i} - T_\infty) \exp\left(-\frac{\overline{U}A_s}{\dot{m}c_p}\right)$$

where $\overline{U} = \left[1/h_i + 1/h_o\right]^{-1} = \left[1/365 \text{ W/m}^2\cdot\text{K} + 1/500 \text{ W/m}^2\cdot\text{K}\right]^{-1} = 211 \text{ W/m}^2\cdot\text{K}$.

Thus $\quad T_{m,o1} = 20°\text{C} + (90°\text{C} - 20°\text{C}) \exp\left(-\frac{211 \text{ W/m}^2\cdot\text{K} \times \pi \times 0.01 \text{ m} \times 0.25 \text{ m}}{0.005 \text{ kg/s} \times 2000 \text{ J/kg}\cdot\text{K}}\right) = 79.3°\text{C}$

Coiled Section. The critical Reynolds number in the coiled section is given by Equation 8.74,

$$Re_{D,C,h} = Re_{D,C}\left[1 + 12(D/C)^{0.5}\right]$$

where $Re_{D,C} = 2300$. Since this must be greater than 2300, the flow in the coiled section, with Re_D = 159, is still laminar. The length of the coiled section is 6.5 π C = 6.5 π (0.075 m) = 1.53 m. Since development lengths are 20 to 50% shorter in coiled tubes than in straight tubes the flow can be approximated as fully developed. The Nusselt number is given by Equation 8.76, with

$$a = \left[1 + \frac{957\,(C/D)}{Re_D^2\,Pr}\right] = \left[1 + \frac{957\,(75 \text{ mm}/10 \text{ mm})}{(159)^2 \times 16}\right] = 1.018$$

and b = 1 + 0.477/Pr = 1+ 0.477/16 = 1.030. Note that $Re_D\,(D/C)^{1/2} = 58$, therefore the criteria for using Equations 8.76 and 8.77 are satisfied. Thus assuming $\mu_s = \mu$,

$$Nu_D = \left[\left(3.66 + \frac{4.343}{a}\right)^3 + 1.158\left(\frac{Re_D\,(D/C)^{1/2}}{b}\right)^{3/2}\right]^{1/3}$$

$$= \left[\left(3.66 + \frac{4.343}{1.018}\right)^3 + 1.158\left(\frac{159\,(10 \text{ mm}/75 \text{ mm})^{1/2}}{1.030}\right)^{3/2}\right]^{1/3} = 9.96$$

and $h_i = Nu_D k/D = 498 \text{ W/m}^2\cdot\text{K}$.

Then $\quad \overline{U} = \left[1/h_i + 1/h_o\right]^{-1} = \left[1/498 \text{ W/m}^2\cdot\text{K} + 1/500 \text{ W/m}^2\cdot\text{K}\right]^{-1} = 250 \text{ W/m}^2\cdot\text{K}$.

The outlet temperature of the coiled section can be found from Equation 8.45a, with $A_s = (\pi D)(6.5\,\pi C) = 0.048 \text{ m}^2$, and the inlet temperature is the outlet temperature of the straight section:

$$T_{m,o2} = T_\infty + (T_{m,o1} - T_\infty) \exp\left(-\frac{\overline{U}A_s}{\dot{m}c_p}\right)$$

$$T_{m,o2} = 20°\text{C} + (79.3°\text{C} - 20°\text{C}) \exp\left(-\frac{250 \text{ W/m}^2\cdot\text{K} \times 0.048 \text{ m}^2}{0.005 \text{ kg/s} \times 2000 \text{ J/kg}\cdot\text{K}}\right) = 37.9°\text{C}$$

Continued…

PROBLEM 8.104 (Cont.)

2nd Straight Section. The overall heat transfer coefficient would be the same as in the 1st straight section. The outlet temperature can be calculated from Equation 8.45a with the inlet temperature equal to the outlet temperature of the coiled section.

$$T_{m,o3} = T_\infty + (T_{m,o2} - T_\infty)\exp\left(-\frac{\overline{U}A_s}{\dot{m}c_p}\right)$$

$$T_{m,o3} = 20°C + (37.9°C - 20°C)\exp\left(-\frac{211\ W/m^2\cdot K \times \pi \times 0.01\ m \times 0.25\ m^2}{0.005\ kg/s \times 2000\ J/kg\cdot K}\right)$$

$$T_{m,o3} = 35.1°C$$ <

(b) Repeating the calculations with h_i in the straight sections doubled, in the 1st straight section:

$$\overline{U} = \left[1/730\ W/m^2\cdot K + 1/500\ W/m^2\cdot K\right]^{-1} = 297\ W/m^2\cdot K$$

$$T_{m,o1} = 75.4°C$$

In the coiled section, $\overline{U}$ is unchanged, and

$$T_{m,o2} = 36.7°C$$

In the 2nd straight section, $\overline{U} = 297\ W/m^2\cdot K$ and

$$T_{m,o3} = 33.2°C$$

(c) Yes, the orientation of the springs could have an effect, because they introduce swirl that interacts with the swirl introduced in the coiled section. However, the effect is probably small.

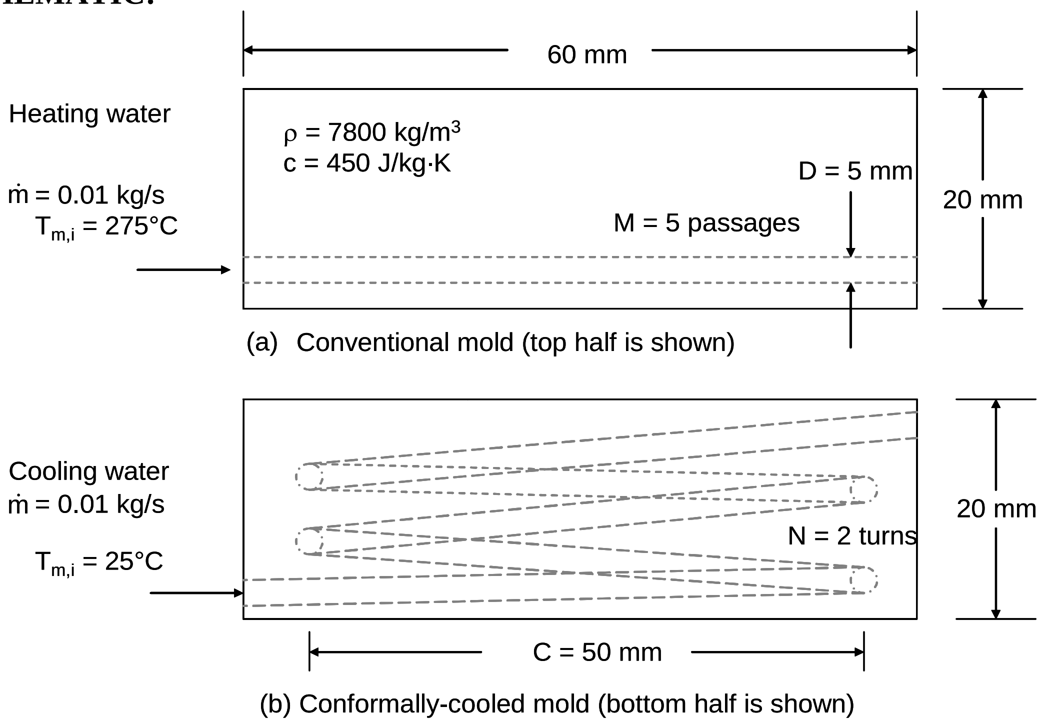
COMMENTS: The analysis is only approximate. In particular, the flow in the last section would be affected by the swirl introduced in the coiled section, which would in turn affect the heat transfer.

PROBLEM 8.105

KNOWN: Pressurized water inlet temperature and total mass flow rate for mold cooling and heating. Water channel dimensions for conventional and conformally-cooled mold. Initial hot and cold mold temperatures, mold dimensions and mold properties.

FIND: (a) Initial heating rate of a cold (100°C) mold, initial cooling rate of a hot (200°C) mold for straight water channels with D = 50 mm, (b) Initial heating rate of a cold (100°C) mold, initial cooling rate of a hot (200°C) mold for a conformally-cooled mold with water channels of diameter D = 50 mm, (c) Surface areas of cooling/heating channels for both molds and determination of which mold will enable production of more parts per day.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Incompressible liquid and negligible viscous dissipation, (3) Fully developed hydrodynamic conditions at the entrance, (4) Negligible part mass, (5) Water sufficiently pressurized to prevent boiling, (6) Negligible heat transfer in short straight sections of the channel for the conformally-cooled case.

PROPERTIES: Table A.6, water: ($\overline{T}_m$ = 260°C, assumed): k = 0.6038 W/m·K, c_p = 4989 J/kg·K, $\mu = 103.1 \times 10^{-6}$ N·s/m^2, Pr = 0.853. ($\overline{T}_m$ = 40°C, assumed): k = 0.6316 W/m·K, c_p = 4179 J/kg·K, $\mu = 656.6 \times 10^{-6}$ N·s/m^2, Pr = 4.344. (T_s = 200°C): $\mu_s = 133.9 \times 10^{-6}$ N·s/m^2.

Continued…

PROBLEM 8.105 (Cont.)

ANALYSIS: (a) Heating, $\overline{T_m} = 260°C$. The Reynolds number is

$$Re_D = \frac{4\dot{m}}{\pi D\mu} = \frac{(4\times 0.01\text{kg/s})/5}{\pi\times 5\times 10^{-3}\text{m}\times 103.1\times 10^{-6}\text{N}\cdot\text{s/m}^2} = 4940$$

From the Gnielinski correlation, with f = $(0.790\ln Re_D – 1.64)^{-2}$ = $(0.790\ln 4940 – 1.64)^{-2}$ = 38.8 × 10^{-3},

$$Nu_D = \frac{(f/8)(Re_D - 1000)Pr}{1+12.7(f/8)^{1/2}(Pr^{2/3}-1)} = \frac{(38.8\times 10^{-3}/8)\times(4940-1000)\times 0.853}{1+12.7(38.8\times 10^{-3}/8)^{1/2}(0.853^{2/3}-1)} = 17.89$$

Therefore, $h_D = Nu_D k/D$ = 17.89 × 0.6038 W/m·K/5 × 10^{-3}m = 2161 W/m^2·K. For P = πD = π × 5 × 10^{-3} m = 15.7 × 10^{-3} m, L = 60 × 10^{-3} m, $\dot{m}$ = 0.01 kg/s/5 = 0.002 kg/s, Equation 8.42 is written

$$\frac{100 - T_{m,o}}{100-275} = \exp\left(-\frac{15.7\times 10^{-3}\text{m}\times 60\times 10^{-3}\text{m}\times 2161\text{W/m}^2\cdot\text{K}}{0.002\text{kg/s}\times 4989\text{J/kg}\cdot\text{K}}\right)$$

from which $T_{m,o}$ = 243°C. Therefore,
$q_w = \dot{m}c_p(T_{m,o} - T_{m,i}) = 0.002\text{kg/s}\times 4989\text{J/kg}\cdot\text{K}\times(243°C - 275°C) = 319\text{W/channel}$ and, for the entire mold, $q_h = -q_w \times M \times 2$ = 319W × 5 × 2 = 3190 W <

Cooling, $\overline{T_m} = 40°C$. The Reynolds number is

$$Re_D = \frac{4\dot{m}}{\pi D\mu} = \frac{(4\times 0.01\text{kg/s})/5}{\pi\times 5\times 10^{-3}\text{m}\times 656.6\times 10^{-6}\text{N}\cdot\text{s/m}^2} = 776$$

Using Equation 8.56,

$$Nu_D = 3.66 + \frac{0.0668(D/L)Re_D Pr}{1+0.04[(D/L)Re_D Pr]^{2/3}} = 3.66 + \frac{0.0668(5/60)\times 776\times 4.344}{1+0.04[(5/60)\times 776\times 4.344]^{2/3}} = 10.57$$

Therefore, $h_D = Nu_D k/D$ = 10.57× 0.6316 W/m·K/5 × 10^{-3}m = 1335 W/m^2·K. Equation 8.42 yields

$$\frac{200 - T_{m,o}}{100-25} = \exp\left(-\frac{15.7\times 10^{-3}\text{m}\times 60\times 10^{-3}\text{m}\times 1335\text{W/m}^2\cdot\text{K}}{0.002\text{kg/s}\times 4179\text{J/kg}\cdot\text{K}}\right)$$

from which $T_{m,o}$ = 49.4°C. Therefore,
$q_w = \dot{m}c_p(T_{m,o} - T_{m,i}) = 0.002\text{kg/s}\times 4179\text{J/kg}\cdot\text{K}\times(49.4°C - 25°C) = 203.9\text{W/channel}$ and, for the entire mold, $q_c = -q_w \times M \times 2$ = -203.9W × 5 × 2 = -2039 W <

Continued…

PROBLEM 8.105 (Cont.)

(b) Heating, $\overline{T_m} = 260°C.$ The critical Reynolds number is

$$Re_{D,c,h} = Re_{D,c}\left[1+12(D/C)^{0.5}\right] = 2300\times\left[1+12(5/50)^{0.5}\right] = 11030$$. The actual

Reynolds number is $Re_D = \dfrac{4\dot{m}}{\pi D\mu} = \dfrac{4\times 0.01\,kg/s}{\pi\times 5\times 10^{-3}\,m\times 103.1\times 10^{-6}\,N\cdot s/m^2} = 24700$ and the flow is turbulent. Using the Gnielinski correlation, with f = $(0.790 \ln Re_D – 1.64)^{-2}$ = $(0.790 \ln 24700 – 1.64)^{-2}$ = 24.8 × 10^{-3},

$$Nu_D = \frac{(f/8)(Re_D - 1000)Pr}{1+12.7(f/8)^{1/2}(Pr^{2/3}-1)} = \frac{\left(24.8\times 10^{-3}/8\right)\times\left(24700-1000\right)\times 0.853}{1+12.7(24.8\times 10^{-3}/8)^{1/2}(0.853^{2/3}-1)} = 62.67$$

Therefore, $h_D = Nu_D k/D$ = 62.67 × 0.6038 W/m·K/5 × 10^{-3}m = 7570 W/m^2·K. For P = 15.7 × 10^{-3} m, L = 2πC = 2 × π × 50 × 10^{-3} m = 0.314 m, and $\dot{m}$ =0.01 kg/s, Equation 8.42 is written as

$$\frac{100 - T_{m,o}}{100 - 275} = \exp\left(-\frac{15.7\times 10^{-3}\,m\times 0.314\,m\times 7570\,W/m^2\cdot K}{0.01\,kg/s\times 4989\,J/kg\cdot K}\right)$$

from which $T_{m,o}$ = 182.8°C. Then, q_h = 0.02 kg/s × 4989 J/kg·K × (182.8°C - 275°C) = 9197 W <

Cooling, $\overline{T_m} = 40°C.$ The Reynolds number is

$$Re_D = \frac{4\dot{m}}{\pi D\mu} = \frac{\left(4\times 0.01\,kg/s\right)}{\pi\times 5\times 10^{-3}\,m\times 656.6\times 10^{-6}\,N\cdot s/m^2} = 3880$$

Since $Re_D < Re_{D,c,h}$, the flow is laminar and $Re_D(D/C)^{1/2}$ = 3880 ×$(5/50)^{1/2}$ = 1227. The values of a and b for use in Equation 8.77 are

$$a = \left(\frac{1+957(C/D)}{Re_D^2\,Pr}\right) = \left(\frac{1+957\times(50/5)}{3880^2\times 4.344}\right) = 146\times 10^{-3};\ \ b = 1 + \frac{0.477}{Pr} = -1 + \frac{0.477}{4.344} = 1.11$$

Equation 8.76 is rearranged to yield

$$h_D = \frac{0.6316\,W/m\cdot K}{5\times 10^{-3}\,m}\left[\left(3.66+\frac{4.343}{146\times 10^{-3}}\right)^3 + 1.158\times\left(\frac{1227}{1.11}\right)^{3/2}\right]^{1/3}\left(\frac{656}{133.9}\right)^{0.14} = 6794\,W/m^2\cdot K$$

Equation 8.42 is written

Continued…

PROBLEM 8.105 (Cont.)

$$\frac{200-T_{m,o}}{100-25}=\exp\left(-\frac{15.7\times10^{-3}\,\text{m}\times0.314\,\text{m}\times6794\,\text{W/m}^2\cdot\text{K}}{0.01\,\text{kg/s}\times4179\,\text{J/kg}\cdot\text{K}}\right)$$

from which $T_{m,o}$ = 121.5°C. Therefore,

$$q_c=\dot{m}c_p(T_{m,o}-T_{m,i})=0.02\,\text{kg/s}\times4179\,\text{J/kg}\cdot\text{K}\times(25°\text{C}-121.5°\text{C})=-8065\,\text{W}$$ <

(c) For the conventional mold,

$A_{cp} = 2M\pi DL = 2 \times 5 \times \pi \times 5 \times 10^{-3}$ m × 60 × 10^{-3} m = 9.42 × 10^{-3} m^2. For the conformally-cooled mold, $A_{cc} = 2N\pi C\pi D = 2 \times 2 \times \pi^2 \times 50 \times 10^{-3}$ m × 5 × 10^{-3} m = 9.87 × 10^{-3} m^2.

The time rate of change of the mold temperature is

$$\frac{dT}{dt}=\frac{q}{V\rho C}=\frac{q}{(60\times10^{-3}\,\text{m})^2\times40\times10^{-3}\,\text{m}\times7800\,\text{kg/m}^3\times450\,\text{J/kg}\cdot\text{K}}=\frac{q}{505.4\,\text{W}\cdot\text{s/K}}$$

The results are summarized in the following table.

Mold Type	q (W)	Flow Regime	dT/dt (K/s)
Conventional heating	3190	turbulent	6.51
Conventional cooling	-2039	laminar	4.03
Conformal heating	9197	turbulent	18.20
Conformal cooling	-8065	laminar enhanced	15.96

The conformally-cooled mold will increase production by a factor of 3 to 4 times, using the same cooling area.

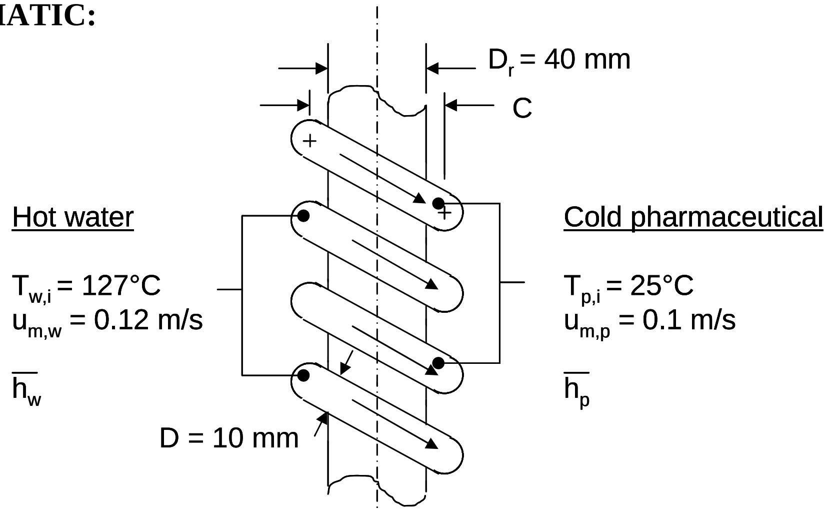
COMMENTS: (1) The average mean temperature for heating is 258.8°C and 230°C for the conventional and conformally-cooled molds, respectively. The assumed average mean temperature (260°C) is very good for the conventional mold case. A more accurate solution would be obtained by re-calculating the answer for the conformally-cooled case based upon a better estimate of the average mean temperature. (2) The average mean temperature for cooling is 37.2°C and 73.3°C for the conventional and conformally-cooled molds, respectively. The assumed average mean temperature for cooling (40°C) is very good for the conventional mold case. A more accurate solution would be obtained by re-calculating the answer for the conformally-cooled case based upon a better estimate of the average mean temperature. (3) The conformally-cooled mold offers enhanced performance due to higher mean velocity in the case of heating, and enhanced laminar flow due to curvature in the case of cooling. (4) Equation 8.76 has been extended slightly beyond its range of recommended application. Care should be taken in using the predictions.

PROBLEM 8.106

KNOWN: Inlet temperatures and flow rates of a pharmaceutical product and pressurized water, tube diameter, coil diameter and number of coils.

FIND: (a) The outlet temperature of the pharmaceutical product, (b) The variation of the pharmaceutical outlet temperature with the pressurized water flow rate.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties and steady-state conditions, (2) Incompressible liquid and negligible viscous dissipation, (3) Fully developed flow, (4) Negligible tube wall thermal resistance, (5) Negligible heat loss to surroundings and ambient.

PROPERTIES: Table A.6, water: ($\overline{T}_m$ = 380 K): k = 0.683 W/m·K, c_p = 4226 J/kg·K, μ = 260 × 10^{-6} N·s/m^2, Pr = 1.61, ρ = 953.3 kg/m^3. Pharmaceutical (given): k = 0.80 W/m·K, c_p = 4000 J/kg·K, μ = 2 × 10^{-3} kg/s·m, Pr = 10, ρ = 1000 kg/m^3.

ANALYSIS: For the water,

$$\dot{m}_w = \frac{\rho u_w \pi D^2}{4} = \frac{953.3\,\text{kg/m}^3 \times 0.12\,\text{m/s} \times \pi \times (0.01\,\text{m})^2}{4} = 0.00899\,\text{kg/s}$$

$$Re_{D,w} = \frac{4\dot{m}_w}{\pi D \mu} = \frac{4 \times 0.00899\,\text{kg/s}}{\pi \times 0.01\,\text{m} \times 260 \times 10^{-6}\,\text{kg/s}\cdot\text{m}} = 4400$$

For the pharmaceutical,

$$\dot{m}_p = \frac{\rho u_m \pi D^2}{4} = \frac{1000\,\text{kg/m}^3 \times 0.10\,\text{m/s} \times \pi \times (0.01\,\text{m})^2}{4} = 0.00785\,\text{kg/s}$$

Continued…

PROBLEM 8.106 (Cont.)

$$Re_{D,p} = \frac{4\dot{m}_p}{\pi D \mu} = \frac{4 \times 0.00785\text{kg/s}}{\pi \times 0.01\text{m} \times 2 \times 10^{-3}\text{kg/s}\cdot\text{m}} = 500$$

The flow of the pharmaceutical is laminar ($Re_{D,p} < 2300$). For the coiled tube, $C = D_r + 2(D/2)$ = 40 mm + 2 ×5 mm = 50 mm. Using Equation 8.74, $Re_{D,c,h,w} = 2300[1 + 12 \times (10/50)^{0.5}] = 14,640$. Therefore, the flow of the pressurized water is laminar ($Re_{D,w} = 4400 < 14,640$).

For the pharmaceutical product, $Re_{D,p}(D/C)^{1/2} = 500 \times (10/50)^{1/2} = 223$, while for the water $Re_{D,w}(D/C)^{1/2} = 4400 \times (10/50)^{1/2} = 1967$. For each tube, $C/D = 50/10 = 5 > 3$.

For the pharmaceutical product and water, the overall energy balances are

$$q = \dot{m}_p c_{p,p}(T_{p,o} - T_{p,i}) \quad ; \quad q = \dot{m}_w c_{p,w}(T_{w,i} - T_{w,o}) \qquad (1,2)$$

For the pharmaceutical and water, Equation 8.42 is

$$\frac{T_s - T_{p,o}}{T_s - T_{p,i}} = \exp\left(-\frac{\pi DL}{\dot{m}_p c_{p,p}}\overline{h}_p\right) \quad ; \quad \frac{T_s - T_{w,o}}{T_s - T_{w,i}} = \exp\left(-\frac{\pi DL}{\dot{m}_w c_{p,w}}\overline{h}_w\right) \qquad (3,4)$$

Once we determine $\overline{h}_p$ and $\overline{h}_w$, we may solve Equations (1) through (4) simultaneously for four unknowns: q, $T_{p,o}$, $T_{w,o}$ and T_s. We will use Equation 8.76, but be aware that we are using the correlation outside of its recommended range of applicability for the water. For the pharmaceutical product, Equation 8.77 yields

$$a = \left(1 + \frac{957 \times (50/10)}{(500)^2 \times 10}\right) = 1.002 \quad ; \quad b = 1 + \frac{0.477}{10} = 1.048$$

Therefore, Equation 8.76 becomes

$$Nu_{D,p} = \left[\left(3.66 + \frac{4.343}{1.002}\right)^3 + 1.158\left(\frac{500(10/50)^{1/2}}{1.048}\right)^{3/2}\right]^{1/3} = 16.03$$

Therefore, $\overline{h}_p = Nu_{D,p} k_p / D = 16.03 \times 0.80\text{W/m}\cdot\text{K}/0.01\text{m} = 1283\text{W/m}^2\cdot\text{K}$. For the pressurized water, Equation 8.77 yields

$$a = \left(1 + \frac{957 \times (50/10)}{(4400)^2 \times 1.61}\right) = 1.00 \quad ; \quad b = 1 + \frac{0.477}{1.61} = 1.296$$

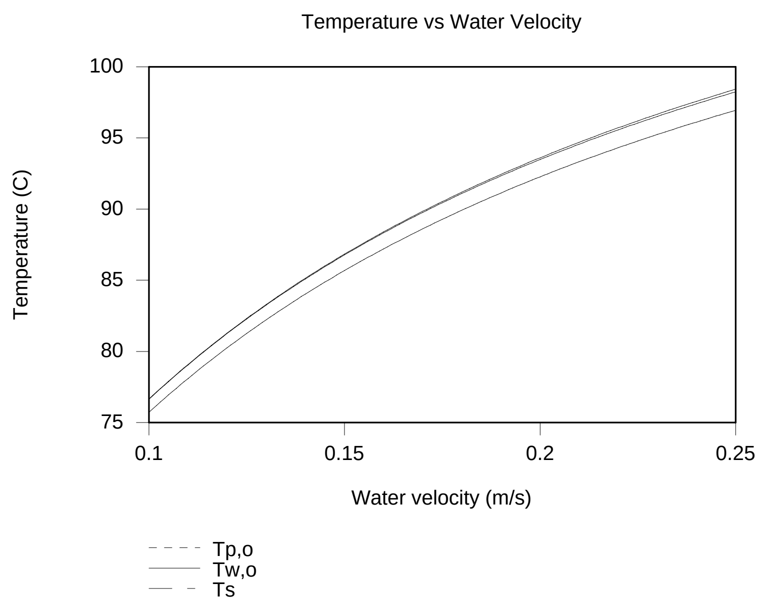
Continued…

PROBLEM 8.106 (Cont.)

Proceeding as before, we find $Nu_{D,w} = 41.01, \overline{h_w} = 2801 W/m^2 \cdot K$. The tube length is L = N × π × D_r = 20 ×π × 0.05 m = 3.14 m. Substituting values into Equations (1) through (4) and solving simultaneously yields

q = 1736 W, $T_{p,o}$ = 80.25°C, $T_{w,o}$ = 81.28°C, T_s = 81.25°C <

(b) The dependence of the pharmaceutical outlet temperature on the water velocity is shown in the graph below. Note that the pharmaceutical product's outlet temperature can be controlled accurately by modifying the water flow rate.



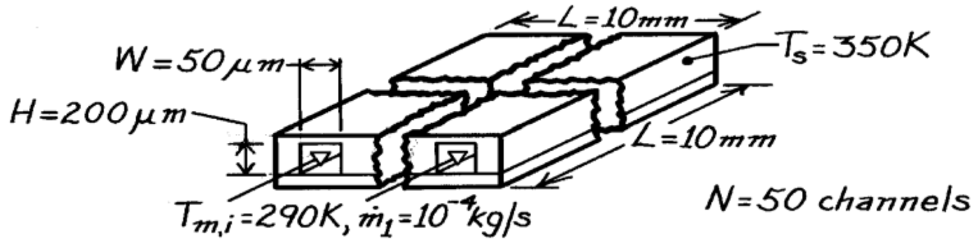
COMMENTS: (1) The pharmaceutical outlet temperature will be relatively uniform across the diameter of the tube due to mixing associated with secondary flow. (2) Although we have applied Equation 8.76 outside of its range of general applicability, the actual behavior is not expected to be significantly different than predicted. That is, we would still expect the pharmaceutical outlet temperature to be highly controllable by adjusting the water flow rate. Actual outlet temperatures could be easily measured and the water flow rate adjusted to provide the desired thermal response. (3) The average mean water temperature is $\overline{T}_m = (T_{w,i} + T_{w,o})/2$ = (127°C + 81.3°C)/2 = 104°C = 377 K. The assumed mean temperature of 380 K is reasonable.

PROBLEM 8.107

KNOWN: Chip and cooling channel dimensions. Channel flowrate and inlet temperature. Chip temperature.

FIND: Water outlet temperature and chip power.

SCHEMATIC:



ASSUMPTIONS: (1) Incompressible liquid with negligible viscous dissipation, (2) Uniform channel surface temperature, (3) $\overline{T}_m$ = 300 K, (4) Fully developed flow.

PROPERTIES: *Table A-6*, Water ($\overline{T}_m$ = 300 K): c_p = 4179 J/kg·K, μ = 855 × 10^{-6} kg/s·m, k = 0.613 W/m·K, Pr = 5.83.

ANALYSIS: Using the hydraulic diameter, find the Reynolds number,

$$D_h = \frac{4(H \times W)}{2(H+W)} = \frac{2(50 \times 200)\,\mu m^2}{250\ \mu m} 10^{-6}\ m/\mu m = 8 \times 10^{-5}\ m$$

$$Re_D = \frac{\rho\, u_m D_h}{\mu} = \frac{\dot{m}_1 D_h}{A_c \mu} = \frac{10^{-4}\ kg/s\left(8 \times 10^{-5}\ m\right)}{(50 \times 200)10^{-12}\ m^2\left(855 \times 10^{-6}\ kg/s \cdot m\right)} = 936.$$

Hence, the flow is laminar and, from Table 8.1, Nu_D = 4.44, so that

$$h = Nu_D \frac{k}{D_h} = \frac{4.44(0.613\ W/m \cdot K)}{8 \times 10^{-5}\ m} = 34,022\ W/m^2 \cdot K.$$

With P = 2(H + W) = 2(250 μm) 10^{-6} m/μm = 5 ×10^{-4} m, Eq. 8.41b yields

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \frac{350K - T_{m,o}}{60\ K} = \exp\left(-\frac{PL}{\dot{m}_1\ c_p} h\right) = \exp\left(-\frac{5 \times 10^{-6}\ m^2 \times 34,022\ W/m^2 \cdot K}{10^{-4}\ kg/s \times 4179\ J/kg \cdot K}\right)$$

$$T_{m,o} = 350K - 60\ K\ \exp(-0.407) = 310\ K.$$ <

Hence, from Eq. 8.34,

$$q = \dot{m}\, c_p\left(T_{m,o} - T_{m,i}\right) = N\dot{m}_1 c_p\left(T_{m,o} - T_{m,i}\right) = 50 \times 10^{-4}\ kg/s(4179\ J/kg \cdot K)(20\ K) = 418\ W.$$ <

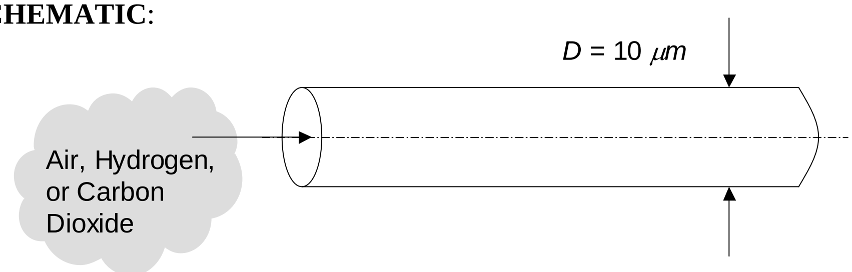
COMMENTS: (1) The chip heat flux of 418 W/cm^2 is extremely large and the method provides a very efficient means of heat removal from high power chips. However, clogging of the microchannels is a potential problem which could seriously compromise reliability. (2) L/D_h = 125 and 0.05 Re_DPr = 272. Hence, fully developed conditions are not realized and $\overline{h}$ > 34,022. The actual power dissipation is therefore greater than 418 W.

PROBLEM 8.108

KNOWN: Flow of an ideal gas through a small diameter tube.

FIND: Expression for the transition density, below which microscale effects become important. Value of the transition density for hydrogen, air and carbon dioxide.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Ideal gas.

PROPERTIES: Figure 2.8 and *Table A.4* (p = 1 atm, T = 300 K) Air: $\mathcal{M}$ = 28.97 kmol/kg, d = 0.372 nm, ρ = 1.161 kg/m^3, H_2: $\mathcal{M}$ = 2.016 kmol/kg, d = 0.274 nm, ρ = 0.0808 kg/m^3, CO_2: $\mathcal{M}$ = 44.01 kmol/kg, d = 0.464 nm, ρ = 1.773 kg/m^3.

ANALYSIS: From Eq. 2.11 the mean free path is

$$\lambda_{\text{mfp}} = \frac{k_B T}{\sqrt{2}\pi d^2 p}$$

and from the ideal gas equation of state, $p = \rho\mathcal{R}T/\mathcal{M}$. Microscale effects become important at $\lambda_{\text{mfp}}/D \approx$ 0.01. Therefore,

$$\frac{\lambda_{\text{mfp}}}{D} = 0.01 = \frac{k_B\mathcal{M}}{\sqrt{2}\pi d^2 \rho_c \mathcal{R} D} \quad \text{or} \quad \rho_c = \frac{100 k_B \mathcal{M}}{\sqrt{2}\pi d^2 \mathcal{R} D}$$

<

For air,

$$\rho_{c,\text{Air}} = \frac{100 k_B \mathcal{M}}{\sqrt{2}\pi d^2 \mathcal{R} D} = \frac{100 \times 1.381 \times 10^{-23} \text{J/K} \times 28.97 \text{ kmol/kg}}{\sqrt{2}\pi \times \left(0.372 \times 10^{-9}\text{m}\right)^2 \times 8315 \text{ J/kmol}\cdot\text{K} \times 10 \times 10^{-6} \text{ m}} = 0.783 \text{ kg/m}^3$$ <

Repeating the calculation for hydrogen and CO_2 yields

$$\rho_{c,\text{H2}} = 0.100 \text{ kg/m}^3; \; \rho_{c,\text{CO2}} = 0.764 \text{ kg/m}^3.$$ <

The ratios of the transition to molecular density at p = 1 atm, T = 300 K, for the three gases are:

Gas	Ratio
Air	0.783/1.161 = 0.674
H_2	0.100/0.0808 = 1.24
CO_2	0.764/1.773 = 0.431

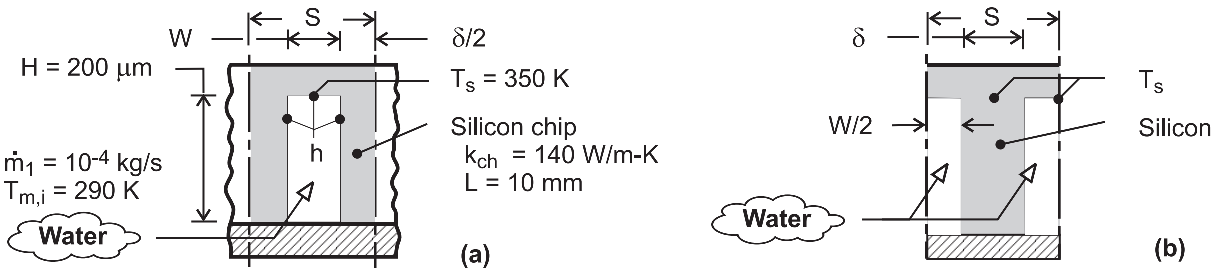
COMMENT: Microscale effects could be important, especially for hydrogen at atmospheric pressure and T = 300 K.

PROBLEM 8.109

KNOWN: Chip and cooling channel dimensions. Channel flow rate and inlet temperature. Temperature of chip at base of channel.

FIND: (a) Water outlet temperature and chip power, (b) Effect of channel width and pitch on power dissipation.

SCHEMATIC:



ASSUMPTIONS: (1) Incompressible liquid with negligible viscous dissipation, (2) Flow may be approximated as fully developed and channel walls as isothermal for purposes of estimating the convection coefficient, (3) One-dimensional conduction along channel side walls, (4) Adiabatic condition at end of side walls, (5) Heat dissipation is exclusively through fluid flow in channels, (6) Constant properties.

PROPERTIES: *Table A-6*, Water ($\overline{T}_m$ = 300K): c_p = 4179 J/kg·K, $\mu = 855 \times 10^{-6}$ kg/s·m, k = 0.613 W/m·K, Pr = 5.83.

ANALYSIS: (a) The channel sidewalls act as fins, and a *unit* channel/sidewall combination is shown in schematic (a), where the total number of unit cells corresponds to N = L/S. With N = 50 and L = 10 mm, S = 200 μm and δ = S – W = 150 μm. Alternatively, the unit cell may be represented in terms of a single fin of thickness δ, as shown in schematic (b). The thermal resistance of the unit cell may be obtained from the expression for a fin array, Eq. (3.108), $R_{t,o} = (\eta_o h A_t)^{-1}$, where $A_t = A_f + A_b$ = L (2 H + W) = 0.01m $(4 \times 10^{-4} + 0.5 \times 10^{-4})$ m $= 4.5 \times 10^{-6}$ m^2. With D_h = 4 (H × W)/2 (H + W) = 4 (2 × 10^{-4}m × 0.5 × 10^{-4}m)/2 (2.5 × 10^{-4}m) = 8 × 10^{-5}m, the Reynolds number is $Re_D = \rho u_m D_h/\mu = \dot{m}_1 D_h/A_c\mu = 10^{-4}$ kg/s × 8 × 10^{-5}m/(2 × 10^{-4}m × 0.5 × 10^{-4}m) 855 × 10^{-6} kg/s·m = 936. Hence, the flow is laminar, and assuming fully developed conditions throughout a channel with uniform surface temperature, Table 8.1 yields Nu_D = 4.44. Hence,

$$h = \frac{k}{D_h} Nu_D = \frac{0.613\,W/m\cdot K \times 4.44}{8 \times 10^{-5} m} = 34,022\,W/m^2\cdot K$$

With $m = (2h/k_{ch}\delta)^{1/2} = (68,044\ W/m^2\cdot K/140\ W/m\cdot K \times 1.5 \times 10^{-4} m)^{1/2} = 1800\ m^{-1}$ and mH = 0.36, the fin efficiency is

$$\eta_f = \frac{\tanh\ mH}{mH} = \frac{0.345}{0.36} = 0.958$$

and the overall surface efficiency is

$$\eta_o = 1 - \frac{A_f}{A_t}(1-\eta_f) = 1 - \frac{4.0\times10^{-6}}{4.5\times10^{-6}}(1-0.958) = 0.963$$

The thermal resistance of the unit cell is then

Continued …

PROBLEM 8.109 (Cont.)

$$R_{t,o} = \left(\eta_o h A_t\right)^{-1} = \left(0.963 \times 34{,}022\,W/m^2 \cdot K \times 4.5 \times 10^{-6} m^2\right)^{-1} = 6.78\,K/W$$

The outlet temperature follows from Eq. (8.45b),

$$T_{m,o} = T_s - \left(T_s - T_{m,i}\right)\exp\left(-\frac{1}{\dot{m}_1 c_p \; R_{t,o}}\right) = 350K - \left(60K\right) \times$$

$$\exp\left(-\frac{1}{10^{-4} kg/s \times 4179\,J/kg \cdot K \times 6.78\,K/W}\right) = 307.8K$$ <

The heat rate per channel is then

$$q_1 = \dot{m}_1 c_p \left(T_{m,o} - T_{m,i}\right) = 10^{-4} kg/s \times 4179\,J/kg \cdot K\left(17.8K\right) = 7.46\,W$$

and the chip power dissipation is

$$q = Nq_1 = 50 \times 7.46\,W = 373\,W$$ <

(b) The foregoing result indicates significant heat transfer from the channel side walls due to the large value of η_f. If the pitch is reduced by a factor of 2 (S = 100 μm), we obtain

$$S = 100\mu m,\; W = 50\mu m,\; \delta = 50\mu m,\; N = 100 : q_1 = 7.04\,W,\; q = 704\,W$$ <

Hence, although there is a reduction in η_f due to the reduction in δ (η_f = 0.89) and therefore a slight reduction in the value of q_l, the effect is more than compensated by the increase in the number of channels. Additional benefit may be derived by further reducing the pitch to whatever minimum value of δ is imposed by manufacturing or structural limitations. There would also be an advantage to increasing the channel hydraulic diameter and or flowrate, such that turbulent flow is achieved with a correspondingly larger value of h.

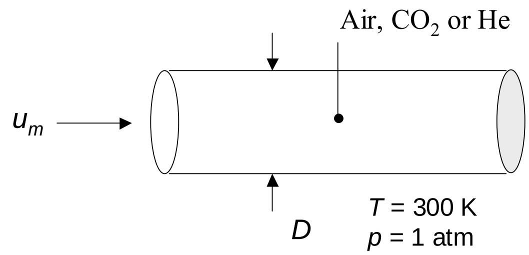
COMMENTS: (1) Because electronic devices fail by contact with a polar fluid such as water, great care would have to be taken to hermetically seal the devices from the coolant channels. In lieu of water, a dielectric fluid could be used, thereby permitting contact between the fluid and the electronics. However, all such fluids, such as air, are less effective as coolants. (2) With L/D_h = 125 and $L/D_h)_{fd} \approx 0.05\, Re_D\, Pr$ = 273, fully developed flow is not achieved and the value of $h = h_{fd}$ underestimates the actual value of $\overline{h}$ in the channel. The coefficient is also underestimated by using a Nusselt number that presumes heat transfer from all four (rather than three) surfaces of a channel.

PROBLEM 8.110

KNOWN: Temperature and pressure of a gas flowing in a circular tube.

FIND: The critical tube diameter, D_c, below which incompressible turbulent flow cannot exist for (*a*) air (*b*) CO_2, and (*c*) He.

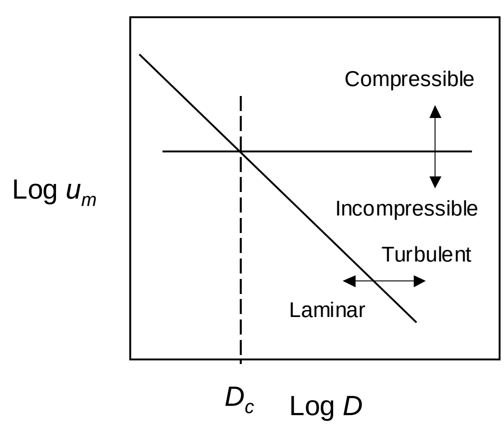
SCHEMATIC:



ASSUMPTIONS: (1) Ideal gas behavior. (2) Fully-developed flow.

PROPERTIES: Table A.4 (T = 300 K): Air; c_p = 1007 J/kg·K, μ = 184.6 × 10^{-7} N·s/m^2. CO_2; c_p = 851 J/kg·K, μ = 149 × 10^{-7} N·s/m^2. He; c_p = 5193 J/kg·K, μ = 199 × 10^{-7} N·s/m^2 . Figure 2.8: Air; $\mathcal{M}$ = 28.97 kg/kmol. CO_2; $\mathcal{M}$ = 44.01 kg/kmol He; $\mathcal{M}$ = 4.003 kg/kmol.

ANALYSIS: The relationship $Re_{D,c} = u_m D/\nu \approx 2300$ may be plotted on a *log-log* scale, as shown in the figure below. Laminar flow occurs to the left of the sloped line, while turbulent flow occurs to the right of the line. The critical Mach number $Ma_c = u_m/a \approx 0.3$ is drawn as the horizontal line that separates regions of incompressible flow (below the line) and compressible flow (above the line). It is evident that below a critical diameter, D_c, turbulent incompressible flow and heat transfer cannot exist.



(*a*) From the ideal gas equation of state,

$$\rho = p/RT \tag{1}$$

and from Section 6.4.2 the speed of sound is

$$a = \sqrt{\gamma RT} \tag{2}$$

Continued…

where $\gamma \equiv c_p/c_v$ is the ratio of specific heats. The mean velocity may be related to the Mach number, Ma, and is

$$u_m = Ma \cdot a \tag{3}$$

Combining the preceding equations yields

$$Re = \frac{Ma \cdot p}{\mu}\sqrt{\frac{\gamma}{RT}}D \tag{4}$$

Specifying $Re = Re_c$ and $Ma = Ma_c$ leads to the following expression for the critical tube diameter

$$D_c = \frac{Re_c}{Ma_c}\sqrt{\frac{RT}{\gamma}}\frac{\mu}{p} \tag{5}$$

For air, the ideal gas constant, specific heat at constant volume, and ratio of specific heats are

$$R = \frac{\mathcal{R}}{\mathcal{M}} = \frac{8.315\ \text{kJ/kmol}\cdot\text{K}}{28.97\ \text{kg/kmol}} = 0.287\ \frac{\text{kJ}}{\text{kg}\cdot\text{K}};$$

$$c_v = c_p - R = 1.007\frac{\text{kJ}}{\text{kg}\cdot\text{K}} - 0.287\frac{\text{kJ}}{\text{kg}\cdot\text{K}} = 0.720\frac{\text{kJ}}{\text{kg}\cdot\text{K}};\quad \gamma = \frac{c_p}{c_v} = \frac{1.007}{0.720} = 1.399$$

Therefore,

$$D_c = \frac{2300}{0.3}\sqrt{\frac{287\ \text{J/kg}\cdot\text{K}\times 300\ \text{K}}{1.399}} \times \frac{184.6\times10^{-7}\ \text{N}\cdot\text{s/m}^2}{1.0133\times10^5\ \text{N/m}^2} = 346\times10^{-6}\text{m} = 0.346\ \text{mm}$$ <

(b,c) The calculations may be repeated for CO_2 and He, yielding the following results.

Gas	R (kJ/kg·K)	c_v (kJ/kg·K)	γ	D_c (mm)	
CO_2	0.189	0.662	1.285	0.237	<
He	2.077	3.116	1.667	0.920	<

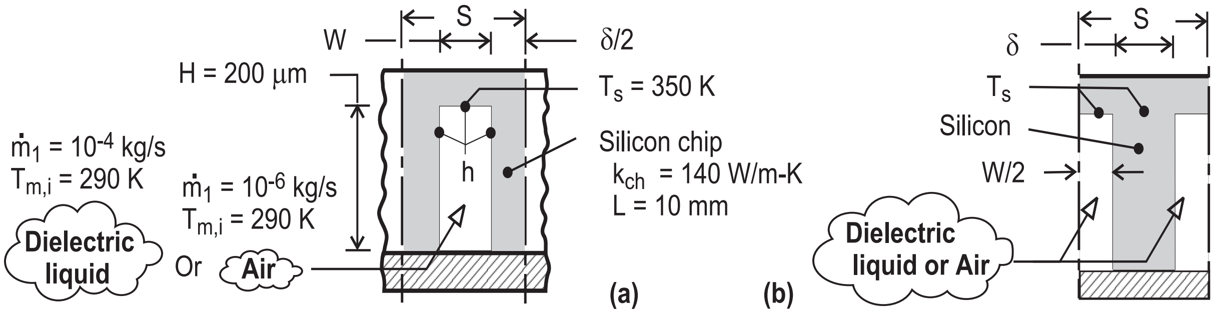
COMMENTS: (1) Below the critical diameter, D_c, the effects of compressibility must *always* be accounted for if the flow is turbulent, and are *often* important if the flow is laminar. Because the correlations of Chapter 8 do not account for the effects of compressibility, they may not be applied to situations where turbulence exists and the tube diameter is less than D_c. The correlations must be used with caution if the flow is laminar and $D < D_c$ since compressibility effects might be important. (2) The critical diameter is moderately dependent on the specific gas of interest, for the three gases considered here.

PROBLEM 8.111

KNOWN: Chip and cooling channel dimensions. Channel flow rate and inlet temperature. Temperature of chip at base of channel.

FIND: (a) Outlet temperature and chip power dissipation for dielectric liquid, (b) Outlet temperature and chip power dissipation for air.

SCHEMATIC:



ASSUMPTIONS: (1)Applicability of Eq. 8.34, (2) Flow may be approximated as fully developed and channel walls as isothermal for purposes of estimating the convection coefficient, (3) One-dimensional conduction along the channel side walls, (4) Adiabatic condition at end of side walls, (5) Heat dissipation is exclusively through fluid flow in channels, (6) Constant properties.

PROPERTIES: Prescribed. Dielectric liquid: $c_p = 1050$ J/kg·K, k = 0.065 W/m·K, $\mu = 0.0012$ N·s/m^2, Pr = 15. Air: $c_p = 1007$ J/kg·K, k = 0.0263 W/m·K, $\mu = 185 \times 10^{-7}$ N·s/m^2, Pr = 0.707.

ANALYSIS: (a) The channel side walls act as fins, and a *unit* channel/sidewall combination is shown in schematic (a), where $\delta = S - W = 150\ \mu$m. Alternatively, the unit cell may be represented in terms of a single fin of thickness δ, as shown in schematic (b). The thermal resistance of the unit cell may be obtained from the expression for a fin array, Eq. (3.108), $R_{t,o} = (\eta_o\, h\, A_t)^{-1}$, where $A_t = A_f + A_b = L\,(2H + W) = 4.5 \times 10^{-6}\ m^2$. With $A_c = H \times W = 10^{-8}\ m^2$ and $D_h = 4A_c/2(H + W) = 8 \times 10^{-5}$m, the Reynolds number is $Re_D = \rho u_m D_h/\mu = \dot{m}_1 D_h/A_c\mu = 667$. Hence, the flow is laminar, and assuming fully developed conditions throughout a channel with uniform surface temperature, Table 8.1 yields $Nu_D = 4.44$. Hence,

$$h = \frac{k}{D_h} Nu_D = \frac{0.065\,W/m\cdot K \times 4.44}{8 \times 10^{-5}\,m} = 3608\,W/m^2\cdot K$$

With $m = (2\,h/k_{ch}\,\delta)^{1/2} = 586\ m^{-1}$ and mH = 0.117, the fin efficiency is

$$\eta_f = \frac{\tanh mH}{mH} = \frac{0.1167}{0.117} = 0.995$$

and the overall surface efficiency is

$$\eta_o = 1 - \frac{A_f}{A_t}(1 - \eta_f) = 1 - \frac{4.0 \times 10^{-6}}{4.5 \times 10^{-6}}(1 - 0.995) = 0.996.$$

The thermal resistance of the unit cell is then

$$R_{t,o} = (\eta_o h A_t)^{-1} = \left(0.996 \times 3608\,W/m^2\cdot K \times 4.5 \times 10^{-6} m^2\right)^{-1} = 61.9\,K/W$$

The outlet temperature follows from Eq. (8.45b),

$$T_{m,o} = T_s - (T_s - T_{m,i})\exp\left(-\frac{1}{\dot{m}_1 c_p R_{t,o}}\right) = 350K$$

Continued …

$$-\left(60\text{K}\right)\exp\left(-\frac{1}{10^{-4}\,\text{kg/s}\times 1050\,\text{J/kg}\cdot\text{K}\times 61.9\,\text{K/W}}\right) = 298.6\text{K} \qquad <$$

The heat rate per channel is then

$$q_1 = \dot{m}_1 c_p\left(T_{m,o} - T_{m,i}\right) = 10^{-4}\,\text{kg/s}\times 1050\,\text{J/kg}\cdot\text{K}\times 8.6\,\text{K} = 0.899\,\text{W}$$

and the chip power dissipation is

$$q = Nq_1 = 50\times 0.899\,\text{W} = 45.0\,\text{W} \qquad <$$

(b) With $\dot{m}_1 = 10^{-6}\,\text{kg/s}$, $Re_D = \dot{m}_1 D_h / A_c\mu = 432$ and the flow is laminar. Hence, with $Nu_D = 4.44$,

$$h = \frac{k}{D_h}Nu_D = \frac{0.0263\,\text{W/m}\cdot\text{K}\times 4.44}{8\times 10^{-5}\text{m}} = 1460\,\text{W/m}^2\cdot\text{K}$$

With $m = (2\,h/k_{ch}\delta)^{1/2} = 373\ \text{m}^{-1}$ and mH = 0.0746, the fin efficiency is

$$\eta_f = \frac{\tanh mH}{mH} = \frac{0.0744}{0.0746} = 0.998$$

and the overall surface efficiency is

$$\eta_o = 1 - \frac{A_f}{A_t}\left(1-\eta_f\right) = 1 - \frac{4.0\times 10^{-6}}{4.5\times 10^{-6}}\left(1-0.998\right) = 0.998$$

Hence, $$R_{t,o} = \left(\eta_o h A_t\right)^{-1} = \left(0.998\times 1460\,\text{W/m}^2\cdot\text{K}\times 4.5\times 10^{-6}\text{m}^2\right)^{-1} = 153\,\text{K/W}$$

The outlet temperature is then

$$T_{m,o} = T_s - \left(T_s - T_{m,i}\right)\exp\left(-\frac{1}{\dot{m}_1 c_p R_{t,o}}\right) = 350\text{K}$$

$$-\left(60\text{K}\right)\exp\left(-\frac{1}{10^{-6}\,\text{kg/s}\times 1007\,\text{J/kg}\cdot\text{K}\times 153\,\text{K/W}}\right) = 349.9\,\text{K} \qquad <$$

$$q_1 = \dot{m}_1 c_p\left(T_{m,o} - T_{m,i}\right) = 10^{-6}\,\text{kg/s}\times 1007\,\text{J/kg}\cdot\text{K}\times 59.9\,\text{K} = 0.060\,\text{W}$$

$$q = Nq_1 = 3.02\,\text{W} \qquad <$$

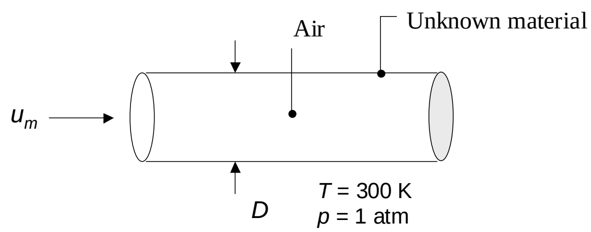
COMMENTS: (1) For laminar flow in the channels, there is a clear advantage to using the dielectric liquid instead of air. (2) The prescribed channel geometry is by no means optimized, and the number of fins should be increased by reducing S. Also, channel dimensions and/or flow rates could be increased to achieve turbulent flow and hence much larger values of h. (3) With $L/D_h = 125$ and $L/Dh)_{fd} \approx 0.05\,Re_D\,Pr = 500$ for the dielectric liquid, fully developed flow is not achieved and its assumption yields a conservative (under) estimate of the convection coefficient. The coefficient is also underestimated by using a Nusselt number that presumes heat transfer from all four (rather than three) surfaces of a channel.

PROBLEM 8.112

KNOWN: Temperature and pressure of air flowing in a circular tube of known diameter. Thermal and momentum accommodation coefficients. Fully developed laminar flow with constant heat flux.

FIND: Graph of the Nusselt number versus tube diameter for 1 μm ≤ D ≤ 1 mm and (*a*) $\alpha_t = 1$, $\alpha_p = 1$, (*b*) $\alpha_t = 0.1$, $\alpha_p = 0.1$, (*c*) $\alpha_t = 1$, $\alpha_p = 0.1$ and (*d*) $\alpha_t = 0.1$, $\alpha_p = 1$.

SCHEMATIC:



ASSUMPTIONS: (1) Ideal gas behavior. (2) Fully-developed laminar flow.

PROPERTIES: Table A.4 (T = 300 K): Air; c_p = 1007 J/kg·K, Pr = 0.707. Figure 2.8: Air; $\mathcal{M}$ = 28.97 kg/kmol, $d = 0.372 \times 10^{-9}$ m.

ANALYSIS: The ideal gas constant, specific heat at constant volume, and ratio of specific heats are:

$$R = \frac{\mathcal{R}}{\mathcal{M}} = \frac{8.315 \text{ kJ/kmol} \cdot \text{K}}{28.97 \text{ kg/kmol}} = 0.287 \ \frac{\text{kJ}}{\text{kg} \cdot \text{K}};$$

$$c_v = c_p - R = 1.007 \frac{\text{kJ}}{\text{kg} \cdot \text{K}} - 0.287 \frac{\text{kJ}}{\text{kg} \cdot \text{K}} = 0.720 \frac{\text{kJ}}{\text{kg} \cdot \text{K}}; \quad \gamma = \frac{c_p}{c_v} = \frac{1.007}{0.720} = 1.399$$

From Equation 2.11 the mean free path of air is

$$\lambda_{\text{mfp}} = \frac{k_B T}{\sqrt{2}\pi d^2 p} = \frac{1.381 \times 10^{-23} \text{ J/K} \times 300 \text{ K}}{\sqrt{2}\pi \left(0.372 \times 10^{-9} \text{ m}\right)^2 \left(1.0133 \times 10^5 \text{ N/m}^2\right)} = 66.5 \times 10^{-9} \text{ m} = 66.5 \text{ nm}$$

From Equation 8.78, the Nusselt number may be expressed as

$$Nu_D = \frac{hD}{k} = \frac{48}{11 - 6\zeta + \zeta^2 + 48\Gamma_t} \qquad (1)$$

where

$$\Gamma_t = \frac{2 - \alpha_t}{\alpha_t} \frac{2\gamma}{\gamma + 1} \left[\frac{\lambda_{\text{mfp}}}{PrD}\right] \qquad (2)$$

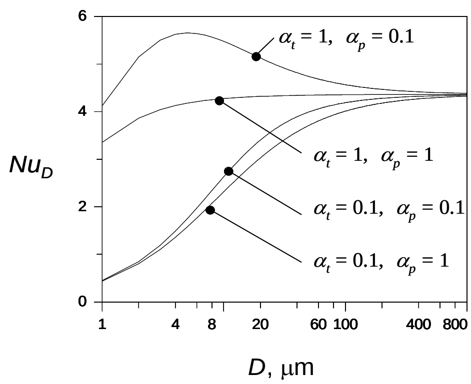
Continued…

PROBLEM 8.112 (Cont.)

$$\Gamma_p = \frac{2-\alpha_p}{\alpha_p}\left[\frac{\lambda_{\text{mfp}}}{D}\right] \tag{3}$$

$$\zeta = \frac{8\Gamma_p}{\left(1+8\Gamma_p\right)} \tag{4}$$

Equations 1 through 4 may be combined to yield the following graph that shows the variation of the Nusselt number over the tube diameter range 1 μm ≤ D ≤ 1000 μm.



<

The accommodation coefficients begin to influence the Nusselt number (and hence the convection heat transfer coefficient) at diameters less than approximately 400 μm. <

The Nusselt number is least sensitive to changes in the tube diameter for $\alpha_t = \alpha_p = 1$. <

The Nusselt number can exceed 4.36 when the momentum accommodation coefficient is small and the thermal accommodation coefficient is large. <

Small values of the thermal accommodation coefficient in conjunction with large values of the momentum accommodation coefficient result in the most significant reductions in the Nusselt number. <

The Nusselt number can increase or decrease relative to the value associated with conventional flows, and the change in the Nusselt number can be quite large. Hence prediction of convection heat transfer coefficients in nano- and some microscale devices involving gas flow is typically subject to a high degree of uncertainty. <

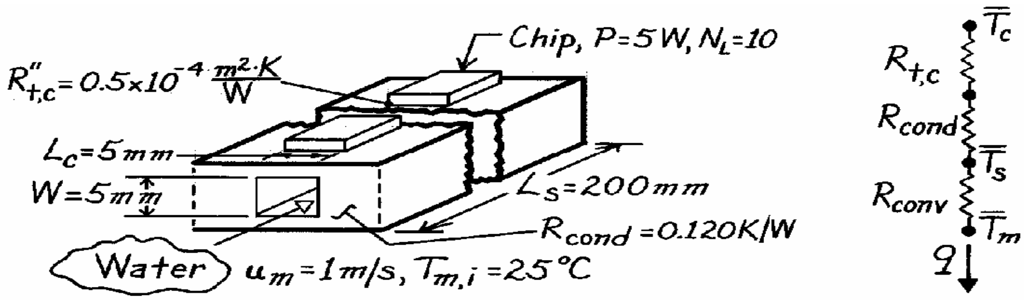
Comment: Thermal accommodation coefficients can be of very small value, as discussed in Chapter 3.

PROBLEM 8.113

KNOWN: Arrangement of chips and cooling channels for a substrate. Contact and conduction resistances. Coolant velocity and inlet temperature.

FIND: (a) Coolant temperature rise, (b) Chip and substrate temperatures.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Fully-developed flow, (3) Incompressible liquid with negligible viscous dissipation, (4) Heat transfer exclusively to water, (5) Steady-state conditions.

PROPERTIES: Water (given): ρ = 1000 kg/m^3, c_p = 4180 J/kg·K, k = 0.610 W/m·K, Pr = 5.8, μ = 855 × 10^{-6} kg/s·m.

ANALYSIS: (a) For a single flow channel, the overall energy balance yields

$$T_{m,o} - T_{m,i} = \frac{q}{\dot{m}\, c_p} = \frac{N_L P}{\rho\, u_m A_c c_p} = \frac{10 \times 5\ \text{W}}{1000\ \text{kg/m}^3 (1\ \text{m/s})(0.005\ \text{m})^2\ 4180\ \text{J/kg}\cdot\text{K}} = 0.48^\circ\text{C}. \quad <$$

From the thermal circuit,

$$q = \frac{T_o - \overline{T}_m}{R_{t,c} + R_{cond} + R_{conv}} \qquad R_{t,c} = R''_{t,c} / A_s = \left(0.5 \times 10^{-4}\ \text{m}^2 \cdot \text{K/W}\right)/10\left(0.005\ \text{m}\right)^2 = 0.2\ \text{K/W}.$$

With D_h = 4A_c/P = 4(0.005 m)^2/4(0.005 m) = 0.005 m,

$$Re_D = \frac{\rho\, u_m D_h}{\mu} = \frac{1000\ \text{kg/m}^3 (1\ \text{m/s})\, 0.005\ \text{m}}{855 \times 10^{-6}\ \text{kg/s}\cdot\text{m}} = 5848.$$

With turbulent flow, the Gnielinski correlation yields

$$h = \frac{k}{D}\frac{(f/8)(Re_D - 1000)\,Pr}{1 + 12.7(f/8)^{1/2}(Pr^{2/3} - 1)} = \frac{0.61\text{W/m}\cdot\text{K}}{0.005\text{m}}\frac{(0.0368/8)(5848 - 1000)5.8}{1 + 12.7(0.0368/8)^{1/2}(5.8^{2/3} - 1)} = 5406\text{W/m}^2\cdot\text{K}$$

where f = $(0.79\ln Re_D - 1.64)^{-2}$ = 0.0368.

$$R_{conv} = \left(hA_s\right)^{-1} = \left(5406\ \text{W/m}^2 \cdot \text{K} \times 4 \times 0.005\ \text{m} \times 0.2\ \text{m}\right)^{-1} = 0.046\ \text{K/W}.$$

Approximating T_m as $(T_{m,i} + T_{m,o})/2$ = 25.24°C,

$$\overline{T}_c = \overline{T}_m + q\left(R_{t,c} + R_{cond} + R_{conv}\right) = 25.24^\circ\text{C} + 50\ \text{W}\left(0.2 + 0.12 + 0.046\right)\text{K/W} = 43.6^\circ\text{C}. \quad <$$

Similarly, from the thermal circuits,

$$\overline{T}_s = \overline{T}_m + q \times R_{conv} = 25.24^\circ\text{C} + 50\text{W} \times 0.046\text{K/W} = 27.6^\circ\text{C} \quad <$$

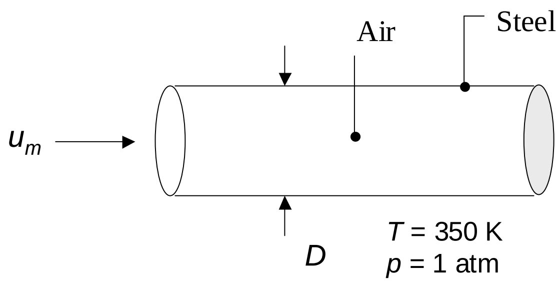
COMMENTS: (1) Since the coolant temperature rise is less than 0.5°C, all chip temperatures will be within 0.5°C of each other. (2) The channel surface temperature may also be obtained from Eq. 8.41b, yielding the same result.

PROBLEM 8.114

KNOWN: Temperature and pressure of a gas flowing in a circular tube of known diameter with constant surface heat flux. Thermal and momentum accommodation coefficients. Fully developed laminar flow.

FIND: Graph of the Nusselt number for tube diameters of 1 μm ≤ D ≤ 1 mm.

SCHEMATIC:



ASSUMPTIONS: (1) Ideal gas behavior. (2) Fully-developed laminar flow.

PROPERTIES: Table A.4 (T = 350 K): Air; c_p = 1009 J/kg·K, k = 0.030 W/m·K, Pr = 0.70. Figure 2.8: Air; $\mathcal{M}$ = 28.97 kg/kmol, d = 0.372 × 10^{-9} m.

ANALYSIS: The ideal gas constant, specific heat at constant volume, and ratio of specific heats are:

$$R = \frac{\mathcal{R}}{\mathcal{M}} = \frac{8.315 \text{ kJ/kmol}\cdot\text{K}}{28.97 \text{ kg/kmol}} = 0.287 \ \frac{\text{kJ}}{\text{kg}\cdot\text{K}};$$

$$c_v = c_p - R = 1.009\frac{\text{kJ}}{\text{kg}\cdot\text{K}} - 0.287\frac{\text{kJ}}{\text{kg}\cdot\text{K}} = 0.722\frac{\text{kJ}}{\text{kg}\cdot\text{K}}; \quad \gamma = \frac{c_p}{c_v} = \frac{1.009}{0.722} = 1.398$$

From Equation 2.11 the mean free path of air is

$$\lambda_{\text{mfp}} = \frac{k_B T}{\sqrt{2}\pi d^2 p} = \frac{1.381\times10^{-23} \text{ J/K}\times 350 \text{ K}}{\sqrt{2}\pi\left(0.372 \times 10^{-9} \text{ m}\right)^2\left(1.0133\times10^5 \text{ N/m}^2\right)} = 77.6\times10^{-9} \text{ m} = 77.6 \text{ nm}$$

From Equation 8.78 the Nusselt number may be expressed as

$$Nu_D = \frac{hD}{k} = \frac{48}{11 - 6\zeta + \zeta^2 + 48\Gamma_t} \quad (1)$$

where

Continued…

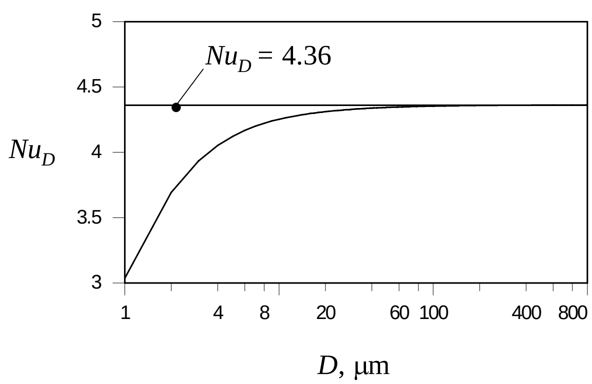
PROBLEM 8.114 (Cont.)

$$\Gamma_t = \frac{2-\alpha_t}{\alpha_t}\frac{2\gamma}{\gamma+1}\left[\frac{\lambda_{\text{mfp}}}{PrD}\right] = \frac{2-0.92}{0.92}\cdot\frac{2\times1.398}{1.398+1}\left[\frac{77.6\times10^{-9}\text{ m}}{0.700D}\right] = \frac{152\times10^{-9}\text{ m}}{D} \quad (2)$$

$$\Gamma_p = \frac{2-\alpha_p}{\alpha_p}\left[\frac{\lambda_{\text{mfp}}}{D}\right] = \frac{2-0.87}{0.87}\cdot\left[\frac{77.6\times10^{-9}\text{ m}}{D}\right] = \frac{101\times10^{-9}\text{ m}}{D} \quad (3)$$

$$\zeta = \frac{8\Gamma_p}{\left(1+8\Gamma_p\right)} \quad (4)$$

Equations 1 through 4 may be combined to yield the following graph that shows the variation of the Nusselt number over the tube diameter range 1 μm ≤ D ≤ 1000 μm.



<

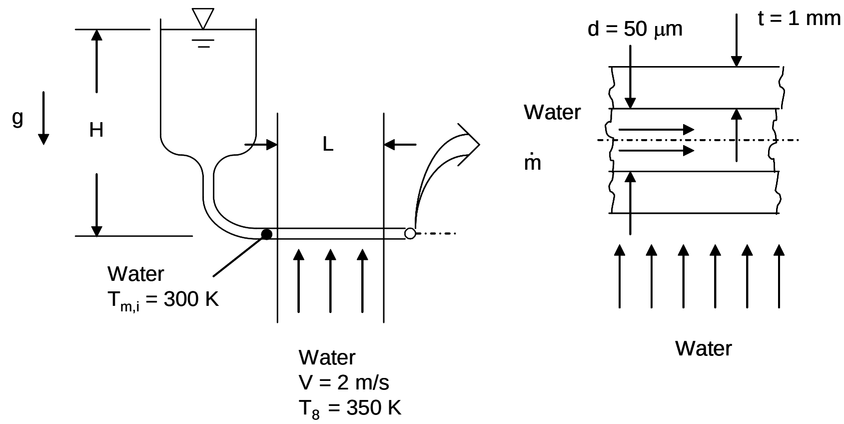
COMMENTS: (1) The Nusselt number begins to be affected by the tube dimension at a tube diameter of $D \approx 100$ µm. (2) Equation 8.78 is associated with constant heat flux conditions. We would expect a similar reduction in Nusselt numbers for constant temperature wall conditions.

PROBLEM 8.115

KNOWN: Inner diameter of microscale tube, wall thickness of tube, temperature of water inside the tube, and temperature of water in cross flow over the tube.

FIND: (a) Required tube length at Re_D = 2000, (b) Water outlet temperature, (c) Pressure drop associated with the flow of water inside the tube, (d) Height of water column needed to supply the required inlet pressure and time needed to collect 0.1 liter of water. Discuss measurement of outlet water temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties and steady-state conditions, (2) Incompressible liquid and negligible viscous dissipation, (3) Negligible microscale or nanoscale effects.

PROPERTIES: Table A.6, water: ($\overline{T}_m$ = 305 K): k = 0.620 W/m·K, c_p = 4178 J/kg·K, μ = 769 × 10^{-6} N·s/m^2, Pr = 5.2, ρ = 995 kg/m^3: ($\overline{T}$ = 330 K): k = 0.650 W/m·K, c_p = 4194 J/kg·K, μ = 489 × 10^{-6} N·s/m^2, Pr = 3.15, ρ = 984 kg/m^3. Table A.3 glass: k = 1.4 W/m·K.

ANALYSIS: (a) At Re_D = 2000, Equation 8.3 yields $x_{fd,h} = 0.05Re_DPrD$ = 0.05 × 2000 × 5.2 × 50 × 10^{-6} m = 26 × 10^{-3} m. Therefore, L = $2x_{fd,h}$ = 2 × 26 × 10^{-3} m = 52 × 10^{-6} m = 52 mm. <

(b) Equation 8.45a is

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp\left(-\frac{\overline{U}A_s}{\dot{m}c_p}\right) \qquad (1)$$

where we will use $\overline{U} = \overline{U}_i$, $A_s = A_{s,i}$. Note that $Re_D = 4\dot{m}/(\pi D\mu)$ so that $\dot{m} = Re_D\,\pi D\mu/4$ = 2000 × π × 50 × 10^{-6} m × 769 × 10^{-6} N·s/m^2/4 = 60.4 × 10^{-6} kg/s. Therefore, $u_m = \dot{m}/(\rho A_c)$ = 60.4 × 10^{-6} kg/s × 4/ (995 kg/m^3× π × (50 × 10^{-6} m)^2) = 31 m/s. From Equation 3.36,

Continued…

PROBLEM 8.115 (Cont.)

$$\overline{U}_i = \frac{1}{\frac{1}{h_i} + \frac{d/2}{k_g}\ln\left[\frac{(d/2+t)}{d/2}\right] + \frac{d/2}{(d/2+t)}\frac{1}{h_o}} \tag{2}$$

$A_{s,i} = \pi dL = \pi \times 50 \times 10^{-6}$ m $\times$ 52 $\times 10^{-3}$ m = 8.17 $\times 10^{-6}$ m^2. From Equation 8.56,

$$\overline{Nu}_D = 3.66 + \frac{0.0668(50\times10^{-6}/53\times10^{-3})\times2000\times5.3}{1+0.04\left[(50\times10^{-6}/53\times10^{-3})\times2000\times5.3\right]^{2/3}} = 4.371$$

and $\overline{h}_D = h_i = \overline{Nu}_D \dfrac{k}{D} = 4.371\times0.620\,W/m\cdot K/50\times10^{-6}\,m = 54.2\times10^3\,W/m^2\cdot K$.

For the cross flow of water over the tube, $Re_D = VD\rho/\mu$ = 2 m/s $\times$ (50 $\times 10^{-6}$ m + 2 $\times$ 1 $\times 10^{-3}$ m)(984 kg/m^3)/489 $\times 10^{-6}$ N·s/m^2 = 8253. From Equation 7.54,

$$\overline{Nu}_D = 0.3 + \frac{0.62(8253)^{1/2}(3.15)^{1/3}}{\left[1+(0.4/3.15)^{2/3}\right]^{1/4}}\left[1+\left(\frac{8253}{282,000}\right)^{5/8}\right]^{4/5} = 85.14$$

and

$$\overline{h}_D = h_o = \overline{Nu}_D k/(d+2t) = 85.14\times0.65\,W/m\cdot K/(50\times10^{-6}\,m + 2\times1\times10^{-3}\,m) = 27.0\times10^3\,W/m^2\cdot K$$

Therefore,

$$\overline{U}_i = \frac{1}{\left[\begin{array}{l}\dfrac{1}{54.2\times10^3\,W/m\cdot K} + \dfrac{50\times10^{-6}\,m/2}{1.4\,W/m\cdot K}\ln\left[\dfrac{(50\times10^{-6}\,m/2+1\times10^{-3}\,m)}{50\times10^{-6}\,m/2}\right] \\ +\dfrac{50\times10^{-6}\,m/2}{(50\times10^{-6}\,m/2+1\times10^{-3}\,m)}\times\dfrac{1}{27.0\times10^3\,W/m^2\cdot K}\end{array}\right]} = 11.7\times10^3\,W/m^2\cdot K$$

Equation (1) becomes

$$\frac{350K - T_{m,o}}{350K - 300K} = \exp\left(-\frac{11.7\times10^3\,W/m^2\cdot K\times8.17\times10^{-6}\,m^2}{60.4\times10^{-6}\,kg/s\cdot4194\,J/kg\cdot K}\right)$$

or, $T_{m,o}$ = 316 K <

Continued…

PROBLEM 8.115 (Cont.)

(c) For laminar flow, Equation 8.19 yields f = 64/Re_D = 64/2000 = 32 × 10^{-3}. Equation 8.22a yields

$$\Delta p = f\,\frac{\rho u_m^2}{2D}L = \frac{32\times10^{-3}\times995\,\text{kg/m}^3\times(31\,\text{m/s})^2\times52\times10^{-3}\,\text{m}}{2(50\times10^{-6}\,\text{m})} = 15.9\times10^6\,\text{Pa}$$ <

(d) The pressure generated by the water column must offset the pressure drop in the tube. Therefore,

$$\rho g H = \Delta p \quad \text{or} \quad H = \Delta p/\rho g = 15.9\times10^6\,\text{N/m}^2/(995\,\text{kg/m}^3\times9.8\,\text{m/s}^2) = 1630\,\text{m} = 1.63\,\text{km}$$ <

The time required for a particular volume of water to flow through the system is

$$t = \frac{V\rho}{m} = \frac{0.1\times\dfrac{1\text{m}^3}{1000\text{ml}}\times995\,\text{kg/m}^3}{60.4\times10^{-6}\,\text{kg/s}} = 1650\,\text{s}$$ <

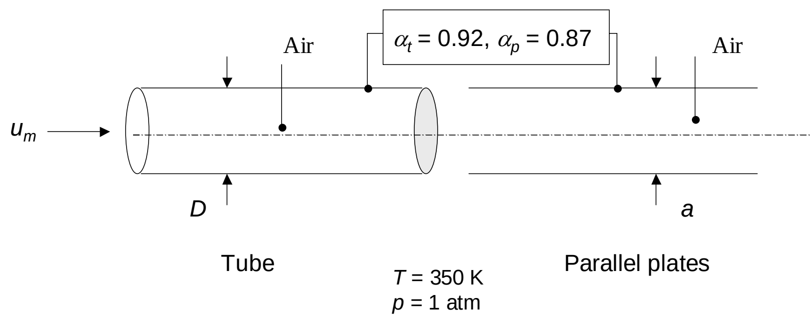
COMMENTS: (1) Microscale experimentation is often very difficult to perform. In addition to the difficulty in measuring the water outlet temperature, establishing a constant flow rate with such a large inlet pressure would be very difficult. (2) Turbulent conditions in microscale systems are rare in nature, and are difficult to achieve experimentally. (3) The glass tube wall is relatively thick. Therefore, conduction in the axial direction is likely to be significant. (4) The average mean water temperature inside the tube is $\overline{T}_m$ = ($T_{m,i}$ + $T_{m,o}$)/2 = (300 K + 316 K)/2 = 308 K. The assumed mean temperature of 305 K is good.

PROBLEM 8.116

KNOWN: Temperature and pressure of air flowing in a circular tube or between parallel plates. Thermal and momentum accommodation coefficients.

FIND: Tube diameter D and plate spacing a that correspond to a 10 percent reduction in the Nusselt number.

SCHEMATIC:



ASSUMPTIONS: (1) Ideal gas behavior. (2) Fully-developed laminar flow.

PROPERTIES: Table A.4 (T = 350 K): Air; c_p = 1009 J/kg·K, Pr = 0.70. Figure 2.8: Air; $\mathcal{M}$ = 28.97 kg/kmol, $d = 0.372 \times 10^{-9}$ m.

ANALYSIS: The ideal gas constant, specific heat at constant volume, and ratio of specific heats are:

$$R = \frac{\mathcal{R}}{\mathcal{M}} = \frac{8.315 \text{ kJ/kmol}\cdot\text{K}}{28.97 \text{ kg/kmol}} = 0.287 \ \frac{\text{kJ}}{\text{kg}\cdot\text{K}};$$

$$c_v = c_p - R = 1.009\frac{\text{kJ}}{\text{kg}\cdot\text{K}} - 0.287\frac{\text{kJ}}{\text{kg}\cdot\text{K}} = 0.722\frac{\text{kJ}}{\text{kg}\cdot\text{K}}; \quad \gamma = \frac{c_p}{c_v} = \frac{1.009}{0.722} = 1.398$$

From Equation 2.11 the mean free path of air is

$$\lambda_{\text{mfp}} = \frac{k_B T}{\sqrt{2}\pi d^2 p} = \frac{1.381\times10^{-23} \text{ J/K}\times 350 \text{ K}}{\sqrt{2}\pi\left(0.372\times10^{-9} \text{ m}\right)^2\left(1.0133\times10^5 \text{ N/m}^2\right)} = 77.6\times10^{-9} \text{ m} = 77.6 \text{ nm}$$

From Equation 8.78 the Nusselt number for the tube may be expressed as

$$Nu_D = \frac{48}{11 - 6\zeta + \zeta^2 + 48\Gamma_t} = 0.9\times4.36 = 3.92 \tag{1}$$

where

$$\Gamma_t = \frac{2-\alpha_t}{\alpha_t}\frac{2\gamma}{\gamma+1}\left[\frac{\lambda_{\text{mfp}}}{PrD}\right] = \frac{2-0.92}{0.92}\cdot\frac{2\times1.398}{1.398+1}\left[\frac{77.6\times10^{-9} \text{ m}}{0.700D}\right] = \frac{152\times10^{-9} \text{ m}}{D} \tag{2}$$

Continued…

PROBLEM 8.116 (Cont.)

$$\Gamma_p = \frac{2-\alpha_p}{\alpha_p}\left[\frac{\lambda_{\text{mfp}}}{D}\right] = \frac{2-0.87}{0.87}\cdot\left[\frac{77.6\times10^{-9}\ \text{m}}{D}\right] = \frac{101\times10^{-9}\ \text{m}}{D} \qquad (3)$$

$$\zeta = \frac{8\Gamma_p}{\left(1+8\Gamma_p\right)} \qquad (4)$$

Equations 1 through 4 may be solved by trial-and-error to yield $D = 2.94 \times 10^{-6}$ m = 2.94 μm. <

From Equation 8.79 the Nusselt number for the parallel plate configuration may be expressed as

$$Nu_D = \frac{140}{17-6\zeta+(2/3)\zeta^2+70\Gamma_t} = 0.9\times8.23 = 7.41 \qquad (5)$$

where

$$\Gamma_t = \frac{2-\alpha_t}{\alpha_t}\frac{2\gamma}{\gamma+1}\left[\frac{\lambda_{\text{mfp}}}{PrD_h}\right] = \frac{2-0.92}{0.92}\cdot\frac{2\times1.398}{1.398+1}\left[\frac{77.6\times10^{-9}\ \text{m}}{0.700D_h}\right] = \frac{152\times10^{-9}\ \text{m}}{D_h} \qquad (6)$$

$$\Gamma_p = \frac{2-\alpha_p}{\alpha_p}\left[\frac{\lambda_{\text{mfp}}}{D_h}\right] = \frac{2-0.87}{0.87}\cdot\left[\frac{77.6\times10^{-9}\ \text{m}}{D_h}\right] = \frac{101\times10^{-9}\ \text{m}}{D_h} \qquad (7)$$

$$\zeta = \frac{6\Gamma_p}{\left(1+6\Gamma_p\right)} \qquad (8)$$

Equations 5 through 8 may be solved by trial-and-error to yield $D_h = 3.97 \times 10^{-6}$ m = 3.97 μm. The plate spacing $a = D_h/2$ = 3.97 μm/2 = 1.99 μm. <

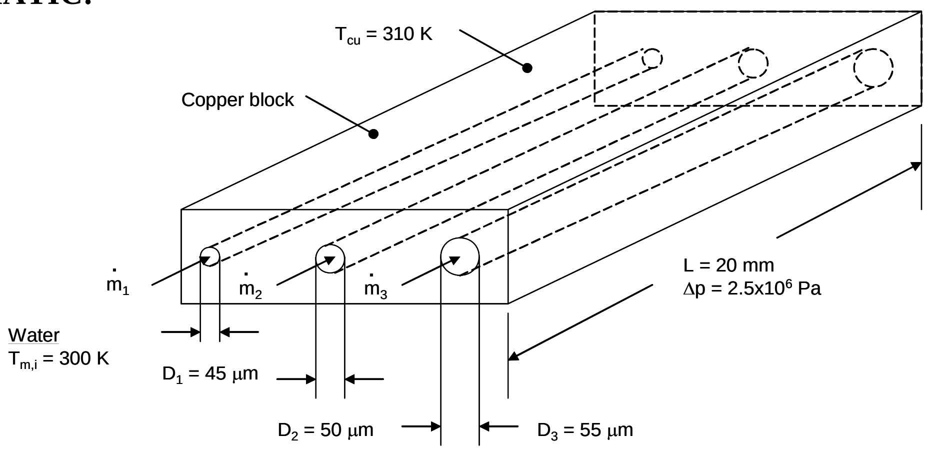
COMMENTS: The tube diameter and plate spacing required to reduce the Nusselt number by 10 percent are quite small. In situations involving characteristic dimensions that are not extremely small, the effect of the molecule-wall interaction can typically be neglected.

PROBLEM 8.117

KNOWN: Diameters and length of three microchannels machined in a copper block. Inlet temperature of water flowing through the channels, copper block temperature, pressure difference from inlet to outlet of the channels.

FIND: (a) Mass flow rate and outlet temperature in each channel, (b) Average flow rate through each channel and average, mixed temperature of water collected from all three channels, (c) Comparison between average flow rates and average heat transfer rates based upon experiment to that calculated based upon a single microchannel diameter of 50 μm.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties and steady-state conditions, (2) Incompressible liquid and negligible viscous dissipation, (3) Negligible microscale or nanoscale effects, (4) Negligible entrance or exit losses in the microchannels, (5) Fully developed flow for purposes of calculating the mass flow rate in each channel, (6) Isothermal copper block.

PROPERTIES: Table A.6, water: ($\bar{T}_m$ = 305 K): k = 0.620 W/m·K, c_p = 4178 J/kg·K, μ = 769 × 10^{-6} N·s/m^2, ν = 7.728 × 10^{-7} m^2/s, Pr = 5.2, ρ = 995 kg/m^3.

ANALYSIS: (a) For the D = 50 μm channel, from Equation 8.22a,

$$\Delta p = f\rho u_m^2 L/2D = f \times 995 \text{kg}/\text{m}^3 \times u_m^2 \times 20\times10^{-3}\text{m}/(2\times50\times10^{-6}\text{m}) \qquad (1)$$

where the friction factor may be evaluated using the Petukhov expression,

$$f = (0.790\ln Re_D - 1.64)^{-2} \qquad (2)$$

The Reynolds number may be expressed as

$$Re_D = \frac{u_m D}{\nu} = \frac{u_m \times 50\times10^{-6}\text{m}}{7.728\times10^{-7}\text{m}^2/\text{s}} \qquad (3)$$

Continued…

PROBLEM 8.117 (Cont.)

Simultaneous solution of Equations (1) through (3) yields, for the D = 50 μm channel, Re_D = 845, u_m = 13.06 m/s. The mass flow rate is

$$\dot{m} = \rho u_m \pi D^2/4 = 995\text{kg}/\text{m}^3 \times 13.06\text{m/s} \times \pi \times (50\times10^{-6}\text{m})^2/4 = 2.55\times10^{-5}\text{kg/s}$$ <

The thermal entrance length is $x_{fd,t} = 0.05Re_D PrD = 0.05 \times 845 \times 5.2 \times 50 \times 10^{-6}$ m = 11.0× 10^{-3} m = 11.0 mm. From the Hausen correlation,

$$\overline{Nu}_D = 3.66 + \frac{0.0668\times(50\times10^{-6}\text{m}/20\times10^{-3}\text{m})\times845\times5.2}{1+0.04\times\left[(50\times10^{-6}\text{m}/20\times10^{-3}\text{m})\times845\times5.2\right]^{2/3}} = 4.27$$

Hence,

$$\bar{h} = \frac{\overline{Nu}_D k}{D} = \frac{4.27\times0.62\text{W/m}\cdot\text{K}}{50\times10^{-6}\text{m}} = 5.29\times10^4\text{W/m}^2\cdot\text{K}$$

From Equation 8.42,

$$T_m(x=L) = T_s - \left[T_s - T_{m,i}\right]\exp\left(-\frac{PL}{\dot{m}c_p}\bar{h}\right)$$

$$= 310\text{K} - [310\text{K} - 300\text{K}]\exp\left(-\frac{\pi\times50\times10^{-6}\text{m}}{2.55\times10^{-5}\text{kg/s}\times4178\text{J/kg}\cdot\text{K}}\times5.29\times10^4\text{W/m}^2\cdot\text{K}\right)$$

$$= 307.9\text{K} = 34.9°\text{C} = T_{m,o}$$

<

Results for the three different channels are shown in the table below. <

	D = 45 μm (case 1)	D = 50 μm (case 2)	D = 55 μm (case 3)
Re_D	690	845	1012
u_m (m/s)	11.85	13.06	14.23
$\dot{m}$ (kg/s)	1.88×10^{-5}	2.55×10^{-5}	3.36×10^{-5}
$x_{fd,t}$ (mm)	8.1	11.0	14.5
$\overline{Nu}_D$	4.12	4.27	4.44
$\bar{h}(\text{W/m}^2\cdot\text{K})$	5.68×10^4	5.29×10^4	5.01×10^4
$T_{m,o}$ (K)	308.7	307.9	307.1

Continued…

PROBLEM 8.117 (Cont.)

(b) The average mass flow rate is

$$\overline{\dot{m}} = (\dot{m}_1 + \dot{m}_2 + \dot{m}_3)/3 = \left[(1.88\times10^{-5} + 2.55\times10^{-5} + 3.36\times10^{-5})\text{kg/s}\right]/3 = 2.60\times10^{-5}\,\text{kg/s} \quad <$$

(c) The average, mixed outlet temperature is

$$T_{m,o} = (\dot{m}_1 T_{m,o,1} + \dot{m}_2 T_{m,o,2} + \dot{m}_3 T_{m,o,3})/(\dot{m}_1 + \dot{m}_2 + \dot{m}_3)$$

$$= \frac{(1.88\times10^{-5}\,\text{kg/s}\times308.7\text{K} + 2.55\times10^{-5}\,\text{kg/s}\times307.9\text{K} + 3.36\times10^{-5}\,\text{kg/s}\times307.1\text{K})}{(1.88\times10^{-5} + 2.55\times10^{-5} + 3.36\times10^{-5})\text{kg/s}} = 307.7\text{K}$$

(d) Equation 8.42 may be re-arranged to

$$\overline{h} = -\frac{\dot{m}c_p}{PL}\ln\left(\frac{T_s - T_{m,o}}{T_s - T_{m,L}}\right) = -\frac{2.60\times10^{-5}\,\text{kg/s}\times4178\,\text{J/kg}\cdot\text{K}}{\pi\times50\times10^{-6}\,\text{m}\times20\times10^{-3}\,\text{m}}\ln\left(\frac{310-307.7}{310-300}\right) = 50{,}800\,\text{W/m}^2\cdot\text{K}$$

Thus, the inferred value of the mass flow rate is 2% greater than the predicted value for a 50 μm diameter channel. The inferred value of the convection coefficient (50,800 W/m2·K) is 4% less than the predicted value for a 50 μm diameter channel. The experimenter must carefully assess his or her claims since the differences are small and might be attributed to variations in the channel dimensions that occur during their manufacture.

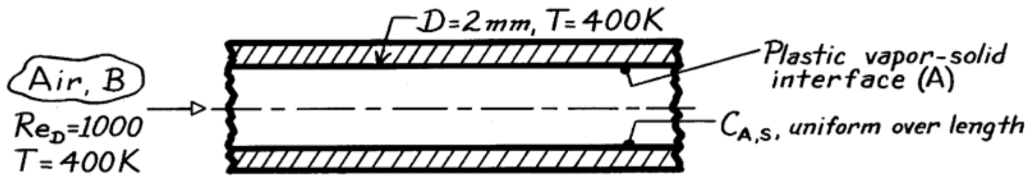
COMMENTS: (1) Experimentation at the microscale is challenging. Misinterpretation of the experimental results might occur unless the experimental system is designed very carefully. For example, the diameters of the channels might need to be measured after their manufacture. (2) When boring holes, the hole diameter is always greater than the diameter of the tool. If the experimentalist assumes that the actual hole size is the same as the tool size, what (inappropriate) conclusions might he or she make regarding possible microscale fluid flow and heat transfer effects when analyzing the measured results?

PROBLEM 8.118

KNOWN: Air flow through a plastic tube in which evaporation occurs.

FIND: Convection mass transfer coefficient, h_m.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Heat-mass transfer analogy applicable, (4) Fully-developed flow and mass transfer conditions.

PROPERTIES: Plastic-air (given, 400K): $Sc = \nu/D_{AB} = 2.0$; *Table A-4*, Air (400K, 1 atm): $\nu = 26.41 \times 10^{-6}\ m^2/s$.

ANALYSIS: For fully-developed flow and thermal conditions with laminar flow and a uniform surface temperature,

$$Nu_D = \frac{h\,D}{k} = 3.66$$

This situation is analogous to the evaporation of plastic vapor into the air stream with the inner surface remaining at a constant concentration of plastic vapor, $C_{A,s}$, along the length of the tube. Invoking the heat-mass transfer analogy,

$$Sh_D = \frac{h_m D}{D_{AB}} = 3.66.$$

Recognizing that $Sc = \nu/D_{AB}$,

$$h_m = 3.66\left(\frac{\nu}{Sc}\right)\frac{1}{D} = 3.66 \times \frac{26.4\times10^{-6}m^2/s}{2.0} \times \frac{1}{2\times10^{-3}m} = 2.42\times10^{-2} m/s. \qquad <$$

COMMENTS: (1) The heat-mass transfer analogy requires that the vapor (A) have a negligible effect on the flow. Hence, the flow is that of air (B) and $\nu = \nu_B$.

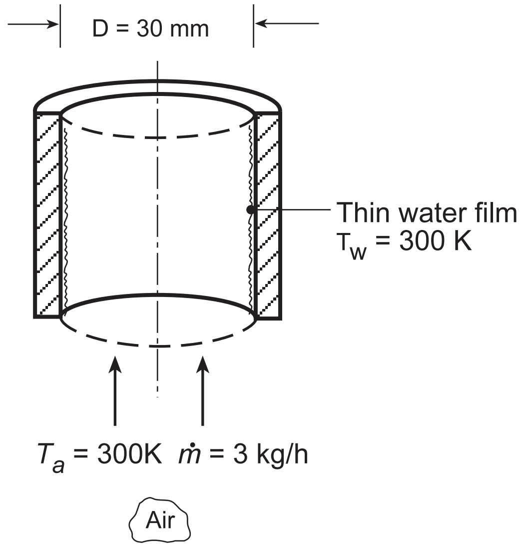
(2) Only the mixture property D_{AB} is required to characterize the plastic vapor for this evaporation process.

PROBLEM 8.119

KNOWN: Air passing upward through a tube having a thin water film on its inside surface.

FIND: Convection mass transfer coefficient.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Heat-mass analogy applicable, and (4) Fully developed flow and thermal conditions.

PROPERTIES: *Table A.4*, Air (300 K, 1 atm): $\mu = 184.6 \times 10^{-7}$ N·s/m^2, k = 0.0263 W/m·K; *Table A.8*, Water vapor-air (300 K, 1atm): $D_{AB} = 0.26 \times 10^{-4}$ m^2/s.

ANALYSIS: Begin by characterizing the air flow with the Reynolds number,

$$Re_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times (3/3600)\,\text{kg/s}}{\pi \times 0.030\text{m} \times 184.6 \times 10^{-7}\ \text{N/s} \cdot \text{m}^2} = 1916$$

Since the flow is laminar, and assuming fully developed flow and thermal conditions, Eq. 8.55 is appropriate for the uniform T_s wall condition,

$$Nu_D = \frac{hD}{k} = 3.66 \qquad\qquad h = \frac{0.0263\,\text{W/m} \cdot \text{K}}{0.030\text{m}} \times 3.66 = 3.21\,\text{W/m}^2 \cdot \text{K}$$

Invoking the heat-mass analogy, for laminar flow conditions,

$$Sh_D = \frac{h_m D}{D_{AB}} = Nu_D$$

$$h_m = \frac{D_{AB}}{D} Nu_D = \frac{0.26 \times 10^{-4}\ \text{m}^2/\text{s}}{0.030\text{m}} \times 3.66 = 0.0032\,\text{m/s}$$ <

COMMENTS: (1) The heat-mass analogy requires that the water vapor (A) have negligible effect on the velocity boundary layer. It is important to recognize that the vapor is species (A) and the air species (B). Hence the flow is that of air (B) and hence $\mu = \mu_B$.

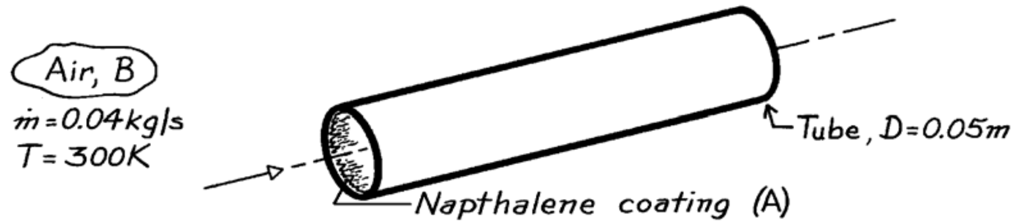
(2) Note only the mixture property D_{AB} is required to characterize the water vapor for this evaporation process.

PROBLEM 8.120

KNOWN: Temperature and flow rate of air in a tube with a naphthalene coated inner surface.

FIND: Convection mass transfer coefficient under fully developed conditions and velocity and concentration entry lengths.

SCHEMATIC:



ASSUMPTIONS: (1) Heat and mass transfer analogy is applicable, (2) Uniform vapor concentration along inner surface.

PROPERTIES: *Table A-4*, Air (300 K, 1 atm): $\mu = 184.6 \times 10^{-7}$ N·s/m^2, $\nu = 15.89 \times 10^{-6}$ m^2/s; *Table A-8*, Naphthalene-air (300K, 1 atm): $D_{AB} = 6.2 \times 10^{-6}$ m^2/s, Sc = μ/D_{AB} = 2.56.

ANALYSIS: For air flow through the tube,

$$Re_D = \frac{4\,\dot{m}}{\pi\, D\mu} = \frac{4 \times 0.04\ \text{kg/s}}{\pi(0.05\text{m})\ 184.6 \times 10^{-7}\text{N}\cdot\text{s/m}^2} = 55{,}178.$$

Hence the flow is turbulent and from Eq. 8.88,

$$Sh_D = 0.023\, Re_D^{4/5}\, Sc^{0.4} = 0.023(55{,}178)^{4/5}(2.56)^{0.4} = 208$$

$$h_m = \frac{D_{AB}}{D} Sh_D = \frac{6.2 \times 10^{-6}\text{m}^2/\text{s}}{0.05\ \text{m}} 208 = 0.026\ \text{m/s}. \quad <$$

From Eq. 8.4, it follows that

$$10D \le x_{fd,h} \approx x_{fd,c} \le 60D$$

or

$$0.5\ \text{m} \le x_{fd,h} \approx x_{fd,c} \le 3\ \text{m}. \quad <$$

An entry length of 0.5 m is assumed.

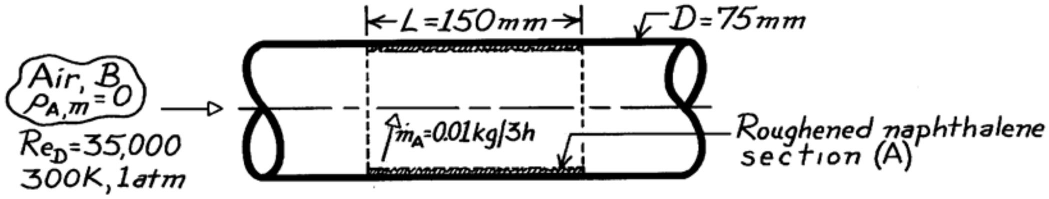
COMMENTS: Note that the flow properties are taken to be those of the air, with the contribution of the naphthalene vapor assumed to be negligible.

PROBLEM 8.121

KNOWN: Air flow over roughened section of tube constructed from naphthalene.

FIND: Mass and heat transfer convection coefficients associated with the roughened section; contrast these results with those for a smooth section.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Heat-mass transfer analogy applicable, (3) Negligible naphthalene vapor in airstream, $\rho_{A,m} = 0$, (4) Constant properties, (5) Naphthalene vapor behaves as perfect gas.

PROPERTIES: *Table A-4*, Air (300K, 1 atm): $\nu = 15.89 \times 10^{-6}$ m^2/s, k = 0.0263 W/m·K, Pr = 0.707; *Table A-8*, Naphthalene-air mixture (300K, 1 atm): $D_{AB} = 0.62 \times 10^{-5}$ m^2/s, Sc= ν_B/D_{AB} = 2.563; Naphthalene (given, 300K): $p_{sat,A} = 1.31 \times 10^{-4}$ bar, $\mathcal{M}_A$ = 128.16 kg/kmol.

ANALYSIS: Using the rate equation with the experimentally observed sublimination rate of naphthalene vapor, the average mass transfer coefficient for the section is

$$h_m = \dot{m}_A / (\pi\ DL)\ \left(\rho_{A,s} - \rho_{A,m}\right)$$

$$\rho_{A,m} = 0 \qquad \rho_{A,s} = \rho_{A,sat}\left(300K\right) = M_A\ p_{sat,A} / \Re T$$

$$\rho_{A,s} = 128.16\ \text{kg/kmol} \times \frac{1.31\times10^{-4}\text{bar}}{8.314\times10^{-2}\text{m}^3\cdot\text{bar/kmol}\cdot\text{K}\times300\text{K}} = 6.731\times10^{-4}\ \text{kg/m}^3$$

$$h_m = \frac{0.010\ \text{kg}}{3\times3600\ \text{s}} / \left(\pi\times0.075\text{m}\times0.150\text{m}\right)\ \left(6.731\times10^{-4} - 0\right)\ \text{kg/m}^3 = 3.89\times10^{-2}\text{m/s}. \qquad <$$

Invoking the heat-mass transfer analogy, the associated heat transfer coefficient is

$$h = h_m \frac{k}{D_{AB}}\left(\frac{Pr}{Sc}\right)^{1/3} = 3.89\times10^{-2}\text{m/s}\frac{0.0263\ \text{W/m}\cdot\text{K}}{0.62\times10^{-5}\text{m}^2/\text{s}}\left(\frac{0.707}{2.563}\right)^{1/3} = 107\ \text{W/m}^2\cdot\text{K}. \qquad <$$

The corresponding convection coefficients for a *smooth* section can be estimated using the Dittus-Boelter relation (the heating condition, n = 0.4, has been selected),

$$h = \frac{k}{D}0.023\ Re_D^{4/5}\ Pr^{0.4} = \left(0.0263\ \text{W/m}\cdot\text{K}/0.075\ \text{m}\right)\times0.023\left(35,000\right)^{4/5}\left(0.707\right)^{0.4} = 30\ \text{W/m}^2\cdot\text{K} \qquad <$$

Using the analogous mass transfer relation, Eq. 8.88,

$$h_m = \left(D_{AB} / D\right)0.023\ Re_D^{4/5}Sc^{0.4} = \left(0.62\times10^{-5}\text{m}^2/\text{s}/0.075\ \text{m}\right)\times0.023\left(35,000\right)^{4/5}\left(2.563\right)^{0.4}$$

$$h_m = 1.20 \times 10^{-2}\ \text{m/s} \qquad <$$

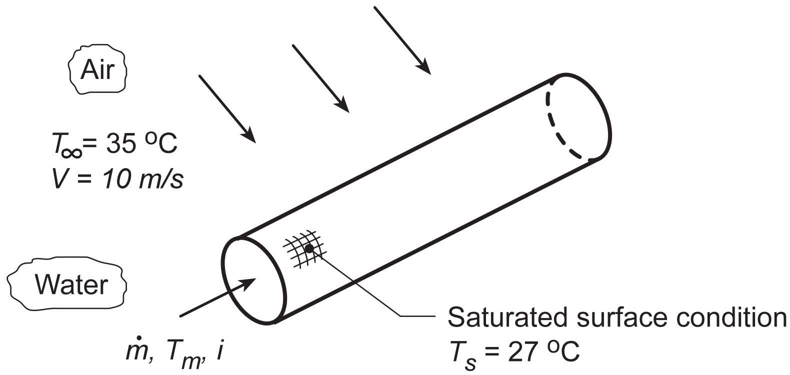
COMMENTS: The effect of roughening is to increase the convection coefficients over the corresponding value for the smooth condition; in this case, by a factor of approximately 3.5.

PROBLEM 8.122

KNOWN: Dry air with prescribed velocity and temperature flowing over a thin-walled tube with a water-saturated fibrous coating. Water passes at a prescribed rate through the tube to maintain an approximately uniform surface temperature $T_s = 27°C$.

FIND: (a) Heat rate from the external surface of the tube considering heat and mass transfer processes and (b) For a flow rate of $\dot{m} = 0.025$ kg/s, the inlet temperature, $T_{m,i}$, of the water that must be supplied to the tube.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Heat-mass analogy applicable, and (4) Water in tube flow is incompressible with negligible viscous dissipation.

PROPERTIES: *Table A.4*, Air ($\overline{T}_f = (T_s + T_\infty)/2 = 304$ K): $\rho = 1.148$ kg/m^3, $c_p = 1007$ J/kg·K, $\nu = 16.29 \times 10^{-6}$ m^2/s, k = 0.0266 W/m·K, $\alpha = 23.09 \times 10^{-6}$ m^2/s, Pr = 0.706; *Table A.6*, Water (T_s = 300 K): $\rho_{A,s} = 1/v_g = 0.02556$ kg/m^3, $h_{fg} = 2438$ kJ/kg, $\mu = 855 \times 10^{-6}$ N·s/m^2; *Table A.6*, Water ($\overline{T}_m$ = 305 K): $\rho = 995$ kg/m^3, $c_p = 4178$ J/kg·K, $\mu = 769 \times 10^{-6}$ N·s/m^2, k = 0.620 W/m·K, Pr = 5.20; *Table A.8*, Water vapor-air (T_s = 300 K): $D_{AB} = 0.26 \times 10^{-4}$ m^2/s.

ANALYSIS: (a) On the Schematic above, the surface energy balance yields

$$q_{out} = q_{conv} + q_{evap} \qquad (1)$$

and substituting the rate equations,

$$q_{conv} = \overline{h}_o A_s \left(T_s - T_\infty\right) \qquad q_{evap} = n_A h_{fg} = \overline{h}_m A_s \left(\rho_{A,s} - \rho_{A,\infty}\right) h_{fg} \qquad (2,3)$$

where $\overline{h}_o$ can be estimated from an appropriate correlation and $\overline{h}_m$ from the heat-mass analogy using $\overline{h}_o$.

Estimation of the heat transfer coefficient, $\overline{h}_o$: The Reynolds number, evaluated with properties at $\overline{T}_f = (T_s + T_\infty)/2 = 304$ K, is

$$Re_{D_o} = \frac{VD}{\nu} = \frac{10\,\text{m/s} \times 0.020\,\text{m}}{1.629 \times 10^{-5}\,\text{m}^2/\text{s}} = 12,277 \qquad (4)$$

Using the Churchill-Bernstein correlation, Eq. 7.54, for cross flow over a cylinder, find $\overline{h}_o$

$$Nu_{D,o} = 0.3 + \frac{0.62\,Re_{D,o}^{1/2}\,Pr_o^{1/3}}{\left[1 + \left(0.4/Pr_o\right)^{2/3}\right]^{1/4}} \left[1 + \left(\frac{Re_{D,o}}{282,000}\right)^{5/8}\right]^{4/5} \qquad (5)$$

Continued...

PROBLEM 8.122 (Cont.)

$$Nu_{D,o} = 0.3 + \frac{0.62(12,277)^{1/2}(0.706)^{1/3}}{\left[1+(0.4/0.706)^{2/3}\right]^{1/4}}\left[1+\left(\frac{12,277}{282,000}\right)^{5/8}\right]^{4/5}$$

$$\bar{h}_o = \frac{k}{D}Nu_{D,o} = \frac{0.0266\,\text{W/m}\cdot\text{K}}{0.020\,\text{m}} \times 60.1 = 80.0\,\text{W/m}^2\cdot\text{K}$$

The Heat-Mass Analogy: From Eq. 6.60, with n = 1/3,

$$\frac{\bar{h}_o}{\bar{h}_m} = \rho c_p Le^{2/3} = \rho c_p\left(\frac{\alpha}{D_{AB}}\right)^{2/3} \quad (6)$$

$$\bar{h}_m = 80.0\,\text{W/m}^2\cdot\text{K}\Big/\left[1.148\,\text{kg/m}^3 \times 1007\,\text{J/kg}\cdot\text{K}\left(23.09\times10^{-6}\,\text{m}^2/\text{s}\big/0.26\times10^{-4}\,\text{m}^2/\text{s}\right)^{2/3}\right] = 0.0749\,\text{m/s}$$

Hence, the heat rate leaving the tube surface from Eq. (1) is,

$$q_{out} = \left[80\,\text{W/m}^2\cdot\text{K}(27-35)^\circ\text{C} + 0.0749\,\text{m/s}(0.02556-0)\,\text{kg/m}^3 \times 2438\times10^3\,\text{J/kg}\right](\pi\times0.020\,\text{m}\times0.200\,\text{m})$$

$$q_{out} = -8.04\,\text{W} + 58.65 = 50.6\,\text{W}$$ <

(b) For tube flow analysis, the heat rate and rate equations are

$$q = \dot{m}c_p\left(T_{m,o} - T_{m,i}\right) \qquad \frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{\pi DL}{\dot{m}c_p}\right)\bar{h}_i \quad (7,8)$$

where T_s = 27°C, the uniform temperature of the tube surface, and q = -50.6 W according to the analysis of part (a). To estimate $\bar{h}_i$, first characterize the flow,

$$Re_{D,i} = \frac{4\dot{m}}{\pi D\mu_i} = \frac{4\times0.025\,\text{kg/s}}{\pi\times0.020\,\text{m}\times769\times10^{-6}\,\text{N}\cdot\text{s/m}^2} = 2070 \quad (9)$$

using properties evaluated at an assumed mean temperature, $\bar{T}_m$ = 305 K (slightly above T_s). The flow is laminar, and with Pr > 5, the Hausen correlation, Eq. 8.57 applies, with $Gz_D = (D/L)Re_D Pr$ = (0.02 m/0.2 m) × 2070 × 5.2 = 1076. Thus,

$$\overline{Nu}_{D,i} = \frac{\bar{h}_i D}{k} = 3.66 + \frac{0.0668\,Gz_D}{1+0.04Gz_D^{2/3}} = 3.66 + \frac{0.0668\times1076}{1+0.04(1076)^{2/3}} = 17.5$$

$$\bar{h}_i = \frac{k_i}{D}\overline{Nu}_{D,i} = \frac{0.620\,\text{W/m}\cdot\text{K}}{0.020\,\text{m}}\times17.5 = 542\,\text{W/m}^2\cdot\text{K}$$

Referring to Eqs. (7) and (8), recognize that there are two unknowns, $T_{m,i}$ and $T_{m,o}$, as we have evaluated both q and $\bar{h}_i$. Using the IHT solver,

$T_{m,i}$ = 307.7 K, $T_{m,o}$ = 307.2 K <

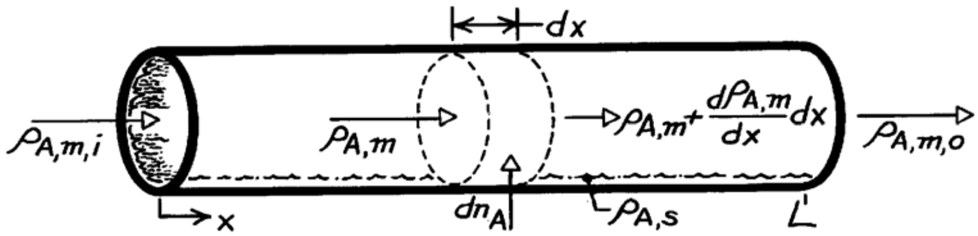
PROBLEM 8.123

KNOWN: Density and flow rate of gas through a tube with evaporation or sublimation at the tube surface.

FIND: (a) Longitudinal distribution of mean vapor density, (b) Total rate of vapor transfer.

SCHEMATIC:



ASSUMPTIONS: (1) Steady, incompressible flow, (2) Flow rate is independent of x, (3) Negligible chemical reactions, (4) Uniform perimeter P.

ANALYSIS: (a) Applying conservation of species to a differential control volume

$$\rho_{A,m}\, u_m\, A_c + dn_A = \left(\rho_{A,m} + \frac{d\rho_{A,m}}{dx}dx\right) u_m\, A_c$$

or, with $u_m A_c = \dot{m}/\rho$ and $dn_A = h_m P\, dx\left(\rho_{A,s} - \rho_{A,m}\right)$,

$$\frac{\dot{m}}{\rho}\,\frac{d\,\rho_{A,m}}{dx}dx = h_m P\, dx\left(\rho_{A,s} - \rho_{A,m}\right).$$

Separating variables and integrating,

$$\int_{\rho_{A,mi}}^{\rho_{A,m}} \frac{d\,\rho_{A,m}}{\rho_{A,s} - \rho_{A,m}} = \int_0^x \frac{\rho\, h_m\, P}{\dot{m}}dx = \frac{\rho\, P}{\dot{m}}\int_0^x h_m\, dx$$

$$\ell n\frac{\rho_{A,s} - \rho_{A,m}}{\rho_{A,s} - \rho_{A,m,i}} = -\frac{\rho\, Px\bar{h}_m}{\dot{m}} \quad \text{or} \quad \frac{\rho_{A,s} - \rho_{A,m}(x)}{\rho_{A,s} - \rho_{A,m,i}} = \exp\left(-\frac{\rho\, P\, x}{\dot{m}}\bar{h}_m\right). \qquad (1)$$ <

(b) With $\Delta\rho_A \equiv \rho_{A,s} - \rho_{A,m}$,

$$n_A = (\dot{m}/\rho)\,\left(\rho_{A,m,o} - \rho_{A,m,i}\right) = -(\dot{m}/\rho)\,\left(\Delta\rho_{A,o} - \Delta\rho_{A,i}\right)$$

and from Eq. (1) with

$$-\frac{\dot{m}}{\rho} = P\, L\, \bar{h}_m / \ell n\,\frac{\Delta\rho_{A,o}}{\Delta\rho_{A,i}}$$

it follows that

$$n_A = \bar{h}_m\, P\, L\, \frac{\Delta\rho_{A,o} - \Delta\rho_{A,i}}{\ell n\left(\Delta\rho_{A,o}/\Delta\rho_{A,i}\right)}.$$ <

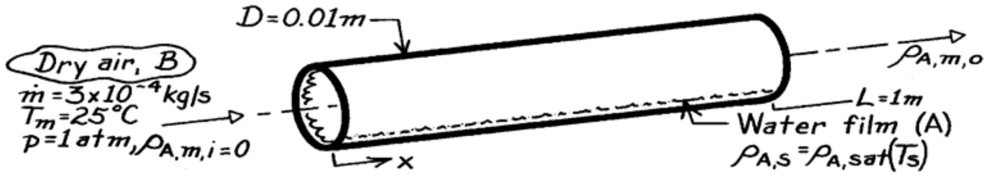
COMMENTS: Due to the addition of vapor, $\dot{m}$ will actually increase with x. However, if the specific humidity of the saturated gas-vapor mixture is small (as is usually the case), the change in $\dot{m}$ will be small.

PROBLEM 8.124

KNOWN: Flow rate and temperature of air. Tube diameter and length. Presence of water film on tube inner surface.

FIND: (a) Vapor density at tube outlet, (b) Evaporation rate.

SCHEMATIC:



ASSUMPTIONS: (1) Steady, incompressible flow, (2) Constant flow rate, (3) Isothermal system (water film maintained at 25°C).

PROPERTIES: *Table A-4*, Air (1 atm, 298 K): $\rho = 1.1707$ kg/m^3, $\mu = 183.6 \times 10^{-7}$ N·s/m^2, $\nu = 15.71 \times 10^{-6}$ m^2/s; *Table A-6*, Water vapor (298 K): $\rho_{A,sat} = 1/v_g = (1/44.25$ m^3/kg$) = 0.0226$ kg/m^3; *Table A-8*, Air-vapor (298 K): $D_{AB} = 26 \times 10^{-6}$ m^2/s; $Sc = \nu/D_{AB} = 0.60$.

ANALYSIS: (a) We begin by determining the whether the flow is laminar or turbulent.

$$Re_D = \frac{4\,\dot{m}}{\pi\,D\mu} = \frac{4\times3\times10^{-4}\,\text{kg/s}}{\pi(0.01\text{ m})183.6\times10^{-7}\,\text{N}\cdot\text{s/m}^2} = 2080.$$

Flow is laminar and from Eq. 8.3 and the mass transfer analogy to Eq. 8.23,

$x_{fd,h} = 0.05Re_DD = 0.05\times2080\times0.01$ m $= 1.04$ m, $x_{fd,c} = x_{fd,h}Sc = 1.04$ m $\times\ 0.60 = 0.62$ m

Thus this is a combined entry length situation and the mass transfer analogy to the Baehr and Stephan correlation, Eq. 8.58, is appropriate. By analogy to Eq. 8.57, $Gz_{m,D} = (D/L)Re_DSc = (0.01\text{ m}/1\text{ m})\times2080\times0.60 = 12.5$, and

$$\overline{Sh}_D = \frac{\overline{h}_mD}{D_{AB}} = \frac{\dfrac{3.66}{\tanh[2.264Gz_{m,D}^{-1/3} + 1.7Gz_{m,D}^{-2/3}]} + 0.0499Gz_{m,D}\tanh(Gz_{m,D}^{-1})}{\tanh(2.432Sc^{1/6}Gz_{m,D}^{-1/6})}$$

$$= \frac{\dfrac{3.66}{\tanh[2.264\times12.5^{-1/3} + 1.7\times12.5^{-2/3}]} + 0.0499\times12.5\tanh(12.5^{-1})}{\tanh(2.432\times0.60^{1/6}\times12.5^{-1/6})} = 4.79$$

$$\overline{h}_m = \frac{\overline{Sh}_D\ D_{AB}}{D} = \frac{4.79\times26\times10^{-6}\text{m}^2/\text{s}}{0.01\text{ m}} = 0.0125\text{ m/s}$$

From Equation 8.86,

$$\rho_{A,m,o} = \rho_{A,s} - (\rho_{A,s} - \rho_{A,m,i})\exp\left(-\frac{\pi\,DL}{\dot{m}}\rho\overline{h}_m\right)$$

where $\rho_{A,s} = \rho_{A,sat} = 0.0226$ kg/m^3. Thus,

Continued …

PROBLEM 8.124 (Cont.)

$$\rho_{A,m,o} = 0.0226 \text{ kg/m}^3$$
$$-\left(0.0226 \text{ kg/m}^3 - 0\right)\exp\left(-\frac{\pi\ 0.01 \text{ m} \times 1 \text{ m}}{3\times10^{-4} \text{ kg/s}} \times 1.1707 \text{ kg/m}^3 \times 0.0125 \text{ m/s}\right)$$ <
$$= 0.0177 \text{ kg/m}^3$$

(b) The evaporation rate is

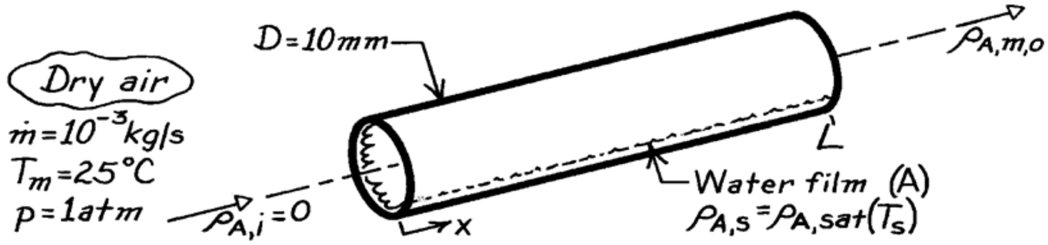
$$n_A = u_m A_c\left(\rho_{A,m,o} - \rho_{A,m,i}\right) = \frac{\dot{m}}{\rho}\left(\rho_{A,m,o}\right) = \frac{3\times10^{-4} \text{ kg/s}}{1.1707 \text{ kg/m}^3} 0.0177 \frac{\text{kg}}{\text{m}^3} = 4.54\times10^{-6} \text{ kg/s.}$$ <

PROBLEM 8.125

KNOWN: Flow rate and temperature of air in circular tube of prescribed diameter. Inner tube surface is wetted. Flow is fully developed and inlet air is dry.

FIND: Tube length required to reach 99% of saturation.

SCHEMATIC:



ASSUMPTIONS: (1) Steady, incompressible flow, (2) Constant flow rate, (3) Water film is also at 25°C.

PROPERTIES: *Table A-4*, Air (298 K, 1 atm): $\rho = 1.17$ kg/m^3, $\mu = 183.6 \times 10^{-7}$ N·s/m^2, $\nu = 15.71 \times 10^{-6}$ m^2/s; *Table A-6*, Water vapor (298 K): $\rho_{A,sat} = 1/v_g = (1/44.25$ m^3/kg$) = 0.0226$ kg/m^3; *Table A-8*, Air-vapor (298 K): $D_{AB} = 26 \times 10^{-6}$ m^2/s, $Sc = \nu/D_{AB} = 0.60$.

ANALYSIS: If $\rho_{A,m,o} = 0.99\ \rho_{A,s}$, it follows from Equation 8.86 that

$$\frac{\rho_{A,s} - 0.99\ \rho_{A,s}}{\rho_{A,s}} = 0.01 = \exp\left(-\frac{\pi\ DL\rho}{\dot{m}}\overline{h}_m\right).$$

With

$$Re_D = \frac{4\ \dot{m}}{\pi\ D\mu} = \frac{4\times10^{-3}\text{kg/s}}{\pi(0.01\text{ m})\ 183.6\times10^{-7}\text{N}\cdot\text{s/m}^2} = 6935$$

the flow is turbulent and from Eq. 8.88

$$Sh_D = 0.023\ Re_D^{4/5}\ Sc^{0.4} = 0.023(6935)^{4/5}(0.60)^{0.4} = 22.2$$

$$h_m = \frac{Sh_D\ D_{AB}}{D} = \frac{22.2\times26\times10^{-6}\text{m}^2/\text{s}}{0.01\text{ m}} = 0.0576\text{ m/s.}$$

Hence

$$0.01 = \exp\left(-\frac{\pi\times0.01\text{ m}\times L\times1.17\text{ kg/m}^3}{10^{-3}\text{ kg/s}}0.0576\text{ m/s}\right)$$

$$0.01 = \exp(-2.12\ L)$$

$$L = 2.2\text{ m.}$$ <

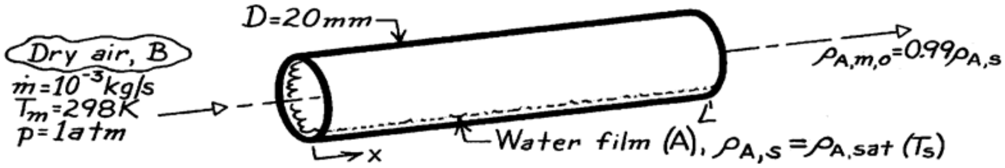
COMMENT: With $Re_D < 10{,}000$, the mass transfer analog of the Gnielinski correlation would be preferable.

PROBLEM 8.126

KNOWN: Flow rate and temperature of atmospheric air in circular tube of prescribed diameter. Flow is fully developed, and air is dry. Inner tube surface is wetted.

FIND: (a) Tube length required to reach 99% saturation, (b) Heat rate needed to maintain tube surface at air temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady, incompressible flow, (2) Constant flow rate.

PROPERTIES: *Table A-4*, Air (298 K, 1 atm): $\rho = 1.17$ kg/m^3, $\mu = 183.6 \times 10^{-7}$ N·s/m^2, $\nu = 15.71 \times 10^{-6}$ m^2/s; *Table A-6*, Water vapor (298 K): $v_g = 44.25$ m^3/kg, $\rho_{A,sat} = 1/v_g = 0.0226$ kg/m^3, $h_{fg} = 2443$ kJ/kg; *Table A-8*, Air-vapor (298 K): $D_{AB} = 26 \times 10^{-6}$ m^2/s, $Sc = \nu/D_{AB} = 0.60$.

ANALYSIS: (a) If $\rho_{A,m,o} = 0.99\,\rho_{A,s}$, it follows from Eq. 8.86 that

$$\frac{\rho_{A,s} - 0.99\,\rho_{A,s}}{\rho_{A,s}} = 0.01 = \exp\left(-\frac{\pi\,DL\rho}{\dot{m}}\bar{h}_m\right).$$

With $$Re_D = \frac{4\,\dot{m}}{\pi\,D\mu} = \frac{4\times10^{-3}\text{ kg/s}}{\pi(0.02\text{m})\;183.6\times10^{-7}\text{N}\cdot\text{s/m}^2} = 3467,$$

The flow is turbulent (weakly) and Eq. 888 yields

$$Sh_D = 0.023\,Re_D^{4/5}\,Sc^{0.4} = 0.023(3467)^{4/5}(0.60)^{0.4} = 12.7$$

$$h_m = \frac{Sh_D\,D_{AB}}{D} = \frac{12.7\times26\times10^{-6}\text{m}^2/\text{s}}{0.02\text{ m}} = 0.0166\text{ m/s}.$$

Hence,

$$L = -\frac{\dot{m}}{\pi\,D\rho\bar{h}_m}\ell n(0.01) = -\frac{10^{-3}\text{kg/s}\times\ell n(0.01)}{\pi(0.02\text{m})1.17\text{ kg/m}^3(0.0166\text{ m/s})} = 3.78\text{ m}.$$ <

(b) The required heat rate is

$$q = n_A\,h_{fg} \qquad n_A = \bar{h}_m\pi\,DL\frac{\Delta\rho_{A,o} - \Delta\rho_{A,i}}{\ell n(\Delta\rho_{A,o}/\Delta\rho_{A,i})}\text{ with }\rho_{A,s} = \rho_{A,sat}$$

$$n_A = 0.0166\text{ m/s}\times\pi(0.02\text{m})3.78\text{ m}\frac{0.01\,\rho_{A,s} - \rho_{A,s}}{\ell n(0.01)}$$

$$n_A = -8.55\times10^{-4}\text{m}^3/\text{s}\left(-0.99\times0.0226\text{ kg/m}^3\right) = 1.91\times10^{-5}\text{kg/s}$$

$$q = n_A\,h_{fg} = 1.91\times10^{-5}\text{kg/s}\times2.443\times10^6\text{ J/kg} = 46.7\text{ W}.$$ <

COMMENTS: (1) The evaporation rate is low; hence the heat requirement is small. (2) The evaporation rate can also be calculated from

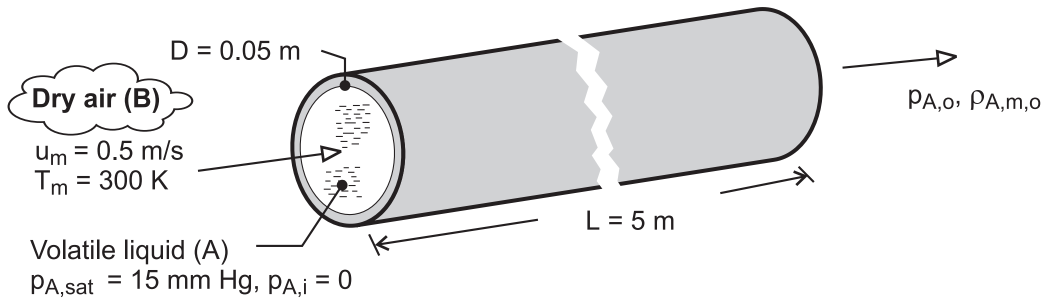
$n_A = \dot{m}(\rho_{A,o}/\rho - \rho_{A,i}/\rho) - \dot{m}/\rho(0.99\rho_{A,s}) = 1.91\times10^{-5}\text{kg/s}$ which agrees with the preceding result.

PROBLEM 8.127

KNOWN: Tube length, diameter and temperature. Air temperature and velocity. Saturation pressure of thin liquid film and properties of vapor.

FIND: (a) Partial pressure and mass fraction of vapor at tube exit, (b) Mass rate at which liquid is removed from the tube.

SCHEMATIC:



ASSUMPTIONS: (1) System is isothermal at 300K, (2) Steady, incompressible flow, (3) Perfect gas behavior, (4) Mass flow rate is independent of x.

PROPERTIES: *Table A-4*, Air (300 K, 1 atm): $\rho = 1.16\ \text{kg/m}^3$, $\nu = 15.9 \times 10^{-6}\ \text{m}^2/\text{s}$. Prescribed, Vapor (300K): $p_{A,sat} = 15$ mm Hg, $\mathfrak{M}_A = 70$ kg/kmol, $D_{AB} = 10^{-5}\ \text{m}^2/\text{s}$.

ANALYSIS: (a) With the vapor assumed to behave as an ideal gas, $p_A = C_A \Re T = \rho_A (\Re / \mathfrak{M}_A) T$, and isothermal conditions, the vapor pressure at the outlet may be obtained from the expression

$$\frac{p_{A,sat} - p_{A,o}}{p_{A,sat} - p_{A,i}} = \frac{\rho_{A,s} - \rho_{A,m,o}}{\rho_{A,s} - \rho_{A,m,i}} = \exp\left(-\frac{\rho \pi D L \bar{h}_m}{\dot{m}}\right)$$

where $\dot{m} = \rho u_m A_c = 1.16\ \text{kg/m}^3 \times 0.5\ \text{m/s} \times \pi (0.05\text{m})^2 / 4 = 1.14 \times 10^{-3}\ \text{kg/s}$. With $Re_D = u_m D/\nu$ = 0.5 m/s × 0.05m/15.9 × 10^{-6} m^2/s = 1570, the flow is laminar. From Eq. 8.3 and the mass transfer analogy to Eq. 8.23, with Sc = ν/D_{AB} = 1.59,

$x_{fd,h} = 0.05 Re_D D = 0.05 \times 1570 \times 0.05$ m = 3.93 m, $x_{fd,c} = x_{fd,h} Sc = 3.93\ \text{m} \times 1.59 = 6.24$ m

Thus this is a combined entry length situation and the mass transfer analogy to the Baehr and Stephan correlation, Eq. 8.58, is appropriate. By analogy to Eq. 8.57, $Gz_{m,D} = (D/L) Re_D Sc$ = (0.05 m/5 m) ×1570×1.59 = 25.0, and

$$\overline{Sh}_D = \frac{\bar{h}_m D}{D_{AB}} = \frac{\dfrac{3.66}{\tanh[2.264 Gz_{m,D}^{-1/3} + 1.7 Gz_{m,D}^{-2/3}]} + 0.0499 Gz_{m,D} \tanh(Gz_{m,D}^{-1})}{\tanh(2.432 Sc^{1/6} Gz_{m,D}^{-1/6})}$$

$$= \frac{\dfrac{3.66}{\tanh[2.264 \times 25.0^{-1/3} + 1.7 \times 25.0^{-2/3}]} + 0.0499 \times 25.0 \tanh(25.0^{-1})}{\tanh(2.432 \times 1.59^{1/6} \times 25.0^{-1/6})} = 5.41$$

$$\bar{h}_m = \frac{\overline{Sh}_D D_{AB}}{D} = 5.41 \times \frac{10^{-5} \text{m}^2/\text{s}}{0.05\text{m}} = 1.08 \times 10^{-3}\ \text{m/s}$$

Hence, with $p_{A,i} = 0$

Continued …

PROBLEM 8.127 (Cont.)

$$p_{A,o} = p_{A,sat}\left[1 - \exp\left(-\frac{\rho \pi D L \bar{h}_m}{\dot{m}}\right)\right] = 15\,\text{mm Hg}\Big[1 -$$

$$\exp\left(-\frac{1.16\,\text{kg/m}^3 \times \pi \times 0.05\text{m} \times 5\text{m} \times 1.08 \times 10^{-3}\text{m/s}}{1.14 \times 10^{-3}\,\text{kg/s}}\right)\Big] = 8.7\,\text{mm Hg} \qquad <$$

The corresponding mass density of the vapor is

$$\rho_{A,m,o} = \frac{p_{A,o}\mathfrak{M}_A}{\Re T} = \frac{8.7\,\text{mm Hg} \times 70\,\text{kg/kmol}}{(760\,\text{mm Hg/atm})\left(0.082\,\text{m}^3 \cdot \text{atm/kmol} \cdot \text{K}\right)300\text{K}} = 0.0326\,\text{kg/m}^3 \qquad <$$

(b) The evaporation rate is

$$n_A = u_m A_c\left(\rho_{A,m,o} - \rho_{A,m,i}\right) = 0.5\text{m/s} \times 1.96 \times 10^{-3}\text{m}^2 \times 0.0326\,\text{kg/m}^3 = 3.20 \times 10^{-5}\,\text{kg/s} \qquad <$$

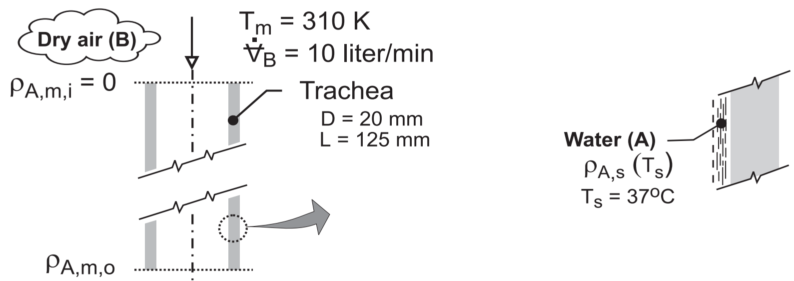
COMMENTS: (1) Since the evaporation rate ($n_A = 3.2 \times 10^{-5}$ kg/s) is much less than the air flow rate ($\dot{m}$ = 1.14×10^{-3} kg/s), the assumption of a fixed flow rate is reasonable. (2) The evaporation rate is also given by $n_A = \bar{h}_m \, \pi \, D \, L \, \Delta \rho_{A,lm} = - \bar{h}_m \, \pi \, D \, L \, \rho_{A,m,o} / \ln [(p_{A,sat} - p_{A,o})/p_{A,sat}] = 3.22 \times 10^{-5}$ kg/s, which agrees with the calculation of part (b).

PROBLEM 8.128

KNOWN: Air flow rate through trachea of diameter D and length L.

FIND: (a) Average mass transfer convection coefficient, $\overline{h}_m$, and (b) Rate of water loss per day (liter/day).

SCHEMATIC:



ASSUMPTIONS: (1) Trachea can be approximated as a smooth tube with uniform surface temperature, (2) Laminar, fully developed flow, (3) Trachea inner surface is saturated with water at body temperature, T_s = 37°C, (4) Negligible water vapor in air at 310 K during inhalation, and (5) Heat-mass analogy is applicable.

PROPERTIES: *Table A-4*, Air (310 K, 1 atm): $\rho_B = 1.128\ \text{kg/m}^3$, $\mu = 1.893 \times 10^{-5}\ \text{N·s/m}^2$; *Table A-6*, Water ($T_s$ = 37°C = 310 K): $\rho_{A,f} = 993\ \text{kg/m}^3$, $\rho_{A,g} = 0.04361\ \text{kg/m}^3$; *Table A-8*, Water-vapor air (310 K, 1 atm): $D_{AB} = 0.26 \times 10^{-4}\ (310/298)^{3/2} = 2.76 \times 10^{-5}\ \text{m}^2/\text{s}$.

ANALYSIS: (a) Begin by characterizing the air (B) flow in the trachea modeled as a smooth tube,

$$Re_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4\dot{\forall}\rho_B}{\pi D \mu}$$

$$Re_D = \frac{4 \times 10\ \text{liter/min} \times 10^{-3}\text{m}^3/\text{liter} \times 1\text{min}/60\text{s} \times 1.128\,\text{kg/m}^3}{\pi \times 0.020\ \text{m} \times 1.893 \times 10^{-5}\,\text{N}\cdot\text{s/m}^2} = 632$$

Hence, the flow is laminar, and for fully developed conditions and invoking the heat-mass analogy

$$Nu_D = Sh_D = 3.66 \qquad\qquad Sh = \overline{h}_m D / D_{AB}$$

$$\overline{h}_m = 3.66\ D_{AB}/D = 3.66 \times 2.76 \times 10^{-5}\text{m}^2/\text{s}/0.020\ \text{m} = 0.0050\ \text{m/s} \qquad <$$

(b) The species (A) transfer rate equation, Eq. 8.83, has the form

$$n_A = \overline{h}_m A_s \Delta\rho_{A,\ell m}$$

$$\Delta\rho_{A,\ell m} = \frac{\left(\rho_{A,s} - \rho_{A,m,o}\right) - \left(\rho_{A,s} - \rho_{A,m,i}\right)}{\ell m\left[\left(\rho_{A,s} - \rho_{A,m,o}\right)/\left(\rho_{A,s} - \rho_{A,m,i}\right)\right]}$$

where the mean outlet species density, $\rho_{A,m,o}$, can be determined from Eq. 8.86

$$\frac{\rho_{A,s} - \rho_{A,m,o}}{\rho_{A,s} - \rho_{A,m,i}} = \exp\left(-\frac{\overline{h}_m \rho P L}{\dot{m}}\right)$$

where $\dot{m}/\rho = u_m A_c = \forall_B$. Substituting numerical values with $P = \pi D$, find

$$\rho_{A,m,o} = 0.009233 \qquad\qquad n_A = 1.54 \times 10^{-6}\,\text{kg/s}$$

The volumetric rate of water loss on a daily basis, assuming a 12 hour inhalation period, is

$$\dot{V}_A = \left(1.54 \times 10^{-6}\,\text{kg/s}/993\ \text{kg/m}^3\right) \times 10^3\text{liter/m}^3 \times \left(3600\,\text{s/h} \times 24\ \text{h/day}\right)$$

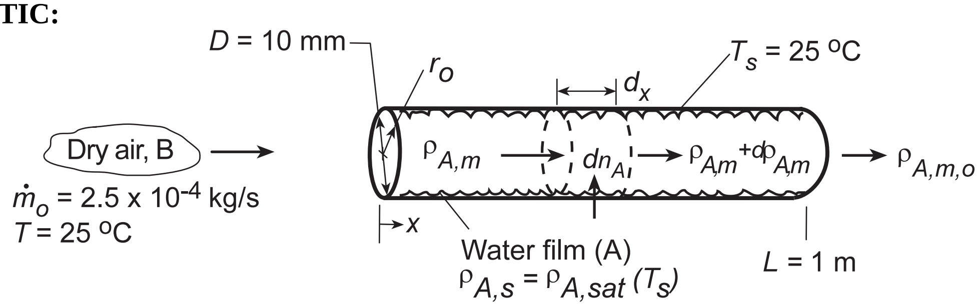
$$\dot{V}_A = 0.134\ \text{liter/day}$$

PROBLEM 8.129

KNOWN: Air (species B) is in fully developed, laminar flow as it enters a circular tube wetted with liquid A (water). Tube length and diameter. Flow rate of air and system temperature.

FIND: (a) Governing differential equation for species transfer, (b) Heat transfer analog and an expression for $\overline{Sh}_D$, (c) General expression for $\rho_{A,m,o}$, (d) Value of $\rho_{A,m,o}$ for prescribed conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Steady, incompressible flow, (2) Flow rate is independent of x, (3) Laminar, fully developed flow (hydrodynamically), (4) Isothermal conditions, (5) Dry air at inlet.

PROPERTIES: *Table A.4*, Air (298 K, 1 atm): $\rho = 1.1707$ kg/m^3, $\mu = 183.6 \times 10^{-7}$ N·s/m^2, $\nu = 15.71 \times 10^{-6}$ m^2/s; *Table A.6*, Water vapor (298 K): $\rho_{A,sat} = 1/v_g = 0.0266$ kg/m^3; *Table A.8*, Air-vapor (298 K): $D_{AB} = 26 \times 10^{-6}$ m^2/s, $Sc = \nu/D_{AB} = 0.60$.

ANALYSIS: (a) The governing differential equation may be inferred by analogy to Eq. 8.48. In this case, the dependent variable is the vapor mass density, ρ_A (x,r), and the diffusivity is D_{AB}. It follows that

$$u\frac{\partial \rho_A}{\partial x} = \frac{D_{AB}}{r}\frac{\partial}{\partial r}\left(r\frac{\partial \rho_A}{\partial r}\right) \qquad <$$

The entrance condition is

$$\rho_A(0,r) = 0 \qquad <$$

and the boundary conditions are

$$\rho_A(r_o, x) = \rho_{A,s} \qquad \rho_A\big|_{r=0} \text{ is finite} \qquad <$$

(b) The foregoing conditions are analogous to those of the thermal entry length condition associated with Eq. 8.57. Invoking this analogy the average Sherwood number for laminar, fully developed flow is

$$\overline{Sh}_D = 3.66 + \frac{0.0668(D/L)Re_D\,Sc}{1+0.04\left[(D/L)Re_D\,Sc\right]^{2/3}} \qquad <$$

where the mass transfer analogy to Eq. 8.56 was used for the Graetz number.

(c) Applying conservation of species to the differential control volume,

$$\rho_{A,m}u_m A_c + dn_A = \left(\rho_{A,m} + \frac{d\rho_{A,m}}{dx}dx\right)u_m A_c$$

or, with $u_m A_c = \dot{m}/\rho$ and $dn_A = h_m \pi D dx\left(\rho_{A,s} - \rho_{A,m}\right)$

$$\frac{\dot{m}}{\rho}\frac{d\rho_{A,m}}{dx}dx = h_m \pi D dx\left(\rho_{A,s} - \rho_{A,m}\right)$$

Continued...

PROBLEM 8.129 (Cont.)

$$\int_{\rho_{A,m,i}}^{\rho_{A,m}} \frac{d\rho_{A,m}}{\rho_{A,s} - \rho_{A,m}} = \int_o^x \frac{\rho \pi D h_m}{\dot{m}} dx$$

or

$$\frac{\rho_{A,s} - \rho_{A,m}(x)}{\rho_{A,s} - \rho_{A,m,i}} = \exp\left(- \frac{\rho \pi D x \bar{h}_m(x)}{\dot{m}} \right)$$

at x = L,

$$\frac{\rho_{A,s} - \rho_{A,m,o}}{\rho_{A,s} - \rho_{A,m,i}} = \exp\left(- \frac{\rho \pi D L \bar{h}_m}{\dot{m}} \right)$$ <

(d) For the prescribed conditions, $Re_D = 4\dot{m}/\pi D\mu = 4\left(2.5 \times 10^{-4}\ kg/s\right)/\pi(0.01 m)183.6 \times 10^{-7}\ N \cdot s/m^2$ = 1734 and $(D/L)Re_D Sc$ = (0.01 m/1 m)1734(0.6) = 10.4. Hence,

$$\overline{Sh}_D = 3.66 + \frac{0.0668(10.4)}{1 + 0.04(10.4)^{2/3}} = 4.24$$

$$\bar{h}_m = \overline{Sh}_D \left(D_{AB}/D\right) = 4.24\left(26 \times 10^{-6}\ m^2/s/0.01 m\right) = 0.011 m/s$$

Hence,

$$\frac{\rho_{A,s} - \rho_{A,m,o}}{\rho_{A,s} - \rho_{A,m,i}} = \exp\left(- \frac{1.1707\ kg/m^3 \times \pi \times 0.01 m \times 1 m \times 0.011 m/s}{2.5 \times 10^{-4}\ kg/s} \right) = 0.198$$

$$\rho_{A,m,o} = \rho_{A,s} - 0.198\left(\rho_{A,s} - \rho_{A,m,i}\right) = 0.0226\ kg/m^3 (1 - 0.198) = 0.0181 kg/m^3$$ <

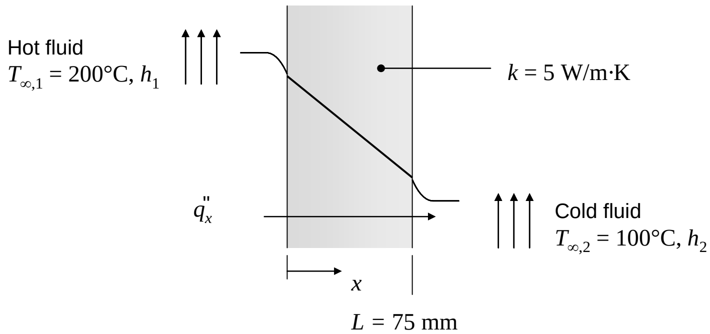
COMMENTS: Due to evaporation, $\dot{m}$ actually increases with increasing x. However, the increase is small, and the assumption of fixed $\dot{m}$ is good.

PROBLEM 9.1

KNOWN: Thickness and thermal conductivity of plane wall. Fluid temperatures.

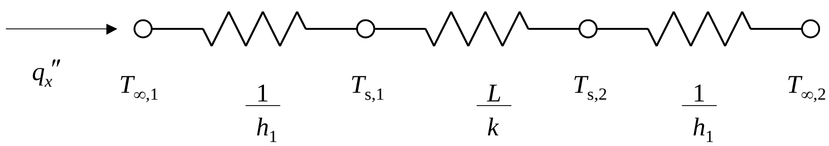
FIND: Expected minimum and maximum steady-state heat fluxes through the wall for (a) free convection in gases, (b) free convection in liquids, (c) forced convection in gases, (d) forced convection in liquids, and (e) convection with phase change.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties. (2) Steady state conditions. (3) Negligible radiation.

ANALYSIS: The thermal resistance network is



From Table 1.1 for free convection in gases, the minimum convective heat transfer coefficient is h = 2 W/m^2·K. Therefore, the corresponding heat flux is

$$q_x'' = \frac{T_{\infty,1} - T_{\infty,2}}{\frac{1}{h_1} + \frac{L}{k} + \frac{1}{h_2}} = \frac{200°\text{C} - 100°\text{C}}{\frac{1}{2\ \text{W/m}^2\cdot\text{K}} + \frac{75\times 10^{-3}\ \text{m}}{5\ \text{W/m}\cdot\text{K}} + \frac{1}{2\ \text{W/m}^2\cdot\text{K}}} = 98.5\ \text{W/m}^2$$

Proceeding in the same manner, we find the following results

	Process	h_{min} (W/m^2·K)	h_{max} (W/m^2·K)	$q''_{x,min}$	$q''_{x,max}$	$q''_{x,max} / q''_{x,min}$	
(a)	Free convection, gas	2	25	98.5	1053	10.7	<
(b)	Free convection, liquid	50	1000	1818	5882	3.23	<
(c)	Forced convection, gas	25	250	1053	4348	4.12	<
(d)	Forced convection, liquid	100	20,000	2857	6623	2.32	<
(e)	Phase change	2500	100,000	6329	6658	1.05	<

COMMENTS: For either gases or liquids, the dependence of the heat flux on the range of convection coefficients associated with each type of convective heat transfer process, as quantified by the ratio $q''_{x,max} / q''_{x,min}$, is strongest for free convection, and weakest for convection involving phase change. The temptation to attach less significance to free convection because the convection coefficients are small is to be resisted. Free convection poses large thermal resistance, and therefore can be the dominant factor in thermal engineering processes and design.

PROBLEM 9.2

KNOWN: Tabulated values of density for water and definition of the volumetric thermal expansion coefficient, β.

FIND: Value of the volumetric expansion coefficient at 300K; compare with tabulated values.

PROPERTIES: *Table A-6*, Water (300K): $\rho = 1/v_f = 1/1.003 \times 10^{-3}\ m^3/kg = 997.0\ kg/m^3$, $\beta = 276.1 \times 10^{-6}\ K^{-1}$; (295K): $\rho = 1/v_f = 1/1.002 \times 10^{-3}\ m^3/kg = 998.0\ kg/m^3$; (305K): $\rho = 1/v_f = 1/1.005 \times 10^{-3}\ m^3/kg = 995.0\ kg/m^3$.

ANALYSIS: The volumetric expansion coefficient is defined by Eq. 9.4 as

$$\beta = -\frac{1}{\rho}\left(\frac{\partial \rho}{\partial T}\right)_p .$$

The density change with temperature at constant pressure can be estimated as

$$\left(\frac{\partial \rho}{\partial T}\right)_p \approx \left(\frac{\rho_1 - \rho_2}{T_1 - T_2}\right)_p$$

where the subscripts (1,2) denote the property values just above and below, respectively, the condition for T = 300K denoted by the subscript (o). That is,

$$\beta_o \approx -\frac{1}{\rho_o}\left(\frac{\rho_1 - \rho_2}{T_1 - T_2}\right)_p .$$

Substituting numerical values, find

$$\beta_o \approx \frac{-1}{997.0\ kg/m^3}\ \frac{(995.0 - 998.0)\ kg/m^3}{(305 - 295)K} = 300.9 \times 10^{-6}\ K^{-1}.$$ <

Compare this value with the tabulation, $\beta = 276.1 \times 10^{-6}\ K^{-1}$, to find our estimate is 8.7% high.

COMMENTS: (1) The poor agreement between our estimate and the tabulated value is due to the poor precision with which the density change with temperature is estimated. The tabulated values of β were determined from accurate equation of state data.

(2) Note that β is negative for T < 275K. Why? What is the implication for free convection?

PROBLEM 9.3

KNOWN: Relation for the Rayleigh number.

FIND: Rayleigh number for four fluids for prescribed conditions.

SCHEMATIC:

ASSUMPTIONS: (1) Perfect gas behavior for specified gases.

PROPERTIES: *Table A-4*, Air (400K, 1 atm): $\nu = 26.41 \times 10^{-6}$ m^2/s, $\alpha = 38.3 \times 10^{-6}$ m^2/s, $\beta = 1/T = 1/400K = 2.50 \times 10^{-3}$ K^{-1}; *Table A-4,* Helium (400K, 1 atm): $\nu = 199 \times 10^{-6}$ m^2/s, $\alpha = 295 \times 10^{-6}$ m^2/s, $\beta = 1/T = 2.50 \times 10^{-3}$ K^{-1}; *Table A-5*, Glycerin (12°C = 285K): $\nu = 2830 \times 10^{-6}$ m^2/s, $\alpha = 0.964 \times 10^{-7}$ m^2/s, $\beta = 0.475 \times 10^{-3}$ K^{-1}; *Table A-6*, Water (37°C = 310K, sat. liq.): $\nu = \mu_f v_f = 695 \times 10^{-6}$ N·s/m^2 $\times$ 1.007 $\times 10^{-3}$ m^3/kg = 0.700 $\times 10^{-6}$ m^2/s, $\alpha = k_f v_f/c_{p,f}$ = 0.628 W/m·K $\times$ 1.007 $\times 10^{-3}$ m^3/kg/4178 J/kg·K = 0.151 $\times 10^{-6}$ m^2/s, $\beta_f = 361.9 \times 10^{-6}$ K^{-1}.

ANALYSIS: The Rayleigh number, a dimensionless parameter used in free convection analysis, is defined as the product of the Grashof and Prandtl numbers.

$$\mathrm{Ra_L} \equiv \mathrm{Gr} \cdot \mathrm{Pr} = \frac{g\beta\Delta T L^3}{\nu^2} \frac{\mu c_p}{k} = \frac{g\beta\Delta T L^3}{\nu^2} \cdot \frac{(\nu\rho) c_p}{k} = \frac{g\beta\Delta T L^3}{\nu\alpha}$$

where $\alpha = k/\rho c_p$ and $\nu = \mu/\rho$. The numerical values for the four fluids follow:

Air (400K, 1 atm)

$$\mathrm{Ra_L} = 9.8\mathrm{m/s^2}\ (1/400\mathrm{K})\ 30\mathrm{K}(0.01\mathrm{m})^3 / 26.41\times10^{-6}\ \mathrm{m^2/s} \times 38.3\times10^{-6}\ \mathrm{m^2/s} = 727 \quad <$$

Helium (400K, 1 atm)

$$\mathrm{Ra_L} = 9.8\mathrm{m/s^2}(1/400\mathrm{K})\ 30\mathrm{K}(0.01\mathrm{m})^3 / 199\times10^{-6}\mathrm{m^2/s} \times 295\times10^{-6}\mathrm{m^2/s} = 12.5 \quad <$$

Glycerin (285K)

$$\mathrm{Ra_L} = 9.8\mathrm{m/s^2}\left(0.475\times10^{-3}\mathrm{K^{-1}}\right) 30\mathrm{K}(0.01\mathrm{m})^3 / 2830\times10^{-6}\mathrm{m^2/s} \times 0.964\times10^{-7}\mathrm{m^2/s} = 512 \quad <$$

Water (310K)

$$\mathrm{Ra_L} = 9.8\mathrm{m/s^2}\left(0.362\times10^{-3}\mathrm{K^{-1}}\right) 30\mathrm{K}(0.01\mathrm{m})^3 / 0.700\times10^{-6}\mathrm{m^2/s} \times 0.151\times10^{-6}\mathrm{m^2/s} = 1.01\times10^6. \quad <$$

COMMENTS: (1) Note the wide variation in values of Ra for the four fluids. A large value of Ra implies enhanced free convection, however, other properties affect the value of the heat transfer coefficient.

PROBLEM 9.4

KNOWN: Form of the Nusselt number correlation for natural convection and fluid properties.

FIND: Expression for figure of merit F_N and values for air, water and a dielectric liquid.

PROPERTIES: Prescribed. Air: k = 0.026 W/m·K, β = 0.0035 K^{-1}, ν = 1.5 × 10^{-5} m^2/s, Pr = 0.70. Water: k = 0.600 W/m·K, β = 2.7 × 10^{-4} K^{-1}, ν = 10^{-6} m^2/s, Pr = 5.0. Dielectric liquid: k = 0.064 W/m·K, β = 0.0014 K^{-1}, ν = 10^{-6} m^2/s, Pr = 25

ANALYSIS: With $Nu_L \sim Ra^n$, the convection coefficient may be expressed as

$$h \sim \frac{k}{L}\left(\frac{g\beta\Delta TL^3}{\alpha\nu}\right)^n \sim \frac{\left(g\Delta TL^3\right)^n}{L}\left(\frac{k\,\beta^n}{\alpha^n\nu^n}\right)$$

The figure of merit is therefore

$$F_N = \frac{k\,\beta^n}{\alpha^n\nu^n}$$ <

and for the three fluids, with n = 0.33 and $\alpha = \nu / Pr$,

	Air	Water	Dielectric
$F_N\left(W \cdot s^{2/3} / m^{7/3} \cdot K^{4/3}\right)$	5.8	663	209	<

Water is clearly the superior heat transfer fluid, while air is the least effective.

COMMENTS: The figure of merit indicates that heat transfer is enhanced by fluids of large k, large β and small values of α and ν.

PROBLEM 9.5

KNOWN: Temperature and pressure of air in a free convection application.

FIND: Figure of merit for T = 27°C and P = 1, 10 and 100 bar.

ASSUMPTIONS: (1) Ideal gas, (2) Thermal conductivity, dynamic viscosity and specific heat are independent of pressure.

PROPERTIES: Table A.4, air: (T_f = 300 K, p = 1 atm): k = 0.0263 W/m·K, c_p = 1007 J/kg·K, $\nu = 15.89 \times 10^{-6}$ m²/s, $\alpha = 22.5 \times 10^{-6}$ m²/s.

ANALYSIS: With $Nu_L \approx Ra^n$, the convection coefficient may be expressed as

$$h \approx \frac{k}{L}\left(\frac{g\beta\Delta TL^3}{\alpha\nu}\right) \approx \frac{\left(g\Delta TL^3\right)^n}{L}\left(\frac{k\beta^n}{\alpha^n\nu^n}\right)$$

and the figure of merit is $F_N = \dfrac{k\beta^n}{\alpha^n\nu^n}$.

For an ideal gas, $\beta = 1/T$. The thermal diffusivity is $\alpha = k/\rho c_p$. Since k and c_p are independent of pressure, and the density is proportional to pressure for an ideal gas, $\alpha \propto 1/p$. The kinematic viscosity is $\nu = \mu/\rho$. Therefore, for an ideal gas, $\nu \propto 1/p$. Thus, the properties and the figure of merit, using n = 0.33, at the three pressures are

$p = 1\text{ bar} = 1 \times 10^5\text{ N/m}^2$	$p = 10\text{ bar}$	$p = 100\text{ bar}$
$\beta = 1/300\text{ K}^{-1}$	$\beta = 1/300\text{ K}^{-1}$	$\beta = 1/300\text{ K}^{-1}$
k = 0.0263 W/m·K	k = 0.0263 W/m·K	k = 0.0263 W/m·K
$\alpha = 22.5\times10^{-6}\text{ m}^2\text{/s}\times\left(\frac{1.0133}{1}\right)$	$\alpha = 22.5\times10^{-6}\text{ m}^2\text{/s}\times\left(\frac{1.0133}{10}\right)$	$\alpha = 22.5\times10^{-6}\text{ m}^2\text{/s}\times\left(\frac{1.0133}{100}\right)$
$= 2.28 \times 10^{-5}\text{ m}^2\text{/s}$	$= 2.28 \times 10^{-6}\text{ m}^2\text{/s}$	$= 2.28 \times 10^{-7}\text{ m}^2\text{/s}$
$\nu = 1.589\times10^{-5}\text{ m}^2\text{/s}\times\left(\frac{1.0133}{1}\right)$	$\nu = 1.589\times10^{-5}\text{ m}^2\text{/s}\times\left(\frac{1.0133}{10}\right)$	$\nu = 1.589\times10^{-5}\text{ m}^2\text{/s}\times\left(\frac{1.0133}{100}\right)$
$= 1.610 \times 10^{-5}\text{ m}^2\text{/s}$	$= 1.610 \times 10^{-6}\text{ m}^2\text{/s}$	$= 1.610 \times 10^{-7}\text{ m}^2\text{/s}$

Therefore, for P = 1 bar, $F_N = \dfrac{0.0263\text{ W/m}\cdot\text{K}\times(1/300\text{K})^{0.33}}{(2.28\times10^{-5}\text{m}^2\text{/s})^{0.33}\times(1.61\times10^{-5}\text{m}^2\text{/s})^{0.33}}$ = 5.20. Similarly, for

P = 10 bar, F_N = 23.78 while for P = 100 bar, F_N = 108.7. <

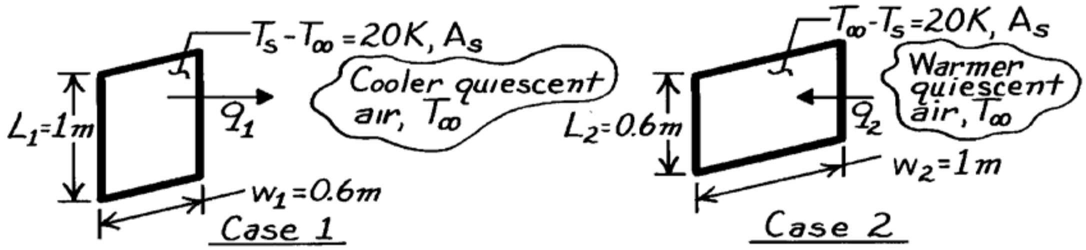
COMMENT: The efficacy of natural convection cooling within sealed enclosures can be increased significantly by increasing the pressure of the gas.

PROBLEM 9.6

KNOWN: Heat transfer rate by convection from a vertical surface, 1m high by 0.6m wide, to quiescent air that is 20K cooler.

FIND: Ratio of the heat transfer rate for the above case to that for a vertical surface that is 0.6m high by 1m wide with quiescent air that is 20K warmer.

SCHEMATIC:



ASSUMPTIONS: (1) Thermophysical properties independent of temperature; evaluate at 300K; (2) Negligible radiation exchange with surroundings, (3) Quiescent ambient air.

PROPERTIES: *Table A-4,* Air (300K, 1 atm): $\nu = 15.89 \times 10^{-6}$ m^2/s, $\alpha = 22.5 \times 10^{-6}$ m^2/s.

ANALYSIS: The rate equation for convection between the plates and quiescent air is

$$q = \bar{h}_L\ A_s \Delta T \tag{1}$$

where ΔT is either $(T_s - T_\infty)$ or $(T_\infty - T_s)$; for both cases, $A_s = Lw$. The desired heat transfer ratio is then

$$\frac{q_1}{q_2} = \frac{\bar{h}_{L1}}{\bar{h}_{L2}}. \tag{2}$$

To determine the dependence of $\bar{h}_L$ on geometry, first calculate the Rayleigh number,

$$Ra_L = g\,\beta\,\Delta T L^3/\nu\alpha \tag{3}$$

and substituting property values at 300K, find,

Case 1: $Ra_{L1} = 9.8\ m/s^2\ (1/300K)\ 20K\ (1m)^3/15.89 \times 10^{-6}\ m^2/s \times 22.5 \times 10^{-6}\ m^2/s = 1.82 \times 10^9$

Case 2: $Ra_{L2} = Ra_{L1}\ (L_2/L_1)^3 = 1.82 \times 10^4\ (0.6m/1.0m)^3 = 3.94 \times 10^8$.

Hence, Case 1 is turbulent and Case 2 is laminar. Using the correlation of Eq. 9.24,

$$\overline{Nu}_L = \frac{\bar{h}_L L}{k} = C\left(Ra_L\right)^n \qquad \bar{h}_L = \frac{k}{L} C\ Ra_L^n \tag{4}$$

where for *Case 1*: $C_1 = 0.10$, $n_1 = 1/3$ and for *Case 2*: $C_2 = 0.59$, $n_2 = 1/4$. Substituting Eq. (4) into the ratio of Eq. (2) with numerical values, find

$$\frac{q_1}{q_2} = \frac{\left(C_1/L_1\right)Ra_{L1}^{n_1}}{\left(C_2/L_2\right)Ra_{L2}^{n_2}} = \frac{\left(0.10/1m\right)\left(1.82\times10^9\right)^{1/3}}{\left(0.59/0.6m\right)\left(3.94\times10^8\right)^{1/4}} = 0.881$$ <

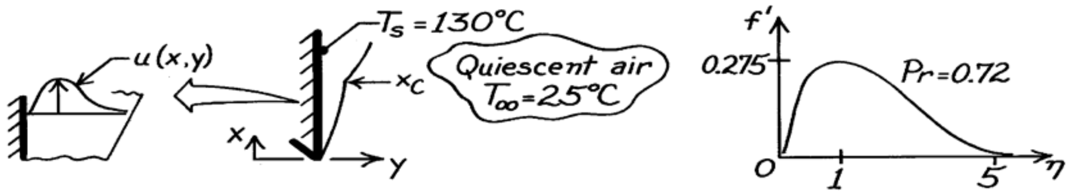
COMMENTS: Is this result to be expected? How do you explain this effect of plate orientation on the heat rates?

PROBLEM 9.7

KNOWN: Large vertical plate with uniform surface temperature of 130°C suspended in quiescent air at 25°C and atmospheric pressure.

FIND: (a) Boundary layer thickness at 0.25 m from lower edge, (b) Maximum velocity in boundary layer at this location and position of maximum, (c) Heat transfer coefficient at this location, (d) Location where boundary layer becomes turbulent.

SCHEMATIC:



ASSUMPTIONS: (1) Isothermal, vertical surface in an extensive, quiescent medium, (2) Boundary layer assumptions valid.

PROPERTIES: *Table A-4*, Air $\left(T_f = \left(T_s + T_\infty\right)/2 = 350\text{K, 1 atm}\right)$: $\nu = 20.92 \times 10^{-6}$ m²/s, k = 0.030 W/m·K, Pr = 0.700.

ANALYSIS: (a) From the similarity solution results, Fig. 9.4 (see above right), the boundary layer thickness corresponds to a value of η ≈ 5. From Eqs. 9.13 and 9.12,

$$y = \eta x\left(Gr_x/4\right)^{-1/4} \quad (1)$$

$$Gr_x = g\beta\left(T_s - T_\infty\right)x^3/\nu^2 = 9.8\frac{m}{s^2}\times\frac{1}{350K}(130-25)\,K\,x^3/\left(20.92\times10^{-6}m^2/s\right)^2 = 6.718\times10^9\ x^3 \quad (2)$$

$$y \approx 5(0.25m)\left(6.718\times10^9(0.25)^3/4\right)^{-1/4} = 1.746\times10^{-2}m = 17.5\text{ mm.} \quad (3)$$ <

(b) From the similarity solution shown above, the maximum velocity occurs at η ≈ 1 with $f'(\eta) = 0.275$. From Eq. 9.15, find

$$u = \frac{2\nu}{x}Gr_x^{1/2}\ f'(\eta) = \frac{2\times20.92\times10^{-6}m^2/s}{0.25m}\left(6.718\times10^9(0.25)^3\right)^{1/2}\times0.275 = 0.47\text{ m/s.}$$ <

The maximum velocity occurs at a value of η = 1; using Eq. (3), it follows that this corresponds to a position in the boundary layer given as

$$y_{max} = 1/5\ (17.5\text{ mm}) = 3.5\text{ mm.}$$ <

(c) From Eq. 9.19, the local heat transfer coefficient at x = 0.25 m is

$$Nu_x = h_x x/k = \left(Gr_x/4\right)^{1/4}\ g(Pr) = \left(6.718\times10^9(0.25)^3/4\right)^{1/4}0.50 = 35.7$$

$$h_x = Nu_x k/x = 35.7\times0.030\text{ W/m}\cdot\text{K/0.25 m} = 4.3\text{ W/m}^2\cdot\text{K.}$$ <

The value for g(Pr) is determined from Eq. 9.20 with Pr = 0.700.

(d) According to Eq. 9.23, the boundary layer becomes turbulent at x_c given as

$$Ra_{x,c} = Gr_{x,c}\,Pr \approx 10^9 \qquad x_c \approx \left[10^9/6.718\times10^9(0.700)\right]^{1/3} = 0.60\text{ m.}$$ <

COMMENTS: Note that β = 1/T_f is a suitable approximation for air.

PROBLEM 9.8

KNOWN: Laminar free convection on a vertical plate.

FIND: Exact values of *C* from the similarity solution for *Pr* = 0.01, 1, 10 and 100.

ASSUMPTIONS: (1) Constant properties. (2) Steady state conditions. (3) Parameter *n* = ¼.

ANALYSIS: The similarity solution for the average Nusselt number is

$$\overline{Nu}_L = \frac{4}{3}\left(\frac{Gr_L}{4}\right)^{1/4}\left[\frac{0.75Pr^{1/2}}{\left(0.609+1.221Pr^{1/2}+1.238Pr\right)^{1/4}}\right] \quad (1)$$

while the correlation for the average Nusselt number is expressed as

$$\overline{Nu}_L = CRa_L^n = C\left(Gr_L \cdot Pr\right)^n = C\left(Gr_L \cdot Pr\right)^{1/4} \quad (2)$$

Equating the preceding two expressions yields

$$C = \frac{4}{3}\left(\frac{1}{4}\right)^{1/4}\left[\frac{0.75Pr^{1/4}}{\left(0.609+1.221Pr^{1/2}+1.238Pr\right)^{1/4}}\right] \quad (3)$$

Values of *C* may be determined by substituting *Pr* = 0.01, 1, 10 and 100 into Equation 3.

Pr	*C*
0.01	0.241
1	0.534
10	0.621
100	0.654

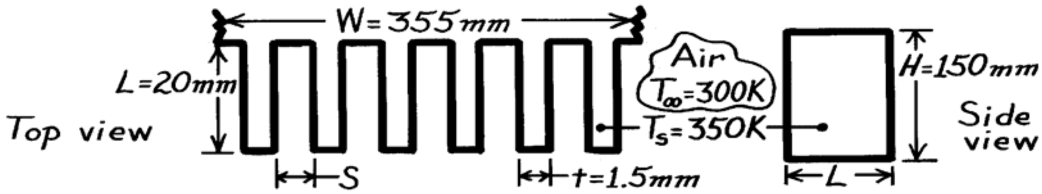
COMMENTS: (1) The correlation should not be used for liquid metals (i.e. low *Pr* fluids). (2) The average value of *C* for *Pr* = 1, 10 and 100 is 0.60 ≈ 0.59. Use of the correlation for *Pr* ≥ 0.7 results in an error of approximately 10% as compared to the similarity solution. (3) There are few if any fluids characterized by *Pr* ≈ 0.1. Hence, this range of the Prandtl numbers is not included in the comparison, and is omitted from Figure 9.4.

PROBLEM 9.9

KNOWN: Dimensions of vertical rectangular fins. Temperature of fins and quiescent air.

FIND: (a) Optimum fin spacing, (b) Rate of heat transfer from an array of fins at the optimal spacing.

SCHEMATIC:



ASSUMPTIONS: (1) Fins are isothermal, (2) Radiation effects are negligible, (3) Air is quiescent.

PROPERTIES: *Table A-4*, Air (T_f = 325K, 1 atm): $\nu = 18.41 \times 10^{-6}$ m^2/s, k = 0.0282 W/m·K, Pr = 0.703.

ANALYSIS: (a) If fins are too close, boundary layers on adjoining surfaces will coalesce and heat transfer will decrease. If fins are too far apart, the surface area becomes too small and heat transfer decreases. $S_{op} \approx \delta_{x=H}$. From Fig. 9.4, the edge of boundary layer corresponds to

$$\eta = (\delta / H)\ (Gr_H / 4)^{1/4} \approx 5.$$

Hence, $$Gr_H = \frac{g\beta(T_s - T_\infty)H^3}{\nu^2} = \frac{9.8\ m/s^2 (1/325K)\ 50K\ (0.15m)^3}{\left(18.41\times10^{-6} m^2/s\right)^2} = 1.5\times10^7$$

$$\delta(H) = 5(0.15m)/\left(1.5\times10^7/4\right)^{1/4} = 0.017m = 17mm \qquad S_{op} \approx 34mm.$$ <

(b) The number of fins N can be found as

$$N = W/\left(S_{op} + t\right) = 355/35.5 = 10$$

and the rate is $\quad q = 2\ N\ \bar{h}(H\cdot L)\ (T_s - T_\infty).$

For laminar flow conditions

$$\overline{Nu}_H = 0.68 + 0.67\ Ra_L^{1/4} / \left[1 + (0.492/Pr)^{9/16}\right]^{4/9}$$

$$\overline{Nu}_H = 0.68 + 0.67\left(1.5\times10^7 \times 0.703\right)^{1/4} / \left[1 + (0.492/0.703)^{9/16}\right]^{4/9} = 30$$

$$\bar{h} = k\ Nu_H / H = 0.0282\ W/m\cdot K(30)/0.15\ m = 5.6\ W/m^2\cdot K$$

$$q = 2(10)5.6\ W/m^2\cdot K(0.15m \times 0.02m)\ (350 - 300)K = 16.8\ W.$$ <

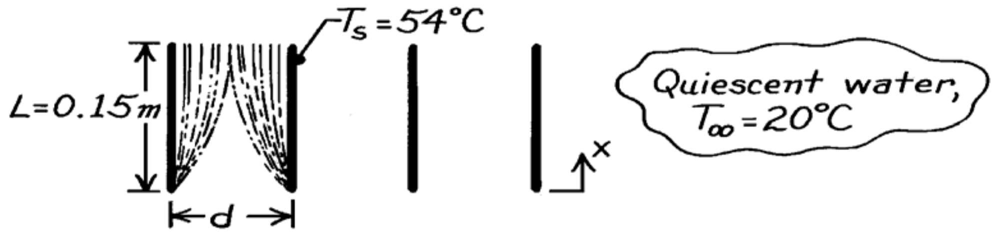
COMMENTS: Part (a) result is a conservative estimate of the optimum spacing. The increase in area resulting from a further reduction in S would more than compensate for the effect of fluid entrapment due to boundary layer merger. From a more rigorous treatment (see Section 9.7.1), $S_{op} \approx 10$ mm is obtained for the prescribed conditions.

PROBLEM 9.10

KNOWN: Thin, vertical plates of length 0.15m at 54°C being cooled in a water bath at 20°C.

FIND: Minimum spacing between plates such that no interference will occur between free-convection boundary layers.

SCHEMATIC:



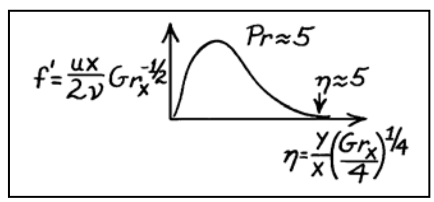
ASSUMPTIONS: (a) Water in bath is quiescent, (b) Plates are at uniform temperature.

PROPERTIES: *Table A-6*, Water ($T_f = (T_s + T_\infty)/2 = (54 + 20)°C/2 = 310K$): $\rho = 1/v_f = 993.05$ kg/m^3, $\mu = 695 \times 10^{-6}$ N·s/m^2, $\nu = \mu/\rho = 6.998 \times 10^{-7}$ m^2/s, Pr = 4.62, $\beta = 361.9 \times 10^{-6}$ K^{-1}.

ANALYSIS: The minimum separation distance will be twice the thickness of the boundary layer at the trailing edge where x = 0.15m. Assuming laminar, free convection boundary layer conditions, the similarity parameter, η, given by Eq. 9.13, is

$$\eta = \frac{y}{x}\left(Gr_x / 4\right)^{1/4}$$

where y is measured normal to the plate (see Fig. 9.3). According to Fig. 9.4, the boundary layer thickness occurs at a value $\eta \approx 5$.
It follows then that,



$$y_{bl} = \eta\ x\ \left(Gr_x / 4\right)^{-1/4}$$

where $Gr_x = \dfrac{g\,\beta\,\left(T_s - T_\infty\right)x^3}{\nu^2}$

$$Gr_x = 9.8\text{ m/s}^2 \times 361.9\times10^{-6}\text{ K}^{-1}\left(54-20\right)\text{K}\times\left(0.15\text{m}\right)^3 / \left(6.998\times10^{-7}\text{ m}^2/\text{s}\right)^2 = 8.310\times10^8. \quad <$$

Hence, $y_{bl} = 5\times0.15\text{m}\left(8.310\times10^8/4\right)^{-1/4} = 6.247\times10^{-3}\text{m} = 6.3\text{ mm}$

and the minimum separation is

$$d = 2\ y_{bl} = 2\times6.3\text{ mm} = 12.6\text{ mm}. \quad <$$

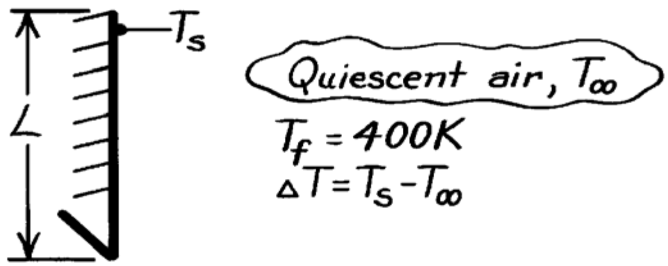
COMMENTS: According to Eq. 9.23, the critical Grashof number for the onset of turbulent conditions in the boundary layer is $Gr_{x,c}\,Pr \approx 10^9$. For the conditions above, $Gr_x\,Pr = 8.31 \times 10^8 \times 4.62 = 3.8 \times 10^9$. We conclude that the boundary layer is indeed turbulent at x = 0.15m and our calculation is only an estimate which is likely to be low. Therefore, the plate separation should be greater than 12.6 mm.

PROBLEM 9.11

KNOWN: Vertical plate experiencing free convection with quiescent air at atmospheric pressure and film temperature 400 K.

FIND: Form of correlation for average heat transfer coefficient in terms of ΔT and characteristic length.

SCHEMATIC:



ASSUMPTIONS: (1) Air is extensive, quiescent medium, (2) Perfect gas behavior.

PROPERTIES: *Table A-6*, Air (T_f = 400K, 1 atm): $\nu = 26.41 \times 10^{-6}\ m^2/s$, k = 0.0338 W/m·K, $\alpha = 38.3 \times 10^{-6}\ m^2/s$.

ANALYSIS: Consider the correlation having the form of Eq. 9.24 with Ra_L defined by Eq. 9.25.

$$\overline{Nu}_L = \bar{h}_L L/k = C Ra_L^n \tag{1}$$

where

$$Ra_L = \frac{g\beta\left(T_s - T_\infty\right)L^3}{\nu\alpha} = \frac{9.8\ m/s^2\left(1/400\ K\right)\Delta T \cdot L^3}{26.41\times10^{-6} m^2/s \times 38.3\times10^{-6} m^2/s} = 2.422\times10^7\,\Delta T\cdot L^3. \tag{2}$$

Combining Eqs. (1) and (2),

$$\bar{h}_L = \left(k/L\right)C Ra_L^n = \frac{0.0338\ W/m\cdot K}{L} C\left(2.422\times10^7 \Delta T L^3\right)^n. \tag{3}$$

From Fig. 9.6, note that for laminar boundary layer conditions, $10^4 < Ra_L < 10^9$, C = 0.59 and n = 1/4. Using Eq. (3),

$$\bar{h} = 1.40\left[L^{-1}\left(\Delta T\cdot L^3\right)^{1/4}\right] = 1.40\left(\frac{\Delta T}{L}\right)^{1/4}$$ <

For turbulent conditions in the range $10^9 < Ra_L < 10^{13}$, C = 0.10 and n = 1/3. Using Eq. (3),

$$\bar{h}_L = 0.98\left[L^{-1}\left(\Delta T\cdot L^3\right)^{1/3}\right] = 0.98\Delta T^{1/3}.$$ <

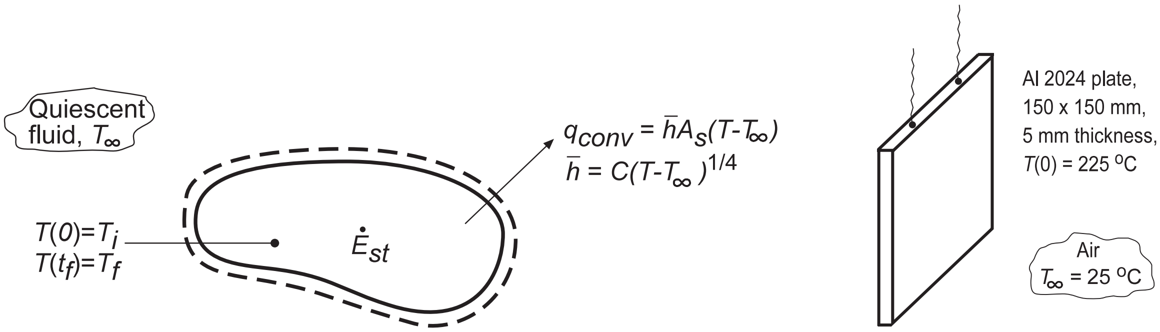
COMMENTS: Note the dependence of the average heat transfer coefficient on ΔT and L for laminar and turbulent conditions. The characteristic length L does not influence $\bar{h}_L$ for turbulent conditions.

PROBLEM 9.12

KNOWN: Temperature dependence of free convection coefficient, $\bar{h} = C\Delta T^{1/4}$, for a solid suddenly submerged in a quiescent fluid.

FIND: (a) Expression for cooling time, t_f, (b) Considering a plate of prescribed geometry and thermal conditions, the time required to reach 80°C using the appropriate correlation from Problem 9.11 and (c) Plot the temperature-time history obtained from part (b) and compare with results using a constant $\bar{h}_o$ from an appropriate correlation based upon an average surface temperature $\bar{T} = (T_i + T_f)/2$.

SCHEMATIC:



ASSUMPTIONS: (1) Lumped capacitance approximation is valid, (2) Negligible radiation, (3) Constant properties.

PROPERTIES: *Table A.1*, Aluminum alloy 2024 $\left(\bar{T} = (T_i + T_f)/2 \approx 400\,K\right)$: ρ = 2770 kg/m^3, c_p = 925 J/kg·K, k = 186 W/m·K; *Table A.4*, Air ($\bar{T}_{film}$ = 362 K): ν = 2.221 × 10^{-5} m^2/s, k = 0.03069 W/m·K, α = 3.187 × 10^{-5} m^2/s, Pr = 0.6976, $\beta = 1/\bar{T}_{film}$.

ANALYSIS: (a) From Eq. 5.28,

$$\frac{\theta}{\theta_i} = \left[\frac{nCA_s\theta_i^n}{\rho Vc}t+1\right]^{-1/n} \qquad (1)$$

where θ = T – T_∞ and n = 1/4. Solving for t_f, the time at which T = T_f,

$$t_f = \frac{4\rho Vc}{CA_s(T_i - T_\infty)^{1/4}}\left[\left(\frac{T_i - T_\infty}{T_f - T_\infty}\right)^{1/4} - 1\right] \qquad (2) <$$

(b) Considering the aluminum plate, initially at T(0) = 225°C, and suddenly exposed to ambient air at $T_\infty = 25^\circ C$, from Problem 9.11 the convection coefficient has the form

$$\bar{h}_i = 1.40\left(\frac{\Delta t}{L}\right)^{1/4} \qquad \bar{h}_i = C\Delta T^{1/4}$$

where C = 1.40/L$^{1/4}$ = 1.40/(0.150)$^{1/4}$ = 2. 2496 $W/m^2 \cdot K^{3/4}$. Using Eq. (2), find

Continued...

PROBLEM 9.12 (Cont.)

$$t_f = \frac{4\times 2770\,\text{kg}/\text{m}^3\left(0.150^2\times 0.005\right)\text{m}^3\times 925\,\text{J/kg}\cdot\text{K}}{2.2496\,\text{W}/\text{m}^2\cdot\text{K}^{3/4}\times 2\times(0.150\text{m})^2(225-25)^{1/4}\,\text{K}^{1/4}}\left[\left(\frac{225-25}{80-25}\right)^{1/4}-1\right] = 1154\text{s}$$

(c) For the vertical plate, Eq. 9.27 is an appropriate correlation. Evaluating properties at

$$\overline{T}_{film} = \left(\overline{T}_s + T_\infty\right)/2 = \left(\left(T_i + T_f\right)/2 + T_\infty\right)/2 = 362\text{ K}$$

where $\overline{T}_s = 426\text{K}$, the average plate temperature, find

$$Ra_L = \frac{g\beta\left(\overline{T}_s - T_\infty\right)L^3}{\nu\alpha} = \frac{9.8\,\text{m/s}^2\,(1/362\text{K})(426-298)\text{K}\,(0.150\text{m})^3}{2.221\times10^{-5}\,\text{m}^2/\text{s}\times 3.187\times10^{-5}\,\text{m}^2/\text{s}} = 1.652\times10^7$$

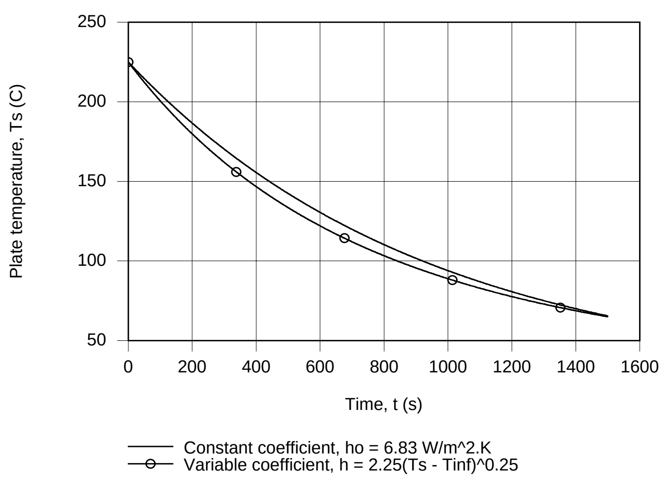
$$\overline{Nu}_L = 0.68 + \frac{0.670 Ra_L^{1/4}}{\left[1+(0.492/Pr)^{9/16}\right]^{4/9}} = 0.68 + \frac{0.670\left(1.652\times10^7\right)^{1/4}}{\left[1+(0.492/0.6976)^{9/16}\right]^{4/9}} = 33.4$$

$$\overline{h}_o = \frac{k}{L}\overline{Nu}_L = \frac{0.03069\,\text{W/m}\cdot\text{K}}{0.150\text{m}}\times 33.4 = 6.83\,\text{W}/\text{m}^2\cdot\text{K}$$

From Eq. 5.6, the temperature-time history with a constant convection coefficient is

$$T(t) = T_\infty + \left(T_i - T_\infty\right)\exp\left[-\left(\overline{h}_o A_s/\rho V c\right)t\right] \qquad (3)$$

where $A_s/V = 2L^2/(L\times L\times w) = 2/w = 400\text{m}^{-1}$. The temperature-time histories for the h = $C\Delta T^{1/4}$ and $\overline{h}_o$ analyses are shown in plot below.



COMMENTS: (1) The times to reach $T(t_o)$ = 80°C were 1154 and 1212s for the variable and constant coefficient analysis, respectively, a difference of 5%. For convenience, it is reasonable to evaluate the convection coefficient as described in part (b).

(2) Note that $Ra_L < 10^9$ so indeed the expression selected from Problem 9.11 was the appropriate one.

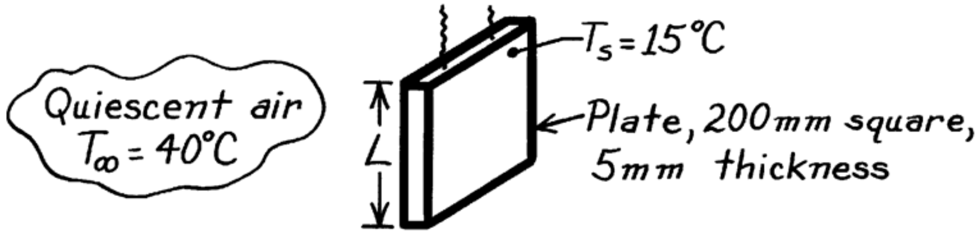
(3) Recognize that if the emissivity of the plate were unity, the average linearized radiation coefficient using Eq. (1.9) is $\overline{h}_{rad} = 11.0\,\text{W}/\text{m}^2\cdot\text{K}$ and radiative exchange becomes an important process.

PROBLEM 9.13

KNOWN: Square aluminum plate at 15°C suspended in quiescent air at 40°C.

FIND: Average heat transfer coefficient by two methods – using results of boundary layer similarity and results from an empirical correlation.

SCHEMATIC:



ASSUMPTIONS: (1) Uniform plate surface temperature, (2) Quiescent room air, (3) Surface radiation exchange with surroundings negligible, (4) Perfect gas behavior for air, $\beta = 1/T_f$.

PROPERTIES: *Table A-4*, Air ($T_f = (T_s + T_\infty)/2 = (40 + 15)°C/2 = 300K$, 1 atm): $\nu = 15.89 \times 10^{-6}$ m^2/s, k = 0.0263 W/m·K, $\alpha = 22.5 \times 10^{-6}$ m^2/s, Pr = 0.707.

ANALYSIS: Calculate the Rayleigh number to determine the boundary layer flow conditions,

$$Ra_L = g\,\beta\,\Delta T\,L^3/\nu\,\alpha$$

$$Ra_L = 9.8\ \text{m/s}^2\,(1/300\text{K})\ (40-15)°\text{C}\,(0.2\text{m})^3 / \left(15.89\times10^{-6}\text{m}^2/\text{s}\right)\ \left(22.5\times10^{-6}\text{m}^2/\text{s}\right) = 1.827\times10^7$$

where $\beta = 1/T_f$ and $\Delta T = T_\infty - T_s$. Since $Ra_L < 10^9$, the flow is laminar and the *similarity solution* of Section 9.4 is applicable. From Eqs. 9.21 and 9.20,

$$\overline{Nu}_L = \frac{\bar{h}_L\,L}{k} = \frac{4}{3}\left(Gr_L/4\right)^{1/4}\ g(Pr)\ \text{ where } g(Pr) = \frac{0.75\ Pr^{1/2}}{\left[0.609 + 1.221\ Pr^{1/2} + 1.238\ Pr\right]^{1/4}}$$

and substituting numerical values with $Gr_L = Ra_L/Pr$, find

$$g(Pr) = 0.75(0.707)^{1/2}/\left[0.609 + 1.22(0.707)^{1/2} + 1.238\times0.707\right]^{1/4} = 0.501$$

$$\bar{h}_L = \left(\frac{0.0263\ \text{W/m}\cdot\text{K}}{0.20\text{m}}\right)\times\frac{4}{3}\left(\frac{1.827\times10^7/0.707}{4}\right)^{1/4}\times0.501 = 4.42\ \text{W/m}^2\cdot\text{K}. \quad <$$

The appropriate empirical correlation for estimating $\bar{h}_L$ is given by Eq. 9.27,

$$\overline{Nu}_L = \frac{\bar{h}_L\,L}{k} = 0.68 + \frac{0.670\ Ra_L^{1/4}}{\left[1 + (0.492/Pr)^{9/16}\right]^{4/9}}$$

$$\bar{h}_L = (0.0263\ \text{W/m}\cdot\text{K}/0.20\text{m})\ \left[0.68 + 0.670\left(1.827\times10^7\right)^{1/4}/\left[1 + (0.492/0.707)^{9/16}\right]^{4/9}\right]$$

$$\bar{h}_L = 4.51\ \text{W/m}^2\cdot\text{K} \quad <$$

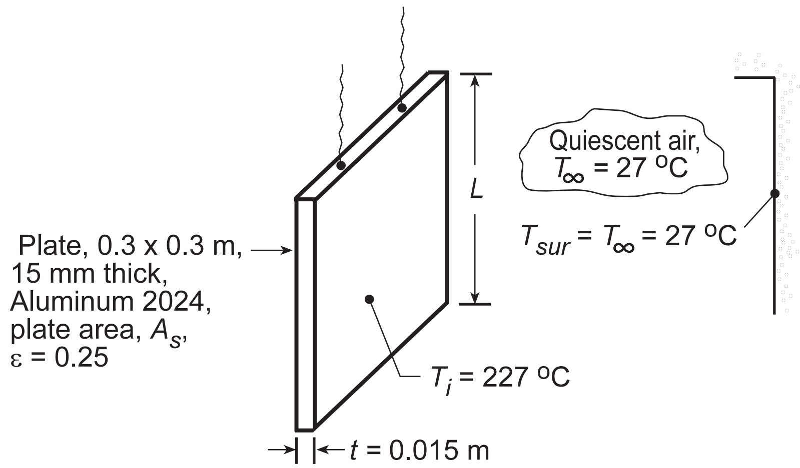
COMMENTS: The agreement of $\bar{h}_L$ calculated by these two methods is excellent. Using the Churchill-Chu correlation, Eq. 9.26, find $\bar{h}_L = 4.87\ \text{W/m}\cdot\text{K}$. This relation is not the most accurate for the laminar regime, but is suitable for both laminar and turbulent regions.

PROBLEM 9.14

KNOWN: Aluminum plate (alloy 2024) at an initial uniform temperature of 227°C is suspended in a room where the ambient air and surroundings are at 27°C.

FIND: (a) Expression for time rate of change of the plate, (b) Initial rate of cooling (K/s) when plate temperature is 227°C, (c) Validity of assuming a uniform plate temperature, (d) Decay of plate temperature and the convection and radiation rates during cooldown.

SCHEMATIC:



ASSUMPTIONS: (1) Plate temperature is uniform, (2) Ambient air is quiescent and extensive, (3) Surroundings are large compared to plate.

PROPERTIES: *Table A.1*, Aluminum alloy 2024 (T = 500 K): ρ = 2770 kg/m^3, k = 186 W/m·K, c = 983 J/kg·K; *Table A.4*, Air (T_f = 400 K, 1 atm): ν = 26.41 × 10^{-6} m^2/s, k = 0.0388 W/m·K, α = 38.3 × 10^{-6} m^2/s, Pr = 0.690.

ANALYSIS: (a) From an energy balance on the plate with free convection and radiation exchange, $-\dot{E}_{out} = \dot{E}_{st}$, we obtain

$$-\bar{h}_L 2A_s\left(T_s - T_\infty\right) - \varepsilon 2A_s\sigma\left(T_s^4 - T_{sur}^4\right) = \rho A_s tc\frac{dT}{dt} \quad \text{or} \quad \frac{dT}{dt} = \frac{-2}{\rho tc}\left[\bar{h}_L\left(T_s - T_\infty\right) + \varepsilon\sigma\left(T_s^4 - T_{sur}^4\right)\right] <$$

where T_s, the plate temperature, is assumed to be uniform at any time.

(b) To evaluate (dT/dt), estimate $\bar{h}_L$. First, find the Rayleigh number,

$$Ra_L = g\beta\left(T_s - T_\infty\right)L^3/\nu\alpha = \frac{9.8\,m/s^2\left(1/400\,K\right)\left(227-27\right)K \times \left(0.3\,m\right)^3}{26.41\times10^{-6}\,m^2/s \times 38.3\times10^{-6}\,m^2/s} = 1.308\times10^8 .$$

Eq. 9.27 is appropriate; substituting numerical values, find

$$\overline{Nu}_L = 0.68 + \frac{0.670 Ra_L^{1/4}}{\left[1+\left(0.492/Pr\right)^{9/16}\right]^{4/9}} = 0.68 + \frac{0.670\left(1.308\times10^8\right)^{1/4}}{\left[1+\left(0.492/0.690\right)^{9/16}\right]^{4/9}} = 55.5$$

$$\bar{h}_L = \overline{Nu}_L k/L = 55.5 \times 0.0338\,W/m\cdot K/0.3\,m = 6.25\,W/m^2\cdot K$$

Continued...

PROBLEM 9.14 (Cont.)

$$\frac{dT}{dt} = \frac{-2}{2770\,\mathrm{kg/m^3} \times 0.015\,\mathrm{m} \times 983\,\mathrm{J/kg\cdot K}} \times$$

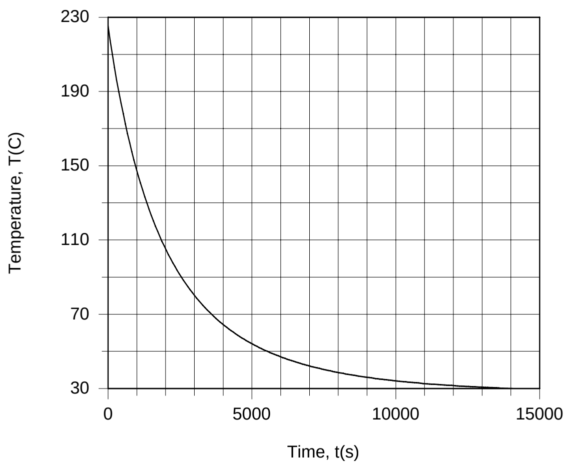
$$\left[6.25\,\mathrm{W/m^2\cdot K}\left(227-27\right)\mathrm{K} + 0.25\left(5.67\times10^{-8}\,\mathrm{W/m^2\cdot K^4}\right)\left(500^4 - 300^4\right)\mathrm{K}^4\right] = -0.099\,\mathrm{K/s}\,. \qquad <$$

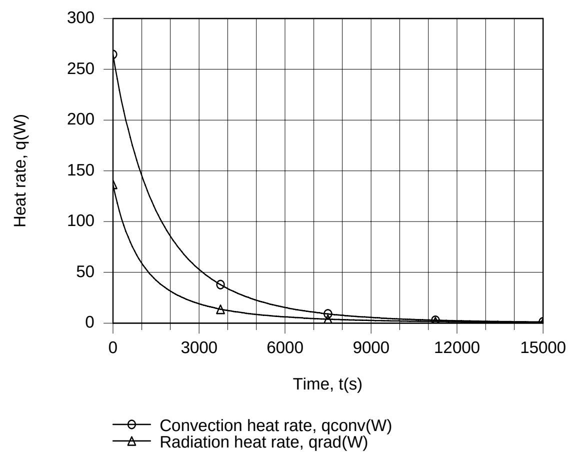
(c) The uniform temperature assumption is justified if the Biot number criterion is satisfied. With $L_c \equiv (V/2A_s) = (A_s \cdot t/2A_s) = (t/2)$ and $\bar{h}_{tot} = \bar{h}_{conv} + \bar{h}_{rad}$, Bi = $\bar{h}_{tot}\left(t/2\right)/k \le 0.1$. Using the linearized radiation coefficient relation, find

$$\bar{h}_{rad} = \varepsilon\sigma\left(T_s + T_{sur}\right)\left(T_s^2 + T_{sur}^2\right) = 0.25\left(5.67\times10^{-8}\,\mathrm{W/m^2\cdot K^4}\right)\left(500+300\right)\left(500^2+300^2\right)\mathrm{K}^3 = 3.86\,\mathrm{W/m^2\cdot K}$$

Hence, Bi = (6.25 + 3.86) $\mathrm{W/m^2\cdot K}$(0.015 m/2)/186 W/m·K = 4.07×10^{-4}. Since Bi << 0.1, the assumption is appropriate.

(d) The temperature history of the plate was computed by combining the *Lumped Capacitance Model* of IHT with the appropriate *Correlations* and *Properties* Toolpads.





Due to the small values of $\bar{h}_L$ and $\bar{h}_{rad}$, the plate cools slowly and does not reach 30°C until t ≈ 14000s = 3.89h. The convection and radiation rates decrease rapidly with increasing t (decreasing T), thereby decelerating the cooling process.

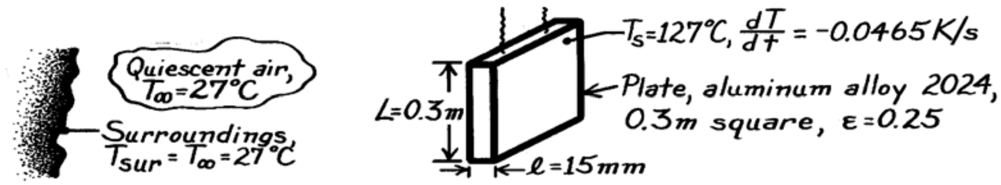
COMMENTS: The reduction in the convection rate with increasing time is due to a reduction in the thermal conductivity of air, as well as the values of $\bar{h}_L$ and T.

PROBLEM 9.15

KNOWN: Instantaneous temperature and time rate of temperature change of a vertical plate cooling in a room.

FIND: Average free convection coefficient for the prescribed conditions; compare with standard empirical correlation.

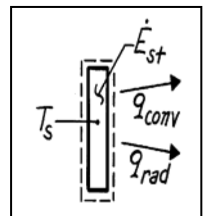
SCHEMATIC:



ASSUMPTIONS: (1) Uniform plate temperature, (2) Quiescent room air, (3) Large surroundings.

PROPERTIES: *Table A-1*, Aluminum alloy 2024 (T_s = 127°C = 400K): ρ = 2770 kg/m^3, c_p = 925 J/kg·K; *Table A-4*, Air ($T_f = (T_s + T_\infty)/2$ = 350K, 1 atm): $\nu = 20.92 \times 10^{-6}$ m^2/s, k = 0.030 W/m·K, $\alpha = 29.9 \times 10^{-6}$ m^2/s, Pr = 0.700.

ANALYSIS: From an energy balance on the plate considering free convection *and* radiation exchange,



$$\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st}$$

$$-\bar{h}_L(2A_s)(T_s - T_\infty) - \varepsilon(2A_s)\sigma\left(T_s^4 - T_{sur}^4\right) = \rho A_s \ell c_p \frac{dT}{dt}.$$

Noting that the plate area is $2A_s$, solving for $\bar{h}_L$, and substituting numerical values, find

$$\bar{h}_L = \left[-\rho\ell c_p \frac{dT}{dt} - 2\varepsilon\sigma\left(T_s^4 - T_{sur}^4\right)\right] / 2(T_s - T_\infty)$$

$$\bar{h}_L = \left[-2770\text{kg/m}^3 \times 0.015\text{m} \times 925\text{J/kg}\cdot\text{K}(-0.0465\text{K/s}) - 2 \times 0.25 \times 5.67 \times 10^{-8}\text{W/m}^2\cdot\text{K}^4\left(400^4 - 300^4\right)\text{K}^4\right]$$

$$/2(127-27)^\circ\text{C} = (8.936 - 2.455)\text{W/m}^2\cdot\text{K}$$

$$\bar{h}_L = 6.5\,\text{W/m}^2\cdot\text{K}.$$ <

To select an appropriate empirical correlation, first evaluate the Rayleigh number,

$$Ra_L = g\beta\Delta TL^3/\nu\alpha$$

$$Ra_L = 9.8\text{m/s}^2(1/350\text{K})(127-27)\text{K}(0.3\text{m})^3/\left(20.92\times10^{-6}\text{m}^2/\text{s}\right)\left(29.9\times10^{-6}\text{m}^2/\text{s}\right) = 1.21\times10^8.$$

Since $Ra_L < 10^9$, the flow is laminar and Eq. 9.27 is applicable,

$$\overline{Nu}_L = \frac{\bar{h}_L L}{k} = 0.68 + \frac{0.670\,Ra_L^{1/4}}{\left[1 + (0.492/Pr)^{9/16}\right]^{4/9}}$$

$$\bar{h}_L = \left(\frac{0.030\text{W/m}\cdot\text{K}}{0.3\text{m}}\right)\left\{0.68 + 0.670\left(1.21\times10^8\right)^{1/4}/\left[1+(0.492/0.700)^{9/16}\right]^{4/9}\right\} = 5.5\,\text{W/m}^2\cdot\text{K}.$$ <

COMMENTS: (1) The correlation estimate is 15% lower than the experimental result. (2) This transient method, useful for obtaining an average free convection coefficient for spacewise isothermal objects, requires Bi ≤ 0.1.

PROBLEM 9.16

KNOWN: Interior air and wall temperatures; wall height.

FIND: (a) Average heat transfer coefficient when $T_\infty = 20°C$ and $T_s = 10°C$, (b) Average heat transfer coefficient when $T_\infty = 27°C$ and $T_s = 37°C$.

SCHEMATIC:

ASSUMPTIONS: (a) Wall is at a uniform temperature, (b) Room air is quiescent.

PROPERTIES: *Table A-4*, Air (T_f = 288K, 1 atm): $\beta = 1/T_f = 3.472 \times 10^{-3}$ K^{-1}, $\nu = 14.82 \times 10^{-6}$ m^2/s, k = 0.0253 W/m·K, $\alpha = 20.9 \times 10^{-6}$ m^2/s, Pr = 0.710; (T_f = 305K, 1 atm): $\beta = 1/T_f = 3.279 \times 10^{-3}$ K^{-1}, $\nu = 16.39 \times 10^{-6}$ m^2/s, k = 0.0267 W/m·K, $\alpha = 23.2 \times 10^{-6}$ m^2/s, Pr = 0.706.

ANALYSIS: The appropriate correlation for the average heat transfer coefficient for free convection on a vertical wall is Eq. 9.26.

$$\overline{Nu}_L = \frac{\bar{h}L}{k} = \left\{0.825 + \frac{0.387\, Ra_L^{0.1667}}{\left[1+(0.492/Pr)^{0.563}\right]^{0.296}}\right\}^2$$

where $Ra_L = g\,\beta\,\Delta T\, L^3/\nu\alpha$, Eq. 9.25, with $\Delta T = T_s - T_\infty$ or $T_\infty - T_s$.

(a) Substituting numerical values typical of *winter* conditions gives

$$Ra_L = \frac{9.8\text{ m/s}^2 \times 3.472\times10^{-3}\text{ K}^{-1}(20-10)\text{ K }(2.5\text{m})^3}{14.82\times10^{-6}\text{m}^2/\text{s}\times 20.96\times10^{-6}\text{m}^2/\text{s}} = 1.711\times10^{10}$$

$$\overline{Nu}_L = \left\{0.825 + \frac{0.387\left(1.711\times10^{10}\right)^{0.1667}}{\left[1+(0.492/0.710)^{0.563}\right]^{0.296}}\right\}^2 = 299.6.$$

Hence, $\bar{h} = \overline{Nu}_L\ k/L = 299.6(0.0253\text{ W/m}\cdot\text{K})/2.5\text{m} = 3.03\text{ W/m}^2\cdot\text{K}.$ <

(b) Substituting numerical values typical of *summer* conditions gives

$$Ra_L = \frac{9.8\text{ m/s}^2 \times 3.279\times10^{-3}\text{ K}^{-1}(37-27)\text{ K }(2.5\text{ m})^3}{23.2\times10^{-6}\text{m}^2/\text{s}\times 16.39\times10^{-6}\text{m}^2/\text{s}} = 1.320\times10^{10}$$

$$\overline{Nu}_L = \left\{0.825 + \frac{0.387\left(1.320\times10^{10}\right)^{0.1667}}{\left[1+(0.492/0.706)^{0.563}\right]^{0.296}}\right\}^2 = 275.8.$$

Hence, $\bar{h} = \overline{Nu}_L\ k/L = 275.8\times0.0267\text{ W/m}\cdot\text{K/2.5m} = 2.94\text{ W/m}^2\cdot\text{K}.$ <

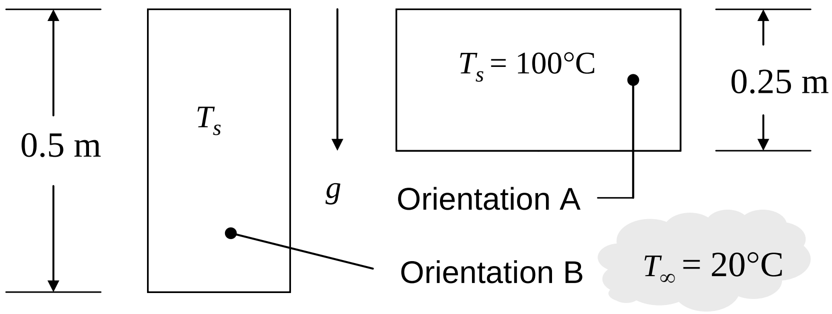
COMMENTS: There is a small influence due to T_f on $\bar{h}$ for these conditions. We should expect radiation effects to be important with such low values of $\bar{h}$.

PROBLEM 9.17

KNOWN: Dimensions of vertical plate. Plate and ambient temperatures.

FIND: Preferred orientation to minimize convective heat transfer and convective heat transfer rate for that orientation.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Ideal gas, (4) Quiescent environment.

PROPERTIES: *Table A.4*, air ($\bar{T}$ = 60°C = 333 K): $\nu = 19.21\times10^{-6}$ m²/s, $\alpha = 27.4\times10^{-6}$ m²/s, Pr = 0.702, k = 0.0287 W/m·K.

ANALYSIS: Note that the maximum value of the Rayleigh number is associated with Orientation B.

$$Ra_{\max} = \frac{g\beta(T_s - T_\infty)L^3}{\nu\cdot\alpha} = \frac{9.81\text{m/s}^2 \times (1/333\text{K}) \times (100-20)°\text{C} \times (0.5\text{m})^3}{19.21\times10^{-6}\text{m}^2/\text{s} \times 27.4\times10^{-6}\text{m}^2/\text{s}} = 560\times10^6$$

Since the maximum Rayleigh number is less than $Ra_{x,c} = 10^9$, flow conditions are laminar for both orientations. Hence, to minimize heat transfer from the plate, we wish to maximize the thickness of the boundary layer and therefore maximize the plate length in the vertical direction. Therefore, Orientation B is preferred. <

Selecting Eq. 9.27,

$$\bar{h} = \frac{k}{L}\left\{0.68 + \frac{0.67 Ra_L^{1/4}}{\left[1+(0.492/Pr)^{9/16}\right]^{4/9}}\right\}$$

$$= \frac{0.0287\text{ W/(m}\cdot\text{K)}}{0.5\text{m}}\left\{0.68 + \frac{0.67\times(560\times10^6)^{1/4}}{\left[1+(0.492/0.702)^{9/16}\right]^{4/9}}\right\} = 4.57\frac{\text{W}}{\text{m}^2\cdot\text{K}}$$

and

$$q = \bar{h}A(T_s - T_\infty) = 4.57\text{W/m}^2\cdot\text{K}\times(0.25\text{m}\times0.50\text{m})\times(100-20)°C = 45.7\text{ W}$$ <

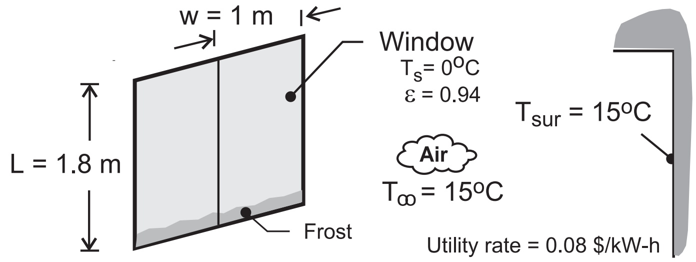
COMMENTS: 1. For Orientation A, $Ra = 7\times 10^7$, $\bar{h}$ = 5.48 W/m²·K and q = 54.8 W. Although the Rayleigh and Nusselt numbers are smaller for Orientation A, the length scale in the Nusselt number is half that of Orientation B, leading to an overall increase in the convection coefficient and heat transfer rate. 2. Radiation heat transfer will be significant.

PROBLEM 9.18

KNOWN: During a winter day, the window of a patio door with a height of 1.8 m and width of 1.0 m shows a frost line near its base.

FIND: (a) Explain why the window would show a frost layer at the base of the window, rather than at the top, and (b) Estimate the heat loss through the window due to free convection and radiation. If the room has electric baseboard heating, estimate the daily cost of the window heat loss for this condition based upon the utility rate of 0.18 \$/kW·h.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Window has a uniform temperature, (3) Ambient air is quiescent, and (4) Room walls are isothermal and large compared to the window.

PROPERTIES: *Table A-4*, Air ($T_f = (T_s + T_\infty)/2 = 280$ K, 1 atm): $\nu = 14.11 \times 10^{-6}$ m^2/s, k = 0.0247 W/m·K, $\alpha = 1.986 \times 10^{-5}$ m^2/s, Pr = 0.710.

ANALYSIS: (a) For these winter conditions, a frost line could appear and it would be at the bottom of the window. The boundary layer is thinnest at the top of the window, and hence the heat flux from the warmer room is greater than compared to that at the bottom portion of the window where the boundary layer is thicker. Also, the air in the room may be stratified and cooler near the floor compared to near the ceiling.

(b) The heat loss from the room to the window having a uniform temperature $T_s = 0°C$ by convection and radiation is

$$q_{loss} = q_{cv} + q_{rad} \tag{1}$$

$$q_{loss} = A_s\left[\bar{h}_L\left(T_\infty - T_s\right) + \varepsilon\sigma\left(T_{sur}^4 - T_s^4\right)\right] \tag{2}$$

The average convection coefficient is estimated from the Churchill-Chu correlation, Eq. 9.26, using properties evaluated at $T_f = (T_s + T_\infty)/2$.

$$\overline{Nu}_L = \frac{\bar{h}_L L}{k} = \left\{0.825 + \frac{0.387\ Ra_L^{1/6}}{\left[1+\left(0.492/Pr\right)^{9/16}\right]^{8/27}}\right\}^2 \tag{3}$$

$$Ra_L = g\beta T\left(T_\infty - T_s\right)L^3/\nu\alpha \tag{4}$$

Substituting numerical values in the correlation expressions, find

$$Ra_L = 1.084\times10^{10} \qquad \overline{Nu}_L = 258.9 \qquad \bar{h}_L = 3.6\ W/m^2\cdot K$$

Continued …

PROBLEM 9.18 (Cont.)

Using Eq. (2), the heat loss with $\sigma = 5.67 \times 10^{-8}$ W/m^2·K^4 is

$$q_{loss} = (1 \times 1.8)\,m^2 \left[3.6\ W/m^2 \cdot K\,(15\ K) + 0.940\,\sigma\left(288^4 - 273^4\right)K^4\right]$$

$$q_{loss} = (96.1 + 127.1)\,W = 223\ W$$

The daily cost of the window heat loss for the given utility rate is

$$cost = q_{loss} \times (\text{utility rate}) \times 24\ \text{hours}$$

$$cost = 223\ W \times (10^{-3}\ kW/W) \times 0.18\ \$/kW{\cdot}h \times 24\ h$$

$$cost = 0.96\ \$/day$$ <

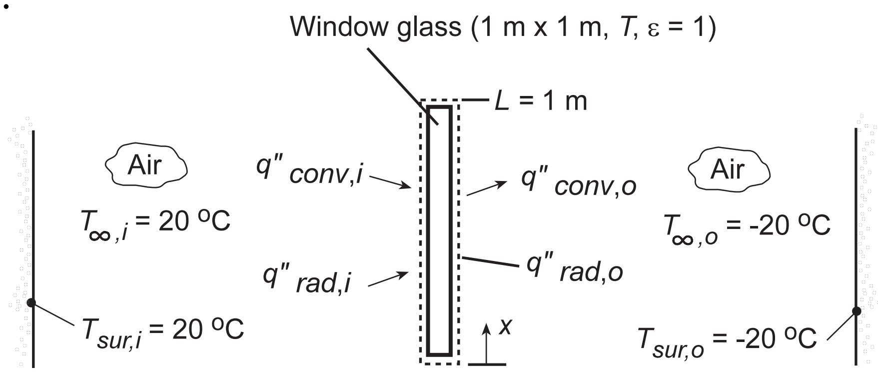
COMMENTS: Note that the heat loss by radiation is 30% larger than by free convection.

PROBLEM 9.19

KNOWN: Room and ambient air conditions for window glass.

FIND: Temperature of the glass and rate of heat loss.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible temperature gradients in the glass, (3) Inner and outer surfaces exposed to large surroundings.

PROPERTIES: *Table A.4*, air ($T_{f,i}$ and $T_{f,o}$): Obtained from the IHT *Properties* Tool Pad.

ANALYSIS: Performing an energy balance on the window pane, it follows that $\dot{E}_{in} = \dot{E}_{out}$, or

$$\varepsilon\sigma\left(T_{sur,i}^4 - T^4\right) + \bar{h}_i\left(T_{\infty,i} - T\right) = \varepsilon\sigma\left(T^4 - T_{sur,o}^4\right) + \bar{h}_o\left(T - T_{\infty,o}\right)$$

where $\bar{h}_i$ and $\bar{h}_o$ may be evaluated from Eq. 9.26.

$$\overline{Nu}_L = \left\{0.825 + \frac{0.387 Ra_L^{1/6}}{\left[1 + \left(0.492/Pr\right)^{9/16}\right]^{8/27}}\right\}^2$$

Using the *First Law* Model for an *Isothermal Plane Wall* and the *Correlations* and *Properties* Tool Pads of IHT, the energy balance equation was formulated and solved to obtain

$$T = 273.8\ K$$ <

The heat rate is then $q_i = q_o$, or

$$q_i = L^2\left[\varepsilon\sigma\left(T_{sur,i}^4 - T^4\right) + \bar{h}_i\left(T_{\infty,i} - T\right)\right] = 174.8\ W$$ <

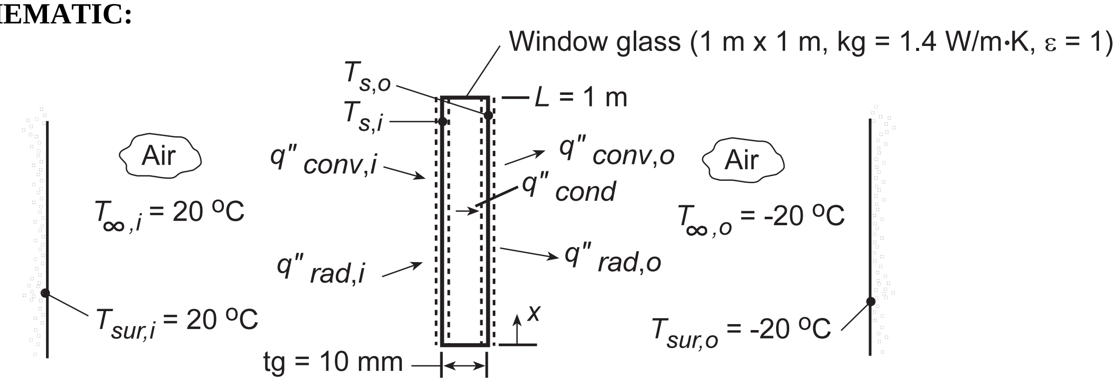
COMMENTS: The radiative and convective contributions to heat transfer at the inner and outer surfaces are $q_{rad,i}$ = 99.04 W, $q_{conv,i}$ = 75.73 W, $q_{rad,o}$ = 86.54 W, and $q_{conv,o}$ = 88.23 W, with corresponding convection coefficients of $\bar{h}_i$ = 3.95 W/m^2·K and $\bar{h}_o$ = 4.23 W/m^2·K. The heat loss could be reduced significantly by installing a double pane window.

PROBLEM 9.20

KNOWN: Room and ambient air conditions for window glass. Thickness and thermal conductivity of glass.

FIND: Inner and outer surface temperatures and heat loss.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in the glass, (3) Inner and outer surfaces exposed to large surroundings.

PROPERTIES: *Table A.4*, air ($T_{f,i}$ and $T_{f,o}$): Obtained from the IHT *Properties* Tool Pad.

ANALYSIS: Performing energy balances at the inner and outer surfaces, we obtain, respectively,

$$\varepsilon\sigma\left(T_{sur,i}^4 - T_{s,i}^4\right) + \bar{h}_i\left(T_{\infty,i} - T_{s,i}\right) = \left(kg/tg\right)\left(T_{s,i} - T_{s,o}\right) \quad (1)$$

$$\left(kg/tg\right)\left(T_{s,i} - T_{s,o}\right) = \varepsilon\sigma\left(T_{s,o}^4 - T_{sur,o}^4\right) + \bar{h}_o\left(T_{s,o} - T_{\infty,o}\right) \quad (2)$$

where Eq. 9.26 may be used to evaluate $\bar{h}_i$ and $\bar{h}_o$

$$\overline{Nu}_L = \left\{0.825 + \frac{0.387 Ra_L^{1/6}}{\left[1 + \left(0.492/Pr\right)^{9/16}\right]^{8/27}}\right\}^2$$

Using the *First Law* Model for *One-dimensional Conduction* in a *Plane Wall* and the *Correlations* and *Properties* Tool Pads of IHT, the energy balance equations were formulated and solved to obtain

$T_{s,i} = 274.4$ K $\qquad T_{s,o} = 273.2$ K <

from which the heat loss is

$$q = \frac{k_g L^2}{t_g}\left(T_{s,i} - T_{s,o}\right) = 168.8\,W$$ <

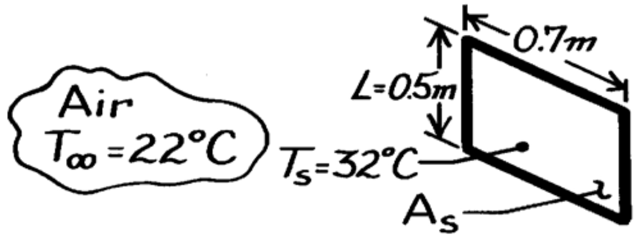
COMMENTS: By accounting for the thermal resistance of the glass, the heat loss is smaller (168.8 W) than that determined in the preceding problem (174.8 W) by assuming an isothermal pane.

PROBLEM 9.21

KNOWN: Oven door with average surface temperature of 32°C in a room with ambient air at 22°C.

FIND: Heat loss to the room. Also, find effect on heat loss if emissivity of door is unity and the surroundings are at 22°C.

SCHEMATIC:



ASSUMPTIONS: (1) Ambient air is quiescent, (2) Surface radiation effects are negligible.

PROPERTIES: *Table A-4*, Air (T_f = 300K, 1 atm): $\nu = 15.89 \times 10^{-6}\ m^2/s$, k = 0.0263 W/m·K, $\alpha = 22.5 \times 10^{-6}\ m^2/s$, Pr = 0.707, $\beta = 1/T_f = 3.33 \times 10^{-3}\ K^{-1}$.

ANALYSIS: The heat rate from the oven door surface by convection to the ambient air is

$$q = \bar{h} A_s \left(T_s - T_\infty\right) \quad (1)$$

where $\bar{h}$ can be estimated from the free-convection correlation for a vertical plate, Eq. 9.26,

$$\overline{Nu}_L = \frac{\bar{h} L}{k} = \left\{0.825 + \frac{0.387\, Ra_L^{1/6}}{\left[1+\left(0.492/Pr\right)^{9/16}\right]^{8/27}}\right\}^2 . \quad (2)$$

The Rayleigh number, Eq. 9.25, is

$$Ra_L = \frac{g\beta\left(T_s - T_\infty\right)L^3}{\nu\alpha} = \frac{9.8\, m/s^2 \left(1/300K\right)\left(32-22\right)K \times 0.5^3 m^3}{15.89\times10^{-6} m^2/s \times 22.5\times10^{-6} m^2/s} = 1.142\times10^8.$$

Substituting numerical values into Eq. (2), find

$$\overline{Nu}_L = \left\{0.825 + \frac{0.387\left(1.142\times10^8\right)^{1/6}}{\left[1+\left(0.492/0.707\right)^{9/16}\right]^{8/27}}\right\}^2 = 63.5$$

$$\bar{h}_L = \frac{k}{L}\overline{Nu}_L = \frac{0.0263\, W/m\cdot K}{0.5m} \times 63.5 = 3.34\, W/m^2\cdot K.$$

The heat rate using Eq. (1) is

$$q = 3.34\, W/m^2\cdot K \times \left(0.5\times0.7\right)m^2 \left(32-22\right)K = 11.7\, W. \quad <$$

Heat loss by radiation, assuming ε = 1, is

$$q_{rad} = \varepsilon A_s \sigma\left(T_s^4 - T_{sur}^4\right)$$

$$q_{rad} = 1\left(0.5\times0.7\right)m^2 \times 5.67\times10^{-8} W/m^2\cdot K^4\left[\left(273+32\right)^4 - \left(273+22\right)^4\right]K^4 = 21.4\, W. \quad <$$

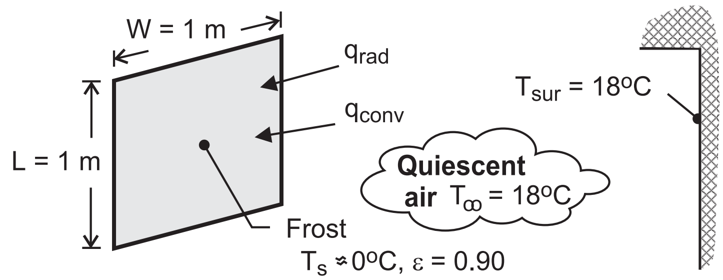
Note that heat loss by radiation is nearly double that by free convection. Using Eq. (1.9), the radiation heat transfer coefficient is h_{rad} = 6.4 W/m^2·K, which is twice the coefficient for the free convection process.

PROBLEM 9.22

KNOWN: Dimensions of window pane with frost formation on inner surface. Temperature of room air and walls.

FIND: Heat loss through window.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Surface of frost is isothermal with $T_s \approx 0°C$, (3) Radiation exchange is between a small surface (window) and a large enclosure (walls of room), (4) Room air is quiescent.

PROPERTIES: *Table A-4*, air (T_f = 9°C = 282 K): k = 0.0249 W/m·K, $\nu = 14.3 \times 10^{-6}$ m^2/s, $\alpha = 20.1 \times 10^{-6}$ m^2/s, Pr = 0.712, $\beta = 3.55 \times 10^{-3}$ K^{-1}.

ANALYSIS: Under steady-state conditions, the heat loss through the window corresponds to the rate of heat transfer to the frost by convection and radiation.

$$q = q_{conv} + q_{rad} = W \times L\left[\overline{h}\left(T_\infty - T_s\right) + \varepsilon\sigma\left(T_{sur}^4 - T_s^4\right)\right]$$

With $Ra_L = g\beta\left(T_\infty - T_s\right)L^3/\alpha\nu = 9.8\,m/s^2 \times 0.00355\,K^{-1} \times 18\,K\,(1m)^3/\left(14.3 \times 20.1 \times 10^{-12}\,m^4/s^2\right)$

$= 2.18 \times 10^9$, Eq. (9.26) yields

$$\overline{Nu}_L = \left\{0.825 + \frac{0.387\,Ra_L^{1/6}}{\left[1 + \left(0.492/Pr\right)^{9/16}\right]^{8/27}}\right\}^2 = 156.5$$

$$\overline{h} = \overline{Nu}_L \frac{k}{L} = 156.5\left(\frac{0.0249\,W/m \cdot K}{1m}\right) = 3.9\,W/m^2 \cdot K$$

$$q = 1m^2\left[3.9\,W/m^2 \cdot K\,(18K) + 0.90 \times 5.67 \times 10^{-8}\,W/m^2 \cdot K^4\left(291^4 - 273^4\right)\right]$$

$$= 70.2\,W + 82.5\,W = 152.7\,W$$ <

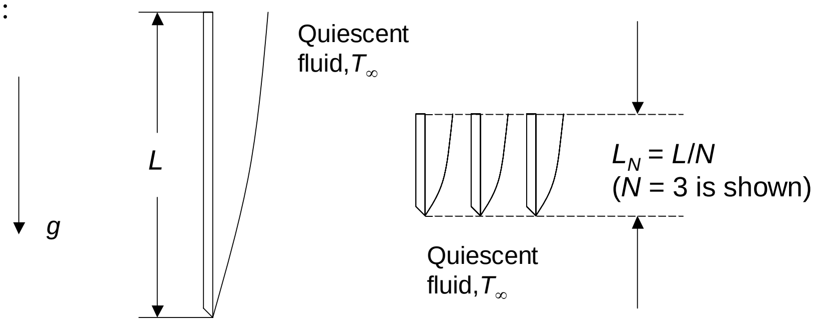
COMMENTS: (1) The thickness of the frost layer does not affect the heat loss, since the inner surface of the layer remains at $T_s \approx 0°C$. However, the temperature of the glass/frost interface decreases with increasing thickness, from a value of 0°C for negligible thickness. (2) Since the thermal boundary layer thickness is zero at the top of the window and has its maximum value at the bottom, the temperature of the glass will actually be largest and smallest at the top and bottom, respectively. Hence, frost will first begin to form at the bottom.

PROBLEM 9.23

KNOWN: Length of isothermal vertical plate, *L*.

FIND: Expression for the ratio of the average heat transfer coefficients for *N* plates each of length $L_N = L/N$ to the average coefficient for the single plate.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties.

ANALYSIS: Equation 9.21 yields, for the single plate,

$$\overline{Nu}_L = \frac{\bar{h}L}{k} = \frac{4}{3}\left(\frac{Gr_L}{4}\right)^{1/4} g(Pr) \quad \text{or} \quad \bar{h}_{L,1} = \frac{4k}{3L}\left(\frac{Gr_L}{4}\right)^{1/4} g(Pr) \qquad (1)$$

For multiple plates,

$$\overline{Nu}_{L,N} = \frac{\bar{h}_{L,N} L_N}{k} = \frac{4}{3}\left(\frac{Gr_{L,N}}{4}\right)^{1/4} g(Pr) \quad \text{where} \quad L_N = L/N \text{ and } Gr_{L,N} = Gr_L/(N^3) \qquad (2a, b, c)$$

Combining Equations 2a, 2b and 2c yields

$$\bar{h}_{L,N} = \frac{4Nk}{3L}\left(\frac{Gr_L}{4N^3}\right)^{1/4} g(Pr) \qquad (3)$$

Dividing Equation 3 by Equation 1 yields

$$\bar{h}_{L,N} / \bar{h}_{L,1} = N\left(\frac{1}{N^3}\right)^{1/4} = N^{1/4} \qquad <$$

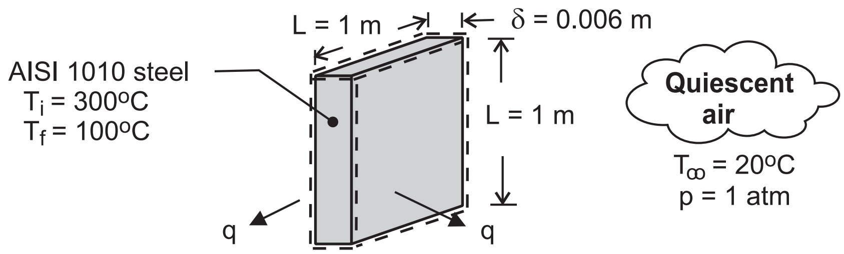
COMMENTS: (1) By breaking the single plate into shorter segments, the average boundary layer thickness is reduced, resulting in a modest increase in the average heat transfer coefficient and, in turn, the convective heat transfer from the plate. (2) The relationship for laminar *forced* convection for an isothermal plate in parallel flow is $\bar{h}_{L,N} / \bar{h}_{L,1} = N^{1/2}$, illustrating that, in general, enhancement of free convection heat transfer is more challenging than enhancement of forced convection. See Problem 7.11.

PROBLEM 9.24

KNOWN: Plate dimensions, initial temperature, and final temperature. Air temperature.

FIND: (a) Initial cooling rate, (b) Time to reach prescribed final temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Plate is spacewise isothermal as it cools (lumped capacitance approximation), (2) Negligible heat transfer from minor sides of plate, (3) Thermal boundary layer development corresponds to that for an isolated plate (negligible interference between adjoining boundary layers). (4) Negligible radiation. (5) Constant properties.

PROPERTIES: *Table A-1*, AISI 1010 steel $\left(\overline{T} = 473\,K\right)$: ρ = 7832 kg/m^3, c = 513 J/kg·K. *Table A-4*, air ($T_{f,i}$ = 433 K): ν = 30.4 × 10^{-6} m^2/s, k = 0.0361 W/m·K, α = 44.2 × 10^{-6} m^2/s, Pr = 0.687, β = 0.0023 K^{-1}.

ANALYSIS: (a) The initial rate of heat transfer is $q_i = \overline{h}\,A_s\left(T_i - T_\infty\right)$, where $A_s \approx 2\,L^2 = 2\,m^2$. With $Ra_{L,i} = g\beta(T_i - T_\infty)L^3/\alpha\nu$ = 9.8 m/s^2 × 0.0021 (280)1m^3/44.2 × 10^{-6} m^2/s × 30.4 × 10^{-6} m^2/s = 4.72 × 10^9, Eq. 9.26 yields

$$\overline{h} = \frac{0.0361\,W/m\cdot K}{1m}\left\{0.825 + \frac{0.387\left(4.72\times10^9\right)^{1/6}}{\left[1+\left(0.492/0.687\right)^{9/16}\right]^{8/27}}\right\}^2 = 7.16\,W/m^2\cdot K$$

Hence, $$q_i = 7.16\,W/m^2\cdot K\times 2m^2\times 280°C = 4010\,W$$ <

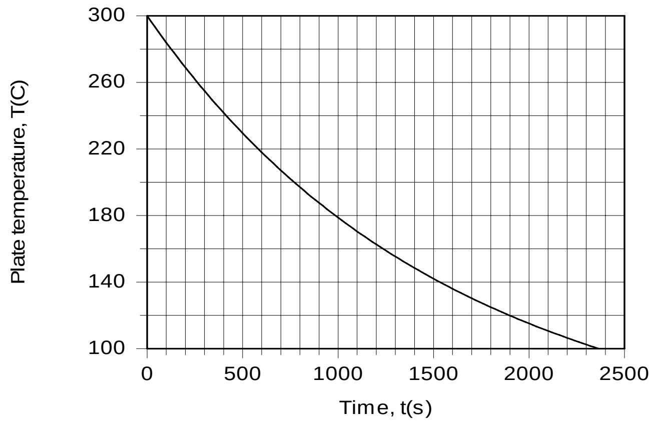
(b) From an energy balance at an instant of time for a control surface about the plate, $-q = \dot{E}_{st} = \rho L^2\,\delta c\,dT/dt$, the rate of change of the plate temperature is

$$\frac{dT}{dt} = -\frac{\overline{h}\,2L^2\left(T - T_\infty\right)}{\rho L^2\,\delta c} = -\frac{2\overline{h}}{\rho\,\delta c}\left(T - T_\infty\right)$$

where the Rayleigh number, and hence $\overline{h}$, changes with time due to the change in the temperature of the plate. Integrating the foregoing equation with the DER function of IHT, the following results are obtained for the temperature history of the plate.

Continued …

PROBLEM 9.24 (Cont.)



The time for the plate to cool to 100°C is

$t \approx 2365\,s$ <

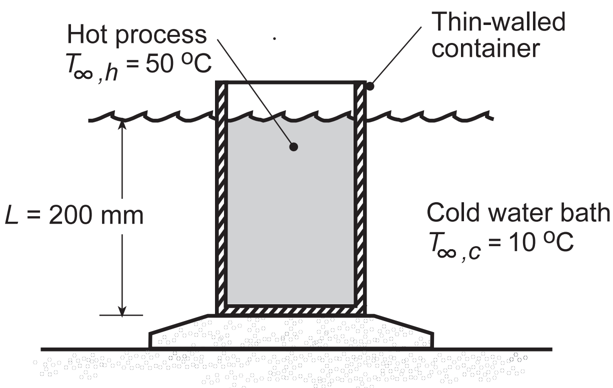
COMMENTS: (1) Although the plate temperature is comparatively large and radiation emission is significant relative to convection, much of the radiation leaving one plate is intercepted by the adjoining plate if the spacing between plates is small relative to their width. The net effect of radiation on the plate temperature would then be small. (2) Because of the increase in β and reductions in ν and α with increasing t, the Rayleigh number decreases only slightly as the plate cools from 300°C to 100°C (from 4.72×10^9 to 4.48×10^9), despite the significant reduction in $(T - T_\infty)$. The reduction in $\overline{h}$ from 7.2 to 5.6 $W/m^2 \cdot K$ is principally due to a reduction in the thermal conductivity.

PROBLEM 9.25

KNOWN: Thin-walled container with hot process fluid at 50°C placed in a quiescent, cold water bath at 10°C.

FIND: (a) Overall heat transfer coefficient, U, between the hot and cold fluids, and (b) Compute and plot U as a function of the hot process fluid temperature for the range $20 \le T_{\infty,h} \le 50°C$.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Heat transfer at the surfaces approximated by free convection from a vertical plate, (3) Fluids are extensive and quiescent, (4) Hot process fluid thermophysical properties approximated as those of water, and (5) Negligible container wall thermal resistance.

PROPERTIES: *Table A.6*, Water (assume $T_{f,h}$ = 310 K): $\rho_h = 1/1.007 \times 10^{-3} = 993\ kg/m^3$, $c_{p,h} = 4178$ J/kg·K, $\nu_h = \mu_h/\rho_h = 695 \times 10^{-6}\ N \cdot s/m^2 / 993\ kg/m^3 = 6.999 \times 10^{-7}\ m^2/s$, $k_h = 0.628$ W/m·K, $Pr_h = 4.62$, $\alpha_h = k_h/\rho_h c_{p,h} = 1.514 \times 10^{-7}\ m^2/s$, $\beta_h = 361.9 \times 10^{-6}\ K^{-1}$; *Table A.6*, Water (assume $T_{f,c}$ = 295 K): $\rho_c = 1/1.002 \times 10^{-3} = 998\ kg/m^3$, $c_{p,c} = 4181$ J/kg·K, $\nu_c = \mu_c/\rho_c = 959 \times 10^{-6}\ N \cdot s/m^2/998\ kg/m^3 = 9.609 \times 10^{-7}\ m^2/s$, $k_c = 0.606$ W/m·K, $Pr_c = 6.62$, $\alpha_c = k_c/\rho_c c_{p,c} = 1.452 \times 10^{-7}\ m^2/s$, $\beta_c = 227.5 \times 10^{-6}\ K^{-1}$.

ANALYSIS: (a) The overall heat transfer coefficient between the hot process fluid, $T_{\infty,h}$, and the cold water bath fluid, $T_{\infty,c}$, is

$$U = \left(1/\bar{h}_h + 1/\bar{h}_c\right)^{-1} \qquad (1)$$

where the average free convection coeffieicnts can be estimated from the vertical plate correlation Eq. 9.26, with the Rayleigh number, Eq. 9.25,

$$\overline{Nu}_L = \left\{0.825 + \frac{0.387 Ra_L^{1/6}}{\left[1 + (0.492/Pr)^{9/16}\right]^{8/27}}\right\}^2 \qquad Ra_L = \frac{g\beta\Delta T L^3}{\nu\alpha} \qquad (2,3)$$

To affect a solution, assume $T_s = \left(T_{\infty,h} + T_{\infty,c}\right)/2 = 30°C = 303\,K$, so that the hot and cold fluid film temperatures are $T_{f,h}$ = 313 K ≈ 310 K and $T_{f,c}$ = 293 K ≈ 295 K. From an energy balance across the container walls,

$$\bar{h}_h\left(T_{\infty,h} - T_s\right) = \bar{h}_c\left(T_s - T_{\infty,c}\right) \qquad (4)$$

the surface temperature T_s can be determined. Evaluating the correlation parameters, find:

Hot process fluid:

$$Ra_{L,h} = \frac{9.8\,m/s^2 \times 361.9 \times 10^{-6}\,K^{-1}\,(50-30)\,K\,(0.200m)^3}{6.999 \times 10^{-7}\,m^2/s \times 1.514 \times 10^{-7}\,m^2/s} = 5.357 \times 10^9$$

Continued...

PROBLEM 9.25 (Cont.)

$$\overline{Nu}_{L,h} = \left\{0.825 + \frac{0.387\left(5.357\times10^{9}\right)^{1/6}}{\left[1+\left(0.492/4.62\right)^{9/16}\right]^{8/27}}\right\}^2 = 251.5$$

$$\bar{h}_h = \overline{Nu}_{L,h}\,\frac{h_h}{L} = 251.5\times0.628\,W/m^2\cdot K/0.200m = 790\,W/m^2\cdot K$$

Cold water bath:

$$Ra_{L,c} = \frac{9.8\dot{m}/s^2\times227.5\times10^{-6}K^{-1}(30-10)K(0.200m)^3}{9.609\times10^{-7}\,m^2/s\times1.452\times10^{-7}\,m^2/s} = 2.557\times10^9$$

$$\overline{Nu}_{L,c} = \left\{0.825 + \frac{0.387\left(2.557\times10^{9}\right)^{1/6}}{\left[1+\left(0.492/6.62\right)^{9/16}\right]^{8/27}}\right\}^2 = 203.9$$

$$\bar{h}_c = 203.9\times0.606\,W/m\cdot K/0.200\,m = 618\,W/m^2\cdot K$$

From Eq. (1) find

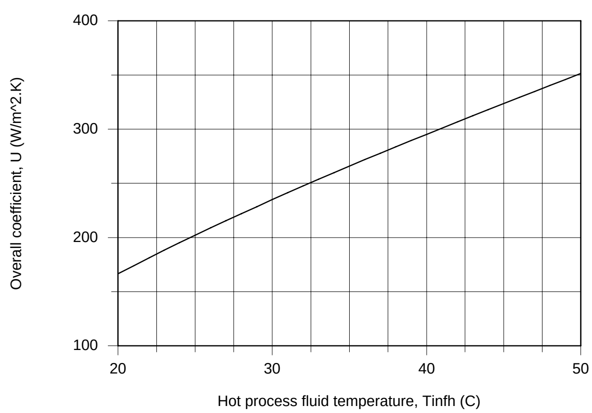
$$U = \left(1/790+1/618\right)^{-1}\,W/m^2\cdot K = 347\,W/m^2\cdot K \qquad <$$

Using Eq.(4), find the resulting surface temperature

$$790\,W/m^2\cdot K\left(50-T_s\right)K = 618\,W/m^2\cdot K\left(T_s-10\right)K \qquad T_s = 32.4^\circ C$$

Which compares favorably with our assumed value of 30°C.

(b) Using the *IHT Correlations Tool, Free Convection, Vertical Plate* and following the foregoing approach, the overall coefficient was computed as a function of the hot fluid temperature and is plotted below. Note that U increases almost linearly with $T_{\infty,h}$.



COMMENTS: For the conditions of part (a), using the IHT model of part (b) with thermophysical properties evaluated at the proper film temperatures, find U = 352 W/m·K with T_s = 32.4°C. Our approximate solution was a good one.

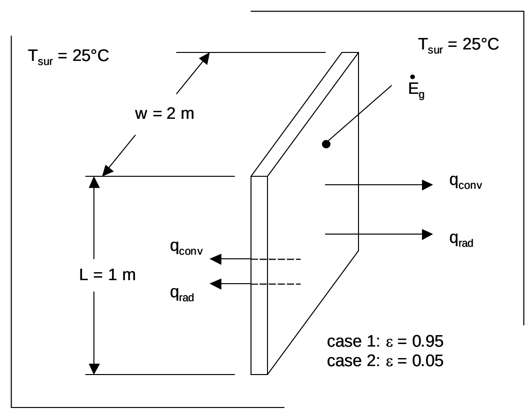
(2) Because the set of equations for part (b) is quite stiff, when using the IHT model you should follow the suggestions in the IHT Example 9.2 including use of the intrinsic function Tfluid_avg (T1,T2).

PROBLEM 9.26

KNOWN: Size and emissivity of a vertical heated plate. Temperature of the ambient and surroundings.

FIND: (a) Electrical power to be supplied to the plate in order to achieve a plate temperature of T_s = 35°C for ε = 0.95. Fraction of the plate exposed to turbulent conditions, (b) Steady-state plate temperature for ε = 0.05 and fraction of the plate exposed to turbulent conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties and steady-state conditions, (2) Large surroundings, (3) Isothermal plate, (4) Critical Rayleigh number of $Ra_{x,c} = 10^9$.

PROPERTIES: Table A.4, air: (T_f = 303 K): k = 0.02652 W/m·K, ν = 1.619 × 10^{-5} m^2/s, α = 2.294 × 10^{-5} m^2/s, Pr = 0.7066.

ANALYSIS: (a) The Rayleigh number is

$$Ra_L = \frac{g\beta\Delta TL^3}{\nu\alpha} = \frac{9.8\,m/s^2 \times (1/303K)\times 10°C \times (1m)^3}{1.619\times10^{-5} m^2/s \times 2.294\times10^{-5} m^2/s} = 8.71\times10^8 \qquad (1)$$

Since Ra < $Ra_{x,c}$, the boundary layer is completely laminar. The electric power required is

$$P = \dot{E}_g = q_{conv} + q_{rad} = \bar{h}A(T_s - T_\infty) + \varepsilon A\sigma(T_s^4 - T_{sur}^4) \qquad (2)$$

The convection coefficient may be found from the Churchill and Chu correlation

$$\overline{Nu}_L = \left\{0.825 + \frac{0.387\times\left(8.71\times10^8\right)^{1/6}}{\left[1+\left(0.492/0.7066\right)^{9/16}\right]^{8/27}}\right\}^2 = 117.6 \qquad (3)$$

Thus, the convection coefficient is

Continued…

PROBLEM 9.26 (Cont.)

$$\bar{h} = \overline{Nu}_L k/L = 117.6 \times 0.02652\,W/m \cdot K/1m = 3.12\,W/m^2 \cdot K$$

Hence, Equation 2 is written

$$P = 2 \times (1m \times 2m) \times 3.12\,W/m^2 \cdot K \times (35 - 25)°C$$
$$+ 0.95 \times 5.67 \times 10^{-8}\,W/m^2 \cdot K^4 \times (308^4 - 298^4)K^4$$
$$= 124.8W + 239.8W = 364.2W \qquad <$$

(b) Equations 1, 2 and 3 may be solved simultaneously with the constraint that P = 364.6 W. Property variations may be taken into account by using IHT. A simultaneous solution of Equations 1 through 3 yields

$$Ra_L = 1.71 \times 10^9, \overline{Nu}_L = 144.9, \bar{h} = 3.906\,W/m^2 \cdot K, T_s = 319.5K = 46.5°C \qquad <$$

The length of the plate that is subjected to laminar conditions may be found from the definition of the Rayleigh number, $Ra_L = g\beta\Delta TL^3/\nu\alpha$ and the knowledge that T_f = (319.5 K = 298 K)/2 = 308.8 K.

$$L = \left(\frac{Ra_{x,c}\nu\alpha}{g\beta\Delta T}\right)^{1/3} = \left(\frac{10^9 \times 1.677 \times 10^{-5} m^2/s \times 2.379 \times 10^{-5} m^2/s}{9.8m/s \times (1/308.8K) \times (319.5K - 298K}\right)^{1/3} = 0.836\text{ m} \qquad <$$

Therefore, 1m – 0.836m = 0.164m or 16.4% of the plate is exposed to turbulent conditions.

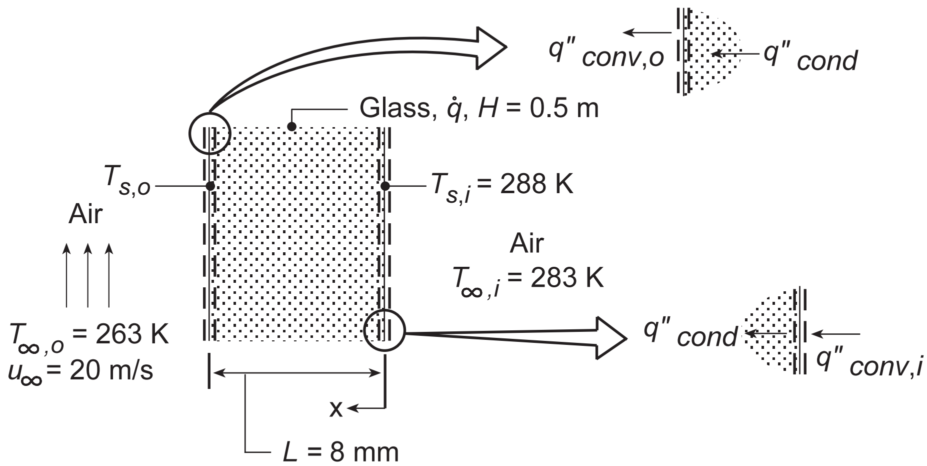
COMMENTS: (1) In part (b), the convection and radiation heat rates are 335.9 W and 28.74 W, respectively. Convection dominates in part (b) while in part (a) radiation losses are significantly larger than convection losses. (2) Radiation exchange can fundamentally alter the nature of the flow in free convection systems. (3) The polished plate would slowly oxidize over time, causing *drift* in the experimentalist's measurements of the transition to turbulent flow. (4) The properties used in part (b) are evaluated at the film temperature of T_f = 308.8 K and are k = 0.02695 W/m·K, $\nu = 1.677 \times 10^{-5}$ m²/s, $\alpha = 2.397 \times 10^{-5}$ m²/s, Pr = 0.7058.

PROBLEM 9.27

KNOWN: Boundary conditions associated with a rear window experiencing uniform volumetric heating.

FIND: (a) Volumetric heating rate $\dot{q}$ needed to maintain inner surface temperature at $T_{s,i}$ = 15°C, (b) Effects of $T_{\infty,o}$, u_∞, and $T_{\infty,i}$ on $\dot{q}$ and $T_{s,o}$.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, one-dimensional conditions, (2) Constant properties, (3) Uniform volumetric heating in window, (4) Convection heat transfer from interior surface of window to interior air may be approximated as free convection from a vertical plate, (5) Heat transfer from outer surface is due to forced convection over a flat plate in parallel flow.

PROPERTIES: *Table A.3*, Glass (300 K): k = 1.4 W/m·K: *Table A.4*, Air ($T_{f,i}$ = 12.5°C, 1 atm): $\nu = 14.6 \times 10^{-6}$ m^2/s, k = 0.0251 W/m·K, $\alpha = 20.59 \times 10^{-6}$ m^2/s, $\beta = (1/285.5) = 3.503 \times 10^{-3}$ K^{-1}, Pr = 0.711; ($T_{f,o} \approx 0$°C): $\nu = 13.49 \times 10^{-6}$ m^2/s, k = 0.0241 W/m·K, Pr = 0.714.

ANALYSIS: (a) The temperature distribution in the glass is governed by the appropriate form of the heat equation, Eq. 3.44, whose general solution is given by Eq. 3.45.

$$T(x) = -(\dot{q}/2k)x^2 + C_1 x + C_2 .$$

The constants of integration may be evaluated by applying appropriate boundary conditions at x = 0. In particular, with $T(0) = T_{s,i}$, $C_2 = T_{s,i}$. Applying an energy balance to the inner surface, $q''_{cond} = q''_{conv,i}$

$$-k\frac{dT}{dx}\bigg|_{x=0} = \bar{h}_i\left(T_{\infty,i} - T_{s,i}\right) \qquad -k\left(-\frac{\dot{q}}{k}x + C_1\right)\bigg|_{x=0} = \bar{h}_i\left(T_{\infty,i} - T_{s,i}\right)$$

$$C_1 = -\left(\bar{h}_i/k\right)\left(T_{\infty,i} - T_{s,i}\right)$$

$$T(x) = -(\dot{q}/2k)x^2 - \frac{\bar{h}_i\left(T_{\infty,i} - T_{s,i}\right)}{k}x + T_{s,i} \qquad (1)$$

The required generation may then be obtained by formulating an energy balance at the outer surface, where $q''_{cond} = q''_{conv,o}$. Using Eq. (1),

$$-k\frac{dT}{dx}\bigg|_{x=L} = \bar{h}_o\left(T_{s,o} - T_{\infty,o}\right) \qquad (2)$$

Continued...

PROBLEM 9.27 (Cont.)

$$-k\left.\frac{dT}{dx}\right|_{x=L} = -k\left(-\frac{\dot{q}L}{k}\right)+\bar{h}_i\left(T_{\infty,i}-T_{s,i}\right)=\dot{q}L+\bar{h}_i\left(T_{\infty,i}-T_{s,i}\right) \quad (3)$$

Substituting Eq. (3) into Eq. (2), the energy balance becomes

$$\dot{q}L = \bar{h}_o\left(T_{s,o}-T_{\infty,o}\right)+\bar{h}_i\left(T_{s,i}-T_{\infty,i}\right) \quad (4)$$

where $T_{s,o}$ may be evaluated by applying Eq. (1) at x = L.

$$T_{s,o} = -\frac{\dot{q}L^2}{2k}-\frac{\bar{h}_i\left(T_{\infty,i}-T_{s,i}\right)}{k}L+T_{s,i}\,. \quad (5)$$

The *inside* convection coefficient may be obtained from Eq. 9.26. With

$$Ra_H = \frac{g\beta\left(T_{s,i}-T_{\infty,i}\right)H^3}{\nu\alpha}=\frac{9.8\,m/s^2\left(3.503\times10^{-3}K^{-1}\right)(15-10)K\,(0.5\,m)^3}{14.60\times10^{-6}\,m^2/s\times20.59\times10^{-6}\,m^2/s}=7.137\times10^7\,,$$

$$\overline{Nu}_H = \left[0.825+\frac{0.387Ra_H^{1/6}}{\left[1+(0.492/Pr)^{9/16}\right]^{8/27}}\right]^2=\left[0.825+\frac{0.387\left(7.137\times10^7\right)^{1/6}}{\left[1+(0.492/0.711)^{9/16}\right]^{8/27}}\right]^2=55.2$$

$$\bar{h}_i = \overline{Nu}_H\frac{k}{H}=\frac{55.2\times0.0251\,W/m\cdot K}{0.5\,m}=2.77\,W/m^2\cdot K$$

The *outside* convection coefficient may be obtained by first evaluating the Reynolds number. With

$$Re_H = \frac{u_\infty H}{\nu}=\frac{20\,m/s\times0.5\,m}{13.49\times10^{-6}\,m^2/s}=7.413\times10^5$$

and with $Re_{x,c} = 5 \times 10^5$, mixed boundary layer conditions exist. Hence,

$$\overline{Nu}_H = \left(0.037\,Re_H^{4/5}-871\right)Pr^{1/3}=\left[0.037\left(7.413\times10^5\right)^{4/5}-871\right](0.714)^{1/3}=864$$

$$\bar{h}_o = \overline{Nu}_H\,(k/H)=(864\times0.0241\,W/m\cdot K)/0.5\,m=41.6\,W/m^2\cdot K\,.$$

Eq. (5) may now be expressed as

$$T_{s,o} = -\frac{\dot{q}\,(0.008\,m)^2}{2(1.4\,W/m\cdot K)}-\frac{2.77\,W/m^2\cdot K\,(10-15)K}{1.4\,W/m\cdot K}\times0.008\,m+288\,K=-2.286\times10^{-5}\dot{q}+288.1\,K$$

or, solving for $\dot{q}$,
$$\dot{q}=-43,745\left(T_{s,o}-288.1\right) \quad (6)$$

and substituting into Eq. (4),

$$-43,745\left(T_{s,o}-288.1\right)(0.008\,m)=41.6\,W/m^2\cdot K\left(T_{s,o}-263\,K\right)+2.77\,W/m^2\cdot K\,(288\,K-283\,K)\,.$$

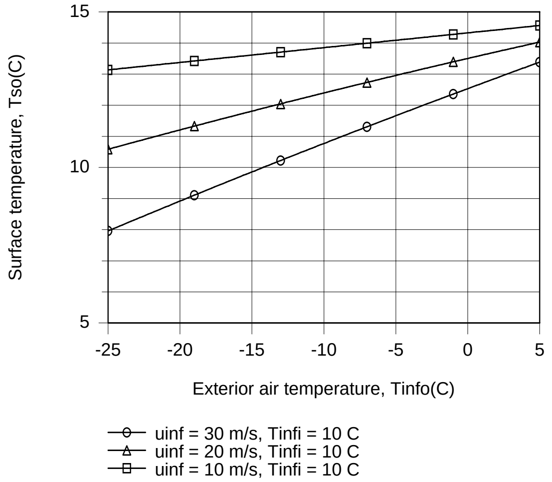
It follows that $T_{s,o}$ = 285.4 K in which case, from Eq. (6)

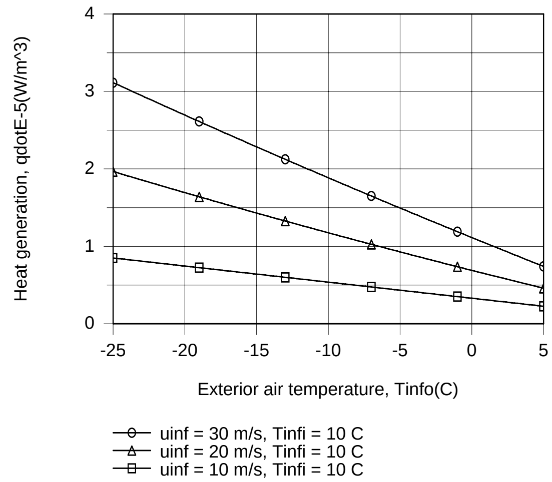
$$\dot{q}=118\,kW/m^3\,.$$
<

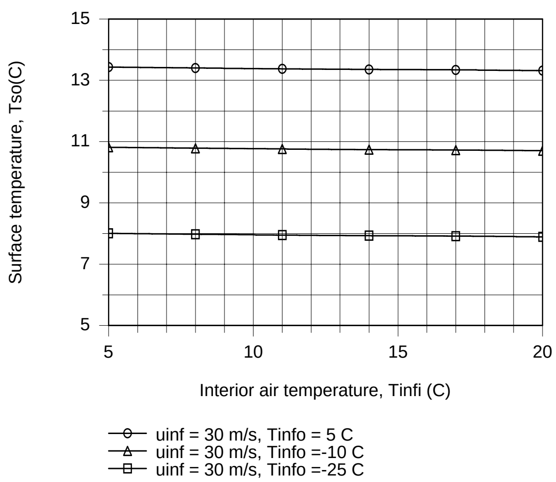
(b) The parametric calculations were performed using the *One-Dimensional*, *Steady-state Conduction* Model of IHT with the appropriate *Correlations* and *Properties* Tool Pads, and the results are as follows.

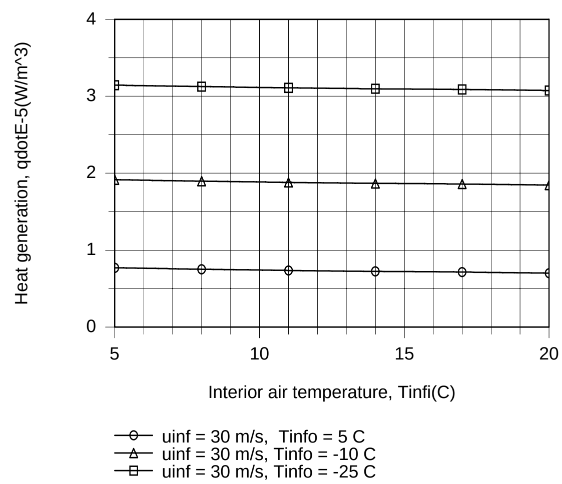
Continued...

PROBLEM 9.27 (Cont.)









For fixed $T_{s,i}$ and $T_{\infty,i}$, $T_{s,o}$ and $\dot{q}$ are strongly influenced by $T_{\infty,o}$ and u_∞, increasing and decreasing, respectively, with increasing $T_{\infty,o}$ and decreasing and increasing, respectively with increasing u_∞. For fixed $T_{s,i}$ and u_∞, $T_{s,o}$ and $\dot{q}$ are independent of $T_{\infty,i}$, but increase and decrease, respectively, with increasing $T_{\infty,o}$.

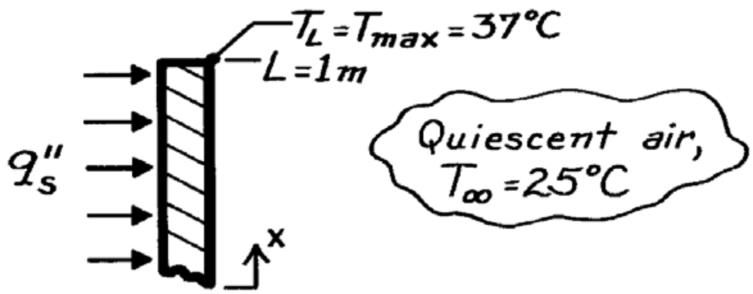
COMMENTS: In lieu of performing a surface energy balance at x = L, Eq. (4) may also be obtained by applying an energy balance to a control volume about the entire window.

PROBLEM 9.28

KNOWN: Vertical panel with uniform heat flux exposed to ambient air.

FIND: Allowable heat flux if maximum temperature is not to exceed a specified value, T_{max}.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Radiative exchange with surroundings negligible.

PROPERTIES: *Table A-4*, Air ($T_f = (T_{L/2} + T_\infty)/2 = (35.4 + 25)°C/2 = 30.2°C = 303K$, 1 atm): $\nu = 16.19 \times 10^{-6}\ m^2/s$, $k = 26.5 \times 10^{-3}$ W/m·K, $\alpha = 22.9 \times 10^{-6}\ m^2/s$, Pr = 0.707.

ANALYSIS: Following the treatment of Section 9.6.1 for a vertical plate with uniform heat flux (constant q''_s), the heat flux can be evaluated as

$$q''_s = \overline{h}\Delta T_{L/2} \qquad \text{where} \qquad \Delta T_{L/2} = T_s(L/2) - T_\infty \qquad (1,2)$$

and $\overline{h}$ is evaluated using an appropriate correlation for a constant temperature vertical plate. From Eq. 9.28,

$$\Delta T_x \equiv T_x - T_\infty = 1.15(x/L)^{1/5}\Delta T_{L/2} \qquad (3)$$

and recognizing that the maximum temperature will occur at the top edge, x = L, use Eq. (3) to find

$$\Delta T_{L/2} = (37-25)^\circ C/1.15(1/1)^{1/5} = 10.4^\circ C \qquad \text{or} \qquad T_{L/2} = 35.4^\circ C.$$

Calculate now the Rayleigh number based upon $\Delta T_{L/2}$, with $T_f = (T_{L/2} + T_\infty)/2 = 303K$,

$$Ra_L = \frac{g\beta\Delta TL^3}{\nu\alpha} \qquad \text{where} \qquad \Delta T = \Delta T_{L/2} \qquad (4)$$

$$Ra_L = 9.8m/s^2(1/303K)\times 10.4K(1m)^3/16.19\times 10^{-6}m^2/s\times 22.9\times 10^{-6}m^2/s = 9.07\times 10^8.$$

Since $Ra_L < 10^9$, the boundary layer flow is laminar; hence the correlation of Eq. 9.27 is appropriate,

$$\overline{Nu}_L = \frac{\overline{h}L}{k} = 0.68 + \frac{0.670\,Ra_L^{1/4}}{\left[1+(0.492/Pr)^{9/16}\right]^{4/9}} \qquad (5)$$

$$\overline{h} = \left[\frac{0.0265\,W/m\cdot K}{1m}\right]\left\{0.68 + 0.670\left(9.07\times 10^8\right)^{1/4} / \left[1+(0.492/0.707)^{9/16}\right]^{4/9}\right\} = 2.38\,W/m^2\cdot K.$$

From Eqs. (1) and (2) with numerical values for $\overline{h}$ and $\Delta T_{L/2}$, find

$$q''_s = 2.38\,W/m^2\cdot K\times 10.4^\circ C = 24.8\,W/m^2.$$ <

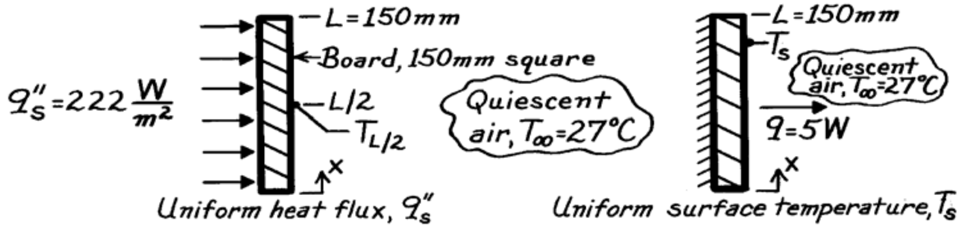
COMMENTS: Recognize that radiation exchange with the environment will be significant. Assuming $\overline{T}_s = T_{L/2}$, $T_{sur} = T_\infty$ and ε = 1, find $q''_{rad} = \sigma\left(\overline{T}_s^{-4} - T_{sur}^4\right) = 66\,W/m^2$.

PROBLEM 9.29

KNOWN: Vertical circuit board dissipating 5W to ambient air.

FIND: (a) Maximum temperature of the board assuming uniform surface heat flux and (b) Temperature of the board for an isothermal surface condition.

SCHEMATIC:



ASSUMPTIONS: (1) Either uniform q_s'' or T_s on the board, (2) Quiescent room air.

PROPERTIES: *Table A-4*, Air ($T_f = (T_{L/2} + T_\infty)/2$ or $(T_s + T_\infty)/2$, 1 atm), values used in iterations:

Iteration	T_f(K)	$\nu \cdot 10^6 (m^2/s)$	$k \cdot 10^3$(W/m·K)	$\alpha \cdot 10^6 (m^2/s)$	Pr
1	312	17.10	27.2	24.3	0.705
2	324	18.30	28.1	26.1	0.704
3	319	17.80	27.7	25.3	0.704
4	320	17.90	27.8	25.4	0.704

ANALYSIS: (a) For the uniform heat flux case (see Section 9.6.1), the heat flux is

$$q_s'' = \bar{h} \Delta T_{L/2} \qquad \text{where} \qquad \Delta T_{L/2} = T_{L/2} - T_\infty \qquad (1,2)$$

and $\quad q_s'' = q/A_s = 5W/(0.150m)^2 = 222\,W/m^2.$

The maximum temperature on the board will occur at x = L and from Eq. 9.28 is

$$\Delta T_x = 1.15 (x/L)^{1/5}\ \Delta T_{L/2} \qquad (3)$$

$$T_L = T_{max} = T_\infty + 1.15 \Delta T_{L/2}.$$

The average heat transfer coefficient $\bar{h}$ is estimated from a vertical (uniform T_s) plate correlation based upon the temperature difference $\Delta T_{L/2}$. Recognize that an iterative procedure is required: (i) assume a value of $T_{L/2}$, use Eq. (2) to find $\Delta T_{L/2}$; (ii) evaluate the Rayleigh number

$$Ra_L = g\beta \Delta T_{L/2} L^3 / \nu\alpha \qquad (4)$$

and select the appropriate correlation (either Eq. 9.26 or 9.27) to estimate $\bar{h}$; (iii) use Eq. (1) with values of $\bar{h}$ and $\Delta T_{L/2}$ to find the calculated value of q_s''; and (iv) repeat this procedure until the calculated value for q_s'' is close to q_s'' = 222 W/m^2, the required heat flux.

Continued …

To evaluate properties for the correlation, use the film temperature,

$$T_f = \left(T_{L/2} + T_\infty\right)/2. \qquad (5)$$

Iteration #1: Assume $T_{L/2}$ = 50°C and from Eqs. (2) and (5) find

$$\Delta T_{L/2} = (50 - 27)^\circ C = 23^\circ C \qquad T_f = (50 + 27)^\circ C/2 = 312K.$$

From Eq. (4), with $\beta = 1/T_f$, the Rayleigh number is

$$Ra_L = 9.8 m/s^2 (1/312K) \times 23^\circ C (0.150m)^3 / \left(17.10 \times 10^{-6} m^2/s\right) \times \left(24.3 \times 10^{-6} m^2/s\right) = 5.868 \times 10^6.$$

Since $Ra_L < 10^9$, the flow is laminar and Eq. 9.27 is appropriate

$$\overline{Nu}_L = \frac{\bar{h}L}{k} = 0.68 + \frac{0.670\, Ra_L^{1/4}}{\left[1 + (0.492/Pr)^{9/16}\right]^{4/9}}$$

$$\bar{h}_L = \frac{0.0272\, W/m \cdot K}{0.150m}\left\{0.68 + 0.670\left(5.868 \times 10^6\right)^{1/4} / \left[1 + (0.492/0.705)^{9/16}\right]^{4/9}\right\} = 4.71\, W/m^2 \cdot K.$$

Using Eq. (1), the calculated heat flux is

$$q_s'' = 4.71 W/m^2 \cdot K \times 23^\circ C = 108\, W/m^2.$$

Since q_s'' < 222 W/m^2, the required value, another iteration with an increased estimate for $T_{L/2}$ is warranted. Further iteration results are tabulated.

Iteration	$T_{L/2}$(°C)	$\Delta T_{L/2}$(°C)	T_f(K)	Ra_L	$\bar{h}\left(W/m^2 \cdot K\right)$	$q_s''\left(W/m^2\right)$
2	75	48	324	1.026×10^7	5.57	268
3	65	38	319	8.749×10^6	5.29	201
4	68	41	320	9.321×10^6	5.39	221

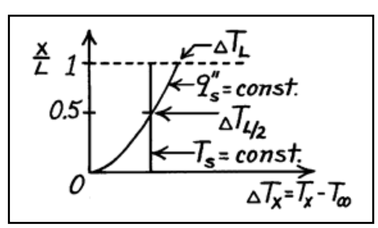
After Iteration 4, close agreement between the calculated and required q_s'' is achieved with $T_{L/2}$ = 68°C. From Eq. (3), the maximum board temperature is

$$T_L = T_{max} = 27^\circ C + 1.15(41)^\circ C = 74^\circ C.$$ <

(b) For the uniform temperature case, the procedure for estimation of the average heat transfer coefficient is the same. Hence,

$$T_s = T_{L/2}\big|_{q_s''} = 68^\circ C.$$ <

COMMENTS: In both cases, q = 5W and $\bar{h} = 5.38\, W/m^2$. However, the temperature distributions for the two cases are quite different as shown on the sketch. For q_s'' = constant, $\Delta T_x \sim x^{1/5}$ according to Eq. 9.28.

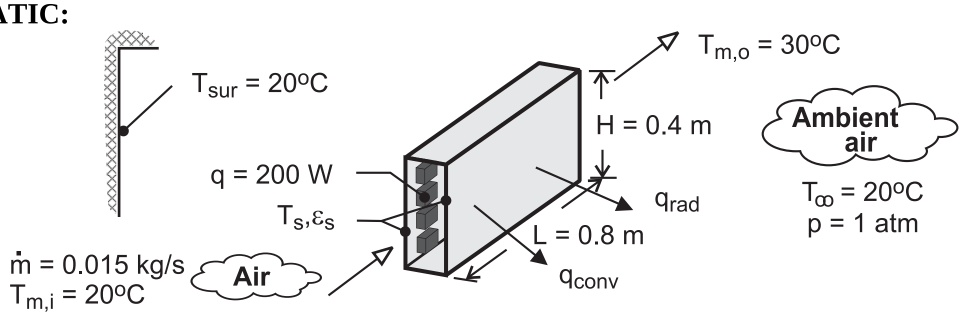


PROBLEM 9.30

KNOWN: Coolant flow rate and inlet and outlet temperatures. Dimensions and emissivity of channel side walls. Temperature of surroundings. Power dissipation.

FIND: (a) Temperature of sidewalls for $\varepsilon_s = 0.15$, (b) Temperature of sidewalls for $\varepsilon_s = 0.90$, (c) Sidewall temperatures with loss of coolant for $\varepsilon_s = 0.15$ and $\varepsilon_s = 0.90$.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Negligible heat transfer from top and bottom surfaces of duct, (3) Isothermal side walls, (4) Large surroundings, (5) Coolant is incompressible liquid with negligible viscous dissipation, (6) Constant properties.

PROPERTIES: *Table A-4*, air $(\overline{T}_m = 298\,K)$: $c_p = 1007$ J/kg·K. Air properties required for the free convection calculations depend on T_s and were evaluated as part of the iterative solution obtained using the IHT software.

ANALYSIS: (a) The heat dissipated by the components is transferred by forced convection to the coolant (q_c), as well as by natural convection (q_{conv}) and radiation (q_{rad}) to the ambient air and the surroundings. Hence,

$$q = q_c + q_{conv} + q_{rad} = 200\,W \quad (1)$$

$$q_c = \dot{m}c_p\left(T_{m,o} - T_{m,i}\right) = 0.015\,kg/s \times 1007\,J/kg\cdot K \times 10°C = 151\,W \quad (2)$$

$$q_{conv} = 2\overline{h}\,A_s\left(T_s - T_\infty\right) \quad (3)$$

where $A_s = H \times L = 0.32\,m^2$ and $\overline{h}$ is obtained from Eq. 9.26, with $Ra_H = g\beta\left(T_s - T_\infty\right)H^3/\alpha\nu$.

$$\overline{h} = \frac{k}{H}\left\{0.825 + \frac{0.387\,Ra_H^{1/6}}{\left[1+\left(0.492/Pr\right)^{9/16}\right]^{8/27}}\right\}^2 \quad (3a)$$

$$q_{rad} = 2\,A_s\,\varepsilon_s\,\sigma\left(T_s^4 - T_{sur}^4\right) \quad (4)$$

Substituting Eqs. (2) – (4) into (1) and solving using the IHT software with $\varepsilon_s = 0.15$, we obtain

$$T_s = 308.8\,K = 35.8°C$$ <

The corresponding heat rates are $q_{conv} = 39.6$ W and $q_{rad} = 9.4$ W.

(b) For $\varepsilon_s = 0.90$ and $q_c = 151$ W, the solution to Eqs. (1) – (4) yields

Continued …

PROBLEM 9.30 (Cont.)

$$T_s = 301.8\,K = 28.8°C$$ <

with q_{conv} = 18.7 W and q_{rad} = 30.3 W. Hence, enhanced emission from the surface yields a lower operating temperature and heat transfer by radiation now exceeds that due to conduction.

(c) With loss of coolant flow, we can expect all of the heat to be dissipated from the sidewalls (q_c = 0). Solving Eqs. (1), (3) and (4), we obtain

$$\varepsilon_s = 0.15: \qquad T_s = 341.8\,K = 68.8°C$$ <

$$q_{conv} = 165.9\,W, \qquad q_{rad} = 34.1\,W$$

$$\varepsilon_s = 0.90: \qquad T_s = 322.5\,K = 49.5°C$$ <

$$q_{conv} = 87.6\,W, \qquad q_{rad} = 112.4\,W$$

Since the temperature of the electronic components exceeds that of the sidewalls, the value of T_s = 68.8°C corresponding to ε_s = 0.15 may be unacceptable, in which case the high emissivity coating should be applied to the walls.

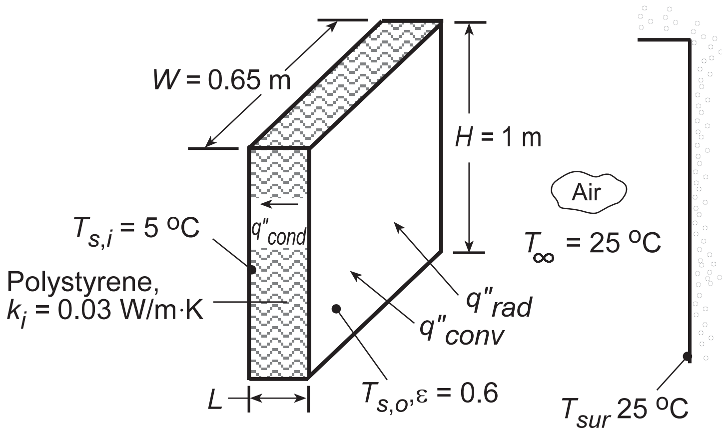
COMMENTS: For the foregoing cases the convection coefficient is in the range 3.31 ≤ $\overline{h}$ ≤ 5.31 $W/m^2 \cdot K$, with the smallest value corresponding to (q_c = 151 W, ε_s = 0.90) and the largest value to (q_c = 0, ε_s = 0.15). The radiation coefficient is in the range 0.93 ≤ h_{rad} ≤ 5.96 $W/m^2 \cdot K$, with the smallest value corresponding to (q_c = 151 W, ε_s = 0.15) and the largest value to (q_c = 0, ε_s = 0.90).

PROBLEM 9.31

KNOWN: Dimensions, interior surface temperature, and exterior surface emissivity of a refrigerator door. Temperature of ambient air and surroundings.

FIND: (a) Heat gain with no insulation, (b) Heat gain as a function of thickness for polystyrene insulation.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible thermal resistance of steel and polypropylene sheets, (3) Negligible contact resistance between sheets and insulation, (4) One-dimensional conduction in insulation, (5) Quiescent air.

PROPERTIES: *Table A.4*, air (T_f = 288 K): $\nu = 14.82 \times 10^{-6}$ m²/s, $\alpha = 20.92 \times 10^{-6}$ m²/s, k = 0.0253 W/m·K, Pr = 0.71, $\beta = 0.00347$ K^{-1}.

ANALYSIS: (a) Without insulation, $T_{s,o} = T_{s,i}$ = 278 K and the heat gain is

$$q_{wo} = \bar{h}A_s\left(T_\infty - T_{s,i}\right) + \varepsilon\sigma A_s\left(T_{sur}^4 - T_{s,i}^4\right)$$

where A_s = HW = 0.65 m². With a Rayleigh number of $Ra_H = g\beta\left(T_\infty - T_{s,i}\right)H^3/\alpha\nu$ = 9.8 m/s²(0.00347 K^{-1})(20 K)(1)³/(20.92 × 10^{-6} m²/s)(14.82 × 10^{-6} m²/s) = 2.19 × 10^9, Eq. 9.26 yields

$$\overline{Nu}_H = \left\{0.825 + \frac{0.387\left(2.19\times10^9\right)^{1/6}}{\left[1+\left(0.492/0.71\right)^{9/16}\right]^{8/27}}\right\}^2 = 156.6$$

$$\bar{h} = \overline{Nu}_H\left(k/H\right) = 156.6\left(0.0253\,W/m\cdot K/1\,m\right) = 4.0\,W/m^2\cdot K$$

$$q_{wo} = 4.0\,W/m^2\cdot K\left(0.65\,m^2\right)\left(20\,K\right) + 0.6\left(5.67\times10^{-8}\,W/m^2\cdot K^4\right)\left(0.65\,m^2\right)\left(298^4 - 278^4\right)K^4$$

$$q_{wo} = \left(52.00 + 42.3\right)W = 94.3\,W$$ <

(b) With the insulation, $T_{s,o}$ may be determined by performing an energy balance at the outer surface, where $q''_{conv} + q''_{rad} = q''_{cond}$, or

$$\bar{h}\left(T_\infty - T_{s,o}\right) + \varepsilon\sigma\left(T_{sur}^4 - T_{s,o}^4\right) = \frac{k_i}{L}\left(T_{s,o} - T_{s,i}\right)$$

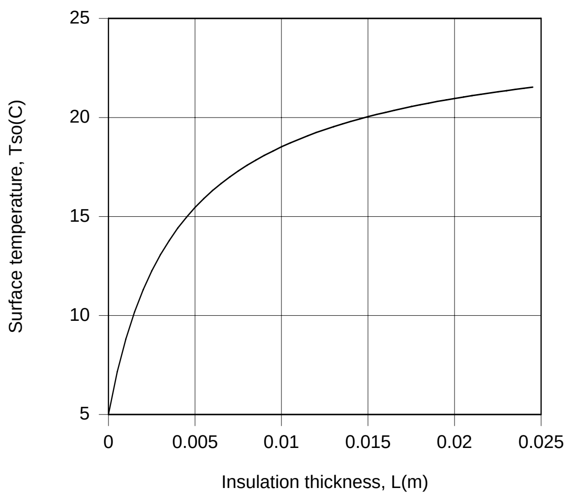
Using the *IHT First Law* Model for a *Nonisothermal Plane Wall* with the appropriate *Correlations* and *Properties* Tool Pads and evaluating the heat gain from

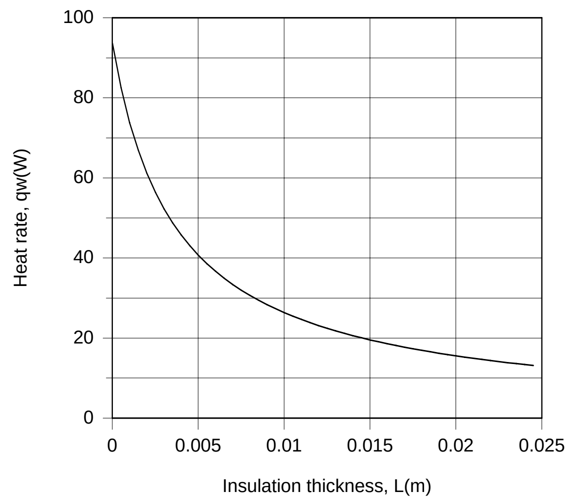
Continued...

PROBLEM 9.31 (Cont.)

$$q_w = \frac{k_i A_s}{L}\left(T_{s,o} - T_{s,i}\right)$$

the following results are obtained for the effect of L on $T_{s,o}$ and q_w.





The outer surface temperature increases with increasing L, causing a reduction in the rate of heat transfer to the refrigerator compartment. For L = 0.025 m, $\overline{h}$ = 2.29 $W/m^2 \cdot K$, h_{rad} = 3.54 $W/m^2 \cdot K$, q_{conv} = 5.16 W, q_{rad} = 7.99 W, q_w = 13.15 W, and $T_{s,o}$ = 21.5°C.

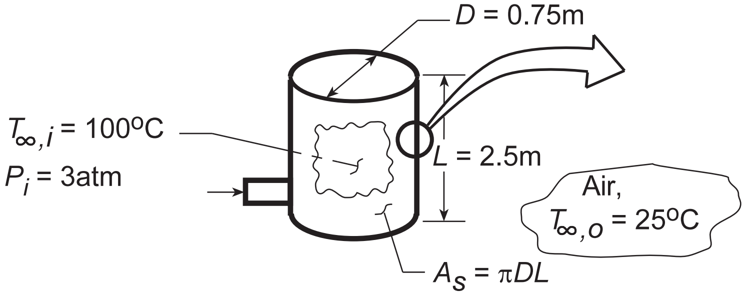
COMMENTS: The insulation is very effective in reducing the heat load, and there would be little value to increasing L beyond 25 mm.

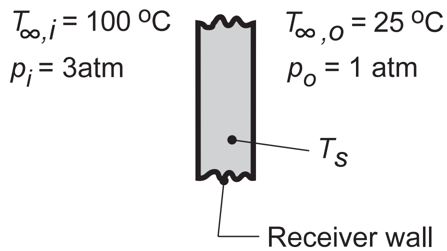
PROBLEM 9.32

KNOWN: Air receiving tank of height 2.5 m and diameter 0.75 m; inside air is at 3 atm and 100°C while outside ambient air is 25°C.

FIND: (a) Receiver wall temperature and heat transfer to the ambient air; assume receiver wall is T_s = 60°C to facilitate use of the free convection correlations; (b) Whether film temperatures $T_{f,i}$ and $T_{f,o}$ were reasonable; if not, use an iteration procedure to find consistent values; and (c) Receiver wall temperatures, $T_{s,i}$ and $T_{s,o,}$ considering radiation exchange from the exterior surface ($\varepsilon_{s,o}$ = 0.85) and thermal resistance of the wall (20 mm thick, k = 0.25W/m·K); represent the system by a thermal circuit.

SCHEMATIC:

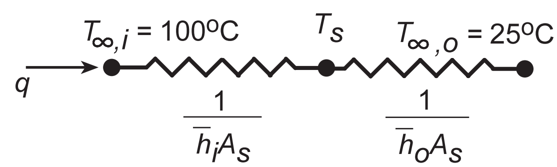




ASSUMPTIONS: (1) Surface radiation effects are negligible, parts (a,b), (2) Losses from top and bottom of receiver are negligible, (3) Thermal resistance of receiver wall is negligible compared to free convection resistance, parts (a,b), (4) Interior and exterior air is quiescent and extensive.

PROPERTIES: *Table A-4*, Air (assume $T_{f,o}$ = 315 K, 1 atm): $\nu = 1.74 \times 10^{-5}$ m²/s, k = 0.02741 W/m·K, $\alpha = 2.472 \times 10^{-5}$ m²/s, Pr =0.7049; *Table A-4*, Air (assume $T_{f,i}$ = 350 K, 3 atm): $\nu = 2.092 \times 10^{-5}$ m²/s/3= 6.973×10^{-6} m²/s, k = 0.030 W/m·K, $\alpha = 2.990 \times 10^{-5}$ m²/s/3 = 9.967×10^{-6} m²/s, Pr = 0.700. Note that the pressure effect is present for ν and α since ρ(1 atm) = 1/3ρ(3 atm); other properties (c_p, k, μ) are assumed independent of pressure.

ANALYSIS: The heat transfer rate from the receiver follows from the thermal circuit,



$$q = \frac{\Delta T}{R_t} = \frac{T_{\infty,i} - T_{\infty,o}}{1/\bar{h}_o A_s + 1/\bar{h}_i A_s} = \frac{A_s\left(T_{\infty,i} - T_{\infty,o}\right)}{1/\bar{h}_o + 1/\bar{h}_i} s \quad (1)$$

where $\bar{h}_o$ and $\bar{h}_i$ must be estimated from free convection correlations. We must assume a value of T_s in order to obtain first estimates for $\Delta T_o = T_s - T_{\infty,o}$ and $\Delta T_i = T_{\infty,o} - T_s$ as well as $T_{f,o}$ and $T_{f,i}$. Assume that T_s = 60°C, then ΔT_o = 60 - 25 = 35°C, $T_{f,o}$ = 315 K and ΔT_i = 100 - 60 = 40°C, and $T_{f,i}$ = 350 K.

$$Ra_{L,o} = \frac{g\beta\Delta TL^3}{\nu\alpha} = \frac{9.8\,m/s^2\,(1/315\,K)\times 35\,K\,(2.5\,m)^3}{1.74\times10^{-5}\,m^2/s\times 2.472\times10^{-5}\,m^2/s} = 3.952\times10^{10}$$

$$Ra_{L,i} = \frac{9.8\,m/s^2\,(1/350\,K)\times 40\,K\,(2.5\,m)^3}{6.973\times10^{-6}\,m^2/s\times 9.967\times10^{-6}\,m^2/s} = 2.518\times10^{11}$$

Approximating the receiver wall as a vertical plate, Eq. 9.26 yields

Continued...

PROBLEM 9.32 (Cont.)

$$\overline{Nu}_{L,o} = \left[0.825 + \frac{0.387 Ra_{L,o}^{1/6}}{\left[1+(0.492/Pr)^{9/16}\right]^{8/27}}\right]^2 = \left[0.825 + \frac{0.387\left(3.952\times10^{10}\right)^{1/6}}{\left[1+(0.492/0.7049)^{9/16}\right]^{8/27}}\right]^2 = 390.0$$

$$\overline{Nu}_{L,i} = \frac{\overline{h}_{L,i} L}{k} = \left[0.825 + \frac{0.387\left(2.518\times10^{11}\right)^{1/6}}{\left[1+(0.492/0.700)^{9/16}\right]^{8/27}}\right]^2 = 706.4$$

$$\overline{h}_{L,o} = \frac{0.02741\,W/m\cdot K}{2.5m}\times 390.0 = 4.27\,W/m^2\cdot K \qquad \overline{h}_{L,i} = \frac{0.030\,W/m\cdot K}{2.5m}\times 706.4 = 8.48\,W/m^2\cdot K$$

From Eq. (1),

$$q = \pi\times0.75m\times2.5m(100-25)K\Big/\left[\frac{1}{4.27}+\frac{1}{8.48}\right]m^2/K\cdot W = 1225W$$ <

Also,

$$T_s = T_{\infty,i} - q/\overline{h}_i A_s = 100^\circ C - 1255\,W\Big/\left(8.48\,W/m^2\cdot K\times\pi\times0.75\,m\times2.5\,m\right) = 74.9^\circ C$$ <

(b) From the above result for T_s, the computed film temperatures are

$$T_{f,o} = 323\,K \qquad T_{f,i} = 360\,K$$

as compared to assumed values of 315 and 350 K, respectively. Using *IHT Correlation Tools* for the *Free Convection, Vertical Plate*, and the thermal circuit representing Eq. (1) to find T_s, rather than using as assumed value,

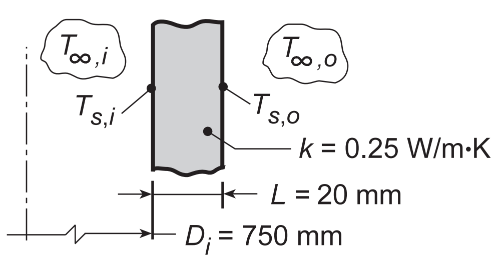
$$\frac{T_{\infty,o} - T_s}{1/\overline{h}_o} = \frac{T_s - T_{\infty,o}}{1/\overline{h}_o}$$

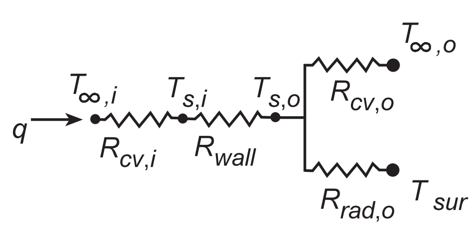
we found

q = 1262 W $\qquad$ T_s = 71.4°C <

with $T_{f,o}$ = 321K and 359 K. The iteration only influenced the heat rate slightly.

(c) Considering effects due to thermal resistance of the tank wall and radiation exchange, the thermal resistance network representing the system is shown below.





Continued …

PROBLEM 9.32 (Cont.)

Using the *IHT Model*, *Thermal Network*, with the *Correlation Tool for Free Convection*, *Vertical Plate*, and *Properties Tool* for *Air*, a model was developed which incorporates all the foregoing equations of parts (a,b), but includes the thermal resistance of the wall, Table 3.3,

$$R_{wall} = \frac{\ell n\left(D_i / D_o\right)}{2\pi Lk} \qquad\qquad D_o = D_i + 2 \times t$$

The results of the analyses are tabulated below showing for comparison those from parts (a) and (b):

Part	$R_{cv,i}$ (K/W)	R_w (K/W)	$R_{cv,o}$ (K/W)	R_{rad} (K/W)	$T_{s,i}$ (°C)	$T_{s,o}$ (°C)	q W
(a)	0.0200	0	0.0398	∞	74.9*	74.9*	1255
(b)	0.0227	0	0.0367	∞	71.4	71.4	1262
(c)	0.0219	0.0132	0.0419	0.0280	68.4	49.3	1445

*Recall we assumed T_s = 60°C in order to simplify the correlation calculation with fixed values of ΔT_i, ΔT_o as well as $T_{f,o}$, $T_{f,i}$.

COMMENTS: (1) In the table note the slight difference between results using assumed values for T_f and ΔT in the correlations (part (a)) and the exact solution (part (b)).

(2) In the part (c) results, considering thermal resistance of the wall and the radiation exchange process, the net effect was to reduce the overall thermal resistance of the system and, hence, the heat rate increased.

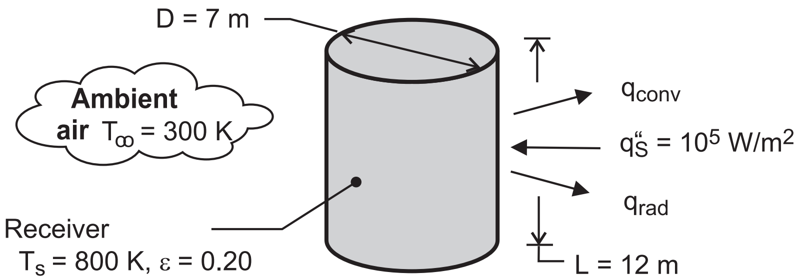
(3) In the part (c) analysis, the *IHT Thermal Resistance Network* model was used to create the thermal circuit and generate the required energy balances. The convection resistances were determined from appropriate *Convection Correlation Tools*. The code was developed in two steps: (1) Solve the energy balance relations from the *Network* with assigned values for h_i and h_o to demonstrate that the energy relations were correct and then (2) Call in the *Convection Correlations* and solve with variable coefficients. Because this equation set is very stiff, we used the intrinsic heat transfer function *Tfluid_avg* and followed these steps in the solution: Step (1): Assign constant values to the film temperatures, T_{fi} and T_{fo}, and to the temperature differences in the convection correlations, ΔT_i and ΔT_o; and in the *Initial Guesses* table, restrain all thermal resistances to be positive (minimum value = 1e-20); *Solve*; Step (2): Allow the film temperatures to be unknowns but keep assigned variables for the temperature differences; use the *Load* option and *Solve*. Step (3): Repeat the previous step but allowing the temperature differences to be unknowns. Even though you get a "successful solve" message, repeat the *Load-Solve* sequence until you see no changes in key variables so that you are assured that the Solver has fully converged on the solution.

PROBLEM 9.33

KNOWN: Dimensions and emissivity of cylindrical solar receiver. Incident solar flux. Temperature of ambient air.

FIND: (a) Heat loss and collection efficiency for a prescribed receiver temperature, (b) Effect of receiver temperature on heat losses and collector efficiency.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Ambient air is quiescent, (3) Incident solar flux is uniformly distributed over receiver surface, (4) All of the incident solar flux is absorbed by the receiver, (5) Negligible irradiation from the surroundings, (6) Uniform receiver surface temperature, (7) Curvature of cylinder has a negligible effect on boundary layer development, (8) Constant properties.

PROPERTIES: *Table A-4*, air (T_f = 550 K): k = 0.0439 W/m·K, $\nu = 45.6 \times 10^{-6}$ m^2/s, $\alpha = 66.7 \times 10^{-6}$ m^2/s, Pr = 0.683, $\beta = 1.82 \times 10^{-3}$ K^{-1}.

ANALYSIS: (a) The total heat loss is

$$q = q_{rad} + q_{conv} = A_s \varepsilon \sigma T_s^4 + \bar{h} A_s \left(T_s - T_\infty\right)$$

With $Ra_L = g\beta(T_s - T_\infty)L^3/\nu\alpha = 9.8\ \text{m/s}^2\ (1.82 \times 10^{-3}\ \text{K}^{-1})\ 500\text{K}\ (12\text{m})^3/(45.6 \times 66.7 \times 10^{-12}\ \text{m}^4/\text{s}^2) = 5.07 \times 10^{12}$, Eq. 9.26 yields

$$\bar{h} = \frac{k}{L}\left\{0.825 + \frac{0.387\, Ra_L^{1/6}}{\left[1+\left(0.492/\Pr\right)^{9/16}\right]^{8/27}}\right\}^2 = \frac{0.0439\ \text{W/m}\cdot\text{K}}{12\text{m}}\left\{0.825 + 42.4\right\}^2 = 6.83\ \text{W/m}^2\cdot\text{K}$$

Hence, with $A_s = \pi DL = 264$ m^2

$$q = 264\,\text{m}^2 \times 0.2 \times 5.67 \times 10^{-8}\ \text{W/m}^2\cdot\text{K}^4 \left(800\,\text{K}\right)^4 + 264\,\text{m}^2 \times 6.83\,\text{W/m}^2\cdot\text{K}\left(500\,\text{K}\right)$$

$$q = q_{rad} + q_{conv} = 1.23 \times 10^6\,\text{W} + 9.01 \times 10^5\,\text{W} = 2.13 \times 10^6\,\text{W} \qquad <$$

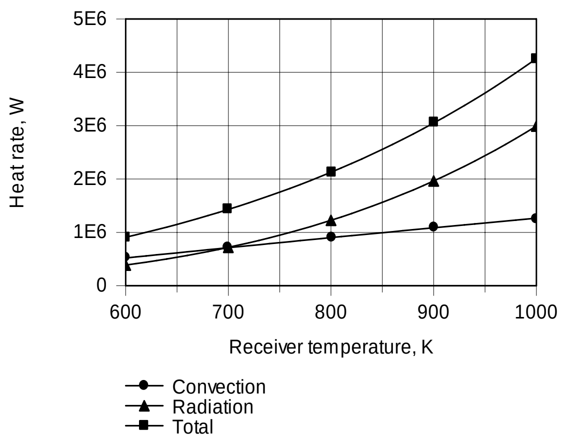
With $A_s\, q''_s = 2.64 \times 10^7$ W, the collector efficiency is

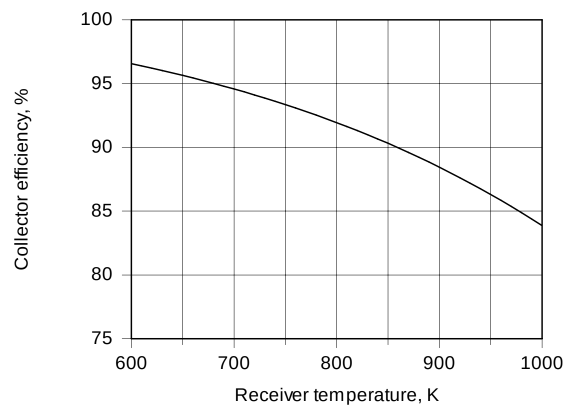
$$\eta = \left(\frac{A_s\, q''_s - q}{A_s\, q''_s}\right)100 = \frac{\left(2.64 \times 10^7 - 2.13 \times 10^6\right)\text{W}}{2.64 \times 10^7\ \text{W}}\left(100\right) = 91.9\% \qquad <$$

Continued …

PROBLEM 9.33 (Cont.)

(b) As shown below, because of its dependence on temperature to the fourth power, q_{rad} increases more significantly with increasing T_s than does q_{conv}, and the effect on the efficiency is pronounced.





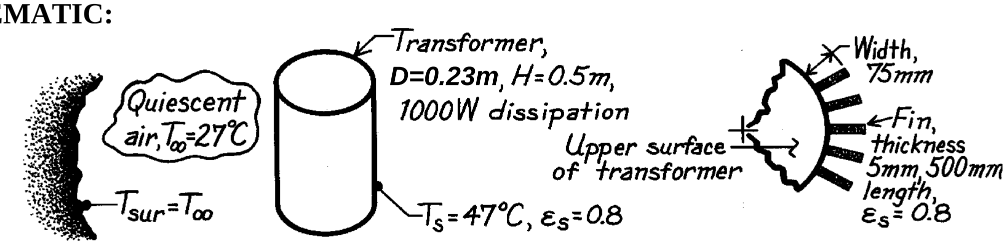
COMMENTS: The collector efficiency is also reduced by the inability to have a perfectly absorbing receiver. Partial reflection of the incident solar flux will reduce the efficiency by at least several percent.

PROBLEM 9.34

KNOWN: Transformer which dissipates 1000 W whose surface is to be maintained at 47°C in quiescent air and surroundings at 27°C.

FIND: Power removal (a) by free convection and radiation from lateral and upper horizontal surfaces and (b) with 30 vertical fins attached to lateral surface.

SCHEMATIC:



ASSUMPTIONS: (1) Fins are isothermal at lateral surface temperature, T_s, (2) Vertical fins and lateral surface behave as vertical plate, (3) Transformer has isothermal surfaces and loses heat only on top and side.

PROPERTIES: *Table A-4*, Air (T_f = (27+47)°C/2=310K, 1 atm): $\nu = 16.90 \times 10^{-6}$ m^2/s, $k = 27.0 \times 10^{-3}$ W/m·K, $\alpha = 23.98 \times 10^{-6}$ m^2/s, Pr = 0.706, $\beta = 1/T_f$.

ANALYSIS: (a) For the vertical lateral (lat) and top horizontal (top) surfaces, the heat loss by radiation and convection is

$$q = q_{lat} + q_{top} = \left(\bar{h}_{lat} + h_r\right)\pi DL\left(T_s - T_\infty\right) + \left(\bar{h}_{top} + h_r\right)\left(\pi^2 D/4\right)\left(T_s - T_\infty\right)$$

where, from Eq. 1.9, the linearized radiation coefficient is

$$h_r = \varepsilon\sigma\left(T_s + T_\infty\right)\left(T_s^2 + T_\infty^2\right)$$

$$h_r = 0.8 \times 5.67 \times 10^{-8}\,W/m^2 \cdot K^4\left(320 + 300\right)K\left(320^2 + 300^2\right)K^2 = 5.41\,W/m^2 \cdot K.$$

The free convection coefficient for the lateral and top surfaces is:

Lateral-vertical plate: Using Eq. 9.26 with

$$Ra_L = \frac{g\beta\left(T_s - T_\infty\right)H^3}{\nu\alpha} = \frac{9.8\,m/s^2\left(1/310\,K\right)\left(47-27\right)K\left(0.5\,m\right)^3}{16.90 \times 10^{-6}m^2/s \times 23.98 \times 10^{-6}m^2/s} = 1.950 \times 10^8$$

$$\overline{Nu}_L = \left\{0.825 + \frac{0.387 Ra_L^{1/6}}{\left[1 + \left(0.492/Pr\right)^{9/16}\right]^{8/27}}\right\}^2$$

$$\overline{Nu}_L = \left\{0.825 + \frac{0.387\left(1.950 \times 10^8\right)^{1/6}}{\left[1 + \left(0.492/0.706\right)^{9/16}\right]^{8/27}}\right\}^2 = 74.5$$

$$\bar{h}_{lat} = \overline{Nu}_L \cdot k/H = 74.5 \times 0.027\,W/m \cdot K/0.5\,m = 4.02\,W/m^2 \cdot K.$$

Continued …

PROBLEM 9.34 (Cont.)

Top-horizontal plate: Using Eq. 9.30 with

$$L_c = A_s / P = \frac{\pi D^2/4}{\pi D} = D/4 = 0.0575\,\text{m}$$

$$Ra_L = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu\alpha} = \frac{9.8\,\text{m/s}^2(1/310\,\text{K})(47-27)\text{K}(0.0575\,\text{m})^3}{16.90\times10^{-6}\,\text{m}^2/\text{s}\times23.98\times10^{-6}\,\text{m}^2/\text{s}} = 2.97\times10^5$$

$$\overline{Nu}_L = 0.54 Ra_L^{1/4} = 0.54\left(2.97\times10^5\right)^{1/4} = 12.6$$

$$\bar{h}_{top} = \overline{Nu}_L \cdot k/L_c = 12.6\times0.027\,\text{W/m}\cdot\text{K}/0.0575\,\text{m} = 5.92\,\text{W/m}^2\cdot\text{K}.$$

Hence, the heat loss by convection and radiation is

$$q = (4.02+5.41)\,\text{W/m}^2\cdot\text{K}(\pi\times0.23\,\text{m}\times0.50\,\text{m})(47-27)\text{K}$$
$$+(5.92+5.41)\,\text{W/m}^2\cdot\text{K}\left(\pi\times0.23^2\,\text{m}^2/4\right)(47-27)\text{K}$$

$$q = (68.2+4.50)\,\text{W} = 72.7\,\text{W}.$$ <

(b) The effect of adding the vertical fins is to increase the area of the lateral surface to

$$A_{wf} = [\pi DH - 30(t\cdot H)] + 30\times2(w\cdot H)$$

$$A_{wf} = \left[\pi 0.23\,\text{m}\times0.50\,\text{m} - 30(0.005\times0.500)\text{m}^2\right] + 30\times2(0.075\times0.500)\text{m}^2$$

$$A_{wf} = [0.361-0.075]\text{m}^2 + 2.25\,\text{m}^2 = 2.536\,\text{m}^2.$$

where t and w are the thickness and width of the fins, respectively. Hence, the heat loss is now

$$q = q_{lat} + q_{top} = \left(\bar{h}_{lat} + h_r\right)A_{wf}\left(T_s - T_\infty\right) + q_{top}$$

$$q = (4.02+5.41)\,\text{W/m}^2\times2.536\,\text{m}^2\times20\,\text{K} + 4.50\,\text{W} = 483\,\text{W}.$$ <

Adding the fins to the lateral surface increases the heat loss by a factor of more than six.

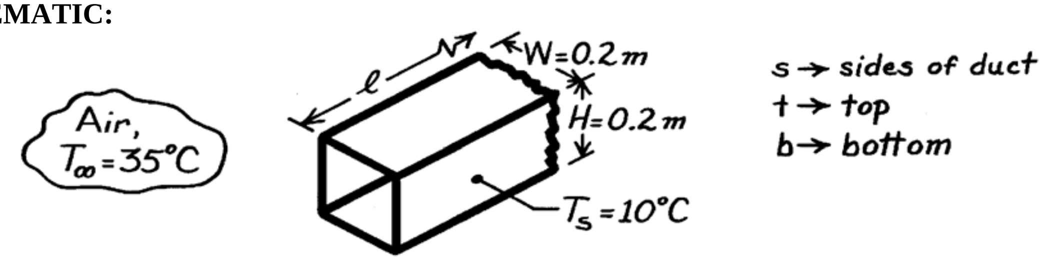
COMMENTS: Since the fins are not likely to have 100% efficiency, our estimate is optimistic. Further, since the fins see one another, as well as the lateral surface, the radiative heat loss is over predicted.

PROBLEM 9.35

KNOWN: Surface temperature of a long duct and ambient air temperature.

FIND: Heat gain to the duct per unit length of the duct.

SCHEMATIC:



ASSUMPTIONS: (1) Surface radiation effects are negligible, (2) Ambient air is quiescent.

PROPERTIES: *Table A-4*, Air ($T_f = (T_\infty + T_s)/2 \approx 300K$, 1 atm): $\nu = 15.89 \times 10^{-6}$ m^2/s, k = 0.0263 W/m·K, $\alpha = 22.5 \times 10^{-6}$ m^2/s, Pr = 0.707, $\beta = 1/T_f$.

ANALYSIS: The heat gain to the duct can be expressed as

$$q' = 2q'_s + q'_t + q'_b = \left(2\,\bar{h}_s \cdot H + \bar{h}_t \cdot W + \bar{h}_b \cdot W\right)\left(T_\infty - T_s\right). \quad (1)$$

Consider now correlations to estimate $\bar{h}_s, \bar{h}_t$, and $\bar{h}_b$. From Eq. 9.25, for the sides with L ≡ H,

$$Ra_L = \frac{g\beta\left(T_\infty - T_s\right)L^3}{\nu\alpha} = \frac{9.8\,m/s^2\left(1/300K\right)\left(35-10\right)K \times \left(0.2m\right)^3}{15.89\times10^{-6}m^2/s \times 22.5\times10^{-6}m^2/s} = 1.827\times10^7. \quad (2)$$

Eq. 9.27 is appropriate to estimate $\bar{h}_s$,

$$\overline{Nu}_L = 0.68 + \frac{0.670\,Ra_L^{1/4}}{\left[1+\left(0.492/Pr\right)^{9/16}\right]^{4/9}} = 0.68 + \frac{0.670\left(1.827\times10^7\right)^{1/4}}{\left[1+\left(0.492/0.707\right)^{9/16}\right]^{4/9}} = 34.29$$

$$\bar{h}_s = \overline{Nu}_L \cdot k/L = 34.29 \times 0.0263\,W/m\cdot K/0.2m = 4.51\,W/m^2\cdot K. \quad (3)$$

For the top and bottom portions of the duct, $L \equiv A_s/P \approx W/2$, (see Eq. 9.29), find the Rayleigh number from Eq. (2) with L = 0.1 m, $Ra_L = 2.284 \times 10^6$. From the correlations, Eqs. 9.30 and 9.32 for the top and bottom surfaces, respectively, find

$$\bar{h}_t = \frac{k}{\left(W/2\right)} \times 0.54\,Ra_L^{1/4} = \frac{0.0263\,W/m\cdot K}{0.1m} \times 0.54\left(2.284\times10^6\right)^{1/4} = 5.52\,W/m^2\cdot K. \quad (4)$$

$$\bar{h}_b = \frac{k}{\left(W/2\right)} \times 0.52\,Ra_L^{1/5} = \frac{0.0263\,W/m\cdot K}{0.1m} \times 0.52\left(2.284\times10^6\right)^{1/5} = 2.56\,W/m^2\cdot K. \quad (5)$$

The heat rate, Eq. (1), can now be evaluated using the heat transfer coefficients estimated from Eqs. (3), (4), and (5).

$$q' = \left(2\times4.51\,W/m^2\cdot K\times0.2m + 5.52\,W/m^2\cdot K\times0.2m + 2.56\,W/m^2\cdot K\times0.2m\right)\left(35-10\right)K$$

$$q' = 85.5\,W/m.$$

<

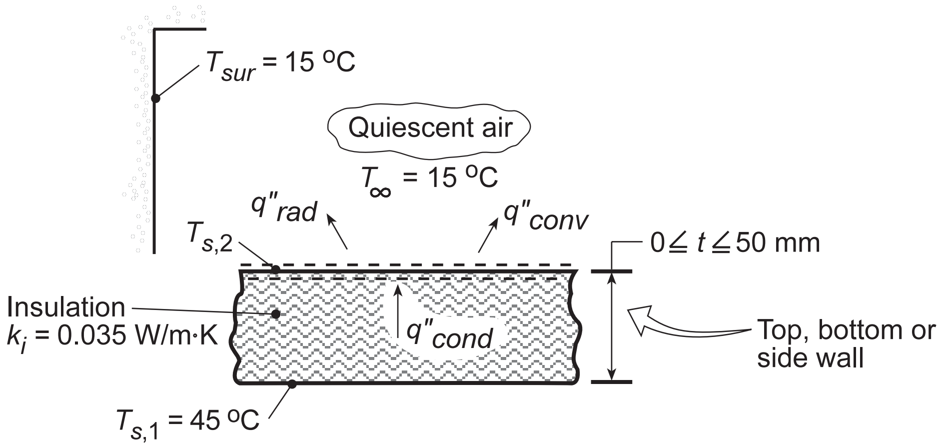
COMMENTS: Radiation surface effects will be significant in this situation. With knowledge of the duct emissivity and surroundings temperature, the radiation heat exchange could be estimated.

PROBLEM 9.36

KNOWN: Inner surface temperature and dimensions of rectangular duct. Thermal conductivity, thickness and emissivity of insulation.

FIND: (a) Outer surface temperatures and heat losses from the walls, (b) Effect of insulation thickness on outer surface temperatures and heat losses.

SCHEMATIC:



ASSUMPTIONS: (1) Ambient air is quiescent, (2) One-dimensional conduction, (3) Steady-state.

PROPERTIES: *Table A.4*, air (obtained from *Properties* Tool Pad of IHT).

ANALYSIS: (a) The analysis follows that of Example 9.3, except the surface energy balance must now include the effect of radiation. Hence, $q''_{cond} = q''_{conv} + q''_{rad}$, in which case

$$(k_i/t)(T_{s,1} - T_{s,2}) = \bar{h}(T_{s,2} - T_\infty) + h_r(T_{s,2} - T_{sur})$$

where $h_r = \varepsilon\sigma(T_{s,2} + T_{sur})(T_{s,2}^2 + T_{sur}^2)$. Applying this expression to each of the top, bottom and side walls, with the appropriate correlation obtained from the *Correlations* Tool Pad of IHT, the following results are determined for t = 25 mm.

Sides: $T_{s,2}$ = 19.3°C, $\bar{h}$ = 2.82 W/m²·K, h_{rad} = 5.54 W/m²·K

Top: $T_{s,2}$ = 19.3°C, $\bar{h}$ = 2.94 W/m²·K, h_{rad} = 5.54 W/m²·K <

Bottom: $T_{s,2}$ = 20.1°C, $\bar{h}$ = 1.34 W/m²·K, h_{rad} = 5.56 W/m²·K

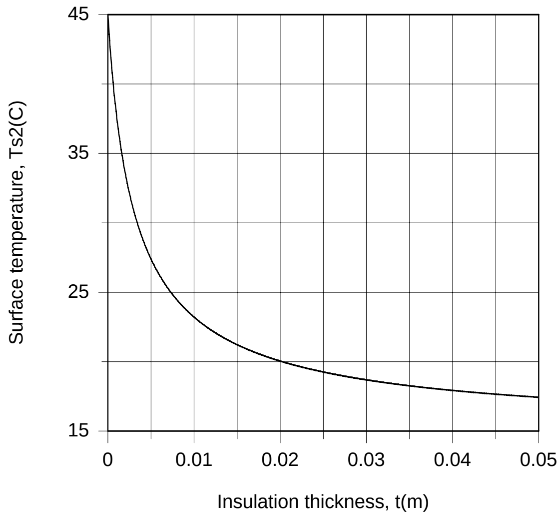
With $q'' = q''_{cond}$, the surface heat losses may also be evaluated, and we obtain

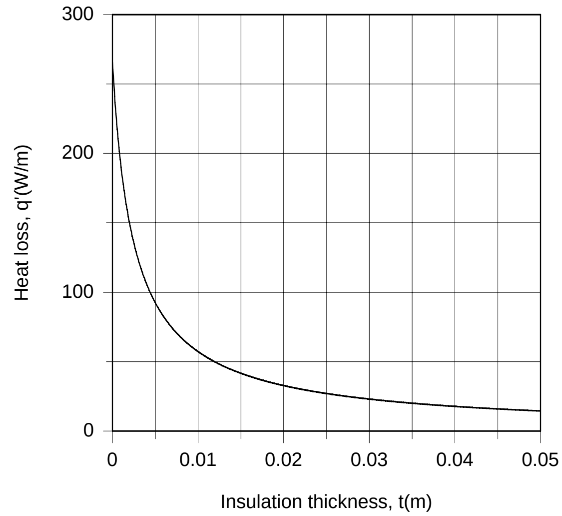
Sides: $q' = 2H\,q''$ = 21.6 W/m; *Top:* $q' = w\,q''$ = 27.0 W/m; *Bottom:* $q' = w\,q''$ = 26.2 W/m <

(b) For the top surface, the following results are obtained from the parametric calculations

Continued...

PROBLEM 9.36 (Cont.)





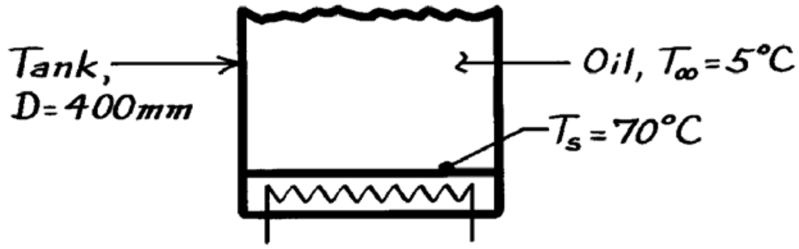
COMMENTS: Contrasting the heat rates of part (a) with those predicted in Comment 1 of Example 9.3, it is evident that radiation is significant and increases the total heat loss from 57.6 W/m to 74.8 W/m. As shown in part (b), reductions in $T_{s,o}$ and q' may be effected by increasing the insulation thickness above 0.025 W/m·K, although attendant benefits diminish with increasing t.

PROBLEM 9.37

KNOWN: Electric heater at bottom of tank of 400mm diameter maintains surface at 70°C with engine oil at 5°C.

FIND: Power required to maintain 70°C surface temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Oil is quiescent, (2) Quasi-steady state conditions exist.

PROPERTIES: *Table A-5*, Engine Oil ($T_f = (T_\infty + T_s)/2 = 310K$): $\nu = 288 \times 10^{-6}$ m^2/s, k = 0.145 W/m·K, $\alpha = 0.847 \times 10^{-7}$ m^2/s, $\beta = 0.70 \times 10^{-3}$ K^{-1}.

ANALYSIS: The heat rate from the bottom heater surface to the oil is

$$q = \bar{h} A_s (T_s - T_\infty)$$

where $\bar{h}$ is estimated from the appropriate correlation depending upon the Rayleigh number Ra_L, from Eq. 9.25, using the characteristic length, L, from Eq. 9.29,

$$L = \frac{A_s}{P} = \frac{\pi D^2/4}{\pi D} = \frac{D}{4} = \frac{0.4m}{4} = 0.1m.$$

The Rayleigh number is

$$Ra_L = \frac{g\beta(T_s - T_\infty)L^3}{\nu\alpha}$$

$$Ra_L = \frac{9.8 m/s^2 \times 0.70 \times 10^{-3} K^{-1} (70-5) K \times 0.1^3 m^3}{288 \times 10^{-6} m^2/s \times 0.847 \times 10^{-7} m^2/s} = 1.828 \times 10^7.$$

The appropriate correlation is Eq. 9.31 giving

$$\overline{Nu}_L = \frac{\bar{h}L}{k} = 0.15 Ra_L^{1/3} = 0.15 \left(1.828 \times 10^7\right)^{1/3} = 39.5$$

$$\bar{h} = \frac{k}{L}\overline{Nu}_L = \frac{0.145 W/m \cdot K}{0.1m} \times 39.5 = 57.3 W/m^2 \cdot K.$$

The heat rate is then

$$q = 57.3 W/m^2 \cdot K (\pi/4)(0.4m)^2 (70-5) K = 468 W.$$ <

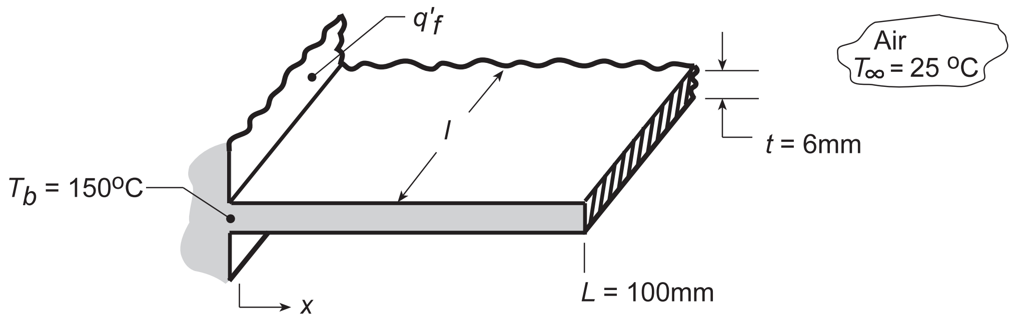
COMMENTS: Note that the characteristic length is D/4 and not D; however, A_s is based upon D. Recognize that if the oil is being continuously heated by the plate, T_∞ could change. Hence, here we have analyzed a quasi-steady state condition.

PROBLEM 9.38

KNOWN: Horizontal, straight fin fabricated from plain carbon steel with thickness 6 mm and length 100 mm; base temperature is 150°C and air temperature is 25°C.

FIND: (a) Fin heat rate per unit width, q'_f, assuming an average fin surface temperature $\overline{T}_s = 125°C$ for estimating free convection and linearized radiation coefficient; how sensitive is q'_f to the assumed value for $\overline{T}_s$?; (b) Compute and plot the heat rate, q'_f as a function of emissivity $0.05 \le \varepsilon \le 0.95$; show also the fraction of the total heat rate due to radiation exchange.

SCHEMATIC:



ASSUMPTIONS: (1) Air is quiescent medium, (2) Surface radiation effects are negligible, (3) One dimensional conduction in fin, (4) Characteristic length, $L_c = A_s/P = \ell L(2\ell + 2L) \approx L/2$.

PROPERTIES: Plain carbon steel, Given $\left(\overline{T}_{fin} \approx 125°C \approx 400\,K\right)$: $k = 57\,W/m\cdot K$, $\varepsilon = 0.5$; *Table A-4,* Air ($T_f = \left(\overline{T}_{fin} + T_\infty\right)/2 = (125+25)°C/2 \approx$ 350 K, 1 atm): $\nu = 20.92 \times 10^{-6}$ m²/s, $\alpha = 29.9 \times 10^{-6}$ m²/s, k = 0.030 W/m·K, Pr = 0.70, $\beta = 1/T_f$.

ANALYSIS: (a) We estimate $\overline{h}$ as the average of the values for a heated plate facing upward and a heated plate facing downward. See Table 9.2, Case 3(a) and (b). Begin by evaluating the Rayleigh number, using Eq. 9.29 for L_c.

$$Ra_L = \frac{g\beta\left(\overline{T}_{fin} - T_\infty\right)L_c^3}{\nu\alpha} = \frac{9.8\,m/s^2\,(1/350K)(125-25)K \times (0.1\,m/2)^3}{20.92\times10^{-6}\,m^2/s \times 29.9\times10^{-6}\,m^2/s} = 5.595\times10^5$$

An average fin temperature of $\overline{T}_{fin} \approx 125°C$ has been assumed in evaluating properties and Ra_L. According to Table 9.2, Eqs. 9.30 and 9.32 are appropriate. For the *upper* fin surface, Eq. 9.30,

$$\overline{Nu}_L = \overline{h}\,L_c/k = 0.54 Ra_L^{1/4} = 0.54\left(5.595\times10^5\right)^{1/4} = 14.77$$

$$\overline{h}_{upper} = \overline{Nu}_L\,k/L_c = 14.77\times0.030\,W/m\cdot K/0.05\,m = 8.86\,W/m^2\cdot K.$$

For the *lower* fin surface, Eq. 9.32,

$$\overline{Nu}_L = \overline{h}\,L/k = 0.52 Ra_L^{1/5} = 0.52\left(5.595\times10^5\right)^{1/5} = 7.34$$

$$\overline{h}_{lower} = \overline{Nu}_L\,k/L = 7.34\times0.030\,W/m\cdot K/0.05\,m = 4.40\,W/m^2\cdot K.$$

The linearized radiation coefficient follows from Eq. 1.9

$$\overline{h}_r = \varepsilon\sigma\left(\overline{T}_{fin} + T_{sur}\right)\left(\overline{T}_{fin}^2 + T_{sur}^2\right)$$

$$\overline{h}_r = 0.5\times5.67\times10^{-8}\,W/m^2\cdot K^4\,(398+298)\left(398^2+298^2\right)K^3 = 4.88\,W/m^2\cdot K$$

Continued …

PROBLEM 9.38 (Cont.)

Hence, the average heat transfer coefficient for the fin is

$$\bar{h} = \left(\bar{h}_{upper} + \bar{h}_{lower}\right)/2 + \bar{h}_r = \left[(8.86 + 4.40)/2 + 4.88\right] W/m^2 \cdot K = 11.51\, W/m^2 \cdot K$$

Assuming the fin tip is adiabatic, from Eq. 3.81,

$$q_f = M \tanh(mL)$$

$$M = \left(\bar{h}PkA_c\right)^{1/2} \theta_b = \left(11.51\, W/m^2 \cdot K \times 2\ell \times 57\, W/m \cdot K \left(6 \times 10^{-3} m \times \ell\right)\right)^{1/2} (150 - 25)\, K = 350.7\, W$$

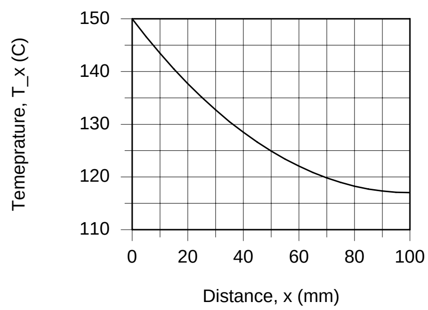
$$m = \left(\bar{h}\, P/k\, A_c\right)^{1/2} = \left(11.51\, W/m^2 \cdot K \times 2\ell / 57\, W/m \cdot K \left(6 \times 10^{-3} m \times \ell\right)\right)^{1/2} = 8.20\, m^{-1}$$

$$mL = 8.20\, m^{-1} \times 0.1\, m = 0.820$$

$$q_f' = q_f/\ell = 350.7\ W/m \times \tanh(0.820) = 237\ W/m .$$ <

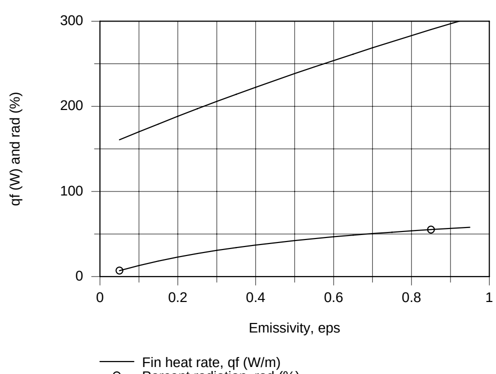
To determine how sensitive the estimate for $\bar{h}$ is to the choice of the average fin surface temperature, the foregoing calculations were repeated using the *IHT Correlations Tool and Extended Surface Model* and the results are tabulated below; coefficients have units $W/m^2 \cdot K$,

$\bar{T}_{fin}\ (^\circ C)$	125	135	145
$\bar{h}_{lower}$	4.40	4.49	4.56
$\bar{h}_{upper}$	8.87	9.05	9.21
$\bar{h}_r$	4.88	5.11	5.35
$\bar{h}$	11.5	11.9	12.2
$q'\ (W/m)$	237	243	249



The temperature distribution for the $\bar{T}_{fin} = 125^\circ C$ case is shown above. With $\bar{T}_{fin} = 145^\circ C$, the tip temperature is about $2^\circ C$ higher. It appears that $\bar{T}_{fin} = 125^\circ C$ was a reasonable choice. Note $\bar{T}_{fin}$ is the value at the mid length.

(b) Using the IHT code developed for part (a), the fin heat rate, q_f, was plotted as a function of the emissivity. In this analysis, the convection and radiation coefficients were evaluated for an average fin temperature $\bar{T}_{fin}$ evaluated at L/2. On the same plot we have also shown rad (%) = $\left(\bar{h}_r/\bar{h}\right) \times 100$, which is the portion of the total heat rate due to radiation exchange.

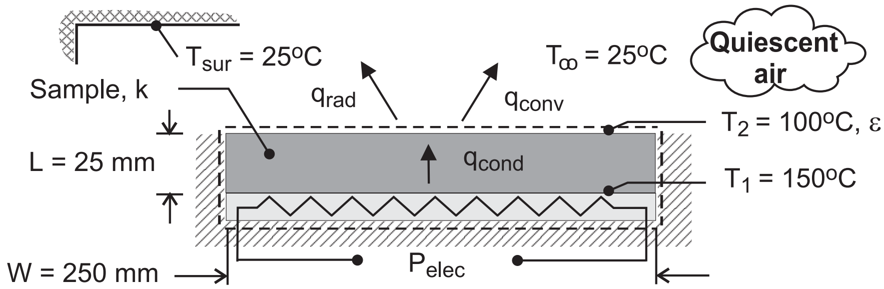


PROBLEM 9.39

KNOWN: Width and thickness of sample material. Rate of heat dissipation at bottom surface of sample and temperatures of top and bottom surfaces. Temperature of quiescent air and surroundings.

FIND: Thermal conductivity and emissivity of the sample.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) One-dimensional conduction in sample, (3) Quiescent air, (4) Sample is small relative to surroundings, (5) All of the heater power dissipation is transferred through the sample, (6) Constant properties.

PROPERTIES: *Table A-4*, air (T_f = 335.5K): $\nu = 19.5 \times 10^{-6}$ m^2/s, k = 0.0289 W/m·K, $\alpha = 27.8 \times 10^{-6}$ m^2/s, Pr = 0.703, $\beta = 0.00298$ K^{-1}.

ANALYSIS: The thermal conductivity is readily obtained by applying Fourier's law to the sample. Hence, with q = P_{elec},

$$k = \frac{P_{elec}/W^2}{(T_1 - T_2)/L} = \frac{70\,W/(0.250m)^2}{50°C/0.025m} = 0.560\,W/m \cdot K \qquad <$$

The surface emissivity may be obtained by applying an energy balance to a control surface about the sample, in which case

$$P_{elec} = q_{conv} + q_{rad} = \left[\bar{h}(T_2 - T_\infty) + \varepsilon\sigma\left(T_2^4 - T_{sur}^4\right)\right]W^2$$

$$\varepsilon = \frac{\left(P_{elec}/W^2\right) - \bar{h}(T_2 - T_\infty)}{\sigma\left(T_2^4 - T_{sur}^4\right)}$$

With L = A_s/P = W^2/4W = W/4 = 0.0625m, $Ra_L = g\beta(T_2 - T_\infty) L^3/\nu\alpha = 9.86 \times 10^5$ and Eq. 9.30 yields

$$\bar{h} = \frac{\overline{Nu}_L\,k}{L} = \frac{k}{L}0.54\,Ra_L^{1/4} = \frac{0.0289\,W/m \cdot K}{0.0625m}0.54\left(9.86 \times 10^5\right)^{1/4} = 7.87\,W/m^2 \cdot K \qquad <$$

Hence,

$$\varepsilon = \frac{70\,W/(0.250m)^2 - 7.87\,W/m^2 \cdot K(75°C)}{5.67 \times 10^{-8}\,W/m^2 \cdot K^4\left(373^4 - 298^4\right)K^4} = 0.815 \qquad <$$

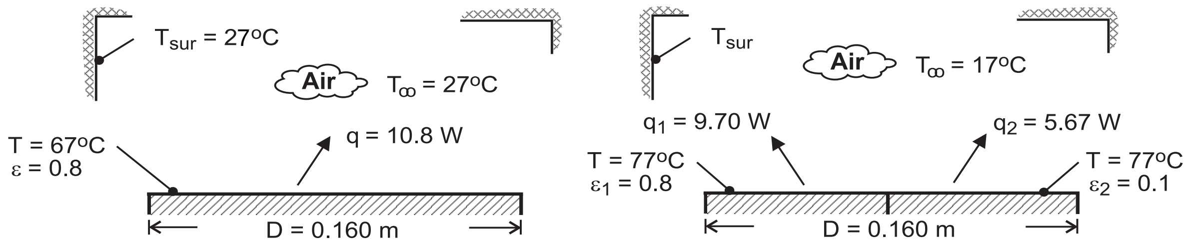
COMMENTS: The uncertainty in the determination of ε is strongly influenced by uncertainties associated with using Eq. 9.30. If, for example, $\bar{h}$ is overestimated by 10%, the actual value of ε would be 0.905.

PROBLEM 9.40

KNOWN: Diameter, power dissipation, emissivity and temperature of gage(s). Air temperature (Cases A and B) and temperature of surroundings (Case A).

FIND: (a) Convection heat transfer coefficient (Case A), (b) Convection coefficient and temperature of surroundings (Case B).

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Quiescent air, (3) Net radiation exchange from surface of gage approximates that of a small surface in large surroundings, (4) All of the electrical power is dissipated by convection and radiation heat transfer from the surface(s) of the gage, (5) Negligible thickness of strip separating semi-circular disks of Part B, (6) Constant properties.

PROPERTIES: *Table A-4*, air (T_f = 320K): $\nu = 17.9 \times 10^{-6}$ m^2/s, $\alpha = 25.5 \times 10^{-6}$ m^2/s, k = 0.0278 W/m·K, Pr = 0.704, $\beta = 0.00313$ K^{-1}.

ANALYSIS: (a) With $q = q_{conv} + q_{rad} = P_{elec}$ and $A_s = \pi D^2/4 = 0.0201$ m^2,

$$\overline{h}_{meas} = \frac{P_{elec} - \varepsilon\sigma A_s\left(T^4 - T_{sur}^4\right)}{A_s\left(T - T_\infty\right)} = \frac{10.8\,W - 0.8\times 5.67\times 10^{-8}\,W/m^2\cdot K^4 \times 0.0201 m^2\left(340^4 - 300^4\right)K^4}{0.0201\,m^2\left(40\,K\right)} = 7.46\,W/m^2\cdot K$$ <

With $L = A_s/P = D/4 = 0.04$ m and $Ra_L = g\beta(T - T_\infty)L^3/\nu\alpha = 1.72 \times 10^5$, Eq. 9.30 yields

$$\overline{h} = \frac{k}{L}0.54\,Ra_L^{1/4} = \frac{0.0278\,W/m\cdot K\times 0.54\left(1.72\times 10^5\right)^{1/4}}{0.04m} = 7.64\,W/m^2\cdot K$$ <

Agreement between the two values of $\overline{h}$ is well within the uncertainty of the measurements.

(b) Since the semi-circular disks have the same temperature, each is characterized by the same convection coefficient and $q_{conv,1} = q_{conv,2}$. Hence, with

$$P_{elec,1} = q_{conv,1} + \varepsilon_1\,\sigma\left(A_s/2\right)\left(T^4 - T_{sur}^4\right) \qquad (1)$$

$$P_{elec,2} = q_{conv,2} + \varepsilon_2\,\sigma\left(A_s/2\right)\left(T^4 - T_{sur}^4\right) \qquad (2)$$

$$T_{sur} = \left[T^4 - \frac{P_{elec,1} - P_{elec,2}}{\left(\varepsilon_1 - \varepsilon_2\right)\sigma\left(A_s/2\right)}\right]^{1/4} = \left[\left(350\right)^4 - \frac{4.03\,W}{0.7\times 5.67\times 10^{-8}\,W/m^2\cdot K^4\times 0.01\,m^2}\right]^{1/4}$$

$$T_{sur} = 264\,K$$ <

From Eq. (1), the convection coefficient is then

$$\overline{h}_{meas} = \frac{P_{elec,1} - \varepsilon_1\,\sigma\left(A_s/2\right)\left(T^4 - T_{sur}^4\right)}{\left(A_s/2\right)\left(T - T_\infty\right)} = \frac{9.70\,W - 4.60\,W}{\left(0.01\times 60\right)m^2\cdot K} = 8.49\,W/m^2\cdot K$$ <

With $Ra_L = 2.58 \times 10^5$, Eq. 9.30 yields

$$\overline{h} = \frac{k}{L}0.54\,Ra_L^{1/4} = \frac{0.0278\,W/m\cdot K}{0.04m}0.54\left(2.58\times 10^5\right)^{1/4} = 8.46\,W/m^2\cdot K$$ <

Again, agreement between the two values of $\overline{h}$ is well within the experimental uncertainty of the measurements.

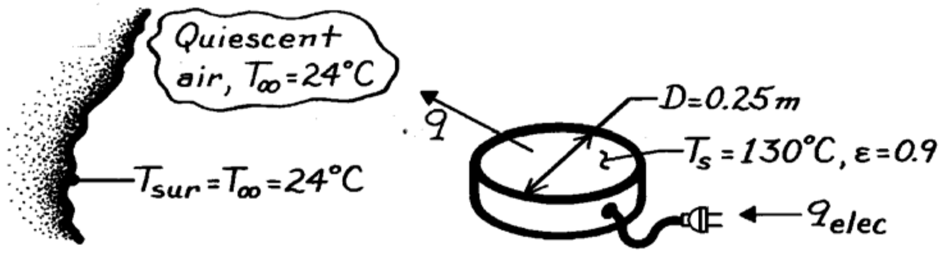
COMMENTS: Because the semi-circular disks are at the same temperature, the characteristic length corresponds to that of the circular disk, L = D/4.

PROBLEM 9.41

KNOWN: Horizontal, circular grill of 0.2m diameter with emissivity 0.9 is maintained at a uniform surface temperature of 130°C when ambient air and surroundings are at 24°C.

FIND: Electrical power required to maintain grill at prescribed surface temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Room air is quiescent, (2) Surroundings are large compared to grill surface.

PROPERTIES: *Table A-4*, Air ($T_f = (T_\infty + T_s)/2 = (24 + 130)°C/2 = 350K$, 1 atm): $\nu = 20.92 \times 10^{-6}\ m^2/s$, $k = 0.030$ W/m·K, $\alpha = 29.9 \times 10^{-6}\ m^2/s$, $\beta = 1/T_f$.

ANALYSIS: The heat loss from the grill is due to free convection with the ambient air and to radiation exchange with the surroundings.

$$q = A_s\left[\bar{h}\left(T_s - T_\infty\right) + \varepsilon\sigma\left(T_s^4 - T_{sur}^4\right)\right]. \quad (1)$$

Calculate Ra_L from Eq. 9.25,

$$Ra_L = g\beta\left(T_s - T_\infty\right)L_c^3/\nu\alpha$$

where for a horizontal disc from Eq. 9.29, $L_c = A_s/P = (\pi D^2/4)/\pi D = D/4$. Substituting numerical values, find

$$Ra_L = \frac{9.8\,m/s^2\,(1/350K)(130-24)K\,(0.25m/4)^3}{20.92\times10^{-6}m^2/s\times29.9\times10^{-6}m^2/s} = 1.158\times10^6.$$

Since the grill has a *hot upper surface*, Eq. 9.30 is the appropriate correlation,

$$\overline{Nu}_L = \bar{h}_L L_c/k = 0.54\,Ra_L^{1/4} = 0.54\left(1.158\times10^6\right)^{1/4} = 17.72$$

$$\bar{h}_L = \overline{Nu}_L\,k/L_c = 17.72\times0.030\,W/m\cdot K/\left(0.25m/4\right) = 8.50\,W/m^2\cdot K. \quad (2)$$

Substituting from Eq. (2) for $\bar{h}$ into Eq. (1), the heat loss or required electrical power, q_{elec}, is

$$q = \frac{\pi}{4}(0.25m)^2\left[8.50\frac{W}{m^2\cdot K}(130-24)K + 0.9\times5.67\times10^{-8}\frac{W}{m^2\cdot K^4}\left((130+273)^4 - (24+273)^4\right)K^4\right]$$

$$q = 44.2\,W + 46.0\,W = 90.2\,W.$$ <

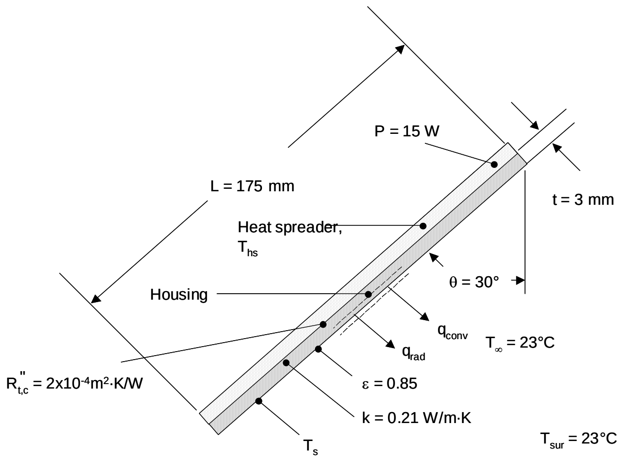
COMMENTS: Note that for this situation, free convection and radiation modes are of equal importance. If the grill were highly polished such that ε ≈ 0.1, the required power would be reduced by nearly 50%.

PROBLEM 9.42

KNOWN: Power dissipation by a laptop computer CPU. Dimensions and emissivity of the laptop screen assembly. Thickness and thermal conductivity of plastic casing as well as thermal contact resistance between heat spreader and plastic casing. Temperature of the surroundings and of the ambient.

FIND: Temperature of the heat spreader and magnitudes of convection, radiation, conduction and contact resistances.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties and steady-state conditions, (2) Large surroundings, (3) Isothermal heat spreader, (4) Laptop screen can be treated as a suspended plate.

PROPERTIES: Table A.4, air: (T_f = 310 K assumed): k = 0.02704 W/m·K, $\nu = 1.690 \times 10^{-5}$ m^2/s, $\alpha = 2.398 \times 10^{-5}$ m^2/s, Pr = 0.7056.

ANALYSIS: An energy balance on the control surface shown in the schematic yields

$$P = q_{conv} + q_{rad} = Lw\left[\bar{h}\left(T_s - T_\infty\right) + \varepsilon\sigma\left(T_s^4 - T_{sur}^4\right)\right]$$

or

$$15W = 0.275m \times 0.175m\left[\bar{h}\left(T_s - 298K\right) + 0.85 \times 5.67 \times 10^{-8} W/m^2 \cdot K^4)\left(T_s^4 - (298^4)K^4\right)\right] \quad (1)$$

The convection coefficient can be found by using the Churchill and Chu correlation with g replaced by $g\cos\theta$. Hence,

$$Ra_L = \frac{g\left(\cos\theta\right)\beta(T_s - T_\infty)L^3}{\nu \cdot \alpha}$$

Continued…

PROBLEM 9.42 (Cont.)

$$Ra_L = \frac{9.8 m/s^2 \times \cos 30° \times (1/310K) \times (T_s - 298K) \times (0.175m)^3}{1.690 \times 10^{-5} m^2/s \times 2.398 \times 10^{-5} m^2/s} \quad (2)$$

and

$$\bar{h} = \frac{0.02704 W/m \cdot K}{0.175m} \times \left\{ 0.825 + \frac{0.387 \times Ra_L^{1/6}}{\left[1 + (0.492/0.7056)^{9/16}\right]^{8/27}} \right\}^2 \quad (3)$$

Simultaneous solution of Equations 1 through 3 yields

$$Ra_L = 1.048 \times 10^7, \overline{Nu}_L = 31.6, \bar{h} = 4.89 W/m^2 \cdot K, T_s = 325.2K = 52.2°C$$

The temperature of the heat spreader is

$$T_{hs} = T_s + \frac{P}{Lw}\left[R''_{t,c} + t/k\right] \text{ or}$$

$$T_{hs} = 52.2°C + \frac{15W}{0.175m \times 0.275m}\left[2 \times 10^{-4} \frac{m^2 \cdot K}{W} + \frac{3 \times 10^{-3} m}{0.21 W/m \cdot K}\right] = 56.7°C \quad <$$

Knowing A = Lw = 0.275 m× 0.175 m = 4.81×10^{-3} m^2, the convection resistance is

$$R_{t,conv} = \frac{1}{\bar{h}A} = \frac{1}{4.89 W/m^2 \cdot K \times 4.81 \times 10^{-3} m^2} = 4.30 K/W \quad <$$

The radiation resistance, using

$$h_r = \varepsilon\sigma(T_s + T_{sur})(T_s^2 + T_{sur}^2)$$
$$= 0.85 \times 5.67 \times 10^{-8} (W/m^2 \cdot K^4) \times (325.2K + 298K) \times (325.2^2 + 298^2) K^2 = 5.84 W/m^2 \cdot K$$

is

$$R_{t,rad} = \frac{1}{h_r A} = \frac{1}{5.84 W/m^2 \cdot K \times 4.81 \times 10^{-3} m^2} = 3.56 K/W \quad <$$

The conduction resistance is

$$R_{t,cond} = \frac{t}{kA} = \frac{3 \times 10^{-3} m}{0.21 W/m \cdot K \times 4.81 \times 10^{-3} m^2} = 0.30 K/W \quad <$$

Continued…

PROBLEM 9.42 (Cont.)

The contact resistance is

$$R_{t,c} = \frac{R''_{t,c}}{A} = \frac{2 \times 10^{-4} \text{m}^2 \cdot \text{K/W}}{4.81 \times 10^{-3} \text{m}^2} = 4.2 \times 10^{-3} \text{K/W} \quad <$$

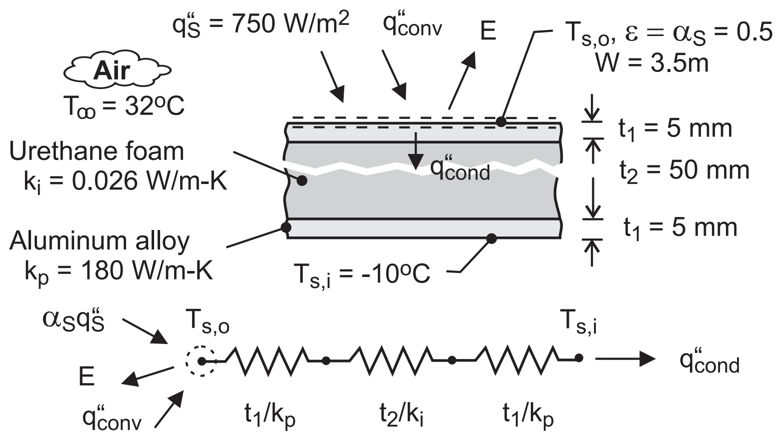
COMMENTS: (1) The actual film temperature is T_f = (23°C + 52.2°C)/2 = 37.6°C = 310.6 K. The assumed value of the film temperature is excellent. (2) The convection and radiation resistances are large. The radiation resistance cannot be reduced significantly since the emissivity of the plastic is high. The convection resistance would vary as the laptop screen angle is changed.

PROBLEM 9.43

KNOWN: Material properties, inner surface temperature and dimensions of roof of refrigerated truck compartment. Solar irradiation and ambient temperature.

FIND: Outer surface temperature of roof and rate of heat transfer to compartment.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible irradiation from the sky, (2) $T_{s,o} > T_\infty$ (hot surface facing upward) and $Ra_L > 10^7$, (3) Constant properties.

PROPERTIES: *Table A-4*, air (p = 1 atm, $T_f \approx 310K$): $\nu = 16.9 \times 10^{-6}$ m^2/s, k = 0.0270 W/m·K, Pr = 0.706, $\alpha = \nu/Pr = 23.9 \times 10^{-6}$ m^2/s, $\beta = 0.00323$ K^{-1}.

ANALYSIS: From an energy balance for the outer surface,

$$\alpha_S G_S - q''_{conv} - E = q''_{cond} = \frac{T_{s,o} - T_{s,i}}{R''_{tot}}$$

$$\alpha_S G_S - \bar{h}\left(T_{s,o} - T_\infty\right) - \varepsilon\sigma T_{s,o}^4 = \frac{T_{s,o} - T_{s,i}}{2R''_p + R''_i}$$

where $R''_p = \left(t_1 / k_p\right) = 2.78 \times 10^{-5} m^2 \cdot K/W$ and $R''_i = \left(t_2 / k_i\right) = 1.923\,m^2 \cdot K/W$. For a hot surface facing upward and $Ra_L = g\beta\left(T_{s,o} - T_\infty\right)L^3/\alpha\nu > 10^7$, $\bar{h}$ is obtained from Eq. 9.31. Hence, with cancellation of L,

$$\bar{h} = \frac{k}{L} 0.15\, Ra_L^{1/3} = 0.15 \times 0.0270\,W/m\cdot K\left(\frac{9.8\,m/s^2 \times 0.00323\,K^{-1}}{16.9 \times 23.9 \times 10^{-12} m^4/s^2}\right)^{1/3}\left(T_{s,o} - T_\infty\right)^{1/3}$$

$$= 1.73\,W/m^2 \cdot K^{4/3}\left(T_{s,o} - 305\,K\right)^{1/3}$$

Hence,

$$0.5\left(750\,W/m^2 \cdot K\right) - 1.73\,W/m^2 \cdot K^{4/3}\left(T_{s,o} - 305\right)^{4/3} - 0.5 \times 5.67 \times 10^{-8}\,W/m^2 \cdot K^4\, T_{s,o}^4 = \frac{T_{s,o} - 263K}{\left(5.56 \times 10^{-5} + 1.923\right) m^2 \cdot K/W}$$

Solving, we obtain $\quad T_{s,o} = 318.3K = 45.3°C$ <

Hence, the heat load is $\quad q = \left(W \cdot L_t\right) q''_{cond} = \left(3.5m \times 10m\right)\dfrac{\left(45.3 + 10\right)°C}{1.923\,m^2 \cdot K/W} = 1007\,W$ <

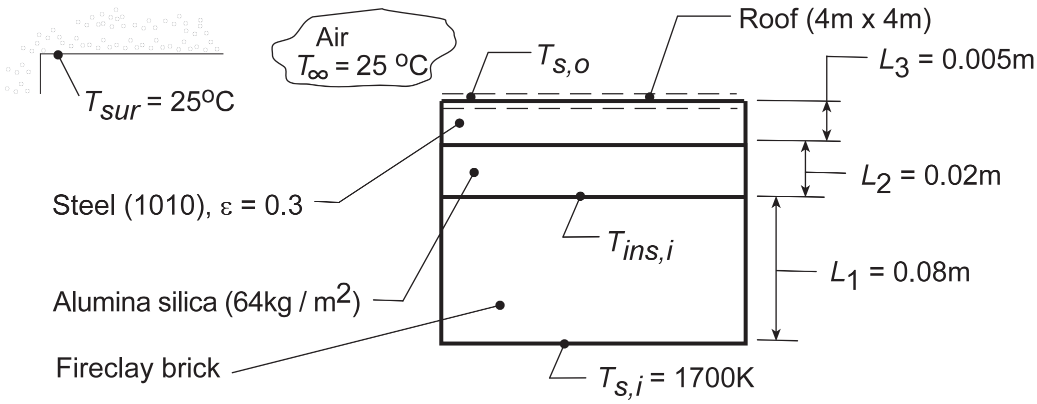
COMMENTS: (1) The thermal resistance of the aluminum panels is negligible compared to that of the insulation. (2) The value of the convection coefficient is $\bar{h} = 1.73\left(T_{s,o} - T_\infty\right)^{1/3} = 4.10\,W/m^2 \cdot K$.

PROBLEM 9.44

KNOWN: Inner surface temperature and composition of a furnace roof. Emissivity of outer surface and temperature of surroundings.

FIND: (a) Heat loss through roof with no insulation, (b) Heat loss with insulation and inner surface temperature of insulation, and (c) Thickness of fire clay brick which would reduce the insulation temperature, $T_{ins,i}$, to 1350 K.

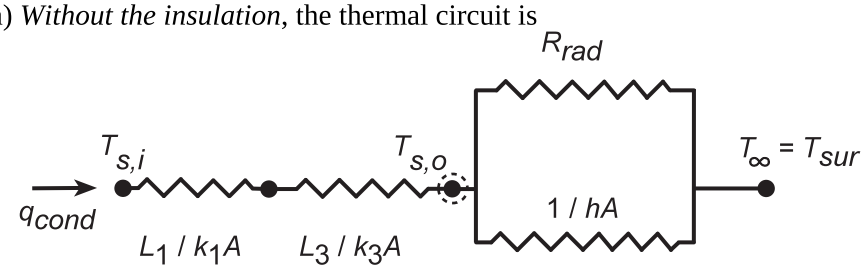
SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction through the composite wall, (3) Negligible contact resistance, (4) Constant properties.

PROPERTIES: *Table A-4*, Air ($T_f \approx 400$ K, 1 atm): k = 0.0338 W/m·K, $\nu = 26.4 \times 10^{-6}$ m²/s, $\alpha = 38.3 \times 10^{-6}$ m²/s, Pr = 0.69, $\beta = (400\text{ K})^{-1} = 0.0025\text{ K}^{-1}$; *Table A-1*, Steel 1010 (600 K): k = 48.8 W/m·K; *Table A-3* Alumina-Silica blanket (64 kg/m³, 750 K): k = 0.125 W/m·K; *Table A-3*, Fire clay brick (1478 K): k = 1.8 W/m·K.

ANALYSIS: (a) *Without the insulation*, the thermal circuit is



Performing an energy balance at the outer surface, it follows that

$$q_{cond} = q_{conv} + q_{rad} \qquad \frac{T_{s,i} - T_{s,o}}{L_1/k_1A + L_3/k_3A} = hA\left(T_{s,o} - T_\infty\right) + \varepsilon\sigma A\left(T_{s,o}^4 - T_{sur}^4\right) \quad (1,2)$$

where the radiation term is evaluated from Eq. 1.7. The characteristic length associated with free convection from the roof is, from Eq. 9.29 $L = A_s/P = 16\text{m}^2/16\text{ m} = 1\text{ m}$. From Eq. 9.25, with an assumed value for the film temperature, $T_f = 400$ K,

$$Ra_L = \frac{g\beta\left(T_{s,o} - T_\infty\right)L^3}{\nu\alpha} = \frac{9.8\text{ m/s}^2\left(0.0025\text{ K}^{-1}\right)\left(T_{s,o} - T_\infty\right)(1\text{ m})^3}{26.4\times10^{-6}\text{ m}^2/\text{s}\times 38.3\times10^{-6}\text{ m}^2/\text{s}} = 2.42\times10^7\left(T_{s,o} - T_\infty\right)$$

Hence, from Eq. 9.31

$$h = \frac{k}{L}0.15Ra_L^{1/3} = \frac{0.0338\text{ W/m}\cdot\text{K}}{1\text{ m}}0.15\left(2.42\times10^7\right)^{1/3}\left(T_{s,o} - T_\infty\right)^{1/3} = 1.47\left(T_{s,o} - T_\infty\right)^{1/3}\text{ W/m}^2\cdot\text{K}. (3)$$

Continued...

PROBLEM 9.44 (Cont.)

The energy balance can now be written

$$\frac{(1700 - T_{s,o})\,\text{K}}{(0.08\text{m}/1.8\,\text{W/m}\cdot\text{K} + 0.005\text{m}/48.8\,\text{W/m}\cdot\text{K})} = 1.47(T_{s,o} - 298\,\text{K})^{4/3}$$

$$+0.3\times 5.67\times 10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left[T_{s,o}^4 - (298\,\text{K})^4\right]$$

and from iteration, find $T_{s,o} \approx 895$ K. Hence,

$$q = 16\text{m}^2\left\{1.47(895-298)^{4/3}\,\text{W/m}^2 + 0.3\times 5.67\times 10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left[(895\,\text{K})^4 - (298\,\text{K})^4\right]\right\}$$

$$q = 16\text{m}^2\{7,389 + 10,780\}\,\text{W/m}^2 = 2.91\times 10^5\,\text{W}.$$ <

(b) *With the insulation*, an additional conduction resistance is provided and the energy balance at the outer surface becomes

$$\frac{T_{s,i} - T_{s,o}}{L_1/k_1A + L_2/k_2A + L_3/k_3A} = hA(T_{s,o} - T_\infty) + \varepsilon\sigma A\left(T_{s,o}^4 - T_{sur}^4\right) \quad (4)$$

$$\frac{(1700 - T_{s,o})\,\text{K}}{(0.08\text{m}/1.8 + 0.02/0.125 + 0.005/48.8)\,\text{m}^2\cdot\text{K/W}} = 1.47(T_{s,o} - 298\text{K})^{4/3}$$

$$+0.3\times 5.67\times 10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left[T_{s,o}^4 - (298\,\text{K})^4\right].$$

From an iterative solution, it follows that $T_{s,o} \approx 610$ K. Hence,

$$q = 16\text{m}^2\left\{1.47(610-298)^{4/3}\,\text{W/m}^2 + 0.3\times 5.67\times 10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left[(610\,\text{K})^4 - (298\,\text{K})^4\right]\right\}$$

$$q = 16\text{m}^2\{3111 + 2221\}\,\text{W/m}^2 = 8.53\times 10^4\,\text{W}.$$ <

The insulation inner surface temperature is given by

$$q = \frac{T_{s,i} - T_{ins,i}}{L_1/k_1A}.$$

Hence

$$T_{ins,i} = -q\frac{L_1}{k_1A} + T_{s,i} = -8.53\times 10^4\,\text{W}\frac{0.08\,\text{m}}{1.8\,\text{W/m}\cdot\text{K}\times 16\text{m}^2} + 1700\,\text{K} = 1463\,\text{K}.$$ <

(c) To determine the required thickness L_1 of the fire clay brick to reduce $T_{ins,i}$ = 1350 K, we keyed Eq. (4) into the IHT Workspace and found

L_1 = 0.13 m. <

COMMENTS: (1) The accuracy of the calculations could be improved by re-evaluating thermophysical properties at more appropriate temperatures.

(2) Convection and radiation heat losses from the roof are comparable. The relative contribution of radiation increases with increasing $T_{s,o}$, and hence decreases with the addition of insulation.

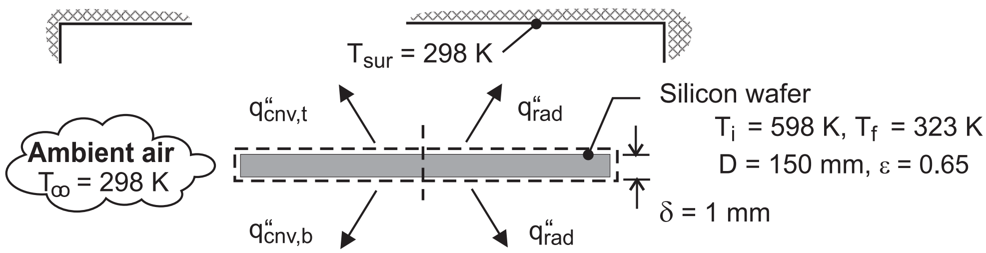
(3) Note that with the insulation, $T_{ins,i}$ = 1463 K exceeds the melting point of aluminum (933 K). Hence, molten aluminum, which can seep through the refractory, would penetrate, and thereby degrade the insulation, under the specified conditions.

PROBLEM 9.45

KNOWN: Diameter, thickness, emissivity and initial temperature of silicon wafer. Temperature of air and surrounding.

FIND: (a) Initial cooling rate, (b) Time required to achieve prescribed final temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat transfer from side of wafer, (2) Large surroundings, (3) Wafer may be treated as a lumped capacitance, (4) Constant properties, (5) Quiescent air.

PROPERTIES: *Table A-1*, Silicon ($\overline{T}$ = 187°C = 460K): ρ = 2330 kg/m^3, c_p = 813 J/kg·K, k = 87.8 W/m·K. *Table A-4*, Air ($T_{f,i}$ = 175°C = 448K): $\nu = 32.15 \times 10^{-6}$ m^2/s, k = 0.0372 W/m·K, $\alpha = 46.8 \times 10^{-6}$ m^2/s, Pr = 0.686, β = 0.00223 K^{-1}.

SOLUTION: (a) Heat transfer is by natural convection and net radiation exchange from top and bottom surfaces. Hence, with $A_s = \pi D^2/4 = 0.0177$ m^2,

$$q = A_s\left[\left(\overline{h}_t + \overline{h}_b\right)\left(T_i - T_\infty\right) + 2\varepsilon\sigma\left(T_i^4 - T_{sur}^4\right)\right]$$

where the radiation flux is obtained from Eq. 1.7, and with $L = A_s/P = 0.0375$m and $Ra_L = g\beta(T_i - T_\infty)L^3/\alpha\nu = 2.30 \times 10^5$, the convection coefficients are obtained from Eqs. 9.30 and 9.32. Hence,

$$\overline{h}_t = \frac{k}{L}\left(0.54\,Ra_L^{1/4}\right) = \frac{0.0372\,W/m\cdot K \times 11.8}{0.0375m} = 11.7\,W/m^2\cdot K$$

$$\overline{h}_b = \frac{k}{L}\left(0.52\,Ra_L^{1/5}\right) = \frac{0.0372\,W/m\cdot K \times 6.14}{0.0375m} = 6.1\,W/m^2\cdot K$$

$$q = 0.0177\,m^2\left[\left(11.7+6.1\right)W/m^2\cdot K\left(300K\right) + 2\times0.65\times5.67\times10^{-8}W/m^2\cdot K^4\left(598^4 - 298^4\right)K^4\right]$$

$$q = 0.0177\,m^2\left[\left(5350+8845\right)W/m^2\right] = 251\,W$$ <

(b) From the generalized lumped capacitance model, Eq. 5.15,

$$\rho c A_s\delta\frac{dT}{dt} = -\left[\left(\overline{h}_t + \overline{h}_b\right)\left(T - T_\infty\right) + 2\varepsilon\sigma\left(T^4 - T_{sur}^4\right)\right]A_s$$

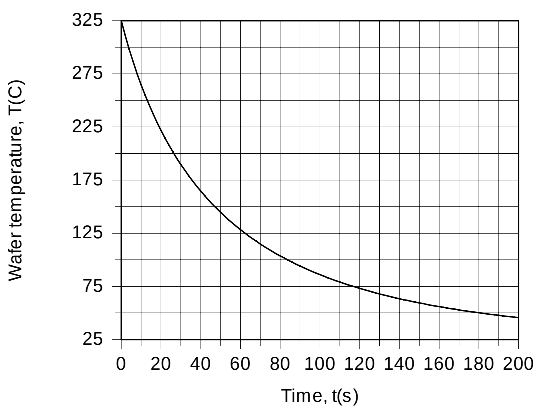
$$\int_{Ti}^{T} dT = -\int_0^t\left[\frac{\left(\overline{h}_t + \overline{h}_b\right)\left(T - T_\infty\right) + 2\varepsilon\sigma\left(T^4 - T_{sur}^4\right)}{\rho c\delta}\right]dt$$

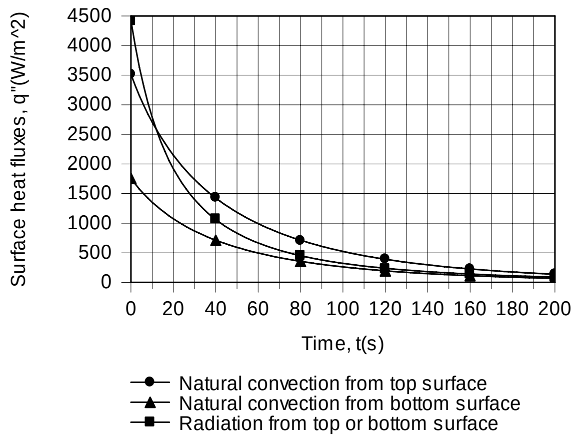
Continued …..

PROBLEM 9.45 (Cont.)

Using the DER function of IHT to perform the integration, thereby accounting for variations in $\overline{h}_t$ and $\overline{h}_b$ with T, the time t_f to reach a wafer temperature of 50°C is found to be

$$t_f\left(T = 323\ \text{K}\right) = 179\ \text{s}$$ <





As shown above, the rate at which the wafer temperature decays with increasing time decreases due to reductions in the convection and radiation heat fluxes. Initially, the surface radiative flux (top or bottom) exceeds the heat flux due to natural convection from the top surface, which is twice the flux due to natural convection from the bottom surface. However, because q''_{rad} and q''_{cnv} decay approximately as T^4 and $T^{5/4}$, respectively, the reduction in q''_{rad} with decreasing T is more pronounced, and at t = 181s, q''_{rad} is well below $q''_{cnv,t}$ and only slightly larger than $q''_{cnv,b}$.

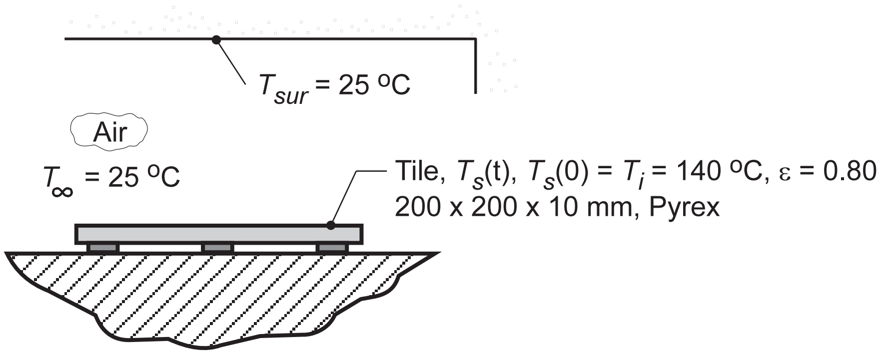
COMMENTS: With $\overline{h}_{r,i} = \varepsilon\sigma\left(T_i + T_{sur}\right)\left(T_i^2 + T_{sur}^2\right) = 14.7\ \text{W/m}^2\cdot\text{K}$, the largest cumulative coefficient of $\overline{h}_{tot} = \overline{h}_{r,i} + \overline{h}_{t,i} = 26.4\ \text{W/m}^2\cdot\text{K}$ corresponds to the top surface. If this coefficient is used to estimate a Biot number, it follows that $Bi = \overline{h}_{tot}\left(\delta/2\right)/k = 1.5\times10^{-4} \ll 1$ and the lumped capacitance approximation is excellent.

PROBLEM 9.46

KNOWN: Pyrex tile, initially at a uniform temperature T_i = 140°C, experiences cooling by convection with ambient air and radiation exchange with surroundings.

FIND: (a) Time required for tile to reach the safe-to-touch temperature of T_f = 40°C with free convection and radiation exchange; use $\overline{T} = (T_i + T_f)/2$ to estimate the average free convection and linearized radiation coefficients; comment on how sensitive result is to this estimate, and (b) Time-to-cool if ambient air is blown in parallel flow over the tile with a velocity of 10 m/s.

SCHEMATIC:



ASSUMPTIONS: (1) Tile behaves as spacewise isothermal object, (2) Backside of tile is perfectly insulated, (3) Surroundings are large compared to the tile, (4) For forced convection situation, part (b), assume flow is fully turbulent.

PROPERTIES: *Table A.3*, Pyrex (300 K): ρ = 2225 kg/m^3, c_p = 835 J/kg·K, k = 1.4 W/m·K, ε = 0.80 (given); *Table A.4*, Air $\left(T_f = (\overline{T}_s + T_\infty)/2 = 330.5\,\text{K}, 1\,\text{atm}\right)$: ν = 18.96 × 10^{-6} m^2/s, k = 0.0286 W/m·K, α = 27.01 × 10^{-6} m^2/s, Pr = 0.7027, β = 1/T_f.

ANALYSIS: (a) For the lumped capacitance system with a constant coefficient, from Eq. 5.6,

$$\frac{T_s(t) - T_\infty}{T_i - T_\infty} = \exp\left[-\left(\frac{\overline{h}A_s}{\rho Vc}\right)t\right] \qquad (1)$$

where $\overline{h}$ is the combined coefficient for the convection and radiation processes,

$$\overline{h} = \overline{h}_{cv} + \overline{h}_{rad} \qquad (2)$$

and $\quad A_s = L^2 \qquad V = L^2 d \qquad (3,4)$

The linearized radiation coefficient based upon the average temperature, $\overline{T}_s$, is

$$\overline{T}_s = (T_i + T_f)/2 = (140 + 40)^\circ\text{C}/2 = 90^\circ\text{C} = 363\,\text{K} \qquad (5)$$

$$\overline{h}_{rad} = \varepsilon\sigma\left(\overline{T}_s + T_{sur}\right)\left(\overline{T}_s^2 + T_{sur}^2\right) \qquad (6)$$

$$\overline{h}_{rad} = 0.8 \times 5.67 \times 10^{-8}\,\text{W/m}^2\cdot\text{K}^4\,(363 + 298)\left(363^2 + 298^2\right)\text{K}^3 = 6.61\,\text{W/m}^2\cdot\text{K}$$

The free convection coefficient can be estimated from the correlation for the flat plate, Eq. 9.30, with

$$Ra_L = \frac{g\beta\Delta TL^3}{\nu\alpha} \qquad\qquad L = A_s/P = L^2/4L = 0.25L \qquad (7,8)$$

Continued...

PROBLEM 9.46 (Cont.)

$$Ra_L = \frac{9.8\,m/s^2\,(1/330\,K)(363-298)\,K\,(0.25\times0.200\,m)^3}{18.96\times10^{-6}\,m^2/s\times27.01\times10^{-6}\,m^2/s} = 4.712\times10^5$$

$$\overline{Nu}_L = 0.54 Ra_L^{1/4} = 0.54\left(4.712\times10^5\right)^{1/4} = 14.18$$

$$\bar{h}_{cv} = \overline{Nu}_L\,k/L = 14.18\times0.0286\,W/m\cdot K/0.25\times0.200\,m = 8.09\,W/m^2\cdot K$$

From Eq. (2), it follows

$$\bar{h} = (6.61+8.09)\,W/m^2\cdot K = 14.7\,W/m^2\cdot K$$

From Eq. (1), with $A_s/V = 1/d$, where d is the tile thickness, the time-to-cool is found as

$$\frac{40-25}{140-25} = \exp\left[-\frac{14.7\,W/m^2\cdot K\times t_f}{2225\,kg/m^3\times0.010\,m\times835\,J/kg\cdot K}\right]$$

$$t_f = 2574s = 42.9\,min$$ <

Using the *IHT Lumped Capacitance Model* with the *Correlations Tool, Free Convection, Flat Plate*, we can perform the analysis where both h_{cv} and h_{rad} are evaluated as a function of the tile temperature. The time-to-cool is

$$t_f = 2860s = 47.7\,min$$ <

which is 10% higher than the approximate value.

(b) Considering parallel flow with a velocity, $u_\infty = 10\,m/s$ over the tile, the Reynolds number is

$$Re_L = \frac{u_\infty L}{\nu} = \frac{10\,m/s\times0.200m}{18.96\times10^{-6}\,m^2/s} = 1.055\times10^5$$

but, assuming the flow is turbulent at the upstream edge, use Eq. 7.38 with A = 0 to estimate $\bar{h}_{cv}$,

$$\overline{Nu}_L = 0.037\,Re_L^{4/5}\,Pr^{1/3} = 0.037\left(1.055\times10^5\right)^{4/5}(0.7027)^{1/3} = 343.3$$

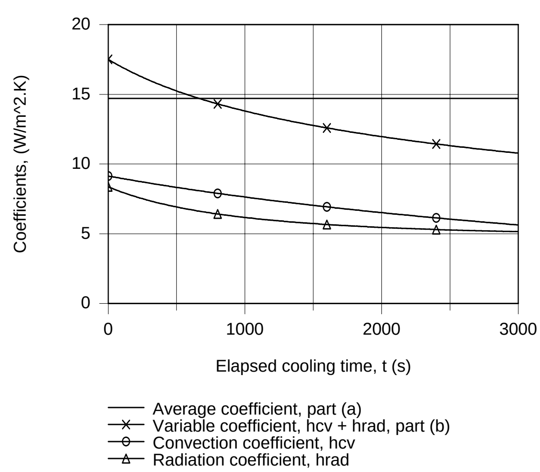
$$\bar{h}_{cv} = \overline{Nu}_L k/L = 343.3\times0.0286\,W/m\cdot K/0.200m = 49.1\,W/m^2\cdot K$$

Hence, using Eqs. (2) and (1), find

$$\bar{h} = 57.2\,W/m^2\cdot K \qquad t_f = 661s = 11.0\,min$$ <

COMMENTS: (1) For the conditions of part (a), Bi = hd/k= 14.7 W/m^2·K × 0.01m / 1.4 W/m·K = 0.105. We conclude that the lumped capacitance analysis is marginally applicable. For the condition of part (b), Bi = 0.4 and, hence, we need to consider spatial effects as explained in Section 5.4. If we considered spatial effects, would our estimates for the time-to-cool be greater or less than those from the foregoing analysis?

(2) For the conditions of part (a), the convection and radiation coefficients are shown in the plot below as a function of cooling time. Can you use this information to explain the relative magnitudes of the t_f estimates?

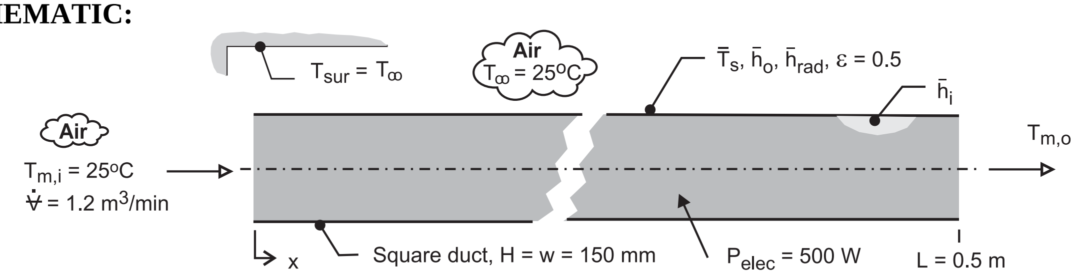


PROBLEM 9.47

KNOWN: Stacked IC boards within a duct dissipating 500 W with prescribed air flow inlet temperature, flow rate, and internal convection coefficient. Outer surface has emissivity of 0.5 and is exposed to ambient air and large surroundings at 25°C.

FIND: Develop a model to estimate outlet temperature of the air, $T_{m,o}$, and the average surface temperature of the duct, $\overline{T}_s$, following these steps: (a) Estimate the average free convection for the outer surface, $\overline{h}_o$, assuming an average surface temperature of 37°C; (b) Estimate the average (linearized) radiation coefficient for the outer surface, $\overline{h}_{rad}$, assuming an average surface temperature of 37°C; (c) Perform an overall energy balance on the duct considering (i) advection of the air flow, (ii) dissipation of electrical power in the ICs, and (iii) heat transfer from the fluid to the ambient air and surroundings. Express the last process in terms of thermal resistances between the mean fluid temperature, $\overline{T}_m$, and the outer temperatures T_∞ and T_{sur}; (d) Substituting numerical values into the expression of part (c), calculate $T_{m,o}$ and $\overline{T}_s$; comment on your results and the assumptions required to develop your model.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Air in duct is ideal gas with negligible viscous dissipation and pressure variation, (3) Constant properties, (4) Power dissipated in IC boards nearly uniform in longitudinal direction, (5) Ambient air is quiescent, and (5) Surroundings are isothermal and large relative to the duct.

PROPERTIES: *Table A-4*, Air ($T_f = (\overline{T}_s + T_\infty)/2 = 304$ K): $\nu = 1.629 \times 10^{-5}$ m^2/s, $\alpha = 2.309 \times 10^{-5}$ m^2/s, k = 0.0266 W/m·K, $\beta = 0.003289$ K^{-1}, Pr = 0.706, $\rho = 1.148$ kg/m^3, $c_p = 1007$ J/kg·K.

ANALYSIS: (a) *Average, free-convection coefficient over the duct.* Heat loss by free convection occurs on the vertical sides and horizontal top and bottom. The methodology for estimating the average coefficient assuming the average duct surface temperature $\overline{T}_s = 37°C$ follows that of Example 9.3. For the *vertical sides*, from Eq. 9.25 with L = H, find

$$Ra_L = \frac{g\beta\left(\overline{T}_s - T_\infty\right)H^3}{\nu\alpha}$$

$$Ra_L = \frac{9.8 \text{ m/s}^2 \times 0.003289 \text{ K}^{-1}(37-25)\text{K} \times (0.150 \text{ m})^3}{1.629\times10^{-5} \text{ m}^2/\text{s} \times 2.309\times10^{-5} \text{m}^2/\text{s}} = 3.47\times10^6$$

The free convection is laminar, and from Eq. 9.27,

$$\overline{Nu}_L = 0.68 + \frac{0.670 \, Ra_L^{1/4}}{\left[1+(0.492/Pr)^{9/16}\right]^{4/9}}$$

Continued…..

$$\overline{Nu}_L = \frac{\bar{h}_v H}{k} = 0.68 + \frac{0.670 \times \left(3.47 \times 10^6\right)^{1/4}}{\left[1 + \left(0.492/0.706\right)^{9/16}\right]^{4/9}} = 22.9$$

$$\bar{h}_v = 4.05\ \text{W/m}^2 \cdot \text{K}$$

For the top and bottom surfaces, $L_c = (A_s/P) = (w \times L)/(2w + 2L) = 0.0577$ m, hence, $Ra_L = 1.974 \times 10^5$ and with Eqs. 9.30 and 9.32, respectively,

Top surface: $\overline{Nu}_L = \frac{\bar{h}_t L_c}{k} = 0.54\ Ra_L^{1/4};$ $\bar{h}_t = 5.25\ \text{W/m}^2 \cdot \text{K}$

Bottom surface: $\overline{Nu}_L = \frac{\bar{h}_b L_c}{k} = 0.52\ Ra_L^{1/5};$ $\bar{h}_b = 2.75\ \text{W/m}^2 \cdot \text{K}$

The average coefficient for the entire duct is

$$\bar{h}_{cv,o} = \left(2\bar{h}_v + \bar{h}_t + \bar{h}_b\right)/4 = \left(2 \times 4.05 + 5.25 + 2.75\right)\text{W/m}^2 \cdot \text{K}/4 = 4.03\ \text{W/m}^2 \cdot \text{K}$$ <

(b) *Average (linearized) radiation coefficient over the duct.* Heat loss by radiation exchange between the duct outer surface and the surroundings on the vertical sides and horizontal top and bottom. With $\bar{T}_s = 37°\text{C}$, from Eq. 1.9,

$$\bar{h}_{rad} = \varepsilon\sigma\left(\bar{T}_s + T_{sur}\right)\left(\bar{T}_s^2 + T_{sur}^2\right)$$

$$\bar{h}_{rad} = 0.5 \times 5.67 \times 10^{-8}\ \text{W/m}^2 \cdot \text{K}^4 \left(310 + 298\right)\left(310^2 + 298^2\right)\text{K}^3 = 3.2\ \text{W/m}^2 \cdot \text{K}$$ <

(c) *Overall energy balance on the fluid in the duct.* The control volume is shown in the schematic below and the energy balance is

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_{gen} = 0$$

$$-q_{adv} + P_{elec} - q_{out} = 0 \qquad (1)$$

The advection term has the form, with $\dot{m} = \dot{\forall}\rho$,

$$q_{adv} = \dot{m}\, c_p \left(T_{m,o} - T_{m,i}\right) \qquad (2)$$

and the heat rate q_{out} is represented by the thermal circuit shown below and has the form, with $T_{sur} = T_\infty$,

$$q_{out} = \frac{\bar{T}_m - T_\infty}{R_{cv,i} + \left(1/R_{cv,o} + 1/R_{rad}\right)^{-1}} \qquad (3)$$

where $\bar{T}_m$ is the average mean temperature of the fluid, $(T_{m,i} + T_{m,o})/2$. The thermal resistances are evaluated with $A_s = 2(w + H)\,L = 0.3\ \text{m}^2$ as

$$R_{cv,i} = 1/\bar{h}_i A_s \qquad (4)$$

$$R_{cv,o} = 1/\bar{h}_{cv,o} A_s \qquad (5)$$

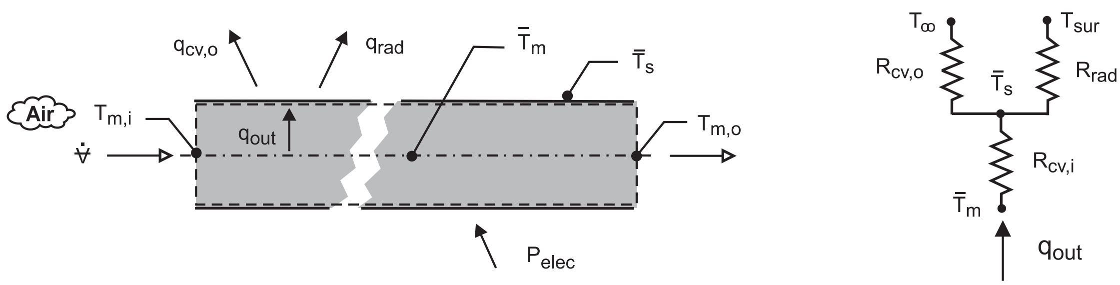
$$R_{rad} = 1/\bar{h}_{rad} A_s \qquad (6)$$

Continued …

PROBLEM 9.47 (Cont.)

Using this energy balance, the outlet temperature of the air can be calculated. From the thermal circuit, the average surface temperature can be calculated from the relation

$$q_{out} = \left(\overline{T}_m - \overline{T}_s\right) / R_{cv,i} \tag{7}$$



(d) *Calculating $T_{m,o}$ and* $\overline{T}_s$. Substituting numerical values into the expressions of Part (c), find

$$T_{m,o} = 45.7°C \qquad \overline{T}_s = 34.0°C$$ <

The heat rates and thermal resistance results are

$$q_{adv} = 480.5\ W \qquad q_{out} = 19.5\ W$$

$$R_{cv,i} = 0.0667\ K/W \qquad R_{cv,o} = 0.827\ K/W \qquad R_{rad} = 1.05\ K/W$$

COMMENTS: (1) We assumed $\overline{T}_s = 37°C$ for estimating $\overline{h}_{cv,o}$ and $\overline{h}_{rad}$, whereas from the energy balance we found the value was 34.0°C. Performing an interative solution, with different assumed $\overline{T}_s$ we would find that the results are not sensitive to the $\overline{T}_s$ value, and that the foregoing results are satisfactory.

(2) From the results of Part (d) for the heat rates, note that about 4% of the electrical power is transferred from the duct outer surface. The present arrangement does not provide a practical means to cool the IC boards.

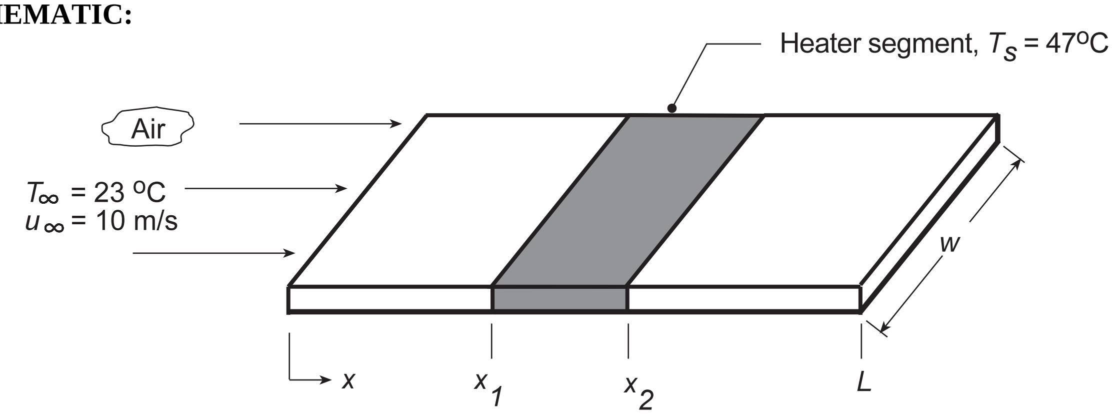
(3) Note that $T_{m,i} < T_s < T_{m,o}$. As such, we can't utilize the usual log-mean temperature (LMTD) expression, Eq. 8.44, in the rate equation for the internal flow analysis. It is for this reason we used the overall coefficient approach representing the heat transfer by the thermal circuit. The average surface temperature of the duct, $\overline{T}_s$, is only used for the purposes of estimating $\overline{h}_{cv,o}$ and $\overline{h}_{rad}$. We represented the effective temperature difference between the fluid and the ambient/surroundings as $\overline{T}_m - T_\infty$. Because the fluid temperature rise is not very large, this assumption is a reasonable one.

PROBLEM 9.48

KNOWN: Parallel flow of air over a highly polished aluminum plate flat plate maintained at a uniform temperature T_s = 47°C by a series of segmented heaters.

FIND: (a) Electrical power required to maintain the heater segment covering the section between x_1 = 0.2 m and x_2 = 0.3m and (b) Temperature that the surface would reach if the air blower malfunctions and heat transfer occurs by free, rather than forced, convection.

SCHEMATIC:



ASSUMPTIONS : (l) Steady-state conditions, (2) Backside of plate is perfectly insulated, (3) Flow is turbulent over the entire length of plate, part (a), (4) Ambient air is extensive, quiescent at 23°C for part (b).

PROPERTIES: *Table A.4,* Air ($T_f = (T_s + T_\infty)/2$ = 308K): $\upsilon = 16.69 \times 10^{-6}$ m²/s, k = 0.02689 W/m·K, $\alpha = 23.68 \times 10^{-6}$ m²/s, Pr = 0.7059, $\beta = 1/T_f$; *Table A.12,* Aluminum, highly polished: ε = 0.03.

ANALYSIS: (a) The power required to maintain the segmented heater (x_1 - x_2) is

$$P_e = \bar{h}_{x1-x2}\left(x_2 - x_1\right)w\left(T_s - T_\infty\right) \qquad (1)$$

where $\bar{h}_{x1-x2}$ is the average coefficient for the section between x_1 and x_2, and can be approximated as the average of the local values at x_1 and x_2,

$$\bar{h}_{x1-x2} = \left(h\left(x_1\right) + h\left(x_2\right)\right)/2 \qquad (2)$$

Using Eq. 7.36 appropriate for fully turbulent flow, with $Re_x = u_\infty x /k$,

$$Nu_{x1} = 0.0296\, Re_x^{4/5}\, Pr^{1/3}$$

$$Nu_{x1} = 0.0296\left(\frac{10\text{m/s} \times 0.2\text{m}}{16.69 \times 10^{-6}\ \text{m}^2/\text{s}}\right)^{4/5}\left(0.7059\right)^{1/3} = 304.6$$

$$h_{x1} = Nu_{x1}\,k/x_1 = 304.6 \times 0.02689\,\text{W/m}\cdot\text{K}/0.2\text{m} = 40.9\,\text{W/m}^2\cdot\text{K}$$

$$Nu_{x2} = 421.3 \qquad h_{x2} = 37.8\,\text{W/m}^2\cdot\text{K}$$

Hence, from Eq (2) to obtain $\bar{h}_{x1-x2}$ and Eq. (1) to obtain P_e,

$$\bar{h}_{x1-x2} = \left(40.9 + 37.8\right)\text{W/m}^2\cdot\text{K}/2 = 39.4\,\text{W/m}^2\cdot\text{K}$$

$$P_e = 39.4\,\text{W/m}^2\cdot\text{K}\left(0.3 - 0.2\right)\text{m} \times 0.2\text{m}\left(47 - 23\right)^\circ\text{C} = 18.9\,\text{W} \qquad <$$

Continued...

PROBLEM 9.48 (Cont.)

(b) Without the airstream flow, the heater segment experiences free convection and radiation exchange with the surroundings,

$$P_e = \left[\bar{h}_{cv}\left(T_s - T_\infty\right) + \varepsilon\sigma\left(T_s^4 - T_{sur}^4\right)\right]\left(x_2 - x_1\right)w \qquad (3)$$

We will assume that the free convection coefficient, $\bar{h}_{cv}$, for the segment is the same as that for the entire plate. Using the correlation for a flat plate, Eq. 9.30, with

$$Ra_L = \frac{g\beta\Delta T L_c^3}{\nu\alpha} \qquad L_c = \frac{A_s}{P} = \frac{0.2 \times 0.5\,m^2}{2\left(0.2 + 0.5\right)m} = 0.0714\,m$$

and evaluating properties at T_f = 308 K,

$$Ra_L = \frac{9.8\,m/s^2\left(1/308K\right)\left(47 - 23\right)\left(0.0714m\right)^3}{16.69 \times 10^{-6}\,m/s^2 \times 23.68 \times 10^{-6}\,m^2/s} = 7.033 \times 10^5$$

$$\overline{Nu}_L = 0.54 Ra_L^{1/4} = 0.54\left(7.033 \times 10^5\right)^{1/4} = 15.64$$

$$\bar{h}_{cv} = \overline{Nu}_L\,k/L_c = 15.64 \times 0.02689\,W/m \cdot K/0.0714m = 5.89\,W/m^2 \cdot K$$

Substituting numerical values into Eq. (3),

$$18.9W = \left[5.89\,W/m^2 \cdot K\left(T_s - 296\right) + 0.03 \times 5.67 \times 10^{-8}\,W/m^2 \cdot K^4\left(T_s^4 - 296^4\right)\right]\left(0.3 - 0.2\right)m \times 0.2m$$

$$T_s = 447\,K = 174^\circ C$$ <

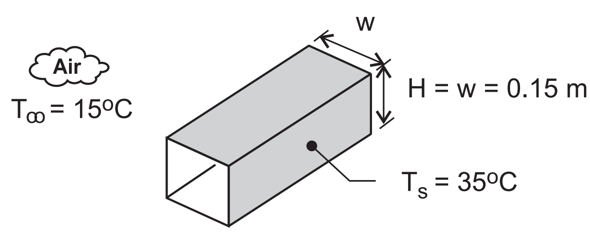
COMMENTS: Recognize that in part (b), the assumed value for T_f = 308 K is a poor approximation. Using the above relations in the IHT work space with the *Properties Tool*, find that T_s = 406 K = 133 °C using the properly evaluated film temperature (T_f) and temperature difference (ΔT) in the correlation. From this analysis, $\bar{h}_{cv} = 8.29\,W/m^2 \cdot K$ and h_{rad} = 0.3 W/m^2·K. Because of the low emissivity of the plate, the radiation exchange process is not significant.

PROBLEM 9.49

KNOWN: Correlation for estimating the average free convection coefficient for the exterior surface of a long horizontal rectangular cylinder (duct) exposed to a quiescent fluid. Consider a horizontal 0.15 m-square duct with a surface temperature of 35°C passing through ambient air at 15°C.

FIND: (a) Calculate the average convection coefficient and the heat rate per unit length using the H-D correlation, (b) Calculate the average convection coefficient and the heat rate per unit length considering the duct as formed by vertical plates (sides) and horizontal plates (top and bottom), and (c) Using an appropriate correlation, calculate the average convection coefficient and the heat rate per unit length for a duct of circular cross-section having a diameter equal to the wetted perimeter of the rectangular duct of part (a). Do you expect the estimates for parts (b) and (c) to be lower or higher than those obtained with the H-D correlation? Explain the differences, if any.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Ambient air is quiescent, (3) Duct surface has uniform temperature.

PROPERTIES: *Table A-4*, air ($T_f = (T_s + T_\infty)/2 = 298$ K, 1 atm): $\nu = 1.571 \times 10^{-5}$ m²/s, k = 0.0261 W/m·K, $\alpha = 2.22 \times 10^{-5}$ m²/s, Pr = 0.708.

ANALYSIS: (a) The Hahn-Didion (H-D) correlation [ASHRAE Proceedings, Part 1, pp 262-67, 1972] has the form

$$\overline{Nu}_p = 0.55\, Ra_p^{1/4}\left(\frac{H}{p}\right)^{1/8} \qquad Ra_p \le 10^7$$

where the characteristic length is the half-perimeter, p = (w + H), and w and H are the horizontal width and vertical height, respectively, of the duct. The thermophysical properties are evaluated at the film temperature. Using *IHT*, with the correlation and thermophysical properties, the following results were obtained.

Ra_p	$\overline{Nu}_p$	$\overline{h}_p\left(W/m^2\cdot K\right)$	$q'_p\left(W/m\right)$	
5.08×10^7	42.6	3.71	44.5	<

where the heat rate per unit length of the duct is

$$q'_p = \overline{h}_p\, 2\left(H + w\right)\left(T_s - T_\infty\right).$$

(b) Treating the duct as a combination of horizontal (*top*: hot-side up and *bottom*: hot-side down) and two vertical plates (v) as considered in Example 9.3, the following results were obtained

$\overline{h}_t$ (W/m²·K)	$\overline{h}_b$ (W/m²·K)	$\overline{h}_v$ (W/m²·K)	$\overline{h}_{hv}$ (W/m²·K)	q'_{hv} (W/m)	
5.62	2.81	4.78	4.50	54.0	<

Continued...

PROBLEM 9.49 (Cont.)

where the average coefficient and heat rate per unit length for the horizontal-vertical plate duct are

$$\overline{h}_{hv} = \left(\overline{h}_t + \overline{h}_b + 2\,\overline{h}_v\right)/4$$

$$q'_{hv} = \overline{h}_{hv}\,2\left(H + w\right)\left(T_s - T_\infty\right).$$

(c) Consider a circular duct having a wetted perimeter equal to that of the rectangular duct, for which the diameter is

$$\pi D = 2\left(H + w\right) \qquad\qquad D = 0.191\text{ m}$$

Using the Churchill-Chu correlation, Eq. 9.34, the following results are obtained.

Ra_D	$\overline{Nu}_D$	$\overline{h}_D\left(W/m^2\cdot K\right)$	$q'_D\left(W/m\right)$	
1.31×10^7	30.6	4.19	50.3	<

where the heat rate per unit length for the circular duct is

$$q'_D = \pi D\,\overline{h}_D\left(T_s - T_\infty\right).$$

COMMENTS: (1) The H-D correlation, based upon experimental measurements, provided the lowest estimate for $\overline{h}$ and q'. The circular duct analysis results are in closer agreement than are those for the horizontal-vertical plate duct.

(2) An explanation for the relative difference in $\overline{h}$ and q' values can be drawn from consideration of the boundary layers and induced flows around the surfaces. Viewing the cross-section of the square duct, recognize that flow induced by the bottom surface flows around the vertical sides, joining the vertical plume formed on the top surface. The flow over the vertical sides is quite different than would occur if the vertical surface were modeled as an *isolated* vertical surface. Also, flow from the top surface is likewise modified by flow rising from the sides, and doesn't behave as an *isolated* horizontal surface. It follows that treating the duct as a combination of horizontal-vertical plates (hv results), each considered as *isolated*, would over estimate the average coefficient and heat rate.

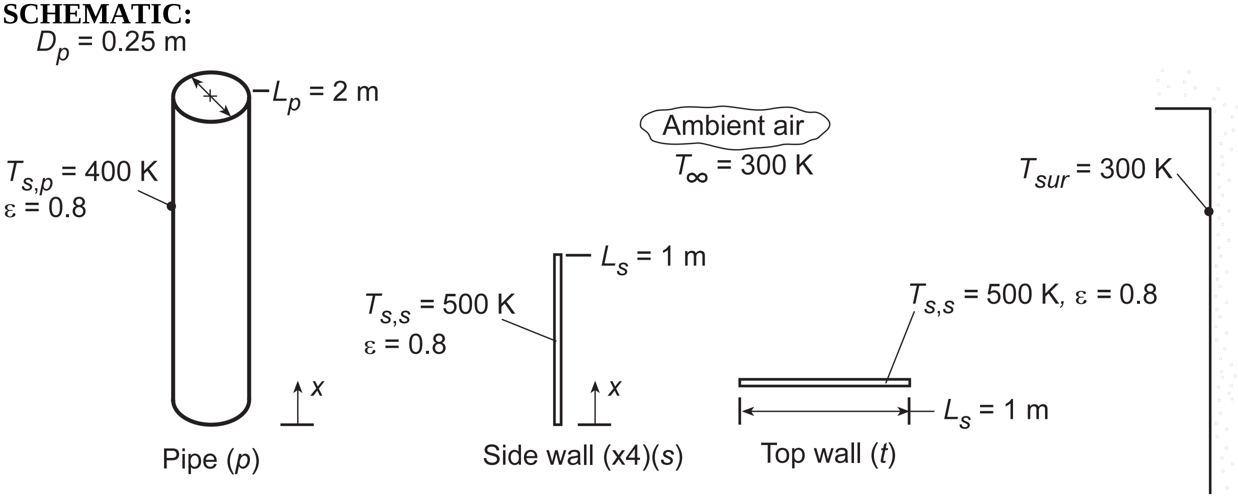
(3) It follows that flow over the horizontal cylinder more closely approximates the situation of the square duct. However, the flow is more streamlined; thinnest along the bottom, and of increasing thickness as the flow rises and eventually breaks away from the upper surface. The edges of the duct disrupt the rising flow, lowering the convection coefficient. As such, we expect the horizontal cylinder results to be systematically higher than for the H-D correlation that accounts for the edges.

PROBLEM 9.50

KNOWN: Dimensions, emissivity and operating temperatures of a wood burning stove. Temperature of ambient air and surroundings.

FIND: Rate of heat transfer.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Quiescent air, (3) Negligible heat transfer from pipe elbow, (4) Free convection from pipe corresponds to that from a vertical plate.

PROPERTIES: *Table A.4*, air (T_f = 400 K): $\nu = 26.41 \times 10^{-6}$ m^2/s, k = 0.0338 W/m·K, $\alpha = 38.3 \times 10^{-6}$ m^2/s, $\beta = 0.0025$ K^{-1}, Pr = 0.69. *Table A.4*, air (T_f = 350 K): $\nu = 20.92 \times 10^{-6}$ m^2/s, k = 0.030 W/m·K, $\alpha = 29.9 \times 10^{-6}$ m^2/s, Pr = 0.70, $\beta = 0.00286$ K^{-1}.

ANALYSIS: Three distinct contributions to the heat rate are made by the 4 side walls, the top surface, and the pipe surface. Hence $q_t = 4q_s + q_t + q_p$, where each contribution includes transport due to convection and radiation.

$$q_s = \bar{h}_s L_s^2 \left(T_{s,s} - T_\infty\right) + h_{rad,s} L_s^2 \left(T_{s,s} - T_{sur}\right)$$

$$q_t = \bar{h}_t L_s^2 \left(T_{s,s} - T_\infty\right) + h_{rad,s} L_s^2 \left(T_{s,s} - T_{sur}\right)$$

$$q_p = \bar{h}_p \left(\pi D_p L_p\right)\left(T_{s,p} - T_\infty\right) + h_{rad,p}\left(\pi D_p L_p\right)\left(T_{s,p} - T_{sur}\right)$$

The radiation coefficients are

$$h_{rad,s} = \varepsilon\sigma\left(T_{s,s} + T_{sur}\right)\left(T_{s,s}^2 + T_{sur}^2\right) = 12.3\,\text{W/m}^2\cdot\text{K}$$

$$h_{rad,p} = \varepsilon\sigma\left(T_{s,p} + T_{sur}\right)\left(T_{s,p}^2 + T_{sur}^2\right) = 7.9\,\text{W/m}^2\cdot\text{K}$$

For the stove side walls, $Ra_{L,s} = g\beta\left(T_{s,s} - T_\infty\right)L_s^3/\alpha\nu$ = 4.84 × 10^9. Similarly, with $(A_s/P) = L_s^2/4L_s$ = 0.25 m, $Ra_{L,t} = 7.57 \times 10^7$ for the top surface, and with L_p = 2 m, $Ra_{L,p} = 3.59 \times 10^{10}$ for the stove pipe.

For the side walls and the pipe, the average convection coefficient may be determined from Eq. 9.26,

$$\overline{Nu}_L = \left\{0.825 + \frac{0.387 Ra_L^{1/6}}{\left[1 + \left(0.492/Pr\right)^{9/16}\right]^{8/27}}\right\}^2$$

Continued...

PROBLEM 9.50 (Cont.)

which yields $\overline{Nu}_{L,s}$ = 199.9 and $\overline{Nu}_{L,p}$ = 377.6. For the top surface, the average coefficient may be obtained from Eq. 9.31,

$$\overline{Nu}_L = 0.15 Ra_L^{1/3}$$

which yields $\overline{Nu}_{L,t}$ = 63.5. With $\bar{h} = \overline{Nu}(k/L)$, the convection coefficients are

$$\bar{h}_s = 6.8\,W/m^2 \cdot K, \quad \bar{h}_t = 8.6\,W/m^2 \cdot K, \quad \bar{h}_p = 5.7\,W/m^2 \cdot K$$

Hence,

$$q_s = \left(\bar{h}_s + h_{rad,s}\right) L_s^2 \left(T_{s,s} - 300\,K\right) = 19.1\,W/m^2 \cdot K\left(1\,m^2\right)\left(200\,K\right) = 3820\,W$$

$$q_t = \left(\bar{h}_t + h_{rad,s}\right) L_s^2 \left(T_{s,s} - 300\,K\right) = 20.9\,W/m^2 \cdot K\left(1\,m^2\right)\left(200\,K\right) = 4180\,W$$

$$q_p = \left(\bar{h}_p + h_{rad,p}\right)\left(\pi D_p L_p\right)\left(T_{s,p} - 300\,K\right) = 13.6\,W/m^2 \cdot K\left(\pi \times 0.25\,m \times 2\,m\right)\left(100\,K\right) = 2140\,W$$

and the total heat rate is

$$q_{tot} = 4q_s + q_t + q_p = 21,600\,W$$ <

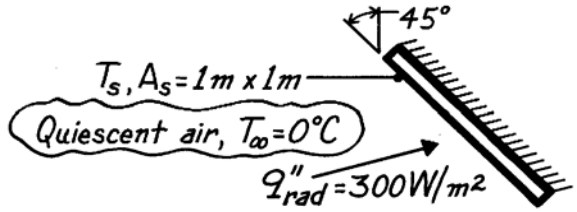
COMMENTS: The amount of heat transfer is significant, and the stove would be capable of maintaining comfortable conditions in a large, living space under harsh (cold) environmental conditions.

PROBLEM 9.51

KNOWN: Plate, 1m × 1m, inclined at 45° from the vertical is exposed to a net radiation heat flux of 300 W/m^2; backside of plate is insulated and ambient air is at 0°C.

FIND: Temperature plate reaches for the prescribed conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Net radiation heat flux (300 W/m^2) includes exchange with surroundings, (2) Ambient air is quiescent, (3) No heat losses from backside of plate, (4) Steady-state conditions.

PROPERTIES: *Table A-4*, Air (assuming T_s = 84°C, $T_f = (T_s + T_\infty)/2$ = (84 + 0)°C/2 = 315K, 1 atm): $\nu = 17.40 \times 10^{-6}$ m^2/s, k = 0.0274 W/m·K, $\alpha = 24.7 \times 10^{-6}$ m^2/s, Pr = 0.705, $\beta = 1/T_f$.

ANALYSIS: From an energy balance on the plate, it follows that $q''_{rad} = q''_{conv}$. That is, the net radiation heat flux into the plate is equal to the free convection heat flux to the ambient air. The temperature of the surface can be expressed as

$$T_s = T_\infty + q''_{rad} / \bar{h}_L \qquad (1)$$

where $\bar{h}_L$ must be evaluated from an appropriate correlation. Since this is the *bottom surface of a heated inclined plate*, "*g*" may be replaced by "*g cos θ*"; hence using Eq. 9.25, find

$$Ra_L = \frac{g\cos\theta\beta\left(T_s - T_\infty\right)L^3}{\nu\alpha} = \frac{9.8\,\text{m/s}^2 \times \cos 45°\left(1/315\text{K}\right)\left(84-0\right)\text{K}\,\left(1\text{m}\right)^3}{17.40\times10^{-6}\text{m}^2/\text{s}\times 24.7\times10^{-6}\text{m}^2/\text{s}} = 4.30\times10^9.$$

Since $Ra_L > 10^9$, conditions are turbulent and Eq. 9.26 is appropriate for estimating $\overline{Nu}_L$

$$\overline{Nu}_L = \left\{0.825 + \frac{0.387\,Ra_L^{1/6}}{\left[1+\left(0.492/Pr\right)^{9/16}\right]^{8/27}}\right\}^2 \qquad (2)$$

$$\overline{Nu}_L = \left\{0.825 + \frac{0.387\left(4.30\times10^9\right)^{1/6}}{\left[1+\left(0.492/0.705\right)^{9/16}\right]^{8/27}}\right\}^2 = 193.2$$

$$\bar{h}_L = \overline{Nu}_L\, k/L = 193.2\times0.0274\,\text{W/m}\cdot\text{K}/1\text{m} = 5.29\,\text{W/m}^2\cdot\text{K}. \qquad (3)$$

Substituting $\bar{h}_L$ from Eq. (3) into Eq. (1), the plate temperature is

$$T_s = 0°\text{C} + 300\,\text{W/m}^2/5.29\,\text{W/m}^2\cdot\text{K} = 57°\text{C}.$$ <

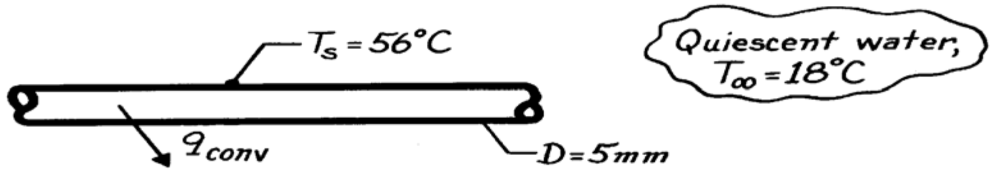
COMMENTS: Note that the resulting value of $T_s \approx 57$°C is substantially lower than the assumed value of 84°C. The calculation should be repeated with a new estimate of T_s, say, 60°C. An alternate approach is to write Eq. (2) in terms of T_s, the unknown surface temperature and then combine with Eq. (1) to obtain an expression which can be solved, by trial-and-error, for T_s.

PROBLEM 9.52

KNOWN: Horizontal rod immersed in water maintained at a prescribed temperature.

FIND: Free convection heat transfer rate per unit length of the rod, q'_{conv}

SCHEMATIC:



ASSUMPTIONS: (1) Water is extensive, quiescent medium.

PROPERTIES: *Table A-6*, Water ($T_f = (T_s + T_\infty)/2 = 310K$): $\rho = 1/v_f = 993.0\ kg/m^3$, $\nu = \mu/\rho = 695 \times 10^{-6}\ N \cdot s/m^2/993.0\ kg/m^3 = 6.999 \times 10^{-7}\ m^2/s$, $\alpha = k/\rho c = 0.628\ W/m \cdot K/993.0\ kg/m^3 \times 4178\ J/kg \cdot K = 1.514 \times 10^{-7}\ m^2/s$, Pr = 4.62, $\beta = 361.9 \times 10^{-6}\ K^{-1}$.

ANALYSIS: The heat rate per unit length by free convection is given as

$$q'_{conv} = \bar{h}_D \cdot \pi D \left(T_s - T_\infty\right). \tag{1}$$

To estimate $\bar{h}_D$, first find the Rayleigh number, Eq. 9.25,

$$Ra_D = \frac{g\beta\left(T_s - T_\infty\right)D^3}{\nu\alpha} = \frac{9.8\,m/s^2\left(361.9 \times 10^{-6} K^{-1}\right)\left(56 - 18\right)K\left(0.005m\right)^3}{6.999 \times 10^{-7} m^2/s \times 1.514 \times 10^{-7} m^2/s} = 1.587 \times 10^5$$

and use Eq. 9.34 for a horizontal cylinder,

$$\overline{Nu}_D = \left\{0.60 + \frac{0.387\,Ra_D^{1/6}}{\left[1 + \left(0.599/Pr\right)^{9/16}\right]^{8/27}}\right\}^2$$

$$\overline{Nu}_D = \left\{0.60 + \frac{0.387\left(1.587 \times 10^5\right)^{1/6}}{\left[1 + \left(0.599/4.62\right)^{9/16}\right]^{8/27}}\right\}^2 = 10.40$$

$$\bar{h}_D = \overline{Nu}_D\,k/D = 10.40 \times 0.628\,W/m \cdot K/0.005m = 1306\,W/m^2 \cdot K. \tag{2}$$

Substituting for $\bar{h}_D$ from Eq. (2) into Eq. (1),

$$q'_{conv} = 1306\,W/m^2 \cdot K \times \pi\left(0.005m\right)\left(56 - 18\right)K = 780\,W/m.$$ <

COMMENTS: (1) Note the relatively large value of $\bar{h}_D$; if the rod were immersed in air, the heat transfer coefficient would be close to 5 $W/m^2 \cdot K$.

(2) Eq. 9.33 with appropriate values of C and n from Table 9.1 could also be used to estimate $\bar{h}_D$. Find

$$\overline{Nu}_D = C\,Ra_D^n = 0.48\left(1.587 \times 10^5\right)^{0.25} = 9.58$$

$$\bar{h}_D = \overline{Nu}_D\,k/D = 9.58 \times 0.628\,W/m \cdot K/0.005m = 1203\,W/m^2 \cdot K.$$

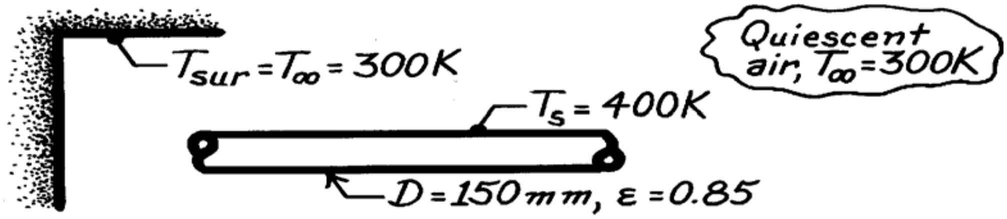
By comparison with the result of Eq. (2), the disparity of the estimates is ~8%.

PROBLEM 9.53

KNOWN: Horizontal, uninsulated steam pipe passing through a room.

FIND: Heat loss per unit length from the pipe.

SCHEMATIC:



ASSUMPTIONS: (1) Pipe surface is at uniform temperature, (2) Air is quiescent medium, (3) Surroundings are large compared to pipe.

PROPERTIES: *Table A-4*, Air ($T_f = (T_s + T_\infty)/2 = 350K$, 1 atm): $\nu = 20.92 \times 10^{-6}\ m^2/s$, $k = 0.030\ W/m\cdot K$, $\alpha = 29.9 \times 10^{-6}\ m^2/s$, $Pr = 0.700$, $\beta = 1/T_f = 2.857 \times 10^{-3}\ K^{-1}$.

ANALYSIS: Recognizing that the heat loss from the pipe will be by free convection to the air and by radiation exchange with the surroundings, we can write

$$q' = q'_{conv} + q'_{rad} = \pi D\left[\bar{h}_D\left(T_s - T_\infty\right) + \varepsilon\sigma\left(T_s^4 - T_{sur}^4\right)\right]. \quad (1)$$

To estimate $\bar{h}_D$, first find Ra_L, Eq. 9.25, and then use the correlation for a horizontal cylinder, Eq. 9.34,

$$Ra_L = \frac{g\beta\left(T_s - T_\infty\right)D^3}{\nu\alpha} = \frac{9.8m/s^2\left(1/350K\right)\left(400-300\right)K\left(0.150m\right)^3}{20.92\times10^{-6}m^2/s\times29.9\times10^{-6}m^2/s} = 1.511\times10^7$$

$$\overline{Nu}_D = \left\{0.60 + \frac{0.387\,Ra_L^{1/6}}{\left[1+\left(0.559/Pr\right)^{9/16}\right]^{8/27}}\right\}^2$$

$$\overline{Nu}_D = \left\{0.60 + \frac{0.387\left(1.511\times10^7\right)^{1/6}}{\left[1+\left(0.559/0.700\right)^{9/16}\right]^{8/27}}\right\}^2 = 31.88$$

$$\bar{h}_D = \overline{Nu}_D \cdot k/D = 31.88\times0.030\,W/m\cdot K/0.15m = 6.38\,W/m^2\cdot K. \quad (2)$$

Substituting for $\bar{h}_D$ from Eq. (2) into Eq. (1), find

$$q' = \pi\left(0.150m\right)\left[6.38\,W/m^2\cdot K\left(400-300\right)K + 0.85\times5.67\times10^{-8}W/m^2\cdot K^4\left(400^4 - 300^4\right)K^4\right]$$

$$q' = 301\,W/m + 397\,W/m = 698\,W/m.$$ <

COMMENTS: (1) Note that for this situation, heat transfer by radiation and free convection are of equal importance.

(2) Using Eq. 9.33 with constants C,n from Table 9.1, the estimate for $\bar{h}_D$ is

$$\overline{Nu}_D = CRa_L^n = 0.125\left(1.511\times10^7\right)^{0.333} = 30.73$$

$$\bar{h}_D = \overline{Nu}_D k/D = 30.73\times0.030\,W/m\cdot K/0.150m = 6.15\,W/m^2\cdot K.$$

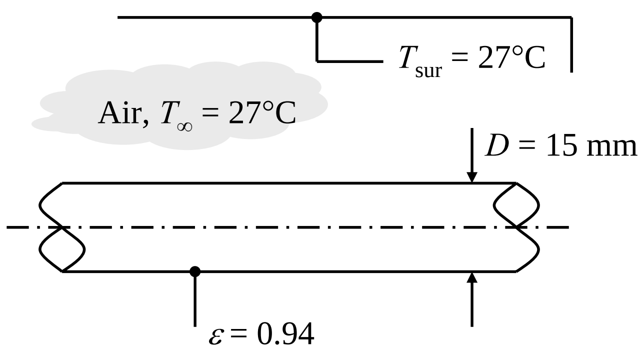
The agreement is within 4% of the Eq. 9.34 result.

PROBLEM 9.54

KNOWN: Diameter and emissivity of horizontal glass cylinder. Temperature of air and surroundings.

FIND: Temperature at which lumped capacitance approximation may be applied.

SCHEMATIC:



ASSUMPTIONS: (1) The quasi-steady approximation holds: the heat transfer coefficient can be evaluated based on steady-state conditions, (2) Air properties can be evaluated at 350 K, (3) Radiation is to large surroundings.

PROPERTIES: *Table A-3*, Glass (T = 300 K): k_g = 1.4 W/m·K; *Table A-4,* Air (T = 350 K): ν = 20.92 $\times 10^{-6}$ m^2/s, α = 29.9 $\times 10^{-6}$ m^2/s, k = 30 $\times 10^{-3}$ W/m·K, Pr = 0.700, $\beta = 1/T_s$ = 1/(350 K) = 0.00286 K^{-1}.

ANALYSIS: The largest heat transfer coefficient for which the lumped capacitance approximation is valid can be found from Bi = 0.1, where the characteristic length is the cylinder radius, r_o. In this case, the heat transfer coefficient should be the effective value that includes both convection and radiation,

$$h_{\text{eff}} = \overline{h} + h_r \tag{1}$$

Therefore, with $Bi = h_{\text{eff}}D/k_g$,

$$h_{\text{eff}} = 0.2\frac{k_g}{D} = 0.2\frac{1.4 \text{ W/m}\cdot\text{K}}{0.015 \text{ m}} = 18.67 \text{ W/m}^2\cdot\text{K} \tag{2}$$

The radiation heat transfer coefficient is given by

$$h_r = \varepsilon\sigma(T_s + T_{\text{sur}})(T_s^2 + T_{\text{sur}}^2) \tag{3}$$

The free convection heat transfer coefficient can be found from the Churchill-Chu correlation,

$$\overline{Nu}_D = \frac{\overline{h}D}{k} = \left\{0.60 + \frac{0.387 Ra_D^{1/6}}{\left[1 + (0.559/Pr)^{9/16}\right]^{8/27}}\right\}^2 \tag{4}$$

Continued...

PROBLEM 9.54 (Cont.)

where the Rayleigh number is:

$$Ra_D = \frac{g\beta(T_s - T_\infty)D^3}{\nu\alpha} \tag{5}$$

Equations (1)-(5) can be solved for the unknowns, including the surface temperature. This can easily be done using *IHT*, but it can also be solved by hand as follows. We begin by taking T_s = 400 K for the purpose of estimating the radiation heat transfer coefficient of Eq. (3):

$$\begin{aligned} h_r &= \varepsilon\sigma(T_s + T_{\text{sur}})(T_s^2 + T_{\text{sur}}^2) \\ &= 0.94 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (400 + 300)\text{K} \times (400^2 + 300^2)\text{K}^2 = 9.33 \text{ W/m}^2 \cdot \text{K} \end{aligned}$$

From Eqs. (1) and (2), $\bar{h} = h_{\text{eff}} - h_r = (18.67 - 9.33) \text{ W/m}^2 \cdot \text{K} = 9.34 \text{ W/m}^2 \cdot \text{K}$ and

$$\overline{Nu}_D = \frac{\bar{h}D}{k} = \frac{9.34 \text{ W/m}^2 \cdot \text{K} \times 0.015 \text{ m}}{30 \times 10^{-3} \text{ W/m} \cdot \text{K}} = 4.67$$

Then Eq. (4) can be solved for Ra_D,

$$\begin{aligned} Ra_D &= \left\{ \frac{1}{0.387} \left(\sqrt{\overline{Nu}_D} - 0.60 \right) \left[1 + (0.559/Pr)^{9/16} \right]^{8/27} \right\}^6 \\ &= \left\{ \frac{1}{0.387} \left(\sqrt{4.67} - 0.60 \right) \left[1 + (0.559/0.707)^{9/16} \right]^{8/27} \right\}^6 = 13{,}200 \end{aligned}$$

Eq. (5) can now be solved for T_s:

$$T_s = T_\infty + Ra_D \frac{\nu\alpha}{g\beta D^3} = 300 \text{ K} + 13{,}200 \times \frac{20.92 \times 10^{-6} \text{ m}^2\text{/s} \times 29.9 \times 10^{-6} \text{ m}^2\text{/s}}{9.8 \text{ m/s}^2 \times 0.00286 \text{ K}^{-1} \times (0.015 \text{ m})^3} = 388 \text{ K}$$

This is reasonably close to the initial assumption of T_s = 400 K. Greater accuracy could be obtained by repeating the calculations with the new estimate of T_s and evaluating air properties at the film temperature. Repeated iterations converge on T_s = 395 K, thus the lumped capacitance approximation is valid for T_s < 395 K. <

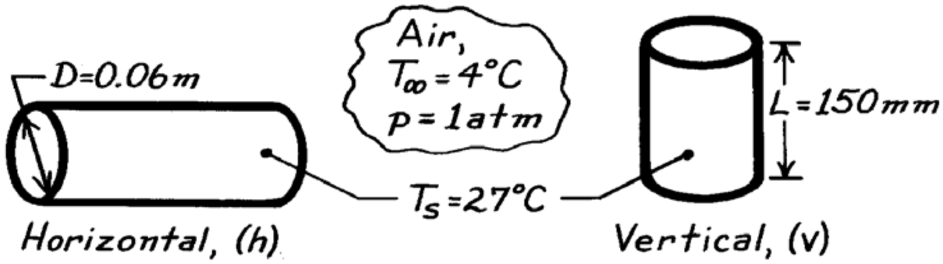
COMMENTS: (1) Because of the relatively small thermal conductivity of glass, the effective heat transfer coefficient must be fairly small, 18.67 $\text{W/m}^2 \cdot \text{K}$, for the lumped capacitance approximation to be valid. (2) The conclusion that lumped capacitance is valid for T_s < 395 K requires further evaluation. If the rod is initially hotter than 395 K, it would be subject to large spatial temperature gradients in the initial stages of cooling. When the temperature meets the Biot criterion, there would still be residual temperature gradients in the rod from the preceding cooling period, so the lumped capacitance method might never be applicable.

PROBLEM 9.55

KNOWN: Dimensions and temperature of beer can in refrigerator compartment.

FIND: Orientation which maximizes cooling rate.

SCHEMATIC:



ASSUMPTIONS: (1) End effects are negligible, (2) Compartment air is quiescent, (3) Constant properties.

PROPERTIES: *Table A-4*, Air (T_f = 288.5K, 1 atm): $\nu = 14.87 \times 10^{-6}\ m^2/s$, k =0.0254 W/m·K, $\alpha = 21.0 \times 10^{-6}\ m^2/s$, Pr = 0.71, $\beta = 1/T_f = 3.47 \times 10^{-3}\ K^{-1}$.

ANALYSIS: The ratio of cooling rates may be expressed as

$$\frac{q_v}{q_h} = \frac{\bar{h}_v}{\bar{h}_h}\frac{\pi DL}{\pi DL}\frac{(T_s - T_\infty)}{(T_s - T_\infty)} = \frac{\bar{h}_v}{\bar{h}_h}.$$

For the *vertical* surface, find

$$Ra_L = \frac{g\beta(T_s - T_\infty)}{\nu\alpha}L^3 = \frac{9.8\,m/s^2 \times 3.47\times10^{-3}\,K^{-1}(23°C)}{(14.87\times10^{-6}m^2/s)(21\times10^{-6}m^2/s)}L^3 = 2.5\times10^9 L^3$$

$$Ra_L = 2.5\times10^9(0.15)^3 = 8.44\times10^6,$$

and using the correlation of Eq. 9.26, $$\overline{Nu}_L = \left\{0.825 + \frac{0.387(8.44\times10^6)^{1/6}}{\left[1+(0.492/0.71)^{9/16}\right]^{8/27}}\right\}^2 = 29.7.$$

Hence $$\bar{h}_L = \bar{h}_v = \overline{Nu}_L\frac{k}{L} = 29.7\frac{0.0254\,W/m\cdot K}{0.15m} = 5.03\,W/m^2\cdot K.$$

For the *horizontal* surface, find $Ra_D = \frac{g\beta(T_s - T_\infty)}{\nu\alpha}D^3 = 2.5\times10^9(0.06)^3 = 5.4\times10^5$

and using the correlation of Eq. 9.34, $$\overline{Nu}_D = \left\{0.60 + \frac{0.387(5.4\times10^5)^{1/6}}{\left[1+(0.559/0.71)^{9/16}\right]^{8/27}}\right\}^2 = 12.24$$

$$\bar{h}_D = \bar{h}_h = \overline{Nu}_D\frac{k}{D} = 12.24\frac{0.0254\,W/m\cdot K}{0.06m} = 5.18\,W/m^2\cdot K.$$

Hence $$\frac{q_v}{q_h} = \frac{5.03}{5.18} = 0.97.$$ <

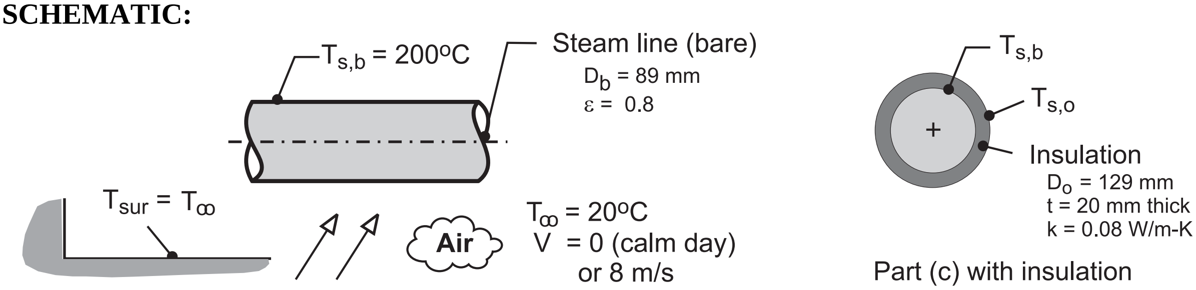
COMMENTS: In view of the uncertainties associated with Eqs. 9.26 and 9.34 and the neglect of end effects, the above result is inconclusive. The cooling rates are approximately the same.

PROBLEM 9.56

KNOWN: A long uninsulated steam line with a diameter of 89 mm and surface emissivity of 0.8 transports steam at 200°C and is exposed to atmospheric air and large surroundings at an equivalent temperature of 20°C.

FIND: (a) The heat loss per unit length for a calm day when the ambient air temperature is 20°C; (b) The heat loss on a breezy day when the wind speed is 8 m/s; and (c) For the conditions of part (a), calculate the heat loss with 20-mm thickness of insulation (k = 0.08 W/m·K). Would the heat loss change significantly with an appreciable wind speed?

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Calm day corresponds to quiescent ambient conditions, (3) Breeze is in crossflow over the steam line, (4) Atmospheric air and large surroundings are at the same temperature; and (5) Emissivity of the insulation surface is 0.8.

PROPERTIES: *Table A-4*, Air ($T_f = (T_s + T_\infty)/2 = 383$ K, 1 atm): $\nu = 2.454 \times 10^{-5}$ m^2/s, k = 0.03251 W/m·K, $\alpha = 3.544 \times 10^{-5}$ m^2/s, Pr = 0.693.

ANALYSIS: (a) The heat loss per unit length from the pipe by convection and radiation exchange with the surroundings is

$$q'_b = q'_{cv} + q'_{rad}$$

$$q'_b = \bar{h}_D P_b \left(T_{s,b} - T_\infty\right) + \varepsilon P_b \sigma \left(T_{s,b}^4 - T_\infty^4\right) \qquad P_b = \pi D_b \tag{1,2}$$

where D_b is the diameter of the bare pipe. Using the Churchill-Chu correlation, Eq. 9.34, for free convection from a horizontal cylinder, estimate $\bar{h}_D$

$$\overline{Nu}_D = \frac{\bar{h} D_b}{k} = \left\{ 0.60 + \frac{0.387\ Ra_D^{1/6}}{\left[1 + \left(0.559 / Pr\right)^{9/16}\right]^{8/27}} \right\}^2 \tag{3}$$

where properties are evaluated at the film temperature, $T_f = (T_s + T_\infty)/2$ and

$$Ra_D = \frac{g\beta\left(T_s - T_\infty\right) D_b^3}{\nu\alpha} \tag{4}$$

Substituting numerical values, find for the *bare* steam line

Ra_D	$\overline{Nu}_D$	$\bar{h}_D$ (W/m^2·K)	q'_{cv} (W/m)	q'_{rad} (W/m)	q'_b (W/m)	
3.73×10^6	21.1	7.71	388	541	929	<

Continued …

PROBLEM 9.56 (Cont.)

(b) For forced convection conditions with V = 8 m/s, use the Churchill-Bernstein correlation, Eq. 7.54,

$$\overline{Nu}_D = \frac{\bar{h}_D D_b}{k} = 0.3 + \frac{0.62\, Re_D^{1/2}\, Pr^{1/3}}{\left[1+\left(0.4/Pr\right)^{2/3}\right]^{1/4}}\left[1+\left(\frac{Re_D}{282,000}\right)^{5/8}\right]^{4/5}$$

where $Re_D = VD/\nu$. Substituting numerical values, find

Re_D	$\overline{Nu}_D$	$\bar{h}_{D,b}$ $(W/m^2 \cdot K)$	q'_{cv} (W/m)	q'_{rad} (W/m)	q'_b (W/m)
2.90×10^4	97.7	35.7	1800	541	2340

<

(c) With 20-mm thickness insulation, and for the calm-day condition, the heat loss per unit length is

$$q'_{ins} = \left(T_{s,o} - T_\infty\right)/R'_{tot} \qquad (1)$$

$$R'_t = R'_{ins} + \left[1/R'_{cv} + 1/R'_{rad}\right]^{-1} \qquad (2)$$

where the thermal resistance of the insulation from Eq. 3.33 is

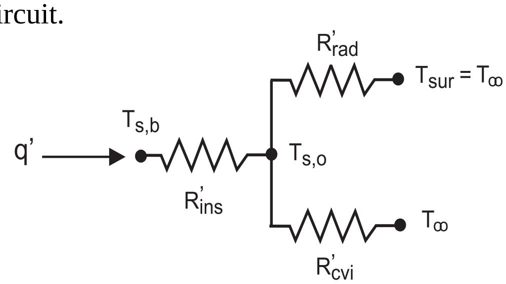
$$R'_{ins} = \ell n\left(D_o/D_b\right)/\left[2\pi k\right] \qquad (3)$$

and the convection and radiation thermal resistances are

$$R'_{cv} = 1/\left(\bar{h}_{D,o}\pi D_o\right) \qquad (4)$$

$$R'_{rad} = 1/\left(\bar{h}_{rad}\ \pi D_o\right) \qquad \bar{h}_{rad,o} = \varepsilon\sigma\left(T_{s,o}+T_\infty\right)\left(T_{s,o}^2 + T_\infty^2\right) \qquad (5,6)$$

The outer surface temperature of the insulation, $T_{s,o}$, can be determined by an energy balance on the *surface node of* the thermal circuit.



$$\frac{T_{s,b} - T_{s,o}}{R'_{ins}} = \frac{T_{s,o} - T_\infty}{\left[1/R'_{cv} + 1/R'_{rad}\right]^{-1}}$$

Substituting numerical values with $D_{b,o}$ = 129 mm, find the following results.

$R'_{ins} = 0.7384\ m \cdot K/W$ $\qquad$ $\bar{h}_{D,o} = 5.30\ W/m^2 \cdot K$

$R'_{cv} = 0.4655\ K/W$ $\qquad$ $\bar{h}_{rad} = 5.65\ W/m^2 \cdot K$

$R'_{rad} = 0.4371\ K/W$ $\qquad$ $q'_{ins} = 187\ W/m$ <

$T_{s,o} = 62.1°C$

Continued …

PROBLEM 9.56 (Cont.)

COMMENTS: (1) For the calm-day conditions, the heat loss by radiation exchange is 58% of the total loss. Using a reflective shield (say, $\varepsilon = 0.1$) on the outer surface could reduce the heat loss by 50%.

(2) The effect of a 8-m/s breeze over the steam line is to increase the heat loss by more than a factor of two above that for a calm day. The heat loss by radiation exchange is approximately 25% of the total loss.

(3) The effect of the 20-mm thickness insulation is to reduce the heat loss to 20% the rate by free convection or to 9% the rate on the breezy day. From the results of part (c), note that the insulation resistance is nearly 3 times that due to the combination of the convection and radiation process thermal resistances. The effect of increased wind speed is to reduce R'_{cv}, but since R'_{ins} is the dominant resistance, the effect will not be very significant.

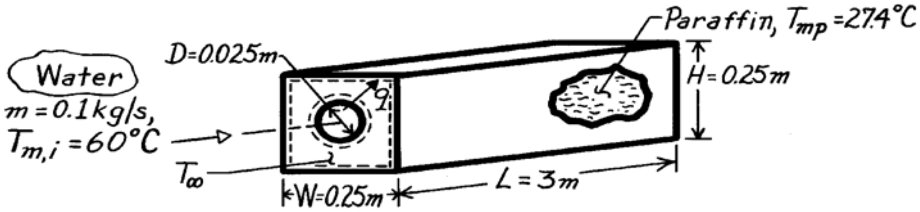
(4) The convection correlation models in *IHT* are especially useful for applications such as the present one to eliminate the tediousness of evaluating properties and performing the calculations. However, it is essential that you have experiences in hand calculations with the correlations before using the software.

PROBLEM 9.57

KNOWN: Length and diameter of tube submerged in paraffin of prescribed dimensions. Properties of paraffin. Inlet temperature, flow rate and properties of water in the tube.

FIND: (a) Water outlet temperature, (b) Heat rate, (c) Time for complete melting.

SCHEMATIC:



ASSUMPTIONS: (1) Water is incompressible liquid with negligible viscous dissipation, (2) Constant properties for water and paraffin, (3) Negligible tube wall conduction resistance, (4) Free convection at outer surface associated with horizontal cylinder in an infinite quiescent medium, (5) Negligible heat loss to surroundings, (6) Fully developed flow in tube.

PROPERTIES: Water (given): c_p = 4185 J/kg·K, k = 0.653 W/m·K, μ = 467 × 10^{-6} kg/s·m, Pr = 2.99; Paraffin (given): T_{mp} = 27.4°C, h_{sf} = 244 kJ/kg, k = 0.15 W/m·K, β = 8 × 10^{-4} K^{-1}, ρ = 770 kg/m^3, ν = 5 × 10^{-6} m^2/s, α = 8.85 × 10^{-8} m^2/s.

ANALYSIS: (a) The overall heat transfer coefficient is

$$\frac{1}{U}=\frac{1}{h_i}+\frac{1}{h_o}.$$

To estimate h_i, find $\quad Re_D=\frac{4\dot{m}}{\pi D\mu}=\frac{4\times 0.1\,kg/s}{\pi\times 0.025m\times 467\times 10^{-6}\,kg/s\cdot m}=10{,}906$

and noting the flow is turbulent, use the Dittus-Boelter correlation

$$Nu_D=0.023\,Re_D^{4/5}\,Pr^{0.3}=0.023(10{,}906)^{4/5}(2.99)^{0.3}=54.3$$

$$h_i=\frac{Nu_D\,k}{D}=\frac{54.3\times 0.653\,W/m\cdot K}{0.025m}=1418\,W/m^2\cdot K.$$

To estimate h_o, find

$$Ra_D=\frac{g\beta(T_s-T_\infty)D^3}{\nu\alpha}=\frac{\left(9.8\,m/s^2\right)8\times 10^{-4}K^{-1}(55-27.4)K(0.025m)^3}{5\times 10^{-6}m^2/s\times 8.85\times 10^{-8}m^2/s}$$

$$Ra_D=7.64\times 10^6$$

and using the correlation of Eq. 9.34, $\quad \overline{Nu}_D=\left\{0.60+\frac{0.387\,Ra_D^{1/6}}{\left[1+(0.559/Pr)^{9/16}\right]^{8/27}}\right\}^2=35.0$

$$h_o=\overline{Nu}_D\frac{k}{D}=35.0\frac{0.15\,W/m\cdot K}{0.025m}=210\,W/m^2\cdot K.$$

Alternatively, using the correlation of Eq. 9.33,

Continued …

PROBLEM 9.57 (Cont.)

$$\overline{Nu}_D = C Ra_D^n \text{ with } C = 0.48,\ n = 0.25 \qquad \overline{Nu}_D = 25.2$$

$$\overline{h}_o = 25.2 \frac{0.15\,W/m\cdot K}{0.025m} = 151\,W/m^2\cdot K.$$

The significant difference in $\overline{h}_o$ values for the two correlations may be due to difficulties associated with high Pr applications of one or both correlations. Continuing with the result from Eq. 9.34,

$$\frac{1}{\overline{U}} = \frac{1}{h_i} + \frac{1}{\overline{h}_o} = \frac{1}{1418} + \frac{1}{210} = 5.467\times10^{-3} m^2\cdot K/W$$

$$\overline{U} = 183\,W/m^2\cdot K.$$

Using Eq. 8.45a, find

$$\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}} = \exp\left(-\frac{\pi DL}{\dot{m}c_p}\overline{U}\right) = \exp\left(-\frac{\pi\times 0.025m\times 3m}{0.1kg/s\times 4185\,J/kg\cdot K}183\frac{W}{m^2\cdot K}\right)$$

$$T_{m,o} = T_\infty - \left(T_\infty - T_{m,i}\right)0.902 = \left[27.4 - \left(27.4-60\right)0.902\right]°C$$

$$T_{m,o} = 56.8°C.$$ <

(b) From an energy balance, the heat rate is

$$q = \dot{m}c_p\left(T_{m,i} - T_{m,o}\right) = 0.1kg/s\times 4185\,J/kg\cdot K\left(60-56.8\right)K = 1335\,W$$ <

or using the rate equation,

$$q = \overline{U}A\Delta T_{\ell m} = 183\,W/m^2\cdot K\pi\left(0.025m\right)3m\frac{\left(60-27.4\right)K - \left(56.8-27.4\right)K}{\ell n\dfrac{60-27.4}{56.8-27.4}}$$

$$q = 1335\,W.$$

(c) Applying an energy balance to a control volume about the paraffin,

$$E_{in} = \Delta E_{st}$$

$$q\cdot t = \rho V h_{sf} = \rho L\left[WH - \pi D^2/4\right]h_{sf}$$

$$t = \frac{770\,kg/m^3\times 3m}{1335\,W}\left[\left(0.25m\right)^2 - \frac{\pi}{4}\left(0.025m\right)^2\right]2.44\times10^5\,J/kg$$

$$t = 2.618\times10^4 s = 7.27\,h.$$ <

COMMENTS: (1) The value of $\overline{h}_o$ is overestimated by assuming an infinite quiescent medium. The fact that the paraffin is enclosed will increase the resistance due to free convection and hence decrease q and increase t.

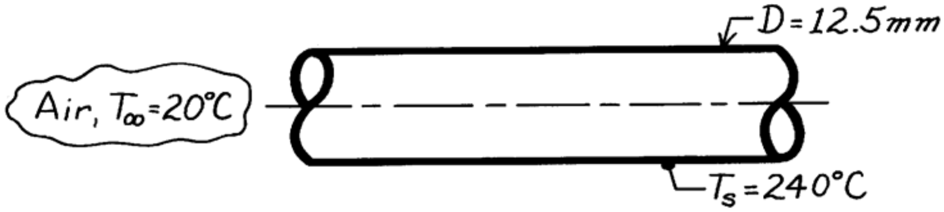
(2) Using $\overline{h}_o = 151\,W/m^2\cdot K$ results in $\overline{U} = 136\,W/m^2\cdot K,\ T_{m,o} = 57.6°C,$ q = 1009 W and t = 9.62 h.

PROBLEM 9.58

KNOWN: Horizontal tube, 12.5mm diameter, with surface temperature 240°C located in room with an air temperature 20°C.

FIND: Heat transfer rate per unit length of tube due to convection.

SCHEMATIC:



ASSUMPTIONS: (1) Ambient air is quiescent, (2) Surface radiation effects are not considered.

PROPERTIES: *Table A-4*, Air (T_f = 400K, 1 atm): $\nu = 26.41 \times 10^{-6}$ m^2/s, k= 0.0338 W/m·K, α = 38.3×10^{-6} m^2/s, Pr = 0.690, $\beta = 1/T_f = 2.5 \times 10^{-3}$ K^{-1}.

ANALYSIS: The heat rate from the tube, per unit length of the tube, is

$$q' = \bar{h}\pi D\left(T_s - T_\infty\right)$$

where $\bar{h}$ can be estimated from the correlation, Eq. 9.34,

$$\overline{Nu}_D = \left\{0.60 + \frac{0.387\,Ra_D^{1/6}}{\left[1+\left(0.559/Pr\right)^{9/16}\right]^{8/27}}\right\}^2 .$$

From Eq. 9.25,

$$Ra_D = \frac{g\beta\left(T_s - T_\infty\right)D^3}{\nu\alpha} = \frac{9.8\,m/s^2 \times 2.5\times10^{-3}K^{-1}\left(240-20\right)K\times\left(12.5\times10^{-3}m\right)^3}{26.41\times10^{-6}m^2/s\times38.3\times10^{-6}m^2/s} = 10,410.$$

Hence, $$\overline{Nu}_D = \left\{0.60 + \frac{0.387\left(10,410\right)^{1/6}}{\left[1+\left(0.559/0.690\right)^{9/16}\right]^{8/27}}\right\}^2 = 4.40$$

$$\bar{h} = \frac{k}{D}\overline{Nu}_D = \frac{0.0338\,W/m\cdot K}{12.5\times10^{-3}m}\times4.40 = 11.9\,W/m^2\cdot K.$$

The heat rate is

$$q' = 11.9\,W/m^2\cdot K\times\pi\left(12.5\times10^{-3}m\right)\left(240-20\right)K = 103\,W/m.$$ <

COMMENTS: Heat loss rate by radiation, assuming an emissivity of 1.0 for the surface, is

$$q'_{rad} = \varepsilon P\sigma\left(T_s^4 - T_\infty^4\right) = 1\times\pi\left(12.5\times10^{-3}m\right)\times5.67\times10^{-8}\frac{W}{m^2\cdot K^4}\left[\left(240+273\right)^4-\left(20+273\right)^4\right]K^4$$

$$q'_{rad} = 138\,W/m.$$

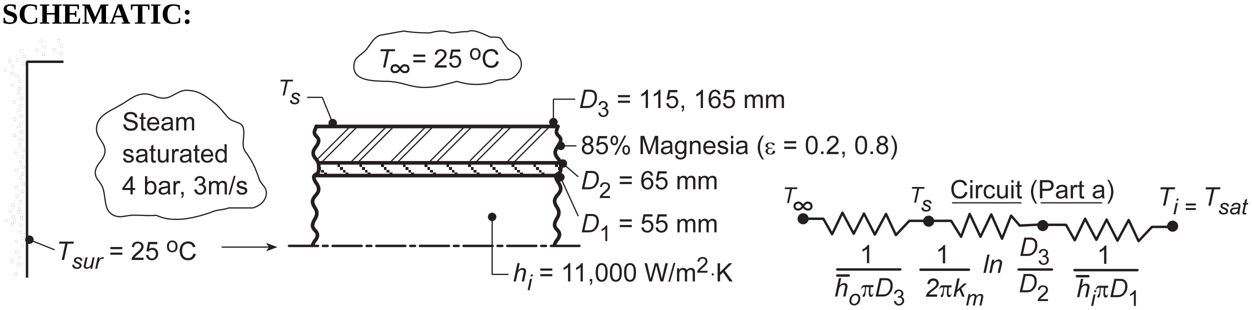
Note that P = π D. Note also this estimate assumes the surroundings are at ambient air temperature. In this instance, $q'_{rad} > q'_{conv}$.

PROBLEM 9.59

KNOWN: Insulated steam tube exposed to atmospheric air and surroundings at 25°C.

FIND: (a) Heat transfer rate by free convection to the room, per unit length of the tube; effect on quality, x, at outlet of 30 m length of tube; (b) Effect of radiation on heat transfer and quality of outlet flow; (c) Effect of emissivity and insulation thickness on heat rate.

SCHEMATIC:



ASSUMPTIONS: (1) Ambient air is quiescent, (2) Negligible surface radiation (part a), (3) Tube wall resistance negligible.

PROPERTIES: Steam tables, steam (sat., 4 bar): i_f = 566 kJ/kg, T_{sat} = 416 K, i_g = 2727 kJ/kg, $i_{fg} = h_{fg}$ 2160 kJ/kg, v_g = 0.476 m^3/kg; *Table A.3*, magnesia, 85% (310 K): k_m = 0.051 W/m·K; *Table A.4*, air (assume T_s = 60°C, T_f = (60 + 25)°C/2 = 315 K, 1 atm): ν = 17.4 × 10^{-6} m^2/s, k = 0.0274 W/m·K, α = 24.7 × 10^{-6} m^2/s, Pr = 0.705, T_f = 1/315 K = 3.17 × 10^{-3} K^{-1}.

ANALYSIS: (a) The heat rate per unit length of the tube (see sketch) is given as,

$$q' = \frac{T_i - T_\infty}{R'_t} \qquad \text{where} \qquad \frac{1}{R'_t} = \left[\frac{1}{\bar{h}_o \pi D_3} + \frac{1}{2\pi k_m}\ln\frac{D_3}{D_2} + \frac{1}{\bar{h}_i \pi D_1}\right]^{-1} \qquad (1,2)$$

To estimate $\bar{h}_o$, we have assumed $T_s \approx 60°C$ in order to calculate Ra_L from Eq. 9.25,

$$Ra_D = \frac{g\beta(T_s - T_\infty)D_3^3}{\nu\alpha} = \frac{9.8\,m/s^2 \times 3.17\times10^{-3}\,K^{-1}(60-25)K(0.115\,m)^3}{17.4\times10^{-6}\,m^2/s \times 24.7\times10^{-6}\,m^2/s} = 3.85\times10^6 .$$

The appropriate correlation is Eq. 9.34; find

$$\overline{Nu}_D = \left\{0.60 + \frac{0.387(Ra_D)^{1/6}}{\left[1+(0.559/Pr)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.60 + \frac{0.387\left(3.85\times10^6\right)^{1/6}}{\left[1+(0.559/0.705)^{9/16}\right]^{8/27}}\right\}^2 = 21.4$$

$$\bar{h}_o = \frac{k}{D_3}\overline{Nu}_D = \frac{0.0274\,W/m\cdot K}{0.115\,m}\times 21.4 = 5.09\,W/m^2\cdot K .$$

Substituting numerical values into Eq. (2), find

$$\frac{1}{R'_t} = \left[\frac{1}{5.09\,W/m^2\cdot K\times\pi 0.115\,m} + \frac{1}{2\pi\times0.051\,W/m\cdot K}\ln\frac{115}{65} + \frac{1}{11,000\,W/m^2\cdot K\pi\times0.055\,m}\right]^{-1} = 0.430\,W/m\cdot K$$

and from Eq. (1), $$q' = 0.430\,W/m\cdot K(416-298)K = 50.8\,W/m$$ <

Continued...

PROBLEM 9.59 (Cont.)

We need to verify that the assumption of $T_s = 60°C$ is reasonable. From the thermal circuit,

$$T_s = T_\infty + q'/\bar{h}_o \pi D_3 = 25^\circ C + 50.8\,W/m \Big/ \left(5.09\,W/m^2 \cdot K \times \pi \times 0.115\,m\right) = 53^\circ C.$$

Another calculation using $T_s = 53°C$ would be appropriate for a more precise result.

Assuming q' is constant, the enthalpy of the steam at the outlet (L = 30 m), i_2, is

$$i_2 = i_1 - q' \cdot L/\dot{m} = 2727\,kJ/kg - 50.8\,W/m \times 30\,m/0.015\,kg/s = 2625\,kJ/kg$$

where $\dot{m} = \rho_g A_c u_m$ with $\rho_g = 1/v_g$ and $A_c = \pi D_1^2/4$. For negligible pressure drop,

$$x = \left(i_2 - i_f\right)/i_{fg} = \left(2625 - 566\right)kJ/kg \Big/ \left(2160\,kJ/kg\right) = 0.953.$$ <

(b) With radiation, we first determine T_s by performing an energy balance at the outer surface, where

$$q_i' = q_{conv,o}' + q_{rad}'$$

$$\frac{T_i - T_s}{R_i'} = \bar{h}_o \pi D_3 \left(T_s - T_\infty\right) + \pi D_3 \varepsilon \sigma \left(T_s^4 - T_{sur}^4\right)$$

and

$$R_i' = \frac{1}{\bar{h}_i \pi D_1} + \frac{1}{2\pi k_m} \ln \frac{D_3}{D_2}$$

From knowledge of T_s, $q_i' = \left(T_i - T_s\right)/R_i'$ may then be determined. Using the *Correlations* and *Properties* Tool Pads of IHT to determine $\bar{h}_o$ and the properties of air evaluated at $T_f = (T_s + T_\infty)/2$, the following results are obtained.

	Condition	T_s (°C)	q_i' (W/m)	x	
	ε = 0.8, D_3 = 115 mm	41.8	56.9	0.948	<
(c)	ε = 0.8, D_3 = 165 mm	33.7	37.6	0.966	<
	ε = 0.2, D_3 = 115 mm	49.4	52.6	0.952	<
	ε = 0.2, D_3 = 165 mm	38.7	35.9	0.967	<

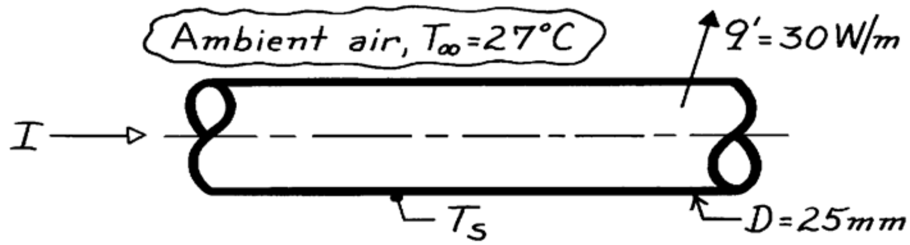
COMMENTS: Clearly, a significant reduction in heat loss may be realized by increasing the insulation thickness. Although T_s, and hence $q_{conv,o}'$, increases with decreasing ε, the reduction in q_{rad}' is more than sufficient to reduce the heat loss.

PROBLEM 9.60

KNOWN: Dissipation rate of an electrical cable suspended in air.

FIND: Surface temperature of the cable, T_s.

SCHEMATIC:



ASSUMPTIONS: (1) Quiescent air, (2) Cable in horizontal position, (3) Negligible radiation exchange.

PROPERTIES: *Table A-4,* Air ($T_f = (T_s + T_\infty)/2 = 325K$, based upon initial estimate for T_s, 1 atm): $\nu = 18.41 \times 10^{-6}$ m^2/s, k = 0.0282 W/m·K, $\alpha = 26.2 \times 10^{-6}$ m^2/s, Pr = 0.704.

ANALYSIS: From the rate equation on a unit length basis, the surface temperature is

$$T_s = T_\infty + q'/\pi D\bar{h}$$

where $\bar{h}$ is estimated by an appropriate correlation. Since such a calculation requires knowledge of T_s, an iteration procedure is required. Begin by assuming $T_s = 77°C$ and calculated Ra_D,

$$Ra_D = g\beta\Delta T D^3/\nu\alpha \quad \text{where} \quad \Delta T = T_s - T_\infty \quad \text{and} \quad T_f = (T_s + T_\infty)/2 \qquad (1,2,3)$$

For air, $\beta = 1/T_f$, and substituting numerical values,

$$Ra_D = 9.8\frac{m}{s^2}(1/325K)(77-27)K(0.025m)^3/18.41\times10^{-6}\frac{m^2}{s}\times26.2\times10^{-6}\frac{m^2}{s} = 4.884\times10^4.$$

Using the Churchill-Chu relation, find $\bar{h}$.

$$\overline{Nu}_D = \frac{\bar{h}D}{k} = \left\{0.60 + \frac{0.387\,Ra_D^{1/6}}{\left[1+(0.559/Pr)^{9/16}\right]^{8/27}}\right\}^2 \qquad (4)$$

$$\bar{h} = \frac{0.0282\,W/m\cdot K}{0.025m}\left\{0.60 + \frac{0.387\left(4.884\times10^4\right)^{1/6}}{\left[1+(0.559/0.704)^{9/16}\right]^{8/27}}\right\}^2 = 7.28\,W/m^2\cdot K.$$

Substituting numerical values into Eq. (1), the calculated value for T_s is

$$T_s = 27°C + (30\,W/m)/\pi\times0.025m\times7.28\,W/m^2\cdot K = 79.5°C.$$

This value is very close to the assumed value (77°C), but an iteration with a new value of 79°C is warranted. Using the same property values, find for this iteration:

$$Ra_D = 5.08\times10^4 \qquad \bar{h} = 7.35\,W/m^2\cdot K \qquad T_s = 79°C.$$ <

We conclude that T_s = 79°C is a good estimate for the surface temperature.

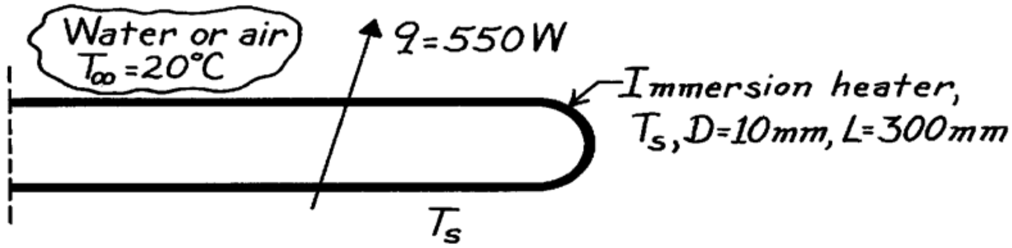
COMMENTS: Recognize that radiative exchange is likely to be significant and would have the effect of reducing the estimate for T_s.

PROBLEM 9.61

KNOWN: Dissipation rate of an immersion heater in a large tank of water.

FIND: Surface temperature in water and, if accidentally operated, in air.

SCHEMATIC:



ASSUMPTIONS: (1) Quiescent ambient fluid, (2) Negligible radiative exchange.

PROPERTIES: *Table A-6*, Water and *Table A-4*, Air:

	T(K)	$k\cdot 10^3$(W/m·K)	$\nu\cdot 10^7$(μ/ρ,m^2/s)	$\alpha\cdot 10^7$(k/ρc_p,m^2/s)	Pr	$\beta\cdot 10^6$(K^{-1})
Water	315	634	6.25	1.531	4.16	400.4
Air	1500	100	2400	3500	0685	666.7

ANALYSIS: From the rate equation, the surface temperature, T_s, is

$$T_s = T_\infty + q/\left(\pi D L \bar{h}\right) \qquad (1)$$

where $\bar{h}$ is estimated by an appropriate correlation. Since such a calculation requires knowledge of T_s, an iteration procedure is required. Begin by assuming for *water* that T_s = 64°C such that T_f = 315K. Calculate the Rayleigh number,

$$Ra_D = \frac{g\beta\Delta T D^3}{\nu\alpha} = \frac{9.8\,m/s^2 \times 400.4\times10^{-6}K^{-1}(64-20)K(0.010m)^3}{6.25\times10^{-7}m^2/s\times1.531\times10^{-7}m^2/s} = 1.804\times10^6. \qquad (2)$$

Using the Churchill-Chu relation, find

$$\overline{Nu}_D = \frac{\bar{h}D}{k} = \left\{0.60 + \frac{0.387\,Ra_D^{1/6}}{\left[1+\left(0.559/Pr\right)^{9/16}\right]^{8/27}}\right\}^2 \qquad (3)$$

$$\bar{h} = \frac{0.634\,W/m\cdot K}{0.01m}\left\{0.60 + \frac{0.387\left(1.804\times10^6\right)^{1/6}}{\left[1+\left(0.559/4.16\right)^{9/16}\right]^{8/27}}\right\}^2 = 1301\,W/m^2\cdot K.$$

Substituting numerical values into Eq. (1), the calculated value for T_s in *water* is

$$T_s = 20°C + 550\,W/\pi\times0.010m\times0.30m\times1301\,W/m^2\cdot K = 64.8°C.$$ <

Continued …

PROBLEM 9.61 (Cont.)

Our initial assumption of $T_s = 64°C$ is in excellent agreement with the calculated value.

With accidental operation in *air*, the heat transfer coefficient will be nearly a factor of 100 less. Suppose $\bar{h} \approx 25\,W/m^2 \cdot K$, then from Eq. (1), $T_s \approx 2360°C$. Very likely the heater will burn out. Using air properties at $T_f \approx 1500K$ and Eq. (2), find $Ra_D = 1.815 \times 10^2$. Using Eq. 9.33, $Nu_D = C\,Ra_D^n$ with C= 0.85 and n = 0.188 from Table 9.1, find $\bar{h} = 22.6\,W/m^2 \cdot K$. Hence, our first estimate for the surface temperature in *air* was reasonable,

$$T_s \approx 2300°C. \qquad <$$

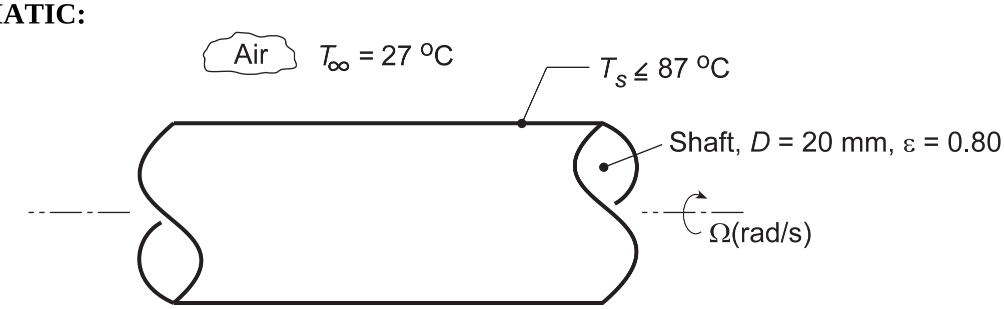
However, radiation exchange will be the dominant mode, and would reduce the estimate for T_s. Generally such heaters could not withstand operating temperatures above 1000°C and safe operation in air is not possible.

PROBLEM 9.62

KNOWN: Motor shaft of 20-mm diameter operating in ambient air at T_∞ = 27°C with surface temperature $T_s \leq 87°C$.

FIND: Convection coefficients and/or heat removal rates for different heat transfer processes: (a) For a rotating horizontal cylinder as a function of rotational speed 5000 to 15,000 rpm using the recommended correlation, (b) For free convection from a horizontal stationary shaft; investigate whether mixed free and forced convection effects for the range of rotational speeds in part (a) are significant using the recommended criterion; (c) For radiation exchange between the shaft having an emissivity of 0.8 and the surroundings also at ambient temperature, $T_{sur} = T_\infty$; and (d) For cross flow of ambient air over the stationary shaft, required air velocities to remove the heat rates determined in part (a).

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Shaft is horizontal with isothermal surface.

PROPERTIES: *Table A.4*, Air ($T_f = (T_s + T_\infty)/2$ = 330 K, 1 atm): $\nu = 18.91 \times 10^{-6}\ m^2/s$, k = 0.02852 W/m·K, $\alpha = 26.94 \times 10^{-6}\ m^2/s$, Pr = 0.7028, $\beta = 1/T_f$.

ANALYSIS: (a) The recommended correlation for a horizontal rotating shaft is

$$\overline{Nu}_D = 0.133 Re_D^{2/3} Pr^{1/3} \qquad Re_D < 4.3\times10^5 \qquad 0.7 < Pr < 670$$

where the Reynolds number is

$$Re_D = \Omega D^2/\nu$$

and $\Omega\ (rad/s)$ is the rotational velocity. Evaluating properties at $T_f = (T_s + T_\infty)/2$, find for ω = 5000 rpm,

$$Re_D = (5000 rpm \times 2\pi\ rad/rev / 60 s/min)(0.020 m)^2 / 18.91\times10^{-6}\ m^2/s = 11,076$$

$$\overline{Nu}_D = 0.133(11,076)^{2/3}(0.7028)^{1/3} = 58.75$$

$$\overline{h}_{D,rot} = \overline{Nu}_D\, k/D = 58.75 \times 0.02852\ W/m\cdot K/0.020 m = 83.8\ W/m^2\cdot K \qquad <$$

The heat rate per unit shaft length is

$$q'_{rot} = \overline{h}_{D,rot}(\pi D)(T_s - T_\infty) = 83.8\ W/m^2\cdot K(\pi\times0.020 m)(87-27)^\circ C = 316\ W/m \qquad <$$

The convection coefficient and heat rate as a function of rotational speed are shown in a plot below.

(b) For the stationary shaft condition, the free convection coefficient can be estimated from the Churchill-Chu correlation, Eq. (9.34) with

Continued...

PROBLEM 9.62 (Cont.)

$$\mathrm{Ra_D} = \frac{g\beta\Delta T D^3}{\nu\alpha}$$

$$\mathrm{Ra_D} = \frac{9.8\,\mathrm{m/s^2}\,(1/330\mathrm{K})(87-27)\mathrm{K}\,(0.020\mathrm{m})^3}{18.91\times10^{-6}\,\mathrm{m^2/s}\times 26.94\times10^{-6}\,\mathrm{m^2/s}} = 27,981$$

$$\overline{\mathrm{Nu}}_D = \left\{0.60 + \frac{0.387\mathrm{Ra}_D^{1/6}}{\left[1+(0.559/\mathrm{Pr})^{9/16}\right]^{8/27}}\right\}^2$$

$$\overline{\mathrm{Nu}}_D = \left\{0.60 + \frac{0.387(27,981)^{1/6}}{\left[1+(0.559/0.7028)^{9/16}\right]^{8/27}}\right\}^2 = 5.61$$

$$\bar{h}_{D,fc} = \overline{\mathrm{Nu}}_D\, k/D = 5.61\times 0.02852\,\mathrm{W/m\cdot K}/0.020\mathrm{m} = 8.00\,\mathrm{W/m^2\cdot K}$$

$$q'_{fc} = 8.00\,\mathrm{W/m^2\cdot K}\,(\pi\times0.020\mathrm{m})(87-27)^\circ\mathrm{C} = 30.2\,\mathrm{W/m}$$ <

Mixed free and forced convection effects may be significant if

$$\mathrm{Re_D} < 4.7\left(\mathrm{Gr}_D^3/\mathrm{Pr}\right)^{0.137}$$

where $Gr_D = Ra_D/Pr$, find using results from above and in part (a) for ω = 5000 rpm,

$$11,076\ \ ?<?\ \ 4.7\left[(27,981/0.7028)^3/0.7018\right]^{0.137} = 383$$

We conclude that free convection effects are not significant for rotational speeds above 5000 rpm.

(c) Considering radiation exchange between the shaft and the surroundings,

$$h_{rad} = \varepsilon\sigma(T_s + T_{sur})\left(T_s^2 + T_{sur}^4\right)$$

$$h_{rad} = 0.8\times5.67\times10^{-8}\,\mathrm{W/m^2\cdot K}(360+300)\left(360^2+300^2\right)\mathrm{K}^3 = 6.57\,\mathrm{W/m^2\cdot K}$$ <

and the heat rate by radiation exchange is

$$q'_{rad} = h_{rad}(\pi D)(T_s - T_{sur})$$

$$q'_{rad} = 6.57\,\mathrm{W/m^2\cdot K}(\pi\times0.020\mathrm{m})(87-27)\mathrm{K} = 24.8\,\mathrm{W/m}$$ <

(d) For cross flow of ambient air at a velocity V over the shaft, the convection coefficient can be estimated using the Churchill-Bernstein correlation, Eq. 7.54, with

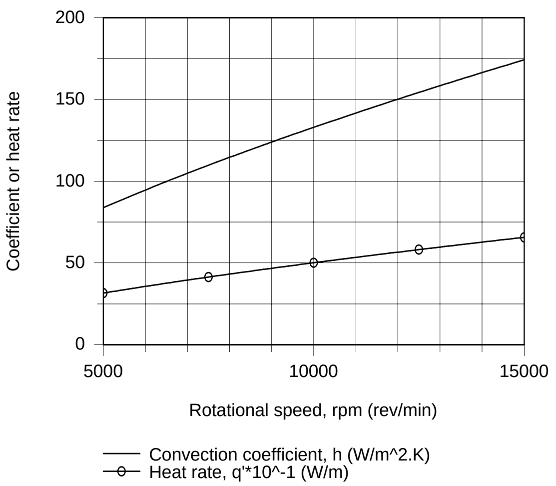
$$\mathrm{Re}_{D,cf} = \frac{VD}{\nu}$$

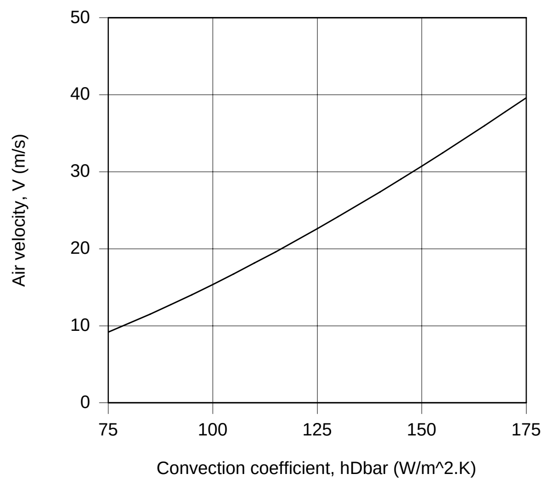
$$\overline{\mathrm{Nu}}_{D,cf} = \bar{h}_{D,cf}\,D/k = 0.3 + \frac{0.62\,\mathrm{Re}_{D,cf}^{1/2}\,\mathrm{Pr}^{1/3}}{\left[1+(0.4/\mathrm{Pr})^{2/3}\right]^{1/4}}\left[1+\left(\frac{\mathrm{Re}_{D,cf}}{282,000}\right)^{5/8}\right]^{4/5}$$

Continued...

PROBLEM 9.62 (Cont.)

From the plot below (left) for the rotating shaft condition of part (a), $\overline{h}_{D,rot}$ vs. rpm, note that the convection coefficient varies from approximately 75 to 175 W/m^2 · K. Using the *IHT Correlations Tool, Forced Convection, Cylinder*, which is based upon the above relations, the range of air velocities V required to achieve $\overline{h}_{D,cf}$ in the range 75 to 175 W/m^2 · K was computed and is plotted below (right).





Note that the air cross-flow velocities are quite substantial in order to remove similar heat rates for the rotating shaft condition.

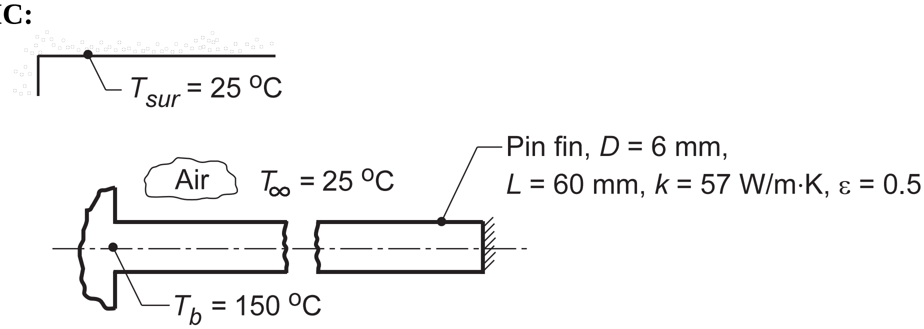
COMMENTS: We conclude for the rotational speed and surface temperature conditions, free convection effects are not significant. Further, radiation exchange, part (c) result, is less than 10% of the convection heat loss for the lowest rotational speed condition.

PROBLEM 9.63

KNOWN: Horizontal pin fin of 6-mm diameter and 60-mm length fabricated from plain carbon steel (k = 57 W/m·K, ε = 0.5). Fin base maintained at T_b = 150°C. Ambient air and surroundings at 25°C.

FIND: Fin heat rate, q_f, by two methods: (a) Analytical solution using average fin surface temperature of $\overline{T}_s = 125^\circ C$ to estimate the free convection and linearized radiation coefficients; comment on sensitivity of fin heat rate to choice of $\overline{T}_s$; and, (b) Finite-difference method when coefficients are based upon local temperatures, rather than an average fin surface temperature; compare result of the two solution methods.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in the pin fin, (3) Ambient air is quiescent and extensive, (4) Surroundings are large compared to the pin fin, and (5) Fin tip is adiabatic.

PROPERTIES: *Table A.4*, Air ($T_f = \left(\overline{T}_s + T_\infty\right)/2$ = 348 K): ν = 20.72 × 10^{-6} m^2/s, k = 0.02985 W/m·K, α = 29.60 × 10^{-6} m^2/s, Pr = 0.7003, β = $1/T_f$.

ANALYSIS: (a) The heat rate for the pin fin with an adiabatic tip condition is, Eq. 3.81,

$$q_f = M \tanh(mL) \qquad (1)$$

$$M = \left(\overline{h}_{tot} PkA_c\right)^{1/2} \theta_b \qquad m = \left(hP/kA_c\right)^{1/2} \qquad (2,3)$$

$$P = \pi D \qquad A_c = \pi D^2/4 \qquad \theta_b = T_b - T_\infty \qquad (4\text{-}6)$$

and the average coefficient is the sum of the convection and linearized radiation processes, respectively,

$$\overline{h}_{tot} = \overline{h}_{fc} + \overline{h}_{rad} \qquad (7)$$

evaluated at $\overline{T}_s = 125^\circ C$ with $\overline{T}_f = \left(\overline{T}_s + T_\infty\right)/2 = 75^\circ C = 348\,K$.

Estimating $\overline{h}_{fc}$*:* For the horizontal cylinder, Eq. 9.34, with

$$Ra_D = \frac{g\beta\Delta T D^3}{\nu\alpha}$$

Continued …

PROBLEM 9.63 (Cont.)

$$Ra_D = \frac{9.8\,m/s^2\,(1/348K)(125-25)(0.006m)^3}{20.72\times10^{-6}\,m^2/s\times29.60\times10^{-6}\,m^2/s} = 991.79$$

$$\overline{Nu}_D = \left\{0.60 + \frac{0.387\,Ra_D^{1/6}}{\left[1+(0.559/Pr)^{9/16}\right]^{8/27}}\right\}^2$$

$$\overline{Nu}_D = \left\{0.60 + \frac{0.387\,(991.79)^{1/6}}{\left[1+(0.559/0.7003)^{9/16}\right]^{8/27}}\right\}^2 = 2.603$$

$$\overline{h}_{fc} = \overline{Nu}_D\,k/D = 2.603\times0.02985\,W/m\cdot K/0.006m = 12.95\,W/m^2\cdot K$$

Calculating $\overline{h}_{rad}$ **:** The linearized radiation coefficient is

$$\overline{h}_{rad} = \varepsilon\sigma\left(\overline{T}_s + T_{sur}\right)\left(\overline{T}_s^2 + T_{sur}^2\right) \qquad (8)$$

$$\overline{h}_{rad} = 0.5\times5.67\times10^{-8}\,W/m^2\cdot K^4\,(398+298)\left(398^2+298^2\right)K^3 = 4.88\,W/m^2\cdot K$$

Substituting numerical values into Eqs. (1-7) , find

$$q_{fin} = 2.04W$$ <

with $\theta_b = 125\,K,\ A_c = 2.827\times10^{-5}m^2,\ P = 0.01885\,m,\ m = 14.44\,m^{-1},\ M = 2.909\,W,$ and $\overline{h}_{tot} = 17.83\,W/m^2\cdot K$.

Using the *IHT Model, Extended Surfaces, Rectangular Pin Fin,* with the *Correlations Tool* for *Free Convection* and the *Properties Tool* for *Air*, the above analysis was repeated to obtain the following results.

$\overline{T}_s\,(^\circ C)$	115	120	125	130	135
$q_f\,(W)$	1.989	2.012	2.035	2.057	2.079
$(q_f - q_{f,o})/q_{fo}$ (%)	-2.3	-1.1	0	+1.1	+2.2

The fin heat rate is not very sensitive to the choice of $\overline{T}_S$ for the range T_s = 125 ± 10 °C. For the base case condition, the fin tip temperature is T(L) = 114 °C so that $\overline{T}_S \approx (T(L) + T_b)/2$ = 132°C would be consistent assumed value.

Continued …

PROBLEM 9.63 (Cont.)

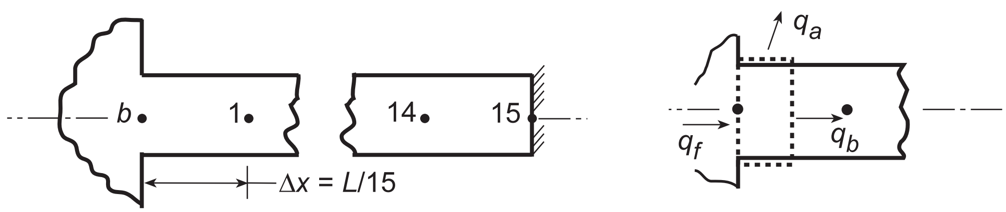
(b) Using the *IHT Tool, Finite-Difference Equation, Steady- State, Extended Surfaces,* the temperature distribution was determined for a 15-node system from which the fin heat rate was determined. The local free convection and linearized radiation coefficients $h_{tot} = h_{fc} + h_{rad,}$ were evaluated at local temperatures, T_m, using IHT with the *Correlations Tool, Free Convection, Horizontal Cylinder*, and the *Properties Tool* for *Air*, and Eq. (8). The local coefficient h_{tot} vs. T_s is nearly a linear function for the range $114 \le T_s \le 150°C$ so that it was reasonable to represent h_{tot} (T_s) as a *Lookup Table Function.* The fin heat rate follows from an energy balance on the base node, (see schematic next page)

$$q_f = q_a + q_b = (0.08949 + 1.879)\,W = 1.97\,W$$ <

$$q_a = h_b\,(P\Delta x/2)(T_b - T_\infty)$$

$$q_b = kA_c\,(T_b - T_1)/\Delta x$$

where T_b = 150°C, T_1 = 418.3 K = 145.3°C, and $h_b = h_{tot}$ (T_b) = l8.99 $W/m^2 \cdot K$.



Considering variable coefficients, the fin heat rate is -3.3% lower than for the analytical solution with the assumed $\overline{T}_S$ = 125°C.

COMMENTS: (1) To validate the FDE model for part (b), we compared the temperature distribution and fin heat rate using a constant h_{tot} with the analytical solution ($\overline{T}_S$ = 125°C). The results were identical indicating that the 15-node mesh is sufficiently fine.

(2) The fin temperature distribution (K) for the IHT finite-difference model of part (b) is

Tb	T01	T02	T03	T04	T05	T06	T07
423	418.3`	414.1	410.3	406.8	403.7	401	398.6

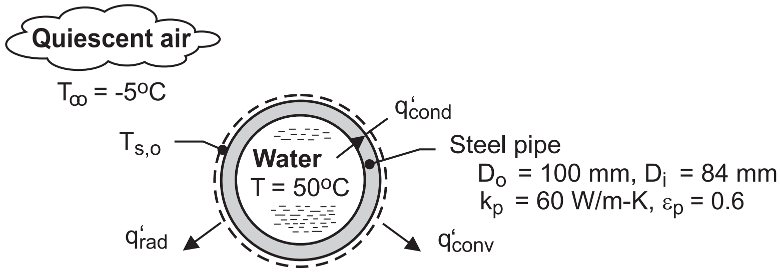
T08	T09	T10	T11	T12	T13	T14	T15
396.6	394.9	393.5	392.4	391.7	391.2	391	390.9

PROBLEM 9.64

KNOWN: Diameter, thickness, emissivity and thermal conductivity of steel pipe. Temperature of water flow in pipe. Cost of producing hot water.

FIND: Cost of daily heat loss from an uninsulated pipe.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Negligible convection resistance for water flow, (3) Negligible radiation from pipe surroundings, (4) Quiescent air, (5) Constant properties.

PROPERTIES: *Table A-4*, air (p = 1 atm, $T_f \approx 295K$): $k_a = 0.0259$ W/m·K. $\nu = 15.45 \times 10^{-6}$ m²/s, $\alpha = 21.8 \times 10^{-6}$ m²/s, Pr = 0.708, $\beta = 3.39 \times 10^{-3}$ K^{-1}.

ANALYSIS: Performing an energy balance for a control surface about the outer surface, $q'_{cond} = q'_{conv} + q'_{rad}$, it follows that

$$\frac{T - T_{s,o}}{R'_{cond}} = \bar{h}\pi D_o \left(T_{s,o} - T_\infty\right) + \varepsilon_p \pi D_o \sigma T_{s,o}^4 \qquad (1)$$

where $R'_{cond} = \ell n\left(D_o / D_i\right)/2\pi k_p = \ell n\left(100/84\right)/2\pi\left(60\,W/m\cdot K\right) = 4.62 \times 10^{-4}\,m\cdot K/W$. The convection coefficient may be obtained from the Churchill and Chu correlation. Hence, with $Ra_D = g\beta(T_{s,o} - T_\infty)\, D_o^3/\alpha\nu = 9.8\,m/s^2 \times 3.39\times10^{-3}K^{-1}\left(0.1m\right)^3\left(T_{s,o} - 268K\right)/\left(21.8\times15.45\times10^{-12}m^4/s^2\right)$

$= 98,637\ \left(T_{s,o} - 268\right)$,

$$\overline{Nu}_D = \left\{0.60 + \frac{0.387\,Ra_D^{1/6}}{\left[1+\left(0.559/Pr\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.60 + 2.182\left(T_{s,o} - 268\right)^{1/6}\right\}^2$$

$$\bar{h} = \frac{k_a}{D_o}\overline{Nu}_D = 0.259\,W/m^2\cdot K\left\{0.60 + 2.182\left(T_{s,o} - 268\right)^{1/6}\right\}^2$$

Substituting the foregoing expression for $\bar{h}$, as well as values of R'_{cond}, D_o, ε_p and σ into Eq. (1), an iterative solution yields $\qquad T_{s,o} = 322.9\,K = 49.9°C$

It follows that $\bar{h} = 6.10\,W/m^2\cdot K$, and the heat loss per unit length of pipe is

$$q' = q'_{conv} + q'_{rad} = 6.10\,W/m^2\cdot K\left(\pi\times0.1m\right)54.9K + 0.6\left(\pi\times0.1m\right)5.67\times10^{-8}\,W/m^2\cdot K^4\left(322.9K\right)^4$$

$$= \left(105.2 + 116.2\right)W/m = 221.4\,W/m$$

The corresponding daily energy loss is $\quad Q' = 0.221\,kW/m \times 24\,h/d = 5.3\,kW\cdot h/m\cdot d$

and the associated cost is $\quad C' = \left(5.3\,kW\cdot h/m\cdot d\right)\left(\$0.10/kW\cdot h\right) = \$0.53/m\cdot d \qquad <$

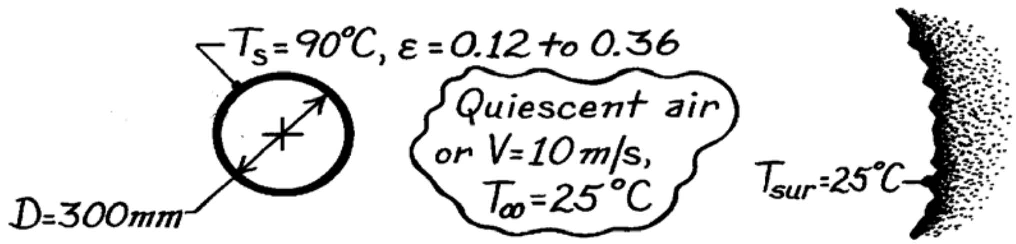
COMMENTS: (1) The heat loss is significant, and the pipe should be insulated. (2) The conduction resistance of the pipe wall is negligible relative to the combined convection and radiation resistance at the outer surface. Hence, the temperature of the outer surface is only slightly less than that of the water.

PROBLEM 9.65

KNOWN: Insulated, horizontal pipe with aluminum foil having emissivity which varies from 0.12 to 0.36 during service. Pipe diameter is 300 mm and its surface temperature is 90°C.

FIND: Effect of emissivity degradation on heat loss with ambient air at 25°C and (a) quiescent conditions and (b) cross-wind velocity of 10 m/s.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Surroundings are large compared to pipe, (3) Pipe has uniform temperature.

PROPERTIES: *Table A-4*, Air (T_f = (90 + 25)°C/2 = 330K, 1 atm): $\nu = 18.9 \times 10^{-6}$ m^2/s, k = 28.5×10^{-3} W/m·K, $\alpha = 26.9 \times 10^{-6}$ m^2/s, Pr = 0.703.

ANALYSIS: The heat loss per unit length from the pipe is

$$q' = \bar{h}P\left(T_s - T_\infty\right) + \varepsilon\sigma P\left(T_s^4 - T_{sur}^4\right)$$

where P = πD and $\bar{h}$ needs to be evaluated for the two ambient air conditions.

(a) *Quiescent air*. Treating the pipe as a horizontal cylinder, find

$$Ra_D = \frac{g\beta\left(T_s - T_\infty\right)D^3}{\nu\alpha} = \frac{9.8\,m/s^2\left(1/330K\right)\left(90-25\right)K\left(0.30\,m\right)^3}{18.9\times10^{-6}m^2/s\times26.9\times10^{-6}m^2/s} = 1.025\times10^8$$

and using the Churchill-Chu correlation for $10^{-5} < Ra_D < 10^{12}$.

$$\overline{Nu}_D = \left\{0.60 + \frac{0.387Ra_D^{1/6}}{\left[1+\left(0.559/Pr\right)^{9/16}\right]^{8/27}}\right\}^2$$

$$\overline{Nu}_D = \left\{0.60 + \frac{0.387\left(1.025\times10^8\right)^{1/6}}{\left[1+\left(0.559/0.703\right)^{9/16}\right]^{8/27}}\right\}^2 = 56.93$$

$$\bar{h}_D = \overline{Nu}_D k/D = 56.93\times0.0285\ W/m\cdot K/0.300m = 5.4\,W/m^2\cdot K.$$

Continued …

PROBLEM 9.65 (Cont.)

Hence, the heat loss is

$$q' = 5.4\,\text{W/m}^2\cdot\text{K}\left(\pi 0.30\text{m}\right)\left(90-25\right)\text{K} + \varepsilon\times 5.67\times 10^{-8}\,\text{W/m}^2\cdot\text{K}\left(\pi 0.300\text{m}\right)\left(363^4-298^4\right)\text{K}^4$$

$$q' = 331+506\varepsilon\ \begin{cases}\varepsilon = 0.12 \rightarrow q' = (331+61) = 392\,\text{W/m} & <\\ \varepsilon = 0.36 \rightarrow q' = (331+182) = 513\,\text{W/m} & <\end{cases}$$

The radiation effect accounts for 16 and 35%, respectively, of the heat rate.

(b) *Cross-wind condition*. With a cross-wind, find

$$Re_D = \frac{VD}{\nu} = \frac{10\,\text{m/s}\times 0.30\text{m}}{18.9\times 10^{-6}\text{m}^2/\text{s}} = 1.587\times 10^5$$

and using the Hilpert correlation where C = 0.027 and m = 0.805 from Table 7.2,

$$\overline{Nu}_D = C\,Re_D^m\,Pr^{1/3} = 0.027\left(1.587\times 10^5\right)^{0.805}(0.703)^{1/3} = 368.9$$

$$\bar{h}_D = Nu_D\cdot k/D = 368.9\times 0.0285\,\text{W/m}\cdot\text{K}/0.300\text{m} = 35\,\text{W/m}^2\cdot\text{K}.$$

Recognizing that *combined* free and forced convection conditions may exist, from Eq. 9.64 with n = 4,

$$Nu_m^4 = Nu_F^4 + Nu_N^4 \qquad \bar{h}_m = \left(5.4^4+35^4\right)^{1/4} = 35\,\text{W/m}^2\cdot\text{K}$$

we find forced convection dominates. Hence, the heat loss is

$$q' = 35\,\text{W/m}^2\cdot\text{K}\left(\pi 0.300\text{m}\right)\left(90-25\right)\text{K} + \varepsilon\times 5.67\times 10^{-8}\,\text{W/m}^2\cdot\text{K}\left(\pi 0.300\text{m}\right)\left(393^4-298^4\right)\text{K}^4$$

$$q' = 2144+853\varepsilon\ \begin{cases}\varepsilon = 0.12 \rightarrow q' = 2144+102 = 2246\,\text{W/m} & <\\ \varepsilon = 0.36 \rightarrow q' = 2144+307 = 2451\,\text{W/m} & <\end{cases}$$

The radiation effect accounts for 5 and 13%, respectively, of the heat rate.

COMMENTS: (1) For high velocity wind conditions, radiation losses are quite low and the degradation of the foil is not important. However, for low velocity and quiescent air conditions, radiation effects are significant and the degradation of the foil can account for a nearly 25% change in heat loss.

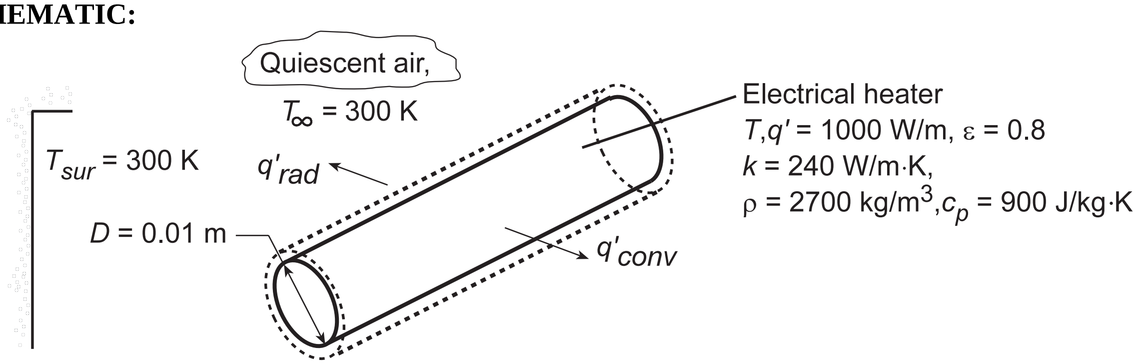
(2) The radiation coefficient is in the range 0.83 to 2.48 $\text{W/m}^2\cdot\text{K}$ for ε = 0.12 and 0.36, respectively. Compare these values with those for convection.

PROBLEM 9.66

KNOWN: Diameter, emissivity, and power dissipation of cylindrical heater. Temperature of ambient air and surroundings.

FIND: Steady-state temperature of heater and time required to come within 10°C of this temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Air is quiescent, (2) Duct wall forms large surroundings about heater, (3) Heater may be approximated as a lumped capacitance.

PROPERTIES: *Table A.4*, air (Obtained from *Properties* Tool Pad of IHT).

ANALYSIS: Performing an energy balance on the heater, the final (steady-state) temperature may be obtained from the requirement that $q' = q'_{conv} + q'_{rad}$, or

$$q' = \overline{h}(\pi D)(T - T_\infty) + h_r(\pi D)(T - T_{sur})$$

where $\overline{h}$ is obtained from Eq. 9.34 and $h_r = \varepsilon\sigma(T + T_{sur})(T^2 + T_{sur}^2)$. Using the *Correlations* Tool Pad of IHT to evaluate $\overline{h}$, this expression may be solved to obtain

T = 854 K = 581°C <

Under transient conditions, the energy balance is of the form, $\dot{E}'_{st} = q' - q'_{conv} - q'_{rad}$, or

$$\rho c_p \left(\pi D^2/4\right) dT/dt = q' - \overline{h}(\pi D)(T - T_\infty) - h_r(\pi D)(T - T_{sur})$$

Using the IHT *Lumped Capacitance* model with the *Correlations* Tool Pad, the above expression is integrated from t = 0, for which T_i = 562.4 K, to the time for which T = 844 K. The integration yields

t = 183s <

The value of T_i = 562.4 K corresponds to the steady-state temperature for which the power dissipation is balanced by forced convection and radiation (see solution to Problem 7.50).

COMMENTS: The forced convection coefficient (Problems 7.49 and 7.50) of 105 W/m²·K is much larger than that associated with free convection for the steady-state conditions of this problem (14.6 W/m²·K). However, because of the correspondingly larger heater temperature, the radiation coefficient with free convection (42.9 W/m²·K) is much larger than that associated with forced convection (15.9 W/m²·K).

PROBLEM 9.67

KNOWN: Cylindrical sensor of 12.5 mm diameter positioned horizontally in quiescent air at 27°C.

FIND: An expression for the free convection coefficient as a function of only $\Delta T = T_s - T_\infty$ where T_s is the sensor temperature.

ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform temperature over cylindrically shaped sensor, (3) Ambient air extensive and quiescent.

PROPERTIES: *Table A-4*, Air (T_f, 1 atm): $\beta = 1/T_f$ and

T_s (°C)	T_f (K)	$\nu \times 10^6$ m²/s	$\alpha \times 10^6$ m²/s	$k \times 10^3$ W/m·K	Pr
30	302	16.09	22.8	26.5	0.707
55	314	17.30	24.6	27.3	0.705
80	327	18.61	26.5	28.3	0.703

ANALYSIS: For the cylindrical sensor, using Eqs. 9.25 and 9.34,

$$Ra_D = \frac{g\beta\Delta T D^3}{\nu\alpha} \qquad \overline{Nu}_D = \frac{\bar{h}_D D}{k} = \left\{0.60 + \frac{0.387 Ra_D^{1/6}}{\left[1+\left(0.559/Pr\right)^{9/16}\right]^{8/27}}\right\}^2 \qquad (1,2)$$

where properties are evaluated at $T_f = (T_s + T_\infty)/2$. With $30 \le T_s \le 80$°C and $T_\infty = 27$°C, $302 \le T_f \le 326$ K. Using properties evaluated at the mid-range of T_f, $\bar{T}_f = 314\,K$, find

$$Ra_D = \frac{9.8\,m/s^2\left(1/314K\right)\Delta T\left(0.0125\,m\right)^3}{17.30\times10^{-6} m^2/s \times 24.6\times10^{-6} m^2/s} = 143.2\Delta T$$

$$\bar{h}_D = \frac{0.0273\,W/m\cdot K}{0.0125\,m}\left\{0.60 + \frac{0.387\left(143\Delta T\right)^{1/6}}{\left[1+\left(0.559/0.705\right)^{9/16}\right]^{8/27}}\right\}^2$$

$$\bar{h}_D = 2.184\left\{0.60 + 0.734\Delta T^{1/6}\right\}^2. \qquad (3) \quad <$$

COMMENTS: (1) The effect of using a fixed film temperature, $\bar{T}_f = 314\,K = 41$°C, for the full range $30 \le T_s \le 80$°C can be seen by comparing results from the approximate Eq. (3) and the correlation, Eq. (2), with the proper film temperature. The results are summarized in the table.

		Correlation			Eq. (3)
T_s (°C)	$\Delta T = T_s - T_\infty$ (°C)	Ra_D	$\overline{Nu}_D$	$\bar{h}_D\left(W/m^2\cdot K\right)$	$\bar{h}_D\left(W/m^2\cdot K\right)$
30	3	518	2.281	4.83	4.80
55	28	4011	3.534	7.72	7.71

The approximate expression for $\bar{h}_D$ is in excellent agreement with the correlation.

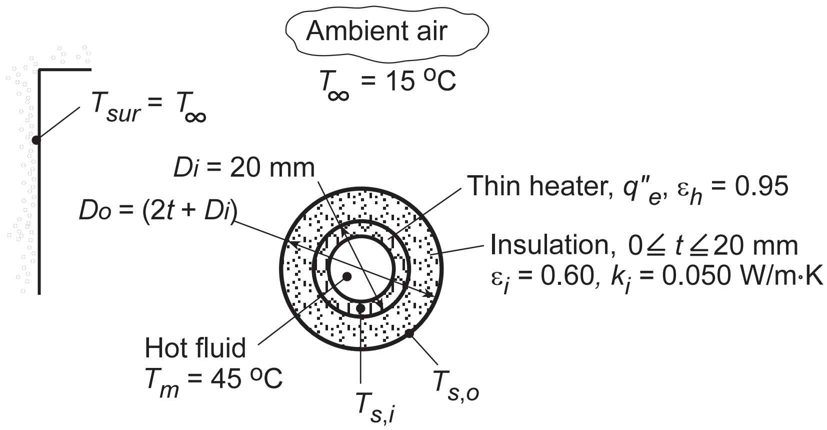
(2) In calculating heat rates it may be important to consider radiation exchange with the surroundings.

PROBLEM 9.68

KNOWN: Thin-walled tube mounted horizontally in quiescent air and wrapped with an electrical tape passing hot fluid in an experimental loop.

FIND: (a) Heat flux q''_e from the heating tape required to prevent heat loss from the hot fluid when (a) neglecting and (b) including radiation exchange with the surroundings, (c) Effect of insulation on q''_e and convection/radiation rates.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Ambient air is quiescent and extensive, (3) Surroundings are large compared to the tube.

PROPERTIES: *Table A.4*, Air ($T_f = (T_s + T_\infty)/2 = (45 + 15)°C/2 = 303$ K, 1 atm): $\nu = 16.19 \times 10^{-6}$ m²/s, $\alpha = 22.9 \times 10^{-6}$ m²/s, $k = 26.5 \times 10^{-3}$ W/m·K, Pr = 0.707, $\beta = 1/T_f$.

ANALYSIS: (a,b) To prevent heat losses from the hot fluid, the heating tape temperature must be maintained at T_m; hence $T_{s,i} = T_m$. From a surface energy balance,

$$q''_e = q''_{conv} + q''_{rad} = \left(\bar{h}_{D_i} + h_r\right)\left(T_{s,i} - T_\infty\right)$$

where the linearized radiation coefficient, Eq. 1.9, is $h_r = \varepsilon\sigma\left(T_{s,i} + T_\infty\right)\left(T_{s,i}^2 + T_\infty^2\right)$, or

$$h_r = 0.95 \times 5.67 \times 10^{-8}\,\text{W/m}^2 \cdot \text{K}^4\,(318 + 288)\left(318^2 + 288^2\right)\text{K}^3 = 6.01\,\text{W/m}^2 \cdot \text{K}.$$

Neglecting radiation: For the horizontal cylinder, Eq. 9.34 yields

$$Ra_D = \frac{g\beta\left(T_{s,i} - T_\infty\right)D_i^3}{\nu\alpha} = \frac{9.8\,\text{m/s}^2\,(1/303\,\text{K})(45 - 15)\,\text{K}\,(0.020\,\text{m})^3}{16.19 \times 10^{-6}\,\text{m}^2/\text{s} \times 22.9 \times 10^{-6}\,\text{m}^2/\text{s}} = 20,900$$

$$\overline{Nu}_D = \frac{\bar{h}_{D_i} D_i}{k} = \left\{0.60 + \frac{0.387 Ra_D^{1/6}}{\left[1 + \left(0.559/Pr\right)^{9/16}\right]^{8/27}}\right\}^2$$

Continued …

PROBLEM 9.68 (Cont.)

$$\bar{h}_{D_i} = \frac{0.0265\,W/m\cdot K}{0.020\,m}\left\{0.60 + \frac{0.386\left(20,900\right)^{1/6}}{\left[1+\left(0.559/0.707\right)^{9/16}\right]^{8/27}}\right\}^2 = 6.90\,W/m^2\cdot K$$

Hence, neglecting radiation, the required heat flux is

$$q''_e = 6.90\,W/m^2\cdot K\left(45-15\right)K = 207\,W/m^2\cdot K$$ <

Considering radiation: The required heat flux considering radiation is

$$q''_e = \left(6.90+6.01\right)W/m^2\cdot K\left(45-15\right)K = 387\,W/m^2\cdot K$$ <

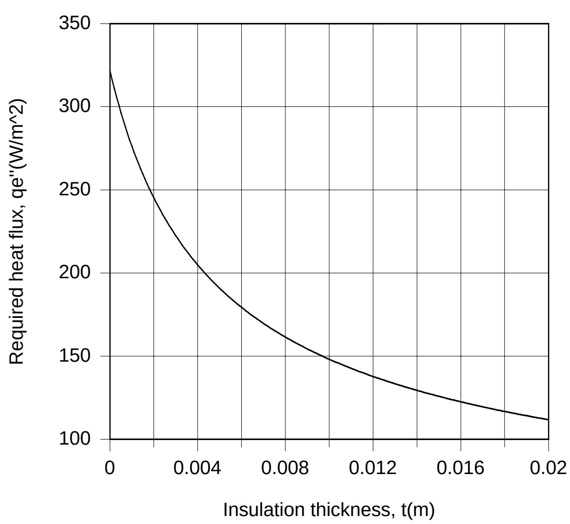
(c) With insulation, the surface energy balance must be modified to account for an increase in the outer diameter from D_i to $D_o = D_i + 2t$ and for the attendant thermal resistance associated with conduction across the insulation. From an energy balance at the inner surface of the insulation,

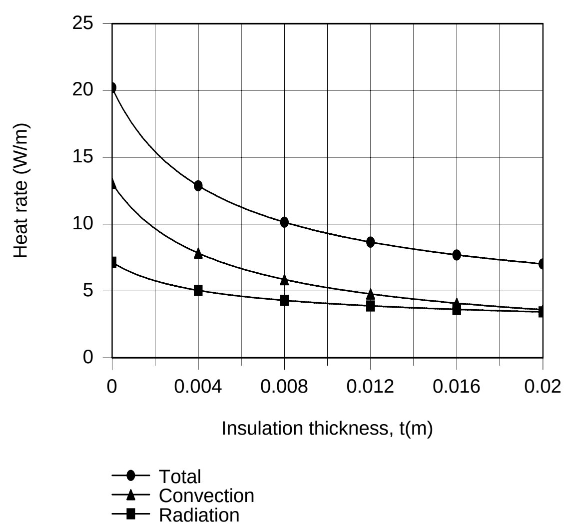
$$q''_e\left(\pi D_i\right) = q'_{cond} = \frac{2\pi k_i\left(T_m - T_{s,o}\right)}{\ln\left(D_o/D_i\right)}$$

and from an energy balance at the outer surface,

$$q'_{cond} = q'_{conv} + q'_{rad} = \pi D_o\left(\bar{h}_{D_o} + h_r\right)\left(T_{s,o} - T_\infty\right)$$

The foregoing expressions may be used to determine $T_{s,o}$ and q''_e as a function of t, with the IHT *Correlations* and *Properties* Tool Pads used to evaluate $\bar{h}_{D_o}$. The desired results are plotted as follows.





By adding 20 mm of insulation, the required power dissipation is reduced by a factor of approximately 3. Convection and radiation heat rates at the outer surface are comparable.

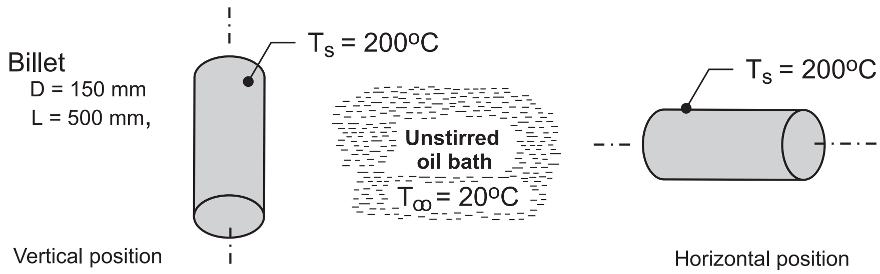
COMMENTS: Over the range of insulation thickness, $T_{s,o}$ decreases from 45°C to 20°C, while $\bar{h}_{D_o}$ and h_r decrease from 6.9 to 3.5 $W/m^2\cdot K$ and from 3.8 to 3.3 $W/m^2\cdot K$, respectively.

PROBLEM 9.69

KNOWN: A billet of stainless steel AISI 316 with a diameter of 150 mm and length 500 mm emerges from a heat treatment process at 200°C and is placed into an unstirred oil bath maintained at 20°C.

FIND: (a) Determine whether it is advisable to position the billet in the bath with its centerline horizontal or vertical in order to decrease to the cooling time, and (b) Estimate the time for the billet to cool to 30°C for the better positioning arrangement.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions for part (a), (2) Oil bath approximates a quiescent fluid, (3) Consider only convection from the lateral surface of the cylindrical billet; and (4) For part (b), the billet has a uniform initial temperature.

PROPERTIES: *Table A-5*, Engine oil ($T_f = (T_s + T_\infty)/2$): see Comment 1. *Table A-1*, AISI 316 (400 K): ρ = 8238 kg/m^3, c_p = 468 J/kg·K, k = 15 W/m·K.

ANALYSIS: (a) For the purpose of determining whether the horizontal or vertical position is preferred for faster cooling, consider only free convection from the lateral surface. The heat loss from the lateral surface follows from the rate equation

$$q = \bar{h}\, A_s \left(T_s - T_\infty\right)$$

Vertical position. The lateral surface of the cylindrical billet can be considered as a vertical surface of height L, width P = πD, and area A_s = PL. The Churchill-Chu correlation, Eq. 9.26, is appropriate to estimate $\bar{h}_L$,

$$\overline{Nu}_L = \frac{\bar{h}_L L}{k} = \left\{0.825 + \frac{0.387\ Ra_L^{1/6}}{\left[1+\left(0.492/Pr\right)^{9/16}\right]^{8/27}}\right\}^2$$

$$Ra_L = \frac{g\beta\left(T_s - T_\infty\right)L^3}{\nu\alpha}$$

with properties evaluated at $T_f = (T_s + T_\infty)/2$.

Horizontal position. In this position, the billet is considered as a long horizontal cylinder of diameter D for which the Churchill-Chu correlation of Eq. 9.34 is appropriate to estimate $\bar{h}_D$,

$$\overline{Nu}_L = \frac{\bar{h}_D D}{k} = \left\{0.60 + \frac{0.387\ Ra_D^{1/6}}{\left[1+\left(0.559/Pr\right)^{9/16}\right]^{8/27}}\right\}^2$$

Continued …

PROBLEM 9.69 (Cont.)

$$Ra_D = \frac{g\beta(T_s - T_\infty)D^3}{\nu\alpha}$$

with properties evaluated at T_f. The heat transfer area is also $A_s = PL$.

Using the foregoing relations in *IHT* with the thermophysical properties library as shown in Comment 1, the analysis results are tabulated below.

$Ra_L = 1.36 \times 10^{11}$	$\overline{Nu}_L = 801$	$\bar{h}_L = 218\ W/m^2 \cdot K$	(vertical)
$Ra_D = 3.67 \times 10^9$	$\overline{Nu}_D = 245$	$\bar{h}_D = 221\ W/m^2 \cdot K$	(horizontal)

Recognize that the orientation has a small effect on the convection coefficient for these conditions, but we'll select the horizontal orientation as the preferred one.

(b) Evaluate first the Biot number to determine if the lumped capacitance method is valid.

$$Bi = \frac{\bar{h}_D(D_o/2)}{k} = \frac{221\ W/m^2 \cdot K(0.150\ m/2)}{15\ W/m \cdot K} = 1.1$$

Since Bi >> 0.1, the spatial effects are important and we should use the one-term series approximation for the infinite cylinder, Eq. 5.52. Since $\bar{h}_D$ will decrease as the billet cools, we need to estimate an average value for the cooling process from 200°C to 30°C. Based upon the analysis summarized in Comment 1, use $\bar{h}_D = 119\ W/m^2 \cdot K$. Using the transient model for the infinite cylinder in *IHT*, (see Comment 2) find for $T(r_o, t_o) = 30°C$,

$$t_o = 3845\ s = 1.1\ h$$ <

COMMENTS: (1) The *IHT* code using the convection correlation functions to estimate the coefficients is shown below. This same code was used to calculate $\bar{h}_D$ for the range $30 \le T_s \le 200°C$ and determine that an average value for the cooling period of part (b) is 119 $W/m^2 \cdot K$.

```

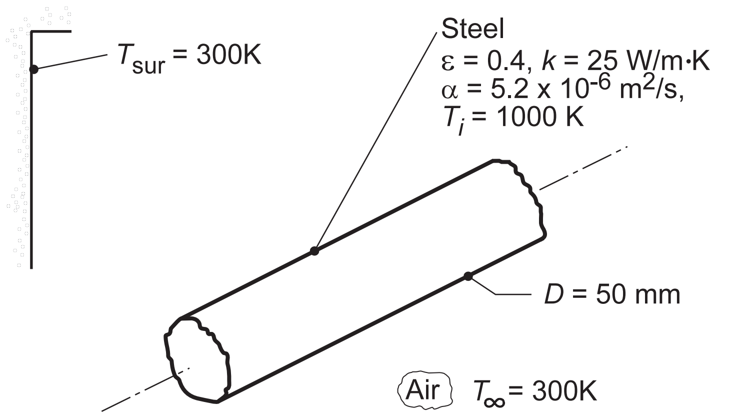
PROBLEM 9.70

KNOWN: Diameter, initial temperature and emissivity of long steel rod. Temperature of air and surroundings.

FIND: (a) Average surface convection coefficient, (b) Effective radiation coefficient, (c,d) Maximum allowable conveyor time.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible effect of forced convection, (2) Constant properties, (3) Large surroundings, (4) Quiescent air.

PROPERTIES: Stainless steel (given): k = 25 W/m·K, $\alpha = 5.2 \times 10^{-6}$ m^2/s; *Table A.4*, Air (T_f = 650 K, 1 atm): $\nu = 6.02 \times 10^{-5}$ m^2/s, $\alpha = 8.73 \times 10^{-5}$ m^2/s, k = 0.0497 W/m·K, Pr = 0.69.

ANALYSIS: (a) For free convection from a horizontal cylinder,

$$Ra_D = \frac{g\beta(T_s - T_\infty)D^3}{\alpha\nu} = \frac{9.8\,m/s^2\,(1/650\,K)(1000-300)K\,(0.05\,m)^3}{6.02\times 8.73\times 10^{-10}\,m^4/s^2} = 2.51\times 10^5$$

The Churchill and Chu correlation yields

$$\overline{Nu}_D = \left\{0.60 + \frac{0.387 Ra_D^{1/6}}{\left[1+(0.559/Pr)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.60 + \frac{0.387\left(2.51\times 10^5\right)^{1/6}}{\left[1+(0.559/0.69)^{9/16}\right]^{8/27}}\right\}^2 = 9.9$$

$$\bar{h} = \overline{Nu}_D\,k/D = 9.9(0.0497\,W/m\cdot K)/0.05\,m = 9.84\,W/m^2\cdot K$$ <

(b) The radiation heat transfer coefficient is

$$h_r = \varepsilon\sigma(T_s + T_{sur})\left(T_s^2 + T_{sur}^2\right) = 0.4\times 5.67\times 10^{-8}\,W/m^2\cdot K^4\,(1000$$
$$+300)K\left[(1000)^2 + (300)^2\right]K^2 = 32.1\,W/m^2\cdot K$$ <

(c) For the long stainless steel rod and the initial values of $\bar{h}$ and h_r,

$$Bi = \left(\bar{h} + h_r\right)(r_o/2)/k = 42.0\,W/m^2\cdot K\times 0.0125\,m/25\,W/m\cdot K = 0.021.$$

Hence, the lumped capacitance method can be used.

$$\frac{T - T_\infty}{T_i - T_\infty} = \frac{600\,K}{700\,K} = \exp(-Bi\cdot Fo) = \exp(-0.021 Fo)$$

Continued...

PROBLEM 9.70 (Cont.)

$$\mathrm{Fo} = 7.34 = \alpha t \Big/ (r_o/2)^2 = 0.0333t$$

t = 221 s. <

(d) Using the IHT *Lumped Capacitance* Model with the *Correlations* and *Properties* Tool Pads, a more accurate estimate of the maximum allowable transit time may be obtained by evaluating the numerical integration,

$$\int_o^t dt = -\frac{\rho c_p D}{4} \int_{1000\,K}^{900\,K} \frac{dT}{\left(\bar{h} + h_r\right)\left(T - T_\infty\right)}$$

where $\rho c_p = k/\alpha = 4.81 \times 10^6\ \mathrm{J/K \cdot m^3}$. The integration yields

t = 245 s <

At this time, the convection and radiation coefficients are $\bar{h}$ = 9.75 and h_r = 24.5 W/m^2·K, respectively.

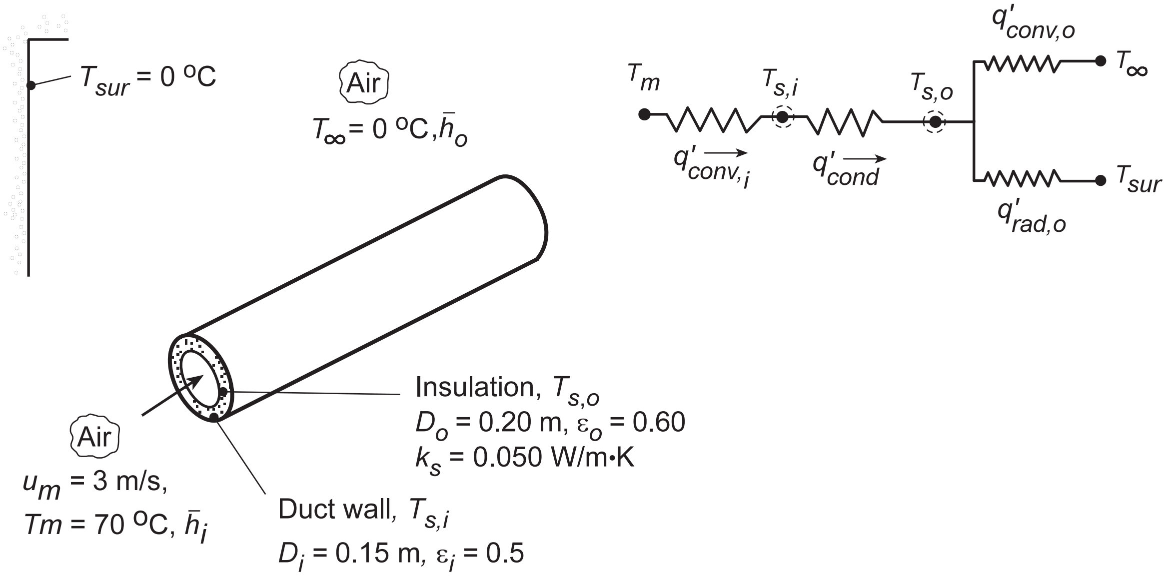
COMMENTS: Since $\bar{h}$ and h_r decrease with increasing time, the maximum allowable conveyor time is underestimated by the result of part (c).

PROBLEM 9.71

KNOWN: Velocity and temperature of air flowing through a duct of prescribed diameter. Temperature of duct surroundings. Thickness, thermal conductivity and emissivity of applied insulation.

FIND: (a) Duct surface temperature and heat loss per unit length with no insulation, (b) Surface temperatures and heat loss with insulation.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Fully-developed internal flow, (3) Negligible duct wall resistance, (4) Duct outer surface is diffuse-gray, (5) Outside air is quiescent, (6) Pressure of inside and outside air is atmospheric.

PROPERTIES: *Table A.4*, Air (T_m = 70°C): $\nu = 20.22 \times 10^{-6}$ m²/s, Pr = 0.70, k = 0.0295 W/m·K; *Table A.4*, Air ($T_f \approx 27$°C): $\nu = 15.89 \times 10^{-6}$ m²/s, Pr = 0.707, k = 0.0263 W/m·K, $\alpha = 22.5 \times 10^{-6}$ m²/s, β = 0.00333 K^{-1}.

ANALYSIS: (a) Performing an energy balance on the duct wall with no insulation ($T_{s,i} = T_{s,o}$),

$$q'_{conv,i} = q'_{conv,o} + q'_{rad,o} \qquad h_i(\pi D_i)(T_m - T_{s,i}) = h_o(\pi D_i)(T_{s,i} - T_\infty) + \varepsilon_i \sigma(\pi D_i)\left(T_{s,i}^4 - T_{sur}^4\right)$$

with $Re_{D,i} = u_m D_i/\nu$ = 3 m/s × 0.15 m/(20.22 × 10^{-6} m²/s) = 2.23 × 10^4, the internal flow is turbulent, and from the Dittus-Boelter correlation,

$$h_i = \frac{k}{D_i} 0.023 Re_{D,i}^{4/5} Pr^{0.3} = \frac{0.0295\, W/m\cdot K}{0.15\, m} 0.023\left(2.23\times10^4\right)^{4/5}(0.7)^{0.3} = 12.2\, W/m^2\cdot K.$$

For free convection, the Rayleigh number is

$$Ra_{D,i} = \frac{g\beta(T_{s,i} - T_\infty)D_i^3}{\nu\alpha} = \frac{9.8\,m/s^2\,(0.0033)(T_{s,i} - 273)(0.15)^3\,m^3}{15.89\times10^{-6}\,m^2/s \times 22.5\times10^{-6}\,m^2/s} = 3.08\times10^5(T_{s,i} - T_\infty)$$

and from Eq. 9.34,

$$\bar{h}_o = \frac{k}{D_i}\left[0.60 + \frac{0.387 Ra_{D,i}^{1/6}}{\left[1+(0.559/Pr)^{9/16}\right]^{8/27}}\right]^2 = \frac{0.0263}{0.15}\left[0.60 + \frac{0.387\left[3.08\times10^5(T_{s,i} - T_\infty)\right]^{1/6}}{\left[1+(0.559/0.707)^{9/16}\right]^{8/27}}\right]^2$$

Continued...

$$\overline{h}_o = 0.175\left[0.60 + 2.64\left(T_{s,i} - T_\infty\right)^{1/6}\right]^2$$

Hence

$$12.2\left(343 - T_{s,i}\right) = 0.175\left\{0.60 + 2.64\left(T_{s,i} - 273\right)^{1/6}\right\}^2\left(T_{s,i} - 273\right) + 0.5 \times 5.67 \times 10^{-8}\left[T_{s,i}^4 - \left(273\right)^4\right]$$

A trial-and-error solution gives $T_{s,i} \approx 314.7\,\text{K} \approx 41.7^\circ\text{C}$ <

The heat loss per unit length is then

$$q' = q'_{conv,i} \approx 12.2\left(\pi \times 0.15\right)\left(70 - 42\right) \approx 163\,\text{W/m}\,.$$ <

(b) Performing energy balances at the inner and outer surfaces, we obtain, respectively,

$$q'_{conv,i} = q'_{cond}$$

or,

$$\overline{h}_i\left(\pi D_i\right)\left(T_m - T_{s,i}\right) = \frac{2\pi k_s\left(T_{s,i} - T_{s,o}\right)}{\ln\left(D_o/D_i\right)}$$

and,

$$q'_{cond} = q'_{conv,o} + q'_{rad,o}$$

or,

$$\frac{2\pi k_s\left(T_{s,i} - T_{s,o}\right)}{\ln\left(D_o/D_i\right)} = \overline{h}_o\left(\pi D_o\right)\left(T_s - T_\infty\right) + \varepsilon_o\sigma\left(\pi D_o\right)\left(T_{s,o}^4 - T_{sur}^4\right)$$

Using the IHT workspace with the *Correlations* and *Properties* Tool Pads to solve the energy balances for the unknown surface temperatures, we obtain

$T_{s,i} = 60.8^\circ\text{C}$ $\qquad$ $T_{s,o} = 12.5°\text{C}$ <

With the heat loss per unit length again evaluated from the inside convection process, we obtain

$$q' = q'_{conv,i} = 52.8\,\text{W/m}$$ <

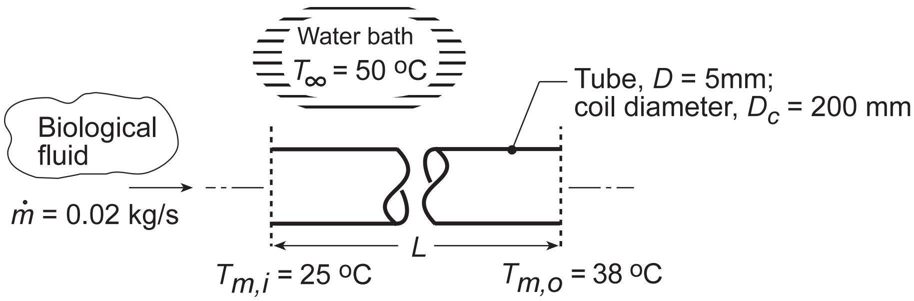
COMMENTS: For part (a), the outside convection coefficient is $\overline{h}_o$ = 5.4 W/m^2·K < h_i. The outside heat transfer rates are $q'_{conv,o}$ ≈ 106 W/m and $q'_{rad,o}$ ≈ 57 W/m. For part (b), $\overline{h}_o$ = 3.74 W/m^2·K, $q'_{conv,o}$ = 29.4 W/m, and $q'_{rad,o}$ = 23.3 W/m. Although $T_{s,i}$ increases with addition of the insulation, there is a substantial reduction in $T_{s,o}$ and hence the heat loss.

PROBLEM 9.72

KNOWN: Biological fluid with prescribed flow rate and inlet temperature flowing through a coiled, thin-walled, 5-mm diameter tube submerged in a large water bath maintained at 50°C.

FIND: (a) Length of tube and number of coils required to provide an exit temperature of $T_{m,o}$ = 38°C, and (b) Variations expected in $T_{m,o}$ for a ±10 % change in the mass flow rate for the tube length determined in part (a) .

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Coiled tube approximates a horizontal tube experiencing free convection in a quiescent, extensive medium (water bath), (3) Biological fluid has thermophysical properties of water, (4) Negligible tube wall thermal resistance, (5) Biological fluid flow is incompressible with negligible viscous dissipation, and (6) Flow in tube is fully developed.

PROPERTIES: *Table A.4* Water - cold side ($T_{m,c} = (T_{m,i} + T_{m,o}) / 2$ = 304.5 K) : $c_{p,c}$ = 4178 J/kg·K, μ_c = 7.776 × 10^{-4} N·s/m^2 , k_c = 0.6193 W/m·K , Pr_c = 5.263 ; *Table A.4,* Water - hot side ($\bar{T}_f = (T_s + T_\infty)/2$ = 315.7 K, see comment 1): k_h = 0.635 W/m·K , Pr_h = 4.11, ν_h = 6.294 × 10^{-7} m^2/s , α_h = 1.533 × 10^{-7} m^2/s, β_h = 4.054 × 10^{-4} K^{-1}; Water (T_s = 308.4 K): μ_s = 7.28 × 10^{-4} N·s/m^2.

ANALYSIS: (a) Following the treatment of Section 8.3.3, the coil experiences internal flow of the cold biological fluid (c) and free convection with the external hot fluid (h). From Eq. 8.45a, we can solve for $\bar{U}A_s$,

$$\bar{U}A_s = -\dot{m}c_{p,c}\ln\left(\frac{T_\infty - T_{m,o}}{T_\infty - T_{m,i}}\right) = -0.02\text{ kg/s} \times 4178\text{ J/kg}\cdot\text{K} \times \ln\left(\frac{50-38}{50-25}\right) = 61.3\text{ W/K}$$

with $A_s = \pi DL$ and for the overall coefficient $\bar{U} = (1/\bar{h}_c + 1/\bar{h}_h)^{-1}$, $\bar{h}_c$ and $\bar{h}_h$ are the average convection coefficients for internal flow and external free convection, respectively.

Internal flow, $\bar{h}_c$*:* To characterize the flow, calculate the Reynolds number,

$$Re_{D,c} = \frac{4\dot{m}}{\pi D\mu_c} = \frac{4\times 0.02\text{ kg/s}}{\pi\times 0.005\text{m}\times 777.6\times 10^{-6}\text{ N}\cdot\text{s/m}^2} = 6550$$

evaluating properties at $\bar{T}_m = (T_{m,i} + T_{m,o})/2 = (25+38)^\circ\text{C}/2 = 31.5^\circ\text{C} = 304.5\text{K}$. Note that transition to turbulence occurs at a higher Reynolds number in a coiled tube flow, as given by Eq. 8.74,

$$Re_{D,c,cr} = Re_{D,cr}\left[1+12(D/D_c)^{0.5}\right] = 2300\times\left[1+12(0.005\text{ m}/0.2\text{ m})^{0.5}\right] = 6664$$

Therefore the flow is laminar and the Nusselt number is given by Eq. 8.76 with Eqs. 8.77.

Continued...

PROBLEM 9.72 (Cont.)

$$\overline{Nu}_{D,c} = \left[\left(3.66+\frac{4.343}{a}\right)^3 + 1.158\left(\frac{Re_{D,c}(D/D_c)^{0.5}}{b}\right)^{1.5}\right]^{1/3}\left(\frac{\mu_c}{\mu_s}\right)^{0.14}$$

where

$$a = \left(1+\frac{957(D_c/D)}{Re_{D,c}^2 Pr_c}\right) \qquad b = 1+\frac{0.477}{Pr_c}$$

Substituting numerical values yields $\overline{Nu}_{D,c}$ = 32.8, therefore

$$\bar{h}_c = \overline{Nu}_{D,c} k_c / D = 32.8 \times 0.6193\,W/m\cdot K / 0.005m = 4065\,W/m^2\cdot K$$

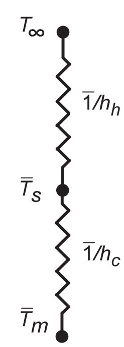
External free convection , $\bar{h}_h$: For the horizontal tube, Eq. 9.34,

$$\overline{Nu}_{D,h} = \frac{\bar{h}_h D}{k_h} = \left\{0.60 + \frac{0.387 Ra_D^{1/4}}{\left[1+(0.559/Pr)^{9/16}\right]^{8/27}}\right\}^2 \qquad (1)$$

with

$$Ra_{D,h} = \frac{g\beta_h(\bar{T}_s - T_\infty)D^3}{\nu_h \alpha_h} \qquad (2)$$

where $\bar{T}_s$ is the average tube wall temperature determined from the thermal circuit for which



$$\bar{h}_c\left(\bar{T}_m - \bar{T}_s\right) = \bar{h}_h\left(\bar{T}_s - T_\infty\right) \qquad (3)$$

and the average film temperature at which to evaluate properties is

$$\bar{T}_f = \left(\bar{T}_s + T_\infty\right)/2 \qquad (4)$$

We need to guess a value for $\bar{T}_s$ and iterate the solution of the system of equations (1-4) and property evaluation until all the equations are satisfied. See Comments 1 and 2.

Results of the analysis: Using the foregoing relations in IHT (see Comment 2) the following results were obtained

$\bar{T}_s = 308.4\,K$, $\bar{T}_f = 315.7\,K$, $Ra_D = 7.53\times10^4$, $\bar{h}_h = 1078\,W/m^2\cdot K$

Then

$$\bar{U} = (1/\bar{h}_c + 1/\bar{h}_h)^{-1} = (1/4065\ W/m^2\cdot K + 1/1078\ W/m^2\cdot K)^{-1} = 852\ W/m^2\cdot K$$

$$L = \bar{U}A_s/\bar{U}\pi D = 61.3\ W/K / 852\ W/m^2\cdot K \times \pi \times 0.005\ m = 4.58\ m$$ <

Continued...

PROBLEM 9.72(Cont.)

From knowledge of the tube length with the diameter of the coil D_c = 200 mm, the number of coils required is

$$N = \frac{L}{\pi D_c} = \frac{4.58\text{ m}}{\pi \times 0.200\text{m}} = 7.3 \approx 7$$ <

(b) With the length fixed at L = 4.58 m, we can backsolve the foregoing IHT workspace model to find what effect a ±10% change in the mass flow rate has on the outlet temperature, $T_{m,o}$. The results of the analysis are tabulated below.

$\dot{m}\left(\text{kg/s}\right)$	0.018	0.02	0.022
$T_{m,o}\left({}^\circ\text{C}\right)$	38.8	38.0	37.3

That is, a ±10 % change in the flow rate causes less than a ±1°C change in the outlet temperature. While this change seems quite small, the effect on biological processes can be significant.

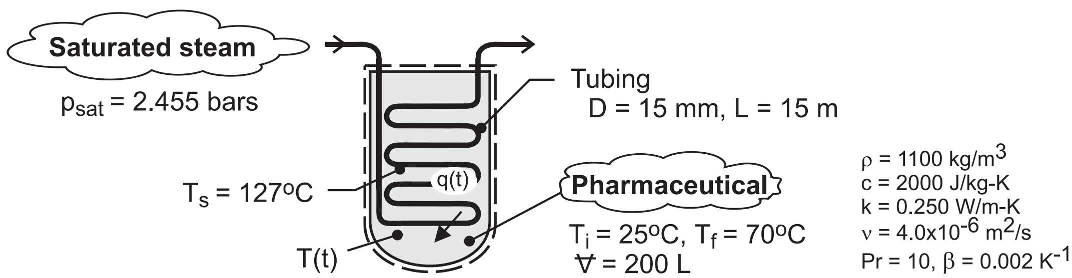
COMMENTS: (1) For the hot fluid, the Properties section shows the relevant thermophysical properties evaluated at the proper average (rather than a guess value for the film temperature). (2) For the tube L/D = 4.58 m/0.005 m = 916 which is substantially greater than the entrance length criterion, $0.05Re_D = 0.05\times 6550 = 328$. Hence, the assumption of fully developed internal flow is justified, especially since the entrance length is shorter in a coiled tube. (3) We are slightly outside of the range for Eq. 8.76, since $Re_{D,c}(D/C)^{1/2} = 1036 > 1000$, but it should give a reasonable estimate. (4) The IHT model for the system can be constructed beginning with the *Rate Equation Tools*, *Tube Flow*, *Constant Surface Temperature* along with the *Correlation Tools* for *Free Convection, Horizontal Cylinder* and the *Properties Tool* for the hot and cold fluids (water). The correlation for the internal flow in a coiled tube must be keyed in by hand. The full set of equations is extensive and very stiff. Review of the IHT Example 8.6 would be helpful in understanding how to organize the complete model.

PROBLEM 9.73

KNOWN: Volume, thermophysical properties, and initial and final temperatures of a pharmaceutical. Diameter and length of submerged tubing. Pressure of saturated steam flowing through the tubing.

FIND: (a) Initial rate of heat transfer to the pharmaceutical, (b) Time required to heat the pharmaceutical to 70°C and the amount of steam condensed during the process.

SCHEMATIC:



ASSUMPTIONS: (1) Pharmaceutical may be approximated as an infinite, quiescent fluid of uniform, but time-varying temperature, (2) Free convection heat transfer from the coil may be approximated as that from a heated, horizontal cylinder, (3) Negligible thermal resistance of condensing steam and tube wall, (4) Negligible heat transfer from tank to surroundings, (5) Constant properties.

PROPERTIES: *Table A-4*, Saturated water (2.455 bars): T_{sat} = 400K = 127°C, $h_{fg} = 2.183 \times 10^6$ J/kg. Pharmaceutical: See schematic.

ANALYSIS: (a) The initial rate of heat transfer is $q = \overline{h}A_s\left(T_s - T_i\right)$, where $A_s = \pi DL = 0.707\ m^2$ and $\overline{h}$ is obtained from Eq. 9.34. With $\alpha = \nu/Pr = 4.0 \times 10^{-7}\ m^2/s$ and $Ra_D = g\beta(T_s - T_i)\,D^3/\alpha\nu = 9.8\ m/s^2\ (0.002\ K^{-1})\ (102K)\ (0.015m)^3/16 \times 10^{-13}\ m^4/s^2 = 4.22 \times 10^6$,

$$\overline{Nu}_D = \left\{0.60 + \frac{0.387\,Ra_D^{1/6}}{\left[1+\left(0.559/Pr\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.60 + \frac{0.387\left(4.22\times10^6\right)^{1/6}}{\left[1+\left(0.559/10\right)^{9/16}\right]^{8/27}}\right\}^2 = 27.7$$

Hence, $$\overline{h} = \overline{Nu}_D\,k/D = 27.7\times0.250\,W/m\cdot K/0.015m = 462\,W/m^2\cdot K$$

and $$q = \overline{h}A_s\left(T_s - T_i\right) = 462\,W/m^2\cdot K\times0.707\,m^2\left(102°C\right) = 33,300\,W$$ <

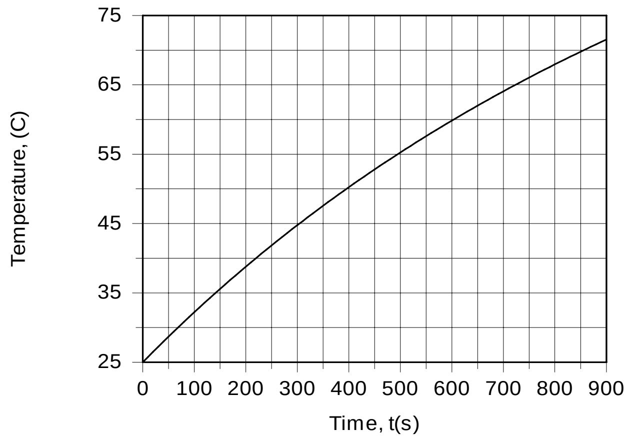
(b) Performing an energy balance at an instant of time for a control surface about the liquid,

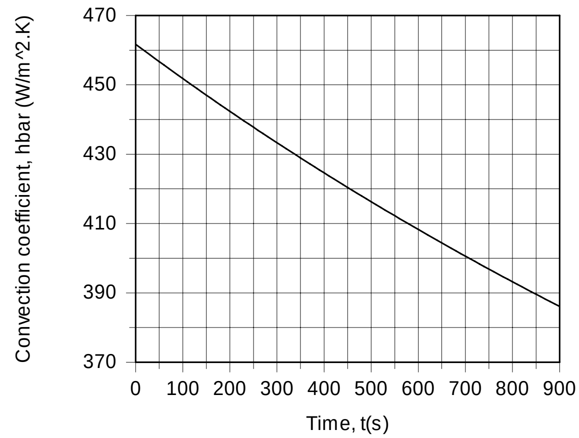
$$\frac{d\left(\rho\forall cT\right)}{dt} = q\left(t\right) = \overline{h}\left(t\right)A_s\left(T_s - T\left(t\right)\right)$$

where the Rayleigh number, and hence $\overline{h}$, changes with time due to the change in the temperature of the liquid. Integrating the foregoing equation using the DER function of IHT, the following results are obtained for the variation of T and $\overline{h}$ with t.

Continued …

PROBLEM 9.73 (Cont.)





The time at which the liquid reaches 70°C is

$$t_f \approx 855\,s \quad <$$

The temperature increases at a decreasing rate due to the corresponding reduction in $(T_s - T)$, and hence reductions in Ra_D, $\overline{h}$ and q. The Rayleigh number decreases from 4.22×10^6 to 2.16×10^6, while the heat rate decreases from 33,300 to 14,000 W. The convection coefficient decreases approximately as $(T_s - T)^{1/3}$, while $q \sim (T_s - T)^{4/3}$. The latent energy released by the condensed steam corresponds to the increase in thermal energy of the pharmaceutical. Hence, $m_c h_{fg} = \rho \forall c\left(T_f - T_i\right)$, and

$$m_c = \frac{\rho \forall c\left(T_f - T_i\right)}{h_{fg}} = \frac{1100\,kg/m^3 \times 0.2\,m^3 \times 2000\,J/kg \cdot K \times 45°C}{2.183 \times 10^6\,J/kg} = 9.07\,kg \quad <$$

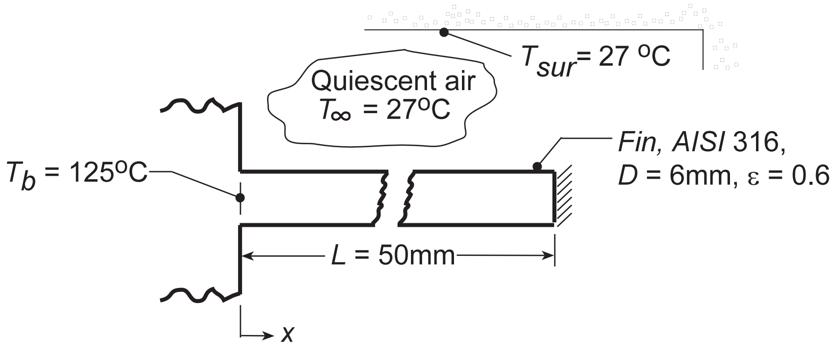
COMMENTS: (1) Over such a large temperature range, the fluid properties are likely to vary significantly, particularly ν and Pr. A more accurate solution could therefore be performed if the temperature dependence of the properties were known. (2) Condensation of the steam is a significant process expense, which is linked to the equipment (capital) and energy (operating) costs associated with steam production.

PROBLEM 9.74

KNOWN: Fin of uniform cross section subjected to prescribed conditions.

FIND: Tip temperature and fin effectiveness based upon (a) *average* values for free convection and radiation coefficients and (b) *local* values using a numerical method of solution.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Surroundings are isothermal and large compared to the fin, (3) One-dimensional conduction in fin, (4) Constant fin properties, (5) Tip of fin is insulated, (6) Fin surface is diffuse-gray.

PROPERTIES: *Table A-4,* Air (T_f = 325 K, 1 atm): $\nu = 18.41 \times 10^{-6}$ m^2/s, k = 0.0282 W/m·K, $\alpha = 26.2 \times 10^{-6}$ m^2/s, Pr = 0.704, $\beta = 1/T_f = 3.077 \times 10^{-3}\,K^{-1}$; *Table A-1,* Steel AISI 316 $\left(\overline{T}_s = 350\,K\right)$: k = 14.3 W/m·K.

ANALYSIS: (a) *Average value* $\overline{h}_c$ *and* $\overline{h}_r$: From Table 3.4 for a fin of constant cross section with an insulated tip and constant heat transfer coefficient $\overline{h}$, the tip temperature (x = L) is given by Eq. 3.80,

$$\theta_L = \theta_b \frac{\cosh m(L-x)}{\cosh mL} = \theta_b / \cosh(mL) \qquad m = \left(\overline{h}P/kA_c\right)^{1/2} \qquad (1,2)$$

where $\theta_L = T_L - T_\infty$ and $\theta_b = T_b - T_\infty$. For this situation, the average heat transfer coefficient is

$$\overline{h} = \overline{h}_c + \overline{h}_r \qquad (3)$$

and is evaluated at the average temperature of the fin. The fin effectiveness ε_f follows from Eqs. 3.81 and 3.86

$$\varepsilon_f \equiv q_f / \overline{h}A_{c,b}\theta_b, \qquad q_f = M \cdot \tanh(mL), \qquad M = \left(\overline{h}PkA_c\right)^{1/2}\theta_b. \qquad (4,5,6)$$

To estimate the coefficients, assume a value of $\overline{T}_s$; the lowest $\overline{T}_s$ occurs when the tip reaches T_∞. That is,

$$\overline{T}_s = \left(\overline{T}_\infty + T_b\right)/2 = (27+125)^\circ C/2 = 76^\circ C \approx 350\,K$$

$$T_f = \left(\overline{T}_s + T_\infty\right)/2 = 325\text{ K.}$$

The free convection coefficient can be estimated from Eq. 9.33,

$$\overline{Nu}_D = \frac{\overline{h}_c D}{k} = CRa_D^n \qquad (7)$$

$$Ra_D = \frac{g\beta\Delta TD^3}{\nu\alpha} = \frac{9.8\,m/s^2 \times 3.077\times10^{-3}K^{-1}(350-300)K(0.006\,m)^3}{18.41\times10^{-6}\ m^2/s \times 26.2\times10^{-6}\ m^2/s} = 675$$

and from Table 9.1 with $10^2 < Ra_L < 10^4$, C = 0.850 and n = 0.188. Hence

Continued...

PROBLEM 9.74 (Cont.)

$$\bar{h}_c = \frac{0.0282\ \mathrm{W/m\cdot K}}{0.006\mathrm{m}} \times 0.850(675)^{0.188} = 13.6\ \mathrm{W/m^2\cdot K}. \qquad (8)$$

The radiation coefficient is estimated from Eq. 1.9,

$$\bar{h}_r = \varepsilon\sigma\left(\bar{T}_s + T_{sur}\right)\left(\bar{T}_s^2 + T_{sur}^2\right)$$

$$\bar{h}_r = 0.6\times5.67\times10^{-8}\ \mathrm{W/m^2\cdot K^4}(350+300)\left(350^2+300^2\right)\mathrm{K^3} = 4.7\ \mathrm{W/m^2\cdot K} \qquad (9)$$

Hence, the average coefficient, Eq. (3), is

$$\bar{h} = (13.6+4.7)\ \mathrm{W/m^2\cdot K} = 18.3\ \mathrm{W/m^2\cdot K}.$$

Evaluate the fin parameters, Eq. (2) and (6) with

$$P = \pi D = \pi\times0.006\mathrm{m} = 1.885\times10^{-2}\mathrm{m} \qquad A_c = \pi D^2/4 = \pi(0.006\mathrm{m})^2/4 = 2.827\times10^{-5}\mathrm{m}^2$$

$$m = \left(18.3\ \mathrm{W/m^2\cdot K}\times1.885\times10^{2}\ \mathrm{m}/14.3\ \mathrm{W/m\cdot K}\times2.827\times10^{-5}\right)^{1/2} = 29.21\mathrm{m}^{-1}$$

$$M = \left(18.3\ \mathrm{W/m^2\cdot K}\times1.885\times10^{-2}\mathrm{m}\times14\cdot3\ \mathrm{W/m\cdot K}\times2.827\times10^{-5}\mathrm{m^2}\right)^{1/2}(125-27)\mathrm{K} = 1.157\ \mathrm{W}.$$

From Eq. (1), the tip temperature is

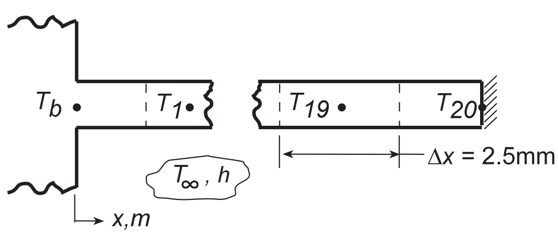
$$\theta_L = T_L - T_b = (125-27)\mathrm{K}/\cosh\left(29.21\mathrm{m}^{-1}\times0.050\mathrm{m}\right) = 43.2\mathrm{K} \qquad T_L = 70.2^\circ\mathrm{C} = 343\mathrm{K}. \ <$$

Note this value of T_L provides for $\bar{T}_s \approx 370$ K; so we underestimated $\bar{T}_s$. For best results, an iteration is warranted. The fin effectiveness, Eqs. (4) and (5), is

$$q_f = 1.157\ \mathrm{W}\tanh\left(29.21\mathrm{m}^{-1}\times0.050\mathrm{m}\right) = 1.039\ \mathrm{W}$$

$$\varepsilon_f = 1.039\ \mathrm{W}/18.3/\ \mathrm{W/m^2\cdot K}\times2.827\times10^{-5}\mathrm{m^2}(125-27)\mathrm{K} = 20.5. \qquad <$$

(b) *Local values* h_c *and* h_r: Consider the nodal arrangement for using a numerical method to find the tip temperature T_L, the heat rate q_f, and the fin effectiveness ε.



From an energy balance on a control volume about node m, the finite-difference equation is of the form

$$T_m = \left[T_{m+1} + T_{m-1} + (h_c+h_r)\left(4\Delta x^2/kD\right)T_\infty\right]\Big/\left[2+(h_r+h_c)\left(4\Delta x^2/kD\right)\right]. \qquad (10)$$

The local coefficient h_c follows from Eq. (3), with Eq. 9.33, yielding

$$h_c = \frac{k}{D}CRa_D^n$$

$$h_c = \frac{0.0282\ \mathrm{W/m\cdot K}}{0.006\ \mathrm{m}}\times0.850\left(675\left[\Delta T/(350-300)\right]\right)^{0.188} = 6.517(T_m-300)^{0.188}. \qquad (11)$$

The local coefficient h_r follows from Eq. (9),

$$h_r = 0.6\times5.67\times10^{-8}\ \mathrm{W/m^2\cdot K^4}(T_m+300)\left(T_m^2+300^2\right)$$

Continued...

PROBLEM 9.74 (Cont.)

$$h_r = 3.402\times10^{-8}\left(T_m + 300\right)\left(T_m^2 + 300^2\right). \qquad (12)$$

The 20-node system of finite-difference equations based upon Eq. (10) with the variable coefficients h_c and h_r prescribed Eqs. (11) and (12), respectively, can be solved simultaneously using IHT or another approach. The temperature distribution is

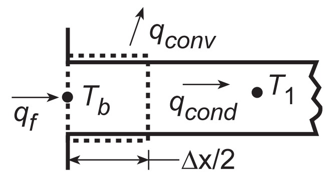
Node	T_m(K)	Node	T_m(K)	Node	T_m(K)	Node	T_m(K)
1	391.70	6	367.61	11	353.02	16	345.49
2	385.95	7	364.03	12	351.00	17	344.70
3	380.70	8	360.81	13	349.25	18	344.15
4	375.92	9	357.91	14	347.75	19	343.82
5	371.56	10	355.32	15	346.50	20	343.71

From these results the tip temperature is

$$T_L = T_{fd} = 343.7\,K = 70.7^\circ C\,. \qquad <$$

The fin heat rate follows from an energy balance for the control surface about node b.

$$q_f = q_{conv} + q_{cond}$$



$$q_f = h_b P\frac{\Delta x}{2}\left(T_b - T_\infty\right) + kA_c\frac{T_b - T_1}{\Delta x}$$

where h_b follows from Eqs. (11) and (12), with $T_b = 125^\circ C = 398$ K,

$$h_b = 6.517\left(398-300\right)^{0.188} + 3.402\times10^{-8}\left(398+300\right)\left(398^2+300^2\right) = 21.33\,W/m^2\cdot K$$

$$q_f = 21.33\,W/m^2\cdot K\times1.855\times10^{-2}\,m\left(0.0025\,m/2\right)\left(398-300\right)K$$

$$+14.3\,W/m\cdot K\times2.827\times10^{-5}\,m^2\frac{\left(398-391.70\right)K}{0.0025m} = \left(0.049+1.018\right)W = 1.067\,W\,.$$

The effectiveness follows from Eq. (4)

$$\varepsilon_f = 1.067\,W/21.33\,W/m^2\cdot K\times2.827\times10^{-5}m^2\left(125-27\right)K = 18.1$$

COMMENTS: (1) The results by the two methods of solution compare as follows:

Coefficients	T(L),K	q_f(W)	ε_f
average	343.1	1.039	20.5
local	343.7	1.067	18.1

The temperature predictions are in excellent agreement and the heat rates very close, within 4%.

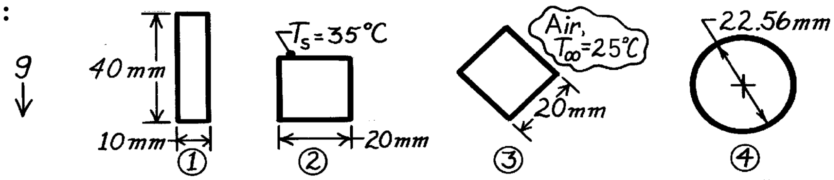
(2) To obtain the finite-different equation for node n = 20, use Eq. (10) but consider the adiabatic surface as a symmetry plane.

PROBLEM 9.75

KNOWN: Horizontal tubes of different shapes each of the same cross-sectional area transporting a hot fluid in quiescent air. Lienhard correlation for immersed bodies.

FIND: Tube shape which has the minimum heat loss to the ambient air by free convection.

SCHEMATIC:



ASSUMPTIONS: (1) Ambient air is quiescent, (2) Negligible heat loss by radiation, (3) All shapes have the same cross-sectional area and uniform surface temperature.

PROPERTIES: *Table A-4*, Air ($T_f \approx 300K$, 1 atm): $\nu = 15.89 \times 10^{-6}\ m^2/s$, $\alpha = 22.5 \times 10^{-6}\ m^2/s$, k = 0.0263 W/m·K, Pr = 0.707, $\beta = 1/T_f$.

ANALYSIS: The Lienhard correlation approximates the laminar convection coefficient for an immersed body on which the boundary layer does not separate from the surface by $\overline{Nu}_\ell = (\bar{h}\ell)/k = 0.52 Ra_\ell^{1/4}$, where the characteristic length, ℓ, is the length of travel of the fluid in the boundary layer across the shape surface. The heat loss per unit length from any shape is $q' = \bar{h}P(T_s - T_\infty)$. For the shapes,

$$Ra_\ell = \frac{g\beta\Delta T\ell^3}{\nu\alpha} = \frac{9.8\,m/s^2\,(1/300\,K)(35-25)\,K\,\ell^3 m^3}{15.89\times10^{-6} m^2/s \times 22.5\times10^{-6} m^2/s} = 9.137\times10^8\,\ell^3$$

$$\bar{h}_\ell = (0.0263\,W/m\cdot K/\ell)\,0.52\left(9.137\times10^8\,\ell^3\right)^{1/4} = 2.378\ell^{-1/4}.$$

For the shapes, ℓ is half the total wetted perimeter P. Evaluating $\bar{h}_\ell$ and q', find

Shape	P (mm)	ℓ (mm)	$\bar{h}_\ell\ (W/m^2\cdot K)$	$q'\ (W/m)$
1	2 × 40 + 2 × 10 = 100	50	5.03	5.03
2	4 × 20 = 80	40	5.32	4.26
3	4 × 20 = 80	40	5.32	4.26
4	π × 22.56 = 70.9	35.4	5.48	3.89

Hence, it follows that shape 4 has the minimum heat loss. <

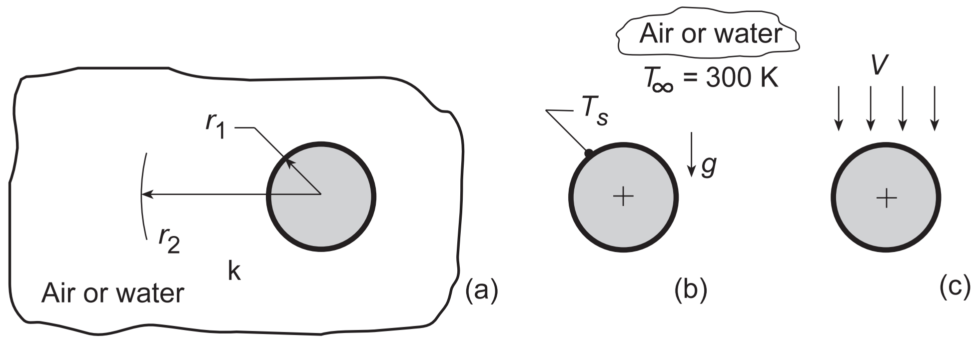
COMMENTS: Using the Lienhard correlation for a sphere of D = 22.56 mm, find $\ell = 35.4\,mm$, the same as for a cylinder, namely, $h_4 = 5.48\ W/m^2\cdot K$. Using the Churchill correlation, Eq. 9.35, find $\bar{h} = 7.69\,W/m^2\cdot K$. Hence, the approximation for the sphere is 29% low. For a cylinder, using Eq. 9.34, find $\bar{h} = 5.15\,W/m^2\cdot K$. The approximation for the cylinder is 6% high.

PROBLEM 9.76

KNOWN: Sphere of 2-mm diameter immersed in a fluid at 300 K.

FIND: (a) The conduction limit of heat transfer from the sphere to the quiescent, extensive fluid, $Nu_{D,cond} = 2$; (b) Considering free convection, surface temperature at which the Nusselt number is twice that of the conduction limit for the fluids air and water; and (c) Considering forced convection, fluid velocity at which the Nusselt number is twice that of the conduction limit for the fluids air and water.

SCHEMATIC:



ASSUMPTIONS: (1) Sphere is isothermal, (2) For part (a), fluid is stationary, and (3) For part (b), fluid is quiescent, extensive.

ANALYSIS: (a) Following the hint provided in the problem statement, the thermal resistance of a hollow sphere, Eq. 3.40 of inner and outer radii, r_1 and r_2 , respectively, and thermal conductivity k, is

$$R_{t,cond} = \frac{1}{4\pi k}\left(\frac{1}{r_1} - \frac{1}{r_2}\right) \tag{1}$$

and as $r_2 \to \infty$, that is the medium is extensive

$$R_{t,cond} = \frac{1}{4\pi k r_1} = \frac{1}{2\pi k D} \tag{2}$$

The Nusselt number can be expressed as

$$Nu = \frac{hD}{k} \tag{3}$$

and the conduction resistance in terms of a convection coefficient is

$$R_{t,cond} = \frac{1}{hA_s} = \frac{1}{h\pi D^2} \tag{4}$$

Combining Eqs. (3) and (4)

$$Nu_{D,cond} = \frac{\left(1/R_{t,cond}\pi D^2\right)D}{k} = \frac{\left[1/\left(1/2\pi kD\right)\left(\pi D^2\right)\right]D}{k} = 2$$ <

(b) For free convection, the recommended correlation, Eq. 9.35, is

$$\overline{Nu}_D = 2 + \frac{0.589 Ra_D^{1/4}}{\left[1 + \left(0.469/Pr\right)^{9/16}\right]^{4/9}}$$

Continued...

PROBLEM 9.76 (Cont.)

$$Ra_D = \frac{g\beta\Delta T D^3}{\nu\alpha} \qquad \Delta T = T_s - T_\infty$$

where properties are evaluated at $T_f = (T_s + T_\infty)/2$. What value of T_s is required for $\overline{Nu}_D = 4$ for the fluids air and water? Using the *IHT Correlations Tool, Free Convection, Sphere* and the *Properties Tool* for *Air* and *Water*, find

Air: $\overline{Nu} \le 3.1$ for all $T_s > 300$ <

Water: $T_s = 301.1K$ <

(c) For forced convection, the recommended correlation, Eq. 7.56, is

$$\overline{Nu}_D = 2 + \left(0.4\,Re_D^{1/2} + 0.06\,Re_D^{2/3}\right)Pr^{0.4}\left(\mu/\mu_s\right)^{1/4}$$

$$Re_D = VD/\nu$$

where properties are evaluated at T_∞, except for μ_s evaluated at T_s. What value of V is required for $\overline{Nu}_D = 4$ if the fluids are air and water? Using the *IHT Correlations Tool, Forced Convection, Sphere* and the *Properties Tool* for *Air* and *Water,* find (evaluating all properties at 300 K)

Air: V = 0.17 m/s   *Water*: V = 0.00185 m/s <

COMMENTS: (1) For water, $\overline{Nu}_D = 2 \times \overline{Nu}_{D,cond}$ can be achieved by $\Delta T \approx 1$ for free convection and with very low velocity, V< 0.002 m/s, for forced convection.

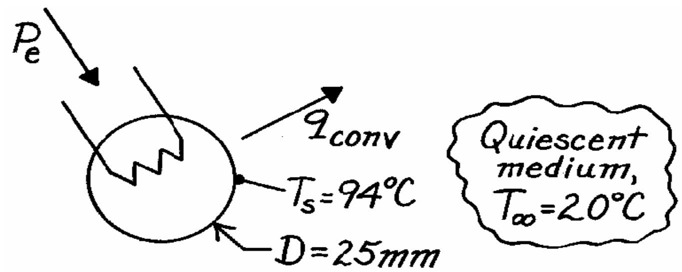
(2) For air, $\overline{Nu}_D = 2 \times \overline{Nu}_{D,cond}$ can be achieved in forced convection with low velocities, V< 0.2 m/s. In free convection, $\overline{Nu}_D$ increases with increasing T_s and reaches a maximum, $\overline{Nu}_{D,max} = 3.1$, around 450 K. Why is this so? Hint: Plot Ra_D as a function of T_s and examine the role of β and ΔT as a function of T_s.

PROBLEM 9.77

KNOWN: Sphere with embedded electrical heater is maintained at a uniform surface temperature when suspended in various media.

FIND: Required electrical power for these media: (a) atmospheric air, (b) water, (c) ethylene glycol.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible surface radiation effects, (2) Extensive and quiescent media.

PROPERTIES: Evaluated at $T_f = (T_s + T_\infty)/2 = 330K$:

	$\nu \cdot 10^6$, m^2/s	$k \cdot 10^3$, W/m·K	$\alpha \cdot 10^6$, m^2/s	Pr	$\beta \cdot 10^3$, K^{-1}
Table A-4, Air (1 atm)	18.91	28.5	26.9	0.711	3.03
Table A-6, Water	0.497	650	0.158	3.15	0.504
Table A-5, Ethylene glycol	5.15	260	0.0936	55.0	0.65

ANALYSIS: The electrical power (P_e) required to offset convection heat transfer is

$$q_{conv} = \bar{h} A_s \left(T_s - T_\infty\right) = \pi \bar{h} D^2 \left(T_s - T_\infty\right). \quad (1)$$

The free convection heat transfer coefficient for the sphere can be estimated from Eq. 9.35 using Eq. 9.25 to evaluate Ra_D.

$$\overline{Nu}_D = 2 + \frac{0.589\, Ra_D^{1/4}}{\left[1 + \left(0.469/Pr\right)^{9/16}\right]^{4/9}} \begin{cases} Pr \geq 0.7 \\ Ra_D \leq 10^{11} \end{cases} \qquad Ra_D = \frac{g\beta \Delta T D^3}{\nu\alpha}. \quad (2,3)$$

(a) For air

$$Ra_D = \frac{9.8\,m/s^2 \left(3.03 \times 10^{-3} K^{-1}\right)(94-20)K\,(0.025m)^3}{18.91 \times 10^{-6} m^2/s \times 26.9 \times 10^{-6} m^2/s} = 6.750 \times 10^4$$

$$\bar{h}_D = \frac{k}{D}\overline{Nu}_D = \frac{0.0285\,W/m \cdot K}{0.025m}\left\{2 + \frac{0.589\left(6.750 \times 10^4\right)^{1/4}}{\left[1 + \left(0.469/0.711\right)^{9/16}\right]^{4/9}}\right\} = 10.6\,W/m^2 \cdot K$$

$$q_{conv} = \pi \times 10.6\,W/m^2 \cdot K\,(0.025m)^2\,(94-20)K = 1.55\,W.$$

Continued …

PROBLEM 9.77 (Cont.)

(b,c) Summary of the calculations above and for water and ethylene glycol:

Fluid	Ra_D	$\bar{h}_D \left(W/m^2 \cdot K\right)$	q(W)	
Air	6.750×10^4	10.6	1.55	<
Water	7.273×10^7	1299	187	<
Ethylene glycol	15.82×10^6	393	57.0	<

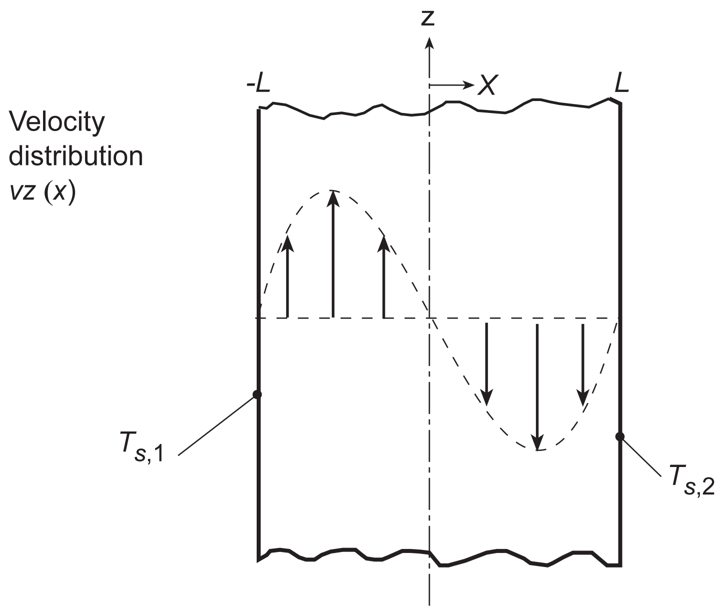
COMMENTS: Note large differences in the coefficients and heat rates for the fluids.

PROBLEM 9.78

KNOWN: Temperatures and spacing of vertical, isothermal plates.

FIND: (a) Shape of velocity distribution, (b) Forms of mass, momentum and energy equations for laminar flow, (c) Expression for the temperature distribution, (d) Vertical pressure gradient, (e) Expression for the velocity distribution.

SCHEMATIC:



ASSUMPTIONS: (1) Laminar, incompressible, fully-developed flow, (2) Constant properties, (3) Negligible viscous dissipation, (4) Boussinesq approximation.

ANALYSIS: (a) For the prescribed conditions, there must be buoyancy driven ascending and descending flows along the surfaces corresponding to $T_{s,1}$ and $T_{s,2}$, respectively (see schematic). However, conservation of mass dictates equivalent rates of *upflow* and *downflow* and, assuming constant properties, inverse symmetry of the velocity distribution about the midplane.

(b) For fully-developed flow, which is achieved for *long* plates, $v_x = 0$ and the continuity equation yields

$$\partial v_z / \partial z = 0 \qquad <$$

With both surface temperatures independent of z, the fully-developed temperature distribution will also have $\partial T / \partial z = 0$. Hence, there is no net transfer of momentum or energy by advection, and the corresponding equations are, respectively,

$$0 = -(dp/dz) + \mu\left(d^2 v_z / dx^2\right) - \rho\left(g/g_c\right) \qquad <$$

$$0 = (dT^2/dx^2) \qquad <$$

(c) Integrating the energy equation twice, we obtain

$$T = C_1 x + C_2$$

and applying the boundary conditions, $T(-L) = T_{s,1}$ and $T(L) = T_{s,2}$, it follows that $C_1 = -(T_{s,1} - T_{s,2})/2L$ and $C_2 = (T_{s,1} + T_{s,2})/2 \equiv T_m$, in which case,

$$\frac{T - T_m}{T_{s,1} - T_{s,2}} = -\frac{x}{2L} \qquad <$$

Continued...

PROBLEM 9.78 (Cont.)

(d) From hydrostatic considerations and the assumption of a constant density ρ_m, the balance between the gravitational and net pressure forces may be expressed as $dp/dz = -\rho_m(g/g_c)$. The momentum equation is then of the form

$$0 = \mu\left(d^2v_z/dx^2\right) - (\rho - \rho_m)(g/g_c)$$

or, invoking the Boussinesq approximation, $\rho - \rho_m \approx -\beta\rho_m(T - T_m)$,

$$d^2v_z/dx^2 = -(\beta\rho_m/\mu)(g/g_c)(T - T_m)$$

or, from the known temperature distribution,

$$d^2v_z/dx^2 = (\beta\rho_m/2\mu)(g/g_c)\left(T_{s,1} - T_{s,2}\right)(x/L)$$ <

(e) Integrating the foregiong expression, we obtain

$$dv_z/dx = (\beta\rho_m/4\mu)(g/g_c)\left(T_{s,1} - T_{s,2}\right)\left(x^2/L\right) + C_1$$

$$v_z = (\beta\rho_m/12\mu)(g/g_c)\left(T_{s,1} - T_{s,2}\right)\left(x^3/L\right) + C_1x + C_2$$

Applying the boundary conditions $v_z(-L) = v_z(L) = 0$, it follows that $C_1 = -(\beta\rho_m/12\mu)(g/g_c)\left(T_{s,1} - T_{s,2}\right)L$ and $C_2 = 0$. Hence,

$$v_z = \left(\beta\rho_m L^2/12\mu\right)(g/g_c)\left(T_{s,1} - T_{s,2}\right)\left[\left(x^3/L^3\right) - (x/L)\right]$$ <

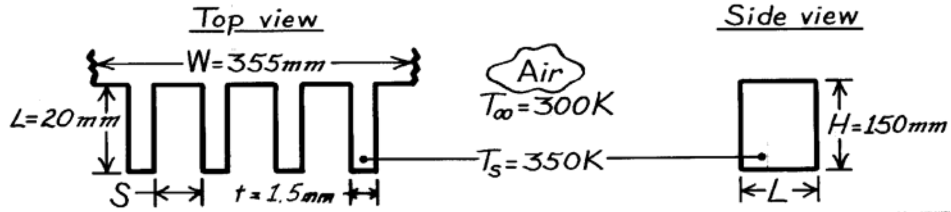
COMMENTS: The validity of assuming fully-developed conditions improves with increasing plate length and would be satisfied precisely for infinite plates.

PROBLEM 9.79

KNOWN: Dimensions of vertical rectangular fins. Temperature of fins and quiescent air.

FIND: Optimum fin spacing and corresponding fin heat transfer rate.

SCHEMATIC:



ASSUMPTIONS: (1) Isothermal fins, (2) Negligible radiation, (3) Quiescent air, (4) Negligible heat transfer from fin tips, (5) Negligible radiation.

PROPERTIES: *Table A-4*, Air (T_f = 325K, 1 atm): $\nu = 18.41 \times 10^{-6}$ m^2/s, k = 0.0282 W/m·K, α = 26.1×10^{-6} m^2/s, Pr = 0.703.

ANALYSIS: From Table 9.3

$$S_{opt} = 2.71\left(Ra_S / S^3 H\right)^{-1/4} = 2.71\left[\frac{g\beta\left(T_s - T_\infty\right)}{\alpha\nu H}\right]^{-1/4}$$

$$S_{opt} = 2.71\left[\frac{9.8\,\text{m/s}^2\,(325\,\text{K})^{-1}(50\,\text{K})}{26.1\times10^{-6}\text{m}^2/\text{s}\times18.4\times10^{-6}\text{m}^2/\text{s}\times0.15\,\text{m}}\right]^{-1/4} = 7.12\,\text{mm} \quad <$$

From Eq. 9.45 and Table 9.3

$$\overline{Nu}_s = \left[\frac{576}{\left(Ra_S S/L\right)^2} + \frac{2.87}{\left(Ra_S S/L\right)^{1/2}}\right]^{-1/2}$$

$$Ra_S(S/L) = \frac{g\beta\left(T_s - T_\infty\right)S^4}{\alpha\nu H} = \frac{9.8\,\text{m/s}^2\,(325\,\text{K})^{-1}(50\,\text{K})\left(7.12\times10^{-3}\text{m}\right)^4}{25.4\times10^{-6}\text{m}^2/\text{s}\times18.4\times10^{-6}\text{m}^2/\text{s}\times0.15\,\text{m}}$$

$$Ra_S(S/L) = 53.2$$

$$\overline{Nu}_S = \left[\frac{576}{(53.2)^2} + \frac{2.87}{(53.2)^{1/2}}\right]^{-1/2} = [0.204 + 0.393]^{-1/2} = 1.29$$

$$\bar{h} = \overline{Nu}_S\, k/S = 1.29\left(0.0282\,\text{W/m}\cdot\text{K}/0.00712\,\text{m}\right) = 5.13\,\text{W/m}^2\cdot\text{K}.$$

With N = W/(t + S) = (355 mm)/(8.62×10^{-3} m) = 41.2 ≈ 41,

$$q = 2N\bar{h}(L\times H)\left(T_s - T_\infty\right) = 82\left(5.13\,\text{W/m}^2\cdot\text{K}\right)(0.02\,\text{m}\times0.15\,\text{m})50\text{K}$$

$$q = 63.1\,\text{W}. \quad <$$

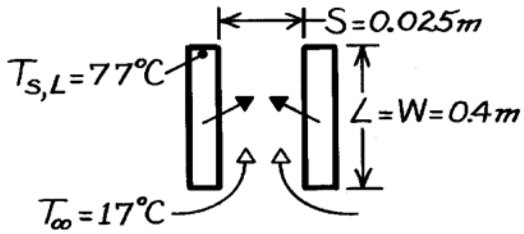
COMMENTS: S_{opt} = 7.12 mm is considerably less than the value of 34 mm predicted from previous considerations. Hence, the corresponding value of q = 63.1 W is considerably larger than that of the previous prediction.

PROBLEM 9.80

KNOWN: Length, width and spacing of vertical circuit boards. Maximum allowable board temperature.

FIND: Maximum allowable power dissipation per board.

SCHEMATIC:



ASSUMPTIONS: (1) Circuit boards are flat with uniform heat flux at each surface, (2) Negligible radiation.

PROPERTIES: *Table A-4*, Air $\left(\overline{T} = 320\text{K}, 1\text{ atm}\right)$: $\nu = 17.9 \times 10^{-6}$ m²/s, k = 0.0278 W/m·K, $\alpha = 25.5 \times 10^{-6}$ m²/s.

ANALYSIS: From Eqs. 9.41 and 9.46 and Table 9.3,

$$\frac{q_s''}{T_{s,L} - T_\infty}\frac{S}{k} = \left[\frac{48}{Ra_S^* S/L} + \frac{2.51}{\left(Ra_S^* S/L\right)^{2/5}}\right]^{-1/2}$$

where $$Ra_S^* \frac{S}{L} = \frac{g\beta q_s'' S^5}{k\alpha\nu L} = \frac{9.8\,\text{m/s}^2\,(320\,\text{K})^{-1}(0.025\,\text{m})^5\, q_s''}{0.0278\,\text{W/m}\cdot\text{K}\left(25.5\times10^{-6}\text{m}^2/\text{s}\right)\left(17.9\times10^{-6}\text{m}^2/\text{s}\right)0.4\,\text{m}}$$

$$Ra_S^* \frac{S}{L} = 58.9 q_s''$$

and $$\frac{q_s''}{T_{s,L} - T_\infty}\frac{S}{k} = \frac{0.025\text{ m}\cdot q_s''}{(60\text{ K})0.0278\,\text{W/m}\cdot\text{K}} = 0.015 q_s''.$$

Hence, $$0.015 q_s'' = \left[\frac{0.815}{q_s''} + \frac{0.492}{(q_s'')^{0.4}}\right]^{-1/2}.$$

A trial-and-error solution yields

$$q_s'' = 287\ \text{W/m}^2.$$

Hence, $$q = 2A_s q_s'' = 2(0.4\,\text{m})^2\left(287\,\text{W/m}^2\right) = 91.8\ \text{W}.$$ <

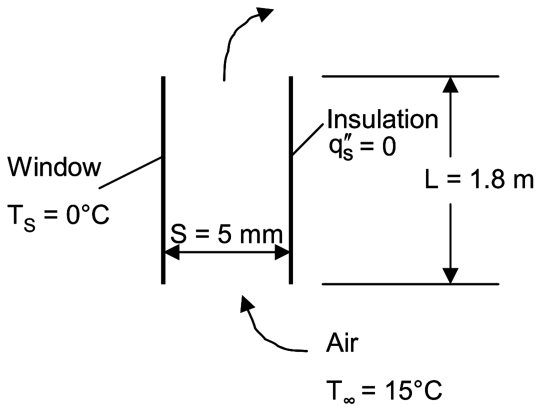
COMMENTS: Larger heat rates may be achieved by using a fan to superimpose a forced flow on the buoyancy driven flow.

PROBLEM 9.81

KNOWN: Dimensions of window and gap between window and insulation. Temperature of window and surrounding air.

FIND: (a) Heat loss through the window and associated weekly cost, (b) Heat loss through window as a function of gap spacing.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible radiation heat loss. (2) Insulation creates adiabatic condition.

PROPERTIES: Table A-4, Air (assumed $\overline{T} = 7°C = 280$ K): $\nu = 14.11 \times 10^{-6}$ m²/s, k = 0.0247 W/m·K, $\alpha = 19.9 \times 10^{-6}$ m²/s, $\beta = 1/\overline{T} = 0.0036$ K^{-1}.

ANALYSIS:

(a) This is a case of free convection in a vertical parallel plate channel. The window can be approximated as isothermal and the insulation can be modeled as adiabatic. Therefore we can use Equation 9.45 to find the average Nusselt number, with $C_1 = 144$, $C_2 = 2.87$ in Table 9.3. We begin by calculating the Rayleigh number from Equation 9.38:

$$Ra_S = \frac{g\,\beta\,|T_s - T_\infty| S^3}{\alpha\,\nu} \tag{1}$$

$$Ra_S = \frac{9.8\text{ m/s}^2 \times 0.0036\text{ K}^{-1} \times |0°C - 15°C| \times (0.005\text{ m})^3}{19.9 \times 10^{-6}\text{ m}^2/\text{s} \times 14.11 \times 10^{-6}\text{ m}^2/\text{s}} = 234$$

Then

$$\overline{Nu}_S = \left[\frac{C_1}{(Ra_S\,S/L)^2} + \frac{C_2}{(Ra_S\,S/L)^{1/2}}\right]^{-1/2} \tag{2}$$

$$\overline{Nu}_S = \left[\frac{144}{(234 \times 0.005\text{ m}/1.8\text{ m})^2} + \frac{2.87}{(234 \times 0.005\text{ m}/1.8\text{ m})^{1/2}}\right]^{-1/2} = 0.0538$$

From Equation 9.37 (noting that heat transfer is in the direction from the air to the surface)

$$q = \overline{Nu}_S\,k\,A\,(T_\infty - T_S)/S \tag{3}$$

$$= 0.0538 \times 0.0247\text{ W/m}\cdot\text{K} \times 1.8\text{ m}^2 (15°C - 0°C)/0.005\text{ m}$$

$$= 7.2\text{ W}$$ <

Then the weekly cost is

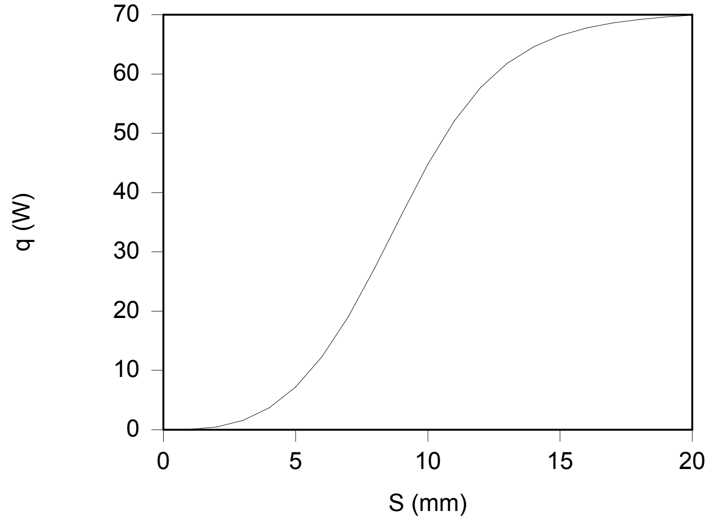
$$\text{Cost} = 7.2\text{ W} \times 0.18 \times 10^{-3}\text{ \$/W}\cdot\text{h} \times 24\text{ h/day} \times 7\text{ days}$$

$$\text{Cost} = \$0.22$$ <

Continued…

PROBLEM 9.81 (Cont.)

(b) Solving Equations (1), (2), and (3) for 1 mm $\le$ S $\le$ 20 mm, the following graph can be generated.



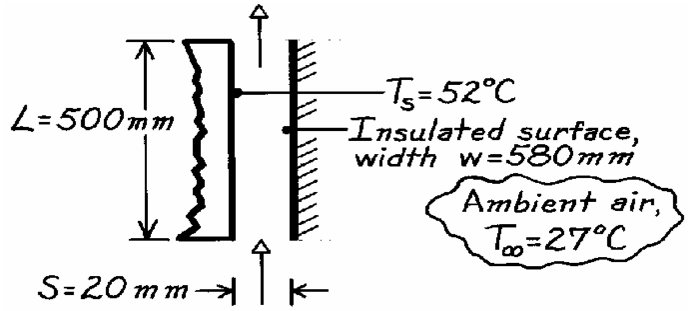
COMMENTS: (1) Despite the poor workmanship there is a significant cost savings. (2) With $Ra_S S/L = 0.65 < 10$ in part (a), we could have used the fully developed results, Equation 9.40. However this equation is not valid for $Ra_S S \gtrsim 10$, which corresponds to $S \gtrsim 10$ mm.

PROBLEM 9.82

KNOWN: Vertical air vent in front door of dishwasher with prescribed width and height. Spacing between isothermal and insulated surface of 20 mm.

FIND: (a) Heat loss from the tub surface and (b) Effect on heat rate of changing spacing by ± 10 mm.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Vent forms vertical parallel isothermal/adiabatic plates, (3) Ambient air is quiescent.

PROPERTIES: *Table A-4*, ($T_f = (T_s + T_\infty)/2 = 312.5$K, 1 atm): $\nu = 17.15 \times 10^{-6}$ m^2/s, $\alpha = 24.4 \times 10^{-6}$ m^2/s, k = 27.2×10^{-3} W/m·K, $\beta = 1/T_f$.

ANALYSIS: The vent arrangement forms two vertical plates, one is isothermal, T_s, and the other is adiabatic $(q'' = 0)$. The heat loss can be estimated from Eq. 9.37 with the correlation of Eq. 9.45 using $C_1 = 144$ and $C_2 = 2.87$ from Table 9.3:

$$Ra_S = \frac{g\beta(T_s - T_\infty)S^3}{\nu\alpha} = \frac{9.8\,m/s^2(1/312.5\text{ K})(52-27)\text{K}(0.020\,m)^3}{17.15\times10^{-6}m^2/s \times 24.4\times10^{-6}m^2/s} = 14,988$$

$$q = A_s(T_s - T_\infty)\frac{k}{S}\left[\frac{C_1}{(Ra_S S/L)^2} + \frac{C_2}{(Ra_S S/L)^{1/2}}\right]^{-1/2} = (0.500\times0.580)m^2 \times$$

$$(52-27)\text{K}\frac{0.0272\,\text{W/m}\cdot\text{K}}{0.020\,m}\left[\frac{C_1}{(Ra_S S/L)^2} + \frac{C_2}{(Ra_S S/L)^{1/2}}\right]^{-1/2} = 28.8\text{W}. \quad <$$

(b) To determine the effect of the spacing at S = 30 and 10 mm, we need only repeat the above calculations with these results

S (mm)	Ra_S	q (W)	
10	1874	26.1	<
30	50,585	28.8	<

Since it would be desirable to minimize heat losses from the tub, based upon these calculations, you would recommend a decrease in the spacing.

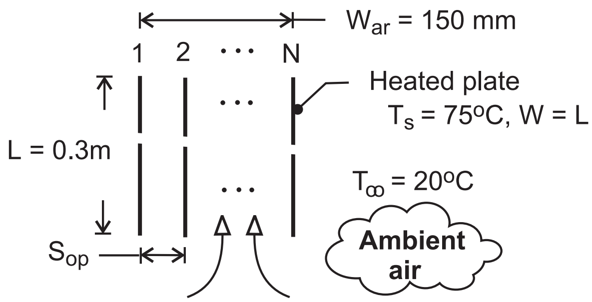
COMMENTS: For this situation, according to Table 9.3, the spacing corresponding to the maximum heat transfer rate is $S_{max} = (S_{max}/S_{opt}) \times 2.15(Ra_S/S^3L)^{-1/4} = 14.5$ mm. Find $q_{max} = 28.5$ W. Note that the heat rate is not very sensitive to spacing for these conditions.

PROBLEM 9.83

KNOWN: Dimensions, spacing and temperature of plates in a vertical array. Ambient air temperature. Total width of the array.

FIND: Optimal plate spacing for maximum heat transfer from the array and corresponding number of plates and heat transfer.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Negligible plate thickness, (3) Constant properties.

PROPERTIES: *Table A-4*, air $(p = 1\,\text{atm},\ \overline{T} = 320\text{K})$: $\nu = 17.9 \times 10^{-6}$ m^2/s, k = 0.0278 W/m·K, α = 25.5 × 10^{-6} m^2/s, Pr = 0.704, β = 0.00313 K^{-1}.

ANALYSIS: With $Ra_S/S^3L = g\beta(T_s - T_\infty)/\alpha\nu L$ = (9.8 m/s^2 × 0.00313 K^{-1} × 55°C)/(25.5 × 17.9 × 10^{-12} m^4/s^2 × 0.3m) = 1.232 × 10^{10} m^4, from Table 9.3, the spacing which maximizes heat transfer for the array is

$$S_{opt} = \frac{2.71}{\left(Ra_S/S^3L\right)^{1/4}} = \frac{2.71}{\left(1.232\times10^{10}\,\text{m}^{-4}\right)^{1/4}} = 8.13\times10^{-3}\,\text{m} = 8.13\,\text{mm} \qquad <$$

With the requirement that (N – 1) $S_{opt} \le W_{ar}$, it follows that N ≤ 1 + 150 mm/8.13 mm = 19.4, in which case

$$N = 19 \qquad <$$

The corresponding heat rate is $q = N(2WL)\overline{h}(T_s - T_\infty)$, where, from Eq. 9.45 and Table 9.3,

$$\overline{h} = \frac{k}{S}\overline{Nu}_S = \frac{k}{S}\left[\frac{576}{(Ra_S S/L)^2} + \frac{2.87}{(Ra_S S/L)^{1/2}}\right]^{1/2}$$

With Ra_S S/L = $(Ra_S/S^3L)S^4$ = 1.232 × 10^{10} m^{-4} × (0.00813m)^4 = 53.7,

$$\overline{h} = \frac{0.0278\,\text{W/m}\cdot\text{K}}{0.00813\text{m}}\left[\frac{576}{(53.7)^2} + \frac{2.87}{(53.7)^{1/2}}\right] = 3.42(0.200 + 0.392) = 2.02\,\text{W/m}^2\cdot\text{K}$$

$$q = 19(2\times0.3\text{m}\times0.3\text{m})\,2.02\,\text{W/m}^2\cdot\text{K}\times55°\text{C} = 380\,\text{W} \qquad <$$

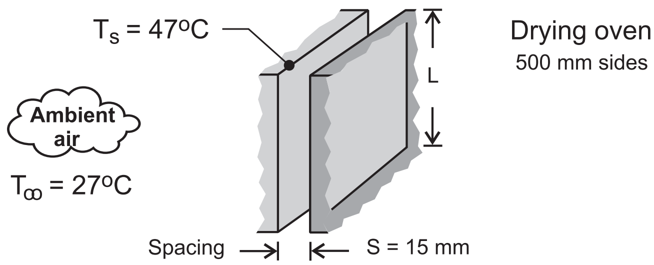
COMMENTS: It would be difficult to fabricate heater plates of thickness $\delta << S_{opt}$. Hence, subject to the constraint imposed on W_{ar}, N would be reduced, where N ≤ 1 + $W_{ar}/(S_{opt} + \delta)$.

PROBLEM 9.84

KNOWN: A bank of drying ovens is mounted on a rack in a room with an ambient temperature of 27°C; the cubical ovens are 500 mm to a side and the spacing between the ovens is 15 mm.

FIND: (a) Estimate the heat loss from the facing side of an oven when its surface temperature is 47°C, and (b) Explore the effect of the spacing dimension on the heat loss. At what spacing is the heat loss a maximum? Describe the boundary layer behavior for this condition. Can this condition be analyzed by treating the oven side-surface as an isolated vertical plate?

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Adjacent oven sides form a vertical channel with symmetrically heated plates, (3) Room air is quiescent, and channel sides are open to the room air, and (4) Constant properties.

PROPERTIES: *Table A-4*, Air ($T_f = (T_s + T_\infty)/2 = 310$ K, 1 atm): $\nu = 1.69 \times 10^{-5}$ m^2/s, k = 0.0270 W/m·K, $\alpha = 2.40 \times 10^{-5}$ m^2/s, Pr = 0.706, $\beta = 1/T_f$.

ANALYSIS: (a) For the isothermal plate channel, Eq. 9.45 with Eqs. 9.37 and 9.38, allow for calculation of the heat transfer from a plate to the ambient air.

$$\overline{Nu}_S = \left[\frac{C_1}{(Ra_S S/L)^2} + \frac{C_2}{\left(Ra_S S/L\right)^{1/2}}\right]^{-1/2} \qquad (1)$$

$$\overline{Nu}_S = \frac{q/A}{T_s - T_\infty}\frac{S}{k} \qquad (2)$$

$$Ra_S = \frac{g\beta\left(T_s - T_\infty\right)S^3}{\alpha\nu} \qquad (3)$$

where, from Table 9.3, for the *symmetrical isothermal plates*, $C_1 = 576$ and $C_2 = 2.87$. Properties are evaluated at the film temperature T_f. Substituting numerical values, evaluate the correlation parameters and the heat rate.

$$Ra_S = \frac{9.8\text{ m/s}^2\left(1/310\text{ K}\right)\left(47-27\right)\text{K}\left(0.015\text{ m}\right)^3}{2.40\times10^{-5}\text{ m}^2/\text{s}\times1.69\times10^{-5}\text{ m}^2/\text{s}} = 5267$$

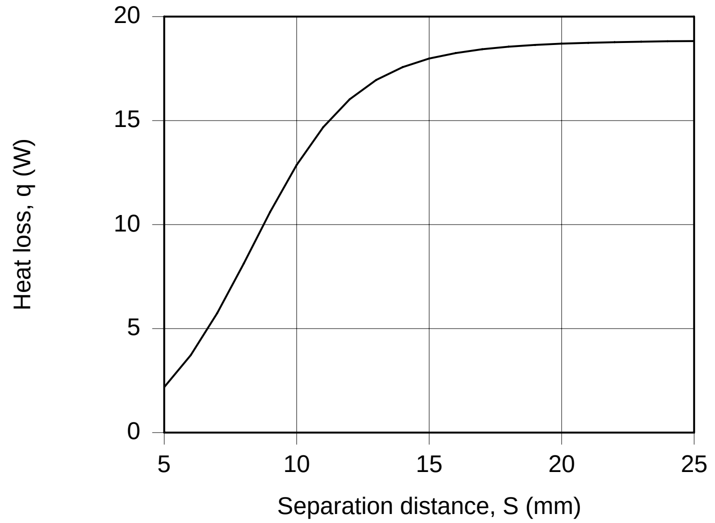
$$\overline{Nu}_S = \left[\frac{576}{(5267\times0.015\text{ m}/0.50\text{ m})^2} + \frac{2.87}{\left(5267\times0.015\text{ m}/0.050\text{ m}\right)^{1/2}}\right]^{-1/2} = 1.994$$

$$1.994 = \frac{q/\left(0.50\times0.50\right)\text{m}^2}{\left(47-27\right)\text{K}}\,\frac{0.015\text{ m}}{0.0270\text{ W/m}\cdot\text{K}} \qquad q = 18.0\text{ W}$$ <

Continued …

PROBLEM 9.84 (Cont.)

(b) Using the foregoing relations in *IHT*, the heat rate is calculated for a range of spacing S.



Note that the heat rate increases with increasing spacing up to about S = 20 mm. This implies that for S > 20 mm, the side wall of the oven behaves as an *isolated vertical plate*. From the treatment of the vertical channel, Section 9.7.1, the spacing to provide maximum heat rate from a plate occurs at S_{max} which, from Table 9.3, is evaluated by

$$S_{max} = 1.71\, S_{opt} = 0.01964 \text{ m} = 19.6 \text{ mm}$$

$$S_{opt} = 2.71\left(Ra_S / S^3 L\right)^{-1/4} = 0.01147 \text{ m}$$

For the condition $S = S_{max}$, the spacing is sufficient that the boundary layers on the plates do not overlap.

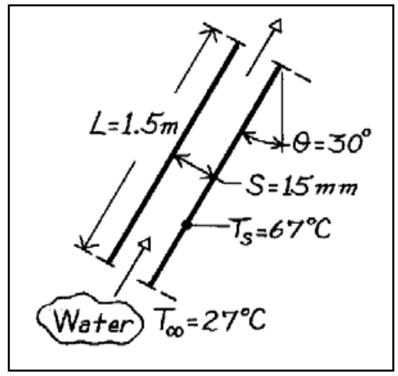
COMMENTS: Using the Churchill-Chu correlation, Eq. 9.26, for the isolated vertical plate, where the characteristic dimension is the height L, find q = 20.2 W ($Ra_L = 1.951 \times 10^8$ and $\overline{h}_L = 4.03$ $W/m^2 \cdot K$). This value is slightly larger than that from the channel correlation when $S > S_{max}$, but a good approximation.

PROBLEM 9.85

KNOWN: Inclination angle of parallel plate solar collector. Plate spacing. Absorber plate and inlet temperature.

FIND: Rate of heat transfer to collector fluid.

SCHEMATIC:



ASSUMPTIONS: (1) Flow in collector corresponds to buoyancy driven flow between parallel plates with quiescent fluids at the inlet and outlet, (2) Constant properties.

PROPERTIES: *Table A-6*, Water $(\bar{T} = 320\text{K})$: ρ = 989 kg/m^3, c_p = 4180 J/kg·K, $\mu = 577 \times 10^{-6}$ kg/s·m, k = 0.640 W/m·K, $\beta = 436.7 \times 10^{-6}$ K^{-1}.

ANALYSIS: With

$$\alpha = \frac{k}{\rho c_p} = \frac{0.640\,\text{W/m}\cdot\text{K}}{989\,\text{kg/m}^3(4180\,\text{J/kg}\cdot\text{K})} = 1.55\times10^{-7}\,\text{m}^2/\text{s}$$

$$\nu = (\mu/\rho) = \left(577\times10^{-6}\,\text{kg/s}\cdot\text{m}\right)/989\,\text{kg/m}^3 = 5.83\times10^{-7}\,\text{m}^2/\text{s}$$

find

$$Ra_S\frac{S}{L} = \frac{g\beta(T_s - T_\infty)S^4}{\alpha\nu L} = \frac{9.8\,\text{m/s}^2\left(436.7\times10^{-6}\,\text{K}^{-1}\right)(40\,\text{K})(0.015\,\text{m})^4}{\left(1.55\times10^{-7}\,\text{m}^2/\text{s}\right)\left(5.83\times10^{-7}\,\text{m}^2/\text{s}\right)1.5\,\text{m}}$$

$$Ra_S\frac{S}{L} = 6.39\times10^4.$$

Since $Ra_S(S/L) > 200$, Eq. 9.47 may be used,

$$\overline{Nu}_S = 0.645\left[Ra_S(S/L)\right]^{1/4} = 0.645\left(6.39\times10^4\right)^{1/4} = 10.3$$

$$\bar{h} = \overline{Nu}_S\frac{k}{S} = 10.3(0.64\,\text{W/m}\cdot\text{K}/0.015\,\text{m}) = 438\,\text{W/m}^2\cdot\text{K}.$$

Hence the heat rate is

$$q = \bar{h}A(T_s - T_\infty) = 438\,\text{W/m}^2\cdot\text{K}(1.5\,\text{m})(67-27)\text{K} = 26{,}300\,\text{W/m}. \quad <$$

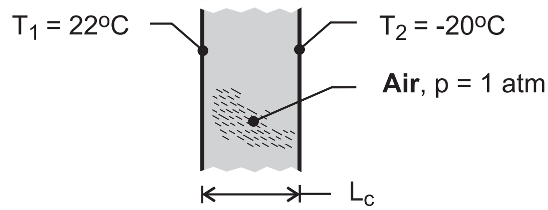
COMMENTS: Such a large heat rate would necessitate use of a concentrating solar collector for which the normal solar flux would be significantly amplified.

PROBLEM 9.86

KNOWN: Critical Rayleigh number for onset of convection in vertical cavity filled with atmospheric air. Temperatures of opposing surfaces.

FIND: Maximum allowable spacing for heat transfer by conduction across the air. Effect of surface temperature and air pressure.

SCHEMATIC:



ASSUMPTIONS: (1) Critical Rayleigh number is $Ra_{L,c} = 2000$, (2) Constant properties.

PROPERTIES: *Table A-4*, air [$T = (T_1 + T_2)/2 = 1°C = 274K$]: $\nu = 13.6 \times 10^{-6}\ m^2/s$, $k = 0.0242\ W/m\cdot K$, $\alpha = 19.1 \times 10^{-6}\ m^2/s$, $\beta = 0.00365\ K^{-1}$.

ANALYSIS: With $Ra_{L,c} = g\,\beta\,(T_1 - T_2)\,L_c^3/\alpha\nu$,

$$L_c = \left[\frac{\alpha\nu\,Ra_{L,c}}{g\beta(T_1 - T_2)}\right]^{1/3} = \left[\frac{19.1\times13.6\times10^{-12}\,m^4/s^2\times2000}{9.8\,m/s^2\times0.00365\,K^{-1}\times42°C}\right]^{1/3} = 0.007\,m = 7\,mm$$ <

The critical value of the spacing, and hence the corresponding thermal resistance of the air space, increases with a decreasing temperature difference, $T_1 - T_2$, and decreasing air pressure. With $\nu = \mu/\rho$ and $\alpha \equiv k/\rho c_p$, both quantities increase with decreasing p, since ρ decreases while μ, k and c_p are approximately unchanged.

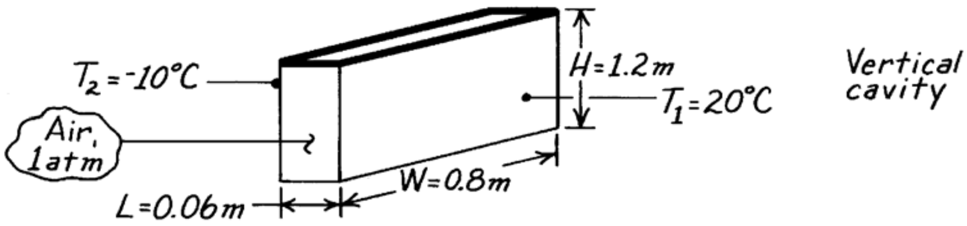
COMMENTS: (1) For the prescribed conditions and $L_c = 7$ mm, the conduction heat flux across the air space is $q'' = k(T_1 - T_2)/L_c = 0.0242\,W/m\cdot K \times 42°C/0.007m = 145\,W/m^2$, (2) With triple pane construction, the conduction heat loss could be reduced by a factor of approximately two, (3) Heat loss is also associated with radiation exchange between the panes.

PROBLEM 9.87

KNOWN: Temperatures and dimensions of a window-storm window combination.

FIND: Rate of heat loss by free convection.

SCHEMATIC:



ASSUMPTIONS: (1) Both glass plates are of uniform temperature with insulated interconnecting walls and (2) Negligible radiation exchange.

PROPERTIES: *Table A-4*, Air (278K, 1 atm): $\nu = 13.93 \times 10^{-6}$ m^2/s, k = 0.0245 W/m·K, $\alpha = 19.6 \times 10^{-6}$ m^2/s, Pr = 0.71, $\beta = 0.00360$ K^{-1}.

ANALYSIS: For the vertical cavity,

$$Ra_L = \frac{g\beta(T_1 - T_2)L^3}{\alpha\nu} = \frac{9.8\,m/s^2\left(0.00360\,K^{-1}\right)(30°C)(0.06m)^3}{19.6\times10^{-6}m^2/s\times13.93\times10^{-6}m^2/s}$$

$$Ra_L = 8.37\times10^5.$$

With (H/L) = 20, Eq. 9.52 may be used as a first approximation for Pr = 0.71,

$$\overline{Nu}_L = 0.42\,Ra_L^{1/4}\,Pr^{0.012}(H/L)^{-0.3} = 0.42\left(8.37\times10^5\right)^{1/4}(0.71)^{0.012}(20)^{-0.3}$$

$$\overline{Nu}_L = 5.2$$

$$\bar{h} = \overline{Nu}_L\,\frac{k}{L} = 5.2\,\frac{0.0245\,W/m\cdot K}{0.06m} = 2.1\,W/m^2\cdot K.$$

The heat loss by free convection is then

$$q = \bar{h}\,A\left(T_1 - T_2\right)$$

$$q = 2.1\,W/m^2\cdot K\left(1.2m\times0.8m\right)(30°C) = 61\,W.$$ <

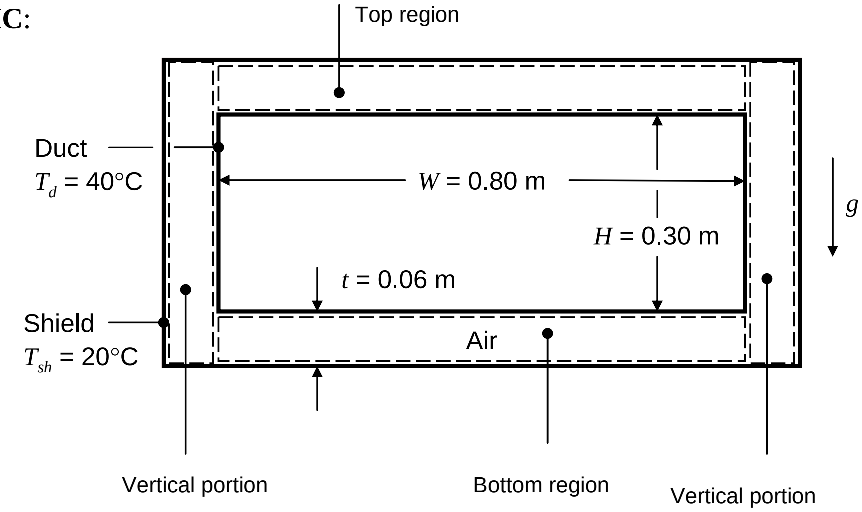
COMMENTS: In such an application, radiation losses should also be considered, and infiltration effects could render heat loss by free convection significant.

PROBLEM 9.88

KNOWN: Dimensions of horizontal rectangular duct and radiation shield. Temperatures of duct and shield walls.

FIND: Convection heat loss per unit length.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Uniform duct and shield wall temperatures, (3) Constant properties, (4) Convection occurs in four distinct rectangular regions, (4) Convection is two-dimensional.

PROPERTIES: *Table A-4*, Air (T = 303 K): $\nu = 16.19 \times 10^{-6}$ m^2/s, $\alpha = 22.94 \times 10^{-6}$ m^2/s, $k = 26.5 \times 10^{-3}$ W/m · K, $Pr = 0.707$, $\beta = 1/T = 0.0033$ K^{-1}.

ANALYSIS: Within the vertical portions of the enclosure, motion will occur in the vertical direction and will likely extend from the bottom to the top of the shield wall. Thus, the aspect ratio for the vertical regions is $(H + 2t)/t = 0.42/0.06 = 7$. The Rayleigh number based on the enclosure width, t, is

$$Ra_t = \frac{g\beta(T_1 - T_2)t^3}{\nu\alpha} = \frac{9.8 \text{ m/s}^2 \times 0.0033 \text{ K}^{-1} \times (40-20)°\text{C} \times (0.06 \text{ m})^3}{16.19 \times 10^{-6} \text{ m}^2/\text{s} \times 22.94 \times 10^{-6} \text{ m}^2/\text{s}} = 3.76 \times 10^5$$

Therefore, Eq. 9.50 holds, and yields

$$\overline{Nu}_t = 0.22\left(\frac{Pr}{0.2+Pr}Ra_t\right)^{0.28}\left(\frac{H+2t}{t}\right)^{-1/4} = 0.22\left(\frac{0.707}{0.2+0.707}3.76\times10^5\right)^{0.28}(7)^{-1/4} = 4.59$$

and

$$\bar{h}_{\text{vert}} = \overline{Nu}_t k / t = 4.59 \times 26.5 \times 10^{-3} \text{ W/m}\cdot\text{K} / 0.06 \text{ m} = 2.03 \text{ W/m}^2\cdot\text{K}$$

The two horizontal regions differ from one another. The bottom region is heated from above. There is therefore no air motion and $\overline{Nu}_t = 1$, which yields

$$\bar{h}_{\text{bot}} = \overline{Nu}_{t,\text{bot}} k / t = 1 \times 26.5 \times 10^{-3} \text{ W/m}\cdot\text{K} / 0.06 \text{ m} = 0.442 \text{ W/m}^2\cdot\text{K}$$

The top region is heated from below and the Rayleigh number exceeds the critical value for convection to occur, $Ra_{t,\text{crit}} = 1708$. From Eq. 9.49,

Continued...

PROBLEM 9.88 (Cont.)

$$\overline{Nu}_{t,\text{top}} = 0.069 Ra_t^{1/3} Pr^{0.074} = 4.85$$

and

$$\bar{h}_{\text{top}} = \overline{Nu}_{t,\text{top}} k/t = 4.85 \times 26.5 \times 10^{-3}\ \text{W/m}\cdot\text{K}/0.06\ \text{m} = 2.15\ \text{W/m}^2\cdot\text{K}$$

Finally, the convection heat loss per unit length is

$$q'_{\text{conv}} = \left[2\bar{h}_{\text{vert}}(H+2t) + (\bar{h}_{\text{bot}} + \bar{h}_{\text{top}})W\right](T_1 - T_2)$$

$$= \left[2 \times 2.03\ \text{W/m}^2\cdot\text{K}(0.42\ \text{m}) + (0.442 + 2.15)\ \text{W/m}^2\cdot\text{K} \times 0.8\ \text{m}\right](40-20)°\text{C} = 75.5\ \text{W/m}$$ <

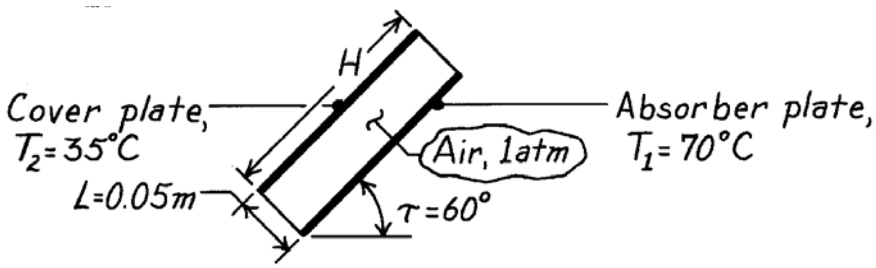
COMMENTS: (1) The identified rectangular regions do not satisfy the adiabatic end condition. (2) Presumably the shield would have a small emissivity to reduce radiation. However, if both surfaces have an emissivity of one, radiation across the enclosure is given by $q'_{\text{rad}} = \sigma\left[2W + 2H\right](T_1^4 - T_2^4)$ $= 5.67 \times 10^{-8}\ \text{W/m}^2\cdot\text{K}^4 \times \left[2 \times 0.8\ \text{m} + 2 \times 0.3\ \text{m}\right] \times (313^4 - 293^4)\ \text{K}^4$ = 278 W/m. Radiation can be more significant than free convection.

PROBLEM 9.89

KNOWN: Absorber plate and cover plate temperatures and geometry for a flat plate solar collector.

FIND: Heat flux due to free convection.

SCHEMATIC:



ASSUMPTIONS: (1) Aspect ratio, H/L, is greater than 12.

PROPERTIES: *Table A-4*, Air (325K, 1 atm): $\nu = 18.4 \times 10^{-6}$ m^2/s, k = 0.028 W/m·K, α = 26.2×10^{-6} m^2/s, Pr = 0.703, $\beta = 3.08 \times 10^{-3}$ K^{-1}.

ANALYSIS: For the inclined enclosure,

$$\mathrm{Ra_L} = \frac{g\beta(T_1 - T_2)L^3}{\alpha\nu} = \frac{9.8\,\mathrm{m/s^2}\left(3.08\times10^{-3}\mathrm{K^{-1}}\right)(70-35)^\circ\mathrm{C}\left(0.05\mathrm{m}\right)^3}{\left(26.2\times10^{-6}\mathrm{m^2/s}\right)\left(18.4\times10^{-6}\mathrm{m^2/s}\right)}$$

$$\mathrm{Ra_L} = 2.74\times10^5.$$

With $\tau < \tau^* = 70°$, Table 9.4,

$$\overline{\mathrm{Nu}}_L = 1 + 1.44\left[1 - \frac{1708}{\mathrm{Ra_L}\cos\tau}\right]^\bullet \left[1 - \frac{1708(\sin 1.8\tau)^{1.6}}{\mathrm{Ra_L}\cos\tau}\right] + \left[\left(\frac{\mathrm{Ra_L}\cos\tau}{5830}\right)^{1/3} - 1\right]^\bullet$$

$$\overline{\mathrm{Nu}}_L = 1 + 1.44(0.99)(0.99) + 1.86 = 4.28$$

$$\bar{h} = \overline{\mathrm{Nu}}_L \frac{k}{L} = 4.28\frac{0.028\,\mathrm{W/m\cdot K}}{0.05\mathrm{m}} = 2.4\,\mathrm{W/m^2\cdot K}.$$

Hence, the heat flux is

$$q'' = h(T_1 - T_2) = 2.4\mathrm{W/m^2\cdot K}(70-35)^\circ\mathrm{C}$$

$$q'' = 84\,\mathrm{W/m^2}.$$ <

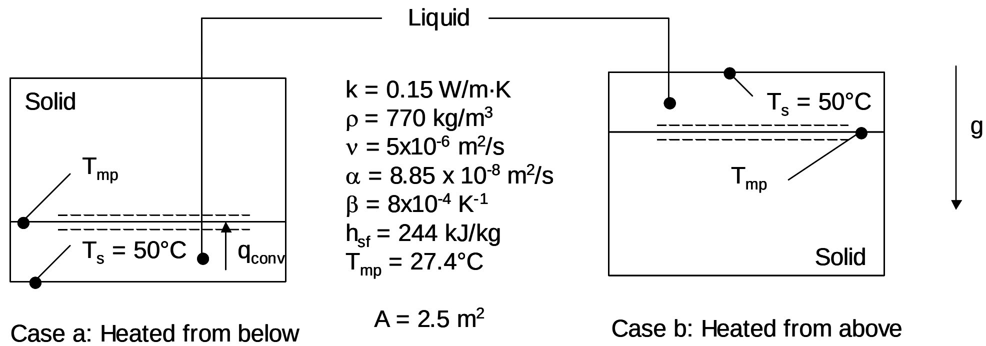
COMMENTS: Radiation exchange between the absorber and cover plates will also contribute to heat loss from the collector.

PROBLEM 9.90

KNOWN: Dimensions and properties of paraffin slab, initial liquid layer thickness. Temperature of the hot surface.

FIND: (a) Amount of paraffin melted over a period of 5 hours in response to bottom heating, (b) Amount of energy used to melt the paraffin and amount of energy needed to raise the average temperature of the liquid paraffin, (c) Amount of paraffin melted over a period of 5 hours with top heating.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Neglect change of sensible energy of the liquid, (3) One-dimensional heat transfer.

PROPERTIES: Given, see schematic.

ANALYSIS: (a) Neglecting the change in the sensible energy, the mass melted is

$$M = E/h_{sf} = q''At/h_{sf} = \bar{h}A(T_s - T_{mp})t/h_{sf}$$

Using the Globe and Dropkin correlation,

$$h = 0.069k\left[g\beta(T_s - T_{mp})/\nu\alpha\right]^{1/3} Pr^{0.074}$$

Combining the equations gives

$$M = 0.15 W/m\cdot K \times 0.069 \times \left[\frac{9.8 m/s^2 \times 8\times10^{-4} K^{-1} \times (50-27.4)°C}{5\times10^{-6} m^2/s \times 8.85\times10^{-8} m^2/s}\right]^{1/3} \times \left[\frac{5\times10^{-6} m^2/s}{8.85\times10^{-8} m^2/s}\right]^{0.074}$$

$$\times \frac{2.5 m^2 \times (50-27.4)°C \times 5 h \times 3600 s/h}{244\times10^3 J/kg}$$

= 429 kg <

(b) The energy consumed to melt the paraffin is

Continued…

PROBLEM 9.90 (Cont.)

$$E_m = Mh_{sf} = 429\,kg \times 244 \times 10^3\,J/kg = 105 \times 10^6\,J$$ <

The energy associated with raising the temperature to $\overline{T} = (50°C + 27.4°C)/2 = 38.7°C$ is

$$E_s = Mc_p(\overline{T} - T_{mp}) = M(k/\rho\alpha)(\overline{T} - T_{mp})$$

$$= 429\,kg \times \left(\frac{0.15\,W/m\cdot K}{770\,kg/m^3 \cdot 8.85 \times 10^{-8}\,m^2/s}\right) \times (38.7 - 27.4°C) = 10.7 \times 10^6\,J$$

The ratio of the change of sensible energy to energy absorbed in the phase change is

$$E_s/E_m = 10.7\times 10^6\,J/105\times10^6\,J = 0.102$$ <

(c) The liquid layer is heated from above. Heat transfer in the liquid phase is by conduction. The temperature distribution in the liquid is linear if the change in sensible energy of the liquid is neglected. Hence, an energy balance on the control surface shown in the schematic yields

$$q'' = k\frac{(T_s - T_{mp})}{s} = \rho h_{sf}\frac{ds}{dt}$$

Separating variables and integrating

$$\frac{k(T_s - T_{mp})}{\rho h_{sf}}\int_{t=0}^{t} dt = \int_{s_i}^{s(t)} s\,ds \quad \text{or} \quad s(t) = \sqrt{\frac{2k(T_s - T_{mp})t}{\rho h_{sf}} + s_i^2}$$

Therefore,

$$s(t = 5h) = \sqrt{\frac{2 \times 0.15\,W/m\cdot K \times (50 - 27.4)°C \times 5h \times 3600\,s/h}{770\,kg/m^3 \times 244 \times 10^3\,J/kg} + (0.01m)^2}$$

$$= 27 \times 10^{-3}\,m = 27\,mm$$

$$M = A\rho[s(t = 5h) - s_i] = 2.5m^2 \times 770\,kg/m^3 \times (27 \times 10^{-3}m - 10 \times 10^{-3}m) = 33.4\,kg$$ <

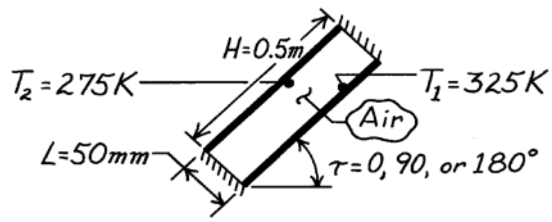
COMMENTS: (1) For the bottom heated case at t = 5 h, the solid-liquid interface is located at $M/\rho A + s_i$ = 429 kg/(770 kg/m^3 × 2.5 m^2) + 0.01 m = 0.233 m. The Rayleigh numbers associated with the bottom heating case range from $Ra_s = g\beta(T_s - T_{mp})s_i^3/\nu\alpha$ = 9.8m/s^2 × 8 × 10^{-4} K^{-1} × (50 – 27.4)°C × (0.01m)^3/(5 × 10^{-6} m^2/s × 8.85 × 10^{-8} m^2/s) = 4 × 10^5 to 5 × 10^9 at t = 5 h. Hence, use of the Globe and Dropkin correlation is justified. (2) The ratio of the change in sensible energy to the absorption of latent energy is referred to as the liquid phase Stefan number. Since the liquid phase Stefan number is much less than unity, it is reasonable to neglect the change of sensible energy of the liquid phase when calculating the melting rate or solid-liquid interface location.

PROBLEM 9.91

KNOWN: Rectangular cavity of two parallel, 0.5m square plates with insulated inter-connecting sides and with prescribed separation distance and surface temperatures.

FIND: Heat flux between surfaces for three orientations of the cavity: (a) Vertical τ = 90°C, (b) Horizontal with τ = 0°, and (c) Horizontal with τ = 180°.

SCHEMATIC:



ASSUMPTIONS: (1) Radiation exchange is negligible, (2) Air is at atmospheric pressure.

PROPERTIES: *Table A-4*, Air ($T_f = (T_1 + T_2)/2$ = 300K, 1 atm): $\nu = 15.89 \times 10^{-6}$ m^2/s, k = 0.0263 W/m·K, $\alpha = 22.5 \times 10^{-6}$ m^2/s, Pr = 0.707, $\beta = 1/T_f = 3.333 \times 10^{-3}$ K^{-1}.

ANALYSIS: The convective heat flux between the two cavity plates is

$$q''_{conv} = \bar{h}\left(T_1 - T_2\right)$$

where $\bar{h}$ is estimated from the appropriate enclosure correlation which will depend upon the Rayleigh number. From Eq. 9.25, find

$$Ra_L = \frac{g\beta\left(T_1 - T_2\right)L^3}{\nu\alpha} = \frac{9.8\,m/s^2 \times 3.333\times10^{-3}K^{-1}\left(325-275\right)K\left(0.05m\right)^3}{15.89\times10^{-6}m^2/s\times22.5\times10^{-6}m^2/s} = 5.710\times10^5.$$

Note that H/L = 0.5/0.05 = 10, a factor which is important in selecting correlations.

(a) With τ = 90°, for a vertical cavity, Eq. 9.50, is appropriate,

$$\overline{Nu}_L = 0.22\left(\frac{Pr}{0.2+Pr}Ra_L\right)^{0.28}\left(\frac{H}{L}\right)^{-1/4} = 0.22\left(\frac{0.707}{0.2+0.707}\times5.71\times10^5\right)^{0.28}\left(10\right)^{-1/4} = 4.72$$

$$\bar{h}_L = \frac{k}{L}\overline{Nu}_L = \frac{0.0263\,W/m\cdot K}{0.05m}\times4.72 = 2.48\,W/m^2\cdot K$$

$$q''_{conv} = 2.48\,W/m^2\cdot K\left(325-275\right)K = 124\,W/m^2.$$ <

(b) With τ = 0° for a horizontal cavity heated from below, Eq. 9.49 is appropriate.

$$\bar{h} = \frac{k}{L}\overline{Nu}_L = 0.069\frac{k}{L}Ra_L^{1/3}Pr^{0.074} = 0.069\frac{0.0263\,W/m\cdot K}{0.05m}\left(5.710\times10^5\right)^{1/3}\left(0.707\right)^{0.074}$$

$$\bar{h} = 2.92\,W/m^2\cdot K$$

$$q''_{conv} = 2.92\,W/m^2\cdot K\left(325-275\right)K = 146\,W/m^2.$$ <

(c) For τ = 180° corresponding to the horizontal orientation with the heated plate on the top, heat transfer will be by conduction. That is,

$$\overline{Nu}_L = 1 \qquad \text{or} \qquad \bar{h}_L = \overline{Nu}_L\cdot\frac{k}{L} = 1\times0.0263\,W/m\cdot K/\left(0.05m\right) = 0.526\,W/m^2\cdot K.$$

$$q''_{conv} = 0.526\,W/m^2\cdot K\left(325-275\right)K = 26.3\,W/m^2.$$ <

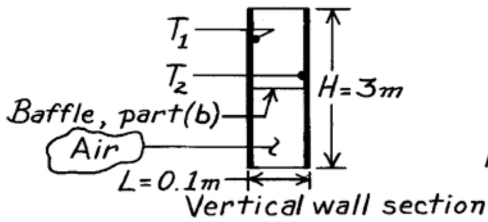
COMMENTS: Compare the heat fluxes for the various orientations and explain physically their relative magnitudes.

PROBLEM 9.92

KNOWN: Horizontal flat roof and vertical wall sections of same dimensions exposed to identical temperature differences.

FIND: (a) Ratio of convection heat rate for horizontal section to that of the vertical section and (b) Effect of inserting a baffle at the mid-height of the vertical wall section on the convection heat rate.

SCHEMATIC:



ASSUMPTIONS: (1) Ends of sections and baffle adiabatic, (2) Steady-state conditions.

PROPERTIES: *Table A-4*, Air $\left(\bar{T} = (T_1 + T_2)/2 = 277\text{K}, 1\text{atm}\right)$: $\nu = 13.84 \times 10^{-6}$ m^2/s, k = 0.0245 W/m·K, $\alpha = 19.5 \times 10^{-6}$ m^2/s, Pr = 0.713.

ANALYSIS: (a) The ratio of the convection heat rates is

$$\frac{q_{hor}}{q_{vert}} = \frac{\bar{h}_{hor} A_s \Delta T}{\bar{h}_{vert} A_s \Delta T} = \frac{\bar{h}_{hor}}{\bar{h}_{vert}}. \qquad (1)$$

To estimate coefficients, recognizing both sections have the same characteristics length, L = 0.1m, with $Ra_L = g\beta\Delta TL^3/\nu\alpha$ find

$$Ra_L = \frac{9.8\,\text{m/s}^2 \times (1/277\text{K})(18-(-10))\text{K}(0.1\text{m})^3}{13.84\times10^{-6}\text{m}^2/\text{s}\times19.5\times10^{-6}\text{m}^2/\text{s}} = 3.67\times10^6.$$

The appropriate correlations for the sections are Eqs. 9.49 and 9.52 (with H/L = 30),

$$\overline{Nu}_L\Big|_{hor} = 0.069\,Ra_L^{1/3}\,Pr^{0.074} \qquad \overline{Nu}_L\Big|_{vert} = 0.42\,Ra_L^{1/4}\,Pr^{0.012}\,(H/L)^{-0.3}. \qquad (3,4)$$

Using Eqs. (3) and (4), the ratio of Eq. (1) becomes,

$$\frac{q_{hor}}{q_{vert}} = \frac{0.069\,Ra_L^{1/3}\,Pr^{0.074}}{0.42\,Ra_L^{1/4}\,Pr^{0.012}\,(H/L)^{-0.3}} = \frac{0.069\left(3.67\times10^6\right)^{1/3}(0.713)^{0.074}}{0.42\left(3.67\times10^6\right)^{1/4}(0.713)^{0.012}(30)^{-0.3}} = 1.57.$$ <

(b) The effect of the baffle in the vertical wall section is to reduce H/L from 30 to 15. Using Eq. 9.52, it follows,

$$\frac{q_{baf}}{q} = \frac{\bar{h}_{baf}}{\bar{h}} = \frac{(H/L)_{baf}^{-0.3}}{(H/L)^{-0.3}} = \left(\frac{15}{30}\right)^{-0.3} = 1.23.$$ <

That is, the effect of the baffle is to increase the convection heat rate.

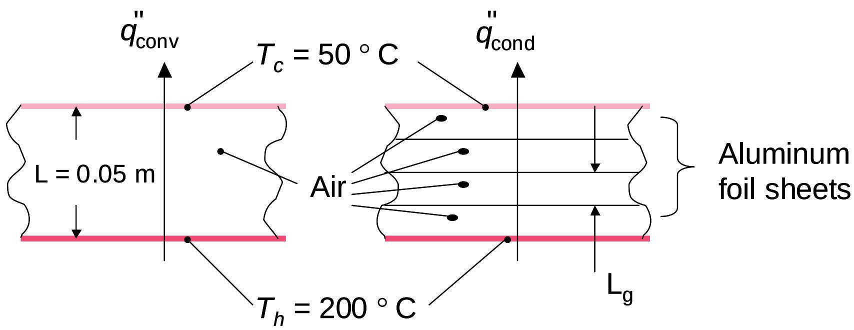
COMMENTS: (1) Note that the heat rate for the horizontal section is 57% larger than that for the vertical section for the same $(T_1 - T_2)$. This indicates the importance of heat losses from the ceiling or roofs in house construction. (2) Recognize that for Eq. 9.52, the Pr > 1 requirement is not completely satisfied. (3) What is the physical explanation for the result of part (b)?

PROBLEM 9.93

KNOWN: Dimensions of horizontal air space separating plates of known temperature.

FIND: (a) Convective heat flux for a 50 mm gap, hot and cold plate temperatures of T_h = 200°C and T_c = 50°C, respectively, (b) Minimum number of thin aluminum sheets needed to suppress convection, (c) Conduction heat flux with the sheets in place.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Steady-state conditions, (3) Foil sheets have negligible conduction resistance and negligible thickness.

PROPERTIES: Table A.4, air: (T_f = (200°C + 50°C)/2 = 125°C): k = 0.03365 W/m·K, ν = 2.619×10^{-5} m²/s, α = 3.796×10^{-5} m²/s, Pr = 0.6904.

ANALYSIS: (a) The Rayleigh number is

$$\begin{aligned} Ra &= g\beta(T_h - T_c)L^3/\nu\cdot\alpha \\ &= 9.8\,m/s^2 \times \frac{1}{(125+273)K} \times (200-50)°C \times (0.05m)^3/(2.619\times10^{-5}m^2/s \times 3.796\times10^{-5}m^2/s) \\ &= 4.64\times10^5 \end{aligned}$$

Using the Globe and Dropkin correlation,

$$\overline{h}_L = 0.069(k/L)Ra^{1/3}Pr^{0.074} = 0.069\times(0.03365W/m\cdot K/5\times10^{-3}m)\times(4.64\times10^5)^{1/3}\times(0.6904)^{0.074}$$

$$= 3.50\ W/m^2\cdot K$$

Therefore, $q''_{conv} = 3.50W/m^2\cdot K \times (200-50)°C = 525W/m^2$ <

(b) For Ra_{Lg} < 1708, there will be no convection in an air layer. The number of gaps is N_g = N + 1. The gap width is L_g = L/(N + 1) and, as a first estimate, the temperature difference across each gap is ΔT_g = (T_h – T_c)/(N + 1). We require 1708 > Ra_{Lg}, or

Continued…

PROBLEM 9.93 (Cont.)

$$\frac{g\beta\left[\left(T_h - T_c\right)\left(N+1\right)\right]\left[L/(N+1)\right]^3}{\nu\cdot\alpha} < 1708$$

or

$$\frac{9.8\,m/s^2 \times \left[1/(273+125)\right]K^{-1} \times \left[\left(200-50\right)°C/(N+1)\right] \times \left[0.05\,m/(N+1)\right]^3}{2.619\times10^{-5}\,m^2/s \times 3.796\times10^{-5}\,m^2/s} < 1708$$

from which we may determine N > 3.06. Therefore, we specify N = 4. <

(c) Neglecting the thickness and thermal resistance of the foil sheets,

$$q''_{cond} = k(T_h - T_c)/L = 0.03365\,W/m\cdot K \times (200-50)°C/0.05\,m = 101\,W/m^2$$ <

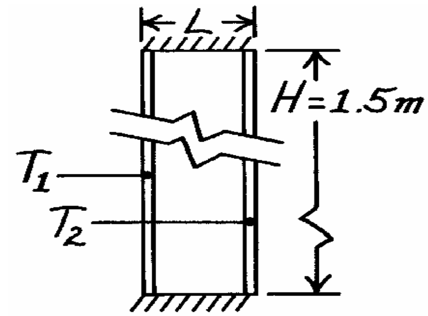
COMMENTS: (1) Installation of the foils results in a 100 – 101/525 = 81 % reduction in heat transfer across the large gap. (2) Because of the temperature dependence of the thermophysical properties, we should check to make sure the Rayleigh numbers associated with the top and bottom gaps do not exceed 1708. Assuming $\Delta T_g = (T_h - T_c)/(N + 1) = 150°C/(5) = 30°C$ and evaluating properties at the average gap temperatures of 65°C and 185°C, respectively, we find Ra_{Lg} = 1569 for the top gap and 394 for the bottom gap. We therefore conclude that convection is in fact suppressed in all the gaps. (3) A more accurate handling of the thermophysical property variation would account for the temperature variation of the thermal conductivity in each gap and, in turn, the variation in the temperatures of the individual foil sheets. Equating the conduction heat transfer through each gap and evaluating the thermal conductivity for each gap at the average air temperature in the gap, one finds (using an iterative procedure or IHT) foil temperatures of (top to bottom): T_1 = 84.3°C, T_2 = 116.1°C, T_3 = 145.7°C and T_4 = 173.6°C. Values of Ra_{Lg} are 1742 and 340 for the top and bottom gaps, respectively. Hence, with 4 foils, the top gap will experience very weak convection and a conservative specification would call for installation of N = 5 foils. (4) As will become evident in Chapter 13, the foils will also reduce radiation heat transfer across the gap.

PROBLEM 9.94

KNOWN: Double-glazed window of variable spacing L between panes filled with either air or carbon dioxide.

FIND: Heat transfer across window for variable spacing when filled with either gas. Consider these conditions (outside, T_1; inside, T_2): winter (-10, 20°C) and summer (35°C, 25°C).

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Radiation exchange is negligible, (3) Gases are at atmospheric pressure, (4) Perfect gas behavior.

PROPERTIES: *Table A-4*: Winter, $\overline{T} = (-10+20)°C/2 = 288\,K$, Summer, $\overline{T} = (35+25)°C/2 = 303\,K$:

Gas (1 atm)	$\overline{T}$ (K)	α ($m^2/s \times 10^6$)	ν ($m^2/s \times 10^6$)	$k \times 10^3$ (W/m·K)
Air	288	20.5	14.82	24.9
Air	303	22.9	16.19	26.5
CO_2	288	10.2	7.78	15.74
CO_2	303	11.2	8.55	16.78

ANALYSIS: The heat flux by convection across the window is

$$q'' = h(T_1 - T_2)$$

where the convection coefficient is estimated from the correlation of Eq. 9.53 for large aspect ratios 10< H/L < 40, for which $\overline{h}$ is independent of L,

$$\overline{Nu}_L = \overline{h}L/k = 0.046 Ra_L^{1/3}.$$

Substituting numerical values for winter (w) and summer (s) conditions,

$$Ra_{L,w,air} = \frac{9.8\,m/s^2(1/288\,K)(20-(-10))KL^3}{20.5\times10^{-6}\,m^2/s \times 14.82\times10^{-6}\,m^2/s} = 3.360\times10^9 L^3$$

$$Ra_{L,s,air} = 8.724\times10^8 L^3 \qquad Ra_{L,w,CO_2} = 1.286\times10^{10} L^3 \qquad Ra_{L,s,CO_2} = 3.378\times10^9 L^3$$

the heat transfer coefficients are

$$\overline{h}_{w,air} = (0.0249\,W/m\cdot K/L)\times 0.046\left(3.360\times10^9 L^3\right)^{1/3} = 1.72\,W/m^2\cdot K$$

$$h_{s,air} = 1.16\,W/m^2\cdot K \quad h_{w,CO_2} = 1.70\,W/m^2\cdot K \qquad h_{s,CO_2} = 1.16\,W/m^2\cdot K.$$

Thus,

$$q''_{w,air} = 51.5\,W/m^2 \quad q''_{s,air} = 11.6\,W/m^2 \quad q''_{w,CO_2} = 50.9\,W/m^2 \quad q''_{s,CO_2} = 11.6\,W/m^2.$$

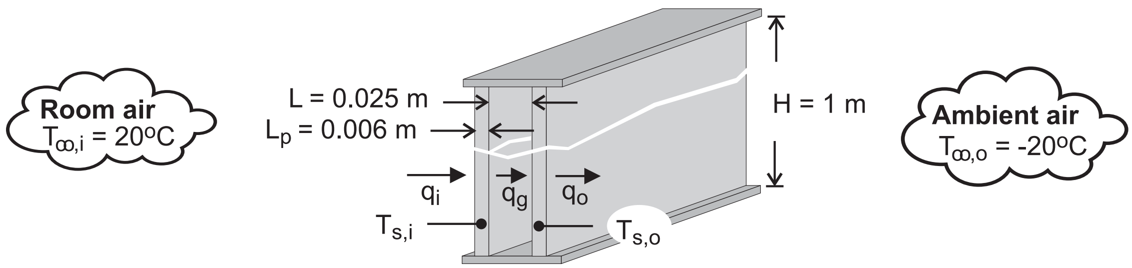
COMMENTS: (1) The correlation is valid for $10^6 < Ra_L < 10^9$. As an example, for a spacing L = 10 mm, the Rayleigh number would be less than 10^6 in all four cases, and Eq. 9.52 should be used instead. However, note that H/L = 150, which is out of the range of validity of both correlations. (2) For this particular case, the smaller k for CO_2 is almost exactly offset by the smaller α and ν which lead to larger Ra_L, and there is very little difference between the results for air and CO_2.

PROBLEM 9.95

KNOWN: Dimensions of double pane window. Thickness of air gap. Temperatures of room and ambient air.

FIND: (a) Temperatures of glass panes and heat rate through window, (b) Resistance of glass pane relative to smallest convection resistance.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Negligible glass pane thermal resistance, (3) Constant properties.

PROPERTIES: *Table A-3*, Plate glass: $k_p = 1.4$ W/m·K. *Table A-4*, Air (p = 1 atm). $T_{f,i} = 287.6$K: $\nu_i = 14.8 \times 10^{-6}$ m^2/s, $k_i = 0.0253$ W/m·K, $\alpha_i = 20.9 \times 10^{-6}$ m^2/s, $Pr_i = 0.710$, $\beta_i = 0.00348$ K^{-1}. $\overline{T} = (T_{s,i} + T_{s,o})/2 = 272.8$K: $\nu = 13.49 \times 10^{-6}$ m^2/s, k = 0.0241 W/m·K, $\alpha = 18.9 \times 10^{-6}$ m^2/s, Pr = 0.714, $\beta = 0.00367$ K^{-1}. $T_{f,o} = 258.2$K: $\nu_o = 12.2 \times 10^{-6}$ m^2/s, $k_o = 0.0230$W/m·K, $\alpha = 17.0 \times 10^{-6}$ m^2/s, Pr = 0.718, $\beta_o = 0.00387$ K^{-1}.

ANALYSIS: (a) The heat rate may be expressed as

$$q = q_o = \overline{h}_o H^2 \left(T_{s,o} - T_{\infty,o}\right) \tag{1}$$

$$q = q_g = \overline{h}_g H^2 \left(T_{s,i} - T_{s,o}\right) \tag{2}$$

$$q = q_i = \overline{h}_i H^2 \left(T_{\infty,i} - T_{s,i}\right) \tag{3}$$

where $\overline{h}_o$ and $\overline{h}_i$ may be obtained from Eq. (9.26),

$$\overline{Nu}_H = \left\{0.825 + \frac{0.387\,Ra_H^{1/6}}{\left[1+\left(0.492/Pr\right)^{9/16}\right]^{8/27}}\right\}^2$$

with $Ra_H = g\beta_o\left(T_{s,o} - T_{\infty,o}\right)H^3/\alpha_o\nu_o$ and $Ra_H = g\beta_i\left(T_{\infty,i} - T_{s,i}\right)H^3/\alpha_i\nu_i$, respectively. Assuming $10^4 < Ra_L < 10^7$, $\overline{h}_g$ is obtained from

$$\overline{Nu}_L = 0.42\,Ra_L^{1/4}\,Pr^{0.012}\left(H/L\right)^{-0.3}$$

where $Ra_L = g\beta\left(T_{s,i} - T_{s,o}\right)L^3/\alpha\nu$. A simultaneous solution to Eqs. (1) – (3) for the three unknowns yields

Continued …

PROBLEM 9.95 (Cont.)

$$T_{s,i} = 9.1°C, \quad T_{s,o} = -9.6°C, q = 35.7 \text{ W}$$ <

where $\bar{h}_i = 3.29 \text{ W/m}^2 \cdot \text{K}$, $\bar{h}_o = 3.45 \text{ W/m}^2 \cdot \text{K}$ and $\bar{h}_g = 1.90 \text{ W/m}^2 \cdot \text{K}$.

(b) The unit conduction resistance of a glass pane is $R''_{cond} = L_p / k_p = 0.00429 \text{ m}^2 \cdot \text{K/W}$, and the smallest convection resistance is $R''_{conv,o} = (1/\bar{h}_o) = 0.290 \text{ m}^2 \cdot \text{K/W}$. Hence,

$$R''_{cond} << R''_{conv,min}$$ <

and it is reasonable to neglect the thermal resistance of the glass.

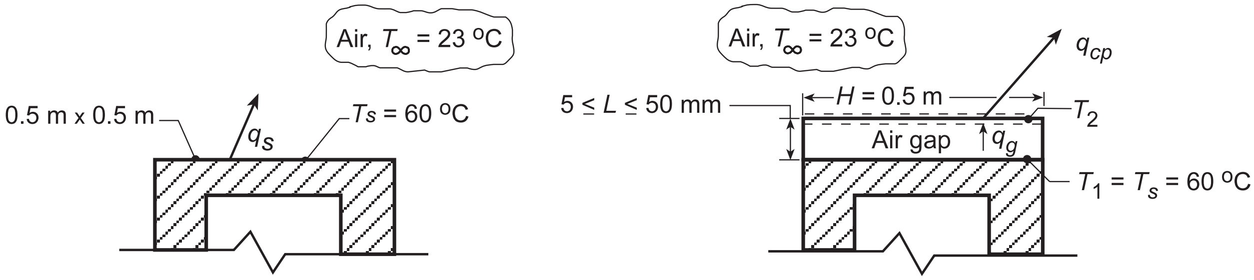
COMMENTS: (1) Assuming a heat flux of 35.7 W/m^2 through a glass pane, the corresponding temperature difference across the pane is $\Delta T = q''(L_p / k_p) = 0.15°C$. Hence, the assumption of an isothermal pane is good. (2) Equations (1) – (3) were solved using the IHT workspace and the temperature-dependent air properties provided by the software. The property values provided in the PROPERTIES section of this solution were obtained from the software.

PROBLEM 9.96

KNOWN: Top surface of an oven maintained at 60°C.

FIND: (a) Reduction in heat transfer from the surface by installation of a cover plate with specified air gap; temperature of the cover plate, (b) Effect of cover plate spacing.

SCHEMATIC:



Exposed surface   With cover plate

ASSUMPTIONS: (1) Steady-state conditions, (2) Oven surface at $T_1 = T_s$ for both cases, (3) Negligible radiative exchange with surroundings and across air gap.

PROPERTIES: *Table A.4*, Air ($T_f = (T_s + T_\infty)/2$ = 315 K, 1 atm): $\nu = 17.40 \times 10^{-6}$ m²/s, k = 0.0274 W/m·K, $\alpha = 24.7 \times 10^{-6}$ m²/s; *Table A.4*, Air ($\overline{T} = (T_1 + T_2)/2$ and $T_{f2} = (T_2 + T_\infty)/2$): Properties obtained form *Correlations Toolpad* of IHT.

ANALYSIS: (a) The convective heat loss from the exposed top surface of the oven is $q_s = \overline{h} A_s(T_s - T_\infty)$. With $L = A_s/P = (0.5\text{ m})^2/(4 \times 0.5\text{ m}) = 0.125$ m,

$$Ra_L = \frac{g\beta\Delta TL^3}{\nu\alpha} = \frac{9.8\,\text{m/s}^2\,(1/315\,\text{K})(60-23)^\circ\text{C}(0.125\,\text{m})^3}{17.40\times10^{-6}\,\text{m/s}^2 \times 24.7\times10^{-6}\,\text{m/s}^2} = 5.231\times10^6 .$$

The appropriate correlation for a heated plate facing upwards, Eq. 9.30, is

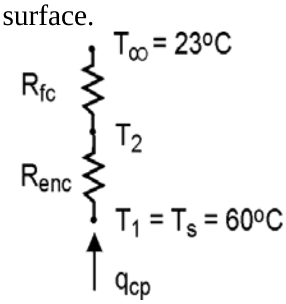
$$\overline{Nu}_L = \frac{\overline{h}L}{k} = 0.54 Ra_L^{1/4} \qquad 10^4 \le Ra_L \le 10^7$$

$$\overline{h} = \left(\frac{0.0274\,\text{W/m}\cdot\text{K}}{0.125\,\text{m}}\right) \times 0.54\left(5.231\times10^6\right)^{1/4} = 5.66\,\text{W/m}^2\cdot\text{K}$$

Hence, the heat rate for the exposed surface is

$$q_s = 5.66\,\text{W/m}^2\cdot\text{K}\,(0.5\,\text{m})^2\,(60-23)^\circ\text{C} = 52.4\,\text{W} . \qquad <$$

With the cover plate, the surface temperature ($T_s = T_2$) is unknown and must be obtained by performing an energy balance at the top surface.



Continued…

PROBLEM 9.96 (Cont.)

Equating heat flow across the gap to that from the top surface, $q_g = q_{cp}$. Hence, for a unit surface area,

$$\bar{h}_g (T_1 - T_2) = \bar{h}_{cp} (T_2 - T_\infty)$$

where $\bar{h}_{cp}$ is obtained from Eq. 9.30 and $\bar{h}_g$ is evaluated from Eq. 9.49.

$$\overline{Nu}_L = \frac{\bar{h}_g L}{k} = 0.069 Ra_L^{1/3} Pr^{0.074}$$

Entering this expression from the keyboard and Eq. 9.30 from the *Correlations* Toolpad, with the *Properties* Toolpad used to evaluate air properties at $\bar{T}$ and T_{fs}, IHT was used with L = 0.05 m to obtain

$T_2 = 35.4°C$ $\qquad\qquad$ $q_{cp} = 13.5$ W $\qquad$ <

where $\bar{h}_g = 2.2\, W/m^2 \cdot K$ and $\bar{h}_{cp}$ = 4.4 W/m^2·K. Hence, the effect of installing the cover plate creating the enclosure is to reduce the heat loss by

$$\frac{q_s - q_{cp}}{q_s} \times 100 = \frac{52.4 - 13.5}{52.4} \times 100 = 74\% .$$ <

Note, however, that for L = 0.05 m, $Ra_L = 2.05 \times 10^5$ is slightly less than the lower limit of applicability for Eq. 9.49.

(b) If we use the foregoing model to evaluate T_2 and q_{cp} for $0.005 \le L \le 0.05$ m, we find that there is no effect. This seemingly unusual result is a consequence of the fact that, in Eq. 9.49, $\overline{Nu}_L \propto Ra_L^{1/3}$, in which case $\bar{h}_g$ is independent of L. However, Ra_L and Nu_L do decrease with decreasing L, eventually approaching conditions for which transport across the airspace is determined by conduction and not convection. If transport is by conduction, the heat rate must be determined from Fourier's law, for which q''_g = (k/L)(T_1 - T_2) and the equivalent, *pseudo*, Nusselt number is $\overline{Nu}_L = \bar{h}L/k = 1$. If this expression is used to determine $\bar{h}_g$ in the energy balance, q_{cp} increases with decreasing L. The results would only apply if there is negligible advection in the airspace and hence for Rayleigh numbers less than 1708, which corresponds to L ≈ 10.5 mm. For this value of L, q_{cp} = 15.4 W exceeds that previously determined for L = 50 mm. Hence, there is little variation in q_{cp} over the range 10.5 < L < 50 mm. However, q_{cp} increases with decreasing L below 10.5 mm, achieving a value of 24.2 W for L = 5 mm. Hence, a value of L slightly larger than 10.5 mm could be considered an optimum.

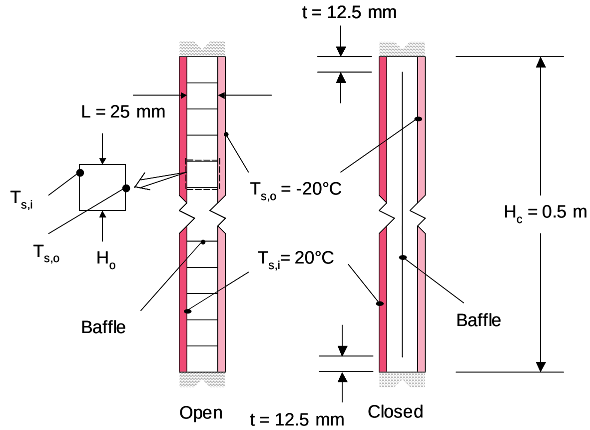
COMMENTS: Radiation exchange across the cavity and with the surroundings is likely to be significant and should be considered in a more detailed analysis.

PROBLEM 9.97

KNOWN: Dimensions of air space between windows, dimensions of individual blinds. Temperatures of windows.

FIND: Convection heat transfer rates between windows when the blinds are in the open and closed positions, respectively. Explanation of the small effect of the closed blinds on the convective heat transfer rate.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Steady-state conditions, (3) Isothermal windows, (4) Blinds are adiabatic, (5) Neglect presence of the blind when in the closed position.

PROPERTIES: Table A.4, air: (T_f = 273 K): k = 0.02414 W/m·K, $\nu = 1.349 \times 10^{-5}$ m²/s, α = 1.894×10^{-5} m²/s, Pr = 0.714.

ANALYSIS:

Case A, Open Position The aspect ratio of a typical cell is H_o/L = 25/25 = 1. The Rayleigh number is

$$Ra = g\beta\frac{(T_{s,o} - T_{s,i})L^3}{\nu\alpha} = 9.8\,m/s^2 \times (1/273)K^{-1} \times \frac{(20-(-20))°C \times (0.025m)^3}{1.349\times10^{-5}m^2/s \times 1.894\times10^{-5}m^2/s} = 87.81\times10^3$$

and (RaPr)/(0.2 + Pr) = $(87.81 \times 10^3 \times 0.714)/(0.2 + 0.714)$ = 68,600. Therefore, Equation 9.51 may be used, resulting in

$$\overline{Nu}_L = 0.18\left[\frac{0.714}{(0.2+0.714)}\times 87.81\times10^3\right]^{0.29} = 4.55 \quad \text{and}$$

$$\bar{h}_L = \overline{Nu}_L k/L = 4.55\times0.02414\,W/m\cdot K/0.025m = 4.39\,W/m^2\cdot K$$

The same value of the convection heat transfer coefficient exists for each cell. Hence,

Continued…

PROBLEM 9.97 (Cont.)

$$q_{conv} = 4.39\,W/m^2 \cdot K \times 0.5\,m \times 0.5\,m \times (20°C - (-20°C)) = 43.9\,W$$ <

Case B, Closed Position The aspect ratio of the cavity is H_c/L = 0.5 m/0.025 m = 20. The Rayleigh number is 87.81×10^3, as before. Therefore, select Equation 9.52, resulting in

$$\overline{Nu}_L = 0.42 \times (87.81 \times 10^3)^{1/4} \times (0.714)^{0.012} \times (20)^{-3} = 2.931$$

$$\bar{h}_L = \overline{Nu}_L k/L = 2.931 \times 0.02414\,W/m \cdot K/0.025\,m = 2.83\,W/m^2 \cdot K \quad \text{Hence,}$$

$$q_{conv} = 2.83\,W/m^2 \cdot K \times 0.5\,m \times 0.5\,m \times (20°C - (-20°C)) = 28.3\,W$$ <

The closed blinds may be neglected if the core of the air layer is nearly stagnant. <

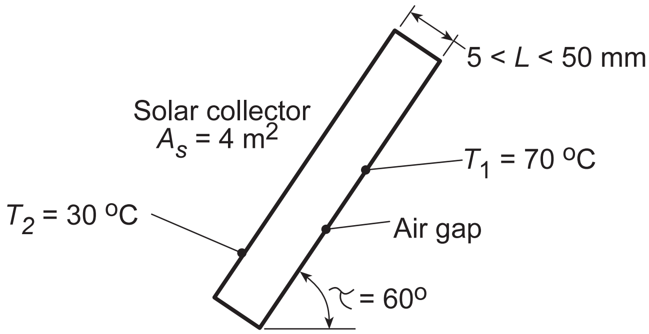
COMMENTS: (1) Equation 9.52 has been extrapolated slightly outside of its range of application with respect to the suggested Prandtl number limits. (2) In the open blind case, recirculating flow will exist in each small square sub-enclosure, yielding larger values of the convection coefficient relative to the closed blind case. (3) The blind material will have a higher thermal conductivity than air, and the open blinds will serve as extended surfaces, further increasing heat loss through the window. Since the blinds will participate in the heat transfer when in the open position, treating the top and bottom surfaces of the small square sub-enclosures is an aggressive assumption. (4) Net radiation transfer between the two window surfaces will be greater for the open blind case.

PROBLEM 9.98

KNOWN: Dimensions and surface temperatures of a flat-plate solar collector.

FIND: (a) Heat loss across collector cavity, (b) Effect of plate spacing on the heat loss.

SCHEMATIC:



ASSUMPTIONS: Negligible radiation.

PROPERTIES: *Table A.4*, Air ($\overline{T} = (T_1 + T_2)/2 = 323$ K): $\nu = 18.2 \times 10^{-6}$ m²/s, k = 0.028 W/m·K, $\alpha = 25.9 \times 10^{-6}$ m²/s, $\beta = 0.0031$ K^{-1}.

ANALYSIS: (a) Since H/L = 2 m/0.03 m = 66.7 > 12, $\tau < \tau^*$ and Eq. 9.54 may be used to evaluate the convection coefficient associated with the air space. Hence, $q = \overline{h} A_s(T_1 - T_2)$, where $\overline{h} = (k/L)\overline{Nu}_L$ and

$$\overline{Nu}_L = 1 + 1.44\left[1 - \frac{1708}{Ra_L \cos\tau}\right]^{\bullet}\left[1 - \frac{1708(\sin 1.8\tau)^{1.6}}{Ra_L \cos\tau}\right] + \left[\left(\frac{Ra_L \cos\tau}{5830}\right)^{1/3} - 1\right]^{\bullet}$$

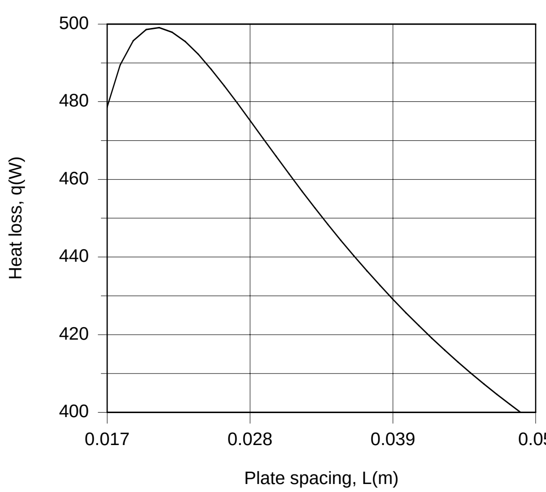
For L = 30 mm, the Rayleigh number is

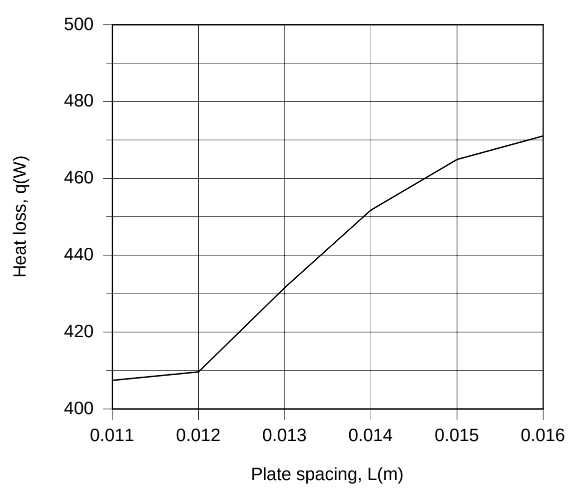
$$Ra_L = \frac{g\beta(T_1 - T_2)L^3}{\alpha\nu} = \frac{9.8\,m/s^2\left(0.0031\,K^{-1}\right)\left(40^\circ C\right)\left(0.03\,m\right)^3}{25.9\times10^{-6}\,m^2/s \times 18.2\times10^{-6}\,m^2/s} = 6.96\times10^4$$

and $Ra_L \cos\tau = 3.48 \times 10^4$. It follows that $\overline{Nu}_L = 3.12$ and $\overline{h} = (0.028$ W/m·K/0.03 m$)3.12 = 2.91$ W/m²·K. Hence,

$$q = 2.91\,W/m^2\cdot K\left(4\,m^2\right)\left(40^\circ C\right) = 466\,W$$ <

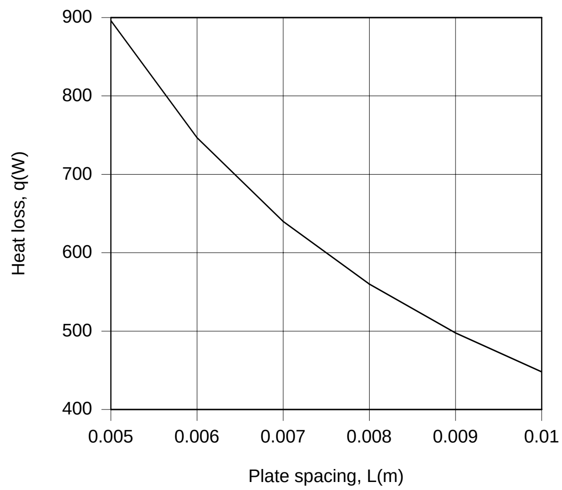
(b) The foregoing model was entered into the workspace of IHT, and results of the calculations are plotted as follows.





Continued...

PROBLEM 9.98 (Cont.)



The plots are influenced by the fact that the third and second terms on the right-hand side of the correlation are set to zero at $L \approx 0.017$ m and $L \approx 0.011$ m, respectively. For the range of conditions, minima in the heat loss of $q \approx 410$ W and $q = 397$ W are achieved at $L \approx 0.012$ m and $L = 0.05$ m, respectively. Operation at $L \approx 0.02$ m corresponds to a maximum and is clearly undesirable, as is operation at $L < 0.011$ m, for which conditions are conduction dominated.

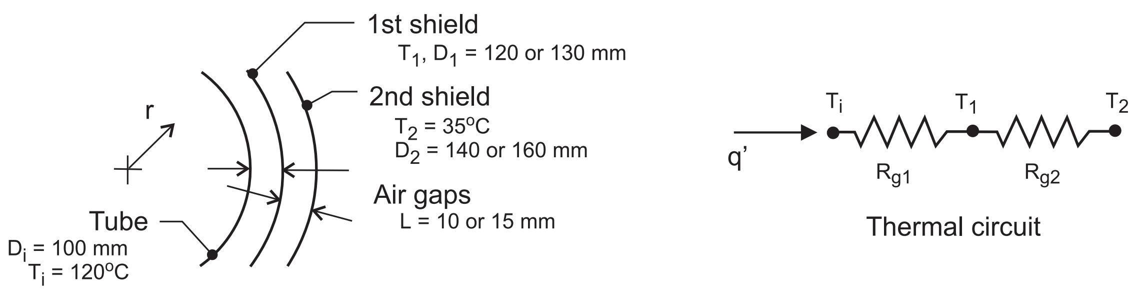
COMMENTS: Because the convection coefficient is low, radiation effects would be significant.

PROBLEM 9.99

KNOWN: Cylindrical 120-mm diameter radiation shield of Example 9.5 installed concentric with a 100-mm diameter tube carrying steam; spacing provides for an air gap of L = 10 mm.

FIND: (a) Heat loss per unit length of the tube by convection when a second shield of diameter 140 m is installed; compare the result to that for the single shield calculation of the example; and (b) The heat loss per unit length if the gap dimension is made L = 15 mm (rather than 10 mm). Do you expect the heat loss to increase or decrease?

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, and (b) Constant properties.

PROPERTIES: *Table A-4*, Air ($T_f = (T_s + T_\infty)/2$ = 350 K, 1 atm): $\nu = 20.92 \times 10^{-6}$ m^2/s, k = 0.030 W/m·K, Pr = 0.700.

ANALYSIS: (a) The thermal circuit representing the tube with two concentric cylindrical radiation shields having gap spacings L = 10 mm is shown above. The heat loss per unit length by convection is

$$q' = \frac{T_i - T_2}{R'_{g1} + R'_{g2}} = \frac{T_i - T_1}{R'_{g1}}$$

(1)

where the R'_g represents the thermal resistance of the annular gap (spacing). From Eqs. 9.58, 59 and 60, find

$$R'_g = \frac{\ell n\left(D_o / D_i\right)}{2\pi k_{eff}} \tag{2}$$

$$\frac{k_{eff}}{k} = 0.386\left(\frac{Pr}{0.861 + Pr}\right)^{1/4}\left(Ra_c\right)^{1/4} \tag{3}$$

$$Ra_c = g\beta\left(T_o - T_i\right)L_c^3 / \alpha\nu \tag{4}$$

where $L_c = \dfrac{2\left[\ln(r_o / r_i)\right]^{4/3}}{(r_i^{-3/5} + r_o^{-3/5})^{5/3}}$

where the properties are evaluated at the average temperature of the bounding surfaces, $T_f = (T_i + T_o)/2$. Recognize that the above system of equations needs to be solved iteratively by initial guess values of T_1, or solved simultaneously using equation-solving software with a properties library. The results are tabulated below.

Continued …

PROBLEM 9.99 (Cont.)

(b) Using the foregoing relations, the analyses can be repeated with L = 15 mm, so that D_i = 130 mm and D_2 = 160 mm. The results are tabulated below along with those from Example 9.5 for the single-shield configuration.

Shields	L(mm)	R'_{g1} (m·K/W)	R'_{g2} (m·K/W)	R'_{tot} (m·K/W)	T_1(°C)	q' (W/m)
1	10	0.7658	---	0.76	---	100
2	10	1.008	0.8855	1.89	74.8	44.9
2	15	0.9751	0.8224	1.80	73.9	47.3

COMMENTS: (1) The effect of adding the second shield is to more than double the thermal resistance of the shields to convection heat transfer.

(2) The effect of gap increase from 10 to 15 mm for the two-shield configuration is slight. Increasing L allows for greater circulation in the annular space, thereby reducing the thermal resistance.

(3) Note the difference in thermal resistances for the annular spaces R'_{g1} of the one-and two-shield configurations with L = 10 mm. Why are they so different (0.7658 vs. 1.008 m·K/W, respectively)?

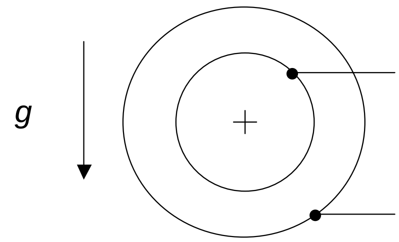
(4) See Example 9.5 for details on how to evaluate the properties for use with the correlation.

PROBLEM 9.100

KNOWN: Concentric cylinders or concentric spheres of uniform inner and outer surface temperatures.

FIND: Expressions for the critical Rayleigh numbers, $Ra_{c,\text{crit}}$ and $Ra_{s,\text{crit}}$ below which k_{eff} is minimized. Evaluate $Ra_{c,\text{crit}}$ and $Ra_{s,\text{crit}}$ for air, water, and glycerin at a mean temperature of 300 K. Comment on the convection heat transfer rate associated with $Ra_{c,\text{crit}}$ and $Ra_{s,\text{crit}}$.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties.

PROPERTIES: Table A.4, air (300 K): Pr = 0.707. Table A.6 water (300 K): Pr = 5.83. Table A.5 glycerin (300 K): Pr = 6780.

ANALYSIS: When heat transfer across the gap is conduction-dominated, $k_{\text{eff}} = k$. When convection becomes significant, $k_{\text{eff}}/k > 1$. Hence, the minimum heat transfer rate occurs when $k_{\text{eff}}/k = 1$.

Concentric Cylinders: (Equation 9.59)

$$\frac{k_{\text{eff}}}{k} = 1 = 0.386\left(\frac{Pr}{0.861+Pr}\right)^{1/4} Ra_{c,\text{crit}}^{1/4} \quad \text{or} \quad Ra_{c,\text{crit}} = \left[\frac{1}{0.386}\left(\frac{0.861+Pr}{Pr}\right)^{1/4}\right]^4 = 45.0\left(\frac{0.861+Pr}{Pr}\right) \quad <$$

Concentric Spheres: (Equation 9.62)

$$\frac{k_{\text{eff}}}{k} = 1 = 0.74\left(\frac{Pr}{0.861+Pr}\right)^{1/4} Ra_{s,\text{crit}}^{1/4} \quad \text{or} \quad Ra_{s,\text{crit}} = \left[\frac{1}{0.74}\left(\frac{0.861+Pr}{Pr}\right)^{1/4}\right]^4 = 3.33\left(\frac{0.861+Pr}{Pr}\right) \quad <$$

For the three fluids of interest the critical Rayleigh numbers, $Ra_{c,\text{crit}}$ and $Ra_{s,\text{crit}}$ are:

	Concentric Cylinders, $Ra_{c,\text{crit}}$	Concentric Spheres, $Ra_{s,\text{crit}}$ <
Air	100	7.39
Water	51.6	3.82
Glycerin	45.0	3.33

For specified inner and outer surface temperatures and inner surface radius, the heat transfer rates vary with the outer surface radius as shown in the figure on the following page. For Rayleigh numbers exceeding $Ra_{c,\text{crit}}$ or $Ra_{s,\text{crit}}$ the heat transfer rate increases as free convection becomes more vigorous. For Rayleigh numbers less than $Ra_{c,\text{crit}}$ or $Ra_{s,\text{crit}}$ conduction occurs within the fluid and the conduction heat transfer rate increases as the gap between the surfaces becomes small. Hence conditions associated with $Ra_{c,\text{crit}}$ or $Ra_{s,\text{crit}}$ correspond to the minimum heat transfer rate.

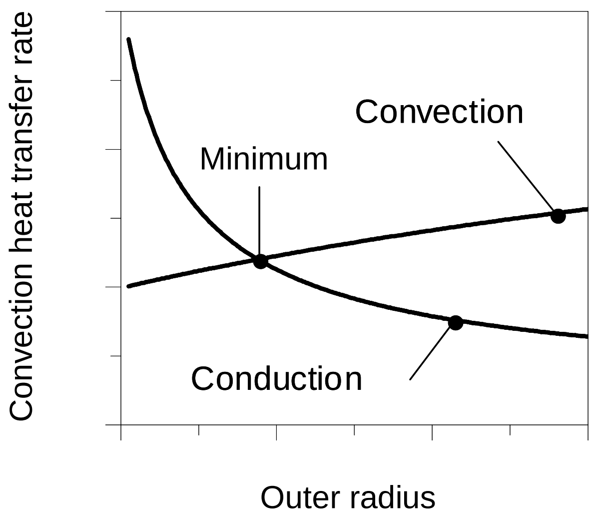
PROBLEM 9.100 (Cont.)



<

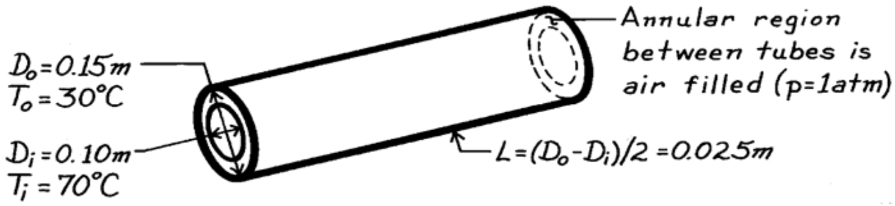
COMMENTS: (1) For glycerin, both correlations have been extrapolated slightly beyond the recommended upper limit of the Prandtl number. (2) The critical Rayleigh numbers for the cylinder are substantially larger than those for the sphere. This reflects the fact that, for a given r_o/r_i ratio, the concentric sphere arrangement has a lower surface area to gas volume ratio than the concentric cylinder arrangement. Hence, the fluid is less constrained by the no-slip boundary conditions of the solid surfaces in the concentric sphere geometry.

PROBLEM 9.101

KNOWN: Operating conditions of a concentric tube solar collector.

FIND: Convection heat transfer per unit length across air space between tubes.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Long tubes.

PROPERTIES: *Table A-4*, Air (T = 50°C, 1 atm): $\nu = 18.2 \times 10^{-6}\ m^2/s$, k = 0.028 W/m·K, $\alpha = 25.9 \times 10^{-6}\ m^2/s$, Pr = 0.71, $\beta = 0.0031\ K^{-1}$.

ANALYSIS: The length scale in Ra_c is given by Eq. 9.60,

$$L_c = \frac{2\left[\ln(r_o/r_i)\right]^{4/3}}{(r_i^{-3/5} + r_o^{-3/5})^{5/3}} = \frac{2\left[\ln(0.075/0.05)\right]^{4/3}}{\left[(0.075\ m)^{-3/5} + (0.05\ m)^{-3/5}\right]^{5/3}} = 0.0114\ m$$

Then

$$Ra_c = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu\alpha} = \frac{9.8\ m/s^2 \times 0.0031\ K^{-1}(70 - 30)°C\ (0.0114\ m)^3}{18.2 \times 10^{-6}\ m^2/s \times 25.9 \times 10^{-6}\ m^2/s} = 3860$$

Next, Eq. 9.59 may be used, in which case

$$k_{eff} = 0.386\,k\left(\frac{Pr}{0.861 + Pr}\right)^{1/4}\left(Ra_c\right)^{1/4}$$

$$k_{eff} = 0.386\left(0.028\ W/m \cdot K\right)\left(\frac{0.71}{0.861 + 0.71}\right)^{1/4}\left(3860\right)^{1/4} = 0.07\ W/m \cdot K.$$

From Eq. 9.58, it then follows that

$$q' = \frac{2\pi k_{eff}}{\ln\left(r_o/r_i\right)}\left(T_i - T_o\right) = \frac{2\pi\left(0.07\ W/m \cdot K\right)}{\ln\left(0.15/0.10\right)}\left(70 - 30\right)°C = 43.4\ W/m. \quad <$$

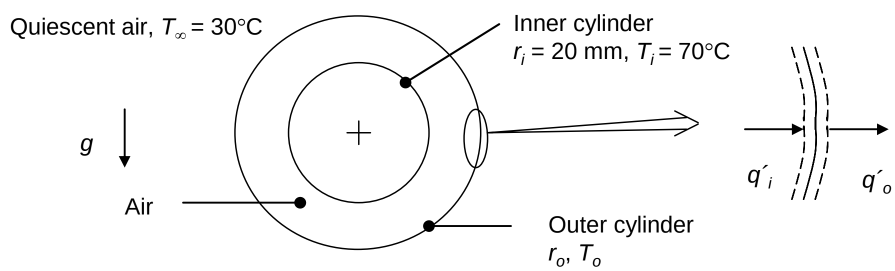
COMMENTS: An additional heat loss is related to thermal radiation exchange between the inner and outer surfaces.

PROBLEM 9.102

KNOWN: Concentric cylinders. Radius of inner cylinder. Temperature of inner cylinder and ambient temperature.

FIND: Outer diameter for minimizing heat loss. Comparison of the heat loss to the situation with no outer cylinder.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Negligible radiation heat transfer, (3) Steady state, (4) Isothermal and thin outer cylinder, (5) Quiescent environment.

PROPERTIES: Table A.4, air (50°C = 323 K): k = 0.028 W/m·K, $\alpha = 2.59 \times 10^{-5}$ m²/s, $\nu = 1.82 \times 10^{-5}$ m²/s, $\beta = 0.003096$ K^{-1}, Pr = 0.704.

ANALYSIS: Neither the radius of the outer cylinder nor the temperature of the outer cylinder is specified. Therefore, an iterative process must be used in order to solve for the optimal radius of the outer cylinder and its temperature. Furthermore, it is not known whether the fluid motion in the annulus is vigorous enough to produce an effective thermal conductivity that is greater than unity. Hence, the analysis will be carried out based upon the assumption of either conduction or convection occurring in the gap; the actual situation corresponds to the larger heat transfer rate per unit length.

For the exterior of the outer cylinder, $q'_o = h_o 2\pi r_o\left(T_o - T_\infty\right) = h_o 2\pi r_o\left(T_o - 30°\text{C}\right)$ (1)

and the Churchill and Chu correlation may be used to evaluate h_o,

$$h_o = \frac{0.028\ \text{W/m}\cdot\text{K}}{2r_o}\left\{0.60 + \frac{0.387 Ra_D^{1/6}}{\left[1+\left(0.559/0.704\right)^{9/16}\right]^{8/27}}\right\}^2 \tag{2}$$

where

$$Ra_D = \frac{g\beta(T_o - T_\infty)(2r_o)^3}{\nu\alpha} = \frac{9.81\ \text{m/s}^2\, 0.003096\ \text{K}^{-1}(T_o - 30°\text{C})(2r_o)^3}{1.82\times10^{-5}\text{m}^2/\text{s}\times 2.59\times10^{-5}\text{m}^2/\text{s}} \tag{3}$$

For the annular region between the cylinders,

$$q'_i = \frac{2\pi k_{\text{eff}}(T_i - T_o)}{\ln(r_o/r_i)} = \frac{2\pi k_{\text{eff}}(70°\text{C} - T_o)}{\ln(r_o/0.020\ \text{m})} \tag{4}$$

where the Raithby and Hollands formulation may be used to determine the value of k_{eff},

Continued…

PROBLEM 9.102 (Cont.)

$$k_{\text{eff}} = 0.386k\left(\frac{Pr}{0.861+Pr}\right)^{1/4} Ra_c^{1/4} = 0.386\times 0.028\ \text{W/m}\cdot\text{K}\left(\frac{0.704}{0.861+0.704}\right)Ra_c^{1/4} \tag{5}$$

The characteristic length in the Rayleigh number is

$$L_c = \frac{2\left[\ln(r_o/r_i)\right]^{4/3}}{\left(r_i^{-3/5}+r_o^{-3/5}\right)^{5/3}} = \frac{2\left[\ln(r_o/0.020\ \text{m})\right]^{4/3}}{\left((0.020\ \text{m})^{-3/5}+r_o^{-3/5}\right)^{5/3}} \tag{6}$$

and $$Ra_c = g\beta(T_i - T_o)L_c^3/\nu\alpha. \tag{7}$$

From the surface energy balance shown in the schematic,

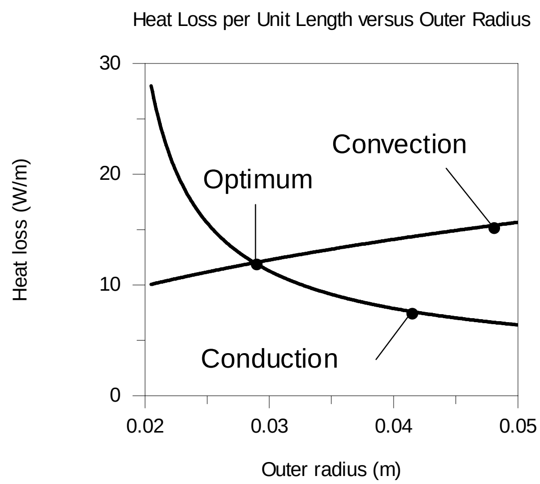
$$q_i' = q_o' \tag{8}$$

Equations 1 through 8 include 9 unknowns, q_i' , q_o' , L_c, r_o, T_o, k_{eff}, Ra_D, Ra_c, and h_o. IHT was used to solve these equations simultaneously over a range of r_o, and the results are plotted below.

For small gap widths, it is expected that augmentation of heat transfer rates due to free convection in the annulus will be small. For these cases,

$$k_{\text{eff}} = k = 0.028\ \text{W/m}\cdot\text{K} \tag{8}$$

Equations 1 through 4, 7 and 8 may be solved simultaneously for q_i' , q_o' , r_o, T_o and h_o. IHT was used to solve the equations, and to plot the results shown below.



Heat losses are calculated based upon the two assumptions of (i) convection in the annulus and (ii) conduction in the annulus. The actual heat loss sensitivity to the outer cylinder radius follows the conduction curve until the optimum point is reached, then follows the convection curve after the optimal outer radius. From IHT it is determined that the optimal outer radius is

$r_{o,\text{opt}} = 0.0289$ m = 28.9 mm, yielding a heat transfer rate of $q' = 11.99$ W/m. <

Continued…

PROBLEM 9.102 (Cont.)

Without the outer cylinder, the heat loss is determined by the Raithby and Hollands formula with

$$Ra_D = \frac{g\beta(T_i - T_\infty)(2r_i)^3}{\nu\alpha} = \frac{9.81\ \text{m/s}^2\, 0.003096\ \text{K}^{-1}(70°\text{C} - 30°\text{C})(0.040\text{m})^3}{1.82\times10^{-5}\text{m}^2/\text{s}\times 2.59\times10^{-5}\text{m}^2/\text{s}} = 165 \times 10^3$$

Hence,

$$h = \frac{0.028\ \text{W/m}\cdot\text{K}}{0.040\ \text{m}}\left\{0.060 + \frac{0.387\left(165\times10^3\right)^{1/6}}{\left[1+\left(0.559/0.707\right)^{9/16}\right]^{8/27}}\right\}^2 = 4.16\ \text{W/m}^2\cdot\text{K}$$

and $q' = 2\pi r_i h(T_i - T_\infty) = 2\pi \times 0.02\ \text{m} \times\ 4.16\text{W/m}^2\cdot\text{K}\times(70°\text{C} - 30°\text{C}) = 20.9\ \text{W/m}$. <

The scheme reduces the convective heat transfer loss by [(20.9 – 12)/20.9] × 100 = 43 %. The scheme is somewhat effective.

COMMENTS: (1) For the outer cylinder of optimal radius, the surface temperature is T_o = 44.9°C. The Rayleigh number for the outer cylinder is 1.9×10^5. (2) The IHT code is shown below.

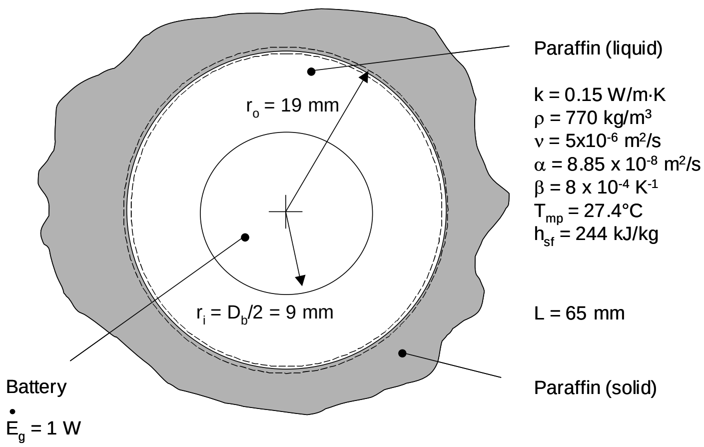
PROBLEM 9.103

KNOWN: Dimensions and heat generation rate associated with horizontally-oriented lithium ion battery. Size of annulus filled with liquid paraffin. Properties and fusion temperature of the paraffin.

FIND: (a) Battery surface temperature when r_o = 19 mm, (b) Rate at which r_o is increasing with time, (c) Plot of battery surface temperature versus r_o for 15 mm ≤ r_o ≤ 30 mm and explanation of relative insensitivity of battery temperature to size of the annulus.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties and steady-state conditions, (2) Solid paraffin at melting point temperature.

PROPERTIES: Given, see schematic.

ANALYSIS: (a) The length scale used in the Rayleigh number is given by Equation 9.60.

$$L_c = \frac{2\left[\ln(r_o/r_i)\right]^{4/3}}{\left(r_i^{-3/5} + r_o^{-3/5}\right)^{5/3}} = \frac{2\times\left[\ln(19/9)\right]^{4/3}}{\left[\left(9\times10^{-3}\,\text{m}\right)^{-3/5} + \left(19\times10^{-3}\,\text{m}\right)^{-3/5}\right]^{5/3}} = 5.36\times10^{-3}\,\text{m}$$

The Rayleigh number is

$$\begin{aligned} Ra_c &= \frac{g\beta\left(T_s - T_{mp}\right)L_c^3}{\nu\cdot\alpha} = \frac{9.8\,\text{m/s}^2\times8\times10^{-4}\,\text{K}^{-1}\times\left(T_s - 27.4\right)°\text{C}\times(5.36\times10^{-3}\,\text{m})^3}{5\times10^{-6}\,\text{m}^2/\text{s}\times8.85\times10^{-8}\,\text{m}^2/\text{s}} \qquad (1) \\ &= 2728\,\text{K}^{-1}\times(T_s - 27.4°\text{C}) \end{aligned}$$

The Prandtl number is Pr = ν/α = 5 × 10^{-6} m^2/s/8.85 × 10^{-8} m^2/s = 56.5, and the effective thermal conductivity is given by Equation 9.59,

Continued…

PROBLEM 9.103 (Cont.)

$$k_{eff} = 0.386k\left(\frac{Pr}{0.861+Pr}\right)^{1/4} Ra_c^{1/4} = 0.386 \times 0.15 W/m \cdot K \times \left(\frac{56.5}{0.861+565}\right)^{1/4} Ra_c^{1/4}$$

$$k_{eff} = 0.0577 Ra_c^{1/4} \quad (2)$$

The effective thermal conductivity may also be expressed in terms of Equation 9.58,

$$k_{eff} = \frac{\dot{E}_g \ln(r_o/r_i)}{2\pi L(T_s - T_{mp})} = \frac{1W \times \ln(19/9)}{2\pi \times 65 \times 10^{-3} m \times (T_s - 27.4°C)} = \frac{1.829 W/m}{(T_s - 27.4°C)} \quad (3)$$

Equations 1, 2 and 3 may be solved simultaneously to yield

Ra_c = 8901, k_{eff} = 0.5603 W/m·K, T_s = 30.7°C. <

(b) An energy balance on the control surface shown in the schematic yields

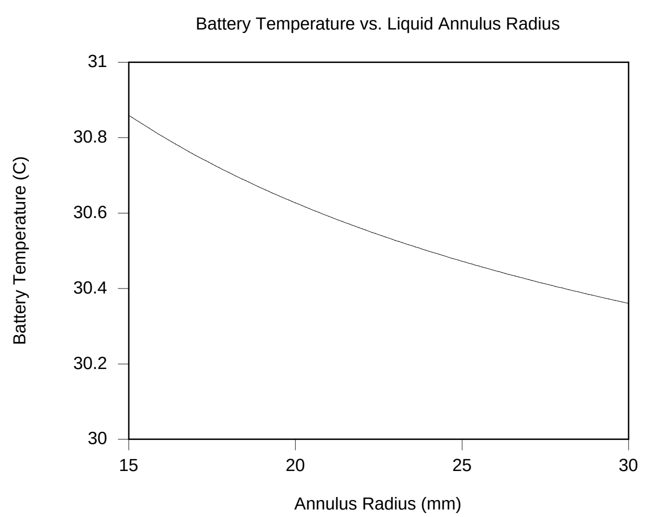
$$q_{conv} = \dot{E}_g = A\rho h_{sf} dr_o/dt$$

or

$$\frac{dr_o}{dt} = \frac{\dot{E}_g}{2\pi r_o L\rho h_{sf}} = \frac{1W}{2\times\pi\times 19\times 10^{-3} m \times 65 \times 10^{-3} m \times 770 kg/m^3 \times 244 \times 10^3 J/kg} \quad <$$

$$= 685 \times 10^{-9} m/s = 0.685 \mu m/s$$

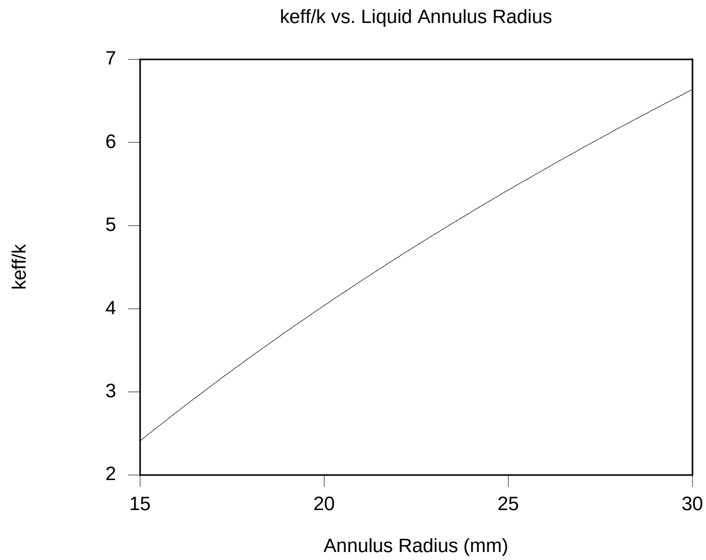
(c) Equations 1 through 3 may be re-solved for various outer radii of the annular region. As evident, the battery surface temperature is very insensitive to the size of the annular region. If heat transfer in the annulus were conduction-dominated, one would expect the battery surface temperature to *increase* as the annulus becomes larger. The opposite trend is evident here.



Continued…

PROBLEM 9.103 (Cont.)

As the annulus becomes larger, fluid velocities associated with free convection increase and the effective thermal conductivity is expected to increase as well. The ratio of the effective thermal conductivity to the bulk thermal conductivity of the paraffin and its sensitivity to the size of the annulus is shown in the plot below. The enhanced fluid motion associated with the larger enclosures increases the effective thermal conductivity of the fluid significantly. Hence, both the numerator and denominator of Equation 9.58 increase with increasing size of the annular region, yielding relatively constant battery surface temperatures.

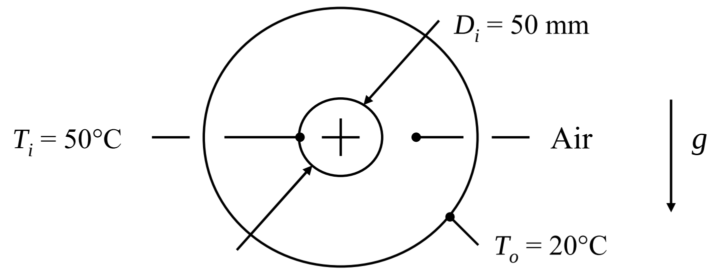


PROBLEM 9.104

KNOWN: Temperatures of concentric spheres and diameter of inner sphere.

FIND: Outer sphere diameter required so that convection heat transfer is same as for inner sphere in a large, quiescent environment at 20°C.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Uniform sphere surface temperatures, (3) Constant properties.

PROPERTIES: *Table A-4*, Air (T = 308 K): $\nu = 16.69 \times 10^{-6}$ m²/s, $\alpha = 23.68 \times 10^{-6}$ m²/s, $k = 26.9 \times 10^{-3}$ W/m · K, $Pr = 0.706$, $\beta = 1/T = 0.00325$ K^{-1}.

ANALYSIS: For the single inner sphere in a large quiescent enclosure, the Rayleigh number based on inner diameter is

$$Ra_D = \frac{g\beta(T_i - T_\infty)D_i^3}{\nu\alpha} = \frac{9.8 \text{ m/s}^2 \times 0.00325 \text{ K}^{-1} \times (50-20)°\text{C} \times (0.05 \text{ m})^3}{16.69 \times 10^{-6} \text{ m}^2/\text{s} \times 23.68 \times 10^{-6} \text{ m}^2/\text{s}} = 3.02 \times 10^5$$

Eq. 9.35 holds, and yields

$$\overline{Nu}_D = 2 + \frac{0.589 Ra_D^{1/4}}{\left[1 + (0.469/Pr)^{9/16}\right]^{4/9}} = 12.7$$

and

$$q_1 = \bar{h}\pi D_i^2 (T_i - T_\infty) = \overline{Nu}_D k\pi D_i (T_i - T_\infty) = 12.7 \times 26.9 \times 10^{-3} \text{ W/m}\cdot\text{K} \times \pi \times 0.05 \text{ m} \times (50-20)°\text{C} = 1.60 \text{ W}$$

For the concentric spheres, the Rayleigh number is based on the length scale given by Eq. 9.63,

$$Ra_s = \frac{g\beta(T_i - T_o)}{\nu\alpha} \frac{\left(1/r_i - 1/r_o\right)^4}{2(r_i^{-7/5} + r_o^{-7/5})^5} \quad (1)$$

Substituting this into Eq. 9.62 and substituting Eq. 9.62 in Eq. 9.61 yields

Continued...

PROBLEM 9.104 (Cont.)

$$q_2 = 4\pi k(T_i - T_o)0.74\left(\frac{Pr}{0.861 + Pr}\right)^{1/4}\left(\frac{g\beta(T_i - T_o)}{\nu\alpha}\right)^{1/4}\frac{1}{2^{1/4}(r_i^{-7/5} + r_o^{-7/5})^{5/4}} \qquad (2)$$

$$= 4\pi \times 26.9\times10^{-3}\ \text{W/m}\cdot\text{K}\times(50-20)°\text{C}\times0.74\times\left(\frac{0.706}{0.861+0.706}\right)^{1/4}$$

$$\times\left(\frac{9.8\ \text{m/s}^2\times0.00325\ \text{K}^{-1}\times(50-20)°\text{C}}{16.69\times10^{-6}\ \text{m}^2/\text{s}\times23.68\times10^{-6}\ \text{m}^2/\text{s}}\right)^{1/4}\frac{1}{2^{1/4}(r_i^{-7/5} + r_o^{-7/5})^{5/4}}$$

$$= 1146\ \text{W/m}^{7/4}\frac{1}{(r_i^{-7/5} + r_o^{-7/5})^{5/4}}$$

Setting $q_2 = q_1 = 1.60$ W, and solving for r_o yields

$$r_o = \left[\left(\frac{1146\ \text{W/m}^{7/4}}{1.60\ \text{W}}\right)^{4/5} - r_i^{-7/5}\right]^{-5/7} = \left[\left(\frac{1146\ \text{W/m}^{7/4}}{1.60\ \text{W}}\right)^{4/5} - (0.025\ \text{m})^{-7/5}\right]^{-5/7} = 0.130\ \text{m}$$

Thus the required diameter of the outer cylinder is

$$D_o = 260\ \text{mm}$$ <

From Eq. (1), $Ra_s = 5000$, so the correlation for concentric spheres is within its range of applicability.

COMMENTS: It is of interest whether the concentric sphere correlation approaches the single sphere limit as $r_o \to \infty$. From Eq. (2) above, it can be seen that q_2 reaches an asymptote. This can be rephrased in terms of a heat transfer coefficient for concentric spheres, h_2, defined such that $q_2 = h_2\pi D_i^2(T_i - T_o)$. The corresponding Nusselt number, $\overline{Nu}_D = h_2 D_i / k$, is then

$$\overline{Nu}_D = \frac{0.74 Ra_D^{1/4}}{(1 + 0.861/Pr)^{1/4}}$$

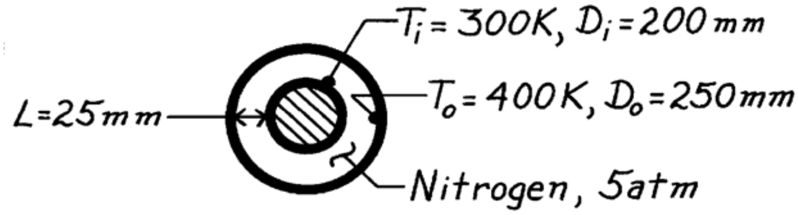
This has the same asymptotic Rayleigh number dependence as Eq. 9.35 (as long as the leading 2 is negligible), but not the same Prandtl number dependence. When researchers fit experimental data to a correlating equation, they must make a judgment as to whether it is appropriate, based on the range of their experimental data, to impose the correct limiting behavior.

PROBLEM 9.105

KNOWN: Annulus formed by two concentric, horizontal tubes with prescribed diameters and surface temperatures is filled with nitrogen at 5 atm.

FIND: Convective heat transfer rate per unit length of the tubes.

SCHEMATIC:



ASSUMPTIONS: (1) Thermophysical properties k, μ, and Pr, are independent of pressure, (2) Density is proportional to pressure, (3) Perfect gas behavior.

PROPERTIES: *Table A-4*, Nitrogen $\left(\overline{T} = \left(T_i + T_o\right)/2 = 350\text{K, 5 atm}\right)$: k = 0.0293 W/m·K, μ = 200×10^{-7} N·s/m^2, ρ(5 atm) = 5 ρ (1 atm) = 5 × 0.9625 kg/m^3 = 4.813 kg/m^3, Pr = 0.711, ν = μ/ρ = 4.155×10^{-6} m^2/s, α = k/ρc = 0.0293 W/m·K/(4.813 kg/m^3 × 1042 J/kg·K) = 5.842×10^{-6} m^2/s.

ANALYSIS: The length scale in Ra_c is given by Eq. 9.60,

$$L_c = \frac{2\left[\ln\left(r_o/r_i\right)\right]^{4/3}}{\left(r_i^{-3/5} + r_o^{-3/5}\right)^{5/3}} = \frac{2\left[\ln\left(125/100\right)\right]^{4/3}}{\left[(0.1\text{ m})^{-3/5} + (0.125\text{ m})^{-3/5}\right]^{5/3}} = 0.0095\text{ m}$$

Then

$$Ra_c = \frac{g\beta(T_s - T_\infty)L_c^3}{\nu\alpha} = \frac{9.8\text{ m/s}^2 \times (1/350\text{ K})\,(400 - 300)\text{K}\,(0.0095\text{ m})^3}{4.155 \times 10^{-6}\text{ m}^2\text{/s} \times 5.842 \times 10^{-6}\text{ m}^2\text{/s}} = 98{,}800$$

The effective thermal conductivity is found from Eq. 9.59,

$$\frac{k_{eff}}{k} = 0.386\left(\frac{Pr}{0.861 + Pr}\right)^{1/4} Ra_c^{1/4}$$

$$\frac{k_{eff}}{k} = 0.386\left(\frac{0.711}{0.861 + 0.711}\right)^{1/4}\left(98{,}800\right)^{1/4} = 5.61.$$

Hence, the heat rate, Eq. (1), becomes

$$q' = \frac{2\pi \times 5.61 \times 0.0293\text{ W/m}\cdot\text{K}}{\ell n\left(125/100\right)}\left(400 - 300\right)\text{K} = 463\text{ W/m}. \qquad <$$

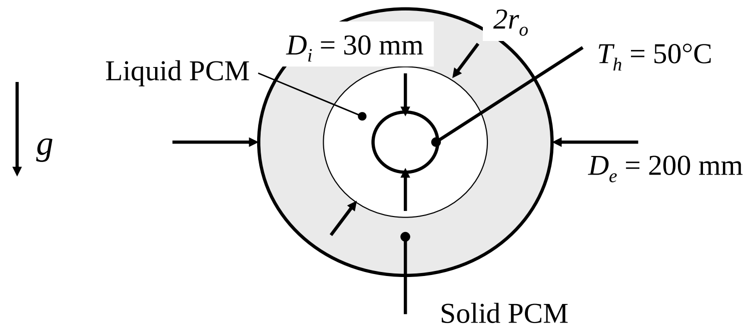
COMMENTS: Note that the heat loss by convection is nearly six times that for conduction. Radiation transfer is likely to be important for this situation. The effect of nitrogen pressure is to decrease ν which in turn increases Ra_L; that is, free convection heat transfer will increase with increase in pressure.

PROBLEM 9.106

KNOWN: Diameter of cylindrical enclosure housing solid PCM. Diameter and temperature of heated inner concentric cylinder. Initial PCM temperature.

FIND: Time to melt half of PCM.

SCHEMATIC:



ASSUMPTIONS: (1) The quasi-steady approximation holds: the heat transfer coefficient can be evaluated based on steady-state conditions, (2) Constant properties, (3) The sensible energy associated with the portion of PCM above its melting temperature is negligible.

PROPERTIES: From Problems 8.47 and 9.57, PCM: T_m = 27.4°C, h_{sf} = 244 kJ/kg, ρ = 770 kg/m^3, k = 0.15 W/m · K, $\beta = 8 \times 10^{-4}$ K^{-1}, $\nu = 5 \times 10^{-6}$ m^2/s, $\alpha = 8.85 \times 10^{-8}$ m^2/s, $Pr = \nu/\alpha = 56.5$, $c_p = k/\rho\alpha$ = 2200 J/kg · K.

ANALYSIS: The molten PCM occupies the region between the heater radius, r_i, and the solid-liquid interface, r_o. The latter radius is a function of time. According to the quasi-steady approximation, the convection heat transfer rate can be found from Eqs. 9.58, 9.59, and 9.60 using the instantaneous value of r_o. Combining these equations yields the convection heat transfer rate per unit length:

$$q' = 2\pi k(T_i - T_o)0.386\left(\frac{Pr}{0.861+Pr}\right)^{1/4}\left(\frac{g\beta(T_i - T_o)}{\nu\alpha}\right)^{1/4}\frac{2^{3/4}}{(r_i^{-3/5}+r_o^{-3/5})^{5/4}} = \frac{A}{(r_i^{-3/5}+r_o^{-3/5})^{5/4}} \quad (1)$$

where $T_o = T_m$ = 27.4°C and $T_i = T_h$ = 50°C. The constant A is defined by the above equation and has the value $A = 1.10 \times 10^4$ W/m$^{7/4}$. The rate at which heat reaches the solid-liquid interface is equal to the rate of change of mass of molten PCM (kg/s) multiplied by the latent heat of fusion, thus

$$q' = \frac{dm'}{dt}h_{sf} = \frac{d}{dt}\left(\rho\pi(r_o^2 - r_i^2)\right)h_{sf} = 2\pi r_o \rho h_{sf}\frac{dr_o}{dt} \quad (2)$$

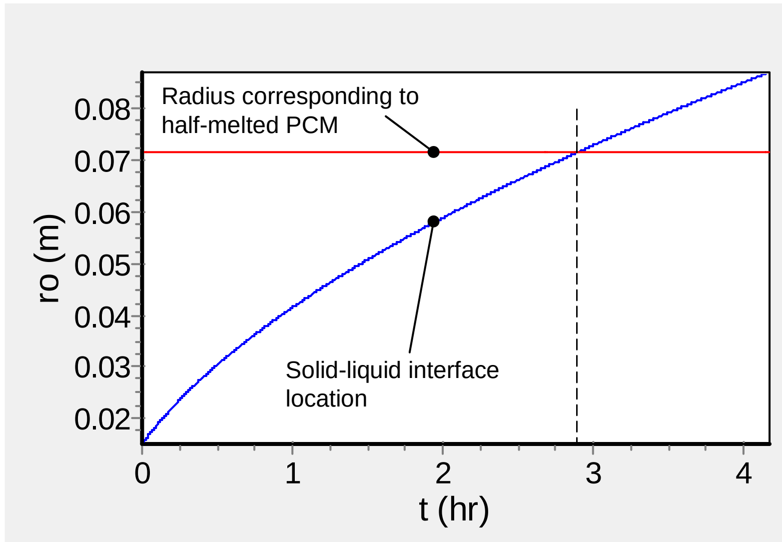
Combining Eqs. (1) and (2) yields a differential equation for $r_o(t)$:

$$\frac{dr_o}{dt} = \frac{A/2\pi\rho h_{sf}}{r_o(r_i^{-3/5}+r_o^{-3/5})^{5/4}}$$

The criterion that half the PCM has been melted is satisfied when $\pi(r_{o,\text{final}}^2 - r_i^2) = \frac{1}{2}\pi(r_e^2 - r_i^2)$, where $r_e = \frac{1}{2}D_e = 0.1$ m. Thus, $r_{o,\text{final}} = \left[\frac{1}{2}(r_e^2 + r_i^2)\right]^{1/2} = 0.0715$ m. The above differential equation is most easily solved numerically. It has been solved using IHT to generate the following graph.

Continued…

PROBLEM 9.106 (Cont.)



The final radius criterion, r_o = 0.0715 m, is satisfied at t = 2.88 h. <

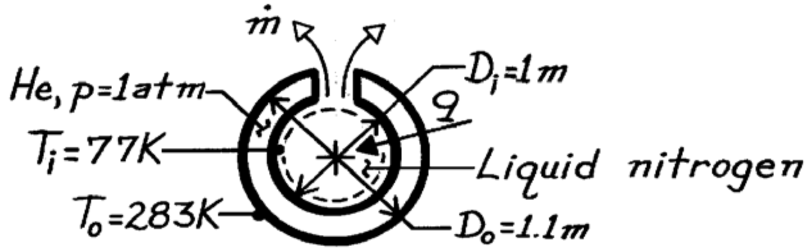
COMMENTS: (1) The solid-liquid interface moves slowly, traveling around 70 mm in 2.88 h. It is likely that the free convection motion can adjust to the instantaneous conditions relatively quickly compared with the rate at which the interface is moving. That is, the quasi-steady approximation is probably accurate. (2) The sensible energy associated with the portion of PCM above its melting temperature was neglected. The temperature of the molten PCM varies from the melting temperature to the heater temperature. We can estimate the average PCM temperature as (27.4+50)°C/2 = 38.7°C. The ratio of the sensible energy to the latent energy is $mc_p(T - T_m)/mh_{sf} = c_p(T - T_m)/h_{sf}$. This ratio is a dimensionless parameter known as the Stefan number, *Ste*. Here *Ste* = 0.10. Thus, the error associated with neglecting the sensible energy is on the order of 10%.

PROBLEM 9.107

KNOWN: Diameters and temperatures of concentric spheres.

FIND: Rate at which stored nitrogen is vented.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible radiation.

PROPERTIES: Liquid nitrogen (given): $h_{fg} = 2 \times 10^5$ J/kg; *Table A-4*, Helium ($\overline{T} = (T_i + T_o)/2 =$ 180K, 1 atm): $\nu = 51.3 \times 10^{-6}$ m²/s, k = 0.107 W/m·K, $\alpha = 76.2 \times 10^{-6}$ m²/s, Pr = 0.673, $\beta = 0.00556$ K^{-1}.

ANALYSIS: Performing an energy balance for a control surface about the liquid nitrogen, it follows that

$$q = q_{conv} = \dot{m}h_{fg}.$$

From the Raithby and Hollands expressions for free convection between concentric spheres,

$$q_{conv} = \frac{4\pi k_{eff}\left(T_i - T_o\right)}{(1/r_i) - (1/r_o)}$$

$$k_{eff} = 0.74k\left[Pr/\left(0.861 + Pr\right)\right]^{1/4}\left(Ra_s\right)^{1/4}$$

where $$L_s = \frac{(1/r_i - 1/r_o)^{4/3}}{2^{1/3}(r_i^{-7/5} + r_o^{-7/5})^{5/3}} = 5.69 \times 10^{-3} \text{ m}$$

$$Ra_s = \frac{g\beta\left(T_o - T_i\right)L_s^3}{\nu\alpha} = \frac{9.8\,\text{m/s}^2\left(0.00556\text{K}^{-1}\right)\left(206\,\text{K}\right)\left(5.69\times10^{-3}\,\text{m}\right)^3}{\left(51.3\times10^{-6}\text{m}^2/\text{s}\right)\left(76.2\times10^{-6}\text{m}^2/\text{s}\right)} = 528$$

$$k_{eff} = 0.74\left(0.107\,\text{W/m}\cdot\text{K}\right)\left[0.673/\left(0.861+0.673\right)\right]^{1/4}\left(528\right)^{1/4} = 0.309\,\text{W/m}\cdot\text{K}.$$

Hence, $$q_{conv} = \frac{(0.309\text{ W/m}\cdot\text{K}) \times 4\pi\,(206\text{ K})}{(1/0.5\text{ m}) - (1/0.55\text{ m})} = 4399\text{ W}$$

The rate at which nitrogen is lost from the system is therefore

$$\dot{m} = q_{conv}/h_{fg} = 4399\,\text{W}/2\times10^5\,\text{J/kg} = 0.022\ \text{kg/s}.$$ <

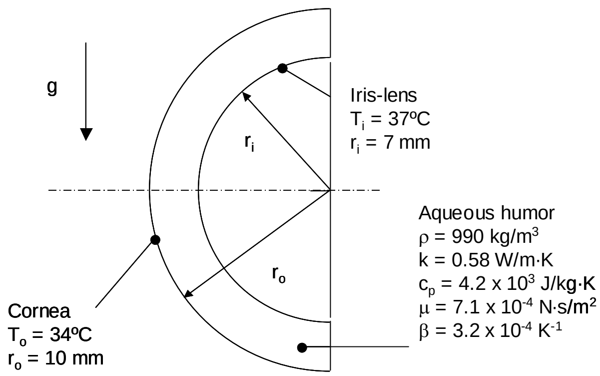
COMMENTS: The heat gain and mass loss are large. Helium should be replaced by a noncondensing gas of smaller k, or the cavity should be evacuated.

PROBLEM 9.108

KNOWN: Dimensions of enclosure, surface temperatures, and properties of aqueous humor.

FIND: The ratio of the effective to the bulk thermal conductivity of the aqueous humor.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Steady-state conditions, (3) Person is standing or sitting vertically.

PROPERTIES: Given, see schematic.

ANALYSIS: The kinematic viscosity is $\nu = \mu/\rho = 7.1 \times 10^{-4}$ N·s/m^2/990 kg/m^3 = 7.17×10^{-9} m^2/s. The thermal diffusivity is $\alpha = k/\rho c$ = 0.58 W/m·K/(990 kg/m$^3 \times 4.2 \times 10^3$ J/kg·K) = 139.5×10^{-4} m^2/s, while the Prandtl number is Pr = ν/α = (7.17×10^{-9} m^2/s)/(139.5×10^{-4} m^2/s) = 5.14. The characteristic length for use in Equation 9.61 is

$$L_s = \frac{\left(\frac{1}{r_i} - \frac{1}{r_o}\right)^{4/3}}{2^{1/3}\left(r_i^{-7/5} + r_o^{-7/5}\right)^{5/3}} = \frac{\left(\frac{1}{7\times10^{-3}\text{m}} - \frac{1}{10\times10^{-3}\text{m}}\right)^{4/3}}{2^{1/3}\left((7\times10^{-3}\text{m})^{-7/5} + (10\times10^{-3}\text{m})^{-7/5}\right)^{5/3}} = 506\times10^{-6}\text{m}$$

The Rayleigh number is

$$Ra_s = \frac{g\beta\left(T_s - T_o\right)L_s^3}{\nu\cdot\alpha} = \frac{9.8\text{m/s}^2 \times 3.2\times10^{-4}\text{K}^{-1} \times \left(37-34\right)°\text{C} \times (506\times10^{-6}\text{m})^3}{7.17\times10^{-9}\text{m}^2/\text{s} \times 139.5\times10^{-4}\text{m}^2/\text{s}} = 12.2$$

The ratio of the effective thermal conductivity to bulk thermal conductivity is

$$\frac{k_{eff}}{k} = 0.74\left(\frac{Pr}{0.861 + Pr}\right)^{1/4} Ra_s^{1/4} = 0.74 \times \left(\frac{5.14}{0.861 + 5.14}\right)^{1/4} \times (12.2)^{1/4} = 1.33 \quad <$$

Since $k_{eff}/k > 1$, we conclude that free convection does occur in the aqueous humor.

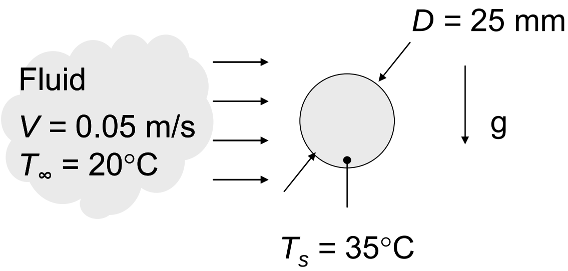
Comments: (1). The velocity of the aqueous humor could be estimated by performing a detailed simulation using a CFD (computational fluid dynamics) tool. (2) Fluid motion is upward near the iris and downward adjacent to the cornea when the person is standing or sitting vertically.

PROBLEM 9.109

KNOWN: Diameter and temperature of cylinder. Velocity and temperature of fluid in cross flow. Four different fluids.

FIND: Whether heat transfer by free convection is significant.

SCHEMATIC:



ASSUMPTIONS: (1) Steady state, (2) Constant properties, (3) Air can be modeled as an ideal gas.

PROPERTIES: Air (300K, 1 atm): $\beta = 1/T_f = 3.333 \times 10^{-3}$ K^{-1}; *Table A-6*, Water ($T_f = (T_\infty + T_s)/2 =$ 300K): $\beta = 276.1 \times 10^{-6}$ K^{-1}; *Table A-5*, Engine oil ($T_f = (T_\infty + T_s)/2 = 300$K): $\beta = 0.7 \times 10^{-3}$ K^{-1}; *Table A-5*, Mercury ($T_f = (T_\infty + T_s)/2 = 300$K): $\beta = 0.181 \times 10^{-3}$ K^{-1}.

ANALYSIS: Following the discussion of Section 9.9, the general criterion for delineating the relative significance of free and forced convection depends upon the value of Gr/Re^2. Free convection is insignificant if $Gr/Re^2 << 1$, where $Gr = g\beta(T_s - T_\infty)D^3/\nu^2$ and $Re = VD/\nu$. Thus,

$$Gr / Re^2 = g\beta(T_s - T_\infty)D / V^2$$

The only material property that impacts the determination of the significance of free convection is the thermal expansion coefficient, β. Furthermore with all other parameters held fixed, it is useful to express $Gr/Re^2 = G\beta$, where

$$G = g(T_s - T_\infty)D/V^2 = 9.8 \text{ m/s}^2 \times (35 - 20)°\text{C} \times 0.025 \text{ m}/(0.05 \text{ m/s})^2 = 1470 \text{ K}$$

Thus, for air,

$$Gr/Re^2 = G\beta = 1470 \text{ K} \times 3.333 \times 10^{-3} \text{ K}^{-1} = 4.90$$

Since $Gr/Re^2 > 1$, free convection is significant. <

For water,

$$Gr/Re^2 = G\beta = 1470 \text{ K} \times 276.1 \times 10^{-6} \text{ K}^{-1} = 0.406$$

Since Gr/Re^2 is not small compared to 1, free convection is likely to be important. <

Continued…

For engine oil,

$$Gr/Re^2 = G\beta = 1470 \text{ K} \times 0.7 \times 10^{-3} \text{ K}^{-1} = 1.03$$

Since Gr/Re^2 is of order 1, free and forced convection are likely to be equally important. <

For mercury,

$$Gr/Re^2 = G\beta = 1470 \text{ K} \times 0.181 \times 10^{-3} \text{ K}^{-1} = 0.266$$

Since Gr/Re^2 is somewhat small compared to 1, free convection might be negligible, depending on the desired accuracy of the solution. <

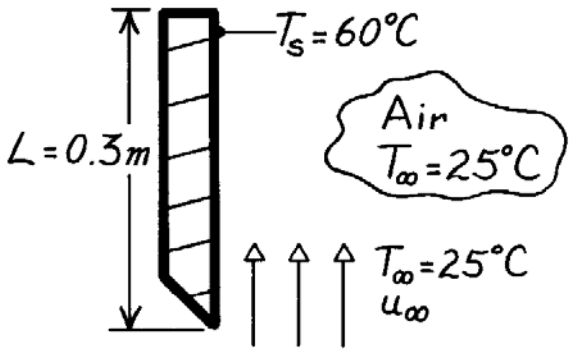
COMMENTS: (1) None of the situations considered here correspond to conditions where heat transfer is clearly dominated by either natural or forced convection. In such situations, it may be necessary to determine the convection heat transfer rates experimentally, or by solving the three-dimensional, unsteady forms of the convection transfer equations computationally. (2) Gr/Re^2 is sometimes referred to as the Richardson number, *Ri*.

PROBLEM 9.110

KNOWN: Parallel air flow over a uniform temperature, heated vertical plate; the effect of free convection on the heat transfer coefficient will be 5% when $Gr_L / Re_L^2 = 0.08$.

FIND: Minimum vertical velocity required of air flow such that free convection effects will be less than 5% of the heat rate.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Criterion for combined free-forced convection determined from experimental results.

PROPERTIES: *Table A-4*, Air ($T_f = (T_s + T_\infty)/2 = 315K$, 1 atm): $\nu = 17.40 \times 10^{-6}\ m^2/s$, $\beta = 1/T_f$.

ANALYSIS: To delineate flow regimes, according to Section 9.9, the general criterion for predominately forced convection is that

$$Gr_L / Re_L^2 << 1. \qquad (1)$$

From experimental results, when $Gr_L / Re_L^2 \approx 0.08$, free convection will be equal to 5% of the total heat rate.

For the vertical plate using Eq. 9.12,

$$Gr_L = \frac{g\beta(T_1 - T_2)L^3}{\nu^2} = \frac{9.8\,m/s^2 \times 1/315K \times (60-25)K \times (0.3m)^3}{\left(17.40 \times 10^{-6} m^2/s\right)^2} = 9.711 \times 10^7. \qquad (2)$$

For the vertical plate with forced convection,

$$Re_L = \frac{u_\infty L}{\nu} = \frac{u_\infty (0.3m)}{17.4 \times 10^{-6} m^2/s} = 1.724 \times 10^4 u_\infty. \qquad (3)$$

By combining Eqs. (2) and (3),

$$\frac{Gr_L}{Re_L^2} = \frac{9.711 \times 10^7}{\left[1.724 \times 10^4\, u_\infty\right]^2} = 0.08$$

find that

$$u_\infty = 2.02\,m/s. \qquad <$$

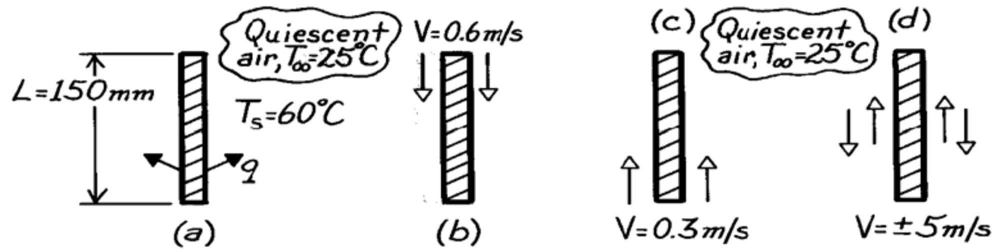
That is, when $u_\infty \geq 2.02$ m/s, free convection effects will not exceed 5% of the total heat rate.

PROBLEM 9.111

KNOWN: Vertical array of circuit boards 0.15m high with maximum allowable uniform surface temperature for prescribed ambient air temperature.

FIND: Allowable electrical power dissipation per board, $q'[W/m]$, for these cooling arrangements: (a) Free convection only, (b) Air flow downward at 0.6 m/s, (c) Air flow upward at 0.3 m/s, and (d) Air flow upward or downward at 5 m/s.

SCHEMATIC:



ASSUMPTIONS: (1) Uniform surface temperature, (2) Board horizontal spacing sufficient that boundary layers don't interfere, (3) Ambient air behaves as quiescent medium, (4) Perfect gas behavior.

PROPERTIES: *Table A-4*, Air ($T_f = (T_s + T_\infty)/2 \approx 315K$, 1 atm): $\nu = 17.40 \times 10^{-6}$ m^2/s, k = 0.0274 W/m·K, $\alpha = 24.7 \times 10^{-6}$ m^2/s, Pr = 0.705, $\beta = 1/T_f$.

ANALYSIS: (a) For *free convection* only, the allowable electrical power dissipation rate is

$$q' = \bar{h}_L (2L)(T_s - T_\infty) \tag{1}$$

where $\bar{h}_L$ is estimated using the appropriate correlation for free convection from a vertical plate. Find the Rayleigh number,

$$Ra_L = \frac{g\beta\Delta T L^3}{\nu\alpha} = \frac{9.8\,m/s^2 (1/315K)(60-25)K(0.150m)^3}{17.4\times10^{-6} m^2/s \times 24.7\times10^{-6} m^2/s} = 8.551\times10^6. \tag{2}$$

Since $Ra_L < 10^9$, the flow is laminar. With Eq. 9.27 find

$$\overline{Nu}_L = \frac{\bar{h}L}{k} = 0.68 + \frac{0.670\,Ra_L^{1/4}}{\left[1+(0.492/Pr)^{9/16}\right]^{4/9}} = 0.68 + \frac{\left(0.670\left[8.551\times10^6\right]^{1/4}\right)}{\left[1+(0.492/0.705)^{9/16}\right]^{4/9}} = 28.47 \tag{3}$$

$$\bar{h}_L = (0.0274\,W/m\cdot K/0.150m)\times 28.47 = 5.20\,W/m^2\cdot K.$$

Hence, the allowable electrical power dissipation rate is,

$$q' = 5.20\,W/m^2\cdot K(2\times0.150m)(60-25)°C = 54.6\,W/m.$$ <

(b) With *downward velocity* V = 0.6 m/s, the possibility of mixed forced-free convection must be considered. With $Re_L = VL/\nu$, find

$$\left(Gr_L/Re_L^2\right) = \left(\frac{Ra_L}{Pr}/Re_L^2\right) \tag{4}$$

$$\left(Gr_L/Re_L^2\right) = \left(8.551\times10^6/0.705\right)/\left(0.6\,m/s\times0.150m/17.40\times10^{-6} m^2/s\right)^2 = 0.453.$$

Continued …

PROBLEM 9.111 (Cont.)

Since $\left(Gr_L / Re_L^2\right) \sim 1,$ flow is mixed and the average heat transfer coefficient may be found from a correlating equation of the form

$$\overline{Nu}^n = Nu_F^n \pm Nu_N^n \tag{5}$$

where n = 3 for the vertical plate geometry and the minus sign is appropriate since the natural convection (N) flow opposes the forced convection (F) flow. For the forced convection flow, Re_L = 5172 and the flow is laminar; using Eq. 7.30,

$$\overline{Nu}_F = 0.664\ Re_L^{1/2}\ Pr^{1/3} = 0.664(5172)^{1/2}(0.705)^{1/3} = 42.50. \tag{6}$$

Using $\overline{Nu}_N = 28.47$ from Eq. (3), Eq. (5) now becomes

$$\overline{Nu}^3 = \left(\frac{\bar{h}L}{k}\right)^3 = (42.50)^3 - (28.47)^3 \qquad \overline{Nu} = 37.72$$

$$\bar{h} = \left(\frac{0.0274\,W/m\cdot K}{0.150m}\right) \times 37.72 = 6.89\,W/m^2\cdot K.$$

Substituting for $\bar{h}$ into the rate equation, Eq. (1), the allowable power dissipation with a downward velocity of 0.6 m/s is

$$q' = 6.89\,W/m^2\cdot K(2\times 0.150m)(60-25)°C = 72.3\ W/m. \qquad <$$

(c) With an *upward velocity* V = 0.3 m/s, the positive sign of Eq. (5) applies since the N-flow is assisting the F-flow. For forced convection, find

$$Re_L = VL/\nu = 0.3\,m/s \times 0.150m/\left(17.40\times 10^{-6} m^2/s\right) = 2586.$$

The flow is again laminar, hence Eq. (6) is appropriate.

$$\overline{Nu}_F = 0.664(2586)^{1/2}(0.705)^{1/3} = 30.05.$$

From Eq. (5), with the positive sign, and $\overline{Nu}_N$ from Eq. (4),

$$\overline{Nu}^3 = (30.05)^3 + (28.47)^3 \quad \text{or} \quad \overline{Nu} = 36.88 \quad \text{and} \quad \bar{h} = 6.74\,W/m^2\cdot K.$$

From Eq. (1), the allowable power dissipation with an upward velocity of 0.3 m/s is

$$q' = 6.74\,W/m^2\cdot K(2\times 0.150m)(60-25)°C = 70.7\,W/m. \qquad <$$

(d) With a *forced convection* velocity V = 5 m/s, very likely forced convection will dominate. Check by evaluating whether $\left(Gr_L / Re_L^2\right) << 1$ where Re_L = VL/ν = 5 m/s × 0.150m/(17.40 × 10^{-6} m^2/s) = 43,103. Hence,

$$\left(Gr_L / Re_L^2\right) = \left(\frac{Ra_L}{Pr}/Re_L^2\right) = \left(8.551\times 10^6/0.705\right)/43{,}103^2 = 0.007.$$

The flow is not mixed, but pure forced convection. Using Eq. (6), find

$$\bar{h} = (0.0274\,W/m\cdot K/0.150m)0.664(43{,}103)^{1/2}(0.705)^{1/3} = 22.4\,W/m^2\cdot K$$

and the allowable dissipation rate is

$$q' = 22.4\,W/m^2\cdot K(2\times 0.150m)(60-25)°C = 235\,W/m. \qquad <$$

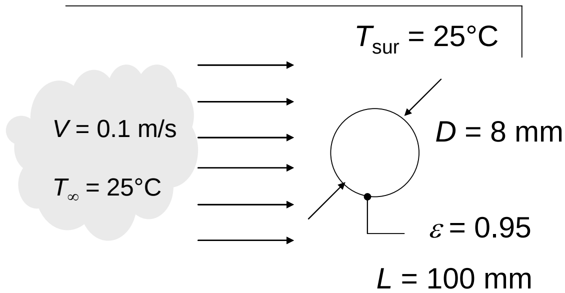
COMMENTS: Be sure to compare dissipation rates to see relative importance of mixed flow conditions.

PROBLEM 9.112

KNOWN: Dimensions of horizontal tube in wind tunnel. Air velocity and temperature, surroundings temperature, emissivity of tube surface, power dissipation.

FIND: (a) Tube surface temperature for T_∞ = 25°C, V = 0.1 m/s, (b) Plot of the tube surface temperature versus the cross flow velocity for 0.05 m/s ≤ V ≤ 1 m/s.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Large surroundings, (3) Steady-state conditions, (4) Ideal gas.

PROPERTIES: Table A.4, air ($T_f \approx$ 300 K): $\nu = 15.89 \times 10^{-6}$ m²/s, k = 0.0263 W/m·K, $\alpha = 22.5 \times 10^{-6}$ m²/s, Pr = 0.707, $\beta = 1/T_f = 0.0033$ K^{-1}.

ANALYSIS: (a) An energy balance on the cylinder yields

$$P = 1.5W = q_{\text{conv}} + q_{\text{rad}} = \pi DL\left[\bar{h}\left(T_s - T_\infty\right) + \varepsilon\sigma\left(T_s^4 - T_{\text{sur}}^4\right)\right]$$

$$= \pi 0.008\text{m} \times 0.10\text{m}\left[\bar{h}\left(T_s - (25+273)\text{K}\right) + 0.95 \times 5.67 \times 10^{-8}\text{W/m}^2\cdot\text{K}^4\left(T_s^4 - (25+273\text{ K})^4\right)\right] \quad (1)$$

From Equation 9.64 for mixed convection from a cylinder in transverse flows,

$$\overline{Nu}_D^4 = \overline{Nu}_{D,F}^4 + \overline{Nu}_{D,N}^4 \quad (2)$$

where the forced convection Nusselt number, $\overline{Nu}_{D,F}$, is provided by the Churchill and Bernstein correlation of Chapter 7, and $Re_D = VD/\nu = (0.1\text{ m/s} \times 0.008\text{ m})/15.89 \times 10^{-6}\text{m}^2/\text{s} = 50.35$.

$$\overline{Nu}_{D,F} = 0.3 + \frac{0.62Re_D^{1/2}Pr^{1/3}}{\left[1+(0.4/Pr)^{2/3}\right]^{1/4}}\left[1+\left(\frac{Re_D}{282{,}000}\right)^{5/8}\right]^{4/5}$$

$$= 0.3 + \frac{0.62 \times 50.35^{1/2} \times 0.707^{1/3}}{\left[1+(0.4/0.707)^{2/3}\right]^{1/4}}\left[1+\left(\frac{50.35}{282{,}000}\right)^{5/8}\right]^{4/5} = 3.75 \quad (3)$$

The natural (free) convection Nusselt number, $\overline{Nu}_{D,N}$, is found from the Churchill and Chu correlation,

Continued…

PROBLEM 9.112 (Cont.)

$$\overline{Nu}_{D,N} = \left\{ 0.60 + \frac{0.387 Ra_D^{1/6}}{\left[1 + (0.559/Pr)^{9/16}\right]^{8/27}} \right\}^2 \qquad (4a)$$

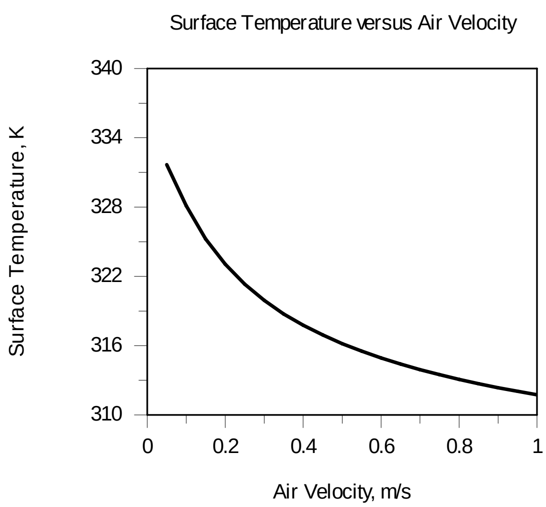
where the Rayleigh number is,

$$Ra_D = \frac{g\beta(T_s - T_\infty)D^3}{\nu\alpha} = \frac{9.8\ \text{m/s}^2 \times (0.0033\text{K}^{-1}) \times (T_s - (25+273)\text{K}) \times (0.008\ \text{m})^3}{15.89\text{m}^2/\text{s} \times 22.5 \times 10^{-12}\ \text{m}^2/\text{s}} \qquad (4b)$$

Finally, $\bar{h} = \overline{Nu}_D k / D$ (5)

Simultaneous solution of Equations (1) through (5) yields T_s = 328.1 K = 55.1°C <

(b) The dependence of the surface temperature on the air velocity is shown below.



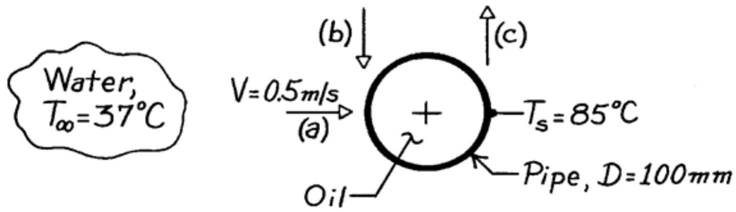
COMMENTS: (1) In part (a), the convective and radiative heat rates are q_{conv} = 1W and q_{rad} = 0.5 W, respectively. Therefore, it is important to include radiative losses in the analysis, (2) If free convection is ignored in part (a), the predicted surface temperature is T_s = 329.4 K. Alternatively, if the forced convection component is ignored, T_s = 334.3 K, (3) The surface temperature is strongly dependent on the air velocity, as evident in the solution to part (b). Using modern infrared detectors, the resolution of the surface temperature measurement could be as small as ΔT = 0.05 K. Hence, the measured surface temperature could be used to determine the air velocity.

PROBLEM 9.113

KNOWN: Horizontal pipe passing hot oil used to heat water.

FIND: Effect of water flow direction on the heat rate.

SCHEMATIC:



ASSUMPTIONS: (1) Uniform pipe surface temperature, (2) Constant properties.

PROPERTIES: *Table A-6*, Water ($T_f = (T_s + T_\infty)/2 \approx 335K$): $\nu = \mu_f\, v_f = 4.625 \times 10^{-7}\ m^2/s$, k = 0.656 W/m·K, $\alpha = k\, v_f/c_p = 1.595 \times 10^{-7}\ m^2/s$, Pr = 2.88, $\beta = 535.5 \times 10^{-6}\ K^{-1}$; *Table A-6*, Water ($T_\infty$ = 310K): $\nu = \mu_f\, v_f = 6.999 \times 10^{-7}\ m^2/s$, k = 0.028 W/m·K, Pr = 4.62; *Table A-6*, Water (T_s = 358K): Pr = 2.07

ANALYSIS: The rate equation for the flow situations is of the form

$$q' = \overline{h}(\pi D)(T_s - T_\infty).$$

To determine whether mixed flow conditions are present, evaluate $\left(Gr_D / Re_D^2\right)$.

$$Gr_D = \frac{g\,\beta \Delta T\, D^3}{\nu^2} = \frac{9.8\,m/s^2 \times 535.5\times10^{-6}\,K^{-1}(85-37)K(0.100m)^3}{\left(4.625\times10^{-7}\,m^2/s\right)^2} = 1.178\times10^9$$

$$Re_D = VD/\nu = 0.5\,m/s \times 0.100m / 6.999\times10^{-7}\,m^2/s = 7.144\times10^4.$$

It follows that $\left(Gr_D / Re_D^2\right) = 0.231$; since this ratio is of order unity, the flow condition is mixed. Using

Eq. 9.64, $\overline{Nu}^n = \overline{Nu}_F^n \pm \overline{Nu}_N^n$ and for the three flow arrangements,

(a) Transverse flow: $\overline{Nu}^4 = \overline{Nu}_F^4 + \overline{Nu}_N^4$

(b) Opposing flow: $\overline{Nu}^3 = \overline{Nu}_F^3 - \overline{Nu}_N^3$

(c) Assisting flow: $\overline{Nu}^3 = \overline{Nu}_F^3 + \overline{Nu}_N^3$

For *natural convection* from the cylinder, use Eq. 9.34 with Ra = Gr·Pr.

$$\overline{Nu}_N = \left\{0.60 + \frac{0.387\,Ra_D^{1/6}}{\left[1+\left(0.559/Pr\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.60 + \frac{0.387\left(1.178\times10^9 \times 2.88\right)^{1/6}}{\left[1+\left(0.559/2.88\right)^{9/16}\right]^{8/27}}\right\}^2 = 201.2$$

For *forced convection* in cross flow over the cylinder, from Table 7-4 use

$$\overline{Nu}_F = C\ Re_D^m\, Pr^n \left(Pr/Pr_s\right)^{1/4}$$

$$\overline{Nu}_F = 0.26\left(7.144\times10^4\right)^{0.6}\left(4.62\right)^{0.37}\left(4.62/2.07\right)^{1/4} = 457.5$$

PROBLEM 9.113 (Cont.)

where n = 0.37 since Pr ≤ 10. The results of the calculations are tabulated.

Flow	$\overline{Nu}$	$\overline{h}\left(W/m^2\cdot K\right)$	$q'\times10^{-4}\left(W/m\right)$
(a) Transverse	461.7	3029	4.57
(b) Opposing	444.1	2913	4.39
(c) Assisting	470.1	3083	4.65

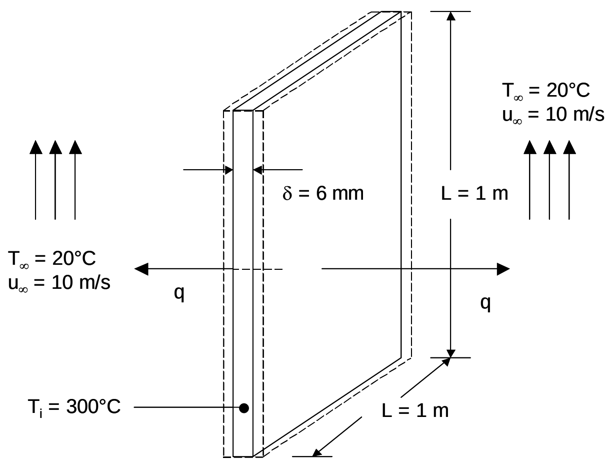
COMMENTS: Note that the flow direction has a minor effect (<6%) for these conditions.

PROBLEM 9.114

KNOWN: Plate dimensions and initial temperature. Velocity and temperature of air in parallel flow over plates.

FIND: Initial rate of heat transfer from plate. Initial rate of change of plate temperature. Graph of the free, forced and mixed convection heat transfer coefficients over the range $2 \le u_\infty \le 10$ m/s.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible radiation, (2) Negligible effect of conveyor velocity on boundary layer development, (3) Lumped capacitance behavior, (4) Negligible heat transfer from sides of plate.

PROPERTIES: Table A.1, AISI 1010 steel (T = 573 K): k_p = 49.2 W/m·K, c = 549 J/kg·K, ρ = 7832 kg/m^3. Table A.4, air: (p = 1 atm, T_f = 433 K): k = 0.0361 W/m·K, ν = 30.4 × 10^{-6} m^2/s, α = 4.417 × 10^{-5} m^2/s, Pr = 0.688.

ANALYSIS: The initial rate of heat transfer from the plate is

$$q_i = 2\overline{h}A_s(T_i - T_\infty) = 2\overline{h}L(T_i = T_\infty)$$

With $Re_L = u_\infty L/\nu$ = 10m/s × 1m/30.4 × 10^{-6}m^2/s = 3.29 × 10^5, the forced convection is laminar. Therefore, $\overline{Nu}_L = Nu_F = 0.664\,Re_L^{1/2}\,Pr^{1/3} = 0.664 \times (3.29 \times 10^5)^{1/2} \times (0.688)^{1/3} = 336$. With Ra_L = $g\beta(T_i - T_\infty)L^3/\nu\alpha$ = 9.8m/s^2 × (1/433 K) × (300 – 20)°C × (1 m)^3/(30.4 × 10^{-6} m^2/s × 4.417 × 10^{-5} m^2/s) = 4.72 × 10^9, The Churchill and Chu correlation yields

$$\overline{Nu}_L = Nu_N = \left\{0.825 + \frac{0.387Ra^{1/6}}{\left[1+(0.492/Pr)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.825 + \frac{0.387(4.72\times10^9)^{1/6}}{\left[1+(0.492/0.688)^{9/16}\right]^{8/27}}\right\}^2 = 198$$

Continued…

PROBLEM 9.114 (Cont.)

Since the forced and free convection induced flows are transverse, $Nu = \left(Nu_F^3 + Nu_N^3\right)^{1/3} =$ $(336^3+198^3) = 357$. Hence, $\bar{h} = Nuk/L = 357 \times 0.0361 W/m \cdot K/1m = 12.9 W/m^2 \cdot K$ and

$$q_i = 2 \times 12.9 \text{ W/m}^2\cdot\text{K} \times (1\text{m})^2 \times (300 - 20)°\text{C} = 7224 \text{ W}$$ <

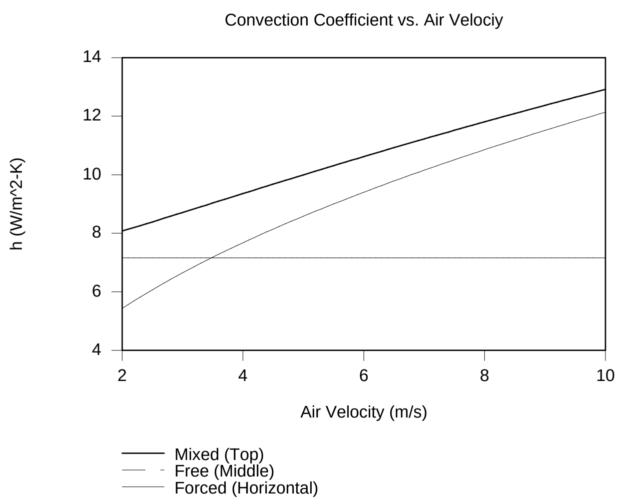
Performing an energy balance at an instant in time for the plate, $-\dot{E}_{out} = \dot{E}_{st}$, we obtain

$$\rho \delta L^2 c \left.\frac{dT}{dt}\right|_i = -\bar{h} 2L^2 (T_i - T_\infty)$$

or

$$\left.\frac{dT}{dt}\right|_i = \frac{2 \times 12.9 W/m^2 \cdot K \times (300-20)°C}{7832 kg/m^3 \times 0.006 m \times 549 J/kg \cdot K} = -0.28°C/s$$ <

The heat transfer coefficient may be evaluated over the velocity range $2 \le u_\infty \le 10$ /ms, yielding



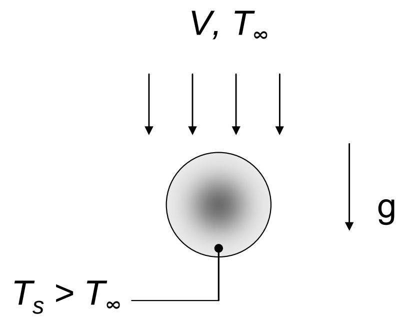
COMMENTS: (1) The Grashof number is $Gr_L = Ra_L/Pr = 4.72 \times 10^9/0.688 = 6.86 \times 10^9$. For the $u_\infty = 10$ m/s case, $Gr_L/Re_L^2 = 6.86 \times 10^9/(3.29 \times 10^5)^2 = 0.063 << 1$. We therefore expect free convection effects to be minor. (2) At $u_\infty \approx 3.5$ m/s the value of the free convection coefficient exceeds that of the forced convection coefficient. Free convection effects dominate at lower air forced velocities. (3) The Reynolds number, Re_L, is smaller than the transition Reynolds number ($Re_{x,c} = 5 \times 10^5$) while the Rayleigh number, Ra_L, exceeds the value associated with transition to turbulent flow ($Ra_{x,c} \approx 10^9$). This implies that flow conditions are very complex and the estimates of heat transfer rates are, at best, approximate. (4) At very low air forced velocities the plate motion will likely affect the boundary layer development. (5) The Biot number is $Bi = \bar{h}\,\delta/k_p =$ $12.9 \text{ W/m}^2\cdot\text{K} \times 0.006 \text{ m}/49.2 \text{ W/m}\cdot\text{K} = 0.0016$ and the lumped capacitance approximation is valid.

PROBLEM 9.115

KNOWN: Very small sphere.

FIND: Minimum value of the convection heat transfer coefficient expressed in terms of the sphere diameter and the thermal conductivity of air.

SCHEMATIC:



ASSUMPTIONS: Steady-state conditions.

ANALYSIS: According to Eq. 9.64, the Nusselt number for opposing flow is given by

$$Nu^n = Nu_F^n - Nu_N^n$$

The Nusselt number for pure forced convection past a sphere is given by Eq. 7.56. In the limit as $D \to 0$, $Re_D \to 0$, and

$$Nu_F = 2$$

For pure free convection past a sphere, the Nusselt number is given by Eq. 9.35, and in the limit as $D \to 0$, $Ra_D \to 0$, and

$$Nu_N = 2$$

Therefore, according to Eq. 9.64,

$$Nu^n = Nu_F^n - Nu_N^n = 0, \qquad Nu = 0$$

Thus, Eq. 9.64 *implies* that convection heat losses could be entirely eliminated by incorporating the assistant's suggestion. However, this conclusion is flawed. The limiting values of Nusselt numbers for *both* the pure forced and pure free convection cases correspond to the conduction limit, that is, the limit of zero velocity everywhere. The best one could possibly achieve by superimposing a forced flow in opposition to free convection would be to eliminate the fluid motion. This condition would then correspond to heat loss from the sphere by pure conduction, yielding

$$Nu = 2 \text{ and } h = Nu(k/D) = 2k/D \qquad <$$

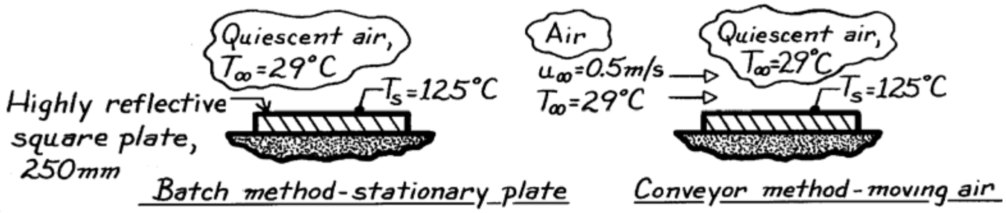
COMMENTS: (1) It is not possible to completely eliminate heat losses, since heat transfer by conduction cannot be eliminated (except in a vacuum). (2) This exercise illustrates the approximate nature of Eq. 9.64, which is not correct in the limit of pure conduction. (3) In reality, it is not possible to completely eliminate motion at all points in the flow by superimposing a uniform downward flow on free convection.

PROBLEM 9.116

KNOWN: Horizontal square panel removed from an oven and cooled in quiescent or moving air.

FIND: Initial convection heat rates for both methods of cooling.

SCHEMATIC:



ASSUMPTIONS: (1) Quasi-steady state conditions, (2) Backside of plates insulated, (3) Air flow is in the length-wise (not diagonal) direction, (4) Constant properties, (5) Radiative exchange negligible.

PROPERTIES: *Table A-4*, Air ($T_f = (T_\infty + T_s)/2 = 350K$, 1 atm): $\nu = 20.92 \times 10^{-6}$ m²/s, k = 0.030 W/m·K, $\alpha = 29.9 \times 10^{-6}$ m²/s, Pr = 0.700, $\beta = 1/T_f$.

ANALYSIS: The initial heat transfer rate from the plates by convection is given by the rate equation $q = \bar{h} A_s (T_s - T_\infty)$. Test for the existence of combined free-forced convection by calculation of the ratio Gr_L / Re_L^2. Use the same characteristic length in both parameters, L = 250mm, the side length.

$$Gr_L = \frac{g \beta \Delta T L^3}{\nu^2} = \frac{9.8\text{m/s}^2 (1/350\text{K})(125-29)\text{K}(0.250\text{m})^3}{\left(20.92\times10^{-6}\text{m/s}^2\right)^2} = 9.597\times10^7$$

$$Re_L = u_\infty L/\nu = 0.5\text{m/s}\times0.250\text{m}/\left(20.92\times10^{-6}\text{m}^2/\text{s}\right) = 5.975\times10^3.$$

Since $Gr_L / Re_L^2 = 2.69$ flow is mixed. For the *stationary plate*, $Ra_L = Gr_L \cdot Pr = 6.718 \times 10^7$ and Eq. 9.31 is the appropriate correlation,

$$\overline{Nu}_N = \frac{\bar{h}L}{k} = 0.15\,Ra_L^{1/3} = 0.15\left(6.718\times10^7\right)^{1/3} = 60.9$$

$$\bar{h} = (0.030\,\text{W/m}\cdot\text{K}/0.250\text{m})\times60.9 = 7.31\,\text{W/m}^2\cdot\text{K}.$$

$$q = 7.31\,\text{W/m}^2\cdot\text{K}\times(0.250\text{m})^2(125-29)\text{K} = 43.9\,\text{W}.$$ <

For the *plate with moving air*, $Re_L = 5.975 \times 10^3$ and the flow is laminar.

$$\overline{Nu}_F = 0.664\,Re_L^{1/2}\,Pr^{1/3} = 0.664\left(5.975\times10^3\right)^{1/2}(0.700)^{1/3} = 45.6.$$

For combined free-forced convection, use the correlating equation with n = 7/2.

$$\overline{Nu}^{7/2} = \overline{Nu}_F^{7/2} + \overline{Nu}_N^{7/2} = (45.6)^{7/2} + (60.9)^{7/2} \qquad \overline{Nu} = 66.5.$$

$$\bar{h} = \overline{Nu}\,k/L = 66.5(0.030\,\text{W/m}\cdot\text{K}/0.25\text{m}) = 7.99\,\text{W/m}^2\cdot\text{K}$$

$$q = 7.99\,\text{W/m}^2\cdot\text{K}(0.250\text{m})^2(125-29)\text{K} = 47.9\,\text{W}.$$ <

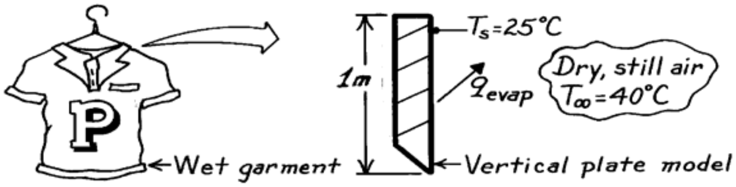
COMMENTS: (1) The conveyor method provides only slight enhancement of heat transfer.

PROBLEM 9.117

KNOWN: Wet garment at 25°C hanging in a room with still, dry air at 40°C.

FIND: Drying rate per unit width of garment.

SCHEMATIC:



ASSUMPTIONS: (1) Analogy between heat and mass transfer applies, (2) Water vapor at garment surface is saturated at T_s, (3) Perfect gas behavior of vapor and air.

PROPERTIES: *Table A-4*, Air ($T_f \approx (T_s + T_\infty)/2$ = 305K, 1 atm): $\nu = 16.39 \times 10^{-6}$ m^2/s; *Table A-6*, Water vapor (T_s = 298K, 1 atm): $p_{A,s}$ = 0.0317 bar, $\rho_{A,s} = 1/v_f$ = 0.02660 kg/m^3; *Table A-8*, Air-water vapor (305 K): $D_{AB} = 0.27 \times 10^{-4}$ m^2/s, Sc = ν/DAB = 0.607.

ANALYSIS: The drying rate per unit width of the garment is

$$\dot{m}'_A = \overline{h}_m \cdot L\left(\rho_{A,s} - \rho_{A,\infty}\right)$$

where $\overline{h}_m$ is the mass transfer coefficient associated with a vertical surface that models the garment. From the heat and mass transfer analogy, Eq. 9.24 with C and n from Section 9.6.1 yields

$$\overline{Sh}_L = 0.59\left(Gr_L\, Sc\right)^{1/4}$$

where $GrL = g\Delta\rho L^3/\rho\nu^2$ and $\Delta\rho = \rho_s - \rho_\infty$. Since the still air is dry, $\rho_\infty = \rho_{B,\infty} = p_{B,\infty}/R_B\, T_\infty$, where $R_B = \Re / \mathcal{M}_B = 8.314 \times 10^{-2}$ m^3·bar/kmol·K/29 kg/kmol = 0.00287 m^3·bar/kg·K. With $p_{B,\infty}$ = 1 atm = 1.0133 bar,

$$\rho_\infty = \frac{1.0133 \text{ bar}}{0.00287 \text{ m}^3 \cdot \text{bar/kg} \cdot \text{K} \times 313 \text{ K}} = 1.1280 \text{ kg/m}^3$$

The density of the air/vapor mixture at the surface is $\rho_s = \rho_{A,s} + \rho_{B,s}$. With $p_{B,s}$ = 1 atm – $p_{A,s}$ = 1.0133 bar – 0.0317 bar = 0.9816 bar,

$$\rho_{B,s} = \frac{p_{B,s}}{R_B\, T_s} = \frac{0.9816 \text{ bar}}{0.00287\left(\text{m}^3 \cdot \text{bar/kg} \cdot \text{K}\right) \times 298 \text{ K}} = 1.1477 \text{ kg/m}^3$$

Hence, ρ_s = (0.0266 + 1.1477) kg/m^3 = 1.1743 kg/m^3 and $\rho = (\rho_s + \rho_\infty)/2$ = 1.1512 kg/m^3. The Grashof number is then

$$Gr_L = \frac{9.8 \text{ m/s}^2 \times (1.1743 - 1.1280) \text{kg/m}^3 (1 \text{ m})^3}{1.1512 \text{ kg/m}^3 \times \left(16.39 \times 10^{-6} \text{m}^2/\text{s}\right)^2} = 1.467 \times 10^9$$

and (Gr_L Sc) = 8.905 × 10^8. The convection coefficient is then

$$\overline{h}_m = \frac{D_{AB}}{L}\overline{Sh}_L = \frac{0.27 \times 10^{-4} \text{m}^2/\text{s}}{1 \text{ m}} \times 0.59\left(8.905 \times 10^8\right)^{1/4} = 0.00275 \text{ m/s}$$

The drying rate is then

$$\dot{m}'_A = 2.750 \times 10^{-3} \text{m/s} \times 1.0\text{m}\left(0.0226 - 0\right)\text{kg/m}^3 = 6.21 \times 10^{-5} \text{ kg/s} \cdot \text{m}. \qquad <$$

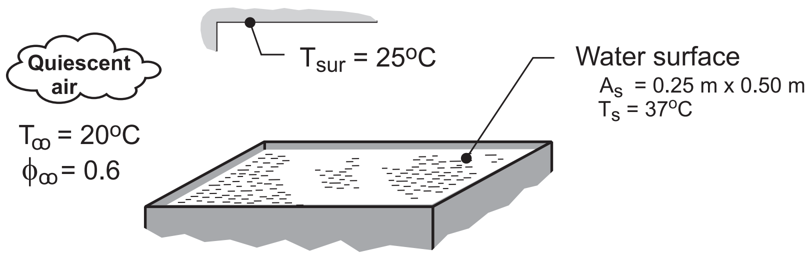
COMMENTS: Since $\rho_s > \rho_\infty$, the buoyancy driven flow *descends* along the garment.

PROBLEM 9.118

KNOWN: A water bath maintained at a uniform temperature of 37°C with top surface exposed to draft-free air and uniform temperature walls in a laboratory.

FIND: (a) The heat loss from the surface of the bath by radiation exchange with the surroundings; (b) Calculate the Grashof number using Eq. 9.65 with a characteristic length L that is appropriate for the exposed surface of the water bath; (c) Estimate the free convection heat transfer coefficient using the result for Gr_L obtained in part (b); (d) Invoke the heat-mass analogy and use an appropriate correlation to estimate the mass transfer coefficient using Gr_L; calculate the water evaporation rate on a daily basis and the heat loss by evaporation; and (e) Calculate the total heat loss from the surface and compare relative contributions of the sensible, latent and radiative effects. Review assumptions made in your analysis, especially those relating to the heat-mass analogy.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Laboratory air is quiescent, (3) Laboratory walls are isothermal and large compared to water bath exposed surface, (4) Emissivity of the water surface is 0.96, (5) Heat-mass analogy is applicable, and (6) Constant properties.

PROPERTIES: *Table A-6*, Water vapor (T_∞ = 293 K): $\rho_{A,\infty,sat} = 0.01693$ kg/m^3; (T_s = 310 K): $\rho_{A,s} = 0.04361$ kg/m^3, $h_{fg} = 2.414 \times 10^6$ J/kg; *Table A-4*, Air (T_∞ = 293 K, 1 atm): $\rho_{B,\infty} = 1.194$ kg/m^3; (T_s = 310 K, 1 atm): $\rho_{B,s} = 1.128$ kg/m^3; ($T_f = (T_s + T_\infty)/2$ = 302 K, 1 atm): $\nu_B = 1.604 \times 10^{-5}$ m^2/s, k = 0.0270 W/m·K, Pr = 0.706; *Table A-8*, Water vapor-air (T_f = 302 K, 1 atm): $D_{AB} = 0.24 \times 10^{-4}$ m^2/s $(302/298)^{3/2} = 2.45 \times 10^{-5}$ m^2/s.

ANALYSIS: (a) Using the linearized form of the radiation exchange rate equation, the heat rate and radiation coefficient can be estimated.

$$h_{rad} = \varepsilon\sigma\left(T_s + T_{sur}\right)\left(T_s^2 + T_{sur}^2\right) \tag{1}$$

$$h_{rad} = 0.96\sigma\left(310+298\right)\left(310^2 + 298^2\right)K^3 = 6.12\ \text{W/m}^2\cdot\text{K} \quad <$$

$$q_{rad} = h_{rad}A_s\left(T_s - T_{sur}\right) \tag{2}$$

$$q_{rad} = 6.12\ \text{W/m}^2\cdot\text{K} \times \left(0.25\times0.50\right)\text{m}^2 \times \left(37-25\right)\text{K} = 9.18\ \text{W}$$

(b) The general form of the Grashof number, Eq. 9.65, applied to natural convection flows driven by concentration gradients

$$Gr_L = g\left(\rho_\infty - \rho_s\right)L^3/\rho\nu^2 \tag{3}$$

where L is the characteristic length defined in Eq. 9.29 as $L = A_s/P$, where A_s and P are the exposed surface area and perimeter, respectively; ρ_s and ρ_∞ are the density of the mixture at the surface and in the quiescent fluid, respectively; and, ρ is the mean boundary layer density, $(\rho_\infty + \rho_s)/2$, and ν is the kinematic viscosity of fluid B, evaluated at the film temperature $T_f = (T_s + T_\infty)/2$. Using the property values from above,

Continued …

PROBLEM 9.118 (Cont.)

$$\rho_s = \rho_{A,s} + \rho_{B,s} = (0.04361 + 1.128)\,kg/m^3 = 1.1716\ kg/m^3$$

$$\rho_\infty = \rho_{A,\infty} + \rho_{B,\infty} = \phi_\infty \rho_{A,\infty,sat} + \rho_{B,\infty}$$

$$\rho_\infty = (0.6 \times 0.01693 + 1.194)\,kg/m^3 = 1.2042\ kg/m^3$$

$$\rho = (\rho_s + \rho_\infty)/2 = 1.188\ kg/m^3$$

Substituting numerical values in Eq. (3), find the Grashof number.

$$Gr_L = \frac{9.8\ m/s^2 (1.2042 - 1.1716)\,kg/m^3 \times (0.0833\ m)^3}{1.188\ kg/m^3 \left(1.604 \times 10^{-5} m^2/s\right)^2}$$

$$Gr_L = 6.040 \times 10^5 \qquad <$$

where the characteristic length is defined by Eq. 9.29,

$$L = A_s/P = (0.25 \times 0.5)\,m^2 / 2(0.25 + 0.50)\,m = 0.0833\ m$$

(c) The free convection heat transfer coefficient for the horizontal surface, Eq. 9.30, for *upper surface of heated plate*, is estimated as follows:

$$Ra_L = Gr_L\,Pr_L = 6.040 \times 10^5 \times 0.706 = 4.264 \times 10^5$$

$$\overline{Nu}_L = \frac{\bar{h}L}{k} = 0.54\ Ra_L^{1/4} = 13.80$$

$$\bar{h} = 13.80 \times 0.0270\ W/m \cdot K / 0.0833\ m = 4.47\ W/m^2 \cdot K \qquad <$$

(d) Invoking the heat-mass analogy, the mass transfer coefficient is estimated as follows,

$$Ra_{L,m} = Gr_L Sc = 6.040 \times 10^5 \times 0.655 = 3.954 \times 10^5$$

where the Schmidt number is given as

$$Sc = \nu / D_{AB} = 1.604 \times 10^{-5} m^2/s / 2.45 \times 10^{-5} m^2/s = 0.655$$

The correlation has the form

$$\overline{Sh}_L = \frac{\bar{h}_m L}{D_{AB}} = 0.54\ Ra_{L,m}^{1/4} = 13.54$$

$$\bar{h}_m = 13.54 \times 2.45 \times 10^{-5} m^2/s / 0.0833\ m = 0.00398\ m/s \qquad <$$

The water evaporation rate on a daily basis is

$$n_A = \bar{h}_m A_s \left(\rho_{A,sat} - \rho_{A,\infty}\right)$$

$$n_A = 0.00398\ m/s (0.25 \times 0.50)\,m^2 \,(0.04361 - 0.6 \times 0.01693)\,kg/m^3$$

Continued …

PROBLEM 9.118 (Cont.)

$$n_A = 1.66\times10^{-5}\,\text{kg/s} = 1.44\ \text{kg/day}$$ <

and the *heat loss by evaporation* is

$$q_{evap} = n_A\,h_{fg} = 1.66\times10^{-5}\,\text{kg/s}\times2.414\times10^{6}\,\text{J/kg} = 40.2\ \text{W}$$ <

(e) The *convective heat loss* is that of free convection,

$$q_{cv} = \bar{h}A_s\left(T_s - T_\infty\right)$$

$$q_{cv} = 4.47\ \text{W/m}^2\times\left(0.25\times0.50\right)\text{m}^2\left(37-20\right)\text{K} = 9.50\ \text{W}$$ <

In summary, the *total heat loss* from the surface of the bath, which must be supplied as electrical power to the bath heaters, is

$$q_{tot} = q_{rad} + q_{cv} + q_{evap}$$

$$q_{tot} = \left(9.18 + 9.50 + 40.2\right)\text{W} = 59\ \text{W}$$ <

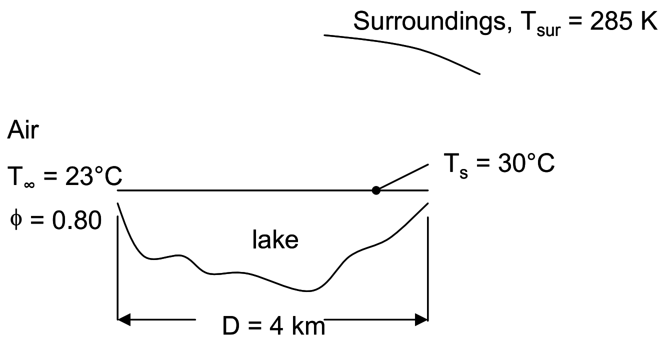
The *sensible heat losses* are by convection (q_{rad} + q_{cv}), which represent 31% of the total; the balance is the *latent loss* by evaporation, 68%.

PROBLEM 9.119

KNOWN: Diameter and surface temperature of lake. Temperature and relative humidity of air. Surroundings temperature.

FIND: Heat loss from lake by radiation, free convection, and evaporation. Justify use of heat transfer correlation outside of Ra_L range.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions. (2) Negligible breeze. (3) Heat-mass transfer analogy is applicable. (4) Heat transfer correlation can be used outside of Ra_L range.

PROPERTIES: Table A-6, Water vapor (T_∞ = 296 K): $\rho_{A,\infty,sat} = 0.02025$ kg/m^3; (T_s = 303 K): $\rho_{A,s}$ = 0.02985 kg/m^3, $h_{fg} = 2.431 \times 10^6$ J/kg; *Table A-4*, Air (T_∞ = 296 K, 1 atm): $\rho_{B,\infty}$ = 1.180 kg/m^3; (T_s = 303 K, 1 atm): $\rho_{B,s}$ = 1.151 kg/m^3; ($T_f = (T_s + T_\infty)/2 \approx 300$ K, 1 atm): $\nu_B = 1.589 \times 10^{-5}$ m^2/s, k = 0.0263 W/m·K, Pr = 0.707; *Table A-8*, Water vapor-air ($T_f \approx 300$ K, 1 atm): $D_{AB} = 0.26 \times 10^{-4}$ m^2/s $(300/298)^{3/2} = 2.63 \times 10^{-5}$ m^2/s; *Table A-11*, Water ($T_s \approx 300$ K): $\varepsilon = 0.96$.

ANALYSIS: The radiation heat transfer can be calculated from

$$q_{rad} = \varepsilon\sigma A_s\left(T_s^4 - T_{sur}^4\right) \tag{1}$$

$$= 0.96 \times 5.67 \times 10^{-8}\ \text{W/m}^2\cdot\text{K}^4 \times \frac{\pi(4000\ \text{m})^2}{4} \times \left(303^4 - 285^4\right)\text{K}^4 = 1253\ \text{MW}$$ <

The natural convection above the lake surface is driven by the combination of temperature and concentration gradient. The general form of the Grashof number, Equation 9.65, is

$$Gr_L = g\left(\rho_\infty - \rho_s\right)L^3/\rho\nu^2 \tag{2}$$

where L is the characteristic length defined in Eq. 9.29 as $L = A_s/P$, where A_s and P are the exposed surface area and perimeter, respectively; ρ_s and ρ_∞ are the density of the mixture at the surface and in the quiescent fluid, respectively; ρ is the mean boundary layer density, $(\rho_\infty + \rho_s)/2$; and ν is the kinematic viscosity of the mixture (approximated here as the value for pure air), evaluated at the film temperature $T_f = (T_s + T_\infty)/2$. Using the property values from above,

$$\rho_s = \rho_{A,s} + \rho_{B,s} = (0.02985 + 1.151)\,\text{kg/m}^3 = 1.181\ \text{kg/m}^3$$

$$\rho_\infty = \rho_{A,\infty} + \rho_{B,\infty} = \phi_\infty\rho_{A,\infty,sat} + \rho_{B,\infty}$$

$$\rho_\infty = (0.8 \times 0.02025 + 1.180)\,\text{kg/m}^3 = 1.196\ \text{kg/m}^3$$

$$\rho = (\rho_s + \rho_\infty)/2 = 1.189\ \text{kg/m}^3$$

$$L = A_s/P = \left(\frac{\pi(4000)^2}{4}\right)\text{m}^2/\pi(4000)\ \text{m} = 1000\ \text{m}$$

Substituting numerical values in Equation (2) for the Grashof number,

Continued…

PROBLEM 9.119 (Cont.)

$$Gr_L = \frac{9.8\ m/s^2 (1.196 - 1.181) kg/m^3 \times (1000\ m)^3}{1.189\ kg/m^3 \left(1.589 \times 10^{-5} m^2/s\right)^2} = 5.01 \times 10^{17}$$

Then $Ra_L = Gr_L Pr = 5.01 \times 10^{17} \times 0.707 = 3.54 \times 10^{17}$ <

The free convection heat transfer coefficient for the upper surface of a hot plate is given by Equation 9.31, but the Rayleigh number is larger than the upper limit specified for this correlation. However, since Ra_L is raised to the 1/3 power, this correlation yields a heat transfer coefficient which is independent of L. Therefore it is reasonable to expect that the heat transfer coefficient calculated by this correlation is valid even though Ra_L is outside the range. Proceeding,

$$\overline{Nu}_L = \frac{\bar{h}L}{k} = 0.15\ Ra_L^{1/3} = 1.06 \times 10^5$$

$$\bar{h} = 1.06 \times 10^5 \times 0.0263\ W/m \cdot K / 1000\ m = 2.79\ W/m^2 \cdot K$$

$$q_{cv} = \bar{h} A_s (T_s - T_\infty)$$

$$q_{cv} = 2.79\ W/m^2 \times \left(\frac{\pi (4000)^2}{4}\right) m^2 (30 - 23) K = 246\ MW$$ <

Invoking the heat-mass analogy, the mass transfer coefficient is estimated as follows,

$$Ra_{L,m} = Gr_L Sc = 5.01 \times 10^{17} \times 0.604 = 3.03 \times 10^{17}$$

where the Schmidt number is given as

$$Sc = \nu / D_{AB} = 1.589 \times 10^{-5} m^2/s / 2.63 \times 10^{-5} m^2/s = 0.604$$

The correlation has the form

$$\overline{Sh}_L = \frac{\bar{h}_m L}{D_{AB}} = 0.15\ Ra_{L,m}^{1/3} = 1.01 \times 10^5$$

$$\bar{h}_m = 1.01 \times 10^5 \times 2.63 \times 10^{-5} m^2/s / 1000\ m = 2.65 \times 10^{-3}\ m/s$$

The water evaporation rate on a daily basis is

$$n_A = \bar{h}_m A_s \left(\rho_{A,sat} - \rho_{A,\infty}\right)$$

$$n_A = 2.65 \times 10^{-3}\ m/s \times \pi \left(4000^2/4\right) m^2 (0.02985 - 0.8 \times 0.02025) kg/m^3$$

$$n_A = 4.54 \times 10^2 kg/s = 3.93 \times 10^7\ kg/day$$

and the *heat loss by evaporation* is

$$q_{evap} = n_A h_{fg} = 4.54 \times 10^2 kg/s \times 2.431 \times 10^6 J/kg = 1105\ MW$$ <

In summary, the *total heat loss* from the surface of the lake, which determines the rate at which the lake can be used to cool the condenser, is

$$q_{tot} = q_{rad} + q_{cv} + q_{evap} = 1253\ MW + 246\ MW + 1105\ MW = 2604\ MW$$ <

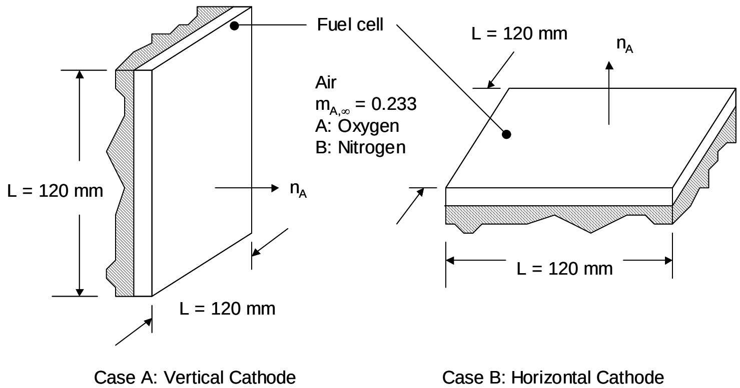
COMMENTS: The *sensible heat losses* are by convection ($q_{rad} + q_{cv}$), which represent 58% of the total; the balance is the *latent loss* by evaporation, 42%.

PROBLEM 9.120

KNOWN: Fuel cell cathode dimensions, oxygen mass fraction in the ambient and adjacent to the cathode, orientation of cathode, relationship between oxygen transfer rate and electrical current.

FIND: Maximum possible electrical current produced by the fuel cell.

SCHEMATIC:



ASSUMPTIONS: (1) Ideal gas behavior, (2) Isothermal conditions, (3) Thermophysical properties of species B are those of air, except for the mass density.

PROPERTIES: Table A.4, air: (p = 1 atm, T_f = 298 K): $\nu = 1.571 \times 10^{-5}$ m²/s, Table A.8, oxygen in air: $D_{AB} = 0.21 \times 10^{-4}$ m²/s.

ANALYSIS: The molecular weights of oxygen (A) and nitrogen (B) are $\mathcal{M}_A$ = 32 kg/kmol and $\mathcal{M}_B$ = 28 kg/kmol, respectively. The mole fraction of A in the ambient is $x_{A,\infty} = (m_{A,\infty}/\mathcal{M}_A)/[m_{A,\infty}/\mathcal{M}_A + (1 - m_{A,\infty})/\mathcal{M}_B]$ = (0.233/32 kg/kmol/[0.233/32 kg/kmol + (1 – 0.233)/28 kg/kmol] = 0.210. Therefore, $x_{B,\infty}$ = 1 – 0.210 = 0.790. The molecular weight of the ambient gas is $\mathcal{M}_\infty = x_{A,\infty}\mathcal{M}_A + (1-x_{A,\infty})\mathcal{M}_B$ = 0.210 × 32 kg/kmol + (1 – 0.210) × 28 kg/kmol = 28.84 kg/mol. The gas constant of the ambient is $R_\infty = \mathcal{R}/\mathcal{M}_\infty$ = 8.315 kJ/kmol·K/28.84 kg/kmol = 288.3 × 10^{-3} kJ/kg·K.

The mole fraction of A at the surface is $x_{A,s} = (m_{A,s}/\mathcal{M}_A)/[m_{A,s}/\mathcal{M}_A + (1 - m_{A,s})/\mathcal{M}_B]$ = (0.10/32 kg/kmol)/[0.1/32 kg/kmol + (1-0.1)/28kg/kmol] = 0.089. Therefore, $x_{B,s}$ = 1 – 0.089 = 0.911. The molecular weight of the gas at the surface is $\mathcal{M}_s = x_{A,s}\mathcal{M}_A + (1 - x_{A,s})\mathcal{M}_B$ = 0.089 × 32 kg/kmol + (1 – 0.089) × 28 kg/kmol = 28.36 kg/kmol. The gas constant of the fluid at the surface is $R_s = \mathcal{R}/\mathcal{M}_s$ = 8.315 kJ/kmol·K/28.36 kg/kmol = 293.2 × 10^{-3} kJ/kg·K.

The ambient gas density is

$$\rho_\infty = \frac{p}{R_\infty T} = \frac{1.0133\times10^5\,\mathrm{N/m^2}}{288.3\times10^{-3}\,\mathrm{kJ/kg\cdot K}\times(25+273)\mathrm{K}}\times0.001\,\mathrm{kJ/J} = 1.1794\,\mathrm{kg/m^3}$$

The surface gas density is

Continued…

PROBLEM 9.120 (Cont.)

$$\rho_s = \frac{p}{R_s T} = \frac{1.0133\times 10^5\,\text{N/m}^2}{293.2\times 10^{-3}\,\text{kJ/kg}\cdot\text{K}\times(25+273)\text{K}} \times 0.001\,\text{kJ/J} = 1.1597\,\text{kg/m}^3$$

The average gas density is $\rho = (1.1794\ \text{kg/m}^3 + 1.1597\ \text{kg/m}^3)/2 = 1.1696\ \text{kg/m}^3$.

Case a: Vertical Cathode. The Rayleigh number is

$$Ra_L = Gr_L Sc = \left[g\left(\rho_s - \rho_\infty\right)L^3/\rho\nu^2\right]\times[\nu/D_{AB}]$$
$$= \frac{9.8\,\text{m/s}^2 \times (1.1597 - 1.1794)\text{kg/m}^3 \times (0.12\text{m})^3}{1.1696\,\text{kg/m}^3 \times 1.571\times 10^{-5}\,\text{m}^2/\text{s}\times 0.21\times 10^{-4}\,\text{m}^2/\text{s}} = 865\times 10^3$$

and the Schmidt number is $Sc = \nu/D_{AB} = 1.571 \times 10^{-5}\ \text{m}^2/\text{s}/0.21 \times 10^{-4}\ \text{m}^2/\text{s} = 0.748$. The heat and mass transfer analogy may be applied to the Churchill and Chu correlation to yield

$$\bar{h}_{m,L} = \frac{D_{AB}}{L}\left\{0.825 + \frac{0.387 Ra_L^{1/6}}{\left[1+(0.492/Sc)^{9/16}\right]^{8/27}}\right\}^2$$
$$= \frac{0.21\times 10^{-4}\,\text{m}^2/\text{s}}{0.12\,\text{m}} \times \left\{0.825 + \frac{0.387\times(865\times 10^3)^{1/6}}{\left[1+(0.492/0.748)^{9/16}\right]^{8/27}}\right\}^2 = 0.0028\,\text{m/s}$$

The mass transfer rate is

$$n_A = \bar{h}_{m,L} A_s(\rho_{A,s} - \rho_{A,\infty}) = 0.0028\,\text{m/s}\times(0.12\text{m})^2 \times (1.1597\,\text{kg/m}^3 \times 0.1 - 1.1794\,\text{kg/m}^3 \times 0.233)$$
$$= -6.4\times 10^{-6}\,\text{kg/s}$$

The negative sign implies oxygen transfer to the cathode. The electric current is

$$I = 4 n_A \mathcal{F}/\mathcal{M}_A = \frac{4\times 6.4\times 10^{-6}\,\text{kg/s}\times 96489\,\text{coulombs/mol}\times 1000\,\text{mol/kmol}}{32\,\text{kg/kmol}} = 77\,\text{A} \quad <$$

Case b: Horizontal, Upward Facing Cathode. Since $\rho_s < \rho_\infty$, the analogous situation is the upper surface of a hot plate. The characteristic length is $L = A_s/P = L^2/4L = L/4 = 0.12\ \text{m}/4 = 0.03\ \text{m}$. The Rayleigh number is

$$Ra_L = \frac{9.8\,\text{m/s}^2 \times (1.1597 - 1.1794)\text{kg/m}^3 \times (0.03\text{m})^3}{1.1696\,\text{kg/m}^3 \times 1.571\times 10^{-5}\,\text{m}^2/\text{s}\times 0.21\times 10^{-4}\,\text{m}^2/\text{s}} = 13500$$

Continued…

PROBLEM 9.120 (Cont.)

From Equation 9.30,

$$\overline{Sh}_L = 0.54 \times (13500)^{1/4} = 5.82 \text{ and } \bar{h}_L = \overline{Sh}_L D_{AB} / L = 5.82 \times 0.21 \times 10^{-4} m^2 / s / 0.03m = 0.0041m / s$$

Hence, the mass transfer rate is

$$n_A = 0.0041m / s \times (0.12m)^2 \times (1.1597kg / m^3 \times 0.1 - 1.1794kg / m^3 \times 0.233) = -9.38 \times 10^{-6} kg / s$$

and the electric current is

$$I = \frac{4 \times 9.38 \times 10^{-6} kg / s \times 96489 coulombs / mol \times 1000 mol / kmol}{32 kg / kmol} = 102A \quad <$$

COMMENTS: Although the analysis is approximate because of the assumption of isothermal conditions, the fuel cell performance is clearly dependent upon its orientation.

PROBLEM 10.1

KNOWN: Water at 1 atm with $T_s - T_{sat} = 10°C$.

FIND: Show that the Jakob number is much less than unity; what is the physical significance of the result; does result apply to other fluids?

ASSUMPTIONS: (1) Boiling situation, $T_s > T_{sat}$.

PROPERTIES: *Table A-5* and *Table A-6*, (1 atm):

	h_{fg} (kJ/kg)	$c_{p,\ell}$ (J/kg·K)	T_{sat}(K)
Water	2257	4217	373
Ethylene glycol	812	2742*	470
Mercury	301	135.5*	630
R-134a	217	1281	247

* Estimated based upon value at highest temperature cited in Table A-5.

ANALYSIS: The Jakob number is the ratio of the maximum sensible energy absorbed by the vapor or liquid to the latent energy absorbed during boiling or condensation. That is,

$$Ja = c_p \Delta T / h_{fg}$$

The Jakob number can be based on the liquid or vapor specific heat depending on the circumstances. Since they are the same order of magnitude and we have liquid specific heats available for all the fluids listed above, we will use $c_{p,\ell}$.

For *water* with an excess temperature $\Delta T_s = T_e - T_\infty = 10°C$, find

$$Ja = \left(4217\ J/kg \cdot K \times 10K\right) / 2257 \times 10^3 J/kg$$

$$Ja = 0.019.$$

Since Ja << 1, the implication is that the sensible energy absorbed by the vapor is much less than the latent energy absorbed during the boiling phase change. Using the appropriate thermophysical properties for three other fluids, the Jakob numbers are:

Ethylene glycol: $Ja = \left(2742\,J/kg \cdot K \times 10K\right)/812 \times 10^3\,J/kg = 0.0338$ <

Mercury: $Ja = \left(135.5\,J/kg \cdot K \times 10K\right)/301 \times 10^3\,J/kg = 0.0045$ <

Refrigerant, R-12: $Ja = \left(1281\,J/kg \cdot K \times 10K\right)/217 \times 10^3\,J/kg = 0.059$ <

For ethylene glycol and R-12, the Jakob number is larger than the value for water, but still much less than unity. Based upon these example fluids, we conclude that generally we'd expect Ja to be much less than unity.

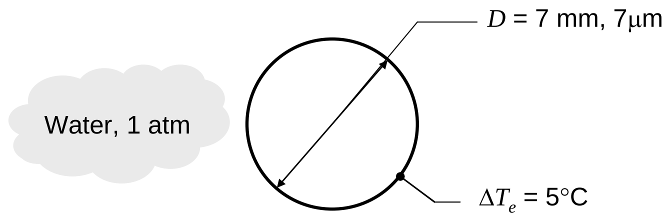
COMMENTS: We would expect the same low value of Ja for the condensation process since $c_{p,g}$ and $c_{p,f}$ are of the same order of magnitude.

PROBLEM 10.2

KNOWN: Diameter and temperature of horizontal cylinder or wire.

FIND: Heat flux due to natural convection and comparison with values shown in Figure 10.4

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) No bubble nucleation.

PROPERTIES: *Table A-6*, Water (Saturated liquid, $T_f = (T_{sat} + T_s)/2 = 102.5°C = 375.5$ K): $k = 0.681$ W/m·K, $\nu = 2.85 \times 10^{-7}$ m²/s, $\rho = 956.6$ kg/m³, $c_p = 4221$ J/kg·K, $Pr = 1.69$, $\beta = 765 \times 10^{-6}$ K⁻¹.

ANALYSIS: The thermal diffusivity is $\alpha = k/\rho c_p = 0.681$ W/m·K/(956.6 kg/m³ × 4221 J/kg·K) = 1.68×10^{-7} m²/s. For the $D = 7$ mm cylinder, the Rayleigh number is

$$Ra_D = \frac{g\beta\Delta T_e D^3}{\nu\alpha} = \frac{9.81\text{ m/s}^2 \times 765\times10^{-6}\text{K}^{-1}\times 5\text{ K}\times(7/1000\text{ m})^3}{2.85\times10^{-7}\text{ m}^2\text{/s} \times 1.68\times10^{-7}\text{ m}^2\text{/s}} = 2.77\times10^5$$

Using the Churchill-Chu correlation,

$$\overline{Nu}_D = \frac{\bar{h}D}{k} = \left\{0.60 + \frac{0.387 Ra_D^{1/6}}{\left[1+(0.559/Pr)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.60 + \frac{0.387\times\left(2.77\times10^5\right)^{1/6}}{\left[1+(0.559/1.69)^{9/16}\right]^{8/27}}\right\}^2 = 11.12$$

from which $\bar{h} = \overline{Nu}_D k/D = 11.12\times0.681\text{ W/m}\cdot\text{K}/(7/1000\text{ m}) = 1083\text{ W/m}^2\cdot\text{K}$.

Hence, $q'' = h(\Delta T_e) = 1083\text{ W/m}^2\cdot\text{K} \times 5\text{ K} = 5413\text{ W/m}^2$. <

The preceding calculations may be repeated for the $D = 7$ μm wire, yielding

$Ra_D = 0.00027$, $\overline{Nu}_D = 0.471$, $\bar{h} = 4.586 \times 10^4$ W/m²·K, $q'' = 2.29 \times 10^5$ W/m². <

From Figure 10.4, the heat flux corresponding to $\Delta T_e = 5°C$ is approximately 8,000 W/m². The heat flux for the $D = 7$ mm diameter cylinder is approximately 67% of this value. However, for the $D = 7$ μm wire, the heat flux is nearly 29 times greater than shown in Figure 10.4 and corresponds to values associated with vigorous nucleate boiling. Hence, Figure 10.4 is *not* generally applicable to all situations involving boiling of water at 1 atmosphere pressure and should be used, with caution, only in the absence of more detailed information. <

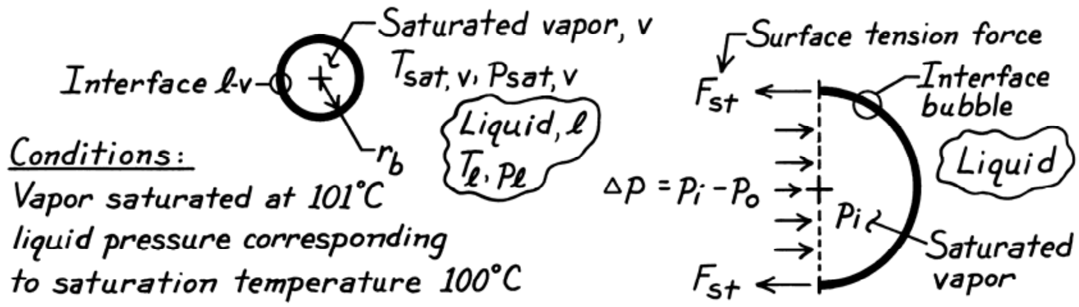
Comments. (1) Use of Equation 9.33 to calculate the heat flux for the wire yields $\bar{h} = (0.681\text{ W/m}\cdot\text{K}/7\times10^{-6}\text{ m})\times0.675\times0.00027^{0.058} = 4.076\times10^4\text{ W/m}^2\cdot\text{K}$ and $q'' = 2.04 \times 10^5$ W/m². This is in good agreement with the value calculated from the Churchill-Chu relation. (2) We would expect the boiling heat flux from the small wire to far exceed the values shown in Figure 10.4.

PROBLEM 10.3

KNOWN: Spherical bubble of pure saturated vapor in mechanical and thermal equilibrium with its liquid.

FIND: (a) Expression for the bubble radius, (b) Bubble vapor and liquid states on a p-v diagram; how changes in these conditions cause bubble to collapse or grow, and (c) Bubble size for specified conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Liquid-vapor medium, (2) Thermal and mechanical equilibrium.

PROPERTIES: *Table A-6*, Water (T_{sat} = 101°C = 374.15K): p_{sat} = 1.0502 bar; (T_{sat} = 100°C = 373.15K): p_{sat} = 1.0133 bar, $\sigma = 58.9 \times 10^{-3}$ N/m.

ANALYSIS: (a) For mechanical equilibrium, the difference in pressure between the vapor inside the bubble and the liquid outside the bubble will be offset by the surface tension of the liquid-vapor interface. The force balance follows from the free-body diagram shown above (right),

$$F_{st} = \left(\pi r_b^2\right)\Delta p = \left(p_i - p_o\right)\left(\pi r_b^2\right)$$

$$\left(2\pi r_b\right)\sigma = \left(\pi r_b^2\right)\left(p_i - p_o\right)$$

$$r_b = 2\sigma / \left(p_i - p_o\right) \qquad (1)$$

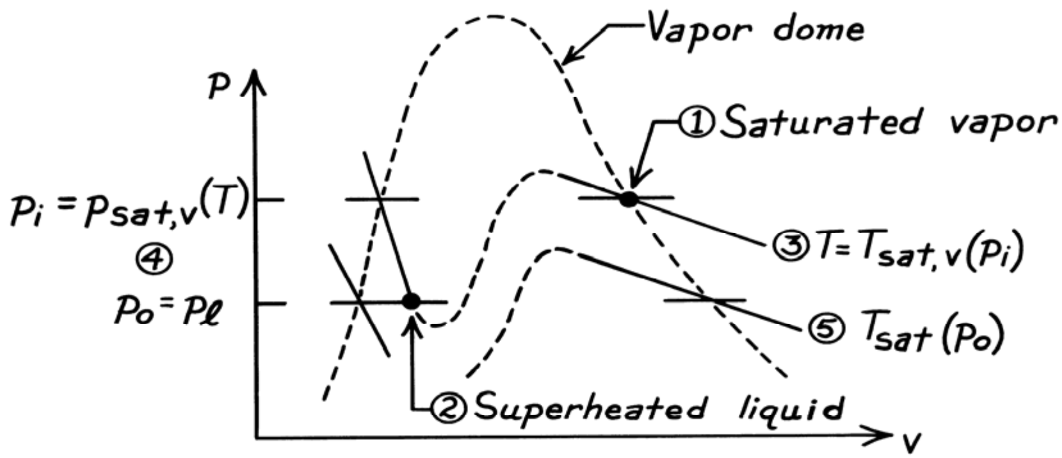
Thermal equilibrium requires that the temperatures of the vapor and liquid be equal. Since the vapor inside the bubble is saturated, $p_i = p_{sat,v}$ (T). Since $p_o < p_i$, it follows that the liquid outside the bubble must be superheated; hence, $p_o = p_\ell$ (T), the pressure of superheated liquid at T. Hence, we can write,

$$r_b = 2\sigma / \left(p_{sat,v} - p_\ell\right) \qquad (2) \quad <$$

(b) The vapor [1] and liquid [2] states are represented on the following p-v diagram. Thermal equilibrium requires both the vapor and liquid to be at the same temperature [3]. But mechanical equilibrium requires that the outside liquid pressure be less than the inside vapor pressure [4]. Hence the liquid must be in a superheated state. That is, its saturation temperature, $T_{sat}(p_o)$ [5] is less than $T_{sat}(p_i)$; $T_\ell = T_{sat}(p_o)$ and $p_o = p_\ell$.

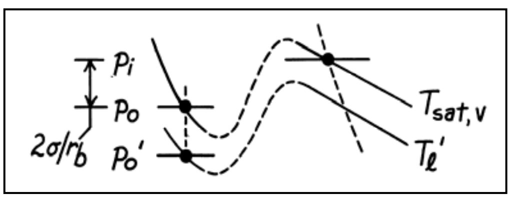
Continued …

PROBLEM 10.3 (Cont.)



<

The equilibrium condition for the bubble is unstable. Consider situations for which the pressure of the surrounding liquid is greater or less than the equilibrium value. These situations are presented on portions of the p-v diagram



When $p_o' < p_o$, $T_\ell' < T_{sat,v}$ and heat must be transferred out of the bubble and vapor condenses. Hence, the bubble collapses.

A similar argument for the condition $p_o' > p_o$ leads to $T_\ell' > T_{sat,v}$ and heat is transferred into the bubble causing evaporation with the formation of vapor. Hence, the bubble begins to grow.

(c) Consider the specific conditions

$$T_{sat,v} = 101°C \qquad \text{and} \qquad T_\ell = T_{sat}(p_o) = 100°C$$

and calculate the radius of the bubble using the appropriate properties in Eq. (2).

$$r_b = 2 \times 58.9 \times 10^{-3} \frac{N}{m} / (1.0502 - 1.0133)\,\text{bar} \times \left(10^5 \frac{N}{m^2} / \text{bar}\right)$$

$$r_b = 0.032\,\text{mm}.$$

<

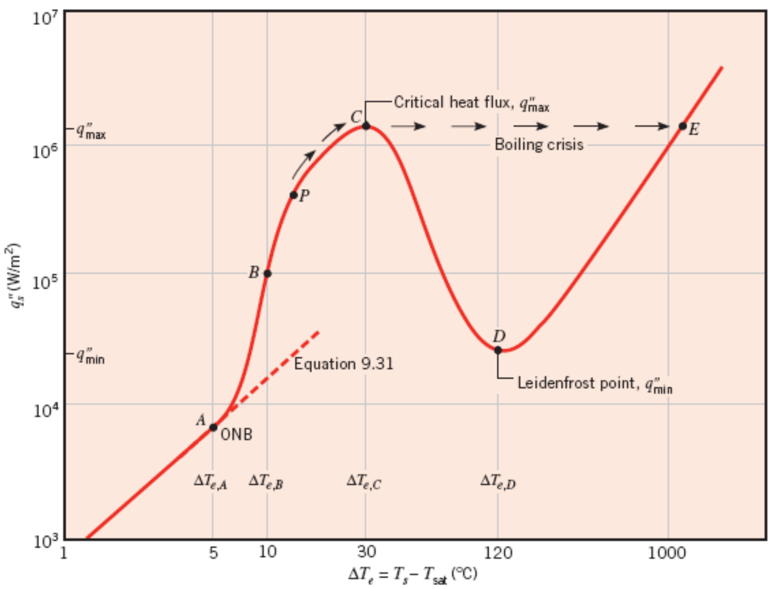
Note the small bubble size. This implies that nucleation sites of the same magnitude formed by pits and crevices are important in promoting the boiling process.

PROBLEM 10.4

KNOWN: Boiling curve of Figure 10.4.

FIND: Heat transfer coefficient associated with Points A, B, C, D, and E. Which points are associated with the largest and smallest values of h. Thickness of vapor blanket at the Leidenfrost point.

SCHEMATIC:



ASSUMPTIONS: (1) Neglect radiation during film boiling, (2) Surface is flat, (3) Vapor thermal conductivity can be evaluated at the film temperature.

PROPERTIES: *Table A-6*, Water vapor (T = 433 K) = 0.0308 W/m · K.

ANALYSIS: Since $h = q''_s/\Delta T_e$, the values of h can be found by reading q''_s and ΔT_e from the graph.

Point	q''_s (W/m^2)	ΔT_e (°C)	h (W/m^2 · K)
A	6700	5	1300
B	10^5	10	10,000
C	1.4×10^6	30	47,000
D	2.5×10^4	120	210
E	1.4×10^6	1200	1200

Among these points, the largest heat transfer coefficient occurs at point C, corresponding to the critical heat flux. The smallest heat transfer coefficient occurs at point D, the Leidenfrost point. <

Continued…

PROBLEM 10.4 (Cont.)

At the Leidenfrost point, if radiation is neglected, heat transfer is due solely to conduction through the vapor film. The surface temperature is $T_s = \Delta T_e + T_{sat} = 120°C + 100°C = 220°C$, so the film temperature is $T_f = (220 + 100)°C/2 = 160°C = 433$ K. Evaluating the vapor thermal conductivity at the film temperature, the film thickness is given by

$$\ell = k_v \Delta T_e / q'' = 0.0308 \text{ W/m} \cdot \text{K} \times 120°\text{C} / 2.5 \times 10^4 \text{ W/m}^2 = 1.5 \times 10^{-4} \text{ m} = 0.15 \text{ mm}$$ <

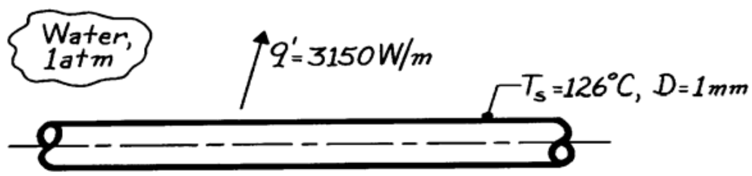
COMMENTS: (1) Section 10.4.4 describes how to account for radiation heat transfer in film boiling. From Eq. 10.11, assuming $\varepsilon = 1$ to maximize the effect of radiation, and using $T_s = 220°C$ corresponding to the Leidenfrost point, we find $\bar{h}_{rad} = 19 \text{ W/m}^2 \cdot \text{K}$. This is considerably smaller than the overall heat transfer coefficient of $h = 210 \text{ W/m}^2 \cdot \text{K}$. Figure 10.4 is based on experimental data, and therefore includes the effect of radiation, which becomes more significant as ΔT_e increases. (2) Leidenfrost boiling can be observed by sprinkling water drops on a very hot flat pan surface. The vapor blanket beneath the droplets provides a means for the droplets to meander about the surface, and the droplets remain suspended for a relatively long time, indicative of relatively low heat transfer rates.

PROBLEM 10.5

KNOWN: Long wire, 1 mm diameter, reaches a surface temperature of 126°C in water at 1 atm while dissipating 3150 W/m.

FIND: (a) Boiling heat transfer coefficient and (b) Correlation coefficient, $C_{s,f}$, if nucleate boiling occurs.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Nucleate boiling.

PROPERTIES: *Table A-6*, Water (saturated, 1 atm): $T_s = 100°C$, $\rho_\ell = 1/v_f = 957.9\ kg/m^3$, $\rho_f = 1/v_g = 0.5955\ kg/m^3$, $c_{p,\ell} = 4217\ J/kg \cdot K$, $\mu_\ell = 279 \times 10^{-6}\ N \cdot s/m^2$, $Pr_\ell = 1.76$, $h_{fg} = 2257\ kJ/kg$, $\sigma = 58.9 \times 10^{-3}\ N/m$.

ANALYSIS: (a) For the boiling process, the rate equation can be rewritten as

$$\bar{h} = q_s'' / \left(T_s - T_{sat}\right) = \frac{q_s'}{\pi D} / \left(T_s - T_{sat}\right)$$

$$\bar{h} = \frac{3150\ W/m}{\pi \times 0.001m} / \left(126 - 100\right)°C = 1.00 \times 10^6\ \frac{W}{m^2} / 26°C = 38,600\ W/m^2 \cdot K. \qquad <$$

Note the heat flux is very close to q''_{max}, and nucleate boiling does exist.

(b) For nucleate boiling, the Rohsenow correlation may be solved for $C_{s,f}$ to give

$$C_{s,f} = \left\{\frac{\mu_\ell h_{fg}}{q_s''}\right\}^{1/3} \left[\frac{g\left(\rho_\ell - \rho_v\right)}{\sigma}\right]^{1/6} \left(\frac{c_{p,\ell}\, \Delta T_e}{h_{fg}\, Pr_\ell^n}\right).$$

Assuming the liquid-surface combination is such that n = 1 and substituting numerical values with $\Delta T_e = T_s - T_{sat}$, find

$$C_{s,f} = \left\{\frac{279 \times 10^{-6}\ N \cdot s/m^2 \times 2257 \times 10^3\ J/kg}{1.00 \times 10^6\ W/m^2}\right\}^{1/3} \left[\frac{9.8\dfrac{m}{s^2}\left(957.9 - 0.5955\right)\dfrac{kg}{m^3}}{58.9 \times 10^{-3}\ N/m}\right]^{1/6} \times$$

$$\left(\frac{4217\ J/kg \cdot K \times 26K}{2257 \times 10^3\ J/kg \times 1.76}\right)$$

$$C_{s,f} = 0.017. \qquad <$$

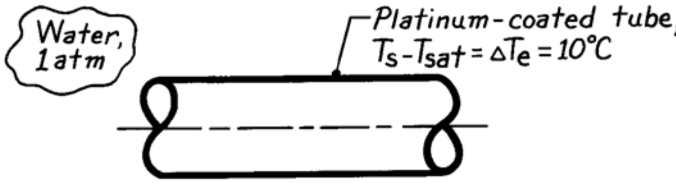
COMMENTS: By comparison with the values of $C_{s,f}$ for other water-surface combinations of Table 10.1, the $C_{s,f}$ value for the wire is large, suggesting that its surface must be highly polished. Note that the value of the boiling heat transfer coefficient is much larger than values common to single-phase convection.

PROBLEM 10.6

KNOWN: Nucleate pool boiling on a 10 mm-diameter tube maintained at $\Delta T_e = 10°C$ in water at 1 atm; tube is platinum-plated.

FIND: Heat transfer coefficient.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Nucleate pool boiling.

PROPERTIES: *Table A-6*, Water (saturated, 1 atm): $T_s = 100°C$, $\rho_\ell = 1/v_f = 957.9\ kg/m^3$, $\rho_v = 1/v_g = 0.5955\ kg/m^3$, $c_{p,\ell} = 4217\ J/kg\cdot K$, $\mu_\ell = 279 \times 10^{-6}\ N\cdot s/m^2$, $Pr_\ell = 1.76$, $h_{fg} = 2257\ kJ/kg$, $\sigma = 58.9 \times 10^{-3}\ N/m$.

ANALYSIS: The heat transfer coefficient can be estimated using the Rohsenow nucleate-boiling correlation and the rate equation

$$h = \frac{q_s''}{\Delta T_e} = \frac{\mu_\ell h_{fg}}{\Delta T_e}\left[\frac{g(\rho_\ell - \rho_v)}{\sigma}\right]^{1/2}\left(\frac{c_{p,\ell}\,\Delta T_e}{C_{s,f}\, h_{fg}\, Pr_\ell^n}\right)^3.$$

From Table 10.1, find $C_{s,f} = 0.013$ and $n = 1$ for the water-platinum surface combination. Substituting numerical values,

$$h = \frac{279\times10^{-6}\,N\cdot s/m^2 \times 2257\times10^3\,J/kg}{10K}\left[\frac{9.8\,m/s^2(957.9-0.5955)\,kg/m^3}{58.9\times10^{-3}\,N/m}\right]^{1/2}\times$$

$$\left(\frac{4217\,J/kg\cdot K\times10K}{0.013\times2257\times10^3\,J/kg\times1.76}\right)^3$$

$$h = 13,690\ W/m^2\cdot K.$$ <

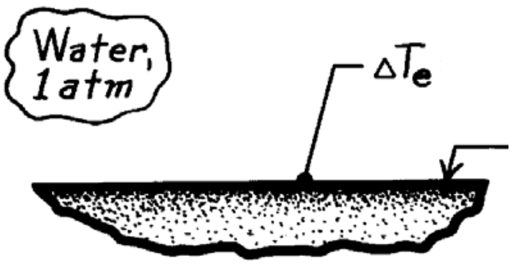
COMMENTS: For this liquid-surface combination, $q_s'' = 0.137\,MW/m^2$, which is in general agreement with the *typical* boiling curve of Fig. 10.4. To a first approximation, the effect of the tube diameter is negligible.

PROBLEM 10.7

KNOWN: Saturated water at 1 atm boiling on large, horizontal, polished copper plate.

FIND: Nucleate boiling heat flux over excess temperature range 5ºC ≤ ΔT_e ≤ 30ºC. Compare with Figure 10.4. Find excess temperature corresponding to critical heat flux.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions. (2) Nucleate pool boiling.

PROPERTIES: *Table A-6*, Saturated water (1 atm): T_{sat} = 100°C, ρ_ℓ = 957.9 kg/m^3, ρ_v = 0.596 kg/m^3, $c_{p,\ell}$ = 4217 J/kg·K, μ_ℓ = 279 × 10^{-6} N·s/m^2, Pr_ℓ = 1.76, σ = 58.9 × 10^{-3} N/m, h_{fg} = 2257 kJ/kg.

ANALYSIS: The nucleate pool boiling heat flux can be estimated using the Rohsenow correlation.

$$q''_s = \mu_\ell h_{fg} \left[\frac{g(\rho_\ell - \rho_v)}{\sigma} \right]^{1/2} \left(\frac{c_{p,\ell} \Delta T_e}{C_{s,f} h_{fg} Pr_\ell^n} \right)^3 .$$

From Table 10.1, find for this liquid-surface combination, $C_{s,f}$ = 0.0128 and n = 1, and substituting numerical values,

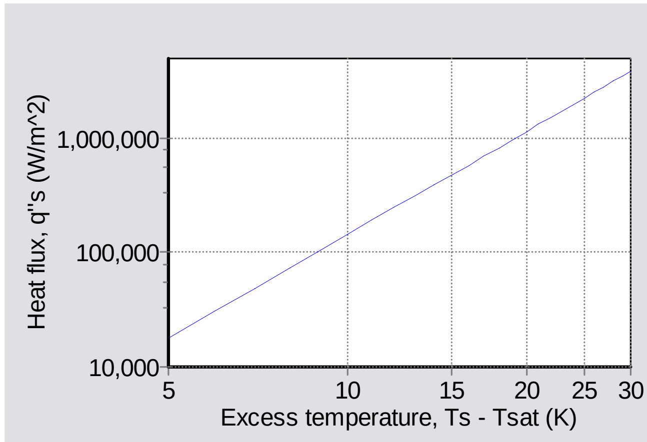
$$q''_s = 279 \times 10^{-6} \mathrm{N \cdot s/m^2} \times 2257 \times 10^3 \mathrm{J/kg} \left[\frac{9.8\ \mathrm{m/s^2} (957.9 - 0.596)\, \mathrm{kg/m^3}}{58.9 \times 10^{-3} \mathrm{N/m}} \right]^{1/2} \times \left(\frac{4217\ \mathrm{J/kg \cdot K} \times \Delta T_e}{0.0128 \times 2257 \times 10^3 \mathrm{J/kg} \times 1.76} \right)^3$$

$$q''_s = 143(\Delta T_e)^3\ \mathrm{W/m^2}.$$ <

This is plotted below.

Continued…

PROBLEM 10.7 (Cont.)



Compared with Figure 10.4, we see that this curve is a straight line on a log-log plot. The heat flux is higher than in Figure 10.4, especially for the higher values of excess temperature.

To find the excess temperature corresponding to the critical heat flux, we equate Eqs. (10.5) and (10.6) and solve for ΔT_e.

$$\mu_\ell h_{fg}\left[\frac{g(\rho_\ell-\rho_v)}{\sigma}\right]^{1/2}\left(\frac{c_{p,\ell}\,\Delta T_e}{C_{s,f}\,h_{fg}\,Pr_\ell^n}\right)^3 = Ch_{fg}\rho_v\left[\frac{\sigma g(\rho_\ell-\rho_v)}{\rho_v^2}\right]^{1/4}$$

$$\Delta T_e = \frac{C_{s,f}\,h_{fg}\,Pr_\ell^n}{c_{p,\ell}}\left\{Ch_{fg}\rho_v\left[\frac{\sigma g(\rho_\ell-\rho_v)}{\rho_v^2}\right]^{1/4}\Bigg/\left(\mu_\ell h_{fg}\left[\frac{g(\rho_\ell-\rho_v)}{\sigma}\right]^{1/2}\right)\right\}^{1/3}$$

where C = 0.149 for a large horizontal plate. Substituting numbers we find

$$\Delta T_e = 20.6°C$$ <

COMMENTS: (1) The correlation and Figure 10.4 do not agree extremely well. The error is worst near ONB (70% error at ΔT_e = 5ºC) and CHF (170% error at ΔT_e = 30ºC). Since the correlation is a straight line on a log-log plot, it doesn't reproduce the curvature at the two ends of the curve. Since the correlation isn't accurate near CHF, it does not do an excellent job of predicting ΔT_e, which appears to be around 30°C from Figure 10.4. (2) Figure 10.4 is a *typical* boiling curve. The boiling curve will shift as different boiling surfaces and geometries (and, in turn, different values of $C_{s,f}$) are considered.

PROBLEM 10.8

KNOWN: Simple expression to account for the effect of pressure on the nucleate boiling convection coefficient in water.

FIND: Compare predictions of this expression with the Rohsenow correlation for specified ΔT_e and pressures (2 and 5 bar) applied to a horizontal plate.

ASSUMPTIONS: (1) Steady-state conditions, (2) Nucleate pool boiling, (3) $C_{s,f} = 0.013$, n = 1.

PROPERTIES: *Table A-6*, Saturated water (2 bar): $\rho_\ell = 942.7\ \text{kg/m}^3$, $c_{p,\ell} = 4244.3$ J/kg·K, $\mu_\ell = 230.7 \times 10^{-6}\ \text{N·s/m}^2$, $Pr_\ell = 1.43$, $h_{fg} = 2203$ kJ/kg, $\sigma = 54.97 \times 10^{-3}$ N/m, $\rho_v = 1.1082\ \text{kg/m}^3$; Saturated water (5 bar): $\rho_\ell = 914.7\ \text{kg/m}^3$, $c_{p,\ell} = 4316$ J/kg·K, $\mu_\ell = 179 \times 10^{-6}\ \text{N·s/m}^2$, $Pr_\ell = 1.13$, $h_{fg} = 2107.8$ kJ/kg, $\sigma = 48.4 \times 10^{-3}$ N/m, $\rho_v = 2.629\ \text{kg/m}^3$.

ANALYSIS: The simple expression by Jakob accounting for pressure effects is

$$h = C(\Delta T_e)^n (p/p_a)^{0.4} \qquad (1)$$

where p and p_a are the system and standard atmospheric pressures. For a horizontal plate, C = 5.56 and n = 3 for the range $15 < q_s'' < 235\ \text{kW/m}^2$. For $\Delta T_e = 10°C$,

p = 2 bar $\quad h = 5.56(10)^3(2\,\text{bar}/1.0133\,\text{bar})^{0.4} = 7,298\ \text{W/m}^2\cdot\text{K}, \quad q_s'' = 73\ \text{kW/m}^2$ <

p = 5 bar $\quad h = 5.56(10)^3(5\,\text{bar}/1.0133\,\text{bar})^{0.4} = 10,529\ \text{W/m}^2\cdot\text{K}, \quad q_s'' = 105\ \text{kW/m}^2$ <

where $q_s'' = h\Delta T_e$. The Rohsenow correlation, Eq. 10.5, with $C_{s,f} = 0.013$ and n = 1, is of the form

$$q_s'' = \mu_\ell h_{fg}\left[\frac{g(\rho_\ell - \rho_v)}{\sigma}\right]^{1/2}\left[\frac{c_{p,\ell}\Delta T_e}{C_{s,f}\, h_{fg}\, Pr_\ell^n}\right]^3. \qquad (2)$$

p = 2 bar: $q_s'' = 230.7 \times 10^{-6}\ \frac{\text{N}\cdot\text{s}}{\text{m}^2} \times 2203 \times 10^3\ \frac{\text{J}}{\text{kg}}\left[\frac{9.8\frac{\text{m}}{\text{s}^2}(942.7 - 1.1082)\frac{\text{kg}}{\text{m}^3}}{54.97 \times 10^{-3}\ \text{N/m}}\right]^{1/2} \times \left[\frac{4244.3\ \text{J/kg}\cdot\text{K} \times 10\text{K}}{0.013 \times 2203 \times 10^3\ \frac{\text{J}}{\text{kg}} \times 1.43^1}\right]^3$

$q_s'' = 232\ \text{kW/m}^2$ <

p = 5 bar: $q_s'' = 439\ \text{kW/m}^2$. <

COMMENTS: For ease of comparison, the results with $p_a = 1.0133$ bar are:

Correlation/p (bar)	$q_s''\ (\text{kW/m}^2)$ 1	2	4
Simple	56	73	105
Rohsenow	135	232	439

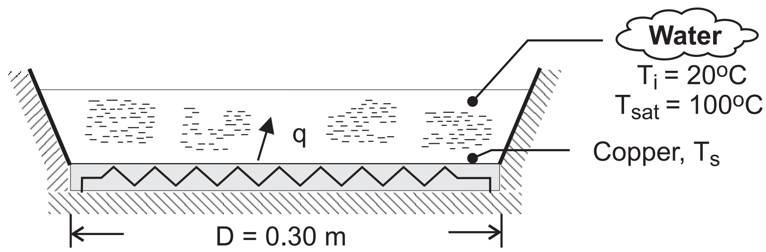
Note that the range of q_s'' is within the limits of the Simple correlation. The comparison is poor and therefore the correlation is not to be recommended. By manipulation of the Rohsenow results, find that the $(p/p_o)^m$ dependence provides $m \approx 0.75$, compared to the exponent of 0.4 in the Simple correlation.

PROBLEM 10.9

KNOWN: Diameter of copper pan. Initial temperature of water and saturation temperature of boiling water. Range of heat rates ($1 \le q \le 100$ kW).

FIND: (a) Variation of pan temperature with heat rate for boiling water, (b) Pan temperature shortly after start of heating with q = 8 kW.

SCHEMATIC:



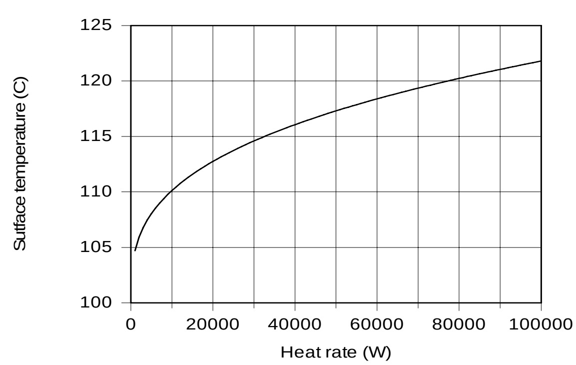
ASSUMPTIONS: (1) Conditions of part (a) correspond to steady nucleate boiling, (2) Surface of pan corresponds to polished copper, (3) Conditions of part (b) correspond to natural convection from a heated plate to an infinite quiescent medium, (4) Negligible heat loss to surroundings.

PROPERTIES: *Table A-6*, saturated water (T_{sat} = 100°C): $\rho_\ell = 957.9\ \text{kg/m}^3$, $\rho_v = 0.60\ \text{kg/m}^3$, $c_{p,\ell} = 4217\ \text{J/kg}\cdot\text{K}$, $\mu_\ell = 279 \times 10^{-6}\ \text{N}\cdot\text{s/m}^2$, $\text{Pr}_\ell = 1.76$, $h_{fg} = 2.257 \times 10^6\ \text{J/kg}$, $\sigma = 0.0589\ \text{N/M}$. *Table A-6*, saturated water (assume T_s = 100°C, T_f = 60°C = 333 K): $\rho = 983\ \text{kg/m}^3$, $\mu = 467 \times 10^{-6}\ \text{N}\cdot\text{s/m}^2$, k = 0.654 W/m·K, Pr = 2.99, $\beta = 523 \times 10^{-6}\ \text{K}^{-1}$. Hence, $\nu = 0.475 \times 10^{-6}\ \text{m}^2/\text{s}$, $\alpha = 0.159 \times 10^{-6}\ \text{m}^2/\text{s}$.

ANALYSIS: (a) From Eq. (10.5),

$$\Delta T_e = T_s - T_{sat} = \frac{C_{s,f}\ h_{fg}\ \text{Pr}_\ell^n}{c_{p,\ell}} \times \left\{ \frac{q_s / \mu_\ell h_{fg} A_s}{\left[g\left(\rho_\ell - \rho_v\right)/\sigma\right]^{1/2}} \right\}^{1/3}$$

For n = 1.0, $C_{s,f} = 0.0128$ and $A_s = \pi D^2/4 = 0.0707\ \text{m}^2$, the following variation of T_s with q_s is obtained.



<

As indicated by the correlation, the surface temperature increases as the cube root of the heat rate, permitting large increases in q for modest changes in T_s. For q = 1 kW, Ts = 104.7°C, which is barely sufficient to sustain boiling.

(b) Assuming $10^7 < Ra_L < 10^{11}$, the convection coefficient may be obtained from Eq. (9.31). Hence, with $L = A_s/P = D/4 = 0.075$m,

Continued …

PROBLEM 10.9 (Cont.)

$$\bar{h} = \left(\frac{k}{L}\right)0.15\,Ra_L^{1/3} = \left(\frac{0.654\,W/m\cdot K}{0.075m}\right)0.15\left[\frac{9.8\,m/s^2 \times 523\times10^{-6}\,K^{-1}\left(T_s - T_i\right)\left(0.075m\right)^3}{0.475\times0.159\times10^{-12}\,m^4/s^2}\right]^{1/3}$$

$$= 1.308\left(2.86\times10^7\right)^{1/3}\left(T_s - T_i\right)^{1/3} = 400\left(T_s - T_i\right)^{1/3}$$

With $A_s = \pi D^2/4 = 0.0707\ m^2$, the heat rate is then

$$q = \bar{h}A_s\left(T_s - T_i\right) = \left(400\,W/m^2\cdot K^{4/3}\right)0.0707\,m^2\left(T_s - T_i\right)^{4/3}$$

With q = 8000 W,

$$T_s = T_i + 69°C = 89°C$$ <

COMMENTS: (1) With $(T_s - T_i) = 69°C$, $Ra_L = 1.97 \times 10^9$, which is within the assumed Rayleigh number range. (2) The surface temperature increases as the temperature of the water increases, and bubbles may nucleate when it exceeds 100°C. However, while the water temperature remains below the saturation temperature, the bubbles will collapse in the subcooled liquid.

PROBLEM 10.10

KNOWN: Fluids at 1 atm: mercury, ethanol, R-134a.

FIND: Critical heat flux; compare with value for water also at 1 atm.

ASSUMPTIONS: (1) Steady-state conditions, (2) Nucleate pool boiling.

PROPERTIES: *Table A-5* and *Table A-6* at 1 atm,

	h_{fg} (kJ/kg)	ρ_v (kg/m^3)	ρ_ℓ (kg/m^3)	$\sigma \times 10^3$ (N/m)	T_{sat} (K)
Mercury	301	3.90	12,740	417	630
Ethanol	846	1.44	757	17.7	351
R-134a	217	5.26	1,377	15.4	247
Water	2257	0.596	957.9	58.9	373

ANALYSIS: The critical heat flux can be estimated by Eq. 10.6 with C = 0.149,

$$q''_{max} = 0.149\ h_{fg}\ \rho_v \left[\frac{\sigma g(\rho_\ell - \rho_v)}{\rho_v^2}\right]^{1/4}.$$

To illustrate the calculation procedure, consider numerical values for *mercury*.

$$q''_{max} = 0.149 \times 301 \times 10^3 \text{J/kg} \times 3.90 \text{kg/m}^3 \times \left[\frac{417 \times 10^{-3} \text{N/m} \times 9.8 \text{m/s}^2 (12,740 - 3.90) \text{kg/m}^3}{\left(3.90 \text{kg/m}^3\right)^2}\right]^{1/4}$$

$$q''_{max} = 1.34\ \text{MW/m}^2.$$

For the other fluids, the results are tabulated along with the ratio of the critical heat fluxes to that for water.

Flluid	$q''_{max}\left(\text{MW/m}^2\right)$	$q''_{max} / q''_{max,water}$
Mercury	1.34	1.06
Ethanol	0.512	0.41
R-134a	0.281	0.22
Water	1.26	1.00

<

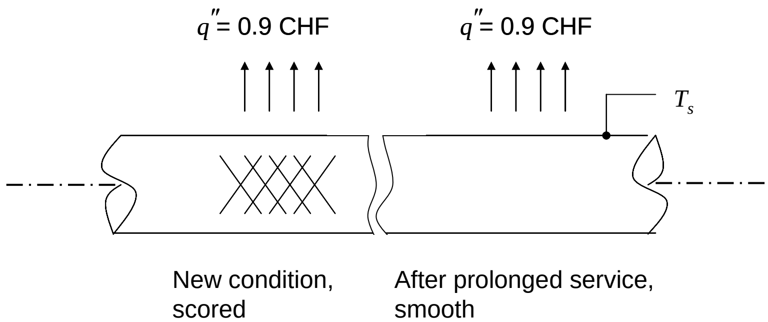
COMMENTS: Note that, despite the large difference between mercury and water properties, their critical heat fluxes are similar.

PROBLEM 10.11

KNOWN: Water at atmospheric pressure boiling on horizontal copper tube. Heat flux is 90% of critical value.

FIND: Tube surface temperature under scored conditions and conditions similar to a polished surface.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Uniform tube wall temperature, (3) Nucleate boiling at outer surface of tube, (4) Constant properties.

PROPERTIES: *Table A-6*, Water (T = 373 K): ρ_l = 957.9 kg/m^3, ρ_v = 0.596 kg/m^3, h_{fg} = 2257 kJ/kg, $c_{p,l}$ = 4.217 kJ/kg·K, μ_l = 279 × 10^{-6} N · s/m^2, k_l = 0.680 W/m · K, Pr_l = 1.76, σ = 58.9 × 10^{-3} N/m.

ANALYSIS: The heat flux is 90% of the critical heat flux given by Eq. 10.6, thus with C = 0.131 for a large horizontal tube,

$$q''_s = 0.9Ch_{fg}\rho_v\left[\frac{\sigma g(\rho_l-\rho_v)}{\rho_v^2}\right]^{1/4} = 0.9\times0.131\times2257\times10^3 \text{ J/kg}\times0.596 \text{ kg/m}^3$$

$$\times\left[\frac{58.9\times10^{-3} \text{ N/m}\times9.8 \text{ m/s}^2\times(957.9 \text{ kg/m}^3-0.596 \text{ kg/m}^3)}{(0.596 \text{ kg/m}^3)^2}\right]^{1/4}$$

$$= 9.96\times10^5 \text{ W/m}^2$$

The nucleate boiling heat flux is given by Eq. 10.5, with $C_{s,f}$ = 0.0068, n = 1.0 for a scored copper surface. Solving for the excess temperature,

$$\Delta T_e = \frac{C_{s,f}h_{fg}Pr_l^n}{c_{p,l}}\left\{\frac{q''_s}{\mu_l h_{fg}}\left[\frac{\sigma}{g(\rho_l-\rho_v)}\right]^{1/2}\right\}^{1/3} = \frac{0.0068\times2257\times10^3 \text{ J/kg}\times1.76}{4217 \text{ J/kg}\cdot\text{K}}$$

$$\times\left\{\frac{9.96\times10^5 \text{ W/m}^2}{279\times10^{-6} \text{ N}\cdot\text{s/m}^2\times2257\times10^3 \text{ J/kg}}\left[\frac{58.9\times10^{-3} \text{ N/m}}{9.8 \text{ m/s}^2(957.9-0.596) \text{ kg/m}^3}\right]^{1/2}\right\}^{1/3}$$

$$= 10.1°\text{C}$$

Thus, for the scored surface

$$T_s = \Delta T_e + T_{sat} = 10.1°\text{C} + 100°\text{C} = 110.1°\text{C}$$ <

Continued…

PROBLEM 10.11 (Cont.)

After the surface degrades to conditions similar to a polished surface, the value of $C_{s,f}$ becomes 0.0128. Recognizing that ΔT_e is proportional to $C_{s,f}$, $\Delta T_e = 10.1°C(0.0128/0.0068) = 19.1°C$. Hence, after prolonged service,

$$T_s = \Delta T_e + T_{sat} = 19.1°C + 100°C = 119.1°C \qquad <$$

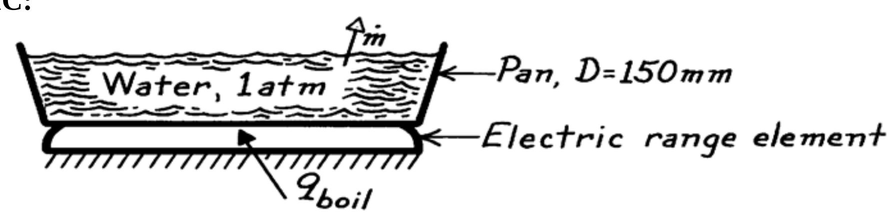
COMMENTS: (1) A scored surface provides nucleation sites that enhance nucleate boiling, resulting in a smaller excess temperature relative to a smooth surface, for the same heat flux.

PROBLEM 10.12

KNOWN: Copper pan, 150 mm diameter and filled with water at 1 atm, is maintained at 115°C.

FIND: Power required to boil water and the evaporation rate; ratio of heat flux to critical heat flux; pan temperature required to achieve critical heat flux.

SCHEMATIC:



ASSUMPTIONS: (1) Nucleate pool boiling, (2) Copper pan is polished surface.

PROPERTIES: *Table A-6*, Water (1 atm): T_{sat} = 100°C, ρ_ℓ = 957.9 kg/m^3, ρ_v = 0.5955 kg/m^3, $c_{p,\ell}$ = 4217 J/kg·K, μ_ℓ = 279 × 10^{-6} N·s/m^2, Pr_ℓ = 1.76, h_{fg} = 2257 kJ/kg, σ = 58.9 × 10^{-3} N/m.

ANALYSIS: The power requirement for boiling and the evaporation rate can be expressed as follows,

$$q_{boil} = q_s'' \cdot A_s \qquad \dot{m} = q_{boil} / h_{fg}.$$

The heat flux for nucleate pool boiling can be estimated using the Rohsenow correlation.

$$q_s'' = \mu_\ell h_{fg}\left[\frac{g\left(\rho_\ell - \rho_v\right)}{\sigma}\right]^{1/2}\left(\frac{c_{p,\ell}\Delta T_e}{C_{s,f}\, h_{fg}\, Pr_\ell^n}\right)^3.$$

Selecting $C_{s,f}$ = 0.0128 and n = 1 from Table 10.1 for the polished copper finish, find

$$q_s'' = 279\times10^{-6}\,\frac{N\cdot s}{m^2}\times2257\times10^3\,\frac{J}{kg}\left[\frac{9.8\,\frac{m}{s^2}\left(957.9-0.5955\right)\frac{kg}{m^3}}{58.9\times10^{-3}\,N/m}\right]^{1/2}\left(\frac{4217\,\frac{J}{kg\cdot K}\times15°C}{0.0128\times2257\times10^3\,\frac{J}{kg}\times1.76}\right)^3$$

$$q_s'' = 4.839\times10^5\ W/m^2.$$

The power and evaporation rate are

$$q_{boil} = 4.839\times10^5\ W/m^2\times\frac{\pi}{4}\left(0.150m\right)^2 = 8.55\,kW \qquad <$$

$$\dot{m}_{boil} = 8.55\,kW/2257\times10^3 J/kg = 3.79\times10^{-3} kg/s = 14 kg/h. \qquad <$$

The maximum or critical heat flux was found in Example 10.1 as

$$q_{max}'' = 1.26\,MW/m^2.$$

Hence, the ratio of the operating to maximum heat flux is

$$\frac{q_s''}{q_{max}''} = 4.619\times10^5\ W/m^2 / 1.26\,MW/m^2 = 0.384. \qquad <$$

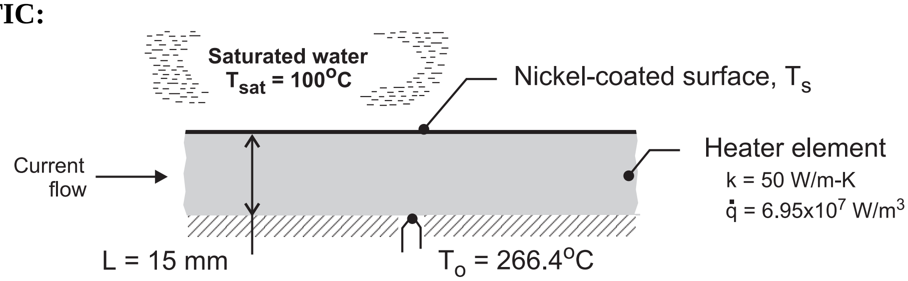
From the boiling curve, Fig. 10.4, $\Delta T_e \approx$ 30°C will provide the maximum heat flux. <

PROBLEM 10.13

KNOWN: Nickel-coated heater element exposed to saturated water at atmospheric pressure; thermocouple attached to the insulated, backside surface indicates a temperature T_o = 266.4°C when the electrical power dissipation in the heater element is 6.950×10^7 W/m^3.

FIND: (a) From the foregoing data, calculate the surface temperature, T_s, and the heat flux at the exposed surface, and (b) Using an appropriate boiling correlation, estimate the surface temperature based upon the surface heat flux determined in part (a).

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Water exposed to standard atmospheric pressure and uniform temperature, T_{sat}, and (3) Nucleate pool boiling occurs on exposed surface, (4) Uniform volumetric generation in element, and (5) Backside of heater is perfectly insulated.

PROPERTIES: *Table A-6*, Saturated water, liquid (100°C): $\rho_\ell = 1/v_f = 957.9\ \text{kg/m}^3$, $c_{p,\ell} = c_{p,f} = 4.217\ \text{kJ/kg}\cdot\text{K}$, $\mu_\ell = \mu_f = 279\times10^{-6}\ \text{N}\cdot\text{s/m}^2$, $Pr_\ell = Pr_f = 1.76$, h_{fg} = 2257 kJ/kg, $\sigma = 58.9 \times 10^{-3}$ N/m; Saturated water, vapor (100°C): $\rho_v = 1/v_g = 0.5955$ kg/m^3.

ANALYSIS: (a) From Eq. 3.58, the temperature at the exposed surface, T_s, is

$$T_s = T_o - \frac{\dot{q}L^2}{2k} = 266.4°\text{C} - \frac{6.95\times10^7\ \text{W/m}^3 (0.015\ \text{m})^2}{2\times50\ \text{W/m}\cdot\text{K}}$$

$$T_s = 110.0°\text{C} \qquad <$$

The heat flux at the exposed surface is

$$q_s'' = \dot{q}L = 6.95\times10^7\ \text{W/m}^3 \times 0.015\ \text{m} = 1.043\times10^6\ \text{W/m}^2 \qquad <$$

(b) Since $\Delta T_e = T_s - T_{sat}$ = (110 – 100)°C = 10°C, nucleate pool boiling occurs and the Rohsenow correlation, Eq. 10.5, with q_s'' from part (a) can be used to estimate the surface temperature, $T_{s,c}$,

$$q_s'' = \mu_\ell h_{fg} \left[\frac{g(\rho_\ell - \rho_v)}{\sigma}\right]^{1/2} \left(\frac{c_{p,\ell}\,\Delta T_{e,c}}{C_{s,f}\, h_{fg}\, Pr_\ell^n}\right)^3$$

From Table 10.1, for the water-nickel surface-fluid combination, $C_{s,f}$ = 0.006 and n = 1.0. Substituting numerical values, find $\Delta T_{e,c}$ and $T_{s,c}$.

Continued …

PROBLEM 10.13 (Cont.)

$$1.043\times10^{6}\ \mathrm{W/m^2} = 279\times10^{-6}\ \mathrm{N\cdot s/m^2}\times2257\times10^{3}\ \mathrm{J/kg}$$

$$\times\left[\frac{9.8\ \mathrm{m/s^2}\left(957.9-0.5955\right)\mathrm{kg/m^3}}{58.9\times10^{-3}\ \mathrm{N/m}}\right]^{1/2}$$

$$\times\left(\frac{4.217\times10^{3}\ \mathrm{J/kg\cdot K}\times\Delta T_{e,c}}{0.006\times2257\times10^{3}\ \mathrm{J/kg}\times1.76}\right)^{3}$$

$\Delta T_{e,c} = T_{s,c} - T_{sat} = 9.1°C$ $\qquad$ $T_{s,c} = 109.1°C$ $\qquad$ <

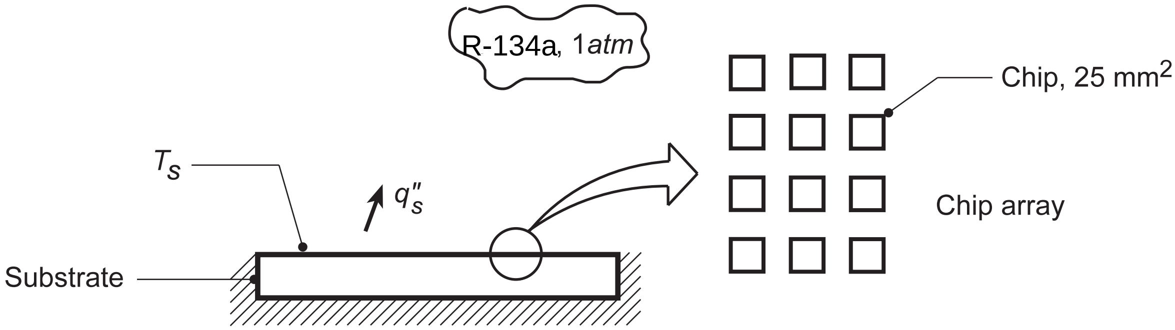
COMMENTS: From the experimental data, part (a), the surface temperature is determined from the conduction analysis as T_s = 110.0°C. Using the traditional nucleate boiling correlation with the experimental value for the heat flux, the surface temperature is estimated as $T_{s,c}$ = 109.1°C. The two approaches provide excess temperatures that are 10.0 vs. 9.1°C, which amounts to nearly a 10% difference.

PROBLEM 10.14

KNOWN: Chips on a ceramic substrate operating at power levels corresponding to 50% of the critical heat flux.

FIND: (a) Chip power level and temperature rise of the chip surface, and (b) Compute and plot the chip temperature T_s as a function of heat flux for the range $0.25 \le q''_s/q''_{max} \le 0.90$.

SCHEMATIC:



ASSUMPTIONS: (1) Nucleate boiling, (2) Fluid-surface with $C_{s,f}$ = 0.004, n = 1.7 for Rohsenow correlation, (3) Backside of substrate insulated.

PROPERTIES: *Table A-5*, Refrigerant R-134a (1 atm): T_{sat} = 247 K = -26°C, ρ_ℓ = 1377 kg/m^3, ρ_v = 5.26 kg/m^3, h_{fg} = 217 kJ/kg, $\sigma = 15.4 \times 10^{-3}$ N/m; R-134a, sat. liquid (given, 247 K): $c_{p,\ell}$ = 1551 J/kg·K, $\mu_\ell = 1.46 \times 10^{-4}$ N·s/m^2, Pr_ℓ = 3.2.

ANALYSIS: (a) The operating power level (flux) is $0.50\,q''_{max}$, where the critical heat flux is estimated from Eq. 10.6 with C=0.149 for nucleate pool boiling,

$$q''_{max} = 0.149 h_{fg}\rho_v\left[\sigma g\left(\rho_\ell - \rho_v\right)/\rho_v^2\right]^{1/4}$$

$$q''_{max} = 0.149 \times 217 \times 10^3 \frac{J}{kg} \times 5.26 \frac{kg}{m^3}\left[15.4 \times 10^{-3}\frac{N}{m} \times 9.8\frac{m}{s^2}(1377 - 5.26)\frac{kg}{m^3} / \left(5.26\frac{kg}{m^3}\right)^2\right]^{1/4}$$

$$q''_{max} = 281\,kW/m^2.$$

Hence, the heat flux on a chip is 0.5 × 281 kW/m^2 = 141 kW/m^2 and the power level is

$$q_{chip} = q''_s \times A_s = 141 \times 10^3\,W/m^2 \times 25\,mm^2\left(10^{-3}\,m/mm\right)^2 = 3.5\,W. \quad <$$

To determine the chip surface temperature for this condition, use the Rohsenow equation to find $\Delta T_e = T_s - T_{sat}$ with $q''_s = 141 \times 10^3$ W/m^2. The correlation, Eq. 10.5, solved for ΔT_e is

$$\Delta T_e = \frac{C_{s,f}\,h_{fg}\,Pr_\ell^n}{c_{p,\ell}}\left(\frac{q''_s}{\mu_\ell h_{fg}}\right)^{1/3}\left[\frac{\sigma}{g\left(\rho_\ell - \rho_v\right)}\right]^{1/6} = \frac{0.004 \times 217 \times 10^3\,J/kg\,(3.2)^{1.7}}{1551\,J/kg \cdot K} \times$$

$$\left(\frac{141 \times 10^3\,W/m^2 \cdot}{1.46 \times 10^{-4}\frac{N \cdot s}{m^2} \times 217 \times 10^3\frac{J}{kg}}\right)^{1/3}\left[\frac{15.4 \times 10^{-3}\,N/m}{9.8\frac{m}{s^2}(1377 - 5.26)\frac{kg}{m^3}}\right]^{1/6} = 6.8^\circ C.$$

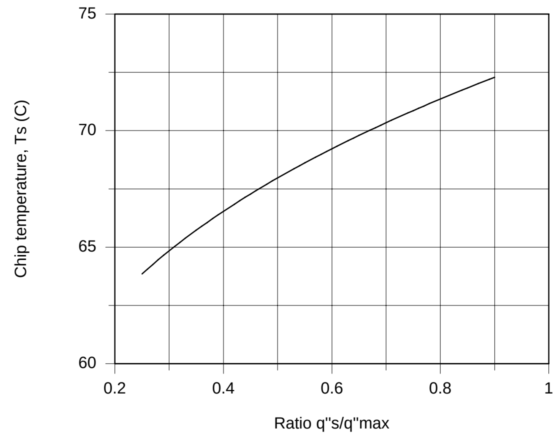
Hence, the chip surface temperature is

Continued...

PROBLEM 10.14 (Cont.)

$$T_s = T_{sat} + \Delta T_e = -26^\circ C + 6.8^\circ C \approx -19^\circ C.$$ <

(b) Using the *IHT Correlations Tools, Boiling, Nucleate Pool Boiling -- Heat flux* and *Maximum heat flux,* the chip surface temperature, T_s, was calculated as a function of the ratio q''_s / q''_{max} . The required thermophysical properties as provided in the problem statement were entered directly into the IHT workspace. The results are plotted below.



COMMENTS: (1) A copy of the *IHT Workspace* model used to generate the above plot is shown below.

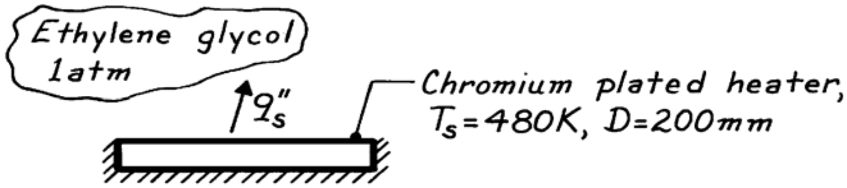
PROBLEM 10.15

KNOWN: Saturated ethylene glycol at 1 atm heated by a chromium-plated heater of 200 mm diameter and maintained at 480K.

FIND: Heater power, rate of evaporation, and ratio of required power to maximum power for critical heat flux.

SCHEMATIC:



ASSUMPTIONS: (1) Nucleate pool boiling, (2) Fluid-surface, $C_{s,f} = 0.010$ and n = 1.

PROPERTIES: *Table A-5*, Saturated ethylene glycol (1atm): $T_{sat} = 470K$, $h_{fg} = 812$ kJ/kg, $\rho_f = 1111$ kg/m^3, $\sigma = 32.7 \times 10^{-3}$ N/m; Saturated ethylene glycol (given, 470K): $\rho_v = 1.66$kg/m^3, $\mu_\ell = 0.38 \times 10^{-3}$ N·s/m^2, $c_{p,\ell} = 3280$ J/kg·K, $Pr_\ell = 8.7$.

ANALYSIS: The power requirement for boiling and the evaporation rate are $q_{boil} = q_s'' \cdot A_s$ and $\dot{m} = q_{boil} / h_{fg}$. Using the Rohsenow correlation,

$$q_s'' = \mu_\ell h_{fg} \left[\frac{g(\rho_\ell - \rho_v)}{\sigma}\right]^{1/2} \left(\frac{c_{p,\ell} \Delta T_e}{C_{s,f} h_{fg} Pr_\ell^n}\right)^3$$

$$q_s'' = 0.38 \times 10^{-3} \frac{N \cdot s}{m^2} \times 812 \times 10^3 \frac{J}{kg} \left[\frac{9.8 m/s^2 (1111 - 1.66) kg/m^3}{32.7 \times 10^{-3} N/m}\right]^{1/2} \left(\frac{3280 J/kg \cdot K (480 - 470) K}{0.01 \times 812 \times 10^3 \frac{J}{kg} (8.7)^1}\right)^3$$

$$q_s'' = 1.78 \times 10^4 W/m^2 \qquad q_{boil} = 1.78 \times 10^4 W/m^2 \times \pi/4 (0.200m)^2 = 559 \ W$$ <

$$\dot{m} = 559 \ W / 812 \times 10^3 \ J/kg = 6.89 \times 10^{-4} kg/s.$$ <

For this fluid, the critical heat flux is estimated from Eq. 10.6 with C=0.149,

$$q_{max}'' = 0.149 \ h_{fg} \ \rho_v \left[\sigma g (\rho_\ell - \rho_v) / \rho_v^2\right]^{1/4}$$

$$q_{max}'' = 0.149 \times 812 \times 10^3 \frac{J}{kg} \times 1.66 \frac{kg}{m^3} \left[\frac{32.7 \times 10^{-3} N/m \times 9.8 m/s^2 (1111 - 1.66) kg/m^3}{(1.66 kg/m^3)^2}\right]^{1/4}$$

$$q_{max}'' = 6.77 \times 10^5 W/m^2.$$

Hence, the ratio of the operating heat flux to the critical heat flux is,

$$\frac{q_s''}{q_{max}''} = \frac{1.78 \times 10^4 W/m^2}{6.77 \times 10^5 W/m^2} \approx 0.026 \qquad \text{or} \qquad 2.6\%.$$ <

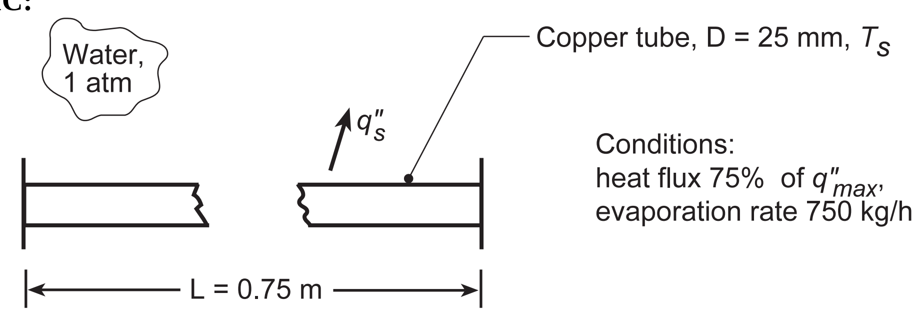
COMMENTS: Recognize that the results are crude approximations since the values for $C_{s,f}$ and n are just estimates. This fluid is not normally used for boiling processes since it decomposes at higher temperatures.

PROBLEM 10.16

KNOWN: Copper tubes, 25 mm diameter × 0.75 m long, used to boil saturated water at 1 atm operating at 75% of the critical heat flux.

FIND: (a) Number of tubes, N, required to evaporate at a rate of 750 kg/h; tube surface temperature, T_s, for these conditions, and (b) Compute and plot T_s and N required to provide the prescribed vapor production as a function of the heat flux ratio, $0.25 \le q_s''/q_{max}'' \le 0.90$.

SCHEMATIC:



ASSUMPTIONS: (1) Nucleate pool boiling, (2) Polished copper tube surfaces.

PROPERTIES: *Table A-6*, Saturated water (100°C): ρ_ℓ = 957.9 kg/m^3, $c_{p,\ell}$ = 4217 J/kg·K, μ_ℓ = 279 × 10^{-6} N·s/m^2, Pr_ℓ = 1.76, h_{fg} = 2257 kJ/kg, σ = 58.9 × 10^{-3} N/m, ρ_v = 0.5955 kg/m^3.

ANALYSIS: (a) The total number of tubes, N, can be evaluated from the rate equations

$$q = q_s'' A_s = q_s'' N\pi DL \qquad q = \dot{m}h_{fg} \qquad N = \dot{m}h_{fg}/q_s''\pi DL. \qquad (1,2,3)$$

The tubes are operated at 75% of the critical flux. From Eq. 10.6, the heat flux is

$$q''_{max} = 0.75 \times Ch_{fg}\rho_v\left[\frac{\sigma g(\rho_\ell - \rho_v)}{\rho_v^2}\right]^{1/4} = 0.75 \times 0.131 \times 2257 \times 10^3\ \text{J/kg} \times 0.5955\ \text{kg/m}^3 \times$$

$$\left[\frac{58.9 \times 10^{-3}\ \text{N/m} \times 9.8\ \text{m/s}^2 (957.9 - 0.5955)\ \text{kg/m}^3}{\left(0.5955\ \text{kg/m}^3\right)^2}\right]^{1/4} = 8.30 \times 10^5\ \text{W/m}^2$$

Substituting numerical values into Eq. (3), find

$$N = \frac{750\ \text{kg/h}}{3600\ \text{s/h}} \times 2257 \times 10^3\ \text{J/kg}\Big/\left(8.30 \times 10^5\ \text{W/m}^2 \times \pi \times 0.025\,\text{m} \times 0.75\,\text{m}\right) = 9.6 \approx 10. <$$

To determine the tube surface temperature, use the Rohsenow correlation,

$$\Delta T_e = \frac{C_{s,f}\, h_{fg}\, Pr_\ell^n}{c_{p,\ell}}\left(\frac{q_s''}{\mu_\ell h_{fg}}\right)^{1/3}\left[\frac{\sigma}{g(\rho_\ell - \rho_v)}\right]^{1/6}.$$

From Table 10.1 for the polished copper-water combination, $C_{s,f}$ = 0.0128 and n = 1.0.

Continued...

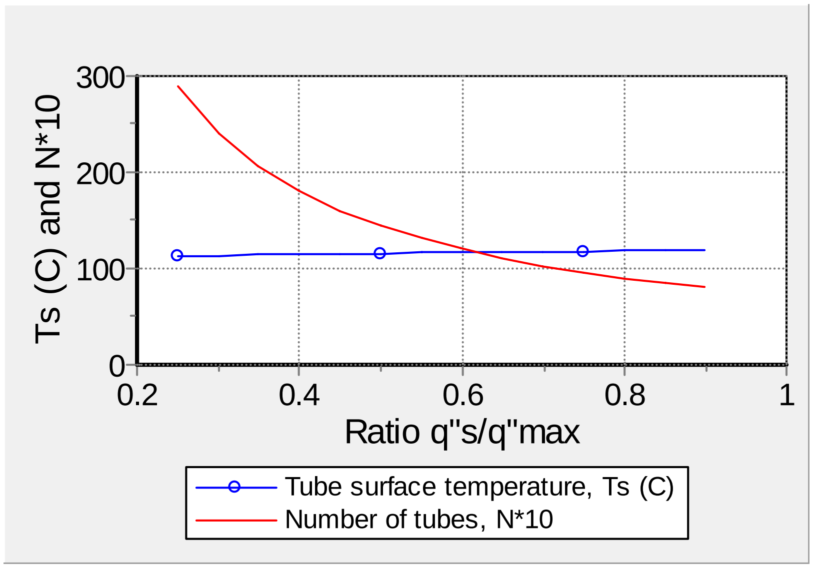
PROBLEM 10.16 (Cont.)

$$\Delta T_e = \frac{0.0128 \times 2257 \times 10^3 \, J/kg \, (1.76)^1}{4217 \, J/kg \cdot K} \left(\frac{8.30 \times 10^5 \, W/m^2}{279 \times 10^{-6} \, N \cdot s/m^2 \times 2257 \times 10^3 \, J/kg} \right)^{1/3} \times \left[\frac{58.9 \times 10^{-3} \, N/m}{9.8 \, m/s^2 \, (957.9 - 0.5955) \, kg/m^3} \right]^{1/6} = 18.0^\circ C.$$

Hence,

$$T_s = T_{sat} + \Delta T_e = (100 + 18.0)^\circ C = 118^\circ C. \qquad <$$

(b) Using the *IHT Correlations Tool*, *Boiling*, *Nucleate Pool Boiling*, *Heat flux* and the *Properties Tool* for *Water*, combined with Eqs. (1,2,3) above, the surface temperature T_s and N can be computed as a function of q''_s/q''_{max}. The results are plotted below.



Note that the tube surface temperature increases only slightly (112 to 119°C) as the ratio q''_s/q''_{max} increases. The number of tubes required to provide the prescribed evaporation rate decreases markedly as q''_s/q''_{max} increases.

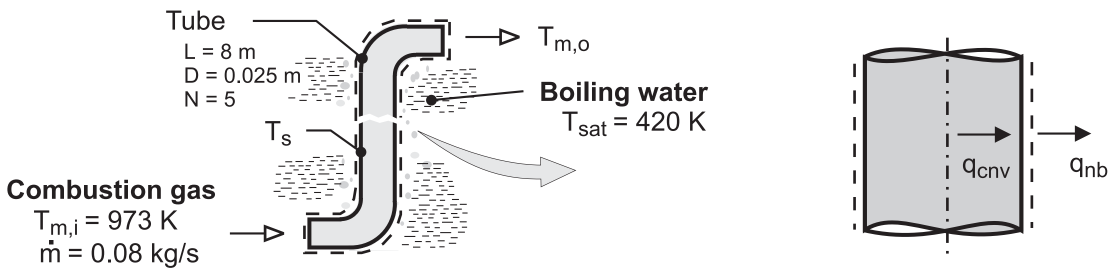
COMMENTS: The critical heat flux for pool boiling on a flat plate is calculated in Example 10.1 to be q''_{max} =1.26 MW/m^2. For a horizontal cylinder, the critical heat flux is smaller by a factor of 0.131/0.149 = 0.88. Hence, surface curvature effects can impact boiling phenomena.

PROBLEM 10.17

KNOWN: Diameter and length of tube submerged in pressurized water. Water pressure. Flowrate and inlet temperature of gas flow through the tube.

FIND: Tube wall and gas outlet temperatures for (a) new, scored tube surfaces and (b) aged conditions with smooth tube walls.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Uniform tube wall temperature, (3) Nucleate boiling at outer surface of tube, (4) Fully developed flow in tube, (5) Combustion gas is ideal with negligible viscous dissipation and pressure work, (6) Constant properties, (7) Thin tube wall.

PROPERTIES: *Table A-6*, saturated water (p_{sat} = 4.37 bars): T_{sat} = 420 K, $h_{fg} = 2.123 \times 10^6$ J/kg, $\rho_\ell = 919\,\text{kg/m}^3$, $\rho_v = 2.4$ kg/m^3, $\mu_\ell = 185 \times 10^{-6}\,\text{N}\cdot\text{s/m}^2$, $c_{p,\ell} = 4302\,\text{J/kg}\cdot\text{K}$, $\Pr_\ell = 1.16$, σ = 0.0494 N/m. *Table A-4*, air $\left(p = 1\,\text{atm}, \overline{T}_m \approx 700\,\text{K}\right)$: c_p = 1075 J/kg·K, $\mu = 339 \times 10^{-7}$ N·s/m^2, k = 0.0524 W/m·K, Pr = 0.695.

ANALYSIS: (a) From an energy balance performed for a control surface that bounds the tube, we know that the rate of heat transfer by convection from the gas to the inner surface must equal the rate of heat transfer due to boiling at the outer surface. Hence, from Eqs. 8.34 and 10.5, the energy balance for a single tube is of the form

$$\dot{m}c_p(T_{mi} - T_{mo}) = A_s\mu_\ell h_{fg}\left[\frac{g(\rho_\ell - \rho_v)}{\sigma}\right]^{1/2}\left(\frac{c_{p,\ell}\Delta T_e}{C_{s,f}\,h_{fg}\,\Pr_\ell^n}\right)^3 \qquad (1)$$

where $C_{s,f} = 0.0068$ and n = 1.0 from Table 10.1. The corresponding unknowns are the wall temperature T_s and gas outlet temperature, $T_{m,o}$, which are also related through Eq. 8.41b.

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{\pi DL}{\dot{m}\,c_p}\overline{h}\right) \qquad (2)$$

For $Re_D = 4\dot{m}/\pi D\mu = 119,600$, the flow is turbulent, and with n = 0.3, Eq. 8.60 yields,

$$\overline{h} = h_{fd} = \left(\frac{k}{D}\right)0.023\,Re_D^{4/5}\,\Pr^{0.3} = \left(\frac{0.0524\,\text{W/m}\cdot\text{K}}{0.025\text{m}}\right)0.023(119,600)^{4/5}(0.695)^{0.3} = 502\,\text{W/m}^2\cdot\text{K}$$

Continued…

PROBLEM 10.17 (Cont.)

Solving Eqs. (1) and (2), we obtain

$$T_s = 150°C, \qquad T_{m,o} = 164°C$$ <

(b) When the surface degrades to become similar to a polished surface, the value of $C_{s,f}$ changes to 0.00128. Repeating the calculations yields

$$T_s = 152.6°C, \qquad T_{m,o} = 166.7°C$$ <

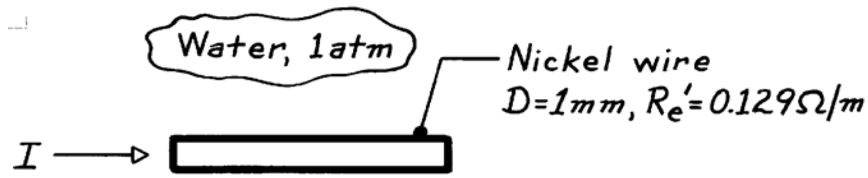
COMMENTS: (1) The heat rate per tube in part (a) is $q = \dot{m} c_p (T_{m,i} - T_{m,o})$ = 46,100 W, and the total heat rate is Nq = 230,500 W, in which case the rate of steam production is $\dot{m}_{steam} = q / h_{fg} = 0.109$ kg/s. (2) The boiling heat transfer coefficient, $h_{boil} = q_s''/(T_s - T_{sat})$, is 2.5×10^4 and 1.3×10^4 $W/m^2 \cdot K$ in parts (a) and (b), respectively. This large change has only a small effect on the surface and outlet temperatures because the dominant resistance is the internal forced convection gas resistance. (3) It would not be possible to maintain isothermal tube walls without a large wall thickness, and T_s, as well as the intensity of boiling, would decrease with increasing distance from the tube entrance. However the foregoing analysis suffices as a first approximation.

PROBLEM 10.18

KNOWN: Nickel wire passing current while submerged in water at atmospheric pressure.

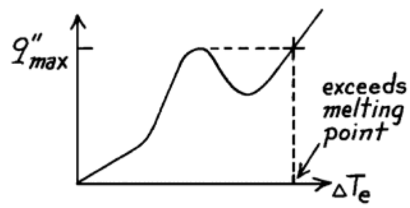
FIND: Current at which wire burns out.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Pool boiling.

ANALYSIS: The burnout condition will occur when electrical power dissipation creates a surface heat flux exceeding the critical heat flux, q''_{max}. This burn out condition is illustrated on the boiling curve to the right and in Figure 10.3.



The criterion for burnout can be expressed as

$$q''_{max} \cdot \pi D = q'_{elec} \qquad q'_{elec} = I^2 R'_e. \qquad (1,2)$$

That is,

$$I = \left[q''_{max} \pi D / R'_e\right]^{1/2}. \qquad (3)$$

For pool boiling of water at 1 atm, we found in Example 10.1 that

$$q''_{max} = 1.26\,MW/m^2.$$

Substituting numerical values into Eq. (3), find

$$I = \left[1.26\times10^6\,W/m^2\left(\pi\times0.001m\right)/0.129\Omega/m\right]^{1/2} = 175\,A. \qquad <$$

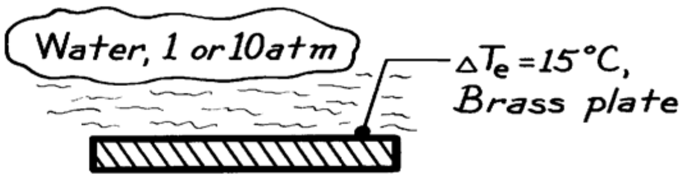
COMMENTS: The magnitude of the current required to burn out the 1 mm diameter wire is very large. What current would burn out the wire in air?

PROBLEM 10.19

KNOWN: Saturated water boiling on a brass plate maintained at $\Delta T_e = 15°C$.

FIND: Power required (W/m^2) for pressures of 1 and 10 atm; fraction of critical heat flux at which plate is operating.

SCHEMATIC:



ASSUMPTIONS: (1) Nucleate pool boiling, (2) $\Delta T_e = 15°C$ for both pressure levels.

PROPERTIES: *Table A-6*, Saturated water, liquid (1 atm, $T_{sat} = 100°C$): $\rho_\ell = 957.9\ kg/m^3$, $c_{p,\ell} = 4217\ J/kg\cdot K$, $\mu_\ell = 279 \times 10^{-6}\ N\cdot s/m^2$, $Pr_\ell = 1.76$, $h_{fg} = 2257\ kJ/kg$, $\sigma = 58.9 \times 10^{-3}\ N/m$; *Table A-6*, Saturated water, vapor (1 atm): $\rho_v = 0.596\ kg/m^3$; *Table A-6*, Saturated water, liquid (10 atm = 10.133 bar, $T_{sat} = 453.4\ K = 180.4°C$): $\rho_\ell = 886.7\ kg/m^3$, $c_{p,\ell} = 4410\ J/kg\cdot K$, $\mu_\ell = 149 \times 10^{-6}\ N\cdot s/m^2$, $Pr_\ell = 0.98$, $h_{fg} = 2012\ kJ/kg$, $\sigma = 42.2 \times 10^{-3}\ N/m$; *Table A-6*, Water, vapor (10.133 bar): $\rho_v = 5.155\ kg/m^3$.

ANALYSIS: With $\Delta T_e = 15°C$, we expect nucleate pool boiling. The Rohsenow correlation with $C_{s,f} = 0.006$ and $n = 1.0$ for the brass-water combination gives

$$q_s'' = \mu_\ell h_{fg}\left[\frac{g(\rho_\ell - \rho_v)}{\sigma}\right]^{1/2}\left(\frac{c_{p,\ell}\Delta T_e}{C_{s,f}\ h_{fg}\ Pr_\ell^n}\right)^3$$

1 atm: $$q_s'' = 279\times10^{-6} N\cdot s/m^2 \times 2257\times10^3 J/kg\left[\frac{9.8\,m/s^2(957.9-0.596)kg/m^3}{58.9\times10^{-3} N/m}\right]^{1/2}\times$$

$$\left(\frac{4217\ J/kg\cdot K\times15K}{0.006\times2257\times10^3 J/kg\times1.76^1}\right)^3 = 4.70 MW/m^2$$

10 atm: $q_s'' = 23.8 MW/m^2$

From Example 10.1, $q''_{max}(1atm) = 1.26\,MW/m^2$. To find the critical heat flux at 10 atm, use the correlation of Eq. 10.6 with C = 0.149,

$$q''_{max} = 0.149\ h_{fg}\ \rho_v\left[\sigma g(\rho_\ell - \rho_v)/\rho_v^2\right]^{1/4}.$$

$$q''_{max}(10\ atm) = 0.149\times2012\times10^3 J/kg\times5.155 kg/m^3\times$$

$$\left[\frac{42.2\times10^{-3} N/m\times9.8\,m/s^2(886.7-5.16)kg/m^3}{(5.155\,kg/m^3)^2}\right]^{1/4} = 2.97 MW/m^2.$$

For both conditions, the Rohsenow correlation predicts a heat flux that exceeds the maximum heat flux, q''_{max}. We conclude that the boiling condition with $\Delta T_e = 15°C$ for the brass-water combination is beyond the inflection point (P, see Fig. 10.4) where the boiling heat flux is no longer proportional to ΔT_e^3.

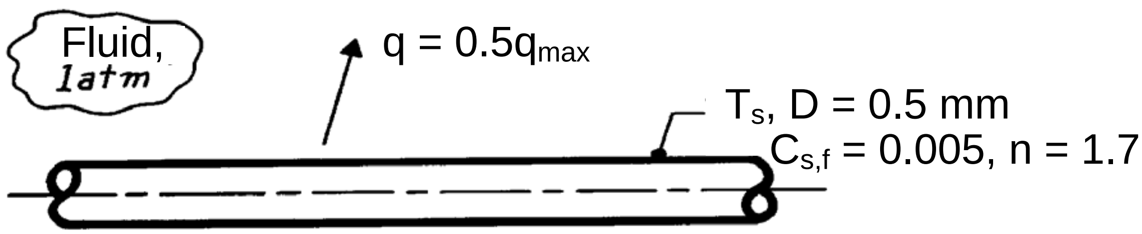
$$q_s'' \approx q''_{max}(1\ atm) \le 1.26\,MW/m^2 \qquad q_s'' \approx q''_{max}(10\ atm) \le 2.97\,MW/m^2.$$ <

PROBLEM 10.20

KNOWN: Properties of dielectric fluid boiling at 1 atm on a horizontal platinum wire of 0.5 mm diameter. Nucleate boiling constants. Correction factor for small horizontal cylinders.

FIND: Temperature of wire when heated at 50% of critical heat flux.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions. (2) Nucleate pool boiling.

PROPERTIES: Dielectric fluid, given: T_{sat} = 34°C, ρ_ℓ = 1400 kg/m^3, ρ_v = 7.2 kg/m^3, $c_{p,\ell}$ = 1300 J/kg·K, k_ℓ = 0.075 W/m·K, $\nu_\ell = 0.32 \times 10^{-6}$ N·s/m^2, $\sigma = 12.4 \times 10^{-3}$ N/m, h_{fg} = 142 kJ/kg.

ANALYSIS: The critical heat flux for a large horizontal cylinder can be estimated using Eq. 10.6, with C = 0.131.

$$q''_{max,large} = Ch_{fg}\rho_v\left[\frac{\sigma g(\rho_\ell - \rho_v)}{\rho_v^2}\right]^{1/4}$$
$$= 0.131 \times 142 \times 10^3 \text{ J/kg} \times 7.2 \text{ kg/m}^3$$
$$\times\left[\frac{12.4 \times 10^{-3} \text{ N/m} \times 9.8 \text{ m/s}^2 \times (1400 - 7.2) \text{ kg/m}^3}{(7.2 \text{ kg/m}^3)^2}\right]^{1/4}$$
$$= 180 \text{ kW/m}^2$$

The Confinement number is given by $\text{Co} = \sqrt{\sigma/[g(\rho_\ell - \rho_v)]}/R = 3.81$, which is in the range of applicability of the expression for the correction factor, F,

$$F = 0.89 + 2.27\exp(-3.44\text{Co}^{-1/2}) = 0.89 + 2.27\exp[-3.44(3.81)^{-1/2}] = 1.28$$

The wire is operated at 50% of the critical heat flux or,

$$q''_s = 0.5Fq''_{max,large} = 0.5 \times 1.28 \times 180 \text{ kW/m}^2 = 115 \text{ kW/m}^2$$

The excess temperature can then be found from Eq. 10.5, the Rohsenow correlation,

$$q''_s = \mu_\ell h_{fg}\left[\frac{g(\rho_\ell - \rho_v)}{\sigma}\right]^{1/2}\left(\frac{c_{p,\ell}\Delta T_e}{C_{s,f}\, h_{fg}\, Pr_\ell^n}\right)^3 = 115 \text{ kW/m}^2$$

Continued…

PROBLEM 10.20 (Cont.)

Substituting numerical values, with $\mu_\ell = \nu_\ell \rho_\ell = 4.48\times10^{-4}$ m/s^2 and $\Pr_\ell = \mu_\ell c_{p,\ell}/k_\ell = 7.77$,

$$4.48\times10^{-4}\,\text{N}\cdot\text{s/m}^2\times142\times10^3\,\text{J/kg}\left[\frac{9.8\ \text{m/s}^2\left(1400-7.2\right)\text{kg/m}^3}{12.4\times10^{-3}\,\text{N/m}}\right]^{1/2}\times$$

$$\left(\frac{1300\ \text{J/kg}\cdot\text{K}\times\Delta T_e}{0.005\times142\times10^3\,\text{J/kg}\times7.77^{1.7}}\right)^3 = 115\times10^3\ \text{W/m}^2$$

$$\Delta T_e = 21.4°\text{C}$$

Thus

T_s = 34°C + 21.4°C = 55.4°C <

COMMENTS: The critical heat flux on the small wire is 28% higher than on a large cylinder.

PROBLEM 10.21

KNOWN: Zuber-Kutateladze correlation for critical heat flux, q''_{max}.

FIND: Pressure dependence of q''_{max} for water; demonstrate maximum value occurs at approximately 1/3 p_{crit}; suggest coordinates for a universal curve to represent other fluids.

ASSUMPTIONS: Nucleate pool boiling conditions.

PROPERTIES*:* *Table A-6*, Water, saturated at various pressures; see below.

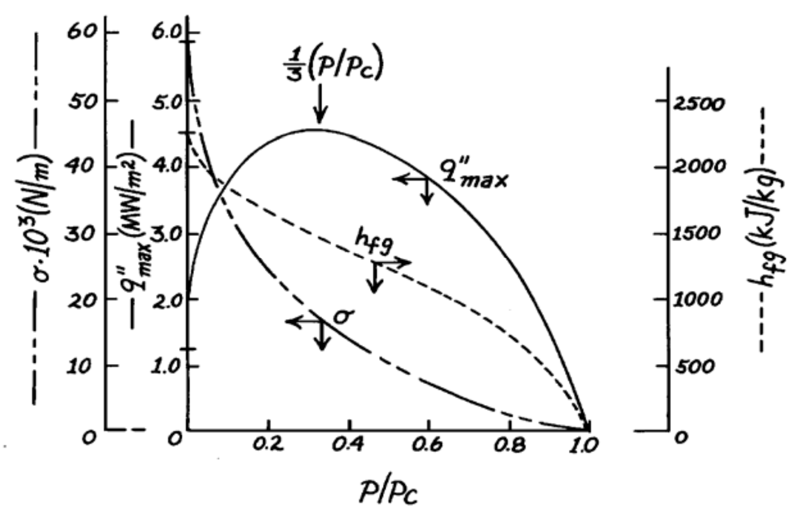
ANALYSIS: The Z-K correlation for estimating the critical heat flux, has the form

$$q''_{max} = 0.149\ \rho_v h_{fg} \left[\frac{g\sigma(\rho_\ell - \rho_v)}{\rho_v^2} \right]^{1/4}$$

where the properties for saturation conditions are a function of pressure. The properties (Table A-6) and the values for q''_{max} are as follows:

p (bar)	p/pc	ρ_ℓ	ρ_v (kg/m^3)	h_{fg} (kJ/kg)	$\sigma \times 10^3$ (N/m)	q''_{max} (MW/m^2)
1.01	0.0045	957.9	0.59552257	58.9		1.258
11.71	0.053	879.5	5.988	1989	40.7	3.138
26.40	0.120	831.3	13.05	1825	31.6	3.935
44.58	0.202	788.1	22.47	1679	24.5	4.398
61.19	0.277	755.9	31.55	1564	19.7	4.549
82.16	0.372	718.4	43.86	1429	15.0	4.520
123.5	0.557	648.9	72.99	1176	8.4	4.047
169.1	0.765	562.4	117.6	858	3.5	2.905
221.2	1.000	315.5	315.5	0	0	0

The q''_{max} values are plotted as a function of p/p_c, where p_c is the critical pressure. Note the rapid decrease of h_{fg} and σ with increasing pressure. The universal curve coordinates would be q''_{max} / q''_{max} $(1/3\ p_{crit})$ vs. p/p_c.



<

PROBLEM 10.22

KNOWN: Kutateladze's dimensional analysis and the bubble diameter parameter.

FIND: Verify the dimensional consistency of the critical heat flux expression.

ASSUMPTIONS: Nucleate pool boiling.

ANALYSIS: Kutateladze postulated that the critical flux was dependent upon four parameters,

$$q''_{max} = q''_{max}\left(h_{fg}, \rho_v, \sigma, D_b\right)$$

where D_b is the bubble diameter parameter having the form

$$D_b = \left[\sigma / g\left(\rho_\ell - \rho_v\right)\right]^{1/2}. \qquad (1)$$

The form of the critical heat flux expression was presumed to be

$$q''_{max} = C\ h_{fg}\ \rho_v^{1/2}\ D_b^{-1/2}\ \sigma^{1/2} \qquad (2)$$

where C is a constant. It is not possible to derive this equation from a dimensional (Pi) analysis. We can only determine that the equation is dimensionally consistent. Using SI units, check Eq. (1) for D_b,

$$D_b \Rightarrow \left[\left(Nm^{-1}\right)\left(m^{-1}s^2\right)\left(kg^{-1}m^3\right)\right]^{1/2} \Rightarrow \left[N\left(\frac{s^2}{kg \cdot m}\right)m^2\right]^{1/2} \Rightarrow [m]$$

and in Eq. (2) for q''_{max},

$$q''_{max} \Rightarrow \left[\left(J\,kg^{-1}\right)\left(kg^{1/2}m^{-3/2}\right)\left(m^{-1/2}\right)\left(N^{1/2}m^{-1/2}\right)\right] \Rightarrow \left[\frac{J}{s}\cdot\left(\frac{N \cdot s^2}{kg \cdot m}\right)^{1/2} m^{-2}\right] \Rightarrow \left[\frac{W}{m^2}\right].$$

Hence, the equations are dimensionally consistent.

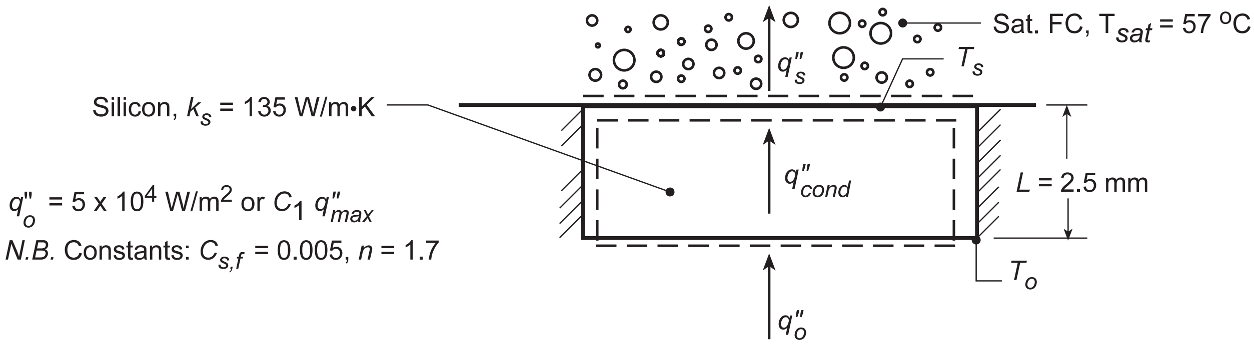
COMMENTS: Dimensional (Pi) analysis yields the following result: $q''_{max} / \rho_v h_{fg}^{2/3} = f(\sigma / \rho_v h_{fg} D_b)$.
If $f(\sigma/\rho_v h_{fg} D_b) = C(\sigma/\rho_v h_{fg} D_b)^{1/2}$, we recover Eq.(2).

PROBLEM 10.23

KNOWN: Thickness and thermal conductivity of a silicon chip. Properties of saturated fluorocarbon liquid.

FIND: (a) Temperature at bottom surface of chip for a prescribed heat flux and 90% of CHF, (b) Effect of heat flux on chip surface temperatures; maximum allowable heat flux.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform heat flux and adiabatic sides, hence one-dimensional conduction in chip, (3) Constant properties, (4) Nucleate boiling in liquid.

PROPERTIES: Saturated fluorocarbon (given): $c_{p,\ell}$ = 1100 J/kg·K, h_{fg} = 84,400 J/kg, ρ_ℓ = 1619.2 kg/m^3, ρ_v = 13.4 kg/m^3, $\sigma = 8.1 \times 10^{-3}$ kg/s^2, $\mu_\ell = 440 \times 10^{-6}$ kg/m·s, Pr_ℓ = 9.01.

ANALYSIS: (a) Energy balances at the top and bottom surfaces yield $q''_o = q''_{cond} = k_s(T_o - T_s)/L = q''_s$; where T_s and q''_s are related by the Rohsenow correlation,

$$T_s - T_{sat} = \frac{C_{s,f} h_{fg} Pr_\ell^n}{c_{p,\ell}} \left(\frac{q''_s}{\mu_\ell h_{fg}} \right)^{1/3} \left[\frac{\sigma}{g(\rho_\ell - \rho_v)} \right]^{1/6}$$

Hence, for $q''_s = 5 \times 10^4$ W/m^2,

$$T_s - T_{sat} = \frac{0.005(84,400\,J/kg)9.01^{1.7}}{1100\,J/kg \cdot K} \left(\frac{5 \times 10^4\,W/m^2}{440 \times 10^{-6}\,kg/m \cdot s \times 84,400\,J/kg} \right)^{1/3}$$

$$\times \left[\frac{8.1 \times 10^{-3}\,kg/s^2}{9.8\,m/s^2\,(1619.2 - 13.4)\,kg/m^3} \right]^{1/6} = 15.9^\circ C$$

$$T_s = (15.9 + 57)^\circ C = 72.9^\circ C.$$

From Fourier's law,

$$T_o = T_s + \frac{q''_o L}{k_s} = 72.9^\circ C + \frac{5 \times 10^4\,W/m^2 \times 0.0025\,m}{135\,W/m \cdot K} = 73.8^\circ C$$ <

For a heat flux which is 90% of the critical heat flux (C_1 = 0.9), it follows that

$$q''_o = 0.9 q''_{max} = 0.9 \times 0.149 h_{fg} \rho_v \left[\frac{\sigma g(\rho_\ell - \rho_v)}{\rho_v^2} \right]^{1/4} = 0.9 \times 0.149 \times 84,400\,J/kg \times 13.4\,kg/m^3$$

Continued...

PROBLEM 10.23 (Cont.)

$$\times\left[\frac{8.1\times10^{-3}\,\text{kg}/\text{s}^2\times9.8\,\text{m}/\text{s}^2\,(1619.2-13.4)\,\text{kg}/\text{m}^3}{\left(13.4\,\text{kg}/\text{m}^3\right)^2}\right]^{1/4}$$

$$q''_o = 0.9\times15.5\times10^4\ \text{W}/\text{m}^2 = 13.9\times10^4\ \text{W}/\text{m}^2$$

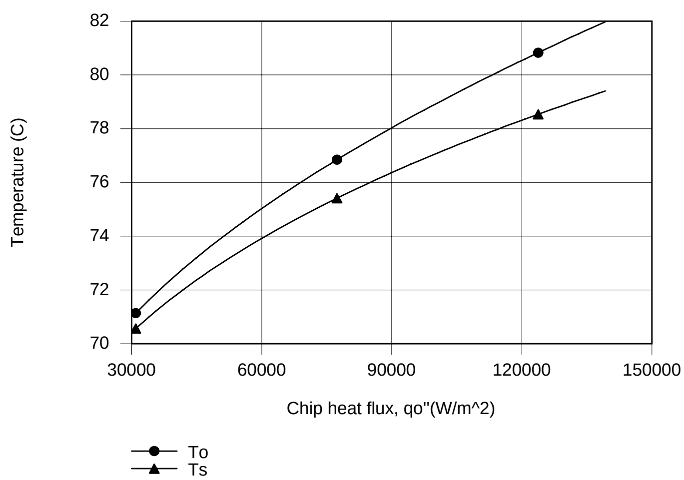
From the results of the previous calculation and the Rohsenow correlation, it follows that

$$\Delta T_e = 15.9^\circ\text{C}\left(q''_o/5\times10^4\ \text{W}/\text{m}^2\right)^{1/3} = 15.9^\circ\text{C}(13.9/5)^{1/3} = 22.4^\circ\text{C}$$

Hence, T_s = 79.4°C and

$$T_o = 79.4^\circ\text{C} + \frac{13.9\times10^4\ \text{W}/\text{m}^2\times0.0025\,\text{m}}{135\,\text{W}/\text{m}\cdot\text{K}} = 82^\circ\text{C}$$ <

(b) Using the energy balance equations with the *Correlations* Toolpad of IHT to perform the parametric calculations for $0.2 \le C_1 \le 0.9$, the following results are obtained.



The chip surface temperatures, as well as the difference between temperatures, increase with increasing heat flux. The maximum chip temperature is associated with the bottom surface, and T_o = 80°C corresponds to

$$q''_{o,max} = 11.3\times10^4\ \text{W}/\text{m}^2$$ <

which is 73% of CHF (q''_{max} = 15.5 × 10^4 W/m^2).

COMMENTS: Many of today's VLSI chip designs involve heat fluxes well in excess of 15 W/cm^2, in which case pool boiling in a fluorocarbon would not be an appropriate means of heat dissipation.

PROBLEM 10.24

KNOWN: Boiling water at 1 atm pressure on moon where the gravitational field is 1/6 that of the earth.

FIND: Critical heat flux.

ASSUMPTIONS: Nucleate pool boiling conditions.

PROPERTIES: *Table A-6*, Water (1 atm): T_{sat} = 100°C, ρ_ℓ = 957.9 kg/m^3, ρ_v = 0.5955 kg/m^3, h_{fg} = 2257 kJ/kg, σ = 58.9 × 10^{-3} N/m.

ANALYSIS: The critical heat flux is given by Eq. 10.6 with C=0.149.

$$q''_{max} = 0.149\,\rho_v^{1/2} h_{fg}\left[\sigma g\left(\rho_\ell - \rho_v\right)\right]^{1/4}.$$

The relation predicts the critical flux dependency on the gravitational acceleration as

$$q''_{max} \sim g^{1/4}.$$

It follows that if g_{moon} = (1/6) g_{earth} and recognizing $q''_{max,e}$ = 1.26 MW/m^2 for earth acceleration (see Example 10.1),

$$q''_{max,moon} = q''_{max,earth}\left(g_{moon}/g_{earth}\right)^{1/4}$$

$$q''_{max,moon} = 1.26\frac{MW}{m^2}\left(\frac{1}{6}\right)^{1/4} = 0.81\ MW/m^2. \qquad <$$

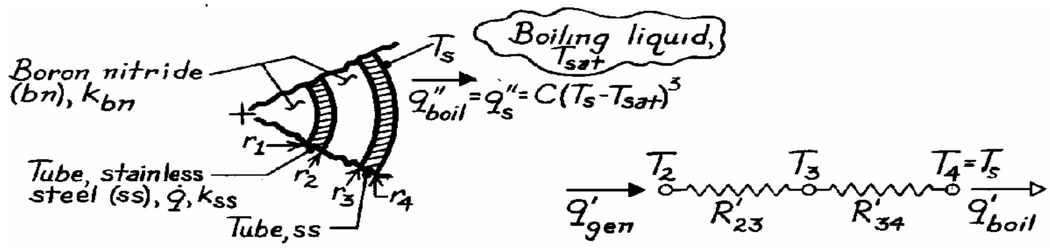
COMMENTS: Note from the discussion in Section 10.4.5 that the $g^{1/4}$ dependence on the critical heat flux has been experimentally confirmed. In the nucleate pool boiling regime, the heat flux is nearly independent of the gravitational field.

PROBLEM 10.25

KNOWN: Concentric stainless steel tubes packed with dense boron nitride powder. Inner tube has heat generation while outer tube surface is exposed to boiling heat flux, $q''_s = C(T_s - T_{sat})^3$. Saturation temperature of boiling liquid and temperature of the outer tube surface.

FIND: Expressions for the maximum temperature in the stainless steel (ss) tubes and in the boron nitride (bn).

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional (cylindrical) steady-state heat transfer in tubes and boron nitride.

ANALYSIS: Construct the thermal circuit shown above where R'_{23} and R'_{34} represent the resistances due to the boron nitride between r_2 and r_3 and to the outer stainless steel tube, respectively. From an overall energy balance,

$$q'_{gen} = q'_{boil},$$

$$\dot{q}\pi\left(r_2^2 - r_1^2\right) = \left(2\pi r_4\right)C\left(T_s - T_{sat}\right)^3.$$

With prescribed values for T_{sat}, T_s and C, the required volumetric heating of the inner stainless steel tube is

$$\dot{q} = \frac{2r_4}{\left(r_2^2 - r_1^2\right)}C\left(T_s - T_{sat}\right)^3.$$

Using the thermal circuit, we can write expressions for the *maximum* temperature of the stainless steel (ss) and boron nitride (bn).

Stainless steel: $T_{ss,max}$ occurs at r_1. Using the results of Section 3.5.2, the temperature distribution in a radial tube of inner and outer radii r_1 and r_2 is

$$T(r) = -\frac{\dot{q}}{4k_{ss}}r^2 + C_1 \ln r + C_2$$

for which the boundary conditions are

$$\text{BC\#1:} \qquad r = r_1 \qquad \frac{dT}{dr} = 0 \qquad 0 = -\frac{\dot{q}}{4k_{ss}}2r_1 + \frac{C_1}{r_1} + 0 \rightarrow C_1 = +\frac{\dot{q}r_1^2}{2k_{ss}}$$

Continued …

PROBLEM 10.25 (Cont.)

BC#2: $r = r_2$ $\quad T(r_2) = T_2$ $\quad T_2 = -\frac{\dot{q}}{4k_{ss}} r_2^2 + \frac{\dot{q}r_1^2}{2k_{ss}} \ln r_2 + C_2$

$$C_2 = T_2 + \frac{\dot{q}}{4k_{ss}} r_2^2 - \frac{\dot{q}r_1^2}{2k_{ss}} \ln r_2$$

Hence,

$$T(r) = -\frac{\dot{q}}{4k_{ss}}\left(r^2 - r_2^2\right) + \frac{\dot{q}r_1^2}{2k_{ss}} \ln(r / r_2) + T_2.$$

Using the thermal circuit, find T_2 in terms of known parameters T_s, T_{sat} and C.

$$\frac{T_2 - T_s}{R'_{23} + R'_{34}} = (2\pi r_4) C (T_s - T_{sat})^3.$$

Hence, the maximum temperature in the inner stainless steel tube ($r = r_1$) is

$$T_{ss,max} = T(r_1) = -\frac{\dot{q}}{4k_{ss}}\left(r_1^2 - r_2^2\right) + \frac{\dot{q}r_1^2}{2k_{ss}} \ln(r_1 / r_2) + T_s$$
$$+ (R'_{23} + R'_{34})(2\pi r_4) C (T_s - T_{sat})^3 \quad <$$

where from Eq. 3.33

$$R'_{23} = \frac{\ln(r_3 / r_2)}{2\pi k_{bn}} \qquad R'_{34} = \frac{\ln(r_4 / r_3)}{2\pi k_{ss}}.$$

Boron nitride: $T_{bn,max}$ occurs at r_1. Hence

$$T_{bn,max} = T(r_1) \quad <$$

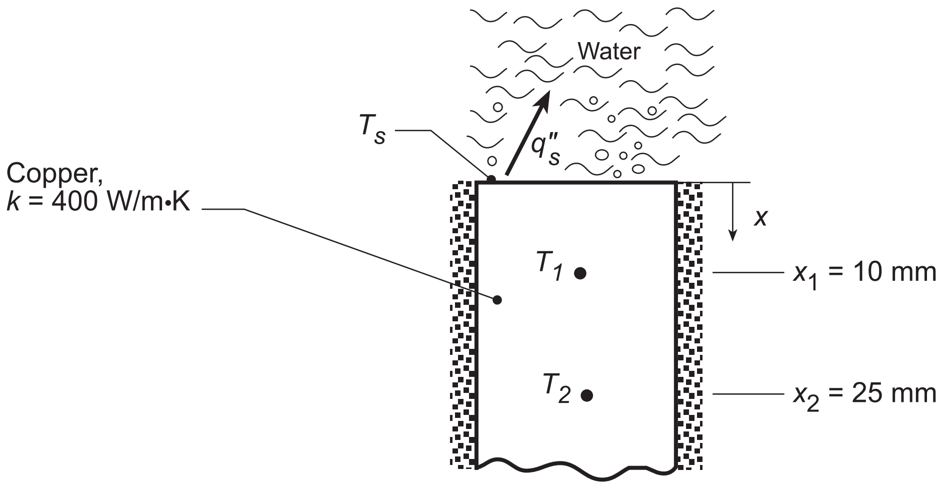
as derived above for the inner stainless steel tube.

PROBLEM 10.26

KNOWN: Operating conditions of apparatus used to determine surface boiling characteristics.

FIND: (a) Nucleate boiling coefficient for special coating, (b) Surface temperature as a function of heat flux; apparatus temperatures for a prescribed heat flux; applicability of nucleate boiling correlation for a specified heat flux.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, steady-state conduction in the bar, (2) Water is saturated at 1 atm, (3) Applicability of Rohsenow correlation with n = 1.

PROPERTIES: *Table A.6*, saturated water (100°C): ρ_ℓ = 957.9 kg/m^3, $c_{p,\ell}$ = 4217 J/kg·K, μ_ℓ = 279 × 10^{-6} N·s/m^2, Pr_ℓ = 1.76, h_{fg} = 2.257 × 10^6 J/kg, σ = 0.0589 N/m, ρ_v = 0.5955 kg/m^3.

ANALYSIS: (a) The coefficient $C_{s,f}$ associated with Eq. 10.5 may be determined if q''_s and T_s are known. Applying Fourier's law between x_1 and x_2,

$$q''_s = q''_{cond} = k\frac{T_2 - T_1}{x_2 - x_1} = 400\,W/m\cdot K \times \frac{(158.6-133.7)^\circ C}{0.015\,m} = 6.64\times10^5\,W/m^2$$

Since the temperature distribution in the bar is linear, $T_s = T_1 - (dT/dx)x_1 = T_1 - [(T_2 - T_1)/(x_2 - x_1)]x_1$. Hence,

$$T_s = 133.7^\circ C - \left[24.9^\circ C/0.015\,m\right]0.01\,m = 117.1^\circ C$$

From Eq. 10.5, with n = 1,

$$C_{s,f} = \frac{c_{p,\ell}\Delta T_e}{h_{fg}\,Pr_\ell}\left(\frac{\mu_\ell h_{fg}}{q''_s}\right)^{1/3}\left[\frac{g(\rho_\ell - \rho_v)}{\sigma}\right]^{1/6}$$

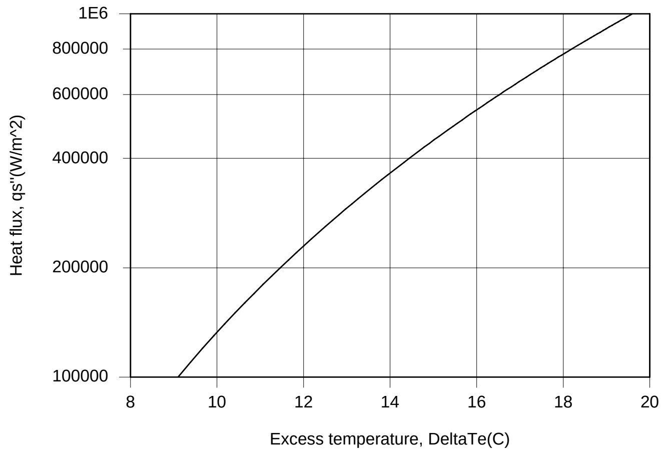
$$C_{s,f} = \frac{4217\,J/kg\cdot K\left(17.1^\circ C\right)}{2.257\times10^6\,J/kg\,(1.76)}\left(\frac{279\times10^{-6}\,kg/s\cdot m\times2.257\times10^6\,J/kg}{6.64\times10^5\,W/m^2}\right)^{1/3}\left[\frac{9.8\,m/s^2\times957.3\,kg/m^3}{0.0589\,kg/s^2}\right]^{1/6}$$

$C_{s,f}$ = 0.0131 <

(b) Using the appropriate IHT *Correlations* and *Properties* Toolpads, the following portion of the nucleate boiling regime was computed.

Continued...

PROBLEM 10.26 (Cont.)



For q''_s = 10^6 W/m^2 = q''_{cond}, T_s = 119.6°C and

T_1 = 144.6°C and T_2 = 182.1°C <

With the critical heat flux given by Eq. 10.6 with C=0.149,

$$q''_{max} = 0.149 h_{fg} \rho_v \left[\frac{\sigma g (\rho_\ell - \rho_v)}{\rho_v^2} \right]^{1/4}$$

$$q''_{max} = 0.149 \left(2.257 \times 10^6 \text{ J/kg}\right) 0.5955 \text{ kg/m}^3 \left[\frac{0.0589 \text{ kg/s}^2 \times 9.8 \text{ m/s}^2 \times 957.3 \text{ kg/m}^3}{\left(0.5955 \text{ kg/m}^3\right)^2} \right]^{1/4}$$

$$q''_{max} = 1.25 \times 10^6 \text{ W/m}^2$$

Since q''_s = 1.5 × 10^6 W/m^2 > q''_{max}, the heat flux exceeds that associated with nucleate boiling and the foregoing results can not be used.

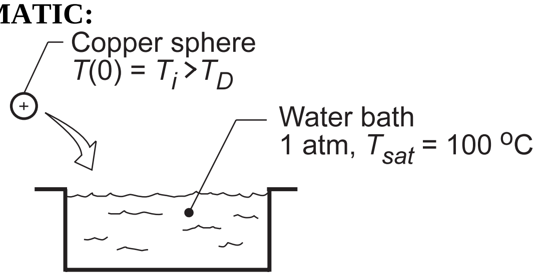
COMMENTS: For $q''_s > q''_{max}$, conditions correspond to film boiling, for which T_s may exceed acceptable operating conditions.

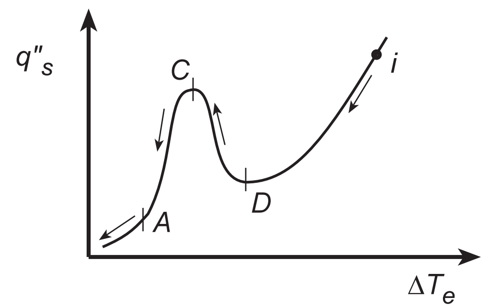
PROBLEM 10.27

KNOWN: Small copper sphere, initially at a uniform temperature, T_i, greater than that corresponding to the Leidenfrost point, T_D, suddenly immersed in a large fluid bath maintained at T_{sat}.

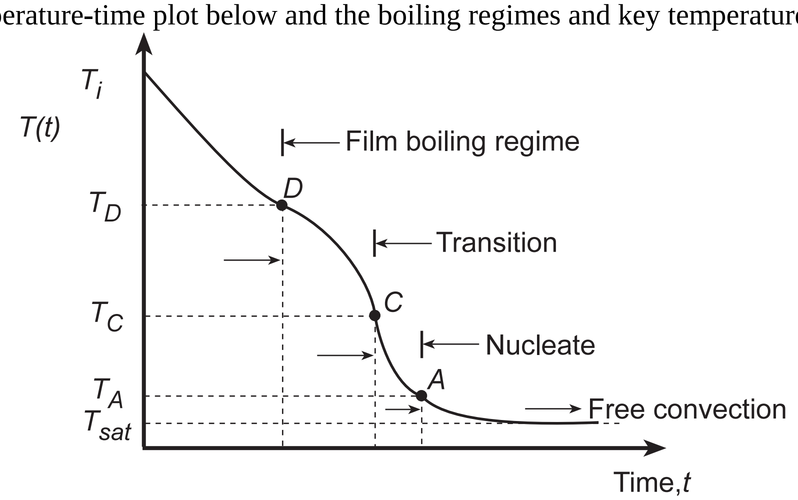
FIND: (a) Sketch the temperature-time history, T(t), during the quenching process; indicate temperature corresponding to T_i , T_D, and T_{sat} , identify regimes of film, transition and nucleate boiling and the single-phase convection regime; identify key features; and (b) Identify times(s) in this quenching process when you expect the surface temperature of the sphere to deviate most from its center temperature.

SCHEMATIC:





ANALYSIS: (a) In the right-hand schematic above, the quench process is shown on the "boiling curve" similar to Figure 10.4. Beginning at an initial temperature, $T_i > T_D$, the process proceeds as indicated by the arrows: film regime from i to D, transition regime from D to C, nucleate regime from C to A, and single-phase (free convection) from A to the condition when $\Delta T_e = T_s - T_{sat} = 0$. The quench process is shown on the temperature-time plot below and the boiling regimes and key temperatures are labeled..



The highest temperature-time change should occur in the nucleate pool boiling regime, especially near the critical flux condition, T_c . The lowest temperature-time change will occur in the single-phase, free convection regime.

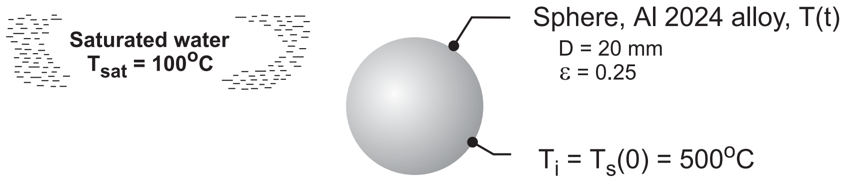
(b) The difference between the center and surface temperatures will be greatest when the Biot number is largest, which occurs in regimes with the highest convection coefficients. The convection coefficient is maximum at point P on the boiling curve of Fig. 10.4, which falls between points C and A on the above plots.

PROBLEM 10.28

KNOWN: A sphere (aluminum alloy 2024) with a uniform temperature of 500°C and emissivity of 0.25 is suddenly immersed in a saturated water bath maintained at atmospheric pressure.

FIND: (a) The total heat transfer coefficient for the initial condition; fraction of the total coefficient contributed by radiation; and (b) Estimate the temperature of the sphere 30 s after it has been immersed in the bath.

SCHEMATIC:



ASSUMPTIONS: (1) Water exposed to standard atmospheric pressure and uniform temperature, T_{sat}, and (2) Lumped capacitance method is valid.

PROPERTIES: See Comment 2; properties obtained with *IHT* code.

ANALYSIS: (a) For the initial condition with T_s = 500°C, *film boiling* will occur and the coefficients due to convection and radiation are estimated using Eqs. 10.8 and 10.11, respectively,

$$\overline{Nu}_D = \frac{\bar{h}_{conv} D}{k_v} = C\left[\frac{g(\rho_\ell - \rho_v) h'_{fg} D^3}{\nu_v k_v (T_s - T_{sat})}\right]^{1/4} \tag{1}$$

$$\bar{h}_{rad} = \frac{\varepsilon\sigma\left(T_s^4 - T_{sat}^4\right)}{T_s - T_{sat}} \tag{2}$$

where C = 0.67 for spheres and $\sigma = 5.67 \times 10^{-8}$ W/m$^2\cdot$K^4. The corrected latent heat is

$$h'_{fg} = h_{fg} + 0.8\, c_{p,v}(T_s - T_{sat}) \tag{3}$$

The total heat transfer coefficient is given by Eq. 10.9 as

$$\bar{h}^{4/3} = \bar{h}_{conv}^{4/3} + \bar{h}_{rad} \cdot \bar{h}^{1/3} \tag{4}$$

The vapor properties are evaluated at the film temperature,

$$T_f = (T_s + T_{sat})/2 \tag{5}$$

while the liquid properties are evaluated at the saturation temperature. Using the foregoing relations in *IHT* (see Comments), the following results are obtained.

$\overline{Nu}_D$	$\bar{h}_{cnv}\left(W/m^2\cdot K\right)$	$\bar{h}_{rad}\left(W/m^2\cdot K\right)$	$\bar{h}\left(W/m^2\cdot K\right)$	
85.5	171	12.0	180	<

The radiation process contribution is 6.7% that of the total heat rate.

(b) For the lumped-capacitance method, from Section 5.3, the energy balance is

$$-\bar{h}A_s(T_s - T_{sat}) = \rho_s V c_s \frac{dT_s}{dt} \tag{6}$$

where ρ_s and c_s are properties of the sphere. To determine $T_s(t)$, it is necessary to evaluate $\bar{h}$ as a function of T_s. Using the foregoing relations in *IHT* (see Comments), the sphere temperature after 30s is

$$T_s(30s) = 300°C. \qquad <$$

Continued …

PROBLEM 10.28 (Cont.)

COMMENTS: (1) The Biot number associated with the aluminum alloy sphere cooling process for the initial condition is Bi = 0.019. Hence, the lumped-capacitance method is valid.

(2) The *IHT* code to solve this application uses the film-boiling correlation, the water properties functions, and the lumped capacitance energy balance, Eq. (6). The results for part (a), including the properties required of the correlation, are shown at the outset of the code.

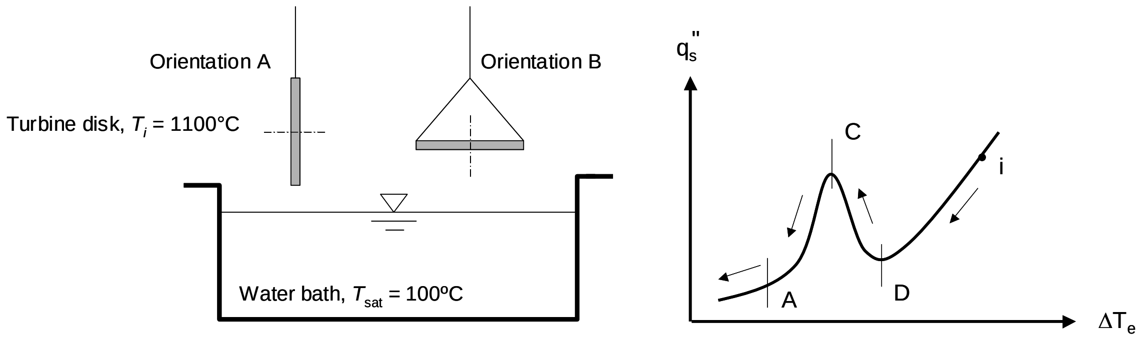
PROBLEM 10.29

KNOWN: Initial temperature of hot rotor, temperature of water quenching bath, rotor orientation.

FIND: (a) Sketch of the rotor temperature versus time for Orientation A, (b) Relative cooling rate of the rotor for Orientation B.

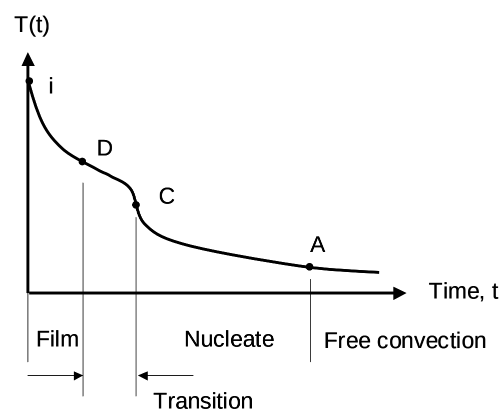
SCHEMATIC:



ASSUMPTIONS: (1) Lumped capacitance behavior, (2) Constant properties.

ANALYSIS: Assuming lumped capacitance behavior for the rotor, the time rate of change of the rotor temperature is proportional to the instantaneous heat flux from the rotor surface. In either orientation, the quenching process begins at an initial rotor temperature associated with film boiling (see Fig. 10.4 and the RHS schematic).

(a) For Orientation A, the rotor temperature versus time is shown in the sketch below. In the film boiling regime, the slope of the *T*(*t*) curve continually decreases as the boiling heat flux decreases until the Leidenfrost point (Point D) is reached. Between Points D and C, transition boiling occurs and the heat flux increases as the rotor temperature decreases until the critical heat flux value (Point C) is reached. Point C corresponds to a local maximum rotor cooling rate. As the rotor continues to cool, the heat flux continues to decreases throughout the nucleate boiling regime until Point A is reached, corresponding to the curtailment of boiling, the onset of free convection cooling, and very slow decreases in the rotor temperature with time.



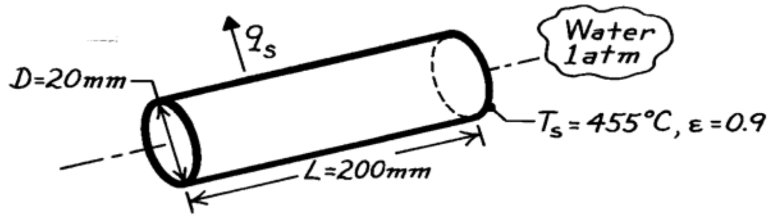
(b) For Orientation A, vapor rises unimpaired from the vicinity of the rotor. For Orientation B, however, the rotor obstructs the movement of vapor away from the bottom surface of the rotor. Hence, even in the nucleate boiling regime, an insulating vapor blanket would tend to form on the bottom surface, resulting in slower cooling relative to Orientation A.

PROBLEM 10.30

KNOWN: Steel bar upon removal from a furnace immersed in water bath.

FIND: Initial heat transfer rate from bar.

SCHEMATIC:



ASSUMPTIONS: (1) Uniform bar surface temperature, (2) Film pool boiling conditions.

PROPERTIES: *Table A-6*, Water, liquid (1 atm, T_{sat} = 100°C): ρ_ℓ = 957.9 kg/m^3, h_{fg} = 2257 kJ/kg; *Table A-4*, Water, vapor ($T_f = (T_s + T_{sat})/2$ = 550K): ρ_v = 0.4005 kg/m^3, $c_{p,v}$ = 1997 J/kg·K, $\nu_v = 47.04 \times 10^{-6}$ m^2/s , k_v = 0.0379 W/m·K.

ANALYSIS: The total heat transfer rate from the bar at the instant of time it is removed from the furnace and immersed in the water is

$$q_s = \bar{h} A_s (T_s - T_{sat}) = \bar{h} A_s \Delta T_e \quad (1)$$

where ΔT_e = 455 – 100 = 355K. According to the boiling curve of Figure 10.4, with such a high ΔT_e, film pool boiling will occur. From Eq. 10.9 or 10.10,

$$\bar{h}^{4/3} = \bar{h}_{conv}^{4/3} + \bar{h}_{rad} \cdot \bar{h}^{1/3} \quad \text{or} \quad \bar{h} = \bar{h}_{conv} + \frac{3}{4}\bar{h}_{rad} \ \left(\text{if } h_{conv} > h_{rad}\right). \quad (2)$$

To estimate the convection coefficient, use Eq. 10.8,

$$\overline{Nu}_D = \frac{\bar{h}_{conv} D}{k_v} = C\left[\frac{g(\rho_\ell - \rho_v) h'_{fg} D^3}{\nu_v k_v \Delta T_e}\right]^{1/4} \quad (3)$$

where C = 0.62 for the horizontal cylinder and $h'_{fg} = h_{fg} + 0.8\, c_{p,v}(T_s - T_{sat})$. Find

$$\bar{h}_{conv} = \frac{0.0379 \text{ W/m}\cdot\text{K}}{0.020 \text{ m}} 0.62\left[\frac{9.8 \text{ m/s}^2 (957.9 - 0.4005) \text{ kg/m}^3 \left[2257\times10^3 + 0.8\times1997\times355\right] \text{J/kg} (0.020\text{m})^3}{(47.04\times10^{-6}) \text{m}^2/\text{s} \times 0.0379 \text{ W/m}\cdot\text{K}\times355\text{K}}\right]^{1/4}$$

$$\bar{h}_{conv} = 159 \text{ W/m}^2\cdot\text{K}.$$

To estimate the radiation coefficient, use Eq. 10.11,

$$\bar{h}_{rad} = \frac{\varepsilon\sigma\left(T_s^4 - T_{sat}^4\right)}{T_s - T_{sat}} = \frac{0.9\times5.67\times10^{-8} \text{ W/m}^2\cdot\text{K}^4\left(728^4 - 373^4\right)\text{K}^4}{355\text{K}} = 37.6 \text{ W/m}^2\cdot\text{K}.$$

Substituting numerical values into the simpler form of Eq. (2), find

$$\bar{h} = \left(159 + (3/4)37.6\right) \text{W/m}^2\cdot\text{K} = 187 \text{ W/m}^2\cdot\text{K}.$$

Using Eq. (1), the heat rate, with $A_s = \pi D L$, is

$$q_s = 187 \text{ W/m}^2\cdot\text{K}(\pi\times0.020\text{m}\times0.200\text{m})\times355\text{K} = 835\text{W}.$$ <

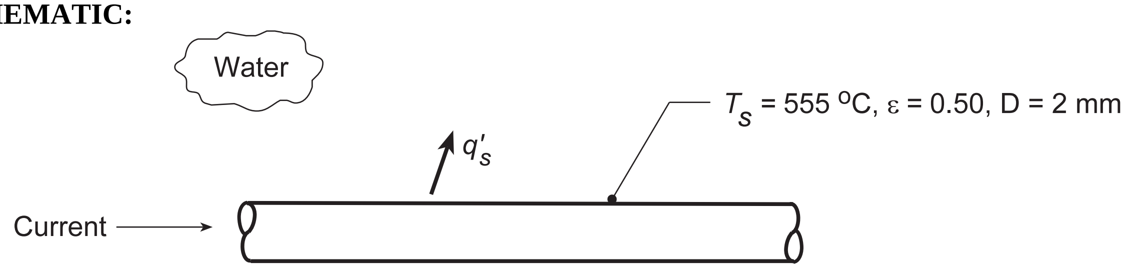
COMMENTS: For these conditions, the combined radiation and convection heat transfer coefficient is 18% larger than the convection coefficient alone.

PROBLEM 10.31

KNOWN: Electrical conductor with prescribed surface temperature immersed in water.

FIND: (a) Power dissipation per unit length, q'_s and (b) Compute and plot q'_s as a function of surface temperature $250 \le T_s \le 650°C$ for conductor diameters of 1.5, 2.0, and 2.5 mm; separately plot the percentage contribution of radiation as a function of T_s.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Water saturated at l atm, (3) Film pool boiling.

PROPERTIES: *Table A-6*, Water, liquid (1 atm, T_{sat} = 100°C): $\rho_\ell = 957.9\ kg/m^3$, $h_{fg} = 2257\ kJ/kg$; *Table A-4*, Water, vapor ($T_f = (T_s + T_{sat})/2 = 600\ K$): $\rho_v = 0.3652\ kg/m^3$, $c_{p,v} = 2026\ J/kg\cdot K$, $\nu_v = 56.60 \times 10^{-6}\ m^2/s$, $k_v = 0.0422\ W/m\cdot K$.

ANALYSIS: (a) The heat rate per unit length due to electrical power dissipation is

$$q'_s = \frac{q_s}{\ell} = \bar{h}\frac{A_s}{\ell}\left(T_s - T_{sat}\right) = \bar{h}\pi D\Delta T_e$$

where ΔT_e = (555 - 100)°C = 455°C. According to the boiling curve of Figure 10.4, with such a high ΔT_e, film pool boiling will occur. From Eq 10.9 or 10.10,

$$\bar{h}^{4/3} = \bar{h}_{conv}^{4/3} + \bar{h}_{rad}\cdot\bar{h}^{1/3} \qquad \text{or} \qquad \bar{h} = \bar{h}_{conv} + \frac{3}{4}\bar{h}_{rad} \qquad \left(\text{if } \bar{h}_{conv} > \bar{h}_{rad}\right).$$

To estimate the convection coefficient, use Eq. 10.8,

$$\overline{Nu}_D = \frac{\bar{h}_{conv}D}{k_v} = C\left[\frac{g\left(\rho_\ell - \rho_v\right)h'_{fg}D^3}{\nu_v k_v \Delta T_e}\right]^{1/4}$$

where C = 0.62 for the horizontal cylinder and $h'_{fg} = h_{fg} + 0.8c_{p,v}(T_s - T_{sat})$. Find

$$\bar{h}_{conv} = \frac{0.0422\ W/m\cdot K}{0.002\ m}\times 0.62\left[\frac{9.8\ m/s^2\left(957.9 - 0.3652\right)kg/m^3\left[2257\times10^3 + 0.8\times2026\times455\right]J/kg\left(0.002m\right)^3}{\left(56.60\times10^{-6}\right)m^2/s\times0.0422\ W/m\cdot K\times455\ K}\right]^{1/4}$$

$$\bar{h}_{conv} = 279\ W/m^2\cdot K.$$

To estimate the radiation coefficient, use Eq. 10.11.

$$\bar{h}_{rad} = \frac{\varepsilon\sigma\left(T_s^4 - T_{sat}^4\right)}{T_s - T_{sat}} = \frac{0.5\times5.67\times10^{-8}\ W/m^2\cdot K^4\left(828^4 - 373^4\right)K^4}{455\ K} = 28\ W/m^2\cdot K.$$

Since $h_{conv} > h_{rad}$, the simpler form of Eq. 10.10 is appropriate. Find,

$$\bar{h} = \left(279 + (3/4)\times28\right)W/m^2\cdot K = 300\ W/m^2\cdot K$$

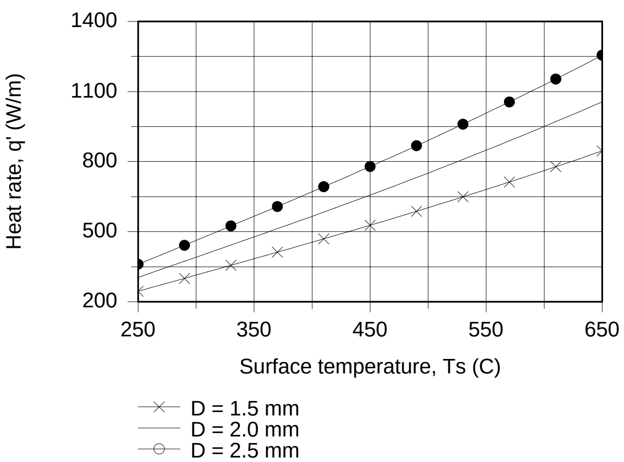
Continued...

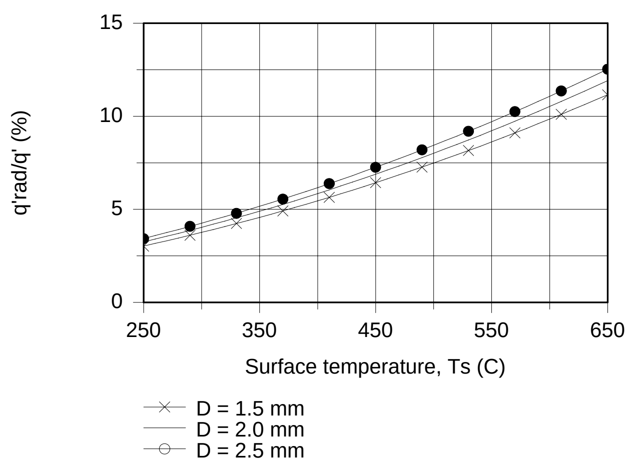
PROBLEM 10.31 (Cont.)

The heat rate is

$$q' = 300\,\mathrm{W/m^2 \cdot K} \times \pi(0.002\mathrm{m}) \times 455\,\mathrm{K} = 858\,\mathrm{kW/m}. \qquad <$$

(b) Using the *IHT Correlation Tool, Boiling, Film Pool Boiling,* combined with the *Properties Tool* for *Water Vapor*, the heat rate, q', was calculated as a function of the surface temperature, T_s, for conductor diameters of 1.5, 2.0, and 2.5 mm. Also plotted below is the ratio (%) of q'_{rad}/q' as a function of surface temperature.





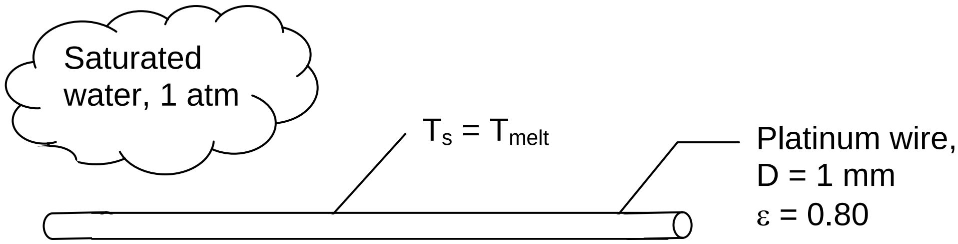
From the q' vs. T_s plot, note that the heat rate increases with increasing surface temperature, and as expected, the heat rate increases with increasing diameter. From the q'_{rad}/q' vs. T_s plot, the maximum contribution by radiation is 14%, and occurs at the maximum surface temperature.

PROBLEM 10.32

KNOWN: Diameter and emissivity of heated platinum wire in saturated water at atmospheric pressure. Water vapor properties at film temperature.

FIND: Heat flux from wire when it is at its melting temperature and corresponding centerline temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Film pool boiling occurs.

PROPERTIES: *Table A.1*, Platinum: T_{melt} = 2045 K, k_p = 99.4 W/m·K. *Table A.6*, Saturated water, liquid (T_{sat} = 100°C, 1 atm): ρ_ℓ = 957.9 kg/m^3, h_{fg} = 2257 kJ/kg; Water vapor at film temperature (T_f = 1209 K, 1 atm), given: ρ_v = 0.189 kg/m^3, $c_{p,v}$ = 2404 J/kg·K, $\nu_v = 231 \times 10^{-6}$ N·s/m^2, k_v = 0.113 W/m·K.

ANALYSIS: The heat flux is

$$q_s'' = \bar{h}\left(T_s - T_{sat}\right) = \bar{h}\Delta T_e \qquad (1)$$

where ΔT_e = (2045 - 373)K = 1672 is indicative of film boiling. From Eq. 10.9,

$$\bar{h}^{4/3} = \bar{h}_{conv}^{4/3} + \bar{h}_{rad}\bar{h}^{1/3}$$

For $\bar{h}_{conv}$ use Eq. 10.8 with C = 0.62 for a horizontal cylinder,

$$\overline{Nu}_D = \frac{\bar{h}_{conv}D}{k_v} = C\left[\frac{g\left(\rho_\ell - \rho_v\right)h'_{fg}D^3}{\nu_v k_v\left(T_s - T_{sat}\right)}\right]^{1/4}$$

$$\frac{\bar{h}_{conv} \times 0.001\,\text{m}}{0.113\,\text{W/m}\cdot\text{K}} = 0.62\left[\frac{9.8\,\text{m/s}^2\left(957.9 - 0.189\right)\text{kg/m}^3 \times 5473 \times 10^3\,\text{J/kg}\left(0.001\,\text{m}\right)^3}{231 \times 10^{-6}\,\text{m/s}^2 \times 0.113\,\text{W/m}\cdot\text{K}\left(2045 - 373\right)\text{K}}\right]^{1/4}$$

$$\bar{h}_{conv} = 410\ \text{W/m}^2\cdot\text{K}$$

where

$h'_{fg} = h_{fg} + 0.8c_{p,v}\left(T_s - T_{sat}\right) = 2257\,\text{kJ/kg} + 0.8 \times 2.404\,\text{kJ/kg}\cdot\text{K}\left(2045 - 373\right)\text{K} = 5473\,\text{kJ/kg}$. To estimate the radiation coefficient, use Eq. 10.11,

$$\bar{h}_{rad} = \frac{\varepsilon\sigma\left(T_s^4 - T_{sat}^4\right)}{T_s - T_{sat}} = \frac{0.80 \times 5.67 \times 10^{-8}\ \text{W/m}^2\cdot\text{K}^4\left(2045^4 - 373^4\right)\text{K}^4}{\left(2045 - 373\right)\text{K}} = 474\,\text{W/m}^2\cdot\text{K}.$$

Continued…

PROBLEM 10.32 (Cont.)

Then Eq. 10.9 becomes

$$\bar{h}^{4/3} = \left(410\ \text{W/m}^2 \cdot \text{K}\right)^{4/3} + \left(474\ \text{W/m}^2 \cdot \text{K}\right)\bar{h}^{1/3}$$

Solving iteratively, find $\bar{h} = 802\,\text{W}/\text{m}^2 \cdot \text{K}$. Then, using Eq. (1), find

$$q_s'' = 802\,\text{W}/\text{m}^2 \cdot \text{K}\left(2045 - 373\right)\text{K} = 1.34\,\text{MW}/\text{m}^2. \qquad <$$

The volumetric heat generation rate due to the electrical current can be found from the energy balance,

$$q_s''\pi D = \dot{q}\pi D^2 / 4 \qquad \dot{q} = 4q'' / D = 4 \times 1.34\ \text{MW/m}^2 / 0.001\ \text{m} = 5.36 \times 10^9\ \text{W/m}^3$$

From Eq. 3.59,

$$T_c = T(r = 0) = \frac{\dot{q}r_o^2}{4k} + T_s$$

$$= \frac{5.36 \times 10^9\ \text{W/m}^2 \times (0.0005\ \text{m})^2}{4 \times 99.4\ \text{W/m} \cdot \text{K}} + 2045\ \text{K} = 2048\ \text{K} \qquad <$$

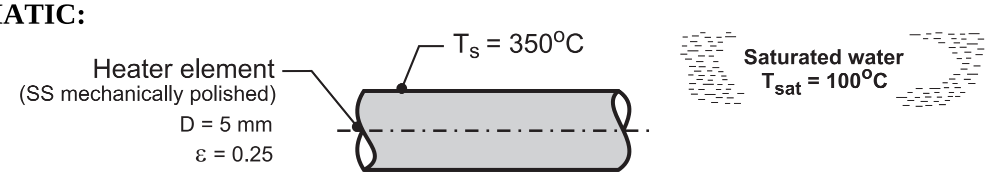
COMMENTS: (1) The film boiling heat flux which causes the platinum wire to melt is not much greater than the critical heat flux. A system which was operating near the critical heat flux and underwent a small, unintentional increase in electrical power could cause destruction of the wire. (2) Radiation accounts for 60% of the heat flux from the wire at burnout. (3) Radial temperature differences in the wire are small because of the small radius and large thermal conductivity.

PROBLEM 10.33

KNOWN: Heater element of 5-mm diameter maintained at a surface temperature of 350°C when immersed in water under atmospheric pressure; element sheath is stainless steel with a mechanically polished finish having an emissivity of 0.25.

FIND: (a) The electrical power dissipation and the rate of evaporation per unit length; (b) If the heater element were operated at the same power dissipation rate in the nucleate boiling regime, what temperature would the surface achieve? Calculate the rate of evaporation per unit length for this operating condition; and (c) Make a sketch of the boiling curve and represent the two operating conditions of parts (a) and (b). Compare the results of your analysis. If the heater element is operated in the power-controlled mode, explain how you would achieve these two operating conditions beginning with a cold element.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, and (2) Water exposed to standard atmospheric pressure and uniform temperature, T_{sat}.

PROPERTIES: *Table A-6*, Saturated water, liquid (100°C): $\rho_\ell = 957.9\ \text{kg/m}^3$, $c_{p,\ell} = 4217$ J/kg·K, $\mu_\ell = 279 \times 10^{-6}\ \text{N}\cdot\text{s/m}^2$, $\text{Pr}_\ell = 1.76$, h_{fg} = 2257 kJ/kg, $h'_{fg} = h_{fg} + 0.80\ c_{p,v}(T_s - T_{sat})$ = 2654 kJ/kg, σ = 58.9 × 10^{-3} N/m; Saturated water, vapor (100°C): ρ_v = 0.5955 kg/m^3; *Table A-4*, Water vapor ($T_f \approx$ 500 K): ρ_v = 0.4405 kg/m^3, $c_{p,v}$ = 1985 J/kg·K, k_v = 0.0339 W/m·K, ν_v = 38.68 × 10^{-6} m^2/s.

ANALYSIS: (a) Since ΔT_e > 120°C, the element is operating in the *film-boiling* (FB) regime. The electrical power dissipation per unit length is

$$q'_s = \bar{h}(\pi D)(T_s - T_{sat}) \tag{1}$$

where the total heat transfer coefficient is

$$\bar{h}^{4/3} = \bar{h}_{conv}^{4/3} + \bar{h}_{rad}\,\bar{h}^{1/3} \tag{2}$$

The convection coefficient is given by the correlation, Eq. 10.8, with C = 0.62,

$$\frac{\bar{h}_{conv} D}{k_v} = C\left[\frac{g(\rho_\ell - \rho_v)h'_{fg}D^3}{\nu_v k_v (T_s - T_{sat})}\right]^{1/4} \tag{3}$$

$$\bar{h}_{conv} = \frac{0.339\ \text{W/m}\cdot\text{K}}{0.005\ \text{m}}(0.62)\left[\frac{9.8\ \text{m/s}^2(833.9 - 0.4405)\text{kg/m}^3 \times 2.654\times10^6\ \text{J/kg}\cdot\text{K}(0.005\ \text{m})^3}{38.68\times10^{-6}\text{m}^2/\text{s}\times 0.0339\ \text{W/m}\cdot\text{K}(350-100)\text{K}}\right]^{1/4}$$

$$\bar{h}_{conv} = 225\ \text{W/m}^2\cdot\text{K}$$

The radiation coefficient, Eq. (10.11), with σ = 5.67 × 10^{-8} W/m^2·K^4, is

PROBLEM 10.33 (Cont.)

$$\bar{h}_{rad} = \frac{\varepsilon\sigma\left(T_s^4 - T_{sat}^4\right)}{\left(T_s - T_{sat}\right)}$$

$$\bar{h}_{rad} = \frac{0.25\sigma\left(623^4 - 373^4\right)K^4}{(350-100)K} = 7.4\ W/m^2\cdot K$$

Substituting numerical values into Eq. (2) for $\bar{h}$, and into Eq. (1) for q'_s, find

$$\bar{h} = 231\ W/m^2\cdot K$$

$$q'_s = 231\,W/m^2\cdot K\left(\pi\times0.005\ m\right)(350-100)K = 907\ W/m$$ <

$$q''_s = q'_s/\pi D = 57.8\ kW/m^2$$

The evaporation rate per unit length is

$$\dot{m}'_b = q'_s/h_{fg} = 1.4\ kg/h\cdot m$$ <

(b) For the same heat flux, $q''_s = 57.8\ kW/m^2$, using the Rohsenow correlation for the *nucleate boiling* (NB) regime, find ΔT_e, and hence T_s.

$$q''_s = \mu_\ell h_{fg}\left[\frac{g\left(\rho_\ell - \rho_v\right)}{\sigma}\right]^{1/2}\left(\frac{c_{p,\ell}\,\Delta T_e}{C_{s,f}h_{fg}\,Pr_\ell^n}\right)^3$$

where, from Table 10.1, for stainless steel mechanically polished finish with water, $C_{s,f}$ = 0.0132 and n = 1.0.

$$57.8\times10^3\,W/m^2 = 279\times10^{-6}\,N\cdot s/m^2\times2.257\times10^6\,J/kg$$

$$\times\left[\frac{9.8\ m/s^2\,(957.9-0.5955)\,kg/m^3}{58.9\times10^{-3}\,N/m}\right]^{1/2}$$

$$\times\left(\frac{4217\ J/kg\cdot K\times\Delta T_e}{0.0132\times2.257\times10^6\,J/kg\times1.76}\right)^3$$

$$\Delta T_e = T_s - T_{sat} = 7.6\ K \qquad T_s = 107.6°C$$ <

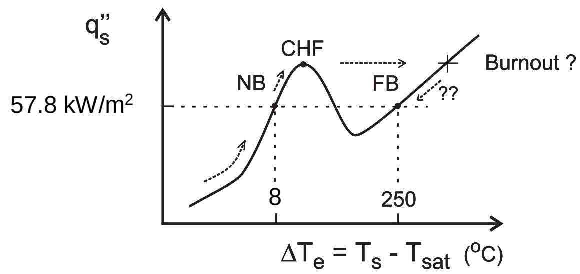
The evaporation rate per unit length is

$$\dot{m}'_b = q''_s\left(\pi D\right)h_{fg} = 1.4\ kg/h\cdot m$$ <

Continued …

PROBLEM 10.33 (Cont.)

(c) The two operating conditions are shown on the boiling curve, which is fashioned after Figure 10.4. For FB the surface temperature is $T_s = 350°C$ ($\Delta T_e = 250°C$). The element can be operated at NB with the same heat flux, $q''_s = 57.8\ kW/m^2$, with a surface temperature of $T_s = 108°C$ ($\Delta T_e = 8°C$). Since the heat fluxes are the same for both conditions, the evaporation rates are the same.



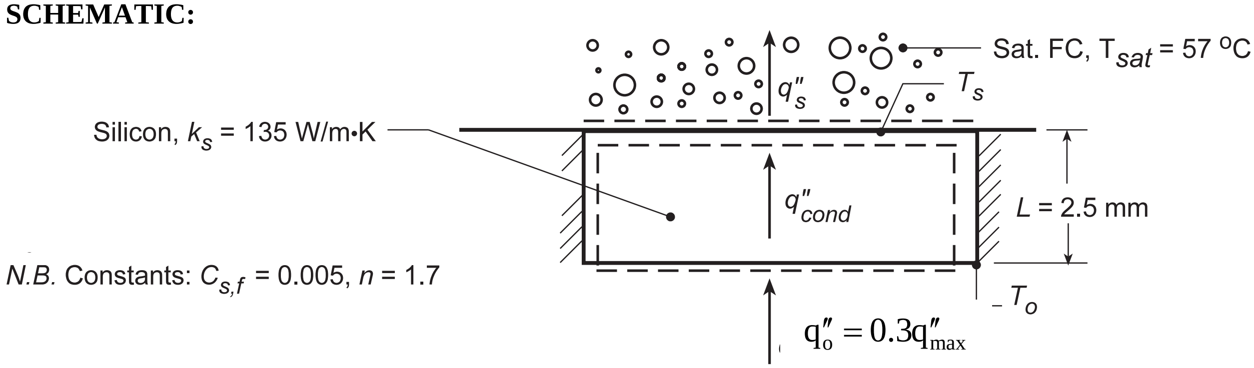
If the element is cold, and operated in a power-controlled mode, the element would be brought to the NB condition following the arrow shown next to the boiling curve near $\Delta T_e = 0$. If the power is increased beyond that for the NB point, the element will approach the critical heat flux (CHF) condition. If q''_s is increased beyond q''_{max}, the temperature of the element will increase abruptly, and the burnout condition will likely occur. If burnout does not occur, reducing the heat flux would allow the element to reach the FB point.

PROBLEM 10.34

KNOWN: Thickness and thermal conductivity of silicon chip. Properties of saturated fluorocarbon boiling on top of chip. Nucleate boiling constants. Surge in heat flux causes film boiling, then returns to 30% of critical heat flux.

FIND: (a) Boiling regime when heat flux returns to original value. (b) How much clock speed must be reduced to return to nucleate boiling regime.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform heat flux and adiabatic sides, hence one-dimensional conduction in chip, (3) Constant properties.

PROPERTIES: Saturated fluorocarbon (given): $c_{p,\ell}$ = 1100 J/kg·K, h_{fg} = 84,400 J/kg, ρ_ℓ = 1619.2 kg/m^3, ρ_v = 13.4 kg/m^3, $\sigma = 8.1 \times 10^{-3}$ kg/s^2, $\mu_\ell = 440 \times 10^{-6}$ kg/m·s, Pr_ℓ = 9.01.

ANALYSIS: (a) We begin by calculating the critical heat flux from Eq. 10.6 with C = 0.149 for a large horizontal plate.

$$q''_{max} = 0.149 h_{fg}\rho_v\left[\frac{\sigma g(\rho_\ell - \rho_v)}{\rho_v^2}\right]^{1/4}$$

$$= 0.149 \times 84,400\,\text{J/kg} \times 13.4\,\text{kg/m}^3 \times \left[\frac{8.1\times10^{-3}\,\text{kg/s}^2 \times 9.8\,\text{m/s}^2\,(1619.2 - 13.4)\,\text{kg/m}^3}{\left(13.4\,\text{kg/m}^3\right)^2}\right]^{1/4}$$

$$= 1.55\times10^5\ \text{W/m}^2$$

Thus the design heat flux is $q''_{des} = 0.3q''_{max} = 4.64\times10^4\ \text{W/m}^2$. When a power surge causes film boiling and then the heat flux returns to this value, the regime will still be film boiling if this value exceeds the minimum heat flux. However, if it drops below the minimum heat flux it will return to nucleate boiling. The minimum heat flux can be calculated from Eq. 10.7,

$$q''_{min} = 0.09 h_{fg}\rho_v\left[\frac{\sigma g(\rho_\ell - \rho_v)}{(\rho_\ell + \rho_v)^2}\right]^{1/4}$$

Continued...

PROBLEM 10.34 (Cont.)

$$q''_{min} = 0.09 \times 84,400\,\text{J/kg} \times 13.4\,\text{kg}/\text{m}^3 \times \left[\frac{8.1 \times 10^{-3}\,\text{kg}/\text{s}^2 \times 9.8\,\text{m}/\text{s}^2 (1619.2 - 13.4)\,\text{kg}/\text{m}^3}{\left(1619.2 + 13.4\,\text{kg}/\text{m}^3\right)^2} \right]^{1/4}$$

$$= 8.46 \times 10^3\ \text{W/m}^2$$

Thus $q''_{des} > q''_{min}$ and the chip will operate in the film boiling regime after the heat flux returns to the design value. <

(b) The heat flux must be reduced below $q''_{min} = 8.46 \times 10^3\ \text{W/m}^2$ in order to return to the nucleate boiling regime. That is, it must be reduced to 18% of the design value, or a reduction of 82%. <

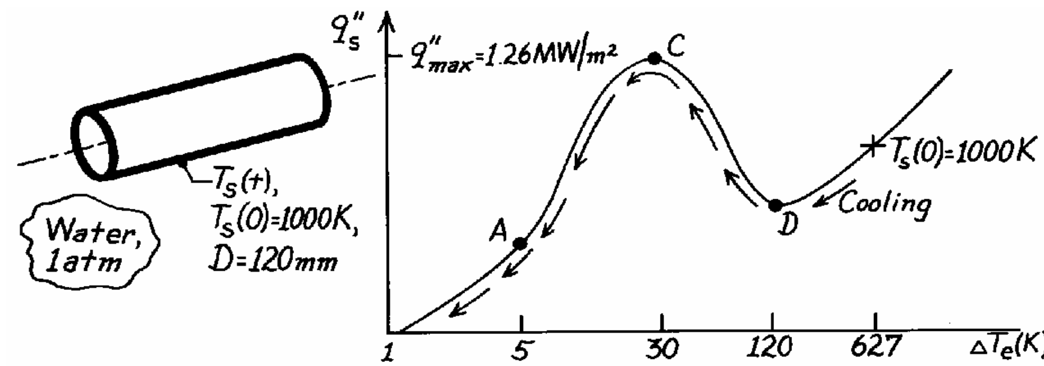
COMMENTS: In addition to having limited capability to cool VLSI chips (see Solution to Problem 10.23), boiling limits their reliability since, for all practical purposes, the chip must cease functioning in order to return to a safe operating condition.

PROBLEM 10.35

KNOWN: Cylinder of 120 mm diameter at 1000K quenched in saturated water at 1 atm

FIND: Describe the quenching process and estimate the maximum heat removal rate per unit length during cooling.

SCHEMATIC:



ASSUMPTIONS: Water exposed to 1 atm pressure, T_{sat} = 100°C.

ANALYSIS: At the start of the quenching process, the surface temperature is $T_s(0)$ = 1000K. Hence, $\Delta T_e = T_s - T_{sat}$ = 1000K – 373K = 627K, and from the typical boiling curve of Figure 10.4, film boiling occurs, with $q'' < q''_{max}$.

As the cylinder temperature decreases, ΔT_e decreases, and the cooling process follows the boiling curve sketched above. The cylinder boiling process passes through the Leidenfrost point D, into the transition or unstable boiling regime (D → C).

At point C, the boiling heat flux has reached a maximum, q''_{max} = 1.26 MW/m^2 (see Example 10.1). Hence, the heat rate per unit length of the cylinder is

$$q'_s = q'_{max} = q''_{max}(\pi D) = 1.26\,\text{MW/m}^2\left[\pi(0.120\text{m})\right] = 0.475\,\text{MW/m.} \qquad <$$

As the cylinder cools further, nucleate boiling occurs (C → A) and the heat rate drops rapidly. Finally, at point A, boiling no longer is present and the cylinder is cooled by free convection.

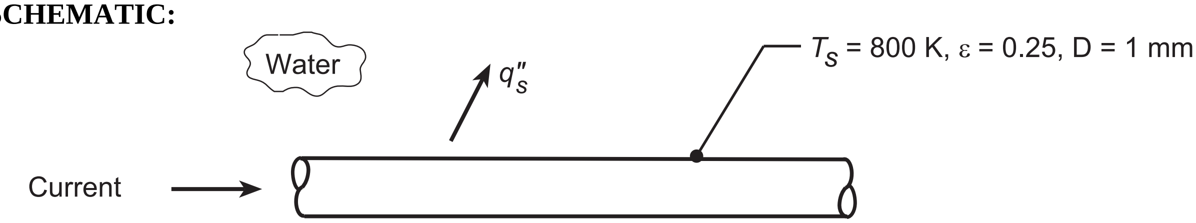
COMMENTS: Why doesn't the quenching process follow the cooling curve of Figure 10.3?

PROBLEM 10.36

KNOWN: Horizontal platinum wire of diameter of 1 mm, emissivity of 0.25, and surface temperature of 800 K in saturated water at 1 atm pressure.

FIND: (a) Surface heat flux, q''_s, when the surface temperature is T_s = 800 K and (b) Compute and plot on log-log coordinates the heat flux as a function of the excess temperature, $\Delta T_e = T_s - T_{sat}$, for the range $150 \le \Delta T_e \le 550$ K for emissivities of 0.1, 0.25, and 0.95; separately plot the percentage contribution of radiation as a function of ΔT_e.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Film pool boiling.

PROPERTIES: *Table A.6*, Saturated water, liquid (T_{sat} = 100°C, 1 atm): ρ_ℓ = 957.9 kg/m^3, h_{fg} = 2257 kJ/kg; *Table A.4*, Water, vapor ($T_f = (T_s + T_{sat})/2$ = (800 + 373)K/2 = 587 K): ρ_v = 0.3744 kg/m^3, $c_{p,v}$ = 2018 J/kg·K, $\nu_v = 54.11 \times 10^{-6}$ m^2/s, $k_v = 41.1 \times 10^{-3}$ W/m·K.

ANALYSIS: (a) The heat flux is

$$q''_s = \overline{h}\left(T_s - T_{sat}\right) = \overline{h}\Delta T_e$$

where ΔT_e = (800 - 373)K = 427 is indicative of film boiling. From Eq. 10.9 or 10.10,

$$\overline{h}^{4/3} = \overline{h}_{conv}^{4/3} + \overline{h}_{rad}\overline{h}^{-1/3} \qquad \text{or} \qquad \overline{h} = \overline{h}_{conv} + (3/4)\overline{h}_{rad}$$

if $h_{rad} < h_{conv}$. Use Eq. 10.8 with C = 0.62 for a horizontal cylinder,

$$\overline{Nu}_D = \frac{\overline{h}_{conv}D}{k_v} = C\left[\frac{g\left(\rho_\ell - \rho_v\right)h'_{fg}D^3}{\nu_v k_v\left(T_s - T_{sat}\right)}\right]^{1/4}$$

$$\frac{\overline{h}_{conv} \times 0.001\,\text{m}}{41.1\times10^{-3}\ \text{W/m}\cdot\text{K}} = 0.62\left[\frac{9.8\,\text{m/s}^2\left(957.9 - 0.3744\right)\text{kg/m}^3 \times 2946\,\text{kJ/kg}\left(0.001\,\text{m}\right)^3}{\left(54.11\times10^{-6}\text{m}^2/\text{s}\right)\times 0.0411\,\text{W/m}\cdot\text{K}\left(800-373\right)\text{K}}\right]^{1/4}$$

$$\overline{h}_{conv} = 333\ \text{W/m}^2\cdot\text{K}$$

where $h'_{fg} = h_{fg} + 0.8c_{p,v}\left(T_s - T_{sat}\right) = 2257\,\text{kJ/kg} + 0.8\times2018\,\text{J/kg}\cdot\text{K}\left(800-373\right)\text{K} = 2946\,\text{kJ/kg}$. To estimate the radiation coefficient, use Eq. 10.11,

$$\overline{h}_{rad} = \frac{\varepsilon\sigma\left(T_s^4 - T_{sat}^4\right)}{T_s - T_{sat}} = \frac{0.25\sigma\left(800^4 - 373^4\right)\text{K}^4}{\left(800-373\right)\text{K}} = 13.0\,\text{W/m}^2\cdot\text{K}.$$

Since $\overline{h}_{rad} < \overline{h}_{conv}$, use the simpler expression,

$$\overline{h} = 333\,\text{W/m}^2\cdot\text{K} + (3/4)13.0\,\text{W/m}^2\cdot\text{K} = 343\,\text{W/m}^2\cdot\text{K}.$$

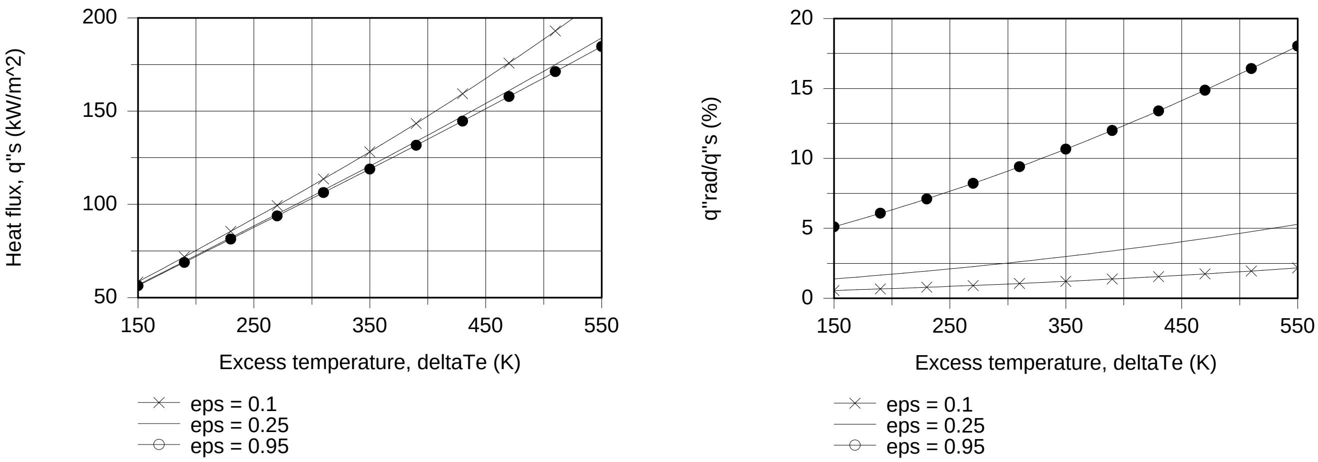
Using the rate equation, find

Continued...

PROBLEM 10.36 (Cont.)

$$q''_s = 343\,\text{W/m}^2\cdot\text{K}\,(800-373)\,\text{K} = 146\ \text{kW/m}^2. \quad <$$

b) Using the *IHT Correlation Tool, Boiling, Film Pool Boiling,* combined with the *Properties Tool* for *Water Vapor*, the heat flux, q''_s, was calculated as a function of the surface temperature, ΔT_e, for emissivities of 0.1, 0.25, and 0.95. Also plotted below is the ratio (%) of q''_{rad}/q''_s as a function of ΔT_e.



From the q''_s vs. ΔT_e plot, note that the heat flux increases with increasing excess temperature and increasing emissivity. The heat flux falls between the minimum heat flux (Liedenfrost point) of 18.9 kW/m^2 and the critical heat flux, 1.26 MW/m^2 (see Example 10.1 for these values), however for sufficiently large excess temperature, the film boiling heat flux will exceed the critical heat flux. From the q''_{rad}/q''_s vs. ΔT_e plot, the maximum contribution by radiation is around 16%, and occurs at the maximum surface temperature.

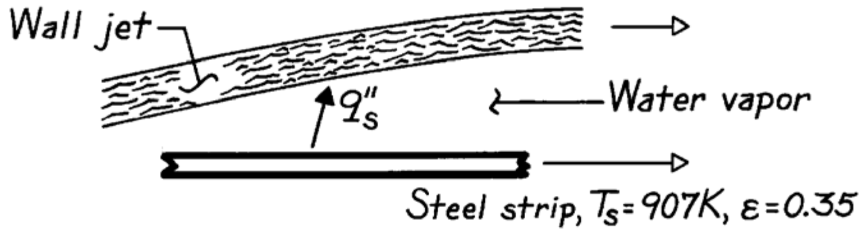
COMMENTS: Since $q''_s < q''_{max} = 1.26\,\text{MW/m}^2$, the prescribed condition can only be achieved in power-controlled heating by first exceeding q''_{max} and then decreasing the flux to 146 kW/m^2.

PROBLEM 10.37

KNOWN: Surface temperature and emissivity of strip steel.

FIND: Heat flux across vapor blanket.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Vapor/jet interface is at T_{sat} for p = 1 atm, (3) Negligible effect of jet and strip motion.

PROPERTIES: *Table A-6*, Saturated water (100°C): ρ_ℓ = 957.9 kg/m^3, h_{fg} = 2257 kJ/kg; *Table A-4*, Water vapor (T_f = 640K): ρ_v = 0.3434 kg/m^3, $c_{p,v}$ = 2050 J/kg·K, ν_v = 64.50 × 10^{-6} m^2/s, k = 0.0456 W/m·K.

ANALYSIS: The heat flux is $q''_s = \bar{h}\Delta T_e$

where $\quad \Delta T_e = 907\text{ K} - 373\text{ K} = 534\text{ K}$

and $\quad \bar{h}^{4/3} = \bar{h}_{conv}^{4/3} + \bar{h}_{rad}\bar{h}^{1/3} \quad$ or $\quad \bar{h} = \bar{h}_{conv} + (3/4)\bar{h}_{rad}. \qquad (1,2)$

With $\quad h'_{fg} = h_{fg} + 0.80c_{p,v}\left(T_s - T_{sat}\right) = 3.13\times10^6\text{ J/kg}$

Equation 10.9 yields

$$\overline{Nu}_D = 0.62\left[\frac{9.8\,\text{m/s}^2\left(957.9-0.3434\right)\text{kg/m}^3\left(3.13\times10^6\text{ J/kg}\right)\left(1\text{ m}\right)^3}{64.50\times10^{-6}\text{ m}^2\text{/s}\left(0.0456\text{ W/m}\cdot\text{K}\right)\left(907-373\right)\text{K}}\right]^{1/4} = 1290.$$

Hence,

$$\bar{h}_{conv} = \overline{Nu}_D k_v / D = 1290\,\text{W/m}^2\cdot\text{K}\left(0.0456\text{ W/m}\cdot\text{K}/1\text{ m}\right) = 58.8\text{ W/m}^2\cdot\text{K}$$

$$\bar{h}_{rad} = \frac{\varepsilon\sigma\left(T_s^4 - T_{sat}^4\right)}{T_s - T_{sat}} = \frac{0.35\times5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4\left(907^4 - 373^4\right)\text{K}^4}{\left(907-373\right)\text{K}}$$

$$\bar{h}_{rad} = 24\text{ W/m}^2\cdot\text{K}$$

Hence, $\quad \bar{h} = 58.8\text{ W/m}^2\cdot\text{K} + (3/4)\left(24\text{ W/m}^2\cdot\text{K}\right) = 77.1\text{ W/m}^2\cdot\text{K}$

Since h_{conv} and h_{rad} are the same order of magnitude, greater accuracy can be found by iterating on Eq.(1), which yields $\bar{h}$ =78.0 W/m^2·K. Then,

$$q''_s = 78.0\text{ W/m}^2\cdot\text{K}\left(907-373\right)\text{K} = 4.16\times10^4\text{ W/m}^2. \qquad <$$

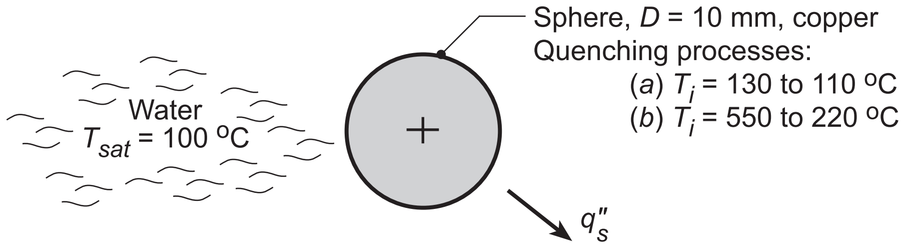
COMMENTS: The foregoing analysis is a very rough approximation to a complex problem. A more rigorous treatment is provided by Zumbrunnen et al. in ASME Paper 87-WA/HT-5.

PROBLEM 10.38

KNOWN: Copper sphere, 10 mm diameter, initially at a prescribed elevated temperature is quenched in a saturated (1 atm) water bath.

FIND: The time for the sphere to cool (a) from T_i = 130 to 110°C and (b) from T_i = 550°C to 220°C .

SCHEMATIC:



ASSUMPTIONS: (1) Sphere approximates lumped capacitance, (2) Water saturated at 1 atm, (3) Negligible radiation during film boiling process due to low emissivity of polished copper, (4) Average sphere temperature can be used in evaluating properties.

PROPERTIES: *Table A-1*, Copper: ρ = 8933 kg/m^3, (T = (130 + 120)°C/2 = 110°C = 383 K) c_p = 392 J/kg · K; (T = (550 + 220)°C/2 = 385°C = 658 K, c_p = 422 J/kg · K. *Table A.11*, Copper (polished) : ε = 0.04, typical value; *Table A.6*, *Water* (T = 373 K), $\rho_l = 1/v_f$ = 958 kg/m^3, $\rho_v = 1/v_g$ = 0.596 kg/m^3, h_{fg} = 2257 kJ/kg, $c_{p,l}$ = 4.217 kJ/kg · K, μ_l = 279 × 10^{-6} N · s/m^2, σ = 58.9 × 10^{-3} N/m, Pr_l = 1.76; *Table A.4, Water* ($T_f = (T_s + T_{sat})/2 \approx$ 515 K), $\rho_v = 1/v_g$ = 0.428 kg/m^3, $c_{p,v}$ = 1.989 kJ/kg · K, ν_v =4.13 × 10^{-5} m^2/s, k_v = 0.0351 W/m · K.

ANALYSIS: For a heat transfer coefficient of the form given by Eq. 5.26, namely $h = C(T - T_\infty)^n$, the temperature distribution is given by Eq. 5.28. For boiling, T_∞ is replaced with T_{sat} in the expression for h. Making use of this substitution in Eq. 5.28 yields

$$\frac{\theta}{\theta_i} = \frac{T - T_{sat}}{T_i - T_{sat}} = \left[\frac{nCA_{s,c}(T_i - T_{sat})^n}{\rho V c} t + 1\right]^{-1/n} \qquad (1)$$

Solving for t,

$$t = \frac{\rho V c}{nCA_{s,c}(T_i - T_{sat})^n}\left[\left(\frac{T - T_{sat}}{T_i - T_{sat}}\right)^{-n} - 1\right] \qquad (2)$$

(a) For cooling from T_i =130° to 110°C, with T_{sat} = 100°C, ΔT_e = 30° to 10°C. From Figure 10.4 the regime is nucleate pool boiling. From the Rohsenow correlation, Eq. 10.5, $h = q''_s / \Delta T_e = C(\Delta T_e)^2$, where

$$C = \mu_l h_{fg}\left[\frac{g(\rho_l - \rho_v)}{\sigma}\right]^{1/2}\left(\frac{c_{p,l}}{C_{s,f} h_{fg} Pr_l^m}\right)^3$$

Note that exponent m has been used instead of n, to distinguish from the n exponent in Eqs. (1) and (2). From Table 10.1, $C_{s,f}$ = 0.0128, m = 1.0, thus

Continued...

PROBLEM 10.38 (Cont.)

$$C = 279\times10^{-6}\ \text{N}\cdot\text{s/m}^2\times2257\times10^3\ \text{J/kg}\times\left[\frac{9.81\ \text{m/s}^2(958\ \text{kg/m}^3-0.596\ \text{kg/m}^3)}{58.9\times10^{-3}\ \text{N/m}}\right]^{1/2}$$

$$\times\left(\frac{4217\ \text{J/kg}\cdot\text{K}}{0.0128\times2257\times10^3\ \text{J/kg}\times1.76^{1.0}}\right)^3 = 143\ \text{W/m}^2\cdot\text{K}^3$$

Thus, from Eq. (2), with $n = 2$

$$t = \frac{8933\ \text{kg/m}^3\times395\ \text{J/kg}\cdot\text{K}\times0.010\ \text{m/6}}{2\times143\ \text{W/m}^2\cdot\text{K}^3\times(130°\text{C}-100°\text{C})^2}\left[\left(\frac{110°\text{C}-100°\text{C}}{130°\text{C}-100°\text{C}}\right)^{-2}-1\right] = 0.18\ \text{s} \qquad <$$

(b) For cooling from T_i =550° to 220°C, with T_{sat} = 100°C, ΔT_{e} = 450° to 120°C. From Figure 10.4 the regime is film pool boiling. From Eq. 10.8 with C = 0.67 for a sphere, $h = C(\Delta T_e)^{-1/4}$, where

$$C = 0.67\frac{k_v}{D}\left[\frac{g(\rho_l-\rho_v)h'_{fg}D^3}{\nu_v k_v}\right]^{1/4}$$

In this expression, h'_{fg} is a function of temperature, $h'_{fg} = h_{fg} + 0.80c_{p,v}(T - T_{\text{sat}})$. However, since Eqs. (1) and (2) are only valid for C = const., we evaluate h'_{fg} at the average temperature, T = (550 + 220)°C/2 = 385°C. This is a reasonable approximation since the temperature-dependent second term is substantially smaller than h_{fg}. Thus,

$$h'_{fg} = h_{fg} + 0.80c_{p,v}(T - T_{\text{sat}}) = 2257\ \text{kJ/kg} + 0.80\times1.989\ \text{kJ/kg}\cdot\text{K}\times(385-100)°\text{C} = 2710\ \text{kJ/kg}$$

and

$$C = 0.67\frac{0.0351\ \text{W/m}\cdot\text{K}}{0.010\ \text{m}}\left[\frac{9.81\ \text{m/s}^2(958\ \text{kg/m}^3-0.428\ \text{kg/m}^3)\times2710\times10^3\ \text{J/kg}\times(0.010\ \text{m})^3}{4.13\times10^{-5}\ \text{m}^2/\text{s}\times0.0351\ \text{W/m}\cdot\text{K}}\right]^{1/4}$$

$$= 856\ \text{W/m}^2\cdot\text{K}^{3/4}$$

Thus, from Eq. (2), with $n = -1/4$,

$$t = \frac{8933\ \text{kg/m}^3\times422\ \text{J/kg}\cdot\text{K}\times0.010\ \text{m/6}}{-(1/4)\times856\ \text{W/m}^2\cdot\text{K}^{3/4}\times(550°\text{C}-100°\text{C})^{-1/4}}\left[\left(\frac{220°\text{C}-100°\text{C}}{550°\text{C}-100°\text{C}}\right)^{1/4}-1\right] = 38.0\ \text{s} \qquad <$$

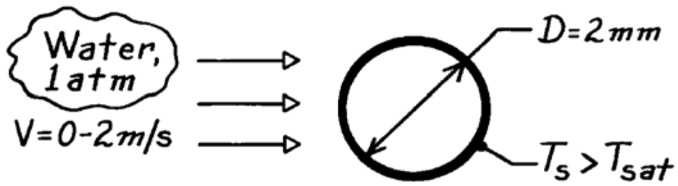
COMMENTS: Comparing the elapsed times for the two processes, the nucleate pool boiling process cools 20°C in 0.18s (110°C/s) vs. 330°C in 38.0s (8.7°C/s) for the film pool boiling process.

PROBLEM 10.39

KNOWN: Saturated water at 1 atm is heated in cross flow with velocities 0 – 2 m/s over a 2 mm-diameter tube.

FIND: Plot the critical heat flux as a function of water velocity; identify the pool boiling and transition regions between the low and high velocity ranges.

SCHEMATIC:



ASSUMPTIONS: Nucleate boiling in the presence of external forced convection.

PROPERTIES: *Table A-6*, Water (1 atm): $T_{sat} = 100°C$, $\rho_\ell = 957.9\ kg/m^3$, $\rho_v = 0.5955\ kg/m^3$, $h_{fg} = 2257\ kJ/kg$, $\sigma = 58.9 \times 10^{-3}\ N/m$.

ANALYSIS: The Lienhard-Eichhorn correlations for forced convection boiling with cross flow over a cylinder are appropriate for estimating q''_{max}, Eqs. 10.12 and 10.13.

Low Velocity

$$q''_{max} = \frac{\rho_v h_{fg}}{\pi}\left[1+\left(\frac{4\sigma}{\rho_v V^2 D}\right)^{1/3}\right]V$$

$$q''_{max} = \frac{1}{\pi}0.5955\frac{kg}{m^3}\times 2257\times 10^3\frac{J}{kg}\left[1+\left(\frac{4\times 58.9\times 10^{-3}\,N/m}{0.5955 kg/m^3 V^2 0.002m}\right)^{1/3}\right]V$$

$$q''_{max} = 4.2782\times 10^5 V + 2.493\times 10^6 V^{1/3}.$$

High Velocity

$$q''_{max} = \frac{\rho_v h_{fg}}{\pi}\left[\frac{1}{169}\left(\frac{\rho_\ell}{\rho_v}\right)^{3/4} + \frac{1}{19.2}\left(\frac{\rho_\ell}{\rho_v}\right)^{1/2}\left(\frac{\sigma}{\rho_v V^2 D}\right)^{1/3}\right]V$$

$$q''_{max} = \frac{1}{\pi}0.5955\frac{kg}{m^3}\times 2257\times 10^3\frac{J}{kg}\left[\frac{1}{169}\left(\frac{957.9}{0.5955}\right)^{3/4} + \right.$$

$$\left.\frac{1}{19.2}\left(\frac{957.9}{0.5955}\right)^{1/2}\left(\frac{58.9\times 10^{-3}\,N/m}{0.5955\,kg/m^3 V^2\,0.002m}\right)^{1/3}\right]V$$

$$q''_{max} = 6.4299\times 10^5 V + 3.280\times 10^6 V^{1/3}$$

Continued …

PROBLEM 10.39 (Cont.)

The *transition* between the low and high velocity regions occurs when

$$q''_{max} = \rho_v h_{fg} V\left[\frac{0.275}{\pi}\left(\frac{\rho_\ell}{\rho_v}\right)^{1/2} + 1\right]$$

$$q''_{max} = 0.5955\frac{kg}{m^3} \times 2257 \times 10^3 \frac{J}{kg} V\left[\frac{0.275}{\pi}\left(\frac{957.9}{0.5955}\right)^{1/2} + 1\right] = 6.0627 \times 10^6 V. \quad (3)$$

For pool boiling conditions when the velocity is zero, the critical heat flux must be estimated according to the correlation for the small horizontal cylinder as introduced in Problem 10.20. If the cylinder were "large," the critical heat flux would be 1.26 MW/m^2 as given by Eq. 10.6 with C=0.149. The Confinement number and correction factor are

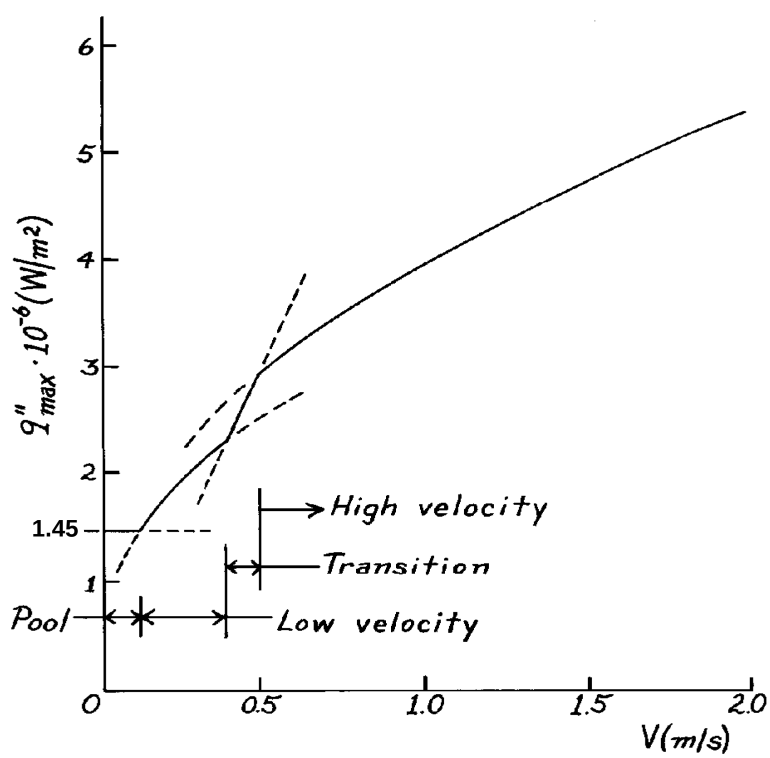
$$Co = \frac{\sqrt{\sigma/g(\rho_\ell - \rho_v)}}{r} = \frac{\sqrt{58.9 \times 10^{-3}\ N/m/9.8\ m/s^2 (957.9 - 0.5955)\ kg/m^3}}{0.001\ m} = 2.51$$

$$F = 0.89 + 2.27 \exp(-3.44\, Co^{-1/2}) = 1.15$$

and the critical heat flux for the "small" 2 mm cylinder is

$$q''_{max})_{pool} = 1.15 \times 1.26\ MW/m^2 = 1.45\ MW/m^2.$$

The graph below identifies four regions: pool boiling where $q''_{max} = 1.45\ MW/m^2$ from V = 0 to 0.17 m/s and the low velocity, transition and high velocity regimes.

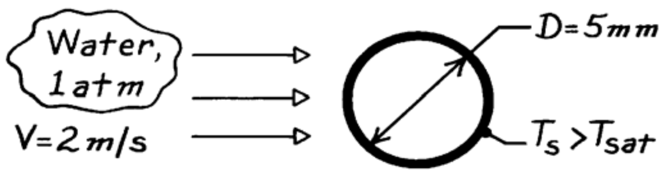


PROBLEM 10.40

KNOWN: Saturated water at 1 atm and velocity 2 m/s in cross flow over a heater element of 5 mm diameter.

FIND: Maximum heating rate, $q'[W/m]$.

SCHEMATIC:



ASSUMPTIONS: Nucleate boiling in the presence of external forced convection.

PROPERTIES: *Table A-6*, Water (1 atm): T_{sat} = 100°C, ρ_ℓ = 957.9 kg/m^3, ρ_v = 0.5955 kg/m^3, h_{fg} = 2257 kJ/kg, σ = 58.9 × 10^{-3} N/m.

ANALYSIS: The Lienhard-Eichhorn correlation for forced convection with cross flow over a cylinder is appropriate for estimating q''_{max}. Assuming high-velocity region flow, Eq. 10.13 with Eq. 10.14 can be written as

$$q''_{max} = \frac{\rho_v h_{fg} V}{\pi}\left[\frac{1}{169}\left(\frac{\rho_\ell}{\rho_v}\right)^{3/4} + \frac{1}{19.2}\left(\frac{\rho_\ell}{\rho_v}\right)^{1/2}\left(\frac{\sigma}{\rho_v V^2 D}\right)^{1/3}\right].$$

Substituting numerical values, find

$$q''_{max} = \frac{1}{\pi}0.5955\,kg/m^3 \times 2257\times10^3\,J/kg \times 2\,m/s\left[\frac{1}{169}\left(\frac{957.9}{0.5955}\right)^{3/4} + \right.$$

$$\left.\frac{1}{19.2}\left(\frac{957.9}{0.5955}\right)^{1/2}\left(\frac{58.9\times10^{-3}\,N/m}{0.5955\,kg/m^3(2\,m/s)^2\,0.005m}\right)^{1/3}\right]$$

$$q''_{max} = 4.331\ MW/m^2.$$

The high-velocity region assumption is satisfied if

$$\frac{q''_{max}}{\rho_v h_{fg} V} \overset{?}{<} \frac{0.275}{\pi}\left(\frac{\rho_\ell}{\rho_v}\right)^{1/2} + 1$$

$$\frac{4.331\times10^6\,W/m^2}{0.5955\,kg/m^3\times2257\times10^3\,J/kg\times2\,m/s} = 1.61 \overset{?}{<} \frac{0.275}{\pi}\left(\frac{957.9}{0.5955}\right)^{1/2} + 1 = 4.51.$$

The inequality is satisfied. Using the q''_{max} estimate, the maximum heating rate is

$$q'_{max} = q''_{max}\cdot\pi D = 4.331\,MW/m^2\times\pi(0.005m) = 68.0\,kW/m. \qquad <$$

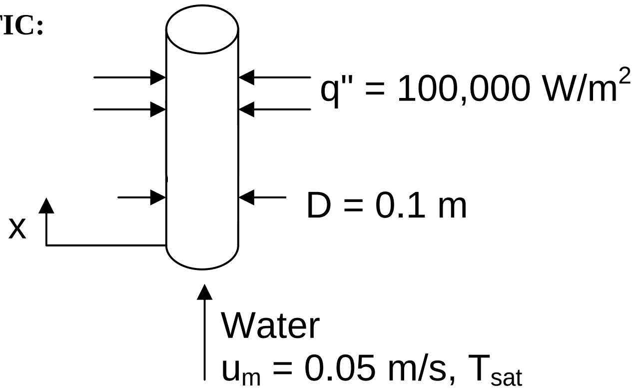
COMMENTS: Note that the effect of the forced convection is to increase the critical heat flux by 4.33/1.26 = 3.4 over the pool boiling case.

PROBLEM 10.41

KNOWN: Diameter and wall heat flux for vertical steel tube. Velocity and pressure of saturated liquid water entering at bottom end.

FIND: (a) Tube wall temperature and water quality at x = 15 m. (b) Tube wall temperature at location where single-phase vapor flow exists at mean temperature T_{sat}. (c) Plot tube wall temperature for -5 m ≤ x ≤ 30 m.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties. (3) $G_{sf} = 1$.

PROPERTIES: *Table A.6*, Saturated water, liquid (10 bars): $T_{sat} = 452.8$ K, $\rho_\ell = 887.3$ kg/m^3, h_{fg} = 2014 kJ/kg, $\mu_\ell = 149.4 \times 10^{-6}$ N·s/m^2, $\nu_\ell = \mu_\ell / \rho_\ell = 1.684 \times 10^{-7}$ m^2/s, $k_\ell = 0.6766$ W/m·K, Pr_ℓ = 0.979. *Table A.4*, water vapor (T = 452.8 K): $\rho_v = 5.094$ kg/m^3, $\mu_v = 14.95 \times 10^{-6}$ N·s/m^2, k_v = 0.03353 W/m·K, $Pr_v = 1.149$.

ANALYSIS: (a) The mass flow rate is

$$\dot{m} = \rho_\ell u_m A_c = 887.3 \text{ kg/m}^3 \times 0.05 \text{ m/s} \times \pi (0.1 \text{ m})^2 / 4 = 0.348 \text{ kg/s}$$

Then from Eq. 10.16,

$$\bar{X}(x = 15 \text{ m}) = \frac{q''_s \pi D x}{\dot{m} h_{fg}} = \frac{100{,}000 \text{ W/m}^2 \times \pi \times 0.1 \text{ m} \times 15 \text{ m}}{0.348 \text{ kg/s} \times 2.014 \times 10^6 \text{ J/kg}} = 0.672 \qquad (1) \qquad <$$

To find the wall temperature, we must first find the convection coefficient from Eq. 10.15. The Reynolds number is

$$Re_D = u_m D / \nu_\ell = 0.05 \text{ m/s} \times 0.1 \text{ m} \big/ 1.684 \times 10^{-7} \text{ m}^2/\text{s} = 2.97 \times 10^4$$

Thus the flow is turbulent and the single phase convection coefficient can be calculated from Eq. 8.62,

$$Nu_D = \frac{(f/8)(Re_D - 1000) Pr_\ell}{1 + 12.7 (f/8)^{1/2} (Pr_\ell^{2/3} - 1)} = \frac{(0.0237/8)(2.97 \times 10^4 - 1000)\, 0.979}{1 + 12.7 (0.0237/8)^{1/2} (0.979^{2/3} - 1)} = 84.0$$

where from Equation 8.21,

$$f = (0.790 \ln Re_D - 1.64)^{-2} = (0.790 \ln (2.97 \times 10^4) - 1.64)^{-2} = 0.0237$$

Thus

$$h_{sp} = Nu_D k_\ell / D = 84.0 \times 0.6766 \text{ W/m} \cdot \text{K} / 0.1 \text{ m} = 568 \text{ W/m}^2 \cdot \text{K}$$

Continued…

PROBLEM 10.41 (Cont.)

We must evaluate h from both Eqs. 10.15a and 10.15b and take the larger value. From Eq. 10.15b (which yields the larger value),

$$\frac{h}{h_{sp}} = 1.136\left(\frac{\rho_\ell}{\rho_v}\right)^{0.45} \overline{X}^{0.72}(1-\overline{X})^{0.08} f(Fr) + 667.2\left(\frac{q_s''}{\dot{m}'' h_{fg}}\right)^{0.7} (1-\overline{X})^{0.8} G_{sf} \qquad (2)$$

$$= 1.136\left(\frac{887.3}{5.094}\right)^{0.45} 0.672^{0.72}(1-0.672)^{0.08} \times 1 + 667.2\left(\frac{10^5 \text{ W/m}^2}{44.4 \text{ kg/m}^2 \cdot \text{s} \times 2.014 \times 10^6 \text{ J/kg}}\right)^{0.7} (1-0.672)^{0.8} \times 1$$

$$= 10.3$$

where $\dot{m}'' = \rho_\ell u_m = 44.4$ kg/m²·K, f(Fr) = 1 for a vertical tube, and $G_{sf} = 1$. Thus h = 10.3(568 W/m²·K) = 5860 W/m²·K and from Eq. 10.3,

$$T_s = T_{sat} + q''/h = 452.8 \text{ K} + 10^5 \text{ W/m}^2 / 5860 \text{ W/m}^2 \cdot \text{K} = 470 \text{ K} = 197°\text{C} \qquad (3)$$ <

(b) The mass flow rate is unchanged, but the viscosity is now that of the vapor, therefore,

$$Re_D = 4\dot{m}/\pi D \mu_v = 4 \times 0.348 \text{ kg/s} / \pi \times 0.1 \text{ m} \times 14.95 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 = 2.97 \times 10^5$$

And once again from Eqs. 8.62 and 8.21,

$$Nu_D = \frac{(f/8)(Re_D - 1000) Pr_v}{1 + 12.7 (f/8)^{1/2}(Pr_v^{2/3} - 1)} = \frac{(0.0145/8)(2.97 \times 10^5 - 1000) 1.149}{1 + 12.7 (0.0145/8)^{1/2}(1.149^{2/3} - 1)} = 584$$

where

$$f = (0.790 \ln Re_D - 1.64)^{-2} = (0.790 \ln (2.97 \times 10^5) - 1.64)^{-2} = 0.0145$$

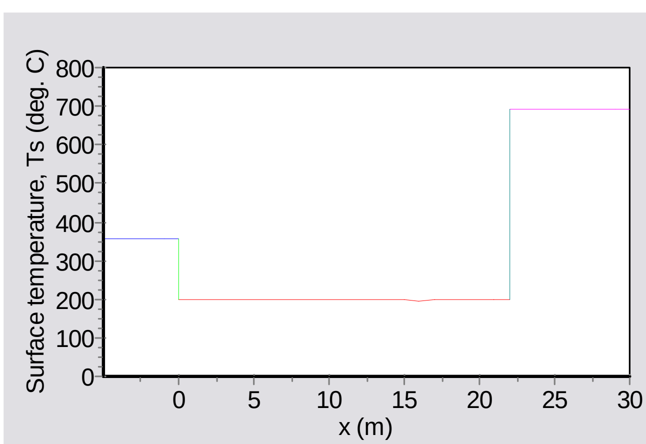
Thus

$$h = Nu_D k_v / D = 584 \times 0.03353 \text{ W/m} \cdot \text{K} / 0.1 \text{ m} = 196 \text{ W/m}^2 \cdot \text{K}$$

and

$$T_s = T_{sat} + q''/h = 452.8 \text{ K} + 10^5 \text{ W/m}^2 / 196 \text{ W/m}^2 \cdot \text{K} = 964 \text{ K} = 691°\text{C}$$ <

(c) For x < 0, the liquid is at its saturation temperature and the heat transfer coefficient is the single-phase value calculated in part (a). Thus the surface temperature is $T_s = T_{sat} + q''/h_{sp} = 356°$C. For x > 0 (until the fluid becomes fully vapor) Eqs. (1), (2), and (3) were entered into the *IHT* workspace along with the property values, previously calculated values of $\dot{m}$, $\dot{m}''$, and h_{sp}, and other inputs. For locations where pure single-phase vapor exists, $T_s = 691°$C as calculated in part (b). The results are shown below.



Continued….

PROBLEM 10.41 (Cont.)

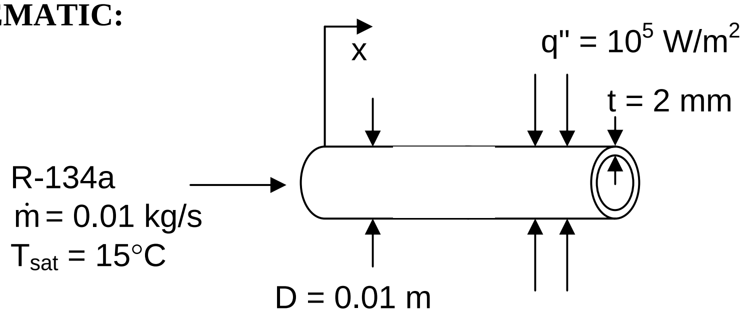
COMMENTS: (1) During pool boiling, we are concerned about approaching the critical heat flux. During forced convection boiling, an analogous situation exists whereby, once the liquid phase is entirely consumed, surface temperatures rise very rapidly, potentially melting the tube material. In applications where production of superheated steam is desired, such as in a Rankine power cycle, precautions must be made to ensure the tube material will survive the high temperatures in regions associated with pure vapor conditions. (2) Surface temperatures at negative x values will be slightly less than shown for the pure liquid flow. This is because the fluid quality is averaged across the tube radius and, for $x < 0$, fluid near the centerline of the tube will consist of subcooled liquid while superheated vapor exists near the tube wall. This situation can yield values of $\bar{X}$ equal to zero, even though two-phase flow exists in the fluid, increasing the convection coefficient. Similarly, the average quality reaches a value of unity at $x = 22.3$ m. Just beyond this location, the flow consists mainly of vapor, but a subcooled liquid mist can exist near the core of the flow, suppressing tube surface temperatures relative to those indicated just beyond $x = 22.3$ m. (3) The quality reaches a value of 0.8 at $x = 17.8$ m and Equation 10.15 is no longer applicable. The surface temperatures reported in the range $17.8 \text{ m} \leq x \leq 22.3$ m will be less accurate than for those further upstream. (4) The pressure will decrease with increasing x due to friction losses. Prediction of pressure drops in flow boiling is difficult.

PROBLEM 10.42

KNOWN: Diameter and wall thickness of horizontal tube. Saturation temperature and flow rate of R-134a. Wall heat flux.

FIND: Maximum wall temperature at x = 0.4 m for (a) copper tube, (b) stainless steel tube.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Steady-state conditions, (3) The heat flux value of 10^5 W/m^2 is based on the inner wall surface area.

PROPERTIES: *Table A.5*, Saturated liquid R-134a: (T_{sat} = 288 K): k_ℓ = 0.0855 W/m·K, $c_{p,\ell}$ = 1387 J/kg·K, μ_ℓ = 2.213 × 10^{-4} N·s/m^2, Pr_ℓ = 3.54, ρ_ℓ = 1243.8 kg/m^3, h_{fg} = 186.6 kJ/kg. Saturated vapor R-134a (given): ρ_v = 23.75 kg/m^3. *Table A.1*, Pure copper (T ≈ 300 K): k_w = 401 W/m·K. *Table A.1*, AISI 316 SS (T ≈ 300 K): k_w = 13.4 W/m·K.

ANALYSIS: (a) From Eq. 10.16,

$$\bar{X}(x = 0.4\text{ m}) = \frac{q''_s \pi D x}{\dot{m} h_{fg}} = \frac{10^5\text{ W/m}^2 \times \pi \times 0.01\text{ m} \times 0.4\text{ m}}{0.01\text{ kg/s} \times 186.6 \times 10^3\text{ J/kg}} = 0.673$$

To find the wall temperature, we must first find the convection coefficient from Eq. 10.15. The Reynolds number is

$$Re_D = 4\dot{m}/\pi D\mu_\ell = 4 \times 0.01\text{ kg/s}/\pi \times 0.01\text{ m} \times 2.213 \times 10^{-4}\text{ N}\cdot\text{s/m}^2 = 5753$$

Thus the flow is turbulent and the single phase convection coefficient can be calculated from Eq. 8.62,

$$Nu_D = \frac{(f/8)(Re_D - 1000)\,Pr_\ell}{1 + 12.7\,(f/8)^{1/2}(Pr_\ell^{2/3} - 1)} = \frac{(0.0370/8)\,(5753 - 1000)\,3.54}{1 + 12.7\,(0.0370/8)^{1/2}(3.54^{2/3} - 1)} = 36.3$$

where from Equation 8.21,

$$f = (0.790 \ln Re_D - 1.64)^{-2} = (0.790 \ln(5753) - 1.64)^{-2} = 0.0370$$

Thus

$$h_{sp} = Nu_D k_\ell / D = 36.3 \times 0.0855\text{ W/m}\cdot\text{K}/0.01\text{ m} = 311\text{ W/m}^2\cdot\text{K}$$

Continued…

PROBLEM 10.42 (Cont.)

We must evaluate h from both Eqs. 10.15a and 10.15b and take the larger value. We first calculate $\dot{m}'' = \dot{m}/A_c = 127\ \text{kg/m}^2\cdot\text{s}$, $Fr = (\dot{m}''/\rho_\ell)^2/gD = 0.1069$, $f(Fr) = 2.63Fr^{0.3} = 1.34$, and note that $G_{sf} = 1.63$ from Table 10.2. Then, from Eq. 10.15a (which yields the larger value),

$$\frac{h}{h_{sp}} = 0.6683\left(\frac{\rho_\ell}{\rho_v}\right)^{0.1}\bar{X}^{0.16}(1-\bar{X})^{0.64}f(Fr) + 1058\left(\frac{q_s''}{\dot{m}''h_{fg}}\right)^{0.7}(1-\bar{X})^{0.8}G_{sf}$$

$$= 0.6683\left(\frac{1243.8}{23.75}\right)^{0.1}0.673^{0.16}(1-0.673)^{0.64}\times 1.34 + 1058\left(\frac{10^5\ \text{W/m}^2}{127\ \text{kg/m}^2\cdot\text{s}\times 186.6\times 10^3\ \text{J/kg}}\right)^{0.7}(1-0.673)^{0.8}\times 1.63$$

$$= 15.9$$

Thus $h = 15.9(311\ \text{W/m}^2\cdot\text{K}) = 4942\ \text{W/m}^2\cdot\text{K}$ and from Eq. 10.3,

$$T_s = T_{sat} + q''/h = 15°\text{C} + 10^5\ \text{W/m}^2/4942\ \text{W/m}^2\cdot\text{K} = 35.2°\text{C}$$

This is the inner wall temperature. The maximum wall temperature is the outer wall temperature, given by

$$T_{s.o} = T_s + q''r_i\ln(r_o/r_i)/k_w = 35.2°\text{C} + 10^5\ \text{W/m}^2\times 0.005\ \text{m}\ln(0.007/0.005)/401\ \text{W/m}\cdot\text{K}$$

$$T_{s,o} = 35.6°\text{C}$$ <

(b) For stainless steel, the value of G_{sf} changes, $G_{sf} = 1$, and the wall thermal conductivity is lower. Repeating the calculations (with Eq. 10.15b now yielding the larger value of h) we find h = 3776 $\text{W/m}^2\cdot\text{K}$, $T_s = 41.5°\text{C}$, and

$$T_{s,o} = 54.0°\text{C}$$ <

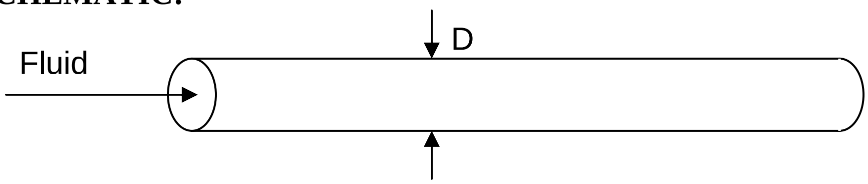
COMMENTS: (1) The confinement number is Co = 0.089 which is less than 1/2, therefore Eq. 10.15 may be used. (2) For vertical tubes, the corresponding maximum wall temperatures are T_{max} = 35.9ºC and 58.1ºC, respectively.

PROBLEM 10.43

KNOWN: Various fluids at atmospheric pressure boiling in a tube.

FIND: Tube diameter associated with a Confinement number of 0.5.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties.

PROPERTIES: *Table A.5*, Saturated ethanol (p = 1 atm): ρ_ℓ = 757 kg/m^3, ρ_v = 1.44 kg/m^3, $\sigma = 17.7 \times 10^{-3}$ N/m. Saturated mercury (p = 1 atm): ρ_ℓ = 12,740 kg/m^3, ρ_v = 3.90 kg/m^3, $\sigma = 417 \times 10^{-3}$ N/m. Saturated R-134a (p = 1 atm): ρ_ℓ = 1377 kg/m^3, ρ_v = 5.26 kg/m^3, $\sigma = 15.4 \times 10^{-3}$ N/m. Saturated dielectric fluid, given in Problem 10.23 (p = 1 atm): ρ_ℓ = 1619.2 kg/m^3, ρ_v = 13.4 kg/m^3, $\sigma = 8.1 \times 10^{-3}$ N/m. *Table A.6*, Saturated water (p = 1 atm): ρ_ℓ = 989 kg/m^3, ρ_v = 0.595 kg/m^3, $\sigma = 58.9 \times 10^{-3}$ N/m.

ANALYSIS: The Confinement number is defined as,

$$\text{Co} = \sqrt{\sigma/[g(\rho_\ell - \rho_v)]}\,/\,D$$

Thus for a critical Confinement number of 0.5,

$$D = 2\sqrt{\sigma/[g(\rho_\ell - \rho_v)]}$$

The results are tabulated below for all five fluids.

Fluid	**Critical diameter (mm)**
Ethanol	3.03
Mercury	3.65
Water	4.93
R-134a	2.14
Dielectric fluid	1.43

<

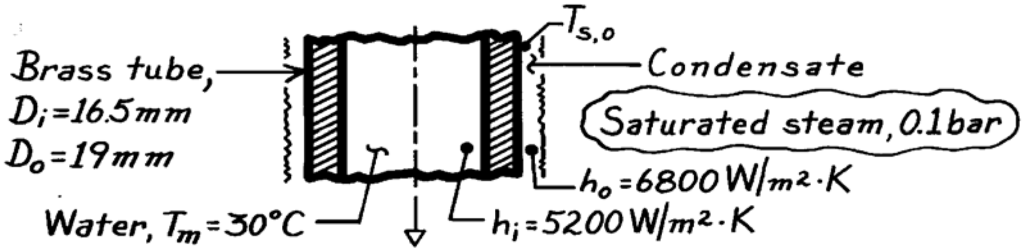
COMMENTS: Despite the wide range of individual property values, the critical tube diameter below which the bubble occupies a significant fraction of the tube volume is confined to a relatively narrow range.

PROBLEM 10.44

KNOWN: Saturated steam condensing on the outside of a brass tube and water flowing on the inside of the tube; convection coefficients are prescribed.

FIND: Steam condensation rate per unit length of the tube.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions.

PROPERTIES: *Table A-6*, Water, vapor (0.1 bar): $T_{sat} \approx 320K$, $h_{fg} = 2390 \times 10^3$ J/kg; *Table A-1*, Brass $(\overline{T} = (T_m + T_{sat})/2 \approx 300K)$: $k = 110\ W/m \cdot K$

ANALYSIS: The condensation rate per unit length follows from Eq. 10.34 written as

$$\dot{m}' = q'/h'_{fg} \tag{1}$$

where the heat rate follows from Eq. 10.33 using an overall heat transfer coefficient

$$q' = U_o \cdot \pi D_o (T_{sat} - T_m) \tag{2}$$

and from Eq. 3.36,

$$U_o = \left[\frac{1}{h_o} + \frac{D_o/2}{k}\ell n\frac{D_o}{D_i} + \frac{D_o}{D_i}\frac{1}{h_i}\right]^{-1} \tag{3}$$

$$U_o = \left[\frac{1}{6800\,W/m^2 \cdot K} + \frac{0.0095m}{110\,W/m \cdot K}\ell n\frac{19}{16.5} + \frac{19}{16.5}\frac{1}{5200\,W/m^2 \cdot K}\right]^{-1}$$

$$U_o = \left[147.1\times10^{-6} + 12.18\times10^{-6} + 192.3\times10^{-6}\right]^{-1} W/m^2 \cdot K = 2627\,W/m^2 \cdot K.$$

Combining Eqs. (1) and (2) and substituting numerical values (see below for h'_{fg}), find

$$\dot{m}' = U_o \pi D_o (T_{sat} - T_m)/h'_{fg}$$

$$\dot{m}' = 2627\,W/m^2 \cdot K \pi (0.019m)(320 - 303)K/2410\times10^3 J/kg = 1.11\times10^{-3} kg/s. \quad <$$

COMMENTS: (1) Note from evaluation of Eq. (3) that the thermal resistance of the brass tube is not negligible. (2) From Eq. 10.27, with Ja = $c_{p,\ell}(T_{sat} - T_s)/h_{fg}$, $h'_{fg} = h_{fg}[1 + 0.68\,Ja]$. Note from expression for U_o, that the internal resistance is the largest. Hence, estimate $T_{s,o} \approx T_o - (R_o/\Sigma R)(T_o - T_m) \approx 313K$. Hence,

$$h'_{fg} \approx 2390\times10^3 J/kg\left[1 + 0.68\times4179\,J/kg \cdot K(320 - 313)K/2390\times10^3 J/kg\right]$$

$$h'_{fg} = 2410\,kJ/kg$$

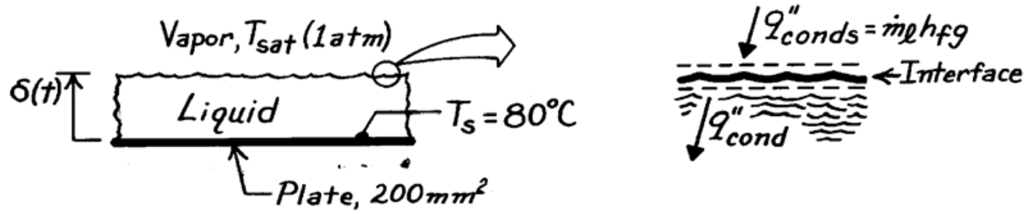
where $c_{p,\ell}$ for water (liquid) is evaluated at $T_f = (T_{s,o} + T_o)/2 \approx 317K$.

PROBLEM 10.45

KNOWN: Insulated container having cold bottom surface and exposed to saturated vapor.

FIND: Expression for growth rate of liquid layer, δ(t); thickness formed for prescribed conditions; compare with vertical plate condensate for same conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Side wall effects are negligible and, (2) Vapor-liquid interface is at T_{sat}, (3) Temperature distribution in liquid is linear, (4) Constant properties.

PROPERTIES: *Table A-6*, Saturated vapor (p = 1.0133 bar): T_{sat} = 100°C, ρ_v = 0.596 kg/m^3, h_{fg} = 2257 kJ/kg; *Table A-6*, Saturated liquid (T_f = 90°C = 363K): ρ_ℓ = 965 kg/m^3, μ_ℓ = 313 × 10^{-6} N·s/m^2, k_ℓ = 0.676 W/m·K, $c_{p,\ell}$ = 4207 J/kg·K, $\nu_\ell = \mu_\ell / \rho_\ell$ = 3.24 × 10^{-7} m^2/s.

ANALYSIS: Perform a surface energy balance on the interface (see above) recognizing that $\dot{m}_\ell / A = \rho_\ell \, d\delta / dt$ from an overall mass rate balance on the liquid to obtain

$$\dot{E}''_{in} - \dot{E}''_{out} = q''_{conds} - q''_{cond} = \frac{\dot{m}}{A} h_{fg} - k_\ell \frac{T_{sat} - T_s}{\delta} = \rho_\ell \frac{d\delta}{dt} h_{fg} - k_\ell \frac{T_{sat} - T_s}{\delta} = 0 \quad (1)$$

where q''_{conds} is the condensation heat flux and q''_{cond} is the conduction heat flux into the liquid layer of thickness δ with linear temperature distribution. Eq. (1) can be rewritten as

$$\rho_\ell h_{fg} \frac{d\delta}{dt} = k_\ell \frac{T_{sat} - T_s}{\delta}.$$

Separate variables and integrate with limits shown to obtain the liquid layer growth rate,

$$\int_0^\delta \delta d\delta = \int_0^t \frac{k_\ell (T_{sat} - T_s)}{\rho_\ell h_{fg}} dt \qquad \text{or} \qquad \delta = \left[\frac{2k_\ell (T_{sat} - T_s)}{\rho_\ell h_{fg}} t \right]^{1/2}. \qquad (2) \quad <$$

For the prescribed conditions, the liquid layer thickness and condensate formed in one hour are

$$\delta(1h) = \left[2 \times 0.676 \frac{W}{m \cdot K} (100 - 80)°C \times 3600s / 965 \frac{kg}{m^3} \times 2257 \times 10^3 \frac{J}{kg} \right]^{1/2} = 6.69\, mm \quad <$$

$$M(1h) = \rho_\ell A \delta = 965 kg/m^3 \times 200 \times 10^{-6} m^2 \times 6.69 \times 10^{-3} m = 1.29 \times 10^{-3} kg. \quad <$$

Continued …

PROBLEM 10.45 (Cont.)

The condensate formed on a vertical plate of length $L = \sqrt{200\ \text{mm}^2} = 0.0141\ \text{m}$ with the same conditions follows from Eq. 10.34,

$$M_{vp} = \dot{m} \cdot t = \bar{h}_L A\left(T_{sat} - T_s\right) \cdot t / h'_{fg}$$

where h'_{fg} and $\bar{h}_L$ follow from Eqs. 10.27 and one of Eqs. 10.43 - 10.45, respectively, with P given by Eq. 10.42.

$$h'_{fg} = h_{fg}\left(1 + 0.68\,\text{Ja}\right) = h_{fg}\left(1 + 0.68\,c_{p,\ell}\,\Delta T / h_{fg}\right)$$

$$h'_{fg} = 2257 \times 10^3\ \text{J/kg}\left(1 + 0.68 \times 4207\,\frac{\text{J}}{\text{kg} \cdot \text{K}}\left(100 - 80\right)°\text{C} / 2257 \times 10^3\ \text{J/kg}\right) = 2314\text{kJ/kg}$$

From Eq. 10.42,

$$P = \frac{k_\ell L(T_{sat} - T_s)}{\mu_\ell h'_{fg}(\nu_\ell^{\,2}/g)^{1/3}}$$

$$= \frac{0.676\ \text{W/m} \cdot \text{K} \times 0.0141\ \text{m}(100 - 80)°\text{C}}{313 \times 10^{-6}\ \text{N} \cdot \text{s/m}^2 \times 2314 \times 10^3\ \text{J/kg} \times \left[(3.24 \times 10^{-7}\ \text{m}^2/\text{s})^2/9.8\ \text{m/s}^2\right]^{1/3}} = 11.9$$

Since P < 15.8, Eq. 10.43 gives

$$\bar{h}_L = \frac{k_\ell}{(\nu_\ell^2/g)^{1/3}} 0.943 P^{-1/4} = \frac{0.676\ \text{W/m} \cdot \text{K}}{\left[(3.24 \times 10^{-7}\ \text{m}^2/\text{s})^2/9.8\ \text{m/s}^2\right]^{1/3}} 0.943 \times 11.9^{-1/4} = 15{,}560\ \text{W/m}^2 \cdot \text{K}$$

Hence,

$$M_{vp} = 15{,}560\,\text{W/m}^2 \cdot \text{K} \times 200 \times 10^{-6}\,\text{m}^2\left(100 - 80\right)°\text{C} \times 3600\text{s} / 2314 \times 10^3\text{J/kg}$$

$$M_{vp} = 9.7 \times 10^{-2}\,\text{kg}. \qquad <$$

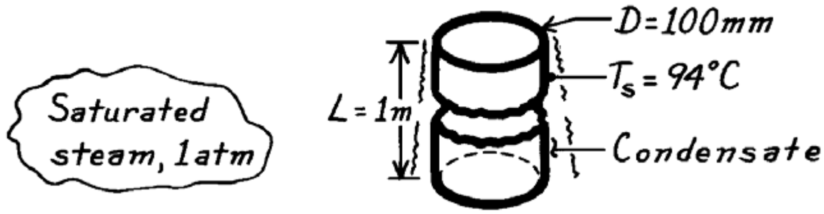
COMMENTS: Note that the condensate formed by the vertical plate is almost two orders of magnitude larger. For the vertical plate the rate of condensate formation is constant. For the container bottom surface, the rate decreases with increasing time since the conduction resistance increases as the liquid layer thickness increases.

PROBLEM 10.46

KNOWN: Vertical tube experiencing condensation of steam on its outer surface.

FIND: Heat transfer and condensation rates.

SCHEMATIC:



ASSUMPTIONS: (1) Film condensation, (2) Negligible non-condensibles, (3) D/2 >> δ, vertical plate behavior.

PROPERTIES: *Table A-6*, Water, vapor (1.0133 bar): T_{sat} = 100°C, ρ_v = 0.596 kg/m^3, h_{fg} = 2257 kJ/kg; *Table A-6*, Water, liquid (T_f = 97°C): ρ_ℓ = 960.6 kg/m^3, μ_ℓ = 289 × 10^{-6} N·s/m^2, $c_{p,\ell}$ = 4214 J/kg·K, k_ℓ = 0.679 W/m·K, $\nu_\ell = \mu_\ell/\rho_\ell$ = 3.01 × 10^{-7} m^2/s.

ANALYSIS: The heat transfer and condensation rates are

$$q = \overline{h}_L(\pi DL)(T_{sat} - T_s) \qquad \dot{m} = q/h'_{fg}$$

where $h'_{fg} = h_{fg}(1 + 0.68\,Ja)$ and $Ja = c_{p,\ell}(T_{sat} - T_s)/h_{fg}$. Hence Ja = 4214 J/kg·K (100 - 94)K/2257 × 10^3 J/kg = 0.0112 and h'_{fg} = 2274 kJ/kg.

Eq. 10.42 yields,

$$P = \frac{k_\ell L(T_{sat} - T_s)}{\mu_\ell h'_{fg}(\nu_\ell^2/g)^{1/3}} = \frac{0.679 \text{ W/m}\cdot\text{K} \times 1 \text{ m} \times (100-94)°\text{C}}{289\times10^{-6} \text{ N}\cdot\text{s/m}^2 \times 2274 \times 10^3 \text{ J/kg} \times \left[(3.01 \times 10^{-7} \text{ m}^2/\text{s})^2/9.8 \text{ m/s}^2\right]^{1/3}} = 295$$

Since 15.8 < P < 2530, Eq. 10.44 yields

$$\overline{h}_L = \frac{k_\ell}{(\nu_\ell^2/g)^{1/3}}\frac{1}{P}(0.68P + 0.89)^{0.82}$$

$$= \frac{0.679 \text{ W/m}\cdot\text{K}}{\left[(3.01 \times 10^{-7} \text{ m}^2/\text{s})^2/9.8 \text{ m/s}^2\right]^{1/3}}\frac{1}{295}(0.68\times295 + 0.89)^{0.82} = 8500 \text{ W/m}^2\cdot\text{K}$$

Then from Eqs. 10.33 and 10.34,

$$q = \overline{h}_L A(T_{sat} - T_s) = 8500 \text{ W/m}^2\cdot\text{K} \times \pi \times 0.1 \text{ m} \times 1 \text{ m} \times (100-94)°\text{C} = 16.0 \text{ kW}$$ <

$$\dot{m} = q/h'_{fg} = (16.0\times10^3\text{W})/(2.274 \times 10^6 \text{ J/kg}) = 7.1 \times 10^{-3} \text{ kg/s}$$ <

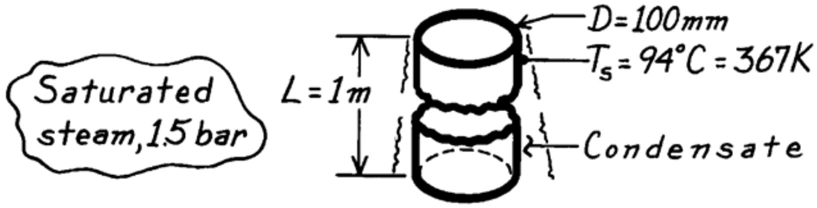
COMMENTS: To determine whether the assumption D/2 >> δ is satisfied, use Eq. 10.26 to estimate δ(L) ≈ 0.12mm. Despite the laminar film assumption, clearly the assumption is justified and the vertical plate correlation is applicable.

PROBLEM 10.47

KNOWN: Vertical tube experiencing condensation of steam on its outer surface.

FIND: Heat transfer and condensation rates.

SCHEMATIC:



ASSUMPTIONS: (1) Film condensation, (2) Negligible condensibles in steam, (3) D/2 >> δ, vertical plate behavior.

PROPERTIES: *Table A-6*, Water, vapor (1.5 bar): $T_{sat} \approx 385K$, $\rho_v = 0.876$ kg/m^3, $h_{fg} = 2225$ kJ/kg; *Table A-6*, Water, (liquid $T_f = 376K$): $\rho_\ell = 956.2$ kg/m^3, $c_{p,\ell} = 4220$ J/kg·K, $\mu_\ell = 271 \times 10^{-6}$ N·s/m^2, $k_\ell = 0.681$ W/m·K, $\nu_\ell = \mu_\ell / \rho_\ell = 2.83 \times 10^{-7}$ m^2/s.

ANALYSIS: The heat transfer and condensation rates are

$$q = \bar{h}_L (\pi D L)(T_{sat} - T_s) \qquad\qquad \dot{m} = q / h'_{fg}$$

where $h'_{fg} = h_{fg}(1 + 0.68\,Ja)$ and $Ja = c_{p,\ell}(T_{sat} - T_s)/h_{fg}$. Hence, Ja = 4220 J/kg·K (385 – 367)K/2225 × 10^3 J/kg = 0.0171 and $h'_{fg} = 2277$ kJ/kg.
Eq. 10.42 yields,

$$P = \frac{k_\ell L(T_{sat} - T_s)}{\mu_\ell h'_{fg}(\nu_\ell^2/g)^{1/3}} = \frac{0.681\text{ W/m}\cdot\text{K} \times 1\text{ m} \times (385-367)\text{K}}{271\times10^{-6}\text{ N}\cdot\text{s/m}^2 \times 2277 \times 10^3\text{ J/kg} \times \left[(2.83 \times 10^{-7}\text{ m}^2\text{/s})^2/9.8\text{ m/s}^2\right]^{1/3}} = 986$$

Since 15.8 < P < 2530, Eq. 10.44 yields

$$\bar{h}_L = \frac{k_\ell}{(\nu_\ell^2/g)^{1/3}} \frac{1}{P}(0.68P + 0.89)^{0.82}$$

$$= \frac{0.681\text{ W/m}\cdot\text{K}}{\left[(2.83 \times 10^{-7}\text{ m}^2\text{/s})^2/9.8\text{ m/s}^2\right]^{1/3}} \frac{1}{986}(0.68\times986 + 0.89)^{0.82} = 7130\text{ W/m}^2\cdot\text{K}$$

Hence, $q = 7130\,\text{W/m}^2\cdot\text{K}(\pi \times 0.1\text{m} \times 1\text{m})(385 - 367)\text{K} = 40.3\,\text{kW}$ <

$\dot{m} = 40.3\times10^3\,\text{W}/2277\times10^3\,\text{J/kg} = 0.0177\,\text{kg/s}.$ <

COMMENTS: By comparing these results with those of Problem 10.46, the effect of increased pressure on condensation can be seen.

p (bar)	T_{sat}(K)	T_{sat}-T_s(K)	$\bar{h}_L\left(W/m^2\cdot K\right)$	q (kW)	$\dot{m}\cdot10^3\,(kg/s)$
1.01	373	6	8500	16.0	7.1
1.5	385	18	7130	40.3	17.7

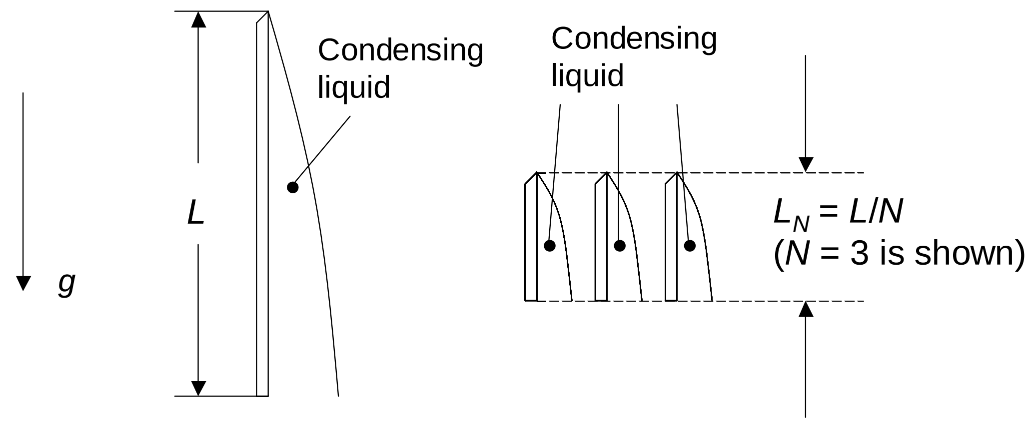
The effect of increasing the pressure from 1.01 to 1.5 bar is to increase the excess temperature three-fold, to decrease $\bar{h}_L$ by 16%, and to increase the rates by a factor of 2.5.

PROBLEM 10.48

KNOWN: Length of isothermal vertical plate, *L*, experiencing wave-free laminar condensation.

FIND: Expression for the average heat transfer coefficients for *N* plates each of length $L_N = L/N$ to the average coefficient for the single plate.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties.

ANALYSIS: Equation 10.42 gives

$$P = \frac{k_\ell L(T_{sat} - T_s)}{\mu_\ell h'_{fg}(\nu_\ell^2 / g)^{1/3}}$$

For wave free laminar condensation, Eq. 10.43 reveals that

$$\bar{h}_{L,1} \propto P^{-1/4} \propto L^{-1/4}$$

For multiple plates, each of length $L_N = L/N$,

$$\bar{h}_{L,N} \propto L_N^{-1/4} \propto \left(\frac{L}{N}\right)^{-1/4}$$

Therefore, $\bar{h}_{L,N} / \bar{h}_{L,1} = N^{1/4}$ <

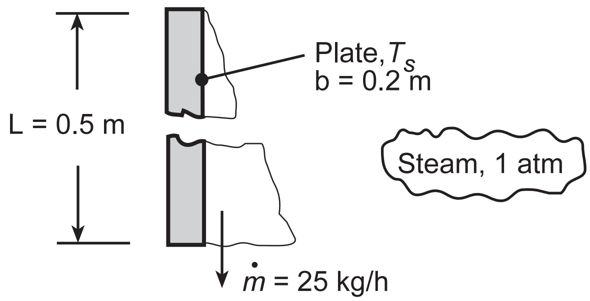
COMMENTS: By breaking the single plate into shorter segments, the average liquid film thickness is reduced, resulting in a modest increase in the average heat transfer coefficient, resulting in heat transfer *enhancement*.

PROBLEM 10.49

KNOWN: Cooled vertical plate 500-mm high and 200-mm wide condensing saturated steam at 1 atm.

FIND: (a) Surface temperature, T_s, required to achieve a condensation rate of $\dot{m}$ = 25 kg/h, (b) Compute and plot T_s as a function of the condensation rate for the range $15 \le \dot{m} \le 50\ \text{kg/h}$, and (c) Compute and plot T_s for the same range of $\dot{m}$, but if the plate is 200 mm high and 500 mm wide (vs. 500 mm high and 200 mm wide for parts (a) and (b)).

SCHEMATIC:



ASSUMPTIONS: (1) Film condensation, (2) Negligible non-condensables in steam.

PROPERTIES: *Table A-6*, Water, vapor (1.0133 bar): T_{sat} = 100°C, h_{fg} = 2257 kJ/kg; *Table A-6*, Water, liquid (T_f ≈ (74 + 100)°C/2 ≈ 360 K): ρ_ℓ = 967.1 kg/m^3, $c_{p,\ell}$ = 4203 J/kg·K, $\mu_\ell = 324 \times 10^{-6}$ N·s/m^2, k_ℓ = 0.674 W/m·K, $\nu_\ell = \mu_\ell/\rho_\ell = 3.35 \times 10^{-7}$ m^2/s.

ANALYSIS: (a) With knowledge of $\dot{m} = 25\ \text{kg/h} = 6.94 \times 10^{-4}$ kg/s, Re_δ can be calculated from Eq. 10.36,

$$Re_\delta = \frac{4\dot{m}}{\mu_\ell b} = \left(4 \times 6.94 \times 10^{-4}\ \text{kg/s}\right) \Big/ 324 \times 10^{-6}\ \text{N}\cdot\text{s/m}^2 \times 0.2\ \text{m} = 429$$

Thus the flow is wavy laminar and Eq. 10.39 applies, from which

$$\bar{h}_L = \frac{k_\ell}{(\nu_\ell^2/g)^{1/3}} \frac{Re_\delta}{1.08\,Re_\delta^{1.22} - 5.2}$$

$$= \frac{0.674\ \text{W/m}\cdot\text{K}}{\left[(3.35 \times 10^{-7}\ \text{m}^2\text{/s})^2 / 9.8\ \text{m/s}^2\right]^{1/3}} \frac{429}{1.08 \times 429^{1.22} - 5.2} = 7320\ \text{W/m}^2\cdot\text{K}$$

Equation 10.34 can then be solved for $T_{sat} - T_s$, making use of Eq. 10.27, to give

$$T_{sat} - T_s = \frac{\dot{m} h_{fg}}{\bar{h}_L A - 0.68\dot{m} c_{p,\ell}} = \frac{6.94 \times 10^{-4}\ \text{kg/s} \times 2257 \times 10^3\ \text{J/kg}\cdot\text{K}}{7320\ \text{W/m}^2\cdot\text{K} \times 0.1\ \text{m}^2 - 0.68 \times 6.94 \times 10^{-4}\ \text{kg/s} \times 4203\ \text{J/kg}\cdot\text{K}} = 22.0°\text{C}$$

Thus

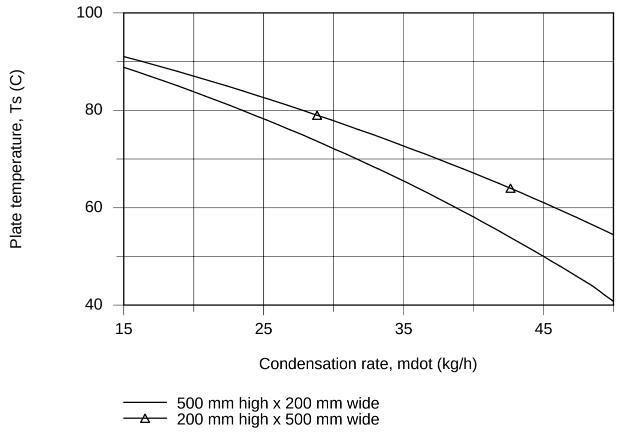
T_s = 78°C <

This value is to be compared to the assumed value of 74°C used for evaluating properties. See comment 1.

(b,c) Using the *IHT Correlations Tool*, *Film Condensation*, *Vertical Plate* for *laminar*, *wavy-laminar* and *turbulent regions*, combined with the *Properties Tool* for *Water*, the surface temperature T_s was calculated as a function of the condensation rate, $\dot{m}$, considering the two plate configurations as indicated in the plot below.

Continued…

PROBLEM 10.49 (Cont.)



As expected the condensation rate increases with decreasing surface temperature. The plate with the shorter height (L = 200 mm vs 500 mm) will have the thinner boundary layer and, hence, the higher average convection coefficient. Since both plate configurations have the same total surface area, the 200-mm height plate will have the larger heat transfer and condensation rates. For the range of conditions examined, the condensate flow is in the wavy-laminar region.

COMMENTS: (1) With the IHT model developed for parts (b) and (c), the result for the part (a) conditions with $\dot{m} = 25$ kg/h is $T_s = 77.9°C$ ($Re_\delta = 438$ and $\overline{h}_L = 7400\ W/m^2 \cdot K$). Hence, the assumed value ($T_s = 74°C$) required to initiate the analysis was a good one.

(2) A copy of the IHT Workspace model used to generate the above plot is shown below.

```
/* Correlations Tool
- Film Condensation, Vertical Plate, Laminar, wavy-laminar and turbulent regions: */
NuLbar = NuL_bar_FCO_VP(Redelta,Prl)     // Eq 10.38, 39, 40
NuLbar = hLbar * (nul^2 / g)^(1/3) / kl
g = 9.8                          // Gravitational constant, m/s^2
Ts =  Ts_C + 273                        // Surface temperature, K
Ts_C = 78                               // Initial guess value used to solve the model
Tsat =  100 + 273                       // Saturation temperature, K
// The liquid properties are evaluated at the film temperature, Tf,
Tf = Tfluid_avg(Ts,Tsat)
// The condensation and heat rates are
q = hLbar * As * (Tsat - Ts)     // Eq 10.33
As = L * b                              // Surface Area, m^2
mdot = q / h'fg                         // Eq 10.34
h'fg = hfg + 0.68 * cpl * (Tsat - Ts)   // Eq 10.27
// The Reynolds number based upon film thickness is
Redelta = 4 * mdot / (mul * b)          // Eq 10.36
// Assigned Variables:

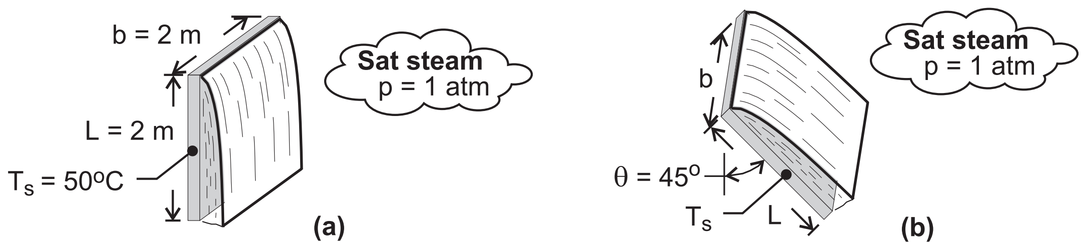
kl = k_Tx("Water",Tf,xl)         // Thermal conductivity, W/m·K
Prl = Pr_Tx("Water",Tf,xl)       // Prandtl number
```

PROBLEM 10.50

KNOWN: Plate dimensions, temperature and inclination. Pressure of saturated steam.

FIND: (a) Heat transfer and condensation rates for vertical plate, (b) Heat transfer and condensation rates for inclined plate.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties.

PROPERTIES: *Table A-6*, saturated vapor (p=1.0133 bars): T_{sat} = 100°C, h_{fg} = 2257 kJ/kg. *Table A-6*, saturated liquid (T_f = 75°C): $\rho_\ell = 975\,\text{kg/m}^3$, $\mu_\ell = 375 \times 10^{-6}\,\text{N}\cdot\text{s/m}^2$, $k_\ell = 0.668\,\text{W/m}\cdot\text{K}$, $c_{p,\ell} = 4193\,\text{J/kg}\cdot\text{K}$, $\nu_\ell = \mu_\ell/\rho_\ell$ = 3.85 × 10^{-7} m^2/s, Pr_ℓ = 2.35.

ANALYSIS: (a) Equation 10.27 gives $h'_{fg} = h_{fg} + 0.68c_{p,\ell}(T_{sat} - T_s)$= 2400 kJ/kg. Then, from Eq. 10.42,

$$P = \frac{k_\ell L(T_{sat} - T_s)}{\mu_\ell h'_{fg}(\nu_\ell^2/g)^{1/3}}$$

$$= \frac{0.668\ \text{W/m}\cdot\text{K} \times 2\ \text{m} \times (100-50)°\text{C}}{375\times10^{-6}\ \text{N}\cdot\text{s/m}^2 \times 2400 \times 10^3\ \text{J/kg} \times \left[(3.85\times10^{-7}\ \text{m}^2/\text{s})^2/9.8\ \text{m/s}^2\right]^{1/3}} = 3000$$

Therefore, Eq. 10.45 applies, and

$$\overline{h}_L = \frac{k_\ell}{(\nu_\ell^2/g)^{1/3}}\frac{1}{P}\left[\left(0.024P - 53\right)Pr_\ell^{1/2} + 89\right]^{4/3}$$

$$= \frac{0.668\ \text{W/m}\cdot\text{K}}{\left[(3.85\times10^{-7}\ \text{m}^2/\text{s})^2/9.8\ \text{m/s}^2\right]^{1/3}}\frac{1}{3000}\left[\left(0.024\times3000-53\right)\times2.35^{1/2}+89\right]^{4/3} = 5220\ \text{W/m}^2\cdot\text{K}$$

From Eqs. (10.33) and (10.34) the heat and condensation rates are then

$$q = \overline{h}_L A(T_{sat} - T_s) = 5220\ \text{W/m}^2\cdot\text{K}\times2\ \text{m}\times2\ \text{m}\times(100-50)°\text{C} = 1.04\times10^6\ \text{W}$$ <

$$\dot{m} = q/h'_{fg} = (1.04\times10^6\ \text{W})/(2400\times10^3\ \text{J/kg}) = 0.435\ \text{kg/s}$$ <

(b) With $\overline{h}_{L(incl)} \approx (\cos\theta)^{1/4}\,\overline{h}_L$, we obtain $\overline{h}_{L(incl)} \approx 0.917\times5220\,\text{W/m}^2\cdot\text{K} = 4820\,\text{W/m}^2\cdot\text{K}$. If the inclination reduces $\overline{h}_L$ by 8.4%, the heat and condensation rates are reduced by equivalent amounts. Hence,

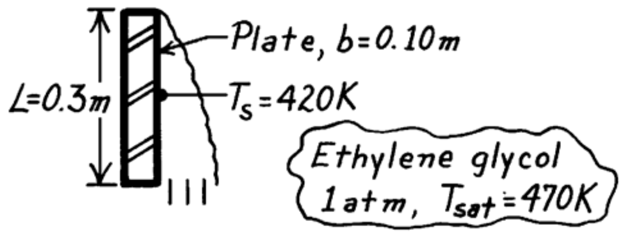
$$q = 0.964\times10^6\ \text{W}, \qquad \dot{m} = 0.402\,\text{kg/s}$$ <

PROBLEM 10.51

KNOWN: Saturated ethylene glycol (1 atm) condensing on a vertical plate at 420 K.

FIND: Heat transfer rate to the plate and condensation rate.

SCHEMATIC:



ASSUMPTIONS: (1) Film condensation, (2) Negligible non-condensible gases in vapor.

PROPERTIES: *Table A-5*, Ethylene glycol vapor (1 atm): T_{sat} = 470 K, $\rho_v \approx 0$ kg/m^3, h_{fg} = 812 kJ/kg; *Table A-5*, Ethylene glycol, liquid ($T_f = (T_s + T_{sat})/2 \approx$ 445K; use properties at upper limit of table 373K): ρ_ℓ = 1058.5 kg/m^3, $c_{p,\ell}$ = 2742 J/kg·K, $\mu_\ell = 0.215 \times 10^{-2}$ N·s/m^2, k_ℓ = 0.263 W/m·K, $\nu_\ell = 2.03 \times 10^{-6}$ m^2/s.

ANALYSIS: Equation 10.27 gives $h'_{fg} = h_{fg} + 0.68c_{p,\ell}(T_{sat} - T_s)$= 905 kJ/kg. Then Eq. 10.42 yields,

$$P = \frac{k_\ell L(T_{sat} - T_s)}{\mu_\ell h'_{fg}(\nu_\ell^2/g)^{1/3}} = \frac{0.263\ \text{W/m}\cdot\text{K} \times 0.3\ \text{m} \times (470-420)\text{K}}{0.215\times10^{-2}\ \text{N}\cdot\text{s/m}^2 \times 905 \times 10^3\ \text{J/kg} \times \left[(2.03 \times 10^{-6}\ \text{m}^2/\text{s})^2/9.8\ \text{m/s}^2\right]^{1/3}} = 27.1$$

Since 15.8 < P < 2530, Eq. 10.44 yields

$$\bar{h}_L = \frac{k_\ell}{(\nu_\ell^2/g)^{1/3}}\frac{1}{P}\left(0.68P + 0.89\right)^{0.82}$$

$$= \frac{0.263\ \text{W/m}\cdot\text{K}}{\left[(2.03 \times 10^{-6}\ \text{m}^2/\text{s})^2/9.8\ \text{m/s}^2\right]^{1/3}}\frac{1}{27.1}\left(0.68\times27.1+0.89\right)^{0.82} = 1470\ \text{W/m}^2\cdot\text{K}$$

Then from Eqs. 10.33 and 10.34,

$$q = \bar{h}_L A(T_{sat} - T_s) = 1470\ \text{W/m}^2\cdot\text{K} \times 0.3\ \text{m} \times 0.1\ \text{m} \times (470-420)\text{K} = 2200\ \text{W} \quad <$$

$$\dot{m} = q/h'_{fg} = (2200\ \text{W})/(905 \times 10^3\ \text{J/kg}) = 2.43 \times 10^{-3}\ \text{kg/s} \quad <$$

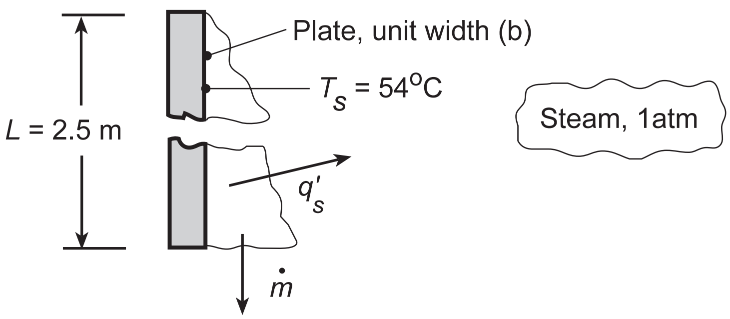
COMMENTS: Laminar condensation would yield results for the heat and mass rates within 1.2% of the wavy laminar values.

PROBLEM 10.52

KNOWN: Vertical plate 2.5 m high at a surface temperature $T_s = 54°C$ exposed to steam at atmospheric pressure.

FIND: (a) Condensation and heat transfer rates per unit width, (b) Whether flow regime would stay the same or change if the height were halved, and (c) Compute and plot the condensation rates for the two plate heights (2.5 m and 1.25 m) as a function of surface temperature for the range, $54 \le T_s \le 90°C$.

SCHEMATIC:



ASSUMPTIONS: (1) Film condensation, (2) Negligible non-condensables in steam.

PROPERTIES: *Table A-6*, Water, vapor (1 atm): $T_{sat} = 100°C$, $h_{fg} = 2257$ kJ/kg; *Table A-6*, Water, liquid ($T_f = (100 + 54)°C/2 = 350$ K): $\rho_\ell = 973.7$ kg/m^3, $k_\ell = 0.668$ W/m·K, $\mu_\ell = 365 \times 10^{-6}$ N·s/m^2, $c_{p,\ell} = 4195$ J/kg·K, $Pr_\ell = 2.29$, $\nu_\ell = \mu_\ell / \rho_\ell = 3.75 \times 10^{-7}$ m^2/s.

ANALYSIS: (a) From Equation 10.27, $h'_{fg} = h_{fg} + 0.68c_{p,\ell}(T_{sat} - T_s) = 2388$ kJ/kg. Then Eq. 10.42 yields,

$$P = \frac{k_\ell L(T_{sat} - T_s)}{\mu_\ell h'_{fg}(\nu_\ell^2/g)^{1/3}} = \frac{0.668\ \text{W/m}\cdot\text{K} \times 2.5\ \text{m} \times (100-54)°\text{C}}{365\times10^{-6}\ \text{N}\cdot\text{s/m}^2 \times 2388 \times 10^3\ \text{J/kg} \times \left[(3.75 \times 10^{-7}\ \text{m}^2/\text{s})^2/9.8\ \text{m/s}^2\right]^{1/3}} = 3630$$

Since P > 2530, the regime is turbulent and Eq. 10.45 yields

$$\bar{h}_L = \frac{k_\ell}{(\nu_\ell^2/g)^{1/3}} \frac{1}{P}\left[(0.024P - 53)Pr_\ell^{1/2} + 89\right]^{4/3}$$

$$= \frac{0.668\ \text{W/m}\cdot\text{K}}{\left[(3.75 \times 10^{-7}\ \text{m}^2/\text{s})^2/9.8\ \text{m/s}^2\right]^{1/3}} \frac{1}{3630}\left[(0.024\times3630-53)\times2.29^{1/2} + 89\right]^{4/3} = 5540\ \text{W/m}^2\cdot\text{K}$$

Then from Eqs. 10.33 and 10.34,

$$q' = \bar{h}_L L(T_{sat} - T_s) = 5540\ \text{W/m}^2\cdot\text{K} \times 2.5\ \text{m} \times (100-54)°\text{C} = 637\ \text{kW/m}$$ <

$$\dot{m}' = q'/h'_{fg} = 637\times10^3\ \text{W/m} \big/ 2388 \times 10^3\ \text{J/kg} = 0.267\ \text{kg/m}\cdot\text{s}$$ <

(b) If the length is halved, L = 1.25 m, then P will be halved, P = 1810.

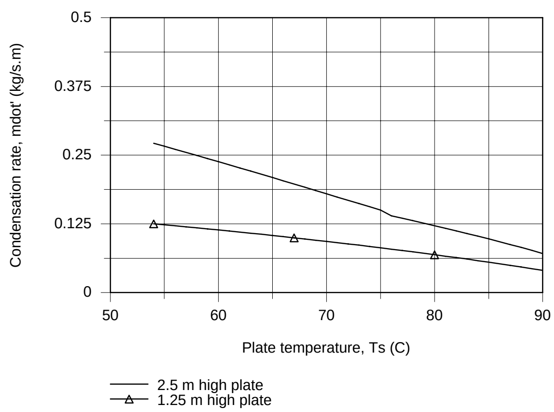
Since 15.8 < P < 2530, the flow regime changes to wavy laminar flow. <

Continued...

PROBLEM 10.52 (Cont.)

Eq. 10.44 then yields $\bar{h}_L = 5190\ W/m^2 \cdot K$ and we find $q' = \bar{h}_L L(T_{sat} - T_s) = 299\ kW/m$ and $\dot{m}' = q'/h'_{fg} =\ 0.125\ kg/m \cdot s$. Note that the height was decreased by a factor of 2 while the rates decreased by a factor of 2.13. Would you have expected this result?

(c) Using the *IHT Correlation Tool*, *Film Condensation, Vertical Plate* for *laminar, wavy-laminar*, and *turbulent regions*, combined with the *Properties Tool* for *Water*, the condensation rates were calculated as a function of the surface temperature considering the two plate heights indicated.



The condensation rate decreases nearly linearly with increasing surface temperature. The inflection in the upper curve (L = 2.5 m) corresponds to the flow transition at P = 2530 between wavy-laminar and turbulent. For surface temperature lower than 76°C, the flow is turbulent over the 2.5 m plate. The flow over the 1.25 m plate is always in the wavy-laminar region. The fact that the 2.5 m plate experiences turbulent flow explains the height-rate relationship mentioned in the closing sentences of part (b).

COMMENTS: A copy of the IHT model used to generate the above plot is shown below.

```
/* Correlations Tool
- Film Condensation, Vertical Plate, Laminar, wavy-laminar and turbulent regions: */
NuLbar = NuL_bar_FCO_VP(Redelta,Prl)     // Eq 10.38, 39, 40
NuLbar = hLbar * (nul^2 / g)^(1/3) / kl
g = 9.8                         // Gravitational constant, m/s^2
Ts =  Ts_C + 273                        // Surface temperature, K
Ts_C = 54                               // Part (a) design condition
Tsat =  100 + 273                       // Saturation temperature, K
// The liquid properties are evaluated at the film temperature, Tf,
Tf = Tfluid_avg(Ts,Tsat)
// The condensation and heat rates are
q = hLbar * As * (Tsat - Ts)            // Eq 10.33
As = L * b                              // Surface Area, m^2
mdot = q / h'fg                         // Eq 10.34
h'fg = hfg + 0.68 * cpl * (Tsat - Ts)   // Eq 10.27
// The Reynolds number based upon film thickness is
Redelta = 4 * mdot / (mul * b)          // Eq 10.36

// Assigned Variables:
L = 1.25                // Height, m
b = 1                   // Width, m

// Properties Tool - Water:

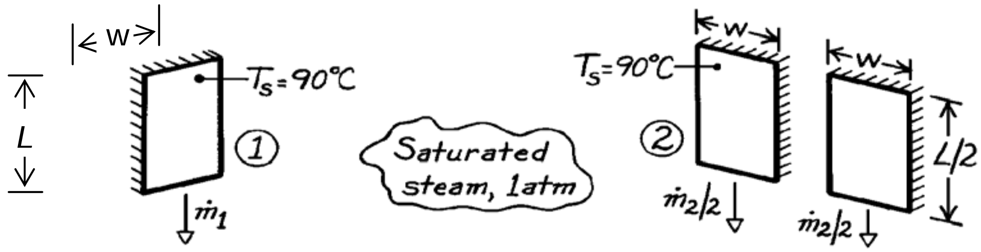
mul = mu_Tx("Water",Tf,xl)      // Viscosity, N·s/m^2
nul = nu_Tx("Water",Tf,xl)      // Kinematic viscosity, m^2/s
kl = k_Tx("Water",Tf,xl)        // Thermal conductivity, W/m·K
Prl = Pr_Tx("Water",Tf,xl)      // Prandtl number
```

PROBLEM 10.53

KNOWN: Two vertical plate configurations maintained at 90°C for condensing saturated steam at 1 atm: single plate L × w and two plates each L/2 × w where L and w are the vertical and horizontal dimensions, respectively.

FIND: Which case will provide the larger heat transfer or condensation rate.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible concentration of non-condensible gases in the steam.

PROPERTIES: *Table A-6*, Saturated water vapor (1 atm): T_{sat} = 100°C, h_{fg} = 2257 kJ/kg; Saturated water ($T_f = (T_s + T_{sat})/2$ = (90 + 100)°C/2 = 95°C = 368K): $\rho_\ell = (1/v_f) = 962$ kg/m^3, $\mu_\ell = 296 \times 10^{-6}$ N·s/m^2, k_ℓ = 0.678 W/m·K, $c_{p,\ell}$ = 4212 J/kg·K, $\nu_\ell = \mu_\ell / \rho_\ell = 3.08 \times 10^{-7}$ m^2/s.

ANALYSIS: The heat transfer and condensation rates are

$$q = \bar{h}_L A_s \left(T_{sat} - T_s\right) \qquad \dot{m} = q / h'_{fg}$$

where the total area, A_s, is the same for the two cases. Hence,

$$\frac{q_1}{q_2} = \frac{\dot{m}_1}{\dot{m}_2} = \frac{\bar{h}_{L,1}}{\bar{h}_{L,2}}$$

where the average convection coefficients $\bar{h}_{L,1}$ and $\bar{h}_{L,2}$ are evaluated for plate lengths of L and L/2, respectively. For *laminar film* condensation on both plates, using the correlation of Eq. 10.31, with $\bar{h}_L \propto L^{-1/4}$,

$$q_1 / q_2 = \left(L / [L/2]\right)^{-1/4} = 0.84.$$

Hence, case 2 is preferred and provides 19% more heat transfer ($q_2 / q_1 = 1/0.84 = 1.19$). <

The laminar solution is valid provided that P < 15.8, therefore from Eq. 10.42 we require

Continued …

PROBLEM 10.53 (Cont.)

$$L < 15.8 \frac{\mu_\ell h'_{fg} (\nu_\ell^2 / g)^{1/3}}{k_\ell (T_{sat} - T_s)} = 15.8 \times \frac{296 \times 10^{-6}\ \text{N} \cdot \text{s/m}^2 \times 2286 \times 10^3\ \text{J/kg} \times \left[(3.08 \times 10^{-7}\ \text{m}^2/\text{s})^2 / 9.8\ \text{m/s}^2\right]^{1/3}}{0.678\ \text{W/m} \cdot \text{K} \times (100 - 90)^\circ\text{C}}$$

$$= 0.035\ \text{m} = 35\ \text{mm}$$

where from Eq. 10.27,

$$h'_{fg} = h_{fg} + 0.68 c_{p,\ell} \left(T_{sat} - T_s\right)$$

$$h'_{fg} = 2257 \text{kJ} / \text{kg} + 0.68 \times 4212\ \text{J} / \text{kg} \cdot \text{K} \left(100 - 90\right) \text{K} = 2286\ \text{kJ} / \text{kg}.$$

We can anticipate for other, larger values of L that the comparison of $\overline{h}_L$ values cannot be so easily made. However, according to Figure 10.13, we expect the same behavior of $\overline{h}_L$ in the *wavy* region since $\overline{h}_L$ decreases with increasing Re_δ (corresponding to increasing L), and anticipate that indeed case 2 will provide the greater condensation rate. Note that in the turbulent region with the increase in $\overline{h}_L$ with Re_δ, we cannot conclude with certainty which case is preferred.

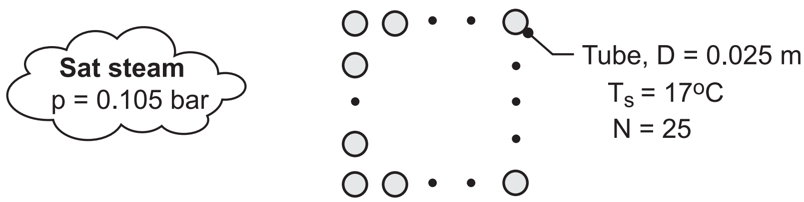
COMMENTS: In dealing with single-phase, forced or free convection, we associate thin thermal boundary layers with higher heat transfer rates. For vertical plates, we would expect the shorter plate to have the higher convection heat transfer coefficient. The results of this problem suggest the same is true for condensation on the vertical plate.

PROBLEM 10.54

KNOWN: Number, diameter and wall temperature of condenser tubes in a square array. Pressure of saturated steam around tubes.

FIND: Rates of heat transfer and condensation per unit length of the array.

SCHEMATIC:



ASSUMPTIONS: (1) Spatially uniform cylinder temperature, (2) Negligible concentration of noncondensable gases in steam, (3) Average heat transfer coefficient varies with tube row as $n = -1/6$ in Eq. 10.49.

PROPERTIES: *Table A-6*, saturated vapor (p_{sat} = 0.105 bar): T_{sat} = 320 K = 47°C, ρ_v = 0.0713 kg/m^3, h_{fg} = 2390 kJ/kg. *Table A-6*, saturated liquid (T_f = 32°C = 305 K): $\rho_\ell = 995\,\text{kg/m}^3$, $\mu_\ell = 769\times10^{-6}\,\text{N}\cdot\text{s/m}^2$, $k_\ell = 0.620\,\text{W/m}\cdot\text{K}$, $c_{p,\ell} = 4178\,\text{J/kg}\cdot\text{K}$.

ANALYSIS: Equation 10.46 may be used to find the convection coefficient for the top, unfinned tube. With $\text{Ja} = c_{p,\ell}\left(T_{sat} - T_s\right)/h_{fg} = 0.052$ and $h'_{fg} = h_{fg}$ (l + 0.68 Ja) = 1.04 (2.390 × 10^6 J/kg) = 2.51 × 10^6 J/kg,

$$\overline{h}_D = 0.729\left[\frac{g\,\rho_\ell\left(\rho_\ell - \rho_v\right)k_\ell^3\,h'_{fg}}{\mu_\ell\left(T_{sat} - T_s\right)D}\right]^{1/4}$$

$$\overline{h}_D = 0.729\left[\frac{9.8\,\text{m/s}^2 \times 995\,\text{kg/m}^3\left(995 - 0.0713\right)\text{kg/m}^3\left(0.62\,\text{W/m}\cdot\text{K}\right)^3 2.51\times10^6\,\text{J/kg}}{769\times10^{-6}\,\text{N}\cdot\text{s/m}^2\left(30°\text{C}\right)0.025\text{m}}\right]^{1/4} = 7308\,\text{W/m}^2\cdot\text{K}$$

From Eq. 10.49 the array-averaged convection coefficient is

$$\overline{h}_{D,N} = \overline{h}_D N^n = 7308\ \text{W/m}^2\cdot\text{K}\times 25^{-1/6} = 4274\ \text{W/m}^2\cdot\text{K}\,.$$

The heat rate per unit length of the array is

$$q' = N^2\overline{h}_{D,N}\left(\pi D\right)\left(T_{sat} - T_s\right) = 625\times 4274\,\text{W/m}^2\cdot\text{K}\left(\pi\times0.025\text{m}\right)30°\text{C} = 6.29\times10^6\,\text{W/m} \qquad <$$

The corresponding condensation rate is

$$\dot{m}' = \frac{q'}{h'_{fg}} = \frac{6.29\times10^6\,\text{W/m}}{2.51\times10^6\,\text{J/kg}} = 2.51\,\text{kg/s}\cdot\text{m} \qquad <$$

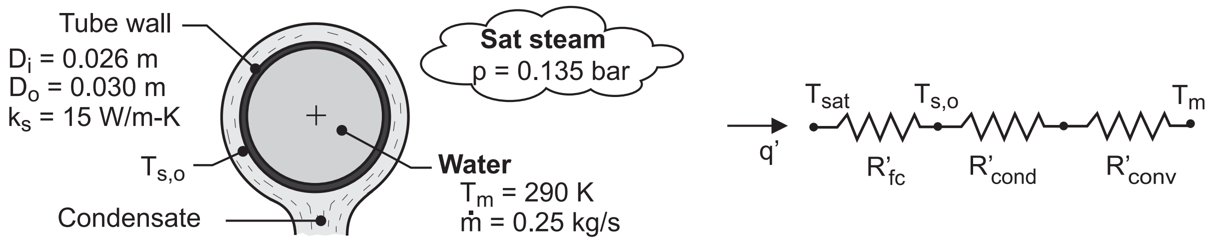
COMMENTS: The heat transfer rate could be increased by adding fins to the tubes.

PROBLEM 10.55

KNOWN: Tube wall diameters and thermal conductivity. Mean temperature and flow rate of water flow through tube. Pressure of saturated steam around tube.

FIND: (a) Rates of heat transfer and condensation per unit length, (b) Effect of flow rate on heat transfer.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible concentration of noncondensible gases in the steam, (2) Uniform tube surface temperatures, (3) Laminar film condensation, (4) Fully-developed internal flow, (5) Constant properties.

PROPERTIES: *Table A-6*, water (T_m = 290 K): $\mu = 0.00108\ N\cdot s/m^2$, k = 0.598 W/m·K, Pr = 7.56. *Table A-6*, saturated vapor (p = 0.135 bar): T_{sat} = 325 K = 52°C, $\rho_v = 0.0904\ kg/m^3$, h_{fg} = 2378 kJ/kg. *Table A-6*, saturated liquid ($T_f \approx T_{sat}$): $\rho_\ell = 987\ kg/m^3$, $c_{p,\ell} = 4182\ J/kg\cdot K$, $\mu_\ell = 528\times10^{-6}\ N\cdot s/m^2$, $k_\ell = 0.645\ W/m\cdot K$.

ANALYSIS: (a) From the thermal circuit, the heat rate may be expressed as

$$q' = \frac{T_{sat} - T_m}{R'_{fc} + R'_{cond} + R'_{conv}} \qquad (1)$$

where, $$R'_{cond} = \ell n\left(D_o / D_i\right)/2\pi k_s = 0.00152\ m\cdot K/W$$

The convection resistance is $R'_{conv} = \left(\pi D_i h_i\right)^{-1}$. With $Re_D = 4\dot{m}/\pi D_i \mu = 11,336$, the flow is turbulent and the Dittus-Boelter correlation yields

$$h_i = \left(\frac{k}{D_i}\right)0.023 Re_D^{4/5} Pr^{0.4} = \left(\frac{0.598\ W/m\cdot K}{0.026m}\right)0.023(11,336)^{4/5}(7.56)^{0.4} = 2082\ W/m^2\cdot K$$

The convection resistance is then

$$R'_{conv} = \left(\pi D_i h_i\right)^{-1} = \left(\pi\times0.026m\times2082\ W/m^2\cdot K\right)^{-1} = 0.00588\ m\cdot K/W$$

The resistance associated with the condensate film is $R'_{fc} = \left(\pi D_o \overline{h}_o\right)^{-1}$, where $\overline{h}_o$ is given by Eq. 10.46. With C = 0.729,

$$\overline{h}_o = C\left[\frac{g\rho_\ell\left(\rho_\ell - \rho_v\right)k_\ell^3 h'_{fg}}{\mu_\ell\left(T_{sat} - T_{s,o}\right)D_o}\right]^{1/4} = 0.729\left[\frac{9.8\ m/s^2\times987(987-0.09)kg^2/m^6\left(0.645\ W/m\cdot K\right)^3 h'_{fg}}{528\times10^{-6}\ N\cdot s/m^2\left(325 - T_{s,o}\right)\times0.030m}\right]^{1/4}$$

$$\overline{h}_o = 462\left(\frac{W^3\cdot kg}{m^8\cdot K^3\cdot s}\right)^{1/4}\left(\frac{h'_{fg}}{325 - T_{s,o}}\right)^{1/4}$$

where $$h'_{fg} = h_{fg} + 0.68 c_{p,\ell}\left(T_{sat} - T_{s,o}\right) = 2.38\times10^6\ J/kg + 2844\ J/kg\cdot K\left(325 - T_{s,o}\right)$$

The unknown surface temperature may be determined from an additional rate equation, such as

Continued …

PROBLEM 10.55 (Cont.)

$$q' = \frac{T_{s,o} - T_m}{R'_{cond} + R'_{conv}} \qquad (2)$$

Substituting the thermal resistances into Eqs. (1) and (2), an iterative solution yields

$$T_{s,o} = 321.6\,K = 48.6°C \qquad q' = 4270\,W/m$$ <

The condensation rate is then

$$\dot{m}'_{cond} = \frac{q'}{h'_{fg}} = \frac{4270\,W/m}{2.39 \times 10^6\,J/kg} = 0.00179\,kg/s \cdot m$$ <

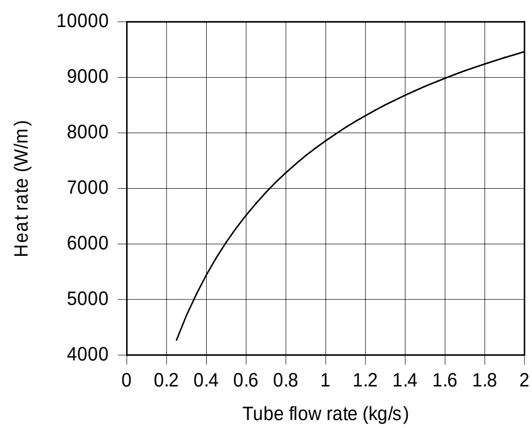
The corresponding values of the condensate convection coefficient and resistance are

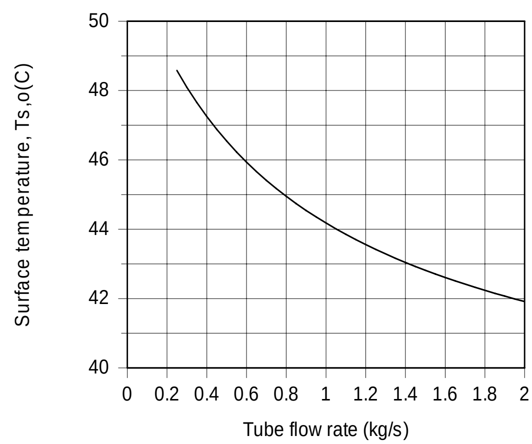
$$\overline{h}_o = 13,380\,W/m^2 \cdot K$$

and $R'_{fc} = 0.000793\,m \cdot K/W$

Because R'_{conv} is much larger than R'_{cond} and R'_{fc}, attention should be paid to reducing the convection resistance in order to increase the heat rate. The resistance to heat flow by convection is the *limiting factor*.

(b) The effects of varying the flow rate are shown below





The effect of increasing $\dot{m}$ on q' is significant and is accompanied by a reduction in $T_{s,o}$.

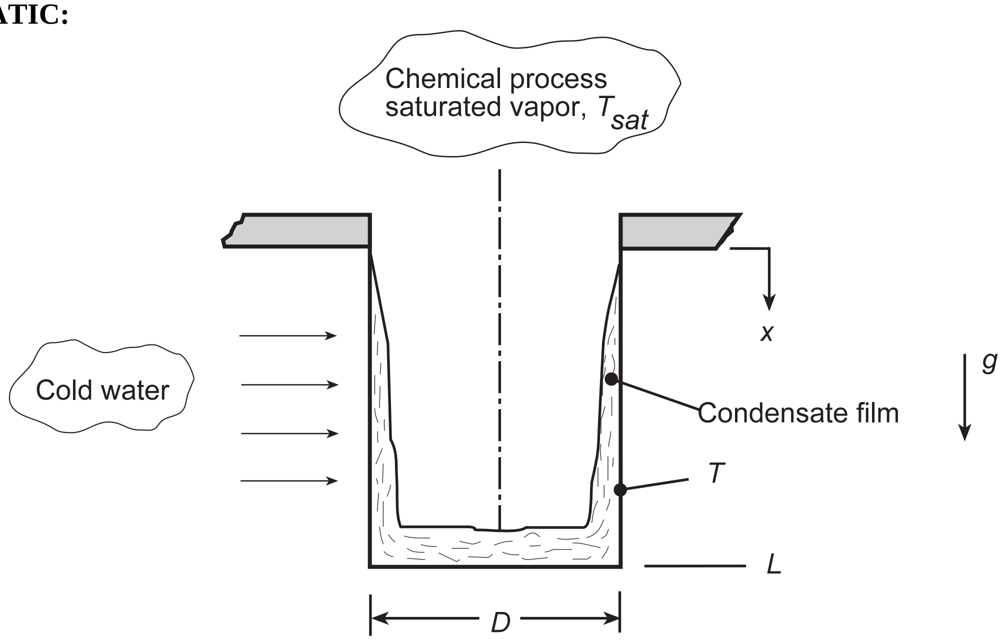
COMMENTS: (1) Use of the IHT convection and condensation correlations, as well as its temperature-dependent properties of water facilitated the numerical solution. (2) Evaluation of the film properties at T_{sat} is reasonable for part (a), since $T_f = (T_{s,o} + T_{sat})/2 = 50.3°C \approx T_{sat}$. However, with increasing $\dot{m}$ and hence decreasing $T_{s,o}$, the approximation would become inappropriate.

PROBLEM 10.56

KNOWN: Inner surface of a vertical thin-walled container of length L and diameter D experiences condensation of a saturated vapor. Container wall maintained at a uniform surface temperature by flowing cold water across its outer surface.

FIND: Expression for the time, t_f , required to fill the container with condensate assuming the condensate film is laminar. Express your result in terms of D, L, $(T_{sat} - T_s)$, g, and appropriate fluid properties.

SCHEMATIC:



ASSUMPTIONS: (1) Laminar film condensation on a vertical surface, (2) Uniform temperature container wall surface, and (3) Mass of liquid condensate in the laminar film negligible compared to liquid mass on bottom of container.

ANALYSIS: From an instantaneous mass balance on the container,

$$\dot{m}(t) = \frac{dM}{dt} \tag{1}$$

Where $\dot{m}$ (t) is the condensate rate and the liquid mass in the container, M, is

$$M = \rho_\ell \left(\pi D^2/4\right)(L - x) \tag{2}$$

The condensate rate from Eq. 10.34 can be expressed as

$$\dot{m}(t) = \frac{q}{h'_{fg}} = \frac{\bar{h}_S A_S \left(T_{sat} - T_s\right)}{h'_{fg}} \tag{3}$$

where the average film coefficient over the height 0 to x from Eq. 10.31 is,

$$\bar{h}_S = 0.943\left[\frac{g\rho_\ell\left(\rho_\ell - \rho_v\right)k_\ell^3 h'_{fg}}{\mu_\ell\left(T_{sat} - T_s\right)x}\right]^{1/4} \tag{4}$$

and the surface area over which condensation occurs is

$$A_S = \pi D x \tag{5}$$

Continued...

PROBLEM 10.56 (Cont.)

Substituting Eqs (2-5) into Eq. (1),

$$0.943\left[\frac{g\rho_\ell(\rho_\ell-\rho_v)k_\ell^3 h'_{fg}}{\mu_\ell(T_{sat}-T_s)L}\right]^{1/4}\frac{L^{1/4}}{x^{1/4}}(\pi Dx)(T_{sat}-T_s)/h'_{fg}=-\rho_\ell\left(\pi D^2/4\right)\frac{dx}{dt} \qquad (6)$$

Separate variables and identify the limits of integration,

$$\left\{0.943\left[\frac{g\rho_\ell(\rho_\ell-\rho_v)k_\ell^3 h'_{fg}}{\mu_\ell(T_{sat}-T_s)L}\right]^{1/4}L^{1/4}(\pi D)(T_{sat}-T_s)\Big/\left[h'_{fg}\rho_\ell\left(\pi D^2/4\right)\right]\right\}\int_0^{t_f}dt=-\int_{x=L}^{0}x^{-3/4}dx$$

(7)

The RHS integrates to

$$-\left[x^{1/4}/(1/4)\right]_L^0=4L^{1/4} \qquad (8)$$

and solving for t_f,

$$t_f=4\left[\frac{\rho_\ell\left(\pi D^2/4\right)Lh'_{fg}}{0.943\left[\frac{g\rho_\ell(\rho_\ell-\rho_v)k_\ell^3 h'_{fg}}{\mu_\ell(T_{sat}-T_s)L}\right]^{1/4}(\pi DL)(T_{sat}-T_s)}\right] \qquad <$$

COMMENTS: The numerator and denominator in the bracketed expression are of special significance. The numerator is the product of the mass in the filled container and the latent heat of vaporization; that is, the total energy removed by the cold water. What is the physical significance of the denominator? Can you interpret the time-to-fill, t_f , expression in light of these terms?

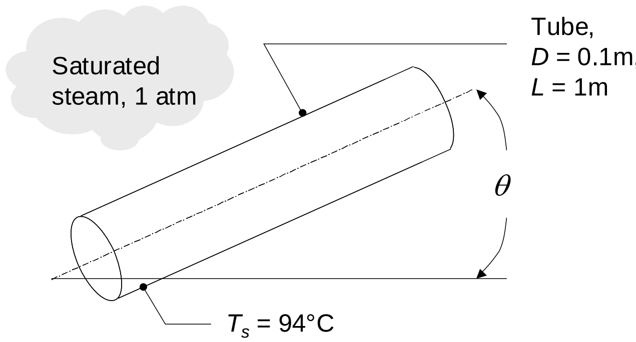
PROBLEM 10.57

Determine the total condensation rate and heat transfer rate for the process of Problem 10.46 when the pipe is oriented at angles of θ = 0, 30, 45 and 60° from the horizontal.

KNOWN: Dimensions and surface temperature of tube exposed to steam. Non-vertical orientation angles.

FIND: Heat transfer and condensation rates.

SCHEMATIC:



ASSUMPTIONS: (1) Laminar film condensation, (2) Negligible end effects, (3) Negligible concentration of non-condensable gases in steam.

PROPERTIES: Table A-6, Water Vapor (1 atm): T_{sat} = 100°C, ρ_v = 0.596 kg/m^3, h_{fg} = 2257 kJ/kg; Table A-6, Liquid Water ($T_f = (T_s + T_{sat})/2$ = 370K): ρ_l = 960.6 kg/m^3, $c_{p,l}$ = 4214 J/kg·K, μ_l = 289 × 10^{-6} N·s/m^2, k_l = 0.679 W/m·K.

ANALYSIS: The tube's length to diameter ratio, L/D = 10, must exceed $B = 1.8\tan\theta$ in order to use Equation 10.46. The value of B is 0, 1.039, 1.8, and 3.118 for θ = 0, 30, 45 and 60°, respectively. Therefore, Equation 10.46 may be used by replacing g with $g\cos\theta$ where the modified latent heat is found from Equation 10.27

$$h'_{fg} = h_{fg}\left(1+0.68Ja\right) = h_{fg} + 0.68c_{p,l}\left(T_{sat} - T_s\right)$$
$$= 2257\text{kJ/kg} + 0.68 \times 4.214\text{kJ/kg}\cdot\text{K}\left(100-94\right)°\text{C} = 2274\text{kJ/kg}$$

Hence,

$$\bar{h}_D = 0.729\left[\frac{g\cos\theta\rho_l\left(\rho_l-\rho_v\right)k_l^3 h'_{fg}}{\mu_l\left(T_{\text{sat}}-T_s\right)D}\right]^{1/4}$$

$$= 0.729\left[\frac{9.81\text{m/s}^2 \times \cos\theta \times 960.6\ \text{kg/m}^3\left(960.6-0.596\right)\text{kg/m}^3 \times \left(0.679\text{W/m}\cdot\text{K}\right)^3 \times 2274\times10^3\text{J/kg}\cdot\text{K}}{289\times10^{-6}\text{N}\cdot\text{s/m}^2\left(100-94\right)°\text{C}\times 0.1\text{m}}\right]^{1/4}$$

$$= 10{,}120\ \text{W/m}^2\cdot\text{K}\left(\cos\theta\right)^{1/4}$$

and the values of $\bar{h}_D$ are 10,120, 9760, 9280 and 8510 W/m^2·K for θ = 0, 30, 45 and 60°, respectively.

For θ = 0°, the heat transfer rate is

$$q = \bar{h}_D(\pi DL)(T_{\text{sat}} - T_s) = 10{,}120\text{W/m}^2\cdot\text{K}\left(\pi\times0.1\text{m}\times1\text{m}\right)\left(100-94\right)°\text{C} = 19{,}076\ \text{W}$$ <

and the condensation rate is $\dot{m} = q/h'_{fg} = 19076\ \text{W}/2274\times10^3\text{J/kg} = 8.39\times10^{-3}\text{kg/s}$ <

Similarly, q = 18,400, 17,500 and 16,000 W and $\dot{m}$ =8.09× 10^{-3}, 7.69 × 10^{-3} and 7.05 × 10^{-3} kg/s, for θ = 30, 45 and 60°, respectively. <

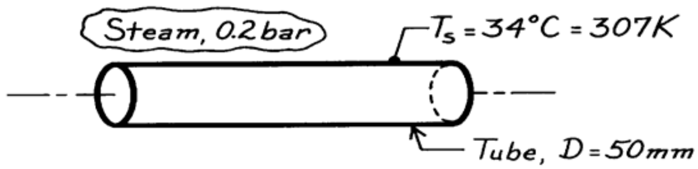
COMMENTS: The condensation rates decrease with increasing θ. Why?

PROBLEM 10.58

KNOWN: Horizontal tube, 50mm diameter, with surface temperature of 34°C is exposed to steam at 0.2 bar.

FIND: Estimate the heat transfer and condensation rates per unit length of the tube.

SCHEMATIC:



ASSUMPTIONS: (1) Laminar film condensation, (2) Negligible non-condensibles in steam.

PROPERTIES: *Table A-6*, Saturated steam (0.2 bar): T_{sat} = 333K, ρ_v = 0.129 kg/m^3, h_{fg} = 2358 kJ/kg; *Table A-6*, Water, liquid ($T_f = (T_s + T_{sat})/2$ = 320K): ρ_ℓ = 989.1 kg/m^3, $c_{p,\ell}$ = 4180 J/kg·K, $\mu_\ell = 577 \times 10^{-6}$ N·s/m^2, k_ℓ = 0.640 W/m·K.

ANALYSIS: From Eqs. 10.33 and 10.34, the heat transfer and condensate rates per unit length of the tube are

$$q' = \bar{h}_D (\pi D)(T_{sat} - T_s) \qquad \dot{m}' = q'/h'_{fg}$$

where from Eq. 10.27 with $Ja = c_{p,\ell}(T_{sat} - T_s)/h_{fg}$,

$$h'_{fg} = h_{fg}[1 + 0.68\ Ja] = 2358\frac{kJ}{kg}\left[1 + 0.68 \times 4180\,J/kg\cdot K(333 - 307)K/2358 \times 10^3 J/kg\right]$$

$$h'_{fg} = 2432\ kJ/kg.$$

For laminar film condensation, Eq. 10.45 is appropriate for estimating $\bar{h}_D$ with C = 0.729,

$$\bar{h}_D = 0.729\left[\frac{g\,\rho_\ell(\rho_\ell - \rho_v)k_\ell^3 h'_{fg}}{\mu_\ell(T_{sat} - T_s)D}\right]^{1/4}$$

$$\bar{h}_D = 0.729\left[\frac{9.8\,m/s^2 \times 989.1\ kg/m^3 (989.1 - 0.129)kg/m^3 (0.640\,W/m\cdot K)^3 \times 2432 \times 10^3 J/kg}{577 \times 10^{-6} N\cdot s/m^2 (333 - 307)K \times 0.050m}\right]^{1/4}$$

$$\bar{h}_D = 6926\ W/m^2\cdot K.$$

Hence, the heat transfer and condensation rates are

$$q' = 6926\ W/m^2\cdot K(\pi \times 0.050m)(333 - 307)K = 28.3\,kW/m$$ <

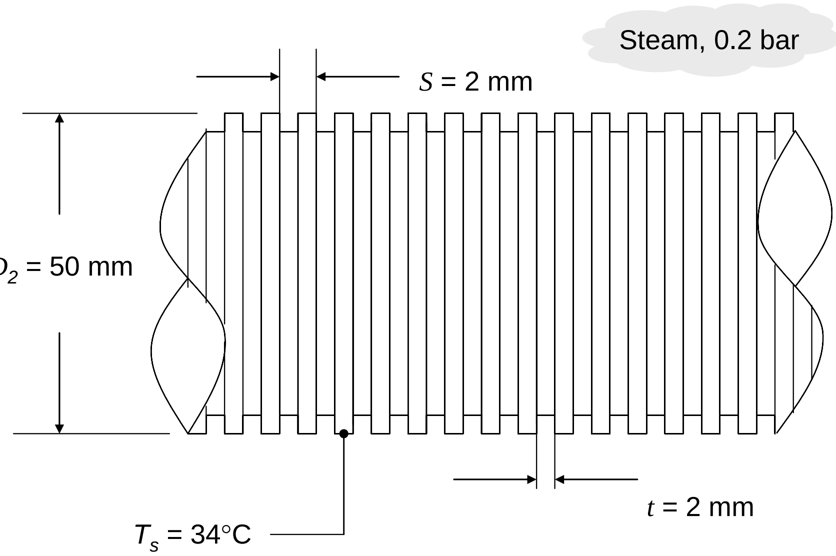
$$\dot{m}' = 28.3 \times 10^3\,W/m/2432 \times 10^3\,J/kg = 1.16 \times 10^{-2} kg/s\cdot m.$$ <

PROBLEM 10.59

KNOWN: Dimensions and surface temperature of grooved horizontal tube exposed to steam at 0.2 bar.

FIND: Minimum condensation and heat transfer rates per unit length of the tube.

SCHEMATIC:



ASSUMPTIONS: (1) Laminar film condensation, (2) Negligible non-condensable gas in steam.

PROPERTIES: *Table A-6*, Saturated steam (0.2 bar): T_{sat} = 333 K, ρ_v = 0.129 kg/m^3, h_{fg} = 2358 kJ/kg, σ = 66.1× 10^{-3} N/m; *Table A-6*, Water, liquid ($T_f = (T_s + T_{sat})/2$ = 320 K): ρ_ℓ = 989.1 kg/m^3, $c_{p,\ell}$ = 4180 J/kg·K, μ_ℓ = 577 × 10^{-6} N·s/m^2, k_ℓ = 0.640 W/m·K.

ANALYSIS: The heat transfer rate of Problem 10.58 is based upon an unmilled tube of diameter D_2 = 50 mm. From Eqs. 10.33 and 10.34, the heat transfer and condensation rates per unit length for this tube are

$$q_2' = \bar{h}_D(\pi D_2)(T_{sat} - T_s) \qquad \dot{m}' = q'/h_{fg}' \qquad (1a,b)$$

where from Eq. 10.27 with $Ja = c_{p,\ell}(T_{sat} - T_s)/h_{fg}$,

$$h_{fg}' = h_{fg}[1 + 0.68\ Ja] = 2358\ \text{kJ/kg}\left[1 + 0.68 \times 4180\,\text{J/kg}\cdot\text{K}(333 - 307)\text{K}/2358 \times 10^3\ \text{J/kg}\right]$$

$$h_{fg}' = 2432\ \text{kJ/kg}.$$

For laminar film condensation, Eq. 10.46 is appropriate for estimating $\bar{h}_D$ with C = 0.729,

$$\bar{h}_D = C\frac{k_l}{D_2}\left[\frac{\rho_l g(\rho_l - \rho_v)h_{fg}' D_2^3}{\mu_l k_l (T_{sat} - T_s)}\right]^{1/4} \qquad (2)$$

Continued…

PROBLEM 10.59 (Cont.)

$$\bar{h}_D = 0.729 \frac{0.640\,\text{W/m}\cdot\text{K}}{0.05\text{ m}}\left[\frac{989.1\,\text{kg/m}^3 \times 9.8\,\text{m/s}^2\left(989.1-0.129\right)\text{kg/m}^3 \times 2432\times10^3\ \text{J/kg}\times(0.05\text{ m})^3}{577\times10^{-6}\ \text{N}\cdot\text{s/m}^2\times 0.640\,\text{W/m}\cdot\text{K}\times\left(333-307\right)\ \text{K}}\right]^{1/4}$$
$$= 6926\,\text{W/m}^2\cdot\text{K}.$$

Hence, the heat transfer and condensation rates for the smooth large tube are

$$q_2' = 6926\,\text{W/m}^2\cdot\text{K}\left(\pi\times0.05\text{ m}\right)\left(333-307\right)\text{K} = 28.3\,\text{kW/m}$$
$$\dot{m}_{\text{cond,2}} = q_2'/h_{fg}' = 28.3\,\text{kW/m}/2432\text{ kJ/kg} = 0.0116\text{ kg/s}\cdot\text{m}$$

The portions of the larger tube that are not milled away serve as fins. Therefore, the heat transfer rate from the grooved large tube is related to the heat transfer rate from a corresponding smooth tube of smaller diameter D_1 = 46 mm, modified by the enhancement ratio, Eq. 10.48. We must first determine the heat transfer rate $q_{\text{uft,1}}'$ from a smooth tube of diameter D_1. From Eqs. (2) and (1a) above, with D_2 replaced by D_1, and the same value for h_{fg}':

$$q_{\text{uft,1}}' = 26.6\text{ kW/m}$$

The enhancement factor is given by Eq. 10.48.

$$\varepsilon_{\text{ft,min}} = \frac{q_{\text{ft,min}}}{q_{\text{uft}}} = \frac{tr_2}{Sr_1}\left[\frac{r_1}{r_2} + 1.02\frac{\sigma r_1}{\left(\rho_l-\rho_v\right)gt^3}\right]^{1/4}$$
$$= \frac{2\text{ mm}\times25\text{ mm}}{4\text{ mm}\times23\text{ mm}}\left[\frac{23\text{ mm}}{25\text{ mm}} + 1.02\frac{66.1\times10^{-3}\text{ N/m}\times0.023\text{ m}}{\left(989.1-0.129\right)9.8\text{ m/s}^2(0.002\text{ m})^3}\right]^{1/4}$$
$$= 1.16$$

Thus the minimum heat transfer rate for the grooved tube is

$$q_{\text{ft,min,1}}' = \varepsilon_{\text{ft,min}}q_{\text{uft,1}}' = 1.16\times26.6\,\text{kW/m} = 30.9\text{ kW/m} \qquad <$$

The corresponding condensation rate is

$$\dot{m}' = 30.9\times10^3\,\text{W/m} / 2432\times10^3\,\text{J/kg} = 1.27\times10^{-2}\text{ kg/s}\cdot\text{m} \qquad <$$

The enhancement due to milling the larger diameter tube, for either heat transfer or condensation rate, is therefore

$$\text{Enhancement ratio} = q_{\text{ft,min,1}}'/q_2' = 30.9\text{ kW/m}/28.3\text{ kW/m} = 1.09 \qquad <$$

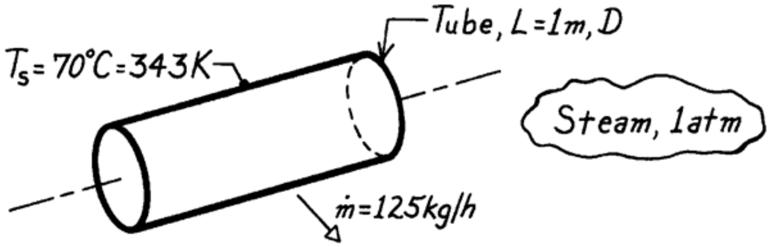
COMMENTS: For a given fluid and operating conditions would an optimum groove geometry exist?

PROBLEM 10.60

KNOWN: Horizontal tube 1m long with surface temperature of 70°C used to condense steam at 1 bar.

FIND: Diameter required for condensation rate of 125 kg/h.

SCHEMATIC:



ASSUMPTIONS: (1) Laminar film condensation, (2) Negligible non-condensibles in steam.

PROPERTIES: *Table A-6*, Water, vapor (1 atm): T_{sat} = 100°C, ρ_v = 0.596 kg/m^3, h_{fg} = 2257 kJ/kg; *Table A-6*, Water, liquid ($T_f = (T_s + T_{sat})/2$ = 358K): ρ_ℓ = 968.6 kg/m^3, $c_{p,\ell}$ = 4201 J/kg·K, μ_ℓ = 332 × 10^{-6} N·s/m^2, k_ℓ = 0.673 W/m·K.

ANALYSIS: From the rate equation, Eq. 10.34, with A = π D L, the required diameter is

$$D = \dot{m}\, h'_{fg} / \pi\, L\, \bar{h}_D \left(T_{sat} - T_s\right) \quad (1)$$

where from Eq. 10.27 with $Ja = c_{p,\ell}\left(T_{sat} - T_s\right)/h_{fg}$,

$$h'_{fg} = h_{fg}\left(1 + 0.68\,Ja\right) = 2257\,\frac{kJ}{kg}\left(1 + 0.68\,\frac{4201\,J/kg\cdot K \times (100-70)\,K}{2257 \times 10^3\,J/kg}\right) = 2343\,kJ/kg. \quad (2)$$

Substituting numerical values, Eq. (1) becomes

$$D = \frac{125}{3600}\frac{kg}{s} \times 2343 \times 10^3\,\frac{J}{kg} / \pi \times 1m \times \bar{h}_D\,(100-70)\,K = 863.2\,\bar{h}_D^{-1}. \quad (3)$$

The appropriate correlation for $\bar{h}_D$ is Eq. 10.46 with C = 0.729,

$$\bar{h}_D = 0.729\left[\frac{g\,\rho_\ell\left(\rho_\ell - \rho_v\right) k_\ell^3\, h'_{fg}}{\mu_\ell\left(T_{sat} - T_s\right) D}\right]^{1/4}. \quad (4)$$

Substitute Eq. (4) for $\bar{h}_D$ into Eq. (3) and use numerical values,

$$863.2\ D^{-1} = 0.729 \times$$

$$\left[\frac{9.8\,m/s^2 \times 968.6\,kg/m^3\,(968.6 - 0.596)\,kg/m^3\,(0.673\,W/m\cdot K)^3 \times 2343 \times 10^3\,J/kg}{332 \times 10^{-6}\,N\cdot s/m^2\,(100-70)\,K \times D}\right]^{1/4}$$

$$863.2\ D^{-1} = 3693.4\ D^{-1/4}$$

$$D = 0.144m = 144mm. \quad <$$

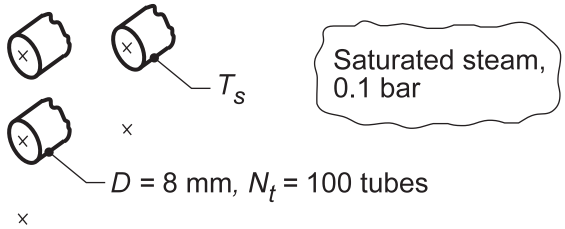
COMMENTS: Note for this situation Ja = 0.06.

PROBLEM 10.61

KNOWN: Array of condenser tubes exposed to saturated steam at 0.1 bar.

FIND: (a) Condensation rate per unit length of square array, (b) Options for increasing the condensation rate.

SCHEMATIC:



ASSUMPTIONS: (1) Spatially uniform cylinder temperature. (2) Average heat transfer coefficient varies with tube row with n = -1/6 in Eq. 10.49. (3) Negligible concentration on noncondensable gases in the steam.

PROPERTIES: *Table A.6*, Saturated water vapor (0.1 bar): $T_{sat} \approx 319$ K, $\rho_v = 0.067$ kg/m^3, $h_{fg} = 2393$ kJ/kg; *Table A.6*, Water, liquid ($T_f = (T_s + T_{sat})/2 = 309$ K): $\rho_\ell = 993$ kg/m^3, $c_{p,\ell} = 4178$ J/kg·K, $\mu_\ell = 703 \times 10^{-6}$ N·s/m^2, $k_\ell = 0.627$ W/m·K.

ANALYSIS: (a) With Ja = $c_{p,\ell}\Delta T/h_{fg} = 4178$ J/kg·K × (319 - 300)K/2393 × 10^3 J/kg = 0.033, h'_{fg} = $h_{fg}(1 + 0.68\,Ja)$ = 2393 kJ/kg(1 + 0.68 × 0.033) = 2470 kJ/kg.

Equation 10.46 may be written for the top tube,

$$\bar{h}_D = 0.729\left[\frac{g\rho_\ell(\rho_\ell - \rho_v)k_\ell^3 h'_{fg}}{\mu_\ell(T_{sat} - T_s)D}\right]^{1/4}$$

$$\bar{h}_D = 0.729\left[\frac{9.8\,\text{m/s}^2 \times 993\,\text{kg/m}^3(993 - 0.067)\,\text{kg/m}^3(0.627\,\text{W/m}\cdot\text{K})^3 \times 2470 \times 10^3\,\text{J/kg}}{703 \times 10^{-6}\,\text{N}\cdot\text{s/m}^2(319 - 300)\,\text{K} \times 0.008\,\text{m}}\right]^{1/4}$$

$$\bar{h}_D = 11{,}190\,\text{W/m}^2\cdot\text{K}.$$

From Eq. 10.49 the array-averaged convection coefficient is

$$\bar{h}_{D,N} = \bar{h}_D N^n = 11{,}190\ \text{W/m}^2\cdot\text{K} \times 10^{-1/6} = 7622\ \text{W/m}^2\cdot\text{K}$$

Hence, the condensation rate for the entire array per unit tube length is

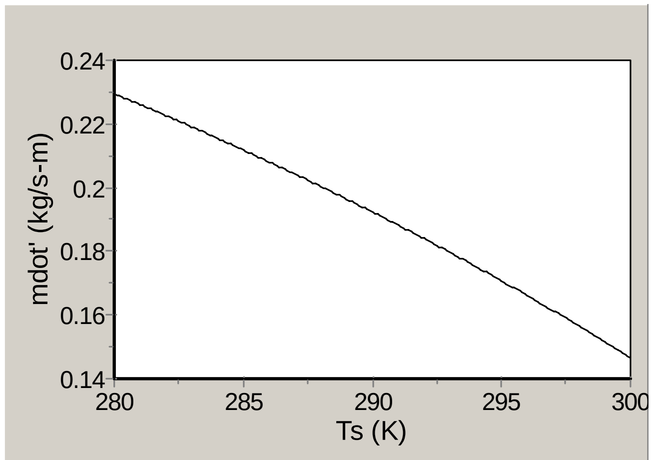
$$\dot{m}' = 7622\,\text{W/m}^2\cdot\text{K}(100)\pi \times 0.008\,\text{m}(319 - 300)\,\text{K}/2470 \times 10^3\,\text{J/kg}$$

$$\dot{m}' = 0.147\,\text{kg/s}\cdot\text{m} = 530\,\text{kg/h}\cdot\text{m}. \qquad <$$

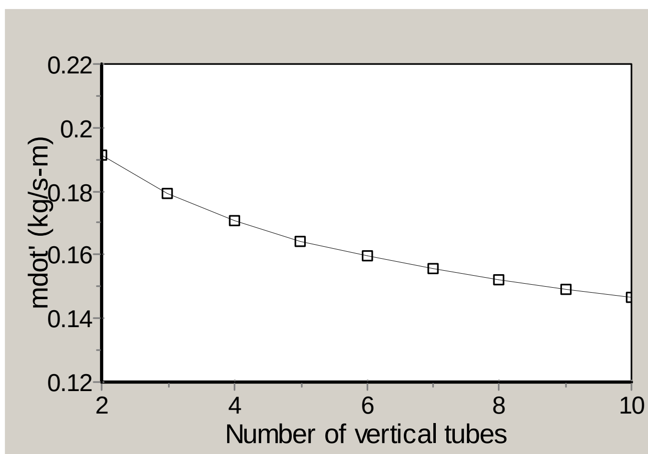
(b) Options for increasing the condensation rate include reducing the surface temperature and/or the number of tubes in a vertical tier. The following results were obtained using IHT.

Continued...

PROBLEM 10.61 (Cont.)



Condensation rate versus tube temperature (10 vertical tubes).



Condensation rate versus number of vertical tubes (T_s = 300K).

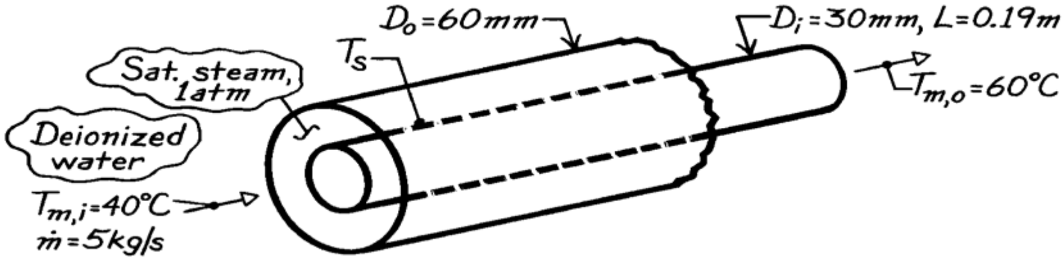
COMMENTS: Note the sensitivity of the condensation rate to the manner in which the tubes are positioned within the array.

PROBLEM 10.62

KNOWN: Thin-walled concentric tube arrangement for heating deionized water by condensation of steam.

FIND: Estimates for convection coefficients on both sides of the inner tube. Inner tube wall outlet temperature. Whether condensation provides fairly uniform inner tube wall temperature approximately equal to the steam saturation temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible thermal resistance of inner tube wall, (2) Internal flow is fully developed.

PROPERTIES: Deionized water (given): ρ = 982.3 kg/m^3, c_p = 4181 J/kg·K, k = 0.643 W/m·K, μ = 548 × 10^{-6} N·s/m^2, Pr = 3.56; *Table A-6*, Saturated vapor (1 atm): T_{sat} = 100°C, $\rho_v = (1/v_g)$ = 0.596 kg/m^3, h_{fg} = 2257 kJ/kg; *Table A-6*, Saturated water (assume $T_s \approx$ 75°C, T_f = (75 + 100)°C/2 = 360K): $\rho_\ell = (1/v_f)$ = 967 kg/m^3, μ_ℓ = 324 × 10^{-6} N·s/m^2, k_ℓ = 0.674 W/m·K, $c_{p,\ell}$ = 4203 J/kg·K.

ANALYSIS: From an energy balance on the inner tube at the outlet assuming a constant wall temperature,

$$\bar{h}_c\left(T_{sat}-T_s\right)=h_i\left(T_s-T_{m,o}\right)$$

where $\bar{h}_c$ and h_i are, respectively, the heat transfer coefficients for condensation (c) on a horizontal cylinder and internal (i) flow in a tube.

Condensation. From Eq. 10.46, for the horizontal tube,

$$\bar{h}_c=0.729\left[\frac{g\,\rho_\ell\left(\rho_\ell-\rho_v\right)k_\ell^3 h'_{fg}}{\mu_\ell\left(T_{sat}-T_s\right)D}\right]^{1/4}$$

where $h'_{fg}=h_{fg}\left\{1+0.68c_{p,\ell}\left(T_{sat}-T_s\right)/h_{fg}\right\}$

$$h'_{fg}=2257\ \text{kJ/kg}\left\{1+0.68\times 4203\ \text{J/kg}\cdot\text{K}\left(100-T_s\right)/2257\times 10^3\ \text{J/kg}\right\}$$

$$h'_{fg}=2257\ \text{kJ/kg}\left\{1+1.266\times 10^{-3}\left(100-T_s\right)\right\}$$

$$\bar{h}_c=0.729\left[9.8\,\text{m/s}^2\times 967\,\text{kg/m}^3\left(967-0.596\right)\text{kg/m}^3\left(0.674\,\text{W/m}\cdot\text{K}\right)^3\times\right.$$

$$\left.2257\left\{1+1.266\times 10^{-3}\left(100-T_s\right)\right\}\text{kJ/kg}/324\times 10^{-6}\,\text{N}\cdot\text{s/m}^2\left(100-T_s\right)0.030\,\text{m}\right]^{1/4}$$

Continued …

PROBLEM 10.62 (Cont.)

$$\bar{h}_c = 2.071\times10^4\left[\frac{1+1.266\times10^{-3}(100-T_s)}{100-T_s}\right]^{1/4}.$$

Internal flow. From Eq. 8.6, evaluating properties at $\bar{T}_m$, find

$$Re_D = \frac{4\dot{m}}{\pi\mu D} = \frac{4\times5\ kg/s}{\pi\times548\times10^{-6}\,N\cdot s/m^2\times0.030\ m} = 3.872\times10^5$$

and for turbulent flow use the Dittus Boelter equation,

$$Nu_D = \frac{h_i D}{k} = 0.023\,Re_D^{0.8}\,Pr^{0.4}$$

$$h_i = \frac{0.023\times0.643\ W/m\cdot K}{0.03\ m}\left(3.872\times10^5\right)^{0.8}(3.56)^{1/3} = 2.42\times10^4\ W/m^2\cdot K. \quad <$$

Substituting numerical values into the energy balance relation,

$$2.071\times10^4\left[\frac{1+1.266\times10^{-3}(100-T_s)}{100-T_{s,o}}\right]^{1/4}(100-T_s)K$$

$$= 2.42\times10^4\ W/m^2\cdot K(T_s-60)K$$

and by trial-and-error, find

$$T_s \approx 70.8°C.$$

With this value of T_s, find that

$$\bar{h}_c = 8990\ W/m^2\cdot K \quad <$$

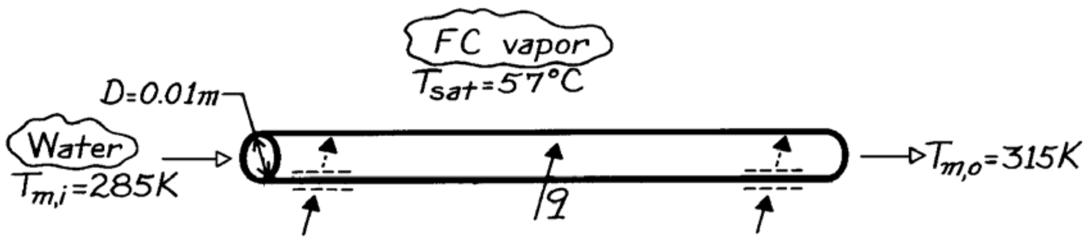
which is approximately half that for the internal flow. Hence, the tube wall cannot be at a uniform temperature. This could only be achieved if $\bar{h}_c \approx h_i$.

PROBLEM 10.63

KNOWN: Heat dissipation from multichip module to saturated liquid of prescribed temperature and properties. Diameter and inlet and outlet water temperatures for a condenser coil.

FIND: (a) Condensation and water flow rates. (b) Tube surface inlet and outlet temperatures. (c) Coil length.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions since rate of heat transfer from the module is balanced by rate of heat transfer to coil, (2) Fully developed flow in tube, (3) Water is incompressible liquid with negligible viscous dissipation.

PROPERTIES: Saturated fluorocarbon (T_{sat} = 57°C, given): k_ℓ = 0.0537 W/m·K, $c_{p,\ell}$ = 1100 J/kg·K, $h'_{fg} \approx h_{fg}$ = 84,400 J/kg. ρ_ℓ = 1619.2 kg/m^3, ρ_v = 13.4 kg/m^3, $\sigma = 8.1 \times 10^{-3}$ kg/s^2, μ_ℓ = 440 × 10^{-6} kg/m·s, Pr_ℓ = 9; *Table A-6*, Water, sat. liquid $\left(\overline{T}_m = 300\text{K}\right)$: ρ = 997 kg/m^3, c_p = 4179 J/kg·K, μ = 855 × 10^{-6} N·s/m^2, k = 0.613 W/m·K, Pr = 5.83.

ANALYSIS: (a) With

$$q = \left(q'' \times A\right)_{module} = 10^5 \text{ W/m}^2 \left(0.1 \text{ m}\right)^2 = 10^3 \text{ W}$$

the condensation rate is

$$\dot{m}_{con} = \frac{q}{h'_{fg}} = \frac{10^3 \text{ W}}{84,400 \text{ J/kg}} = 0.0118 \text{ kg/s} \qquad <$$

and the required water flow rate is

$$\dot{m} = \frac{q}{c_p\left(T_{m,o} - T_{m,i}\right)} = \frac{1000 \text{ W}}{4179 \text{ J/kg}\cdot\text{K}\left(30\text{K}\right)} = 7.98\times10^{-3}\text{kg/s}. \qquad <$$

(b) The Reynolds number for flow through the tube is

$$Re_D = \frac{4\,\dot{m}}{\pi D\mu} = \frac{4\times7.98\times10^{-3}\text{ kg/s}}{\pi\left(0.01 \text{ m}\right)855\times10^{-6}\text{N}\cdot\text{s/m}^2} = 1188.$$

Hence, the flow is laminar. Assuming a uniform wall temperature,

$$h_i = Nu_D\, k/D = 3.66\left(0.613 \text{ W/m}\cdot\text{K}/0.01 \text{ m}\right) = 224 \text{ W/m}^2\cdot\text{K}.$$

Continued …

PROBLEM 10.63 (Cont.)

For film condensation on the outer surface, Eq. 10.46 yields

$$h_o = 0.729\left[\frac{9.8\,m/s^2\left(1619.2\ kg/m^3\right)\left(1605.8\,kg/m^3\right)\left(0.0537\ W/m\cdot K\right)^3 84,400\,J/kg}{440\times10^{-6}\,kg/m\cdot s\times0.01\ m\left(T_{sat}-T_s\right)}\right]^{1/4}$$

$$h_o = 2150\left(57-T_s\right)^{-1/4}.$$

From an energy balance on a portion of the tube surface,

$$h_o\left(T_{sat}-T_s\right) = h_i\left(T_s-T_m\right)$$

or

$$2150\left(57-T_s\right)^{3/4} = 224\left(T_s-T_m\right)$$

At the entrance where $\left(T_{m,i} = 285K\right)$, trial-and-error yields:

$$T_{s,i} = 50.6°C$$ <

and at the exit where $\left(T_{m,o} = 315K\right)$,

$$T_{s,o} = 55.4°C$$ <

We use an average value of $T_s \approx 53°C$ in the following.
(c) From Eqs. 8.43 and 8.44,

$$L = \frac{q}{h_i \pi D \Delta T_{\ell m}}$$

where

$$\Delta T_{\ell m} = \frac{\left(T_s-T_{m,i}\right)-\left(T_s-T_{m,o}\right)}{\ln\left[\left(T_s-T_{m,i}\right)/\left(T_s-T_{m,o}\right)\right]} = \frac{41-11}{\ln\left(41/11\right)} = 22.8°C$$

$$L = \frac{1000\ W}{\left(224\ W/m^2\cdot K\right)\pi\left(0.01\ m\right)22.8°C} = 6.23\ m.$$ <

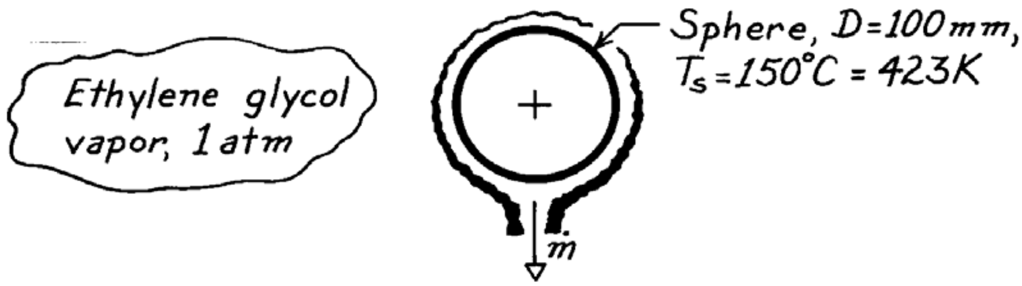
COMMENTS: Some control over system performance may be exercised by adjusting the water flow rate. By increasing $\dot{m}$, $\left(T_{m,o}-T_{m,i}\right)$ is reduced for a prescribed q. The value of h_i is increased substantially if the internal flow is turbulent.

PROBLEM 10.64

KNOWN: Saturated ethylene glycol vapor at 1 atm condensing on a sphere of 100 mm diameter having surface temperature of 150°C.

FIND: Condensation rate.

SCHEMATIC:



ASSUMPTIONS: (1) Laminar film condensation, (2) Negligible non-condensibles in vapor.

PROPERTIES: *Table A-5*, Saturated ethylene glycol, vapor (1 atm): T_{sat} = 470K, $\rho_v \approx 0$ kg/m^3, h_{fg} = 812 kJ/kg; *Table A-5*, Ethylene glycol, liquid (T_f = 423K, but use values at 373K, limit of data in table): ρ_ℓ = 1058.5 kg/m^3, $c_{p,\ell}$ = 2742 J/kg·K, μ_ℓ = 0.215 × 10^{-2} N·s/m^2, k_ℓ = 0.263 W/m·K.

ANALYSIS: The condensation rate is given by Eq. 10.34 as

$$\dot{m} = \frac{q}{h'_{fg}} = \frac{\bar{h}_L\left(\pi D^2\right)\left(T_{sat} - T_s\right)}{h'_{fg}}$$

where A = π D^2 for the sphere and h'_{fg}, with $Ja = c_{p,\ell}\,\Delta T / h_{fg}$, is given by Eq. 10.27 as

$$h'_{fg} = h_{fg}\left(1 + 0.68\,Ja\right) = 812\frac{kJ}{kg}\left(1 + 0.68 \times 2742\frac{J}{kg \cdot K}\left(470 - 423\right)K / 812 \times 10^3\,J/kg\right) = 900\,kJ/kg.$$

The average heat transfer coefficient for the sphere follows from Eq. 10.46 with C = 0.826,

$$\bar{h}_D = 0.826\left[\frac{g\,\rho_\ell\left(\rho_\ell - \rho_v\right)k_\ell^3\,h'_{fg}}{\mu_\ell\left(T_{sat} - T_s\right)D}\right]^{1/4}$$

$$\bar{h}_D = 0.826\left[\frac{9.8\,m/s^2 \times 1058.5\,kg/m^3\left(1058.5 - 0\right)kg/m^3\left(0.263\,W/m \cdot K\right)^3 \times 900 \times 10^3\,J/kg}{0.215 \times 10^{-2}\,N \cdot s/m^2\left(470 - 423\right)K \times 0.100m}\right]^{1/4}$$

$$\bar{h}_D = 1696\ W/m^2 \cdot K.$$

Hence, the condensation rate is

$$\dot{m} = 1696 W/m^2 \cdot K \times \pi\left(0.100m\right)^2\left(470 - 423\right)K / 900 \times 10^3\,J/kg$$

$$\dot{m} = 2.78 \times 10^{-3} kg/s.$$ <

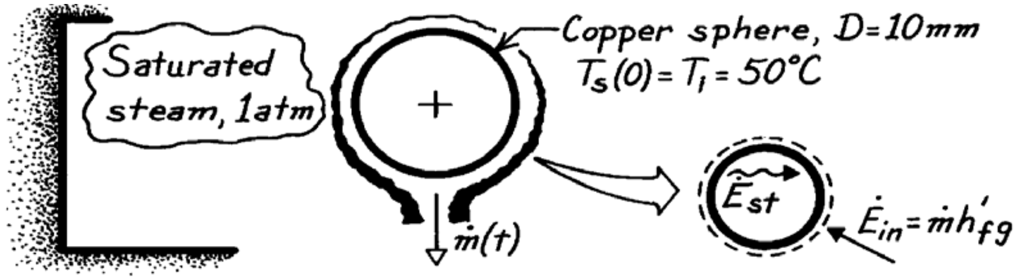
COMMENTS: Recognize this estimate is likely to be a poor one since properties were not evaluated at the proper T_f which was beyond the limit of the table.

PROBLEM 10.65

KNOWN: Copper sphere of 10 mm diameter, initially at 50°C, is placed in a large container filled with saturated steam at 1 atm.

FIND: Time required for sphere to reach equilibrium and the condensate formed during this period.

SCHEMATIC:



ASSUMPTIONS: (1) Laminar film condensation, (2) Negligible non-condensables in vapor, (3) Sphere is spacewise isothermal, (4) Sphere experiences heat gain by condensation only.

PROPERTIES: *Table A-6*, Saturated water vapor (1 atm): T_{sat} = 100°C, ρ_v = 0.596 kg/m^3, h_{fg} = 2257 kJ/kg; *Table A-6*, Water, liquid ($T_f \approx$ (75 + 100)°C/2 = 360K): ρ_ℓ = 967.1 kg/m^3, $c_{p,\ell}$ = 4203 J/kg·K, μ_ℓ = 324 × 10^{-6} N·s/m^2, k_ℓ = 0.674 W/m·K; *Table A-1*, Copper, pure $(\overline{T} = 75°C)$: ρ_{sp} = 8933 kg/m^3, $c_{p,sp}$ = 389 J/kg·K.

ANALYSIS: Using the lumped capacitance approach, an energy balance on the sphere provides,

$$\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st}$$

$$\dot{m}\,h'_{fg} = \overline{h}_D\, A_s\left(T_{sat} - T_s\right) = \rho_{sp}\, c_{p,sp}\, V_s \frac{dT_s}{dt}. \qquad (1)$$

Properties of the sphere, ρ_{sp} and $c_{p,sp}$, will be evaluated at $\overline{T}_s = (50+100)°C/2 = 75°C$, while water (liquid) properties will be evaluated at $\overline{T}_f = (\overline{T}_s + T_{sat})/2 = 87.5°C \approx 360K$. From Eq. 10.27 with Ja = $c_{p,\ell}\,\Delta T / h_{fg}$ where ΔT = Tsat - $\overline{T}_s$, find

$$h'_{fg} = h_{fg}\left(1 + 0.68\,Ja\right) = 2257\frac{kJ}{kg}\left(1 + 0.68\left[4203\frac{J}{kg\cdot K}\times(100-75)K/2257\times10^3 J/kg\right]\right) = 2328\frac{kJ}{kg}. \qquad (2)$$

To estimate the time required to reach equilibrium, we need to integrate Eq. (1) with appropriate limits. However, to perform the integration, an appropriate relation for the temperature dependence of $\overline{h}_D$ needs to be found, as discussed in Chapter 5. Using Eq. 10.46 with C = 0.826,

$$\overline{h}_D = 0.826\left[\frac{g\,\rho_\ell\left(\rho_\ell - \rho_v\right)k_\ell^3\, h'_{fg}}{\mu_\ell\left(T_{sat} - T_s\right)D}\right]^{1/4}.$$

Substitute numerical values and find,

$$\overline{h}_D = 0.826\left[\frac{9.8\,m/s^2\times967.1\,kg/m^3\left(967.1-0.596\right)kg/m^3\left(0.674\,W/m\cdot K\right)^3\times2328\times10^3 J/kg}{324\times10^{-6}\,N\cdot s/m^2\left(T_{sat}-T_s\right)\times0.010m}\right]^{1/4}$$

$$\overline{h}_D = B\left(T_{sat} - T_s\right)^{-1/4} \qquad \text{where} \qquad B = 31{,}120\,W/m^2\cdot(K)^{3/4}. \qquad (3)$$

Continued …

PROBLEM 10.65 (Cont.)

Substitute Eq. (3) into Eq. (1) for $\overline{h}_D$ and recognize $V_s / A_s = \frac{1}{6}\pi D^3 / \pi D^2 = D/6$,

$$B\left(T_{sat} - T_s\right)^{-1/4}\left(T_{sat} - T_s\right) = \rho_{sp}\, c_{p,sp}\left(D/6\right)\frac{dT_s}{dt}. \qquad (4)$$

Note that $d(T_s) = - d(T_{sat} – T_s)$; letting $\Delta T \equiv T_{sat} – T_s$ and separating variables, the energy balance relation has the form

$$\int_0^t dt = -\frac{\rho_{sp}\, c_{p,sp}\left(D/6\right)}{B}\int_{\Delta T_o}^{\Delta T}\frac{d\left(\Delta T\right)}{\Delta T^{3/4}} \qquad (5)$$

where the limits of integration have been identified, with $\Delta T_o = T_{sat} - T_i$ and $T_i = T_s(0)$. Performing the integration, find

$$t = -\frac{\rho_{sp}\, c_{p,sp}\left(D/6\right)}{B}\cdot\frac{1}{1-3/4}\left[\Delta T^{1/4} - \Delta T_o^{1/4}\right].$$

Substituting numerical values with the limits, $\Delta T = 0$ and $\Delta T_o = 100\text{-}50 = 50°C$,

$$t = -\frac{8933\,kg/m^3 \times 389\,J/kg\cdot K\left(0.010m/6\right)}{31{,}120\ W/m^2\cdot K^{3/4}}\times 4\left[0^{1/4} - 50^{1/4}\right]K^{1/4}$$

$$t = 2.0s. \qquad <$$

To determine the total amount of condensate formed during this period, perform an energy balance on a time interval basis,

$$E_{in} - E_{out} = \Delta E = E_{final} - E_{initial}$$

$$E_{in} = \rho_{sp}\, c_{p,sp}\, V\left(T_{final} - T_{initial}\right] \qquad (6)$$

where $T_{final} = T_{sat}$ and $T_{initial} = T_i = T_s(0)$. Recognize that

$$E_{in} = M\, h'_{fg} \qquad (7)$$

where M is the total mass of vapor that condenses. Combining Eqs. (6) and (7),

$$M = \frac{\rho_{sp}\, c_{p,sp}\, V}{h'_{fg}}\left[T_{sat} - T_i\right]$$

$$M = \frac{8933\,kg/m^3 \times 389\,J/kg\cdot K\left(\pi/6\right)\left(0.010m\right)^3}{2328\times 10^3\ J/kg}\left[100-50\right]K$$

$$M = 3.91\times 10^{-5}\,kg. \qquad <$$

COMMENTS: The total amount of condensate could have been evaluated from the integral,

$$M = \int_0^t \dot{m}\,dt = \int_0^t \frac{q}{h'_{fg}}\,dt = \int_0^t \frac{\overline{h}_D\, A_s\left(T_{sat} - T_s\right)dt}{h'_{fg}}$$

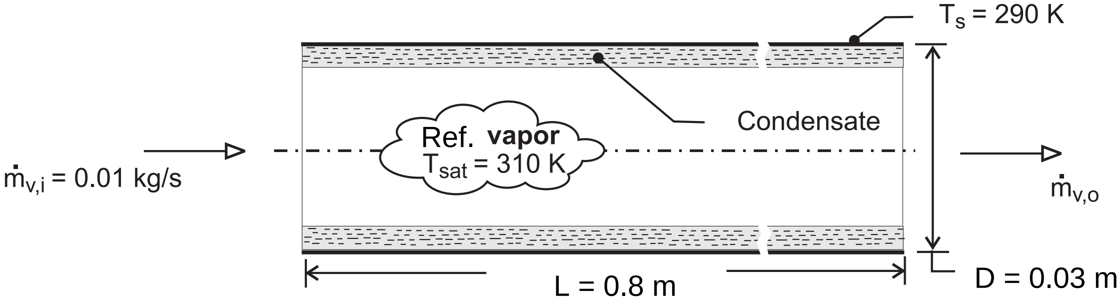
giving the same result, but with more effort.

PROBLEM 10.66

KNOWN: Saturation temperature and inlet flow rate of refrigerant. Diameter, length, and temperature of tube.

FIND: Rate of condensation and outlet flow rate.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible concentration of noncondensable gases in vapor.

PROPERTIES: Given, R-12, saturated vapor (T_{sat} = 310 K): ρ_v = 50.1 kg/m^3, h_{fg} = 160 kJ/kg, μ_v = 150 × 10^{-7} N·s/m^2. Saturated liquid (T_f = 300 K): $\rho_\ell = 1306\ \text{kg/m}^3$, $c_{p,\ell} = 978\ \text{J/kg}\cdot\text{K}$, $\mu_\ell = 0.0254\times10^{-2}\ \text{N}\cdot\text{s/m}^2$, $k_\ell = 0.072\ \text{W/m}\cdot\text{K}$. R-134a, saturated vapor (T_{sat} = 310 K): ρ_v = 46.1 kg/m^3, h_{fg} = 166 kJ/kg, μ_v = 136 × 10^{-7} N·s/m^2. *Table A.5:* R-134a, Saturated liquid (T_f = 300 K): $\rho_\ell = 1199.7\ \text{kg/m}^3$, $c_{p,\ell} = 1432\ \text{J/kg}\cdot\text{K}$, $\mu_\ell = 0.01905\times10^{-2}\ \text{N}\cdot\text{s/m}^2$, $k_\ell = 0.0803\ \text{W/m}\cdot\text{K}$.

ANALYSIS: For R-12: The Reynolds number associated with the inlet vapor flow is $Re_{v,i} = 4\dot{m}_{v,i}/\pi D\mu_v = 0.04\ \text{kg/s}/\pi\times0.03\ \text{m}\times150\times10^{-7}\ \text{N}\cdot\text{s/m}^2 = 28,290 < 35,000$. Hence, the average convection coefficient may be obtained from Eq. 10.46 with C = 0.555, where $h'_{fg} = h_{fg} + 0.375c_{p,\ell}(T_{sat} - T_s)$ = (1.6 × 10^5 + 0.375 × 978 × 20) J/kg = 1.67 × 10^5 J/kg.

$$\bar{h}_D = 0.555\left[\frac{g\rho_\ell(\rho_\ell-\rho_v)k_\ell^3 h'_{fg}}{\mu_\ell(T_{sat}-T_s)D}\right]^{1/4} = 0.555\left[\frac{9.8\ \text{m/s}^2\times1306\ \text{kg/m}^3(1306-50.1)\ \text{kg/m}^3(0.072\ \text{W/m}\cdot\text{K})^3\,1.67\times10^5\ \text{J/kg}}{0.0254\times10^{-2}\ \text{N}\cdot\text{s/m}^2\times20\ \text{K}\times0.03\ \text{m}}\right]^{1/4}$$

$$\bar{h}_D = 889\ \text{W/m}^2\cdot\text{K}$$

The heat rate is then

$$q = \pi DL\bar{h}_D(T_{sat}-T_s) = \pi\times0.03\ \text{m}\times0.8\ \text{m}\times889\ \text{W/m}^2\cdot\text{K}\times20\ \text{K} = 1340\ \text{W}$$

and the condensation rate is

$$\dot{m}_{cond} = \frac{q}{h'_{fg}} = \frac{1340\ \text{W}}{1.67\times10^5} = 0.0080\ \text{kg/s} \qquad <$$

The flow rate of vapor leaving the tube is then

$$\dot{m}_{v,o} = \dot{m}_{v,i} - \dot{m}_{cond} = (0.0100-0.0080)\ \text{kg/s} = 0.0020\ \text{kg/s} \qquad <$$

Continued…

PROBLEM 10.66 (Cont.)

Repeating the analysis for R-134a, we find that $\overline{h}_D = 1007\,W/m^2 \cdot K$, $q = 1520\,W$, $\dot{m}_{cond} = 0.0086\,kg/s$, and $\dot{m}_{v,o} = 0.0014\,kg/s$. $<$

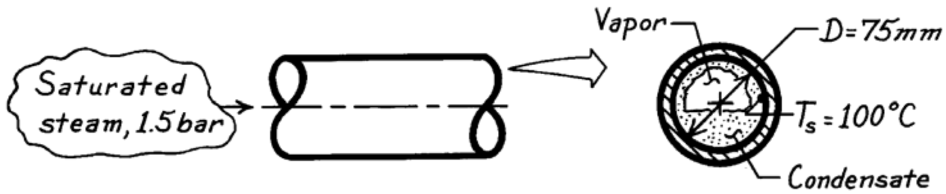
COMMENTS: The behavior of the two refrigerants is comparable since the properties are similar, and R-134a could replace R-12 in many applications. The R-134a provides somewhat higher heat transfer and condensation rates in this application.

PROBLEM 10.67

KNOWN: Saturated steam condensing on the inside of a horizontal pipe.

FIND: Heat transfer coefficient and the condensation rate per unit length of the pipe.

SCHEMATIC:



ASSUMPTIONS: (1) Film condensation with low vapor velocities.

PROPERTIES: *Table A-6*, Saturated water vapor (1.5 bar): $T_{sat} \approx 385K$, $\rho_v = 0.88\ kg/m^3$, $h_{fg} = 2225\ kJ/kg$; *Table A-6*, Saturated water ($T_f = (T_{sat} + T_s)/2 \approx 380K$): $\rho_\ell = 953.3\ kg/m^3$, $c_{p,\ell} = 4226\ J/kg\cdot K$, $\mu_\ell = 260 \times 10^{-6}\ N\cdot s/m^2$, $k_\ell = 0.683\ W/m\cdot K$.

ANALYSIS: The condensation rate per unit length follows from Eq. 10.34 with A = π D L and has the form

$$\dot{m}' = \frac{\dot{m}}{L} = \bar{h}_D(\pi D)(T_{sat} - T_s)/h'_{fg}$$

where $\bar{h}_D$ is estimated from the correlation of Eq. 10.46 with the expression for h'_{fg} following the discussion after Eq. 10.50,

$$\bar{h}_D = 0.555\left[\frac{g\,\rho_\ell(\rho_\ell - \rho_v)k_\ell^3 h'_{fg}}{\mu_\ell(T_{sat} - T_s)D}\right]^{1/4}$$

where

$$h'_{fg} = h_{fg} + \frac{3}{8}c_{p,\ell}(T_{sat} - T_s) = 2225\times10^3\frac{J}{kg} + \frac{3}{8}\times4226\frac{J}{kg\cdot K}(385-373)K$$

$$h'_{fg} = 2244\,kJ/kg.$$

Hence,

$$\bar{h}_D = 0.555\left[\frac{9.8\,m/s^2\times953.3\frac{kg}{m^3}(953.3-0.88)\frac{kg}{m^3}(0.683\,W/m\cdot K)^3\,2244\times10^3\,J/kg}{260\times10^{-6}\,N\cdot s/m^2(385-373)K\times0.075m}\right]^{1/4}$$

$$\bar{h}_D = 7127\,W/m^2\cdot K.$$

It follows that the condensate rate per unit length of the tube is

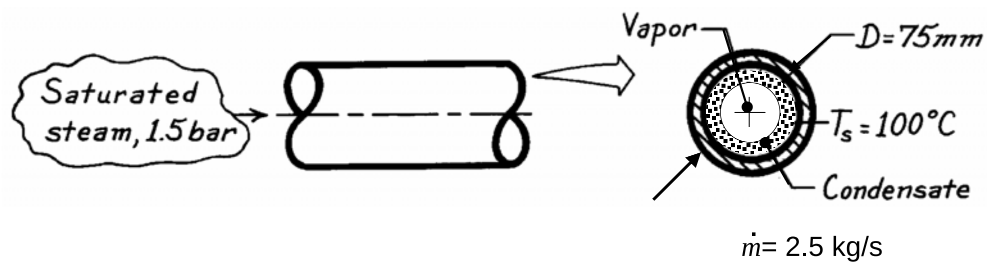
$$\dot{m}' = 7127\,W/m^2\cdot K(\pi\times0.075m)(385-373)K/2224\times10^3\,J/kg = 9.0\times10^{-3}\,kg/s\cdot m. \quad <$$

PROBLEM 10.68

KNOWN: Pressure of saturated steam condensing on the inside of a horizontal pipe. Diameter and surface temperature of pipe. Mass flow rate.

FIND: (a) Heat transfer coefficient and condensation rate per unit length of the pipe for $X = 0.2$. (b) Plot heat transfer coefficient and condensation rate for $0.1 \le X \le 0.3$.

SCHEMATIC:



ASSUMPTIONS: (1) Film condensation with high vapor velocities, annular flow.

PROPERTIES: *Table A-6*, Saturated water (1.5 bar): $T_{sat} \approx 385$ K, $\rho_l = 949.7$ kg/m^3, $\rho_v = 0.88$ kg/m^3, $h_{fg} = 2225$ kJ/kg, $c_{p,l} = 4.232$ kJ/kg, $\mu_l = 248 \times 10^{-6}$ N · s/m^2, $\mu_v = 12.49 \times 10^{-6}$ N · s/m^2, $k_l = 0.685$ W/m · K, $Pr_l = 1.53$.

ANALYSIS: The mass flow rate per unit cross sectional tube area is

$$\frac{\dot{m}}{A_c} = \frac{2.5 \text{ kg/s}}{\pi(0.075 \text{ m})^2 / 4} = 566 \text{ kg/s} \cdot \text{m}^2$$

Since this exceeds 500 kg/s · m^2, the Dobson and Chato correlation, Eq. 10.51a can be used. The Reynolds number is

$$Re_{D,l} = 4\dot{m}(1-X)/(\pi D \mu_l) = 4 \times 2.5 \text{ kg/s} \times (1-0.2)/(\pi \times 0.075 \text{ m} \times 248 \times 10^{-6} \text{ N} \cdot \text{s/m}^2) = 1.37 \times 10^5$$

and the Martinelli parameter is

$$X_{tt} = \left(\frac{1-X}{X}\right)^{0.9} \left(\frac{\rho_v}{\rho_l}\right)^{0.5} \left(\frac{\mu_l}{\mu_v}\right)^{0.1} = \left(\frac{1-0.2}{0.2}\right)^{0.9} \left(\frac{0.88}{949.7}\right)^{0.5} \left(\frac{248}{12.49}\right)^{0.1} = 0.143$$

Then,

$$Nu_D = \frac{hD}{k_l} = 0.023 Re_{D,l}^{0.8} Pr_l^{0.4} \left[1 + \frac{2.22}{X_{tt}^{0.89}}\right] = 0.023 \times (1.37 \times 10^5)^{0.8} \times 1.53^{0.4} \left[1 + \frac{2.22}{0.143^{0.89}}\right] = 4750$$

The heat transfer coefficient is

$$h = Nu_D k_l / D = 4750 \times 0.685 \text{ W/m} \cdot \text{K} / 0.075 \text{ m} = 43{,}300 \text{ W/m}^2 \cdot \text{K}$$ <

Continued…

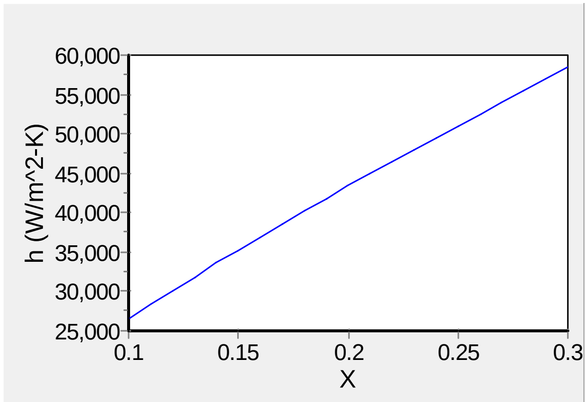
PROBLEM 10.68 (Cont.)

The condensation rate per unit length follows from Eq. 10.34 with $A = \pi DL$ and $h'_{fg} = h_{fg} + 0.375 c_{p,l}(T_{sat} - T_s) = 2225 \text{ kJ/kg} + 0.375 \times 4.232 \text{ kJ/kg}\cdot\text{K} \times (385 - 373) \text{ K} = 2244 \text{ kJ/kg}$. Thus,

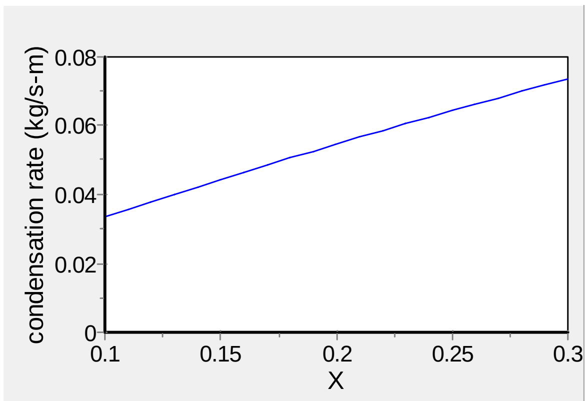
$$\dot{m}'_{cond} = \frac{\dot{m}_{cond}}{L} = h(\pi D)(T_{sat} - T_s)/h'_{fg}$$

$$= 43{,}400 \text{ W/m}^2\cdot\text{K} \times \pi \times 0.075 \text{ m} \times (385 - 373) \text{ K} / 2244 \times 10^3 \text{ J/kg} = 0.0546 \text{ kg/s}\cdot\text{m}$$ <

(b) Solving the same equations for $0.1 \le X \le 0.3$ yields the plots below.



<



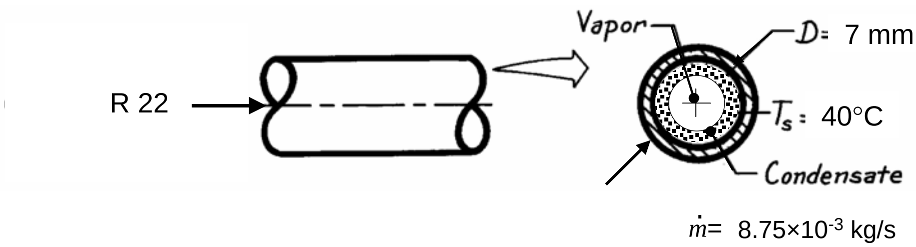
COMMENTS: (1) The value of X strongly impacts the heat transfer coefficient and condensation rate. (2) The condensation rate corresponding to the low vapor velocity case of Problem 10.67 is 9.0×10^{-3} kg/s · m. The higher vapor velocity yields a six-fold increase in heat transfer coefficient and condensation rate. (3) If the fluid were all vapor at the inlet, $X = 1$, the vapor velocity would be $u_v = \dot{m}/(\rho_v A_c) = 2.5/(0.88 \text{ kg/m}^3 \times \pi(0.075 \text{ m})^2/4) = 643$ m/s. The inlet Reynolds number would then be 3.4×10^6, and the criterion for the low vapor velocity solution, Eq. 10.50 would not be satisfied. (4) Treating water vapor as an ideal gas, the speed of sound at 385 K would be 479 m/s as determined in Comment 5. The mass flow rate specified in the problem could not be achieved in a tube of constant cross-sectional area with $X = 1$. (5) For water at $T = 385$ K and $p = 1.5$ bar, $R \equiv \mathcal{R}/\mathcal{M} = 8315$ J/kmol·K/18 kg/kmol = 462 J/kg. The specific heat at constant volume is $c_v \equiv c_p - R = 2080 \text{ J/kg}\cdot\text{K} - 462 \text{ J/kg}\cdot\text{K} = 1618 \text{ J/kg}\cdot\text{K}$. Therefore the specific heat ratio is $\gamma = c_p/c_v = 2080$ J/kg·K/1618 J/kg·K = 1.29 and the speed of sound is $a = \sqrt{1.29 \times 462 \text{ J/kg}\cdot\text{K} \times 385 \text{ K}} = 479 \text{ m/s}$.

PROBLEM 10.69

KNOWN: Mass flow rate and quality of R-22 condensing in tube. Tube diameter. Wall and saturation temperatures. Refrigerant properties.

FIND: Heat transfer coefficient, heat transfer rate, and condensation rate for (a) $X = 0.5$, (b) $0.2 < X < 0.8$.

SCHEMATIC:



ASSUMPTIONS: (1) Film condensation with high vapor velocities, annular flow. (2) Heat of vaporization not strong function of temperature.

PROPERTIES: Refrigerant R-22 (T_{sat} = 318 K): *Given* ρ_v = 77 kg/m^3, $\mu_v = 15 \times 10^{-6}$ N·s/m^2; *Table A-5*, ρ_l = 1106 kg/m^3, $\mu_l = 131 \times 10^{-6}$ N·s/m^2, $c_{p,l}$ = 1377 J/kg · K, k_l = 0.0741 W/m · K, Pr_l = 2.4, h_{fg} = 234 kJ/kg.

ANALYSIS: The mass flow rate per unit cross sectional tube area is

$$\frac{\dot{m}}{A_c} = \frac{8.75 \times 10^{-3} \text{ kg/s}}{\pi (0.007 \text{ m})^2 / 4} = 227 \text{ kg/s} \cdot \text{m}^2$$

Although this is below the recommended threshold of 500 kg/s · m^2, since annular flow was observed, the Dobson and Chato correlation, Eq. 10.51a can be used. The Reynolds number is

$$Re_{D,l} = 4\dot{m}(1-X)/(\pi D \mu_l) = 4 \times 8.75 \times 10^{-3} \text{ kg/s} \times (1-0.5)/(\pi \times 0.007 \text{ m} \times 131 \times 10^{-6} \text{ N} \cdot \text{s/m}^2) = 6070$$

and the Martinelli parameter is

$$X_{tt} = \left(\frac{1-X}{X}\right)^{0.9} \left(\frac{\rho_v}{\rho_l}\right)^{0.5} \left(\frac{\mu_l}{\mu_v}\right)^{0.1} = \left(\frac{1-0.5}{0.5}\right)^{0.9} \left(\frac{77}{1106}\right)^{0.5} \left(\frac{131}{15}\right)^{0.1} = 0.328$$

Then,

$$Nu_D = \frac{hD}{k_l} = 0.023 Re_{D,l}^{0.8} Pr_l^{0.4} \left[1 + \frac{2.22}{X_{tt}^{0.89}}\right] = 0.023 \times (6070)^{0.8} \times 2.4^{0.4} \left[1 + \frac{2.22}{0.328^{0.89}}\right] = 243$$

The heat transfer coefficient and heat transfer rate per unit length are

$$h = Nu_D k_l / D = 243 \times 0.0741 \text{ W/m} \cdot \text{K} / 0.007 \text{ m} = 2570 \text{ W/m}^2 \cdot \text{K}$$ <

$$q_s' = h \pi D (T_{sat} - T_s) = 2570 \text{ W/m}^2 \cdot \text{K} \times \pi \times 0.007 \text{ m} \times (45-40)°\text{C} = 283 \text{ W/m}^2$$ <

Continued…

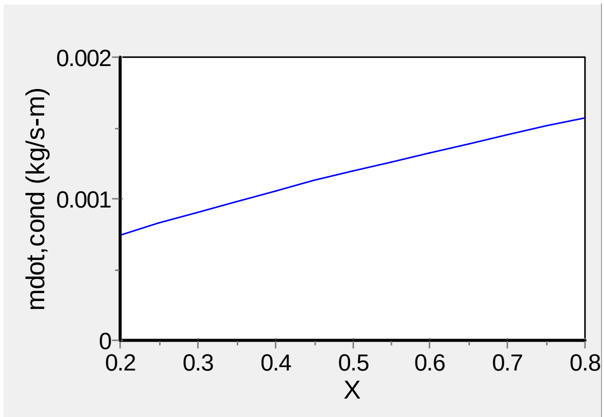
PROBLEM 10.69 (Cont.)

The condensation rate per unit length follows from Eq. 10.34 with $A = \pi DL$ and

$h'_{fg} = h_{fg} + 0.375 c_{p,l}(T_{sat} - T_s) = 234 \text{ kJ/kg} + 0.375 \times 1.377 \text{ kJ/kg} \cdot \text{K} \times (45 - 40)°\text{C} = 237 \text{ kJ/kg}$. Thus,

$$\dot{m}'_{cond} = q'_s / h'_{fg} = 283 \text{ W/m}^2 / 237 \times 10^3 \text{ J/kg} = 1.19 \times 10^{-3} \text{ kg/s} \cdot \text{m} \quad <$$

(b) Solving the same equations for 0.2 < X < 0.8 yields the condensation rate plot below.



<

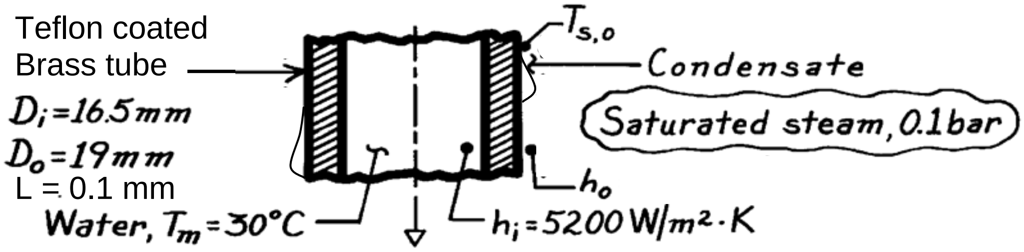
COMMENTS: (1) The value of X strongly impacts the heat transfer coefficient, heat transfer rate, and condensation rate. (2) This problem corresponds to one of the experimental conditions on which the Dobson and Chato correlation is based. Annular flow was observed for this and many, but not all, of the other cases for which the mass flow rate per unit area was less than 500 kg/s · m^2. Annular flow was always observed for values greater than 500 kg/s · m^2. Hence the recommended threshold value of $\dot{m}/A_c$ = 500 kg/s·m^2 is conservative.

PROBLEM 10.70

KNOWN: Inner and outer diameter of brass tube. Thickness of Teflon coating. Saturated steam at 1 bar outside tube. Convection coefficient and mean temperature of water flowing inside tube.

FIND: Condensation convection coefficient. Steam condensation rate per unit length. Comparison with condensation rate for uncoated brass tube.

SCHEMATIC:



ASSUMPTIONS: (1) Dropwise condensation, (2) Correlations for a copper surface can be applied to Teflon, and (3) Negligible effect of noncondensable vapors.

PROPERTIES: *Table A.6*, Water, vapor (0.1 bar): T_{sat} = 318.9 K, $h_{fg} = 2393 \times 10^3$ J/kg; *Table A.1*, Brass $\left(\overline{T} = \left(T_m + T_{sat}\right)/2 \approx 300K\right)$: $k_b = 110$ W/m·K ; *Table A.3*, Teflon (T ≈ 300 K); k_t = 0.35 W/m·K.

ANALYSIS: The condensation rate per unit length follows from Eq. 10.34 written as

$$\dot{m}' = q'/h'_{fg} \qquad (1)$$

where the heat rate per unit length follows from Eq. 10.33 using an overall heat transfer coefficient

$$q' = UP\left(T_{sat} - T_m\right) \qquad (2)$$

where P is the perimeter. From Eq. 3.36, with resistances for the brass tube and Teflon coating,

$$UP = \left[\frac{1}{h_o\pi(D_o + 2L)} + \frac{\ln[(D_o + 2L)/D_o]}{2\pi k_t} + \frac{\ln(D_o/D_i)}{2\pi k_b} + \frac{1}{h_i\pi D_i}\right]^{-1}$$

The outer heat transfer coefficient, $h_o = \overline{h}_{dc}$, can be calculated from Eq. 10.52,

$$\overline{h}_{dc} = 51{,}104 + 2044T_{sat}(°C) = 51{,}104 + 2044(319.9 - 273) = 144{,}900 \text{ W/m}^2\cdot\text{K}$$

Thus

$$UP = \left[\frac{1}{144{,}900\,\text{W/m}^2\cdot\text{K}\times\pi(19.2\times10^{-3}\text{ m})} + \frac{\ln(19.2/19)}{2\pi\times0.35\,\text{W/m}\cdot\text{K}}\right.$$
$$\left.+\frac{\ln(19/16.5)}{2\pi\times110\,\text{W/m}\cdot\text{K}} + \frac{1}{5200\,\text{W/m}^2\cdot\text{K}\times\pi(16.5\times10^{-3}\text{ m})}\right]^{-1}$$

Continued…

PROBLEM 10.70 (Cont.)

$$UP = \left[1.14\times10^{-4} + 4.76\times10^{-3} + 2.04\times10^{-4} + 3.71\times10^{-3}\right]^{-1} W/m\cdot K = 114\, W/m\cdot K.$$

Combining Eqs. (1) and (2) and substituting numerical values (see below for h'_{fg}), find

$$\dot{m}' = UP\left(T_{sat} - T_m\right)/h'_{fg} = 114\, W/m\cdot K\left(318.9 - 303\right)K/2393\times10^3 J/kg$$

$$\dot{m}' = 7.56\times10^{-4} kg/s.$$ <

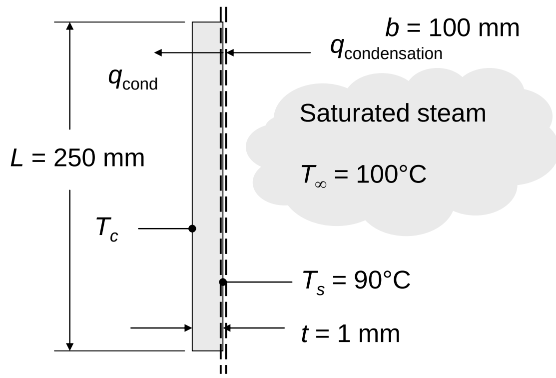
COMMENTS: (1) Since the outer convection resistance is small relative to the sum of the remaining resistances, $T_{s,o} \approx T_{sat}$ and from Eq. 10.27, $h'_{fg} \approx h_{fg}$. (2) The Teflon coating induces a 21-fold increase in the condensation convection coefficient. However, the condensation rate decreases by 25 percent. This is because of the significant conduction resistance posed by the thin Teflon coating. (3) In addition to the conduction resistance, a contact resistance would exist at the Teflon-brass interface as well as constriction resistances at the droplet-Teflon interfaces, further reducing the condensation rate.

PROBLEM 10.71

KNOWN: Conditions of saturated steam. Surface temperature of aluminum and stainless steel plates of known dimension.

FIND: (a) Temperature of the cold surface of the aluminum plate, (b) Temperature of the cold surface of the stainless steel plate.

SCHEMATIC:



ASSUMPTIONS: (1) Dropwise condensation on stainless steel described by Equation 10.52, (2) Filmwise condensation on aluminum, (3) Constant properties, (4) Steady state.

PROPERTIES: *Table A.6*, Water vapor (T_∞ = 100°C = 373 K): $p_{A,sat}$ = 1.008 bar, $h_{fg} = 2.257 \times 10^6$ J/kg; *Table A.6*, Water, liquid ($T_f = (T_s + T_{sat})/2$ = 95°C = 368 K): $c_{p,l}$ = 4212 J/kg·K, μ_l = 0.0002958N·s/m^2, k_l = 0.6782 W/m·K, $\nu_l = 3.076 \times 10^{-7}$ m^2/s; *Table A.1*, Aluminum 2024-T6 (T = 300 K): k_{Al} = 177 W/m·K; *Table A.1* A302 Stainless Steel (T = 300 K): k_{SS} = 15.1 W/m·K.

ANALYSIS: An energy balance for the control surface at T_s yields

$$q = \bar{h}bL\left(T_{sat} - T_s\right) = \frac{k_m bL}{t}\left(T_s - T_c\right) \qquad (1)$$

where k_m is the thermal conductivity of the metal plate. Equation (1) may be rearranged to yield

$$T_c = T_s - \frac{t\bar{h}}{k_m}\left(T_{sat} - T_s\right) \qquad (2)$$

(a) For filmwise condensation on the aluminum plate, $Ja = c_{p,l}(T_{sat} - T_s)/h_{fg}$ = 4212 J/kg·K(100 – 90)K/2.257 × 10^6 J/kg = 0.0187. The modified latent heat is $h'_{fg} = h_{fg}(1 + 0.68Ja) = 2.257 \times 10^6$ J/kg × (1 + 0.68 × 0.0187) = 2.286 × 10^6 J/kg. Evaluation of Equation 10.42 yields

$$P = \frac{k_l L(T_{sat} - T_s)}{\mu_l h'_{fg}(\nu_l^2/g)^{1/3}} = \frac{0.6782 \text{ W/m}\cdot\text{K} \times 0.25 \text{ m} \times (100-90)\text{K}}{0.0002958 \text{ N}\cdot\text{s/m}^2 \times 2.286\times10^6 \text{ J/kg} \times \left[\left(3.076\times10^{-7}\text{ m}^2\text{/s}\right)^2 \Big/ 9.8 \text{ m}^2\text{/s}\right]^{1/3}} = 118$$

which is in the range of application of Equation 10.44. Therefore,

Continued…

PROBLEM 10.71 (Cont.)

$$\bar{h}_L = \frac{k_l}{(\nu_l^2/g)^{1/3}}\frac{1}{P}(0.68P + 0.89)^{0.82}$$
$$= \frac{0.6782 \text{ W/m}\cdot\text{K}}{\left[\left(3.076\times10^{-7}\text{ m}^2/\text{s}\right)^2 \Big/ 9.8 \text{ m}^2/\text{s}\right]^{1/3}}\frac{1}{118}(0.68\times118 + 0.89)^{0.82} = 9930 \text{ W/m}^2\cdot\text{K}$$

From Equation (2), the cold surface temperature is

$$T_{c,\text{AL}} = 90°\text{C} - \frac{0.001 \text{ m}\times 9930\text{W/m}^2\cdot\text{K}}{177 \text{ W/m}\cdot\text{K}}\left(100-90\right)\text{K} = 89.4°\text{C} \quad <$$

(b) For dropwise condensation on the stainless steel plate, Equation 10.52 yields

$$\bar{h} = 51{,}104 + 2044\times100°\text{C} = 255{,}500 \text{ W/m}^2\cdot\text{K}$$

From Equation (2), the cold surface temperature is

$$T_{c,\text{SS}} = 90°\text{C} - \frac{0.001 \text{ m}\times 255{,}500\text{W/m}^2\cdot\text{K}}{15.1 \text{ W/m}\cdot\text{K}}\left(100-90\right)\text{K} = -79°\text{C} \quad <$$

COMMENTS: (1) The required cold surface temperature associated with the stainless steel is very low, compared to the corresponding value associated with the aluminum. (2) The heat transfer rate associated with the aluminum is
$q_{\text{AL}} = \bar{h}bL(T_{\text{sat}} - T_s) = 9930\text{W/m}^2\cdot\text{K}\times0.1 \text{ m}\times0.25 \text{ m}\times(100-90) \text{ K} = 2{,}480 \text{ W}$
while heat transfer rate associated with the stainless steel is
$q_{\text{SS}} = \bar{h}bL(T_{\text{sat}} - T_s) = 255{,}500\text{W/m}^2\cdot\text{K}\times0.1 \text{ m}\times0.25 \text{ m}\times(100-90) \text{ K} = 63{,}900 \text{ W}.$
(3) For the aluminum with film condensation, the thermal resistances associated with conduction and condensation are $R_{t,\text{cond}} = t/kA = 0.001 \text{ m}/(177 \text{ W/m}\cdot\text{K}\times0.25 \text{ m}\times0.1 \text{ m}) = 225\times10^{-6}$ K/W and $R_{t,\text{conv}} = 1/\bar{h}bL = 1/\left[9930 \text{ W/m}^2\cdot\text{K}\times0.25 \text{ m}\times0.1 \text{ m}\right] = 4030\times10^{-6}$ K/W respectively. Hence, if dropwise condensation could be promoted on the aluminum plate, the overall thermal resistance would decrease and the heat transfer rate would increase. (4) For the stainless steel with dropwise condensation, the thermal resistances associated with conduction and condensation are
$R_{t,\text{cond}} = t/kA = 0.001 \text{ m}/(15.1 \text{ W/m}\cdot\text{K}\times0.25 \text{ m}\times0.1 \text{ m}) = 2650\times10^{-6}$ K/W and
$R_{t,\text{conv}} = 1/\bar{h}bL = 1/\left[255{,}500\text{W/m}^2\cdot\text{K}\times0.25 \text{ m}\times0.1 \text{ m}\right] = 157\times10^{-6}$ K/W respectively. Hence, the primary resistance is associated with conduction within the metal. Further increases in the heat transfer coefficient associated with the condensation would not significantly increase the heat transfer rate. (5) Further information on the ion implantation effect on condensation is available in the following two references.

M.H. Rausch, A.P. Fröba, A. Leipertz, "Dropwise condensation heat transfer on ion implanted aluminum surfaces," *International Journal of Heat and Mass Transfer*, Vol. 51, pp. 1061 – 1070, 2008.

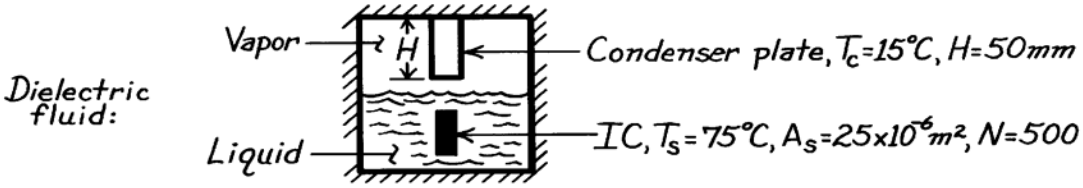
A. Bani Kananeh, M.H. Rausch, A.P. Fröba, A. Leipertz, "Experimental study of dropwise condensation on plasma-ion implanted stainless steel tubes," *International Journal of Heat and Mass Transfer*, Vol. 49, pp. 5018-5026, 2006.

PROBLEM 10.72

KNOWN: Surface temperature and area of integrated circuits submerged in a dielectric fluid of prescribed properties. Height and temperature of condenser plates.

FIND: (a) Heat dissipation by an integrated circuit, (b) Condenser surface area needed to balance heat load.

SCHEMATIC:



ASSUMPTIONS: (1) Nucleate pool boiling in liquid, (2) Laminar film condensation of vapor, (3) Negligible heat loss to surroundings.

PROPERTIES: Dielectric fluid (given, T_{sat} = 50°C): ρ_ℓ = 1700kg/m^3, $c_{p,\ell}$ = 1005J/kg·K, μ_ℓ = 6.80 × 10^{-4} kg/s·m, k_ℓ = 0.062W/m·K, Pr_ℓ = 11, σ = 0.013 kg/s^2, h_{fg} = 1.05 × 10^5 J/kg, $C_{s,f}$ = 0.004, n = 1.7, $\nu_\ell = \mu_\ell / \rho_\ell = 4.0 \times 10^{-7}$ m^2/s .

ANALYSIS: (a) For nucleate pool boiling,

$$q_s'' = \mu_\ell h_{fg}\left[\frac{g(\rho_\ell - \rho_v)}{\sigma}\right]^{1/2}\left(\frac{c_{p,\ell}\Delta T_e}{C_{s,f} h_{fg} Pr_\ell^n}\right)^3 \approx 6.8\times10^{-4}\ \text{kg/s}\cdot\text{m}\left(1.05\times10^5\ \text{J/kg}\right)$$

$$\times\left[\frac{9.8\ \text{m/s}^2\times1700\ \text{kg/m}^3}{0.013\ \text{kg/s}^2}\right]^{1/2}\left(\frac{1005\ \text{J/kg}\cdot\text{K}\times25\text{K}}{0.004\times1.05\times10^5\ \text{J/kg}\times11^{1.7}}\right)^3 = 84,530\ \text{W/m}^2$$

$$q_s = A_s q_s'' = 84,530\ \text{W/m}^2 \times 25\times10^{-6}\ \text{m}^2 = 2.11\ \text{W}.$$ <

(b) From Eq. 10.42,

$$P = \frac{k_\ell L(T_{sat} - T_s)}{\mu_\ell h_{fg}'(\nu_\ell^2/g)^{1/3}}$$

$$= \frac{0.062\ \text{W/m}\cdot\text{K}\times0.05\ \text{m}\ (50-15)\text{K}}{6.80\times10^{-4}\ \text{kg/s}\cdot\text{m}\times1.29\times10^5\ \text{J/kg}\times\left[(4.0\times10^{-7}\ \text{m}^2/\text{s})^2/9.8\ \text{m/s}^2\right]^{1/3}} = 48.8$$

where $h_{fg}' = h_{fg} + 0.68c_{p,\ell}(T_{sat} - T_s) = 1.29\times10^5$ J/kg. With 15.8 < P < 2530, the flow is wavy laminar and Eq. 10.44 gives

$$\overline{h}_L = \frac{k_\ell}{(\nu_\ell^2/g)^{1/3}}\frac{1}{P}(0.68P + 0.89)^{0.82}$$

$$= \frac{0.062\ \text{W/m}\cdot\text{K}}{\left[\left(4.0\times10^{-7}\ \text{m}^2/\text{s}\right)^2/9.8\ \text{m}^2/\text{s}\right]^{1/3}}\frac{1}{48.8}(0.68\times48.8+0.89)^{0.82} = 904\ \text{W/m}^2\cdot\text{K}$$

To balance the heat load, $q_c = Nq_s$, thus from Eq. 10.33,

$$\overline{h}_L A_c (T_{sat} - T_c) = Nq_s = 500 \times 2.11\ \text{W} = 1055\ \text{W}$$

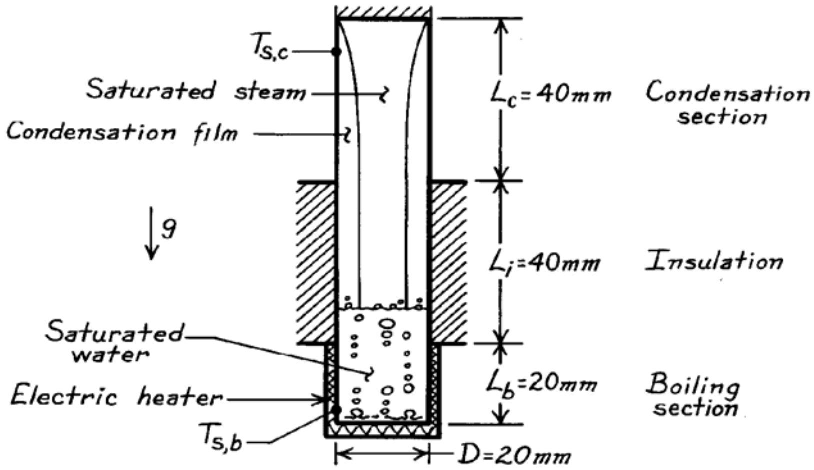
$$A_c = \frac{1055\ \text{W}}{904\ \text{W/m}^2\cdot\text{K}\times(50-15)°\text{C}} = 0.033\ \text{m}^2$$ <

PROBLEM 10.73

KNOWN: Thin-walled thermosyphon. Absorbs heat by boiling saturated water at atmospheric pressure on boiling section L_b. Rejects heat by condensing vapor into a thick film which falls length of condensation section L_c back into boiling section.

FIND: (a) Mean surface temperature, $T_{s,b}$, of the boiling surface if nucleate boiling flux is 30% critical flux, (b) Mean surface temperature, $T_{s,c}$ of condensation section, and total condensation flow rate, $\dot{m}$, in thermosyphon.

SCHEMATIC:



ASSUMPTIONS: (1) Film condensation occurs in condensation section which approximates a vertical plate, (2) Boiling and condensing section are separated by insulated length L_i, (3) Top surface of condensation section is insulated, (4) For condensation, liquid properties evaluated at $T_f = 90°C$.

PROPERTIES: *Table A-6*, Saturated water (100°C): $\rho_\ell = 1/v_f = 957.9\ kg/m^3$, $c_{p,\ell} = 4217$ J/kg·K, $\mu_\ell = 279 \times 10^{-6}\ N \cdot s/m^2$, $Pr_\ell = 1.76$, $h_{fg} = 2257$ kJ/kg, $\sigma = 58.9 \times 10^{-3}$ N/m; Saturated vapor (100°C): $\rho_v = 1/v_g = 0.5955\ kg/m^3$; Saturated water (90°C): $\rho_\ell = 1/v_f = 964.9\ kg/m^3$, $c_{p,\ell} = 4207$ J/kg·K, $\mu_\ell = 313 \times 10^{-6}\ N{\cdot}s/m^2$, $k_\ell = 0.676\ W/m \cdot K$, $\nu_\ell = \mu_\ell/\rho_\ell = 3.24 \times 10^{-7}\ m^2/s$.

ANALYSIS: (a) The heat flux for the boiling section is 30% of the critical heat flux which at atmospheric pressure is

$$q''_{s,b} = 0.30 q''_{max} = 0.30 \times 1.26 \times 10^6\ W/m^2 = 3.78 \times 10^5\ W/m^2.$$

Using the Rohsenow correlation for nucleate boiling with $T_{sat} = 100°C$ and typical values for the surface of $C_{s,f} = 0.0130$ and $n = 1.0$, find

$$q''_{s,b} = \mu_\ell h_{fg} \left[\frac{g(\rho_\ell - \rho_v)}{\sigma} \right]^{1/2} \left(\frac{c_{p,\ell}(T_{s,b} - T_{sat})}{C_{s,f} h_{fg} Pr_\ell^n} \right)^3$$

$$3.78 \times 10^5\ W/m^2 = 279 \times 10^{-6}\ N \cdot s/m^2 \times 2257 \times 10^3\ J/kg \times$$

$$\left[\frac{9.8\,m/s^2 (957.9 - 0.5955) kg/m^3}{58.9 \times 10^{-3}\ N/m} \right]^{1/2} \left(\frac{4217\ J/kg \cdot K (T_{s,b} - 100)}{0.013 \times 2257 \times 10^3\ J/kg\, 1.76^{1.0}} \right)^3$$

Continued …

$$T_{s,b} = 114.0°C.$$ <

(b) The heat transferred into the boiling section must be rejected by film condensation,

$$q_c = q_b = q''_{s,b}\left[\pi D^2/4 + \pi D L_b\right]$$

$$q_c = 3.78\times10^5\ W/m^2\left[\pi\left(0.020\,m\right)^2/4 + \pi\left(0.020\,m\right)\times0.020\,m\right] = 594\ W.$$

Thus from Eq. 10.34, $\dot{m} = q_c / h'_{fg}$ and from Eq. 10.36, $Re_\delta = 4\dot{m}/\mu_\ell b = 4q_c / h'_{fg}\mu_\ell \pi D$, where $h'_{fg} = h_{fg} + 0.68c_{p,\ell}(T_{sat} - T_{s,c})$. We approximate $h'_{fg} = h_{fg}$ and find $Re_\delta \approx 53.5$. Thus the flow is wavy laminar. From Eq. 10.39 we have

$$\bar{h}_L = \frac{k_\ell}{(\nu_\ell^2/g)^{1/3}}\frac{Re_\delta}{1.08Re_\delta^{1.22} - 5.2} =$$

$$= \frac{0.676\ W/m\cdot K}{\left[\left(3.24\times10^{-7}\ m^2/s\right)^2 \Big/ 9.8\ m^2/s\right]^{1/3}}\frac{53.5}{1.08\times53.5^{1.22} - 5.2} = 12{,}290\ W/m^2\cdot K \qquad (1)$$

From Eq. 10.33 we can solve for $T_{sat} - T_{s,c,}$ as

$$T_{sat} - T_{s,c} = q_c / \bar{h}_L \pi DL = 594\ W/(12{,}290\ W/m^2\cdot K \times \pi \times 0.02\ m \times 0.04\ m) = 19.2°C \qquad (2)$$

This solution can now be iterated by recalculating h'_{fg} and Re_δ and re-solving Eqs. (1) and (2). The iterations converge to $T_{sat} - T_{s,c} = 19.1°C$. Thus

$$T_{s,c} = 80.9°C$$ <

Finally, with $h'_{fg} = 2.31\times10^6 J/kg$,

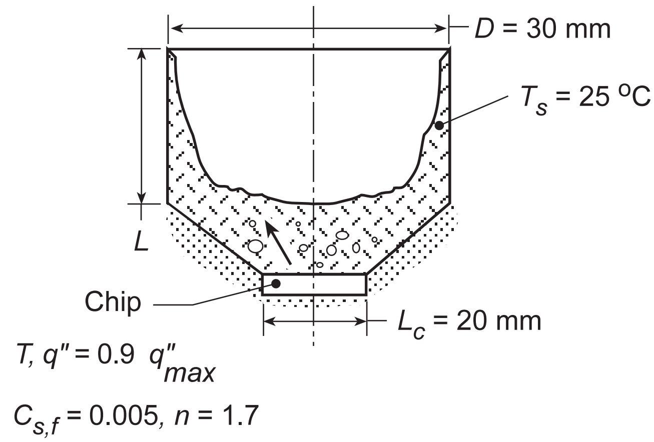
$$\dot{m} = q_c / h'_{fg} = 594\ W/2.31 \times 10^6\ J/kg = 2.6 \times 10^{-4}\ kg/s.$$ <

PROBLEM 10.74

KNOWN: Thermosyphon configuration for cooling a computer chip of prescribed size.

FIND: (a) Chip temperature and total power dissipation when chip operates at 90% of critical heat flux, (b) Required condenser length.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Saturated liquid/vapor conditions, (3) Negligible heat transfer from bottom of chip.

PROPERTIES: Fluorocarbon (prescribed): T_{sat} = 57°C, $c_{p,l}$ = 1100 J/kg·K, h_{fg} = 84,400 J/kg, ρ_ℓ = 1619.2 kg/m³, ρ_v = 13.4 kg/m³, σ = 8.1 × 10⁻³ kg/s², μ_ℓ = 440 × 10⁻⁶ kg/m·s, Pr_ℓ = 9.01, k_ℓ = 0.054 W/m·K, $\nu_\ell = \mu_\ell/\rho_\ell$ = 0.272 × 10⁻⁶ m²/s.

ANALYSIS: (a) With $q'' = 0.9\ q''_{max}$ and the critical heat flux given by Eq. 10.6 with C=0.149, the chip power dissipation is

$$q = 0.9L_c^2 \times 0.149 h_{fg}\rho_v\left[\frac{\sigma g\left(\rho_\ell - \rho_v\right)}{\rho_v^2}\right]^{1/4}$$

$$q = 0.9\left(0.02\,\text{m}\right)^2 \times 0.149\left(84,400\,\text{J/kg}\right)13.4\,\text{kg/m}^3\left[\frac{0.0081\,\text{kg/s}^2\left(9.8\,\text{m/s}^2\right)\left(1605.8\,\text{kg/m}^3\right)}{\left(13.4\,\text{kg/m}^3\right)^2}\right]^{1/4}$$

$$q_c = 0.9\left(4\times10^{-4}\,\text{m}^2\right)1.55\times10^5\,\text{W/m}^2 = 55.7\,\text{W}$$ <

With operation at q'' = 1.40 × 10⁵ W/m² in the nucleate boiling region, Eq. 10.5 yields

$$T = T_{sat} + \frac{C_{s,f}h_{fg}Pr_\ell^n}{c_{p,\ell}}\left(\frac{q''}{\mu_\ell h_{fg}}\right)^{1/3}\left[\frac{\sigma}{g\left(\rho_\ell - \rho_v\right)}\right]^{1/6}$$

$$T = 57^\circ\text{C} + \frac{0.005\left(84,400\,\text{J/kg}\right)\left(9.01\right)^{1.7}}{1100\,\text{J/kg}\cdot\text{K}}\left(\frac{1.40\times10^5\,\text{W/m}^2}{4.4\times10^{-4}\,\text{kg/m}\cdot\text{s}\times84,400\,\text{J/kg}}\right)^{1/3}\left[\frac{0.0081\,\text{kg/s}^2}{9.8\,\text{m/s}^2\left(1605.8\,\text{kg/m}^3\right)}\right]^{1/6}$$

Continued...

PROBLEM 10.74 (Cont.)

$$T = 57^\circ C + 22.4^\circ C = 79.4^\circ C$$ <

(b) The power dissipated by the chip must be balanced by the rate of heat transfer from the condensing section. We combine Eqs. 10.34 and 10.36 to obtain $Re_\delta = 4q/\mu_\ell b h'_{fg}$, where b = πD = 0.0942 m and $h'_{fg} = h_{fg} + 0.68c_{p,l}(T_{sat} - T_s) = 84{,}400\,J/kg + 0.68(1100\,J/kg\cdot K)32^\circ C$ = 108,300 J/kg. Hence, Re_δ = 4(55.7 W)/4.4 × 10^{-4} kg/m·s(0.0942 m)108,300 J/kg = 49.6 and the condensate film is in the laminar-wavy region. Hence, from Eq. 10.39

$$\overline{h}_L = \frac{k_\ell}{(\nu_\ell^2/g)^{1/3}}\frac{Re_\delta}{1.08Re_\delta^{1.22} - 5.2} =$$

$$= \frac{0.054\ W/m\cdot K}{\left[\left(0.272\times10^{-6}\ m^2/s\right)^2 \Big/ 9.8\ m^2/s\right]^{1/3}}\frac{49.6}{1.08\times 49.6^{1.22} - 5.2} = 1130\ W/m^2\cdot K$$

and from Eq. 10.33,

$$L = \frac{q_c}{\overline{h}_L \pi D(T_{sat} - T_s)} = \frac{55.7\ W}{1130\ W/m^2\cdot K\times 0.0942\ m\times 32°C} = 16.4\,mm$$ <

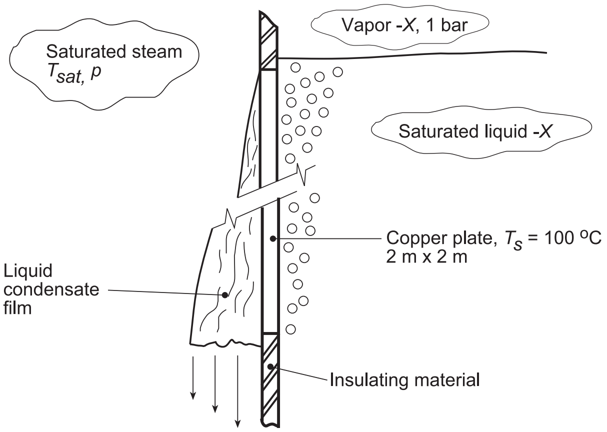
COMMENTS: The chip operating temperature (T = 79.4°C) is not excessive, and the proposed scheme provides a compact means of cooling high performance chips.

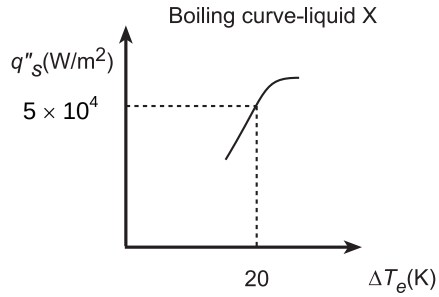
PROBLEM 10.75

KNOWN: Copper plate, 2m × 2m, in a condenser-boiler section maintained at $T_s = 100°C$ separates condensing saturated steam and nucleate-pool boiling of saturated liquid X.

FIND: (a) Rates of evaporation and condensation (kg/s) for the two fluids and (b) Saturation temperature T_{sat} and pressure p for the steam, assuming that film condensation occurs.

SCHEMATIC:





ASSUMPTIONS: (1) Steady-state conditions, (2) Isothermal copper plate.

PROPERTIES: *Fluid-X* (Given, 1 atm): $T_{sat} = 80°C$, $h_{fg} = 700$ kJ/kg, portion of boiling curve shown above for operating condition, $\Delta T_e = T_s - T_{sat} = (100 - 80)°C = 20°C$, $q''_s = 5 \times 10^4\ W/m^2$; *Table A.6*, Water (saturated, $T_f \approx 100°C$): $\rho_\ell = 957.9\ kg/m^3$, $h_{fg} = 2257$ kJ/kg , $c_{p,\ell} = 4217$ J/kg, $\mu_\ell = 279 \times 10^{-6}$ $N \cdot s/m^2$, $k_\ell = 0.680$ W/m·K, $Pr_\ell = 1.76$, $\nu_\ell = \mu_\ell / \rho_\ell = 2.91 \times 10^{-7}\ m^2/s$.

ANALYSIS: (a) For fluid-X, with $\Delta T_e = T_s - T_{sat} = (100 - 80)°C = 20$ K, the heat flux from the boiling curve is

$$q''_s = 50,000\ W/m^2$$

and the heat rate from the copper plate section into liquid-X is

$$q_s = q''_s \times A_s = 50,000\ W/m^2 \times (2 \times 2)\ m^2 = 200,000\ W$$

From an energy balance around liquid-X, the evaporation rate for fluid-X is

$$\dot{m}_X = q_s / h_{fg,X} = 200,000\ W / 700,000\ J/kg = 0.286\ kg/s \qquad <$$

The heat rate into the copper plate section from the steam is $q_s = 200,000$ W, and from an energy balance around the condensate film, the condensation rate for steam (w)

$$\dot{m}_w = q_s / h'_{fg,w} = 200,000\ W / 2.257 \times 10^6\ J/kg = 0.0886\ kg/s$$

where we are assuming that $T_{sat,w}$ is only a few degrees above T_s so that $h'_{fg} \approx h_{fg}$.

(b) With T_{sat} unknown, we begin by evaluating the liquid water properties at 100°C as given above. Then from Eq. 10.36,

$$Re_\delta = 4\dot{m}_w/\mu_\ell b = 4 \times 0.0886\ kg/s / 279 \times 10^{-6}\ N \cdot s/m^2 \times 2\ m = 635$$

Continued…

PROBLEM 10.75 (Cont.)

Thus the flow is wavy laminar. From Eq. 10.39 we have

$$\overline{h}_L = \frac{k_\ell}{(\nu_\ell^2/g)^{1/3}} \frac{Re_\delta}{1.08 Re_\delta^{1.22} - 5.2} =$$

$$= \frac{0.680 \text{ W/m} \cdot \text{K}}{\left[\left(2.91 \times 10^{-7} \text{ m}^2\text{/s}\right)^2 \Big/ 9.8 \text{ m}^2\text{/s}\right]^{1/3}} \frac{635}{1.08 \times 635^{1.22} - 5.2} = 7430 \text{ W/m}^2 \cdot \text{K}$$

From Eq. 10.33 we can solve for $T_{sat} - T_{s,c,}$ as

$T_{sat} - T_{s,c} = q_c / \overline{h}_L A = 200{,}000 \text{ W}/(7430 \text{ W/m}^2\cdot\text{K} \times 4 \text{ m}^2) = 6.7°\text{C}$

Thus

$T_{sat} = 106.7°\text{C} = 379.7 \text{ K}$ <

From Table A.6, $p = p_{sat}(379.7 \text{ K}) = 1.27$ bars <

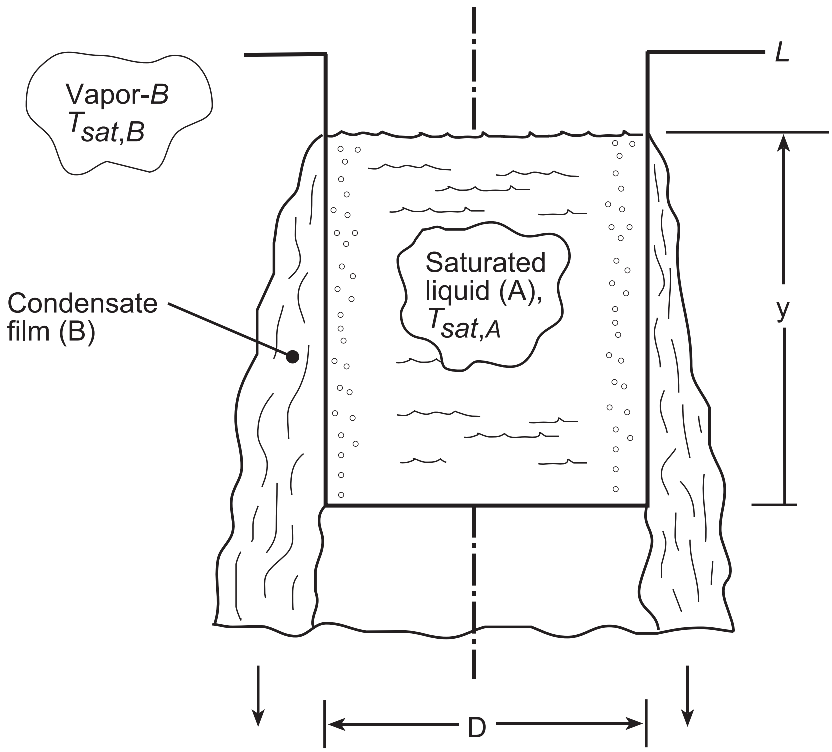
COMMENTS: The calculation could be repeated with properties evaluated at $T_f = 103°\text{C}$ and with $h'_{fg} \neq h_{fg}$, but the results would not change much.

PROBLEM 10.76

KNOWN: Thin-walled container filled with a low boiling point liquid (A) at $T_{sat,A}$. Outer surface of container experiences laminar-film condensation with the vapor of a high-boiling point fluid (B). Laminar film extends from the location of the liquid-A free surface. The heat flux for nucleate pool boiling in liquid-A along the container wall is given as $q''_{npb} = C(T_s - T_{sat})^3$, where C is a known empirical constant.

FIND: (a) Expression for the average temperature of the container wall, T_s; assume that the properties of fluids A and B are known; (b) Heat rate supplied to liquid-A, and (c) Time required to evaporate all the liquid-A in the container, assuming that initially the container is filled, y = L.

SCHEMATIC:



ASSUMPTIONS: (1) Nucleate pool boiling occurs on the inner surface of the container with liquid-A, (2) Laminar film condensation occurs on the outer surface of the container with fluid-B over the liquid-A free surface, y, and (3) Negligible wall thermal resistance.

ANALYSIS: (a) Perform an energy balance on the control surface about the container wall along locations experiencing boiling (A) and condensation (B) as shown in the schematic above.

$$\dot{E}''_{in} - \dot{E}''_{out} = 0 \quad (1)$$

$$q''_{cond} - q''_{npb} = 0 \quad (2)$$

$$\bar{h}_y(\pi D y)\left(T_{sat,B} - T_s\right) - (\pi D y) C\left(T_s^3 - T_{sat,A}\right) = 0$$

$$\bar{h}_y\left(T_{sat,B} - T_s\right) = C\left(T_s - T_{sat,A}\right)^3 \quad (3) <$$

where $\bar{h}_y$ is the average convection coefficient for laminar film condensation over the surface length 0 to y. From Eqs. 10.31 and 10.27,

Continued...

PROBLEM 10.76 (Cont.)

$$\bar{h}_y = 0.943\left[\frac{g\rho_\ell(\rho_\ell - \rho_v)k_\ell^3 h'_{fg}}{\mu_\ell(T_{sat} - T_s)y}\right]_B^{1/4} \tag{3}$$

$$h'_{fg} = h_{fg,B} + 0.68c_{p,B}\left(T_{sat,B} - T_s\right) \tag{4}$$

where the properties are for fluid-B.

(b) The heat flux supplied to liquid-A is, from Eq. (2), $q''_{cond} = q''_{npb}$. Since $\bar{h}_y$ is a function of y, T_s and, hence, the heat fluxes will be functions of y, the height of liquid A in the container.

(c) To determine the dry-out time, t_f, begin with an energy balance on the inside of the container (fluid-A). The heat transfer supplied to liquid-A results in an evaporation rate of liquid-A,

$$q''_{npb}(\pi Dy) - \frac{dM}{dt}h_{fg} = 0 \tag{4}$$

where M is the mass of liquid-A in the container,

$$M = \rho_{\ell,A}\left(\pi D^2/4\right)y \tag{5}$$

Substituting Eq. (5) into (4), separating variables and identifying integration limits, find

$$C\left(T_s - T_{sat,A}\right)^3(\pi Dy) = \frac{d}{dt}\left[\rho_{\ell,A}\left(\pi D^2/4\right)y\right]h_{fg}$$

$$\int_0^{t_f} dt = t_f = \frac{\rho_{\ell,A}\left(\pi D^2/4\right)h_{fg}}{C\pi D}\int_L^0 \frac{dy}{\left(T_s - T_{sat,A}\right)^3 y} \tag{6}$$

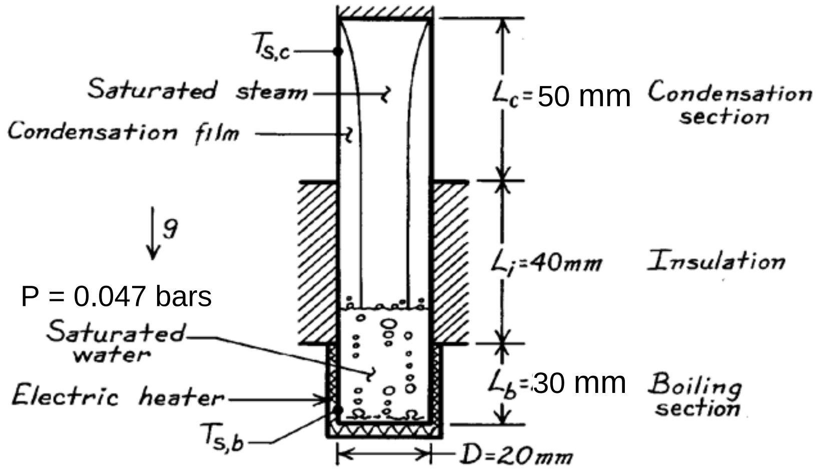
The definite integral could be numerically evaluated using values for $T_s(y)$ obtained by solving Eq. (3).

PROBLEM 10.77

KNOWN: Dimensions of ten thin-walled thermosyphons with boiling, insulated, and condensing sections of known lengths. Working fluid is saturated water at 0.047 bars.

FIND: (a) Heating rate delivered by thermosyphons if nucleate boiling heat flux is 25% of CHF and mean temperatures of boiling and condensing sections, (b) Heat loss from hot water tank to cool attic.

SCHEMATIC:



ASSUMPTIONS: (1) Bottom of thermosyphon can be treated as a large horizontal surface, (2) Nucleate boiling constants are typical values of $C_{s,f}$ = 0.0130 and n = 1.0, (3) Boiling and condensing section are separated by insulated length L_i, (4) Laminar film condensation occurs in condensation section which approximates a vertical plate, (5) Top surface of condensation section is insulated, (6) For condensation, liquid properties evaluated at T_f = 300 K.

PROPERTIES: *Table A-6*, Saturated water (p = 0.047 bars): T_{sat} = 305 K, $\rho_\ell = 1/v_f$ = 995 kg/m^3, $c_{p,\ell}$ = 4178 J/kg·K, $\mu_\ell = 769 \times 10^{-6}\ \text{N}\cdot\text{s/m}^2$, $\Pr_\ell = 5.20$, h_{fg} = 2426 kJ/kg, $\sigma = 70.9 \times 10^{-3}$ N/m; Saturated vapor (p = 0.047 bars): $\rho_v = 1/v_g$ = 0.0336 kg/m^3; Saturated water (300 K): $\rho_\ell = 1/v_f = 997\ \text{kg/m}^3$, $c_{p,\ell}$ = 4179 J/kg·K, $\mu_\ell = 855 \times 10^{-6}$ N·s/m^2, $\nu_\ell = \mu_\ell/\rho_\ell = 8.58 \times 10^{-7}$ m^2/s, k_ℓ = 0.613 W/m·K.

ANALYSIS: (a) The heat flux for the boiling section is 25% of the critical heat flux, which is given by Eq. 10.6 with C = 0.149 for a large horizontal surface,

$$q''_{s,b} = 0.25q''_{max} = (0.25)0.149 h_{fg}\rho_v \left[\frac{\sigma g(\rho_\ell - \rho_v)}{\rho_v^2}\right]^{1/4}$$

Continued …

PROBLEM 10.77 (Cont.)

$$= (0.25)0.149 \times 2426 \times 10^3 \text{ J/kg} \times 0.0336 \text{ kg/m}^3 \times \left[\frac{70.9 \times 10^{-3} \text{ N/m} \times 9.8 \text{ m/s}^2 (995 - 0.0336)\text{kg/m}^3}{(0.0336 \text{ kg/m}^3)^2}\right]^{1/4}$$

$$= 84,900 \text{ W/m}^2$$

Using the Rohsenow correlation for nucleate boiling, find

$$q''_{s,b} = \mu_\ell h_{fg}\left[\frac{g(\rho_\ell - \rho_v)}{\sigma}\right]^{1/2}\left(\frac{c_{p,\ell}(T_{s,b} - T_{sat})}{C_{s,f} h_{fg} Pr_\ell^n}\right)^3$$

$$84,900 \text{ W/m}^2 = 769 \times 10^{-6} \text{ N} \cdot \text{s/m}^2 \times 2426 \times 10^3 \text{ J/kg} \times$$

$$\left[\frac{9.8 \text{ m/s}^2 (995 - 0.0336)\text{kg/m}^3}{70.9 \times 10^{-3} \text{ N/m}}\right]^{1/2}\left(\frac{4178 \text{ J/kg} \cdot \text{K}(T_{s,b} - 305)}{0.013 \times 2426 \times 10^3 \text{ J/kg} \times 5.20^{1.0}}\right)^3$$

$T_{s,b} = 325$ K. <

The heat transferred into the boiling section must be rejected by film condensation,

$$q_c = q_b = q''_{s,b}\left[\pi D^2/4 + \pi D L_b\right]$$

$$q_c = 84,900 \text{ W/m}^2\left[\pi(0.020 \text{ m})^2/4 + \pi(0.020 \text{ m}) \times 0.030 \text{ m}\right] = 187 \text{ W}.$$

For all ten thermosyphons, the heating rate is therefore

$$q_{tot} = 1870 \text{ W}$$ <

Thus from Eq. 10.34, $\dot{m} = q_c / h'_{fg}$ and from Eq. 10.36, $Re_\delta = 4\dot{m}/\mu_\ell b = 4q_c / h'_{fg}\mu_\ell \pi D$, where $h'_{fg} = h_{fg} + 0.68c_{p,\ell}(T_{sat} - T_{s,c})$. We approximate $h'_{fg} = h_{fg}$ and find $Re_\delta \approx 5.7$. Thus the flow is laminar as assumed. From Eq. 10.38 we have

$$\bar{h}_L = \frac{k_\ell}{(\nu_\ell^2/g)^{1/3}} 1.47 Re_\delta^{-1/3} =$$

$$= \frac{0.613 \text{ W/m} \cdot \text{K}}{\left[\left(8.58 \times 10^{-7} \text{ m}^2/\text{s}\right)^2 \big/ 9.8 \text{ m}^2/\text{s}\right]^{1/3}} 1.47 \times 5.7^{-1/3} = 11,930 \text{ W/m}^2 \cdot \text{K} \quad (1)$$

Continued …

PROBLEM 10.77 (Cont.)

From Eq. 10.33 we can solve for $T_{sat} - T_{s,c}$, as

$$T_{sat} - T_{s,c} = q_c/\overline{h}_L\, \pi D L_c = 187\ \text{W}/(11{,}930\ \text{W/m}^2\cdot\text{K} \times \pi \times 0.02\ \text{m} \times 0.05\ \text{m}) = 5.0°\text{C} \qquad (2)$$

This solution can now be iterated by recalculating h'_{fg} and Re_δ and re-solving Eqs. (1) and (2). Subsequent iterations do not change the value of $T_{sat} - T_{s,c}$. Thus

$$T_{s,c} = T_{sat} - 5.0\ \text{K} = 300\ \text{K}$$ <

Note that $T_f = 302.5$ K, which is not far from the assumed value of 300 K.

(b) There would be heat conduction through thermally-stratified water vapor in the thermospyphon tubes (neglecting tube wall conduction) which would yield a very small heat transfer rate. Hence the heat loss is approximately zero. <

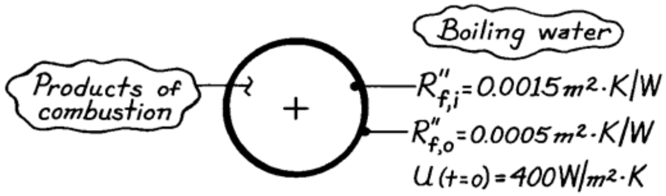
COMMENTS: (1)The thermosyphon is a unique device in that it acts like a *thermal diode*, promoting high heat transfer rates in one direction, while serving as an effective insulator in the opposite direction. (2) The convective resistance between the boiling section and the attic air will be extremely large for an un-finned thermosyphon. Hence, it would be necessary to significantly reduce this resistance by, for example, attaching annular fins to each boiling section and using a fan to heat the fins with forced convection. (3) The operating temperatures in the boiling and condensation sections of the thermosyphon may not be optimal values. Adjustment of these temperatures can be accomplished by changing the pressure within the thermosyphon, or by using a working fluid other than water.

PROBLEM 11.1

KNOWN: Initial overall heat transfer coefficient of a fire-tube boiler. Fouling factors following one year's application.

FIND: Whether cleaning should be scheduled.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible tube wall conduction resistance, (2) Negligible changes in h_c and h_h.

ANALYSIS: From Equation 11.1b, the overall heat transfer coefficient after one year is

$$\frac{1}{U} = \frac{1}{h_i} + \frac{1}{h_o} + R''_{f,i} + R''_{f,o}.$$

Since the first two terms on the right-hand side correspond to the reciprocal of the initial overall coefficient,

$$\frac{1}{U} = \frac{1}{400\ \text{W/m}^2\cdot\text{K}} + (0.0015 + 0.0005)\,\text{m}^2\cdot\text{K/W} = 0.0045\ \text{m}^2\cdot\text{K/W}$$

$$U = 222\ \text{W/m}^2\cdot\text{K}.$$

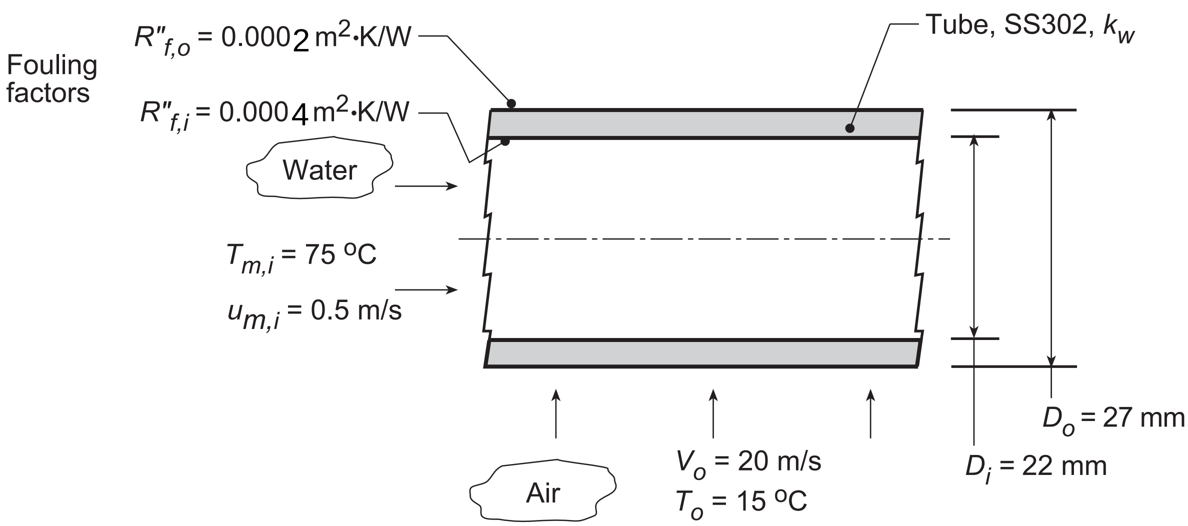
COMMENTS: Periodic cleaning of the tube inner surfaces is essential to maintaining efficient fire-tube boiler operations.

PROBLEM 11.2

KNOWN: Type-302 stainless tube with prescribed inner and outer diameters used in a cross-flow heat exchanger. Prescribed fouling factors and internal water flow conditions.

FIND: (a) Overall coefficient based upon the outer surface, U_o, with air at T_o =15°C and velocity V_o = 20 m/s in cross-flow; compare thermal resistances due to convection, tube wall conduction and fouling; (b) Overall coefficient, U_o, with water (rather than air) at T_o = 15°C and velocity V_o = 1 m/s in cross-flow; compare thermal resistances due to convection, tube wall conduction and fouling; (c) For the water-air conditions of part (a), compute and plot U_o as a function of the air cross-flow velocity for $5 \le V_o \le 30$ m/s for water mean velocities of $u_{m,i}$ = 0.2, 0.5 and 1.0 m/s; and (d) For the water-water conditions of part (b), compute and plot U_o as a function of the water mean velocity for $0.5 \le u_{m,i} \le 2.5$ m/s for air cross-flow velocities of V_o = 1, 3 and 8 m/s.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Fully developed internal flow,

PROPERTIES: *Table A.1*, Stainless steel, AISI 302 (300 K): k_w = 15.1 W/m·K; *Table A.6*, Water ($\overline{T}_{m,i}$ = 348 K): ρ_i = 974.8 kg/m^3, $\mu_i = 3.746 \times 10^{-4}$ N·s/m^2, k_i = 0.668 W/m·K, Pr_i = 2.354; *Table A.4,* Air (assume $\overline{T}_{f,o}$ = 315K, 1 atm): k_o = 0.02737 W/m·K, $\nu_o = 17.35 \times 10^{-6}$ m^2/s, Pr_o = 0.705.

ANALYSIS: (a) For the water-air condition, the overall coefficient, Eq. 11.1, based upon the outer area can be expressed as the sum of the thermal resistances due to convection (cv), tube wall conduction (w) and fouling (f):

$$1/U_o A_o = R_{tot} = R_{cv,i} + R_{f,i} + R_w + R_{f,o} + R_{cv,o}$$

$$R_{cv,i} = 1/\overline{h}_i A_i \qquad R_{cv,o} = 1/\overline{h}_o A_o$$

$$R_{f,i} = R''_{f,i}/A_i \qquad R_{f,o} = R''_{f,o}/A_o$$

and from Eq. 3.33,

$$R_w = \ln\left(D_o/D_i\right)/\left(2\pi L k_w\right)$$

The convection coefficients can be estimated from appropriate correlations.

Continued...

PROBLEM 11.2 (Cont.)

Estimating $\overline{h}_i$: For internal flow, characterize the flow evaluating thermophysical properties at $T_{m,i}$ with

$$Re_{D,i} = \frac{u_{m,i}D_i}{\nu_i} = \frac{0.5\,m/s \times 0.022m}{3.746 \times 10^{-4}\,N \cdot s/m^2 / 974.8\,kg/m^3} = 28,625$$

For the turbulent flow, use the Dittus-Boelter correlation, Eq. 8.60,

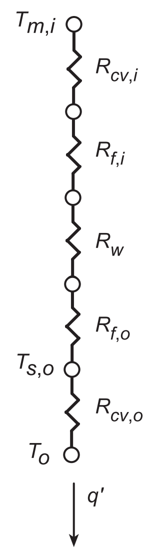
$$Nu_{D,i} = 0.023\,Re_{D,i}^{0.8}\,Pr_i^{0.3}$$

$$Nu_{D,i} = 0.023(28,625)^{0.8}(2.354)^{0.3} = 109.3$$

$$\overline{h}_i = Nu_{D,i}\,k_i/D_i = 109.3 \times 0.668\,W/m^2 \cdot K / 0.022m = 3313\,W/m^2 \cdot K$$

Estimating $\overline{h}_o$: For external flow, characterize the flow with

$$Re_{D,o} = \frac{V_o D_o}{\nu_o} = \frac{20\,m/s \times 0.027m}{17.35 \times 10^{-6}\,m^2/s} = 31,124$$



evaluating thermophysical properties at $T_{f,o} = (T_{s,o} + T_o)/2$ when the surface temperature is determined from the thermal circuit analysis result,

$$(T_{m,i} - T_o)/R_{tot} = (T_{s,o} - T_o)/R_{cv,o}$$

Assume $T_{f,o}$ = 315 K, and check later. Using the Churchill-Bernstein correlation, Eq. 7.54, find

$$\overline{Nu}_{D,o} = 0.3 + \frac{0.62\,Re_{D,o}^{1/2}\,Pr_o^{1/3}}{\left[1 + (0.4/Pr_o)^{2/3}\right]^{1/4}}\left[1 + \left(\frac{Re_{D,o}}{282,000}\right)^{5/8}\right]^{4/5}$$

$$\overline{Nu}_{D,o} = 0.3 + \frac{0.62(31,124)^{1/2}(0.705)^{1/3}}{\left[1 + (0.4/0.705)^{2/3}\right]^{1/4}}\left[1 + \left(\frac{31,124}{282,000}\right)^{5/8}\right]^{4/5}$$

$$\overline{Nu}_{D,o} = 102.6$$

$$\overline{h}_o = \overline{Nu}_{D,o}\,k_o/D_o = 102.6 \times 0.02737\,W/m \cdot K / 0.027m = 104.0\,W/m \cdot K$$

Using the above values for $\overline{h}_i$, and $\overline{h}_o$, and other prescribed values, the thermal resistances and overall coefficient can be evaluated and are tabulated below.

$R_{cv,i}$ (K/W)	$R_{f,i}$ (K/W)	R_w (K/W)	$R_{f,o}$ (K/W)	$R_{cv,o}$ (K/W)	U_o ($W/m^2 \cdot K$)	R_{tot} (K/W)
0.00436	0.00578	0.00216	0.00236	0.1134	92.1	0.128

The major thermal resistance is due to outside (air) convection, accounting for 89% of the total resistance. The other thermal resistances are of similar magnitude, nearly 50 times smaller than $R_{cv,o}$.

(b) For the water-water condition, the method of analysis follows that of part (a). For the internal flow, the estimated convection coefficient is the same as part (a). For an assumed outer film coefficient, $\overline{T}_{f,o}$ = 292 K, the convection correlation for the outer water flow condition V_o = 1 m/s and T_o = 15°C,

Continued...

PROBLEM 11.2 (Cont.)

find

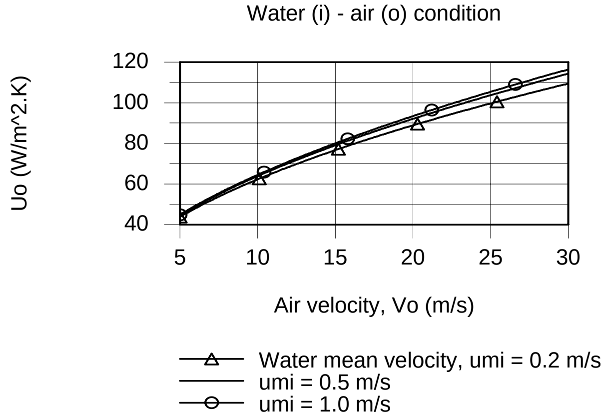
$$Re_{D,o} = 26,260 \qquad Nu_{D,o} = 220.6 \qquad \bar{h}_o = 4914\ W/m^2 \cdot K$$

The thermal resistances and overall coefficient are tabulated below.

$R_{cv,i}$ (K/W)	$R_{f,i}$ (K/W)	R_w (K/W)	$R_{f,o}$ (K/W)	$R_{cv,o}$ (K/W)	R_{tot} (K/W)	U_o ($W/m^2 \cdot K$)
0.00436	0.00579	0.00216	0.00236	0.00240	0.0171	691

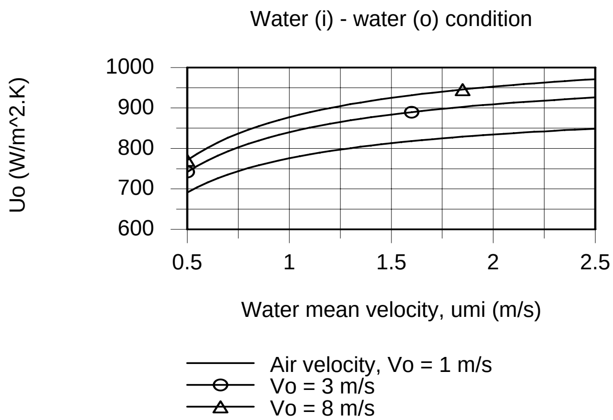
Note that the thermal resistances are of similar magnitude. In contrast with the results for the water-air condition of part (a), the thermal resistance of the outside convection process, $R_{cv,o}$, is nearly 50 times smaller. The overall coefficient for the water-water condition is 7.5 times greater than that for the water-air condition.

(c) For the water-air condition, using the IHT workspace with the analysis of part (a), U_o was calculated as a function of the air cross-flow velocity for selected mean water velocities.



The effect of increasing the cross-flow air velocity is to increase U_o since the $R_{cv,o}$ is the dominant thermal resistance for the system. While increasing the water mean velocity will increase $\bar{h}_i$, because $R_{cv,i} << R_{cv,o}$, this increase has only a small effect on U_o.

(d) For the water-water condition, using the IHT workplace with the analysis of part (b), U_o was calculated as a function of the mean water velocity for selected air cross-flow velocities.



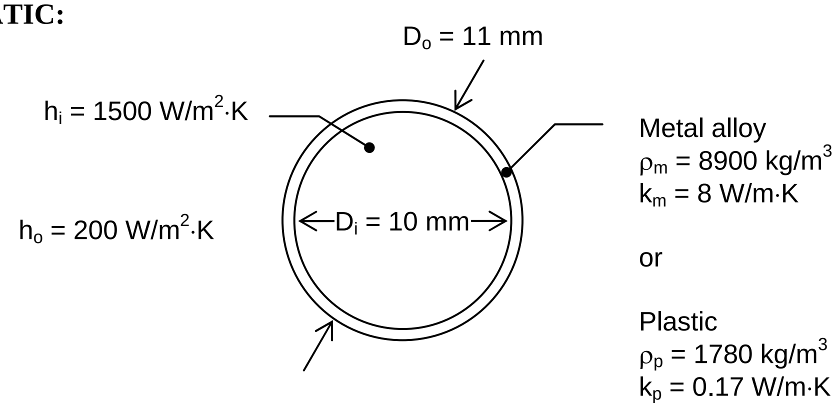
Because the thermal resistances for the convection processes, $R_{cv,i}$ and $R_{cv,o}$, are of similar magnitude according to the results of part (b), we expect to see U_o significantly increase with increasing water mean velocity and air cross-flow velocity.

PROBLEM 11.3

KNOWN: Inner and outer diameters of tubes in shell-and-tube heat exchanger. Inner and outer heat transfer coefficients. Properties of plastic and metal candidate wall materials.

FIND: (a) Ratio of surface areas for the two materials for the same heat transfer rate, (b) Ratio of masses for the two materials, (c) Which tube material would be lower cost.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible fouling.

ANALYSIS: (a) From Eq. 11.14, the heat transfer rates will be the same for the two wall materials when UA is the same for both. From Eq. 11.1, with no fouling or fins, and with the wall resistance given by Eq. 3.33,

$$\frac{1}{UA} = \left(\frac{1}{h_i \pi D_i} + \frac{\ln(D_o / D_i)}{2\pi k_w} + \frac{1}{h_o \pi D_o} \right) \frac{1}{L} = \left(R'_{conv,i} + R'_w + R'_{conv,o} \right) \frac{1}{L} \qquad (1)$$

where

$$R'_{conv,i} = \frac{1}{h_i \pi D_i} = \frac{1}{1500\ W/m^2 \cdot K \times \pi \times 0.01\ m} = 0.0212\ m \cdot K/W$$

$$R'_{conv,o} = \frac{1}{h_o \pi D_o} = \frac{1}{200\ W/m^2 \cdot K \times \pi \times 0.011\ m} = 0.1447\ m \cdot K/W$$

and

$$R'_w = \frac{\ln(D_o / D_i)}{2\pi k_w} = \begin{cases} \dfrac{\ln(11/10)}{2\pi \times 8\ W/m \cdot K} = 0.0019\ W/m \cdot K & \text{metal alloy} \\ \dfrac{\ln(11/10)}{2\pi \times 0.17\ W/m \cdot K} = 0.0892\ W/m \cdot K & \text{plastic} \end{cases}$$

Thus, from Eq. (1), $(UA)_m = (UA)_p$ implies the following ratio of areas,

Continued…

PROBLEM 11.3 (Cont.)

$$\frac{A_p}{A_m} = \frac{L_p}{L_m} = \frac{R_{conv,i} + R_{w,p} + R_{conv,o}}{R_{conv,i} + R_{w,m} + R_{conv,o}}$$

$$= \frac{0.0212 \text{ m}\cdot\text{K/W} + 0.0892 \text{ m}\cdot\text{K/W} + 0.1447 \text{ m}\cdot\text{K/W}}{0.0212 \text{ m}\cdot\text{K/W} + 0.0019 \text{ m}\cdot\text{K/W} + 0.1447 \text{ m}\cdot\text{K/W}}$$

$$\frac{A_p}{A_m} = 1.52$$ <

(b) The mass ratio is found as follows,

$$\frac{m_p}{m_m} = \frac{\rho_p A_p}{\rho_m A_m} = \frac{1780 \text{ kg/m}^3}{8900 \text{ kg/m}^3} 1.52 = 0.304$$ <

(c) The cost ratio is

$$\frac{C_p}{C_m} = \frac{m_p}{3m_m} = \frac{1}{3} 0.304 = 0.10$$

The plastic should be specified on the basis of cost. <

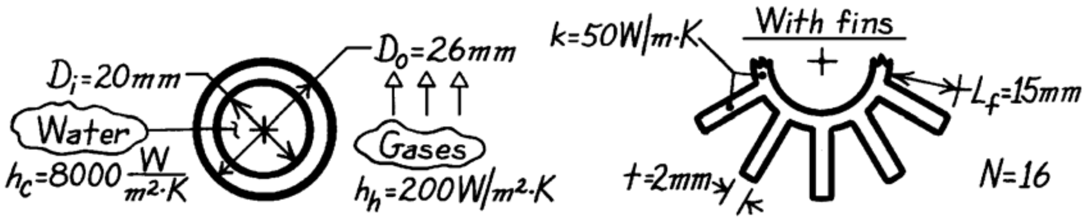
COMMENTS: (1) Because of its lower thermal conductivity, the plastic heat exchanger wall requires 50% more surface area than the metal wall. Nonetheless, it is 70% lighter and 90% less expensive. (2) Plastic heat exchanger components must operate at temperatures below their glass transition point, which for PVDF is approximately 160°C. If the plastic heat exchanger is operated above the glass transition temperature, it will soften and lose all structural rigidity. (3) The cost-based selection of the material will change depending on the values of the inside and outside heat transfer coefficients. For example, as the inside and outside heat transfer coefficients approach infinity, the metal core should be selected on the basis of cost. For applications involving condensation or boiling, the heat transfer coefficients will depend strongly on the tube material, as discussed in Chapter 10.

PROBLEM 11.4

KNOWN: Dimensions of heat exchanger tube with or without fins. Cold and hot side convection coefficients.

FIND: Cold side overall heat transfer coefficient without and with fins.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible fouling, (2) Negligible contact resistance between fins and tube wall, (3) h_h is not affected by fins, (4) One-dimensional conduction in fins, (5) Adiabatic fin tip.

ANALYSIS: From Eq. 11.1,

$$\frac{1}{U_c} = \frac{1}{(\eta_o h)_c} + \frac{D_i \ln(D_o/D_i)}{2k} + \frac{A_c}{(\eta_o hA)_h}$$

Without fins: $\eta_{o,c} = \eta_{o,h} = 1$

$$\frac{1}{U_c} = \frac{1}{8000\ W/m^2 \cdot K} + \frac{(0.02m)\ln(26/20)}{100\ W/m \cdot K} + \frac{1}{200\ W/m^2 \cdot K}\frac{20}{26}$$

$$1/U_c = \left(1.25\times10^{-4} + 5.25\times10^{-5} + 3.85\times10^{-3}\right)m^2 \cdot K/W = 4.02\times10^{-3}\ m^2 \cdot K/W$$

$$U_c = 249\ W/m^2 \cdot K.$$ <

With fins: $\eta_{o,c} = 1,\ \eta_{o,h} = 1-(A_f/A)(1-\eta_f)$ Per unit length along the tube axis,

$$A_f = N(2L_f + t) = 16(30+2)mm = 512\ mm$$

$$A_h = A_f + (\pi D_o - 16t) = (512 + 81.7 - 32)mm = 561.7\ mm$$

With $m = (2h/kt)^{1/2} = \left(400\ W/m^2 \cdot K / 50\ W/m \cdot K \times 0.002m\right)^{1/2} = 63.3\,m^{-1}$

$$mL_f = \left(63.3\,m^{-1}\right)(0.015m) = 0.95$$

and Eq. 11.4 yields

$$\eta_f = \tanh(mL_f)/mL_f = 0.739/0.95 = 0.778.$$

The overall surface efficiency is then

$$\eta_o = 1-(A_f/A_h)(1-\eta_f) = 1-(512/561.7)(1-0.778) = 0.798.$$

Hence $\frac{1}{U_c} = \left(1.25\times10^{-4} + 5.25\times10^{-5} + \frac{\pi(20)}{0.798(200)561.7}\right)m^2 \cdot K/W = 8.78\times10^{-4}m^2 \cdot K/W$

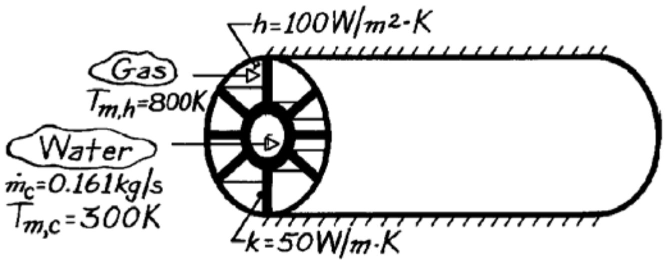
$$U_c = 1138\ W/m^2 \cdot K.$$ <

PROBLEM 11.5

KNOWN: Geometry of finned, annular heat exchanger. Gas-side temperature and convection coefficient. Water-side flowrate and temperature.

FIND: Heat rate per unit length.

SCHEMATIC:



D_o = 60 mm
$D_{i,1}$ = 24 mm
$D_{i,2}$ = 30 mm
t = 3 mm = 0.003m
L = (60-30)/2 mm = 0.015m

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) One-dimensional conduction in strut, (4) Adiabatic outer surface conditions, (5) Negligible gas-side radiation, (6) Fully-developed internal flow, (7) Negligible fouling.

PROPERTIES: *Table A-6*, Water (300 K): k = 0.613 W/m·K, Pr = 5.83, $\mu = 855 \times 10^{-6}$ N·s/m^2.

ANALYSIS: The heat rate is

$$q = (UA)_c \left(T_{m,h} - T_{m,c}\right)$$

where

$$1/(UA)_c = 1/(hA)_c + R_w + 1/(\eta_o hA)_h$$

$$R_w = \frac{\ln\left(D_{i,2}/D_{i,1}\right)}{2\pi kL} = \frac{\ln(30/24)}{2\pi(50\ \text{W/m}\cdot\text{K})1\text{m}} = 7.10\times10^{-4}\ \text{K/W}.$$

With

$$Re_D = \frac{4\dot{m}}{\pi D_{i,1}\mu} = \frac{4\times0.161\ \text{kg/s}}{\pi(0.024\text{m})855\times10^{-6}\ \text{N}\cdot\text{s/m}^2} = 9990$$

internal flow is turbulent and the Dittus-Boelter correlation gives

$$h_c = \left(k/D_{i,1}\right)0.023\,Re_D^{4/5}\,Pr^{0.4} = \left(\frac{0.613\ \text{W/m}\cdot\text{K}}{0.024\text{m}}\right)0.023(9990)^{4/5}(5.83)^{0.4} = 1883\ \text{W/m}^2\cdot\text{K}$$

$$(hA)_c^{-1} = \left(1883\ \text{W/m}^2\cdot\text{K}\times\pi\times0.024\text{m}\right)^{-1} = 7.043\times10^{-3}\ \text{K/W}.$$

Find the fin efficiency as

$$\eta_o = 1 - \left(A_f/A\right)\left(1-\eta_f\right)$$

$$A_f = 8\times2(L\cdot w) = 8\times2(0.015\text{m}\times1\text{m}) = 0.24\text{m}^2$$

$$A = A_f + \left(\pi D_{i,2} - 8t\right)w = 0.24\text{m}^2 + (\pi\times0.03\text{m} - 8\times0.003\text{m}) = 0.31\text{m}^2.$$

Continued…

PROBLEM 11.5 (Cont.)

From Eq. 11.4,

$$\eta_f = \frac{\tanh(mL)}{mL}$$

where

$$m = [2h/kt]^{1/2} = \left[2 \times 100\ W/m^2 \cdot K / 50\ W/m \cdot K(0.003m)\right]^{1/2} = 36.5\,m^{-1}$$

$$mL = (2h/kt)^{1/2} L = 36.5\,m^{-1} \times 0.015m = 0.55$$

$$\tanh\left[(2h/kt)^{1/2} L\right] = 0.499.$$

Hence

$$\eta_f = 0.499/0.55 = 0.911$$

$$\eta_o = 1 - (A_f / A)(1 - \eta_f) = 1 - (0.24/0.31)(1 - 0.911) = 0.931$$

$$(\eta_o hA)_h^{-1} = \left(0.931 \times 100\ W/m^2 \cdot K \times 0.31m^2\right)^{-1} = 0.0347\ K/W.$$

Hence

$$(UA)_c^{-1} = \left(7.043 \times 10^{-3} + 7.1 \times 10^{-4} + 0.0347\right) K/W$$

$$(UA)_c = 23.6\ W/K$$

and

$$q = 23.6\ W/K(800 - 300)K = 11{,}800\ W$$ <

for a 1m long section.

COMMENTS: (1) The gas-side resistance is substantially decreased by using the fins ($A_f >> \pi D_{i,2}$) and q is increased.

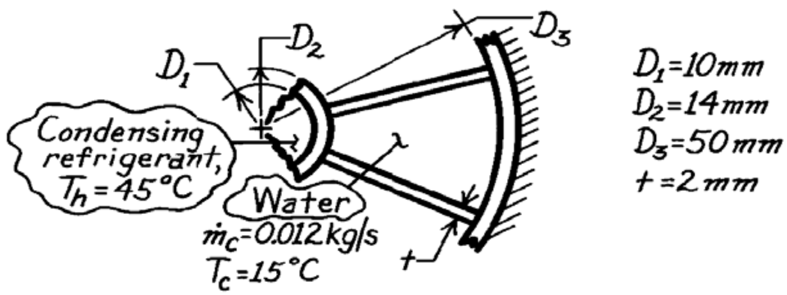
(2) Heat transfer enhancement by the fins could be increased further by using a material of larger k, but material selection would be limited by the large $T_{m,h}$.

PROBLEM 11.6

KNOWN: Condenser arrangement of tube with six longitudinal fins (k = 200 W/m·K). Condensing refrigerant at temperature 45°C flows axially through inner tube while water flows at 0.012 kg/s and 15°C through the six channels formed by the splines.

FIND: Heat removal rate per unit length of the exchanger.

SCHEMATIC:



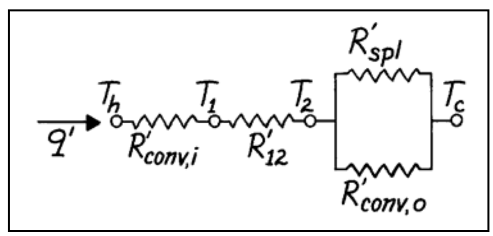
ASSUMPTIONS: (1) No heat loss/gain to the surroundings, (2) Water is incompressible liquid with negligible viscous dissipation, (3) Negligible thermal resistance on condensing refrigerant side, $h_i \to \infty$, (4) Water flow is fully developed, (5) Negligible thermal contact between splines and inner tube, (6) Heat transfer from outer tube negligible.

PROPERTIES: *Table A-6*, Water ($\overline{T}_c$ = 15°C = 288 K): ρ = 1000 kg/m^3, k = 0.595 W/m·K, $\nu = \mu/\rho$ = 1138 × 10^{-6} N·s/m^2/1000 kg/m^3 = 1.138 × 10^{-6} m^2/s, Pr = 8.06; Tube fins (given): k = 200 W/m·K.

ANALYSIS: Following the discussion of Section 11.2,

$$q' = UA'(T_h - T_c)$$

$$\frac{1}{UA'} = R'_h + R'_w + R'_c = R'_w + \frac{1}{(\eta_o hA')_c}$$



where $R'_h = 0$, due to the negligible thermal resistance on the refrigerant side (h), and

$$R'_w = \frac{\ln(D_2/D_1)}{2\pi k} = \frac{\ln(14/10)}{2\pi(200\ \mathrm{W/m\cdot K})} = 2.678\times10^{-4}\,\mathrm{m\cdot K/W}.$$

To estimate the thermal resistance on the water side (c), first evaluate the convection coefficient. The hydraulic diameter for a passage, where A_c is the cross-sectional area of the passage is

$$D_{h,c} = \frac{4A_c}{P} = \frac{4\left[\pi\left(D_3^2 - D_2^2\right)/4 - 6(D_3 - D_2)t/2\right]/6}{(\pi D_2 - 6t)/6 + (\pi D_3 - 6t)/6 + 2(D_3 - D_2)/2}$$

$$D_{h,c} = \frac{4\left[\pi\left(50^2 - 14^2\right)/4 - 6(50-14)\right]\times10^{-6}\,\mathrm{m}^2/6}{\left[(14\pi - 6\times2)/6 + (50\pi - 6\times2)/6 + (50-14)\right]\times10^{-3}\,\mathrm{m}}$$

$$D_{h,c} = \frac{4\times2.656\times10^{-4}\,\mathrm{m}^2}{6.551\times10^{-2}\,\mathrm{m}} = 0.01622\,\mathrm{m}.$$

Hence the Reynolds number is

Continued …

PROBLEM 11.6 (Cont.)

$$Re_{D,c} = \frac{\left[\left(0.012\ \text{kg/s}/6\right)/\left(1000\ \text{kg/m}^3 \times 2.656\times10^{-4}\text{m}^2\right)\right]\times 0.01622\text{m}}{1.138\times10^{-6}\text{m}^2/\text{s}} = 107$$

and assuming the flow is fully developed,

$$Nu_{D,c} = \frac{h_c D_{h,c}}{k} = 3.66$$

$$h_c = 3.66\times 0.595\ \text{W/m}\cdot\text{K}/0.01622 = 134\ \text{W/m}^2\cdot\text{K}.$$

The temperature effectiveness of the splines (fins) on the cold side is

$$\eta_o = 1 - \frac{A_{f,c}}{A_c}\left(1-\eta_f\right)$$

where $A_{f,c}$ and A_c are, respectively, the finned and total (fin plus prime) surface areas, while

$$\eta_f = \frac{\tanh(mL)}{mL}$$

$$m = \left(2h_c/kt\right)^{1/2} = \left[\left(2\times134\ \text{W/m}^2\cdot\text{K}\right)/\left(200\ \text{W/m}\cdot\text{K}\times0.002\text{m}\right)\right]^{1/2} = 25.88\,\text{m}^{-1}$$

$$\eta_f = \frac{\tanh\left(25.88\,\text{m}^{-1}\times0.018\text{m}\right)}{25.88\,\text{m}^{-1}\times0.018\text{m}} = \frac{0.4348}{0.4658} = 0.934.$$

Hence

$$\eta_o = 1 - \frac{6\left(D_3 - D_2\right)}{6\left(D_3-D_2\right)+\left(\pi D_2 - 6t\right)}\left[1-\eta_f\right]$$

$$\eta_o = 1 - \frac{6(50-14)}{6(50-14)+(14\pi - 6\times2)}(1-0.934) = 0.943$$

$$\frac{1}{\eta_o h A'_c} = \frac{1}{0.943\times134\ \text{W/m}^2\cdot\text{K}\left[6(50-14)+(14\pi-6\times2)\right]\times10^{-3}\text{m}} = 3.22\times10^{-2}\ \text{m}\cdot\text{K/W}$$

and the heat rate is

$$q' = \frac{T_h - T_c}{R'_w + 1/\left(\eta_o h A'\right)_c}$$

$$q' = \frac{(45-15)\text{K}}{2.678\times10^{-4}\text{m}\cdot\text{K/W} + 3.22\times10^{-2}\text{m}\cdot\text{K/W}} = 924\ \text{W/m}. \quad <$$

COMMENTS: (1) The effective length of the fin representing the splines was conservatively estimated. The heat transfer by conduction through the splines to the outer tube and then by convection to the water was ignored.

(2) Without the splines, find $D_h = (D_3 - D_2) = 36$ mm so that $h_c = 60.5\ \text{W/m}^2\cdot\text{K}$. The heat rate with $A'_c = \pi D_2$ is

$$q' = \left(hA'_c\right)\left(T_h - T_c\right) = 60.5\ \text{W/m}^2\cdot\text{K}\left(0.014\pi\ \text{m}\right)(45-15)\text{K} = 79\ \text{W/m}.$$

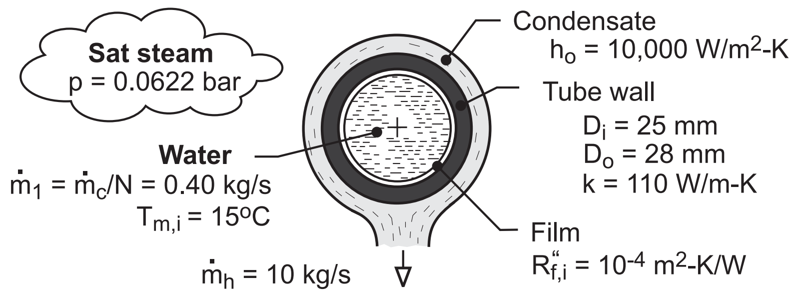
The splines enhance the heat transfer rate by a factor of 924/79 = 11.7.

PROBLEM 11.7

KNOWN: Number, inner and outer diameters, and thermal conductivity of condenser tubes. Convection coefficient at outer surface. Overall flow rate, inlet temperature and properties of water flow through the tubes. Flow rate and pressure of condensing steam. Fouling factor for inner surface.

FIND: (a) Overall coefficient based on outer surface area, U_o, without fouling, (b) Overall coefficient with fouling, (c) Temperature of water leaving the condenser.

SCHEMATIC:



ASSUMPTIONS: (1) Water is incompressible with negligible viscous dissipation, (2) Fully-developed flow in tubes, (3) Negligible effect of fouling on D_i.

PROPERTIES: Water (Given): $c_p = 4180$ J/kg·K, $\mu = 9.6 \times 10^{-4}$ N·s/m^2, k = 0.60 W/m·K, Pr = 6.6. *Table A-6*, Water, saturated vapor (p = 0.0622 bars): $T_{sat} = 310$ K, $h_{fg} = 2.414 \times 10^6$ J/kg.

ANALYSIS: (a) Without fouling, Eq. 11.5 yields

$$\frac{1}{U_o} = \frac{1}{h_i}\left(\frac{D_o}{D_i}\right) + \frac{D_o \ln(Do/Di)}{2k_t} + \frac{1}{h_o}$$

With $Re_{D_i} = 4\dot{m}_1/\pi D_i \mu = 1.60\,\text{kg/s}/\left(\pi \times 0.025\text{m} \times 9.6 \times 10^{-4}\,\text{N}\cdot\text{s/m}^2\right) = 21,220$, flow in the tubes is turbulent, and from Eq. 8.60

$$h_i = \left(\frac{k}{D_i}\right) 0.023 Re_{D_i}^{4/5} Pr^{0.4} = \left(\frac{0.60\,\text{W/m}\cdot\text{K}}{0.025\text{m}}\right) 0.023(21,200)^{4/5}(6.6)^{0.4} = 3400\,\text{W/m}^2\cdot\text{K}$$

$$U_o = \left[\frac{1}{3400}\left(\frac{28}{25}\right) + \frac{0.028\ln(28/25)}{2\times 110} + \frac{1}{10,000}\right]^{-1} \text{W/m}^2\cdot\text{K} =$$

$$\left(3.29\times 10^{-4} + 1.44\times 10^{-5} + 10^{-4}\right)^{-1} \text{W/m}^2\cdot\text{K} = 2255\,\text{W/m}^2\cdot\text{K} \quad <$$

(b) With fouling, Eq. 11.5 yields

$$U_o = \left[4.43\times 10^{-4} + (Do/Di)R''_{f,i}\right]^{-1} = \left(5.55\times 10^{-4}\right)^{-1} = 1800\,\text{W/m}^2\cdot\text{K} \quad <$$

(c) The rate at which energy is extracted from the steam equals the rate of heat transfer to the water, $\dot{m}_h h_{fg} = \dot{m}_c c_p (T_{m,o} - T_{m,i})$, in which case

$$T_{m,o} = T_{m,i} + \frac{\dot{m}_h h_{fg}}{\dot{m}_c c_p} = 15^\circ\text{C} + \frac{10\,\text{kg/s}\times 2.414\times 10^6\,\text{J/kg}}{400\,\text{kg/s}\times 4180\,\text{J/kg}\cdot\text{K}} = 29.4^\circ\text{C} \quad <$$

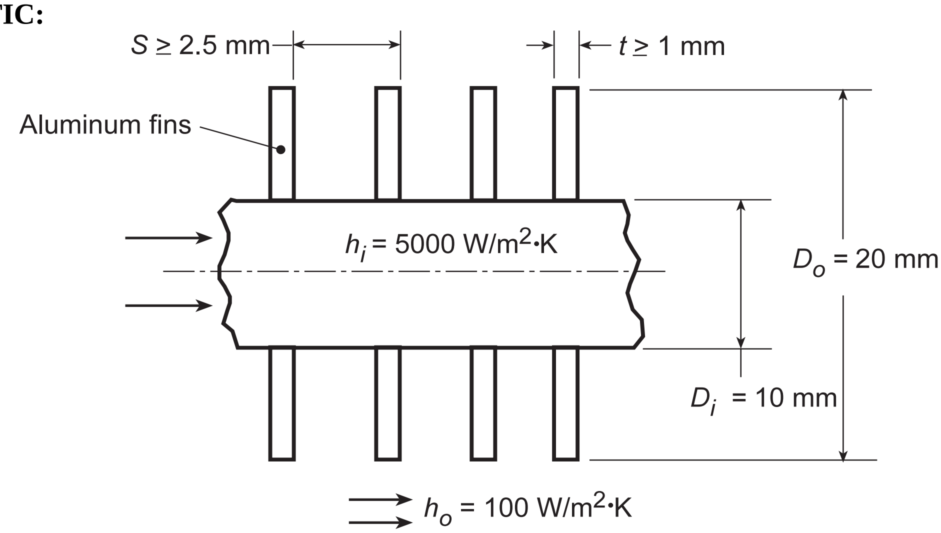
COMMENTS: (1) The largest contribution to the thermal resistance is due to convection at the interior of the tube. To increase U_o, hi could be increased by increasing $\dot{m}_1$, either by increasing $\dot{m}_c$ or decreasing N. (2) Note that $T_{m,o} = 302.4$ K < $T_{sat} = 310$ K, as must be the case.

PROBLEM 11.8

KNOWN: Diameter and inner and outer convection coefficients of a condenser tube. Thickness, outer diameter, and pitch of aluminum fins.

FIND: (a) Overall heat transfer coefficient without fins, (b) Effect of fin thickness and pitch on overall heat transfer coefficient with fins.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible tube wall conduction resistance, (2) Negligible fouling and fin contact resistance, (3) One-dimensional conduction in fin.

PROPERTIES: *Table A.1*, Aluminum (T = 300 K): k = 237 W/m·K.

ANALYSIS: (a) With no fins, Eq. 11.1 yields

$$U = \left(h_i^{-1} + h_o^{-1}\right)^{-1} = \left(2\times10^{-4} + 0.01\right)^{-1} \mathrm{W/m^2\cdot K} = 98.0\,\mathrm{W/m^2\cdot K}$$ <

(b) With fins and a unit tube length, Eqs. 11.1 and 11.3 yield

$$\frac{1}{U_i \pi D_i} = \frac{1}{h_i \pi D_i} + \frac{1}{\eta_o h_o A'_o}$$

and $\eta_o = 1 - \left(A'_f / A'_o\right)\left(1-\eta_f\right)$. The total fin surface area per unit length is $A'_f = N' 2\pi\left(r_{oc}^2 - r_i^2\right)$, where the number of fins per unit length is $N' = 1\mathrm{m}/S(\mathrm{m})$. The total outside surface area per unit length is A'_o = A'_f + (1 - $N't$)πD_i, and the fin efficiency is given by Eq. 3.96 or Fig. 3.20.

For t = 0.0015 m and S = 0.0035 m, $r_{oc} = (D_o/2) + (t/2) = 0.01075$ m, $N' \approx 286$, $A'_f = 0.163\ \mathrm{m^2/m}$, and $A'_o = (0.163 + 0.018)\ \mathrm{m^2/m} = 0.181\ \mathrm{m^2/m}$. With $r_{oc}/r_i = 2.15$, $L_c = 0.00575$ m, $A_p = 8.625 \times 10^{-6}\ \mathrm{m^2}$, and $L_c^{3/2}\left(h_o/kA_p\right)^{1/2} = 0.0964$, Fig. 3.20 yields $\eta_f \approx 0.99$. Hence, $\eta_o \approx 1 - (0.163/0.181)(0.01) = 0.99$ and

$$U_i = \left[\left(1/h_i\right) + \left(\pi D_i / \eta_o h_o A'_o\right)\right]^{-1}$$

$$U_i = \left[2\times10^{-4}\,\mathrm{m^2\cdot K/W} + \pi\times0.01\,\mathrm{m} \big/ 0.99\times100\,\mathrm{W/m^2\cdot K}\times0.181\,\mathrm{m^2/m}\right]^{-1} = 512\,\mathrm{W/m^2\cdot K}$$ <

We may use the IHT *Extended Surface* Model (*Performance Calculations* for a *Circular Rectangular Fin Array*) to consider the effect of varying t and S. To maximize N', the minimum allowable value of

Continued...

PROBLEM 11.8 (Cont.)

S - t = 1.5 mm should be selected. It is then a matter of choosing between a large number of thin fins or a smaller number of thicker fins. Calculations were performed for the following options.

t (mm)	S (mm)	N′	U_i ($W/m^2 \cdot K$)
1	2.5	400	640
2	3.5	286	512
3	4.5	222	460
4	5.5	182	420

Since heat transfer increases with U_i, the best configuration corresponds to t = 1 mm and S = 2.5 mm, which provides the largest airside surface area.

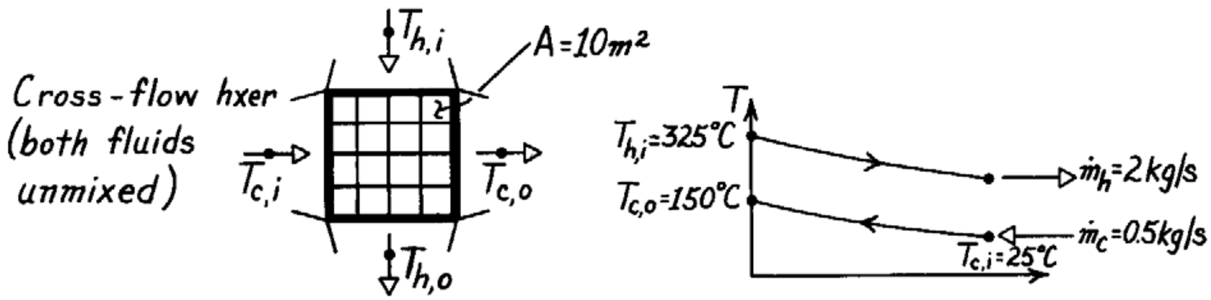
COMMENTS: The best performance is always associated with a large number of closely spaced fins, so long as the flow between adjoining fins is sufficient to maintain the convection coefficient.

PROBLEM 11.9

KNOWN: Operating conditions and surface area of a finned-tube, cross-flow exchanger.

FIND: Overall heat transfer coefficient.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Exhaust gas properties are those of air.

PROPERTIES: *Table A-6*, Water $\left(\overline{T}_m = 87°C\right)$: $\overline{c}_p = 4203\ J/kg \cdot K$; *Table A-4*, Air $\left(T_m \approx 275°C\right)$: $\overline{c}_p = 1040\ J/kg \cdot K$.

ANALYSIS: Since this is a cross-flow heat exchanger, we will use the ε – NTU method, for which

$$C_c = \dot{m}_c c_{p,c} = 0.5\ kg/s \times 4203\ J/kg \cdot K = 2102\ W/K$$

$$C_h = \dot{m}_h c_{p,h} = 2\ kg/s \times 1040\ J/kg \cdot K = 2080\ W/K$$

$$C_r = C_{min}/C_{max} = 0.990$$

$$q_{max} = C_{min}(T_{h,i} - T_{c,i}) = 2080\ W/K\ (325 - 25)°C = 6.24 \times 10^5\ W$$

$$q = C_c(T_{c,o} - T_{c,i}) = 2102\ W/K\ (150 - 25)°C = 2.63 \times 10^5\ W$$

Thus

$$\varepsilon = q/q_{max} = 0.421$$

and from Figure 11.14 or solving Eq. 11.32 iteratively for NTU,

$$NTU = 0.81$$

and

$$U = C_{min} NTU/A = 2080\ W/K \times 0.81/10\ m^2 = 168\ W/m^2 \cdot K$$ <

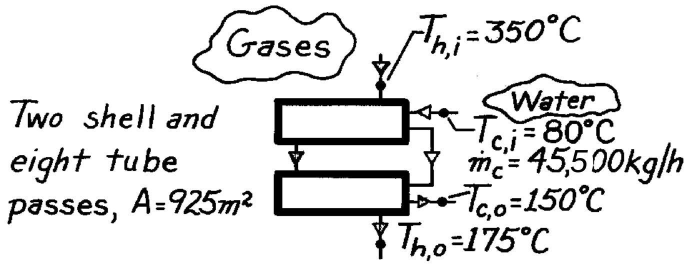
COMMENTS: The hot outlet temperature is found from $q = C_h\,(T_{h,i} - T_{h,o})$ to be 199°C, thus properties of the hot fluid should be evaluated at around 262°C. This will have little effect since c_p is not a strong function of temperature for water.

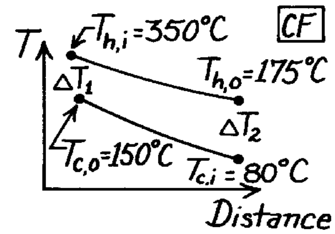
PROBLEM 11.10

KNOWN: Heat exchanger with two shell passes and eight tube passes having an area 925m^2; 45,500 kg/h water is heated from 80°C to 150°C; hot exhaust gases enter at 350°C and exit at 175°C.

FIND: Overall heat transfer coefficient.

SCHEMATIC:





ASSUMPTIONS: (1) Negligible losses to surroundings, (2) Constant properties, (3) Exhaust gas properties are approximated as those of atmospheric air.

PROPERTIES: *Table A-6*, Water $\left(\overline{T}_c = (80+150)°C/2 = 388K\right)$: $c_c = c_{p,f} = 4236$ J/kg·K.

ANALYSIS: Since this is a shell-and-tube heat exchanger, we will use the ε - NTU method, for which

$$C_c = \dot{m}_c c_c = \frac{45{,}500 \text{ kg/h}}{3600 \text{ s/h}} \times 4236 \text{ J/kg}\cdot\text{K} = 5.35 \times 10^4 \text{ W/K}$$

$$q = C_c(T_{c,o} - T_{c,i}) = 5.35 \times 10^4 \text{ W/K } (150-80)°C = 3.75 \times 10^6 \text{ W}$$

Then we can find C_h from an energy balance on the hot stream,

$$C_h = q/(T_{h,i} - T_{h,o}) = 3.75 \times 10^6 \text{ W}/(350-175)°C = 2.14 \times 10^4 \text{ W/K}$$

Thus

$$C_r = C_{min}/C_{max} = 0.40$$

$$\varepsilon = q/C_{min}(T_{h,i} - T_{c,i}) = 3.75 \times 10^6 \text{ W}/2.14 \times 10^4 \text{ W/K } (350-80)°C = 0.648$$

From Eqs. 11.31b and c, with n = 2,

$$F = \left(\frac{\varepsilon C_r - 1}{\varepsilon - 1}\right)^{1/n} = 1.45, \quad \varepsilon_1 = \frac{F-1}{F-C_r} = 0.429$$

From Eqs. 11.30c and 11.30b,

$$E = \frac{2/\varepsilon_1 - (1 + C_r)}{(1 + C_r^2)^{1/2}} = 3.0$$

$$(NTU)_1 = -(1 + C_r^2)^{-1/2} \ln\left[\frac{E-1}{E+1}\right] = 0.637$$

and from Eq. 11.31d,

$$NTU = n(NTU)_1 = 1.27$$

Therefore,

$$U = NTU \times C_{min}/A = 1.27 \times 2.14 \times 10^4 \text{ W/K}/(925 \text{ m}^2) = 29.5 \text{ W/m}^2\cdot\text{K}$$ <

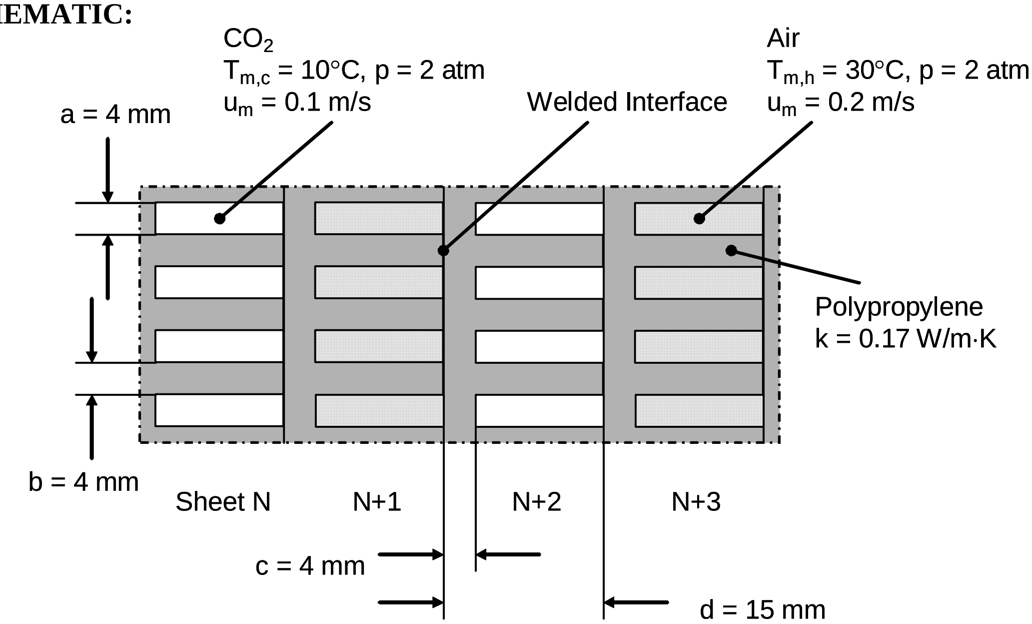
COMMENTS: Compare the above result with representative values for air-water exchangers, as given in Table 11.2.

PROBLEM 11.11

KNOWN: Geometry of heat exchanger made from extruded polypropylene sheets. Thermal conductivity of polypropylene. Temperature, pressure, and velocity, of air and carbon dioxide flowing in channels.

FIND: Product of overall heat transfer coefficient and surface area, UA, for 200 cool and 200 warm channels.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties and steady-state conditions, (2) Density of air and CO_2 is proportional to pressure, (3) Wall temperature is approximately uniform along channels, (4) Thermal resistance at welded interface is negligible, (5) Channel walls can be treated as fins.

PROPERTIES: *Table A.5*, Air: ($T_{m,h}$ = 303 K, p = 2 atm): k_h = 0.0265 W/m·K, $c_{p,h}$ = 1007 J/kg·K, $\mu_h = 186 \times 10^{-7}$ N·s/m^2, Pr_h = 0.707, ρ_h = 2.303 kg/m^3: CO_2 ($T_{m,c}$ = 283 K): k_c = 0.0154 W/m·K, $c_{p,c}$ = 833 J/kg·K, $\mu_c = 141 \times 10^{-7}$ N·s/m^2, Pr_c = 0.765, ρ_c = 3.76 kg/m^3. Polypropylene (given): k_p = 0.17 W/m·K.

ANALYSIS: We begin by finding the heat transfer coefficients for air and CO_2. In both cases, the hydraulic diameter is $D_h = 4A_c/P = 4\times11\times4/(2(11+4)$ mm = 5.87 mm. The Reynolds number for air is

$$Re_{D,h} = \frac{\rho_h u_{m,h} D_h}{\mu_h} = \frac{2.303 \text{ kg/m}^3 \times 0.2 \text{ m/s} \times 0.00587 \text{ m}}{186 \times 10^{-7} \text{ N} \cdot \text{s/m}^2} = 145$$

A similar calculation for CO_2 gives $Re_{D,c}$ = 156, thus both flows are laminar. From Table 8.1, assuming uniform wall temperature and interpolating for an aspect ratio of (d-c)/a = 2.75, we find Nu_D = 3.82. Then for air,

Continued…

PROBLEM 11.11 (Cont.)

$$h_h = Nu_{D,h} k_h / D_h = 3.82 \times 0.0265 \text{ W/m}\cdot\text{K} / 0.00587 \text{ m} = 17.2 \text{ W/m}^2\cdot\text{K}$$

And a similar calculation for CO_2 yields $h_c = 10.0$ W/m^2·K.

Focusing on one vertical wall of thickness c in the schematic above, we see that it has fins extending to the right and left into the two fluids. By symmetry, the midpoint of those fins is an adiabat, and we can treat the fins as having length L = (d-c)/2 = 5.5 mm, with an insulated tip. We will use Eq. 11.1 for UA, with Eqs. 11.3 and 11.4 for the fin efficiency. Note that for channels of length w, $P/A_c = 2(w+b)/wb \approx 2/b$. For air,

$$m_h = \sqrt{\frac{h_h P}{k_p A_c}} = \sqrt{\frac{2h_h}{k_p b}} = \sqrt{\frac{2 \times 17.2 \text{ W/m}^2\cdot\text{K}}{0.17 \text{ W/m}\cdot\text{K} \times 0.004 \text{ m}}} = 225 \text{ m}^{-1}$$

$$m_h L = 225 \text{ m}^{-1} \times 0.0055 \text{ m} = 1.24$$

$$\eta_{f,h} = \tanh(m_h L)/m_h L = \tanh(1.24)/1.24 = 0.682$$

Then $A_f/A = 2L/(2L + a) = 0.733$ and

$$\eta_{o,h} = 1 - \frac{A_f}{A}(1-\eta_{f,h}) = 1 - 0.733(1-0.682) = 0.767$$

A similar calculation for CO_2 yields $\eta_{o,c} = 0.839$. Finally, we use Eq. 11.1 to calculate UA. Note that for N = 200 channels (and N fins) of depth w, A = 2LwN + awN = 3w m^2 and A_w = (a+b)wN = 1.6w m^2. Thus, for a unit length of the heat exchanger (w = 1 m),

$$\frac{1}{UA} = \frac{1}{(\eta_o hA)_c} + \frac{c}{k_p A_w} + \frac{1}{(\eta_o hA)_c}$$

$$= \frac{1}{0.839 \times 10.0 \text{ W/m}^2\cdot\text{K} \times 3 \text{ m}^2} + \frac{0.004 \text{ m}}{0.17 \text{ W/m}\cdot\text{K} \times 1.6 \text{ m}^2} + \frac{1}{0.767 \times 17.2 \text{ W/m}^2\cdot\text{K} \times 3 \text{ m}^2}$$

UA = 12.6 W/m^2·K <

COMMENTS: (1) The product of the overall heat transfer coefficient and the heat transfer area is not large, but the design enables production of a compact heat exchanger that is not prone to corrosion and can be constructed at low cost. (2) The low thermal conductivity of the "fins" may result in significant temperature variation across their thickness, rendering the assumption of one-dimensional heat transfer in these extended surfaces invalid. (3) The contact resistance at the welded interfaces may not be negligible. In this case the system is not symmetric about the channel centerlines. (4) A numerical solution could account for two-dimensional conduction and address the considerations of Comments 2 and 3. (5) The thermal boundary condition at the channel boundaries is neither constant temperature nor constant heat flux. (6) Polypropylene is a semitransparent material (see Chapter 12) and radiation transfer may occur between the two gases. Since the temperatures are relatively low and the convective heat transfer coefficient is relatively high, radiation heat transfer will not be significant.

PROBLEM 11.12

KNOWN: Properties and flow rates for the hot and cold fluid of a heat exchanger.

FIND: Which fluid limits the heat transfer rate of the exchanger?

ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, and (3) Negligible losses to the surroundings.

ANALYSIS: The properties and flow rates for the hot and cold fluid of the heat exchanger are tabulated below.

	Cold fluid	*Hot fluid*
Density, kg/m^3	997	1247
Specific heat, J/kg·K	4179	2564
Thermal conductivity, W/m·K	0.613	0.287
Viscosity, $N \cdot s/m^2$	8.55×10^{-4}	1.68×10^{-4}
Flow rate, m^3/h	14	16

The fluid which limits the heat transfer rate of the exchanger is the minimum fluid, $C_{min} = \left(\dot{m} \cdot c\right)_{min}$. For the hot and cold fluids, find

$$C_h = \dot{m}_h\, c_h = 16\ m^3/h \times 1247\ kg/m^3 \times 2564\ J/kg \cdot K \times \left(1h/3600s\right) = 14.21\ kW/K$$

$$C_c = \dot{m}_c\, c_c = 14\ m^3/h \times 997\ kg/m^3 \times 4179\ J/kg \cdot K \times \left(1h/3600s\right) = 16.20\ kW/K$$

Hence, the hot fluid is the minimum fluid,

$$C_{min} = C_h$$ <

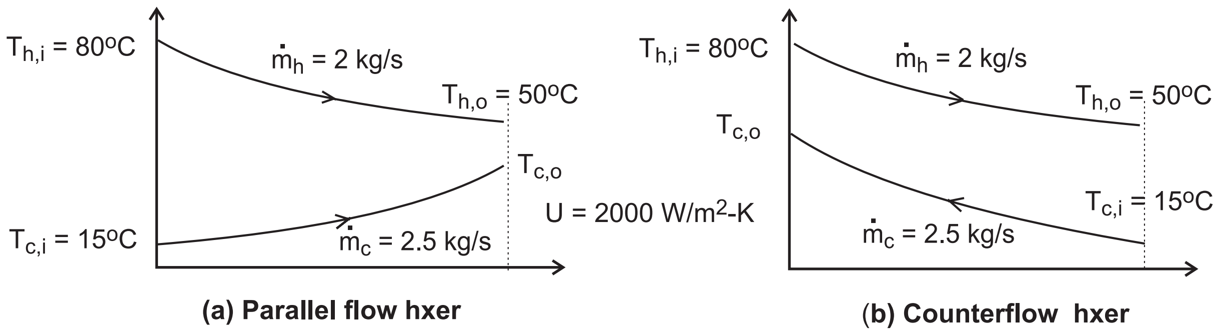
For any exchanger, the heat rate is $q = \varepsilon\, q_{max}$, where ε depends upon the exchanger type. The maximum heat rate is $q_{max} = C_{min}\,(T_{h,i} - T_{c,i})$. Hence, it is the conditions for the minimum fluid that limit the performance of the exchanger.

PROBLEM 11.13

KNOWN: Process (hot) fluid having a specific heat of 3500 J/kg·K and flowing at 2 kg/s is to be cooled from 80°C to 50°C with chilled-water (cold fluid) supplied at 2.5 ks/g and 15°C assuming an overall heat transfer coefficient of 2000 W/m^2·K.

FIND: The required heat transfer areas for the following heat exchanger configurations; (a) Concentric tube (CT) - parallel flow, (b) CT - counterflow, (c) Shell and tube, one-shell pass and 2 tube passes; (d) Cross flow, single pass, both fluids unmixed. Use the *IHT Tools | Heat Exchanger* models as your solution tool.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible losses to the surroundings, (3) Overall heat transfer coefficient remains constant with different configurations, and (4) Constant properties.

ANALYSIS: The *IHT Tools | Heat Exchanger* models are based upon the effectiveness-NTU method and suited for design-type problems. The table below summarizes the results of our analysis using the IHT models including model equations, figures, and the required heat transfer area. The cold fluid outlet temperature for all configurations is $T_{c,o}$ = 35.1°C. The IHT code for the concentric tube, parallel flow heat exchanger is provided in the Comments.

Heat exchanger type	*Eqs.*	*Figs*	*A(m^2)*
(a) CT -Parallel flow	11.28b	11.10	3.09
(b) CT -Counterflow	11.29b	11.11	2.64
(c) Shell and tube (1 - sp, 2 - tp)	11.30b	11.12	2.83
(d) Crossflow (1 - p, unmixed)	11.32	11.14	2.84

COMMENTS: (1) Referring to the tabulated results, note that for the concentric tube exchangers, the area required for parallel flow is 17% larger than for counterflow. Under what circumstances would you choose to use the PF arrangement if the area has to be significantly larger?

(2) The shell-tube and crossflow exchangers require nearly the same heat transfer area. What are other factors that might influence your decision to select one type over the other for an application?

(3) Based upon area considerations only, the CF arrangement requires the smallest heat transfer area. What practical issues need to be considered in making a CF heat exchanger with a 2.6 m^2 area?

Continued …

PROBLEM 11.13 (Cont.)

(4) The *IHT* code used for the concentric tube, parallel flow heat exchanger is shown below. Note the use of the water property function, *cp_Tx*, and the intrinsic function, *Tfluid_avg*, to provide the specific heat at the mean water (cold fluid) temperature.

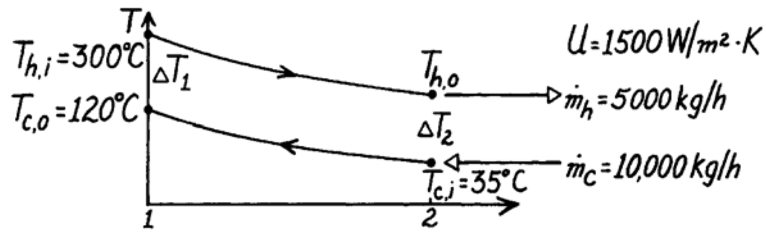
PROBLEM 11.14

KNOWN: A shell and tube Hxer (two shells, four tube passes) heats 10,000 kg/h of pressurized water from 35°C to 120°C with 5,000 kg/h water entering at 300°C.

FIND: Required heat transfer area, A_s.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties.

PROPERTIES: *Table A-6*, Water $(\overline{T}_c = 350\,K)$: c_p = 4195 J/kg·K; *Table A-6*, Water (Assume $T_{h,o} \approx$ 150°C, $\overline{T}_h \approx 500$ K): c_p = 4660 J/kg·K.

ANALYSIS: For a shell and tube heat exchanger, we use the ε – NTU method. An energy balance on the cold fluid yields

$$q = \dot{m}_c\, c_{p,c}\left(T_{c,o} - T_{c,i}\right) = \frac{10,000\ kg/h}{3600\ s/h} \times 4195\frac{J}{kg\cdot K}\left(120-35\right)K = 9.905\times10^5\ W.$$

An energy balance on the hot fluid yields

$$T_{h,o} = T_{h,i} - q/\dot{m}_h\, c_{p,h} = 300°C - 9.905\times10^5\ W / \frac{5000}{3600}\frac{kg}{s}\times 4660\frac{J}{kg\cdot K} = 147°C.$$

Thus $\overline{T_h}$ = (300 + 147)°C/2 = 497 K is the proper temperature for evaluating properties of the hot fluid. Then

$$C_c = \dot{m}_c c_{p,c} = \frac{10,000\ kg/h}{3,600\ s/h} \times 4195\ J/kg\cdot K = 11,650\ W/K$$

$$C_h = \dot{m}_h c_{p,h} = \frac{5,000\ kg/h}{3,600\ s/h} \times 4660\ J/kg\cdot K = 6470\ W/K$$

$$C_r = C_{min}/C_{max} = 6470/11,650 = 0.555$$

$$q_{max} = C_{min}(T_{h,i} - T_{c,i}) = 6470\ W/K\ (300 - 35)°C = 1.75\times10^6\ W$$

$$\varepsilon = q/q_{max} = 9.905\times10^5\ W/1.72\times10^6\ W = 0.577$$

From Eqs. 11.31c, 11.31b, and 11.30c, with n =2,

$$F = \left(\frac{\varepsilon C_r - 1}{\varepsilon - 1}\right)^{1/n} = 1.27, \quad \varepsilon_1 = \frac{F-1}{F-C_r} = 0.376$$

$$E = \frac{2/\varepsilon_1 - (1 + C_r)}{(1 + C_r^2)^{1/2}} = 3.29$$

then from Eqs. 11.30b and 11.31d,

$$NTU = n\,(NTU)_1 = -n\,(1 + C_r^2)^{-1/2}\ln\left[\frac{E-1}{E+1}\right] = 1.10$$

Finally,

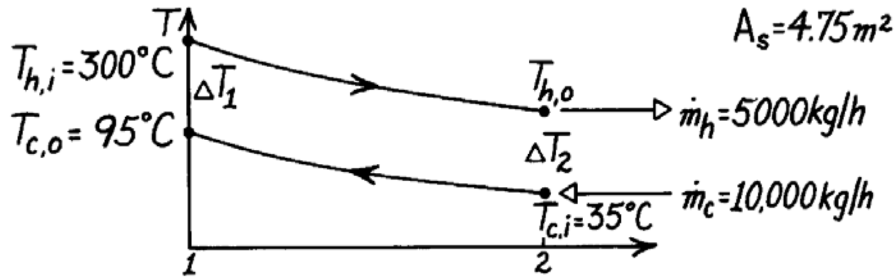
$$A = NTU \times C_{min}/U = (1.10 \times 6470\ W/K)/(1500\ W/m^2\cdot K) = 4.75\ m^2$$ <

PROBLEM 11.15

KNOWN: The shell and tube Hxer (two shells, four tube passes) of Problem 11.14, known to have an area 4.75m^2, provides 95°C water at the cold outlet (rather than 120°C) after several years of operation. Flow rates and inlet temperatures of the fluids remain the same.

FIND: The fouling factor, R_f.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Thermal resistance for the clean condition is $R''_t = (1500 \text{ W/m}^2\cdot\text{K})^{-1}$.

PROPERTIES: *Table A-6*, Water ($\overline{T}_c \approx 338$ K): c_p = 4187 J/kg·K; *Table A-6*, Water (Assume $T_{h,o} \approx$ 190°C, $\overline{T}_h \approx 520$ K): c_p = 4840 J/kg·K.

ANALYSIS: The overall heat transfer coefficient can be expressed as

$$U = 1/\left(R''_t + R''_f\right) \qquad \text{or} \qquad R''_f = 1/U - R''_t \qquad (1)$$

where R''_t is the thermal resistance for the clean condition and R''_f, the fouling factor, represents the additional resistance due to fouling of the surface. We use the ε – NTU method as follows,

$$C_c = \dot{m}_c c_{p,c} = \frac{10{,}000 \text{ kg/h}}{3{,}600 \text{ s/h}} \times 4187 \text{ J/kg}\cdot\text{K} = 1.16 \times 10^4 \text{ W/K}$$

$$C_h = \dot{m}_h c_{p,h} = \frac{5{,}000 \text{ kg/h}}{3{,}600 \text{ s/h}} \times 4840 \text{ J/kg}\cdot\text{K} = 6.72 \times 10^3 \text{ W/K}$$

$$C_r = C_{min}/C_{max} = 0.578$$

$$q_{max} = C_{min}(T_{h,i} - T_{c,i}) = 6.72\times10^3 \text{ W/K } (300-35)°\text{C} = 1.78 \times 10^6 \text{ W}$$

$$q = C_c(T_{c,o} - T_{c,i}) = 1.16 \times 10^4 \text{ W/K } (95-35)°\text{C} = 6.98 \times 10^5 \text{ W}$$

$$\varepsilon = q/q_{max} = 0.392$$

Note, that $T_{h,o} = T_{h,i} - q/C_h$ = 196°C, so properties should be evaluated at $\overline{T}_h = (T_{h,i} + T_{h,o})/2 = 248°\text{C} = 521$ K, very close to the assumed value. From Eqs. 11.31 and 11.30, with n =2,

$$F = \left(\frac{\varepsilon C_r - 1}{\varepsilon - 1}\right)^{1/n} = 1.13, \qquad \varepsilon_1 = \frac{F-1}{F-C_r} = 0.232,$$

$$E = \frac{2/\varepsilon_1 - (1 + C_r)}{(1 + C_r^2)^{1/2}} = 6.09$$

$$NTU = -n\,(1 + C_r^2)^{-1/2} \ln\left[\frac{E-1}{E+1}\right] = 0.574$$

Continued…

PROBLEM 11.15 (Cont.)

Thus,

$$U = NTU \times C_{min}/A = (0.574 \times 6.72 \times 10^3 \text{ W/K})/(4.75 \text{ m}^2) = 813 \text{ W/m}^2\cdot\text{K}$$

From Eq. (1), the fouling factor is

$$R''_f = \frac{1}{813 \text{ W/m}^2\cdot\text{K}} - \frac{1}{1500 \text{ W/m}^2\cdot\text{K}} = 5.64\times10^{-4} \text{ m}^2\cdot\text{K/W}. \quad <$$

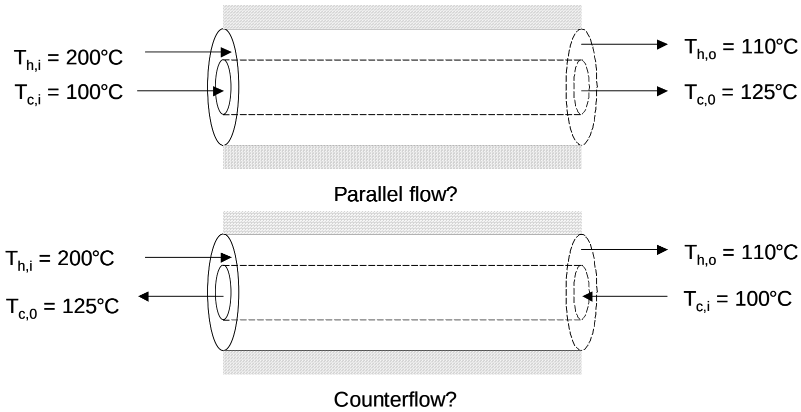
COMMENTS: Note that the effect of fouling is to nearly double ($U_{clean}/U_{fouled} = 1500/813 \approx 1.9$) the resistance to heat transfer. Note also the assumption for $T_{h,o}$ used for property evaluation is satisfactory.

PROBLEM 11.16

KNOWN: Inlet and outlet temperatures of hot and cold fluid streams in a concentric tube heat exchanger.

FIND: Whether the heat exchanger is operated in counter- or parallel flow, heat exchanger effectiveness, heat exchanger NTU.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat transfer between the heat exchanger and the surroundings, (2) Constant properties.

ANALYSIS: The heat exchanger must be operating in a counterflow configuration because $T_{h,o} < T_{c,o}$. <

From energy balances on each fluid, $q = C_h(T_{h,i} - T_{h,o}) = C_c(T_{c,o} - T_{c,i})$, from which

$$C_h/C_c = C_{\min}/C_{\max} = (T_{c,o} - T_{c,i})/(T_{h,i} - T_{h,o}) = 25/90 = 0.278 \text{ and } C_{\min} = C_h.$$

From the definition of the effectiveness, $q = \varepsilon C_{\min}(T_{h,i} - T_{c,i}) = \varepsilon C_h(T_{h,i} - T_{c,i}) = C_h(T_{h,o} - T_{h,i})$ from which

$$\varepsilon = (T_{h,o} - T_{h,i})/(T_{h,i} - T_{c,i}) = 90/100 = 0.90$$ <

From Fig. 11.11, NTU ≈ 2.8 <

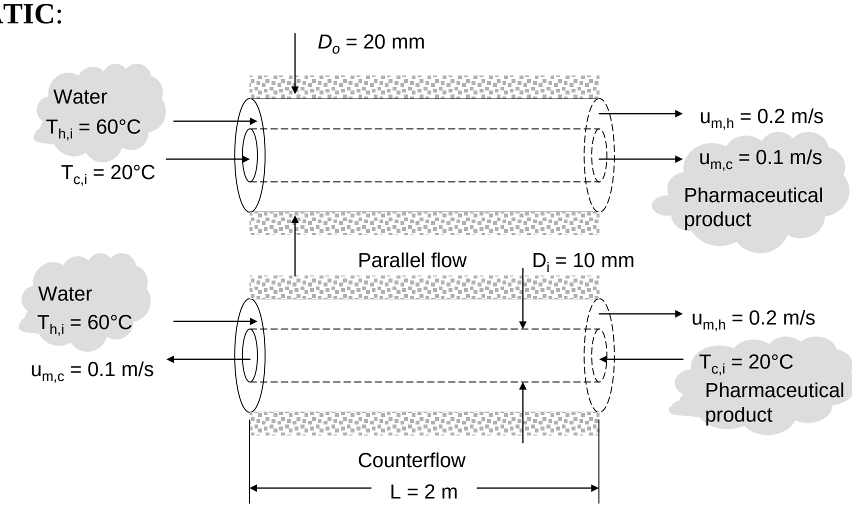
COMMENTS: The NTU may also be found from Eq. 11.28b, yielding NTU = 2.79.

PROBLEM 11.17

KNOWN: Inlet temperatures of pharmaceutical product and water in a concentric tube heat exchanger. Tube diameters and fluid velocities.

FIND: (a) Value of the overall heat transfer coefficient, U, (b) Mean outlet temperature of the pharmaceutical product for counterflow operation, (c) Mean outlet temperature of the pharmaceutical product for parallel-flow operation.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat transfer between the heat exchanger and the surroundings, (2) Constant properties, (3) Negligible conduction resistance posed by the thin-walled inner tube, (4) Smooth tube surfaces.

PROPERTIES: Pharmaceutical product (given): $\nu = 10 \times 10^{-6}$ m^2/s, k = 0.25 W/m·K, ρ = 1100 kg/m^3 and c_p = 2460 J/kg·K. *Table A.6*, water ($\overline{T_h}$ = 50°C): $\nu = 5.54 \times 10^{-7}$ m^2/s, k = 0.643 W/m·K, ρ = 987.9 kg/m^3, Pr = 3.56 and c_p = 4181 J/kg·K.

ANALYSIS: (a) The Prandtl number of the pharmaceutical product is $Pr_c = \rho c_p \nu/k$ = (1100 kg/m^3 × 2460 J/kg·K × 10 × 10^{-6} m^2/s)/0.25 W/m·K = 108. The overall heat transfer coefficient is $U = (1/h_i + 1/h_o)^{-1}$. For the flow in the inner tube, $Re_{Di} = u_{m,c}D_i/\nu$ = (0.1 m/s × 0.01 m)/10 × 10^{-6} m^2/s = 100. The thermal entrance length is $x_{fd,t} = 0.05Re_{Di}PrD_i = 0.05Re_{Di}(\rho c_p \nu/k)D_i$ = 0.05 × 100 × (1100 kg/m^3 × 2460 J/kg·K × 10 × 10^{-6} m^2/s/0.25 W/m·K) × 0.01m = 5.41 m. Therefore, entrance effects are important. The Hausen correlation is appropriate for determining the average Nusselt number associated with the inner tube flow.

$$\overline{Nu}_{Di} = 3.66 + \frac{0.0668(D/L)Re_{Di}Pr}{1+0.04\left[(D/L)Re_{Di}Pr\right]^{2/3}} = 3.66 + \frac{0.0668\times(0.01/2)\times100\times108}{1+0.04\left[(0.01/2)\times100\times108\right]^{2/3}} = 5.96$$

Therefore,

$$h_i = \frac{\overline{Nu}_{Di}k}{D_i} = \frac{5.96\times0.25\text{W/m}\cdot\text{K}}{0.01\text{m}} = 149\text{W/m}^2\cdot\text{K}$$

Continued…

Problem 11.17 (Cont.)

For the annular flow, $Re_{Dh} = u_{m,h}(D_o - D_i)/\nu$ = 0.2 m/s × 0.01 m/5.54 × 10^{-7} m^2/s = 3610. Hence, the Gnielinski correlation is appropriate for use. The friction factor for the annular region is obtained from Eq. 8.21 and is

$$f = \left(0.790 \ln Re_{Dh} - 1.64\right)^{-2} = \left(0.790 \ln\left(3610\right) - 1.64\right)^{-2} = 0.0428$$

Therefore,

$$\overline{Nu}_{Dh} = \frac{\left(f/8\right)\left(Re_{Dh} - 1000\right)Pr}{1 + 12.7\left(f/8\right)^{1/2}\left(Pr^{2/3} - 1\right)} = \frac{\left(0.0428/8\right)\left(3610 - 1000\right)3.56}{1 + 12.7\left(0.0428/8\right)^{1/2}\left(3.56^{2/3} - 1\right)} = 22.22$$

and

$$h_o = \frac{\overline{Nu}_{Dh} k}{D_o - D_i} = \frac{22.22 \times 0.643 \mathrm{W/m \cdot K}}{0.01 \mathrm{m}} = 1430 \mathrm{W/m^2 \cdot K}$$

The overall heat transfer coefficient is

$U = (1/h_i + 1/h_o)^{-1} = [1/(1430\ \mathrm{W/m^2 \cdot K}) + 1/(149\ \mathrm{W/m^2 \cdot K})]^{-1} = 135\ \mathrm{W/m^2 \cdot K}$. <

(b) The heat capacity rate of the cold (pharmaceutical product) stream is

$$C_c = \dot{m}_c c_p = \left[u_{m,c} \rho \pi D_i^2 / 4\right] c_p = \left[\frac{0.1 \mathrm{m/s} \times 1100 \mathrm{kg/m^3} \times \pi \times \left(0.01 \mathrm{m}\right)^2}{4}\right] \times 2460\ \mathrm{J/kg \cdot K} = 21.3\ \mathrm{W/K}$$

The heat capacity rate of the hot (water) stream is

$$C_c = \dot{m}_c c_p = \left[u_{m,c} \rho \pi \left(D_o^2 - D_i^2\right)/4\right] c_p$$
$$= \left[\frac{0.2 \mathrm{m/s} \times 987.9\ \mathrm{kg/m^3} \times \pi \times \left[\left(0.02 \mathrm{m}\right)^2 - \left(0.01 \mathrm{m}\right)^2\right]}{4}\right] \times 4181\ \mathrm{J/kg \cdot K} = 195\ \mathrm{W/K}$$

Therefore, $C_r = C_{min}/C_{max}$ = (21.3 W/K)/(195 W/K) = 0.11 and the number of transfer units is NTU = $UA/C_{min} = U\pi D_i L/C_{min}$ = (135 $\mathrm{W/m^2 \cdot K}$ × π × 0.01 m × 2m)/21.3 W/K = 0.398. The effectiveness of the counterflow heat exchanger is obtained from Eq. 11.29a and is

$$\varepsilon = \frac{1 - \exp\left[-\mathrm{NTU}(1 - C_r)\right]}{1 - C_r \exp\left[-\mathrm{NTU}(1 - C_r)\right]} = \frac{1 - \exp\left[-0.398(1 - 0.11)\right]}{1 - 0.11 \exp\left[-0.398(1 - 0.11)\right]} = 0.323$$

Continued…

Problem 11.17 (Cont.)

The heat transfer rate is

$$q = \dot{m}_c c_p (T_{c,o} - T_{c,i}) = \varepsilon C_{\min} (T_{h,i} - T_{c,i})$$ from which

$$T_{c,o} = T_{c,i} + \frac{\varepsilon C_{\min}\left(T_{h,i} - T_{c,i}\right)}{\rho u_{m,c}\left(\pi D_i^2/4\right)c_p} = 20°\text{C} + \frac{0.323 \times 21.3\,\text{W/K} \times (60°\text{C} - 20°\text{C})}{1100\,\text{kg/m}^3 \times 0.1\,\text{m/s} \times \left(\pi(0.01\,\text{m})^2/4\right) 2460\,\text{J/kg}\cdot\text{K}} = 33.0°\text{C}$$ <

(c) For parallel-flow operation,

$$\varepsilon = \frac{1 - \exp\left[-NTU\left(1 + C_r\right)\right]}{1 + C_r} = \frac{1 - \exp\left[-0.398\left(1 + 0.11\right)\right]}{1 + 0.11} = 0.322$$

Therefore, the cold stream outlet temperature is

$$T_{c,o} = T_{c,i} + \frac{\varepsilon C_{\min}\left(T_{h,i} - T_{c,i}\right)}{\rho u_{m,c}\left(\pi D_i^2/4\right)c_p} = 20°\text{C} + \frac{0.322 \times 21.3\,\text{W/K} \times (60°\text{C} - 20°\text{C})}{1100\,\text{kg/m}^3 \times 0.1\,\text{m/s} \times \left(\pi(0.01\,\text{m})^2/4\right) 2460\,\text{J/kg}\cdot\text{K}} = 31.2°\text{C}$$ <

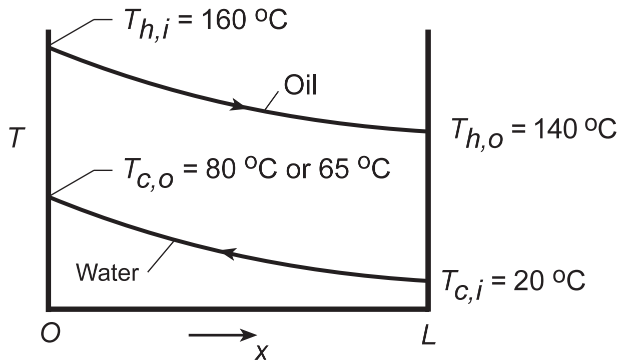
COMMENTS: There is little difference in the outlet temperature of the pharmaceutical product. However, if the outlet temperature of the pharmaceutical product cannot exceed some critical value, the heat exchanger should be operated in parallel-flow since the ultimate outlet temperature associated with a very long concentric tube apparatus would be determined by the conservation of energy principle.

PROBLEM 11.18

KNOWN: Inner tube diameter (D = 0.02 m) and fluid inlet and outlet temperatures corresponding to design conditions for a counterflow, concentric tube heat exchanger. Overall heat transfer coefficient ($U = 500\ W/m^2\cdot K$) and desired heat rate (q = 3000 W). Cold fluid outlet temperature after three years of operation.

FIND: (a) Required heat exchanger length, (b) Heat rate, hot fluid outlet temperature, overall heat transfer coefficient, and fouling factor after three years.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to the surroundings, (2) Negligible tube wall conduction resistance, (3) Constant properties.

ANALYSIS: (a) The tube length needed to achieve the prescribed conditions may be obtained from Eqs. 11.14 and 11.15 where $\Delta T_1 = T_{h,i} - T_{c,o} = 80°C$ and $\Delta T_2 = T_{h,o} - T_{c,i} = 120°C$. Hence, $\Delta T_{1m} = (120 - 80)°C/\ln(120/80) = 98.7°C$ and

$$L = \frac{q}{(\pi D) U \Delta T_{1m}} = \frac{3000\,W}{(\pi \times 0.02\,m)500\,W/m^2\cdot K \times 98.7^\circ C} = 0.968\,m$$ <

(b) With $q = C_c(T_{c,o} - T_{c,i})$, the following ratio may be formed in terms of the design and 3 year conditions.

$$\frac{q}{q_3} = \frac{C_c\left(T_{c,o} - T_{c,i}\right)}{C_c\left(T_{c,o} - T_{c,i}\right)_3} = \frac{60^\circ C}{45^\circ C} = 1.333$$

Hence,

$$q_3 = q/1.33 = 3000\,W/1.333 = 2250\,W$$ <

Having determined the ratio of heat rates, it follows that

$$\frac{q}{q_3} = \frac{C_h\left(T_{h,i} - T_{h,o}\right)}{C_h\left(T_{h,i} - T_{h,o}\right)_3} = \frac{20^\circ C}{160^\circ C - T_{h,o(3)}} = 1.333$$

Hence,

$$T_{h,o(3)} = 160^\circ C - 20^\circ C/1.333 = 145^\circ C$$ <

With $\Delta T_{lm,3} = (125 - 95)/\ln(125/95) = 109.3^\circ C$,

$$U_3 = \frac{q_3}{(\pi DL)\Delta T_{lm,3}} = \frac{2250\,W}{\pi(0.02\,m)0.968\,m\left(109.3^\circ C\right)} = 338\,W/m^2\cdot K$$ <

Continued...

PROBLEM 11.18 (Cont.)

With $U = \left[(1/h_i) + (1/h_o)\right]^{-1}$ and $U_3 = \left[(1/h_i) + (1/h_o) + R''_{f,c}\right]^{-1}$,

$$R''_{f,c} = \frac{1}{U_3} - \frac{1}{U} = \left(\frac{1}{338} - \frac{1}{500}\right) m^2 \cdot K/W = 9.59 \times 10^{-4} m^2 \cdot K/W$$ <

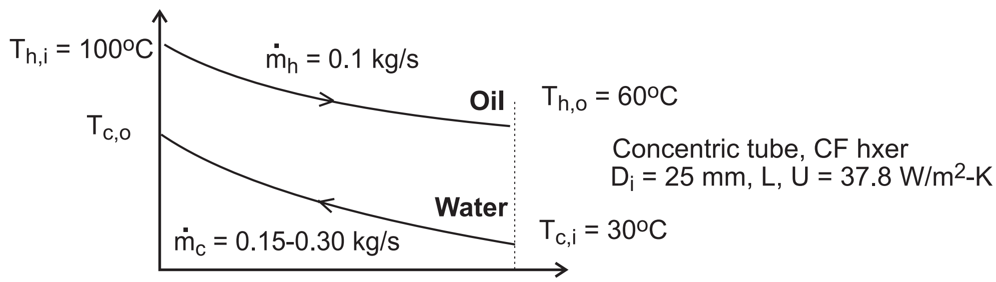
COMMENTS: Over time fouling will always contribute to a degradation of heat exchanger performance. In practice it is desirable to remove fluid contaminants and to implement a regular maintenance (cleaning) procedure.

PROBLEM 11.19

KNOWN: Counterflow, concentric tube heat exchanger of Example 11.1; maintaining the outlet oil temperature of 60°C, but with variable rate of cooling water, all other conditions remaining the same.

FIND: (a) Calculate and plot the required exchanger tube length L and water outlet temperature $T_{c,o}$ for the cooling water flow rate in the range 0.15 to 0.3 kg/s, and (b) Calculate U as a function of the water flow rate assuming the water properties are independent of temperature; justify using a constant value of U for the part (a) calculations.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible losses to the surroundings, (3) Overall heat transfer coefficient independent of water flow rate for this range, and (4) Constant properties.

PROPERTIES: *Table A-6*, Water $\left(\overline{T}_c = 35^\circ C = 308\ K\right)$: $c_p = 4178\ J/kg\cdot K$, $\mu = 725\times10^{-6}$ $N\cdot s/m^2$, $k = 0.625\ W/m\cdot K$, $Pr = 4.85$, *Table A-4*, Unused engine oil $\left(\overline{T}_h = 353\ K\right)$: $c_p = 2131\ J/kg\cdot K$.

ANALYSIS: (a) The NTU-ε method will be used to calculate the tube length L and water outlet temperature $T_{c,o}$ using this system of equations in the *IHT* workspace:

NTU relation, CF hxer, Eq. 11.29b

$$NTU = \frac{1}{C_r - 1}\ln\frac{(\varepsilon - 1)}{(\varepsilon C_r - 1)} \qquad C_r = C_{max}/C_{min} \qquad (1, 2)$$

$$NTU = U\cdot A/C_{min} \qquad (3)$$

$$A = \pi D_i \cdot L \qquad (4)$$

Capacity rates, find minimum fluid

$$C_h = \dot{m}_h\, c_h = 0.1\ kg/s \times 2131\ J/kg\cdot K = 213.1\ W/K$$

$$C_c = \dot{m}_c\, c_c = (0.15\text{ to }0.30)\,kg/s \times 4178\ J/kg\cdot K = 626.7 - 1253\ W/K \qquad (5)$$

$$C_{min} = C_h \qquad (6)$$

Effectiveness and maximum heat rate, Eqs. 11.18 and 11.19

$$\varepsilon = q/q_{max} \qquad (7)$$

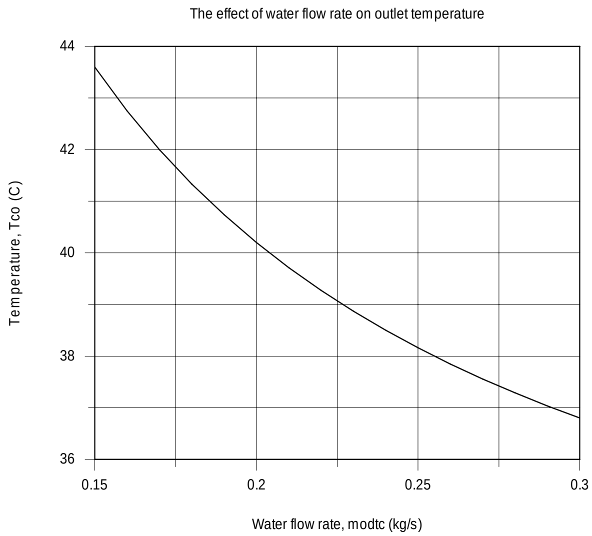
$$q_{max} = C_{min}\left(T_{h,i} - T_{c,i}\right) = C_c\left(T_{h,i} - T_{c,i}\right) \qquad (8)$$

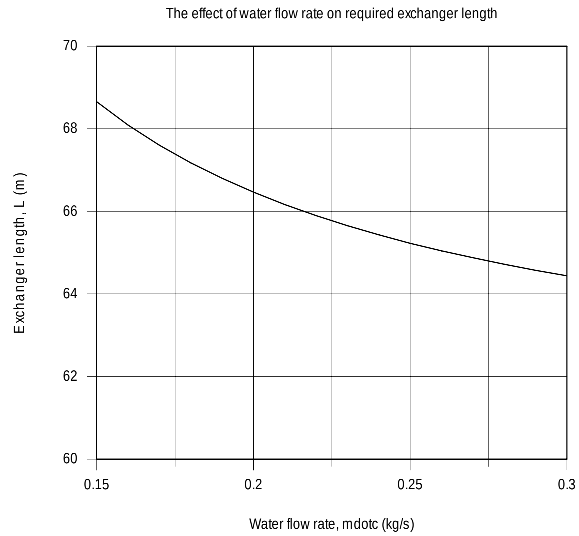
Continued …

PROBLEM 11.19 (Cont.)

$$q = C_h\left(T_{h,i} - T_{h,o}\right) \tag{9}$$

With the foregoing equations and the parameters specified in the schematic, the results are plotted in the graphs below.





(b) The overall coefficient can be written in terms of the inner (cold) and outer (hot) side convection coefficients,

$$U = 1/\left(1/h_i + 1/h_o\right) \tag{10}$$

From Example 11.1, $h_o = 38.8\ W/m^2\cdot K$, and h_i will vary with the flow rate from Eq. 8.60 as

$$h_i = h_{i,b}\left(\dot{m}_i / \dot{m}_{i,b}\right)^{0.8} \tag{11}$$

where the subscript *b* denotes the base case when $\dot{m}_i = 0.2\ kg/s$. From these equations, the results are tabulated.

$\dot{m}_c (kg/s)$	$h_i\ (W/m^2\cdot K)$	$h_o\ (W/m^2\cdot K)$	$U\ (W/m^2\cdot K)$
015	1787	38.8	38.0
0.20	2250	38.8	38.1
0.25	2690	38.8	38.2
0.30	3112	38.8	38.3

Note that while h_i varies nearly 50%, there is a negligible effect on the value of U.

COMMENTS: Note from the graphical results, that by doubling the flow rate (from 0.15 to 0.30 kg/s), the required length of the exchanger can be decreased by approximately 6%. Increasing the flow rate is not a good strategy for reducing the length of the exchanger. However, any increase in the hot-side (oil) convection coefficient would provide a proportional decrease in the length.

PROBLEM 11.20

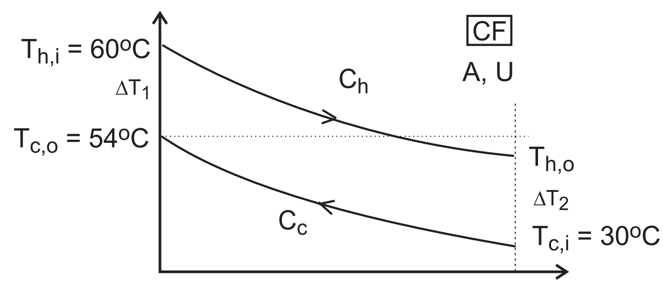
KNOWN: Concentric tube heat exchanger with area of 50 m^2 with operating conditions as shown on the schematic.

FIND: (a) Outlet temperature of the hot fluid; (b) Whether the exchanger is operating in counterflow or parallel flow; or can't tell from information provided; (c) Overall heat transfer coefficient; (d) Effectiveness of the exchanger; and (e) Effectiveness of the exchanger if its length is made very long

SCHEMATIC:

Operating conditions
Concentric tube HXer, A = 50 m^2

	Hot fluid (h)	Cold fluid (c)
Capacity rate, kW/K	6	3
Inlet temperature, °C	60	30
Outlet temperature, °C	--	54



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties.

ANALYSIS: From overall energy balances on the hot and cold fluids, find the hot fluid outlet temperature

$$q = C_c\left(T_{c,o} - T_{c,i}\right) = C_h\left(T_{h,i} - T_{h,o}\right) \qquad (1)$$

$$3000\ \text{W/K}\ (54-30)\text{K} = 6000\left(60 - T_{h,o}\right) \qquad T_{h,o} = 48°\text{C} \qquad <$$

(b) HXer must be operating in counterflow (CF) since $T_{h,o} < T_{c,o}$. See schematic for temperature distribution.

(c) From the rate equation with A = 50 m^2, with Eq. (1) for q,

$$q = C_c\left(T_{c,o} - T_{c,i}\right) = UA\Delta T_{\ell m} \qquad (2)$$

$$\Delta T_{\ell m} = \frac{\Delta T_1 - \Delta T_2}{\ell m\left(\Delta T_1/\Delta T_2\right)} = \frac{(60-54)\text{K} - (48-30)\text{K}}{\ell n(6/18)} = 10.9°\text{C} \qquad (3)$$

$$3000\ \text{W/K}(54-30)\text{K} = U \times 50\ \text{m}^2 \times 10.9\,\text{K}$$

$$U = 132\ \text{W/m}^2\cdot\text{K} \qquad <$$

(d) The effectiveness, from Eq. 11.19, with the cold fluid as the minimum fluid, $C_c = C_{min}$,

$$\varepsilon = \frac{q}{q_{max}} = \frac{C_c\left(T_{c,o} - T_{c,i}\right)}{C_{min}\left(T_{h,i} - T_{c,i}\right)} = \frac{(54-30)\text{K}}{(60-30)\text{K}} = 0.8 \qquad <$$

(e) For a very long CF HXer, the outlet of the minimum fluid, $C_{min} = C_c$, will approach $T_{h,i}$. That is,

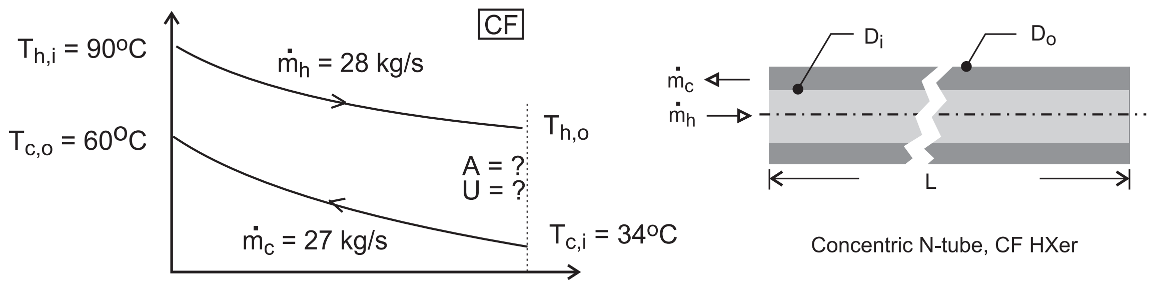
$$q \to C_{min}\left(T_{c,o} - T_{c,i}\right) \to q_{max} \qquad \varepsilon = 1 \qquad <$$

PROBLEM 11.21

KNOWN: Specifications for a water-to-water heat exchanger as shown in the schematic including the flow rate, and inlet and outlet temperatures.

FIND: (a) Design a heat exchanger to meet the specifications; that is, size the heat exchanger, and (b) Evaluate your design by identifying what features and configurations could be explored with your customer in order to develop more complete, detailed specifications.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Tube walls have negligible thermal resistance, (3) Flow is fully developed, and (4) Constant properties.

ANALYSIS: (a) Referring to the schematic above and using the rate equation, we can determine the value of the UA product required to satisfy the design requirements. Sizing the heat exchanger involves determining the heat transfer area, A (tube diameter, length and number), and the associated overall convection coefficient, U, such that U × A satisfies the required UA product. Our approach has five steps: (1) *Calculate the UA product:* Select a configuration and calculate the required UA product; (2) *Estimate the area, A:* Assume a range for the overall coefficient, calculate the area and consider suitable tube diameter(s); (3) *Estimate the overall coefficient, U:* For selected tube diameter(s), use correlations to estimate hot- and cold-side convection coefficients and the overall coefficient; (4) *Evaluate first-pass design:* Check whether the A and U values (U × A) from Steps 2 and 3 satisfy the required UA product; if not, then (5) *Repeat the analysis:* Iterate on different values for area parameters until a satisfactory match is made, (U × A) = UA.

To perform the analysis, *IHT* models and tools will be used for the effectiveness-NTU method relations, internal flow convection correlations, and thermophysical properties. See the Comments section for details.

Step 1 Calculate the required UA. For the initial design, select a concentric tube, counterflow heat exchanger. Calculate UA using the following set of equations, Eqs. 11.29a,

$$\varepsilon = \frac{1-\exp\left[-NTU\left(1-C_r\right)\right]}{1-C_r\exp\left[-NTU\left(1-C_r\right)\right]} \quad (1)$$

$$NTU = UA/C_{min} \qquad C_r = C_{min}/C_{max} \quad (2,3)$$

$$\varepsilon = q/q_{max} \qquad q_{max} = C_{min}\left(T_{h,i}-T_{c,i}\right) \quad (4,5)$$

where $C = \dot{m}c_p$, and c_p is evaluated at the average mean temperature of the fluid, $\overline{T}_m = (T_{m,i} + T_{m,o})/2$. Substituting numerical values, find

$$\varepsilon = 0.464 \qquad NTU = 0.8523 \quad q = 2.934\times10^6\,W \qquad T_{h,o} = 65.0°C$$

Continued …

PROBLEM 11.21 (Cont.)

$$UA = 9.62 \times 10^4 \, W/K$$ <

Step 2 Estimate the area, A. From Table 11.2, the typical range of U for water-to-water exchangers is 850 – 1700 W/m^2·K. With UA = 9.619 × 10^4 W/K, the range for A is 57 – 113 m^2, where

$$A = \pi D_i LN \tag{6}$$

where L and N are the length and number of tubes, respectively. Consider these values of D_i with L = 10 m to describe the exchanger:

Case	D_i (mm)	L (m)	N	A (m^2)
1	25	10	73-146	57-113
2	50	10	36-72	57-113
3	75	10	24-48	57-113

<

Step 3 Estimate the overall coefficient, U. With the inner (hot) and outer (cold) fluids in the concentric tube arrangement, the overall coefficient is

$$1/U = 1/\bar{h}_i + 1/\bar{h}_o \tag{7}$$

and the $\bar{h}$ are estimated using the Dittus-Boelter correlation assuming fully developed turbulent flow.

Coefficient, hot side, $\bar{h}_i$. For flow in the inner tube,

$$Re_{Di} = \frac{4\,\dot{m}_{h,i}}{\pi D_i \mu_h} \qquad \dot{m}_h = \dot{m}_{hi} \cdot N \tag{8,9}$$

and the correlation, Eq. 8.60 with n = 0.3, is

$$\overline{Nu}_D = \frac{\bar{h}_i D_i}{k} = 0.037\, Re_{Di}^{4/5} Pr^{0.3} \tag{10}$$

where properties are evaluated at the average mean temperature, $\bar{T}_h = \left(T_{hi} + T_{ho}\right)/2$.

Coefficient, cold side, $\bar{h}_o$. For flow in the annular space, $D_o - D_i$, the above relations apply where the characteristic dimension is the hydraulic diameter,

$$D_{h,o} = 4A_{c,o}/P_o \qquad A_{c,o} = \pi\left(D_o^2 - D_i^2\right)/4 \qquad P_o = \pi\left(D_o + D_i\right) \tag{11-13}$$

To determine the outer diameter D_o, require that the inner and outer fluid flow areas are the same, that is,

$$A_{c,i} = A_{c,o} \qquad \pi D_i^2/4 = \pi\left(D_o^2 - D_i^2\right)/4 \tag{14,15}$$

Summary of the convection coefficient calculations. The results of the analysis with L = 10 m are summarized below.

Continued …

PROBLEM 11.21 (Cont.)

Case	D_i (mm)	N	A (m^2)	$\bar{h}_i$ ($W/m^2 \cdot K$)	$\bar{h}_o$ ($W/m^2 \cdot K$)	U ($W/m^2 \cdot K$)	U × A W/K
1a	25	73	57	4795	4877	2418	1.39×10^5
2a	50	36	57	2424	2465	1222	6.91×10^4
3a	75	24	57	1616	1644	814	4.61×10^4

For all these cases, the Reynolds numbers are above 10,000 and turbulent flow occurs.

Step 4 Evaluate first-pass design. The required UA product value determined in step 1 is UA = 9.62 × 10^4 W/K. By comparison with the results in the above table, note that the U × A values for cases 1a and 2a are, respectively, larger and smaller than that required. In this first-pass design trial we have identified the range of D_i and N (with L = 10 m) that could satisfy the exchanger specifications. A strategy can now be developed in *Step 5* to iterate the analysis on values for D_i and N, as well as with different L, to identify a combination that will meet specifications.

(b) What information could have been provided by the customer to simplify the analysis for design of the exchanger? Looking back at the analysis, recognize that we had to assume the exchanger configuration (type) and overall length. Will knowledge of the customer's installation provide any insight? While no consideration was given in our analysis to pumping power limitations, that would affect the flow velocities, and hence selection of tube diameter.

COMMENTS: The *IHT* workspace with the relations for step 3 analysis is shown below, including summary of key correlation parameters. The set of equations is quite stiff so that good initial guesses are required to make the initial solve.

```

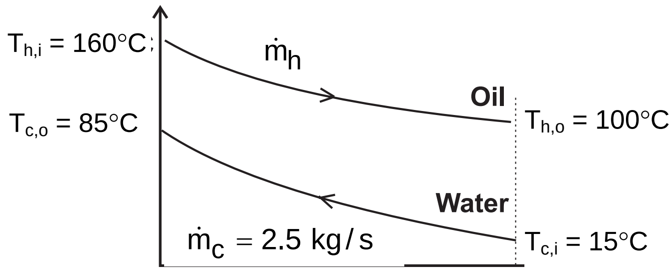
PROBLEM 11.22

KNOWN: Inlet and outlet temperatures for a shell-and-tube heat exchanger with 10 tubes making eight passes. Heat transfer coefficient for oil flowing in shell. Mass flow rate of water in tubes. Tube diameter.

FIND: Oil flow rate required to achieve specified outlet temperature. Tube length required to achieve specified water heating.

SCHEMATIC:



Shell and tube hx
1 shell pass
8 tube passes
10 tubes
D = 25 mm
h_o = 400 W/m^2·K

ASSUMPTIONS: (1) Negligible heat loss to the surroundings, (2) Constant properties, (3) Negligible tube wall thermal resistance and fouling effects, (4) Fully developed water flow in tubes.

PROPERTIES: *Table A.5*, unused engine oil: ($\bar{T}_h$ = 130°C): c_p = 2350 J/kg·K. *Table A.6*, water ($\bar{T}_c$ = 50°C): c_p = 4181 J/kg·K, $\mu = 548 \times 10^{-6}$ N·s/m^2, k = 0.643 W/m·K, Pr = 3.56.

ANALYSIS: From the overall energy balance, Eq. 11.7b, the heat transfer required of the exchanger is

$$q = \dot{m}_c c_{p,c}(T_{c,o} - T_{c,i}) = 2.5\text{ kg/s} \times 4181\text{ J/kg}\cdot\text{K}(85-15)°\text{C} = 7.317 \times 10^5\text{ W}$$

Hence from Eq. 11.6b,

$$\dot{m}_h = \frac{q}{c_{p,h}(T_{h,i} - T_{h,o})} = \frac{7.317 \times 10^5\text{ W}}{2350\text{ J/kg}\cdot\text{K}(160-100)°\text{C}} = 5.19\text{ kg/s} \quad <$$

The required tube length may be obtained using the ε-NTU method. We first calculate the heat capacity rates, $C_h = \dot{m}_h c_{p,h}$ = 12,195 W/K, $C_c = \dot{m}_c c_{p,c}$ =10,453 W/K. Thus, $C_{min} = C_c$, and $C_r = C_{min}/C_{max}$ = 0.857. Then from Eq. 11.21,

$$\varepsilon = \frac{T_{c,o} - T_{c,i}}{T_{h,i} - T_{c,i}} = \frac{(85-15)°\text{C}}{(160-15)°\text{C}} = 0.483$$

Using Eqs. 11.30b,c for one shell pass and an even number of tube passes, we find

Continued…

PROBLEM 11.22 (Cont.)

$$E = \frac{2/\varepsilon - (1 + C_r)}{(1 + C_r^2)^{1/2}} = \frac{2/0.483 - (1 + 0.857)}{(1 + 0.857^2)^{1/2}} = 1.74$$

$$NTU = -(1 + C_r^2)^{-1/2} \ln\left(\frac{E-1}{E+1}\right) = -(1 + 0.857^2)^{-1/2} \ln\left(\frac{1.74-1}{1.74+1}\right) = 0.997$$

Thus UA = NTU×C_{min} = 10,420 W/K. To find the required tube length, we must know the heat transfer coefficients for the water flow. We calculate the Reynolds number, with $\dot{m}_1 = \dot{m}_c / N$ = 0.25 kg/s defined as the water flow rate per tube, Eq. 8.6 yields

$$Re_D = \frac{4\dot{m}_1}{\pi D \mu_c} = \frac{4 \times 0.25 \text{ kg/s}}{\pi(0.025 \text{ m})548 \times 10^{-6} \text{ N} \cdot \text{s/m}^2} = 23,234$$

Hence the flow is turbulent, and from Eq. 8.60,

$$Nu_D = 0.023 Re_D^{4/5} Pr^{0.4} = 0.023(23,234)^{4/5}(3.56)^{0.4} = 119$$

and

$$h_c = \frac{k_c}{D} Nu_D = \frac{0.643 \text{ W/m} \cdot \text{K}}{0.025 \text{ m}} 119 = 3060 \text{ W/m}^2 \cdot \text{K}$$

Hence U = $[1/h_c + 1/h_h]^{-1}$ = 354 W/m^2·K and we can find the required tube length from

$$L = \frac{UA}{UN\pi D} = \frac{10,420 \text{ W/K}}{354 \text{ W/m}^2 \cdot \text{K} \times 10 \times \pi \times 0.025 \text{ m}} = 37.5 \text{ m}$$ <

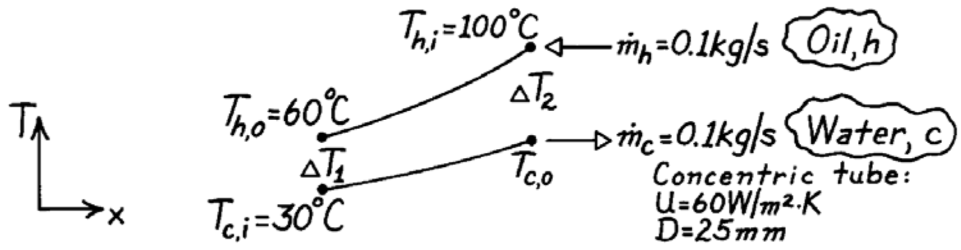
COMMENTS: (1) With L/D = 1516, the assumption of fully developed conditions throughout the tube is justified. (2) With eight passes, the shell length is approximately L/8 = 4.7 m.

PROBLEM 11.23

KNOWN: Counterflow concentric tube heat exchanger.

FIND: (a) Total heat transfer rate and outlet temperature of the water and (b) Required length.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible thermal resistance due to tube wall thickness.

PROPERTIES: (given):

	ρ (kg/m^3)	c_p (J/kg·K)	ν (m^2/s)	k (W/m·K)	Pr
Water	1000	4200	7×10^{-7}	0.64	4.7
Oil	800	1900	1×10^{-5}	0.134	140

ANALYSIS: (a) With the outlet temperature, $T_{c,o}$ = 60°C, from an overall energy balance on the hot (oil) fluid, find

$$q = \dot{m}_h c_h \left(T_{h,i} - T_{h,o}\right) = 0.1\ \text{kg/s} \times 1900\ \text{J/kg}\cdot\text{K}\left(100-60\right)°\text{C} = 7600\ \text{W}. \qquad <$$

From an energy balance on the cold (water) fluid, find

$$T_{c,o} = T_{c,i} + q/\dot{m}_c c_c = 30°\text{C} + 7600\ \text{W}/0.1\ \text{kg/s} \times 4200\ \text{J/kg}\cdot\text{K} = 48.1°\text{C}. \qquad <$$

(b) Using the LMTD method, the length of the CF heat exchanger follows from

$$q = UA\Delta T_{lm,CF} = U\left(\pi DL\right)\Delta T_{lm,CF} \qquad L = q/U\left(\pi D\right)\Delta T_{lm,CF}$$

where

$$\Delta T_{lm,CF} = \frac{\Delta T_1 - \Delta T_2}{\ln\left(\Delta T_1/\Delta T_2\right)} = \frac{\left(60-30\right)°\text{C} - \left(100-48.1\right)°\text{C}}{\ln\left(30/51.9\right)} = 40.0°\text{C}$$

$$L = 7600\ \text{W}/60\ \text{W/m}^2\cdot\text{K}\left(\pi \times 0.025\,\text{m}\right) \times 40.0°\text{C} = 40.3\,\text{m}. \qquad <$$

COMMENTS: Using the ε-NTU method, find $C_{min} = C_h$ = 190 W/K and $C_{max} = C_c$ = 420 W/K. Hence

$$q_{max} = C_{min}\left(T_{h,i} - T_{c,i}\right) = 190\ \text{W/K}\left(100-30\right)\text{K} = 13{,}300\ \text{W}$$

and $\varepsilon = q/q_{max}$ = 0.571. With $C_r = C_{min}/C_{max}$ = 0.452 and using Eq. 11.29b,

$$NTU = \frac{UA}{C_{min}} = \frac{1}{C_r - 1}\ln\left(\frac{\varepsilon - 1}{\varepsilon C_r - 1}\right) = \frac{1}{0.452-1}\ln\left(\frac{0.571-1}{0.571 \times 0.452 - 1}\right) = 1.00$$

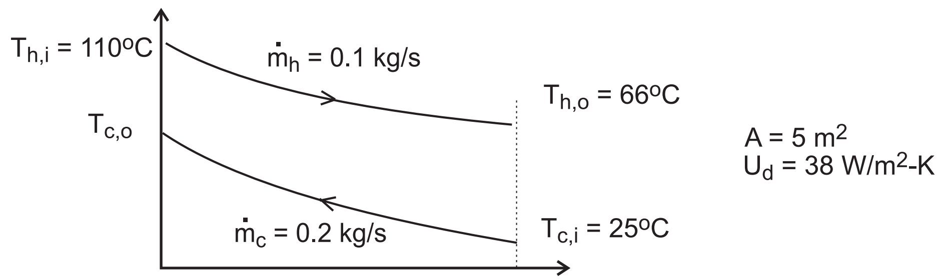
so that with $A = \pi DL$, find L = 40.3 m.

PROBLEM 11.24

KNOWN: Counterflow, concentric tube heat exchanger undergoing test after service for an extended period of time; surface area of 5 m^2 and design value for the overall heat transfer coefficient of $U_d = 38\ W/m^2 \cdot K$.

FIND: Fouling factor, if any, based upon the test results of engine oil flowing at 0.1 kg/s cooled from 110°C to 66°C by water supplied at 25°C and a flow rate of 0.2 kg/s.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible losses to the surroundings, (3) Constant properties.

PROPERTIES: *Table A-5*, Engine oil ($\bar{T}_h$ = 361 K): c = 2166 J/kg·K; *Table A-6*, Water $\left(\bar{T}_c = 304\ \text{K, assuming}\ T_{c,o} = 36^\circ C\right)$: c = 4178 J/kg·K.

ANALYSIS: For the CF conditions shown in the Schematic, find the heat rate, q, from an energy balance on the hot fluid (oil); the cold fluid outlet temperature, $T_{c,o}$, from an energy balance on the cold fluid (water); the overall coefficient U from the rate equation; and a fouling factor, R, by comparison with the design value, U_d.

Energy balance on hot fluid

$$q = \dot{m}_h c_h \left(T_{h,i} - T_{h,o}\right) = 0.1\ kg/s \times 2166\ J/kg \cdot K\ (110 - 66) K = 9530\ W$$

Energy balance on the cold fluid

$$q = \dot{m}_c c_c \left(T_{c,o} - T_{c,i}\right), \qquad \text{find} \quad T_{c,o} = 36.4^\circ C$$

Rate equation

$$q = UA\Delta T_{\ell n,CF}$$

$$\Delta T_{\ell n,CF} = \frac{\left(T_{h,i} - T_{c,o}\right) - \left(T_{h,o} - T_{c,i}\right)}{\ell n\left[\left(T_{h,i} - T_{c,o}\right)/\left(T_{h,o} - T_{c,i}\right)\right]} = \frac{(110 - 36.4)^\circ C - (66 - 25)^\circ C}{\ell n[73.6/41.0]} = 55.7^\circ C$$

$$9530\ W = U \times 5\ m^2 \times 55.7^\circ C$$

$$U = 34.2\ W/m^2 \cdot K$$

Overall resistance including fouling factor

$$U = 1/\left[1/U_d + R''_f\right]$$

$$34.2\ W/m^2 \cdot K = 1/\left[1/38\ W/m^2 \cdot K + R''_f\right]$$

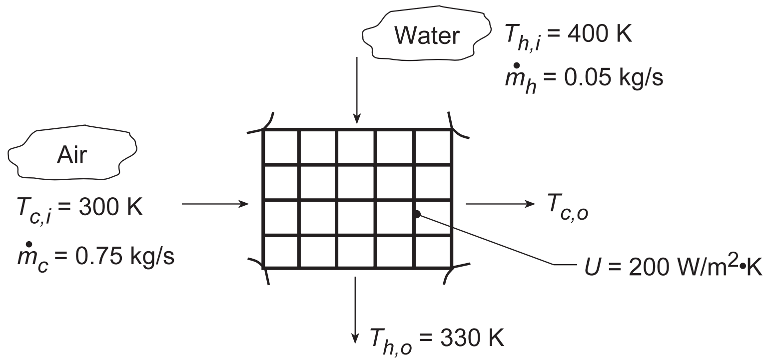
$$R''_f = 0.0029\ m^2 \cdot K/W$$ <

PROBLEM 11.25

KNOWN: Flow rates and inlet temperatures for automobile radiator configured as a cross-flow heat exchanger with both fluids unmixed. Overall heat transfer coefficient.

FIND: (a) Area required to achieve hot fluid (water) outlet temperature, $T_{m,o}$ = 330 K, and (b) Outlet temperatures, $T_{h,o}$ and $T_{c,o}$, as a function of the overall coefficient for the range, $200 \le U \le 400$ W/m^2·K with the surface area A found in part (a) with all other heat transfer conditions remaining the same as for part (a).

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties.

PROPERTIES: *Table A.6*, Water ($\overline{T}_h$ = 365 K): $c_{p,h}$ = 4209 J/kg·K; *Table A.4*, Air $\left(\overline{T}_c \approx 310\,K\right)$: $c_{p,c}$ = 1007 J/kg·K.

ANALYSIS: (a) The required heat transfer rate is

$$q = \dot{m}_h c_{p,h}\left(T_{h,i} - T_{h,o}\right) = 0.05\,kg/s\left(4209\,J/kg\cdot K\right)70\,K = 14,732\,W\,.$$

Using the ε -NTU method,

$$C_{min} = C_h = 210.45\,W/K \qquad C_{max} = C_c = 755.25\,W/K\,.$$

Hence, C_{min}/C_{max} = 0.279 and

$$q_{max} = C_{min}\left(T_{h,i} - T_{c,i}\right) = 210.45\ W/K\,(100\ K) = 21,045\,W$$

$$\varepsilon = q/q_{max} = 14,732\,W/21,045\,W = 0.700\,.$$

Figure 11.14 yields NTU ≈ 1.5, hence,

$$A = NTU\left(C_{min}/U\right) = 1.5 \times 210.45\,W/K\Big/\left(200\,W/m^2\cdot K\right) = 1.58\,m^2\,. \quad <$$

(b) Using the *IHT Heat Exchanger Tool* for *Cross-flow with both fluids unmixed* arrangement and the *Properties Tool* for *Air* and *Water*, a model was generated to solve part (a) evaluating the efficiency using Eq. 11.32. The following results were obtained:

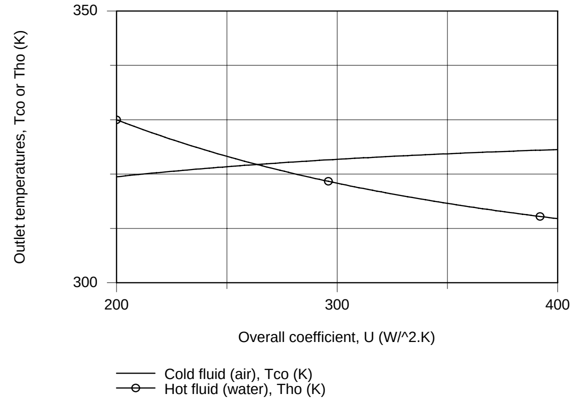
$$A = 1.516\,m^2 \qquad NTU = 1.441 \qquad T_{c,o} = 319.5\,K$$

Using the model but assigning A = 1.516 m^2, the outlet temperature $T_{h,o}$ and $T_{c,o}$ were calculated as a function of U and the results plotted below.

Continued...

PROBLEM 11.25 (Cont.)

With a higher U, the outlet temperature of the hot fluid (water) decreases. A benefit is enhanced heat removal from the engine block and a cooler operating temperature. If it is desired to cool the engine with water at 330 K, the heat exchanger surface area and, hence its volume in the engine component could be reduced.



COMMENTS: (1) For the results of part (a), the air outlet temperature is

$$T_{c,o} = T_{c,i} + q/C_c = 300\,K + (14,732\,W/755.25\,W/K) = 319.5\,K\,.$$

(2) The IHT workspace with the model to generate the above plot is shown below. Note that it is necessary to enter the overall energy balances on the fluids from the keyboard.

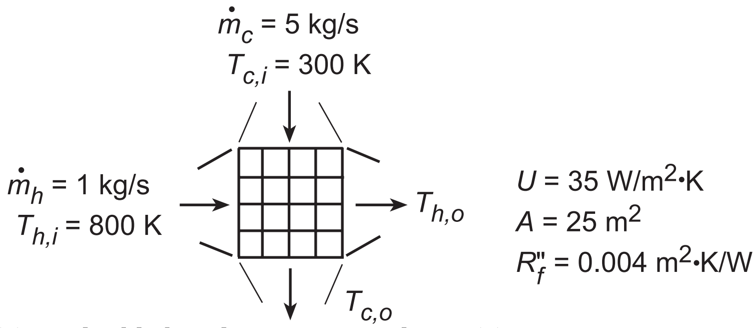
```
// Heat Exchanger Tool - Cross-flow with both fluids unmixed:
// For the cross-flow, single-pass heat exchanger with both fluids unmixed,
eps = 1 - exp((1 / Cr) * (NTU^0.22) * (exp(-Cr * NTU^0.78) - 1))      // Eq 11.32
// where the heat-capacity ratio is
Cr = Cmin / Cmax
// and the number of transfer units, NTU, is
NTU = U * A / Cmin                        // Eq 11.24
// The effectiveness is defined as
eps = q / qmax
qmax = Cmin * (Thi - Tci)                 // Eq 11.18, 11.19
// See Tables 11.3 and 11.4 and Fig 11.14
// Overall Energy Balances on Fluids:
q = mdoth * cph * (Thi - Tho)
q = mdotc * cpc * (Tco - Tci)
// Assigned Variables:
Cmin = Ch                  // Capacity rate, minimum fluid, W/K
Ch = mdoth * cph           // Capacity rate, hot fluid, W/K
mdoth = 0.05               // Flow rate, hot fluid, kg/s
Thi = 400                  // Inlet temperature, hot fluid, K
Tho = 330                  // Outlet temperature, hot fluid, K; specified for part (a)
Cmax = Cc                  // Capacity rate, maximum fluid, W/K
Cc = mdotc * cpc           // Capacity rate, cold fluid, W/K
mdotc = 0.75               // Flow rate, cold fluid, kg/s
Tci = 300                  // Inlet temperature, cold fluid, K
U = 200                    // Overall coefficient, W/m^2.K
// Properties Tool - Water (h)
// Water property functions :T dependence, From Table A.6
// Units: T(K), p(bars);
xh =  0                                   // Quality (0=sat liquid or 1=sat vapor)
rhoh = rho_Tx("Water",Tmh,xh)             // Density, kg/m^3
cph = cp_Tx("Water",Tmh,xh)               // Specific heat, J/kg·K
Tmh =  Tfluid_avg(Thi,Tho )
// Properties Tool - Air(c)
// Air property functions : From Table A.4
// Units: T(K); 1 atm pressure
rhoc = rho_T("Air",Tmc)                   // Density, kg/m^3
cpc = cp_T("Air",Tmc)                     // Specific heat, J/kg·K
Tmc = Tfluid_avg(Tci,Tco)
```

PROBLEM 11.26

KNOWN: Flowrates and inlet temperatures of a cross-flow heat exchanger with both fluids unmixed. Total surface area and overall heat transfer coefficient for clean surfaces. Fouling resistance associated with extended operation.

FIND: (a) Fluid outlet temperatures, (b) Effect of fouling, (c) Effect of UA on air outlet temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Negligible tube wall resistance.

PROPERTIES: Air and gas (given): c_p = 1040 J/kg·K.

ANALYSIS: (a) With $C_{min} = C_h$ = 1 kg/s × 1040 J/kg·K = 1040 W/K and $C_{max} = C_c$ = 5 kg/s × 1040 J/kg·K = 5200 W/K, C_{min}/C_{max} = 0.2. Hence, NTU = UA/C_{min} = 35 W/m^2·K(25 m^2)/1040 W/K = 0.841 and Fig. 11.14 yields ε ≈ 0.57. With $C_{min}(T_{h,i} - T_{c,i})$ = 1040 W/K(500 K) = 520,000 W = q_{max}, Eqs. (11.20) and (11.21) yield

$$T_{h,o} = T_{h,i} - \varepsilon q_{max}/C_h = 800\,K - 0.57(520{,}000\,W)/1040\,W/K = 515\,K$$ <

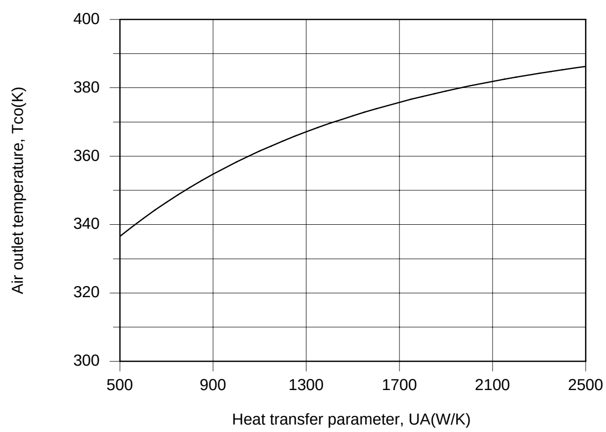
$$T_{c,o} = T_{c,i} + \varepsilon q_{max}/C_c = 300\,K + 0.57(520{,}000\,W)/5200\,W/K = 357\,K$$ <

(b) With fouling, the overall heat transfer coefficient is reduced to

$$U_f = \left(U^{-1} + R''_f\right)^{-1} = \left[(0.029 + 0.004)\,m^2 \cdot K/W\right]^{-1} = 30.7\,W/m^2 \cdot K$$

This 12% reduction in performance is large enough to justify cleaning of the tubes. <

(c) Using the *Heat Exchangers* option from the IHT Toolpad to explore the effect of UA, we obtain the following result.



The heat rate, and hence the air outlet temperature, increases with increasing UA, with $T_{c,o}$ approaching a maximum outlet temperature of 400 K as UA → ∞ and ε → 1.

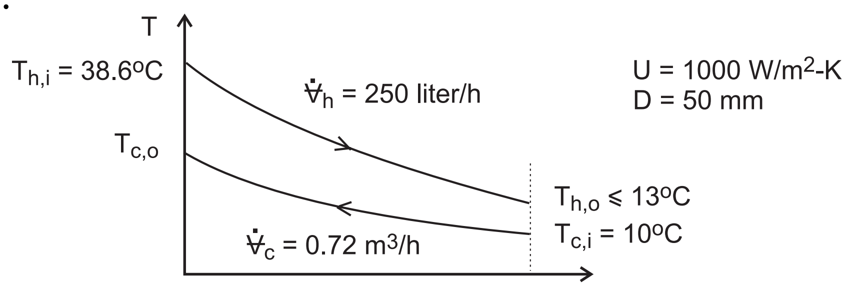
COMMENTS: Note that, for conditions of part (a), Eq. 11.32 yields a value of ε = 0.538, which reveals the level of approximation associated with reading ε from Fig. 11.14.

PROBLEM 11.27

KNOWN: Cooling milk from a dairy operation to a safe-to-store temperature, $T_{h,o} \leq 13°C$, using ground water in a counterflow concentric tube heat exchanger with a 50-mm diameter inner pipe and overall heat transfer coefficient of 1000 $W/m^2 \cdot K$.

FIND: (a) The UA product required for the chilling process and the length L of the exchanger, (b) The outlet temperature of the ground water, and (c) the milk outlet temperatures for the cases when the water flow rate is halved and doubled, using the UA product found in part (a)

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat loss to surroundings, and (3) Constant properties.

PROPERTIES: *Table A-6*, Water $\left(\overline{T}_c = 287\text{ K},\ \text{assume } T_{c,o} = 18°C\right)$: $\rho = 1000\text{ kg/m}^3$, $c_p = 4187\text{ J/kg}\cdot\text{K}$; Milk (given): $\rho = 1030\text{ kg/m}^3$, $c_p = 3860\text{ J/kg}\cdot\text{K}$.

ANALYSIS: (a) Using the effectiveness-NTU method, determine the capacity rates and the minimum fluid.

Hot fluid, milk:

$$\dot{m}_h = \rho_h \dot{\forall}_h = 1030\text{ kg/m}^3 \times 250\text{ liter/h} \times 10^{-3}\text{m}^3/\text{liter} \times 1\text{ h}/3600\text{ s} = 0.0715\text{ kg/s}$$

$$C_h = \dot{m}_h c_h = 0.0715\text{ kg/s} \times 3860\text{ J/kg}\cdot\text{K} = 276\text{ W/K}$$

Cold fluid, water:

$$C_c = \dot{m}_c c_c = 1000\text{ kg/m}^3 \times \left(0.72/3600\text{ m}^3/\text{s}\right) \times 4187\text{ J/kg}\cdot\text{K} = 837\text{ W/K}$$

It follows that $C_{min} = C_h$. The effectiveness of the exchanger from Eq. 11.20 is

$$\varepsilon = \frac{q}{q_{max}} = \frac{C_h\left(T_{h,i} - T_{h,o}\right)}{C_{min}\left(T_{h,i} - T_{c,i}\right)} = \frac{(38.6 - 13)\text{K}}{(38.6 - 10)\text{K}} = 0.895 \qquad (1)$$

The NTU can be calculated from Eq. 11.29b, where $C_r = C_{min}/C_{max} = 0.330$,

$$\text{NTU} = \frac{1}{C_r - 1}\ell n\left(\frac{\varepsilon - 1}{\varepsilon C_r - 1}\right) \qquad (2)$$

$$\text{NTU} = \frac{1}{0.330 - 1}\ell n\left(\frac{0.895 - 1}{0.895 \times 0.330 - 1}\right) = 2.842$$

Continued …

PROBLEM 11.27 (Cont.)

From Eq. 11.24, find UA

$$[UA] = NTU \cdot C_{min} = 2.842 \times 276\ W/K = 785\ W/K$$ <

and the exchanger tube length with A = π DL is

$$L = [UA]/\pi DU = 785\ W/K/\pi 0.050\ m \times 1000\ W/m^2 \cdot K = 5.0\ m$$ <

(b) The water outlet temperature, $T_{c,o}$, can be calculated from the heat rates,

$$C_h\left(T_{h,i} - T_{h,o}\right) = C_c\left(T_{c,o} - T_{c,i}\right) \quad (3)$$

$$276\ W/K\ (38.6 - 13)K = 837\ W/K\left(T_{c,o} - 10\right)K$$

$$T_{c,o} = 18.4^\circ C$$ <

(c) Using the foregoing Eqs. (1 - 3) in the *IHT* workspace, the hot fluid (milk) outlet temperatures are evaluated with UA = 785 W/K for different water flow rates. The results, including the hot fluid outlet temperatures, are compared to the base case, part (a).

Case	*C_c (W/K)*	*$T_{c,o}$ (°C)*	*$T_{h,o}$ (°C)*
1, halved flow rate	419	14.9	25.6
Base, part (a)	837	13	18.4
2, doubled flow rate	1675	12.3	14.3

COMMENTS: (1) From the results table in part (c), note that if the water flow rate is halved, the milk will not be properly chilled, since $T_{c,o}$ = 14.9°C > 13°C. Doubling the water flow rate reduces the outlet milk temperature by less than 1°C.

(2) From the results table, note that the water outlet temperature changes are substantially larger than those of the milk with changes in the water flow rate. Why is this so? What operational advantage is achieved using the heat exchanger under the present conditions?

(3) The water thermophysical properties were evaluated at the average cold fluid temperature, $\overline{T}_c = \left(T_{c,i} + T_{c,o}\right)/2$. We assumed an outlet temperature of 18°C, which as the results show, was a good choice. Because the water properties are not highly temperature dependent, it was acceptable to use the same values for the calculations of part (c). You could, of course, use the properties function in *IHT* that will automatically use the appropriate values.

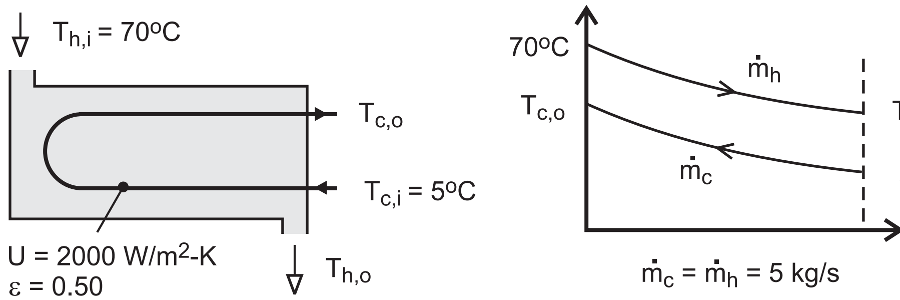
(4) The value of the overall heat transfer coefficient, U, will change as the mass flow rate is varied. The answer to part (c) would be different if this variation is accounted for.

PROBLEM 11.28

KNOWN: Flow rate, inlet temperatures and overall heat transfer coefficient for a regenerator. Desired regenerator effectiveness. Cost of natural gas.

FIND: (a) Heat transfer area required for regenerator and corresponding heat recovery rate and outlet temperatures, (b) Annual energy and fuel cost savings.

SCHEMATIC:



ASSUMPTIONS: (a) Negligible heat loss to surroundings, (b) Constant properties.

PROPERTIES: Problem 11.27, milk: c_p = 3860 J/kg·K.

ANALYSIS: (a) With C_r = 1 and ε = 0.50 for one shell and two tube passes, Eq. 11.30c yields E = 1.414. With C_{min} = 5 kg/s × 3860 J/kg·K = 19,300 W/K, Eq. 11.30b then yields

$$A = -\frac{C_{min}}{U}\frac{\ln\left[(E-1)/(E+1)\right]}{\left(1+C_r^2\right)^{1/2}} = -\frac{19,300\,W/K}{2000\,W/m^2\cdot K}\frac{\ln(0.171)}{1.414} = 12.03\,m^2 \quad <$$

With ε = 0.50, the heat recovery rate is then

$$q = \varepsilon C_{min}\left(T_{h,i} - T_{c,i}\right) = 627,000\,W \quad <$$

and the outlet temperatures are

$$T_{c,o} = T_{c,i} + \frac{q}{C_c} = 5°C + \frac{627,000\,W}{19,300\,W/K} = 37.5°C \quad <$$

$$T_{h,o} = T_{h,i} - \frac{q}{C_h} = 70°C - \frac{627,000\,W}{19,300\,W/K} = 37.5°C \quad <$$

(b) The amount of energy recovered for continuous operation over 365 days is

$$\Delta E = 627,000\,W \times 365\,d/yr \times 24\,h/d \times 3600\,s/h = 1.98 \times 10^{13}\,J/yr$$

The annual fuel savings S_A is then

$$S_A = \frac{\Delta E \times C_{ng}}{\eta} = \frac{1.98 \times 10^7\,MJ/yr \times \$0.02/MJ}{0.9} = \$440,000/yr \quad <$$

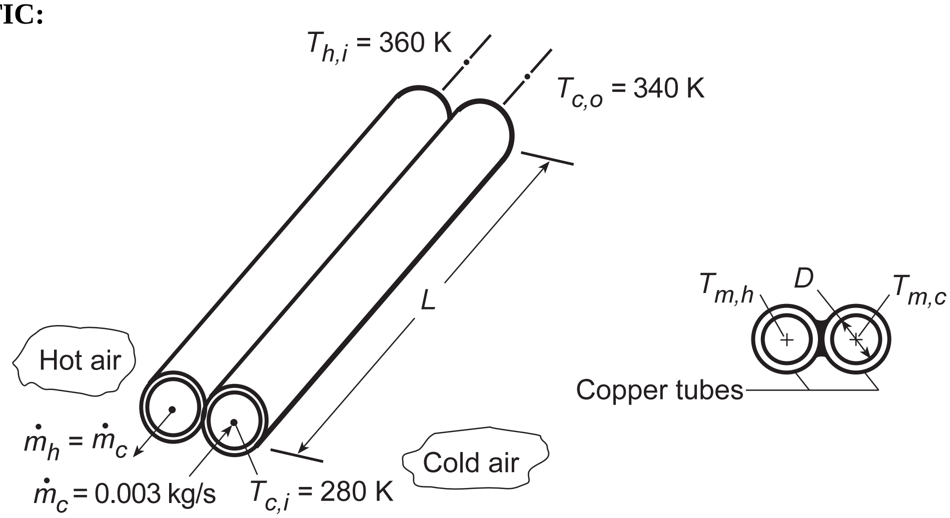
COMMENTS: (1) With $C_c = C_h$, the temperature changes are the same for the two fluids, (2) A larger effectiveness and hence a smaller value of A can be achieved with a counterflow exchanger (compare Figs. 11.11 and 11.12 for C_r = 1), (c) The savings are significant and well worth the cost of the heat exchanger. An additional benefit is that, with $T_{h,o}$ reduced from 70 to 37.5°C, less energy is consumed by the refrigeration system used to restore the milk temperature to 5°C.

PROBLEM 11.29

KNOWN: Twin-tube counterflow heat exchanger with balanced flow rates, $\dot{m}$ = 0.003 kg/s. Cold airstream enters at 280 K and must be heated to 340 K. Maximum allowable pressure drop of cold airstream is 10 kPa.

FIND: (a) Tube diameter D and length L which satisfies the heat transfer and pressure drop requirements, and (b) Compute and plot the cold stream outlet temperature $T_{c,o}$, the heat rate q, and pressure drop Δp as a function of the balanced flow rate from 0.002 to 0.004 kg/s.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat loss to surroundings, (3) Average pressure of the airstreams is 1 atm, (4) Tube walls act as fins with 100% efficiency, (4) Fully developed flow.

PROPERTIES: *Table A.4*, Air ($\bar{T}_m$ = 310 K, 1 atm) : ρ = 1.128 kg/m^3, c_p = 1007 J/kg·K, μ = 18.93 × 10^{-6} m^2 / s, k = 0.0270 W/m·K, Pr = 0.7056.

ANALYSIS: (a) The heat exchanger diameter D and length L can be specified through two analyses: (1) heat transfer based upon the effectiveness-NTU method to meet the cold air heating requirement and (2) pressure drop calculation to meet the requirement of 10 kPa. The *heat transfer analysis* begins by determining the effectiveness from Eq. 11.21, since $C_{min} = C_{max}$ and $C_r = 1$,

$$\varepsilon = \frac{q}{q_{max}} = \frac{C\left(T_{c,o} - T_{c,i}\right)}{C\left(T_{h,i} - T_{c,i}\right)} = \frac{(340-280)\,K}{(360-280)\,K} = 0.750 \qquad (1)$$

From Table 11.4, Eq. 11.29b for C_r = 1,

$$NTU = \frac{\varepsilon}{1-\varepsilon} = \frac{0.750}{1-0.750} = 3 \qquad (2)$$

where NTU, following its definition, Eq. 11.24, is

$$NTU = \frac{\bar{U}A}{C_{min}} \qquad (3)$$

with

$$C_{min} = \dot{m}c_p = 0.003\,kg/s \times 1007\,J/kg\cdot K = 3.021\,K/W \qquad (4)$$

Continued...

PROBLEM 11.29 (Cont.)

and $1/\overline{U}A$ represents the thermal resistance between the two fluids at $T_{m,h}$ and $T_{m,c}$ as illustrated in the above-right schematic. Since the tube walls are isothermal, it follows that

$$1/UA = 1/\overline{h}_c A + 1/\overline{h}_h A \quad (5)$$

and since the flow conditions are nearly identical $\overline{h}_c = \overline{h}_h$ so that

$$U = 0.5\overline{h} \quad (6)$$

where the heat transfer area is

$$A = \pi DL \quad (7)$$

This is a consequence of the assumption that the walls act as fins with 100% efficiency. Hence, Eq. (3) can now be expressed as

$$3 = \frac{0.5\overline{h}(\pi DL)}{3.021\,K/W}$$

$$\overline{h}DL = 5.7697 \quad (8)$$

Assuming an average mean temperature $\overline{T}_{m,c} = 310\,K$, characterize the flow with

$$Re_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4 \times 0.003\,kg/s}{\pi \times D \times 18.93 \times 10^{-6}\,m^2/s} = \frac{201.78}{D} \quad (9)$$

and assuming the flow is both turbulent and fully developed using the Dittus-Boelter, Eq. 8.60,

$$\overline{Nu}_D = \frac{\overline{h}D}{k} = 0.023\,Re_D^{0.8}\,Pr^{0.4}$$

$$\overline{h}D = 0.023 \times 0.0270\,W/m \cdot K\,(201.78/D)^{0.8}\,(0.7056)^{0.4}$$

$$\overline{h}D^{1.8} = 0.0377 \quad (10)$$

Note that the heating condition has been selected (n = 0.4) for both streams, as an estimate.
The *pressure drop* for fully developed flow, Eq. 8.22a, is

$$\Delta p = f\,\frac{\rho u_m^2}{2D}\,L \quad (11)$$

where the mean velocity is $u_m = \dot{m}/(\rho\pi D^2/4)$ so that

$$\Delta p = f\,\frac{\rho\left(4\dot{m}/\rho\pi D^2\right)^2 L}{2D} = \frac{8}{\pi^2}\,f\,\frac{\dot{m}^2 L}{\rho D^5}$$

$$\Delta p = \frac{8}{\pi^2}\,f\,\frac{(0.003\,kg/s)^2\,L}{(1.128\,kg/m^3)D^5} = 6.467 \times 10^{-6}\,f\,L\,D^{-5} \quad (12)$$

Recall that the pressure drop requirement is $\Delta p = 10$ kPa $= 10^4$ N/m^2, so that Eq. (12) can be rewritten as

$$fLD^{-5} = 1.546 \times 10^9 \quad (13)$$

Continued...

PROBLEM 11.29 (Cont.)

For the Reynolds number range, $3000 \le Re_D \le 5 \times 10^6$, Eq. 8.21 provides an estimate for the friction factor,

$$f = \left[\left(0.790\ell n\left(Re_D\right) - 1.64\right)\right]^{-2}$$

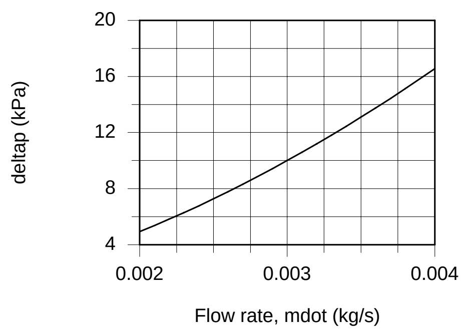
$$f = \left[\left(0.790\ell n\left(201.78/D\right) - 1.64\right)\right]^{-2} \qquad (14)$$

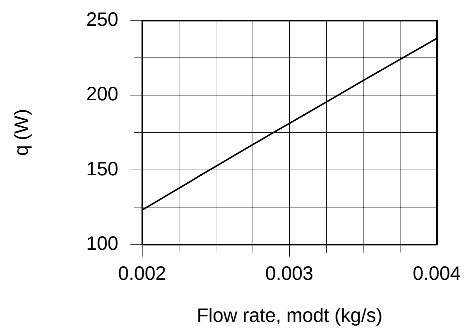
In the foregoing analysis, there are 4 unknowns (D, L, f, $\bar{h}$) and 4 equations (8, 10, 13, 14). Using the IHT workspace, find

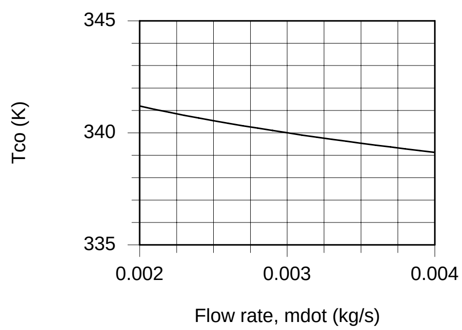
$$D = 9.0\,\text{mm} \quad L = 3.5\,\text{m} \quad f = 0.0254 \quad \bar{h} = 183\,\text{W/m}^2 \cdot \text{K}$$

For this configuration, Re_D = 22,500 so the flow is turbulent and since L/D = 3.5/0.0090 = 390 >> 10, the fully developed assumption is reasonable.

(b) The foregoing analysis entered into the IHT workspace was used to determine $T_{c,o}$, q and Δp as a function of the balanced flow rate, $\dot{m}$.







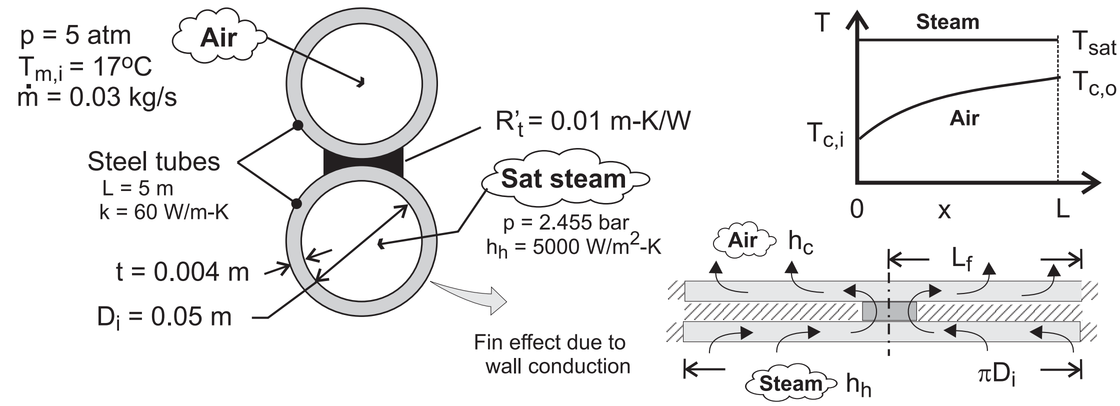
The outlet temperature of the cold air, $T_{c,o}$, is nearly insensitive to the flow rate. It follows that the heat rate, q, must be nearly proportional to the flow rate as can be seen in the q vs. $\dot{m}$ plot above. The pressure drop varies with the mean velocity squared.

PROBLEM 11.30

KNOWN: Dimensions and thermal conductivity of twin-tube, counterflow heat exchanger. Contact resistance between tubes. Air inlet conditions for one tube and pressure of saturated steam in other tube.

FIND: Air outlet temperature and condensation rate.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat exchange with surroundings, (2) Fully developed air flow, (3) Negligible fouling, (4) Constant properties.

PROPERTIES: *Table A-4*, air $\left(\overline{T}_c \approx 325\,\text{K},\ p = 5\,\text{atm}\right)$: c_p = 1008 J/kg·K, $\mu = 196.4 \times 10^{-7}$ N·s/m², k = 0.0281 W/m·K, Pr = 0.703. *Table A-6*, sat. steam (p = 2.455 bar): $T_{h,i} = T_{h,o}$ = 400 K, h_{fg} = 2183 kJ/kg.

ANALYSIS: With $C_{max} \to \infty$, C_r = 0 and Eqs. 11.21 and 11.35a yield

$$\varepsilon = \frac{T_{c,o} - T_{c,i}}{T_{h,i} - T_{c,i}} = 1 - \exp(-NTU) \qquad (1)$$

From Eq. 11.1,

$$\frac{1}{UA} = \frac{1}{(\eta_o hA)_c} + \frac{R'_t}{L} + \frac{1}{(\eta_o hA)_h} \qquad (2)$$

With $Re_D = 4\dot{m}/\pi D_i \mu = 0.12\ \text{kg/s}/\pi(0.05\text{m})196.4\times10^{-7}\ \text{N}\cdot\text{s/m}^2 = 38{,}900,$ the air flow is turbulent and the Dittus-Boelter correlation yields

$$h_c \approx h_{fD} = \left(\frac{k}{D_i}\right)0.023\ Re_D^{4/5}\ Pr^{0.4} = \left(\frac{0.0281\ \text{W/m}\cdot\text{K}}{0.05\text{m}}\right)0.023(38{,}900)^{4/5}(0.703)^{0.4} = 52.7\ \text{W/m}^2\cdot\text{K}$$

As shown on the inset, each tube wall may be modelled as two fins, each of length $L_f \approx \pi D_i/2$ = 0.0785m. The total surface area for heat transfer is $A_t = \pi D_i L$ = 0.785 m² = A_c, which is equivalent to the surface area of the fins. With $NA_f = A_t$ from Eq. 3.102, $\eta_o = \eta_f$. Because the outer surface of the tube is insulated, a wall thickness of 2t must be used in evaluating η_f. With m = $(2h/k \times 2t)^{1/2}$ = $(h/kt)^{1/2}$ = [52.7 W/m²·K/(60 W/m·K × 0.004m)]$^{1/2}$ = 14.8 m^{-1}, $L_c = L_f$ for an adiabatic tip, and mL_f = 1.163, Eq. 3.92 yields

$$\eta_f = \frac{\tanh\ mL_f}{mL_f} = \frac{0.821}{1.163} = 0.706 = \eta_{o,c}$$

Continued …

PROBLEM 11.30 (Cont.)

Similarly, for the steam tube, $m = (h/kt)^{1/2} = [5{,}000\ W/m^2 \cdot K/(60\ W/m \cdot K \times 0.004m)]^{1/2} = 144.3\ m^{-1}$ and $mL_f = 11.33$. Hence,

$$\eta_f = \frac{\tanh\ mL_f}{mL_f} = \frac{1.00}{11.33} = 0.088 = \eta_{o,h}$$

Substituting into Eq. (2),

$$UA = \left[\frac{1}{0.706 \times 52.7 \times 0.785} + \frac{0.01}{5} + \frac{1}{0.088 \times 5000 \times 0.785}\right]^{-1} \frac{W}{K} = 25.6 \frac{W}{K}$$

Hence, with $C_{min} = \left(\dot{m}\, c_p\right)_c = 0.03\ kg/s \times 1008\ J/kg \cdot K = 30.2\ W/K$, NTU = $UA/C_{min} = 0.847$ and $\varepsilon = 1 - \exp(-NTU) = 0.571$. From Eq. (1), the air outlet temperature is then

$$T_{c,o} = T_{c,i} + \varepsilon\left(T_{h,i} - T_{c,i}\right) = 17°C + 0.571(127 - 17)°C = 79.8°C$$ <

The rate of heat transfer to the air is

$$q = \dot{m}\, c_p\left(T_{c,o} - T_{c,i}\right) = 0.03\,kg/s \times 1008\,J/kg \cdot K \times 62.8°C = 1900\,W$$

and the rate of condensation is

$$\dot{m}_{cond} = \frac{q}{h_{fg}} = \frac{1900\,W}{2.183 \times 10^6\ J/kg} = 8.70 \times 10^{-4}\ kg/s$$ <

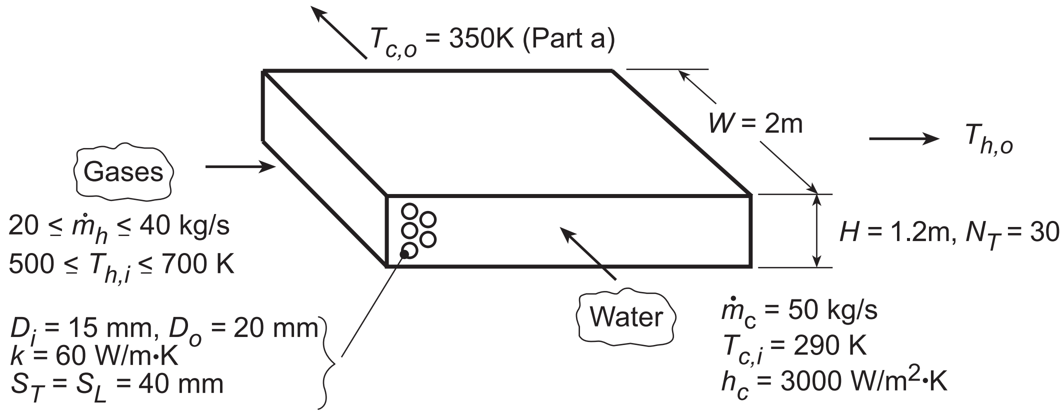
COMMENTS: (1) With $\overline{T}_c = 321.4\,K$, the initial estimate of 325K is reasonable and iteration on the property values is not necessary, (2) The major contribution to the total thermal resistance is due to air-side convection, (3) The foregoing results are independent of air pressure.

PROBLEM 11.31

KNOWN: Tube inner and outer diameters and longitudinal and transverse pitches for a cross-flow heat exchanger. Number of tubes in transverse plane. Water and gas flow rates and inlet temperatures. Water outlet temperature.

FIND: (a) Gas outlet temperature and number of longitudinal tube rows, (b) Effect of gas flowrate and inlet temperature on fluid outlet temperatures.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Negligible fouling.

PROPERTIES: *Table A.6*, Water ($\overline{T}_c$ = 320 K): c_p = 4180 J/kg·K, $\mu = 577 \times 10^{-6}$ N·s/m², k_f = 0.640 W/m·K, Pr = 3.77; *Table A.4*, Air ($\overline{T}_h \approx 550$ K): c_p = 1040 J/kg·K, $\mu = 288.4 \times 10^{-7}$ N·s/m², k = 0.0439 W/m·K, Pr = 0.683, ρ = 0.633 kg/m³.

ANALYSIS: (a) The required heat transfer rate is

$$q = \dot{m}_c c_{p,c}\left(T_{c,o} - T_{c,i}\right) = 50\,\text{kg/s}\left(4180\,\text{J/kg}\cdot\text{K}\right)60\,\text{K} = 1.254\times10^{7}\,\text{W}.$$

Hence, with $T_{h,o} = T_{h,i} - q/\dot{m}_h c_{p,h}$,

$$T_{h,o} = 700\,\text{K} - 1.254\times10^{7}\,\text{W}/\left(40\,\text{kg/s}\times1040\,\text{J/kg}\cdot\text{K}\right) = 398.6\,\text{K}$$ <

Use the ε - NTU method to compute the hot side HX surface area, A_H. To calculate U_h, we must find h_h. For the tube bank, S_D = 44.7 mm > $(S_T + D)/2$ = 30 mm. Hence, with $\rho V_{max} = \left[S_T/\left(S_T - D_o\right)\right]\rho V$ = $\left[S_T/\left(S_T - D_o\right)\right]\left(\dot{m}_h/WH\right)$,

$$\rho V_{max} = (40/20)\left[40\,\text{kg/s}/\left(2\times1.2\right)\text{m}^2\right] = 33.3\,\text{kg/s}\cdot\text{m}^2$$

$$Re_{D,max} = \left(\rho V_{max} D_o\right)/\mu = \left[33.3\,\text{kg/s}\cdot\text{m}^2\left(0.02\,\text{m}\right)\right]/288.4\times10^{-7}\,\text{N}\cdot\text{s/m}^2 = 23{,}116.$$

From the Zukauskas correlation, with $(Pr/Pr_s) \approx 1$, and Table 7.5,

$$\overline{Nu}_D = 0.35\,Re_D^{0.6}\,Pr^{0.36} = 0.35\left(23{,}116\right)^{0.6}\left(0.683\right)^{0.36} = 127$$

where it is assumed that $N_L > 20$. Hence,

$$h_h = \overline{Nu}_D\left(k/D_o\right) = 127\left(0.0439\,\text{W/m}\cdot\text{K}/0.02\,\text{m}\right) = 279\,\text{W/m}^2\cdot\text{K}.$$

From Eq. 11.1,

Continued...

PROBLEM 11.31 (Cont.)

$$\frac{1}{U_h} = \frac{1}{h_c}\frac{D_o}{D_i} + \frac{D_o \ln(D_o/D_i)}{2k} + \frac{1}{h_h} = \frac{1}{3000\,W/m^2\cdot K}\frac{20}{15} + \frac{0.02\,m\ln(20/15)}{60\,W/m\cdot K} + \frac{1}{279\,W/m^2\cdot K}$$

$$\frac{1}{U_h} = \left(4.44\times10^{-4} + 9.59\times10^{-5} + 3.58\times10^{-3}\right)m^2\cdot K/W = 4.12\times10^{-3}m^2\cdot K/W$$

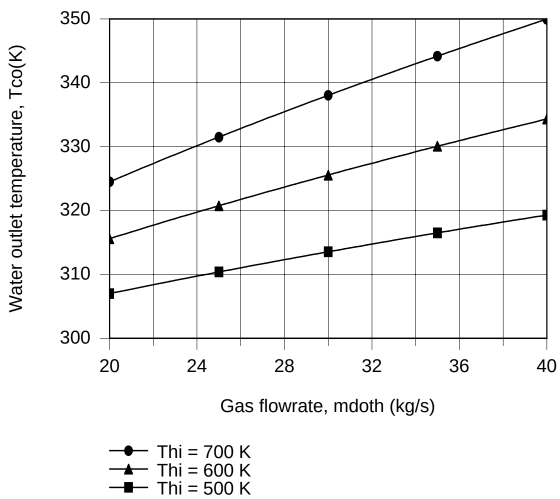
$$U_h = 243\,W/m^2\cdot K.$$

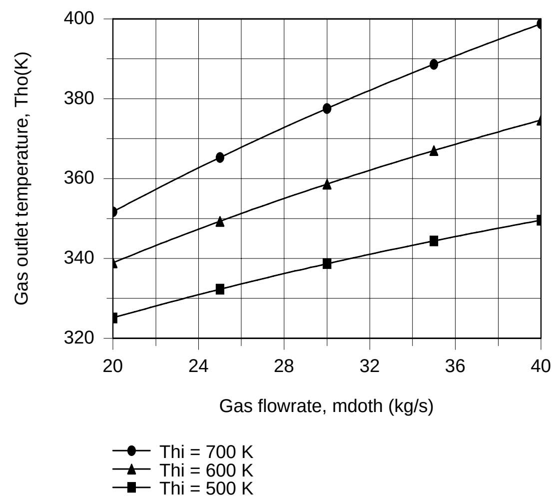
With $C_h = C_{min} = 4.160 \times 10^4$ W/K and $C_c = C_{max} = 2.09 \times 10^5$ W/K, $C_{min}/C_{max} = 0.199$ and $q_{max} = C_{min}(T_{h,i} - T_{c,i}) = 4.16 \times 10^4$ W/K(410 K) $= 1.71 \times 10^7$ W. Hence, $\varepsilon = (q/q_{max}) = (1.254 \times 10^7\ W/1.71 \times 10^7\ W) = 0.735$. With C_{min} mixed and C_{max} unmixed, Eq. 11.34b gives NTU = 1.54 and

$$A_h = NTU(C_{min}/U_h) = 1.54\left(4.160\times10^4\ W/K / 243\,W/m^2\cdot K\right) = 264\,m^2.$$

Hence, $N_L = \dfrac{A_h}{(\pi D_o W)N_T} = \dfrac{264\,m^2}{\pi(0.02)2(30)m^2} = 70$ <

(b) Using the IHT *Correlations*, *Heat Exchangers* and *Properties* Toolpads to perform the parametric calculations, we obtain the following results for $N_L = 90$.





Since h_h, and hence U_h, increases with $\dot{m}_h$, q, and hence, $T_{c,o}$, increases with increasing $\dot{m}_h$, as well as with increasing $T_{h,i}$. Although q increases with $\dot{m}_h$, the proportionality is not linear ($q \propto \dot{m}_h^a$, where a < 1) and $(T_{h,i} - T_{h,o})$ must decrease with increasing $\dot{m}_h$, in which case $T_{h,o}$ must increase. From the above results, it is clear that operation is restricted to $\dot{m}_h \geq 40$ kg/s and $T_{h,i} \geq 700$ K, if corrosion of the heat exchanger surfaces is to be avoided.

COMMENTS: To check the presumed value of $h_c = 3000\ W/m^2\cdot K$, compute

$$Re_D = \frac{4(\dot{m}_c/N)}{\pi D_i \mu} = \frac{4(50\,kg/s)/70\times30}{\pi(0.015\,m)577\times10^{-6}\,N\cdot s/m^2} = 3500.$$

Hence, $Nu_D = 0.023 Re_D^{4/5} Pr^{0.4} = 0.023(3500)^{4/5}(3.77)^{0.4} = 26.8$

$$h_c = (k/D)Nu_D = (0.640\,W/m\cdot K/0.015\,m)26.8 = 1142\,W/m^2\cdot K.$$

Hence, the cold side convection coefficient has been overestimated and the calculations should be repeated using a value of h_c calculated from the Gnielinski correlation, which applies in this Reynolds number range.

PROBLEM 11.32

KNOWN: Single pass, cross-flow heat exchanger with hot exhaust gases (mixed) to heat water (unmixed)

FIND: Required surface area.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Exhaust gas properties assumed to be those of air.

PROPERTIES: *Table A-6*, Water ($\overline{T}_c$ = (80 + 30)°C/2 = 328 K): c_p = 4184 J/kg·K; *Table A-4*, Air (1 atm, $\overline{T}_h$ = (100 + 225)°C/2 = 436 K): c_p = 1019 J/kg·K.

ANALYSIS: Using the ε-NTU method,

$$C_c = \dot{m}_c c_c = 3\text{kg/s} \times 4184\ \text{J/kg}\cdot\text{K} = 12{,}552\ \text{W/K}$$

$$q = C_c(T_{c,o} - T_{c,i}) = 12{,}552\text{W/K}(80-30)°\text{C} = 627{,}600\ \text{W}$$

From an energy balance on the hot fluid,

$$C_h = q/(T_{h,i} - T_{h,o}) = 627{,}600\ \text{W}/(225-100)°\text{C} = 5{,}021\ \text{W/K}$$

Thus, $C_r = C_{min}/C_{max} = 0.40$ and $\varepsilon = q/C_{min}(T_{h,i} - T_{c,i}) = 0.641$. With C_{min} mixed and C_{max} unmixed, Eq. 11.34b yields

$$\text{NTU} = -\frac{1}{C_r}\ln\left[C_r \ln(1-\varepsilon)+1\right] = -\frac{1}{0.4}\ln\left[0.4\ln(1-0.641)+1\right] = 1.32$$

Thus,

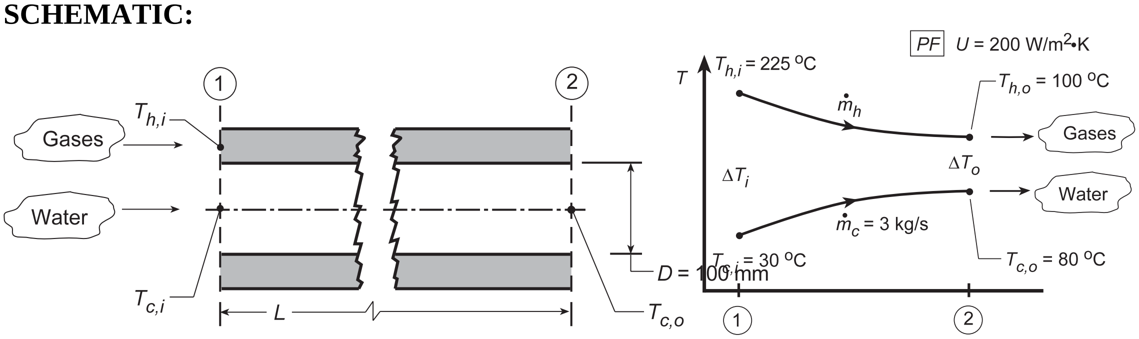
$$A = \text{NTU} \times C_{min}/U = 1.32 \times 5021\ \text{W/K} / 200\text{W/m}^2\cdot\text{K} = 33.1\ \text{m}^2$$ <

PROBLEM 11.33

KNOWN: Concentric tube heat exchanger operating in parallel flow (PF) conditions with a thin-walled separator tube of 100-mm diameter; fluid conditions as specified.

FIND: (a) Required length for the exchanger; (b) Convection coefficient for water flow, assumed to be fully developed; (c) Compute and plot the heat transfer rate, q, and fluid inlet temperatures, $T_{h,o}$ and $T_{c,o}$, as a function of the tube length for $60 \le L \le 400$ m with the PF arrangement and overall coefficient $\left(U = 200\,W/m^2\cdot K\right)$, inlet temperatures ($T_{h,i}$ = 225°C and $T_{c,i}$ = 30°C), and fluid flow rates from Problem 11.32; (d) Reduction in required length relative to the value found in part (a) if the exchanger were operated in the counterflow (CF) arrangement; and (e) Compute and plot the effectiveness and fluid outlet temperatures as a function of tube length for $60 \le L \le 400$ m for the CF arrangement of part (c).

SCHEMATIC:



ASSUMPTIONS: (1) No losses to surroundings, (2) Separation tube has negligible thermal resistance, (3) Water flow is fully developed, (4) Constant properties, (5) Exhaust gas properties are those of atmospheric air.

PROPERTIES: *Table A-4*, Hot fluid, Air (1 atm, $\overline{T}$ = (225 +100)°C /2 = 436 K): c_p = 1019 J/kg·K; *Table A-6*, Cold fluid, Water $\overline{T}$ = (30 + 80)°C /2 ≈ 328 K): $\rho = 1/v_f$ = 985.4 kg/m^3, c_p = 4183 J/kg·K, k = 0.648 W/m·K, $\mu = 505 \times 10^{-6}$ N·s/m^2, Pr = 3.58.

ANALYSIS: (a) From the rate equation, Eq. 11.14, with A = πDL, the length of the exchanger is

$$L = q/U\cdot\pi D\cdot\Delta T_{\ell m,PF}\,. \qquad (1)$$

The heat rate follows from an energy balance on the cold fluid, using Eq. 11.7, find

$$q = \dot{m}_c c_c\left(T_{c,o} - T_{c,i}\right) = 3\,kg/s \times 4183\,J/kg\cdot K\left(80-30\right)K = 627.5\times10^3\,W\,.$$

Using an energy balance on the hot fluid, find $\dot{m}_h$ for later use.

$$\dot{m}_h = q/c_h\left(T_{h,i} - T_{h,o}\right) = 627.5\times10^3\,W/1019\,J/kg\cdot K\left(225-100\right)K = 4.93\,kg/s \qquad (2)$$

For parallel flow, Eqs. 11.15 and 11.16,

$$\Delta T_{\ell m,PF} = \frac{\Delta T_1 - \Delta T_2}{\ell n\Delta T_1/\Delta T_2} = \frac{\left(225-30\right)^\circ C - \left(100-80\right)^\circ C}{\ell n\left(225-30\right)/\left(100-80\right)} = 76.8^\circ C\,.$$

Substituting numerical values into Eq. (1), find

$$L = 627.5\times10^3\,W/200\,W/m^2\cdot K\left(\pi\times0.1m\right)76.8K = 130m\,.$$ <

Continued...

PROBLEM 11.33 (Cont.)

(b) Considering the water flow within the separator tube, from Eq. 8.6,

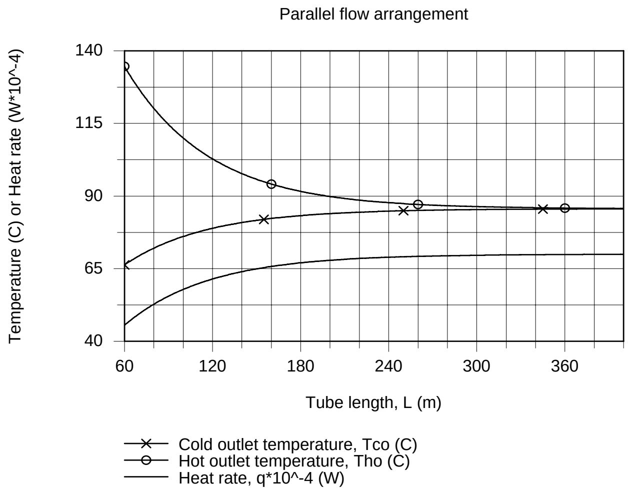
$$Re_D = 4\dot{m}/\pi D\mu = 4\times 3\,kg/s\Big/\left(\pi\times 0.1m\times 505\times 10^{-6}\,N/s\cdot m^2\right) = 75,638\,.$$

Since $R_{eD} > 2300$, the flow is turbulent and since flow is assumed to be fully developed, use the Dittus-Boelter correlation with n = 0.4 for heating,

$$Nu_D = 0.023Re_D^{0.8}\,Pr^{0.4} = 0.023(75,638)^{0.8}(3.58)^{0.4} = 306.4$$

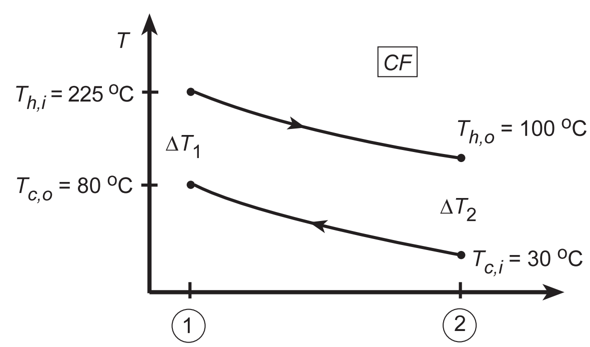
$$h = Nu_D\frac{k}{D} = 306.4\times 0.648\,W/m\cdot K/(0.1m) = 1985\,W\Big/m^2\cdot K\,.$$ <

(c) Using the *IHT Heat Exchanger Tool*, *Concentric Tube*, *Parallel Flow*, *Effectiveness relation*, and the *Properties Tool* for *Water* and *Air*, a model was developed for the PF arrangement. With U = 200 W/m^2·K and prescribed inlet temperatures, $T_{h,i}$ = 225°C and $T_{c,i}$ = 30°C, the outlet temperatures, $T_{h,o}$ and $T_{c,o}$ and heat rate, q, were computed as a function of tube length L.



As the tube length increases, the outlet temperatures approach one another and eventually reach $T_{h,o} = T_{c,o}$ = 85.6°C.

(d) If the exchanger as for part (a) is operated in counterflow (rather than parallel flow), the log mean temperature difference is



$$\Delta T_{\ell m,CF} = \frac{\Delta T_i - \Delta T_2}{\ell n\Delta T_1/\Delta T_2}$$

$$\Delta T_{\ell m,CF} = \frac{(225-80)-(100-30)}{\ell n(225-80)/100-30} = 103.0^\circ C\,.$$

Using Eq. (1), the required length is

$$L = 627.5\times 10^3\,W/200\,W\Big/m^2\cdot K\times\pi\times 0.1m\times 103.0\,K = 97\,m\,.$$

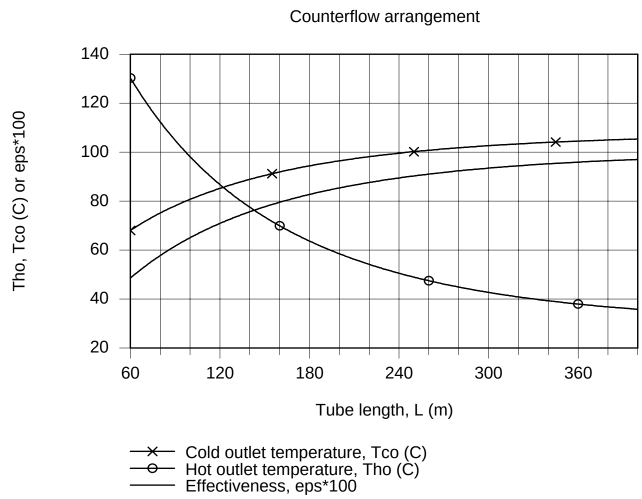
The reduction in required length of CF relative to PF operation is

Continued...

PROBLEM 11.33 (Cont.)

$$\Delta L = \left(L_{PF} - L_{CF}\right)/L_{PF} = \left(103 - 97\right)/103 = 5.8\% \quad <$$

(e) Using the *IHT Heat Exchanger Tool*, *Concentric Tube*, *Counterflow*, *Effectiveness relation*, and the *Properties Tool* for *Water* and *Air*, a model was developed for the CF arrangement. For the same conditions as part (c), but CF rather than PF, the effectiveness and fluid outlet temperatures were computed as a function of tube length L.



Note that as the length increases, the effectiveness tends toward unity, and the hot fluid outlet temperature tends toward $T_{c,i}$ = 30°C. Remember the heat rate for an infinitely long CF heat exchanger is q_{max} and the minimum fluid (hot in our case) experiences the temperature change, $T_{h,i}$ - $T_{c,i}$.

COMMENTS: (1) As anticipated, the required length for CF operations was less than for PF operation.

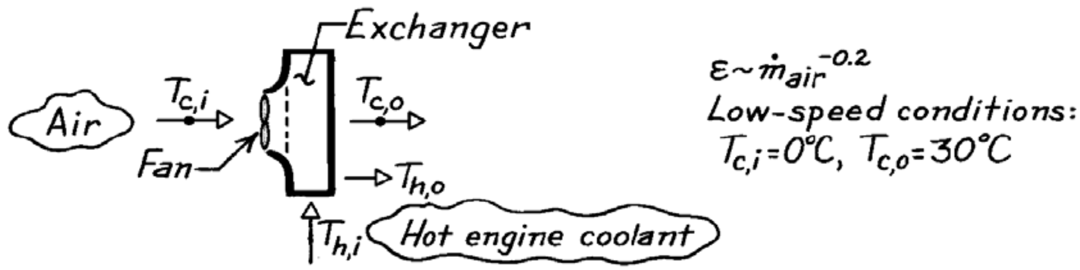
(2) Note that U is substantially less than h_i implying that the gas-side coefficient must be the controlling thermal resistance.

PROBLEM 11.34

KNOWN: Heat exchanger in car operating between warm radiator fluid and cooler outside air. Effectiveness of heater is $\varepsilon \sim \dot{m}_{air}^{-0.2}$ since water flow rate is large compared to that of the air. For low-speed fan condition, heater warms outdoor air from 0°C to 30°C.

FIND: (a) Increase in heat added to car for high-speed fan condition causing $\dot{m}_{air}$ to be doubled while inlet temperatures remain the same, and (b) Air outlet temperature for medium-speed fan condition where air flow rate increases 50% and heat transfer increases 20%.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat losses from heat exchanger to surroundings, (2) $T_{h,i}$ and $T_{c,i}$ remain fixed for all fan-speed conditions, (3) Water flow rate is much larger than that of air.

ANALYSIS: (a) Assuming the flow rate of the water is much larger than that of air,

$$C_{min} = C_c = \dot{m}_{air}\, c_{p,c}.$$

Hence, the heat rate can be written as

$$q = \varepsilon q_{max} = \varepsilon C_{min}\left(T_{h,i} - T_{c,i}\right) = \varepsilon \cdot \dot{m}_{air} c_{p,air}\left(T_{h,i} - T_{c,i}\right).$$

Taking the ratio of the heat rates for the high and low speed fan conditions, find

$$\frac{q_{hi}}{q_{lo}} = \frac{\left(\varepsilon \dot{m}_{air}\right)_{hi}}{\left(\varepsilon \dot{m}_{air}\right)_{lo}} = \frac{\left(\dot{m}_{air}^{0.8}\right)_{hi}}{\left(\dot{m}_{air}^{0.8}\right)_{lo}} = 2^{0.8} = 1.74$$ <

where we have used $\varepsilon \sim \dot{m}_{air}^{-0.2}$ and recognized that for the high speed fan condition, the air flow rate is doubled. Hence the heat rate is increased by 74%.

(b) Considering the medium and low speed conditions, it was observed that,

$$\frac{q_{med}}{q_{lo}} = 1.2 \qquad \frac{\left(\dot{m}_{air}\right)_{med}}{\left(\dot{m}_{air}\right)_{lo}} = 1.5.$$

To find the outlet air temperature for the medium speed condition,

$$\frac{q_{med}}{q_{lo}} = \frac{\left[\dot{m}_{air} c_{p,c}\left(T_{c,o} - T_{c,i}\right)\right]_{med}}{\left[\dot{m}_{air} c_{p,c}\left(T_{c,o} - T_{c,i}\right)\right]_{lo}}$$

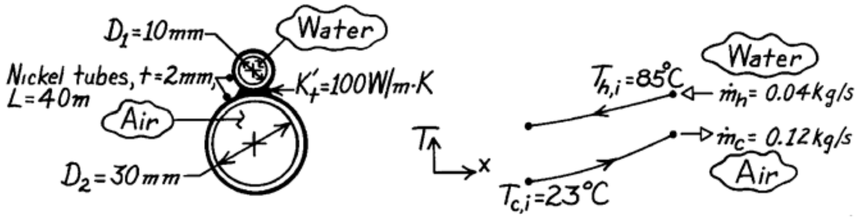
$$1.2 = \frac{1.5\left(T_{c,o} - 0°C\right)}{\left(30 - 0°C\right)} \qquad T_{c,o} = 24°C.$$ <

PROBLEM 11.35

KNOWN: Counterflow heat exchanger formed by two brazed tubes with prescribed hot and cold fluid inlet temperatures and flow rates.

FIND: Outlet temperature of the air.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible loss/gain from tubes to surroundings, (2) Flow in tubes is fully developed since L/D_h = 40 m/0.030m = 1333.

PROPERTIES: *Table A-6,* Water ($\overline{T}_h$ = 335 K): $c_h = c_{p,h}$ = 4186 J/kg·K, μ = 453 × 10^{-6} N·s/m^2, k = 0.656 W/m·K, Pr = 2.88; *Table A-4,* Air (300 K): $c_c = c_{p,c}$ = 1007 J/kg·K, μ = 184.6 × 10^{-7} N·s/m^2, k = 0.0263 W/m·K, Pr = 0.707; *Table A-1*, Nickel ($\overline{T}$ = (23 + 85)°C/2 = 327 K): k = 88 W/m·K.

ANALYSIS: Using the NTU - ε method, from Eq. 11.28a,

$$\varepsilon = \frac{1-\exp\left[-NTU\left(1-C_r\right)\right]}{1-C_r\exp\left[-NTU\left(1-C_r\right)\right]} \qquad NTU = UA/C_{min} \qquad C_r = C_{min}/C_{max}. \qquad (1,2,3)$$

Estimate UA from a model of the tubes and flows, and determine the outlet temperature from the expression

$$\varepsilon = C_c\left(T_{c,o}-T_{c,i}\right)/C_{min}\left(T_{h,i}-T_{c,i}\right). \qquad (4)$$

Water-side: $$Re_D = \frac{4\dot{m}_h}{\pi D\mu} = \frac{4\times 0.04\ kg/s}{\pi\times 0.010m\times 453\times 10^{-6}\,N\cdot s/m^2} = 11,243.$$

The flow is turbulent and since fully developed, use the Dittus-Boelter correlation,

$$\overline{Nu}_h = \bar{h}_h D/k = 0.023 Re_D^{0.8} Pr^{0.3} = 0.023(11,243)^{0.8}(2.88)^{0.3} = 54.99$$

$$\bar{h}_h = 54.99\times 0.656\ W/m\cdot K/0.01m = 3,607\ W/m^2\cdot K.$$

Air-side: $$Re_D = \frac{4\dot{m}_c}{\pi D\mu} = \frac{4\times 0.120\ kg/s}{\pi\times 0.030m\times 184.6\times 10^{-7}\ N\cdot s/m^2} = 275,890.$$

The flow is turbulent and since fully developed, again use the correlation

$$\overline{Nu}_c = \bar{h}_c D/k = 0.023 Re_D^{0.8} Pr^{0.4} = 0.023(275,890)^{0.8}(0.707)^{0.4} = 450.9$$

$$\bar{h}_c = 450.9\times 0.0263\ W/m\cdot K/0.030m = 395.3\ W/m^2\cdot K.$$

Overall coefficient: From Eq. 11.1, considering the temperature effectiveness of the tube walls and the thermal conductance across the brazed region,

Continued …

PROBLEM 11.35 (Cont.)

$$\frac{1}{UA}=\frac{1}{(\eta_o hA)_h}+\frac{1}{K_t' L}+\frac{1}{(\eta_o hA)_c} \qquad (5)$$

where η_o needs to be evaluated for each of the tubes. Note that each tube can be viewed as two fins of length $\pi D/2$. However, since the fins exchange heat on only one side, they can be combined into a single fin of length $\pi D/2$ and thickness 2t, exchanging heat on both sides.

Water-side temperature effectiveness: $A_h = \pi D_h L = \pi(0.010\text{m})40\text{m} = 1.257\,\text{m}^2$

$$\eta_{o,h} = \eta_{f,h} = \tanh(mL_h)/mL_h \qquad m = \left(\bar{h}_h P/kA\right)^{1/2} = \left(h_h/kt\right)^{1/2}$$

$$m = \left(3607\ \text{W/m}^2\cdot\text{K}/88\ \text{W/m}\cdot\text{K}\times 0.002\text{m}\right)^{1/2} = 143.2\,\text{m}^{-1}$$

and with $L_h = 0.5\,\pi D_h$, $\eta_{o,h}$ = tanh(143.2 m^{-1} × 0.5 π × 0.010m)/143.2 m^{-1} × 0.5 π × 0.010 m = 0.435.

Air-side temperature effectiveness: $A_c = \pi D_c L = \pi(0.030\text{m})40\text{m} = 3.770\ \text{m}^2$

$$\eta_{o,c} = \eta_{f,c} = \tanh(mL_c)/mL_c \quad m = \left(395.3\ \text{W/m}^2\cdot\text{K}/88\ \text{W/m}\cdot\text{K}\times 0.002\text{m}\right)^{1/2} = 47.39\,\text{m}^{-1}$$

and with $L_c = 0.5\pi D_c$, $\eta_{o,c}$ = tanh(47.39 m^{-1} × 0.5 π × 0.030m)/47.39 m^{-1} × 0.5 π × 0.030m = 0.438.

Hence, the *overall heat transfer coefficient* using Eq. (5) is

$$\frac{1}{UA}=\frac{1}{0.435\times 3607\ \text{W/m}^2\cdot\text{K}\times 1.257\,\text{m}^2}+\frac{1}{100\ \text{W/m}\cdot\text{K}(40\text{m})}+\frac{1}{0.438\times 395.3\ \text{W/m}^2\cdot\text{K}\times 3.770\,\text{m}^2}$$

$$UA = \left[5.070\times 10^{-4} + 2.50\times 10^{-4} + 1.533\times 10^{-3}\right]^{-1}\text{W/K} = 437\ \text{W/K}.$$

Evaluating now the *heat exchanger effectiveness* from Eq. (1) with

$$\left.\begin{array}{l} C_h = \dot{m}_h c_h = 0.040\,\text{kg/s}\times 4186\ \text{J/kg}\cdot\text{K} = 167.4\ \text{W/K} \leftarrow C_{max} \\ C_c = \dot{m}_c c_c = 0.120\,\text{kg/s}\times 1007\ \text{J/kg}\cdot\text{K} = 120.8\ \text{W/K} \leftarrow C_{min} \end{array}\right\} C_r = C_{min}/C_{max} = 0.722$$

$$NTU = \frac{UA}{C_{min}} = \frac{437\ \text{W/K}}{120.8\ \text{W/K}} = 3.62 \qquad \varepsilon = \frac{1-\exp[-3.62(1-0.722)]}{1-0.722\ \exp[-3.62(1-0.722)]} = 0.862$$

and finally from Eq. (4) with $C_{min} = C_c$,

$$0.862 = \frac{C_c\left(T_{c,o} - 23°\text{C}\right)}{C_c(85-23)°\text{C}} \qquad T_{c,o} = 76.4°\text{C}$$ <

COMMENTS: (1) Using overall energy balances, the water outlet temperature is

$$T_{h,o} = T_{h,i} + (C_c/C_h)\left(T_{c,o} - T_{c,i}\right) = 85°\text{C} - 0.722(76.4-23)°\text{C} = 46.4°\text{C}.$$

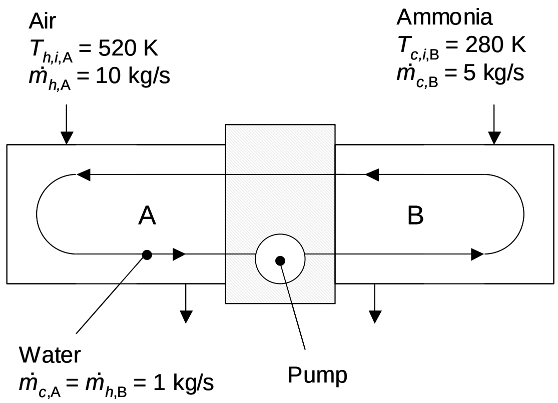
(2) To initially evaluate the properties, we assumed that $\overline{T}_h \approx 335$ K and $\overline{T}_c \approx 300$ K. From the calculated values of $T_{h,o}$ and $T_{c,o}$, more appropriate estimates of $\overline{T}_h$ and $\overline{T}_c$ are 338 K and 322 K, respectively. We conclude that proper thermophysical properties were used for water but that the estimates could be improved for air.

PROBLEM 11.36

KNOWN: Air and ammonia flow rates and inlet temperatures. Relationship of *UA* product to water flow rate. Water mass flow rates in tubes. Heat exchanger type.

FIND: (a) Air and ammonia outlet temperatures and heat transfer rate. (b) Air and ammonia outlet temperatures for water flow rates in the range 0 kg/s ≤ $\dot{m}_{c,A} = \dot{m}_{h,B} \leq$ 2 kg/s**.**

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat transfer between heat exchangers and surroundings, negligible heat transfer between two heat exchangers, (2) Constant properties, (3) Negligible energy added to the system by the pump.

PROPERTIES: *Table A.6* (water) ($\bar{T}$ = 400 K): c_p = 4256 J/kg·K. *Table A.4* (air) ($\bar{T}$ = 500 K): c_p = 1030 J/kg·K. *Table A.4* (ammonia) ($\bar{T}$ = 300 K): c_p = 2158 J/kg·K.

ANALYSIS: (a) For heat exchanger A, $C_{h,A}$ = 10 kg/s × 1030 J/kg·K = 10,300 W/K. For heat exchanger B, $C_{c,B}$ = 5kg/s × 2158 J/kg·K = 10790 W/K. For the water, $C_{c,A} = C_{h,B}$ = 1kg/s × 4256 J/kg·K = 4256 W/K. Therefore, $C_{min,A} = C_{min,B}$ = 4256 W/K. For heat exchanger A, UA_A = 6000 W/K + 100 J/kg·K × 1 kg/s = 6100 W/K while for heat exchanger B, $UA_B = 1.2UA_A$ = 7320 W/K. The relative heat rates are $C_{r,A}$ = 4256/10,300 = 0.4132 and $C_{r,B}$ = 4256/10,790 = 0.3944. The number of transfer units for heat exchanger A is NTU_A = 6100/4256 = 1.433, while for heat exchanger B NTU_B = 7320/4256 = 1.720. The effectiveness may be evaluated using Eq. 11.30a resulting in ε_A = 0.6468, ε_B = 0.6966.

For heat exchangers A and B, the following equations may be written, making special note that the water temperature is the same between the inlet and outlet of the shell-side of each heat exchanger.

$$q_A = \varepsilon_A C_{min,A}(T_{h,i,A} - T_{c,i,A}) = 0.6468 \times 4256 W/K \times (520K - T_{c,i,A}) \quad (1)$$

$$q_B = \varepsilon_B C_{min,B}(T_{h,i,B} - T_{c,i,B}) = 0.6966 \times 4256 W/K \times (T_{h,i,B} - 280K) \quad (2)$$

$$T_{h,o,A} = T_{h,i,A} - q_A / C_{max,A} = 520K - q_A / 10300 W/K \quad (3)$$

$$T_{c,o,B} = T_{c,i,B} + q_B / C_{max,B} = 280K + q_B / 10790 W/K \quad (4)$$

$$T_{h,i,B} = T_{c,o,A} \quad (5)$$

$$T_{h,o,B} = T_{c,i,A} \quad (6)$$

Equations (1) through (6) may be solved simultaneously to yield

$q_A = q_B = 5.17 \times 10^5$ W, $T_{h,o,A}$ = 469.8 K, $T_{c,o,B}$ = 327.9 K <

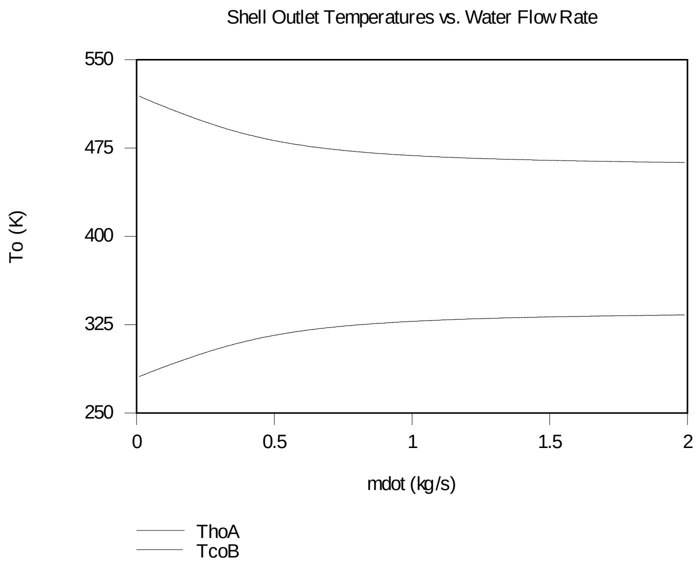
Continued…

PROBLEM 11.36 (Cont.)

In addition, we note that

$$T_{h,i,\mathrm{B}} = T_{c,o,\mathrm{A}} = 454.5\mathrm{K} \qquad\qquad T_{h,o,\mathrm{B}} = T_{c,i,\mathrm{A}} = 332.9\mathrm{K}$$

(b) *IHT* was used to solve the preceding equations simultaneously, and to plot the following results.



<

COMMENTS: (1) The *IHT* code used in part (b) is listed below. (2) As evident in part (b), fine-tuning is feasible, but to a limited degree for the conditions of this problem. The capability to fine-tune the device is dependent upon the *UA* values associated with each heat exchanger. Neglecting the dependence of *UA* on the water mass flow rate, the calculations were repeated and the outlet temperatures of the air in heat exchanger A are shown in the plot below.

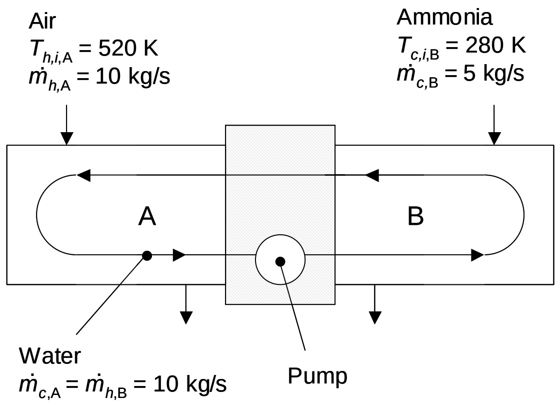
PROBLEM 11.37

KNOWN: Air and ammonia flow rates and inlet temperatures. Relationship of *UA* product to water flow rate. Mass flow rate of water in tubes.

FIND: (a) Air and ammonia outlet temperatures and heat transfer rate. (b) Air and ammonia outlet temperatures for water flow rates in the range 5 kg/s ≤ $\dot{m}_{c,\text{A}} = \dot{m}_{h,\text{B}} \le$ 50 kg/s.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat transfer between heat exchangers and surroundings, negligible heat transfer between two heat exchangers, (2) Constant properties.

PROPERTIES: *Table A.6* (water) ($\bar{T}$ = 400 K): c_p = 4256 J/kg·K. *Table A.4* (air) ($\bar{T}$ = 500 K): c_p = 1030 J/kg·K. *Table A.4* (ammonia) ($\bar{T}$ = 300 K): c_p = 2158 J/kg·K.

ANALYSIS: (a) For heat exchanger A, $C_{h,\text{A}}$ = 10 kg/s × 1030 J/kg·K = 10,300 W/K. For heat exchanger B, $C_{c,\text{B}}$ = 5kg/s × 2158 J/kg·K = 10,790 W/K. For the water, $C_{c,\text{A}} = C_{h,\text{B}}$ = 10kg/s × 4256 J/kg·K = 42,560 W/K. Therefore, $C_{\text{min,A}}$ = 10,300 W/K and $C_{\text{min,B}}$ = 10,790 W/K. For heat exchanger A, UA_A = 6000 W/K + 100 J/kg·K × 10 kg/s = 7000 W/K while for heat exchanger B, $UA_\text{B} = 1.2UA_\text{A}$ = 8400 W/K. The relative heat rates are $C_{r,\text{A}}$ = 10,300/42,560 = 0.2420 and $C_{r,\text{B}}$ = 10,790/42,560 = 0.2535. The number of transfer units for heat exchanger A is NTU_A = 7000/10,300 = 0.6796, while for heat exchanger B NTU_B = 8400/10,790 = 0.779. The effectiveness may be evaluated using Eq. 11.30a resulting in ε_A = 0.4647, ε_B = 0.5052.

For heat exchangers A and B, we may write the following, making special note that the water temperature is the same between the inlet and outlet of the shell-side of each heat exchanger.

$$q_\text{A} = \varepsilon_\text{A} C_{\text{min,A}}(T_{h,i,\text{A}} - T_{c,i,\text{A}}) = 0.4647 \times 10300\text{W/K} \times (520\text{K} - T_{c,i,\text{A}}) \quad (1)$$

$$q_\text{B} = \varepsilon_\text{B} C_{\text{min,B}}(T_{h,i,\text{B}} - T_{c,i,\text{B}}) = 0.5052 \times 10790\text{W/K} \times (T_{h,i,\text{B}} - 280\text{K}) \quad (2)$$

$$T_{h,o,\text{A}} = T_{h,i,\text{A}} - q_\text{A} / C_{\text{max,A}} = 520\text{K} - q_\text{A} / 10300\text{W/K} \quad (3)$$

$$T_{c,o,\text{B}} = T_{c,i,\text{B}} + q_\text{B} / C_{\text{max,B}} = 280\text{K} + q_\text{B} / 10790\text{W/K} \quad (4)$$

$$T_{h,i,\text{B}} = T_{c,o,\text{A}} \quad (5)$$

$$T_{h,o,\text{B}} = T_{c,i,\text{A}} \quad (6)$$

Equations (1) through (6) may be solved simultaneously to yield

$q_\text{A} = q_\text{B} = 6.51 \times 10^5$ W, $T_{h,o,\text{A}}$ = 456.8 K, $T_{c,o,\text{B}}$ = 340.3 K <

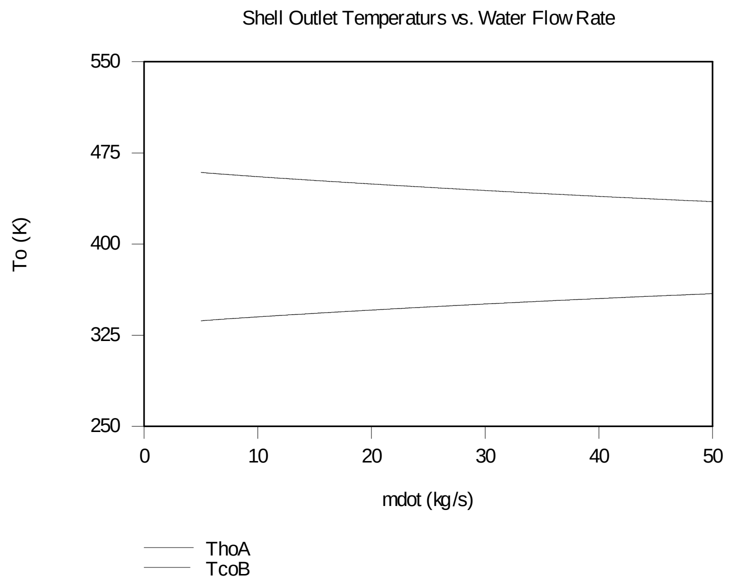
Continued…

PROBLEM 11.37 (Cont.)

In addition, we note that

$$T_{h,i,\mathrm{B}} = T_{c,o,\mathrm{A}} = 399.4\mathrm{K} \qquad T_{h,o,\mathrm{B}} = T_{c,i,\mathrm{A}} = 384.1\mathrm{K}$$

(b) *IHT* was used to solve the preceding equations simultaneously, and to plot the following results.



<

COMMENTS: (1) The *IHT* code used in part (b) is listed below. (2) As evident in part (b), fine-tuning is feasible.

```
//IHT code for Cmin associated with the shell-side flows

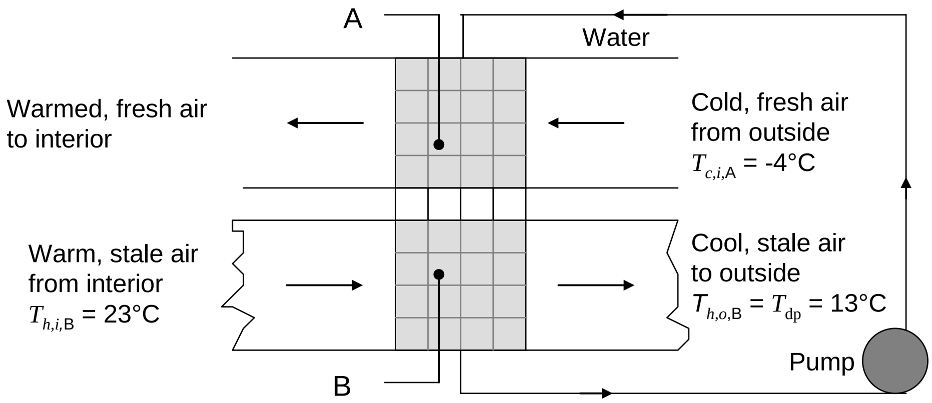
PROBLEM 11.38

KNOWN: Air flow rate, cold outside temperature, warm indoor temperature, dew point temperature, *UA* product.

FIND: (a) Required water flow rate.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat transfer between heat exchangers and surroundings, negligible heat transfer between two heat exchangers, (2) Constant properties, (3) Negligible energy added to the system by the pump, (4) C_{max} is associated with the air, (5) Properties of water with anti-freeze agent are the same as properties of water.

PROPERTIES: *Table A.6* (water) ($\bar{T}$ = 9°C = 283 K): c_p = 4194 J/kg·K. *Table A.4* (air) ($\bar{T}$ = 9°C = 283 K): c_p = 1007 J/kg·K.

ANALYSIS: (a) Note that $C_{\max} = C_{\text{air}} = \dot{m}c_p = 1.50\text{kg/s} \times 1007\text{J/kg}\cdot\text{K} = 1510\ \text{W/K}$. The heat transfer rate is $q = q_A = q_B = C_{max}\times(T_{h,i,B} - T_{h,o,B})$ = 1510 W/K × (23 – 13)°C = 15,100 W. The following equations describe the behavior of the system.

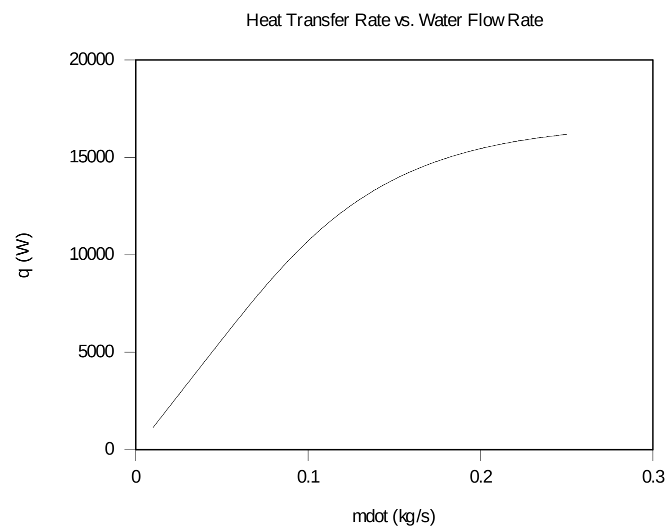
$$\text{NTU} = UA/C_{\min} = (2500\text{W/K})/C_{\min}$$
$$q = \varepsilon C_{\min}(T_{h,i,A} - T_{c,i,A}) = 15{,}100\text{W} = \varepsilon C_{\min}(T_{h,i,A} - (-4°C))$$
$$q = \varepsilon C_{\min}(T_{h,i,B} - T_{c,i,B}) = 15{,}100\text{W} = \varepsilon C_{\min}(23°C - T_{c,i,B})$$
$$q = C_{\min}(T_{c,o,B} - T_{c,i,B}) = 15{,}100\text{W} = C_{\min}(T_{c,o,B} - T_{c,i,B})$$
$$C_r = C_{min}/C_{max}$$
$$T_{c,o,B} = T_{h,i,A}$$
$$T_{h,o,A} = T_{c,i,B}$$
$$\varepsilon = 1 - \exp\left[\left(\frac{1}{C_r}\right)(\text{NTU})^{0.22}\left\{\exp\left[-C_r(\text{NTU})^{0.78}\right] - 1\right\}\right]$$

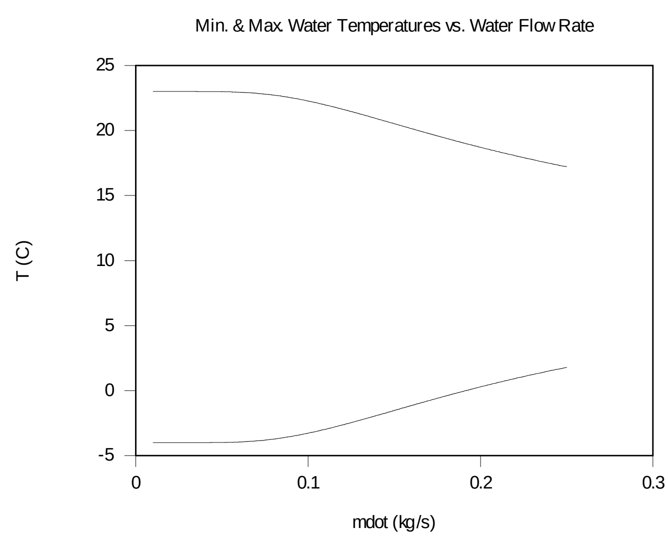
A trial-and-error solution yields $\dot{m}_w = C_{\min}/c_{p,w} = (776\text{K/W})/4194\text{J/kg}\cdot\text{K} = 0.185\text{kg/s}$ <

Continued…

PROBLEM 11.38 (Cont.)

COMMENTS: (1) Note that the maximum allowable water flow rate to justify the assumption that C_{max} is associated with the air flow is $\dot{m}_{max} = C_{max}/c_{p,w}$ = 1510 W/K/4194 J/kg·K = 0.36 kg/s. The assumption is valid. (2) The maximum heat transfer rate is associated with an infinite water flow rate. For this case, the water temperature is constant at an average value of $\bar{T}$ = 9°C = 283 K and C_{min} is associated with the air flow and is equal to 1510 K/W. Assuming a constant value of *UA*, the effectiveness for an infinite C_{max} is given by Eq. 11.35a and is ε = 1 – exp(-NTU) = 1 – exp(-2500/1510) = 0.81. Hence, for an infinite water flow rate, q = 0.81 × 1510W/K × (23 – 9.5)°C = 16,500 W. (3) The heat transfer rate, as well as the maximum and minimum water temperatures as a function of the water flow rate, are shown in the plots below (letting the cool stale air temperature be unknown). Note that at water mass flow rates of approximately 0.25 kg/s, the heat transfer rate asymptotically approaches that of an infinite water flow rate calculated in Comment 2.



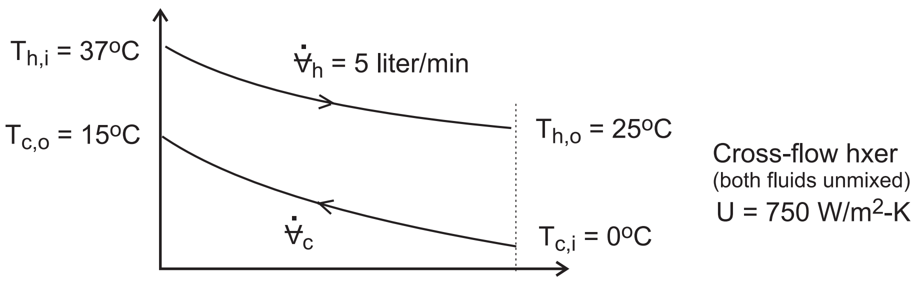


PROBLEM 11.39

KNOWN: Cross-flow heat exchanger (both fluids unmixed) cools blood to induce body hypothermia using ice-water as the coolant.

FIND: (a) Heat transfer rate from the blood, (b) Water flow rate, $\dot{\forall}_c$ (liter/min), (c) Surface area of the exchanger, and (d) Calculate and plot the blood and water outlet temperatures as a function of the water flow rate for the range, $2 \le \dot{\forall} \le 4$ liter/min, assuming all other parameters remain unchanged.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible losses to the surroundings, (3) Overall heat transfer coefficient remains constant with water flow rate changes, and (4) Constant properties.

PROPERTIES: *Table A-6*, Water $\left(\overline{T}_c = 280\text{K}\right)$, $\rho = 1000\text{ kg/m}^3$, $c = 4198\text{ J/kg}\cdot\text{K}$. Blood (given): $\rho = 1050\text{ kg/m}^3$, $c = 3740\text{ J/kg}\cdot\text{K}$.

ANALYSIS: (a) The heat transfer rate from the blood is calculated from an energy balance on the hot fluid,

$$\dot{m}_h = \rho_h \dot{\forall}_h = 1050\text{ kg/m}^3 \times \left(5\text{ liter/min} \times 1\text{ min/60 s}\right) \times 10^{-3}\text{m}^3\text{/liter} = 0.0875\text{ kg/s}$$

$$q = \dot{m}_h c_h \left(T_{h,i} - T_{h,o}\right) = 0.0875\text{ kg/s} \times 3740\text{ J/kg}\cdot\text{K}\left(37 - 25\right)\text{K} = 3927\text{ W} \quad < \quad (1)$$

(b) From an energy balance on the cold fluid, find the coolant water flow rate,

$$q = \dot{m}_c\, c_c \left(T_{c,o} - T_{c,i}\right) \quad (2)$$

$$3927\text{ W} = \dot{m}_c \times 4198\text{ J/kg}\cdot\text{K}\left(15 - 0\right)\text{K} \qquad \dot{m}_c = 0.0624\text{ kg/s}$$

$$\dot{\forall}_c = \dot{m}_c / \rho_c = 0.0624\text{ kg/s} / 1000\text{ kg/m}^3 \times 10^3\text{liter/m}^3 \times 60\text{ s/min} = 3.74\text{ liter/min} \quad <$$

(c) The surface area can be determined using the effectiveness-NTU method. The capacity rates for the exchanger are

$$C_h = \dot{m}_h c_h = 327\text{ W/K} \qquad C_c = \dot{m}_c\, c_c = 262\text{ W/K} \qquad C_{min} = C_c \quad (3, 4, 5)$$

From Eq. 11.18 and 11.19, the maximum heat rate and effectiveness are

Continued …..

PROBLEM 11.39 (Cont.)

$$q_{max} = C_{min}\left(T_{h,i} - T_{c,i}\right) = 262\ W/K\ (37-0)K = 9694\ W \qquad (6)$$

$$\varepsilon = q/q_{max} = 3927/9694 = 0.405 \qquad (7)$$

For the cross flow exchanger, with both fluids unmixed, substitute numerical values into Eq. 11.32 to find the number of transfer units, NTU, where $C_r = C_{min}/C_{max}$.

$$\varepsilon = 1 - \exp\left[(1/C_r)NTU^{0.22}\left\{\exp\left[-C_r NTU^{0.78}\right] - 1\right\}\right] \qquad (8)$$

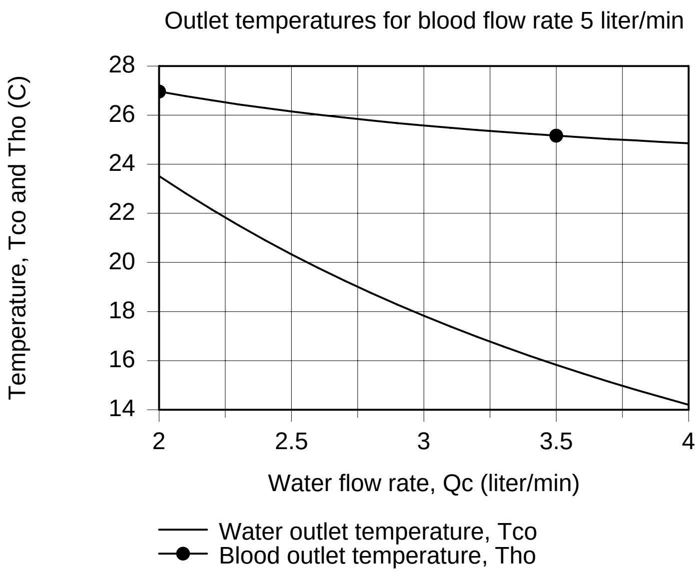
$$NTU = 0.691$$

From Eq. 11.24, find the surface area, A.

$$NTU = UA/C_{min}$$

$$A = 0.691 \times 262\ W/K / 750\ W/m^2 \cdot K = 0.241\ m^2$$ <

(d) Using the foregoing equations in the *IHT* workspace, the blood and water outlet temperatures, $T_{h,o}$ and $T_{c,o}$, respectively, are calculated and plotted as a function of the water flow rate, all other parameters remaining unchanged.



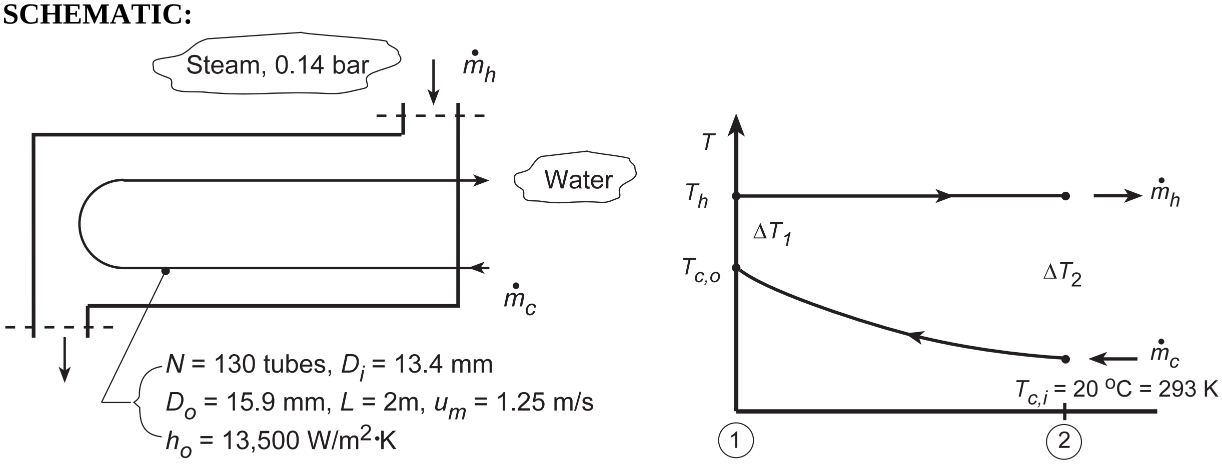
From the graph, note that with increasing water flow rate, both the blood and water outlet temperatures decrease. However, the effect of the water flow rate is greater on the water outlet temperature. This is an advantage for this application, since it is desirable to have the blood outlet temperature relatively insensitive to changes in the water flow rate. That is, if there are pressure changes on the water supply line or a slight mis-setting of the water flow rate controller, the outlet blood temperature will not change markedly.

PROBLEM 11.40

KNOWN: Steam at 0.14 bar condensing in a shell and tube HXer (one shell, two tube passes consisting of 130 brass tubes of length 2 m, D_i = 13.4 mm, D_o = 15.9 mm). Cooling water enters at 20°C with a mean velocity 1.25 m/s. Heat transfer convection coefficient for condensation on outer tube surface is h_o = 13,500 W/m^2 ·K.

FIND: (a) Overall heat transfer coefficient, U, for the HXer, outlet temperature of cooling water, $T_{c,o}$, and condensation rate of the steam $\dot{m}_h$; and (b) Compute and plot $T_{c,o}$ and $\dot{m}_h$ as a function of the water flow rate $10 \le \dot{m}_c \le 30$ kg/s with all other conditions remaining the same, but accounting for changes in U.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Fully developed water flow in tubes.

PROPERTIES: *Table A-6,* Steam (0.14 bar): $T_{sat} = T_h$ = 327 K, h_{fg} = 2373 kJ/kg, c_p = 1898 J/kg·K; *Table A-6,* Water (Assume $T_{c,o} \approx 44°C$ or $\overline{T}_c \approx 305$ K): $v_f = 1.005 \times 10^{-3}$ m^3/kg , c_p = 4178 J/kg·K, $\mu_f = 769 \times 10^{-6}$ N·s/m^2 , k_f = 0.620 W/m·K, Pr_f = 5.2; *Table A-1,* Brass - 70/30 (Evaluate at $\overline{T} = (T_h + \overline{T}_c)/2 = 316$ K): k = 114 W/m·K.

ANALYSIS: (a) The overall heat transfer coefficient based upon the outside tube area follows from Eq. 11.5,

$$U_o = \left[\frac{1}{h_o} + \frac{r_o}{k}\ell n\frac{r_o}{r_i} + \left(\frac{r_o}{r_i}\right)\frac{1}{h_i}\right]^{-1}. \qquad (1)$$

The value for h_i can be estimated from an appropriate internal flow correlation. First determine the nature of the flow within the tubes. From Eq. 8.1,

$$Re_{D_i} = \rho u_m \frac{D_i}{\mu} = \frac{\left(1.005\times10^{-3}\,m^3/kg\right)^{-1}\times1.25\,m/s\times13.4\times10^{-3}\,m}{769\times10^{-6}\,N\cdot s/m^2} = 21,673.$$

The water flow is turbulent and fully developed (L/D_i = 2 m /13.4 × 10^{-3} m = 150 > 10). The Dittus-Boelter correlation with n = 0.4 is appropriate,

$$Nu_D = h_i D_i/k_f = 0.023 Re_D^{0.8} Pr_f^{0.4} = 0.023\times\left(21,673\right)^{0.8}\left(5.2\right)^{0.4} = 130.9$$

Continued...

PROBLEM 11.40 (Cont.)

$$h_i = \frac{k_f}{D_i} Nu_D = \frac{0.620\,W/m\cdot K}{13.4\times10^{-3}m}\times130.9 = 6057\,W/m^2\cdot K.$$

Substituting numerical values into Eq. (1), the overall heat transfer coefficient is

$$U_o = \left[\frac{1}{13,500\,W/m^2\cdot K} + \frac{\left(15.9\times10^{-3}m\right)/2}{114\,W/m\cdot K}\ell n\frac{15.9}{13.4} + \frac{15.9}{13.4}\times\frac{1}{6057\,W/m^2\cdot K}\right]^{-1}$$

$$U_o = \left[7.407\times10^{-5} + 1.193\times10^{-5} + 19.590\times10^{-5}\right]^{-1} W/m^2\cdot K = 3549\,W/m^2\cdot K.$$ <

To find the outlet temperature of the water, we'll employ the ε – NTU method. From an energy balance on the cold fluid,

$$T_{c,o} = T_{c,i} + q/C_c \quad (3)$$

where the heat rate can be expressed as

$$q = \varepsilon q_{max} \qquad q_{max} = C_{min}\left(T_{h,i} - T_{h,o}\right). \quad (4,5)$$

The minimum capacity rate is that of the cold water since $C_h \to \infty$. Evaluating, find

$$C_{min} = C_c = \left(\dot{m}c_p\right)_c = 22.8\,kg/s\times4178\,J/kg\cdot K = 95,270\,W/K.$$

where

$$\dot{m}_c = \left(\rho A u_m\right)N = 995.0\,kg/m^3\times\pi/4\left(0.0134m\right)^2\times1.25\,m/s\times130 = 22.8\,kg/s$$

To determine ε, use Fig. 11.12 (one shell and any multiple of tube passes) with $C_r = 0$ and

$$NTU = \frac{U_o A_o}{C_{min}} = \frac{3549\,W/m^2\cdot K\left(\pi 0.0159m\times2m\times130\times2\right)}{95,270\,W/K} = 0.968$$

where 130 and 2 represent the number of tubes and passes, respectively, to find ε ≈ 0.62. Combining Eqs. (4) and (5) into Eq. (3), find

$$T_{c,o} = T_{c,i} + \varepsilon C_{min}\left(T_{h,i} - T_{c,i}\right)/C_c = 20^\circ C + 0.62\left(327 - 293\right)K = 41.1^\circ C.$$ <

The condensation rate of the steam is given by

$$\dot{m}_h = q/h_{fg} \quad (6)$$

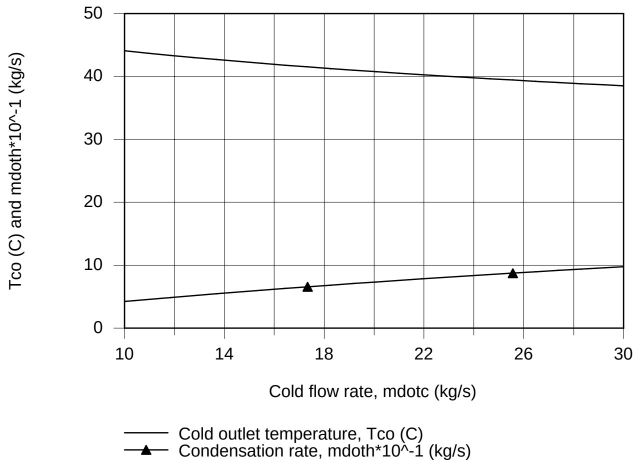
where the heat rate can be determined from Eq. (3) with $T_{c,o}$,

$$\dot{m}_h = C_c\left(T_{c,o} - T_{c,i}\right)/h_{fg} = 95,270\,W/K\left(41.1 - 20.0\right)K/2373\times10^3\,J/kg\cdot K = 0.85\,kg/s.$$ <

(b) Using the *IHT Heat Exchanger Tool, All Exchangers, $C_r = 0$*, and the *Properties Tool* for *Water*, a model was developed and the cold outlet temperature and condensation rate were computed and plotted.

Continued...

PROBLEM 11.40 (Cont.)



With increasing cold flow rate, the cold outlet temperature decreases as expected. The condensation rate increases with increasing cold flow rate. Note that $T_{c,o}$ and $\dot{m}_h$ are nearly linear with the cold flow rate.

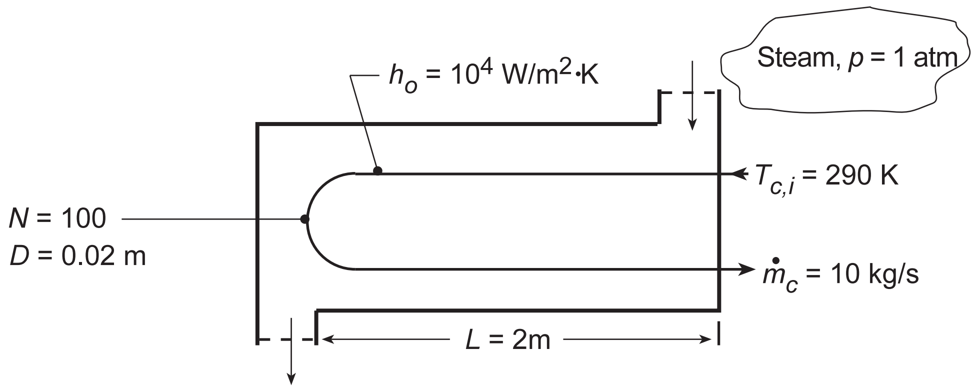
COMMENTS: For part (a) analysis, note that the assumption $T_{c,o} \approx 44°C$ used for evaluation of the cold fluid properties was reasonable. Using the IHT model of part (b), we found $T_{c,o} = 40.2°C$ and $\dot{m}_h$ = 0.812 kg /s.

PROBLEM 11.41

KNOWN: Shell-and-tube (one shell, two tube passes) heat exchanger design. Water flow rate and inlet temperature. Steam pressure and convection coefficient.

FIND: (a) Water outlet temperature, $T_{c,o}$; (b) $T_{c,o}$ as a function of flow rate, $\dot{m}_c$, for the range, $5 \leq \dot{m}_c \leq 20$ kg/s, with all other conditions remaining the same, but accounting for changes in the overall coefficient, U; and (c) Plot $T_{c,o}$ on the same graph considering fouling factors of $R''_f = 0.0002$ and $0.0005\ m^2\cdot K/W$

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible wall conduction and fouling resistances, (3) Constant properties.

PROPERTIES: *Table A-6*, Sat. water (p = 1.0133 bar): $T_{sat} = T = 373.1$ K; ($\bar{T}_c \approx 320$ K): $c_p = 4180$ J/kg·K, $\mu = 577 \times 10^{-6}\ N\cdot s/m^2$, k = 0.640 W/m·K, Pr = 3.77.

ANALYSIS: Using the NTU-effectiveness method, calculate U by finding h_i. With

$$Re_D = 4\dot{m}/\pi D\mu = \left[4(10\,kg/s)/100\right] \Big/ \left[\pi(0.02m)\left(577\times10^{-6}\ N\cdot s/m^2\right)\right] = 11,033 \quad (1)$$

and using the Dittus-Boelter correlation,

$$Nu_D = 0.023 Re_D^{4/5} Pr^{0.4} = 0.023(11,033)^{4/5}(3.77)^{0.4} = 67.05 \quad (2)$$

$$h_i = (k/D)Nu_D = (0.640\,W/m\cdot K/0.02m)\,67.05 = 2146\,W/m^2\cdot K.$$

From Eq. 11.5

$$1/U = 1/h_i + 1/h_o = \left[(1/10,000) + (1/2146)\right] m^2\cdot K/W = 5.66\times10^{-4}\,m^2\cdot K/W \quad (3)$$

$$U = 1766\,W/m^2\cdot K.$$

The heat transfer surface area, capacity rates and NTU are

$$A = N(\pi D)2L = 100(\pi 0.02m)2\times 2m = 25.1m^2$$

$$C_{min} = C_c = 10\,kg/s(4180\,J/kg\cdot K) = 41,800\,W/K$$

$$NTU = UA/C_{min} = 1766\,W/m^2\cdot K\times 25.1\,m^2/41,800\,W/K = 1.06$$

From Eq. 11.35a

Continued...

PROBLEM 11.41 (Cont.)

$$\varepsilon = 1 - \exp(-NTU) = 1 - \exp(-1.06) = 0.654 \, . \qquad (4)$$

With

$$q_{max} = C_{min}\left(T_{h,i} - T_{c,i}\right) = 41,800\,W/K\left(373.15 - 290\right)K = 3.48 \times 10^6\,W \qquad (5)$$

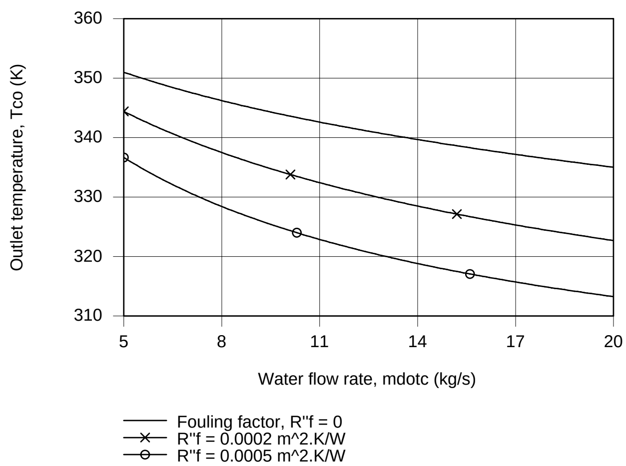
$$q = \varepsilon q_{max} = 0.654\left(3.48 \times 10^6\,W\right) = 2.27 \times 10^6\,W$$

find

$$T_{c,o} = T_{c,i} + \left(q/C_c\right) = 290\,K + \left(2.27 \times 10^6\,W/41,800\,W/K\right) = 344.4\,K \, . \qquad (6) <$$

(b,c) Using the *IHT Heat Exchanger Tool, All Exchangers, $C_r = 0$,* the *Properties Tool* for *Water* and the *Correlation Tool, Forced Convection, Internal Flow,* for *Turbulent, fully developed conditions*, a model was developed following the foregoing analysis to compute and plot the outlet temperature $T_{c,o}$ as a function of the cold fluid flow rate, $\dot{m}_c$. The expression for the overall coefficient, Eq.(1), was modified to include the fouling factor,

$$1/U = 1/h_i + R''_f + 1/h_o \, .$$



The effect of increasing the cold flow rate is to decrease the outlet temperature. The effect of the fouling resistance is to decrease the outlet temperature as well.

COMMENTS: (1) For the part (a) analysis, $\overline{T}_c = 317$ K and the initial guess of 320 K was reasonably good.

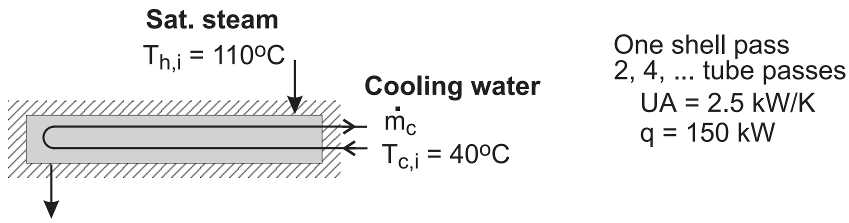
(2) In the anlysis of parts (b,c), $Re_{D,c}$ is as low as 4880, below the turbulent range (10,000) and above the laminar range (2300). We chose to treat the flow as turbulent.

PROBLEM 11.42

KNOWN: Saturated steam at 110°C condensing in a shell and tube heat exchanger (one shell pass, 2, 4, tube passes) with a UA value of 2.5 kW/K; cooling water enters at 40°C.

FIND: Cooling water flow rate required to maintain a heat rate of 150 kW; and (b) Calculate and plot the water flow rate required to provide heat rates over the range 130 to 160 kW, assuming that UA is independent of flow rate. Comment on the validity of the assumption.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) UA independent of flow rate, and (3) Constant properties.

PROPERTIES: *Table A-6*, Water ($T_{m,c} = (T_{c,i} + T_{c,o})/2$ = 49.5°C = 322.5 K): $c_{p,c}$ = 4181 J/kg·K.

ANALYSIS: (a) For the shell-tube heat exchanger with any multiple of two-tube passes, from Eq. 11.35a with $C_r = 0$, using Eqs. 11.19 and 11.22,

$$\varepsilon = 1 - \exp(-NTU) \qquad NTU = UA / C_{min} \tag{1,2}$$

$$\varepsilon = q / q_{max} \qquad q_{max} = C_c \left(T_{h,i} - T_{c,i}\right) \tag{3,4}$$

By combining the equations with $C_{min} = C_c = \dot{m}_c\, c_{p,c}$,

$$\frac{q}{\dot{m}_c\, c_{p,c}\left(T_{h,i} - T_{c,i}\right)} = 1 - \exp\left(-\frac{UA}{\dot{m}_c\, c_{p,c}}\right) \tag{5}$$

Substituting numerical values, and solving using *IHT* find

$$\dot{m}_c = 1.89\ \text{kg/s}$$ <

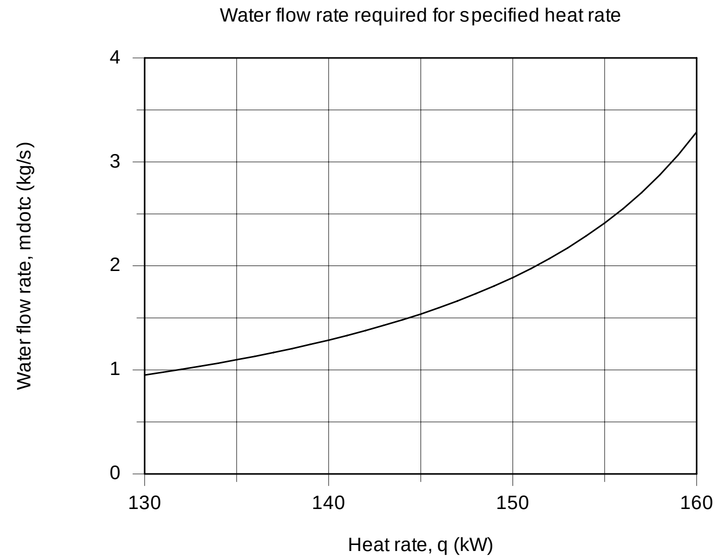
The specific heat of the cold fluid, $c_{p,c}$, is evaluated at the average of the mean inlet and outlet temperatures, $T_{m,c} = (T_{c,i} + T_{c,o})/2$, with $T_{c,o}$ determined from the energy balance equation,

$$q = \dot{m}\, c_{p,c}\left(T_{c,o} - T_{c,i}\right). \tag{6}$$

(b) Solving the above system of equations in the *IHT* workspace, the graph below illustrates the water flow rate required to provide a range of heat rates.

Continued …

PROBLEM 11.42 (Cont.)



COMMENTS: (1) The assumption that UA is constant with flow rate is a poor one. Because the heat transfer coefficient for condensation is so high, the overall coefficient is controlled by the water-side coefficient. Presuming the flow is turbulent, from the Dittus-Boelter correlation, we'd expect $U \propto m_c^{0.8}$. Over the range of the graph above, U will vary by approximately a factor of $(3.5/1)^{0.8}$ = 2.7.

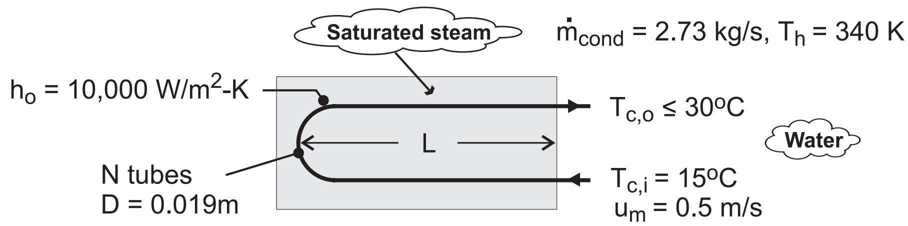
(2) If we considered UA to vary with the cold water flow rate as just described, make a sketch of $\dot{m}_c$ vs. q and compare it to the graph above.

PROBLEM 11.43

KNOWN: Temperature, convection coefficient and condensation rate of saturated steam. Tube diameter for shell-and-tube heat exchanger with one shell pass and two tube passes. Velocity and inlet and maximum allowable exit temperatures of cooling water.

FIND: (a) Minimum number of tubes and tube length per pass, (b) Effect of tube-side heat transfer enhancement on tube length.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat exchange with surroundings, (2) Negligible tube wall conduction and fouling resistance, (3) Constant properties, (4) Fully developed internal flow throughout.

PROPERTIES: *Table A-6*, Sat. water (340 K): $h_{fg} = 2.342 \times 10^6$ J/kg; Sat. water $\left(\overline{T}_c = 22.5°C \approx 295\text{ K}\right)$: ρ=998 kg/m^3, c_p = 4181 J/kg·K, $\mu = 959 \times 10^{-6}$ N·s/m^2, k = 0.606 W/m·K, Pr = 6.62.

ANALYSIS: (a) The required heat rate and the maximum allowable temperature rise of the water determine the minimum allowable flow rate. That is, with

$$q = q_{cond} = \dot{m}_{cond} h_{fg} = 2.73\text{ kg/s} \times 2.342 \times 10^6\text{ J/kg} = 6.39 \times 10^6\text{ W}$$

$$\dot{m}_{c,min} = \frac{q}{c_{p,c}\left(T_{c,o} - T_{c,i}\right)} = \frac{6.39 \times 10^6\text{ W}}{4181\text{ J/kg}\cdot\text{K}\left(15°C\right)} = 101.9\text{ kg/s}$$

With a specified flow rate per tube of $\dot{m}_{c,1} = \rho u_m \pi D^2/4$ = 998 kg/m^3 × 0.5 m/s × π (0.019m)^2/4 = 0.141 kg/s, the minimum number of tubes is

$$N_{min} = \frac{\dot{m}_{c,min}}{\dot{m}_{c,1}} = \frac{101.9\text{ kg/s}}{0.141\text{ kg/s}} = 720$$ <

To determine the corresponding tube length, we must first find the required heat transfer surface area. With $Re_D = \rho u_m D/\mu$ = 998 kg/m^3 (0.5 m/s) 0.019m/959 × 10^{-6} N·s/m^2 = 9,886, the Dittus-Boelter equation yields

$$\overline{h}_i = (k/D)0.023\, Re_D^{4/5}\, Pr^{0.4} = (0.606\text{ W/m}\cdot\text{K}/0.019\text{m})0.023(9886)^{4/5}(6.62)^{0.4} = 2454\text{ W/m}^2\cdot\text{K}$$

Continued …

PROBLEM 11.43 (Cont.)

Hence, $U = \left[\bar{h}_i^{-1} + h_o^{-1}\right]^{-1} = 1970\ \text{W/m}^2\cdot\text{K}$

With $C_r = 0$, $C_{min} = \dot{m}_c\ c_{p,c}$ = 101.9 kg/s × 4181 J/kg·K = 4.26 × 10^5 W/K, $q_{max} = C_{min}\,(T_{h,i} - T_{c,i})$ = 4.26 × 10^5 W/K (340 – 288) K = 2.215 × 10^7 W and ε = q/q_{max} = 0.289, Eq. 11.35b yields NTU = – ln (1 – ε) = – ln (1 – 0.289) = 0.341. Hence the tube length per pass is

$$L = \frac{A}{2N\pi D} = \frac{NTU \times C_{min}}{2N\pi DU} = \frac{0.341 \times 4.26 \times 10^5\ \text{W/K}}{2 \times 720 \times \pi(0.019\text{m})1970\ \text{W/m}^2\cdot\text{K}} = 0.858\text{m}$$ <

(b) If the tube-side convection coefficient is doubled, $\bar{h}_i = 4908\ \text{W/m}^2\cdot\text{K}$ and U = 3292 W/m^2·K. Since q, C_r, C_{min}, q_{max} and hence ε are unchanged, the number of transfer units is still NTU = 0.341. Hence, the tube length per pass is now

$$L = \frac{NTU \times C_{min}}{2N\pi DU} = \frac{0.341 \times 4.26 \times 10^5\ \text{W/K}}{2 \times 720 \times \pi(0.019\text{m})3292\ \text{W/m}^2\cdot\text{K}} = 0.513\text{m}$$ <

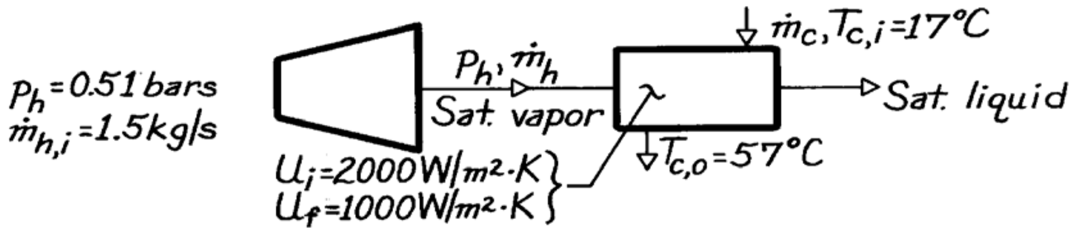
COMMENTS: Heat transfer enhancement for the flow with the smallest convection coefficient significantly reduces the size of the heat exchanger.

PROBLEM 11.44

KNOWN: Pressure and initial flow rate of water vapor. Water inlet and outlet temperatures. Initial and final overall heat transfer coefficients.

FIND: (a) Surface area for initial U and water flow rate, (b) Vapor flow rate for final U.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible wall conduction resistance.

PROPERTIES: *Table A-6*, Sat. water ($\overline{T}_c$ = 310 K): $c_{p,c}$ = 4178 J/kg·K; (p = 0.51 bars): T_{sat} = 355 K, h_{fg} = 2304 kJ/kg.

ANALYSIS: (a) The required heat transfer rate is

$$q = \dot{m}_h h_{fg} = 1.5 \text{ kg/s}\left(2.304\times10^6 \text{ J/kg}\right) = 3.46\times10^6 \text{ W}$$

and the corresponding heat capacity rate for the water is

$$C_c = C_{min} = q/\left(T_{c,o} - T_{c,i}\right) = 3.46\times10^6 \text{ W}/40 \text{ K} = 86,400 \text{ W/K}.$$

Hence, $$\varepsilon = q/\left(C_{min}\left[T_{h,i} - T_{c,i}\right]\right) = 3.46\times10^6 \text{ W}/86,400 \text{ W/K}\left(65 \text{ K}\right) = 0.62.$$

Since $C_{min}/C_{max} = 0$, Eq. 11.35b yields

$$NTU = -\ln\left(1-\varepsilon\right) = -\ln\left(1-0.62\right) = 0.97$$

and $$A = NTU\left(C_{min}/U\right) = 0.97\left(86,400 \text{ W/K}/2000 \text{ W/m}^2\cdot\text{K}\right) = 41.9 \text{ m}^2$$ <

$$\dot{m}_c = C_c/c_{p,c} = 86,400 \text{ W/K}/4178 \text{ J/kg}\cdot\text{K} = 20.7 \text{ kg/s}.$$ <

(b) Using the final overall heat transfer coefficient, find

$$NTU = UA/C_{min} = 1000 \text{ W/m}^2\cdot\text{K}\left(41.9 \text{ m}^2\right)/86,400 \text{ W/K} = 0.485.$$

Since $C_{min}/C_{max} = 0$, Eq. 11.35a yields

$$\varepsilon = 1 - \exp\left(-NTU\right) = 1 - \exp\left(-0.485\right) = 0.384.$$

Hence, $$q = \varepsilon C_{min}\left(T_{h,i} - T_{c,i}\right) = 0.384\left(86,400 \text{ W/K}\right)65 \text{ K} = 2.16\times10^6 \text{ W}$$

$$\dot{m}_h = q/h_{fg} = 2.16\times10^6 \text{ W}/2.304\times10^6 \text{ J/kg} = 0.936 \text{ kg/s}.$$ <

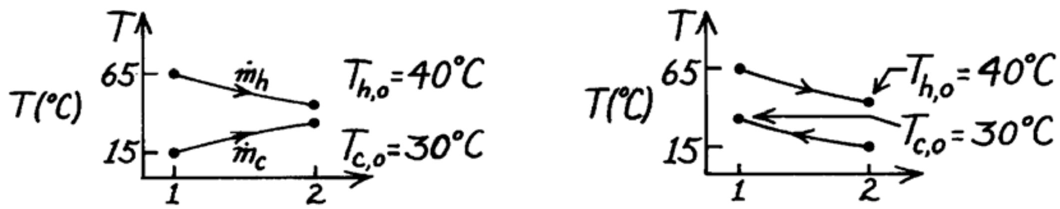
COMMENTS: The significant reduction (38%) in $\dot{m}_h$ represents a significant loss in turbine power. Periodic cleaning of condenser surfaces should be employed to minimize the adverse effects of fouling.

PROBLEM 11.45

KNOWN: Two-fluid heat exchanger with prescribed inlet and outlet temperatures of the two fluids.

FIND: (a) Whether exchanger is operating in parallel or counter flow, (b) Effectiveness of the exchanger when $C_c = C_{min}$.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to the surroundings.

ANALYSIS: (a) To determine whether operation is PF or CF, consider the temperature distributions. From the distributions we note that PF or CF operation is possible.

(b) The effectiveness of the exchanger follows from Eq. 11.19,

$$\varepsilon = q / q_{max} \tag{1}$$

where from Eq. 11.18,

$$q_{max} = C_{min}\left(T_{h,i} - T_{c,i}\right). \tag{2}$$

Since the hot fluid undergoes a larger temperature change than the cold fluid, $C_{min} = C_h$ and performing an energy balance on the cold fluid, Eq. (1) with Eq. (2) becomes

$$\varepsilon = C_h\left(T_{h,i} - T_{h,o}\right)/C_{min}\left(T_{h,i} - T_{c,i}\right) = \left(T_{h,i} - T_{h,o}\right)/\left(T_{h,i} - T_{c,i}\right)$$

$$\varepsilon = (65 - 40)°C/(65 - 15)°C = 0.50.$$ <

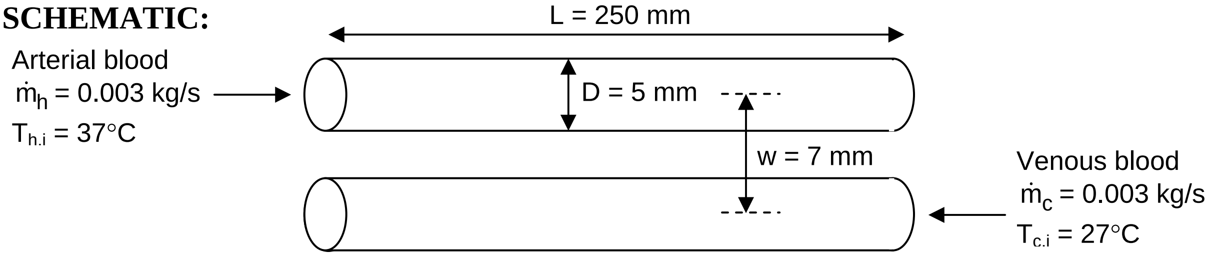
COMMENTS: If $T_{c,o}$ were greater than $T_{h,o}$, parallel-flow operation would not be possible.

PROBLEM 11.46

KNOWN: Length and diameters of vein and artery running from chest to base of skull. Separation distance. Inlet temperatures and mass flow rates of blood flowing in opposite directions in vein and artery. Thermal conductivity of surrounding tissue.

FIND: Outlet temperature of arterial blood. How much higher the arterial blood inlet temperature can be if blood flow rate is halved and exit temperature must still be below 37°C.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties and steady-state conditions, (2) Blood properties are those of water, (3) All heat leaving artery enters vein, (4) Vessel walls have negligible thermal resistance. (4) Properties of both flows can be evaluated at 305 K, (5) Uniform wall temperature correlation is appropriate, (5) Flows are hydrodynamically and thermally fully developed.

PROPERTIES: *Table A.6*, water: (T = 305 K): c_p = 4178 J/kg·K, μ = 769 × 10^{-6} N·s/m^2, k = 0.620 W/m·K,. Tissue (given): k_t = 0.5 W/m·K.

ANALYSIS: The pair of vessels can be seen as a counterflow heat exchanger. We begin by evaluating the heat transfer coefficients, which will be the same in both vessels. From Eq. 8.6,

$$Re_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 0.003 \text{ kg/s}}{\pi (0.005 \text{ m}) 769 \times 10^{-6} \text{ N} \cdot \text{s/m}^2} = 993$$

Hence the flow is laminar and Nu_D = 3.66. Therefore,

$$h_c = \frac{k}{D} Nu_D = \frac{0.620 \text{ W/m} \cdot \text{K}}{0.005 \text{ m}} 3.66 = 454 \text{ W/m}^2 \cdot \text{K}$$

With the assumption that all the heat that leaves the artery enters the vein, conduction between the two cylinders can be represented by the shape factor in Table 4.1, case 4. Then

$$R_{cond} = \frac{1}{Sk_t} = \frac{\cosh^{-1}\left(\dfrac{4w^2 - 2D^2}{2D^2}\right)}{2\pi L k_t} = \frac{\cosh^{-1}\left(\dfrac{4(0.007 \text{ m})^2 - 2(0.005 \text{ m})^2}{2(0.005 \text{ m})^2}\right)}{2\pi \times 0.250 \text{ m} \times 0.5 \text{ W/m} \cdot \text{K}} = 2.208 \text{ K/W}$$

Then we can find UA for heat transfer between the two blood flows.

Continued…

PROBLEM 11.46 (Cont.)

$$UA^{-1} = \frac{1}{h\pi DL} + R_{cond} + \frac{1}{h\pi DL}$$

$$= 2\frac{1}{454\ W/m^2 \cdot K \times \pi \times 0.005\ m \times 0.25\ m} + 2.208\ K/W = 3.33\ K/W$$

$$UA = 0.300\ W/K$$

Now using the ε-NTU method, with equal heat capacity rates for the two flows,

$$NTU = \frac{UA}{\dot{m}c_p} = \frac{0.300\ W/K}{0.003\ kg/s \times 4178\ J/kg \cdot K} = 0.0240, \qquad C_r = 1$$

From Eq. 11.29b, with $C_r = 1$ and using Eq. 11.20

$$\varepsilon = \frac{NTU}{NTU+1} = \frac{0.024}{0.024+1} = 0.0234 = \frac{T_{h,i} - T_{h,o}}{T_{h,i} - T_{c,i}}$$

Thus

$$T_{h,o} = T_{h,i} - \varepsilon(T_{h,i} - T_{c,i}) = 37°C - 0.0234(37°C - 27°C)$$

$$T_{h,o} = 36.8°C$$ <

If the mass flow rate is halved, the flows remain laminar and the heat transfer coefficients are unchanged, as is UA. Thus, NTU doubles, i.e. NTU = 0.0480, and ε = 0.048/1.048 = 0.0458. Thus

$$\varepsilon = \frac{T_{h,i} - T_{h,o}}{T_{h,i} - T_{c,i}}, \qquad T_{h,i} = \frac{T_{h,o} - \varepsilon T_{c,i}}{1-\varepsilon} = \frac{37°C - 0.0458 \times 27°C}{1 - 0.0458} = 37.5°C$$ <

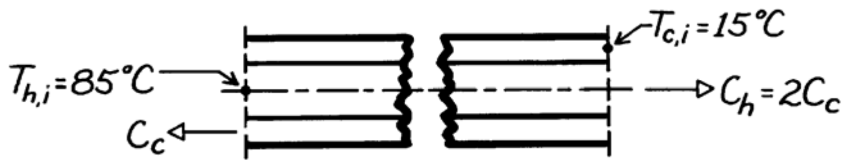
COMMENTS: (1) The assumed mean temperature is not accurate, but this is not worth correcting since the properties of blood are not those of water. (2) With $x_{fd,h} = 0.05 Re_D Pr D = 1.3$ m, the flow is not fully developed thermally. The actual heat transfer coefficients would be greater and there would be a larger temperature change between inlet and outlet. (3) Heat transfer from the artery to the cooler neck surface can have a comparable or somewhat larger effect on cooling the arterial blood.

PROBLEM 11.47

KNOWN: A *very long*, concentric tube heat exchanger having hot and cold water inlet temperatures, 85°C and 15°C, respectively; flow rate of hot water is twice that of the cold water.

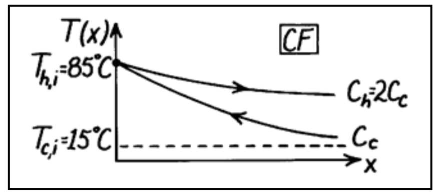
FIND: Outlet temperatures for counterflow and parallel flow operation.

SCHEMATIC:



ASSUMPTIONS: (1) Equivalent hot and cold water specific heats, (2) No heat loss to surroundings.

ANALYSIS: The heat rate for a concentric tube heat exchanger with very large surface area operating in the *counterflow* mode is



$$q = q_{max} = C_{min}\left(T_{h,i} - T_{c,i}\right)$$

where $C_{min} = C_c$. From an energy balance on the hot fluid,

$$q = C_h\left(T_{h,i} - T_{h,o}\right).$$

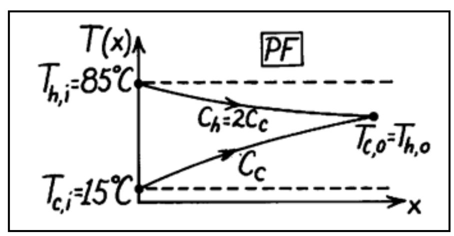
Combining the above relations and rearranging, find

$$T_{h,o} = -\frac{C_{min}}{C_h}\left(T_{h,i} - T_{c,i}\right) + T_{h,i} = -\frac{C_c}{C_h}\left(T_{h,i} - T_{c,i}\right) + T_{h,i}.$$

Substituting numerical values,

$$T_{h,o} = -\frac{1}{2}(85 - 15)°C + 85°C = 50°C. \qquad <$$

For *parallel flow* operation, the hot and cold outlet temperatures will be equal; that is, $T_{c,o} = T_{h,o}$. Hence,



$$C_c\left(T_{c,o} - T_{c,i}\right) = C_h\left(T_{h,i} - T_{h,o}\right).$$

Setting $T_{c,o} = T_{h,o}$ and rearranging,

$$T_{h,o} = \left(T_{h,i} + \frac{C_c}{C_h}T_{c,i}\right) \Big/ \left(1 + \frac{C_c}{C_h}\right)$$

$$T_{h,o} = \left(85 + \frac{1}{2}\times 15\right)°C \Big/ \left(1 + \frac{1}{2}\right) = 61.7°C. \qquad <$$

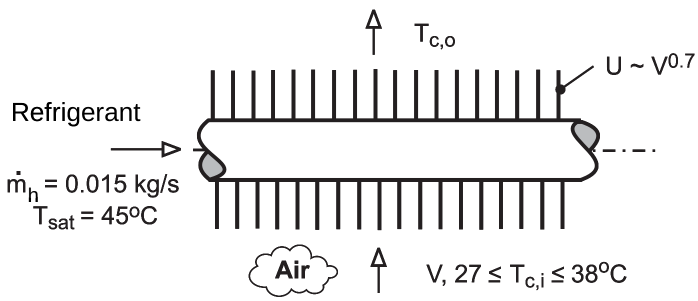
COMMENTS: Note that while ε = 1 for CF operation, for PF operation find $\varepsilon = q/q_{max} = 0.67$.

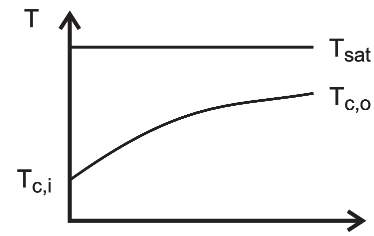
PROBLEM 11.48

KNOWN: Saturation temperature and condensation rate of refrigerant. Frontal area of condenser and dependence of overall coefficient on inlet velocity. Operational range of the air inlet temperature.

FIND: (a) Required heat exchanger area and air outlet temperature for prescribed air inlet velocity and temperature, (b) Variation in air velocity needed to achieve prescribed condensation rate.

SCHEMATIC:





ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties.

PROPERTIES: Given (Refrigerant): $h_{fg} = 1.35 \times 10^5$ J/kg. *Table A-4,* air ($T_{c,i}$ = 303 K): $\rho_c = 1.17$ kg/m^3, $c_{p,c}$ = 1007 J/kg·K.

ANALYSIS: (a) With $\dot{m}_c = \rho_c V A_{fr} = 1.17\,\text{kg/m}^3 \times 2\,\text{m/s} \times 0.25\,\text{m}^2 = 0.585\,\text{kg/s}$, $C_{min} = \dot{m}_c c_{p,c} = 589\,\text{W/K}$. Hence, from Eq. 11.18, with $T_{h,i} = T_{sat}$,

$$q_{max} = C_{min}\left(T_{h,i} - T_{c,i}\right) = 589\,\text{W/K}\left(45 - 30\right)\text{K} = 8,836\,\text{W}$$

and with $q = \dot{m}_h h_{fg} = 0.015\,\text{kg/s} \times 1.35 \times 10^5\,\text{J/kg} = 2025\,\text{W}$

$$\varepsilon = \frac{q}{q_{max}} = \frac{2025}{8836} = 0.229$$

From Eq. 11.35b we then obtain (for $C_r = 0$),

$$A = \frac{C_{min}}{U}\text{NTU} = -\frac{C_{min}}{U}\ln\left(1-\varepsilon\right) = -\frac{589\,\text{W/K}}{50\,\text{W/m}^2\cdot\text{K}}\ln\left(0.771\right) = 3.067\,\text{m}^2 \qquad <$$

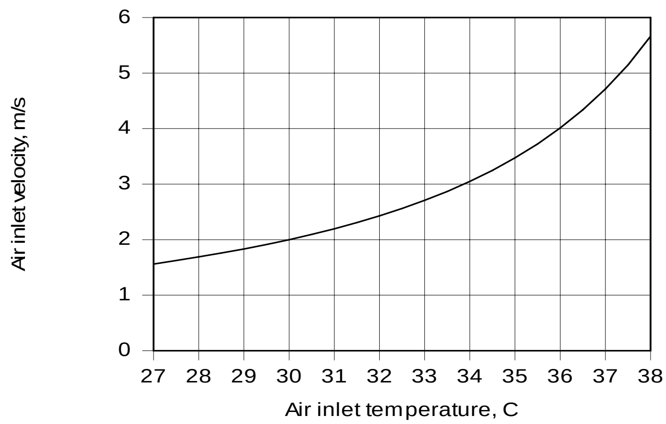
With $q = C_{min}(T_{c,o} - T_{c,i})$, the outlet temperature is

$$T_{c,o} = T_{c,i} + \frac{q}{C_{min}} = 30°\text{C} + \frac{2025\,\text{W}}{589\,\text{W/K}} = 33.4°\text{C} \qquad <$$

(b) With q = 2025 W, A = 3.06 m^2 and U = 50 W/m^2·K $(V/2)^{0.7}$, the foregoing equations may be solved to obtain V as a function of $T_{c,i}$.

Continued…

PROBLEM 11.48 (Cont.)



With increasing $T_{c,i}$, the driving potential for heat transfer, $T_{h,i} - T_{c,i}$, decreases and a larger value of U, and hence V, is needed to maintain the required heat rate. For $27 \le T_{c,i} \le 38°C$, $1.56 \le V \le 5.66$ m/s and $42.1 \le U \le 103.6\ W/m^2 \cdot K$.

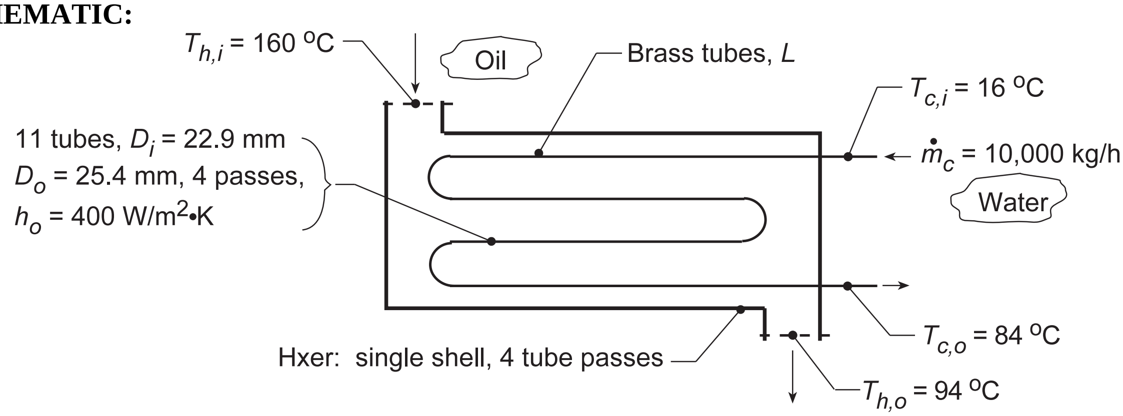
COMMENTS: The variation of V with $T_{c,i}$ is nonlinear, and, in principle, $V \to \infty$ as $T_{c,i} \to T_{sat}$.

PROBLEM 11.49

KNOWN: Conditions of oil and water for heat exchanger, one shell with 4 tube passes.

FIND: Length of exchanger tubes per pass, L; and (b) Compute and plot the effectiveness, ε, fluid outlet temperatures, $T_{h,o}$ and $T_{c,o}$, and water-side convection coefficient, h_c, as a function of the water flow rate for $5000 \le \dot{m}_c \le 15{,}000$ kg / h for the tube length found in part (a) with all other conditions remaining the same.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Fully-developed flow in tubes.

PROPERTIES: *Table A-1*, Brass (400 K): k = 137 W/m·K; *Table A-5*, Water (323 K): ρ = 998.1 kg/m^3, k = 0.643 W/m·K, c_p = 4182 J/kg·K, μ = 548 × 10^{-6} N·s/m^2, Pr = 3.56.

ANALYSIS: (a) Using the ε-NTU method,

$$C_c = \dot{m}_c c_c = \frac{10{,}000 \text{ kg/h}}{3600 \text{ s/h}} \times 4182 \text{ J/kg}\cdot\text{K} = 11{,}620 \text{ W/K}$$

From an energy balance on the water, $q = C_c(T_{c,o} - T_{c,i}) = 11{,}620 \text{ W/K}(84-16)°\text{C} = 789{,}900 \text{ W}$

From an energy balance on the oil, $C_h = q/(T_{h,i} - T_{h,o}) = 789{,}900 \text{ W}/(160-94)°\text{C} = 11{,}970 \text{ W/K}$

Thus, $C_r = C_{min}/C_{max} = 0.971$, $q_{max} = C_{min}(T_{h,i} - T_{c,i}) = 11{,}620$ W/K(160 – 16)°C = 1.673 × 10^6 W, and ε = q/q_{max} = 0.472. From Eqs. 11.30c and 11.30b,

$$E = \frac{2/\varepsilon - (1+C_r)}{\left(1+C_r^2\right)^{1/2}} = \frac{2/0.472 - (1+0.971)}{\left(1+0.971^2\right)^{1/2}} = 1.625$$

$$NTU = -\left(1+C_r^2\right)^{-1/2} \ln\left(\frac{E-1}{E+1}\right) = -\left(1+0.971^2\right)^{-1/2} \ln\left(\frac{1.625-1}{1.625+1}\right) = 1.03 \qquad (1)$$

and since NTU = UA/C_{min}, A_o = NTU × C_{min}/U_o (2)

Thus we can determine L if we know U_o. From Eq. 11.5,

$$U_o = \left[\frac{1}{h_o} + \frac{r_o}{k}\ell n\frac{r_o}{r_i} + \frac{r_o}{r_i}\frac{1}{h_i}\right]^{-1}$$

where h_i must be estimated from the appropriate correlation. With N = 11, the number of tubes,

Continued...

PROBLEM 11.49 (Cont.)

$$Re_D = \frac{4\dot{m}/N}{\pi D\mu} = \frac{4\times(10,000/3600)\,kg/s/(11)}{\pi\times 22.9\times 10^{-3}\,m\times 548\times 10^{-6}\,N\cdot s/m^2} = 25,621.$$

For fully developed turbulent flow, the Dittus-Boelter correlation with n = 0.4 yields

$$Nu_D = h_i\,D/k = 0.023\,Re_D^{0.8}\,Pr^{0.4} = 0.023(25,621)^{0.8}(3.56)^{0.4} = 128.6$$

$$h_i = Nu_D\,(k/D) = 128.6\times 0.643\,W/m\cdot K/\left(22.9\times 10^{-3}\,m\right) = 3610\,W/m^2\cdot K.$$

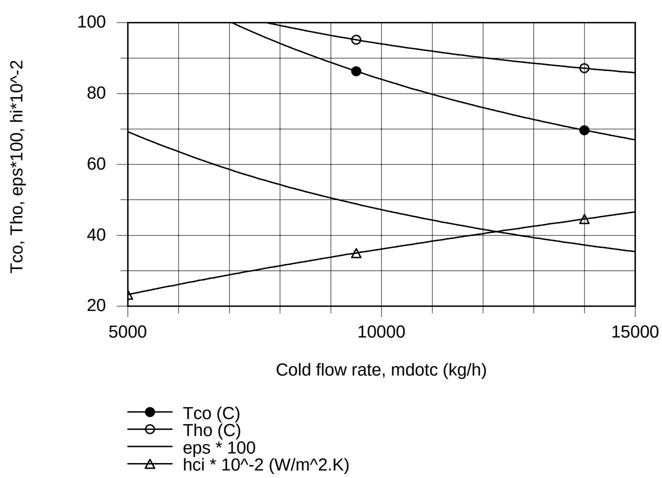
$$U_o = \left[\frac{1}{400\,W/m^2\cdot K} + \frac{25.4\times 10^{-3}\,m}{2\times 137\,W/m\cdot K}\ell n\frac{25.4}{22.9} + \frac{25.4}{22.9}\times\frac{1}{3610\,W/m^2\cdot K}\right]^{-1} = 355\,W/m^2\cdot K.$$

Returning now to Eq. (2), find A_o, then the length,

$$A_o = \pi D_o L \times \text{No. of Passes} \times \text{No. of Tubes} = \pi\times 25.4\times 10^{-3}\,m\times 4\times 11\,L = 3.511\,L$$

$$L = NTU\times C_{min}/3.511U_o = 1.03\times 11,620\,W/K/3.511\,m\times 355\,W/m^2\cdot K = 9.6\,m$$ <

(b) Using the *IHT Heat Exchanger Tool, Shell and Tube, One-shell pass* and *N tube passes,* the *Correlation Tool, Forced Convection, Internal Flow* for *Turbulent, fully developed condition,* and the *Properties Tool* for *Water,* a model was developed using the effectiveness - NTU method to compute and plot $T_{c,o}$, $T_{h,o}$, ε, and h_i as a function of $\dot{m}_c$.



In order to avoid a boiling condition in the cold fluid, the cold flow rate should not be less than 8000 kg/h. As expected, $T_{c,o}$ and $T_{h,o}$ decrease and the internal convection coefficient increases nearly linearly with increasing flow rate. The effectiveness increases with increasing flow rate since the overall convection coefficient is increasing.

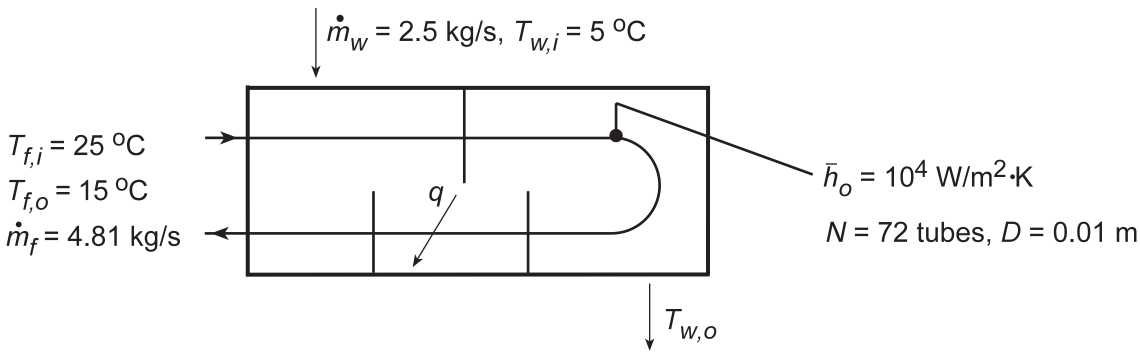
COMMENT: The thermal resistance of the brass tubes is negligible. Since L/D_i = 400, fully-developed conditions are reasonable.

PROBLEM 11.50

KNOWN: Properties and flow rate of computer coolant. Diameter and number of heat exchanger tubes. Heat exchanger transfer rate and inlet temperature of computer coolant. Flow rate, specific heat, inlet temperature, and average convection coefficient of water.

FIND: (a) Tube flow convection coefficient, $\overline{h}_i$, (b) Tube length/pass required to achieve prescribed fluid outlet temperature, (c) Compute and plot the dielectric fluid outlet temperature, $T_{f,o}$, as a function of its flow rate $\dot{m}_f$ for the range $4 \le \dot{m}_f \le 6$ kg/s based upon the length/pass found in part (c), (d) the effect of ±10% change in the water flow rate, $\dot{m}_w$, on $T_{f,o}$ and (e) the effect of ±3°C change in inlet water temperature, $T_{w,i}$, on $T_{f,o}$. For parts (c, d, e), account for any changes in the overall convection coefficient, while all other conditions remain the same.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, fouling and tube wall resistance; (2) Constant properties; (3) Fully developed flow, (4) Convection coefficient on shell side, $\overline{h}_o$, remains constant for all operating conditions.

PROPERTIES: Coolant (given): c_p = 1040 J/kg·K, $\mu = 7.65 \times 10^{-4}$ kg/s·m, k = 0.058 W/m·K, Pr = 14; Water (given): c_p = 4200 J/kg·K.

ANALYSIS: (a) For flow through a single tube,

$$Re_D = \frac{4\dot{m}_{f,t}}{\pi D \mu} = \frac{4(4.81\,kg/s)/72}{\pi(0.01m)7.65\times10^{-4}\,kg/s\cdot m} = 11{,}120$$

and using the Dittus-Boelter correlation, find

$$h_i = (k/D)0.023\,Re_D^{4/5}\,Pr^{0.3} = 0.023\frac{0.058\,W/m\cdot K}{0.01m}(11{,}120)^{4/5}(14)^{0.3} = 508\,W/m^2\cdot K. \quad <$$

(b) Find the capacity ratio

$$C_f = \dot{m}_f c_{p,f} = 4.81\,kg/s(1040\,J/kg\cdot K) = 5002\,W/K = C_{min}$$

$$C_w = \dot{m}_w c_{p,w} = 2.5\,kg/s(4200\,J/kg\cdot K) = 10{,}500\,W/K = C_{max}$$

hence, $C_r = C_{min}/C_{max} = 0.476$ and

$$\varepsilon = \frac{q}{q_{max}} = \frac{C_f\left(T_{f,i} - T_{f,o}\right)}{C_f\left(T_{f,i} - T_{w,i}\right)} = \frac{(25-15)^\circ C}{(25-5)^\circ C} = 0.500.$$

Using Fig. 11.12 with NTU = $(UA/C_{min}) = (UN\pi D2L/C_{min}) \approx 0.85$,

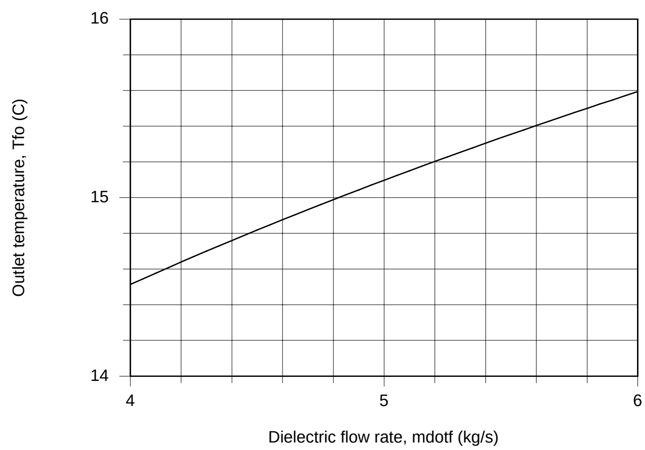
Continued...

PROBLEM 11.50 (Cont.)

$$U = \left(h_i^{-1} + h_o^{-1}\right)^{-1} = \left[(508)^{-1} + \left(10^4\right)^{-1}\right]^{-1} \text{W/m}^2 \cdot \text{K} = 483\,\text{W/m}^2 \cdot \text{K}$$

$$L = 0.85(5002\ \text{W/K}) \Big/ 144\pi\left(483\,\text{W/m}^2 \cdot \text{K}\right) 0.01\text{m} = 1.95\text{m}.$$ <

(c) Using the *IHT Heat Exchanger Tool*, *Shell and Tube*, *One-shell pass and N-tube passes*, and the *Correlation Tool*, *Forced Convection*, *Internal Flow* for *Turbulent*, *fully developed conditions*, a model was developed using the effectiveness-NTU method employed above to compute and plot $T_{f,o}$ as a function of $\dot{m}_f$.



A change in the dielectric fluid flow rate of ±1 kg/s causes approximately ±0.5°C change in its outlet temperature.

(d) Using the above IHT model with the base conditions for part (c), the effect of a ±10% change in the water flow rate from its design value, $\dot{m}_w$ = 2.5 kg/s (2.25 ≤ $\dot{m}_w$ ≤ 2.75 kg/s) causes the dielectric fluid outlet temperature to change as

$$T_{f,o} = 15 \pm 0.14^\circ\text{C}$$ <

(e) Using the IHT model of part (c) with the base case conditions for part (c), the effect of a ±3°C in the water inlet temperature from its design value, $T_{c,i}$ = 5°C (2 ≤ $T_{c,i}$ ≤ 8°C) cause the dielectric fluid outlet temperature to change as

$$T_{f,o} = 15 \pm 1.5^\circ\text{C}$$ <

COMMENTS: (1) For the analyses of part (a), Eq. 11.30b,c yields NTU = 0.85 and q = 50 kW and $T_{w,o}$ = 9.76°C.

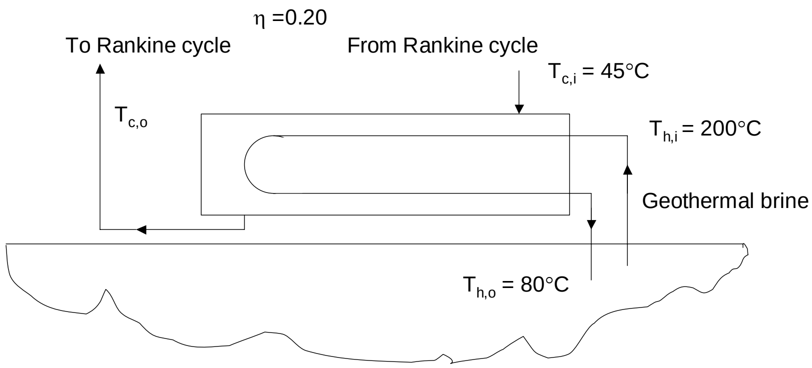
(2) The results of the analyses provide operating performance information on the effect of changes due to dielectric fluid flow rate (±1 kg/s of $\dot{m}_f$), water fluid flow rate (≤ 10% of $\dot{m}_w$) and water inlet temperature (±3°C of $T_{w,i}$) on the dielectric fluid outlet temperature, $T_{f,o}$, supplied to the computer. The greatest effect on $T_{f,o}$, is that by the input water temperature.

PROBLEM 11.51

KNOWN: Inlet temperatures of brine and working fluid in a geothermal power plant heat exchanger. Brine outlet temperature. Electric power generation and thermal efficiency of the geothermal plant. Overall heat transfer coefficients under clean and fouled conditions.

FIND: (a) Brine flow rate, heat exchanger effectiveness, required heat transfer surface area for clean conditions. (b) Electric power generated under fouled conditions**.**

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat transfer between heat exchanger and surroundings, (2) Constant properties.

PROPERTIES: *Table A.6* brine (water), $\overline{T}$ = 140°C: c_p = 4285 J/kg·K.

ANALYSIS: (a) The heat input to the working fluid of the Rankine cycle is supplied from the heat exchanger and is $q = P/\eta = 25 \times 10^6$W/0.20 = 125×10^6 W. Therefore, the required brine flow rate is

$$\dot{m} = q/[c_p(T_{h,i} - T_{h,o})] = 125 \times 10^6 \text{ W}/[4285 \text{ J/kg}\cdot\text{K} \times (200°\text{C} - 80°\text{C})] = 243 \text{ kg/s} \qquad <$$

and $C_{\min} = \dot{m}c_p = 243 \text{ kg/s} \times 4285 \text{ J/kg}\cdot\text{K} = 1.04 \times 10^6 \text{ W/K}$. The required effectiveness is

$$\varepsilon = q/[C_{\min}(T_{h,i} - T_{c,i})] = 125 \times 10^6 \text{W}/[1.04 \times 10^6 \text{ W/K}(200°\text{C} - 45°\text{C})] = 0.775 \qquad <$$

From Fig. 11.12, the NTU is 1.5 and $A = \text{NTU}\cdot C_{\min}/U = (1.5 \times 1.04 \times 10^6 \text{ W/K})/4000 \text{ W/m}^2\cdot\text{K}$
= 390 m^2. <

(b) Under fouled conditions, NTU = $UA/C_{\min}$ = 2000 W/m^2·K × 390 m^2/(1.04 × 10^6 W/m^2·K) = 0.75. From Fig. 11.12, the effectiveness is ε = 0.55. Hence, $q = \varepsilon C_{\min}(T_{h,i} - T_{c,i})$ = 0.55 × 1.04 × 10^6 W/K × (200° - 45°C) = 88.7 × 10^6 W and the electric power generated is $P = \eta q$ = 0.20 × 88.7 × 10^6 W = 17.7 × 10^6 W = 17.7 MW (electric).

<

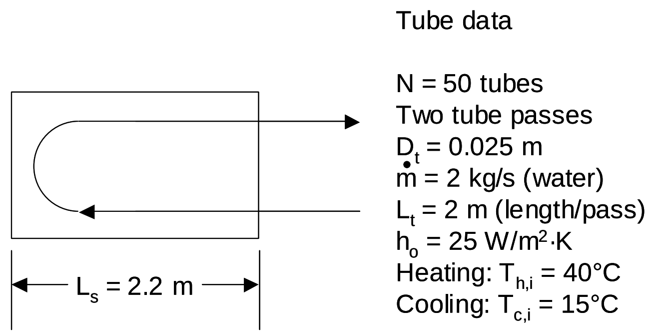
COMMENTS: (1) With this analysis, the electric power output is reduced by [(25 – 17.7)/25] × 100 = 29% due to fouling. (2) The outlet brine temperature as well as the inlet Rankine fluid temperature would also change as a result of fouling. A more accurate estimate of the effect of fouling would require coupling the heat transfer analysis with an analysis of the Rankine cycle and its components. (3) Use of Eq. 11.35b yields NTU = 1.49 in part (a) and ε = 0.525 and P = 17.0 MW in part (b). (4) See Tester et al., "Impact of Enhanced Geothermal Systems on U.S. Energy Supply in the Twenty-First Century," *Philosophical Transactions of the Royal Society A*, Vol. 365, pp. 1057 – 1094, 2007 for a discussion of the geothermal energy potential in the United States.

PROBLEM 11.52

KNOWN: Warm water flow rate and temperature. Cold water flow rate and temperature. Configuration of a shell-and-tube heat exchanger including number of tube passes, number of tubes, and tube length and tube diameter. Outside heat transfer coefficient during melting of the phase change material. Duration of melting.

FIND: (a) Volume of phase change material melted over a 12-hour period. Diameter of shell. (b) Heat transfer rate during solidification of phase change material relative to heat transfer rate in part (a)**.**

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat transfer between heat exchanger and surroundings, (2) Negligible fouling effects, (3) Negligible wall resistance, (4) Negligible convective resistance on inside of tubing, (5) Negligible sensible energy change in phase change material, (6) Constant properties.

PROPERTIES: *n*-octadecane (Problem 8.47): T_f = 27.4°C, h_{sf} = 244 kJ/kg, ρ = 770 kg/m^3. *Table A.6* (water) ($\overline{T}$ = 27°C = 300 K): c_p = 4179 J/kg·K.

ANALYSIS: (a) With no change in the n-octadecane temperature, the minimum heat rate is associated with the water and is $C_{\min} = C_h = \dot{m}c_p$ = 2kg/s × 4179 J/kg·K = 8358 W/K. The heat transfer area is $A = 2N(\pi D_t L_t)$ = 2× 50 × (π × 0.025 m × 2m) = 15.7 m^2. For negligible convective and tube wall resistances and negligible fouling effects, $U = h_o$ = 25 W/m^2·K. Therefore, NTU = $UA/C_{\min}$ = (25 W/m^2·K × 15.7 m^2)/8358 W/K = 0.047. The effectiveness is

$$\varepsilon = 1 - \exp(-\text{NTU}) = 1 - \exp(-0.047) = 0.0458.$$

and the heat transfer rate is

$$q = \varepsilon C_{\min}(T_{h,i} - T_f) = 0.0458 \times 8358\text{W/K} \times (40 - 27.4)°\text{C} = 4823\text{W}$$

Over a 12-hour period, the volume of phase change material that is melted is

$$V_{pcm} = qt/(\rho h_{s,f}) = (4823\text{W} \times 12\text{h} \times 60\,\text{min/h} \times 60\text{s/min})/(770\text{kg/m}^3 \times 244 \times 10^3\text{J/kg}) = 1.11\text{m}^3 \quad <$$

so the total volume of phase change material in the shell is V_{tot} = 1.5×1.11 m^3 = 1.66 m^3 .

Continued…

PROBLEM 11.52 (Cont.)

The total shell volume is occupied by (i) phase change material and (ii) tubing. The tubing volume is

$$V_{tub} = 2NL_t(\pi D_t^2/4) = 2 \times 50 \times 2\text{m} \times (\pi\left[0.025\text{m}\right]^2/4) = 0.098\text{m}^3$$

Therefore, the shell diameter is

$$D_s = \sqrt{\frac{4(V_{tub} + V_{pcm})}{\pi L_s}} = \sqrt{\frac{4(0.098\text{m}^3 + 1.66\text{m}^3)}{\pi \times 2.2\text{m}}} = 1.0 \text{ m}$$ <

(b) The difference between the water temperature and the melting temperature of the phase change material is approximately 12.5 degrees Celsius for both heating and cooling modes. However, during solidification of the phase change material, the solid phase will form adjacent to the cold tube wall. Since the thermal conductivity of the phase change material is small (k = 0.653 W/m·K; Problem 8.47) we expect the conduction resistance posed by the solid material to be very large and will increase as the solidification ensues. Hence, the overall heat transfer coefficient, U, will be much smaller during solidification and the overall heat transfer rate will be much smaller relative to that of part (a). <

COMMENTS: (1) Evaluating water properties at 40°C and for N = 50 tubes, $Re_D = 4\dot{m}/(N\pi D\mu) = 3100$, $Nu_D = 22.2$ and h_i = 560 W/m^2·K using the Dittus-Boelter relationship of Chapter 8. Since $h_i >> h_o$, the assumption of negligible convection resistance on the inside of the tube is reasonable. (2) The outlet temperature of the warm water is

$$T_{h,o} = T_{h,i} - q/C_{\min} = 40°\text{C} - 4823\text{W}/8358\text{K}/\text{W} = 39.4°\text{C}$$

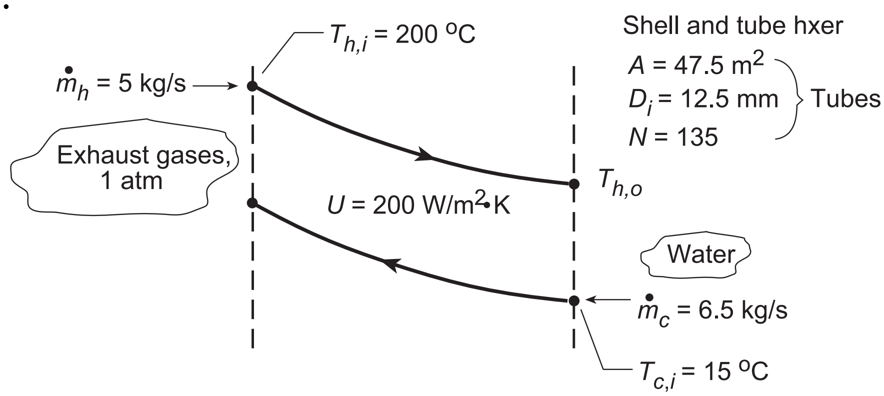
(3) During melting, the value of the overall heat transfer coefficient will vary with time as the distance between the warm tube wall and the solid-liquid interface increases. (4) A detailed analysis would be necessary to determine the time-variation of the overall heat transfer coefficient, particularly when operating in the solidification mode.

PROBLEM 11.53

KNOWN: Shell and tube heat exchanger with 135 tubes (one shell, double pass) of inner diameter 12.5 mm and surface area 47.5 m^2.

FIND: (a) Exchanger gas and water outlet temperatures, (b) Tube heat transfer coefficient, $\overline{h}_i$, assuming fully developed flow, (c) Compute and plot the effectiveness and fluid outlet temperatures, $T_{c,o}$ and $T_{h,o}$ for the water flow rate range $6 \le \dot{m}_c \le 12$ kg/s with all other conditions remaining the same, and (d) Hot gas inlet temperature, $T_{h,i}$, required to supply 10 kg/s of hot water with an outlet temperature of 42°C with all other conditions the same; determine also the effectiveness.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat lost to surroundings, (2) Fully-developed conditions for internal flow of water in tubes, (3) Exhaust gas properties are those of air, and (4) The overall coefficient remains unchanged for the operating conditions examined.

PROPERTIES: *Table A-6*, Water ($\overline{T}_c \approx 300$ K): ρ = 997 kg/m³, c = 4179 J/kg·K, k = 0.613 W/m·K, μ = 855 × 10^{-6} N·s/m², Pr = 5.83; *Table A-4*, Air (1 atm, $\overline{T}_h \approx 400$ K): ρ = 0.8711 kg/m³, c = 1014 J/kg·K.

ANALYSIS: (a) Using the ε-NTU method, first find the capacity rates, $C = \dot{m}c$,

$$C_c = 6.5\,\text{kg/s} \times 4179\,\text{J/kg}\cdot\text{K} = 27{,}164\,\text{W/K} \qquad C_h = 5.0\,\text{kg/s} \times 1014\,\text{J/kg}\cdot\text{K} = 5{,}070\,\text{W/K}.$$

Recognize that $C_h = C_{min}$ and determine

$$\frac{C_{min}}{C_{max}} = \frac{C_h}{C_c} = \frac{5{,}070}{27{,}164} = 0.19 \qquad NTU = \frac{AU}{C_{min}} = \frac{47.5\text{m}^2 \times 200\,\text{W/m}^2\cdot\text{K}}{5{,}070\,\text{W/K}} = 1.87.$$

From Fig. 11.12 for the shell and tube exchanger, find with NTU = 1.87 and C_{min}/C_{max} = 0.19 that ε ≈ 0.78. From the definition of effectiveness,

$$\varepsilon = \frac{q}{q_{max}} = \frac{C_h\left(T_{h,i} - T_{h,o}\right)}{C_{min}\left(T_{h,i} - T_{c,i}\right)} = \frac{200 - T_{h,o}}{200 - 15} = 0.78 \quad \text{or} \quad T_{h,o} = 55.7^\circ\text{C}. \qquad <$$

From energy balances on the two fluids, $C_h (T_{h,i} - T_{h,o}) = C_c (T_{c,o} - T_{c,i})$, find

$$T_{c,o} = T_{c,i} + \left(C_h/C_c\right)\left(T_{h,i} - T_{h,o}\right) = 15^\circ\text{C} + 0.19\left(200 - 55.7\right)^\circ\text{C} = 41.9^\circ\text{C}. \qquad <$$

(b) To estimate $\overline{h}_i$ for the water, find first the Reynolds number. From Eq. 8.6,

Continued...

PROBLEM 11.53 (Cont.)

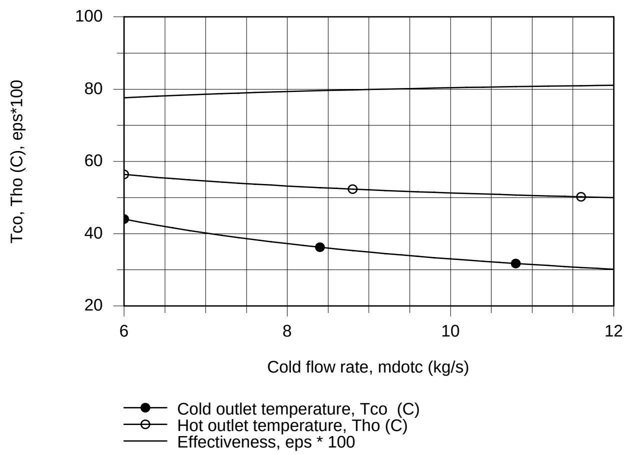
$$Re_{D_i} = \frac{4\dot{m}}{\pi D_i \mu} = \frac{4\dot{m}_c/N}{\pi D_i \mu} = \frac{4 \times 6.5\,kg/s/135}{\pi 12.5 \times 10^{-3}\,m \times 855 \times 10^{-6}\,N/s \cdot m^2} = 5736$$

While the flow is fully developed and turbulent, Re_D = 10,000 such that Dittus-Boelter correlation is not strictly applicable. However, its use allows a first estimate.

$$\overline{Nu}_{D_i} = \bar{h}\, D_i/k = 0.023\, Re_D^{4/5}\, Pr^{0.4} = 0.023(5736)^{4/5}(5.83)^{0.4} = 47.3$$

$$\bar{h}_i = \overline{Nu}_D\, k/D_i = 47.3 \times 0.613\, W/m^2 \cdot K / 12.5 \times 10^{-3}\, m = 2320\, W/m^2 \cdot K\,.$$ <

(c) Using the *IHT Heat Exchanger Tool*, *Shell and Tube*, *One-shell pass and N-tube passes*, and the prescribed properties, a model was developed following the analysis of part (a) to compute and plot ε, $T_{c,o}$, and $T_{h,o}$ for a function of $\dot{m}_c$.



The outlet temperatures decrease nearly linearly with increasing cold fluid flow rate; the decrease in the cold outlet temperature is nearly twice that of the hot fluid. The change in the effectiveness with increasing flow rate is only slightly increased.

(d) Using the above IHT model, the hot inlet temperature $T_{h,i}$, required to provide $\dot{m}_c$ = 10 kg/s with $T_{c,o}$ = 42°C and the effectiveness for this operating condition are

$$T_{h,i} = 74.4^\circ C \qquad \varepsilon = 0.55$$ <

COMMENTS: (1) Check that assumptions for $\bar{T}_h$ and $\bar{T}_c$ used in part (a) for evaluation of the fluid properties are satisfactory as $\bar{T}_h = 400.7\ K$ and $\bar{T}_c = 301.5\ K$.

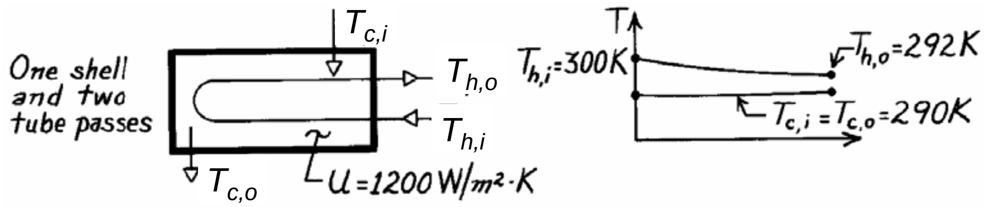
(2) From part (b), with $\bar{h}_i$ = 2320 W/m^2·K and U = 200 W/m^2·K, the shell-side convection coefficient is $\bar{h}_o$ = 219 W/m^2·K. As such, U is controlled by shell-side conditions. Assuming U as a constant in part (c) with changes in $\dot{m}_c$ is therefore reasonable. However, for part (d) with $\dot{m}_h$ doubling, we should expect U to increase.

PROBLEM 11.54

KNOWN: Power output and efficiency of an ocean energy conversion system. Temperatures and overall heat transfer coefficient of shell-and-tube evaporator.

FIND: (a) Evaporator area, (b) Water flow rate.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties.

PROPERTIES: *Table A-6*, Water ($\overline{T}_m$ = 296 K): c_p = 4181 J/kg·K.

ANALYSIS: (a) The efficiency is

$$\eta = \frac{\dot{W}}{q} = \frac{2\,\text{MW}}{q} = 0.03.$$

Hence the required heat transfer rate is $q = \dfrac{2\,\text{MW}}{0.03} = 66.7\,\text{MW}.$

From the ε-NTU method, $C_c \rightarrow \infty$, and $C_h = C_{min}$ can be found from an energy balance on the hot fluid,

$$C_h = q/(T_{h,i} - T_{h,o}) = 66.7 \times 10^6\,\text{W}/(300 - 292)\text{K} = 8.33 \times 10^6\,\text{W/K}$$

Thus $q_{max} = C_{min}(T_{h,i} - T_{c,i}) = 8.33 \times 10^7$ W and $\varepsilon = q/q_{max} = 0.80$. Then, from Eqs. 11.30 b and c,

$$E = \frac{2/\varepsilon - (1 + C_r)}{\left(1 + C_r^2\right)^{1/2}} = \frac{2/0.8 - (1+0)}{1} = 1.50$$

$$\text{NTU} = -\left(1 + C_r^2\right)^{-1/2} \ln\left(\frac{E-1}{E+1}\right) = -\ln\left(\frac{1.5-1}{1.5+1}\right) = 1.61$$

Then, $A = \text{NTU} \times C_{min}/U = 1.61 \times 8.33 \times 10^6\ \text{W/K} / 1200\ \text{W/m}^2\cdot\text{K} = 11{,}200\ \text{m}^2$ <

(b) The water flow rate through the evaporator is

$$\dot{m}_h = \frac{q}{c_{p,h}\left(T_{h,i} - T_{h,o}\right)} = \frac{6.67 \times 10^7\,\text{W}}{4181\,\text{J/kg}\cdot\text{K}\left(300 - 292\right)}$$

$$\dot{m}_h = 1994\ \text{kg/s}.$$ <

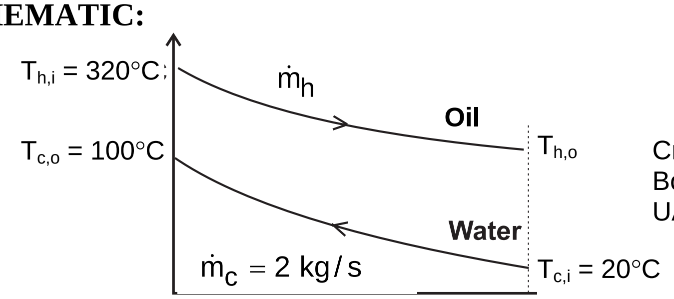
COMMENT: (1) The required heat exchanger size is enormous due to the small temperature differences involved.

PROBLEM 11.55

KNOWN: Single-pass cross-flow heat exchanger with both fluids unmixed. Flow rate and inlet and outlet temperatures of cold water. Inlet temperature of hot exhaust gases. Value of UA.

FIND: Required mass flow rate of exhaust gases.

SCHEMATIC:



Cross flow hx
Both fluids unmixed
UA = 4700 W/K

ASSUMPTIONS: (1) Constant properties and steady-state conditions, (2) Negligible heat loss to surroundings, (3) U independent of mass flow rates.

PROPERTIES: Water (given): $c_{p,c}$ = 4200 J/kg·K. Oil (given): $c_{p,h}$ = 1200 J/kg·K.

ANALYSIS: We use the ε-NTU method, but without knowing the hot mass flow rate or the hot outlet temperature we don't know which fluid is the minimum fluid. We begin by assuming the cold fluid is the minimum fluid: if this leads to a solution for which the cold heat capacity rate is indeed lower than for the hot fluid, this is the correct solution. If it does not lead to a consistent solution, our assumption is incorrect. Thus, we assume

$$C_{min} = \dot{m}_c c_{p,c} = 2\ \text{kg/s} \times 4200\ \text{J/kg}\cdot\text{K} = 8400\ \text{W/K}$$

Thus, NTU = UA/C_{min} = 4700/8400 = 0.560, $q = C_c(T_{c,o} - T_{c,i}) = 6.72\times10^5$ W and from Eqs. 11.18 and 11.19,

$$\varepsilon = \frac{q}{C_{min}(T_{h,i} - T_{c,i})} = \frac{6.72\times10^5\ \text{W}}{8400\ \text{W/K}\ (320-20)°\text{C}} = 0.267$$

Referring to Figure 11.14, we see that there is no solution for NTU = 0.560, ε = 0.267, therefore our initial assumption was incorrect and the hot fluid is the minimum fluid. We have the following four equations relating the four unknowns ε, C_{min}, NTU, and C_r,

$$\varepsilon = \frac{q}{C_{min}(T_{h,i} - T_{c,i})} = \frac{6.72\times10^5\ \text{W}}{C_{min}(320-20)°\text{C}} = \frac{2240\ \text{W/K}}{C_{min}} \quad (1)$$

$$\text{NTU} = \frac{UA}{C_{min}} = \frac{4700\ \text{W/K}}{C_{min}}, \qquad C_r = \frac{C_{min}}{C_{max}} = \frac{C_{min}}{8400\ \text{W/K}} \quad (2,3)$$

and from Eq. 11.32,

Continued…

PROBLEM 11.55 (Cont.)

$$\varepsilon = 1 - \exp\left[\left(\frac{1}{C_r}\right)(NTU)^{0.22}\left\{\exp\left[-C_r(NTU)^{0.78}\right] - 1\right\}\right] \quad (4)$$

These equations can be solved simultaneously using *IHT*, or by hand. One approach to solving the equations by hand is as follows. Substituting Eqs. (1), (2), and (3) into Eq. (4) yields (where the units have been omitted),

$$\frac{2240}{C_{min}} = 1 - \exp\left[\frac{8400}{C_{min}}\left(\frac{4700}{C_{min}}\right)^{0.22}\left\{\exp\left[-\frac{C_{min}}{8400}\left(\frac{4700}{C_{min}}\right)^{0.78}\right] - 1\right\}\right]$$

Beginning with an assumed value of C_{min} and substituting it into the right hand side, we solve for C_{min} on the left hand side, and repeat the process until it converges. Beginning with C_{min} = 5000, the sequence of C_{min} values is 5000, 4375, 3984, 3745, 3601, 3515, 3463, 3434, 3416, 3406, 3400, 3396, 3394, 3393, 3392, 3392. Thus

$$\dot{m}_h = C_{min}/c_{p,h} = 3392 \text{ W/K}/1200 \text{ J/kg}\cdot\text{K} = 2.83 \text{ kg/s}$$ <

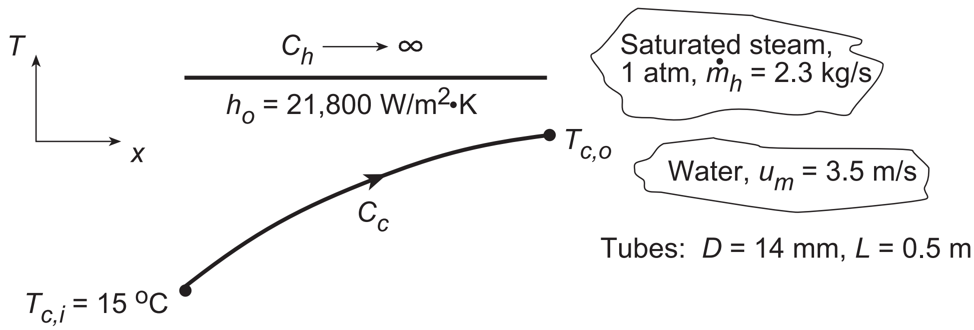
COMMENTS: It is easier to solve the system of simultaneous equations using *IHT* or other non-linear equation solver.

PROBLEM 11.56

KNOWN: Shell(1)-and-tube (two passes, p = 2) heat exchanger for condensing saturated steam at 1 atm. Inlet cooling water temperature and mean velocity. Thin-walled tube diameter and length prescribed, as well as, convective heat transfer coefficient on outer tube surface, h_o.

FIND: (a) Number of tubes/pass, N, required to condense 2.3 kg/s of steam, (b) Outlet water temperature, $T_{c,o}$, (c) Maximum condensation rate possible for same water flowrate and inlet temperature, and (d) Compute and plot $T_{c,o}$ and the condensation rate, $\dot{m}_h$, for water mean velocity, u_m, in the range 1 $\le u_m \le$ 5 ms/, using the heat transfer surface area found in part (a) assuming the shell-side convection coefficient remains unchanged.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible thermal resistance due to the tube walls.

PROPERTIES: *Table A.6*, Saturated steam (1 atm): T_{sat} = 100°C, h_{fg} = 2257 kJ/kg; Water (assume $T_{c,o}$ ≈ 25°C, $\overline{T}_m = (T_h + T_c)/2 \approx 295$ K): $\rho = 1/v_f = 998$ kg/m^3, $c_c = c_{p,f} = 4181$ J/kg·K, $\mu = \mu_f = 959 \times 10^{-6}$ N·s/m^2, $k = k_f = 0.606$ W/m·K, Pr = Pr_f = 6.62.

ANALYSIS: (a) The heat transfer rate for the heat exchanger is

$$q = \dot{m}_h h_{fg} = 2.3\,\text{kg/s} \times 2257 \times 10^3\,\text{J/kg} = 5.191 \times 10^6\,\text{W} \qquad (1)$$

Using the ε-NTU method, evaluate the following parameters:

Water-side heat transfer coefficient:

$$Re_D = \frac{u_m D}{\mu/\rho} = \frac{3.5\,\text{m/s} \times 0.014\,\text{m}}{959 \times 10^{-6}\,\text{N}\cdot\text{s/m}^2 / 998\,\text{kg/m}^3} = 50,993 \qquad (2)$$

$$h_i = \frac{k}{D} Nu_D = \frac{k}{D} 0.023 Re_D^{0.8} Pr^{0.4} = \frac{0.606\,\text{W/m}\cdot\text{K}}{0.014\,\text{m}} \times 0.023 (50,993)^{0.8} (6.62)^{0.4} = 12,400\,\text{W/m}^2\cdot\text{K} \quad (3)$$

using the Dittus-Boelter equation for fully developed turbulent conditions.

Overall coefficient:

$$\overline{U} = (1/h_i + 1/h_o)^{-1} = (1/12,400 + 1/21,800)^{-1} = 7900\,\text{W/m}^2\cdot\text{K} \qquad (4)$$

Effectiveness relations: With $C_{min} = C_c$ and $\dot{m}_c = \rho(\pi D^2/4)u_m N$,

$$q = \varepsilon q_{max} = \varepsilon C_{min}\left(T_{h,i} - T_{c,i}\right) \qquad (5)$$

$$C_{min} = \dot{m}_c c_c = 998\,\text{kg/m}^3 \left(\pi \times 0.014^2\,\text{m}^2/4\right) \times 3.5\,\text{m/s} \times N \times 4181\,\text{J/kg}\cdot\text{K} = 2248\,N \qquad (6)$$

Continued...

PROBLEM 11.56 (Cont.)

$$5.191\times10^{6}\,\mathrm{W} = \varepsilon\times2248\,\mathrm{N}\,(100-15)\,\mathrm{K}$$

$$\varepsilon N = 27.17 \qquad (7)$$

From Eq. 11.35a with $C_r = 0$, the effectiveness is

$$\varepsilon = 1-\exp(-\mathrm{NTU}) = 1-\exp(-0.155) = 0.144 \qquad (8)$$

where, using $A_s = \pi DLNP$, NTU is evaluated as,

$$\mathrm{NTU} = \frac{\bar{U}A_s}{C_{min}} = \frac{7900\,\mathrm{W/m^2\cdot K}\,(\pi\times0.014\,\mathrm{m}\times0.5\,\mathrm{m})\,N\times2}{2248\,N} = 0.155$$

Hence, using Eq. (7), the required number of tubes is

$$N = 27.17/\varepsilon = 205.8 \approx 189$$ <

and the total surface area is

$$A_s = \pi DLNP = \pi\times0.014\,\mathrm{m}\times0.5\,\mathrm{m}\times189\times2 = 8.31\,\mathrm{m^2}.$$

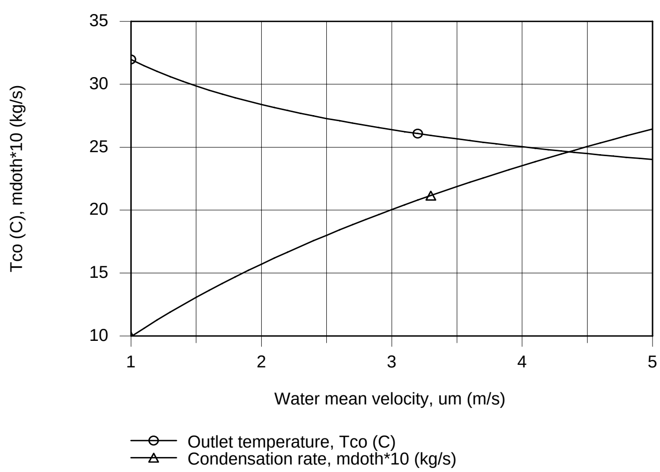
(b) The water outlet temperature with C_{min} = 2248 N = 424,900 W/K,

$$T_{c,o} = T_{c,i} + q/C_{min} = 15^\circ\mathrm{C} + 5.191\times10^{6}\,\mathrm{W}/424{,}900\,\mathrm{W/K} = 27.2^\circ\mathrm{C}$$ <

(c) The maximum condensation rate will occur when $q = q_{max}$. Hence

$$\dot{m}_{h,max} = \frac{q_{max}}{h_{fg}} = \frac{C_{min}(T_{h,i}-T_{c,i})}{h_{fg}} = \frac{424{,}900\,\mathrm{W/K}\,(100-15)\,\mathrm{K}}{2257\times10^{3}\,\mathrm{J/kg}} = 16.0\,\mathrm{kg/s}.$$ <

(d) Using the *IHT Heat Exchanger Tool*, *All Exchangers*, *$C_r = 0$*, along with the *Properties Tool* for *Water*, the foregoing analysis was performed to obtain $T_{h,o}$ and $\dot{m}_h$ using the heat transfer surface area A_s = 8.31 m^2 (part a) as a function of u_m.



Note that the condensation rate increases nearly linearly with the water mean velocity. The cold water outlet temperature decreases nearly linearly with u_m. We should expect this behavior from energy balance considerations. Since h_h is nearly two times greater than h_c, $\bar{U}$ is controlled by the water side coefficient. Hence $\bar{U}$ will increase with increasing u_m.

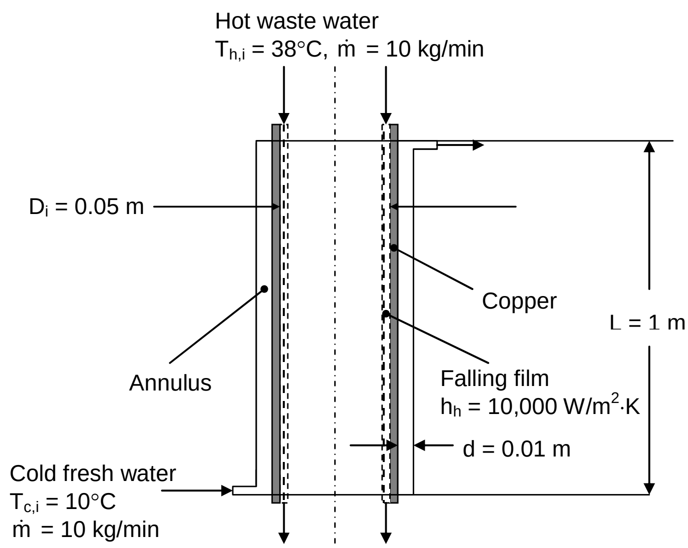
COMMENTS: Note that the assumed value for $\bar{T}_m$ to evaluate water properties in part (a) was a good choice.

PROBLEM 11.57

KNOWN: Dimensions of counterflow, concentric tube heat exchanger for recovering heat from shower drains. Inlet temperatures of hot and cold water streams. Heat transfer coefficient of inner (hot) flow. Mass flow rate of outer (cold) flow.

FIND: (a) Heat transfer rate and outlet temperature of cold flow, (b) Heat transfer rate and outlet temperature of cold flow when helical spring provides specified outer heat transfer coefficient, (c) Daily savings if 15,000 students each take a 10-minute shower per day and cost of heating water is \$0.07/kW·h.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties and steady-state conditions, (2) Negligible heat transfer to surroundings, (3) Fully developed flow in the annular gap, (4) Uniform surface temperature correlation is appropriate, (5) Inner tube wall thermal resistance is negligible.

PROPERTIES: *Table A.6*, water (T ≈ 285 K): k = 0.591 W/m·K, c_p = 4189 J/kg·K, μ = 1225 × 10^{-6} N·s/m^2, Pr = 8.81.

ANALYSIS: (a) We begin by finding the heat transfer coefficient for the flow in the annular gap. The Reynolds number is

$$Re_D = \frac{\rho u_m D_h}{\mu} = \frac{\dot{m}}{\mu}\frac{D_h}{A_c} = \frac{4\dot{m}}{\mu P} = \frac{4 \times 10 \text{ kg/min}/60 \text{ min/s}}{1225 \times 10^{-6} \text{ N}\cdot\text{s/m}^2 \times \pi(0.05 \text{ m} + 0.07 \text{ m})} = 1444$$

Thus the flow is laminar, and from Table 8.2 with D_i/D_o = 0.71, Nu_i = 5.36. Hence,

$$h_c = \frac{Nu_i k}{D_h} = \frac{5.36 \times 0.591 \text{ W/m}\cdot\text{K}}{0.02 \text{ m}} = 158 \text{ W/m}^2\cdot\text{K}$$

Continued...

PROBLEM 11.57 (Cont.)

Then the overall heat transfer coefficient is

$$U = [1/h_c + 1/h_h]^{-1} = [1/158 \text{ W/m}^2 \cdot \text{K} + 1/10,000 \text{ W/m}^2 \cdot \text{K}]^{-1} = 156 \text{ W/m}^2 \cdot \text{K}$$

and using the ε-NTU method, with $C_{min} = C_{max} = \dot{m}c_p = 698$ W/K, $C_r = 1$, we have

$$NTU = UA/C_{min} = U\pi D_i L/C_{min} = 156 \text{ W/m}^2\cdot\text{K} \times \pi \times 0.05 \text{ m} \times 1 \text{ m}/698 \text{ W/K} = 0.035$$

And from Eq. 11.29a, $\varepsilon = NTU/(1 + NTU) = 0.034$. Thus from Eqs. 11.18 and 11.19,

$$q = \varepsilon C_{min}(T_{h,i} - T_{c,i}) = 0.034 \times 698 \text{ W/K } (38 - 10)°\text{C} = 661 \text{ W}$$ <

and from Eq. 11.7b,

$$T_{c,o} = T_{c,i} + q/C_c = 10°\text{C} + 661 \text{ W}/698 \text{ W/K} = 11.0°\text{C}$$ <

(b) The value of U changes to $U = [1/9050 \text{ W/m}^2\cdot\text{K} + 1/10,000 \text{ W/m}^2\cdot\text{K}]^{-1} = 4751$ W/K. Then NTU = 1.07, ε = 0.517, and

$$q = \varepsilon C_{min}(T_{h,i} - T_{c,i}) = 0.517 \times 697 \text{ W/K } (38 - 10)°\text{C} = 10,100 \text{ W}$$ <

$$T_{c,o} = T_{c,i} + q/C_c = 10°\text{C} + 10,100 \text{ W}/698 \text{ W/K} = 24.5°\text{C}$$ <

(c) The savings is the cost of the energy transferred from the wastewater to the cold water,

$$\text{Savings} = 10.1 \text{ kW} \times 600 \text{ s} \times 15,000/3600 \text{ s/h} \times \$0.07/\text{kW}\cdot\text{h} = \$1767$$ <

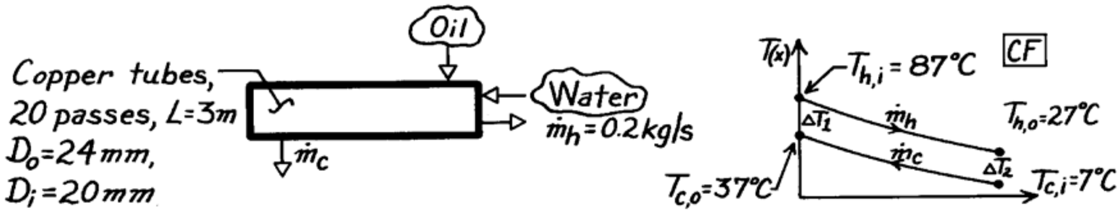
COMMENTS: (1) Commercially-available devices that are used in high density buildings such as dormitories are typically installed on larger drains that collect shower water from multiple showers, rather than on individual showers. The devices use heat transfer enhancement techniques to ensure large values of the cold side heat transfer coefficient. (2) With $x_{fd,t} = 0.05Re_D Pr D_h = 13$ m, the flow in the annular gap is not fully developed, and the actual heat transfer coefficient would be higher than predicted in part (a). (3) In part (a), the mean temperature of the cold stream is 283.5 K. Evaluation of properties at 285 K is appropriate.

PROBLEM 11.58

KNOWN: Shell-and-tube heat exchanger with one shell pass and 20 tube passes.

FIND: Average convection coefficient for the outer tube surface.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Type of oil not specified, (4) Thermal resistance of tubes negligible; no fouling.

PROPERTIES: *Table A-6*, Water, liquid ($\overline{T}_h$ = 330 K): c_p = 4184 J/kg·K, k = 0.650 W/m·K, μ = 489 × 10^{-6} N·s/m^2, Pr = 3.15.

ANALYSIS: To find the average coefficient for the outer tube surface, h_o, we need to evaluate h_i for the internal tube flow and U, the overall coefficient. From Eq. 11.5,

$$\frac{1}{UA} = \frac{1}{h_i A_i} + \frac{1}{h_o A_o} = \frac{1}{N_t \pi L}\left[\frac{1}{h_i D_i} + \frac{1}{h_o D_o}\right]$$

where N_t is the total number of tubes. Solving for h_o,

$$h_o = D_o^{-1}\left[(UA)^{-1} N_t \pi L - 1/h_i D_i\right]^{-1}. \quad (1)$$

Evaluate h_i from an appropriate correlation; begin by calculating the Reynolds number.

$$Re_{D,i} = \frac{4\,\dot{m}_h}{\pi D_i \mu} = \frac{4 \times 0.2\ \text{kg/s}}{\pi (0.020\text{m}) 489 \times 10^{-6}\ \text{N}\cdot\text{s/m}^2} = 26{,}038.$$

Hence, flow is turbulent and since L >> D_i, the flow is likely to be fully developed. Use the Dittus-Boelter correlation with n = 0.3 since $T_s < T_m$, $Nu_D = 0.023\ Re_D^{4/5}\ Pr^{0.3}$

$$h_i = \frac{k}{D} Nu_D = \frac{0.650\ \text{W/m}\cdot\text{K}}{0.020\text{m}} \times 0.023(26{,}038)^{4/5}(3.15)^{0.3} = 3594\ \text{W/m}^2\cdot\text{K}. \quad (2)$$

To evaluate UA, we use the ε-NTU method.

$$C_h = \dot{m}_h c_{p,h} = 0.2\ \text{kg/s} \times 4184\ \text{J/kg}\cdot\text{K} = 836.8\ \text{W/K}$$

$$q = C_h(T_{h,i} - T_{h,o}) = 836.8\ \text{W/K}(87 - 27)°\text{C} = 50{,}208\ \text{W}$$

Then from an energy balance on the cold fluid,

$$C_c = q/(T_{c,o} - T_{c,i}) = 50{,}208\ \text{W}/(37 - 7)°\text{C} = 1674\ \text{W/K}$$

Thus $C_r = C_{min}/C_{max} = 0.50$, $q_{max} = C_{min}(T_{h,i} - T_{c,i}) = 66{,}944$ W, and $\varepsilon = q/q_{max} = 0.75$. From Eqs. 11.30b,c,

Continued…

PROBLEM 11.58 (Cont.)

$$E = \frac{2/\varepsilon - (1 + C_r)}{(1 + C_r^2)^{1/2}} = \frac{2/0.75 - (1 + 0.5)}{(1 + 0.5^2)^{1/2}} = 1.04$$

$$NTU = -(1 + C_r^2) \ln\left(\frac{E - 1}{E + 1}\right) = 3.44$$

Therefore,

$$UA = NTU \times C_{min} = 3.44 \times 836.8 \text{ W/K} = 2881 \text{ W/K} \qquad (3)$$

and

$$h_o = (0.024\text{m})^{-1}\left[(2881 \text{ W/K})^{-1} \times 20 \times \pi \times 3\text{m} - 1/3594 \text{ W/m}^2 \cdot \text{K} \times 0.020\text{m}\right]^{-1}$$

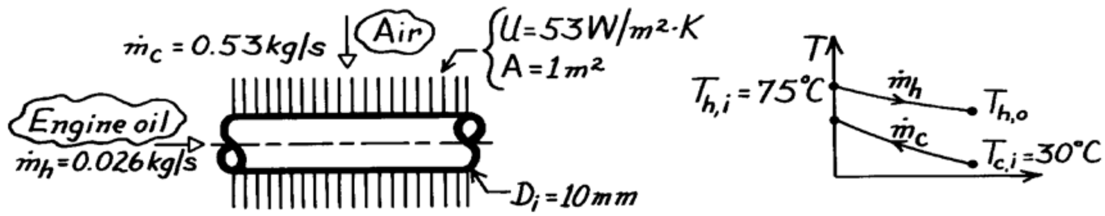
$$= 808 \text{ W/m}^2 \cdot \text{K}.$$ <

PROBLEM 11.59

KNOWN: Engine oil cooled by air in a cross-flow heat exchanger with both fluids unmixed.

FIND: (a) Heat transfer coefficient on oil side of exchanger assuming fully-developed conditions and constant wall heat flux, (b) Effectiveness, and (c) Outlet temperature of the oil.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Oil flow and thermal conditions are fully developed, (4) Oil cooling process approximates constant wall flux conditions.

PROPERTIES: *Table A-5*, Engine oil (assume $T_{h,o} \approx 45°C$, $\overline{T}_h$ = (45 + 75)°C/2 = 333 K): c_h = 2047 J/kg·K, $\mu = 7.45 \times 10^{-2}$ N·s/m^2, k = 0.140 W/m·K; *Table A-4*, Air (assume $T_{c,o} \approx 40°C$, $\overline{T}_c$ = (30 + 40)°C/2 = 308 K, 1 atm): c_c = 1007 J/kg·K.

ANALYSIS: (a) For the oil side, using Eq. 8.6, find,

$$Re_D = 4\,\dot{m}/\pi D\,\mu = 4\left(0.026\text{ kg/s}\right)/\left(\pi\left(0.01\text{m}\right)7.45\times10^{-2}\,\text{N}\cdot\text{s/m}^2\right) = 44.4$$

Since Re_D < 2000 the flow is laminar. For the fully-developed conditions with constant wall flux,

$$Nu_D = \frac{h_i D}{k} = 4.36, \qquad h_i = 4.36\frac{k}{D} = 4.36\frac{0.140\text{ W/m}\cdot\text{K}}{0.01\text{m}} = 61.0\text{ W/m}^2\cdot\text{K}. \qquad <$$

(b) The effectiveness can be determined by the ε-NTU method.

$$C_h = \dot{m}_h c_h = 0.026\text{ kg/s}\times 2047\text{ J/kg}\cdot\text{K} = 53.22\text{ W/K} \qquad C_{min} = C_h$$

$$C_c = \dot{m}_c c_c = 0.53\text{ kg/s}\times1007\text{ J/kg}\cdot\text{K} = 533.7\text{ W/K} \qquad C_{min}/C_{max} = 0.10$$

$$NTU = UA/C_{min} = 53\text{ W/m}^2\cdot\text{K}\times1\text{m}^2/53.22\text{ W/K} = 1.00.$$

Using Fig. 11.14, with C_{min}/C_{max} = 0.1 and NTU = 1, find $\varepsilon \approx 0.64$. <

(c) From Eqs. 11.19 and 11.18,

$$\varepsilon = \frac{q}{q_{max}} = \frac{C_h\left(T_{h,i}-T_{h,o}\right)}{C_{min}\left(T_{h,i}-T_{c,i}\right)} = \frac{T_{h,i}-T_{h,o}}{T_{h,i}-T_{c,i}}.$$

Solving for $T_{h,o}$ and substituting numerical values, find

$$T_{h,o} = T_{h,i} - \varepsilon\left(T_{h,i}-T_{c,i}\right) = 75°C - 0.64\left(75-30\right)°C = 46.2°C. \qquad <$$

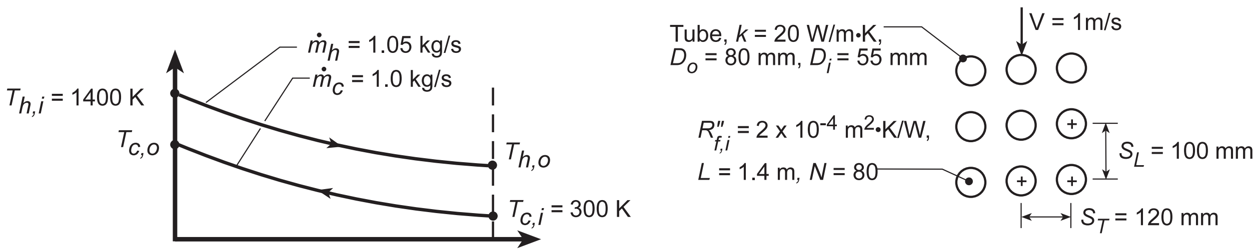
COMMENTS: Note that the $\overline{T}_h$ value at which the oil properties were evaluated is reasonable.

PROBLEM 11.60

KNOWN: Dimensions, configuration and material of a single-pass, cross-flow heat exchanger. Inlet conditions of inner and outer flow. Fouling factor of inner surface.

FIND: (a) Percent fuel savings for prescribed conditions, (b) Effect of UA on air outlet temperature and fuel savings.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Air properties are those of atmospheric air at 300 K, (3) Gas properties are those of atmospheric air at 1400 K, (4) Tube wall temperature may be approximated as 800 K for treating variable property effects.

PROPERTIES: *Table A.4*, Air (1 atm, T = 300 K): $\nu = 15.89 \times 10^{-6}$ m^2/s, c_p = 1007 J/kg·K, k = 0.0263 W/m·K, Pr = 0.707; (T = 1400 K): $\mu = 530 \times 10^{-7}$ kg/s·m, c_p = 1207 J/kg·K, k = 0.091 W/m·K, Pr = 0.703; (T = 800 K): Pr = 0.709.

ANALYSIS: (a) With capacity rates of $C_c = \dot{m}_c c_{p,c}$ = 1 kg/s × 1007 J/kg·K = 1007 W/K = C_{min} and $C_h = \dot{m}_h c_{p,h}$ = 1.05 kg/s × 1207 J/kg·K = 1267 W/K = C_{max}, C_{min}/C_{max} = 0.795. The overall coefficient is

$$\frac{1}{UA} = \frac{1}{h_i A_i} + \frac{R''_{f,i}}{A_i} + \frac{\ln(D_o/D_i)}{(2\pi kL)N} + \frac{1}{h_o A_o}.$$

For flow through a single tube,

$$Re_D = \frac{4\dot{m}_h}{N\pi D_i \mu} = \frac{4 \times 1.05\,kg/s}{80\pi(0.055\,m)530 \times 10^{-7}\,kg/s \cdot m} = 5733.$$

Assuming fully developed turbulent flow throughout and using the Gnielinski correlation,

$$Nu_D = \frac{(f/8)(Re_D - 1000)\,Pr}{1 + 12.7(f/8)^{1/2}(Pr^{2/3} - 1)} = 18.8$$

where f = $(0.79 \ln Re_D - 1.64)^{-2}$ = 0.0370

$$h_i = Nu_D k/D_i = 18.8(0.091\,W/m \cdot K)/0.055\,m = 31.1\,W/m^2 \cdot K.$$

For flow over the tube bank,

$$V_{max} = [S_T/(S_T - D_o)]V = [0.12\,m/(0.12 - 0.08)\,m]1\,m/s = 3\,m/s$$

$$Re_{D,max} = \frac{V_{max} D_o}{\nu} = \frac{3\,m/s(0.08\,m)}{15.89 \times 10^{-6}\,m^2/s} = 15{,}100$$

From the Zukauskas correlation for a tube bank,

$$\overline{Nu}_D = 0.27(15{,}100)^{0.63}(0.707)^{0.36}(0.707/0.709)^{1/4} = 102.3$$

$$\bar{h}_o = \overline{Nu}_D(k/D_o) = 102.3(0.0263\,W/m \cdot K)/0.08\,m = 33.6\,W/m^2 \cdot K.$$

Hence, based on the inner surface, the *overall coefficient* is

Continued...

PROBLEM 11.60 (Cont.)

$$\frac{1}{U_i} = \frac{1}{h_i} + R''_{f,i} + \frac{D_i \ln(D_o/D_i)}{2k} + \frac{D_i}{D_o h_o}$$

$$\frac{1}{U_i} = \left(0.0322 + 0.0002 + \frac{0.055 \ln(0.08/0.055)}{20} + \frac{0.055}{0.08 \times 33.6}\right) m^2 \cdot K/W$$

$$U_i = \left[0.0322 + 0.0002 + 0.001 + 0.0205 m^2 \cdot K/W\right]^{-1} = 18.6\, W/m^2 \cdot K\,.$$

Hence, $(UA)_i = U_i N \pi D_i L = 18.6\, W/m^2 \cdot K \times 80\pi (0.055\, m) 1.4\, m = 360\, W/K$. The number of transfer units is then NTU = UA/C_{min} = 360 W/K/1007 W/K = 0.357, and with $C_{mixed}/C_{unmixed} = C_c/C_h = C_{min}/C_{max}$ = 0.795, Fig. 11.15 yields $\varepsilon \approx 0.29$ or, from Eq. 11.34 a,

$$\varepsilon = 1 - \exp\left(-C_r^{-1}\left\{1 - \exp\left[-C_r \cdot NTU\right]\right\}\right) = 0.267\,.$$

Hence, with

$$q_{max} = C_{min}\left(T_{h,i} - T_{c,i}\right) = 1007\, W/K\,(1100\, K) = 1.11 \times 10^6\, W$$

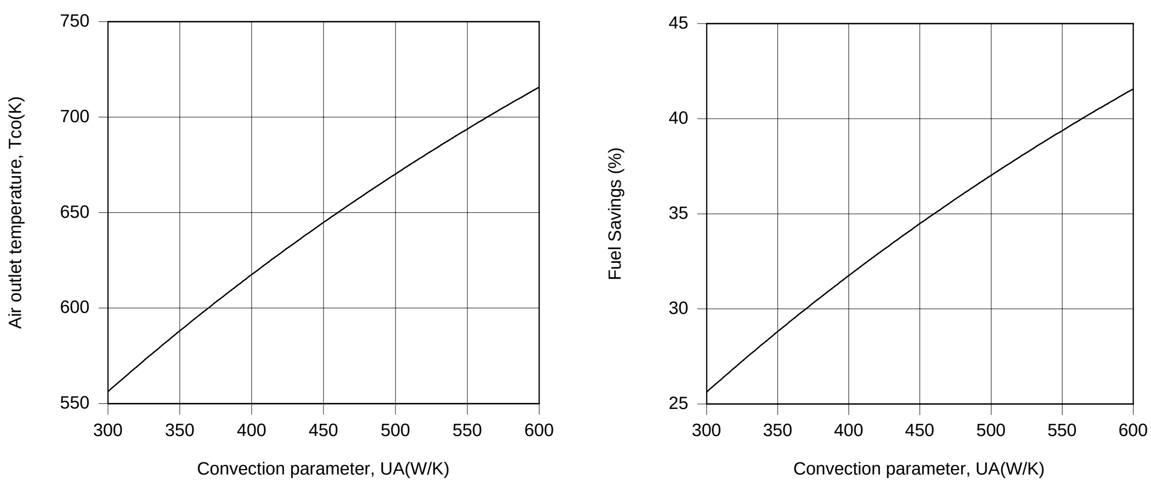
$$q = \varepsilon q_{max} = 0.267 \times 1.11 \times 10^6\, W = 295{,}800\, W$$

$$T_{c,o} = T_{c,i} + q/C_{min} = 300\, K + (295{,}800\, W/1007\, W/K) = 594\, K\,.$$

Hence,

$$\%\text{ fuel savings} \equiv FS = (\Delta T_c/10\, K) \times 1\% = (294\, K/10\, K) \times 1\% = 29.4\% \qquad <$$

(b) Using the Heat Exchangers Toolpad of IHT to perform the parametric calculations, the following results are obtained.



Significant benefits are derived by increasing UA, with values of $T_{c,o}$ = 716 K and FS = 41.6% obtained for UA = 600 W/K. The major contributions to the total resistance are made by the inner and outer convection resistances. These contributions could be reduced by using extended surfaces on both the inner and outer surfaces.

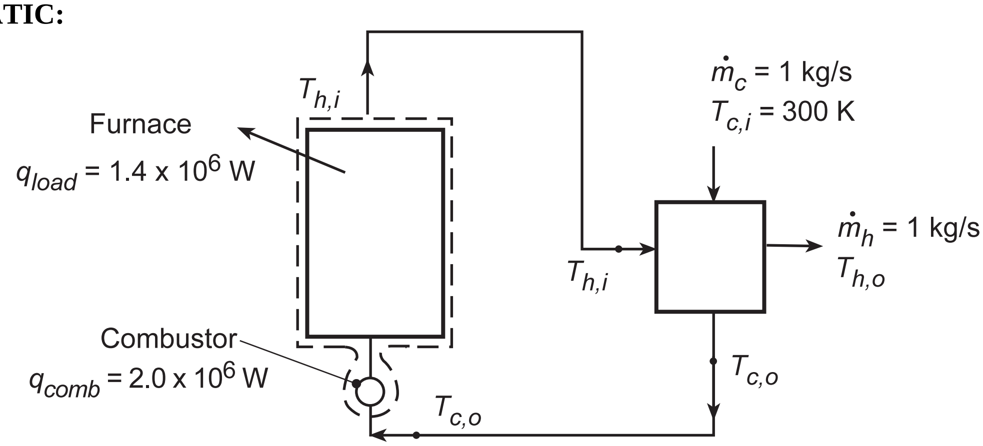
COMMENTS: For part (a), properties of the flue gas should be evaluated at $(T_{h,i} + T_{h,o})/2$ and the calculations repeated.

PROBLEM 11.61

KNOWN: Rate of thermal energy production in combustor and transfer to load in furnace. Cold air and flue gas flowrates and specific heats in recuperator. Recuperator cold air inlet temperature.

FIND: Recuperator hot gas inlet and outlet temperatures and air outlet temperature for a recuperator effectiveness of ε = 0.3. Value of ε needed to achieve a recuperator outlet temperature of 800 K.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) Negligible effect of fuel addition on flow rate.

PROPERTIES: Air and gas: $c_{p,c} = c_{p,h} = 1200$ J/kg·K.

ANALYSIS: With $C_c = C_h = C_{min}$, the effectiveness of the recuperator, $\varepsilon = q/q_{max}$, may be expressed as

$$\varepsilon = \frac{C_c\left(T_{c,o} - T_{c,i}\right)}{C_{min}\left(T_{h,i} - T_{c,i}\right)} = \frac{T_{c,o} - 300\,K}{T_{h,i} - 300\,K} = 0.3$$

The unknown temperatures, $T_{c,o}$ and $T_{h,i}$, are also related through an energy balance performed on the air entering the combustor and leaving the furnace. Specifically,

$$C\left(T_{h,i} - T_{c,o}\right) = q_{comb} - q_{load} = 0.6 \times 10^6\,W$$

where C = 1 kg/s × 1200 J/kg·K = 1200 W/K. Solving the foregoing equations, we obtain

$T_{h,i} = 1014\,K$ $\qquad$ $T_{c,o} = 514$ K <

Expressing the effectiveness as

$$\varepsilon = \frac{C_h\left(T_{h,i} - T_{h,o}\right)}{C_{min}\left(T_{h,i} - T_{c,i}\right)} = \frac{1014\,K - T_{h,o}}{714\,K}$$

we also obtain $\quad T_{h,o} = 800$ K. <

For a combustor air inlet temperature of $T_{c,o} = 800$ K and $T_{h,i} = 1014$ K, the required effectiveness is

$$\varepsilon = \frac{T_{c,o} - T_{c,i}}{T_{h,i} - T_{c,i}} = \frac{(800 - 300)\,K}{(1014 - 300)\,K} = 0.70$$ <

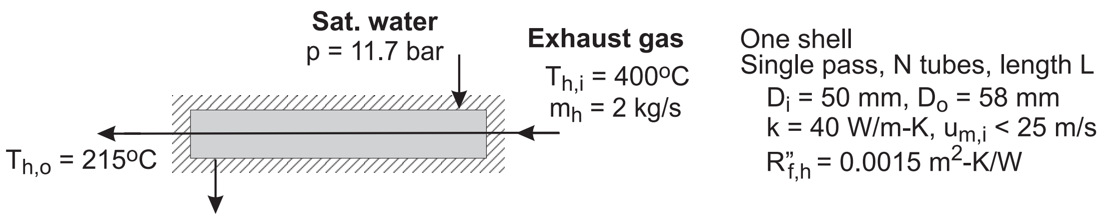
COMMENTS: The effectiveness of the recuperator may be increased by increasing NTU and hence UA, as, for example, by increasing the number of tubes.

PROBLEM 11.62

KNOWN: Shell-tube heat exchanger with one shell and single tube pass; Tube side: exhaust gas with specified flow rate and temperature change; Shell side: supply of saturated water at 11.7 bar; Tube dimensions and thermal conductivity, and fouling resistance on gas side, $R''_{f,h}$, specified.

FIND: Number of tubes and their length if the gas velocity is not to exceed $u_{m,i}$ = 25 m/s.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible losses to the surroundings, (3) Negligible water-side thermal resistance, (4) Exhaust gas properties are those of atmospheric air, (5) Gas-side flow is fully developed, and (6) Constant properties.

PROPERTIES: *Table A-4*, Air $\left(\overline{T}_h = 581\text{ K}\right)$: $\rho = 0.600\text{ kg/m}^3$, $c = 1047\text{ J/kg}\cdot\text{K}$, $\nu = 4.991\times10^{-5}\text{ m}^2\text{/s}$, $k = 0.0457\text{ W/m}\cdot\text{K}$, $\text{Pr} = 0.684$. *Table A-6*, Water (11.7 bar, saturated): $T_{c,i} = 460\text{ K} = 187^\circ\text{C}$.

ANALYSIS: We'll employ the NTU-ε method to design the exchanger. Since $C_r = 0$, use Eq. 11.35b.

$$\text{NTU} = -\ell n(1-\varepsilon)$$

where the effectiveness can be evaluated from Eqs. 11.18 and 11.19.

$$C_{min} = C_h = \dot{m}_h c_h = 2\text{ kg/s}\times1047\text{ J/kg}\cdot\text{K} = 2094\text{ W/K}$$

$$\varepsilon = \frac{C_h\left(T_{h,i}-T_{h,o}\right)}{C_{min}\left(T_{h,i}-T_{c,i}\right)} = \frac{(400-215)^\circ\text{C}}{(400-187)^\circ\text{C}} = 0.868$$

$$\text{NTU} = -\ell n(1-0.868) = 2.029$$

From Eq. 11.24,

$$UA = C_{min}\cdot\text{NTU} = 2094\text{ W/K}\times2.029 = 4249\text{ W/K} \qquad (1)$$

Considering the gas-side flow rate and velocity criteria, find the number of tubes required as

$$\dot{m}_h = N\cdot\rho_h\cdot A_c\cdot u_{m,i} = N\cdot\rho_h\left(\pi D_i^2/4\right)u_{m,i}$$

Continued …

PROBLEM 11.62 (Cont.)

$$2\ \text{kg/s} = N \times 0.600\ \text{kg/m}^3 \times \pi (0.050\ \text{m})^2 / 4 \times 25\ \text{m/s}$$

$$N = 67.9\ \text{tubes, specify } 68$$ <

The overall coefficient, considering the convection process, fouling resistance and the tube thermal resistance, is evaluated as

$$U_i = 1/\left[R''_{f,i} + R''_{cv,i} + R''_{cd,t}\right] = 56.4\ \text{W/m}^2 \cdot \text{K}$$

$$R''_{f,i} = 0.0015\ \text{m}^2 \cdot \text{K/W}$$

$$R''_{cv,i} = 1/h_i = 1/62\ \text{W/m}^2 \cdot \text{K} = 0.0161\ \text{m}^2 \cdot \text{K/W}$$

$$R''_{cd,t} = \frac{D_i\ \ell n\left(D_o / D_i\right)}{2\ k} = \frac{0.050\ \text{m}\ \ell n(58/50)}{2 \times 40\ \text{W/m} \cdot \text{K}} = 9.28 \times 10^{-5}\ \text{m}^2 \cdot \text{K/W}$$

where the gas-side convection coefficient estimate is explained in the Comments section. Substituting numerical values, determine the required tube length

$$[UA] = U_i \cdot A_i = U_i\left(N\ \pi\ D_i\ L\right)$$

$$4249\ \text{W/K} = 56.4\ \text{W/m}^2 \cdot \text{K} \times 68 \times \pi \times 0.050\ \text{m} \times L$$

$$L = 7.1\ \text{m}$$ <

COMMENTS: (1) Is the assumption of negligible water-side thermal resistance reasonable? Explain why.

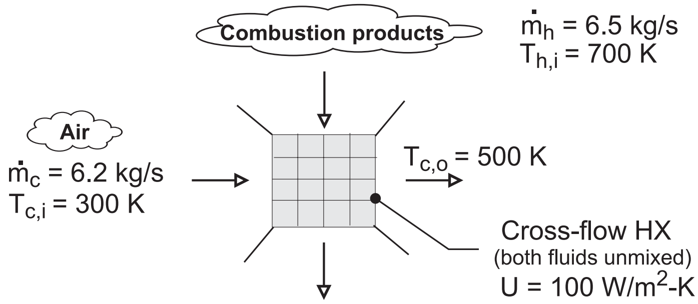
(2) Knowing the tube gas-side velocity, the usual convection correlation calculation methodology is followed. The flow is turbulent, $Re_{Di} = 2.5 \times 10^4$, and assuming fully developed flow, use the Dittius-Boelter correlation, Eq. 8.60, to find $Nu_{Di} = 67.8$ and $h_i = 62.0\ \text{W/m}^2 \cdot \text{K}$.

PROBLEM 11.63

KNOWN: Hot and cold gas flow rates and inlet temperatures of a recuperator. Overall heat transfer coefficient. Desired cold gas outlet temperature.

FIND: (a) Required surface area, (b) Effect of surface area on cold-gas outlet temperature.

SCHEMATIC:



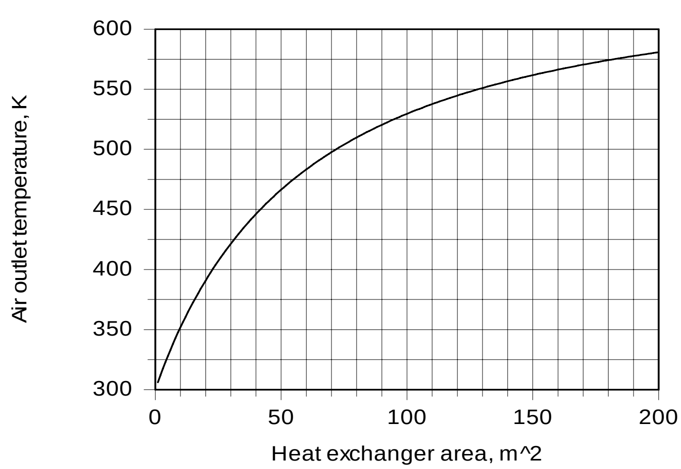
ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties.

PROPERTIES: Given: $c_{p,c} = c_{p,h}$ = 1040 W/m·K.

ANALYSIS: (a) With $C_{min} = C_c$ = 6.2 kg/s × 1040 J/kg·K = 6,448 W/K, $C_{max} = C_h$ = 6.5 kg/s × 1040 J/kg·K = 6,760 W/K, $C_r = C_{min}/C_{max}$ = 0.954, $q = C_c\,(T_{c,o} - T_{c,i})$ = 6,448 W/K (200 K) = 1.29 × 10^6 W, $q_{max} = C_{min}\,(T_{h,i} - T_{c,i})$ = 6,448 W/K (400 K) = 2.58 × 10^6 W, and $\varepsilon = q/q_{max}$ = 0.50, Fig. 11.14 yields NTU ≈ 1.10. Hence

$$A = \frac{NTU \times C_{min}}{U} = \frac{1.10 \times 6,448\ W/K}{100\ W/m^2 \cdot K} = 70.9\ m^2$$ <

(b) Using the Heat Exchanger option of *IHT*, the following result was obtained



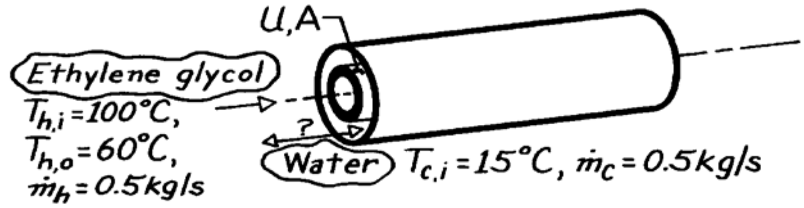
The air outlet temperature increases, of course, with increasing heat exchanger area, but the approach to the maximum possible outlet temperature, $T_{h,i}$, is slow and the heat exchanger size needed to achieve a large outlet temperature may be prohibitively expensive.

PROBLEM 11.64

KNOWN: Inlet temperature and flow rates for a concentric tube heat exchanger. Hot fluid outlet temperature.

FIND: (a) Maximum possible heat transfer rate and effectiveness, (b) Preferred mode of operation.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state operation, (2) Negligible heat loss to surroundings, (3) Fixed overall heat transfer coefficient.

PROPERTIES: *Table A-5*, Ethylene glycol ($\overline{T}_m$ = 80°C): c_p = 2650 J/kg·K; *Table A-6*, Water ($\overline{T}_m$ ≈ 30°C): c_p = 4178 J/kg·K.

ANALYSIS: (a) Using the ε-NTU method, find

$$C_{min} = C_h = \dot{m}_h c_{p,h} = (0.5 \text{ kg/s})(2650 \text{ J/kg}\cdot\text{K}) = 1325 \text{ W/K}.$$

Hence from Eqs. 11.18 and 11.6,

$$q_{max} = C_{min}(T_{h,i} - T_{c,i}) = (1325 \text{ W/K})(100-15)°C = 1.13\times10^5 \text{ W}.$$

$$q = \dot{m}_h c_{p,h}(T_{h,i} - T_{h,o}) = 0.5 \text{ kg/s}(2650 \text{ J/kg}\cdot\text{K})(100-60)°C = 0.53\times10^5 \text{ W}. \quad <$$

Hence from Eq. 11.19,

$$\varepsilon = q/q_{max} = 0.53\times10^5 / 1.13\times10^5 = 0.47. \quad <$$

(b) From Eq. 11.7,

$$T_{c,o} = T_{c,i} + \frac{q}{\dot{m}_c c_{p,c}} = 15°C + \frac{0.53\times10^5}{0.5 \text{kg/s} \times 4178 \text{J/kg}\cdot\text{K}} = 40.4°C.$$

Since $T_{c,o} < T_{h,o}$, a *parallel flow* mode of operation is possible. However, with $(C_{min}/C_{max}) = (\dot{m}_h c_{p,h}/\dot{m}_c c_{p,c}) = 0.63$,

$$\text{Fig. 11.10} \rightarrow (NTU)_{PF} \approx 0.95 \qquad \text{Fig. 11.11} \rightarrow (NTU)_{CF} \approx 0.75.$$

Hence from Eq. 11.24

$$(A_{CF}/A_{PF}) = (NTU)_{CF}/(NTU)_{PF} \approx (0.75/0.95) = 0.79.$$

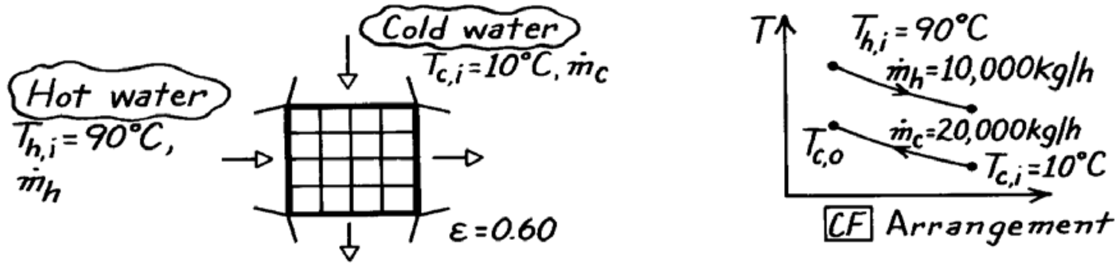
Because of the reduced size requirement, and hence capital investment, the *counterflow* mode of operation is preferred.

PROBLEM 11.65

KNOWN: Single-pass, cross-flow heat exchanger with both fluids (water) unmixed; hot water enters at 90°C and at 10,000 kg/h while cold water enters at 10°C and at 20,000 kg/h; effectiveness is 60%.

FIND: Cold water exit temperature, $T_{c,o}$.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties.

PROPERTIES: *Table A-6*, Water ($\overline{T}_c$ ≈ (10 + 40)°C/2 ≈ 300 K): c_c = 4179 J/kg·K; *Table A-6*, Water ($\overline{T}_h$ ≈ (90 + 60)°C/2 ≈ 350 K): c_h = 4195 J/kg·K.

ANALYSIS: From an energy balance on the cold fluid, Eq. 11.7, the outlet temperature can be expressed as

$$T_{c,o} = T_{c,i} + q / \dot{m}_c C_c.$$

The heat rate can be written in terms of the effectiveness and q_{max}. Using Eqs. 11.19 and 11.18,

$$q = \varepsilon q_{max} = \varepsilon C_{min}\left(T_{h,i} - T_{c,i}\right).$$

By inspection, it can be noted that the hot fluid is the minimum capacity fluid. Substituting numerical values,

$$q = \varepsilon\left(\dot{m}_h c_h\right)\left(T_{h,i} - T_{c,i}\right)$$

$$q = 0.60\left(10,000\,kg/h / 3600\,s/h\right)4195\,J/kg\cdot K\left(90-10\right)°C = 559.3\times10^3\,W.$$

The exit temperature of the cold water is then

$$T_{c,o} = 10°C + 559.3\times10^3\,W / \frac{20,000}{3600}\,kg/s\times4179\,J/kg\cdot K = 34.1°C. \qquad <$$

COMMENTS: (1) The properties of the cold fluid should be evaluated at $\overline{T}$ = ($T_{c,o}$ + $T_{c,i}$)/2 = (34.1 + 10)°C/2 = 295 K. Note the analysis assumed $\overline{T}_c$ ≈ 300 K, hence little error is incurred. For best precision, one should check $\overline{T}_h$ and C_h.

(2) From Fig. 11.14, the value of NTU could be determined. First evaluate the term

$$C_{min}/C_{max} = \dot{m}_h C_h / \dot{m}_c C_c = \frac{10,000\times4195}{20,000\times4179} = 0.50$$

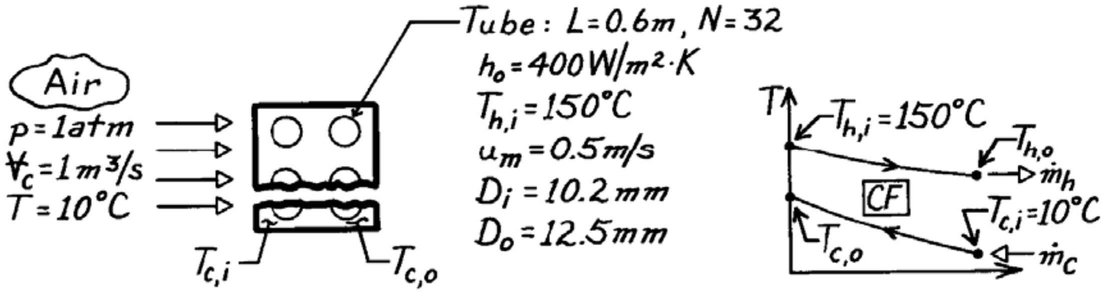
and with ε = 0.60, find NTU ≈ 1.2.

PROBLEM 11.66

KNOWN: Hxer consisting of 32 tubes in 0.6m square duct. Hot water enters tubes at 150°C with mean velocity 0.5 m/s. Atmospheric air at 10°C enters exchanger with volumetric flow rate of 1 m^3/s. Heat transfer coefficient on tube outer surfaces is 400 $W/m^2 \cdot K$.

FIND: Outlet temperatures of the fluids, $T_{c,o}$ and $T_{h,o}$.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Hxer is a single-pass, cross-flow type with one fluid mixed (air) and the other unmixed (water), (4) Tube water flow is fully developed, (5) Negligible thermal resistance due to tube wall.

PROPERTIES: *Table A-4*, Air ($T_{c,i}$ = 10°C = 283 K, 1 atm): ρ = 1.2407 kg/m^3; *Table A-4*, Air (assume $T_{c,o} \approx$ 40°C, $\overline{T}_c$ = (10 + 40)°C/2 = 298 K, 1 atm): c_p = 1007 J/kg·K; *Table A-6*, Water (assume $T_{h,o} \approx$ 140°C, $\overline{T}_h$ = (140 + 150)°C/2 = 418 K): $\rho = 1/v_f = 1/1.0850 \times 10^{-3}$ m^3/kg, c_p = 4297 J/kg·K, $\mu_f = 188 \times 10^{-6}$ $N \cdot s/m^2$, k_f = 0.688 W/m·K, Pr_f = 1.18.

ANALYSIS: Using the ε-NTU method, first find the capacity rates.

$$C_h = \dot{m}_h c_{p,h} = \left(\rho A_c u_m\right)_h N \cdot c_{p,h}$$

$$C_h = \frac{1}{1.0850 \times 10^{-3}\,m^3/kg} \times \frac{\pi}{4}\left(10.2 \times 10^{-3}\,m\right)^2 \times 0.5\frac{m}{s} \times 32 \times 4297\frac{J}{kg \cdot K} = 5178\frac{W}{K}$$

$$C_c = \dot{m}_c c_{p,c} = \left(\rho V\right)_c c_{p,c} = 1.2407\frac{kg}{m^3} \times 1m^3/s \times 1007\,J/kg \cdot K = 1249\frac{W}{K}. \qquad (1,2)$$

Note that the cold fluid is the minimum fluid, $C_c = C_{min}$. The overall heat transfer coefficient follows from Eq. 11.5,

$$U_o A_o = \left[\frac{1}{h_i A_i} + \frac{1}{h_o A_o}\right]^{-1} \qquad (3)$$

where h_i must be estimated from an appropriate internal flow correlation. The Reynolds number for water flow is

$$Re_D = \frac{\rho u_m D_i}{\mu} = \frac{\left(1/1.0850 \times 10^{-3} m^3 kg\right) \times 0.5 m/s \times \left(10.2 \times 10^{-3} m\right)}{188 \times 10^{-6} N \cdot s/m^2} = 25{,}002. \qquad (4)$$

Continued …

PROBLEM 11.66 (Cont.)

The flow is turbulent and since $L/D_i = 0.6\text{m}/10.2 \times 10^{-3}\text{m} = 59$, fully developed conditions may be assumed. The Dittus-Boelter correlation with n = 0.3 is appropriate.

$$Nu_D = \frac{h_i D_i}{k} = 0.023 Re_D^{0.8} Pr^{0.3} = 0.023(25,002)^{0.8}(1.18)^{0.3} = 79.7$$

$$h_i = \frac{k}{D_i} Nu_D = \frac{0.688\,W/m\cdot K}{10.2\times10^{-3}m} \times 79.7 = 5376\,W/m^2\cdot K.$$

Substituting numerical values into Eq. (3), find

$$U_o = \left[\left(\frac{12.5mm}{10.2mm}\right)\frac{1}{5376\,W/m^2\cdot K} + \frac{1}{400\,W/m^2\cdot K}\right]^{-1} = 366.6\,W/m^2\cdot K.$$

It follows from Eq. 11.24, with $A_o = N(\pi D_o L)$, that

$$NTU = \frac{U_o A_o}{C_{min}} = 366.6\frac{W}{m^2\cdot K}\times\left(32\times\pi\times12.5\times10^{-3}m\times0.6m\right)/1249\frac{W}{K} = 0.22.$$

From Fig. 11.15, noting that $C_{min} = C_c$ is the mixed fluid (solid curves),

$$\frac{C_{mixed}}{C_{unmixed}} = \frac{C_{min}}{C_{max}} = \frac{C_c}{C_h} = \frac{1249\,W/K}{5178\,W/K} = 0.24$$

and with NTU = 0.22 find $\varepsilon \approx 0.19$. From the definition of effectiveness, Eq. 11.19,

$$\varepsilon = \frac{q}{q_{max}} = \frac{C_c\left(T_{c,o} - T_{c,i}\right)}{C_{min}\left(T_{h,i} - T_{c,i}\right)}$$

$$T_{c,o} = T_{c,i} + \varepsilon\left(T_{h,i} - T_{c,i}\right) = 10°C + 0.19(150-10)°C = 36.6°C.$$ <

Equating the energy balances on both fluids,

$$C_c\left(T_{c,o} - T_{c,i}\right) = C_h\left(T_{h,i} - T_{h,o}\right)$$

or

$$T_{h,o} = T_{h,i} - \frac{C_c}{C_h}\left(T_{c,o} - T_{c,i}\right)$$

$$T_{h,o} = 150°C - \frac{1249\,W/K}{5178\,W/K}(36.6-10)°C = 143.5°C.$$ <

COMMENTS: (1) Note that the assumptions of $T_{h,o}$ and $T_{c,o}$ used in evaluating properties are reasonable.

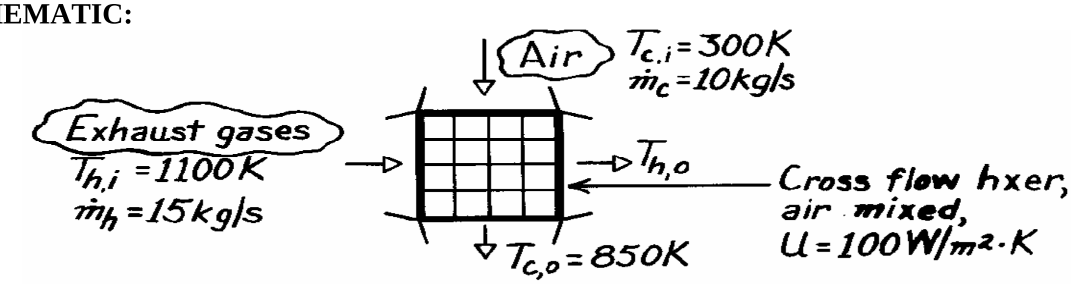
(2) Note that to calculate $\dot{m}_c$ from V, the density at 10°C is more appropriate than at $\overline{T}_c$.

PROBLEM 11.67

KNOWN: Flow rates and inlet temperatures of exhaust gases and combustion air used in a cross-flow (one fluid mixed) heat exchanger. Overall heat transfer coefficient. Desired air outlet temperature.

FIND: Required heat exchanger surface area.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat loss to surroundings, (3) Constant properties, (4) Gas properties are those of air.

PROPERTIES: *Table A-4*, Air ($\overline{T}_m \approx 700$ K, 1 atm): $c_p = 1075$ J/kg·K.

ANALYSIS: Using the ε – NTU method,

$$C_c = \dot{m}_c c_{p,c} = 10 \text{ kg/s} \times 1075 \text{ J/kg}\cdot\text{K} = 10{,}750 \text{ W/K}$$

$$C_h = \dot{m}_h c_{p,h} = 15 \text{ kg/s} \times 1075 \text{ J/kg}\cdot\text{K} = 16{,}125 \text{ W/K}$$

Thus $C_r = C_{min}/C_{max} = 0.667, \quad \varepsilon = q/q_{max} = (T_{c,o} - T_{c,i})/(T_{h,i} - T_{c,i}) = 0.688$

From Eq. 11.34b,

$$\text{NTU} = -\frac{1}{C_r}\ln\left[C_r \ln(1-\varepsilon) + 1\right] = -\frac{1}{0.667}\ln\left[0.667 \ln(1-0.688) + 1\right] = 2.24$$

Therefore,

$$A = \text{NTU} \times C_{min}/U = (2.24 \times 10{,}750 \text{ W/K})/(100 \text{ W/m}^2\cdot\text{K}) = 241 \text{ m}^2$$ <

PROBLEM 11.68

KNOWN: Heat exchanger with $C_r = 0$.

FIND: Derivation of Equation 11.35a.

ASSUMPTIONS: (1) Negligible heat transfer between heat exchangers and surroundings, negligible heat transfer between two heat exchangers, (2) Constant properties.

ANALYSIS: For $C_r = 0$, $C_{max} \to \infty$. If the hot stream is associated with C_{max}, then $T_{h,i} = T_{h,o}$. From Eq. 8.45 with $T_\infty = T_{h,i}$ and $T_{m,o} = T_{c,o}$, $T_{m,i} = T_{c,i}$,

$$\frac{T_{h,i} - T_{c,o}}{T_{h,i} - T_{c,i}} = \exp\left(-\frac{UA}{\dot{m}c_p}\right) = \exp\left(-\text{NTU}\right) \quad (1)$$

where $\dot{m}c_p = C_c = C_{min}$ or

$$T_{c,o} = T_{h,i} - \left(T_{h,i} - T_{c,i}\right)\exp\left(-\text{NTU}\right) \quad (2)$$

and

$$q = \dot{m}c_p\left(T_{m,o} - T_{m,i}\right) = C_{min}\left(T_{c,o} - T_{c,i}\right) = C_{min}\left[T_{h,i} - \left(T_{h,i} - T_{c,i}\right)\exp(-\text{NTU}) - T_{c,i}\right] \quad (3)$$

From Eq. 11.22,

$$q = \varepsilon C_{min}(T_{h,i} - T_{c,i}) \quad (4)$$

Equating Eqs. (3) and (4) yields

$$\varepsilon C_{min}(T_{h,i} - T_{c,i}) = C_{min}\left[T_{h,i} - \left(T_{h,i} - T_{c,i}\right)\exp(-\text{NTU}) - T_{c,i}\right]$$

or

$$\varepsilon = 1 - \exp\left(-\text{NTU}\right)$$ <

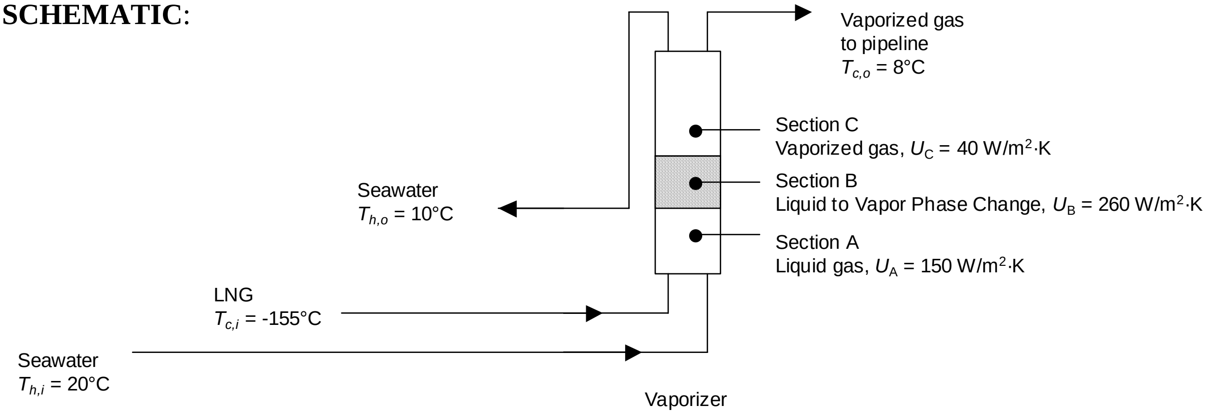
COMMENTS: Eq. 11.35a may be used to solve a wide variety of problems, beyond those associated with two-fluid heat exchangers, involving constant surface temperature conditions.

PROBLEM 11.69

KNOWN: Inlet and outlet temperatures of natural gas and seawater in an LNG vaporizer. LNG flow rate and properties of its liquid and vapor phases, as well as phase change temperature and latent heat of vaporization. Overall heat transfer coefficients for three sections of the vaporizer. Seawater properties.

FIND: Required vaporizer heat transfer area.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat transfer between the heat exchanger and the surroundings, (2) Constant properties, (3) Parallel flow.

PROPERTIES: Given. NG: $c_{p,l}$ = 4200 J/kg·K, $c_{p,v}$ = 2210 J/kg·K, h_{fg} = 575 kJ/kg, T_f = -75°C. SW: $c_{p,\text{SW}}$ = 3985 J/kg·K.

ANALYSIS: Application of the conservation of energy principle to the gas stream yields

$$q = \dot{m}_{\text{NG}}\left[c_{p,l}\left(T_f - T_{c,i}\right) + h_{fg} + c_{p,v}\left(T_{c,o} - T_f\right)\right] = q_A + q_B + q_C$$

$$= 150 \text{ kg/s}\left[4200\text{J/kg}\cdot\text{K}\left(-75-(-155)°\text{C}\right) + 575\times10^3\text{J/kg}\cdot\text{K} + 2210\text{J/kg}\cdot\text{K}\left(8-(-75)°\text{C}\right)\right]$$

$$= 50.4\times10^6 \text{ W} + 86.3\times10^6 \text{ W} + 27.5\times10^6 \text{ W} = 164\times10^6 \text{ W} = 164 \text{ MW}$$

The flow rate of seawater is

$$\dot{m}_{\text{sw}} = q/\left[c_{p,\text{sw}}\left(T_{h,i} - T_{h,o}\right)\right] = 164\times10^6 \text{ W}/\left[3985 \text{ J/kg}\cdot\text{K}\left(10°\text{C}\right)\right] = 4120 \text{ kg/s}$$

Recognizing that the outlet conditions of Section A (B) serve as inlet conditions to Section B (C), we may analyze the vaporizer on a section-by-section basis.

<u>Section A</u> The heat capacity rates are

$$\text{NG: } \dot{m}c_{p,l} = 150 \text{ kg/s}\times4200 \text{ J/kg}\cdot\text{K} = 630\times10^3 \text{ W/K} = C_{\text{min,A}}$$

$$\text{SW: } \dot{m}c_{p,sw} = 4120 \text{ kg/s}\times3985 \text{ J/kg}\cdot\text{K} = 16.4\times10^6 \text{ W/K} = C_{\text{max,A}}$$

$$C_{r,\text{A}} = C_{\text{min,A}}/C_{\text{max,A}} = 630\times10^3/16.4\times10^6 = 0.0384$$

Continued…

PROBLEM 11.69 (Cont.)

The effectiveness is

$$\varepsilon_{\rm A} = \frac{q_{\rm A}}{C_{\rm min,A}(T_{h,i,\rm A} - T_{c,i,\rm A})} = \frac{50.4\times10^6 \text{ W}}{630\times10^3 \text{ W/K}\times(20-(-155)°\text{C})} = 0.457$$

and the NTU is determined from Equation 11.28b

$$\text{NTU}_{\rm A} = -\frac{\ln\left[1-0.457\left(1+0.0384\right)\right]}{1+0.0384} = 0.620\ ;\ A_{\rm A} = \frac{\text{NTU}_{\rm A}C_{\rm min,A}}{U_{\rm A}} = \frac{0.620\times630\times10^3 \text{ W/K}}{150\text{W}/\text{m}^2\cdot\text{K}} = 2600 \text{ m}^2$$

while the outlet temperature of the seawater is

$$T_{h,o,\rm A} = T_{h,i,\rm A} - q_{\rm A}/C_{\rm max,A} = 20°\text{C} - 50.4\times10^6 \text{ W}/16.4\times10^6 \text{ W/K} = 16.9°\text{C}$$

<u>Section B</u> The heat capacity rates are

NG: $C_{\rm max,B} \to \infty$

SW: $\dot{m}c_{p,sw} = 4120 \text{ kg/s}\times3985 \text{ J/kg}\cdot\text{K} = 16.4\times10^6 \text{ W/K} = C_{\rm min,B}$

$C_{r,\rm B} = C_{\rm min,B}/C_{\rm max,B} = 0$

The effectiveness is

$$\varepsilon_{\rm B} = \frac{q_{\rm B}}{C_{\rm min,B}(T_{h,i,\rm B} - T_{c,i,\rm B})} = \frac{q_{\rm B}}{C_{\rm min,B}(T_{h,o,\rm A} - T_f)} = \frac{86.3\times10^6 \text{ W}}{16.4\times10^6 \text{ W/K}\times(16.9-(-75)°\text{C})} = 0.0572$$

and the NTU is determined from Equation 11.28b

$$\text{NTU}_{\rm B} = -\frac{\ln\left[1-0.0572\right]}{1} = 0.0588\ \ ;\ A_{\rm B} = \frac{\text{NTU}_{\rm B}C_{\rm min,B}}{U_{\rm B}} = \frac{0.0588\times16.4\times10^6 \text{ W/K}}{260\text{W}/\text{m}^2\cdot\text{K}} = 3720 \text{ m}^2$$

while the outlet temperature of the seawater is

$$T_{h,o,\rm B} = T_{h,i,\rm B} - q_{\rm B}/C_{\rm min,B} = 16.9°\text{C} - 86.3\times10^6 \text{ W}/16.4\times10^6 \text{ W/K} = 11.7°\text{C}$$

<u>Section C</u> The heat capacity rates are

NG: $\dot{m}c_{p,v} = 150 \text{ kg/s}\times2210 \text{ J/kg}\cdot\text{K} = 332\times10^3 \text{ W/K} = C_{\rm min,C}$

SW: $\dot{m}c_{p,sw} = 4120 \text{ kg/s}\times3985 \text{ J/kg}\cdot\text{K} = 16.4\times10^6 \text{ W/K} = C_{\rm max,C}$

$C_{r,\rm C} = C_{\rm min,C}/C_{\rm max,C} = 332\times10^3/16.4\times10^6 = 0.020$

The effectiveness is

$$\varepsilon_{\rm C} = \frac{q_{\rm C}}{C_{\rm min,C}(T_{h,i,\rm C} - T_{c,i,\rm C})} = \frac{q_{\rm C}}{C_{\rm min,C}(T_{h,o,\rm B} - T_f)} = \frac{27.5\times10^6 \text{ W}}{332\times10^3 \text{ W/K}\times(11.7-(-75)°\text{C})} = 0.958$$

Continued…

PROBLEM 11.69 (Cont.)

and the NTU is found from Equation 11.28b

$$NTU_C = -\frac{\ln\left[1-0.958(1+0.020)\right]}{1+0.020} = 3.69\,;\ A_C = \frac{\text{NTU}_C C_{\text{min,C}}}{U_C} = \frac{3.69 \times 332 \times 10^3\ \text{W/K}}{40\text{W}/\text{m}^2 \cdot \text{K}} = 30,600\ \text{m}^2$$

Therefore, the total heat transfer area for the vaporizer is

$$A = A_A + A_B + A_C = 2600\ \text{m}^2 + 3720\ \text{m}^2 + 30,600\ \text{m}^2 = 36,900\ \text{m}^2 \qquad <$$

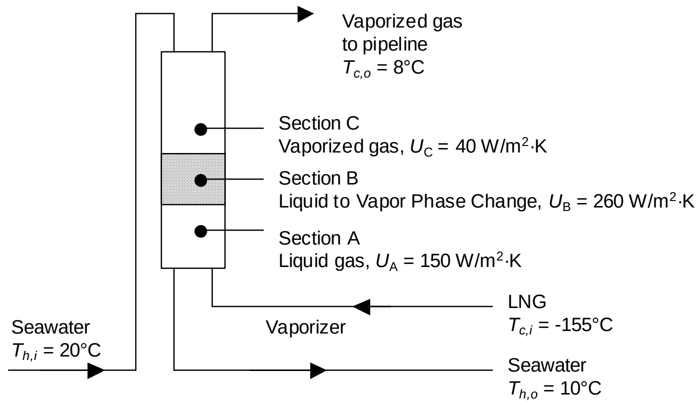
COMMENTS: (1) The scheme may not be feasible in a cold-weather port due to the potential of freezing the seawater. In cold-weather ports, approximately 2% of the natural gas will be burned, with the combustion products sent through the vaporizer to supply the necessary heating. See B. Eisentrout, S. Wintercorn and B. Weber, "Study Focuses on Six LNG Regasification Systems," *LNG Journal*, July/August, pp. 21 – 22, 2006. (2) For a counterflow vaporizer with sea water introduced at the top of the heat exchanger, the required area is A = 23,700 m^2, a 36% size reduction. See Problem 11.70.

PROBLEM 11.70

KNOWN: Inlet and outlet temperatures of natural gas and seawater in an LNG vaporizer. LNG flow rate and properties of its liquid and vapor phases, as well as phase change temperature and latent heat of vaporization. Overall heat transfer coefficients for three sections of the vaporizer. Seawater properties.

FIND: Required vaporizer heat transfer area.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat transfer between the heat exchanger and the surroundings, (2) Constant properties, (3) Counterflowing fluids.

PROPERTIES: Given. NG: $c_{p,l}$ = 4200 J/kg·K, $c_{p,v}$ = 2210 J/kg·K, h_{fg} = 575 kJ/kg, T_f = -75°C. SW: $c_{p,\text{SW}}$ = 3985 J/kg·K.

ANALYSIS: Application of the conservation of energy principle to the gas stream yields

$$q = \dot{m}_{\text{NG}}\left[c_{p,l}\left(T_f - T_{c,i}\right) + h_{fg} + c_{p,v}\left(T_{c,o} - T_f\right)\right] = q_{\text{A}} + q_{\text{B}} + q_{\text{C}}$$

$$= 150 \text{ kg/s}\left[4200\text{J/kg}\cdot\text{K}\left(-75-(-155)°\text{C}\right) + 575\times10^3\text{J/kg}\cdot\text{K} + 2210\text{J/kg}\cdot\text{K}\left(8-(-75)°\text{C}\right)\right]$$

$$= 50.4\times10^6 \text{ W} + 86.3\times10^6 \text{ W} + 27.5\times10^6 \text{ W} = 164\times10^6 \text{ W} = 164 \text{ MW}$$

The flow rate of seawater is

$$\dot{m}_{\text{sw}} = q/\left[c_{p,\text{SW}}\left(T_{h,i} - T_{h,o}\right)\right] = 164\times10^6 \text{ W}/\left[3985 \text{ J/kg}\cdot\text{K}\left(10°C\right)\right] = 4120 \text{ kg/s}$$

Recognizing that the NG (cold stream) outlet conditions of Section A (B) serve as NG inlet conditions to Section B (C), and that the SW (hot stream) outlet conditions of Section C (B) serve as the SW inlet conditions for Section B(A), we may write

$$T_{h,i,\text{C}} = T_{h,i} = 20°\text{C} \;\; ; \;\; T_{h,i,\text{B}} = T_{h,i,\text{C}} - q_{\text{C}}/\dot{m}_{\text{SW}}c_{p,sw} = 20°\text{C} - 27.5\times10^6 \text{ W}/\left(4120 \text{ kg/s}\times3985 \text{ J/kg}\cdot\text{K}\right) = 18.3°\text{C}$$

$$T_{h,i,\text{A}} = T_{h,i,\text{B}} - q_{\text{B}}/\dot{m}_{\text{sw}}c_{p,sw} = 18.3°\text{C} - 86.3\times10^6 \text{ W}/\left(4120 \text{ kg/s}\times3985 \text{ J/kg}\cdot\text{K}\right) = 13.1°\text{C}$$

$$T_{c,i,\text{A}} = T_{c,i} = -155°\text{C} \;\; ; \;\; T_{c,i,\text{B}} = T_f = -75°\text{C} \;\; ; \;\; T_{c,i,\text{C}} = T_f = -75°\text{C}$$

<u>Section A</u> The heat capacity rates are

$$\text{NG: } \dot{m}c_{p,l} = 150 \text{ kg/s}\times4200 \text{ J/kg}\cdot\text{K} = 630\times10^3 \text{ W/K} = C_{\text{min,A}}$$

Continued…

PROBLEM 11.70 (Cont.)

SW: $\dot{m}c_{p,\text{sw}} = 4120\ \text{kg/s} \times 3985\ \text{J/kg}\cdot\text{K} = 16.4 \times 10^6\ \text{W/K} = C_{\max,\text{A}}$

$C_{r,\text{A}} = C_{\min,\text{A}} / C_{\max,\text{A}} = 630 \times 10^3 / 16.4 \times 10^6 = 0.0384$

The effectiveness is

$$\varepsilon_\text{A} = \frac{q_\text{A}}{C_{\min,\text{A}}(T_{h,i,\text{A}} - T_{c,i,\text{A}})} = \frac{50.4 \times 10^6\ \text{W}}{630 \times 10^3\ \text{W/K} \times (13.1 - (-155)°\text{C})} = 0.476$$

The NTU is determined from Equation 11.29b

$$\text{NTU}_\text{A} = \frac{1}{C_{r,\text{A}} - 1} \ln\left(\frac{\varepsilon_\text{A} - 1}{\varepsilon_\text{A} C_{r,A} - 1}\right) = \frac{1}{0.0384 - 1} \ln\left(\frac{0.476 - 1}{0.476 \times 0.0384 - 1}\right) = 0.653$$

and the area of Section A is

$$A_\text{A} = \frac{\text{NTU}_\text{A} C_{\min,\text{A}}}{U_\text{A}} = \frac{0.653 \times 630 \times 10^3\ \text{W/K}}{150 \text{W}/\text{m}^2 \cdot \text{K}} = 2740\ \text{m}^2$$

<u>Section B</u> The heat capacity rates are

NG: $C_{\max,\text{B}} \to \infty$

SW: $\dot{m}c_{p,\text{sw}} = 4120\ \text{kg/s} \times 3985\ \text{J/kg}\cdot\text{K} = 16.4 \times 10^6\ \text{W/K} = C_{\min,\text{B}}$

$C_{r,\text{A}} = C_{\min,\text{B}} / C_{\max,\text{B}} = 0$

The effectiveness is

$$\varepsilon_\text{B} = \frac{q_\text{B}}{C_{\min,\text{B}}(T_{h,i,\text{B}} - T_{c,i,\text{B}})} = \frac{q_\text{B}}{C_{\min,\text{B}}(T_{h,i,\text{B}} - T_f)} = \frac{86.3 \times 10^6\ \text{W}}{16.4 \times 10^6\ \text{W/K} \times (18.3 - (-75)°\text{C})} = 0.0563$$

and the NTU is determined from Equation 11.29b

$$\text{NTU}_\text{B} = -\frac{\ln[1 - 0.0563]}{1} = 0.0579 \quad ; \quad A_\text{B} = \frac{\text{NTU}_\text{B} C_{\min,\text{B}}}{U_\text{B}} = \frac{0.0579 \times 16.4 \times 10^6\ \text{W/K}}{260 \text{W}/\text{m}^2 \cdot \text{K}} = 3660\ \text{m}^2$$

<u>Section C</u> The heat capacity rates are

NG: $\dot{m}c_{p,v} = 150\ \text{kg/s} \times 2210\ \text{J/kg}\cdot\text{K} = 332 \times 10^3\ \text{W/K} = C_{\min,\text{C}}$

SW: $\dot{m}c_{p,\text{sw}} = 4120\ \text{kg/s} \times 3985\ \text{J/kg}\cdot\text{K} = 16.4 \times 10^6\ \text{W/K} = C_{\max,\text{C}}$

$C_{r,\text{C}} = C_{\min,\text{C}} / C_{\max,\text{C}} = 332 \times 10^3 / 16.4 \times 10^6 = 0.020$

The effectiveness is

$$\varepsilon_\text{C} = \frac{q_\text{C}}{C_{\min,\text{C}}(T_{h,i,\text{C}} - T_{c,i,\text{C}})} = \frac{q_\text{C}}{C_{\min,\text{C}}(T_{h,i,\text{C}} - T_f)} = \frac{27.5 \times 10^6\ \text{W}}{332 \times 10^3\ \text{W/K} \times (20 - (-75)°\text{C})} = 0.874$$

and the NTU is found from Equation 11.29b

Continued…

PROBLEM 11.70 (Cont.)

$$\mathrm{NTU_C} = \frac{1}{0.020-1}\ln\left(\frac{0.874-1}{0.874\times 0.020-1}\right) = 2.09\,;\; A_\mathrm{C} = \frac{\mathrm{NTU_C}C_\mathrm{min,C}}{U_\mathrm{C}} = \frac{2.09\times 332\times 10^3\ \mathrm{W/K}}{40\mathrm{W/m^2\cdot K}} = 17{,}300\ \mathrm{m^2}$$

Therefore, the total heat transfer area for the vaporizer is

$$A = A_\mathrm{A} + A_\mathrm{B} + A_\mathrm{C} = 2740\ \mathrm{m^2} + 3660\ \mathrm{m^2} + 17{,}300\ \mathrm{m^2} = 23{,}700\ \mathrm{m^2} \qquad <$$

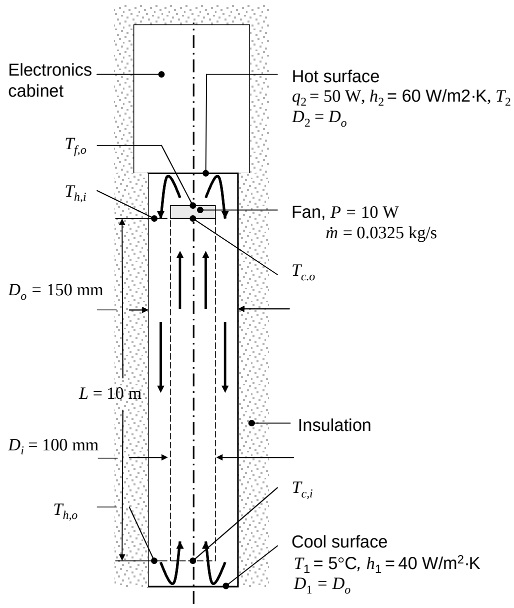
COMMENTS: (1) The scheme may not be feasible in a cold-weather port due to the potential of freezing the seawater. In cold-weather ports, approximately 2% of the natural gas will be burned, with the combustion products sent through the vaporizer to supply the necessary heating. See B. Eisentrout, S. Wintercorn and B. Weber, “Study Focuses on Six LNG Regasification Systems,” *LNG Journal*, July/August, pp. 21 – 22, 2006. (2) For a parallel flow vaporizer with sea water introduced at the bottom of the heat exchanger, the required area is $A = 36{,}900\ \mathrm{m^2}$, a 55% larger heat exchanger. See Problem 11.69.

PROBLEM 11.71

KNOWN: Heat dissipation by electronics in sealed enclosure and dissipation from air-handling fan, mass flow rate of air, dimensions of concentric tube tower, temperature of ground water, heat transfer coefficients at top and bottom surfaces.

FIND: Temperature of the hot plate, T_2, for infinite and zero conduction resistance in the inner concentric tube. Determine whether maximum temperatures are maintained below 80°C.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat transfer between the device and the surroundings, (2) Constant properties.

PROPERTIES: *Table A.4* (air) ($\bar{T}$ = 300 K): c_p = 1014 J/kg·K, $\mu = 185 \times 10^{-7}$ N·s/m², k = 0.0263 W/m·K, Pr = 0.707.

ANALYSIS: The overall heat transfer coefficient associated with the concentric tube section of the device depends on the values of the inside and outside convective heat transfer coefficients, h_i and h_o. For the inside convection coefficient, the Reynolds number is

$$Re_D = \frac{4\dot{m}}{\pi D \mu} = \frac{4 \times 0.0325 \text{ kg/s}}{\pi \times 0.100 \text{ m} \times 185 \times 10^{-7} \text{ N} \cdot \text{s/m}^2} = 22370$$

Since L/D = 10 m/ 0.100 m = 100, the flow is fully-developed and turbulent. Using the Dittus-Boelter correlation,

$$Nu_D = 0.023 \times (22370)^{4/5} \times 0.707^{0.4} = 60.43 \;;\; h_i = 60.43 \times 0.0263 \text{W/m} \cdot \text{K} / 0.100 \text{ m} = 15.90 \text{W/m}^2 \cdot \text{K}$$

For the annulus, the characteristic length is the hydraulic diameter, $D_h = D_o - D_i$ = 0.150 m – 0.100 m = 0.050 m. Hence, the Reynolds number for the annular flow is Re_D = 22370 × 2 = 44740. Therefore, the annular flow is also turbulent and fully-developed. Using the Dittus-Boelter correlation,

$$Nu_D = 0.023 \times (44740)^{4/5} \times 0.707^{0.3} = 108.9 \;;\; h_o = 108.9 \times 0.0263 \text{W/m} \cdot \text{K} / 0.050 \text{ m} = 57.28 \text{ W/m}^2 \cdot \text{K}$$

Continued…

PROBLEM 11.71 (Cont.)

The overall heat transfer coefficient is $U = (1/h_i + 1/h_o)^{-1} = 12.44\ \text{W/m}^2\cdot\text{K}$, assuming no wall conduction resistance. The heat capacity rates of the two air streams are identical and are $C_{\min} = C_{\max} = \dot{m}\, c_p = 0.0325\ \text{kg/s} \times 1014\ \text{J/kg}\cdot\text{K} = 32.73\ \text{W/K}$. The relative heat capacity rate is $C_r = 1$. Hence, $\text{NTU} = UA/C_{\min} = 12.44\ \text{W/m}^2\cdot\text{K} \times \pi \times 0.100\ \text{m} \times 10\ \text{m}/[32.73\ \text{W/K}] = 1.19$. From Eq. 11.29a, the effectiveness is $\varepsilon = \text{NTU}/(1 + \text{NTU}) = 1.19/2.19 = 0.543$. The heat transfer rate in the concentric tube, counter-flow heat exchanger, q_{HX}, is

$$q_{\text{HX}} = \varepsilon C_{\min}(T_{h,i} - T_{c,i}) = 0.543 \times 32.73\text{W/K}(T_{h,i} - T_{c,i}) \qquad (1)$$

$$q_{\text{HX}} = \dot{m}c_p(T_{h,i} - T_{h,o}) = 0.0325\text{kg/s} \times 1014\text{J/kg}\cdot\text{K}(T_{h,i} - T_{h,o}) \qquad (2)$$

At Surface 1, the heat flux is

$$q_1'' = \frac{(q+P)}{A_c} = \frac{(50\text{W} + 10\text{W})}{\left(\pi\left(0.15\text{m}\right)^2/4\right)} = \overline{h}_1\left(T_{h,o} - T_1\right) = 40\text{W/m}^2\cdot\text{K}\left(T_{h,o} - T_1\right) \qquad (3)$$

At Surface 2, the heat flux may be expressed as

$$q_2'' = \frac{q}{A_c} = \frac{50\text{W}}{\left(\pi\left(0.15\text{m}\right)^2/4\right)} = \overline{h}_2\left(T_2 - T_{f,o}\right) = 60\text{W/m}^2\cdot\text{K}\left(T_2 - T_{f,o}\right) \qquad (4)$$

By considering a control volume about the fan,

$$P = 10\text{W} = \dot{m}c_p(T_{f,o} - T_{c,o}) = 10\text{W} = 0.0325\text{kg/s} \times 1014\text{J/kg}\cdot\text{K}(T_{f,o} - T_{c,o}) \qquad (5)$$

For the control volume in the vicinity of Surface 1,

$$P + q = \dot{m}c_p(T_{h,o} - T_{c,i}) = 50\text{W} + 10\text{W} = 0.0325\text{kg/s} \times 1014\text{J/kg}\cdot\text{K} \times (T_{h,o} - T_{c,i}) \qquad (6)$$

For the control volume in the vicinity of Surface 2,

$$q = \dot{m}c_p(T_{h,i} - T_{f,o}) = 50\text{W} = 0.0325\text{kg/s} \times 1014\text{J/kg}\cdot\text{K} \times (T_{h,i} - T_{f,o}) \qquad (7)$$

Equations (1) through (7) may be solved simultaneously to yield the following results.

$U = 12.44\ \text{W/m}^2\cdot\text{K}$ (zero conduction resistance):

T_2	$T_{f,o}$	$T_{c,i}$	$T_{c,o}$	$T_{h,i}$	$T_{h,o}$	q_{HX}
137.6°C	90.49°C	88.06°C	90.19°C	92.01°C	89.88°C	70.1 W

$U = 0\ \text{W/m}^2\cdot\text{K}$ (infinite conduction resistance):

T_2	$T_{f,o}$	$T_{c,i}$	$T_{c,o}$	$T_{h,i}$	$T_{h,o}$	q_{HX}
135.5°C	88.37°C	88.06°C	88.06°C	89.88°C	89.88°C	0 W

Neither case provides acceptable maximum temperatures. <

Continued…

PROBLEM 11.71 (Cont.)

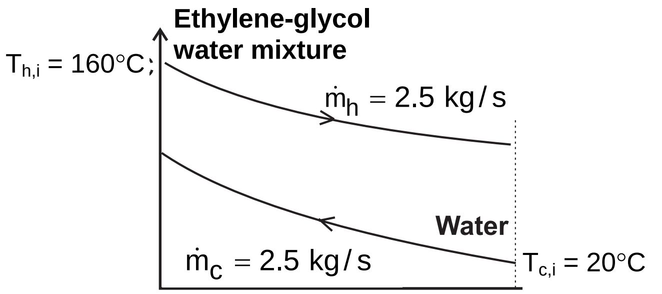
COMMENTS: (1). The heat transfer coefficients at Surfaces 1 and 2 are relatively small. Improved performance would result by increasing the surface area available for transfer through, for example, addition of fins. (2). Significantly improved performance would result by replacing the air and fan arrangement with liquid water and a pump. (3) See Hadim, Mehmedagic, and Wendell, "A New GEOPOLE Cooling Technique for Outdoor Electronic Enclosures," *International Journal of Energy Research*, Vol. 30, pp. 459 – 470, 2006, for more information.

PROBLEM 11.72

KNOWN: Inlet and outlet temperatures and flow rates for a shell-and-tube heat exchanger with a single shell and 100 tubes making two passes. Tube inner and outer diameters and length. Heat transfer coefficient for ethylene-glycol water mixture flowing in shell.

FIND: (a) Heat transfer rate and outlet temperatures when the tubes are copper. (b) For nylon tubes, heat exchanger length required to transfer the same amount of energy as in part (a).

SCHEMATIC:



Shell and tube hx
1 shell pass
2 tube passes
100 tubes
D_i = 3.6 mm
D_o = 3.8 mm
L = 0.8 m (0.4 m per pass)
h_o = 11,000 W/m^2·K

ASSUMPTIONS: (1) Negligible heat loss to the surroundings, (2) Constant properties, (3) Fully developed water flow in tubes.

PROPERTIES: *Table A.6*, water (T ≈ 300 K): k = 0.613 W/m·K, c_p = 4179 J/kg·K, μ = 855 × 10^{-6} N·s/m^2, Pr = 5.83. Ethylene-glycol water mixture (given): ρ = 1040 kg/m^3, c_p = 3660 J/kg·K. Copper (T ≈ 300 K): k_c = 401 W/m·K. Nylon (given): k_n = 0.31 W/m·K.

ANALYSIS: (a) We begin by finding the heat transfer coefficient for the flow in tubes. The Reynolds number is

$$\mathrm{Re}_D = \frac{4\dot{m}_1}{\pi D_i \mu_c} = \frac{4 \times 2.5\ \mathrm{kgs}/100}{\pi \times 0.0036\ \mathrm{m} \times 855 \times 10^{-6}\ \mathrm{N \cdot s/m^2}} = 1.03 \times 10^4$$

Hence the flow is turbulent and we can use the Dittus-Boelter correlation,

$$h_c = (k/D_i)0.023\mathrm{Re}_D^{4/5}\mathrm{Pr}^{0.4} = (0.613\ \mathrm{W/m \cdot K}/0.0036\ \mathrm{m})0.023(1.03 \times 10^4)^{4/5}(5.83)^{0.4}$$
$$= 1.29 \times 10^4\ \mathrm{W/m^2 \cdot K}$$

Then UA can be found from

$$UA = \left[\frac{1}{h_i \pi D_i} + \frac{\ln(D_o/D_i)}{2\pi k_c} + \frac{1}{h_o \pi D_o}\right]^{-1} LN$$

$$= \left[6.85 \times 10^{-3} + 2.15 \times 10^{-5} + 7.62 \times 10^{-3}\right]^{-1} \mathrm{W/m \cdot K} \times 0.8\ \mathrm{m} \times 100 = 5522\ \mathrm{W/K}$$

Continued…

PROBLEM 11.72 (Cont.)

Using the ε-NTU method, $C_{min} = C_h = 2.5$ kg/s × 3600 J/kg·K = 9000 W/K, $C_{max} = 2.5$ kg/s × 4179 J/kg·K = 10,450 W/K, $C_r = 0.861$, and NTU = UA/C_{min} = 0.614. Then from Eq. 11.30a,

$$\varepsilon = 2\left\{1 + C_r + (1+C_r^2)^{1/2} \times \frac{1+\exp\left[-NTU(1+C_r^2)^{1/2}\right]}{1-\exp\left[-NTU(1+C_r^2)^{1/2}\right]}\right\}^{-1} = 0.378$$

and from Eqs. 11.18, 11.19, 11.6b, and 11.7b,

$q = \varepsilon C_{min}(T_{h,i} - T_{c,i}) = 0.378 \times 9000$ W/K (80 – 20)°C = 204 kW <

$T_{h,o} = T_{h,i} - q/C_h$ = 80°C - 204,000 W/9000 W/K = 57.3°C <

$T_{c,o} = T_{c,i} + q/C_c$ = 20°C + 204,000 W/10,450 W/K = 42.7°C <

(b) In order to maintain the same heat rate, we must have the same effectiveness, which means that NTU and UA must be the same as in part (a). When the tubes are nylon, we can recalculate UA from Eq. (1),

$$UA = \left[\frac{1}{h_i \pi D_i} + \frac{\ln(D_o/D_i)}{2\pi k_n} + \frac{1}{h_o \pi D_o}\right]^{-1} LN$$

$$= \left[6.85\times10^{-3} + 2.78\times10^{-2} + 7.62\times10^{-3}\right]^{-1} W/m\cdot K \times 100 \times L\ (m) = 5522\ W/K$$

Solving for L,

L = 2.33 m <

COMMENTS: (1) The nylon tube bundle is significantly larger due to nylon's low thermal conductivity relative to the copper. Based upon a nylon density of 1150 kg/m^3, the masses of the two tube bundles are 0.83 kg and 0.39 kg for the copper and nylon, respectively. The cost difference between the two raw materials is negligible. However, the nylon heat exchanger may ultimately be less expensive when assembly costs are considered. Time-consuming and expensive brazing, joining, and welding processes associated with construction of the copper heat exchanger are avoided with use of materials such as nylon. (2) With L/D ≈ 200, the fully developed assumption is excellent. (3) The properties of the cold stream should have been calculated at the mean temperature of 304 K, very close to the assumed value.

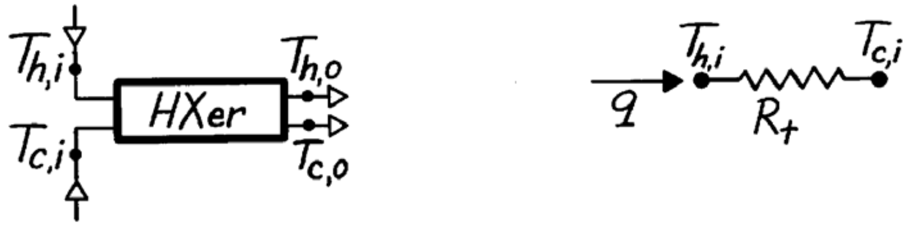
www.konkur.in

PROBLEM 11.73

KNOWN: Heat exchanger operating in parallel-flow configuration.

FIND: Expression for R_{lm}/R_t which doesn't involve temperatures. Plot result.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible change in kinetic and potential energy.

ANALYSIS: (a) For the exchanger, the rate equation is

$$q = UA\Delta T_{lm}$$

and we can define thermal resistances as

$$R_t = \left(T_{h,i} - T_{c,i}\right)/q \qquad \text{or} \qquad R_{lm} = \left(\Delta T_{lm}\right)/q = 1/UA.$$

Using the rate equation and the definition of effectiveness, find the thermal resistance based upon the inlet temperatures of the hot and cold fluids as

$$R_t = C_{min}\left(T_{h,i} - T_{c,i}\right)/C_{min} \cdot q = 1/\varepsilon C_{min}.$$

The ratio of these resistances is

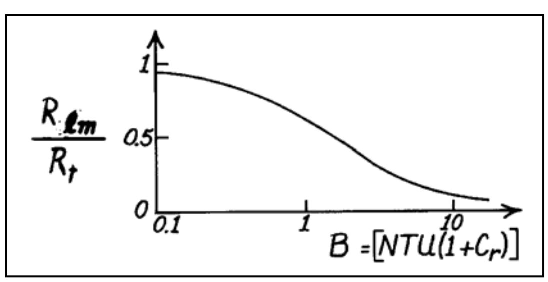
$$\frac{R_{lm}}{R_t} = \frac{1/UA}{1/\varepsilon C_{min}} = \frac{\varepsilon}{UA/C_{min}} = \frac{\varepsilon}{NTU}$$

and for the parallel flow, concentric tube configuration using Eq. 11.28a,

$$\frac{R_{lm}}{R_t} = \frac{1-\exp\left[-NTU\left(1+C_r\right)\right]}{NTU\left(1+C_r\right)} = \frac{1-\exp(-B)}{B}$$ <

where B = NTU(1 + C_r). Evaluating the ratio for various values of B, find <

B	R_{lm}/R_t
0.1	0.95
0.5	0.79
1.0	0.63
3.0	0.32
5.0	0.20
10.0	0.10



COMMENTS: (1) For $C_{max} \rightarrow \infty$, $C_r \rightarrow 0$; hence B $\rightarrow$ NTU. (2) For $C_{max} \approx C_{min}$, B $\rightarrow$ 2NTU or B ~ C_{min}^{-1}. (3) For B << 1, $R_{lm}/R_t \rightarrow 1$. (4) For B >> 1, $R_{lm}/R_t \rightarrow B^{-1}$. (5) We conclude that care must be taken in representing heat exchangers with a thermal resistance, recognizing that the resistance will depend on flow rates for wide ranges of conditions.

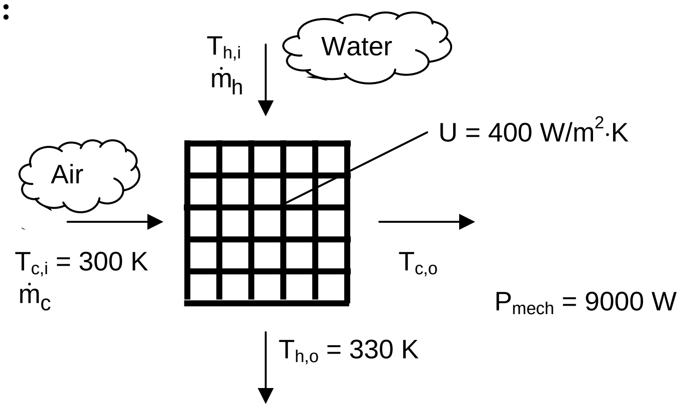
Telegram: @uni_k

PROBLEM 11.74

KNOWN: Required power for automobile. Overall heat transfer coefficient for radiator, analyzed as a cross-flow heat exchanger with both fluids unmixed. Inlet temperature of air for cooling.

FIND: (a) Required heat transfer area if engine efficiency is 35%, water inlet and outlet temperatures are 400 and 330 K, respectively, and air flow rate is 3 kg/s. (b) Required heat transfer area and engine coolant (water) mass flow rate if vehicle is powered by 50% efficient fuel cell, water inlet and outlet temperatures are 335 and 330 K, respectively, and air flow rate is proportional to radiator surface area. (c) Required heat transfer area and coolant (water) outlet temperature for fuel cell powered vehicle if air flow rate is 3 kg/s.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to the surroundings, (2) Constant properties, (3) Negligible fouling factors.

PROPERTIES: *Table A.6*, water: ($\overline{T}_m$ = 365 K): c_p = 4209 J/kg·K: *Table A.4*, air ($\overline{T}_m$ ≈ 350 K): c_p = 1009 J/kg·K.

ANALYSIS: (a) We can determine how much heat must be removed by the radiator as follows. The required mechanical power is 9 kW, which is 35% of the total engine power, i.e. P_{tot} = 9 kW/0.35 = 25.7 kW. The waste heat is 65% of the total power, or

$$q = 0.65P_{tot} = 0.65 \times 25.7 \text{ kW} = 16.7 \text{ kW}$$

Then from Eq. 11.6b,

$$C_h = q/(T_{h,i} - T_{h,o}) = 16.7 \text{ kW}/(400 - 330)\text{K} = 239 \text{ W/K}$$

The heat capacity rate for the air is

$$C_c = (\dot{m}c_p)_c = 3 \text{ kg/s} \times 1009 \text{ J/kg} \cdot \text{K} = 3027 \text{ W/K}$$

Continued…

PROBLEM 11.74 (Cont.)

Thus $C_{min} = C_h$, $C_r = 239/3027 = 0.0789$ and $\varepsilon = q/C_{min}(T_{h,i} - T_{h,o}) = 0.699$. Then from Fig. 11.14, NTU ≈ 1.25, and we can refine this estimate by solving Eq. 11.32 iteratively, to yield NTU = 1.26. Thus, UA = NTU × C_{min} = 1.26 × 239 W/K = 301 W/K. With U = 400 $W/m^2 \cdot K$,

$$A = UA/U = 301\ W/K / 400\ W/m^2 \cdot K = 0.752\ m^2$$ <

(b) With 50% efficiency, P_{tot} = 9 kW/0.50 = 18 kW and q = 0.50P_{tot} = 9 kW. Then

$$C_h = q/(T_{h,i} - T_{h,o}) = 9\ kW/(355 - 330)K = 360\ W/K$$

and

$$\dot{m}_h = C_h / c_{p,h} = 360\ W/K / 4209\ J/kg \cdot K = 0.0855\ kg/s$$ <

The heat capacity rate for the air is unknown, but can be expressed as follows, where the "o" subscript refers to the baseline conditions of part (a),

$$C_c = (\dot{m}c_p)_c = (\dot{m}_o c_p)_c \frac{A}{A_o} = 3027\ W/K \frac{A}{0.752\ m^2} = (4025\ W/m^2 \cdot K)A$$

Assuming the hot fluid is still the minimum fluid, C_{min} = 360 W/K,

$$\varepsilon = q/C_{min}(T_{h,i} - T_{c,i}) = 9\ kW/[360\ W/K(355 - 300)K] = 0.455 \quad (1)$$

$$C_r = (360\ W/K / 4025\ W/m^2 \cdot K)A^{-1} = (0.0895\ m^2)\ A^{-1} \quad (2)$$

$$NTU = UA/C_{min} = (400\ W/m^2 \cdot K/360\ W/K)A = (1.11\ m^{-2})A \quad (3)$$

And from Eq. 11.32,

$$\varepsilon = 1 - \exp\left[\left(\frac{1}{C_r}\right)(NTU)^{0.22}\left\{\exp\left[-C_r(NTU)^{0.78}\right] - 1\right\}\right] \quad (4)$$

Substituting Eqs. (1), (2), and (3) into Eq. (4),

$$0.455 = 1 - \exp\left[\left(\frac{A}{0.0895\ m^2}\right)(1.11\ m^{-2}A)^{0.22}\left\{\exp\left[-\frac{0.0895\ m^2}{A}(1.11\ m^{-2}A)^{0.78}\right] - 1\right\}\right]$$

Solving iteratively for A results in

$$A = 0.576\ m^2$$ <

Note that C_c = 2.30 kg/s × 1009 J/kg·K = 2319 W/K, so that our assumption that the hot fluid is the minimum was correct.

Continued…

PROBLEM 11.74 (Cont.)

(c) With the same coolant (water) flow rate as in part (a), $C_h = 239$ W/K. Then

$$\varepsilon = q/C_{min}(T_{h,i} - T_{c,i}) = 9 \text{ kW}/[239 \text{ W/K}(355 - 300)\text{K}] = 0.685 \quad (5)$$

$$C_r = (239 \text{ W/K} / 4025 \text{ W/m}^2\cdot\text{K})A^{-1} = (0.0594 \text{ m}^2)\, A^{-1} \quad (6)$$

$$NTU = UA/C_{min} = (400 \text{ W/m}^2\cdot\text{K}/239 \text{ W/K})A = (1.67 \text{ m}^{-2})A \quad (7)$$

And substituting Eqs. (5), (6), and (7) into Eq. (4),

$$0.685 = 1 - \exp\left[\left(\frac{A}{0.0594 \text{ m}^2}\right)(1.67 \text{ m}^{-2}A)^{0.22}\left\{\exp\left[-\frac{0.0594 \text{ m}^2}{A}(1.67 \text{ m}^{-2}A)^{0.78}\right] - 1\right\}\right]$$

Solving iteratively for A results in

$$A = 0.723 \text{ m}^2$$ <

The outlet temperature of the coolant (water) is calculated from Eq. 11.6b,

$$T_{h,o} = T_{h,i} - q/C_h = 355 \text{ K} - 9000 \text{ W}/239 \text{ W/K} = 317 \text{ K}$$ <

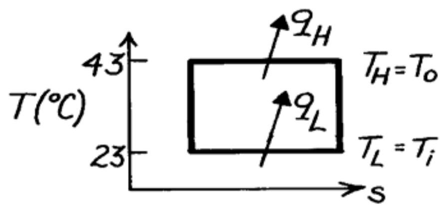
COMMENTS: (1) The heat that must be rejected from the radiator when the fuel cell is used is 9000 W/16700 W × 100 = 53% of that associated with the internal combustion engine. (2) As seen in Part (b), using the fuel cell and increasing the flow rate of the coolant results in a significantly smaller radiator size. (3) As seen in Part (c), if the coolant flow rate is the same as that of the internal combustion engine the coolant exits the radiator at a lower value since its residence time in the radiator is larger. (4) Reduced radiator sizes will provide opportunities to enhance streamlining of the front of the vehicle and will reduce drag forces, further increasing fuel economy. The radiator size can be reduced significantly with the fuel cell in place if a metal hydride hydrogen storage system is on board and waste heat from the fuel cell is used to desorb the hydrogen, as discussed in Example 7.5.

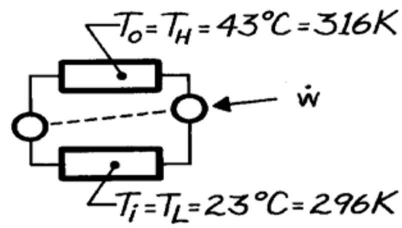
PROBLEM 11.75

KNOWN: Air conditioner modeled as a reversed Carnot heat engine, with refrigerant as the working fluid, operating between indoor and outdoor temperatures of 23 and 43°C, respectively, removing 5 kW from a building. Compressor and fan motor efficiency of 80%.

FIND: (a) Required motor power assuming negligible thermal resistances *between* the refrigerant in the condenser and the outside air and *between* the refrigerant in the evaporator and the inside air, and (b) Required power if thermal resistances are each 3×10^{-3} K/W.

SCHEMATIC:





ASSUMPTIONS: (1) Ideal heat exchanger with no losses, (2) Air conditioner behaves as reversed Carnot engine.

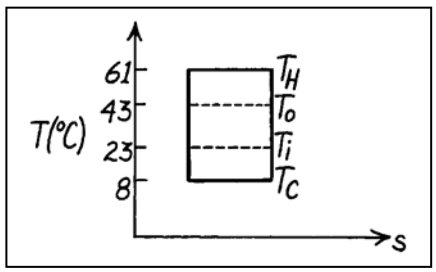
ANALYSIS: (a) With negligible thermal resistances, the Carnot cycle and reversed heat engine can be represented as shown above. Hence, from Chapter 1

$$\dot{w}_{ideal} = q_H - q_L = q_L\left[\left(T_H / T_L\right) - 1\right] = 5\text{kW}\left[\left(316\text{ K} / 296\text{ K}\right) - 1\right] = 0.3378\text{ kW}.$$

Considering the fan power requirement and the efficiency of the motor,

$$\dot{w}_{act} = \left(\dot{w}_{ideal} + \dot{w}_{fan}\right) / \eta_c = \left(0.3378 + 0.200\right)\text{kW} / 0.8 = 0.672\text{ kW}. \qquad <$$

(b) Consider now thermal resistances of $R_t = 3 \times 10^{-3}$ K/W on the high temperature (condenser) and low temperature (evaporator) sides.



Low side: in order to remove heat from the room, $T_C < T_i$. That is

$$T_i - T_C = qR_t = 5\text{ kW}\left(3 \times 10^{-3}\text{ K/W}\right) = 15\text{ K}$$

$$T_C = T_i - 15\text{ K} = 23°\text{C} - 15\text{ K} = 8°\text{C}.$$

High side: in order to reject heat from the condenser to the outside air, $T_H > T_o$,

$$T_H - T_o = q_H R_t = q_c\left(T_H / T_c\right)R_t$$

$$T_H - \left(43 + 273\right)\text{K} = 5\text{ kW}\left[T_H / \left(8 + 273\right)\right]3 \times 10^{-3}\text{ K/W} \qquad T_H = 333.9\text{ K} = 61°\text{C}.$$

The work required for this cycle is

$$\dot{w}_{ideal} = q_H - q_L = q_L\left[\left(T_H / T_L\right) - 1\right] = 5\text{ kW}\left[\left(61 + 273\right)\text{K} / \left(8 + 273\right)\text{K} - 1\right] = 0.943\text{ kW}$$

$$\dot{w}_{act} = \left(\dot{w}_{ideal} + \dot{w}_{fan}\right) / \eta_c = \left(0.943 + 0.2\right)\text{kW} / 0.8 = 1.43\text{ kW}. \qquad <$$

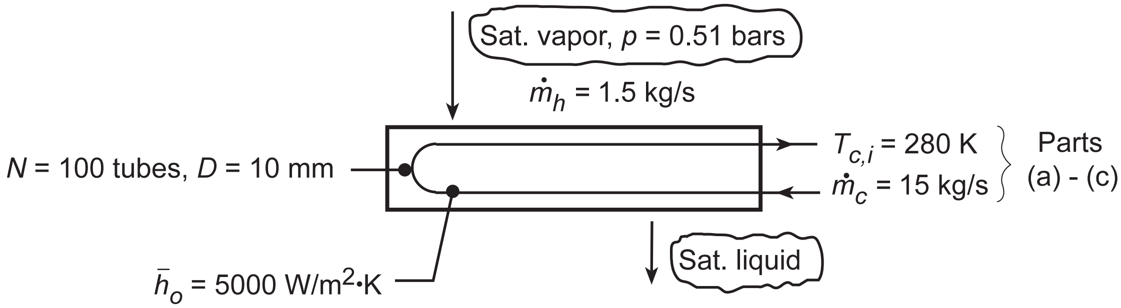
The effect of finite thermal resistances in the evaporator and condenser is to increase the power by a factor of two.

PROBLEM 11.76

KNOWN: Flow rate and pressure of saturated vapor entering a condenser. Number and diameter of condenser tubes. Water flow rate and inlet temperature. Tube outside convection coefficient.

FIND: (a) Water outlet temperature, (b) Total tube length, (c) Effect of fouling on mass condensation, (d) Effect of water flow rate and inlet temperature on condenser performance.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Negligible wall conduction resistance and fouling (initially).

PROPERTIES: Water (given): c_p = 4178 J/kg·K, $\mu = 700 \times 10^{-6}$ kg/s·m, k = 0.628 W/m·K, Pr = 4.6; *Table A.6*, Sat. steam (355 K): $h_{fg} = 2.304 \times 10^6$ J/kg; With fouling: $R''_f = 0.0003$ m^2·K/W.

ANALYSIS: (a) From an energy balance, $q_h = \dot{m}_h\left(i_{h,i} - i_{h,o}\right) = \dot{m}_h h_{fg} = q_c = \dot{m}_c c_{p,c}\left(T_{c,o} - T_{c,i}\right)$, or

$$T_{c,o} = T_{c,i} + \frac{\dot{m}_h h_{fg}}{\dot{m}_c c_{p,c}} = 280\,\text{K} + \frac{1.5\,\text{kg/s} \times 2.304 \times 10^6\ \text{J/kg}}{15\,\text{kg/s} \times 4178\,\text{J/kg}\cdot\text{K}} = 335.1\,\text{K}.$$ <

(b) Since $C_r = 0$, NTU = -ln(1 - ε), where

$$\varepsilon = \frac{q}{q_{max}} = \frac{\dot{m}_c c_{p,c}\left(T_{c,o} - T_{c,i}\right)}{\dot{m}_c c_{p,c}\left(T_{h,i} - T_{c,i}\right)} = \frac{(335.1 - 280)\,\text{K}}{(355 - 280)\,\text{K}} = 0.735$$

Hence, NTU = -ln(1 - 0.735) = 1.327 = UA/C_{min}. The overall heat transfer coefficient is given by 1/U = $1/\bar{h}_i + 1/\bar{h}_o$. For the internal tube flow,

$$Re_D = \frac{4\dot{m}_{c,1}}{\pi D \mu} = \frac{4 \times 15\,\text{kg/s}/100}{\pi(0.01\,\text{m})\,700 \times 10^{-6}\ \text{kg/s}\cdot\text{m}} = 27,284$$

Hence, assuming fully developed flow with the Dittus-Boelter correlation,

$$Nu_D = 0.023\,Re_D^{4/5}\,Pr^n = 0.023(27,284)^{4/5}(4.6)^{0.4} = 149.8$$

$$\bar{h}_i = (k/D)\,Nu_D = \frac{0.628\,\text{W/m}\cdot\text{K}}{0.01\,\text{m}}149.8 = 9408\,\text{W/m}^2\cdot\text{K}$$

and $U = \left[(1/9408) + (1/5000)\right]^{-1}\text{W/m}^2\cdot\text{K} = 3265\,\text{W/m}^2\cdot\text{K}$. Hence, the heat transfer area is

$$A = \dot{m}_c c_{p,c}\left(\text{NTU}/U\right) = 15\,\text{kg/s}\left(4178\,\text{J/kg}\cdot\text{K}\right)\left(1.327/3265\,\text{W/m}^2\cdot\text{K}\right) = 25.5\,\text{m}^2$$

and the tube length is L = A/NπD = 25.5 m^2/100π(0.01 m) = 8.11 m. <

(c) With fouling, the overall heat transfer coefficient is $1/U_w = 1/U_{wo} + R''_f$. Hence,

Continued...

PROBLEM 11.76 (Cont.)

$$1/U_w = \left(3.063\times10^{-4} + 3\times10^{-4}\right) m^2 \cdot K/W$$

$U_w = 1649\ W/m^2\cdot K$.

$$NTU = UA/C_{min} = \left(1649\ W/m^2\cdot K \times 25.5\ m^2\right) / \left(15\ kg/s \times 4178\ J/kg\cdot K\right) = 0.671$$

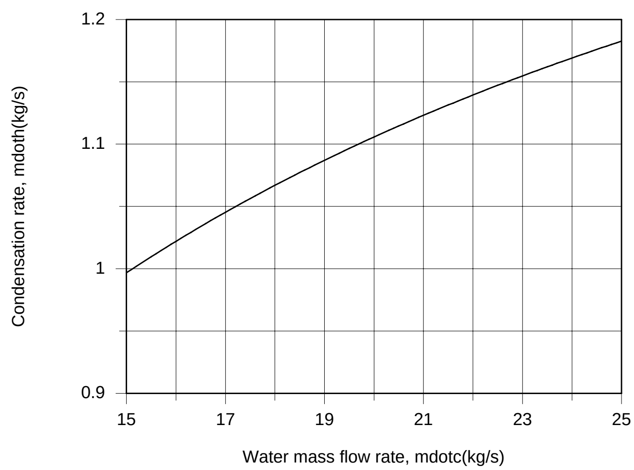
From Eq. 11.35a, $\varepsilon = 1 - \exp(-NTU) = 1 - \exp(-0.671) = 0.489$. Hence, $q = \varepsilon q_{max} = 0.489 \times 15\ kg/s \times 4178\ J/kg\cdot K(355 - 280)K = 2.30 \times 10^6\ W$. Without fouling the heat rate was

$$q = \dot{m}_h h_{fg} = 1.5\ kg/s \times 2.304\times10^6\ J/kg = 3.46\times10^6\ W.$$

Hence, $\dot{m}_{h,w}/\dot{m}_{h,wo} = 2.30\times10^6 / 3.46\times10^6 = 0.666$. $<$

The condensation rate with fouling is then $\dot{m}_{h,w} = 0.666\times1.5\ kg/s = 0.998\ kg/s$.

(d) The prescribed water inlet temperature of $T_{c,i} = 280$ K is already at the lower limit of available sources, and it would not be feasible to consider smaller values. In addition, with $\bar{h}_i$ already quite large, an increase in $\dot{m}_c$ is not likely to provide a significant improvement in performance. Using the *Heat Exchanger* and *Correlations* Tools from IHT, the following results were obtained for $15 \le \dot{m}_c \le 25$ kg/s.



Over the specified range of $\dot{m}_c$, there is approximately an 18% increase in the heat rate, and hence in the condensation rate. This increase is, in part, due to the increase in $\bar{h}_i$ from 9408 to 14,160 $W/m^2\cdot K$, which increases U from 1649 to 1752 $W/m^2\cdot K$, as well as to a reduction in $T_{c,o}$ from 316.6 to 306.0 K, which increases the mean driving potential for heat transfer.

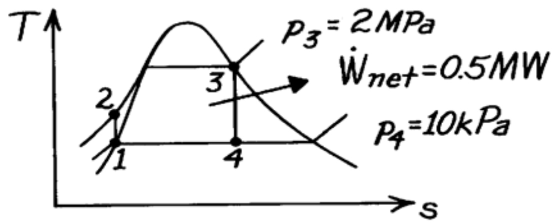
COMMENTS: There is a significant reduction in performance due to fouling, which can not be restored by increasing $\dot{m}_c$. The desired performance could be achieved by oversizing the condenser, that is, by increasing the number of tubes and/or the tube length.

PROBLEM 11.77

KNOWN: Rankine cycle with saturated steam leaving the boiler at 2 MPa and a condenser pressure of 10 kPa. Net reversible work of 0.5 MW.

FIND: (a) Thermal efficiency of ideal Rankine cycle, (b) Required cooling water flow rate to condenser at 15°C with allowable temperature rise of 10°C, and (c) Design of a shell and tube heat exchanger (one shell and multiple tube passes) to satisfy condenser flow rate and temperature rise.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible loss from condenser to surroundings, (2) Ideal Rankine cycle, and (3) Negligible thermal resistance on condensate side of exchanger tubes.

PROPERTIES: *Steam Tables*, (Wark, 4th Edition): (1) $p_1 = p_4 = 10$ kPa = 0.10 bar, $T_{sat} = 45.8°C = 319$ K, $v_f = 1.0102 \times 10^{-3}$ m^3/kg, $h_f = 191.83$ kJ/kg; (3) $p_2 = p_3 = 2$ MPa = 20 bar, $h_g = 2799.5$ kJ/kg, $s_g = 6.3409$ kJ/kg·K; (4) $s_4 = s_3 = 6.3409$ kJ/kg·K, $p_4 = 0.10$ bar, $s_f = 0.6493$ kJ/kg·K, $s_g = 8.1502$ kJ/kg·K, $h_f = 191.83$ kJ/kg·K, $h_{fg} = 2392.8$ kJ/kg; *Table A-6*, Water ($T_{sat} = 293$ K): $c_{p,c} = 4182$ J/kg·K, $\mu = 1007 \times 10^{-6}$ N·s/m^2, k = 0.603 W/m·K, Pr = 7.0. Note: 1 bar = 10^5 N/m^2 = 10^5 Pa.

ANALYSIS: (a) Referring to Chapter 1 and your thermodynamics text, find that

$$\eta = \frac{w_{net}}{Q_H} = \frac{w_t - w_p}{Q_H} = \frac{(h_3 - h_4) - v_1(p_2 - p_1)}{h_3 - h_2}$$

where the net work is the turbine minus the pump work. Assuming the liquid in the pump is incompressible,

$$w_p = v_1(p_2 - p_1) = 1.0102 \times 10^{-3}\, m^3/kg\left(2\times10^6 - 10\times10^3\right) N/m^2 = 2.01\ kJ/kg.$$

To find the enthalpies at states 2, 3, and 4, consider the individual processes. For the *pump*,

$$h_2 = h_1 + w_p = (191.83 + 2.01)\,kJ/kg = 193.84\ kJ/kg.$$

Since the exit state of the boiler is saturated at p_3 = 2 MPa,

$$h_3 = h_g = 2799.5\ kJ/kg.$$

$$Q_H = h_3 - h_2 = (2799.5 - 193.84)\,kJ/kg = 2605.7\ kJ/kg.$$

Since the process from 3 to 4 is isentropic, $s_4 - s_3$, hence

$$x_4 = (s_4 - s_f)/(s_g - s_f) = (6.3409 - 0.6493)/(8.1502 - 0.6493) = 0.759$$

$$h_4 = h_f + xh_{fg} = [191.83 + 0.759(2392.8)]\,kJ/kg = 2007.5\ kJ/kg.$$

Continued …

PROBLEM 11.77 (Cont.)

$$w_t = h_3 - h_4 = (2799.5 - 2007.5)\,\text{kJ/kg} = 792.0\ \text{kJ/kg}.$$

Substituting appropriate values, the thermal efficiency is

$$\eta = \frac{(792.0 - 2.01)\,\text{kJ/kg}}{2605.7\ \text{kJ/kg}} = 0.303 = 30.3\%. \quad <$$

(b) From an overall balance on the cycle, the heat rejected to the condenser is

$$Q_c = Q_H - w_{net} = [2605.7 - (792.0 - 2.01)]\,\text{kJ/kg} = 1815.7\ \text{kJ/kg}.$$

Since the net reversible power is 0.5 MW, the required steam rate (h) is

$$\dot{m}_h = \dot{W}_{net} / w_{net} = 0.5 \times 10^6\ \text{W} / (792.0 - 2.01)\,\text{kJ/kg} = 0.6329\ \text{kg/s}.$$

Hence, the heat rate to be removed by the cold water passing through the condenser is

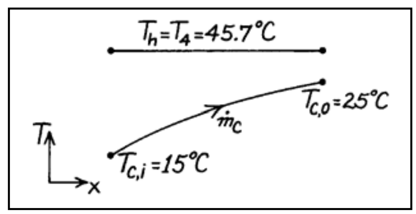
$$q_c = Q_c \cdot \dot{m}_h = \dot{m}_c\, c_{p,c}\left(T_{c,out} - T_{c,in}\right)$$

$$1815.7\ \text{kJ/kg} \times 0.6329\ \text{kg/s} = 1.149 \times 10^6\ \text{W} = \dot{m}_c \times 4182\ \text{J/kg}\cdot\text{K}\,(25 - 15)\,\text{K}$$

$$\dot{m}_c = 27.47\ \text{kg/s} \quad <$$

where $c_{p,c} = c_{p,f}$ is evaluated at T_2, $T_{c,in}$ = 15°C and $T_{c,out} - T_{c,in}$ = 10°C, the specified allowable rise.

(c) To design the heat exchanger we need to evaluate UA. Considering the shell-tube configuration and since $C_r = C_{min}/C_{max} = 0$,



$$\varepsilon = 1 - \exp(-NTU) = 1 - \exp\left[-\left(UA / C_{min}\right)\right]$$

$$\varepsilon = \frac{q}{q_{max}} = \frac{q_c}{\dot{m}_c\, c_{p,c}\left(T_h - T_{c,i}\right)}$$

$$\varepsilon = \frac{1.149 \times 10^6\ \text{W}}{27.47\,\text{kg/s} \times 4182\ \text{J/kg}\cdot\text{K}\,(45.7 - 15)\,\text{K}} = 0.326$$

$$0.326 = 1 - \exp\left(-\frac{UA}{27.47\ \text{kg/s} \times 4182\ \text{J/kg}\cdot\text{K}}\right)$$

$$UA_s = 45{,}372\ \text{W/K}$$

where $C_{min} = \dot{m}_c\, c_{p,c}$. Our design process will involve the following steps: select tube diameter, D = 15 mm; set u_m = 2 m/s in each tube and find number of tubes; perform internal flow calculation to estimate $\bar{h}_c$ and then determine the length.

$$\dot{m}_c = \rho A_c N u_m = \left(1.010 \times 10^{-3}\ \text{m}^3/\text{kg}\right)^{-1} \left(\pi (0.015\text{m})^2 / 4\right) 2\text{m/s} \times N = 27.47\ \text{kg/s}$$

$$N = 78.5 \approx 79.$$

Continued …

PROBLEM 11.77 (Cont.)

For flow in a single tube,

$$\mathrm{Re}_D = \frac{4\dot{m}_t}{\pi D \mu} = \frac{4(27.47\ \mathrm{kg/s}/79)}{\pi(0.015\mathrm{m})1007\times10^{-6}\ \mathrm{N\cdot s/m^2}} = 29,310.$$

Assuming the flow is fully developed and using the Dittus-Boelter correlation,

$$\mathrm{Nu} = \frac{hD}{k} = 0.023\,\mathrm{Re}_D^{0.8}\,\mathrm{Pr}^{0.4} = 0.023(29,310)^{0.8}(7.00)^{0.4} = 187.7$$

$$h = 0.603\ \mathrm{W/m\cdot K}\times187.7/0.015\mathrm{m} = 7544\ \mathrm{W/m^2\cdot K}.$$

Hence, the tube length is

$$UA_s = h(\pi DL)N = 45,372\ \mathrm{W/K}$$

$$L = 45,372\ \mathrm{W/K}/7544\ \mathrm{W/m^2\cdot K}\times\pi(0.015\mathrm{m})79 = 1.6\mathrm{m}$$

and our design has the following parameters:

$N = 79$ tubes $\qquad L = 1.6\mathrm{m} \qquad D = 15$ mm. $\quad <$

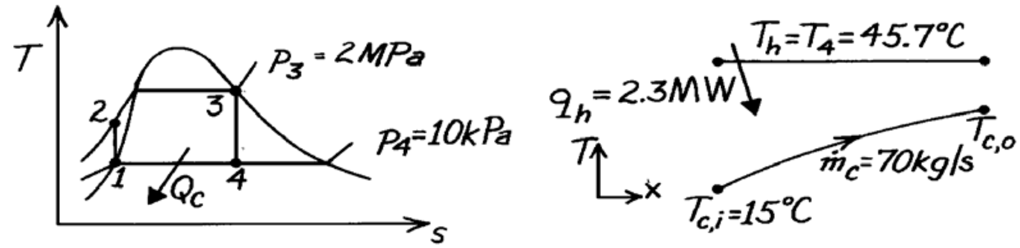
COMMENTS: (1) The selection of the tube diameter and water velocity values (15 mm, 2 m/s) was based upon prior experience; they seemed reasonable. We could, however, establish other requirements which would influence these choices such as allowable pressure drop and standard tube sizes.

PROBLEM 11.78

KNOWN: Rankine cycle with saturated steam leaving the boiler at 2 MPa and a condenser pressure of 10 kPa. Heat rejected to the condenser of 2.3 MW. Condenser supplied with cooling water at rate of 70 kg/s at 15°C.

FIND: (a) Size of the condenser as determined by the parameter, UA, and (b) Reduction in thermal efficiency of the cycle if U decreases by 10% due to fouling assuming water flow rate and inlet temperature and the condenser steam pressure remain fixed.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible loss from condenser to surroundings, (2) Ideal Rankine cycle, (3) For fouled operating condition, $\dot{m}_c$, $T_{c,i}$ and p_4 remain the same.

PROPERTIES: *Steam Tables* (Thermodynamics text): See previous problem for calculations to obtain cycle enthalpies; h_1 = 191.83 kJ/kg, h_4 = 2007.5 kJ/kg.

ANALYSIS: (a) For the condenser, recognize that $C_{min} = C_c$, and $C_r = C_{min}/C_{max} = 0$,

$$\varepsilon = \frac{q}{q_{max}} = 1 - \exp(-NTU) = 1 - \exp(-UA/C_{min})$$

$$C_{min} = \dot{m}_c c_{p,c} = 70 \text{ kg/s} \times 4182 \text{ J/kg}\cdot\text{K} = 292,740 \text{ W/K}$$

$$q_{max} = C_{min}(T_h - T_{c,i}) = 292,740 \text{ W/K}(45.7 - 15)\text{K} = 8.987 \times 10^6 \text{ W.}$$

$$q = q_h = 2.30 \times 10^6 \text{ W}$$

$$\frac{2.30 \times 10^6 \text{ W}}{8.987 \times 10^6 \text{ W}} = 0.256 = 1 - \exp\left(-\frac{UA}{292,740 \text{ W/K}}\right)$$

$$UA = 86,538 \text{ W/K.}$$ <

(b) In the fouled condition, U is reduced 10%, hence

$$U_f A = 0.9\, UA = 77,884 \text{ W/K}$$

and

$$NTU_f = \frac{U_f A}{C_{min}} = \frac{77,884 \text{ W/K}}{292,740 \text{ W/K}} = 0.266$$

$$\varepsilon_f = 1 - \exp(-NTU_f) = 1 - \exp(-0.266) = 0.234.$$

Continued …

PROBLEM 11.78 (Cont.)

If we operate the cycle at the same back pressure p_4 = 10 kPa so that T_h = 45.7°C, the heat removal rate must decrease,

$$q_h = \varepsilon q_{max} = 0.234 \times 8.987 \times 10^6 \text{ W} = 2.103 \times 10^6 \text{ W}$$

since $q_{max} = C_{min} (T_h - T_{c,i})$ remains the same. From the previous problem, we found the heat rejected as

$$h_4 - h_1 = (2007.5 - 191.83) \text{kJ/kg} = 1815.7 \text{ kJ/kg}$$

and hence the cycle steam rate through the *fouled* condenser is

$$\dot{m}_{h,f} = q_h / (h_4 - h_1) = 2.103 \times 10^6 \text{ W} / 1815.7 \text{ kJ/kg} = 1.158 \text{ kg/s.}$$

For the *unfouled* condenser of part (a), the steam rate was

$$\dot{m}_h = 2.3 \text{ MW} / 1815.7 \text{ kJ/kg} = 1.267 \text{ kg/s.}$$

Hence, we see that fouling reduces the steam rate by 8.5% when U is decreased 10%. Since p_4 remains the same, the thermal efficiency remains unchanged,

$$\eta = 30.3\% \qquad \lt$$

as calculated in the previous problem. However, the net work of the cycle will decrease 8.5%.

COMMENTS: Fouling of the condenser heat exchanger has no effect on the thermal efficiency of the cycle since the back pressure at the condenser is maintained constant. The effect is, however, to reduce the heat rejection rate while maintaining exchanger flow rate and inlet temperature fixed. Comparing the conditions:

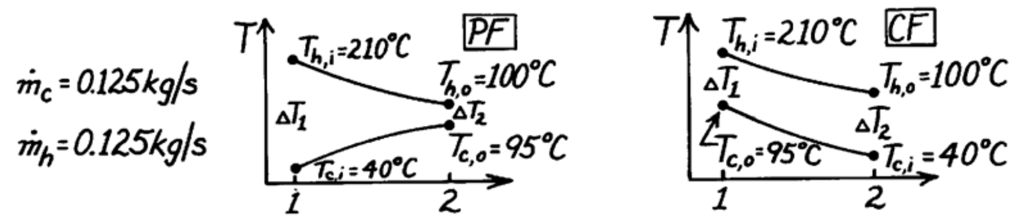
Parameter	Clean	Fouled	Change (%)
UA, W/K	86,538	77,884	-10.0
ε	0.256	0.234	-8.6
q_h, MW	2.300	2.103	-8.6
$\dot{w}_{net}$	--	--	-8.6

PROBLEM 11.79

KNOWN: Concentric tube heat exchanger with prescribed conditions.

FIND: (a) Maximum possible heat transfer, (b) Effectiveness, (c) Whether heat exchanger should be run in PF or CF to minimize size or weight; determine ratio of required areas for the two flow conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Overall heat transfer coefficient remains unchanged for PF or CF conditions.

PROPERTIES: Hot fluid (given): c = 2100 J/kg·K; Cold fluid (given): c = 4200 J/kg·K.

ANALYSIS: (a) The maximum possible heat transfer rate is given by Eq. 11.18.

$$q_{max} = C_{min}\left(T_{h,i} - T_{c,o}\right).$$

The minimum capacity fluid is the hot fluid with $C_{min} = \dot{m}_h \; c_h$, giving

$$q_{max} = \dot{m}_h \, c_h \left(T_{h,i} - T_{c,o}\right) = 0.125\frac{kg}{s} \times 2100\frac{J}{kg \cdot K}\left(210 - 40\right)K = 44,625\,W. \qquad <$$

(b) The effectiveness is defined by Eq. 11.19 and the heat rate, q, can be determined from an energy balance on the cold fluid.

$$\varepsilon = q / q_{max} = \dot{m}_c \, c_c \left(T_{c,o} - T_{c,i}\right) / q_{max}$$

$$\varepsilon = 0.125 \; kg/s \times 4200 \; J/kg \cdot K\left(95 - 40\right)K / 44,625\,W = 0.65. \qquad <$$

(c) Operating the heat exchanger under CF conditions will require a smaller heat transfer area than for PF conditions. The ratio of the areas is

$$\frac{A_{CF}}{A_{PF}} = \frac{q / U\,\Delta T_{\ell m,CF}}{q / U\,\Delta T_{\ell m,PF}} = \frac{\Delta T_{\ell m,PF}}{\Delta T_{\ell m,CF}}.$$

To calculate the LMTD, first find $T_{h,o}$ from overall energy balances on the two fluids.

$$T_{h,o} = T_{h,i} - \frac{\dot{m}_c \, c_c}{\dot{m}_h \, c_h}\left(T_{c,o} - T_{c,i}\right) = 210°C - \frac{0.125 \times 4200}{0.125 \times 2100}\left(95 - 40\right)°C = 100°C.$$

Using Eq. 11.15 with ΔT_1 and ΔT_2 as shown below, find $\Delta T_{\ell m} = (\Delta T_1 - \Delta T_2)/\ell n(\Delta T_1/\Delta T_2)$. Substituting values, find

$$\frac{A_{CF}}{A_{PF}} = \frac{\left[\left(210 - 40\right) - \left(100 - 95\right)\right] / \ell n\left(170/5\right)}{\left[\left(210 - 95\right) - \left(100 - 40\right)\right] \ell n\left(115/60\right)} = \frac{46.8°C}{84.5°C} = 0.55. \qquad <$$

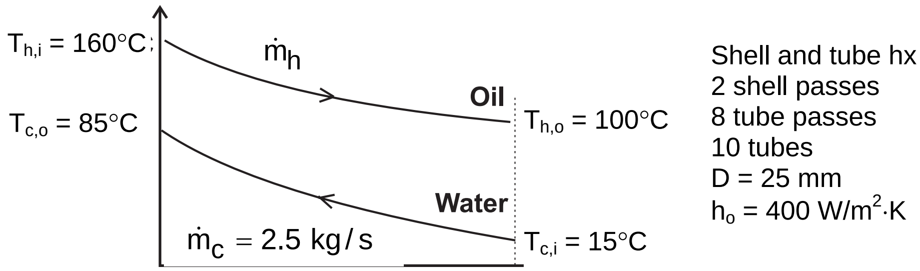
COMMENTS: In solving part (c), it is also possible to use Figs. 11.11 and 11.12 to evaluate NTU values for corresponding ε and C_{min}/C_{max} values. With knowledge of NTU it is then possible to find A_{CF}/A_{PF}.

PROBLEM 11.80

KNOWN: Inlet and outlet temperatures for a shell-and-tube heat exchanger with two shells, each with 10 tubes making eight passes. Heat transfer coefficient for oil flowing in shell. Mass flow rate of water in tubes. Tube diameter.

FIND: Is the required tube length sufficiently small to fit in an 8 m long facility, if the floor space must be at least 2.5 times the length of the heat exchanger?

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to the surroundings, (2) Constant properties, (3) Negligible tube wall thermal resistance and fouling effects, (4) Fully developed water flow in tubes.

PROPERTIES: *Table A.5*, unused engine oil: ($\bar{T}_h$ = 130°C): c_p = 2350 J/kg·K. *Table A.6*, water ($\bar{T}_c$ = 50°C): c_p = 4181 J/kg·K, $\mu = 548 \times 10^{-6}$ N·s/m^2, k = 0.643 W/m·K, Pr = 3.56.

ANALYSIS: From the overall energy balance, Eq. 11.7b, the heat transfer required of the exchanger is

$$q = \dot{m}_c c_{p,c}(T_{c,o} - T_{c,i}) = 2.5\ \text{kg/s} \times 4181\ \text{J/kg}\cdot\text{K}(85 - 15)°\text{C} = 7.317 \times 10^5\ \text{W}$$

Hence from Eq. 11.6b,

$$\dot{m}_h = \frac{q}{c_{p,h}(T_{h,i} - T_{h,o})} = \frac{7.317 \times 10^5\ \text{W}}{2350\ \text{J/kg}\cdot\text{K}(160 - 100)°\text{C}} = 5.19\ \text{kg/s}$$

The required tube length may be obtained using the ε-NTU method. We first calculate the heat capacity rates, $C_h = \dot{m}_h c_{p,h}$ = 12,195 W/K, $C_c = \dot{m}_c c_{p,c}$ =10,453 W/K. Thus, $C_{min} = C_c$, and $C_r = C_{min}/C_{max}$ = 0.857. Then from Eq. 11.21,

$$\varepsilon = \frac{T_{c,o} - T_{c,i}}{T_{h,i} - T_{c,i}} = \frac{(85 - 15)°\text{C}}{(160 - 15)°\text{C}} = 0.483$$

Using Eqs. 11.31c, 11.31b, 11.30c, 11.30b, and 11.31d, in that order, we find, F = 1.06, ε_1 = 0.311,

Continued…

PROBLEM 11.80 (Cont.)

$$E = \frac{2/\varepsilon_1 - (1 + C_r)}{(1 + C_r^2)^{1/2}} = \frac{2/0.311 - (1 + 0.857)}{(1 + 0.857^2)^{1/2}} = 3.47$$

$$(NTU)_1 = -(1 + C_r^2)^{-1/2} \ln\left(\frac{E-1}{E+1}\right) = -(1 + 0.857^2)^{-1/2} \ln\left(\frac{3.47-1}{3.47+1}\right) = 0.451$$

$$NTU = n(NTU)_1 = 2 \times 0.451 = 0.901$$

Thus UA = NTU×C_{min} = 9420 W/K. To find the required tube length, we must know the heat transfer coefficient for the water flow. We calculate the Reynolds number from Eq. 8.6, with the water flow rate per tube as $\dot{m}_1 = \dot{m}_c / N = 0.25$ kg/s,

$$Re_D = \frac{4\dot{m}_1}{\pi D \mu_c} = \frac{4 \times 0.25 \text{ kg/s}}{\pi(0.025 \text{ m})548 \times 10^{-6} \text{ N} \cdot \text{s/m}^2} = 23{,}234$$

Hence the flow is turbulent, and from Eq. 8.60,

$$Nu_D = 0.023 Re_D^{4/5} Pr^{0.4} = 0.023(23{,}234)^{4/5}(3.56)^{0.4} = 119$$

and

$$h_c = \frac{k_c}{D} Nu_D = \frac{0.643 \text{ W/m} \cdot \text{K}}{0.025 \text{ m}} 119 = 3060 \text{ W/m}^2 \cdot \text{K}$$

Hence U = $[1/h_c + 1/h_h]^{-1}$ = 354 W/m^2·K and we can find the required tube length from

$$L = \frac{UA}{UN\pi D} = \frac{9420 \text{ W/K}}{354 \text{ W/m}^2 \cdot \text{K} \times 10 \times \pi \times 0.025 \text{ m}} = 33.9 \text{ m}$$

This is the total tube length for all ten tubes in both shells, therefore the length of the heat exchanger shell must be

$$L_{shell} = L/(8 \times 2) = 2.12 \text{ m}$$

Therefore the room would have to be 2.12 m × 2.5 = 5.3 m.

Yes, the floorspace of 8 m is sufficiently long to service the heat exchanger. <

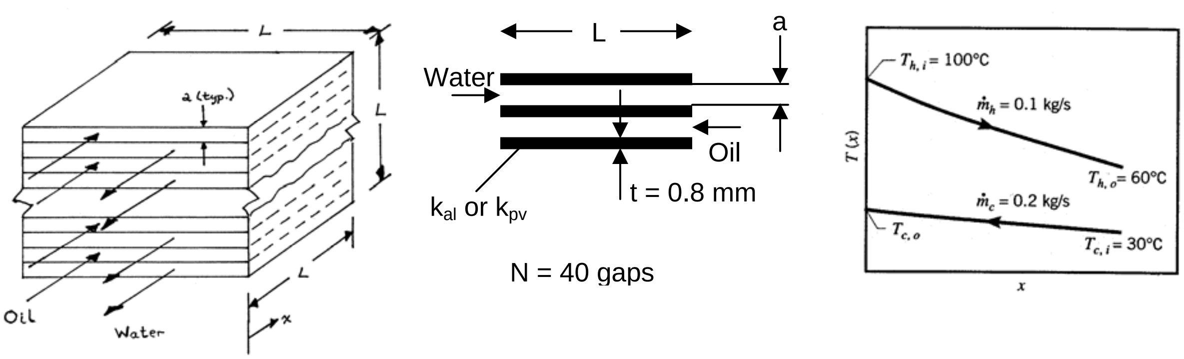
COMMENTS: (1) With L/D = 33.9/0.025 = 1356, the assumption of fully developed conditions throughout the tube is justified. (2) The floor-to-ceiling height must be sufficiently large to stack one shell above the other.

PROBLEM 11.81

KNOWN: Configuration of a cubical plate-type heat exchanger with 40 gaps. Fluid flow rates, inlet temperatures, and desired oil outlet temperature.

FIND: (a) Core dimension, L, of the heat exchanger, when the sheet thickness is 0.8 mm, for aluminum and PVDF sheets. (b) Plot core dimension as a function of sheet thickness for aluminum and PVDF over the range $0 \le t \le 1$ mm.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to the surroundings, (2) Constant properties, (3) Negligible fouling factors, (4) Laminar, fully developed conditions for the water and oil, (5) Identical gap-to-gap heat transfer coefficients. (6) Heat exchanger exterior dimension is large compared to the gap width.

PROPERTIES: *Table A.6*, water ($\overline{T}_c \approx 35$°C): $\mu = 725 \times 10^{-6}$ N·s/m^2, k = 0.625 W/m·K. *Table A.5*, unused engine oil ($\overline{T}_h$ = 353 K): $\mu = 3.25 \times 10^{-2}$ N·s/m^2, k = 0.138 W/m·K. Aluminum (given): k_{al} = 237 W/m·K. PVDF (given): k_{pv} = 0.17 W/m·K.

ANALYSIS: (a) From Example 11.2, assuming the flow is still laminar,

$$h_c = 7.54k/D_h = 7.54k/2a, \quad h_c a = 7.54 \times 0.625 \text{ W/m·K}/2 = 2.36 \text{ W/m·K} \tag{1a}$$

$$h_h = 7.54k/D_h = 7.54k/2a, \quad h_h a = 7.54 \times 0.138 \text{ W/m·K}/2 = 0.520 \text{ W/m·K} \tag{1b}$$

and the overall convection coefficient, including the wall thermal resistance, is given by

$$U^{-1} = 1/h_c + t/k_w + 1/h_h = a/(h_c a) + t/k_w + a/(h_h a) \tag{2}$$

where ($h_c a$) and ($h_h a$) are constants given by Eq. (1). In addition, from Example 11.1, the required log mean temperature difference and heat transfer rate are ΔT_{lm} = 43.2°C and q = 8524 W, respectively. Thus with $A = (N-1)L^2$, we have

$$U^{-1} = \frac{A\Delta T_{lm}}{q} = \frac{39 \times 43.2\text{°C} \times L^2}{8524 \text{ W}} = 0.198 \text{ K/W } L^2 \tag{3}$$

Continued…

PROBLEM 11.81 (Cont.)

The core dimension, L, is related to the gap dimension, a, and sheet thickness, t, (neglecting the exterior plates) by the expression

$$L = Na + (N\text{-}1)t \tag{4}$$

Thus, Eq. (3) becomes

$$U^{-1} = 0.198\ \text{K/W}\left[Na + (N-1)t\right]^2 \tag{5}$$

Equating Eqs. (2) and (5), we can solve the resulting quadratic equation for a,

$$a/(h_c a) + t/k_w + a/(h_h a) = 0.198\ \text{K/W}\left[Na + (N-1)t\right]^2$$

$$Aa^2 + Ba + C = 0, \qquad a = \frac{-B \pm \sqrt{B^2 - 4AC}}{2A}$$

where

$$A = 0.198\ \text{K/W}\ N^2 = 0.198\ \text{K/W} \times 40^2 = 316\ \text{K/W}$$

$$B = 2(0.198\ \text{K/W})N(N-1)t - \frac{1}{h_c a} - \frac{1}{h_h a}$$

$$= 0.395\ \text{K/W} \times 40 \times 39 \times 0.0008\ \text{m} - \frac{1}{2.36\ \text{W/m}\cdot\text{K}} - \frac{1}{0.520\ \text{W/m}\cdot\text{K}} = -1.85\ \text{m}\cdot\text{K/W}$$

$$C = (0.198\ \text{W/K})(N-1)^2 t^2 - \frac{t}{k_w}$$

$$= (0.198\ \text{K/W})39^2(0.0008\ \text{m})^2 - \frac{0.0008\ \text{m}}{237\ \text{W/m}\cdot\text{K}} = 1.89 \times 10^{-4}\ \text{m}^2\cdot\text{K/W}$$

We have used $k_w = k_{al}$ in evaluating C. Thus

$$a = \frac{-B \pm \sqrt{B^2 - 4AC}}{2A} = \frac{1.85 \pm \sqrt{1.85^2 - 4 \times 316 \times 1.89 \times 10^{-4}}}{2 \times 316}\ \text{m}$$

$$= 1.04 \times 10^{-4}\ \text{m or } 0.0058\ \text{m}$$

See the Comments for a discussion of the two different solutions. Hence from Eq. (4), when the sheets are aluminum,

$$L_{al} = \begin{cases} 0.0354\ \text{m} \\ 0.261\ \text{m} \end{cases}$$ <

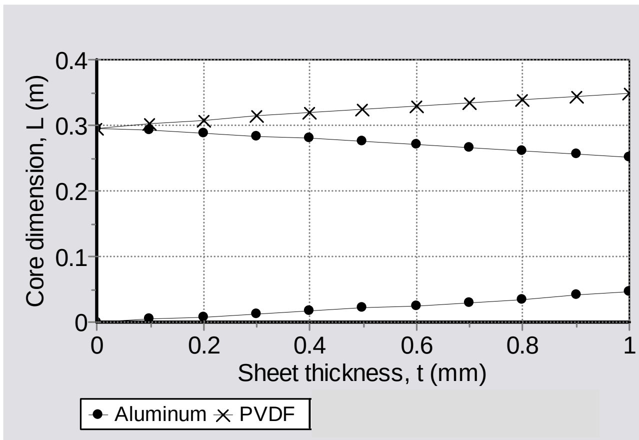
Continued…

PROBLEM 11.81 (Cont.)

Repeating the calculations for PVDF, we find only one (positive) solution, a = 0.00771 m, for which

$$L_{pv} = 0.340 \text{ m}$$ <

(b) The calculations were keyed into the *IHT* workspace and solved for $0 \le t \le 1$ mm. The solution is shown below for aluminum and PVDF sheets.



<

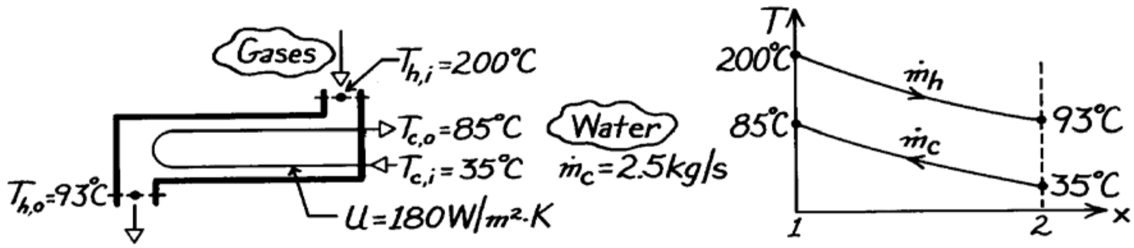
COMMENTS: (1) We can check the Reynolds number to see if the flow is truly laminar. The largest Reynolds number would be for water, since it is less viscous and has a higher flow rate. Thus Re = $4\dot{m}_1/\mu P \approx 4\dot{m}/(N/2)/2\mu L$. For the smaller value of L, Re = 779. Hence the flow is laminar for both oil and water. (2) As expected, utilization of PVDF results in a larger heat exchanger due to its lower thermal conductivity. (3) For aluminum sheets, there are two solutions. The very small spacing gives rise to high heat transfer coefficients that enable a small heat exchange area. The larger spacing corresponds to smaller heat transfer coefficients that require a larger heat exchange area. For PVDF, the thermal resistance of the sheets is larger and it is impossible to increase the value of U sufficiently to enable the smaller channel solution. (4) Manufacturing of the smaller channels would pose a challenge, and the pressure drop could be prohibitively large. Fouling could also be more of a problem in the smaller channels. (5) If the heat exchanger didn't have to be cubical, there could be solutions with superior properties with respect to pressure drop and manufacturing constraints.

PROBLEM 11.82

KNOWN: Shell and tube heat exchanger for cooling exhaust gases with water.

FIND: Required surface area using ε-NTU method.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Gases have properties of air.

PROPERTIES: *Table A-6*, Water, liquid ($\overline{T}_c$ = (85 + 35)°C/2 = 333 K): c_p = 4185 J/kg·K.

ANALYSIS: Using the ε-NTU method, the area can be expressed as

$$A = NTU \cdot C_{min} / U \tag{1}$$

where NTU must be found from knowledge of ε and $C_{min}/C_{max} = C_r$. The capacity rates are:

$$C_c = \dot{m}_c c_{p,c} = 2.5\,kg/s \times 4185\ J/kg\cdot K = 10,463\,W/K$$

Equating the energy balance relation for each fluid,

$$C_h = C_c\left(T_{c,o} - T_{c,i}\right)/\left(T_{h,i} - T_{h,o}\right) = 10,463\,W/K\left(85-35\right)/\left(200-93\right) = 4889\,W/K.$$

Hence,

$$C_r = C_{min}/C_{max} = C_h/C_c = 4889/10,463 = 0.467.$$

The effectiveness of the exchanger, with $q_{max} = C_{min}(T_{h,i} - T_{c,i})$ and $C_{min} = C_h$, is

$$\varepsilon = q/q_{max} = C_h\left(T_{h,i} - T_{h,o}\right)/C_h\left(T_{h,i} - T_{c,i}\right) = \left(200-93\right)/\left(200-35\right) = 0.648.$$

Considering the HXer to be a single shell with 2,4….tube passes, Eqs. 11.30b,c are appropriate to evaluate NTU.

$$NTU = -\left(1 + C_r^2\right)^{-1/2} \ell n \frac{E-1}{E+1} \qquad E = \frac{2/\varepsilon_1 - \left(1 + C_r\right)}{\left(1 + C_r^2\right)^{1/2}}.$$

Substituting numerical values,

$$E = \frac{2/0.648 - \left(1 + 0.467\right)}{\left(1 + 0.467^2\right)^{1/2}} = 1.467 \quad NTU = -\left(1 + \left(0.467\right)^2\right)^{-1/2} \ell n \frac{1.467-1}{1.467+1} = 1.51.$$

Using the appropriate numerical values in Eq. (1), the required area is

$$A = 1.51 \times 4889\,W/K / 180\,W/m^2 \cdot K = 40.9\,m^2.$$ <

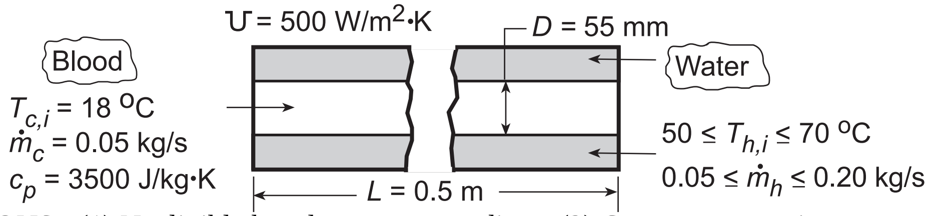
COMMENTS: Figure 11.12 could also have been used with C_r and ε to find NTU.

PROBLEM 11.83

KNOWN: Dimensions, fluid flow rates, and fluid temperatures for a counterflow heat exchanger used to heat blood.

FIND: (a) Outlet temperature of the blood, (b) Effect of water flowrate and inlet temperature on heat rate and blood outlet temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties.

PROPERTIES: *Table A.6*, Water ($\overline{T}_m \approx 55°C$): c_p = 4183 J/kg·K.

ANALYSIS: (a) Using the ε - NTU method, we first obtain $C_h = (\dot{m}_h c_{p,h}) = (0.10\text{ kg/s} \times 4183\text{ J/kg·K}) = 418.3\text{ W/K}$ and $C_c = (\dot{m}_c c_{p,c}) = (0.05\text{ kg/s} \times 3500\text{ J/kg·K}) = 175\text{ W/K} = C_{min}$. Hence, $(C_{min}/C_{max}) = 0.418$ and

$$\text{NTU} = \frac{UA}{C_{min}} = \frac{\left(500\,\text{W/m}^2\cdot\text{K}\right)\pi\left(0.055\,\text{m}\right)\left(0.5\,\text{m}\right)}{175\,\text{W/K}} = 0.247\,.$$

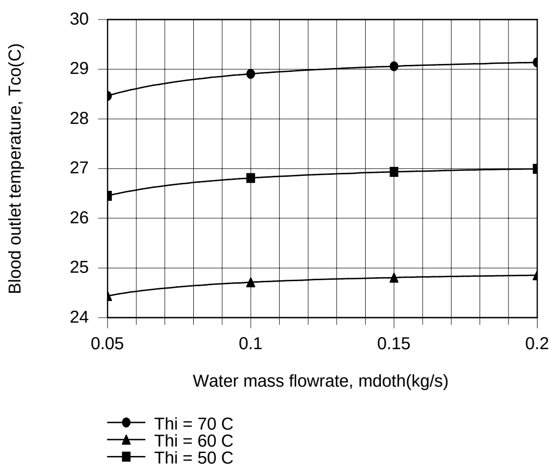
From Eq. 11.29a, ε = 0.21. Hence, from Eq. 11.22

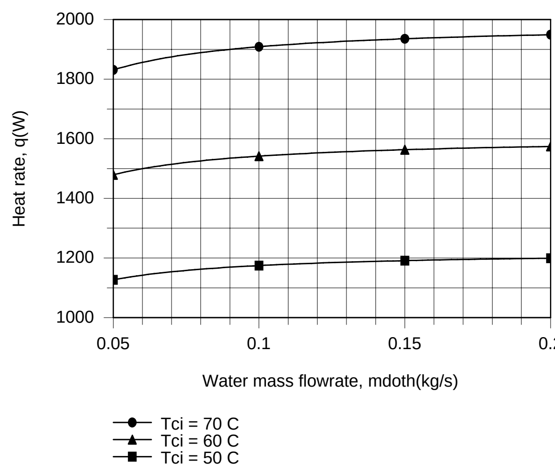
$$q = \varepsilon C_{min}\left(T_{h,i} - T_{c,i}\right) = 0.21\left(175\,\text{W/K}\right)\left(60-18\right)^\circ\text{C} = 1544\,\text{W}\,.$$

From Eq. 11.7,

$$T_{c,o} = T_{c,i} + \frac{q}{C_c} = 18^\circ\text{C} + \frac{1544\,\text{W}}{175\,\text{W/K}} = 26.8^\circ\text{C}$$ <

(b) Because the variation of C_{min}/C_{max} with $\dot{m}_h$ does not have a significant effect on ε for the prescribed NTU, $T_{c,o}$ and q increase only slightly with increasing $\dot{m}_h$.





However, the water inlet temperature does have a significant effect, and accelerated heating is achieved with $T_{h,i}$ = 70°C.

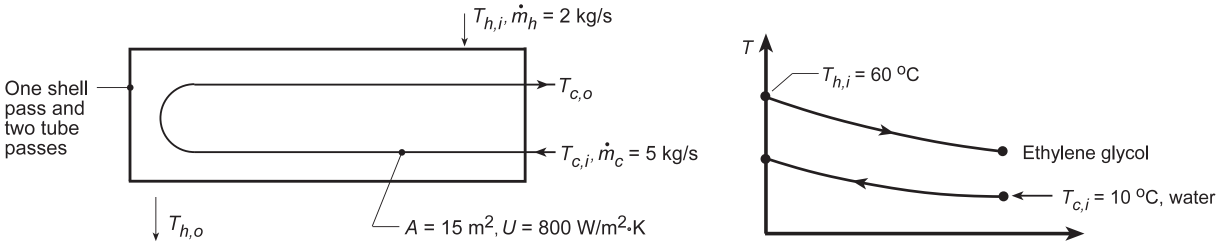
COMMENTS: With $\dot{m}_h$ = 0.2 kg/s and $T_{h,i}$ = 70°C, the outlet temperature of the blood is still below the desired level of $T_{c,o} \approx 37°C$. This value of $T_{c,o}$ could be increased by increasing L or $T_{h,i}$.

PROBLEM 11.84

KNOWN: Inlet temperatures and flow rates of water (c) and ethylene glycol (h) in a shell-and-tube heat exchanger (one shell pass and two tube passes) of prescribed area and overall heat transfer coefficient.

FIND: (a) Heat transfer rate and fluid outlet temperatures and (b) Compute and plot the effectiveness, ε, and fluid outlet temperatures, $T_{c,o}$ and $T_{h,o}$ as a function of the flow rate of ethylene glycol, $\dot{m}_h$, for the range $0.5 \le \dot{m}_h \le 5$ kg/s.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties, and (3) Overall coefficient remains unchanged.

PROPERTIES: *Table A-5*, Ethylene glycol ($\overline{T}_m \approx 40$°C): c_p = 2474 J/kg·K; *Table A-6*, Water ($\overline{T}_m \approx$ 15°C): c_p = 4186 J/kg·K.

ANALYSIS: (a) Using the ε-NTU method we first obtain

$$C_h = \left(\dot{m}_h c_{p,h}\right) = \left(2\,\text{kg/s} \times 2474\,\text{J/kg}\cdot\text{K}\right) = 4948\,\text{W/K}$$

$$C_c = \left(\dot{m}_c c_{p,c}\right) = \left(5\,\text{kg/s} \times 4186\,\text{J/kg}\cdot\text{K}\right) = 20{,}930\,\text{W/K}\,.$$

Hence with $C_{min} = C_h$ = 4948 W/K and $C_r = C_{min}/C_{max}$ = 0.236,

$$NTU = \frac{UA}{C_{min}} = \frac{\left(800\,\text{W/m}^2\cdot\text{K}\right)15\,\text{m}^2}{4948\,\text{W/K}} = 2.43\,.$$

From Fig. 11.12, ε = 0.81 and from Eq. 11.22

$$q = \varepsilon C_{min}\left(T_{h,i} - T_{c,i}\right) = 0.81\left(4948\,\text{W/K}\right)\left(60-10\right)\text{K} = 2\times10^5\,\text{W}\,. \qquad <$$

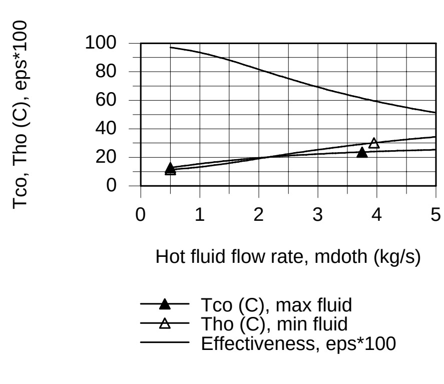
From Eqs. 11.6 and 11.7, energy balances on the fluids,

$$T_{h,o} = T_{h,i} - \frac{q}{C_h} = 60^\circ\text{C} - \frac{2\times10^5\,\text{W}}{4948\,\text{W/K}} = 19.6^\circ\text{C} \qquad <$$

$$T_{c,o} = T_{c,i} + \frac{q}{C_c} = 10^\circ\text{C} + \frac{2\times10^5\,\text{W}}{20{,}930\,\text{W/K}} = 19.6^\circ\text{C}\,. \qquad <$$

(b) Using the *IHT Heat Exchanger Tool*, *Shell and Tube*, and the *Properties Tool* for *Water* and *Ethylene Glycol*, $T_{c,o}$, $T_{h,o}$, and ε as a function of $\dot{m}_h$ were computed and plotted.

At very low C_{min}, (low $\dot{m}_h$) note that $\varepsilon \to 1$ while $T_{h,o} \to T_{c,i}$. As $\dot{m}_h$ increases, both fluid outlet temperatures increase and the effectiveness decreases.

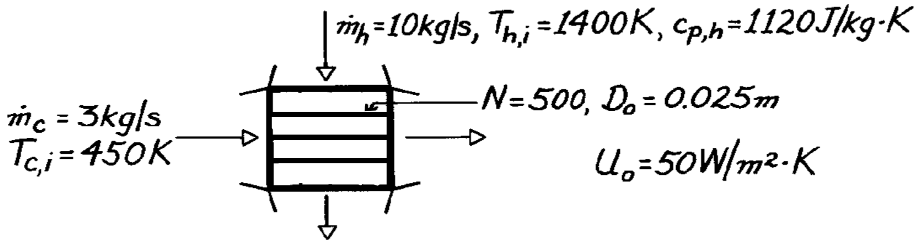


PROBLEM 11.85

KNOWN: Flow rate, specific heat and inlet temperature of gas in cross-flow heat exchanger. Flow rate and temperature of water which enters as saturated liquid and leaves as saturated vapor. Number of tubes, tube diameter and overall heat transfer coefficient.

FIND: Required tube length.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant gas specific heat.

PROPERTIES: *Table A-6*, Saturated Water, (T = 450 K): $h_{fg} = 2.024 \times 10^6$ J/kg.

ANALYSIS: Use effectiveness-NTU method

$$\varepsilon = \frac{q}{q_{max}} = \frac{q}{C_{min}\left(T_{h,i} - T_{c,i}\right)} = \frac{q}{\dot{m}_h\, c_{p,h}\left(T_{h,i} - T_{c,i}\right)}$$

$$q = \dot{m}_c\, h_{fg} = 3\ \text{kg/s} \times 2.024 \times 10^6\ \text{J/kg} = 6.072 \times 10^6\,\text{W}$$

$$\varepsilon = \frac{6.072 \times 10^6\,\text{W}}{10\ \text{kg/s} \times 1120\,\text{J/kg}\cdot\text{K}\left(1400 - 450\right)\text{K}} = 0.571 \qquad\qquad C_{min}/C_{max} = 0.$$

From Fig. 11.15, find

$$\text{NTU} \approx 0.8 \approx U_o N \pi D_o L / C_{min}$$

$$L \approx \frac{0.8 \times 10\ \text{kg/s} \times 1120\,\text{J/kg}\cdot\text{K}}{50\ \text{W/m}^2\cdot\text{K} \times 500\pi \times 0.025\text{m}} = 4.56\text{m.}$$ <

COMMENTS: The gas outlet temperature is

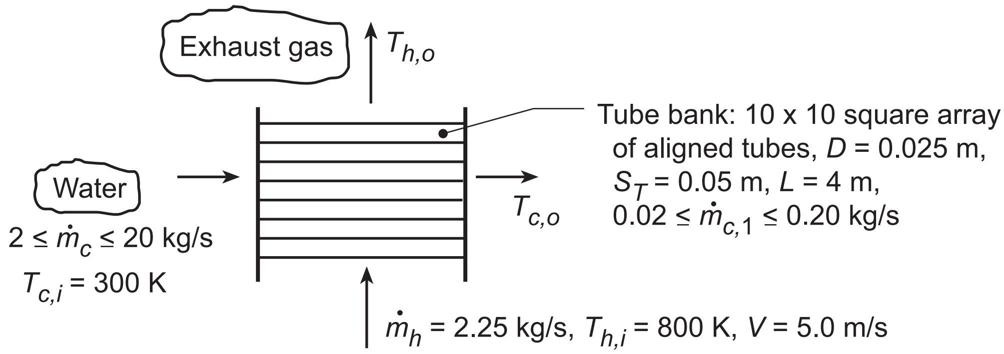
$$T_{h,o} = T_{h,i} - q/\dot{m}_h\, c_{p,h} = 1400\text{K} - 6.072 \times 10^6\,\text{W}/10\,\text{kg/s} \times 1120\,\text{J/kg}\cdot\text{K} = 857.9\,\text{K.}$$

PROBLEM 11.86

KNOWN: Gas flow conditions upstream of a tube bank of prescribed geometry. Flow rate and inlet temperature of water passing through the tubes.

FIND: (a) Overall heat transfer coefficient, (b) Water and gas outlet temperatures, (c) Effect of water flow rate on heat recovery and outlet temperatures.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Negligible heat loss to the surroundings, (3) Negligible tube fouling and wall thermal resistance, (4) Fully developed water flow, (5) Gas properties are those of air.

PROPERTIES: *Table A.6*, Water (Assume $\overline{T}_m \approx 340$ K): c_p = 4188 J/kg·K, $\mu = 420 \times 10^{-6}$ N·s/m^2, k = 0.660 W/m·K, Pr = 2.66; *Table A.4*, Air (Assume $\overline{T}_m \approx 600$ K): c_p = 1051 J/kg·K, $\nu = 52.7 \times 10^{-6}$ m^2/s, k = 0.047 W/m·K, Pr = 0.69.

ANALYSIS: (a) For the prescribed conditions, $U = (1/h_i + 1/h_o)^{-1}$. For the *internal* flow, with $\dot{m}_{c,1}$ = 0.025 kg/s,

$$Re_D = \frac{4\dot{m}_{c,1}}{\pi D \mu} = \frac{4 \times 0.025\,\text{kg/s}}{\pi(0.025\,\text{m})420 \times 10^{-6}\,\text{N}\cdot\text{s/m}^2} = 3032.$$

Hence, from the Gnielinski correlation,

$$NuD = \frac{(f/8)(Re_D - 1000)\,Pr}{1 + 12.7(f/8)^{1/2}(Pr^{2/3} - 1)} = \frac{(0.0454/8)(3032 - 1000)2.66}{1 + 12.7(0.0454/8)^{1/2}(2.66^{2/3} - 1)} = 16.3$$

where f = (0.79 ln ReD – 1.64)$^{-2}$ = 0.0454

$$h_i = \frac{k}{D} Nu_D = \frac{0.660\,\text{W/m}\cdot\text{K}}{0.025\,\text{m}} 16.3 = 431\ \text{W/m}^2\cdot\text{K}.$$

For the external flow, $V_{max} = \dfrac{0.05\,\text{m}}{(0.05 - 0.025)\,\text{m}} 5.0\,\text{m/s} = 10.0\,\text{m/s}$. Hence

$$Re_{D,max} = \frac{V_{max} D}{\nu} = \frac{10\,\text{m/s} \times 0.025}{52.7 \times 10^{-6}\,\text{m}^2/\text{s}} = 4744$$

From the Zukauskas correlation and Tables 7.5 and 7.6, $\overline{Nu}_D = (0.97)0.27\,Re_{D,max}^{0.63}\,Pr^{0.36}\,(Pr/Pr_s)^{1/4}$.

Neglecting the Prandtl number ratio,

$$\overline{Nu}_D = (0.97)0.27(4744)^{0.63}(0.69)^{0.36} = 47.4$$

$$\overline{h}_o = \frac{k}{D}\overline{Nu}_D = \frac{0.047\,\text{W/m}\cdot\text{K}}{0.025\,\text{m}} 47.4 = 89.1\,\text{W/m}^2\cdot\text{K}.$$

Continued...

PROBLEM 11.86 (Cont.)

Hence, $U = (1/431 + 1/89.1)^{-1} = 73.9\ W/m^2\cdot K$. <

(b) The fluid outlet temperatures may be determined from the ε-NTU method. With $\dot{m}_c = 2.5$ kg/s, $C_c = \dot{m}_c c_{p,c} = 2.5\ kg/s \times 4188\ J/kg\cdot K = 10{,}470\ W/K$. With $C_h = \dot{m}_h c_{p,h} = 2.25\ kg/s \times 1051\ J/kg\cdot K = 2365\ W/K$, $C_{min}/C_{max} = C_{mixed}/C_{unmixed} = 2365/10{,}470 = 0.23$. Hence, with $A = N\pi DL = 100\pi \times 0.025\ m \times 4\ m = 31.4\ m^2$,

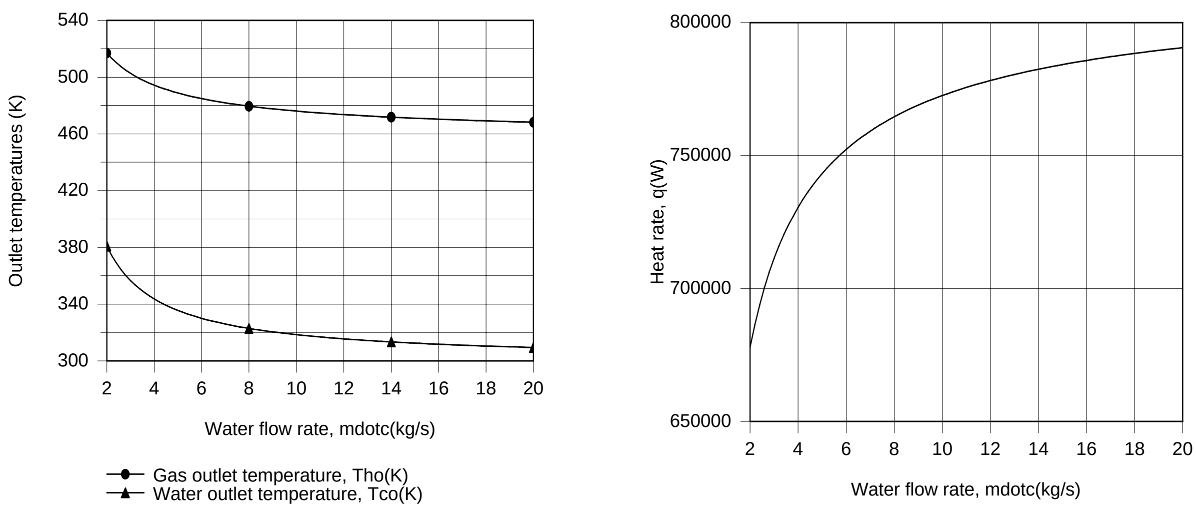
$$NTU = \frac{UA}{C_{min}} = \frac{73.9\ W/m^2\cdot K\left(31.4\ m^2\right)}{2365\ W/K} = 0.98$$

From Fig. 11.15, ε ≈ 0.61. From Eq. 11.18, $q_{max} = C_{min}(T_{h,i} - T_{c,i}) = 2365\ W/K(800 - 300)K = 1.18 \times 10^6\ W$. Hence, $q = \varepsilon q_{max} = 0.72 \times 10^6$ W. From Eq. 11.6b,

$$\left(T_{h,i} - T_{h,o}\right) = \frac{q}{C_h} = \frac{0.72\times10^6\ W}{2365\ W/K} = 304\ K \qquad T_{h,o} = 496\ K$$ <

From Eq. 11.7b, $$\left(T_{c,o} - T_{c,i}\right) = \frac{q}{C_c} = \frac{0.72\times10^6\ W}{10{,}470\ W/K} = 69\ K \qquad T_{c,o} = 369\ K$$ <

(c) Using the appropriate *Heat Exchangers*, *Correlations* and *Properties* Toolpads of IHT, the following results were obtained.



With increasing $\dot{m}_c$ (and $\dot{m}_{c,1}$), h_i increases, thereby increasing U and q. However, because the total resistance is dominated by the gas-side condition, $\dot{m}_c = 20$ kg/s only yields $U = 83.9\ W/m^2\cdot K$, despite the fact that $h_i = 2180\ W/m^2\cdot K$. Because the extent to which q increases with increasing $\dot{m}_c$ is much smaller than the increase in $\dot{m}_c$ itself, $T_{c,o}$ decreases with increasing $\dot{m}_c$. Hence, there is a trade-off between the amount of hot water and the temperature at which it is delivered. If, for example, the temperature must exceed 50°C ($T_{c,o} > 323$ K), $\dot{m}_c$ cannot exceed 8 kg/s. To maintain an acceptable value of $T_{c,o}$, while increasing $\dot{m}_c$, $\dot{m}_h$ (and V) should be increased, thereby increasing h_o, and hence U and q.

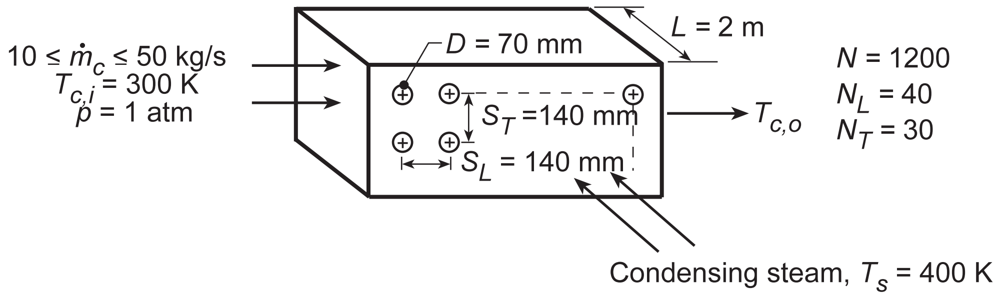
COMMENTS: If the air and water property functions of IHT are used to evaluate properties at appropriate mean values of the inlet and outlet fluid temperatures and Eq. 11.34a is used to evaluate ε, the following, more accurate, results would be obtained for Parts (a) and (b): ε = 0.565, $q = 0.677 \times 10^6$ W, $T_{c,o} = 364.6$ K, $T_{h,o} = 517.5$ K, $h_i = 383\ W/m^2\cdot K$, $h_o = 86.3\ W/m^2\cdot K$ and $U = 70.5\ W/m^2\cdot K$.

PROBLEM 11.87

KNOWN: Tube arrangement in steam-to-air, cross-flow heat exchanger. Flow rate $\dot{m}_C$ and inlet temperature of air. Condensing temperature of steam.

FIND: (a) Air outlet temperature for $\dot{m}_c$ = 12 kg/s, (b) Effect of $\dot{m}_C$ on air outlet temperature, heat rate and condensation rate.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible steam side convection and tube wall conduction resistance, (3) Mean air temperature is 350 K.

PROPERTIES: *Table A.4*, Air (Assume $\overline{T}_C \equiv \left(T_{c,i} + T_{c,o}\right)/2 \approx 350$ K, 1 atm): $\rho = 0.995$ kg/m^3, c_p = 1009 J/kg·K, $\nu = 20.92 \times 10^{-6}$ m^2/s, k = 0.030 W/m·K, Pr = 0.700; T_s = 400 K: Pr = 0.690.

ANALYSIS: (a) For a single-pass, cross-flow heat exchanger with one fluid mixed and the other unmixed, Fig. 11.15 can be used to obtain ε, where $C_{min}/C_{max} = C_{mixed}/C_{unmixed} = 0$ and NTU = UA/C_{min} = $U(\pi DL)N/\dot{m}_C c_p$. From Eq. 11.5, U = $\overline{h}_o$, and the Zukauskas correlation may be used to estimate $\overline{h}_o$. The upstream velocity may be obtained from $\dot{m}_C = \rho VA \approx \rho V N_T L S_T$. Hence,

$$V = \frac{\dot{m}_C}{\rho N_T L S_T} = \frac{12\,\text{kg/s}}{0.995\,\text{kg/m}^3 \times 30 \times 2\,\text{m} \times 0.14\,\text{m}} = 1.44\,\text{m/s}.$$

For aligned tubes,

$$V_{max} = \frac{S_T}{S_T - D} V = \frac{0.14\,\text{m}}{(0.14 - 0.07)\,\text{m}} 1.44\,\text{m/s} = 2.88\,\text{m/s}$$

$$Re_{D,max} = \frac{V_{max} D}{\nu} = \frac{2.88\,\text{m/s} \times 0.07\,\text{m}}{20.92 \times 10^{-6}\,\text{m}^2/\text{s}} = 9637\,.$$

From Table 7.5, select values of C = 0.27 and m = 0.63. Hence,

$$\overline{Nu}_D = 0.27\, Re_{D,max}^{0.63}\, Pr^{0.36} \left(Pr/Pr_s\right)^{0.25}$$

$$\overline{Nu}_D = 0.27 (9637)^{0.63} (0.70)^{0.36} (0.70/0.69)^{0.25} = 77.1$$

$$\overline{h}_o = \overline{Nu}_D \frac{k}{D} = 77.1 \frac{0.030\,\text{W/m}\cdot\text{K}}{0.07\,\text{m}} = 33.0\,\text{W/m}^2\cdot\text{K}\,.$$

Hence,

$$NTU = \frac{\overline{h}_o \pi D L N}{\dot{m}_C c_p} = \frac{33.0\,\text{W/m}^2\cdot\text{K} \times \pi (0.07\,\text{m})\, 2\,\text{m}\, (1200)}{12\,\text{kg/s} \times 1009\,\text{J/kg}\cdot\text{K}} = 1.44\,.$$

From Fig. 11.15, find ε ≈ 0.77 and then determine

Continued...

PROBLEM 11.87 (Cont.)

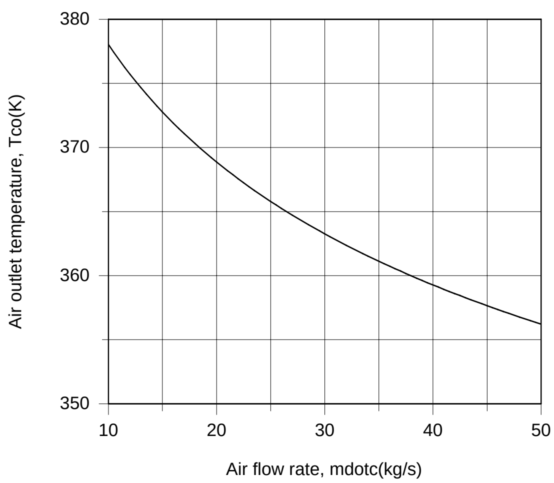
$$\varepsilon = \frac{q}{q_{max}} = \frac{\dot{m}_c c_{p,c}\left(T_{c,o} - T_{c,i}\right)}{\dot{m}_c c_{p,c}\left(T_s - T_{c,i}\right)} = \frac{T_{c,o} - T_{c,i}}{T_s - T_{c,i}}$$

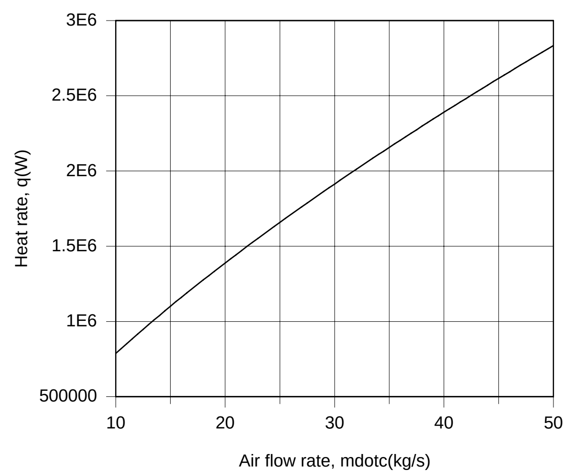
$$T_{c,o} = T_{c,i} + \varepsilon\left(T_s - T_{c,i}\right) = 300\,\text{K} + 0.77\left(400 - 300\right)\text{K} = 377\,\text{K} = 104^\circ\text{C} \qquad <$$

(b) With $q = \varepsilon q_{max} = \varepsilon C_c(T_s - T_{c,i})$ and the condensation rate given by Eqs. 10.34 and 10.27,

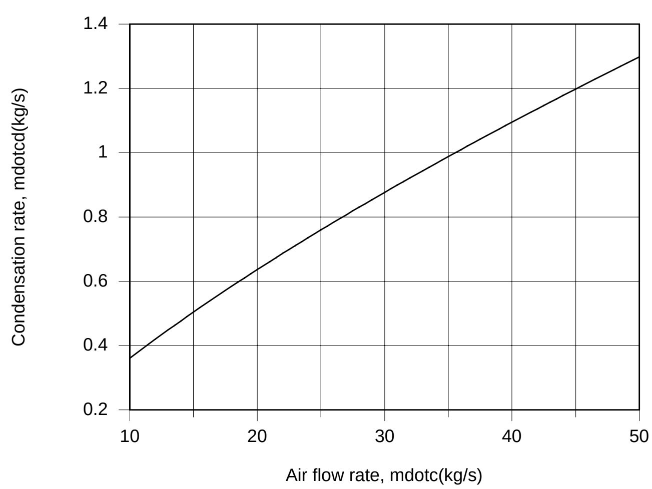
$$\dot{m}_{cd} = \frac{q}{h'_{fg}} \approx \frac{q}{h_{fg}}$$

the foregoing model may be used with the Heat Exchangers, Correlations and Properties Toolpads of IHT to determine the effect of $\dot{m}_c$ on $T_{c,o}$, q and $\dot{m}_{cd}$.





Since $\overline{h}_o$ increases with increasing $\dot{m}_c$, q must also increase. However, since the increase in q is proportionally less than the increase in $\dot{m}_c$, $T_{c,o}$ decreases with increasing $\dot{m}_c$.



The condensation rate increases proportionally with the increase in q, and if the objective is to maximize the condensation rate, the largest value of $\dot{m}_c$ should be maintained.

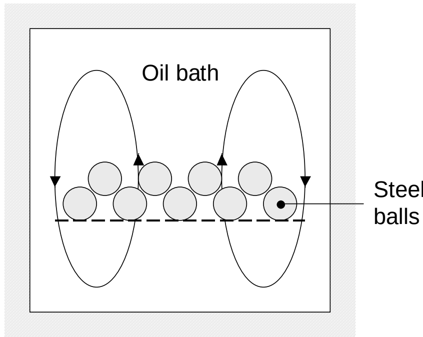
COMMENTS: If the objective is to heat the air, there is obviously a trade-off between maintaining elevated values of the flow rate and outlet temperature.

PROBLEM 11.88

KNOWN: Steel balls cooled in an oil bath.

FIND: Derivation of the expression for the modified effectiveness of Comment 4 of Example 11.8.

SCHEMATIC:



ASSUMPTIONS: (1) Spatially uniform bath and ball temperature at any instant, (2) Constant properties, (3) Negligible heat losses from bath.

ANALYSIS: From Comment 4 of Example 11.8,

$$\Delta E_{\max} = C_{t,\min}(T_{h,i} - T_{c,i}) \quad ; \quad \varepsilon^* = \frac{\Delta E}{\Delta E_{\max}} \quad ; \quad \mathrm{NTU}^* = \frac{UA\Delta t}{C_{t,\min}} \qquad (1, 2, 3)$$

Combining Eqs. (1) and (2) yields

$$\Delta E = \varepsilon^* C_{t,\min}(T_{h,i} - T_{c,i}) \qquad (4)$$

Assuming $C_{t,\min} = C_{t,h}$, it follows that $\varepsilon^* = \dfrac{T_{h,i} - T_{h,f}}{T_{h,i} - T_{c,i}}$ (5)

and therefore,

$$\frac{C_{t,\min}}{C_{t,\max}} = \frac{m_h c_h}{m_c c_c} = \frac{T_{c,f} - T_{c,i}}{T_{h,i} - T_{h,f}} \qquad (6)$$

Note that Eqs. (1) through (6) are analogous to Eqs. 11.18, 11.19, 11.24, 11.22, 11.25 and 11.26 in the text.

From Comment 3 of Example 11.8,

$$\ln\left(\frac{\Delta T_2}{\Delta T_1}\right) = \ln\left(\frac{T_{h,f} - T_{c,f}}{T_{h,i} - T_{c,i}}\right) = -UA\left(\frac{1}{C_{t,h}} + \frac{1}{C_{t,c}}\right)\Delta t = -\mathrm{NTU}^*\left(1 + \frac{C_{t,\min}}{C_{t,\max}}\right)$$

Continued…

Problem 11.88 (Cont.)

or

$$\frac{T_{h,f} - T_{c,f}}{T_{h,i} - T_{c,i}} = \exp\left[-\text{NTU}*\left(1 + \frac{C_{t,\min}}{C_{t,\max}}\right)\right] \tag{7}$$

Equation (7) is identical in form to Eq. 11.27 in the text.

Noting the analogy between Eqs.(1) through (7) with the equations in the text, we may proceed in a manner identical to that of the text, after Equation 11.27, obtaining

$$\varepsilon* = \frac{1 - \exp\left[-\text{NTU}*(1 + C_{t,r})\right]}{1 + C_{t,r}}$$ <

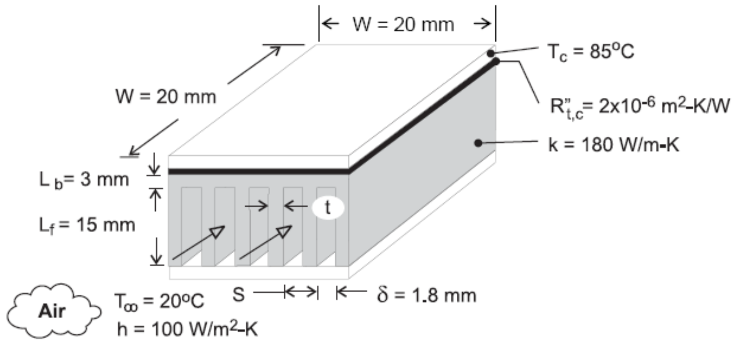
COMMENTS: The derivation is straightforward, once the analogy between the parallel-flow concentric tube heat exchanger analysis is recognized.

PROBLEM 11.89

KNOWN: Dimensions and maximum allowable temperature of an electronic chip. Thermal contact resistance between chip and heat sink. Dimensions and thermal conductivity of heat sink. Inlet temperature and convection coefficient associated with air flow through the heat sink.

FIND: (a) Inlet air velocity using an appropriate correlation from Chapter 8, (b) Chip power, q_c and the outlet temperature of the air exiting the channels. (c) Chip power and air outlet temperature for air velocity half of the value calculated in part (a).

SCHEMATIC



ASSUMPTIONS: (1) Steady state, (2) One-dimensional heat transfer in fins and base, (3) Isothermal chip, (4) Negligible heat transfer from top of chip, (5) Uniform convection coefficient over exposed surfaces, (6) Negligible radiation, (7) Negligible axial conduction in the heat sink, (8) Laminar flow, (9) Combined entry length.

PROPERTIES: Given. Aluminum, k_{hs} = 180 W/m·K. Air (T = 300 K; *Table A.4*) ρ = 1.1614 kg/m^3, c_p = 1007 J/kg·K, k = 0.0263 W/m·K, ν = 15.89 × 10^{-6} m^2/s, Pr = 0.707.

ANALYSIS: (a) The hydraulic diameter is $D_h = 4A_c/P = 4L_f(S – t)/[2(S - t) + 2L_f]$ = 4 × 0.0018 m × 0.015 m/[2 × 0.0018 m + 2 × 0.015 m] = 0.00321 m. From the specified convection coefficient,

$$\overline{Nu}_{D_h} = \frac{\bar{h}D_h}{k} = \frac{100\ \text{W/m}^2\cdot\text{K}\times 0.00321\ \text{m}}{0.0263\ \text{W/m}\cdot\text{K}} = 12.22$$

Using Eq. 8.58 $$\overline{Nu}_{D_h} = 12.22 = \frac{\dfrac{3.66}{\tanh\left[2.264Gr_{D_h}^{-1/3} + 1.7Gz_{D_h}^{-2/3}\right]} + 0.0499Gz_{D_h}\tanh\left(Gz_{D_h}^{-1}\right)}{\tanh\left(2.432Pr^{1/6}Gz_{D_h}^{-1/6}\right)}$$

from which $Gz_{D_h} = 204 = (D_h/W)Re_{D_h}Pr = (0.00321/0.02)\times Re_{D_h}\times 0.707$. This yields Re_{D_h} = 1800. The flow is in the upper laminar range. From the definition of the Reynolds number,

$$u_w = \frac{Re_{D_h}\nu}{D_h} = \frac{1800\times 15.89\times 10^{-6}\text{m}^2/\text{s}}{0.00321\ \text{m}} = 8.89\ \text{m/s}$$ <

(b) The resistances between the chip and the channel flow are due to the chip-heat sink interface ($R_{t,c}$), the base of the heat sink ($R_{t,b}$) and the fin array resistance ($R_{t,o}$). The resistance values are:

$$R_{t,c} = R''_{t,c}/W^2 = 2\times 10^{-6}\text{m}^2\cdot\text{K/W}/(0.02\ \text{m})^2 = 0.005\ \text{K/W}$$

Continued...

PROBLEM 11.89 (Cont.)

$$R_{t,b} = L_b/(k_{hs}W^2) = 0.003 \text{ m}/(180 \text{ W/m}\cdot\text{K} \times [0.02 \text{ m}]^2) = 0.042 \text{ K/W}$$

$$R_{t,o} = \frac{1}{\eta_o h A_t} \text{ where } \eta_o = 1 - \frac{NA_f}{A_t}(1-\eta_f) \text{ and } A_t = NA_f + A_b$$

where $A_f = 2WL_f = 2\times 0.02 \text{ m} \times 0.015 \text{ m} = 6 \times 10^{-4} \text{ m}^2$ and $A_b = W^2 - N(tW) = (0.02 \text{ m})^2 - 11(0.182 \times 10^{-3} \text{ m} \times 0.02 \text{ m}) = 3.6 \times 10^{-4} \text{ m}^2$. With $mL_f = (2\bar{h}/k_{hs}t)^{1/2}L_f = (200 \text{ W/m}^2\cdot\text{K}/180 \text{ W/m}\cdot\text{K} \times 0.182 \times 10^{-3} \text{ m})^{1/2}(0.015 \text{ m}) = 1.17$, tanh $(mL_f) = 0.824$ and Eq. (3.87) yields $\eta_f = (\tanh mL_f)/mL_f = 0.824/1.17 = 0.704$. It follows that $A_t = 6.96 \times 10^{-3}\text{m}^2$, $\eta_o = 0.719$ and $R_{t,o} = 2.00$ K/W. Accounting for the air flow within the heat sink only, the value of the minimum heat capacity rate is

$$C_{\min} = \dot{m}c_p = u_w L_f (S-t)(N-1)\rho c_p$$
$$= 8.89 \text{ m/s} \times 0.015 \text{ m} \times 0.0018 \text{ m} \times 10 \times 1.1614 \text{ kg/m}^3 \times 1007 \text{J/kg}\cdot\text{K} = 2.80 \text{ W/K}$$

The NTU is

$$\text{NTU} = UA/C_{\min} = \frac{1}{(R_{t,c}+R_{t,b}+R_{t,o})C_{\min}} = \frac{1}{(0.005 \text{ K/W} + 0.042 \text{ K/W} + 2.00 \text{ K/W})2.80 \text{ W/K}} = 0.174$$

while the effectiveness is found from Eq. 8.35a.

$$\varepsilon = 1 - \exp(-\text{NTU}) = 1 - \exp(-0.174) = 0.160$$

yielding a heat rate of

$$q_c = 0.160 \times 2.80 \text{ W/K}(85-20)\text{K} = 29.1 \text{ W}$$ <

The temperature of the air exiting the heat sink is found from

$$T_o = T_\infty + q_c/C_{\min} = 20°\text{C} + 29.1 \text{ W}/(2.80 \text{ W/K}) = 30.4°\text{C}$$ <

(c) If the air flow velocity is halved, $Gz_{D_h} = 102$ and $\bar{h} = 75.2 \text{ W/m}^2\cdot\text{K}$

yielding $mL_f = 1.016$ and $\tanh(mL_f) = 0.768$. Following the steps described in part (b), $\eta_f = 0.769/1.0183 = 0.756$ and $\eta_o = 0.768$. Also, $R_{t,o} = 2.48$ K/W, NTU = 0.281 and $\varepsilon = 0.245$. The heat rate is $q_c = 22.4$ W and the outlet air temperature is $T_o = 36.0°$C. <

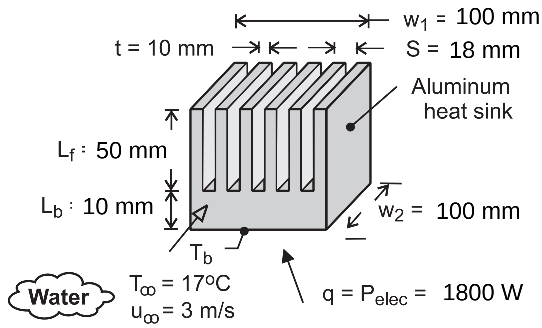
COMMENTS: (1) Without accounting for the increase in the air flow temperature, the answer for Part (a) is (from Problem 3.144) $q_c = 31.8$ W. As expected, the increasing air temperature, as it makes its way through the heat sink, reduces the heat transfer rate. (2) The heat rate in Part (c) is reduced because of the combined effects of (i) decreasing value of the convective heat transfer coefficient and (ii) decreasing average temperature difference between the chip and the coolant. (3) Although the flow is laminar, the value of the heat transfer coefficient is relatively high. How much would the allowable heat rate increase (or decrease) if the flow in Part (a) was treated as turbulent?

PROBLEM 11.90

KNOWN: Dimensions of aluminum heat sink. Temperature and velocity of coolant (water) flow through the heat sink. Power dissipation of electronic package attached to the heat sink.

FIND: Base temperature of heat sink.

SCHEMATIC:



ASSUMPTIONS: (1) Average convection coefficient associated with water flow over fin surfaces may be approximated as that for a flat plate in parallel flow, (2) All of the electric power is dissipated by the heat sink, (3) Transition Reynolds number of $Re_{x,c} = 5 \times 10^5$, (4) Constant properties, (5), Water does not exit the upper surface of the heat sink.

PROPERTIES: Given. Aluminum, k_{hs} = 180 W/m·K. Water, ρ = 995 kg/m^3, c_p = 4178 J/kg·K, k_w = 0.62 W/m·K, $\nu = 7.73 \times 10^{-7}$ m^2/s, Pr = 5.2.

ANALYSIS: The heat transfer rate is

$$q = P_{\text{elec}} = \varepsilon C_{\min}(T_b - T_{c,i}) = \varepsilon C_{\min}(T_b - T_\infty) \qquad (1)$$

where ε = 1 - exp(-NTU) = 1 – exp($-UA/C_{\min}$) = 1 – exp($-1/[(R_b + R_{t,o})C_{\min}]$) (2)

The base resistance is $R_b = L_b/k_{hs}(w_1 \times w_2)$ = 0.01m/180W/m·K(0.10 m)^2 = 5.56×10^{-3} K/W and from Eqs. 3.107 and 3.108,

$$R_{t,o} = \left\{\bar{h}A_t\left[1 - \frac{NA_f}{A_t}\left(1-\eta_f\right)\right]\right\}^{-1} \qquad (3)$$

The Reynolds number is $Re_{w2} = u_\infty w_2/\nu$ = 3 m/s × 0.10 m/7.73 × 10^{-7} m^2/s = 3.88 × 10^5, and the flow is laminar. Hence,

$$\bar{h} = \left(\frac{k_w}{w_2}\right)0.664 Re_{w_2}^{1/2} Pr^{1/3} = \left(\frac{0.62\text{W/m}\cdot\text{K}}{0.10\text{m}}\right) \times 0.664 \times \left(3.88\times10^5\right)^{1/2}\left(5.2\right)^{1/3} = 4443 \text{ W/m}^2\cdot\text{K}$$

The fin area is $A_f = 2_{w2}(L_f + t/2)$ = 0.2 m (0.055 m) = 0.011 m^2 while the total surface area of the array is $A_t = NA_f + A_b = NA_f + (N-1)(S-t)w_2$ = 6(0.011 m^2) + 5(0.008 m)0.1m = 0.070 m^2. The fin parameter $m = (2\bar{h}/k_{hs}t)^{1/2}$ = ([2 × 4443 W/m^2·K]/[180 W/m·K × 0.01 m])$^{1/2}$ = 70.3 m^{-1} and $L_c = L_f + t/2$ = 0.050 m + 0.010/2 m = 0.055 m. Hence, Eq. 3.94 yields $\eta_f = \tanh(mL_c)/(mL_c)$ = 0.259.

Continued…

PROBLEM 11.90 (Cont.)

Hence,

$$R_{t,o} = \left\{4443\ \text{W/m}^2 \cdot \text{K} \times 0.070\ \text{m}^2 \left[1 - \frac{0.066\ \text{m}^2}{0.070\ \text{m}^2}(1 - 0.259)\right]\right\}^{-1} = 0.0107\ \text{K/W}$$

The heat capacity rate is $C_{\min} = \rho(N-1)L_f(S-t)u_\infty c_p = 995\ \text{kg/m}^3 \times (6-1) \times 0.050\ \text{m} \times (0.018\ \text{m} - 0.010\ \text{m}) \times 3\ \text{m/s} \times 4178\ \text{J/kg·K} = 24{,}940$.

Equations (1) and (2) can be combined to yield

$$T_b = T_\infty + \frac{P_{\text{elec}}}{\left[1 - \exp\left(-\frac{1}{(R_b + R_{t,o})C\min}\right)\right]C_{\min}}$$

$$= 17°\text{C} + \frac{1800\ \text{W}}{\left[1 - \exp\left(-\frac{1}{(5.56\times10^{-3}\text{K/W} + 0.0107\text{K/W})24{,}940\ \text{W/K}}\right)\right]24{,}940\ \text{W/K}}$$

$= 46.3$ °C. <

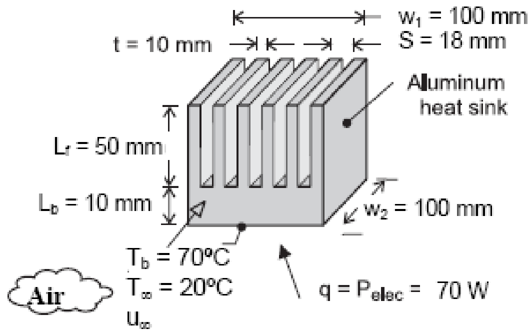
COMMENTS: (1) The outlet water temperature is $T_{c,o} = T_{c,i} + P_{\text{elec}}/C_{\min}$ = 17°C + 1800 W/24,940 W/K = 17.1°C and the assumption of constant water temperature made in Problem 7.29 is valid. (2) The hydrodynamic boundary layer thickness at the exit of the heat sink is $\delta = 5w_2 Re_{w2}^{-1/2}$ = 0.80 mm which is much less than $S - t$ = 8 mm. Hence, the assumption of flow over a flat plate is reasonable. (3) For this problem, reduced water flow rates, or use of a gaseous coolant may invalidate the assumption of constant coolant temperature and a heat exchanger-based analysis would be needed. (4) To ensure against coolant loss from the upper surface of the heat sink, a shroud would normally be added.

PROBLEM 11.91

KNOWN: Dimensions of aluminum heat sink. Temperature of air entering the heat sink and specified base temperature.

FIND: Plot of the allowable power dissipation and air exit temperature as a function of air velocity over the range 1 m/s ≤ u_∞ ≤ 5 m/s.

SCHEMATIC:



ASSUMPTIONS: (1) Average convection coefficient associated with air flow over fin surfaces may be approximated as that for a channel composed of isothermal parallel plates of width L_f, (2) All of the electric power is dissipated by the heat sink, (3) Laminar flow, (4) Constant properties, (5), Air does not exit through the upper surface of the heat sink.

PROPERTIES: Given. Aluminum, k_{hs} = 180 W/m·K. Air, ρ = 1.145 kg/m^3, c_p = 1007 J/kg·K, k = 0.027 W/m·K, ν = 16.4 × 10^{-6} m^2/s, Pr = 0.706.

ANALYSIS: Assuming laminar flow, from Eq. 8.58 the average Nusselt number (for a hydraulic diameter of $D_h = 4A_c/P = 4L_f(S - t)/[2(S - t) + 2L_f]$ = 4 × 0.05 m × (0.018 m – 0.010 m)/[2 × (0.018 m – 0.010 m) + 2 × 0.050 m] = 0.0138 m) is,

$$\overline{Nu}_{D_h} = \frac{\dfrac{3.66}{\tanh\left[2.264 Gr_{D_h}^{-1/3} + 1.7 Gz_{D_h}^{-2/3}\right]} + 0.0499 Gz_{D_h} \tanh\left(Gz_{D_h}^{-1}\right)}{\tanh\left(2.432 \Pr^{1/6} Gz_{D_h}^{-1/6}\right)} \quad (1a)$$

where $Gz_{D_h} = (D_h / w_2) Re_{D_h} Pr = (0.0138/0.01) \times (u_{\text{air}} \times 0.0138\ \text{m}/16.4\times10^{-6}\ \text{m}^2/\text{s}) \times 0.706$ (1b)

and $\bar{h} = Nu_{D_h} k / D_h = Nu_{D_h} \times 0.027\ \text{W/m}\cdot\text{K}/0.0138\ \text{m}$ (1c)

The total resistance consists of the base and fin resistances in series. The base resistance is $R_b = L_b/k_{hs}(w_1 \times w_2)$ = 0.01m/180W/m·K(0.10 m)^2 = 5.56 × 10^{-3} K/W and from Eqs. 3.107 and 3.108,

$$R_{t,o} = \left\{\bar{h} A_t \left[1 - \frac{NA_f}{A_t}\left(1 - \eta_f\right)\right]\right\}^{-1} \quad (2)$$

The fin area is $A_f = 2w_2(L_f + t/2)$ = 0.2 m (0.055 m) = 0.011 m^2 while the total surface area of the array is $A_t = NA_f + A_b = NA_f + (N - 1)(S - t)w_2$ = 6(0.011 m^2) + 5(0.008 m)0.1 m = 0.070 m^2. To find the fin efficiency, note that the fin parameter, m, is

Continued...

PROBLEM 11.91 (Cont.)

$$m = (2\bar{h}/k_{hs}t)^{1/2} = ([2 \times \bar{h}\ \text{W/m}^2\cdot\text{K}]/[180\ \text{W/m}\cdot\text{K} \times 0.01\ \text{m}])^{1/2} \quad (3)$$

and $L_c = L_f + t/2 = 0.050$ m + 0.010/2 m = 0.055 m. From Eq. 3.94, the fin array efficiency is

$$\eta_f = \tanh(mL_c)/(mL_c) = \tanh(m \times 0.055\ \text{m})/(m \times 0.055\ \text{m}) \quad (4)$$

The minimum heat capacity rate is

$$\begin{aligned} C_{\min} &= u_\infty \rho c_p (N-1)(S-t)L_f \\ &= u_\infty \times 1.145\ \text{kg/m}^3 \times 1007\ \text{J/kg}\cdot\text{K} \times (6-1) \times (0.018\ \text{m} - 0.010\ \text{m}) \times 0.050\ \text{m} \end{aligned} \quad (5)$$

and the effectiveness is

$$\begin{aligned} \varepsilon &= 1-\exp(-\text{NTU}) = 1-\exp(-UA/C_{\min}) = 1-\exp\left(-\frac{1}{(R_{t,o}+R_b)C_{\min}}\right) \\ &= 1-\exp\left(-\frac{1}{(R_{t,o}+5.56\times10^{-3}\ \text{K/W})C_{\min}}\right) \end{aligned} \quad (6)$$

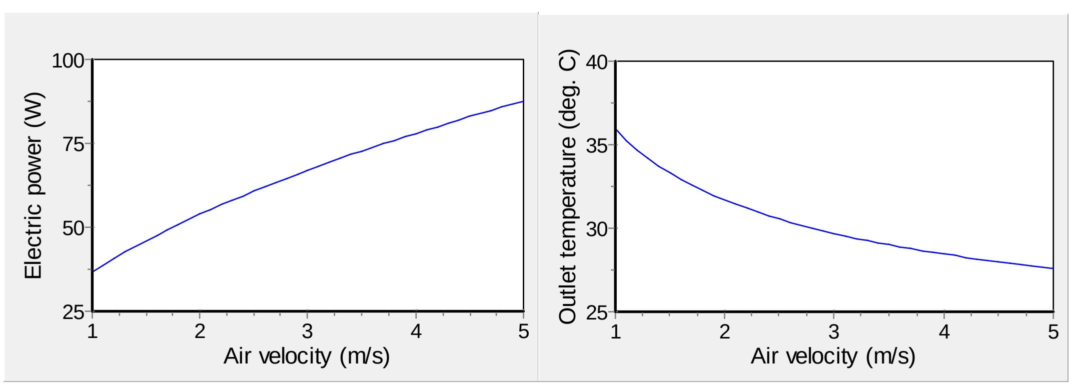
The heat transfer rate may be expressed as

$$q = P_{\text{elec}} = \varepsilon C_{\min}(T_b - T_\infty) = \varepsilon C_{\min}(70°\text{C} - 20°\text{C}) \quad (7)$$

and the outlet air temperature is

$$T_o = T_\infty + P_{elec}/C_{\min} \quad (8)$$

Equations 1 through 7 can be solved using IHT as noted in Comment 1. The allowable power and exit air temperatures are shown below.



Continued…

PROBLEM 11.91 (Cont.)

COMMENTS: (1) The IHT code is shown below. (2) Values of the Reynolds number range from 841 to 4205 for air velocities ranging from 1 m/s to 5 m/s. Hence, the flow will be transitioning to a turbulent state at velocities greater than approximately 3 m/s. (3) To dissipate P_{elec} = 70 W, it is necessary to provide an air velocity of u_∞ = 3.3 m/s, corresponding to a Reynolds number of 2775. (4) Increasing air velocity has two effects, (i) the heat transfer coefficient is increased (from 13 to 28 $W/m^2 \cdot K$ for the range of velocities considered here), and (ii) the average air temperature is reduced, as evident in the graph above.

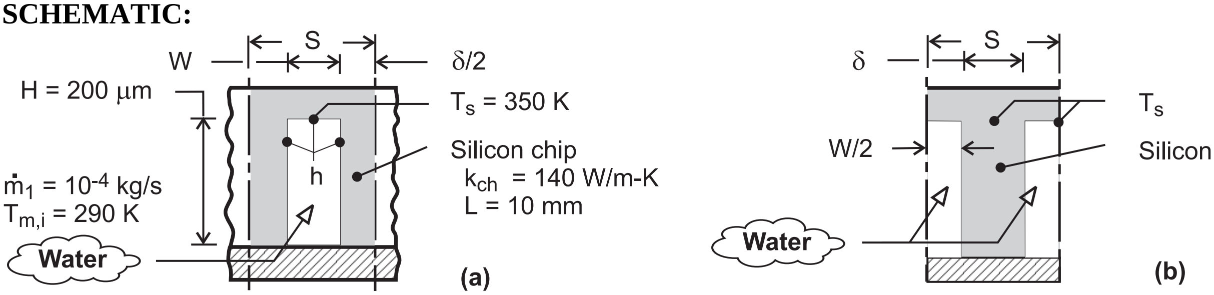
PROBLEM 11.92

KNOWN: Chip and cooling channel dimensions. Water flow rate and inlet temperature. Temperature of chip at base of channel. Chip thermal conductivity.

FIND: Water outlet temperature and chip power.

SCHEMATIC:



ASSUMPTIONS: (1)Incompressible liquid with negligible viscous dissipation, (2) Flow may be approximated as fully developed and channel walls as isothermal for purposes of estimating the convection coefficient, (3) One-dimensional conduction along channel side walls, (4) Adiabatic condition at end of side walls, (5) Heat dissipation is exclusively through fluid flow in channels, (6) Constant properties.

PROPERTIES: *Table A-6*, Water ($\overline{T}_m$ = 300K): c_p = 4179 J/kg·K, $\mu = 855 \times 10^{-6}$ kg/s·m, k = 0.613 W/m·K, Pr = 5.83.

ANALYSIS: Since the heat sink's bottom surface temperature is spatially uniform, and axial conduction is neglected, the heat sink's thermal behavior corresponds to a single stream heat exchanger. We may use Equation 11.22 to determine the heat transfer rate,

$$q = \varepsilon C_{\min}(T_{h,i} - T_{c,i}) \qquad (1)$$

where $C_{\min} = C_c = \dot{m}_c c_{p,c}$ and $C_r \to 0$. From Section 11.2 and the discussion surrounding Equations 8.45b and 8.46b, we note that the term $1/UA$ used in the definition of NTU corresponds to the overall thermal resistance between the two fluid streams of a heat exchanger. In this example, $UA = 1/R_{\text{tot}}$ where R_{tot} is the total thermal resistance between the bottom of the heat sink and the fluid. Therefore, Equation 11.35a may be written as

$$\varepsilon = 1 - \exp(-\text{NTU}) = 1 - \exp\left(-\frac{UA}{C_{\min}}\right) = 1 - \exp\left(-\frac{1}{R_{\text{tot}}C_{\min}}\right) \qquad (2)$$

Once $C_{\min}$ and R_{tot} are evaluated, the effectiveness can be found from Equation 2, and the heat rate may be determined from Equation 1.

Determination of R_{tot}. The channel sidewalls act as fins, and a *unit* channel/sidewall combination is shown in schematic (a), where the total number of unit cells corresponds to N = L/S. With N = 50 and L = 10 mm, S = 200 μm and δ = S – W = 150 μm. Alternatively, the unit cell may be represented in terms of a single fin of thickness δ, as shown in schematic (b). The thermal resistance of the unit cell may be obtained from the expression for a fin array, Eq. (3.108), $R_{t,o} = (\eta_o h A_t)^{-1}$, where $A_t = A_f + A_b$ = L (2 H + W) = 0.01m $(4 \times 10^{-4} + 0.5 \times 10^{-4})$ m = 4.5×10^{-6} m^2. With D_h = 4 (H × W)/2 (H + W) = 4 $(2 \times 10^{-4}\text{m} \times 0.5 \times 10^{-4}\text{m})/2\ (2.5 \times 10^{-4}\text{m}) = 8 \times 10^{-5}$m, the Reynolds number is $Re_D = \rho u_m D_h/\mu = \dot{m}_1 D_h/A_c\mu = 10^{-4}$ kg/s × 8×10^{-5}m/$(2 \times 10^{-4}\text{m} \times 0.5 \times 10^{-4}\text{m})\ 855 \times 10^{-6}$ kg/s·m = 936. Hence, the flow is laminar, and assuming fully developed conditions throughout a channel with uniform surface temperature, Table 8.1 yields Nu_D = 4.44. Hence,

Continued...

PROBLEM 11.92 (Cont.)

$$h = \frac{k}{D_h} Nu_D = \frac{0.613\,W/m\cdot K \times 4.44}{8\times10^{-5} m} = 34,022\,W/m^2\cdot K$$

With $m = (2h/k_{ch}\delta)^{1/2} = (68,044\ W/m^2\cdot K/140\ W/m\cdot K \times 1.5 \times 10^{-4} m)^{1/2} = 1800\ m^{-1}$ and mH = 0.36, the fin efficiency is

$$\eta_f = \frac{\tanh\ mH}{mH} = \frac{0.345}{0.36} = 0.958$$

and the overall surface efficiency is

$$\eta_o = 1 - \frac{A_f}{A_t}(1-\eta_f) = 1 - \frac{4.0\times10^{-6}}{4.5\times10^{-6}}(1-0.958) = 0.963$$

The thermal resistance of the unit cell is then

$$R_{tot} = (\eta_o h A_t)^{-1} = \left(0.963\times 34,022\,W/m^2\cdot K\times 4.5\times10^{-6} m^2\right)^{-1} = 6.78\,K/W$$

Determination of C_{min}. The minimum heat capacity rate is

$$C_{min} = \dot{m}_1 c_p = 10^{-4} kg/s \times 4179\,J/kg\cdot K = 0.4179\ W/K$$

From Equation 2,

$$\varepsilon = 1 - \exp\left(-\frac{1}{R_{tot}C_{min}}\right) = 1 - \exp\left(-\frac{1}{6.78\ K/W \times 0.4179\ W/K}\right) = 0.297$$

and from Equation 1, the heat rate per channel is

$$q_1 = \varepsilon C_{min}(T_h - T_{c,i}) = 0.297 \times 0.4179\ W/K \times (350\ K - 290\ K) = 7.46\ W$$

and the chip power dissipation is

$$q = Nq_1 = 50 \times 7.46\,W = 373\,W$$ <

The outlet temperature follows from an energy balance on a channel,

$$q_1 = C_{min}\left(T_{m,o} - T_{m,i}\right),\ T_{m,o} = T_{m,i} + \frac{q_1}{C_{min}} = 290\ K + \frac{7.46\,W}{0.4179\ W/K} = 307.8\ K$$ <

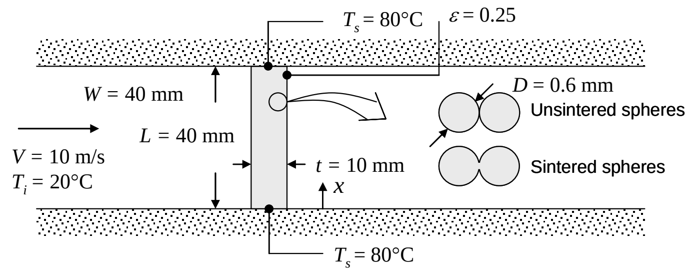
COMMENTS: (1) With $L/D_h = 125$ and $(L/D_h)_{fd} \approx 0.05\ Re_D\ Pr = 273$, fully developed flow is not achieved and the value of $h = h_{fd}$ underestimates the actual value of $\bar{h}$ in the channel. The coefficient is also underestimated by using a Nusselt number that presumes heat transfer from all four (rather than three) surfaces of a channel.

PROBLEM 11.93

KNOWN: Dimensions, particle diameter, and porosity of bronze foam sheet. Temperature of upper and lower surfaces of foam. Velocity and inlet temperature of air flowing through foam.

FIND: Convection heat transfer rate to air accounting for both the increase in the air temperature as it flows through the foam and thermal resistance due to conduction in the foam. Whether actual heat transfer rate would be greater, less, or the same.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Heat transfer coefficient between foam and air can be determined from packed bed analysis, (4) Foam behaves as extended surface, (5) Effective thermal conductivity of foam can be found from Maxwell's relation, (6) Negligible radiation transfer.

PROPERTIES: *Table A-1*, Commercial bronze ($T \approx$ 325 K): k_b = 52 W/m·K. *Table A-4*, Air ($T \approx$ 325 K): ρ = 1.0782 kg/m^3, c_p = 1008 J/kg·K, k = 0.0282 W/m·K, $\nu = 18.41 \times 10^{-6}$ m^2/s, Pr = 0.704.

ANALYSIS: Following Example 11.7, the air flow can be treated as flow through a single stream heat exchanger, exchanging heat with a surface at T_s through a single fin resistance. Due to symmetry, the foam sheet can be treated as a fin of length L/2 with an insulated fin tip.

Because the fin is foam and the air flows through it, the heat transfer coefficient can be found from the packed bed analysis of Equation 7.81:

$$\varepsilon \bar{j}_H = \varepsilon \frac{\bar{h}}{\rho c_p V} Pr^{2/3} = 2.06 Re_D^{-0.575}$$

where $Re_D = VD/\nu = 10 \text{ m/s} \times 0.0006 \text{ m}/18.41 \times 10^{-6} \text{ m}^2\text{/s} = 326$

$$\bar{h} = \frac{2.06 \rho c_p V}{\varepsilon} Re_D^{-0.575} Pr^{-2/3}$$

$$= \frac{2.06 \times 1.0782 \text{ kg/m}^3 \times 1008 \text{ J/kg} \cdot \text{K} \times 10 \text{ m/s}}{0.25} (326)^{-0.575} (0.704)^{-2/3} = 4060 \text{ W/m}^2 \cdot \text{K}$$

The surface area of the sintered particles can be found as follows, where N = number of particles:

$V_p = N\pi D^3/6 = (1 - \varepsilon)V_{\text{tot}} = (1 - \varepsilon)WtL$ and

$$A_{p,t} = N\pi D^2 = 6(1 - \varepsilon)WtL/D = = \frac{6 \times 0.75 \times 0.04 \text{ m} \times 0.01 \text{ m} \times 0.04 \text{ m}}{0.0006 \text{ m}} = 0.12 \text{ m}^2$$

Continued…

PROBLEM 11.93 (Cont.)

For a slice of the foam of length dx, the surface area of foam in contact with the air is $dA_s = A_{p,t}dx/L$. Thus,

$$dq_{\text{conv}} = \frac{\bar{h}A_{p,t}dx}{L}(T(x) - T_\infty)$$

By analogy with $dq_{\text{conv}} = hPdx(T(x) - T_\infty)$ for a solid fin, we find

$$P_{\text{eff}} = \frac{A_{p,t}}{L} = \frac{0.12 \text{ m}^2}{0.04 \text{ m}} = 3.0 \text{ m}$$

From Equation 3.25, with $k_s = k_b$,

$$k_{\text{eff}} = \left[\frac{k_f + 2k_b - 2\varepsilon(k_b - k_f)}{k_f + 2k_b + \varepsilon(k_b - k_f)}\right]k_b$$

$$= \left[\frac{(0.0282 + 2\times 52 - 2\times 0.25\times(52 - 0.0282))\text{W/m}\cdot\text{K}}{(0.0282 + 2\times 52 + 0.25\times(52 - 0.0282))\text{W/m}\cdot\text{K}}\right]\times 52 \text{ W/m}\cdot\text{K} = 34.7 \text{ W/m}\cdot\text{K}$$ <

The fin efficiency is given by Equation 11.4, where A_c is the fin cross-sectional area, $A_c = Wt = 0.04$ m $\times$ 0.01 m = 4×10^{-4} m^2. We first calculate

$$mL_f = \sqrt{\bar{h}P_{\text{eff}} / k_{\text{eff}} A_c}\,(L/2) = \sqrt{4060 \text{ W/m}^2\cdot\text{K}\times 3 \text{ m}/(34.7 \text{ W/m}\cdot\text{K}\times 4\times 10^{-4} \text{ m}^2)}\times 0.02 \text{ m} = 18.7$$

Then

$$\eta_f = \frac{\tanh(mL_f)}{mL_f} = \frac{\tanh(18.7)}{18.7} = 0.0535$$

The fin is inefficient because it is significantly longer than it needs to be to maximize heat transfer between the air and foam. From Equation 3.97, the fin resistance is

$$R_{t,f} = 1/\bar{h}A_{p,t}\eta_f = 1/(4060 \text{ W/m}^2\cdot\text{K}\times 0.12 \text{ m}^2\times 0.0535) = 0.0384 \text{ K/W}$$

Note that the fin surface area is $A_{p,t}$, since this is the area for heat transfer between the foam and air. Following the approach in Example 11.7,

$$C_{\min} = \dot{m}_c c_{p,c} = \rho V A_{c,b} c_p$$
$$= 1.0782 \text{ kg/m}^3\times 10 \text{ m/s}\times(0.04 \text{ m})^2\times 1008 \text{ J/kg}\cdot\text{K} = 17.4 \text{ W/K}$$

Continued…

PROBLEM 11.93 (Cont.)

$$\varepsilon = 1 - \exp(-\text{NTU}) = 1 - \exp\left(-\frac{1}{R_{t,f}C_{\min}}\right) = 1 - \exp\left(-\frac{1}{0.0384 \text{ K/W} \times 17.4 \text{ W/K}}\right) = 0.776$$

Finally,

$$q = \varepsilon C_{\min}(T_s - T_{c,i}) = 0.776 \times 17.4 \text{ W/K} \times (80°\text{C} - 20°\text{C}) = 810 \text{ W} \quad <$$

This is probably close to the correct answer, although temperature gradients in the streamwise direction in the foam are not accounted for. The actual value would therefore be less than 810 W. <

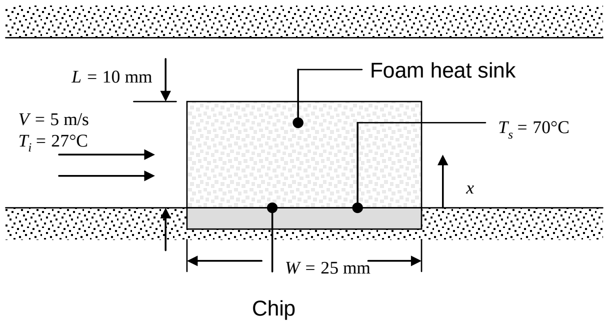
COMMENTS: The solution to Problem 7.113 was achieved in two ways: (a) assuming the foam temperature is uniform at T_s and accounting for the variation of air temperature in the flow direction, and (b) assuming the air temperature is uniform at T_i and accounting for the variation of foam temperature in the *x*-direction. Both of these approaches significantly overestimate the actual heat transfer rate.

PROBLEM 11.94

KNOWN: Dimensions, particle diameter, and porosity of bronze foam heat sink attached to silicon chip. Chip temperature. Velocity and inlet temperature of air flowing through foam.

FIND: Heat transfer rate from chip.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Constant properties, (3) Heat transfer coefficient between foam and air can be determined from packed bed analysis, (4) Foam behaves as extended surface, (5) Effective thermal conductivity of foam can be found from Maxwell's relation, (6) Air flows uniformly through foam rather than being diverted toward open region above heat sink, (7) Negligible radiation transfer.

PROPERTIES: *Table A-1*, Commercial bronze ($T \approx 323$ K): $k_b = 52$ W/m·K. *Table A-4*, Air ($T \approx 325$ K): $\rho_a = 1.0782$ kg/m^3, $c_{p,a} = 1008$ J/kg·K, $k_a = 0.0282$ W/m·K, $\nu_a = 18.41 \times 10^{-6}$ m^2/s, $Pr = 0.704$.

ANALYSIS: Following Example 11.7, the air flow can be treated as flow through a single stream heat exchanger, exchanging heat with a surface at T_s through a single fin resistance. Because the fin is foam and the air flows through it, the heat transfer coefficient can be found from the packed bed analysis of Equation 7.81:

$$\varepsilon \bar{j}_H = \varepsilon \frac{\bar{h}}{\rho c_p V} Pr^{2/3} = 2.06 Re_D^{-0.575}$$

where $Re_D = VD/\nu = 5 \text{ m/s} \times 0.0006 \text{ m}/18.41 \times 10^{-6} \text{ m}^2/\text{s} = 163$

$$\bar{h} = \frac{2.06 \rho c_p V}{\varepsilon} Re_D^{-0.575} Pr^{-2/3}$$

$$= \frac{2.06 \times 1.0782 \text{ kg/m}^3 \times 1008 \text{ J/kg} \cdot \text{K} \times 5 \text{ m/s}}{0.25} (163)^{-0.575} (0.704)^{-2/3} = 3030 \text{ W/m}^2 \cdot \text{K}$$

The surface area of the sintered particles can be found as follows, where N = number of particles:

$V_p = N\pi D^3/6 = (1 - \varepsilon)V_{tot} = (1 - \varepsilon)W^2 L$ and

$$A_{p,t} = N\pi D^2 = 6(1 - \varepsilon)W^2 L/D = = \frac{6 \times 0.75 \times (0.025 \text{ m})^2 \times 0.01 \text{ m}}{0.0006 \text{ m}} = 0.0469 \text{ m}^2$$

Continued…

PROBLEM 11.94 (Cont.)

For a slice of the foam of length *dx*, the surface area of foam in contact with the air is $dA_s = A_{p,t}dx/L$. Thus,

$$dq_{\text{conv}} = \frac{\bar{h}A_{p,t}dx}{L}(T(x) - T_\infty)$$

By analogy with $dq_{\text{conv}} = hPdx(T(x) - T_\infty)$ for a solid fin, we find

$$P_{\text{eff}} = \frac{A_{p,t}}{L} = \frac{0.0469\ \text{m}^2}{0.01\ \text{m}} = 4.69\ \text{m}$$

From Equation 3.25, with $k_s = k_b$,

$$k_{\text{eff}} = \left[\frac{k_f + 2k_b - 2\varepsilon(k_b - k_f)}{k_f + 2k_b + \varepsilon(k_b - k_f)}\right]k_b$$

$$= \left[\frac{(0.0282 + 2 \times 52 - 2 \times 0.25 \times (52 - 0.0282))\text{W/m}\cdot\text{K}}{(0.0282 + 2 \times 52 + 0.25 \times (52 - 0.0282))\text{W/m}\cdot\text{K}}\right] \times 52\ \text{W/m}\cdot\text{K} = 34.7\ \text{W/m}\cdot\text{K}$$

The fin efficiency is given by Equation 11.4, where A_c is the fin cross-sectional area, $A_c = W^2 = (0.025\ \text{m})^2 = 6.25 \times 10^{-4}\ \text{m}^2$. We first calculate

$$mL = \sqrt{\bar{h}P_{\text{eff}} / k_{\text{eff}} A_c}\,L = \sqrt{3030\ \text{W/m}^2\cdot\text{K} \times 4.69\ \text{m} / (34.7\ \text{W/m}\cdot\text{K} \times 6.25 \times 10^{-4}\ \text{m}^2)} \times 0.01\ \text{m} = 8.09$$

Then

$$\eta_f = \frac{\tanh(mL_f)}{mL_f} = \frac{\tanh(8.09)}{8.09} = 0.124$$

From Equation 3.97, the fin resistance is

$$R_{t,f} = 1/\bar{h}A_{p,t}\eta_f = 1/(3030\ \text{W/m}^2\cdot\text{K} \times 0.0469\ \text{m}^2 \times 0.124) = 0.0570\ \text{K/W}$$

Note that the fin surface area is $A_{p,t}$, since this is the area for heat transfer between the foam and air. Following the approach in Example 11.7,

$$C_{\min} = \dot{m}_c c_{p,c} = \rho V A_{c,b} c_p$$

$$= 1.0782\ \text{kg/m}^3 \times 5\ \text{m/s} \times 0.01\ \text{m} \times 0.025\ \text{m} \times 1008\ \text{J/kg}\cdot\text{K} = 1.36\ \text{W/K}$$

Continued…

PROBLEM 11.94 (Cont.)

$$\varepsilon = 1 - \exp(-\text{NTU}) = 1 - \exp\left(-\frac{1}{R_{t,f}C_{\min}}\right) = 1 - \exp\left(-\frac{1}{0.0570\ \text{K/W} \times 1.36\ \text{W/K}}\right) = 1.0$$

Finally,

$$q = \varepsilon C_{\min}(T_s - T_{c,i}) = 1.0 \times 1.36\ \text{W/K} \times (70°\text{C} - 27°\text{C}) = 58.4\ \text{W}$$ <

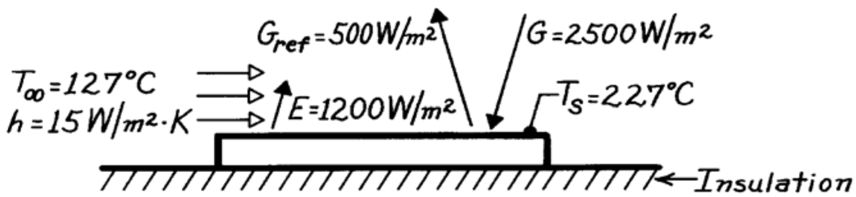
COMMENTS: (1) With a fin efficiency of unity, the foam temperature is essentially uniform at T_s, and the heat transfer rate is identical to that which would be found from a packed bed analysis that ignored the conduction resistance in the foam. This is an indication that the heat sink design could be improved to reduce its weight without significantly sacrificing performance. (2) The heat sink poses a resistance to air flow, and much of the air would be diverted around the foam block toward the open area above it, reducing its performance. The design could be altered to inhibit diversion of the air to the open region.

PROBLEM 12.1

KNOWN: Opaque, horizontal plate, well insulated on backside, is subjected to a prescribed irradiation. Also known are the reflected irradiation, emissive power, plate temperature and convection coefficient for known air temperature.

FIND: (a) Emissivity, absorptivity and radiosity and (b) Net heat transfer per unit area of the plate.

SCHEMATIC:



ASSUMPTIONS: (1) Plate is insulated on backside, (2) Plate is opaque.

ANALYSIS: (a) The emissivity of the plate according to Table 12.1 is

$$\varepsilon = \frac{E}{E_b(T_s)} = \frac{E}{\sigma T_s^4} = \frac{1200 \text{ W/m}^2}{5.67\times10^{-8} \text{ W/m}^2\cdot\text{K}^4 \times (227+273)^4 \text{ K}^4} = 0.34. \quad <$$

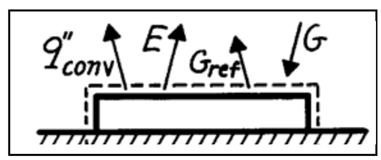
The absorptivity is related to the reflectivity by Eq. 12.3 for an opaque surface. That is, $\alpha = 1 - \rho$. By definition, the reflectivity is the fraction of irradiation reflected, such that

$$\alpha = 1 - G_{ref}/G = 1 - 500 \text{ W/m}^2 / \left(2500 \text{ W/m}^2\right) = 1 - 0.20 = 0.80. \quad <$$

The radiosity, J, is defined as the radiant flux leaving the surface by emission and reflection per unit area of the surface (Eq. 12.4).

$$J = \rho G + \varepsilon E_b = G_{ref} + E = 500 \text{ W/m}^2 + 1200 \text{ W/m}^2 = 1700 \text{ W/m}^2. \quad <$$

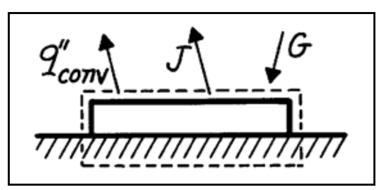
(b) The net heat transfer to the surface is determined from an energy balance,



$$q''_{net} = q''_{in} - q''_{out} = G - G_{ref} - E - q''_{conv}$$

$$q''_{net} = (2500 - 500 - 1200) \text{W/m}^2 - 15 \text{ W/m}^2\cdot\text{K}(227-127)\text{K} = -700 \text{ W/m}^2. \quad <$$

An alternate approach to the energy balance using the radiosity, Eq. 12.5,



$$q''_{net} = G - J - q''_{conv}$$

$$q''_{net} = (2500 - 1700 - 1500) \text{W/m}^2$$

$$q''_{net} = -700 \text{W/m}^2.$$

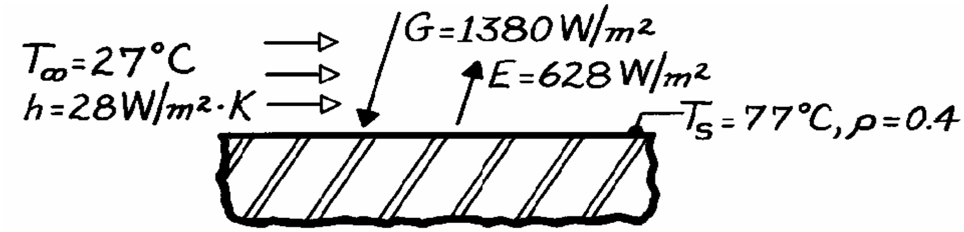
COMMENTS: (1) Since the net heat rate per unit area is negative, energy must be added to the plate in order to maintain it at $T_s = 227°C$. (2) Note that $\alpha \neq \varepsilon$. Hence, the plate is not a gray surface, as described in Section 1.2.3. (3) Note the use of radiosity in performing energy balances. That is, considering only the radiation processes, $q''_{net} = G - J$.

PROBLEM 12.2

KNOWN: Horizontal, opaque surface at steady-state temperature of 77°C is exposed to a convection process; emissive power, irradiation and reflectivity are prescribed.

FIND: (a) Absorptivity of the surface, (b) Net radiation heat transfer rate for the surface; indicate direction, (c) Total heat transfer rate for the surface; indicate direction.

SCHEMATIC:

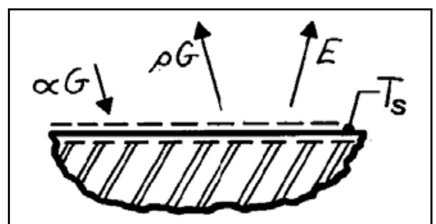


ASSUMPTIONS: (1) Surface is opaque, (2) Effect of surroundings included in the specified irradiation, (3) Steady-state conditions.

ANALYSIS: (a) From the definition of the thermal radiative properties and a radiation balance for an opaque surface, according to Eq. 12.3,

$$\alpha = 1 - \rho = 1 - 0.4 = 0.6.$$ <

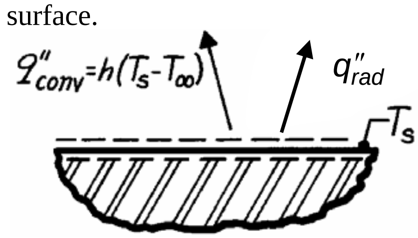
(b) The net radiation heat transfer rate from the surface is



$$q''_{rad} = E + \rho G - G = (628 + 0.4 \times 1380 - 1380)\,W/m^2 = -200\,W/m^2.$$ <

Since q''_{rad} is negative, the net radiation heat transfer rate is *to* the surface.

(c) Performing a surface energy balance considering all heat transfer processes, the local heat transfer rate is

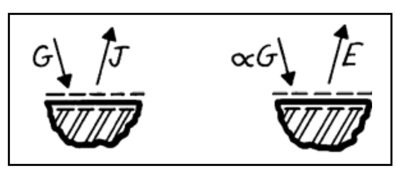


$$q''_{tot} = q''_{rad} + q''_{conv}$$

$$q''_{tot} = -200\ W/m^2 + 28\ W/m^2 \cdot K\,(77 - 27)\,K = 1200\ W/m^2.$$ <

The total heat flux is shown as a positive value indicating the heat flux is *from* the surface.

COMMENTS: (1) Note that the surface radiation balance could also be expressed as



$$q''_{rad} = J - G \quad \text{or} \quad E - \alpha G.$$

Note the use of radiosity to express the radiation flux leaving the surface.

(2) From knowledge of the surface emissive power and T_s, find the emissivity as

$$\varepsilon \equiv E/\sigma T_s^4 = 628\ W/m^2 / \left(5.67 \times 10^{-8}\ W/m^2 \cdot K^4\right)(77 + 273)^4\ K^4 = 0.74.$$

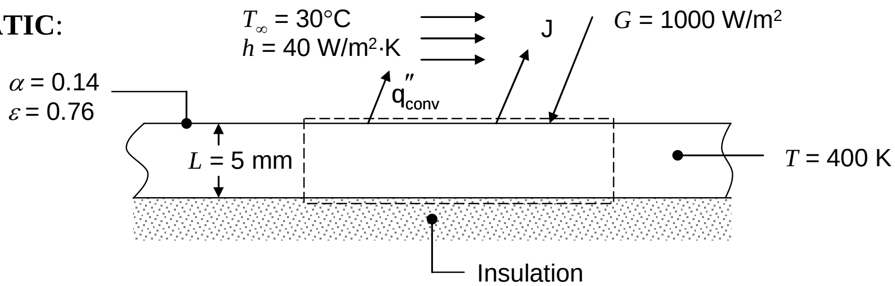
COMMENT: Since $\varepsilon \neq \alpha$, we know the surface is not gray, as discussed in Section 1.2.3.

PROBLEM 12.3

KNOWN: Thickness and temperature of aluminum plate. Irradiation. Convection conditions. Absorptivity and emissivity.

FIND: Radiosity and net radiation heat flux at top plate surface, rate of change of plate temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Plate temperature is uniform, (2) Plate is opaque, $\tau = 0$.

PROPERTIES: *Table A-1*, Pure aluminum (T = 400 K): ρ = 2702 kg/m^3, c = 949 J/kg·K.

ANALYSIS: The radiosity is equal to the sum of emitted and reflected radiation:

$$J = \rho G + \varepsilon E_b = (1-\alpha)G + \varepsilon\sigma T^4$$

$$= (1-0.14)\times 1000\text{ W/m}^2 + 0.76\times 5.67\times 10^{-8}\text{ W/m}^2\cdot\text{K}^4 \times (400\text{ K})^4$$

$$= 1963\text{ W/m}^2 \qquad <$$

The net radiation heat flux from the plate is equal to the radiosity minus the irradiation:

$$q''_{\text{rad}} = J - G = 1963\text{ W/m}^2 - 1000\text{ W/m}^2 = 963\text{ W/m}^2 \qquad <$$

The rate of change of the plate temperature can be found from an energy balance on the plate, accounting for heat loss by both radiation and convection,

$$\frac{dT}{dt} = -\frac{q_{\text{conv}} + q_{\text{rad}}}{\rho c V} = -\frac{q''_{\text{conv}} + q''_{\text{rad}}}{\rho c L} = -\frac{h(T - T_\infty) + q''_{\text{rad}}}{\rho c L}$$

$$= -\frac{40\text{ W/m}^2\cdot\text{K}\times(400\text{ K} - (30+273)\text{K}) + 963\text{ W/m}^2}{2702\text{ kg/m}^3\times 949\text{ J/kg}\cdot\text{K}\times 0.005\text{ m}} = -\ 0.378\text{ K/s} \qquad <$$

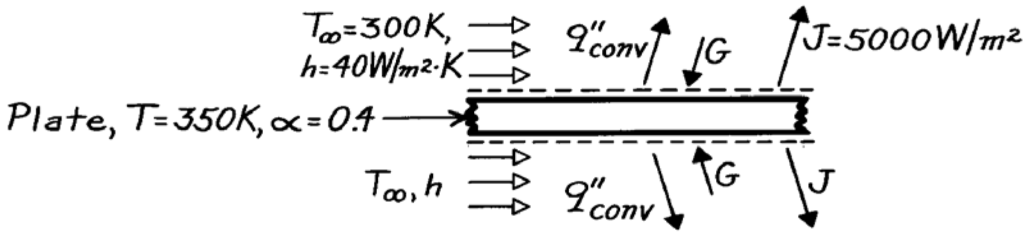
COMMENTS: (1) The values given for absorptivity and emissivity correspond to solar irradiation and room temperature emission for anodized aluminum. (2) The surroundings temperature is not needed for this solution since the irradiation value is given.

PROBLEM 12.4

KNOWN: Temperature, absorptivity, transmissivity, radiosity and convection conditions for a semitransparent plate.

FIND: Plate irradiation and total hemispherical emissivity.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Uniform surface conditions.

ANALYSIS: From an energy balance on the plate

$$\dot{E}_{in} = \dot{E}_{out}$$

$$2G = 2q''_{conv} + 2J.$$

Solving for the irradiation and substituting numerical values,

$$G = 40\ W/m^2 \cdot K(350 - 300)K + 5000\ W/m^2 = 7000\ W/m^2. \qquad <$$

From the definition of the radiosity J,

$$J = E + \rho G + \tau G = E + (1 - \alpha)G.$$

Solving for the emissivity and substituting numerical values,

$$\varepsilon = \frac{J - (1-\alpha)G}{\sigma T^4} = \frac{\left(5000\ W/m^2\right) - 0.6\left(7000\ W/m^2\right)}{5.67 \times 10^{-8}\ W/m^2 \cdot K^4 (350\,K)^4} = 0.94. \qquad <$$

Hence,

$$\alpha \neq \varepsilon$$

and the surface is not gray for the prescribed conditions.

COMMENTS: The emissivity may also be determined by expressing the plate energy balance as

$$2\alpha G = 2q''_{conv} + 2E.$$

Hence

$$\varepsilon \sigma T^4 = \alpha G - h(T - T_\infty)$$

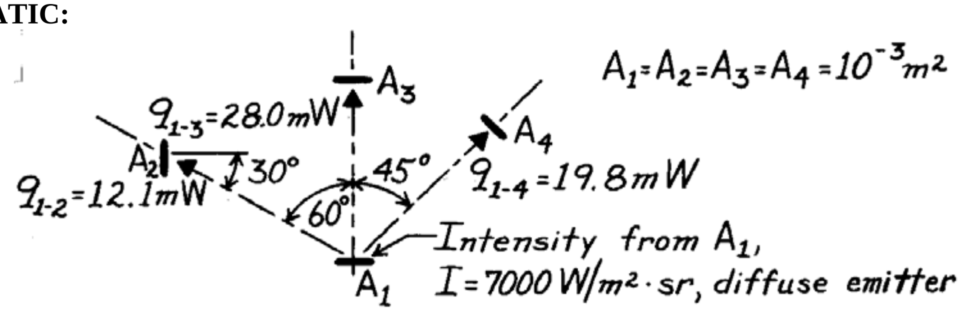
$$\varepsilon = \frac{0.4\left(7000\ W/m^2\right) - 40\ W/m^2 \cdot K(50\ K)}{5.67 \times 10^{-8} W/m^2 \cdot K^4 (350\ K)^4} = 0.94.$$

PROBLEM 12.5

KNOWN: Rate at which radiation is intercepted by each of three surfaces (see Example 12.1).

FIND: Irradiation, G [W/m^2], at each of the three surfaces.

SCHEMATIC:



ANALYSIS: The irradiation at a surface is the rate at which radiation is incident on a surface per unit area of the surface. The irradiation at surface j due to emission from surface 1 is

$$G_j = \frac{q_{1-j}}{A_j}.$$

With $A_1 = A_2 = A_3 = A_4 = 10^{-3}$ m^2 and the incident radiation rates q_{1-j} from the results of Example 12.1, find

$$G_2 = \frac{12.1 \times 10^{-3}\,\text{W}}{10^{-3}\,\text{m}^2} = 12.1\ \text{W/m}^2$$ <

$$G_3 = \frac{28.0 \times 10^{-3}\,\text{W}}{10^{-3}\,\text{m}^2} = 28.0\ \text{W/m}^2$$ <

$$G_4 = \frac{19.8 \times 10^{-3}\,\text{W}}{10^{-3}\,\text{m}^2} = 19.8\ \text{W/m}^2.$$ <

COMMENTS: The irradiation could also be computed from Eq. 12.18, which, for the present situation, takes the form

$$G_j = I_1 \cos\theta_j\, \omega_{1-j}$$

where $I_1 = I = 7000$ W/m^2·sr and ω_{1-j} is the solid angle subtended by surface 1 with respect to j. For example,

$$G_2 = I_1 \cos\theta_2\, \omega_{1-2}$$

$$G_2 = 7000\ \text{W/m}^2 \cdot \text{sr} \times$$

$$\cos 30° \frac{10^{-3}\,\text{m}^2 \times \cos 60°}{(0.5\text{m})^2}$$

$$G_2 = 12.1\ \text{W/m}^2.$$

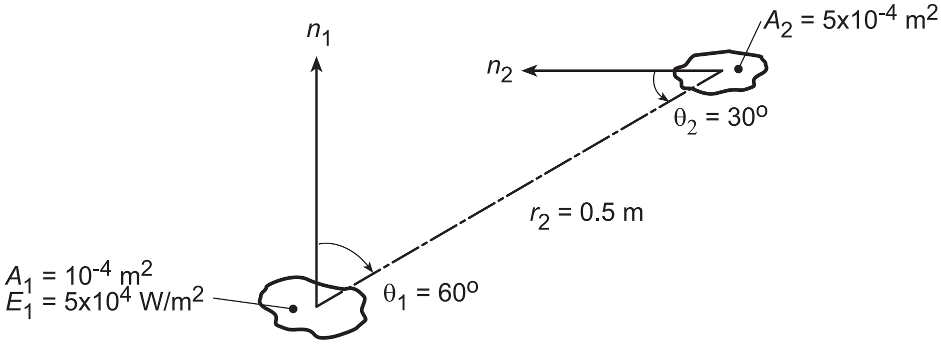
Note that, since A_1 is a diffuse radiator, the intensity I is independent of direction.

PROBLEM 12.6

KNOWN: A diffuse surface of area $A_1 = 10^{-4} m^2$ emits diffusely with total emissive power $E = 5 \times 10^4$ W/m^2 .

FIND: (a) Rate this emission is intercepted by small surface of area $A_2 = 5 \times 10^{-4}$ m^2 at a prescribed location and orientation, (b) Irradiation G_2 on A_2, and (c) Compute and plot G_2 as a function of the separation distance r_2 for the range $0.25 \le r_2 \le 1.0$ m for zenith angles $\theta_2 = 0$, 30 and 60°.

SCHEMATIC:



ASSUMPTIONS: (1) Surface A_1 emits diffusely, (2) A_1 may be approximated as a differential surface area and that $A_2/r_2^2 \ll 1$.

ANALYSIS: (a) The rate at which emission from A_1 is intercepted by A_2 follows from Eq. 12.11 written on a total rather than spectral basis.

$$q_{1\to 2} = I_{e,1}(\theta,\phi) A_1 \cos\theta_1 d\omega_{2-1}. \qquad (1)$$

Since the surface A_1 is diffuse, it follows from Eq. 12.16 that

$$I_{e,1}(\theta,\phi) = I_{e,1} = E_1/\pi \ . \qquad (2)$$

The solid angle subtended by A_2 with respect to A_1 is

$$d\omega_{2-1} \approx A_2 \cdot \cos\theta_2 / r_2^2 \ . \qquad (3)$$

Substituting Eqs. (2) and (3) into Eq. (1) with numerical values gives

$$q_{1\to 2} = \frac{E_1}{\pi} \cdot A_1 \cos\theta_1 \cdot \frac{A_2 \cos\theta_2}{r_2^2} = \frac{5\times 10^4\ W/m^2}{\pi\ sr} \times \left(10^{-4} m^2 \times \cos 60^\circ\right) \times \left[\frac{5\times 10^{-4} m^2 \times \cos 30^\circ}{(0.5m)^2}\right] sr \quad (4)$$

$$q_{1\to 2} = 15,915\ W/m^2 sr \times \left(5\times 10^{-5} m^2\right) \times 1.732\times 10^{-3} sr = 1.378\times 10^{-3} W. \qquad <$$

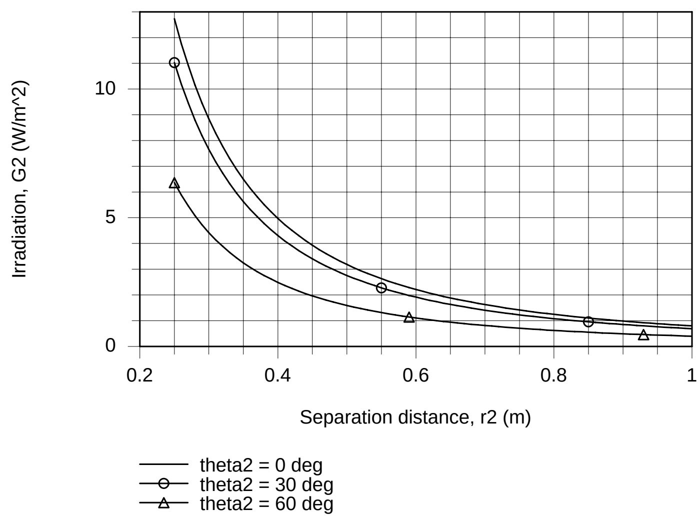
(b) From section 12.3.3, the irradiation is the rate at which radiation is incident upon the surface per unit surface area,

$$G_2 = \frac{q_{1\to 2}}{A_2} = \frac{1.378\times 10^{-3} W}{5\times 10^{-4} m^2} = 2.76\ W/m^2 \qquad (5) \ <$$

(c) Using the IHT workspace with the foregoing equations, the G_2 was computed as a function of the separation distance for selected zenith angles. The results are plotted below.

Continued...

PROBLEM 12.6 (Cont.)



For all zenith angles, G_2 decreases with increasing separation distance r_2 . From Eq. (3), note that $d\omega_{2-1}$ and, hence G_2, vary inversely as the square of the separation distance. For any fixed separation distance, G_2 is a maximum when $\theta_2 = 0°$ and decreases with increasing θ_2, proportional to cos θ_2.

COMMENTS: (1) For a diffuse surface, the intensity, I_e, is independent of direction and related to the emissive power as $I_e = E/\pi$. Note that π has the units of $[\text{sr}]$ in this relation.

(2) Note that Eq. 12.12 is an important relation for determining the radiant power leaving a surface in a prescribed manner. It has been used here on a total rather than spectral basis.

(3) Returning to part (b) and referring to Figure 12.10, the irradiation on A_2 may be expressed as

$$G_2 = I_{i,2} \cos\theta_2 \frac{A_1 \cos\theta_1}{r_2^2}$$

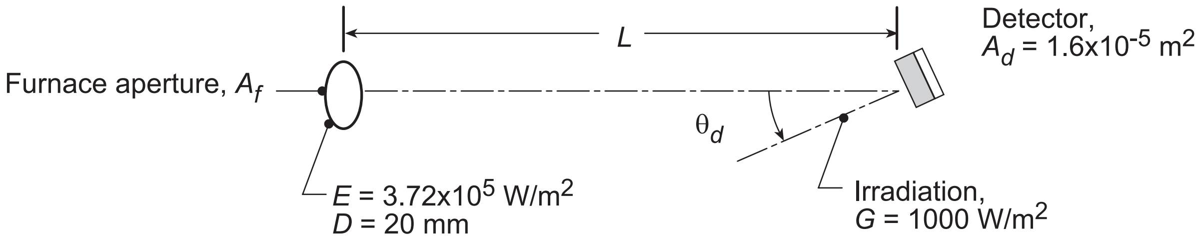
Show that the result is $G_2 = 2.76 \text{ W/m}^2$. Explain how this expression follows from Eq. 12.18.

PROBLEM 12.7

KNOWN: Furnace with prescribed aperture and emissive power.

FIND: (a) Position of gauge such that irradiation is G = 1000 W/m^2, (b) Irradiation when gauge is tilted $\theta_d = 20^o$, and (c) Compute and plot the gage irradiation, G, as a function of the separation distance, L, for the range $100 \le L \le 300$ mm and tilt angles of θ_d = 0, 20, and 60^o.

SCHEMATIC:



ASSUMPTIONS: (1) Furnace aperture emits diffusely, (2) $A_d << L^2$.

ANALYSIS: (a) The irradiation on the detector area is defined as the power incident on the surface per unit area of the surface. That is

$$G = q_{f \to d} / A_d \qquad q_{f \to d} = I_e A_f \cos\theta_f \, \omega_{d-f} \qquad (1,2)$$

where $q_{f \to d}$ is the radiant power which leaves A_f and is intercepted by A_d. From Eqs. 12.7 and 12.12, ω_{d-f} is the solid angle subtended by surface A_d with respect to A_f,

$$\omega_{d-f} = A_d \cos\theta_d / L^2 . \qquad (3)$$

Noting that since the aperture emits diffusely, $I_e = E/\pi$ (see Eq. 12.17), and hence

$$G = (E/\pi) A_f \cos\theta_f \left(A_d \cos\theta_d / L^2 \right) / A_d \qquad (4)$$

Solving for L^2 and substituting for the condition $\theta_f = 0^o$ and $\theta_d = 0^o$,

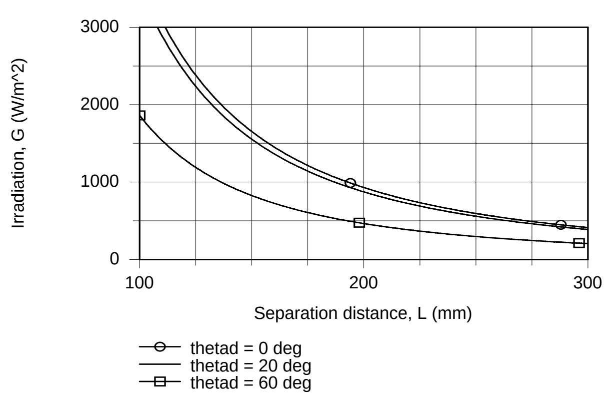
$$L^2 = E \cos\theta_f \cos\theta_d \, A_f / \pi G . \qquad (5)$$

$$L = \left[3.72 \times 10^5 \, W/m^2 \times \frac{\pi}{4} (20 \times 10^{-3})^2 \, m^2 / \pi \times 1000 \, W/m^2 \right]^{1/2} = 193 \text{ mm} . \qquad <$$

(b) When $\theta_d = 20^o$, $q_{f \to d}$ will be reduced by a factor of cos θ_d since ω_{d-f} is reduced by a factor cos θ_d. Hence,

$$G = 1000 \, W/m^2 \times \cos\theta_d = 1000 W/m^2 \times \cos 20^o = 940 \, W/m^2 . \qquad <$$

(c) Using the IHT workspace with Eq. (4), G is computed and plotted as a function of L for selected θ_d. Note that G decreases inversely as L^2. As expected, G decreases with increasing θ_d and in the limit, approaches zero as θ_d approaches 90^o.

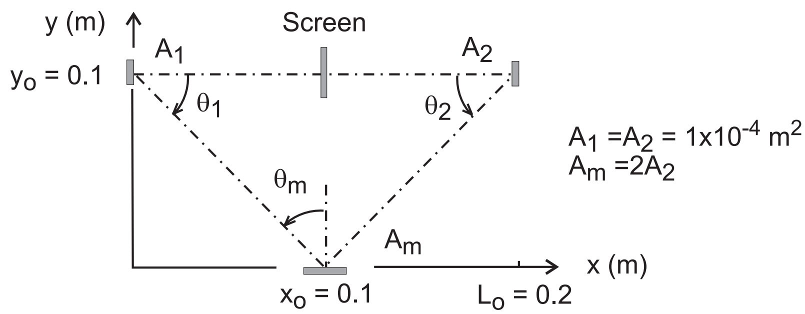


PROBLEM 12.8

KNOWN: Radiation from a diffuse radiant source A_1 with intensity $I_1 = 1.2 \times 10^5$ W/m^2·sr is incident on a mirror A_m, which reflects radiation onto the radiation detector A_2.

FIND: (a) Radiant power incident on A_m due to emission from the source, A_1, $q_{1\rightarrow m}$ (mW), (b) Intensity of radiant power leaving the perfectly reflecting, diffuse mirror A_m, I_m (W/m^2·sr), and (c) Radiant power incident on the detector A_2 due to the reflected radiation leaving A_m, $q_{m\rightarrow 2}$ (μW), (d) Plot the radiant power $q_{m\rightarrow 2}$ as a function of the lateral separation distance y_o for the range $0 \le y_o \le$ 0.2 m; explain features of the resulting curve.

SCHEMATIC:



ASSUMPTIONS: (1) Surface A_1 emits diffusely, (2) Surface A_m does not emit, but reflects perfectly and diffusely, and (3) Surface areas are much smaller than the square of their separation distances.

ANALYSIS: (a) The radiant power leaving A_1 that is incident on A_m is

$$q_{1\rightarrow m} = I_1 \cdot A_1 \cdot \cos\theta_1 \cdot \Delta\omega_{m\text{-}1}$$

where $\omega_{m\text{-}1}$ is the solid angle A_m subtends with respect to A_1, Eq. 12.7,

$$\Delta\omega_{m\text{-}1} \equiv \frac{dA_n}{r^2} = \frac{A_m \cos\,\theta_m}{x_o^2 + y_o^2} = \frac{2\times 10^{-4}\ \text{m}^2 \cdot \cos 45°}{\left[0.1^2 + 0.1^2\right]\text{m}^2} = 7.07\times 10^{-3}\ \text{sr}$$

with $\theta_m = 90° - \theta_1$ and $\theta_1 = 45°$,

$$q_{1\rightarrow m} = 1.2\times 10^5\ \text{W/m}^2\cdot\text{sr}\times 1\times 10^{-4}\ \text{m}^2 \times \cos 45° \times 7.07\times 10^{-3}\ \text{sr} = 60\ \text{mW} \quad <$$

(b) The intensity of radiation leaving A_m, after perfect and diffuse reflection, is

$$I_m = \left(q_{1\rightarrow m}/A_m\right)/\pi = \frac{60\times 10^{-3}\ \text{W}}{\pi\times 2\times 10^{-4}\ \text{m}^2} = 95.5\ \text{W/m}^2\cdot\text{sr}$$

(c) The radiant power leaving A_m due to reflected radiation leaving A_m is

$$q_{m\rightarrow 2} = q_2 = I_m \cdot A_m \cdot \cos\,\theta_m \cdot \Delta\omega_{2-m}$$

where $\Delta\omega_{2\text{-}m}$ is the solid angle that A_2 subtends with respect to A_m, Eq. 12.7,

Continued …

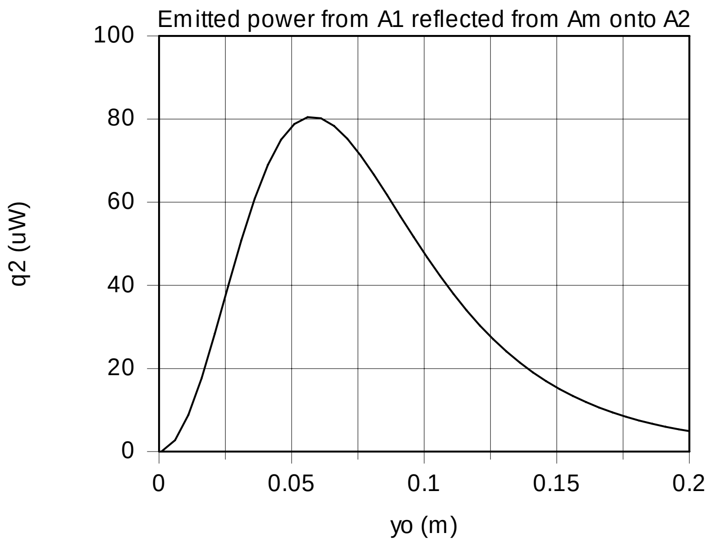
PROBLEM 12.8 (Cont.)

$$\Delta\omega_{2-m} \equiv \frac{dA_n}{r^2} = \frac{A_2 \cos\theta_2}{(L_o - x_o)^2 + y_o^2} = \frac{1\times10^{-4}\ m^2 \times \cos 45°}{\left[0.1^2 + 0.1^2\right] m^2} = 3.54\times10^{-3}\ sr$$

with $\theta_2 = 90° - \theta_m$

$$q_{m\to2} = q_2 = 95.5\ W/m^2\cdot sr \times 2\times10^{-4}\ m^2 \times \cos 45° \times 3.54\times10^{-3}\ sr = 47.8\ \mu W \quad <$$

(d) Using the foregoing equations in the *IHT* workspace, q_2 is calculated and plotted as a function of y_o for the range $0 \le y_o \le 0.2$ m.



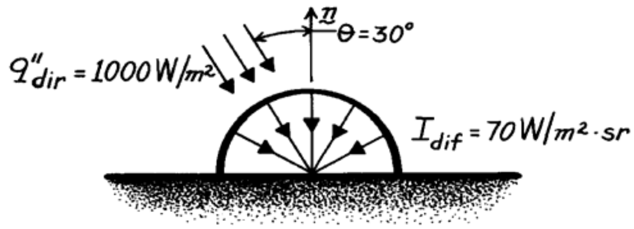
From the relations, note that q_2 is dependent upon the geometric arrangement of the surfaces in the following manner. For small values of y_o, that is, when $\theta_1 \approx 0°$, the cos θ_1 term is at a maximum, near unity. But, the solid angles $\Delta\omega_{m-1}$ and $\Delta\omega_{2-m}$ are very small. As y_o increases, the cos θ_1 term doesn't diminish as much as the solid angles increase, causing q_2 to increase. A maximum in the power is reached as the cos θ_1 term decreases and the solid angles increase. The maximum radiant power occurs when $y_o = 0.058$ m which corresponds to $\theta_1 = 30°$.

PROBLEM 12.9

KNOWN: Flux and intensity of direct and diffuse components, respectively, of solar irradiation.

FIND: Total irradiation.

SCHEMATIC:



ANALYSIS: Since the irradiation is based on the actual surface area, the contribution due to the direct solar radiation is

$$G_{dir} = q''_{dir} \cdot \cos\theta.$$

From Eq. 12.17 the contribution due to the diffuse radiation is

$$G_{dif} = \pi I_{dif}.$$

Hence

$$G = G_{dir} + G_{dif} = q''_{dir} \cdot \cos\theta + \pi I_{dif}$$

or

$$G = 1000\,W/m^2 \times 0.866 + \pi sr \times 70\,W/m^2 \cdot sr$$

$$G = (866 + 220)\,W/m^2$$

or

$$G = 1086\ W/m^2.$$ <

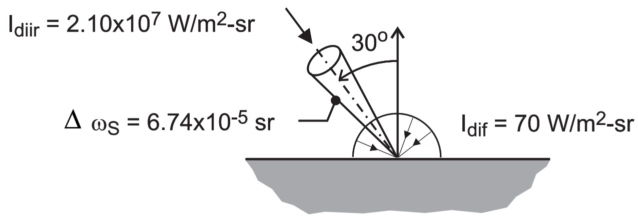
COMMENTS: Although a diffuse approximation is often made for the non-direct component of solar radiation, the actual directional distribution deviates from this condition, providing larger intensities at angles close to the direct beam.

PROBLEM 12.10

KNOWN: Daytime solar radiation conditions with direct solar intensity $I_{dir} = 2.10 \times 10^7$ W/m^2·sr within the solid angle subtended with respect to the earth, $\Delta\omega_S = 6.74 \times 10^{-5}$ sr, and diffuse intensity $I_{dif} = 70$ W/m^2·sr.

FIND: (a) Total solar irradiation at the earth's surface when the direct radiation is incident at 30°, and (b) Verify the prescribed value of $\Delta\omega_S$ recognizing that the diameter of the earth is $D_S = 1.39 \times 10^9$ m, and the distance between the sun and the earth is $r_{e-S} = 1.496 \times 10^{11}$ m (1 astronomical unit).

SCHEMATIC:



ANALYSIS: (a) From Eq. 12.22 the diffuse irradiation is

$$G_{dif} = \pi I_{dif} = \pi \text{ sr} \times 70 \text{ W/m}^2 \cdot \text{sr} = 220 \text{ W/m}^2$$

The direct irradiation follows from Eq. 12.18, expressed in terms of the solid angle

$$G_{dir} = I_{dir} \cos\theta \, \Delta\omega_S$$

$$G_{dir} = 2.10 \times 10^7 \text{ W/m}^2 \cdot \text{sr} \times \cos 30° \times 6.74 \times 10^{-5} \text{ sr} = 1226 \text{ W/m}^2$$

The total solar irradiation is the sum of the diffuse and direct components,

$$G_S = G_{dif} + G_{dir} = (220 + 1226) \text{W/m}^2 = 1446 \text{ W/m}^2 \quad <$$

(b) The solid angle the sun subtends with respect to the earth is calculated from Eq. 12.7,

$$\Delta\omega_S = \frac{dA_n}{r^2} = \frac{\pi D_S^2/4}{r_{e-S}^2} = \frac{\pi (1.39 \times 10^9 \text{ m})^2 / 4}{(1.496 \times 10^{11} \text{ m})^2} = 6.74 \times 10^{-5} \text{ sr} \quad <$$

where dA_n is the projected area of the sun and r_{e-S}, the distance between the earth and sun. We are assuming that $r_{e-S}^2 >> D_S^2$.

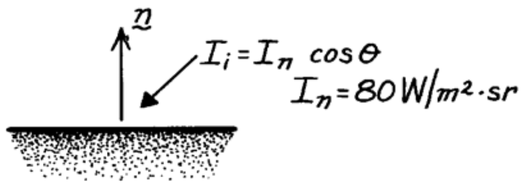
COMMENTS: Can you verify that the direct solar intensity, I_{dir}, is a reasonable value, assuming that the solar disk emits as a black body at 5800 K? $\left(I_{b,S} = \sigma T_S^4 / \pi = \sigma (5800 \text{ K})^4 / \pi = 2.04 \times 10^7 \text{ W/m}^2 \cdot \text{sr}\right)$. Because of local cloud formations, it is possible to have an appreciable diffuse component. But it is not likely to have such a high direct component as given in the problem statement.

PROBLEM 12.11

KNOWN: Directional distribution of solar radiation intensity incident at earth's surface on an overcast day.

FIND: Solar irradiation at earth's surface.

SCHEMATIC:



ASSUMPTIONS: (1) Intensity is independent of azimuthal angle θ.

ANALYSIS: Applying Eq. 12.18 to the total intensity

$$G = \int_0^{2\pi}\int_0^{\pi/2} I_i(\theta)\cos\theta\sin\theta\,d\theta\,d\phi$$

$$G = 2\pi I_n \int_0^{\pi/2} \cos^2\theta\sin\theta\,d\theta$$

$$G = (2\pi\,sr)\times 80\,W/m^2\cdot sr\left(-\frac{1}{3}\cos^3\theta\right)\Bigg|_0^{\pi/2}$$

$$G = -167.6\,W/m^2\cdot sr\left(\cos^3\frac{\pi}{2} - \cos^3 0\right)$$

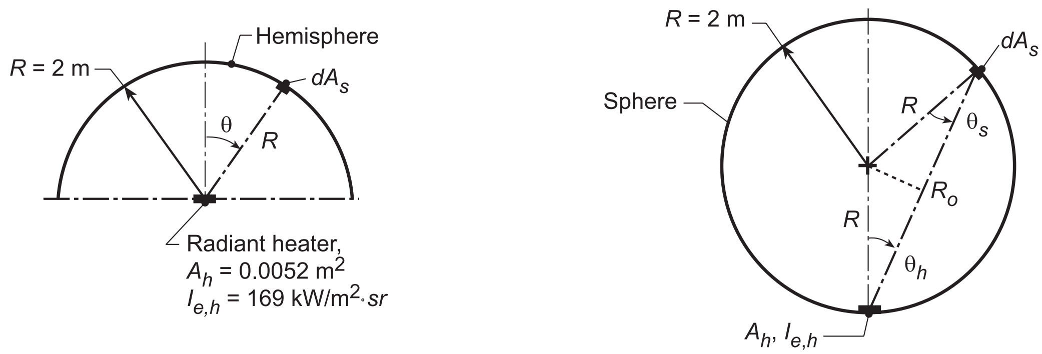
$$G = 167.6\,W/m^2.$$ <

PROBLEM 12.12

KNOWN: Hemispherical and spherical arrangements for radiant heat treatment of a thin-film material. Heater emits diffusely with intensity $I_{e,h}$ = 169,000 W/ m^2·sr and has an area 0.0052 m^2.

FIND: (a) Expressions for the irradiation on the film as a function of the zenith angle, θ, and (b) Identify arrangement which provides the more uniform irradiation, and hence better quality control for the treatment process.

SCHEMATIC:



ASSUMPTIONS: (1) Heater emits diffusely, (2) All radiation leaving the heater is absorbed by the thin film.

ANALYSIS: (a) The irradiation on any differential area, dA_s, due to emission from the heater, A_h , follows from its definition, Section 12.3.3,

$$G = \frac{q_{h \to s}}{dA_s} \tag{1}$$

Where $q_{h\to s}$ is the radiant heat rate leaving A_h and intercepted by dA_s.   From Eq. 12.12,

$$q_{h \to s} = I_{e,h} \cdot dA_h \cos\theta_h \cdot \omega_{s-h} \tag{2}$$

where $\omega_{s\text{-}h}$ is the solid angle dA_s subtends with respect to any point on A_h. From the definition, Eq. 12.7,

$$\omega = \frac{dA_n}{r^2} \tag{3}$$

where dA_n is normal to the viewing direction and r is the separation distance.

For the hemisphere: Referring to the schematic above, the solid angle is

$$\omega_{s-h} = \frac{dA_s}{R^2}$$

and the irradiation distribution on the hemispheric surface as a function of θ_h is

$$G = I_{e,h} A_h \cos\theta_h / R^2 \tag{1}$$ <

For the sphere: From the schematic, the solid angle is

$$\omega_{s,h} = \frac{dA_s \cos\theta_s}{R_o^2} = \frac{dA_s}{4R^2 \cos\theta_h}$$

where R_o, from the geometry of sphere cord and radii with $\theta_s = \theta_h$, is

Continued...

PROBLEM 12.12 (Cont.)

$$R_o = 2R\cos\theta_h$$

and the irradiation distribution on the spherical surface as a function of θ_h is

$$G = I_{e,h} d A_h / 4R^2 \qquad (2) <$$

(b) The spherical shape provides more uniform irradiation as can be seen by comparing Eqs. (1) and (2). In fact, for the spherical shape, the irradiation on the thin film is uniform and therefore provides for better quality control for the treatment process. Substituting numerical values, the irradiations are:

$$G_{hem} = 169{,}000\,W/m^2\cdot sr \times 0.0052 m^2 \cos\theta_h/(2m)^2 = 219.7\cos\theta_h\ W/m^2 \qquad (3)$$

$$G_{sph} = 169{,}000\,W/m^2\cdot sr \times 0.0052\,m^2/4(2m)^2 = 54.9\,W/m^2 \qquad (4)$$

COMMENTS: (1) The radiant heat rate leaving the diffuse heater surface by emission is

$$q_{tot} = \pi I_{e,h} A_h = 2761 W$$

The average irradiation on the *spherical surface*, $A_{sph} = 4\pi R^2$,

$$\bar{G}_{sph} = q_{tot}/A_{sph} = 2761 W/4\pi(2m)^2 = 54.9\,W/m^2$$

while the average irradiation on the *hemispherical surface*, $A_{hem} = 2\pi R^2$ is

$$\bar{G}_{hem} = 2761 W/2\pi(2m)^2 = 109.9\,W/m^2$$

(2) Note from the foregoing analyses for the *sphere* that the result for $\bar{G}_{sph}$ is identical to that found as Eq. (4). That follows since the irradiation is uniform.

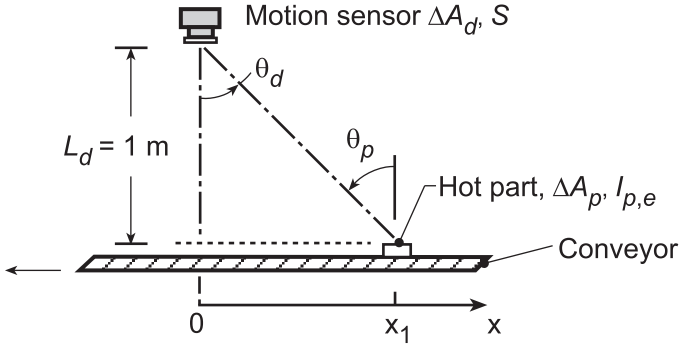
(3) Note that $\bar{G}_{hem} > \bar{G}_{sph}$ since the surface area of the hemisphere is half that of the sphere. Recognize that for the hemisphere thin film arrangement, the distribution of the irradiation is quite variable with a maximum at θ = 0° (top) and half the maximum value at θ = 30°.

PROBLEM 12.13

KNOWN: Hot part, ΔA_p, located a distance x_1 from an origin directly beneath a motion sensor at a distance $L_d = 1$ m.

FIND: (a) Location x_1 at which sensor signal S_1 will be 75% that corresponding to x = 0, directly beneath the sensor, S_o, and (b) Compute and plot the signal ratio, S/S_o, as a function of the part position x_1 for the range $0.2 \le S/S_o \le 1$ for L_d = 0.8, 1.0 and 1.2 m; compare the x-location for each value of L_d at which $S/S_o = 0.75$.

SCHEMATIC:



ASSUMPTIONS: (1) Hot part is diffuse emitter, (2) $L_d^2 >> \Delta A_p, \Delta A_o$.

ANALYSIS: (a) The sensor signal, S, is proportional to the radiant power leaving ΔA_p and intercepted by ΔA_d,

$$S \sim q_{p\to d} = I_{p,e}\Delta A_p \cos\theta_p \Delta\omega_{d-p} \tag{1}$$

when

$$\cos\theta_p = \cos\theta_d = \frac{L_d}{R} = L_d \Big/ (L_d^2 + x_1^2)^{1/2} \tag{2}$$

$$\Delta\omega_{d-p} = \frac{\Delta A_d \cdot \cos\theta_d}{R^2} = \Delta A_d \cdot L_d \Big/ (L_d^2 + x_1^2)^{3/2} \tag{3}$$

Hence,

$$q_{p\to d} = I_{p,e}\Delta A_p \Delta A_d \frac{L_d^2}{(L_d^2 + x_1^2)^2} \tag{4}$$

It follows that, with S_o occurring when x= 0 and L_d = 1 m,

$$\frac{S}{S_o} = \frac{L_d^2 \big/ (L_d^2 + x_1^2)^2}{L_d^2 \big/ (L_d^2 + 0^2)^2} = \left[\frac{L_d^2}{L_d^2 + x_1^2}\right]^2 \tag{5}$$

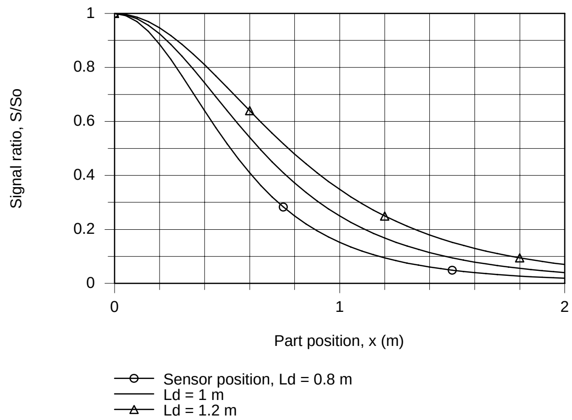
so that when $S/S_o = 0.75$, find,

$x_1 = 0.393$ m <

(b) Using Eq. (5) in the IHT workspace, the signal ratio, S/S_o, has been computed and plotted as a function of the part position x for selected L_d values.

Continued...

PROBLEM 12.13 (Cont.)



When the part is directly under the sensor, x = 0, $S/S_o = 1$ for all values of L_d. With increasing x, S/S_o decreases most rapidly with the smallest L_d. From the IHT model we found the part position x corresponding to $S/S_o = 0.75$ as follows.

S/S_o	L_d (m)	x_1 (m)
0.75	0.8	0.315
0.75	1.0	0.393
0.75	1.2	0.472

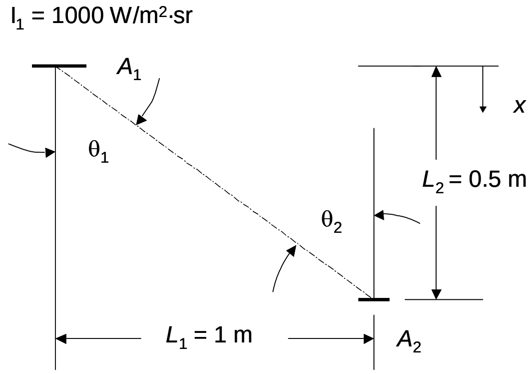
If the sensor system is set so that when S/S_o reaches 0.75 a process is initiated, the technician can use the above plot and table to determine at what position the part will begin to experience the treatment process.

PROBLEM 12.14

KNOWN: Surface area, and emission from area A_1. Size and orientation of area A_2.

FIND: (a) Irradiation of A_2 by A_1 for $L_1 = 1$ m, $L_2 = 0.5$ m, (b) Irradiation of A_2 over the range $0 \le L_2 \le 10$ m.

SCHEMATIC:



ASSUMPTIONS: Diffuse emission.

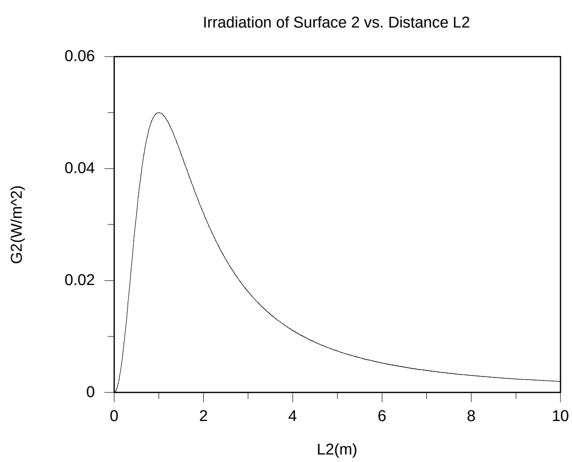
ANALYSIS: (a) The irradiation of Surface 1 is $G_{1\text{-}2} = q_{1\text{-}2}/A_2$ and from Example 12.1,

$$q_{1\text{-}2} = I_1 A_1 \cos\theta_1 \omega_{2\text{-}1} = I_1 A_1 \cos\theta_1 A_2 \cos\theta_2 / r^2$$

Since $\theta_1 = \theta_2 = \theta = \tan^{-1}(L_1/L_2) = \tan^{-1}(1/0.5) = 63.43°$ and $r^2 = L_1^2 + L_2^2 = (1\text{m})^2 + (0.5\text{m})^2 = 1.25\ \text{m}^2$,

$$G_{1\text{-}2} = I_1 A_1 \cos^2\theta / r^2 = 1000\text{W/m}^2\cdot\text{sr} \times 2 \times 10^{-4}\ \text{m}^2 \times \cos^2(63.43°)/1.25\text{m}^2 = 0.032\ \text{W/m}^2 \quad <$$

(b) The preceding equations may be solved for various values of L_2. The irradiation over the range $0 \le L_2 \le 10$ m is shown below.



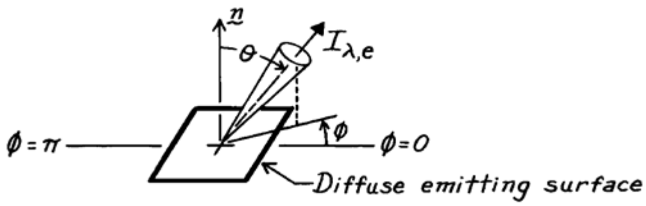
COMMENTS: The irradiation is zero for $L_2 = 0$ and $L_2 \to \infty$.

PROBLEM 12.15

KNOWN: Emissive power of a diffuse surface.

FIND: Fraction of emissive power that leaves surface in the directions $\pi/4 \le \theta \le \pi/2$ and $0 \le \phi \le \pi$.

SCHEMATIC:



ASSUMPTIONS: (1) Diffuse emitting surface.

ANALYSIS: According to Eq. 12.15, the total, hemispherical emissive power is

$$E = \int_0^\infty \int_0^{2\pi} \int_0^{\pi/2} I_{\lambda,e}(\lambda,\theta,\phi)\cos\theta\sin\theta\, d\theta\, d\phi\, d\lambda.$$

For a diffuse surface $I_{\lambda,e}$ (λ, θ, ϕ) is independent of direction, and as given by Eq. 12.17,

$$E = \pi I_e.$$

The emissive power, which has directions prescribed by the limits on θ and ϕ, is

$$\Delta E = \int_0^\infty I_{\lambda,e}(\lambda)\,d\lambda \left[\int_0^\pi d\phi\right]\left[\int_{\pi/4}^{\pi/2}\cos\theta\sin\theta\, d\theta\right]$$

$$\Delta E = I_e\left[\phi\right]_0^\pi \times \left[\frac{\sin^2\theta}{2}\right]_{\pi/4}^{\pi/2} = I_e\left[\pi\right]\left[\frac{1}{2}\left(1-0.707^2\right)\right]$$

$$\Delta E = 0.25\pi I_e.$$

It follows that

$$\frac{\Delta E}{E} = \frac{0.25\pi I_e}{\pi I_e} = 0.25.$$ <

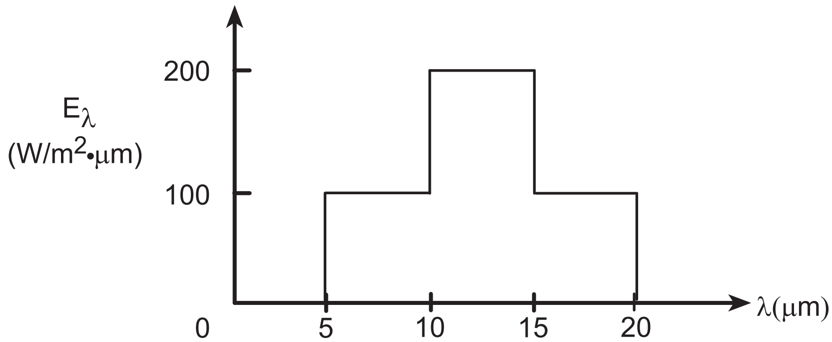
COMMENTS: The diffuse surface is an important concept in radiation heat transfer, and the directional independence of the intensity should be noted.

PROBLEM 12.16

KNOWN: Spectral distribution of E_λ for a diffuse surface.

FIND: (a) Total emissive power E, (b) Total intensity associated with directions $\theta = 0^o$ and $\theta = 30^o$, and (c) Fraction of emissive power leaving the surface in directions $\pi/4 \le \theta \le \pi/2$.

SCHEMATIC:



ASSUMPTIONS: (1) Diffuse emission.

ANALYSIS: (a) From Eq. 12.14 it follows that

$$E = \int_0^\infty E_\lambda(\lambda)\,d\lambda = \int_0^5 (0)\,d\lambda + \int_5^{10}(100)\,d\lambda + \int_{10}^{15}(200)\,d\lambda + \int_{15}^{20}(100)\,d\lambda + \int_{20}^{\infty}(0)\,d\lambda$$

$$E = 100\ W/m^2 \cdot \mu m\ (10-5)\ \mu m + 200 W/m^2 \cdot \mu m\ (15-10)\ \mu m + 100\ W/m^2 \cdot \mu m\ (20-15)\ \mu m$$

$$E = 2000\ W/m^2$$ <

(b) For a diffuse emitter, I_e is *independent* of θ and Eq. 12.17 gives

$$I_e = \frac{E}{\pi} = \frac{2000\ W/m^2}{\pi\ sr}$$

$$I_e = 637\ W/m^2 \cdot sr$$ <

(c) Since the surface is diffuse, use Eqs. 12.13 and 12.17,

$$\frac{E(\pi/4 \to \pi/2)}{E} = \frac{\int_0^{2\pi}\int_{\pi/4}^{\pi/2} I_e \cos\theta \sin\theta\, d\theta\, d\phi}{\pi I_e}$$

$$\frac{E(\pi/4 \to \pi/2)}{E} = \frac{\int_{\pi/4}^{\pi/2}\cos\theta\sin\theta\, d\theta \int_0^{2\pi} d\phi}{\pi} = \frac{1}{\pi}\left[\frac{\sin^2\theta}{2}\right]_{\pi/4}^{\pi/2} \phi\Big|_0^{2\pi}$$

$$\frac{E(\pi/4 \to \pi/2)}{E} = \frac{1}{\pi}\left[\frac{1}{2}(1^2 - 0.707^2)(2\pi - 0)\right] = 0.50$$ <

COMMENTS: (1) Note how a spectral integration may be performed in parts.

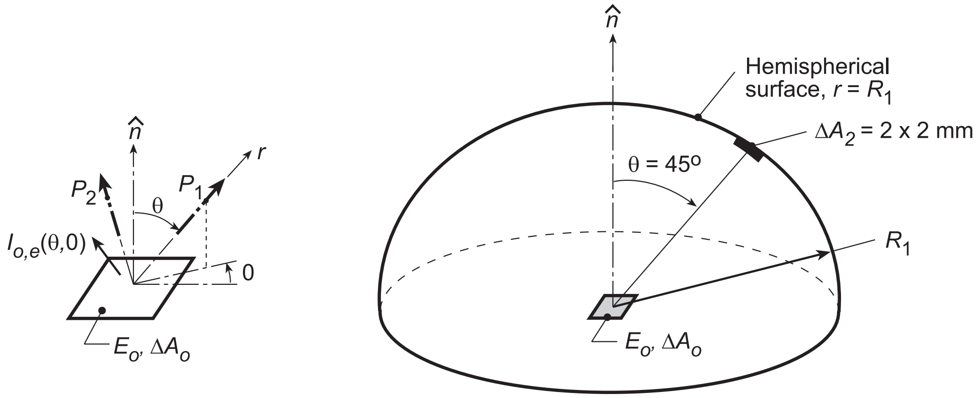
(2) In performing the integration of part (c), recognize the significance of the diffuse emission assumption for which the intensity is uniform in all directions.

PROBLEM 12.17

KNOWN: Diffuse surface ΔA_o, 5-mm square, with total emissive power $E_o = 4000\ W/m^2$.

FIND: (a) Rate at which radiant energy is emitted by ΔA_o, q_{emit}; (b) Intensity $I_{o,e}$ of the radiation field emitted from the surface ΔA_o; (c) Expression for q_{emit} presuming knowledge of the intensity $I_{o,e}$ beginning with Eq. 12.13; (d) Rate at which radiant energy is incident on the hemispherical surface, $r = R_1 = 0.5$ m, due to emission from ΔA_o; (e) Rate at which radiant energy leaving ΔA_o is intercepted by the small area ΔA_2 located in the direction $(40^o, \phi)$ on the hemispherical surface using Eq. 12.10; also determine the irradiation on ΔA_2; (f) Repeat part (e), for the location $(0^o, \phi)$; are the irradiations at the two locations equal? and (g) Irradiation G_1 on the hemispherical surface at $r = R_1$ using Eq. 12.18.

SCHEMATIC:



ASSUMPTIONS: (1) Diffuse surface, ΔA_o, (2) Medium above ΔA_o is also non-participating, (3) $R_1^2 >> \Delta A_o, \Delta A_2$.

ANALYSIS: (a) The radiant power leaving ΔA_o by emission is

$$q_{emit} = E_o \cdot \Delta A_o = 4000\ W/m^2\ (0.005\ m \times 0.005\ m) = 0.10\ W$$ <

(b) The emitted intensity is $I_{o,e}$ and is independent of direction since ΔA_o is a diffuser emitter,

$$I_{o,e} = E_o / \pi = 1273\ W/m^2 \cdot sr$$ <

The intensities at points P_1 and P_2 are also $I_{o,e}$ and the intensity in the directions shown in the schematic above will remain constant no matter how far the point is from the surface ΔA_o since the space is non-participating.

(c) From knowledge of $I_{o,e}$, the radiant power leaving ΔA_o from Eq. 12.13 is,

$$q_{emit} = \int_h I_{o,e} \Delta A_o \cos\theta \sin\theta d\theta d\phi = I_{o,e} \Delta A_o \int_{\phi=0}^{2\pi} \int_{\theta=0}^{\pi/2} \cos\theta \sin\theta d\theta d\phi = \pi I_{o,e} \Delta A_o = 0.10\ W$$ <

(d) Defining control surfaces above ΔA_o and on A_1, the radiant power leaving ΔA_o must pass through A_1. That is,

$$q_{1,inc} = E_o \Delta A_o = 0.10\ W$$ <

Recognize that the average irradiation on the hemisphere, A_1, where $A_1 = 2\pi R_1^2$, based upon the definition, Section 12.3.3,

$$\bar{G}_1 = q_{1,inc} / A_1 = E_o \Delta A_o / 2\pi R_1^2 = 63.7\ mW/m^2$$

where $q_{1,inc}$ is the radiant power incident on surface A_1.

Continued...

PROBLEM 12.17 (Cont.)

(e) The radiant power leaving ΔA_o intercepted by ΔA_2, where $\Delta A_2 = 4\times10^{-6}$ m^2, located at ($\theta = 45^o$, ϕ) as per the schematic, follows from Eq. 12.10,

$$q_{\Delta A_o \to \Delta A_2} = I_{o,e}\Delta A_o \cos\theta_o \Delta\omega_{2-o}$$

where $\theta_o = 45^o$ and the solid angle ΔA_2 subtends with respect to ΔA_o is

$$\Delta\omega_{2-o} = \Delta A_2 \cos\theta_2 \Big/ R_1^2 = 4\times10^{-6}\,m^2 \cdot 1\Big/(0.5m)^2 = 1.60\times10^{-5}\,sr$$

where $\theta_2 = 0^o$, the direction normal to ΔA_2,

$$q_{\Delta A_o \to \Delta A_2} = 1273\,W\Big/m^2 \cdot sr \times 25\times10^{-6}\,m^2 \cos 45^o \times 1.60\times10^{-5}\,sr = 3.60\times10^{-7}\ W \qquad <$$

From the definition of irradiation, Section 12.3.3,

$$G_2 = q_{\Delta A_o \to \Delta A_2}\Big/\Delta A_2 = 90\,mW\Big/m^2$$

(f) With ΔA_2, located at ($\theta = 0^o$, ϕ), where $\cos\theta_o = 1$, $\cos\theta_2 = 1$, find

$$\Delta\omega_{2-o} = 1.60\times10^{-5}\,sr \qquad q_{\Delta A_o \to \Delta A_2} = 5.09\times10^{-7}\ W \qquad G_2 = 127\,mW\Big/m^2 \qquad <$$

Note that the irradiation on ΔA_2 when it is located at (0^o, ϕ) is larger than when ΔA_2 is located at (45^o, ϕ); that is, 127 mW/m^2 > 90 W/m^2. Is this intuitively satisfying?

(g) Using Eq. 12.18, based upon Figure 12.10, find

$$\bar{G}_1 = \int_h I_{1,i} dA_1 \cdot d\omega_{0-1}\big/A_1 = \pi I_{o,e}\,\Delta A_o\big/\Delta A_1 = 63.7\,mW\Big/m^2 \qquad <$$

where the elemental area on the hemispherical surface A_1 and the solid angle ΔA_o subtends with respect to ΔA_1 are, respectively,

$$dA_1 = R_1^2 \sin\theta\, d\theta\, d\phi \qquad\qquad d\omega_{o-1} = \Delta A_o \cos\theta\Big/R_1^2$$

From this calculation you found that the *average* irradiation on the hemisphere surface, $r = R_1$, is $\bar{G}_1 = 63.7\,mW\Big/m^2$. From parts (e) and (f), you found irradiations, G_2 on ΔA_2 at (0^o, ϕ) and (45^o, ϕ) as 127 mW/m^2 and 90 mW/m^2, respectively. Did you expect $\bar{G}_1$ to be less than either value for G_2? How do you explain this?

COMMENTS: (1) Note that from Parts (e) and (f) that the irradiation on A_1 is not uniform. Parts (d) and (g) give an average value.

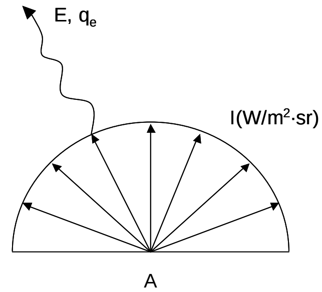
(2) What conclusions would you reach regarding G_1 if ΔA_o were a sphere?

PROBLEM 12.18

KNOWN: Intensities of radiating various surfaces of known areas.

FIND: Surface temperature and emitted energy assuming blackbody behavior.

SCHEMATIC:



ANALYSIS: For blackbody emission, $T = \left(\frac{E}{\sigma}\right)^{1/4}$ and $E = \pi I$. Therefore,

$$T = \left(\frac{\pi I_e}{\sigma}\right)^{1/4} \quad ; \quad q_e = AE = A\pi I_e \qquad (1,2)$$

Equations (1) and (2) may be used to find T and q_e as follows. <

Problem	I_e (W/m²·sr)	A(m²)	T(K)	q_e(W)
Example 12.1	7000	10^{-3}	789	22
Problem 12.8	1.2×10^5	10^{-4}	1606	37.7
Problem 12.12	169,000	0.0052	1750	2761
Problem 12.14	1000	2×10^{-4}	485	0.628

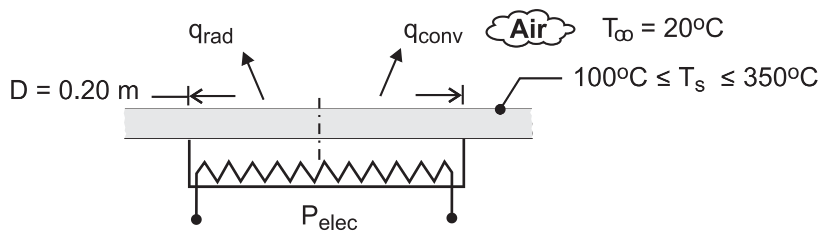
COMMENTS: If the surface is not black, the intensity leaving the surface will include a reflected component.

PROBLEM 12.19

KNOWN: Diameter and temperature of burner. Temperature of ambient air. Burner efficiency.

FIND: (a) Radiation and convection heat rates, and wavelength corresponding to maximum spectral emission. Rate of electric energy consumption. (b) Effect of burner temperature on convection and radiation rates.

SCHEMATIC:



ASSUMPTIONS: (1) Burner emits as a blackbody, (2) Negligible irradiation of burner from surrounding, (3) Ambient air is quiescent, (4) Constant properties.

PROPERTIES: *Table A-4*, air (T_f = 408 K): k = 0.0344 W/m·K, $\nu = 27.4 \times 10^{-6}$ m^2/s, $\alpha = 39.7 \times 10^{-6}$ m^2/s, Pr = 0.70, $\beta = 0.00245$ K^{-1}.

ANALYSIS: (a) For emission from a blackbody

$$q_{rad} = A_s\ E_b = \left(\pi D^2/4\right)\sigma T^4 = \left[\pi\left(0.2\text{m}\right)^2/4\right]5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4\left(523\,\text{K}\right)^4 = 133\ \text{W} \qquad <$$

With L = A_s/P = D/4 = 0.05m and $Ra_L = g\beta(T_s - T_\infty)\,L^3/\alpha\nu$ = 9.8 m/s^2 × 0.00245 K^{-1} (230 K) (0.05m)^3/(27.4 × 39.7 × 10^{-12} m^4/s^2) = 6.35 × 10^5, Eq. 9.30 yields

$$\bar{h} = \frac{k}{L}\overline{Nu}_L = \left(\frac{k}{L}\right)0.54\ Ra_L^{1/4} = \left(\frac{0.0344\ \text{W/m}\cdot\text{K}}{0.05\text{m}}\right)0.54\left(6.35\times10^5\right)^{1/4} = 10.5\ \text{W/m}^2\cdot\text{K}$$

$$q_{conv} = \bar{h}\,A_s\left(T_s - T_\infty\right) = 10.5\ \text{W/m}^2\cdot\text{K}\left[\pi\left(0.2\text{m}\right)^2/4\right]230\,\text{K} = 75.7\ \text{W} \qquad <$$

The electric power requirement is then

$$P_{elec} = \frac{q_{rad} + q_{conv}}{\eta} = \frac{\left(133 + 75.7\right)\text{W}}{0.9} = 232\ \text{W} \qquad <$$

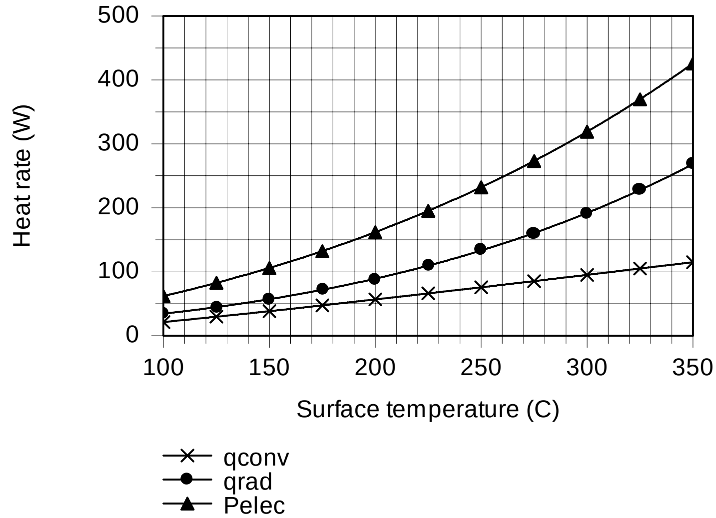
The wavelength corresponding to peak emission is obtained from Wien's displacement law, Eq. 12.31

$$\lambda_{max} = 2898\mu\text{m}\cdot\text{K}/523\text{K} = 5.54\mu\text{m} \qquad <$$

(b) As shown below, and as expected, the radiation rate increases more rapidly with temperature than the convection rate due to its stronger temperature dependence $\left(T_s^4\ \text{vs.}\ T_s^{5/4}\right)$.

Continued …

PROBLEM 12.19 (Cont.)



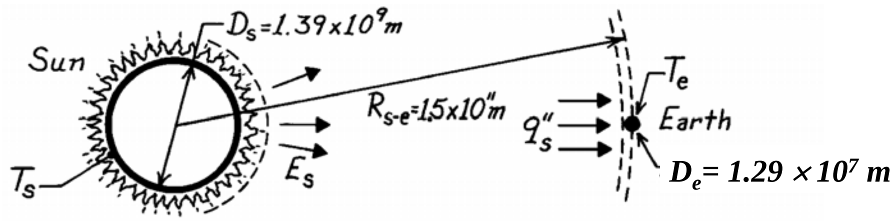
COMMENTS: If the surroundings are treated as a large enclosure with isothermal walls at $T_{sur} = T_\infty$ = 293 K, irradiation of the burner would be $G = \sigma T_{sur}^4 = 418\ W/m^2$ and the corresponding heat rate would be $A_s G = 13$ W. This input is much smaller than the energy outflows due to convection and radiation and is justifiably neglected.

PROBLEM 12.20

KNOWN: Solar flux at outer edge of earth's atmosphere, 1368 W/m^2.

FIND: (a) Emissive power of sun, (b) Surface temperature of sun, (c) Wavelength of maximum solar emission, (d) Earth equilibrium temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Sun and earth emit as blackbodies, (2) No attenuation of solar radiation enroute to earth, (3) Earth atmosphere has no effect on earth energy balance.

ANALYSIS: (a) Applying conservation of energy to the solar energy crossing two concentric spheres, one having the radius of the sun and the other having the radial distance from the edge of the earth's atmosphere to the center of the sun

$$E_s\left(\pi D_s^2\right) = 4\pi\left(R_{s-e} - \frac{D_e}{2}\right)^2 q''s.$$

Hence

$$E_s = \frac{4\left(1.5\times10^{11}\,\text{m} - 0.65\times10^{7}\,\text{m}\right)^2 \times 1368\ \text{W/m}^2}{\left(1.39\times10^{9}\,\text{m}\right)^2} = 6.37\times10^{7}\ \text{W/m}^2. \qquad <$$

(b) From Eq. 12.32, the temperature of the sun is

$$T_s = \left(\frac{E_s}{\sigma}\right)^{1/4} = \left(\frac{6.37\times10^{7}\ \text{W/m}^2}{5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4}\right)^{1/4} = 5790\ \text{K}. \qquad <$$

(c) From Wien's displacement law, Eq. 12.25, the wavelength of maximum emission is

$$\lambda_{max} = \frac{C_3}{T} = \frac{2898\,\mu\text{m}\cdot\text{K}}{5790\ \text{K}} = 0.50\ \mu\text{m}.$$

(d) From an energy balance on the earth's surface

$$E_e\left(\pi D_e^2\right) = q''_S\left(\pi D_e^2/4\right).$$

Hence, from Eq. 12.26,

$$T_e = \left(\frac{q''_S}{4\sigma}\right)^{1/4} = \left(\frac{1368\ \text{W/m}^2}{4\times5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4}\right)^{1/4} = 279\ \text{K}. \qquad <$$

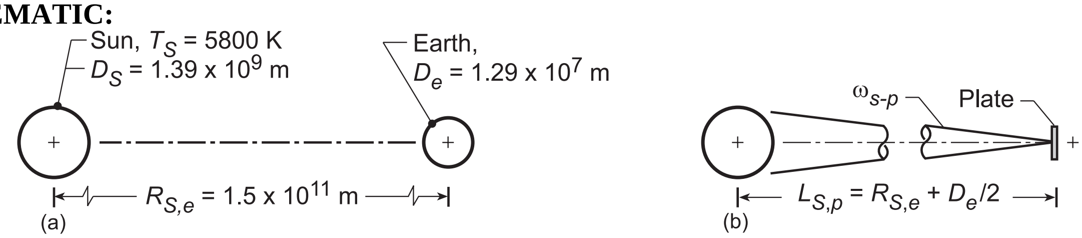
COMMENTS: The average earth temperature is higher than 279 K due to the shielding effect of the earth's atmosphere (transparent to solar radiation but not to longer wavelength earth emission).

PROBLEM 12.21

KNOWN: Small flat plate positioned just beyond the earth's atmosphere oriented such that its normal passes through the center of the sun. Pertinent earth-sun dimensions from Problem 12.20.

FIND: (a) Solid angle subtended by the sun about a point on the surface of the plate, (b) Incident intensity, I_i, on the plate using the known value of the solar irradiation about the earth's atmosphere, $G_S = 1368\ W/m^2$, and (c) Sketch of the incident intensity as a function of the zenith angle θ, where θ is measured from the normal to the plate.

SCHEMATIC:



ASSUMPTIONS: (1) Plate oriented normal to centerline between sun and earth, (2) Height of earth's atmosphere negligible compared to distance from the sun to the plate, (3) Dimensions of the plate are very small compared to sun-earth dimensions.

ANALYSIS: (a) The pertinent sun-earth dimensions are shown in the schematic (a) above while the position of the plate relative to the sun and the earth is shown in (b). The solid angle subtended by the sun with respect to any point on the plate follows from Eq. 12.7,

$$\omega_{S-p} = \frac{A_S \cos\theta_p}{L_{S,p}^2} = \frac{\left(\pi D_S^2/4\right)\cos\theta_p}{\left(R_{S,e}\right)^2} = \frac{\pi\left(1.39\times10^9\,m\right)^2/4\times1}{\left(1.5\times10^{11}m\right)^2} = 6.74\times10^{-5}sr \qquad (1) \quad <$$

where A_S is the projected area of the sun (the solar disk), θ_p is the zenith angle measured between the plate normal and the centerline between the sun and earth, and $L_{S,p}$ is the separation distance between the plate at the sun's center.

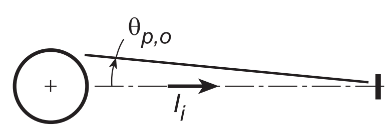
(b) The plate is irradiated by solar flux in the normal direction only (not diffusely). Using Eq. 12.18, the radiant power incident on the plate can be expressed as

$$G_S \Delta A_p = I_i \cdot \Delta A_p \cos\theta_p \cdot \omega_{S-p} \qquad (2)$$

and the intensity I_i due to the solar irradiation G_S with $\cos\theta_p = 1$,

$$I_i = G_S/\omega_{S-p} = 1368\,W/m^2/6.74\times10^{-5}\,sr = 2.03\times10^7\ W/m^2\cdot sr \quad <$$

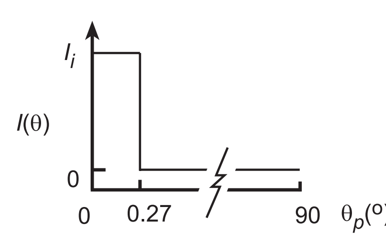
(c) As illustrated in the schematic to the right, the intensity I_i will be constant for the zenith angle range $0 \le \theta_p \le \theta_{p,o}$ where



$$\theta_{p,o} = \frac{D_S/2}{L_{S,p}} = \frac{1.39\times10^9\,m/2}{1.5\times10^{11}m}$$

$$\theta_{p,o} = 4.633\times10^{-3}rad \approx 0.27^\circ$$

For the range $\theta_p > \theta_{p,o}$, the intensity will be zero. Hence the I_i as a function of θ_p will appear as shown to the right.

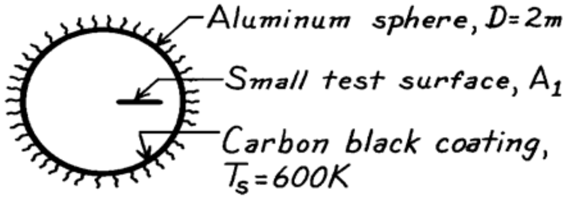


PROBLEM 12.22

KNOWN: Evacuated, aluminum sphere (D = 2m) serving as a radiation test chamber.

FIND: Irradiation on a small test object when the inner surface is lined with carbon black and at 600K. What effect will surface coating have?

SCHEMATIC:



ASSUMPTIONS: (1) Sphere walls are isothermal, (2) Test surface area is small compared to the enclosure surface.

ANALYSIS: It follows from the discussion of Section 12.4 that this isothermal sphere is an enclosure behaving as a blackbody. For such a condition, see Fig. 12.11(c), the irradiation on a small surface within the enclosure is equal to the blackbody emissive power at the temperature of the enclosure. That is

$$G_1 = E_b\left(T_s\right) = \sigma T_s^4$$

$$G_1 = 5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left(600\text{K}\right)^4 = 7348\,\text{W/m}^2. \qquad <$$

The irradiation is independent of the nature of the enclosure surface coating properties.

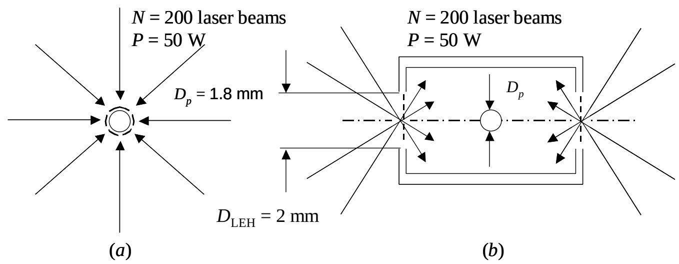
COMMENTS: (1) The irradiation depends only upon the enclosure surface temperature and is independent of the enclosure surface properties. (2) Note that the test surface area must be small compared to the enclosure surface area. This allows for inter-reflections to occur such that the radiation field, within the enclosure will be uniform (diffuse) or isotropic. (3) The irradiation level would be the same if the enclosure were not evacuated since, in general, air would be a non-participating medium.

PROBLEM 12.23

KNOWN: Diameter of spherical fuel pellet. Pellet emissivity and absorptivity. Laser power and number of lasers. Laser entrance hole diameters.

FIND: (a) Maximum fuel temperature for direct laser irradiation. (b) Maximum fuel temperature for irradiation using the enclosure.

SCHEMATIC:



ASSUMPTIONS: (1) Steady state conditions. (2) Negligible irradiation from surroundings. (3) Uniform temperature inside enclosure. (4) Enclosure behaves as a blackbody. (5) Negligible heat loss through enclosure walls.

PROPERTIES: Given: $\varepsilon = 0.8$, $\alpha = 0.3$.

ANALYSIS:

(a) An energy balance on the spherical pellet yields

$$\dot{E}_{in} = \dot{E}_{out} = \alpha NP = \left(\pi D_p^2\right)\varepsilon\sigma T_p^4$$

or

$$T_p = \left(\frac{\alpha NP}{\varepsilon\sigma\pi D_p^2}\right)^{1/4} = \left(\frac{0.3\times 200\times 500\ \text{W}}{0.8\times 5.67\times 10^{-8}\ \text{W/m}^2\text{K}^4\times\pi\times(1.8\times 10^{-3}\ \text{m})^2}\right)^{1/4} = 15{,}970\ \text{K}$$ <

(b) An energy balance on the enclosure yields

$$\dot{E}_{in} = \dot{E}_{out} = NP = 2\left(\pi D_{\text{LEH}}^2/4\right)\sigma T_e^4$$

or

$$T_e = \left(\frac{2NP}{\sigma\pi D_{\text{LEH}}^2}\right)^{1/4} = \left(\frac{2\times 200\times 500\ \text{W}}{5.67\times 10^{-8}\ \text{W/m}^2\text{K}^4\times\pi\times(2.0\times 10^{-3}\ \text{m})^2}\right)^{1/4} = 23{,}020\ \text{K}$$

Since the enclosure temperature is assumed to be uniform, $T_p = T_e = 23{,}020$ K <

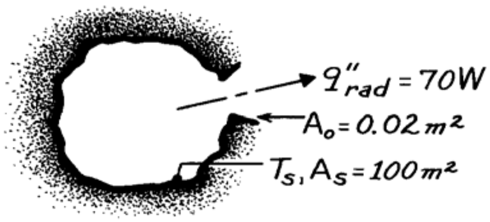
COMMENTS: (1) The temperature of the pellet is increased by 44% by placing it in the enclosure. (2) The actual maximum temperature of the pellet in the enclosure can be much less than calculated if the area of the laser entrance holes is not small relative to the interior area of the enclosure. (3) The temperatures are extremely high, as required. (4) This problem is motivated by the U.S. National Ignition Facility at the Lawrence Livermore National Laboratory. The lasers used to heat the 1.8 mm diameter pellet occupy a facility that is 10 stories tall with a footprint the size of three football fields.

PROBLEM 12.24

KNOWN: Isothermal enclosure of surface area, A_s, and small opening, A_o, through which 70W emerges.

FIND: (a) Temperature of the interior enclosure wall if the surface is black, (b) Temperature of the wall surface having $\varepsilon = 0.15$.

SCHEMATIC:



ASSUMPTIONS: (1) Enclosure is isothermal, (2) $A_o \ll A_s$.

ANALYSIS: A characteristic of an isothermal enclosure, according to Section 12.4, is that the radiant power emerging through a small aperture will correspond to blackbody conditions. Hence

$$q_{rad} = A_o E_b(T_s) = A_o \sigma T_s^4$$

where q_{rad} is the radiant power leaving the enclosure opening. That is,

$$T_s = \left(\frac{q_{rad}}{A_o \sigma}\right)^{1/4} = \left(\frac{70W}{0.02m^2 \times 5.670 \times 10^{-8} W/m^2 \cdot K^4}\right)^{1/4} = 498K. \quad <$$

Recognize that the radiated power will be independent of the emissivity of the wall surface. As long as $A_o \ll A_s$ *and* the enclosure is isothermal, then the radiant power will depend only upon the temperature.

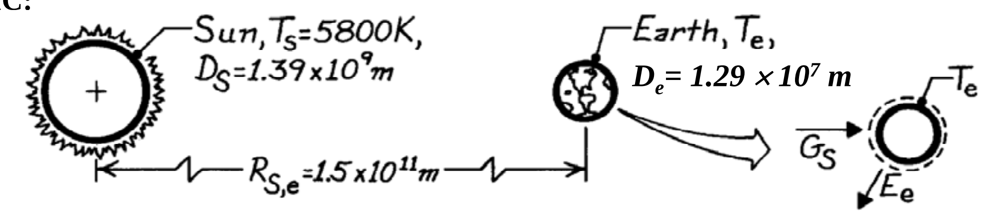
COMMENTS: It is important to recognize the unique characteristics of isothermal enclosures. See Fig. 12.11 to identify them.

PROBLEM 12.25

KNOWN: Sun has equivalent blackbody temperature of 5800 K. Diameters of sun and earth as well as separation distance are prescribed.

FIND: Temperature of the earth assuming the earth is black.

SCHEMATIC:



ASSUMPTIONS: (1) Sun and earth emit as blackbodies, (2) No attenuation of solar irradiation enroute to earth, and (3) Earth atmosphere has no effect on earth energy balance.

ANALYSIS: Performing an energy balance on the earth,

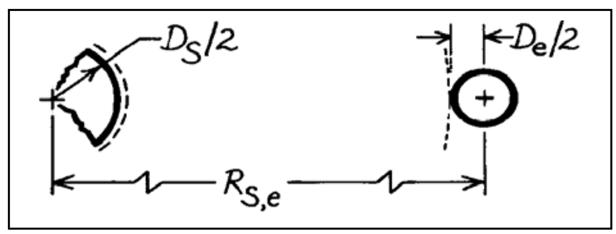
$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$A_{e,p} \cdot G_S = A_{e,s} \cdot E_b(T_e)$$

$$\left(\pi D_e^2 / 4\right) G_S = \pi D_e^2 \sigma T_e^4$$

$$T_e = \left(G_S / 4\sigma\right)^{1/4}$$

where $A_{e,p}$ and $A_{e,s}$ are the projected area and total surface area of the earth, respectively. To determine the irradiation G_S at the earth's surface, equate the rate of emission from the sun to the rate at which this radiation passes through a spherical surface of radius $R_{S,e} - D_e/2$.



$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$\pi D_S^2 \cdot \sigma T_S^4 = 4\pi\left[R_{S,e} - D_e/2\right]^2 G_S$$

$$\pi\left(1.39\times10^9\text{ m}\right)^2 \times 5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4\left(5800\text{ K}\right)^4$$

$$= 4\pi\left[1.5\times10^{11} - 1.27\times10^7/2\right]^2\text{ m}^2 \times G_S$$

$$G_S = 1377.5\text{ W/m}^2.$$

Substituting numerical values, find

$$T_e = \left(1377.5\text{ W/m}^2 / 4\times5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4\right)^{1/4} = 279\text{ K.}$$ <

COMMENTS: (1) The average earth's temperature is greater than 279 K since the effect of the atmosphere is to reduce the heat loss by radiation.

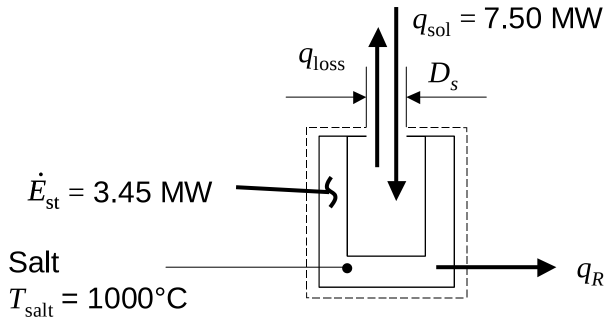
(2) Note carefully the different areas used in the earth energy balance. Emission occurs from the total spherical area, while solar irradiation is absorbed by the projected spherical area.

PROBLEM 12.26

KNOWN: Solar power concentrated into cavity, energy storage rate for salt, salt temperature, cavity opening diameter.

FIND: Thermal energy delivered to the Rankine cycle.

SCHEMATIC:



ASSUMPTIONS: (1) Temperatures are not changing with time. (2) Negligible irradiation from surroundings and convective losses. (3) Cavity opening area is small relative to cavity surface area.

ANALYSIS:

(a) An energy balance on the control volume shown in the schematic yields

$$q_R = q_{\text{sol}} - \dot{E}_{st} - q_{\text{loss}}$$

where the heat loss through the cavity opening is

$$q_{\text{loss}} = \frac{\pi D_s^2}{4}\sigma T_{\text{salt}}^4 = \frac{\pi(1\text{ m})^2}{4} \times 5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4 \times (1000+273\text{ K})^4 = 117,000\text{ W} = 0.12\text{ MW}$$

Hence the heat transfer to the Rankine cycle is

$$q_R = 7.50 - 3.45 - 0.12 = 3.93\text{ MW}$$ <

COMMENTS: (1) The radiation heat loss through the cavity opening is relatively small, but could be reduced further by decreasing the size of the cavity opening. Reducing the size of the opening would require more expensive heliostats and mirrors in order to more precisely direct the concentrated solar irradiation into the cavity. (2) Convection losses through the cavity opening may be large, necessitating placement of a radiatively-transparent window over the cavity opening.

PROBLEM 12.27

KNOWN: Spectral distribution of the emissive power given by Planck's distribution.

FIND: Approximations to the Planck distribution for the extreme cases when (a) $C_2/\lambda T >> 1$, Wien's law and (b) $C_2/\lambda T << 1$, Rayleigh-Jeans law.

ANALYSIS: Planck's distribution provides the spectral, hemispherical emissive power of a blackbody as a function of wavelength and temperature, Eq. 12.30,

$$E_{\lambda,b}(\lambda,T) = C_1/\lambda^5\left[\exp(C_2/\lambda T)-1\right].$$

We now consider the extreme cases of $C_2/\lambda T >> 1$ and $C_2/\lambda T << 1$.

(a) When $C_2/\lambda T >> 1$ (or $\lambda T << C_2$), it follows $\exp(C_2/\lambda T) >> 1$. Hence, the –1 term in the denominator of the Planck distribution is insignificant, giving

$$E_{\lambda,b}(\lambda,T) \approx \left(C_1/\lambda^5\right)\exp(-C_2/\lambda T). \quad <$$

This approximate relation is known as *Wien's law*. The ratio of the emissive power by Wien's law to that by the Planck law is,

$$\frac{E_{\lambda,b,Wien}}{E_{\lambda,b,Planck}} = \frac{1/\exp(C_2/\lambda T)}{1/\left[\exp(C_2/\lambda T)-1\right]}.$$

For the condition $\lambda T = \lambda_{max} T = 2898\ \mu m\cdot K$, $C_2/\lambda T = \dfrac{14388\ \mu m\cdot K}{2898\ \mu m\cdot K} = 4.966$ and

$$\frac{E_{\lambda,b}\big|_{Wien}}{E_{\lambda,b}\big|_{Planck}} = \frac{1/\exp(4.966)}{1/\left[\exp(4.966)-1\right]} = 0.9930. \quad <$$

That is, for $\lambda T \le 2898\ \mu m\cdot K$, Wien's law is a good approximation to the Planck distribution.

(b) If $C_2/\lambda T << 1$ (or $\lambda T >> C_2$), the exponential term may be expressed as a series that can be approximated by the first two terms. That is,

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \ldots \approx 1 + x \qquad \text{when} \qquad x << 1.$$

The *Rayleigh-Jeans* approximation is then

$$E_{\lambda,b}(\lambda,T) \approx C_1/\lambda^5\left[1+(C_2/\lambda T)-1\right] = C_1 T/C_2\lambda^4.$$

For the condition $\lambda T = 100{,}000\ \mu m\cdot K$, $C_2/\lambda T = 0.1439$

$$\frac{E_{\lambda,b,R-J}}{E_{\lambda,b,Planck}} = \frac{C_1 T/C_2\lambda^4}{C_1/\lambda^5}\left[\exp(C_2/\lambda T)-1\right]^{-1} = (\lambda T/C_2)\left[\exp(C_2/\lambda T)-1\right] = 1.0754. \quad <$$

That is, for $\lambda T \ge 100{,}000\ \mu m\cdot K$, the Rayleigh-Jeans law is a good approximation (better than 10%) to the Planck distribution.

COMMENTS: Wien's law is used extensively in optical pyrometry for values of λ near 0.65 μm and temperatures above 700 K. The Rayleigh-Jeans law is of limited use in heat transfer but of utility for far infrared applications.

PROBLEM 12.28

KNOWN: Various surface temperatures.

FIND: (a) Wavelength corresponding to maximum emission for each surface, (b) Fraction of solar emission in UV, VIS and IR portions of the spectrum.

ASSUMPTIONS: (1) Spectral distribution of emission from each surface is approximately that of a blackbody, (2) The sun emits as a blackbody at 5800 K.

ANALYSIS: (a) From Wien's displacement law, Eq. 12.31, the wavelength of maximum emission for blackbody radiation is

$$\lambda_{max} = \frac{C_3}{T} = \frac{2898\ \mu m \cdot K}{T}.$$

For the prescribed surfaces

Surface	Sun (5800K)	Tungsten (2500K)	Hot metal (1500K)	Skin (305K)	Cool metal (60K)	
$\lambda_{max}(\mu m)$	0.50	1.16	1.93	9.50	48.3	<

(b) From Fig. 12.3, the spectral regions associated with each portion of the spectrum are

Spectrum	Wavelength limits, μm
UV	0.01 – 0.4
VIS	0.4 – 0.7
IR	0.7 - 100

For T = 5800K and each of the wavelength limits, from Table 12.1 find:

$\lambda(\mu m)$	10^{-2}	0.4	0.7	10^{2}
$\lambda T(\mu m \cdot K)$	58	2320	4060	5.8×10^{5}
$F_{(0 \to \lambda)}$	0	0.125	0.491	1

Hence, the fraction of the solar emission in each portion of the spectrum is:

$F_{UV} = 0.125 – 0 = 0.125$ <

$F_{VIS} = 0.491 – 0.125 = 0.366$ <

$F_{IR} = 1 – 0.491 = 0.509.$ <

COMMENTS: (1) Spectral concentration of surface radiation depends strongly on surface temperature. (2) Much of the UV solar radiation is absorbed in the earth's atmosphere.

PROBLEM 12.29

KNOWN: Thermal imagers operating in the spectral regions 3 to 5 μm and 8 to 14 μm.

FIND: (a) Band-emission factors for each of the spectral regions, 3 to 5 μm and 8 to 14 μm, for temperatures of 300 and 900 K, (b) Calculate and plot the band-emission factors for each of the spectral regions for the temperature range 300 to 1000 K; identify the maxima, and draw conclusions concerning the choice of an imager for an application; and (c) Considering imagers operating at the maximum-fraction temperatures found from the graph of part (b), determine the sensitivity (%) required of the radiation detector to provide a noise-equivalent temperature (NET) of 5°C.

ASSUMPTIONS: The sensitivity of the imager's radiation detector within the operating spectral region is uniform.

ANALYSIS: (a) From Eqs. 12.34 and 12.35, the band-emission fraction F(λ1 → λ2, T) for blackbody emission in the spectral range λ_1 to λ_2 for a temperature T is

$$F_{(\lambda 1 \to \lambda 2,\ T)} = F_{(0 \to \lambda 2,\ T)} - F_{(0 \to \lambda 1,\ T)}$$

Using the *IHT Radiation | Band Emission* tool (or Table 12.1), evaluate $F_{(0-\lambda T)}$ at appropriate λ·T products:

3 to 5 μm region

$$F_{(\lambda 1-\lambda 2,\ 300\ K)} = 0.1375 - 0.00017 = 0.01373 \quad <$$

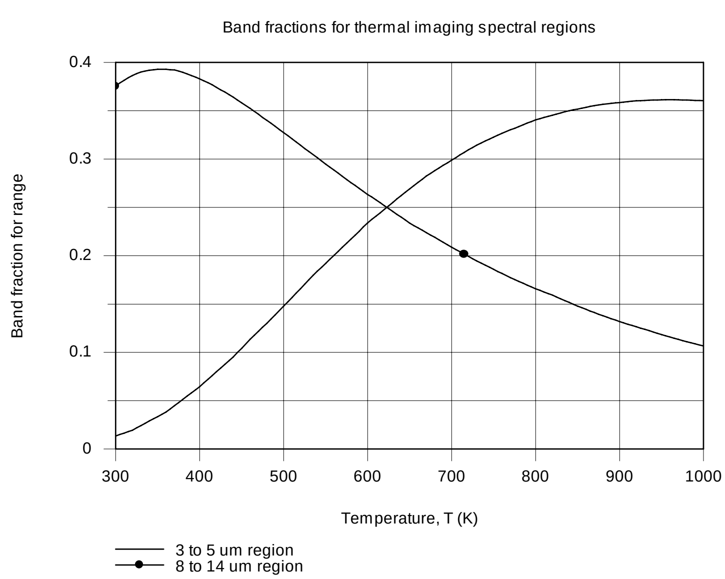
$$F_{(\lambda 1-\lambda 2,\ 900\ K)} = 0.5640 - 0.2055 = 0.3585 \quad <$$

8 to 14μm region

$$F_{(\lambda 1-\lambda 2,\ 300\ K)} = 0.5160 - 0.1403 = 0.3757 \quad <$$

$$F_{(\lambda 1-\lambda 2,\ 900\ K)} = 0.9511 - 0.8192 = 0.1319 \quad <$$

(b) Using the *IHT Radiation | Band Emission* tool, the band-emission fractions for each of the spectral regions is calculated and plotted below as a function of temperature.



Continued …

PROBLEM 12.29 (Cont.)

For the 3 to 5 μm imager, the band-emission factor increases with increasing temperature. For low temperature applications, not only is the radiant power $\left(\sigma T^4,\ T \approx 300\ K\right)$ low, but the band fraction is small. However, for high temperature applications, the imager operating conditions are more favorable with a large band-emission factor, as well as much higher radiant power $\left(\sigma T^4,\ T \to 900\ K\right)$.

For the 8 to 14 μm imager, the band-emission factor decreases with increasing temperature. This is a more favorable instrumentation feature, since the band-emission factor (proportionally more power) becomes larger as the radiant power decreases. This imager would be preferred over the 3 to 5 μm imager at lower temperatures since the band-emission factor is 8 to 10 times higher.

Recognizing that from Wien's displacement law, the peaks of the blackbody curves for 300 and 900 K are approximately 10 and 3.3 μm, respectively, it follows that the imagers will receive the most radiant power when the peak target spectral distributions are close to the operating spectral region. It is good application practice to chose an imager having a spectral operating range close to the peak of the blackbody curve (or shorter than, if possible) corresponding to the target temperature.

The maxima band fractions for the 3 to 5 μm and 8 to 14 μm spectral regions correspond to temperatures of 960 and 355 K, respectively. Other application factors not considered (like smoke, water vapor, etc), the former imager is better suited with higher temperature scenes, and the latter with lower temperature scenes.

(c) Consider the 3 to 5 μm and 8 to 14 μm imagers operating at their band-emission peak temperatures, 355 and 960 K, respectively. The sensitivity S (% units) of the imager to resolve an NET of 5°C can be expressed as

$$S(\%) = \frac{F(\lambda 1 - \lambda 2,\ T1) - F(\lambda 1 - \lambda 2,\ T2)}{F(\lambda 1 - \lambda 2,\ T1)} \times 100$$

where T_1 = 355 or 960 K and T_2 = 360 or 965 K, respectively. Using this relation in the *IHT* workspace, find

$$S_{3-5} = 0.035\% \qquad\qquad S_{8-14} = 0.023\% \qquad <$$

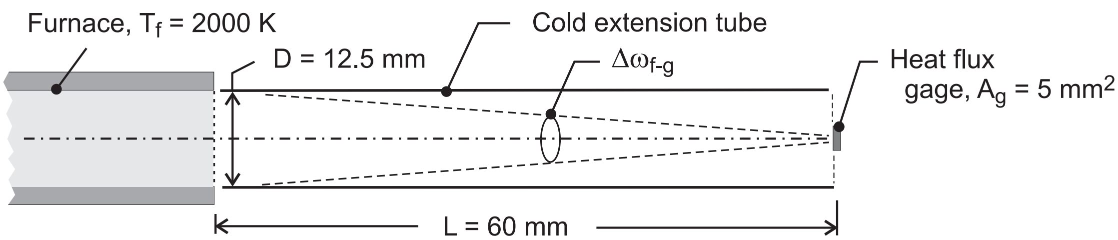
That is, we require the radiation detector (with its signal-processing system) to resolve the output signal with the foregoing precision in order to indicate a 5°C change in the scene temperature.

PROBLEM 12.30

KNOWN: Tube furnace maintained at T_f = 2000 K used to calibrate a heat flux gage of sensitive area 5 mm^2 mounted coaxial with the furnace centerline, and positioned 60 mm from the opening of the furnace.

FIND: (a) Heat flux (kW/m^2) on the gage, (b) Radiant flux in the spectral region 0.4 to 2.5 μm, the sensitive spectral region of a solid-state (photoconductive type) heat-flux gage, and (c) Calculate and plot the heat fluxes for each of the gages as a function of the furnace temperature for the range 2000 ≤ T_f ≤ 3000 K. Compare the values for the two types of gages; explain why the solid-state gage will always indicate systematically low values; does the solid-state gage performance improve, or become worse as the source temperature increases?

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Graphite tube furnace behaves as a blackbody, (3) Areas of gage and furnace opening are small relative to separation distance squared, and (4) Extension tube is cold relative to the furnace.

ANALYSIS: (a) The heat flux to the gage is equal to the irradiation, G_g, on the gage and can be expressed as (see Section 12.3.3)

$$G_g = I_f \cdot \cos\theta_g \cdot \Delta\omega_{f-g}$$

where $\Delta\omega_{f-g}$ is the solid angle that the furnace opening subtends relative to the gage. From Eq. 12.7, with $\theta_g = 0°$

$$\Delta\omega_{f-g} \equiv \frac{dA_n}{r^2} = \frac{A_f \cos\theta_g}{L^2} = \frac{\pi(0.0125\text{ m})^2/4\times 1}{(0.060\text{ m})^2} = 3.409\times 10^{-2}\text{ sr}$$

The intensity of the radiation from the furnace is

$$I_f = E_{b,f}(T_f)/\pi = \sigma T_f^4/\pi = 5.67\times 10^{-8}\text{ W/m}^2\cdot\text{K}^4\,(2000\text{ K})^4/\pi = 2.888\times 10^5\text{ W/m}^2\cdot\text{sr}$$

Substituting numerical values,

$$G_g = 2.888\times 10^5\text{ W/m}^2\cdot\text{sr}\times 1\times 3.409\times 10^{-2}\text{ sr} = 9.84\text{ kW/m}^2$$ <

(b) The solid-state detector gage, sensitive only in the spectral region λ_1 = 0.4 μm to λ_2 = 2.5 μm, will receive the band irradiation.

$$G_{g,\lambda 1-\lambda 2} = F_{(\lambda 1\rightarrow\lambda 2,\,Tf)}\cdot G_{g,b} = \left[F_{(0\rightarrow\lambda 2,\,Tf)} - F_{(0\rightarrow\lambda 1,\,Tf)}\right] G_{g,b}$$

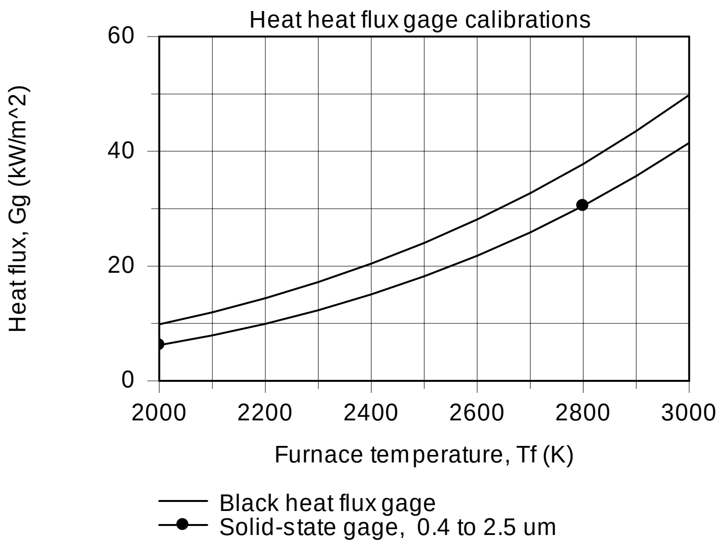
Continued …

PROBLEM 12.30 (Cont.)

where for $\lambda_1 T_f$ = 0.4 μm × 2000 K = 800 μm·K, $F_{(0 - \lambda 1)}$ = 0.0000 and for $\lambda_2 \cdot T_f$ = 2.5 μm × 2000 K = 5000 μm·K, $F_{(0 - \lambda 2)}$ = 0.6337. Hence,

$$G_{g,\lambda 1-\lambda 2} = [0.6337 - 0.0000] \times 9.84 \text{ kW/m}^2 = 6.24 \text{ kW/m}^2 \quad <$$

(c) Using the foregoing equation in the *IHT* workspace, the heat fluxes for each of the gage types are calculated and plotted as a function of the furnace temperature.



For the black gage, the irradiation received by the gage, G_g, increases as the fourth power of the furnace temperature. For the solid-state gage, the irradiation increases slightly greater than the fourth power of the furnace temperature since the band-emission factor for the spectral region, $F_{(\lambda 1 - \lambda 2, Tf)}$, increases with increasing temperature. The solid-state gage will always indicate systematic low readings since its band-emission factor never approaches unity. However, the error will decrease with increasing temperature as a consequence of the corresponding increase in the band-emission factor.

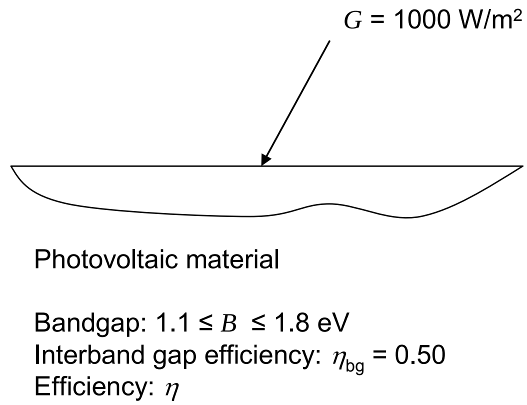
COMMENTS: For this furnace-gage geometrical arrangement, evaluating the solid angle, $\Delta\omega_{f - g}$, and the areas on a differential basis leads to results that are systematically high by 1%. Using the view factor concept introduced in Chapter 13, the results for the black and solid-state gages are 9.74 and 6.17 kW/m^2, respectively.

PROBLEM 12.31

KNOWN: Bandgap of photovoltaic material. Relationship between wavelength and energy state of photon. Inter-band gap efficiency. Half of incident photons not converted to electricity are absorbed as thermal energy. Solar irradiation and associated blackbody temperature.

FIND: Wavelengths of solar irradiation corresponding to material's band gap. Overall efficiency. Heat absorption per unit surface area.

SCHEMATIC:



ASSUMPTIONS: Wavelength distribution of solar irradiation corresponds to a blackbody at 5800 K.

ANALYSIS: The lower boundary of the band-gap, B = 1.1 eV, corresponds to a wavelength of

$$\lambda_2 = \frac{1240 \text{ eV} \cdot \text{nm}}{B} = \frac{1240 \text{ eV} \cdot \text{nm}}{1.1 \text{ eV}} = 1127 \text{ nm} = 1.127 \ \mu\text{m}$$

Similarly, the upper boundary, B = 1.8 eV, corresponds to λ_1 = 0.689 μm. Thus, the wavelength range corresponding to the band gap is

$$0.689 \ \mu\text{m} \le \lambda \le 1.127 \ \mu\text{m}$$ <

The fraction of the irradiation that falls in this wavelength range can be found from Table 12.1. With T = 5800 K, $\lambda_1 T$ = 0.689 μm × 5800 K = 4000 μm·K, $\lambda_2 T$ = 6540 μm·K, thus

$$F_{(\lambda_1 \to \lambda_2)} = F_{(0 \to \lambda_2)} - F_{(0 \to \lambda_1)} = 0.7647 - 0.4809 = 0.2838$$

Hence the overall efficiency is

$$\eta = \eta_{bg} F_{bg} = 0.50 \times 0.2838 = 0.1419$$ <

If half of the irradiation that is *not* converted to electricity is absorbed as thermal energy, then the fraction absorbed is 0.5 × (1 – 0.1419) = 0.4290. Thus, the absorbed energy is

$$q = 0.4290 \times 1000 \text{ W/m}^2 = 429 \text{ W/m}^2$$ <

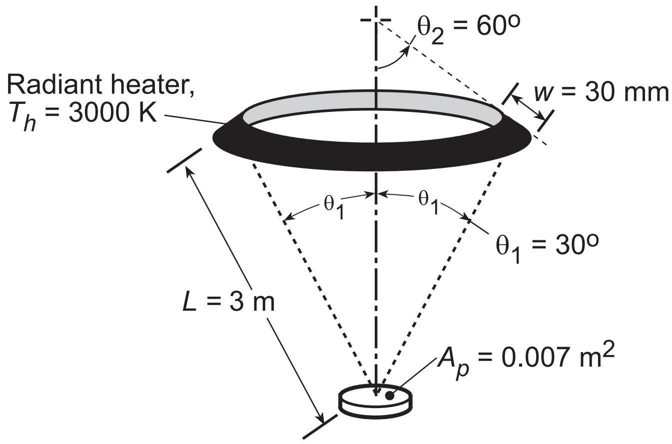
COMMENT: The irradiation that is neither converted to electricity nor converted to thermal energy is reflected from or transmitted through the material.

PROBLEM 12.32

KNOWN: Geometry and temperature of a ring-shaped radiator. Area of irradiated part and distance from radiator.

FIND: Rate at which radiant energy is incident on the part.

SCHEMATIC:



ASSUMPTIONS: (1) Heater emits as a blackbody.

ANALYSIS: Expressing Eq. 12.12 on the basis of the total radiation, $dq = I_e\, dA_h \cos\theta\, d\omega$, the rate at which radiation is incident on the part is

$$q_{h-p} = \int dq = I_e \int\int \cos\theta d\omega_{p-h} dA_h \approx I_e \cos\theta \cdot \omega_{p-h} \cdot A_h$$

Since radiation leaving the heater in the direction of the part is oriented normal to the heater surface, $\theta = 0$ and $\cos\theta = 1$. The solid angle subtended by the part with respect to the heater is $\omega_{p-h} = A_p \cos\theta_1/L^2$, while the area of the heater is $A_h \approx 2\pi r_h W = 2\pi(L \sin\theta_1)W$. Hence, with $I_e = E_b/\pi = \sigma T_h^4/\pi$,

$$q_{h-p} \approx \frac{5.67\times10^{-8}\, W/m^2\cdot K^4 (3000\,K)^4}{\pi} \times \frac{0.007\,m^2 (\cos 30^\circ)}{(3\,m)^2} \times 2\pi(1.5\,m)0.03\,m$$

$$q_{h-p} \approx 278.4\,W$$ <

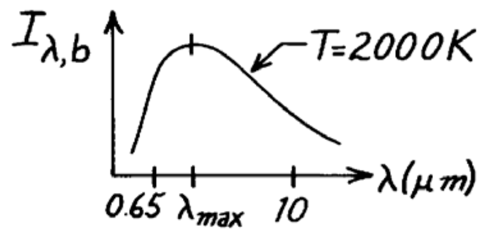
COMMENTS: The foregoing representation for the double integral is an excellent approximation since $W << L$ and $A_p << L^2$.

PROBLEM 12.33

KNOWN: Aperture of an isothermal furnace emits as a blackbody.

FIND: (a) An expression for the ratio of the fractional change in the spectral intensity to the fractional change in temperature of the furnace aperture, (b) Allowable variation in temperature of a furnace operating at 2000 K such that the spectral intensity at 0.65μm will not vary by more than 1/2%. Allowable variation for 10μm.

SCHEMATIC:



ASSUMPTIONS: (1) Furnace is isothermal and aperture radiates as a blackbody.

ANALYSIS: (a) The Planck spectral distribution, Eq. 12.30, is

$$I_\lambda(\lambda, T) = C_1/\pi\lambda^5\left[\exp(C_2/\lambda T) - 1\right].$$

Taking natural logarithms of both sides, find $\ell n I_\lambda = \ell n\left[C_1/\pi\lambda^5\right] - \ell n\left[\exp(C_2/\lambda T) - 1\right]$. Take the total derivative of both sides, but consider the λ variable as a constant.

$$\frac{dI_\lambda}{I_\lambda} = -\frac{d\left[\exp(C_2/\lambda T) - 1\right]}{\left[\exp(C_2/\lambda T) - 1\right]} = -\frac{\{\exp(C_2/\lambda T)\}(C_2/\lambda)\left(-1/T^2\right)dT}{\left[\exp(C_2/\lambda T) - 1\right]}$$

$$\frac{dI_\lambda}{I_\lambda} = \frac{C_2}{\lambda T}\cdot\frac{\exp(C_2/\lambda T)}{\left[\exp(C_2/\lambda T) - 1\right]}\cdot\frac{dT}{T} \quad \text{or} \quad \frac{dI_\lambda/I_\lambda}{dT/T} = \frac{C_2}{\lambda T}\cdot\frac{1}{1 - \exp(-C_2/\lambda T)}. \quad <$$

(b) If the furnace operates at 2000 K and the desirable fractional change of the spectral intensity is 0.5% at 0.65 μm, the allowable temperature variation is

$$\frac{dT}{T} = \frac{dI_\lambda}{I_\lambda}/\left\{\frac{C_2}{\lambda T}\frac{1}{\left[1 - \exp(-C_2/\lambda T)\right]}\right\}$$

$$\frac{dT}{T} = 0.005/\left\{\frac{14,388\,\mu m\cdot K}{0.65\,\mu m\times 2000\,K}/\left[1 - \exp\left(\frac{-14,388\,\mu m\cdot K}{0.65\,\mu m\times 2000\,K}\right)\right]\right\} = 4.517\times 10^{-4}.$$

That is, the allowable fractional variation in temperature is 0.045%; at 2000 K, the allowable temperature variation is

$$\Delta T \approx 4.517\times 10^{-4}\,T = 4.517\times 10^{-4}\times 2000\,K = 0.90\,K. \quad <$$

Substituting with T = 2000 K and λ = 10 μm, find that

$$\frac{dT}{T} = 3.565\times 10^{-3} \quad \text{and} \quad \Delta T \approx 3.565\times 10^{-3}\,T = 7.1K. \quad <$$

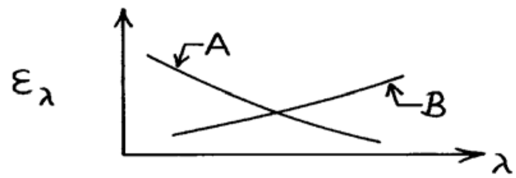
COMMENTS: Note that the power control requirements to satisfy the spectral intensity variation for 0.65 μm and 10 μm conditions are quite different. The peak of the blackbody curve for 2000 K is λ_{max} = 2898 μm·K/2000 K=1.45 μm.

PROBLEM 12.34

KNOWN: Variation of spectral, hemispherical emissivity with wavelength for two materials.

FIND: Nature of the variation with temperature of the total, hemispherical emissivity.

SCHEMATIC:



ASSUMPTIONS: (1) ε_λ is independent of temperature.

ANALYSIS: The total, hemispherical emissivity may be obtained from knowledge of the spectral, hemispherical emissivity by using Eq. 12.43

$$\varepsilon(T) = \frac{\int_0^\infty \varepsilon_\lambda(\lambda) E_{\lambda,b}(\lambda,T) d\lambda}{E_b(T)} = \int_0^\infty \varepsilon_\lambda(\lambda) \frac{E_{\lambda,b}(\lambda,T)}{E_b(T)} d\lambda.$$

We also know that the spectral emissive power of a blackbody becomes more concentrated at lower wavelengths with increasing temperature (Fig. 12.12). That is, the weighting factor, $E_{\lambda,b}(\lambda,T)/E_b(T)$ increases at lower wavelengths and decreases at longer wavelengths with increasing T. Accordingly,

Material A: $\varepsilon(T)$ increases with increasing T <

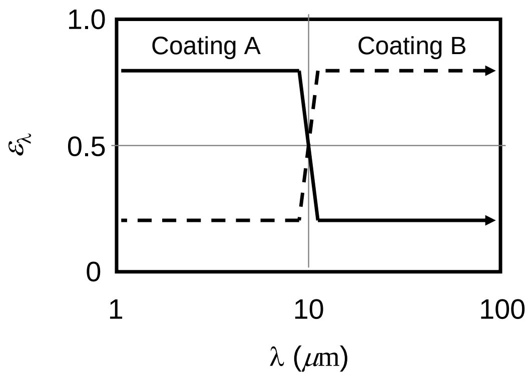
Material B: $\varepsilon(T)$ decreases with increasing T. <

PROBLEM 12.35

KNOWN: Initial and final object temperature. Variation of spectral emissivity with wavelength for two coatings.

FIND: Which coating cools faster.

SCHEMATIC:



ASSUMPTIONS: (1) Surface is a diffuse emitter, (2) Negligible radiation from low-temperature vacuum chamber to object, (3) The spectral emissivity distribution can be approximated as a step change.

ANALYSIS: The object cools by radiation to the surroundings, and the object will cool faster if its emissivity is greater. The total, hemispherical emissivity is given by Equation 12.43, and changes with time as the temperature of the object changes. From Equation 12.43,

$$\varepsilon(T) = \frac{\int_0^\infty \varepsilon_\lambda E_{\lambda,b} d\lambda}{E_b(T)} = \frac{\varepsilon_1 \int_0^{\lambda_c} E_{\lambda,b} d\lambda + \varepsilon_2 \int_0^{\lambda_c} E_{\lambda,b} d\lambda}{E_b(T)}$$

$$= \varepsilon_1 F_{(0\to\lambda_c)} + \varepsilon_2 \left(1 - F_{(0\to\lambda_c)}\right)$$

where λ_c = 10 μm is the cut-off wavelength at which the emissivity changes from ε_1 to ε_2. For coating A, ε_1 is the higher value and ε_2 is the lower value, and vice versa for coating B. At the initial temperature of 1000 K, we find $\lambda_c T$ = 10,000 μm·K, and from Table 12.1, $F_{(0\to\lambda_c)}$ = 0.914. Therefore coating A has the higher emissivity value over 91.4% of the spectrum and has the higher total emissivity. At the final temperature of 500 K, we find $\lambda_c T$ = 5000 μm·K, and from Table 12.1, $F_{(0\to\lambda_c)}$ = 0.0634. Thus, coating A still has the higher emissivity value.

Coating A will cause the object to cool faster. <

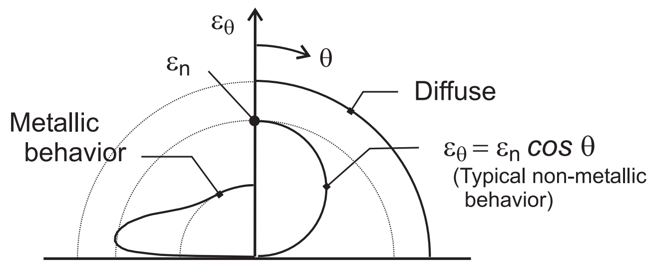
COMMENTS: The emissivity of coatings A and B are the same when $F_{(0\to\lambda_c)}$ = 0.5. From Table 12.1, this occurs at a temperature of T = 411 K. Below this temperature, coating B will cause faster cooling than coating A. If the object were to be cooled below 411 K, a more complex analysis would be required to determine which coating would lead to the fastest cooling over the entire time period.

PROBLEM 12.36

KNOWN: The total directional emissivity of non-metallic materials may be approximated as $\varepsilon_\theta = \varepsilon_n \cos\theta$ where ε_n is the total normal emissivity.

FIND: Show that for such materials, the total hemispherical emissivity, ε, is 2/3 the total normal emissivity.

SCHEMATIC:



ANALYSIS: From Eq. 12.42, written on a total rather than spectral basis, the hemispherical emissivity ε can be determined from the directional emissivity ε_θ as

$$\varepsilon = 2\int_0^{\pi/2} \varepsilon_\theta \cos\theta \sin\theta \, d\theta$$

With $\varepsilon_\theta = \varepsilon_n \cos\theta$, find

$$\varepsilon = 2\,\varepsilon_n \int_0^{\pi/2} \cos^2\theta \sin\theta \, d\theta$$

$$\varepsilon = -2\,\varepsilon_n \left(\cos^3\theta/3\right)\Big|_0^{\pi/2} = 2/3\,\varepsilon_n$$ <

COMMENTS: (1) Refer to Fig. 12.16 illustrating on cartesian coordinates representative directional distributions of the total, directional emissivity for nonmetallic and metallic materials. In the schematic above, we've shown ε_θ vs. θ on a polar plot for both types of materials, in comparison with a diffuse surface.

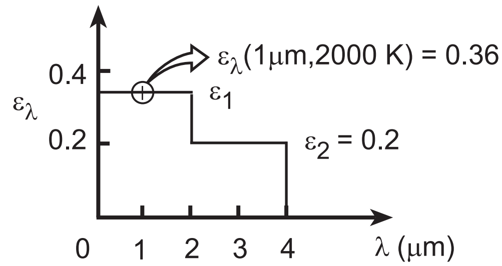
(2) See Section 12.5 for discussion on other characteristics of emissivity for materials.

PROBLEM 12.37

KNOWN: Metallic surface with prescribed spectral, directional emissivity at 2000 K and 1 μm (see Example 12.7) and additional measurements of the spectral, hemispherical emissivity.

FIND: (a) Total hemispherical emissivity, ε, and the emissive power, E, at 2000 K, (b) Effect of temperature on the emissivity.

SCHEMATIC:



ANALYSIS: (a) The total, hemispherical emissivity, ε, may be determined from knowledge of the spectral, hemispherical emissivity, ε_λ, using Eq. 12.43.

$$\varepsilon(T) = \int_0^\infty \varepsilon_\lambda(\lambda) E_{\lambda,b}(\lambda,T)\, d\lambda / E_b(T) = \varepsilon_1 \int_0^{2\mu m} \frac{E_{\lambda,b}(\lambda,T)d\lambda}{E_b(T)} + \varepsilon_2 \int_{2\mu m}^{4\mu m} \frac{E_{\lambda,b}(\lambda,T)d\lambda}{E_b(T)}$$

or from Eq. 12.34,

$$\varepsilon(T) = \varepsilon_1 F_{(0\to\lambda_1)} + \varepsilon_2 \left[F_{(0\to\lambda_2)} - F_{(0\to\lambda_1)} \right]$$

From Table 12.1,

$$\lambda_1 = 2\,\mu m, \quad T = 2000\text{ K}: \quad \lambda_1 T = 4000\,\mu m\cdot K, \quad F_{(0\to\lambda_1)} = 0.481$$

$$\lambda_2 = 4\,\mu m, \quad T = 2000\text{ K}: \quad \lambda_2 T = 8000\,\mu m\cdot K, \quad F_{(0\to\lambda_2)} = 0.856$$

Hence,

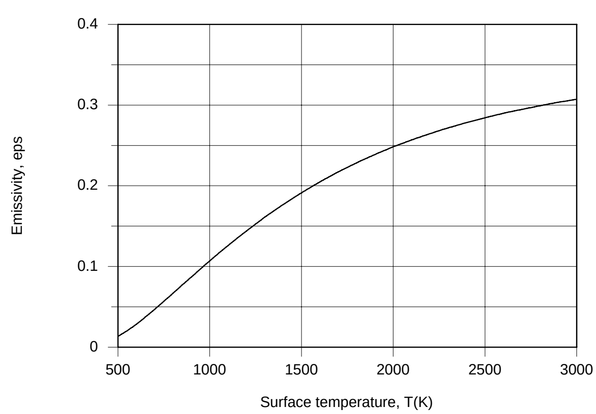
$$\varepsilon(T) = 0.36\times 0.481 + 0.20(0.856 - 0.481) = 0.25$$ <

The total emissive power at 2000 K is

E(2000 K) = ε (2000 K) · E_b (2000 K)

$$E(2000\text{ K}) = 0.25\times 5.67\times 10^{-8}\text{ W/m}^2\cdot K^4 \times (2000\text{ K})^4 = 2.27\times 10^5\text{ W/m}^2 .$$ <

(b) Using the *Radiation* Toolpad of IHT, the following result was generated.



Continued...

PROBLEM 12.37 (Cont.)

At T ≈ 500 K, most of the radiation is emitted in the far infrared region (λ > 4 μm), in which case ε ≈ 0. With increasing T, emission is shifted to lower wavelengths, causing ε to increase. As T → ∞, ε → 0.36.

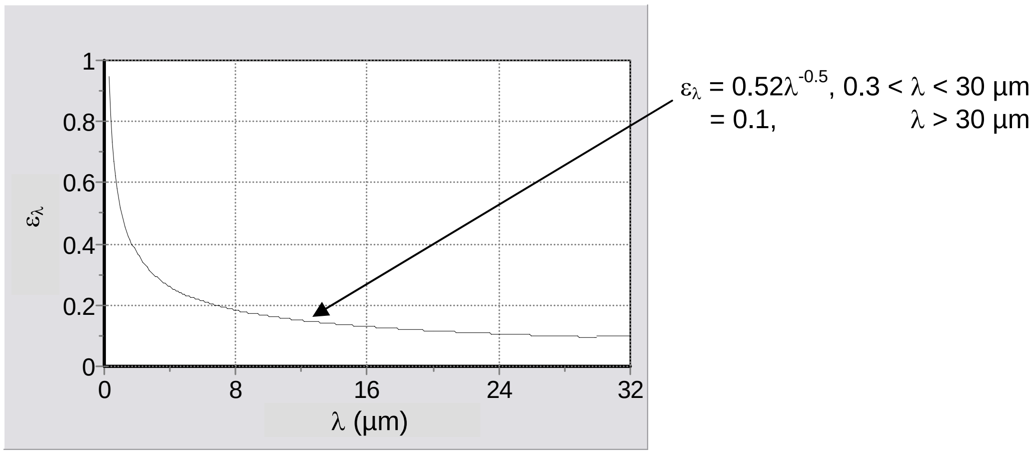
COMMENTS: Note that the value of ε_λ for 0 < λ ≤ 2 μm cannot be read directly from the ε_λ distribution provided in the problem statement. This value is calculated from knowledge of $\varepsilon_{\lambda,\theta}(\theta)$ in Example 12.7.

PROBLEM 12.38

KNOWN: Expression for spectral emissivity of titanium at room temperature.

FIND: (a) Emissive power of titanium surface at 300 K. (b) Value of λ_{max} for emissive power of surface in part (a).

SCHEMATIC:



ANALYSIS: (a) Combining Eqs. 12.40 and 12.43, the emissive power is given by

$$E(T) = \varepsilon(T)E_b(T) = \int_0^\infty \varepsilon_\lambda(\lambda,T)E_{\lambda,b}(\lambda,T)d\lambda = I_1 + I_2 + I_3$$

where

$$I_1 = \int_0^{0.3\ \mu m} \varepsilon_\lambda(\lambda,T)E_{\lambda,b}(\lambda,T)d\lambda \le \int_0^{0.3\ \mu m} E_{\lambda,b}(\lambda,T)d\lambda = F_{(0\to 0.3\mu m)}E_b(T)$$

$$I_2 = 0.52\int_{0.3\ \mu m}^{30\ \mu m} \lambda^{-0.5}E_{\lambda,b}(\lambda,T)d\lambda$$

$$I_3 = 0.1\int_{30\ \mu m}^{\infty} E_{\lambda,b}(\lambda,T)d\lambda = 0.1F_{(30\mu m\to\infty)}E_b(T)$$

From Table 12.1, with $\lambda_1 T$ = 0.3 μm × 300 K = 90 μm·K and $\lambda_2 T$ = 30 μm × 300 K = 9000 μm·K,

$$F_{(0\to 0.3\mu m)} \approx 0$$

$$F_{(30\mu m\to\infty)} = 1 - F_{(0\to 30\mu m)} = 1 - 0.890029 = 0.110$$

Thus

$$I_1 \approx 0$$

$$I_3 = 0.1\times 0.110\times 5.67\times 10^{-8}\ W/m^2\cdot K^4 \times (300\ K)^4 = 5.05\ W/m^2$$

The integral I_2 must be evaluated numerically. Making use of Eq. 12.30 for $E_{\lambda,b}$,

$$I_2 = 0.52\int_{0.3\ \mu m}^{30\ \mu m} \lambda^{-0.5}\frac{C_1}{\lambda^5\left[\exp(C_2/\lambda T)-1\right]}d\lambda$$

Continued…

PROBLEM 12.38 (Cont.)

This integral can be evaluated using the INTEGRAL function of IHT. The result is $I_2 = 61.16$ W/m^2. Thus,

$$E(T) = I_1 + I_2 + I_3 = 0 + 61.16\ W/m^2 + 5.05\ W/m^2 = 66.2\ W/m^2 \qquad <$$

(b) The value of λ_{max} is the value of λ for which E_λ is maximum. The maximum in $E_{\lambda,b}$ occurs for $\lambda_{max}T = 2898$ μm·K, or at 300 K, $\lambda_{max} = 9.66$ μm. However, for $E_\lambda = \varepsilon_\lambda E_{\lambda,b}$, the maximum will be shifted because of the dependence of ε_λ on λ. We consider

$$\frac{dE_\lambda}{d\lambda} = \frac{d(\varepsilon_\lambda E_{\lambda,b})}{d\lambda} = \varepsilon_\lambda \frac{dE_{\lambda,b}}{d\lambda} + \frac{d\varepsilon_\lambda}{d\lambda} E_{\lambda,b} = 0$$

Considering the range 0.3 μm ≤ λ ≤ 30 μm, for which $\varepsilon_\lambda = 0.52\lambda^{-0.5}$, this becomes

$$0.52\lambda^{-0.5}\frac{dE_{\lambda,b}}{d\lambda} - 0.5\left(0.52\lambda^{-1.5}\right)E_{\lambda,b} = 0$$

$$\lambda\frac{dE_{\lambda,b}}{d\lambda} - 0.5E_{\lambda,b} = 0 \qquad (1)$$

Then

$$\frac{dE_{\lambda,b}}{d\lambda} = \frac{-5C_1}{\lambda^6\left[\exp(C_2/\lambda T)-1\right]} + \frac{-C_1\exp(C_2/\lambda T)}{\lambda^5\left[\exp(C_2/\lambda T)-1\right]^2}\left(-\frac{C_2}{\lambda^2 T}\right)$$

$$\frac{dE_{\lambda,b}}{d\lambda} = -5\frac{E_{\lambda,b}}{\lambda} + \frac{E_{\lambda,b}\exp(C_2/\lambda T)}{\left[\exp(C_2/\lambda T)-1\right]}\left(\frac{C_2}{\lambda^2 T}\right) \qquad (2)$$

Substituting Eq. (2) into Eq. (1) and simplifying,

$$\frac{\exp(C_2/\lambda T)}{\left[\exp(C_2/\lambda T)-1\right]}\left(\frac{C_2}{\lambda T}\right) = 5.5 \qquad (3)$$

Solving this implicit equation for $C_2/\lambda T$ yields

$$\frac{C_2}{\lambda T} = 5.477$$

Thus

$$\lambda_{max} = \frac{C_2}{5.477T} = \frac{1.439\times 10^4\ \mu m\cdot K}{5.477\times 300\ K} = 8.76\ \mu m \qquad <$$

$E_{\lambda,b}$ will be smaller in the ranges $\lambda < 0.3$ μm, and $\lambda > 30$ μm.

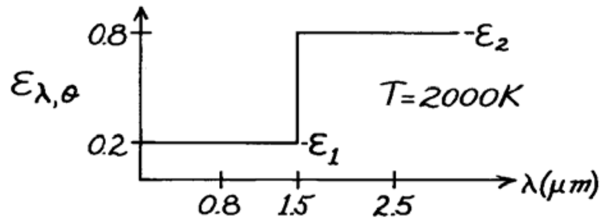
COMMENTS: Because the titanium has an emissivity that increases with decreasing wavelength, the value of λ_{max} is smaller than would have been predicted with use of Wien's displacement law, $\lambda_{max,W} = 2898$ μm·K/300K = 9.66 μm.

PROBLEM 12.39

KNOWN: Spectral directional emissivity of a diffuse material at 2000K.

FIND: (a) Total, hemispherical emissivity, (b) Emissive power over the spectral range 0.8 to 2.5 μm and for directions $0 \le \theta \le \pi/6$.

SCHEMATIC:



ASSUMPTIONS: (1) Surface is diffuse emitter.

ANALYSIS: (a) Since the surface is diffuse, $\varepsilon_{\lambda,\theta}$ is independent of direction; from Eq. 12.42, $\varepsilon_{\lambda,\theta} = \varepsilon_\lambda$. Using Eq. 12.43,

$$\varepsilon(T) = \int_0^\infty \varepsilon_\lambda(\lambda) E_{\lambda,b}(\lambda, T) d\lambda / E_b(T)$$

$$E(T) = \int_0^{1.5} \varepsilon_1 E_{\lambda,b}(\lambda, 2000) d\lambda / E_b + \int_{1.5}^\infty \varepsilon_2 E_{\lambda,b}(\lambda, 2000) d\lambda / E_b.$$

Written now in terms of $F_{(0\to\lambda)}$, with $F_{(0\to 1.5)} = 0.2732$ at $\lambda T = 1.5 \times 2000 = 3000$ μm·K, (Table 12.1) find,

$$\varepsilon(2000\,K) = \varepsilon_1 \times F_{(0\to1.5)} + \varepsilon_2\left[1 - F_{(0\to1.5)}\right] = 0.2 \times 0.2732 + 0.8[1 - 0.2732] = 0.636.$$ <

(b) For the prescribed spectral and geometric limits, from an equation similar to Eq. 12.15,

$$\Delta E = \int_{0.8}^{2.5} \int_0^{2\pi} \int_0^{\pi/6} \varepsilon_{\lambda,\theta} I_{\lambda,b}(\lambda, T) \cos\theta \sin\theta \, d\theta \, d\phi \, d\lambda$$

where $I_{\lambda,e}(\lambda, \theta, \phi) = \varepsilon_{\lambda,\theta} I_{\lambda,b}(\lambda,T)$. Since the surface is diffuse, $\varepsilon_{\lambda,\theta} = \varepsilon_\lambda$, and noting $I_{\lambda,b}$ is independent of direction and equal to $E_{\lambda,b}/\pi$, we can write

$$\Delta E = \left\{\int_0^{2\pi} \int_0^{\pi/6} \cos\theta \sin\theta \, d\theta \, d\phi\right\} \frac{E_b(T)}{\pi} \left\{\frac{\int_{0.8}^{1.5} \varepsilon_1 E_{\lambda,b}(\lambda,T) d\lambda}{E_b(T)} + \frac{\int_{1.5}^{2.5} \varepsilon_2 E_{\lambda,b}(\lambda,T) d\lambda}{E_b(T)}\right\}$$

or in terms $F_{(0\to\lambda)}$ values,

$$\Delta E = \left\{\phi\Big|_0^{2\pi} \times \frac{\sin^2\theta}{2}\Big|_0^{\pi/6}\right\} \frac{\sigma T^4}{\pi} \left\{\varepsilon_1\left[F_{0\to1.5} - F_{0\to0.8}\right] + \varepsilon_2\left[F_{0\to2.5} - F_{0\to1.5}\right]\right\}.$$

From Table 12.1: $\lambda T = 0.8 \times 2000 = 1600$ μm·K $\qquad F_{(0\to0.8)} = 0.0197$

$\lambda T = 2.5 \times 2000 = 5000$ μm·K $\qquad F_{(0\to2.5)} = 0.6337$

$$\Delta E = \left\{2\pi \times \frac{\sin^2 \pi/6}{2}\right\} \frac{5.67 \times 10^{-8} \times 2000^4}{\pi} \frac{W}{m^2} \cdot \left\{0.2[0.2732 - 0.0197] + 0.8[0.6337 - 0.2732]\right\}$$

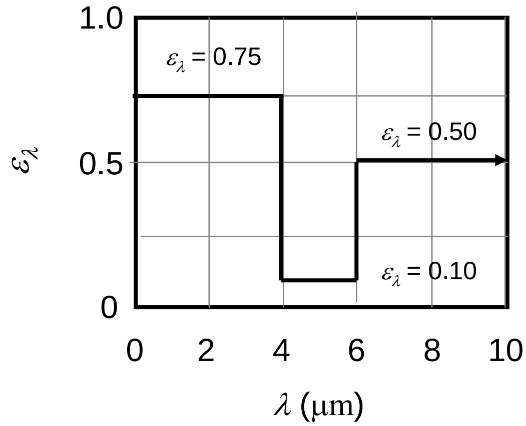
$$\Delta E = 0.25 \times \left(5.67 \times 10^{-8} \times 2000^4\right) W/m^2 \times 0.339 = 76.89 \text{ kW/m}^2.$$ <

PROBLEM 12.40

KNOWN: Spectral emissivity distribution of diffuse surface. Surface temperature range.

FIND: Temperature at which the emissive power is minimized.

SCHEMATIC:



ASSUMPTIONS: Surface is a diffuse emitter.

ANALYSIS: The emissive power is $E(T) = \varepsilon(T)E_b(T)$. It is known that $E_b(T)$ increases with T, but it is not immediately obvious how $\varepsilon(T)$ varies with temperature since as temperature increases, the heaviest weighting of the spectral emissivity distribution shifts from higher to lower wavelengths. From Eq. 12.43,

$$\varepsilon(T) = \frac{\int_0^\infty \varepsilon_\lambda E_{\lambda,b} d\lambda}{E_b(T)} = \frac{\varepsilon_1 \int_0^{\lambda_1} E_{\lambda,b} d\lambda + \varepsilon_2 \int_0^{\lambda_2} E_{\lambda,b} d\lambda + \varepsilon_3 \int_0^{\lambda_3} E_{\lambda,b} d\lambda}{E_b(T)}$$

$$= \varepsilon_1 F_{(0\to\lambda_1)} + \varepsilon_2 \left(F_{(0\to\lambda_2)} - F_{(0\to\lambda_1)}\right) + \varepsilon_3 \left(1 - F_{(0\to\lambda_2)}\right)$$

where $\lambda_1 = 4\ \mu$m, $\lambda_2 = 6\ \mu$m, $\varepsilon_1 = 0.75$, $\varepsilon_2 = 0.\ 10$, and $\varepsilon_3 = 0.50$. At $T = 300$ K,

$$\lambda_1 T = 1200\ \mu\text{m}\cdot\text{K},\ \lambda_2 T = 1800\ \mu\text{m}\cdot\text{K}.$$

From Table 12.1,

$$F_{(0\to\lambda_1)} = 0.002134, \quad F_{(0\to\lambda_2)} = 0.039341.$$

Thus,

$$\varepsilon(300\text{ K}) = 0.75 \times 0.002134 + 0.10 \times (0.039341 - 0.002134) + 0.50 \times (1 - 0.039341) = 0.486$$

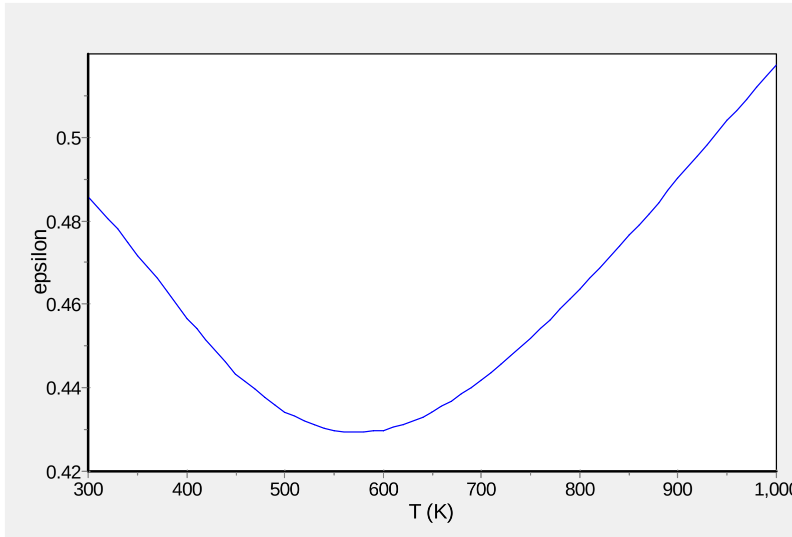
and

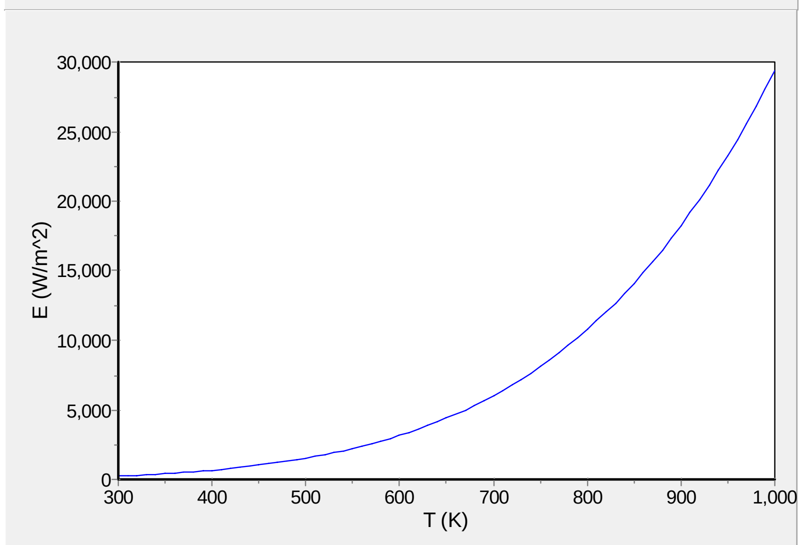
$$E(300\text{ K}) = \varepsilon(300\text{ K})\sigma T^4 = 0.486 \times 5.67 \times 10^{-8}\ \text{W/m}^2 \cdot \text{K} \times (300\text{ K})^4 = 223\ \text{W/m}^2$$

Repeating these calculations over the temperature range $300 \le T_s \le 1000$ K, the following plots can be generated.

Continued…

PROBLEM 12.40 (Cont.)





It can be seen that $\varepsilon(T)$ has a minimum around 570 K, however

the minimum value of E occurs at 300 K <

and is E_{min} = 223 W/m^2.

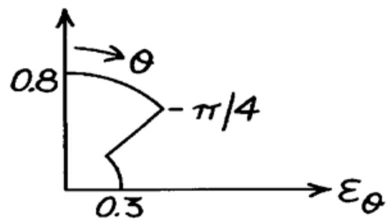
COMMENTS: The blackbody emissive power varies as T^4. The variation of emissivity with temperature is nowhere near as strong and therefore does not give rise to a local minimum in emissive power.

PROBLEM 12.41

KNOWN: Directional emissivity, ε_θ, of a selective surface.

FIND: Ratio of the normal emissivity, ε_n, to the hemispherical emissivity, ε.

SCHEMATIC:



ASSUMPTIONS: Surface is isotropic in ϕ direction.

ANALYSIS: From Eq. 12.42 written on a total, rather than spectral, basis, the hemispherical emissivity is

$$\varepsilon = 2\int_0^{\pi/2} \varepsilon_\theta(\theta)\cos\theta\sin\theta\, d\theta.$$

Recognizing that the integral can be expressed in two parts, find

$$\varepsilon = 2\left[\int_0^{\pi/4} \varepsilon(\theta)\cos\theta\sin\theta\, d\theta + \int_{\pi/4}^{\pi/2} \varepsilon(\theta)\cos\theta\sin\theta\, d\theta\right]$$

$$\varepsilon = 2\left[0.8\int_0^{\pi/4} \cos\theta\sin\theta\, d\theta + 0.3\int_{\pi/4}^{\pi/2} \cos\theta\sin\theta\, d\theta\right]$$

$$\varepsilon = 2\left[0.8\frac{\sin^2\theta}{2}\bigg|_0^{\pi/4} + 0.3\frac{\sin^2\theta}{2}\bigg|_{\pi/4}^{\pi/2}\right]$$

$$\varepsilon = 2\left[0.8\frac{1}{2}(0.50-0) + 0.3\times\frac{1}{2}(1-0.50)\right] = 0.550.$$

The ratio of the normal emissivity (ε_n) to the hemispherical emissivity is

$$\frac{\varepsilon_n}{\varepsilon} = \frac{0.8}{0.550} = 1.45. \qquad <$$

COMMENTS: Note that Eq. 12.42 is based on the assumption that the directional emissivity is independent of the ϕ coordinate. If this is not the case, then Eq. 12.41 would need to be evaluated.

PROBLEM 12.42

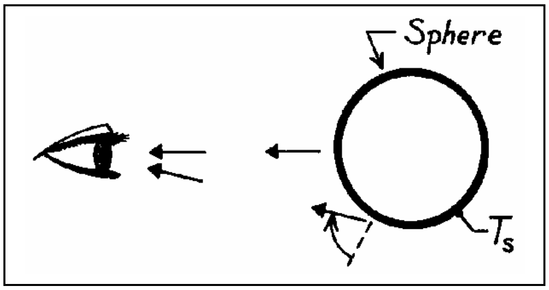
KNOWN: Incandescent sphere suspended in air within a darkened room exhibiting these characteristics:

initially: brighter around the rim
after some time: brighter in the center

FIND: Plausible explanation for these observations.

ASSUMPTIONS: (1) The sphere is at a uniform surface temperature, T_s.

ANALYSIS: Recognize that in observing the sphere by eye, emission from the central region is in a nearly normal direction. Emission from the rim region, however, has a large angle from the normal to the surface.



Note now the directional behavior, ε_θ, for conductors and non-conductors as represented in Fig. 12.16.

Assume that the sphere is fabricated from a *metallic* material. Then, the rim would appear brighter than the central region. This follows since ε_θ is higher at higher angles of emission.

If the metallic sphere oxidizes with time, then the ε_θ characteristics change. Then ε_θ at small angles of θ become larger than at higher angles. This would cause the sphere to appear brighter at the center portion of the sphere.

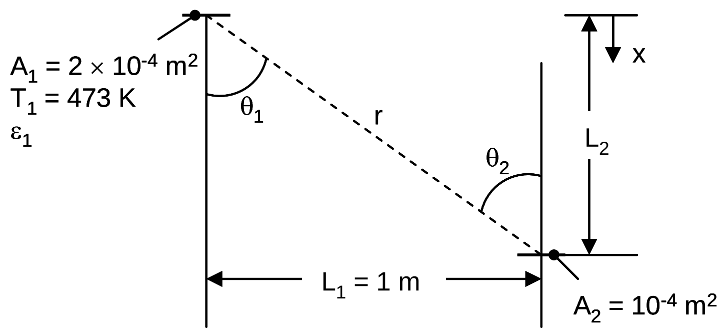
COMMENTS: Since the emissivity of non-conductors is generally larger than for metallic materials, you would also expect the oxidized sphere to appear brighter for the same surface temperature.

PROBLEM 12.43

KNOWN: Surface area, temperature, and emissivity of the heated surface A_1. Surface area and orientation of area A_2. Distance L_1 between the two surfaces.

FIND: (a) Distance, L_2, between the two surfaces associated with maximum irradiation on surface 2, when surface 1 emits diffusely with $\varepsilon = 0.85$. (b) Distance associated with maximum irradiation, when the directional emissivity of surface 1 is $\varepsilon_\theta = \varepsilon_n \cos\theta$. (c) Plot irradiation on surface 2 for $0 \le L_2 \le 10$ m.

SCHEMATIC:



ASSUMPTIONS: (1) Surfaces can be treated as differential areas.

ANALYSIS: (a) Treating both surfaces as differential areas, from Eq. 12.7 and Example 12.1,

$$\omega_{2-1} = A_2\cos\theta_2/r^2$$

Then from Eq. 12.11 the total radiation from surface 1 to surface 2 is,

$$q_{1-2} = I_{e1}A_1\cos\theta_1\omega_{2-1} = (\varepsilon_1 E_{b1}/\pi)A_1\cos\theta_1(A_2\cos\theta_2/r^2) \qquad (1)$$

Since $\cos\theta_1 = \cos\theta_2 = L_2/r$ and $r^2 = L_1^2 + L_2^2$, Eq. (1) can be written

$$q_{1-2} = (\varepsilon_1 E_{b1}/\pi)A_1A_2L_2^2/(L_1^2+L_2^2)^2 \qquad (2)$$

We can find the value of L_2 corresponding to the maximum value of q_{1-2} by differentiating Eq. (2) with respect to L_2 and setting the derivative equal to zero,

$$\frac{dq_{1-2}}{dL_2} = \frac{\varepsilon_1 E_{b1}}{\pi}A_1A_2\left(\frac{2L_2(L_1^2+L_2^2)-4L_2^3}{(L_1^2+L_2^2)^3}\right) = 0$$

$$L_{2,crit} = L_1$$ <

Continued…

PROBLEM 12.43 (Cont.)

(b) We repeat the calculation for the case in which surface 1 is no longer diffuse. The radiation heat transfer rate is still given by Eq. (2), except that the emissivity is the value for radiation in the direction corresponding to θ_1. That is,

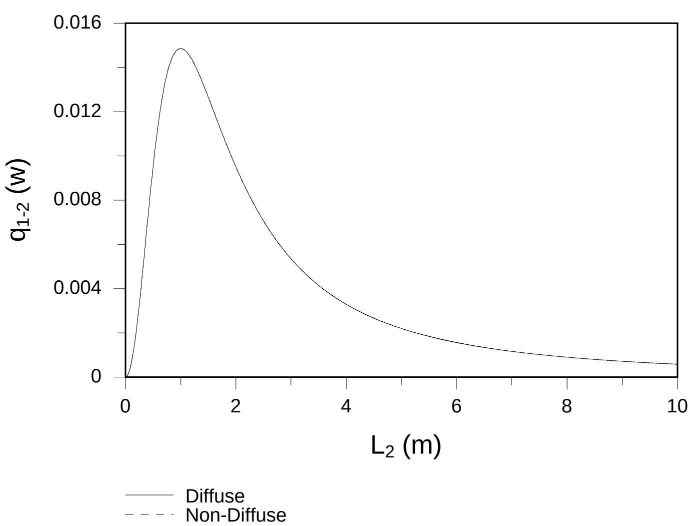
$$q_{1-2} = (\varepsilon_{n1}\cos\theta_1 E_{b1}/\pi)A_1A_2L_2^2/(L_1^2+L_2^2)^2 = (\varepsilon_{n1}E_{b1}/\pi)A_1A_2L_2^3/(L_1^2+L_2^2)^{2.5} \qquad (3)$$

Differentiating Eq. (3),

$$\frac{dq_{1-2}}{dL_2} = \frac{\varepsilon_{n1}E_{b1}}{\pi}A_1A_2\left(\frac{3L_2^2(L_1^2+L_2^2)-5L_2^4}{(L_1^2+L_2^2)^{3.5}}\right) = 0$$

$$L_2 = \sqrt{3/2}L_1 = 1.225L_1$$ <

(c) Eqs. (2) and (3) were keyed into the *IHT* workspace and the following graph was generated.



<

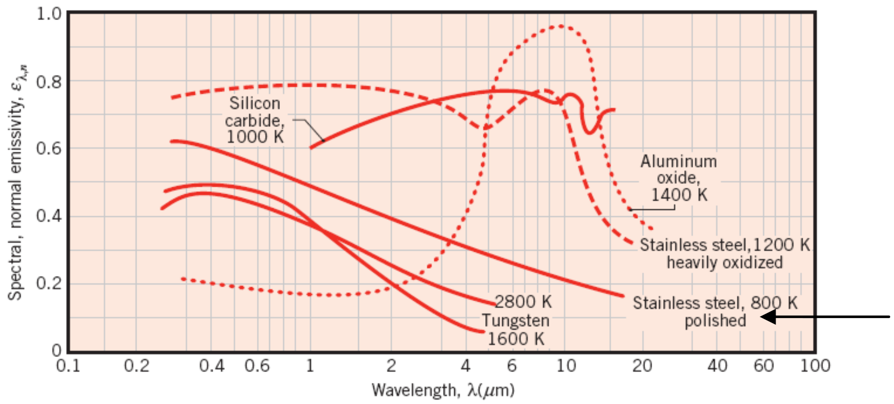
COMMENTS: (1) The value of $L_{2,crit}$ is independent of the object's temperature or emissivity, but does depend on the directional nature of the emissivity. If the detector is calibrated to respond to the proximity of a diffuse object and the object emits as a typical non-metallic material, an error of (1.225 – 1)/1.225 = 18% results. (2) The value of $L_{2,crit}$ can be changed by changing the separation distance, L_1. (3) The temperature and emissivity of the hotter surface must be relatively high, otherwise the reflected component will dominate and the device will not work.

PROBLEM 12.44

KNOWN: Temperature of polished stainless steel. Spectral emissivity distribution.

FIND: Total hemispherical emissivity using 5-band integration. Emissive power.

SCHEMATIC:



ASSUMPTIONS: Spectral hemispherical and normal emissivities are equal.

ANALYSIS: From Equation 12.43,

$$\varepsilon(T) = \frac{\int_0^\infty \varepsilon_\lambda E_{\lambda,b} d\lambda}{E_b} = \frac{\sum_{i=1}^{5} \varepsilon_i \int_{\Delta\lambda_i} E_{\lambda,b} d\lambda}{E_b} = \sum_{i=1}^{5} \varepsilon_i F_{(\lambda,i \to \lambda,i+1)} = \sum_{i=1}^{5} \varepsilon_i (0.2)$$

The last equality results from the choice that each band contains 20% of the blackbody emission. The median wavelength for the first band is chosen such that $F_{(0\to\lambda_m)}$ = 0.1. Interpolating in Table 12.1, $F_{(0\to\lambda_m)}$ = 0.1 when $\lambda_{m,1}T$ = 2195 μm·K. For T = 800 K, $\lambda_{m,1}$ = 2195 μm·K/800 K = 2.74 μm. From Figure 12.17, $\varepsilon_1 = \varepsilon_{n,1} \approx 0.35$. The following table can be constructed for all the bands:

Band	$F_{(0\to\lambda_m)}$	λ_m (μm)	ε
1	0.1	2.74	0.35
2	0.3	3.90	0.31
3	0.5	5.14	0.28
4	0.7	6.99	0.26
5	0.9	11.73	0.20

Thus,

$$\varepsilon = (\varepsilon_1 + \varepsilon_2 + \varepsilon_3 + \varepsilon_4 + \varepsilon_5)(0.2) = (0.35 + 0.31 + 0.28 + 0.26 + 0.20)/5 = 0.28 \quad <$$

The surface emissive power is

$$E = \varepsilon\sigma T^4 = 0.28 \times 5.67 \times 10^{-8}\ \text{W/m}^2\cdot\text{K} \times (800\ \text{K})^4 = 6500\ \text{W/m}^2 \quad <$$

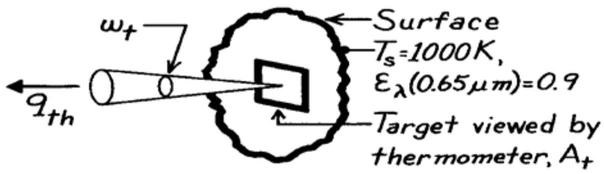
COMMENTS: Estimating the average emissivity value directly from Figure 12.17 might suggest an average value of about 0.4, leading to a 40% error in the emissive power calculation. Much of the high emissivity data plotted in Figure 12.17 are for regions for which there is negligible blackbody radiation at 800 K (see Figure 12.12).

PROBLEM 12.45

KNOWN: Radiation thermometer responding to radiant power within a prescribed spectral interval and calibrated to indicate the temperature of a blackbody.

FIND: (a) Whether radiation thermometer will indicate temperature greater than, less than, or equal to T_s when surface has $\varepsilon < 1$, (b) Expression for T_s in terms of spectral radiance temperature and spectral emissivity, (c) Indicated temperature for prescribed conditions of T_s and ε_λ.

SCHEMATIC:



ASSUMPTIONS: (1) Surface is a diffuse emitter, (2) Thermometer responds to radiant flux over interval dλ about λ.

ANALYSIS: (a) The radiant power which reaches the radiation thermometer is

$$q_\lambda = \varepsilon_\lambda I_{\lambda,b}(\lambda, T_s) \cdot A_t \cdot \omega_t \tag{1}$$

where A_t is the area of the surface viewed by the thermometer (referred to as the target) and ω_t the solid angle through which A_t is viewed. The thermometer responds as if it were viewing a blackbody at T_λ, the spectral radiance temperature,

$$q_\lambda = I_{\lambda,b}(\lambda, T_\lambda) \cdot A_t \cdot \omega_t. \tag{2}$$

By equating the two relations, Eqs. (1) and (2), find

$$I_{\lambda,b}(\lambda, T_\lambda) = \varepsilon_\lambda I_{\lambda,b}(\lambda, T_s). \tag{3}$$

Since $\varepsilon_\lambda < 1$, it follows that $I_{\lambda,b}(\lambda, T_\lambda) < I_{\lambda,b}(\lambda, T_s)$ or that $T_\lambda < T_s$. That is, the thermometer will always indicate a temperature lower than the true or actual temperature for a surface with $\varepsilon < 1$.

(b) Using Wien's distribution in Eq. (3), find

$$I_\lambda(\lambda, T) = \frac{1}{\pi} C_1 \lambda^{-5} \exp(-C_2/\lambda T)$$

$$\frac{1}{\pi} C_1 \lambda^{-5} \exp(-C_2/\lambda T_\lambda) = \varepsilon_\lambda \cdot \frac{1}{\pi} C_1 \lambda^{-5} \exp(-C_2/\lambda T_s).$$

Canceling terms $(C_1\lambda^{-5}/\pi)$, taking natural logs of both sides of the equation and rearranging, the desired expression is

$$\frac{1}{T_s} = \frac{1}{T_\lambda} + \frac{\lambda}{C_2} \ln \varepsilon_\lambda. \tag{4}$$ <

(c) For T_s = 1000K and ε = 0.9, from Eq. (4), the indicated temperature is

$$\frac{1}{T_\lambda} = \frac{1}{T_s} - \frac{\lambda}{C_2} \ln \varepsilon_\lambda = \frac{1}{1000\text{K}} - \frac{0.65\,\mu\text{m}}{14{,}388\,\mu\text{m}\cdot\text{K}} \ln(0.9) \qquad T_\lambda = 995.3\text{K}.$$ <

That is, the thermometer indicates 5K less than the true temperature. The ratio of the emissive power by Wien's distribution to that by the Planck distribution is,

$$\frac{E_{\lambda,b,\text{Wien}}}{E_{\lambda,b,\text{Planck}}} = \frac{1/\exp(C_2/\lambda T)}{1/\left[\exp(C_2/\lambda T) - 1\right]}.$$

Continued...

Problem 12.45 (Cont.)

For the condition $\lambda T = 0.65\ \mu m \times 1000\ K = 650\ \mu m \cdot K$, $C_2/\lambda T = 14388\ \mu m \cdot K/650\ \mu m \cdot K = 22.14$ and

$$\frac{E_{\lambda,b}\big|_{Wien}}{E_{\lambda,b}\big|_{Planck}} = \frac{1/\exp(22.14)}{1/\left[\exp(22.14)-1\right]} = 0.995.$$ <

Thus, Wien's spectral distribution is an excellent approximation to Planck's distribution for this situation.

PROBLEM 12.46

KNOWN: Spectral distribution of emission from a blackbody. Uncertainty in measurement of intensity.

FIND: Corresponding uncertainities in using the intensity measurement to determine (a) the surface temperature or (b) the emissivity.

ASSUMPTIONS: Diffuse surface behavior.

ANALYSIS: From Eq. 12.29, the spectral intensity associated with emission may be expressed as

$$I_{\lambda,e} = \varepsilon_\lambda I_{\lambda,b} = \frac{\varepsilon_\lambda C_1/\pi}{\lambda^5\left[\exp(C_2/\lambda T)-1\right]}$$

(a) To determine the effect of temperature on intensity, we evaluate the derivative,

$$\frac{\partial I_{\lambda,e}}{\partial T} = -\frac{(\varepsilon_\lambda C_1/\pi)\lambda^5 \exp(C_2/\lambda T)\left(-C_2/\lambda T^2\right)}{\left\{\lambda^5\left[\exp(C_2/\lambda T)-1\right]\right\}^2}$$

$$\frac{\partial I_{\lambda,e}}{\partial T} = \frac{\left(C_2/\lambda T^2\right)\exp(C_2/\lambda T)}{\exp(C_2/\lambda T)-1} I_{\lambda,e}$$

Hence,

$$\frac{dT}{T} = \frac{1-\exp(-C_2/\lambda T)}{(C_2/\lambda T)}\frac{d I_{\lambda,e}}{I_{\lambda,e}}$$

With $\left(d I_{\lambda,e}/I_{\lambda,e}\right) = 0.1$, $C_2 = 1.439\times10^4\,\mu m\cdot K$ and $\lambda = 10\,\mu m$,

$$\frac{dT}{T} = \left[\frac{1-\exp(-1439\,K/T)}{1439\,K/T}\right]\times 0.1$$

T = 500 K: dT/T = 0.033 → 3.3% uncertainty <

T = 1000 K: dT/T = 0.053 → 5.3% uncertainty <

(b) To determine the effect of the emissivity on intensity, we evaluate

$$\frac{\partial I_{\lambda,e}}{\partial \varepsilon_\lambda} = I_{\lambda,b} = \frac{I_{\lambda,e}}{\varepsilon_\lambda}$$

Hence, $\dfrac{d\varepsilon_\lambda}{\varepsilon_\lambda} = \dfrac{d I_{\lambda,e}}{I_{\lambda,e}} = 0.10 \rightarrow 10\%$ uncertainty <

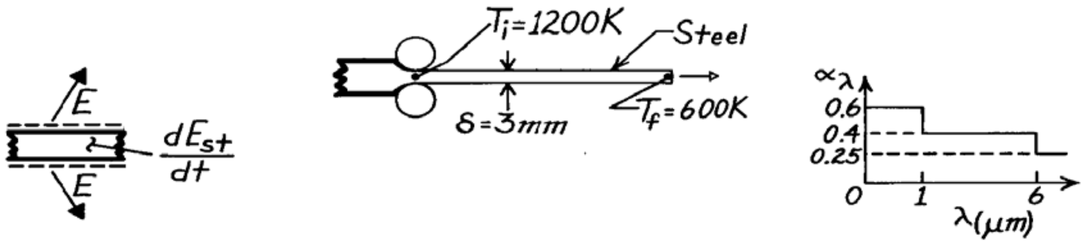
COMMENTS: The uncertainty in the temperature is less than that of the intensity, but increases with increasing temperature (and wavelength). In the limit as $C_2/\lambda T \rightarrow 0$, $\exp(-C_2/\lambda T) \rightarrow 1 - C_2/\lambda T$ and $dT/T \rightarrow d I_{\lambda,e}/I_{\lambda,e}$. The uncertainty in temperature then corresponds to that of the intensity measurement. The same is true for the uncertainty in the emissivity, irrespective of the value of T or λ.

PROBLEM 12.47

KNOWN: Temperature, thickness and spectral emissivity of steel strip emerging from a hot roller. Temperature dependence of total, hemispherical emissivity.

FIND: (a) Initial total, hemispherical emissivity, (b) Initial cooling rate, (c) Time to cool to prescribed final temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible conduction (in longitudinal direction), convection and radiation from surroundings, (2) Negligible transverse temperature gradients.

PROPERTIES: Steel (given): $\rho = 7900$ kg/m^3, c = 640 J/kg·K, $\varepsilon = 1200\varepsilon_i/T$ (K).

ANALYSIS: (a) The initial total hemispherical emissivity is

$$\varepsilon_i = \int_0^\infty \varepsilon_\lambda \left[E_{\lambda b}(1200)/E_b(1200)\right] d\lambda$$

and integrating by parts using values from Table 12.1, find

$$\lambda T = 1200\,\mu m \cdot K \rightarrow F_{(0-1\,\mu m)} = 0.002; \quad \lambda T = 7200\,\mu m \cdot K \rightarrow F_{(0-6\,\mu m)} = 0.819$$

$$\varepsilon_i = 0.6 \times 0.002 + 0.4(0.819 - 0.002) + 0.25(1 - 0.819) = 0.373. \qquad <$$

(b) From an energy balance on a unit surface area of strip (top and bottom),

$$-\dot{E}_{out} = dE_{st}/dt \qquad -2\varepsilon\sigma T^4 = d(\rho\delta c T)/dt$$

$$\left.\frac{dT}{dt}\right)_i = -\frac{2\varepsilon_i \sigma T_i^4}{\rho\delta c} = \frac{-2(0.373)5.67\times10^{-8}\ W/m^2\cdot K^4 (1200\ K)^4}{7900\ kg/m^3(0.003\ m)(640\ J/kg\cdot K)} = -5.78\ K/s. \qquad <$$

(c) From the energy balance,

$$\frac{dT}{dt} = -\frac{2\varepsilon_i(1200/T)\sigma T^4}{\rho\delta c}, \quad \int_{T_i}^{T_f}\frac{dT}{T^3} = -\frac{2400\varepsilon_i\sigma}{\rho\delta c}\int_0^t dt, \quad t = \frac{\rho\delta c}{4800\varepsilon_i\sigma}\left(\frac{1}{T_f^2} - \frac{1}{T_i^2}\right)$$

$$t = \frac{7900\ kg/m^3(0.003\,m)640\ J/kg\cdot K}{4800\ K\times0.373\times5.67\times10^{-8}\ W/m^2\cdot K^4}\left(\frac{1}{600^2} - \frac{1}{1200^2}\right)K^{-2} = 311\ s. \qquad <$$

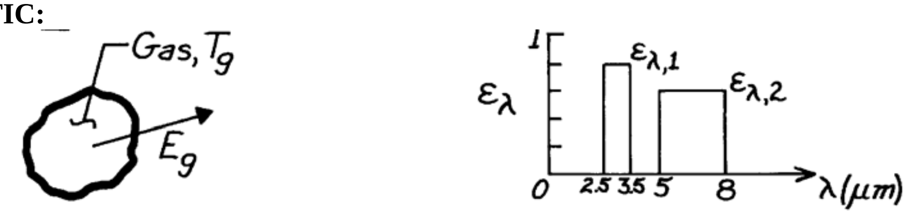
COMMENTS: Initially, from Eq. 1.9, $h_r \approx \varepsilon_i\sigma T_i^3$ = 36.6 W/m^2·K. Assuming a plate width of W = 1m, the Rayleigh number may be evaluated from $Ra_L = g\beta(T_i - T_\infty)(W/2)^3/\nu\alpha$. Assuming T_∞ = 300 K and evaluating properties at T_f = 750 K, $Ra_L = 1.8 \times 10^8$. From Eq. 9.31, Nu_L = 84, giving $\overline{h}$ = 9.2 W/m^2·K. Hence heat loss by radiation exceeds that associated with free convection. To check the validity of neglecting transverse temperature gradients, compute Bi = h(δ/2)/k. With h = 36.6 W/m^2·K and k = 28 W/m·K, Bi = 0.002 << 1. Hence the assumption is valid.

PROBLEM 12.48

KNOWN: Large body of nonluminous gas at 1200 K has emission bands between 2.5 – 3.5 μm and between 5 – 8 μm with effective emissivities of 0.8 and 0.6, respectively.

FIND: Emissive power of the gas.

SCHEMATIC:



ASSUMPTIONS: (1) Gas radiates only in specified bands, (2) Emitted radiation is diffuse.

ANALYSIS: The emissive power of the gas is

$$E_g = \varepsilon E_b\left(T_g\right) = \int_0^\infty \varepsilon_\lambda E_{\lambda,b}\left(T_g\right)d\lambda$$

$$E_g = \int_{2.5}^{3.5} \varepsilon_{\lambda,1} E_{\lambda,b}\left(T_g\right)d\lambda + \int_5^8 \varepsilon_{\lambda,2} E_{\lambda,b}\left(T_g\right)d\lambda$$

$$E_g = \left[\varepsilon_1 F_{(2.5-3.5\,\mu m)} + \varepsilon_2 F_{(5-8\,\mu m)}\right]\sigma T_g^4.$$

Using the blackbody function $F_{(0-\lambda T)}$ from Table 12.1 with T_g = 1200 K,

λT(μm·K)	2.5 × 1200 3000	3.5 × 1200 4200	5 × 1200 6000	8 × 1200 9600
$F_{(0-\lambda T)}$	0.273	0.516	0.738	0.905

so that

$$F_{(2.5-3.5\,\mu m)} = F_{(0-3.5\,\mu m)} - F_{(0-2.5\,\mu m)} = 0.516 - 0.273 = 0.243$$

$$F_{(5-8\,\mu m)} = F_{(0-8\,\mu m)} - F_{(0-5\,\mu m)} = 0.905 - 0.738 = 0.167.$$

Hence the emissive power is

$$E_g = [0.8 \times 0.243 + 0.6 \times 0.167]\,5.67 \times 10^{-8}\ W/m^2 \cdot K^4 (1200\ K)^4$$

$$E_g = 0.295 \times 117{,}573\ W/m^2 = 34{,}684\ W/m^2. \qquad <$$

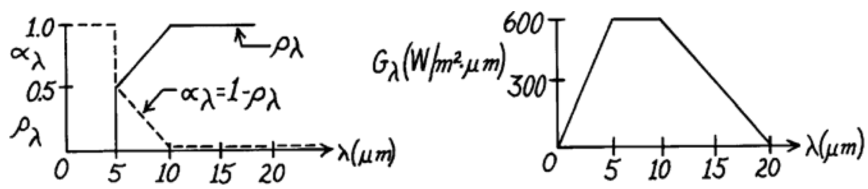
COMMENTS: Note that the effective emissivity for the gas is 0.295. This seems surprising since emission occurs only at the discrete bands. Since λ_{max} = 2.4 μm, all of the spectral emissive power is at wavelengths beyond the peak of blackbody radiation at 1200 K.

PROBLEM 12.49

KNOWN: An opaque surface with prescribed spectral, hemispherical reflectivity distribution is subjected to a prescribed spectral irradiation.

FIND: (a) The spectral, hemispherical absorptivity, (b) Total irradiation, (c) The absorbed radiant flux, and (d) Total, hemispherical absorptivity.

SCHEMATIC:



ASSUMPTIONS: (1) Surface is opaque.

ANALYSIS: (a) The spectral, hemispherical absorptivity, α_λ, for an opaque surface is given by Eq. 12.62,

$$\alpha_\lambda = 1 - \rho_\lambda \quad <$$

which is shown as a dashed line on the ρ_λ distribution axes.

(b) The total irradiation, G, follows from Eq. 12.19 which can be integrated by parts,

$$G = \int_0^\infty G_\lambda d\lambda = \int_0^{5\,\mu m} G_\lambda d\lambda + \int_{5\,\mu m}^{10\,\mu m} G_\lambda d\lambda + \int_{10\,\mu m}^{20\,\mu m} G_\lambda d\lambda$$

$$G = \frac{1}{2}\times 600\frac{W}{m^2\cdot\mu m}(5-0)\mu m + 600\frac{W}{m^2\cdot\mu m}(10-5)\mu m + \frac{1}{2}\times 600\frac{W}{m^2\cdot\mu m}\times(20-10)\mu m$$

$$G = 7500\ W/m^2. \quad <$$

(c) The absorbed irradiation follows from Eqs. 12.51 and 12.52 with the form

$$G_{abs} = \int_0^\infty \alpha_\lambda G_\lambda d\lambda = \alpha_1\int_0^{5\,\mu m} G_\lambda d\lambda + G_{\lambda,2}\int_{5\,\mu m}^{10\,\mu m}\alpha_\lambda d\lambda + \alpha_3\int_{10\,\mu m}^{20\,\mu m} G_\lambda d\lambda.$$

Noting that $\alpha_1 = 1.0$ for $\lambda = 0 \to 5\ \mu m$, $G_{\lambda,2} = 600\ W/m^2\cdot\mu m$ for $\lambda = 5 \to 10\ \mu m$ and $\alpha_3 = 0$ for $\lambda >$ 10 μm, find that

$$G_{abs} = 1.0\left(0.5\times 600\ W/m^2\cdot\mu m\right)(5-0)\mu m + 600\ W/m^2\cdot\mu m(0.5\times 0.5)(10-5)\mu m + 0$$

$$G_{abs} = 2250\ W/m^2. \quad <$$

(d) The total, hemispherical absorptivity is defined as the fraction of the total irradiation that is absorbed. From Eq. 12.51,

$$\alpha = \frac{G_{abs}}{G} = \frac{2250\ W/m^2}{7500\ W/m^2} = 0.30. \quad <$$

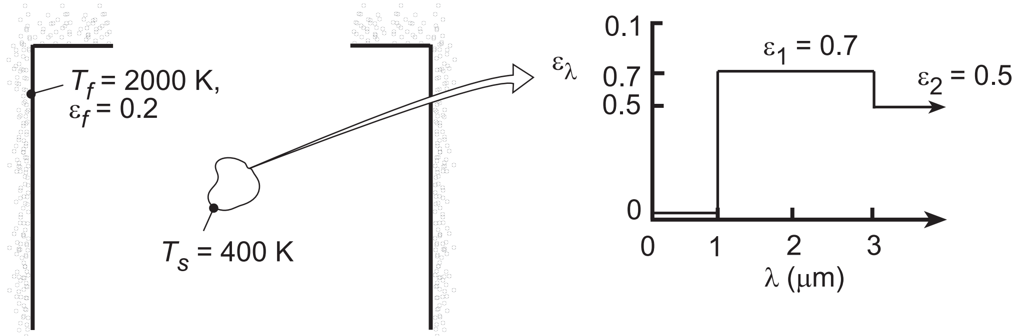
COMMENTS: Recognize that the total, hemispherical absorptivity, $\alpha = 0.3$, is for the given spectral irradiation. For a different G_λ, one would then expect a different value for α.

PROBLEM 12.50

KNOWN: Temperature and spectral emissivity of small object suspended in large furnace of prescribed temperature and total emissivity.

FIND: (a) Total surface emissivity and absorptivity, (b) Reflected radiative flux and net radiative flux to surface, (c) Spectral emissive power at $\lambda = 2\ \mu m$, (d) Wavelength $\lambda_{1/2}$ for which one-half of total emissive power is in spectral region $\lambda \geq \lambda_{1/2}$.

SCHEMATIC:



ASSUMPTIONS: (1) Surface is opaque and diffuse, (2) Walls of furnace are much larger than object.

ANALYSIS: (a) The emissivity of the object may be obtained from Eq. 12.43, which is expressed as

$$\varepsilon(T_s) = \frac{\int_o^\infty \varepsilon_\lambda(\lambda) E_{\lambda,b}(\lambda, T_s) d\lambda}{E_b(T)} = \varepsilon_1\left[F_{(0\to 3\mu m)} - F_{(0\to 1\mu m)}\right] + \varepsilon_2\left[1 - F_{(0\to 3\mu m)}\right]$$

where, with $\lambda_1 T_s = 400\ \mu m\cdot K$ and $\lambda_2 T_s = 1200\ \mu m\cdot K$, $F_{(0\to 1\mu m)} = 0$ and $F_{(0\to 3\mu m)} = 0.002$. Hence,

$$\varepsilon(T_s) = 0.7(0.002) + 0.5(0.998) = 0.500$$ <

The absorptivity of the surface is determined by Eq. 12.52,

$$\alpha = \frac{\int_o^\infty \alpha_\lambda(\lambda) G_\lambda(\lambda) d\lambda}{\int_o^\infty G_\lambda(\lambda) d\lambda} = \frac{\int_o^\infty \alpha_\lambda(\lambda) E_{\lambda,b}(\lambda, T_f) d\lambda}{E_b(T_f)}$$

Hence, with $\lambda_1 T_f = 2000\ \mu m\cdot K$ and $\lambda_2 T_f = 6000\ \mu m\cdot K$, $F_{(0\to 1\mu m)} = 0.067$ and $F_{(0\to 3\mu m)} = 0.738$. It follows that

$$\alpha = \alpha_1\left[F_{(0\to 3\mu m)} - F_{(0\to 1\mu m)}\right] + \alpha_2\left[1 - F_{(0\to 3\mu m)}\right] = 0.7\times 0.671 + 0.5\times 0.262 = 0.601$$ <

(b) The reflected radiative flux is

$$G_{ref} = \rho G = (1-\alpha) E_b(T_f) = 0.399 \times 5.67\times 10^{-8}\ W/m^2\cdot K^4 (2000\ K)^4 = 3.620\times 10^5\ W/m^2$$ <

The net radiative flux to the surface is

$$q''_{rad} = G - \rho G - \varepsilon E_b(T_s) = \alpha E_b(T_f) - \varepsilon E_b(T_s)$$

$$q''_{rad} = 5.67\times 10^{-8}\ W/m^2\cdot K^4\left[0.601(2000\ K)^4 - 0.500(400\ K)^4\right] = 5.438\times 10^5\ W/m^2$$ <

(c) At $\lambda = 2\ \mu m$, $\lambda T_s = 800$ K and, from Table 12.1, $I_{\lambda,b}(\lambda,T)/\sigma T^5 = 0.991 \times 10^{-7}\ (\mu m\cdot K\cdot sr)^{-1}$. Hence,

Continued...

PROBLEM 12.50 (Cont.)

$$I_{\lambda,b} = 0.991\times10^{-7} \times 5.67\times10^{-8} \frac{W/m^2\cdot K^4}{\mu m\cdot K\cdot sr} \times (400\,K)^5 = 0.0575 \frac{W}{m^2\cdot\mu m\cdot sr}$$

Hence, with $E_\lambda = \varepsilon_\lambda E_{\lambda,b} = \varepsilon_\lambda \pi I_{\lambda,b}$,

$$E_\lambda = 0.7(\pi sr)\,0.0575\,W/m^2\cdot\mu m\cdot sr = 0.126\,W/m^2\cdot\mu m$$ <

(d) From Table 12.1, $F_{(0\to\lambda)} = 0.5$ corresponds to $\lambda T_s \approx 4100\ \mu m\cdot K$, in which case,

$$\lambda_{1/2} \approx 4100\,\mu m\cdot K/400\,K \approx 10.3\,\mu m$$ <

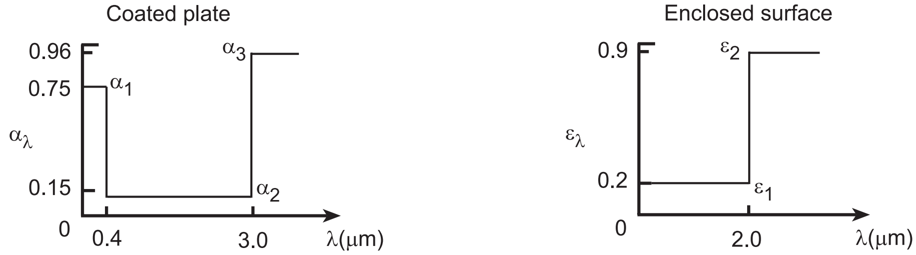
COMMENTS: Because of the significant difference between T_f and T_s, $\alpha \neq \varepsilon$. With increasing $T_s \to T_f$, ε would increase and approach a value of 0.601.

PROBLEM 12.51

KNOWN: Small flat plate maintained at 400 K coated with white paint having spectral absorptivity distribution (Figure 12.22) approximated as a stairstep function. Enclosure surface maintained at 3000 K with prescribed spectral emissivity distribution.

FIND: (a) Total emissivity of the enclosure surface, ε_{es}, and (b) Total emissivity, ε, and absorptivity, α, of the surface.

SCHEMATIC:



ASSUMPTIONS: (1) Coated plate with white paint is diffuse and opaque, so that $\alpha_\lambda = \varepsilon_\lambda$, (2) Plate is small compared to the enclosure surface, and (3) Enclosure surface is isothermal, diffuse and opaque.

ANALYSIS: (a) The total emissivity of the enclosure surface at T_{es} = 3000 K follows from Eq. 12.43 which can be expressed in terms of the bond emission factor, $F_{(0-\lambda T)}$, Eq. 12.35,

$$\varepsilon_{e,s} = \varepsilon_1 F_{(0-\lambda_1 T_{es})} + \varepsilon_2\left[1 - F_{(0-\lambda_1 T_{es})}\right] = 0.2\times 0.738 + 0.9\left[1-0.738\right] = 0.383$$ <

where, from Table 12.1, with $\lambda_1 T_{es}$ = 2 μm × 3000 K = 6000 μm·K, $F_{(0-\lambda T)}$ = 0.738.

(b) The total emissivity of the coated plate at T = 400 K can be expressed as

$$\varepsilon = \alpha_1 F_{(0-\lambda_1 T_s)} + \alpha_2\left[F_{(0-\lambda_2 T_s)} - F_{(0-\lambda_1 T_s)}\right] + \alpha_3\left[1 - F_{(0-\lambda_2 T_s)}\right]$$

$$\varepsilon = 0.75\times 0 + 0.15\left[0.002134 - 0.000\right] + 0.96\left[1 - 0.002134\right] = 0.958$$ <

where, from Table 12.1, the band emission factors are: for $\lambda_1 T_s$ = 0.4 × 400 = 160 μm·K, find $F_{(0-\lambda_1 T_s)}$ = 0.000; for $\lambda_2 T_{es}$ = 3.0 × 400 = 1200 μm·K, find $F_{(0-\lambda_2 T_s)}$ = 0.002134. The total absorptivity for the irradiation due to the enclosure surface at T_{es} = 3000 K is

$$\alpha = \alpha_1 F_{(0-\lambda_1 T_{es})} + \alpha_2\left[F_{(0-\lambda_2 T_{es})} - F_{(0-\lambda_2 T_{es})}\right] + \alpha_3\left[1 - F_{(0-\lambda_2 T_{es})}\right]$$

$$\alpha = 0.75\times 0.002134 + 0.15\left[0.8900 - 0.002134\right] + 0.96\left[1 - 0.8900\right] = 0.240$$ <

where, from Table 12.1, the band emission factors are: for $\lambda_1 T_{es}$ = 0.4 × 3000 = 1200 μm·K, find $F_{(0-\lambda_1 T_{es})}$ = 0.002134; for $\lambda_2 T_{es}$ = 3.0 × 3000 = 9000 μm·K, find $F_{(0-\lambda_2 T_{es})}$ = 0.8900.

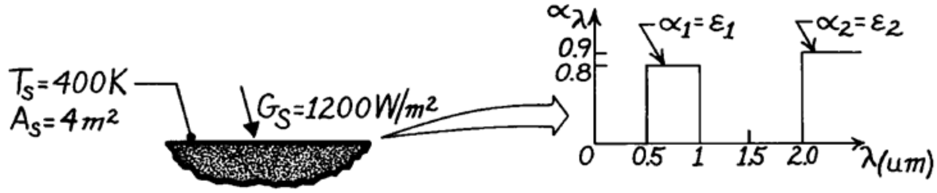
COMMENTS: (1) In evaluating the total emissivity and absorptivity, remember that $\varepsilon = \varepsilon(\varepsilon_\lambda, T_s)$ and $\alpha = \alpha(\alpha_\lambda, G_\lambda)$ where T_s is the temperature of the surface and G_λ is the spectral irradiation, which if the surroundings are large and isothermal, $G_\lambda = E_{b,\lambda}(T_{sur})$. Hence, $\alpha = \alpha(\alpha_\lambda, T_{sur})$. For the opaque, diffuse surface, $\alpha_\lambda = \varepsilon_\lambda$. (2) Note that the coated plate (white paint) has an absorptivity for the 3000 K-enclosure surface irradiation of α = 0.240. You would expect it to be a low value since the coating appears visually "white". (3) The emissivity of the coated plate is quite high, ε = 0.958. Would you have expected this of a "white paint"? Most paints are oxide systems (high absorptivity at long wavelengths) with pigmentation (controls the "color" and hence absorptivity in the visible and near infrared regions).

PROBLEM 12.52

KNOWN: Area, temperature, irradiation and spectral absorptivity of a surface.

FIND: Absorbed irradiation, emissive power, radiosity and net radiation transfer from the surface.

SCHEMATIC:



ASSUMPTIONS: (1) Opaque, diffuse surface behavior, (2) Spectral distribution of solar radiation corresponds to emission from a blackbody at 5800 K.

ANALYSIS: The absorptivity to solar irradiation is

$$\alpha_S = \frac{\int_0^\infty \alpha_\lambda G_\lambda d\lambda}{G} = \frac{\int_0^\infty \alpha_\lambda E_{\lambda b}(5800\text{ K})d\lambda}{E_b} = \alpha_1 F_{(0.5\to 1\mu m)} + \alpha_2 F_{(2\to\infty)}.$$

From Table 12.1,	$\lambda T = 2900\ \mu m\cdot K$:	$F_{(0\to 0.5\ \mu m)} = 0.250$
	$\lambda T = 5800\ \mu m\cdot K$:	$F_{(0\to 1\ \mu m)} = 0.720$
	$\lambda T = 11,600\ \mu m\cdot K$:	$F_{(0\to 2\ \mu m)} = 0.941$

$$\alpha_S = 0.8(0.720 - 0.250) + 0.9(1 - 0.941) = 0.429.$$

Hence, $$G_{abs} = \alpha_S G_S = 0.429\left(1200\text{ W/m}^2\right) = 515\text{ W/m}^2. \quad <$$

The emissivity is

$$\varepsilon = \int_0^\infty \varepsilon_\lambda E_{\lambda b}(400\text{ K})d\lambda / E_b = \varepsilon_1 F_{(0.5\to 1\mu m)} + \varepsilon_2 F_{(2\to\infty)}.$$

From Table 12.1,	$\lambda T = 200\ \mu m\cdot K$:	$F_{(0\to 0.5\ \mu m)} = 0$
	$\lambda T = 400\ \mu m\cdot K$:	$F_{(0\to 1\ \mu m)} = 0$
	$\lambda T = 800\ \mu m\cdot K$	$F_{(0\to 2\ \mu m)} = 0.$

Hence, $\varepsilon = \varepsilon_2 = 0.9$,

$$E = \varepsilon\sigma T_s^4 = 0.9 \times 5.67 \times 10^{-8}\text{ W/m}^2\cdot K^4 (400\text{ K})^4 = 1306\text{ W/m}^2. \quad <$$

The radiosity is

$$J = E + \rho_S G_S = E + (1 - \alpha_S)G_S = [1306 + 0.571 \times 1200]\text{W/m}^2 = 1991\text{ W/m}^2. \quad <$$

The net radiation transfer from the surface is

$$q_{net} = (E - \alpha_S G_S)A_s = (1306 - 515)\text{W/m}^2 \times 4\text{ m}^2 = 3164\text{ W}. \quad <$$

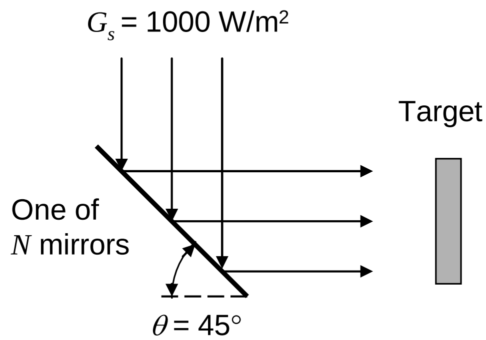
COMMENTS: Unless 3164 W are supplied to the surface by other means (for example, by convection), the surface temperature will decrease with time.

PROBLEM 12.53

KNOWN: Solar irradiation, specular reflectivity of polished silver, absorptivity of wood, cumulative irradiation of N mirrors from N students, $G_{s,N}$ = 70,000 W/m^2 as in Problem 4.51.

FIND: (a) Number of students, N, for first-surface mirrors, (b) Number of students, N, for second-surface mirrors.

SCHEMATIC:



ASSUMPTIONS: (1) Spectral transmissivity of plain glass as in Problem 12.62, (2) Solar irradiation is that of a blackbody at T_s = 5800 K.

ANALYSIS: (a) From the schematic for the first-surface mirror,

$$G_{s,N} = NG_s\rho_m\alpha_w \quad \text{or} \quad N = \frac{G_{s,N}}{G_s\rho_m\alpha_w} = \frac{70{,}000\,\text{W/m}^2}{1000\ \text{W/m}^2 \times 0.98 \times 0.80} = 90$$ <

where ρ_m is the reflectivity of the silver surface and α_w is the absorptivity of the wood.

(b) From the schematic for a second-surface mirror, $G_{s,N} = NG_s\tau_g\rho_m\alpha_w$ where τ_g is the transmissivity of the plain glass. Using Table 12.1,

λ_2 = 2.5 μm	$\lambda_2 T$ = 2.5 μm × 5800 K = 14,500 μm·K	$F(0\rightarrow\lambda_2)$ = 0.966
λ_1 = 0.3 μm	$\lambda_1 T$ = 0.3 μm × 5800 K = 1740 μm·K	$F(0\rightarrow\lambda_1)$ = 0.033

τ_g = 0.9(0.966 – 0.033) = 0.839 and

$$N = \frac{G_{s,N}}{G_s\tau_g\rho_m\alpha_w} = \frac{70{,}000\,\text{W/m}^2}{1000\ \text{W/m}^2 \times 0.839 \times 0.98 \times 0.80} = 106$$ <

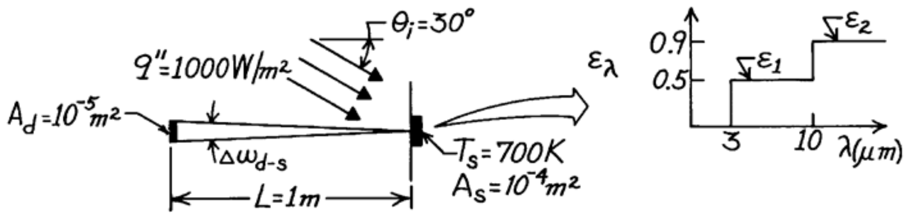
COMMENTS: (1)The first-surface mirror is preferred in order to maximize the irradiation of the target. (2) First-surface mirrors are used in applications involving large radiation heat fluxes, such as in laser processing. Use of a second-surface mirrors might lead to excessive heating of the mirror material (glass) and failure of the mirrors.

PROBLEM 12.54

KNOWN: Temperature and spectral emissivity of a receiving surface. Direction and spectral distribution of incident flux. Distance and aperture of surface radiation detector.

FIND: Radiant power received by the detector.

SCHEMATIC:



ASSUMPTIONS: (1) Target surface is diffuse, (2) $A_d/L^2 << 1$.

ANALYSIS: The radiant power received by the detector depends on emission and reflection from the target.

$$q_d = I_{e+r} A_s \cos\theta_{d-s} \Delta\omega_{d-s}$$

$$q_d = \frac{\varepsilon\sigma T_s^4 + \rho G}{\pi} A_s \frac{A_d}{L^2}$$

$$\varepsilon = \frac{\int_0^\infty \varepsilon_\lambda E_{\lambda b}(700\text{ K})d\lambda}{E_b(700\text{ K})} = \varepsilon_1 F_{(3\to 10\,\mu m)} + \varepsilon_2 F_{(10\to\infty)}.$$

From Table 12.1, $\lambda T = 2100\ \mu m\cdot K$: $F_{(0\to 3\ \mu m)} = 0.0838$

$\lambda T = 7000\ \mu m\cdot K$: $F_{(0\to 10\ \mu m)} = 0.8081$.

The emissivity can be expected as

$$\varepsilon = 0.5(0.8081 - 0.0838) + 0.9(1 - 0.8081) = 0.535.$$

Also,

$$\rho = \frac{\int_0^\infty \rho_\lambda G_\lambda d\lambda}{G} = \frac{\int_0^\infty (1-\varepsilon_\lambda) q''_\lambda d\lambda}{q''} = 1\times F_{(1\to 3\,\mu m)} + 0.5\times F_{(3\to 6\,\mu m)}$$

$$\rho = 1\times 0.4 + 0.5\times 0.6 = 0.70.$$

Hence, with $G = q''\cos\theta_i = 866\ W/m^2$,

$$q_d = \frac{0.535\times 5.67\times 10^{-8}\ W/m^2\cdot K^4 (700\ K)^4 + 0.7\times 866\ W/m^2}{\pi} 10^{-4} m^2 \frac{10^{-5} m^2}{(1m)^2}$$

$$q_d = 2.51\times 10^{-6}\ W.$$ <

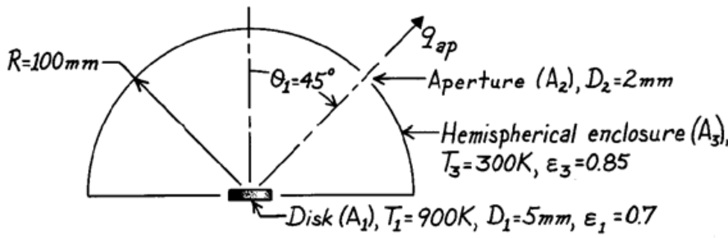
COMMENTS: A total radiation detector cannot discriminate between emitted and reflected radiation from a surface.

PROBLEM 12.55

KNOWN: Small disk positioned at center of an isothermal, hemispherical enclosure with a small aperture.

FIND: Radiant power [μW] leaving the aperture.

SCHEMATIC:



ASSUMPTIONS: (1) Disk is diffuse-gray, (2) Enclosure is isothermal and has area much larger than disk, (3) Aperture area is very small compared to enclosure area, (4) Areas of disk and aperture are small compared to radius squared of the enclosure.

ANALYSIS: The radiant power leaving the aperture is due to radiation leaving the disk and to irradiation on the aperture from the enclosure. That is,

$$q_{ap} = q_{1\to2} + G_2 \cdot A_2. \qquad (1)$$

The radiation leaving the disk can be written in terms of the radiosity of the disk. For the diffuse disk,

$$q_{1\to2} = \frac{1}{\pi} J_1 \cdot A_1 \cos\theta_1 \cdot \omega_{2-1} \qquad (2)$$

and with $\varepsilon = \alpha$ for the gray behavior, the radiosity is

$$J_1 = \varepsilon_1 E_b(T_1) + \rho G_1 = \varepsilon_1 \sigma T_1^4 + (1-\varepsilon_1)\sigma T_3^4 \qquad (3)$$

where the irradiation G_1 is the emissive power of the black enclosure, $E_b(T_3)$; $G_1 = G_2 = E_b(T_3)$. The solid angle ω_{2-1} follows from Eq. 12.7,

$$\omega_{2-1} = A_2 / R^2. \qquad (4)$$

Combining Eqs. (2), (3) and (4) into Eq. (1) with $G_2 = \sigma T_3^4$, the radiant power is

$$q_{ap} = \frac{1}{\pi}\sigma\left[\varepsilon_1 T_1^4 + (1-\varepsilon_1)T_3^4\right]A_1\cos\theta_1 \cdot \frac{A_2}{R^2} + A_2\sigma T_3^4$$

$$q_{ap} = \frac{1}{\pi}5.67\times10^{-8}\frac{\text{W}}{\text{m}^2\cdot\text{K}^4}\left[0.7(900\text{K})^4 + (1-0.7)(300\text{K})^4\right]\frac{\pi}{4}(0.005\text{m})^2\cos45°\times$$

$$\frac{\pi/4(0.002\text{m})^2}{(0.100\text{m})^2} + \frac{\pi}{4}(0.002\text{m})^2\, 5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4(300\text{K})^4$$

$$q_{ap} = (36.2 + 0.19 + 1443)\,\mu\text{W} = 1479\,\mu\text{W}.$$ <

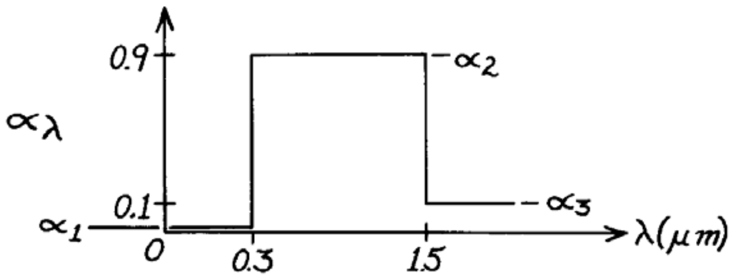
COMMENTS: Note the relative magnitudes of the three radiation components. Also, recognize that the emissivity of the enclosure ε_3 doesn't enter into the analysis. Why?

PROBLEM 12.56

KNOWN: Spectral, hemispherical absorptivity of an opaque surface.

FIND: (a) Solar absorptivity, (b) Total, hemispherical emissivity for T_s = 340K.

SCHEMATIC:



ASSUMPTIONS: (1) Surface is opaque, (2) $\varepsilon_\lambda = \alpha_\lambda$, (3) Solar spectrum has $G_\lambda = G_{\lambda,S}$ proportional to $E_{\lambda,b}$ (λ, 5800K).

ANALYSIS: (a) The solar absorptivity follows from Eq. 12.53.

$$\alpha_S = \int_0^\infty \alpha_\lambda(\lambda) E_{\lambda,b}(\lambda, 5800K) d\lambda / \int_0^\infty E_{\lambda,b}(\lambda, 5800K) d\lambda.$$

The integral can be written in three parts using $F_{(0 \to \lambda)}$ terms.

$$\alpha_S = \alpha_1 F_{(0\to 0.3\mu m)} + \alpha_2 \left[F_{(0\to 1.5\mu m)} - F_{(0\to 0.3\mu m)} \right] + \alpha_3 \left[1 - F_{(0\to 1.5\mu m)} \right].$$

From Table 12.1,

$\lambda T = 0.3 \times 5800 = 1740\ \mu m \cdot K$	$F_{(0 \to 0.3\ \mu m)} = 0.0335$
$\lambda T = 1.5 \times 5800 = 8700\ \mu m \cdot K$	$F_{(0 \to 1.5\ \mu m)} = 0.8805.$

Hence,

$$\alpha_S = 0 \times 0.0355 + 0.9[0.8805 - 0.0335] + 0.1[1 - 0.8805] = 0.774. \quad <$$

(b) The total, hemispherical emissivity for the surface at 340K will be

$$\varepsilon = \int_0^\infty \varepsilon_\lambda(\lambda) E_{\lambda,b}(\lambda, 340K) d\lambda / E_b(340K).$$

If $\varepsilon_\lambda = \alpha_\lambda$, then using the α_λ distribution above, the integral can be written in terms of $F_{(0 \to \lambda)}$ values. It is readily recognized that since

$$F_{(0\to 1.5\,\mu m, 340K)} \approx 0.000 \qquad \text{at} \qquad \lambda T = 1.5 \times 340 = 510\ \mu m \cdot K$$

there is negligible spectral emissive power below 1.5 μm. It follows then that

$$\varepsilon = \varepsilon_\lambda = \alpha_\lambda = 0.1 \quad <$$

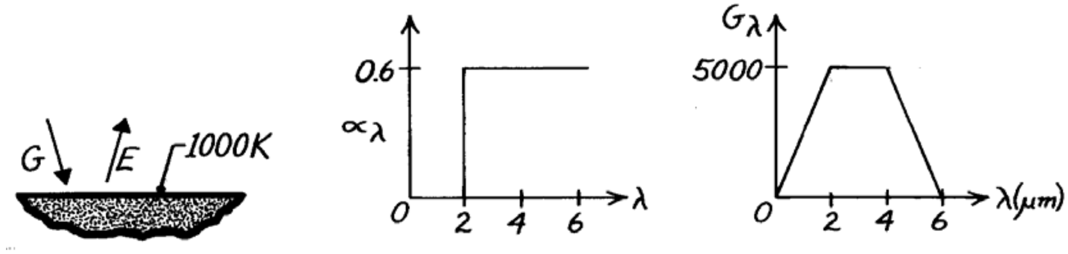
COMMENTS: The assumption $\varepsilon_\lambda = \alpha_\lambda$ can be satisfied if this surface were irradiated diffusely or if the surface itself were diffuse. Note that for this surface under the specified conditions of solar irradiation and surface temperature $\alpha_S \neq \varepsilon$. Such a surface is referred to as a spectrally selective surface.

PROBLEM 12.57

KNOWN: Spectral distribution of the absorptivity and irradiation of a surface at 1000 K.

FIND: (a) Total, hemispherical absorptivity, (b) Total, hemispherical emissivity, (c) Net radiant flux to the surface.

SCHEMATIC:



ASSUMPTIONS: (1) $\alpha_\lambda = \varepsilon_\lambda$.

ANALYSIS: (a) From Eq. 12.52,

$$\alpha = \frac{\int_0^\infty \alpha_\lambda G_\lambda d_\lambda}{\int_0^\infty G_\lambda d_\lambda} = \frac{\int_0^{2\,\mu m} \alpha_\lambda G_\lambda d\lambda + \int_2^{4\,\mu m} \alpha_\lambda G_\lambda d\lambda + \int_4^{6\,\mu m} \alpha_\lambda G_\lambda d\lambda}{\int_0^{2\,\mu m} G_\lambda d\lambda + \int_2^{4\,\mu m} G_\lambda d\lambda + \int_4^{6\,\mu m} G_\lambda d\lambda}$$

$$\alpha = \frac{0 \times 1/2(2-0)5000 + 0.6(4-2)5000 + 0.6 \times 1/2(6-4)5000}{1/2(2-0)5000 + (4-2)(5000) + 1/2(6-4)5000}$$

$$\alpha = \frac{9000}{20,000} = 0.45.$$ <

(b) From Eq. 12.43,

$$\varepsilon = \frac{\int_0^\infty \varepsilon_\lambda E_{\lambda,b} d\lambda}{E_b} = \frac{0\int_0^{2\,\mu m} E_{\lambda,b} d\lambda}{E_b} + \frac{0.6\int_2^\infty E_{\lambda,b} d\lambda}{E_b}$$

$$\varepsilon = 0.6 F_{(2\,\mu m \to \infty)} = 0.6\left[1 - F_{(0 \to 2\,\mu m)}\right].$$

From Table 12.1, with $\lambda T = 2\ \mu m \times 1000K = 2000\ \mu m \cdot K$, find $F_{(0 \to 2\ \mu m)} = 0.0667$. Hence,

$$\varepsilon = 0.6[1 - 0.0667] = 0.56.$$ <

(c) The net radiant heat flux *to* the surface is

$$q''_{rad,net} = \alpha G - E = \alpha G - \varepsilon \sigma T^4$$

$$q''_{rad,net} = 0.45\left(20,000\ W/m^2\right) - 0.56 \times 5.67 \times 10^{-8}\ W/m^2 \cdot K^4 \times (1000K)^4$$

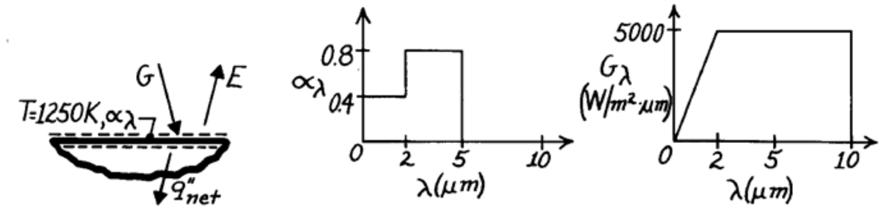
$$q''_{rad,net} = (9000 - 31,751)\ W/m^2 = -22,751\ W/m^2.$$ <

PROBLEM 12.58

KNOWN: Spectral distribution of surface absorptivity and irradiation. Surface temperature.

FIND: (a) Total absorptivity, (b) Emissive power, (c) Nature of surface temperature change.

SCHEMATIC:



ASSUMPTIONS: (1) Opaque, diffuse surface behavior, (2) Convection effects are negligible.

ANALYSIS: (a) From Eqs. 12.51 and 12.52, the absorptivity is defined as

$$\alpha \equiv G_{abs} / G = \int_0^\infty \alpha_\lambda G_\lambda d\lambda \Big/ \int_0^\infty G_\lambda d\lambda.$$

The absorbed irradiation is,

$$G_{abs} = 0.4\left(5000\,W/m^2\cdot\mu m \times 2\,\mu m\right)/2 + 0.8\times 5000\,W/m^2\cdot\mu m\left(5-2\right)\mu m + 0 = 14,000\ W/m^2.$$

The irradiation is,

$$G = \left(2\,\mu m \times 5000\ W/m^2\cdot\mu m\right)/2 + \left(10-2\right)\mu m \times 5000\ W/m^2\cdot\mu m = 45,000\ W/m^2.$$

Hence, $\alpha = 14,000\ W/m^2 / 45,000\ W/m^2 = 0.311.$ <

(b) From Eq. 12.43, the emissivity is

$$\varepsilon = \int_0^\infty \varepsilon_\lambda E_{\lambda,b}\, d\lambda / E_b = 0.4\int_0^2 E_{\lambda,b}\, d\lambda / E_b + 0.8\int_2^5 E_{\lambda,b}\, d\lambda / E_b$$

From Table 12.1, $\lambda T = 2\ \mu m \times 1250K = 2500K$, $F_{(0-2)} = 0.162$

$\lambda T = 5\ \mu m \times 1250K = 6250K$, $F_{(0-5)} = 0.757$.

Hence, $\varepsilon = 0.4\times 0.162 + 0.8\left(0.757 - 0.162\right) = 0.54.$

$$E = \varepsilon E_b = \varepsilon\sigma T^4 = 0.54\times 5.67\times 10^{-8}\ W/m^2\cdot K^4\left(1250K\right)^4 = 74,751\ W/m^2.$$ <

(c) From an energy balance on the surface, the net heat flux *to* the surface is

$$q''_{net} = \alpha G - E = \left(14,000 - 74,751\right) W/m^2 = -60,751\, W/m^2.$$

Hence the temperature of the surface is *decreasing.* <

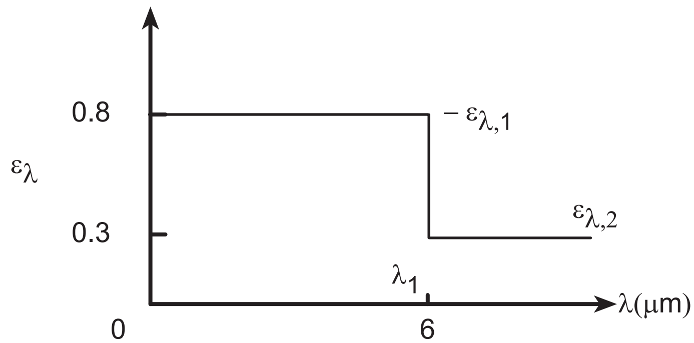
COMMENTS: Note that $\alpha \neq \varepsilon$. Hence the surface is not gray for the prescribed conditions.

PROBLEM 12.59

KNOWN: Spectral emissivity of an opaque, diffuse surface.

FIND: (a) Total, hemispherical emissivity of the surface when maintained at 1000 K, (b) Total, hemispherical absorptivity when irradiated by large surroundings of emissivity 0.8 and temperature 1500 K, (c) Radiosity when maintained at 1000 K and irradiated as prescribed in part (b), (d) Net radiation flux into surface for conditions of part (c), and (e) Compute and plot each of the parameters of parts (a)-(c) as a function of the surface temperature T_s for the range $750 < T_s \leq 2000$ K.

SCHEMATIC:



ASSUMPTIONS: (1) Surface is opaque, diffuse, and (2) Surroundings are large compared to the surface.

ANALYSIS: (a) When the surface is maintained at 1000 K, the total, hemispherical emissivity is evaluated from Eq. 12.43 written as

$$\varepsilon = \int_0^\infty \varepsilon_\lambda E_{\lambda,b}(T)\,d\lambda \big/ E_b(T) = \varepsilon_{\lambda,1}\int_0^{\lambda_1} E_{\lambda,b}(T)\,d\lambda \big/ E_b(T) + \varepsilon_{\lambda,2}\int_{\lambda 1}^\infty E_{\lambda,b}(T)\,d\lambda \big/ E_b(T)$$

$$\varepsilon = \varepsilon_{\lambda,1} F_{(0-\lambda_1 T)} + \varepsilon_{\lambda,2}\left(1 - F_{(0-\lambda_1 T)}\right)$$

where for $\lambda T = 6\mu m \times 1000\ K = 6000\mu m \cdot K$, from Table 12.1, find $F_{0-\lambda T} = 0.738$. Hence,

$$\varepsilon = 0.8 \times 0.738 + 0.3(1 - 0.738) = 0.669. \quad <$$

(b) When the surface is irradiated by large surroundings at $T_{sur} = 1500$ K, $G = E_b(T_{sur})$.
From Eq. 12.52,

$$\alpha = \int_0^\infty \alpha_\lambda G_\lambda\,d\lambda \Big/ \int_0^\infty G_\lambda\,d\lambda = \int_0^\infty \varepsilon_\lambda E_{\lambda,b}(T_{sur})\,d\lambda \big/ E_b(T_{sur})$$

$$\alpha = \varepsilon_{\lambda,1} F_{(0-\lambda_1 T_{sur})} + \varepsilon_{\lambda,2}\left(1 - F_{(0-\lambda_1 T_{sur})}\right)$$

where for $\lambda_1 T_{sur} = 6\ \mu m \times 1500\ K = 9000\ \mu m \cdot K$, from Table 12.1, find $F_{(0-\lambda T)} = 0.890$. Hence,

$$\alpha = 0.8 \times 0.890 + 0.3\,(1 - 0.890) = 0.745. \quad <$$

Note that $\alpha_\lambda = \varepsilon_\lambda$ for all conditions and the emissivity of the surroundings is irrelevant.

(c) The radiosity for the surface maintained at 1000 K and irradiated as in part (b) is

$$J = \varepsilon E_b(T) + \rho G = \varepsilon E_b(T) + (1 - \alpha) E_b(T_{sur})$$

$$J = 0.669 \times 5.67 \times 10^{-8}\ W/m^2 \cdot K^4\ (1000\ K)^4 + (1 - 0.745)\ 5.67 \times 10^{-8}\ W/m^2 \cdot K^4\ (1500\ K)^4$$

$$J = (37{,}932 + 73{,}196)\ W/m^2 = 111{,}128\ W/m^2 \quad <$$

Continued...

PROBLEM 12.59 (Cont.)

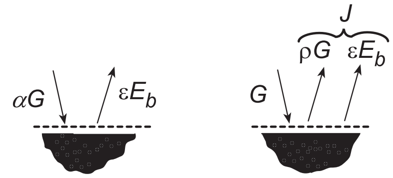
(d) The net radiation flux into the surface with $G = \sigma T_{sur}^4$ is

$$q''_{rad,in} = \alpha G - \varepsilon E_b(T) = G - J$$

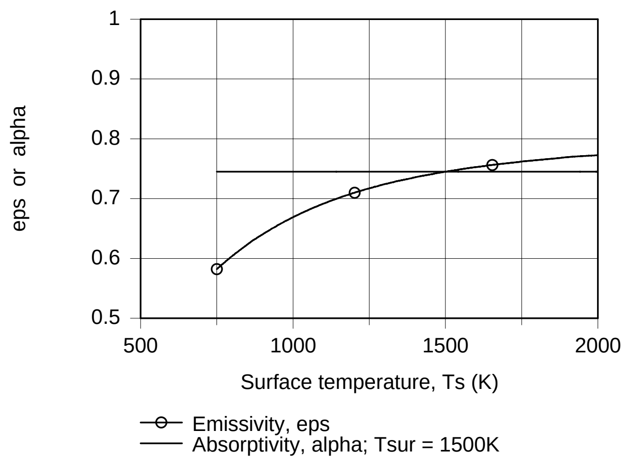
$$q''_{rad,in} = 5.67 \times 10^{-8}\ W/m^2 \cdot K\ (1500\ K)^4 - 111{,}128\ W/m^2$$

$$q''_{rad,in} = 175{,}915\ W/m^2.$$

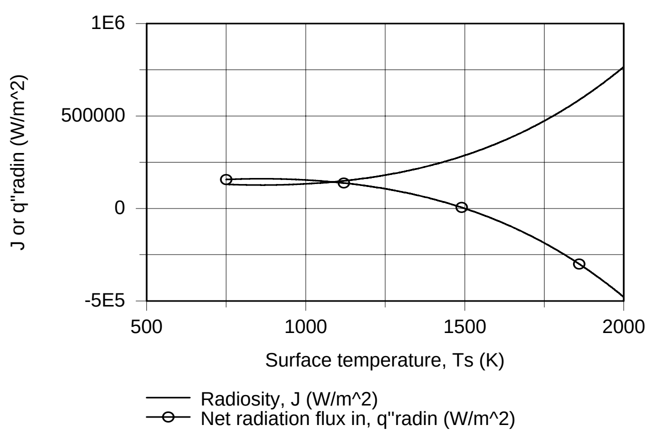
<



(e) The foregoing equations were entered into the IHT workspace along with the *IHT Radiaton Tool, Band Emission Factor,* to evaluate $F_{(0-\lambda T)}$ values and the respective parameters for parts (a)-(d) were computed and are plotted below.



Note that the absorptivity, $\alpha = \alpha(\alpha_\lambda, T_{sur})$, remains constant as T_s changes since it is a function of α_λ (or ε_λ) and Tsur only. The emissivity $\varepsilon = \varepsilon(\varepsilon_\lambda, T_s)$ is a function of T_s and increases as T_s increases. Could you have surmised as much by looking at the spectral emissivity distribution? At what condition is $\varepsilon = \alpha$?



The radiosity, J_1 increases with increasing T_s since $E_b(T)$ increases markedly with temperature; the reflected irradiation, $(1 - \alpha)E_b(T_{sur})$ decreases only slightly as T_s increases compared to $E_b(T)$. Since G is independent of T_s, it follows that the variation of $q''_{rad,in}$ will be due to the radiosity change; note the sign difference.

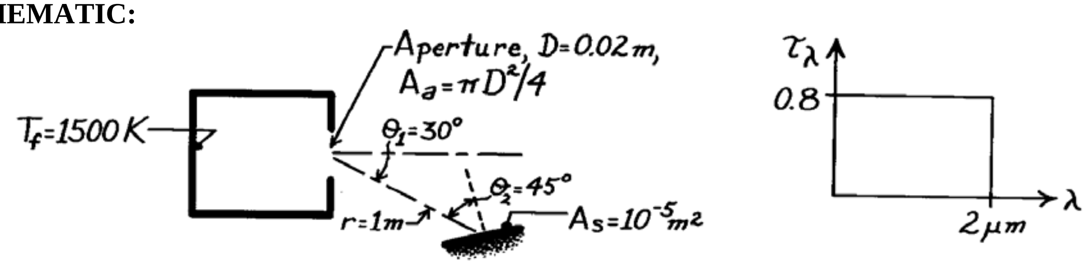
COMMENTS: We didn't use the emissivity of the surroundings (ε = 0.8) to determine the irradiation onto the surface. Why?

PROBLEM 12.60

KNOWN: Furnace wall temperature and aperture diameter. Distance of detector from aperture and orientation of detector relative to aperture.

FIND: (a) Rate at which radiation from the furnace is intercepted by the detector, (b) Effect of aperture window of prescribed spectral transmissivity on the radiation interception rate.

SCHEMATIC:



ASSUMPTIONS: (1) Radiation emerging from aperture has characteristics of emission from a blackbody, (2) Cover material is diffuse, (3) Aperture and detector surface may be approximated as infinitesimally small.

ANALYSIS: (a) From Eq. 12.12, the heat rate leaving the furnace aperture and intercepted by the detector is

$$q = I_e A_a \cos\theta_1 \omega_{s-a}.$$

From Eqs. 12.17 and 12.32

$$I_e = \frac{E_b(T_f)}{\pi} = \frac{\sigma T_f^4}{\pi} = \frac{5.67\times10^{-8}(1500)^4}{\pi} = 9.14\times10^4 \text{ W/m}^2\cdot\text{sr}.$$

From Eq. 12.7,

$$\omega_{s-a} = \frac{A_n}{r^2} = \frac{A_s\cdot\cos\theta_2}{r^2} = \frac{10^{-5}\text{m}^2\times\cos45°}{(1\text{m})^2} = 0.707\times10^{-5}\text{ sr}.$$

Hence

$$q = 9.14\times10^4\text{W/m}^2\cdot\text{sr}\left[\pi(0.02\text{m})^2/4\right]\cos30°\times0.707\times10^{-5}\text{sr} = 1.76\times10^{-4}\text{W}. \quad <$$

(b) With the window, the heat rate is

$$q = \tau\left(I_e A_a \cos\theta_1 \omega_{s-a}\right)$$

where τ is the transmissivity of the window to radiation emitted by the furnace wall. From Eq. 12.61,

$$\tau = \frac{\int_0^\infty \tau_\lambda G_\lambda\, d\lambda}{\int_0^\infty G_\lambda\, d\lambda} = \frac{\int_0^\infty \tau_\lambda E_{\lambda,b}(T_f)\,d\lambda}{\int_0^\infty E_{\lambda,b}\, d\lambda} = 0.8\int_0^2\left(E_{\lambda,b}/E_b\right)d\lambda = 0.8F_{(0\to2\,\mu\text{m})}.$$

With λT = 2 μm × 1500K = 3000 μm·K, Table 12.1 gives $F_{(0\to2\,\mu m)}$ = 0.273. Hence, with τ = 0.273 × 0.8 = 0.218, find

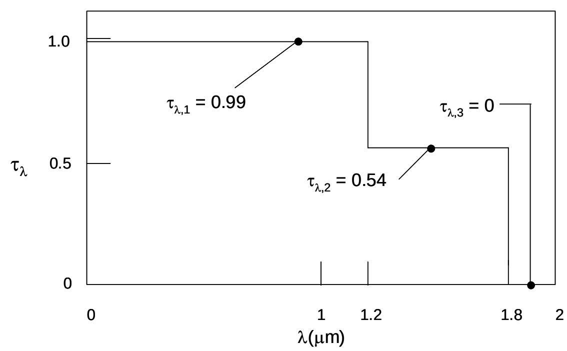
$$q = 0.218\times1.76\times10^{-4}\text{W} = 0.384\times10^{-4}\text{W}. \quad <$$

PROBLEM 12.61

KNOWN: Approximate spectral transmissivity of 1-mm thick liquid water layer.

FIND: (a) Transmissivity of a 1-mm thick water layer adjacent to surface at the critical temperature (T_s = 647.3 K), (b) Transmissivity of a 1-mm thick water layer subject to irradiation from a melting platinum wire (T_s = 2045 K), (c) Transmissivity of a 1-mm thick water layer subject to solar irradiation at T_s = 5800 K.

SCHEMATIC:



ASSUMPTIONS: Irradiation is proportional to that of a blackbody.

ANALYSIS: From Eq. 12.61 and incorporating the assumption, the transmissivity is expressed as

$$\tau = \frac{\int_0^\infty \tau_\lambda E_{\lambda,b} d\lambda}{E_b} = \frac{\tau_{\lambda,1}\int_0^{1.2} E_{\lambda,b} d\lambda}{E_b} + \frac{\tau_{\lambda,2}\int_{1.2}^{1.8} E_{\lambda,b} d\lambda}{E_b} + \frac{\tau_{\lambda,3}\int_{1.8}^{\infty} E_{\lambda,b} d\lambda}{E_b} \quad \text{or}$$

$$\tau = \tau_{\lambda,1} F_{(0-1.2\mu m)} + \tau_{\lambda,2} F_{(1.2-1.8\mu m)} + \tau_{\lambda,3} F_{(1.8\mu m-\infty)}$$

where $F_{(1.2 - 1.8\mu m)} = F_{(0 - 1.8\mu m)} - F_{(0 - 1.2\mu m)}$ and $F_{(1.8\mu m - \infty)} = 1 - F_{(0 - 1.2\mu m)} - F_{(1.2 - 1.8\mu m)}$

(a) For a source temperature of 647.3 K,

$F_{(0 - 1.2\mu m)} = 1.414 \times 10^{-5}$, $F_{(0 - 1.8\mu m)} = 0.001818$

$\tau = 0.99 \times 1.414 \times 10^{-5} + 0.54 \times (0.001818 - 1.414 \times 10^{-5}) = 0.00099$ <

(b) For a source temperature of 2045 K,

$F_{(0 - 1.2\mu m)} = 0.1518$, $F_{(0 - 1.8\mu m)} = 0.4197$

$\tau = 0.99 \times 0.1518 + 0.54 \times (0.4197 - 0.1518) = 0.295$ <

(c) For a source temperature of 5800 K,

$F_{(0 - 1.2\mu m)} = 0.8057$, $F_{(0 - 1.8\mu m)} = 0.9226$

$\tau = 0.99 \times 0.8057 + 0.54 \times (0.9226 - 0.8057) = 0.861$ <

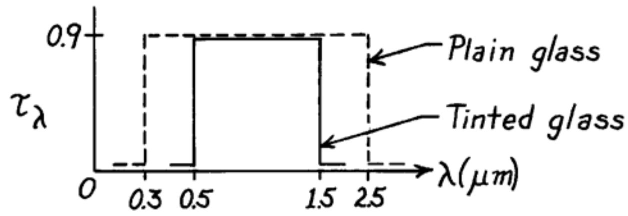
COMMENTS: Liquid water may be treated as opaque for most engineering applications. Exceptions include applications involving solar irradiation, irradiation from very high temperature plasmas that can achieve temperatures at tens of thousands of kelvins, and situations involving very thin layers of liquid water.

PROBLEM 12.62

KNOWN: Spectral transmissivity of a plain and tinted glass.

FIND: (a) Solar energy transmitted by each glass, (b) Visible radiant energy transmitted by each with solar irradiation.

SCHEMATIC:



ASSUMPTIONS: (1) Spectral distribution of solar irradiation is proportional to spectral emissive power of a blackbody at 5800K.

ANALYSIS: To compare the energy transmitted by the glasses, it is sufficient to calculate the transmissivity of each glass for the prescribed spectral range when the irradiation distribution is that of the solar spectrum. From Eq. 12.61,

$$\tau_S = \int_0^\infty \tau_\lambda \cdot G_{\lambda,S} d\lambda / \int_0^\infty G_{\lambda,S} d\lambda = \int_0^\infty \tau_\lambda \cdot E_{\lambda,b}(\lambda, 5800K) d\lambda / E_b(5800K).$$

Recognizing that τ_λ will be constant for the range $\lambda_1 \to \lambda_2$, using Eq. 12.29, find

$$\tau_S = \tau_\lambda \cdot F_{(\lambda_1 \to \lambda_2)} = \tau_\lambda \left[F_{(0\to\lambda_2)} - F_{(0\to\lambda_1)} \right].$$

(a) For the two glasses, the solar transmissivity, using Table 12.1 for F, is then

Plain glass: $\lambda_2 = 2.5\ \mu m$ $\lambda_2 T = 2.5\ \mu m \times 5800K = 14,500\ \mu m \cdot K$ $F_{(0\to\lambda 2)} = 0.966$

$\lambda_1 = 0.3\ \mu m$ $\lambda_1 T = 0.3\ \mu m \times 5800K = 1,740\ \mu m \cdot K$ $F_{(0\to\lambda_1)} = 0.033$

$\tau_S = 0.9\ [0.966 - 0.033] = 0.839.$ <

Tinted glass: $\lambda_2 = 1.5\ \mu m$ $\lambda_2 T = 1.5\ \mu m \times 5800K = 8,700\ \mu m \cdot K$ $F_{(0\to\lambda_2)} = 0.881$

$\lambda_1 = 0.5\ \mu m$ $\lambda_1 T = 0.5\ \mu m \times 5800K = 2,900\ \mu m \cdot K$ $F_{(0\to\lambda_1)} = 0.250$

$\tau_S = 0.9\ [0.881 - 0.250] = 0.568.$ <

(b) The limits of the visible spectrum are $\lambda_1 = 0.4$ and $\lambda_2 = 0.7\ \mu m$. For the tinted glass, $\lambda_1 = 0.5\ \mu m$ rather than 0.4 μm. From Table 12.1,

$\lambda_2 = 0.7\ \mu m$ $\lambda_2 T = 0.7\ \mu m \times 5800K = 4,060\ \mu m \cdot K$ $F_{(0\to\lambda_2)} = 0.491$

$\lambda_1 = 0.5\ \mu m$ $\lambda_1 T = 0.5\ \mu m \times 5800K = 2,900\ \mu m \cdot K$ $F_{(0\to\lambda_1)} = 0.250$

$\lambda_1 = 0.4\ \mu m$ $\lambda_1 T = 0.4\ \mu m \times 5800K = 2,320\ \mu m \cdot K$ $F_{(0\to\lambda_1)} = 0.125$

Plain glass: $\tau_{vis} = 0.9\ [0.491 - 0.125] = 0.329$ <

Tinted glass: $\tau_{vis} = 0.9\ [0.491 - 0.250] = 0.217$ <

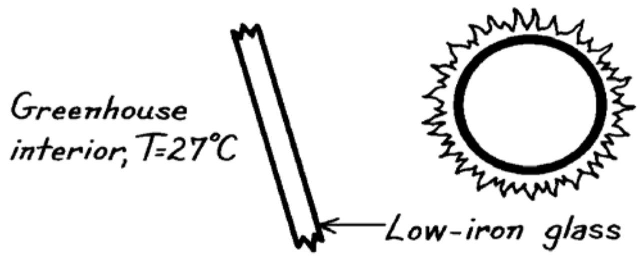
COMMENTS: For solar energy, the transmissivities are 0.839 for the plain glass vs. 0.568 for the tinted glass. Within the visible region, τ_{vis} is 0.329 vs. 0.217. Tinting reduces solar flux by 32% and visible solar flux by 34%.

PROBLEM 12.63

KNOWN: Spectral transmissivity of low iron glass (see Fig. 12.23).

FIND: Interpretation of the greenhouse effect.

SCHEMATIC:



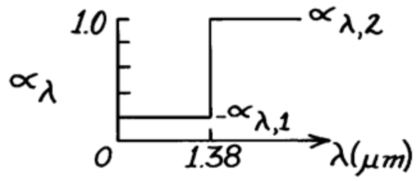
ANALYSIS: The glass affects the net radiation transfer to the contents of the greenhouse. Since most of the solar radiation is in the spectral region $\lambda < 3\ \mu m$, the glass will transmit a large fraction of this radiation. However, the contents of the greenhouse, being at a comparatively low temperature, emit most of their radiation in the medium to far infrared. This radiation is not transmitted by the glass. Hence the glass allows short wavelength solar radiation to enter the greenhouse, but does not permit long wavelength radiation to leave.

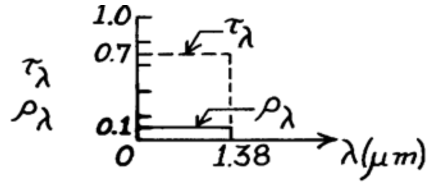
PROBLEM 12.64

KNOWN: Spectrally selective, diffuse surface exposed to solar irradiation.

FIND: (a) Spectral transmissivity, τ_λ, (b) Transmissivity, τ_S, reflectivity, ρ_S, and absorptivity, α_S, for solar irradiation, (c) Emissivity, ε, when surface is at T_s = 350K, (d) Net heat flux by radiation to the surface.

SCHEMATIC:





ASSUMPTIONS: (1) Surface is diffuse, (2) Spectral distribution of solar irradiation is proportional to $E_{\lambda,b}$ (λ, 5800K).

ANALYSIS: (a) Conservation of radiant energy requires, according to Eq. 12.54, that $\rho_\lambda + \alpha_\lambda + \tau_\lambda$ =1 or $\tau_\lambda = 1 - \rho_\lambda - \alpha_\lambda$. Hence, the spectral transmissivity appears as shown above (dashed line). Note that the surface is opaque for λ > 1.38 μm.

(b) The transmissivity to solar irradiation, G_S, follows from Eq. 12.61,

$$\tau_S = \int_0^\infty \tau_\lambda G_{\lambda,S} d\lambda / G_S = \int_0^\infty \tau_\lambda E_{\lambda,b}(\lambda, 5800K) d\lambda / E_b(5800K)$$

$$\tau_S = \tau_{\lambda,b} \int_0^{1.38} E_{\lambda,b}(\lambda, 5800K) d\lambda / E_b(5800K) = \tau_{\lambda,1} F_{(0\to\lambda_1)} = 0.7 \times 0.856 = 0.599 \qquad <$$

where $\lambda_1 T_S$ = 1.38 × 5800 = 8000 μm·K and from Table 12.1, $F_{(0\to\lambda_1)}$ = 0.856. From Eqs. 12.58 and 12.63,

$$\rho_S = \int_0^\infty \rho_\lambda G_{\lambda,S} d\lambda / G_S = \rho_{\lambda,1} F_{(0\to\lambda_1)} = 0.1 \times 0.856 = 0.086 \qquad <$$

$$\alpha_S = 1 - \rho_S - \tau_S = 1 - 0.086 - 0.599 = 0.315. \qquad <$$

(c) For the surface at T_s = 350K, the emissivity can be determined from Eq. 12.43. Since the surface is diffuse, according to Eq. 12.67, $\alpha_\lambda = \varepsilon_\lambda$, the expression has the form

$$\varepsilon = \int_0^\infty \varepsilon_\lambda E_{\lambda,b}(T_s) d\lambda / E_b(T_s) = \int_0^\infty \alpha_\lambda E_{\lambda,b}(350K) d\lambda / E_b(350K)$$

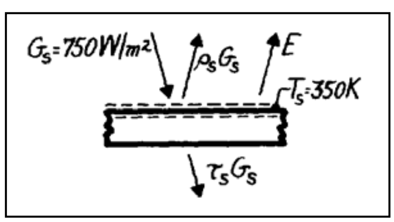
$$\varepsilon = \alpha_{\lambda,1} F_{(0-1.38\,\mu m)} + \alpha_{\lambda,2}\left[1 - F_{(0-1.38\,\mu m)}\right] = \alpha_{\lambda,2} = 1 \qquad <$$

where from Table 12.1 with $\lambda_1 T_S$ = 1.38 × 350 = 483 μm·K, $F_{(0-\lambda T)} \approx 0$.

(d) The net heat flux by radiation *to* the surface is determined by a radiation balance

$$q''_{rad} = G_S - \rho_S G_S - \tau_S G_S - E$$

$$q''_{rad} = \alpha_S G_S - E$$



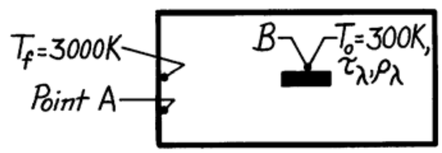
$$q''_{rad} = 0.315 \times 750\ W/m^2 - 1.0 \times 5.67 \times 10^{-8}\ W/m^2 \cdot K^4 (350K)^4 = -615\ W/m^2. \qquad <$$

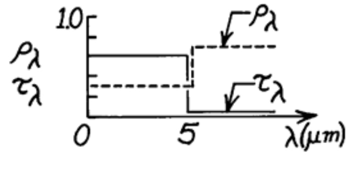
PROBLEM 12.65

KNOWN: Large furnace with diffuse, opaque walls (T_f, ε_f) and a small diffuse, spectrally selective object (T_o, τ_λ, ρ_λ).

FIND: For points on the furnace wall and the object, find ε, α, E, G and J.

SCHEMATIC:





ASSUMPTIONS: (1) Furnace walls are isothermal, diffuse, and gray, (2) Object is isothermal and diffuse.

ANALYSIS: Consider first the furnace wall (A). Since the wall material is diffuse and gray, it follows that

$$\varepsilon_A = \varepsilon_f = \alpha_A = 0.85. \qquad <$$

The emissive power is

$$E_A = \varepsilon_A E_b(T_f) = \varepsilon_A \sigma T_f = 0.85 \times 5.67 \times 10^{-8}\ W/m^2 \cdot K^4 (3000\ K)^4 = 3.904 \times 10^6\ W/m^2. \qquad <$$

Since the furnace is an isothermal enclosure, blackbody conditions exist such that

$$G_A = J_A = E_b(T_f) = \sigma T_f^4 = 5.67 \times 10^{-8} W/m^2 \cdot K^4 (3000 K)^4 = 4.593 \times 10^6\ W/m^2. \qquad <$$

Considering now the semitransparent, diffuse, spectrally selective object at T_o = 300 K. From the radiation balance requirement, find

$$\alpha_\lambda = 1 - \rho_\lambda - \tau_\lambda \quad \text{or} \quad \alpha_1 = 1 - 0.6 - 0.3 = 0.1 \quad \text{and} \quad \alpha_2 = 1 - 0.7 - 0.0 = 0.3$$

$$\alpha_B = \int_0^\infty \alpha_\lambda G_\lambda d\lambda / G = F_{0-\lambda T} \cdot \alpha_1 + (1 - F_{0-\lambda T}) \cdot \alpha_2 = 0.970 \times 0.1 + (1 - 0.970) \times 0.3 = 0.106 \qquad <$$

where $F_{0-\lambda T}$ = 0.970 at λT = 5 μm × 3000 K = 15,000 μm·K since G = $E_b(T_f)$. Since the object is diffuse, $\varepsilon_\lambda = \alpha_\lambda$, hence

$$\varepsilon_B = \int_0^\infty \varepsilon_\lambda E_{\lambda,b}(T_o) d\lambda / E_{b,o} = F_{0-\lambda T}\alpha_1 + (1 - F_{0-\lambda T}) \cdot \alpha_2 = 0.0138 \times 0.1 + (1 - 0.0138) \times 0.3 = 0.297 \qquad <$$

where $F_{0-\lambda T}$ = 0.0138 at λT = 5 μm × 300 K = 1500 μmK. The emissive power is

$$E_B = \varepsilon_B E_{b,B}(T_o) = 0.297 \times 5.67 \times 10^{-8} W/m^2 \cdot K^4 (300\ K)^4 = 136.5\ W/m^2. \qquad <$$

The irradiation is that due to the large furnace for which blackbody conditions exist,

$$G_B = G_A = \sigma T_f^4 = 4.593 \times 10^6\ W/m^2. \qquad <$$

The radiosity leaving point B is due to emission and reflected irradiation,

$$J_B = E_B + \rho_B G_B = 136.5\ W/m^2 + 0.3 \times 4.593 \times 10^6\ W/m^2 = 1.378 \times 10^6\ W/m^2. \qquad <$$

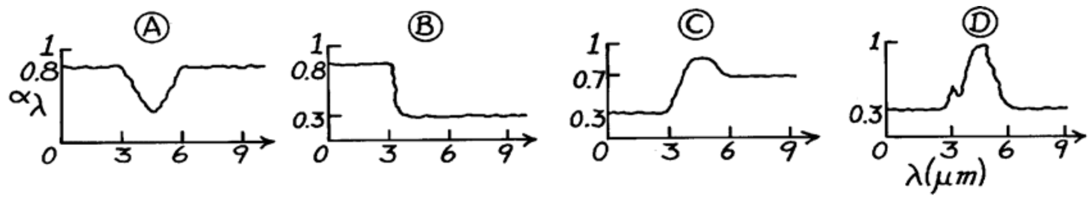
If we include transmitted irradiation, $J_B = E_B + (\rho_B + \tau_B) G_B = E_B + (1 - \alpha_B) G_B = 4.106 \times 10^6\ W/m^2$. In the first calculation, note how we set $\rho_B \approx \rho_\lambda$ (λ < 5 μm).

PROBLEM 12.66

KNOWN: Spectral characteristics of four diffuse surfaces exposed to solar radiation.

FIND: Surfaces which may be assumed to be gray.

SCHEMATIC:



ASSUMPTIONS: (1) Diffuse surface behavior.

ANALYSIS: A gray surface is one for which α_λ and ε_λ are constant over the spectral regions of the irradiation and the surface emission.

For λ = 3 μm and T = 5800K, λT = 17,400 μm·K and from Table 12.1, find $F_{(0 \to \lambda)} = 0.984$. Hence, 98.4% of the solar radiation is in the spectral region below 3 μm.

For λ = 6 μm and T = 300K, λT = 1800 μm·K and from Table 12.1, find $F_{(0 \to \lambda)} = 0.039$. Hence, 96.1% of the surface emission is in the spectral region above 6 μm.

Hence: Surface A is gray: $\alpha_S \approx \varepsilon = 0.8$ <

Surface B is not gray: $\alpha_S \approx 0.8$, $\varepsilon \approx 0.3$ <

Surface C is not gray: $\alpha_S \approx 0.3$, $\varepsilon \approx 0.7$ <

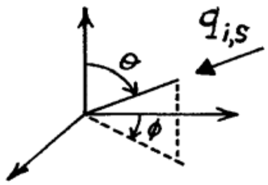
Surface D is gray: $\alpha_S \approx \varepsilon = 0.3$. <

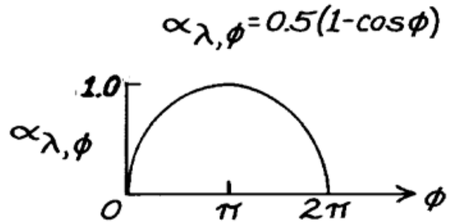
PROBLEM 12.67

KNOWN: A gray, but directionally selective, material with α (θ, ϕ) = 0.5(1 - cosϕ).

FIND: (a) Hemispherical absorptivity when irradiated with collimated solar flux in the direction (θ = 45° and ϕ = 0°) and (b) Hemispherical emissivity of the material.

SCHEMATIC:





ASSUMPTIONS: (1) Gray surface behavior.

ANALYSIS: (a) The surface has the directional absorptivity given as

$$\alpha(\theta,\phi) = \alpha_{\lambda,\phi} = 0.5[1-\cos\phi].$$

When irradiated in the direction θ = 45° and ϕ = 0°, the directional absorptivity for this condition is

$$\alpha(45°, 0°) = 0.5\left[1-\cos(0°)\right] = 0.$$ <

That is, the surface is completely reflecting (or transmitting) for irradiation in this direction.

(b) From Kirchhoff's law, Eq. 12.68

$$\alpha_{\theta,\phi} = \varepsilon_{\theta,\phi}$$

so that

$$\varepsilon_{\theta,\phi} = \alpha_{\theta,\phi} = 0.5(1-\cos\phi).$$

Using Eq. 12.41 find

$$\varepsilon = \frac{\int_0^{2\pi}\int_0^{\pi/2} \varepsilon_{\theta,\phi,\lambda} \cos\theta \sin\theta \, d\theta \, d\phi}{\int_0^{2\pi}\int_0^{\pi/2} \cos\theta \sin\theta \, d\theta \, d\phi}$$

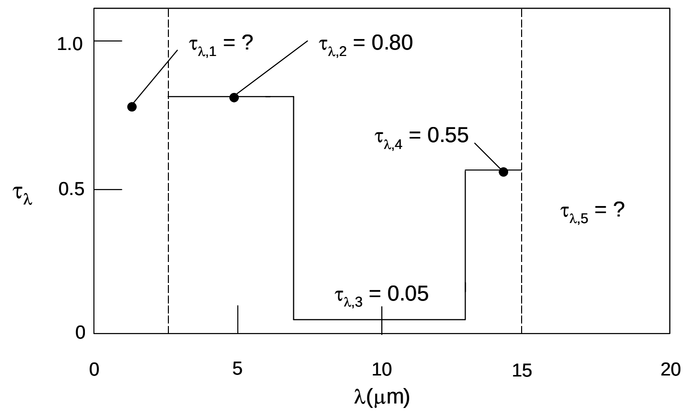
$$\varepsilon = \frac{\int_0^{2\pi} 0.5(1-\cos\phi)\, d\phi}{\int_0^{2\pi} d\phi} = \left.\frac{0.5(\phi - \sin\phi)}{2\pi}\right|_0^{2\pi} = 0.5.$$ <

PROBLEM 12.68

KNOWN: Approximate spectral transmissivity of polymer film over the range 2.5 μm ≤ λ ≤ 15 μm.

FIND: (a) Maximum possible total transmissivity for irradiation from blackbody at 30°C, (b) Minimum possible total transmissivity for irradiation from blackbody at 30°C, (c) Maximum and minimum possible total transmissivities for a source temperature of 600°C.

SCHEMATIC:



ASSUMPTIONS: (1) Irradiation is proportional to that of a blackbody.

ANALYSIS: (a) The maximum possible total transmissivity is associated with $\tau_{\lambda,1} = \tau_{\lambda,5} = 1$. From Eq. 12.61 and incorporating the assumption, the total transmissivity is written as

$$\tau = \frac{\int_0^\infty \tau_\lambda E_{\lambda,b} d\lambda}{E_b} = \frac{\tau_{\lambda,1}\int_0^{2.5} E_{\lambda,b} d\lambda}{E_b} + \frac{\tau_{\lambda,2}\int_{2.5}^{7} E_{\lambda,b} d\lambda}{E_b}$$
$$+\frac{\tau_{\lambda,3}\int_{7}^{13} E_{\lambda,b} d\lambda}{E_b} + \frac{\tau_{\lambda,4}\int_{13}^{15} E_{\lambda,b} d\lambda}{E_b} + \frac{\tau_{\lambda,5}\int_{15}^{\infty} E_{\lambda,b} d\lambda}{E_b}$$

or

$$\tau = \tau_{\lambda,1}F_{(0-2.5\mu m)} + \tau_{\lambda,2}F_{(2.5-7\mu m)} + \tau_{\lambda,3}F_{(7-13\mu m)} + \tau_{\lambda,4}F_{(13-15\mu m)} + \tau_{\lambda,5}F_{(15\mu m-\infty)}$$

where, at T_s = 30°C + 273 K = 303 K,

$$F_{(2.5-7\mu m)} = F_{(0-7\mu m)} - F_{(0-2.5\mu m)} = 0.08739 - 1.26\times10^{-5} = 0.08738$$
$$F_{(7-13\mu m)} = F_{(0-13\mu m)} - F_{(0-7\mu m)} = 0.4694 - 0.008739 = 0.3820$$
$$F_{(13-15\mu m)} = F_{(0-15\mu m)} - F_{(0-13\mu m)} = 0.5709 - 0.4694 = 0.1015$$
$$F_{(15\mu m-\infty)} = 1 - F_{(0-15\mu m)} = 1 - 0.5709 = 0.4291$$

Therefore,

Continued…

PROBLEM 12.68 (Cont.)

$\tau_{max} = 1 \times 1.26 \times 10^{-5} + 0.80 \times 0.08738 + 0.05 \times 0.3820 + 0.55 \times 0.1015 + 1 \times 0.4291 = 0.574$ <

(b) The minimum possible total transmissivity is associated with $\tau_{\lambda,1} = \tau_{\lambda,5} = 0$. Hence,

$\tau_{min} = 0 \times 1.26 \times 10^{-5} + 0.80 \times 0.08738 + 0.05 \times 0.3820 + 0.55 \times 0.1015 + 0 \times 0.4291 = 0.145$ <

(c) at T_s = 600°C + 273 K = 873 K,

$$F_{(2.5-7\mu m)} = F_{(0-7\mu m)} - F_{(0-2.5\mu m)} = 0.7469 - 0.0979 = 0.6490$$
$$F_{(7-13\mu m)} = F_{(0-13\mu m)} - F_{(0-7\mu m)} = 0.9375 - 0.7469 = 0.1906$$
$$F_{(13-15\mu m)} = F_{(0-15\mu m)} - F_{(0-13\mu m)} = 0.9559 - 0.9375 = 0.0184$$
$$F_{(15\mu m-\infty)} = 1 - F_{(0-15\mu m)} = 1 - 0.9559 = 0.0441$$

Therefore,

$\tau_{max} = 1 \times 0.0979 + 0.80 \times 0.6490 + 0.05 \times 0.1906 + 0.55 \times 0.0184 + 1 \times 0.0441 = 0.681$ <

The minimum possible total transmissivity is associated with $\tau_{\lambda,1} = \tau_{\lambda,5} = 0$. Hence,

$\tau_{min} = 0 \times 0.0979 + 0.80 \times 0.6490 + 0.05 \times 0.1906 + 0.55 \times 0.0184 + 0 \times 0.0441 = 0.539$ <

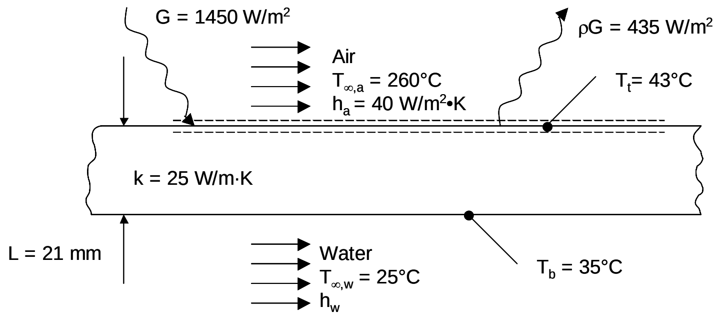
COMMENTS: (1) For irradiation from the low temperature source, 43% of the irradiation is in the wavelength range greater that 15 μm. Since the spectral transmissivity is not known in this wavelength range, there is a very large uncertainty regarding the total transmissivity of the polymer film. (2) For irradiation from the high temperature source, 9.8% + 4.4% = 14.4% of the irradiation is in wavelength ranges less than 2.5 μm and greater than 15 μm. Hence, the uncertainty of the total transmissivity of the polymer film is significantly smaller than that associated with the low temperature source. (3) A source temperature exists for which the uncertainty in the total transmissivity is minimum. This temperature is between 30°C and 600°C. Why?

PROBLEM 12.69

KNOWN: Thickness, thermal conductivity and surface temperatures of a flat plate. Irradiation on the top surface, reflected irradiation, air and water temperatures, air convection coefficient.

FIND: Transmissivity, reflectivity, absorptivity, and emissivity of the plate. Radiosity of the surface. Convection coefficient associated with the water flow.

SCHEMATIC:



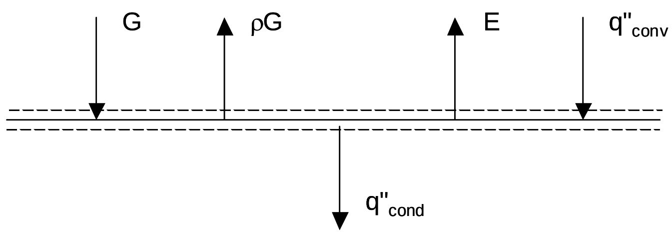
ASSUMPTIONS: (1) Opaque and diffuse surface, (2) Water is opaque to thermal radiation.

ANALYSIS: The plate is opaque. Therefore, $\tau = 0$ <

The reflectivity is $\rho = \rho G/G = (435\ \text{W/m}^2)/(1450\ \text{W/m}^2) = 0.3$ <

The absorptivity is $\alpha = 1 - \tau - \rho = 1 - 0 - 0.3 = 0.7$ <

Consider an energy balance on the top surface.



$q''_{cond} = G + q''_{conv} - \rho G - E$ where $E = \varepsilon\sigma T_s^4$. Rearranging, we see that

$$\varepsilon = (G + q''_{conv} - \rho G - q''_{cond})/(\sigma T_t^4)$$

$$= \frac{\begin{bmatrix} 1450\ \text{W/m}^2 + 40\text{W/m}^2\cdot\text{K}\times(260 - 43)°\text{C} - 435\text{W/m}^2 \\ - 25\text{W/m}\cdot\text{K}\times(43 - 35)°\text{C}/0.021\text{m} \end{bmatrix}}{5.67\times10^{-8}\text{W/m}^2\cdot\text{K}^4 \times (273+43)^4\ \text{K}^4} = 0.303$$ <

Since $\alpha \neq \varepsilon$, the plate is not gray. <

Continued…

PROBLEM 12.69 (Cont.)

The radiosity associated with the top surface is

$$J = E + \rho G = 0.303 \times 5.67 \times 10^{-8}\ W/m^2\cdot K^4 \times (273 + 43)^4\ K^4 + 435\ W/m^2 = 606\ W/m^2 \quad <$$

Consider an energy balance on the bottom surface with $q''_{cond} = q''_{conv}$ which yields

$$h_w = k(T_t - T_b)/[L(T_b - T_{\infty,w})]$$
$$= [25\ W/m\cdot K \times (43 - 35)°C]/[0.021m \times (35 - 25)°C] = 952\ W/m^2\cdot K. \quad <$$

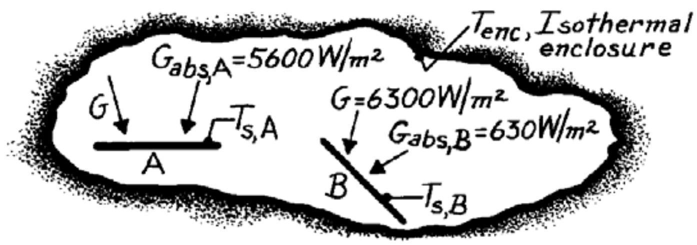
COMMENTS: (1) The calculated emissivity is extremely sensitive to the plate thickness. Conduction through the plate is much larger than the emission; small changes in the conduction heat flux result in very large changes in the calculated emission. For example, reducing the plate thickness to 20 mm yields a negative emissivity, while increasing the plate thickness to 22 mm yields an emissivity greater than unity. In reality, as the plate thickness is modified, the surface temperatures would also change.

PROBLEM 12.70

KNOWN: Isothermal enclosure at a uniform temperature provides a known irradiation on two small surfaces whose absorption rates have been measured.

FIND: (a) Net heat transfer rates and temperatures of the two surfaces, (b) Absorptivity of the surfaces, (c) Emissive power of the surfaces, (d) Emissivity of the surfaces.

SCHEMATIC:



ASSUMPTIONS: (1) Enclosure is at a uniform temperature and large compared to surfaces A and B, (2) Surfaces A and B have been in the enclosure a long time, (3) Irradiation to both surfaces is the same.

ANALYSIS: (a) Since the surfaces A and B have been within the enclosure a long time, thermal equilibrium conditions exist. That is,

$$q_{A,net} = q_{B,net} = 0.$$

Furthermore, the surface temperatures are the same as the enclosure, $T_{s,A} = T_{s,B} = T_{enc}$. Since the enclosure is at a uniform temperature, it follows that blackbody radiation exists within the enclosure (see Fig. 12.11) and

$$G = E_b\left(T_{enc}\right) = \sigma T_{enc}^4$$

$$T_{enc} = \left(G/\sigma\right)^{1/4} = \left(6300\,W/m^2 / 5.67\times10^{-8}\,W/m^2\cdot K^4\right)^{1/4} = 577.4K. \qquad <$$

(b) From Eq. 12.51, the absorptivity is G_{abs}/G,

$$\alpha_A = \frac{5600\ W/m^2}{6300\ W/m^2} = 0.89 \qquad \alpha_B = \frac{630\ W/m^2}{6300\ W/m^2} = 0.10. \qquad <$$

(c) Since the surfaces experience zero net heat transfer, the energy balance is $G_{abs} = E$. That is, the absorbed irradiation is equal to the emissive power,

$$E_A = 5600\ W/m^2 \qquad E_B = 630\ W/m^2. \qquad <$$

(d) The emissive power, E(T), is written as

$$E = \varepsilon E_b\left(T\right) = \varepsilon\sigma T^4 \qquad \text{or} \qquad \varepsilon = E/\sigma T^4.$$

Since the temperature of the surfaces and the emissive powers are known,

$$\varepsilon_A = 5600\ W/m^2 / \left[5.67\times10^{-8}\frac{W}{m^2\cdot K^4}\left(577.4K\right)^4\right] = 0.89 \qquad \varepsilon_B = 0.10. \qquad <$$

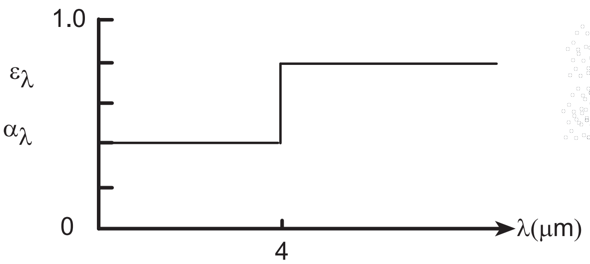
COMMENTS: Note for this equilibrium condition, $\varepsilon = \alpha$.

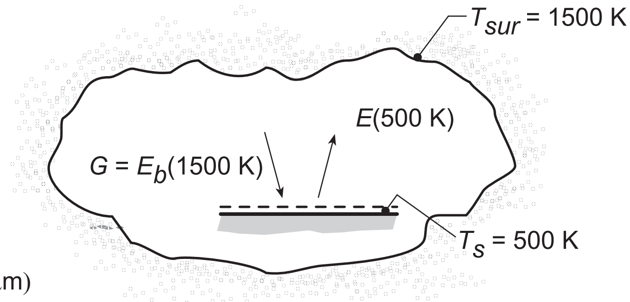
PROBLEM 12.71

KNOWN: Temperature and spectral characteristics of a diffuse surface at T_s = 500 K situated in a large enclosure with uniform temperature, T_{sur} = 1500 K.

FIND: (a) Sketch of spectral distribution of E_λ and $E_{\lambda,b}$ for the surface, (b) Net heat flux to the surface, $q''_{rad,in}$ (c) Compute and plot $q''_{rad,in}$ as a function of T_s for the range $500 \le T_s \le 1000$ K; also plot the heat flux for a diffuse, gray surface with total emissivities of 0.4 and 0.8; and (d) Compute and plot ε and α as a function of the surface temperature for the range $500 \le T_s \le 1000$ K.

SCHEMATIC:

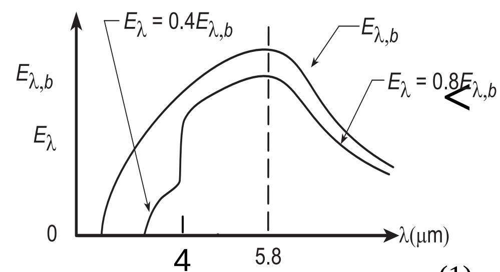




ASSUMPTIONS: (1) Surface is diffuse, (2) Convective effects are negligible, (3) Surface irradiation corresponds to blackbody emission at 1500 K.

ANALYSIS: (a) From Wien's displacement law, Eq. 12.31, $\lambda_{max} T$ = 2898 μm·K. Hence, for blackbody emission from the surface at T_s = 500 K,

$$\lambda_{max} = \frac{2898 \mu m \cdot K}{500 \text{ K}} = 5.80 \mu m .$$



<

(b) From an energy balance on the surface, the net heat flux to the surface is

$$q''_{rad,in} = \alpha G - E = \alpha E_b(1500 \text{ K}) - \varepsilon E_b(500 \text{ K}). \quad (1)$$

From Eq. 12.52,

$$\alpha = 0.4\int_0^4 \frac{E_{\lambda,b}(1500)}{E_b} d\lambda + 0.8\int_4^\infty \frac{E_{\lambda,b}(1500)}{E_b} d\lambda = 0.4 F_{(0-4\mu m)} - 0.8[1 - F_{(0-4\mu m)}].$$

From Table 12.1 with λT = 4μm × 1500 K = 6000 μm·K, $F_{(0-4)}$ = 0.738, find

$$\alpha = 0.4 \times 0.738 + 0.8\,(1 - 0.738) = 0.505.$$

From Eq. 12.43

$$\varepsilon = 0.4\int_0^4 \frac{E_{\lambda,b}(500)}{E_b} d\lambda + 0.8\int_4^\infty \frac{E_{\lambda,b}(500)}{E_b} d\lambda = 0.4 F_{(0-4\mu m)} + 0.8[1 - F_{(0-4\mu m)}].$$

From Table 12.1 with λT = 4μm × 500 K = 2000 μm·K, $F_{(0-4)}$ = 0.0667, find

$$\varepsilon = 0.4 \times 0.0667 + 0.8\,(1 - 0.0667) = 0.773.$$

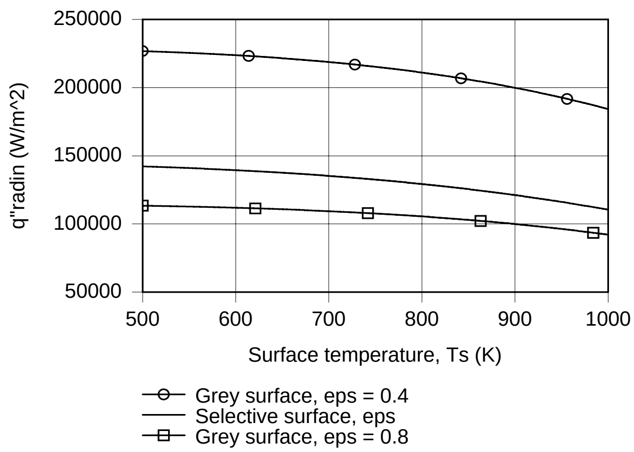
Hence, the net heat flux to the surface is

$$q''_{rad,in} = 5.67\times10^{-8}\, W/m^2 \cdot K^4 [0.505 \times (1500\text{ K})^4 - 0.773 \times (500\text{ K})^4] = 1.422 \times 10^5\, W/m^2 .$$ <

Continued...

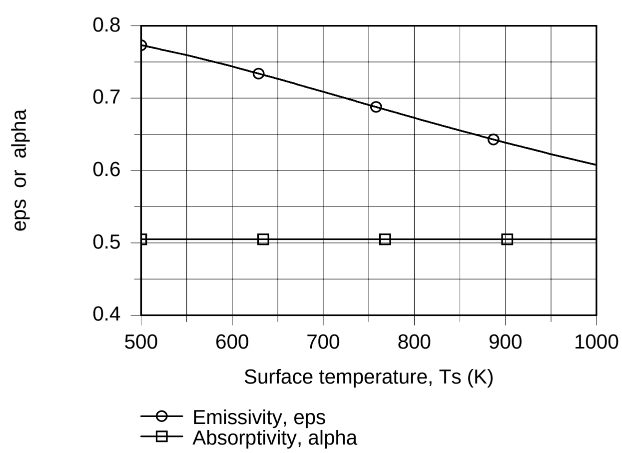
PROBLEM 12.71 (Cont.)

(c) Using the foregoing equations in the IHT workspace along with the *IHT Radiation Tool*, *Band Emission Factor*, $q''_{rad,in}$ was computed and plotted as a function of T_s.



The net radiation heat rate, $q''_{rad,in}$ decreases with increasing surface temperature since E increases with T_s and the absorbed irradiation remains constant according to Eq. (1). The heat flux is largest for the gray surface with $\varepsilon = 0.4$ and the smallest for the gray surface with $\varepsilon = 0.8$. As expected, the heat flux for the selective surface is between the limits of the two gray surfaces.

(d) Using the IHT model of part (c), the emissivity and absorptivity of the surface are computed and plotted below.



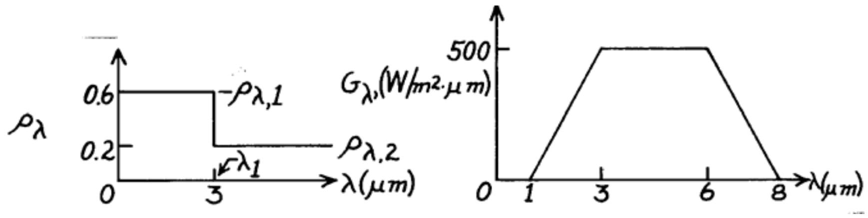
The absorptivity, $\alpha = \alpha(\alpha_\lambda, T_{sur})$, remains constant as T_s changes since it is a function of α_λ (or ε_λ) and T_{sur} only. The emissivity, $\varepsilon = \varepsilon(\varepsilon_\lambda, T_s)$ is a function of T_s and decreases as T_s increases. Could you have surmised as much by looking at the spectral emissivity distribution? Under what condition would you expect $\alpha = \varepsilon$?

PROBLEM 12.72

KNOWN: Opaque, diffuse surface with prescribed spectral reflectivity and at a temperature of 750K is subjected to a prescribed spectral irradiation, G_λ.

FIND: (a) Total absorptivity, α, (b) Total emissivity, ε, (c) Net radiative heat flux to the surface.

SCHEMATIC:



ASSUMPTIONS: (1) Opaque and diffuse surface, (2) Backside insulated.

ANALYSIS: (a) The total absorptivity is determined from Eq. 12.52 and 12.62,

$$\alpha_\lambda = 1-\rho_\lambda \qquad \text{and} \qquad \alpha = \int_0^\infty \alpha_\lambda G_\lambda d\lambda / G. \qquad (1,2)$$

Evaluating by separate integrals over various wavelength intervals.

$$\alpha = \frac{\left(1-\rho_{\lambda,1}\right)\int_1^3 G_\lambda\, d\lambda + \left(1-\rho_{\lambda,2}\right)\int_3^6 G_\lambda\, d\lambda + \left(1-\rho_{\lambda,2}\right)\int_6^8 G_\lambda\, d\lambda}{\int_1^3 G_\lambda\, d\lambda + \int_3^6 G_\lambda\, d\lambda + \int_6^8 G_\lambda\, d\lambda} = \frac{G_{abs}}{G}$$

$$G_{abs} = (1-0.6)\left[0.5\times 500\,\text{W/m}^2\cdot\mu\text{m}(3-1)\mu\text{m}\right] + (1-0.2)\left[500\,\text{W/m}^2\cdot\mu\text{m}(6-3)\mu\text{m}\right]$$
$$+(1-0.2)\left[0.5\times 500\,\text{W/m}^2\cdot\mu\text{m}(8-6)\mu\text{m}\right]$$

$$G = 0.5\times 500\,\text{W/m}^2\cdot\mu\text{m}\times(3-1)\mu\text{m} + 500\,\text{W/m}^2\cdot\mu\text{m}(6-3)\mu\text{m} + 0.5\times 500\,\text{W/m}^2\cdot\mu\text{m}(8-6)\mu\text{m}$$

$$\alpha = \frac{[200+1200+400]\,\text{W/m}^2}{[500+1500+500]\,\text{W/m}^2} = \frac{1800\,\text{W/m}^2}{2500\,\text{W/m}^2} = 0.720. \qquad <$$

(b) The total emissivity of the surface is determined from Eq. 12.43 and 12.62,

$$\varepsilon_\lambda = \alpha_\lambda \qquad \text{and, hence} \qquad \varepsilon_\lambda = 1-\rho_\lambda. \qquad (3,4)$$

The total emissivity can then be expressed as

$$\varepsilon = \int_0^\infty \varepsilon_\lambda E_{\lambda,b}(\lambda,T_s)d\lambda / E_b(T_s) = \int_0^\infty (1-\rho_\lambda)E_{\lambda,b}(\lambda,T_s)d\lambda / E_b(T_s)$$

$$\varepsilon = \left(1-\rho_{\lambda,1}\right)\int_0^3 E_{\lambda,b}(\lambda,T_s)d\lambda / E_b(T_s) + \left(1-\rho_{\lambda,2}\right)\int_3^\infty E_{\lambda,b}(\lambda,T_s)d\lambda / E_b(T_s)$$

$$\varepsilon = \left(1-\rho_{\lambda,1}\right)F_{(0\to 3\mu\text{m})} + \left(1-\rho_{\lambda,2}\right)\left[1-F_{(0\to 3\mu\text{m})}\right]$$

$$\varepsilon = (1-0.6)\times 0.111 + (1-0.2)[1-0.111] = 0.756 \qquad <$$

where Table 12.1 is used to find $F_{(0-\lambda)} = 0.111$ for $\lambda_1 T_s = 3 \times 750 = 2250\ \mu\text{m}\cdot\text{K}$.

(c) The net radiative heat flux *to* the surface is

$$q''_{rad} = \alpha G - \varepsilon E_b(T_s) = \alpha G - \varepsilon\sigma T_s^4$$

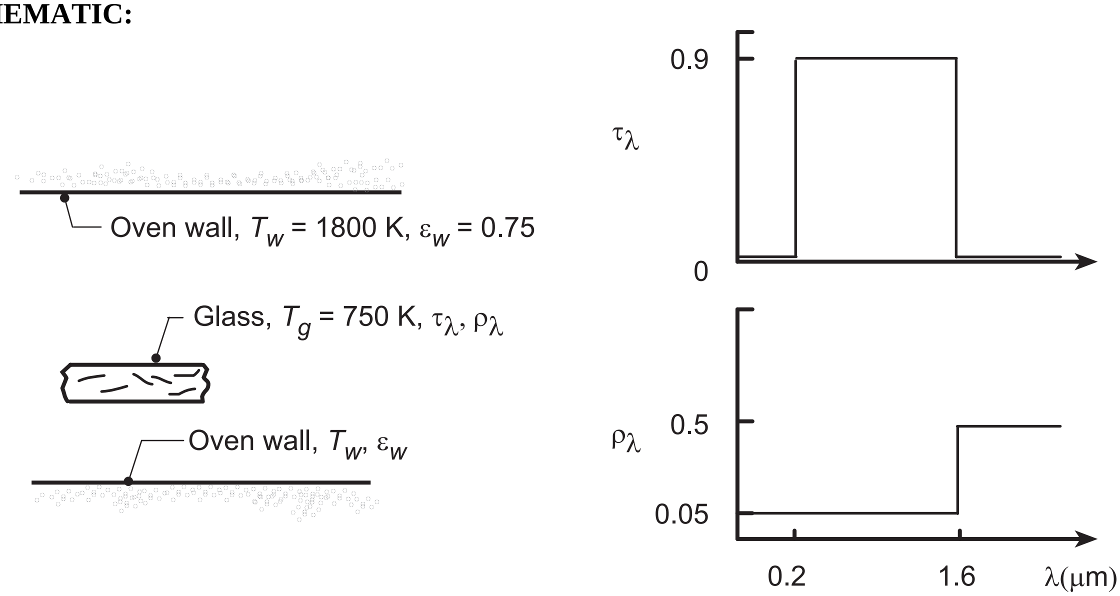
$$q''_{rad} = 0.720\times 2500\,\text{W/m}^2$$
$$-0.756\times 5.67\times 10^{-8}\,\text{W/m}^2\cdot\text{K}^4(750\text{K})^4 = -11{,}763\,\text{W/m}^2. \qquad <$$

PROBLEM 12.73

KNOWN: Diffuse glass at T_g = 750 K with prescribed spectral radiative properties being heated in a large oven having walls with emissivity of 0.75 and 1800 K.

FIND: (a) Total transmissivity r, total reflectivity ρ, and total emissivity ε of the glass; Net radiative heat flux to the glass, (b) $q''_{rad,in}$; and (c) Compute and plot $q''_{rad,in}$ as a function of glass temperatures for the range $500 \le T_g \le 800$ K for oven wall temperatures of T_w = 1500, 1800 and 2000 K.

SCHEMATIC:



ASSUMPTIONS: (1) Glass is of uniform temperature, (2) Glass is diffuse, (3) Furnace walls large compared to the glass; ε_w plays no role, (4) Negligible convection.

ANALYSIS: (a) From knowledge of the spectral transmittance,τ_w, and spectral reflectivity, ρ_λ, the following radiation properties are evaluated:

Total transmissivity, τ: For the irradiation from the furnace walls, $G_\lambda = E_{\lambda,b}(\lambda, T_w)$. Hence

$$\tau = \int_0^\infty \tau_\lambda E_{\lambda,b}(\lambda, T_w)\, d\lambda \Big/ \sigma T_w^4 \approx \tau_{\lambda 1} F_{(0-\lambda T)} = 0.9 \times 0.25 = 0.225 .$$ <

where λT = 1.6 μm × 1800 K = 2880 μm·K ≈ 2898 μm·K giving $F_{(0-\lambda T)} \approx 0.25$.

Total reflectivity, ρ: With $G_\lambda = E_{\lambda,b}(\lambda,T_w)$, T_w = 1800 K, and $F_{0-\lambda T} = 0.25$,

$$\rho \approx \rho_{\lambda 1} F_{(0-\lambda T)} + \rho_{\lambda 2}\left(1 - F_{(0-\lambda T)}\right) = 0.05 \times 0.25 + 0.5(1 - 0.25) = 0.388$$ <

Total absorptivity, α : To perform the energy balance later, we'll need α. Employ the conservation expression,

$$\alpha = 1 - \rho - \tau = 1 - 0.388 - 0.225 = 0.387 .$$

Emissivity, ε: Based upon surface temperature T_g = 750 K, for

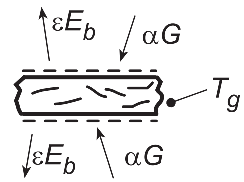
$$\lambda T = 1.6\,\mu m \times 750 K = 1200\,\mu m \cdot K, \qquad F_{0-\lambda T} \approx 0.002 .$$

Hence for λ > 1.6 μm, $\varepsilon \approx \varepsilon_\lambda \approx 0.5$. <

(b) Performing an energy balance on the glass, the net radiative heat flux by radiation into the glass is,

Continued...

PROBLEM 12.73 (Cont.)



$$q''_{net,in} = E''_{in} - E''_{out}$$

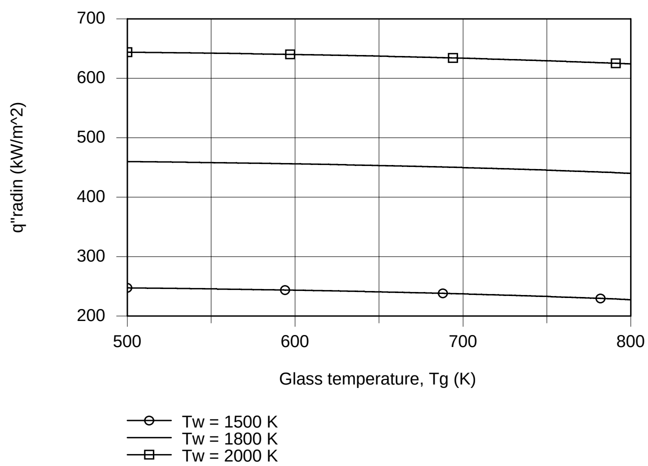
$$q''_{net,in} = 2\left(\alpha G - \varepsilon E_b\left(T_g\right)\right)$$

where $G = \sigma T_w^4$

$$q''_{net,in} = 2\left[0.387\sigma\left(1800K\right)^4 - 0.5\sigma\left(750K\right)^4\right]$$

$$q''_{net,in} = 442.8\,kW/m^2 .$$

(b) Using the foregoing equations in the IHT Workspace along with the *IHT Radiation Tool, Band Emission Factor,* the net radiative heat flux, $q''_{rad,in}$, was computed and plotted as a function of T_g for selected wall temperatures T_w .



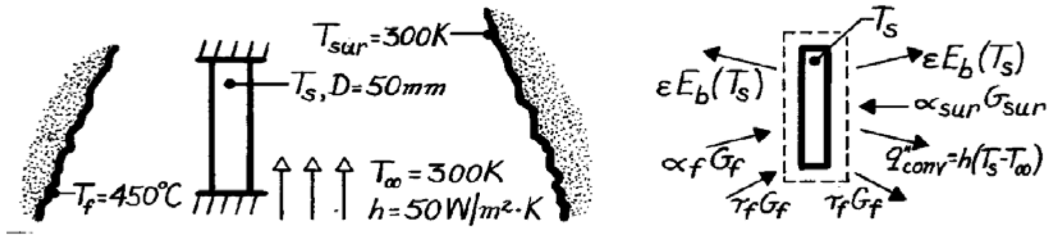
As the glass temperature increases, the rate of emission increases so we'd expect the net radiative heat rate into the glass to decrease. Note that the decrease is not very significant. The effect of increased wall temperature is to increase the irradiation and, hence the absorbed irradiation to the surface and the net radiative flux increase.

PROBLEM 12.74

KNOWN: Material with prescribed radiative properties covering the peep hole of a furnace and exposed to surroundings on the outer surface.

FIND: Steady-state temperature of the cover, T_s; heat loss from furnace.

SCHEMATIC:



ASSUMPTIONS: (1) Cover is isothermal, no gradient, (2) Surroundings of the outer surface are large compared to cover, (3) Cover is insulated from its mount on furnace wall, (4) Negligible convection on interior surface.

PROPERTIES: Cover material (given): For irradiation from the furnace interior: $\tau_f = 0.8$, $\rho_f = 0$; For room temperature emission: $\tau = 0$, $\varepsilon = 0.8$.

ANALYSIS: Perform an energy balance identifying the modes of heat transfer,

$$\dot{E}_{in} - \dot{E}_{out} = 0 \qquad \alpha_f G_f + \alpha_{sur} G_{sur} - 2\varepsilon E_b(T_s) - h(T_s - T_\infty) = 0. \qquad (1)$$

Recognize that $$G_f = \sigma T_f^4 \qquad G_{sur} = \sigma T_{sur}^4. \qquad (2,3)$$

From Eq. 12.63, it follows that $$\alpha_f = 1 - \tau_f - \rho_f = 1 - 0.8 - 0.0 = 0.2. \qquad (4)$$

Since the irradiation G_{sur} will have nearly the same spectral distribution as the emissive power of the cover, $E_b(T_s)$, and since G_{sur} is diffuse irradiation,

$$\alpha_{sur} = \varepsilon = 0.8. \qquad (5)$$

This reasoning follows from Eqs. 12.69 and 12.70. Substituting Eqs. (2-5) into Eq. (1) and using numerical values,

$$0.2 \times 5.67 \times 10^{-8}(450 + 273)^4 \text{ W/m}^2 + 0.8 \times 5.67 \times 10^{-8} \times 300^4 \text{ W/m}^2 \qquad (2\text{-}5)$$
$$-2 \times 0.8 \times 5.67 \times 10^{-8} T_s^4 \text{ W/m}^2 - 50 \text{ W/m}^2 \cdot \text{K}(T_s - 300)\text{K} = 0 \quad <$$

$$9.072 \times 10^{-8} T_s^4 + 50 T_s = 18,466 \qquad \text{or} \qquad T_s = 344\text{K}.$$

The heat loss from the furnace (see energy balance schematic) is

$$q_{f,loss} = A_s\left[\alpha_f G_f + \tau_f G_f - \varepsilon E_b(T_s)\right] = \frac{\pi D^2}{4}\left[(\alpha_f + \tau_f)G_f - \varepsilon E_b(T_s)\right]$$

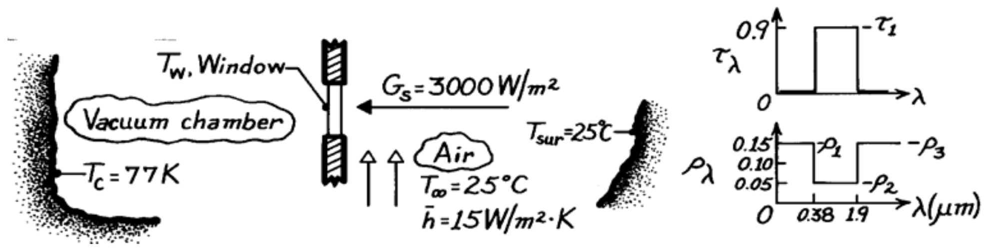
$$q_{f,loss} = \pi(0.050\text{m})^2/4\Big[(0.8 + 0.2)(723\text{K})^4$$
$$-0.8(344\text{K})^4\Big]5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 = 29.2 \text{ W}. \quad <$$

PROBLEM 12.75

KNOWN: Window with prescribed τ_λ and ρ_λ mounted on cooled vacuum chamber passing radiation from a solar simulator.

FIND: (a) Solar transmissivity of the window material, (b) State-state temperature reached by window with simulator operating, (c) Net radiation heat transfer to chamber.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Diffuse behavior of window material, (3) Chamber and room surroundings large compared to window, (4) Solar simulator flux has spectral distribution of 5800K blackbody, (5) Window insulated from its mount, (6) Window is isothermal at T_w.

ANALYSIS: (a) Using Eq. 12.61 and recognizing that $G_{\lambda,S} \sim E_{b,\lambda}$ (λ, 5800K),

$$\tau_S = \tau_1 \int_{0.38}^{1.9} E_{\lambda,b}(\lambda, 5800K)\, d\lambda / E_b(5800K) = \tau_1 \left[F_{(0\to1.9\mu m)} - F_{(0\to0.38\mu m)} \right].$$

From Table 12.1 at $\lambda T = 1.9 \times 5800 = 11{,}020$ μm·K, $F_{(0\to\lambda)} = 0.932$; at $\lambda T = 0.38 \times 5800$ μm·K = 2,204 μm·K, $F_{(0\to\lambda)} = 0.101$; hence

$$\tau_S = 0.90[0.932 - 0.101] = 0.748. \quad <$$

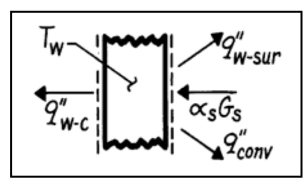
Recognizing that later we'll need α_S, use Eq. 12.58 to find ρ_S

$$\rho_S = \rho_1 F_{(0\to0.38\mu m)} + \rho_2 \left[F_{(0\to1.9\mu m)} - F_{(0\to0.38\mu m)} \right] + \rho_3 \left[1 - F_{(0\to1.9\mu m)} \right]$$

$$\rho_S = 0.15 \times 0.101 + 0.05[0.932 - 0.101] + 0.15[1 - 0.932] = 0.067$$

$$\alpha_S = 1 - \rho_S - \tau_S = 1 - 0.067 - 0.748 = 0.185.$$

(b) Perform an energy balance on the window.



$$\alpha_S G_S - q''_{w-c} - q''_{w-sur} - q''_{conv} = 0$$

$$\alpha_S G_S - \varepsilon\sigma\left(T_w^4 - T_c^4\right) - \varepsilon\sigma\left(T_w^4 - T_{sur}^4\right) - \bar{h}\left(T_w - T_\infty\right) = 0.$$

Recognize that ρ_λ ($\lambda > 1.9$) = 0.15 and that $\varepsilon \approx 1 - 0.15 = 0.85$ since T_w will be near 300K. Substituting numerical values, find by trial and error,

$$0.185 \times 3000\ W/m^2 - 0.85 \times \sigma\left[2T_w^4 - 298^4 - 77^4\right]K^4 - 28\ W/m^2 \cdot K\left(T_w - 298\right)K = 0$$

$$T_w = 302.6K = 29.6°C. \quad <$$

(c) The net radiation transfer per unit area of the window to the vacuum chamber, excluding the transmitted simulated solar flux is

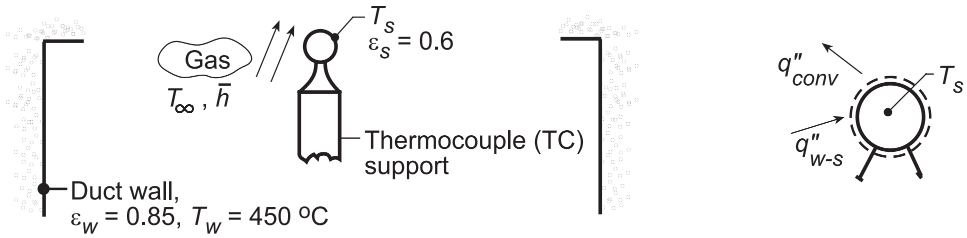
$$q''_{w-c} = \varepsilon\sigma\left(T_w^4 - T_c^4\right) = 0.85 \times 5.67 \times 10^{-8}\ W/m^2 \cdot K^4 \left[302.6^4 - 77^4\right]K^4 = 402\ W/m^2. \quad <$$

PROBLEM 12.76

KNOWN: Reading and emissivity of a thermocouple (TC) located in a large duct to measure gas stream temperature. Duct wall temperature and emissivity; convection coefficient.

FIND: (a) Gas temperature, T_∞, (b) Effect of convection coefficient on measurement error.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat loss from TC sensing junction to support, (3) Duct wall much larger than TC, (4) TC surface is diffuse-gray.

ANALYSIS: (a) Performing an energy balance on the thermocouple, it follows that

$$q''_{w-s} - q''_{conv} = 0\,.$$

Hence,

$$\varepsilon_s \sigma (T_w^4 - T_s^4) - \bar{h}(T_s - T_\infty) = 0\,.$$

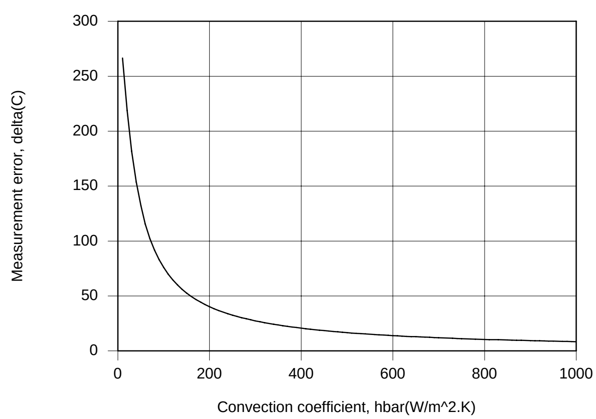
Solving for T_∞ with $T_s = 180$°C,

$$T_\infty = T_s - \frac{\varepsilon_s \sigma}{\bar{h}}(T_w^4 - T_s^4)$$

$$T_\infty = (180+273)\text{K} - \frac{0.6(5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4)}{125\ \text{W/m}^2\cdot\text{K}}\left([450+273]^4 - [180+273]^4\right)\text{K}^4$$

$$T_\infty = 453\ \text{K} - 62.9\ \text{K} = 390\ \text{K} = 117^\circ\text{C}\,.$$ <

(b) Using the IHT *First Law* model for an *Isothermal Solid Sphere* to solve the foregoing energy balance for T_s, with $T_\infty = 125$°C, the measurement error, defined as $\Delta T = T_s - T_\infty$, was determined and is plotted as a function of $\bar{h}$.



The measurement error is enormous ($\Delta T \approx 270$°C) for $\bar{h} = 10$ W/m^2·K, but decreases with increasing $\bar{h}$. However, even for $\bar{h} = 1000$ W/m^2·K, the error ($\Delta T \approx 8$°C) is not negligible. Such errors must always be considered when measuring a gas temperature in surroundings whose temperature differs significantly from that of the gas.

Continued...

PROBLEM 12.76 (Cont.)

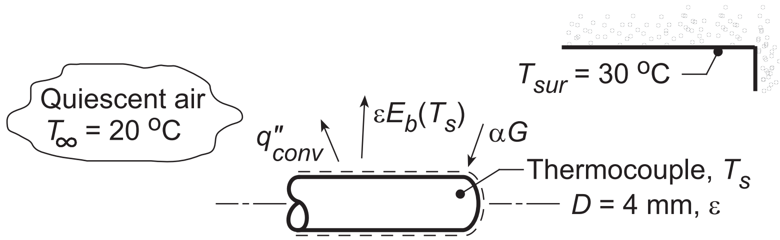
COMMENTS: (1) Because the duct wall surface area is much larger than that of the thermocouple, its emissivity is not a factor. (2) For such a situation, a shield about the thermocouple would reduce the influence of the hot duct wall on the indicated TC temperature. A low emissivity thermocouple coating would also help.

PROBLEM 12.77

KNOWN: Diameter and emissivity of a horizontal thermocouple (TC) sheath located in a large room. Air and wall temperatures.

FIND: (a) Temperature indicated by the TC, (b) Effect of emissivity on measurement error.

SCHEMATIC:



ASSUMPTIONS: (1) Room walls approximate isothermal, large surroundings, (2) Room air is quiescent, (3) TC approximates horizontal cylinder, (4) No conduction losses, (5) TC surface is opaque, diffuse and gray.

PROPERTIES: *Table A-4*, Air (assume T_s = 25 °C, $T_f = (T_s + T_\infty)/2 \approx 296$ K, 1 atm):
$\nu = 15.53\times10^{-6}\ m^2/s$, $k = 0.026\ W/m\cdot K$, $\alpha = 22.0\times10^{-6}\ m^2/s$, $Pr = 0.708$, $\beta = 1/T_f$.

ANALYSIS: (a) Perform an energy balance on the thermocouple considering convection and radiation processes. On a unit area basis, with $q''_{conv} = \overline{h}(T_s - T_\infty)$,

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$\alpha G - \varepsilon E_b(T_s) - \overline{h}(T_s - T_\infty) = 0\,. \quad (1)$$

Since the surroundings are isothermal and large compared to the thermocouple, $G = E_b(T_{sur})$. For the gray-diffuse surface, α = ε. Using the Stefan-Boltzmann law, $E_b = \sigma T^4$, Eq. (1) becomes

$$\varepsilon\sigma(T_{sur}^4 - T_s^4) - \overline{h}(T_s - T_\infty) = 0\,. \quad (2)$$

Using the Churchill-Chu correlation for a horizontal cylinder, estimate $\overline{h}$ due to free convection.

$$\overline{Nu}_D = \frac{\overline{h}D}{k} = \left\{0.60 + \frac{0.387 Ra_D^{1/6}}{\left[1+\left(0.559/Pr\right)^{9/16}\right]^{8/27}}\right\}^2, \quad Ra_D = \frac{g\beta\Delta T D^3}{\nu\alpha}\,. \quad (3,4)$$

To evaluate Ra_D and $\overline{Nu}_D$, assume T_s = 25°C, giving

$$Ra_D = \frac{9.8\,m/s^2 (1/296\ K)(25-20)K(0.004m)^3}{15.53\times10^{-6}\ m^2/s \times 22.0\times10^{-6}\ m^2/s} = 31.0$$

$$\overline{h} = \frac{0.026\ W/m\cdot K}{0.004m}\left\{0.60 + \frac{0.387(31.0)^{1/6}}{\left[1+\left(0.559/0.708\right)^{9/16}\right]^{8/27}}\right\}^2 = 8.89\ W/m^2\cdot K\,. \quad (5)$$

With ε = 0.4, the energy balance, Eq. (2), becomes

$$0.4\times5.67\times10^{-8}\ W/m^2\cdot K^4[(30+273)^4 - T_s^4]K^4 - 8.89\ W/m^2\cdot K[T_s - (20+273)]K = 0 \quad (6)$$

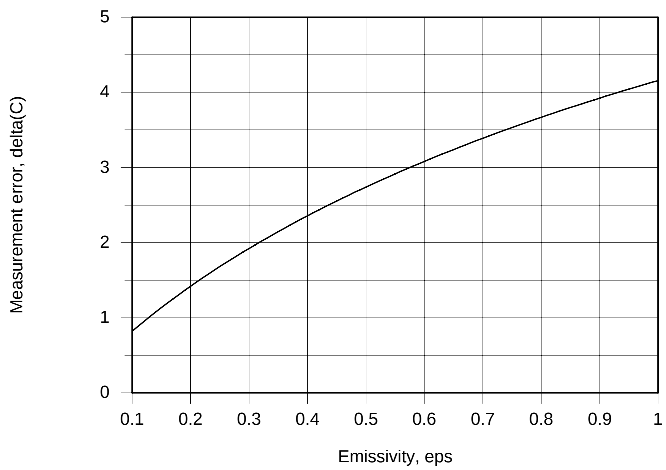
where all temperatures are in kelvin units. By trial-and-error, find

$T_s \approx 22.2$°C <

Continued...

PROBLEM 12.77 (Cont.)

(b) The thermocouple measurement error is defined as $\Delta T = T_s - T_\infty$ and is a consequence of radiation exchange with the surroundings. Using the IHT *First Law* Model for an *Isothermal Solid Cylinder* with the appropriate *Correlations* and *Properties* Toolpads to solve the foregoing energy balance for T_s, the measurement error was determined as a function of the emissivity.



The measurement error decreases with decreasing ε, and hence a reduction in net radiation transfer from the surroundings. However, even for $\varepsilon = 0.1$, the error ($\Delta T \approx 1^oC$) is not negligible.

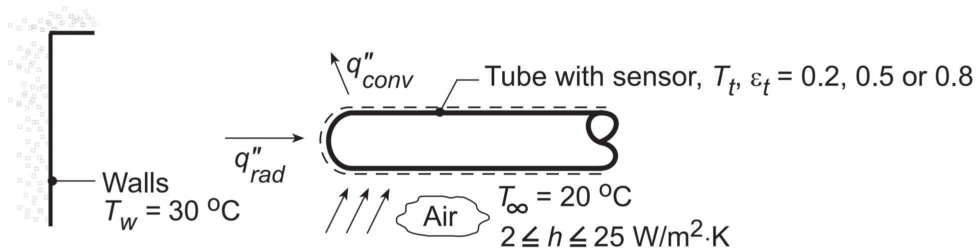
COMMENT: A trial-and-error solution accounting for the effect of temperature-dependent properties and various values of $\overline{h}$ yields $T_s = 22.1°C$ ($\overline{h} = 7.85\ W/m^2\cdot K$).

PROBLEM 12.78

KNOWN: Temperature sensor imbedded in a diffuse, gray tube of emissivity 0.8 positioned within a room with walls and ambient air at 30 and 20 °C, respectively. Convection coefficient is 5 $W/m^2 \cdot K$.

FIND: (a) Temperature of sensor for prescribed conditions, (b) Effect of surface emissivity and using a fan to induce air flow over the tube.

SCHEMATIC:



ASSUMPTIONS: (1) Room walls (surroundings) much larger than tube, (2) Tube is diffuse, gray surface, (3) No losses from tube by conduction, (4) Steady-state conditions, (5) Sensor measures temperature of tube surface.

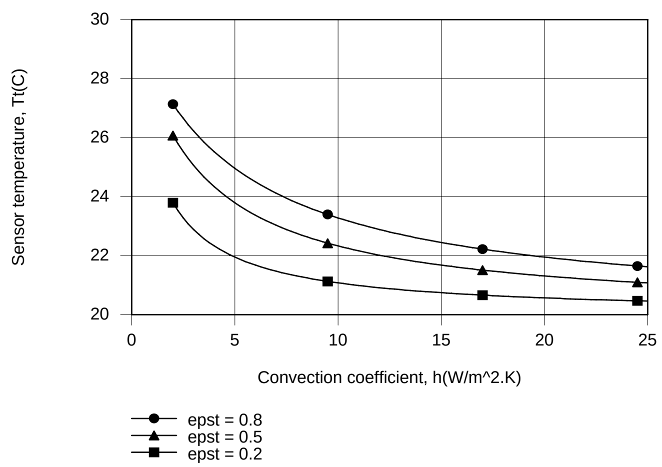
ANALYSIS: (a) Performing an energy balance on the tube, $\dot{E}_{in} - \dot{E}_{out} = 0$. Hence, $q''_{rad} - q''_{conv} = 0$, or $\varepsilon_t \sigma (T_w^4 - T_t^4) - h(T_t - T_\infty) = 0$. With h = 5 $W/m^2 \cdot K$ and ε_t = 0.8, the energy balance becomes

$$0.8 \times 5.67 \times 10^{-8} \, W/m^2 \cdot K^4 \left[(30 + 273)^4 - T_t^4 \right] K^4 = 5 \, W/m^2 \cdot K \left[T_t - (20 + 273) \right] K$$

$$4.5360 \times 10^{-8} \left[303^4 - T_t^4 \right] = 5 \left[T_t - 293 \right]$$

which yields T_t = 298 K = 25°C. <

(b) Using the IHT *First Law* Model, the following results were determined.



The sensor temperature exceeds the air temperature due to radiation absorption, which must be balanced by convection heat transfer. Hence, the excess temperature $T_t - T_\infty$, may be reduced by increasing h or by decreasing α_t, which equals ε_t for a diffuse-gray surface, and hence the absorbed radiation.

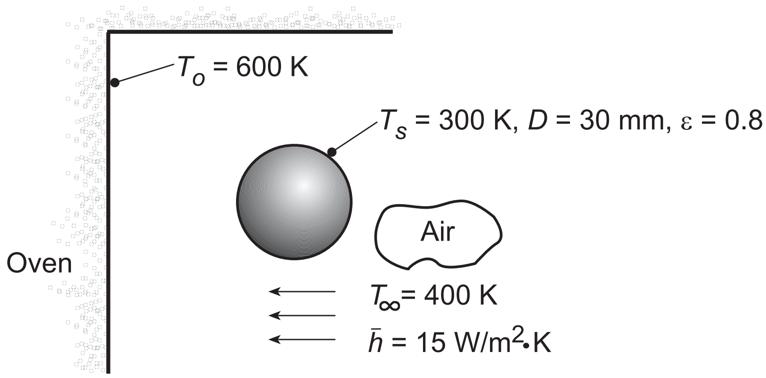
COMMENTS: A fan will increase the air velocity over the sensor and thereby increase the convection heat transfer coefficient. Hence, the sensor will indicate a temperature closer to T_∞.

PROBLEM 12.79

KNOWN: Diffuse-gray sphere is placed in large oven with known wall temperature and experiences convection process.

FIND: (a) Net heat transfer rate to the sphere when its temperature is 300 K, (b) Steady-state temperature of the sphere, (c) Time required for the sphere, initially at 300 K, to come within 20 K of the steady-state temperature, and (d) Elapsed time of part (c) as a function of the convection coefficient for $10 \le h \le 25$ $W/m^2 \cdot K$ for emissivities 0.2, 0.4 and 0.8.

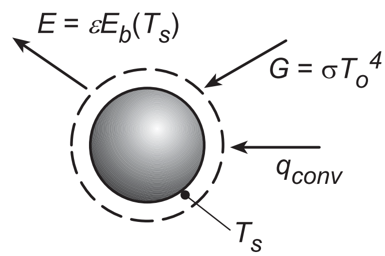
SCHEMATIC:



ASSUMPTIONS: (1) Sphere surface is diffuse-gray, (2) Sphere area is much smaller than the oven wall area, (3) Sphere surface is isothermal.

PROPERTIES: Sphere (Given) : $\alpha = 7.25 \times 10^{-5}$ m^2/s, k = 185 W/m·K.

ANALYSIS: (a) From an energy balance on the sphere find



$$q_{net} = q_{in} - q_{out}$$

$$q_{net} = \alpha G A_s + q_{conv} - E A_s$$

$$q_{net} = \alpha \sigma T_o^4 A_s + h A_s \left(T_\infty - T_s\right) - \varepsilon \sigma T_s^4 A_s . \qquad (1)$$

Note that the irradiation to the sphere is the emissive power of a blackbody at the temperature of the oven walls. This follows since the oven walls are isothermal and have a much larger area than the sphere area. Substituting numerical values, noting that α = ε since the surface is diffuse-gray and that $A_s = \pi D^2$, find

$$q_{net} = \Big[0.8 \times 5.67 \times 10^{-8} \, W/m^2 \cdot K^4 \left(600K\right)^4 + 15\, W/m^2 \cdot K \times \left(400 - 300\right) K$$

$$- 0.8 \times 5.67 \times 10^{-8} \, W/m^2 \cdot K^4 \, (300K)^4 \Big] \pi \left(30 \times 10^{-3} m\right)^2$$

$$q_{net} = \left[16.6 + 4.2 - 1.0\right] W = 19.8\, W . \qquad (1) \quad <$$

(b) For steady-state conditions, q_{net} in the energy balance of Eq. (1) will be zero,

$$0 = \alpha \sigma T_o^4 A_s + h A_s \left(T_\infty - T_{ss}\right) - \varepsilon \sigma T_{ss}^4 A_s \qquad (2)$$

Substitute numerical values and find the steady-state temperature as

$$T_{ss} = 538.2K \qquad <$$

Continued...

PROBLEM 12.79 (Cont.)

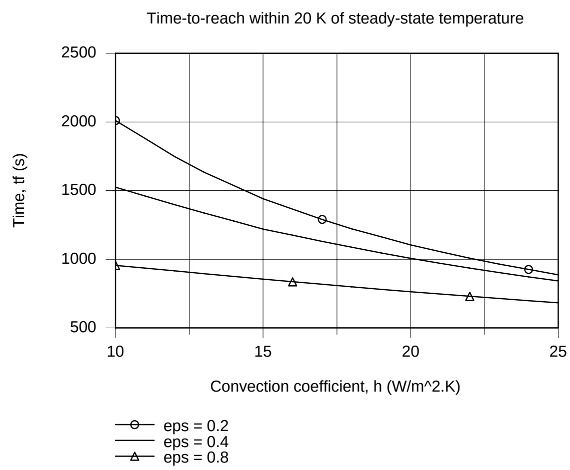
(c) Using the *IHT Lumped Capacitance Model* considering convection and radiation processes, the temperature- time history of the sphere, initially at $T_s(0) = T_i = 300$ K, can be determined. The elapsed time required to reach

$$T_s(t_o) = (538.2 - 20)\,\text{K} = 518.2\text{K}$$

was found as

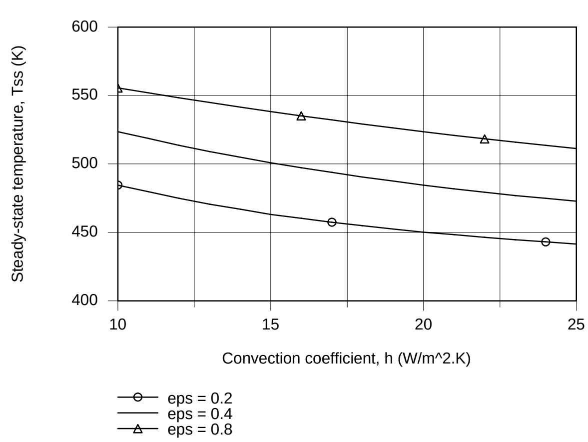
$$t_o = 855\text{s} = 14.3\,\text{min}$$ <

(d) Using the IHT model of part (c), the elapsed time for the sphere to reach within 20 K of its steady-state temperature, t_f, as a function of the convection coefficient for selected emissivities is plotted below.



For a fixed convection coefficient, t_f increases with decreasing ε since the radiant heat transfer into the sphere decreases with decreasing emissivity. For a given emissivity, the t_f decreases with increasing h since the convection heat rate increases with increasing h. However, the effect is much more significant with lower values of emissivity.

COMMENTS: (1) Why is t_f more strongly dependent on h for a lower sphere emissivity? Hint: Compare the relative heat rates by convection and radiation processes. (2) The steady-state temperature, T_{ss}, as a function of the convection coefficient for selected emmissivities calculated using (2) is plotted below. Are these results consistent with the above plot of t_f vs h ?

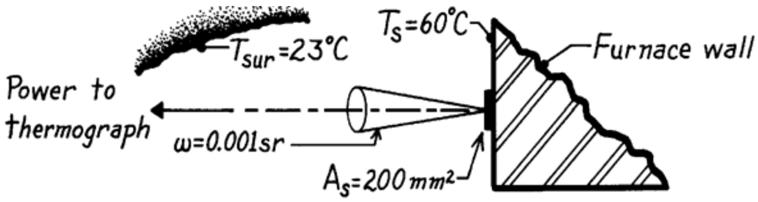


PROBLEM 12.80

KNOWN: Thermograph with spectral response in 9 to 12 μm region views a target of area 200mm^2 with solid angle 0.001 sr in a normal direction.

FIND: (a) For a black surface at 60°C, the emissive power in 9 – 12 μm spectral band, (b) Radiant power (W), received by thermograph when viewing black target at 60°C, (c) Radiant power (W) received by thermograph when viewing a gray, diffuse target having ε = 0.7 and considering the surroundings at T_{sur} = 23°C.

SCHEMATIC:



ASSUMPTIONS: (1) Wall is diffuse, (2) Surroundings are black with T_{sur} = 23°C.

ANALYSIS: (a) Emissive power in spectral range 9 to 12 μm for a 60°C black surface is

$$E_t \equiv E_b(9-12\,\mu m) = E_b\left[F(0\to 12\,\mu m) - F(0-9\,\mu m)\right]$$

where $E_b(T_s) = \sigma T_s^4$. From Table 12.1:

$$\lambda_2 T_s = 12\times(60+273) \approx 4000\,\mu m\ K, \qquad F(0-12\,\mu m) = 0.481$$

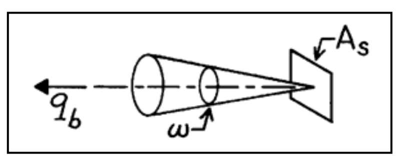
$$\lambda_1 T_s = 9\times(60+273) \approx 3000\,\mu m\ K, \qquad F(0-9\,\mu m) = 0.273.$$

Hence

$$E_t = 5.667\times10^{-8}\,W/m^2\cdot K^4 \times (60+273)^4\,K^4\,[0.481-0.273] = 145\ W/m^2. \qquad <$$

(b) The radiant power, q_b (W), received by the thermograph from a black target is determined as

$$q_b = \frac{E_t}{\pi}\cdot A_s\cos\theta_1\cdot\omega$$



where E_t = emissive power in 9 – 12 μm spectral region, part (a) result
A_s = target area viewed by thermograph, 200mm^2 (2×10^{-4} m^2)
ω = solid angle thermograph aperture subtends when viewed from the target, 0.001 sr
θ = angle between target area normal and view direction, 0°.

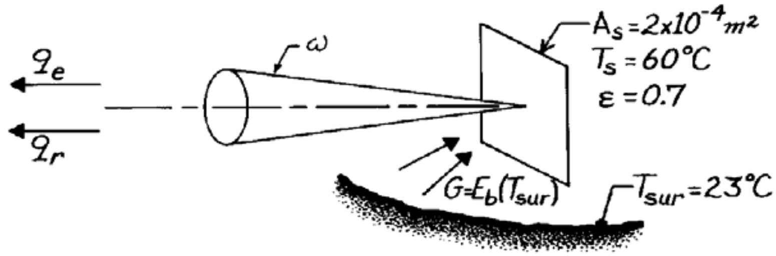
Hence,

$$q_b = \frac{145\ W/m^2}{\pi\ sr}\times\left(2\times10^{-4}\,m^2\right)\times\cos 0°\times 0.001\ sr = 9.23\,\mu W. \qquad <$$

Continued …

PROBLEM 12.80 (Cont.)

(c) When the target is a gray, diffuse emitter, ε = 0.7, the thermograph will receive emitted power from the target and reflected irradiation resulting from the surroundings at T_{sur} = 23°C. Schematically:



The power is expressed as

$$q = q_e + q_r = \varepsilon q_b + I_r \cdot A_s \cos\theta_1 \cdot \omega \left[F_{(0 \to 12\,\mu m)} - F_{(0 \to 9\,\mu m)} \right]$$

where

q_b = radiant power from black surface, part (b) result

$F_{(0 - \lambda)}$ = band emission fraction for T_{sur} = 23°C; using Table 12.1

$\lambda_2 T_{sur}$ = 12 × (23 + 273) = 3552 μm·K, $F_{(0-\lambda_2)} = 0.394$

$\lambda_1 T_{sur}$ = 9 × (23 + 273) = 2664 μm·K, $F_{(0-\lambda_1)} = 0.197$

I_r = reflected intensity, which because of diffuse nature of surface

$$I_r = \rho \frac{G}{\pi} = (1 - \varepsilon) \frac{E_b(T_{sur})}{\pi}.$$

Hence

$$q = 0.7 \times 9.23\,\mu W + (1 - 0.7) \frac{5.667 \times 10^{-8}\, W/m^2 \cdot K^4 \times (273 + 23)^4\, K}{\pi\ sr}$$

$$\times \left(2 \times 10^{-4}\, m^2\right) \times \cos 0° \times 0.001\, sr \left[0.394 - 0.197\right]$$

$$q = 6.46\,\mu W + 1.64\,\mu W = 8.10\,\mu W.$$ <

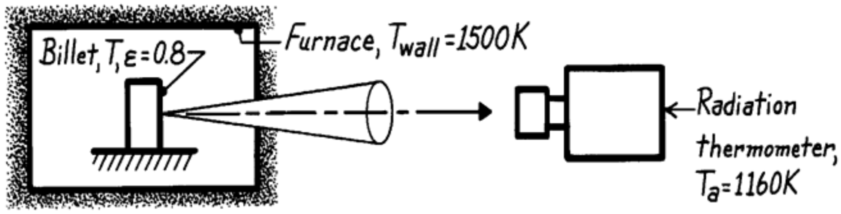
COMMENTS: (1) Comparing the results of parts (a) and (b), note that the power to the thermograph is slightly less for the gray surface with ε = 0.7. From part (b) see that the effect of the irradiation is substantial; that is, 1.64/8.10 ≈ 20% of the power received by the thermograph is due to reflected irradiation. Ignoring such effects leads to misinterpretation of temperature measurements using thermography. (2) Many thermography devices have a spectral response in the 3 to 5 μm wavelength region as well as 9 – 12 μm.

PROBLEM 12.81

KNOWN: Radiation thermometer (RT) viewing a steel billet being heated in a furnace.

FIND: Temperature of the billet when the RT indicates 1160K.

SCHEMATIC:



ASSUMPTIONS: (1) Billet is diffuse-gray, (2) Billet is small object in large enclosure, (3) Furnace behaves as isothermal, large enclosure, (4) RT is a radiometer sensitive to total (rather than a prescribed spectral band) radiation and is calibrated to correctly indicate the temperature of a black body, (5) RT receives radiant power originating from the target area on the billet.

ANALYSIS: The radiant power reaching the radiation thermometer (RT) is proportional to the radiosity of the billet. For the diffuse-gray billet within the large enclosure (furnace), the radiosity is

$$J = \varepsilon E_b(T) + \rho G = \varepsilon E_b(T) + (1-\varepsilon) E_b(T_w)$$

$$J = \varepsilon \sigma T^4 + (1-\varepsilon)\sigma T_w^4 \tag{1}$$

where $\alpha = \varepsilon$, $G = E_b(T_w)$ and $E_b = \sigma T^4$. When viewing the billet, the RT indicates $T_a = 1100K$, referred to as the apparent temperature of the billet. That is, the RT *indicates* the billet is a blackbody at T_a for which the radiosity will be

$$E_b(T_a) = J_a = \sigma T_a^4. \tag{2}$$

Recognizing that $J_a = J$, set Eqs. (1) and (2) equal to one another and solve for T, the billet true temperature.

$$T = \left[\frac{1}{\varepsilon} T_a^4 - \frac{1-\varepsilon}{\varepsilon} T_w^4\right]^{1/4}.$$

Substituting numerical values, find

$$T = \left[\frac{1}{0.8}(1160K)^4 - \frac{1-0.8}{0.8}(1500K)^4\right]^{1/4} = 999K. \quad <$$

COMMENTS: (1) The effect of the reflected wall irradiation from the billet is to cause the RT to indicate a temperature higher than the true temperature.

(2) What temperature would the RT indicate when viewing the furnace wall assuming the wall emissivity were 0.85?

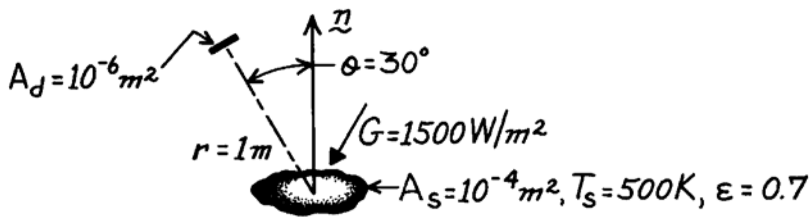
(3) What temperature would the RT indicate if the RT were sensitive to spectral radiation at 0.65 μm instead of total radiation? Hint: in Eqs. (1) and (2) replace the emissive power terms with spectral intensity. Answer: 1365K.

PROBLEM 12.82

KNOWN: Irradiation and temperature of a small surface.

FIND: Rate at which radiation is received by a detector due to emission and reflection from the surface.

SCHEMATIC:



ASSUMPTIONS: (1) Opaque, diffuse-gray surface behavior, (2) A_s and A_d may be approximated as differential areas.

ANALYSIS: Radiation intercepted by the detector is due to emission and reflection from the surface, and from the definition of the intensity, it may be expressed as

$$q_{s-d} = I_{e+r} A_s \cos\theta \, \Delta\omega.$$

The solid angle intercepted by A_d with respect to a point on A_s is

$$\Delta\omega = \frac{A_d}{r^2} = 10^{-6}\,\text{sr}.$$

Since the surface is diffuse it follows from Eq. 12.27 that

$$I_{e+r} = \frac{J}{\pi}$$

where, since the surface is opaque and gray ($\varepsilon = \alpha = 1 - \rho$),

$$J = E + \rho G = \varepsilon E_b + (1-\varepsilon)G.$$

Substituting for E_b from Eq. 12.32

$$J = \varepsilon\sigma T_s^4 + (1-\varepsilon)G = 0.7 \times 5.67 \times 10^{-8} \frac{W}{m^2 \cdot K^4}(500K)^4 + 0.3 \times 1500 \frac{W}{m^2}$$

or

$$J = (2481 + 450)\,W/m^2 = 2931\,W/m^2.$$

Hence

$$I_{e+r} = \frac{2931\ W/m^2}{\pi\ \text{sr}} = 933\,W/m^2 \cdot \text{sr}$$

and

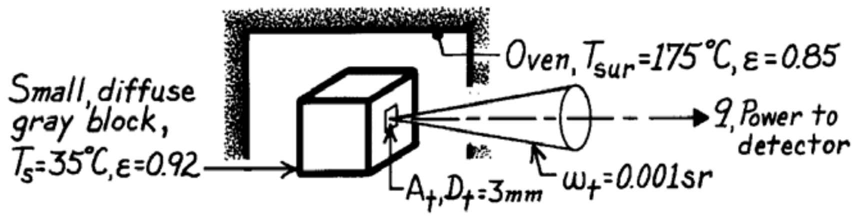
$$q_{s-d} = 933\ W/m^2 \cdot \text{sr}\left(10^{-4}\,m^2 \times 0.866\right)10^{-6}\,\text{sr} = 8.08 \times 10^{-8}\,W.$$ <

PROBLEM 12.83

KNOWN: Small, diffuse, gray block with ε = 0.92 at 35°C is located within a large oven whose walls are at 175°C with ε = 0.85.

FIND: Radiant power reaching detector when viewing (a) a deep hole in the block and (b) an area on the block's surface.

SCHEMATIC:



ASSUMPTIONS: (1) Block is isothermal, diffuse, gray and small compared to the enclosure, (2) Oven is isothermal enclosure.

ANALYSIS: (a) The small, deep hole in the isothermal block approximates a blackbody at T_s. The radiant power to the detector can be determined from Eq. 12.11 written in the form:

$$q = I_e \cdot A_t \cdot \omega_t = \frac{\sigma T_s^4}{\pi} \cdot A_t \cdot \omega_t$$

$$q = \frac{1}{\pi \text{ sr}}\left[5.67\times10^{-8}\times(35+273)^4\right]\frac{\text{W}}{\text{m}^2}\times\frac{\pi\left(3\times10^{-3}\right)^2 \text{m}^2}{4}\times0.001 \text{ sr} = 1.15\,\mu\text{W} \quad <$$

where $A_t = \pi D_t^2 / 4$. Note that the hole diameter must be greater than 3mm diameter.

(b) When the detector views an area on the surface of the block, the radiant power reaching the detector will be due to emission and reflected irradiation originating from the enclosure walls. In terms of the radiosity, Section 12.3.4, we can write using Eq. 12.23,

$$q = I_{e+r} \cdot A_t \cdot \omega_t = \frac{J}{\pi} \cdot A_t \cdot \omega_t.$$

Since the surface is diffuse and gray, the radiosity can be expressed as

$$J = \varepsilon E_b(T_s) + \rho G = \varepsilon E_b(T_s) + (1-\varepsilon) E_b(T_{sur})$$

recognizing that ρ = 1 - ε and G = E_b (T_{sur}). The radiant power is

$$q = \frac{1}{\pi}\left[\varepsilon E_b(T_s) + (1-\varepsilon) E_b(T_{sur})\right] \cdot A_t \cdot \omega_t$$

$$q = \frac{1}{\pi \text{ sr}}\left[0.92\times5.67\times10^{-8}(35+273)^4 + (1-0.92)\times5.67\times10^{-8}(175+273)^4\right]\text{W/m}^2\times$$

$$\frac{\pi\left(3\times10^{-3}\right)^2 \text{m}^2}{4}\times0.001 \text{ sr} = 1.47\,\mu\text{W}. \quad <$$

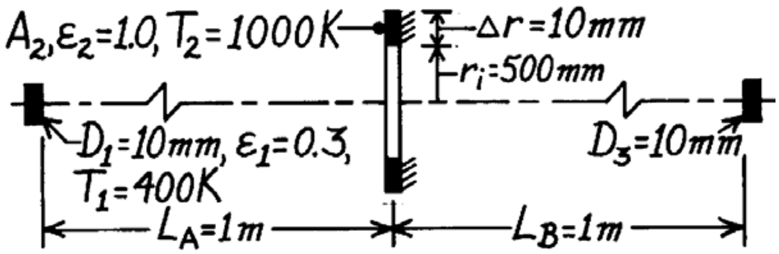
COMMENTS: The effect of reflected irradiation when ε < 1 is important for objects in enclosures. The practical application is one of measuring temperature by radiation from objects within furnaces.

PROBLEM 12.84

KNOWN: Diffuse, gray opaque disk (1) coaxial with a ring-shaped disk (2), both with prescribed temperatures and emissivities. Cooled detector disk (3), also coaxially positioned at a prescribed location.

FIND: Rate at which radiation is incident on the detector due to emission and reflection from A_1.

SCHEMATIC:



ASSUMPTIONS: (1) A_1 is diffuse-gray, (2) A_2 is black, (3) A_1 and $A_3 << R^2$, the distance of separation, (4) $\Delta r << r_i$, such that $A_2 \approx 2\pi r_i \Delta r$, and (5) Backside of A_2 is insulated.

ANALYSIS: The radiant power leaving A_1 intercepted by A_3 is of the form

$$q_{1\to3} = (J_1/\pi) A_1 \cos\theta_1 \cdot \omega_{3-1}$$

where for this configuration of A_1 and A_3,

$$\theta_1 = 0° \qquad \omega_{3-1} = A_3 \cos\theta_3 / (L_A + L_B)^2 \qquad \theta_3 = 0°.$$

Hence,

$$q_{1\to3} = (J_1/\pi) A_1 \cdot A_3 / (L_A + L_B)^2 \qquad J_1 = \rho G_1 + \varepsilon E_b(T_1) = \rho G_1 + \varepsilon\sigma T_1^4.$$

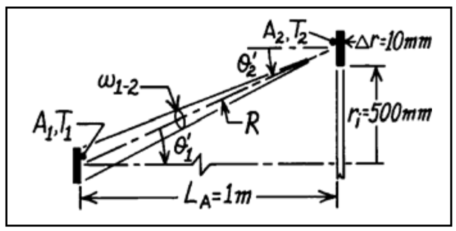
The irradiation on A_1 due to emission from A_2, G_1, is

$$G_1 = q_{2\to1}/A_1 = (I_2 \cdot A_2 \cos\theta_2' \cdot \omega_{1-2})/A_1$$

where

$$\omega_{1-2} = A_1 \cos\theta_1' / R^2$$

is constant over the surface A_2. From geometry,



$$\theta_1' = \theta_2' = \tan^{-1}\left[(r_i + \Delta r/2)/L_A\right] = \tan^{-1}\left[(0.500 + 0.005)/1.000\right] = 26.8°$$

$$R = L_A / \cos\theta_1' = 1\text{ m}/\cos 26.8° = 1.12\text{m}.$$

Hence,

$$G_1 = \left(\sigma T_2^4/\pi\right) A_2 \cos 26.8° \cdot \left[A_1 \cos 26.8° / (1.12\text{ m})^2\right] / A_1 = 360.2\text{ W/m}^2$$

using $A_2 = 2\pi r_i \Delta r = 3.142 \times 10^{-2}\text{ m}^2$ and

$$J_1 = (1 - 0.3) \times 360.2\text{ W/m}^2 + 0.3 \times 5.67 \times 10^{-8}\text{ W/m}^2 \cdot \text{K}^4 (400\text{ K})^4 = 687.7\text{ W/m}^2.$$

Hence the radiant power is

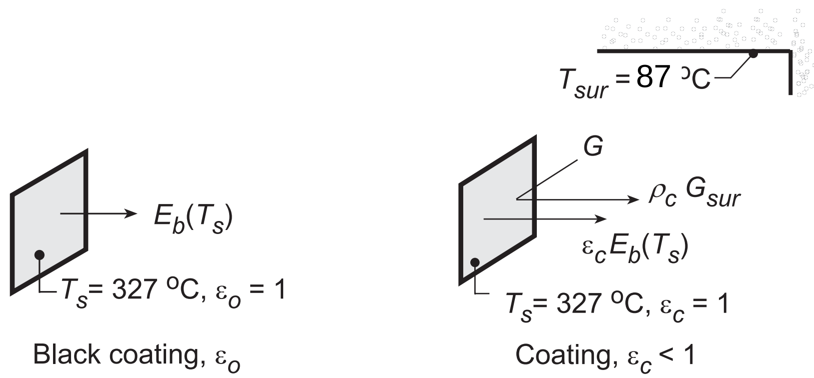
$$q_{1\to3} = \left(687.7\text{ W/m}^2/\pi\right)\left[\pi(0.010\text{ m})^2/4\right]^2 / (1\text{ m} + 1\text{ m})^2 = 337.6 \times 10^{-9}\text{ W.} \quad <$$

PROBLEM 12.85

KNOWN: Infrared thermograph with a 3- to 5-micrometer spectral bandpass views a metal plate maintained at T_s = 327°C having four diffuse, gray coatings of different emissivities. Surroundings at T_{sur} = 87°C.

FIND: (a) Expression for the output signal, S_o, in terms of the responsivity, R (μV·m²/W), the black coating (ε_o = 1) emissive power and appropriate band emission fractions; assuming R = 1 μV·m²/W, evaluate S_o(V); (b) Expression for the output signal, S_c, in terms of the responsivity R, the blackbody emissive power of the coating, the blackbody emissive power of the surroundings, the coating emissivity, ε_c, and appropriate band emission fractions; (c) Thermograph signals, S_c (μV), when viewing with emissivities of 0.8, 0.5 and 0.2 assuming R = 1 μV·m²/W; and (d) Apparent temperatures which the device will indicate based upon the signals found in part (c) for each of the three coatings.

SCHEMATIC:



ASSUMPTIONS: (1) Plate has uniform temperature, (2) Surroundings are isothermal and large compared to the plate, and (3) Coatings are diffuse and gray so that ε = α and ρ = 1 - ε.

ANALYSIS: (a) When viewing the black coating (ε_o = 1), the scanner output signal can be expressed as

$$S_o = RF_{(\lambda_1-\lambda_2,T_s)}E_b(T_s) \quad (1)$$

where R is the responsivity (μV·m²/W), $E_b(T_s)$ is the blackbody emissive power at T_s and $F_{(\lambda_1-\lambda_2,T_s)}$ is the fraction of the spectral band between λ_1 and λ_2 in the spectrum for a blackbody at T_s,

$$F_{(\lambda_1-\lambda_2,T_s)} = F_{(0-\lambda_2,T_s)} - F_{(0-\lambda_1,T_s)} \quad (2)$$

where the band fractions Eq. 12.35 are evaluated using Table 12.1 with $\lambda_1 T_s$ = 3 μm (327 + 273)K = 1800 μm·K ($F_{0-\lambda 1}$ = 0.0393) and $\lambda_2 T_s$ = 5 μm (327 + 273) = 3000 μm·K ($F_{0-\lambda 2}$ = 0.2732). Substituting numerical values with R = 1 μV·m²/W, find

$$S_o = 1\mu V\cdot m^2/W[0.2732-0.0393]5.67\times10^{-8}\,W/m^2\cdot K^4(600K)^4$$

$$S_o = 1718\,\mu V$$ <

(b) When viewing one of the coatings ($\varepsilon_c < \varepsilon_o$ = 1), the output signal as illustrated in the schematic above will be affected by the emission and reflected irradiation from the surroundings,

$$S_c = R\left\{F_{(\lambda_1-\lambda_2,T_s)}\varepsilon_c E_b(T_s) + F_{(\lambda_1-\lambda_2,T_{sur})}\rho_c G_c\right\} \quad (3)$$

where the reflected irradiation parameters are

Continued...

PROBLEM 12.85 (Cont.)

$$\rho_c = 1 - \varepsilon_c \qquad G_c = \sigma T_{sur}^4 \qquad (4,5)$$

and the related band fractions are

$$F_{(\lambda_1 - \lambda_2, T_{sur})} = F_{(0-\lambda_2, T_{sur})} - F_{(0-\lambda_1, T_{sur})} \qquad (6)$$

Combining Eqs. (2-6) above, the scanner output signal when viewing a coating is

$$S_c = R\left\{\left[F_{(0-\lambda_2 T_s)} - F_{(0-\lambda_1 T_s)}\right]\varepsilon_c \sigma T_s^4 + \left[F_{(0-\lambda_2 T_{sur})} - F_{(0-\lambda_2 T_{sur})}\right](1-\varepsilon_c)\sigma T_{sur}^4\right\} \qquad (7)$$

(c) Substituting numerical values into Eq. (7), find

$$S_c = 1\,\mu V\cdot m^2/W\left\{[0.2732 - 0.0393]\varepsilon_c \sigma (600K)^4 + [0.0393 - 0.0010](1-\varepsilon_c)\sigma(360K)^4\right\}$$

where for $\lambda_2 T_{sur}$ = 5 μm × 360 K = 1800 μm·K, $F_{(0-\lambda_2 T_{sur})}$ = 0.0393 and $\lambda_1 T_{sur}$ = 3 μm × 360 K = 1080 μm·K, $F_{(0-\lambda_1 T_{sur})}$ = 0.0010. For ε_c = 0.80, find

$$S_c(\varepsilon_c = 0.8) = 1\,\mu V\cdot m^2/W\{1375 + 7.295\}\,W/m^2 = 1382\,\mu V \qquad <$$

$$S_c(\varepsilon_c = 0.5) = 1\,\mu V\cdot m^2/W\{859.4 + 18.238\}\,W/m^2 = 878\,\mu V \qquad <$$

$$S_c(\varepsilon_c = 0.2) = 1\,\mu V\cdot m^2/W\{343.8 + 29.180\}\,W/m^2 = 373\,\mu V \qquad <$$

(d) The thermograph calibrated against a black surface (ε_1 = 1) interprets the radiation reaching the detector by emission and reflected radiation from a coating target ($\varepsilon_c < \varepsilon_o$) as that from a blackbody at an apparent temperature T_a. That is,

$$S_c = RF_{(\lambda_1 - \lambda_2, T_a)} E_b(T_a) = R\left[F_{(0-\lambda_2 T_a)} - F_{(0-\lambda_1 T_a)}\right]\sigma T_a^4 \qquad (8)$$

For each of the coatings in part (c), solving Eq. (8) using the IHT workspace with the *Radiation Tool*, *Band Emission Factor*, the following results were obtained,

ε_c	S_c (μV)	T_a (K)	$T_a - T_s$ (K)
0.8	1382	579.3	-20.7
0.5	878	539.2	-60.8
0.2	373	476.7	-123.3

COMMENTS: (1) From part (c) results for S_c, note that the contribution of the reflected irradiation becomes relatively more significant with lower values of ε_c.

(2) From part (d) results for the apparent temperature, note that the error, $(T - T_a)$, becomes larger with decreasing ε_c. By rewriting Eq. (8) to include the emissivity of the coating,

$$S_c' = R\left[F_{(0-\lambda_2 T_a)} - F_{(0-\lambda_1 T_a)}\right]\varepsilon_c \sigma T_a^4$$

The apparent temperature T_a' will be influenced only by the reflected irradiation. The results correcting only for the emissivity, ε_c, are

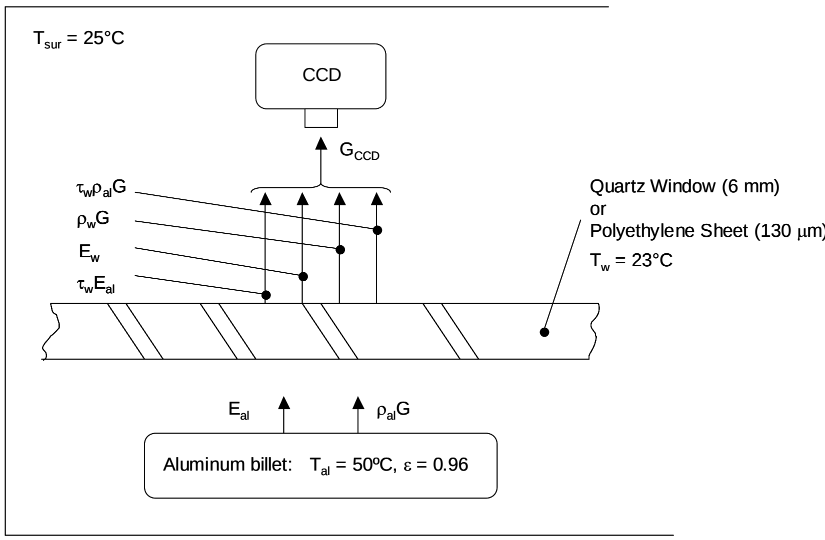
ε_c	0.8	0.5	0.2
T_a'(K)	600.5	602.2	608.5
$T_a' - T_s$(K)	+0.5	+2.2	+8.5

PROBLEM 12.86

KNOWN: Spectral range of a CCD device used for infrared temperature measurement, thickness of quartz window, transmissivity of polyethylene sheet, emissivity of painted aluminum billet, temperatures of the billet, window and surroundings.

FIND: (a) Temperature indicated by the CCD device when quartz window is used, (b) Temperature indicated by the CCD device when polyethylene window is used.

SCHEMATIC:



ASSUMPTIONS: (1) Large surroundings, (2) Diffuse surfaces, (3) Radiative properties do not vary in the spectral range of the CCD device, (4) Reflection from bottom of window is negligible.

ANALYSIS: (a) In the spectral range of the CCD detector,

$$G_{CCD,9-12} = \tau_w E_{al}\left[F_{(0-12\mu m)} - F_{(0-9\mu m)}\right] + E_w\left[F_{(0-12\mu m)} - F_{(0-9\mu m)}\right] + \rho_w G\left[F_{(0-12\mu m)} - F_{(0-9\mu m)}\right] + \tau_w \rho_{al} G\left[F_{(0-12\mu m)} - F_{(0-9\mu m)}\right] \qquad (1)$$

From Figure 12.23, $\tau_w \approx 0$ in the spectral range ($9\ \mu m \le \lambda \le 12\ \mu m$). Hence, Equation 1 becomes

$$G_{CCD,9-12} = \left[F_{(0-12\mu m)} - F_{(0-9\mu m)}\right]\left[\varepsilon_w \sigma T_w^4 + \rho_w \sigma T_{sur}^4\right]$$

Since $\alpha_w + \rho_w = 1$ and $\alpha_w = \varepsilon_w$ for a diffuse surface that is at the same temperature at the surroundings (see Equation 12.36) it follows that

$$G_{CCD,9-12} = \left[F_{(0-12\mu m)} - F_{(0-9\mu m)}\right]\sigma T_{sur}^4 = \left[F_{(0-12\mu m)} - F_{(0-9\mu m)}\right]\sigma T_d^4$$

where Td is the temperature indicated by the detector. Hence, $T_d = T_{sur} = 23°C$. <

Continued…

PROBLEM 12.86 (Cont.)

(b) With the polyethylene sheet as the window and an aluminum temperature of T_{al} = 50°C + 273 K = 323 K,

$$G_{CCD,9-12} = \tau_w \varepsilon_{al} \sigma T_{al}^4 \left[F_{(0-12\mu m \cdot 323K)} - F_{(0-9\mu m \cdot 323K)} \right] + \varepsilon_w \sigma T_w^4 \left[F_{(0-12\mu m \cdot 300K)} - F_{(0-9\mu m \cdot 300K)} \right]$$
$$+ \rho_w \sigma T_{sur}^4 \left[F_{(0-12\mu m \cdot 300K)} - F_{(0-9\mu m \cdot 300K)} \right] + \tau_w \rho_{al} \sigma T_{sur}^4 \left[F_{(0-12\mu m \cdot 300K)} - F_{(0-9\mu m \cdot 300K)} \right]$$

For the window, $\alpha_w + \rho_w + \tau_w = 1$. Since $\alpha_{\lambda,w} = \varepsilon_{\lambda,w}$ for the diffuse surface and since $T_w = T_{sur}$, $\alpha_w = \varepsilon_w$ as evident in Equation 12.43. Hence,

$$G_{CCD,9-12} = \left[F_{(0-12\mu m \cdot T_d)} - F_{(0-9\mu m \cdot T_d)} \right] \sigma T_d^4 = \tau_w \varepsilon_{al} \sigma T_{al}^4 \left[F_{(0-12\mu m \cdot 323K)} - F_{(0-9\mu m \cdot 323K)} \right]$$
$$+ \sigma T_{sur}^4 (1 - \tau_w) \left[F_{(0-12\mu m \cdot 300K)} - F_{(0-9\mu m \cdot 300K)} \right] + \tau_w (1 - \varepsilon_{al}) \sigma T_{sur}^4 \left[F_{(0-12\mu m \cdot 300K)} - F_{(0-9\mu m \cdot 300K)} \right]$$

or

$$T_d = \left[\frac{\tau_w \varepsilon_{al} T_{al}^4 \left[F_{(0-12\mu m \cdot 323K)} - F_{(0-9\mu m \cdot 323K)} \right] + (1 - \tau_w \varepsilon_{al}) T_{sur}^4 \left[F_{(0-12\mu m \cdot 300K)} - F_{(0-9\mu m \cdot 300K)} \right]}{\left[F_{(0-12\mu m \cdot T_d)} - F_{(0-9\mu m \cdot T_d)} \right]} \right]^{1/4}$$

Substituting values,

$$T_d = \left[\frac{0.78 \times 0.96 \times (323K)^4 \left[0.4576 - 0.2521 \right] + (1 - 0.78 \times 0.96) \times (300K)^4 \left[0.4036 - 0.2055 \right]}{\left[F_{(0-12\mu m \cdot T_d)} - F_{(0-9\mu m \cdot T_d)} \right]} \right]^{1/4}$$

A trial-and-error solution, or solution using IHT yields

$$T_d = 317.6 \text{ K} = 44.6°\text{C} \qquad <$$

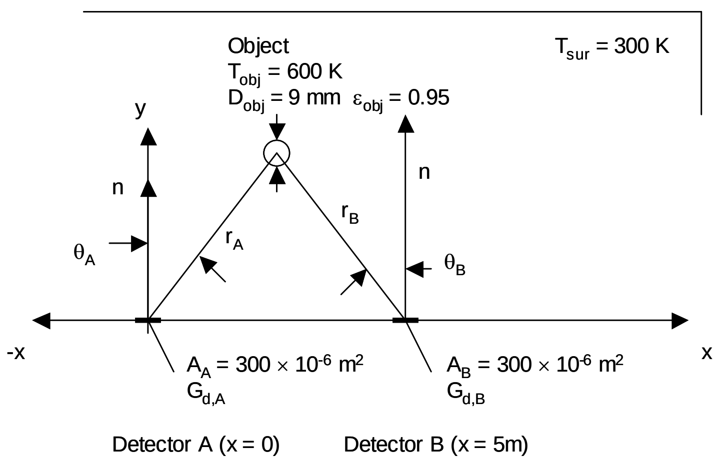
COMMENTS: (1) Materials that are transparent in the visible spectrum, such as quartz, are often opaque in the infrared part of the spectrum. The quartz window does not allow the warm billet to be viewed by the CCD device. (2) This analysis could be extended to calibrate the CCD device so that the indicated temperature is identical to the actual temperature.

PROBLEM 12.87

KNOWN: Diameter, emissivity and temperature of a spherical object. Aperture areas, locations, and spectral transmissivity of the optics of two detectors. Surroundings temperature and irradiation detected at two times.

FIND: Velocity of the object, location and time at which the object will strike the y = 0 plane.

SCHEMATIC:



ASSUMPTIONS: (1) Diffuse object, (2) Object travels in a straight line, (3) Object is located above y = 2 m.

ANALYSIS: We begin by analyzing the situation at time t = 0. For Detector A, the irradiation that is detected, $G_{d,A}$, is composed of irradiation from the surroundings, G_{sur}, and irradiation from the object, G_{obj}. Hence, $G_{d,A} = G_{sur,d,A} + G_{obj,d,A}$. The irradiation from the surroundings that is detected is

$$G_{sur,d,A} = \pi I_b F_{(0-2.5\mu m)} \tau_\lambda = E_b(300K) F_{(0-2.5\mu m)} \tau_\lambda$$
$$= 5.67 \times 10^{-8} W/m^2 \cdot K^4 \times 300^4 K^4 \times 1.2 \times 10^{-5} \times 0.9 = 4.96 \times 10^{-3} W/m^2$$

Therefore, $G_{obj,d,A} = 5.06 \times 10^{-3}$ W/m² – 4.96×10^{-3} W/m² = 100×10^{-6} W/m². Proceeding as in Example 12.1,

$$G_{obj,d,A} = \left[I_{obj} A_{obj} \cos\theta_{obj} A_A \cos\theta_A / A_A r_A^2 \right] \times F_{(0-2.5\mu m)} \tau_\lambda$$

Since the projected area of the sphere is a circle, $A_{obj} \cos\theta_{obj} = \pi D_{obj}^2 / 4$. In addition, $I_{obj} = \varepsilon_{obj} \sigma T_{obj}^4 / 4$. Therefore,

Continued…

PROBLEM 12.87 (Cont.)

$$100\times10^{-6}\,\mathrm{W/m^2} = \left[0.95\times5.67\times10^{-8}\,\mathrm{W/m^2\cdot K^4}\times(600\mathrm{K})^4\times(9\times10^{-3}\mathrm{m})^2\times\cos\theta_A\times0.01375\times0.9\right]/4r_A^2$$

Simplifying the preceding expression results in

$$\frac{\cos\theta_A}{r_A^2} = 57.14\times10^{-3}\mathrm{m}^{-2} \qquad (1)$$

We also note that

$$x_{obj,1} = r_A\sin\theta_A,\ y_{obj,1} = r_A\cos\theta_A \qquad (2,3)$$

where $x_{obj,1}$ and $y_{obj,1}$ are the x- and y-locations of the object. For Detector B, $G_{d,B} = G_{sur,d,B} + G_{obj,d,B}$ where $G_{sur,d,B} = G_{sur,d,A} = 4.96\times10^{-3}$ W/m^2. Therefore, $G_{obj,d,B} = 5.00\times10^{-3}$ W/m^2 – 4.96×10^{-3} W/m^2 = 40×10^{-6} W/m^2. As for Detector A,

$$G_{obj,d,B} = \left[I_{obj}A_{obj}\cos\theta_{obj}A_B\cos\theta_B/A_Br_B^2\right]\times F_{(0-2.5\mu m)}\tau_\lambda$$

Therefore,

$$40\times10^{-6}\,\mathrm{W/m^2} = \left[0.95\times5.67\times10^{-8}\,\mathrm{W/m^2\cdot K^4}\times(600\mathrm{K})^4\times(9\times10^{-3}\mathrm{m})^2\times\cos\theta_B\times0.01375\times0.9\right]/4r_B^2$$

Simplifying the preceding expression results in

$$\frac{\cos\theta_B}{r_B^2} = 22.86\times10^{-3}\mathrm{m}^{-2} \qquad (4)$$

where

$$x_{obj,1} = r_B\sin\theta_B + 5\mathrm{m},\ y_{obj,1} = r_B\cos\theta_B \qquad (5,6)$$

Equations 1 through 3 may be solved simultaneously to find all possible positions of the object at t = 0, as determined from Detector A. Equations 4 through 6 may be solved simultaneously to find all possible positions of the object at t = 0, as determined from Detector B. These results are plotted below in the first graph. Note that there are two possible locations. Since we know the object is located above y = 2 m, the object is located at the single position shown, which corresponds to x_{obj} = 1.078 m, y_{obj} = 3.965 m.

Now, consider t = 4 ms. The analysis proceeds as for t = 0, resulting in

$$\frac{\cos\theta_A}{r_A^2} = 28.57\times10^{-3}\mathrm{m}^{-2} \qquad (7)$$

$$x_{obj,2} = r_A\sin\theta_A,\ y_{obj,2} = r_A\cos\theta_A \qquad (8,9)$$

$$\frac{\cos\theta_B}{r_B^2} = 51.43\times10^{-3}\mathrm{m}^{-2} \qquad (10)$$

Continued…

PROBLEM 12.87 (Cont.)

$$x_{obj,2} = r_B \sin\theta_B + 5 \text{ m}, \quad y_{obj,2} = r_B \cos\theta_B \qquad (11,12)$$

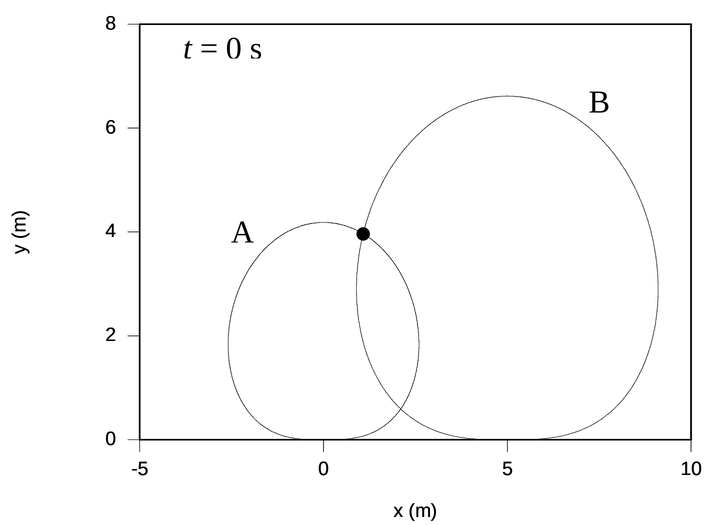
Equations 7 through 9 may be solved simultaneously to find all possible positions of the object at t = 4 ms as determined from Detector A. Equations 10 through 12 may be solved to find all possible positions at t = 4 ms, as determined from Detector B. The two possible positions are shown in the second plot below. Since the object is located above y = 2 m, the object is at the single position shown, which is $x_{obj,2} = 3.360$ m, $y_{obj,2} = 3.903$ m.

The velocity components of the object are

$$v_x = \frac{(x_{obj,2} - x_{obj,1})}{\Delta t} = \frac{(3.360 \text{ m} - 1.078 \text{ m})}{4 \times 10^{-3} \text{ s}} = 571 \text{ m/s} \qquad <$$

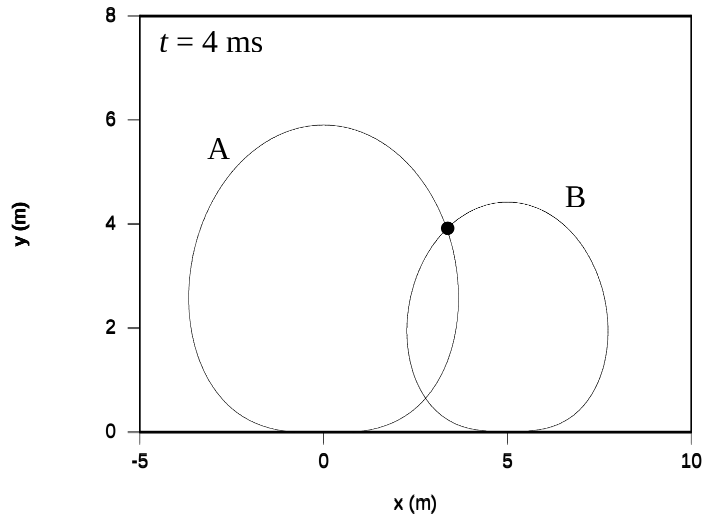
$$v_y = \frac{(y_{obj,2} - y_{obj,1})}{\Delta t} = \frac{(3.903 \text{ m} - 3.965 \text{ m})}{4 \times 10^{-3} \text{ s}} = -15.5 \text{ m/s} \qquad <$$

The object's time of flight is $t_f = y_{obj,1}/|v_y| = 3.965 \text{ m}/15.5 \text{ m/s} = 0.256 \text{ s}$ and the object will travel a distance of $d = v_x t_f = 570.5 \text{ m} \times 0.256 \text{ s} = 146$ m. $<$



Continued…

PROBLEM 12.87 (Cont.)



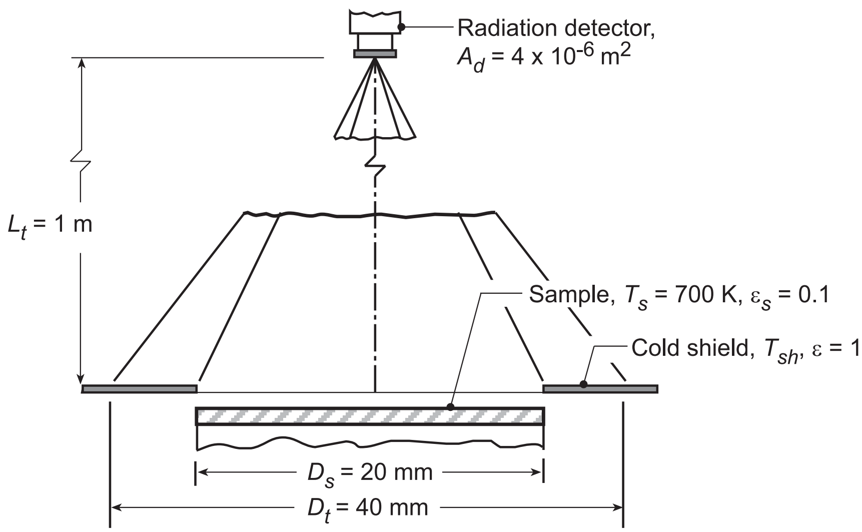
COMMENTS: (1) This is known as an "inverse" problem. Multiple solutions exist to such problems. (2) Use of a third detector would allow one to determine the object's position in three-dimensional space.

PROBLEM 12.88

KNOWN: Sample at T_s = 700 K with ring-shaped cold shield viewed normally by a radiation detector.

FIND: (a) Shield temperature, T_{sh}, required so that its emitted radiation is 1% of the total radiant power received by the detector, and (b) Compute and plot T_{sh} as a function of the sample emissivity for the range $0.05 \le \varepsilon \le 0.35$ subject to the parametric constraint that the radiation emitted from the cold shield is 0.05, 1 or 1.5% of the total radiation received by the detector.

SCHEMATIC:



ASSUMPTIONS: (1) Sample is diffuse and gray, (2) Cold shield is black, and (3) $A_d, D_s^2, D_t^2 << L_t^2$.

ANALYSIS: (a) The radiant power intercepted by the detector from within the target area is

$$q_d = q_{s\to d} + q_{sh\to d}$$

The contribution from the sample is

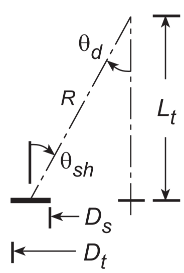
$$q_s \to d = I_{s,e} A_s \cos\theta_s \, \Delta\omega_{d-s} \qquad \theta_s = 0^\circ$$

$$I_{s,e} = \varepsilon_s E_b / \pi = \varepsilon_s \sigma T_s^4 / \pi$$

$$\Delta\omega_{d-s} = \frac{A_d \cos\theta_d}{L_t^2} = \frac{A_d}{L_t^2} \qquad \theta_d = 0^\circ$$

$$q_{s\to d} = \varepsilon_s \sigma T_s^4 A_s A_d / \pi L_t^2 \qquad (1)$$

The contribution from the ring-shaped cold shield is



$$q_{sh\to d} = I_{sh,e} A_{sh} \cos\theta_{sh} \Delta\omega_{d-sh}$$

$$I_{sh,e} = E_b / \pi = \sigma T_{sh}^4 / \pi$$

and, from the geometry of the shield -detector,

$$A_{sh} = \frac{\pi}{4}\left(D_t^2 - D_s^2\right)$$

$$\cos\theta_{sh} = L_t \Big/ \left[\left(\bar{D}/2\right)^2 = L_t^2\right]^{1/2}$$

Continued...

PROBLEM 12.88 (Cont.)

where $\bar{D} = (D_s + D_t)/2$

$$\Delta\omega_{d-sh} = \frac{A_d \cos\theta_d}{R^2} \qquad \cos\theta_d = \cos\theta_{sh}$$

where $R = \left[L_t^2 + \bar{D}^2\right]^{1/2}$

$$q_{sh\to d} = \frac{\sigma T_{sh}^4}{\pi} A_{sh} \left[\frac{L_t}{\left[((D_s + D_t)/4)^2 + L_t^2\right]^{1/2}}\right]^2 \frac{A_d}{\left[((D_s + D_t)/4)^2 + L_t^2\right]} \qquad (2)$$

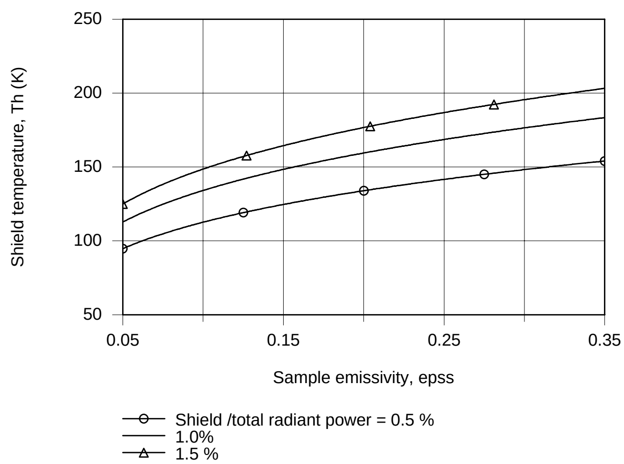
The requirement that the emitted radiation from the cold shield is 1% of the total radiation intercepted by the detector is expressed as

$$\frac{q_{sh-d}}{q_{tot}} = \frac{q_{sh-d}}{q_{sh-d} + q_{s-d}} = 0.01 \qquad (3)$$

By evaluating Eq. (3) using Eqs. (1) and (3), find

$$T_{sh} = 134\,K$$ <

(b) Using the foregoing equations in the IHT workspace, the required shield temperature for q_{sh-d}/q_{tot} = 0.5, 1 or 1.5% was computed and plotted as a function of the sample emissivity.



As the shield emission-to-total radiant power ratio decreases (from 1.5 to 0.5%) , the required shield temperature decreases. The required shield temperature increases with increasing sample emissivity for a fixed ratio.

PROBLEM 12.89

KNOWN: Wavelengths associated with a two-color pyrometer.

FIND: The ratio of intensities emitted by the surface at nominal wavelength of λ = 5 μm and $\Delta\lambda$ = 0.1, 0.5 and 1 μm.

ASSUMPTIONS: Surface is hot relative to the surroundings so that reflection is negligible relative to emission.

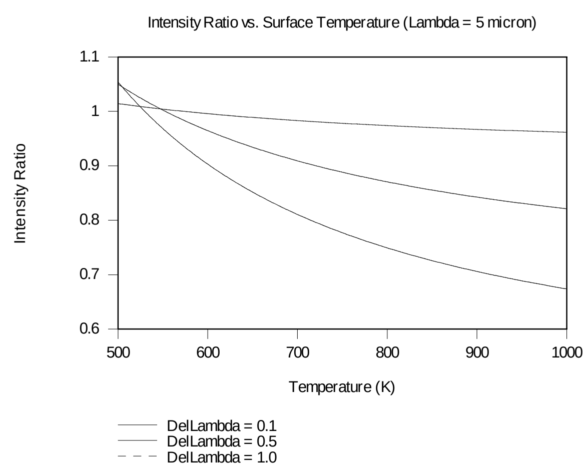
ANALYSIS: The spectral intensity emitted by the surface is

$$I_{\lambda,e} = \varepsilon_\lambda I_{\lambda,b}(\lambda,T) = \frac{\varepsilon_\lambda 2hc_o^2}{\lambda^5\left[\exp(hc_o/\lambda kt)-1\right]}$$

Assuming the spectral emissivity is independent of wavelength over $\Delta\lambda$, the intensity ratio, R, is

$$R = \frac{\lambda^5\left[\exp(hc_o/\lambda kT)-1\right]}{(\lambda+\Delta\lambda)^5\left[\exp(hc_o/(\lambda+\Delta\lambda)kT)-1\right]}$$

with h = 6.626×10^{-34} J·s, k = 1.381×10^{-23} J/K, $c_o = 2.998 \times 10^8$ m/s, λ = 5 μm and $\Delta\lambda$ = 0.1, 0.5 and 1.0 μm, the variation of R over the range 500 K $\leq$ T $\leq$ 1000 K is shown below.



As $\Delta\lambda$ increases, the ratio of intensities exhibits higher sensitivity to the surface temperature. However, a tradeoff exists since the assumption of uniform spectral emissivity over $\Delta\lambda$ becomes less robust as the difference between λ_1 and λ_2 becomes large.

COMMENTS: (1) The pyrometer will also detect the reflection from the surface. If the surface reflectivity is large, or if the surface is cold relative to the surroundings, care must be made when interpreting the detector's output. (2) Care should be taken if the surface emissivity exhibits highly spectral behavior. (3) The intensity ratio is greater than unity at relatively low temperatures and less than unity at higher temperatures. Can you explain why?

PROBLEM 12.90

KNOWN: Two wavelength values associated with a two-color pyrometer. Ratio of detected radiation from stainless steel.

FIND: Temperature of stainless steel.

ASSUMPTIONS: (1) Surface is hot relative to the surroundings so that reflection is negligible relative to emission, (2) Wien's law holds, (3) Emissivity does not vary greatly over the wavelength range associated with the pyrometer.

ANALYSIS: From Problem 12.27, Wien's law is

$$E_{\lambda,b} \approx \frac{C_1}{\lambda^5}\exp\left(-\frac{C_2}{\lambda T}\right)$$

The detected radiation flux is equal to the radiation flux emitted from the steel surface, since reflection has been assumed negligible. The ratio of intensities is equal to the ratio of emissive power (since $I_\lambda = \pi E_\lambda$). Thus,

$$\frac{I_{\lambda_1}}{I_{\lambda_2}} = \frac{E_{\lambda_1}}{E_{\lambda_2}} = \frac{\varepsilon_1 E_{\lambda_1,b}}{\varepsilon_2 E_{\lambda_2,b}} = \frac{\lambda_2^5}{\lambda_1^5}\exp\left[-\frac{C_2}{T}\left(\frac{1}{\lambda_1}-\frac{1}{\lambda_2}\right)\right] = 2.15$$

where the assumption $\varepsilon_1 \approx \varepsilon_2$ has been used. Solving for T,

$$T = C_2\frac{\left(\frac{1}{\lambda_2}-\frac{1}{\lambda_1}\right)}{\ln\left(2.15\frac{\lambda_1^5}{\lambda_2^5}\right)} = 1.439\times10^4\ \mu\text{m}\cdot\text{K}\frac{\left(\frac{1}{0.63\mu\text{m}}-\frac{1}{0.65\mu\text{m}}\right)}{\ln\left(2.15\left(\frac{0.65\mu\text{m}}{0.63\mu\text{m}}\right)^5\right)} = 762\ \text{K}$$ <

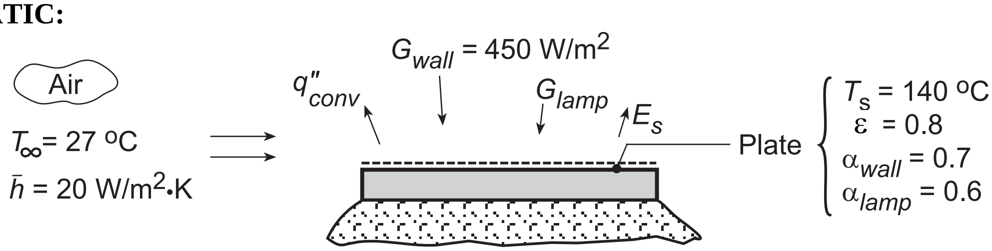
COMMENTS: Comparing Eq. 12.30 to Wien's law, it can be seen that Wien's law is accurate provided that $\exp(C_2/\lambda T) >> 1$. For the conditions of this problem, $\exp(C_2/\lambda_1 T) = 4\times10^{12}$ and Wien's law is highly accurate.

PROBLEM 12.91

KNOWN: Painted plate located inside a large enclosure being heated by an infrared lamp bank.

FIND: (a) Lamp irradiation required to maintain plot at $T_s = 140^oC$ for the prescribed convection and enclosure irradiation conditions, (b) Compute and plot the lamp irradiation, G_{lamp}, required as a function of the plate temperature, T_s, for the range $100 \le T_s \le 300\ ^oC$ and for convection coefficients of h = 15, 20 and 30 $W/m^2 \cdot K$, and (c) Compute and plot the air stream temperature, T_∞, required to maintain the plate at 140^oC as a function of the convection coefficient h for the range $10 \le h \le 30\ W/m^2 \cdot K$ with a lamp irradiation $G_{lamp} = 3000\ W/m^2$.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) No losses on backside of plate.

ANALYSIS: (a) Perform an energy balance on the plate, per unit area,

$$\dot{E}_{in} - \dot{E}_{out} = 0 \tag{1}$$

$$\alpha_{wall} \cdot G_{wall} + \alpha_{lamp} G_{lamp} - q''_{conv} - E_s = 0 \tag{2}$$

where the emissive power of the surface and convective fluxes are

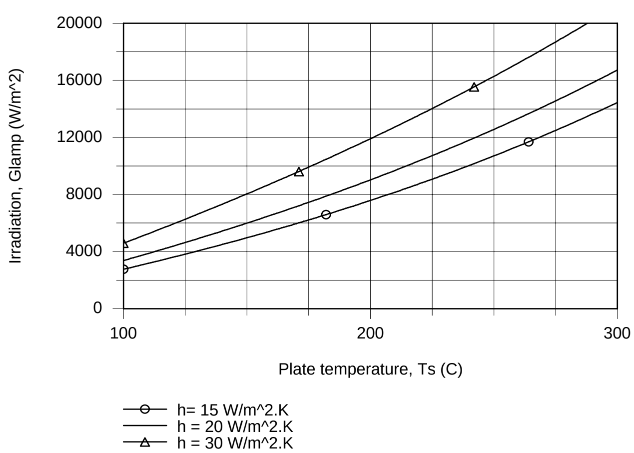
$$E_s = \varepsilon_s E_b(T_s) = \varepsilon_s \cdot \sigma T_s^4 \qquad q''_{conv} = h(T_s - T_\infty) \tag{3,4}$$

Substituting values, find the lamp irradiation

$$0.7 \times 450\ W/m^2 + 0.6 \times G_{lamp} - 20\ W/m^2 \cdot K(413 - 300)\ K$$
$$-0.8 \times 5.67 \times 10^{-8}\ W/m^2 \cdot K^4 (413\ K)^4 = 0 \tag{5}$$

$$G_{lamp} = 5441\ W/m^2$$ <

(b) Using the foregoing equations in the IHT workspace, the irradiation, G_{lamp}, required to maintain the plate temperature in the range $100 \le T_s \le 300\ ^oC$ for selected convection coefficients was computed. The results are plotted below.

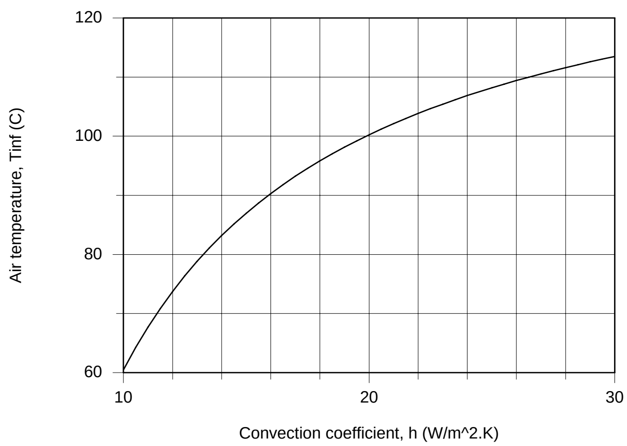


Continued...

PROBLEM 12.91 (Cont.)

As expected, to maintain the plate at higher temperatures, the lamp irradiation must be increased. At any plate operating temperature condition, the lamp irradiation must be increased if the convection coefficient increases. With forced convection (say, $h \geq 20\ W/m^2 \cdot K$) of the airstream at 27^oC, excessive irradiation levels are required to maintain the plate above the cure temperature of 140^oC.

(c) Using the IHT model developed for part (b), the airstream temperature, T_∞, required to maintain the plate at $T_s = 140^oC$ as a function of the convection coefficient with $G_{lamp} = 3000\ W/m^2 \cdot K$ was computed and the results are plotted below.



As the convection coefficient increases, for example by increasing the airstream velocity over the plate, the required air temperature must increase. Give a physical explanation for why this is so.

COMMENTS: (1) For a spectrally selective surface, we should expect the absorptivity to depend upon the spectral distribution of the source and $\alpha \neq \varepsilon$.

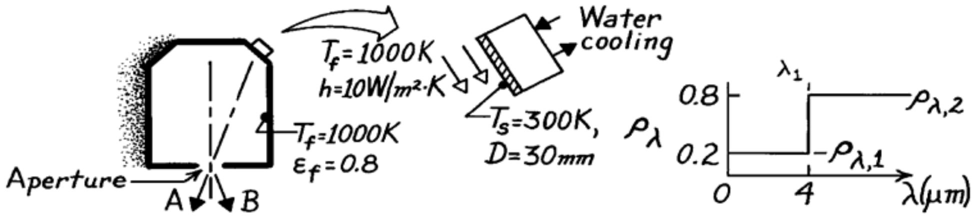
(2) Note the new terms used in this problem; use your Glossary, Section 12.10 to reinforce their meaning.

PROBLEM 12.92

KNOWN: Small sample of reflectivity, ρ_λ, and diameter, D, is irradiated with an isothermal enclosure at T_f.

FIND: (a) Absorptivity, α, of the sample with prescribed ρ_λ, (b) Emissivity, ε, of the sample, (c) Heat removed by coolant to the sample, (d) Explanation of why system provides a measure of ρ_λ.

SCHEMATIC:



ASSUMPTIONS: (1) Sample is diffuse and opaque, (2) Furnace is an isothermal enclosure with area much larger than the sample, (3) Aperture of furnace is small.

ANALYSIS: (a) The absorptivity, α, follows from Eq. 12.48, where the irradiation on the sample is $G = E_b\,(T_f)$ and $\alpha_\lambda = 1 - \rho_\lambda$.

$$\alpha = \int_0^\infty \alpha_\lambda G_\lambda \, d\lambda / G = \int_0^\infty (1-\rho_\lambda) E_{\lambda,b}(\lambda, 1000K) d\lambda / E_b(1000K)$$

$$\alpha = (1-\rho_{\lambda,1}) F_{(0\to\lambda_1)} + (1-\rho_{\lambda,2})\left[1 - F_{(0\to\lambda_1)}\right].$$

Using Table 12.1 for $\lambda_1 T_f = 4 \times 1000 = 4000\ \mu m\cdot K$, $F_{(0-\lambda)} = 0.481$ giving

$$\alpha = (1-0.2)\times 0.481 + (1-0.8)\times(1-0.481) = 0.49.$$ <

(b) The emissivity, ε, follows from Table 12.1 with $\varepsilon_\lambda = \alpha_\lambda = 1 - \rho_\lambda$ since the sample is diffuse.

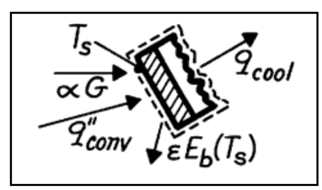
$$\varepsilon = E(T_s)/E_b(T_s) = \int_0^\infty \varepsilon_\lambda E_{\lambda,b}(\lambda, 300K) d\lambda / E_b(300K)$$

$$\varepsilon = (1-\rho_{\lambda,1}) F_{(0-\lambda_1)} + (1-\rho_{\lambda,2})\left[1 - F_{(0\to\lambda_1)}\right].$$

Using Table 12.1 for $\lambda_1 T_s = 4 \times 300 = 1200\ \mu m\cdot K$, $F_{(0-\lambda)} = 0.002$ giving

$$\varepsilon = (1-0.2)\times 0.002 + (1-0.8)\times(1-0.002) = 0.20.$$

(c) Performing an energy balance on the sample, the heat removal rate by the cooling water is



$$q_{cool} = A_s\left[\alpha G + q''_{conv} - \varepsilon E_b(T_s)\right]$$

where $$G = E_b(T_f) = E_b(1000K)$$

$$q''_{conv} = h(T_f - T_s) \qquad A_s = \pi D^2/4$$

$$q_{cool} = (\pi/4)(0.03m)^2\Big[0.49\times 5.67\times 10^{-8} W/m^2\cdot K^4 \times (1000K)^4$$

$$+ 10\, W/m^2\cdot K(1000-300)K - 0.20\times 5.67\times 10^{-8} W/m^2\cdot K^4\times(300K)^4\Big] = 24.5\ W.$$ <

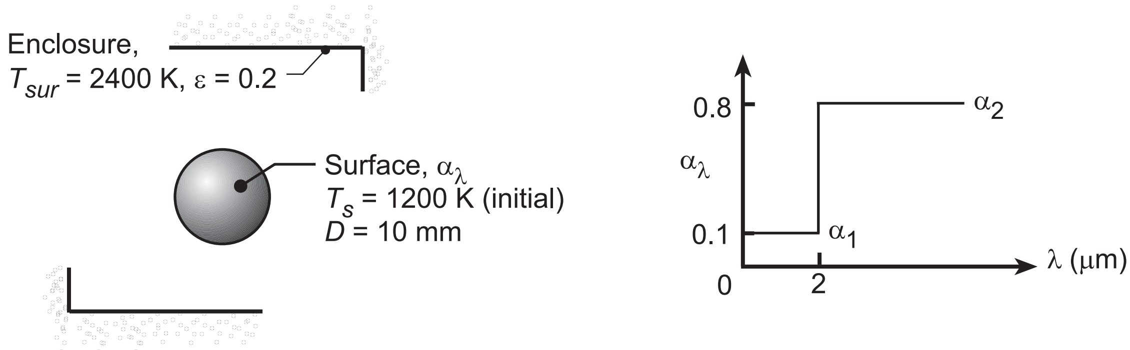
(d) Assume that reflection makes the dominant contribution to the radiosity of the sample. When viewing in the direction A, the spectral radiant power is proportional to $\rho_\lambda\, G_\lambda$. In direction B, the spectral radiant power is proportional to $E_{\lambda,b}\,(T_f)$. Noting that $G_\lambda = E_{\lambda,b}\,(T_f)$, the ratio gives ρ_λ.

PROBLEM 12.93

KNOWN: Small, opaque surface initially at 1200 K with prescribed α_λ distribution placed in a large enclosure at 2400 K.

FIND: (a) Total, hemispherical absorptivity of the sample surface, (b) Total, hemispherical emissivity, (c) α and ε after long time has elapsed, (d) Variation of sample temperature with time.

SCHEMATIC:



ASSUMPTIONS: (1) Surface is diffusely radiated. (2) Enclosure is much larger than surface and at a uniform temperature.

PROPERTIES: *Table A.1*, Tungsten (T ≈ 1800 K): ρ = 19,300 kg/m^3, c_p = 163 J/kg·K, k ≈ 102 W/m·K.

ANALYSIS: (a) The total, hemispherical absorptivity follows from Eq. 12.52, where $G_\lambda = E_{\lambda,b}(T_{sur})$. That is, the irradiation corresponds to the spectral emissive power of a blackbody at the enclosure temperature and is independent of the enclosure emissivity.

$$\alpha = \int_0^\infty \alpha_\lambda G_\lambda \, d\lambda \Big/ \int_0^\infty G_\lambda \, d\lambda = \int_0^\infty \alpha_\lambda E_{\lambda,b}(\lambda, T_{sur}) d\lambda / E_b(T_{sur})$$

$$\alpha = \alpha_1 \int_0^{2\mu m} E_{\lambda,b}(\lambda, T_{sur}) d\lambda / \sigma T_{sur}^4 + \alpha_2 \int_{2\mu m}^\infty E_{\lambda,b}(\lambda, T_{sur}) d\lambda \Big/ \sigma T_{sur}^4$$

$$\alpha = \alpha_1 F_{(0\to 2\mu m)} + \alpha_2 \left[1 - F_{(0\to 2\mu m)}\right] = 0.1 \times 0.6076 + 0.8[1 - 0.6076] = 0.375 \quad <$$

where at $\lambda T = 2 \times 2400 = 4800\,\mu m \cdot K$, $F_{(0\to 2\mu m)} = 0.6076$ from Table 12.1.

(b) The total, hemispherical emissivity follows from Eq. 12.43,

$$\varepsilon = \int_0^\infty \varepsilon_\lambda E_{\lambda,b}(\lambda, T_s) d\lambda \Big/ \int_0^\infty E_{\lambda,b}(\lambda, T_s) d\lambda .$$

Since the surface is diffuse, $\varepsilon_\lambda = \alpha_\lambda$ and the integral can be expressed as

$$\varepsilon = \alpha_1 \int_0^{2\mu m} E_{\lambda,b}(\lambda, T_s) d\lambda \Big/ \sigma T_s^4 + \alpha_2 \int_{2\mu m}^\infty E_{\lambda,b}(\lambda, T_s) d\lambda \Big/ \sigma T_s^4$$

$$\varepsilon = \alpha_1 F_{(0\to 2\mu m)} + \alpha_2 \left[1 - F_{(0\to 2\mu m)}\right] = 0.1 \times 0.1403 + 0.8[1 - 0.1403] = 0.702 \quad <$$

where at λT = 2 × 1200 = 2400 μm · K, find $F_{(0\to 2\mu m)} = 0.1403$ from Table 12.1.

(c) After a long period of time, the surface will be at the temperature of the enclosure. This condition of thermal equilibrium is described by Kirchoff's law, for which

$$\varepsilon = \alpha = 0.375. \quad <$$

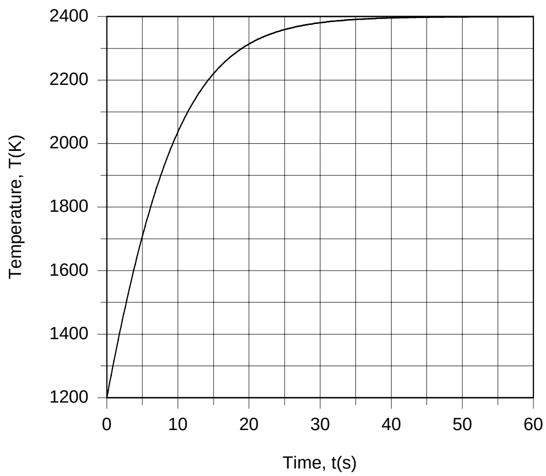
Continued...

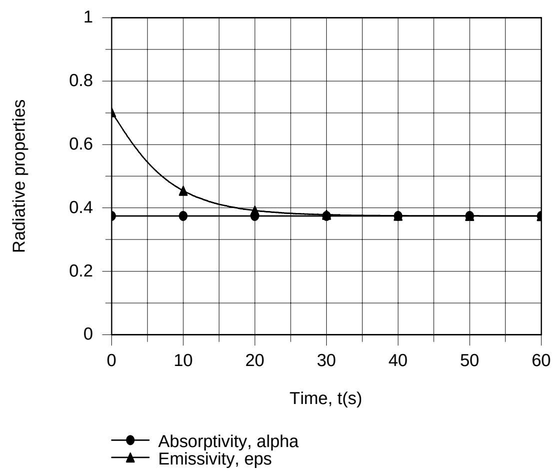
PROBLEM 12.93 (Cont.)

(d) Using the IHT *Lumped Capacitance* Model, the energy balance relation is of the form

$$\rho c_p \forall \frac{dT}{dt} = A_s[\alpha G - \varepsilon(T)E_b(T)]$$

where T = T_s, $\forall = \pi D^3/6$, $A_s = \pi D^2$ and $G = \sigma T_{sur}^4$. Integrating over time in increments of Δt = 0.5s and using the *Radiation* Toolpad to determine ε(t), the following results are obtained.





The temperature of the specimen increases rapidly with time and achieves a value of 2399 K within t ≈ 47s. The emissivity decreases with increasing time, approaching the absorptivity as T approaches T_{sur}.

COMMENTS: (1) Recognize that α always depends upon the spectral irradiation distribution, which, in this case, corresponds to emission from a blackbody at the temperature of the enclosure.

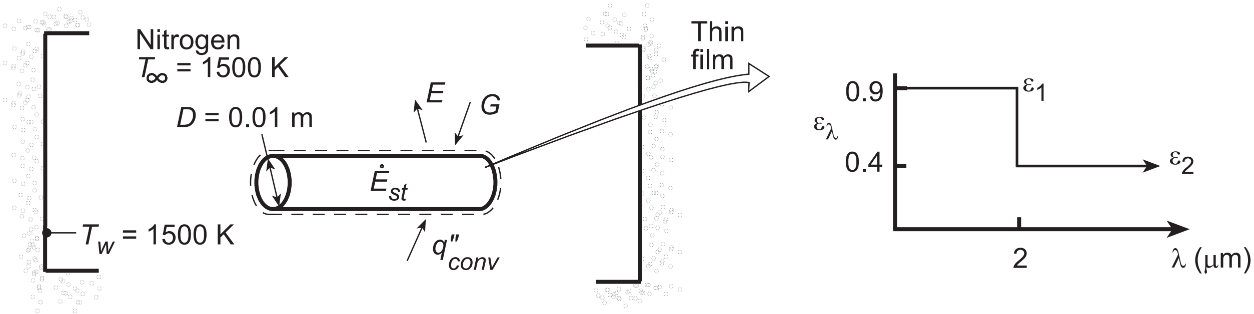
(2) With $h_r = \varepsilon\sigma(T + T_{sur})(T^2 + T_{sur}^2) \approx 0.375\sigma 4T_{sur}^3 = 1176\, W/m^2 \cdot K$, $Bi = h_r\,(r_o/3)/k$ $= (1176\, W/m^2 \cdot K)\, 1.667 \times 10^{-3}\, m/102\, W/m \cdot K = 0.0192 << 1$, use of the lumped capacitance model is justified.

PROBLEM 12.94

KNOWN: Diameter and initial temperature of copper rod. Wall and gas temperature.

FIND: (a) Expression for initial rate of change of rod temperature, (b) Initial rate for prescribed conditions, (c) Transient response of rod temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Applicability of lumped capacitance approximation, (2) Furnace approximates a blackbody cavity, (3) Thin film is diffuse and has negligible thermal resistance, (4) Properties of nitrogen approximate those of air (Part c).

PROPERTIES: *Table A.1*, copper (T = 300 K): c_p = 385 J/kg·K, ρ = 8933 kg/m^3, k = 401 W/m·K. *Table A.4*, nitrogen (p = 1 atm, T_f = 900 K): ν = 100.3 × 10^{-6} m^2/s, α = 139 × 10^{-6} m^2/s, k = 0.0597 W/m·K, Pr = 0.721.

ANALYSIS: (a) Applying conservation of energy at an instant of time to a control surface about the cylinder, $\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st}$, where energy inflow is due to natural convection and radiation from the furnace wall and energy outflow is due to emission. Hence, for a unit cylinder length,

$$q_{conv} + q_{rad,net} = \frac{\rho\pi D^2}{4} c_p \frac{dT}{dt}$$

where

$$q_{conv} = \bar{h}(\pi D)(T_\infty - T)$$

$$q_{rad,net} = \pi D(\alpha G - \varepsilon E_b) = \pi D\left[\alpha E_b(T_w) - \varepsilon E_b(T)\right]$$

Hence, at t = 0 ($T = T_i$),

$$dT/dt)_i = (4/\rho c_p D)\left[\bar{h}(T_\infty - T_i) + \alpha E_b(T_w) - \varepsilon E_b(T_i)\right]$$

(b) With $Ra_D = \frac{g\beta(T_\infty - T_i)D^3}{\alpha\nu} = \frac{9.8\,m/s^2(1/900\,K)(1200\,K)(0.01\,m)^3}{100.3\times139\times10^{-12}\,m^4/s^2} = 937$, the Churchill-Chu correlation of Chapter 9 yields

$$\overline{Nu}_D = \left\{0.60 + \frac{0.387 Ra_D^{1/6}}{\left[1+(0.559/Pr)^{9/16}\right]^{8/27}}\right\}^2 = 2.58$$

$$\bar{h} = k\frac{\overline{Nu}_D}{D} = \frac{(0.0597\,W/m\cdot K)2.58}{0.01\,m} = 15.4\,W/m^2\cdot K$$

With $T = T_i$ = 300 K, λT = 600 μm·K yields $F_{(0\to\lambda)}$ = 0, in which case $\varepsilon = \varepsilon_1 F_{(0\to\lambda)} + \varepsilon_2\left[1 - F_{(0\to\lambda)}\right] = 0.4$.

With $T = T_w$ = 1500 K, λT = 3000 K yields $F_{(0\to\lambda)}$ = 0.273. Hence, with $\alpha_\lambda = \varepsilon_\lambda$, $\alpha = \varepsilon_1 F_{(0\to\lambda)} + \varepsilon_2[1 - F_{(0\to\lambda)}]$ = 0.9(0.273) + 0.4(1 - 0.273) = 0.537. It follows that

Continued...

PROBLEM 12.94 (Cont.)

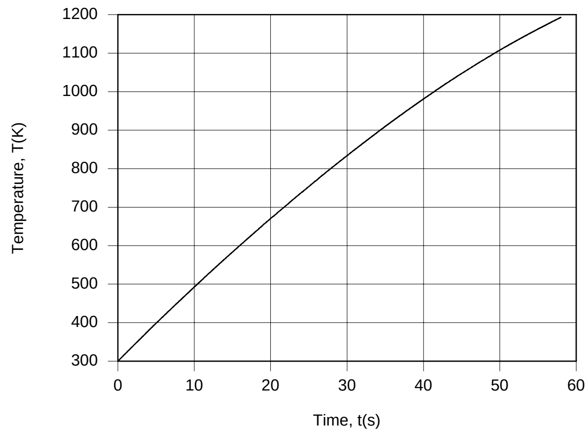
$$\left.\frac{dT}{dt}\right)_i = \frac{4}{8933\,\frac{kg}{m^3}\left(385\,\frac{J}{kg\cdot K}\right)0.01\,m}\left[15.4\,\frac{W}{m^2\cdot K}(1500-300)\,K\right.$$

$$\left.+0.537\times 5.67\times 10^{-4}\,\frac{W}{m^2\cdot K^4}(1500\,K)^4 - 0.4\times 5.67\times 10^{-8}\,\frac{W}{m^2\cdot K^4}(300\,K)^4\right]$$

$$dT/dt)_i = 1.163\times 10^{-4}\,m^2\cdot K/J\left[18,480+154,140-180\right]W/m^2 = 20\,K/s \quad <$$

Defining a pseudo radiation coefficient as $h_r = (\alpha G - \varepsilon E_b)/(T_w - T_i)$ = (153,960 W/m^2)/1200 K = 128.3 W/m^2·K, Bi = $(h + h_r)(D/4)/k$ = 143.7 W/m^2·K (0.0025 m)/401 W/m·K = 0.0009. Hence, the lumped capacitance approximation is appropriate.

(c) Using the IHT *Lumped Capacitance* Model with the *Correlations*, *Radiation* and *Properties* (copper and air) Toolpads, the transient response of the rod was computed for $300 \le T < 1200$ K, where the upper limit was determined by the temperature range of the copper property table.



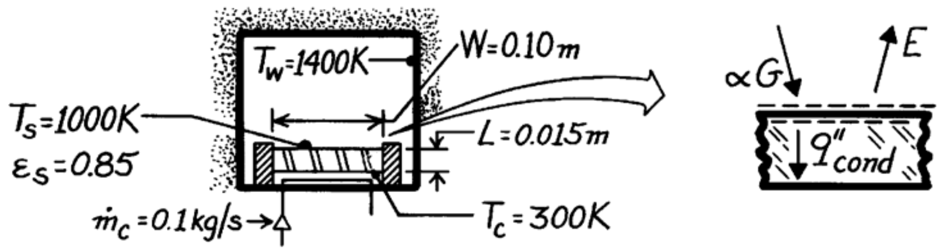
The rate of change of the rod temperature, dT/dt, decreases with increasing temperature, in accordance with a reduction in the convective and *net* radiative heating rates. Note, however, that even at T ≈ 1200 K, αG, which is fixed, is large relative to q''_{conv} and εE_b and dT/dt is still significant.

PROBLEM 12.95

KNOWN: Temperatures of furnace wall and top and bottom surfaces of a planar sample. Dimensions and emissivity of sample.

FIND: (a) Sample thermal conductivity, (b) Validity of assuming uniform bottom surface temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional conduction in sample, (3) Constant k, (4) Diffuse-gray surface, (5) Irradiation equal to blackbody emission at 1400K.

PROPERTIES: *Table A-6,* Water coolant (300K): $c_{p,c}$ = 4179 J/kg·K

ANALYSIS: (a) From energy balance at top surface,

$$\alpha G - E = q''_{cond} = k_s\left(T_s - T_c\right)/L$$

where $E = \varepsilon_s \sigma T_s^4, G = \sigma T_w^4, \alpha = \varepsilon_s$ giving

$$\varepsilon_s \sigma T_w^4 - \varepsilon_s \sigma T_s^4 = k_s\left(T_s - T_c\right)/L.$$

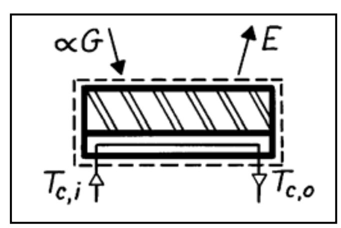
Solving for the thermal conductivity and substituting numerical values, find

$$k_s = \frac{\varepsilon_s L \sigma}{T_s - T_c}\left(T_w^4 - T_s^4\right)$$

$$k_s = \frac{0.85 \times 0.015\text{m} \times 5.67 \times 10^{-8}\text{W/m}^2 \cdot \text{K}^4}{(1000-300)\text{K}}\left[(1400\text{K})^4 - (1000\text{K})^4\right]$$

$$k_s = 2.93\ \text{W/m} \cdot \text{K}.$$ <

(b) Non-uniformity of bottom surface temperature depends on coolant temperature rise. From the energy balance



$$q = \dot{m}_c c_{p,c} \Delta T_c = \left(\alpha G - E\right) W^2$$

$$\Delta T_c = 0.85 \times 5.67 \times 10^{-8}\text{W/m}^2 \cdot \text{K}^4\left[1400^4 - 1000^4\right]\text{K}^4 (0.10\text{m})^2 / 0.1\text{kg/s} \times 4179\ \text{J/kg} \cdot \text{K}$$

$$\Delta T_c = 3.3\text{K}.$$ <

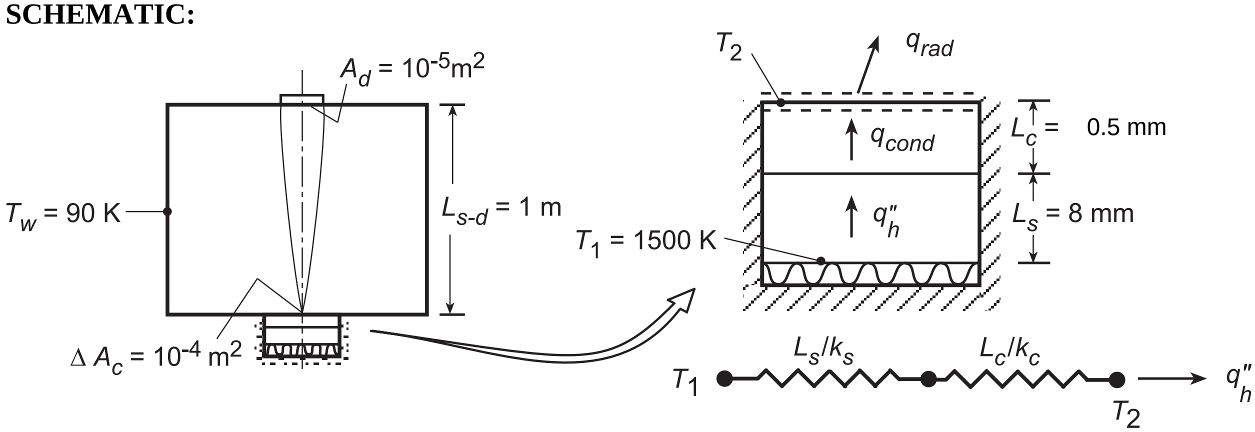
The variation in T_c (~ 3K) is small compared to $(T_s - T_c) \approx 700$K. Hence it is not large enough to introduce significant error in the k determination.

PROBLEM 12.96

KNOWN: Thicknesses and thermal conductivities of a ceramic/metal composite. Emissivity of ceramic surface. Temperatures of vacuum chamber wall and substrate lower surface. Receiving area of radiation detector, distance of detector from sample, and sample surface area viewed by detector.

FIND: (a) Ceramic top surface temperature and heat flux, (b) Rate at which radiation emitted by the ceramic is intercepted by detector, (c) Effect of an interfacial (ceramic/substrate) contact resistance on sample top and bottom surface temperatures.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, steady-state conduction in sample, (2) Constant properties, (3) Chamber forms a blackbody enclosure at T_w, (4) Ceramic surface is diffuse/gray, (5) Negligible interface contact resistance for part (a).

PROPERTIES: Ceramic: $k_c = 6$ W/m·K, $\varepsilon_c = 0.8$. Substrate: $k_s = 25$ W/m·K.

ANALYSIS: (a) From an energy balance at the exposed ceramic surface, $q''_{cond} = q''_{rad}$, or

$$\frac{T_1 - T_2}{(L_s/k_s) + (L_c/k_c)} = \varepsilon_c \sigma \left(T_2^4 - T_w^4\right)$$

$$\frac{1500\,K - T_2}{\dfrac{0.008\,m}{25\,W/m\cdot K} + \dfrac{0.0005\,m}{6\,W/m\cdot K}} = 0.8 \times 5.67 \times 10^{-8}\,W/m^2\cdot K^4 \left(T_2^4 - 90^4\right) K^4$$

$$3.72 \times 10^6 - 2479 T_2 = 4.54 \times 10^{-8} T_2^4 - 2.98$$

$$4.54 \times 10^{-8} T_2^4 + 2479 T_2 = 3.72 \times 10^6$$

Solving, we obtain

$$T_2 = 1425\text{ K}$$ <

$$q''_h = \frac{T_1 - T_2}{(L_s/k_s) + (L_c/k_c)} = \frac{(1500 - 1425)\,K}{4.033 \times 10^{-4}\,m^2 \cdot K/W} = 1.87 \times 10^5\,W/m^2$$ <

(b) Since the ceramic surface is diffuse, the total intensity of radiation emitted in all directions is $I_e = \varepsilon_c E_b(T_s)/\pi$. Hence, the rate at which *emitted* radiation is intercepted by the detector is

$$q_{c(em)-d} = I_e \Delta A_c \left(A_d / L_{s-d}^2\right)$$

$$q_{c(em)-d} = \frac{0.8 \times 5.67 \times 10^{-8}\,W/m^2\cdot K^4\,(1425\,K)^4}{\pi sr} \times 10^{-4}\,m^2 \times 10^{-5} sr = 5.95 \times 10^{-5}\,W$$

Continued...

PROBLEM 12.96 (Cont.)

(c) With the development of an interfacial thermal contact resistance and fixed values of q''_h and T_w, (i) T_2 remains the same (its value is determined by the requirement that $q''_h = \varepsilon_c \sigma \left(T_2^4 - T_w^4\right)$, while (ii) T_1 increases (its value is determined by the requirement that $q''_h = \left(T_1 - T_2\right)/R''_{tot}$, where R''_{tot} = [(L_s/k_s) + $R''_{t,c}$ + (L_c/k_c)]; if q''_h and T_2 are fixed, T_1 must increase with increasing R''_{tot}).

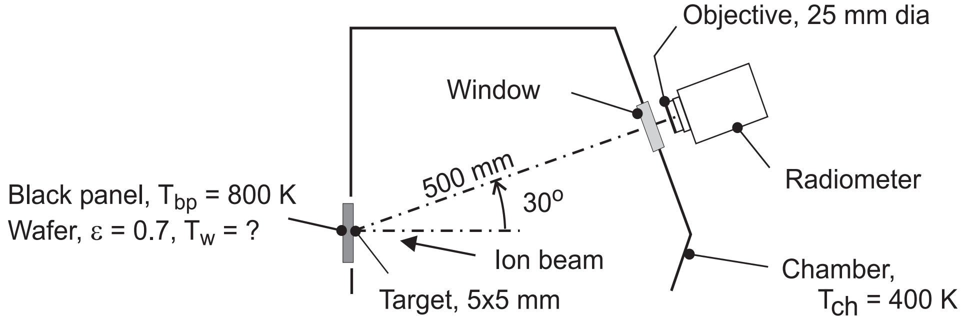
COMMENTS: The detector will also see radiation which is reflected from the ceramic. The corresponding radiation rate is $q_{c(reflection)-d} = \rho_c G_c \Delta A_c \, A_d / L_{s-d}^2 = 0.2\,\sigma(90\text{ K})^4 \times 10^{-4}\text{ m}^2 \times (10^{-5}\text{ sr}) = 7.44 \times 10^{-10}$ W. Hence, reflection is negligible.

PROBLEM 12.97

KNOWN: Wafer heated by ion beam source within large process-gas chamber with walls at uniform temperature; radiometer views a 5 × 5 mm target on the wafer. Black panel mounted in place of wafer in a pre-production test of the equipment.

FIND: (a) Radiant power (μW) received by the radiometer when the black panel temperature is T_{bp} = 800 K and (b) Temperature of the wafer, T_w, when the ion beam source is adjusted so that the radiant power received by the radiometer is the same as that of part (a)

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Chamber represents large, isothermal surroundings, (3) Wafer is opaque, diffuse-gray, and (4) Target area << square of distance between target and radiometer objective.

ANALYSIS: (a) The radiant power leaving the black-panel target and reaching the radiometer as illustrated in the schematic below is

$$q_{bp-rad} = \left[E_{b,bp}\left(T_{bp}\right)/\pi\right] A_t \cos\theta_t \cdot \Delta\omega_{rad-t} \tag{1}$$

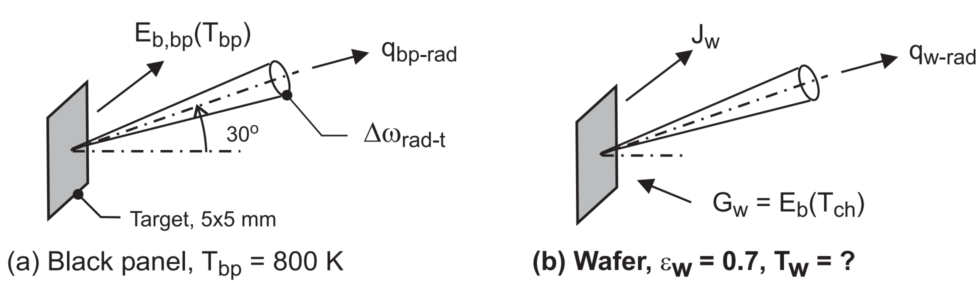
where $\theta_t = 0°$ and the solid angle the radiometer subtends with respect to the target follows from Eq. 12.7,

$$\Delta\omega_{rad-t} = \frac{dA_n}{r^2} = \frac{\left(\pi D_o^2/4\right)}{r^2} = \frac{\pi(0.025\text{ m})^2/4}{(0.500\text{ m})^2} = 1.964\times10^{-3}\text{ sr}$$

With $E_{b,bp} = \sigma T_{bp}^4$, find

$$q_{bp-rad} = \left[5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4(800\text{ K})^4/\pi\text{ sr}\right]$$
$$\times(0.005\text{ m})^2\times\cos 30°\times1.964\times10^{-3}\text{ sr}$$

$$q_{bp-rad} = 314\ \mu\text{W}$$ <



Continued …

PROBLEM 12.97 (Cont.)

(b) With the wafer mounted, the ion beam source is adjusted until the radiometer receives the same radiant power as with part (a) for the black panel. The power reaching the radiometer is expressed in terms of the wafer radiosity,

$$q_{w-rad} = [J_w / \pi] A_t \cos\theta_t \cdot \Delta\omega_{rad-t} \quad (2)$$

Since $q_{w-rad} = q_{bp-rad}$ (see Eq. (1)), recognize that

$$J_w = E_{b,bp}(T_{bp}) \quad (3)$$

where the radiosity is

$$J_w = \varepsilon_w E_{b,w}(T_w) + \rho_w G_w = \varepsilon_w E_{b,w}(T_w) + (1-\varepsilon_w) E_b(T_{ch}) \quad (4)$$

and G_w is equal to the blackbody emissive power at T_{ch}. Using Eqs. (3) and (4) and substituting numerical values, find

$$\sigma T_{bp}^4 = \varepsilon_w \sigma T_w^4 + (1-\varepsilon_w)\sigma T_{ch}^4$$

$$(800\text{ K})^4 = 0.7\, T_w^4 + 0.3(400\text{ K})^4$$

$$T_w = 871\text{ K}$$ <

COMMENTS: (1) Explain why T_w is higher than 800 K, the temperature of the black panel, when the radiometer receives the same radiant power for both situations.

(2) If the chamber walls were cold relative to the wafer, say near liquid nitrogen temperature, T_{ch} = 80 K, and the test repeated with the same indicated radiometer power, is the wafer temperature higher or lower than 871 K?

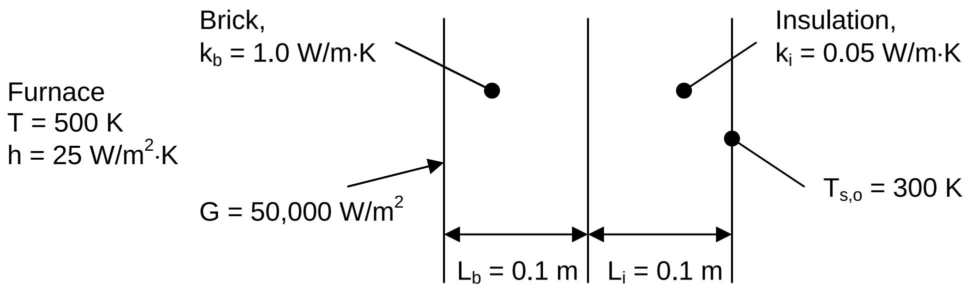
(3) If the chamber walls were maintained at 800 K, and the test repeated with the same indicated radiometer power, what is the wafer temperature?

PROBLEM 12.98

KNOWN: Spectral emissivity of fire brick wall used to construct brick oven. Magnitude and distribution of irradiation on wall. Temperature and heat transfer coefficient of gases adjacent to wall. Wall thickness and thermal conductivity.

FIND: Wall interior surface temperature if heat loss through wall is negligible. Wall interior surface temperature if wall is insulated and exterior surface temperature of insulation is 300 K.

SCHEMATIC:



ASSUMPTIONS: (1) Brick wall is opaque and diffuse, (2) Spectral distribution of irradiation reaching brick wall approximates that due to emission from a blackbody at 2000 K.

PROPERTIES: Fire brick wall (given in Example 12.10): $\varepsilon_\lambda \approx 0.1$, $\lambda < 1.5$ μm, $\varepsilon_\lambda \approx 0.5$, 1.5 μm $\le \lambda <$ 10 μm, $\varepsilon_\lambda \approx 0.8$, $\lambda \ge 10$ μm; $\alpha = 0.395$ (for irradiation with spectral distribution proportional to blackbody at 2000 K).

ANALYSIS: Neglecting heat transfer through the wall, an energy balance on the wall can be written,

$$\dot{E}_{in} - \dot{E}_{out} = \alpha G - E - q''_{conv} = 0$$

$$\alpha G - E(T_s) - h(T_s - T_\infty) = 0 \qquad (1)$$

From Example 12.10, we know that the absorptivity to irradiation having the spectral distribution of a blackbody at 2000 K is $\alpha = 0.395$. Now we must find the emissive power of the wall from Table 12.1 and Eq. 12.43,

$$E(T_s) = \varepsilon(T_s)E_b(T_s) = \int_0^\infty \varepsilon_\lambda(\lambda)E_{\lambda,b}(\lambda,T_s)d\lambda = I_1 + I_2 + I_3$$

where

$$I_1 = 0.1\int_0^{1.5\ \mu m} E_{\lambda,b}(\lambda,T_s)d\lambda = 0.1F_{(0\to 1.5\mu m)}E_b(T_s)$$

$$I_2 = 0.5\int_{1.5\ \mu m}^{10\ \mu m} E_{\lambda,b}(\lambda,T_s)d\lambda = 0.5F_{(1.5\mu m\to 10\mu m)}E_b(T_s)$$

$$I_3 = 0.8\int_{10\ \mu m}^{\infty} E_{\lambda,b}(\lambda,T_s)d\lambda = 0.8F_{(10\mu m\to\infty)}E_b(T_s)$$

Continued…

PROBLEM 12.98 (Cont.)

Thus,

$$E(T_s) = \left[0.1F_{(0\to 1.5\mu m)} + 0.5\left(F_{(0\to 10\mu m)} - F_{(0\to 1.5\mu m)}\right) + 0.8\left(1 - F_{(0\to 10\mu m)}\right)\right]E_b(T_s) \qquad (2)$$

Eqs. (1) and (2) are two equations in the two unknowns, T_s and $E(T_s)$, where each of the F's also depends on T_s (from Table 12.1). A numerical solution is required. An *IHT* code to solve this problem is shown in the Comments section. The solution is

$T_s = 796$ K <

With conduction through the wall, the energy balance becomes

$$\dot{E}_{in} - \dot{E}_{out} = \alpha G - E - q''_{conv} - q''_{cond} = 0$$

$$\alpha G - E(T_s) - h(T_s - T_\infty) - (T_s - T_{s,o})/R''_{tot} = 0 \qquad (3)$$

where

$$R''_{tot} = L_b/k_b + L_i/k_i = 0.1\text{ m}/1.0\text{ W/m}\cdot\text{K} + 0.1\text{ m}/0.05\text{ W/m}\cdot\text{K} = 2.1\text{ m}^2\cdot\text{K/W}$$

Eqs. (2) and (3) can once again be solved using *IHT*, to find

$T_s = 793$ K <

COMMENTS: (1) If the conduction heat flux is included, the surface temperature drops by only 3 K. (2) The *IHT* code to solve the problem is shown below. Note that if Eq. (1) or (3) is used directly, the code does not converge to a solution for T_s. Instead, the code is set up to calculate a variable "qnet" that is the net heat flux at the surface, and T_s is varied until qnet is approximately zero.

```
//Energy balance on inner surface
/* To effect convergence, calculate qnet as a function of Ts, and "Explore" Ts to find value for which qnet =
0. */
qnet = alpha*G - E - h*(Ts - Tinf) - qcond
Ts = 500

//Calculate qcond. Select from two options below.
qcond = (Ts - Tso)/Rtot
//qcond = 0

//Calculate E(Ts).
lambda1 = 1.5
lambda2 = 10
/* The blackbody band emission factor, Figure 12.14 and Table 12.1, is */
FLT1 = F_lambda_T(lambda1,Ts)    // Eq 12.34
FLT2 = F_lambda_T(lambda2,Ts)    // Eq 12.34
// where units are lambda (micrometers, mum) and T (K)
E = (0.1*FLT1 + 0.5*(FLT2 - FLT1) + 0.8*(1-FLT2))*Eb
Eb = sigma*Ts^4
sigma = 5.67e-8

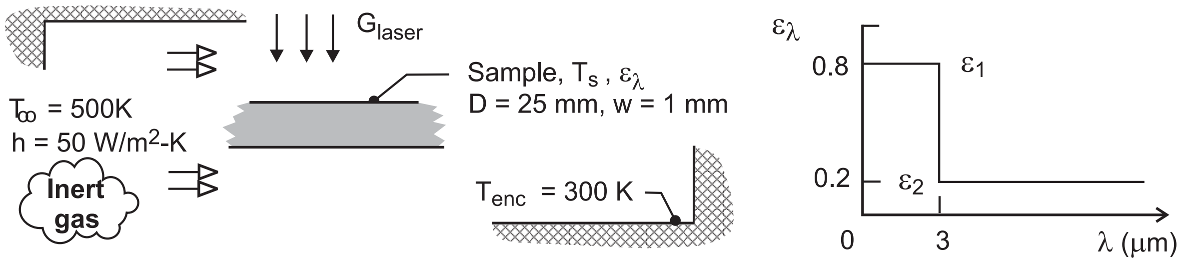
//Inputs
alpha = 0.395
G = 50000
h = 25
Tinf = 500
Tso = 300
Rtot = 0.1/1.0 + 0.1/0.05
```

PROBLEM 12.99

KNOWN: Laser-materials-processing apparatus. Spectrally selective sample heated to the operating temperature $T_s = 2000$ K by laser irradiation (0.5 μm), G_{laser}, experiences convection with an inert gas and radiation exchange with the enclosure.

FIND: (a) Total emissivity of the sample, ε ; (b) Total absorptivity of the sample, α, for irradiation from the enclosure; (c) Laser irradiation required to maintain the sample at $T_s = 2000$ K by performing an energy balance on the sample; (d) Sketch of the sample emissivity during the cool-down process when the laser and inert gas flow are deactivated; identify key features including the emissivity for the final condition ($t \to \infty$); and (e) Time-to-cool the sample from the operating condition at $T_s(0) = 2000$ K to a safe-to-touch temperature of $T_s(t) = 40$°C; use the lumped capacitance method and include the effects of convection with inert gas ($T_\infty = 300$ K , $h = 50$ W/ m^2·K) as well as radiation exchange $T_{enc} = T_\infty$.

SCHEMATIC:



ASSUMPTIONS: (1) Enclosure is isothermal and large compared to the sample, (2) Sample is opaque and diffuse, but spectrally selective, so that $\varepsilon_\lambda = \alpha_\lambda$, (3) Sample is isothermal.

PROPERTIES: Sample (Given) $\rho = 3900$ kg/m^3, $c_p = 760$ J/kg , $k = 45$ W/m·K.

ANALYSIS: (a) The total emissivity of the sample, ε, at $T_s = 2000$ K follows from Eq. 12.43 which can be expressed in terms of the band emission factor, $F_{(0-\lambda,T)}$ Eq. 12.34,

$$\varepsilon = \varepsilon_1 F_{(0-\lambda_1 T_s)} + \varepsilon_2\left[1 - F_{(0-\lambda_1 T_s)}\right] \qquad (1)$$

$$\varepsilon = 0.8 \times 0.7378 + 0.2\left[1 - 0.7378\right] = 0.643$$ <

where from Table 12.1, with $\lambda_1 T_s = 3\mu m \times 2000$ K = 6000 μm·K, $F_{(0-\lambda T)} = 0.7378$.

(b) The total absorptivity of the sample, α, for irradiation from the enclosure at $T_{enc} = 300$ K, is

$$\alpha = \varepsilon_1 F_{(0-\lambda_1 T_{enc})} + \varepsilon_2\left[1 - F_{(0-\lambda_1 T_{enc})}\right] \qquad (2)$$

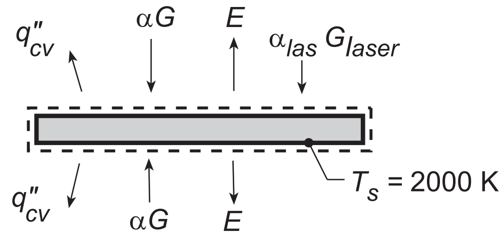
$$\alpha = 0.8 \times 0 + 0.2\left[1 - 0\right] = 0.200$$ <

where, from Table 12.1, with $\lambda_1 T_{enc} = 3$ μm × 300 K = 900 μm·K, $F_{(0-\lambda T)} = 0$.

Continued...

PROBLEM 12.99 (Cont.)

(c) The energy balance on the sample, on a per unit area basis, as shown in the schematic at the right is



$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$+\alpha_{las} G_{laser} + 2\alpha G - 2\varepsilon E_b(T_s) - q''_{cv} = 0$$

$$\alpha_{las} G_{laser} + 2\alpha\sigma T_{enc}^4 - 2\varepsilon\sigma T_s^4 - 2h(T_s - T_\infty) = 0 \quad (3)$$

Recognizing that $\alpha_{las}(0.5\ \mu m) = 0.8$, and substituting numerical values find,

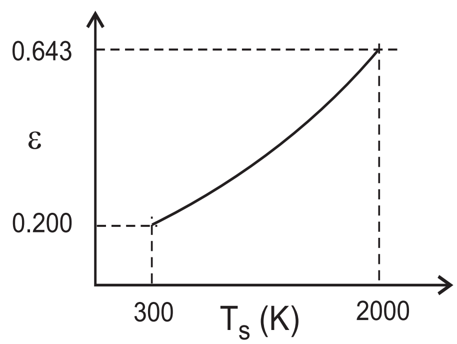
$$0.8 \times G_{laser} + 2 \times 0.200 \times 5.67 \times 10^{-8}\ W/m^2 \cdot K^4 (300\ K)^4$$

$$-2 \times 0.643 \times 5.67 \times 10^{-8}\ W/m^2 \cdot K^4 (2000\ K)^4 - 2 \times 50\ W/m^2 \cdot K (2000 - 500) K = 0$$

$$0.8 \times G_{laser} = \left[-184.6 + 1.167 \times 10^6 + 1.500 \times 10^5\right] W/m^2$$

$$G_{laser} = 1646\ kW/m^2$$ <

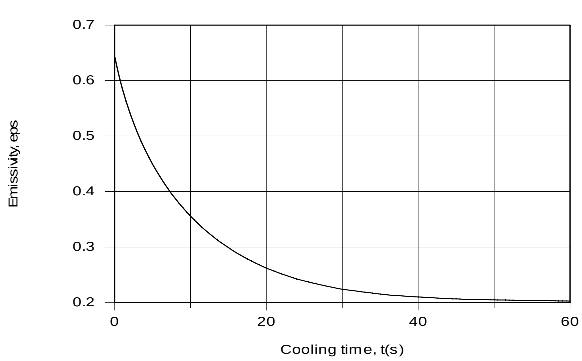
(d) During the cool-down process, the total emissivity ε will decrease as the temperature decreases, T_s (t). In the limit, $t \to \infty$, the sample will reach that of the enclosure, $T_s(\infty) = T_{enc}$ for which ε = α = 0.200.

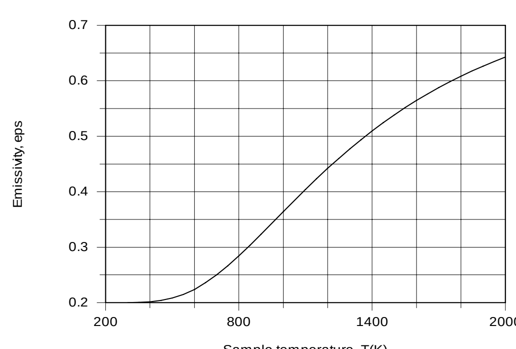


(e) Using the *IHT Lumped Capacitance Model* considering radiation exchange (T_{enc} = 300 K) and convection (T_∞ = 300 K, h = 50 W/m$^2\cdot$K) and evaluating the emissivity using Eq. (1) with the *Radiation Tool*, *Band Emission Factors*, the temperature-time history was determined and the time-to-cool to T(t) = 40°C was found as

$$t = 119\ s$$ <

COMMENTS: (1) From the IHT model used for part (e), the emissivity as a function of cooling time and sample temperature were computed and are plotted below. Compare these results to your sketch of part (c).





Continued...

PROBLEM 12.99 (Cont.)

(2) The IHT workspace model to perform the lumped capacitance analysis with variable emissivity is shown below.

```
// Lumped Capacitance Model - convection and emission/irradiation radiation processes:
/* Conservation of energy requirement on the control volume, CV.  */
Edotin - Edotout = Edotst
Edotin = As * ( + Gabs)
Edotout = As * ( + q''cv + E )
Edotst = rho * vol * cp * Der(T,t)
T_C = T - 273
// Absorbed irradiation from large surroundings on CS
Gabs = alpha * G
G =  sigma * Tsur^4
sigma = 5.67e-8                    // Stefan-Boltzmann constant, W/m^2·K^4
// Emissive power of CS
E = eps * Eb
Eb = sigma * T^4
//sigma = 5.67e-8                  // Stefan-Boltzmann constant, W/m^2·K^4
//Convection heat flux for control surface CS
q''cv = h * ( T - Tinf )
/* The independent variables for this system and their assigned numerical values are */
As =     2 * 1          // surface area, m^2; unit area, top and bottom surfaces
vol =  1 * w             // vol, m^3
w = 0.001                // sample thickness, m
rho =   3900            // density, kg/m^3
cp =   760               // specific heat, J/kg·K
// Convection heat flux, CS
h =    50                // convection coefficient, W/m^2·K
Tinf =  300              // fluid temperature, K
// Emission, CS
//eps =   0.5            // emissivity; value used to test the model initially
// Irradiation from large surroundings, CS
alpha = 0.200            // absorptivity; from Part (b); remains constant during cool-down
Tsur =   300             // surroundings temperature, K

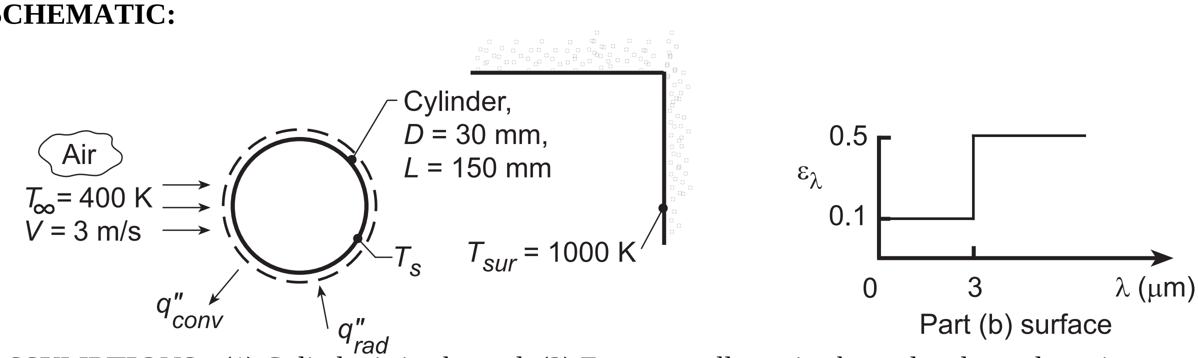
// Radiation Tool - Band emission factor:
eps = eps1 * FL1T  + eps2 * ( 1 - FL1T )
/* The blackbody band emission factor, Figure 12.12 and Table 12.1, is */
FL1T = F_lambda_T(lambda1,T)    // Eq 12.34
// where units are lambda (micrometers, mum) and T (K)
lambda1 = 3              // wavelength, mum
eps1 = 0.8               // spectral emissivity; for lambda < lambda1
eps2 = 0.2               // spectral emissivity; for lambda > lambda1
```

PROBLEM 12.100

KNOWN: Cross flow of air over a cylinder placed within a large furnace.

FIND: (a) Steady-state temperature of the cylinder when it is diffuse and gray with $\varepsilon = 0.5$, (b) Steady-state temperature when surface has spectral properties shown below, (c) Steady-state temperature of the diffuse, gray cylinder if air flow is parallel to the cylindrical axis, (d) Effect of air velocity on cylinder temperature for conditions of part (a).

SCHEMATIC:



ASSUMPTIONS: (1) Cylinder is isothermal, (2) Furnace walls are isothermal and very large in area compared to the cylinder, (3) Steady-state conditions.

PROPERTIES: *Table A.4*, Air ($T_f \approx 600$ K): $\nu = 52.69 \times 10^{-6}\ m^2/s$, $k = 46.9 \times 10^{-3}$ W/m·K, Pr = 0.685.

ANALYSIS: (a) When the cylinder surface is gray and diffuse with $\varepsilon = 0.5$, the energy balance is of the form, $q''_{rad} - q''_{conv} = 0$. Hence,

$$\varepsilon\sigma(T_{sur}^4 - T_s^4) - \bar{h}(T_s - T_\infty) = 0\,.$$

The heat transfer coefficient, $\bar{h}$, can be estimated from the Churchill-Bernstein correlation of Chapter 7,

$$\overline{Nu}_D = (\bar{h}D/k) = 0.3 + \frac{0.62\,Re_D^{1/2}\,Pr^{1/3}}{\left[1+(0.4/Pr)^{2/3}\right]^{1/4}}\left[1+\left(\frac{Re_D}{282,000}\right)^{5/8}\right]^{4/5}$$

where $Re_D = VD/\nu = 3\,m/s \times 30 \times 10^{-3}\,m / 52.69 \times 10^{-6}\,m^2/s = 1710$. Hence,

$$\overline{Nu}_D = 20.8$$

$$\bar{h} = 20.8 \times 46.9 \times 10^{-3}\,W/m\cdot K \Big/ 30 \times 10^{-3}\,m = 32.5\,W/m^2\cdot K\,.$$

Using this value of $\bar{h}$ in the energy balance expression, we obtain

$$0.5 \times 5.67 \times 10^{-8}(1000^4 - T_s^4)\,W/m^2 - 32.5\,W/m^2\cdot K(T_s - 400)\,K = 0$$

which yields $T_s \approx 839$ K. <

(b) When the cylinder has the spectrally selective behavior, the energy balance is written as

$$\alpha G - \varepsilon E_b(T_s) - q''_{conv} = 0$$

where $G = E_b\,(T_{sur})$. With $\alpha = \int_0^\infty \alpha_\lambda G_\lambda\, d\lambda / G$,

$$\alpha = 0.1 \times F_{(0\to 3\mu m)} + 0.5 \times \left(1 - F_{(0\to 3\mu m)}\right) = 0.1 \times 0.273 + 0.5(1 - 0.273) = 0.391$$

where, using Table 12.1 with $\lambda T = 3 \times 1000 = 3000$ μm·K, $F_{(0\to 3)} = 0.273$. Assuming T_s is such that emission in the spectral region $\lambda < 3$ μm is negligible, the energy balance becomes

Continued...

PROBLEM 12.100 (Cont.)

$$0.391\times5.67\times10^{-8}\times1000^{4}\ \text{W/m}^2 - 0.5\times5.67\times10^{-8}\times T_s^4\ \text{W/m}^2 - 32.5\ \text{W/m}^2\cdot\text{K}(T_s - 400)\ \text{K} = 0$$

which yields $T_s \approx 770$ K. <

Note that, for $\lambda T = 3 \times 770 = 2310\ \mu\text{m}\cdot\text{K}$, $F_{(0\rightarrow\lambda)} \approx 0.11$; hence the assumption of $\varepsilon = 0.5$ is acceptable. Note that the value of $\bar{h}$ based upon $T_f = 600$ K is also acceptable.

(c) When the cylinder is diffuse-gray with air flow in the longitudinal direction, the characteristic length for convection is different. Assume conditions can be modeled as flow over a flat plate of L = 150 mm. With

$$Re_L = VL/\nu = 3\,\text{m/s}\times150\times10^{-3}\,\text{m}/52.69\times10^{-6}\,\text{m}^2/\text{s} = 8540$$

$$\overline{Nu}_L = (\bar{h}L/k) = 0.664\,Re_L^{1/2}\,Pr^{1/3} = 0.664(8540)^{1/2}0.685^{1/3} = 54.1$$

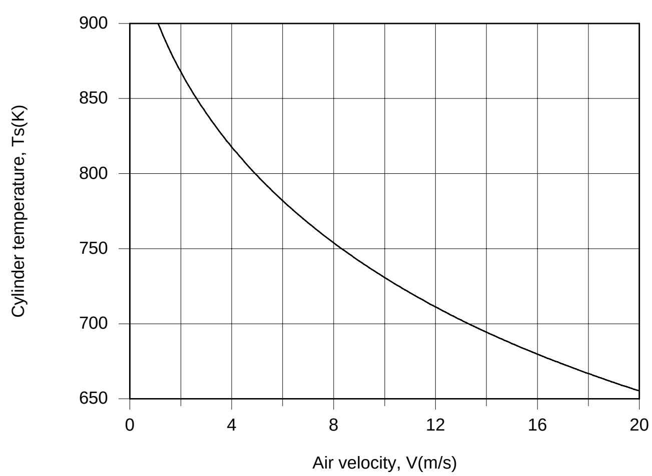
$$\bar{h} = 54.1\times0.0469\,\text{W/m}\cdot\text{K}/0.150\,\text{m} = 16.9\,\text{W/m}^2\cdot\text{K}.$$

The energy balance now becomes

$$0.5\times5.667\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4(1000^4 - T_s^4)\text{K}^4 - 16.9\,\text{W/m}^2\cdot\text{K}(T_s - 400)\text{K} = 0$$

which yields $T_s \approx 850$ K. <

(b) Using the IHT *First Law* Model with the *Correlations* and *Properties* Toolpads, the effect of velocity may be determined and the results are as follows:



Since the convection coefficient increases with increasing V (from 18.5 to 90.6 $\text{W/m}^2\cdot\text{K}$ for $1 \le V \le 20$ m/s), the cylinder temperature decreases, since a smaller value of $(T_s - T_\infty)$ is needed to dissipate the absorbed irradiation by convection.

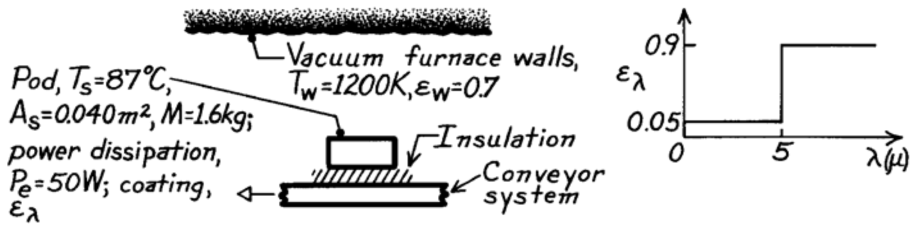
COMMENTS: The cylinder temperature exceeds the air temperature due to absorption of the incident radiation. The cylinder temperature would approach T_∞ as $\bar{h} \rightarrow \infty$ and/or $\alpha \rightarrow 0$. If $\alpha \rightarrow 0$ and $\bar{h}$ has a small to moderate value, would T_s be larger than, equal to, or less than T_∞? Why?

PROBLEM 12.101

KNOWN: Instrumentation pod, initially at 87°C, on a conveyor system passes through a large vacuum brazing furnace. Inner surface of pod surrounded by a mass of phase-change material (PCM). Outer surface with special diffuse, opaque coating of ε_λ. Electronics in pod dissipate 50 W.

FIND: How long before all the PCM changes to the liquid state?

SCHEMATIC:



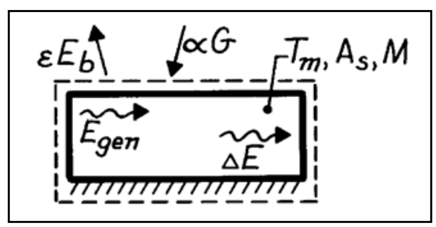
ASSUMPTIONS: (1) Surface area of furnace walls much larger than that of pod, (2) No convection, (3) No heat transfer to pod from conveyor, (4) Pod coating is diffuse, opaque, (5) Initially pod internal temperature is uniform at T_{pcm} = 87°C and remains so during time interval Δt_m, (6) Surface area provided is that exposed to walls.

PROPERTIES: Phase-change material, PCM (given): Fusion temperature, T_f = 87°C, h_{fg} = 25 kJ/kg.

ANALYSIS: Perform an energy balance on the pod for an interval of time Δt_m which corresponds to the time for which the PCM changes from solid to liquid state,

$$E_{in} - E_{out} + E_{gen} = \Delta E$$

$$\left[\left(\alpha G - \varepsilon E_b\right) A_s + P_e\right] \Delta t_m = M h_{fg}$$



where P_e is the electrical power dissipation rate, M is the mass of PCM, and h_{fg} is the heat of fusion of PCM.

Irradiation: $G = \sigma T_w = 5.67 \times 10^{-8}\ W/m^2 \cdot K^4 (1200\ K)^4 = 117{,}573\ W/m^2$

Emissive power: $E_b = \sigma T_m^4 = \sigma\left(87 + 273\right)^4 = 952\ W/m^2$

Emissivity: $\varepsilon = \varepsilon_1 F_{(0-\lambda T)} + \varepsilon_2(1 - F_{(0-\lambda T)})$ $\qquad \lambda T = 5 \times 360 = 1800\ \mu m \cdot K$

$\varepsilon = 0.05 \times 0.0393 + 0.9\ (1 - 0.0393)$ $\qquad F_{0-\lambda T} = 0.0393$ (Table 12.1)

$\varepsilon = 0.867$

Absorptivity: $\alpha = \alpha_1 F_{(0-\lambda T)} + \alpha_2(1 - F_{(0-\lambda T)})$ $\qquad \lambda T = 5 \times 1200 = 6000\ \mu m \cdot K$

$\alpha = 0.05 \times 0.7378 + 0.9\ (1 - 0.7378)$ $\qquad F_{0-\lambda T} = 0.7378$ (Table 12.1)

$\alpha = 0.273$

Substituting numerical values into the energy balance, find,

$$\left[\left(0.273 \times 117{,}573 - 0.867 \times 952\right) W/m^2 \times 0.040\ m^2 + 50\ W\right] \Delta t_m = 1.6 kg \times 25 \times 10^3\ J/kg$$

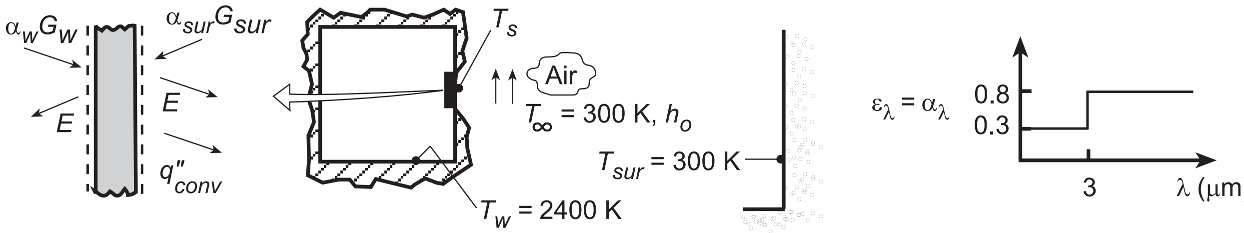
$$\Delta t_m = 32.5\ s = 0.54\ min.$$ <

PROBLEM 12.102

KNOWN: Temperatures of furnace and surroundings separated by ceramic plate. Maximum allowable temperature and spectral absorptivity of plate.

FIND: (a) Minimum value of air-side convection coefficient, h_o, (b) Effect of h_o on plate temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Diffuse surface, (2) Negligible temperature gradients in plate, (3) Negligible inside convection, (4) Furnace and surroundings act as blackbodies.

ANALYSIS: (a) From a surface energy balance on the plate, $\alpha_w G_w + \alpha_{sur} G_{sur} = 2E + q''_{conv}$. Hence,

$\alpha_w \sigma T_w^4 + \alpha_{sur} \sigma T_{sur}^4 = 2\varepsilon\sigma T_s^4 + h_o (T_s - T_\infty)$.

$$h_o = \frac{\alpha_w \sigma T_w^4 + \alpha_{sur} \sigma T_{sur}^4 - 2\varepsilon\sigma T_s^4}{(T_s - T_\infty)}$$

Evaluating the absorptivities and emissivity,

$$\alpha_w = \int_0^\infty \alpha_\lambda G_\lambda \, d\lambda / G = \int_0^\infty \alpha_\lambda E_{\lambda b}(T_w) / E_b(T_w) d\lambda = 0.3F_{(0-3\mu m)} + 0.8\left[1 - F_{(0-3\mu m)}\right]$$

With $\lambda T_w = 3\,\mu m \times 2400\ K = 7200\,\mu m \cdot K$, Table 12.1 $\rightarrow F_{(0-3\mu m)} = 0.819$. Hence,

$$\alpha_w = 0.3 \times 0.819 + 0.8(1 - 0.819) = 0.391$$

Since T_{sur} = 300 K, irradiation from the surroundings is at wavelengths well above 3 μm. Hence,

$$\alpha_{sur} = \int_0^\infty \alpha_\lambda E_{\lambda b}(T_{sur}) / E_b(T_{sur}) d\lambda \approx 0.800 .$$

The emissivity is $\varepsilon = \int_0^\infty \varepsilon_\lambda E_{\lambda b}(T_s) / E_b(T_s) d\lambda = 0.3F_{(0-3\mu m)} + 0.8\left[1 - F_{(0-3\mu m)}\right]$. With $\lambda T_s = 5400\,\mu m \cdot K$, Table 12.1 $\rightarrow F_{(0-3\mu m)} = 0.680$. Hence, ε = 0.3 × 0.68 + 0.8(1 – 0.68) = 0.460.

For the maximum allowable value of T_s = 1800 K, it follows that

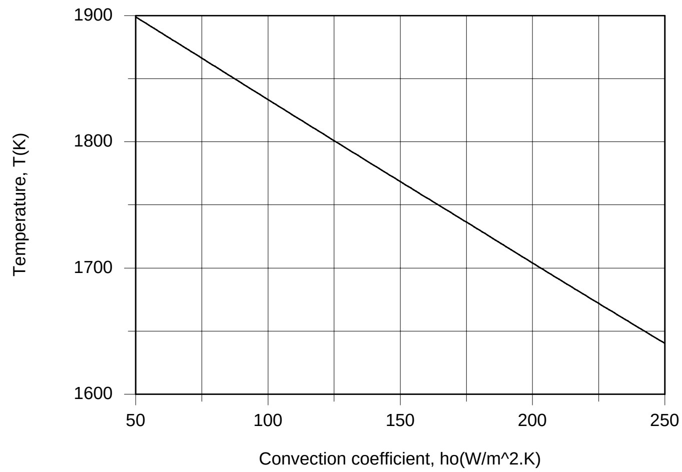
$$h_o = \frac{0.391 \times 5.67 \times 10^{-8} (2400)^4 + 0.8 \times 5.67 \times 10^{-8} (300)^4 - 2 \times 0.46 \times 5.67 \times 10^{-8} (1800)^4}{(1800 - 300)}$$

$$h_o = \frac{7.335 \times 10^5 + 3.674 \times 10^2 - 5.476 \times 10^5}{1500} = 126\ W/m^2 \cdot K .$$ <

(b) Using the IHT *First Law* Model with the *Radiation* Toolpad, parametric calculations were performed to determine the effect of h_o.

Continued...

PROBLEM 12.102 (Cont.)



With increasing h_o, and hence enhanced convection heat transfer at the outer surface, the plate temperature is reduced.

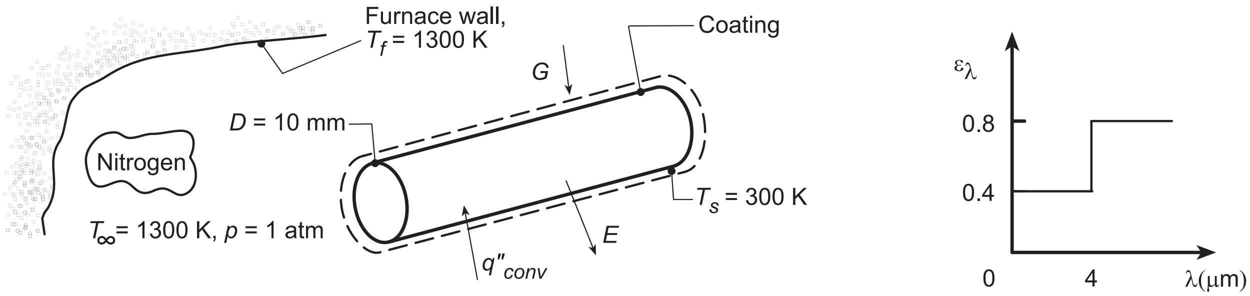
COMMENTS: (1) The surface is not gray. (2) The required value of $h_o \geq 126\,W/m^2 \cdot K$ is well within the range of air cooling.

PROBLEM 12.103

KNOWN: Spectral radiative properties of thin coating applied to long circular copper rods of prescribed diameter and initial temperature. Wall and atmosphere conditions of furnace in which rods are inserted.

FIND: (a) Emissivity and absorptivity of the coated rods when their temperature is T_s = 300 K, (b) Initial rate of change of their temperature, dT_s/dt, (c) Emissivity and absorptivity when they reach steady-state temperature, and (d) Time required for the rods, initially at T_s = 300 K, to reach 1000 K.

SCHEMATIC:



ASSUMPTIONS: (1) Rod temperature is uniform, (2) Nitrogen is quiescent, (3) Constant properties, (4) Diffuse, opaque surface coating, (5) Furnace walls form a blackbody cavity about the cylinders, G = $E_b(T_f)$, (6) Negligible end effects.

PROPERTIES: *Table A.1*, Copper (300 K): ρ = 8933 kg/m^3, c_p = 385 J/kg·K, k = 401 W/m·K; *Table A.4*, Nitrogen (T_f = 800 K, 1 atm): $\nu = 82.9 \times 10^{-6}$ m^2/s, k = 0.0548 W/m·K, $\alpha = 116 \times 10^{-6}$ m^2/s, Pr = 0.715, $\beta = (T_f)^{-1} = 1.25 \times 10^{-3}$ K^{-1}.

ANALYSIS: (a) The total emissivity of the copper rod, ε, at T_s = 300 K follows from Eq. 12.43 which can be expressed in terms of the band emission factor, $F(0 - \lambda T)$, Eq. 12.34,

$$\varepsilon = \varepsilon_1 F(0-\lambda_1 T_s) + \varepsilon_2 \left[1 - F(0-\lambda_1 T_s)\right] \quad (1)$$

$$\varepsilon = 0.4 \times 0.0021 + 0.8[1 - 0.0021] = 0.799$$ <

where, from Table 12.1, with $\lambda_1 T_s = 4\ \mu m \times 300\ K = 1200\ \mu m\cdot K$, $F(0 - \lambda T) = 0.0021$. The total absorptivity, α, for irradiation for the furnace walls at T_f = 1300 K, is

$$\alpha = \varepsilon_1 F(0-\lambda_1 T_f) + \varepsilon_2 \left[1 - F(0-\lambda_1 T_f)\right] \quad (2)$$

$$\alpha = 0.4 \times 0.6590 + 0.8[1 - 0.6590] = 0.536$$ <

where, from Table 12.1, with $\lambda_1 T_f = 4\ \mu m \times 1300\ K = 5200\ K$, $F(0 - \lambda T) = 0.6590$.

(b) From an energy balance on a control volume about the rod,

$$\dot{E}_{st} = \rho c_p \left(\pi D^2/4\right) L\,(dT/dt) = \dot{E}_{in} - \dot{E}_{out} = \pi D L\left[\alpha G + \bar{h}(T_\infty - T_s) - E\right]$$

$$dT_s/dt = 4\left[\alpha G + \bar{h}(T_\infty - T_s) - \varepsilon\sigma T_s^4\right] \Big/ \rho c_p D\,. \quad (3)$$

With

$$Ra_D = \frac{g\beta(T_\infty - T_s)D^3}{\nu\alpha} = \frac{9.8\,m^2/s\left(1.25\times10^{-3}K^{-1}\right)1000\,K\,(0.01\,m)^3}{82.9\times10^{-6}\,m^2/s \times 116\times10^{-6}\,m^2/s} = 1274 \quad (4)$$

The Churchill-Chu correlation of Chapter 9 gives

Continued...

PROBLEM 12.103 (Cont.)

$$\bar{h} = \frac{0.0548}{0.01\,\text{m}}\left\{0.60 + \frac{0.387(1274)^{1/6}}{\left[1+(0.559/0.715)^{9/16}\right]^{8/27}}\right\}^2 = 15.1\,\text{W/m}^2\cdot\text{K} \qquad (5)$$

With values of ε and α from part (a), the rate of temperature change with time is

$$dT_s/dt = \frac{4\left[0.53\times5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\times(1300\,\text{K})^4 + 15.1\,\text{W/m}^2\cdot\text{K}\times1000\,\text{K} - 0.8\times5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}\times(300\,\text{K})^4\right]}{8933\,\text{kg/m}^3\times385\,\text{J/kg}\cdot\text{K}\times0.01\,\text{m}}$$

$$dT_s/dt = 1.16\times10^{-4}\left[85,829+15,100-3767\right]\text{K/s} = 11.7\,\text{K/s}. \qquad <$$

(c) Under steady-state conditions, $T_s = T_\infty = T_f = 1300$ K. For this situation, ε = α, hence

$$\varepsilon = \alpha = 0.536 \qquad <$$

(d) The time required for the rods, initially at $T_s(0) = 300$ K, to reach 1000 K can be determined using the lumped capacitance method. Using the *IHT Lumped Capacitance Model*, considering convection, irradiation and emission processes; the *Correlations Tool*, *Free Convection*, *Horizontal Cylinder*; *Radiation Tool*, *Band Emission Fractions*; and a user-generated *Lookup Table Function* for the nitrogen thermophysical properties, find

$T_s(t_o) = 1000$ K $\qquad t_o = 81.8$ s $\qquad <$

COMMENTS: (1) To determine the validity of the lumped capacitance method to this heating process, evaluate the approximate Biot number, $Bi = \bar{h}D/k = 15\ \text{W/m}^2\cdot\text{K} \times 0.010\ \text{m}/401\ \text{W/m}\cdot\text{K} = 0.0004$. Since $Bi << 0.1$, the method is appropriate.

(2) The IHT workspace with the model used for part (c) is shown below.

```

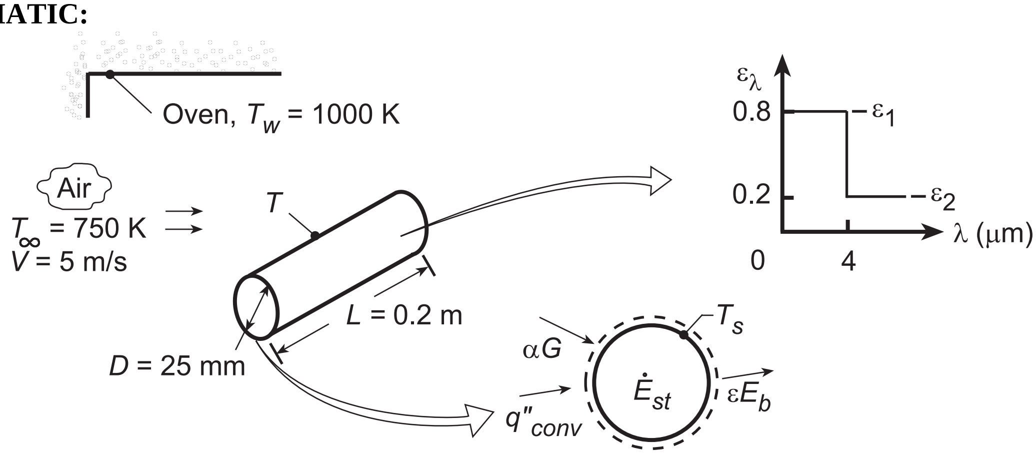
PROBLEM 12.104

KNOWN: Large combination convection-radiation oven heating a cylindrical product of a prescribed spectral emissivity.

FIND: (a) Initial heat transfer rate to the product when first placed in oven at 300 K, (b) Steady-state temperature of the product, (c) Time to achieve a temperature within 50°C of the steady-state temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Cylinder is opaque-diffuse, (2) Oven walls are very large compared to the product, (3) Cylinder end effects are negligible, (4) ε_λ is dependent of temperature.

PROPERTIES: *Table A-4*, Air (T_f = 525 K, 1 atm): $\nu = 42.2\times10^{-6}\ \text{m}^2/\text{s}, k = 0.0423\ \text{W/m}\cdot\text{K}$, Pr = 0.684; ($T_f$ = 850 K (assumed), 1 atm): $\nu = 93.8\times10^{-6}\ \text{m}^2/\text{s}$, k = 0.0596 W/m·K, Pr = 0.716.

ANALYSIS: (a) The net heat rate to the product is $q_{net} = A_s(q''_{conv} + \alpha G - \varepsilon E_b)$, or

$$q_{net} = \pi DL[\bar{h}(T_\infty - T) + \alpha G - \varepsilon\sigma T^4] \qquad (1)$$

Evaluating properties at T_f = 525 K, $Re_D = VD/\nu = 5\,\text{m/s}\times0.025\,\text{m}/42.2\times10^{-6}\,\text{m}^2/\text{s} = 2960$, and the Churchill-Bernstein correlation of Chapter 7 yields

$$\overline{Nu}_D = \frac{\bar{h}D}{k} = 0.3 + \frac{0.62\,Re_D^{1/2}\ Pr^{1/3}}{[1+(0.4/Pr)^{2/3}]^{1/4}}\left[1+\left(\frac{Re_D}{282,000}\right)^{5/8}\right]^{4/5} = 27.5$$

Hence,

$$\bar{h} = \frac{0.0423\,\text{W/m}\cdot\text{K}}{0.025\text{m}}\times27.5 = 46.5\,\text{W/m}^2\cdot\text{K}.$$

The total, hemispherical emissivity of the diffuse, spectrally selective surface follows from Eq. 12.43,

$\varepsilon = \int_0^\infty \varepsilon_\lambda(\lambda, T_s)E_{\lambda,b}\big/\sigma T_s^4 = \varepsilon_1 F_{(0\to4\mu m)} + \varepsilon_2(1-F_{(0\to4\mu m)})$, where λT = 4 μm × 300 K = 1200 μm·K and $F_{(0-\lambda T)}$ = 0.002 (Table 12.1). Hence, ε = 0.8 × 0.002 + 0.2 (1 – 0.002) = 0.201.

The absorptivity is for irradiation from the oven walls which, because they are large and isothermal, behave as a black surface at 1000 K. From Eq. 12.52, with $G_\lambda = E_{\lambda,b}$ (λ, 1000 K) and $\alpha_\lambda = \varepsilon_\lambda$,

$$\alpha = \varepsilon_1 F_{(0\to4\mu m)} + \varepsilon_2(1-F_{(0\to4\mu m)}) = 0.8\times0.481 + 0.2(1-0.481) = 0.489$$

where, for λT = 4 × 1000 = 4000 μm·K from Table 12.1, $F_{(0-\lambda T)}$ = 0.481. From Eq. (1) the net initial heat rate is $q_{net} = \pi\times0.025\text{m}\times0.2\,\text{m}[46.5\,\text{W/m}^2\cdot\text{K}(750-300)\ \text{K} + 0.489\sigma(1000)^4\text{K}^4 - 0.201\sigma(300\ \text{K})^4]$

Continued...

PROBLEM 12.104 (Cont.)

$q = 763$ W. <

(b) For the steady-state condition, the net heat rate will be zero, and the energy balance yields,

$$0 = \bar{h}(T_\infty - T) + \alpha G - \varepsilon\sigma T^4 \quad (2)$$

Evaluating properties at an assumed film temperature of $T_f = 850$ K, $Re_D = VD/\nu = 5$ m/s × 0.025 m/93.8 × 10^{-6} m^2/s = 1333, and the Churchill-Bernstein correlation yields $\overline{Nu}_D = 18.6$. Hence, $\bar{h}$ = 18.6 (0.0596 W/m · K)/0.025 m = 44.3 W/m^2 · K. Since irradiation from the oven walls is fixed, the absorptivity is unchanged, in which case α = 0.489. However, the emissivity depends on the product temperature. *Assuming* T = 950 K, we obtain

$$\varepsilon = \varepsilon_1 F_{(0\to 4\mu m)} + \varepsilon_2 (1 - F_{(0\to 4\mu m)}) = 0.8 \times 0.443 + 0.2(1 - 0.443) = 0.466$$

where for λT = 4 × 950 = 3800 μm·K, $F_{0-\lambda T} = 0.443$, from Table 12.1. Substituting values into Eq. (2) with σ = 5.67 × 10^{-8} W/m^2·K^4,

$$0 = 44.3\,(750 - T) + 0.489\,\sigma\,(1000\text{ K})^4 - 0.466\,\sigma\,T^4.$$

A trial-and-error solution yields T ≈ 930 K. <

(c) Using the IHT *Lumped Capacitance* Model with the *Correlations*, *Properties* (for copper and air) and *Radiation* Toolpads, the transient response of the cylinder was computed and the time to reach T = 880 K is

t ≈ 537 s. <

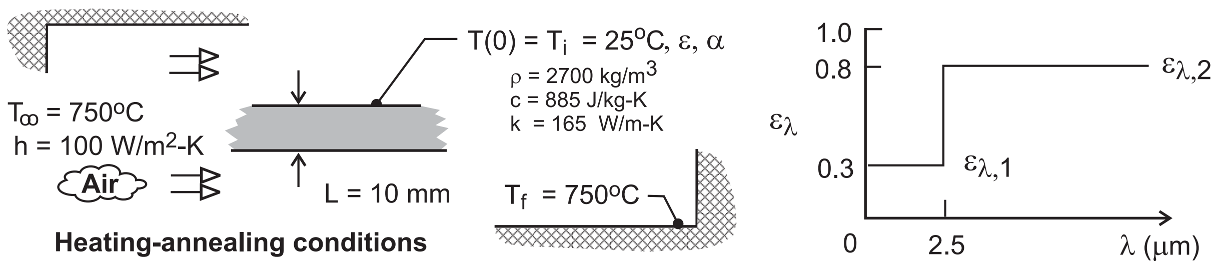
COMMENTS: Note that $\bar{h}$ is relatively insensitive to T, while ε is not. At T = 930 K, ε = 0.456.

PROBLEM 12.105

KNOWN: Workpiece, initially at 25°C, to be annealed at a temperature above 725°C for a period of 5 minutes and then cooled; furnace wall temperature and convection conditions; cooling surroundings and convection conditions.

FIND: (a) Emissivity and absorptivity of the workpiece at 25°C when it is placed in the furnace, (b) Net heat rate per unit area into the workpiece for this initial condition; change in temperature with time, dT/dt, for the workpiece; (c) Calculate the time for the workpiece to cool from 750°C to a safe-to-touch temperature of 40°C if the cool surroundings and cooling air temperature are 25°C and the convection coefficient is 100 W/m^2·K.

SCHEMATIC:



ASSUMPTIONS: (1) Workpiece is opaque and diffuse, (2) Spectral emissivity is independent of temperature, and (3) Furnace and cooling environment are large isothermal surroundings.

ANALYSIS: (a) Using Eqs. 12.43 and 12.52, ε and α can be determined using band-emission factors, Eq. 12.34 and 12.35.

Emissivity, workpiece at 25°C

$$\varepsilon = \varepsilon_{\lambda 1} \cdot F_{(0-\lambda T)} + \varepsilon_{\lambda 2}\left(1 - F_{(0-\lambda T)}\right)$$

$$\varepsilon = 0.3 \times 1.6 \times 10^{-5} + 0.8 \times \left(1 - 1.6 \times 10^{-5}\right) = 0.8$$ <

where $F_{(0-\lambda T)}$ is determined from Table 12.1 with λT = 2.5 μm × 298 K = 745 μm·K.

Absorptivity, furnace temperature T_f = 750°C

$$\alpha = \varepsilon_{\lambda 1} \cdot F_{(0-\lambda,\, T)} + \varepsilon_{2} \cdot \left(1 - F_{(0-\lambda,\, T)}\right)$$

$$\alpha = 0.3 \times 0.174 + 0.8 \times \left(1 - 0.174\right) = 0.713$$ <

where $F_{(0\text{ - }\lambda T)}$ is determined with λT = 2.5 μm × 1023 K = 2557.5 μm·K.

(b) For the initial condition, T(0) = T_i, the energy balance shown schematically below is written in terms of the net heat rate *in*,

Continued …

$$\dot{E}''_{in} - \dot{E}''_{out} = \dot{E}''_{st} \qquad \text{and} \qquad q''_{net,in} = \dot{E}''_{in} - \dot{E}''_{out}$$

$$q''_{net,in} = 2\left[q''_{cv} - \varepsilon\, E_b\left(T_i\right) + \alpha E_b\left(T_f\right)\right]$$

where $G = E_b\,(T_f)$. Substituting numerical values,

$$q''_{net,in} = 2\left[h\left(T_\infty - T_i\right) - \varepsilon\sigma T_i^4 + \alpha\sigma T_f^4\right]$$

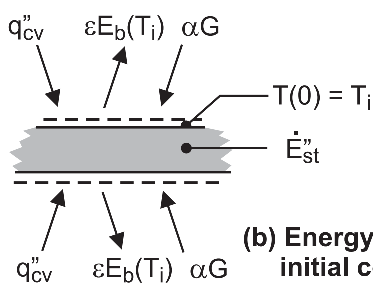
$$q''_{net,in} = 2\left[100\ \mathrm{W/m^2\cdot K}\ (750 - 25)\mathrm{K} - 0.8 \times 5.67 \times 10^{-8}\ \mathrm{W/m^2\cdot K^4}(298\ \mathrm{K})^4 + 0.713 \times 5.67 \times 10^{-8}\ \mathrm{W/m^2\cdot K^4}\ (1023\ \mathrm{K})^4\right]$$

$$q''_{net,in} = 2 \times 116.4\ \mathrm{kW/m^2} = 233\ \mathrm{kW/m^2}$$ <

Considering the energy storage term,

$$\dot{E}''_{st} = \rho c L\left(\frac{dT}{dt}\right)_i = q''_{net,in}$$

$$\left.\frac{dT}{dt}\right)_i = \frac{q''_{net,in}}{\rho c L} = \frac{233\ \mathrm{kW/m^2}}{2700\ \mathrm{kg/m^3} \times 885\ \mathrm{J/kg\cdot K} \times 0.010\ \mathrm{m}} = 9.75\ \mathrm{K/s}$$ <



(b) Energy balance, initial condition

(c) The energy balance of Part (b), using the lumped capacitance method with the *IHT DER (T,t)* function, has the form,

$$2\left[h\left(T_\infty - T\right) - \varepsilon\sigma T^4 + \alpha\sigma T_f^4\right] = \rho c L\ \mathrm{DER}\ (T, t)$$

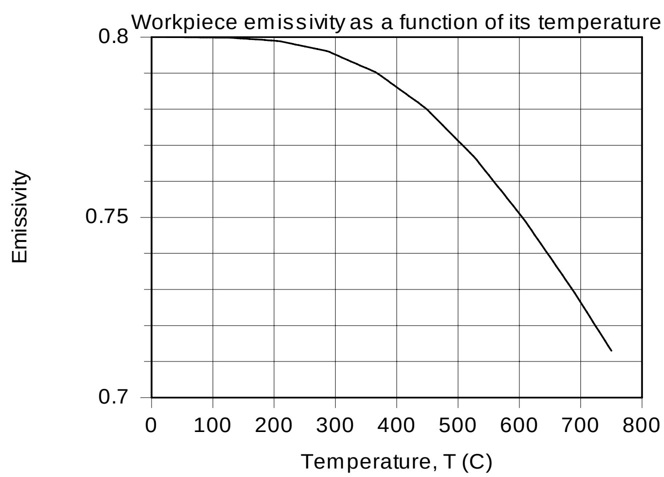
Continued …

PROBLEM 12.105 (Cont.)

The time to cool the workpiece from 750°C to the safe-to-touch temperature of 40°C can be determined using the *IHT* code in the Comments. The cooling conditions are T_∞ = 25°C and h = 100 $W/m^2 \cdot K$ with T_{sur} = 25°C. The emissivity is still evaluated as in the Comments, but the absorptivity, which depends upon the surrounding temperature, is α = 0.80. From the results in the *IHT* workspace, find

$$T(t_c) = 40^\circ C \qquad \text{when} \qquad t_c = 413\ s$$ <

COMMENTS: (1) With the relation for ε of Part (a) in the *IHT* workspace, and using the *Radiation* | *Band Emission* tool, ε as a function of workpiece temperature is calculated and plotted below.



As expected, ε decreases with increasing T, and when T = T_f = 750°C, $\varepsilon = \alpha$ = 0.713. Why is that so?

(2) The *IHT* code to obtain the heating time, including emissivity as a function of the workpiece temperature, Part (b), is shown below, complete except for the input variables.

```

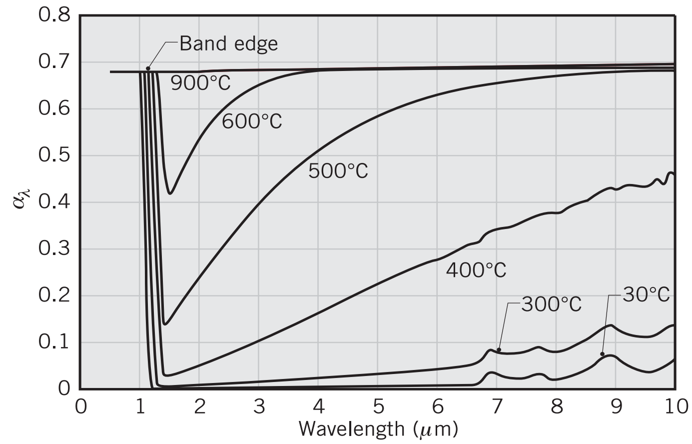
PROBLEM 12.106

KNOWN: For the semiconductor silicon, the spectral distribution of absorptivity, α_λ, at selected temperatures. High-intensity, tungsten halogen lamps having spectral distribution approximating that of a blackbody at 2800 K.

FIND: (a) 1%-limits of the spectral band that includes 98% of the blackbody radiation corresponding to the spectral distribution of the lamps; spectral region for which you need to know the spectral absorptivity; (b) Sketch the variation of the total absorptivity as a function of silicon temperature; explain key features; (c) Calculate the total absorptivity at 400, 600 and 900°C for the lamp irradiation; explain results and the temperature dependence; Calculate the total emissivity of the wafer at 600 and 900°C; explain results and the temperature dependence; and (d) Irradiation on the upper surface required to maintain the wafer at 600°C in a vacuum chamber with walls at 20°C. Use the *Look-up Table* and *Integral Functions* of *IHT* to perform the necessary integrations.

SCHEMATIC:



ASSUMPTIONS: (1) Silicon is a diffuse emitter, (2) Chamber is large, isothermal surroundings for the wafer, (3) Wafer is isothermal.

ANALYSIS: (a) From Eqs. 12.28 and 12.29, using Table 12.1 for the band emission factors, $F_{(0\,-\,\lambda T)}$, equal to 0.01 and 0.99 are:

$$F_{(0\rightarrow\lambda 1\cdot T)} = 0.01 \text{ at } \lambda_1 \cdot T = 1437\ \mu m \cdot K$$

$$F_{(0\rightarrow\lambda 2\cdot T)} = 0.99 \text{ at } \lambda_2 \cdot T = 23{,}324\ \mu m \cdot K$$

So that we have λ_1 and λ_2 limits for several temperatures, the following values are tabulated.

T(°C)	T(K)	λ_1(μm)	λ_2(μm)
-	2800	0.51	8.33
400	673	2.14	34.7
600	873	1.65	26.7
900	1173	1.23	19.9

<

For the 2800 K blackbody lamp irradiation, we need to know the spectral absorptivity over the spectral range 0.51 to 8.33 μm in order to include 98% of the radiation.

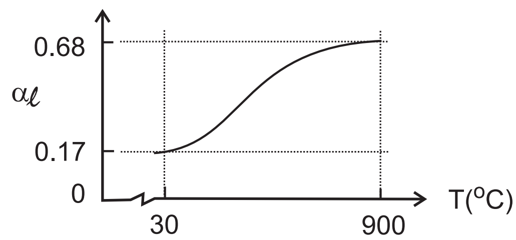
(b) The spectral absorptivity is calculated from Eq. 12.52 in which the spectral distribution of the lamp irradiation G_λ is proportional to the blackbody spectral emissive power $E_{\lambda,b}(\lambda, T)$ at the temperature of lamps, T_ℓ = 2800 K.

$$\alpha_\ell = \frac{\int_0^\infty \alpha_\lambda G_\lambda d\lambda}{\int_0^\infty G_\lambda d\lambda} = \frac{\int_0^\infty \alpha_\lambda\, E_{\lambda,b}(\lambda,\ 2800\ K)}{\sigma T_\ell^4}$$

Continued …

PROBLEM 12.106 (Cont.)

For 2800 K, the peak of the blackbody curve is at 1 μm; the limits of integration for 98% coverage are 0.5 to 8.3 μm according to part (a) results. Note that α_λ increases at all wavelengths with temperature, until around 900°C where the behavior is gray. Hence, we'd expect the total absorptivity of the wafer for lamp irradiation to appear as shown in the graph below.



At 900°C, since the wafer is gray, we expect $\alpha_\ell = \alpha_\lambda \approx 0.68$. Near room temperature, since $\alpha_\lambda \approx 0$ beyond the band edge, α_ℓ is dependent upon α_λ in the spectral region below and slightly beyond the peak. From the blackbody tables, the band emission fraction to the short-wavelength side of the peak is 0.25. Hence, estimate $\alpha_\ell \approx 0.68 \times 0.25 = 0.17$ at these low temperatures. The increase of α_ℓ with temperature is at first moderate, since the longer wavelength region is less significant than is the shorter region. As temperature increases, the α_λ closer to the peak begin to change more noticeably, explaining the greater dependence of α_ℓ on temperature.

(c) The integration of part (b) can be performed numerically using the *IHT INTEGRAL* function and specifying the spectral absorptivity in a *Lookup Table* file (*.lut). The code is shown in the Comments (1) and the results are:

T_w(°C)	400	600	900	
α_ℓ	0.30	0.59	0.68	<

The total emissivity can be calculated from Eq. 12.36, recognizing that $\varepsilon_\lambda = \alpha_\lambda$ and that for silicon temperatures of 600 and 900°C, the 1% limits for the spectral integration are 1.65 - 26.7 μm and 1.23 - 19.9 μm, respectively. The integration is performed in the same manner as described above; see Comments (2).

T(°C)	600	900	
ε	0.66	0.68	<

As the silicon temperature increases, the peak of the corresponding blackbody emissive power shifts to shorter wavelengths. In general, this will reduce ε. However, this reduction is offset by the dependence of ε_λ on temperature, which is quite strong. As the temperature increases, ε_λ increases significantly.

(d) From an energy balance on the silicon wafer with irradiation on the upper surface as shown in the schematic below, calculate the irradiation required to maintain the wafer at 600°C.

$$\dot{E}''_{in} - \dot{E}''_{out} = 0 \qquad \alpha_\ell G_\ell - 2\left[\varepsilon E_b\left(T_w\right) - \alpha_{sur} E_b\left(T_{sur}\right)\right] = 0$$

Recognize that α_{sur} corresponds to the spectral distribution of $E_{\lambda,b}(T_{sur})$; that is, upon α_λ for long wavelengths ($\lambda_{max} \approx 10$ μm). We assume $\alpha_{sur} \approx 0.1$, and with $T_{sur} = 20$°C, find

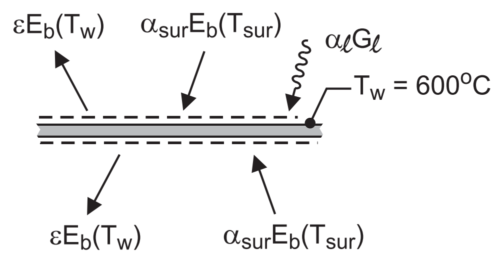
Continued …

PROBLEM 12.106 (Cont.)

$$0.59G_{\ell} - 2\sigma\left[0.66(600+273)^4 K^4 - 0.1(20+273)^4 K^4\right] = 0$$

$$G_{\ell} = 73.5 \text{ kW/m}^2$$ <

where $E_b(T) = \sigma T^4$ and $\sigma = 5.67 \times 10^{-8}$ W/m$^2 \cdot$K^4.



COMMENTS: (1) The *IHT* code to obtain the total absorptivity for the lamp irradiation, α_{ℓ} for a wafer temperature of 400°C is shown below. Similar look-up tables were written for the spectral absorptivity for 600 and 800°C.

```
/* Results; integration for total absorptivity of lamp irradiation
T = 400 C; find abs_t = 0.30

```

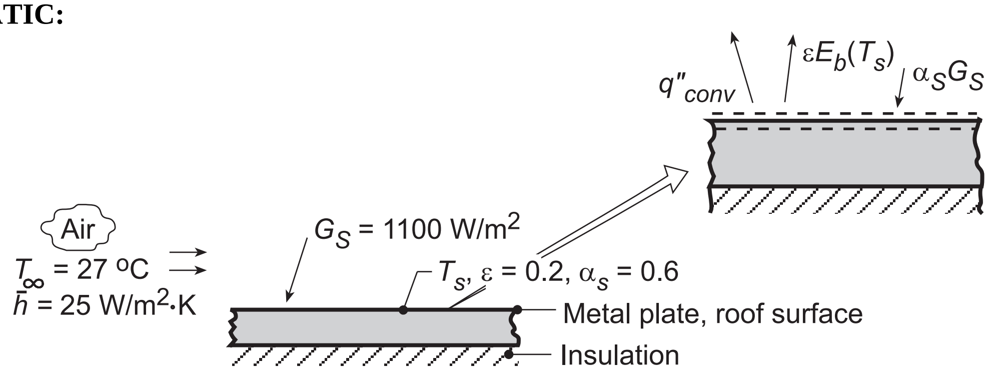
(2) The *IHT* code to obtain the total emissivity for a wafer temperature of 600°C has the same organization as for obtaining the total absorptivity. We perform the integration, however, with the blackbody spectral emissivity evaluated at the wafer temperature (rather than the lamp temperature). The same look-up file for the spectral absorptivity created in the *IHT* code above can be used.

PROBLEM 12.107

KNOWN: Solar irradiation of 1100 W/m^2 incident on a flat roof surface of prescribed solar absorptivity and emissivity; air temperature and convection heat transfer coefficient.

FIND: (a) Roof surface temperature, (b) Effect of absorptivity, emissivity and convection coefficient on temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Back-side of plate is perfectly insulated, (3) Negligible irradiation to plate by atmospheric (sky) emission.

ANALYSIS: (a) Performing a surface energy balance on the exposed side of the plate,

$$\alpha_S G_S - q''_{conv} - \varepsilon E_b(T_s) = 0 \qquad \alpha_S G_S - \bar{h}(T_s - T_\infty) - \varepsilon\sigma T_s^4 = 0$$

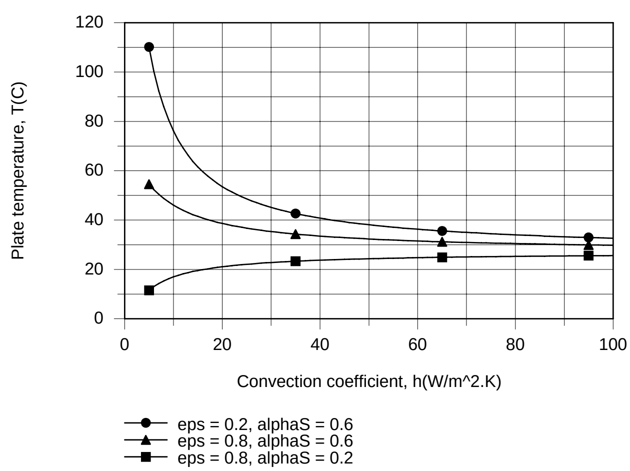
Substituting numerical values and using absolute temperatures,

$$0.6 \times 1100 \frac{W}{m^2} - 25 \frac{W}{m^2 \cdot K}(T_s - 300)K - 0.2(5.67 \times 10^{-8}\, W/m^2 \cdot K^4) T_s^4 = 0$$

Regrouping , $8160 = 25T_s + 1.1340 \times 10^{-8} T_s^4$, and performing a trial-and-error solution,

$$T_s = 321.5\ K = 48.5^\circ C.$$ <

(b) Using the IHT *First Law* Model for a plane wall, the following results were obtained.



Irrespective of the value of $\bar{h}$, T decreases with increasing ε (due to increased emission) and decreasing α_S (due to reduced absorption of solar energy). For moderate to large α_S and/or small ε (net radiation transfer to the surface) T decreases with increasing $\bar{h}$ due to enhanced cooling by convection. However, for small α_S and large ε, emission exceeds absorption, dictating convection heat transfer to the surface and hence $T < T_\infty$. With increasing $\bar{h}$, $T \to T_\infty$, irrespective of the values of α_S and ε.

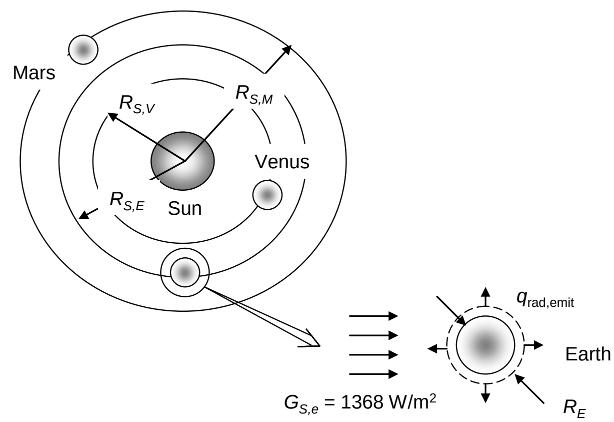
COMMENTS: To minimize the roof temperature, the value of ε/α_S should be maximized.

PROBLEM 12.108

KNOWN: Solar flux above Earth's atmosphere. Distance of Earth, Venus, and Mars from the sun. Measured average temperatures of planets.

FIND: Planet temperatures neglecting atmospheric radiation effects and assuming gray behavior. Planet most affected by radiation transfer through its atmosphere.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Planets are at constant distance from sun, (3) Atmosphere has no effect on radiation heat transfer, (4) Planets have gray surfaces, (5) Negligible radiation from space.

ANALYSIS: The energy balance for each planet is between absorbed solar radiation and emitted radiation. The appropriate area for the intercepted solar radiation is the projected area $A_p = \pi R^2$, where R is the planet's radius, thus

$$q_{\text{rad,abs}} = \alpha G_S A_p$$

Radiation is emitted from the entire surface area of the planet, $A_s = 4\pi R^2$, therefore the emitted radiation is

$$q_{\text{rad,emit}} = \varepsilon \sigma T_s^4 A_s$$

The energy balance becomes

$$q_{\text{rad,abs}} - q_{\text{rad,emit}} = 0$$

$$\alpha G_S \pi R^2 - \varepsilon \sigma T_s^4 4\pi R^2 = 0$$

With gray surface behavior, $\alpha = \varepsilon$, we find

$$T_s = \left(\frac{G_S}{4\sigma} \right)^{1/4}$$

The solar irradiation is different for each planet because they are at different distances from the sun. At a distance R_s from the sun, the solar radiation q_{solar} passes through the spherical area $4\pi R_s^2$, resulting in a solar heat flux

$$G_S = q_{\text{solar}} / 4\pi R_s^2$$

Continued...

PROBLEM 12.108 (Cont.)

Thus, knowing the solar irradiation for Earth, $G_{S,E}$, we can find the solar irradiation for Venus and Mars:

$$G_{S,V} = G_{S,E} R_{S,E}^2 / R_{S,V}^2 = 1368 \text{ W/m}^2 \times (1.50 \times 10^{11} \text{m})^2 / (1.08 \times 10^{11} \text{m})^2 = 2640 \text{ W/m}^2$$
$$G_{S,M} = G_{S,E} R_{S,E}^2 / R_{S,M}^2 = 1368 \text{ W/m}^2 \times (1.50 \times 10^{11} \text{m})^2 / (2.30 \times 10^{11} \text{m})^2 = 580 \text{ W/m}^2$$

Finally, the planet temperatures can be calculated:

$$T_{s,E} = \left(\frac{G_{S,E}}{4\sigma}\right)^{1/4} = \left(\frac{1368 \text{ W/m}^2}{4 \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4}\right)^{1/4} = 279 \text{ K}$$ <

Similarly,

$$T_{s,V} = 329 \text{ K}, \quad T_{s,M} = 225 \text{ K}$$ <

The calculated temperatures are compared with the measured average temperatures in the chart:

Planet	$L_{S\text{-}p}$, m	$\overline{T_p}$, K	T_{calc}, K
Venus	1.08×10^{11}	735	329
Earth	1.50×10^{11}	287	279
Mars	2.30×10^{11}	227	225

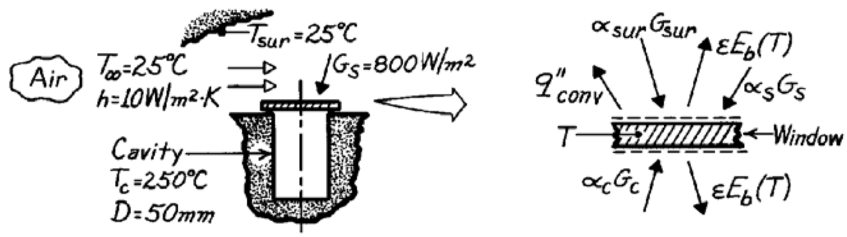
The biggest discrepancy is for Venus, which has a very dense atmosphere and significant radiation absorption, emission and scattering phenomena. <

PROBLEM 12.109

KNOWN: Cavity with window whose outer surface experiences convection and radiation.

FIND: Temperature of the window and power required to maintain cavity at prescribed temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Cavity behaves as a blackbody, (3) Solar spectral distribution is that of a blackbody at 5800K, (4) Window is isothermal, (5) Negligible convection on lower surface of window.

PROPERTIES: Window material: $0.2 \le \lambda \le 4$ μm, $\tau_\lambda = 0.9$, $\rho_\lambda = 0$, hence $\alpha_\lambda = 1 - \tau_\lambda = 0.1$; 4 μm < λ, $\tau_\lambda = 0$, $\alpha = \varepsilon = 0.95$, diffuse-gray, opaque.

ANALYSIS: To determine the window temperature, perform an energy balance on the window,

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$\left[\alpha_{sur}G_{sur} + \alpha_S G_S - \varepsilon E_b - q''_{conv}\right]_{upper} + \left[\alpha_c G_c - \varepsilon E_b(T)\right]_{lower} = 0. \qquad (1)$$

Calculate the absorptivities for various irradiation conditions using Eq. 12.52,

$$\alpha = \int_0^\infty \alpha_\lambda G_\lambda d\lambda \Big/ \int_0^\infty G_\lambda d\lambda \qquad (2)$$

where $G(\lambda)$ is the spectral distribution of the irradiation.

Surroundings, α_{sur}: $G_{sur} = E_b(T_{sur}) = \sigma T_{sur}^4$

$$\alpha_{sur} = 0.1\left[F_{(0\to 4\mu m)} - F_{(0\to 0.2\mu m)}\right] + 0.95\left[1 - F_{(0\to 4\mu m)}\right]$$

where from Table 12.1, with $T = T_{sur} = (25 + 273)K = 298K$,

$$\lambda T = 0.2\mu m \times 298K = 59.6\mu m\cdot K, \quad F_{(0-\lambda T)} = 0.000$$

$$\lambda T = 4\mu m \times 298K = 1192\mu m\cdot K, \quad F_{(0-\lambda T)} = 0.002$$

$$\alpha_{sur} = 0.1[0.002 - 0.000] + 0.95[1 - 0.002] = 0.948. \qquad (3)$$

Solar, α_S: $G_S \sim E_b(5800K)$

$$\alpha_S = 0.1\left[F_{(0\to 4\mu m)} - F_{(0\to 0.2\mu m)}\right] + 0.95\left[1 - F_{(0\to 4\mu m)}\right]$$

where from Table 12.1, with T = 5800K,

$$\lambda T = 0.2\mu m \times 5800K = 1160\mu m\cdot K, \quad F_{(0-\lambda T)} = 0.002$$

$$\lambda T = 4\mu m \times 5800K = 23{,}200\mu m\cdot K, \quad F_{(0-\lambda T)} = 0.990$$

$$\alpha_S = 0.1[0.990 - 0.002] + 0.95[1 - 0.990] = 0.108. \qquad (4)$$

Continued …

PROBLEM 12.109 (Cont.)

Cavity, α_c: $G_c = E_b(T_c) = \sigma T_c^4$

$$\alpha_c = 0.1\left[F_{(0\to 4\mu m)} - F_{(0\to 0.2\mu m)}\right] + 0.95\left[1 - F_{(0\to 4\mu m)}\right]$$

where from Table 12.1 with T_c = 250°C = 523K,

$$\lambda T = 0.2\mu m \times 523K = 104.6\mu m\cdot K, \quad F_{0\to\lambda T} = 0.000$$

$$\lambda T = 4\mu m \times 523K = 2092\mu m\cdot K \quad F_{0\to\lambda T} = 0.082$$

$$\alpha_c = 0.1[0.082 - 0.000] + 0.95[1 - 0.082] = 0.880. \quad (5)$$

To determine the *emissivity* of the window, we need to know its temperature. However, we know that T will be less than T_c and the long wavelength behavior will dominate. That is,

$$\varepsilon \approx \varepsilon_\lambda(\lambda > 4\mu m) = 0.95. \quad (6)$$

With these radiative properties now known, the energy equation, Eq. (1) can now be evaluated using $q''_{conv} = h(T - T_\infty)$ with all temperatures in kelvin units.

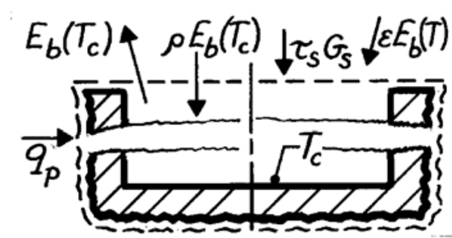
$$0.948\times\sigma(298K)^4 + 0.108\times 800\,W/m^2 - 0.95\times\sigma T^4 - 10\,W/m^2\cdot K(T - 298K)$$
$$+0.880\sigma(523K)^4 - 0.95\times\sigma T^4 = 0$$

$$1.077\times 10^{-7}T^4 + 10T - 7223 = 0.$$

Using a trial-and-error approach, find the window temperature as

$$T = 413K = 139°C. \quad <$$

To determine the power required to maintain the cavity at T_c = 250°C, perform an energy balance on the cavity.



$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$q_p + A_c\left[\rho E_b(T_c) + \tau_S G_S + \varepsilon E_b(T) - E_b(T_c)\right] = 0.$$

For simplicity, we have assumed the window opaque to irradiation from the surroundings. It follows that

$$\tau_S = 1 - \rho_S - \alpha_S = 1 - 0 - 0.108 = 0.892$$

$$\rho = 1 - \alpha = 1 - \varepsilon = 1 - 0.95 = 0.05.$$

Hence, the power required to maintain the cavity, when $A_c = (\pi/4)D^2$, is

$$q_p = A_c\left[\sigma T_c^4 - \rho\sigma T_c^4 - \tau_S G_S - \varepsilon\sigma T^4\right]$$

$$q_p = \frac{\pi}{4}(0.050m)^2\left[\sigma(523K)^4 - 0.05\sigma(523K)^4 - 0.892\times 800\,W/m^2 - 0.95\sigma(412K)^4\right]$$

$$q_p = 3.47W. \quad <$$

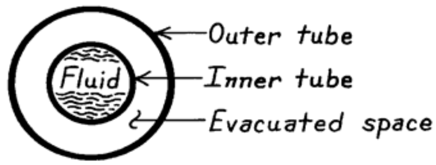
COMMENTS: Note that the assumed value of ε = 0.95 is not fully satisfied. With T = 412K, we would expect ε = 0.929. Hence, an iteration may be appropriate.

PROBLEM 12.110

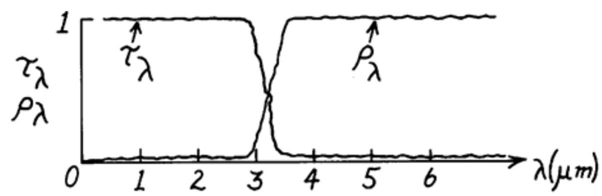
KNOWN: Features of an evacuated tube solar collector.

FIND: Ideal surface spectral characteristics.

SCHEMATIC:

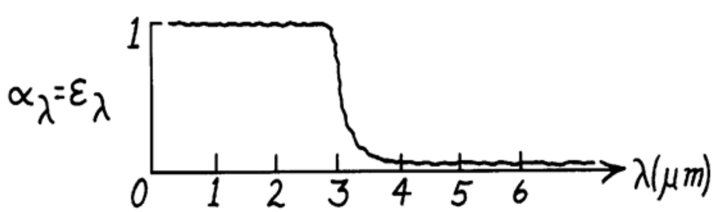


ANALYSIS: The outer tube should be transparent to the incident solar radiation, which is concentrated in the spectral region $\lambda \leq 3\mu m$, but it should be opaque and highly reflective to radiation emitted by the outer surface of the inner tube, which is concentrated in the spectral region above 3μm. Accordingly, ideal spectral characteristics for the outer tube are



Note that large ρ_λ is desirable for the outer, as well as the inner, surface of the outer tube. If the surface is diffuse, a large value of ρ_λ yields a small value of $\varepsilon_\lambda = \alpha_\lambda = 1 - \rho_\lambda$. Hence losses due to emission from the outer surface to the surroundings would be negligible.

The opaque outer surface of the inner tube should absorb all of the incident solar radiation ($\lambda \leq 3\mu m$) and emit little or no radiation, which would be in the spectral region $\lambda > 3\mu m$. Accordingly, assuming diffuse surface behavior, ideal spectral characteristics are:

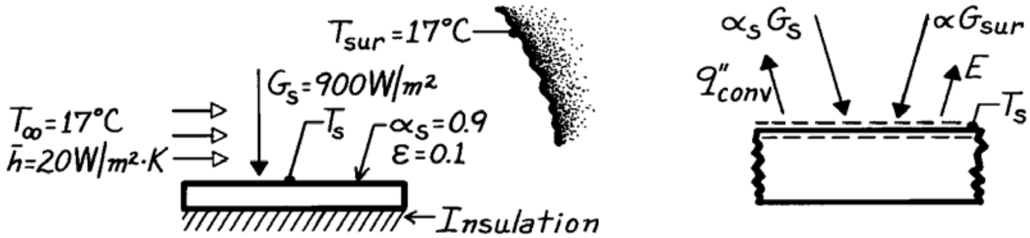


PROBLEM 12.111

KNOWN: Plate exposed to solar flux with prescribed solar absorptivity and emissivity; convection and surrounding conditions also prescribed.

FIND: Steady-state temperature of the plate.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Plate is small compared to surroundings, (3) Backside of plate is perfectly insulated, (4) Diffuse behavior.

ANALYSIS: Perform a surface energy balance on the top surface of the plate.

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$\alpha_S G_S + \alpha G_{sur} - q''_{conv} - \varepsilon E_b(T_s) = 0$$

Note that the effect of the surroundings is to provide an irradiation, G_{sur}, on the plate; since the spectral distribution of G_{sur} and $E_{\lambda,b}(T_s)$ are nearly the same, according to Kirchoff's law, $\alpha = \varepsilon$. Recognizing that $G_{sur} = \sigma T_{sur}^4$ and using Newton's law of cooling, the energy balance is

$$\alpha_S G_S + \varepsilon\sigma T_{sur}^4 - \bar{h}(T_s - T_\infty) - \varepsilon \cdot \sigma T_s^4 = 0.$$

Substituting numerical values,

$$0.9\times 900\ W/m^2 + 0.1\times 5.67\times 10^{-8} W/m^2\cdot K\times(17+273)^4 K^4$$
$$-20 W/m^2\cdot K(T_s - 290)K - 0.1\left(5.67\times 10^{-8} W/m^2\cdot K^4\right)T_s^4 = 0$$

$$6650\ W/m^2 = 20\ T_s + 5.67\times 10^{-9}\ T_s^4.$$

From a trial-and-error solution, find

$$T_s = 329.2\ K.$$ <

COMMENTS: (1) When performing an analysis with both convection and radiation processes present, all temperatures must be expressed in absolute units (K).

(2) Note also that the terms $\alpha\ G_{sur} - \varepsilon\ E_b(T_s)$ could be expressed as a radiation exchange term, written as

$$q''_{rad} = q/A = \varepsilon\sigma\left(T_{sur}^4 - T_s^4\right).$$

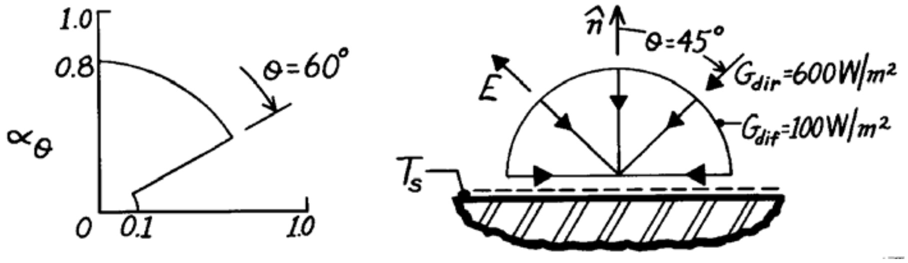
The conditions for application of this relation were met and are namely: surroundings much larger than surface, diffuse surface, and spectral distributions of irradiation and emission are similar (or the surface is gray).

PROBLEM 12.112

KNOWN: Directional distribution of α_θ for a horizontal, opaque, gray surface exposed to direct and diffuse irradiation.

FIND: (a) Absorptivity to direct radiation at 45° and to diffuse radiation, and (b) Equilibrium temperature for specified direct and diffuse irradiation components.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Opaque, gray surface behavior, (3) Negligible convection at top surface and perfectly insulated back surface.

ANALYSIS: (a) From knowledge of α_θ (θ) – see graph above – it is evident that the absorptivity of the surface to the direct radiation (45°) is

$$\alpha_{dir} = \alpha_\theta(45°) = 0.8. \qquad <$$

The absorptivity to the diffuse radiation is the hemispherical absorptivity given by Eq. 12.50. Dropping the λ subscript,

$$\alpha_{dir} = 2\int_0^{\pi/2} \alpha_\theta(\theta)\cos\theta\sin\theta\, d\theta \qquad (1)$$

$$\alpha_{dir} = 2\left[0.8\frac{\sin^2\theta}{2}\bigg|_0^{\pi/3} + 0.1\frac{\sin^2\theta}{2}\bigg|_{\pi/3}^{\pi/2}\right]$$

$$\alpha_{dir} = 0.625. \qquad <$$

(b) Performing a surface energy balance,

$$\dot{E}''_{in} - \dot{E}''_{out} = 0$$

$$\alpha_{dir}\, G_{dir} + \alpha_{dif}\, G_{dif} - \varepsilon\sigma T_s^4 = 0. \qquad (2)$$

The total, hemispherical emissivity may be obtained from Eq. 12.42 where again the subscript may be deleted. Since this equation is of precisely the same form as Eq. 12.50 – see Eq. (1) above – and since $\alpha_\theta = \varepsilon_\theta$, it follows that

$$\varepsilon = \alpha_{dif} = 0.625$$

and from Eq. (2), find

$$T_s^4 = \frac{(0.8\times600 + 0.625\times100)\,W/m^2}{0.625\times5.67\times10^{-8}\,W/m^2\cdot K^4} = 1.53\times10^{10}\,K^4, \qquad T_s = 352\text{ K}. \qquad <$$

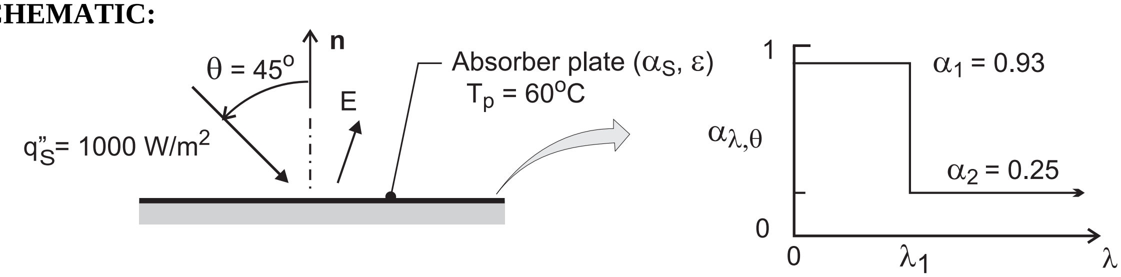
COMMENTS: In assuming *gray* surface behavior, spectral effects are not present, and total and spectral properties are identical. However, the surface is *not diffuse* and hence hemispherical and directional properties differ.

PROBLEM 12.113

KNOWN: Plate temperature and spectral and directional dependence of its absorptivity. Direction and magnitude of solar flux.

FIND: (a) Expression for total absorptivity, (b) Expression for total emissivity, (c) Net radiant flux, (d) Effect of cut-off wavelength associated with directional dependence of the absorptivity.

SCHEMATIC:



ASSUMPTIONS: (1) Diffuse component of solar flux is negligible, (2) Spectral distribution of solar radiation may be approximated as that from a blackbody at 5800 K, (3) Properties are independent of azimuthal angle ϕ.

ANALYSIS: (a) For $\lambda < \lambda_c$ and $\theta = 45°$, $\alpha_\lambda = \alpha_1 \cos\theta = 0.707\ \alpha_1$. From Eq. 12.53 the total absorptivity is then

$$\alpha_S = 0.707\ \alpha_1 \left\{ \frac{\int_0^{\lambda_c} E_{\lambda,b}\ (\lambda, 5800\ K) d\lambda}{E_b} \right\} + \alpha_2 \left\{ \frac{\int_{\lambda_c}^{\infty} E_{\lambda,b}\ (\lambda, 5800\ K) d\lambda}{E_b} \right\}$$

$$\alpha_S = 0.707\ \alpha_1\ F_{(0\to\lambda_c)} + \alpha_2 \left[1 - F_{(0\to\lambda_c)}\right] \qquad <$$

For the prescribed value of λ_c, $\lambda_c T$ = 11,600 μm·K and, from Table 12.1, $F_{(0\to\lambda c)} = 0.941$. Hence,

$$\alpha_S = 0.707 \times 0.93 \times 0.941 + 0.25(1 - 0.941) = 0.619 + 0.015 = 0.634 \qquad <$$

(b) With $\varepsilon_{\lambda,\theta} = \alpha_{\lambda,o}$, Eq 12.42 may be used to obtain ε_λ for $\lambda < \lambda_c$.

$$\varepsilon_\lambda (\lambda, T) = 2\alpha_1 \int_0^{\pi/2} \cos^2\theta \sin\theta\, d\theta = -2\alpha_1 \frac{\cos^3\theta}{3}\Big|_0^{\pi/2} = \frac{2}{3}\alpha_1$$

From Eq. 12.43,

$$\varepsilon = 0.667\,\alpha_1 \frac{\int_0^{\lambda_c} E_{\lambda,b}(\lambda, T_p) d\lambda}{E_b} + \alpha_2 \frac{\int_{\lambda_c}^{\infty} E_{\lambda,b}(\lambda, T_p) d\lambda}{E_b}$$

$$\varepsilon = 0.667\,\alpha_1 F_{(0\to\lambda_c)} + \alpha_2 \left[1 - F_{(0-\lambda_c)}\right] \qquad <$$

For λ_c = 2 μm and T_p = 333 K, $\lambda_c T$ = 666 μm·K and, from Table 12.1, $F_{(0-\lambda c)} = 0$. Hence,

$$\varepsilon = \alpha_2 = 0.25 \qquad <$$

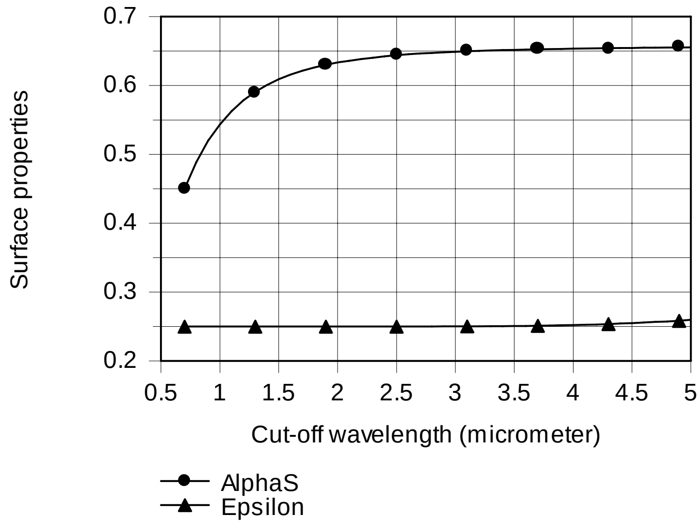
Continued …

PROBLEM 12.113 (Cont.)

(c) $$q''_{net} = \alpha_S q''_S - \varepsilon\sigma T_p^4 = 634\ W/m^2 - 0.25 \times 5.67 \times 10^{-8}\ W/m^2 \cdot K^4 (333\ K)^4$$

$$q''_{net} = 460\ W/m^2$$ <

(d) Using the foregoing model with the Radiation/Band Emission Factor option of *IHT*, the following results were obtained for α_S and ε. The absorptivity increases with increasing λ_c, as more of the incident solar radiation falls within the region of $\alpha_1 > \alpha_2$. Note, however, the limit at $\lambda \approx 3\ \mu m$, beyond which there is little change in α_S. The emissivity also increases with increasing λ_c, as more of the emitted radiation is at wavelengths for which $\varepsilon_1 = \alpha_1 > \varepsilon_2 = \alpha_2$. However, the surface temperature is low, and even for $\lambda_c = 5\ \mu m$, there is little emission at $\lambda < \lambda_c$. Hence, ε only increases from 0.25 to 0.26 as λ_c increases from 0.7 to 5.0 μm.



The net heat flux increases from 276 W/m^2 at $\lambda_c = 2\ \mu m$ to a maximum of 477 W/m^2 at $\lambda_c = 4.2\ \mu m$ and then decreases to 474 W/m^2 at $\lambda_c = 5\ \mu m$. The existence of a maximum is due to the upper limit on the value of α_S and the increase in ε with λ_c.

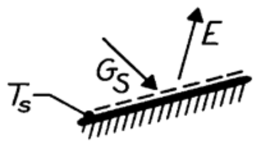
COMMENTS: Spectrally and directionally selective coatings may be used to enhance the performance of solar collectors.

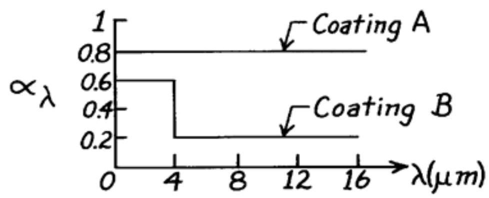
PROBLEM 12.114

KNOWN: Spectral distribution of α_λ for two roof coatings.

FIND: Preferred coating for summer and winter use. Ideal spectral distribution of α_λ.

SCHEMATIC:





ASSUMPTIONS: (1) Opaque, diffuse surface behavior, (2) Negligible convection effects and heat transfer from bottom of roof, negligible atmospheric irradiation, (3) Steady-state conditions.

ANALYSIS: From an energy balance on the roof surface

$$\varepsilon \sigma T_s^4 = \alpha_S G_S.$$

Hence

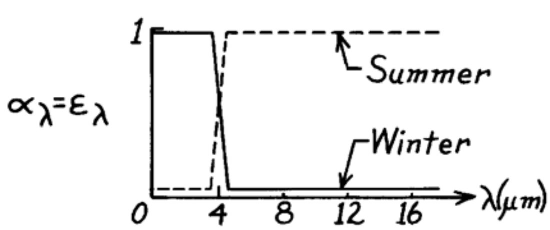
$$T_s = \left(\frac{\alpha_S}{\varepsilon} \frac{G_S}{\sigma} \right)^{1/4}.$$

Solar irradiation is concentrated in the spectral region $\lambda < 4\mu m$, while surface emission is concentrated in the region $\lambda > 4\mu m$. Hence, with $\alpha_\lambda = \varepsilon_\lambda$

Coating A: $\alpha_S \approx 0.8$, $\varepsilon \approx 0.8$

Coating B: $\alpha_S \approx 0.6$, $\varepsilon \approx 0.2$.

Since $(\alpha_S/\varepsilon)_A = 1 < (\alpha_S/\varepsilon)_B = 3$, Coating A would result in the lower roof temperature and is preferred for summer use. In contrast, Coating B is preferred for winter use. The ideal coating is one which minimizes (α_S/ε) in the summer and maximizes it in the winter.

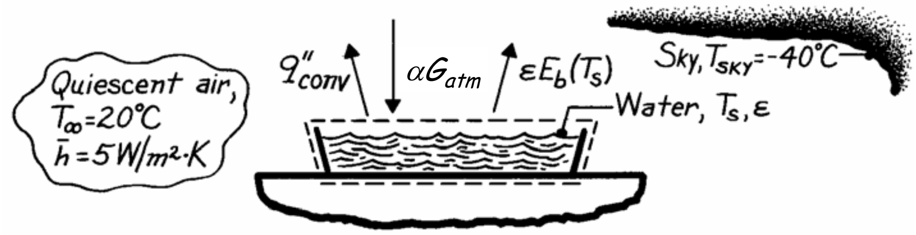


PROBLEM 12.115

KNOWN: Shallow pan of water exposed to night desert air and sky conditions.

FIND: Whether water will freeze.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Bottom of pan is well insulated, (3) Water surface is diffuse-gray, (4) Sky provides blackbody irradiation, $G_{atm} = \sigma T_{sky}^4$.

PROPERTIES: *Table A-11*, Water (300 K): ε = 0.96.

ANALYSIS: To estimate the water surface temperature for these conditions, begin by performing an energy balance on the pan of water considering convection and radiation processes.

$$\dot{E}''_{in} - \dot{E}''_{out} = 0$$

$$\alpha G_{atm} - \varepsilon E_b - \bar{h}(T_s - T_\infty) = 0$$

$$\varepsilon \sigma \left(T_{sky}^4 - T_s^4\right) - \bar{h}(T_s - T_\infty) = 0.$$

Note that, from Eq. 12.73, $G_{atm} = \sigma T_{sky}^4$ and from Assumption 3, α = ε. Substituting numerical values, with all temperatures in kelvin units, the energy balance is

$$0.96 \times 5.67 \times 10^{-8} \frac{W}{m^2 \cdot K^4}\left[(-40+273)^4 - T_s^4\right]K^4 - 5\frac{W}{m^2 \cdot K}\left[T_s - (20+273)\right]K = 0$$

$$5.443 \times 10^{-8}\left[233^4 - T_s^4\right] - 5\left[T_s - 293\right] = 0.$$

Using a trial-and-error approach, find the water surface temperature,

$$T_s = 268.5\ K.$$ <

Since T_s < 273 K, it follows that the water surface will freeze under the prescribed air and sky conditions.

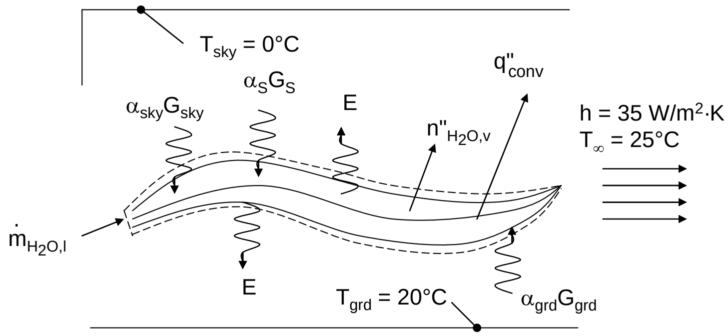
COMMENTS: If the heat transfer coefficient were to increase as a consequence of wind, freezing might not occur. Verify that for the given T_∞ and T_{sky}, that if $\bar{h}$ increases by more than 40%, freezing cannot occur.

PROBLEM 12.116

KNOWN: Environmental conditions associated with a corn leaf, evaporative fluxes in rural and urban settings due to differences in ambient CO_2 concentrations, absorptivity and emissivity values.

FIND: Leaf temperature for high (urban) and low (rural) ambient CO_2 concentrations.

SCHEMATIC:



PROPERTIES: (Given) h_{fg} = 2400 kJ/kg.

ASSUMPTIONS: (1) Steady state conditions, (2) Ground and sky represent large surroundings, (3) Negligible irradiation from other leaves, (4) $\alpha = \varepsilon$ for radiation at long wavelengths, (5) Evaporation flux on top and bottom of leaf.

ANALYSIS: Performing an energy balance on the leaf on a per unit area basis,

$$\alpha_s G_s + \alpha_{\text{sky}}\sigma T_{\text{sky}}^4 + \alpha_{\text{grd}}\sigma T_{\text{grd}}^4 = 2h(T - T_\infty) + 2\varepsilon\sigma T^4 + 2n''_{H_2O}h_{\text{fg}}$$

Substituting values for the lower CO_2 environment, high evaporation rate (rural) case,

$$0.76 \times 600\text{W/m}^2 + 0.97 \times 5.67 \times 10^{-8}\text{W/m}^2 \cdot \text{K}^4 \times (273+0)^4\text{K}^4 + 0.97 \times 5.67 \times 10^{-8}\text{W/m}^2 \cdot \text{K}^4 \times (273+20)^4\text{K}^4$$

$$=$$

$$2 \times 35\text{W/m}^2 \cdot \text{K} \times \left[T - (273+25)\right]\text{K}$$

$$+2 \times 0.97 \times 5.67 \times 10^{-8}\text{W/m}^2 \cdot \text{K}^4 \times (T)^4\text{K}^4 + 2 \times 50 \times 10^{-6}\text{kg/m}^2 \cdot \text{s} \times 2400 \times 10^3\text{J/kg}$$

which yields T = 298.7 K = 25.7°C <

Substituting n''_{H_2O} = 5 × 10^{-6} kg/s for the low evaporation (urban) case yields T = 301.4 K = 28.4°C <

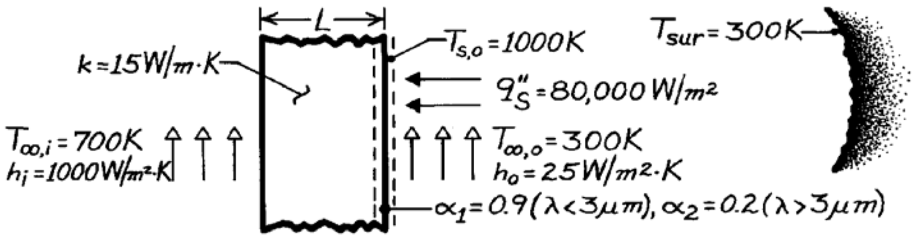
COMMENTS: (1) Carbon dioxide levels in urban areas can easily be more than three times greater than in rural communities due to, primarily, fossil fuel combustion corresponding to high traffic density. The sensitivity of the leaf temperature to the local CO_2 concentration is significant. (2) Reduced leaf evaporation rates associated with the higher CO_2 concentration makes corn and other so-called C4 photosynthesis plants more drought-tolerant in urban areas. See, for example, Wall et al., "Elevated Atmospheric CO_2 Improved Sorghum Plant Water Status by Ameliorating the Adverse Effects of Drought," *New Phytologist*, Vol. 152, pp. 231 – 248, 2001. (3) Higher rates of respiratory ailments in urban versus rural communities have been attributed to increased pollen production by plants such as ragweed in cities. The increased pollen production is associated with the increased drought tolerance of ragweed due to elevated CO_2 levels. See L.H. Ziska et al., "Cities as Harbingers of Climate Change: Common Ragweed, Urbanization, and Public Health," *Journal of Allergy and Clinical Immunology*, Vol. 111, pp. 290 - 295, 2003.

PROBLEM 12.117

KNOWN: Thermal conductivity, spectral absorptivity and inner and outer surface conditions for wall of central solar receiver.

FIND: Minimum wall thickness needed to prevent thermal failure. Collector efficiency.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Outer surface is opaque and diffuse, (3) Spectral distribution of solar radiation corresponds to blackbody emission at 5800 K.

ANALYSIS: From an energy balance at the outer surface, $\dot{E}_{in} = \dot{E}_{out}$,

$$\alpha_S q''_S + \alpha_{sur} G_{sur} = \varepsilon\sigma T_{s,o}^4 + h_o\left(T_{s,o} - T_{\infty,o}\right) + \frac{T_{s,o} - T_{\infty,i}}{(L/k) + (1/h_i)}$$

Since radiation from the surroundings is in the far infrared, $\alpha_{sur} = 0.2$. From Table 12.1, $\lambda T = (3\ \mu m \times 5800\ K) = 17{,}400\ \mu m\cdot K$, find $F_{(0\to 3\mu m)} = 0.979$. Hence,

$$\alpha_s = \frac{\int_0^\infty \alpha_\lambda E_{\lambda,b}(5800\ K)\,d\lambda}{E_b} = \alpha_1 F_{(0\to 3\mu m)} + \alpha_2 F_{(3\to\infty)} = 0.9(0.979) + 0.2(0.021) = 0.885.$$

From Table 12.1, $\lambda T = (3\ \mu m \times 1000\ K) = 3000\ \mu m\cdot K$, find $F_{(0\to 3\mu m)} = 0.273$. Hence,

$$\varepsilon_s = \frac{\int_o^\infty \varepsilon_\lambda E_{\lambda,b}(1000\ K)\,d\lambda}{E_b} = \varepsilon_1 F_{(0\to 3)} + \varepsilon_2 F_{(3\to\infty)} = 0.9(0.273) + 0.2(0.727) = 0.391.$$

Substituting numerical values in the energy balance, find

$$0.885\left(80,000\ W/m^2\right) + 0.2 \times 5.67\times10^{-8}\ W/m^2\cdot K^4\,(300\ K)^4 = 0.391\times 5.67\times10^{-8}\ W/m^2\cdot K^4\,(1000\ K)^4$$

$$+25\ W/m^2\cdot K(700\ K) + (300\ K)/\left[(L/15\ W/m\cdot K) + \left(1/1000\ W/m^2\cdot K\right)\right]$$

$$L = 0.129\ m.$$ <

The corresponding collector efficiency is

$$\eta = \frac{q''_{use}}{q''_S} = \left[\frac{T_{s,o} - T_{\infty,i}}{(L/k) + (1/h_i)}\right] / q''_S$$

$$\eta = \left[\frac{300\ K}{(0.129\ m/15\ W/m\cdot K) + \left(0.001\ m^2\cdot K/W\right)}\right] / 80,000\ W/m^2 = 0.391 \text{ or } 39.1\%.$$ <

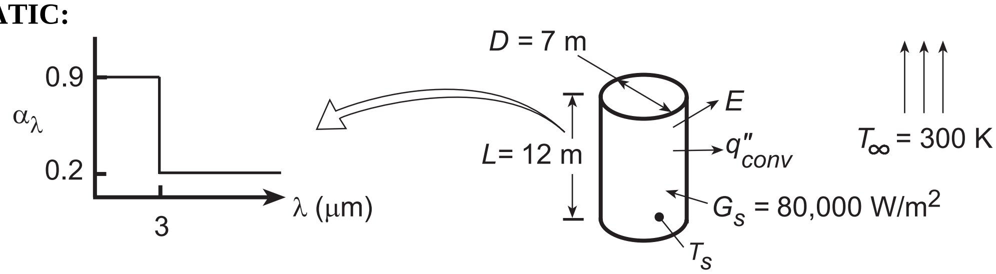
COMMENTS: The collector efficiency could be increased and the outer surface temperature reduced by decreasing the value of L.

PROBLEM 12.118

KNOWN: Dimensions, spectral absorptivity, and temperature of solar receiver. Solar irradiation and ambient temperature.

FIND: (a) Rate of energy collection q and collector efficiency η, (b) Effect of receiver temperature on q and η.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Uniform irradiaton, (3) Opaque, diffuse surface.

PROPERTIES: *Table A.4*, air (T_f = 550 K): $\nu = 45.6 \times 10^{-6}$ m²/s, k = 0.0439 W/m·K, $\alpha = 66.7 \times 10^{-6}$ m²/s, Pr = 0.683.

ANALYSIS: (a) The rate of heat transfer to the receiver is $q = A_S\left(\alpha_S G_S - E - q''_{conv}\right)$, or

$$q = \pi DL\left[\alpha_S G_S - \varepsilon\sigma T_s^4 - \bar{h}\left(T_s - T_\infty\right)\right]$$

For λT = 3 μm × 5800 K = 17,400, $F_{(0\to\lambda)}$ = 0.979. Hence,

$$\alpha_S = \alpha_1 F_{(0\to\lambda)} + \alpha_2\left(1 - F_{(0\to\lambda)}\right) = 0.9\times 0.979 + 0.2(0.021) = 0.885$$

For λT = 3 μm × 800 K = 2400 μm·K, $F_{(0\to\lambda)}$ = 0.140. Hence,

$$\varepsilon = \varepsilon_1 F_{(0\to\lambda)} + \varepsilon_2\left(1 - F_{(0\to\lambda)}\right) = 0.9\times 0.140 + 0.2(0.860) = 0.298 .$$

With $Ra_L = g\beta(T_s - T_\infty)L^3/\alpha\nu$ = 9.8 m/s²(1/550 K)(500 K)(12 m)³/66.7 × 10⁻⁶ m²/s × 45.6 × 10⁻⁶ m²/s = 5.06 × 10¹², Eq. 9.26 yields

$$\overline{Nu}_L = \left\{0.825 + \frac{0.387 Ra_L^{1/6}}{\left[1 + (0.492/Pr)^{9/16}\right]^{8/27}}\right\}^2 = 1867$$

$$\bar{h} = \overline{Nu}_L \frac{k}{L} = 1867 \frac{0.0439\ W/m\cdot K}{12\ m} = 6.83\ W/m^2\cdot K$$

Hence,

$$q = \pi(7\ m\times 12\ m)\left[0.885\times 80,000\ W/m^2 - 0.298\times 5.67\times 10^{-8}\ W/m^2\cdot K^4(800\ K)^4 - 6.83\ W/m^2\cdot K(500\ K)\right]$$

$$q = 263.9\ m^2(70,800 - 6,920 - 3415)\ W/m^2 = 1.60\times 10^7\ W$$ <

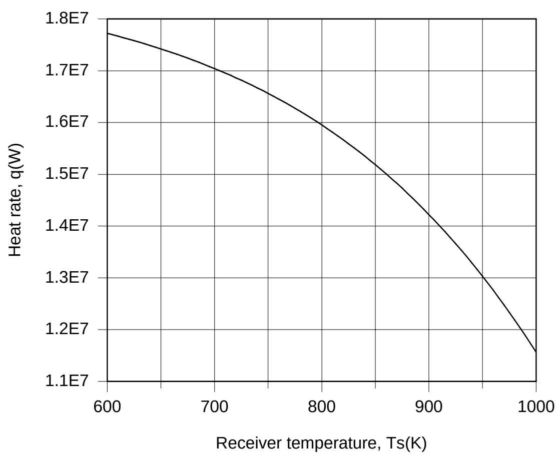
The collector efficiency is $\eta = q/A_s G_S$. Hence

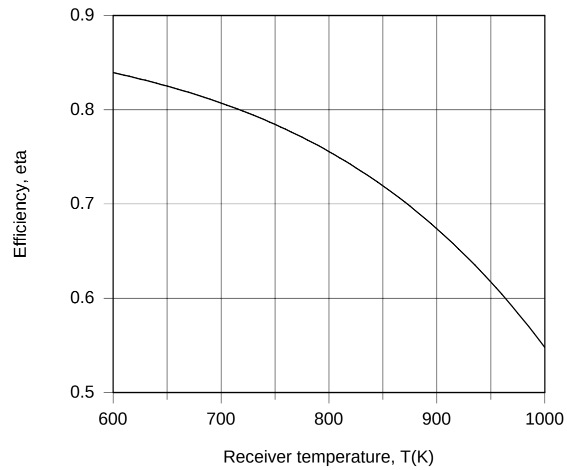
$$\eta = \frac{1.60\times 10^7\ W}{263.9\ m^2\left(80,000\ W/m^2\right)} = 0.758$$ <

Continued …

PROBLEM 12.118 (Cont.)

(b) The IHT *Correlations*, *Properties* and *Radiation* Toolpads were used to obtain the following results.





Losses due to emission and convection increase with increasing T_s, thereby reducing q and η.

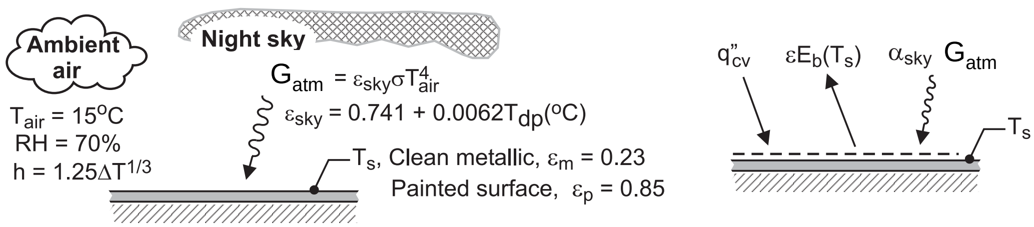
COMMENTS: The increase in radiation emission is due to the increase in T_s, as well as to the effect of T_s on ε, which increases from 0.228 to 0.391 as T_s increases from 600 to 1000 K.

PROBLEM 12.119

KNOWN: Flat plate exposed to night sky and in ambient air at T_{air} = 15°C with a relative humidity of 70%. Radiation from the atmosphere or sky estimated as a fraction of the blackbody radiation corresponding to the near-ground air temperature, $G_{sky} = \varepsilon_{sky}\,\sigma\,T_{air}$, and for a clear night, ε_{sky} = 0.741 + 0.0062 T_{dp} where T_{dp} is the dew point temperature (°C). Convection coefficient estimated by correlation, $\bar{h}\left(W/m^2\cdot K\right) = 1.25\Delta T^{1/3}$ where ΔT is the plate-to-air temperature difference (K).

FIND: Whether dew will form on the plate if the surface is (a) clean metal with ε_m = 0.23 and (b) painted with ε_p = 0.85.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Surfaces are diffuse, gray, and (3) Backside of plate is well insulated.

PROPERTIES: *Psychrometric charts* (Air), T_{dp} = 9.4°C for dry bulb temperature 15°C and relative humidity 70%.

ANALYSIS: From the schematic above, the energy balance on the plate is

$$\dot{E}''_{in} - \dot{E}''_{out} = 0$$

$$\alpha_{sky} G_{atm} + q''_{cv} - \varepsilon E_b(T_s) = 0$$

$$\varepsilon\left[\left(0.741 + 0.0062\ T_{dp}\left(^\circ C\right)\right)\sigma T_{air}^4\right] + 1.25\left(T_{air} - T_s\right)^{4/3}\ W/m^2 - \varepsilon\sigma T_s^4\ W/m^2 = 0$$

where $G_{atm} = \varepsilon_{sky}\,\sigma\,T_{air}$, ε_{sky} = 0.741 + 0.062 T_{dp} (°C); T_{dp} has units (°C); and, other temperatures in kelvins. Since the surface is diffuse-gray, $\alpha_{sky} = \varepsilon$.

(a) *Clean metallic surface*, ε_m = 0.23

$$0.23\left[\left(0.741 + 0.0062\ T_{dp}\left(^\circ C\right)\right)\sigma\left(15 + 273\right)^4 K^4\right]$$

$$+1.25\left(289 - T_{s,m}\right)^{4/3}\ W/m^2 - 0.23\,\sigma T_{s,m}^4\ W/m^2 = 0$$

$$T_{s,m} = 282.7\ K = 9.7^\circ C \qquad <$$

(b) *Painted surface*, $\varepsilon_p = 0.85$ $\qquad T_{s,p}$ = 278.5 K = 5.5°C $\qquad <$

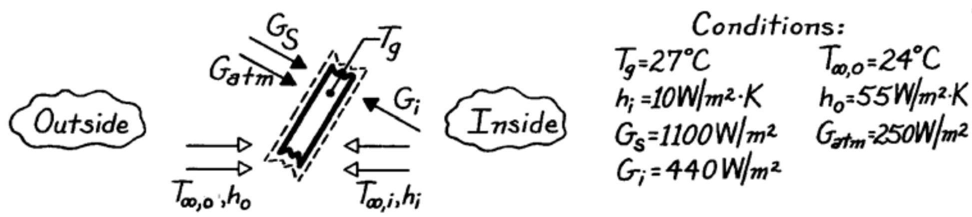
COMMENTS: For the painted surface, ε_p = 0.85, find that $T_s < T_{dp}$, so we expect dew formation. For the clean, metallic surface, $T_s > T_{dp}$, so we do not expect dew formation.

PROBLEM 12.120

KNOWN: Glass sheet, used on greenhouse roof, is subjected to solar flux, G_S, atmospheric emission, G_{atm}, and interior surface emission, G_i, as well as to convection processes.

FIND: (a) Appropriate energy balance for a unit area of the glass, (b) Temperature of the greenhouse ambient air, $T_{\infty,i}$, for prescribed conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Glass is at a uniform temperature, T_g, (2) Steady-state conditions.

PROPERTIES: Glass: $\tau_\lambda = 1$ for $\lambda \le 1\mu m$; $\tau_\lambda = 0$ and $\alpha_\lambda = 1$ for $\lambda > 1$ μm.

ANALYSIS: (a) Performing an energy balance on the glass sheet with $\dot{E}_{in} - \dot{E}_{out} = 0$ and considering two convection processes, emission and three absorbed irradiation terms, find

$$\alpha_S G_S + \alpha_{atm} G_{atm} + h_o\left(T_{\infty,o} - T_g\right) + \alpha_i G_i + h_i\left(T_{\infty,i} - T_g\right) - 2\varepsilon\sigma T_g^4 = 0 \qquad (1)$$

where α_S = solar absorptivity for absorption of $G_{\lambda,S} \sim E_{\lambda,b}$ (λ, 5800K)

$\alpha_{atm} = \alpha_i$ = absorptivity of long wavelength irradiation (λ >> 1 μm) ≈ 1

$\varepsilon = \alpha_\lambda$ for λ >> 1 μm, emissivity for long wavelength emission ≈ 1

(b) For the prescribed conditions, $T_{\infty,i}$ can be evaluated from Eq. (1). As noted above, $\alpha_{atm} = \alpha_i = 1$ and ε = 1. The solar absorptivity of the glass follows from Eq. 12.53 where $G_{\lambda,S} \sim E_{\lambda,b}$ (λ, 5800K),

$$\alpha_S = \int_0^\infty \alpha_\lambda G_{\lambda,S}\, d\lambda / G_s = \int_0^\infty \alpha_\lambda E_{\lambda,b}\left(\lambda, 5800K\right) d\lambda / E_b\left(5800K\right)$$

$$\alpha_S = \alpha_1 F_{(0\to 1\mu m)} + \alpha_2\left[1 - F_{(0\to 1\mu m)}\right] = 0\times 0.720 + 1.0\left[1 - 0.720\right] = 0.28.$$

Note that from Table 12.1 for λT = 1 μm × 5800K = 5800 μm·K, $F_{(0-\lambda)} = 0.720$. Substituting numerical values into Eq. (1),

$$0.28\times 1100\,W/m^2 + 1\times 250\,W/m^2 + 55\,W/m^2\cdot K\left(24-27\right)K + 1\times 440\,W/m^2 +$$
$$10\,W/m^2\cdot K\left(T_{\infty,i} - 27\right)K - 2\times 1\times 5.67\times 10^{-8}\,W/m^2\cdot K\left(27+273\right)^4 K^4 = 0$$

find that

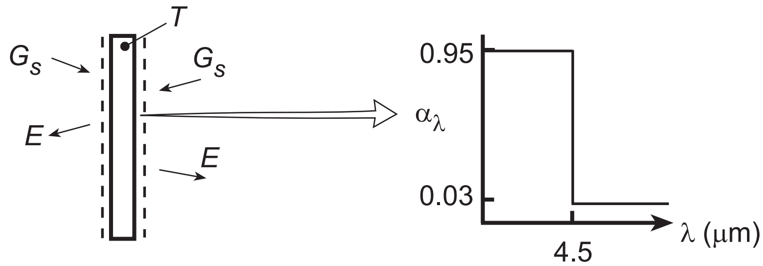
$$T_{\infty,i} = 35.5°C.$$ <

PROBLEM 12.121

KNOWN: Plate temperature and spectral absorptivity of coating.

FIND: (a) Solar irradiation, (b) Effect of solar irradiation on plate temperature, total absorptivity, and total emissivity.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Opaque, diffuse surface, (3) Isothermal plate, (4) Negligible radiation from surroundings.

ANALYSIS: (a) Performing an energy balance on the plate, $2\alpha_S G_S - 2E = 0$ and

$$\alpha_S G_S - \varepsilon\sigma T^4 = 0$$

For $\lambda T = 4.5\ \mu m \times 2000\ K = 9000\ \mu m\cdot K$, Table 12.1 yields $F_{(o\to\lambda)} = 0.890$. Hence,

$$\varepsilon = \varepsilon_1 F_{(0\to\lambda)} + \varepsilon_2\left(1 - F_{(o\to\lambda)}\right) = 0.95\times 0.890 + 0.03(1-0.890) = 0.849$$

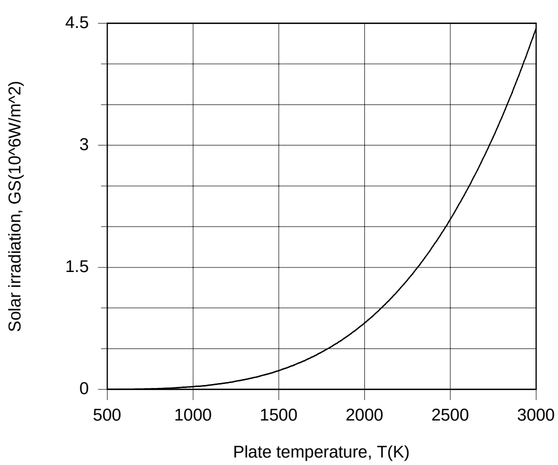
For $\lambda T = 4.5\ \mu m \times 5800\ K = 26{,}100$, $F_{(o\to\lambda)} = 0.993$. Hence,

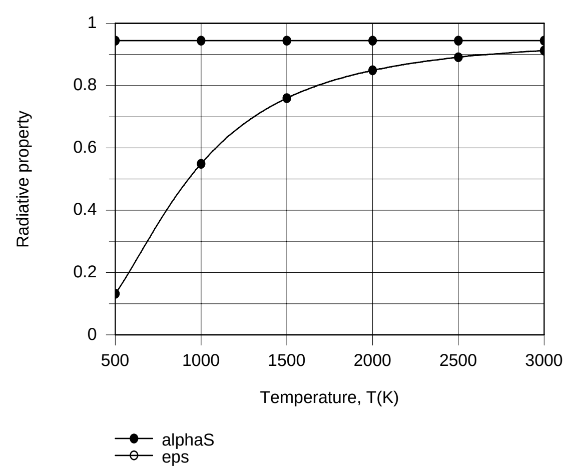
$$\alpha_S = \alpha_1 F_{(0\to\lambda)} + \alpha_2\left(1 - F_{(0\to\lambda)}\right) = 0.95\times 0.993 + 0.03\times 0.007 = 0.944$$

Hence,

$$G_S = (\varepsilon/\alpha_S)\sigma T^4 = (0.849/0.944)5.67\times 10^{-8}\ W/m^2\cdot K^4\,(2000\,K)^4 = 8.16\times 10^5\ W/m^2 \quad <$$

(b) Using the IHT *First Law* Model and the *Radiation* Toolpad, the following results were obtained.





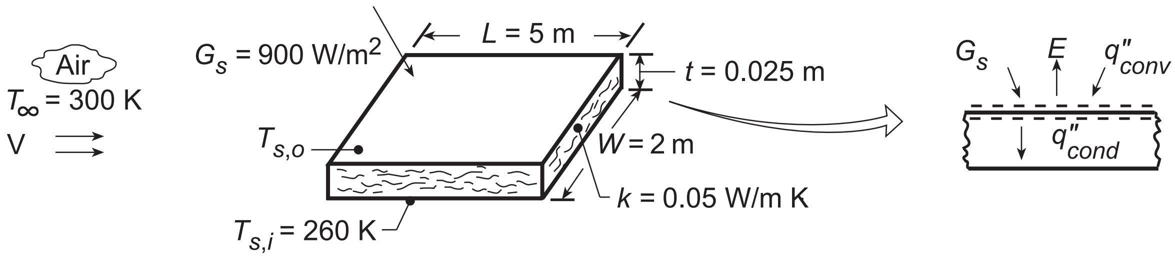
The required solar irradiation increases with T to the fourth power. Since α_S is determined by the spectral distribution of solar radiation, its value is fixed. However, with increasing T, the spectral distribution of emission is shifted to lower wavelengths, thereby increasing the value of ε.

PROBLEM 12.122

KNOWN: Dimensions and construction of truck roof. Roof interior surface temperature. Truck speed, ambient air temperature, and solar irradiation.

FIND: (a) Preferred roof coating, (b) Roof surface temperature, (c) Heat load through roof, (d) Effect of velocity on surface temperature and heat load.

SCHEMATIC:



ASSUMPTIONS: (1) Turbulent boundary layer development over entire roof, (2) Constant properties, (3) Negligible atmospheric (sky) irradiation, (4) Negligible contact resistance.

PROPERTIES: *Table A.4*, Air ($T_{s,o} \approx$ 300 K, 1 atm): $\nu = 15 \times 10^{-6}\ m^2/s$, $k = 0.026\ W/m \cdot K$, Pr = 0.71.

ANALYSIS: (a) To minimize heat transfer through the roof, minimize solar absorption relative to surface emission. Hence, use zinc oxide white for which α_S = 0.16 and ε = 0.93. (Table A.12) <

(b) Performing an energy balance on the outer surface of the roof, $\alpha_S G_S + q''_{conv} - E - q''_{cond} = 0$, it follows that

$$\alpha_S G_S + \bar{h}(T_\infty - T_{s,o}) = \varepsilon \sigma T_{s,o}^4 + (k/t)(T_{s,o} - T_{s,i})$$

where it is assumed that convection is from the air to the roof. With an analysis based upon the content of Chapter 7

$$Re_L = \frac{VL}{\nu} = \frac{30\, m/s(5\, m)}{15 \times 10^{-6}\ m^2/s} = 10^7$$

$$\overline{Nu}_L = 0.037\, Re_L^{4/5}\ Pr^{1/3} = 0.037(10^7)^{4/5}(0.71)^{1/3} = 13{,}141$$

$$\bar{h} = \overline{Nu}_L (k/L) = 13{,}141(0.026\, W/m \cdot K/5\, m = 68.3\, W/m^2 \cdot K\ .$$

Substituting numerical values in the energy balance and solving by trial-and-error, we obtain

$$T_{s,o} = 295.2\ K.$$ <

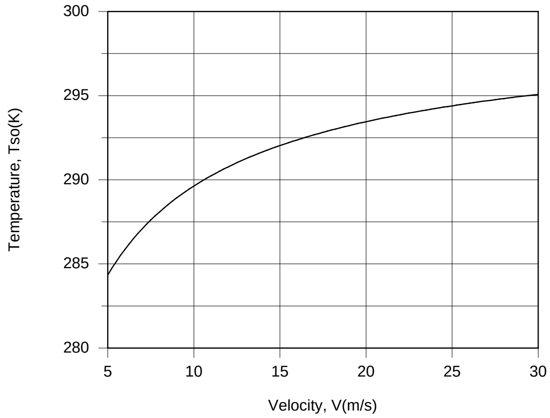
(c) The heat load through the roof is

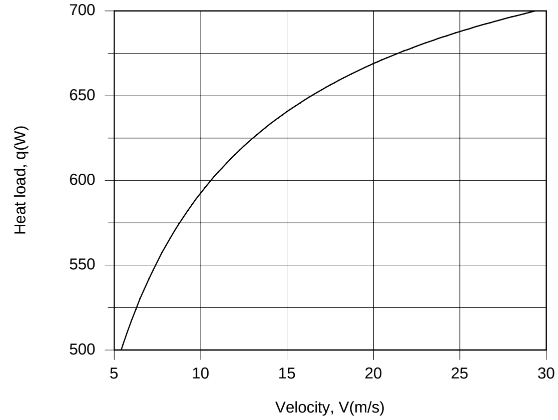
$$q = (kA_s/t)(T_{s,o} - T_{s,i}) = (0.05\, W/m \cdot K \times 10\, m^2/0.025\, m)35.2\ K = 704\, W\ .$$ <

(d) Using the IHT *First Law* Model with the *Correlations* and *Properties* Toolpads, the following results are obtained.

Continued...

PROBLEM 12.122 (Cont.)





The surface temperature and heat load decrease with decreasing V due to a reduction in the convection heat transfer coefficient and hence convection heat transfer from the air.

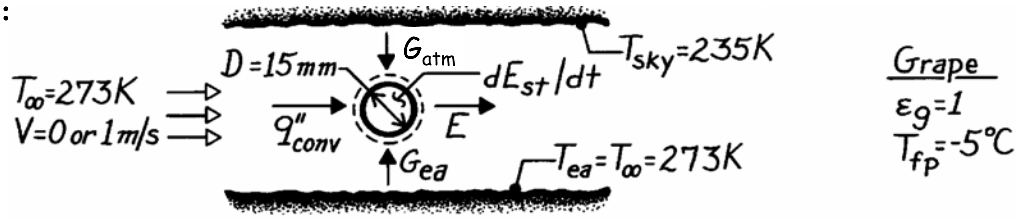
COMMENTS: The heat load would increase with increasing α_S/ε.

PROBLEM 12.123

KNOWN: Sky, ground, and ambient air temperatures. Grape of prescribed diameter and properties.

FIND: (a) General expression for rate of change of grape temperature, (b) Whether grapes will freeze in quiescent air, (c) Whether grapes will freeze for a prescribed air speed.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible temperature gradients in grape, (2) Uniform blackbody irradiation over top and bottom hemispheres, (3) Properties of grape are those of water at 273 K, (4) Properties of air are constant at values for T_∞, (5) Negligible buoyancy for V = 1 m/s.

PROPERTIES: *Table A-6*, Water (273 K): c_p = 4217 J/kg·K, ρ = 1000 kg/m^3; *Table A-4*, Air (273 K, 1 atm): ν = 13.49 × 10^{-6} m^2/s, k = 0.0241 W/m·K, α = 18.9 × 10^{-6} m^2/s, Pr = 0.714, β = 3.66 × 10^{-3} K^{-1}.

ANALYSIS: (a) Performing an energy balance for a control surface about the grape,

$$\frac{dE_{st}}{dt} = \rho_g \frac{\pi D^3}{6} c_{p\cdot g} \frac{dT_g}{dt} = \bar{h}\pi D^2 \left(T_\infty - T_g\right) + \frac{\pi D^2}{2}\left(G_{ea} + G_{atm}\right) - E\pi D^2.$$

where $G_{atm} = = \sigma T_{sky}^4$. Hence, the rate of temperature change with time is

$$\frac{dT_g}{dt} = \frac{6}{\rho_g c_{p\cdot g} D}\left[\bar{h}\left(T_\infty - T_g\right) + \sigma\left(\left(T_{ea}^4 + T_{sky}^4\right)/2 - \varepsilon_g T_g^4\right)\right]. \quad <$$

(b) The grape freezes if $dT_g/dt < 0$ when $T_g = T_{fp}$ = 268 K. With

$$Ra_D = \frac{g\beta\left(T_\infty - T_g\right)D^3}{\alpha\nu} = \frac{9.8\ m/s^2\left(3.66\times10^{-3}\ K^{-1}\right)5K\left(0.015\ m\right)^3}{18.9\times10^{-6}\times13.49\times10^{-6}\ m^4/s^2} = 2374$$

using Eq. 9.35 find

$$\overline{Nu}_D = 2 + \frac{0.589\left(2374\right)^{1/4}}{\left[1+\left(0.469/Pr\right)^{9/16}\right]^{4/9}} = 5.17$$

$$\bar{h} = \left(k/D\right)\overline{Nu}_D = \left[\left(0.0241\ W/m\cdot K\right)/\left(0.015\ m\right)\right]5.17 = 8.31\ W/m^2\cdot K.$$

Hence, the rate of temperature change is

$$\frac{dT_g}{dt} = \frac{6}{\left(1000\ kg/m^3\right)4217\ J/kg\cdot K\left(0.015\ m\right)}\left[8.31\ W/m^2\cdot K\left(5\ K\right)\right.$$

$$\left. + 5.67\times10^{-8}\ W/m^2\cdot K^4\left[\left(273^4 + 235^4\right)/2 - 268^4\right]K^4\right.$$

Continued …

PROBLEM 12.123 (Cont.)

$$\frac{dT_g}{dt} = 9.49 \times 10^{-5}\ \text{K} \cdot \text{m}^2/\text{J}\left[41.55 - 48.56\right]\text{W/m}^2 = -6.66 \times 10^{-4}\ \text{K/s}$$ <

and since $dT_g/dt < 0$, the grape *will freeze*.

(c) For V = 1 m/s,

$$Re_D = \frac{VD}{\nu} = \frac{1\ \text{m/s}(0.015\ \text{m})}{13.49 \times 10^{-6}\ \text{m}^2/\text{s}} = 1112.$$

Hence with $(\mu/\mu_s)^{1/4} = 1$ and from an analysis based upon the content of Chapter 7,

$$\overline{Nu}_D = 2 + \left(0.4\,Re_D^{1/2} + 0.06\,Re_D^{2/3}\right)Pr^{0.4} = 19.3$$

$$\bar{h} = \overline{Nu}_D \frac{k}{D} = 21.8\frac{0.0241}{0.015} = 31\ \text{W/m}^2 \cdot \text{K}.$$

Hence the rate of temperature change with time is

$$\frac{dT_g}{dt} = 9.49 \times 10^{-5}\ \text{K} \cdot \text{m}^2/\text{J}\left[31\ \text{W/m}^2 \cdot \text{K}(5\ \text{K}) - 48.56\ \text{W/m}^2\right] = -0.016\ \text{K/s}$$

and since $dT_g/dt < 0$ and $\left|dT_g/dt\right|_c > \left|dT_g/dt\right|_b$, the grape *will freeze sooner than in part (b).* <

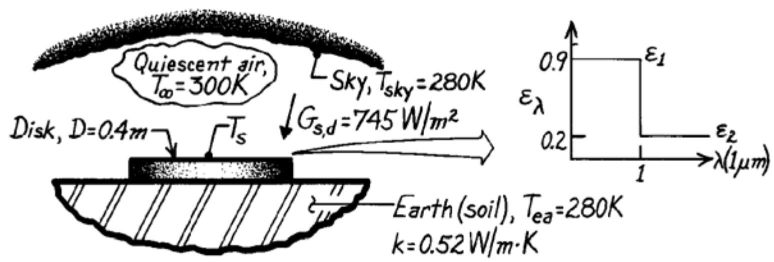
COMMENTS: With $Gr_D = Ra_D/Pr = 3325$ and $Gr_D/Re_D^2 = 0.0027$, the assumption of negligible buoyancy for V = 1 m/s is reasonable.

PROBLEM 12.124

KNOWN: Metal disk exposed to environmental conditions and placed in good contact with the earth.

FIND: (a) Fraction of direct solar irradiation absorbed, (b) Emissivity of the disk, (c) Average free convection coefficient of the disk upper surface, (d) Steady-state temperature of the disk (confirm the value 340 K).

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Disk is diffuse, (3) Disk is isothermal, (4) Negligible contact resistance between disk and earth, (5) Solar irradiance has spectral distribution of $E_{\lambda,b}$ (λ, 5800 K).

PROPERTIES: *Table A-4*, Air (1 atm, $T_f = (T_s + T_\infty)/2 = (340 + 300)$ K/2 = 320 K): $\nu = 17.90 \times 10^{-6}$ m²/s, k = 0.0278 W/m·K, $\alpha = 25.5 \times 10^{-6}$ m²/s, Pr = 0.704.

ANALYSIS: (a) The solar absorptivity follows from Eq. 12.53 with $G_{\lambda,S}$ α $E_{\lambda,b}$ (λ, 5800 K), and $\alpha_\lambda = \varepsilon_\lambda$, since the disk surface is diffuse.

$$\alpha_S = \int_0^\infty \alpha_\lambda E_{\lambda,b}(\lambda, 5800\,K)/E_b(5800\ K)$$

$$\alpha_S = \varepsilon_1 F_{(0\to 1\mu m)} + \varepsilon_2\left(1 - f_{(0\to 1\mu m)}\right).$$

From Table 12.1 with

$$\lambda T = 1\ \mu m \times 5800\ K = 5800\ \mu m\cdot K \quad \text{find} \quad F_{(0\to\lambda T)} = 0.720$$

giving

$$\alpha_S = 0.9\times 0.720 + 0.2(1 - 0.720) = 0.704. \qquad <$$

Note this value is appropriate for diffuse or direct solar irradiation since the surface is diffuse.

(b) The emissivity of the disk depends upon the surface temperature T_s which we believe to be 340 K. (See part (d)). From Eq. 12.43,

$$\varepsilon = \int_0^\infty \varepsilon_\lambda E_{\lambda,b}(\lambda, T_s)/E_b(T_s)$$

$$\varepsilon = \varepsilon_1 F_{(0\to 1\mu m)} + \varepsilon_2\left(1 - F_{(0\to 1\mu m)}\right)$$

Continued …

PROBLEM 12.124 (Cont.)

From Table 12.1 with

$$\lambda T = 1\ \mu m \times 340\ K = 340\ \mu m \cdot K \qquad \text{find} \qquad F_{(0\to\lambda T)} = 0.000$$

giving

$$\varepsilon = 0.9 \times 0.000 + 0.2(1 - 0.000) = 0.20.$$ <

(c) The disk is a hot surface facing upwards for which the free convection correlation of Eq. 9.30 is appropriate. Evaluating properties at $T_f = (T_s + T_\infty)/2 = 320$ K,

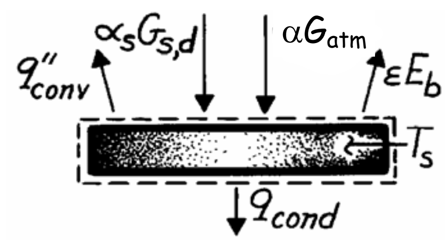
$$Ra_L = g\beta\Delta T L^3/\nu\alpha \qquad \text{where } L = A_s/P = D/4$$

$$Ra_L = 9.8\ m/s^2 (1/320\ K)(340-300) K (0.4\ m/4)^3 / 17.90\times10^{-6}\ m^2/s \times 25.5\times10^{-6}\ m^2/s = 2.684\times10^6$$

$$\overline{Nu}_L = \bar{h}L/k = 0.54 Ra_L^{1/4} \qquad 10^4 \le Ra_L \le 10^7$$

$$\bar{h} = 0.0278\ W/m\cdot K/(0.4\ m/4) \times 0.54\left(3.042\times10^6\right)^{1/4} = 6.07\ W/m^2\cdot K.$$ <

(d) To determine the steady-state temperature, perform an energy balance on the disk.



$$\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st}$$

$$\left(\alpha_S G_{s,d} + \alpha G_{atm} - \varepsilon E_b - q''_{conv}\right) A_s - q_{cond} = 0.$$

Since G_{atm} is predominately long wavelength radiation, it follows that $\alpha = \varepsilon$. The conduction heat rate between the disk and the earth is

$$q_{cond} = kS(T_s - T_{ea}) = k(2D)(T_s - T_{ea})$$

where S, the conduction shape factor, is that of an isothermal disk on a semi-infinite medium, Table 4.1. Substituting numerical values, with $As = \pi D^2/4$,

$$\left[0.704\times745\ W/m^2 + 0.20\sigma(280\ K)^4 - 0.20\sigma T_s^4 \right.$$
$$\left. -6.07\ W/m^2\cdot K(T_s - 300\ K)\right]\pi(0.4\ m)^2/4 - 0.52\ W/m\cdot K(2\times0.4\ m)(T_s - 280\ K) = 0$$

$$65.908\ W + 8.759\ W - 1.425\times10^{-9} T_s^4 - 0.763(T_s - 300) - 0.416(T_s - 280) = 0.$$

By trial-and-error, find

$$T_s \approx 340\ K.$$ <

so indeed the assumed value of 340 K was proper.

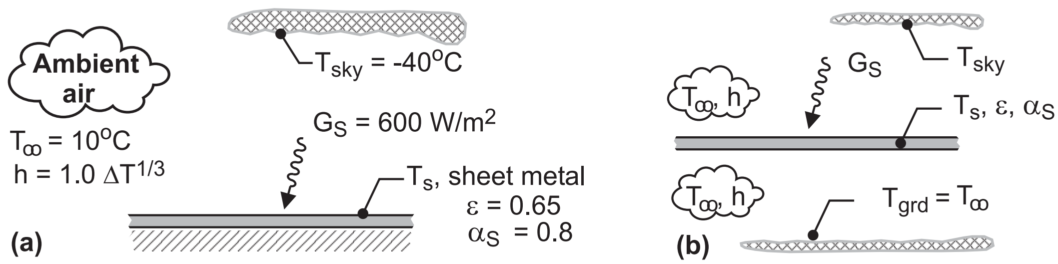
COMMENTS: Note why it is not necessary for this situation to distinguish between direct and diffuse irradiation. Why does $\alpha_{sky} = \varepsilon$?

PROBLEM 12.125

KNOWN: Shed roof of weathered galvanized sheet metal exposed to solar insolation on a cool, clear spring day with ambient air at - 10°C and convection coefficient estimated by the empirical correlation $\overline{h} = 1.0\ \Delta T^{1/3}$ ($W/m^2 \cdot K$ with temperature units of kelvins).

FIND: Temperature of the roof, T_s, (a) assuming the backside is well insulated, and (b) assuming the backside is exposed to ambient air with the same convection coefficient relation and experiences radiation exchange with the ground, also at the ambient air temperature. Comment on whether the roof will be a comfortable place for the neighborhood cat to snooze for these conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) The roof surface is diffuse, spectrally selective, (3) Sheet metal is thin with negligible thermal resistance, and (3) Roof is a small object compared to the large isothermal surroundings represented by the sky and the ground.

ANALYSIS: (a) For the backside-insulated condition, the energy balance, represented schematically below, is

$$\dot{E}''_{in} - \dot{E}''_{out} = 0$$

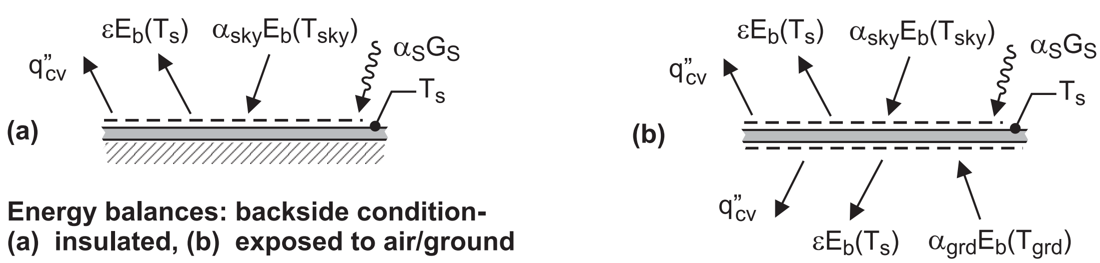
$$\alpha_{sky}\, E_b\left(T_{sky}\right) + \alpha_S G_S - q''_{cv} - \varepsilon\, E_b\left(T_s\right) = 0$$

$$\alpha_{sky}\sigma T_{sky}^4 + \alpha_S G_S - 1.0\left(T_s - T_\infty\right)^{4/3} - \varepsilon\sigma T_s^4 = 0$$

With $\alpha_{sky} = \varepsilon$ (see Comment 2) and $\sigma = 5.67 \times 10^{-8}\ W/m^2 \cdot K^4$, find T_s.

$$0.65\ \sigma(233\ K)^4\ W/m^2 + 0.8 \times 600\ W/m^2 - 1.0\left(T_s - 283\ K\right)^{4/3}\ W/m^2 - 0.65\ \sigma T_s^4 = 0$$

$$T_s = 328.2\ K = 55.2^\circ C$$ <



Continued …

PROBLEM 12.125 (Cont.)

(b) With the backside exposed to convection with the ambient air and radiation exchange with the ground, the energy balance, represented schematically above, is

$$\alpha_{sky} E_b(T_{sky}) + \alpha_{grd} E_b(T_{grd}) + \alpha_S G_S - 2q''_{cv} - 2\varepsilon E_b(T_s) = 0$$

Substituting numerical values, recognizing that $T_{grd} = T_\infty$, and $\alpha_{grd} = \varepsilon$ (see Comment 2), find T_s.

$$0.65\ \sigma(233\ \text{K})^4\ \text{W/m}^2 + 0.65\ \sigma(283\ \text{K})^4 \text{W/m}^2 + 0.8 \times 600\ \text{W/m}^2$$
$$-2 \times 1.0\ (T_s - 283\ \text{K})^{4/3}\ \text{W/m}^2 - 2 \times 0.65\ \sigma T_s^4 = 0$$

$T_s = 308.9\ \text{K} = 35.9^\circ\text{C}$ <

COMMENTS: (1) For the insulated-backside condition, the cat would find the roof too hot remembering that 43°C represents a safe-to-touch temperature. For the exposed-backside condition, the cat would find the roof comfortable, certainly compared to an area not exposed to the solar insolation (that is, exposed only to the ambient air through convection).

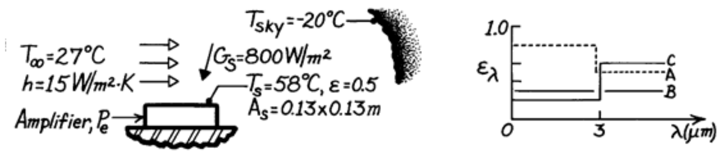
(2) For this spectrally selective surface, the absorptivity for the sky irradiation is equal to the emissivity, $\alpha_{sky} = \varepsilon$, since the sky irradiation and surface emission have the same approximate spectral regions. The same reasoning applies for the absorptivity of the ground irradiation, $\alpha_{grd} = \varepsilon$.

PROBLEM 12.126

KNOWN: Amplifier operating and environmental conditions.

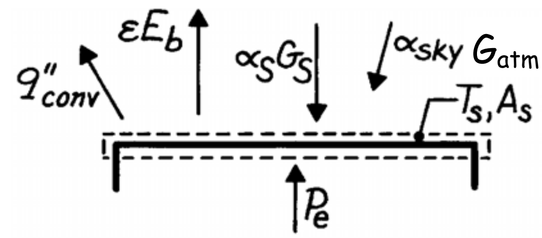
FIND: (a) Power generation when T_s = 58°C with diffuse coating ε = 0.5, (b) Diffuse coating from among three (A, B, C) which will give greatest reduction in T_s, and (c) Surface temperature for the conditions with coating chosen in part (b).

SCHEMATIC:



ASSUMPTIONS: (1) Environmental conditions remain the same with all surface coatings, (2) Coatings A, B, C are opaque, diffuse.

ANALYSIS: (a) Performing an energy balance on the amplifier's exposed surface, $\dot{E}_{in} - \dot{E}_{out} = 0$, we find



$$P_e + A_s\left[\alpha_S G_S + \alpha_{atm} Gatm - \varepsilon E_b - q''_{conv}\right] = 0$$

$$P_e = A_s\left[\varepsilon\sigma T_s^4 + h\left(T_s - T_\infty\right) - \alpha_S G_S - \alpha_{atm}\sigma T_{sky}^4\right]$$

$$P_e = 0.13\times 0.13\ m^2\left[0.5\times\sigma\left(331\right)^4 + 15\left(331-300\right) - 0.5\times 800 - 0.5\times\sigma\left(253\right)^4\right] W/m^2$$

$$P_e = 0.0169\,m^2\left[0.5\times 680.6 + 465 - 0.5\times 800 - 0.5\times 232.3\right] W/m^2 = 4.887\ W. \qquad <$$

(b) From above, recognize that we seek a coating with low α_S and high ε to decrease T_s. Further, recognize that α_S is determined by values of $\alpha_\lambda = \varepsilon_\lambda$ for λ < 3 μm and ε by values of ε_λ for λ > 3 μm. Find approximate values as

Coating	A	B	C
ε	0.5	0.3	0.6
α_S	0.8	0.3	0.2
α_S/ε	1.6	1	0.333

Note also that $\alpha_{atm} \approx \varepsilon$. We conclude that coating C is likely to give the lowest T_s since its α_S/ε is substantially lower than for B and C. While α_{atm} for C is twice that of B, because G_{atm} is nearly 25% that of G_S, we expect coating C to give the lowest T_s.

(c) With the values of α_S, α_{atm} and ε for coating C from part (b), rewrite the energy balance as

$$P_e/A_s + \alpha_S G_S + \alpha_{atm}\sigma T_{sky}^4 - \varepsilon\sigma T_s^4 - h\left(T_s - T_\infty\right) = 0$$

$$4.887\ W/\left(0.13\ m\right)^2 + 0.2\times 800\ W/m^2 + 0.6\times 232.3\ W/m^2 - 0.6\times\sigma T_s^4 - 15\left(T_s - 300\right) = 0$$

Using trial-and-error, find T_s = 316.5 K = 43.5°C. $<$

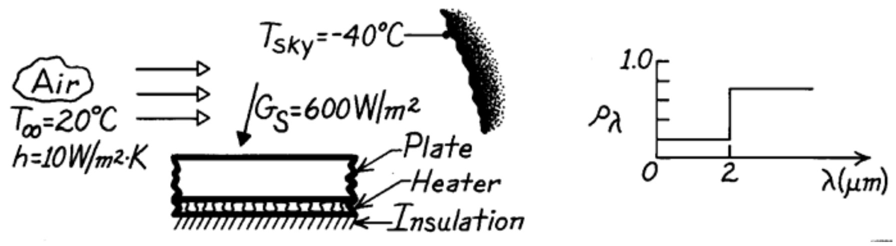
COMMENTS: (1) Using coatings A and B, find T_s = 71 and 54°C, respectively. (2) For more precise values of α_S, α_{sky} and ε, use T_s = 43.5°C. For example, at λT_s = 3 × (43.5 + 273) = 950 μm·K, $F_{0-\lambda T}$ = 0.000 while at λT_{solar} = 3 × 5800 = 17,400 μm·K, $F_{0-\lambda T} \approx$ 0.98; we conclude little effect will be seen.

PROBLEM 12.127

KNOWN: Opaque, spectrally-selective horizontal plate with electrical heater on backside is exposed to convection, solar irradiation and sky irradiation.

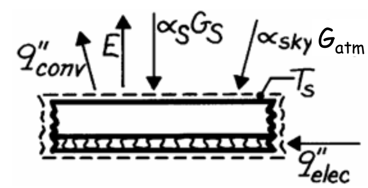
FIND: Electrical power required to maintain plate at 60°C.

SCHEMATIC:



ASSUMPTIONS: (1) Plate is opaque, diffuse and uniform, (2) No heat lost out the backside of heater.

ANALYSIS: From an energy balance on the plate-heater system, per unit area basis,



$$\dot{E}''_{in} - \dot{E}''_{out} = 0$$

$$q''_{elec} + \alpha_S G_S + \alpha G_{atm} - \varepsilon E_b(T_s) - q''_{conv} = 0$$

where $G_{atm} = \sigma T_{sky}^4$, $E_b = \sigma T_s^4$, and $q''_{conv} = h(T_s - T_\infty)$. The *solar absorptivity* is

$$\alpha_S = \int_0^\infty \alpha_\lambda G_{\lambda,S} d\lambda \Big/ \int_0^\infty G_{\lambda,S} d\lambda = \int_0^\infty \alpha_\lambda E_{\lambda,b}(\lambda, 5800\text{ K}) d\lambda \Big/ \int_0^\infty E_{\lambda,b}(\lambda, 5800\text{ K}) d\lambda$$

where $G_{\lambda,S} \sim E_{\lambda,b}$ (λ, 5800 K). Noting that $\alpha_\lambda = 1 - \rho_\lambda$,

$$\alpha_S = (1-0.2)F_{(0-2\mu m)} + (1-0.7)\left(1 - F_{(0-2\mu m)}\right)$$

where at $\lambda T = 2\ \mu m \times 5800\text{ K} = 11{,}600\ \mu m\cdot K$, find from Table 12.1, $F_{(0-\lambda T)} = 0.941$,

$$\alpha_S = 0.80 \times 0.941 + 0.3(1 - 0.941) = 0.771.$$

The *total, hemispherical emissivity* is

$$\varepsilon = (1-0.2)F_{(0-2\mu m)} + (1-0.7)\left(1 - F_{(0-2\mu m)}\right).$$

At $\lambda T = 2\ \mu m \times 333\text{ K} = 666\text{ K}$, find $F_{(0-\lambda T)} \approx 0.000$; hence $\varepsilon = 0.30$. The *total, hemispherical absorptivity* for sky irradiation is $\alpha = \varepsilon = 0.30$ since the surface is gray for this emission and irradiation process. Substituting numerical values,

$$q''_{elec} = \varepsilon\sigma T_s^4 + h(T_s - T_\infty) - \alpha_S G_S - \alpha\sigma T_{sky}^4$$

$$q''_{elec} = 0.30 \times \sigma(333\text{ K})^4 + 10\text{ W/m}^2\cdot\text{K}(60-20)^\circ\text{C} - 0.771 \times 600\text{ W/m}^2 - 0.30 \times \sigma(233\text{ K})^4$$

$$q''_{elec} = 209.2\text{ W/m}^2 + 400.0\text{ W/m}^2 - 462.6\text{ W/m}^2 - 50.1\text{ W/m}^2 = 96.5\text{ W/m}^2. \quad <$$

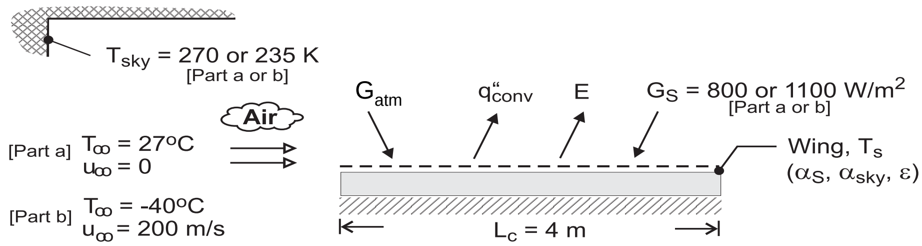
COMMENTS: (1) Note carefully why $\alpha_{sky} = \varepsilon$ for the sky irradiation.

PROBLEM 12.128

KNOWN: Chord length and spectral emissivity of wing. Ambient air temperature, sky temperature and solar irradiation for ground and in-flight conditions. Flight speed.

FIND: Temperature of top surface of wing for (a) ground and (b) in-flight conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Negligible heat transfer from back of wing surface, (3) Diffuse surface behavior, (4) Negligible solar radiation for $\lambda > 3\ \mu$m ($\alpha_S = \alpha_{\lambda \le 3\ \mu m} = \varepsilon_{\lambda \le 3\ \mu m} = 0.6$), (5) Negligible sky radiation and surface emission for $\lambda \le 3\ \mu$m ($\alpha_{sky} = \alpha_{\lambda > 3\ \mu m} = \varepsilon_{\lambda > 3\ \mu m} = 0.3 = \varepsilon$), (6) Quiescent air for ground condition, (7) Air foil may be approximated as a flat plate, (8) Negligible viscous heating in boundary layer for in-flight condition, (9) The wing span W is much larger than the chord length L_c, (10) In-flight transition Reynolds number is 5×10^5.

PROPERTIES: Part (a). *Table A-4*, air ($T_f \approx 325$ K): $\nu = 1.84 \times 10^{-5}$ m²/s, $\alpha = 2.62 \times 10^{-5}$ m²/s, k = 0.0282 W/m·K, $\beta = 0.00307$. Part (b). Given: $\rho = 0.470$ kg/m³, $\mu = 1.50 \times 10^{-5}$ N·s/m², k = 0.021 W/m·K, Pr = 0.72.

ANALYSIS: For both ground and in-flight conditions, a surface energy balance yields

$$\alpha_{sky} G_{sky} + \alpha_S G_S = \varepsilon\sigma T_s^4 + \bar{h}\left(T_s - T_\infty\right) \quad (1)$$

where $\alpha_{sky} = \varepsilon = 0.3$, and $\alpha_S = 0.6$.

(a) For the ground condition, $\bar{h}$ may be evaluated from Eq. 9.30 or 9.31, where $L = A_s/P = L_c \times W/2(L_c + W) \approx L_c/2 = 2$m and $Ra_L = g\beta(T_s - T_\infty)L^3/\nu\alpha$. Using the *IHT* software to solve Eq. (1) and accounting for the effect of temperature-dependent properties, the surface temperature is

$$T_s = 350.6\ \text{K} = 77.6°\text{C} \quad <$$

where $Ra_L = 2.52 \times 10^{10}$ and $\bar{h} = 6.2$ W/m²·K. Heat transfer from the surface by emission and convection is 257.0 and 313.6 W/m², respectively.

(b) For the in-flight condition, $Re_L = \rho u_\infty L_c/\mu = 0.470$ kg/m³ × 200 m/s × 4m/1.50 × 10⁻⁵ N·s/m² = 2.51×10^7. For mixed, laminar/turbulent boundary layer conditions (Chapter 7) and a transition Reynolds number of $Re_{x,c} = 5 \times 10^5$.

$$\overline{Nu}_L = \left(0.037\, Re_L^{4/5} - 871\right) Pr^{1/3} = 26,800$$

$$\bar{h} = \frac{k}{L} Nu_L = \frac{0.021\ \text{W/m} \cdot \text{K} \times 26,800}{4\text{m}} = 141\ \text{W/m}^2 \cdot \text{K}$$

Substituting into Eq. (1), a trial-and-error solution yields

$$T_s = 237.7\ \text{K} = -35.3°\text{C} \quad <$$

Heat transfer from the surface by emission and convection is now 54.3 and 657.6 W/m², respectively.

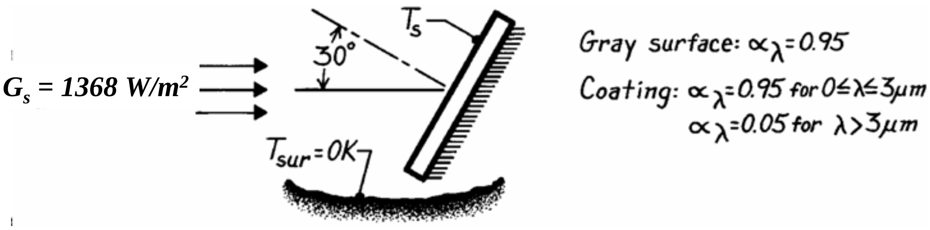
COMMENTS: The temperature of the wing is strongly influenced by the convection heat transfer coefficient, and the large coefficient associated with flight yields a surface temperature that is within 5°C of the air temperature.

PROBLEM 12.129

KNOWN: Spectrally selective and gray surfaces in earth orbit are exposed to solar irradiation, G_S, in a direction 30° from the normal to the surfaces.

FIND: Equilibrium temperature of each plate.

SCHEMATIC:



ASSUMPTIONS: (1) Plates are at uniform temperature, (2) Surroundings are at 0K, (3) Steady-state conditions, (4) Solar irradiation has spectral distribution of $E_{\lambda,b}(\lambda, 5800K)$, (5) Back side of plate is insulated.

ANALYSIS: Noting that the solar irradiation is directional (at 30° from the normal), the radiation balance has the form

$$\alpha_S G_S \cos\theta - \varepsilon E_b(T_s) = 0. \tag{1}$$

Using $E_b(T_s) = \sigma T_s^4$ and solving for T_s, find

$$T_s = \left[(\alpha_S/\varepsilon)(G_S \cos\theta/\sigma)\right]^{1/4}. \tag{2}$$

For the *gray surface*, $\alpha_S = \varepsilon = \alpha_\lambda$ and the temperature is independent of the magnitude of the absorptivity.

$$T_s = \left(\frac{0.95}{0.95} \times \frac{1368\ W/m^2 \times \cos 30°}{5.67 \times 10^{-8}\ W/m^2 \cdot K^4}\right)^{1/4} = 380\ K.$$ <

For the *selective surface*, $\alpha_S = 0.95$ since nearly all the solar spectral power is in the region $\lambda < 3\mu m$. The value of ε depends upon the surface temperature T_s and would be determined by the relation.

$$\varepsilon = 0.95\ F_{(0\to\lambda T_s)} + 0.05\left[1 - F_{(0\to\lambda T_s)}\right] \tag{3}$$

where $\lambda = 3\mu m$ and T_s is as yet unknown. To find T_s, a trial-and-error procedure as follows will be used: (1) assume a value of T_s, (2) using Eq. (3), calculate ε with the aid of Table 12.1 evaluating $F_{(0\to\lambda T)}$ at $\lambda T_s = 3\mu m \cdot T_s$, (3) with this value of ε, calculate T_s from Eq. (2) and compare with assumed value of T_s. The results of the iterations are:

T_s(K), assumed value	633	700	666	650	655
ε, from Eq. (3)	0.098	0.125	0.110	0.104	0.106
T_s(K), from Eq. (2)	656	629	650	659	656

Hence, for the coating, $T_s \approx 656K$. <

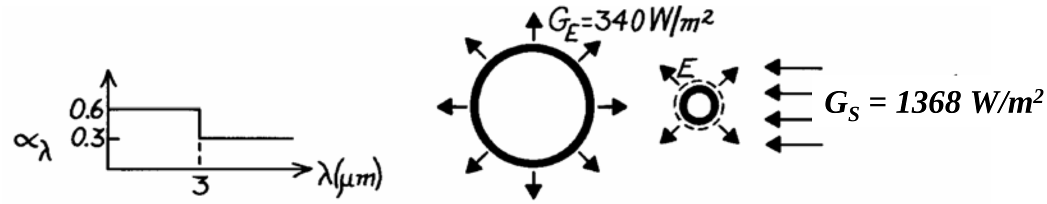
COMMENTS: Note the role of the ratio α_S/ε in determining the equilibrium temperature of an isolated plate exposed to solar irradiation in space. This is an important property of the surface in spacecraft thermal design and analysis.

PROBLEM 12.130

KNOWN: Spectral distribution of coating on satellite surface. Irradiation from earth and sun.

FIND: (a) Steady-state temperature of satellite on dark side of earth, (b) Steady-state temperature on bright side.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Opaque, diffuse-gray surface behavior, (3) Spectral distributions of earth and solar emission may be approximated as those of blackbodies at 280K and 5800K, respectively, (4) Satellite temperature is less than 500K.

ANALYSIS: Performing an energy balance on the satellite,

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$\alpha_E G_E \left(\pi D^2/4\right) + \alpha_S G_S \left(\pi D^2/4\right) - \varepsilon \sigma T_s^4 \left(\pi D^2\right) = 0$$

$$T_s = \left(\frac{\alpha_E G_E + \alpha_S G_S}{4\varepsilon\sigma}\right)^{1/4}.$$

From Table 12.1, with 98% of radiation below 3μm for λT = 17,400μm·K,

$$\alpha_S \cong 0.6.$$

With 98% of radiation above 3μm for λT = 3μm × 500K = 1500μm·K,

$$\varepsilon \approx 0.3 \qquad \alpha_E \approx 0.3.$$

(a) On *dark* side,

$$T_s = \left(\frac{\alpha_E G_E}{4\varepsilon\sigma}\right)^{1/4} = \left(\frac{0.3 \times 340\,W/m^2}{4 \times 0.3 \times 5.67 \times 10^{-8}\,W/m^2 \cdot K^4}\right)^{1/4}$$

$$T_s = 197\ K. \qquad <$$

(b) On *bright* side,

$$T_s = \left(\frac{\alpha_E G_E + \alpha_S G_S}{4\varepsilon\sigma}\right)^{1/4} = \left(\frac{0.3 \times 340\ W/m^2 + 0.6 \times 1368\,W/m^2}{4 \times 0.3 \times 5.67 \times 10^{-8}\,W/m^2 \cdot K^4}\right)^{1/4}$$

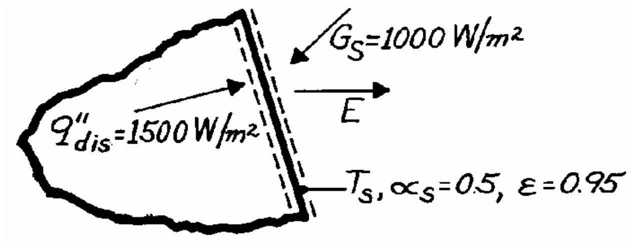
$$T_s = 341K. \qquad <$$

PROBLEM 12.131

KNOWN: Radiative properties and operating conditions of a space radiator.

FIND: Equilibrium temperature of the radiator.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible irradiation due to earth emission.

ANALYSIS: From a surface energy balance, $\dot{E}''_{in} - \dot{E}''_{out} = 0$.

$$q''_{dis} + \alpha_S G_S - E = 0.$$

Hence

$$T_s = \left(\frac{q''_{dis} + \alpha_S G_S}{\varepsilon \sigma} \right)^{1/4}$$

$$T_s = \left(\frac{1500\,W/m^2 + 0.5 \times 1000\,W/m^2}{0.95 \times 5.67 \times 10^{-8}\,W/m^2 \cdot K^4} \right)^{1/4}$$

or

$$T_s = 439K.$$ <

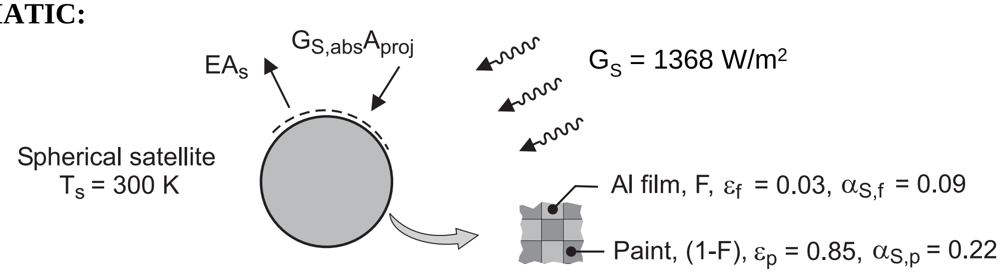
COMMENTS: *Passive* thermal control of spacecraft is practiced by using surface coatings with desirable values of α_S and ε.

PROBLEM 12.132

KNOWN: Spherical satellite exposed to solar irradiation of 1368 m^2; surface is to be coated with a checker pattern of evaporated aluminum film, (fraction, F) and white zinc-oxide paint (1 - F).

FIND: The fraction F for the checker pattern required to maintain the satellite at 300 K.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Satellite is isothermal, and (3) No internal power dissipation.

ANALYSIS: Perform an energy balance on the satellite, as illustrated in the schematic, identifying absorbed solar irradiation on the projected area, A_p, and emission from the spherical area A_s.

$$\dot{E}_{in} + \dot{E}_{out} = 0$$

$$\left(F \cdot \alpha_{S,f} + (1-F) \cdot \alpha_{S,p}\right) G_S\, A_p - \left(F \cdot \varepsilon_f + (1-F) \cdot \varepsilon_p\right) E_b\,(T_s)\, A_s = 0$$

where $A_p = \pi D^2/4$, $A_s = \pi D^2$, $E_b = \sigma T^4$ and $\sigma = 5.67 \times 10^{-8}\ W/m^2 \cdot K^4$. Substituting numerical values, find *F*.

$$\frac{\left[F \times 0.09 + (1-F) \times 0.22)\right] \times 1368\ W/m^2}{4} - \left[F \times 0.03 + (1-F) \times 0.85 \times \sigma \times (300K)^4\right] = 0$$

$$F = 0.94$$ <

COMMENTS: (1) If the thermal control engineer desired to maintain the spacecraft at 325 K, would the fraction F (aluminum film) be increased or decreased? Verify your opinion with a calculation.

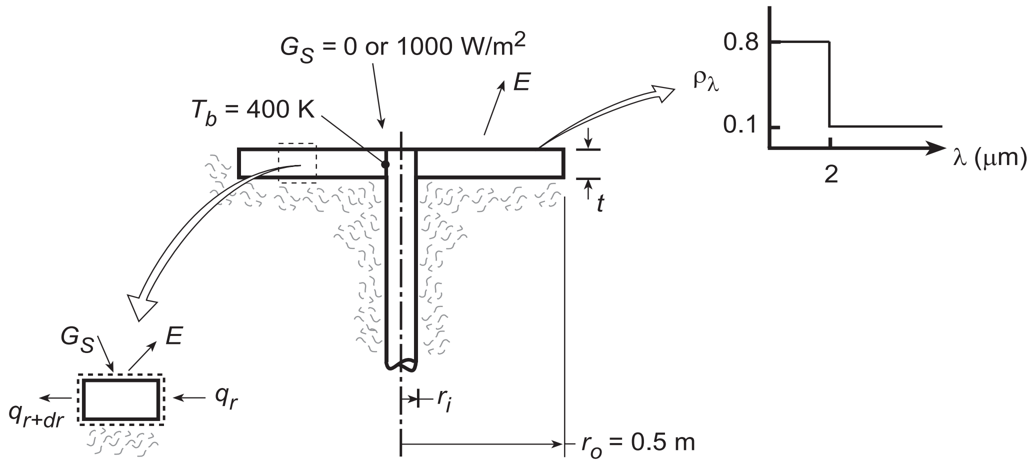
(2) If the internal power dissipation per unit surface area is 150 W/m^2, what fraction F will maintain the satellite at 300 K?

PROBLEM 12.133

KNOWN: Inner and outer radii, spectral reflectivity, and thickness of an annular fin. Base temperature and solar irradiation.

FIND: (a) Rate of heat dissipation if $\eta_f = 1$, (b) Differential equation governing radial temperature distribution in fin if $\eta_f < 1$.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) One-dimensional radial conduction, (3) Adiabatic tip and bottom surface, (4) Opaque, diffuse surface ($\alpha_\lambda = 1 - \rho_\lambda,\ \varepsilon_\lambda = \alpha_\lambda$).

ANALYSIS: (a) If $\eta_f = 1$, $T(r) = T_b = 400$ K across the entire fin and

$$q_f = \left[\varepsilon E_b\left(T_b\right) - \alpha_S G_S\right]\pi r_o^2$$

With $\lambda T = 2\ \mu m \times 5800\ K = 11{,}600\ \mu m\cdot K$, $F_{(0\to 2\mu m)} = 0.941$. Hence $\alpha_S = \alpha_1 F_{(0\to 2\mu m)} + \alpha_2\left[1 - F_{(0\to 2\mu m)}\right] = 0.2 \times 0.941 + 0.9 \times 0.059 = 0.241$. With $\lambda T = 2\ \mu m \times 400\ K = 800\ \mu m\cdot K$, $F_{(0\to 2\mu m)} = 0$ and $\varepsilon = 0.9$. Hence, for $G_S = 0$,

$$q_f = 0.9 \times 5.67 \times 10^{-8}\ W/m^2\cdot K^4\left(400\,K\right)^4\pi\left(0.5\,m\right)^2 = 1026\,W \qquad <$$

and for $G_S = 1000\ W/m^2$,

$$q_f = 1026\,W - 0.241\left(1000\,W/m^2\right)\pi\left(0.5\,m\right)^2 = \left(1026 - 189\right)W = 837\,W \qquad <$$

(b) Performing an energy balance on a differential element extending from r to r+dr, we obtain

$$q_r + \alpha_S G_S\left(2\pi r dr\right) - q_{r+dr} - E\left(2\pi r dr\right) = 0$$

where

$$q_r = -k\left(dT/dr\right)2\pi r t \qquad \text{and} \qquad q_{r+dr} = q_r + \left(dq_r/dr\right)dr\,.$$

Hence,

$$\alpha_S G_S\left(2\pi r dr\right) - d\left[-k\left(dT/dr\right)2\pi r t\right]dr - E\left(2\pi r dr\right) = 0$$

$$2\pi r t k\frac{d^2T}{dr^2} + 2\pi t k\frac{dT}{dr} + \alpha_S G_S 2\pi r - E 2\pi r = 0$$

$$kt\left(\frac{d^2T}{dr^2} + \frac{1}{r}\frac{dT}{dr}\right) + \alpha_S G_S - \varepsilon\sigma T^4 = 0 \qquad <$$

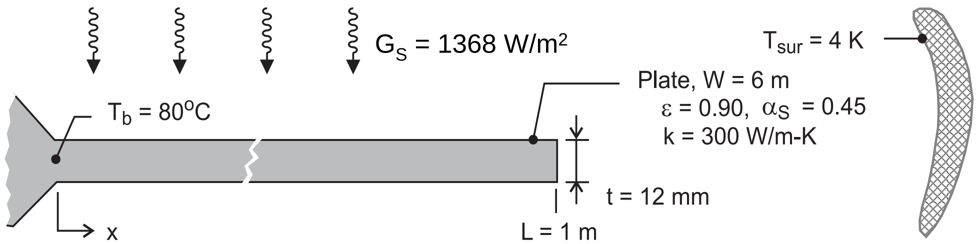
COMMENTS: The radiator should be constructed of a light weight, high thermal conductivity material (aluminum).

PROBLEM 12.134

KNOWN: Rectangular plate, with prescribed geometry and thermal properties, for use as a radiator in a spacecraft application. Radiator exposed to solar radiation on upper surface, and to deep space on both surfaces.

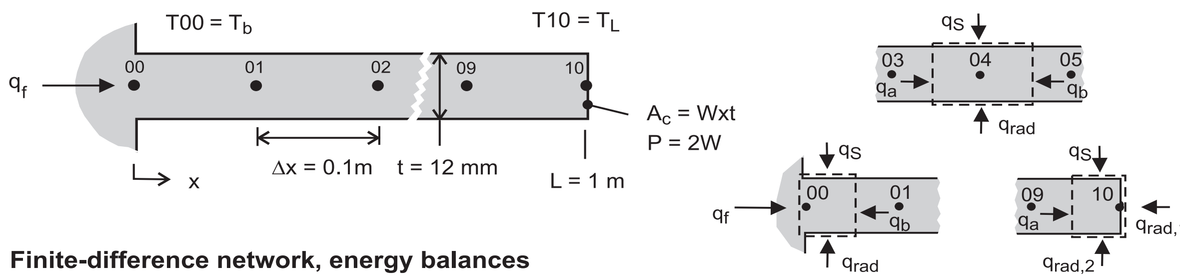
FIND: Using a computer-based, finite-difference method with a space increment of 0.1 m, find the tip temperature, T_L, and rate of heat rejection, q_f, when the base temperature is maintained at 80°C for the cases: (a) when exposed to the sun, (b) on the dark side of the earth, not exposed to the sun; and (c) when the thermal conductivity is extremely large. Compare the case (c) results with those obtained from a hand calculation assuming the radiator is at a uniform temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (b) Plate-radiator behaves as an extended surface with one-dimensional conduction, and (c) Radiating tip condition.

ANALYSIS: The finite-difference network with 10 nodes and a space increment Δx = 0.1 m is shown in the schematic below. The finite-difference equations (FDEs) are derived for an interior node (nodes 01 - 09) and the tip node (10). The energy balances are represented also in the schematic below where q_a and q_b represent conduction heat rates, q_S represents the absorbed solar radiation, and q_{rad} represents the radiation exchange with outer space.



Finite-difference network, energy balances

Interior node 04

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$q_a + q_b + q_S + q_{rad} = 0$$

$$kA_c \left(T_{03} - T_{04}\right) / \Delta x + kA_c \left(T_{05} - T_{04}\right) / \Delta x$$

$$+\alpha_S \, G_S \, (P/2)\Delta x + \varepsilon P \Delta x \sigma \left(T_{sur}^4 - T_{04}^4\right) = 0$$

where P = 2W and $A_c = W \cdot t$.

Tip node 10

$$q_a + q_S + q_{rad,1} + q_{rad,2} = 0$$

$$kA_c \left(T_{09} - T_{10}\right) / \Delta x + \alpha_S G_S \, (P/2) \, (\Delta x / 2)$$

$$+\varepsilon \, A_c \sigma \left(T_{sur}^4 - T_{10}^4\right) + \varepsilon P(\Delta x / 2)\sigma\left(T_{sur}^4 - T_{04}^4\right) = 0$$

Continued …

PROBLEM 12.134 (Cont.)

Heat rejection, q_f. From an energy balance on the base node 00,

$$q_f + q_{01} + q_S + q_{rad} = 0$$

$$q_f + kA_c\left(T_{01} - T_{00}\right)/\Delta x + \alpha_S G_S (P/2)(\Delta x/2)$$

$$+ \varepsilon P(\Delta x/2)\sigma\left(T_{sur}^4 - T_{00}^4\right) = 0$$

The foregoing nodal equations and the heat rate expression were entered into the *IHT* workspace to obtain solutions for the three cases. See Comment 2 for the *IHT* code, and Comment 1 for code validation remarks.

Case	k(W/m·K)	G_S(W/m^2)	T_L(°C)	q_f(W)	
a	300	1368	30.9	2746	<
b	300	0	-7.6	4720	<
c	1×10^{10}	0	80.0	9565	<

Case (c) using the *IHT* code with k = 1×10^{10} W/m·K corresponds to the condition of the plate at the uniform temperature of the base; that is $T(x) = T_b$. For this condition, the heat rejection from the upper and lower surfaces and the tip area can be calculated as

$$q_{f,u} = \varepsilon\sigma\left(T_b^4 - T_{sur}^4\right)\left[P \cdot L + A_c\right]$$

$$q_{f,u} = 0.9\sigma\left[(80 + 273)^4 - 4^4\right]\text{W/m}^2\left[12 + 6 \times 0.012\right]\text{m}^2$$

$$= 9674 \text{ W}$$

Note that the heat rejection rate for the uniform plate is in excellent agreement with the result of the FDE analysis when the thermal conductivity is made extremely large. We have confidence that the code is properly handling the conduction and radiation processes; but, we have not exercised the portion of the code dealing with the absorbed irradiation. What analytical solution/model could you use to validate this portion of the code?

COMMENTS: (1) The *IHT* code with the 10-nodal FDEs for the temperature distribution and the heat rejection rate is as follows.

```
//Properties and dimensions

W = 6                          //m
t = 12/1000                    //m
k = 300                        //thermal conductivity (W/m-K)
eps = 0.90                     //emissivity
absS = 0.45                    //solar absorptivity
//Conditions
Tsur = 4                       // (K)
T00 = 80 + 273                 // (K)
GS = 1368                      // (W/m^2)
Ac = t*W                 //cross sectional area (m^2)
P = 2*W                        //perimeter (m)
deltax = 0.1                   // (m)
sigma=5.67e-8
```

```

(2) To determine the validity of the one-dimensional, extended surface analysis, calculate the Biot number estimating the linearized radiation coefficient based upon the uniform plate condition, T_b = 80°C.

$$Bi = h_{rad}(t/2)/k$$

$$h_{rad} = \varepsilon\sigma(T_b + T_{sur})\left(T_b^2 + T_{sur}^2\right) \approx \varepsilon\sigma T_b^3 = 2.25\ W/m^2 \cdot K$$

$$Bi = 2.25\ W/m^2 \cdot K(0.012\ m/2)/300\ W/m \cdot K = 4.5 \times 10^{-5}$$

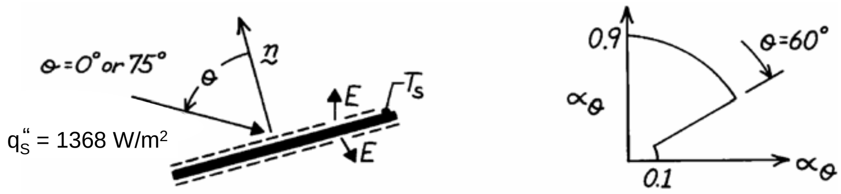
Since Bi << 0.1, the assumption of one-dimensional conduction is appropriate.

PROBLEM 12.135

KNOWN: Directional absorptivity of a plate exposed to solar radiation on one side.

FIND: (a) Ratio of normal absorptivity to hemispherical emissivity, (b) Equilibrium temperature of plate at 0° and 75° orientation relative to sun's rays.

SCHEMATIC:



ASSUMPTIONS: (1) Surface is gray, (2) Properties are independent of φ.

ANALYSIS: (a) From the prescribed α_θ (θ), α_n = 0.9. Since the surface is gray, $\varepsilon_\theta = \alpha_\theta$. Hence from Eq. 12.42, which applies for total as well as spectral properties.

$$\varepsilon = 2\int_0^{\pi/2} \varepsilon_\theta \cos\theta \sin\theta \, d\theta = 2\left[0.9\frac{\sin^2\theta}{2}\Bigg|_0^{\pi/3} + 0.1\frac{\sin^2\theta}{2}\Bigg|_{\pi/3}^{\pi/2}\right]$$

$$\varepsilon = 2\left[0.9(0.375) + 0.1(0.5 - 0.375)\right] = 0.70.$$

Hence

$$\frac{\alpha_n}{\varepsilon} = \frac{0.9}{0.7} = 1.286.$$

(b) Performing an energy balance on the plate,

$$\alpha_\theta q_S'' \cos\theta - 2\varepsilon\sigma T_S^4 = 0$$

or

$$T_S = \left[\frac{\alpha_\theta}{2\varepsilon\sigma} q_S'' \cos\theta\right]^{1/4}.$$

Hence for θ = 0°, α_θ = 0.9 and cosθ = 1,

$$T_S = \left[\frac{0.9}{2\times 0.7\times 5.67\times 10^{-8}}\times 1368\right]^{1/4} = 353\text{K}.$$ <

For θ = 75°, α_θ = 0.1 and cosθ = 0.259

$$T_S = \left[\frac{0.1}{2\times 0.7\times 5.67\times 10^{-8}}\times 1368\times 0.259\right]^{1/4} = 145\text{K}.$$ <

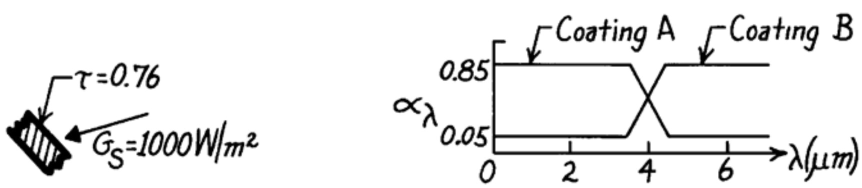
COMMENTS: Since the surface is not diffuse, its absorptivity depends on the directional distribution of the incident radiation.

PROBLEM 12.136

KNOWN: Transmissivity of cover plate and spectral absorptivity of absorber plate for a solar collector.

FIND: Absorption rate for prescribed solar flux and preferred absorber plate coating.

SCHEMATIC:



ASSUMPTIONS: (1) Solar irradiation of absorber plate retains spectral distribution of blackbody at 5800K, (2) Coatings are diffuse.

ANALYSIS: At the absorber plate we wish to maximize solar radiation absorption and minimize losses due to emission. The solar radiation is concentrated in the spectral region $\lambda < 4\mu m$, and for a representative plate temperature of $T \leq 350K$, emission from the plate is concentrated in the spectral region $\lambda > 4\mu m$. Hence,

Coating A is vastly superior. <

With $G_{\lambda,S} \sim E_{\lambda,b}$ (5800K), it follows from Eq. 12.53

$$\alpha_A \approx 0.85\ F_{(0-4\mu m)} + 0.05\ F_{(4\mu m-\infty)}.$$

From Table 12.1, $\lambda T = 4\mu m \times 5800K = 23{,}200\mu m\cdot K$,

$$F_{(0-4\mu m)} \approx 0.99.$$

Hence

$$\alpha_A = 0.85(0.99) + 0.05(1-0.99) \approx 0.85.$$

With $G_S = 1000\ W/m^2$ and $\tau = 0.84$ (Ex. 12.9), the absorbed solar flux is

$$G_{S,abs} = \alpha_A\,(\tau G_S) = 0.85\left(0.84 \times 1000\ W/m^2\right)$$

$$G_{S,abs} = 714\ W/m^2.$$ <

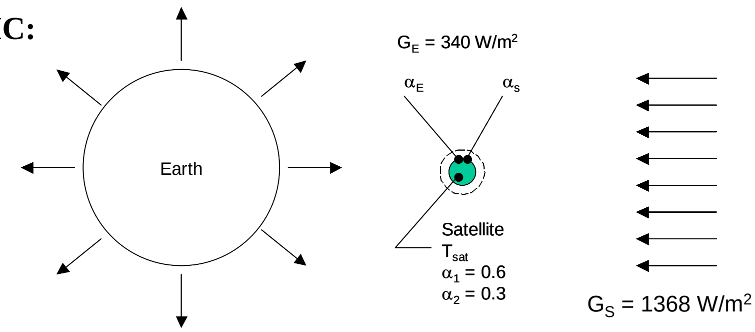
COMMENTS: Since the absorber plate emits in the infrared ($\lambda > 4\mu m$), its emissivity is $\varepsilon_A \approx 0.05$. Hence $(\alpha/\varepsilon)_A = 17$. A large value of α/ε is desirable for solar absorbers.

PROBLEM 12.137

KNOWN: Irradiation of satellite from earth and sun. Two emissivities associated with the satellite.

FIND: (a) Steady-state satellite temperature when satellite is on bright side of earth for $\alpha_E/\alpha_s > 1$ and $\alpha_E/\alpha_s < 1$, (b) Steady-state satellite temperature when satellite is on dark side of earth for $\alpha_E/\alpha_s > 1$ and $\alpha_E/\alpha_s < 1$, (c) Scheme to minimize temperature variations of the satellite.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Opaque, diffuse gray behavior.

ANALYSIS: Performing an energy balance on the satellite, it follows that $\dot{E}_{in} = \dot{E}_{out}$ or

$$\alpha_E G_E(\pi D^2/4) + \alpha_s G_s(\pi D^2/4) - \varepsilon_E \sigma T_{sat}^4(\pi D^2/2) - \varepsilon_s \sigma T_{sat}^4(\pi D^2/2) = 0$$

or

$$T_{sat} = \left[\frac{\alpha_E G_E + \alpha_s G_s}{2(\varepsilon_E + \varepsilon_s)\sigma}\right]^{1/4}$$

(a) Bright Side of Earth (G_s = 1368 W/m²).

For $\alpha_E = \varepsilon_E = \alpha_2 = 0.3$, $\alpha_s = \varepsilon_s = \alpha_1 = 0.6$,

$$T_{sat} = \left[\frac{0.3 \times 340\,W/m^2 + 0.6 \times 1353\,W/m^2}{2 \times (0.3 + 0.6) \times 5.67 \times 10^{-8}\,W/m^2 \cdot K^4}\right]^{1/4} = 308K$$ <

For $\alpha_E = \varepsilon_E = \alpha_1 = 0.6$, $\alpha_s = \varepsilon_s = \alpha_2 = 0.3$,

$$T_{sat} = \left[\frac{0.6 \times 340\,W/m^2 + 0.3 \times 1353\,W/m^2}{2 \times (0.6 + 0.3) \times 5.67 \times 10^{-8}\,W/m^2 \cdot K^4}\right]^{1/4} = 279K$$ <

(b) Dark Side of Earth (G_s = 0 W/m²).

For $\alpha_E = \varepsilon_E = \alpha_1 = 0.6$, $\alpha_s = \varepsilon_s = \alpha_2 = 0.3$,

Continued…

PROBLEM 12.137 (Cont.)

$$T_{sat} = \left[\frac{0.6 \times 340 \text{W/m}^2}{2 \times (0.6 + 0.3) \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4} \right]^{1/4} = 211\text{K}$$ <

For $\alpha_E = \varepsilon_E = \alpha_2 = 0.3$, $\alpha_s = \varepsilon_s = \alpha_1 = 0.6$,

$$T_{sat} = \left[\frac{0.3 \times 340 \text{W/m}^2}{2 \times (0.3 + 0.6) \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4} \right]^{1/4} = 178\text{K}$$ <

(c) To minimize the temperature variations of the satellite, we would have the high emissivity coating always facing earth.

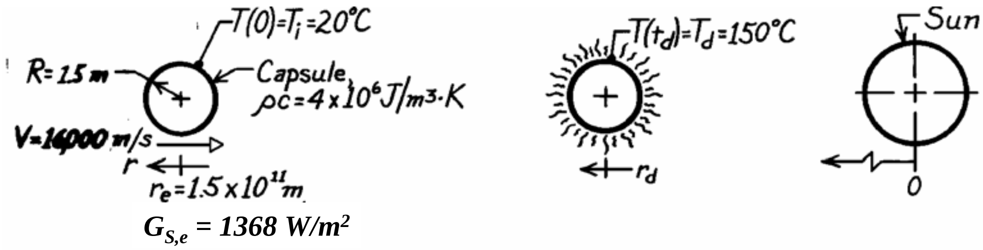
COMMENTS: If the entire satellite were covered with either coating, the temperatures on the bright and dark sides of earth would be T_s = 294 K and 197 K, respectively. Use of the two emissivity coatings reduces temperature variations from 294 K – 197 K = 97 K to 278 K – 211 K = 67 K.

PROBLEM 12.138

KNOWN: Space capsule fired from earth orbit platform in direction of sun.

FIND: (a) Differential equation predicting capsule temperature as a function of time, (b) Position of capsule relative to sun when it reaches its destruction temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Capsule behaves as lumped capacitance system, (2) Capsule surface is black, (3) Temperature of surroundings approximates absolute zero, (4) Capsule velocity is constant.

ANALYSIS: (a) To find the temperature as a function of time, perform an energy balance on the capsule considering absorbed solar irradiation and emission,

$$\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st} \qquad G_S \cdot \pi R^2 - \sigma T^4 \cdot 4\pi R^2 = \rho c (4/3)\pi R^3 (dT/dt). \qquad (1)$$

Note the use of the projected capsule area (πR^2) and the surface area ($4\pi R^2$). The solar irradiation will increase with decreasing radius (distance toward the sun) as

$$G_S(r) = G_{S,e}(r_e/r)^2 = G_{S,e}\left(r_e/(r_e - Vt)\right)^2 = G_{S,e}\left(1/(1 - Vt/r_e)\right)^2 \qquad (2)$$

where r_e is the distance of earth orbit from the sun and $r = r_e - Vt$. Hence, Eq. (1) becomes

$$\frac{dT}{dt} = \frac{3}{\rho c R}\left[\frac{G_{S,e}}{4(1 - Vt/r_e)^2} - \sigma T^4\right].$$

The rate of temperature change is

$$\frac{dT}{dt} = \frac{3}{\left(4\times10^6 J/m^3 \cdot K \times 1.5m\right)}\left[\frac{1368\ W/m^2}{4\left(1 - 16\times10^3 m/s \times t/1.5\times10^{11} m\right)^2} - \sigma T^4\right]$$

$$\frac{dT}{dt} = 1.691\times10^{-4}\left(1 - 1.067\times10^{-7}\ t\right)^{-2} - 2.835\times10^{-14}\ T^4$$

where T[K] and t(s). For the initial condition, t = 0, with T = 20°C = 293K,

$$\frac{dT}{dt}(0) = -3.9\times10^{-5}\ K/s. \qquad <$$

That is, the capsule will cool for a period of time and then begin to heat.

(b) The differential equation cannot be explicitly solved for temperature as a function of time. Using a numerical method with a time increment of $\Delta t = 5 \times 10^5$s, find

$$T(t) = 150°C = 423\ K \qquad \text{at} \qquad t \approx 5.5\times10^6 s. \qquad <$$

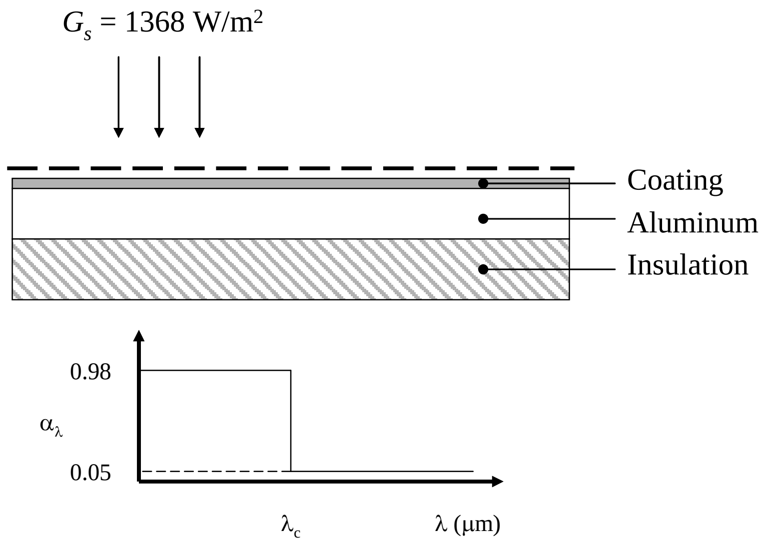
Note that in this period of time the capsule traveled $(r_e - r) = Vt = 16 \times 10^3$ m/s $\times 5.5 \times 10^6 = 1.472 \times 10^{10}$ m. That is, $r = 1.353 \times 10^{11}$ m.

PROBLEM 12.139

KNOWN: Solar irradiation of coated aluminum. Spectral absorptivities above and below cutoff wavelength. Cutoff wavelength under normal conditions.

FIND: (a) Equilibrium temperature for normal conditions with λ_c = 0.15 μm. (b) Value of λ_c that will maximize surface temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady state conditions. (2) Solar irradiation approximated as that from a blackbody at T = 5800 K.

ANALYSIS: (a) For the control surface shown in the schematic $\dot{E}_{in} = \dot{E}_{out}$ or $G_s = J$ or $\alpha_s G_s = \varepsilon\sigma T_s^4$. Therefore,

$$T_s = \left[\frac{\alpha_s G_s}{\varepsilon\sigma}\right]^{1/4} \quad (1)$$

The solar irradiation is approximated as that of a blackbody at 5800 K. From Table 12.1, $F_{(0-\lambda_c)} = F_{(0-0.15\mu m)} \approx 0$. Therefore,

$$\alpha_s = \alpha_{\lambda,1}F_{(0-\lambda_c)} + \alpha_{\lambda,2}\left[1 - F_{(0-\lambda_c)}\right] = 0.98\times 0 + 0.05\times[1-0] = 0.05$$

The surface emissivity may be expressed as $\varepsilon = \alpha_{\lambda,1}F_{(0-\lambda_c\cdot T_s)} + \alpha_{\lambda,2}\left[1 - F_{(0-\lambda_c\cdot T_s)}\right]$ (2)

where the variable $F_{(0-\lambda_c\cdot T_s)}$ is the fraction of blackbody radiation in the band between 0 μm·K and $\lambda_c T_s$. Combining Equations 1 and 2 yields

Continued…

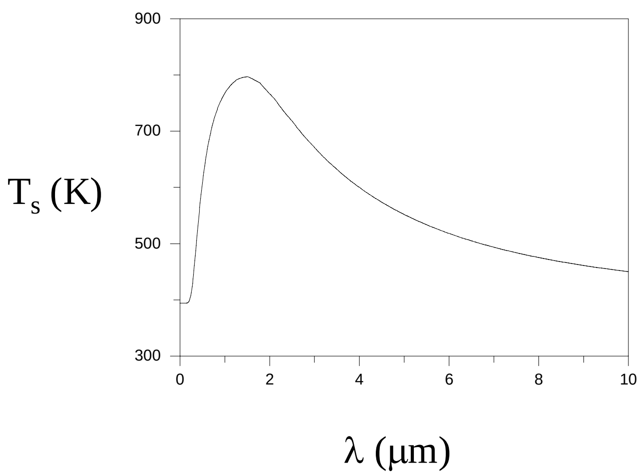
PROBLEM 12.139 (Cont.)

$$T_s = \left[\frac{0.05 \times 1368 \text{ W/m}^2}{\left\{0.98 \times F_{(0-\lambda_c \cdot T_s)} + 0.05 \times \left[1 - F_{(0-\lambda_c \cdot T_s)}\right]\right\} \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} \right]^{1/4}$$

which may be solved by trial-and-error (since $F_{(0-\lambda_c \cdot T_s)}$ is a function of T_s) to yield T_s = 394.1 K. <

Equations 1 and 2 may be solved by trial-and-error to yield a maximum surface temperature of T_s = 797 K at a cutoff wavelength of λ_c = 1.50 μm. <

COMMENTS: (1) The small value of λ_c that exists under normal conditions, coupled with the relatively low surface temperature, yields a surface emissivity of 0.05. (2) The emissivity and absorptivity associated with the surface temperature of T_s = 797 K are ε = 0.052 and α = 0.869, respectively. (3) The variation of the surface temperature with the cutoff wavelength is shown in the plot below. Manipulation of the cutoff wavelength is an effective approach for achieving desired thermal performance.

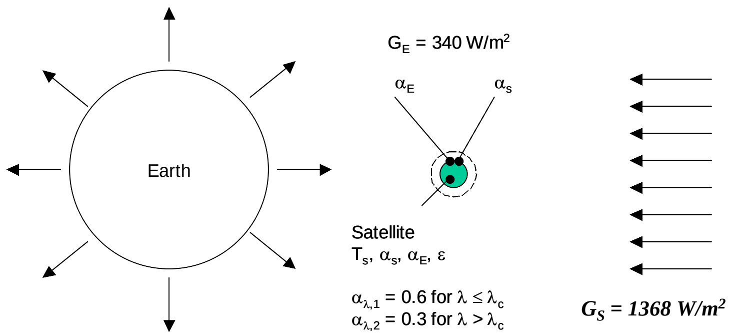


PROBLEM 12.140

KNOWN: Irradiation from the sun and earth on a spherical satellite. Spectral absorptivities of the satellite surface below and above a cutoff wavelength.

FIND: (a) Cutoff wavelength to minimize satellite temperature on bright side of earth, corresponding satellite temperature on dark side of earth, (b) Cutoff wavelength to maximize satellite temperature on dark side of earth, corresponding satellite temperature on bright side of earth.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Opaque, diffuse satellite surface.

ANALYSIS: Performing an energy balance on the satellite, it follows that $\dot{E}_{in} = \dot{E}_{out}$ or

$$\alpha_E G_E (\pi D^2/4) + \alpha_s G_s (\pi D^2/4) - \varepsilon\sigma T_s^4 (\pi D^2) = 0$$

or

$$T_s = \left[\frac{\alpha_E G_E + \alpha_s G_s}{4\varepsilon\sigma}\right]^{1/4} \qquad (1)$$

(a) Bright Side of Earth, Minimize T_s.

For earth irradiation being approximated as that of a blackbody at 280 K,

$$\alpha_E = \alpha_{\lambda,1} F_{(0-\lambda_c \cdot 280K)} + \alpha_{\lambda,2}\left[1 - F_{(0-\lambda_c \cdot 280K)}\right] \qquad (2)$$

For solar irradiation being approximated as that of a blackbody at 5800K,

$$\alpha_s = \alpha_{\lambda,1} F_{(0-\lambda_c \cdot 5800K)} + \alpha_{\lambda,2}\left[1 - F_{(0-\lambda_c \cdot 5800K)}\right] \qquad (3)$$

The satellite emissivity is, with $\varepsilon_\lambda = \alpha_\lambda$, $\varepsilon = \alpha_{\lambda,1} F_{(0-\lambda_c \cdot T_s)} + \alpha_{\lambda,2}\left[1 - F_{(0-\lambda_c \cdot T_s)}\right]$ (4)

Equations 1 through 4 may be solved using various λ_c yielding a minimum satellite temperature of T_s = 295 K for λ_c = 0 or ∞. <

Continued…

PROBLEM 12.140 (Cont.)

(a) Dark Side of Earth, Maximize T_s.

For the satellite on the dark side of earth with a spectrally-selective coating, Equation 1 becomes

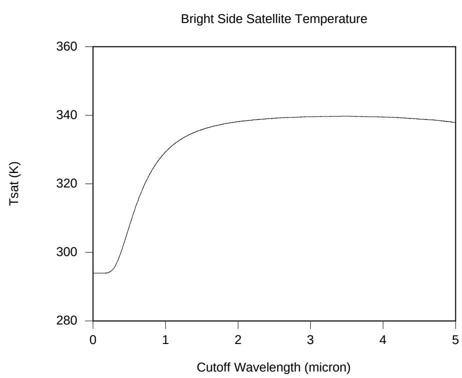
$$T_s = \left[\frac{\alpha_E G_E}{4\varepsilon\sigma}\right]^{1/4} \qquad (5)$$

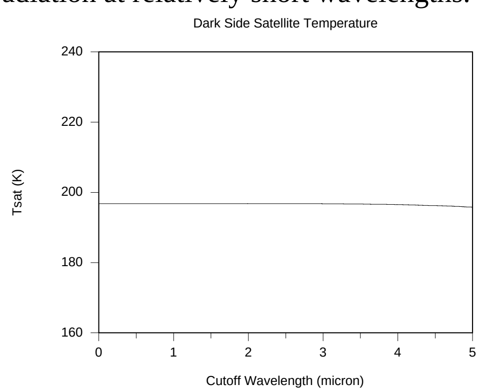
Equations 2 through 5 may be solved using various λ_c, yielding a maximum satellite temperature of T_s = 205 K at λ_c = 13.57 μm. <

The corresponding values of α_E, α_s and ε are 0.4330, 0.5999 and 0.3672, respectively.

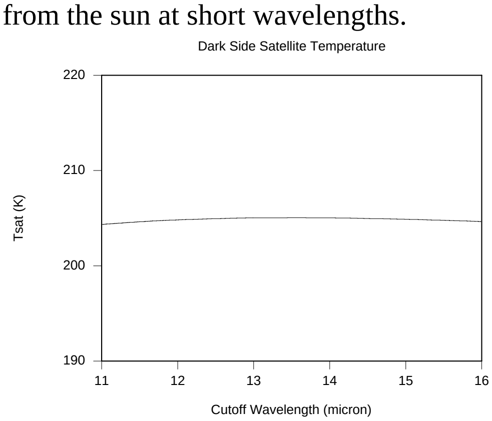
When the satellite is on the bright side with λ_c = 13.57 μm, the satellite temperature may be found by solving Equations 1 through 4 yielding a temperature of T_s = 310.4 K. The corresponding values of α_E, α_s and ε are 0.4330, 0.5999 and 0.4554, respectively. <

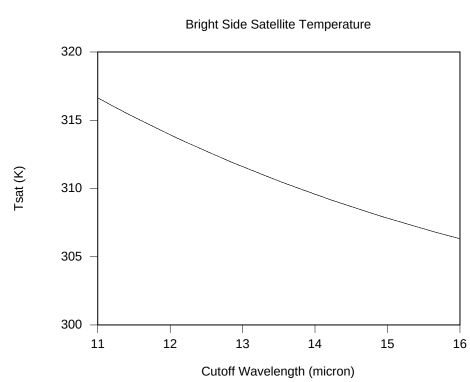
COMMENT: In part (a) of the problem the satellite temperature is very sensitive to the cutoff wavelength of λ_c = 0 when the satellite is on the bright side of earth. This is because of the presence of a significant amount of solar irradiation at relatively short wavelengths.





For part (b) of the problem, the dark side satellite temperature is relatively insensitive to the cutoff wavelength because of the similar spectral distributions of the earth irradiation and the satellite emission. In contrast, however, the temperature of the satellite on the bright side of earth is much more sensitive to the cutoff wavelength because of the presence of significant irradiation from the sun at short wavelengths.



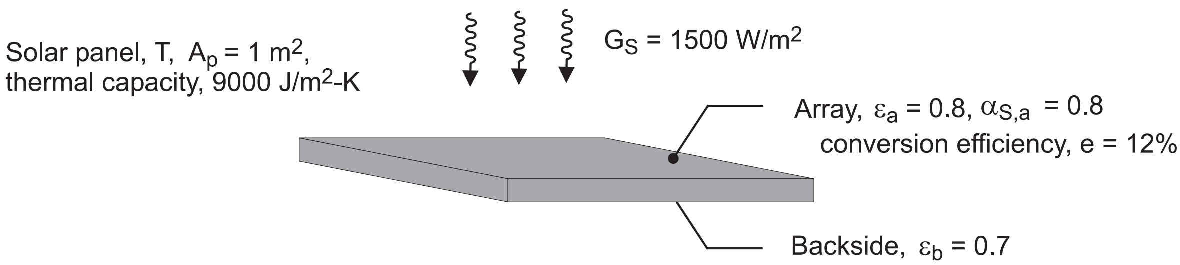


PROBLEM 12.141

KNOWN: Solar panel mounted on a spacecraft of area 1 m^2 having a solar-to-electrical power conversion efficiency of 12% with specified radiative properties.

FIND: (a) Steady-state temperature of the solar panel and electrical power produced with solar irradiation of 1500 W/m^2, (b) Steady-state temperature if the panel were a thin plate (no solar cells) with the same radiative properties and for the same prescribed conditions, and (c) Temperature of the solar panel 1500 s after the spacecraft is eclipsed by a planet; thermal capacity of the panel per unit area is 9000 $J/m^2\cdot K$.

SCHEMATIC:



ASSUMPTIONS: (1) Solar panel and thin plate are isothermal, (2) Solar irradiation is normal to the panel upper surface, and (3) Panel has unobstructed view of deep space at 0 K.

ANALYSIS: (a) The energy balance on the solar panel is represented in the schematic below and has the form

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$\alpha_S G_S \cdot A_p - (\varepsilon_a + \varepsilon_b)\, E_b\left(T_{sp}\right)\cdot A_p - P_{elec} = 0 \qquad (1)$$

where $E_b(T) = \sigma T^4$, $\sigma = 5.67 \times 10^{-8}$ $W/m^2\cdot K^4$, and the electrical power produced is

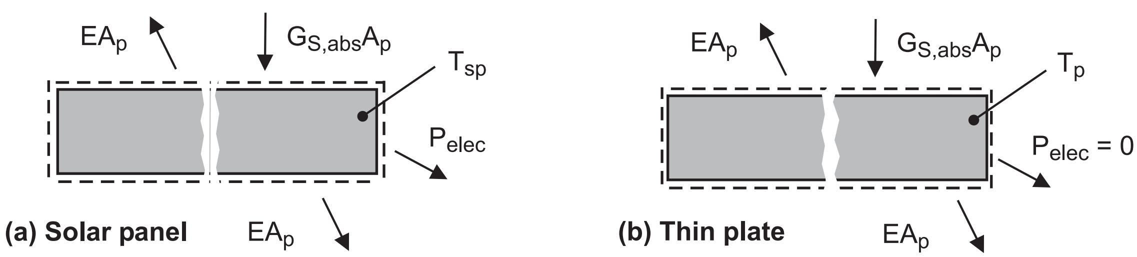
$$P_{elec} = e \cdot G_S \cdot A_p \qquad (2)$$

$$P_{elec} = 0.12 \times 1500\ W/m^2 \times 1\ m^2 = 180\ W$$ <

Substituting numerical values into Eq. (1), find

$$0.8 \times 1500\ W/m^2 \times 1\ m^2 - (0.8 + 0.7)\sigma T_{sp}^4 \times 1\ m^2 - 180\ W = 0$$

$$T_{sp} = 330.9\ K = 57.9^\circ C$$ <



(b) The energy balance for the thin plate shown in the schematic above follows from Eq. (1) with $P_{elec} = 0$ yielding

$$0.8 \times 1500\ W/m^2 \times /m^2 - (0.8 + 0.7)\sigma T_p^4 \times 1\ m^2 = 0 \qquad (3)$$

$$T_p = 344.7\ K = 71.7^\circ C$$ <

Continued …

PROBLEM 12.141 (Cont.)

(c) Using the lumped capacitance method, the energy balance on the solar panel as illustrated in the schematic below has the form

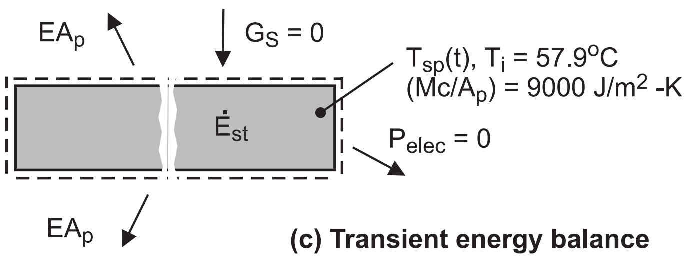
$$\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st}$$

$$-(\varepsilon_a + \varepsilon_b)\sigma T_{sp}^4 \cdot A_p = TC'' \cdot A_p \frac{dT_{sp}}{dt} \qquad (4)$$

where the thermal capacity per unit area is $TC'' = (Mc / A_p) = 9000 \text{ J/m}^2 \cdot \text{K}$.

Eq. 5.18 provides the solution to this differential equation in terms of t = t (T_i, T_{sp}). Alternatively, use Eq. (4) in the *IHT* workspace (see Comment 4 below) to find

$$T_{sp}(1500 \text{ s}) = 242.6 \text{ K} = -30.4^\circ\text{C}$$ <



(c) Transient energy balance

COMMENTS: (1) For part (a), the energy balance could be written as

$$\dot{E}_{in} - \dot{E}_{out} + \dot{E}_g = 0$$

where the energy generation term represents the *conversion process from thermal energy to electrical energy*. That is,

$$\dot{E}_g = -e \cdot G_S \cdot A_p$$

(2) The steady-state temperature for the thin plate, part (b), is higher than for the solar panel, part (a). This is to be expected since, for the solar panel, some of the absorbed solar irradiation (thermal energy) is converted to electrical power.

(3) To justify use of the lumped capacitance method for the transient analysis, we need to know the effective thermal conductivity or internal thermal resistance of the solar panel.

(4) Selected portions of the *IHT* code using the *Models Lumped* | *Capacitance* tool to perform the transient analysis based upon Eq. (4) are shown below.

```
// Energy balance, Model | Lumped Capacitance
/ * Conservation of energy requirement on the control volume, CV. * /
Edotin - Edotout = Edotst
Edotin = 0
Edotout = Ap * (+q"rad)
Edostat = rhovolcp * Ap * Der(T,t)
// rhovolcp = rho * vol * cp       // thermal capacitance per unit area, J/m^2·K

// Radiation exchange between Cs and large surroundings
q"rad = (eps_a + eps_b) * sigma * (T^4 - Tsur^4)
sigma = 5.67e-8    // Stefan-Boltzmann constant, W/m^2·K^4

// Initial condition
// Ti = 57.93 + 273 = 330.9                    // From part (a), steady-state condition
T_C = T - 273
```

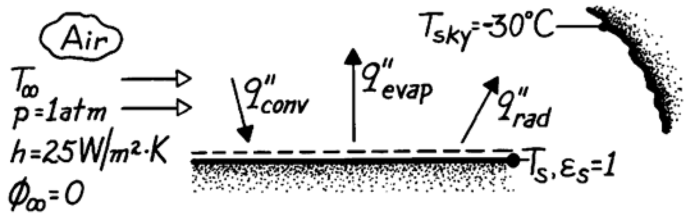
(5) The solar flux exceeds the solar constant value of 1368 W/m^2. Hence the spacecraft is closer to the sun than is earth.

PROBLEM 12.142

KNOWN: Effective sky temperature and convection heat transfer coefficient associated with a thin layer of water.

FIND: Lowest air temperature for which the water will not freeze (without and with evaporation).

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Bottom of water is adiabatic, (3) Heat and mass transfer analogy is applicable, (4) Air is dry.

PROPERTIES: *Table A-4*, Air (273 K, 1 atm): $\rho = 1.287\ kg/m^3$, $c_p = 1.01\ kJ/kg\cdot K$, $\nu = 13.49 \times 10^{-6}\ m^2/s$, Pr = 0.72; *Table A-6*, Saturated vapor ($T_s = 273$ K): $\rho_A = 4.8 \times 10^{-3}\ kg/m^3$, $h_{fg} = 2502$ kJ/kg; *Table A-8*, Vapor-air (298 K): $D_{AB} \approx 0.36 \times 10^{-4}\ m^2/s$, $Sc = \nu/D_{AB} = 0.52$.

ANALYSIS: Without evaporation, the surface heat loss by radiation must be balanced by heat gain due to convection. An energy balance gives

$$q''_{conv} = q''_{rad} \qquad \text{or} \qquad h\left(T_\infty - T_s\right) = \varepsilon_s \sigma \left(T_s^4 - T_{sky}^4\right).$$

At freezing, $T_s = 273$ K. Hence

$$T_\infty = T_s + \frac{\varepsilon_s \sigma}{h}\left(T_s^4 - T_{sky}^4\right) = 273\ K + \frac{5.67 \times 10^{-8}\ W/m^2 \cdot K^4}{25\ W/m^2 \cdot K}\left[274^4 - 243^4\right]K^4 = 4.69°C. \qquad <$$

With evaporation, the surface energy balance is now

$$q''_{conv} = q''_{evap} + q''_{rad} \ \text{ or } \ h\left(T_\infty - T_s\right) = h_m\left[\rho_{A,sat}\left(T_s\right) - \rho_{A,\infty}\right]h_{fg} + \varepsilon_s \sigma \left(T_s^4 - T_{sky}^4\right).$$

$$T_\infty = T_s + \frac{h_m}{h}\rho_{A,sat}\left(T_s\right)h_{fg} + \frac{\varepsilon_s \sigma}{h}\left(T_s^4 - T_{sky}^4\right).$$

Substituting from Eq. 6.60, with $n \approx 0.33$,

$$h_m / h = \left(\rho c_p Le^{0.67}\right)^{-1} = \left[\rho c_p \left(Sc / Pr\right)^{0.67}\right]^{-1}$$

$$= \left[1.287\ kg/m^3 \times 1010\ J/kg \cdot K\left(0.52/0.72\right)^{0.67}\right]^{-1}$$

$$= 9.57 \times 10^{-4}\ m^3 \cdot K/J,$$

$$T_\infty = 273\ K + 9.57 \times 10^{-4}\ m^3 \cdot K/J \times 4.8 \times 10^{-3} kg/m^3 \times 2.5 \times 10^6 J/kg + 4.69\ K = 16.2°C. \qquad <$$

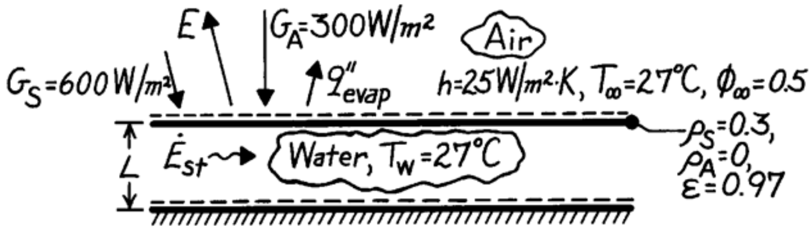
COMMENTS: The existence of clear, cold skies and dry air will allow water to freeze for ambient air temperatures well above 0°C (due to radiative and evaporative cooling effects, respectively). The lowest air temperature for which the water will not freeze increases with decreasing ϕ_∞, decreasing T_{sky} and decreasing h.

PROBLEM 12.143

KNOWN: Temperature and environmental conditions associated with a shallow layer of water.

FIND: Whether water temperature will increase or decrease with time.

SCHEMATIC:



ASSUMPTIONS: (1) Water layer is well mixed (uniform temperature), (2) All non-reflected radiation is absorbed by water, (3) Bottom is adiabatic, (4) Heat and mass transfer analogy is applicable, (5) Perfect gas behavior for water vapor.

PROPERTIES: *Table A-4*, Air (T = 300 K, 1 atm): ρ_a = 1.161 kg/m^3, $c_{p,a}$ = 1007 J/kg·K, Pr = 0.707; *Table A-6*, Water (T = 300 K, 1 atm): ρ_w = 997 kg/m^3, $c_{p,w}$ = 4179 J/kg·K; Vapor (T = 300 K, 1 atm): $\rho_{A,sat}$ = 0.0256 kg/m^3, h_{fg} = 2.438 × 10^6 J/kg; *Table A-8*, Water vapor-air (T = 300 K, 1 atm): $D_{AB} \approx 0.26 \times 10^{-4}$ m^2/s; with $\nu_a = 15.89 \times 10^{-6}$ m^2/s from *Table A-4*, Sc = ν_a/D_{AB} = 0.61.

ANALYSIS: Performing an energy balance on a control volume about the water,

$$\dot{E}_{st} = \left(G_{S,abs} + G_{A,abs} - E - q''_{evap}\right)A$$

$$\frac{d\left(\rho_w c_{p,w} LAT_w\right)}{dt} = \left[\left(1-\rho_s\right)G_S + \left(1-\rho_A\right)G_A - \varepsilon\sigma T_w^4 - h_m h_{fg}\left(\rho_{A,sat} - \rho_{A,\infty}\right)\right]A$$

or, with $T_\infty = T_w$, $\rho_{A,\infty} = \phi_\infty \rho_{A,sat}$ and

$$\rho_w c_{p,w} L\frac{dT_w}{dt} = \left(1-\rho_s\right)G_S + \left(1-\rho_A\right)G_A - \varepsilon\sigma T_w^4 - h_m h_{fg}\left(1-\phi_\infty\right)\rho_{A,sat}.$$

From Eq. 6.60, with a value of n = 1/3,

$$h_m = \frac{h}{\rho_a c_{p,a} Le^{1-n}} = \frac{h}{\rho_a c_{p,a}\left(Sc/Pr\right)^{1-n}} = \frac{25\,W/m^2\cdot K\left(0.707\right)^{2/3}}{1.161\,kg/m^3 \times 1007\ J/kg\cdot K\left(0.61\right)^{2/3}} = 0.0236\,m/s.$$

Hence

$$\rho_w c_{p,w} L\frac{dT_w}{dt} = \left(1-0.3\right)600 + \left(1-0\right)300 - 0.97\times 5.67\times 10^{-8}\left(300\right)^4$$
$$-0.0236\times 2.438\times 10^6\left(1-0.5\right)0.0256$$

$$\rho_w c_{p,w} L\frac{dT_w}{dt} = \left(420+300-445-736\right)W/m^2 = -461\ W/m^2.$$

Hence the water will *cool*. <

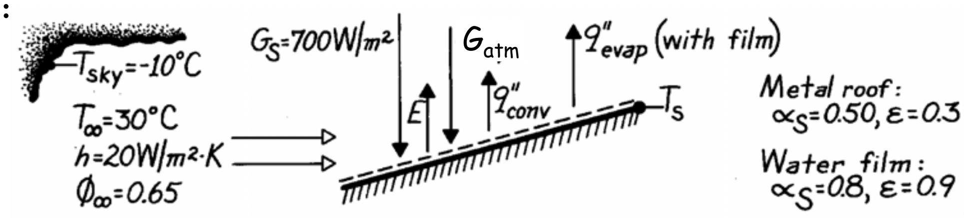
COMMENTS: (1) Since $T_w = T_\infty$ for the prescribed conditions, there is no convection of sensible energy. However, as the water cools, there will be convection heat transfer from the air. (2) If L = 1m, $(dT_w/dt) = -461/(997 \times 4179 \times 1) = -1.11 \times 10^{-4}$ K/s.

PROBLEM 12.144

KNOWN: Environmental conditions for a metal roof with and without a water film.

FIND: Roof surface temperature (a) without the film, (b) with the film.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Diffuse-gray surface behavior in the infrared (for the metal, $\alpha_{sky} = \varepsilon = 0.3$; for the water, $\alpha_{sky} = \varepsilon = 0.9$), (3) Adiabatic roof bottom, (4) Perfect gas behavior for vapor.

PROPERTIES: *Table A-4*, Air (T ≈ 300 K): $\rho = 1.16$ kg/m^3, $c_p = 1007$ J/kg·K, $\alpha = 22.5 \times 10^{-6}$ m^2/s; *Table A-6*, Water vapor (T ≈ 303 K): $\nu_g = 32.4$ m^3/kg or $\rho_{A,sat} = 0.031$ kg/m^3; *Table A-8*, Water vapor-air (T = 298 K): $D_{AB} = 0.26 \times 10^{-4}$ m^2/s.

ANALYSIS: (a) From an energy balance on the metal roof

$$\alpha_S G_S + \alpha_{sky} G_{atm} = E + q''_{conv}$$

$$0.5\left(700\ \text{W/m}^2\right) + 0.3 \times 5.67 \times 10^{-8}\ \text{W/m}^2 \cdot \text{K}^4 \left(263\ \text{K}\right)^4$$

$$= 0.3 \times 5.67 \times 10^{-8}\ \text{W/m}^2 \cdot \text{K}^4 \left(T_s^4\right) + 20\ \text{W/m}^2 \cdot \text{K}\left(T_s - 303\ \text{K}\right)$$

$$431\ \text{W/m}^2 = 1.70 \times 10^{-8} T_s^4 + 20\left(T_s - 303\right).$$ <

From a trial-and-error solution, $T_s = 316.1$ K = 43.1°C.

(b) From an energy balance on the water film,

$$\alpha_S G_S + \alpha_{sky} G_{atm} = E + q''_{conv} + q''_{evap}$$

$$0.8\left(700\ \text{W/m}^2\right) + 0.9 \times 5.67 \times 10^{-8}\ \text{W/m}^2 \cdot \text{K}^4 \left(263\ \text{K}\right)^4 = 0.9 \times 5.67 \times 10^{-8}\ \text{W/m}^2 \cdot \text{K}^4 \left(T_s^4\right)$$

$$+20\ \text{W/m}^2 \cdot \text{K}\left(T_s - 303\right) + h_m\left(\rho_{A,sat}\left(T_s\right) - 0.65 \times 0.031\ \text{kg/m}^3\right) h_{fg}.$$

From Eq. 6.60, assuming n = 0.33,

$$h_m = \frac{h}{\rho c_p Le^{0.67}} =$$

$$\frac{h}{\rho c_p \left(\alpha / D_{AB}\right)^{0.67}} = \frac{20\ \text{W/m}^2 \cdot \text{K}}{1.16\ \text{kg/m}^3 \times 1007\ \text{J/kg} \cdot \text{K}\left(0.225 \times 10^{-4} / 0.260 \times 10^{-4}\right)^{0.67}} = 0.019\ \text{m/s}.$$

$$804\ \text{W/m}^2 = 5.10 \times 10^{-8} T_s^4 + 20\left(T_s - 303\right) + 0.019\left[\rho_{A,sat}\left(T_s\right) - 0.020\right] h_{fg}.$$

From a trial-and-error solution, obtaining $\rho_{A,sat}(T_s)$ and h_{fg} from Table A-6 for each assumed value of T_s, it follows that

$$T_s = 302.2\ \text{K} = 29.2°\text{C}.$$ <

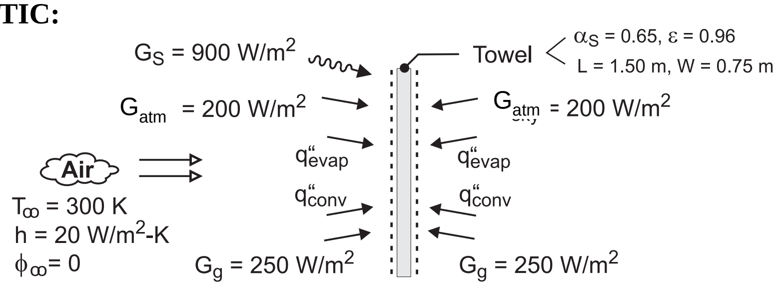
COMMENTS: (1) The film is an effective coolant, reducing T_s by 13.9°C. (2) With the film E ≈ 425 W/m^2, $q''_{conv} \approx -16$ W/m^2 and $q''_{evap} \approx 428$ W/m^2.

PROBLEM 12.145

KNOWN: Solar, sky and ground irradiation of a wet towel. Towel dimensions, emissivity and solar absorptivity. Temperature, relative humidity and convection heat transfer coefficient associated with air flow over the towel.

FIND: Temperature of towel and evaporation rate.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Diffuse-gray surface behavior of towel in the infrared ($\alpha_{sky} = \alpha_g = \varepsilon = 0.96$), (3) Perfect gas behavior for vapor.

PROPERTIES: *Table A-4*, Air (T ≈ 300 K): $\rho = 1.16$ kg/m^3, $c_p = 1007$ J/kg·K, $\alpha = 0.225 \times 10^{-4}$ m^2/s; *Table A-6*, Water vapor (T_∞ = 300 K): $\rho_{A,sat} = 0.0256$ kg/m^3; *Table A-8*, Water vapor/air (T = 298 K): $D_{AB} = 0.26 \times 10^{-4}$ m^2/s.

ANALYSIS: From an energy balance on the towel, it follows that

$$\alpha_S G_S + 2\alpha_{sky} G_{atm} + 2\alpha_g G_g = 2E + 2q''_{evap} + 2q''_{conv}$$

$$0.65 \times 900 \text{W/m}^2 + 2 \times 0.96 \times 200 \text{ W/m}^2 + 2 \times 0.96 \times 250 \text{ W/m}^2$$

$$= 2 \times 0.96\, \sigma T_s^4 + 2n''_A h_{fg} + 2h\left(T_s - T_\infty\right) \qquad (1)$$

where $\quad n''_A = h_m\left[\rho_{A,sat}\left(T_s\right) - \phi_\infty\, \rho_{A,sat}\left(T_\infty\right)\right]$

From the heat and mass transfer analogy, Eq. 6.60, with an assumed exponent of n = 1/3,

$$h_m = \frac{h}{\rho c_p \left(\alpha / D_{AB}\right)^{2/3}} = \frac{20 \text{ W/m}^2 \cdot \text{K}}{1.16 \text{kg/m}^3 \left(1007 \text{ J/kg} \cdot \text{K}\right)\left(\dfrac{0.225}{0.260}\right)^{2/3}} = 0.0189 \text{ m/s}$$

From a trial-and-error solution, we find that for T_s = 298 K, $\rho_{A,sat} = 0.0226$ kg/m^3, $h_{fg} = 2.442 \times 10^6$ J/kg and $n''_A = 1.380 \times 10^{-4}$ kg/s·m^2. Substituting into Eq. (1),

$$\left(585 + 384 + 480\right) \text{W/m}^2 = 2 \times 0.96 \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 \left(298 \text{ K}\right)^4$$

$$+2 \times 1.380 \times 10^{-4} \text{kg/s} \cdot \text{m}^2 \times 2.442 \times 10^6 \text{ J/kg}$$

$$+2 \times 20 \text{ W/m}^2 \cdot \text{K}\left(-2 \text{ K}\right)$$

$$1449 \text{W/m}^2 = \left(859 + 674 - 80\right) \text{W/m}^2 = 1453 \text{W/m}^2$$

The equality is satisfied to a good approximation, in which case

$$T_s \approx 298 \text{ K} = 25°\text{C} \qquad <$$

and $\quad n_A = 2 A_s n''_A = 2\left(1.50 \times 0.75\right) \text{m}^2 \left(1.38 \times 10^{-4} \text{ kg/s} \cdot \text{m}^2\right) = 3.11 \times 10^{-4} \text{ kg/s} \qquad <$

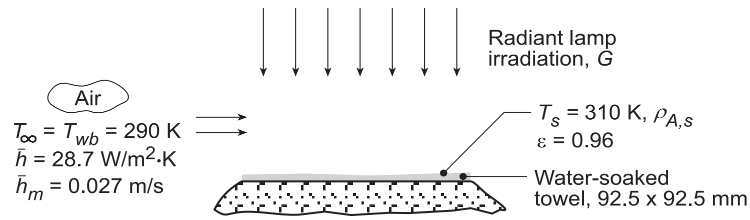
COMMENTS: Note that the temperature of the air exceeds that of the towel, in which case convection heat transfer is to the towel. Reduction of the towel's temperature below that of the air is due to the evaporative cooling effect.

PROBLEM 12.146

KNOWN: Wet paper towel experiencing forced convection heat and mass transfer and irradiation from radiant lamps. Prescribed convection parameters including wet and dry bulb temperature of the air stream, T_{wb} and T_∞, average heat and mass transfer coefficients, $\overline{h}$ and $\overline{h}_m$. Towel temperature T_s.

FIND: (a) Vapor densities, $\rho_{A,s}$ and $\rho_{A,\infty}$; the evaporation rate n_A (kg/s); and the net rate of radiation transfer to the towel q_{rad} (W); and (b) Emissive power E, the irradiation G, and the radiosity J, using the results from part (a).

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat loss from the bottom side of the towel, (3) Uniform irradiation on the towel, and (4) Water surface is diffuse, gray.

PROPERTIES: *Table A.6*, Water (T_s = 310 K): h_{fg} = 2414 kJ/kg.

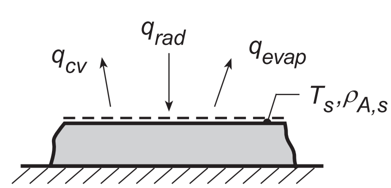
ANALYSIS: (a) Since $T_{wb} = T_\infty$, the free stream contains water vapor at its saturation condition. The water vapor at the surface is saturated since it is in equilibrium with the liquid in the towel. From Table A.6,

T (K)	v_g (m³/kg)	ρ_g (kg/m³)
$T_\infty = 290$	69.7	$\rho_{A,\infty} = 1.435 \times 10^{-2}$
$T_s = 310$	22.93	$\rho_{A,s} = 4.361 \times 10^{-2}$

Using the mass transfer convection rate equation, the water evaporation rate from the towel is

$$n_A = \overline{h}_m A_s \left(\rho_{A,s} - \rho_{A,\infty}\right) = 0.027\,\text{m/s}\left(0.0925\,\text{m}\right)^2 \left(4.361 - 1.435\right) \times 10^{-2}\,\text{kg/m}^3 = 6.76 \times 10^{-6}\,\text{kg/s} \quad <$$

To determine the net radiation heat rate q''_{rad}, perform an energy balance on the water film,



$$\dot{E}_{in} - \dot{E}_{out} = 0 \qquad q_{rad} - q_{cv} - q_{evap} = 0$$

$$q_{rad} = q_{cv} + q_{evap} = \overline{h}_s A_s \left(T_s - T_\infty\right) + n_A h_{fg}$$

and substituting numerical values find

$$q_{rad} = 28.7\,\text{W/m}^2\cdot\text{K}\left(0.0925\,\text{m}\right)^2 \left(310 - 290\right)\text{K} + 6.76 \times 10^{-6}\,\text{kg/s} \times 2414 \times 10^3\,\text{J/kg}$$

$$q_{rad} = \left(4.91 + 16.32\right)\text{W} = 21.2\,\text{W} \quad <$$

(b) The radiation parameters for the towel surface are now evaluated. The emissive power is

$$E = \varepsilon E_b\left(T_s\right) = \varepsilon\sigma T_s^4 = 0.96 \times 5.67 \times 10^{-8}\,\text{W/m}^2\cdot\text{K}^4 \left(310\,\text{K}\right)^4 = 502.7\,\text{W/m}^2 \quad <$$

To determine the irradiation G, recognize that the net radiation heat rate can be expressed as,

$$q_{rad} = \left(\alpha G - E\right) A_s \qquad 21.2\,\text{W} = \left(0.96G - 502.7\right)\text{W/m}^2 \times \left(0.0925\,\text{m}\right)^2 \quad G = 3105\ \text{W/m}^2 \quad <$$

where α = ε since the water surface is diffuse, gray. From the definition of the radiosity,

$$J = E + \rho G = \left[502.7 + \left(1 - 0.96\right) \times 3105\right]\text{W/m}^2 = 626.9\,\text{W/m}^2 \quad <$$

where ρ = 1 - α = 1 - ε.

COMMENTS: An alternate method to evaluate J is to recognize that q''_{rad} = G - J.

PROBLEM 13.1

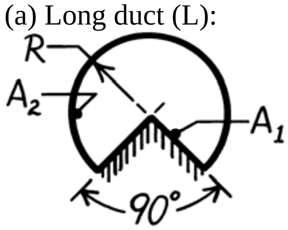
KNOWN: Various geometric shapes involving two areas A_1 and A_2.

FIND: Shape factors, F_{12} and F_{21}, for each configuration.

ASSUMPTIONS: Surfaces are diffuse.

ANALYSIS: The analysis is not to make use of tables or charts. The approach involves use of the reciprocity relation, Eq. 13.3, and summation rule, Eq. 13.4. Recognize that reciprocity applies to two surfaces; summation applies to an enclosure. Certain shape factors will be identified by inspection. Note L is the length normal to page.

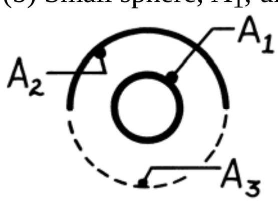
(a) Long duct (L):



By inspection, $F_{12} = 1.0$ <

By reciprocity, $F_{21} = \frac{A_1}{A_2} F_{12} = \frac{2\,RL}{(3/4)\cdot 2\pi RL} \times 1.0 = \frac{4}{3\pi} = 0.424$ <

(b) Small sphere, A_1, under concentric hemisphere, A_2, where $A_2 = 2A$

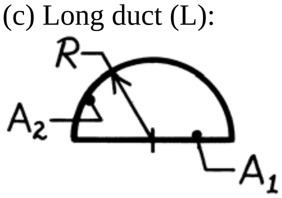


Summation rule $F_{11} + F_{12} + F_{13} = 1$

But $F_{12} = F_{13}$ by symmetry, hence $F_{12} = 0.50$ <

By reciprocity, $F_{21} = \frac{A_1}{A_2} F_{12} = \frac{A_1}{2A_1} \times 0.5 = 0.25.$ <

(c) Long duct (L):

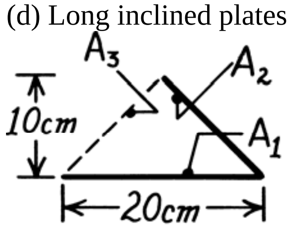


By inspection, $F_{12} = 1.0$

By reciprocity, $F_{21} = \frac{A_1}{A_2} F_{12} = \frac{2RL}{\pi RL} \times 1.0 = \frac{2}{\pi} = 0.637$ <

Summation rule, $F_{22} = 1 - F_{21} = 1 - 0.64 = 0.363.$ <

(d) Long inclined plates (L):

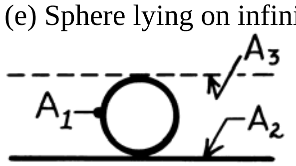


Summation rule, $F_{11} + F_{12} + F_{13} = 1$

But $F_{12} = F_{13}$ by symmetry, hence $F_{12} = 0.50$ <

By reciprocity, $F_{21} = \frac{A_1}{A_2} F_{12} = \frac{20L}{10(2)^{1/2}\,L} \times 0.5 = 0.707.$ <

(e) Sphere lying on infinite plane



Summation rule, $F_{11} + F_{12} + F_{13} = 1$

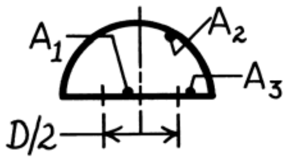
But $F_{12} = F_{13}$ by symmetry, hence $F_{12} = 0.5$ <

By reciprocity, $F_{21} = \frac{A_1}{A_2} F_{12} \to 0$ since $A_2 \to \infty$. <

Continued …

PROBLEM 13.1 (Cont.)

(f) Hemisphere over a disc of diameter D/2; find also F_{22} and F_{23}.



By inspection, $F_{12} = 1.0$ <

Summation rule for surface A_3 is written as

$F_{31} + F_{32} + F_{33} = 1$. Hence, $F_{32} = 1.0$.

By reciprocity, $$F_{23} = \frac{A_3}{A_2} F_{32}$$

$$F_{23} = \left\{ \left[\frac{\pi D^2}{4} - \frac{\pi (D/2)^2}{4} \right] / \frac{\pi D^2}{2} \right\} 1.0 = 0.375.$$

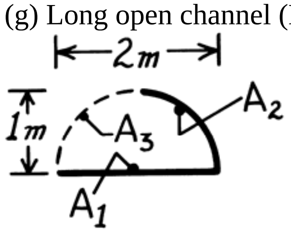
By reciprocity, $$F_{21} = \frac{A_1}{A_2} F_{12} = \left\{ \frac{\pi}{4} \left[\frac{D}{2} \right]^2 / \frac{\pi D^2}{2} \right\} \times 1.0 = 0.125.$$ <

Summation rule for A_2, $$F_{21} + F_{22} + F_{23} = 1 \text{ or}$$

$$F_{22} = 1 - F_{21} - F_{23} = 1 - 0.125 - 0.375 = 0.5.$$ <

Note that by inspection you can deduce $F_{22} = 0.5$

(g) Long open channel (L):



Summation rule for A_1

$F_{11} + F_{12} + F_{13} = 0$

but $F_{12} = F_{13}$ by symmetry, hence $F_{12} = 0.50$. <

By reciprocity, $$F_{21} = \frac{A_1}{A_2} F_{12} = \frac{2 \times L}{(2\pi 1)/4 \times L} = \frac{4}{\pi} \times 0.50 = 0.637.$$

COMMENTS: (1) Note that the summation rule is applied to an enclosure. To complete the enclosure, it was necessary in several cases to define a third surface which was shown by dashed lines.

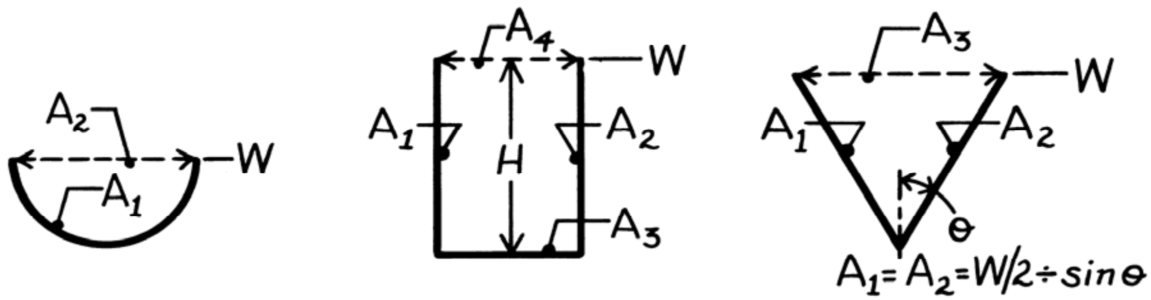
(2) Recognize that the solutions follow a systematic procedure; in many instances it is possible to deduce a shape factor by inspection.

PROBLEM 13.2

KNOWN: Geometry of semi-circular, rectangular and V grooves.

FIND: (a) View factors of grooves with respect to surroundings, (b) View factor for sides of V groove, (c) View factor for sides of rectangular groove.

SCHEMATIC:



ASSUMPTIONS: (1) Diffuse surfaces, (2) Negligible end effects, “long grooves”.

ANALYSIS: (a) Consider a unit length of each groove and represent the surroundings by a hypothetical surface (dashed line).

Semi-Circular Groove:

$$F_{21} = 1; \qquad F_{12} = \frac{A_2}{A_1} F_{21} = \frac{W}{(\pi W/2)} \times 1$$

$$F_{12} = 2/\pi. \qquad <$$

Rectangular Groove:

$$F_{4(1,2,3)} = 1; \qquad F_{(1,2,3)4} = \frac{A_4}{A_1 + A_2 + A_3} F_{4(1,2,3)} = \frac{W}{H + W + H} \times 1$$

$$F_{(1,2,3)4} = W/(W + 2H). \qquad <$$

V Groove:

$$F_{3(1,2)} = 1; \qquad F_{(1,2)3} = \frac{A_3}{A_1 + A_2} F_{3(1,2)} = \frac{W}{\frac{W/2}{\sin\theta} + \frac{W/2}{\sin\theta}}$$

$$F_{(1,2)3} = \sin\theta.$$

(b) From Eqs. 13.3 and 13.4, $F_{12} = 1 - F_{13} = 1 - \frac{A_3}{A_1} F_{31}.$

From Symmetry, $F_{31} = 1/2.$

Hence, $F_{12} = 1 - \frac{W}{(W/2)/\sin\theta} \times \frac{1}{2}$ or $F_{12} = 1 - \sin\theta.$ <

(c) From Fig. 13.4, with X/L = H/W =2 and Y/L → ∞,

$$F_{12} \approx 0.62. \qquad <$$

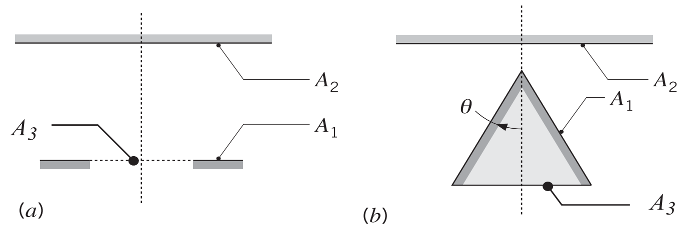
COMMENTS: (1) Note that for the V groove, $F_{13} = F_{23} = F_{(1,2)3} = \sin\theta$, (2) In part (c), Fig. 13.4 could also be used with Y/L = 2 and X/L = ∞. However, obtaining the limit of F_{ij} as X/L → ∞ from the figure is somewhat uncertain.

PROBLEM 13.3

KNOWN: Two arrangements (a) circular disk and coaxial, ring shaped disk, and (b) circular disk and coaxial, right-circular cone.

FIND: Derive expressions for the view factor F_{12} for the arrangements (a) and (b) in terms of the areas A_1 and A_2, and any appropriate hypothetical surface area, as well as the view factor for coaxial parallel disks (Table 13.2, Figure 13.5). For the disk-cone arrangement, sketch the variation of F_{12} with θ for $0 \le \theta \le \pi/2$, and explain the key features.

SCHEMATIC:



ASSUMPTIONS: Diffuse surfaces with uniform radiosities.

ANALYSIS: (a) Define the hypothetical surface A_3, a co-planar disk inside the ring of A_1. Using the additive view factor relation, Eq. 13.5,

$$A_{(1,3)}\,F_{(1,3)} = A_1\,F_{12} + A_3\,F_{32}$$

$$F_{12} = \frac{1}{A_1}\left[A_{(1,3)}\,F_{(1,3)} - A_3\,F_{32}\right] \quad <$$

where the parenthesis denote a composite surface. All the F_{ij} on the right-hand side can be evaluated using Fig. 13.5.

(b) Define the hypothetical surface A_3, the disk at the bottom of the cone. The radiant power leaving A_2 that is intercepted by A_1 can be expressed as

$$F_{21} = F_{23} \qquad (1)$$

That is, the same power also intercepts the disk at the bottom of the cone, A_3. From reciprocity,

$$A_1\,F_{12} = A_2\,F_{21} \qquad (2)$$

and using Eq. (1),

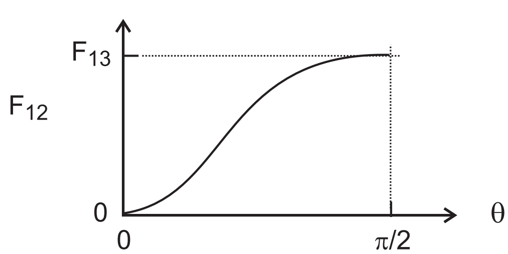
$$F_{12} = \frac{A_2}{A_1}\,F_{23} \quad <$$

The variation of F_{12} as a function of θ is shown below for the disk-cone arrangement. In the limit when $\theta \to \pi/2$, the cone approaches a disk of area A_3. That is,

$$F_{12}\left(\theta \to \pi/2\right) = F_{13}$$

When $\theta \to 0$, the cone area A_2 diminishes so that

$$F_{12}\left(\theta \to 0\right) = 0$$

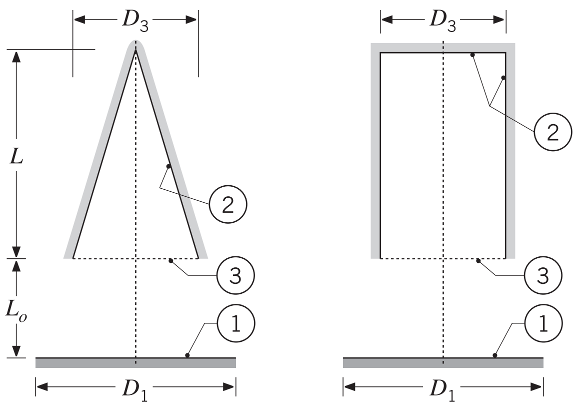


PROBLEM 13.4

KNOWN: Right circular cone and right-circular cylinder of same diameter D and length L positioned coaxially a distance L_o from the circular disk A_1; hypothetical area corresponding to the openings identified as A_3.

FIND: (a) Show that $F_{21} = (A_1/A_2) F_{13}$ and $F_{22} = 1 - (A_3/A_2)$, where F_{13} is the view factor between two, coaxial parallel disks (Table 13.2), for both arrangements, (b) Calculate F_{21} and F_{22} for $L = L_o = 50$ mm and $D_1 = D_3 = 50$ mm; compare magnitudes and explain similarities and differences, and (c) Magnitudes of F_{21} and F_{22} as L increases and all other parameters remain the same; sketch and explain key features of their variation with L.

SCHEMATIC:



(a) Right-circular cone (b) Right-circular cylinder

ASSUMPTIONS: (1) Diffuse surfaces with uniform radiosities, and (2) Inner base and lateral surfaces of the cylinder treated as a single surface, A_2.

ANALYSIS: (a) For both configurations,

$$F_{13} = F_{12} \quad (1)$$

since the radiant power leaving A_1 that is intercepted by A_3 is likewise intercepted by A_2. Applying reciprocity between A_1 and A_2,

$$A_1 F_{12} = A_2 F_{21} \quad (2)$$

Substituting from Eq. (1), into Eq. (2), solving for F_{21}, find

$$F_{21} = (A_1 / A_2)F_{12} = (A_1 / A_2)F_{13} \quad <$$

Treating the cone and cylinder as two-surface enclosures, the summation rule for A_2 is

$$F_{22} + F_{23} = 1 \quad (3)$$

Apply reciprocity between A_2 and A_3, solve Eq. (3) to find

$$F_{22} = 1 - F_{23} = 1 - (A_3 / A_2)F_{32}$$

and since $F_{32} = 1$, find

$$F_{22} = 1 - A_3 / A_2 \quad <$$

Continued …

PROBLEM 13.4 (Cont.)

(b) For the specified values of L, L_o, D_1 and D_2, the view factors are calculated and tabulated below. Relations for the areas are:

Disk-cone: $A_1 = \pi D_1^2/4 \qquad A_2 = \pi D_3/2\left(L^2 + (D_3/2)^2\right)^{1/2} \qquad A_3 = \pi D_3^2/4$

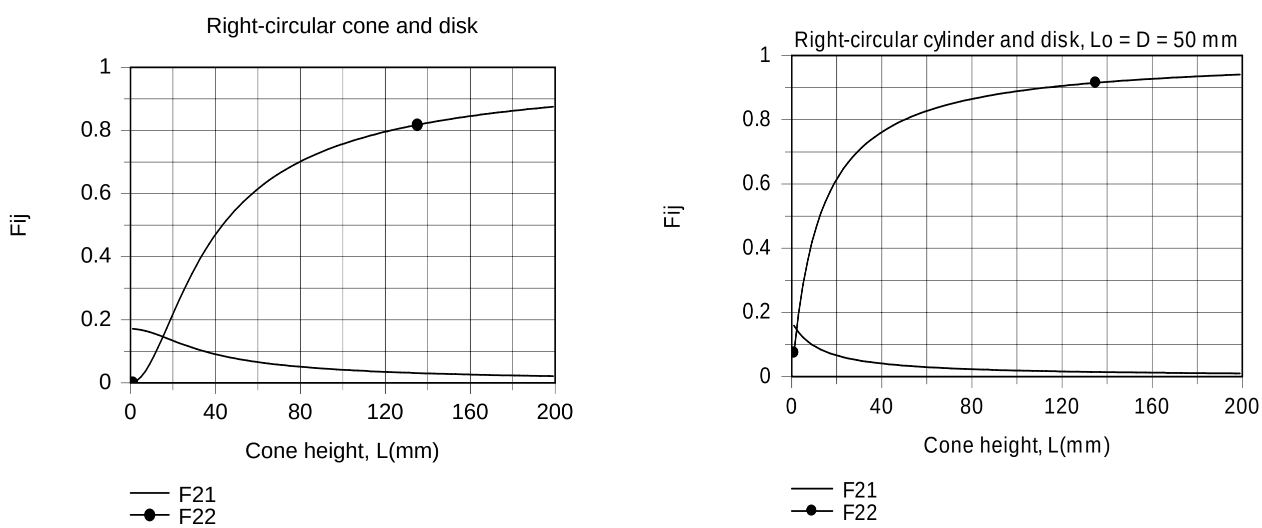
Disk-cylinder: $A_1 = \pi D_1^2/4 \qquad A_2 = \pi D_3^2/4 + \pi D_3 L \qquad A_3 = \pi D_3^2/4$

The view factor F_{13} is evaluated from Table 13.2, coaxial parallel disks (Fig. 13.5); find $F_{13} = 0.1716$.

	F_{21}	F_{22}
Disk-cone	0.0767	0.553
Disk-cylinder	0.0343	0.800

It follows that F_{21} is greater for the disk-cone (a) than for the cylinder-cone (b). That is, for (a), surface A_2 sees more of A_1 and less of itself than for (b). Notice that F_{22} is greater for (b) than (a); this is a consequence of $A_{2,b} > A_{2,a}$.

(c) Using the foregoing equations in the IHT workspace, the variation of the view factors F_{21} and F_{22} with L were calculated and are graphed below.



Note that for both configurations, when L = 0, find that $F_{21} = F_{13} = 0.1716$, the value obtained for coaxial parallel disks. As L increases, find that $F_{22} \rightarrow 1$; that is, the interior of both the cone and cylinder see mostly each other. Notice that the changes in both F_{21} and F_{22} with increasing L are greater for the disk-cylinder; F_{21} decreases while F_{22} increases.

COMMENTS: From the results of part (b), why isn't the sum of F_{21} and F_{22} equal to unity?

PROBLEM 13.5

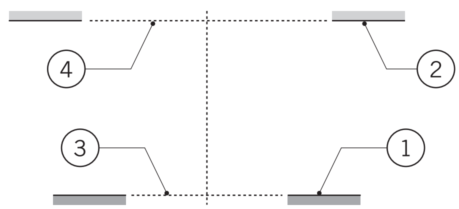
KNOWN: Two parallel, coaxial, ring-shaped disks.

FIND: Show that the view factor F_{12} can be expressed as

$$F_{12} = \frac{1}{A_1}\left\{A_{(1,3)}\, F_{(1,3)(2,4)} - A_3\, F_{3(2,4)} - A_4\left(F_{4(1,3)} - F_{43}\right)\right\}$$

where all the F_{ig} on the right-hand side of the equation can be evaluated from Figure 13.5 (see Table 13.2) for coaxial parallel disks.

SCHEMATIC:



ASSUMPTIONS: Diffuse surfaces with uniform radiosities.

ANALYSIS: Using the additive rule, Eq. 13.5, where the parenthesis denote a composite surface,

$$F_{1(2,4)} = F_{12} + F_{14}$$

$$F_{12} = F_{1(2,4)} - F_{14} \qquad (1)$$

Relation for $F_{1(2,4)}$: Using the additive rule

$$\overset{\surd}{A_{(1,3)}\, F_{(1,3)(2,4)}} = A_1\, F_{1(2,4)} + A_3\, \overset{\surd}{F_{3(2,4)}} \qquad (2)$$

where the check mark denotes a F_{ij} that can be evaluated using Fig. 13.5 for coaxial parallel disks.

Relation for F_{14}: Apply reciprocity

$$A_1\, F_{14} = A_4\, F_{41} \qquad (3)$$

and using the additive rule involving F_{41},

$$A_1\, F_{14} = A_4\left[\overset{\surd}{F_{4(1,3)}} - F_{43}\right] \qquad (4)$$

Relation for F_{12}: Substituting Eqs. (2) and (4) into Eq. (1),

$$F_{12} = \frac{1}{A_1}\left\{A_{(1,3)}\, F_{(1,3)(2,4)} - A_3\, F_{3(2,4)} - A_4\left(F_{4(1,3)} - F_{43}\right)\right\}$$ <

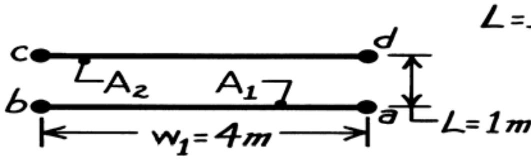
COMMENTS: (1) The F_{ij} on the right-hand side can be evaluated using Fig. 13.5.

(2) To check the validity of the result, substitute numerical values and test the behavior at special limits. For example, as A_3, $A_4 \to 0$, the expression reduces to the identity $F_{12} \equiv F_{12}$.

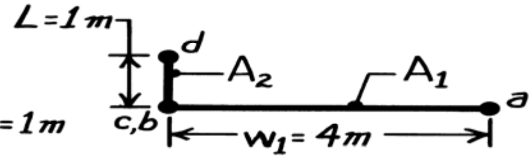
PROBLEM 13.6

KNOWN: Dimensions of four geometrical arrangements.
FIND: View factors using “crossed-strings” method; compare with appropriate graphs and analytical expressions.

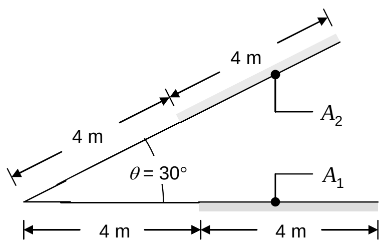
SCHEMATIC:



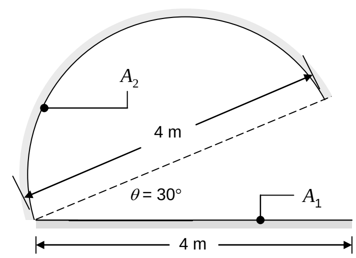
(a) Parallel plates



(b) Perpendicular plates with common edge



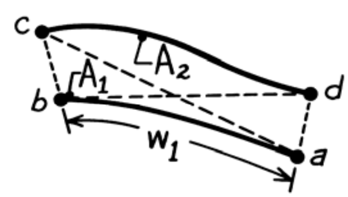
(c) Angled plates



(d) Semi-circle and plate

ASSUMPTIONS: Plates infinite in extent in direction normal to page.

ANALYSIS: The crossed-strings method is applicable to surfaces of infinite extent in one direction having an unobstructed view of one another.



$$F_{12} = (1/2w_1)\left[(ac+bd)-(ad+bc)\right].$$

(a) *Parallel plates:* From the schematic, the edge and diagonal distances are

$$ac = bd = \left(w_1^2 + L^2\right)^{1/2} \qquad bc = ad = L.$$

With w_1 as the width of the plate, find

$$F_{12} = \frac{1}{2w_1}\left[2\left(w_1^2+L^2\right)^{1/2} - 2(L)\right] = \frac{1}{2\times 4\ \text{m}}\left[2\left(4^2+1^2\right)^{1/2}\ \text{m} - 2(1\ \text{m})\right] = 0.781.$$ <

Using Fig. 13.4 with X/L = 4/1 = 4 and Y/L = ∞, find $F_{12} \approx 0.80$. Also, using the first relation of Table 13.1,

$$F_{ij} = \left\{\left[\left(W_i + W_j\right)^2 + 4\right]^{1/2} - \left[\left(W_i - W_j\right)^2 + 4\right]^{1/2}\right\} / 2\,W_i$$

where $w_i = w_j = w_1$ and W = w/L = 4/1 = 4, find

$$F_{12} = \left\{\left[(4+4)^2+4\right]^{1/2} - \left[(4-4)^2+4\right]^{1/2}\right\} / 2\times 4 = 0.781.$$

Continued...

PROBLEM 13.6 (Cont.)

(b) *Perpendicular plates* with a common edge: From the schematic, the edge and diagonal distances are

$ac = w_1$ $\qquad$ $bd = L$ $\qquad$ $ad = \left(w_1^2 + L^2\right)$ $\qquad$ $bc = 0.$

With w_1 as the width of the horizontal plates, find

$$F_{12} = \left(1/2w_1\right)\left[2\left(w_1 + L\right) - \left(\left(w_1^2 + L^2\right)^{1/2} + 0\right)\right]$$

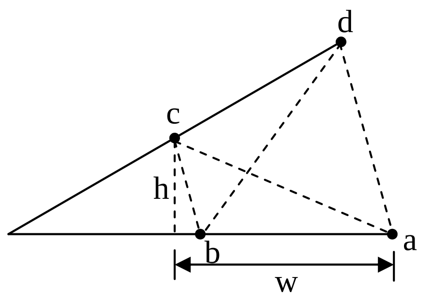
$$F_{12} = \left(1/2 \times 4\ \text{m}\right)\left[\left(4+1\right)\text{m} - \left(\left(4^2 + 1^2\right)^{1/2}\ \text{m} + 0\right)\right] = 0.110. \qquad <$$

From the third relation of Table 13.1, with $w_i = w_1 = 4$ m and $w_j = L = 1$ m, find

$$F_{ij} = \left\{1 + \left(w_j / w_i\right) - \left[1 + \left(w_j / w_i\right)^2\right]^{1/2}\right\}/2$$

$$F_{12} = \left\{1 + \left(1/4\right) - \left[1 + \left(1/4\right)^2\right]^{1/2}\right\}/2 = 0.110.$$

(c) *Plates at an angle to one another.* From the schematic below, the edge and diagonal distances can be calculated as follows:

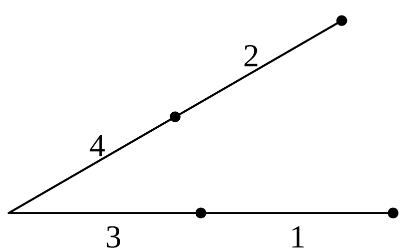


$h = 4\sin30°$, $w = 8 - 4\cos30°$, $ac = \sqrt{h^2 + w^2} = 4.96$ m
By symmetry, $bd = ac = 4.96$ m
$bc = 2(4\sin15°) = 2.07$ m
$ad = 2(8\sin15°) = 4.14$ m

We find

$$F_{12} = \left(1/8\right)\left[\left(4.96 + 4.96\right) - \left(4.14 + 2.07\right)\right] = 0.463. \qquad <$$

The same result can be found using the second and fourth view factors in Table 13.1, along with Equations 13.5 and 13.6.



From Eq. 13.5 with i = 3 and j representing the combination (24),

$F_{3\text{-}(24)} = F_{32} + F_{34}$.

Then from Table 13.1 4th entry,

$F_{3\text{-}(24)} = (w_3 + w_{24} - bd)/2w_3 = (4+8-4.96)/8 = 0.880$

Continued...

PROBLEM 13.6 (Cont.)

From Table 13.1, 2nd entry, $F_{34} = 1–\sin(30°/2) = 0.741$. Thus $F_{32} = 0.880–0.741 = 0.139$. Using Eq. 13.5 again, with i representing the combination of (13) and j representing the combination (24),

$$F_{(13)\text{-}(24)} = F_{(13)\text{-}2} + F_{(13)\text{-}4}$$

$F_{(13)\text{-}4}$ can be found using reciprocity, namely $F_{(13)\text{-}4} = A_4F_{4\text{-}(13)}/A_{13} = A_4F_{3\text{-}(24)}/A_{13} = 0.5F_{3\text{-}(24)} = 0.440$. Then from Table 13.1, 2nd entry, it can be seen that $F_{(13)\text{-}(24)} = F_{34} = 0.741$. Thus,

$$F_{(13)\text{-}2} = F_{(13)\text{-}(24)} – F_{(13)\text{-}4} = 0.301$$

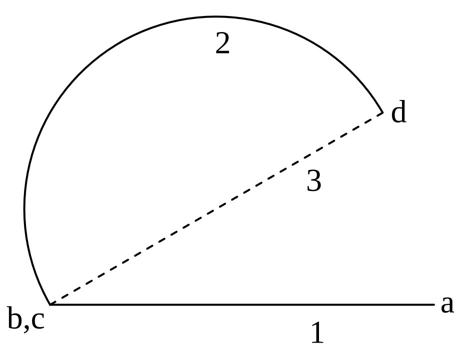
Finally, from Eq. 13.6, with i = 2 and j representing the combination (13),

$$A_{13}F_{(13)\text{-}2} = A_1F_{12} + A_3F_{32}$$

Therefore,

$$F_{12} = (A_{13}F_{(13)\text{-}2} – A_3F_{32})/A_1 = (8×0.301 – 4×0.139)/4 = 0.463.$$

(d) *Semi-circle and plate at angle to each other.*



The edge and diagonal distances are

ac = 8 m, bc = 0 m, ad = 2(8sin15°) = 4.14 m, bd = 8 m

We find

$$F_{12} = (1/16)\left[(8+8)-(4.14+0)\right] = 0.741.$$

<

The same result can be found using view factor relations in Table 13.1. Since radiation traveling from 1 to 2 must pass through 3, $F_{12} = F_{13}$. From Table 13.1, 2nd entry,

$$F_{12} = 1–\sin(30°/2) = 0.741$$

COMMENTS: (1) Hottel's method can be a significant time-saver. (2) The application of Hottel's method to cases where the view is obstructed between the two surfaces is discussed in Siegel, R., J.R. Howell, and M.P. Menguc, *Thermal Radiation Heat Transfer*, 5th ed., CRC Press, Taylor & Francis Group, New York, 2010 and in Modest, M.F., *Radiative Heat Transfer*, 2nd ed., Academic Press, San Diego, 2003.

PROBLEM 13.7

KNOWN: Right-circular cylinder of diameter D, length L and the areas A_1, A_2, and A_3 representing the base, inner lateral and top surfaces, respectively.

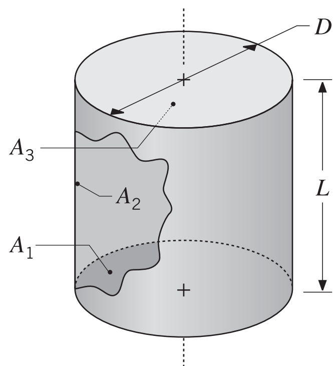
FIND: (a) Show that the view factor between the base of the cylinder and the inner lateral surface has the form

$$F_{12} = 2\,H\left[\left(1+H^2\right)^{1/2} - H\right]$$

where H = L/D, and (b) Show that the view factor for the inner lateral surface to itself has the form

$$F_{22} = 1 + H - \left(1+H^2\right)^{1/2}$$

SCHEMATIC:



ASSUMPTIONS: Diffuse surfaces with uniform radiosities.

ANALYSIS: (a) *Relation for F_{12}, base-to-inner lateral surface*. Apply the summation rule to A_1, noting that $F_{11} = 0$

$$F_{11} + F_{12} + F_{13} = 1$$

$$F_{12} = 1 - F_{13} \qquad (1)$$

From Table 13.2, Fig. 13.5, with i = 1, *j* = 3,

$$F_{13} = \frac{1}{2}\left\{S - \left[S^2 - 4\left(D_3 / D_1\right)^2\right]^{1/2}\right\} \qquad (2)$$

$$S = 1 + \frac{1+R_3^2}{R_1^2} = \frac{1}{R^2} + 2 = 4\,H^2 + 2 \qquad (3)$$

where $R_1 = R_3 = R = D/2L$ and H = L/D. Combining Eqs. (2) and (3) with Eq. (1), find after some manipulation

Continued …

PROBLEM 13.7 (Cont.)

$$F_{12} = 1 - \frac{1}{2}\left\{4\,H^2 + 2 - \left[\left(4\,H^2 + 2\right)^2 - 4\right]^{1/2}\right\}$$

$$F_{12} = 2\,H\left[\left(1 + H^2\right)^{1/2} - H\right] \tag{4}$$

(b) *Relation for F_{22}, inner lateral surface*. Apply summation rule on A_2, recognizing that $F_{23} = F_{21}$,

$$F_{21} + F_{22} + F_{23} = 1 \qquad\qquad F_{22} = 1 - 2\,F_{21} \tag{5}$$

Apply reciprocity between A_1 and A_2,

$$F_{21} = \left(A_1 / A_2\right) F_{12} \tag{6}$$

and substituting into Eq. (5), and using area expressions

$$F_{22} = 1 - 2\,\frac{A_1}{A_2}\,F_{12} = 1 - 2\,\frac{D}{4\,L}F_{12} = 1 - \frac{1}{2\,H}F_{12} \tag{7}$$

where $A_1 = \pi D^2/4$ and $A_2 = \pi DL$.

Substituting from Eq. (4) for F_{12}, find

$$F_{22} = 1 - \frac{1}{2\,H}2\,H\left[\left(1 + H^2\right)^{1/2} - H\right] = 1 + H - \left(1 + H^2\right)^{1/2}$$ <

PROBLEM 13.8

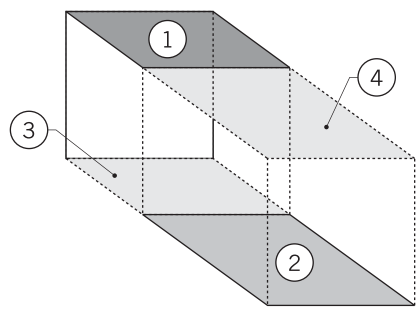
KNOWN: Arrangement of plane parallel rectangles.

FIND: Show that the view factor between A_1 and A_2 can be expressed as

$$F_{12} = \frac{1}{2\,A_1}\left[A_{(1,4)}\,F_{(1,4)(2,3)} - A_1\,F_{13} - A_4\,F_{42}\right]$$

where all F_{ij} on the right-hand side of the equation can be evaluated from Fig. 13.4 (see Table 13.2) for aligned parallel rectangles.

SCHEMATIC:



ASSUMPTIONS: Diffuse surfaces with uniform radiosity.

ANALYSIS: Using the additive rule where the parenthesis denote a composite surface,

$$A_{(1,4)}\,F^*_{(1,4)(2,3)} = A_1\,F^*_{13} + A_1\,F_{12} + A_4\,F_{43} + A_4\,F^*_{42} \qquad (1)$$

where the asterisk (*) denotes that the F_{ij} can be evaluated using the relation of Figure 13.4. Now, find suitable relation for F_{43}. By symmetry,

$$F_{43} = F_{21} \qquad (2)$$

and from reciprocity between A_1 and A_2,

$$F_{21} = \frac{A_1}{A_2}F_{12} \qquad (3)$$

Multiply Eq. (2) by A_4 and substitute Eq. (3), with $A_4 = A_2$,

$$A_4\,F_{43} = A_4\,F_{21} = A_4\,\frac{A_1}{A_2}F_{12} = A_1\,F_{12} \qquad (4)$$

Substituting for $A_4\,F_{43}$ from Eq. (4) into Eq. (1), and rearranging,

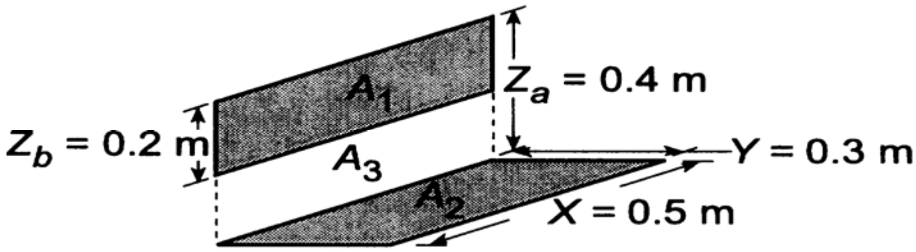
$$F_{12} = \frac{1}{2\,A_1}\left[A_{(1,4)}\,F^*_{(1,4)(2,3)} - A_1\,F^*_{13} - A_4\,F^*_{42}\right]$$ <

PROBLEM 13.9

KNOWN: Two perpendicular rectangles not having a common edge.

FIND: (a) Shape factor, F_{12}, and (b) Compute and plot F_{12} as a function of Z_b for $0.05 \le Z_b \le 0.4$ m; compare results with the view factor obtained from the two-dimensional relation for perpendicular plates with a common edge, Table 13.1.

SCHEMATIC:



ASSUMPTIONS: (1) All surfaces are diffuse, (2) Plane formed by $A_1 + A_3$ is perpendicular to plane of A_2.

ANALYSIS: (a) Introducing the hypothetical surface A_3, we can write

$$F_{2(3,1)} = F_{23} + F_{21}. \qquad (1)$$

Using Fig. 13.6, applicable to perpendicular rectangles with a common edge, find

$$F_{23} = 0.19: \quad \text{with } Y = 0.3, \quad X = 0.5, \quad Z = Z_a - Z_b = 0.2, \text{ and } \frac{Y}{X} = \frac{0.3}{0.5} = 0.6, \quad \frac{Z}{X} = \frac{0.2}{0.5} = 0.4$$

$$F_{2(3,1)} = 0.25: \quad \text{with } Y = 0.3, \ X = 0.5, \ Z_a = 0.4, \text{ and } \frac{Y}{X} = \frac{0.3}{0.5} = 0.6, \quad \frac{Z}{X} = \frac{0.4}{0.5} = 0.8$$

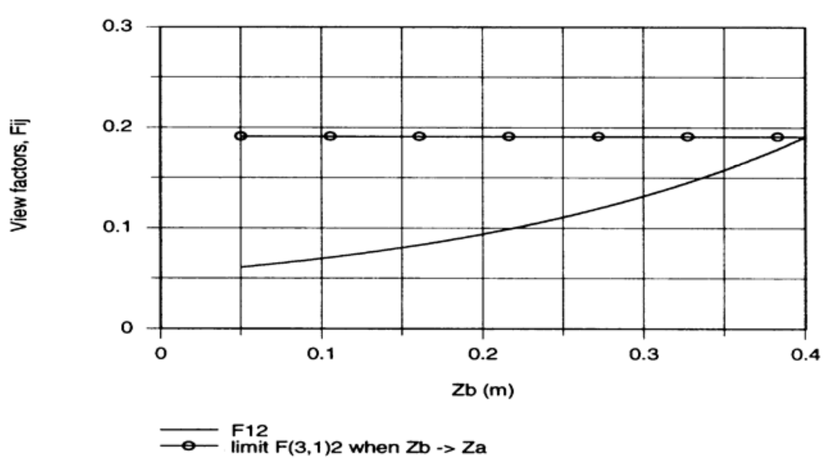
Hence from Eq. (1)

$$F_{21} = F_{2(3.1)} - F_{23} = 0.25 - 0.19 = 0.06$$

By reciprocity,

$$F_{12} = \frac{A_2}{A_1} F_{21} = \frac{0.5 \times 0.3\,\text{m}^2}{0.5 \times 0.2\,\text{m}^2} \times 0.06 = 0.09 \qquad (2)$$ <

(b) Using the *IHT Tool – View Factors* for *Perpendicular Rectangles with a Common Edge* and Eqs. (1,2) above, F_{12} was computed as a function of Z_b. Also shown on the plot below is the view factor $F_{(3,1)2}$ for the limiting case $Z_b \to Z_a$.

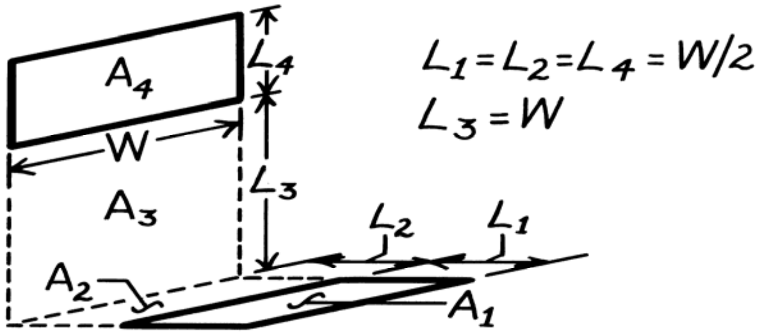


PROBLEM 13.10

KNOWN: Arrangement of perpendicular surfaces without a common edge.

FIND: (a) A relation for the view factor F_{14} and (b) The value of F_{14} for prescribed dimensions.

SCHEMATIC:



ASSUMPTIONS: (1) Diffuse surfaces.

ANALYSIS: (a) To determine F_{14}, it is convenient to define the hypothetical surfaces A_2 and A_3. From Eq. 13.6,

$$(A_1 + A_2) F_{(1,2)(3,4)} = A_1 F_{1(3,4)} + A_2 F_{2(3,4)}$$

where $F_{(1,2)(3,4)}$ and $F_{2(3,4)}$ may be obtained from Fig. 13.6. Substituting for $A_1 F_{1(3,4)}$ from Eq. 13.5 and combining expressions, find

$$A_1 F_{1(3,4)} = A_1 F_{13} + A_1 F_{14}$$

$$F_{14} = \frac{1}{A_1}\left[(A_1 + A_2) F_{(1,2)(3,4)} - A_1 F_{13} - A_2 F_{2(3,4)}\right].$$

Substituting for $A_1 F_{13}$ from Eq. 13.6, which may be expressed as

$$(A_1 + A_2) F_{(1,2)3} = A_1 F_{13} + A_2 F_{23}.$$

The desired relation is then

$$F_{14} = \frac{1}{A_1}\left[(A_1 + A_2) F_{(1,2)(3,4)} + A_2 F_{23} - (A_1 + A_2) F_{(1,2)3} - A_2 F_{2(3,4)}\right].$$ <

(b) For the prescribed dimensions and using Fig. 13.6, find these view factors:

Surfaces (1,2)(3,4) $\quad (Y/X) = \frac{L_1 + L_2}{W} = 1, \quad (Z/X) = \frac{L_3 + L_4}{W} = 1.45, \quad F_{(1,2)(3,4)} = 0.22$

Surfaces 23 $\quad (Y/X) = \frac{L_2}{W} = 0.5, \quad (Z/X) = \frac{L_3}{W} = 1, \quad F_{23} = 0.28$

Surfaces (1,2)3 $\quad (Y/X) = \frac{L_1 + L_2}{W} = 1, \quad (Z/X) = \frac{L_3}{W} = 1, \quad F_{(1,2)3} = 0.20$

Surfaces 2(3,4) $\quad (Y/X) = \frac{L_2}{W} = 0.5, \quad (Z/X) = \frac{L_3 + L_4}{W} = 1.5, \quad F_{2(3,4)} = 0.31$

Using the relation above, find

$$F_{14} = \frac{1}{(WL_1)}\left[(WL_1 + WL_2)0.22 + (WL_2)0.28 - (WL_1 + WL_2)0.20 - (WL_2)0.31\right]$$

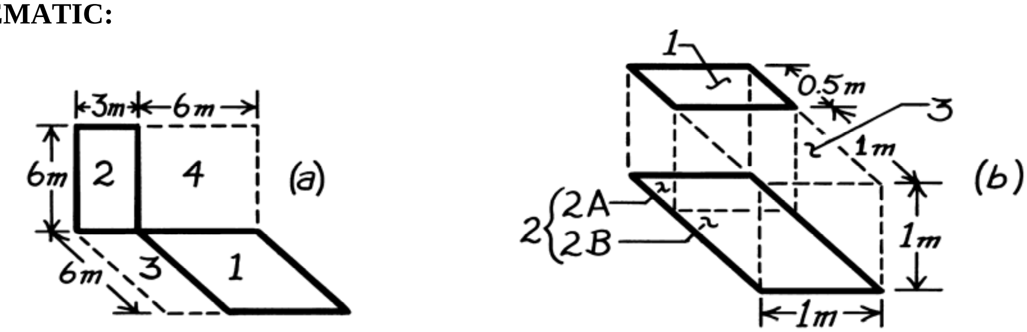
$$F_{14} = [2(0.22) + 1(0.28) - 2(0.20) - 1(0.31)] = 0.01.$$ <

PROBLEM 13.11

KNOWN: Arrangements of rectangles.

FIND: The shape factors, F_{12}.

SCHEMATIC:



ASSUMPTIONS: (1) Diffuse surface behavior.

ANALYSIS: (a) Define the hypothetical surfaces shown in the sketch as A_3 and A_4. From the additive view factor rule, Eq. 13.6, we can write

$$A_{(1,3)}\overset{\surd}{F}_{(1,3)(2,4)} = A_1F_{12} + A_1\overset{\surd}{F}_{14} + A_3\overset{\surd}{F}_{32} + A_3F_{34} \quad (1)$$

Note carefully which factors can be evaluated from Fig. 13.6 for perpendicular rectangles with a common edge. (See √). It follows from symmetry that

$$A_1F_{12} = A_4F_{43}. \quad (2)$$

Using reciprocity,

$$A_4F_{43} = A_3F_{34}, \qquad \text{then} \qquad A_1F_{12} = A_3F_{34}. \quad (3)$$

Solving Eq. (1) for F_{12} and substituting Eq. (3) for A_3F_{34}, find that

$$F_{12} = \frac{1}{2A_1}\left[A_{(1,3)}F_{(1,3)(2,4)} - A_1F_{14} - A_3F_{32}\right]. \quad (4)$$

Evaluate the view factors from Fig. 13.6:

F_{ij}	Y/X	Z/X	F_{ij}
(1,3) (2,4)	$\frac{6}{9} = 0.67$	$\frac{6}{9} = 0.67$	0.23
14	$\frac{6}{6} = 1$	$\frac{6}{6} = 1$	0.20
32	$\frac{6}{3} = 2$	$\frac{6}{3} = 2$	0.14

Substituting numerical values into Eq. (4) yields

$$F_{12} = \frac{1}{2\times(6\times6)\,m^2}\left[(6\times9)\,m^2\times0.23 - (6\times6)\,m^2\times0.20 - (6\times3)\,m^2\times0.14\right]$$

$$F_{12} = 0.038. \qquad <$$

Continued …

PROBLEM 13.11 (Cont.)

(b) Define the hypothetical surface A_3 and divide A_2 into two sections, A_{2A} and A_{2B}. From the additive view factor rule, Eq. 13.6, we can write

$$A_{1,3}\overset{\surd}{F}_{(1,3)2} = A_1F_{12} + A_3F_{3(2A)} + A_3\overset{\surd}{F}_{3(2B)}. \qquad (5)$$

Note that the view factors checked can be evaluated from Fig. 13.4 for aligned, parallel rectangles. To evaluate $F_{3(2A)}$, we first recognize a relationship involving $F_{(24)1}$ will eventually be required. Using the additive rule again,

$$A_{2A}F_{(2A)(1,3)} = A_{2A}\overset{\surd}{F}_{(2A)1} + A_{2A}F_{(2A)3}. \qquad (6)$$

Note that from symmetry considerations,

$$A_{2A}F_{(2A)(1,3)} = A_1F_{12} \qquad (7)$$

and using reciprocity, Eq. 13.3, note that

$$A_{2A}F_{2A3} = A_3F_{3(2A)}. \qquad (8)$$

Substituting for $A_3F_{3(2A)}$ from Eq. (8), Eq. (5) becomes

$$A_{(1,3)}\overset{\surd}{F}_{(1,3)2} = A_1F_{12} + A_{2A}F_{(2A)3} + A_3\overset{\surd}{F}_{3(2B)}.$$

Substituting for $A_{2A}\,F_{(2A)3}$ from Eq. (6) using also Eq. (7) for $A_{2A}\,F_{(2A)(1,3)}$ find that

$$A_{(1,3)}\overset{\surd}{F}_{(1,3)2} = A_1F_{12} + \left(A_1F_{12} - A_{2A}\overset{\surd}{F}_{(2A)1}\right) + A_3\overset{\surd}{F}_{3(2B)} \qquad (9)$$

and solving for F_{12}, noting that $A_1 = A_{2A}$ and $A_{(1,3)} = A_2$

$$F_{12} = \frac{1}{2A_1}\left[A_2\overset{\surd}{F}_{(1,3)2} + A_{2A}\overset{\surd}{F}_{(2A)1} - A_3\overset{\surd}{F}_{3(2B)}\right]. \qquad (10)$$

Evaluate the view factors from Fig. 13.4:

F_{ij}	X/L	Y/L	F_{ij}
(1,3) 2	$\frac{1}{1}=1$	$\frac{1.5}{1}=1.5$	0.25
(2A)1	$\frac{1}{1}=1$	$\frac{0.5}{1}=0.5$	0.11
3(2B)	$\frac{1}{1}=1$	$\frac{1}{1}=1$	0.20

Substituting numerical values into Eq. (10) yields

$$F_{12} = \frac{1}{2(0.5\times1)\,m^2}\left[(1.5\times1.0)\,m^2\times0.25 + (0.5\times1)\,m^2\times0.11 - (1\times1)\,m^2\times0.20\right]$$

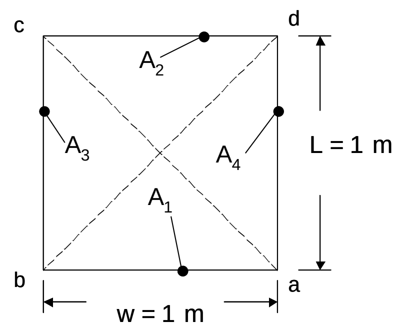
$$F_{12} = 0.23.$$ <

PROBLEM 13.12

KNOWN: Parallel plate geometry.

FIND: (a) The view factor F_{12} using the results of Figure 13.4, (b) F_{12} using the first case of Table 13.1, (c) F_{12} using Hottel's crossed-string method, (d) F_{12} using the second case of Table 13.1, (e) F_{12} for w = L = 2 m using Figure 13.4.

SCHEMATIC:



ASSUMPTIONS: (a) Two-dimensional system, (b) Diffuse, gray surfaces.

ANALYSIS: (a) Using Figure 13.4, X/L = 1m/ 1m = 1, Y/L → ∞, $F_{12} = 0.41$ <

(b) For case 1 of Table 13.1, $W_1 = W_2 = 1\text{m}/1\text{m} = 1$ and

$$F_{12} = \frac{\left[2^2+4\right]^{1/2} - 4^{1/2}}{2} = 0.414$$ <

(c) From Problem 13.6,

$$F_{12} = \frac{1}{2\times 1\text{ m}}\left[2\times\frac{1\text{ m}}{\cos(45°)} - 2\text{ m}\right] = 0.414$$ <

(d) For case 2 of Table 13.1, w = 1m, $\alpha = 90°$, $F_{13} = 1 - \sin(45°) = 0.293$. By symmetry, F_{14} = 0.293 and by the summation rule,

$$F_{12} = 1 - F_{13} - F_{14} = 1 - 2 \times 0.293 = 0.414$$ <

(e) Using Figure 13.4, X/L = 2m/2m = 1, Y/L → ∞, $F_{12} = 0.41$ <

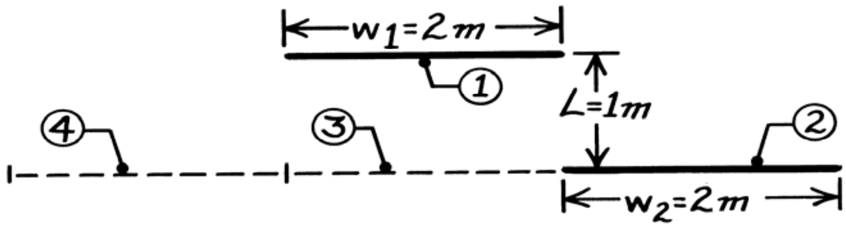
COMMENTS: For most radiation heat transfer problems involving enclosures composed of diffuse gray surfaces, there are many alternative approaches that may be used to determine the appropriate view factors. It is highly unlikely that the view factors will be evaluated the same way by different individuals when solving a radiation heat transfer problem.

PROBLEM 13.13

KNOWN: Parallel plates of infinite extent (1,2) having aligned opposite edges.

FIND: View factor F_{12} by using (a) appropriate view factor relations and results for opposing parallel plates and (b) Hottel's string method described in Problem 13.6.

SCHEMATIC:



ASSUMPTIONS: (1) Parallel planes of infinite extent normal to page and (2) Diffuse surfaces with uniform radiosity.

ANALYSIS: From symmetry consideration ($F_{12} = F_{14}$) and Eq. 13.5, it follows that

$$F_{12} = (1/2)\left[F_{1(2,3,4)} - F_{13}\right]$$

where A_3 and A_4 have been defined for convenience in the analysis. Each of these view factors can be evaluated by the first relation of Table 13.1 for parallel plates with midlines connected perpendicularly.

F_{13}: $\quad W_1 = w_1/L = 2 \qquad W_2 = w_2/L = 2$

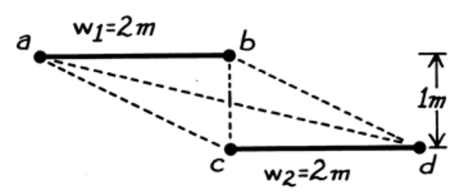
$$F_{13} = \frac{\left[(W_1+W_2)^2+4\right]^{1/2} - \left[(W_2-W_1)^2+4\right]^{1/2}}{2W_1} = \frac{\left[(2+2)^2+4\right]^{1/2} - \left[(2-2)^2+4\right]^{1/2}}{2\times 2} = 0.618$$

$F_{1(2,3,4)}$: $\quad W_1 = w_1/L = 2 \qquad W_{(2,3,4)} = 3w_2/L = 6$

$$F_{1(2,3,4)} = \frac{\left[(2+6)^2+4\right]^{1/2} - \left[(6-2)^2+4\right]^{1/2}}{2\times 2} = 0.944.$$

Hence, find $\quad F_{12} = (1/2)[0.944 - 0.618] = 0.163.$ <

(b) Using Hottel's string method,



$$F_{12} = (1/2w_1)\left[(ac+bd)-(ad+bc)\right]$$

$$ac = \left(1+4^2\right)^{1/2} = 4.123$$

$$bd = 1$$

$$ad = \left(1^2+2^2\right)^{1/2} = 2.236$$

$$bc = ad = 2.236$$

and substituting numerical values find

$$F_{12} = (1/2\times 2)\left[(4.123+1)-(2.236+2.236)\right] = 0.163.$$ <

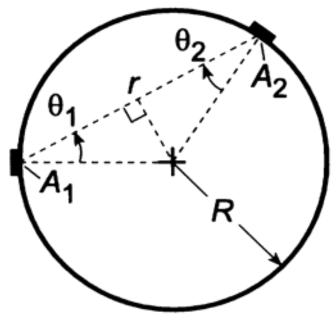
COMMENTS: Remember that Hottel's string method is applicable only to surfaces that are of infinite extent in one direction and have unobstructed views of one another.

PROBLEM 13.14

KNOWN: Two small diffuse surfaces, A_1 and A_2, on the inside of a spherical enclosure of radius R.

FIND: Expression for the view factor F_{12} in terms of A_2 and R by two methods: (a) Beginning with the expression $F_{ij} = q_{ij}/A_i J_i$ and (b) Using the view factor integral, Eq. 13.1.

SCHEMATIC:



ASSUMPTIONS: (1) Surfaces A_1 and A_2 are diffuse and (2) A_1 and $A_2 << R^2$.

ANALYSIS: (a) The view factor is defined as the fraction of radiation leaving A_i which is intercepted by surface j and, from Section 13.1.1, can be expressed as

$$F_{ij} = \frac{q_{ij}}{A_i J_i} \qquad (1)$$

From Eq. 12.11, the radiation leaving intercepted by A_1 and A_2 on the spherical surface is

$$q_{1\to 2} = (J_1/\pi)\cdot A_1 \cos\theta_1 \cdot \omega_{2-1} \qquad (2)$$

where the solid angle A_2 subtends with respect to A_1 is

$$\omega_{2-1} = \frac{A_{2,n}}{r^2} = \frac{A_2 \cos\theta_2}{r^2} \qquad (3)$$

From the schematic above,

$$\cos\theta_1 = \cos\theta_2 \qquad r = 2R\cos\theta_1 \qquad (4,5)$$

Hence, the view factor is

$$F_{ij} = \frac{(J_1/\pi) A_1 \cos\theta_1 \cdot A_2 \cos\theta_2 / 4R^2 \cos\theta_1}{A_1 J_1} = \frac{A_2}{4\pi R^2} \qquad <$$

(b) The view factor integral, Eq. 13.1, for the small areas A_1 and A_2 is

$$F_{12} = \frac{1}{A_1}\int_{A_1}\int_{A_2} \frac{\cos\theta_1 \cos\theta_2}{\pi r^2} dA_1 dA_2 = \frac{\cos\theta_1 \cos\theta_2 A_2}{\pi r^2}$$

and from Eqs. (4,5) above,

$$F_{12} = \frac{A_2}{4\pi R^2} \qquad <$$

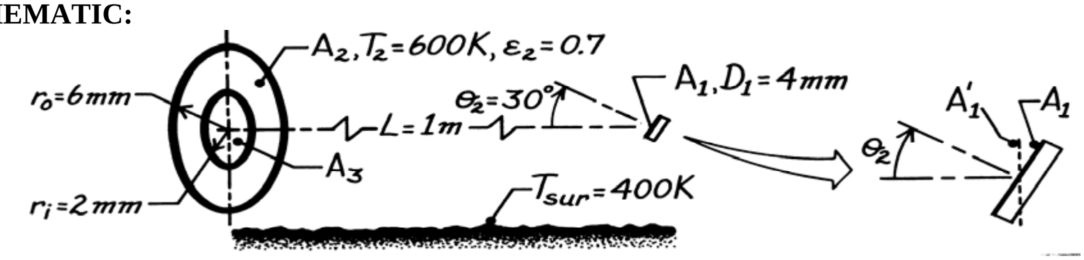
COMMENTS: Recognize the importance of the second assumption. We require that A_1, A_2, $<< R^2$ so that the areas can be considered as of differential extent, $A_1 = dA_1$, and $A_2 = dA_2$. It may be shown, however, that due to the unique geometry of a sphere, $F_{12} = A_2/(4\pi R^2)$ even when the areas are not small. See M.F. Modest, Radiation Heat Transfer, 2nd edition, Academic Press, San Diego, 2003.

PROBLEM 13.15

KNOWN: Disk A_1, located coaxially, but tilted 30° of the normal, from the diffuse-gray, ring-shaped disk A_2. Surroundings at 400 K.

FIND: Irradiation on A_1, G_1, due to the radiation from A_2.

SCHEMATIC:



ASSUMPTIONS: (1) A_2 is diffuse-gray surface, (2) Uniform radiosity over A_2, (3) The surroundings are large with respect to A_1 and A_2.

ANALYSIS: The irradiation on A_1 is

$$G_1 = q_{21}/A_1 = \left(F_{21} \cdot J_2 A_2\right)/A_1 \tag{1}$$

where J_2 is the radiosity from A_2 evaluated as

$$J_2 = \varepsilon_2 E_{b,2} + \rho_2 G_2 = \varepsilon_2 \sigma T_2^4 + \left(1-\varepsilon_2\right)\sigma T_{sur}^4$$

$$J_2 = 0.7 \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 \left(600 \text{ K}\right)^4 + \left(1-0.7\right)5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 \left(400 \text{ K}\right)^4$$

$$J_2 = 5144 + 436 = 5580 \text{ W/m}^2. \tag{2}$$

Using the view factor relation of Eq. 13.8, evaluate view factors between A_1', the normal projection of A_1, and A_3 as

$$F_{1'3} = \frac{D_i^2}{D_i^2 + 4L^2} = \frac{\left(0.004 \text{ m}\right)^2}{\left(0.004 \text{ m}\right)^2 + 4\left(1 \text{ m}\right)^2} = 4.00 \times 10^{-6}$$

and between A_1' and ($A_2 + A_3$) as

$$F_{1'(23)} = \frac{D_o^2}{D_o^2 + 4L^2} = \frac{\left(0.012\right)^2}{\left(0.012\right)^2 + 4\left(1 \text{ m}\right)^2} = 3.60 \times 10^{-5}$$

giving $$F_{1'2} = F_{1'(23)} - F_{1'3} = 3.60 \times 10^{-5} - 4.00 \times 10^{-6} = 3.20 \times 10^{-5}.$$

From the reciprocity relation it follows that

$$F_{21'} = A_1' F_{1'2}/A_2 = \left(A_1 \cos\theta_1 / A_2\right) F_{1'2} = 3.20 \times 10^{-5} \cos\theta_1 \left(A_1/A_2\right). \tag{3}$$

By inspection we note that all the radiation striking A_1' will also intercept A_1; that is

$$F_{21} = F_{21'}. \tag{4}$$

Hence, substituting for Eqs. (3) and (4) for F_{21} into Eq. (1), find

$$G_1 = \left(3.20 \times 10^{-5} \cos\theta_1 \left(A_1/A_2\right) \times J_2 \times A_2\right)/A_1 = 3.20 \times 10^{-5} \cos\theta_1 \cdot J_2 \tag{5}$$

$$G_1 = 3.20 \times 10^{-5} \cos\left(30°\right) \times 5580 \text{ W/m}^2 = 27.7 \ \mu\text{W/m}^2.$$ <

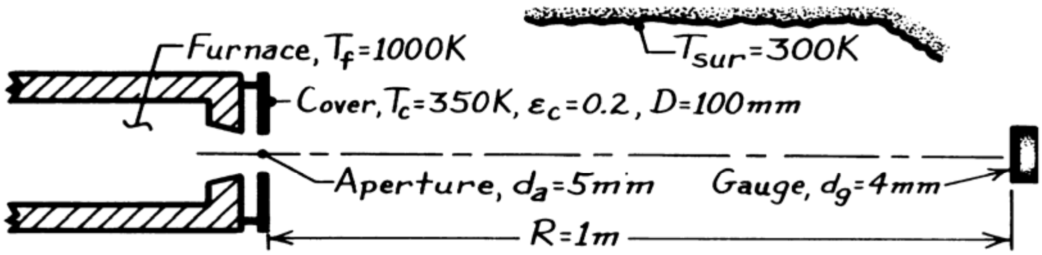
COMMENTS: (1) Note from Eq. (5) that $G_1 \sim \cos\theta_1$ such that G_1 is a maximum when A_1 is normal to disk A_2.

PROBLEM 13.16

KNOWN: Heat flux gage positioned normal to a blackbody furnace. Cover of furnace is at 350 K while surroundings are at 300 K.

FIND: (a) Irradiation on gage, G_g, considering only emission from the furnace aperture and (b) Irradiation considering radiation from the cover *and* aperture.

SCHEMATIC:



ASSUMPTIONS: (1) Furnace aperture approximates blackbody, (2) Shield is opaque, diffuse and gray with uniform temperature, (3) Shield has uniform radiosity, (4) $A_g << R^2$, so that $\omega_{g\text{-}f} = A_g/R^2$, (5) Surroundings are large, uniform at 300 K.

ANALYSIS: (a) The irradiation on the gage due *only* to aperture emission is

$$G_g = q_{f-g}/A_g = \left(I_{e,f}\cdot A_f\cos\theta_f\cdot\omega_{g-f}\right)/A_g = \frac{\sigma T_f^4}{\pi}\cdot A_f\cdot\frac{A_g}{R^2}/A_g$$

$$G_g = \frac{\sigma T_f^4}{\pi R^2}A_f = \frac{5.67\times10^{-8}\,W/m^2\cdot K^4\,(1000\ K)^4}{\pi(1\ m)^2}\times(\pi/4)(0.005\ m)^2 = 354.4\ mW/m^2. \quad <$$

(b) The irradiation on the gage due to radiation from the *aperture* (a) and *cover (c)* is

$$G_g = G_{g,a} + \frac{F_{c-g}\cdot J_c A_c}{A_g}$$

where $F_{c\text{-}g}$ and the cover radiosity are

$$F_{c-g} = F_{g-c}\left(A_g/A_c\right) \approx \frac{D_c^2}{4R^2 + D_c^2}\cdot\frac{A_g}{A_c} \qquad\qquad J_c = \varepsilon_c E_b(T_c) + \rho_c G_c$$

but $G_c = E_b(T_{sur})$ and $\rho_c = 1-\alpha_c = 1-\varepsilon_c, J_c = \varepsilon_c\sigma T_c^4 + (1-\varepsilon_c)\sigma T_{sur}^4 = (170.2+387.4)\,W/m^2.$
Hence, the irradiation is

$$G_g = G_{g,a} + \frac{1}{A_g}\left(\frac{D_c^2}{4R^2+D_c^2}\cdot\frac{A_g}{A_c}\right)\left[\varepsilon_c\sigma T_c^4 + (1-\varepsilon_c)\sigma T_{sur}^4\right]A_c$$

$$G_g = 354.4\ mW/m^2 + \left(\frac{0.10^2}{4\times1^2+0.10^2}\right)\left[0.2\times\sigma(350)^4 + (1-0.2)\times\sigma(300)^4\right]W/m^2$$

$$G_g = 354.4\ mW/m^2 + 424.4\ mW/m^2 + 916.2\ mW/m^2 = 1,695\ mW/m^2.$$

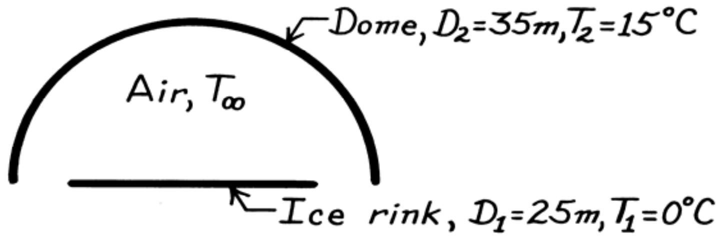
COMMENTS: (1) Note we have assumed $A_f << A_c$ so that effect of the aperture is negligible. (2) In part (b), the irradiation due to radiosity from the shield can be written also as $G_{g,c} = q_{c\text{-}g}/A_g = (J_c/\pi)\cdot A_c\cdot\omega_{g\text{-}c}/A_g$ where $\omega_{g\text{-}c} = A_g/R^2$. This is an excellent approximation since $A_c << R^2$.

PROBLEM 13.17

KNOWN: Temperature and diameters of a circular ice rink and a hemispherical dome.

FIND: Net rate of heat transfer to the ice due to radiation exchange with the dome.

SCHEMATIC:



ASSUMPTIONS: (1) Blackbody behavior for dome and ice. (2) Surfaces have uniform irradiation and radiosity.

ANALYSIS: From Eq. 13.13,

$$q_{21} = A_2 F_{21} \sigma \left(T_2^4 - T_1^4\right)$$

From reciprocity, $A_2\, F_{21} = A_1\, F_{12} = \left(\pi D_1^2 / 4\right)1$

$$A_2 F_{21} = (\pi / 4)(25\text{ m})^2 1 = 491\text{ m}^2.$$

Hence

$$q_{21} = 491\text{ m}^2 \left(5.67\times10^{-8}\text{W/m}^2\cdot\text{K}^4\right)\left[(288\text{ K})^4 - (273\text{ K})^4\right]$$

$$q_{21} = 3.69\times10^4\text{ W.}$$ <

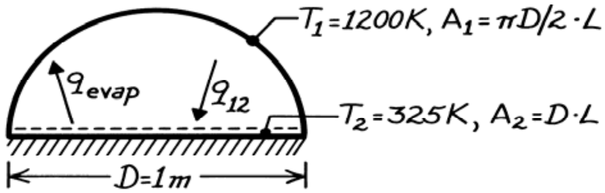
COMMENTS: (1) If the air temperature, T_∞, exceeds T_1, there will also be heat transfer by convection to the ice. The radiation and convection transfer to the ice determine the heat load which must be handled by the cooling system. (2) Because they are isothermal and black, the two surfaces have uniform radiosity. Do you expect them each to be uniformly irradiated? Would non-uniform irradiation of either surface affect the answer?

PROBLEM 13.18

KNOWN: Surface temperature of a semi-circular drying oven.

FIND: Drying rate per unit length of oven.

SCHEMATIC:



ASSUMPTIONS: (1) Blackbody behavior for furnace wall and water, (2) Convection effects are negligible and bottom is insulated, (3) Uniform surface irradiation and radiosity.

PROPERTIES: *Table A-6*, Water (325 K): $h_{fg} = 2.378 \times 10^6 \text{ J/kg}$.

ANALYSIS: Applying a surface energy balance,

$$q_{12} = q_{evap} = \dot{m} h_{fg}$$

where it is assumed that the net radiation heat transfer to the water is balanced by the evaporative heat loss. From Eq. 13.13,

$$q_{12} = A_1 F_{12} \sigma \left(T_1^4 - T_2^4\right).$$

From inspection and the reciprocity relation,

$$F_{12} = \frac{A_2}{A_1} F_{21} = \frac{D \cdot L}{(\pi D/2) \cdot L} \times 1 = 0.637.$$

Hence

$$\dot{m}' = \frac{\dot{m}}{L} = \frac{\pi D}{2} F_{12} \sigma \frac{\left(T_1^4 - T_2^4\right)}{h_{fg}}$$

$$\dot{m}' = \frac{\pi(1 \text{ m})}{2} \times 0.637 \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \frac{(1200 \text{ K})^4 - (325 \text{ K})^4}{2.378 \times 10^6 \text{ J/kg}}$$

or

$$\dot{m}' = 0.0492 \text{ kg/s} \cdot \text{m}.$$ <

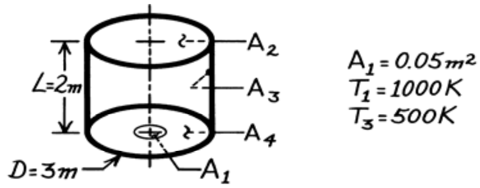
COMMENTS: (1) Air flow through the oven is needed to remove the water vapor. The water surface temperature, T_2, is determined by a balance between radiation heat transfer to the water and the convection of latent and sensible energy from the water. (2) Because the surfaces are black and isothermal, they have uniform radiosity.

PROBLEM 13.19

KNOWN: Arrangement of three black surfaces with prescribed geometries and surface temperatures.

FIND: (a) View factor F_{13}, (b) Net radiation heat transfer from A_1 to A_3.

SCHEMATIC:



ASSUMPTIONS: (1) Interior surfaces behave as blackbodies, (2) $A_2 >> A_1$, (3) Surfaces are uniformly irradiated and have uniform radiosities.

ANALYSIS: (a) Define the enclosure as the interior of the cylindrical form and identify A_4. Applying the view factor summation rule, Eq. 13.4,

$$F_{11} + F_{12} + F_{13} + F_{14} = 1. \quad (1)$$

Note that $F_{11} = 0$ and $F_{14} = 0$. From Eq. 13.8,

$$F_{12} = \frac{D^2}{D^2 + 4L^2} = \frac{(3m)^2}{(3m)^2 + 4(2m)^2} = 0.36. \quad (2)$$

From Eqs. (1) and (2),

$$F_{13} = 1 - F_{12} = 1 - 0.36 = 0.64.$$ <

(b) From Eq. 13.13,

$$q_{13} = A_1 \; F_{13} \; \sigma\left(T_1^4 - T_3^4\right)$$

$$q_{13} = 0.05m^2 \times 0.64 \times 5.67 \times 10^{-8} W/m^2 \cdot K^4 \left(1000^4 - 500^4\right) K^4 = 1700\,W.$$ <

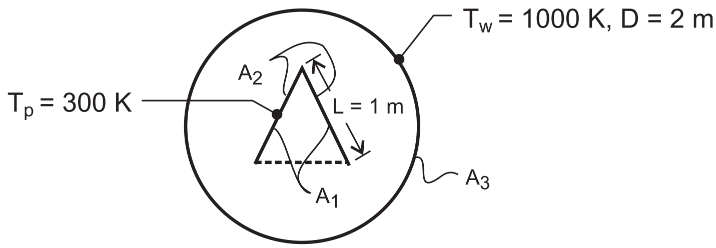
COMMENTS: (1) Note that the summation rule, Eq. 13.4, applies to an enclosure; that is, the total region above the surface must be considered. (2) Because the surfaces are black and isothermal, their radiosities are uniform. Is the irradiation of each surface uniform?

PROBLEM 13.20

KNOWN: Furnace diameter and temperature. Dimensions and temperature of suspended part.

FIND: Net rate of radiation transfer per unit length to the part.

SCHEMATIC:



ASSUMPTIONS: (1) All surfaces may be approximated as blackbodies. (2) Uniform surface irradiation and radiosity.

ANALYSIS: From symmetry considerations, it is convenient to treat the system as a three-surface enclosure consisting of the inner surfaces of the vee (1), the outer surfaces of the vee (2) and the furnace wall (3). The net rate of radiation heat transfer to the part is then

$$q'_{w,p} = A'_3 F_{31} \sigma \left(T_w^4 - T_p^4\right) + A'_3 F_{32} \sigma \left(T_w^4 - T_p^4\right)$$

From reciprocity,

$$A'_3 F_{31} = A'_1 F_{13} = 2L \times 0.5 = 1\text{m}$$

where surface 3 may be represented by the dashed line and, from symmetry, $F_{13} = 0.5$. Also,

$$A'_3 F_{32} = A'_2 F_{23} = 2L \times 1 = 2\text{m}$$

Hence,

$$q'_{w,p} = (1+2)\text{m} \times 5.67 \times 10^{-8}\ \text{W/m}^2 \cdot \text{K}^4 \left(1000^4 - 300^4\right)\text{K}^4 = 1.69 \times 10^5\ \text{W/m} \quad <$$

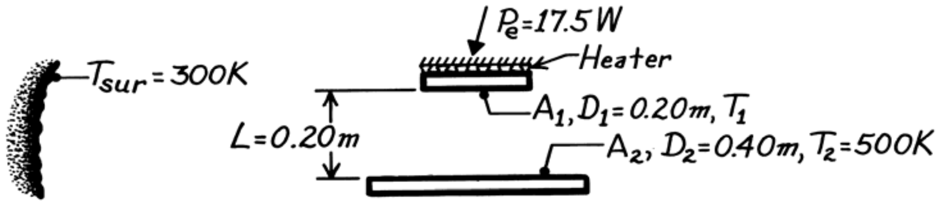
COMMENTS: (1) With all surfaces approximated as blackbodies, the result is independent of the tube diameter. (2) Note that $F_{11} = 0.5$. (3) Because the surfaces are approximated as blackbodies and are isothermal they have uniform radiosity. The irradiation of the surfaces is, however, non-uniform. Will this affect the answer?

PROBLEM 13.21

KNOWN: Coaxial, parallel black plates with surroundings. Lower plate (A_2) maintained at prescribed temperature T_2 while electrical power is supplied to upper plate (A_1).

FIND: Temperature of the upper plate T_1.

SCHEMATIC:



ASSUMPTIONS: (1) Plates are black surfaces of uniform temperature. (2) Backside of heater on A_1 insulated. (3) Uniform surface irradiation and radiosity.

ANALYSIS: The net radiation heat rate leaving A_i is

$$P_e = \sum_{j=1}^{N} q_{ij} = A_1 F_{12}\sigma\left(T_1^4 - T_2^4\right) + A_1 F_{13}\sigma\left(T_1^4 - T_3^4\right)$$

$$P_e = A_1\sigma\left[F_{12}\left(T_1^4 - T_2^4\right) + F_{13}\left(T_1^4 - T_{sur}^4\right)\right] \quad (1)$$

From Fig. 13.5 for coaxial disks (see Table 13.2),

$$R_1 = r_1 / L = 0.10\ \text{m} / 0.20\ \text{m} = 0.5 \qquad R_2 = r_2 / L = 0.20\ \text{m} / 0.20\ \text{m} = 1.0$$

$$S = 1 + \frac{1 + R_2^2}{R_1^2} = 1 + \frac{1 + 1^2}{(0.5)^2} = 9.0$$

$$F_{12} = \frac{1}{2}\left\{S - \left[S^2 - 4\left(r_2/r_1\right)^2\right]^{1/2}\right\} = \frac{1}{2}\left\{9 - \left[9^2 - 4\left(0.2/0.1\right)^2\right]^{1/2}\right\} = 0.469.$$

From the summation rule for the enclosure A_1, A_2 and A_3 where the last area represents the surroundings with $T_3 = T_{sur}$, $F_{12} + F_{13} = 1$ and $F_{13} = 1 - F_{12} = 1 - 0.469 = 0.531$.

Substituting numerical values into Eq. (1), with $A_1 = \pi D_1^2/4 = 3.142 \times 10^{-2}\text{m}^2$,

$$17.5\ \text{W} = 3.142 \times 10^{-2}\text{m}^2 \times 5.67 \times 10^{-8}\text{W/m}^2\cdot\text{K}^4\left[0.469\left(T_1^4 - 500^4\right)\text{K}^4 + 0.531\left(T_1^4 - 300^4\right)\text{K}^4\right]$$

$$9.823 \times 10^9 = 0.469\left(T_1^4 - 500^4\right) + 0.531\left(T_1^4 - 300^4\right)$$

we find that $T_1 = 456\ \text{K}$. <

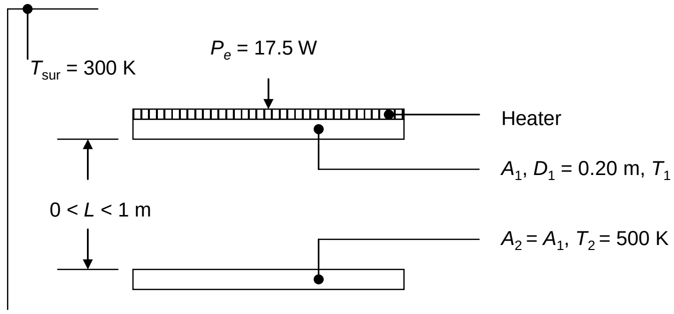
COMMENTS: (1) Note that if the upper plate were adiabatic, T_1 = 427 K. (2) Would you expect the surfaces to experience uniform irradiation? If the heater were constructed of a low thermal conductivity material, temperature gradients would likely develop in the radial direction. If this were the case, the heater surface would no longer be isothermal, and would no longer have a uniform radiosity. A more detailed analysis involving more radiation surface might be warranted in practice.

PROBLEM 13.22

KNOWN: Dimensions and separation distance of coaxial, parallel black plates. Temperatures of lower plate and surroundings. Electrical power supplied to upper plate.

FIND: Temperature of the upper plate for circular and square plates and dependence on separation distance.

SCHEMATIC:



ASSUMPTIONS: (1) Plates are black surfaces of uniform temperature. (2) Backside of heater on A_1 insulated. (3) Surfaces have uniform irradiation and radiosity.

ANALYSIS: The net radiation heat rate leaving A_i is

$$P_e = \sum_{j=1}^{N} q_{ij} = A_1 F_{12}\sigma\left(T_1^4 - T_2^4\right) + A_1 F_{13}\sigma\left(T_1^4 - T_3^4\right)$$

$$P_e = A_1\sigma\left[F_{12}\left(T_1^4 - T_2^4\right) + F_{13}\left(T_1^4 - T_{sur}^4\right)\right] \quad (1)$$

From Table 13.2 for coaxial disks (or Fig. 13.5),

$$R_1 = R_2 = r / L = 0.10 \text{ m} / 0.20 \text{ m} = 0.5$$

$$S = 1 + \frac{1 + R_2^2}{R_1^2} = 1 + \frac{1 + (0.5)^2}{(0.5)^2} = 6$$

$$F_{12} = \frac{1}{2}\left\{S - \left[S^2 - 4\left(r_2 / r_1\right)^2\right]^{1/2}\right\} = \frac{1}{2}\left\{6 - \left[6^2 - 4\right]^{1/2}\right\} = 0.172.$$

From the summation rule for the enclosure A_1, A_2, and A_3 where the last area represents the surroundings with $T_3 = T_{sur}$,

$$F_{12} + F_{13} = 1 \qquad F_{13} = 1 - F_{12} = 1 - 0.172 = 0.828.$$

From Eq. (1), with $A_1 = \pi D_1^2 / 4 = 3.142 \times 10^{-2} \text{ m}^2$,

$$T_1 = \left[\frac{\left(\dfrac{P_e}{A_1\sigma} + F_{12}T_2^4 + F_{13}T_{sur}^4\right)}{F_{12} + F_{13}}\right]^{1/4} \quad (2)$$

Continued…

PROBLEM 13.22 (Cont.)

$$T_1 = \left[\frac{\left(\frac{17.5\ \text{W}}{3.142 \times 10^{-2}\,\text{m}^2 \times 5.67 \times 10^{-8}\,\text{W/m}^2 \cdot \text{K}^4} + 0.172 \times 500^4\ \text{K}^4 + 0.828 \times 300^4\ \text{K}^4 \right)}{1} \right]^{1/4}$$

$T_1 = 406\ \text{K}.$ <

For the coaxial squares, $X = (\pi/4)^{1/2} D = 0.177$ m. Then F_{12} is found from Table 13.2 for aligned rectangles (or Fig. 13.4),

$$\bar{X} = \bar{Y} = X / L = 0.177\,\text{m} / 0.20\ \text{m} = 0.886$$

$$F_{12} = \frac{2}{\pi \bar{X}^2} \left\{ \ln \left[\frac{(1+\bar{X}^2)^2}{1+2\bar{X}^2} \right]^{1/2} + 2\bar{X}(1+\bar{X}^2)^{1/2} \tan^{-1}\left[\frac{\bar{X}}{(1+\bar{X}^2)^{1/2}} \right] - 2\bar{X} \tan^{-1} \bar{X} \right\} = 0.170.$$

Then,

$$F_{12} + F_{13} = 1 \qquad F_{13} = 1 - F_{12} = 1 - 0.170 = 0.830.$$

Finally, from Eq. (2)

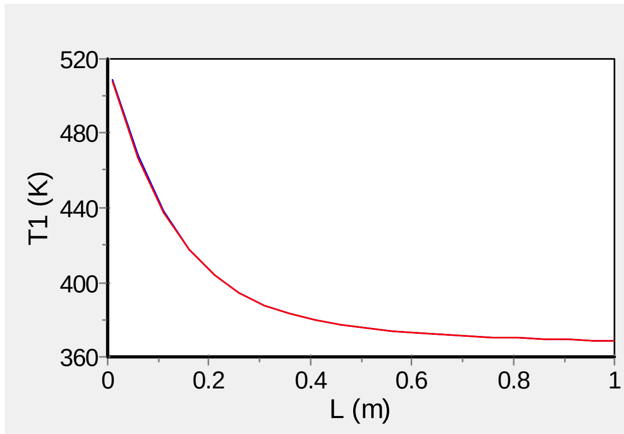
$$T_1 = \left[\frac{\left(\frac{17.5\ \text{W}}{3.142 \times 10^{-2}\,\text{m}^2 \times 5.67 \times 10^{-8}\,\text{W/m}^2 \cdot \text{K}^4} + 0.170 \times 500^4\ \text{K}^4 + 0.830 \times 300^4\ \text{K}^4 \right)}{1} \right]^{1/4}$$

$T_1 = 406\ \text{K}.$ <

Continued…

PROBLEM 13.22 (Cont.)

Results were generated for $0 < L \le 1$ m using IHT and are shown below. The results for the circular disks and aligned squares are plotted together and are virtually indistinguishable.



<

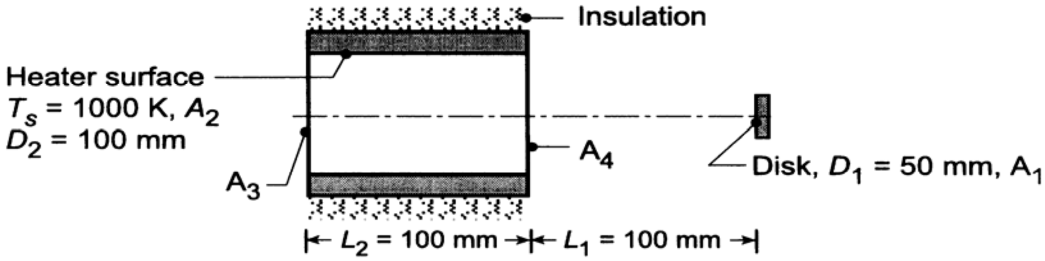
COMMENTS: (1) For either geometry, as the plates approach one another the cooling effect of the surroundings vanishes, and the temperature of plate 1 adjusts to adhere to an energy balance between the power supplied by the heater and the heat loss to plate 2 at 500 K. That is, $P_e = A_1\sigma\left(T_1^4 - T_2^4\right)$, resulting in $T_1 = 519$ K. (2) As the plates become far apart, the effect of plate 2 on plate 1 vanishes. The temperature of plate 1 adjusts to adhere to an energy balance between the power supplied by the heater and the heat loss to the cool surroundings. That is, $P_e = A_1\sigma\left(T_1^4 - T_2^4\right)$, resulting in $T_1 = 366$ K. (3)The shape factors for the two geometries are nearly the same and therefore the temperature of plate 1 is almost the same for either geometry. (4) The surfaces are not uniformly irradiated. If the heater were constructed of low thermal conductivity material, it may experience a spatial temperature distribution. As such, it would no longer be isothermal and would no longer have a uniform radiosity. A more detailed analysis involving many radiation surfaces may be warranted in practice.

PROBLEM 13.23

KNOWN: Tubular heater radiates like blackbody at 1000 K.

FIND: (a) Radiant power from the heater surface, A_s, intercepted by a disc, A_1, at a prescribed location $q_{s\to1}$; irradiation on the disk, G_1; and (b) Compute and plot $q_{s\to1}$ and G_1 as a function of the separation distance L_1 for the range $0 \le L_1 \le 200$ mm for disk diameters D_1 = 25, and 50 and 100 mm.

SCHEMATIC:



ASSUMPTIONS: (1) Heater surface behaves as blackbody with uniform temperature. (2) Surfaces have uniform radiosity and irradiation.

ANALYSIS: (a) The radiant power leaving the inner surface of the tubular heater that is intercepted by the disk is

$$q_{2\to1} = \left(A_2 E_{b2}\right) F_{21} \tag{1}$$

where the heater is surface 2 and the disk is surface 1. It follows from the reciprocity rule, Eq. 13.3, that

$$F_{21} = \frac{A_1}{A_2} F_{12}. \tag{2}$$

Define now the hypothetical disks, A_3 and A_4, located at the ends of the tubular heater. By inspection, it follows that

$$F_{14} = F_{12} + F_{13} \qquad \text{or} \qquad F_{12} = F_{14} - F_{13}$$

(3)

where F_{14} and F_{13} may be determined from Fig. 13.5. Substituting numerical values, with $D_3 = D_4 = D_2$,

$$F_{13} = 0.08 \qquad \text{with} \qquad \frac{L}{r_i} = \frac{L_1 + L_2}{D_1/2} = \frac{200}{50/2} = 8 \qquad \frac{r_j}{L} = \frac{D_3/2}{L_1 + L_2} = \frac{100/2}{200} = 0.25$$

$$F_{14} = 0.20 \qquad \text{with} \qquad \frac{L}{r_i} = \frac{L_1}{D_1/2} = \frac{100}{50/2} = 4 \qquad \frac{r_j}{L} = \frac{D_4/2}{L_1} = \frac{100/2}{100} = 0.5$$

Substituting Eq. (3) into Eq. (2) and then into Eq. (1), the result is

$$q_{2\to1} = A_1\left(F_{14} - F_{13}\right) E_{b2}$$

$$q_{2\to1} = \left[\pi\left(50\times10^{-3}\right)^2 \text{m}^2/4\right]\left(0.20 - 0.08\right)\times 5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left(1000\ \text{K}\right)^4 = 13.4\text{W} \qquad <$$

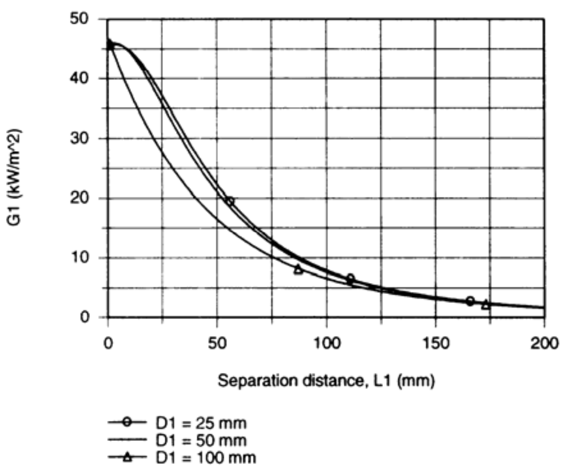
where $E_{b2} = \sigma T_s^4$. The irradiation G_1 originating from emission leaving the heater surface is

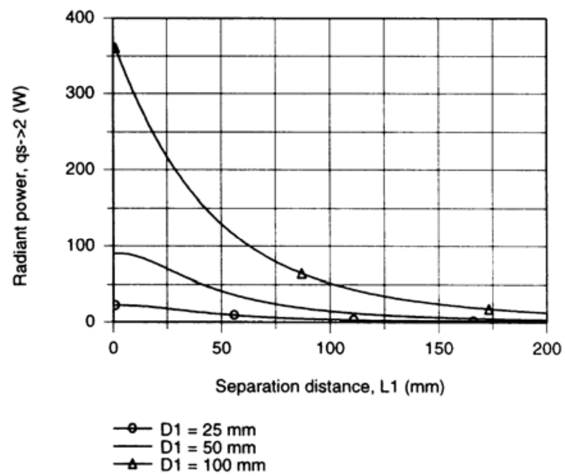
$$G_1 = \frac{q_{s\to1}}{A_1} = \frac{13.4\ \text{W}}{\pi\left(0.050\ \text{m}\right)^2/4} = 6825\,\text{W/m}^2. \tag{4} \quad <$$

Continued …

PROBLEM 13.23 (Cont.)

(b) Using the foregoing equations in *IHT* along with the *Radiation Tool-View Factors* for *Coaxial Parallel Disks,* G_1 and $q_{s\rightarrow 1}$ were computed as a function of L_1 for selected values of D_1. The results are plotted below.





In the upper left-hand plot, G_1 decreases with increasing separation distance. For a given separation distance, the irradiation decreases with increasing diameter. With values of D_1 = 25 and 50 mm, the irradiation values are only slightly different, which diminishes as L_1 increases. In the upper right-hand plot, the radiant power from the heater surface reaching the disk, $q_{s\rightarrow 2}$, decreases with increasing L_1 and decreasing D_1. Note that while G_1 is nearly the same for D_1 = 25 and 50 mm, their respective $q_{s\rightarrow 2}$ values are quite different. Why is this so?

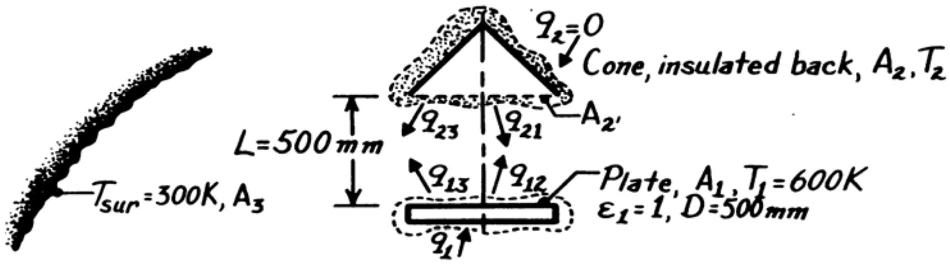
Comment. Since the tube surface is assumed to be black and isothermal, it will have uniform radiosity distributions. However, its irradiation is not uniform. Will the nonuniformity of the irradiation affect the answer?

PROBLEM 13.24

KNOWN: Circular plate (A_1) maintained at 600 K positioned coaxially with a conical shape (A_2) whose backside is insulated. Plate and cone are black surfaces and located in large, insulated enclosure at 300 K.

FIND: (a) Temperature of the conical surface T_2 and (b) Electric power required to maintain plate at 600 K.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Plate and cone are black, (3) Cone behaves as insulated, reradiating surface, (4) Surroundings are large compared to plate and cone, (5) Uniform irradiation and radiosity.

ANALYSIS: (a) Recognizing that the plate, cone, and surroundings from a three-(black) surface enclosure, perform a radiation balance on the cone.

$$q_2 = 0 = q_{23} + q_{21} = A_2F_{23}\,\sigma\left(T_2^4 - T_3^4\right) + A_2F_{21}\,\sigma\left(T_2^4 - T_1^4\right)$$

where the view factor F_{21} can be determined from the *coaxial parallel disks* relation (Table 13.2 or Fig. 13.5) with $R_i = r_i/L=250/500 = 0.5$, $R_j = 0.5$, $S = 1 + \left(1+R_j^2\right)/R_i^2 = 1 + (1 + 0.5^2)/0.5^2 = 6.00$, and noting $F_{2'1} = F_{21}$,

$$F_{21} = 0.5\left\{S - \left[S^2 - 4\left(r_j/r_i\right)^2\right]^{1/2}\right\} = 0.5\left\{6 - \left[6^2 - 4\left(0.5/0.5\right)^2\right]^{1/2}\right\} = 0.172.$$

For the enclosure, the summation rule provides, $F_{2'3} = 1 - F_{2'1} = 1 - 0.172 = 0.828$. Hence,

$$0.828\left(T_2^4 - 300^4\right) = 0 + 0.172\left(T_2^4 - 600^4\right)$$

$$T_2 = 413\ \text{K}. \qquad <$$

(b) The power required to maintain the plate at T_2 follows from a radiation balance,

$$q_1 = q_{12} + q_{13} = A_1F_{12}\sigma\left(T_1^4 - T_2^4\right) + A_1F_{13}\sigma\left(T_1^4 - T_3^4\right)$$

where $F_{12} = A_{2'}F_{2'1}/A_1 = F_{21} = 0.172$ and $F_{13} = 1 - F_{12} = 0.828$,

$$q_1 = \left(\pi 0.5^2/4\right)\text{m}^2\sigma\left[0.172\left(600^4 - 413^4\right)\text{K}^4 + 0.828\left(600^4 - 300^4\right)\text{K}^4\right]$$

$$q_1 = 1312\ \text{W}. \qquad <$$

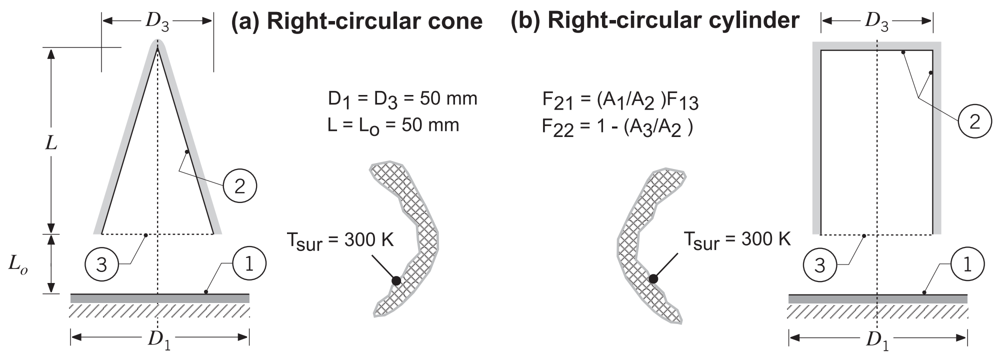
Comment: Because the surfaces are black and isothermal, they each are characterized by a uniform radiosity. Will the non-uniformity of the irradiation of the surfaces affect the answer?

PROBLEM 13.25

KNOWN: Conical and cylindrical furnaces (A_2) as illustrated and dimensioned in Problem 13.4 supplied with power of 50 W. Workpiece (A_1) with insulated backside located in large room at 300 K.

FIND: Temperature of the workpiece, T_1, and the temperature of the inner surfaces of the furnaces, T_2. Use expressions for the view factors F_{21} and F_{22} given in the statement for Problem 13.4.

SCHEMATIC:



ASSUMPTIONS: (1) Diffuse, black surfaces with uniform radiosities, (2) Backside of workpiece is perfectly insulated, (3) Inner base and lateral surfaces of the cylindrical furnace treated as single surface, (4) Negligible convection heat transfer, (5) Room behaves as large, isothermal surroundings.

ANALYSIS: Considering the furnace surface (A_2), the workpiece (A_1) and the surroundings (A_s) as an enclosure, the net radiation transfer from A_1 and A_2 follows from Eq. 13.13,

Workpiece $$q_1 = 0 = A_1 F_{12}\left(E_{b1} - E_{b2}\right) + A_1 F_{1s}\left(E_{b1} - E_{bs}\right) \quad (1)$$

Furnace $$q_2 = 50\text{ W} = A_2 F_{21}\left(E_{b2} - E_{b1}\right) + A_2 F_{2s}\left(E_{b2} - E_{bs}\right) \quad (2)$$

where $E_b = \sigma T^4$ and $\sigma = 5.67 \times 10^{-8}$ W/m$^2\cdot$K^4. From summation rules on A_1 and A_2, the view factors F_{1s} and F_{2s} can be evaluated. Using reciprocity, F_{12} can be evaluated.

$$F_{1s} = 1 - F_{12} \qquad F_{2s} = 1 - F_{21} - F_{22} \qquad F_{12} = \left(A_2 / A_1\right)F_{21}$$

The expressions for F_{21} and F_{22} are provided in the schematic. With $A_1 = \pi D_1^2 / 4$ the A_2 are:

Cone: $$A_2 = \pi D_3 / 2\left(L^2 + \left(D_3 / 2\right)^2\right)^{1/2}$$ *Cylinder*: $$A_2 = \pi D_3^2 / 4 + \pi D_3 L$$

Examine Eqs (1) and (2) and recognize that there are two unknowns, T_1 and T_2, and the equations must be solved simultaneously. Using the foregoing equations in the *IHT* workspace, the results are

$$T_1 = 544\text{ K} \qquad T_2 = 828\text{ K}$$ <

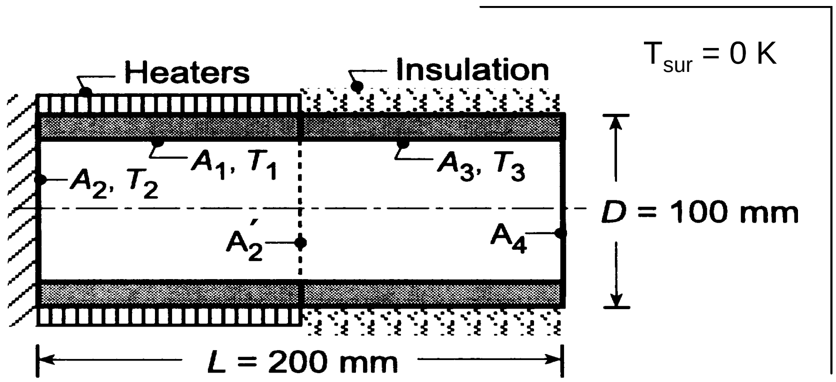
COMMENTS: (1) From the *IHT* analysis, the relevant view factors are: $F_{12} = 0.1716$; $F_{1s} = 0.8284$; *Cone:* $F_{21} = 0.07673$, $F_{22} = 0.5528$; *Cylinder:* $F_{21} = 0.03431$, $F_{22} = 0.80$. (2) That both furnace configurations provided identical results may not, at first, be intuitively obvious. Since both furnaces (A_2) are black, they can be represented by the hypothetical black area A_3 (the opening of the furnaces). As such, the analysis is for an enclosure with the workpiece (A_1), the furnace represented by the disk A_3 (at T_2), and the surroundings. As an exercise, perform this analysis to confirm the above results. (3) Since the surfaces are assumed to be black and isothermal, their radiosities are uniform. The irradiation of the surfaces is not uniform. This may lead to non-uniform temperature distributions in the workpiece in a real application.

PROBLEM 13.26

KNOWN: Furnace constructed in three sections: insulated circular (2) and cylindrical (3) sections, as well as, an intermediate cylindrical section (1) with imbedded electrical resistance heaters. Cylindrical sections (1,3) are of equal length.

FIND: (a) Electrical power required to maintain the heated section at T_1 = 1000 K if all the surfaces are black, (b) Temperatures of the insulated sections, T_2 and T_3, and (c) Compute and plot q_1, T_2 and T_3 as functions of the length-to-diameter ratio, with $1 \le L/D \le 5$ and D = 100 mm.

SCHEMATIC:



ASSUMPTIONS: (1) All surfaces are black, (2) Areas (1, 2, 3) are isothermal. (3) Uniform surface radiosity and irradiation.

ANALYSIS: (a) To complete the enclosure representing the furnace, define the hypothetical surface A_4 as the opening at 0 K with unity emissivity. For each of the enclosure surfaces 1, 2, and 3, the energy balances following Eq. 13.13 are

$$q_1 = A_1F_{12}\left(E_{b1} - E_{b2}\right) + A_1F_{13}\left(E_{b1} - E_{b3}\right) + A_1F_{14}\left(E_{b1} - E_{b4}\right) \quad (1)$$

$$0 = A_2F_{21}\left(E_{b2} - E_{b1}\right) + A_2F_{23}\left(E_{b2} - E_{b3}\right) + A_2F_{24}\left(E_{b2} - E_{b4}\right) \quad (2)$$

$$0 = A_3F_{31}\left(E_{b3} - E_{b1}\right) + A_3F_{32}\left(E_{b3} - E_{b2}\right) + A_3F_{34}\left(E_{b3} - E_{b4}\right) \quad (3)$$

where the emissive powers are

$$E_{b1} = \sigma T_1^4 \qquad E_{b2} = \sigma T_2^4 \qquad E_{b3} = \sigma T_3^4 \qquad E_{b4} = 0 \quad (4-7)$$

For this four surface enclosure, there are N^2 = 16 view factors and N (N – 1)/2 = 4 × 3/2 = 6 must be directly determined (by inspection or formulas) and the remainder can be evaluated from the summation rule and reciprocity relation. By inspection,

$$F_{22} = 0 \qquad F_{44} = 0 \quad (8,9)$$

From the coaxial parallel disk relation, Table 13.2, find F_{24}

$$S = 1 + \frac{1 + R_4^2}{R_2^2} = 1 + \frac{1 + (0.250)^2}{(0.250)^2} = 18.00$$

$$R_2 = r_2 / L = 0.050\,\text{m} / 0.200\,\text{m} = 0.250 \qquad R_4 = r_4 / L = 0.250$$

$$F_{24} = 0.5\left\{S - \left[S^2 - 4\left(r_4 / r_2\right)^2\right]^{1/2}\right\}$$

$$F_{24} = 0.5\left\{18.00 - \left[18.00^2 - 4(1)^2\right]^{1/2}\right\} = 0.0557 \quad (10)$$

Consider the three-surface enclosure $1-2-2'$ and find F_{11} as beginning with the summation rule,

Continued …

PROBLEM 13.26 (Cont.)

$$F_{11} = 1 - F_{12} - F_{12'} \quad (11)$$

where, from symmetry, $F_{12} = F_{12'}$, and using reciprocity,

$$F_{12} = A_2 F_{21} / A_1 = \left(\pi D^2 / 4\right) F_{23} / \left(\pi DL / 2\right) = DF_{21} / 2L \quad (12)$$

and from the summation rule on A_2

$$F_{21} = 1 - F_{22'} = 1 - 0.172 = 0.828, \quad (13)$$

Using the coaxial parallel disk relation, Table 13.2, to find $F_{22'}$,

$$S = 1 + \frac{1 + R_{2'}^2}{R_2^2} = 1 + \frac{1 + 0.50^2}{0.50^2} = 6.000$$

$$R_2 = r_2 / L = 0.050\,\text{m} / \left(0.200 / 2\,\text{m}\right) = 0.500 \qquad R_{2'} = 0.500$$

$$F_{22'} = 0.5\left\{S - \left[S^2 - 4\left(r_{2'} / r_2\right)^2\right]^{1/2}\right\}$$

$$F_{22'} = 0.5\left\{6 - \left[6^2 - 4\left(1\right)^2\right]^{1/2}\right\} = 0.1716$$

Evaluating F_{12} from Eq. (12), find

$$F_{12} = 0.100\ \text{m} \times 0.828 / 2 \times 0.200\ \text{m} = 0.2071$$

and evaluating F_{11} from Eq. (11), find

$$F_{11} = 1 - 2 \times F_{12} = 1 - 2 \times 0.207 = 0.586$$

From symmetry, recognize that $F_{33} = F_{11}$ and $F_{43} = F_{21}$. To this point we have directly determined six view factors (underlined in the matrix below) and the remaining F_{ij} can be evaluated from the summation rules and appropriate reciprocity relations. The view factors written in matrix form, $[F_{ij}]$ are.

<u>0.5858</u>	<u>0.2071</u>	0.1781	0.02896
<u>0.8284</u>	<u>0</u>	0.1158	<u>0.05573</u>
0.1781	0.028960.5858	0.2071	
0.1158	0.055730.8284	<u>0</u>	

Knowing all the required view factors, the energy balances and the emissive powers, Eqs. (4-6), can be solved simultaneously to obtain:

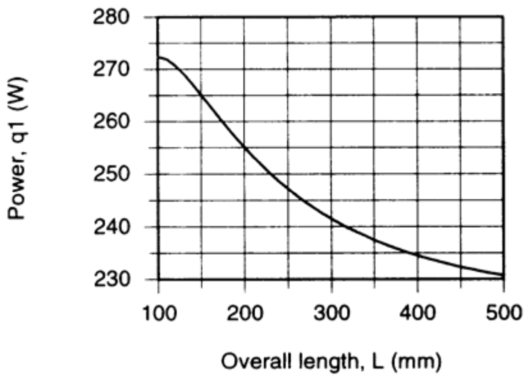
$q_1 = 255\,\text{W} \qquad E_{b2} = 5.02 \times 10^4\,\text{W/m}^2 \qquad E_{b3} = 2.79 \times 10^4\,\text{W/m}^2$ <

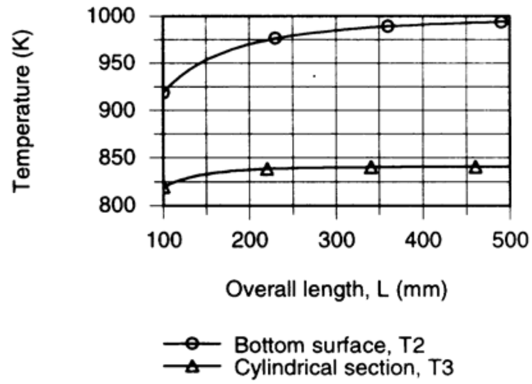
$T_2 = 970\,\text{K} \qquad T_3 = 837.5\,\text{K}$ <

Continued …

PROBLEM 13.26 (Cont.)

(b) Using the energy balances, Eqs. (1-3), along with the *IHT Radiation Tool, View Factors, Coaxial parallel disks*, a model was developed to calculate q_1, T_2, and T_3 as a function of length L for fixed diameter D = 100 m. The results are plotted below.





For fixed diameter, as the overall length increases, the power required to maintain the heated section at T_1 = 1000 K decreases. This follows since the furnace opening area is a smaller fraction of the enclosure surface area as L increases. As L increases, the bottom surface temperature T_2 increases as L increases and, in the limit, will approach that of the heated section, T_1 = 1000 K. As L increases, the temperature of the insulated cylindrical section, T_3, increases, but only slightly. The limiting value occurs when $E_{b3} = 0.5 \times E_{b1}$ for which $T_3 \rightarrow 840$ K. Why is that so?

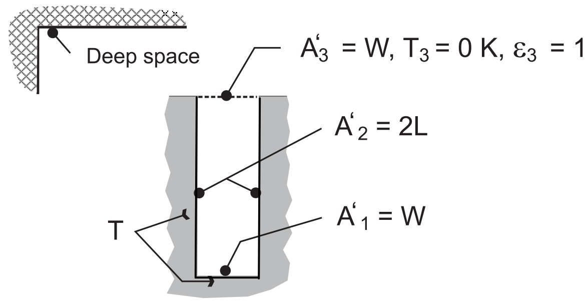
COMMENT: If the electrical heating is uniformly distributed, the temperature of the heated section will not be uniform. In practice, a more detailed analysis involving more radiation surfaces might be warranted.

PROBLEM 13.27

KNOWN: Dimensions and temperature of a rectangular fin array radiating to deep space.

FIND: Expression for rate of radiation transfer per unit length from a unit section of the array.

SCHEMATIC:



ASSUMPTIONS: (1) Surfaces may be approximated as blackbodies, (2) Surfaces are isothermal, (3) Length of array (normal to page) is much larger than W and L.

ANALYSIS: Deep space may be represented by the hypothetical surface A_3', which acts as a blackbody at absolute zero temperature. The net rate of radiation heat transfer to this surface is therefore equivalent to the rate of heat rejection by a unit section of the array.

$$q_3' = A_1' F_{13}\,\sigma\left(T_1^4 - T_3^4\right) + A_2' F_{23}\,\sigma\left(T_2^4 - T_3^4\right)$$

With $\quad A_2' F_{23} = A_3' F_{32} = A_1' F_{12},\ T_1 = T_2 = T$ and $T_3 = 0$,

$$q_3' = A_1'\left(F_{13} + F_{12}\right)\sigma T^4 = W\sigma T^4$$ <

Radiation from a unit section of the array corresponds to emission from the base. Hence, if blackbody behavior can, indeed, be maintained, the fins do nothing to enhance heat rejection.

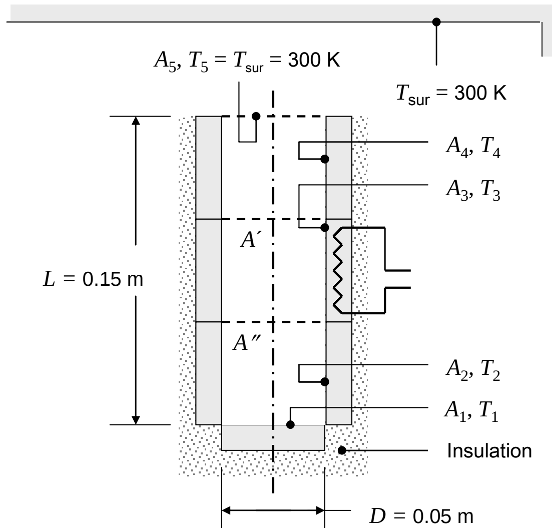
COMMENTS: (1) The foregoing result should come as no surprise since the surfaces of the unit section form an isothermal blackbody cavity for which emission is proportional to the area of the opening. (2) Because surfaces 1 and 2 have the same temperature, the problem could be treated as a two-surface enclosure consisting of the combined (1, 2) and 3. It follows that $q_3' = q'_{(1,2)3} = A'_{(1,2)} F_{(1,2)3}\,\sigma T^4 = A_3' F_{3(1,2)}\,\sigma T^4 = W\sigma T^4$, (3) If blackbody behavior cannot be achieved $\left(\varepsilon_1, \varepsilon_2 < 1\right)$, enhancement would be afforded by the fins.

PROBLEM 13.28

KNOWN: Geometry of furnace. Total power. Heat flux is uniform. Temperature of surroundings.

FIND: Temperature of four surfaces.

SCHEMATIC:



ASSUMPTIONS: (1) Interior surfaces behave as blackbodies with uniform temperature, radiosity, and irradiation. (2) Heat transfer by convection is negligible. (3) Backs of electrically-heated surfaces are adiabatic.

ANALYSIS: With a total heat loss of q = 1522 W, the heat flux is

$$q'' = \frac{q}{\pi D^2/4 + \pi DL} = \frac{1522 \text{ W}}{\pi(0.05 \text{ m})^2/4 + \pi \times 0.05 \text{ m} \times 0.15 \text{ m}} = 59{,}630 \text{ W/m}^2$$

The view factors from the surroundings to the furnace surfaces were found in Example 13.3, but it will be a little easier here to work with the view factors from the furnace surfaces to the surroundings:

$$F_{15} = \frac{A_5 F_{51}}{A_1} = F_{51} = 0.0263$$

$$F_{25} = \frac{A_5 F_{52}}{A_2} = \frac{(\pi D^2/4) F_{52}}{\pi DL/3} = \frac{3D}{4L} F_{52} = \frac{3 \times 0.05 \text{ m}}{4 \times 0.15 \text{ m}} 0.0294 = 0.00735$$

$$F_{35} = \frac{A_5 F_{53}}{A_3} = \frac{3D}{4L} F_{53} = \frac{3 \times 0.05 \text{ m}}{4 \times 0.15 \text{ m}} 0.1163 = 0.0291$$

$$F_{45} = \frac{A_5 F_{54}}{A_4} = \frac{3D}{4L} F_{54} = \frac{3 \times 0.05 \text{ m}}{4 \times 0.15 \text{ m}} 0.828 = 0.207$$

Continued...

PROBLEM 13.28 (Cont.)

As in Example 13.3, the electric power delivered to each surface balances the corresponding radiation loss. Equations (1)-(4) from Example 13.3 can be solved for the temperatures of each surface. Recognizing that $q_1/A_1 = q_2/A_2 = q_3/A_3 = q_4/A_4 = q''$, we find

$$T_1 = \left(\frac{q_1}{A_1 F_{15}\sigma} + T_5^4\right)^{1/4} = \left(\frac{q''}{F_{15}\sigma} + T_5^4\right)^{1/4} = \left(\frac{59,630 \text{ W/m}^2}{0.0263 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} + 300^4 \text{ K}^4\right)^{1/4} = 2515 \text{ K}$$ <

$$T_2 = \left(\frac{q''}{F_{25}\sigma} + T_5^4\right)^{1/4} = \left(\frac{59,630 \text{ W/m}^2}{0.00735 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} + 300^4 \text{ K}^4\right)^{1/4} = 3459 \text{ K}$$ <

$$T_3 = \left(\frac{q''}{F_{35}\sigma} + T_5^4\right)^{1/4} = \left(\frac{59,630 \text{ W/m}^2}{0.0291 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} + 300^4 \text{ K}^4\right)^{1/4} = 2452 \text{ K}$$ <

$$T_4 = \left(\frac{q''}{F_{45}\sigma} + T_5^4\right)^{1/4} = \left(\frac{59,630 \text{ W/m}^2}{0.207 \times 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4} + 300^4 \text{ K}^4\right)^{1/4} = 1502 \text{ K}$$ <

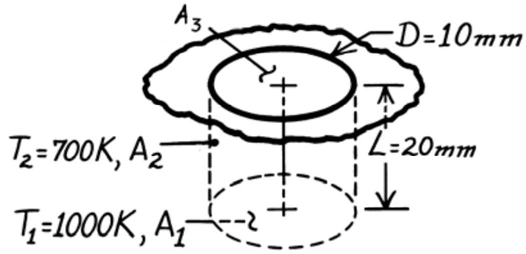
COMMENTS: (1) The hottest surface is surface 2, which has the smallest view factor from itself to the surroundings. (2) The large variation in temperature between the four surfaces suggests that the actual temperature of *each* surface would also vary substantially, invalidating the assumptions of uniform radiosity and irradiation. A more accurate analysis could be performed by following the methodology of Comment 3 of Example 13.3.

PROBLEM 13.29

KNOWN: Dimensions and temperatures of side and bottom walls in a cylindrical cavity.

FIND: Emissive power of the cavity.

SCHEMATIC:



ASSUMPTIONS: (1) Blackbody behavior for surfaces 1 and 2. (2) Uniform surface radiosity and irradiation distributions.

ANALYSIS: The emissive power is defined as

$$E = q_3 / A_3$$

where

$$q_3 = A_1 F_{13} E_{b1} + A_2 F_{23} E_{b2}.$$

From symmetry, $F_{23} = F_{21}$, and from reciprocity, $F_{21} = (A_1/A_2) F_{12}$. With $F_{12} = 1 - F_{13}$, it follows that

$$q_3 = A_1 F_{13} E_{b1} + A_1 (1 - F_{13}) E_{b2} = A_1 E_{b2} + A_1 F_{13} (E_{b1} - E_{b2}).$$

Hence, with $A_1 = A_3$,

$$E = \frac{q_3}{A_3} = E_{b2} + F_{13} (E_{b1} - E_{b2}) = \sigma T_2^4 + F_{13} \sigma \left(T_1^4 - T_2^4\right).$$

From Fig. 13.5, with $(L/r_i) = 4$ and $(r_j/L) = 0.25$, $F_{13} \approx 0.05$. Hence

$$E = 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 (700^4) \text{K}^4 + 0.05 \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 \left(1000^4 - 700^4\right) \text{K}^4$$

$$E = 1.36 \times 10^4 \text{W/m}^2 + 0.22 \times 10^4 \text{W/m}^2$$

$$E = 1.58 \times 10^4 \text{W/m}^2.$$ <

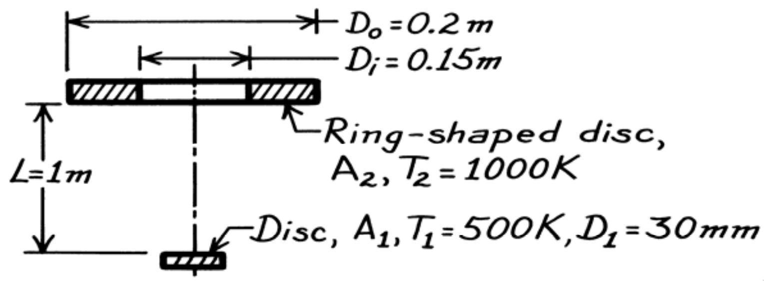
COMMENT: (1) The surfaces will not experience uniform irradiation. Will this affect the answer?

PROBLEM 13.30

KNOWN: Aligned, parallel discs with prescribed geometry and orientation.

FIND: Net radiative heat exchange between the discs.

SCHEMATIC:



ASSUMPTIONS: (1) Surfaces behave as blackbodies, (2) $A_1 << A_2$.

ANALYSIS: From Eq. 13.13

$$q_{12} = A_1 \ F_{12} \ \sigma\left(T_1^4 - T_2^4\right).$$

The view factor can be determined from Eq. 13.8 which is appropriate for a small disc, aligned and parallel to a much larger disc.

$$F_{ij} = \frac{D_j^2}{D_j^2 + 4L^2}$$

where D_j is the diameter of the larger disk and L is the distance of separation. It follows that

$$F_{12} = F_{1o} - F_{1i} = 0.00990 - 0.00559 = 0.00431$$

where

$$F_{1o} = D_o^4 / \left(D_o^2 + 4L^2\right) = 0.2^2 m^2 / \left(0.2^2 m^2 + 4 \times 1 \ m^2\right) = 0.00990$$

$$F_{1i} = D_i / \left(D_i^2 + 4L^2\right) = 0.15^2 m^2 / \left(0.15^2 m^2 + 4 \times 1 \ m^2\right) = 0.00559.$$

The net radiation exchange is then

$$q_{12} = \frac{\pi\left(0.03m\right)^2}{4} \times 0.00431 \times 5.67 \times 10^{-8} \frac{W}{m^2 \cdot K^4}\left(500^4 - 1000^4\right) K^4 = -0.162 \, W.$$

COMMENTS: F_{12} can be approximated using solid angle concepts if $D_o << L$. That is, the view factor for A_1 to A_o (whose diameter is D_o) is

$$F_{1o} \approx \frac{\omega_{o-1}}{\pi} = \frac{A_o / L^2}{\pi} = \frac{\pi D_o^2}{4\pi L^2} = \frac{D_o^2}{4L^2}.$$

Numerically, F_{1o} = 0.0100 and it follows $F_{1i} \approx D_i^2 / 4L^2 = 0.00563$. This gives F_{12} = 0.00437. An analytical expression can be obtained from Example 13.1 by replacing the lower limit of integration by $D_i/2$, giving

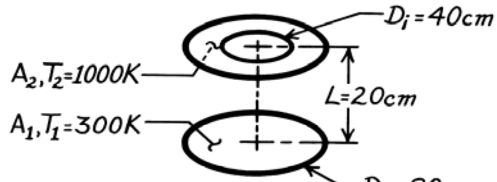
$$F_{12} = L^2\left[-1/\left(D_o^2 / 4 + L^2\right) + 1/\left(D_i^2 / 4 + L^2\right)\right] = 0.00431.$$

PROBLEM 13.31

KNOWN: Two black, plane discs, one being solid, the other ring-shaped.

FIND: Net radiative heat exchange between the two surfaces.

SCHEMATIC:



ASSUMPTIONS: (1) Discs are parallel and coaxial, (2) Discs are black, diffuse surfaces, (3) Convection effects are not being considered.

ANALYSIS: From Eq. 13.13

$$q_{12} = A_1 F_{12}\,\sigma\left(T_1^4 - T_2^4\right)$$

The view factor F_{12} can be determined from Fig. 13.5 after some manipulation. Define these two hypothetical surfaces;

$$A_3 = \frac{\pi D_o^2}{4},$$ located co-planar with A_2, but a solid surface

$$A_4 = \frac{\pi D_i^2}{4},$$ located co-planar with A_2, representing the missing center.

From view factor relations and Fig. 13.5, it follows that

$$F_{12} = F_{13} - F_{14} = 0.62 - 0.20 = 0.42$$

F_{14}: $\quad \frac{r_j}{L} = \frac{40/2}{20} = 1, \qquad \frac{L}{r_i} = \frac{20}{80/2} = 0.5, \qquad F_{14} = 0.20$

F_{13}: $\quad \frac{r_j}{L} = \frac{80/2}{20} = 2, \qquad \frac{L}{r_i} = \frac{20}{80/2} = 0.5, \qquad F_{13} = 0.62.$

Hence

$$q_{12} = \left(\pi 0.80^2/4\right)m^2 \times 0.42 \times 5.67 \times 10^{-8}\,W/m^2 \cdot K^4\left(300^4 - 1000^4\right)K^4$$

$$q_{12} = -11.87\ kW.$$ <

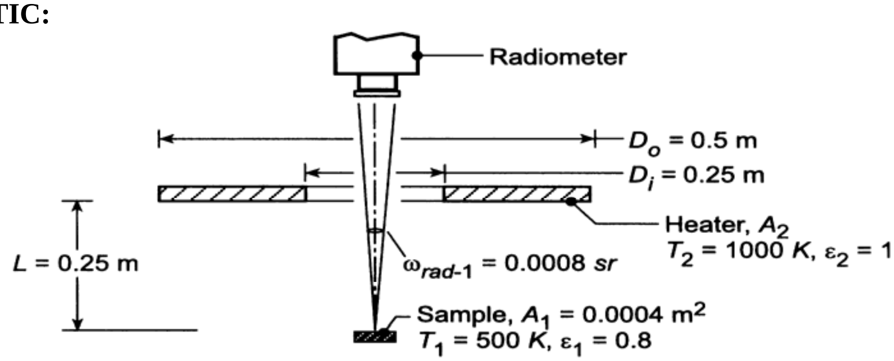
Assuming negligible radiation exchange with the surroundings, the negative sign implies that q_1 = -11.87 kW and q_2 = +11.87 kW.

PROBLEM 13.32

KNOWN: Radiometer viewing a small target area (1), A_1, with a solid angle ω = 0.0008 sr. Target has an area $A_1 = 0.004\ m^2$ and is diffuse, gray with emissivity ε = 0.8. The target is heated by a ring-shaped disc heater (2) which is black and operates at $T_2 = 1000$ K.

FIND: (a) Expression for the radiant power leaving the target which is collected by the radiometer in terms of the target radiosity, J_1, and relevant geometric parameters; (b) Expression for the target radiosity in terms of its irradiation, emissive power and appropriate radiative properties; (c) Expression for the irradiation on the target, G_1, due to emission from the heater in terms of the heater emissive power, the heater area and an appropriate view factor; numerically evaluate G_1; and (d) Determine the radiant power collected by the radiometer using the foregoing expressions and results.

SCHEMATIC:



ASSUMPTIONS: (1) Target is diffuse, gray, (2) Target area is small compared to the square of the separation distance between the sample and the radiometer, and (3) Negligible irradiation from the surroundings onto the target area.

ANALYSIS: (a) From Eq. 12.27 with $I_1 = I_{1,e+r} = J_1/\pi$, the radiant power leaving the target collected by the radiometer is, from Eq. 12.11

$$q_{1\to rad} = \frac{J_1}{\pi} A_1 \cos\theta_1 \omega_{rad-1} \quad < \quad (1)$$

where $\theta_1 = 0°$ and ω_{rad-1} is the solid angle the radiometer subtends with respect to the target area.

(b) From Eq. 12.4, the radiosity is the sum of the emissive power plus the reflected irradiation.

$$J_1 = E_1 + \rho G_1 = \varepsilon E_{b,1} + (1-\varepsilon) G_1 \quad < \quad (2)$$

where $E_{b1} = \sigma T_1^4$ and ρ = 1 - ε since the target is diffuse, gray (α = ε).

(c) The irradiation onto G_1 due to emission from the heater area A_2 is

$$G_1 = \frac{q_{2\to 1}}{A_1}$$

where $q_{2\to 1}$ is the radiant power leaving A_2 which is intercepted by A_1 and can be written as

$$q_{2\to 1} = A_2 F_{21} E_{b2} \quad (3)$$

where $E_{b2} = \sigma T_2^4$. F_{21} is the fraction of radiant power leaving A_2 which is intercepted by A_1. The view factor F_{12} can be written as

Continued …

PROBLEM 13.32 (Cont.)

$$F_{12} = F_{1-o} - F_{1-i} \qquad F_{12} = 0.5 - 0.2 = 0.3$$

where from Eq. 13.8,

$$F_{1-o} = \frac{D_o^2}{D_o^2 + 4L^2} = \frac{0.5^2}{0.5^2 + 4(0.25)^2} = 0.5 \qquad (3)$$

$$F_{1-i} = \frac{D_i^2}{D_1^2 + 4L^2} = \frac{0.25^2}{0.25^2 + 4(0.25)^2} = 0.2$$

and from the reciprocity rule,

$$F_{21} = \frac{A_1 F_{12}}{A_2} = \frac{0.0004\text{m}^2 \times 0.3}{\pi/4\left(0.5^2 - 0.25^2\right)\text{m}^2} = 0.000815$$

Substituting numerical values into Eq. (3), find

$$G_1 = \frac{\pi/4\left(0.5^2 - 0.25^2\right)\text{m}^2 \times 0.000815 \times 5.67 \times 10^{-8}\,\text{W/m}^2\cdot\text{K}^4 (1000\ \text{K})^4}{0.0004\,\text{m}^2}$$

$$G_1 = 17{,}013\,\text{W/m}^2 \qquad <$$

(d) Substituting numerical values into Eq. (1), the radiant power leaving the target collected by the radiometer is

$$q_{1\rightarrow rad} = \left(6238\,\text{W/m}^2/\pi\,\text{sr}\right) \times 0.0004\,\text{m}^2 \times 1 \times 0.0008\,\text{sr} = 635\,\mu\text{W} \qquad <$$

where the radiosity, J_1, is evaluated using Eq. (2) and G_1.

$$J_1 = 0.8 \times 5.67 \times 10^{-8}\,\text{W/m}^2\cdot\text{K}^4 \times (500\ \text{K})^4 + (1 - 0.8) \times 17{,}013\,\text{W/m}^2$$

$$J_1 = (2835 + 3403)\,\text{W/m}^2 = 6238\,\text{W/m}^2 \qquad <$$

COMMENTS: (1) Note that the emitted and reflected irradiation components of the radiosity, J_1, are of the same magnitude.

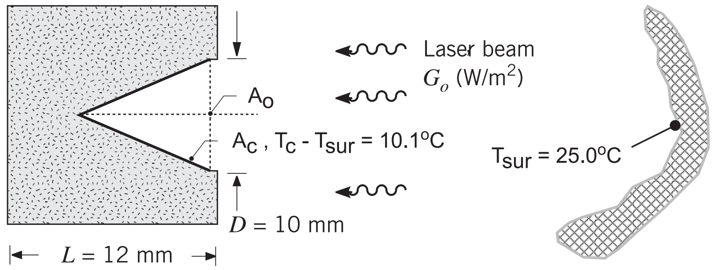
(2) Suppose the surroundings were at room temperature, T_{sur} = 300 K. Would the reflected irradiation due to the surroundings contribute significantly to the radiant power collected by the radiometer? Justify your conclusion.

PROBLEM 13.33

KNOWN: Thin-walled, black conical cavity with opening D = 10 mm and depth of L = 12 mm that is well insulated from its surroundings. Temperature of meter housing and surroundings is 25.0°C.

FIND: Radiant flux of laser beam, G_o (W/m^2), incident on the cavity when the fine-wire thermocouple indicates a temperature rise of 10.1°C.

SCHEMATIC:



ASSUMPTIONS: (1) Cavity surface is black and perfectly insulated from its mounting material in the meter, (2) Negligible convection heat transfer from the cavity surface, and (3) Surroundings are large, isothermal.

ANALYSIS: Perform an energy balance on the walls of the cavity considering absorption of the laser irradiation, absorption from the surroundings and emission.

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$A_o\, G_o + A_o\, G_{sur} - A_o\, E_b\left(T_c\right) = 0$$

where $A_o = \pi\, D^2/4$ represents the opening of the cavity. All of the radiation entering or leaving the cavity passes through this hypothetical surface. Hence, we can treat the cavity as a black disk at T_c. Since $G_{sur} = E_b\,(T_{sur})$, and $E_b = \sigma\, T^4$ with $\sigma = 5.67 \times 10^{-8}$ $W/m^2 \cdot K^4$, the energy balance has the form

$$G_o + \sigma(25.0 + 273)^4 K^4 - \sigma(25.0 + 10.1 + 273)^4 K^4 = 0$$

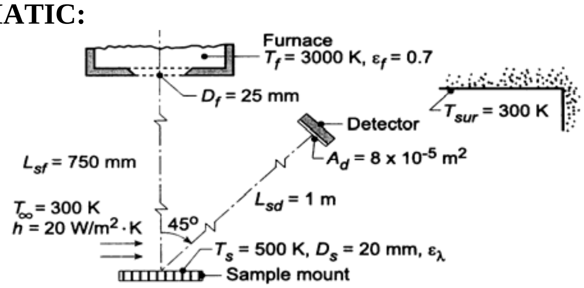
$$G_o = 63.8\ W/m^2 \qquad <$$

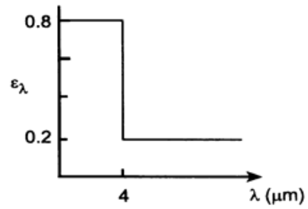
PROBLEM 13.34

KNOWN: Electrically heated sample maintained at T_s = 500 K with diffuse, spectrally selective coating. Sample is irradiated by a furnace located coaxial to the sample at a prescribed distance. Furnace has isothermal walls at T_f = 3000 K with ε_f = 0.7 and an aperture of 25 mm diameter. Sample experiences convection with ambient air at T_∞ = 300 K and h = 20 W/m^2·K. The surroundings of the sample are large with a uniform temperature T_{sur} = 300 K. A radiation detector sensitive to only power in the spectral region 3 to 5 μm is positioned at a prescribed location relative to the sample.

FIND: (a) Electrical power, P_e, required to maintain the sample at T_s = 500 K, and (b) Radiant power incident on the detector within the spectral region 3 to 5 μm considering both emission and reflected irradiation from the sample.

SCHEMATIC:

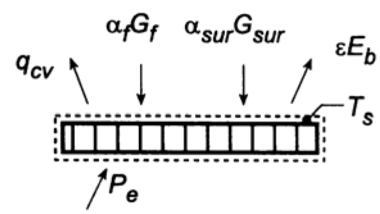




ASSUMPTIONS: (1) Steady-state condition, (2) Furnace is large, isothermal enclosure with small aperture and radiates as a blackbody, (3) Sample coating is diffuse, spectrally selective, (4) Sample and detector areas are small compared to their separation distance squared, (5) Surroundings are large, isothermal.

ANALYSIS: (a) Perform an energy balance on the sample mount, which experiences electrical power dissipation, convection with ambient air, absorbed irradiation from the furnace, absorbed irradiation from the surroundings and emission,

$$\dot{E}_{in} - \dot{E}_{out} = 0$$



$$P_e + \left[-h\left(T_s - T_\infty\right) + \alpha_f G_f + \alpha_{sur} G_{sur} - \varepsilon E_b\left(T_s\right)\right] A_s = 0$$

(1)

where $E_b\left(T_s\right) = \sigma T_s^4$ and $A_s = \pi D_s^2 / 4$.

Irradiations on the sample: The irradiation from the furnace aperture onto the sample can be written as

$$G_f = \frac{q_{f \to s}}{A_s} = \frac{A_f F_{fs} E_{b,f}}{A_s} = \frac{A_f F_{fs} \sigma T_f^4}{A_s} \qquad (2)$$

where $A_f = \pi D_f^2 / 4$ and $A_s = \pi D_s^2 / 4$. The view factor between the furnace aperture and sample follows from the relation for coaxial parallel disks, Table 13.2,

$R_f = r_f / L_{sf} = 0.0125 \text{ m} / 0.750 \text{ m} = 0.01667$ $\qquad$ $R_s = r_s / L_{sf} = 0.0100 \text{ m} / 0.750 \text{ m} = 0.01333$

$$S = 1 + \frac{1 + R_s^2}{R_f^2} = 1 + \frac{1 + 0.01333^2}{0.01667^2} = 3600.2$$

Continued …

PROBLEM 13.34 (Cont.)

$$F_{sf} = 0.5\left\{S - \left[S^2 - 4(r_s / r_f)^2\right]^{1/2}\right\} = 0.5\left\{3600 - \left[3600^2 - 4(0.05/0.0625)^2\right]^{1/2}\right\} = 0.000178$$

Hence the irradiation from the furnace is

$$G_f = \frac{\pi(0.025\ \text{m})^2/4 \times 0.000178 \times 5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4(3000\ \text{K})^4}{\pi\left(0.020^2\ \text{m}^2/4\right)} = 1277\,\text{W/m}^2$$

The irradiation from the surroundings which are large compared to the sample is

$$G_{sur} = \sigma T_{sur}^4 = 5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}(300\text{K})^4 = 459\,\text{W/m}^2$$

Emissivity of the Sample: The total hemispherical emissivity in terms of the spectral distribution can be written following Eq. 12.43 and Eq. 12.34,

$$\varepsilon = \int_0^\infty \varepsilon_\lambda E_{\lambda,b}(T_s)\,d\lambda / \sigma T^4 = \varepsilon_1 F_{(0-\lambda_1 T_s)} + \varepsilon_2\left[1 - F_{(0-\lambda_1 T_s)}\right]$$

$$\varepsilon = 0.8\times0.066728 + 0.2[1 - 0.066728] = 0.240$$

where, from Table 12.1, with $\lambda_1 T_s = 4\ \mu\text{m}\times500\ \text{K} = 2000\ \mu\text{m}\cdot\text{K},\ F_{(0-\lambda T)} = 0.066728$.

Absorptivity of the Sample: The total hemispherical absorptivity due to irradiation from the furnace follows from Eq. 12.52 and Eq. 12.34,

$$\alpha_f = \varepsilon_1 F_{(0-\lambda_1 T_f)} + \varepsilon_2\left[1 - F_{(0-\lambda_1 T_f)}\right] = 0.8\times0.945098 + 0.2[1 - 0.945098] = 0.767$$

where, from Table 12.1, with $\lambda_1 T_f = 4\,\mu\text{m}\times3000\ \text{K} = 12,000\ \mu\text{m}\cdot\text{K},\ F_{(0-\lambda T)} = 0.945098$. The total hemispherical absorptivity due to irradiation from the surroundings is

$$\alpha_{sur} = \varepsilon_1 F_{(0-\lambda_1 T_{sur})} + \varepsilon_2\left[1 - F_{(0-\lambda_1 T_{sur})}\right] = 0.8\times0.00234 + 0.2[1 - 0.002134] = 0.201$$

where, from Table 12.1, with $\lambda_1 T_{sur} = 4\ \mu\text{m}\times300\ \text{K} = 1200\ \mu\text{m}\cdot\text{K}, F_{(0-\lambda T)} = 0.002134$.

Evaluating the Energy Balance: Substituting numerical values into Eq. (1),

$$P_e = \left[+20\,\text{W/m}^2\cdot\text{K}(500-300)\text{K} - 0.767\times1277\,\text{W/m}^2\right.$$

$$\left.-0.201\times459\,\text{W/m}^2 + 0.240\times5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4(500\ \text{K})^4\right]\times4/\left(\pi\times(0.02\text{m})^2\right)$$

$$P_e = 1.256\ \text{W} - 0.308\ \text{W} - 0.029\ \text{W} + 0.267\ \text{W} = 1.19\ \text{W}$$ <

(b) The radiant power leaving the sample which is incident on the detector and within the spectral region, $\Delta\lambda$ = 3 to 5μm, follows from Eq. 12.11 with Eq. 12.34,

$$q_{s-d,\Delta\lambda} = \left[E_{s,\Delta\lambda} + G_{f,ref,\Delta\lambda} + G_{sur,ref,\Delta\lambda}\right](1/\pi)A_s\cos\theta_s\cdot A_d\cos\theta_d / L_{sd}^2$$

where $\theta_s = 45°$ and $\theta_d = 0°$. The *emitted* component is

$$E_{s,\Delta\lambda} = \int_3^{5\mu\text{m}} \varepsilon_{\lambda,b} E_{\lambda,b}(T_s)$$

$$E_{s,\Delta\lambda} = \left\{\varepsilon_1\left[F_{(0-4\mu\text{m},T_s)} - F_{(0-3\mu\text{m},T_s)}\right] + \varepsilon_2\left[F_{(0-5\mu\text{m},T_s)} - F_{(0-4\mu\text{m},T_s)}\right]\right\}\sigma T_s^4$$

Continued …

PROBLEM 13.34 (Cont.)

$$E_{s,\Delta\lambda} = \{0.8[0.066728 - 0.013754] + 0.2[0.16169 - 0.066728]\}\sigma(500K)^4 = 217.5\,W/m^2$$

where, from Table 12.1, $F_{(0-3\mu m, T_s)} = 0.013754$ at $\lambda T = 3\,\mu m \times 500\ K = 1500\ \mu m \cdot K$; $F_{(0-4\mu m, T_s)} = 0.066728$ at $\lambda = 4\,\mu m \times 500\ K = 2000\ \mu m \cdot K$; and $F_{(0-5\mu m, T_s)} = 0.16169$ at λT = 5μm × 500 K = 2500 μm·K.

The *reflected irradiation from the furnace* component is

$$G_{f,ref,\Delta\lambda} = \int_3^{5\mu m} (1-\varepsilon_\lambda) G_{f,\lambda} d\lambda$$

where $G_{f,\lambda} \approx E_{\lambda,b}(T_f)$, using band emission factors,

$$G_{f,ref,\Delta\lambda} = \{(1-\varepsilon)[F_{(0-4\mu m,T_f)} - F_{(0-3\mu m,T_f)}] + (1-\varepsilon_2)[F_{(0-5\mu m,T_f)} - F_{(0-4\mu m,T_f)}]\} G_f$$

$$G_{f,ref,\Delta\lambda} = \{0.2[0.9451 - 0.8900] + 0.8[0.9700 - 0.9451]\} 1277\,W/m^2 = 39.51\,W/m^2$$

where, from Table 12.1, $F_{(0-3\mu m, T_f)} = 0.8900$ at λT_f = 3 μm × 3000 K = 9000 μm·K; $F_{(0-4\mu m, T_f)} = 0.9451$ at λT_f = 4 μm × 3000 K = 12,000 μm·K; and, $F_{(0-5\mu m, T_f)} = 0.9700$ at λT_f = 5 μm × 3000 K = 15,000 μm·K.

The *reflected irradiation from the surroundings* component is

$$G_{sur,ref,\Delta\lambda} = \int_3^{5\mu m} (1-\varepsilon_\lambda) G_{ref,\lambda} d\lambda$$

where $G_{ref,\lambda} \approx E_\lambda(T_{sur})$, using band emission factors,

$$G_{sur,ref,\Delta\lambda} = \{(1-\varepsilon_1)[F_{(0-4\mu m,T_{sur})} - F_{(0-3\mu m,T_{sur})}] + (1-\varepsilon_2)[F_{(0-5\mu m,T_{sur})} - F_{(0-4\mu m,T_{sur})}]\} G_{sur}$$

$$G_{sur,ref,\Delta\lambda} = \{0.2[0.002134 - 0.0001685] - 0.8[0.013754 - 0.002134]\} 459\,W/m^2 = 4.44\,W/m^2$$

where, from Table 12.1, $F_{(0-3\mu m, T_{sur})} = 0.0001685$ at λT_{sur} = 3 μm ×·300 K = 900 μm·K; $F_{(0-4\mu m, T_{sur})} = 0.002134$ at λT_{sur} = 4 μm × 300 K = 1200 μm·K; and $F_{(0-5\mu m, T_{sur})} = 0.013754$ at λT_{sur} = 5 μm ×300 K=1500 μm·K. Returning to Eq. (3), find

$$q_{sd,\Delta\lambda} = [217.5 + 39.51 + 4.44]\,W/m^2 (1/\pi)[\pi(0.020\ m)^2/4]$$

$$\cos 45° \times 8 \times 10^{-5} m^2 \times \cos 0°/(1\ m)^2 = 1.48\ \mu W \qquad <$$

COMMENTS: (1) Note that F_{fs} is small, since A_f, $A_s << L_{sf}^2$. As such, we could have evaluated $q_{f\rightarrow s}$ using Eq. 12.6 and found

$$G_f = \frac{E_{b,f}/\pi A_f (A_s/L_{sf}^2)}{A_s} = 1276\,W/m^2$$

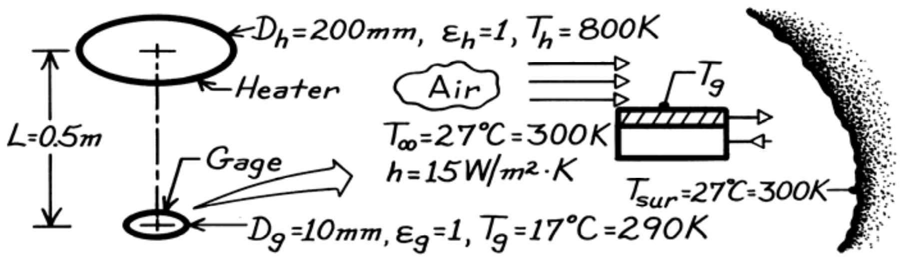
(2) Recognize in the analysis for part (b), Eq. (3), the role of the band emission factors in calculating the fraction of total radiant power for the emitted and reflected irradiation components.

PROBLEM 13.35

KNOWN: Water-cooled heat flux gage exposed to radiant source, convection process and surroundings.

FIND: (a) Net radiation exchange between heater and gage, (b) Net transfer of radiation to the gauge per unit area of the gage, (c) Net heat transfer to the gage per unit area of gage, (d) Heat flux indicated by gage described in Problem 3.98.

SCHEMATIC:



ASSUMPTIONS: (1) Heater and gauge are parallel, coaxial discs having blackbody behavior, (2) $A_g << A_h$, (3) Surroundings are large compared to A_h and A_g.

ANALYSIS: (a) The net radiation exchange between the heater and the gage, both with blackbody behavior, is

$$q_{h-g} = A_h F_{hg} \sigma \left(T_h^4 - T_g^4\right) = A_g F_{gh} \sigma \left(T_h^4 - T_g^4\right).$$

Note the use of reciprocity, Eq. 13.3, for the view factors. From Eq. 13.8,

$$F_{gh} = D_h^2 / \left(4L^2 + D_h^2\right) = (0.2\text{m})^2 / \left(4 \times 0.5^2 \text{m}^2 + 0.2^2 \text{m}^2\right) = 0.0385.$$

$$q_{h-g} = \left(\pi 0.01^2 \text{m}^2 / 4\right) \times 0.0385 \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 \left[800^4 - 290^4\right] \text{K}^4 = 69.0 \text{ mW}. \qquad <$$

(b) The net radiation *to* the gage per unit area will involve exchange with the heater and the surroundings.

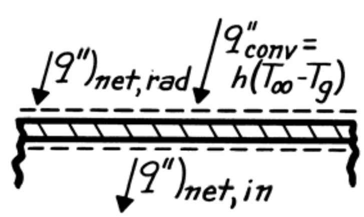
$$q''_{net,rad} = -q_g / A_g = q_{h-g} / A_g + q_{sur-g} / A_g.$$

The net exchange with the surroundings is

$$q_{sur-g} = A_{sur} F_{sur-g} \sigma \left(T_{sur}^4 - T_g^4\right) = A_g F_{g-sur} \sigma \left(T_{sur}^4 - T_g^4\right).$$

$$q''_{net,rad} = \frac{69.0 \times 10^{-3} \text{W}}{\pi (0.01\text{m})^2 / 4} + (1 - 0.0385) 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 \left(300^4 - 290^4\right) \text{K}^4 = 934.5 \text{W/m}^2. \qquad <$$

(c) The net heat transfer rate to the gage per unit area of the gage follows from the surface energy balance



$$q''_{net,in} = q''_{net,rad} + q''_{conv}$$

$$q''_{net,in} = 934.5 \text{W/m}^2 + 15 \text{W/m}^2 \cdot \text{K} (300 - 290) \text{K}$$

$$q''_{net,in} = 1085 \text{W/m}^2. \qquad <$$

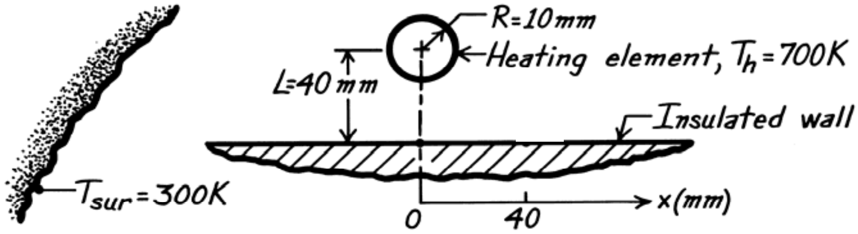
(d) The heat flux gage described in Problem 3.98 would experience a net heat flux to the surface of 1085 W/m^2. The irradiation to the gage from the heater is $G_g = q_{h \to g}/A_g = F_{gh} \sigma T_h^4 = 894$ W/m^2. Since the gage responds to net heat flux, there would be a systematic error in sensing irradiation from the heater.

PROBLEM 13.36

KNOWN: Long cylindrical heating element located a given distance above an insulated wall exposed to cool surroundings. Diameter and temperature of heating element. Surroundings temperature.

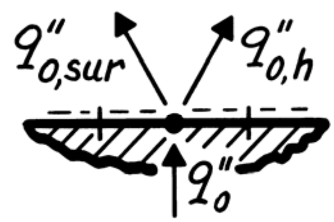
FIND: (a) Maximum temperature attained by wall. (b) Plot the wall temperature over the range –100 mm ≤ x ≤ 100 mm.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Insulated wall, (3) Negligible conduction in wall, (4) All surfaces are black.

ANALYSIS: (a) We begin with a general analysis for the temperature at any point x. Consider an elemental area dA_o at point x. Since the wall is insulated and conduction is negligible, the net radiation leaving dA_o is zero. From Eq. 13.14 (divided by A_i),



$$q''_o = q''_{o,h} + q''_{o,sur} = F_{o,h}\,\sigma\left(T_o^4 - T_h^4\right) + F_{o,sur}\sigma\left(T_o^4 - T_{sur}^4\right) = 0 \quad (1)$$

where $F_{o,sur} = 1 - F_{o,h}$ and $F_{o,h}$ can be found from the relation for a cylinder and parallel rectangle, Table 13.1, with $s_2 = x$ and $s_1 = s_2 + \delta$, in the limit as $\delta \to 0$. From a Taylor series expansion,

$$\lim_{\delta\to 0} \tan^{-1}\left(\frac{s_2+\delta}{L}\right) = \tan^{-1}\left(\frac{s_2}{L}\right) + \frac{\delta / L}{1+(s_2 / L)^2}$$

Thus,

$$F_{o,h} = \frac{r}{s_1 - s_2}\left[\tan^{-1}\frac{s_1}{L} - \tan^{-1}\frac{s_2}{L}\right] = \frac{r}{\delta}\left[\frac{\delta / L}{1+(s_2 / L)^2}\right] = \frac{r / L}{1+(x / L)^2} \quad (2)$$

Rearranging Eq. (1) and substituting numerical values, find

$$T_o = \left[F_{o,h}T_h^4 + \left(1 - F_{o,h}\right)T_{sur}^4\right]^{1/4} \quad (3)$$

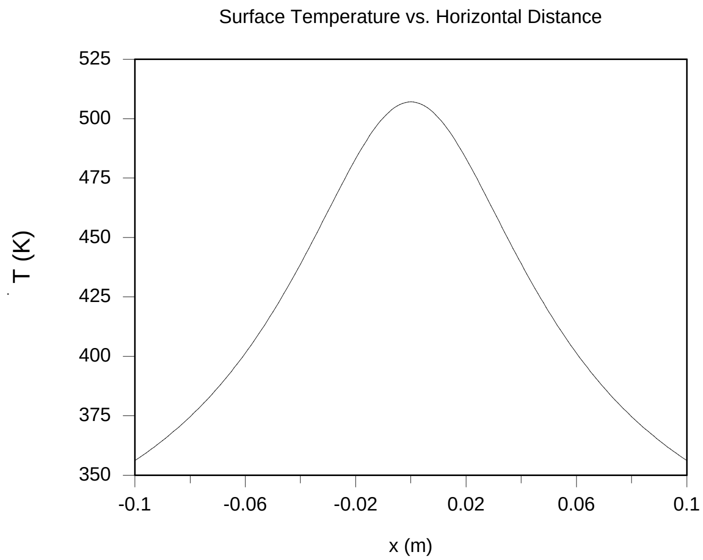
The maximum value of T_o will occur at x = 0, where $F_{o,h} = r/L = 10/40 = 0.25$. Thus,

$$T_{o,max} = \left[0.25(700\text{ K})^4 + (1-0.25)(300\text{ K})^4\right]^{1/4} = 507\text{ K} \quad <$$

(b) Eq. (3) can be evaluated with Eq. (2) for $F_{o,h}$, over the range –100 mm ≤ x ≤ 100 mm. The results are shown below.

Continued…

PROBLEM 13.36 (Cont.)



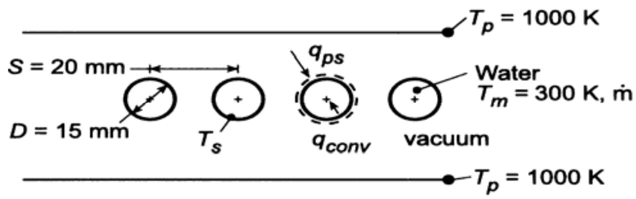
COMMENTS: (1) Note the importance of the assumptions that the wall is insulated and conduction is negligible. (2) In calculating $F_{o,h}$ we are finding the view factor for a small area or point. As an alternative to using a Taylor series expansion, the value can be found by evaluating the view factor from the equation in Table 13.1 for progressively smaller values of $s_1 - s_2$ until the value converges.

PROBLEM 13.37

KNOWN: Diameter and pitch of in-line tubes occupying evacuated space between parallel plates of prescribed temperature. Temperature and flowrate $\dot{m}$ of water through the tubes.

FIND: (a) Tube surface temperature T_s for $\dot{m}$ = 0.20 kg/s, (b) Effect of $\dot{m}$ on T_s.

SCHEMATIC:



ASSUMPTIONS: (1) Surfaces behave as blackbodies, (2) Negligible tube wall conduction resistance, (3) Fully-developed tube flow.

PROPERTIES: *Table A-6*, water (T_m = 300 K): $\mu = 855 \times 10^{-6}$ N·s/m^2, k = 0.613 W/m·K, Pr = 5.83.

ANALYSIS: (a) Performing an energy balance on a single tube, it follows that $q_{ps} = q_{conv}$, or

$$A_p F_{ps} \sigma \left(T_p^4 - T_s^4\right) = h A_s \left(T_s - T_m\right)$$

From Table 13.1 and D/S = 0.75, the view factor is

$$F_{ps} = 1 - \left[1 - \left(\frac{D}{S}\right)^2\right]^{1/2} + \left(\frac{D}{S}\right)\tan^{-1}\left(\frac{S^2 - D^2}{D^2}\right)^{1/2} = 0.881$$

With $Re_D = 4\dot{m}/\pi D\mu = 4\left(0.20\ \text{kg/s}\right)/\pi\left(0.015\,\text{m}\right)855\times10^{-6}\,\text{N}\cdot\text{s/m}^2 = 19{,}856$, fully-developed turbulent flow may be assumed, in which case Eq. 8.60 yields

$$h = \frac{k}{D}\left(0.023\,Re_D^{4/5}\,Pr^{0.4}\right) = \frac{0.613\ \text{W/m}\cdot\text{K}}{0.015\,\text{m}}\left(0.023\right)\left(19{,}856\right)^{4/5}\left(5.83\right)^{0.4} = 5220\,\text{W/m}^2\cdot\text{K}$$

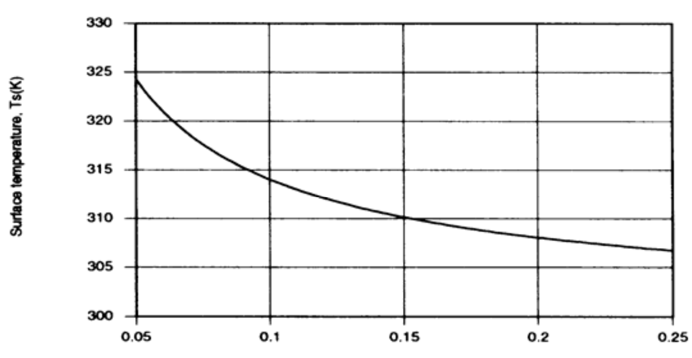
Hence, with $(A_p/A_s) = 2S/\pi D = 0.849$,

$$T_s - T_m = \frac{F_{ps}\sigma}{h}\frac{A_p}{A_s}\left(T_p^4 - T_s^4\right) = \frac{0.881\times5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4}{5220\ \text{W/m}^2\cdot\text{K}}\left(0.849\right)\left(T_p^4 - T_s^4\right)$$

With T_m = 300 K and T_p = 1000 K, a trial-and-error solution yields

$$T_s = 308\ \text{K}$$ <

(b) Using the *Correlations and Radiation* Toolpads of *IHT* to evaluate the convection coefficient and view factor, respectively, the following results were obtained.



The decrease in T_s with increasing $\dot{m}$ is due to an increase in h and hence a reduction in the convection resistance.

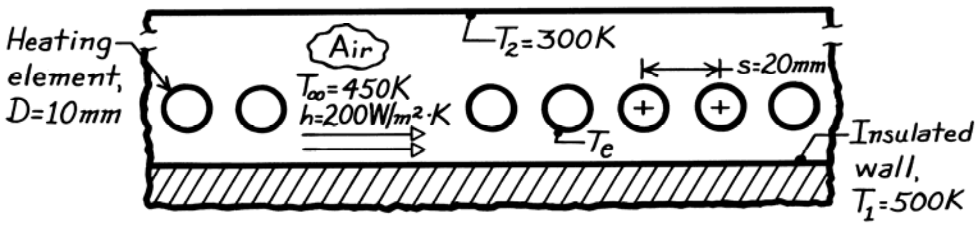
COMMENTS: Due to the large value of h, $T_s << T_p$.

PROBLEM 13.38

KNOWN: Insulated wall exposed to a row of regularly spaced cylindrical heating elements.

FIND: Required operating temperature of the heating elements for the prescribed conditions.

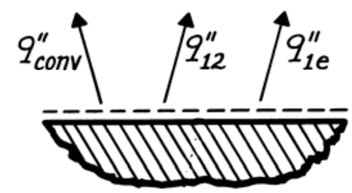
SCHEMATIC:



ASSUMPTIONS: (1) Upper and lower walls are isothermal and infinite, (2) Lower wall is insulated, (3) All surfaces are black, (4) Steady-state conditions.

ANALYSIS: Perform an energy balance on the insulated wall considering convection and radiation.

$$\dot{E}''_{in} - \dot{E}''_{out} = -q''_1 - q''_{conv} = 0$$



where q''_1 is the net radiation leaving the insulated wall per unit area. We know that

$$q''_1 = q''_{1e} + q''_{12} = F_{1e}\sigma\left(T_1^4 - T_e^4\right) + F_{12}\sigma\left(T_1^4 - T_2^4\right)$$

where $F_{12} = 1 - F_{1e}$. Using Newton's law of cooling for q''_{conv} solve for T_e,

$$T_e^4 = \left[T_1^4 + \frac{(1-F_{1e})}{F_{1e}}\left(T_1^4 - T_2^4\right)\right] + \frac{h}{\sigma}\frac{1}{F_{1e}}\left(T_1 - T_\infty\right).$$

The view factor between the insulated wall and the tube row follows from the relation for an infinite plane and row of cylinders, Table 13.1,

$$F_{1e} = 1 - \left[1 - \left(\frac{D}{S}\right)^2\right]^{1/2} + \left(\frac{D}{S}\right)\tan^{-1}\left(\frac{s^2 - D^2}{D^2}\right)^{1/2}$$

$$F_{1e} = 1 - \left[1 - \left(\frac{10}{20}\right)^2\right]^{1/2} + \left(\frac{10}{20}\right)\tan^{-1}\left(\frac{20^2 - 10^2}{10^2}\right)^{1/2} = 0.658.$$

Substituting numerical values, find

$$T_e^4 = \left[(500\ \text{K})^4 + \frac{1-0.658}{0.658}\left(500^4 - 300^4\right)\text{K}^4\right] + \frac{200\ \text{W/m}^2\cdot\text{K}}{5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4} \times \frac{1}{0.658}(500-450)\text{K}$$

$$T_e = 774\ \text{K}.$$ <

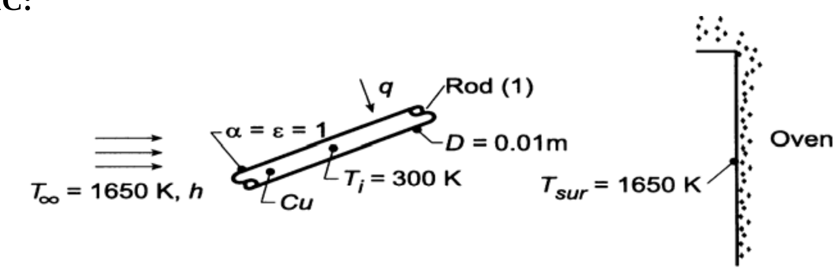
COMMENTS: Always express temperatures in kelvins when considering convection and radiation terms in an energy balance. Why is F_{1e} independent of the distance between the row of tubes and the wall?

PROBLEM 13.39

KNOWN: Surface radiative properties, diameter and initial temperature of a copper rod placed in an evacuated oven of prescribed surface temperature.

FIND: (a) Initial heating rate, (b) Time t_h required to heat rod to 1000 K, (c) Effect of convection on heating time.

SCHEMATIC:



ASSUMPTIONS: (1) Copper may be treated as a lumped capacitance, (b) Radiation exchange between rod and oven may be approximated as blackbody exchange.

PROPERTIES: *Table A-1*, Copper (300 K): ρ = 8933 kg/m^3, c_p = 385 J/kg·K, k = 401 W/m·K.

ANALYSIS: (a) Performing an energy balance on a unit length of the rod, $\dot{E}_{in} = \dot{E}_{st}$, or

$$q = Mc_p \frac{dT}{dt} = \rho\left(\frac{\pi D^2}{4} \times 1\right) c_p \frac{dT}{dt}$$

Neglecting convection, $q = q_{rad} = A_2 F_{21}\ \sigma\left(T_{sur}^4 - T^4\right) = A_1 F_{12}\ \sigma\left(T_{sur}^4 - T^4\right)$, where $A_1 = \pi D \times 1$ and $F_{12} = 1$. It follows that

$$\frac{dT}{dt} = \frac{\sigma \pi D\left(T_{sur}^4 - T^4\right)}{\rho\left(\pi D^2 / 4\right) c_p} = \frac{4\sigma\left(T_{sur}^4 - T^4\right)}{\rho D c_p} \qquad (1)$$

$$\left.\frac{dT}{dt}\right)_i = \frac{4\left[(1650\ \text{K})^4 - (300\ \text{K})^4\right] 5.67 \times 10^{-8}\,\text{W/m}^2 \cdot \text{K}^4}{8933\ \text{kg/m}^3\,(0.01\,\text{m})\,385\,\text{J/kg}\cdot\text{K}} = 48.8\ \text{K/s}. \qquad <$$

(b) Using the *IHT Lumped Capacitance Model* to numerically integrate Eq. (2), we obtain

$$t_s = 15.0\ \text{s} \qquad <$$

(c) With convection, $q = q_{rad} + q_{conv} = A_1 F_{12}\ \sigma\left(T_{sur}^4 - T^4\right) + hA_1 (T_\infty - T)$, and the energy balance becomes

$$\frac{dT}{dt} = \frac{4\sigma\left(T_{sur}^4 - T^4\right)}{\rho D c_p} + \frac{4h\left(T_\infty - T\right)}{\rho D c_p}$$

Performing the numerical integration for the three values of h, we obtain

h (W/m^2·K):	10	100	500
t_h (s):	14.6	12.0	6.8

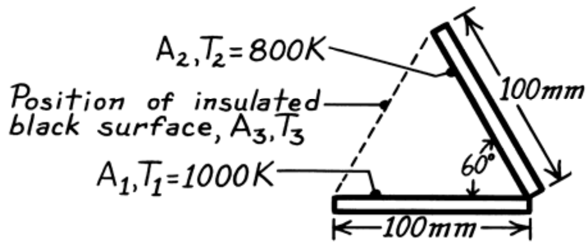
COMMENTS: With an initial value of $h_{rad,i} = \sigma\left(T_{sur}^4 - T^4\right)/(T_{sur} - T)$ = 311 W/m^2·K, Bi = h_{rad} (D/4)/k = 0.002 and the lumped capacitance assumption is justified for parts (a) and (b). With h = 500 W/m^2·K and h + $h_{r,i}$ = 811 W/m·K in part (c), Bi = 0.005 and the lumped capacitance approximation is also valid.

PROBLEM 13.40

KNOWN: Long, inclined black surfaces maintained at prescribed temperatures.

FIND: (a) Net radiation exchange between the two surfaces per unit length, (b) Net radiation transfer to surface A_2 with black, insulated surface positioned as shown below; determine temperature of this surface.

SCHEMATIC:



ASSUMPTIONS: (1) Surfaces behave as blackbodies, (2) Surfaces are very long in direction normal to page.

ANALYSIS: (a) The net radiation exchange between two black surfaces is

$$q_{12} = A_1 F_{12} \sigma \left(T_1^4 - T_2^4\right)$$

Noting that A_1 = width×length (ℓ) and that from symmetry, $F_{12} = 0.5$, find

$$q'_{12} = \frac{q_{12}}{\ell} = 0.1\ \text{m} \times 0.5 \times 5.67 \times 10^{-8}\ \text{W/m}^2 \cdot \text{K}^4 \left(1000^4 - 800^4\right)\text{K}^4 = 1680\ \text{W/m}. \quad <$$

(b) From Eq. 13.14,

$$q'_3 = \frac{q_3}{\ell} = \frac{A_3}{\ell} F_{31}\sigma\left(T_3^4 - T_1^4\right) + \frac{A_3}{\ell} F_{32}\sigma\left(T_3^4 - T_2^4\right) = 0$$

Since $F_{31} = F_{32}$, $\quad T_3 = \left[\left(T_1^4 + T_2^4\right)/2\right]^{1/4} = \left[\left(1000^4 + 800^4\right)/2\right]^{1/4}\ \text{K} = 916\ \text{K}. \quad <$

Also from Eq. 13.14,

$$q'_2 = \frac{q_2}{\ell} = \frac{A_2}{\ell} F_{21}\sigma\left(T_2^4 - T_1^4\right) + \frac{A_2}{\ell} F_{23}\sigma\left(T_2^4 - T_3^4\right) \quad <$$

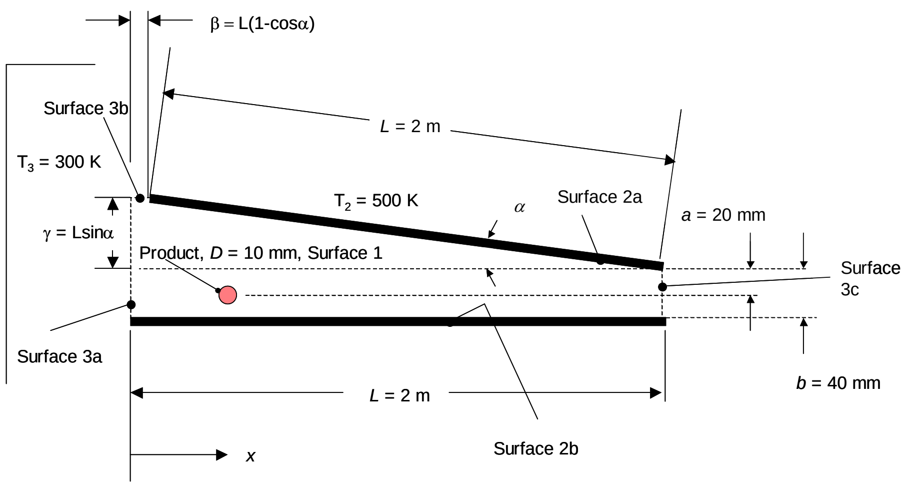
$$= 0.1 \times 0.5 \times 5.67 \times 10^{-8}\ \text{W/m}^2 \cdot \text{K}^4 \times \left(2 \times 800^4 - 1000^4 - 916^4\right)\text{K}^4 = -2508\ \text{W/m}$$

PROBLEM 13.41

KNOWN: Position of long cylindrical-shaped product conveyed in an oven with non-uniform wall temperatures. Product diameter, temperature of surroundings and panel heaters.

FIND: (a) Radiation incident upon the product, per unit length at product locations x = 0.5 m and x = 1.0 m for $\alpha = 0$, (b) Radiation incident upon the product, per unit length, at product locations of x = 0.5 m and x = 1.0 m for $\alpha = \pi/15$.

SCHEMATIC:



ASSUMPTIONS: (1) Two-dimensional system, (2) Steady-state conditions, (3) Blackbody behavior, (4) Large surroundings.

ANALYSIS:

Consider the cylinder and parallel rectangle arrangement of Table 13.1. We note that

$$F_{ij} = \frac{r}{s_1 - s_2}\left[\tan^{-1}\frac{s_1}{L} - \tan^{-1}\frac{s_2}{L}\right]$$

and by reciprocity

$$F_{ji} = \frac{A_i F_{ij}}{A_j} = \frac{(s_1 - s_2)F_{ij}}{2\pi r}$$

Therefore,

$$F_{ji} = \frac{1}{2\pi}\left[\tan^{-1}\frac{s_1}{L} + \tan^{-1}\frac{s_2}{L}\right] \qquad (1)$$

Continued…

PROBLEM 13.41 (Cont.)

(a) For $\alpha = 0$,

$$F_{13a} = \frac{1}{2\pi}\left[\tan^{-1}\left(\frac{a}{x}\right) - \tan^{-1}\left(\frac{-(b-a)}{x}\right)\right]$$

where $s_1 = a$ and $s_2 = -(b - a)$. For x = 0.5 m,

$$F_{13a} = \frac{1}{2\pi}\left[\tan^{-1}\left(\frac{0.02}{0.5}\right) - \tan^{-1}\left(\frac{-(0.04-0.02}{0.5}\right)\right] = 0.0127$$

For x = 1.0 m,

$$F_{13a} = \frac{1}{2\pi}\left[\tan^{-1}\left(\frac{0.02}{1.0}\right) - \tan^{-1}\left(\frac{-(0.04-0.02}{1.0}\right)\right] = 0.0064$$

Since $A_{3b} = 0$ for $\alpha = 0$, $F_{13b} = 0$.

For F_{13c} we note that $s_1 = a$ and $s_2 = -(b – a)$. Therefore,

$$F_{13c} = \frac{1}{2\pi}\left[\tan^{-1}\left(\frac{a}{L-x}\right) - \tan^{-1}\left(\frac{-(b-a)}{L-x}\right)\right]$$

For x = 0.5 m,

$$F_{13c} = \frac{1}{2\pi}\left[\tan^{-1}\left(\frac{0.02}{1.5}\right) - \tan^{-1}\left(\frac{-(0.04-0.02}{1.5}\right)\right] = 0.0042$$

For x = 1.0 m,

$$F_{13c} = \frac{1}{2\pi}\left[\tan^{-1}\left(\frac{0.02}{1.0}\right) - \tan^{-1}\left(\frac{-(0.04-0.02}{1.0}\right)\right] = 0.0064$$

Noting that $F_{13} = F_{13a} + F_{13b} + F_{13c}$, we find for x = 0.5 m, $F_{13} = 0.0127 + 0 + 0.0042 = 0.0169$. Likewise for x = 1.0 m, $F_{13} = 0.0064 + 0 + 0.0064 = 0.0128$. The radiation incident upon the product is $q_{in} = q_{21} + q_{31} = A_2F_{21}\sigma T_1^4 + A_3F_{31}\sigma T_3^4$. Noting that $A_2F_{21} = A_1F_{12} = A_1(1 – F_{13})$ and $A_1 = \pi DL$, the preceding expression becomes

$$q_{in}^{'} = q_{in}/L = \pi D\sigma\left[T_2^4(1-F_{13}) + T_3^4F_{13}\right] \qquad (2)$$

For x = 0.5 m,

Continued…

PROBLEM 13.41 (Cont.)

$$q'_{in} = \pi \times 0.01\text{m} \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \times \left[(500\text{K})^4 \times (1 - 0.0169) + (300\text{K})^4 \times 0.0169 \right] = 109.7 \text{ W/m} <$$

For x = 1.0 m,

$$q'_{in} = \pi \times 0.01\text{m} \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \times \left[(500\text{K})^4 \times (1 - 0.0128) + (300\text{K})^4 \times 0.0128 \right] = 110.1 \text{ W/m} <$$

(b) For $\alpha = \pi/15$,

$$F_{13a} = \frac{1}{2\pi}\left[\tan^{-1}\left(\frac{a+\gamma}{x}\right) - \tan^{-1}\left(\frac{-(b-a)}{x}\right) \right]$$

where $\gamma = L\sin\alpha$, $s_1 = a + L\sin\alpha$ and $s_2 = -(b-a)$.

For x = 0.5 m,

$$F_{13a} = \frac{1}{2\pi}\left[\tan^{-1}\left(\frac{0.02 + 2\sin(\pi/15)}{0.5}\right) - \tan^{-1}\left(\frac{-(0.04 - 0.02}{0.5}\right) \right] = 0.1205$$

Likewise, for x = 1.0 m, $F_{13a} = 0.0686$.

From Eq. (1),

$$F_{13b} = \frac{1}{2\pi}\left[\tan^{-1}\left(\frac{x}{a+\gamma}\right) - \tan^{-1}\left(\frac{\beta}{a+\gamma}\right) \right]$$

where $\beta = L(1 - \cos\alpha)$.

For x = 0.5 m,

$$F_{13b} = \frac{1}{2\pi}\left[\tan^{-1}\left(\frac{0.5}{0.02 + 2\sin(\pi/15)}\right) - \tan^{-1}\left(\frac{0.5 - 2(1 - \cos(\pi/15))}{0.02 + 2\sin(\pi/15)}\right) \right] = 0.0072$$

Likewise, for x = 1.0 m, $F_{13b} = 0.0026$. The values of F_{13c} are the same as in part (a).

For x = 0.5 m, $F_{13} = F_{13a} + F_{13b} + F_{13c} = 0.1205 + 0.0072 + 0.0042 = 0.1319$. Likewise, for x = 1.0 m, $F_{13} = 0.0686 + 0.0026 + 0.0064 = 0.0776$.

Using Eq. (2) for x = 0.5 m,

$$q'_{in} = \pi \times 0.01\text{m} \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \times \left[(500\text{K})^4 (1 - 0.1319) + (300\text{K})^4 \times 0.1319 \right] = 98.5 \text{W/m} <$$

Continued…

PROBLEM 13.41 (Cont.)

Likewise for x = 1.0 m,

$$q'_{in} = \pi \times 0.01\text{m} \times 5.67 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4} \times \left[(500\text{K})^4 (1 - 0.0776) + (300\text{K})^4 \times 0.0776 \right] = 103.8\text{W/m} \quad <$$

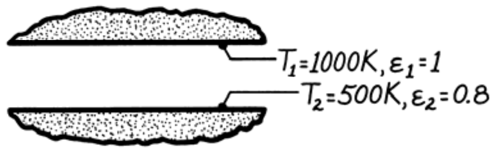
COMMENTS: (1) For the $\alpha = 0$ case, the irradiation of the product at x = 0.5 m is 99.6 % of the irradiation at x = 1 m, where the irradiation is maximized. The influence of the oven openings is very small in the central portion of the oven. (2) Modifying the tilt angle of the upper panel heater is effective in controlling the radiative heating of the product. However, convection heating and/or cooling of the product will also be affected by the change in the oven geometry.

PROBLEM 13.42

KNOWN: Two horizontal, very large parallel plates with prescribed surface conditions and temperatures.

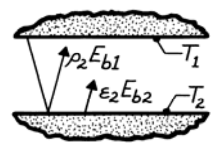
FIND: (a) Irradiation to the top plate, G_1, (b) Radiosity of the top plate, J_1, (c) Radiosity of the lower plate, J_2, (d) Net radiative exchange between the plates per unit area of the plates.

SCHEMATIC:



ASSUMPTIONS: (1) Plates are sufficiently large to form a two surface enclosure and (2) Surfaces are diffuse-gray and have uniform radiation and radiosity distributions.

ANALYSIS: (a) The irradiation to the upper plate is defined as the radiant flux incident on that surface. The irradiation to the upper plate G_1 is comprised of flux emitted by surface 2 and reflected flux emitted by surface 1.



$$G_1 = \varepsilon_2 E_{b2} + \rho_2 E_{b1} = \varepsilon_2 \sigma T_2^4 + (1-\varepsilon_2)\sigma T_1^4$$

$$G_1 = 0.8 \times 5.67 \times 10^{-8}\,\text{W/m}^2 \cdot \text{K}^4 (500\ \text{K})^4 + (1-0.8) \times 5.67 \times 10^{-8}\,\text{W/m}^2 \cdot \text{K}^4 (1000\ \text{K})^4$$

$$G_1 = 2835\,\text{W/m}^2 + 11,340\,\text{W/m}^2 = 14,175\,\text{W/m}^2. \quad <$$

(b) The radiosity is defined as the radiant flux leaving the surface by emission and reflection. For the blackbody surface 1, it follows that

$$J_1 = E_{b1} = \sigma T_1^4 = 5.67 \times 10^{-8}\,\text{W/m}^2 \cdot \text{K}^4 (1000\ \text{K})^4 = 56,700\,\text{W/m}^2. \quad <$$

(c) The radiosity of surface 2 is then,

$$J_2 = \varepsilon_2 E_{b2} + \rho_2 G_2.$$

Since the upper plate is a blackbody, it follows that $G_2 = E_{b1}$ and

$$J_2 = \varepsilon_2 E_{b1} + \rho_2 E_{b1} = \varepsilon_2 \sigma T_2^4 + 1(1-\varepsilon_2)\sigma T_1^4 = 14,175\,\text{W/m}^2. \quad <$$

Note that $J_2 = G_1$. That is, the radiant flux leaving surface 2 (J_2) is incident upon surface 1 (G_1).

(d) The net radiation heat exchange per unit area can be found by three relations.

$$q_1'' = J_1 - G_1 = (56,700 - 14,175)\,\text{W/m}^2 = 42,525\,\text{W/m}^2$$

$$q_{12}'' = J_1 - J_2 = (56,700 - 14,175)\,\text{W/m}^2 = 42,525\,\text{W/m}^2 \quad <$$

The exchange relation, Eq. 13.24, is also appropriate with $\varepsilon_1 = 1$,

$$q_1'' = -q_2'' = q_{12}''$$

$$q_1'' = \varepsilon_2 \sigma \left(T_1^4 - T_2^4\right) = 0.8 \times 5.67 \times 10^{-8}\,\text{W/m}^2 \cdot \text{K}^4 \left(1000^4 - 500^4\right)\text{K}^4 = 42,525\,\text{W/m}^2.$$

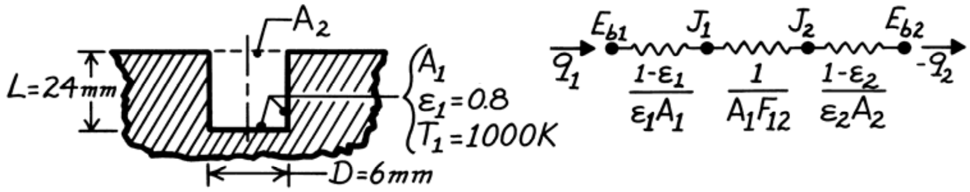
COMMENT: Since the plates are large, the assumption of uniform irradiation and radiosity distributions is excellent.

PROBLEM 13.43

KNOWN: Dimensions and temperature of a flat-bottomed hole.

FIND: (a) Radiant power leaving the opening, (b) Effective emissivity of the cavity, ε_e, (c) Limit of ε_e as depth of hole increases.

SCHEMATIC:



ASSUMPTIONS: (1) Hypothetical surface A_2 is a blackbody at 0 K, (2) Cavity surface is isothermal, opaque and diffuse-gray with uniform radiosity and irradiation distributions.

ANALYSIS: Approximating A_2 as a blackbody at 0 K implies that all of the radiation incident on A_2 from the cavity results (directly or indirectly) from emission by the walls and escapes to the surroundings. It follows that for A_2, $\varepsilon_2 = 1$ and $J_2 = E_{b2} = 0$.

(a) From the thermal circuit, the rate of radiation loss through the hole (A_2) is

$$q_1 = \left(E_{b1} - E_{b2}\right) / \left[\frac{1-\varepsilon_1}{\varepsilon_1 A_1} + \frac{1}{A_1 F_{12}} + \frac{1-\varepsilon_2}{\varepsilon_2 A_2}\right]. \qquad (1)$$

Noting that $F_{21} = 1$ and $A_1 F_{12} = A_2 F_{21}$, also that

$$A_1 = \pi D^2/4 + \pi DL = \pi D\left(D/4 + L\right) = \pi\left(0.006\,\text{m}\right)\left(0.006\,\text{m}/4 + 0.024\,\text{m}\right) = 4.807\times10^{-4}\,\text{m}^2$$

$$A_2 = \pi D^2/4 = \pi\left(0.006\,\text{m}\right)^2/4 = 2.827\times10^{-5}\,\text{m}^2.$$

Substituting numerical values with $E_b = \sigma T^4$, find

$$q_1 = 5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left(1000^4 - 0\right)\text{K}^4 / \left[\frac{1-0.8}{0.8\times4.807\times10^{-4}\,\text{m}^2} + \frac{1}{2.827\times10^{-5}\,\text{m}^2} + 0\right]$$

$$q_1 = 1.580\ \text{W}. \qquad <$$

(b) The effective emissivity, ε_e, of the cavity is defined as the ratio of the radiant power leaving the cavity to that from a blackbody having the same area of the cavity opening and at the temperature of the inner surfaces of the cavity. For the cavity above,

$$\varepsilon_e = \frac{q_1}{A_2 \sigma T_1^4}$$

$$\varepsilon_e = 1.580\,\text{W} / 2.827\times10^{-5}\,\text{m}^2\left(5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\right)\left(1000\ \text{K}\right)^4 = 0.986. \qquad <$$

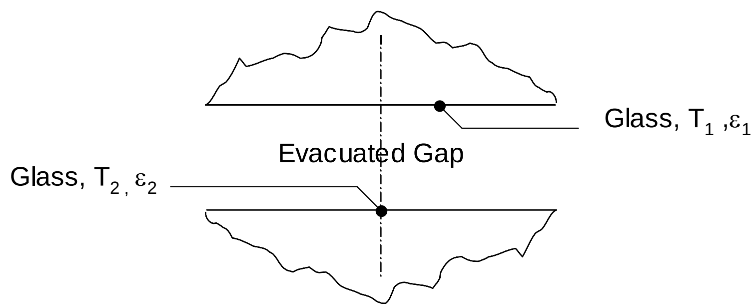
(c) As the depth of the hole increases, the term $(1 - \varepsilon_1)/\varepsilon_1 A_1$ goes to zero such that the remaining term in the denominator of Eq. (1) is $1/A_1 F_{12} = 1/A_2 F_{21}$. That is, as L increases, $q_1 \rightarrow A_2 F_{21} E_{b1}$. This implies that $\varepsilon_e \rightarrow 1$ as L increases. For L/D = 10, one would expect $\varepsilon_e = 0.999$ or better.

PROBLEM 13.44

KNOWN: Temperatures and emissivity of glass surfaces.

FIND: Heat flux through the window for case 1: $\varepsilon_1 = \varepsilon_2 = 0.95$, case 2: $\varepsilon_1 = \varepsilon_2 = 0.05$, and case 3: $\varepsilon_1 = 0.05$, $\varepsilon_2 = 0.95$.

SCHEMATIC:



ASSUMPTIONS: (1) Diffuse-gray surfaces with uniform radiosity and irradiation distributions, (2) Infinite parallel glass surfaces.

ANALYSIS: For case 1, the net radiation heat flux between the glass sheets is

$$q''_{rad} = \frac{\sigma\left(T_1^4 - T_2^4\right)}{\dfrac{1}{\varepsilon_1} + \dfrac{1}{\varepsilon_2} - 1} = \frac{5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left(293\text{K}^4 - 263\text{K}^4\right)}{\dfrac{1}{0.95} + \dfrac{1}{0.95} - 1} = 133\ \text{W/m}^2$$ <

Likewise, for case 2: $\varepsilon_1 = \varepsilon_2 = 0.05$, $q''_{rad} =$ 3.76 W/m^2, <

and for case 3: $\varepsilon_1 = 0.05$, $\varepsilon_2 = 0.95$, $q''_{rad} =$ 7.31 W/m^2. <

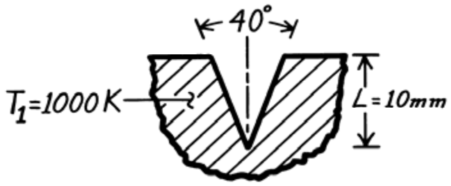
COMMENTS: The reduction associated with case 2 is [(133 – 3.76)/133] × 100 = 97 % while the reduction associated with case 3 is 94.5%. Both cases 2 and 3 provide a significant reduction in the heat flux relative to the uncoated glass of case 1. The decision to specify single- or double-surface coating depends on the cost of applying the low-emissivity coating.

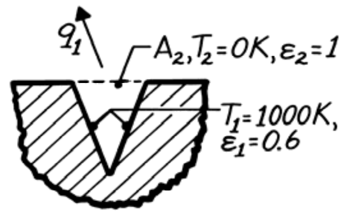
PROBLEM 13.45

KNOWN: Long V-groove machined in an isothermal block.

FIND: Radiant flux leaving the groove to the surroundings and effective emissivity.

SCHEMATIC:





ASSUMPTIONS: (1) Groove surface is diffuse-gray with uniform irradiation and radiosity distributions, (2) Groove is infinitely long, (3) Block is isothermal.

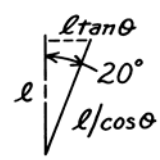
ANALYSIS: Define the hypothetical surface A_2 with $T_2 = 0$ K. The net radiation leaving A_1, q_1, will pass to the surroundings. From the two surface enclosure analysis, Eq. 13.23,

$$q_1 = -q_2 = \frac{\sigma\left(T_1^4 - T_2^4\right)}{\frac{1-\varepsilon_1}{\varepsilon_1 A_1} + \frac{1}{A_1 F_{12}} + \frac{1-\varepsilon_2}{\varepsilon_2 A_2}}$$

Recognize that $\varepsilon_2 = 1$ and that from reciprocity, $A_1 F_{12} = A_2 F_{21}$ where $F_{21} = 1$. Hence,

$$\frac{q_1}{A_2} = \frac{\sigma\left(T_1^4 - T_2^4\right)}{\frac{1-\varepsilon_1}{\varepsilon_1}\frac{A_2}{A_1} + 1}$$

With $A_2/A_1 = 2\ell \tan 20° / \left(2\ell / \cos 20°\right) = \sin 20°$, find



$$q_1'' = \frac{5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left(1000^4 - 0\right)\text{K}^4}{\frac{(1-0.6)}{0.6}\times\sin 20° + 1} = 46.17\ \text{kW/m}^2.$$ <

The effective emissivity of the groove follows from the definition given in Problem 13.43 as the ratio of the radiant power leaving the cavity to that from a blackbody having the area of the cavity opening and at the same temperature as the cavity surface. For the present situation,

$$\varepsilon_e = \frac{q_1''}{E_b(T_1)} = \frac{q_1''}{\sigma T_1^4} = \frac{46.17\times10^3\,\text{W/m}^2}{5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left(1000\ \text{K}\right)^4} = 0.814.$$ <

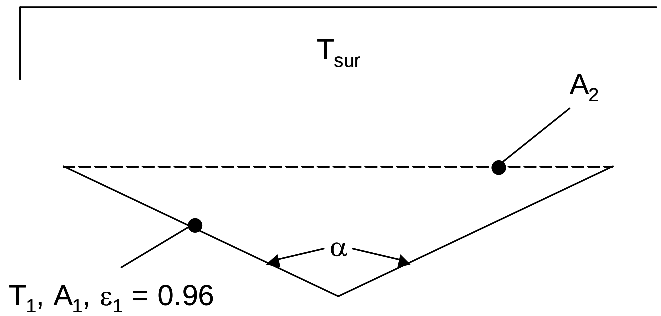
COMMENTS: (1) Note the use of the hypothetical surface defined as black at 0 K. This surface does not emit and absorbs all radiation on it; hence, is the radiant power to the surroundings. (2) Neither the irradiation or radiosity distributions are uniform. How will this affect your predictions?

PROBLEM 13.46

KNOWN: Approximate wave geometry, hemispherical emissivity of water, ε = 0.96.

FIND: (a) Effective emissivity of the water surface for $\alpha = 3\pi/4$, (b) Plot of the effective emissivity normalized by the hemispherical emissivity of water, $\varepsilon_{eff}/\varepsilon$, over the range $\pi/2 \le \alpha \le \pi/$.

SCHEMATIC:



ASSUMPTIONS: (1) Two-dimensional system, (2) Diffuse, gray surfaces.

ANALYSIS: (a) The effective emissivity is defined by the relation

$$\varepsilon_{eff} A_2 \sigma\left(T_1^4 - T_{sur}^4\right) = q_{12} = \frac{\sigma\left(T_1^4 - T_{sur}^4\right)}{\frac{1-\varepsilon_1}{\varepsilon_1 A_1} + -\frac{1}{A_1 F_{12}}}$$

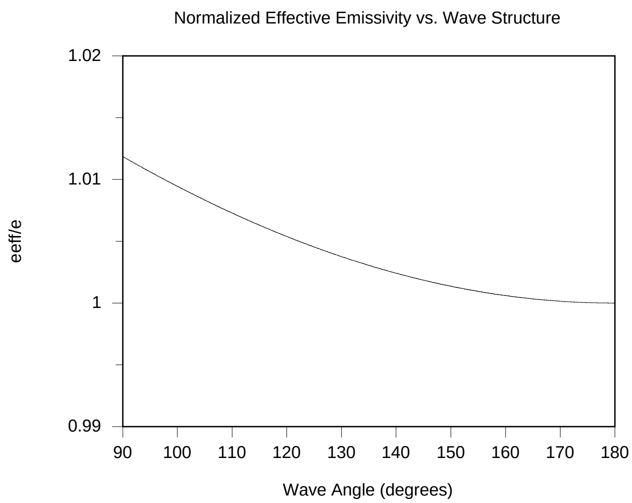
From the schematic we see that $A_2/A_1 = \sin(\alpha/2)$ and $F_{21} = 1$. Therefore, $F_{12} = A_2F_{21}/A_1 = \sin(\alpha/2)$ and the expression for the effective emissivity is

$$\varepsilon_{eff} = \frac{1}{\frac{A_2(1-\varepsilon_1)}{\varepsilon_1 A_1} + \frac{A_2}{A_1 F_{12}}} = \frac{1}{\frac{\sin(\alpha/2)(1-\varepsilon_1)}{\varepsilon_1} + 1} = \frac{1}{\frac{\sin(3\pi/8)(1-0.96)}{0.96} + 1} = 0.963 \quad <$$

(b) The dependence of the normalized effective emissivity to the wave angle is shown in the plot below.

Continued…

PROBLEM 13.46 (Cont.)



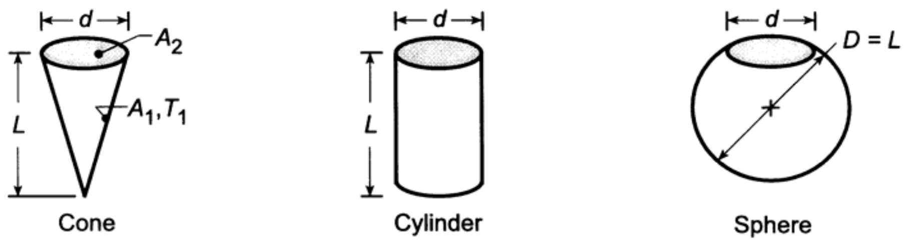
Comment: Although water exhibits nearly black behavior, and the sensitivity of the effective emissivity to the wave structure is small, the heat balance of the earth could be affected by approximately 1% depending on the sea roughness. These types of difficult-to-measure effects have lead to debate on issues related to earth's energy balance.

PROBLEM 13.47

KNOWN: Cavities formed by a cone, cylinder, and sphere having the same opening size (d) and major dimension (L) with prescribed wall emissivity.

FIND: (a) View factor between the inner surface of each cavity and the opening of the cavity; (b) Effective emissivity of each cavity as defined in Problem 13.43, if the walls are diffuse-gray with ε_w; and (c) Compute and plot ε_e as a function of the major dimension-to-opening size ratio, L/d, over the range from 1 to 10 for wall emissivities of ε_w = 0.5, 0.7, and 0.9.

SCHEMATIC:



ASSUMPTIONS: (1) Diffuse-gray surfaces, (2) Uniform radiosity over the surfaces.

ANALYSIS: (a) Using the summation rule and reciprocity, determine the view factor F_{12} for each of the cavities considered as a two-surface enclosure.

Cone: $F_{21} + F_{22} = F_{21} + 0 = 1 \qquad F_{21} = 1$

$$F_{12} = A_2 F_{21}/A_1 = \left(\pi d^2/4\right)/\left(\pi d/2\right)\left[L^2 + (d/2)^2\right]^{1/2} = (1/2)\left[(L/d)^2 + 1/4\right]^{-1/2} \quad <$$

Cylinder: $F_{21} = 1$

$$F_{12} = A_2 F_{21}/A_1 = A_2/A_1 = \left(\pi d^2/4\right)/\left[\pi dL + \pi d^2/4\right] = (1 + 4L/d)^{-1} \quad <$$

Sphere: $F_{21} = 1$

$$F_{12} = A_2 F_{21}/A_1 = A_2/A_1 = \left(\pi d^2/4\right)/\left[\pi D^2 - \pi d^2/4\right] = \left(4D^2/d^2 - 1\right)^{-1}. \quad <$$

(b) The effective emissivity of the cavity is defined as

$$\varepsilon_{eff} = q_{12}/q_c$$

where $q_c = A_2\sigma T_1^4$ which presumes the opening is a black surface at T_1 and for the two-surface enclosure,

$$q_{12} = \frac{\sigma\left(T_1^4 - T_2^4\right)}{(1-\varepsilon_1)/\varepsilon_1 A_1 + 1/A_1 F_{12} + (1-\varepsilon_2)/\varepsilon_2 A_2} = \frac{A_1\sigma T_1^4}{(1-\varepsilon_1)/\varepsilon_1 + 1/F_{12}}$$

since T_2 = 0K and ε_2 = 1. Hence, since $A_2/A_1 = F_{12}$ for all the cavities, with $\varepsilon_1 = \varepsilon_w$

$$\varepsilon_{eff} = \frac{1/F_{12}}{(1-\varepsilon_w)/\varepsilon_w + 1/F_{12}} = \frac{1}{F_{12}(1-\varepsilon_w)/\varepsilon_w + 1}$$

Cone: $$\varepsilon_{eff} = 1\Big/\left\{(1/2)\left[(L/d)^2 + 1/4\right]^{-1/2}(1-\varepsilon_w)/\varepsilon_w + 1\right\} \qquad (1) \quad <$$

Continued …

PROBLEM 13.47 (Cont.)

Cylinder: $\varepsilon_{eff} = 1 \Big/ \left\{ \left[1 + 4L/d \right]^{-1} \left(1 - \varepsilon_w \right) / \varepsilon_w + 1 \right\}$ (2) <

Sphere: $\varepsilon_{eff} = 1 / \left\{ \left[4D^2/d^2 - 1 \right]^{-1} \left(1 - \varepsilon_w \right) / \varepsilon_w + 1 \right\}$ (3) <

(c) Using the *IHT* Workspace with eqs. (1,2,3), the effective emissivity was computed as a function of L/d (cone, cylinder and sphere) for selected wall emissivities. The results are plotted below.

Fig. 1 Cone, cylinder, sphere cavities, eps = 0.7

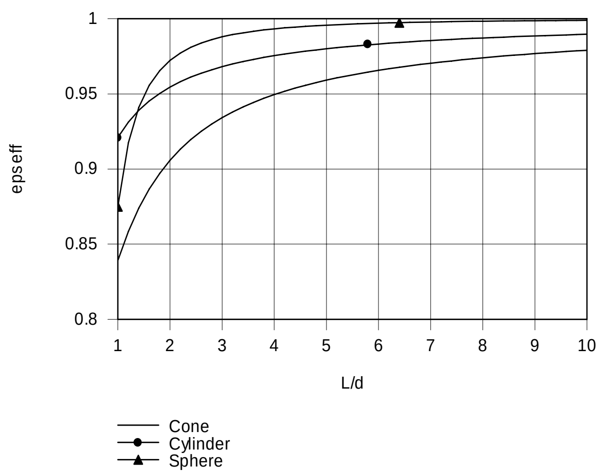


Fig 2 Conical cavity

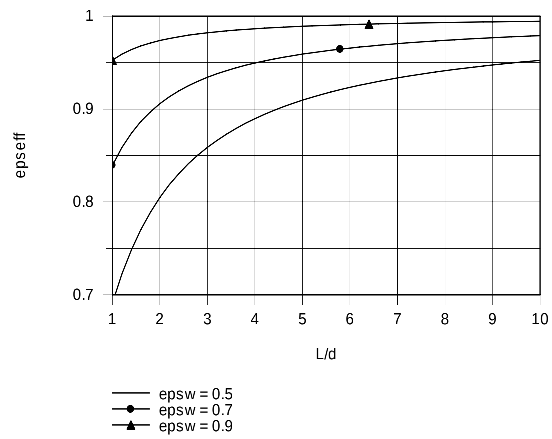

In Fig. 1, ε_{eff} is shown as a function of L/d for $\varepsilon_w = 0.7$. For larger L/d, the sphere has the highest ε_{eff} and the cone the lowest. Figures 2, 3 and 4 illustrate the ε_{eff} vs. L/d for each of the cavity types. As expected, ε_{eff} increases with increasing wall emissivity.

Fig 3 Cylindrical cavity

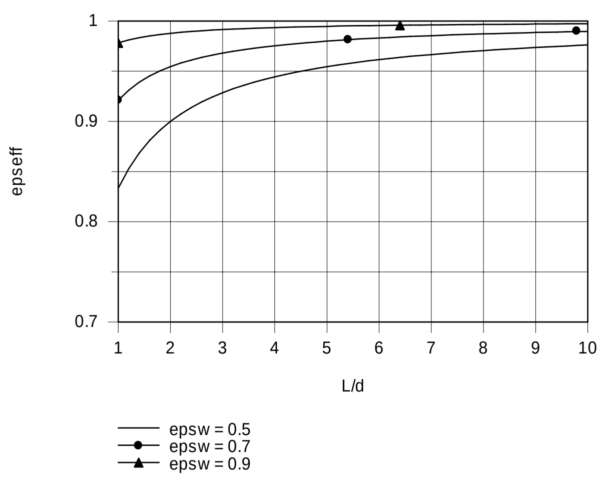

Fig 4 Spherical cavity

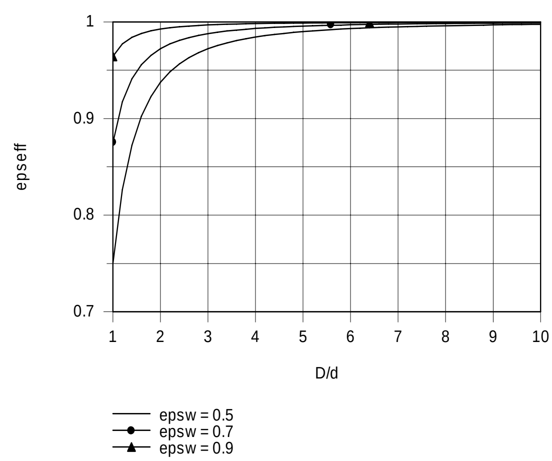


Note that for the spherical cavity, with $L/d \geq 5$, $\varepsilon_{eff} > 0.98$ even with ε_w as low as 0.5. This feature makes the use of spherical cavities for high performance radiometry applications attractive since ε_{eff} is not very sensitive to ε_w.

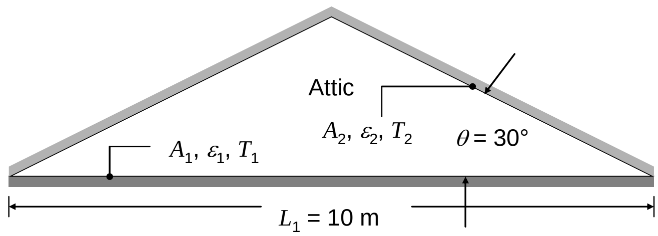
COMMENTS: In Fig. 1, comparing ε_{eff} for the three cavity types, can you give a physical explanation for the results?

PROBLEM 13.48

KNOWN: Dimensions of attic. Emissivity of aluminum foil and of surfaces prior to application of the foil .

FIND: (a) Reduction of radiation heat transfer from the hot roof to the attic floor if foil is installed on the bottom of the roof, (b) Reduction in radiation heat load if foil is installed on the top of the attic floor, (c) Reduction if foiled is installed on both the attic floor and bottom of roof.

SCHEMATIC:



ASSUMPTIONS: (1) Diffuse-gray surfaces of uniform radiosity and irradiation, (2) Temperatures of surfaces are unaffected by surface treatment, (3) Two-dimensional configuration.

ANALYSIS: From Eqn. 13.23 we know that the ratio of the radiation heat load after installation of the foil to the radiation heat load prior to the installation of the foil is

$$R = \left[\frac{1-\varepsilon_o}{\varepsilon_o A_1} + \frac{1}{A_1 F_{12}} + \frac{1-\varepsilon_o}{\varepsilon_o A_2}\right] \Big/ \left[\frac{1-\varepsilon_1}{\varepsilon_1 A_1} + \frac{1}{A_1 F_{12}} + \frac{1-\varepsilon_2}{\varepsilon_2 A_2}\right] \qquad (1)$$

On a per-unit depth basis, $A_1 = 10\ \text{m}^2$ and $A_2 = 10\ \text{m}^2/\cos(30°) = 11.55\ \text{m}^2$, while from inspection, $F_{12} = 1$.

(a) $\underline{\varepsilon_1 = 0.85,\ \varepsilon_2 = 0.07}$. Evaluation of Eqn. (1) yields $R = 0.105$. <

(b) $\underline{\varepsilon_1 = 0.07,\ \varepsilon_2 = 0.85}$. Evaluation of Eqn. (1) yields $R = 0.092$. <

(c) $\underline{\varepsilon_1 = \varepsilon_2 = 0.07}$. Evaluation of Eqn. (1) yields $R = 0.052$. <

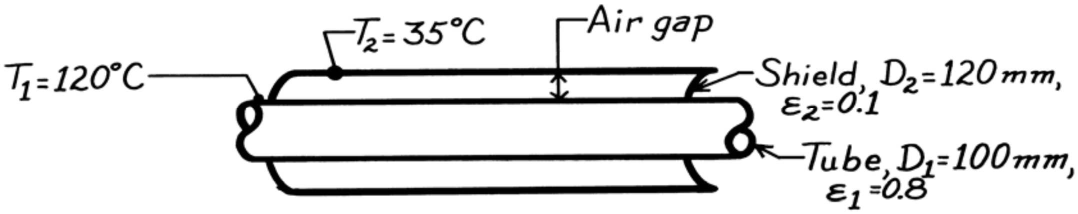
COMMENTS: (1) The reduction in the radiation heat load is least when the foil is installed on the bottom of the attic roof only. The surface formed by the attic roof is relatively large compared to Surface 1. As the roof becomes more steeply pitched, A_2 will increase and will eventually form a large surroundings. Installing foil on the roof, as its area becomes much larger, will become more ineffective. (2) The reduction is most significant when both surfaces are covered with foil, as expected. (3) Over time, the foil installed on the floor may become covered with a layer of dust, reducing the effectiveness of the foil installation on that surface.

PROBLEM 13.49

KNOWN: Long, thin-walled horizontal tube with radiation shield having an air gap of 10 mm. Emissivities and temperatures of surfaces are prescribed.

FIND: Radiant heat transfer from the tube per unit length.

SCHEMATIC:



ASSUMPTIONS: (1) Tube and shield are very long, (2) Surfaces at uniform temperatures, (3) Surfaces are diffuse-gray.

ANALYSIS: The long tube and shield form a two surface enclosure, and since the surfaces are diffuse-gray, the radiant heat transfer from the tube, according to Eq. 13.23, is

$$q_{12} = \frac{\sigma\left(T_1^4 - T_2^4\right)}{\frac{1-\varepsilon_1}{\varepsilon_1 A_1} + \frac{1}{A_1 F_{12}} + \frac{1-\varepsilon_2}{\varepsilon_2 A_2}} \tag{1}$$

By inspection, $F_{12} = 1$. Note that

$$A_1 = \pi D_1 \ell \qquad \text{and} \qquad A_2 = \pi D_2 \ell$$

where ℓ is the length of the tube and shield. Dividing Eq. (1) by ℓ, find the heat rate per unit length,

$$q'_{12} = \frac{q_{12}}{\ell} = \frac{5.67\times10^{-8}\,\mathrm{W/m^2\cdot K}\left[(273+120)^4 - (273+35)^4\right]\mathrm{K}^4}{\frac{1-0.8}{0.8\pi\left(100\times10^{-3}\,\mathrm{m}\right)} + \frac{1}{\pi\left(100\times10^{-3}\,\mathrm{m}\right)\times1} + \frac{1-0.1}{0.1\pi\left(120\times10^{-3}\,\mathrm{m}\right)}}$$

$$q'_{12} = \frac{842.3\ \mathrm{W/m^2}}{(0.7958 + 3.183 + 23.87)\,\mathrm{m}^{-1}} = 30.2\ \mathrm{W/m.}$$ <

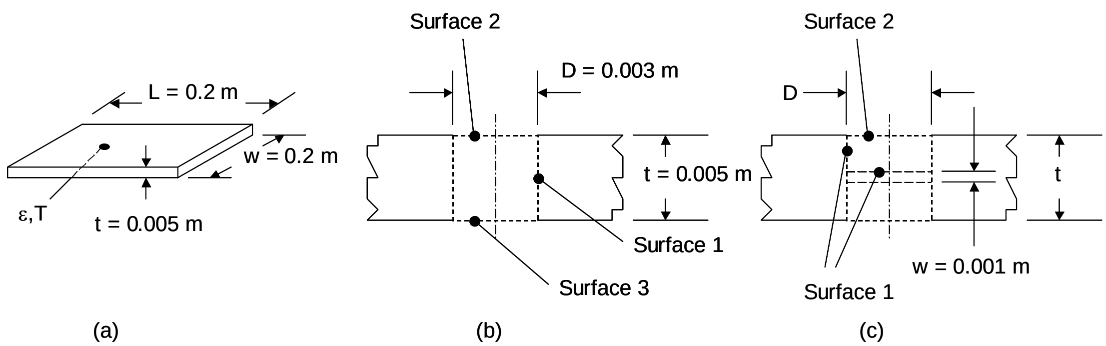
COMMENTS: Recognize that convective heat transfer would be important in this annular air gap. Suitable correlations to estimate the heat transfer coefficient are given in Chapter 9.

PROBLEM 13.50

KNOWN: Dimensions and temperature of an anodized aluminum sheet radiating to deep space.

FIND: (a) Net radiation from both sides of a 200 mm × 200 mm sheet, (b) Net radiation from the sheet with 3-mm diameter holes spaced 5 mm apart, (c) Net radiation from the sheet with 3-mm, flat-bottomed diameter holes of depth 2 mm, spaced 5 mm apart, (d) Ratio of net heat transfer to sheet mass for the three configurations.

SCHEMATIC:



ASSUMPTIONS: Diffuse, gray behavior.

PROPERTIES: Table A.11, anodized aluminum: (T = 300 K): ε = 0.82. Table A.1 aluminum (T = 300 K): $\rho = 2702\ kg/m^3$.

ANALYSIS: (a) For 2 sides,

$$E = 2Lw\varepsilon\sigma T_s^4 = 2\times0.2m\times0.2m\times0.82\times5.67\times10^{-8}\frac{W}{m^2\cdot K^4}\times(300K)^4 = 30.13\ W \quad <$$

(b) The number of holes is $N = Lw/s^2$ where s = 5 mm is the hole spacing. Therefore, $N = (0.2\ m \times 0.2\ m)/(0.005\ m)^2 = 1600$. The sheet area occupied by holes is $A_h = N\pi D^2/4 = 1600 \times \pi \times (0.003m)^2/4 = 11.31 \times 10^{-3}\ m^2$. The emission from the entire sheet is $E = NE_h + E_s$.

The emission from the flat sheet area is $E_s = 2(Lw - A_h)\varepsilon\sigma T_s^4$, or

$$E_s = 2\times(0.2m\times0.2m - 11.31\times10^{-3}m^2)\times0.82\times5.67\times10^{-8}\frac{W}{m^2\cdot K^4}\times(300K)^4 = 21.61\ W$$

Now, consider one hole. From the coaxial parallel disk results of Table 13.2,

$$S = 1+\frac{1+0.32}{0.32} = 13.11 \quad ; \quad F_{23} = \frac{1}{2}\left[13.11-\left(13.11^2-4\right)^{1/2}\right] = 0.0762$$

From the summation rule and reciprocity,

Continued…

PROBLEM 13.50 (Cont.)

$F_{21} = 1 - F_{23}$ and $F_{12} = (1 - F_{23})A_2/A_1 = (1 - F_{23})D/4t = (1 - 0.0762) \times 3/(4 \times 5) = 0.139$.
Therefore, $F_{1-(23)} = 0.277$ and the emission from one hole is

$$E_h = \frac{\sigma T^4}{\frac{1-\varepsilon_1}{\varepsilon_1 A_1} + \frac{1}{A_1 F_{1-(23)}}} = \frac{5.67\times 10^{-8}\frac{W}{m^2\cdot K^4}\times(300K)^4}{\frac{1-0.82}{0.82\times\pi\times 0.05m\times 0.03m} + \frac{1}{\pi\times 0.005m\times 0.003m\times 0.277}} = 5.65\times 10^{-3}\ W$$

Therefore, $E = 21.61\ W + 1600 \times 5.65 \times 10^{-3}\ W = 30.65\ W$ <

(c) We shall treat the sides and bottom of the cavity as one surface with $F_{21} = 1$. For one opening,

$$E_h = \frac{\sigma T^4}{\frac{1-\varepsilon_1}{\varepsilon_1 A_1} + \frac{1}{A_1 F_{12}}} = \frac{\sigma T^4}{\frac{1-\varepsilon_1}{\varepsilon_1 A_1} + \frac{1}{A_2 F_{21}}} = \frac{5.67\times 10^{-8}\frac{W}{m^2\cdot K^4}}{\frac{1-0.82}{0.82\times(\pi\times 0.003m\times 0.002m + \pi\times(0.003m)^2/4)} + \frac{1}{\pi\times\left[(0.003m)^2/4\right]\times 1}}$$

$E_h = 3.063 \times 10^{-3}$ W. Therefore for both sides of the sheet,

$E = 21.61\ W + 1600 \times 2 \times 3.063 \times 10^{-3}\ W = 31.41\ W$ <

(d) The mass of the sheet in part (a) is $M_a = Lwt\rho = 0.2m \times 0.2m \times 0.005m \times 2702\ kg/m^3 = 0.540$ kg. For part (b), $M_b = (Lwt - N\pi D^2 t/4)\rho = (0.2m \times 0.2m \times 0.005m - 1600 \times \pi \times (0.003m)^2 \times 0.005m/4) \times 2702\ kg/m^3 = 0.387$ kg. For part (c), $M_c = (Lwt - N\pi D^2(t - w)/4)\rho = (0.2m \times 0.2m \times 0.005m - 1600 \times \pi \times (0.003m)^2 \times (0.004m)/4) \times 2702\ kg/m^3 = 0.418$ kg.

Therefore, the ratios of the net radiation heat transfer to mass, R, for the three parts of the problem are:

Part (a): $R = E/M_a = 30.13\ W/0.540\ kg = 55.8\ W/kg$.
Part (b): $R = E/M_b = 30.65\ W/0.387\ kg = 79.2\ W/kg$.
Part (c): $R = E/M_c = 31.41\ W/0.418\ kg = 75.1\ W/kg$. <

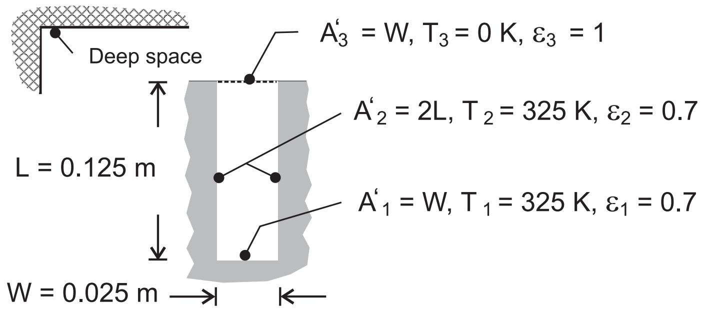
COMMENTS: (1) Boring holes in the sheet results in increased heat transfer rates and reduced mass. If a specific heat loss is required, the size of the sheets with the bored holes could be reduced slightly, leading to reduction in the mass of the bored aluminum sheet. (2) Holes that are bored completely through the sheet may lead to large conduction resistance along the sheet and, in turn, spatial temperature variations on the aluminum sheet. Since the two alternative designs involving holes are characterized by nearly the same emission-to-mass ratio, the third option might be preferred.

PROBLEM 13.51

KNOWN: Temperature, emissivity and dimensions of a rectangular fin array radiating to deep space.

FIND: (a) Rate of radiation transfer per unit length from a unit section to space, (b) Effect of emissivity on heat rejection.

SCHEMATIC:



ASSUMPTIONS: (1) Diffuse/gray surface behavior, (2) Length of array (normal to page) is much larger than W and L, (3) Isothermal surfaces.

ANALYSIS: (a) Since the sides and base of the U-section have the same temperature and emissivity, they can be treated as a single surface and the U-section becomes a two-surface enclosure. Deep space may be represented by the hypothetical surface A'_3, which acts as a blackbody at absolute zero temperature. From Eq. 13.23, with $T_1 = T_2 = T$ and $\varepsilon_1 = \varepsilon_2 = \varepsilon$,

$$q'_{(1,2)3} = \frac{\sigma\left(T^4 - T_3^4\right)}{\dfrac{1-\varepsilon}{\varepsilon A'_{(1,2)}} + \dfrac{1}{A'_{(1,2)} F_{(1,2)3}} + \dfrac{1-\varepsilon}{\varepsilon A'_3}}$$

where $A'_{(1,2)} = 2L + W$, $A'_3 = W$, $A'_{(1,2)} F_{(1,2)3} = A'_3 F_{3(1,2)} = W$. Hence,

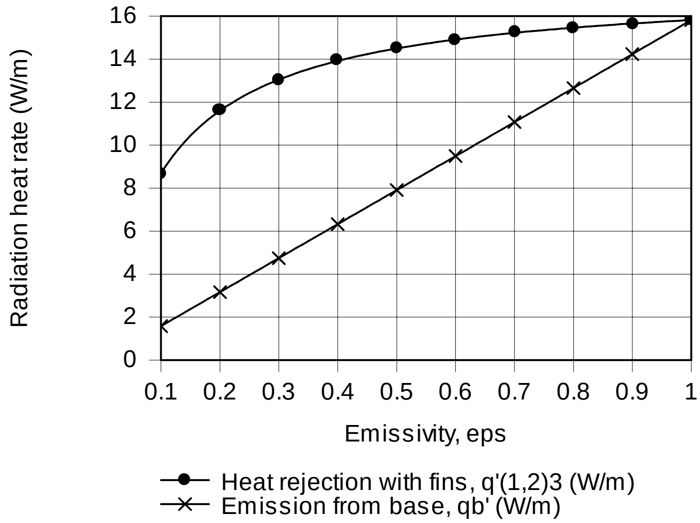
$$q'_{(1,2)3} = \frac{\sigma T^4}{\dfrac{1-\varepsilon}{\varepsilon(2L+W)} + \dfrac{1}{W} + \dfrac{1-\varepsilon}{\varepsilon W}}$$

$$q'_{(1,2)3} = \frac{5,67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4 (325\ \text{K})^4}{\dfrac{1-0.70}{0.70(0.275\text{m})} + \dfrac{1}{0.025\text{m}} + 0} = 15.2\ \text{W/m}$$ <

(b) For ε = 0.7 emission from the base of the U-section is $q'_b = \varepsilon A'_1 \sigma T^4 = 0.7 \times 0.025\text{m} \times 5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4 (325\ \text{K})^4 = 11.1\ \text{W/m}$. The effect of ε on $q'_{(1,2)3}$ and q'_b is shown as follows.

Continued …

PROBLEM 13.51 (Cont.)



The effect of the fins on heat transfer enhancement increases with decreasing emissivity.

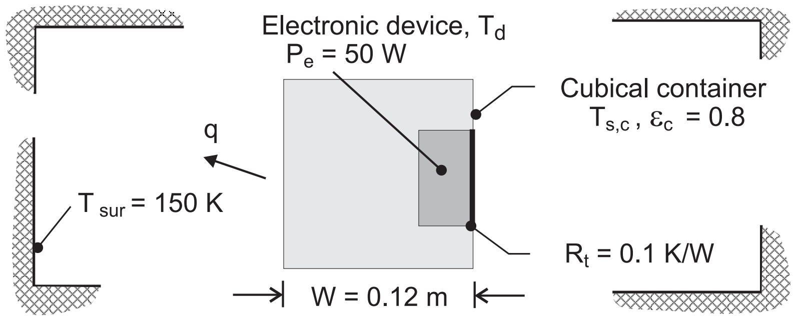
COMMENTS: Note that, if the surfaces behaved as blackbodies ($\varepsilon_1 = \varepsilon_2 = 1.0$), the U-section becomes a blackbody cavity for which heat rejection is simply $A'_3\ E_b\,(T) = q'_b$. Hence, it is no surprise that the $q'_b \rightarrow q'_{(1,2)3}$ as $\varepsilon \rightarrow 1$ in the foregoing figure. For $\varepsilon = 1$, no enhancement is provided by the fins.

PROBLEM 13.52

KNOWN: Power dissipation of electronic device and thermal resistance associated with attachment to inner wall of a cubical container. Emissivity of outer surface of container and wall temperature of service bay.

FIND: Temperatures of cubical container and device.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Device and container are isothermal, (3) Heat transfer from the container is exclusively by radiation exchange with bay (small surface in a large enclosure), (4) Container surface may be approximated as diffuse/gray.

ANALYSIS: From Eq. 13.27

$$P_e = q = \sigma\left(6W^2\right)\varepsilon_c\left(T_{s,c}^4 - T_{sur}^4\right)$$

$$T_{s,c} = \left[\frac{q}{\sigma\left(6W^2\right)\varepsilon_c} + T_{sur}^4\right]^{1/4}$$

$$T_{s,c} = \left[\frac{50\,W}{5.67\times10^{-8}\,W/m^2\cdot K^4\times 6\left(0.12m\right)^2\times 0.8} + \left(150\,K\right)^4\right]^{1/4} = 339.4\,K = 66.4°C \quad <$$

With $q = \left(T_d - T_{s,c}\right)/R_t$,

$$T_d = q\,R_t + T_{s,c} = 50\,W\times 0.1\,K/W + 66.4°C = 71.4°C \quad <$$

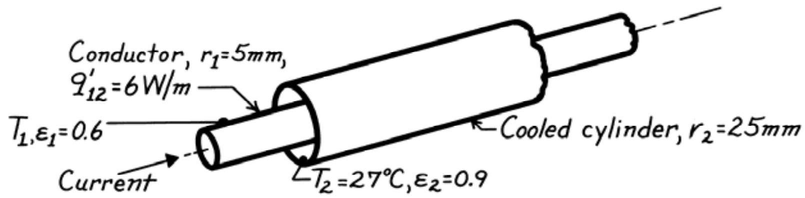
COMMENTS: If the temperature of the device is too large to insure reliable operation, it may be reduced by increasing ε_c or W.

PROBLEM 13.53

KNOWN: Long electrical conductor with known heat dissipation is cooled by a concentric tube arrangement.

FIND: Surface temperature of the conductor.

SCHEMATIC:



ASSUMPTIONS: (1) Surfaces are diffuse-gray, (2) Conductor and cooling tube are concentric and very long, (3) Space between surfaces is evacuated.

ANALYSIS: The heat transfer by radiation exchange between the conductor and the concentric, cooled cylinder is given by Eq. 13.25. For a unit length,

$$q'_{12} = \frac{q_{12}}{\ell} = \sigma \cdot 2\pi r_1 \left(T_1^4 - T_2^4\right) \Big/ \left[\frac{1}{\varepsilon_1} + \frac{1-\varepsilon_2}{\varepsilon_2}\left(\frac{r_1}{r_2}\right)\right] \quad (1)$$

where $A_1 = 2\pi r_1 \cdot \ell$. Solving for T_1 and substituting numerical values, find

$$T_1 = \left\{T_2^4 + \frac{q'_{12}}{\sigma \cdot 2\pi r_1}\left[\frac{1}{\varepsilon_1} + \frac{1-\varepsilon_2}{\varepsilon_2}\left(\frac{r_1}{r_2}\right)\right]\right\}^{1/4}$$

$$T_1 = \left\{(27+273)^4 \,\text{K}^4 + \frac{6\ \text{W/m}}{5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4 \times 2\pi(0.005\text{m})}\left[\frac{1}{0.6} + \frac{1-0.9}{0.9}\left(\frac{5}{25}\right)\right]\right\}^{1/4}$$

$$T_1 = \left\{(300\ \text{K})^4 + 3.368\times10^9\,\text{K}^4\,[1.667 + 0.00222]\right\}^{1/4} \quad (2)$$

$$T_1 = 342.3\ \text{K} = 69°\text{C}. \quad <$$

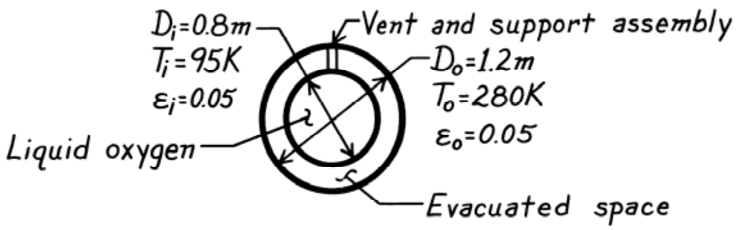
COMMENTS: (1) Note that Eq. (1) implies that $F_{12} = 1$. From Eq. (2) by comparison of the second term in the brackets involving ε_2, note that the influence of ε_2 is small. This follows since $r_1 << r_2$.

PROBLEM 13.54

KNOWN: Temperatures and emissivities of spherical surfaces which form an enclosure.

FIND: Evaporation rate of oxygen stored in inner container.

SCHEMATIC:



PROPERTIES: Oxygen (given): $h_{fg} = 2.13 \times 10^5$ J/kg.

ASSUMPTIONS: (1) Opaque, diffuse-gray surfaces, (2) Evacuated space between surfaces, (3) Negligible heat transfer along vent and support assembly.

ANALYSIS: From an energy balance on the inner container, the net radiation heat transfer to the container may be equated to the evaporative heat loss

$$q_{oi} = \dot{m} h_{fg}.$$

Substituting from Eq. 13.26, where $q_{oi} = - q_{io}$ and $F_{io} = 1$

$$\dot{m} = \frac{-\sigma\left(\pi D_i^2\right)\left(T_i^4 - T_o^4\right)}{h_{fg}\left[\frac{1}{\varepsilon_i} + \frac{1-\varepsilon_o}{\varepsilon_o}\left(\frac{r_i}{r_o}\right)^2\right]}$$

$$\dot{m} = \frac{-5.67\times10^{-8}\,\mathrm{W/m^2\cdot K^4}\times\pi(0.8\mathrm{m})^2\left(95^4 - 280^4\right)\mathrm{K}^4}{2.13\times10^5\,\mathrm{J/kg}\left[\frac{1}{0.05} + \frac{0.95}{0.05}\left(\frac{0.4}{0.6}\right)^2\right]}$$

$$\dot{m} = 1.14\times10^{-4}\,\mathrm{kg/s}.$$ <

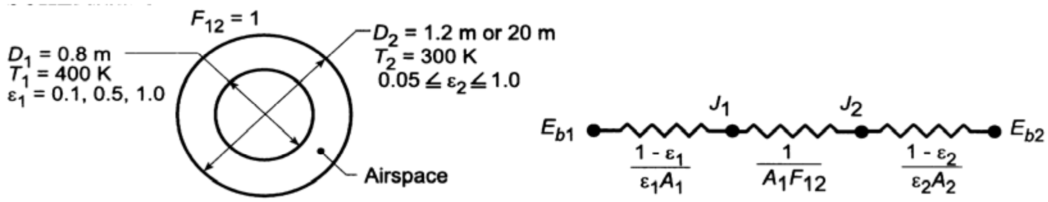
COMMENTS: This loss could be reduced by insulating the outer surface of the outer container and/or by inserting a radiation shield between the containers.

PROBLEM 13.55

KNOWN: Emissivities, diameters and temperatures of concentric spheres.

FIND: (a) Radiation transfer rate for black surfaces. (b) Radiation transfer rate for diffuse-gray surfaces, (c) Effects of increasing the diameter and assuming blackbody behavior for the outer sphere. (d) Effect of emissivities on net radiation exchange.

SCHEMATIC:



ASSUMPTIONS: (1) Blackbody or diffuse-gray surface behavior.

ANALYSIS: (a) Assuming blackbody behavior, it follows that $q_{ij} = A_i F_{ij}(J_i - J_j)$ where $J_i = \sigma T_i^4$ and $J_j = \sigma T_i^4$. Therefore,

$$q_{12} = A_1 F_{12} \sigma \left(T_1^2 - T_2^4 \right) = \pi (0.8\,\text{m})^2 (1) 5.67 \times 10^{-8}\,\text{W/m}^2 \cdot \text{K}^4 \left[(400\text{ K})^4 - (300\text{ K})^4 \right] = 1995\text{ W.} \quad <$$

(b) For diffuse-gray surface behavior, it follows from Eq. 13.26

$$q_{12} = \frac{\sigma A_1 \left(T_1^4 - T_2^4 \right)}{\frac{1}{\varepsilon_1} + \frac{1-\varepsilon_2}{\varepsilon_2}\left(\frac{r_1}{r_2}\right)^2} = \frac{5.67 \times 10^{-8}\,\text{W/m}^2 \cdot \text{K}^4 \pi (0.8\,\text{m})^2 \left[400^4 - 300^4 \right] \text{K}^4}{\frac{1}{0.5} + \frac{1-0.05}{0.05}\left(\frac{0.4}{0.6}\right)^2} = 191\text{ W.} \quad <$$

(c) With $D_2 = 20$ m, it follows that

$$q_{12} = \frac{5.67 \times 10^{-8}\,\text{W/m}^2 \cdot \text{K} \pi (0.8\,\text{m})^2 \left[(400\text{ K})^4 - (300\text{ K})^4 \right]}{\frac{1}{0.5} + \frac{1-0.05}{0.05}\left(\frac{0.4}{10}\right)^2} = 983\text{ W.} \quad <$$

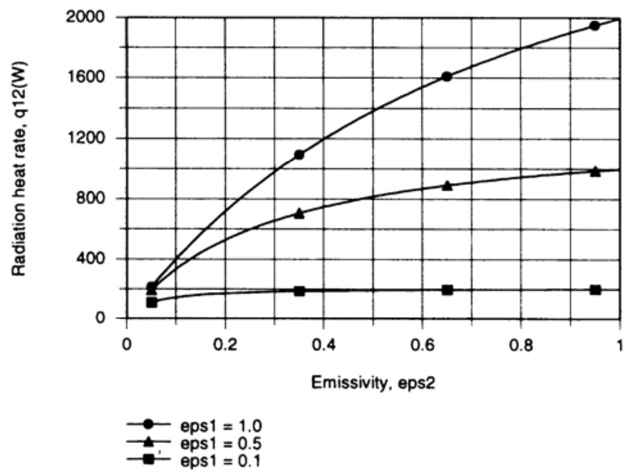
With $\varepsilon_2 = 1$, instead of 0.05, Eq. 13.21 reduces

$$q_{12} = \sigma A_1 \varepsilon_1 \left(T_1^4 - T_2^4 \right) = 5.67 \times 10^{-8}\,\text{W/m}^2 \cdot \text{K}^4 \pi (0.8\,\text{m})^2\, 0.5 \left[(400\text{ K})^4 - (300\text{ K})^4 \right] = 998\text{ W.} \quad <$$

Continued …

PROBLEM 13.55 (Cont.)

(d) Using the *IHT Radiation* Tool Pad, the following results were obtained



Net radiation exchange increases with ε_1 and ε_2, and the trends are due to increases in emission from and absorption by surfaces 1 and 2, respectively.

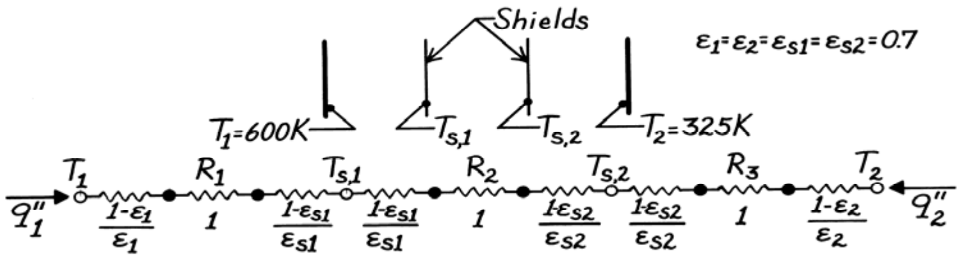
COMMENTS: From part (c) it is evident that the actual surface emissivity of a *large* enclosure has a small effect on radiation exchange with small surfaces in the enclosure. Working with ε_2 = 1.0 instead of ε_2 = 0.05, the value of q_{12} is increased by only (998 – 983)/983 = 1.5%. In contrast, from the results of (d) it is evident that the surface emissivity ε_2 of a *small* enclosure has a large effect on radiation exchange with interior objects, which increases with increasing ε_1.

PROBLEM 13.56

KNOWN: Two radiation shields positioned in the evacuated space between two infinite, parallel planes.

FIND: Steady-state temperature of the shields.

SCHEMATIC:



ASSUMPTIONS: (1) All surfaces are diffuse-gray and (2) All surfaces are parallel and of infinite extent.

ANALYSIS: The planes and shields can be represented by a thermal circuit from which it follows that

$$q_1'' = -q_2'' = \frac{\sigma\left(T_1^4 - T_2^4\right)}{R_1'' + R_2'' + R_3''} = \frac{\sigma\left(T_1^4 - T_{s1}^4\right)}{R_1''} = \frac{\sigma\left(T_{s1}^4 - T_{s2}^4\right)}{R_2''} = \frac{\sigma\left(T_{s2}^4 - T_2^4\right)}{R_3''}.$$

Since all the emissivities involved are equal, $R_1'' = \frac{A_1}{A_1 F_{12}} = 1 = R_2'' = R_3''$, so that

$$T_{s1}^4 = T_1^4 - \frac{R_1''}{R_1'' + R_2'' + R_3''}\left(T_1^4 - T_2^4\right) = T_1^4 - (1/3)\left(T_1^4 - T_2^4\right)$$

$$T_{s1}^4 = (600\text{ K})^4 - (1/3)\left(600^4 - 325^4\right)\text{K}^4 \qquad T_{1s} = 548\text{ K}$$ <

$$T_{s2}^4 = T_2^4 + \frac{R_3''}{R_1'' + R_2'' + R_3''}\left(T_1^4 - T_2^4\right) = T_2^4 + (1/3)\left(T_1^4 - T_2^4\right)$$

$$T_{s2}^4 = (325\text{ K})^4 + (1/3)\left(600^4 - 325^4\right)\text{K}^4 \qquad T_{s2} = 474\text{ K}.$$ <

PROBLEM 13.57

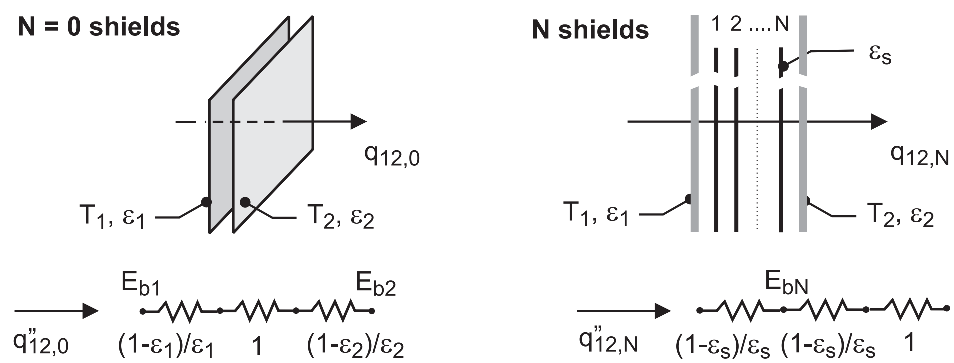
KNOWN: Two large, infinite parallel plates that are diffuse-gray with temperatures and emissivities of T_1 and ε_1 and T_2 and ε_2.

FIND: Show that the ratio of the radiation transfer rate with multiple shields, N, of emissivity ε_s to that with no shields, N = 0, is

$$\frac{q_{12,N}}{q_{12,0}} = \frac{[1/\varepsilon_1 + 1/\varepsilon_2 - 1]}{[1/\varepsilon_1 + 1/\varepsilon_2 - 1] + N[2/\varepsilon_s - 1]}$$

where $q_{12,N}$ and $q_{12,0}$ represent the radiation heat rate with N and N = 0 shields, respectively.

SCHEMATIC:



ASSUMPTIONS: (1) Plane infinite planes with diffuse-gray surfaces and uniform radiosities, and (2) Shield has negligible thermal conduction resistance.

ANALYSIS: Representing the parallel plates by the resistance network shown above for the "no-shield" condition, N = 0, with $F_{12} = 1$, the heat rate per unit area follows from Eq. 13.24 (see also Fig. 13.11) as

$$q''_{12,0} = \frac{E_{b1} - E_{b2}}{1/\varepsilon_1 + 1/\varepsilon_2 - 1} \tag{1}$$

With the addition of each shield as shown in the schematic above, three resistance elements are added to the network: two surface resistances, $(1 - \varepsilon_s)/\varepsilon_s$, and one space resistance, $1/F_{ij} = 1$. Hence, for the "N - shield" condition,

$$q''_{12,N} = \frac{E_{b1} - E_{b2}}{[1/\varepsilon_1 + 1/\varepsilon_2 - 1] + N[2(1-\varepsilon_s)/\varepsilon_s + 1]} \tag{2}$$

The ratio of the heat rates is obtained by dividing Eq. (2) by Eq. (1),

$$\frac{q''_{12,N}}{q_{12,0}} = \frac{[1/\varepsilon_1 + 1/\varepsilon_2 - 1]}{[1/\varepsilon_1 + 1/\varepsilon_2 - 1] + N[2/\varepsilon_s - 1]}$$ <

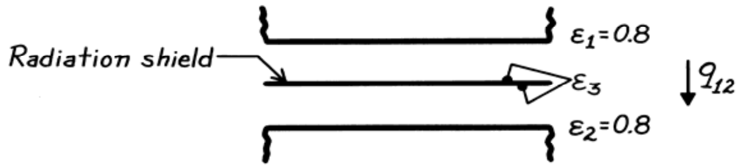
COMMENTS: Can you derive an expression to determine the temperature difference across pairs of the N-shields?

PROBLEM 13.58

KNOWN: Emissivities of two large, parallel surfaces.

FIND: Heat shield emissivity needed to reduce radiation transfer by a factor of 10.

SCHEMATIC:



ASSUMPTIONS: (a) Diffuse-gray surface behavior, (b) Negligible conduction resistance for shield, (c) Same emissivity on opposite sides of shield.

ANALYSIS: For this arrangement, $F_{13} = F_{32} = 1$.

Without (wo) the shield, it follows from Eq. 13.24,

$$(q_{12})_{wo} = \frac{A_1\sigma\left(T_1^4 - T_2^4\right)}{\frac{1}{\varepsilon_1} + \frac{1}{\varepsilon_2} - 1}.$$

With (w) the shield it follows from Eq. 13.28,

$$(q_{12})_{w} = \frac{A_1\sigma\left(T_1^4 - T_2^4\right)}{\frac{1}{\varepsilon_1} + \frac{1}{\varepsilon_2} + \frac{2}{\varepsilon_3} - 2}.$$

Hence, the heat rate ratio is

$$\frac{(q_{12})_w}{(q_{12})_{wo}} = 0.1 = \frac{\frac{1}{\varepsilon_1} + \frac{1}{\varepsilon_2} - 1}{\frac{1}{\varepsilon_1} + \frac{1}{\varepsilon_2} + \frac{2}{\varepsilon_3} - 2} = \frac{\frac{1}{0.8} + \frac{1}{0.8} - 1}{\frac{1}{0.8} + \frac{1}{0.8} + \frac{2}{\varepsilon_3} - 2}.$$

Solving, find

$$\varepsilon_3 = 0.138.$$ <

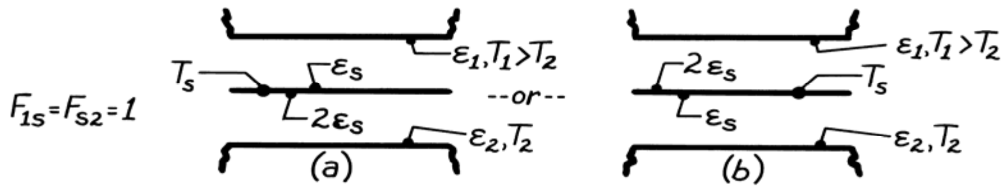
COMMENTS: The foregoing result is independent of T_1 and T_2. It is only necessary that the temperatures be maintained at fixed values, irrespective of whether or not the shield is in place.

PROBLEM 13.59

KNOWN: Surface emissivities of a radiation shield inserted between parallel plates of prescribed temperatures and emissivities.

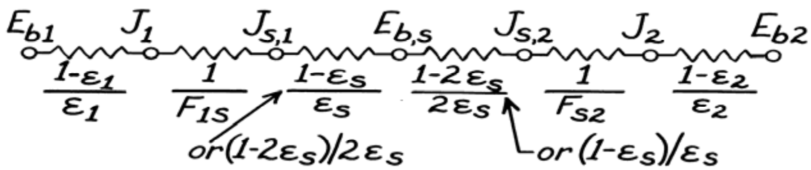
FIND: (a) Effect of shield orientation on radiation transfer, (b) Effect of shield orientation on shield temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Diffuse-gray surface behavior, (2) Shield is isothermal.

ANALYSIS: (a) On a unit area basis, the network representation of the system is



Hence the total radiation resistance,

$$R = \frac{1-\varepsilon_1}{\varepsilon_1} + 1 + \frac{1-\varepsilon_s}{\varepsilon_s} + \frac{1-2\varepsilon_s}{2\varepsilon_s} + 1 + \frac{1-\varepsilon_2}{\varepsilon_2}$$

is independent of orientation. Since $q = (E_{b1} - E_{b2})/R$, the heat transfer rate is independent of orientation.

(b) Considering that portion of the circuit between E_{b1} and E_{bs}, it follows that

$$q = \frac{E_{b1} - E_{bs}}{\frac{1-\varepsilon_1}{\varepsilon_1} + 1 + f(\varepsilon_s)}, \quad \text{where} \quad f(\varepsilon_s) = \frac{1-\varepsilon_s}{\varepsilon_s} \text{ or } \frac{1-2\varepsilon_s}{2\varepsilon_s}.$$

Hence,

$$E_{bs} = E_{b1} - \left[\frac{1-\varepsilon_1}{\varepsilon_1} + 1 + f(\varepsilon_s)\right] q.$$

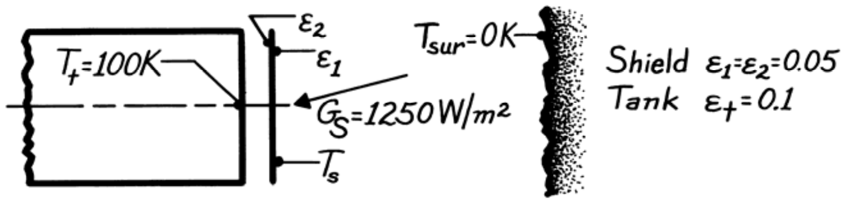
It follows that, since E_{bs} increases with decreasing $f(\varepsilon_s)$ and $(1 - 2\varepsilon_s)/2\varepsilon_s < (1 - \varepsilon_s)/\varepsilon_s$, E_{bs} is larger when the high emissivity ($2\varepsilon_s$) side faces plate 1. Hence T_s is larger for case (b). $<$

PROBLEM 13.60

KNOWN: End of propellant tank with radiation shield is subjected to solar irradiation in space environment.

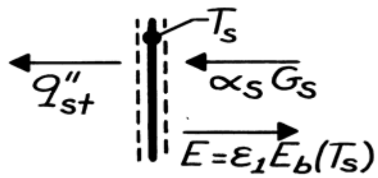
FIND: (a) Temperature of the shield, T_s, and (b) Heat flux to the tank, $q_1''\left(W/m^2\right)$.

SCHEMATIC:



ASSUMPTIONS: (1) All surfaces are diffuse-gray, (2) View factor between shield and tank is unity, $F_{st} = 1$, (3) Space surroundings are black at 0 K, (4) Resistance of shield for conduction is negligible.

ANALYSIS: (a) Perform a radiation balance on the shield. From the schematic,



$$\alpha_S G_S - \varepsilon_1 E_b\left(T_s\right) - q''_{st} = 0 \qquad (1)$$

where q''_{st} is the net heat exchange between the shield and the tank. Considering these two surfaces as large, parallel planes, from Eq. 13.24,

$$q''_{st} = \sigma\left(T_s^4 - T_t^4\right)/\left[1/\varepsilon_2 + 1/\varepsilon_1 - 1\right]. \qquad (2)$$

Substituting q''_{st} from Eq. (2) into Eq. (1), find

$$\alpha_S G_S - \varepsilon_1 \sigma T_s^4 - \sigma\left(T_s^4 - T_1^4\right)/\left[1/\varepsilon_2 + 1/\varepsilon_t - 1\right] = 0.$$

Solving for T_s, find

$$T_s = \left[\frac{\alpha_S G_S + \sigma T_t^4/\left[1/\varepsilon_2 + 1/\varepsilon_t - 1\right]}{\sigma\left(\varepsilon_1 + 1/\left[1/\varepsilon_2 + 1/\varepsilon_t - 1\right]\right)}\right]^{1/4}.$$

Since the shield is diffuse-gray, $\alpha_S = \varepsilon_1$ and then

$$T_s = \left[\frac{0.05 \times 1250\,W/m^2 + \sigma(100)^4 K^4/\left[1/0.05 + 1/0.1 - 1\right]}{\sigma\left(0.05 + 1/\left[1/0.05 + 1/0.1 - 1\right]\right)}\right]^{1/4} = 338\ K. \qquad <$$

(b) The heat flux to the tank can be determined from Eq. (2),

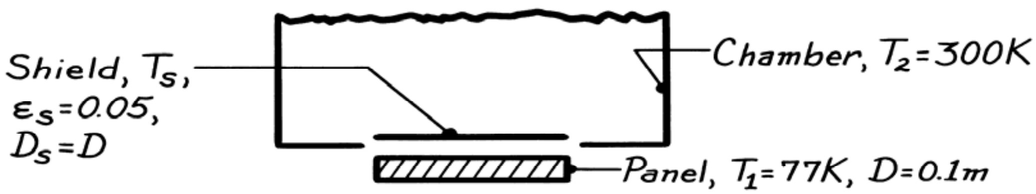
$$q''_{st} = 5.67 \times 10^{-8}\,W/m^2 \cdot K^4\left(338^4 - 100^4\right)K^4/\left[1/0.05 + 1/0.1 - 1\right] = 25.3\,W/m^2. \qquad <$$

PROBLEM 13.61

KNOWN: Black panel at 77 K in large vacuum chamber at 300 K with radiation shield having ε = 0.05.

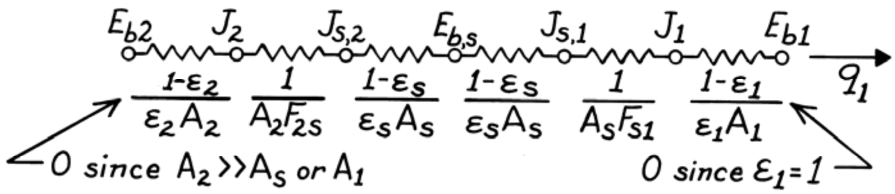
FIND: Net heat transfer by radiation to the panel.

SCHEMATIC:



ASSUMPTIONS: (1) Chamber is large compared to shield, (2) Shape factor between shield and plate is unity, (3) Shield is diffuse-gray, (4) Shield is thin, negligible thermal conduction resistance.

ANALYSIS: The arrangement lends itself to a network representation following Figs. 13.10 and 13.11.



Noting that $F_{2s} = F_{s1} = 1$, and that $A_2F_{2s} = A_sF_{s2}$, the heat rate is

$$q_1 = \left(E_{b2} - E_{b1}\right) / \Sigma R_i = \sigma\left(T_2^4 - T_1 4\right) / \left[\frac{1}{A_s} + 2\left(\frac{1-\varepsilon_s}{\varepsilon_s A_s}\right) + \frac{1}{A_s}\right].$$

Recognizing that $A_s = A_1$ and multiplying numerator and denominator by A_1 gives

$$q_1 = A_1\sigma\left(T_2 - T_1^4\right)\left[2 + 2\left(\frac{1-\varepsilon_s}{\varepsilon_s}\right)\right].$$

Substituting numerical values, find

$$q_1 = \frac{\pi 0.1^2\,\text{m}^2}{4} \times 5.67 \times 10^{-8}\,\text{W/m}^2 \cdot \text{K}^4 \left(300^4 - 77^4\right)\text{K}^4 / \left[2 + 2\left(\frac{1-0.05}{0.05}\right)\right]$$

$$q_1 = 89.8\,\text{mW}.$$ <

COMMENTS: In using the network representation, be sure to designate direction of the net heat rate. In this situation, we have shown q_1 as the net rate *into* the surface A_1. The temperature of the shield, T_s = 253 K, follows from the relation

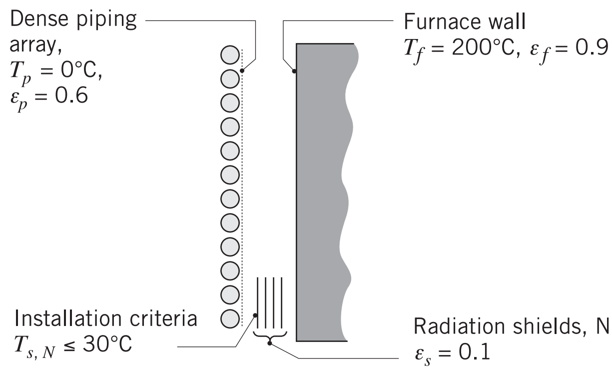
$$q_1 = \left(E_{bs} - E_{b1}\right) / \left[\frac{1-\varepsilon_s}{\varepsilon_s A_s} + \frac{1}{A_1F_{s1}}\right].$$

PROBLEM 13.62

KNOWN: Dense cryogenic piping array located close to furnace wall.

FIND: Number of radiation shields, N, to be installed such that the temperature of the shield closest to the array, $T_{s,N}$, is less than 30°C.

SCHEMATIC:



ASSUMPTIONS: (1) The ice-covered dense piping array approximates a plane surface, (2) Piping array and furnace wall can be represented by infinite parallel plates, (3) Surfaces are diffuse-gray, and (4) Convection effects are negligible.

ANALYSIS: Treating the piping array and furnace wall as infinite parallel plates, the net heat rate by radiation exchange with N shields of identical emissivity, ε_s, on both sides follows from extending the network of Fig. 13.12 to account for the resistances of N shields. (See Problem 13.57) For each shield added, two surface resistances and one space resistance are added,

$$q_{fp} = \frac{\sigma\left(T_f^4 - T_p^4\right)A_f}{\left[1/\varepsilon_f + 1/\varepsilon_p - 1\right] + N\left[2/\varepsilon_s - 1\right]} \qquad (1)$$

where $\sigma = 5.67 \times 10^{-8}$ W/m$^2\cdot$K^4. The requirement that the N-th shield (next to the piping array) has a temperature $T_{s,N} \le 30°C$ will be satisfied when

$$q_{fp} \le \frac{\sigma\left(T_{s,N}4 - T_p4\right)A_f}{\left[1/\varepsilon_s + 1/\varepsilon_p - 1\right]} \qquad (2)$$

Using the foregoing equations in the *IHT* workspace, find that $T_{s,N}$ = 30°C when N = 8.60. So that $T_{s,N}$ is less than 30°C, the number of shields required is

$$N = 9$$ <

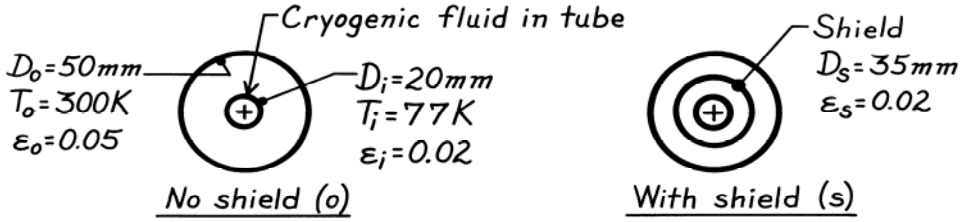
COMMENTS: Note that when N = 0, Eq. (1) reduces to the case of two parallel plates. Show for the case with one shield, N = 1, that Eq. (1) is identical to Eq. 13.28.

PROBLEM 13.63

KNOWN: Concentric tube arrangement with diffuse-gray surfaces.

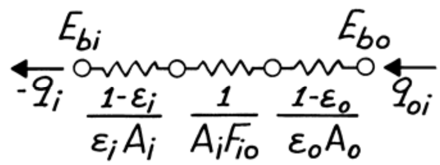
FIND: (a) Heat gain by the cryogenic fluid per unit length of the inner tube (W/m), (b) Change in heat gain if diffuse-gray shield with $\varepsilon_s = 0.02$ is inserted midway between inner and outer surfaces.

SCHEMATIC:



ASSUMPTIONS: (1) Surfaces are diffuse-gray, (2) Space between tubes is evacuated.

ANALYSIS: (a) For the *no shield* case, the thermal circuit is shown at right. It follows that the net heat gain per unit tube length is



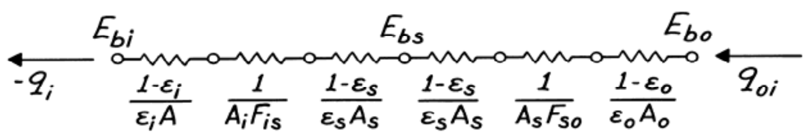
$$-q_1' = \frac{q_{oi}}{L} = \left(E_{bo} - E_{bi}\right) / \left[\frac{1-\varepsilon_o}{\varepsilon \pi D_o} + \frac{1}{\pi D_i F_{io}} + \frac{1-\varepsilon_i}{\varepsilon_i \pi D_i}\right]$$

where $A = \pi DL$. Note that $F_{io} = 1$ and $E_b = \sigma T^4$ giving

$$-q_1' = 5.67 \times 10^{-8}\,\text{W/m}^2 \cdot \text{K}^4 \left(300^4 - 77^4\right)\text{K}^4 / \left[\frac{1-0.05}{0.05\pi \times 50 \times 10^{-3}} + \frac{1}{\pi 20 \times 10^{-3} \times 1} + \frac{1-0.02}{0.02\pi \times 20 \times 10^{-3}}\right]\text{m}^{-1}$$

$$-q_1' = 457\ \text{W/m}^2 / \left[121.0 + 15.9 + 779.8\right]\text{m}^{-1} = 0.501\ \text{W/m}.$$ <

(b) For the *with shield* case, the thermal circuit will include three additional resistances.



From the network, it follows that $-q_i = \left(E_{bo} - E_{bi}\right)/\Sigma R_t$. With $F_{is} = F_{so} = 1$, find

$$-q_i' = 457\,\text{W/m}^2 / \left[121.0 + \frac{1}{\pi 35 \times 10^{-3} \times 1} + \frac{2\left(1-0.02\right)}{0.02\pi 35 \times 10^{-3}} + 15.9 + 779.8\right]\text{m}^{-1}$$

$$-q_i' = 457\,\text{W/m}^2 / \left[121.0 + 9.1 + 891.3 + 15.9 + 779.8\right]\text{m}^{-1} = 0.251\,\text{W/m}.$$

The change (percentage) in heat gain per unit length of the tube as a result of inserting the radiation shield is

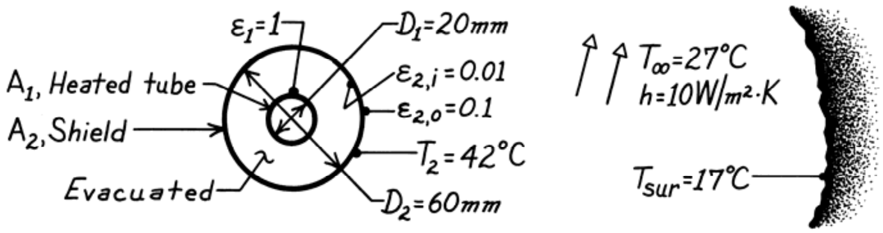
$$\frac{q_{i,s}' - q_{i,ns}'}{q_{i,ns}'} \times 100 = \frac{\left(0.251 - 0.501\right)\text{W/m}}{0.501\,\text{W/m}} \times 100 = -49\%.$$ <

PROBLEM 13.64

KNOWN: Heated tube with radiation shield whose exterior surface is exposed to convection and radiation processes.

FIND: Operating temperature for the tube under the prescribed conditions.

SCHEMATIC:

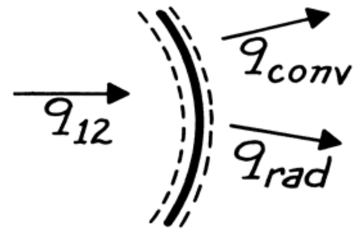


ASSUMPTIONS: (1) Steady-state conditions, (2) No convection in space between tube and shield, (3) Surroundings are large compared to the shield and are isothermal, (4) Tube and shield are infinitely long, (5) Surfaces are diffuse-gray, (6) Shield is isothermal.

ANALYSIS: Perform an energy balance on the shield.

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$q_{12} - q_{conv} - q_{rad} = 0$$



where q_{12} is the net radiation exchange between the tube and inner surface of the shield, which from Eq. 13.25 is,

$$-q_{12} = \frac{A_1 \sigma \left(T_1^4 - T_2^4\right)}{\frac{1}{\varepsilon_1} + \frac{1-\varepsilon_{2,i}}{\varepsilon_{2,i}} \frac{D_1}{D_2}}$$

Using appropriate rate equations for q_{conv} and q_{rad}, the energy balance is

$$\frac{A_1 \sigma \left(T_1^4 - T_2^4\right)}{1 + \frac{1-\varepsilon_{2,i}}{\varepsilon_{2,i}} \frac{D_1}{D_2}} - hA_2\left(T_2 - T_\infty\right) - \varepsilon_{2,o} A_2 \sigma \left(T_2^4 - T_{sur}^4\right) = 0$$

where $\varepsilon_1 = 1$. Substituting numerical values, with $A_1/A_2 = D_1/D_2$, and solving for T_1,

$$\frac{(20/60) \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 \left(T_1^4 - 315^4\right)\text{K}^4}{1 + (1 - 0.01/0.01)(20/60)} - 10 \text{ W/m}^2 \cdot \text{K}(315 - 300)\text{K}$$

$$-0.1 \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 \left(315^4 - 290^4\right)\text{K}^4 = 0$$

$$T_1 = 745 \text{ K} = 472°\text{C}. \qquad <$$

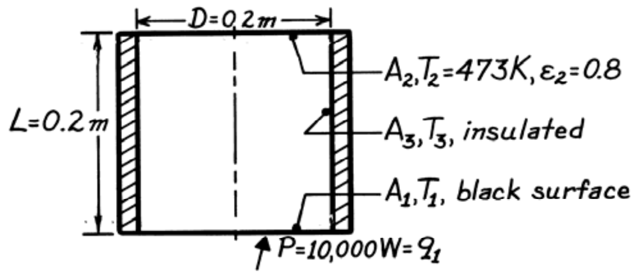
COMMENTS: Note that all temperatures are expressed in kelvins. This is a necessary practice when dealing with radiation and convection modes.

PROBLEM 13.65

KNOWN: Cylindrical-shaped, three surface enclosure with lateral surface insulated.

FIND: Temperatures of the lower plate T_1 and insulated side surface T_3.

SCHEMATIC:



ASSUMPTIONS: (1) Surfaces have uniform radiosity or emissive power, (2) Upper and insulated surfaces are diffuse-gray, (3) Negligible convection.

ANALYSIS: Find the temperature of the lower plate T_1 from Eq. 13.30

$$q_1 = \frac{\sigma\left(T_1^4 - T_2^4\right)}{\left(1-\varepsilon_1\right)/\varepsilon_1 A_1 + \left[A_1F_{12} + \left[\left(1/A_1F_{13}\right)+\left(1/A_2F_{23}\right)\right]^{-1}\right]^{-1} + \left(1-\varepsilon_2\right)/\varepsilon_2 A_2}. \quad (1)$$

From Table 13.2 for parallel coaxial disks,

$$R_1 = r_1/L = 0.1/0.2 = 0.5 \qquad R_2 = r_2/L = 0.1/0.2 = 0.5$$

$$S = 1+\left(1+R_2^2\right)/R_1^2 = 1+\left(1+0.5^2\right)/0.5^2 = 6.0$$

$$F_{12} = 1/2\left\{S-\left[S^2-4\left(r_2/r_1\right)^2\right]^{1/2}\right\} = 1/2\left\{6-\left[6^2-4\left(0.5/0.5\right)^2\right]^{1/2}\right\} = 0.172.$$

Using the summation rule for the enclosure, $F_{13} = 1 - F_{12} = 1 - 0.172 = 0.828$, and from symmetry, $F_{23} = F_{13}$. With $A_1 = A_2 = \pi D^2/4 = \pi(0.2\text{ m})^2/4 = 0.03142\text{ m}^2$ and substituting numerical values into Eq. (1), obtain

$$10,000\ \text{W} = \frac{0.03142\,\text{m}^2 \times 5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left(T_1^4 - 473^4\right)\text{K}^4}{0+\left[0.172+\left[\left(1/0.828\right)+\left(1/0.172\right)\right]^{-1}\right]^{-1}+\left(1-0.8\right)/0.8}$$

$$10,000 = 4.540\times10^{9}\left(T_1^4 - 473^4\right) \qquad T_1 = 1225\ \text{K}. \qquad <$$

The temperature of the insulated side surface can be determined from the radiation balance, Eq. 13.31, with $A_1 = A_2$,

$$\frac{J_1 - J_3}{1/F_{13}} - \frac{J_3 - J_2}{1/F_{23}} = 0 \quad (2)$$

where $J_1 = \sigma T_1^4$ and J_2 can be evaluated from Eq. 13.19,

Continued …

PROBLEM 13.65 (Cont.)

$$q_2 = \frac{E_{b2} - J_2}{(1-\varepsilon_2)/\varepsilon_2 A_2} \qquad -10,000\ \text{W} = \frac{5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\,(473\ \text{K})^4 - J_2}{(1-0.8)/\left(0.8\times0.03142\,\text{m}^2\right)}$$

find J_2 = 82,405 W/m^2. Substituting numerical values into Eq. (2),

$$\frac{5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\,(1225\ \text{K})^4 - J_3}{1/0.172} - \frac{J_3 - 82,405\ \text{W/m}^2}{1/0.172} = 0$$

find J_3 = 105,043 W/m^2. Hence, for this insulated, re-radiating (adiabatic) surface,

$$E_{b3} = \sigma T_3^4 = 105,043\ \text{W/m}^2 \qquad T_3 = 1167\ \text{K}.$$

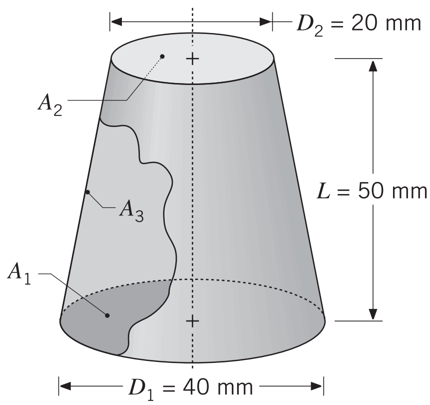
<

PROBLEM 13.66

KNOWN: Furnace in the form of a truncated conical section, floor (1) maintained at T_1 = 1000 K by providing a heat flux $q''_{1,in} = 2200\ W/m^2$; lateral wall (3) perfectly insulated; radiative properties of all surfaces specified.

FIND: (a) Temperature of the upper surface, T_2, and of the lateral wall T_3, and (b) T_2 and T_3 if all the furnace surfaces are black instead of diffuse-gray, with all other conditions remain unchanged. Explain effect of ε_2 on your results.

SCHEMATIC:



ASSUMPTIONS: (1) Furnace is a three-surface, diffuse-gray enclosure, (2) Surfaces have uniform radiosities, (3) Lateral surface is adiabatic, and (4) Negligible convection effects.

ANALYSIS: For the three-surface enclosure, write the radiation surface energy balances, Eq. 13.21, to find the radiosities of the three surfaces.

$$\frac{E_{b,1} - J_1}{(1-\varepsilon_1)/\varepsilon_1 A_1} = \frac{J_1 - J_2}{1/A_1 F_{12}} + \frac{J_1 - J_3}{1/A_1 F_{13}} \tag{1}$$

$$\frac{E_{b,2} - J_2}{(1-\varepsilon_2)/\varepsilon_2 A_2} = \frac{J_2 - J_1}{1/A_2 F_{21}} + \frac{J_2 - J_3}{1/A_2 F_{23}} \tag{2}$$

$$\frac{E_{b,3} - J_3}{(1-\varepsilon_3)/\varepsilon_3 A_3} = \frac{J_3 - J_1}{1/A_3 F_{31}} + \frac{J_3 - J_2}{1/A_3 F_{32}} \tag{3}$$

where the blackbody emissive powers are of the form $E_b = \sigma T^4$ with $\sigma = 5.67 \times 10^{-8}\ W/m^2 \cdot K^4$. From Eq. 13.19, the net radiation leaving A_1 is

$$q_1 = \frac{E_{b,1} - J_1}{(1-\varepsilon_1)/\varepsilon_1 A_1} \tag{4}$$

$$q_1 = q''_{1,in} \cdot A_1 = 2200\ W/m^2 \times \pi(0.040\ m)^2/4 = 2.76\ W$$

Continued …

PROBLEM 13.66 (Cont.)

Since the lateral surface is adiabatic,

$$q_3 = \frac{E_{b,3} - J_3}{(1-\varepsilon_3)/\varepsilon_3 A_3} = 0 \qquad (5)$$

from which we recognize $E_{b,3} = J_3$, but will find that as an outcome of the analysis. For the enclosure, N = 3, there are $N^2 = 9$ view factors, for which N (N - 1)/2 = 3 must be directly determined. Calculations for the F_{ij} are summarized in Comments.

With the foregoing five relations, we can determine the five unknowns: J_1, J_2, J_3, $E_{b,2}$, and $E_{b,3}$. The temperatures T_2 and T_3 will be evaluated from the relation $E_b = \sigma T^4$. Using this analysis approach with the relations in the *IHT* workspace, the results for (a) the diffuse-gray surfaces and (b) black surfaces are tabulated below. <

	J_1 (kW/m^2)	J_2 (kW/m^2)	J_3 (kW/m^2)	T_2 (K)	T_3 (K)
(a) Diffuse-gray	55.76	45.30	53.48	896	986
(b) Black	56.70	46.24	54.42	950	990

COMMENTS: (1) From the tabulated results, it follows that the temperatures of the lateral and top surfaces will be higher when the surfaces are black, rather than diffuse-gray as specified.

(2) From Eq. (5) for the net heat radiation leaving the lateral surface, A_3, the rate is zero since the wall is adiabatic. The consequences are that the blackbody emissive power and the radiosity are equal, and that the emissivity of the surface has no effect in the analysis. That is, this surface emits and absorbs at the same rate; the net is zero.

(3) For the enclosure, N = 3, there are $N^2 = 9$ view factors, for which

$$N\,(N-1)/2 = 3 \times 2/2 = 3$$

must be directly determined. We used the *IHT Tools* | *Radiation* | *View Factors Relations* model that sets up the summation rules and reciprocity relations for the N surfaces. The user is required to specify the 3 F_{ij} that must be determined directly; by inspection, $F_{11} = F_{22} = 0$; and F_{12} can be evaluated using the parallel coaxial disk relation, Table 13.2 (Fig. 13.5). This model is also provided in *IHT* to simplify the calculation task. The results of the view factor analysis are:

$$F_{12} = 0.03348 \qquad F_{13} = 0.9665$$

$$F_{21} = 0.1339 \qquad F_{23} = 0.8661$$

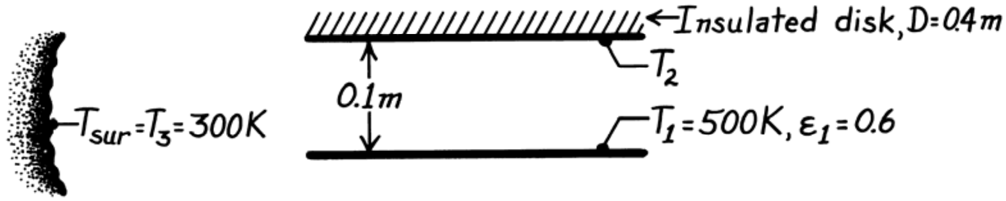
(4) An alternative method of solution for part (a) is to treat the enclosure of part (a) as described in Section 13.3.5. For part (b), the black enclosure analysis is described in Section 13.2. We chose to use the direct approach, Section 13.3.2, to develop a general 3-surface enclosure code in *IHT* that can also handle black surfaces (caution: use ε = 0.999, not 1.000).

PROBLEM 13.67

KNOWN: Parallel, aligned discs located in a large room; one disk is insulated, the other is at a prescribed temperature.

FIND: Temperature of the insulated disc.

SCHEMATIC:



ASSUMPTIONS: (1) Surfaces are diffuse-gray, (2) Surroundings are large, with uniform temperature, behaving as a blackbody, (3) Negligible convection.

ANALYSIS: From an energy balance on surface A_2,

$$q_2 = 0 = \frac{J_2 - J_1}{1/A_2F_{21}} + \frac{J_2 - J_3}{1/A_2F_{23}}. \quad (1)$$

Note that $q_2 = 0$ since the surface is adiabatic. Since A_3 is a blackbody, $J_3 = E_{b3} = \sigma T_3^4$; since A_2 is adiabatic, $J_2 = E_{b2} = \sigma T_2^4$. From Fig. 13.5 and the summation rule for surface A_1, find

$$F_{12} = 0.62 \text{ with } \frac{r_j}{L} = \frac{0.2}{0.1} = 2 \text{ and } \frac{L}{r_i} = \frac{0.1}{0.2} = 0.5, \qquad F_{13} = 1 - F_{12} = 1 - 0.62 = 0.38.$$

Hence, Eq. (1) with $J_3 = 5.67 \times 10^{-8} \times 300^4$ W/m^2 becomes

$$\frac{J_2 - J_1}{1/A_2 \times 0.62} + \frac{J_2 - 459.3\,\text{W/m}^2}{1/A_2 \times 0.38} = 0 \qquad -0.62J_1 + 1.00J_2 = 174.5 \quad (2,3)$$

The radiation balance on surface A_1 with $E_{b3} = 5.67 \times 10^{-8} \times 500^4$ W/m^2 becomes

$$\frac{E_{b1} - J_1}{(1-\varepsilon_1)/\varepsilon_1 A_1} = \frac{J_1 - J_2}{1/A_1F_{12}} + \frac{J_1 - J_3}{1/A_1F_{13}} \quad (4)$$

$$\frac{3543.8 - J_1}{(1-0.6)/0.6A_1} = \frac{J_1 - J_2}{1/A_1 \times 0.62} + \frac{J_1 - 459.3}{1/A_1 \times 0.38} \qquad 2.50J_1 - 0.62J_2 = 5490.2 \quad (5,6)$$

Solve Eqs. (3) and (6) to find $J_2 = 1815$ W/m^2 and since $E_{b2} = J_2$,

$$T_2 = \left(\frac{E_{b2}}{\sigma}\right)^{1/4} = \left(\frac{1815\ \text{W/m}^2}{5.67\times 10^{-8}\,\text{W/m}^2\cdot\text{K}^4}\right)^{1/4} = 423\ \text{K}. \quad <$$

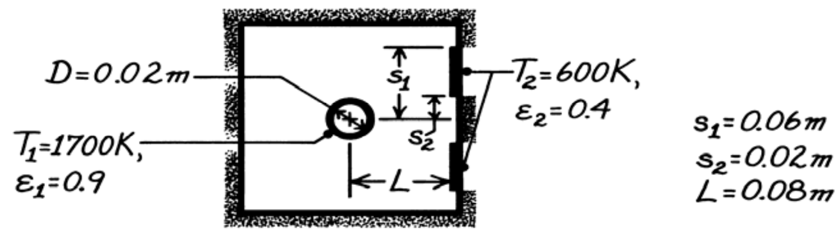
COMMENTS: A network representation would help to visualize the exchange relations. However, it is useful to approach the problem by recognizing there are two unknowns in the problem: J_1 and J_2; hence two radiation balances must be written. Note also the significance of $J_2 = E_{b2}$ and $J_3 = E_{b3}$.

PROBLEM 13.68

KNOWN: Thermal conditions in oven used to cure strip coatings.

FIND: Electrical power requirement.

SCHEMATIC:



ASSUMPTIONS: (1) Diffuse-gray surfaces, (2) Furnace wall is reradiating, (3) Negligible end effects.

ANALYSIS: The net radiant power leaving the heater surface per unit length is

$$q_1' = \frac{E_{b1} - E_{b2}}{\dfrac{1-\varepsilon_1}{\varepsilon_1 A_1'} + \dfrac{1}{A_1'F_{12} + \left[\left(1/A_1F_{1R}\right) + \left(1/A_2'F_{2R}\right)\right]^{-1}} + \dfrac{1-\varepsilon_2}{\varepsilon_2 A_2'}}$$

where $A_1' = \pi D = \pi(0.02\,\text{m}) = 0.0628\,\text{m}$ and $A_2' = 2(s_1 - s_2) = 0.08\,\text{m}$. The view factor between the heater and one of the strips is

$$F_{21} = \frac{D/2}{s_1 - s_2}\left[\tan^{-1}\frac{s_1}{L} - \tan^{-1}\frac{s_2}{L}\right] = \frac{0.01}{0.04}\left[\tan^{-1}\frac{0.06}{0.08} - \tan^{-1}\frac{0.02}{0.08}\right] = 0.10$$

and using the view factor relations find

$$A_1'F_{12} = A_2'F_{21} = 0.08\,\text{m} \times 0.10 = 0.008\,\text{m} \qquad F_{12} = (0.080/0.0628)\,0.10 = 0.127$$

$$F_{1R} = 1 - F_{12} = 1 - 0.127 = 0.873 \qquad F_{2R} = 1 - F_{21} = 1 - 0.10 = 0.90.$$

Hence, with $E_b = \sigma T^4$,

$$q_1' = \frac{5.67\times10^{-8}\left[(1700)^4 - (600)^4\right]}{\dfrac{1-0.9}{0.9\times0.0628} + \dfrac{1}{0.008 + \left[1/(0.0628\times0.873) + 1/(0.08\times0.90)\right]^{-1}} + \dfrac{1-0.4}{0.4\times0.08}}$$

$$q_1' = \frac{4.66\times10^5}{1.77 + 25.56 + 18.75} = 10{,}100\ \text{W/m}.$$ <

COMMENTS: The radiosities for A_1 and A_2 follow from Eq. 13.19,

$$J_1 = E_{b1} - (1-\varepsilon_1)q_1'/\varepsilon_1 A_1' = 4.56\times10^5\ \text{W/m}^2$$

$$J_2 = E_{b2} + (1-\varepsilon_2)q_1'/\varepsilon_2 A_2' = 1.97\times10^5\ \text{W/m}^2.$$

From Eq. 13.31, find J_R and hence T_R as

$$0.0628\times0.873(J_1 - J_R) - 0.08\times0.90(J_R - J_2) = 0$$

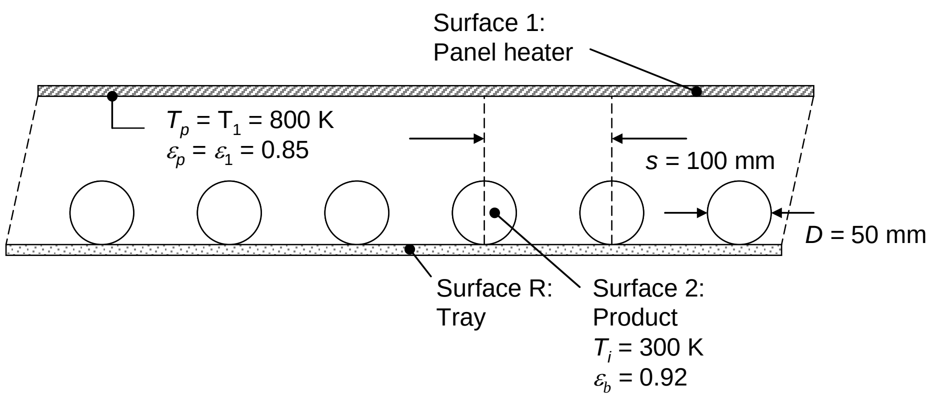
$$J_R = 3.08\times10^5\ \text{W/m}^2 = \sigma T_R^4 \qquad T_R = 1527\ \text{K}.$$

PROBLEM 13.69

KNOWN: Dimensions, temperature and emissivity of cylindrical product. Temperature and emissivity of infrared panel heater.

FIND: (a) Radiative flux delivered to the product and panel heat flux for a spacing of s = 100 mm and a product length of L = 1 m, (b) Plot of the heat flux experienced by the product, and the panel heater heat flux over the range 50 mm ≤ s ≤ 250 mm.

SCHEMATIC:



ASSUMPTIONS: (1) Diffuse-gray surfaces, (2) Negligible convection heat transfer.

ANALYSIS: (a) For the unit cell indicated in the schematic, $A_1 = A_3 = A_R = s$ and $A_2 = \pi D$. From Eq. 13.30,

$$q_1 = -q_2 = \frac{E_{b1} - E_{b2}}{\frac{1-\varepsilon_1}{\varepsilon_1 A_1} + \frac{1}{A_1 F_{12} + \left[(1/A_1 F_{1R}) + (1/A_2 F_{2R})\right]^{-1}} + \frac{1-\varepsilon_2}{\varepsilon_2 A_2}}$$

Substituting the Stefan-Boltzmann equation and expressions for the unit surface areas, and dividing by A_2 and using reciprocity in the form $A_2 F_{2R} = A_R F_{R2}$, the preceding expression may be written as

$$q_2'' = \frac{\sigma T_2^4 - \sigma T_1^4}{\frac{(1-\varepsilon_1)\pi D}{\varepsilon_1 s} + \frac{\pi D}{sF_{12} + \left[(1/sF_{1R}) + (1/sF_{R2})\right]^{-1}} + \frac{1-\varepsilon_2}{\varepsilon_2}} \qquad (1)$$

The view factors are evaluated using the expression given in Table 13.1,

$$F_{R2} = F_{12} = 1 - \left[1 - \left(\frac{50}{100}\right)^2\right]^{1/2} + \left(\frac{50}{100}\right)\tan^{-1}\left[\left(\frac{100^2 - 50^2}{50^2}\right)^{1/2}\right] = 0.657 \qquad (2)$$

and $F_{1R} = 1 - F_{12} = 1 - 0.657 = 0.343$. (3)

Substituting into Eq. 1 yields

Continued…

PROBLEM 13.69 (Cont.)

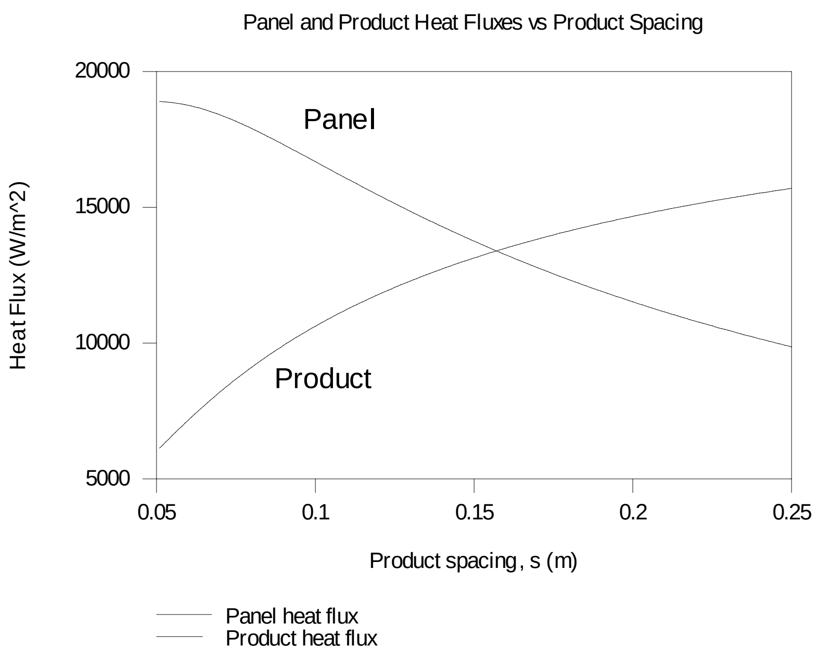
$$q_2'' = \frac{5.67\times10^{-8}\,\mathrm{W/m^2\cdot K^4}\times\left(300\mathrm{K}^4 - 800\mathrm{K}^4\right)}{\dfrac{(1-0.85)\times\pi\times0.05\mathrm{m}}{0.85\times0.10\mathrm{m}} + \dfrac{\pi\times0.05\mathrm{m}}{0.10\mathrm{m}\times0.657 + \left[(1/0.10\mathrm{m}\times0.343)+(1/0.10\mathrm{m}\times0.657)\right]^{-1}} + \dfrac{1-0.92}{0.92}}$$

$= -10{,}616\ \mathrm{W/m^2}$ <

The panel heat flux is found by noting that

$$q_1 = -q_2 = q_1'' sL = -q_2''\pi DL \quad \text{or} \quad q_1'' = -q_2''\frac{\pi D}{s} = 10{,}616\frac{\mathrm{W}}{\mathrm{m^2}}\times\frac{\pi\times0.05\mathrm{m}}{0.10\mathrm{m}} = 16{,}680\frac{\mathrm{W}}{\mathrm{m^2}}$$ <

(b) Using IHT, the radiation heat flux *from* the panel and the radiation heat flux *to* the product, as a function of the product spacing, *s*, is shown below. This was obtained by solving Eqs. 1 – 3 simultaneously. At small product spacing, the heat flux from the panel must be large in order to deliver radiation to the larger product surface area per unit width of the oven. At large product spacing, the product heat flux becomes large as more of the product is exposed to direct irradiation from the panel.



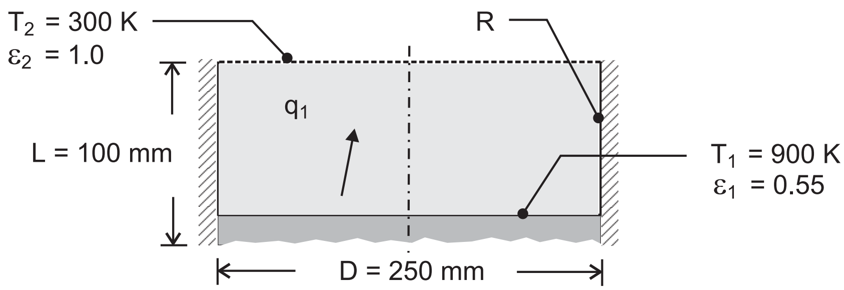
COMMENTS: (1) The product may be heated by a batch or a continuous process. (2) For a batch process, the product temperature would increase with time, with a faster increase in temperature associated with large product spacing. Of course, a smaller amount of total mass would be processed per unit time as the spacing is increased. Would an optimal product spacing, to maximize the product that is produced per unit time, exist? (3) For a continuous process, for example, if the product were placed on a reradiating conveyor tray, individual product would be heated faster at larger product spacing, but the amount of product that could be processed per unit time decreases with increased product spacing (for a given conveyor speed). Hence, a tradeoff would exist during continuous processing between the increased heating and decreased productivity as the product spacing is increased. Would an optimal product spacing, to maximize product throughput, exist?

PROBLEM 13.70

KNOWN: Surface temperature and emissivity of molten alloy and distance of surface from top of container. Container diameter.

FIND: Net rate of radiation heat transfer from surface of melt.

SCHEMATIC:



ASSUMPTIONS: (1) Opaque, diffuse, gray behavior for surface of melt, (2) Large surroundings may be represented by a hypothetical surface of temperature $T = T_{sur}$ and $\varepsilon = 1$, (3) Negligible convection at exposed side wall, (4) Adiabatic side wall.

ANALYSIS: With negligible convection at an adiabatic side wall, the surface may be treated as reradiating. Hence, from Eq. 13.30, with $A_1 = A_2$,

$$q_1 = \frac{A_1\left(E_{b1} - E_{b2}\right)}{\frac{1-\varepsilon_1}{\varepsilon_1} + \frac{1}{F_{12} + \left[\left(1/F_{1R}\right) + \left(1/F_{2R}\right)\right]^{-1}} + \frac{1-\varepsilon_2}{\varepsilon_2}}$$

With $\quad R_i = R_j = \left(D/2\right)/L = 1.25$ and $S = \left[1 + \left(1 + R_j^2\right)/R_i^2\right] = 2.640$, Table 13.2 yields

$$F_{12} = \frac{1}{2}\left\{S - \left[S^2 - 4\left(r_2/r_1\right)^2\right]^{1/2}\right\} = 0.458$$

Hence,

$$F_{1R} = F_{2R} = 1 - F_{12} = 0.542 \text{ and}$$

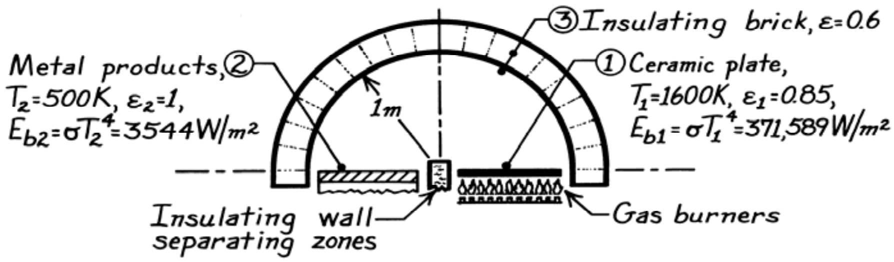
$$q_1 = \frac{\pi\left(0.25\text{m}\right)^2 \times 5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left(900^4 - 300^4\right)\text{K}^4}{\frac{1-0.55}{0.55} + \frac{1}{0.458 + \left(3.69\right)^{-1}} + 0} = 3295\,\text{W}$$ <

PROBLEM 13.71

KNOWN: Long hemi-cylindrical shaped furnace comprised of three zones.

FIND: (a) Heat rate per unit length of the furnace which must be supplied by the gas burners and (b) Temperature of the insulating brick.

SCHEMATIC:



ASSUMPTIONS: (1) Surfaces are opaque, diffuse-gray or black, (2) Surfaces have uniform temperatures and radiosities, (3) Surface 3 is perfectly insulated, (4) Negligible convection, (5) Steady-state conditions.

ANALYSIS: (a) From an energy balance on the ceramic plate, the power required by the burner is $q'_{burners} = q'_1$, the net radiation leaving A_1; hence

$$q'_1 = A_1F_{12}(J_1 - J_2) + A_1F_{13}(J_1 - J_3) = 0 + A_1F_{13}(J_1 - J_3) \quad (1)$$

since $F_{12} = 0$. Note that $J_2 = E_{b2} = \sigma T_2^4$ and that J_1 and J_3 are unknown. Hence, we need to write two radiation balances.

A_1: $$\frac{E_{b1} - J_1}{(1-\varepsilon_1)/\varepsilon_1 A_1} = q'_1 = 0 + A_1F_{13}(J_1 - J_3) \quad (2)$$

A_3: $$0 = A_3F_{31}(J_3 - J_1) + A_3F_{32}(J_3 - E_{b2})$$

$$J_3 = \frac{J_1 + E_{b2}}{2} \quad (3)$$

since $F_{31} = F_{23}$. Substituting Eq. (3) into (2), find

$$(371,589 - J_1)/(1-0.85)/0.85 = 1\left[J_1 - (J_1 + 3,544)/2\right]$$

$$J_1 = 341,748\ \mathrm{W/m^2} \qquad J_3 = 172,646\ \mathrm{W/m^2}$$

using $E_{b1} = \sigma T_1^4 = 371,589\ \mathrm{W/m^2}$ and $E_{b2} = \sigma T_2^4 = 3544\ \mathrm{W/m^2}$. Substituting into Eq. (1), find

$$q'_1 = 1\ \mathrm{m} \times 1(341,748 - 172,646)\ \mathrm{W/m^2} = 169\ \mathrm{kW/m}. \qquad <$$

(b) The temperature of the insulating brick, acting as a reradiating surface, is

$$J_3 = E_{b3} = \sigma T_3^4$$

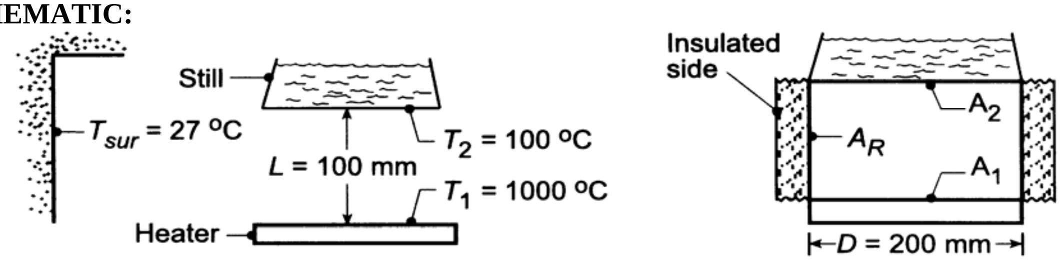
$$T_3 = (J_3/\sigma)^{1/4} = \left(172,646\ \mathrm{W/m^2} / 5.67\times10^{-8}\ \mathrm{W/m^2\cdot K^4}\right)^{1/4} = 1320\ \mathrm{K}. \qquad <$$

PROBLEM 13.72

KNOWN: Steam producing still heated by radiation.

FIND: (a) Factor by which the vapor production could be increased if the cylindrical side of the heater were insulated rather than open to the surroundings, and (b) Compute and plot the net heat rate of radiation transfer to the still, as a function of the separation distance L for the range $15 \le L \le 100$ mm for heater temperatures of 600, 800, 1000°C considering the cylindrical sides to be insulated.

SCHEMATIC:



ASSUMPTIONS: (1) Still and heater surfaces are black, (2) Surroundings are isothermal and large compared to still heater surfaces, (3) Insulation is diffuse-gray, (4) Negligible convection.

ANALYSIS: (a) The vapor production will be proportional to the net radiation exchange to the still. For the case when the sides are open (o) to the surroundings, the net radiation exchange leaving A_2 is from Eq. 13.14.

$$q_{2,o} = q_{21} + q_{2s} = A_2 F_{21} \sigma \left(T_2^4 - T_1^4 \right) + A_2 F_{2s} \sigma \left(T_2^4 - T_{sur}^4 \right)$$

where $F_{2s} = 1 - F_{21}$ and F_{21} follows from Fig. 13.5 with $L/r_i = 100/100 = 1$, $r_j/L = 100/100 = 1$.

$$F_{21} = 0.38$$

With $A_2 = \pi D^2 / 4$, find

$$q_{2,o} = \frac{\pi (0.200\text{m})^2}{4} \times 5.67 \times 10^{-8}\,\text{W/m}^2 \cdot \text{K}^4 \left\{ 0.38\left(373^4 - 1273^4\right)\text{K}^4 + (1 - 0.38)\left(373^4 - 300^4\right)\text{K}^4 \right\}$$

$$q_{2,o} = -1752\,\text{W}. \qquad \text{without insulation}$$ <

With the cylindrical side insulated (i), a three-surface, re-radiating enclosure is formed. Eq. 13.30 can be used to evaluate $q_{2,i}$ and with $\varepsilon_2 = \varepsilon_1 = 1$, the relation is

$$q_{2,i} = \frac{\sigma \left(T_2^4 - T_1 \right)^4}{\dfrac{1}{A_1 F_{12} + \left[(1/A_1 F_{1R}) + (1/A_2 F_{2R}) \right]^{-1}}} = A_1 \left\{ F_{12} + \left[1/F_{1R} + 1/F_{2R} \right]^{-1} \right\} \sigma \left(T_2^4 - T_1^4 \right)$$

Recall $F_{12} = 0.38$ and $F_{1R} = 1 - F_{12} = 1 - 0.38 = 0.62$, giving

$$q_{2,i} = \frac{\pi (0.200\text{ m})^2}{4} \left\{ 0.38 + \left[1/0.62 + 1/0.62 \right]^{-1} \right\} 5.67 \times 10^{-8}\,\text{W/m}^2 \cdot \text{K} \left(373^4 - 1273^4 \right)\text{K}^4$$

$$q_{2,i} = -3204\text{ W}. \qquad \text{with insulation}$$ <

Continued …

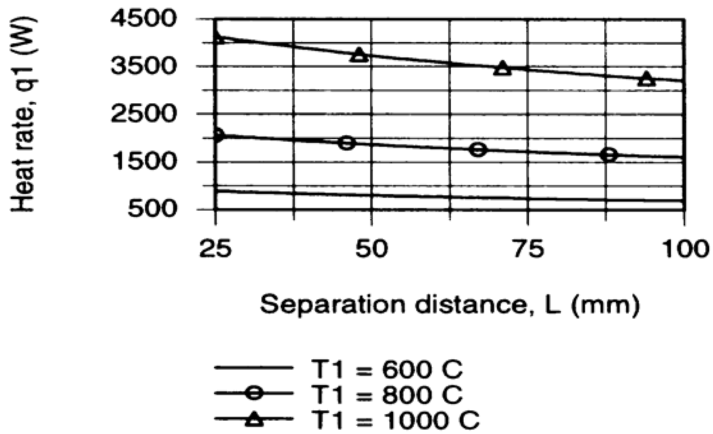
PROBLEM 13.72 (Cont.)

Hence, the vapor production rate is increased by a factor

$$\frac{q_2)_{insul}}{q_2)_{open}} = \frac{3204\,W}{1752\,W} = 1.83$$

That is, the vapor production is increased by 83%. <

(b) The *IHT Radiation Tool – Radiation Exchange Analysis* for the *Three-Surface Enclosure* with a *reradiating surface* can be used directly to compute the net heat rate to the still, $q_1 = q_2$, as a function of the separation distance L for selected heater temperatures T_1. The results are plotted below.



Note that the heat rate for all values of T_1 decreases as expected with increasing separation distances, but not markedly. For any separation distance, increasing the heater temperature greatly influences the heat rate. For example, at L = 50 mm, increasing T_1 from 600 to 800 K, causes a nearly 6 fold increase in the heat rate. But increasing T_1 from 800 to 1000 K causes only a 2 fold increase in the heat rate.

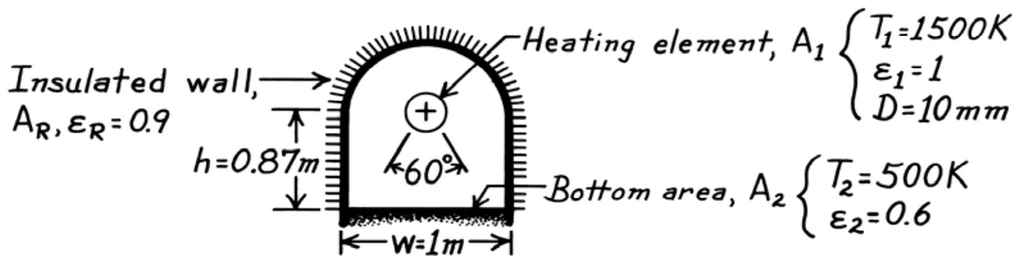
COMMENTS: When assigning the emissivity variables (ε_1, ε_2, ε_3) in the *IHT* model mentioned above, set $\varepsilon = 0.999$, rather than 1.0, to avoid a "division by zero" error message. You could also call up the *Radiation Tool, View Factor Coaxial Parallel Disk* to calculate F_{12}.

PROBLEM 13.73

KNOWN: Furnace with cylindrical heater and re-radiating, insulated walls.

FIND: (a) Power required to maintain steady-state conditions, (b) Temperature of wall area.

SCHEMATIC:



ASSUMPTIONS: (1) Surfaces are diffuse-gray, (2) Furnace is of length ℓ where ℓ >> w, (3) Convection is negligible, (4) $A_1 << A_2$.

ANALYSIS: (a) Consider the furnace as a three surface enclosure with the walls, A_R, represented as a re-radiating surface. The power that must be supplied to the heater is determined by Eq. 13.30.

$$q_1 = \frac{\sigma\left(T_1^4 - T_2^4\right)}{(1-\varepsilon_1)/\varepsilon_1 A_1 + \left[A_1F_{12} + \left[(1/A_1F_{1R}) + (1/A_2F_{2R})\right]^{-1}\right]^{-1} + (1-\varepsilon_2)/\varepsilon_2 A_2}$$

Note that $A_1 = \pi d\ell$ and $A_2 = w\ell$. By inspection and the summation rule, find F_{12} = 60°/360° = 0.167, $F_{1R} = 1 - F_{12}$ = 1 – 0.167 = 0.833, and $F_{2R} \approx 1$. With $q_1' = q_1/\ell$,

$$q_1' = \frac{5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left(1500^4 - 500^4\right)\text{K}^4}{0 + \left[\pi\left(10\times10^{-3}\right)\text{m}\times0.167 + \left[\left(1/\pi\left(10\times10^{-3}\text{m}\right)\times0.83\right) + (1/1\,\text{m}\times1)\right]^{-1}\right]^{-1} + (1-0.6)/0.6\times1\text{ m}}$$

$$q_1' = 8518\ \text{W/m}.$$ <

(b) To determine the wall temperature, apply the radiation balance, Eq. 13.31,

$$\frac{J_1 - J_R}{(1/A_1F_{1R})} = \frac{J_R - J_2}{(1/A_2F_{2R})} \quad \text{or} \quad \frac{J_1 - J_R}{\left(1/\pi 10\times10^{-3}\text{m}\times0.833\right)} = \frac{J_R - J_2}{(1/1\text{m}\times1)}.$$

$$J_R = \sigma T_R^4 = \left(J_1 + 38.21 J_2\right)/39.21. \qquad (1)$$

Since A_1 is a blackbody, $J_1 = E_{b1} = \sigma T_1^4$. To determine J_2, use Eq. 13.19. Noting that $q_1' = -q_2'$, find

$$q_2 = \left(E_{b2} - J_2\right)/(1-\varepsilon_2)/\varepsilon_2 A_2 \qquad \text{or} \qquad J_2 = E_{b2} - q_2(1-\varepsilon_2)/\varepsilon_2 A_2$$

$$J_2 = 5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\,(500\text{ K})^4 - \frac{(-8518\text{ W/m})(1-0.6)}{0.6(1\text{m})} = 9222\ \text{W/m}^2.$$

Substituting this value for J_2 into Eq. (1), the wall temperature can be calculated.

$$J_R = \left(5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\,(1500\text{K})^4 + 38.21\times9222\,\text{W/m}^2\right)/39.21 = 16{,}308\,\text{W/m}^2$$

$$T_R = \left(J_R/\sigma\right)^{1/4} = \left(16{,}308\,\text{W/m}^2/5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\right)^{1/4} = 732\text{ K}.$$ <

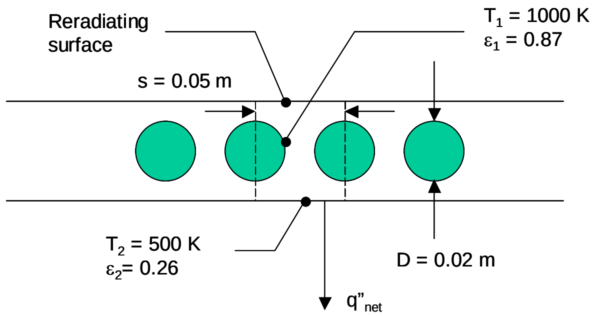
COMMENTS: Considering the entire wall as a single re-radiating surface may be a poor assumption since J_R is not likely to be uniform over this large an area. It would be appropriate to consider several isothermal zones for improved accuracy.

PROBLEM 13.74

KNOWN: Dimensions, temperature and emissivity of radiant heating tubes, temperature and emissivity of heated material, location of reradiating surface.

FIND: Net radiative heat flux to the heated material.

SCHEMATIC:



ASSUMPTIONS: Diffuse, gray behavior.

ANALYSIS: Treating the tubes as a single surface, the heat transfer rate from Surface 1 to Surface 2 is given by

$$q_1 = -q_2 = \frac{E_{b1} - E_{b2}}{\dfrac{1-\varepsilon_1}{\varepsilon_1 A_1} + \dfrac{1}{A_1 F_{12} + \left[(1/A_1 F_{1R}) + (1/A_2 F_{2R})\right]^{-1}} + \dfrac{1-\varepsilon_2}{\varepsilon_2 A_2}}$$

Utilizing the reciprocity relationship, incorporating the Stefan-Boltzmann law, and dividing by area A_2,

$$q_1'' = -q_2'' = \frac{\sigma(T_1^4 - T_2^4)}{\dfrac{(1-\varepsilon_1)A_2}{\varepsilon_1 A_1} + \dfrac{A_2}{A_2 F_{21} + \left[(1/A_R F_{R1}) + (1/A_2 F_{2R})\right]^{-1}} + \dfrac{1-\varepsilon_2}{\varepsilon_2 A_2}} \qquad (1)$$

From Table 13.1 for the infinite plane and row of cylinders,

$$F_{12} = 1 - \left[1 - \left(\frac{D}{s}\right)^2\right]^{1/2} + \left(\frac{D}{s}\right)\tan^{-1}\left[\left(\frac{s^2 - D^2}{D^2}\right)^{1/2}\right]$$

$$F_{21} = 1 - \left[1 - \left(\frac{0.02}{0.05}\right)^2\right]^{1/2} + \left(\frac{0.02}{0.05}\right)\tan^{-1}\left[\left(\frac{0.05^2 - 0.02^2}{0.02^2}\right)^{1/2}\right] = 0.5472 = F_{R1}$$

Therefore, F_{2R} = 1 – 0.5472 = 0.4528.

Continued…

PROBLEM 13.74 (Cont.)

For a unit cell as shown in the schematic, $A_2 = s$, $A_1 = \pi D$, and $A_R = s$. Therefore Eq. (1) is written as,

$$q_1'' = -q_2'' = \frac{\sigma\left(T_1^4 - T_2^4\right)}{\dfrac{(1-\varepsilon_1)s}{\varepsilon_1 \pi D} + \dfrac{s}{sF_{21} + \left[(1/sF_{R1}) + (1/sF_{2R})\right]^{-1}} + \dfrac{(1-\varepsilon_2)}{\varepsilon_2}}$$

or

$$q_1'' = -q_2'' = \frac{5.67\times 10^{-8}\dfrac{W}{m^2\cdot K^4}\left[(1000K)^4 - (500K)^4\right]}{\dfrac{(1-0.87)\times 0.05}{0.87\times\pi\times 0.02} + \dfrac{0.05}{0.05\times 0.5472 + \left[(1/0.05\times 0.5472) + (1/0.05\times 0.4528)\right]^{-1}} + \dfrac{(1-0.26)}{0.26}}$$

$$q_1'' = -q_2'' = 12{,}590 \text{ W/m}^2$$ <

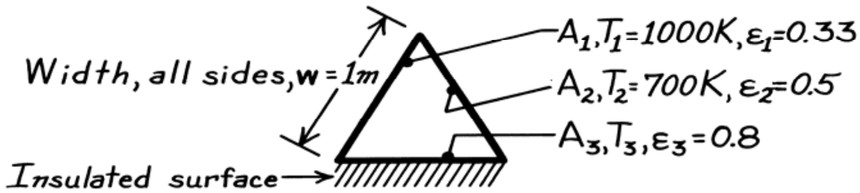
COMMENT: The heat flux is independent of the separation distance between the heater and the material. Does this make sense to you?

PROBLEM 13.75

KNOWN: Very long, triangular duct with walls that are diffuse-gray.

FIND: (a) Net radiation transfer from surface A_1 per unit length of duct, (b) The temperature of the insulated surface, (c) Influence of ε_3 on the results; comment on exactness of results.

SCHEMATIC:



ASSUMPTIONS: (1) Surfaces are diffuse-gray, (2) Duct is very long; end effects negligible.

ANALYSIS: (a) The duct approximates a three-surface enclosure for which the third surface (A_3) is re-radiating. Using Eq. 13.30 with $A_3 = A_R$, the net exchange is

$$q_1 = -q_2 = \frac{E_{b1} - E_{b2}}{\frac{(1-\varepsilon_1)}{\varepsilon_1 A_1} + \frac{1}{A_1F_{12} + \left(1/A_1F_{1R} + 1/A_2F_{2R}\right)^{-1}} + \frac{(1-\varepsilon_2)}{\varepsilon_2 A_2}} \quad (1)$$

From symmetry, $F_{12} = F_{1R} = F_{2R} = 0.5$. With $A_1 = A_2 = w \cdot \ell$, where ℓ is the length normal to the page and w = 1 m,

$$q_1' = q_1/\ell = (q_1/A_1)w$$

$$q_1' = \frac{(56,700 - 13,614)\,\text{W/m}^2 \times 1\text{m}}{\frac{(1-0.33)}{0.33} + \frac{1}{0.5 + (1/0.5 + 1/0.5)^{-1}} + \frac{(1-0.5)}{0.5}} = 9874\ \text{W/m}.$$ <

(b) From a radiation balance on A_R,

$$q_R = q_3 = 0 = \frac{E_{b3} - J_1}{(A_3F_{31})^{-1}} + \frac{E_{b3} - J_2}{(A_3F_{32})^{-1}} \qquad \text{or} \qquad E_{b3} = \frac{J_1 + J_2}{2}. \quad (2)$$

To evaluate J_1 and J_2, use Eq. 13.19,

$$J_i = E_{b,i} - \frac{q_i}{A_i}\frac{(1-\varepsilon_i)}{\varepsilon_i} \begin{cases} J_1 = 56,700 - (9874)\frac{1-0.33}{0.33} = 36,653\ \text{W/m}^2 \\ J_2 = 13,614 - (-9874)\frac{1-0.5}{0.5} = 23,488\ \text{W/m}^2 \end{cases}$$

From Eq. (2), now find

$$T_3 = (E_{b3}/\sigma)^{1/4} = \left([J_1 + J_2]/2\sigma\right)^{1/4} = \left(\frac{(36,653 + 23,488)\,\text{W/m}^2}{2\left(5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\right)}\right)^{1/4} = 853\ \text{K}.$$ <

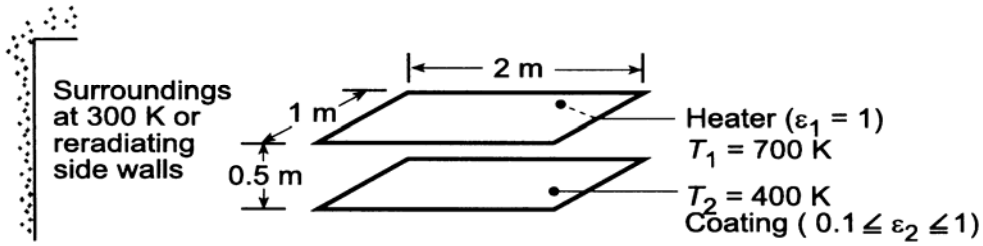
(c) Since A_3 is adiabatic or re-radiating, $J_3 = Eb_3$. Therefore, the value of ε_3 is of no influence on the radiation exchange or on T_3. In using Eq. (1), we require uniform radiosity over the surfaces. This requirement is not met near the corners. For best results we should subdivide the areas such that they represent regions of uniform radiosity. Of course, the analysis then becomes much more complicated.

PROBLEM 13.76

KNOWN: Dimensions for aligned rectangular heater and coated plate. Temperatures of heater, plate and large surroundings.

FIND: (a) Electric power required to operate heater, (b) Heater power required if reradiating sidewalls are added, (c) Effect of coating emissivity and electric power.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Blackbody behavior for surfaces and surroundings (Parts (a) and (b)).

ANALYSIS: (a) For $\varepsilon_1 = \varepsilon_2 = 1$, the net radiation leaving A_1 is

$$q_{elec} = q_1 = A_1 F_{12}\sigma\left(T_1^4 - T_2^4\right) + A_1 F_{1sur}\sigma\left(T_1^4 - T_{sur}^4\right).$$

From Fig. 13.4, with Y/L = 1/0.5 = 2 and X/L = 2/0.5 = 4, the view factors are $F_{12} \approx 0.5$ and $F_{sur} \approx 1 - 0.5 = 0.5$. Hence,

$$q_{elec} = \left(2\text{m}^2\right)0.5\times5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left[(700\ \text{K})^4 - (400\ \text{K})^4\right]$$
$$+\left(2\text{m}^2\right)0.5\times5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left[(700\ \text{K})^4 - (300\ \text{K})^4\right] = (12{,}162 + 13{,}154)\,\text{W} = 25{,}316\,\text{W}. \quad <$$

(b) With the reradiating walls, the net radiation leaving A_1 is $q_{elec} = q_1 = q_{12}$. From Eq. 13.30 with $\varepsilon_1 = \varepsilon_2 = 1$ and $A_1 = A_2$,

$$q_{elec} = A_1\sigma\left(T_1^4 - T_2^4\right)\left\{F_{12} + \left[(1/F_{1R}) + (1/F_{2R})\right]^{-1}\right\}$$

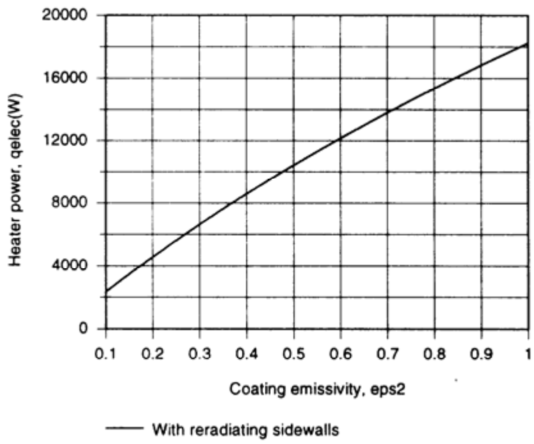
$$q_{elec} = \left(2\,\text{m}^2\right)5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left[(700\ \text{K})^4 - (400\ \text{K})^4\right]\times\left\{0.5 + \left[(1/0.5) + (1/0.5)\right]^{-1}\right\}$$

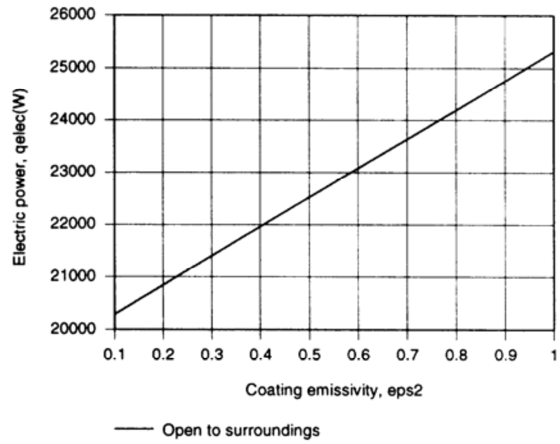
$$q_{elec} = 18{,}243\,\text{W}. \quad <$$

(c) Separately using the *IHT Radiation* Tool Pad for a three-surface enclosure, with one surface reradiating, and to perform a radiation exchange analysis for a three-surface enclosure, with one surface corresponding to large surroundings, the following results were obtained.

Continued …

PROBLEM 13.76 (Cont.)





In both cases, the required heater power decreases with decreasing ε_2, and the trend is attributed to a reduction in $\alpha_2 = \varepsilon_2$ and hence to a reduction in the rate at which radiant energy must be absorbed by the surface to maintain the prescribed temperature.

COMMENTS: With the reradiating walls in part (b), it follows from Eq. 13.31 that

$$J_R = E_{bR} = \left(J_1 + J_2\right)/2 = \left(E_{b1} + E_{b2}\right)/2.$$

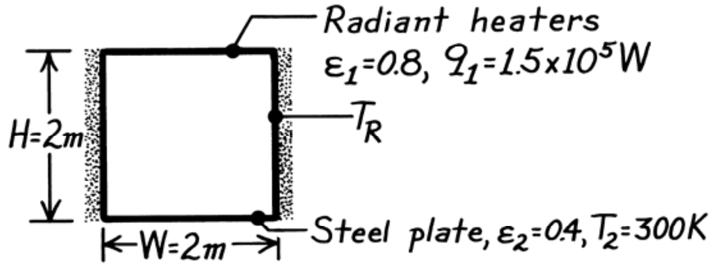
Hence, $T_R = 604$ K. The reduction in q_{elec} resulting from use of the walls is due to the enhancement of radiation to the heater, which, in turn, is due to the presence of the high temperature walls.

PROBLEM 13.77

KNOWN: Configuration and operating conditions of a furnace. Initial temperature and emissivity of steel plate to be treated.

FIND: (a) Heater temperature, (b) Sidewall temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Opaque, diffuse-gray surface behavior, (3) Negligible convection, (4) Sidewalls are re-radiating.

ANALYSIS: (a) From Eq. 13.30

$$q_1 = \frac{E_{b1} - E_{b2}}{\dfrac{1-\varepsilon_1}{\varepsilon_1 A_1} + \dfrac{1}{A_1 F_{12} + \left[\left(A_1 F_{1R}\right)^{-1} + \left(A_2 F_{2R}\right)^{-1}\right]^{-1}} + \dfrac{1-\varepsilon_2}{\varepsilon_2 A_2}} = 1.5\times10^5 \text{ W}$$

Note that $A_1 = A_2 = 4\text{ m}^2$ and $E_{b2} = \sigma T_2^4 = 5.67 \times 10^{-8}\text{ W/m}^2\cdot\text{K}^4\,(300\text{ K})^4 = 459\text{ W/m}^2$. From Fig. 13.4, with X/L = Y/L = 1, $F_{12} = 0.2$; hence $F_{1R} = 1 - F_{12} = 0.8$, and $F_{2R} = F_{1R} = 0.8$. With $(1-\varepsilon_1)/\varepsilon_1 = 0.25$ and $(1 - \varepsilon_2)/\varepsilon_2 = 1.5$, find

$$\frac{1.5\times10^5\text{ W}}{4\text{m}^2} = \frac{E_{b1} - 459\text{ W/m}^2}{0.25 + \dfrac{1}{0.2 + [1.25 + 1.25]^{-1}} + 1.5} = \frac{E_{b1} - 459\text{ W/m}^2}{3.417}$$

$$E_{b1} = 1.28\times10^5\text{ W/m}^2 + 459\text{ W/m}^2 = 1.29\times10^5\text{ W/m}^2 = \sigma T_1^4$$

$$T_1 = \left(1.29\times10^5\text{ W/m}^2 / 5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4\right)^{1/4} = 1228\text{ K.}$$

(b) From Eq. 13.31, it follows that, with $A_1F_{1R} = A_2F_{2R}$,

$$J_R = \sigma T_R^4 = \left(J_1 + J_2\right)/2$$

From Eq. 13.19, $J_1 = E_{b1} - \dfrac{(1-\varepsilon_1)}{\varepsilon_1 A_1} q_1 = 1.29\times10^5\text{ W/m}^2 - \dfrac{0.2\times1.5\times10^5\text{ W}}{0.8\times4\text{m}^2}$

$$J_1 = 1.196\times10^5\text{ W/m}^2.$$

With $q_2 = q_1 = -1.5 \times 10^5$ W,

$$J_2 = E_{b2} - \frac{(1-\varepsilon_2)}{\varepsilon_2 A_2} q_2 = 459\text{ W/m}^2 + \frac{0.6}{0.4\times4\text{m}^2} 1.5\times10^5\text{ W} = 5.67\times10^4\text{ W/m}^2$$

$$T_R = \left(\frac{1.196\times10^5\text{ W/m}^2 + 5.67\times10^4\text{ W/m}^2}{2\times5.67\times10^{-8}\text{ W/m}^2\cdot\text{K}^4}\right)^{1/4} = 1117\text{ K.}$$ <

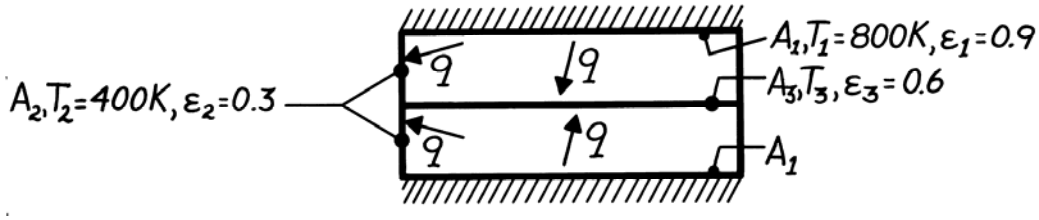
COMMENTS: (1) The above results are approximate, since the process is actually transient. (2) T_1 and T_R will increase with time as T_2 increases.

PROBLEM 13.78

KNOWN: Dimensions, surface radiative properties, and operating conditions of an electrical furnace.

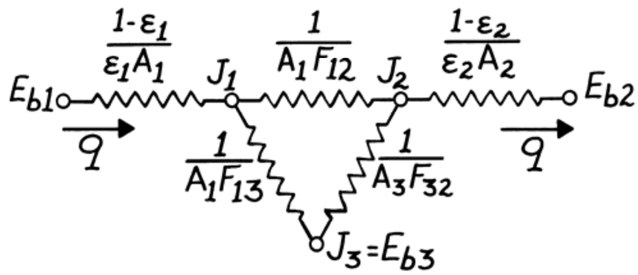
FIND: (a) Equivalent radiation circuit, (b) Furnace power requirement and temperature of a heated plate.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Opaque, diffuse-gray surfaces, (3) Negligible plate temperature gradients, (4) Back surfaces of heater are adiabatic, (5) Convection effects are negligible.

ANALYSIS: (a) Since there is symmetry about the plate, only one-half (top or bottom) of the system need be considered. Moreover, the plate must be adiabatic, thereby playing the role of a re-radiating surface.



<

(b) Note that $A_1 = A_3 = 4\ m^2$ and $A_2 = (0.5\ m \times 2\ m)4 = 4\ m^2$. From Fig. 13.4, with X/L = Y/L = 4, $F_{13} = 0.62$. Hence

$$F_{12} = 1 - F_{13} = 0.38, \quad \text{and} \quad F_{32} = F_{12} = 0.38.$$

It follows that

$$A_1F_{12} = 4(0.38) = 1.52\,m^2$$

$$A_1F_{13} = 4(0.62) = 2.48\,m^2, \qquad (1-\varepsilon_1)/\varepsilon_1 A_1 = 0.1/3.6\,m^2 = 0.0278\,m^{-2}$$

$$A_3F_{32} = 4(0.38) = 1.52\,m^2, \qquad (1-\varepsilon_2)/\varepsilon_2 A_2 = 0.7/1.2\,m^2 = 0.583\,m^{-2}.$$

Also,

$$E_{b1} = \sigma T_1^4 = 5.67\times10^{-8}\,W/m^2\cdot K^4 (800\ K)^4 = 23,224\,W/m^2,$$

$$E_{b2} = \sigma T_2^4 = 5.67\times10^{-8}\,W/m^2\cdot K^4 (400\ K)^4 = 1452\,W/m^2.$$

The system forms a three-surface enclosure, with one surface re-radiating. Hence the net radiation transfer from a single heater is, from Eq. 13.30,

$$q_1 = \frac{E_{b1} - E_{b2}}{\frac{1-\varepsilon_1}{\varepsilon_1 A_1} + \frac{1}{A_1F_{12} + \left[1/A_1F_{13} + 1/A_3F_{32}\right]^{-1}} + \frac{1-\varepsilon_2}{\varepsilon_2 A_2}}$$

Continued …

PROBLEM 13.78 (Cont.)

$$q_1 = \frac{(23,224-1452)\,\text{W/m}^2}{(0.0278+0.4061+0.583)\,\text{m}^{-2}} = 21.4\,\text{kW}.$$

The furnace power requirement is therefore $q_{elec} = 2q_1 = 43.8$ kW, with <

$$q_1 = \frac{E_{b1} - J_1}{(1-\varepsilon_1)/\varepsilon_1 A_1}.$$

where

$$J_1 = E_{b1} - q_1 \frac{1-\varepsilon_1}{\varepsilon_1 A_1} = 23,224\,\text{W/m}^2 - 21,400\,\text{W} \times 0.0278\,\text{m}^{-2}$$

$$J_1 = 22,679\,\text{W/m}^2.$$

Also,

$$J_2 = E_{b2} - q_2 \frac{1-\varepsilon_2}{\varepsilon_2 A_2} = 1,452\,\text{W/m}^2 - (-21,400\,\text{W}) \times 0.583\,\text{m}^{-2}$$

$$J_2 = 13,928\,\text{W/m}^2.$$

From Eq. 13.31,

$$\frac{J_1 - J_3}{1/A_1F_{13}} = \frac{J_3 - J_2}{1/A_3F_{32}}$$

$$\frac{J_1 - J_3}{J_3 - J_2} = \frac{A_3F_{32}}{A_1F_{13}} = \frac{1.52}{2.48} = 0.613$$

$$1.613J_3 = J_1 + 0.613J_2 = 22,629 + 8537 = 31,166\,\text{W/m}^2$$

$$J_3 = 19,321\,\text{W/m}^2$$

Since $J_3 = E_{b3}$,

$$T_3 = (E_{b3}/\sigma)^{1/4} = \left(19,321/5.67\times10^{-8}\right)^{1/4} = 764\ \text{K}.$$ <

COMMENTS: (1) To reduce q_{elec}, the sidewall temperature T_2, should be increased by insulating it from the surroundings. (2) The problem must be solved by simultaneously determining J_1, J_2 and J_3 from the radiation balances of the form

$$\frac{E_{b1} - J_1}{(1-\varepsilon_1)/\varepsilon_1 A_1} = A_1F_{12}(J_1 - J_2) + A_1F_{13}(J_1 - J_3)$$

$$\frac{E_{b2} - J_2}{(1-\varepsilon_2)/\varepsilon_2 A_2} = A_2F_{21}(J_2 - J_1) + A_2F_{23}(J_2 - J_3)$$

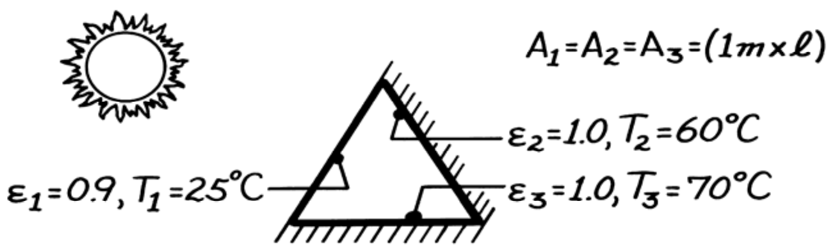
$$0 = A_1F_{13}(J_3 - J_1) + A_2F_{23}(J_3 - J_2).$$

PROBLEM 13.79

KNOWN: Geometry and surface temperatures and emissivities of a solar collector.

FIND: Net rate of radiation transfer to cover plate due to exchange with the absorber plates.

SCHEMATIC:



ASSUMPTIONS: (1) Isothermal surfaces with uniform radiosity, (2) Absorber plates behave as blackbodies, (3) Cover plate is diffuse-gray and opaque to thermal radiation exchange with absorber plates, (4) Duct end effects are negligible.

ANALYSIS: Applying Eq. 13.21 to the cover plate, it follows that

$$E_{b1} - J_1 = \frac{1-\varepsilon_1}{\varepsilon_1 A_1} \sum_{j=1}^{N} \frac{J_1 - J_j}{\left(A_i F_{ij}\right)^{-1}} = \frac{1-\varepsilon_1}{\varepsilon_1 A_1}\left[A_1 F_{12}\left(J_1 - J_2\right) + A_1 F_{13}\left(J_1 - J_3\right)\right].$$

From symmetry, $F_{12} = F_{13} = 0.5$. Also, $J_2 = E_{b2}$ and $J_3 = E_{b3}$. Hence

$$E_{b1} - J_1 = 0.0556\left(2J_1 - E_{b2} - E_{b3}\right)$$

or with $E_b = \sigma T^4$,

$$1.111 J_1 = E_{b1} + 0.0556\left(E_{b2} + E_{b3}\right)$$

$$1.111 J_1 = 5.67\times10^{-8}\left(298\right)^4 \text{ W/m}^2 + 0.0556\left(5.67\times10^{-8}\right)\left[\left(333\right)^4 + \left(343\right)^4\right] \text{W/m}^2$$

$$J_1 = 476.64 \text{ W/m}^2$$

From Eq. 13.19 the net rate of radiation transfer *from* the cover plate is then

$$q_1 = \frac{E_{b1} - J_1}{\left(1-\varepsilon_1\right)/\varepsilon_1 A_1} = \frac{5.67\times10^{-8}\left(298\right)^4 - 476.64}{\left(1-0.9\right)/0.9\left(\ell\right)} = \left(-265.5\ell\right)\text{W}.$$

The net rate of radiation transfer *to* the cover plate per unit length is then

$$q_1' = \left(q_1/\ell\right) = 266 \text{ W/m}. \qquad <$$

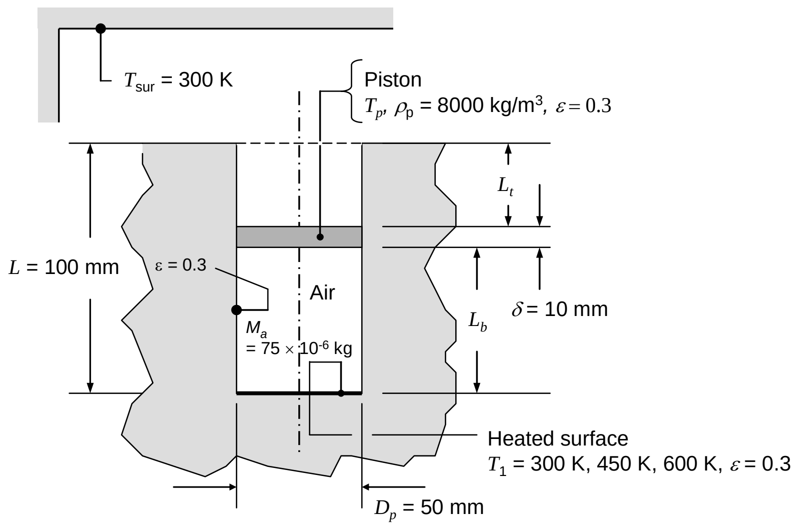
COMMENTS: Solar radiation effects are not relevant to the foregoing problem. All such radiation transmitted by the cover plate is completely absorbed by the absorber plate.

PROBLEM 13.80

KNOWN: Dimensions of cylinder and piston, mass of air contained in the cylinder, emissivity of surfaces, bottom surface temperature and surroundings temperature, density of piston material.

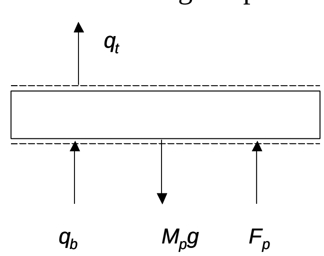
FIND: Distance between bottom of piston and bottom of cylinder and temperature of the piston for T_1 = 300, 450 and 600 K.

SCHEMATIC:



ASSUMPTIONS: (1) Diffuse-gray surfaces with uniform radiosity and irradiation, (2) Negligible convection heat transfer, (3) Ideal gas behavior, (4) Frictionless, isothermal piston, (5) Air temperature is average of bottom surface temperature and piston temperature, (6) Low thermal conductivity material is re-radiating.

ANALYSIS: The position and temperature of the piston are governed by energy and force balances that are applied to a control volume surrounding the piston.



Treating the air as an ideal gas,

$$P_a V_a = M_a(\mathcal{R}/\mathcal{M})\overline{T}_a \tag{1}$$

where $\overline{T}_a = (T_p + T_1)/2$. The force balance yields

$$p_a = M_p g + p_{\text{atm}} = \rho_p(\pi D_p^2/4)\delta g + p_{\text{atm}} \tag{2}$$

At steady state,

$$q_t = q_b \tag{3}$$

Continued…

PROBLEM 13.80 (Cont.)

where the heat rates are determined by evaluating the radiation heat transfer in two enclosures; one enclosure formed by three surfaces below the piston (bottom of cylinder, bottom of piston and reradiating side wall) and the second enclosure formed by three surfaces above the piston (top of piston, hypothetical surface at the top of the cylinder and reradiating side wall).

Using Eq. 13.30 for the bottom enclosure,

$$q_b = \frac{E_{b1} - E_{bp}}{\dfrac{1-\varepsilon_1}{\varepsilon_1 A_1} + \dfrac{1}{A_1 F_{1-p} + \left[\left(1/A_1 F_{1-Rb}\right) + \left(1/A_p F_{p-Rb}\right)\right]^{-1}} + \dfrac{1-\varepsilon_p}{\varepsilon_p A_p}} \tag{4}$$

while for the top enclosure,

$$q_t = \frac{E_{bp} - E_{b\text{sur}}}{\dfrac{1-\varepsilon_p}{\varepsilon_p A_p} + \dfrac{1}{A_p F_{p-\text{sur}} + \left[\left(1/A_p F_{p-Rt}\right) + \left(1/A_{\text{sur}} F_{\text{sur}-p}\right)\right]^{-1}} + \dfrac{1-\varepsilon_{\text{sur}}}{\varepsilon_{\text{sur}} A_{\text{sur}}}} \tag{5}$$

The three emissive powers are

$$E_{b1} = \sigma T_1^4; \quad E_{bp} = \sigma T_p^4; \quad E_{b\text{sur}} = \sigma T_{\text{sur}}^4 \tag{6a,b,c}$$

The surface areas are

$$A_1 = A_p = A_{\text{sur}} = \pi D_p^2/4 \tag{7a,b,c}$$

while the gas volume is

$$V = (\pi D_p^2/4)L_b \tag{8}$$

The universal gas constant is $\mathcal{R}$ = 8315 J/kmol·K and the molecular weight of the air is $\mathcal{M}$ = 28.97 kg/kmol.

View factors for use in Eqs. 4 and 5 are evaluated using the expressions for coaxial parallel disks in Table 13.2. For the bottom enclosure,

$$R_{ib} = R_{jb} = D/(2L_b),\ S_b = 1 + (1 + R_{jb}^2)/R_{ib}^2,\ F_{1-p} = 0.5(S_b - [S_b^2 - 4]^{1/2}),$$
$$F_{1-Rb} = 1 - F_{1-p},\ F_{p-Rb} = F_{1-Rb}. \tag{9a,b,c,d,e,f}$$

For the top enclosure,

$$R_{it} = R_{jt} = D/(2L_t),\ S_t = 1 + (1 + R_{jt}^2)/R_{it}^2,\ F_{p\text{-sur}} = 0.5(S_t - [S_t^2 - 4]^{1/2}),$$
$$F_{p-Rt} = 1 - F_{p-\text{sur}},\ F_{\text{sur}-p} = F_{p-\text{sur}} \tag{10a,b,c,d,e,f}$$

The lengths are related by

Continued…

PROBLEM 13.80 (Cont.)

$$L_b + L_t + \delta = L \tag{11}$$

Simultaneous solution of Eqs. 1 through 11 yields the following results, presented in tabular form.

Input Variable	Results			View Factors					
T_1 (K)	L_b (mm)	T_p (K)	q_b(W)	F_{1-Rb}	F_{1-p}	F_{p-Rb}	F_{p-Rt}	F_{p-sur}	F_{sur-p}
300	0.033	300	0	-	-	-	-	-	-
450	0.045	389.2	0.32	0.804	0.196	0.804	0.799	0.201	0.201
600	0.059	488	1.26	0.865	0.135	0.865	0.691	0.309	0.309

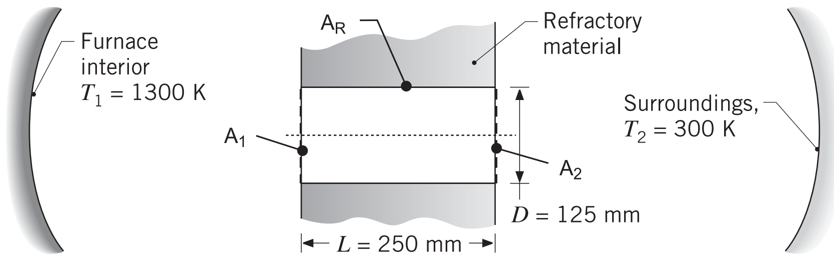
COMMENTS: As the temperature of the bottom surface increases, the gas temperature increases leading to expansion of the air and increased L_b. To solve Eqs. 1 through 11 requires a potentially tedious trial-and-error solution. The tedium is reduced significantly by using IHT. One approach is to guess values of L_b (or L_t) and solve the equations until $q_b = q_t$. In doing so, one discovers that multiple solutions exist, but the second solution is unrealistic since piston temperatures are outside the range $T_1 > T_p > T_{sur}$.

PROBLEM 13.81

KNOWN: Cylindrical peep-hole of diameter D through a furnace wall of thickness L. Temperatures prescribed for the furnace interior and surroundings outside the furnace.

FIND: Heat loss by radiation through the peep-hole.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Furnace interior and exterior surroundings are large, isothermal surroundings for the peep-hole openings, (3) Furnace refractory wall is adiabatic and diffuse-gray with uniform radiosity.

ANALYSIS: The open-ends of the cylindrical peep-hole (A_1 and A_2) and the cylindrical lateral surface of the refractory material (A_R) form a diffuse-gray, three-surface enclosure. The hypothetical areas A_1 and A_2 behave as black surfaces at the respective temperatures of the large surroundings to which they are exposed. Since A_r is adiabatic, it behaves as a re-radiating surface, and its emissivity has no effect on the analysis. From Eq. 13.30, the net radiation leaving A_1 passes through the enclosure into the outer surroundings.

$$q_1 = -q_2 = \frac{E_{b1} - E_{b2}}{\frac{1-\varepsilon_1}{\varepsilon_1 A_1} + \frac{1}{A_1 F_{12} + \left[\left(1/A_1 F_{1R}\right) + \left(1/A_2 F_{2R}\right)\right]^{-1}} + \frac{1-\varepsilon_2}{\varepsilon_2 A_2}}$$

Since $\varepsilon_1 = \varepsilon_2 = 1$, and with $E_b = \sigma T^4$ where $\sigma = 5.67 \times 10^{-8}$ W/m^2·K^4,

$$q_1 = \left\{A_1 F_{12} + \left[\left(1/A_1 F_{1R}\right) + \left(1/A_2 F_{2R}\right)\right]^{-1}\right\}\sigma\left(T_1^4 - T_2^4\right)$$

where $A_1 = A_2 = \pi D^2/4$. The view factor F_{12} can be determined from Table 13.2 (Fig. 13.5) for the coaxial parallel disks ($R_1 = R_2 = 125/(2 \times 250) = 0.25$ and $S = 17.063$) as

$$F_{12} = 0.05573$$

From the summation rule on A_1, with $F_{11} = 0$,

$$F_{11} + F_{12} + F_{1R} = 1$$

$$F_{1R} = 1 - F_{12} = 1 - 0.05573 = 0.9443$$

and from symmetry of the enclosure,

$$F_{2R} = F_{1R} = 0.9443$$

Substituting numerical values into the rate equation, find the heat loss by radiation through the peep-hole to the exterior surroundings as

$$q_{loss} = q_1 = 1046\ \text{W} \quad <$$

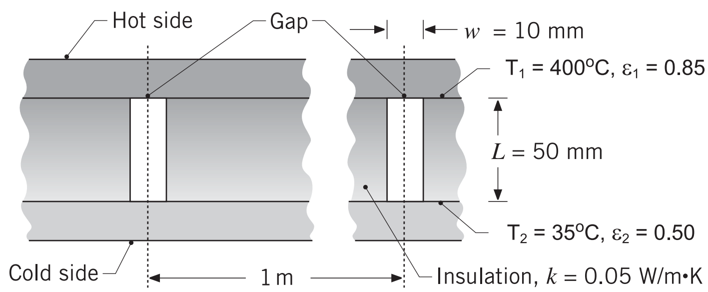
COMMENTS: If you held your hand 50 mm from the exterior opening of the peep-hole, how would that feel? It is standard, safe practice to use optical protection when viewing the interiors of high temperature furnaces as used in petrochemical, metals processing and power generation operations.

PROBLEM 13.82

KNOWN: Composite wall comprised of two large plates separated by sheets of refractory insulation of thermal conductivity k = 0.05 W/m·K; gaps between the sheets of width w = 10 mm, located at 1 - m spacing, allow radiation transfer between the plates.

FIND: (a) Heat loss by radiation through the gap per unit length of the composite wall (normal to the page), and (b) fraction of the total heat loss through the wall that is due to radiation transfer through the gap.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Surfaces are diffuse-gray with uniform radiosities, (3) Refractory insulation surface in the gap is adiabatic, and (4) Heat flow through the wall is one-dimensional between the plates in the direction of the gap centerline, (5) Negligible contact resistance, (6) Negligible free convection in gap.

PROPERTIES: Air (T = 490 K): k = 0.040 W/m·K.

ANALYSIS: (a) The gap of thickness w and infinite extent normal to the page can be represented by a diffuse-gray, three-surface enclosure formed by the plates A_1 and A_2 and the refractory walls, A_R. Since A_R is adiabatic, it behaves as a re-radiating surface, and its emissivity has no effect on the analysis. From Eq. 13.30, the net radiation leaving the plate A_1 passes through the gap into plate A_2.

$$q_1 = -q_2 = \frac{E_{b1} - E_{b2}}{\dfrac{1-\varepsilon_1}{\varepsilon_1 A_1} + \dfrac{1}{A_1 F_{12} + \left[(1/A_1 F_{1R}) + (1/A_2 F_{2R})\right]^{-1}} + \dfrac{1-\varepsilon_2}{\varepsilon_2 A_2}}$$

where $E_b = \sigma T^4$ with $\sigma = 5.67 \times 10^{-8}$ W/m^2·K^4 and $A_1 = A_2 = w \cdot \ell$, but making ℓ = 1 m to obtain $q_1' \,(\mathrm{W/m})$.

The view factor F_{12} can be determined from Table 13.2 (Fig. 13.4) for aligned parallel rectangles where $\overline{X} = X/L = \infty$ since $X \to \infty$ and $\overline{Y} = Y/L = W/L = 10/50 = 0.2$ giving

$$F_{12} = 0.09902$$

From the summation rule on A_1, with $F_{11} = 0$,

$$F_{11} + F_{12} + F_{1R} = 1 \qquad\qquad F_{1R} = 1 - F_{12} = 1 - 0.09902 = 0.901$$

and from symmetry of the enclosure,

Continued …

PROBLEM 13.82 (Cont.)

$$F_{2R} = F_{1R} = 0.901.$$

Substituting numerical values into the rate equation, find the heat loss through the gap due to radiation as

$$q'_{rad} = q'_1 = 37 \text{ W/m}$$ <

(b) The conduction heat rate per unit length (normal to the page) for a 1 - m section is

$$q'_{cond} = q'_{cond,\,ins} + q'_{cond,\,air} = 0.05 \text{ W/m}\cdot\text{K} \times (1 \text{ m} - 0.1\text{m}) \frac{(400-35)\text{K}}{0.050 \text{ mm}}$$

$$+ 0.04\text{W/m}\cdot\text{K} \times 0.01\text{m} \frac{(400-35)\text{K}}{0.050\text{mm}}$$

$$q'_{cond} = 361.4 \text{ W/m} + 2.92 \text{ W/m} = 364 \text{ W/m}$$

The fraction of the total heat transfer through the 1 - m section due to radiation is

$$\frac{q'_{rad}}{q'_{tot}} = \frac{q'_{rad}}{q'_{cond} + q_{rad}} = \frac{37}{364+37} = 9.2\%$$ <

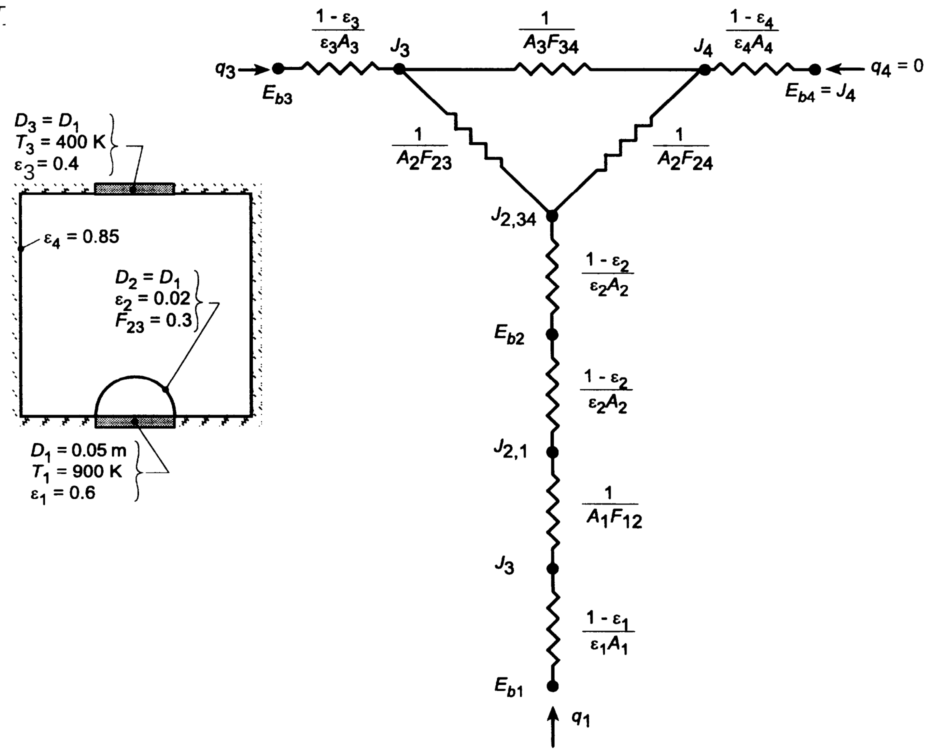
We conclude that if the installation process for the sheet insulation can be accomplished with a smaller gap, there is an opportunity to reduce the cost of operating the furnace.

PROBLEM 13.83

KNOWN: Diameter, temperature and emissivity of a heated disk. Diameter and emissivity of a hemispherical radiation shield. View factor of shield with respect to a coaxial disk of prescribed diameter, emissivity and temperature.

FIND: (a) Equivalent circuit, (b) Net heat rate from the hot disk.

SCHEMATIC:



ASSUMPTIONS: (1) Surfaces may be approximated as diffuse/gray, (2) Surface 4 is reradiating, (3) Negligible convection.

ANALYSIS: (a) The equivalent circuit is shown in the schematic. Since surface 4 is treated as reradiating, the net transfer of radiation from surface 1 is equal to the net transfer of radiation to surface 3 ($q_1 = -q_3$).

(b) From the thermal circuit, the desired heat rate may be expressed as

$$q_1 = \frac{E_{b1} - E_{b3}}{\dfrac{1-\varepsilon_1}{\varepsilon_1 A_1} + \dfrac{1}{A_1 F_{12}} + \dfrac{2(1-\varepsilon_2)}{\varepsilon_2 A_2} + \left[A_2 F_{23} + \dfrac{1}{\dfrac{1}{A_2 F_{24}} + \dfrac{1}{A_3 F_{34}}}\right]^{-1} + \dfrac{1-\varepsilon_1}{\varepsilon_3 A_3}}$$

where $A_1 = A_3 = \pi D_1^2 / 4 = \pi(0.05\text{ m})^2/4 = 1.963 \times 10^{-3}\text{ m}^2$, $A_2 = \pi D_1^2 / 2 = 2A_1 = 3.925 \times 10^{-3}\text{ m}^2$, $F_{12} = 1$, and $F_{24} = 1 - F_{23} = 0.7$. With $F_{34} = 1 - F_{32} = 1 - F_{23}(A_2/A_3) = 1 - 0.3(2) = 0.4$, it follows that

Continued …

PROBLEM 13.83 (Cont.)

$$q_1 = \frac{A_1\sigma\left(T_1^4 - T_3^4\right)}{\frac{1-\varepsilon_1}{\varepsilon_1} + \frac{1}{F_{12}} + \frac{2\left(1-\varepsilon_2\right)}{\varepsilon_2}\frac{A_1}{A_2} + \left[\frac{A_2}{A_1}F_{23} + \frac{1}{\frac{A_1}{A_2F_{24}} + \frac{A_1}{A_3F_{34}}}\right]^{-1} + \frac{1-\varepsilon_3}{\varepsilon_3}}$$

$$q_1 = \frac{A_1\sigma\left(T_1^4 - T_3^4\right)}{0.667 + 1 + 49 + \left[0.6 + \frac{1}{\frac{1}{1.4} + \frac{1}{0.4}}\right]^{-1} + 1.5} = \frac{A_1\sigma\left(T_1^4 - T_3^4\right)}{0.667 + 1 + 49 + 1.098 + 1.5}$$

$$q_1 = 0.0188\left(1.963\times10^{-3}\,\text{m}^2\right)5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left(900^4 - 400^4\right)\text{K}^4$$

$$q_1 = 1.32\,\text{W}$$ <

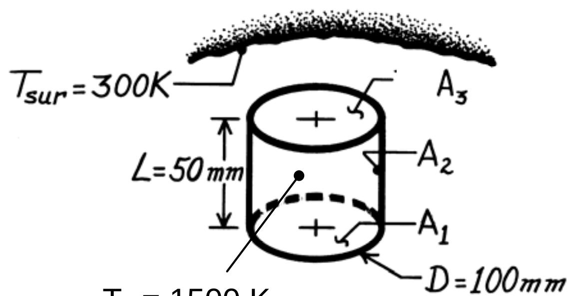
COMMENTS: Radiation transfer from 1 to 3 is impeded and enhanced, respectively, by the radiation shield and the reradiating walls. However, the dominant contribution to the total radiative resistance is made by the shield.

PROBLEM 13.84

KNOWN: Cylindrical cavity with prescribed geometry, wall emissivity, and temperature. Temperature of surroundings.

FIND: (a) Net radiation heat transfer from the cavity treating the bottom and sidewall as one surface. (b) Net radiation heat transfer from the cavity treating the bottom and sidewall as two separate surfaces.

SCHEMATIC:



ASSUMPTIONS: (1) Cavity interior surfaces are diffuse-gray, (2) Surroundings are much larger than the cavity opening A_3.

ANALYSIS: (a) We begin by finding the relevant areas and view factors.

$$A_1 = A_3 = \pi D^2/4 = 7.85\times10^{-3}\,m^2$$

$$A_2 = \pi DL = 1.57\times10^{-2}\,m^2$$

$$A_c = A_1 + A_2 = 2.36\times10^{-2}\,m^2$$

From Table 13.2, Coaxial Parallel Disks, with $r_1/L = 0.050/0.050 = 1$ and $r_3/L = 1$, find

$$F_{13} = F_{31} = 0.382$$

Then, $F_{32} = F_{12} = 1 - F_{13} = 0.618$

$$F_{21} = F_{23} = A_1F_{12}/A_2 = 0.309$$

The shape factor from the combined surfaces 1 and 2 to the surroundings is

$$F_{c-s} = F_{12-3} = A_3F_{3-12}/A_{12} = 7.85\times10^{-3}\,m^2\times1/2.36\times10^{-2}\,m^2 = 0.333$$

The combined surface A_c exchanges radiation with the large surroundings. The net radiation heat transfer from the cavity is given by Eq. 13.23 with A_2 in that equation representing the surroundings, such that $A_2 \to\infty$, and the equation reduces to

$$q_A = \frac{\sigma\left(T_c^4 - T_{sur}^4\right)A_c}{\dfrac{1-\varepsilon_c}{\varepsilon_c} + \dfrac{1}{F_{c-s}}} = \frac{5.67\times10^{-8}\ W/m^2\cdot K^4\left(1500^4 - 300^4\right)K^4\times2.36\times10^{-2}\ m^2}{\dfrac{1-0.6}{0.6} + \dfrac{1}{0.333}}$$

$$q_A = 1842\ W$$ <

(b) Considering surfaces 1 and 2 separately, the heat transfer from the cavity to the surroundings can be found as the heat transfer reaching hypothetical surface 3 (the cavity opening), that is, $q_B = -q_3$, which from Eq. 13.20 is,

$$q_3 = A_3F_{31}\left(J_3 - J_1\right) + A_3F_{32}\left(J_3 - J_2\right). \qquad (1)$$

Continued…

PROBLEM 13.84 (Cont.)

As noted in Example 13.4, openings of enclosures that exchange radiation with large surroundings may be treated as hypothetical, nonreflecting black surfaces ($\varepsilon_3 = 1$) whose temperature is equal to that of the surroundings, $T_3 = T_{sur}$. With $\varepsilon_3 = 1$, $J_3 = E_{b3}$. However, J_1 and J_2 are unknown and must be obtained from the radiation balances, Eq. 13.21,

$$\frac{E_{bi} - J_i}{(1-\varepsilon_i)/\varepsilon_i A_i} = \sum_{j=1}^{N} \frac{J_i - J_i}{\left(A_i F_{ij}\right)^{-1}} \qquad (2)$$

Note also, $E_{b1} = E_{b2} = \sigma T_1^4 = \sigma(1500\text{K})^4 = 287{,}044\ \text{W/m}^2$ and $J_3 = E_{b3} = \sigma T_3^4 = 459.3\ \text{W/m}^2$.

A_1:
$$\frac{E_{b1} - J_1}{(1-\varepsilon_1)/\varepsilon_1 A_1} = \frac{J_1 - J_2}{\left(A_1 F_{12}\right)^{-1}} + \frac{J_1 - J_3}{\left(A_1 F_{13}\right)^{-1}}$$

$$\frac{287{,}044 - J_1}{(1-0.6)/0.6} = \frac{J_1 - J_2}{(0.618)^{-1}} + \frac{J_1 - 459.3}{(0.382)^{-1}} \qquad 2.5J_1 - 0.618J_2 = 430{,}741 \qquad (3)$$

A_2:
$$\frac{E_{b2} - J_2}{(1-\varepsilon_2)/\varepsilon_2 A_2} = \frac{J_2 - J_1}{\left(A_2 F_{21}\right)^{-1}} + \frac{J_2 - J_3}{\left(A_2 F_{23}\right)^{-1}}$$

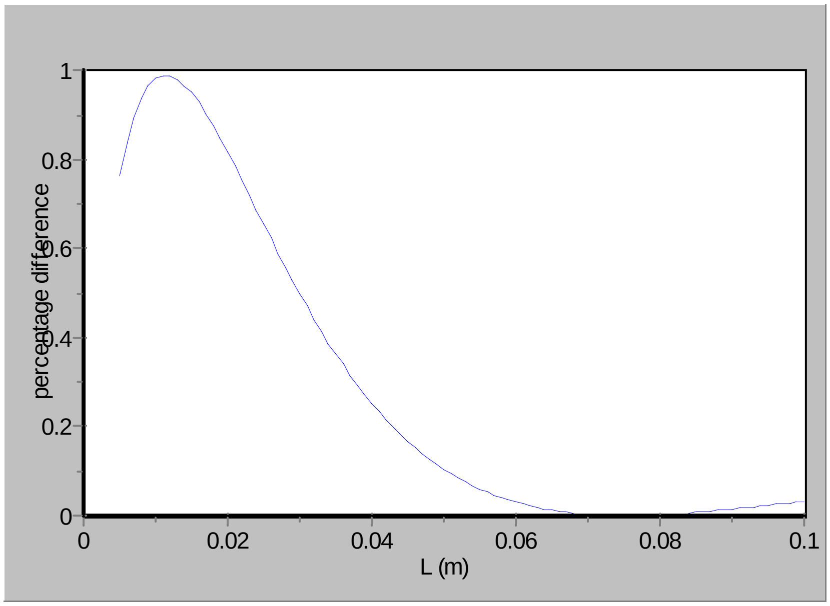
$$\frac{287{,}044 - J_2}{(1-0.6)/0.6} = \frac{J_2 - J_1}{(0.309)^{-1}} + \frac{J_2 - 459.3}{(0.309)^{-1}} \qquad -0.309J_1 + 2.118J_2 = 430{,}708 \qquad (4)$$

Solving Eqs. (3) and (4) simultaneously, find $J_1 = 230{,}491\ \text{W/m}^2$ and $J_2 = 234{,}654\ \text{W/m}^2$, and from Eq. (1), find

$$q_B = 7.854\times10^{-3}\text{m}^2\left[0.382(459.3 - 230{,}491) + 0.618(459.3 - 234{,}654)\right]\text{W/m}^2$$

$$q_B = 1840\ \text{W}$$ <

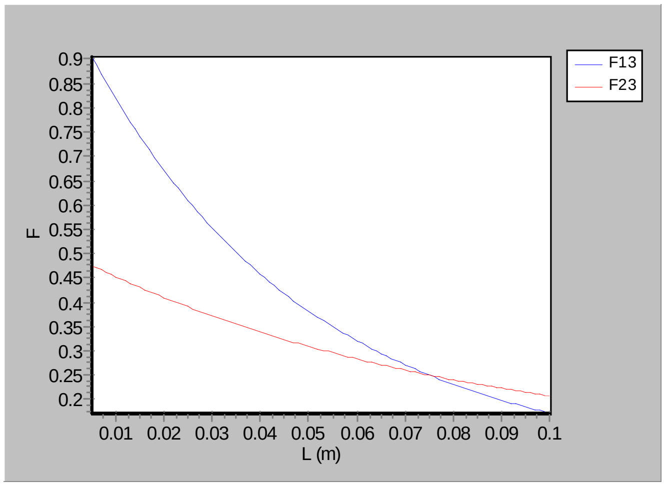
(c) The equations for shape factors were entered into the *IHT* workspace, along with Eqs. (1), (3), and (4). The resulting plot is shown below.

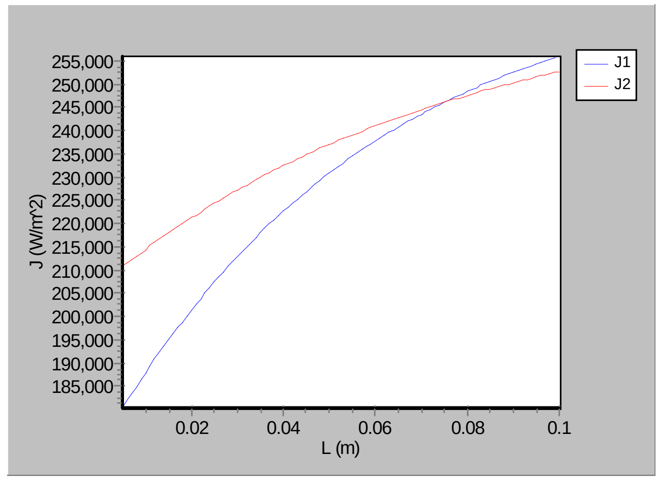


Continued…

PROBLEM 13.84 (Cont.)

COMMENTS: The difference between the two different methods for calculating heat transfer rates is less than 1% over the entire range of *L*. When we treat the sides and bottom as one surface, we are assuming that the radiosity is the same for these two surfaces. This is exactly true when the shape factor between each of those surfaces and the environment is the same, as it is for L around 0.075 m (see below). But from the graphs we see that even when the shape factors and radiosities are not very close for the two surfaces, the net heat transfer rate can still be accurately approximated by treating both surfaces as one.



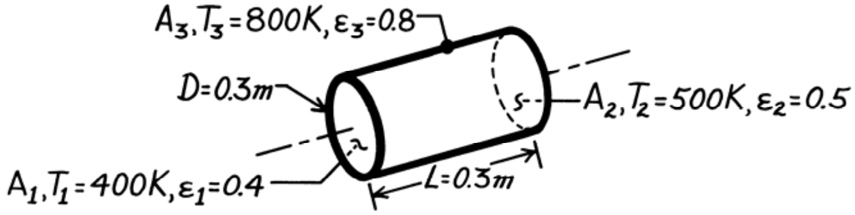


PROBLEM 13.85

KNOWN: Circular furnace with prescribed temperatures and emissivities of the lateral and end surfaces.

FIND: Net radiative heat transfer from each surface.

SCHEMATIC:



ASSUMPTIONS: (1) Surfaces are isothermal and diffuse-gray.

ANALYSIS: To calculate the net radiation heat transfer from each surface, we need to determine its radiosity. First, evaluate terms that will be required.

$$E_{b1} = \sigma T_1^4 = 1452\ \text{W/m}^2 \qquad A_1 = A_2 = \pi D^2/4 = 0.07069\ \text{m}^2 \qquad F_{12} = F_{21} = 0.17$$

$$E_{b2} = \sigma T_2^4 = 3544\ \text{W/m}^2 \qquad A_3 = \pi DL = 0.2827\ \text{m}^2 \qquad F_{23} = F_{13} = 0.83$$

$$E_{b3} = \sigma T_3^4 = 23,224\ \text{W/m}^2$$

The view factor F_{12} results from Fig. 13.5 with $L/r_i = 2$ and $r_j/L = 0.5$. The radiation balances using Eq. 13.21, omitting units for convenience, are:

$$A_1: \quad \frac{1452 - J_1}{\dfrac{(1-0.4)}{0.4\times 0.07069}} = 0.07069\times 0.17(J_1 - J_2) + 0.07069\times 0.83(J_1 - J_3)$$

$$-2.500J_1 + 0.2550J_2 + 1.2450J_3 = -1452 \qquad (1)$$

$$A_2: \quad \frac{3544 - J_2}{\dfrac{(1-0.5)}{0.5\times 0.07069}} = 0.07069\times 0.17(J_2 - J_1) + 0.07069\times 0.83(J_2 - J_3)$$

$$-0.1700J_1 - 2.0000J_2 + 0.8300J_3 = -3544 \qquad (2)$$

$$A_3: \quad \frac{23,224 - J_3}{\dfrac{(1-0.8)}{0.8\times 0.2827}} = 0.07069\times 0.83(J_3 - J_1) + 0.07069\times 0.83(J_3 - J_2)$$

$$0.05189J_1 + 0.05189J_2 - 1.1037J_3 = -23,224 \qquad (3)$$

Solving Eqs. (1) – (3) simultaneously, find

$$J_1 = 12,877\ \text{W/m}^2 \qquad J_2 = 12,086\ \text{W/m}^2 \qquad J_3 = 22,216\ \text{W/m}^2.$$

Using Eq. 13.20, the net radiation heat transfer for each surface follows:

$$q_i = \sum_{j=1}^{N} A_i F_{ij}(J_i - J_j)$$

$$A_1: \ q_1 = 0.07069\times 0.17(12,877 - 12,086)\ \text{W} + 0.07069\times 0.83(12,877 - 22,216)\ \text{W} = -538\ \text{W}$$ <

$$A_2: \ q_2 = 0.07069\times 0.17(12,086 - 12,877)\ \text{W} + 0.07069\times 0.83(12,086 - 22,216)\ \text{W} = -603\ \text{W}$$ <

$$A_3: \ q_3 = 0.07069\times 0.83(22,216 - 12,877)\ \text{W} + 0.07069\times 0.83(22,216 - 12,086)\ \text{W} = 1141\ \text{W}$$ <

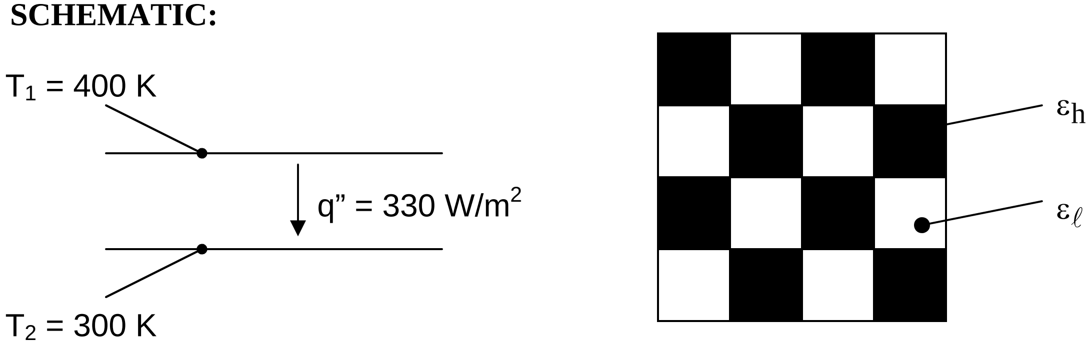
COMMENTS: Note that $\Sigma q_i = 0$. Also, note that $J_2 < J_1$ despite the fact that $T_2 > T_1$; note the role emissivity plays in explaining this.

PROBLEM 13.86

KNOWN: Temperatures of two large parallel plates and desired radiation heat flux between them.

FIND: (a) If plate emissivities are uniform and equal, show that required emissivity is 0.5. (b) If plates are painted with checkerboard patterns having two different emissivities with an average value of 0.5, will heat flux be the desired value?

SCHEMATIC:



ASSUMPTIONS: (1) Surfaces are diffuse, (2) Plates are effectively infinite (no radiation exchange with surroundings), (3) Plate temperatures are uniform.

ANALYSIS: (a) The heat flux between two infinite parallel plates is given by Eq. 13.24. With $\varepsilon_1 = \varepsilon_2 = 0.5$, we find

$$q''_{12} = \frac{\sigma(T_1^4 - T_2^4)}{2/\varepsilon - 1} = \frac{5.67\times10^{-8}\ \mathrm{W/m^2\cdot K^4}(400^4 - 300^4)\mathrm{K}^4}{2/0.5-1} = 331\ \mathrm{W/m^2} \qquad (1)$$

Thus, to a very close approximation, the required emissivity of the plates is 0.5. <

(b) With the checkerboard pattern, we can identify four different surfaces: the high emissivity region on the top surface (1h), the low emissivity region on the top surface (1ℓ), the high emissivity region on the bottom surface (2h), and the low emissivity region on the bottom surface (2ℓ). The view factors can be found by inspection. The view factor between a region on the top plate and a region on the bottom plate is 0.5, that is,

$$F_{1h-2h} = 0.5,\quad F_{1h-2\ell} = 0.5,\quad F_{1\ell-2h} = 0.5,\quad F_{1\ell-2\ell} = 0.5$$
$$F_{2h-1h} = 0.5,\quad F_{2h-1\ell} = 0.5,\quad F_{2\ell-2h} = 0.5,\quad F_{2\ell-2\ell} = 0.5$$

and all other view factors (from a region on one plate to a region on the same plate) are zero. We proceed to write Eq. 13.21 at all four surfaces, recognizing that all regions have the same area,

Continued…

PROBLEM 13.86 (Cont.)

$$\frac{E_{b1} - J_{1h}}{(1-\varepsilon_h)/\varepsilon_h} = \frac{J_{1h} - J_{2h}}{1/0.5} + \frac{J_{1h} - J_{2\ell}}{1/0.5}$$

$$\frac{E_{b1} - J_{1\ell}}{(1-\varepsilon_\ell)/\varepsilon_\ell} = \frac{J_{1\ell} - J_{2h}}{1/0.5} + \frac{J_{1\ell} - J_{2\ell}}{1/0.5}$$

$$\frac{E_{b2} - J_{2h}}{(1-\varepsilon_h)/\varepsilon_h} = \frac{J_{2h} - J_{1h}}{1/0.5} + \frac{J_{2h} - J_{1\ell}}{1/0.5}$$

$$\frac{E_{b2} - J_{2\ell}}{(1-\varepsilon_\ell)/\varepsilon_\ell} = \frac{J_{2\ell} - J_{1h}}{1/0.5} + \frac{J_{2\ell} - J_{1\ell}}{1/0.5}$$

Proceeding with the algebra required to solve these four simultaneous equations results in

$$J_{1h} = \varepsilon_h E_{b1} + \frac{1-\varepsilon_h}{2-\bar{\varepsilon}}\left[E_{b2} + (1-\bar{\varepsilon})E_{b1}\right]$$

$$J_{1\ell} = \varepsilon_\ell E_{b1} + \frac{1-\varepsilon_\ell}{2-\bar{\varepsilon}}\left[E_{b2} + (1-\bar{\varepsilon})E_{b1}\right]$$

$$J_{2h} = \varepsilon_h E_{b2} + \frac{1-\varepsilon_h}{2-\bar{\varepsilon}}\left[E_{b1} + (1-\bar{\varepsilon})E_{b2}\right]$$

$$J_{2\ell} = \varepsilon_\ell E_{b2} + \frac{1-\varepsilon_\ell}{2-\bar{\varepsilon}}\left[E_{b1} + (1-\bar{\varepsilon})E_{b2}\right]$$

where $\bar{\varepsilon} = (\varepsilon_1 + \varepsilon_2)/2$. Then the net radiation heat flux between the two plates can be expressed as, $q''_{net} = (q''_{1h}A_h + q''_{1\ell}A_\ell)/A_{tot} = 0.5(q''_{1h} + q''_{1\ell})$, and making use of Eq. 13.20 for the heat fluxes, we find,

$$q''_{net} = 0.5\left\{\left[0.5(J_{1h} - J_{2h}) + 0.5(J_{1h} - J_{2\ell})\right] + \left[0.5(J_{1\ell} - J_{2h}) + 0.5(J_{1\ell} - J_{2\ell})\right]\right\}$$
$$= 0.5\left[(J_{1h} + J_{1\ell}) - (J_{2h} + J_{2\ell})\right]$$

After much manipulation, this reduces to

$$q''_{net} = \frac{E_{b1} - E_{b2}}{2/\bar{\varepsilon} - 1} \qquad (2)$$

Comparing Eqs. (1) and (2), we see that the checkerboard pattern with an average emissivity $\bar{\varepsilon}$ will result in the same heat flux as uniform emissivity plates with emissivity $\varepsilon = \bar{\varepsilon}$.

With average emissivity of 0.5, the checkerboard pattern will yield the desired heat flux. <

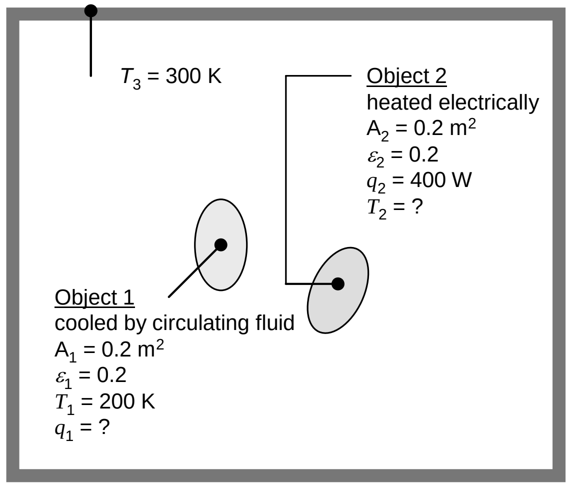
COMMENTS: An alternative to this tedious algebraic proof would be to use *IHT* to solve the four surface enclosure problem and show numerically that average emissivities of 0.5 yield the desired heat flux.

PROBLEM 13.87

KNOWN: Temperature of large enclosure. Areas and emissivity of two convex objects in enclosure, and view factor between them. Power supplied to object 2. Temperature of object 1.

FIND: Heating or cooling rate for object 1. Temperature of object 2.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Objects are gray and diffuse, (3) Large enclosure behaves as blackbody, (4) Each surface experiences uniform irradiation and radiosity.

ANALYSIS: We are given F_{12} = 0.2. Since object 1 is convex, it does not see itself, and $F_{13} = 1 - F_{12}$ = 0.8. The areas of the two objects are the same, therefore from reciprocity $F_{21} = F_{12}$ = 0.2. Finally, since object 2 is convex, $F_{23} = 1 - F_{21}$ = 0.8.

The enclosure is assumed to be large enough to behave as a blackbody, therefore:

$$J_3 = E_{b3} = \sigma T_3^4 = 5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4 \times 300^4\ \text{K}^4 = 459.3\ \text{W/m}^2$$

Equation 13.21 can be written at surface 1 where the temperature is known:

$$\frac{E_{b1} - J_1}{(1-\varepsilon_1)/\varepsilon_1 A_1} = \frac{J_1 - J_2}{1/A_1F_{12}} + \frac{J_1 - J_3}{1/A_1F_{13}} \quad (1)$$

The power is known at surface 2, q_2 = 400 W, so we write Equation 13.22:

$$q_2 = \frac{J_2 - J_1}{1/A_2F_{21}} + \frac{J_2 - J_3}{1/A_2F_{23}} \quad (2)$$

Substituting values into Eqs. (1) and (2) gives

$$0.05\ \text{m}^2(E_{b1} - J_1) = 0.04\ \text{m}^2(J_1 - J_2) + 0.16\ \text{m}^2(J_1 - J_3)$$
$$400\ \text{W} = 0.04\ \text{m}^2(J_2 - J_1) + 0.16\ \text{m}^2(J_2 - J_3)$$

where $E_{b1} = \sigma T_1^4 = 5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4 \times 200^4\ \text{K}^4 = 90.72\ \text{W/m}^2$ and J_3 is given above. Solving these two simultaneous equations yields

Continued...

PROBLEM 13.87 (Cont.)

$$J_1 = 713.7 \text{ W/m}^2,\ J_2 = 2510 \text{ W/m}^2$$

The net rate of radiation leaving object 1 is given by Equation 13.19:

$$q_1 = \frac{E_{b1} - J_1}{(1-\varepsilon_1)/\varepsilon_1 A_1} = 0.05 \text{ m}^2(90.72 \text{ W/m}^2 - 713.7 \text{ W/m}^2) = -31.1 \text{ W}$$ <

There is a net rate of radiation heat transfer *to* object 1 of 31.1 W, which must be *removed* from object 1 by the coolant. <

The temperature of object 2 can be found by solving Equation 13.19 for E_{b2}:

$$E_{b2} = J_2 + q_2 \frac{1-\varepsilon_2}{\varepsilon_2 A_2} = 2510 \text{ W/m}^2 + 400 \text{ W} \frac{1-0.2}{0.2 \times 0.2 \text{ m}^2} = 10{,}510 \text{ W/m}^2$$

Then with $E_{b2} = \sigma T_2^4$ we find T_2 = 656 K. <

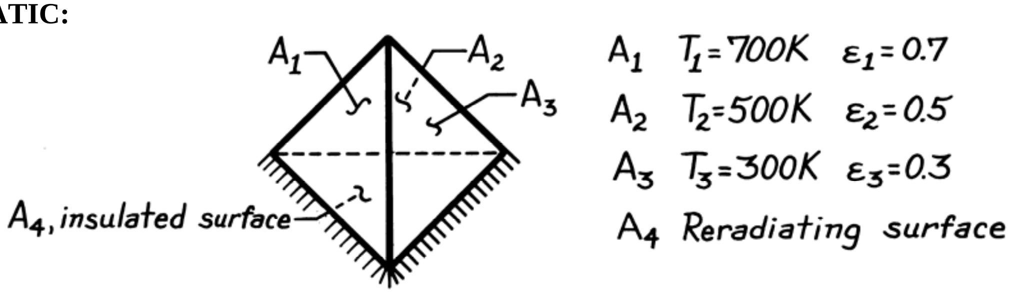
COMMENTS: (1) If the objects were concave, additional information would have to be known about their shapes in order to determine the appropriate view factors. (2) The objects would clearly experience non-uniform irradiation and radiosity. A more detailed analysis would need to be performed in order to determine whether the non-uniform radiation fluxes would affect the answers. As for concave objects, a more detailed analysis of the convex objects would necessitate information regarding the shape of the objects. (3) The coolant must have a freezing point less than 200 K.

PROBLEM 13.88

KNOWN: Four surface enclosure with all sides of equal area; temperatures of three surfaces are specified while the fourth is re-radiating.

FIND: Temperature of the re-radiating surface A_4.

SCHEMATIC:



ASSUMPTIONS: (1) Surfaces are diffuse-gray, (2) Surfaces have uniform radiosities.

ANALYSIS: To determine the temperature of the re-radiating surface A_4, it is necessary to recognize that $J_4 = E_{b4} = \sigma T_4^4$ and that the J_i (i = 1 to 4) values must be evaluated by simultaneously solving four radiation balances of the form, Eq. 13.21,

$$\frac{E_{bi} - J_i}{(1-\varepsilon_i)/\varepsilon_i A_i} = \sum_{j=1}^{N} \frac{J_i - J_j}{(A_i F_{ij})^{-1}}$$

For simplicity, set $A_1 = A_2 = A_3 = A_4 = 1\ m^2$ and from symmetry, it follows that all view factors will be $F_{ij} = 1/3$. The necessary emissive powers are of the form $E_{bi} = \sigma T_1^4$.

$E_{b1} = \sigma(700\ K)^4 = 13{,}614\ W/m^2$, $E_{b2} = \sigma(500\ K)^4 = 3544\ W/m^2$, $E_{b3} = \sigma(300\ K)^4 = 459\ W/m^2$.

The radiation balances are:

A_1: $\frac{13,614 - J_1}{(1-0.7)/0.7} = \frac{1}{3}(J_1 - J_2) + \frac{1}{3}(J_1 - J_3) + \frac{1}{3}(J_1 - J_4)$; $-1.42857J_1 + 0.14826J_2 + 0.14826J_3 + 0.14826J_4 = -13,614$

A_2: $\frac{3544 - J_2}{(1-0.5)/0.5} = \frac{1}{3}(J_2 - J_1) + \frac{1}{3}(J_2 - J_3) + \frac{1}{3}(J_2 - J_4)$ $0.33333J_1 - 2.00000J_2 + 0.33333J_3 + 0.33333J_4 = -3544$

A_3: $\frac{459 - J_3}{(1-0.3)/0.3} = \frac{1}{3}(J_3 - J_1) + \frac{1}{3}(J_3 - J_2) + \frac{1}{3}(J_3 - J_4)$ $0.77778J_1 + 0.77778J_2 - 3.33333J_3 + 0.77778J_4 = -459$

A_4: $0 = \frac{1}{3}(J_4 - J_1) + \frac{1}{3}(J_4 - J_2) + \frac{1}{3}(J_4 - J_3)$ $0.33333J_1 + 0.33333J_2 + 0.33333J_3 - 1.00000J_4 = 0$

Solving this system of equations simultaneously, find

$J_1 = 11{,}572\ W/m^2$, $J_2 = 6031\ W/m^2$, $J_3 = 6088\ W/m^2$, $J_4 = 7897\ W/m^2$.

Since the radiosity and emissive power of the re-radiating surface are equal,

$$T_4^4 = J_4/\sigma$$

$$T_4 = \left(7897\ W/m^2 / 5.67\times10^{-8}\ W/m^2\cdot K^4\right)^{1/4} = 611\ K. \quad <$$

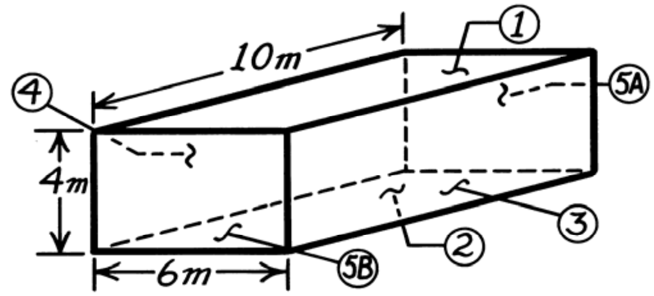
COMMENTS: Note the values of the radiosities; are their relative values what you would have expected? Is the value of T_4 reasonable?

PROBLEM 13.89

KNOWN: A room with electrical heaters embedded in ceiling and floor; one wall is exposed to the outdoor environment while the other three walls are to be considered as insulated.

FIND: Net radiation heat transfer from each surface.

SCHEMATIC:



ASSUMPTIONS: (1) Diffuse-gray surfaces, (2) Surfaces are isothermal and irradiated uniformly, (3) Negligible convection effects, (4) $A_5 = A_{5A} + A_{5B}$.

ANALYSIS: To determine the net radiation heat transfer from each surface, find the surface radiosities using Eq. 13.20.

$$q_i = \sum_{j=1}^{5} A_i F_{ij}\left(J_i - J_j\right) \tag{1}$$

To determine the value of J_i, energy balances must be written for each of the five surfaces. For surfaces 1, 2, and 3, the form is given by Eq. 13.21.

$$\frac{E_{bi} - J_i}{\left(1-\varepsilon_i\right)/\varepsilon_i A_i} = \sum_{j=1}^{5} \frac{J_i - J_j}{\left(A_i F_{ij}\right)^{-1}} \qquad i = 1, 2, \text{ and } 3. \tag{2}$$

For the insulated or adiabatic surfaces, Eq. 13.22 is appropriate with $q_i = 0$; that is

$$q_i = \sum_{j=1}^{N} \frac{J_i - J_j}{\left(A_i F_{ij}\right)^{-1}} = 0 \qquad i = 4 \text{ and } 5. \tag{3}$$

In order to write the energy balances by Eq. (2) and (3), we will need to know view factors. Using Fig. 13.4 (parallel rectangles) or Fig. 13.5 (perpendicular rectangles) find:

$F_{12} = F_{21} = 0.39$ $\quad X/L = 10/4 = 2.5,$ $\quad Y/L = 6/4 = 1.5$

$F_{13} = F_{14} = 0.19$ $\quad Z/X = 4/10 = 0.4,$ $\quad Y/X = 6/10 = 0.6$

$F_{34} = F_{43} = 0.19$ $\quad X/L = 10/6 = 1.66,$ $\quad Y/L = 4/6 = 0.67$

$F_{24} = F_{13} = 0.19$ $\quad Z/X = 4/10 = 0.4,$ $\quad Y/X = 6/10 = 0.6$

Note the use of symmetry in the above relations. Using reciprocity, find,

$$F_{32} = \frac{A_2}{A_3} F_{23} = \frac{A_2}{A_3} F_{13} = \frac{60}{40} \times 0.19 = 0.285; \qquad F_{31} = \frac{A_1}{A_3} F_{13} = \frac{60}{40} \times 0.19 = 0.285$$

$$F_{51} = \frac{A_1}{A_5} F_{15} = \frac{60}{48} \times 0.23 = 0.288; \qquad F_{53} = \frac{A_3}{A_5} F_{35} = \frac{40}{48} \times 0.25 = 0.208.$$

From the summation view factor relation,

$$F_{15} = 1 - F_{12} - F_{13} - F_{14} = 1 - 0.39 - 0.19 - 0.19 = 0.23$$

$$F_{35} = 1 - F_{31} - F_{32} - F_{34} = 1 - 0.285 - 0.285 - 0.19 = 0.24$$

Continued …

PROBLEM 13.89 (Cont.)

Using Eq. (2), now write the energy balances for surfaces 1, 2, and 3. (Note $E_b = \sigma T^4$).

$$\frac{544.2 - J_1}{1-0.8/0.8\times 60} = \frac{J_1 - J_2}{1/60\times 0.39} + \frac{J_1 - J_3}{1/60\times 0.19} + \frac{J_1 - J_4}{1/60\times 0.19} + \frac{J_1 - J_5}{1/60\times 0.23}$$

$$-1.2500J_1 + 0.0975J_2 + 0.0475J_3 + 0.570J_5 = -544.2 \quad (4)$$

$$\frac{617.2 - J_2}{1-0.9/0.9\times 60} = \frac{J_2 - J_1}{1/60\times 0.39} + \frac{J_2 - J_3}{1/60\times 0.19} + \frac{J_2 - J_4}{1/60\times 0.19} + \frac{J_2 - J_5}{1/60\times 0.23}$$

$$+0.0433J_1 - 1.111J_2 + 0.02111J_3 + 0.02111J_4 + 0.02556J_5 = -617.2 \quad (5)$$

$$\frac{390.1 - J_3}{1-0.7/0.7\times 40} = \frac{J_3 - J_1}{1/40\times 0.285} + \frac{J_3 - J_2}{1/40\times 0.285} + \frac{J_3 - J_4}{1/40\times 0.19} + \frac{J_3 - J_5}{1/40\times 0.24}$$

$$+0.1221J_1 + 0.1221J_2 - 1.4284J_3 + 0.08143J_4 + 0.1028J_5 = -390.1 \quad (6)$$

Using Eq. (3), now write the energy balances for surfaces 4 and 5 noting $q_4 = q_5 = 0$.

$$0 = \frac{J_4 - J_1}{1/40\times 0.285} + \frac{J_4 - J_2}{1/40\times 0.285} + \frac{J_4 - J_3}{1/40\times 0.19} + \frac{J_4 - J_5}{1/40\times 0.24}$$

$$0.285J_1 + 0.285J_2 + 0.19J_3 - 1.0J_4 + 0.24J_5 = 0 \quad (7)$$

$$0 = \frac{J_5 - J_1}{1/48\times 0.288} + \frac{J_5 - J_2}{1/48\times 0.288} + \frac{J_5 - J_3}{1/48\times 0.208} + \frac{J_5 - J_4}{1/48\times 0.208}$$

$$0.288J_1 + 0.288J_2 + 0.208J_3 + 0.208J_4 - 0.992J_5 = 0 \quad (8)$$

Note that Eqs. (4) – (8) represent a set of simultaneous equations which can be written in matrix notation. That is, [A] [J] = [C] with

$$A = \begin{bmatrix} -1.250 & 0.0975 & 0.0475 & 0.0475 & 0.0575 \\ 0.0433 & -1.111 & 0.02111 & 0.02111 & 0.02556 \\ 0.1221 & 0.1221 & -1.4284 & 0.08143 & 0.1028 \\ 0.285 & 0.285 & 0.190 & -1.000 & 0.240 \\ 0.288 & 0.288 & 0.208 & 0.208 & -0.992 \end{bmatrix} \qquad C = \begin{bmatrix} -544.2 \\ -617.2 \\ -390.1 \\ 0 \\ 0 \end{bmatrix} \quad J = \begin{bmatrix} 545.1 \\ 607.9 \\ 441.5 \\ 542.3 \\ 5410 \end{bmatrix} \quad W/m^2$$

where the J_i were found using IHT. The net radiation heat transfer from each of the surfaces can now be evaluated using Eq. (1).

$$q_1 = A_1F_{12}(J_1 - J_2) + A_1F_{13}(J_1 - J_3) + A_1F_{14}(J_1 - J_4) + A_1F_{15}(J_1 - J_5)$$

$$q_1 = 60\ m^2[0.39(545.1 - 607.9)$$

$$+0.19(545.1 - 441.5) + 0.19(545.1 - 542.3) + 0.23(545.1 - 541.0)]\ W/m^2 = -200\ W$$ <

$$q_2 = 60\ m^2[0.39(607.9 - 545.1)$$

$$+0.19(607.9 - 441.5) + 0.19(607.9 - 542.3) + 0.23(607.9 - 541.0)\ W/m^2 = 5037\ W$$ <

$$q_3 = 40\ m^2[0.285(441.5 - 545.1) + 0.285(441.5 - 607.9)$$

$$+0.19(441.5 - 542.3) + 0.24(441.5 - 541.0)]\ W/m^2 = -4{,}799\ W$$ <

Since A_4 and A_5 are insulated (adiabatic), $q_4 = q_5 = 0$. <

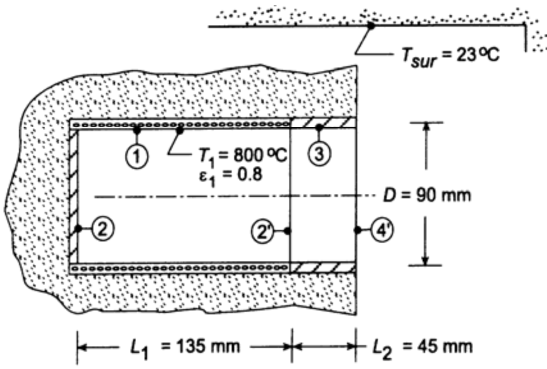
COMMENTS: (1) Note that the sum of $q_1 + q_2 + q_3 = +38$ W; this indicates a precision of less than 1% resulted from the solution of the equations. (2) The net radiation for the ceiling, A_1, is into the surface. Recognize that the embedded heaters function to offset heat losses to the room air by convection.

PROBLEM 13.90

KNOWN: Cylindrical furnace of diameter D = 90 mm and overall length L = 180 mm. Heating elements maintain the refractory liming (ε = 0.8) of section (1), L_1 = 135 mm, at T_1 = 800°C. The bottom (2) and upper (3) sections are refractory lined, but are insulated. Furnace operates in a spacecraft environment.

FIND: Power required to maintain the furnace operating conditions with the surroundings at 23°C.

SCHEMATIC:



ASSUMPTIONS: (1) All surfaces are diffuse gray, (2) Uniform radiosity over the sections 1, 2, and 3, and (3) Negligible convection effects.

ANALYSIS: By defining the furnace opening as the hypothetical area A_4, the furnace can be represented as a four-surface enclosure as illustrated above. The power required to maintain A_1 at T_1 is q_1, the net radiation leaving A_1. To obtain q_1 following the methodology of Section 13.3.2, we must determine the radiosity at all surfaces by simultaneously solving the radiation energy balance equations for each surface which will be of the form, Eqs. 13.20 or 13.21.

$$q_1 = \frac{E_{bi} - J_i}{(1-\varepsilon_i)/\varepsilon_i A_i} = \sum_{j=1}^{N} \frac{J_j - J_j}{1/A_i F_{ij}} \qquad (1,2)$$

Since $\varepsilon_4 = 1$, $J_4 = E_{b4}$, so we only need to perform three energy balances, for A_1, A_2, and A_3, respectively

A_1: $$\frac{E_{b1} - J_1}{(1-\varepsilon_1)/\varepsilon_1 A_1} = \frac{J_1 - J_2}{1/A_1 F_{12}} + \frac{J_1 - J_3}{1/A_1 F_{13}} + \frac{J_1 - J_4}{1/A_1 F_{14}} \qquad (3)$$

A_2: $$0 = \frac{J_2 - J_1}{1/A_2 F_{21}} + \frac{J_2 - J_3}{1/A_2 F_{23}} + \frac{J_2 - J_4}{1/A_2 F_{24}} \qquad (4)$$

A_3: $$0 = \frac{J_3 - J_1}{1/A_3 F_{31}} + \frac{J_3 - J_2}{1/A_3 F_{32}} + \frac{J_3 - J_4}{1/A_3 F_{34}} \qquad (5)$$

Note that $q_2 = q_3 = 0$ since the surfaces are insulated (adiabatic). Recognize that in the above equation set, there are three equations and three unknowns: J_1, J_2, and J_3. From knowledge of J_1, q_1 can be determined using Eq. (1). Next we need to evaluate the view factors. There are $N^2 = 4^2 = 16$ view factors and $N(N-1)/2 = 6$ must be independently evaluated, while the remaining can be determined by the summation rule and appropriate reciprocity relations. The six independently determined F_{ij} are:

By inspection: (1) $F_{22} = 0$ (2) $F_{44} = 0$

Coaxial parallel disks: From Fig. 13.5 or Table 13.5,

Continued …

PROBLEM 13.90 (Cont.)

$$F_{24} = 0.5\left\{S - \left[S^2 - 4(r_4/r_2)^2\right]^{1/2}\right\}$$

(3) $$F_{24} = 0.5\left\{18 - \left[18^2 - 4(1)^2\right]^{1/2}\right\} = 0.05573$$

$$S = 1 + \frac{1 + R_4^2}{R_2^2} = 1 + \frac{1 + 0.250^2}{0.250^2} = 18.00 \qquad R_2 = r_2/L = 45/180 = 0.250 \qquad R_4 = r_4/L = 0.250$$

Enclosure 1-2-2′: from the summation rule for A_2,

(4) $F_{21} = 1 - F_{22'} = 1 - 0.09167 = 0.9083$

where $F_{22'}$ can be evaluated from the coaxial parallel disk relation, Table 13.5. For these surfaces, $R_2 = r_2/L_1 = 45/135 = 0.333$, $R_{2'} = r_2/L_1 = 0.333$, and S = 11.00. From the summation rule for A_1,

(5) $F_{11} = 1 - F_{12} - F_{12'} = 1 - 0.1514 - 0.1514 = 0.6972$

and by symmetry $F_{12} = F_{12'}$ and using reciprocity

$$F_{12} = A_2F_{21}/A_1 = \left[\pi(0.090\text{m})(2/4)\right] \times 0.9083/\pi \times 0.090\text{m} \times 0.135\text{m} = 0.1514$$

Enclosure 2′-3-4: from the summation rule for A_4,

(6) $F_{43} = 1 - F_{42'} - F_{44} = 1 - 0.3820 - 0 = 0.6180$

where $F_{44} = 0$ and using the coaxial parallel disk relation from Table 13.5, with $R_4 = r_4/L_2 = 45/45 = 1$, $R_{2'} = r_2/L_2 = 1$, and S = 3.

The View Factors: Using summation rules and appropriate reciprocity relations, the remaining 10 view factors can be evaluated. Written in matrix form, the F_{ij} are

0.6972*	0.1514	0.09704	0.05438
0.9083*	0*	0.03597	0.05573*
0.2911	0.01798	0.3819	0.3090
0.3262	0.05573	0.6180*	0*

The F_{ij} shown with an asterisk were independently determined.

From knowledge of the relevant view factors, the energy balances, Eqs. (3, 4, 5), can be solved simultaneously to obtain the radiosities,

$$J_1 = 73{,}084\ \text{W/m}^2 \qquad J_2 = 67{,}723\ \text{W/m}^2 \qquad J_3 = 36{,}609\ \text{W/m}^2$$

The net heat rate leaving A_1 can be evaluated using Eq. (1) written as

$$q_1 = \frac{E_{b1} - J_1}{(1-\varepsilon_1)/\varepsilon_1 A_1} = \frac{(75{,}159 - 73{,}084)\ \text{W/m}^2}{(1-0.8)/0.8 \times 0.03817\ \text{m}^2} = 317\ \text{W}$$ <

where $E_{b1} = \sigma T_1^4 = \sigma(800 + 273\text{K})^4 = 75{,}159\ \text{W/m}^2$ and $A_1 = \pi DL_1 = \pi \times 0.090\text{m} \times 0.135\text{m} = 0.03817\ \text{m}^2$.

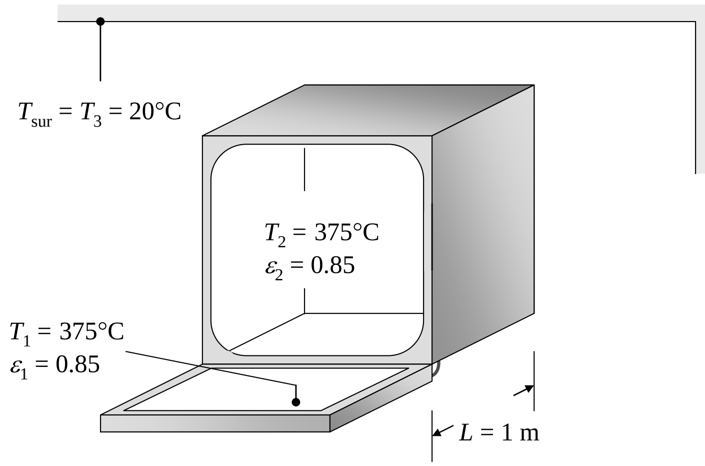
COMMENTS: (1) Recognize the importance of defining the furnace opening as the hypothetical area A_4 which completes the four-surface enclosure representing the furnace. The temperature of A_4 is that of the surroundings and its emissivity is unity since it absorbs all radiation incident on it. (2) To obtain the view factor matrix, we used the *IHT Tool, Radiation, View Factor Relations,* which permits you to specify the independently determined F_{ij} and the tool will calculate the remaining ones.

PROBLEM 13.91

KNOWN: Dimensions of furnace. Emissivity of surfaces. Temperatures of furnace walls and surroundings.

FIND: Rate of radiation heat transfer to surroundings.

SCHEMATIC:



ASSUMPTIONS: (1) Surfaces are gray and diffuse, (2) Surroundings behave as blackbody, (3) Outer surface of furnace is adiabatic, (4) Each identified surface has uniform irradiation and radiosity.

ANALYSIS: The surrounding room is assumed to be large enough to behave as a blackbody, therefore:

$$J_3 = E_{b3} = \sigma T_3^4 = 5.67 \times 10^{-8} \text{ W/m}^2 \cdot \text{K}^4 \times (20 + 273)^4 \text{ K}^4 = 417.9 \text{ W/m}^2$$

The temperature of the oven surfaces is known, therefore we can write Equation 13.21 for surfaces 1 and 2.

$$\frac{E_{b1} - J_1}{(1-\varepsilon_1)/\varepsilon_1 A_1} = \frac{J_1 - J_2}{1/A_1 F_{12}} + \frac{J_1 - J_3}{1/A_1 F_{13}} \qquad (1)$$

$$\frac{E_{b2} - J_2}{(1-\varepsilon_2)/\varepsilon_2 A_2} = \frac{J_2 - J_1}{1/A_2 F_{21}} + \frac{J_2 - J_3}{1/A_2 F_{23}} \qquad (2)$$

The view factor from the oven door (1) to the interior walls of the furnace (2) is the same as from the oven door to the furnace opening. From Table 13.2, 3rd entry, with $X = Y = Z = 1$ m, we find $H = W = 1$ and $F_{12} = 0.2$. Then $F_{13} = 1 - F_{12} = 0.8$. From reciprocity, $F_{21} = A_1F_{12}/A_2 = F_{12}/5 = 0.04$.

The view factor from the interior of the furnace (2) to the surroundings (3) can be found from the following reasoning. The radiation which leaves the interior and reaches either the oven door or the surroundings must have passed through the opening, so it will be useful to know the view factor F_{2o}, where subscript o represents the opening. We know that $F_{o2} = 1$, therefore from reciprocity, $F_{2o} = A_oF_{o2}/A_2 = 1/5 = 0.2$. The radiation that leaves through the opening must go either to the oven door or the surroundings, therefore $F_{2o} = F_{21} + F_{23}$. Finally then, $F_{23} = F_{2o} - F_{21} = 0.16$. Substituting numbers into Eqs. (1) and (2) gives

Continued…

PROBLEM 13.91 (Cont.)

$$5.67\ \text{m}^2(E_{b1} - J_1) = 0.2\ \text{m}^2(J_1 - J_2) + 0.8\ \text{m}^2(J_1 - 417.9\ \text{W/m}^2)$$
$$28.3\ \text{m}^2(E_{b2} - J_2) = 0.2\ \text{m}^2(J_2 - J_1) + 0.8\ \text{m}^2(J_2 - 417.9\ \text{W/m}^2)$$

where $E_{b1} = E_{b2} = \sigma T_1^4 = 5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4 \times (375+273)^4\ \text{K}^4 = 9997\ \text{W/m}^2$. Solving these two simultaneous equations yields

$$J_1 = 8840\ \text{W/m}^2,\ J_2 = 9728\ \text{W/m}^2$$

Then the radiation heat transfer to the room can be found by summing the contributions from surfaces 1 and 2:

$$q_{\text{room}} = -q_3 = A_1F_{13}(J_1 - J_3) + A_2F_{23}(J_2 - J_3)$$
$$= 0.8\ \text{m}^2(8840\ \text{W/m}^2 - 417.9\ \text{W/m}^2) + 0.8\ \text{m}^2(9728\ \text{W/m}^2 - 417.9\ \text{W/m}^2) = 1.42\times10^4\ \text{W}$$ <

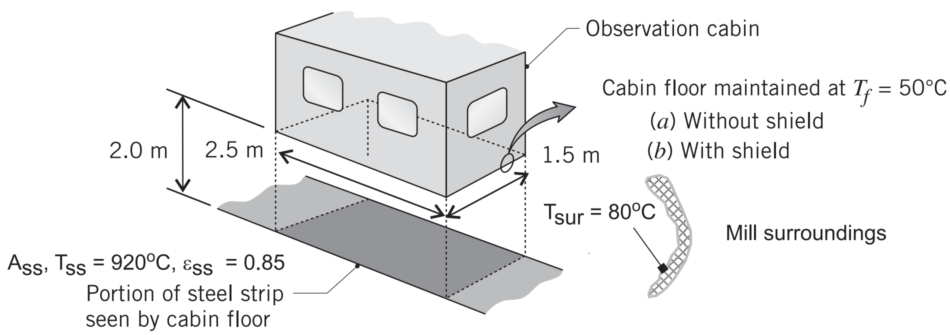
COMMENTS: Subdividing the surfaces into smaller regions in order to more closely satisfy the assumption of uniform irradiation and radiosity would provide a more accurate answer.

PROBLEM 13.92

KNOWN: Observation cabin located in a hot-strip mill directly over the line; cabin floor (f) exposed to steel strip (ss) at T_{ss} = 920°C and to mill surroundings at T_{sur} = 80°C.

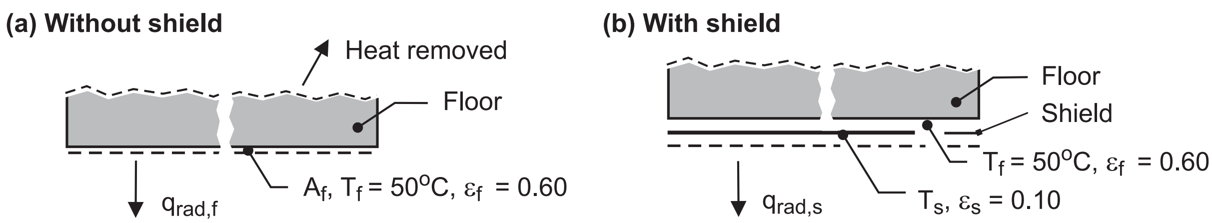
FIND: Coolant system heat removal rate required to maintain the cabin floor at T_f = 50°C for the following conditions: (a) when the floor is directly exposed to the steel strip and (b) when a radiation shield (s) ε_s = 0.10 is installed between the floor and the strip.

SCHEMATIC:



ASSUMPTIONS: (1) Cabin floor (f) or shield (s), steel strip (ss), and mill surroundings (sur) form a three-surface, diffuse-gray enclosure, (2) Surfaces with uniform radiosities, (3) Mill surroundings are isothermal, black, (4) Floor-shield configuration treated as infinite parallel planes, and (5) Negligible convection heat transfer to the cabin floor.

ANALYSIS: A gray-diffuse, three-surface enclosure is formed by the cabin floor (f) (or radiation shield, s), steel strip (ss), and the mill surroundings (sur). The heat removal rate required to maintain the cabin floor at T_f = 50°C is equal to - q_f (or, -q_s), where q_f or q_s is the net radiation leaving the floor or shield. The schematic below represents the details of the surface energy balance on the floor and shield for the conditions *without the shield* (floor exposed) and *with the shield* (floor shielded from strip).



(a) *Without the shield*. Radiation surface energy balances, Eq. 13.21, are written for the floor (f) and steel strip (ss) surfaces to determine their radiosities.

$$\frac{E_{b,f} - J_f}{(1-\varepsilon_f)/\varepsilon_f A_f} = \frac{J_f - J_{ss}}{1/A_f F_{f-ss}} + \frac{J_f - E_{b,sur}}{1/A_f F_{f-sur}} \tag{1}$$

$$\frac{E_{b,ss} - J_{ss}}{(1-\varepsilon_{ss})/\varepsilon_{ss} A_{ss}} = \frac{J_{ss} - J_f}{1/A_{ss} F_{ss-f}} + \frac{J_{ss} - E_{b,sur}}{1/A_{ss} F_{ss\text{-}sur}} \tag{2}$$

Since the surroundings (sur) are black, $J_{sur} = E_{b,sur}$. The blackbody emissive powers are expressed as $E_b = \sigma T^4$ where $\sigma = 5.67 \times 10^{-8}$ W/m^2·K^4. The net radiation leaving the floor, Eq. 13.20, is

$$q_f = A_f F_{f-ss}(J_f - J_{ss}) + A_f F_{f-sur}(J_f - E_{b,sur}) \tag{3}$$

Continued …

PROBLEM 13.92 (Cont.)

The required view factors for the analysis are contained in the summation rule for the areas A_f and A_{ss},

$$F_{f-ss} + F_{f-sur} = 1 \qquad\qquad F_{ss-f} + F_{ss-sur} = 1 \tag{4,5}$$

F_{f-ss} can be evaluated from Fig. 13.4 (Table 13.2) for the aligned parallel rectangles geometry. By symmetry, $F_{ss-f} = F_{f-ss}$, and with the summation rule, all the view factors are determined. Using the foregoing relations in the *IHT* workspace, the following results were obtained:

$$F_{f-ss} = 0.1864 \qquad\qquad J_f = 7959\ \text{W/m}^2$$

$$F_{f-sur} = 0.8136 \qquad\qquad J_{ss} = 97.96\ \text{kW/m}^2$$

and the heat removal rate required of the coolant system (cs) is

$$q_{cs} = -q_f = 41.3\ \text{kW}$$ <

(b) *With the shield*. Radiation surface energy balances are written for the shield (s) and steel strip (ss) to determine their radiosities.

$$\frac{E_{b,s} - J_s}{(1-\varepsilon_s)/\varepsilon_s A_s} = \frac{J_s - J_{ss}}{1/A_s F_{s-ss}} + \frac{J_s - E_{b,sur}}{1/A_s F_{s-sur}} \tag{6}$$

$$\frac{E_{b,ss} - J_{ss}}{(1-\varepsilon_{ss})/\varepsilon_{ss} A_{ss}} = \frac{J_{ss} - J_s}{1/A_{ss} F_{ss-s}} + \frac{J_{ss} - E_{b,sur}}{1/A_{ss} F_{ss-sur}} \tag{7}$$

The net radiation leaving the shield is

$$q_s = A_{ss} F_{ss-s}\left(J_{ss} - J_s\right) + A_{ss} F_{ss-sur}\left(J_{ss} - E_{b,sur}\right) \tag{8}$$

Since the temperature of the shield is unknown, an additional relation is required. The heat transfer from the shield (s) to the floor (f) - the coolant heat removal rate - is

$$-q_s = \frac{\sigma\left(T_s^4 - T_f^4\right)A_s}{1 - 1/\varepsilon_s - 1/\varepsilon_f} \tag{9}$$

where the floor-shield configuration is that of infinite parallel planes, Eq. 13.24. Using the foregoing relations in the *IHT* workspace, with appropriate view factors from part (a), the following results were obtained

$$J_s = 18.13\ \text{kW/m}^2 \qquad J_{ss} = 98.20\ \text{kW/m}^2 \qquad T_s = 377^\circ\text{C}$$

and the heat removal rate required of the coolant system is

$$q_{cs} = -q_s = 6.55\ \text{kW}$$ <

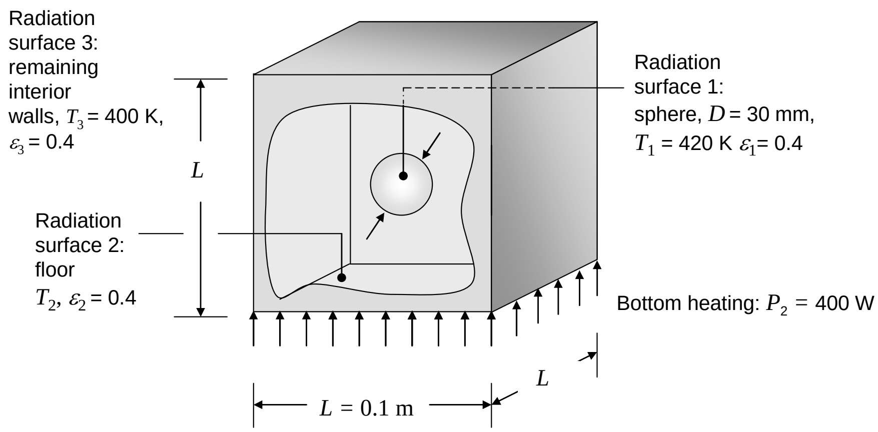
COMMENTS: The effect of the shield is to reduce the coolant system heat rate by a factor of nearly seven. Maintaining the integrity of the reflecting shield ($\varepsilon_s = 0.10$) operating at nearly 400°C in the mill environment to prevent corrosion or oxidation may be necessary.

PROBLEM 13.93

KNOWN: Dimensions of furnace and sphere. Emissivity of surfaces. Power supplied to floor of furnace. Temperature of other five walls. Sphere temperature.

FIND: (a) View factors F_{12}, F_{13}, F_{21}, F_{31}, F_{23}, F_{32}, and F_{33}. (b) Temperature of floor. Net rate of radiation heat transfer leaving sphere. Whether the sphere is under steady-state conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Surfaces are gray and diffuse, (2) Each identified surface has uniform irradiation and radiosity, (3) Outer surface of furnace floor is insulated and all power supplied to heater leaves as radiation into furnace (no storage), (4) Convection can be neglected.

ANALYSIS: (a) Due to symmetry, the view factor from the sphere to each of the six furnace walls must be equal, therefore $F_{12} = 1/6$ and $F_{13} = 5/6$. <

From reciprocity,

$$F_{21} = \frac{A_1 F_{12}}{A_2} = \frac{\pi(0.03\text{ m})^2}{6\times(0.1\text{ m})^2} = 0.0471$$ <

$$F_{31} = \frac{A_1 F_{13}}{A_3} = \frac{5\pi(0.03\text{ m})^2}{6\times5\times(0.1\text{ m})^2} = 0.0471$$ <

Since surface 2 does not see itself, $F_{21} + F_{23} = 1$, therefore $F_{23} = 1 - F_{21} = 0.953$. <

From reciprocity,

$$F_{32} = \frac{A_2 F_{23}}{A_3} = \frac{(0.1\text{ m})^2\times0.953}{5\times(0.1\text{ m})^2} = 0.191$$ <

Finally, $F_{33} = 1 - F_{31} - F_{32} = 0.762$. <

(b) Equation 13.21 can be written at surfaces 1 and 3 where temperature is known:

$$\frac{E_{b1} - J_1}{(1-\varepsilon_1)/\varepsilon_1 A_1} = \frac{J_1 - J_2}{1/A_1F_{12}} + \frac{J_1 - J_3}{1/A_1F_{13}} \qquad (1)$$

Continued...

PROBLEM 13.93 (Cont.)

$$\frac{E_{b3} - J_3}{(1-\varepsilon_3)/\varepsilon_3 A_3} = \frac{J_3 - J_1}{1/A_3F_{31}} + \frac{J_3 - J_2}{1/A_3F_{32}} \quad (2)$$

The power is known at surface 2, $q_2 = P = 400$ W, so we write Equation 13.22:

$$q_2 = \frac{J_2 - J_1}{1/A_2F_{21}} + \frac{J_2 - J_3}{1/A_2F_{23}} \quad (3)$$

Substituting numbers into Eqs. (1) – (3) gives

$$0.00189 \text{ m}^2(E_{b1} - J_1) = 0.000471 \text{ m}^2(J_1 - J_2) + 0.00236 \text{ m}^2(J_1 - J_3)$$
$$0.0333 \text{ m}^2(E_{b3} - J_3) = 0.00236 \text{ m}^2(J_3 - J_1) + 0.00953 \text{ m}^2(J_3 - J_2)$$
$$400 \text{ W} = 0.000471 \text{ m}^2(J_2 - J_1) + 0.00953 \text{ m}^2(J_2 - J_3)$$

where $E_{b1} = \sigma T_1^4 = 5.67\times10^{-8} \text{ W/m}^2\cdot\text{K}^4 \times (420)^4 \text{ K}^4 = 1764 \text{ W/m}^2$ and $E_{b3} = \sigma T_3^4 = 5.67\times10^{-8} \text{ W/m}^2\cdot\text{K}^4 \times (400)^4 \text{ K}^4 = 1452 \text{ W/m}^2$. Solving these three simultaneous equations yields

$$J_1 = 1.24 \times 10^4 \text{ W/m}^2,\ J_2 = 5.28 \times 10^4 \text{ W/m}^2,\ J_3 = 1.29 \times 10^4 \text{ W/m}^2$$

The temperature of the floor can be found by solving Equation 13.19 for E_{b2}:

$$E_{b2} = J_2 + q_2\frac{1-\varepsilon_2}{\varepsilon_2 A_2} = 5.28\times10^4 \text{ W/m}^2 + 400 \text{ W}\frac{1-0.4}{0.4\times(0.1 \text{ m})^2} = 1.128\times10^5 \text{ W/m}^2$$

Then with $E_{b2} = \sigma T_2^4$ we find $T_2 = 1188$ K. <

The net rate of radiation leaving the sphere surface 1 is given by Equation 13.19:

$$q_1 = \frac{E_{b1} - J_1}{(1-\varepsilon_1)/\varepsilon_1 A_1} = 0.00189 \text{ m}^2(1764 \text{ W/m}^2 - 1.24\times10^4 \text{ W/m}^2) = -20 \text{ W}$$ <

Since this is negative, heat is reaching the sphere at the rate of 20 W.
Since the sphere is not being heated or cooled by any mechanism other than radiation, at steady-state the net radiation heat transfer rate must be zero. Since it is not zero, it is not at steady-state. <

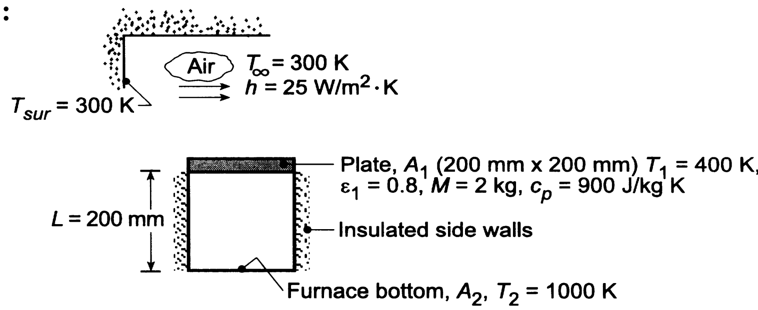
COMMENTS: (1) The bottom surface is very hot. (2) The irradiation and radiosity distributions on the spherical object are highly non-uniform. A more accurate treatment would include the effects of this non-uniformity by considering many additional radiation surfaces, as well as possible spatial temperature distributions within the spherical object. (3) The net heat radiation leaving surface 1 is relatively small and could be of the same magnitude as any convection effects.

PROBLEM 13.94

KNOWN: Opaque, diffuse-gray plate with $\varepsilon_1 = 0.8$ is at $T_1 = 400$ K at a particular instant. The bottom surface of the plate is subjected to radiative exchange with a furnace. The top surface is subjected to ambient air and large surroundings.

FIND: (a) Net radiative heat transfer to the bottom surface of the plate for $T_1 = 400$ K, (b) Change in temperature of the plate with time, dT_1/dt, and (c) Compute and plot dT_1/dt as a function of T_1 for the range $350 \le T_1 \le 900$ K; determine the steady-state temperature of the plate.

SCHEMATIC:



ASSUMPTIONS: (1) Plate is opaque, diffuse-gray and isothermal, (2) Furnace bottom behaves as a blackbody while sides are perfectly insulated, (3) Surroundings are large compared to the plate and behave as a blackbody.

ANALYSIS: (a) Recognize that the plate (A_1), furnace bottom (A_2) and furnace side walls (A_R) form a three-surface enclosure with one surface being re-radiating. The net radiative heat transfer *leaving* A_1 follows from Eq. 13.30 written as

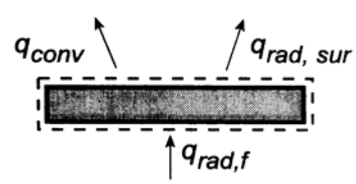
$$q_1 = \frac{E_{b1} - E_{b2}}{\dfrac{1-\varepsilon_1}{\varepsilon_1 A_1} + \dfrac{1}{A_1 F_{12} + \left(1/A_1 F_{1R} + 1/A_2 F_{2R}\right)^{-1}} + \dfrac{1-\varepsilon_2}{\varepsilon_2 A_2}} \quad (1)$$

From Fig. 13.4 with X/L = 0.2/0.2 = 1 and Y/L = 0.2/0.2 = 1, it follows that $F_{12} = 0.2$ and $F_{1R} = 1 - F_{12} = 1 - 0.2 = 0.8$. Hence, with $F_{1R} = F_{2R}$ (by symmetry) and $\varepsilon_2 = 1$.

$$q_1 = \frac{5.67\times10^{-8}\,\mathrm{W/m^2\cdot K^4}\left(400^4 - 1000^4\right)\mathrm{K^4}}{\dfrac{1-0.8}{0.8\times0.04\,\mathrm{m^2}} + \dfrac{1}{0.04\,\mathrm{m^2}\times0.20 + \left(2/0.04\,\mathrm{m^2}\times0.8\right)^{-1}}} = -1153\,\mathrm{W} \quad <$$

It follows the net radiative exchange to the plate is, $q_{rad\cdot f} = 1153$ W.

(b) Perform now an energy balance on the plate written as



$$\dot{E}_{in} - \dot{E}_{out} = \dot{E}_{st}$$

$$q_{rad.f} - q_{conv} - q_{rad,sur} = Mc_p \frac{dT_1}{dt}$$

$$q_{rad.f} - hA_1\left(T_1 - T_\infty\right) - \varepsilon_1 A_1 \sigma\left(T_1^4 - T_{sur}^4\right) = Mc_p \frac{dT_1}{dt}. \quad (2)$$

Substituting numerical values and rearranging to obtain dT/dt, find

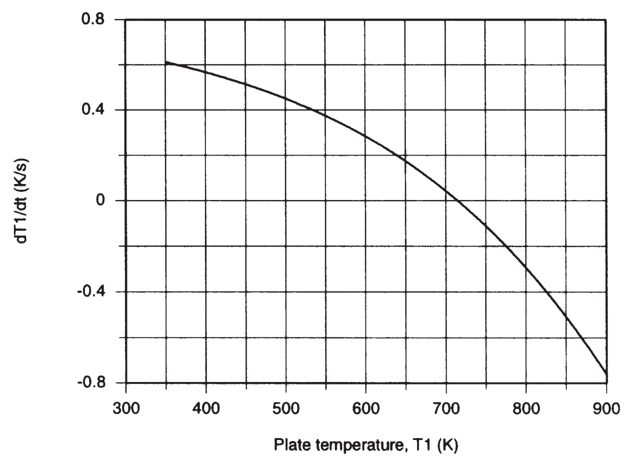
Continued …

PROBLEM 13.94 (Cont.)

$$\frac{dT_1}{dt} = \frac{1}{2\,kg \times 900\,J/kg\cdot K}\Big[+1153W - 25\,W/m^2\cdot K \times 0.04\,m^2\left(400-300\right)K$$
$$-0.8\times 0.04m^2 \times 5.67\times 10^{-8}\,W/m^2\cdot K^4\left(400^4 - 300^4\right)K^4\Big] \quad <$$

$$\frac{dT_1}{dt} = 0.57\,K/s.$$

(c) With Eqs. (1) and (2) in the *IHT* workspace, dT_1/dt was computed and plotted as a function of T_1.



When T_1 = 400 K, the condition of part (b), we found dT_1/dt = 0.57 K/s which indicates the plate temperature is increasing with time. For T_1 = 900 K, dT_1/dt is a negative value indicating the plate temperature will decrease with time. The steady-state condition corresponds to dT_1/dt = 0 for which

$$T_{1,ss} = 715\ K \quad <$$

COMMENTS: Using the *IHT Radiation Tools – Radiation Exchange Analysis, Three Surface Enclosure with Re-radiating Surface and View Factors, Aligned Parallel Rectangle* – the above analysis can be performed. A copy of the workspace follows:

```
// Energy Balance on the Plate, Equation 2:
M * cp * dTdt = - q1 – h * A1 * (T1 – Tinf) – eps1 * A1 * sigma * (T1^4 – Tsur^4)

/* Radiation Tool – Radiation Exchange Analysis,
Three-Surface Enclosure with Reradiating Surface: */
/* For the three-surface enclosure A1, A2 and the reradiating surface AR, the net rate of radiation transfer
from the surface A1 to surface A2 is */
q1 = (Eb1 – Eb2) / ( (1 – eps1) / (eps1 * A1) + 1 / (A1 * F12 + 1/(1/(A1 * F1R) + 1/(A2 * F2R))) + (1 –
eps2) / (eps2 * A2))  //  Eq 13.30
/* The net rate of radiation transfer from surface A2 to surface A1 is */
q2 = -q1
/* From a radiation energy balance on AR, */
(JR – J1) / (1/(AR * FR1)) + (JR – J2) / (1/(AR *FR2)) = 0       // Eq 13.31
/* where the radiosities J1 and J2 are determined from the radiation rate equations expressed in terms of
the surface resistances, Eq 13.22 */
q1 = (Eb1 – J1) / ((1 – eps1) / (eps1 * A1))
q2 = (Eb2 – J2) / ((1-eps2) / (eps2 * A2))
// The blackbody emissive powers for A1 and A2 are
Eb1 = sigma * T1^4
Eb2 = sigma * T2^4
// For the reradiating surface,
JR = EbR
```

Continued …

PROBLEM 13.94 (Cont.)

```
EbR = sigma *TR^4
sigma = 5.67E-8                // Stefan-Boltzmann constant, W/m^2·K^4
```

// Radiation Tool – View Factor:

```
/* The view factor, F12, for aligned parallel rectangles, is */
F12 = Fij_APR(Xbar, Ybar)
// where
Xbar = X/L
Ybar = Y/L
// See Table 13.2 for schematic of this three-dimensional geometry.
```

// View Factors Relations:

```
F1R = 1 – F12
FR1 = F1R * A1 / AR

```

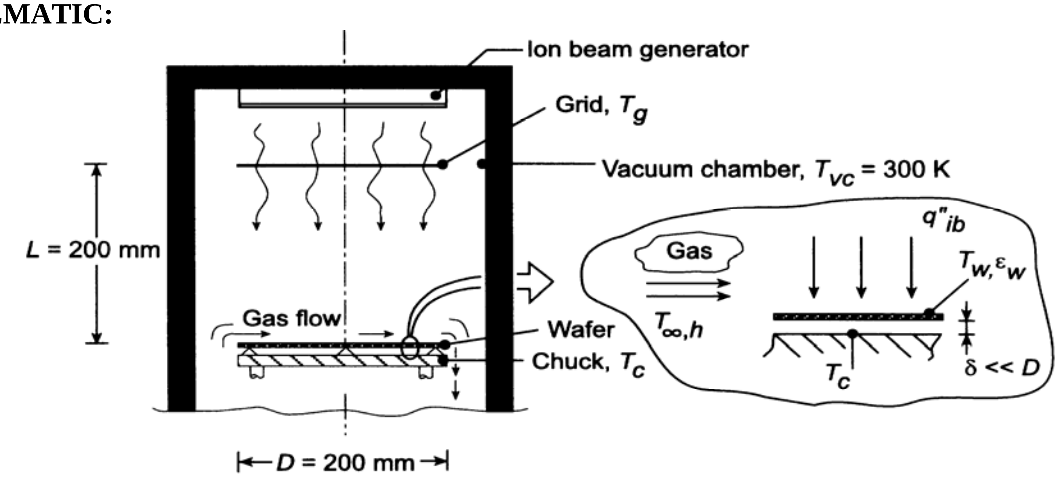
PROBLEM 13.95

KNOWN: Tool for processing silicon wafer within a vacuum chamber with cooled walls. Thin wafer is radiatively coupled on its back side to a chuck which is electrically heated. The top side is irradiated by an ion beam flux and experiences convection with the process gas and radioactive exchange with the ion-beam *grid* control surface and the chamber walls.

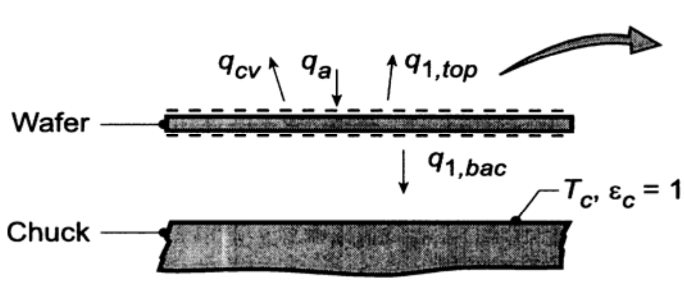
FIND: (a) Show control surfaces and all relevant processes on a schematic of the wafer, and (b) Perform an energy balance on the wafer and determine the chuck temperature T_c required to maintain the prescribed conditions.

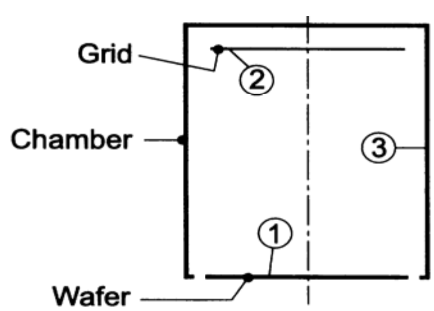
SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Wafer is diffuse, gray, (3) Separation distance between the wafer and chuck is much smaller than the wafer and chuck diameters, (4) Negligible convection in the gap between the wafer and chuck; convection occurs on the wafer top surface with the process gas, (5) Surfaces forming the three-surface enclosure – wafer ($\varepsilon_w = 0.8$), grid ($\varepsilon_g = 1$), and chamber walls ($\varepsilon_c = 1$) have uniform radiosity and are diffuse, gray, and (6) the chuck surface is black.

ANALYSIS: (a) The wafer is shown schematically above in relation to the key components of the tool: the ion beam generator, the grid which is used to control the ion beam flux, q''_{ib}, the chuck which aids in controlling the wafer temperature and the process gas flowing over the wafer top surface. The schematic below shows the control surfaces on the top and back surfaces of the wafer along with the relevant thermal processes: q_{cv}, convection between the wafer and process gas; q_a, applied heat source due to absorption of the ion beam flux, q''_{ib}; $q_{1,top}$, net radiation leaving the top surface of the wafer (1) which is part of the three-surface enclosure – grid (2) and chamber walls (3), and; $q_{1,bac}$, net radiation leaving the backside of the wafer (w) which is part of a two-surface enclosure formed with the chuck (c).





<

Continued …

PROBLEM 13.95 (Cont.)

(b) Referring to the schematic and the identified thermal processes, the energy balance on the wafer has the form,

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$-q_{cv} + q_a - q_{1,bac} - q_{1,top} = 0 \qquad (1)$$

where each of the processes are evaluated as follows:

Convection with the process gas: with $A_w = \pi D^2/4 = \pi(0.200\text{m})^2/4 = 0.03142\,\text{m}^2$,

$$q_{cv} = hA_w\left(T_w - T_g\right) = 10\,\text{W/m}^2 \times 0.03142\text{m}^2 \times (700-500)\,\text{K} = 62.84\,\text{W} \qquad (2)$$

Applied heat source – ion beam:

$$q_a = q''_{ib}A_w = 600\,\text{W/m}^2 \times 0.03142\text{m}^2 = 18.85\,\text{W} \qquad (3)$$

Net radiation heat rate, back side; *enclosure (w,c):* for the two-surface enclosure comprised of the back side of the wafer (w) and the chuck, (c), Eq. 13.24, yields

$$q_{1,bac} = \frac{\sigma\left(T_w^4 - T_c^4\right)A_w}{1/\varepsilon_w} \qquad (4)$$

$$q_{1,bac} = \frac{0.03142\text{m}^2 \times \sigma\left(700^4 - T_c^4\right)\text{K}^4}{1/0.6} = 1.069\times 10^{-9}\left(700^4 - T_c^4\right)$$

Net radiation heat rate, top surface; enclosure (1, 2, 3): from the surface energy balance on A_1, Eq. 13.19.

$$q_{1,top} = \frac{E_{b1} - J_1}{(1-\varepsilon_1)/\varepsilon_1 A_1} \qquad (5)$$

where $\varepsilon_1 = \varepsilon_w$, $A_1 = A_w$, $E_{b1} = \sigma T_1^4$ and the radiosity can be evaluated by an enclosure analysis following the methodology of Section 13.3.2. From the energy balance, Eq. 13.21,

$$\frac{E_{b1} - J_1}{(1-\varepsilon_1)/\varepsilon_1 A_1} = \frac{J_1 - J_2}{1/A_1F_{12}} + \frac{J_1 - J_3}{1/A_1F_{13}} \qquad (6)$$

where $J_2 = E_{b2} = \sigma T_g^4$ and $J_3 = E_{b3} = \sigma T_{vc}^4$ since both surfaces are black ($\varepsilon_g = \varepsilon_{vc} = 1$). The view factor F_{12} can be computed from the relation for coaxial parallel disks, Table 13.5.

$$F_{12} = 0.5\left\{S - \left[S^2 - 4(r_2/r_1)^2\right]^{1/2}\right\} = 0.5\left\{6.0 - \left[6.0^2 - 4(1)^2\right]^{1/2}\right\} = 0.1716$$

$$S = 1 + \frac{1+R_2^2}{R_1^2} = 1 + \frac{1+0.5^2}{0.5^2} = 6.00$$

Continued …

PROBLEM 13.95 (Cont.)

$R_1 = r_1 / L = 100 / 200 = 0.5$ $\qquad$ $R_4 = r_4 / L = 0.5$

The view factor F_{13} follows from the summation rule applied to A_1,

$$F_{13} = 1 - F_{12} = 1 - 0.1716 = 0.8284$$

Substituting numerical values into Eq. (6), with $T_1 = T_w = 700$ K, $T_2 = T_g = 500$ K, and $T_3 = T_{vc} = 300$ K, find J_1,

$$\frac{\sigma T_1^4 - J_1}{(1-\varepsilon_1)/\varepsilon_1 A_1} = \frac{J_1 - \sigma T_g^4}{1/F_{12}} + \frac{J_1 - \sigma T_{vc}^4}{1/F_{13}} \qquad (7)$$

$$J_1 = 8564 \text{ W/m}^2$$

Using Eq. (5), find $q_{1,top}$ with $E_{b2} = \sigma T_w^4 = 13{,}614 \text{ W/m}^2$ and $A_1 = A_w$,

$$q_{1,top} = \frac{(13{,}614 - 8564)\text{ W/m}^2}{(1-0.6)/\left(0.6 \times 0.03142\text{m}^2\right)} = 238\text{ W}$$

Evaluating T_c from the energy balance on the wafer, Eq. (1), and substituting appropriate expressions for each of the processes, find

$$-62.84 \text{ W/m}^2 + 18.85\text{W} - 1.069 \times 10^{-9}\left(700^4 - T_c^4\right) - 238 \text{ W} = 0$$

$$T_c = 842.5\text{ K} \qquad <$$

From Eq. (4), with $T_c = 815$ K, the electrical power required to maintain the chuck is

$$P_c = -q_{1,bac} = 1.069 \times 10^{-9}\left(842.5^4 - 700^4\right) = 282\text{ W}$$

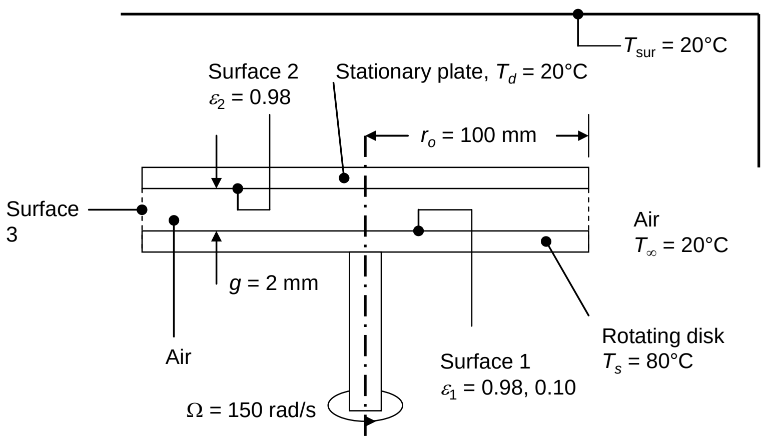
COMMENTS: Recognize that the method of analysis is centered about an energy balance on the wafer. Identifying the processes and representing them on the energy balance schematic, as described in Chapter 1, is a vital step in developing the strategy for a solution.

PROBLEM 13.96

KNOWN: Dimensions and temperatures of rotating and stationary disks, air gap spacing between disks, rotational speed. Ambient and surroundings temperatures. Correlation for the local Nusselt number. Initial painted surfaces and emissivity of exposed base metal on the rotating disk.

FIND: Total power dissipated from the top surface of the rotating disk for painted and unpainted conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Diffuse-gray surfaces with uniform radiosity and irradiation distributions, (4) Large surroundings.

PROPERTIES: *Table A.4*, air (T = (80°C + 20°C)/2 = 50°C ≈ 323K): $\nu = 18.20\times10^{-6}$ m^2/s, k = 0.0280 W/m·K. *Table A.11*, Parsons black paint, $\varepsilon = 0.98$.

ANALYSIS: From Problem 6.17, $Nu_r = \dfrac{h(r)r_o}{k} = 70\left(1+e^{-140G}\right)Re_{r_o}^{-0.456}Re_r^{0.478}$.

Since $Re_r = \Omega r^2/\nu$, the local heat transfer coefficient is

$$h(r) = k\left[70\left(1+e^{-140G}\right)\left(\frac{\Omega r_o^2}{\nu}\right)^{-0.456}\left(\frac{\Omega}{\nu}\right)^{0.478}\right]r^{-0.044}$$

The average heat transfer coefficient may be evaluated from

$$\bar{h} = \frac{1}{A_s}\int_{A_s} h(r)dA_s = \frac{2\pi k}{\pi r_o^2}\left[70\left(1+e^{-140G}\right)\left(\frac{\Omega r_o^2}{\nu}\right)^{-0.456}\left(\frac{\Omega}{\nu}\right)^{0.478}\right]\int_0^{r_o} r\times r^{-0.044}dr$$

or

$$\bar{h} = \frac{1.022k}{r_o^2}\left[70\left(1+e^{-140G}\right)\left(\frac{\Omega r_o^2}{\nu}\right)^{-0.456}\left(\frac{\Omega}{\nu}\right)^{0.478}\right]r_o^{1.956}$$

Continued…

PROBLEM 13.96 (Cont.)

Substituting values,

$$\bar{h} = \frac{1.022 \times 0.0280 \text{W/m}^2 \cdot \text{K}}{(0.100\text{m})^2}$$

$$\times \left[70\left(1 + e^{-140\times 0.02}\right)\left(\frac{150\text{rad/s} \times \left(0.100\text{m}\right)^2}{18.20 \times 10^{-6}\text{m}^2/\text{s}}\right)^{-0.456} \left(\frac{150\text{rad/s}}{18.20 \times 10^{-6}\text{m}^2/\text{s}}\right)^{0.478} \right] \left(0.100\text{m}\right)^{1.956}$$

or

$$\bar{h} = 27.26 \text{ W/m}^2 \cdot \text{K}$$

The convective heat flux from the top surface of the disk is

$$q''_{\text{conv}} = \bar{h}(T_s - T_d) = 27.26\text{W/m}^2 \cdot \text{K} \times (80 - 20)°\text{C} = 1636\text{W/m}^2$$

and the convective heat rate is

$$q_{\text{conv}} = q''\pi r_o^2 = 1636\text{W/m}^2 \times \pi \times (0.10\text{m})^2 = 51.38\text{W}$$

The radiation heat transfer from the rotating disk may be determined by use of Eq. 13.21.

Surfaces 1 and 2:

$$\frac{\sigma T_1^4 - J_1}{\left(1-\varepsilon_1\right)/\varepsilon_1 A_1} = \frac{J_1 - J_2}{1/A_1F_{12}} + \frac{J_1 - J_3}{1/A_1F_{13}} \;\; ; \;\; \frac{\sigma T_2^4 - J_2}{\left(1-\varepsilon_2\right)/\varepsilon_2 A2} = \frac{J_2 - J_1}{1/A_1F_{12}} + \frac{J_2 - J_3}{1/A_2F_{23}} \qquad (1,2)$$

while for black Surface 3, $J_3 = \sigma T_3^4 = 5.67 \times 10^{-8}\text{W/m}^2 \cdot \text{K}^4 \times \left(20 + 273\text{K}\right)^4 = 417.8\text{W/m}^2$. Using the result for coaxial parallel disks in Table 13.2, $R_1 = R_2 = r_o/g$ = 100mm/2mm = 50, S = 1 + 2501/2500 = 2.0004, and

$$F_{12} = \frac{1}{2}\left\{2.0004 - \left[2.0004^2 - 4\right]^{1/2}\right\} = 0.9802 \;\; ; \;\; F_{13} \;=\; 1 - F_{12} = 1 - 0.9802 = 0.0198$$

while $A_1 = A_2 = \pi r_o^2 = \pi \times (0.100\text{m})^2 = 0.0314 \text{ m}^2$. Substituting values of the view factors, areas, emissivities and J_3 into Equations (1) and (2), and solving simultaneously yields

ε_1 = 0.98: J_1 = 871.3 W/m^2, J_2 = 426.8 W/m^2 ; ε_1 = 0.10: J_1 = 464.9 W/m^2, J_2 = 417.9 W/m^2

From Eq. 13.19,

$$q_{1,\text{rad},0.98} = \frac{\sigma T_1^4 - J_1}{(1-\varepsilon_1)/\varepsilon_1 A_1} = \frac{5.67 \times 10^{-8}\text{W/m}^2 \cdot \text{K}^4 \times (80 + 273\text{K})^4 - 871.3\text{W/m}^2}{(1 - 0.98)/(0.98 \times 0.0314\text{m}^2)} = 13.97 \text{ W}$$

Continued…

PROBLEM 13.96 (Cont.)

and

$$q_{1,\text{rad},0.10} = \frac{\sigma T_1^4 - J_1}{(1-\varepsilon_1)/\varepsilon_1 A_1} = \frac{5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4 \times (80+273\text{K})^4 - 464.9\,\text{W/m}^2}{(1-0.10)/(0.10\times0.0314\,\text{m}^2)} = 1.45\text{ W}$$

The total power dissipated from the top surface of the rotating disk is:

ε_1 = 0.98: $q = q_{\text{conv}} + q_{1\text{rad},0.98}$ = 51.38 W + 13.97 W = 65.35 W <

ε_1 = 0.10: $q = q_{\text{conv}} + q_{1\text{rad},0.10}$ = 51.38 W + 1.45 W = 52.83 W <

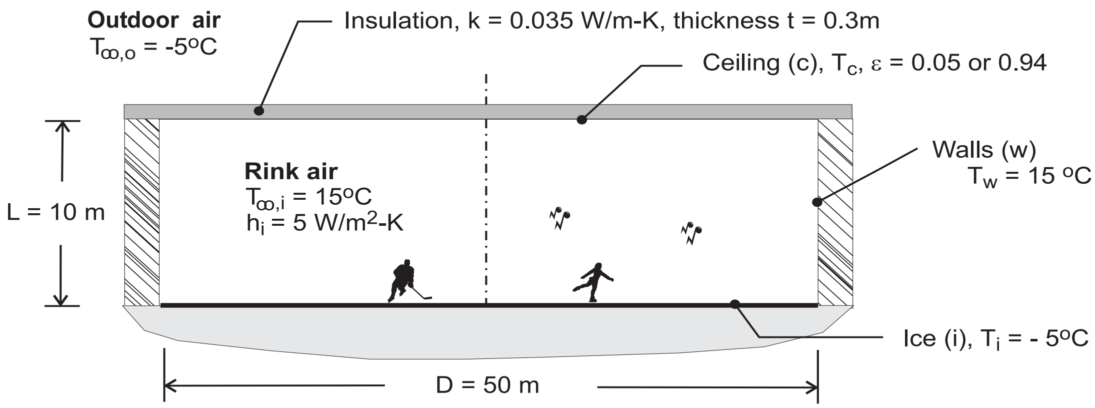
COMMENTS: (1) The influence of the black surroundings is small since the view factors from the disks to the surroundings are small, the stationary disk temperature is the same as that of the surroundings, and the emissivity of the stationary disk is close to unity. Use of the result for infinite parallel surfaces (Equation 13.24) yields heat rates of 13.95 and 1.45 W for the high and low emissivity cases, respectively. (2) See Pelle and Harmand, "Heat Transfer Measurements in an Opened Rotor-Stator System Air-Gap," *Experimental Thermal and Fluid Science*, 'Vol. 31, pp. 165 – 180, 2007, for additional discussion.

PROBLEM 13.97

KNOWN: Ice rink with prescribed ice, rink air, wall, ceiling and outdoor air conditions.

FIND: (a) Temperature of the ceiling, T_c, having an emissivity of 0.05 (highly reflective panels) or 0.94 (painted panels); determine whether condensation will occur for either or both ceiling panel types if the relative humidity of the rink air is 70%, and (b) Calculate and plot the ceiling temperature as a function of ceiling insulation thickness for $0.1 \le t \le 1$ m, identify conditions for which condensation will occur on the ceiling.

SCHEMATIC:



ASSUMPTIONS: (1) Rink comprised of the ice, walls and ceiling approximates a three-surface, diffuse-gray enclosure, (2) Surfaces have uniform radiosities, (3) Ice surface and walls are black, (4) Panels are diffuse-gray, and (5) Thermal resistance for convection on the outdoor side of the ceiling is negligible compared to the conduction thermal resistance of the ceiling insulation.

PROPERTIES: *Psychrometric chart* (Atmospheric pressure; dry bulb temperature, $T_{db} = T_{\infty,i}$ = 15°C; relative humidity, RH = 70%): Dew point temperature, T_{dp} = 9.4°C.

ANALYSIS: The energy balance on the ceiling illustrated in the schematic below has the form

$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$-q_o - q_{conv,c} - q_{rad,c} = 0 \qquad (1)$$

where the rate equations for each process are

$$q_o = \left(T_c - T_{\infty,o}\right)/R_{cond} \qquad R_{cond} = t/kA_c \qquad (2,3)$$

$$q_{conv,c} = h\,A_c\left(T_c - T_{\infty,i}\right) \qquad (4)$$

$$q_{rad,c} = \varepsilon E_b\left(T_c\right)A_c - \alpha A_w F_{wc} E_b\left(T_w\right) - \alpha A_i F_{ic} E_b\left(T_i\right) \qquad (5)$$

The blackbody emissive powers are $E_b = \sigma T^4$ where $\sigma = 5.67 \times 10^{-8}$ W/m^2·K^4. Since the ceiling panels are diffuse-gray, $\alpha = \varepsilon$. The view factors required of Eq. (5): determine F_{ic} (ice to ceiling) from Table 13.2 (Fig. 13.5) for parallel, coaxial disks

$$F_{ic} = 0.672$$

and F_{wc} (wall to ceiling) from the summation rule on the ice (i) and the reciprocity rule,

$$F_{ic} + F_{iw} = 1 \qquad F_{iw} = F_{cw} \text{ (symmetry)}$$

$$F_{cw} = 1 - F_{ic}$$

$$F_{wc} = \left(A_c / A_w\right)F_{cw} = \left(A_c / A_w\right)\left(1 - F_{ic}\right) = 0.410$$

Continued …

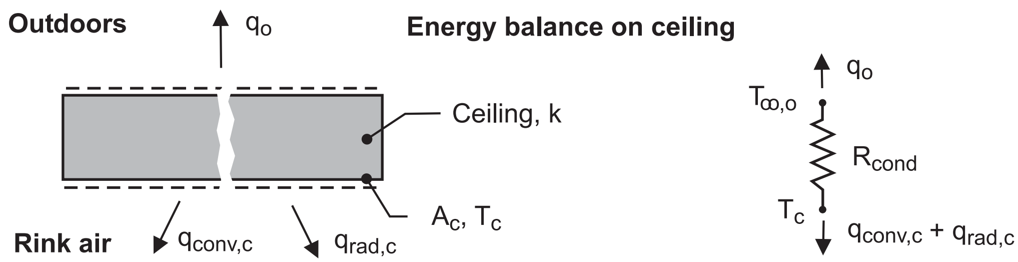
PROBLEM 13.97 (Cont.)

where $A_c = \pi D^2/4$ and $A_w = \pi DL$.

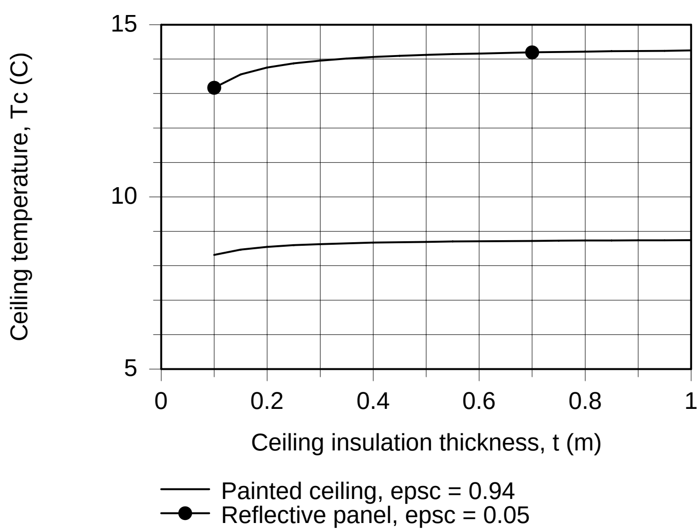
Using the foregoing energy balance, Eq. (1), and the rate equations, Eqs. (2-5), the ceiling temperature is calculated using radiative properties for the two panel types,

Ceiling panel	ε	T_c (°C)	
Reflective	0.05	14.0	
Paint	0.94	8.6	$T_c < T_{dp}$ <

Condensation will occur on the painted panel since $T_c < T_{dp}$.



(b) The equations required of the analysis above were solved using *IHT*. The analysis is extended to calculate the ceiling temperatures for a range of insulation thickness and the results plotted below.



For the reflective panel (ε = 0.05), the ceiling surface temperature is considerably above the dew point. Therefore, condensation will not occur for the range of insulation thickness shown. For the painted panel (ε = 0.94), the ceiling surface temperature is always below the dew point. We expect condensation to occur for the range of insulation thickness shown.

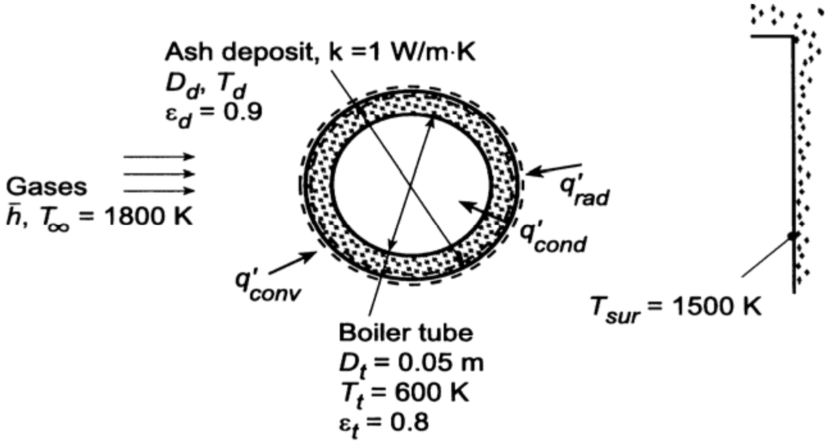
COMMENTS: From the analysis, recognize that the radiative exchange between the ice and the ceiling is the dominant process for influencing the ceiling temperature. With the reflective panel, the rate is reduced nearly 20 times that with the painted panel. With the painted panel ceiling, for most of the conditions likely to exist in the rink, condensation will occur.

PROBLEM 13.98

KNOWN: Diameter, temperature and emissivity of boiler tube. Thermal conductivity and emissivity of ash deposit. Convection coefficient and temperature of gas flow over the tube. Temperature of surroundings.

FIND: (a) Rate of heat transfer to tube without ash deposit, (b) Rate of heat transfer with an ash deposit of diameter D_d = 0.06 m, (c) Effect of deposit diameter and convection coefficient on heat rate and contributions due to convection and radiation.

SCHEMATIC:



ASSUMPTIONS: (1) Diffuse/gray surface behavior, (2) Surroundings form a large enclosure about the tube and may be approximated as a blackbody, (3) One-dimensional conduction in ash, (4) Steady-state.

ANALYSIS: (a) Without an ash deposit, the heat rate per unit tube length may be calculated directly.

$$q' = \bar{h}\pi D_t\left(T_\infty - T_t\right) + \varepsilon_t \sigma \pi D_t\left(T_{sur}^4 - T_t^4\right)$$

$$q' = 100\ \text{W/m}^2\cdot\text{K}(\pi)0.05\,\text{m}(1800-600)\text{K} + 0.8\times 5.67\times 10^{-8}\,\text{W/m}^2\cdot\text{K}^4(\pi)(0.05\,\text{m})\left(1500^4 - 600^4\right)\text{K}$$

$$q' = (18{,}850 + 35{,}150)\,\text{W/m} = 54{,}000\ \text{W/m} \quad <$$

(b) Performing an energy balance for a control surface about the outer surface of the ash deposit, $q'_{conv} + q'_{rad} = q'_{cond}$, or

$$\bar{h}\pi D_d\left(T_\infty - T_d\right) + \varepsilon_d \sigma \pi D_d\left(T_{sur}^4 - T_d^4\right) = \frac{2\pi k\left(T_d - T_t\right)}{\ln\left(D_d / D_t\right)}$$

Hence, canceling π and considering an ash deposit for which D_d = 0.06 m,

$$100\,\text{W/m}^2\cdot\text{K}(0.06\,\text{m})(1800 - T_d)\text{K} + 0.9\times 5.67\times 10^{-8}\,\text{W/m}^2\cdot\text{K}^4(0.06\,\text{m})\left(1500^4 - T_d^4\right)\text{K}^4$$

$$= \frac{2(1\ \text{W/m}\cdot\text{K})(T_d - 600)\text{K}}{\ln(0.06/0.05)}$$

A trial-and-error, or *IHT* solution yields $T_d \approx 1346$ K, from which it follows that

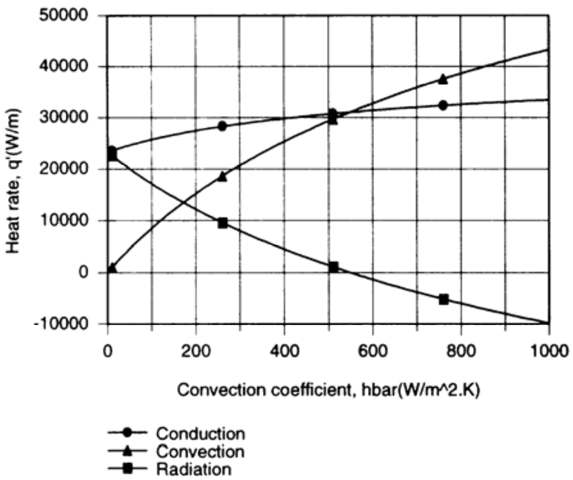
$$q' = \bar{h}\pi D_d\left(T_\infty - T_d\right) + \varepsilon_d \sigma \pi D_d\left(T_{sur}^4 - T_d^4\right)$$

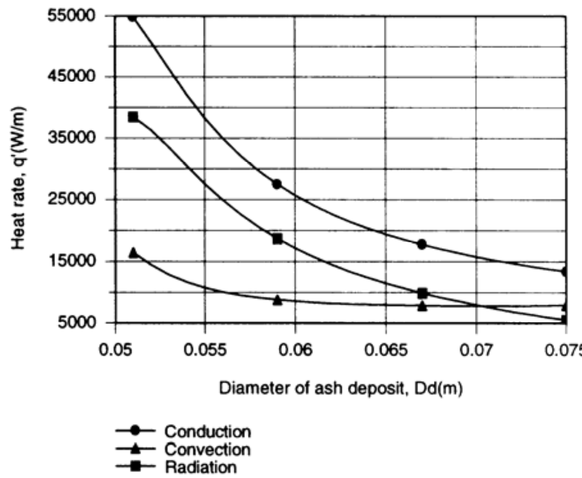
$$q' = 100\,\text{W/m}^2\cdot\text{K}(\pi)0.06\,\text{m}(1800 - 1346)\text{K} + 0.9\times 5.67\times 10^{-8}\,\text{W/m}^2\cdot\text{K}^4(\pi)0.06\,\text{m}\left(1500^4 - 1346^4\right)\text{K}^4$$

Continued …

$$q' = (8560 + 17{,}140)\,W/m = 25{,}700\,W/m$$ <

(c) The foregoing energy balance was entered into the *IHT* workspace and parametric calculations were performed to explore the effects of $\bar{h}$ and D_d on the heat rates.





For D_d = 0.06 m and $10 \le \bar{h} \le 1000\ W/m^2 \cdot K$, the heat rate to the tube, q'_{cond}, as well as the contribution due to convection, q'_{conv}, increase with increasing $\bar{h}$. However, because the outer surface temperature T_d also increases with $\bar{h}$, the contribution due to radiation decreases and becomes negative (heat transfer from the surface) when T_d exceeds 1500 K at $\bar{h} = 540\ W/m^2 \cdot K$. Both the convection and radiation heat rates, and hence the conduction heat rate, increase with decreasing D_d, as T_d decreases and approaches T_t = 600 K. However, even for D_d = 0.051 m (a deposit thickness of 0.5 mm), T_d = 773 K and the ash provides a significant resistance to heat transfer.

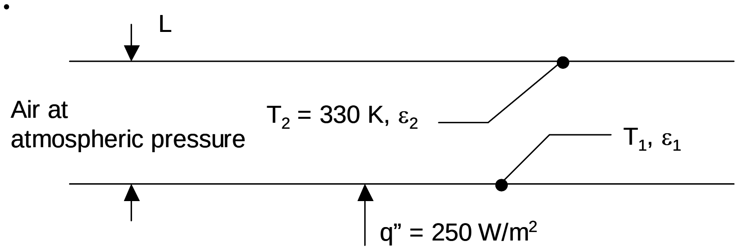
COMMENTS: Boiler operation in an energy efficient manner dictates that ash deposits be removed periodically.

PROBLEM 13.99

KNOWN: Two large parallel plates, separation distance and temperature of top plate. Gap between plates is filled with atmospheric pressure air, and heat flux from the bottom plate.

FIND: (a) Temperature of the bottom plate and the ratio of the convective to radiative heat fluxes for $\varepsilon_1 = \varepsilon_2 = 0.5$, (b) Temperature of the bottom plate and the ratio of the convective to radiative heat fluxes for $\varepsilon_1 = \varepsilon_2 = 0.25$ and 0.75.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional heat transfer, (2) Steady-state conditions, (3) Constant properties, (4) Diffuse, gray surfaces, (5) Ideal gas behavior.

PROPERTIES: Table A.4, air ($\bar{T}$ = 350 K): k = 0.030 W/m·K, $\alpha = 2.99 \times 10^{-5}$ m^2/s, $\nu = 2.092 \times 10^{-5}$ m^2/s, Pr = 0.70.

ANALYSIS: (a) The heat flux is composed of radiation and convection components,

$$q'' = q''_{rad} + q''_{conv} \qquad (1)$$

where

$$q''_{rad} = \frac{\sigma\left(T_1^4 - T_2^4\right)}{\frac{1}{\varepsilon_1} + \frac{1}{\varepsilon_2} - 1} \qquad (2)$$

and

$$q''_{conv} = \bar{h}\left(T_1 - T_2\right) \qquad (3)$$

We evaluate $\bar{h}$ by using the Globe and Dropkin correlation of Chapter 9,

$$\bar{h} = \frac{k}{L}\left[0.069 Ra_L^{1/3} Pr^{0.074}\right] \qquad (4)$$

where

Continued…

PROBLEM 13.99 (Cont.)

$$Ra_L = \frac{g\beta(T_1 - T_2)L^3}{\nu\alpha} \tag{5}$$

Combining Eqs. (1) through (5) yields

$$q'' = \frac{\sigma\left(T_1^4 - T_2^4\right)}{\frac{1}{\varepsilon_1} + \frac{1}{\varepsilon_2} - 1} + \left[0.069k\left(\frac{g\beta(T_1 - T_2)}{\nu\alpha}\right)^{1/3} Pr^{0.074}\right]\left(T_1 - T_2\right) \tag{6}$$

or

$$250 W/m^2 = \frac{5.67 \times 10^{-8} \frac{W}{m^2 \cdot K^4} \times \left[T_1^4 - \left(330K\right)^4\right]}{\frac{1}{0.5} + \frac{1}{0.5} - 1}$$

$$+\left[0.069 \times 0.030 \frac{W}{m \cdot K}\left(\frac{9.81 \frac{m}{s^2} \times \frac{1}{350K} \times \left(T_1 - 330\right)K}{2.092 \times 10^{-5} \frac{m^2}{s} \times 2.99 \times 10^{-5} \frac{m^2}{s}}\right)^{1/3} \times 0.70^{0.074}\right] \times (T_1 - 330)K \quad (7)$$

Equation (7) may be solved iteratively or with *IHT* to yield T_1 = 373 K. <

In addition,

$$Ra_L = \frac{9.8 \frac{m}{s^2} \times \frac{1}{350K} \times \left(373 - 330\right)K \times \left(0.1m\right)^3}{2.092 \times 10^{-5} \frac{m^2}{s} \times 2.99 \times 10^{-5} \frac{m^2}{2}} = 1.93 \times 10^6$$

and

$$h = \frac{0.030 \frac{W}{m \cdot K}}{0.10m}\left[0.069 \times \left(1.93 \times 10^6\right)^{1/3} \times 0.70^{0.074}\right] = 2.51 \frac{W}{m^2 \cdot K}$$

$$q''_{conv} = 2.52 \frac{W}{m^2 \cdot K} \times \left(373 - 300\right)K = 108 \frac{W}{m^2}$$

$$q''_{rad} = q'' - q''_{conv} = 250 \frac{W}{m^2} - 108 \frac{W}{m^2} = 142 \frac{W}{m^2}; \; \frac{q''_{conv}}{q''_{rad}} = \frac{108}{142} = 0.76$$ <

Continued…

PROBLEM 13.99 (Cont.)

(b) Substituting $\varepsilon_1 = \varepsilon_2 = 0.25$ into Eq. (6) yields

$T_1 = 388.4$ K, $Ra_L = 2.6 \times 10^6$, $\bar{h} = 2.78\ W/m^2 \cdot K$, $q''_{conv} = 162\ W/m^2$, $q''_{rad} = 88\ W/m^2$,

$$\frac{q''_{conv}}{q''_{rad}} = \frac{162}{88} = 1.84$$ <

(c) Substituting $\varepsilon_1 = \varepsilon_2 = 0.75$ into Eq. (6) yields

$T_1 = 361.6$ K, $Ra_L = 1.4 \times 10^6$, $\bar{h} = 2.26\ W/m^2 \cdot K$, $q''_{conv} = 72\ W/m^2$, $q''_{rad} = 178\ W/m^2$,

$$\frac{q''_{conv}}{q''_{rad}} = \frac{72}{178} = 0.40$$ <

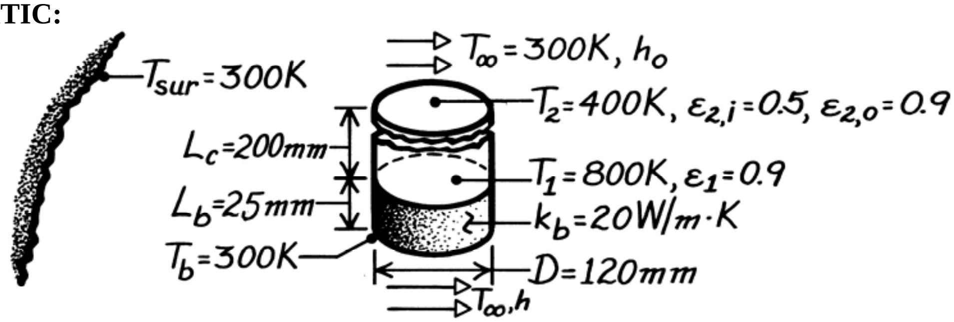
COMMENT: Note the increase in the temperature difference between the plates as the emissivity is reduced. Both the radiation and convection heat fluxes are highly sensitive to the plate emissivity.

PROBLEM 13.100

KNOWN: Dimensions, emissivities and temperatures of heated and cured surfaces at opposite ends of a cylindrical cavity. External conditions.

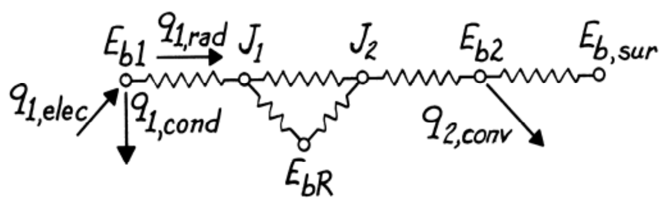
FIND: Required heater power and outside convection coefficient.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Opaque, diffuse-gray surfaces, (3) Negligible convection within cavity, (4) Isothermal disk and heater surfaces, (5) One-dimensional conduction in base, (6) Negligible contact resistance between heater and base, (7) Sidewall is reradiating.

ANALYSIS: The equivalent circuit is



From an energy balance on the heater surface, $q_{1,elec} = q_{1,cond} + q_{1,rad}$,

$$q_{1,elec} = k_b\left(\pi D^2/4\right)\frac{T_1 - T_b}{L_b} + \frac{\sigma\left(T_1^4 - T_2^4\right)}{\dfrac{1-\varepsilon_1}{\varepsilon_1 A_1} + \dfrac{1}{A_1F_{12} + \left[\left(1/A_1F_{1R}\right)+\left(1/A_2F_{2R}\right)\right]^{-1}} + \dfrac{1-\varepsilon_{2,i}}{\varepsilon_{2,i}A_2}}$$

where $A_1 = A_2 = \pi D^2/4 = \pi(0.12\text{ m})^2/4 = 0.0113\text{ m}^2$ and from Fig. 13.5, with $L_c/r_1 = 3.33$ and $r_2/L_c = 0.3$ find $F_{12} = F_{21} = 0.077$; hence, $F_{1R} = F_{2R} = 0.923$. The required heater power is

$$q_{1,elec} = 20\text{ W/m}\cdot\text{K}\times 0.0113\text{ m}^2\frac{(800-300)\text{K}}{0.025\text{ m}}$$

$$+\frac{0.0113\text{ m}^2\times 5.67\times10^{-8}\text{W/m}^2\cdot\text{K}^4\left(800^4-400^4\right)\text{K}^4}{\dfrac{1-0.9}{0.9}+\dfrac{1}{0.077+\left[(1/0.923)+(1/0.923)\right]^{-1}}+\dfrac{1-0.5}{0.5}}$$

$$q_{1,elec} = 4521\text{ W} + 82.9\text{ W} = 4604\text{ W}.$$ <

An energy balance for the disk yields, $q_{rad,2} = q_{rad,1} = h_oA_2\left(T_2 - T_\infty\right) + \varepsilon_{2,o}A_2\sigma\left(T_2^4 - T_{sur}^4\right)$,

$$h_o = \frac{82.9\text{ W} - 0.9\times0.0113\text{ m}^2\times5.67\times10^{-8}\text{W/m}^2\cdot\text{K}^4\left(400^4-300^4\right)\text{K}^4}{0.0113\text{ m}^2\times100\text{ K}} = 64\text{ W/m}^2\cdot\text{K}.$$ <

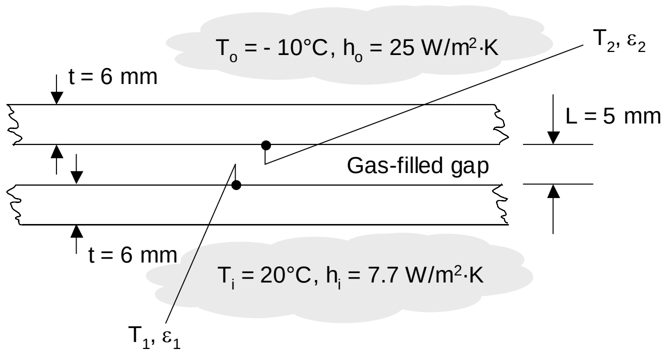
COMMENTS: Conduction through the ceramic base represents an enormous system loss. The base should be insulated to greatly reduce this loss and hence the electric power input.

PROBLEM 13.101

KNOWN: Emissivity of glass sheets. Inside and outside temperatures and convection heat transfer coefficients. Type of gas within gap.

FIND: Heat flux through the window for case 1: $\varepsilon_1 = \varepsilon_2 = 0.95$, case 2: $\varepsilon_1 = \varepsilon_2 = 0.05$, and case 3: $\varepsilon_1 = 0.05$, $\varepsilon_2 = 0.95$, with either air or argon between the glass sheets.

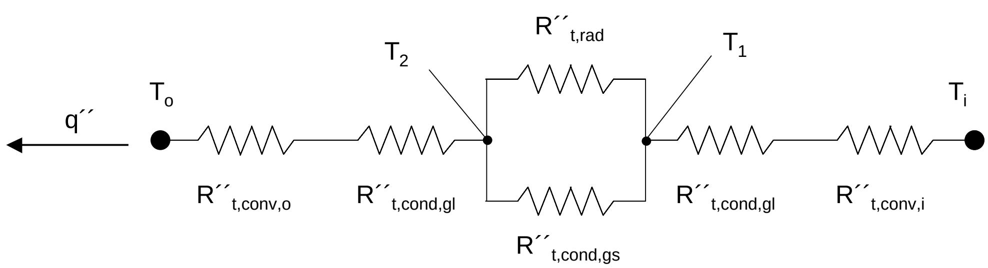
SCHEMATIC:



ASSUMPTIONS: (1) Diffuse-gray surfaces, (2) Infinite parallel glass surfaces, (3) Negligible radiation on exterior surfaces, (4) Negligible natural convection in gap.

PROPERTIES: *Table A.4*, Air (300 K): k = 0.0263 W/m·K. Table A.3, Plate Glass (300 K): k = 1.4 W/m·K.

ANALYSIS: The thermal resistance network is shown below.



The thermal resistances are as follows.

$$R''_{t,\text{conv},o} = 1/h_o = 1/\left(25\ \text{W/m}^2\cdot\text{K}\right) = 0.040\ \text{m}^2\cdot\text{K/W}$$

$$R''_{t,\text{cond},gl} = t/k_g = 0.006\ \text{m}/\left(1.4\ \text{W/m}\cdot\text{K}\right) = 0.0043\ \text{m}^2\cdot\text{K/W}$$

$$R''_{t,\text{cond},gs} = L/k_{gs} = 0.005\ \text{m}/\left(0.0263\ \text{W/m}\cdot\text{K}\right) = 0.190\ \text{m}^2\cdot\text{K/W}\ \ \text{(for air)}$$

$$R''_{t,\text{cond},gs} = L/k_{gs} = 0.005\ \text{m}/\left(0.0177\ \text{W/m}\cdot\text{K}\right) = 0.282\ \text{m}^2\cdot\text{K/W}\ \ \text{(for argon)}$$

$$R''_{t,\text{conv},i} = 1/h_i = 1/\left(7.7\ \text{W/m}^2\cdot\text{K}\right) = 0.130\ \text{m}^2\cdot\text{K/W}$$

$$R''_{t,rad} = \frac{1/\varepsilon_1 + 1/\varepsilon_2 - 1}{\sigma(T_1^2 + T_2^2)(T_1 + T_2)} \qquad (1)$$

Note that the radiation thermal resistance of Eq. 1 depends on the interior surface temperatures, T_1 and T_2. To avoid a tedious iterative procedure, IHT is used to solve three coupled algebraic equations that may be derived by equating the heat flux from T_i to T_1, from T_1 to T_2, and from T_2 to T_o.

Continued…

PROBLEM 13.101 (Cont.)

From T_i to T_1: $q'' = (T_i - T_1)/(R''_{t,conv,i} + R''_{t,cond,gl})$ (2)

From T_1 to T_2: $q'' = (T_1 - T_2)\left[\dfrac{1}{R''_{t,rad}} + \dfrac{1}{R''_{t,\text{cond},gs}}\right]$ (3)

From T_2 to T_o: $q'' = (T_2 - T_o)/(R''_{t,cond,gl} + R''_{t,conv,o})$ (4)

Solving Eqs. (2) through (3) simultaneously, using the resistance values and expressions provided above, yields the following results.

Gas	ε_1	ε_2	q″ (W/m^2)
air	0.95	0.95	106
	0.05	0.05	82.3
	0.05	0.95	83.2
argon	0.95	0.95	97.5
	0.05	0.05	66.5
	0.05	0.95	67.7

<

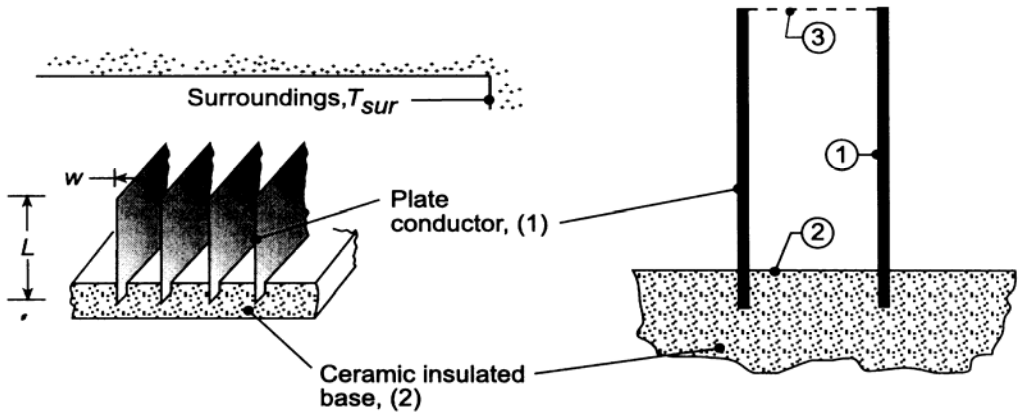
COMMENTS: (1) Switching the gas from air to argon reduces the heat flux in all cases. (2) Applying a low-emissivity coating to the glass reduces the heat flux in all cases. However, coating the interior surfaces of both glass sheets provides little benefit beyond that of coating one surface only. (3) If the gap between the glass sheets could be evacuated so that conduction in the gas becomes negligible, the heat flux through the window would be reduced significantly, to values of 72.6 and 6.98 and 3.67 W/m^2 for the cases 1, 2 and 3, respectively. (4) Natural convection in the gap was ignored. Is this a good assumption? (5) Radiation at the external surfaces of the glass sheets was ignored. Is this a good assumption?

PROBLEM 13.102

KNOWN: Electrical conductors in the form of parallel plates having one edge mounted to a ceramic insulated base. Plates exposed to large, isothermal surroundings, T_{sur}. Operating temperature is T_1 = 500 K.

FIND: (a) Electrical power dissipated in a conductor plate per unit length, q_1', considering only radiative exchange with the surroundings; temperature of the ceramic insulated base T_2; and, (b) q_1' and T_2 when the surfaces experience convection with an air stream at T_∞ = 300 K and a convection coefficient of h = 24 W/m^2·K.

SCHEMATIC:



ASSUMPTIONS: (1) Conductor surfaces are diffuse, gray, (2) Conductor and ceramic insulated base surfaces have uniform temperatures and radiosities, (3) Surroundings are large, isothermal.

ANALYSIS: (a) Define the opening between the conductivities as the hypothetical area A_3 at the temperature of the surroundings, T_{sur}, with an emissivity ε_3 = 1 since all the radiation incident on the area will be absorbed. The conductor (1)-base (2)-opening (3) form a three surface enclosure with one surface reradiating (2). From Eq. 13.30, the net radiation leaving the conductor surface A_1 is

$$q_1 = \frac{E_{b1} - E_{b3}}{\frac{1-\varepsilon_1}{\varepsilon_1 A_1} + \frac{1}{A_1 F_{13} + \left[\left(1/A_1 F_{12}\right) + \left(1/A_3 F_{32}\right)\right]^{-1}} + \frac{1-\varepsilon_3}{\varepsilon_3 A_3}} \quad (1)$$

where $E_{b1} = \sigma T_1^4$ and $E_{b3} = \sigma T_3^4 = J_3 = 5.67 \times 10^{-8}$ W/m$^2 \cdot$ K$^4 \times (300\ \text{K})^4 = 459\ \text{W/m}^2$. The view factors are evaluated as follows:

F_{32}: use the relation for two aligned parallel rectangles, Table 13.2 or Fig. 13.4,

$$\bar{X} = X/L = w/L = 10/40 = 0.25 \qquad \bar{Y} = Y/L = \infty$$

$$F_{32} = 0.1231$$

F_{13}: applying reciprocity between A_1 and A_3, where $A_1 = 2L\ell = 2 \times 0.040\ \text{m}\,\ell = 0.080\ \ell$ and $A_3 = w\ell = 0.010\ \ell$ and ℓ is the length of the conductors normal to the page, $\ell >>$ L or w,

$$F_{13} = \frac{A_3 F_{31}}{A_1} = 0.010\ell \times 0.8769 / 0.080\ell = 0.1096$$

where F_{31} can be obtained by using the summation rule on A_3,

$$F_{31} = 1 - F_{32} = 1 - 0.1231 = 0.8769$$

F_{12}: by symmetry $\qquad F_{12} = F_{13} = 0.1096$

Continued …

PROBLEM 13.102 (Cont.)

Substituting numerical values into Eq. (1), the net radiation leaving the conductor is

$$q_1 = \frac{5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left(500^4-300^4\right)\text{K}^4}{\dfrac{1-0.8}{0.8\times0.080\ell}+\dfrac{1}{0.080\ell\times0.1096+\left[\left(1/0.080\ell\times0.1096\right)+\left(1/0.010\ell\times0.123\right)\right]^{-1}}+0}$$

$$q_1' = q_1/\ell = \frac{(3544-459.3)\,\text{W}}{3.1250+101.557+0} = 29.5\ \text{W/m}$$ <

From Eq. 13.19,

$$J_1 = -\ q_1'\left[(1-\varepsilon_1)/(\varepsilon_1 2L)\right]+\sigma T_1^4$$
$$= -29.5\text{W/m}^2\left[(1-0.8)/(0.8\times2\times0.04\text{m})\right]+5.67\times10^{-8}\text{W/m}^2\cdot\text{K}^4\times(500\text{ K})^4$$
$$= 3452\ \text{W/m}^2$$

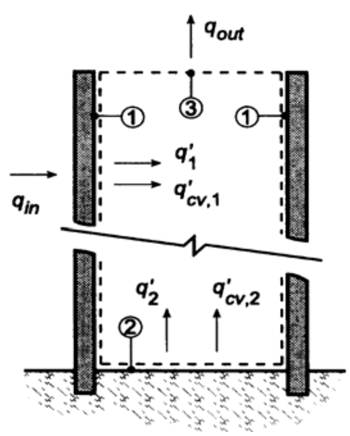
and from Eq. 13.31,

$$J_2 = \frac{J_1A_1F_{12}+J_3A_3F_{32}}{A_1F_{12}+A_3F_{32}} = \frac{3452\times2\times0.040\times.1096+459\times0.010\times0.1231}{2\times0.040\times.1096+0.010\times0.1231} = 3060\ \text{W/m}^2$$

which yields

$$T_2 = \left(\frac{J_2}{\sigma}\right)^{1/4} = \left(\frac{3060\ \text{W/m}^2}{5.67\times10^{-8}\ \text{W/m}^2\cdot\text{K}^4}\right)^{1/4} = 482\ \text{K}$$ <

(b) Consider now convection processes occurring at the conductor (1) and base (2) surfaces, and perform energy balances as illustrated in the schematic below.



Surface 1: The heat rate from the conductor includes convection and the net radiation heat rates,

$$q_{in} = q_{cv,1}+q_1 = h\,A_1\left(T_1-T_\infty\right)+\frac{E_{b1}-J_1}{(1-\varepsilon_1)/\varepsilon_1A_1} \quad (2)$$

Continued...

PROBLEM 13.102 (Cont.)

and the radiosity J_1 can be determined from the radiation energy balance, Eq. 13.15,

$$\frac{E_{b1} - J_1}{(1-\varepsilon_1)/\varepsilon_1 A_1} = \frac{J_1 - J_2}{1/A_1F_{12}} + \frac{J_1 - J_3}{1/A_1F_{13}} \quad (3)$$

where $J_3 = E_{b3} = \sigma T_3^4$ since A_3 is black.

Surface 2: Since the surface is insulated (adiabatic), the energy balance has the form

$$0 = q_{cv,2} + q_2 = hA_2 (T_2 - T_\infty) + \frac{E_{b2} - J_2}{1 - \varepsilon_2 / \varepsilon_2 A_2} \quad (4)$$

and the radiosity J_2 can be determined from the radiation energy balance, Eq. 13.21,

$$\frac{E_{b2} - J_2}{(1-\varepsilon_2)/\varepsilon_2 A_2} = \frac{J_2 - J_1}{1/A_2F_{21}} + \frac{J_2 - J_3}{1/A_2F_{23}} \quad (5)$$

There are 4 equations, Eqs. (2-5), with 4 unknowns: J_2, J_2, T_2 and q_1. Substituting numerical values, the simultaneous solution to the set yields

$$J_1 = 3417\ W/m^2 \qquad J_2 = 1745\ W/m^2 \qquad T_2 = 352\ K \qquad q'_{in} = 441\ W/m$$ <

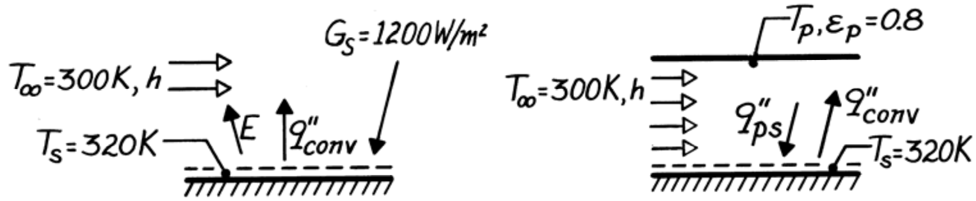
COMMENTS: (1) The effect of convection is substantial, increasing the heat removal rate from 29.5 W to 441 W for the combined modes. (2) With the convection process, the current carrying capacity of the conductors can be increased. Another advantage is that, with the presence of convection, the ceramic base operates at a cooler temperature: 352 K vs. 482 K.

PROBLEM 13.103

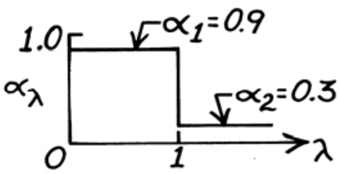
KNOWN: Surface temperature and spectral radiative properties. Temperature of ambient air. Solar irradiation or temperature of shield.

FIND: (a) Convection heat transfer coefficient when surface is exposed to solar radiation, (b) Temperature of shield needed to maintain prescribed surface temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Surface is diffuse ($\alpha_\lambda = \varepsilon_\lambda$), (2) Bottom of surface is adiabatic, (3) Atmospheric irradiation is negligible,
(4) With shield, convection coefficient is unchanged and radiation losses at ends are negligible (two-surface enclosure).



ANALYSIS: (a) From a surface energy balance,

$$\alpha_S G_S = \varepsilon_s \sigma T_s^4 + h\left(T_s - T_\infty\right).$$

Emission occurs mostly at long wavelengths, hence $\varepsilon_s = \alpha_2 = 0.3$. However,

$$\alpha_S = \frac{\int_0^\infty \alpha_\lambda E_{\lambda,b}\left(\lambda, 5800\text{ K}\right)d\lambda}{E_b} = \alpha_1 F_{\left(0-1\mu m\right)} + \alpha_2 F_{\left(1-\infty\right)}$$

and from Table 12.1 at $\lambda T = 5800\ \mu m\cdot K$, $F_{(0-1\mu m)} = 0.720$ and hence, $F_{(1-\infty)} = 0.280$ giving

$$\alpha = 0.9\times 0.72 + 0.3\times 0.280 = 0.732.$$

Hence

$$h = \frac{\alpha_S G_S - \varepsilon\sigma T_s^4}{T_s - T_\infty} = \frac{0.732\left(1200\text{ W/m}^2\right) - 0.3\times 5.67\times 10^{-8}\text{W/m}^2\cdot K^4\left(320\text{ K}\right)^4}{20\text{ K}}$$

$$h = 35\text{ W/m}^2\cdot K. \qquad <$$

(b) Since the plate emits mostly at long wavelengths, $\alpha_s = \varepsilon_s = 0.3$. Hence radiation exchange is between two diffuse-gray surfaces.

$$q''_{ps} = \frac{\sigma\left(T_p^4 - T_s^4\right)}{1/\varepsilon_p + 1/\varepsilon_s - 1} = q''_{conv} = h\left(T_s - T_\infty\right)$$

$$T_p^4 = \left(h/\sigma\right)\left(T_s - T_\infty\right)\left(1/\varepsilon_p + 1/\varepsilon_s - 1\right) + T_s^4$$

$$T_p^4 = \frac{35\text{ W/m}^2\cdot K\left(20\text{ K}\right)}{5.67\times 10^{-8}\text{W/m}^2\cdot K^4}\left(\frac{1}{0.8} + \frac{1}{0.3} - 1\right) + \left(320\text{ K}\right)^4 \qquad T_p = 484\text{ K}. \qquad <$$

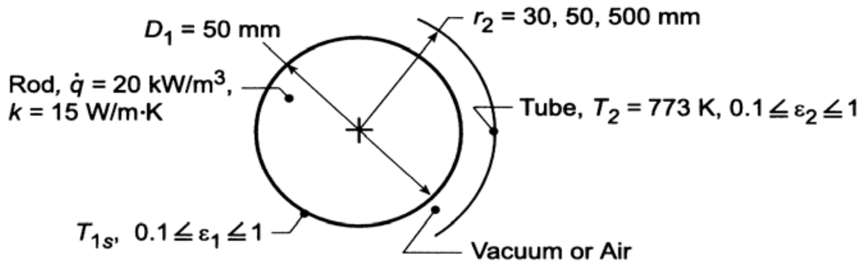
COMMENTS: For $T_p = 484$ K and $\lambda = 1\ \mu m$, $\lambda T = 484\ \mu m\cdot K$ and $F_{(0-\lambda)} = 0.000$. Hence assumption of $\alpha_s = 0.3$ is excellent.

PROBLEM 13.104

KNOWN: Long uniform rod with volumetric energy generation positioned coaxially within a larger circular tube maintained at 500°C.

FIND: (a) Center $T_1(0)$ and surface T_{1s} temperatures of the rod for evacuated space, (b) $T_1(0)$ and T_{1s} for airspace, (c) Effect of tube diameter and emissivity on $T_1(0)$ and T_{1s}.

SCHEMATIC:



ASSUMPTIONS: (1) All surfaces are diffuse-gray.

PROPERTIES: *Table A-4*, Air ($\overline{T}$ = 780 K): $\nu = 81.5 \times 10^{-6}$ m^2/s, k = 0.0563 W/m·K, $\alpha = 115.6 \times 10^{-6}$ m^2/s, β = 0.00128K^{-1}, Pr = 0.706.

ANALYSIS: (a) The net heat exchange by radiation between the rod and the tube is

$$q'_{12} = \frac{\sigma\left(T_1^4 - T_2^4\right)}{\left(1-\varepsilon_1\right)/\varepsilon_1\pi D_1 + 1/\pi D_1 F_{12} + \left(1-\varepsilon_2\right)/\varepsilon_2\pi D_2} \qquad (1)$$

and, from an energy balance on the rod, $-\dot{E}'_{out} + \dot{E}'_{gen} = 0$, or

$$q'_{12} = \dot{q}\left(\pi D_1^2/4\right). \qquad (2)$$

Combining Eqs. (1) and (2) and substituting numerical values, with $F_{12} = 1$, we obtain

$$\dot{q} = \frac{4}{D_1}\left[\frac{\sigma\left(T_1^4 - T_2^4\right)}{\left(1-\varepsilon_1\right)/\varepsilon_1 + 1 + \left[\left(1-\varepsilon_2\right)/\varepsilon_2\right]\left(D_1/D_2\right)}\right]$$

$$20\times10^3\,\frac{W}{m^3} = \frac{4}{0.050m}\left[\frac{5.67\times10^{-8}\,W/m^2\cdot K^4\left(T_{1s}^4 - 773^4\right)K^4}{\left(1-0.2\right)/0.2 + 1 + \left[\left(1-0.2\right)/0.2\right]\left(0.050/0.060\right)}\right]$$

$$= 54.4\times10^{-8}\left(T_{1s}^4 - 773^4\right)\,W/m^3$$

$$T_{1s} = 792\ K. \qquad <$$

From Eq. 3.53, the rod center temperature is

$$T_1(0) = \frac{\dot{q}\left(D_1/2\right)^2}{4k} + T_{1s}$$

$$T_1(0) \approx \frac{20\times10^3\,W/m^3\left(0.050\,m/2\right)^2}{4\times15\,W/m\cdot K} + 792\ K = 0.21\ K + 792\ K = 792.2\ K. \qquad <$$

(b) The convection heat rate is given by Eqs. 9.58 through 9.60. The length scale is $L_c = 2[\ln(0.06/0.05)]^{4/3}/(0.025\ m^{-3/5} + 0.030\ m^{-3/5})^{5/3}$ = 0.0018 m. Assuming a maximum possible value of $(T_{s1} - T_2)$ = 19 K, $Ra_c = g\beta(T_{s1} - T_2)L_c^3/\nu\alpha$ = 9.8 m/s^2(0.00128 K^{-1})19 K (0.0018 m)^3/(81.5 × 10^{-6} m^2/s × 115.6 × 10^{-6} m^2/s) = 0.142 and k_{eff}/k = 0.386×[0.706/(0.861 + 0.706)]$^{1/4}$(0.142)$^{1/4}$ = 0.194. Since k_{eff}/k is predicted to be less than unity, conduction occurs within the gap.

Continued …

PROBLEM 13.104 (Cont.)

Hence, from Eq. 3.32,

$$q'_{cond} = \frac{2\pi k\left(T_{1s} - T_2\right)}{\ln\left(r_2 / r_1\right)} = \frac{2\pi\left(0.0563\ W/m\cdot K\right)\left(T_{1s} - 773\right)K}{\ln\left(30/25\right)} = 1.94\left(T_{1s} - 773\right)$$

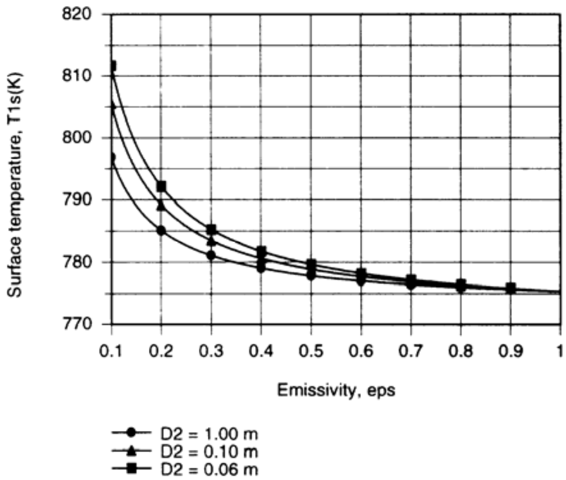
The energy balance then becomes $\dot{q}\left(\pi D_1^2 / 4\right) = q'_{12} + q'_{cond}$, or

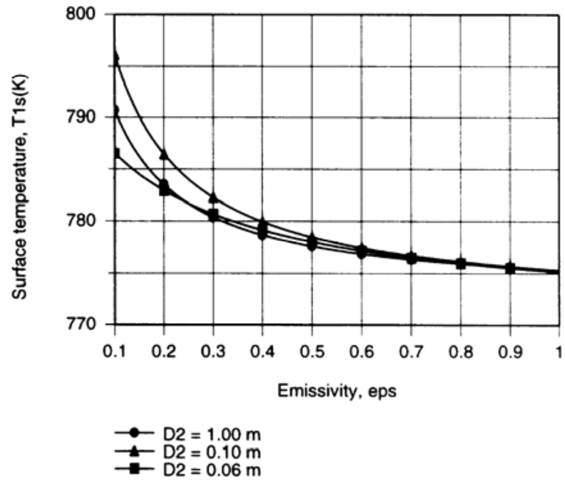
$$\dot{q} = \left(4/\pi D_1^2\right)\left(q'_{12} + q'_{cond}\right)$$

$$2\times10^4 = \left[54.4\times10^{-8}\left(T_{1s}^4 - 773^4\right) + 988\left(T_{1s} - 773\right)\right]$$

$$T_{1s} = 783\ K \qquad T_1(0) = 783.2\ K$$

(c) Entering the foregoing model and the prescribed properties of air into the *IHT* workspace, the parametric calculations were performed for D_2 = 0.06 m and D_2 = 0.10 m. For D_2 = 1.0 m, $Ra_c^* > 100$ and heat transfer across the airspace is by free convection, instead of conduction. In this case, convection was evaluated by entering Eqs. 9.58 – 9.60 into the workspace. The results are plotted as follows.





The first graph corresponds to the evacuated space, and the surface temperature decreases with increasing $\varepsilon_1 = \varepsilon_2$, as well as with D_2. The increased emissivities enhance the effectiveness of emission at surface 1 and absorption at surface 2, both which have the effect of reducing T_{1s}. Similarly, with increasing D_2, more of the radiation emitted from surface 1 is ultimately absorbed at 2 (less of the radiation reflected by surface 2 is intercepted by 1). The second graph reveals the expected effect of a reduction in T_{1s} with inclusion of conduction or convection heat transfer across the air. For small emissivities ($\varepsilon_1 = \varepsilon_2 < 0.2$), conduction across the air is significant relative to radiation, and the small conduction resistance corresponding to D_2 = 0.06 m yields the smallest value of T_{1s}. However, with increasing ε, conduction/convection effects diminish relative to radiation and the trend reverts to one of decreasing T_{1s} with increasing D_2.

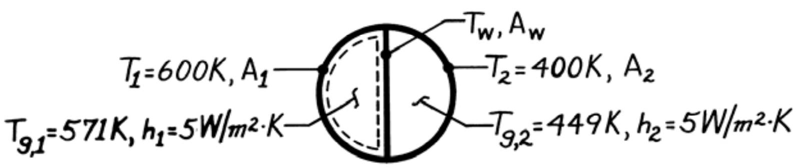
COMMENTS: For this situation, the temperature variation *within* the rod is small and independent of surface conditions.

PROBLEM 13.105

KNOWN: Side wall and gas temperatures for adjoining semi-cylindrical ducts. Gas flow convection coefficients.

FIND: (a) Temperature of intervening wall, (b) Verification of gas temperature on one side.

SCHEMATIC:



ASSUMPTIONS: (1) All duct surfaces may be approximated as blackbodies, (2) Fully developed conditions, (3) Negligible temperature difference across intervening wall, (4) Gases are nonparticipating media.

ANALYSIS: (a) Applying an energy balance to a control surface about the wall yields

$$\dot{E}_{in} = \dot{E}_{out}.$$

Assuming $T_{g,1} > T_w > T_{g,2}$, it follows that

$$q_{rad(1\to w)} + q_{conv(g1\to w)} = q_{rad(w\to 2)} + q_{conv(w\to g2)}$$

$$A_1F_{1w}\sigma\left(T_1^4 - T_w^4\right) + hA_w\left(T_{g,1} - T_w\right) = A_wF_{w2}\sigma\left(T_w^4 - T_2^4\right) + hA_w\left(T_w - T_{g,2}\right)$$

and with

$$A_1F_{1w} = A_wF_{w1} = A_wF_{w2} = A_w$$

and substituting numerical values,

$$2\sigma T_w^4 + 2hT_w = \sigma\left(T_1^4 + T_2^4\right) + h\left(T_{g,1} + T_{g,2}\right)$$

$$11.34\times10^{-8}T_w^4 + 10T_w = 13,900.$$

which yields

$$T_w \approx 526\ \text{K}.$$ <

(b) Applying an energy balance to a control surface about the hot gas (g1) yields

$$\dot{E}_{in} = \dot{E}_{out}$$

$$hA_1\left(T_1 - T_{g1}\right) = hA_w\left(T_{g1} - T_w\right)$$

or

$$T_1 - T_{g1} = \left[D/\left(\pi D/2\right)\right]\left(T_{g1} - T_w\right)$$

$$29°\text{C} = 29°\text{C}.$$ <

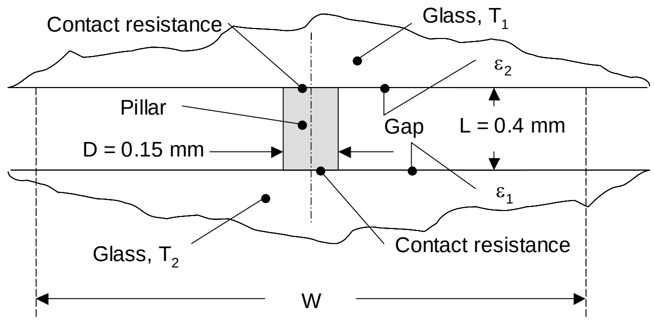
COMMENTS: Since there is no change in any of the temperatures in the axial direction, this scheme simply provides for energy transfer from side wall 1 to side wall 2.

PROBLEM 13.106

KNOWN: Dimensions of stainless steel pillar and nominal glass temperatures. Contact resistance between pillar and glass. Emissivity of inner glass surfaces. Unit area dimensions.

FIND: Ratio of conduction to radiation heat transfer through a unit area.

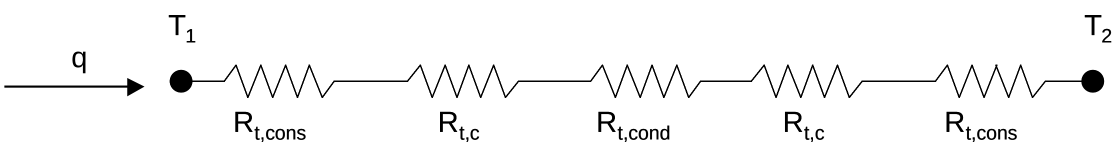
SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties, (3) Diffuse-gray surfaces, (4) Two-dimensional conduction, (5) Pillar does not affect radiation heat transfer ($D/W \ll 1$), (6) Radiation heat transfer does not affect conduction in low-emissivity stainless steel pillar.

PROPERTIES: *Table A.1*, AISI 302 stainless steel (300 K): k_p = 15.1 W/m·K. *Table A.3*, plate glass (300 K): k_g = 1.4 W/m·K.

ANALYSIS: The conduction and radiation processes are decoupled. Conduction through the pillar results in a depression of the glass temperature in the immediate vicinity of the pillar. This is associated with a constriction resistance within each glass sheet. Therefore, the resistance network consists of two constriction resistances, two contact resistances, and a conduction resistance through the pillar as shown below.



Using the shape factor for Case 10 of Table 4.1(a), the resistances are:

$$R_{t,\text{cons}} = 1/(Sk_g) = 1/(2Dk_g) = 1/(2\times 0.15\times 10^{-3}\text{m}\times 1.4\text{ W/m}\cdot\text{K}) = 2381\text{ K/W}$$

$$R_{t,\text{c}} = R''_{t,c}/A_p = 1.5\times 10^{-6}\text{m}^2\cdot\text{K/W}/\left[\pi\times\left(0.15\times 10^{-3}\text{m}\right)^2/4\right] = 84.88\text{ K/W}$$

$$R_{t,\text{cond}} = L/k_pA_p = L/k_p\left(\pi D_p^2/4\right) = 0.4\times 10^{-3}\text{ m}/\left[15.1\text{ W/m}\cdot\text{K}\times\pi\times\left(0.15\times 10^{-3}\text{ m}\right)^2/4\right] = 1500\text{ K/W}$$

Therefore, the total resistance is

$R_{tot} = 2(R_{t,cons} + R_{t,c}) + R_{t,cond} = 2 \times (2381\text{ K/W} + 84.88\text{ K/W}) + 1500\text{ K/W} = 6430\text{ K/W}$

and the conduction through an individual pillar is

$q_{\text{cond}} = (T_1 - T_2)/R_{tot} = [20 - (-10)°\text{C}]/[6430\text{ K/W}] = 4.66 \times 10^{-3}\text{ W} = 4.66\text{ mW}$

Continued…

PROBLEM 13.106 (Cont.)

For W = 10 mm, net radiation heat rate between the glass sheets through the unit area is

$$q_{\text{rad},10} = \frac{W^2\sigma\left(T_1^4 - T_2^4\right)}{\frac{1}{\varepsilon_1}+\frac{1}{\varepsilon_2}-1} = \frac{(0.01\text{ m})^2\, 5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left(293\text{K}^4 - 263\text{K}^4\right)}{\frac{1}{0.95}+\frac{1}{0.05}-1} = 0.73\times10^{-3}\text{ W} = 0.73\text{ mW}$$

Similarly, for W = 20 and 30 mm, $q_{\text{rad},20}$ = 2.9 mW ; $q_{\text{rad},30}$ = 6.6 mW. Therefore, the ratio of conduction to radiation through a unit area is

$$R = 6.38,\ 1.59,\ \text{and}\ 0.709$$ <

for W = 10, 20 and 30 mm, respectively.

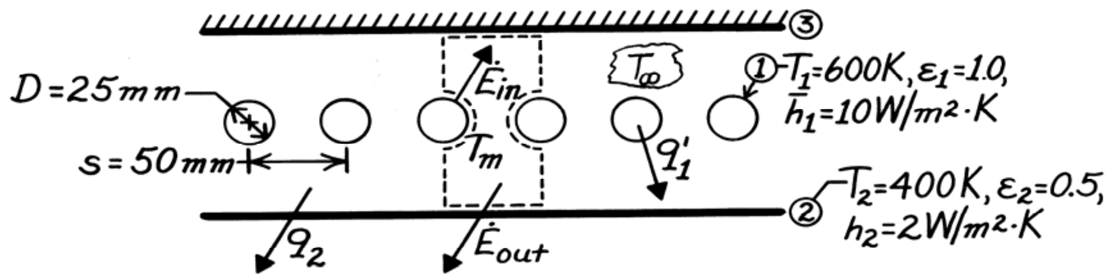
COMMENTS: (1) Although the pillars are small, they account for a large amount of the total heat transfer through the window, especially for small values of W. (2) The radiation and conduction effects become coupled in the immediate vicinity of the pillar. (3) Temperature differences also exist across the glass sheets, however these differences are relatively small. For W = 10 mm, and for a glass sheet thickness of t = 6 mm, the temperature difference across one sheet of glass may be estimated to be $\Delta T = (q_{\text{rad},10} + q_{\text{cond}})t/(k_g W^2) = (0.73\times10^{-3}\text{ W} + 4.66\times10^{-3}\text{W})\times 0.006\text{m}/(1.4\text{ W/m}\cdot\text{K}\times 0.01\text{ m}\times 0.01\text{m}) = 0.23$ K. (4) Heat transfer through the window can be reduced by increasing the pillar length. However, practical limitations exist since sealing the edges of the window in order to maintain a high vacuum becomes more difficult as L increases. (5) See Manz, Brunner and Wullschleger, "Triple Vacuum Glazing: Heat Transfer and Basic Design Constraints," *Solar Energy*, Vol. 80, pp. 1632-1642, 2006 for more information.

PROBLEM 13.107

KNOWN: Temperature, dimensions and arrangement of heating elements between two large parallel plates, one insulated and the other of prescribed temperature. Convection coefficients associated with elements and bottom surface.

FIND: (a) Temperature of gas enclosed by plates, (b) Element electric power requirement, (c) Rate of heat transfer to 1 m × 1m section of panel.

SCHEMATIC:



ASSUMPTIONS: (1) Diffuse-gray surfaces, (2) Negligible end effects since the surfaces form an enclosure, (3) Gas is nonparticipating, (4) Surface 3 is reradiating with negligible conduction and convection.

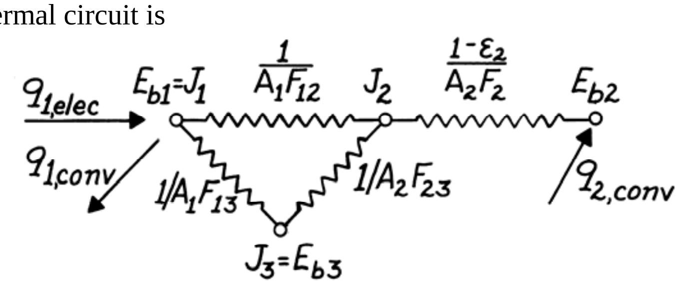
ANALYSIS: (a) Performing an energy balance for a unit control surface about the gas space, $\dot{E}_{in} - \dot{E}_{out} = 0.$

$$\bar{h}_1 \pi D\left(T_1 - T_m\right) - \bar{h}_2 s\left(T_m - T_2\right) = 0$$

$$T_m = \frac{\bar{h}\pi D T_1 + \bar{h}_2 s T_2}{\bar{h}_1 \pi D + \bar{h}_2 s} = \frac{10\ \text{W/m}^2\cdot\text{K}\pi\left(0.025\ \text{m}\right)600\ \text{K} + 2\ \text{W/m}^2\cdot\text{K}\left(0.05\ \text{m}\right)400\ \text{K}}{10\ \text{W/m}^2\cdot\text{K}\,\pi\left(0.025\ \text{m}\right) + 2\ \text{W/m}^2\cdot\text{K}\left(0.05\ \text{m}\right)}$$

$$T_m = 577\ \text{K}.$$ <

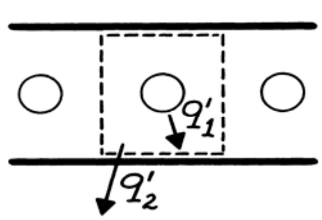
(b) The equivalent thermal circuit is



The energy balance on surface 1 is

$$q'_{1,elec} = q'_{1,conv} + q'_{1,rad}$$

where $q'_{1,rad}$ can be evaluated by considering a unit cell of the form



$$A'_1 = \pi D = \pi\left(0.025\ \text{m}\right) = 0.0785\ \text{m}$$
$$A'_2 = A'_3 = s = 0.05\ \text{m}$$

Continued …

PROBLEM 13.107 (Cont.)

The view factors are:

$$F_{21} = 1 - \left[1 - (D/s)^2\right]^{1/2} + (D/s)\tan^{-1}\left[\left(s^2 - D^2\right)/D^2\right]^{1/2}$$

$$F_{21} = 1 - [1 - 0.25]^{1/2} + 0.5\tan^{-1}(4-1)^{1/2} = 0.658 = F_{31}$$

$$F_{23} = 1 - F_{21} = 0.342 = F_{32}.$$

For the unit cell,

$$A_2'F_{21} = sF_{21} = 0.05\ \text{m} \times 0.658 = 0.0329\ \text{m} = A_1'F_{12} = A_3'F_{31} = A_1'F_{13}$$

$$A_2'F_{23} = sF_{23} = 0.05\ \text{m} \times 0.342 = 0.0171\ \text{m} = A_3'F_{32}.$$

Hence,

$$q'_{1,\text{rad}} = \frac{E_{b1} - E_{b2}}{R'_{\text{equiv}} + (1-\varepsilon_2)/\varepsilon_2 A_2'}$$

$$R'^{-1}_{\text{equiv}} = A_1'F_{12} + \frac{1}{1/A_1'F_{13} + 1/A_2'F_{23}} = \left(0.0329 + \frac{1}{(0.0329)^{-1} + (0.0171)^{-1}}\right)\text{m}$$

$$R'_{\text{equiv}} = 22.6\ \text{m}^{-1}.$$

Hence

$$q'_{1,\text{rad}} = \frac{5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left(600^4 - 400^4\right)\text{K}^4}{\left[22.6 + (1-0.5)/0.5\times0.05\right]\text{m}^{-1}} = 138.3\ \text{W/m}$$

$$q'_{1,\text{conv}} = \bar{h}_1\pi D(T_1 - T_m) = 10\ \text{W/m}^2\cdot\text{K}\,\pi(0.025\ \text{m})(600-577)\text{K} = 17.8\ \text{W/m}$$

$$q'_{1,\text{elec}} = (138.3 + 17.8)\,\text{W/m} = 156\ \text{W/m}.$$ <

(c) Since all energy added via the heating elements must be transferred to surface 2,

$$q_2' = q_1'.$$

Hence, since there are 20 elements in a 1 m wide strip,

$$q_{2(1\text{m}\times1\text{m})} = 20 \times q'_{1,\text{elec}} = 3120\ \text{W}.$$ <

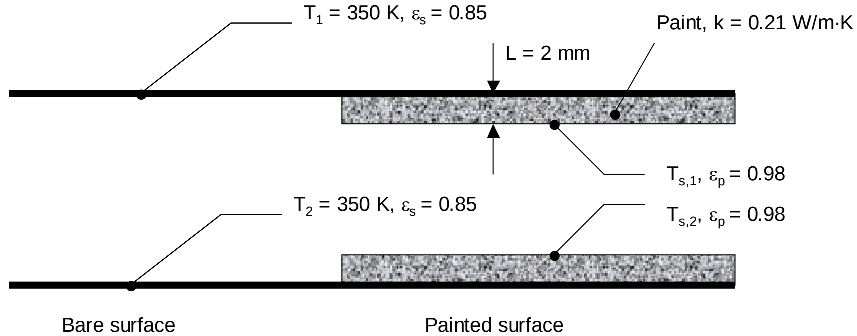
COMMENTS: The bottom panel would have to be cooled (from below) by a heat sink which could dissipate 3120 W/m^2.

PROBLEM 13.108

KNOWN: Two large parallel plates, temperature of each plate. Bare plate and paint emissivities, thickness of paint layers.

FIND: (a) Radiation heat flux across the gap for $\varepsilon_1 = \varepsilon_2 = \varepsilon_s = 0.85$, (b) Radiation heat flux across the gap for $\varepsilon_1 = \varepsilon_2 = \varepsilon_p = 0.98$, (c) Radiation heat flux across the gap when the paint layer thickness is L = 2 mm and paint thermal conductivity is k = 0.21 W/m·K, (d) Plot of the radiation heat flux across the gap as a function of the surface emissivity over the range $0.05 \le \varepsilon_s \le 0.95$. Show the heat flux of the painted surface with thin and thick paint layers on the same graph.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional heat transfer, (2) Diffuse, gray surfaces, (3) Negligible contact resistance between the plate and the paint.

PROPERTIES: Paint (given): k = 0.21 W/m·K.

ANALYSIS: (a) The radiation heat flux across the gap is

$$q''_{rad} = \frac{\sigma\left(T_1^4 - T_2^4\right)}{\frac{1}{\varepsilon_1} + \frac{1}{\varepsilon_2} - 1} = \frac{5.67\times10^{-8}\,\frac{W}{m^2\cdot K^4}\times\left(350^4 - 300^4\right)K^4}{\frac{1}{0.85} + \frac{1}{0.85} - 1} = 289.4\ \frac{W}{m^2} \qquad (1) <$$

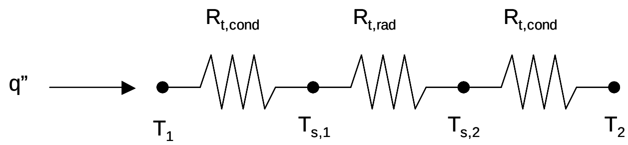
(b) With $\varepsilon_1 = \varepsilon_2 = \varepsilon_p = 0.98$,

$$q''_{rad} = \frac{5.67\times10^{-8}\,\frac{W}{m^2\cdot K^4}\times\left(350^4 - 300^4\right)K^4}{\frac{1}{0.98} + \frac{1}{0.98} - 1} = 376.2\ \frac{W}{m^2} \qquad <$$

(c) After painting both surfaces, the thermal resistance network is

Continued…

PROBLEM 13.108 (Cont.)



$$q'' = \frac{k_p}{L_p}\left(T_1 - T_{s,1}\right) = \frac{0.21\frac{W}{m\cdot K}}{2\times10^{-3}m}\left(350K - T_{s,1}\right) \quad (2)$$

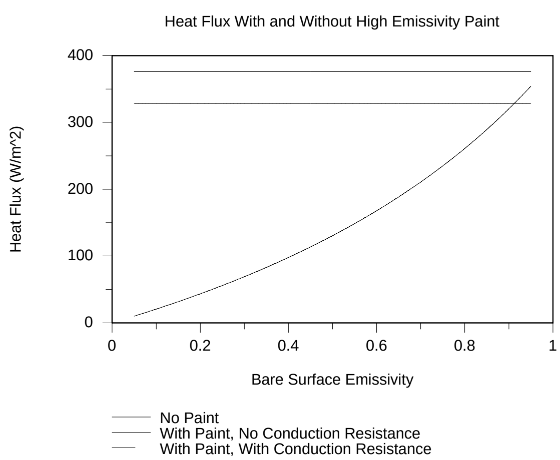
$$q'' = \frac{\sigma\left(T_{s,1}^4 - T_{s,2}^4\right)}{\frac{1}{\varepsilon_p}+\frac{1}{\varepsilon_p}-1} = \frac{5.67\times10^{-8}\frac{W}{m^2\cdot K^4}}{\frac{1}{0.98}+\frac{1}{0.98}-1} \quad (3)$$

$$q'' = \frac{k_p}{L_p}\left(T_{s,2} - T_2\right) = \frac{0.21\frac{W}{m\cdot K}}{2\times10^{-3}m}\left(T_{s,2} - 300K\right) \quad (4)$$

Solving Eqs. (2) through (4) simultaneously yields

$$T_{s,1} = 346.9\text{ K},\ T_{s,2} = 303.1\text{ K},\ q'' = q''_{rad} = q''_{cond} = 328.7\frac{W}{m^2}$$ <

(d) Solving Eq. (1) over the range $0.05 \le \varepsilon \le 0.95$ yields the following.



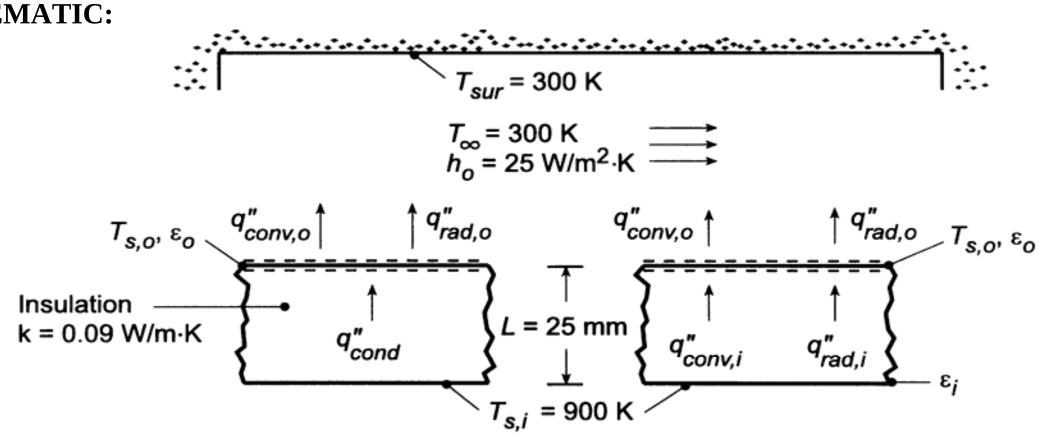
COMMENTS: (1) The paint is effective in increasing radiation heat transfer across the gap for all but very high emissivity bare surfaces. (2) Thick paint layers will result in significant thermal conduction resistances which, in turn, reduce heat transfer across the gap. (3) Use of paints is usually restricted to relatively low temperatures. (4) Thermal contact resistances may be large if flaking or peeling of the paint becomes significant.

PROBLEM 13.109

KNOWN: Ceiling temperature of furnace. Thickness, thermal conductivity, and/or emissivities of alternative thermal insulation systems. Convection coefficient at outer surface and temperature of surroundings.

FIND: (a) Mathematical model for each system, (b) Temperature of outer surface $T_{s,o}$ and heat loss q'' for each system and prescribed conditions, (c) Effect of emissivity on $T_{s,o}$ and q''.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Diffuse/gray surfaces, (3) Surroundings form a large enclosure about the furnace, (4) Radiation in air space corresponds to a two-surface enclosure of large parallel plates.

PROPERTIES: *Table A-4*, air (T_f = 730 K): k = 0.055 W/m·K, $\alpha = 1.09 \times 10^{-4}$ m²/s, $\nu = 7.62 \times 10^{-5}$ m²/s, $\beta = 0.001335$ K^{-1}, Pr = 0.702.

ANALYSIS: (a) To obtain $T_{s,o}$ and q'', an energy balance must be performed at the outer surface of the shield.

Insulation: $q''_{cond} = q''_{conv,o} + q''_{rad,o} = q''$

$$k\frac{\left(T_{s,i} - T_{s,o}\right)}{L} = h_o\left(T_{s,o} - T_\infty\right) + \varepsilon_o\sigma\left(T_{s,o}^4 - T_{sur}^4\right)$$

Air Space: $q''_{conv,i} + q''_{rad,i} = q''_{conv,o} + q''_{rad,o} = q''$

$$h_i\left(T_{s,i} - T_{s,o}\right) + \frac{\sigma\left(T_{s,i}^4 - T_{s,o}^4\right)}{\frac{1}{\varepsilon_i} + \frac{1}{\varepsilon_o} - 1} = h_o\left(T_{s,o} - T_\infty\right) + \varepsilon_o\sigma\left(T_{s,o}^4 - T_{sur}^4\right)$$

where Eq. 13.24 has been used to evaluate $q''_{rad,i}$ and h_i is given by Eq. 9.49

$$\overline{Nu}_L = \frac{h_i L}{k} = 0.069 Ra_L^{1/3} Pr^{0.074}$$

(b) For the prescribed conditions ($\varepsilon_i = \varepsilon_o = 0.5$), the following results were obtained.

Insulation: The energy equation becomes

$$\frac{0.09\ \text{W/m}\cdot\text{K}\left(900 - T_{s,o}\right)\text{K}}{0.025\,\text{m}} = 25\ \text{W/m}^2\cdot\text{K}\left(T_{s,o} - 300\right)\text{K} + 0.5 \times 5.67 \times 10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left(T_{s,o}^4 - 300^4\right)\text{K}^4$$

Continued …

PROBLEM 13.109 (Cont.)

and a trial-and-error solution yields

$$T_{s,o} = 366\ K \qquad q'' = 1920\ W/m^2$$ <

Air-Space: The energy equation becomes

$$h_i\left(900 - T_{s,o}\right)K + \frac{5.67\times10^{-8}\,W/m^2\cdot K^4\left(900^4 - T_{s,o}^4\right)K^4}{3}$$
$$= 25\,W/m^2\cdot K\left(T_{s,o} - 300\right)K + 0.5\times5.67\times10^{-8}\,W/m^2\cdot K^4\left(T_{s,o}^4 - 300^4\right)K^4$$

where

$$h_i = \frac{0.055\ W/m\cdot K}{0.025\ m}0.069\,Ra_L^{1/3}\,Pr^{0.074} \qquad (1)$$

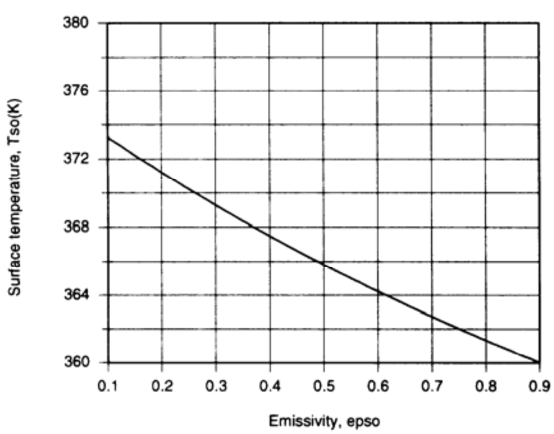
and $Ra_L = g\beta(T_{s,i} - T_{s,o})L^3/\alpha\nu$. A trial-and-error solution, which includes reevaluation of the air properties, yields

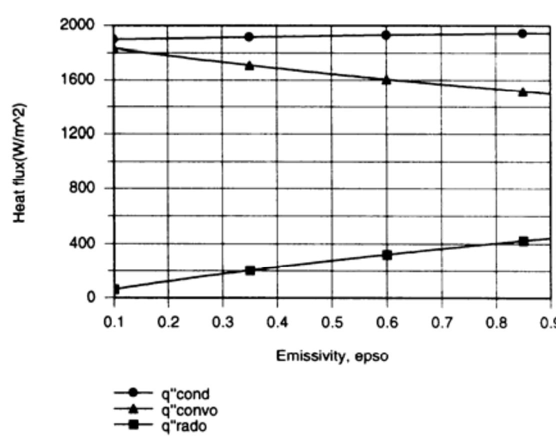
$$T_{s,o} = 598\ K \qquad q'' = 10{,}849\ W/m^2$$ <

The inner and outer heat fluxes are $q''_{conv,i} = 867\ W/m^2$, $q''_{rad,i} = 9982\ W/m^2$, $q''_{conv,o}$ = 7452 W/m^2, and $q''_{rad,o} = 3397\ W/m^2$.

(c) Entering the foregoing models into the *IHT* workspace, the following results were generated.

Insulation:

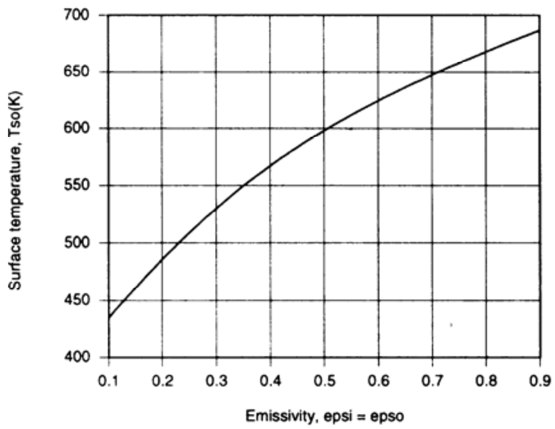


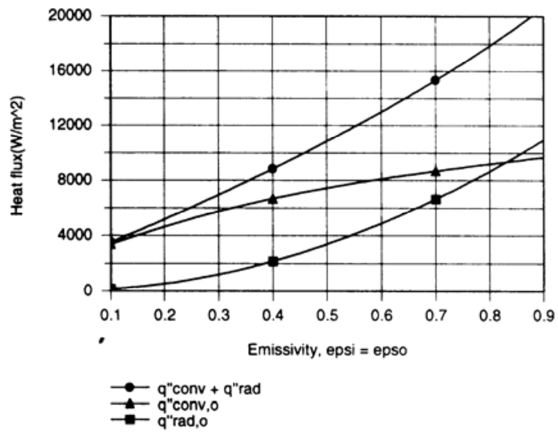


Continued …

PROBLEM 13.109 (Cont.)

As expected, the outer surface temperature decreases with increasing ε_o. However, the reduction in $T_{s,o}$ is not large since heat transfer from the outer surface is dominated by convection.





In this case $T_{s,o}$ increases with increasing $\varepsilon_o = \varepsilon_i$ and the effect is significant. The effect is due to an increase in radiative transfer from the inner surface, with $q''_{rad,i} = q''_{conv,i} = 1750 \text{ W/m}^2$ for $\varepsilon_o = \varepsilon_i = 0.1$ and $q''_{rad,i} = 20{,}100 \text{ W/m}^2 >> q''_{conv,i} = 523 \text{ W/m}^2$ for $\varepsilon_o = \varepsilon_i = 0.9$. With the increase in $T_{s,o}$, the total heat flux increases, along with the relative contribution of radiation $\left(q''_{rad,o}\right)$ to heat transfer from the outer surface.

COMMENTS: (1) With no insulation or radiation shield and $\varepsilon_i = 0.5$, radiation and convection heat fluxes from the ceiling are 18,370 and 15,000 W/m^2, respectively. Hence, a significant reduction in the heat loss results from use of the insulation or the shield, although the insulation is clearly more effective.

(2) Rayleigh numbers associated with free convection in the air space are well below the lower limit of applicability of Eq. (1). Hence, the correlation was used outside its designated range, and the error associated with evaluating h_i may be large.

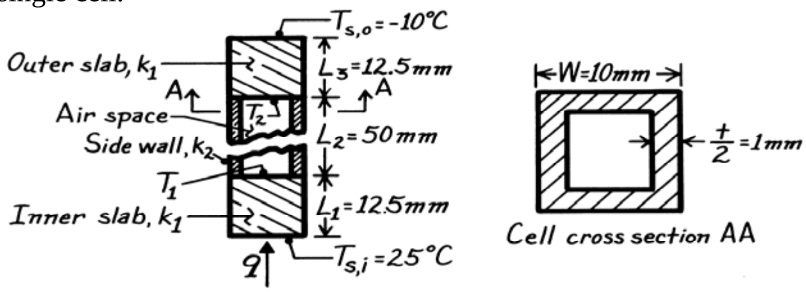
(3) The *IHT* solver had difficulty achieving convergence in the first calculation performed for the radiation shield, since the energy balance involves two nonlinear terms due to radiation and one due to convection. To obtain a solution, a fixed value of Ra_L was prescribed for Eq. (1), while a second value of $Ra_{L,2} \equiv g\beta(T_{s,i} - T_{s,o})L^3/\alpha\nu$ was computed from the solution. The prescribed value of Ra_L was replaced by the value of $Ra_{L,2}$ and the calculations were repeated until $Ra_{L,2} = Ra_L$.

PROBLEM 13.110

KNOWN: Dimensions of a composite insulation consisting of honeycomb core sandwiched between solid slabs.

FIND: Total thermal resistance.

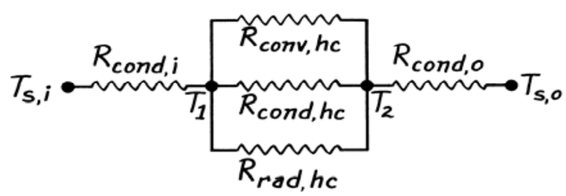
SCHEMATIC: Because of the repetitive nature of the honeycomb core, the cell sidewalls will be adiabatic. That is, there is no lateral heat transfer from cell to cell, and it suffices to consider the heat transfer across a single cell.



ASSUMPTIONS: (1) One-dimensional, steady-state conditions, (2) Equivalent conditions for each cell, (3) Constant properties, (4) Diffuse, gray surface behavior.

PROPERTIES: *Table A-3*, Particle board (low density): $k_1 = 0.078$ W/m·K; Particle board (high density): $k_2 = 0.170$ W/m·K; For both board materials, $\varepsilon = 0.85$; *Table A-4*, Air ($\overline{T} \approx 7.5°C$, 1 atm): $\nu = 14.15 \times 10^{-6}$ m^2/s, k = 0.0247 W/m·K, $\alpha = 19.9 \times 10^{-6}$ m^2/s, Pr = 0.71, $\beta = 3.57 \times 10^{-3}$ K^{-1}.

ANALYSIS: The total resistance of the composite is determined by conduction, convection and radiation processes occurring within the honeycomb and by conduction across the inner and outer slabs. The corresponding thermal circuit is shown.



The total resistance of the composite and equivalent resistance for the honeycomb are

$$R = R_{cond,i} + R_{eq} + R_{cond,o} \qquad R_{eq}^{-1} = \left(R_{cond}^{-1} + R_{conv}^{-1} + R_{rad}^{-1}\right)_{hc}.$$

The component resistances may be evaluated as follows. The inner and outer slabs are plane walls, for which the thermal resistance is given by Eq. 3.6. Hence, since $L_1 = L_3$ and the slabs are constructed from low-density particle board.

$$R_{cond,i} = R_{cond,o} = \frac{L_1}{k_1 W^2} = \frac{0.0125\ \text{m}}{0.078\ \text{W/m}\cdot\text{K}\left(0.01\ \text{m}\right)^2} = 1603\ \text{K/W}.$$

Similarly, applying Eq. 3.6 to the side walls of the cell

$$R_{cond,hc} = \frac{L_2}{k_2\left[W^2 - (W-t)^2\right]} = \frac{L_2}{k_2\left(2Wt - t^2\right)}$$

$$= \frac{0.050\ \text{m}}{0.170\ \text{W/m}\cdot\text{K}\left[2\times 0.01\ \text{m}\times 0.002\ \text{m} - (0.002\ \text{m})^2\right]} = 8170\ \text{K/W}.$$

Continued …

PROBLEM 13.110 (Cont.)

From Eq. 3.9 the convection resistance associated with the cellular airspace may be expressed as

$$R_{conv,hc} = 1/h(W-t)^2.$$

The cell forms an enclosure that may be classified as a horizontal cavity heated from below, and the appropriate form of the Rayleigh number is $Ra_L = g\beta(T_1 - T_2)L_2^3/\alpha\nu$. To evaluate this parameter, however, it is necessary to *assume* a value of the cell temperature difference. As a first approximation, $T_1 - T_2 = 15°C - (-5°C) = 20°C$,

$$Ra_L = \frac{9.8\ m/s^2\left(3.57\times10^{-3}K^{-1}\right)(20\ K)(0.05\ m)^3}{19.9\times10^{-6}m^2/s\times14.15\times10^{-6}m^2/s} = 3.11\times10^5.$$

Applying Eq. 9.49 as a first approximation, it follows that

$$h = (k/L_2)\left[0.069Ra_L^{1/3}Pr^{0.074}\right] = \frac{0.0247\ W/m\cdot K}{0.05\ m}\left[0.069\left(3.11\times10^5\right)^{1/3}(0.71)^{0.074}\right] = 2.25\ W/m^2\cdot K.$$

The convection resistance is then

$$R_{conv,hc} = \frac{1}{2.25\ W/m^2\cdot K(0.01\ m - 0.002\ m)^2} = 6944\ K/W.$$

The resistance to heat transfer by radiation may be obtained by first noting that the cell forms a three-surface enclosure for which the sidewalls are reradiating. The net radiation heat transfer between the end surfaces of the cell is then given by Eq. 13.30. With $\varepsilon_1 = \varepsilon_2 = \varepsilon$ and $A_1 = A_2 = (W-t)^2$, the equation reduces to

$$q_{rad} = \frac{(W-t)^2\sigma\left(T_1^4 - T_2^4\right)}{2(1/\varepsilon - 1) + \left[F_{12} + \left[(F_{1R} + F_{2R})/F_{1R}F_{2R}\right]^{-1}\right.}.$$

However, with $F_{1R} = F_{2R} = (1 - F_{12})$, it follows that

$$q_{rad} = \frac{(W-t)^2\sigma\left(T_1^4 - T_2^4\right)}{2\left(\frac{1}{\varepsilon}-1\right) + \left[F_{12} + \frac{(1-F_{12})^2}{2(1-F_{12})}\right]^{-1}} = \frac{(W-t)^2\sigma\left(T_1^4 - T_2^4\right)}{2\left(\frac{1}{\varepsilon}-1\right) + \frac{2}{1+F_{12}}}.$$

The view factor F_{12} may be obtained from Fig. 13.4, where

$$\frac{X}{L} = \frac{Y}{L} = \frac{W-t}{L_2} = \frac{10\ mm - 2\ mm}{50\ mm} = 0.16.$$

Hence, $F_{12} \approx 0.01$. Defining the radiation resistance as

$$R_{rad,hc} = \frac{T_1 - T_2}{q_{rad}}$$

it follows that

Continued …

PROBLEM 13.110 (Cont.)

$$R_{rad,hc} = \frac{2(1/\varepsilon - 1) + 2/(1+F_{12})}{(W-t)^2 \sigma (T_1^2 + T_2^2)(T_1 + T_2)}$$

where $(T_1^4 - T_2^4) = (T_1^2 + T_2^2)(T_1 + T_2)(T_1 - T_2)$. Accordingly,

$$R_{rad,hc} = \frac{\left[2\left(\frac{1}{0.85} - 1\right) + \frac{2}{1+0.01}\right]}{(0.01\text{ m} - 0.002\text{ m})^2 \times 5.67 \times 10^{-8}\text{ W/m}^2 \cdot \text{K}^4 \left[(288\text{ K})^2 + (268\text{ K})^2\right](288 + 268)\text{K}}$$

where, again, it is *assumed* that T_1 = 15°C and T_2 = -5°C. From the above expression, it follows that

$$R_{rad,hc} = \frac{0.353 + 1.980}{3.123 \times 10^{-4}} = 7471\text{ K/W}.$$

In summary the component resistances are

$$R_{cond,i} = R_{cond,o} = 1603\text{ K/W}$$

$$R_{cond,hc} = 8170\text{ K/W} \qquad R_{conv,hc} = 6944\text{ K/W} \qquad R_{rad,hc} = 7471\text{ K/W}.$$

The equivalent resistance is then

$$R_{eq} = \left(\frac{1}{8170} + \frac{1}{6944} + \frac{1}{7471}\right)^{-1} = 2498\text{ K/W}$$

and the total resistance is

$$R = 1603 + 2498 + 1603 = 5704\text{ K/W}.$$ <

COMMENTS: (1) The solution is iterative, since values of T_1 and T_2 were assumed to calculate $R_{conv,hc}$ and $R_{rad,hc}$. To check the validity of the assumed values, we first obtain the heat transfer rate q from the expression

$$q = \frac{T_{s,1} - T_{s,2}}{R} = \frac{25°\text{C} - (-10°\text{C})}{5704\text{ K/W}} = 6.14 \times 10^{-3}\text{W}.$$

Hence

$$T_1 = T_{s,i} - qR_{cond,i} = 25°\text{C} - 6.14 \times 10^{-3}\text{W} \times 1603\text{ K/W} = 15.2°\text{C}$$

$$T_2 = T_{s,o} + qR_{cond,o} = -10°\text{C} + 6.14 \times 10^{-3}\text{W} \times 1603\text{ K/W} = -0.2°\text{C}.$$

Using these values of T_1 and T_2, $R_{conv,hc}$ and $R_{rad,hc}$ should be recomputed and the process repeated until satisfactory agreement is obtained between the initial and computed values of T_1 and T_2.

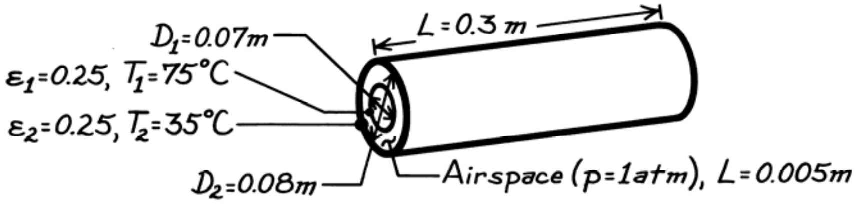
(2) The resistance of a section of low density particle board 75 mm thick ($L_1 + L_2 + L_3$) of area W^2 is 9615 K/W, which exceeds the total resistance of the composite by approximately 70%. Accordingly, use of the honeycomb structure offers no advantages as an insulating material. Its effectiveness as an insulator could be improved (R_{eq} increased) by reducing the wall thickness t to increase R_{cond}, evacuating the cell to increase R_{conv}, and/or decreasing ε to increase R_{rad}. A significant increase in $R_{rad,hc}$ could be achieved by aluminizing the top and bottom surfaces of the cell.

PROBLEM 13.111

KNOWN: Dimensions and surface conditions of a cylindrical thermos bottle filled with hot coffee and lying horizontally.

FIND: Heat loss.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat loss from ends (long infinite cylinders), (3) Diffuse-gray surface behavior.

PROPERTIES: *Table A-4*, Air ($T_f = (T_1 + T_2)/2 = 328$ K, 1 atm): k = 0.0284 W/m·K, $\nu = 23.74 \times 10^{-6}$ m^2/s, $\alpha = 26.6 \times 10^{-6}$ m^2/s, Pr = 0.703, $\beta = 3.05 \times 10^{-3}$ K^{-1}.

ANALYSIS: The heat transfer across the air space is

$$q = q_{rad} + q_{conv}.$$

From Eq. 13.25 for concentric cylinders

$$q_{rad} = \frac{\sigma(\pi D_1 L)\left(T_1^4 - T_2^4\right)}{\frac{1}{\varepsilon_1} + \frac{1-\varepsilon_2}{\varepsilon_2}\left(\frac{r_1}{r_2}\right)} = \frac{5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\,\pi(0.07\times0.3)\,\text{m}^2\left(348^4 - 308^4\right)\text{K}^4}{4 + 3(0.035/0.04)}$$

$$q_{rad} = 3.20 \text{ W}.$$

The convection heat rate is given by Eqs. 9.58 through 9.60. The length scale is $L_c = 2[\ln(0.08/0.07)]^{4/3}/(0.035 \text{ m}^{-3/5} + 0.040 \text{ m}^{-3/5})^{5/3} = 0.0016$ m. The Rayleigh number is

$$Ra_c = \frac{g\beta(T_1 - T_2)L_c^3}{\nu\alpha} = \frac{9.8\text{m/s}^2(3.05\times10^{-3}\text{K}^{-1})(40\text{K})(0.0016\text{m})^3}{26.6\times10^{-6}\text{m}^2/\text{s}\times23.74\times10^{-6}\text{m}^2/\text{s}} = 7.85$$

From Eq. 9.59,

$$k_{eff}/k = 0.386\left(\frac{Pr}{0.861 + Pr}\right)^{1/4} Ra_c^{1/4} = 0.386\left(\frac{0.703}{0.861 + 0.703}\right)^{1/4} 7.85^{1/4} = 0.529$$

Since k_{eff}/k is predicted to be less than unity, conduction occurs in the gap. From Eq. 3.32

$$q_{cond} = \frac{2\pi Lk(T_1 - T_2)}{\ln(r_2/r_1)} = \frac{2\pi\times0.3\text{ m}\times0.0284\text{ W/m}\cdot\text{K}(75-35)\text{K}}{\ln(0.04/0.035)} = 16.04 \text{ W}.$$

Hence the total heat loss is

$$q = q_{rad} + q_{cond} = 19.24 \text{ W}.$$ <

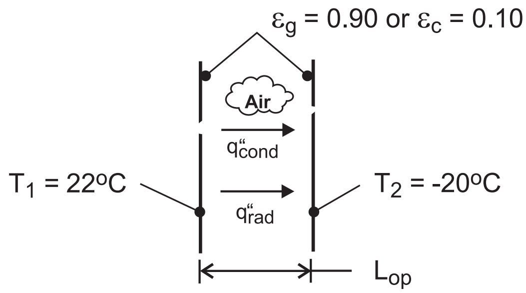
COMMENTS: (1) End effects could be considered in a more detailed analysis, (2) Conduction losses could be eliminated by evacuating the annulus.

PROBLEM 13.112

KNOWN: Temperatures and emissivity of window panes and critical Rayleigh number for onset of convection in air space.

FIND: (a) The conduction heat flux across the air gap for the optimal spacing, (b) The total heat flux for uncoated panes, (c) The total heat flux if one or both of the panes has a low-emissivity coating.

SCHEMATIC:



ASSUMPTIONS: (1) Critical Rayleigh number is $Ra_{L,c}$ = 2000, (2) Constant properties, (3) Radiation exchange between large (infinite), parallel, diffuse-gray surfaces.

PROPERTIES: *Table A-4*, air [T = $(T_1 + T_2)/2$ = 1°C = 274 K]: $\nu = 13.6 \times 10^{-6}$ m²/s, k = 0.0242 W/m·K, $\alpha = 19.1 \times 10^{-6}$ m²/s, $\beta = 0.00365$ K^{-1}.

ANALYSIS: (a) With $Ra_{L,c} = g\beta(T_1 - T_2)L_{op}^3/\alpha\nu$

$$L_{op} = \left[\frac{\alpha\nu Ra_{L,c}}{g\beta(T_1 - T_2)}\right]^{1/3} = \left[\frac{19.1\times 13.6\times 10^{-12}\,m^4/s^2 \times 2000}{9.8\,m/s^2\left(0.00365\ K^{-1}\right)42°C}\right]^{1/3} = 0.0070m$$

The conduction heat flux is then

$$q''_{cond} = k(T_1 - T_2)/L_{op} = 0.0242\,W/m\cdot K(42°C)/0.0070m = 145.2\ W/m^2$$ <

(b) For conventional glass (ε_g = 0.90), Eq. 13.24 yields,

$$q''_{rad} = \frac{\sigma\left(T_1^4 - T_2^4\right)}{\dfrac{2}{\varepsilon_g} - 1} = \frac{5.67\times 10^{-8}\,W/m^2\cdot K^4\left(295^4 - 253^4\right)K^4}{1.222} = 161.3\ W/m^2$$

and the total heat flux is

$$q''_{tot} = q''_{cond} + q''_{rad} = 306.5\ W/m^2$$ <

(c) With only one surface coated,

$$q''_{rad} = \frac{5.67\times 10^{-8}\,W/m^2\cdot K^4\left(295^4 - 253^4\right)}{\dfrac{1}{0.90} + \dfrac{1}{0.10} - 1} = 19.5\ W/m^2$$

Continued …

PROBLEM 13.112 (Cont.)

$$q''_{tot} = 164.7\ W/m^2$$ <

With both surfaces coated,

$$q''_{rad} = \frac{5.67\times10^{-8}\ W/m^2\cdot K^4\left(295^4 - 253^4\right)}{\frac{1}{0.10}+\frac{1}{0.10}-1} = 10.4\ W/m^2$$

$$q''_{tot} = 155.6\ W/m^2$$ <

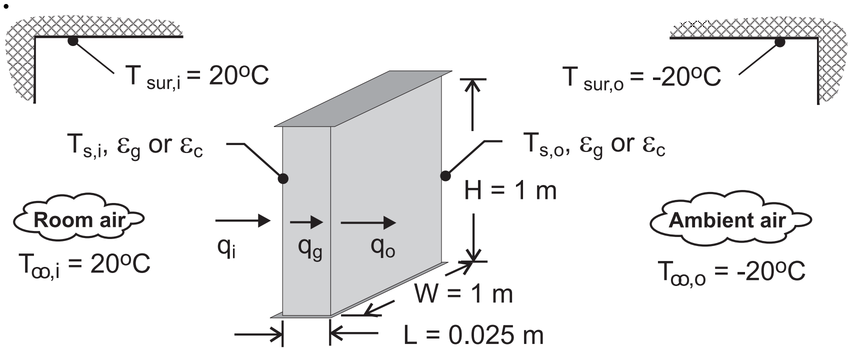
COMMENTS: Without any coating, radiation makes a large contribution (53%) to the total heat loss. With one coated pane, there is a significant reduction (46%) in the total heat loss. However, the benefit of coating both panes is marginal, with only an additional 3% reduction in the total heat loss.

PROBLEM 13.113

KNOWN: Dimensions and emissivity of double pane window. Thickness of air gap. Temperatures of room and ambient air and the related surroundings.

FIND: (a) Temperatures of glass panes and rate of heat transfer through window, (b) Heat rate if gap is evacuated. Heat rate if special coating is applied to window.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Negligible glass pane thermal resistance, (3) Constant properties, (4) Diffuse-gray surface behavior, (5) Radiation exchange between interior window surfaces may be approximated as exchange between infinite parallel plates, (6) Interior and exterior surroundings are very large.

PROPERTIES: *Table A-4*, Air (p = 1 atm). Obtained from using *IHT* to solve for conditions of Part (a): $T_{f,i}$ = 287.4 K: $\nu_i = 14.8 \times 10^{-6}$ m^2/s, k_i = 0.0253 W/m·K, $\alpha_i = 20.8 \times 10^{-6}$ m^2/s, Pr_i = 0.71, β_i = 0.00348 K^{-1}. $\overline{T} = (T_{s,i} + T_{s,o})/2$ = 273.7 K: $\nu = 13.6 \times 10^{-6}$ m^2/s, k = 0.0242 W/m·K, $\alpha = 19.0 \times 10^{-6}$ m^2/s, Pr = 0.71, β = 0.00365 K^{-1}. $T_{f,o}$ = 259.3 K: $\nu_o = 12.3 \times 10^{-6}$ m^2/s, k_o = 0.023 W/m·K, $\alpha_o = 17.1 \times 10^{-6}$ m^2/s, Pr_o = 0.72, β_o = 0.00386 K^{-1}.

ANALYSIS: (a) The heat flux through the window may be expressed as

$$q'' = q''_{rad,i} + q''_{conv,i} = \varepsilon_g \sigma \left(T^4_{sur,i} - T^4_{s,i}\right) + \overline{h}_i \left(T_{\infty,i} - T_{s,i}\right) \quad (1)$$

$$q'' = q''_{rad,gap} + q''_{conv,gap} = \frac{\sigma\left(T^4_{s,i} - T^4_{s,o}\right)}{\frac{1}{\varepsilon_g} + \frac{1}{\varepsilon_g} - 1} + \overline{h}_{gap}\left(T_{s,i} - T_{s,o}\right) \quad (2)$$

$$q'' = q''_{rad,o} + q''_{conv,o} = \varepsilon_g \sigma \left(T^4_{s,o} - T^4_{sur,o}\right) + \overline{h}_o \left(T_{s,o} - T_{\infty,o}\right) \quad (3)$$

where radiation exchange between the window panes is determined from Eq. 13.24. The inner and outer convection coefficients, $\overline{h}_i$ and $\overline{h}_o$, are determined from Eq. 9.26, and $\overline{h}_{gap}$ is obtained from Eq. 9.52.

The foregoing equations may be solved for the three unknowns $\left(q'', T_{s,i}, T_{s,o}\right)$. Using the *IHT* software to effect the solution, we obtain

$$T_{s,i} = 281.8 \text{ K} = 8.8°\text{C}$$ <

Continued …

PROBLEM 13.113 (Cont.)

$T_{s,o} = 265.6\ \text{K} = -7.4°\text{C}$ <

$q = 91.3\ \text{W}$ <

(b) If the air space is evacuated $\left(\bar{h}_g = 0\right)$, we obtain

$T_{s,i} = 283.6\ \text{K} = 10.6°\text{C}$ <

$T_{s,o} = 263.8\ \text{K} = 9.2°\text{C}$ <

$q = 75.5\ \text{W}$ <

If the space is not evacuated but the coating is applied to inner surfaces of the window panes,

$T_{s,i} = 285.9\ \text{K} = 12.9°\text{C}$ <

$T_{s,o} = 261.3\ \text{K} = -11.7°\text{C}$ <

$q = 55.9\ \text{W}$ <

If the space is evacuated and the coating is applied,

$T_{s,i} = 291.7\ \text{K} = 18.7°\text{C}$ <

$T_{s,o} = 254.7\ \text{K} = -18.3°\text{C}$ <

$q = 9.0\ \text{W}$ <

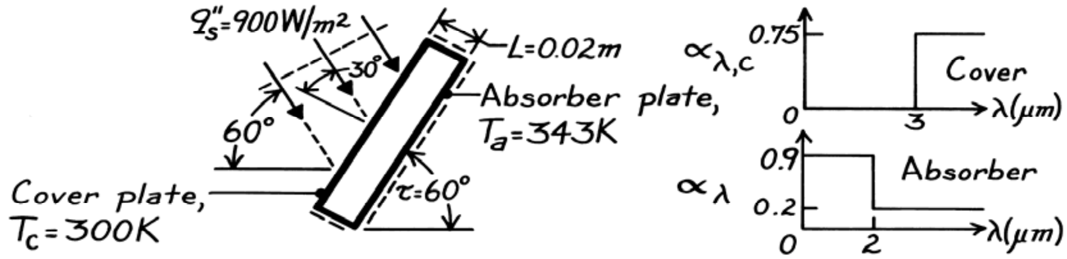
COMMENTS: (1) For the conditions of part (a), the convection and radiation heat fluxes are comparable at the inner and outer surfaces of the window, but because of the comparatively small convection coefficient, the radiation flux is approximately twice the convection flux across the air gap. (2) As the resistance across the air gap is progressively increased (evacuated, coated, evacuated and coated), the temperatures of the inner and outer panes increase and decrease, respectively, and the heat loss decreases. (3) Clearly, there are significant energy savings associated with evacuation of the gap and application of the coating. (4) In all cases, solutions were obtained using the temperature-dependent properties of air provided by the software. The property values listed in the **PROPERTIES** section of this solution pertain to the conditions of part (a).

PROBLEM 13.114

KNOWN: Absorber and cover plate temperatures and spectral absorptivities for a flat plate solar collector. Collector orientation and solar flux.

FIND: (a) Rate of solar radiation absorption per unit area, (b) Heat loss per unit area.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Adiabatic sides and bottom, (3) Cover is transparent to solar radiation, (4) Sun emits as a blackbody at 5800 K, (5) Cover and absorber plates are diffuse-gray to long wave radiation, (6) Negligible end effects, (7) L << width and length.

PROPERTIES: *Table A-4*, Air ($T = T_a + T_c)/2 = 321.5$ K, 1 atm): $\nu = 18.05 \times 10^{-6}$ m^2/s, k = 0.0279 W/m·K, $\alpha = 25.7 \times 10^{-6}$ m^2/s.

ANALYSIS: (a) The absorbed solar irradiation is

$$G_{S,abs} = \alpha_{S,a} G_S$$

where

$$G_S = q_s'' \cos 30° = 900 \times 0.866 = 779.4 \text{ W/m}^2$$

$$\alpha_{S,a} = \frac{\int_0^\infty \alpha_{\lambda,a} G_{\lambda,S} d\lambda}{G_S} = \frac{\int_0^\infty \alpha_{\lambda,a} E_{\lambda,b}(5800 \text{ K}) d\lambda}{E_b(5800 \text{ K})}$$

$$\alpha_{S,a} = \alpha_{\lambda,a,1} F_{(0\to 2\ \mu m)} + \alpha_{\lambda,a2} F_{(2\to\infty)}.$$

For $\lambda T = 2\ \mu m \times 5800$ K = 11,600 μm·K from Table 12.1, $F_{(0\to 2\lambda T)} = 0.941$, find

$$\alpha_{S,a} = 0.9 \times 0.941 + 0.2 \times (1 - 0.941) = 0.859.$$

Hence

$$G_{S,abs} = 0.859 \times 779.4 = 669 \text{ W/m}^2.$$ <

(b) The heat loss per unit area from the collector is

$$q''_{loss} = q''_{conv} + q''_{rad}.$$

The convection heat flux is

$$q''_{conv} = \bar{h}(T_a - T_c)$$

Continued …

PROBLEM 13.114 (Cont.)

and with

$$\mathrm{Ra_L} = \frac{g\beta\left(T_a - T_c\right)L^3}{\alpha\nu}$$

$$\mathrm{Ra_L} = \frac{9.8\ \mathrm{m/s^2} \times \left(321.5\ \mathrm{K}\right)^{-1}\left(343-300\right)\mathrm{K}\left(0.02\ \mathrm{m}\right)^3}{18.05\times10^{-6}\mathrm{m^2/s}\times25.7\times10^{-6}\mathrm{m^2/s}} = 22,604$$

find from Eq. 9.54 with

$$H/L > 12,\ \tau < \tau^*,\ \cos\ \tau = 0.5,\ \mathrm{Ra_L}\ \cos\ \tau = 11,302$$

$$\overline{\mathrm{Nu}}_L = 1 + 1.44\left[1 - \frac{1708}{11,302}\right]\left[1 - \frac{1708\left(\sin 108°\right)^{1.6}}{11,302}\right] + \left[\left(\frac{11,302}{5830}\right)^{1/3} - 1\right]$$

$$\overline{h} = \overline{\mathrm{Nu}}_L\ \frac{k}{L} = 2.30 \times \frac{0.0279\ \mathrm{W/m\cdot K}}{0.02\ \mathrm{m}} = 3.21\ \mathrm{W/m^2\cdot K}.$$

Hence, the convective heat flux is

$$q''_{conv} = 3.21\ \mathrm{W/m^2\cdot K}\left(343-300\right)\mathrm{K} = 138.0\ \mathrm{W/m^2}.$$

The radiative exchange can be determined from Eq. 13.24 treating the cover and absorber plates as a two-surface enclosure,

$$q''_{rad} = \frac{\sigma\left(T_a^4 - T_c^4\right)}{1/\varepsilon_a + 1/\varepsilon_c - 1} = \frac{5.67\times10^{-8}\mathrm{W/m^2\cdot K^4}\left[\left(343\ \mathrm{K}\right)^4 - \left(300\ \mathrm{K}\right)^4\right]}{1/0.2 + 1/0.75 - 1}$$

$$q''_{rad} = 61.1\ \mathrm{W/m^2}.$$

Hence, the total heat loss per unit area from the collector

$$q''_{loss} = \left(138.0 + 61.1\right) = 199\ \mathrm{W/m^2}.$$ <

COMMENTS: (1) Non-solar components of radiation transfer are concentrated at long wavelength for which $\alpha_a = \varepsilon_a = 0.2$ and $\alpha_c = \varepsilon_c = 0.75$.

(2) The collector efficiency is

$$\eta = \frac{669.3 - 199.1}{669.3}\times100 = 70\%.$$

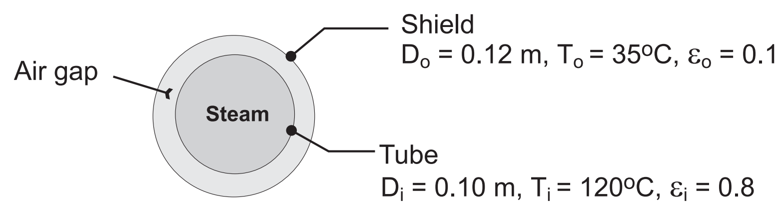
This value is uncharacteristically high due to specification of nearly optimum $\alpha_a(\lambda)$ for absorber.

PROBLEM 13.115

KNOWN: Diameters and temperatures of a heated tube and a radiation shield.

FIND: (a) Total heat loss per unit length of tube, (b) Effect of shield diameter on heat rate.

SCHEMATIC:



ASSUMPTIONS: (1) Opaque, diffuse-gray surfaces, (2) Negligible end effects.

PROPERTIES: *Table A-4*, Air (T_f = 77.5°C ≈ 350 K): k = 0.030 W/m·K, Pr = 0.70, $\nu = 20.92 \times 10^{-6}$ m^2/s, $\alpha = 29.9 \times 10^{-6}$ m^2/s, $\beta = 0.00286$ K^{-1}.

ANALYSIS: (a) Heat loss from the tube is by radiation and free convection

$$q' = q'_{rad} + q'_{conv}$$

From Eq. 13.25

$$q'_{rad} = \frac{\sigma(\pi D_i)\left(T_i^4 - T_o^4\right)}{\dfrac{1}{\varepsilon_i} + \dfrac{1-\varepsilon_o}{\varepsilon_o}\left(\dfrac{r_i}{r_o}\right)}$$

or

$$q'_{rad} = \frac{5.67\times10^{-8}\dfrac{W}{m^2\cdot K^4}(\pi\times0.1m)\left(393^4 - 308^4\right)K^4}{\dfrac{1}{0.8} + \dfrac{0.9}{0.1}\left(\dfrac{0.05}{0.06}\right)} = 30.2\ \frac{W}{m}$$

The convection heat rate is given by Eqs. 9.58 through 9.60. The length scale is L_c = $2[\ln(0.12/0.10)]^{4/3}/(0.05\text{ m}^{-3/5} + 0.05\text{ m}^{-3/5})^{5/3}$ = 0.0036 m. The Rayleigh number is $Ra_c = g\beta(T_i - T_o)L_c^3/\nu\alpha$ = 9.8 m/s^2(0.00286 K^{-1})(120 - 35) K (0.0036 m)^3/(20.92 × 10^{-6} m^2/s × 29.9 × 10^{-6} m^2/s) = 171.6. Also, $k_{eff}/k = 0.386\times[0.700/(0.861 + 0.700)]^{1/4}(171.6)^{1/4}$ = 1.14. Therefore, keff = 1.14 × 0.030 W/m·K = 0.0343 W/m·K. From Eq. 9.58,

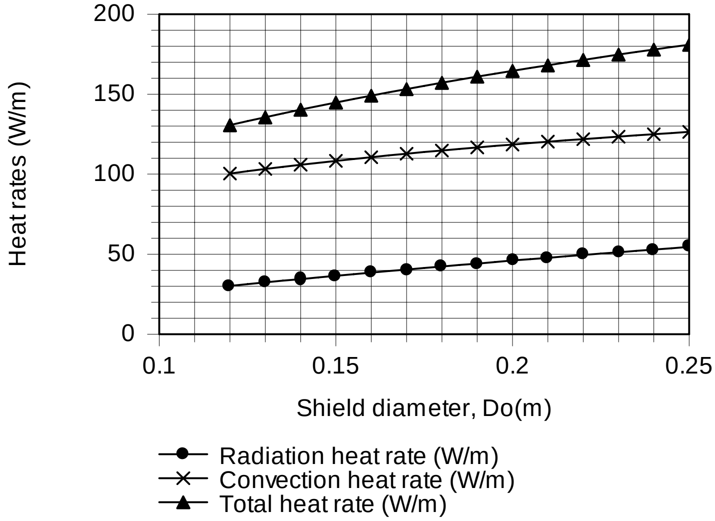
$$q'_{conv}\ \frac{2\pi k_{eff}(T_i - T_o)}{\ln(D_i/D_o)} = \frac{2\times\pi\times0.0343 W/m\cdot K\times(120-35)K}{\ln(0.12/0.10)} = 100.5 W/m$$

$$q' = (30.2 + 100.5)\frac{W}{m} = 130.7\frac{W}{m}$$

Continued...

PROBLEM 13.115 (Cont.)

(b) As shown below, both convection and radiation, and hence the total heat rate, increase with increasing shield diameter. In the limit as $D_o \rightarrow \infty$, the radiation rate approaches that corresponding to net transfer between a small surface and large surroundings at T_o. The rate is independent of ε.



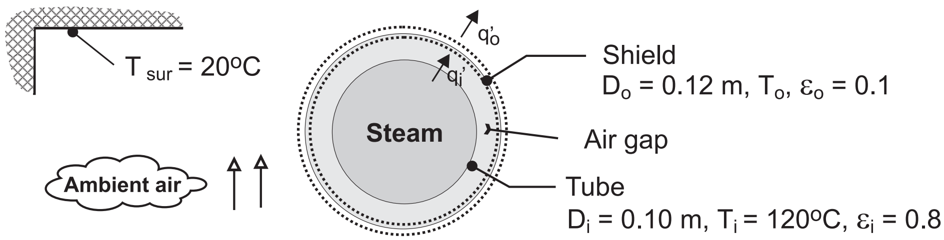
COMMENTS: Designation of a shield temperature is arbitrary. The temperature depends on the nature of the environment external to the shield.

PROBLEM 13.116

KNOWN: Diameters of heated tube and radiation shield. Tube surface temperature and temperature of ambient air and surroundings.

FIND: Temperature of radiation shield and heat loss per unit length of tube.

SCHEMATIC:



ASSUMPTIONS: (1) Opaque, diffuse-gray surfaces, (2) Negligible end effects, (3) Large surroundings, (4) Quiescent air, (5) Steady-state.

PROPERTIES: Determined from use of *IHT* software for iterative solution. Air, $(T_i + T_o)/2 = 362.7$ K: $\nu_i = 2.23 \times 10^{-5}$ m^2/s, $k_i = 0.031$ W/m·K, $\alpha_i = 3.20 \times 10^{-5}$ m^2/s, $\beta_i = 0.00276$ K^{-1}, $Pr_i = 0.698$. Air, $T_f = 312.7$ K: $\nu_o = 1.72 \times 10^{-5}$ m^2/s, $k_o = 0.027$ W/m·K, $\alpha_o = 2.44 \times 10^{-5}$ m^2/s, $\beta_o = 0.0032$ K^{-1}, $Pr_o = 0.705$.

ANALYSIS: From an energy balance on the radiation shield, $q'_i = q'_o$ or $q'_{rad,i} + q'_{conv,i} = q'_{rad,o} + q'_{conv,o}$. Evaluating the inner and outer radiation rates from Eqs. 13.25 and 13.27, respectively, and the convection heat rate in the air gap from Eq. 9.58,

$$\frac{\sigma \pi D_i \left(T_i^4 - T_o^4\right)}{\dfrac{1}{\varepsilon_i} + \dfrac{1-\varepsilon_o}{\varepsilon_o}\left(\dfrac{D_i}{D_o}\right)} + \frac{2\pi k_{eff}\left(T_i - T_o\right)}{\ell n\left(Do/Di\right)} = \sigma \pi D_o \varepsilon_o \left(T_o^4 - T_{sur}^4\right) + \pi D_o \bar{h}_o \left(T_o - T_\infty\right)$$

The convection heat rate is given by Eqs. 9.58 through 9.60. The length scale is $L_c = 2[\ln(0.12/0.10)]^{4/3}/(0.05\text{ m}^{-3/5} + 0.05\text{ m}^{-3/5})^{5/3} = 0.0036$ m. The Rayleigh number is $Ra_c = g\beta_i(T_i - T_o)L_c^3/\nu_i\alpha_i = 9.8\text{ m/s}^2(0.00276\text{ K}^{-1})(120 - T_o)\text{ K }(0.0036\text{ m})^3/(22.3 \times 10^{-6}\text{ m}^2/\text{s} \times 32.0 \times 10^{-6}\text{ m}^2/\text{s})$. Also, $k_{eff}/k = 0.386 \times k_i \times [Pr_i/(0.861 + Pr_i)]^{1/4}(Ra_c)^{1/4} = 1.14$. From Eq. 9.34, the convection coefficient on the outer surface of the shield is

$$\bar{h}_o = \frac{k_o}{D_o}\left\{0.60 + \frac{0.387\, Ra_D^{1/6}}{\left[1 + \left(0.559/Pr_o\right)^{9/16}\right]^{8/27}}\right\}^2$$

The solution to the energy balance is obtained using the *IHT* software, and the result is

$$T_o = 332.5\text{ K} = 59.5°\text{C}$$ <

The corresponding value of the heat loss is

$$q'_i = 88.7\text{ W/m}$$ <

Continued…

PROBLEM 13.116 (Cont.)

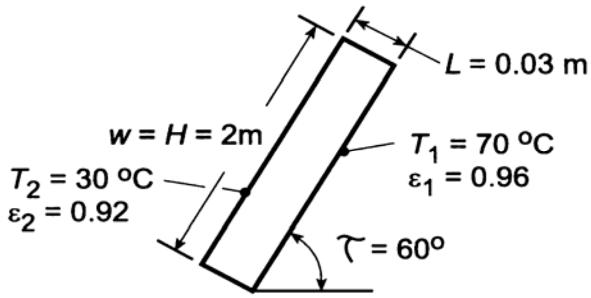
COMMENTS: (1) The radiation and convection heat rates are $q'_{rad,i} = 23.7\ W/m$, $q'_{rad,o} = 10.4\ W/m$, $q'_{conv,i} = 65.0\ W/m$, and $q'_{conv,o} = 78.3\ W/m$. Convection is clearly the dominant mode of heat transfer. (2)With a value of T_o = 59.5°C > 35°C, the heat loss is reduced (88.7 W/m compared to 130.7 W/m if the shield is at 35°C).

PROBLEM 13.117

KNOWN: Dimensions and inclination angle of a flat-plate solar collector. Absorber and cover plate temperatures and emissivities.

FIND: (a) Rate of heat transfer by free convection and radiation, (b) Effect of the absorber plate temperature on the heat rates.

SCHEMATIC:



ASSUMPTIONS: (1) Diffuse-gray, opaque surface behavior.

PROPERTIES: *Table A-4*, air $\left(\overline{T} = (T_1 + T_2)/2 = 323\ K\right)$: $\nu = 18.2 \times 10^{-6}\ m^2/s$, k = 0.028 W/m·K, $\alpha = 25.9 \times 10^{-6}\ m^2/s$, Pr = 0.704, $\beta = 0.0031\ K^{-1}$.

ANALYSIS: (a) The convection heat rate is

$$q_{conv} = \overline{h}A(T_1 - T_2)$$

where A = wH=4 m^2 and, with H/L > 12 and $\tau < \tau^* = 70$ deg, $\overline{h}$ is given by Eq. 9.54. With a Rayleigh number of

$$Ra_L = \frac{g\beta(T_1 - T_2)L^3}{\alpha\nu} = \frac{9.8\,m/s^2\left(0.0031\ K^{-1}\right)(40°C)(0.03\,m)^3}{25.9\times10^{-6}\,m^2/s\times18.2\times10^{-6}\,m^2/s} = 69,600$$

$$\overline{Nu}_L = 1 + 1.44\left[1 - \frac{1708}{0.5(69,600)}\right]\left[1 - \frac{1708(0.923)}{0.5(69,600)}\right] + \left[\left(\frac{0.5\times69,600}{5830}\right)^{1/3} - 1\right]$$

$$\overline{Nu}_L = 1 + 1.44[0.951][0.955] + 0.814 = 3.12$$

$$\overline{h} = (k/L)\overline{Nu}_L = (0.028\ W/m\cdot K/0.03\,m)3.12 = 2.91\ W/m^2\cdot K$$

$$q_{conv} = 2.91\ W/m^2\cdot K\left(4\ m^2\right)(70 - 30)°C = 466\ W$$ <

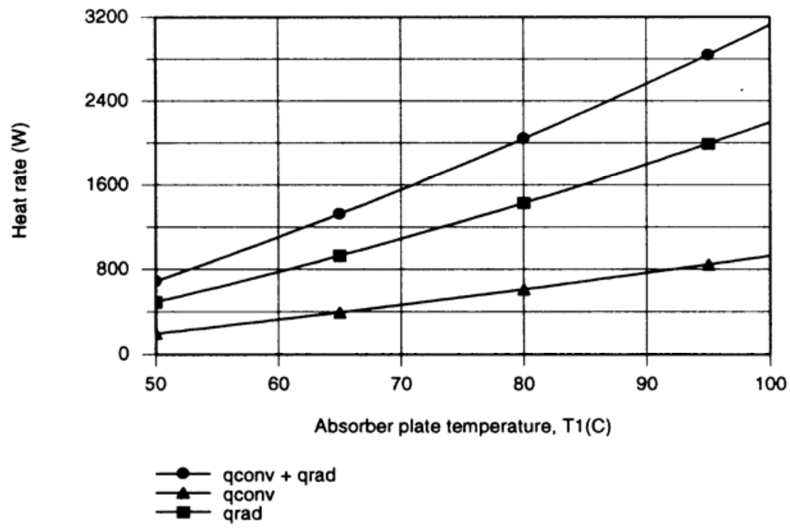
The net rate of radiation exchange is given by Eq. 13.24.

$$q = \frac{A\sigma\left(T_1^4 - T_2^4\right)}{\frac{1}{\varepsilon_1} + \frac{1}{\varepsilon_2} - 1} = \frac{\left(4\ m^2\right)5.67\times10^{-8}\,W/m^2\cdot K^4\left(343^4 - 303^4\right)K^4}{\frac{1}{0.96} + \frac{1}{0.92} - 1} = 1088\ W$$ <

(b) The effect of the absorber plate temperature was determined by entering Eq. 9.54 into the *IHT* workspace and using the *Properties* and *Radiation* Toolpads.

Continued …

PROBLEM 13.117 (Cont.)



As expected, the convection and radiation losses increase with increasing T_i, with the T^4 dependence providing a more pronounced increase for the radiation.

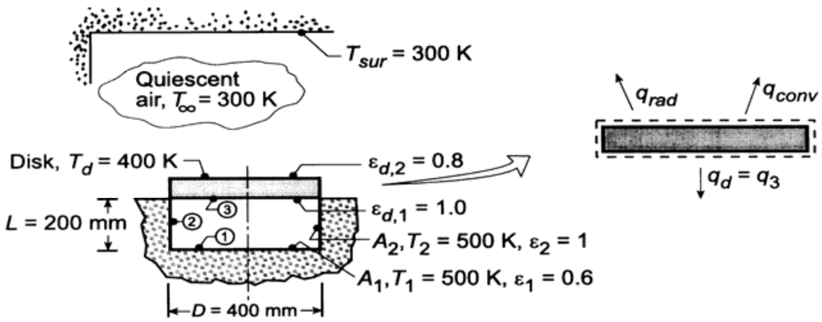
COMMENTS: To minimize heat losses, it is obviously desirable to operate the absorber plate at the lowest possible temperature. However, requirements for the outlet temperature of the working fluid may dictate operation at a low flow rate and hence an elevated plate temperature.

PROBLEM 13.118

KNOWN: Disk heated by an electric furnace on its lower surface and exposed to an environment on its upper surface.

FIND: (a) Net heat transfer to (or from) the disk $q_{net,d}$ when T_d = 400 K and (b) Compute and plot $q_{net,d}$ as a function of disk temperature for the range $300 \le T_d \le 500$ K; determine steady-state temperature of the disk.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Disk is isothermal; negligible thermal resistance, (3) Surroundings are isothermal and large compared to the disk, (4) Non-black surfaces are gray-diffuse, (5) Furnace-disk forms a 3-surface enclosure, (6) Negligible convection in furnace, (7) Ambient air is quiescent.

PROPERTIES: *Table A-4*, Air ($T_f = (T_d + T_\infty)/2$ = 350 K,1 atm): $\nu = 20.92 \times 10^{-6}$ m^2/s, k = 0.30 W/m·K, $\alpha = 29.9 \times 10^{-6}$ m^2/s.

ANALYSIS: (a) Perform an energy balance on the disk identifying: q_{rad} as the net radiation exchange between the disk and surroundings; q_{conv} as the convection heat transfer; and q_3 as the net radiation leaving the disk within the 3-surface enclosure.

$$q_{net,d} = \dot{E}_{in} - \dot{E}_{out} = -q_{rad} - q_{conv} - q_3 \tag{1}$$

Radiation exchange with surroundings: The rate equation is of the form

$$q_{rad} = \varepsilon_{d,2} A_d \sigma \left(T_d^4 - T_{sur}^4\right) \tag{2}$$

$$q_{rad} = 0.8(\pi/4)(0.400\,\text{m})^2\, 5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left(400^4 - 300^4\right)\text{K}^4 = 99.8\ \text{W}.$$

Free convection: The rate equation is of the form

$$q_{conv} = \bar{h} A_d \left(T_d - T_\infty\right) \tag{3}$$

where $\bar{h}$ can be estimated by an appropriate convection correlation. Find first,

$$Ra_L = g\beta\Delta T L^3/\nu\alpha \tag{4}$$

$$Ra_L = 9.8\,\text{m/s}^2\,(1/350\ \text{K})(400-300)\text{K}\,(0.400\,\text{m}/4)^3 / 20.92\times10^{-6}\,\text{m/s}^2 \times 29.9\times10^{-6}\,\text{m}^2/\text{s}$$

$$Ra_L = 4.476\times10^6$$

where $L = A_c/P = D/4$. For the upper surface of a heated plate for which $10^4 \le Ra_L \le 10^7$, Eq. 9.30 is the appropriate correlation,

Continued …

PROBLEM 13.118 (Cont.)

$$\overline{Nu}_L = \bar{h}L / k = 0.54\, Ra_L^{1/4} \tag{5}$$

$$\bar{h} = 0.030\, W/m \cdot K / (0.400\, m / 4) \times 0.54 \left(4.476 \times 10^6\right)^{1/4} = 7.45\, W/m^2 \cdot K$$

Hence, from Eq. (3),

$$q_{conv} = 7.45\, W/m^2 \cdot K (\pi/4)(0.400\, m)^2 (400 - 300)\, K = 93.6\ W.$$

Furnace-disk enclosure: From Eq. 13.20, the net radiation leaving the disk is

$$q_3 = \frac{J_3 - J_1}{(A_3F_{31})^{-1}} + \frac{J_3 - J_2}{(A_3F_{32})^{-1}} = A_3\left[F_{31}(J_3 - J_1) + F_{32}(J_3 - J_2)\right]. \tag{6}$$

The view factor F_{32} can be evaluated from the *coaxial parallel disks* relation of Table 13.1 or from Fig. 13.5.

$$R_i = r_i / L = 200\ mm / 200\ mm = 1,$$

$$R_j = r_j / L = 1,$$

$$S = 1 + \left(1 + R_j^2\right)/R_j^2 = 1 + \left(1 + 1^2\right)1^2 = 3$$

$$F_{31} = 1/2\left\{S - \left[S^2 - 4\left(r_j / r_i\right)^2\right]^{1/2}\right\} = 1/2\left\{3 - \left[3^2 - 4(1)^2\right]^{1/2}\right\} = 0.382. \tag{7}$$

From summation rule, $F_{32} = 1 - F_{33} - F_{31} = 0.618$ with $F_{33} = 0$. Since surfaces A_2 and A_3 are black,

$$J_2 = E_{b2} = \sigma T_2^4 = \sigma (500\ K)^4 = 3544\ W/m^2$$

$$J_3 = E_{b3} = \sigma T_3^4 = \sigma (400\ K)^4 = 1452\ W/m^2.$$

To determine J_1, use Eq. 13.21, the radiation balance equation for A_1, noting that $F_{12} = F_{32}$ and $F_{13} = F_{31}$,

$$\frac{E_{b1} - J_1}{(1 - \varepsilon_1)/\varepsilon_1 A_1} = \frac{J_1 - J_2}{(A_1F_{12})^{-1}} + \frac{J_1 - J_3}{(A_1F_{13})^{-1}}$$

$$\frac{3544 - J_1}{(1 - 0.6)/0.6} = \frac{J_1 - 3544}{(0.618)^{-1}} + \frac{J_1 - 1452}{(0.382)^{-1}} \qquad J_1 = 3226\ W/m^2. \tag{8}$$

Substituting numerical values in Eq. (6), find

$$q_3 = (\pi/4)(0.400\, m)^2\left[0.382(1452 - 3226)\, W/m^2 + 0.618(1452 - 3544)\, W/m^2\right] = -248\ W.$$

Returning to the overall energy balance, Eq. (1), the net heat transfer to the disk is

$$q_{net,d} = -99.8\ W - 93.6\, W - (-248\, W) = +54.6\ W$$ <

That is, there is a net heat transfer rate *into* the disk.

(b) Using the energy balance, Eq. (1), and the rate equation, Eqs. (2) and (3) with the *IHT Radiation Tool, Radiation, Exchange Analysis, Radiation surface energy balances* and the *Correlation Tool, Free Convection, Horizontal Plate (Hot surface up),* the analysis was performed to obtain $q_{net,d}$ as a function of T_d. The results are plotted below.

The steady-state condition occurs when $q_{net,d} = 0$ for which

$$T_d = 413\ K$$ <

```

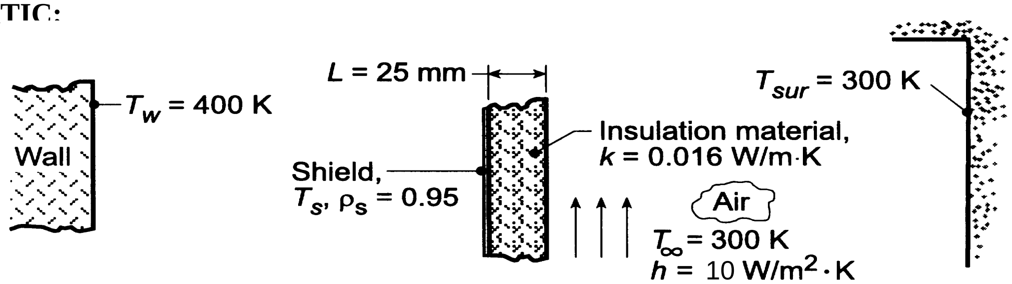
PROBLEM 13.119

KNOWN: Radiation shield facing hot wall at T_w = 400 K is backed by an insulating material of known thermal conductivity and thickness which is exposed to ambient air and surroundings at 300 K.

FIND: (a) Heat loss per unit area from the hot wall, (b) Radiosity of the shield, and (c) Perform a parameter sensitivity analysis on the insulation system considering effects of shield reflectivity ρ_s, insulation thermal conductivity k, overall coefficient h, on the heat loss from the hot wall.

SCHEMATIC:

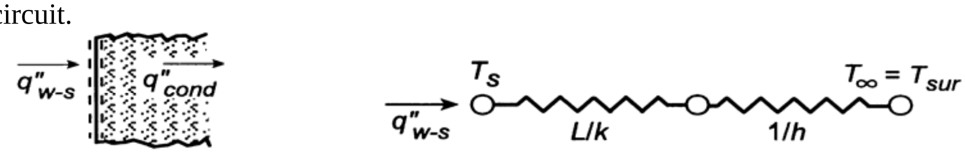


ASSUMPTIONS: (1) Wall is black surface of uniform temperature, (2) Shield and wall behave as parallel infinite plates, (3) Negligible convection in region between shield and wall, (4) Shield is diffuse-gray and very thin, (5) Prescribed coefficient h = 10 W/m^2·K is for convection and radiation.

ANALYSIS: (a) Perform an energy balance on the shield to obtain

$$q''_{w-s} = q''_{cond}$$

But the insulating material and the convection process at the exposed surface can be represented by a thermal circuit.



In equation form, using Eq.13.24 for the wall and shield,

$$q''_{w-s} = \frac{\sigma\left(T_w^4 - T_s^4\right)}{1/\varepsilon_w + 1/\varepsilon_s - 1} = \frac{T_s - T_\infty}{L/k + 1/h} \qquad (1,2)$$

$$\frac{\sigma\left(400^4 - T_s^4\right)}{1 + 1/0.05 - 1} = \frac{\left(T_s - 300\right)K}{\left(0.025/0.016 + 1/10\right)m^2 \cdot K/W}$$

$$T_s = 350 \text{ K}.$$

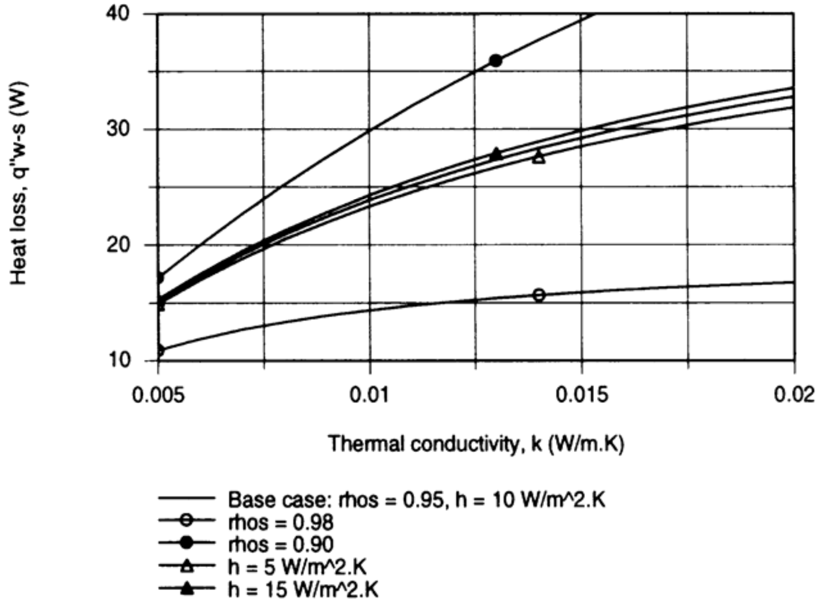
where $\varepsilon_s = 1 - \rho_s$. Hence,

$$q''_{w-s} = \frac{\left(350 - 300\right)K}{\left(0.025/0.016 + 1/10\right)m^2 \cdot K/W} = 30 \text{ W/m}^2. \qquad <$$

(b) Using the Eqs. (1) and (2) in the *IHT* workspace, q''_{w-s} can be computed and plotted for selected ranges of the insulation system variables, ρ_s, k, and h. Intuitively we know that q''_{w-s} will decrease with increasing ρ_s, decreasing k and decreasing h. We chose to generate the following family of curves plotting q''_{w-s} vs. k for selected values of ρ_s and h.

Continued …

PROBLEM 13.119 (Cont.)



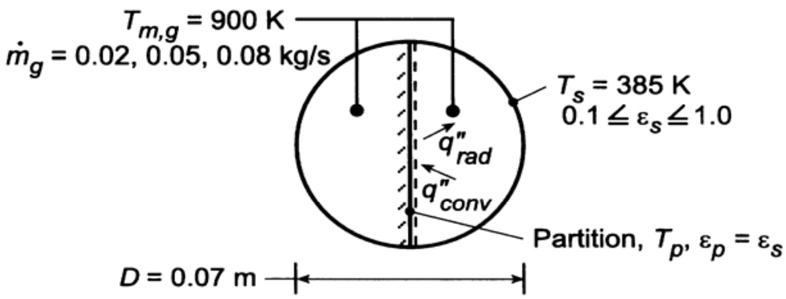
Considering the base condition with variable k, reducing k by a factor of 3, the heat loss is reduced by a factor of 2. The effect of changing h (4 to 24 $W/m^2 \cdot K$) has little influence on the heat loss. However, the effect of shield reflectivity change is very significant. With ρ_S = 0.98, probably the upper limit of a practical reflector-type shield, the heat loss is reduced by a factor of two. To improve the performance of the insulation system, it is most advantageous to increase ρ_S and decrease k.

PROBLEM 13.120

KNOWN: Diameter and surface temperature of a fire tube. Gas low rate and temperature. Emissivity of tube and partition.

FIND: (a) Heat transfer per unit tube length, q', without the partition, (b) Partition temperature, T_p, and heat rate with the partition, (c) Effect of flow rate and emissivity on q' and T_p. Effect of emissivity on radiative and convective contributions to q'.

SCHEMATIC:



ASSUMPTIONS: (1) Fully-developed flow in duct, (2) Diffuse/gray surface behavior, (3) Negligible gas radiation.

PROPERTIES: *Table A-4*, air ($T_{m,g}$ = 900 K): $\mu = 398 \times 10^{-7}$ N·s/m^2, k = 0.062 W/m·K, Pr = 0.72; air (T_s = 385 K): $\mu = 224 \times 10^{-7}$ N·s/m^2.

ANALYSIS: (a) Without the partition, heat transfer to the tube wall is only by convection. With $\dot{m}_g$ = 0.05 kg/s and $Re_D = 4\,\dot{m}_g/\pi D\mu = 4(0.05\text{ kg/s})/\pi(0.07\text{ m})398\times10^{-7}\text{ N}\cdot\text{s/m}^2 = 22{,}850$, the flow is turbulent. From Eq. 8.61,

$$Nu_D = 0.027\,Re_D^{4/5}\,Pr^{1/3}(\mu/\mu_s)^{0.14} = 0.027(22{,}850)^{4/5}(0.72)^{1/3}(398/224)^{0.14} = 80.5$$

$$h = \frac{k}{D}Nu_D = \frac{0.062\text{ W/m}\cdot\text{K}}{0.07\text{ m}}80.5 = 71.3\text{ W/m}^2\cdot\text{K}$$

$$q' = h\pi D\left(T_{m,g} - T_s\right) = 71.3\,\text{W/m}^2\cdot\text{K}(\pi)0.07\text{ m}(900-385) = 8075\text{ W/m}$$ <

(b) The temperature of the partition is determined from an energy balance which equates net radiation exchange with the tube wall to convection from the gas. Hence, $q''_{rad} = q''_{conv}$, where from Eq. 13.23,

$$q''_{rad} = \frac{\sigma\left(T_p^4 - T_s^4\right)}{\dfrac{1-\varepsilon_p}{\varepsilon_p} + \dfrac{1}{F_{ps}} + \dfrac{1-\varepsilon_s}{\varepsilon_s}\dfrac{A_p}{A_s}}$$

where F_{12} = 1 and $A_p/A_s = D/(\pi D/2) = 2/\pi = 0.637$. The flow is now in a noncircular duct for which $D_h = 4A_c/P = 4(\pi D^2/8)/(\pi D/2+D) = \pi D/(\pi + 2) = 0.611\,D = 0.0428$ m and $\dot{m}_{1/2} = \dot{m}_g/2 = 0.025$ kg/s. Hence, $Re_D = \dot{m}_{1/2}\,D_h/A_c\mu = \dot{m}_{1/2}\,D_h/(\pi D^2/8)\mu = 8(0.025\text{ kg/s})(0.0428\text{ m})/\pi(0.07\text{ m})^2\,398 \times 10^{-7}\text{ N}\cdot\text{s/m}^2 = 13{,}970$ and

$$Nu_D = 0.027(13{,}970)^{4/5}(0.72)^{1/3}(398/224)^{0.14} = 54.3$$

$$h = \frac{k}{D_h}Nu_D = \frac{0.062\text{ W/m}\cdot\text{K}}{0.0428\text{ m}}54.3 = 78.7\text{ W/m}^2\cdot\text{K}$$

Continued …

PROBLEM 13.120 (Cont.)

Hence, with $\varepsilon_s = \varepsilon_p = 0.5$ and $q''_{conv} = h\left(T_{m,g} - T_p\right)$,

$$\frac{5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\left(T_p^4 - 385^4\right)\text{K}^4}{1+1+0.637} = 78.7\ \text{W/m}^2\cdot\text{K}\left(900 - T_p\right)\text{K}$$

$$21.5\times10^{-8}T_p^4 + 78.7T_p - 71{,}302 = 0$$

Which may be solved to yield

$$T_p = 796\ \text{K}$$ <

The heat rate to one-half of the tube is then

$$q'_{1/2} = q'_{ps} + q'_{conv} = \frac{D\sigma\left(T_p^4 - T_s^4\right)}{\frac{1-\varepsilon_p}{\varepsilon_p} + \frac{1}{F_{ps}} + \frac{1-\varepsilon_s}{\varepsilon_s}\frac{A_p}{A_s}} + h\left(\pi D/2\right)\left(T_{m,g} - T_s\right)$$

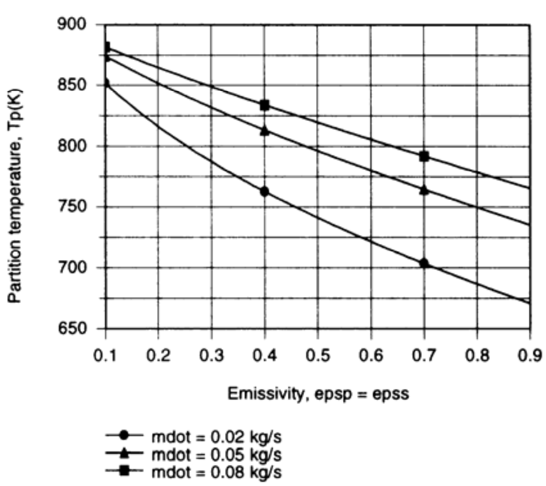
$$q'_{1/2} = \frac{0.07\ \text{m}\left(5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\right)\left(796.4^4 - 385^4\right)\text{K}^4}{2.637} + 78.7\ \text{W/m}^2\cdot\text{K}\left(0.110\ \text{m}\right)\left(900-385\right)\text{K}$$

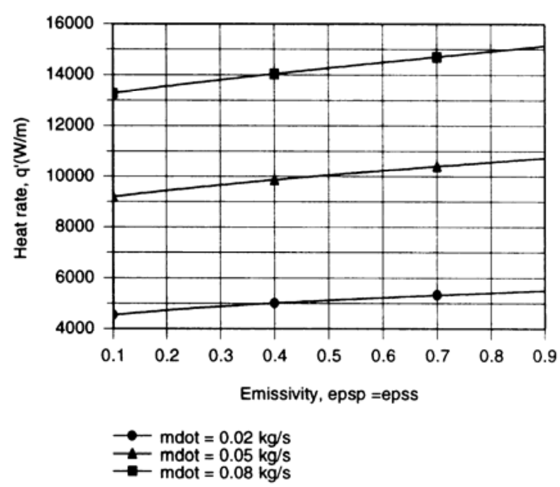
$$q'_{1/2} = 572\ \text{W/m} + 4458\ \text{W/m} = 5030\ \text{W/m}$$

The heat rate for the entire tube is

$$q' = 2q'_{1/2} = 10{,}060\ \text{W/m}$$ <

(c) The foregoing model was entered into the *IHT* workspace, and parametric calculations were performed to obtain the following results.

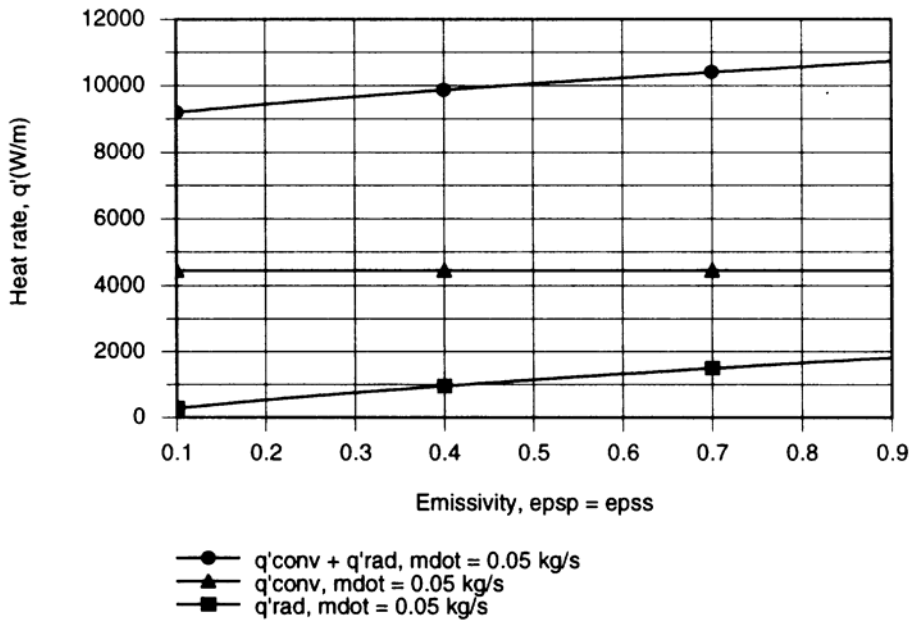




Radiation transfer from the partition increases with increasing $\varepsilon_p = \varepsilon_s$, thereby reducing T_p while increasing q'. Since h increases with increasing $\dot{m}$, T_p and q' also increase with $\dot{m}$.

Continued …

PROBLEM 13.120 (Cont.)



Although the radiative contribution to the heat rate increases with increasing $\varepsilon_p = \varepsilon_s$, it still remains small relative to convection.

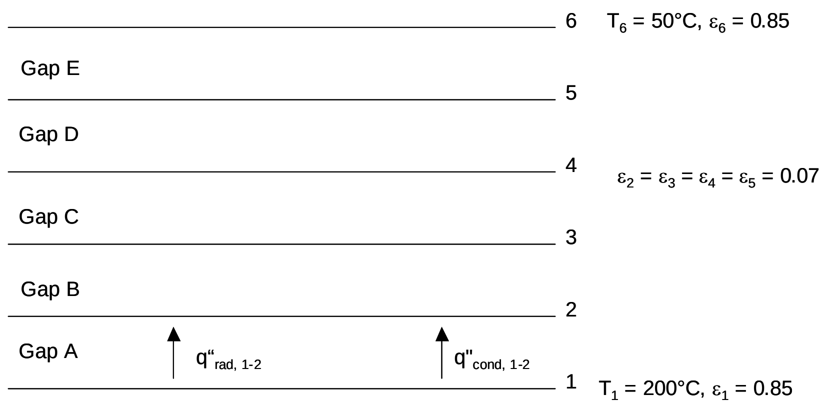
COMMENTS: Contrasting the heat rate predicted for part (b) with that for part (a), it is clear that use of the partition enhances heat transfer to the tube. However, the effect is due primarily to an increase in h and secondarily to the addition of radiation.

PROBLEM 13.121

KNOWN: Dimensions of horizontal air space separating plates of known temperature. Emissivity of end plates and interleaving aluminum sheets.

FIND: (a) Neglecting conduction or convection in the air , determine the heat flux through the system, (b) Neglecting convection and radiation, determine the heat flux through the system, (c) Heat flux through the system accounting for conduction and radiation, (d) Determine whether natural convection is negligible in part (c).

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional heat transfer, (2) Diffuse, gray surfaces, (3) Constant properties in each gap, (4) Negligible natural convection.

PROPERTIES: Air: Properties evaluated using IHT.

ANALYSIS: (a) The radiation heat flux across each of the five gaps is

$$q''_{rad,1-2} = \frac{\sigma\left(T_1^4 - T_2^4\right)}{\frac{1}{\varepsilon_1}+\frac{1}{\varepsilon_2}-1} = \frac{5.67\times10^{-8}\frac{W}{m^2\cdot K^4}\left[\left(473K\right)^4 - T_2^4\right]}{\frac{1}{0.85}+\frac{1}{0.07}-1} \quad (1)$$

$$q''_{rad,2-3} = \frac{\sigma\left(T_2^4 - T_3^4\right)}{\frac{1}{\varepsilon_2}+\frac{1}{\varepsilon_3}-1} = \frac{5.67\times10^{-8}\frac{W}{m^2\cdot K^4}\left[T_2^4 - T_3^4\right]}{\frac{1}{0.07}+\frac{1}{0.07}-1} \quad (2)$$

$$q''_{rad,3-4} = \frac{\sigma\left(T_3^4 - T_4^4\right)}{\frac{1}{\varepsilon_3}+\frac{1}{\varepsilon_4}-1} = \frac{5.67\times10^{-8}\frac{W}{m^2\cdot K^4}\left[T_3^4 - T_4^4\right]}{\frac{1}{0.07}+\frac{1}{0.07}-1} \quad (3)$$

Continued…

PROBLEM 13.121 (Cont.)

$$q''_{rad,4-5} = \frac{\sigma\left(T_4^4 - T_5^4\right)}{\frac{1}{\varepsilon_4} + \frac{1}{\varepsilon_5} - 1} = \frac{5.67 \times 10^{-8} \frac{W}{m^2 \cdot K^4}\left[T_4^4 - T_5^4\right]}{\frac{1}{0.07} + \frac{1}{0.07} - 1} \quad (4)$$

$$q''_{rad,5-6} = \frac{\sigma\left(T_5^4 - T_6^4\right)}{\frac{1}{\varepsilon_5} + \frac{1}{\varepsilon_6} - 1} = \frac{5.67 \times 10^{-8} \frac{W}{m^2 \cdot K^4}\left[T_5^4 - (325K)^4\right]}{\frac{1}{0.07} + \frac{1}{0.85} - 1} \quad (5)$$

where

$$q''_{rad} = q''_{rad,1-2} = q''_{rad,2-3} = q''_{rad,3-4} = q''_{rad,4-5} = q''_{rad,5-6} \quad (6)$$

Solving Eqns. (1) through (6) simultaneously yields

T_2 = 460.5 K, T_3 = 433.5 K, T_4 = 400.1 K, T_5 = 355.4 K, q''_{rad} = 19.89 W/m^2 $<$

(b) The conduction heat flux across each of the five gaps is

$$q''_{cond} = \frac{k_A}{L}\left(T_1 - T_2\right) \quad (7)$$

where k_A is the thermal conductivity of air evaluated at $\overline{T_A} = (T_1 + T_2)/2$. Likewise,

$$q''_{cond,2-3} = \frac{k_B}{L}\left(T_2 - T_3\right); \quad k_B = k_{air}\left(\left[T_2 + T_3\right]/2\right) \quad (8)$$

$$q''_{cond,3-4} = \frac{k_C}{L}\left(T_3 - T_4\right); \quad k_C = k_{air}\left(\left[T_3 + T_4\right]/2\right) \quad (9)$$

$$q''_{cond,4-5} = \frac{k_D}{L}\left(T_4 - T_5\right); \quad k_D = k_{air}\left(\left[T_4 + T_5\right]/2\right) \quad (10)$$

$$q''_{cond,5-6} = \frac{k_E}{L}\left(T_5 - T_6\right); \quad k_E = k_{air}\left(\left[T_5 + T_6\right]/2\right) \quad (11)$$

where

$$q''_{cond} = q''_{cond,1-2} = q''_{cond,2-3} = q''_{cond,3-4} = q''_{cond,4-5} = q''_{cond,5-6} \quad (12)$$

Continued…

PROBLEM 13.121 (Cont.)

Solving Eqns. (7) through (12) simultaneously and using IHT to evaluate k_A, k_B, k_C, k_D and k_E yields

T_2 = 446.5 K, T_3 = 418.6 K, T_4 = 389.1 K, T_5 = 357.4 K, q''_{cond} = 100.6 W/m^2 <

(c) For each gap, $q'' = q''_{cond} + q''_{rad}$. Hence,

$$q''_{1-2} = q''_{rad,1-2} + q''_{cond,1-2} \quad (13)$$

$$q''_{2-3} = q''_{rad,2-3} + q''_{cond,2-3} \quad (14)$$

$$q''_{3-4} = q''_{rad,3-4} + q''_{cond,3-4} \quad (15)$$

$$q''_{4-5} = q''_{rad,4-5} + q''_{cond,4-5} \quad (16)$$

$$q''_{5-6} = q''_{rad,5-6} + q''_{cond,5-6} \quad (17)$$

where $q'' = q''_{1-2} = q''_{2-3} = q''_{3-4} = q''_{4-5} = q''_{5-6}$ (18)

Solving Eqns. (1) through (5), (8) through (11), and (13) through (18) simultaneously and using IHT to evaluate k_A, k_B, k_C, k_D and k_E yields

T_2 = 450.2 K, T_3 = 421.9 K, T_4 = 391.2 K, T_5 = 357.4 K, q'' = 122.1 W/m^2 <

(d) The Rayleigh number for gap A is

$$Ra_{L,A} = \frac{g\beta\left(T_1 - T_2\right)L^3}{\nu\alpha}$$

where T_1 = 473 K and T_2 = 450.2 K. Therefore, $\overline{T} = (473\text{K} + 450.2\text{K})/2 = 461.1\text{K}$. Hence,

$$\beta = \frac{1}{\overline{T}} = \frac{1}{461.1\text{K}},\ \nu = 3.381\times10^{-5}\frac{\text{m}^2}{2} \text{ and } \alpha = 4.931\times10^{-5}\frac{\text{m}^2}{\text{s}}$$

from which

$$Ra_{L,A} = \frac{9.81\frac{\text{m}}{\text{s}^2}\frac{1}{461.1\text{K}}\times\left(473\text{K} - 450.2\text{K}\right)\times0.01\text{m}^3}{3.381\times10^{-5}\frac{\text{m}^2}{\text{s}}\times4.931\times10^{-5}\frac{\text{m}^2}{\text{s}}} = 289.2$$

Continued…

Repeating the calculation for the remaining gaps yields

$$Ra_{L,B} = 463,\ Ra_{L,C} = 690,\ Ra_{L,D} = 1104,\ Ra_{L,E} = 1747.$$

The largest Rayleigh number is slightly higher than the critical value of 1703. Therefore, natural convection in the gaps is negligible. <

COMMENTS: (1) Ignoring the presence of the air will result in an estimated heat flux that is only 16% of the actual value. One must carefully account for conduction or convection effects in radiation problems, in particular when the radiation occurs in conjunction with low emissivity surfaces. (2) The heat flux for combined radiation and conduction exceeds the sum of the individual components acting alone. This is due to the non-linear effects brought about by the fourth-power dependence of the radiation heat flux upon temperature and property variations. (3) The foil temperatures vary for the three simulations. Can you explain why different temperatures exist for the three cases?

qrad45 = sigma*(T4^4-T5^4)/(1/emiss4+1/emiss5-1)
qcon45 = k45*(T4-T5)/L
qtot = qrad45+qcon45

qrad56 = sigma*(T5^4-T6^4)/(1/emiss5+1/emiss6-1)
qcon56 = k56*(T5-T6)/L
qtot = qrad56+qcon56

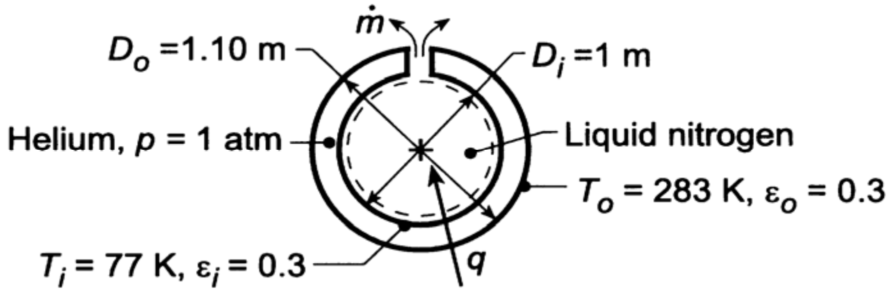
//Note that one must input initial temperatures of around 350 K for all values, or else the system of equations
will not converge.
```

PROBLEM 13.122

KNOWN: Diameters, temperatures, and emissivities of concentric spheres.

FIND: Rate at which nitrogen is vented from the inner sphere. Effect of radiative properties on evaporation rate.

SCHEMATIC:



ASSUMPTIONS: Diffuse-gray surfaces.

PROPERTIES: Liquid nitrogen (given): $h_{fg} = 2 \times 10^5$ J/kg; *Table A-4*, Helium ($\bar{T} = (T_i + T_o)/2 =$ 180 K, 1 atm): $\nu = 51.3 \times 10^{-6}$ m²/s, k = 0.107 W/m·K, $\alpha = 76.2 \times 10^{-6}$ m²/s, Pr = 0.673, $\beta =$ 0.00556 K^{-1}.

ANALYSIS: (a) Performing an energy balance for a control surface about the liquid nitrogen, it follows that $q = q_{conv} + q_{rad} = \dot{m}h_{fg}$. The convection heat rate is given by Eqs. 9.61 through 9.63.

$$L_s = \frac{\left(\frac{1}{r_i} - \frac{1}{r_o}\right)^{4/3}}{2^{1/3}\left(r_i^{-7/5} + r_o^{-7/5}\right)^{5/3}} = \frac{\left(\frac{1}{0.5\text{m}} - \frac{1}{0.55\text{m}}\right)^{4/3}}{2^{1/3}\left(0.5\text{m}^{-7/5} + 0.55\text{m}^{-7/5}\right)^{5/3}} = 0.0057\text{m}$$

The Rayleigh number is

$$Ra_s = \left|\frac{g\beta(T_i - T_o)L_s^3}{\nu\alpha}\right| = \left|\frac{9.8\text{m/s}^2(0.00556\text{K}^{-1})(77-283)\text{K}(0.0057\text{m})^3}{51.3\times10^{-6}\text{m}^2/\text{s}\times76.2\times10^{-6}\text{m}^2/\text{s}}\right| = 529$$

From Eq. 9.62,

$$\frac{k_{eff}}{k} = 0.74\left(\frac{Pr}{0.861 + Pr}\right)^{1/4} Ra_s^{1/4} = 0.74\left(\frac{0.673}{0.861 + 0.673}\right)^{1/4} 529^{1/4} = 2.89$$

Therefore, keff = 2.89 × 0.107 W/m·K = 0.309 W/m·K. From Eq. 9.61,

$$q_{conv} = \frac{4\pi k_{eff}(T_i - T_o)}{(1/r_i) - (1/r_o)} = \frac{4\times\pi\times0.309\text{W/m}\cdot\text{K}\times(206\text{K})}{(1/0.5\text{m}) - (1/0.55\text{m})} = 4399\text{W}$$

Continued...

PROBLEM 13.122 (Cont.)

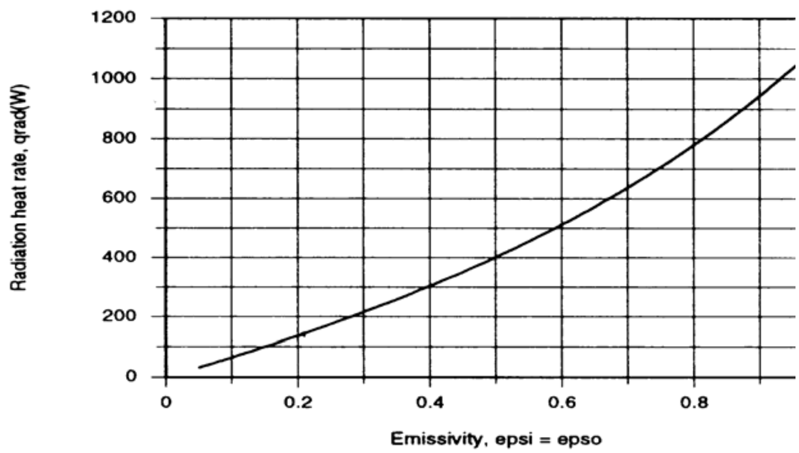
From Table 13.21,

$$q_{rad} = q_{oi} = \frac{\sigma \pi D_1^2 \left(T_o^4 - T_i^4\right)}{1/\varepsilon_i + \left(\left(1-\varepsilon_o\right)/\varepsilon_o\right)\left(D_i / D_o\right)^2}$$

$$= \frac{\left(5.67\times10^{-8}\,\text{W/m}^2\cdot\text{K}^4\right)\pi\left(1\text{ m}\right)^2\left(283^4 - 77^4\right)\text{K}^4}{1/0.3+\left(0.7/0.3\right)\left(1/1.1\right)^2} = 216\text{ W}.$$

Hence, $\dot{m} = q/h_{fg} = \left(4399+216\right)\text{W}/2\times10^5\text{ J/kg} = 0.023\,\text{kg/s}.$ <

With the cavity evacuated, *IHT* was used to compute the radiation heat rate as a function of $\varepsilon_i = \varepsilon_o$.



Clearly, significant advantage is associated with reducing the emissivities and q_{rad} = 31.8 W for $\varepsilon_i = \varepsilon_o$ = 0.05.

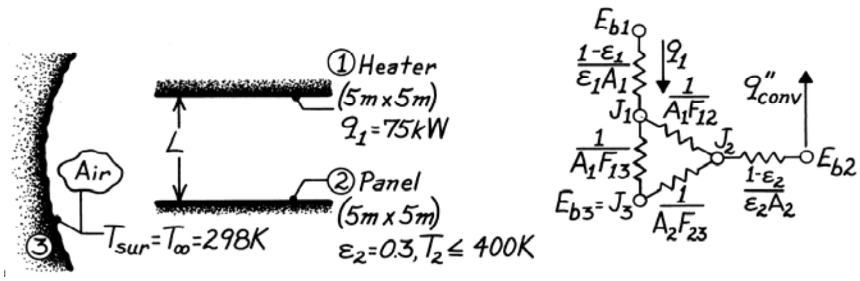
COMMENTS: The convection heat rate is too large. It could be reduced by replacing He with a gas of smaller k, a cryogenic insulator (Table A.3), or a vacuum. Radiation effects are second order for small values of the emissivity.

PROBLEM 13.123

KNOWN: Dimensions, emissivity and upper temperature limit of coated panel. Arrangement and power dissipation of a radiant heater. Temperature of surroundings.

FIND: (a) Minimum panel-heater separation, neglecting convection, (b) Minimum panel-heater separation, including convection.

SCHEMATIC:



ASSUMPTIONS: (1) Top and bottom surfaces of heater and panel, respectively, are adiabatic, (2) Bottom and top surfaces of heater and panel, respectively are diffuse-gray, (3) Surroundings form a large enclosure about the heater-panel arrangement, (4) Steady-state conditions, (5) Heater power is dissipated entirely as radiation (negligible convection), (6) Air is quiescent and convection from panel may be approximated as free convection from a horizontal surface, (7) Air is at atmospheric pressure.

PROPERTIES: *Table A-4*, Air (T_f = (400 + 298)/2 ≈ 350 K, 1 atm): $\nu = 20.9 \times 10^{-6}\ m^2/s$, k = 0.03 W/m·K, Pr = 0.700, $\alpha = 29.9 \times 10^{-6}\ m^2/s$, $\beta = 2.86 \times 10^{-3}\ K^{-1}$.

ANALYSIS: (a) Neglecting convection effects, the panel constitutes a floating potential for which the net radiative transfer must be zero. That is, the panel behaves as a re-radiating surface for which $E_{b2} = J_2$. Hence

$$q_1 = \frac{J_1 - E_{b2}}{1/A_1F_{12}} + \frac{J_1 - E_{b3}}{1/A_1F_{13}} \qquad (1)$$

and evaluating terms

$$E_{b2} = \sigma T_2^4 = 5.67 \times 10^{-8}\ W/m^2 \cdot K^4 (400\ K)^4 = 1452\ W/m^2$$

$$E_{b3} = \sigma T_3^4 = 5.67 \times 10^{-8}\ W/m^2 \cdot K^4 (298\ K)^4 = 447\ W/m^2$$

$$F_{13} = 1 - F_{12} \qquad A_1 = 25\ m^2$$

find that

$$\frac{75,000\ W}{25\ m^2} = \frac{J_1 - 1452}{1/F_{12}} + \frac{J_1 - 447}{1/(1 - F_{12})}$$

$$3000\ W/m^2 = F_{12}(J_1 - 1452) + (J_1 - 447) - F_{12}(J_1 - 447)$$

$$J_1 = 3447 + 1005F_{12}. \qquad (2)$$

Performing a radiation balance on the panel yields

$$\frac{J_1 - E_{b2}}{1/A_1F_{12}} = \frac{E_{b2} - E_{b3}}{1/A_2F_{23}}.$$

Continued …

PROBLEM 13.123 (Cont.)

With $A_1 = A_2$ and $F_{23} = 1 - F_{12}$

$$F_1\left(J_1 - 1452\right) = \left(1 - F_{12}\right)\left(1452 - 447\right)$$

or

$$447F_{12} = F_{12}J_1 - 1005. \qquad (3)$$

Substituting for J_1 from Eq. (2), find

$$447F_{12} = F_{12}\left(3447 + 1005F_{12}\right) - 1005$$

$$1005F_{12}^2 + 3000F_{12} - 1005 = 0$$

$$F_{12} = 0.30.$$

Hence from Fig. 13.4, with X/L = Y/L and F_{ij} = 0.3,

$$X/L \approx 1.45$$

$$L \approx 5\ \text{m}/1.45 = 3.45\ \text{m}.$$ <

(b) Accounting for convection from the panel, the net radiation transfer is no longer zero at this surface and $E_{b2} \neq J_2$. It then follows that

$$q_1 = \frac{J_1 - J_2}{1/A_1F_{12}} + \frac{J_1 - E_{b3}}{1/A_1F_{13}} \qquad (4)$$

where, from an energy balance on the panel,

$$\frac{J_2 - E_{b2}}{\left(1 - \varepsilon_2\right)/\varepsilon_2 A_2} = q_{conv,2} = \overline{h}A_2\left(T_2 - T_\infty\right). \qquad (5)$$

With $L \equiv A_s/P = 25\ \text{m}^2/20\ \text{m} = 1.25$ m,

$$Ra_L = \frac{g\beta\left(T_s - T_\infty\right)L^3}{\nu\alpha} = \frac{9.8\ \text{m/s}^2\left(2.86\times10^{-3}\text{K}^{-1}\right)\left(102\ \text{K}\right)\left(1.25\ \text{m}\right)^3}{\left(20.9\times29.9\right)10^{-12}\ \text{m}^4/\text{s}^2} = 8.94\times10^9.$$

Hence, from Eq. 9.31

$$\overline{Nu}_L = 0.15Ra_L^{1/3} = 0.15\left(8.94\times10^9\right)^{1/3} = 311$$

$$\overline{h} = 311\ k/L = 311\frac{0.03\ \text{W/m}\cdot\text{K}}{1.25\ \text{m}} = 7.46\ \text{W/m}^2\cdot\text{K}$$

$$q''_{conv,2} = 7.46\ \text{W/m}^2\cdot\text{K}\left(102\ \text{K}\right) = 761\ \text{W/m}^2.$$

From Eq. (5)

$$J_2 = E_{b2} + \frac{1 - \varepsilon_2}{\varepsilon_2}q''_{conv,2} = 1452 + \frac{0.7}{0.3}761 = 3228\ \text{W/m}^2.$$

Continued …

PROBLEM 13.123 (Cont.)

From Eq. (4),

$$\frac{75,000}{25} = \frac{J_1 - 3228}{1/F_{12}} + \frac{J_1 - 447}{1/(1 - F_{12})}$$

$$3000 = F_{12}(J_1 - 3228) + J_1 - 447 - F_{12}(J_1 - 447)$$

$$J_1 = 3447 + 2781F_{12}. \qquad (6)$$

From an energy balance on the panel,

$$\frac{J_1 - J_2}{1/A_1F_{12}} + \frac{E_{b3} - J_2}{1/A_2F_{23}} = \frac{J_2 - E_{b2}}{(1-\varepsilon_2)/\varepsilon_2 A_2} = q_{conv,2}$$

$$F_{12}(J_1 - 3228) + (1 - F_{12})(447 - 3228) = 761$$

$$F_{12}J_1 - 447F_{12} = 3542.$$

Substituting from Eq. (6),

$$F_{12}(3447 + 2781F_{12}) - 447F_{12} = 3542$$

$$2781F_{12}^2 + 3000F_{12} - 3542 = 0$$

$$F_{12} = 0.71.$$

Hence from Fig. 13.4, with X/L = Y/L and F_{ij} = 0.71,

$$X/L = 5.7$$

$$L \approx 5\ \text{m}/5.7 = 0.88\ \text{m}. \qquad <$$

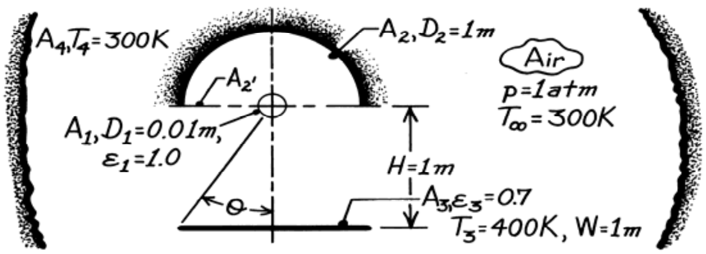
COMMENTS: (1) The results are independent of the heater surface radiative properties. (2) Convection at the heater surface would reduce the heat rate q_1 available for radiation exchange and hence reduce the value of L.

PROBLEM 13.124

KNOWN: Diameter and emissivity of rod heater. Diameter and position of reflector. Width, emissivity, temperature and position of coated panel. Temperature of air and large surroundings.

FIND: (a) Equivalent thermal circuit, (b) System of equations for determining heater and reflector temperatures. Values of temperatures for prescribed conditions, (c) Electrical power needed to operate heater.

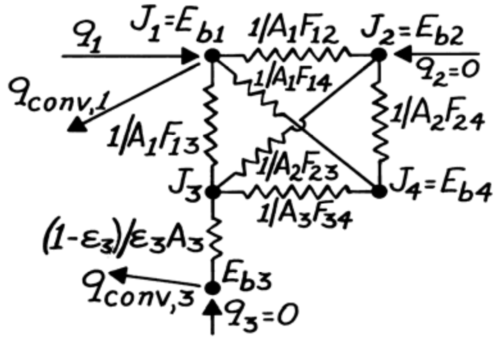
SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Diffuse-gray surfaces, (3) Large surroundings act as blackbody, (4) Surfaces are infinitely long (negligible end effects), (5) Air is quiescent, (6) Negligible convection at reflector, (7) Reflector and panel are perfectly insulated.

PROPERTIES: *Table A-4*, Air (T_f = 350 K, 1 atm): k = 0.03 W/m·K, $\nu = 20.9 \times 10^{-6}$ m^2/s, $\alpha = 29.9 \times 10^{-6}$ m^2/s, Pr = 0.70; (T_f = (1295 + 300)/2 = 800 K): k = 0.0573 W/m·K, $\nu = 84.9 \times 10^{-6}$ m^2/s, $\alpha = 120 \times 10^{-6}$ m^2/s.

ANALYSIS: (a) We have assumed blackbody behavior for A_1 and A_4; hence, $J = E_b$. Also, A_2 is insulated and has negligible convection; hence q = 0 and $J_2 = E_{b2}$. The equivalent thermal circuit is:



(b) Performing surface energy balances at 1, 2 and 3:

$$q_1 - q_{conv,1} = \frac{E_{b1} - E_{b2}}{1/A_1F_{12}} + \frac{E_{b1} - J_3}{1/A_1F_{13}} + \frac{E_{b1} - E_{b4}}{1/A_1F_{14}} \quad (1)$$

$$0 = \frac{E_{b1} - E_{b2}}{1/A_2F_{21}} + \frac{J_3 - E_{b2}}{1/A_2F_{23}} + \frac{E_{b4} - E_{b2}}{1/A_2F_{24}} \quad (2)$$

$$\frac{J_3 - E_{b3}}{(1-\varepsilon_3)/\varepsilon_3 A_3} = \frac{E_{b1} - J_3}{1/A_3F_{31}} + \frac{E_{b2} - J_3}{1/A_3F_{32}} + \frac{E_{b4} - J_3}{1/A_3F_{34}} \quad (3a)$$

where

$$\frac{J_3 - E_{b3}}{(1-\varepsilon_3)/\varepsilon_3 A_3} = q_{conv,3}. \quad (3b)$$

Continued …

PROBLEM 13.124 (Cont.)

Solution procedure with E_{b3} and E_{b4} known: Evaluate $q_{conv,3}$ and use Eq. (3b) to obtain J_3; Solve Eqs. (2) and (3a) simultaneously for E_{b1} and E_{b2} and hence T_1 and T_2; Evaluate $q_{conv,1}$ and use Eq. (1) to obtain q_1.

For *free convection* from a heated, horizontal plate using Eqs. 9.29, 9.25, and 9.31:

$$L_c = \frac{A_s}{P} = \frac{(W \times L)}{(2L + 2W)} \approx \frac{W}{2} = 0.5\ \text{m}$$

$$Ra_L = \frac{g\beta(T_3 - T_\infty)L_c^3}{\alpha\nu} = \frac{9.8\ \text{m/s}^2\,(350\ \text{K})^{-1}(100\ \text{K})(0.5\ \text{m})^3}{20.9 \times 29.9 \times 10^{-12}\,\text{m}^4/\text{s}^2} = 5.6 \times 10^8$$

$$\overline{Nu}_L = 0.15 Ra_L^{1/3} = 0.15\left(5.6 \times 10^8\right)^{1/3} = 123.6$$

$$\bar{h}_3 = \frac{k}{L_c}\overline{Nu}_L = \frac{0.03\ \text{W/m}\cdot\text{K} \times 123.6}{0.5\ \text{m}} = 7.42\ \text{W/m}^2\cdot\text{K}.$$

$$q''_{conv,3} = \bar{h}_3(T_3 - T_\infty) = 742\ \text{W/m}^2.$$

Hence, with

$$E_{b3} = \sigma T_3^4 = 5.67 \times 10^{-8}\text{W/m}^2\cdot\text{K}^4\,(400\ \text{K})^4 = 1451\ \text{W/m}^2$$

using Eq. (3b) find

$$J_3 = E_{b3} + \frac{1-\varepsilon_3}{\varepsilon_3 A_3} q_{conv,3} = \left(1451 + [0.3/0.7]742\right) = 1769\ \text{W/m}^2.$$

View Factors: From symmetry, it follows that $F_{12} = 0.5$. With $\theta = \tan^{-1}(W/2)/H = \tan^{-1}(0.5) = 26.57°$, it follows that

$$F_{13} = 2\theta/360 = 0.148.$$

From summation and reciprocity relations,

$$F_{14} = 1 - F_{12} - F_{13} = 0.352$$

$$F_{21} = (A_1/A_2)F_{12} = (2D_1/D_2)F_{12} = 0.02 \times 0.5 = 0.01$$

$$F_{23} = (A_3/A_2)F_{32} = (2/\pi)(F_{32'} - F_{31}).$$

For X/L = 1, Y/L ≈ ∞, find from Fig. 13.4 that $F_{32'} \approx 0.42$. Also find,

$$F_{31} = (A_1/A_3)F_{13} = (\pi \times 0.01/1)0.148 = 0.00465 \approx 0.005$$

$$F_{23} = (2/\pi)(0.42 - 0.005) = 0.264$$

$$F_{22} \approx 1 - F_{22'} = 1 - (A'_2/A_2)F_{2'2} = 1 - (2/\pi) = 0.363$$

$$F_{24} = 1 - F_{21} - F_{22} - F_{23} = 0.363$$

Continued …

PROBLEM 13.124 (Cont.)

$F_{31} = 0.005,$ $\quad F_{32} = 0.415$

$F_{34} = 1 - F_{32'} = 1 - 0.42 = 0.58.$

With $E_{b4} = \sigma T_4^4 = 5.67 \times 10^{-8}\ W/m^2 \cdot K^4 (300\ K)^4 = 459\ W/m^2$,

Eq. (3a) $\rightarrow$ $0.005(E_{b1} - 1769) + 0.415(E_{b2} - 1769) + 0.58(459 - 1769) = 742$

$$0.005E_{b1} + 0.415Eb2 = 2245 \qquad (4)$$

Eq. (2) $\rightarrow$ $0.01(E_{b1} - E_{b2}) + 0.264(1769 - E_{b2}) + 0.363(459 - E_{b2}) = 0$

$$0.01E_{b1} - 0.637E_{b2} + 633.6 = 0. \qquad (5)$$

Hence, manipulating Eqs. (4) and (5), find

$$E_{b2} = 0.0157E_{b1} + 994.7$$

$$0.005E_{b1} + (0.415)(0.0157E_{b1} + 994.7) = 2245.$$

$$E_{b1} = 159,322\ W/m^2 \qquad T_1 = (E_{b1}/\sigma)^{1/4} = 1295\ K$$ <

$$E_{b2} = 0.0157(159,322) + 994.7 = 3496\ W/m^2 \qquad T_2 = (E_{b2}/\sigma)^{1/4} = 498\ K.$$ <

(c) With T_1 = 1295 K, then T_f = (1295 + 300)/2 ≈ 800 K, and using Eq. 9.33

$$Ra_D = \frac{g\beta(T_1 - T_\infty)D_1^3}{\alpha\nu} = \frac{9.8\ m/s^2(1/800\ K)(1295 - 300)K(0.01\ m)^3}{120 \times 84.9 \times 10^{-12} m^4/s^2} = 1196$$

$$\overline{Nu}_D = 0.85Ra_D^{0.188} = 0.85(1196)^{0.188} = 3.22$$

$$\bar{h}_1 = (k/D_1)\overline{Nu}_D = (0.0573/0.01) \times 3.22 = 18.5\ W/m^2 \cdot K.$$

The convection heat flux is

$$q''_{conv,1} = \bar{h}_1(T_1 - T_\infty) = 18.5(1295 - 300) = 18,407\ W/m^2,$$

Using Eq. (1), find

$$q''_1 = q''_{conv,1} + F_{12}(E_{b1} - E_{b2}) + F_{13}(E_{b1} - J_3) + F_{14}(E_{b1} - E_{b4})$$

$$q''_1 = 18,407 + 0.5(159,322 - 3496)$$
$$+ 0.148(159,322 - 1769) + 0.352(159,322 - 459)$$

$$q''_1 = 18,407 + (77,913 + 23,314 + 55,920)$$

$$q''_1 = 18,407 + 236,381 = 254,788\ W/m^2$$

$$q'_1 = \pi D_1 q''_1 = \pi(0.01)254,788 = 8000\ W/m.$$ <

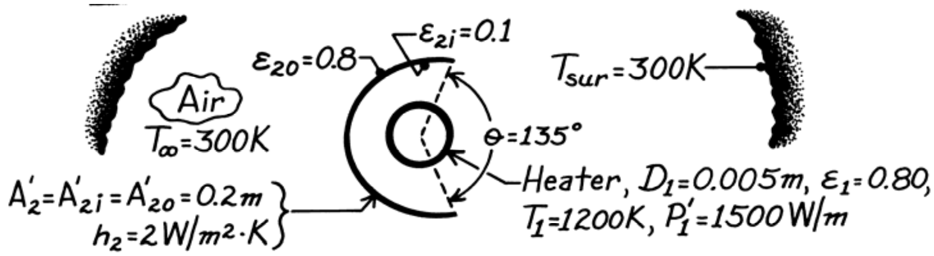
COMMENTS: Although convection represents less than 8% of the net radiant transfer from the heater, it is equal to the net radiant transfer to the panel. Since the reflector is a reradiating surface, results are independent of its emissivity.

PROBLEM 13.125

KNOWN: Temperature, power dissipation and emissivity of a cylindrical heat source. Surface emissivities of a parabolic reflector. Temperature of air and surroundings.

FIND: (a) Radiation circuit, (b) Net radiation transfer from the heater, (c) Net radiation transfer from the heater to the surroundings, (d) Temperature of reflector.

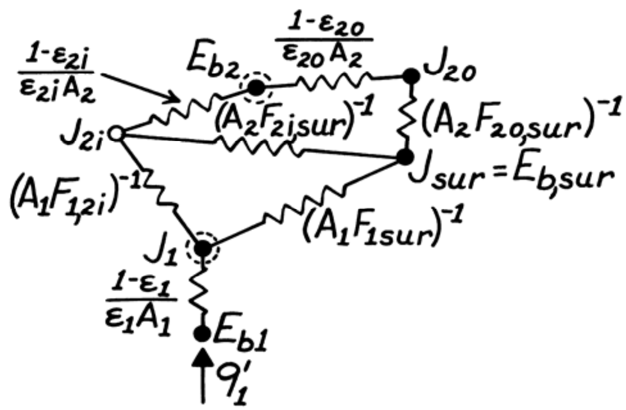
SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Heater and reflector are in quiescent and infinite air, (3) Surroundings are infinitely large, (4) Reflector is thin (isothermal), (5) Diffuse-gray surfaces.

PROPERTIES: *Table A-4*, Air (T_f = 750 K, 1 atm): $\nu = 76.37 \times 10^{-6}$ m^2/s, k = 0.0549 W/m·K, $\alpha = 109 \times 10^{-6}$ m^2/s, Pr = 0.702.

ANALYSIS: (a) The thermal circuit is



(b) Energy transfer from the heater is by radiation and free convection. Hence,

$$P_1' = q_1' + q_{1,conv}'$$

where

$$q_{1,conv}' = \bar{h}\pi D_1 \left(T_1 - T_\infty\right)$$

and

$$Ra_D = \frac{g\beta\left(T_1 - T_\infty\right)D^3}{\nu\alpha} = \frac{9.8\text{ m/s}^2\left(750\text{ K}\right)^{-1}\left(900\text{ K}\right)\left(0.005\text{ m}\right)^3}{76.37\times 109\times 10^{-12}\text{m}^4/\text{s}^2} = 176.6.$$

Using the Churchill and Chu correlation of Chapter 9, find

$$\overline{Nu}_D = \left\{0.6 + \frac{0.387 Ra_D^{1/6}}{\left[1+\left(0.559/Pr\right)^{9/16}\right]^{8/27}}\right\}^2 = \left\{0.6 + \frac{0.387\left(176.6\right)^{1/6}}{\left[1+\left(0.559/0.702\right)^{9/16}\right]^{8/27}}\right\}^2 = 1.85$$

$$\bar{h} = \overline{Nu}_D\left(k/D\right) = 1.85\left(0.0549\text{ W/m}\cdot\text{K}/0.005\text{ m}\right) = 20.3\text{ W/m}^2\cdot\text{K}.$$

Continued …

PROBLEM 13.125 (Cont.)

Hence,

$$q'_{1,conv} = 20.3\ W/m^2 \cdot K\pi(0.005\ m)(1200-300)K = 287\ W/m$$

$$q'_1 = 1500\ W/m - 287\ W/m = 1213\ W/m. \qquad <$$

(c) The net radiative heat transfer from the heater to the surroundings is

$$q'_{1(sur)} = A'_1F_{1sur}(J_1 - J_{sur}).$$

The view factor is

$$F_{1sur} = (135/360) = 0.375$$

and the radiosities are

$$J_{sur} = \sigma T_{sur}^4 = 5.67\times10^{-8} W/m^2\cdot K^4(300\ K)^4 = 459\ W/m^2$$

$$J_1 = E_{b1} - q'_1(1-\varepsilon_1)\varepsilon_1 A'_1 = 5.67\times10^{-8} W/m^2\cdot K^4(1200\ K)^4$$
$$-1213\ W/m[0.2/0.8\pi(0.005\ m)]$$

$$J_1 = 98,268\ W/m^2.$$

Hence

$$q'_{1(sur)} = \pi(0.005\ m)0.375(98,268-459)W/m^2 = 576\ W/m. \qquad <$$

(d) Perform an energy balance on the reflector,

$$q'_{2i} = q'_{2o} + q'_{2,conv}$$

$$\frac{J_{2i} - E_{b2}}{(1-\varepsilon_{2i})/\varepsilon_{2i}A'_2} = \frac{E_{b2} - J_{sur}}{(1-\varepsilon_{2o})/\varepsilon_{2o}A'_2 + 1/A'_2F_{2o(sur)}} + 2\bar{h}_2A'_2(T_2 - T_\infty).$$

The radiosity of the reflector is

$$J_{2i} = J_1 - \frac{q'_{1(2i)}}{A'_1F_{1(2i)}} = 98,268\ W/m^2 - \frac{(1213-576)W/m}{\pi(0.005\ m)(225/360)}$$

$$J_{2i} = 33,384\ W/m^2.$$

Hence

$$\frac{33,384 - 5.67\times10^{-8}(T_2^4)}{(0.9/0.1\times0.2\ m)} = \frac{5.67\times10^{-8}(T_2^4) - 459}{(0.2/0.8\times0.2\ m)+(1/0.2m\times1)} + 2\times0.4(T_2 - 300)$$

$$741.9 - 0.126\times10^{-8}T_2^4 = 0.907\times10^{-8}T_2^4 - 73.4 + 0.8T_2 - 240$$

$$1.033\times10^{-8}T_2^4 + 0.8T_2 = 1005$$

which may be solved to yield

$$T_2 = 502\ K. \qquad <$$

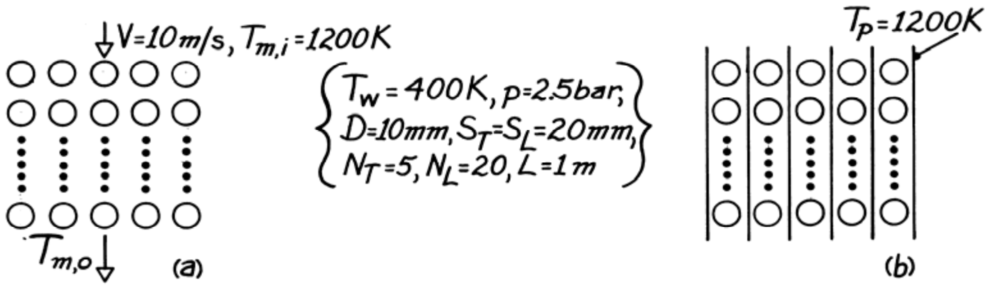
COMMENTS: Choice of small ε_{2i} and large ε_{2o} insures that most of the radiation from heater is reflected to surroundings and reflector temperature remains low.

PROBLEM 13.126

KNOWN: Geometrical conditions associated with tube array. Tube wall temperature and pressure of water flowing through tubes. Gas inlet velocity and temperature when heat is transferred from products of combustion in cross-flow, or temperature of electrically heated plates when heat is transferred by radiation from the plates.

FIND: (a) Steam production rate for gas flow without heated plates, (b) Steam production rate with heated plates and no gas flow, (c) Effects of inserting unheated plates with gas flow.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible gas radiation, (3) Tube and plate surfaces may be approximated as blackbodies, (4) Gas outlet temperature is 600 K.

PROPERTIES: *Table A-4*, Air ($\overline{T}$ = 900 K, 1 atm): ρ = 0.387 kg/m^3, c_p = 1121 J/kg·K, ν = 102.9 × 10^{-6} m^2/s, k = 0.062 W/m·K, Pr = 0.720; (T = 400 K): Pr = 0.686; (T = 1200 K): ρ = 0.29 kg/m^3; *Table A-6*, Sat. water (2.5 bars): h_{fg} = 2.18 × 10^6 J/kg.

ANALYSIS: (a) With

$$V_{max} = \left[S_T / \left(S_T - D\right)\right] V = 20 \text{ m/s}$$

$$Re_D = \frac{V_{max} D}{\nu} = \frac{20 \text{ m/s}\left(0.01 \text{ m}\right)}{102.9 \times 10^{-6} \text{m}^2/\text{s}} = 1944$$

and from the Zukauskas correlation of Chapter 7 with C_1 = 0.27 and m = 0.63,

$$\overline{Nu}_D = 0.27\left(1944\right)^{0.63}\left(0.720\right)^{0.36}\left(0.720/0.686\right)^{1/4} = 28.7$$

$$\overline{h} = 0.062 \text{ W/m} \cdot \text{K} \times 28.7/0.01 \text{ m} = 178 \text{ W/m}^2 \cdot \text{K}.$$

The outlet temperature may be evaluated from

$$\frac{T_s - T_{m,o}}{T_s - T_{m,i}} = \exp\left(-\frac{\overline{h}A}{\dot{m}c_p}\right) = \exp\left(-\frac{\overline{h}N\pi D}{\rho V N_T S_T c_p}\right)$$

$$\frac{400 - T_{m,o}}{400 - 1200} = \exp\left(-\frac{178 \text{ W/m}^2 \cdot \text{K} \times 100 \times \pi \times 0.01 \text{ m}}{0.29 \text{ kg/m}^3 \times 10 \text{ m/s} \times 5 \times 0.02 \text{ m} \times 1121 \text{ J/kg} \cdot \text{K}}\right)$$

$$T_{m,o} = 543 \text{ K.}$$

Continued …

PROBLEM 13.126 (Cont.)

With

$$\Delta T_{\ell m} = \frac{(T_s - T_{m,i}) - (T_s - T_{m,o})}{\ln[(T_s - T_{m,i})/(T_s - T_{m,o})]} = \frac{-800 - (-143)}{\ln(800/143)} = -382\text{ K}$$

find

$$q = \bar{h}A\Delta T_{\ell m} = 178\text{ W/m}^2\cdot\text{K}(100)\pi(0.01\text{ m})1\text{ m}(-382\text{ K})$$

$$q = -214\text{ kW.}$$

If the water enters and leaves as saturated liquid and vapor, respectively, it follows that $-q = \dot{m}\,h_{fg}$, hence

$$\dot{m} = \frac{214,000\text{ W}}{2.18\times10^6\text{ J/kg}} = 0.098\text{ kg/s.}$$ <

(b) The radiation exchange between the plates and tube walls is

$$q = \left[A_p F_{ps}\sigma\left(T_p^4 - T_s^4\right)\right]\cdot 2\cdot N_T$$

where the factor of 2 is due to radiation transfer from two plates. The view factor and area are

$$F_{ps} = 1 - \left[1 - (D/S)^2\right]^{1/2} + (D/S)\tan^{-1}\left[\left(S^2 - D^2\right)/D^2\right]^{1/2}$$

$$F_{ps} = 1 - 0.866 + 0.5\tan^{-1}1.732 = 1 - 0.866 + 0.524$$

$$F_{ps} = 0.658$$

$$A_p = N_L\cdot S_L\cdot 1\text{ m} = 20\times0.02\text{ m}\times1\text{ m} = 0.40\text{ m}^2.$$

Hence,

$$q = 5\times\left[0.80\text{ m}^2\times0.658\times5.67\times10^{-8}\text{W/m}^2\cdot\text{K}^4\left(1200^4 - 400^4\right)\text{K}^4\right]$$

$$q = 305,440\text{ W}$$

and the steam production rate is

$$\dot{m} = \frac{305,440\text{ W}}{2.18\times10^6\text{ J/kg}} = 0.140\text{ kg/s.}$$ <

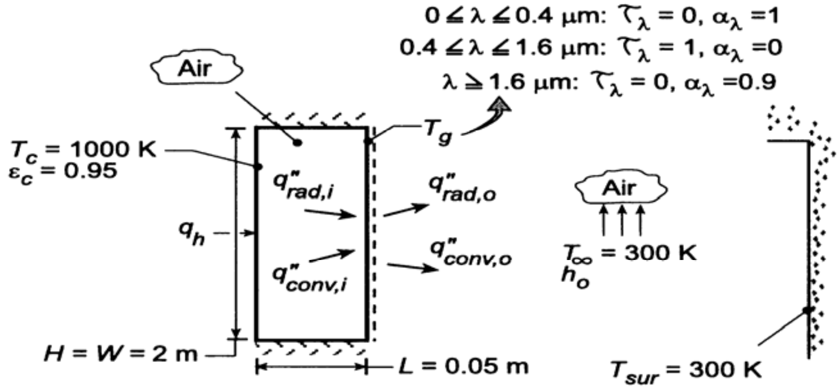
(c) The plate temperature is determined by an energy balance for which convection to the plate from the gas is equal to net radiation transfer from the plate to the tube. Conditions are complicated by the fact that the gas transfers energy to both the plate and the tubes, and its decay is not governed by a simple exponential. Insertion of the plates enhances heat transfer to the tubes and thereby increases the steam generation rate. However, for the prescribed conditions, the effect would be small, since in case (a), the heat transfer is already ≈ 80% of the maximum possible transfer.

PROBLEM 13.127

KNOWN: Temperature and emissivity of ceramic plate which is separated from a glass plate of equivalent height and width by an air space. Temperature of air and surroundings on opposite side of glass. Spectral radiative properties of glass.

FIND: (a) Transmissivity of glass, (b) Glass temperature T_g and total heat rate q_h, (c) Effect of external forced convection on T_g and q_h.

SCHEMATIC:



ASSUMPTIONS: (1) Spectral distribution of emission from ceramic approximates that of a blackbody, (2) Glass surface is diffuse, (3) Atmospheric air in cavity and ambient, (4) Cavity may be approximated as a two-surface enclosure with infinite parallel plates, (5) Glass is isothermal.

PROPERTIES: *Table A-4*, air (p = 1 atm): Evaluated at $\overline{T} = (T_c + T_g)/2$ and $T_f = (T_g + T_\infty)/2$ using *IHT Properties* Toolpad.

ANALYSIS: (a) The total transmissivity of the glass is

$$\tau = \frac{\int_o^\infty \tau_\lambda E_{\lambda b} d\lambda}{E_b} = \int_{\lambda_1=0.4\mu m}^{\lambda_2=1.6\mu m} \left(E_{\lambda,b}/E_b\right) d\lambda = F_{(0\to\lambda_2)} - F_{(0\to\lambda_1)}$$

With $\lambda_2 T$ = 1600 μm·K and $\lambda_1 T$ = 400 μm·K, respectively, Table 12.1 yields $F_{(0\to\lambda_2)} = 0.0197$ and $F_{(0\to\lambda_1)} = 0.0$. Hence,

$$\tau = 0.0197$$ <

With so little transmission of radiation from the ceramic, the glass plate may be assumed to be opaque to a good approximation. Since more than 98% of the incident radiation is at wavelengths exceeding 1.6 μm, for which $\alpha_\lambda = 0.9$, $\alpha_g \approx 0.9$. Also, since $T_g < T_c$, nearly 100% of emission from the glass is at $\lambda > 1.6$ μm, for which $\varepsilon_\lambda = \alpha_\lambda = 0.9$, $\varepsilon_g = 0.9$ and the glass may be approximated as a gray surface.

(b) The glass temperature may be obtained from an energy balance of the form $q''_{conv,i} + q''_{rad,i} = q''_{conv,o} + q''_{rad,o}$. Using Eqs. 13.24 and 13.27 to evaluate $q''_{rad,i}$ and $q''_{rad,o}$, respectively, it follows that

$$\overline{h}_i\left(T_c - T_g\right) + \frac{\sigma\left(T_c^4 - T_g^4\right)}{\frac{1}{\varepsilon_c} + \frac{1}{\varepsilon_g} - 1} = \overline{h}_o\left(T_g - T_\infty\right) + \varepsilon_g\sigma\left(T_g^4 - T_{sur}^4\right)$$

Continued …

PROBLEM 13.127 (Cont.)

where, assuming $10^4 \le Ra_L \le 10^7$, $\overline{h}_i$ and $\overline{h}_o$ are given by Eqs. 9.52 and 9.26, respectively,

$$\overline{h}_i = 0.42 \frac{k_i}{L} Ra_L^{1/4} Pr_i^{0.012} (H/L)^{-0.3}$$

$$\overline{h}_o = \frac{k_o}{H} \left\{ 0.825 + \frac{0.387 Ra_H^{1/6}}{\left[1 + (0.492/Pr_o)^{9/16}\right]^{8/27}} \right\}^2$$

with $Ra_L = g\beta_i (T_c - T_g)L^3/\nu_i\alpha_i$ and $Ra_H = g\beta_o (T_g - T_\infty) H^3/\nu_o\alpha_o$. Entering the energy balance into the *IHT* workspace and using the *Correlations*, *Properties* and *Radiation* Toolpads to evaluate the convection and radiation terms, the following result is obtained.

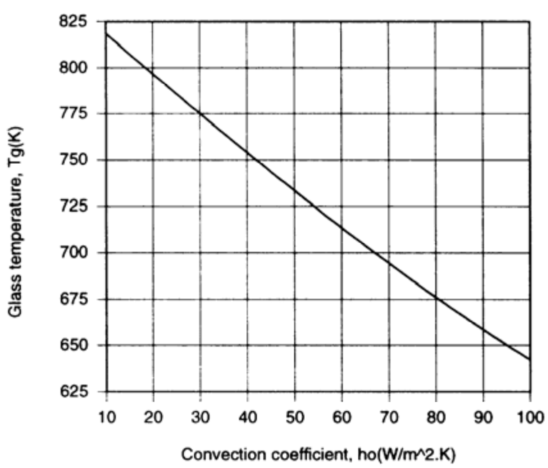
$$T_g = 825 \text{ K}$$ <

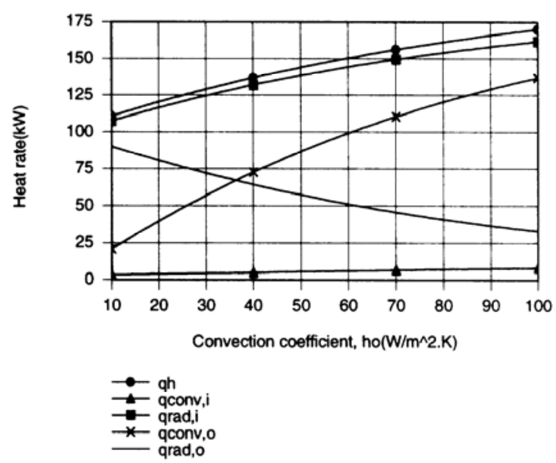
The corresponding value of q_h is

$$q_h = 108 \text{ kW}$$ <

where $q_{conv,i}$ = 3216 W, $q_{rad,i}$ = 104.7 kW, $q_{convo,o}$ = 15,190 W and $q_{rad,o}$ = 92.8 kW. The convection coefficients are $\overline{h}_i = 4.6 \text{ W/m}^2 \cdot \text{K}$ and $\overline{h}_o = 7.2 \text{ W/m}^2 \cdot \text{K}$.

(c) For the prescribed range of $\overline{h}_o$, *IHT* was used to generate the following results.





With increasing $\overline{h}_o$, the glass is cooled more effectively and T_g must decrease. With decreasing T_g, $q_{conv,i}$, $q_{rad,i}$ and hence q_h must increase. Note that radiation makes the dominant contribution to heat transfer across the airspace. Although $q_{rad,o}$ decreases with decreasing T_g, the increase in $q_{conv,o}$ exceeds the reduction in $q_{rad,o}$.

PROBLEM 13.128

KNOWN: Spectral distribution of the absorption coefficient of pure solid silicon.

FIND: (a) The total absorption coefficient for pure solid silicon subject to irradiation from a source at the melting point temperature of silicon. (b) Estimates of the total transmissivity, total absorptivity and total emissivity of a L = 150 μm thick silicon sheet.

ASSUMPTIONS: (1) Irradiation from large surroundings, (2) Kirchoff's law assumed to be valid.

PROPERTIES: *Table A-1*, Silicon: T_f = 1685 K.

ANALYSIS: Treating the irradiation from the large surroundings as black, we have

$$\kappa = \frac{\int_0^\infty \kappa_\lambda G_\lambda(\lambda)d\lambda}{G} \approx \frac{\int_0^\infty \kappa_\lambda(\lambda)E_{\lambda,b}(\lambda,1685\text{ K})d\lambda}{\int_0^\infty E_{\lambda,b}(\lambda,1685\text{ K})d\lambda}$$

$$= \kappa_{\lambda,1}F_{(0\to0.4\mu\text{m})} + \kappa_{\lambda,2}F_{(0.4\to8\mu\text{m})} + \kappa_{\lambda,3}F_{(8\to25\mu\text{m})} + \kappa_{\lambda,4}F_{(25\mu\text{m}\to\infty)}$$

From Table 12.2, $F_{(0\to0.4\mu\text{m}\cdot1685\text{K})} \approx 0$, $F_{(0.4\mu\text{m}\cdot1685\text{K}\to8\,\mu\text{m}\cdot1685\text{K})} = 0.955$, $F_{(8\mu\text{m}\cdot1685\text{K}\to15\mu\text{m}\cdot1685\text{K})} = 0.998 - 0.955 = 0.043$, $F_{(15\mu\text{m}\cdot1685\text{K}\to\infty)} = 1 - 0.998 = 0.002$. Therefore,

$$\kappa = \left(10^8\text{m}^{-1}\times0\right) + \left(0\text{ m}^{-1}\times0.955\right) + \left(10^2\text{m}^{-1}\times0.043\right) + \left(0\text{ m}^{-1}\times0.002\right) = 4.3\text{ m}^{-1}$$ <

(b) The spectral transmissivity is $\tau_\lambda = e^{-\kappa_\lambda L}$ which, for L = 150 μm, gives $\tau_{\lambda,1} = 0$, $\tau_{\lambda,2} = 1$, $\tau_{\lambda,3} = 0.985$, $\tau_{\lambda,4} = 1$. Hence,

$$\tau = (0\times0) + (1\times0.955) + (0.985\times0.043) + (1\times0.002) = 0.999$$ <

The total absorptivity is $\alpha = 1 - \tau = 0.001$, and the total emissivity is $\varepsilon = \alpha = 0.001$. <

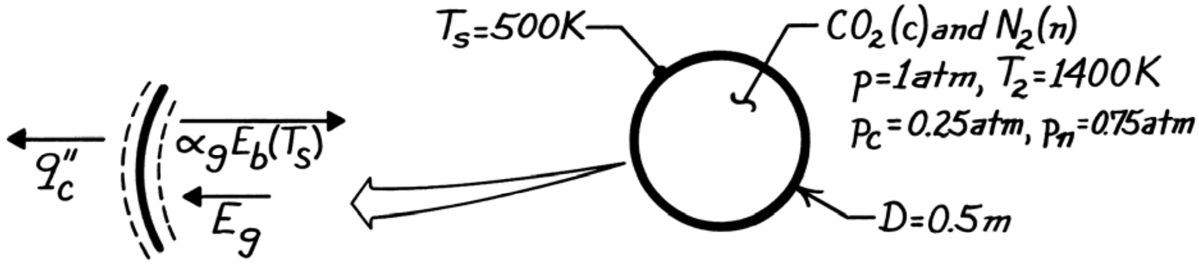
COMMENTS: (1) Solid silicon is almost perfectly transparent to irradiation emanating from high temperature sources. It is a serious error to treat the solid material as opaque. (2) Liquid silicon can, however, be considered to be opaque, except for extremely small thicknesses. (3) *Dopants* are often added to silicon for semiconductor applications in order to tailor the electrical properties of the material. The presence of dopants can significantly increase the spectral absorption coefficients over the entire spectral range.

PROBLEM 13.129

KNOWN: Conditions associated with a spherical furnace cavity.

FIND: Cooling rate needed to maintain furnace wall at a prescribed temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Blackbody behavior for furnace wall, (3) N_2 is non-radiating.

ANALYSIS: From an energy balance on a unit surface area of the furnace wall, the cooling rate per unit area must equal the absorbed irradiation from the gas (E_g) minus the portion of the wall's emissive power absorbed by the gas

$$q''_c = E_g - \alpha_g E_b(T_s)$$

$$q''_c = \varepsilon_g \sigma T_g^4 - \alpha_g \sigma T_s^4.$$

Hence, for the entire furnace wall,

$$q_c = A_s \sigma \left(\varepsilon_g T_g^4 - \alpha_g T_s^4 \right).$$

The gas emissivity, ε_g, follows from the mean beam length of Table 13.4

$$L_e = 0.65D = 0.65 \times 0.5\ \text{m} = 0.325\ \text{m} = 1.066\ \text{ft}.$$

$$p_c L_e = 0.25\ \text{atm} \times 1.066\ \text{ft} = 0.267\ \text{ft} - \text{atm}$$

and from Fig. 13.18, find $\varepsilon_g = \varepsilon_c = 0.09$. From Eq. 13.42,

$$\alpha_g = \alpha_c = C_c \left(\frac{T_g}{T_s} \right)^{0.45} \times \varepsilon_c \left(T_s, p_c L_e \left[T_s / T_g \right] \right).$$

With $C_c = 1$ from Fig. 13.19,

$$\alpha_g = 1(1400/50)^{0.45} \times \varepsilon_c \left(500\text{K},\ 0.095\ \text{ft} - \text{atm} \right)$$

where, from Fig. 13.18,

$$\varepsilon_c \left(500\text{K},\ 0.095\ \text{ft} - \text{atm} \right) = 0.067.$$

Hence

$$\alpha_g = 1(1400/500)^{0.45} \times 0.067 = 0.106$$

and the heat rate is

$$q_c = \pi (0.5\ \text{m})^2\ 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 \left[0.09 (1400\ \text{K})^4 - 0.106 (500\ \text{K})^4 \right]$$

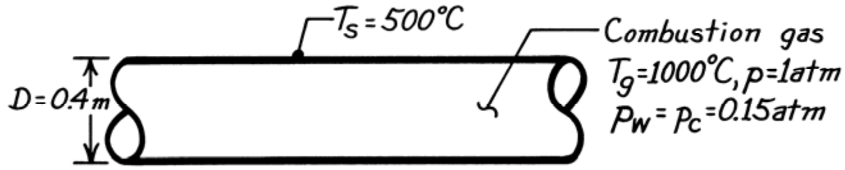
$$q_c = 15.1\ \text{kW}.$$ <

PROBLEM 13.130

KNOWN: Diameter and gas pressure, temperature and composition associated with a gas turbine combustion chamber.

FIND: Net radiative heat flux between the gas and the chamber surface.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Blackbody behavior for chamber surface, (3) Remaining species are non-radiating, (4) Chamber may be approximated as an infinitely long tube.

ANALYSIS: From Eq. 13.40 the net rate of radiation transfer to the surface is

$$q_{net} = A_s\sigma\left(\varepsilon_g T_g^4 - \alpha_g T_s^4\right) \qquad \text{or} \qquad q'_{net} = \pi D\sigma\left(\varepsilon_g T_g^4 - \alpha_g T_s^4\right)$$

with $A_s = \pi DL$. From Table 13.4, $L_e = 0.95D = 0.95 \times 0.4$ m = 0.380 m = 1.25 ft. Hence, $p_w L_e = p_c L_e = 0.152$ atm × 1.25 ft = 0.187 atm-ft.

$$\text{Fig.13.16}\left(T_g = 1273\text{ K}\right), \rightarrow \varepsilon_w \approx 0.069.$$

$$\text{Fig.13.18}\left(T_g = 1273\text{ K}\right), \rightarrow \varepsilon_c \approx 0.085.$$

$$\text{Fig.13.20}\left(p_w/\left(p_c + p_w\right) = 0.5,\ L_c\left(p_w + p_c\right) = 0.375\text{ ft} - \text{atm},\ T_g \geq 930°\text{C}\right), \rightarrow \Delta\varepsilon \geq 0.01.$$

From Eq. 13.38,

$$\varepsilon_g = \varepsilon_w + \varepsilon_c - \Delta\varepsilon = 0.069 + 0.085 - 0.01 \approx 0.144.$$

From Eq. 13.41 for the water vapor,

$$\alpha_w = C_w\left(T_g/T_s\right)^{0.45} \times \varepsilon_w\left(T_s, p_w L_c\left[T_s/T_g\right]\right)$$

where from Fig. 13.16 (773 K, 0.114 ft-atm), $\rightarrow \varepsilon_w \approx 0.083$,

$$\alpha_w = 1\left(1273/773\right)^{0.45} \times 0.083 = 0.104.$$

From Eq. 13.42, using Fig. 13.18 (773 K, 0.114 ft-atm), $\rightarrow \varepsilon_c \approx 0.08$,

$$\alpha_c = 1\left(1273/773\right)^{0.45} \times 0.08 = 0.100.$$

From Fig. 13.20, the correction factor for water vapor at carbon dioxide mixture,

$$\left(p_w/\left(p_c + p_w\right) = 0.1, L_e\left(p_w + p_c\right) = 0.375,\ T_g \approx 540°\text{C}\right), \rightarrow \Delta\alpha \approx 0.004$$

and using Eq. 13.43

$$\alpha_g = \alpha_w + \alpha_c - \Delta\alpha = 0.104 + 0.100 - 0.004 \approx 0.200.$$

Hence, the heat rate is

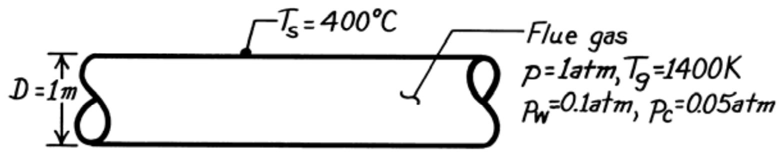
$$q'_{net} = \pi\left(0.4\text{ m}\right)5.67 \times 10^{-8}\text{ W/m}^2 \cdot \text{K}^4\left[0.144\left(1273\right)^4 - 0.200\left(773\right)^4\right] = 21.9\text{ kW/m.} <$$

PROBLEM 13.131

KNOWN: Pressure, temperature and composition of flue gas in a long duct of prescribed diameter.

FIND: Net radiative flux to the duct surface.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Duct surface behaves as a blackbody, (3) Other gases are non-radiating, (4) Flue may be approximated as an infinitely long tube.

ANALYSIS: With $A_s = \pi DL$, it follows from Eq. 13.40 that

$$q'_{net} = \pi D\sigma\left(\varepsilon_g T_g^4 - \alpha_g T_s^4\right)$$

From Table 13.4, $L_e = 0.95D = 0.95 \times 1$ m = 0.95 m = 3.12 ft. Hence

$$p_w L_e = 0.12 \text{ atm} \times 3.12 \text{ m} = 0.312 \text{ atm} - \text{ft}$$

$$p_c L_e = 0.05 \text{ atm} \times 3.12 \text{ m} = 0.156 \text{ atm} - \text{ft}.$$

With T_g = 1400 K, Fig. 13.16 → $\varepsilon_w = 0.083$; Fig. 13.18 → $\varepsilon_c = 0.072$. With $p_w/(p_c + p_w) = 0.67$, $L_e(p_w + p_c) = 0.468$ atm-ft, $T_g \geq 930°C$, Fig. 13.20 → $\Delta\varepsilon = 0.01$. Hence from Eq. 13.38,

$$\varepsilon_g = \varepsilon_w + \varepsilon_c - \Delta\varepsilon = 0.083 + 0.072 - 0.01 = 0.145.$$

From Eq. 13.41,

$$\alpha_w = C_w\left(T_g / T_s\right)^{0.45} \times \varepsilon_w\left(T_s, p_w L_e\left[T_s / T_g\right]\right)$$

$$\alpha_w = 1(1400/400)^{0.45} \times \varepsilon_w \text{ Fig. 13.16} \rightarrow \varepsilon_w\left(400 \text{ K}, 0.0891 \text{ atm} - \text{ft}\right) = 0.1$$

$$\alpha_w = 0.176.$$

From Eq. 13.42,

$$\alpha_c = C_c\left(T_g / T_s\right)^{0.45} \times \varepsilon_c\left(T_s, p_c L_e T_s / T_g\right)$$

$$\alpha_c = 1(1400/400)^{0.45} \times \varepsilon_c \text{ Fig. 13.18} \rightarrow \varepsilon_c\left(400 \text{ K}, 0.0891 \text{ atm} - \text{ft}\right) = 0.053$$

$$\alpha_c = 0.093.$$

With $p_w/(p_c + p_w) = 0.67$, $L_e(p_w + p_c) = 0.468$ atm-ft, $T_g \approx 125°C$, Fig. 13.20 gives

$$\Delta\alpha \approx 0.003.$$

Hence from Eq. 13.43,

$$\alpha_g = \alpha_w + \alpha_c - \Delta\alpha = 0.176 + 0.093 - 0.003 = 0.266.$$

The heat rate per unit length is

$$q'_{net} = \pi(1 \text{ m})5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4\left[0.145(1400 \text{ K})^4 - 0.266(400 \text{ K})^4\right]$$

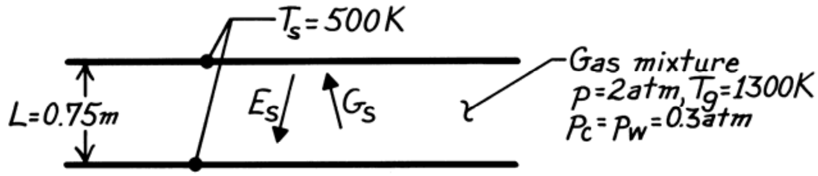
$$q'_{net} = 98 \text{ kW/m}.$$ <

PROBLEM 13.132

KNOWN: Gas mixture of prescribed temperature, pressure and composition between large parallel plates of prescribed separation.

FIND: Net radiation flux to the plates.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Furnace wall behaves as a blackbody, (3) O_2 and N_2 are non-radiating, (4) Negligible end effects.

ANALYSIS: The net radiative flux to a plate is

$$q''_{s,1} = G_s - E_s = \varepsilon_g \sigma T_g^4 - \left(1-\tau_g\right)\sigma T_s^4$$

where $G_s = \varepsilon_g \sigma T_g^4 + \tau_g E_s$, $E_s = \sigma T_s^4$ and $\tau_g = 1-\alpha_g\left(T_s\right)$. From Table 13.4, $L_e = 1.8L = 1.8 \times 0.75$ m = 1.35 m = 4.43 ft. Hence $p_w L_e = p_c L_e = 1.33$ atm-ft. From Figs. 3.16 and 3.18 find $\varepsilon_w \approx 0.22$ and $\varepsilon_c \approx 0.16$ for p = 1 atm. With $(p_w + p)/2 = 1.15$ atm, Fig. 13.17 yields $C_w \approx 1.40$ and from Fig. 13.19, $C_c \approx 1.08$. Hence, the gas emissivities are

$$\varepsilon_w = C_w \varepsilon_w\left(1 \text{ atm}\right) \approx 1.40 \times 0.22 = 0.31 \qquad \varepsilon_c = C_c \varepsilon_c\left(1 \text{ atm}\right) \approx 1.08 \times 0.16 = 0.17.$$

From Fig. 13.20 with $p_w/(p_c + p_w) = 0.5$, $L_e(p_c + p_w) = 2.66$ atm-ft and $T_g > 930°C$, $\Delta\varepsilon \approx 0.047$. Hence, from Eq. 13.38,

$$\varepsilon_g = \varepsilon_w + \varepsilon_c - \Delta\varepsilon \approx 0.31 + 0.17 - 0.047 \approx 0.43.$$

To evaluate α_g at T_s, use Eq. 13.43 with

$$\alpha_w = C_w\left(T_g / T_s\right)^{0.45} \varepsilon_w\left(T_s, p_w L_2 T_s / T_g\right) = C_w\left(1300/500\right)^{0.45} \varepsilon_w\left(500,\ 0.51\right)$$

$$\alpha_w \approx 1.40\left(1300/500\right)^{0.45} 0.22 = 0.47$$

$$\alpha_c = C_c\left(1300/500\right)^{0.45} \varepsilon_c\left(500,\ 0.51\right) \approx 1.08\left(1300/500\right)^{0.45} 0.11 = 0.18.$$

From Fig. 13.20, with $T_g \approx 125°C$ and $L_e(p_w + p_c) = 2.66$ atm-ft, $\Delta\alpha = \Delta\varepsilon \approx 0.024$. Hence

$$\alpha_g = \alpha_w + \alpha_c - \Delta\alpha \approx 0.47 + 0.18 - 0.024 \approx 0.63 \quad \text{and} \quad \tau_g = 1 - \alpha_g \approx 0.37.$$

Hence, the heat flux from Eq. (1) is

$$q''_{s,1} = 0.43 \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 \left(1300 \text{ K}\right)^4 - 0.63 \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 \left(500 \text{ K}\right)^4$$

$$q''_{s,1} \approx 67.4 \text{ kW/m}^2.$$

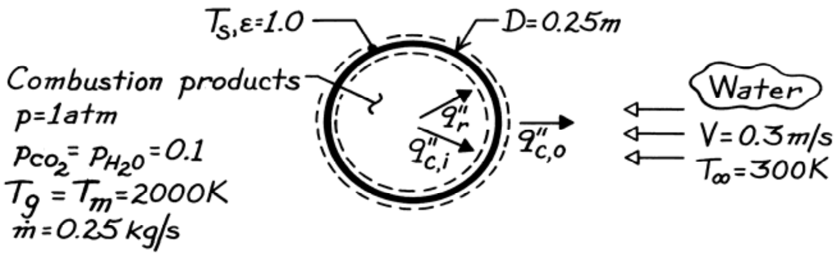
The net radiative flux to both plates is then $q''_{s,2} \approx 134.8 \text{ kW/m}^2$. <

PROBLEM 13.133

KNOWN: Flow rate, temperature, pressure and composition of exhaust gas in pipe of prescribed diameter. Velocity and temperature of external coolant.

FIND: Pipe wall temperature and heat flux.

SCHEMATIC:



ASSUMPTIONS: (1) L/D >> 1 (infinitely long pipe), (2) Negligible axial gradient for gas temperature, (3) Gas is in fully developed flow, (4) Gas thermophysical properties are those of air, (5) Negligible pipe wall thermal resistance, (6) Negligible pipe wall emission.

PROPERTIES: *Table A-4*: Air (T_m = 2000 K, 1 atm): $\rho = 0.174$ kg/m^3, $\mu = 689 \times 10^{-7}$ kg/m·s, k = 0.137 W/m·K, Pr = 0.672; *Table A-6*: Water (T_∞ = 300 K): $\rho = 997$ kg/m^3, $\mu = 855 \times 10^{-6}$ kg/s·m, k = 0.613 W/m·K, Pr = 5.83.

ANALYSIS: Performing an energy balance for a control surface about the pipe wall,

$$q''_r + q''_{c,i} = q''_{c,o}$$

$$\varepsilon_g \sigma T_g^4 + h_i\left(T_m - T_s\right) = \bar{h}_o\left(T_s - T_\infty\right)$$

The gas emissivity is

$$\varepsilon_g = \varepsilon_w + \varepsilon_c - \Delta\varepsilon$$

where

$$L_e = 0.95D = 0.238\ \text{m} = 0.799\ \text{ft}$$

$$p_c L_e = p_w L_e = 0.1\ \text{atm} \times 0.238\ \text{m} = 0.0238\ \text{atm} - \text{m} = 0.0779\ \text{atm} - \text{ft}$$

and from Fig. 13.16 → $\varepsilon_w \approx 0.017$; Fig. 13.18 → $\varepsilon_c \approx 0.031$; Fig. 13.20 → $\Delta\varepsilon \approx 0.001$. Hence ε_g = 0.047. Estimating the *internal flow convection coefficient*, find

$$Re_D = \frac{4\,\dot{m}}{\pi D \mu} = \frac{4 \times 0.25\ \text{kg/s}}{\pi\left(0.25\ \text{m}\right) 689 \times 10^{-7}\ \text{kg/m}\cdot\text{s}} = 18,480$$

and for turbulent flow, we may use the Dittus-Boelter correlation of Chapter 8,

$$Nu_D = 0.023 Re_D^{4/5} Pr^{0.3} = 0.023\left(18,480\right)^{4/5}\left(0.672\right)^{0.3} = 52.9$$

$$h_i = Nu_D \frac{k}{D} = 52.9 \frac{0.137\ \text{W/m}\cdot\text{K}}{0.25\ \text{m}} = 29.0\ \text{W/m}^2\cdot\text{K}.$$

Continued …

Estimating the *external convection coefficient*, find

$$\mathrm{Re}_D = \frac{\rho VD}{\mu} = \frac{997\ \mathrm{kg/m^3} \times 0.3\ \mathrm{m/s} \times 0.25\ \mathrm{m}}{855 \times 10^{-6}\ \mathrm{kg/s \cdot m}} = 87,456.$$

Hence, using the Zukauskas correlation of Chapter 7,

$$\overline{\mathrm{Nu}}_D = 0.26\ \mathrm{Re}_D^{0.6}\ \mathrm{Pr}^{0.37}\left(\mathrm{Pr}/\mathrm{Pr}_s\right)^{1/4}.$$

Assuming $\mathrm{Pr}/\mathrm{Pr}_s \approx 1$,

$$\overline{\mathrm{Nu}}_D = 0.26(87,456)^{0.6}(5.83)^{0.37} = 461$$

$$\bar{h}_o = \overline{\mathrm{Nu}}_D\,(k/D) = 461(0.613\ \mathrm{W/m \cdot K}/0.25\ \mathrm{m}) = 1129\,\mathrm{W/m^2 \cdot K}.$$

Substituting numerical values in the energy balance, find

$$0.047 \times 5.67 \times 10^{-8}\,\mathrm{W/m^2 \cdot K^4}(2000\ \mathrm{K})^4 + 29\ \mathrm{W/m^2 \cdot K}(2000 - T_s)\mathrm{K}$$

$$= 1129\ \mathrm{W/m^2 \cdot K}(T_s - 300)\mathrm{K}$$

$$T_s = 380\ \mathrm{K}.$$ <

The heat flux due to convection is

$$q''_{c,i} = h_i\left(T_m - T_s\right) = 29\ \mathrm{W/m^2 \cdot K}(2000 - 379.4)\mathrm{K} = 46,997\ \mathrm{W/m^2}$$

and the total heat flux is

$$q''_s = q''_r + q''_{c,i} = 42,638 + 46,997 = 89,640\ \mathrm{W/m^2}.$$ <

COMMENTS: Contributions of gas radiation and convection to the wall heat flux are approximately the same. Small value of T_s justifies neglecting emission from the pipe wall to the gas. $\mathrm{Pr}_s = 1.62$ for $T_s = 380 \rightarrow (\mathrm{Pr}/\mathrm{Pr}_s)1/4 = 1.38$. Hence the value of $\bar{h}_o$ should be corrected. The value would ↑, and T_s would ↓.

PROBLEM 13.134

KNOWN: Flow rate, temperature, pressure and composition of combustion gas that is subsequently mixed with saturated steam of known flow rate.

FIND: Gas emission to a pipe wall with and without steam injection.

ASSUMPTIONS: (1) Gas thermophysical properties and molecular weight same as air, (2) ideal gas mixture.

ANALYSIS: The mass flow rate without steam injection is $\dot{m}_1 = 0.25$ kg/s. The mass flow rate of water vapor in the original mixture is $\dot{m}_1 m_{w1}$ where m_{w1} is the mass fraction of water vapor,

$$m_{w1} = p_{w1}\mathcal{M}_w / p\mathcal{M}_{\text{air}}$$
$$= 0.1 \text{ atm} \times 18 \text{ kg/kmol}/(1 \text{ atm } \times 29 \text{ kg/kmol})$$
$$= 0.0621$$

Thus the mass flow rate of the injected steam is

$$\dot{m}_S = 0.5\dot{m}_1 m_{w1} = 0.5 \times 0.25 \text{ kg/s} \times 0.0621 = 0.00776 \text{ kg/s}$$

and the total mass flow rate after injection is $\dot{m}_2 = \dot{m}_1 + \dot{m}_S = 0.2578$ kg/s. Treating the gases as ideal with properties of air, an energy balance on the mixing of the combustion products and injected steam yields

$$\dot{m}_1 T_{g1} + \dot{m}_w T_{w1} = \dot{m}_2 T_g \;;\; T_g = \frac{\dot{m}_1 T_{g1} + \dot{m}_w T_{w1}}{\dot{m}_2} = \frac{0.25 \text{ kg/s} \times 2000 \text{ K} + 0.0076 \text{ kg/s} \times 373 \text{ K}}{0.2578 \text{ kg/s}} = 1951 \text{ K}$$

The gas emissivity is $\varepsilon_g = \varepsilon_w + \varepsilon_c - \Delta\varepsilon$ where L_e = 0.95 D = 0.238 m = 0.799 ft. The partial pressures of the gases are obtained by accounting for the additional water vapor in the pipe relative to Problem 13.133.

$$p_{w2} = x_{w2}p = \frac{x_{w1} + 0.5x_{w1}}{1 + 0.5x_{w1}} p = \frac{0.15}{1.05} p = 0.143 \text{ atm}$$

where x_{w2} is the mole fraction of water in the final mixture. Similarly,

$$p_{c2} = \frac{x_{c1}}{1 + 0.5x_{w1}} p = \frac{0.1}{1.05} p = 0.0952 \text{ atm}$$

The products of the partial pressures and mean beam lengths are therefore

$$p_c L_e = 0.095 \text{ atm} \times 0.799 \text{ ft} = 0.076 \text{ atm-ft} \quad ; \quad p_w L_e = 0.143 \text{ atm} \times 0.799 \text{ ft} = 0.114 \text{ atm-ft}$$

From Fig. 13.15, $\varepsilon_w \approx 0.025$. From Fig. 13.17, $\varepsilon_c \approx 0.034$. From Fig. 13.19, $\Delta\varepsilon \approx 0.002$. Hence, ε_g = 0.025 + 0.034 – 0.002 = 0.057 and the emission from the gas to the pipe wall is

$$E_g = \varepsilon_g \sigma T_g^4 = 0.057 \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 \times (1951 \text{ K})^4 = 46{,}800 \text{ W/m}^2 \qquad <$$

Continued...

PROBLEM 13.134 (Cont.)

Without injection, the partial pressures are $p_w = p_c = 0.1$ atm and the partial pressure – mean beam length products are $p_c L_e = p_w L_e = 0.10 \text{ atm} \times 0.799 \text{ ft} = 0.080 \text{ atm-ft}$ yielding from Fig. 13.15, $\varepsilon_w \approx$ 0.017. From Fig. 13.17, $\varepsilon_c \approx 0.031$. From Fig. 13.19, $\Delta\varepsilon \approx 0.001$. Hence, $\varepsilon_g = 0.047$ and the emission from the gas to the pipe wall is

$$E_g = \varepsilon_g \sigma T_g^4 = 0.047 \times 5.67 \times 10^{-8} \text{W/m}^2 \cdot \text{K}^4 \times (2000 \text{ K})^4 = 42,600 \text{ W/m}^2 \quad <$$

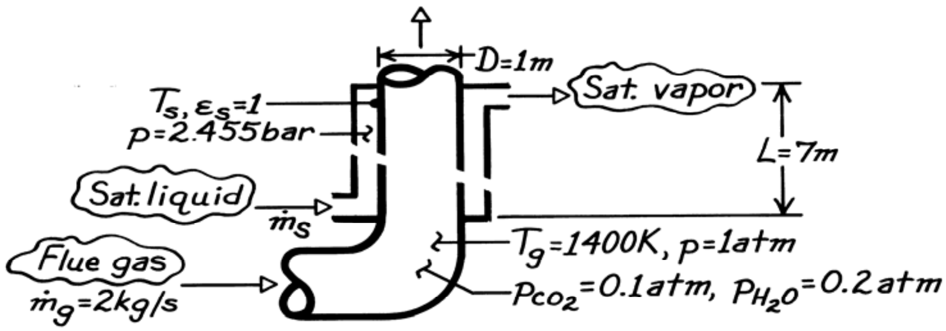
COMMENTS: (1) The gas emissivity is increased significantly with steam injection, but the temperature of the hot gas is reduced due to mixing with the relatively cool steam. The net effect is a modest increase in radiation heat flux to the pipe surface. Injection of a greater amount of steam results in even higher gas emissivities, but the effect is offset by even lower gas temperatures. (2) Injection of *liquid* water would further reduce the gas temperature as the latent heat of vaporization of the water is accounted for. (3) The results are highly dependent upon the accuracy with which one can read the figures in the text. (4) Water vapor properties are taken to be the same as those of air. (5) A more detailed analysis would be appropriate if the scheme were to be considered seriously.

PROBLEM 13.135

KNOWN: Flowrate, composition and temperature of flue gas passing through inner tube of an annular waste heat boiler. Boiler dimensions. Steam pressure.

FIND: Rate at which saturated liquid can be converted to saturated vapor, $\dot{m}_s$.

SCHEMATIC:



ASSUMPTIONS: (1) Inner wall is thin and steam side convection coefficient is very large; hence $T_s = T_{sat}(2.455\text{ bar})$, (2) For calculation of gas radiation, inner tube is assumed infinitely long and gas is approximated as isothermal at T_g.

PROPERTIES: Flue gas (given): $\mu = 530 \times 10^{-7}$ kg/s·m, k = 0.091 W/m·K, Pr = 0.70; *Table A-6*, Saturated water (2.455 bar): $T_s = 400$ K, $h_{fg} = 2183$ kJ/kg.

ANALYSIS: The steam generation rate is

$$\dot{m}_s = q/h_{fg} = \left(q_{conv} + q_{rad}\right)/h_{fg}$$

where

$$q_{rad} = A_s \sigma \left(\varepsilon_g T_g^4 - \alpha_g T_s^4\right)$$

with

$$\varepsilon_g = \varepsilon_w + \varepsilon_c - \Delta\varepsilon \qquad\qquad \alpha_g = \alpha_w + \alpha_c - \Delta\alpha.$$

From Table 13.4, find $L_e = 0.95D = 0.95$ m = 3.117 ft. Hence

$$p_w L_e = 0.2\text{ atm} \times 3.117\text{ ft} = 0.623\text{ ft} - \text{atm}$$

$$p_c L_e = 0.1\text{ atm} \times 3.117\text{ ft} = 0.312\text{ ft} - \text{atm}.$$

From Fig. 13.16, find $\varepsilon_w \approx 0.13$ and Fig. 13.18 find $\varepsilon_c \approx 0.095$. With $p_w/(p_c + p_w) = 0.67$ and $L_e(p_w + p_c) = 0.935$ ft-atm, from Fig. 13.20 find $\Delta\varepsilon \approx 0.036 \approx \Delta\alpha$. Hence $\varepsilon_g \approx 0.13 + 0.095 - 0.036 = 0.189$. Also, with $p_w L_e(T_s/T_g) = 0.2$ atm × 0.95 m(400/1400) = 0.178 ft-atm and $T_s = 400$ K, Fig. 13.16 yields $\varepsilon_w \approx 0.14$. With $p_c L_e(T_s/T_g) = 0.1$ atm × 0.95 m(400/1400) = 0.089 ft-atm and $T_s = 400$ K, Fig. 13.18 yields $\varepsilon_c \approx 0.067$. Hence

$$\alpha_w = \left(T_g/T_s\right)^{0.45} \varepsilon_w \left(T_s,\ p_w L_e T_s/T_g\right)$$

$$\alpha_w = (1400/400)^{0.45}\, 0.14 = 0.246$$

and

$$\alpha_c = \left(T_g/T_s\right)^{0.65} \varepsilon_c \left(T_s, p_c L_e T_s/T_g\right)$$

Continued …

PROBLEM 13.135 (Cont.)

$$\alpha_c = (1400/400)^{0.65}\, 0.067 = 0.151$$

$$\alpha_g = 0.246 + 0.151 - 0.036 = 0.361.$$

Hence

$$q_{rad} = \pi(1\ \text{m})7\ \text{m} \times 5.67 \times 10^{-8}\ \text{W/m}^2 \cdot \text{K}^4 \left[0.189(1400\ \text{K})^4 - 0.361(400\ \text{K})^4\right]$$

$$q_{rad} = (905.3 - 11.5)\,\text{kW} = 893.8\ \text{kW}.$$

For convection,

$$q_{conv} = \bar{h}\pi DL\left(T_g - T_s\right)$$

with

$$Re_D = \frac{4\dot{m}}{\pi D\mu} = \frac{4 \times 2\ \text{kg/s}}{\pi \times 1\ \text{m} \times 530 \times 10^{-7}\ \text{kg/s}\cdot\text{m}} = 48{,}047$$

and assuming fully developed turbulent flow throughout the tube, the Dittus-Boelter correlation of Chapter 8 gives

$$\overline{Nu}_D = 0.023\, Re_D^{4/5}\, Pr^{0.3} = 0.023(48{,}047)^{4/5}(0.70)^{0.3} = 115$$

$$\bar{h} = (k/D)\,\overline{Nu}_D = (0.091\ \text{W/m}\cdot\text{K}/1\ \text{m})115 = 10.5\ \text{W/m}^2\cdot\text{K}.$$

Hence

$$q_{conv} = 10.5\ \text{W/m}^2\cdot\text{K}\,\pi(1\ \text{m})7\ \text{m}(1400 - 400)\,\text{K} = 230.1\ \text{kW}$$

and the vapor production rate is

$$\dot{m}_s = \frac{q}{h_{fg}} = \frac{(893.8 + 230.1)\,\text{kW}}{2183\ \text{kJ/kg}} = \frac{1123.9\ \text{kW}}{2183\ \text{kJ/kg}}$$

$$\dot{m}_s = 0.515\ \text{kg/s}.$$ <

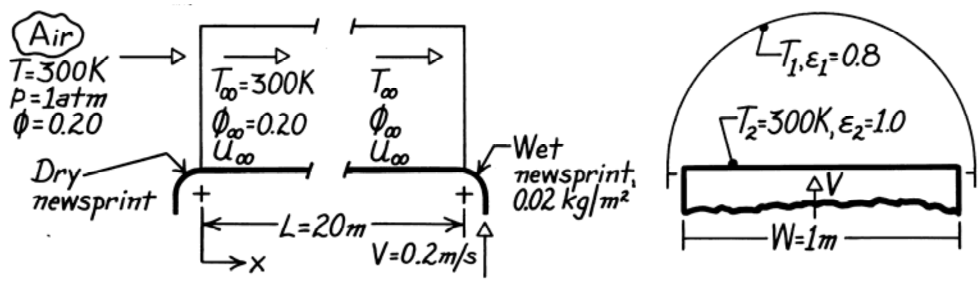
COMMENTS: (1) Heat transfer is dominated by radiation, which is typical of heat recovery devices having a large gas volume. (2) A more detailed analysis would account for radiation exchange involving the ends (upstream and downstream) of the inner tube. (3) Using a representative specific heat of c_p = 1.2 kJ/kg·K, the temperature drop of the gas passing through the tube would be ΔT_g = 1123.9 kW/(2 kg/s × 1.2 kJ/kg·K) = 468 K.

PROBLEM 13.136

KNOWN: Wet newsprint moving through a drying oven.

FIND: Required evaporation rate, air velocity and oven temperature.

SCHEMATIC:

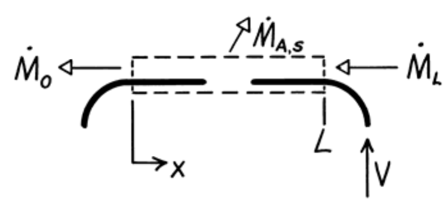


ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible freestream turbulence, (3) Heat and mass transfer analogy applicable, (4) Oven and newsprint surfaces are diffuse gray, (5) Oven end effects negligible.

PROPERTIES: *Table A-6*, Water vapor (300 K, 1 atm): $\rho_{sat} = 1/v_g = 0.0256\ kg/m^3$, $h_{fg} = 2438$ kJ/kg; *Table A-4*, Air (300 K, 1 atm): $\nu = 15.89 \times 10^{-6}\ m^2/s$; *Table A-8*, Water vapor-air (300 K, 1 atm): $D_{AB} = 0.26 \times 10^{-4}\ m^2/s$, $S_c = \nu/D_{AB} = 0.611$.

ANALYSIS: The evaporation rate required to completely dry the newsprint having a water content of $m''_A = 0.02\ kg/m^2$ as it enters the oven (x = L) follows from a species balance on the newsprint.

$$\dot{M}_{A,in} - \dot{M}_{A,out} = \dot{M}_{st}$$



$$\dot{M}_L - \dot{M}_0 - \dot{M}_{A,s} = 0.$$

The rate at which moisture enters in the newsprint is

$$\dot{M}_L = m''_A VW$$

hence,

$$\dot{M}_{A,s} = m''_A VW = 0.02\,kg/m^2 \times 0.2\,m/s \times 1\ m = 4\times10^{-3}\,kg/s.$$ <

The required velocity of the airstream through the oven, u_∞, can be determined from a convection analysis. From the rate equation,

$$\dot{M}_{A,s} = \overline{h}_m WL\left(\rho_{A,s} - \rho_{A,\infty}\right) = \overline{h}_m WL\rho_{A,sat}\left(1-\phi_\infty\right)$$

$$\overline{h}_m = \dot{M}_{A,s} / WL\rho_{A,sat}\left(1-\phi_\infty\right)$$

$$\overline{h}_m = 4\times10^{-3}\,kg/s/1\ m\times 20\ m\times 0.0256\ kg/m^3\left(1-0.2\right) = 9.77\times10^{-3}\,m/s.$$

Now determine what flow velocity is required to produce such a coefficient. Assume flow over a flat plate with

$$\overline{Sh}_L = \overline{h}_m L/D_{AB} = 9.77\times10^{-3}\,m/s\times 20\ m/0.26\times10^{-4}\,m^2/s = 7515$$

Continued …

and, from Section 7.2.1 for laminar flow

$$\mathrm{Re}_L = \left[\overline{\mathrm{Sh}}_L / 0.664\mathrm{Sc}^{1/3}\right]^2 = \left[7515/0.664(0.611)^{1/3}\right]^2 = 1.78\times10^8.$$

However, since $\mathrm{Re}_L > \mathrm{Re}_{Lc} = 5 \times 10^5$, the flow must be turbulent. Using the correlation for mixed laminar and turbulent flow conditions from Section 7.2.3, find

$$\mathrm{Re}_L^{4/5} = \left[\overline{\mathrm{Sh}}_L / \mathrm{Sc}^{1/3} + 871\right]/0.037$$

$$\mathrm{Re}_L^{4/5} = \left[7515/(0.611)^{1/3} + 871\right]/0.037$$

$$\mathrm{Re}_L = 5.95\times10^6$$

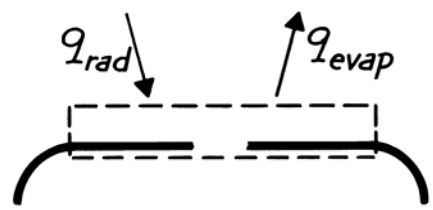
noting $\mathrm{Re}_L > \mathrm{Re}_{Lc}$. Recognize that u_∞^* is the velocity relative to the newsprint,

$$u_\infty^* = \mathrm{Re}_L\,\nu / L = 5.95\times10^6 \times 15.89\times10^{-6}\,\mathrm{m^2/s}/20\,\mathrm{m} = 4.73\ \mathrm{m/s}.$$

The air velocity relative to the oven will be,

$$u_\infty = u_\infty^* - V = (4.73 - 0.2)\,\mathrm{m/s} = 4.53\ \mathrm{m/s}.$$ <

The temperature required of the oven surface follows from an energy balance on the newsprint. Find



$$\dot{E}_{in} - \dot{E}_{out} = 0$$

$$q_{rad} - q_{evap} = 0$$

where

$$q_{evap} = \dot{M}_{A,s} h_{fg} = 4.0\times10^{-3}\,\mathrm{kg/s} \times 2438\times10^3\,\mathrm{J/kg} = 9752\ \mathrm{W}$$

and the radiation exchange is that for a two surface enclosure, Eq. 13.23,

$$q_{rad} = \frac{\sigma\left(T_1^4 - T_2^4\right)}{(1-\varepsilon_1)/\varepsilon_1 A_1 + 1/A_1F_{12} + (1-\varepsilon_2)/\varepsilon_2 A_2}.$$

Evaluate,

$A_1 = \pi/2\ \mathrm{WL}$, $A_2 = \mathrm{WL}$, $F_{21} = 1$, and $A_1F_{12} = A_2F_{21} = \mathrm{WL}$

hence, with $\varepsilon_1 = 0.8$,

$$q_{rad} = \sigma \mathrm{WL}\left(T_1^4 - T_2^4\right)/\left[(1/2\pi) + 1\right]$$

$$T_1^4 = T_2^4 + q_{rad}\left[(1/2\pi) + 1\right]/\sigma \mathrm{WL}$$

$$T_1^4 = (300\ \mathrm{K})^4 + 9752\ \mathrm{W}\left[(1/2\pi + 1)\right]/5.67\times10^{-8}\,\mathrm{W/m^2\cdot K^4} \times 1\ \mathrm{m} \times 20\ \mathrm{m}$$

$$T_1 = 367\ \mathrm{K}.$$ <

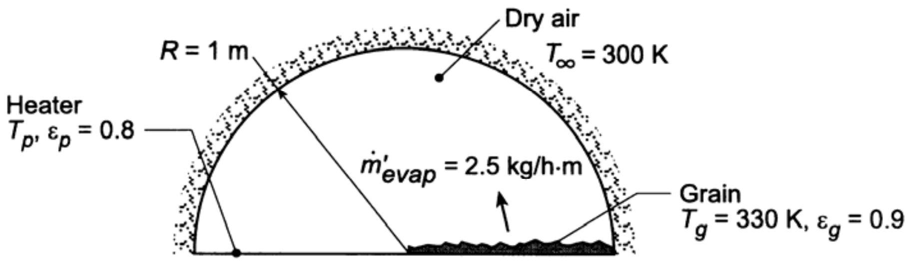
COMMENTS: Note that there is no convection heat transfer since $T_\infty = T_s = 300$ K.

PROBLEM 13.137

KNOWN: Configuration of grain dryer. Emissivities of grain bed and heater surface. Temperature of grain.

FIND: (a)Temperature of heater required for specified drying rate, (b) Convection mass transfer coefficient required to sustain evaporation, (c) Validity of assuming negligible convection heat transfer.

SCHEMATIC:



ASSUMPTIONS: (1) Diffuse/gray surfaces, (2) Oven wall is a reradiating surface, (3) Negligible convection heat transfer, (4) Applicability of heat/mass transfer analogy, (5) Air is dry.

PROPERTIES: *Table A-6*, saturated water (T = 330 K): $v_g = 8.82\ m^3/kg$, $h_{fg} = 2.366 \times 10^6$ J/kg. *Table A-4*, air (assume T ≈ 300 K): $\rho = 1.614\ kg/m^3$, c_p = 1007 J/kg·K, $\alpha = 22.5 \times 10^{-6}\ m^2/s$. *Table A-8*, H_2O(v) – air (T = 298 K): $D_{AB} = 0.26 \times 10^{-4}\ m^2/s$.

ANALYSIS: (a) Neglecting convection, the energy required for evaporation must be supplied by net radiation transfer from the heater plate to the grain bed. Hence,

$$q'_{rad} = \dot{m}'_{evap} h_{fg} = (2.5\ kg/h\cdot m)\left(2.366\times10^6 J/kg\right)/3600 s/h = 1643\ W/m$$

where q'_{rad} is given by Eq. 13.30. With $A'_p = A'_g \equiv A'$,

$$q'_{rad} = \frac{A'\left(E_{bp} - E_{bg}\right)}{\frac{1-\varepsilon_p}{\varepsilon_p} + \frac{1}{F_{pg} + \left[\left(1/F_{pR}\right) + \left(1/F_{gR}\right)\right]^{-1}}} + \frac{1-\varepsilon_g}{\varepsilon_g}$$

where A' = R = 1 m, F_{pg} = 0 and $F_{pR} = F_{gR}$ = 1. Hence,

$$q'_{rad} = \frac{\sigma\left(T_p^4 - 320^4\right)}{0.25 + 2 + 0.111} = 2.40\times10^{-8}\left(T_p^4 - 320^4\right) = 1643\ W/m$$

$$2.40\times10^{-8} T_p^4 - 2518 = 1643$$

$$T_p = 530\ K$$ <

(b) The evaporation rate is given by Eq. 6.12, and with $A'_s = 1$ m, $n'_A = \dot{m}'_{evap}$, and $\rho_{A,\infty} = 0$,

Continued …

PROBLEM 13.137 (Cont.)

$$h_m = \frac{n'_A}{A'_s \rho_{A,s}} = \frac{n'_A v_g}{A'_s} = \frac{2.5\,kg/h\cdot m}{1m} \times \frac{1}{3600\ s} \times 8.82\frac{m^3}{kg} = 6.13\times10^{-3} m/s$$ <

(c) From the heat and mass transfer analogy, Eq. 6.60,

$$h = h_m \rho c_p Le^{2/3}$$

where Le = α/D_{AB} = 22.5/26.0 = 0.865. Hence

$$h = 6.13\times10^{-3} m/s\left(1.161\,kg/m^3\right)1007\ J/kg\cdot K\left(0.865\right)^{2/3} = 6.5\ W/m^2\cdot K.$$

The corresponding convection heat transfer rate is

$$q'_{conv} = hA'\left(T_g - T_\infty\right) = 6.5\,W/m^2\cdot K\left(1\ m\right)\left(330-300\right)K = 195\,W/m$$

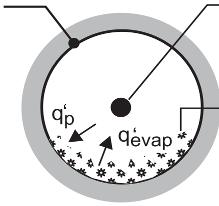
Since $q'_{conv} << q'_{rad}$, the assumption of negligible convection heat transfer is reasonable.

PROBLEM 13.138

KNOWN: Diameters of coaxial cylindrical drum and heater. Heater emissivity. Temperature and emissivity of pellets covering bottom half of drum. Convection mass transfer coefficient associated with flow of dry air over the pellets.

FIND: (a) Evaporation rate per unit length of drum, (b) Surface temperatures of heater and top half of drum.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) Negligible heat transfer from ends of drum, (3) Diffuse-gray surface behavior, (4) Negligible heat loss from the drum to the surroundings, (5) Negligible convection heat transfer from interior surfaces of the drum, (6) Pellet surface area corresponds to that of bottom half of drum.

PROPERTIES *Table A-6*, sat. water (T = 325 K): $\rho_{A,sat} = v_g^{-1}$ = 0.0904 kg/m^3, h_{fg} = 2378 kJ/kg.

ANALYSIS: (a) The evaporation rate is

$$n'_A = h_m(\pi D_d/2)\left[\rho_{A,sat}(T_p) - \rho_{A,\infty}\right]$$

$$n'_A = 0.024 \text{ m/s}(\pi\times 1\text{m}/2)\times 0.0904 \text{ kg/m}^3 = 0.00341 \text{ kg/s}\cdot\text{m}$$ <

(b) From an energy balance on the surface of the pellets,

$$q'_p = q'_{evap} = n'_A h_{fg} = 0.00341 \text{ kg/s}\cdot\text{m}\times 2.378\times 10^6 \text{ J/kg} = 8109 \text{ W/m}$$ <

where q'_p may be determined from analysis of radiation transfer in a three surface enclosure. Since the top half of the enclosure may be treated as reradiating, net radiation transfer to the pellets may be obtained from Eq. 13.30, which takes the form

$$q'_p = \frac{E_{bh} - E_{bp}}{\dfrac{1-\varepsilon_h}{\varepsilon_h A'_h} + \dfrac{1}{A'_h F_{hp} + \left[(1/A'_h F_{hd}) + (1/A'_p F_{pd})\right]^{-1}} + \dfrac{1-\varepsilon_p}{\varepsilon_p A'_p}}$$

where $F_{hp} = F_{hd} = 0.5$, $A'_h = \pi D_h$ and $A'_p = \pi D_d/2$.

The view factor F_{pd} may be obtained from the summation rule,

$$F_{pd} = 1 - F_{ph} - F_{pp}$$

Continued …

PROBLEM 13.138 (Cont.)

where $F_{ph} = A'_h F_{hp} / A'_p = (\pi D_h \times 0.5)/(\pi D_d / 2) = 0.10$ and

$$F_{pp} = 1 - (2/\pi)\left\{\left[1-(0.1)^2\right]^{1/2} + 0.1 \sin^{-1}(0.1)\right\} = 0.360$$

Hence, F_{pd} = 1 – 0.10 – 0.360 = 0.540, and the expression for the heat rate yields

$$8109\ \text{W/m} = \frac{E_{bh} - \sigma(325\ \text{K})^4}{\dfrac{0.25}{\pi \times 0.1\text{m}} + \dfrac{1}{\pi\left\{0.1\text{m} \times 0.5 + \left[(0.1\text{m}\times 0.5)^{-1} + (0.5\text{m}\times 0.54)^{-1}\right]^{-1}\right\}} + \dfrac{0.053}{\pi \times 0.5\text{m}}}$$

$$E_{bh} = \sigma T_h^4 = 35{,}359\ \text{W/m}^2$$

$$T_h = 889\ \text{K}$$ <

Applying Eq. 13.19 to surfaces h and p,

$$J_h = E_{bh} - q'_h(1-\varepsilon_h)/\varepsilon_h A'_h = 35{,}359\ \text{W/m}^2 - 6{,}453\ \text{W/m}^2 = 28{,}906\ \text{W/m}^2$$

$$J_p = E_{bp} + q'_p(1-\varepsilon_p)/\varepsilon_p A'_p = 633\ \text{W/m}^2 + 272\ \text{W/m}^2 = 905\ \text{W/m}^2$$

Hence, from

$$\frac{J_h - J_d}{(A'_h F_{hd})^{-1}} - \frac{J_d - J_p}{(A'_p F_{pd})^{-1}} = 0$$

$$\frac{28{,}906\ \text{W/m}^2 - J_d}{(\pi \times 0.1\text{m} \times 0.5)^{-1}} - \frac{J_d - 905\ \text{W/m}^2}{(\pi \times 0.5\text{m} \times 0.54)^{-1}} = 0$$

$$J_d = \sigma T_d^4 = 24{,}530\ \text{W/m}^2$$

$$T_d = 811\ \text{K}$$ <

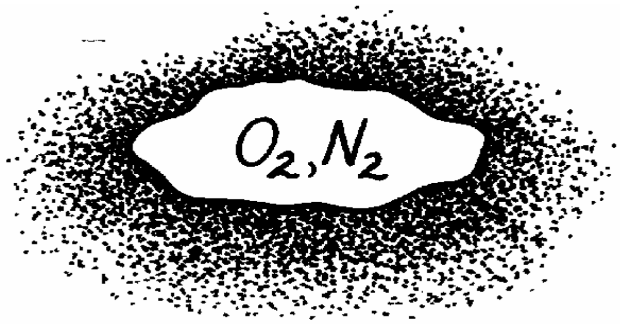
COMMENTS: The required value of T_h could be reduced by increasing D_h, although care must be taken to prevent contact of the plastic with the heater.

PROBLEM 14.1

KNOWN: Mixture of O_2 and N_2 with partial pressures in the ratio 0.21 to 0.79.

FIND: Mass fraction of each species in the mixture.

SCHEMATIC:



$$\frac{p_{O_2}}{p_{N2}} = \frac{0.21}{0.79}$$

$$\mathcal{M}_{O_2} = 32 \text{ kg/kmol}$$

$$\mathcal{M}_{N_2} = 28 \text{ kg/kmol}$$

ASSUMPTIONS: (1) Perfect gas behavior.

ANALYSIS: From the definition of the mass fraction,

$$m_i = \frac{\rho_i}{\rho} = \frac{\rho_i}{\Sigma\rho_i}$$

Hence, with

$$\rho_i = \frac{p_i}{R_i T} = \frac{p_i}{(\Re/\mathcal{M}_i)T} = \frac{\mathcal{M}_i p_i}{\Re T}.$$

Hence

$$m_i = \frac{\mathcal{M}_i p_i / \Re T}{\Sigma \mathcal{M}_i p_i / \Re T}$$

or, canceling terms and dividing numerator and denominator by the total pressure p,

$$m_i = \frac{\mathcal{M}_i x_i}{\Sigma \mathcal{M}_i x_i}.$$

With the mole fractions as

$$x_{O_2} = p_{O_2}/p = \frac{0.21}{0.21 + 0.79} = 0.21$$

$$x_{N_2} = p_{N_2}/p = 0.79,$$

find the mass fractions as

$$m_{O_2} = \frac{32 \times 0.21}{32 \times 0.21 + 28 \times 0.79} = 0.233 \quad <$$

$$m_{N_2} = 1 - m_{O_2} = 0.767. \quad <$$

PROBLEM 14.2

KNOWN: Mole fraction (or mass fraction) and molecular weight of each species in a mixture of n species. Equal mole fractions (or mass fractions) of O_2, N_2 and CO_2 in a mixture.

FIND:

SCHEMATIC:

$$x_{O_2} = x_{N_2} = x_{CO_2} = 0.333$$
or
$$m_{O_2} = m_{N_2} = m_{CO_2} = 0.333$$

$$\mathcal{M}_{CO_2} = 44$$
$$\mathcal{M}_{O_2} = 32,\ \mathcal{M}_{N_2} = 28$$

ASSUMPTIONS: (1) Perfect gas behavior.

ANALYSIS: (a) With

$$m_i = \frac{\rho_i}{\rho} = \frac{\rho_i}{\sum_i \rho_i} = \frac{p_i / R_i T}{\sum_i p_i / R_i T} = \frac{p_i \mathcal{M}_i / \Re T}{\sum_i p_i \mathcal{M}_i / \Re T}$$

and dividing numerator and denominator by the total pressure p,

$$m_i = \frac{\mathcal{M}_i x_i}{\sum_i \mathcal{M}_i x_i}. \qquad <$$

Similarly,

$$x_i = \frac{p_i}{\sum_i p_i} = \frac{\rho_i R_i T}{\sum_i \rho_i R_i T} = \frac{(\rho_i / \mathcal{M}_i)\Re T}{\sum_i (\rho_i / \mathcal{M}_i)\Re T}$$

or, dividing numerator and denominator by the total density ρ

$$x_i = \frac{m_i / \mathcal{M}_i}{\sum_i m_i / \mathcal{M}_i}. \qquad <$$

(b) With

$$\mathcal{M}_{O_2} x_{O_2} + \mathcal{M}_{N_2} x_{N_2} + \mathcal{M}_{CO_2} x_{CO_2} = 32 \times 0.333 + 28 \times 0.333 + 44 \times 0.333 = 34.6$$

$$m_{O_2} = 0.31, \qquad m_{N_2} = 0.27, \qquad m_{CO_2} = 0.42. \qquad <$$

With

$$m_{O_2} / \mathcal{M}_{O_2} + m_{N_2} / \mathcal{M}_{N_2} + m_{CO_2} / \mathcal{M}_{CO_2} = 0.333/32 + 0.333/28 + 0.333/44$$

$$m_{O_2} = 2.987 \times 10^{-2}.$$

find

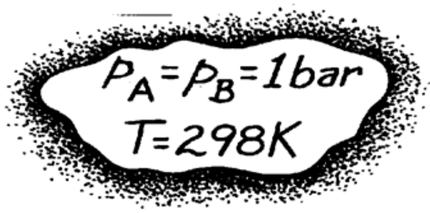
$$x_{O_2} = 0.35, \qquad x_{N_2} = 0.40, \qquad x_{CO_2} = 0.25. \qquad <$$

PROBLEM 14.3

KNOWN: Partial pressures and temperature for a mixture of CO_2 and N_2.

FIND: Molar concentration, mass density, mole fraction and mass fraction of each species.

SCHEMATIC:



$$A \rightarrow CO_2, \mathcal{M}_A = 44 \text{ kg/kmol}$$

$$B \rightarrow N_2, \mathcal{M}_B = 28 \text{ kg/kmol}$$

ASSUMPTIONS: (1) Perfect gas behavior.

ANALYSIS: From the equation of state for an ideal gas,

$$C_i = \frac{p_i}{\Re T}.$$

Hence, with $p_A = p_B$,

$$C_A = C_B = \frac{1 \text{ bar}}{8.314\times10^{-2} \text{ m}^3\cdot\text{bar/kmol}\cdot\text{K}\times 298 \text{ K}}$$

$$C_A = C_B = 0.040 \text{ kmol/m}^3.$$ <

With $\rho_i = \mathcal{M}_i C_i$, it follows that

$$\rho_A = 44 \text{ kg/kmol} \times 0.04 \text{ kmol/m}^3 = 1.78 \text{ kg/m}^3$$ <

$$\rho_B = 28 \text{ kg/kmol} \times 0.04 \text{ kmol/m}^3 = 1.13 \text{ kg/m}^3.$$ <

Also, with

$$x_i = C_i / \Sigma_i C_i$$

find

$$x_A = x_B = 0.04/0.08 = 0.5$$ <

and with

$$m_i = \rho_i / \Sigma \rho_i$$

find

$$m_A = 1.78/(1.78+1.13) = 0.61$$ <

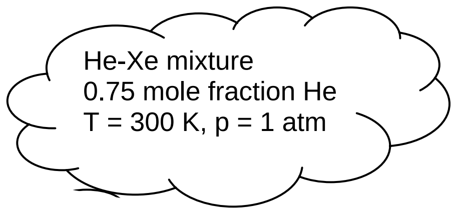
$$m_B = 1.13/(1.78+1.13) = 0.39.$$ <

PROBLEM 14.4

KNOWN: He-Xe mixture containing 0.75 mole fraction of He at 300 K and 1 atm.

FIND: Mass fraction of He and mixture mass density, molar concentration, and molecular weight. Mass of coolant in 10 liters.

SCHEMATIC:



ASSUMPTIONS: Ideal gas mixture.

PROPERTIES: $\mathcal{M}_{He} = 4\ \text{kg/kmol}$, $\mathcal{M}_{Xe} = 131.3\ \text{kg/kmol}$

ANALYSIS: The molar concentration of the mixture can be found directly from the ideal gas law, in the form

$$C = \frac{p}{\Re T} = \frac{1\ \text{atm}}{8.205 \times 10^{-2}\ \text{m}^3 \cdot \text{atm/kmol} \cdot \text{K} \times 300\ \text{K}} = 0.0406\ \text{kmol/m}^3$$ <

The mass density of one component in a mixture can be related to the mole fraction by combining Eqs. 14.11 and 14.1 to yield

$$\rho_i = \mathcal{M}_i x_i C$$

For He this results in

$$\rho_{He} = 4\ \text{kg/kmol} \times 0.75 \times 0.0406\ \text{kmol/m}^3 = 0.1219\ \text{kg/m}^3$$

Then the total mass density can be found by summing the species mass densities,

$$\rho = \sum_i \rho_i = C \sum_i \mathcal{M}_i x_i = 0.0406 \left[4\ \text{kg/kmol} \times 0.75 + 131.3\ \text{kg/kmol} \times 0.25 \right]$$

$$\rho = 1.455\ \text{kg/m}^3$$ <

Thus the helium mass fraction is

$$m_{He} = \frac{\rho_{He}}{\rho} = \frac{0.1219\ \text{kg/m}^3}{1.455\ \text{kg/m}^3} = 0.0837$$ <

Finally, the molecular weight of the mixture can be found from

Continued…

PROBLEM 14.4 (Cont.)

$$\mathcal{M} = \frac{\rho}{C} = \frac{1.455\ \text{kg/m}^3}{0.0406\ \text{kmol/m}^3} = 35.8\ \text{kg/kmol} \qquad <$$

Finally, the mass corresponding to a 10 liter cooling system capacity would be

$$M = \rho V = 1.455\ \text{kg/m}^3 \times 10\ \text{liters} \times 10^{-3}\ \text{m}^3\text{/liter} = 0.0146\ \text{kg} \qquad <$$

COMMENTS: (1) As you may recall from thermodynamics, the molar concentration of an ideal gas is a function only of pressure and temperature, independent of the species. (2) The mass fraction of helium is much less than its mole fraction because its molecular weight is so much less than that of xenon.

PROBLEM 14.5

KNOWN: Mass diffusion coefficients of two binary mixtures at a given temperature, 298 K.

FIND: Mass diffusion coefficients at a different temperature, T = 350 K.

ASSUMPTIONS: (a) Ideal gas behavior, (b) Mixtures at 1 atm total pressure.

PROPERTIES: *Table A-8*, Ammonia-air binary mixture (298 K), $D_{AB} = 0.28 \times 10^{-4}\ m^2/s$; Hydrogen-air binary mixture (298 K), $D_{AB} = 0.41 \times 10^{-4}\ m^2/s$.

ANALYSIS: According to treatment of Section 14.1.4, assuming ideal gas behavior,

$$D_{AB} \sim T^{3/2}$$

where T is in kelvin units. It follows then, that for

$$NH_3 - Air: \quad D_{AB}(350\ K) = 0.28 \times 10^{-4} m^2/s (350\ K/298\ K)^{3/2}$$

$$D_{AB}(350\ K) = 0.36 \times 10^{-4} m^2/s \quad <$$

$$H_2 - Air: \quad D_{AB}(350\ K) = 0.41 \times 10^{-4} m^2/s (350/298)^{3/2}$$

$$D_{AB}(350\ K) = 0.52 \times 10^{-4} m^2/s \quad <$$

COMMENTS: Since the H_2 molecule is smaller than the NH_3 molecule, it follows that

$$D_{H_2-Air} > D_{NH_3-Air}$$

as indeed the numerical data indicate.

PROBLEM 14.6

KNOWN: Pressure and temperature. Substance A and Substance B.

FIND: Plot of D_{AB} versus $\mathcal{M}_A$ for NH_3, H_2O, CO_2, H_2, O_2, acetone, benzene and naphthalene in air.

ASSUMPTIONS: Ideal gas behavior.

PROPERTIES:

Substance A (T, p)	D_{AB}* (m^2/s)	$\mathcal{M}_A$ (kg/kmol)
NH_3 (298 K, 1 atm)	0.28×10^{-4}	17.03 **
H_2O (298 K, 1 atm)	0.26×10^{-4}	18.02 **
CO_2 (298 K, 1 atm)	0.16×10^{-4}	44.01 **
H_2 (298 K, 1 atm)	0.41×10^{-4}	2.016 **
O_2 (298 K, 1 atm)	0.21×10^{-4}	32.00 **
Acetone (273 K, 1 atm)	0.11×10^{-4}	58.08 ***
Benzene (298 K, 1 atm)	0.88×10^{-5}	78.11****
Naphthalene (300 K, 1 atm)	0.62×10^{-5}	128.16 *****

* Table A.8
** Table A.4
*** J.R. Howell and R.O. Buckius, *Fundamentals of Engineering Thermodynamics*, 2nd ed., McGraw-Hill, 1992.
**** M.J. Moran and H.N. Shapiro, *Fundamentals of Engineering Thermodynamics*, 6th ed., John Wiley and Sons, Hoboken, 2008.
***** Problem 6.63

ANALYSIS: The mass diffusivity values must be corrected to account for the temperature and pressure dependence. From Table A.8, $D_{AB} \propto p^{-1}T^{3/2}$ and the corrected mass diffusivity for NH_3 is

$$D_{ABc} = 0.28\times10^{-4}\,\text{m}^2/\text{s}\times(1\text{atm}/1.5\text{atm})\times(320\text{K}/298\text{K})^{3/2} = 0.21\times10^{-4}\,\text{m}^2/\text{s}$$

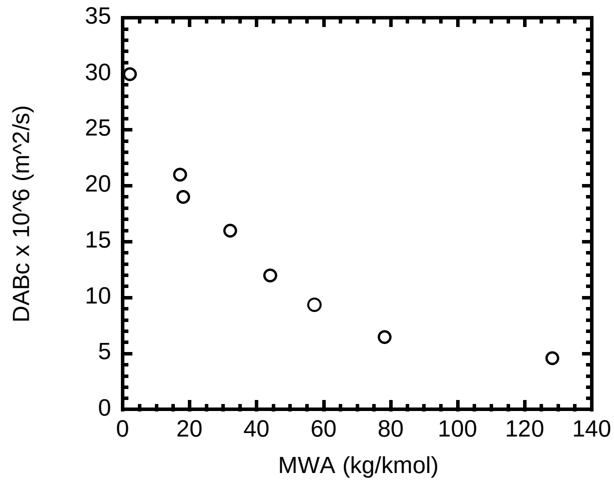
Repeating the calculation for the other substances yields the following.

Substance A	D_{ABc} (m^2/s)
NH_3	0.21×10^{-4}
H_2O	0.19×10^{-4}
CO_2	0.12×10^{-4}
H_2	0.30×10^{-4}
O_2	0.16×10^{-4}
Acetone	0.93×10^{-5}
Benzene	0.65×10^{-5}
Naphthalene	0.46×10^{-5}

A plot of the corrected mass diffusivities versus molecular weight of Substance A follows.

Continued...

PROBLEM 14.6 (Cont.)



According to kinetic theory, the mass diffusivity decreases with increasing molecular weight. This behavior is readily evident in the plot, and therefore the kinetic theory is consistent with measured values. <

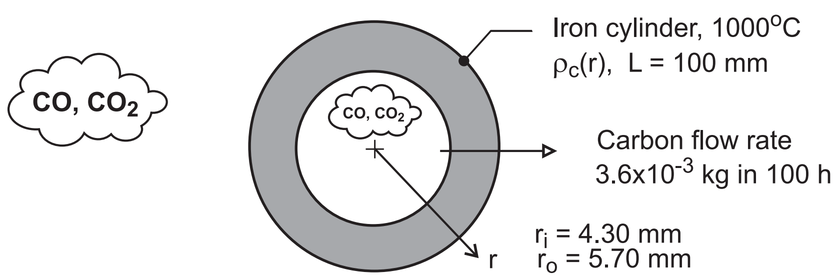
COMMENTS: Small molecules can diffuse through the host medium more readily than large molecules.

PROBLEM 14.7

KNOWN: The inner and outer surfaces of an iron cylinder of 100-mm length are exposed to a carburizing gas (mixtures of CO and CO_2). Observed experimental data on the variation of the carbon composition (weight carbon, %) in the iron at 1000°C as a function of radius. Carbon flow rate under steady-state conditions.

FIND: (a) Beginning with Fick's law, show that $d\rho_c / d(\ell n(r))$ is a constant if the diffusion coefficient, $D_{C\text{-}Fe}$, is a constant; sketch of the carbon mass density, $\rho_c(r)$, as function of ln(r) for such a diffusion process; (b) Create a graph for the experimental data and determine whether $D_{C\text{-}Fe}$ for this diffusion process is constant, increases or decreases with increasing mass density; and (c) Using the experimental data, calculate and tabulate $D_{C\text{-}Fe}$ for selected carbon compositions over the range of the experiment.

SCHEMATIC:



PROPERTIES: *Iron* (1000°C). $\rho = 7730\ kg/m^3$.Experimental observations of carbon composition

r (mm)	4.49	4.66	4.79	4.91	5.16	5.27	5.40	5.53
Wt. C (%)	1.42	1.32	1.20	1.09	0.82	0.65	0.46	0.28

ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional, radial diffusion in a stationary medium, and (3) Uniform total concentration.

ANALYSIS: (a) For the one-dimensional, radial (cylindrical) coordinate system, Fick's law is

$$j_A = -D_{AB}\, A_r \frac{d\rho_A}{dr} \qquad (1)$$

where $A_r = 2\pi rL$. For steady-state conditions, j_A is constant, and if D_{AB} is constant, the product

$$r \frac{d\rho_A}{dr} = C_1 \qquad (2)$$

must be a constant. Using the differential relation dr/r = d (ln r), it follows that

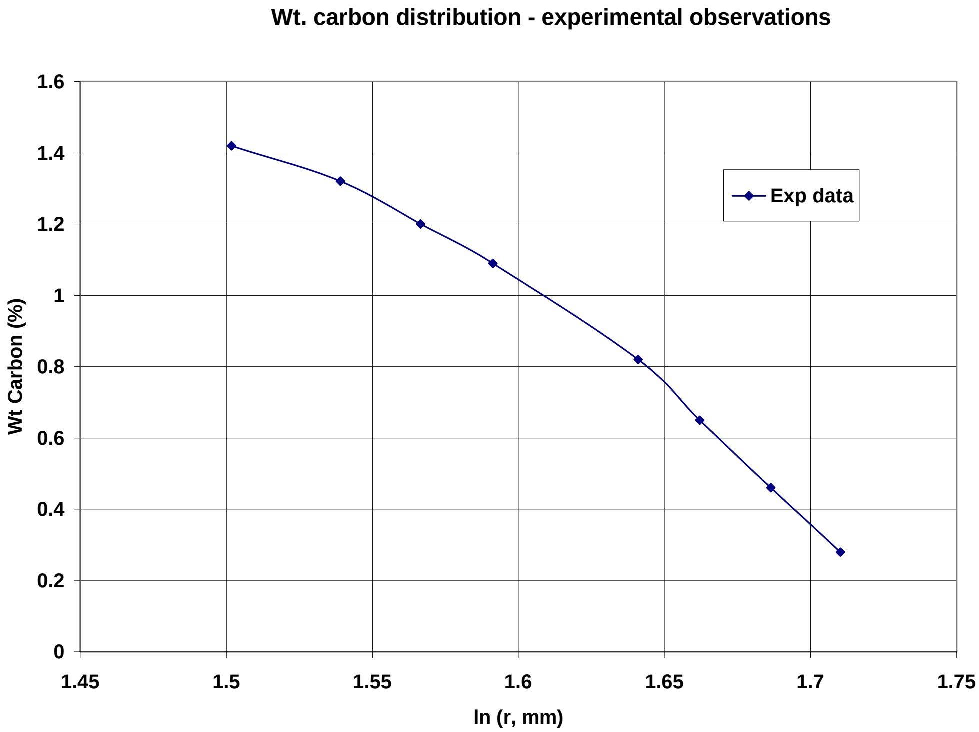
$$\frac{d\rho_A}{d\,(\ln r)} = C_1 \qquad (3)$$

so that on a ln(r) plot, ρ_A is a straight line. See the graph below for this behavior.

Continued ...

PROBLEM 14.7 (Cont.)

(b) To determine whether $D_{C\text{-}Fe}$ is a constant for the experimental diffusion process, the data are represented on a ln(r) coordinate.



Since the plot is not linear, $D_{C\text{-}Fe}$ is not a constant. From the treatment of part (a), if D_{AB} is not a constant, then

$$D_{AB} \frac{d\rho_A}{d(\ln r)} = C_2$$

must be constant. We conclude that $D_{C\text{-}Fe}$ will be lower at the radial position where the gradient is higher. Hence, we expect $D_{C\text{-}Fe}$ to increase with increasing carbon content.

(c) From a plot of Wt - %C vs. r (not shown), the mass fraction gradient is determined at three locations and Fick's law is used to calculate the diffusion coefficient,

$$j_c = -\rho \cdot A_r \cdot D_{C-Fe} \frac{\Delta\,(\text{Wt} - \%\ \text{C})}{\Delta r}$$

where the mass flow rate is

$$j_c = 3.6 \times 10^{-3}\ \text{kg}/100\ \text{h}\ (3600\ \text{s}/\text{h}) = 1 \times 10^{-8}\ \text{kg}/\text{s}$$

and $\rho = 7730\ \text{kg/m}^3$, density of iron. The results of this analysis yield,

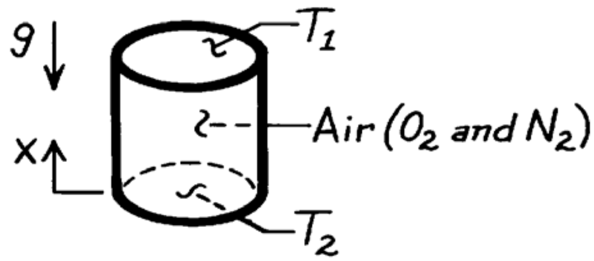
Wt - C (%)	r (mm)	Δ Wt-C/Δr (%/mm)	$D_{C\text{-}Fe} \times 10^{11}$ (m^2/s)
1.32	4.66	-0.679	6.51
0.955	5.04	-1.08	3.79
0.37	5.47	-1.385	2.72

PROBLEM 14.8

KNOWN: Air is enclosed at uniform pressure in a vertical, cylindrical container whose top and bottom surfaces are maintained at different temperatures.

FIND: (a) Conditions in air when bottom surface is colder than top surface, (b) Conditions when bottom surface is hotter than top surface.

SCHEMATIC:



ASSUMPTIONS: (1) Uniform pressure, (2) Perfect gas behavior.

ANALYSIS: (a) If $T_1 > T_2$, the axial temperature gradient (dT/dx) will result in an axial density gradient. However, since $d\rho/dx < 0$ there will be no buoyancy driven, convective motion of the mixture.

There will also be axial species density gradients, $d\rho_{O_2}/dx$ and $d\rho_{N_2}/dx$. However, there is no gradient associated with the mass fractions $\left(dm_{O_2}/dx = 0,\ dm_{N_2}/dx = 0\right)$. Hence, from Fick's law, Eq. 14.12, there is *no* mass transfer by diffusion.

(b) If $T_1 < T_2$, $d\rho/dx > 0$ and there may be a buoyancy driven, convective motion of the mixture. However, $dm_{O_2}/dx = 0$ and $dm_{N_2}/dx = 0$, and there is still *no* mass transfer. Hence, although there is motion of each species with the convective motion of the mixture, there is *no relative motion* between species.

COMMENTS: The commonly used special case of Fick's law,

$$j_A = -D_{AB}\frac{d\rho_A}{dx}$$

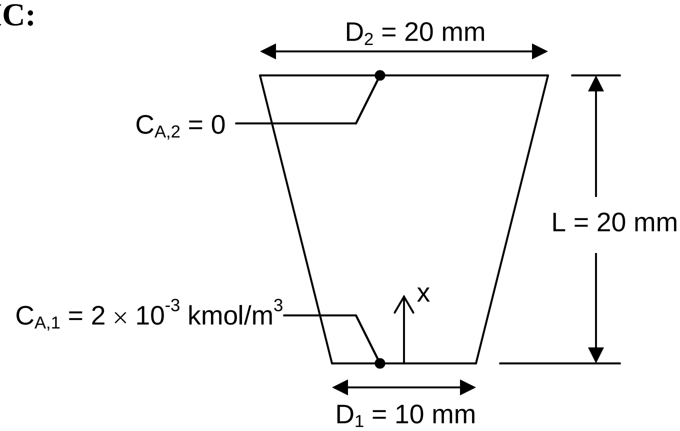
would be inappropriate for this problem since ρ is not uniform. If applied, this special case indicates that mass transfer would occur, thereby providing an incorrect result.

PROBLEM 14.9

KNOWN: Dimensions of rubber stopper in medicine jar. Molar concentration of medicine vapor at top and bottom surfaces. Mass diffusivity of medicine vapor in rubber.

FIND: Rate at which medicine vapor exits through the stopper.

SCHEMATIC:



ASSUMPTIONS: (1) Glass neck is impermeable to medicine vapor, thus there is negligible mass loss out of slanted surface, (2) One-dimensional mass diffusion, (3) Steady state, (4) Constant properties, (5) No chemical reaction.

PROPERTIES: Medicine vapor-rubber (given): $D_{AB} = 0.2 \times 10^{-9}$ m^2/s.

ANALYSIS: The analysis follows the "alternative conduction analysis" approach. For one-dimensional diffusion in the x-direction, Fick's Law in molar form, Eq. 14.13, reduces to

$$J_A^* = -CD_{AB}\frac{dx_A}{dx} = -D_{AB}\frac{dC_A}{dx} \qquad (1)$$

where the total concentration, C, has been assumed constant. The transfer rate of species A through the entire stopper cross-section, N_A, can be expressed as $N_A = J_A^* A_c$, where A_c is the cross-sectional area. For steady-state, one-dimensional diffusion with no chemical reaction, the species transfer rate must be constant. We multiply Eq. (1) by A_c, separate variables, and integrate between the top and bottom of the stopper, as follows

$$N_A = J_A^* A_c = -D_{AB} A_c \frac{dC_A}{dx}$$

$$N_A \int_0^L \frac{dx}{A_c} = -D_{AB}\int_{x_{A1}}^{x_{A2}} dC_A = D_{AB}(C_{A1} - C_{A2}) = D_{AB} C_{A1} \qquad (2)$$

The cross-sectional area is given by

$$A_c = \pi R^2, \text{ where } R = R_1 + (R_2 - R_1)x/L$$

Continued…

PROBLEM 14.9 (Cont.)

Thus $dx = LdR/(R_2 - R_1)$, and Eq. (2) becomes

$$N_A \int_{R_1}^{R_2} \frac{dR}{\pi R^2} \frac{L}{R_2 - R_1} = D_{AB} C_{A1}$$

$$\frac{N_A}{\pi}\left(\frac{1}{R_1} - \frac{1}{R_2}\right)\frac{L}{R_2 - R_1} = D_{AB} C_{A1}$$

Thus

$$N_A = \frac{\pi D_{AB} C_{A1} R_1 R_2}{L}$$

$$= \frac{\pi \times 0.2 \times 10^{-9}\ \mathrm{m}^2/\mathrm{s} \times 2 \times 10^{-3}\ \mathrm{kmol/m}^3 \times 0.005\ \mathrm{m} \times 0.01\ \mathrm{m}}{0.02\ \mathrm{m}}$$

$$N_A = 3.14 \times 10^{-15}\ \mathrm{kmol/s}$$ <

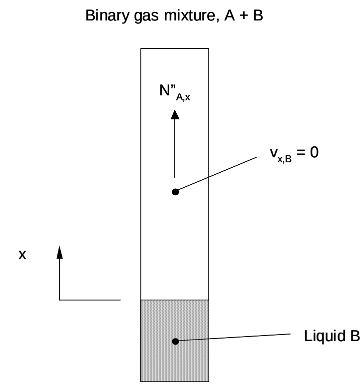
COMMENTS: (1) The assumption of constant concentration, C, is excellent because the "mixture" of rubber and medicine vapor would be dominated by the rubber. (2) Using the properties of water for the medicine, we can estimate how much the liquid would be depleted per year. The molar loss in one year is 3.14×10^{-15} kmol/s × 3.15×10^{7} s/yr = 9.9×10^{-8} kmol/yr. If the molecular weight is 18 kg/kmol, the loss would be 1.8×10^{-6} kg/yr. If the liquid density is 1000 kg/m^3, the volume loss would be 1.8×10^{-9} m^3/yr. For a bottle cross-sectional area of 2×10^{-3} m^2, the liquid level would drop by less than 1 μm per year.

PROBLEM 14.10

KNOWN: Evaporation of liquid A into a column containing vapor A and B. Species B cannot be absorbed in liquid A.

FIND: The relationship between the ratio of the molar-average velocity to the species velocity of species A to the mole fraction of species A.

SCHEMATIC:



ASSUMPTIONS: (1) Steady, one-dimensional diffusion, (2) No chemical reactions.

ANALYSIS: From Section 14.2.2, we know that $N''_{B,x} = 0$. From Eq. 14.27,

$$N''_{A,x} = C_A v_{A,x} \quad \text{and} \quad N''_{B,x} = C_B v_{B,x} = 0 \quad \text{or} \quad v_{B,x} = 0 \tag{1}$$

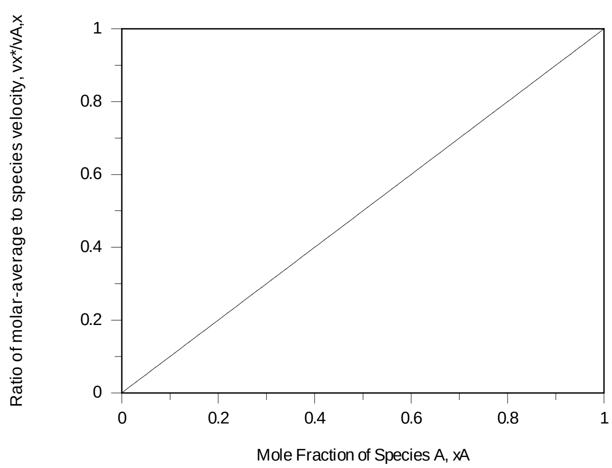
From Eq. 14.29,

$$v_x^* = x_A v_{A,x} \tag{2}$$

Therefore

$$\frac{v_x^*}{v_{A,x}} = x_A$$ <

The relationship is shown in the graph below.



Continued…

PROBLEM 14.10 (Cont.)

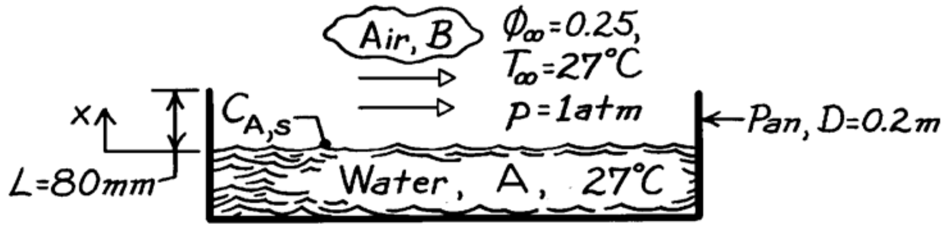
COMMENTS: (1) When the mole fraction of Species A is small and Species B is not in motion, the molar-average velocity is dominated by Species B and is negligible compared to the non-zero species velocity of A. In other words, the vapor in the column can be treated as a stationary medium since, although Species A is in motion, there is very little species A present. (2) When the mole fraction of Species A is large, there is very little Species B present, and the velocity of the mixture is dominated by the velocity of Species A. Hence, the velocity ratio approaches unity as mixture becomes dominated by Species A.

PROBLEM 14.11

KNOWN: Water in an open pan exposed to prescribed ambient conditions.

FIND: Evaporation rate considering (a) diffusion only and (b) convective effects.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional diffusion, (3) Constant properties, (4) Uniform T and p, (5) Perfect gas behavior.

PROPERTIES: *Table A-8,* Water vapor-air (T = 300 K, 1 atm), $D_{AB} = 0.26 \times 10^{-4}\ m^2/s$; *Table A-6*, Water vapor (T = 300 K, 1 atm), $p_{sat} = 0.03531$ bar, $v_g = 39.13\ m^3/kg$.

ANALYSIS: (a) The evaporation rate considering only diffusion follows from Eq. 14.32 simplified for a stationary medium. That is,

$$N_{A,x} = N''_{A,x} \cdot A = -D_{AB} A \frac{dC_A}{dx}.$$

Recognizing that $\phi \equiv p_A/p_{A,sat} = C_A/C_{A,sat}$, the rate is expressed as

$$N_{A,x} = -D_{AB} A \frac{C_{A,\infty} - C_{A,s}}{L} = \frac{D_{AB} A}{L} C_{A,sat}\left(1 - \phi_\infty\right)$$

$$N_{A,x} = \frac{0.26 \times 10^{-4}\, m^2/s\,(\pi/4)(0.2\, m)^2}{80 \times 10^{-3}\, m} \frac{1}{39.13\ m^3/kg \times 18\ kg/kmol}\left(1 - 0.25\right) = 1.087 \times 10^{-8}\, kmol/s$$

where $C_{A,s} = 1/\left(v_g \mathcal{M}_A\right)$ with $\mathcal{M}_A = 18\ kg/kmol$.

(b)The evaporation rate considering convective effects using Eq. 14.40 is

$$N_{A,x} = N''_{A,x} \cdot A = \frac{C D_{AB} A}{L} \ln \frac{1 - x_{AL}}{1 - x_{A,0}}.$$

Using the perfect gas law, the total concentration of the mixture is

$$C = p/\Re T = 1.0133\ bar/\left(8.314 \times 10^{-2} m^3 \cdot bar/kmol \cdot K \times 300K\right) = 0.04063\ kmol/m^3$$

where p = 1 atm = 1.0133 bar. The mole fractions at x = 0 and x = L are

$$x_{A,0} = \frac{p_{A,s}}{p} = \frac{0.03531\ bar}{1.0133\ bar} = 0.0348 \qquad x_{A,L} = \phi_\infty x_{A,0} = 0.0087.$$

Hence

$$N_{A,x} = \frac{0.04063\ kmol/m^3 \times 0.26 \times 10^{-4} m^2/s\,(\pi/4)(0.2\ m)^2}{80 \times 10^{-3}\ m} \ln\frac{1 - 0.0087}{1 - 0.0348} = 1.107 \times 10^{-8} kmol/s. \qquad <$$

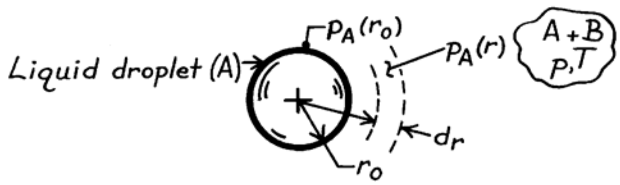
COMMENTS: For this situation, the advective effect is very small but does tend to increase (by 1.5%) the evaporation rate as expected.

PROBLEM 14.12

KNOWN: Spherical droplet of liquid A and radius r_o evaporating into stagnant gas B.

FIND: Evaporation rate of species A in terms of $p_{A,sat}$, partial pressure $p_A(r)$, the total pressure p and other pertinent parameters.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional, radial, species diffusion, (3) Constant properties, including total concentration, (4) Droplet and mixer air at uniform pressure and temperature, (5) Perfect gas behavior.

ANALYSIS: From Eq. 14.32 for a radial spherical coordinate system, the evaporation rate of liquid A into a binary gas mixture A + B is

$$N_{A,r} = -D_{AB} A_r \frac{dC_A}{dr} + \frac{C_A}{C} N_{A,r}$$

where $A_r = 4\pi r^2$ and $N_{A,r} = N_A$, a constant,

$$N_A \left(1 - \frac{C_A}{C}\right) = -D_{AB} \cdot 4\pi r^2 \cdot \frac{dC_A}{dr}.$$

From perfect gas behavior, $C_A = p_A / \Re T$ and $C = p / \Re T$,

$$N_A \left(p - p_A\right) = -D_{AB} \cdot 4\pi r^2 \cdot \frac{p}{\Re T} \frac{dp_A}{dr}$$

Separating variables, setting definite limits, and integrating

$$-N_A \frac{\Re T}{p} \frac{1}{4\pi D_{AB}} \int_{r_o}^{r} \frac{dr}{r^2} = \int_{p_{A,r_o}}^{p_{A,r}} \frac{dp_A}{p - p_A}$$

find that

$$N_A = 4\pi r_o D_{AB} \frac{p}{\Re T} \frac{1}{1 - r_o / r} \ln \frac{p - p_A(r)}{p - p_{A,o}}$$ <

where $p_{A,o} = p_A(r_o) = p_{A,sat}$, the saturation pressure of liquid A at temperature T.

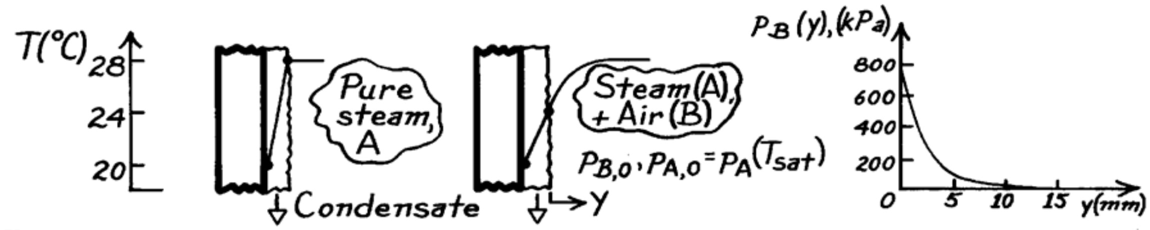
COMMENTS: Compare the method of solution and result with the content of Section 14.2.2, Evaporation in a Column.

PROBLEM 14.13

KNOWN: Clean surface with pure steam has condensate rate of 0.020 kg/m^2·s for the prescribed conditions. With the presence of stagnant air in the steam, the condensate surface drops from 28°C to 24°C and the condensate rate is halved.

FIND: Partial pressure of air in the air-steam mixture as a function of distance from the condensate film.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Constant properties including pressure in air-steam mixture, (3) Perfect gas behavior.

PROPERTIES: *Table A-6*, Water vapor: p_{sat} (28°C = 301 K) = 0.03767 bar; p_{sat} (24°C = 297 K) = 0.02983 bar; *Table A-8*, Water-air (298 K, 1 bar): $D_{AB} = 0.26 \times 10^{-4}$ m^2/s.

ANALYSIS: The partial pressure distribution of the air as a function of distance y can be found from the species (A) rate expression, Eq. 14.40,

$$N''_{A,y} = \left(CD_{AB}/y\right)\ln\left(1 - x_{A,y}\right)/\left(1 - x_{A,0}\right).$$

With $C = p/\Re T$, $x_{B,y} = 1 - x_{A,y}$ and $x_{B,0} = 1 - x_{A,0}$, recognizing that $x_B = p_B/p$, find

$$p_B(y) = p_{B,0} \cdot \exp\left(N''_{A,y}\frac{\Re T}{pD_{AB}}y\right)$$

$$p_{B,0} = p - p_{A,0} = p_{sat}(28°C) - p_{sat}(24°C) = (0.03767 - 0.02983)\text{ bar} = 0.00784 \text{ bar}.$$

With $N''_{A,y} = -(0.020/2)\text{kg/m}^2\cdot\text{s}/29\text{ kg/kmol} = 3.45\times10^{-4}\text{kmol/m}^2\cdot\text{s}$,

$$p_B(y) = 0.0784\text{ bar}\times\exp\left(3.45\times10^{-4}\text{kmol/m}^2\cdot\text{s}\frac{8.314\times10^{-2}\text{m}^3\cdot\text{bar/kmol}\cdot\text{K}\times299\text{ K}}{0.03767\text{ bar}\times6.902\times10^{-4}\text{m}^2/\text{s}}y\right)$$

$$p_B(y) = 784\text{ kPa}\times\exp(-0.330y)$$

with p_B in [kPa] and y in [mm], where T = 26°C = 299 K, the average temperature of the air-steam mixture, and $D_{AB} \approx p^{-1}T^{3/2} = 0.26 \times 10^{-4}$ m^2/s (1/0.03767) (299/298)$^{3/2}$ = 6.902×10^{-4} m^2/s. Selected values for the pressure are shown below and the distribution is shown above:

y (mm)	0	5	10	15
p_B(y) (kPa)	784	151	29.0	5.6

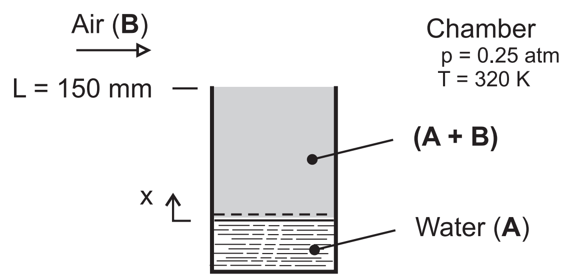
COMMENTS: To minimize inert gas effects, the usual practice is to pass vapor over the surfaces so that the inerts are eventually collected near the outlet region of the condenser. Our estimate shows that the effective region to be swept is approximately 10 mm thick.

PROBLEM 14.14

KNOWN: Column containing liquid phase of water (A) evaporates into the air (B) flowing over the mouth of the column.

FIND: Evaporation rate of water (kg/h·m^2) using the known value of the binary diffusion coefficient for the water vapor - air mixture.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, one-dimensional diffusion in the column, (2) Constant properties, (3) Uniform temperature and pressure throughout the column, (4) Water vapor exhibits ideal gas behavior, and (5) Negligible water vapor in the chamber air.

PROPERTIES: *Table A-6, water* (T = 320 K): p_{sat} = 0.1053 bar; *Table A-8, water vapor-air* (0.25 atm, 320 K): Since $D_{AB} \sim p^{-1}\, T^{3/2}$ find

$$D_{AB} = 0.26 \times 10^{-4}\ m^2/s\,(1.00/0.25)\,(320/298)^{3/2} = 1.157 \times 10^{-4}\ m^2/s$$

ANALYSIS: From Eq. 14.40, the molar flow rate per unit area is

$$N''_{A,x} = \frac{C\,D_{AB}}{L} \ln \frac{1 - x_{A,L}}{1 - x_{A,0}}$$

where C is the mixture concentration determined from the ideal gas law as

$$C = \frac{p}{\mathcal{R}T} = \frac{0.25\ \text{atm}}{8.205 \times 10^{-2}\ m^3 \cdot \text{atm/kmol} \cdot K \times 320\ K} = 0.009397\ \text{kmol/m}^3$$

where $\mathcal{R} = 8.205 \times 10^{-2}\ m^3 \cdot \text{atm/kmol} \cdot K$. The mole fractions at x = 0 and x = L are

$$x_{A,L} = 0 \qquad \text{(no water vapor in air above column)}$$

$$x_{A,0} = p_A / p = 0.1053/0.25 = 0.4212$$

where p_A is the saturation pressure for water at T = 320 K. Substituting numerical values

$$N''_{A,x} = \frac{0.009397\ \text{kmol}/m^3 \times 1.157 \times 10^{-4}\ m^2/s}{0.150\ m} \ln \frac{(1-0)}{(1-0.4212)}$$

$$N''_{A,x} = 3.964 \times 10^{-6}\ \text{kmol}/m^2 \cdot s$$

or, on a mass basis,

$$m''_{A,x} = N''_{A,x}\mathcal{M}_A$$

$$m''_{A,x} = 3.964 \times 10^{-6}\ \text{kmol}/m^2 \cdot s \times 3600\ s/h \times 18\ kg/\text{kmol}$$

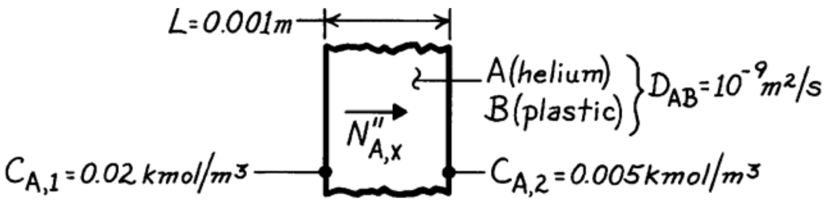
$$m''_{A,x} = 0.257\ kg/m^2 \cdot h$$ <

PROBLEM 14.15

KNOWN: Molar concentrations of helium at the inner and outer surfaces of a plastic membrane. Diffusion coefficient and membrane thickness.

FIND: Molar diffusion flux.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional diffusion in a plane wall, (3) Stationary medium, (4) Uniform $C = C_A + C_B$.

ANALYSIS: The molar flux may be obtained from Eq. 14.54,

$$N''_{A,x} = \frac{D_{AB}}{L}\left(C_{A,1} - C_{A,2}\right) = \frac{10^{-9}\ m^2/s}{0.001\ m}\left(0.02 - 0.005\right) kmol/m^3$$

$$N''_{A,x} = 1.5\times10^{-8}\ kmol/s\cdot m^2.$$ <

COMMENTS: The mass flux is

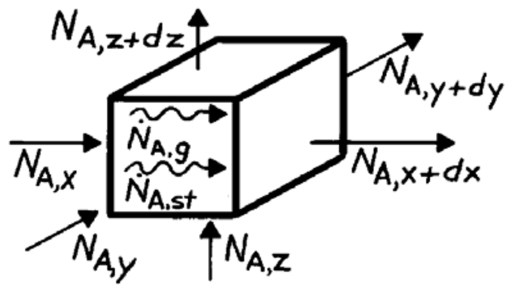
$$n''_{A,x} = \mathcal{M}_A N''_{A,x} = 4\ kg/kmol \times 1.5\times10^{-8}\ kmol/s\cdot m^2 = 6\times10^{-8}\ kg/s\cdot m^2.$$

PROBLEM 14.16

KNOWN: Three-dimensional diffusion of species A in a stationary medium with chemical reactions.

FIND: Derive molar form of diffusion equation.

SCHEMATIC:



ASSUMPTIONS: (1) Uniform total molar concentration, (2) Stationary medium.

ANALYSIS: The derivation parallels that of Section 14.4.2, except that Eq. 14.43 is applied on a molar basis. That is,

$$N_{A,x} + N_{A,y} + N_{A,z} + \dot{N}_{A,g} - N_{A,x+dx} - N_{A,y+dy} - N_{A,z+dz} = \dot{N}_{A,st}.$$

With

$$N_{A,x+dx} = N_{A,x} + \frac{\partial N_{A,x}}{\partial x} dx, \qquad N_{A,y+dy} = ...$$

$$N_{A,x} = -D_{AB}\left(dydz\right)\frac{\partial C_A}{\partial x}, \qquad N_{A,y} = ...$$

$$\dot{N}_{A,g} = \dot{N}_A\left(dxdydz\right), \qquad \dot{N}_{A,st} = \frac{\partial C_A}{\partial t} dxdydz$$

It follows that

$$\frac{\partial}{\partial x}\left(D_{AB}\frac{\partial C_A}{\partial x}\right) + \frac{\partial}{\partial y}\left(D_{AB}\frac{\partial C_A}{\partial y}\right) + \frac{\partial}{\partial z}\left(D_{AB}\frac{\partial C_A}{\partial z}\right) + \dot{N}_A = \frac{\partial C_A}{\partial t}. \qquad <$$

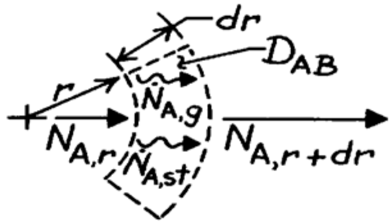
COMMENTS: If D_{AB} is constant, the foregoing result reduces to Eq. 14.48b.

PROBLEM 14.17

KNOWN: Gas (A) diffuses through a cylindrical tube wall (B) and experiences chemical reactions at a volumetric rate, $\dot{N}_A$.

FIND: Differential equation which governs molar concentration of gas in plastic.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional radial diffusion, (2) Uniform total molar concentration, (3) Stationary medium.

ANALYSIS: Dividing the species conservation requirement, Eq. 14.43, by the molecular weight, $\mathcal{M}_A$, and applying it to a differential control volume of unit length normal to the page,

$$N_{A,r} + \dot{N}_{A,g} - N_{A,r+dr} = \dot{N}_{A,st}$$

where

$$N_{A,r} = (2\pi r \cdot 1) N''_{A,r} = -2\pi r D_{AB} \frac{\partial C_A}{\partial r}$$

$$N_{A,r+dr} = N_{A,r} + \frac{\partial N_{A,r}}{\partial r} dr$$

$$\dot{N}_{A,g} = -\dot{N}_A (2\pi r \cdot dr \cdot 1) \qquad \dot{N}_{A,st} = \frac{\partial [C_A (2\pi r dr \cdot 1)]}{\partial t}.$$

Hence

$$-\dot{N}_A (2\pi r dr) + 2\pi D_{AB} \frac{\partial}{\partial r}\left(r \frac{\partial C_A}{\partial r}\right) dr = 2\pi r dr \frac{\partial C_A}{\partial t}$$

or

$$\frac{D_{AB}}{r} \frac{\partial}{\partial r}\left(r \frac{\partial C_A}{\partial r}\right) - \dot{N}_A = \frac{\partial C_A}{\partial t}. \qquad <$$

COMMENTS: (1) The minus sign in the generation term is necessitated by the fact that the reactions deplete the concentration of species A.

(2) From knowledge of $\dot{N}_A(r,t)$, the foregoing equation could be solved for C_A (r,t).

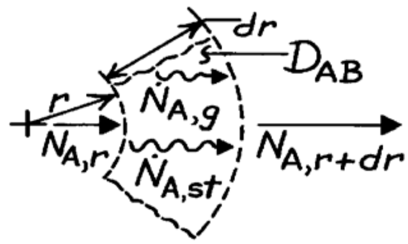
(3) Note the agreement between the above result and the one-dimensional form of Eq. 14.49 for uniform C.

PROBLEM 14.18

KNOWN: One-dimensional, radial diffusion of species A in a stationary, spherical medium with chemical reactions.

FIND: Derive appropriate form of diffusion equation.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, radial diffusion, (2) Uniform total molar concentration, (3) Stationary medium.

ANALYSIS: Dividing the species conservation requirement, Eq. 14.43, by the molecular weight, $\mathcal{M}_A$, and applying it to the differential control volume, it follows that

$$N_{A,r} + \dot{N}_{A,g} - N_{A,r+dr} = \dot{N}_{A,st}$$

where

$$N_{A,r} = -D_{AB} 4\pi r^2 \frac{\partial C_A}{\partial r}$$

$$N_{A,r+dr} = N_{A,r} + \frac{\partial N_{A,r}}{\partial r} dr$$

$$\dot{N}_{A,g} = \dot{N}_A \left(4\pi r^2 dr\right), \qquad \dot{N}_{A,st} = \frac{\partial\left[C_A\left(4\pi r^2 dr\right)\right]}{\partial t}.$$

Hence

$$\dot{N}_A \left(4\pi r^2 dr\right) + 4\pi \frac{\partial}{\partial r}\left(D_{AB} r^2 \frac{\partial C_A}{\partial r}\right) dr = 4\pi r^2 \frac{\partial C_A}{\partial t} dr$$

or

$$\frac{1}{r^2}\frac{\partial}{\partial r}\left(D_{AB} r^2 \frac{\partial C_A}{\partial r}\right) + \dot{N}_A = \frac{\partial C_A}{\partial t}. \qquad <$$

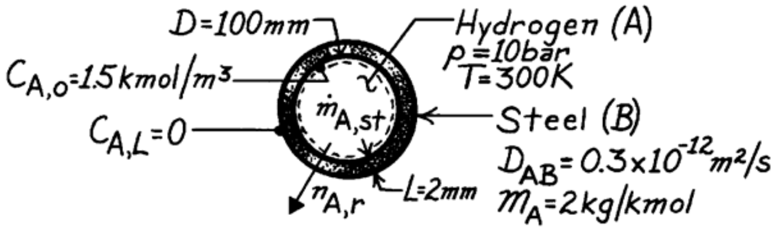
COMMENTS: Equation 14.50 reduces to the foregoing result if C is independent of r and variations in ϕ and θ are negligible.

PROBLEM 14.19

KNOWN: Pressure and temperature of hydrogen stored in a spherical steel tank of prescribed diameter and thickness.

FIND: (a) Initial rate of hydrogen mass loss from the tank, (b) Initial rate of pressure drop in the tank.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional species diffusion in a stationary medium, (2) Uniform total molar concentration, C, (3) No chemical reactions.

ANALYSIS: (a) From Table 14.1

$$N_{A,r} = \frac{C_{A,o} - C_{A,L}}{R_{m,dif}} = \frac{C_{A,o}}{(1/4\pi D_{AB})(1/r_i - 1/r_o)}$$

$$N_{A,r} = \frac{4\pi\left(0.3\times10^{-12}\ \text{m}^2/\text{s}\right)1.5\ \ \text{kmol}/\text{m}^3}{(1/0.05\ \text{m} - 1/0.052\ \text{m})} = 7.35\times10^{-12}\ \text{kmol}/\text{s}$$

or

$$n_{A,r} = \mathcal{M}_A N_{A,r} = 2\ \text{kg}/\text{kmol}\times7.35\times10^{-12}\ \text{kmol}/\text{s} = 14.7\times10^{-12}\ \text{kg}/\text{s}. \qquad <$$

(b) Applying a species balance to a control volume about the hydrogen,

$$\dot{M}_{A,st} = -\dot{M}_{A,out} = -n_{A,r}$$

$$\dot{M}_{A,st} = \frac{d(\rho_A V)}{dt} = \frac{\pi D^3}{6}\frac{d\rho_A}{dt} = \frac{\pi D^3}{6R_A T}\frac{dp_A}{dt} = \frac{\pi D^3 \mathcal{M}_A}{6\Re T}\frac{dp_A}{dt}$$

Hence

$$\frac{dp_A}{dt} = -\frac{6\Re T}{\pi D^3 \mathcal{M}_A} n_{A,r} = -\frac{6\left(0.08314\ \text{m}^3\cdot\text{bar}/\text{kmol}\cdot\text{K}\right)(300\ \text{K})}{\pi(0.1\text{m})^3\, 2\ \text{kg}/\text{kmol}}\times14.7\times10^{-12}\ \text{kg}/\text{s}$$

$$\frac{dp_A}{dt} = -3.50\times10^{-7}\ \text{bar}/\text{s}. \qquad <$$

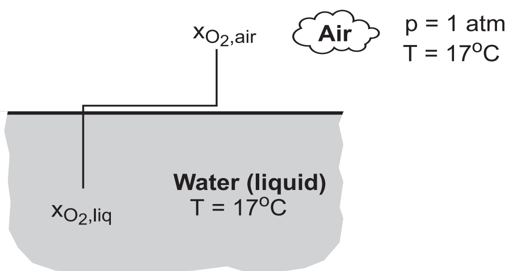
COMMENTS: If the spherical shell is appoximated as a plane wall, $N_{a,x} = D_{AB}(C_{A,o})\ \pi D^2/L = 7.07 \times 10^{-12}$ kmol/s. This result is 4% lower than that associated with the spherical shell calculation.

PROBLEM 14.20

KNOWN: Temperature of atmospheric air and water. Percentage by volume of oxygen in the air.

FIND: (a) Mole and mass fractions of water at the air and water sides of the interface, (b) Mole and mass fractions of oxygen in the air and water.

SCHEMATIC:



$\mathcal{M}_w = 18$, $\mathcal{M}_{air} = 29$

ASSUMPTIONS: (1) Perfect gas behavior for air and water vapor, (2) Thermodynamic equilibrium at liquid/vapor interface, (3) Dilute concentration of oxygen and other gases in water, (4) Molecular weight of air is independent of vapor concentration.

PROPERTIES: *Table A-6*, Saturated water (T = 290 K): $p_{vap} = 0.01917$ bars. *Table A-9*, O_2/water, H = 37,600 bars.

ANALYSIS: (a) Assuming ideal gas behavior, $p_{w,vap} = (N_{w,vap}/V)\,\mathfrak{R}T$ and $p = (N/V)\,\mathfrak{R}T$, in which case

$$x_{w,vap} = \left(p_{w,vap}/p_{air}\right) = \left(0.01917/1.0133\right) = 0.0189 \quad <$$

With $m_{w,vap} = (\rho_{w,vap}/\rho_{air}) = (C_{w,vap}\mathcal{M}_w/C_{air}\mathcal{M}_{air}) = x_{w,vap}\,(\mathcal{M}_w/\mathcal{M}_{air})$. Hence,

$$m_{w,vap} = 0.0189\ (18/29) = 0.0120 \quad <$$

Assuming negligible gas phase concentrations in the liquid,

$$x_{w,liq} = m_{w,liq} = 1 \quad <$$

(b) Since the partial volume of a gaseous species is proportional to the number of moles of the species, its mole fraction is equivalent to its volume fraction. Hence on the air side of the interface

$$x_{O2,air} = 0.205 \quad <$$

$$m_{O2,air} = x_{O2,air}\left(\mathcal{M}_{O2}/\mathcal{M}_{air}\right) = 0.205\left(32/29\right) = 0.226 \quad <$$

The mole fraction of O_2 in the water is

$$x_{O2,liq} = p_{O2,air}/H = 0.208\text{ bars}/37,600\text{ bars} = 5.53\times10^{-6} \quad <$$

where $p_{O2,air} = x_{O2,air}\ p_{atm} = 0.205 \times 1.0133$ bars $= 0.208$ bars. The mass fraction of O_2 in the water is

$$m_{O2,liq} = x_{O2,liq}\left(\mathcal{M}_{O2}/\mathcal{M}_w\right) = 5.53\times10^{-6}\left(32/18\right) = 9.83\times10^{-6} \quad <$$

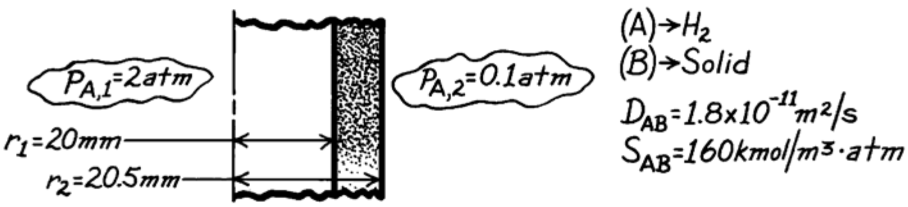
COMMENTS: There is a large discontinuity in the oxygen content between the air and water sides of the interface. Despite the low concentration of oxygen in the water, it is sufficient to support the life of aquatic organisms.

PROBLEM 14.21

KNOWN: Pressure and temperature of hydrogen inside and outside of a circular tube. Diffusivity and solubility of hydrogen in tube wall of prescribed thickness and diameter.

FIND: Rate of hydrogen transfer through tube per unit length.

SCHEMATIC:



ASSUMPTIONS: (1) Steady diffusion in radial direction, (2) Uniform total molar concentration in wall, (3) No chemical reactions, (4) Stationary medium.

ANALYSIS: The mass transfer rate per unit tube length is

$$N'_{A,r} = \frac{C_A(r_1) - C_A(r_2)}{\ln(r_2/r_1)/2\pi D_{AB}}$$

where from Eq. 14.62, $C_{A,s} = Sp_a$,

$$C_A(r_1) = Sp_{A,1} = 160 \text{ kmol/m}^3 \cdot \text{atm} \times 2 \text{ atm} = 320 \text{ kmol/m}^3$$

$$C_A(r_2) = Sp_{A,2} = 160 \text{ kmol/m}^3 \cdot \text{atm} \times 0.1 \text{ atm} = 16 \text{ kmol/m}^3.$$

Hence,

$$N'_{A,r} = \frac{(320-16)\text{kmol/m}^3}{\ln(20.5/20)/2\pi \times 1.8\times10^{-11} \text{m}^2/\text{s}} = \frac{304 \text{ kmol/m}^3}{2.18\times10^8 \text{ s/m}^2}$$

$$N'_{A,r} = 1.39\times10^{-6} \text{kmol/s}\cdot\text{m}.$$ <

COMMENTS: If the wall were assumed to be plane,

$$R'_{m,dif} = \frac{L}{D_{AB}\pi D} = \frac{5\times10^{-4} \text{ m}}{1.8\times10^{-11} \text{ m}^2/\text{s}\,\pi(0.04 \text{ m})} = 2.21\times10^8 \text{ s/m}^2$$

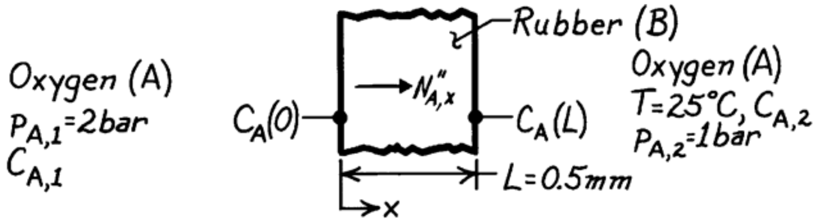
which is close to the value of 2.18×10^8 s/m^2 for the cylindrical wall.

PROBLEM 14.22

KNOWN: Oxygen pressures on opposite sides of a rubber membrane.

FIND: (a) Molar diffusion flux of O_2, (b) Molar concentrations of O_2 outside the rubber.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, steady-state conditions, (2) Stationary medium of uniform total molar concentration, $C = C_A + C_B$, (3) Perfect gas behavior.

PROPERTIES: *Table A-8*, Oxygen-rubber (298 K): $D_{AB} = 0.21 \times 10^{-9}$ m^2/s; *Table A-10*, Oxygen-rubber (298 K): $S = 3.12 \times 10^{-3}$ kmol/m$^3\cdot$bar.

ANALYSIS: (a) For the assumed conditions

$$N''_{A,x} = J^*_{A,x} = -D_{AB}\frac{dC_A}{dx} = D_{AB}\frac{C_A(0) - C_A(L)}{L}.$$

From Eq. 14.62,

$$C_A(0) = Sp_{A,1} = 6.24 \times 10^{-3} \text{kmol/m}^3$$

$$C_A(L) = Sp_{A,2} = 3.12 \times 10^{-3} \text{kmol/m}^3.$$

Hence

$$N''_{A,x} = 0.21 \times 10^{-9} \text{ m}^2/\text{s} \frac{\left(6.24 \times 10^{-3} - 3.12 \times 10^{-3}\right)\text{kmol/m}^3}{0.0005 \text{ m}}$$

$$N''_{A,x} = 1.31 \times 10^{-9} \text{kmol/s}\cdot\text{m}^2.$$ <

(b) From the perfect gas law

$$C_{A,1} = \frac{p_{A,1}}{\Re T} = \frac{2 \text{ bar}}{\left(0.08314 \text{ m}^3\cdot\text{bar/kmol}\cdot\text{K}\right)298 \text{ K}} = 0.0807 \text{ kmol/m}^3$$ <

$$C_{A,2} = 0.5 C_{A,1} = 0.0404 \text{ kmol/m}^3.$$ <

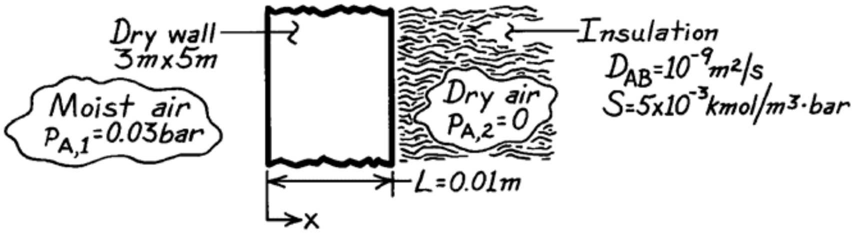
COMMENTS: Recognize that the molar concentrations outside the membrane differ from those within the membrane; that is, $C_{A,1} \neq C_A(0)$ and $C_{A,2} \neq C_A(L)$.

PROBLEM 14.23

KNOWN: Water vapor is transferred through dry wall by diffusion.

FIND: The mass diffusion rate through a 0.01 × 3 × 5 m wall.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional species diffusion, (3) Homogeneous medium, (4) Constant properties, (5) Uniform total molar concentration, (6) Stationary medium with $x_A << 1$, (7) Negligible condensation in the dry wall.

ANALYSIS: From Eq. 14.42,

$$N''_{A,x} = -CD_{AB}\frac{dx_A}{dx} = -D_{AB}\frac{dC_A}{dx} = D_{AB}\frac{C_{A,1} - C_{A,2}}{L}.$$

From Eq. 14.62

$$C_{A,1} = Sp_{A,1} = 0.15 \times 10^{-3}\ \text{kmol/m}^3$$

$$C_{A,2} = Sp_{A,2} = 0\ \text{kmol/m}^3.$$

Hence

$$N''_A = 10^{-9}\ \text{m}^2/\text{s} \times \frac{0.15 \times 10^{-3}\ \text{kmol/m}^3}{0.01\ \text{m}} = 0.15 \times 10^{-10}\ \text{kmol/s}\cdot\text{m}^2.$$

Therefore

$$n_A = \mathcal{M}_A\left(A \cdot N''_A\right) = 18\ \text{kg/kmol} \times 15\ \text{m}^2 \times 0.15 \times 10^{-10}\ \text{kmol/s}\cdot\text{m}^2$$

or

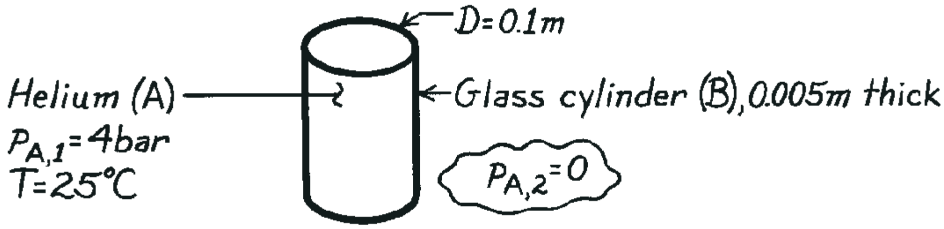
$$n_A = 4.05 \times 10^{-9}\ \text{kg/s}.$$ <

PROBLEM 14.24

KNOWN: Pressure and temperature of helium in a glass cylinder of 100 mm inside diameter and 5 mm thickness.

FIND: Mass rate of helium loss per unit length.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional radial diffusion through cylinder wall, (3) Negligible end losses, (4) Stationary medium, (5) Uniform total molar concentration, (6) Negligible helium concentration outside cylinder.

PROPERTIES: *Table A-8*, He-SiO_2 (298 K): $D_{AB} \approx 0.4 \times 10^{-13}\ m^2/s$; *Table A-10*, He-$SiO_2$ (298 K): $S \approx 0.45 \times 10^{-3}\ kmol/m^3 \cdot bar$.

ANALYSIS: From Table 14.1,

$$N'_{A,r} = \frac{C_{A,S1} - C_{A,S2}}{\ln(r_2/r_1)/2\pi D_{AB}}$$

where, from Eq. 14.62, $C_{A,S} = Sp_A$. Hence

$$C_{A,S1} = Sp_{A,1} = 0.45 \times 10^{-3}\ kmol/m^3 \cdot bar \times 4\ bar = 1.8 \times 10^{-3} kmol/m^3$$

$$C_{A,S2} = SP_{A,2} = 0.$$

Hence

$$N'_{A,r} = \frac{1.8 \times 10^{-3}\ kmol/m^3}{\ln(0.055/0.050)/2\pi\left(0.4 \times 10^{-13}\ m^2/s\right)}$$

$$N'_{A,r} = 4.75 \times 10^{-15}\ kmol/s \cdot m.$$

The mass loss is then

$$n'_{A,r} = \mathcal{M}_A N'_{A,r} = 4\ kg/kmol \times 4.75 \times 10^{-15}\ kmol/s \cdot m$$

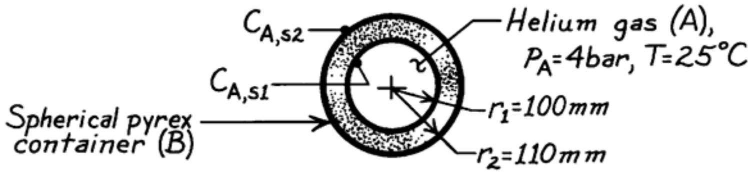
$$n'_{A,r} = 1.90 \times 10^{-14}\ kg/s \cdot m. \qquad <$$

PROBLEM 14.25

KNOWN: Temperature and pressure of helium stored in a spherical pyrex container of prescribed diameter and wall thickness.

FIND: Mass rate of helium loss.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Helium loss by one-dimensional diffusion in radial direction through the pyrex, (3) $C = C_A + C_B$ is independent of r, and $x_A << 1$, (4) Stationary medium.

PROPERTIES: *Table A-8*, He-SiO_2 (293 K): $D_{AB} = 0.4 \times 10^{-13}$ m^2/s; *Table A-10*, He-SiO_2 (293 K): $S = 0.45 \times 10^{-3}$ kmol/m^3·bar.

ANALYSIS: From Table 14.1, the molar diffusion rate may be expressed as

$$N_{A,r} = \frac{C_{A,S1} - C_{A,S2}}{R_{m,dif}}$$

where

$$R_{m,dif} = \frac{1}{4\pi D_{AB}}\left(\frac{1}{r_1} - \frac{1}{r_2}\right) = \frac{1}{4\pi\left(0.4\times10^{-13}\text{m}^2/\text{s}\right)}\left(\frac{1}{0.1\text{m}} - \frac{1}{0.11\text{m}}\right) = 1.81\times10^{12}\,\text{s/m}^3$$

with

$$C_{A,S1} = Sp_A = 0.45\times10^{-3}\text{kmol/m}^3\cdot\text{bar}\times 4\text{ bar} = 1.80\times10^{-3}\text{kmol/m}^3$$

$$C_{A,S2} = 0$$

find

$$N_{A,r} = \frac{1.80\times10^{-3}\text{kmol/m}^3}{1.81\times10^{12}\text{ s/m}^3} = 10^{-15}\text{ kmol/s.}$$

Hence

$$n_{A,r} = \mathcal{M}_A N_{A,r} = 4\text{ kg/mol}\times10^{-15}\text{ kmol/s} = 4\times10^{-15}\text{ kg/s.}$$ <

COMMENTS: Since $r_1 \approx r_2$, the spherical shell could have been approximated as a plane wall with L = 0.01 m and $A \approx 4\pi r_m^2 = 0.139\text{ m}^2$. From Table 14.1,

$$R_{m,dif} = \frac{L}{D_{AB}A} = \frac{0.01\text{ m}}{\left(0.4\times10^{-13}\text{m}^2/\text{s}\right)\left(0.137\text{ m}^2\right)} = 1.8\times10^{12}\text{ s/m}^3 \text{ and}$$

$$N_{A,x} = \frac{C_{A,S1} - C_{A,S2}}{R_{m,dif}} = \frac{1.80\times10^{-3}\text{ kmol/m}^3}{1.8\times10^{12}\text{ s/m}^3} = 10^{-15}\text{ kmol/s.}$$

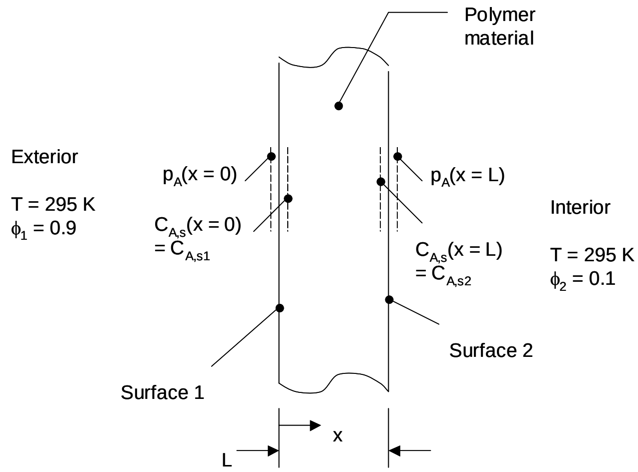
Hence the approximation is excellent.

PROBLEM 14.26

KNOWN: Thickness of polymer packaging material, temperature and humidity conditions in gas on either side of the material.

FIND: (a) Solubility of the packaging material, (b) Total water vapor transfer rate for a material that has 10% of the diffusivity of the material in Example 14.3, (c) Total water vapor transfer rate for a material that has 10% the solubility of the material in Example 14.3, (d) Total water vapor transfer rate after coating the exterior surface with a thin film to reduce its solubility by a factor of 9, leaving the interior surface untreated.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties and steady-state conditions, (2) Stationary medium.

PROPERTIES: Table A.6, water (T = 295 K): p_{sat} = 0.02617 bars.

ANALYSIS:

(a) For the exterior Surface 1, $p_A(x=0) = \phi_1 p_{A,sat}$ = 0.9 × 0.02617 bars = 0.02355 bars. For the interior Surface 2, $p_A(x=L) = \phi_2 p_{A,sat}$ = 0.1 × 0.02617 bars = 0.002617 bars. From Example 14.3, $C_{A,s2} = C_{A,s}(x=L) = 0.5 \times 10^{-3}$ kmol/m^3 so that

$$S = \frac{C_{A,s2}}{p_A(x=L)} = \frac{0.5\times10^{-3}\text{kmol}/\text{m}^3}{0.002617\text{ bar}} = 191 \times 10^{-3}\ \frac{\text{kmol}}{\text{m}^3\text{bar}} \qquad <$$

(b) From Example 14.3, $N_{A,x,p} = 0.32\times10^{-15}$ kmol/s. If the diffusivity is reduced to 10% of its original value,

$$N_{A,x} = 0.1 N_{A,x,p} = 0.1\times0.32\times10^{-15}\text{kmol}/\text{s} = 0.32\times10^{-16}\text{kmol}/\text{s} \qquad <$$

Continued…

PROBLEM 14.26 (Cont.)

(c) If the solubility is reduced to 10% of its original value at both surfaces, $C_{A,s1} = 0.5\times10^{-4}\,\text{kmol/m}^3$ and $C_{A,s2} = 4.5\times10^{-4}\ \text{kmol/m}^3$. Hence,

$$N_{A,x} = 0.1N_{A,x,p} = 0.32\times10^{-16}\ \text{kmol/s}$$ <

(d) If the solubility of exterior Surface 1 is reduced by a factor of 9, $C_{A,s1} = C_{A,s1,p}/9 = 4.5 \times 10^{-3}$ kmol/m^3/9 = 0.5 × 10^{-3} kmol/m^3 = $C_{A,s2}$. Hence,

$$C_{A,s1} - C_{A,s2} = 0 \text{ and } N_{A,x} = 0$$ <

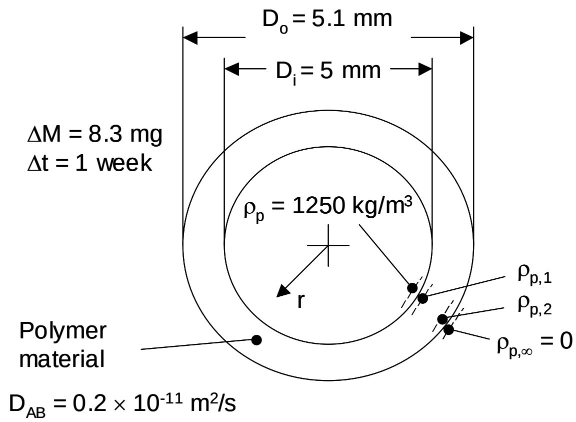
COMMENT: (1) The same value of the solubility may be found in part (a) by considering conditions at Surface 1. (2) By manipulating the solubilities of the surfaces independently, one may eliminate concentration gradients in the material and, in turn, completely eliminate water vapor transfer by diffusion. Materials that have properties designed to change through their thickness in order to promote desired behavior are known as *functionally-graded* materials.

PROBLEM 14.27

KNOWN: Dimensions of sphere containing a pharmaceutical product. Mass loss of sphere over specified time period, mass diffusivity, external conditions.

FIND: The value of the partition coefficient, K.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties and steady-state conditions, (2) Stationary medium.

PROPERTIES: Pharmaceutical product (given): ρ_p = 1250 kg/m^3, $D_{AB} = 0.2 \times 10^{-11}$ m^2/s,

ANALYSIS: By the definition of the partition coefficient provided in the problem statement,

$\rho_{p,1} = K\rho_p$ and $\rho_{p,2} = K\rho_{p,\infty}$. The mass transfer rate through the polymer is found using the one-dimensional species diffusion resistance approach

$$n_{p,r} = \frac{\rho_{p,1} - \rho_{p,2}}{R_{m,dif}} = \frac{K\rho_p}{\dfrac{1}{4\pi D_{AB}}\left(\dfrac{1}{r_1} - \dfrac{1}{r_2}\right)} = \frac{\Delta M}{\Delta t}$$

Hence,

$$K = \frac{\Delta M}{\Delta t \rho_p}\left[\frac{1}{4\pi D_{AB}}\left(\frac{1}{r_1} - \frac{1}{r_2}\right)\right]$$

$$= \frac{8.2 \times 10^{-6}\ \text{kg}}{7\ \text{days} \times 24\ \text{h/day} \times 3600\ \text{s/h}\ \times 1250\ \text{kg/m}^3} \times \left[\frac{1}{4\pi \times 0.2 \times 10^{-11}\ \text{m}^2/\text{s}}\left(\frac{2}{5 \times 10^{-3}\ \text{m}} - \frac{2}{5.1 \times 10^{-3}\ \text{m}}\right)\right]$$

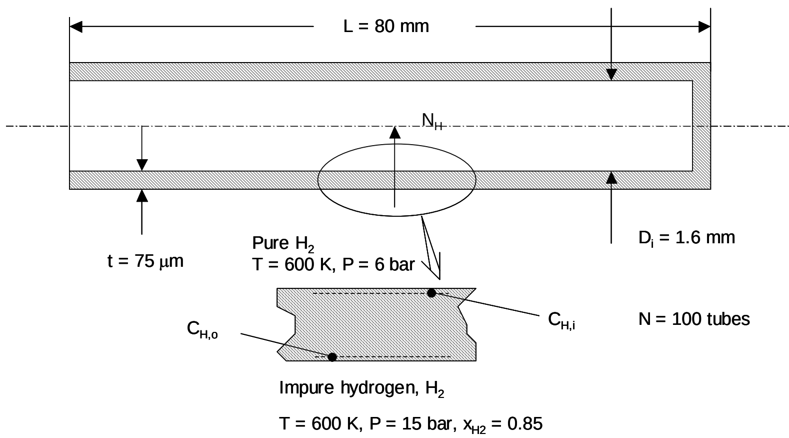
= 0.0034 <

PROBLEM 14.28

KNOWN: Dimensions of N =100 closed-end palladium tubes. Hydrogen (H_2) pressures and temperature on either side of tube wall. Mass diffusivity of atomic hydrogen (H) through the palladium, and Sievert's constant.

FIND: Hourly production rate of pure hydrogen (H_2).

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties and steady-state conditions, (2) Stationary medium.

PROPERTIES: Hydrogen (H) in palladium, given: $D_{AB} = 7 \times 10^{-9}$ m^2/s.

ANALYSIS: The concentration of atomic hydrogen (H) on the outer and inner surfaces of the tube are

$$C_{H,o} = 1.4\ \frac{\text{kmol}}{\text{m}^3\text{bar}^{1/2}} \times (0.85 \times 15\ \text{bar})^{1/2} = 5.00\ \text{kmol/m}^3$$

and

$$C_{H,i} = 1.4\ \frac{\text{kmol}}{\text{m}^3\text{bar}^{1/2}} \times (6\ \text{bar})^{1/2} = 3.43\ \text{kmol/m}^3$$

The one-dimensional species diffusion resistances for the wall and end of one tube are

$$R_{m,dif,w} = \frac{\ln(r_2/r_1)}{2\pi L D_{AB}} = \frac{\ln\left[(0.8 \times 10^{-3}\ \text{m} + 75 \times 10^{-6}\ \text{m})/0.8 \times 10^{-3}\ \text{m}\right]}{2\pi \times 80 \times 10^{-3}\ \text{m} \times 7 \times 10^{-9}\ \text{m}^2/\text{s}} = 25.5 \times 10^6\ \text{s/m}^3$$

and

$$R_{m,dif,e} = \frac{t}{D_{AB}A_c} = \frac{75 \times 10^{-6}\ \text{m}}{7 \times 10^{-9}\ \text{m}^2/\text{s} \times \pi \times (0.8 \times 10^{-3}\ \text{m})^2} = 5.33 \times 10^9\ \text{s/m}^3$$

The molar transfer rate of atomic hydrogen (H) in one tube is therefore

Continued…

PROBLEM 14.28 (Cont.)

$$N_H = \frac{(5.00-3.43)\,\frac{\text{kmol}}{\text{m}^3}}{25.5\times10^6\,\frac{\text{s}}{\text{m}^3}} + \frac{(5.00-3.43)\,\frac{\text{kmol}}{\text{m}^3}}{5.33\times10^9\,\frac{\text{s}}{\text{m}^3}} = 61.9\times10^{-9}\,\frac{\text{kmol}}{\text{s}}$$

The molar transfer rate of molecular hydrogen (H_2) is therefore $N_{H2} = 0.5N_H = 30.95$ kmol/s

The total production rate, $N_{H2,t}$, in kg/h is

$N_{H2,t} = N_{H2} \times \mathcal{M}_{H2} \times N \times t$ = 30.95 kmol/s × 2kg/kmol × 3600 s/h × 100 tubes = 0.022 kg/h $<$

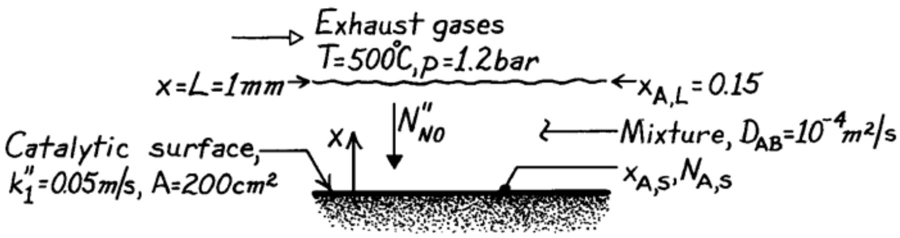
Comments: (1) The concentrations of hydrogen (H_2) in the gas streams are 0.25 kmol/m^3 and 0.12 kmol/m^3, respectively. (2) Palladium and other nanostructured materials, such as carbon nanotubes, can store very high concentrations of hydrogen within their atomic matrix.

PROBLEM 14.29

KNOWN: Conditions of the exhaust gas passing over a catalytic surface for the removal of NO.

FIND: (a) Mole fraction of NO at the catalytic surface, (b) NO removal rate.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional species diffusion through the film, (3) Effects of bulk motion on NO transfer in the film are negligible (stationary medium), (4) No homogeneous reactions of NO within the film, (5) Constant properties, including the total molar concentration, C, throughout the film.

ANALYSIS: Subject to the above assumptions, the transfer of species A (NO) is governed by diffusion in a stationary medium, and the desired results are obtained from Eqs. 14.69 and 14.70. Hence

$$\frac{x_{A,s}}{x_{A,L}} = \frac{1}{1+\left(Lk_1''/D_{AB}\right)} \qquad x_{A,s} = \frac{0.15}{1+0.001\text{ m}\times 0.05\text{ m/s}/\ 10^{-4}\text{ m}^2/\text{s}} = 0.10. \quad <$$

Also

$$N''_{A,s} = -\frac{k_1'' C x_{A,L}}{1+\left(Lk_1''/D_{AB}\right)}$$

where, from the equation of state for a perfect gas,

$$C = \frac{p}{\Re T} = \frac{1.2\text{ bar}}{8.314\times 10^{-2}\text{ m}^3\cdot\text{bar/kmol}\cdot\text{K}\times 773\text{ K}} = 0.0187\text{ kmol/m}^3.$$

Hence

$$N''_{A,s} = -\frac{0.05\text{ m/s}\times 0.0187\text{ kmol/m}^3\times 0.15}{1+\left(0.001\text{ m}\times 0.05\text{ m/s}/10^{-4}\text{ m}^2/\text{s}\right)} = -9.35\times 10^{-5}\text{ kmol/s}\cdot\text{m}^2$$

or

$$n''_{A,S} = \mathcal{M}_A N''_{A,S} = 30\text{ kg/kmol}\left(-9.35\times 10^{-5}\text{ kmol/s}\cdot\text{m}^2\right) = -2.80\times 10^{-3}\text{ kg/s}\cdot\text{m}^2.$$

The molar rate of NO removal for the entire surface is then

$$N_{A,s} = N''_{A,s}A = -9.35\times 10^{-5}\text{ kmol/s}\cdot\text{m}^2\times 0.02\text{ m}^2 = -1.87\times 10^{-6}\text{ kmol/s}$$

or

$$n_{A,S} = -5.61\times 10^{-5}\text{ kg/s}. \quad <$$

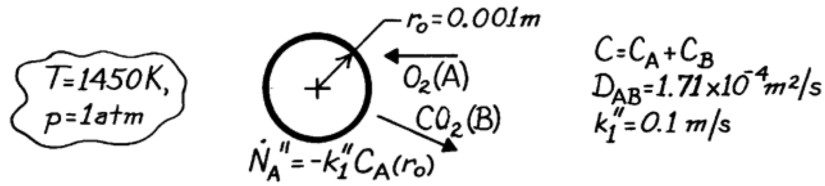
COMMENTS: Because bulk motion is likely to contribute significantly to NO transfer within the film, the above results should be viewed as a first approximation.

PROBLEM 14.30

KNOWN: Radius of coal pellets burning in oxygen atmosphere of prescribed pressure and temperature.

FIND: Oxygen molar consumption rate.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional diffusion in r, (2) Steady-state conditions, (3) Constant properties, (4) Perfect gas behavior, (5) Uniform C and T, (6) Stationary medium.

ANALYSIS: From Equation 14.57,

$$\frac{d}{dr}\left(r^2 \frac{dC_A}{dr}\right) = 0$$

$$dC_A / dr = C_1 / r^2 \qquad \text{or} \qquad C_A = -C_1/r + C_2.$$

The boundary conditions at $r \to \infty$ and $r = r_o$ are, respectively,

$$C_A(\infty) = C \quad \to \quad C_2 = C$$

$$\dot{N}''_A = N''_A(r_o) = -CD_{AB} \left.\frac{dx_A}{dr}\right|_{r_o} = -D_{AB} \left.\frac{dC_A}{dr}\right|_{r_o}$$

Hence

$$-k''_1\left(-C_1/r_o + C\right) = -D_{AB} C_1 / r_o^2$$

$$k''_1\left(C_1/r_o\right) + D_{AB}\left(C_1/r_o^2\right) = k''_1 C \qquad \text{or} \qquad C_1 = \frac{k''_1 C}{\left(k''_1/r_o\right) + \left(D_{AB}/r_o^2\right)}.$$

The oxygen molar consumption rate is

$$N''_A(r_o) = -D_{AB} \left.\frac{dC_A}{dr}\right|_{r_o} = -D_{AB} \frac{k''_1 C}{k''_1 r_o + D_{AB}}$$

where $$C = \frac{p}{\Re T} = \frac{1 \text{ atm}}{\left(8.205\times10^{-2} \text{m}^3 \cdot \text{atm/kmol}\cdot\text{K}\right)1450 \text{ K}} = 8.405\times10^{-3} \text{ kmol/m}^3.$$

Hence,

$$N''_A(r_o) = -1.71\times10^{-4} \text{m}^2/\text{s} \frac{0.1 \text{ m/s}\times 8.405\times10^{-3} \text{kmol/m}^3}{\left(10^{-4} + 1.71\times10^{-4}\right)\text{m}^2/\text{s}} = -5.30\times10^{-4} \text{ kmol/s}\cdot\text{m}^2$$

$$N_A(r_o) = 4\pi r_o^2 N''_A(r_o) = 4\pi\left(0.001 \text{ m}\right)^2 \times 5.30\times10^{-4} \text{ kmol/s}\cdot\text{m}^2$$

$$N_A(r_o) = 6.66\times10^{-9} \text{ kmol/s}.$$ <

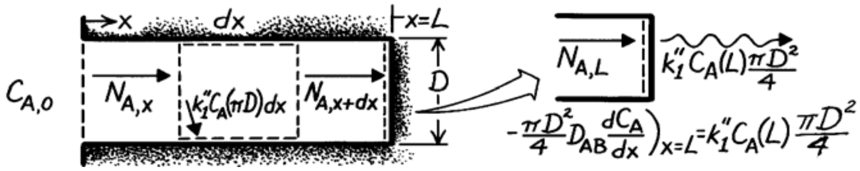
COMMENTS: The O_2 consumption rate would increase with increasing k''_1 and approach a limiting *finite* value as k''_1 approaches infinity.

PROBLEM 14.31

KNOWN: Pore geometry in a catalytic reactor. Concentration of reacting species at pore opening and order of catalytic reaction.

FIND: (a) Differential equation which determines concentration of reacting species, (b) Distribution of reacting species concentration along the pore.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional diffusion in x direction, (3) Stationary medium, (4) Uniform total molar concentration, (5) Stationary medium.

ANALYSIS: (a) Apply the species conservation requirement to the differential control volume,
$N_{A,x} - k_1''C_A(\pi D)dx - N_{A,x+dx} = 0,$ where

$$N_{A,x+dx} = N_{A,x} + \left(dN_{A,x}/dx\right)dx$$

and from Fick's law

$$N_{A,x} = \left(-CD_{AB}\frac{dx_A}{dx}\right)\frac{\pi D^2}{4} = -\frac{\pi D^2}{4}D_{AB}\frac{dC_A}{dx}.$$

Hence

$$-\frac{dN_A}{dx}dx - k_1''C_A(\pi D)dx = \frac{\pi D^2}{4}D_{AB}\frac{d^2C_A}{dx^2} - k_1''C_A(\pi D)dx = 0$$

$$\frac{d^2C_A}{dx^2} - \frac{4k_1''}{DD_{AB}}C_A = 0.$$ <

(b) A solution to the above equation is readily obtained by recognizing that it is of exactly the same form as the energy equation for an extended surface of uniform cross section. Hence for boundary conditions of the form

$$C_A(0) = C_{A,0}, \qquad -D_{AB}\left(dC_A/dx\right)_{x=L} = k_1''C_A(L)$$

the solution must be analogous to that obtained for a fin with a convection tip condition. With the analogous quantities

$$C_A \leftrightarrow \theta \equiv T - T_\infty, \qquad m \equiv \left(4k_1''/DD_{AB}\right)^{1/2} \leftrightarrow \left(4h/Dk\right)^{1/2}$$

$$D_{AB} \leftrightarrow k, \qquad k_1'' \leftrightarrow h$$

the solution is, by analogy to Eq. 3.75

$$C_A(x) = \frac{\cosh m(L-x) + \left(k_1''/mD_{AB}\right)\sinh m(L-x)}{\cosh mL + \left(k_1''/mD_{AB}\right)\sinh mL}.$$ <

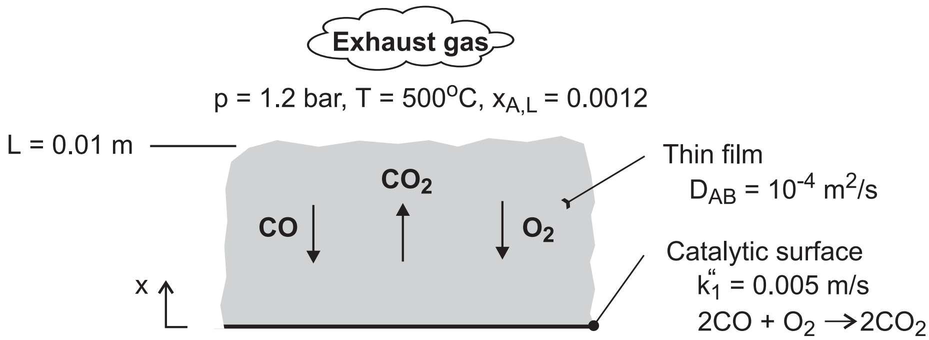
COMMENTS: The total pore reaction rate is $-D_{AB}(\pi D^2/4)(dC_A/dx)_{x=0}$, which can be inferred by applying the analogy to Eq. 3.76.

PROBLEM 14.32

KNOWN: Pressure, temperature and mole fraction of CO in auto exhaust. Diffusion coefficient for CO in gas mixture. Film thickness and reaction rate coefficient for catalytic surface.

FIND: (a) Mole fraction of CO at catalytic surface and CO removal rate, (b) Effect of reaction rate coefficient on removal rate.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, (2) One-dimensional species diffusion in film, (3) Negligible effect of advection in film (stationary medium), (4) Constant total molar concentration and diffusion coefficient in film.

ANALYSIS: From Eq. (14.69) the surface molar concentration is

$$x_A(0) = \frac{x_{A,L}}{1+\left(Lk_1''/D_{AB}\right)} = \frac{0.0012}{1+\left(0.01\text{m}\times 0.005\,\text{m/s}/10^{-4}\text{m}^2/\text{s}\right)} = 0.0008 \qquad <$$

With $C = p/\mathcal{R}T$ = 1.2 bar/(8.314 × 10^{-2} m^3·bar/kmol·K × 773 K) = 0.0187 kmol/m^3, Eq. (14.70) yields a CO molar flux, and hence a CO removal rate, of

$$N''_{A,s} = -N''_A(0) = \frac{k_1'' C\, x_{A,L}}{1+\left(Lk_1''/D_{AB}\right)}$$

$$N''_{A,s} = \frac{0.005\,\text{m/s}\times 0.0187\,\text{kmol/m}^3\times 0.0012}{1+\left(0.01\text{m}\times 0.005\,\text{m/s}/10^{-4}\text{m}^2/\text{s}\right)} = 7.48\times 10^{-8}\,\text{kmol/s}\cdot\text{m}^2 \qquad <$$

If the process is diffusion limited, $Lk_1''/D_{AB} >> 1$ and

$$N''_{A,s} = \frac{C\ D_{AB}\ x_{A,L}}{L} = \frac{0.0187\,\text{kmol/m}^3\times 10^{-4}\text{m}^2/\text{s}\times 0.0012}{0.01\text{m}} = 2.24\times 10^{-7}\,\text{kmol/s}\cdot\text{m}^2 \qquad <$$

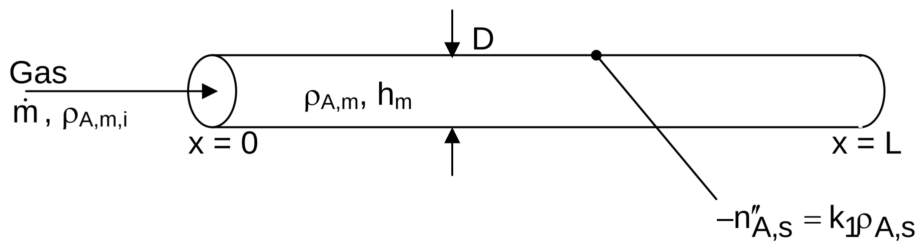
COMMENTS: If the process is reaction limited, $N''_{A,s} \to 0$ as $k_1'' \to 0$.

PROBLEM 14.33

KNOWN: Mass flow rate of gas containing palladium (species A), which flows through a tube and deposits into pores of tube wall. Inlet mass concentration of palladium. Mass transfer coefficient between gas and tube surface. Deposition rate is proportional to mass concentration of palladium at tube surface.

FIND: (a) Expression for variation of mean species density of palladium with x. Expression for local deposition rate for tube of diameter D. (b) Ratio of deposition rates at x = L and x = 0.

SCHEMATIC:



ASSUMPTIONS: (1) Steady state, (2) Constant properties, (3) Constant mass flow rate, (4) Negligible leakage of gas through porous walls.

ANALYSIS: (a) Section 8.9 develops the variation of mean species density, $\rho_{A,m}$, for the case in which the surface species concentration, $\rho_{A,s}$, is uniform. Here, however, the surface concentration will vary as the mean species density decreases with x. Under steady-state conditions, the mass flux of palladium reaching the surface must equal the mass flux of palladium depositing into the pores. Referring to Equation 8.82, where $n''_{A,s}$ is the mass flux *from* the surface,

$$n''_{A,s} = h_m(\rho_{A,s} - \rho_{A,m}) = -k_1\rho_{A,s}$$

Solving for the surface concentration yields $\rho_{A,s} = h_m\rho_{A,m}/(h_m + k_1)$. Then substituting this into either expression for $n''_{A,s}$ yields

$$n''_{A,s} = -U_m\rho_{A,m}, \quad U_m^{-1} = 1/h_m + 1/k_1$$

Comparing this result with Equation 8.82, we see that they are analogous if we replace h_m with U_m and $\rho_{A,s}$ with 0. Applying the same analogy to Equation 8.86, the distribution of the mean species density is

$$\frac{\rho_{A,m}(x)}{\rho_{A,m,i}} = \exp\left(-\frac{U_m\rho P}{\dot{m}}x\right) \qquad (1)$$ <

where P is the perimeter, $P = \pi D$. Note that we could have found this same result by expressing mass species conservation for species A. Noting that the rate at which species A is carried downstream by the flow is $\dot{m}\rho_{A,m}/\rho$, and assuming ρ to be constant, we have

Continued…

PROBLEM 14.33 (Cont.)

$$\frac{\dot{m}}{\rho}\frac{d\rho_{A,m}}{dx} = n''_{A,s}P = -U_m P \rho_{A,m}$$

Integrating with respect to x and applying the inlet condition yields the same result as Equation (1).

The local deposition rate is

$$-n''_{A,s} = U_m \rho_{A,m} = U_m \rho_{A,m,i} \exp\left(-\frac{U_m \rho P}{\dot{m}} x\right) = U_m \rho_{A,m,i} \exp\left(-B\frac{x}{L}\right) \quad (2)$$ <

where $B = U_m \rho PL/\dot{m}$.

(b) The ratio of deposition rates at x = L and x = 0 is

$$\text{ratio of deposition rates} = \exp(-B)$$ <

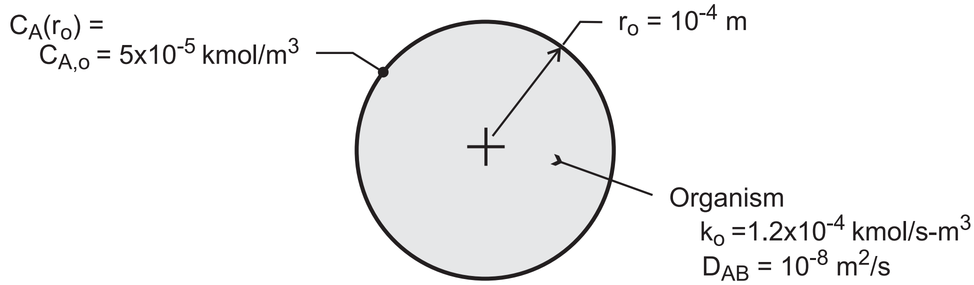
COMMENT: From Eq. (2), the deposition rate decreases exponentially with distance x. Therefore, as the tube length increases, the deposit thickness at the outlet end will become thinner, and the variation in deposit thickness between the inlet and outlet will increase.

PROBLEM 14.34

KNOWN: Radius of a spherical organism and molar concentration of oxygen at surface. Diffusion and reaction rate coefficients.

FIND: (a) Radial distribution of O_2 concentration, (b) Rate of O_2 consumption, (c) Molar concentration at r = 0.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, one-dimensional diffusion, (2) Stationary medium, (3) Uniform total molar concentration, (4) Constant properties (k_0, D_{AB}).

ANALYSIS: (a) For the prescribed conditions and assumptions, Eq. (14.50) reduces to

$$\frac{D_{AB}}{r^2}\frac{d}{dr}\left(r^2\frac{dC_A}{dr}\right)-k_0=0$$

$$r^2\frac{dC_A}{dr}=\frac{k_0 r^3}{3D_{AB}}+C_1$$

$$C_A=\frac{k_0 r^2}{6D_{AB}}-\frac{C_1}{r}+C_2$$

With the requirement that $C_A(r)$ remain finite at r = 0, $C_1 = 0$. With $C_A(r_o) = C_{A,o}$

$$C_2=C_{A,o}-\frac{k_0 r_o^2}{6D_{AB}}$$

$$C_A=C_{A,o}-\left(k_0/6D_{AB}\right)\left(r_o^2-r^2\right) \qquad <$$

Because C_A cannot be less than zero at any location within the organism, the right-hand side of the foregoing equation must always exceed zero, thereby placing limits on the value of $C_{A,o}$. The smallest possible value of $C_{A,o}$ is determined from the requirement that $C_A(0) \geq 0$, in which case

$$C_{A,o}\geq\left(k_0 r_o^2/6D_{AB}\right) \qquad <$$

(b) Since oxygen consumption occurs at a uniform volumetric rate of k_0, the total respiration rate is $\dot{R}=\forall k_0$, or

$$\dot{R}=\left(4/3\right)\pi r_o^3 k_0 \qquad <$$

Continued …

PROBLEM 14.34 (Cont.)

(c) With r = 0,

$$C_A(0) = C_{A,o} - k_0 r_o^2 / 6 D_{AB}$$

$$C_A(0) = 5\times10^{-5}\,\text{kmol/m}^3 - 1.2\times10^{-4}\,\text{kmol/s}\cdot\text{m}^3\left(10^{-4}\,\text{m}\right)^2 / 6\times10^{-8}\,\text{m}^2/\text{s}$$

$$C_A(0) = 3\times10^{-5}\,\text{kmol/m}^3$$ <

COMMENTS: (1) The minimum value of $C_{A,o}$ for which a physically realistic solution is possible is $C_{A,o} = k_0 r_o^2 / 6 D_{AB} = 2\times10^{-5}\,\text{kmol/m}^3$.

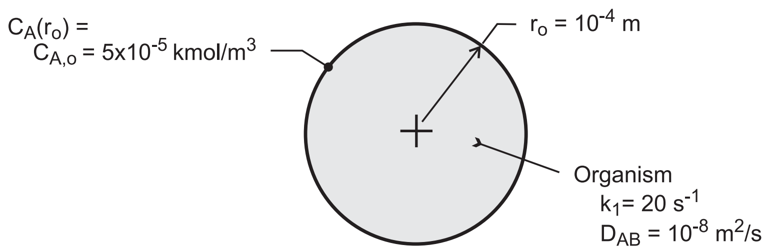
(2) The total respiration rate may also be obtained by applying Fick's law at r = r_o, in which case $\dot{R} = -N_A(r_o) = +D_{AB}\left(4\pi r_o^2\right) dC_A/dr\big|_{r=r_o} = D_{AB}\left(4\pi R_o^2\right)\left(k_o / 6 D_{AB}\right) 2r_o = (4/3)\pi r_o^3 k_0$.
The result agrees with that of part (b).

PROBLEM 14.35

KNOWN: Radius of a spherical organism and molar concentration of oxygen at its surface. Diffusion and reaction rate coefficients.

FIND: (a) Radial distribution of O_2 concentration, (b) Expression for rate of O_2 consumption, (c) Molar concentration at r = 0 and rate of oxygen consumption for prescribed conditions.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state, one-dimensional diffusion, (2) Stationary medium, (3) Uniform total molar concentration, (4) Constant properties (k_1, D_{AB}).

ANALYSIS: (a) For the prescribed conditions and assumptions, Eq. (14.50) reduces to

$$\frac{1}{r^2}\frac{d}{dr}\left(D_{AB}\, r^2 \frac{dC_A}{dr}\right) - k_1 C_A = 0$$

With $y \equiv r\,C_A$, $d\,C_A/dr = (1/r)\,dy/dr - y/r^2$ and

$$\frac{1}{r^2}\frac{d}{dr}\left(D_{AB}\, r^2 \frac{dC_A}{dr}\right) = \frac{D_{AB}}{r^2}\frac{d}{dr}\left(r\frac{dy}{dr} - y\right) = \frac{D_{AB}}{r^2}\left(r\frac{d^2y}{dr^2}\right)$$

The species equation is then

$$\frac{d^2y}{dr^2} - \frac{k_1}{D_{AB}}\, y = 0$$

The general solution is of the form

$$y = C_1 \sinh\left(k_1/D_{AB}\right)^{1/2} r + C_2 \cosh\left(k_1/D_{AB}\right)^{1/2} r$$

or

$$C_A = \frac{C_1}{r}\sinh\left(k_1/D_{AB}\right)^{1/2} r + \frac{C_2}{r}\cosh\left(k_1/D_{AB}\right)^{1/2} r$$

Because C_A must remain finite at r = 0, C_2 = 0. Hence, with $C_A\,(r_o) = C_{A,o}$,

$$C_1 = \frac{C_{A,o}\, r_o}{\sinh\left(k_1/D_{AB}\right)^{1/2} r_o}$$

and

Continued …

PROBLEM 14.35 (Cont.)

$$C_A = C_{A,o}\left(\frac{r_o}{r}\right)\frac{\sinh\left(k_1/D_{AB}\right)^{1/2} r}{\sinh\left(k_1/D_{AB}\right)^{1/2} r_o}$$ <

(b) The total O_2 consumption rate corresponds to the rate of diffusion at the surface of the organism.

$$\dot{R} = -N_A\left(r_o\right) = +D_{AB}\left(4\pi r_o^2\right) d\,C_A/dr\big|_{r_o}$$

$$\dot{R} = 4\pi r_o^2 D_{AB}\,C_{A,o}\,r_o\left[-\frac{1}{r_o^2}+\frac{1}{r_o}\left(k_1/D_{AB}\right)^{1/2}\cot\left(k_1/D_{AB}\right)^{1/2} r_o\right]$$

$$\dot{R} = 4\pi r_o\,D_{AB}\,C_{A,o}\left(\alpha\coth\alpha - 1\right)$$ <

where $\alpha \equiv \left(k_1 r_o^2/D_{AB}\right)^{1/2}$.

(c) For the prescribed conditions, $(k_1/D_{AB})^{1/2} = (20\ s^{-1} \div 10^{-8}\ m^2/s)^{1/2} = 44{,}720\ m^{-1}$ and $\alpha = 4.472$.

$$C_A = \frac{5\times10^{-5}\,\text{kmol/m}^3\times10^{-4}\,\text{m}}{\sinh(4.472)}\times\frac{\sinh\left(k_1/D_{AB}\right)^{1/2} r}{r} = 1.136\times10^{-10}\,\frac{\text{kmol}}{\text{m}^3}\times\frac{\sinh\left(k_1/D_{AB}\right)^{1/2} r}{r}$$

In the limit of $r \to 0$, the foregoing expression yields

$$C_A\left(r\to 0\right) = 5.11\times10^{-6}\,\text{kmol/m}^3$$ <

$$\dot{R} = 4\pi\times10^{-4}\,\text{m}\times10^{-8}\,\text{m}^2/\text{s}\times5\times10^{-5}\,\text{kmol/m}^3\left(4.472\coth 4.472 - 1\right)$$

$$= 2.18\times10^{-15}\,\text{kmol/s}$$

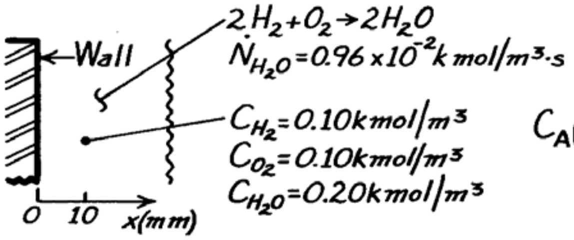
COMMENTS: The total respiration rate may also be obtained by integrating the volumetric rate of consumption over the volume of the organism. That is, $\dot{R} = -\int \dot{N}_A\,d\forall = \int_0^{r_o} k_1 C_A(r)\,4\pi r^2 dr$.

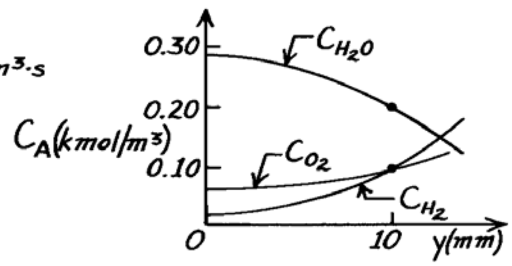
PROBLEM 14.36

KNOWN: Combustion at constant temperature and pressure of a hydrogen-oxygen mixture adjacent to a metal wall according to the reaction $2H_2 + O_2 \rightarrow 2H_2O$. Molar concentrations of hydrogen, oxygen, and water vapor are 0.10, 0.10 and 0.20 kmol/m^3, respectively. Generation rate of water vapor is 0.96×10^{-2} kmol/m$^3\cdot$s.

FIND: (a) Expression for C_{H_2} as function of distance from wall, plot qualitatively, (b) C_{H_2} at the wall, (c) Sketch also curves for $C_{O_2}(x)$ and $C_{H_2O}(x)$, and (d) Molar flux of water at x = 10mm.

SCHEMATIC:





ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional diffusion, (3) Stationary medium, (4) Constant properties including pressure and temperature.

PROPERTIES: Species binary diffusion coefficient (given, for H_2, O_2 and H_2O): $D_{AB} = 0.6 \times 10^{-5}$ m^2/s.

ANALYSIS: (a) The species conservation equation, Eq. 14.48b, and its general solution are

$$\frac{d^2C_A}{dx^2} + \frac{\dot{N}_A}{D_{AB}} = 0 \qquad\qquad C_A(x) = -\frac{\dot{N}_A}{2D_{AB}}x + C_1x + C_2. \qquad (1,2)$$

The boundary condition at the wall must be $dC_A(0)/dx = 0$, such that $C_1 = 0$. For the species hydrogen, evaluate C_2 from knowledge of $C_{H_2}(10\text{ mm}) = 0.10\text{ kmol/m}^3$ and $\dot{N}_{H_2} = -\dot{N}_{H_2O}$, according to the chemical reaction. Hence,

$$0.10\text{ kmol/m}^3 = -\frac{\left(-0.96\times10^{-2}\text{kmol/m}^3\cdot\text{s}\right)}{2\times0.6\times10^{-5}\text{m}^2/\text{s}}(0.010\text{ m})^2 + 0 + C_2$$

$$C_2 = 0.02\text{ kmol/m}^3.$$

Hence, the hydrogen species concentration distribution is

$$C_{H_2}(x) = -\frac{\dot{N}_{H_2}}{2D_{AB}}x^2 + 0.02 = 800x^2 + 0.02 \qquad <$$

which is parabolic with zero slope at the wall; see sketch above.

(b) The value of C_{H_2} at the wall is,

$$C_{H_2}(0) = (0 + 0.02)\text{kmol/m}^3 = 0.02\text{ kmol/m}^3. \qquad <$$

Continued …

PROBLEM 14.36 (Cont.)

(c) The concentration distribution for water vapor species will be of the same form,

$$C_{H_2O}(x) = -\frac{\dot{N}_{H_2O}}{2D_{AB}}x^2 + C_1 x + C_2 \qquad (3)$$

With $C_1 = 0$ for the wall condition, find C_2 from $C_{H_2O}(10\text{ mm})$,

$$0.20\text{ kmol/m}^3 = -\frac{\left(0.96\times10^{-2}\text{ kmol/m}^3\right)}{2\times0.6\times10^{-5}\text{ m}^2/\text{s}}(0.010\text{ m})^2 + C_2 \qquad C_2 = 0.28\text{ kmol/m}^3.$$

Hence, C_{H_2O} at the wall is,

$$C_{H_2O}(0) = 0 + 0 + C_2 = 0.28\text{ kmol/m}^3$$

and its distribution appears as above. Recognizing that $\dot{N}_{O_2} = -0.5\dot{N}_{H_2O}$, by the same analysis, find

$$C_{O_2}(0) = 0.06\text{ kmol/m}^3$$

and its shape, also parabolic with zero slope at the wall is shown above.

(d) The molar flux of water vapor at x = 10 mm is given by Fick's law

$$N''_{H_2O,x} = -D_{AB}\frac{dC_{H_2O}}{dx}$$

and using the concentration distribution of Eq. (3), find

$$N''_{H_2O,x} = -D_{AB}\frac{d}{dx}\left(-\frac{\dot{N}_{H_2O}}{2D_{AB}}x^2\right) = +\dot{N}_{H_2O}x$$

and evaluation at the location x = 10 mm, the species flux is

$$N''_{H_2O,x}(10\text{ mm}) = +\left(0.96\times10^{-2}\text{ kmol/m}^3\cdot\text{s}\right)\times0.010\text{ m} = 9.60\times10^{-5}\text{kmol/m}^2\cdot\text{s}. \qquad <$$

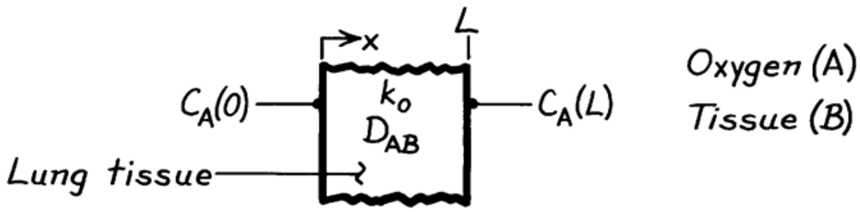
COMMENTS: Note that the generation rate of water vapor is a positive quantity. Whereas for H_2 and O_2, species are consumed and hence $\dot{N}_{H_2}$ and $\dot{N}_{O_2}$ are negative. According to the chemical reaction one mole of H_2 and 0.5 mole of O_2 are consumed to generate one mole of H_2O. Therefore, $\dot{N}_{H_2} = -\dot{N}_{H_2O}$ and $\dot{N}_{O_2} = -0.5\,\dot{N}_{H_2O}$.

PROBLEM 14.37

KNOWN: Molar concentrations of oxygen at inner and outer surfaces of lung tissue. Volumetric rate of oxygen consumption within the tissue.

FIND: (a) Variation of oxygen molar concentration with position in the tissue, (b) Rate of oxygen transfer to the blood per unit tissue surface area.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional species transfer by diffusion through a plane wall, (3) Homogeneous, stationary medium with uniform total molar concentration and constant diffusion coefficient.

ANALYSIS: (a) From Eq. 14.71 the appropriate form of the species diffusion equation is

$$D_{AB}\frac{d^2C_A}{dx^2} - k_o = 0.$$

Integrating,

$$dC_A/dx = (k_o/D_{AB})x + C_1 \qquad C_A = \frac{k_o}{2D_{AB}}x^2 + C_1 x + C_2.$$

With $C_A = C_A(0)$ at $x = 0$ and $C_A = C_A(L)$ at $x = L$,

$$C_2 = C_A(0) \qquad C_1 = \frac{C_A(L) - C_A(0)}{L} - \frac{k_o L}{2D_{AB}}.$$

Hence

$$C_A(x) = \frac{k_o}{2D_{AB}}x(x - L) + \left[C_A(L) - C_A(0)\right]\frac{x}{L} + C_A(0).$$ <

(b) The oxygen assimilation rate per unit area is

$$N''_{A,x}(L) = -D_{AB}(dC_A/dx)_{x=L}$$

$$N''_{A,x}(L) = -D_{AB}\left(\frac{k_o L}{D_{AB}} - \frac{k_o L}{2D_{AB}}\right) - \frac{D_{AB}}{L}\left[C_A(L) - C_A(0)\right]$$

$$N''_{A,x} = -\frac{k_o L}{2} + \frac{D_{AB}}{L}\left[C_A(0) - C_A(L)\right].$$ <

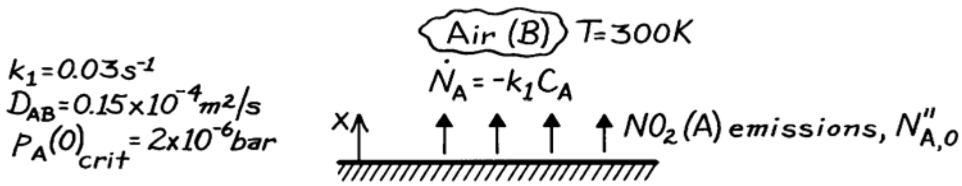
COMMENTS: The above model provides a highly approximate and simplified treatment of a complicated problem. The lung tissue is actually heterogeneous and conditions are transient.

PROBLEM 14.38

KNOWN: Ground level flux of NO_2 in a stagnant urban atmosphere.

FIND: (a) Vertical distribution of NO_2 molar concentration, (b) Critical ground level flux of NO_2, $N''_{A,0,crit}$.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) One-dimensional diffusion in a stationary medium, (3) Total molar concentration C is uniform, (4) Perfect gas behavior.

ANALYSIS: (a) For the prescribed conditions the molar concentration of NO_2 is given by Eq. 14.73, subject to the following boundary conditions.

$$C_A(\infty) = 0, \qquad \left.\frac{dC_A}{dx}\right)_{x=0} = -\frac{N''_{A,0}}{D_{AB}}.$$

From the first condition, $C_1 = 0$. From the second condition,

$$-mC_2 = -N''_{A,0}/D_{AB}.$$

Hence

$$C_A(x) = \frac{N''_{A,0}}{mD_{AB}} e^{-mx} \qquad <$$

where $m = (k_1/D_{AB})^{1/2}$.

(b) At ground level, $C_A(0) = \dfrac{N''_{A,0}}{mD_{AB}}$. Hence, from the perfect gas law,

$$p_A(0) = C_A(0)\Re T = \frac{\Re T N''_{A,0}}{mD_{AB}}.$$

Hence, with $m = (0.03/0.15 \times 10^{-4})^{1/2}\ m^{-1} = 44.7\ m^{-1}$.

$$N''_{A,0,crit} = \frac{mD_{AB}p_A(0)_{crit}}{\Re T} = \frac{44.7\,m^{-1} \times 0.15\times10^{-4}\,m^2/s \times 2\times10^{-6}\,bar}{8.314\times10^{-2}\,m^3\cdot bar/kmol\cdot K \times 300\ K}$$

$$N''_{A,0,crit} = 5.38\times10^{-11}\,kmol/s\cdot m^2. \qquad <$$

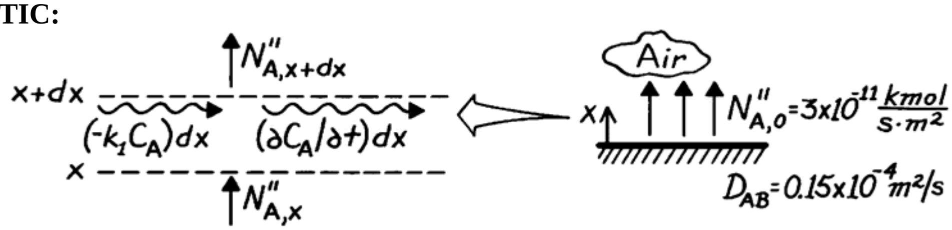
COMMENTS: Because the dispersion of pollutants in the atmosphere is governed strongly by convection effects, the above model should be viewed as a first approximation which describes a worst case condition.

PROBLEM 14.39

KNOWN: Ground level flux of NO_2 in a stagnant urban atmosphere.

FIND: (a) Governing differential equation and boundary conditions for the molar concentration of NO_2, (b) Concentration of NO_2 at ground level three hours after the beginning of emissions.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional diffusion in a stationary medium, (2) Uniform total molar concentration, (3) Constant properties.

ANALYSIS: (a) Applying the species conservation requirement, Eq. 14.43, on a molar basis to a unit area of the control volume,

$$N''_{A,x}-\left(k_1C_A\right)dx-N''_{A,x+dx}=\frac{\partial C_A}{\partial t}dx.$$

With $N''_{A,x+dx}=N''_{A,x}+\left(\partial N''_{A,x}/\partial x\right)dx$ and $N''_{A,x}=-D_{AB}\left(\partial C_A/\partial x\right)$, it follows that

$$D_{AB}\frac{\partial^2 C_A}{\partial x^2}-k_1C_A=\frac{\partial C_A}{\partial t}.$$ <

Initial Condition: $C_A\left(x,0\right)=0.$ <

Boundary Conditions: $-D_{AB}\left.\frac{\partial C_A}{\partial x}\right)_{x=0}=N''_{A,0},\qquad C_A\left(\infty,t\right)=0.$ <

(b) The present problem is analogous to Case (2) of Fig. 5.7 for heat conduction in a semi-infinite medium. Hence by analogy to Eq. 5.62, with $k\leftrightarrow D_{AB}$ and $\alpha\leftrightarrow D_{AB}$,

$$C_A\left(x,t\right)=2N''_{A,0}\left(\frac{t}{\pi D_{AB}}\right)^{1/2}\exp\left(-\frac{x^2}{4D_{AB}t}\right)-\frac{N''_{A,0}x}{D_{AB}}\text{erfc}\left(\frac{x}{2\left(D_{AB}t\right)^{1/2}}\right)$$

At ground level (x = 0) and 3h,

$$C_A\left(0,3h\right)=2N''_{A,0}\left(\frac{t}{\pi D_{AB}}\right)^{1/2}$$

$$C_A\left(0,3h\right)=2\left(3\times10^{-11}\,\text{kmol/s}\cdot\text{m}^2\right)\left(10,800\ \text{s}/\pi\times0.15\times10^{-4}\text{m}^2/\text{s}\right)^{1/2}=9.08\times10^{-7}\,\text{kmol/m}^3.$$ <

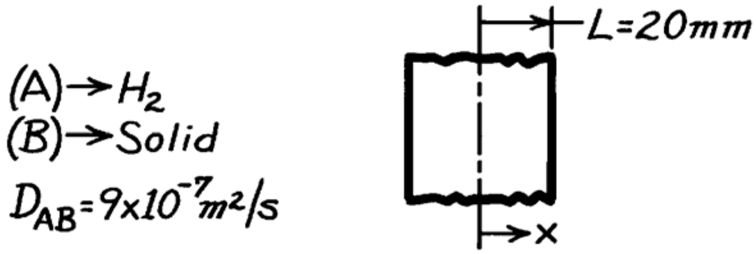
COMMENTS: The concentration decays rapidly to zero with increasing x, and at x = 100 m it is, for all practical purposes, equal to zero.

PROBLEM 14.40

KNOWN: Initial concentration of hydrogen in a sheet of prescribed thickness. Surface concentrations for time t > 0.

FIND: Time required for density of hydrogen to reach prescribed value at midplane of sheet.

SCHEMATIC:



$C_A(x,0) = 3\ \text{kmol/m}^3 = C_{A,i}$
$C_A(0,t_f) = 1.2\ \text{kg/m}^3/2\ \text{kg/kmol}$
$C_A(0,t_f) = 0.6\ \text{kmol/m}^3 = C_A$
$C_A(20\ \text{mm},t) = 0 = C_{A,s}$

ASSUMPTIONS: (1) One-dimensional diffusion in x, (2) Constant D_{AB}, (3) No internal chemical reactions, (4) Uniform total molar concentration, (5) Stationary medium.

ANALYSIS: The mass transfer Biot number is $Bi_m = h_m L/D_{AB} \rightarrow \infty$. Hence, $Bi_m^{-1} = 0$. By analogy to Equation 5.44, the approximate solution, it follows that

$$\gamma_o^* \approx C_1 \exp\left(-\varsigma_1^2 Fo_m\right) = \frac{C_A - C_{A,s}}{C_{A,i} - C_{A,s}} = \frac{0.6-0.0}{3.0-0.0} = 0.2$$

Using values of $\varsigma_1 = 1.57$ and $C_1 = 1.27$ from Table 5.1, it follows that

$$1.27 \exp\left[-(1.57)^2\, Fo_m\right] = 0.2$$

from which

$$Fo_m = 0.75$$

Hence, $t_f = 0.75(0.02\text{m})^2/9\times10^{-7}\ \text{m}^2/\text{s} = 333\ \text{s}$ <

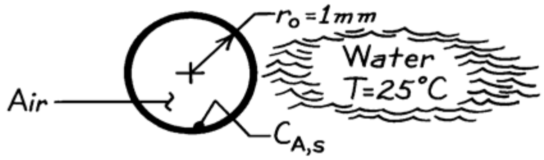
COMMENT: $Fo_m > 0.2$. Hence, the approximate, one-term solution is valid.

PROBLEM 14.41

KNOWN: Radius and temperature of air bubble in water.

FIND: Time to reach 99% of saturated vapor concentration at center.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional radial diffusion of vapor in air, (2) Constant properties, (3) Air is initially dry, (4) Stationary medium.

PROPERTIES: *Table A-8*, Water vapor-air (300 K): $D_{AB} = 0.26 \times 10^{-4}$ m^2/s.

ANALYSIS: If the one-term approximation to the infinite series solution (Eq. 5.53),

$$\theta_0^* = C_1 \exp(-\zeta_1^2 \text{Fo})$$

is used, it follows that,

$$\gamma_o^* \approx C_1 \exp\left(-\zeta_1^2 \text{Fo}_m\right) = \frac{C_A - C_{A,s}}{C_{A,i} - C_{A,s}} = \frac{0.99 - 1}{0.0 - 1} = 0.01.$$

Using values of $C_1 = 2.0$ and $\varsigma_1 = 3.1415$ for $\text{Bi}_m \to \infty$, it follows that

$$0.01 = 2.0 \exp\left[-(3.1415)^2 \text{Fo}_m\right] \quad \text{or} \quad \text{Fo}_m = 0.54$$

Hence, $t = \text{Fo}_m D^2/D_{AB} = 0.54(0.001\text{m})^2/0.26 \times 10^{-4}\ \text{m}^2/\text{s} = 0.02$ s <

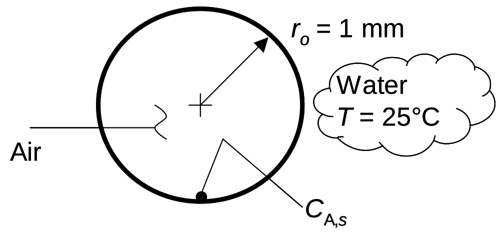
COMMENT: Since Fo > 0.2, the approximate solution is valid.

PROBLEM 14.42

KNOWN: Radius and temperature of air bubble.

FIND: (a) Time to reach 95% of the maximum average water vapor concentration, (b) Time to reach 50% of the maximum average water vapor concentration**.**

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional radial diffusion of vapor in air, (2) Constant properties, (3) Air is initially dry, (4) Stationary medium.

PROPERTIES: *Table A.8*, Water vapor-air (300 K): $D_{AB} = 0.26 \times 10^{-4}$ m^2/s.

ANALYSIS: (a) We may employ the one-term approximation to the infinite series solution (Eq. 5.55)

$$\frac{Q}{Qo} = 1 - \frac{3\theta_o^*}{\zeta_1^3}\left[\sin(\zeta_1) - \zeta_1 \cos(\zeta_1)\right] \quad ; \quad \theta_o^* = C_1 \exp\left(-\zeta_1^2 Fo\right)$$

By analogy, the preceding equations may be written as

$$\frac{\bar{C}_A}{\bar{C}_{A,max}} = 1 - \frac{3\gamma_o^*}{\zeta_1^3}\left[\sin(\zeta_1) - \zeta_1 \cos(\zeta_1)\right] \quad ; \quad \gamma_o^* = \frac{C_A - C_{A,s}}{C_{A,i} - C_{A,s}} = C_1 \exp\left(-\zeta_1^2 Fo_m\right)$$

Using values of C_1 = 2.000 and ζ_1 = 3.1415 from Table 5.1 for $Bi_m \to \infty$, it follows that

$$\frac{\bar{C}_A}{\bar{C}_{A,max}} = 0.95 = 1 - \frac{3\gamma_o^*}{3.1415^3}\left[\sin(3.1415) - 3.1415\cos(3.1415)\right] \quad ;$$

$$\gamma_o^* = \frac{C_A - C_{A,s}}{C_{A,i} - C_{A,s}} = 2.0\exp\left(-3.1415^2 Fo_m\right)$$

Solving the two equations yields γ_o^* = 0.1645, Fo_m = 0.2531. Since Fo_m > 0.2, the approximate solution is valid. Hence,

$$t = Fo_m r_o^2 / D_{AB} = 0.2531(0.001\text{m})^2 / 0.26 \times 10^{-4}\text{m}^2/\text{s} = 9.7 \times 10^{-3}\ \text{s} = 9.7\ \text{ms} \qquad <$$

(b) The time associated with an average water vapor concentration of 50% is expected to be significantly shorter than in part (a). Hence, Fo_m may be less than 0.2 and the one-term approximation to the exact solution may not be valid. Therefore, we employ the approximate solution of Section 5.8 and apply the analogy between heat and mass transfer.

Continued…

PROBLEM 14.42 (Cont.)

From Table 5.2a for $Fo < 0.2$,

$$q^* = \frac{q_s'' r_o}{k(T_s - T_i)} = \frac{1}{\sqrt{\pi Fo}} - 1 \quad ; \quad Fo = \frac{\alpha t}{r_o^2}$$

Substituting the expression for Fo into the first equation yields

$$q_s'' = \frac{k(T_s - T_i)}{r_o}\left[\frac{r_o}{\sqrt{\pi\alpha}} t^{-1/2} - 1\right]$$

We desire an expression for Q/Q_o. Hence,

$$\frac{Q}{Q_o} = \frac{4\pi r_o^2 \int_{t=0}^{t} q_s'' dt}{(4/3)\pi r_o^3 \rho c(T_s - T_i)} = \frac{3\alpha}{r_o^2}\int_{t=0}^{t}\left(\frac{r_o}{\sqrt{\pi\alpha}} t^{-1/2} - 1\right)dt$$

or

$$\frac{Q}{Q_o} = \frac{3\alpha}{r_o^2}\left[\frac{2r_o}{\sqrt{\pi\alpha}} t^{1/2} - t\right]$$

$$= 3\left[\frac{2}{\sqrt{\pi}}\sqrt{Fo} - Fo\right]$$

Applying the analogy between heat and mass transfer,

$$\frac{\bar{C}_{\text{A}}}{\bar{C}_{\text{A,max}}} = 0.50 = 3\left[\frac{2}{\sqrt{\pi}}\sqrt{Fo_m} - Fo_m\right]$$

from which $Fo_m = 0.0305$. Hence,

$$t = Fo_m r_o^2 / D_{\text{AB}} = 0.0305(0.001\text{m})^2 / 0.26\times 10^{-4}\,\text{m}^2/\text{s} = 1.17\times 10^{-3}\ \text{s} = 1.17\ \text{ms} \qquad <$$

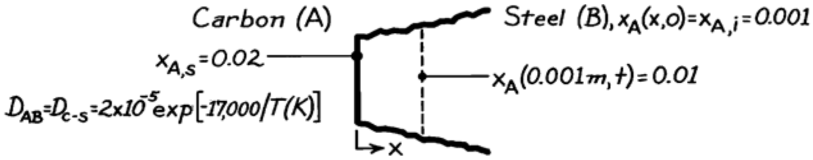
COMMENTS: (1) Use of the approximate solution of Section 5.8 is not valid for part (a) since its use yields $Fo_m = 0.366$, which does not satisfy the criterion $Fo_m < 0.2$. (2) Use of the one-term approximation to the exact solution for part (b) yields a mass transfer Fourier number of $Fo_m = 0.0198$, which does not satisfy the criterion $Fo_m > 0.2$.

PROBLEM 14.43

KNOWN: Initial carbon content and prescribed surface content for heated steel.

FIND: Time required for carbon mole fraction to reach 0.01 at a distance of 1 mm from the surface.

SCHEMATIC:



ASSUMPTIONS: (1) Steel may be approximated as a semi-infinite medium, (2) One-dimensional diffusion in x, (3) Isothermal conditions, (4) No internal chemical reactions, (5) Uniform total molar concentration, (6) Stationary medium.

ANALYSIS: Conditions within the steel are governed by the species diffusion equation of the form

$$\frac{\partial^2 C_A}{\partial x^2} = \frac{1}{D_{AB}} \frac{\partial C_A}{\partial t}$$

or, in molar form,

$$\frac{\partial^2 x_A}{\partial x^2} = \frac{1}{D_{AB}} \frac{\partial x_A}{\partial t}.$$

The initial and boundary conditions are of the form

$$x_A(x,0) = 0.001$$

$$x_A(0,t) = x_{A,s} = 0.02 \qquad x_A(\infty,t) = 0.001.$$

The problem is analogous to that of heat transfer in a semi-infinite medium with constant surface temperature, and by analogy to Eq. 5.60, the solution is

$$\frac{x_A(x,t) - x_{A,s}}{x_{A,i} - x_{A,s}} = \text{erf}\left(\frac{x}{2(D_{AB}t)^{1/2}}\right)$$

where

$$D_{AB} = 2\times10^{-5}\exp[-17,000/1273] = 3.17\times10^{-11}\,\text{m}^2/\text{s}.$$

Hence

$$\frac{0.01-0.02}{0.001-0.02} = 0.526 = \text{erf}\left(\frac{0.001\ \text{m}}{2\left(3.17\times10^{-11}t\right)^{1/2}}\right)$$

where erf w = 0.526 → w ≈ 0.51,

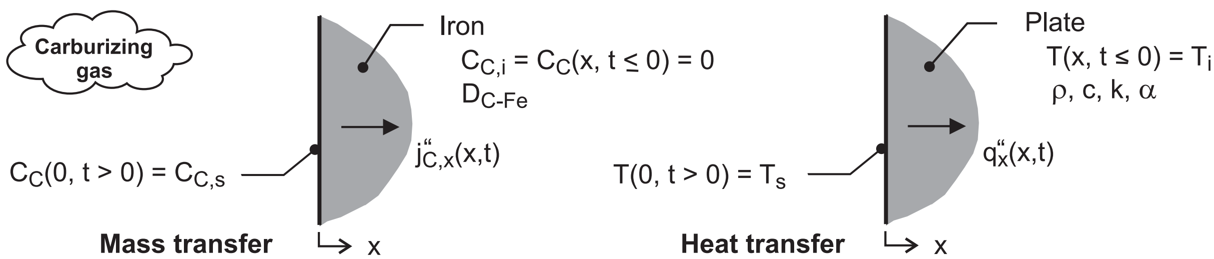
$$0.51 = 0.001/2\left(3.17\times10^{-11}t\right)^{1/2} \qquad \text{or} \qquad t = 30,321\ \text{s} = 8.42\ \text{h.}$$ <

PROBLEM 14.44

KNOWN: Thick plate of pure iron at 1000°C subjected to a carburizing process with sudden exposure to a carbon concentration $C_{C,s}$ at the surface.

FIND: (a) Consider the heat transfer analog to the carburization process; sketch the mass and heat transfer systems; explain correspondence between variables; provide analytical solutions to the mass and heat transfer situation; (b) Determine the carbon concentration ratio, $C_C(x, t)/C_{C,s}$, at a depth of 1 mm after 1 hour of carburization; and (c) From the analogy, show that the time dependence of the mass flux of carbon into the plate can be expressed as $n''_C = \rho_{C,s}\left(D_{C-Fe}/\pi t\right)^{1/2}$; also, obtain an expression for the mass of carbon per unit area entering the iron plate over the time period t.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional transient diffusion, (2) Thick plate approximates a semi-infinite medium for the transient mass and heat transfer processes, and (3) Constant properties, (4) Stationary medium.

ANALYSIS: (a) The analogy between the carburizing mass transfer process in the plate and the heat transfer process is illustrated in the schematic above. The basis for the mass - heat transfer analogy stems from the similarity of the conservation of species and energy equations (Eqs. 14.77 and 5.29, respectively), the general solution to the equations, and their initial and boundary conditions. For both processes, the plate is a semi-infinite medium with initial distributions, $C_C(x, t \le 0) = C_{C,i} = 0$ and $T(x, t \le 0) = T_i$, suddenly subjected to a surface potential, $C_C(0, t > 0) = C_{C,s}$ and $T(0, t > 0) = T_s$. The heat transfer situation corresponds to Case 1, Figure 5.7, from which the following relations were obtained.

Heat transfer

Distributions

$$\frac{T(x,t)-T_s}{T_i-T_s} = \text{erf}\left(\frac{x}{2\sqrt{\alpha t}}\right)$$

Fluxes

$$q''_s(t) = \frac{k(T_s-T_i)}{\sqrt{\pi\alpha t}}$$

Mass transfer

$$\frac{C_c(x,t)-C_{c,s}}{0-C_{c,s}} = \text{erf}\left(\frac{x}{2\sqrt{D_{\text{C-Fe}}t}}\right)$$

or

$$\frac{C_c(x,t)}{C_{c,s}} = \text{erfc}\left(\frac{x}{2\sqrt{D_{\text{C-Fe}}t}}\right)$$

$$n''_{C,s}(t) = \frac{D_{\text{C-Fe}}(\rho_{C,s})}{\sqrt{\pi D_{\text{C-Fe}}t}}$$

Continued …

(b) Using the concentration distribution expression above, with L = 1 mm, t = 1 h and $D_{C\text{-}Fe} = 3 \times 10^{-11}\ m^2/s$, find the concentration ratio,

$$\frac{C_C\,(1\text{ mm},\ 1\text{ h})}{C_{C,s}} = \operatorname{erfc}\left(\frac{0.001\text{ m}}{2\left(3\times10^{-11}\text{ m}^2/\text{s}\times3600\text{ s}\right)^{1/2}}\right) = 0.0314$$ <

(c) From the species flux expression above, the mass flux of carbon can be written as

$$n''_{C,s} = \rho_{C,s}\ \left(D_{C-Fe}/\pi\ t\right)^{1/2}$$ <

The mass per unit area entering the plate over the time period follows from the integration of the rate expression

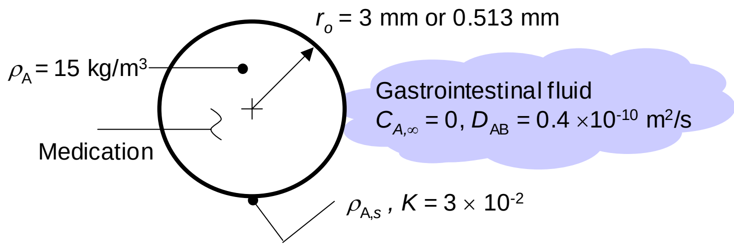
$$m_C\ (t) = \int_0^t n''_{C,s}\ dt = \rho_{C,s}\ \left(D_{C\text{-}Fe}/\pi\right)^{1/2}\ \int_0^t t^{-1/2}\ dt = 2\ \rho_{C,s}\ \left(D_{C-Fe}\ t/\pi\right)^{1/2}$$ <

PROBLEM 14.45

KNOWN: Radius of pharmaceutical product, density of the active ingredient, partition coefficient, and binary diffusion coefficient of the active ingredient in the gastrointestinal tract.

FIND: (a) Dosage delivered over 5 hours from a D = 6 mm diameter tablet, (b) Dosage delivered over 5 hours from N = 200 small, spherical tablets of the same mass.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional radial diffusion of active ingredient, (2) Constant properties, (3) Stationary medium, (4) Constant sphere radius.

PROPERTIES: Given: $D_{AB} = 0.40 \times 10^{-10}$ m^2/s, $K = 3 \times 10^{-2}$.

ANALYSIS: (a) The approximate solution of Chapter 5 for external conduction from an isothermal sphere and the heat-mass transfer analogy will be used. From Table 5.2a,

$$q^*(Fo) = \frac{1}{\sqrt{\pi Fo}} + 1 \quad \text{or,} \quad \frac{q_s'' r_o}{k(T_s - T_\infty)} = \frac{r_o}{\sqrt{\pi \alpha t}} + 1 \qquad (1,2)$$

By analogy, Eq. 2 may be written as

$$\frac{n_{A,s}'' r_o}{D_{AB}(\rho_{A,s} - \rho_{A,\infty})} = \frac{r_o}{\sqrt{\pi D_{AB} t}} + 1 \qquad (3)$$

Rearranging,

$$n_{A,s}'' = \frac{\sqrt{D_{AB}/\pi}\left(\rho_{A,s} - \rho_{A,\infty}\right)}{\sqrt{t}} + \frac{D_{AB}\left(\rho_{A,s} - \rho_{A,\infty}\right)}{r_o}$$

For $\rho_{A,\infty} = 0$, the dosage (for $A_s = 4\pi r_o^2$) is

$$D = \int_0^t 4\pi r_o^2 n_{A,s}'' dt = \int_o^t 4\pi r_o^2 \left[\sqrt{D_{AB}/\pi}(\rho_{A,s})t^{-1/2} + \frac{D_{AB}(\rho_{A,s})}{r_o}\right] dt$$

With $\rho_{A,s} = K\rho_A$, the preceding expression yields

$$D = 4\pi r_o K \rho_A \left[2r_o\sqrt{D_{AB}/\pi}\, t^{1/2} + D_{AB} t\right] \qquad (4)$$

Continued…

PROBLEM 14.45 (Cont.)

Substituting the appropriate values into Eq. 4 results in

$$D = 4\pi \times 3\times10^{-3}\text{m} \times 3\times10^{-2} \times 15\text{kg/m}^3 \times \left[\begin{array}{l} 2\times3\times10^{-3}\text{m}\sqrt{0.4\times10^{-10}\text{m}^2/\text{s}\times18000\text{s}/\pi} \\ +0.4\times10^{-10}\text{m}^2/\text{s}\times18000\text{s} \end{array}\right]$$

D = 60.9 × 10^{-9} kg = 60.9 × 10^{-6} g = 60.9 μg <

(b) For the same initial mass and N = 200 tablets,

$$\frac{4}{3}\pi r_{o,1}^3 = \frac{N4}{3}\pi r_{o,N}^3 \quad \text{or} \quad r_{o,N} = r_{o,1}/N^{1/3} = 3\times10^{-3}\text{m}/200^{1/3} = 0.513\text{ mm}$$

The dosage is $D = ND_1$ where D_1 is the dosage for one tablet. Hence,

$$D = ND_1 = 200\times4\pi\times0.513\times10^{-3}\text{m}\times3\times10^{-2}\times15\text{kg/m}^3\times\left[\begin{array}{l} 2\times0.513\times10^{-3}\text{m}\sqrt{0.4\times10^{-10}\text{m}^2/\text{s}\times18000\text{s}/\pi} \\ +0.4\times10^{-10}\text{m}^2/\text{s}\times18000\text{s} \end{array}\right]$$

D = 703 × 10^{-9} kg = 703 × 10^{-6} g = 703 μg <

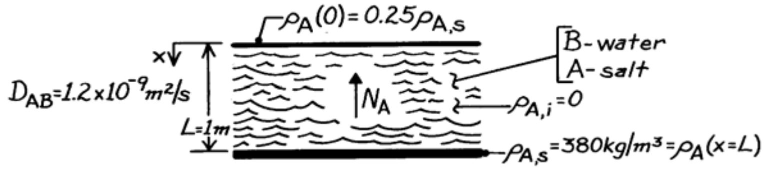
COMMENTS: (1) The dosage is controlled by the tablet size. In this example, the medication dosage is increased by over an order of magnitude by replacing the single tablet with the encapsulated, smaller diameter spherical tablets. (2) The initial mass of the medication is $M = 4/3\rho\pi r_o^3$ = 4/3×15kg/m^3×π×(3×10^{-3}m)^3 = 1.696×10^{-6} kg = 1.696×10^{-3} g = 1.696 mg = 1696 μg. For the smaller tablets, the mass of medication left after 5 hours is 1696 μg – 703 μg = 993 μg. Hence, the tablet radius after 5 hours is r_{5h} = 0.513mm×(993/1696)$^{1/3}$ = 0.429 mm. The assumption of a constant radius is marginally valid.

PROBLEM 14.46

KNOWN: Thickness, initial condition and bottom surface condition of a water layer.

FIND: (a) Time to reach 25% of saturation at top, (b) Amount of salt transfer in that time, (c) Final concentration of salt solution at top and bottom.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional diffusion, (2) Uniform total mass density, (3) Constant D_{AB}, (4) Stationary medium.

ANALYSIS: (a) With constant ρ and D_{AB} and no homogeneous chemical reactions, Eq. 14.47b reduces to

$$\frac{\partial^2 \rho_A}{\partial x^2} = \frac{1}{D_{AB}} \frac{\partial \rho_A}{\partial t}.$$

with the origin of coordinates placed at the top of the layer, the dimensionless mass density is

$$\gamma^*\left(x^*, Fo_m\right) = \frac{\gamma}{\gamma_i} = \frac{\rho_A - \rho_{A,s}}{\rho_{A,i} - \rho_{A,s}} = 1 - \frac{\rho_A}{\rho_{A,s}}$$

Hence, $\gamma^*\left(0,\ Fo_{m,1}\right) = 1 - 0.25 = 0.75$. The initial condition is $\gamma^*\left(x^*, 0\right) = 1$, and the boundary conditions are

$$\left.\frac{\partial \gamma^*}{\partial x^*}\right|_{x^*=0} = 0 \qquad \gamma^*\left(1,\ Fo_m\right) = 0$$

where the condition at $x^* = 1$ corresponds to $Bi_m = \infty$. Hence, the mass transfer problem is analogous to the heat transfer problem governed by Eq. 5.38 through 5.40. Assuming applicability of a one-term approximation ($Fo_m > 0.2$), the solution is analogous to Eq. 5.43.

$$\gamma^* = C_1 \exp\left(-\varsigma_1^2 Fo_m\right)\cos\left(\varsigma_1 x^*\right).$$

With $Bi_m = \infty$, $\varsigma_1 = \pi / 2 = 1.571$ rad and, from Table 5.1, $C_1 \approx 1.273$. Hence, for $x^* = 0$,

$$0.75 = 1.273 \exp\left[-\left(1.571\right)^2 Fo_{m,1}\right]$$

$$Fo_{m,1} = -\ln\left(0.75/1.274\right)/\left(1.571\right)^2 = 0.214.$$

Hence,

$$t_1 = \frac{L^2}{D_{AB}} Fo_{m,1} = \frac{(1\ m)^2}{1.2\times10^{-9}\ m^2/s} 0.214 = 1.79\times10^8 s = 2071\ \text{days}.$$ <

Continued …

(b) The change in the salt mass within the water is

$$\Delta M_A = M_A(t_1) - M_{A,i} = \int(\rho_A - \rho_{A,i})\,dV = A\int_0^L \rho_A dx$$

Hence,

$$\Delta M''_A = \rho_{A,s}\int_0^L (\rho_A / \rho_{A,s})\,dx$$

$$\Delta M''_A = \rho_{A,s} L\int_0^1 \left(1-\gamma^*\right) dx^*$$

$$\Delta M''_A = \rho_{A,s} L\int_0^1 \left[1 - C_1 \exp\left(-\varsigma_1^2 Fo_{m,1}\right)\cos\left(\varsigma_1 x^*\right)\right] dx^*$$

$$\Delta M''_A = \rho_{A,s} L\left[1 - C_1 \exp\left(-\varsigma_1^2 Fo_{m,1}\right)\sin\varsigma_1 / \varsigma_1\right].$$

Substituting numerical values,

$$\Delta M''_A = 380\ kg/m^3 (1\ m)\left[1 - \frac{1.274 \exp\left[-(1.571)^2\ 0.214\right]1}{1.571\,rad}\right]$$

$$\Delta M''_A = 198.3\ kg/m^2. \qquad <$$

(c) Steady-state conditions correspond to a uniform mass density in the water. Hence,

$$\rho_A(0,\infty) = \rho_A(L,\infty) = \Delta M''_A / L = 198.3\ kg/m^3. \qquad <$$

COMMENTS: (1) The assumption of constant ρ is weak, since the density of salt water depends strongly on the salt composition.

(2) The requirement of $Fo_m > 0.2$ for the one-term approximation to be valid is barely satisfied.

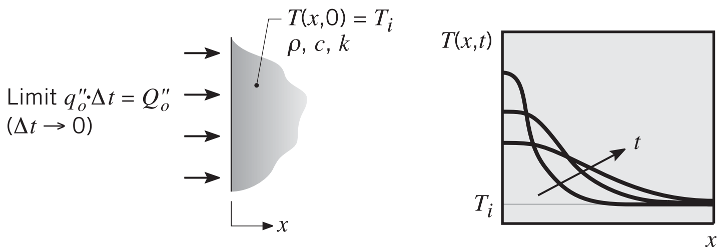
PROBLEM 14.47

KNOWN: Temperature distribution expression for a semi-infinite medium, initially at a uniform temperature, that is suddenly exposed to an instantaneous amount of energy, $Q_o''\left(J/m^2\right)$.

Analogous situation of a silicon (Si) wafer with a 1-μm layer of phosphorous (P) that is placed in a furnace suddenly initiating diffusion of P into Si.

FIND: (a) Explain the correspondence between the variables in the analogous temperature and concentration distribution expressions, and (b) Determine the mole fraction of P at a depth of 0.1 μm in the Si after 30 s.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, transient diffusion, (2) Wafer approximates a semi-infinite medium, (3) Uniform properties, and (4) Diffusion process for Si and P is initiated when the wafer reaches the elevated temperature as a consequence of the large temperature dependence of the diffusion coefficient, (5) Stationary medium.

PROPERTIES: *Given in statement*: $D_{P\text{-}Si} = 1.2 \times 10^{-17}$ m^2/s; Mass densities of Si and P: 2000 and 2300 kg/m^3; Molecular weights of Si and P: 30.97 and 28.09 kg/kmol.

ANALYSIS: (a) For the thermal process illustrated in the schematic, the temperature distribution is

$$T(x,\ t) - T_i = \frac{Q_o''}{\rho c(\pi \alpha t)^{1/2}} \exp\left(-x^2/4\alpha t\right) \qquad \text{(HT)}$$

where T_i is the initial, uniform temperature of the medium. For the mass transfer process, the P concentration has the form

$$C_P(x,\ t) = \frac{M_{P,o}''}{(\pi D_{P-Si}\ t)^{1/2}} \exp\left(-x^2/4\ D_{P-Si}\ t\right) \qquad \text{(MT)}$$

where $M_{P,o}''$ is the molar area density (kmol/m^2) of P represented by the film of concentration C_P and thickness d_o.

The correspondence between mass and heat transfer variables in the equations HT and MT involves the following conditions. The LHS represents the increase with time of the temperature or concentration above the initial uniform distribution. The initial concentration is zero, so only the C_P (x, t) appears. On the RHS note the correspondence of the terms in the exponential parenthesis and in the denominator. The thermal diffusivity and diffusion coefficient are directly analogous; this can be seen by comparing the MT and HT diffusion equations, Eq. 2.21 and 14.77. The terms $Q_o''/\rho c$ and $M_{P,o}''$ for HT and MT represent the energy and mass instantaneously appearing at the surface. The product ρc is the thermal capacity per unit area and appears in the storage term of the HT diffusion equation. For MT, the "capacity" term is the volume itself.

Continued …

PROBLEM 14.47 (Cont.)

(b) The molar area density (kmol/m^2) of P associated with the film of thickness d_o = 1 μm and concentration $C_{P,o}$ is

$$M''_{P,o} = C_{P,o} \cdot d_o = (\rho_P / \mathcal{M}_P) d_o$$

$$M''_{P,o} = \left(2000 \text{ kg/m}^3 / 30.97 \text{ kmol/kg}\right) \times 1 \times 10^{-6} \text{ m}$$

$$M''_{P,o} = 6.458 \times 10^{-5} \text{ kmol/m}^2$$

Substituting numerical values into the MT equation, find

$$C_p(0.1\ \mu\text{m}, 30\text{ s}) = \frac{6.458 \times 10^{-5} \text{ kmol/m}^2}{\left(\pi \times 1.2 \times 10^{-17} \text{ m}^2/\text{s} \times 30 \text{ s}\right)^{1/2}} \exp - \left(0.1 \times 10^{-6} \text{ m}\right)^2 / \left(4 \times 1.2 \times 10^{-17} \text{ m}^2/\text{s} \times 30 \text{ s}\right)\Big]$$

$$C_p = 1.85 \text{ kmol/m}^3$$

The mole fraction of P in the Si wafer is

$$x_P = C_P / C_{Si} = C_P / \left(\rho_{Si} / \mathcal{M}_{Si}\right)$$

$$x_P = 1.85 \text{ kmol/m}^3 / \left(2300 \text{ kg/m}^3 / 28.09 \text{ kmol/kg}\right)$$

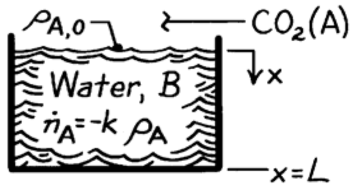
$$x_P = 0.023$$ <

PROBLEM 14.48

KNOWN: Carbon dioxide concentration at water surface and reaction rate constant.

FIND: (a) Differential equation which governs variation with position and time of CO_2 concentration in water, (b) Appropriate boundary conditions and solution for a deep body of water with negligible chemical reactions.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional diffusion in x, (2) Constant properties, including total density ρ, (3) Water is stagnant, (4) Stationary medium.

ANALYSIS: (a) From Eq. 14.47b, it follows that, for the prescribed conditions,

$$D_{AB}\frac{\partial^2 \rho_A}{\partial x^2} - k_1\rho_A = \frac{\partial \rho_A}{\partial t}.$$ <

The first term on the left-hand side represents the *net* transport of CO_2 into a differential control volume by diffusion. The second term represents the rate of CO_2 consumption due to chemical reactions. The term on the right-hand side represents the rate of increase of CO_2 storage within the control volume.

(b) For a deep body of water, appropriate boundary conditions are

$$\rho_A(0,t) = \rho_{A,0}$$

$$\rho_A(\infty,t) = 0$$

and, with negligible chemical reactions, the species diffusion equation reduces to

$$\frac{\partial^2 \rho_A}{\partial x^2} = \frac{1}{D_{AB}}\frac{\partial \rho_A}{\partial t}.$$

With an initial condition, $\rho_A(x,0) \equiv \rho_{A,i} = 0$, the problem is analogous to that involving heat transfer in a semi-infinite medium with constant surface temperature. By analogy to Eq. 5.60, the species concentration is then

$$\frac{\rho_A(x,t) - \rho_{A,0}}{-\rho_{A,0}} = \text{erf}\left(\frac{x}{2(D_{AB}t)^{1/2}}\right)$$

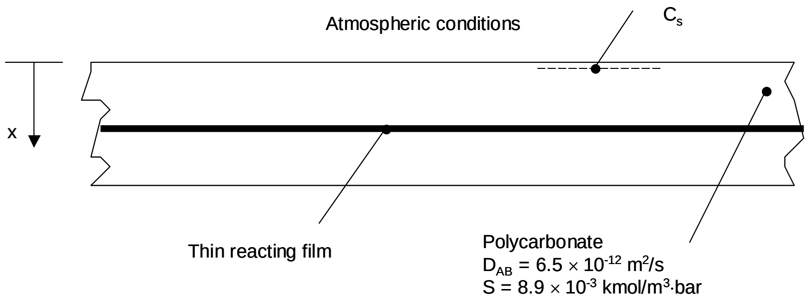
$$\rho_A(x,t) = \rho_{A,0}\,\text{erfc}\left(\frac{x}{2(D_{AB}t)^{1/2}}\right).$$ <

PROBLEM 14.49

KNOWN: Solubility and diffusivity of oxygen (O_2) in polycarbonate. Distance of thin reacting film of polymer from DVD surface. Initial O_2 distribution. Critical concentration needed to start reaction in the thin film.

FIND: Elapsed time before reaction begins in the thin film.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties and steady-state conditions, (2) Stationary medium. (3) Presence of thin, reacting film does not affect the diffusion process, (4) Semi-infinite media.

PROPERTIES: Oxygen (O_2) in polycarbonate, given: $D_{AB} = 6.5 \times 10^{-12}$ m^2/s, S = 8.9×10^{-3} kmol/m^3·bar.

ANALYSIS:
The mole fraction of oxygen in air is 0.21. Therefore, the partial pressure of O_2 in the atmosphere is

$$P_{02} = 0.21 \text{ atm} \times 1.0133 \frac{\text{bar}}{\text{atm}} = 0.213 \text{ bar}$$

and the surface concentration is

$$C_s = C(x{=}0) = SP_{O2} = 8.9 \times 10^{-3} \frac{\text{kmol}}{\text{m}^3 \cdot \text{bar}} \times 0.213 \text{ bar} = 1.89 \times 10^{-3} \frac{\text{kmol}}{\text{m}^3}$$

Incorporating the heat and mass transfer analogy and using Eq. 5.60,

$$\frac{C(x,t) - C_s}{C_i - C_s} = \text{erf}\left(\frac{x}{2\sqrt{D_{AB}t}}\right) = \frac{5 \times 10^{-5} \frac{\text{kmol}}{\text{m}^3} - 1.89 \times 10^{-3} \frac{\text{kmol}}{\text{m}^3}}{0 - 1.89 \times 10^{-3} \frac{\text{kmol}}{\text{m}^3}} = \text{erf}\left(\frac{0.5 \times 10^{-3} \text{m}}{2\sqrt{6.5 \times 10^{-12} \frac{\text{m}^2}{\text{s}} \times t}}\right)$$

which yields

$$t = 3940 \text{ s}$$ <

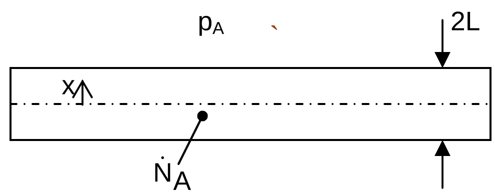
COMMENT: The thin film will convert O_2 to a product of the reaction. A more detailed analysis would include the effects of O_2 conversion on the process.

PROBLEM 14.50

KNOWN: DVD with reacting polymer throughout, undergoing first-order homogeneous reaction between polymer and oxygen, with reaction rate proportional to oxygen molar concentration.

FIND: (a) Governing equations and boundary and initial conditions for oxygen molar concentration. (b) Expression for volume-averaged molar concentration of product of reaction.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) One-dimensional mass diffusion with heterogeneous chemical reaction. (3) Reaction rate is proportional to molar concentration of oxygen.

ANALYSIS: (a) From Eq. 14.48b for one-dimensional diffusion of species A (oxygen),

$$\frac{\partial C_A}{\partial t} = D_{AB}\frac{\partial^2 C_A}{\partial x^2} + \dot{N}_A$$

For a first-order reaction that consumes oxygen, we can write $\dot{N}_A = -k_1 C_A$. Thus,

$$\frac{\partial C_A}{\partial t} = D_{AB}\frac{\partial^2 C_A}{\partial x^2} - k_1 C_A$$ <

The boundary conditions express symmetry about the midplane and relate the molar concentration at the surface to the partial pressure of oxygen in the environment, p_A.

$$\left.\frac{\partial C_A}{\partial x}\right|_{x=0} = 0, \qquad C_A(L,t) = Sp_A$$ <

The initial condition expresses that there is no oxygen initially in the DVD before the pouch is opened, that is,

$$C_A(x,0) = 0$$ <

(b) Since each mole of oxygen that reacts with the polymer results in p moles of product, we can write the following expression for the rate of generation of product: $\dot{N}_{prod} = -p\dot{N}_A = pk_1 C_A$.

Continued…

PROBLEM 14.50 (Cont.)

The volume-averaged molar concentration of product is just the rate of generation integrated over time and averaged over the volume. Thus,

$$\bar{C}_{prod} = \frac{1}{V}\int_V \int_0^t \dot{N}_{prod} dtdV = \frac{1}{2AL}\int_{-L}^{L}\int_0^t \dot{N}_{prod} dt(Adx) = \frac{1}{L}\int_0^L \int_0^t pk_1 C_A dtdx$$

$$\bar{C}_{prod} = \frac{pk_1}{L}\int_0^L \int_0^t C_A(x,t)dtdx$$

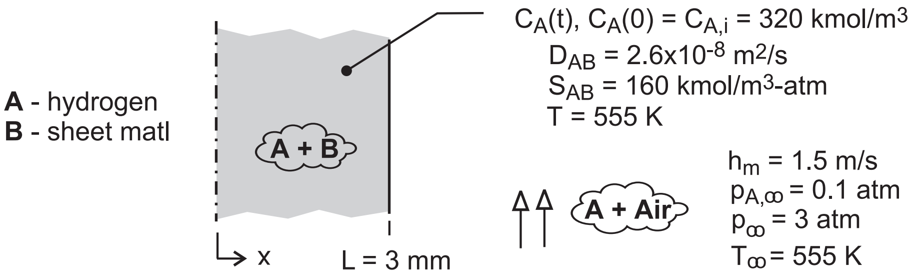
<

PROBLEM 14.51

KNOWN: Sheet material has high, uniform concentration of hydrogen at the end of a process, and is then subjected to an air stream with a specified, low concentration of hydrogen. Mass transfer parameters specified include: convection mass transfer coefficient, h_m, and the mass diffusivity and solubility of hydrogen (A) in the sheet material (B), D_{AB} and S_{AB}, respectively.

FIND: (a) The final mass density of hydrogen in the material if the sheet is exposed to the air stream for a very long time, $\rho_{A,f}$, (b) Identify and evaluate the parameter that can be used to determine whether the transient mass diffusion process in the sheet can be characterized by a uniform concentration at any time; *Hint*: this situation is analogous to the lumped capacitance method for a transient heat transfer process; (c) Determine the time required to reduce the hydrogen concentration to twice the limiting value calculated in part (a).

SCHEMATIC:



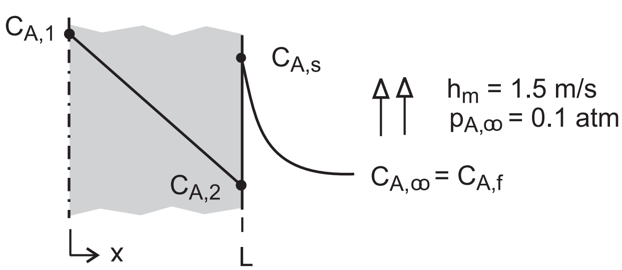
ASSUMPTIONS: (1) One-dimensional diffusion, (2) Stationary medium, (3) Constant properties, (4) Uniform temperature in air stream and material, and (5) Ideal gas behavior.

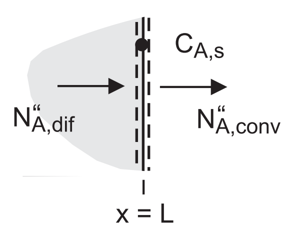
ANALYSIS: (a) The final content of H_2 in the material will depend upon the solubility of H_2 (A) in the material (B) and its partial pressure in the free stream. From Eq. 14.62,

$$C_{A,f} = S_{AB}\, p_{A,\infty} = 160\ \text{kmol/m}^3 \cdot \text{atm} \times 0.1\ \text{atm} = 16\ \text{kmol/m}^3$$

$$\rho_f = \mathcal{M}_A\, C_{A,f} = 2\ \text{kg/kmol} \times 16\ \text{kmol/m}^3 = 32\ \text{kg/m}^3 \qquad <$$

(b) The parameters associated with transient diffusion in the material follow from the analogous treatment of Section 5.2 (Fig. 5.3) and are represented in the schematic.





In the material, from Fick's law, the diffusive flux is

$$N''_{A,dif} = D_{AB}\left(C_{A,1} - C_{A,2}\right)/L \qquad (1)$$

At the surface, x = L, the rate equation, Eq. 6.8, convective flux of species A is

$$N''_{A,conv} = h_m\left(C_{A,s} - C_{A,\infty}\right)$$

Continued …

PROBLEM 14.51 (Cont.)

and substituting the ideal gas law, Eq. 14.9, and introducing the solubility relation, Eq. 14.62,

$$N''_{A,conv} = \frac{h_m}{S_{AB}\ \mathcal{R}\ T_\infty}\left(S_{AB}\ p_{A,s} - S_{AB}\ p_{A,\infty}\right)$$

$$N''_{A,conv} = \frac{h_m}{S_{AB}\ \mathcal{R}\ T_\infty}\left(C_{2,s} - C_{A,\infty}\right) \qquad (2)$$

where $C_{A,\infty} = C_{A,f}$, the final concentration in the material after exposure to the air stream a long time. Considering a surface species flux balance, as shown in the schematic above, with the rate equations (1) and (2),

$$\frac{D_{AB}\left(C_{A,1} - C_{A,2}\right)}{L} = \frac{h_m}{S_{AB}\ \mathcal{R}\ T_\infty}\left(C_{A,s} - C_{A,f}\right)$$

$$\frac{C_{A,1} - C_{A,2}}{C_{A,s} - C_{A,f}} = \frac{h_m / S_{AB}\ \mathcal{R}\ T_\infty}{D_{AB}/L} = \frac{R''_{m,dif}}{R''_{m,conv}} = Bi_m \qquad (3)$$

and introducing resistances to species transfer by diffusion and convection. Recognize from the analogy to heat transfer, Eq. 5.10 and Table 14.2, that when $Bi_m < 0.1$, the concentration can be characterized as uniform during the transient process. That is, the diffusion resistance is negligible compared to the convection resistance,

$$Bi_m = \frac{h_m L}{S_{AB}\ R_u\ T_\infty\ D_{AB}} < 0.1 \qquad (4)$$

$$Bi_m = \frac{(1.5\ m/h \times 3600\ s/h) \times 0.003\ m}{160\ kmol/m^3 \cdot atm \times 8.205 \times 10^{-2}\ m^3 \cdot atm/kmol \cdot K \times 555\ \ K \times 2.68 \times 10^{-8}\ \ m^2/s}$$

$$Bi_m = 6.60 \times 10^{-3} \quad < \quad 0.1$$

Hence, the mass transfer process can be treated as a nearly uniform concentration situation. From conservation of species on the material with uniform concentration,

$$-N''_{A,conv} = \dot{N}''_{A,st}$$

$$-\frac{h_m}{S_{AB}\ \mathcal{R}\ \ T_\infty}\left(C_A - C_{A,f}\right) = L\ \frac{d\,C_A}{dt}$$

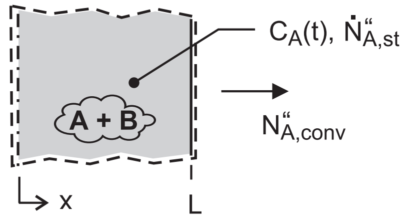
Integrating, with the initial condition $C_A(0) = C_{A,i}$, find

$$\frac{C_A - C_{A,f}}{C_{A,i} - C_{A,f}} = \exp\left(-\frac{h_m\ t}{L\ S_{AB}\ \mathcal{R}\ T_\infty}\right) \qquad (5) \quad <$$

Continued …..

PROBLEM 14.51 (Cont.)

which is similar to the analogous heat transfer relation for the lumped capacitance analysis, Eq. 5.6.



(c) The time, t_o, required for the material to reach a concentration twice that of the limiting value, $C_A(T_o) = 2\,C_{A,f}$, can be calculated from Eq. (5).

$$\frac{(2-1)\times 16\ \text{kmol/m}^3}{(320-16)\ \text{kmol/m}^3} = \exp\left(-\frac{1.5\ \text{m/h}\times t_o}{0.003\ \text{m}\times 160\ \text{kmol/m}^3\cdot\text{atm}\times 8.205\times 10^{-2}\ \text{m}^3\cdot\text{atm/kmol}\cdot\text{K}\times 555\ \text{K}}\right)$$

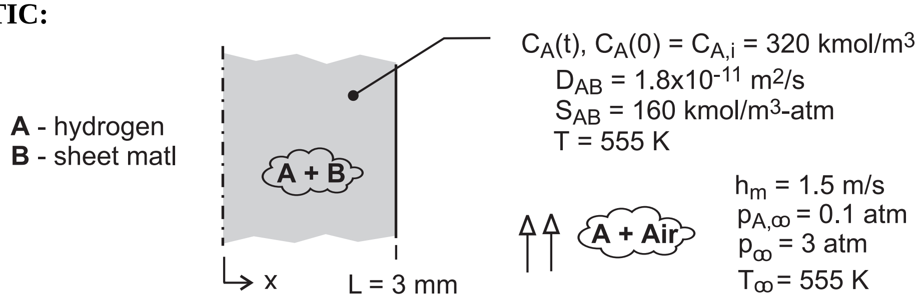
$$t_o = 42.9\ \text{h}$$ <

PROBLEM 14.52

KNOWN: Hydrogen-removal process described in Problem 14.51, but under conditions for which the mass diffusivity of hydrogen gas (A) in the sheet (B) is $D_{AB} = 1.8 \times 10^{-11}$ m^2/s (instead of 2.6×10^{-8} m^2/s). With a smaller D_{AB}, a uniform concentration condition may no longer be assumed to exist in the material during the removal process.

FIND: (a) The final mass density of hydrogen in the material if the sheet is exposed to the air stream for a very long time, $\rho_{A,f}$, (b) Identify and evaluate the parameters that describe the transient mass transfer process in the sheet; *Hint*: this situation is analogous to that of transient heat conduction in a plane wall; (c) Assuming a uniform concentration in the sheet at any time during the removal process, determine the time required to reach twice the limiting mass density calculated in part (a); (d) Using the analogy developed in part (b), determine the time required to reduce the hydrogen concentration to twice the limiting value calculated in part (a); Compare the result with that from part (c).

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional diffusion, (2) Stationary medium, (3) Constant properties, (4) Uniform temperature in air stream and material, and (5) Ideal gas behavior.

ANALYSIS: (a) The final content of H_2 in the material will depend upon the solubility of H_2 (A) in the material (B) at its partial pressure in the free stream. From Eq. 14.62,

$$C_{A,f} = S_{AB}\, p_{A,\infty} = 160\ \text{kmol/m}^3 \cdot \text{atm} \times 0.1\ \text{atm} = 16\ \text{kmol/m}^3$$

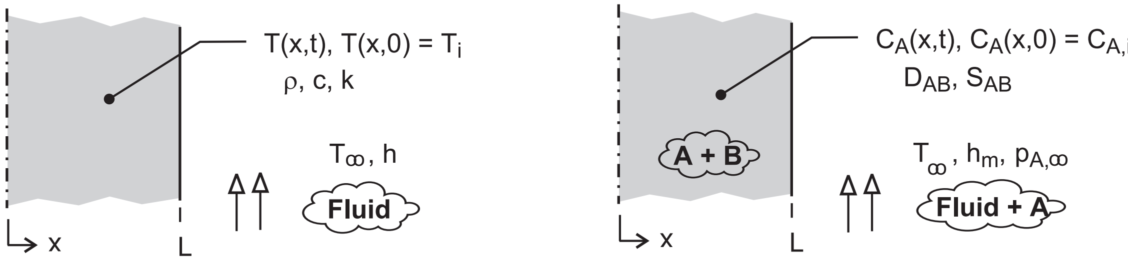
$$\rho_f = \mathcal{M}_A\, C_{A,f} = 2\ \text{kg/kmol} \times 16\ \text{kmol/m}^3 = 32\ \text{kg/m}^3$$ <

(b) For the plane wall shown in the schematic below, the heat and mass transfer conservation equations and their initial and boundary conditions are

Heat transfer	*Mass (Species A) transfer*
$\dfrac{\partial T}{\partial t} = \alpha \dfrac{\partial^2 T}{\partial x^2}$	$\dfrac{\partial C_A}{\partial t} = D_{AB} \dfrac{\partial^2 C_A}{\partial x^2}$
$T(x,0) = T_i$	$C_A(x,0) = C_{A,i}$
$\dfrac{\partial T}{\partial x}(0,t) = 0$	$\dfrac{\partial C_A}{\partial x}(0,t) = 0$
$-k \dfrac{\partial T}{\partial x}(L,t) = h\left[T(L,t) - T_\infty\right]$	$-D_{AB} \dfrac{\partial C_A}{\partial x}(L,t) = \dfrac{h_m}{S_{AB}\,\mathcal{R}\,T}\left[C_A(x,t) - C_f\right]$

Continued …

PROBLEM 14.52 (Cont.)



The derivation for the species transport surface boundary condition is developed in the solution for Problem 14.51. The solution to the mass transfer problem is identical to the analogous heat transfer problem provided the transport coefficients are represented as

$$\frac{h}{k} \Longleftrightarrow \frac{h_m / S_{AB}\,\mathcal{R}\,T}{D_{AB}} \qquad (1)$$

(c) The uniform concentration transient diffusion process is analogous to the heat transfer lumped-capacitance process. From the solution of Problem 14.51, the time to reach twice the limiting concentration, $C_A(t_o) = 2\,C_{A,f}$, can be calculated as

$$\frac{C_A(t_o) - C_{A,f}}{C_{A,i} - C_{A,f}} = \exp\left(-\frac{h_m\,t_o}{L\,S_{AB}\,\mathcal{R}\,T}\right) \qquad (2)$$

$$t_o = 42.9 \text{ hour}$$ <

For the present situation, the mass transfer Biot number is

$$Bi_m = \frac{h_m\,L}{S_{AB}\,\mathcal{R}\,T\,D_{AB}}$$

$$Bi_m = \frac{(1.5\text{ m/h}/3600\text{ s/h}) \times 0.003\text{ m}}{160\text{ kmol/m}^3 \cdot \text{atm} \times 8.205 \times 10^{-2}\text{ m}^3 \cdot \text{atm/kmol} \cdot \text{K} \times 555\text{ K} \times 1.8 \times 10^{-11}\text{ m}^2/\text{s}}$$

$$Bi_m = 9.5 \gg 0.1$$

and hence the concentration of A within B is not uniform

(d) Invoking the analogy with the heat transfer situation, we can use the one-term series solution, Eq. 5.43, with $Bi_m \Longleftrightarrow Bi$ and

$$Fo_m \Longleftrightarrow Fo \qquad Fo_m = \frac{D_{AB}\,t}{L^2} \qquad (3)$$

Continued …

PROBLEM 14.52 (Cont.)

With $Bi_m = 9.5$, find $\zeta_1 = 1.4219$ rad and $C_1 = 1.2609$ from Table 5.1, so that Eq. 5.44 becomes

$$\frac{C_A\left(t_o\right) - C_{A,f}}{C_{A,i} - C_{A,f}} = C_1 \exp\left(-\varsigma_1^2\ Fo_m\right)$$

$$\frac{(2-1)\times 16\ \text{kmol/m}^3}{(320-16)\text{kmol/m}^3} = 1.2609\ \exp\left(-1.4219^2\ Fo_m\right)$$

$$Fo_m = \frac{1.8\times 10^{-11}\ \text{m}^2/\text{s}\times t_o}{(0.003\ \text{m})^2} = 1.571$$

$$t_o = 218\ \text{h} \qquad <$$

COMMENTS: (1) Since $Bi_m = 9.5$, the uniform concentration assumption is not valid, and we expect the analysis to provide a longer time estimate to reach $C_A(t_o) = 2\ C_{A,f}$.

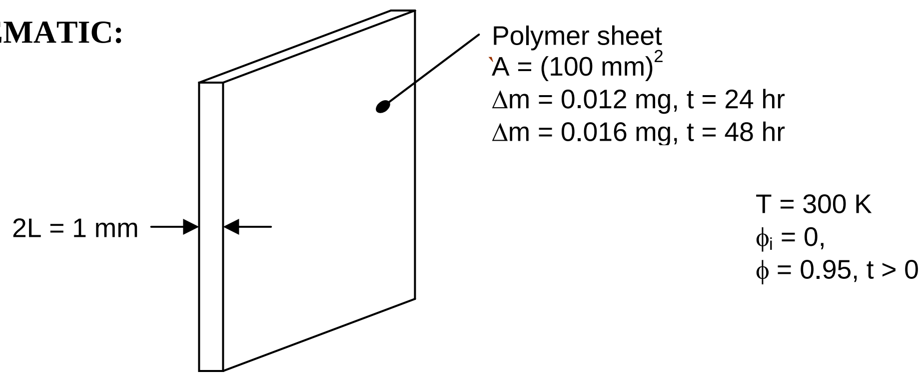
(2) Note that the uniform concentration analysis model of part (c) does not include D_{AB}. Why is this so?

PROBLEM 14.53

KNOWN: Dimensions of polymer sheet. Temperature and relative humidity of environment. Increase in mass of sheet over 24 and 48 hour periods.

FIND: Solubility and mass diffusivity of water vapor in polymer, assuming mass diffusivity is greater than 7×10^{-13} m^2/s.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) One-dimensional mass diffusion, (3) Mass gain is solely due to water vapor diffusing into the sheet.

PROPERTIES: *Table A.6*, saturated water (T = 300 K), $p_{A,sat} = 0.03531$ bars, $\mathcal{M}_A = 18$ kg/kmol.

ANALYSIS: The process of diffusion of water vapor (A) in the polymer (B) sheet is governed by Eq. 14.77 with boundary and initial conditions given by Eqs. 14.78 through 14.80. These equations can be cast in nondimensional form as in Eqs. 14.83 through 14.86, and the analogy with Eqs. 5.37 through 5.40 is apparent (for Bi $\rightarrow\infty$), with the analogous quantities defined in Table 14.2.

Since the mass gained by the polymer sheet is known, it is more convenient to work the problem in mass terms. Making use of Eq. 14.1, we recognize that γ^* defined in Eq. 14.81 can be written in the alternative form,

$$\gamma^* = \frac{C_A - C_{A,s}}{C_{A,i} - C_{A,s}} = \frac{\rho_A - \rho_{A,s}}{\rho_{A,i} - \rho_{A,s}} \qquad (1)$$

Here $\rho_{A,i} = 0$ since the sheet is initially dry, and $\rho_{A,s} = \mathcal{M}_A C_{A,s} = \mathcal{M}_A S p_{A,\infty}$, or

$$\rho_{A,s} = \mathcal{M}_A S \phi p_{A,sat} \qquad (2)$$

where S is the solubility (see Eq. 14.62).

The mass gained by the polymer sheet is then analogous to the energy transfer, Q, in the heat transfer problem. Specifically, for the mass loss, we can write a sequence of equations analogous to Eqs. 5.46 through 5.48,

Continued…

PROBLEM 14.53 (Cont.)

$$\text{Mass loss} = \Delta M_A = -[M_A(t) - M_A(0)] = -\int [\rho_A(x,t) - \rho_{A,i}]dV$$

$$\Delta M_{A,o} \equiv V(\rho_{A,i} - \rho_{A,s})$$

and

$$\frac{\Delta M_A}{\Delta M_{A,o}} = -\int \frac{[\rho_A(x,t) - \rho_{A,i}]}{\rho_{A,i} - \rho_{A,s}} \frac{dV}{V} = \frac{1}{V}\int (1-\gamma^*)dV$$

If $Fo_m > 0.2$, the solution can be approximated by the first term in the series, and the result for the mass loss would be analogous to Eq. 5.49. To determine if the first term approximation can be used, we estimate the mass transfer Fourier number with knowledge that the mass diffusivity is greater than 7×10^{-13} m^2/s,

$$Fo_m = D_{AB}t/L^2, \quad Fo_m > 7 \times 10^{-13} \text{ m}^2\text{/s} \times 24 \text{ h} \times 3600 \text{ s/h} / (0.0005 \text{ m})^2 = 0.24$$

Thus the one-term approximation is valid and by analogy to Eqs. 5.49 and 5.44, the nondimensional mass loss is given by

$$\frac{\Delta M_A}{\Delta M_{A,o}} = 1 - \frac{\sin\zeta_1}{\zeta_1} C_1 \exp(-\zeta_1^2 Fo_m) \tag{3}$$

or

$$\frac{-\Delta M_A}{\rho_{A,s}V} = 1 - \frac{\sin\zeta_1}{\zeta_1} C_1 \exp(-\zeta_1^2 \frac{D_{AB}}{L^2} t) \tag{4}$$

From Table 5.1 for Bi $\rightarrow\infty$, we find $\zeta_1 = 1.5707 = \pi/2$ and $C_1 = 1.2733$. The quantity $-\Delta M_A$ is the mass gain at the two stated times. The unknowns to be determined are D_{AB} and S, which appears in $\rho_{A,s}$ (see Eq. (2)). From Eq. (4) evaluated at the two times, we have two simultaneous equations which can be solved for the unknowns D_{AB} and $\rho_{A,s}$, namely

$$\frac{0.012 \times 10^{-6} \text{ kg}}{\rho_{A,s} \times 10^{-5} \text{ kg/m}^3} = 1 - \frac{\sin\pi/2}{\pi/2} 1.2733 \exp(-\frac{\pi^2}{4} \frac{D_{AB}}{(0.0005 \text{ m})^2} 24 \text{ h} \times 3600 \text{ s/h})$$

$$\frac{0.016 \times 10^{-6} \text{ kg}}{\rho_{A,s} \times 10^{-5} \text{ kg/m}^3} = 1 - \frac{\sin\pi/2}{\pi/2} 1.2733 \exp(-\frac{\pi^2}{4} \frac{D_{AB}}{(0.0005 \text{ m})^2} 48 \text{ h} \times 3600 \text{ s/h})$$

There are two solutions to these two equations,

$D_{AB} = 1.92 \times 10^{-13}$ m^2/s, $\rho_{A,s} = 0.003848$ kg/m^3

or

$D_{AB} = 8.5 \times 10^{-13}$ m^2/s, $\rho_{A,s} = 0.001976$ kg/m^3

Continued…

PROBLEM 14.53 (Cont.)

Since we expect D_{AB} to be greater than 7×10^{-13} m²/s, we choose the second solution. Thus,

$$D_{AB} = 8.5 \times 10^{-13}\ \text{m}^2/\text{s} \qquad <$$

$$S = \rho_{A,s} / \mathcal{M}_A \phi p_{A,sat} = 0.001976\ \text{kg/m}^3 / (18\ \text{kg/kmol} \times 0.95 \times 0.03531\ \text{bars})$$

$$S = 3.3 \times 10^{-3}\ \text{kmol/m}^3 \cdot \text{bar} \qquad <$$

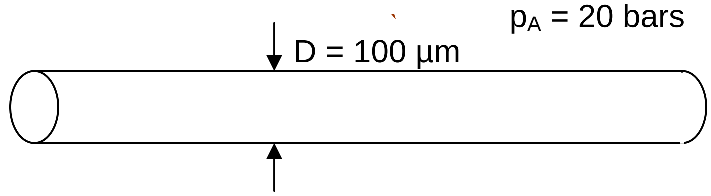
COMMENTS: The system of equations has two solutions, but one of them would yield a mass diffusivity less than 7×10^{-13} m²/s, and is therefore rejected. That solution also has $Fo_m < 0.2$, so the solution is not valid. It does raise the question of whether there is another solution for which $Fo_m < 0.2$. If the problem is solved correctly for $Fo_m < 0.2$, it can be determined that there is no other solution.

PROBLEM 14.54

KNOWN: Diameter of optical fiber sensor in a hydrogen chamber. Pressure of hydrogen (species A) in environment. Mass diffusivity and solubility for hydrogen in glass fiber (species B).

FIND: (a) Average hydrogen concentration in fiber after 100 hours of operation. Change in refractive index, given that $\Delta n = (1.6 \times 10^{-3}\ m^3/kmol) \times \overline{C}$. (b) Average hydrogen concentration and change in refractive index after 1 and 10 hours of operation.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties, (2) One-dimensional mass diffusion.

PROPERTIES: Hydrogen in vitreous silica fiber (given): $D_{AB} = 2.88 \times 10^{-15}\ m^2/s$, $S = 4.15 \times 10^{-3}\ kmol/m^3\cdot bar$.

ANALYSIS: (a) This is a problem of transient mass diffusion in a cylinder, analogous to transient conduction in a cylinder. We begin by calculating the mass transfer Fourier number,

$$Fo_m = D_{AB}t/r_o^2 = 2.88\times10^{-15}\ m^2/s\times100\ h\times3600\ s/h\Big/(50\times10^{-6}\ m)^2 = 0.415$$

With $Fo_m > 0.2$, we can use the first-term approximation to the series solution. The average hydrogen concentration can be found by analogy with the nondimensional energy transfer Q/Q_o defined in Eq. 5.48, with reference to Table 14.3 for the analogous quantities. We define

$$\frac{\Delta M_A}{\Delta M_{A,o}} \equiv \int \frac{-(C_A(x,t)-C_{A,i})}{C_{A,i}-C_{A,s}}\frac{dV}{V} = \frac{1}{V}\int(1-\gamma^*)dV \qquad (1)$$

Here the surface concentration, $C_{A,s}$, is used in place of the environment temperature, T_∞, because this is a problem of specified surface concentration, modeled by allowing $Bi_m\to\infty$. By analogy with Eq. 5.54,

$$\frac{\Delta M_A}{\Delta M_{A,o}} = 1-\frac{2\gamma_o^*}{\zeta_1}J_1(\zeta_1)$$

where from Eq. 5.52c, the centerline value of the nondimensional molar concentration is $\gamma_o^* = C_1\exp(-\zeta_1^2 Fo_m)$. From Table 5.1, $\zeta_1 = 2.4050$, $C_1 = 1.6018$, so $\gamma_o^* = 0.145$. From Table B.4, $J_1(2.4050) \approx 0.52$. Thus,

Continued…

PROBLEM 14.54 (Cont.)

$$\frac{\Delta M_A}{\Delta M_{A,o}} = 1 - \frac{2 \times 0.145}{2.4050} \times 0.52 = 0.937$$

Referring back to Eq. (1), we can determine the average hydrogen concentration,

$$\bar{C}_A = \int C_A(x,t)\frac{dV}{V} = C_{A,i} + \frac{\Delta M_A}{\Delta M_{A,o}}(C_{A,s} - C_{A,i})$$

where $C_{A,i} = 0$ since the fiber initially contains no hydrogen, and $C_{A,s} = Sp_A = 4.15 \times 10^{-3}$ kmol/m^3·bar × 20 bars = 0.0830 kmol/m^3. Thus,

$$\bar{C}_A = 0 + 0.937(.0830\text{ kmol/m}^3 - 0) = 0.0778\text{ kmol/m}^3$$ <

The change in refractive index is then

$$\Delta n = 1.6 \times 10^{-3}\text{ m}^3/\text{kmol} \times 0.0778\text{ kmol/m}^3 = 1.24 \times 10^{-4}$$

(b) For the shorter times, the Fourier number is no longer larger than 0.2, and we must use a different approach. We could use the exact infinite series solution, but it is easier to use the solutions provided in Table 5.2a, which are appropriate for uniform surface concentration. For an infinite cylinder, with $L_c = r_o$,

$$q^* = q''_s r_o / k(T_s - T_i)$$

The analogous quantity is

$$N_A^* = N''_{A,s} r_o / D_{AB}(C_{A,s} - C_{A,i})$$

With knowledge of the molar flux at the surface, $N''_{A,s}$, the average hydrogen concentration can be found as follows. We multiply the flux by the surface area and integrate over time to find how much hydrogen has entered the fiber. Then we divide by the volume to find the average concentration. That is,

$$\bar{C}_A = \int_0^t N''_{A,s} dt \times \frac{2\pi r_o}{\pi r_o^2} = \frac{2}{r_o}\int_0^t N''_{A,s} dt$$

Now from Table 5.2a for the interior case, infinite cylinder, with $Fo_m < 0.2$,

$$N_A^* = N''_{A,s} r_o / D_{AB}(C_{A,s} - C_{A,i}) = \frac{1}{\sqrt{\pi Fo_m}} - 0.50 - 0.65 Fo_m$$

Thus, we have

Continued…

PROBLEM 14.54 (Cont.)

$$\bar{C}_A = \frac{2}{r_o}\int_0^t N''_{A,s}dt = \frac{2}{r_o^2} D_{AB}(C_{A,s} - C_{A,i})\int_0^t \left(\frac{1}{\sqrt{\pi Fo_m}} - 0.50 - 0.65 Fo_m\right)dt$$

$$= 2(C_{A,s} - C_{A,i})\int_0^{Fo_m} \left(\frac{1}{\sqrt{\pi Fo_m}} - 0.50 - 0.65 Fo_m\right)dFo_m$$

$$= 2(C_{A,s} - C_{A,i})\left(\frac{2Fo_m^{1/2}}{\sqrt{\pi}} - 0.50 Fo_m - \frac{0.65}{2} Fo_m^2\right)$$

At 1 hour and 10 hours, Fo_m = 0.00415 and 0.0415, respectively. Then with $C_{A,s}$ = 0.0830 kmol/m^3 and $C_{A,i}$ = 0, we find,

For t = 1 hr, $\bar{C}_A = 0.0117 \text{ kmol/m}^3, \quad \Delta n = 1.9 \times 10^{-5}$ <

For t = 10 hr, $\bar{C}_A = 0.0346 \text{ kmol/m}^3, \quad \Delta n = 5.5 \times 10^{-5}$ <

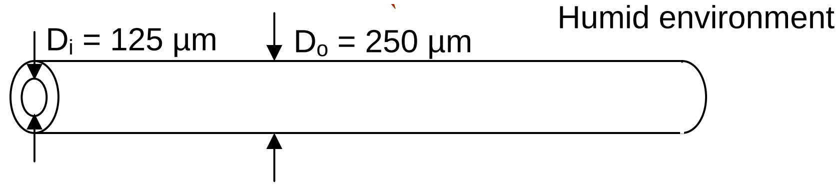
COMMENTS: (1) Hydrogen diffusion into glass optical fibers is highly undesirable because of the effects described in the problem statement. Hermetic coatings are typically applied to the fibers to prevent diffusion of hydrogen and other unwanted species into the glass. (2) At t = 100 hours, $\gamma_o^* = \frac{C_A(0,t) - C_{A,s}}{C_{A,i} - C_{A,s}} = 0.145$. This tells us that the centerline concentration is within 14.5% of reaching the surface concentration. At the same time, the *average* molar concentration is 93.7% of the surface concentration, i.e. within 6.3% of reaching the surface concentration. This is because of the radial geometry, which has greater volume near the surface than near the centerline.

PROBLEM 14.55

KNOWN: Diameters of glass optical fiber and acrylate polymer coating. Mass diffusivity of water vapor in the acrylate.

FIND: Whether microcracking would occur within several hot and humid days.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional mass diffusion. (2) Use of acrylate properties throughout the cylinder is sufficient for estimating the diffusion process in order to answer the question.

PROPERTIES: Water vapor in acrylate polymer (given): $D_{AB} = 5.5 \times 10^{-13}\ m^2/s$.

ANALYSIS: We arbitrarily begin by considering a two-day period. Then the mass transfer Fourier number is,

$$Fo_m = D_{AB} t / r_o^2 = 5.5 \times 10^{-13}\ m^2/s \times 48\ h \times 3600\ s/h \big/ (125 \times 10^{-6}\ m)^2 = 6.1$$

Since $Fo_m > 0.2$, we can use the one-term approximation, analogous to Eq. 5.49a. Referring to Table 14.3 for the analogies,

$$\gamma^* = \frac{C_A(r,t) - C_{A,s}}{C_{A,i} - C_{A,s}} = C_1 \exp(-\zeta_1^2 Fo_m) J_o(\zeta_1 r^*) \qquad (1)$$

where from Table 5.1, as Bi→∞, $\zeta_1 = 2.4050$, $C_1 = 1.6018$. At the outer surface of the glass, $r^* = 0.5$ and from Table B.4, $J_0(2.4050 \times 0.5) \approx J_0(1.2) \approx 0.67$. Thus

$$\gamma^* = 1.6018 \exp(-2.4050^2 \times 6.1) \times 0.67 = 5.6 \times 10^{-16}$$

Referring to the definition of γ^* in Eq. (1), we see that this very small value means that the concentration has essentially already reached the surface concentration. Therefore, careful storage of the optical fiber will not prevent microcracking, since within two days (probably much less), the water vapor has penetrated through the acrylate polymer coating. <

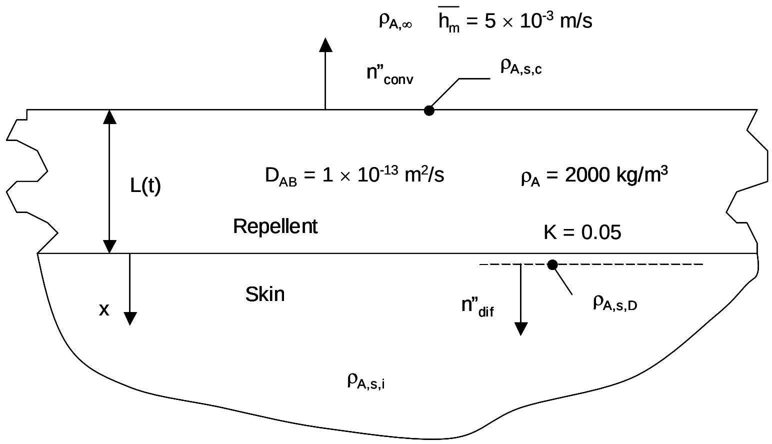
COMMENTS: (1) Equation 5.52 assumes uniform properties throughout the cylinder. Since the glass is impermeable to moisture, the build-up of moisture in the coating would be even more rapid than this equation predicts. (2) The time required for the concentration to be within 5% of the surface concentration ($\gamma^* = 0.05$) is around four hours. (3) Development of *hermetic coatings* for use in fiber optic and other high technology applications is an ongoing area of research.

PROBLEM 14.56

KNOWN: Mass of insect repellent applied to known area of skin. Convective mass transfer coefficient, partition coefficient at the ingredient – skin interface, mass diffusivity of the ingredient in the skin.

FIND: (a) Initial thickness of the active ingredient, (b) Duration of effective treatment, (c) Duration of effective treatment with use of reformulated repellent with a very small partition coefficient.

SCHEMATIC:



ASSUMPTIONS: (1) Constant properties and steady-state conditions, (2) Stationary medium. (3) Skin is semi-infinite medium.

PROPERTIES: Active Ingredient, given: ρ_A = 2000 kg/m^3, $\mathcal{M}_A$= 152 kg/kmol, $p_{A,sat} = 1.2 \times 10^{-5}$ bars, K (active Ingredient-skin interface) = 0.05, D_{AB} (active ingredient in skin) = 1×10^{-13} m^2/s.

ANALYSIS:

(a) For an active ingredient volume fraction of f = 0.25, the initial thickness of the active ingredient is

$$L(t=0) = \frac{fM}{\rho_A A} = \frac{0.25 \times 10 \times 10^{-3}\ \text{kg}}{2000\ \dfrac{\text{kg}}{\text{m}^3} \times 0.5\ \text{m}^2} = 2.5 \times 10^{-6}\ \text{m} = 2.5\ \mu\text{m} \quad <$$

(b) The duration of the effective treatment is associated with the complete depletion of the active ingredient through combined evaporation and absorption. For absorption of the ingredient into the skin, the analogy to Eq. 5.61 may be employed to provide

$$L(t=0) = \frac{1}{\rho_A}\left[\int_0^t n''_{A,conv}dt + \int_0^t n''_{A,dif}dt\right] = \frac{1}{\rho_A}\left[\int_0^t \overline{h_m}(\rho_{A,s,c} - \rho_{A,\infty})dt + \int_0^t \frac{\sqrt{D_{AB}}}{\sqrt{\pi t}}(\rho_{A,s,D} - \rho_{A,i})dt\right]$$

Continued…

PROBLEM 14.56 (Cont.)

Noting that $\rho_{A,\infty} = \rho_{A,i} = 0$ and $\rho_{A,s,D} = K\rho_A$, the integrations may be carried out to yield

$$L(t=0) = \frac{1}{\rho_A}\left[\overline{h_m}(\rho_{A,s,c})t\right] + 2\frac{\sqrt{D_{AB}}K}{\sqrt{\pi}}\sqrt{t}$$

The surface concentration of the active ingredient is

$$\rho_{A,s,c} = \frac{p_{A,sat}(T_s)}{(\mathcal{R}/\mathcal{M}_A)T_s} = \frac{1.2\times10^{-5}\ \text{bar}}{(8.314\times10^{-2}\ \text{m}^3\cdot\text{bar/kmol}\cdot\text{K/152 kmol/kg})\times(273+32)\text{K}} = 71.9\times10^{-6}\,\text{kg/m}^3$$

Substituting the values of $L(t = 0)$, $\rho_{A,s,c}$, and the quantities given in the problem statement, the preceding equation may be solved to yield

$$t = 6130 \text{ s or } 1.7 \text{ h}$$ <

(c) Setting K = 0, the preceding equation may be solved again to yield

$$t = 13900 \text{ s or } 3.9 \text{ h}$$ <

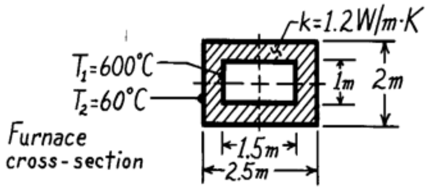
COMMENT: In part (b), convective losses are 43% of the total loss, while losses due to diffusion into the skin are 57%.

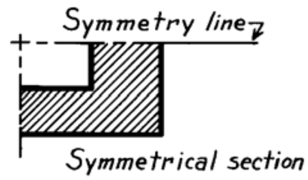
PROBLEM 4S.1

KNOWN: Long furnace of refractory brick with prescribed surface temperatures and material thermal conductivity.

FIND: Shape factor and heat transfer rate per unit length using the flux plot method

SCHEMATIC:



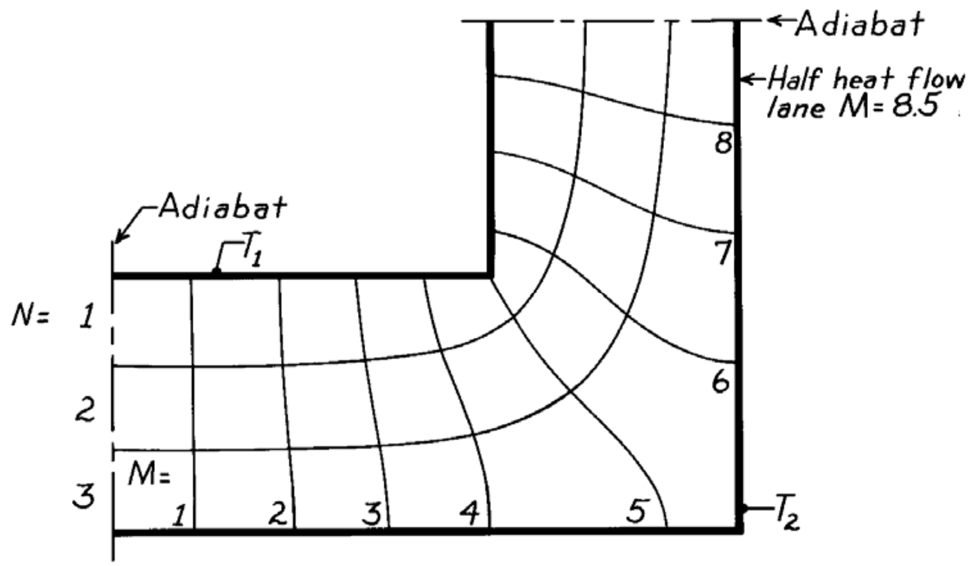


ASSUMPTIONS: (1) Furnace length normal to page, ℓ, >> cross-sectional dimensions, (2) Two-dimensional, steady-state conduction, (3) Constant properties.

ANALYSIS: Considering the cross-section, the cross-hatched area represents a symmetrical element. Hence, the heat rate for the entire furnace per unit length is

$$q' = \frac{q}{\ell} = 4\frac{S}{\ell}k\left(T_1 - T_2\right) \qquad (1)$$

where S is the shape factor for the symmetrical section. Selecting three temperature increments (N = 3), construct the flux plot shown below.



From Equation 4S.7, $S = \frac{M\ell}{N}$ or $\frac{S}{\ell} = \frac{M}{N} = \frac{8.5}{3} = 2.83$ <

and from Equation (1), $q' = 4 \times 2.83 \times 1.2 \frac{W}{m \cdot K}\left(600 - 60\right)^{\circ}C = 7.34\ kW/m.$ <

COMMENTS: The shape factor can also be estimated from the relations of Table 4.1. The symmetrical section consists of two plane walls (horizontal and vertical) with an adjoining edge. Using the appropriate relations, the numerical values are, in the same order,

$$S = \frac{0.75m}{0.5m}\ell + 0.54\ell + \frac{0.5m}{0.5m}\ell = 3.04\ell$$

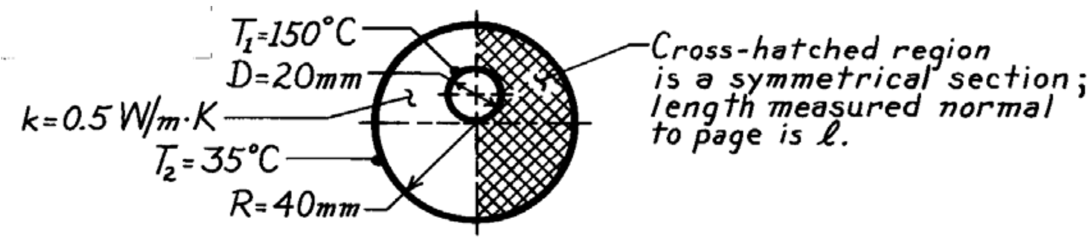
Note that this result compares favorably with the flux plot result of 2.83ℓ.

PROBLEM 4S.2

KNOWN: Hot pipe embedded eccentrically in a circular system having a prescribed thermal conductivity.

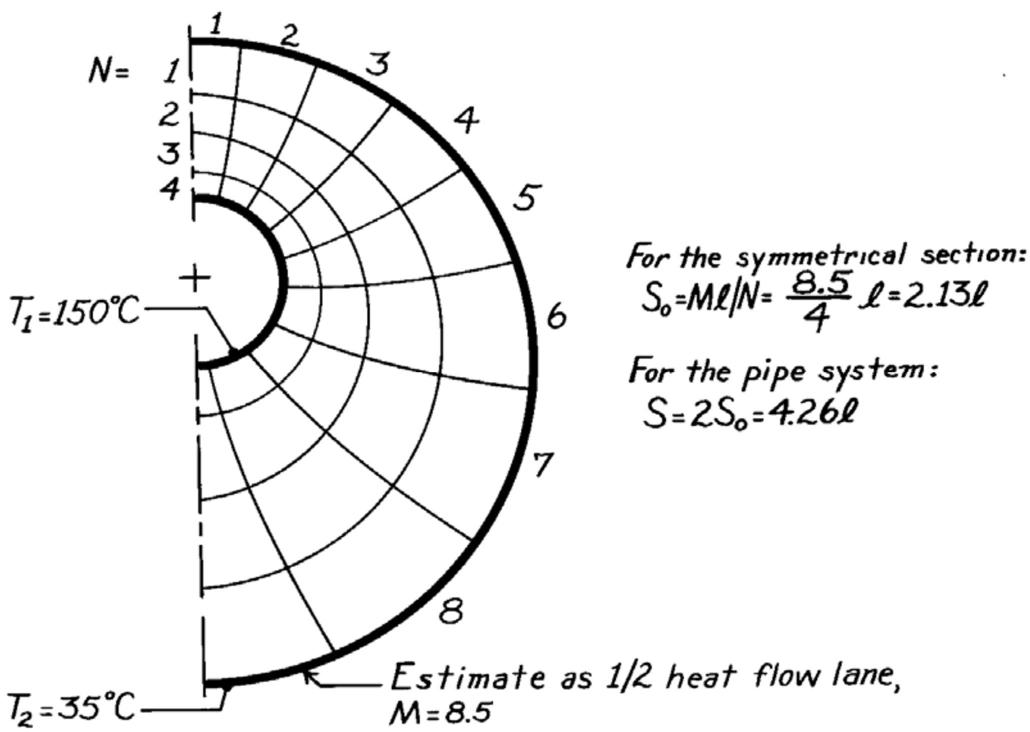
FIND: The shape factor and heat transfer per unit length for the prescribed surface temperatures.

SCHEMATIC:



ASSUMPTIONS: (1) Two-dimensional conduction, (2) Steady-state conditions, (3) Length ℓ >> diametrical dimensions.

ANALYSIS: Considering the cross-sectional view of the pipe system, the symmetrical section shown above is readily identified. Selecting four temperature increments (N = 4), construct the flux plot shown below.



For the pipe system, the heat rate per unit length is

$$q' = \frac{q}{\ell} = kS(T_1 - T_2) = 0.5\frac{W}{m \cdot K} \times 4.26(150 - 35)^\circ C = 245 \text{ W/m.} \qquad <$$

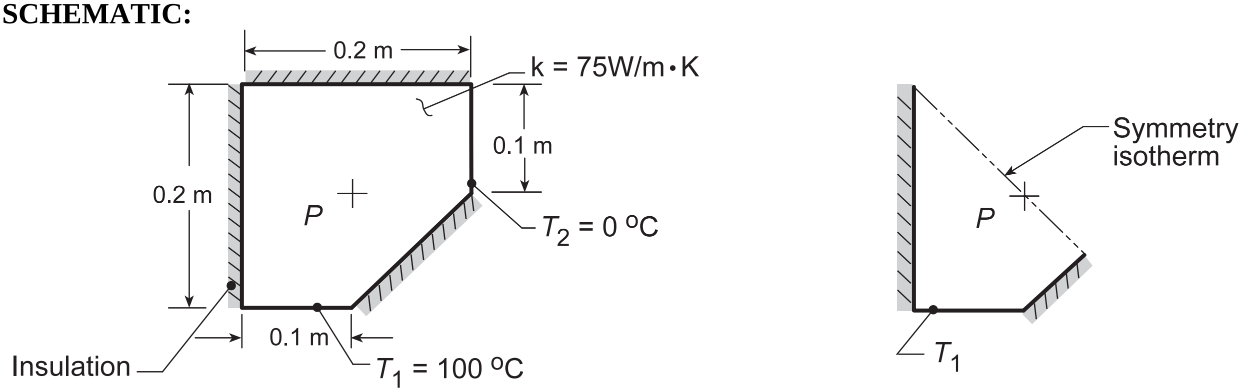
COMMENTS: Note that in the lower, right-hand quadrant of the flux plot, the curvilinear squares are irregular. Further work is required to obtain an improved plot and, hence, obtain a more accurate estimate of the shape factor.

PROBLEM 4S.3

KNOWN: Structural member with known thermal conductivity subjected to a temperature difference.

FIND: (a) Temperature at a prescribed point P, (b) Heat transfer per unit length of the strut, (c) Sketch the 25, 50 and 75°C isotherms, and (d) Same analysis on the shape but with adiabatic-isothermal boundary conditions reversed.

SCHEMATIC:



ASSUMPTIONS: (1) Two-dimensional conduction, (2) Steady-state conditions, (3) Constant properties.

ANALYSIS: (a) When constructing the flux plot, note that the line of symmetry which passes through the point P is an isotherm as shown above. It follows that

$$T(P) = (T_1 + T_2)/2 = (100 + 0)^\circ C/2 = 50^\circ C. \qquad <$$

(b) The flux plot on the symmetrical section is now constructed to obtain the shape factor from which the heat rate is determined. That is, from Equation 4S.6 and 4S.7,

$$q = kS(T_1 - T_2) \quad \text{and} \quad S = M\ell/N. \qquad (1,2)$$

From the plot of the symmetrical section,

$$S_o = 4.2\ell/4 = 1.05\ell.$$

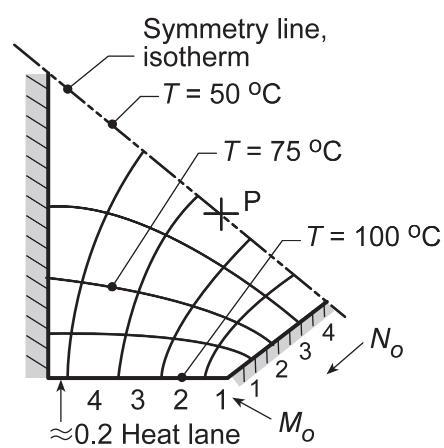
For the full section of the strut,

$$M = M_o = 4.2$$

but N = $2N_o$ = 8. Hence,

$$S = S_o/2 = 0.53\ell$$

and with $q' = q/\ell$, giving



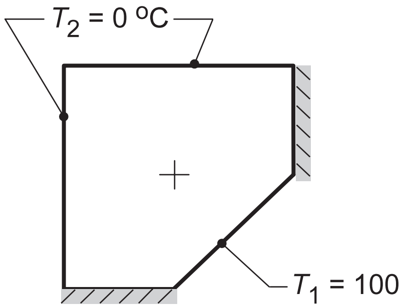
$$q'/\ell = 75\,W/m\cdot K \times 0.53(100-0)^\circ C = 3975\,W/m. \qquad <$$

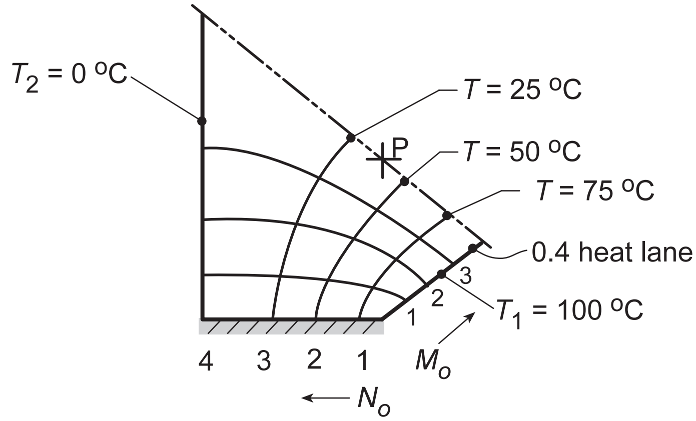
(c) The isotherms for T = 50, 75 and 100°C are shown on the flux plot. The T = 25°C isotherm is symmetric with the T = 75°C isotherm.

(d) By reversing the adiabatic and isothermal boundary conditions, the two-dimensional shape appears as shown in the sketch below. The symmetrical element to be flux plotted is the same as for the strut, except the symmetry line is now an adiabat.

Continued...

PROBLEM 4S.3 (Cont.)





From the flux plot, find $M_o = 3.4$ and $N_o = 4$, and from Equation (2)

$$S_o = M_o \ell / N_o = 3.4\ell/4 = 0.85\ell \qquad S = 2S_o = 1.70\ell$$

and the heat rate per unit length from Equation (1) is

$$q' = 75\,W/m\cdot K \times 1.70(100-0)^\circ C = 12,750\,W/m$$ <

From the flux plot, estimate that

$T(P) \approx 40°C.$ <

COMMENTS: (1) By inspection of the shapes for parts (a) and (b), it is obvious that the heat rate for the latter will be greater. The calculations show the heat rate is greater by more than a factor of three.

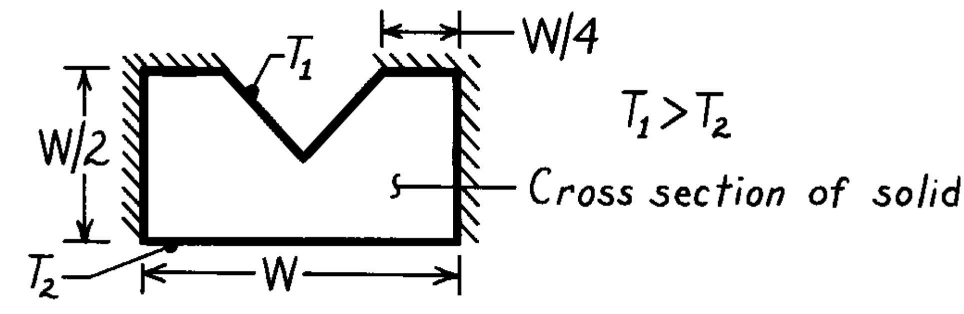
(2) By comparing the flux plots for the two configurations, and corresponding roles of the adiabats and isotherms, would you expect the shape factor for parts (a) to be the reciprocal of part (b)?

PROBLEM 4S.4

KNOWN: Relative dimensions and surface thermal conditions of a V-grooved channel.

FIND: Flux plot and shape factor.

SCHEMATIC:



ASSUMPTIONS: (1) Two-dimensional conduction, (2) Steady-state conditions, (3) Constant properties.

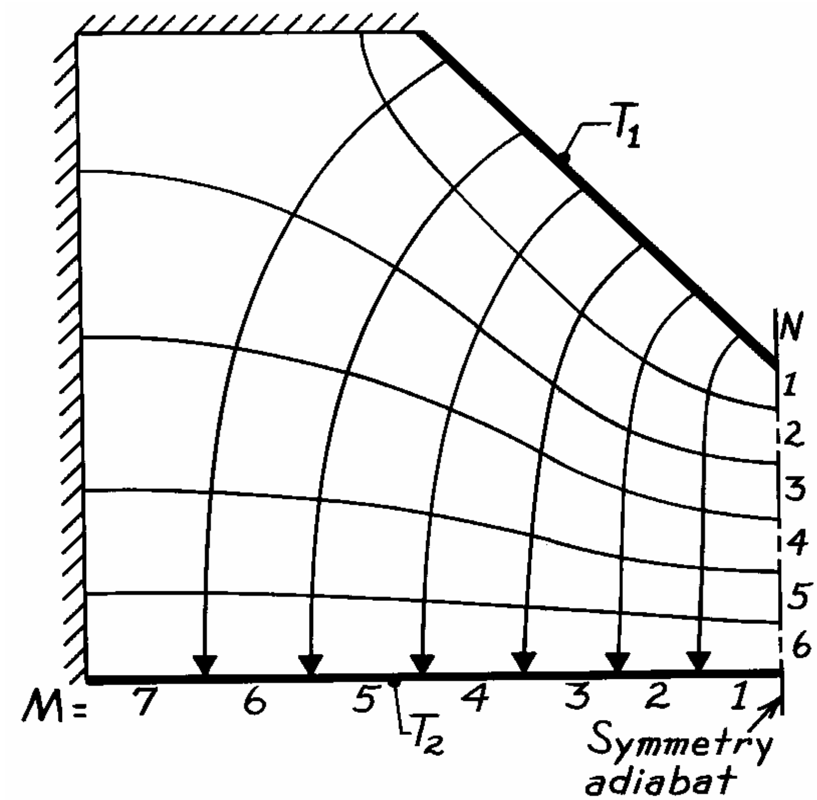
ANALYSIS: With symmetry about the midplane, only one-half of the object need be considered as shown below.

Choosing 6 temperature increments (N = 6), it follows from the plot that M ≈ 7. Hence from Equation 4S.7, the shape factor for the half section is

$$S = \frac{M}{N}\ell = \frac{7}{6}\ell = 1.17\ell.$$

For the complete system, the shape factor is then

$$S = 2.34\ell.$$ <

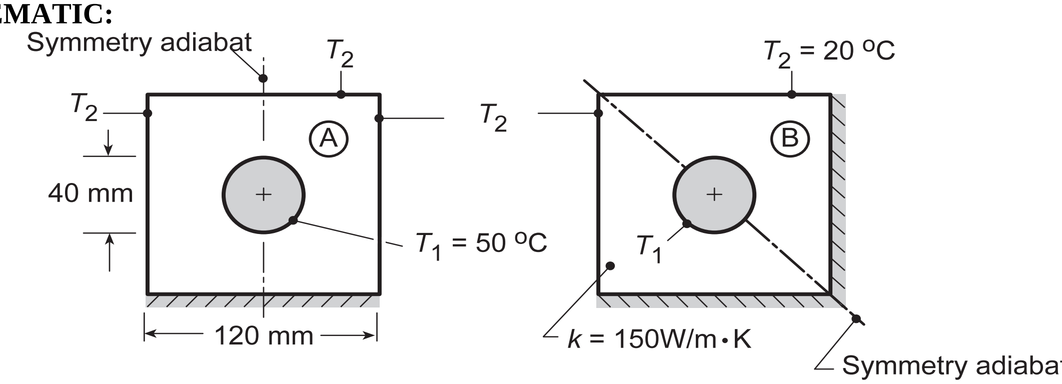


PROBLEM 4S.5

KNOWN: Long conduit of inner circular cross section and outer surfaces of square cross section.

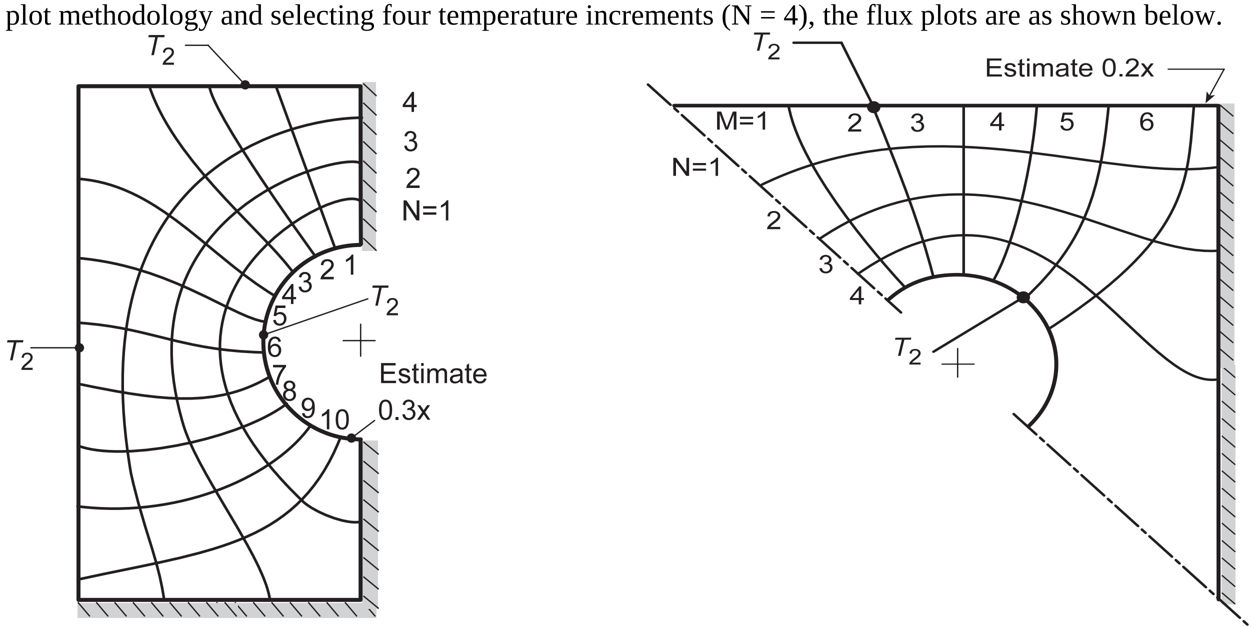
FIND: Shape factor and heat rate for the two applications when outer surfaces are insulated or maintained at a uniform temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Two-dimensional, steady-state conduction, (2) Constant properties and (3) Conduit is very long.

ANALYSIS: The adiabatic symmetry lines for each of the applications is shown above. Using the flux plot methodology and selecting four temperature increments (N = 4), the flux plots are as shown below.



For the symmetrical sections, $S = 2S_o$, where $S_o = M\ell/N$ and the heat rate for each application is $q = 2(S_o/\ell)k(T_1 - T_2)$.

Application	M	N	S_o/ℓ	q' (W/m)	
A	10.3	4	2.58	11,588	<
B	6.2	4	1.55	6,975	<

COMMENTS: (1) For application A, most of the heat lanes leave the inner surface (T_1) on the upper portion.

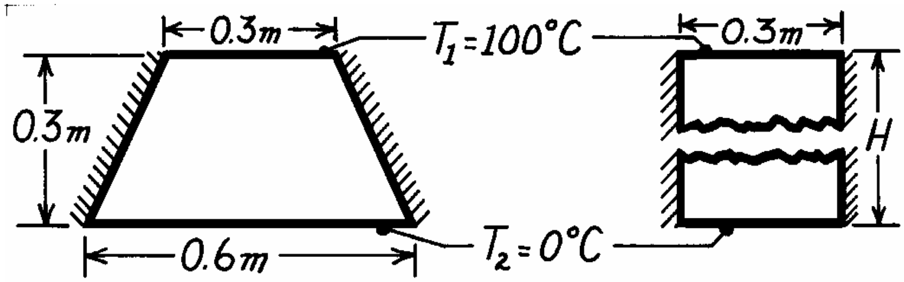
(2) For application B, most of the heat flow lanes leave the inner surface on the upper portion (that is, lanes 1-4). Because the lower, right-hand corner is insulated, the entire section experiences small heat flows (lane 6 + 0.2). Note the shapes of the isotherms near the right-hand, insulated boundary and that they intersect the boundary normally.

PROBLEM 4S.6

KNOWN: Shape and surface conditions of a support column.

FIND: (a) Heat transfer rate per unit length. (b) Height of a rectangular bar of equivalent thermal resistance.

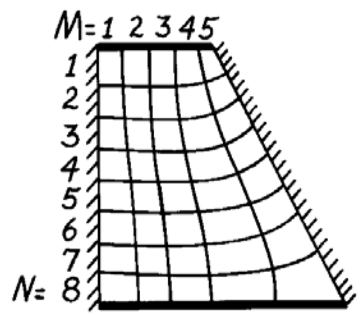
SCHEMATIC:



ASSUMPTIONS: (1)Steady-state conditions, (2) Negligible three-dimensional conduction effects, (3) Constant properties, (4) Adiabatic sides.

PROPERTIES: *Table A-1*, Steel, AISI 1010 (323K): k = 62.7 W/m·K.

ANALYSIS: (a) From the flux plot for the half section, M ≈ 5 and N ≈ 8. Hence for the full section



$$S = 2\frac{M\ell}{N} \approx 1.25\ell$$

$$q = Sk\left(T_1 - T_2\right)$$

$$q' \approx 1.25 \times 62.7\frac{W}{m \cdot K}\left(100 - 0\right)^\circ C$$

$$q' \approx 7.8 \text{ kW/m.}$$ <

(b) The rectangular bar provides for one-dimensional heat transfer. Hence,

$$q = k\,A\frac{\left(T_1 - T_2\right)}{H} = k\left(0.3\ell\right)\frac{\left(T_1 - T_2\right)}{H}$$

Hence, $$H = \frac{0.3k\left(T_1 - T_2\right)}{q'} = \frac{0.3m\left(62.7 \text{ W/m}\cdot\text{K}\right)\left(100^\circ C\right)}{7800 \text{ W/m}} = 0.24\text{m.}$$ <

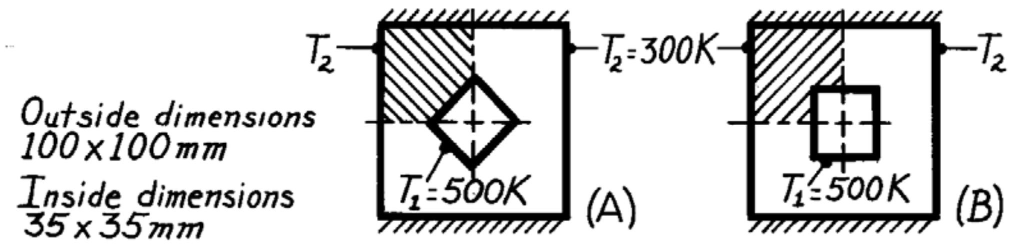
COMMENTS: The fact that H < 0.3m is consistent with the requirement that the thermal resistance of the trapezoidal column must be less than that of a rectangular bar of the same height and top width (because the width of the trapezoidal column increases with increasing distance, x, from the top). Hence, if the rectangular bar is to be of equivalent resistance, it must be of smaller height.

PROBLEM 4S.7

KNOWN: Hollow prismatic bars fabricated from plain carbon steel, 1m in length with prescribed temperature difference.

FIND: Shape factors and heat rate per unit length.

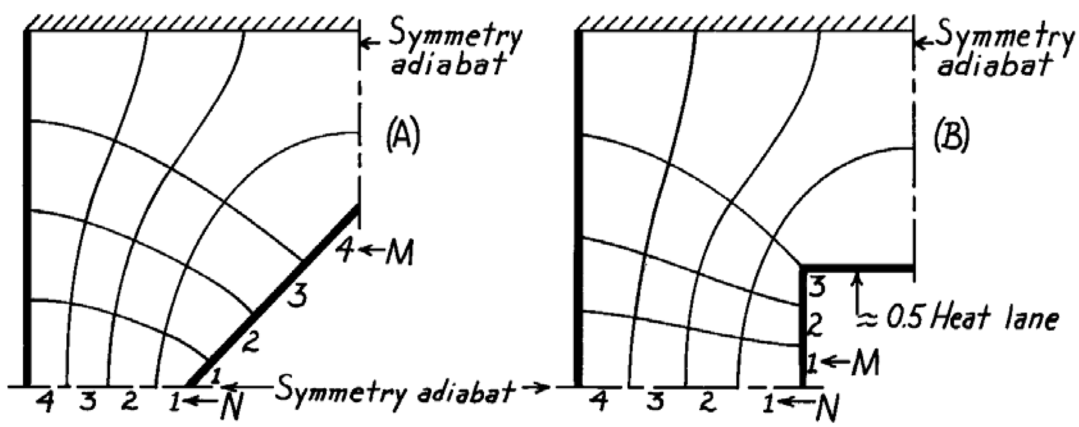
SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Two-dimensional conduction, (3) Constant properties.

PROPERTIES: *Table A-1*, Steel, Plain Carbon (400K), k = 57 W/m·K.

ANALYSIS: Construct a flux plot on the symmetrical sections (shaded-regions) of each of the bars.



The shape factors for the symmetrical sections are,

$$S_{o,A} = \frac{M\ell}{N} = \frac{4}{4}\ell = 1\ell \qquad S_{o,B} = \frac{M\ell}{N} = \frac{3.5}{4}\ell = 0.88\ell.$$

Since each of these sections is ¼ of the bar cross-section, it follows that

$$S_A = 4 \times 1\ell = 4\ell \qquad S_B = 4 \times 0.88\ell = 3.5\ell. \qquad <$$

The heat rate per unit length is $q' = q/\ell = k(S/\ell)(T_1 - T_2)$,

$$q'_A = 57\frac{W}{m \cdot K} \times 4(500 - 300)K = 45.6 \text{ kW/m} \qquad <$$

$$q'_B = 57\frac{W}{m \cdot K} \times 3.5(500 - 300)K = 39.9 \text{ kW/m}. \qquad <$$

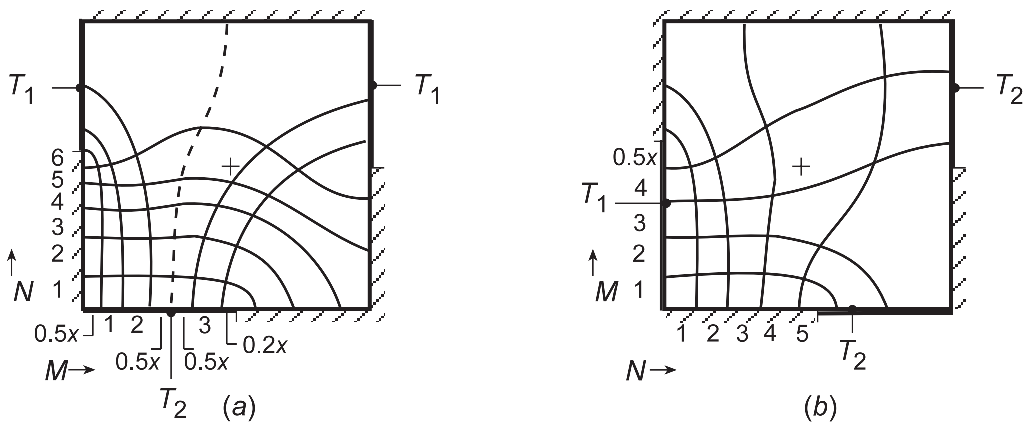
PROBLEM 4S.8

KNOWN: Two-dimensional, square shapes, 1 m to a side, maintained at uniform temperatures as prescribed, perfectly insulated elsewhere.

FIND: Using the flux plot method, estimate the heat rate per unit length normal to the page if the thermal conductivity is 50 W/m·K

ASSUMPTIONS: (1) Steady-state, two-dimensional conduction, (2) Constant properties.

ANALYSIS: Use the methodology of Section 4S.1 to construct the flux plots to obtain the shape factors from which the heat rates can be calculated. With Figure (a), begin at the lower-left side making the isotherms almost equally spaced, since the heat flow will only slightly spread toward the right. Start sketching the adiabats in the vicinity of the T_2 surface. The dashed line represents the adiabat which separates the shape into two segments. Having recognized this feature, it was convenient to identify partial heat lanes. Figure (b) is less difficult to analyze since the isotherm intervals are nearly regular in the lower left-hand corner.



The shape factors are calculated from Equation 4S.7 and the heat rate from Equation 4S.6.

$$S' = \frac{M}{N} = \frac{0.5 + 3 + 0.5 + 0.5 + 0.2}{6} \qquad S' = \frac{M}{N} = \frac{4.5}{5} = 0.90$$

$$S' = 0.70$$

$$q' = kS'(T_1 - T_2) \qquad q' = kS'(T_1 - T_2)$$

$$q' = 50\,W/m \cdot K \times 0.70(100 - 0)K = 3500\,W/m \qquad q' = 50\,W/m \cdot K \times 0.90(100 - 0)K = 4500\,W/m$$ <

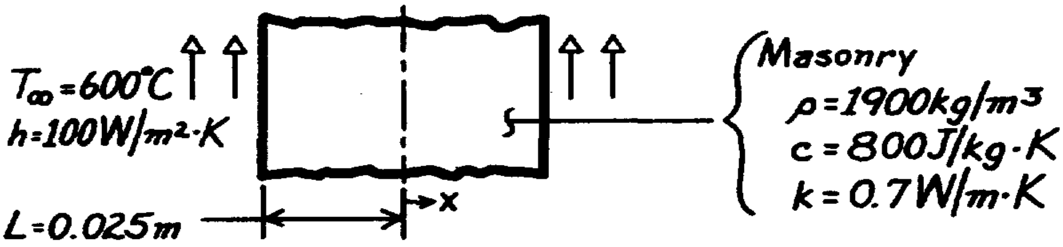
COMMENTS: Using a finite-element package with a fine mesh, we determined heat rates of 4780 and 4575 W/m, respectively, for Figures (a) and (b). The estimate for the less difficult Figure (b) is within 2% of the numerical method result. For Figure (a), our flux plot result was 27% low.

PROBLEM 5S.1

KNOWN: Configuration, initial temperature and charging conditions of a thermal energy storage unit.

FIND: Time required to achieve 75% of maximum possible energy storage and corresponding minimum and maximum temperatures.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction, (2) Constant properties, (3) Negligible radiation exchange with surroundings.

ANALYSIS: For the system, find first

$$Bi = \frac{hL}{k} = \frac{100\ W/m^2 \cdot K \times 0.025m}{0.7\ W/m \cdot K} = 3.57$$

indicating that the lumped capacitance method cannot be used.

Groeber chart, Fig. 5S.3: $Q/Q_o = 0.75$

$$\alpha = \frac{k}{\rho\ c} = \frac{0.7\ W/m \cdot K}{1900\ kg/m^3 \times 800\ J/kg \cdot K} = 4.605 \times 10^{-7}\ m^2/s$$

$$Bi^2 Fo = \frac{h^2 \alpha\ t}{k^2} = \frac{\left(100\ W/m^2 K\right)^2 \times \left(4.605 \times 10^{-7} m^2/s\right) \times t(s)}{\left(0.7\ W/m \cdot K\right)^2} = 9.4 \times 10^{-3} t$$

Find $Bi^2 Fo \approx 11$, and substituting numerical values

$$t = 11/9.4 \times 10^{-3} = 1170s. \qquad <$$

Heisler chart, Fig. 5S.1: T_{min} is at x = 0 and T_{max} at x = L, with

$$Fo = \frac{\alpha\ t}{L^2} = \frac{4.605 \times 10^{-7} m^2/s \times 1170\ s}{\left(0.025m\right)^2} = 0.86 \qquad Bi^{-1} = 0.28.$$

From Fig. 5S.1, $\theta_o^* \approx 0.33$. Hence,

$$T_o \approx T_\infty + 0.33\left(T_i - T_\infty\right) = 600^\circ C + 0.33\left(-575^\circ C\right) = 410^\circ C = T_{min}. \qquad <$$

From Fig. 5S.2, $\theta/\theta_o \approx 0.33$ at x = L, for which

$$T_{x=L} \approx T_\infty + 0.33\left(T_o - T_\infty\right) = 600^\circ C + 0.33\left(-190\right)^\circ C = 537^\circ C = T_{max}. \qquad <$$

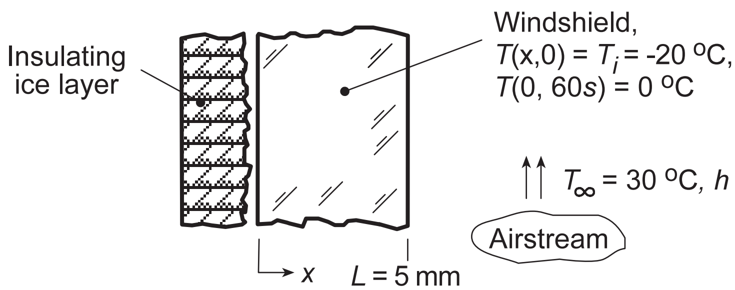
COMMENTS: Comparing masonry (m) with aluminum (Al), see Problem 5.16, $(\rho c)_{Al} > (\rho c)_m$ and $k_{Al} > k_m$. Hence, the aluminum can store more energy and can be charged (or discharged) more quickly.

PROBLEM 5S.2

KNOWN: Car windshield, initially at a uniform temperature of -20°C, is suddenly exposed on its interior surface to the defrost system airstream at 30°C. The ice layer on the exterior surface acts as an insulating layer.

FIND: What airstream convection coefficient would allow the exterior surface to reach 0°C in 60 s?

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional, transient conduction in the windshield, (2) Constant properties, (3) Exterior surface is perfectly insulated.

PROPERTIES: Windshield (Given): ρ = 2200 kg/m^3, c_p = 830 J/kg·K and k = 1.2 W/m·K.

ANALYSIS: For the prescribed conditions, from Equations 5.34 and 5.36,

$$\frac{\theta(0,60\text{s})}{\theta_i} = \frac{\theta_o}{\theta_i} = \frac{T(0,60\text{s}) - T_\infty}{T_i - T_\infty} = \frac{(0-30)^\circ\text{C}}{(-20-30)^\circ\text{C}} = 0.6$$

$$\text{Fo} = \frac{kt}{\rho c L^2} = \frac{1.2\,\text{W/m}\cdot\text{K}\times 60}{2200\,\text{kg/m}^3 \times 830\,\text{J/kg}\cdot\text{K}\times(0.005\,\text{m})^2} = 1.58$$

The single-term series approximation, Eq. 5.44, along with Table 5.1, requires an iterative solution to find an appropriate Biot number. Alternatively, the Heisler charts, Section 5S.1, Figure 5S.1, for the midplane temperature could be used to find

$$\text{Bi}^{-1} = k/hL = 2.5$$

$$h = 1.2\,\text{W/m}\cdot\text{K}/2.5\times 0.005\,\text{m} = 96\,\text{W/m}^2\cdot\text{K}$$ <

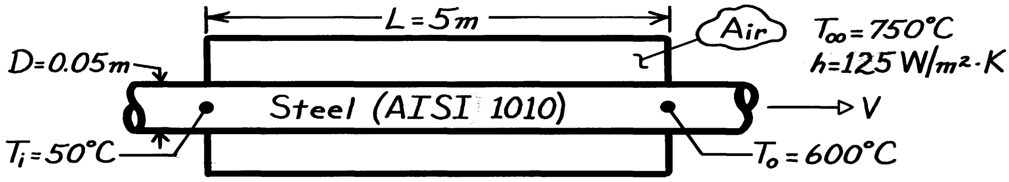
COMMENTS: Using the *IHT*, *Transient Conduction*, *Plane Wall Model*, the convection coefficient can be determined by solving the model with an assumed h and then sweeping over a range of h until the T(0,60s) condition is satisfied. Since the model is based upon multiple terms of the series, the result of h = 99 W/m^2·K is more precise than that found using the chart.

PROBLEM 5S.3

KNOWN: Inlet and outlet temperatures of steel rods heat treated by passage through an oven.

FIND: Rod speed, V.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional radial conduction (axial conduction is negligible), (2) Constant properties, (3) Negligible radiation.

PROPERTIES: *Table A-1*, AISI 1010 Steel $\left(\overline{T} \approx 600\text{K}\right)$: k = 48.8 W/m·K, ρ = 7832 kg/m^3, c_p = 559 J/kg·K, α = (k/ρc_p) = 1.11×10^{-5}m^2/s.

ANALYSIS: The time needed to traverse the rod through the oven may be found from Figure 5S.4.

$$\theta_o^* = \frac{T_o - T_\infty}{T_i - T_\infty} = \frac{600-750}{50-750} = 0.214$$

$$\text{Bi}^{-1} \equiv \frac{k}{hr_o} = \frac{48.8\text{ W/m}\cdot\text{K}}{125\text{ W/m}^2\cdot\text{K}\left(0.025\text{m}\right)} = 15.6.$$

Hence,

$$\text{Fo} = \alpha\ t/r_o^2 \approx 12.2$$

$$t = 12.2\left(0.025\text{m}\right)^2 / 1.11\times10^{-5}\text{m}^2/\text{s} = 687\text{ s}.$$

The rod velocity is

$$V = \frac{L}{t} = \frac{5\text{m}}{687\text{s}} = 0.0073\text{ m/s}.$$

COMMENTS: (1) Since (h r_o/2)/k = 0.032, the lumped capacitance method could have been used. From Equation 5.5 it follows that t = 675 s.

(2) Radiation effects decrease t and hence increase V, assuming there is net radiant transfer from the oven walls to the rod.

(3) Since Fo > 0.2, the approximate analytical solution may be used. With Bi = hr_o/k =0.0641, Table 5.1 yields $\zeta_1 = 0.3549$ rad and C_1 = 1.0158. Hence from Equation 5.52c

$$\text{Fo} = -\left(\zeta_1^2\right)^{-1}\ \ln\left[\frac{\theta_o^*}{C_1}\right] = 12.4,$$

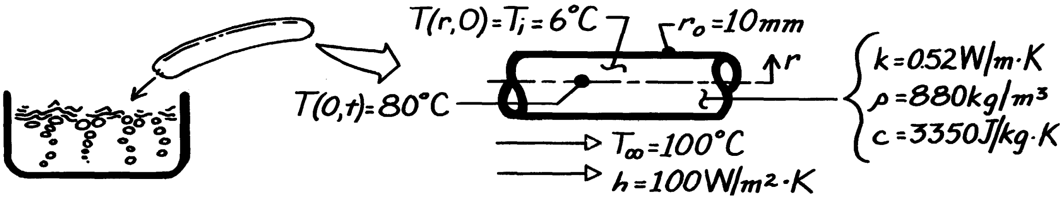
which is in good agreement with the graphical result.

PROBLEM 5S.4

KNOWN: Hot dog with prescribed thermophysical properties, initially at 6°C, is immersed in boiling water.

FIND: Time required to bring centerline temperature to 80°C.

SCHEMATIC:



ASSUMPTIONS: (1) Hot dog can be treated as infinite cylinder, (2) Constant properties.

ANALYSIS: The Biot number, based upon Equation 5.10, is

$$\mathrm{Bi} \equiv \frac{h L_c}{k} = \frac{h r_o / 2}{k} = \frac{100\ \mathrm{W/m^2 \cdot K}\left(10\times10^{-3}\mathrm{m}/2\right)}{0.52\ \mathrm{W/m\cdot K}} = 0.96$$

Since Bi > 0.1, a lumped capacitance analysis is not appropriate. Using the Heisler chart, Figure 5S.4 with

$$\mathrm{Bi} \equiv \frac{hr_o}{k} = \frac{100\mathrm{W/m^2\cdot K} \times 10\times10^{-3}\mathrm{m}}{0.52\ \mathrm{W/m\cdot K}} = 1.92 \quad \text{or} \quad \mathrm{Bi}^{-1} = 0.52$$

and $$\theta_o^* = \frac{\theta_o}{\theta_i} = \frac{T(0,t)-T_\infty}{T_i - T_\infty} = \frac{(80-100)^\circ\mathrm{C}}{(6\text{-}100)^\circ\mathrm{C}} = 0.21 \qquad (1)$$

find $$\mathrm{Fo} = t^* = \frac{\alpha\, t}{r_o^2} = 0.8 \qquad t = \frac{r_o^2}{\alpha}\cdot \mathrm{Fo} = \frac{\left(10\times10^{-3}\mathrm{m}\right)^2}{1.764\times10^{-7}\mathrm{m^2/s}}\times 0.8 = 453.5\mathrm{s} = 7.6\ \mathrm{min}$$ <

where $$\alpha = k/\rho\, c = 0.52\ \mathrm{W/m\cdot K}/880\ \mathrm{kg/m^3}\times 3350\ \mathrm{J/kg\cdot K} = 1.764\times10^{-7}\mathrm{m^2/s}.$$

COMMENTS: (1) Note that $L_c = r_o/2$ when evaluating the Biot number for the lumped capacitance analysis; however, in the Heisler charts, $\mathrm{Bi} \equiv hr_o/k$.

(2) The surface temperature of the hot dog follows from use of Figure 5S.5 with r/r_o = 1 and Bi^{-1} = 0.52; find $\theta(1,t)/\theta_o \approx 0.45$. From Equation (1), note that $\theta_o = 0.21\ \theta_i$ giving

$$\theta(1,t) = T(r_o,t) - T_\infty = 0.45\theta_o = 0.45\left(0.21\left[T_i - T_\infty\right]\right) = 0.45\times0.21\left[6-100\right]^\circ\mathrm{C} = -8.9^\circ\mathrm{C}$$

$$T(r_o,t) = T_\infty - 8.9^\circ\mathrm{C} = (100-8.9)^\circ\mathrm{C} = 91.1^\circ\mathrm{C}$$

(3) Since Fo ≥ 0.2, the approximate solution for θ*, Equation 5.52, is valid. From Table 5.1 with Bi = 1.92, find that $\zeta_1 = 1.3245$ rad and C_1 = 1.2334. Rearranging Equation 5.52 and substituting values,

$$\mathrm{Fo} = -\frac{1}{\zeta_1^2}\ln\left(\theta_o^*/C_1\right) = \frac{1}{(1.3245\ \mathrm{rad})^2}\ln\left[\frac{0.213}{1.2334}\right] = 1.00$$

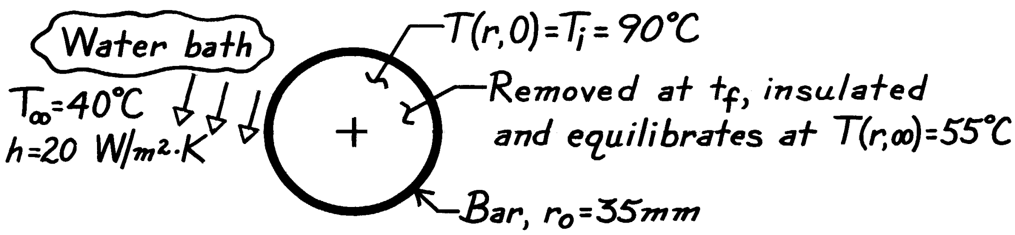
This result leads to a value of t = 9.5 min or 20% higher than that of the graphical method.

PROBLEM 5S.5

KNOWN: Long bar of 70 mm diameter, initially at 90°C, is suddenly immersed in a water bath (T_∞ = 40°C, h = 20 W/m^2·K).

FIND: (a) Time, t_f, that bar should remain in bath in order that, when removed and allowed to equilibrate while isolated from surroundings, it will have a uniform temperature T(r, ∞) = 55°C.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Constant properties.

PROPERTIES: Bar (given): ρ = 2600 kg/m^3, c = 1030 J/kg·K, k = 3.50 W/m·K, α = k/ρc = 1.31×10^{-6} m^2/s.

ANALYSIS: Determine first whether conditions are space-wise isothermal

$$Bi = \frac{hL_c}{k} = \frac{h(r_o/2)}{k} = \frac{20\ W/m^2\cdot K(0.035\ m/2)}{3.50\ W/m\cdot K} = 0.10$$

and since Bi ≥ 0.1, a Heisler solution is appropriate.

(a) Consider an overall energy balance on the bar during the time interval $\Delta t = t_f$ (the time the bar is in the bath).

$$E_{in} - E_{out} = \Delta E$$

$$0 - Q = E_{final} - E_{initial} = Mc(T_f - T_\infty) - Mc(T_i - T_\infty)$$

$$-Q = Mc(T_f - T_\infty) - Q_o$$

$$\frac{Q}{Q_o} = 1 - \frac{T_f - T_\infty}{T_i - T_\infty} = 1 - \frac{(55-40)^\circ C}{(90-40)^\circ C} = 0.70$$

where Q_o is the initial energy in the bar (relative to T_∞; Equation 5.44). With Bi = hr_o/k = 0.20 and Q/Q_o = 0.70, use Figure 5S.6 to find Bi^2Fo = 0.15; hence Fo = 0.15/Bi^2 = 3.75 and

$$t_f = Fo\cdot r_o^2/\alpha = 3.75(0.035\ m)^2/1.31\times10^{-6}\ m^2/s = 3507\ s. \qquad <$$

(b) To determine $T(r_o, t_f)$, use Figures 5S.4 and 5S.5 for $\theta(r_o,t)/\theta_i$ (Fo = 3.75, Bi^{-1} = 5.0) and θ_o/θ_i (Bi^{-1} = 5.0, r/r_o = 1, respectively, to find

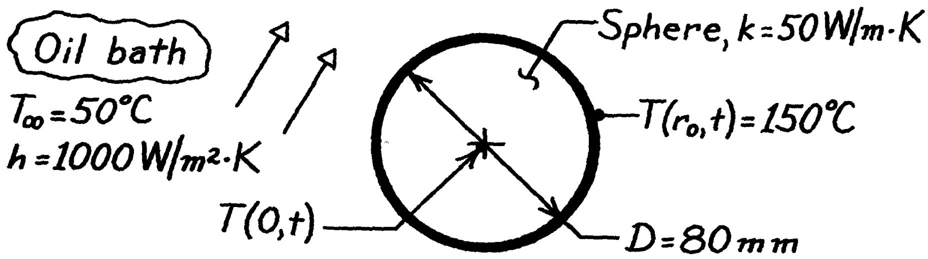
$$T(r_o, t_f) = T_\infty + \frac{\theta(r_o,\ t)}{\theta_o}\cdot\frac{\theta_o}{\theta_i}\cdot\theta_i = 40^\circ C + 0.25\times0.90(90-40)^\circ C = 51^\circ C. \qquad <$$

PROBLEM 5S.6

KNOWN: An 80 mm sphere, initially at a uniform elevated temperature, is quenched in an oil bath with prescribed T_∞, h.

FIND: The center temperature of the sphere, T(0,t) at a certain time when the surface temperature is $T(r_o,t)$ = 150°C.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Initial uniform temperature within sphere, (3) Constant properties, (4) Fo ≥ 0.2.

ANALYSIS: Check first to see if the sphere is spacewise isothermal.

$$Bi_c = \frac{hL_c}{k} = \frac{h(r_o/3)}{k} = \frac{1000\ W/m^2 \cdot K \times 0.040m/3}{50\ W/m \cdot K} = 0.26.$$

Since Bi_c > 0.1, lumped capacitance method is not appropriate. Recognize that when Fo ≥ 0.2, the time dependence of the temperature at any point within the sphere will be the same as the center. Using the Heisler chart method, Figure 5S.8 provides the relation between $T(r_o,t)$ and T(0,t). Find first the Biot number,

$$Bi = \frac{hr_o}{k} = \frac{1000\ W/m^2 \cdot K \times 0.040m}{50\ W/m \cdot K} = 0.80.$$

With Bi^{-1} = 1/0.80 = 1.25 and r/r_o =1, read from Figure 5S.8,

$$\frac{\theta}{\theta_o} = \frac{T(r_o,t) - T_\infty}{T(0,t) - T_\infty} = 0.67.$$

It follows that

$$T(0,t) = T_\infty + \frac{1}{0.67}\left[T(r_o,t) - T_\infty\right] = 50^\circ C + \frac{1}{0.67}[150 - 50]^\circ C = 199^\circ C. \qquad <$$

COMMENTS: (1) There is sufficient information to evaluate Fo; hence, we require that the time be sufficiently long after the start of quenching for this solution to be appropriate.

(2)The approximate series solution could also be used to obtain T(0,t). For Bi = 0.80 from Table 5.1, $\zeta_1 = 1.5044$ rad. Substituting numerical values, r* = 1,

$$\frac{\theta^*}{\theta_o^*} = \frac{T(r_o,t) - T_\infty}{T(0,t) - T_\infty} = \frac{1}{\zeta_1 r^*}\sin\left(\zeta_1 r^*\right) = \frac{1}{1.5044}\sin(1.5044\ rad) = 0.663.$$

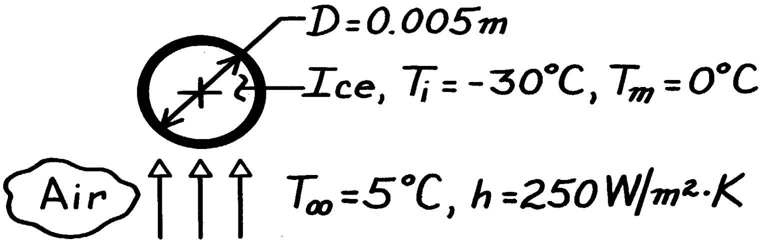
It follows that T(0,t) = 201°C.

PROBLEM 5S.7

KNOWN: Diameter and initial temperature of hailstone falling through warm air.

FIND: (a) Time, t_m, required for outer surface to reach melting point, $T(r_o,t_m) = T_m = 0°C$, (b) Centerpoint temperature at that time, (c) Energy transferred to the stone.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional radial conduction, (2) Constant properties.

PROPERTIES: *Table A-3*, Ice (253K): $\rho = 920$ kg/m^3, k = 2.03 W/m·K, $c_p = 1945$ J/kg·K; $\alpha = k/\rho c_p = 1.13 \times 10^{-6} m^2/s$.

ANALYSIS: (a) Calculate the lumped capacitance Biot number,

$$Bi = \frac{h(r_o/3)}{k} = \frac{250\ W/m^2 \cdot K(0.0025m/3)}{2.03\ W/m \cdot K} = 0.103.$$

Since Bi > 0.1, use the Heisler charts for which

$$\frac{\theta(r_o,t_m)}{\theta_i} = \frac{T(r_o,t_m)-T_\infty}{T_i - T_\infty} = \frac{0-5}{-30-5} = 0.143$$

$$Bi^{-1} = \frac{k}{hr_o} = \frac{2.03\ W/m \cdot K}{250\ W/m^2 \cdot K \times 0.0025m} = 3.25.$$

From Figure 5S.8, find $\frac{\theta(r_o,t_m)}{\theta_o(t_m)} \approx 0.86.$

It follows that $\frac{\theta_o(t_m)}{\theta_i} = \frac{\theta(r_o,t_m)/\theta_i}{\theta(r_o,t_m)/\theta_o(t_m)} \approx \frac{0.143}{0.86} \approx 0.17.$

From Figure 5S.7 find Fo ≈ 2.1. Hence,

$$t_m \approx \frac{Fo\ r_o^2}{\alpha} = \frac{2.1(0.0025)^2}{1.13\times10^{-6} m^2/s} = 12s. \qquad <$$

(b) Since $(\theta_o/\theta_i) \approx 0.17$, find

$$T_o - T_\infty \approx 0.17(T_i - T_\infty) \approx 0.17\ (-30-5) \approx -6.0^\circ C$$

$$T_o(t_m) \approx -1.0^\circ C. \qquad <$$

(c) With $Bi^2 Fo = (1/3.25)^2 \times 2.1 = 0.2$, from Figure 5S.9, find $Q/Q_o \approx 0.82$. From Equation 5.47,

$$Q_o = \rho V c_p \theta_i = \left(920\ kg/m^3\right)\ (\pi/6)(0.005m)^3 1945(J/kg \cdot K)(-35K) = -4.10\ J$$

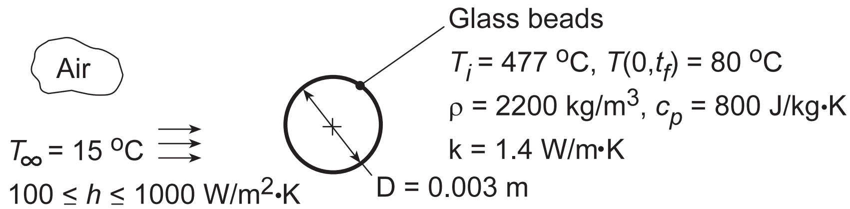
$$Q = 0.82\ Q_o = 0.82(-4.10\ J) = -3.4\ J. \qquad <$$

PROBLEM 5S.8

KNOWN: Properties, initial temperature, and convection conditions associated with cooling of glass beads.

FIND: (a) Time required to achieve a prescribed center temperature, (b) Effect of convection coefficient on center and surface temperature histories.

SCHEMATIC:



ASSUMPTIONS: (1) One-dimensional conduction in r, (2) Constant properties, (3) Negligible radiation, (4) Fo ≥ 0.2.

ANALYSIS: (a) With h = 400 W/m²·K, Bi ≡ h(r_o/3)/k = 400 W/m²·K(0.0005 m)/1.4 W/m·K = 0.143 and the lumped capacitance method should not be used. Instead, use the Heisler charts for which

$$\frac{\theta_o}{\theta_i} = \frac{T(0,t) - T_\infty}{T_i - T_\infty} = \frac{80 - 15}{477 - 15} = 0.141$$

$$Bi^{-1} = \frac{k}{hr_o} = \frac{1.4\ W/m \cdot K}{400\ W/m^2 \cdot K \times 0.0015\ m} = 2.33.$$

From Figure 5S.7, find $Fo \approx 1.8$.

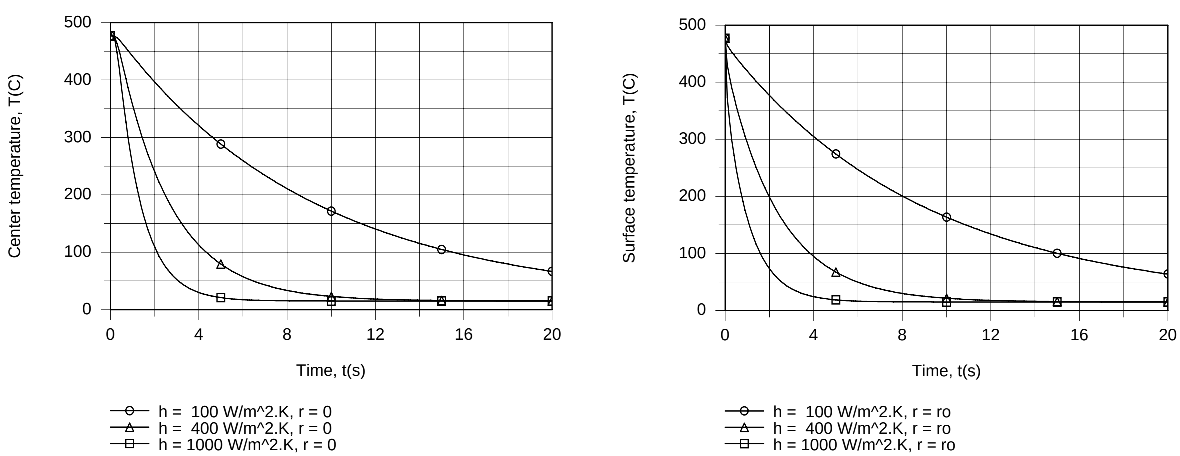
$$t \approx \frac{Fo\ r_o^2}{\alpha} = \frac{1.8(0.0015)^2}{\left[1.4\,W/m \cdot K/(2200\,kg/m^3 \times 800\,J/kg \cdot K)\right]} = 5.1\ s.$$ <

From Figure 5S.8, $$\frac{\theta(r_o,t)}{\theta_o} \approx 0.82.$$

Hence, the corresponding surface temperature is

$$T(r_o,t) \approx T_\infty + 0.82(T_o - T_\infty) = 15^\circ C + 0.82(80^\circ C - 15^\circ C) = 68.3^\circ C$$ <

(b) The effect of h on the surface and center temperatures was determined using the IHT *Transient Conduction Model* for a *Sphere*.



Continued...

PROBLEM 5S.8 (Cont.)

The cooling rate increases with increasing h, particularly from 100 to 400 $W/m^2 \cdot K$. The temperature difference between the center and surface decreases with increasing t and, during the early stages of solidification, with decreasing h.

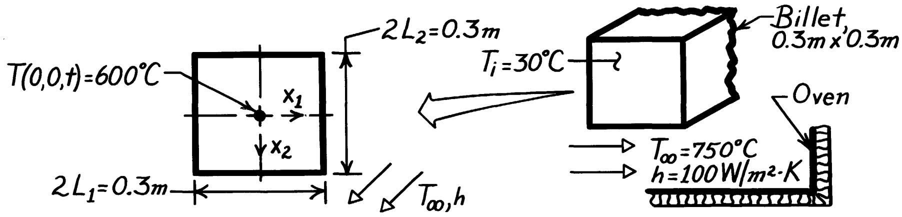
COMMENTS: Temperature gradients in the glass are largest during the early stages of solidification and increase with increasing h. Since thermal stresses increase with increasing temperature gradients, the propensity to induce defects due to crack formation in the glass increases with increasing h. Hence, there is a value of h above which product quality would suffer and the process should not be operated.

PROBLEM 5S.9

KNOWN: Steel (plain carbon) billet of square cross-section initially at a uniform temperature of 30°C is placed in a soaking oven and subjected to a convection heating process with prescribed temperature and convection coefficient.

FIND: Time required for billet center temperature to reach 600°C.

SCHEMATIC:



ASSUMPTIONS: (1) Two-dimensional conduction in x_1 and x_2 directions, (2) Constant properties, (3) Heat transfer to billet is by convection only.

PROPERTIES: *Table A-1*, Steel, plain carbon (T = (30+600)°C/2 = 588K = ≈ 600K): ρ = 7854 kg/m^3, c_p = 559 J/kg·K, k = 48.0 W/m·K, $\alpha = k/\rho c_p = 1.093 \times 10^{-5}$ m^2/s.

ANALYSIS: The billet corresponds to Case (e), Figure 5S.11 (infinite rectangular bar). Hence, the temperature distribution is of the form

$$\theta^*(x_1, x_2, t) = P(x_1, t) \times P(x_2, t)$$

where P(x,t) denotes the distribution corresponding to the plane wall. Because of symmetry in the x_1 and x_2 directions, the P functions are identical. Hence,

$$\frac{\theta(0,0,t)}{\theta_i} = \left[\frac{\theta_o(0,t)}{\theta_i}\right]^2_{\text{Plane wall}} \qquad \text{where} \begin{cases} \theta = T - T_\infty \\ \theta_i = T_i - T_\infty \\ \theta_o = T(0,t) - T_\infty \end{cases} \qquad \text{and } L = 0.15\text{m}.$$

Substituting numerical values, find

$$\frac{\theta_o(0,t)}{\theta_i} = \left[\frac{T(0,0,t) - T_\infty}{T_i - T_\infty}\right]^{1/2} = \left[\frac{(600-750)^\circ\text{C}}{(30-750)^\circ\text{C}}\right]^{1/2} = 0.46.$$

Consider now the Heisler chart for the plane wall, Figure 5S.1. For the values

$$\theta_o^* = \frac{\theta_o}{\theta_i} \approx 0.46 \qquad \text{Bi}^{-1} = \frac{k}{hL} = \frac{48.0 \text{ W/m} \cdot \text{K}}{100 \text{ W/m}^2 \cdot \text{K} \times 0.15\text{m}} = 3.2$$

find

$$t^* = \text{Fo} = \frac{\alpha\, t}{L^2} \approx 3.2.$$

Hence,

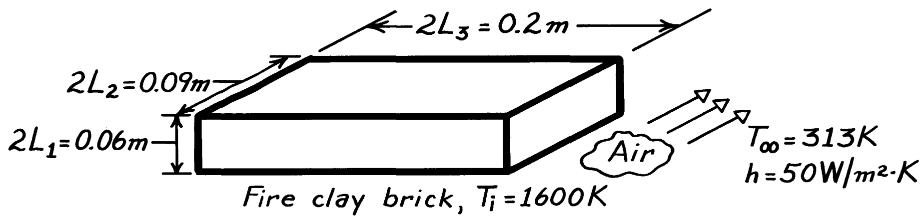
$$t = \frac{3.2\, L^2}{\alpha} = \frac{3.2\ (0.15 \text{ m})^2}{1.093 \times 10^{-5} \text{m}^2/\text{s}} = 6587 \text{ s} = 1.83 \text{ h}. \qquad <$$

PROBLEM 5S.10

KNOWN: Initial temperature of fire clay brick which is cooled by convection.

FIND: Center and corner temperatures after 50 minutes of cooling.

SCHEMATIC:



ASSUMPTIONS: (1) Homogeneous medium with constant properties, (2) Negligible radiation effects.

PROPERTIES: *Table A-3*, Fire clay brick (900K): ρ = 2050 kg/m^3, k = 1.0 W/m·K, c_p = 960 J/kg·K. $\alpha = 0.51 \times 10^{-6}$m^2/s.

ANALYSIS: From Figure 5S.11, the center temperature is given by

$$\frac{T(0,0,0,t)-T_\infty}{T_i - T_\infty} = P_1(0,t)\times P_2(0,t)\times P_3(0,t)$$

where P_1, P_2 and P_3 must be obtained from Figure 5S.1.

$$L_1 = 0.03\text{m:} \qquad Bi_1 = \frac{h\,L_1}{k} = 1.50 \qquad Fo_1 = \frac{\alpha\, t}{L_1^2} = 1.70$$

$$L_2 = 0.045\text{m:} \qquad Bi_2 = \frac{h\,L_2}{k} = 2.25 \qquad Fo_2 = \frac{\alpha\, t}{L_2^2} = 0.756$$

$$L_3 = 0.10\text{m:} \qquad Bi_3 = \frac{h\,L_3}{k} = 5.0 \qquad Fo_3 = \frac{\alpha\, t}{L_3^2} = 0.153$$

Hence from Figure 5S.1,

$$P_1(0,t) \approx 0.22 \qquad P_2(0,t) \approx 0.50 \qquad P_3(0,t) \approx 0.85.$$

Hence, $$\frac{T(0,0,0,t)-T_\infty}{T_i - T_\infty} \approx 0.22\times 0.50\times 0.85 = 0.094$$

and the center temperature is

$$T(0,0,0,t) \approx 0.094(1600-313)\text{K} + 313\text{ K} = 434\text{ K}.$$ <

Continued …

The corner temperature is given by

$$\frac{T(L_1, L_2, L_3, t) - T_\infty}{T_i - T_\infty} = P(L_1, t) \times P(L_2, t) \times P(L_3, t)$$

where

$$P(L_1, t) = \frac{\theta(L_1, t)}{\theta_o} \cdot P_1(0, t), \text{ etc.}$$

and similar forms can be written for L_2 and L_3. From Figure 5S.2,

$$\frac{\theta(L_1, t)}{\theta_o} \approx 0.55 \qquad \frac{\theta(L_2, t)}{\theta_o} \approx 0.43 \qquad \frac{\theta(L_3, t)}{\theta_o} \approx 0.25.$$

Hence,

$$P(L_1, t) \approx 0.55 \times 0.22 = 0.12$$
$$P(L_2, t) \approx 0.43 \times 0.50 = 0.22$$
$$P(L_3, t) \approx 0.85 \times 0.25 = 0.21$$

and

$$\frac{T(L_1, L_2, L_3, t) - T_\infty}{T_i - T_\infty} \approx 0.12 \times 0.22 \times 0.21 = 0.0056$$

or

$$T(L_1, L_2, L_3, t) \approx 0.0056(1600 - 313)\text{K} + 313\text{ K}.$$

The corner temperature is then

$$T(L_1, L_2, L_3, t) \approx 320\text{ K}.$$ <

COMMENTS: (1) The foregoing temperatures are overpredicted by ignoring radiation, which is significant during the early portion of the transient.

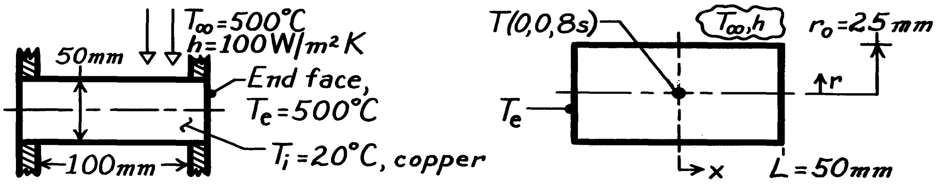
(2) Note that, if the time required to reach a certain temperature were to be determined, an iterative approach would have to be used. The foregoing procedure would be used to compute the temperature for an assumed value of the time, and the calculation would be repeated until the specified temperature were obtained.

PROBLEM 5S.11

KNOWN: Cylindrical copper pin, 100 mm long × 50 mm diameter, initially at 20°C; end faces are subjected to intense heating, suddenly raising them to 500°C; at the same time, the cylindrical surface is subjected to a convective heating process (T_∞,h).

FIND: (a) Temperature at center point of cylinder after a time of 8 seconds from sudden application of heat, (b) Consider parameters governing transient diffusion and justify simplifying assumptions that could be applied to this problem.

SCHEMATIC:



ASSUMPTIONS: (1) Two-dimensional conduction, (2) Constant properties and convection heat transfer coefficient.

PROPERTIES: *Table A-1*, Copper, pure $\left(\bar{T} \approx (500+20)^\circ C/2 \approx 500K\right)$: ρ = 8933 kg/m^3, c = 407 J/kg·K, k = 386 W/m·K, α = k/ρc = 386 W/m·K/8933 kg/m^3 × 407 J/kg·K = 1.064 × 10^{-4} m^2/s.

ANALYSIS: (1) The pin can be treated as a two-dimensional system comprised of an infinite cylinder whose surface is exposed to a convection process (T_∞,h) and of a plane wall whose surfaces are maintained at a constant temperature (T_e). This configuration corresponds to the short cylinder, Case (i) of Figure 5S.11,

$$\frac{\theta(r,x,t)}{\theta_i} = C(r,t) \times P(x,t). \tag{1}$$

For the infinite cylinder, using Figure 5S.4, with

$$Bi = \frac{hr_o}{k} = \frac{100\ W/m^2 \cdot K\left(25\times10^{-3}m\right)}{385\ W/m\cdot K} = 6.47\times10^{-3} \quad \text{and} \quad Fo = \frac{\alpha\, t}{r_o^2} = \frac{1.064\times10^{-4}\ \frac{m^2}{s}\times 8s}{\left(25\times10^{-3}m\right)^2} = 1.36,$$

find

$$C(0,8s) = \left.\frac{\theta(0,8s)}{\theta_i}\right]_{cyl} \approx 1. \tag{2}$$

For the infinite plane wall, using Figure 5S.1, with

$$Bi = \frac{hL}{k} \to \infty \quad \text{or} \quad Bi^{-1} \to 0 \quad \text{and} \quad Fo = \frac{\alpha\, t}{L^2} = \frac{1.064\times10^{-4} m^2/s\times 8s}{\left(50\times10^{-3}m\right)^2} = 0.34,$$

find

$$P(0,8s) = \left.\frac{\theta(0,8s)}{\theta_i}\right]_{wall} \approx 0.5. \tag{3}$$

Combining Equations (2) and (3) with Eq. (1), find $\frac{\theta(0,0,8s)}{\theta_i} = \frac{T(0,0,8s)-T_\infty}{T_i - T_\infty} \approx 1\times0.5 = 0.5$

$$T(0,0,8s) = T_\infty + 0.5\left(T_i - T_\infty\right) = 500 + 0.5(20-500) = 260^\circ C.$$ <

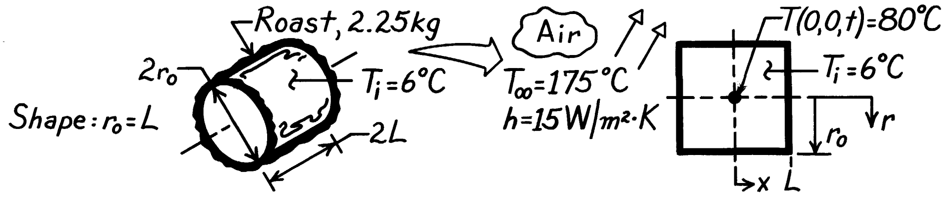
(b) The parameters controlling transient conduction with convective boundary conditions are the Biot and Fourier numbers. Since Bi << 0.1 for the cylindrical shape, we can assume radial gradients are negligible. That is, we need only consider conduction in the x-direction.

PROBLEM 5S.12

KNOWN: Cylindrical-shaped meat roast weighing 2.25 kg, initially at 6°C, is placed in an oven and subjected to convection heating with prescribed (T_∞,h).

FIND: Time required for the center to reach a done temperature of 80°C.

SCHEMATIC:



ASSUMPTIONS: (1) Two-dimensional conduction in x and r directions, (2) Uniform and constant properties, (3) Properties approximated as those of water.

PROPERTIES: *Table A-6*, Water, liquid $\left(\bar{T} = (80+6)^\circ C/2 \approx 315K\right)$:◁ ρ = $1/v_f$ = 1/1.009 × $10^{-3} m^3/kg$ = 991.1 kg/m^3, $c_{p,f}$ = 4179 J/kg·K, k = 0.634 W/m·K, α = k/ρc = 1.531 × $10^{-7} m^2/s$.

ANALYSIS: The dimensions of the roast are determined from the requirement r_o = L and knowledge of its weight and density,

$$M = \rho V = \rho \cdot 2L \cdot \pi r_o^2 \quad \text{or} \quad r_o = L = \left[\frac{M}{2\pi\rho}\right]^{1/3} = \left[\frac{2.25 \text{ kg}}{2\pi 991.1 \text{ kg/m}^3}\right]^{1/3} = 0.0712\text{m}. \qquad (1)$$

The roast corresponds to Case (i), Figure 5S.11, and the temperature distribution may be expressed as the product of one-dimensional solutions, $\frac{T(x,r,t)-T_\infty}{T_i - T_\infty} = P(x,t) \times C(r,t)$, where P(x,t) and C(r,t) are defined by Equations 5S.2 and 5S.3, respectively. For the center of the cylinder,

$$\frac{T(0,0,t)-T_\infty}{T_i - T_\infty} = \frac{(80-175)^\circ C}{(6-175)^\circ C} = 0.56. \qquad (2)$$

In terms of the product solutions,

$$\frac{T(0,0,t)-T_\infty}{T_i - T_\infty} = 0.56 = \left.\frac{T(0,t)-T_\infty}{T_i - T_\infty}\right]_{\text{wall}} \times \left.\frac{T(0,t)-T_\infty}{T_i - T_\infty}\right]_{\text{cylinder}} \qquad (3)$$

For each of these shapes, we need to find values of θ_o/θ_i such that their product satisfies Equation (3). For both shapes,

$$Bi = \frac{h\, r_o}{k} = \frac{hL}{k} = \frac{15 \text{ W/m}^2 \cdot K \times 0.0712\text{m}}{0.634 \text{ W/m} \cdot K} = 1.68 \qquad \text{or} \qquad Bi^{-1} \approx 0.6$$

$$Fo = \alpha\, t/r_o^2 = \alpha\, t/L^2 = 1.53 \times 10^{-7} \text{m}^2/\text{s} \times t/(0.0712\text{m})^2 = 3.020 \times 10^{-5} t.$$

Continued …

PROBLEM 5S.12 (Cont.)

A trial-and-error solution is necessary. Begin by assuming a value of Fo; obtain the respective θ_o/θ_i values from Figures 5S.1 and 5S.4; test whether their product satisfies Equation (3). Two trials are shown as follows:

Trial	Fo	t(hrs)	$\theta_o/\theta_i)_{wall}$	$\theta_o/\theta_i)_{cyl}$	$\left.\frac{\theta_o}{\theta_i}\right]_w \times \left.\frac{\theta_o}{\theta_i}\right]_{cyl}$
1	0.4	3.68	0.72	0.50	0.36
2	0.3	2.75	0.78	0.68	0.53

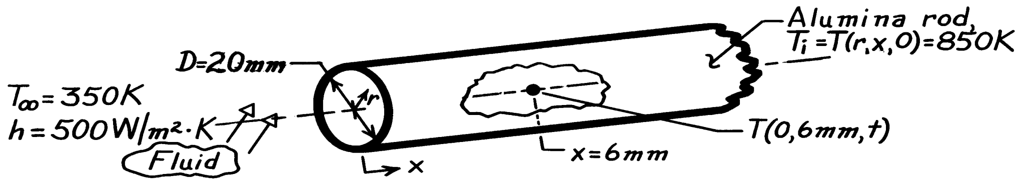
For Trial 2, the product of 0.53 agrees closely with the value of 0.56 from Equation (2). Hence, it will take approximately 2 ¾ hours to roast the meat.

PROBLEM 5S.13

KNOWN: A long alumina rod, initially at a uniform temperature of 850 K, is suddenly exposed to a cooler fluid.

FIND: Temperature of the rod after 30 s, at an exposed end, T(0,0,t), and at an axial distance 6mm from the end, T(0, 6 mm, t).

SCHEMATIC:



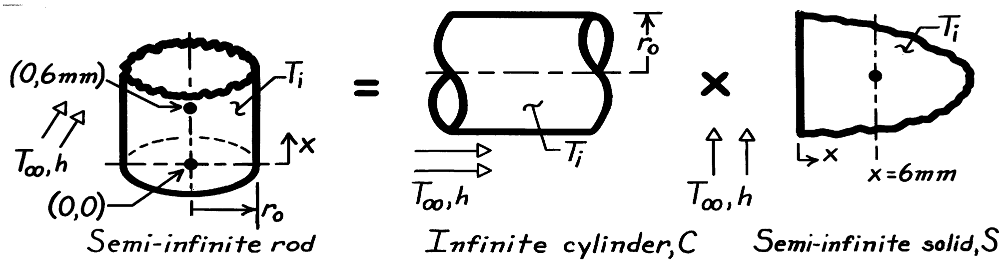
ASSUMPTIONS: (1) Two-dimensional conduction in (r,x) directions, (2) Constant properties, (3) Convection coefficient is same on end and cylindrical surfaces.

PROPERTIES: *Table A-2*, Alumina, polycrystalline aluminum oxide (assume $\bar{T} \approx (850+600)\text{K}/2 = 725\text{K}$): ρ = 3970 kg/m^3, c = 1154 J/kg·K, k = 12.4 W/m·K.

ANALYSIS: First, check if system behaves as a lumped capacitance. Find

$$\text{Bi} = \frac{hL_c}{k} = \frac{h(r_o/2)}{k} = \frac{500\ \text{W/m}\cdot\text{K}(0.010\text{m}/2)}{12.4\ \text{W/m}\cdot\text{K}} = 0.202.$$

Since Bi > 0.1, rod does not behave as spacewise isothermal object. Hence, treat rod as a semi-infinite cylinder, the multi-dimensional system Case (f), Figure 5S.11.



The product solution can be written as

$$\theta^*(r,x,t) = \frac{\theta(r,x,t)}{\theta_i} = \frac{\theta(r,t)}{\theta_i} \times \frac{\theta(x,t)}{\theta_i} = C\left(r^*,t^*\right) \times S\left(x^*,t^*\right)$$

Infinite cylinder, C(r*,t*). Using the Heisler charts with r* = r = 0 and

$$\text{Bi}^{-1} = \left[\frac{h\,r_o}{k}\right]^{-1} = \left[\frac{500\ \text{W/m}^2\cdot\text{K}\times 0.01\text{m}}{12.4\ \text{W/m}\cdot\text{K}}\right]^{-1} = 2.48.$$

Evaluate α = k/ρc = 2.71 × 10^{-6}m^2/s, find $\text{Fo} = \alpha\ t/r_o^2 = 2.71\times10^{-6}\text{m}^2/\text{s}\ \times 30\text{s}/(0.01\text{m})^2$ = 0.812. From the Heisler chart, Figure 5S.4, with Bi^{-1} = 2.48 and Fo = 0.812, read C(0,t*) = $\theta(0,t)/\theta_i$ = 0.61.

Continued …

Semi-infinite medium, S(x*,t*). Recognize this as Case (3), Figure 5.7. From Equation 5.63, note that the LHS needs to be transformed as follows,

$$\frac{T-T_i}{T_\infty - T_i} = 1 - \frac{T-T_\infty}{T_i - T_\infty} \qquad S(x,t) = \frac{T-T_\infty}{T_i - T_\infty}.$$

Thus,

$$S(x,t) = 1 - \left\{ \operatorname{erfc}\left[\frac{x}{2(\alpha\, t)^{1/2}}\right] - \left[\exp\left[\frac{hx}{k} + \frac{h^2 \alpha\, t}{k^2}\right]\right]\left[\operatorname{erfc}\left[\frac{x}{2(\alpha\, t)^{1/2}} + \frac{h(\alpha\, t)^{1/2}}{k}\right]\right]\right\}.$$

Evaluating this expression at the surface (x = 0) and 6 mm from the exposed end, find

$$S(0,30s) = 1 - \left\{ \operatorname{erfc}(0) - \left[\exp\left[0 + \frac{\left(500\ W/m^2 \cdot K\right)^2 2.71\times10^{-6} m^2/s \times 30s}{\left(12.4\ W/m\cdot K\right)^2}\right]\right]\right.$$

$$\left.\left[\operatorname{erfc}\left[0 + \frac{500\ W/m^2 \cdot K\left(2.71\times10^{-6} m^2/s \times 30s\right)^{1/2}}{12.4\ W/m\cdot K}\right]\right]\right\}$$

$$S(0,30s) = 1 - \{1 - [\exp(0.1322)][\operatorname{erfc}(0.3636)]\} = 0.693.$$

Note that Table B.2 was used to evaluate the complementary error function, erfc(w).

$$S(6mm,30s) = 1 - \left\{ \operatorname{erfc}\left[\frac{0.006m}{2\left(2.71\times10^{-6} m^2/s \times 30s\right)^{1/2}}\right] - \right.$$

$$\left.\left[\exp\left[\frac{500\ W/m^2 \cdot K \times 0.006m}{12.4\ W/m\cdot K} + 0.1322\right]\right]\left[\operatorname{erfc}(0.3327 + 0.3636)\right]\right\} = 0.835.$$

The product solution can now be evaluated for each location. At (0,0),

$$\theta^*(0,0,t) = \frac{T(0,0,30s) - T_\infty}{T_i - T_\infty} = C\left(0,t^*\right) \times S\left(0,t^*\right) = 0.61 \times 0.693 = 0.423.$$

Hence, $T(0,0,30s) = T_\infty + 0.423(T_i - T_\infty) = 350K + 0.423(850-350)K = 561\ K.$ <

At (0,6mm),

$$\theta^*(0,6mm,t) = C\left(0,t^*\right) \times S\left(6mm,t^*\right) = 0.61 \times 0.835 = 0.509$$

$$T(0,6mm,30s) = 604\ K.$$ <

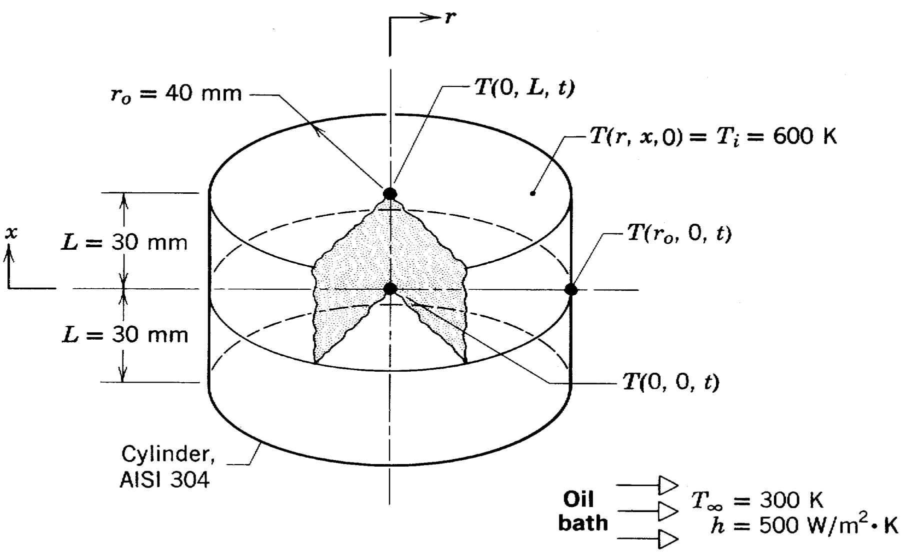
COMMENTS: Note that the temperature at which the properties were evaluated was a good estimate.

PROBLEM 5S.14

KNOWN: Stainless steel cylinder of Example 5S.1, 80-mm diameter by 60-mm length, initially at 600 K, suddenly quenched in an oil bath at 300 K with h = 500 W/m^2·K. Use the *Transient Conduction, Plane Wall* and *Cylinder* models of *IHT* to obtain the following solutions.

FIND: (a) Calculate the temperatures T(r,x,t) after 3 min: at the cylinder center, T(0, 0, 3 min), at the center of a circular face, T(0, L, 3 min), and at the midheight of the side, T(r_o, 0, 3 min); compare your results with those in the example; (b) Calculate and plot temperature histories at the cylinder center, T(0, 0, t), the mid-height of the side, T(r_o, 0, t), for $0 \le t \le 10$ min; comment on the gradients and what effect they might have on phase transformations and thermal stresses; and (c) For $0 \le t \le 10$ min, calculate and plot the temperature histories at the cylinder center, T(0, 0, t), for convection coefficients of 500 and 1000 W/m^2·K.

SCHEMATIC:



ASSUMPTIONS: (1) Two-dimensional conduction in r- and x-coordinates, (2) Constant properties.

PROPERTIES: Stainless steel (*Example 5S.1*): ρ = 7900 kg/m^3, c = 526 J/kg·K, k = 17.4 W/m·K.

ANALYSIS: The following results were obtained using the *Transient Conduction* models for the *Plane Wall* and *Cylinder* of *IHT*. Salient portions of the code are provided in the Comments.

(a) Following the methodology for a product solution outlined in Example 5S.1, the following results were obtained at t = t_o = 3 min

(r, x, t)	P(x, t)	C(r, t)	T(r, x, t)-IHT (K)	T(r, x, t)-Ex (K)
0, 0, t_o	0.6357	0.5388	402.7	405
0, L, t_o	0.4365	0.5388	370.5	372
r_o, 0, t_o	0.6357	0.3273	362.4	365

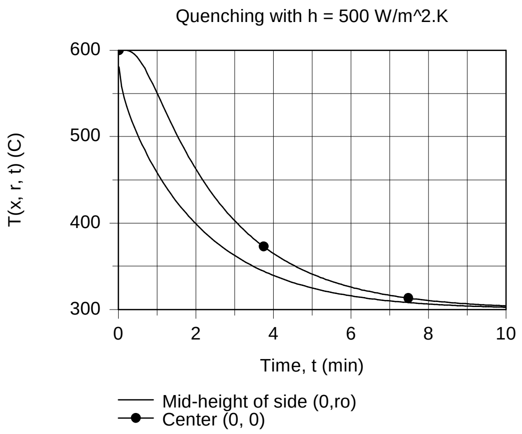
Continued …

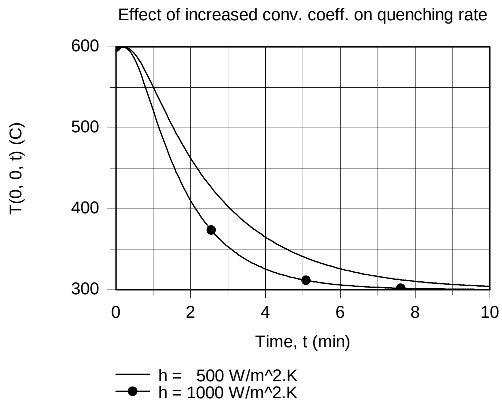
PROBLEM 5S.14 (Cont.)

The temperatures from the one-term series calculations of the Example 5S.1 are systematically higher than those resulting from the *IHT* multiple-term series model, which is the more accurate method.

(b) The temperature histories for the center and mid-height of the side locations are shown in the graph below. Note that at early times, the temperature difference between these locations, and hence the gradient, is large. Large differences could cause variations in microstructure and hence, mechanical properties, as well as induce residual thermal stresses.

(c) Effect of doubling the convection coefficient is to increase the quenching rate, but much less than by a factor of two as can be seen in the graph below.





COMMENTS: From *IHT* menu for *Transient Conduction* | *Plane Wall* and *Cylinder*, the models were combined to solve the product solution. Key portions of the code, less the input variables, are copied below.

```
// Plane wall temperature distribution
// The temperature distribution is
T_xtP = T_xt_trans("Plane Wall",xstar,FoP,BiP,Ti,Tinf)    // Eq 5.42
// The dimensionless parameters are
xstar = x / L
BiP = h * L / k                // Eq 5.9
FoP= alpha * t / L^2       // Eq 5.33
alpha = k/ (rho * cp)
// Dimensionless representation, P(x,t)
P_xt = (T_xtP - Tinf ) / (Ti - Tinf)

// Cylinder temperature distribution
// The temperature distribution T(r,t) is
T_rtC = T_xt_trans("Cylinder",rstar,FoC,BiC,Ti,Tinf)    // Eq 5.50
// The dimensionless parameters are
rstar = r / ro
BiC = h * ro / k
FoC= alpha * t / ro^2
// Dimensionless representation, C(r,t)
C_rt= (T_rtC - Tinf ) / (Ti - Tinf)

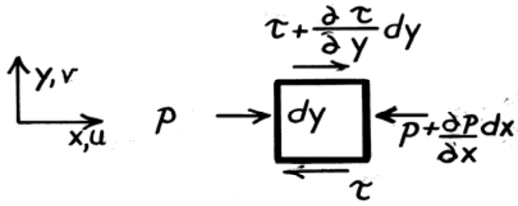
// Product solution temperature distribution
(T_xrt - Tinf) / (Ti - Tinf) = P_xt * C_rt
```

PROBLEM 6S.1

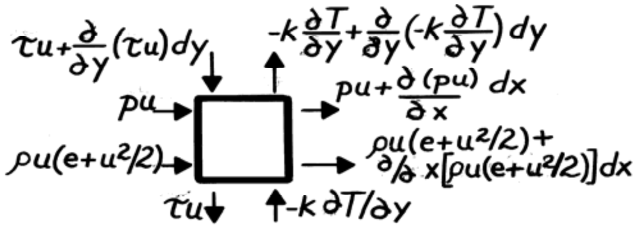
KNOWN: Two-dimensional flow conditions for which v = 0 and T = T(y).

FIND: (a) Verify that u = u(y), (b) Derive the x-momentum equation, (c) Derive the energy equation.

SCHEMATIC:



Pressure & shear forces



Energy fluxes

ASSUMPTIONS: (1) Steady-state conditions, (2) Incompressible fluid with constant properties, (3) Negligible body forces, (4) v = 0, (5) T = T(y) or $\partial T/\partial x = 0$, (6) Thermal energy generation occurs only by viscous dissipation.

ANALYSIS: (a) From the mass continuity equation, it follows from the prescribed conditions that $\partial u/\partial x = 0$. Hence u = u(y).

(b) From Newton's second law of motion, $\Sigma F_x =$ (Rate of increase of fluid momentum)$_x$,

$$\left[p-\left[p+\frac{\partial p}{\partial x}dx\right]\right]dy\cdot 1+\left[-\tau+\left[\tau+\frac{\partial \tau}{\partial y}dy\right]\right]dx\cdot 1=\left\{(\rho u)u+\frac{\partial}{\partial x}[(\rho u)u]dx\right\}dy\cdot 1-(\rho u)u\,dy\cdot 1$$

Hence, with $\tau=\mu(\partial u/\partial y)$, it follows that

$$-\frac{\partial p}{\partial x}+\frac{\partial \tau}{\partial y}=\frac{\partial}{\partial x}[(\rho u)u]=0 \qquad \frac{\partial p}{\partial x}=\mu\frac{\partial^2 u}{\partial y^2}.$$ <

(c) From the conservation of energy requirement and the prescribed conditions, it follows that $\dot{E}_{in}-\dot{E}_{out}=0$, or

$$\left[pu+\rho u\left(e+u^2/2\right)\right]dy\cdot 1+\left[-k\frac{\partial T}{\partial y}+\tau u+\frac{\partial(\tau u)}{\partial y}dy\right]dx\cdot 1$$

$$-\left\{pu+\frac{\partial}{\partial x}(pu)dx+\rho u\left(e+u^2/2\right)+\frac{\partial}{\partial x}\left[\rho u\left(e+u^2/2\right)\right]dx\right\}dy\cdot 1-\left[\tau u-k\frac{\partial T}{\partial y}+\frac{\partial}{\partial y}\left[-k\frac{\partial T}{\partial y}\right]dy\right]dx\cdot 1=0$$

or, $$\frac{\partial(\tau u)}{\partial y}-\frac{\partial}{\partial x}(pu)-\frac{\partial}{\partial x}\left[\rho u\left(e+u^2/2\right)\right]+\frac{\partial}{\partial y}\left[k\frac{\partial T}{\partial y}\right]=0$$

$$\tau\frac{\partial u}{\partial y}+u\frac{\partial \tau}{\partial y}-u\frac{\partial p}{\partial x}+k\frac{\partial^2 T}{\partial y^2}=0.$$

Noting that the second and third terms cancel from the momentum equation,

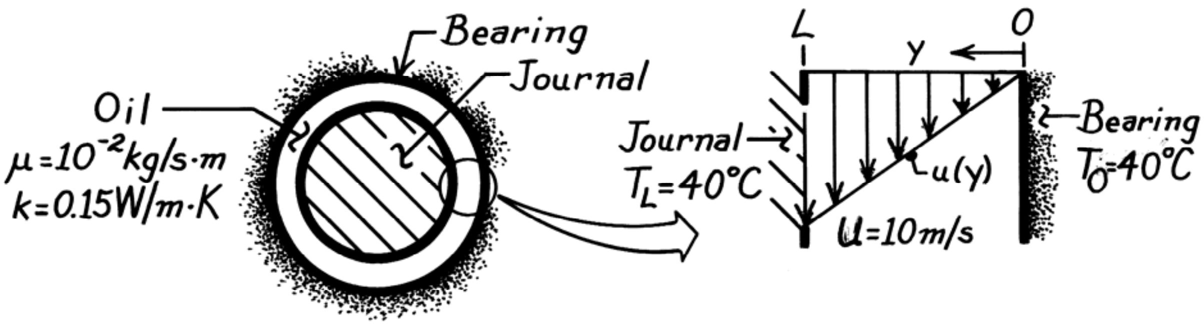
$$\mu\left[\frac{\partial u}{\partial y}\right]^2+k\left[\frac{\partial^2 T}{\partial y^2}\right]=0.$$ <

PROBLEM 6S.2

KNOWN: Oil properties, journal and bearing temperatures, and journal speed for a lightly loaded journal bearing.

FIND: Maximum oil temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Incompressible fluid with constant properties, (3) Clearance is much less than journal radius and flow is Couette.

ANALYSIS: The temperature distribution corresponds to the result obtained in the text Example on Couette flow,

$$T(y) = T_0 + \frac{\mu}{2k} U^2 \left[\frac{y}{L} - \left[\frac{y}{L} \right]^2 \right].$$

The position of maximum temperature is obtained from

$$\frac{dT}{dy} = 0 = \frac{\mu}{2k} U^2 \left[\frac{1}{L} - \frac{2y}{L^2} \right]$$

or, $y = L/2.$

The temperature is a maximum at this point since $d^2T/dy^2 < 0$. Hence,

$$T_{max} = T(L/2) = T_0 + \frac{\mu}{2k} U^2 \left[\frac{1}{2} - \frac{1}{4} \right] = T_0 + \frac{\mu U^2}{8k}$$

$$T_{max} = 40^\circ C + \frac{10^{-2} kg/s \cdot m (10 m/s)^2}{8 \times 0.15\ W/m \cdot K}$$

$$T_{max} = 40.83^\circ C.$$ <

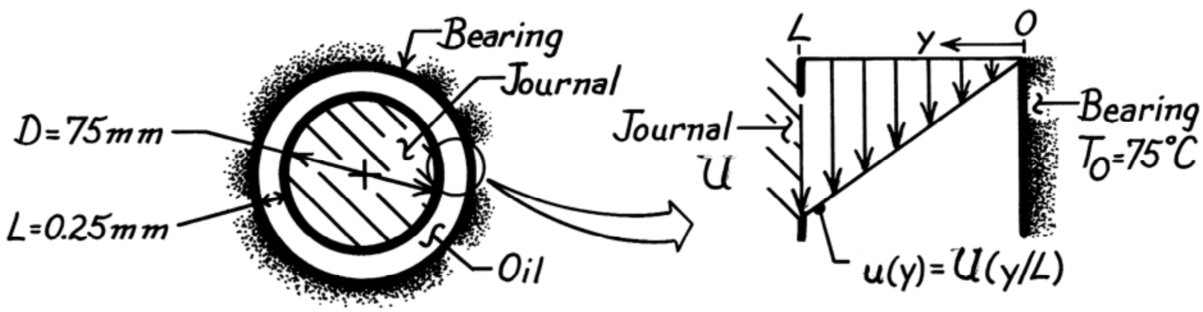
COMMENTS: Note that T_{max} *increases* with *increasing* μ and U, *decreases* with *increasing* k, and is *independent* of L.

PROBLEM 6S.3

KNOWN: Diameter, clearance, rotational speed and fluid properties of a lightly loaded journal bearing. Temperature of bearing.

FIND: (a) Temperature distribution in the fluid, (b) Rate of heat transfer from bearing and operating power.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Incompressible fluid with constant properties, (3) Couette flow.

PROPERTIES: Oil (Given): $\rho = 800\ kg/m^3$, $\nu = 10^{-5}\ m^2/s$, $k = 0.13\ W/m\cdot K$; $\mu = \rho\nu = 8 \times 10^{-3}\ kg/s\cdot m$.

ANALYSIS: (a) For Couette flow, the velocity distribution is linear, u(y) = U(y/L), and the energy equation and general form of the temperature distribution are

$$k\frac{d^2T}{dy^2} = -\mu\left[\frac{du}{dy}\right]^2 = -\mu\left[\frac{U}{L}\right]^2 \qquad T = -\frac{\mu}{2k}\left[\frac{U}{L}\right]^2 y^2 + \frac{C_1}{k}y + C_2.$$

Considering the boundary conditions $dT/dy)_{y=L} = 0$ and $T(0) = T_0$, find $C_2 = T_0$ and $C_1 = \mu U^2/L$. Hence,

$$T = T_0 + \left(\mu U^2\right)/k\left[\left(y/L\right) - 1/2\left(y/L\right)^2\right]. \qquad <$$

(b) Applying Fourier's law at y = 0, the rate of heat transfer per unit length to the bearing is

$$q' = -k\left(\pi\ D\right)\frac{dT}{dy}\bigg]_{y=0} = -\left(\pi\ D\right)\frac{\mu U^2}{L} = -\left(\pi \times 75 \times 10^{-3} m\right)\frac{8\times10^{-3} kg/s\cdot m\ (14.14\ m/s)^2}{0.25\times10^{-3} m} = -1507.5\ W/m$$

where the velocity is determined as

$$U = \left(D/2\right)\omega = 0.0375m \times 3600\ rev/min\ \left(2\pi\ rad/rev\right)/\left(60\ s/min\right) = 14.14\ m/s.$$

The journal power requirement is

$$P' = F'_{(y=L)}U = \tau_{s(y=L)} \cdot \pi\ D \cdot U$$

$$P' = 452.5 kg/s^2 \cdot m\ \left(\pi \times 75 \times 10^{-3} m\right)14.14 m/s = 1507.5 kg \cdot m/s^3 = 1507.5 W/m \qquad <$$

where the shear stress at y = L is

$$\tau_{s(y=L)} = \mu\left(\partial\ u/\partial\ y\right)_{y=L} = \mu\frac{U}{L} = 8\times10^{-3} kg/s\cdot m\left[\frac{14.14\ m/s}{0.25\times10^{-3} m}\right] = 452.5\ kg/s^2 \cdot m.$$

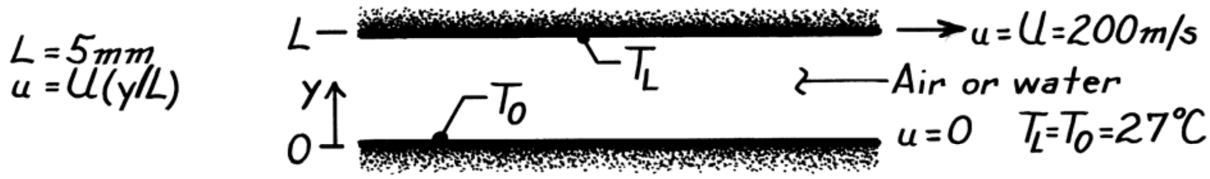
COMMENTS: Note that $q' = P'$, which is consistent with the energy conservation requirement.

PROBLEM 6S.4

KNOWN: Conditions associated with the Couette flow of air or water.

FIND: (a) Force and power requirements per unit surface area, (b) Viscous dissipation, (c) Maximum fluid temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Fully-developed Couette flow, (2) Incompressible fluid with constant properties.

PROPERTIES: *Table A-4*, Air (300K): $\mu = 184.6 \times 10^{-7}$ N·s/m^2, k = 26.3×10^{-3} W/m·K; *Table A-6*, Water (300K): $\mu = 855 \times 10^{-6}$ N·s/m^2, k = 0.613 W/m·K.

ANALYSIS: (a) The force per unit area is associated with the shear stress. Hence, with the linear velocity profile for Couette flow, $\tau = \mu(\mathrm{du/dy}) = \mu(\mathrm{U/L})$.

Air: $$\tau_{air} = 184.6 \times 10^{-7}\ \mathrm{N \cdot s/m^2} \times \frac{200\ \mathrm{m/s}}{0.005\ \mathrm{m}} = 0.738\ \mathrm{N/m^2}$$ <

Water: $$\tau_{water} = 855 \times 10^{-6}\ \mathrm{N \cdot s/m^2} \times \frac{200\ \mathrm{m/s}}{0.005\ \mathrm{m}} = 34.2\ \mathrm{N/m^2}.$$

With the required power given by P/A = $\tau \cdot \mathrm{U}$,

Air: $$(\mathrm{P/A})_{air} = \left(0.738\ \mathrm{N/m^2}\right) 200\ \mathrm{m/s} = 147.6\ \mathrm{W/m^2}$$ <

Water: $$(\mathrm{P/A})_{water} = \left(34.2\ \mathrm{N/m^2}\right) 200\ \mathrm{m/s} = 6840\ \mathrm{W/m^2}.$$

(b) The viscous dissipation is $\mu\Phi = \mu(\mathrm{du/dy})^2 = \mu(\mathrm{U/L})^2$. Hence,

Air: $$(\mu\Phi)_{air} = 184.6 \times 10^{-7}\ \frac{\mathrm{N \cdot s}}{\mathrm{m^2}} \left[\frac{200\ \mathrm{m/s}}{0.005\ \mathrm{m}}\right]^2 = 2.95 \times 10^4\ \mathrm{W/m^3}$$ <

Water: $$(\mu\Phi)_{water} = 855 \times 10^{-6}\ \frac{\mathrm{N \cdot s}}{\mathrm{m^2}} \left[\frac{200\ \mathrm{m/s}}{0.005\ \mathrm{m}}\right]^2 = 1.37 \times 10^6\ \mathrm{W/m^3}.$$

(c) From the solution to Part 4 of Example 6S.1, the location of the maximum temperature corresponds to y_{max} = L/2. Hence, $T_{max} = T_0 + \mu U^2 / 8k$ and

Air: $$(T_{max})_{air} = 27°\mathrm{C} + \frac{184.6 \times 10^{-7}\ \mathrm{N \cdot s/m^2}\,(200\ \mathrm{m/s})^2}{8 \times 0.0263\ \mathrm{W/m \cdot K}} = 30.5°\mathrm{C}$$ <

Water: $$(T_{max})_{water} = 27°\mathrm{C} + \frac{855 \times 10^{-6}\ \mathrm{N \cdot s/m^2}\,(200\ \mathrm{m/s})^2}{8 \times 0.613\ \mathrm{W/m \cdot K}} = 34.0°\mathrm{C}.$$

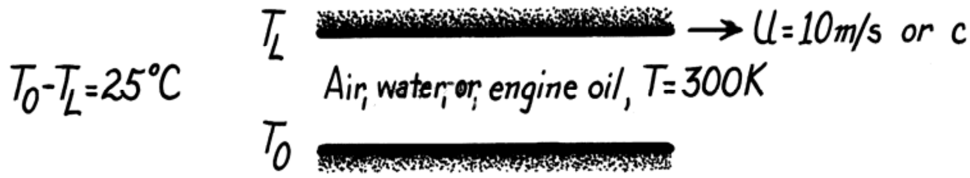
COMMENTS: (1) The viscous dissipation associated with the entire fluid layer, $\mu\Phi(\mathrm{LA})$, must equal the power, P. (2) Although $(\mu\Phi)_{water} >> (\mu\Phi)_{air}$, $k_{water} >> k_{air}$. Hence, $T_{max,water} \approx T_{max,air}$.

PROBLEM 6S.5

KNOWN: Velocity and temperature difference of plates maintaining Couette flow. Mean temperature of air, water or oil between the plates.

FIND: (a) Pr·Ec product for each fluid, (b) Pr·Ec product for air with plate at sonic velocity.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Couette flow, (3) Air is at 1 atm.

PROPERTIES: *Table A-4*, Air (300K, 1atm), c_p = 1007 J/kg·K, Pr = 0.707, γ = 1.4, R= 287.02 J/kg·K; *Table A-6*, Water (300K): c_p = 4179 J/kg·K, Pr = 5.83; *Table A-5*, Engine oil (300K), c_p = 1909 J/kg·K, Pr = 6400.

ANALYSIS: The product of the Prandtl and Eckert numbers is dimensionless,

$$\Pr\cdot Ec = \Pr \frac{U^2}{c_p \Delta T} \frown \frac{m^2/s^2}{(J/kg\cdot K)K} \frown \frac{m^2/s^2}{\left(kg\cdot m^2/s^2\right)/kg}.$$

Substituting numerical values, find

	Air	Water	Oil
Pr·Ec	0.0028	0.0056	13.41

<

(b) For an ideal gas, the speed of sound is

$$c = (\gamma\ R\ T)^{1/2}$$

where R, the gas constant for air, is $R_u/\mathcal{M}$ = 8.315 kJ/kmol·K/(28.97 kg/kmol) = 287.02 J/kg·K. Hence, at 300K for air,

$$U = c = (1.4 \times 287.02\ J/kg\cdot K \times 300K)^{1/2} = 347.2\ m/s.$$

For sonic velocities, it follows that

$$\Pr\cdot Ec = 0.707 \frac{(347.2\ m/s)^2}{1007 J/kg\cdot K \times 25K} = 3.38.$$ <

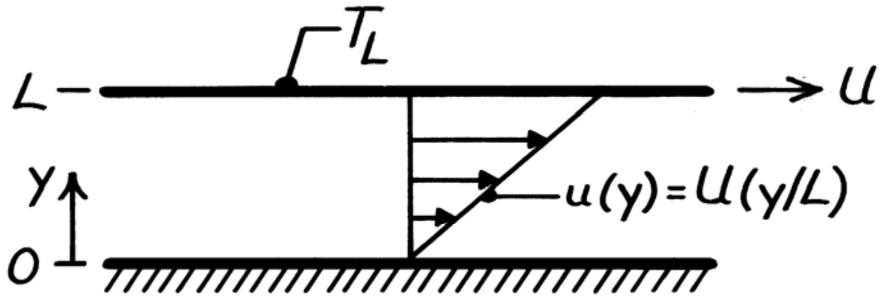
COMMENTS: From the above results it follows that viscous dissipation effects must be considered in the high speed flow of gases and in oil flows at moderate speeds. For Pr·Ec to be less than 0.1 in air with ΔT = 25°C, U should be $\lesssim$ 60 m/s.

PROBLEM 6S.6

KNOWN: Couette flow with moving plate isothermal and stationary plate insulated.

FIND: Temperature of stationary plate and heat flux at the moving plate.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Incompressible fluid with constant properties, (3) Couette flow.

ANALYSIS: The energy equation is given by

$$0 = k\left[\frac{\partial^2 T}{\partial y^2}\right] + \mu\left[\frac{\partial u}{\partial y}\right]^2$$

Integrating twice find the general form of the temperature distribution,

$$\frac{\partial^2 T}{\partial y^2} = -\frac{\mu}{k}\left[\frac{U}{L}\right]^2 \qquad \frac{\partial T}{\partial y} = -\frac{\mu}{k}\left[\frac{U}{L}\right]^2 y + C_1$$

$$T(y) = -\frac{\mu}{2k}\left[\frac{U}{L}\right]^2 y^2 + C_1 y + C_2.$$

Consider the boundary conditions to evaluate the constants,

$$\partial T/\partial y\Big|_{y=0} = 0 \;\rightarrow\; C_1 = 0 \;\text{ and }\; T(L) = T_L \;\rightarrow\; C_2 = T_L + \frac{\mu}{2k}U^2.$$

Hence, the temperature distribution is

$$T(y) = T_L + \left[\frac{\mu U^2}{2k}\right]\left[1 - \left[\frac{y}{L}\right]^2\right].$$

The temperature of the lower plate (y = 0) is

$$T(0) = T_L + \left[\frac{\mu U^2}{2k}\right].$$ <

The heat flux to the upper plate (y = L) is

$$q''(L) = -k\frac{\partial T}{\partial y}\Big|_{y=L} = \frac{\mu U^2}{L}.$$ <

COMMENTS: The heat flux at the top surface may also be obtained by integrating the viscous dissipation over the fluid layer height. For a control volume about a unit area of the fluid layer,

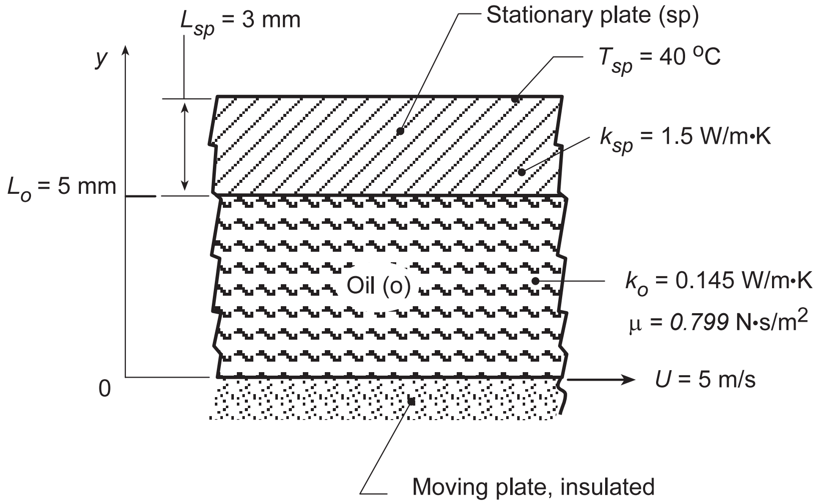
$$\dot{E}''_g = \dot{E}''_{out} \qquad \int_0^L \mu\left[\frac{\partial u}{\partial y}\right]^2 dy = q''(L) \qquad q''(L) = \frac{\mu U^2}{L}.$$

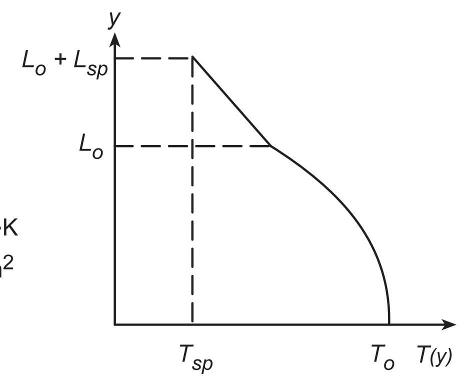
PROBLEM 6S.7

KNOWN: Couette flow with heat transfer. Lower (insulated) plate moves with speed U and upper plate is stationary with prescribed thermal conductivity and thickness. Outer surface of upper plate maintained at constant temperature, T_{sp} = 40°C.

FIND: (a) On T-y coordinates, sketch the temperature distribution in the oil and the stationary plate, and (b) An expression for the temperature at the lower surface of the oil film, $T(0) = T_o$, in terms of the plate speed U, the stationary plate parameters (T_{sp}, k_{sp}, L_{sp}) and the oil parameters (μ, k_o, L_o). Determine this temperature for the prescribed conditions.

SCHEMATIC:





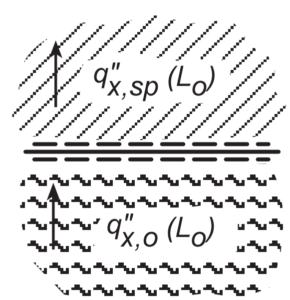
ASSUMPTIONS: (1) Steady-state conditions, (2) Fully developed Couette flow and (3) Incompressible fluid with constant properties.

ANALYSIS: (a) The temperature distribution is shown above with these key features: linear in plate, parabolic in oil film, discontinuity in slope at plate-oil interface, and zero gradient at lower plate surface.

(b) From Example 6S.1, the general solution to the conservation equations for the temperature distribution in the oil film is

$$T_o(y) = -Ay^2 + C_3 y + C_4 \qquad \text{where} \qquad A = \frac{\mu}{2k_o}\left(\frac{U}{L_o}\right)^2$$

and the boundary conditions are,



At y = 0, insulated boundary $\left.\frac{dT_o}{dy}\right)_{y=0} = 0$; $C_3 = 0$

At y = L_o, heat fluxes in oil and plate are equal, $q''_o(L_o) = q''_{sp}(L_o)$

Continued...

PROBLEM 6S.7 (Cont.)

$$-k_o \left.\frac{dT_o}{dy}\right)_{y=L_o} = \frac{T_o(L_o) - T_{sp}}{R_{sp}} \qquad \begin{cases} \left.\dfrac{dT_o}{dy}\right)_{y=L_o} = -2AL_o \\ R_{sp} = L_{sp}/k_{sp} \qquad T_o(L_o) = -AL_o^2 + C_4 \end{cases}$$

$$C_4 = T_{sp} + AL_o^2 \left[1 + 2\frac{k_o}{L_o}\frac{L_{sp}}{k_{sp}}\right]$$

Hence, the temperature distribution at the lower surface is

$$T_o(0) = -A \cdot 0 + C_4$$

$$T_o(0) = T_{sp} + \frac{\mu}{2k_o}U^2\left[1 + 2\frac{k_o}{L_o}\frac{L_{sp}}{k_{sp}}\right] \qquad <$$

Substituting numerical values, find

$$T_o(0) = 40^\circ C + \frac{0.799\,N\cdot s/m^2}{2\times 0.145\,W/m\cdot K}(5\,m/s)^2\left[1 + 2\frac{0.145}{5}\times\frac{3}{1.5}\right] = 116.9^\circ C \qquad <$$

COMMENTS: (1) Give a physical explanation about why the maximum temperature occurs at the lower surface.

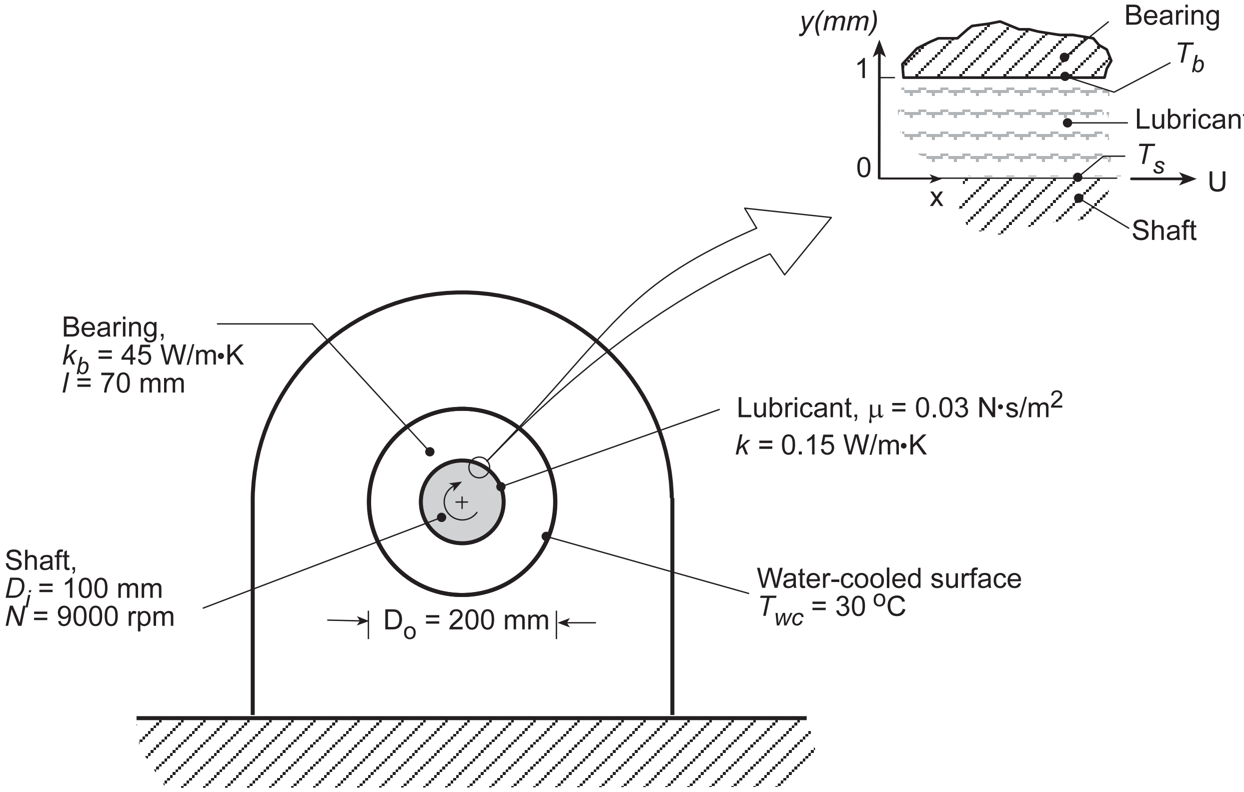
(2) Sketch the temperature distribution if the upper plate moved with a speed U while the lower plate is stationary and all other conditions remain the same.

PROBLEM 6S.8

KNOWN: Shaft of diameter 100 mm rotating at 9000 rpm in a journal bearing of 70 mm length. Uniform gap of 1 mm separates the shaft and bearing filled with lubricant. Outer surface of bearing is water-cooled and maintained at T_{wc} = 30°C.

FIND: (a) Viscous dissipation in the lubricant, $\mu\Phi(W/m^3)$, (b) Heat transfer rate from the lubricant, assuming no heat lost through the shaft, and (c) Temperatures of the bearing and shaft, T_b and T_s.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Fully developed Couette flow, (3) Incompressible fluid with constant properties, and (4) Negligible heat lost through the shaft.

ANALYSIS: (a) The viscous dissipation, μΦ, Eq. 6S.20, for Couette flow from Example 6S.1, is

$$\mu\Phi = \mu\left(\frac{du}{dy}\right)^2 = \mu\left(\frac{U}{L}\right)^2 = 0.03\,N\cdot s/m^2\left(\frac{47.1\,m/s}{0.001\,m}\right)^2 = 6.656\times10^7\ W/m^3 \qquad <$$

where the velocity distribution is linear and the tangential velocity of the shaft is

$$U = \pi DN = \pi(0.100\,m)\times 9000\,rpm\times(min/60s) = 47.1\,m/s\,.$$

(b) The heat transfer rate from the lubricant volume ∀ through the bearing is

$$q = \mu\Phi\cdot\forall = \mu\Phi(\pi D\cdot L\cdot\ell) = 6.65\times10^7\ W/m^3(\pi\times0.100\,m\times0.001\,m\times0.070\,m) = 1462\,W \qquad <$$

where ℓ = 70 mm is the length of the bearing normal to the page.

Continued...

PROBLEM 6S.8 (Cont.)

(c) From Fourier's law, the heat rate through the bearing material of inner and outer diameters, D_i and D_o, and thermal conductivity k_b is, from Eq. (3.32),

$$q_r = \frac{2\pi \ell k_b (T_b - T_{wc})}{\ln(D_o/D_i)}$$

$$T_b = T_{wc} + \frac{q_r \ln(D_o/D_i)}{2\pi \ell k_b}$$

$$T_b = 30^\circ C + \frac{1462\,W \ln(200/100)}{2\pi \times 0.070\,m \times 45\,W/m\cdot K} = 81.2^\circ C$$ <

To determine the temperature of the shaft, $T(0) = T_s$, first the temperature distribution must be found beginning with the general solution, Example 6S.1,

$$T(y) = -\frac{\mu}{2k}\left(\frac{U}{L}\right)^2 y^2 + C_3 y + C_4$$

The boundary conditions are, at y = 0, the surface is adiabatic

$$\left.\frac{dT}{dy}\right)_{y=0} = 0 \qquad C_3 = 0$$

and at y = L, the temperature is that of the bearing, T_b

$$T(L) = T_b = -\frac{\mu}{2k}\left(\frac{U}{L}\right)^2 L^2 + 0 + C_4 \qquad C_4 = T_b + \frac{\mu}{2k}U^2$$

Hence, the temperature distribution is

$$T(y) = T_b + \frac{\mu}{2k}U^2\left(1 - \frac{y^2}{L^2}\right)$$

and the temperature at the shaft, y = 0, is

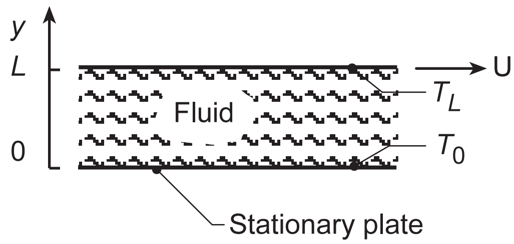
$$T_s = T(0) = T_b + \frac{\mu}{2k}U^2 = 81.3^\circ C + \frac{0.03\,N\cdot s/m^2}{2\times 0.15\,W/m\cdot K}(47.1\,m/s)^2 = 303^\circ C$$ <

PROBLEM 6S.9

KNOWN: Couette flow with heat transfer.

FIND: (a) Dimensionless form of temperature distribution, (b) Conditions for which top plate is adiabatic, (c) Expression for heat transfer to lower plate when top plate is adiabatic.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) incompressible fluid with constant properties, (3) Negligible body forces, (4) Couette flow.

ANALYSIS: (a) From Example 6.4, the temperature distribution is

$$T = T_0 + \frac{\mu}{2k}U^2\left[\frac{y}{L} - \left(\frac{y}{L}\right)^2\right] + (T_L - T_0)\frac{y}{L}$$

$$\frac{T - T_0}{T_L - T_0} = \frac{\mu U^2}{2k(T_L - T_0)}\left[\frac{y}{L} - \left(\frac{y}{L}\right)^2\right] + \frac{y}{L}$$

or, with

$$\theta \equiv (T - T_0)/T_L - T_0, \qquad \eta \equiv y/L,$$

$$\Pr \equiv c_p\mu/k, \qquad Ec \equiv U^2/c_p(T_L - T_0)$$

$$\theta = \frac{\Pr \cdot Ec}{2}\left(\eta - \eta^2\right) + \eta = \eta\left[1 + \frac{1}{2}\Pr \cdot Ec(1 - \eta)\right] \qquad (1) <$$

(b) For there to be zero heat transfer at the top plate, $(dT/dy)_{y=L} = 0$. Hence, $(d\theta/d\eta)_{\eta=1} = 0$.

$$\left.\frac{d\theta}{d\eta}\right)_{\eta=1} = \frac{\Pr \cdot Ec}{2}(1 - 2\eta)\Big|_{\eta=1} + 1 = -\frac{\Pr \cdot Ec}{2} + 1 = 0$$

There is no heat transfer at the top plate if,

$$Ec \cdot \Pr = 2. \qquad (2) <$$

(c) The heat transfer rate to the lower plate (per unit area) is

$$q_0'' = -k\left.\frac{dT}{dy}\right|_{y=0} = -k\frac{(T_L - T_0)}{L}\left.\frac{d\theta}{d\eta}\right|_{\eta=0}$$

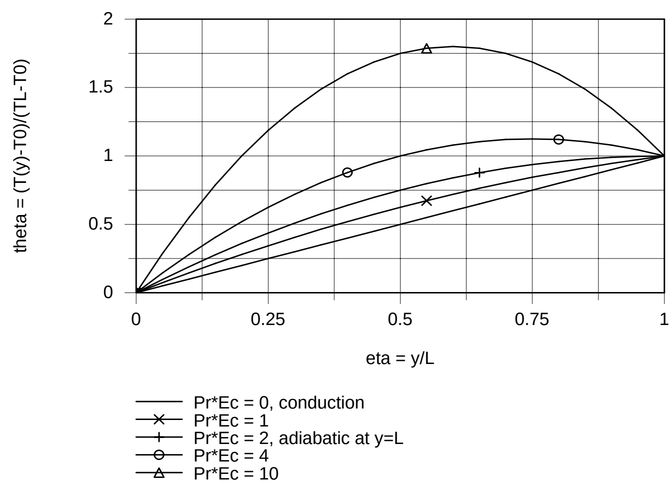
$$q_0'' = -k\frac{T_L - T_0}{L}\left[\frac{\Pr \cdot Ec}{2}(1 - 2\eta)\Big|_{\eta=0} + 1\right]$$

$$q_0'' = -k\frac{T_L - T_0}{L}\left(\frac{\Pr \cdot Ec}{2} + 1\right) = -2k(T_L - T_0)/L \qquad <$$

Continued...

PROBLEM 6S.9 (Cont.)

(d) Using Eq. (1), the dimensionless temperature distribution is plotted as a function of dimensionless distance, $\eta = y/L$. When Pr·Ec = 0, there is no dissipation and the temperature distribution is linear, so that heat transfer is by conduction only. As Pr ·Ec increases, viscous dissipation becomes more important. When Pr·Ec = 2, heat transfer to the upper plate is zero. When Pr·Ec > 2, the heat rate is out of the oil film at both surfaces.

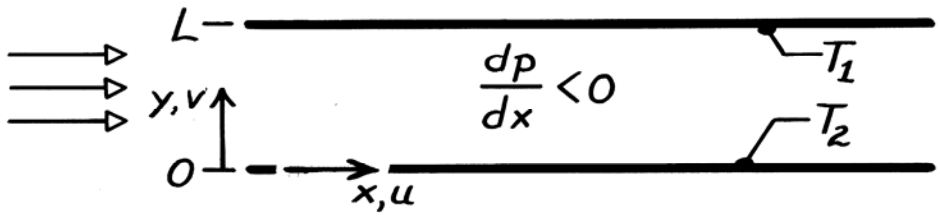


PROBLEM 6S.10

KNOWN: Steady, incompressible, laminar flow between infinite parallel plates at different temperatures.

FIND: (a) Form of continuity equation, (b) Form of momentum equations and velocity profile. Relationship of pressure gradient to maximum velocity, (c) Form of energy equation and temperature distribution. Heat flux at top surface.

SCHEMATIC:



ASSUMPTIONS: (1) Two-dimensional flow (no variations in z) between infinite, parallel plates, (2) Negligible body forces, (3) No internal energy generation, (4) Incompressible fluid with constant properties.

ANALYSIS: (a) For two-dimensional, steady conditions, the continuity equation is

$$\frac{\partial(\rho\,u)}{\partial\,x}+\frac{\partial(\rho\,v)}{\partial\,y}=0.$$

Hence, for an incompressible fluid (constant ρ) in parallel flow (v = 0),

$$\frac{\partial\,u}{\partial\,x}=0.$$ <

The flow is fully developed in the sense that, irrespective of y, u is independent of x.

(b) With the above result and the prescribed conditions, the momentum equations reduce to

$$0=-\frac{\partial\,p}{\partial\,x}+\mu\frac{\partial^2 u}{\partial\,y^2}\qquad 0=-\frac{\partial\,p}{\partial\,y}$$ <

Since p is independent of y, ∂p/∂x = dp/dx is independent of y and

$$\mu\frac{\partial^2 u}{\partial\,y^2}=\mu\frac{d^2u}{dy^2}=\frac{dp}{dx}.$$

Since the left-hand side can, at most, depend only on y and the right-hand side is independent of y, both sides must equal the same constant C. That is,

$$\mu\frac{d^2u}{dy^2}=C.$$

Hence, the velocity distribution has the form

$$u(y)=\frac{C}{2\mu}y^2+C_1y+C_2.$$

Using the boundary conditions to evaluate the constants,

$$u(0)=0\quad\rightarrow\quad C_2=0\quad\text{and}\quad u(L)=0\quad\rightarrow\quad C_1=-CL/2\mu.$$

Continued …..

PROBLEM 6S.10 (Cont.)

The velocity profile is $u(y) = \frac{C}{2\mu}\left(y^2 - Ly\right).$

The profile is symmetric about the midplane, in which case the maximum velocity exists at y = L/2. Hence,

$$u(L/2) = u_{max} = \frac{C}{2\mu}\left[-\frac{L^2}{4}\right] \qquad \text{or} \qquad u_{max} = -\frac{L^2}{8\mu}\frac{dp}{dx}. \qquad <$$

(c) For fully developed thermal conditions, $(\partial T/\partial x) = 0$ and temperature depends only on y. Hence with v = 0, $\partial u/\partial x = 0$, and the prescribed assumptions, the energy equation becomes

$$\rho\, u \frac{\partial i}{\partial x} = k\frac{d^2T}{dy^2} + u\frac{dp}{dx} + \mu\left[\frac{du}{dy}\right]^2.$$

With $i = e + p/\rho$, $\quad \frac{\partial i}{\partial x} = \frac{\partial e}{\partial x} + \frac{1}{\rho}\frac{dp}{dx}$ where $\frac{\partial e}{\partial x} = \frac{\partial e}{\partial T}\frac{\partial T}{\partial x} + \frac{\partial e}{\partial \rho}\frac{\partial \rho}{\partial x} = 0.$

Hence, the energy equation becomes $\quad 0 = k\frac{d^2T}{dy^2} + \mu\left[\frac{du}{dy}\right]^2. \qquad <$

With $du/dy = (C/2\mu)(2y - L)$, it follows that

$$\frac{d^2T}{dy^2} = -\frac{C^2}{4k\mu}\left(4y^2 - 4Ly + L^2\right).$$

Integrating twice,

$$T(y) = -\frac{C^2}{4k\mu}\left[\frac{y^4}{3} - \frac{2Ly^3}{3} + \frac{L^2y^2}{2}\right] + C_3 y + C_4$$

Using the boundary conditions to evaluate the constants,

$$T(0) = T_2 \quad \rightarrow \quad C_4 = T_2 \quad \text{and} \quad T(L) = T_1 \quad \rightarrow \quad C_3 = \frac{C^2L^3}{24k\mu} + \frac{(T_1 - T_2)}{L}.$$

Hence, $\quad T(y) = T_2 + \left[\frac{y}{L}\right](T_1 - T_2) - \frac{C^2}{4k\mu}\left[\frac{y^4}{3} - \frac{2Ly^3}{3} + \frac{L^2y^2}{2} - \frac{L^3y}{6}\right]. \qquad <$

From Fourier's law,

$$q''(L) = -k\left.\frac{\partial T}{\partial y}\right|_{y=L} = \frac{k}{L}(T_2 - T_1) + \frac{C^2}{4\mu}\left[\frac{4}{3}L^3 - 2L^3 + L^3 - \frac{L^3}{6}\right]$$

$$q''(L) = \frac{k}{L}(T_2 - T_1) + \frac{C^2L^3}{24\mu}. \qquad <$$

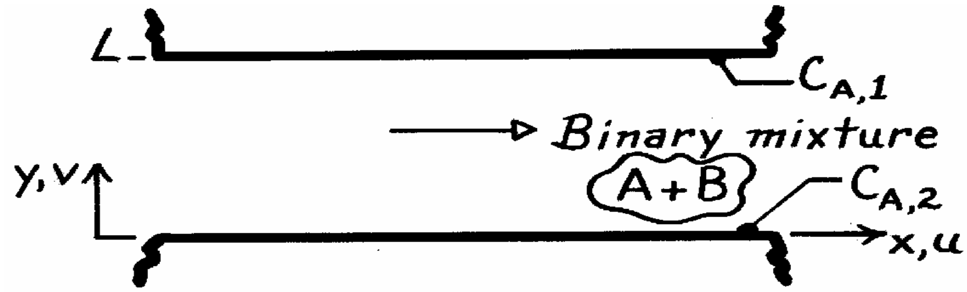
COMMENTS: The third and second terms on the right-hand sides of the temperature distribution and heat flux, respectively, represents the effects of viscous dissipation. If C is large (due to large μ or u_{max}), viscous dissipation is significant. If C is small, conduction effects dominate.

PROBLEM 6S.11

KNOWN: Steady, incompressible flow of binary mixture between infinite parallel plates with different species concentrations.

FIND: Form of species continuity equation and concentration distribution. Species flux at upper surface.

SCHEMATIC:



ASSUMPTIONS: (1) Two-dimensional flow, (2) No chemical reactions, (3) Constant properties.

ANALYSIS: For fully developed conditions, $\partial C_A/\partial x = 0$. Hence with v = 0, the species conservation equation reduces to

$$\frac{d^2C_A}{dy^2} = 0. \qquad <$$

Integrating twice, the general form of the species concentration distribution is

$$C_A(y) = C_1 y + C_2.$$

Using appropriate boundary conditions and evaluating the constants,

$$C_A(0) = C_{A,2} \quad \rightarrow \quad C_2 = C_{A,2}$$
$$C_A(L) = C_{A,1} \quad \rightarrow \quad C_1 = \left(C_{A,1} - C_{A,2}\right)/L,$$

the concentration distribution is

$$C_A(y) = C_{A,2} + (y/L)\left(C_{A,1} - C_{A,2}\right). \qquad <$$

From Fick's law, the species flux is

$$N''_A(L) = -D_{AB}\left.\frac{dC_A}{dy}\right|_{y=L}$$

$$N''_A(L) = \frac{D_{AB}}{L}\left(C_{A,2} - C_{A,1}\right). \qquad <$$

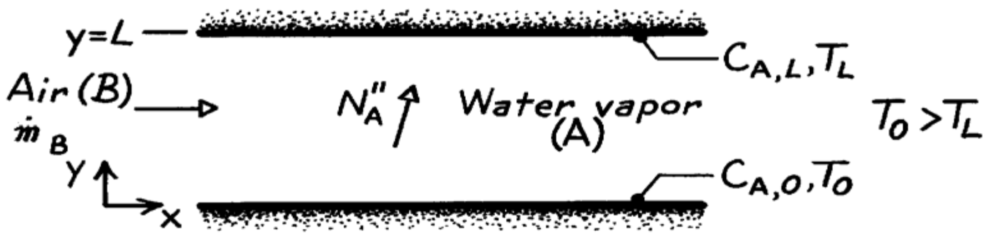
COMMENTS: An analogy between heat and mass transfer exists if viscous dissipation is negligible. The energy equation is then $d^2T/dy^2 = 0$. Hence, both heat and species transfer are influenced only by diffusion. Expressions for T(y) and $q''(L)$ are analogous to those for $C_A(y)$ and $N''_A(L)$.

PROBLEM 6S.12

KNOWN: Flow conditions between two parallel plates, across which vapor transfer occurs.

FIND: (a) Variation of vapor molar concentration between the plates and mass rate of water production per unit area, (b) Heat required to sustain the process.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Fully developed, incompressible flow with constant properties, (3) Negligible body forces, (4) No chemical reactions, (5) All work interactions, including viscous dissipation, are negligible.

ANALYSIS: (a) The flow will be fully developed in terms of the vapor concentration field, as well as the velocity and temperature fields. Hence

$$\frac{\partial C_A}{\partial x} = 0 \qquad \text{or} \qquad C_A(x,y) = C_A(y).$$

Also, with $\partial C_A/\partial t = 0$, $\dot{N}_A = 0$, v = 0 and constant D_{AB}, the species conservation equation reduces to

$$\frac{d^2 C_A}{dy^2} = 0.$$

Separating and integrating twice,

$$C_A(y) = C_1(y) + C_2.$$

Applying the boundary conditions,

$$C_A(0) = C_{A,0} \quad \rightarrow \quad C_2 = C_{A,0}$$

$$C_A(L) = C_{A,L} \quad \rightarrow \quad C_{A,L} = C_1 L + C_2 \qquad C_1 = -\frac{C_{A,0} - C_{A,L}}{L}$$

find the species concentration distribution,

$$C_A(y) = C_{A,0} - \left(C_{A,0} - C_{A,L}\right)\ (y/L). \qquad <$$

From Fick's law, Eq. 6.7, the species transfer rate is

$$N''_A = N''_{A,s} = -D_{AB} \frac{\partial C_A}{\partial y}\bigg]_{y=0} = D_{AB} \frac{C_{A,0} - C_{A,L}}{L}.$$

Continued …..

PROBLEM 6S.12 (Cont.)

Multiplying by the molecular weight of water vapor, $\mathcal{M}_A$, the mass rate of water production per unit area is

$$n''_A = \mathcal{M}_A N''_A = \mathcal{M}_A D_{AB} \frac{C_{A,0} - C_{A,L}}{L}. \qquad <$$

(b) Heat must be supplied to the bottom surface in an amount equal to the latent and sensible heat transfer from the surface,

$$q'' = q''_{lat} + q''_{sen}$$

$$q'' = n''_{A,s}\, h_{fg} + \left[-k \frac{dT}{dy}\right]_{y=0}.$$

The temperature distribution may be obtained by solving the energy equation, which, for the prescribed conditions, reduces to

$$\frac{d^2T}{dy^2} = 0.$$

Separating and integrating twice,

$$T(y) = C_1 y + C_2.$$

Applying the boundary conditions,

$$T(0) = T_0 \quad \rightarrow \quad C_2 = T_0$$

$$T(L) = T_L \quad \rightarrow \quad C_1 = (T_1 - T_0)/L$$

find the temperature distribution,

$$T(y) = T_0 - (T_0 - T_L)\, y/L.$$

Hence,

$$-k \frac{dT}{dy}\bigg]_{y=0} = k \frac{(T_0 - T_L)}{L}.$$

Accordingly,

$$q'' = \mathcal{M}_A D_{AB} \frac{C_{A,0} - C_{A,L}}{L} h_{fg} + k \frac{(T_0 - T_L)}{L}. \qquad <$$

COMMENTS: Despite the existence of the flow, species and energy transfer across the air are uninfluenced by advection and transfer is only by diffusion. If the flow were not fully developed, advection would have a significant influence on the species concentration and temperature fields and hence on the rate of species and energy transfer. The foregoing results would, of course, apply in the case of no air flow. The physical condition is an example of Poiseuille flow with heat and mass transfer.

PROBLEM 6S.13

KNOWN: The conservation equations, Eqs. 6S.24 and 6S.31.

FIND: (a) Describe physical significance of terms in these equations, (b) Identify approximations and special conditions used to reduce these equations to the boundary layer equations, Eqs. 6.29 and 6.30, (c) Identify the conditions under which these two boundary layer equations have the same form and, hence, an analogy will exist.

ANALYSIS: (a) The energy conservation equation, Eq. 6S.24, has the form

$$\underbrace{\rho u\frac{\partial i}{\partial x}}_{1a}+\underbrace{\rho v\frac{\partial i}{\partial y}}_{1b}=\underbrace{\frac{\partial}{\partial x}\left[k\frac{\partial T}{\partial x}\right]}_{2a}+\underbrace{\frac{\partial}{\partial y}\left[k\frac{\partial T}{\partial y}\right]}_{2b}+\underbrace{\left[u\frac{\partial p}{\partial x}+v\frac{\partial p}{\partial y}\right]}_{3}+\underbrace{\mu\Phi}_{4}+\underbrace{\dot{q}}_{5}.$$

The terms, as identified, have the following physical significance:

1. Change of enthalpy (thermal + flow work) advected in x and y directions, <
2. Change of conduction flux in x and y directions,
3. Work done by static pressure forces,
4. Word done by viscous stresses,
5. Rate of energy generation.

The species mass conservation equation for a constant total concentration has the form

$$\underbrace{u\frac{\partial C_A}{\partial x}}_{1a}+\underbrace{v\frac{\partial C_A}{\partial y}}_{1b}=\underbrace{\frac{\partial}{\partial x}\left[D_{AB}\frac{\partial C_A}{\partial x}\right]}_{2a}+\underbrace{\frac{\partial}{\partial y}\left[D_{AB}\frac{\partial C_A}{\partial y}\right]}_{2b}+\underbrace{\dot{N}_A}_{3}$$

1. Change in species transport due to advection in x and y directions, <
2. Change in species transport by diffusion in x and y directions, and
3. Rate of species generation.

(b) The special conditions used to reduce the above equations to the boundary layer equations are: *constant properties, incompressible flow, non-reacting species* $\left(\dot{N}_A = 0\right)$, *without internal heat generation* $\left(\dot{q}=0\right)$, *species diffusion has negligible effect on the thermal boundary layer, u(∂p/∂x) is negligible.* The approximations are,

Velocity boundary layer $\quad \left\{ u >> v \qquad \frac{\partial u}{\partial y} >> \frac{\partial u}{\partial x}, \frac{\partial v}{\partial y}, \frac{\partial v}{\partial x} \right.$

Thermal b.1.: $\quad \left\{ \frac{\partial T}{\partial y} >> \frac{\partial T}{\partial x} \right.$ $\qquad$ Concentration b.1.: $\quad \left\{ \frac{\partial C_A}{\partial y} >> \frac{\partial C_A}{\partial x} \right.$.

The resulting simplified boundary layer equations are

$$\underbrace{u\frac{\partial T}{\partial x}}_{1a}+\underbrace{v\frac{\partial T}{\partial y}}_{1b}=\underbrace{\alpha\frac{\partial^2 T}{\partial y^2}}_{2a}+\underbrace{\frac{\nu}{c}\left[\frac{\partial u}{\partial y}\right]^2}_{3} \qquad \underbrace{u\frac{\partial C_A}{\partial x}}_{1c}+\underbrace{v\frac{\partial C_A}{\partial y}}_{1d}=\underbrace{D_{AB}\frac{\partial^2 C_A}{\partial y^2}}_{2b}$$ <

where the terms are: 1. Advective transport, 2. Diffusion, and 3. Viscous dissipation.

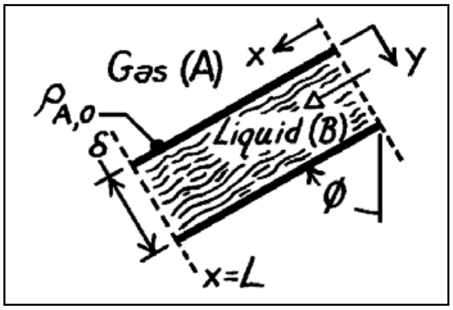
(c) When viscous dissipation effects are negligible, the two boundary layer equations have identical form. If the boundary conditions for each equation are of the same form, an analogy between heat and mass (species) transfer exists.

PROBLEM 6S.14

KNOWN: Thickness and inclination of a liquid film. Mass density of gas in solution at free surface of liquid.

FIND: (a) Liquid momentum equation and velocity distribution for the x-direction. Maximum velocity, (b) Continuity equation and density distribution of the gas in the liquid, (c) Expression for the local Sherwood number, (d) Total gas absorption rate for the film, (e) Mass rate of NH_3 removal by a water film for prescribed conditions.

SCHEMATIC:



NH_3 (A) – Water (B)

$L = 2m$

$\delta = 1$ mm

$D = 0.05m$

$W = \pi D = 0.157m$

$\rho_{A,o} = 25$ kg/m^3

$D_{AB} = 2 \times 10^{-9}$ m^2/s

$\phi = 0°$

ASSUMPTIONS: (1) Steady-state conditions, (2) The film is in fully developed, laminar flow, (3) Negligible shear stress at the liquid-gas interface, (4) Constant properties, (5) Negligible gas concentration at x = 0 and y = δ, (6) No chemical reactions in the liquid, (7) Total mass density is constant, (8) Liquid may be approximated as semi-infinite to gas transport.

PROPERTIES: *Table A-6*, Water, liquid (300K): $\rho_f = 1/v_f = 997$ kg/m^3, $\mu = 855 \times 10^{-6}$ N·s/m^2, $\nu = \mu/\rho_f = 0.855 \times 10^{-6}$ m^2/s.

ANALYSIS: (a) For fully developed flow ($v = w = 0$, $\partial u/\partial x = 0$), the x-momentum equation is

$$0 = \partial\tau_{yx} / \partial y + X \quad \text{where} \quad \tau_{yx} = \mu(\partial u/\partial y) \quad \text{and} \quad X = (\rho g)\cos\phi.$$

That is, the momentum equation reduces to a balance between gravitational and shear forces. Hence,

$$\mu\left(\partial^2 u/\partial y^2\right) = -(\rho g)\cos\phi.$$

Integrating, $\quad \partial u/\partial y = -(g\cos\phi/\nu)y + C_1 \qquad u = -(g\cos\phi/2\nu)y^2 + C_1 y + C_2.$

Applying the boundary conditions,

$$\partial u/\partial y)_{y=0} = 0 \qquad \rightarrow \qquad C_1 = 0$$

$$u(\delta) = 0 \qquad \rightarrow \qquad C_2 = g\cos\phi\,\frac{\delta^2}{2\nu}.$$

Hence, $$u = \frac{g\cos\phi}{2\nu}\left(\delta^2 - y^2\right) = \frac{g\cos\phi\,\delta^2}{2\nu}\left[1 - (y/\delta)^2\right] \qquad <$$

and the maximum velocity exists at y = 0,

$$u_{max} = u(0) = \left(g\cos\phi\,\delta^2\right)/2\nu. \qquad <$$

(b) Species transport within the liquid is influenced by diffusion in the y-direction and advection in the x-direction. Hence, the species continuity equation with u assumed equal to u_{max} throughout the region of gas penetration is

Continued …..

PROBLEM 6S.14 (Cont.)

$$u\frac{\partial \rho_A}{\partial x} = D_{AB}\frac{\partial^2 \rho_A}{\partial y^2} \qquad \frac{\partial^2 \rho_A}{\partial y^2} = \frac{u_{max}}{D_{AB}}\frac{\partial \rho_A}{\partial x}.$$

Appropriate boundary conditions are: $\rho_A(x,0) = \rho_{A,o}$ and $\rho_A(x,\infty) = 0$ and the entrance condition is: $\rho_A(0,y) = 0$. The problem is therefore analogous to transient conduction in a semi-infinite medium due to a sudden change in surface temperature. From Section 5.7, the solution is then

$$\frac{\rho_A - \rho_{A,o}}{0 - \rho_{A,o}} = \text{erf}\,\frac{y}{2\left(D_{AB}x/u_{max}\right)^{1/2}} \qquad \rho_A = \rho_{A,o}\text{erfc}\,\frac{y}{2\left(D_{AB}x/u_{max}\right)^{1/2}} \quad <$$

(c) The Sherwood number is defined as

$$Sh_x = \frac{h_{m,x}x}{D_{AB}} \quad \text{where} \quad h_{m,x} \equiv \frac{n''_{A,x}}{\rho_{A,o}} = \frac{-D_{AB}\partial\rho_A/\partial y|_{y=0}}{\rho_{A,o}}$$

$$\left.\frac{\partial \rho_A}{\partial y}\right|_{y=0} = -\rho_{A,o}\frac{2}{(\pi)^{1/2}}\exp\left[-\frac{y^2 u_{max}}{4D_{AB}x}\right]\left.\frac{1}{2\left(D_{AB}x/u_{max}\right)^{1/2}}\right|_{y=0} = -\rho_{A,o}\left[\frac{u_{max}}{\pi D_{AB}x}\right]^{1/2}.$$

Hence,

$$h_{m,x} = \left[\frac{u_{max}D_{AB}}{\pi x}\right]^{1/2} \qquad Sh_x = \frac{1}{(\pi)^{1/2}}\left[\frac{u_{max}x}{D_{AB}}\right]^{1/2} = \frac{1}{(\pi)^{1/2}}\left[\frac{u_{max}x}{\nu}\right]^{1/2}\left[\frac{\nu}{D_{AB}}\right]^{1/2}$$

and with $Re_x \equiv u_{max}x/\nu$,

$$Sh_x = \left[1/(\pi)^{1/2}\right]Re_x^{1/2}\,Sc^{1/2} = 0.564\,Re_x^{1/2}\,Sc^{1/2}. \quad <$$

(d) The total gas absorption rate may be expressed as

$$n_A = \overline{h}_{m,x}(W\cdot L)\rho_{A,o}$$

where the average mass transfer convection coefficient is

$$\overline{h}_{m,x} = \frac{1}{L}\int_0^L h_{m,x}dx = \frac{1}{L}\left[\frac{u_{max}D_{AB}}{\pi}\right]^{1/2}\int_0^L\frac{dx}{x^{1/2}} = \left[\frac{4u_{max}D_{AB}}{\pi L}\right]^{1/2}.$$

Hence, the absorption rate per unit width is

$$n_A/W = \left(4u_{max}D_{AB}L/\pi\right)^{1/2}\rho_{A,o}. \quad <$$

(e) From the foregoing results, it follows that the ammonia absorption rate is

$$n_A = \left[\frac{4u_{max}D_{AB}L}{\pi}\right]^{1/2}W\rho_{A,o} = \left[\frac{4\,g\cos\phi\,\delta^2 D_{AB}L}{2\pi\nu}\right]^{1/2}W\rho_{A,o}.$$

Substituting numerical values,

$$n_A = \left[\frac{4\times 9.8\text{ m/s}^2\times 1\times\left(10^{-3}\text{m}\right)^2\left(2\times10^{-9}\text{m}^2/\text{s}\right)2\text{m}}{2\pi\times 0.855\times10^{-6}\text{m}^2/\text{s}}\right]^{1/2}(0.157\text{m})\,25\text{ kg/m}^3 = 6.71\times10^{-4}\text{kg/s}. \quad <$$

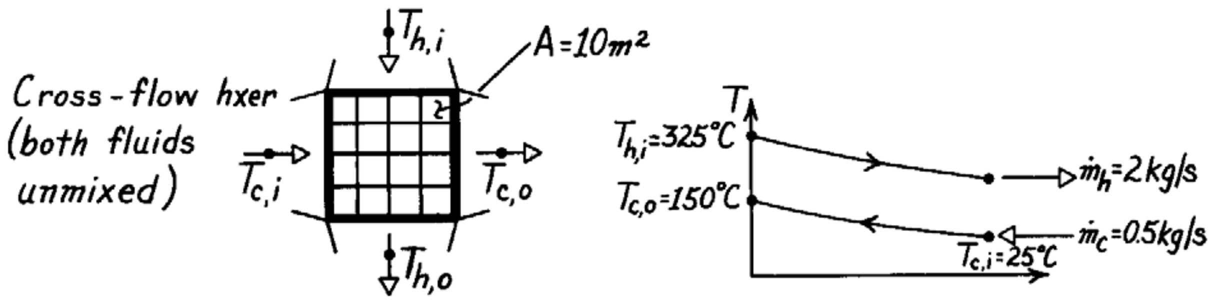
COMMENTS: Note that $\rho_{A,o} \neq \rho_{A,\infty}$, where $\rho_{A,\infty}$ is the mass density of the gas phase. The value of $\rho_{A,o}$ depends upon the pressure of the gas and the solubility of the gas in the liquid.

PROBLEM 11S.1

KNOWN: Operating conditions and surface area of a finned-tube, cross-flow exchanger.

FIND: Overall heat transfer coefficient.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Exhaust gas properties are those of air.

PROPERTIES: *Table A-6*, Water $\left(\overline{T}_m = 87°C\right)$: $\overline{c}_p = 4203\ J/kg\cdot K$; *Table A-4*, Air $\left(T_m \approx 275°C\right)$: $\overline{c}_p = 1040\ J/kg\cdot K$.

ANALYSIS: From the energy balance equations

$$q = \dot{m}_c c_{p,c}\left(T_{c,o} - T_{c,i}\right) = 0.5\,kg/s \times 4203\,J/kg\cdot K\left(150 - 25\right)°C = 2.63\times10^5\,W$$

$$T_{h,o} = T_{h,i} - \frac{q}{\dot{m}_h c_{p,h}} = 325°C - \frac{2.63\times10^5\,W}{2\,kg/s\times1040\,J/kg\cdot K} = 198.6°C.$$

Hence

$$U = q/A\Delta T_{\ell m} \qquad \text{where} \qquad \Delta T_{\ell m} = F\Delta T_{\ell m,CF}.$$

From Fig. 11S.3, with

$$P = \frac{t_o - t_i}{T_i - t_i} = \frac{150-25}{325-25} = 0.42,\ \ R = \frac{T_i - T_o}{t_o - t_i} = \frac{325-198.6}{150-25} = 1.01,\ \ F = 0.94$$

$$\Delta T_{\ell m,CF} = \frac{\left(325-150\right)-\left(198.6-25\right)}{\ell n\dfrac{325-150}{198.6-25}} = 174.3°C.$$

Hence

$$U = \frac{q}{AF\Delta T_{\ell m,CF}} = \frac{2.63\times10^5\,W}{10m^2\times0.94\times174.3°C} = 160\ W/m^2\cdot K.$$ <

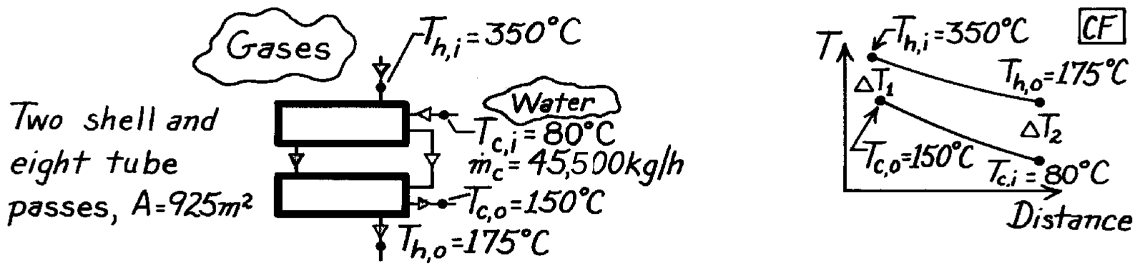
COMMENTS: From the ε - NTU method, C_c = 2102 W/K, C_h = 2080 W/K, $(C_{min}/C_{max}) \approx 1$, $q_{max} = 6.24 \times 10^5$ W and $\varepsilon = 0.42$. Hence, from Fig. 11.14, NTU ≈ 0.75 and U ≈ 156 $W/m^2\cdot K$.

PROBLEM 11S.2

KNOWN: Heat exchanger with two shell passes and eight tube passes having an area 925m^2; 45,500 kg/h water is heated from 80°C to 150°C; hot exhaust gases enter at 350°C and exit at 175°C.

FIND: Overall heat transfer coefficient.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible losses to surroundings, (2) Negligible kinetic and potential energy changes, (3) Constant properties, (4) Exhaust gas properties are approximated as those of atmospheric air.

PROPERTIES: *Table A-6,* Water $\left(\overline{T}_c = (80+150)°C/2 = 388K\right)$: $c_c = c_{p,f}$ = 4236 J/kg·K.

ANALYSIS: The overall heat transfer coefficient follows from Eqs. 11.9 and 11S.1 written in the form

$$U = q / AF\Delta T_{\ell m,CF}$$

where F is the correction factor for the HXer configuration, Fig. 11S.2, and $\Delta T_{\ell m,CF}$ is the log mean temperature difference (CF), Eqs. 11.15 and 11.16. From Fig. 11S.2, find

$$R = \frac{T_{h,i} - T_{h,o}}{T_{c,o} - T_{c,i}} = \frac{(350-175)°C}{(150-80)°C} = 2.5 \quad P = \frac{T_{c,o} - T_{c,i}}{T_{h,i} - T_{c,i}} = \frac{(150-80)°C}{(350-80)°C} = 0.26$$

find F ≈ 0.97. The log-mean temperature difference, Eqs. 11.15 and 11.17, is

$$\Delta T_{\ell m,CF} = \frac{\Delta T_1 - \Delta T_2}{\ell n(\Delta T_1/\Delta T_2)} = \frac{(350-150)°C - (175-80)°C}{\ell n\left[(350-150)/(175-80)\right]} = 141.1°C.$$

From an overall energy balance on the cold fluid (water), the heat rate is

$$q = \dot{m}_c c_c \left(T_{c,o} - T_{c,i}\right)$$

$$q = 45,500\,kg/h \times 1h/3600s \times 4236\ J/kg\cdot K(150-80)°C = 3.748 \times 10^6\ W.$$

Substituting values with A = 925 m^2, find

$$U = 3.748 \times 10^6 W / 925m^2 \times 0.97 \times 141.1K = 29.6\ W/m^2 \cdot K. \quad <$$

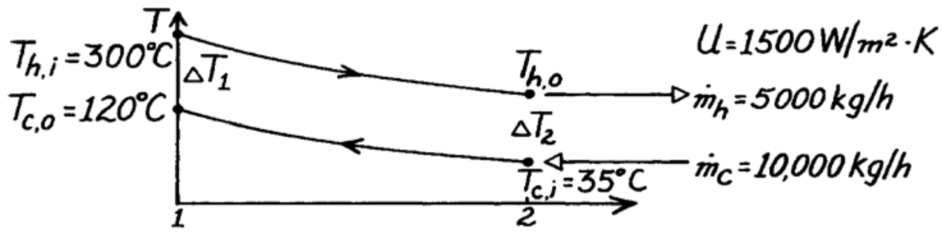
COMMENTS: Compare the above result with representative values for air-water exchangers, as given in Table 11.2. Note that in this exchanger, two shells with eight tube passes, the correction factor effect is very small, since F = 0.97.

PROBLEM 11S.3

KNOWN: A shell and tube Hxer (two shells, four tube passes) heats 10,000 kg/h of pressurized water from 35°C to 120°C with 5,000 kg/h water entering at 300°C.

FIND: Required heat transfer area, A_s.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties.

PROPERTIES: *Table A-6*, Water $(\overline{T}_c = 350\,K)$: c_p = 4195 J/kg·K; *Table A-6*, Water (Assume $T_{h,o} \approx$ 150°C, $\overline{T}_h \approx$ 500 K): c_p = 4660 J/kg·K.

ANALYSIS: The rate equation, Eq. 11.14, can be written in the form

$$A_s = q / U\Delta T_{\ell m} \quad (1)$$

and from Eq. 11S.1,

$$\Delta T_{\ell m} = F\Delta T_{\ell m,CF} \quad \text{where} \quad \Delta T_{\ell m,CF} = \frac{\Delta T_1 - \Delta T_2}{\ell n\left(\Delta T_1 / \Delta T_2\right)}. \quad (2,3)$$

From an energy balance on the cold fluid, the heat rate is

$$q = \dot{m}_c\, c_{p,c}\left(T_{c,o} - T_{c,i}\right) = \frac{10,000\ \text{kg/h}}{3600\ \text{s/h}} \times 4195\frac{J}{kg\cdot K}(120-35)K = 9.905\times10^5\ W.$$

From an energy balance on the hot fluid, the outlet temperature is

$$T_{h,o} = T_{h,i} - q/\dot{m}_h\, c_{p,h} = 300°C - 9.905\times10^5\ W / \frac{5000}{3600}\frac{kg}{s}\times 4660\frac{J}{kg\cdot K} = 147°C.$$

From Fig. 11S.2, determine F from values of P and R, where P = (120 – 35)°C/(300 – 35)°C = 0.32, R = (300 – 147)°C/(120-35)°C = 1.8, and F ≈ 0.97. The log-mean temperature difference based upon a CF arrangement follows from Eq. (3); find

$$\Delta T_{\ell m} = \left[(300-120)-(147-35)\right]K / \ell n\frac{(300-120)}{(147-35)} = 143.3\,K.$$

$$A_s = 9.905\times10^5 W / 1500\,W/m^2\cdot K \times 0.97\times 143.3\,K = 4.75\,m^2$$ <

COMMENTS: (1) Check $\overline{T}_h \approx$ 500 K used in property determination; $\overline{T}_h$ = (300 + 147)°C/2 = 497 K.

(2) Using the NTU-ε method, determine first the capacity rate ratio, C_{min}/C_{max} = 0.56. Then

$$\varepsilon \equiv \frac{q}{q_{max}} = \frac{C_{max}\left(T_{c,o}-T_{c,i}\right)}{C_{min}\left(T_{h,i}-T_{c,i}\right)} = \frac{1}{0.56}\times\frac{(120-35)°C}{(300-35)°C} = 0.57.$$

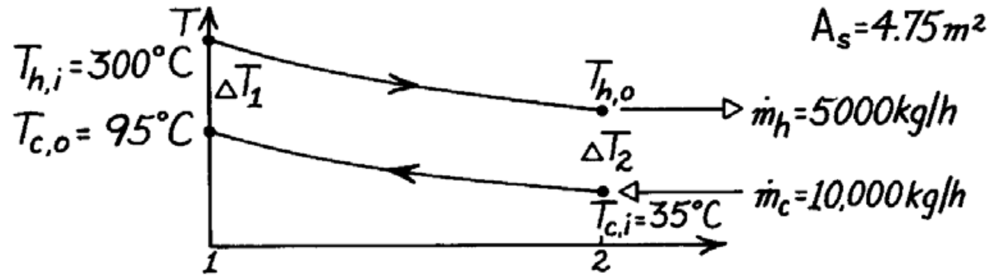
From Fig. 11.13, find that NTU = $AU/C_{min} \approx$ 1.1 giving A_s = 4.7 m^2.

PROBLEM 11S.4

KNOWN: The shell and tube Hxer (two shells, four tube passes) of Problem 11.14, known to have an area 4.75m^2, provides 95°C water at the cold outlet (rather than 120°C) after several years of operation. Flow rates and inlet temperatures of the fluids remain the same.

FIND: The fouling factor, R_f.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Thermal resistance for the clean condition is R''_t = (1500 W/m^2·K)$^{-1}$.

PROPERTIES: *Table A-6*, Water ($\overline{T}_c$ ≈ 338 K): c_p = 4187 J/kg·K; *Table A-6*, Water (Assume $T_{h,o}$ ≈ 190°C, $\overline{T}_h$ ≈ 520 K): c_p = 4840 J/kg·K.

ANALYSIS: The overall heat transfer coefficient can be expressed as

$$U = 1/\left(R''_t + R''_f\right) \qquad \text{or} \qquad R''_f = 1/U - R''_t \qquad (1)$$

where R''_t is the thermal resistance for the clean condition and R''_f, the fouling factor, represents the additional resistance due to fouling of the surface. The rate equation, Eq. 11.14 with Eq. 11S.1, has the form,

$$U = q/A_s F \Delta T_{\ell m,CF} \qquad \Delta T_{\ell m,CF} = \left(\Delta T_1 - \Delta T_2\right)/\ell n\left(\Delta T_1/\Delta T_2\right). \qquad (2)$$

From energy balances on the cold and hot fluids, find

$$q = \dot{m}_c c_{p,c}\left(T_{c,o} - T_{c,i}\right) = \left(10,000/3600\ \text{kg/s}\right)4187\ \text{J/kg}\cdot\text{K}\left(95-35\right)\text{K} = 6.978\times10^5\,\text{W}$$

$$T_{h,o} = T_{h,i} - q/\dot{m}_h c_{p,h} = 300°\text{C} - 6.978\times10^5\,\text{W}/\left(5000/3600\,\text{kg/s}\times4840\,\text{J/kg}\cdot\text{K}\right) = 196.2°\text{C}.$$

The factor, F, follows from values of P and R as given by Fig. 11S.2 with

$$P = \left(95-35\right)/\left(300-35\right) = 0.23 \qquad R = \left(300-196\right)/\left(120-35\right) = 1.22$$

giving F ≈ 1. Based upon CF arrangement,

$$\Delta T_{\ell m,CF} = \left[\left(300-95\right)-\left(196-35\right)\right]°\text{C}/\ell n\left[\left(300-95\right)/\left(196.2-35\right)\right] = 182\,\text{K}.$$

Using Eq. (2), find now the overall heat transfer coefficient as

$$U = 6.978\times10^5\,\text{W}/4.75\text{m}^2\times1\times182\,\text{K} = 806\ \text{W/m}^2\cdot\text{K}.$$

From Eq. (1), the fouling factor is

$$R''_f = \frac{1}{806\ \text{W/m}^2\cdot\text{K}} - \frac{1}{1500\ \text{W/m}^2\cdot\text{K}} = 5.74\times10^{-4}\,\text{m}^2\cdot\text{K/W}. \qquad <$$

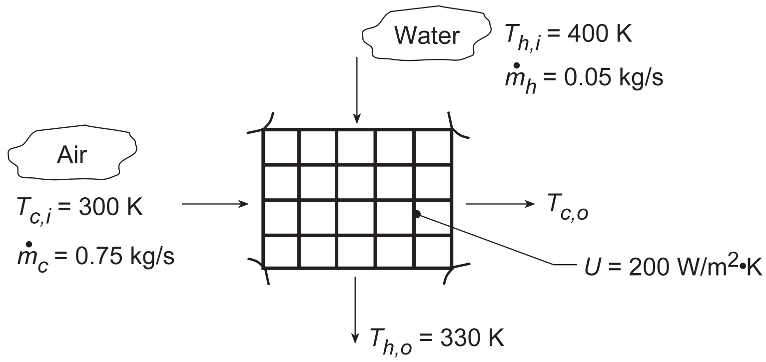
COMMENTS: Note that the effect of fouling is to nearly double (U_{clean}/U_{fouled} = 1500/806 ≈ 1.9) the resistance to heat transfer. Note also the assumption for $T_{h,o}$ used for property evaluation is satisfactory.

PROBLEM 11S.5

KNOWN: Flow rates and inlet temperatures for automobile radiator configured as a cross-flow heat exchanger with both fluids unmixed. Overall heat transfer coefficient.

FIND: (a) Area required to achieve hot fluid (water) outlet temperature, $T_{m,o}$ = 330 K, and (b) Outlet temperatures, $T_{h,o}$ and $T_{c,o}$, as a function of the overall coefficient for the range, $200 \le U \le 400$ W/m^2·K with the surface area A found in part (a) with all other heat transfer conditions remaining the same as for part (a).

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surrounding, (2) Constant properties.

PROPERTIES: *Table A.6*, Water ($\overline{T}_h$ = 365 K): $c_{p,h}$ = 4209 J/kg·K; *Table A.4*, Air $\left(\overline{T}_c \approx 310\,K\right)$: $c_{p,c}$ = 1007 J/kg·K.

ANALYSIS: (a) The required heat transfer rate is

$$q = \dot{m}_h c_{p,h}\left(T_{h,i} - T_{h,o}\right) = 0.05\,kg/s\left(4209\,J/kg\cdot K\right)70\,K = 14,732\,W\,.$$

and from an energy balance on the cold fluid,

$$T_{c,o} = T_{c,i} + q/\dot{m}_c c_{p,c} = 300\text{ K} + 14{,}732\text{ W}/(0.75\text{ kg/s} \times 1007\text{ J/kg}\cdot\text{K}) = 319.5\text{ K}$$

We will use Eq. 11.14 with Eq. 11S.1. From Fig. 11S.3, with $P = (T_{c,o} - T_{c,i}) / (T_{h,i} - T_{c,i}) = 0.20$ and $R = (T_{h,i} - T_{h,o})/ (T_{c,o} - T_{c,i}) = 3.6$, we find $F \approx 0.95$. Then,

$$\Delta T_{lm,CF} = \frac{(T_{h,i} - T_{c,o}) - (T_{h,o} - T_{c,i})}{\ln(T_{h,i} - T_{c,o})/(T_{h,o} - T_{c,i})} = 51.2\text{ K}$$

Thus

$$A = q/UF\Delta T_{1m,CF} = 14{,}732\text{ W}/\ 200\text{ W/m}^2\cdot\text{K} \times 0.95 \times 51.2\text{ K} = 1.5\text{ m}^2$$ <

(b) To solve this "performance" problem using the log mean temperature difference method is very cumbersome. It requires solving the following equations for the two unknown outlet temperatures (and q), where F is also a function of the two outlet temperatures,

$$q = \dot{m}_c c_{p,c}(T_{c,o} - T_{c,i}) \qquad (1)$$

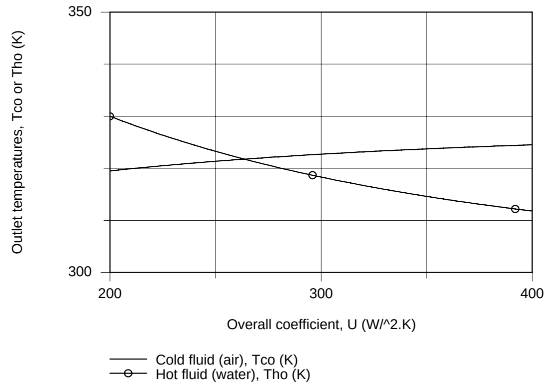
$$q = \dot{m} c_{p,h}(T_{h,i} - T_{h,o}) \qquad (2)$$

$$q = UAF\Delta T_{lm,CF} \qquad \Delta T_{lm,CF} = \frac{(T_{h,i} - T_{c,o}) - (T_{h,o} - T_{c,i})}{\ln(T_{h,i} - T_{c,o})/(T_{h,o} - T_{c,i})} \qquad (3,4)$$

Continued…

PROBLEM 11S.5 (Cont.)

One rational approach is to work backward. For a specified value of q, Eqs. (1) and (2) can be used to solve for the outlet temperatures. Then F and $\Delta T_{lm,CF}$ can be determined, and U can be found from Eq. (3). In this way, we can generate the following plot.



With a higher U, the outlet temperature of the hot fluid (water) decreases. A benefit is enhanced heat removal from the engine block and a cooler operating temperature. If it is desired to cool the engine with water at 330 K, the heat exchanger surface area and, hence its volume in the engine component could be reduced.

COMMENT: This problem is much easier to solve using the ε-NTU method, as shown in this IHT model.

```
// Heat Exchanger Tool - Cross-flow with both fluids unmixed:
// For the cross-flow, single-pass heat exchanger with both fluids unmixed,
eps = 1 - exp((1 / Cr) * (NTU^0.22) * (exp(-Cr * NTU^0.78) - 1))      // Eq 11.32
// where the heat-capacity ratio is
Cr = Cmin / Cmax
// and the number of transfer units, NTU, is
NTU = U * A / Cmin                       // Eq 11.24
// The effectiveness is defined as
eps = q / qmax
qmax = Cmin * (Thi - Tci)                // Eq 11.18, 11.19
// See Tables 11.3 and 11.4 and Fig 11.14
// Overall Energy Balances on Fluids:
q = mdoth * cph * (Thi - Tho)
q = mdotc * cpc * (Tco - Tci)
// Assigned Variables:
Cmin = Ch                  // Capacity rate, minimum fluid, W/K
Ch = mdoth * cph           // Capacity rate, hot fluid, W/K
mdoth = 0.05               // Flow rate, hot fluid, kg/s
Thi = 400                  // Inlet temperature, hot fluid, K
Tho = 330                  // Outlet temperature, hot fluid, K; specified for part (a)
Cmax = Cc                  // Capacity rate, maximum fluid, W/K
Cc = mdotc * cpc           // Capacity rate, cold fluid, W/K
mdotc = 0.75               // Flow rate, cold fluid, kg/s
Tci = 300                  // Inlet temperature, cold fluid, K
U = 200                    // Overall coefficient, W/m^2.K
// Properties Tool - Water (h)
// Water property functions :T dependence, From Table A.6
// Units: T(K), p(bars);
xh =  0                              // Quality (0=sat liquid or 1=sat vapor)
rhoh = rho_Tx("Water",Tmh,xh)        // Density, kg/m^3
cph = cp_Tx("Water",Tmh,xh)          // Specific heat, J/kg·K
Tmh =  Tfluid_avg(Thi,Tho )
// Properties Tool - Air(c)
// Air property functions : From Table A.4
// Units: T(K); 1 atm pressure
rhoc = rho_T("Air",Tmc)              // Density, kg/m^3
cpc = cp_T("Air",Tmc)                // Specific heat, J/kg·K
Tmc = Tfluid_avg(Tci,Tco)
```

PROBLEM 11S.6

KNOWN: Single pass, cross-flow heat exchanger with hot exhaust gases (mixed) to heat water (unmixed)

FIND: Required surface area.

SCHEMATIC:

ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Negligible kinetic and potential energy changes, (3) Exhaust gas properties assumed to be those of air.

PROPERTIES: *Table A-6*, Water ($\overline{T}_c$ = (80 + 30)°C/2 = 328 K): c_p = 4184 J/kg·K; *Table A-4*, Air (1 atm, $\overline{T}_h$ = (100 + 225)°C/2 = 436 K): c_p = 1019 J/kg·K.

ANALYSIS: The rate equation for the heat exchanger follows from Eqs. 11.14 and 11S.1. The area is given as

$$A = q / U\Delta T_{\ell m} = q / UF\Delta T_{\ell m,CF} \quad (1)$$

where F is determined from Fig. 11S.4 using

$$P = \frac{80-30}{225-30} = 0.26 \text{ and } R = \frac{225-100}{80-30} = 2.50 \text{ giving } F \approx 0.92. \quad (2)$$

From an energy balance on the cold fluid, find

$$q = \dot{m}_c c_c \left(T_{c,o} - T_{c,i}\right) = 3\frac{kg}{s} \times 4184 \frac{J}{kg \cdot K}\left(80-30\right)K = 627,600 \text{ W}. \quad (3)$$

From Eq. 11.15, the LMTD for counter-flow conditions is

$$\Delta T_{\ell m,CF} = \frac{\Delta T_1 - \Delta T_2}{\ell n\left(\Delta T_1 / \Delta T_2\right)} = \frac{\left(225-80\right)-\left(100-30\right)}{\ell n\left(145/70\right)} °C = 103.0°C. \quad (4)$$

Substituting numerical values resulting from Eqs. (2-4) into Eq. (1), find the required surface area to be

$$A = 627,600 \text{ W} / 200 W/m^2 \cdot K \times 0.92 \times 103.0K = 33.1m^2.$$ <

COMMENTS: Note that the properties of the exhaust gases were not needed in this method of analysis. If the ε-NTU method were used, find first C_h/C_c = 0.40 with $C_{min} = C_h$ = 5021 W/K. From Eqs. 11.18 and 11.19, with $C_h = C_{min}$, $\varepsilon = q/q_{max} = (T_{h,i} - T_{h,o})/(T_{h,i} - T_{c,i})$ = (225 – 100)/(225 – 30) = 0.64. Using Fig. 11.15 with C_{min}/C_{max} = 0.4 and ε = 0.64, find NTU = UA/C_{min} ≈ 1.4. Hence,

$$A = NTU \cdot C_{min} / U \approx 1.4 \times 5021 \text{ W/K} / 200 \text{ W}/m^2 \cdot K = 35.2\,m^2.$$

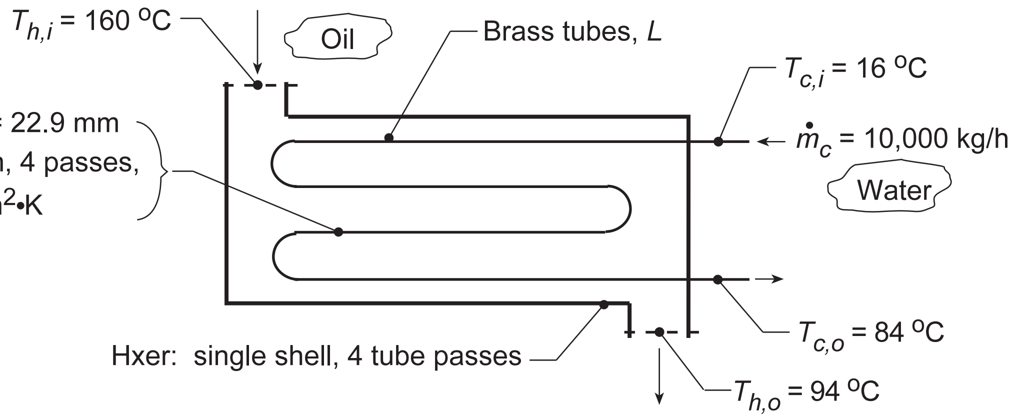
Note agreement with above result.

PROBLEM 11S.7

KNOWN: Conditions of oil and water for heat exchanger, one shell with 4 tube passes.

FIND: Length of exchanger tubes per pass, L; and (b) Compute and plot the effectiveness, ε, fluid outlet temperatures, $T_{h,o}$ and $T_{c,o}$, and water-side convection coefficient, h_c, as a function of the water flow rate for $5000 \le \dot{m}_c \le 15{,}000$ kg / h for the tube length found in part (a) with all other conditions remaining the same.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Fully-developed flow in tubes.

PROPERTIES: *Table A-1*, Brass (400 K): k = 137 W/m·K; *Table A-5*, Water (323 K): ρ = 998.1 kg/m³, k = 0.643 W/m·K, c_p = 4182 J/kg·K, μ = 548 × 10⁻⁶ N·s/m², Pr = 3.56.

ANALYSIS: (a) From an energy balance on the water, the heat rate required is

$$q = \dot{m}_c c_c \left(T_{c,o} - T_{c,i}\right) = 10{,}000/3600\,\text{kg/s} \times 4182\,\text{J/kg}\cdot\text{K}\left(84-16\right)^\circ\text{C} = 789{,}933\,\text{W}. \qquad (1)$$

The required tube length may be obtained from Eqs. 11.14 and 11.15,

$$q = U_o A_o F \Delta T_{\ell m,CF} \qquad (2)$$

$$\Delta T_{\ell m,CF} = \left[\left(160-84\right)^\circ\text{C} - \left(94-16\right)^\circ\text{C}\right] / \ell n\left((160-84)/(94-16)\right) = 77.0^\circ\text{C}.$$

From Fig. 11S.1, F = 0.86 using P = (84 - 16)/(160 - 16) = 0.47 and R = (160 - 94)/(84 - 16) = 0.97. From Eq. 11.5,

$$U_o = \left[\frac{1}{h_o} + \frac{r_o}{k}\ell n\frac{r_o}{r_i} + \frac{r_o}{r_i}\frac{1}{h_i}\right]^{-1}$$

where h_i must be estimated from the appropriate correlation. With N = 11, the number of tubes,

$$Re_D = \frac{4\dot{m}/N}{\pi D\mu} = \frac{4\times\left(10{,}000/3600\right)\text{kg/s}/\left(11\right)}{\pi\times 22.9\times10^{-3}\,\text{m}\times548\times10^{-6}\,\text{N}\cdot\text{s/m}^2} = 25{,}621.$$

For fully developed turbulent flow, the Dittus-Boelter correlation with n = 0.4 yields

$$Nu_D = h_i D/k = 0.023 Re_D^{0.8} Pr^{0.4} = 0.023\left(25{,}621\right)^{0.8}\left(3.56\right)^{0.4} = 128.6$$

$$h_i = Nu_D\left(k/D\right) = 128.6\times0.643\,\text{W/m}\cdot\text{K}/\left(22.9\times10^{-3}\,\text{m}\right) = 3610\,\text{W/m}^2\cdot\text{K}.$$

Continued...

PROBLEM 11S.7 (Cont.)

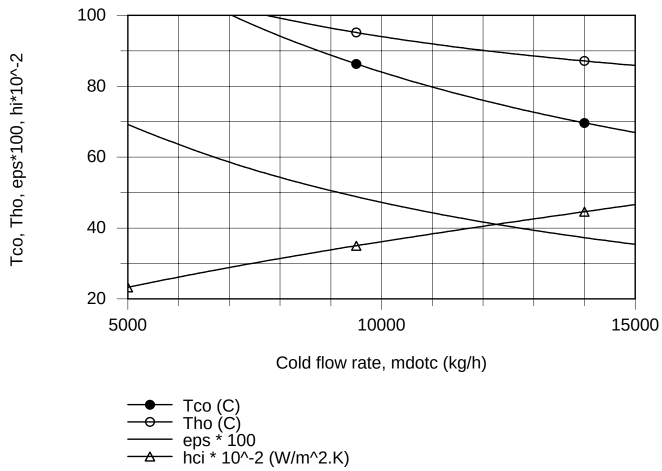
$$U_o = \left[\frac{1}{400\,W/m^2\cdot K} + \frac{25.4\times10^{-3}m}{2\times137\,W/m\cdot K}\ell n\frac{25.4}{22.9} + \frac{25.4}{22.9}\times\frac{1}{3610\,W/m^2\cdot K} \right]^{-1} = 355\,W/m^2\cdot K\,.$$

Returning now to Eq. (2), find A_o, then the length,

$$A_o = \pi D_o L \times \text{No. of Passes} \times \text{No. of Tubes} = \pi \times 25.4\times10^{-3}m \times 4\times11 L = 3.511\ L$$

$$L = 789,933\,W/3.511\ m\times355\,W/m^2\cdot K\times0.86\times77.0^\circ\,C = 9.6\,m$$ <

(b) Using the *IHT Heat Exchanger Tool, Shell and Tube, One-shell pass* and *N tube passes,* the *Correlation Tool, Forced Convection, Internal Flow* for *Turbulent, fully developed condition,* and the *Properties Tool* for *Water,* a model was developed using the effectiveness - NTU method to compute and plot $T_{c,o}$, $T_{h,o}$, ε, and h_i as a function of $\dot{m}_c$.



In order to avoid a boiling condition in the cold fluid, the cold flow rate should not be less than 8000 kg/h. As expected, $T_{c,o}$ and $T_{h,o}$ decrease and the internal convection coefficient increases nearly linearly with increasing flow rate. The effectiveness increases with increasing flow rate since the overall convection coefficient is increasing.

COMMENTS: (1) The thermal resistance of the brass tubes is negligible. Since $L/D_i = 400$, fully-developed conditions are reasonable.

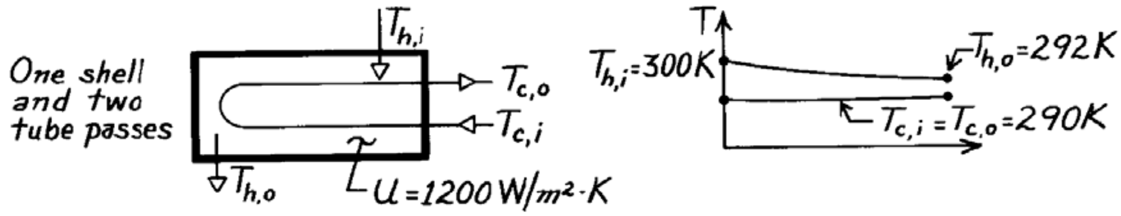
(2) In the analysis of part (b), you have to specify the capacity rate for the hot fluid in order to solve the model. From the analysis of part (a) using the model, we found L = 9.56 m and C_h = 11,974 W/K.

PROBLEM 11S.8

KNOWN: Power output and efficiency of an ocean energy conversion system. Temperatures and overall heat transfer coefficient of shell-and-tube evaporator.

FIND: (a) Evaporator area, (b) Water flow rate.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties.

PROPERTIES: *Table A-6*, Water ($\overline{T}_m$ = 296 K): c_p = 4181 J/kg·K.

ANALYSIS: (a) The efficiency is

$$\eta = \frac{\dot{W}}{q} = \frac{2\,\text{MW}}{q} = 0.03.$$

Hence the required heat transfer rate is

$$q = \frac{2\,\text{MW}}{0.03} = 66.7\,\text{MW}.$$

Also

$$\Delta T_{\ell m,CF} = \frac{(300-290)-(292-290)°C}{\ell n \frac{300-290}{292-290}} = 5°C$$

and, with P = 0 and R = ∞, from Fig. 11S.1 it follows that F = 1. Hence

$$A = \frac{q}{U F \Delta T_{\ell m,CF}} = \frac{6.67\times10^7\,W}{1200\ W/m^2\cdot K\times1\times5°C}$$

$$A = 11{,}100\,m^2.$$ <

(b) The water flow rate through the evaporator is

$$\dot{m}_h = \frac{q}{c_{p,h}\left(T_{h,i}-T_{h,o}\right)} = \frac{6.67\times10^7\,W}{4181\ J/kg\cdot K(300-292)}$$

$$\dot{m}_h = 1994\ kg/s.$$ <

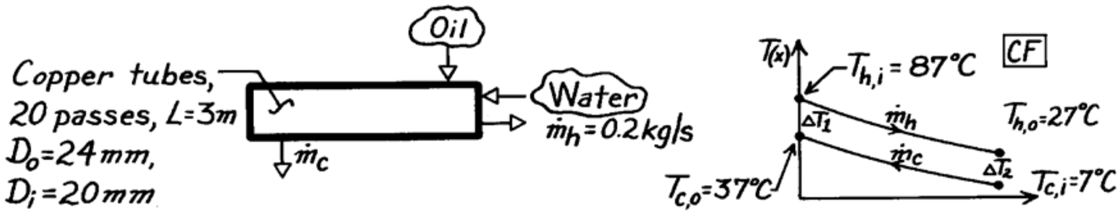
COMMENTS: (1) From the ε-NTU method, (C_{min}/C_{max}) = 0, q_{max} = 8.34 × 10^7 W, ε = 0.80 and from Fig. 11.12, NTU ≈ 1.65, giving A = 11,500 m^2. (2) The required heat exchanger size is enormous due to the small temperature differences involved.

PROBLEM 11S.9

KNOWN: Shell-and-tube heat exchanger with one shell pass and 20 tube passes.

FIND: Average convection coefficient for the outer tube surface.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant properties, (3) Type of oil not specified, (4) Thermal resistance of tubes negligible; no fouling.

PROPERTIES: *Table A-6*, Water, liquid ($\overline{T}_h$ = 330 K): c_p = 4184 J/kg·K, k = 0.650 W/m·K, μ = 489 × 10^{-6} N·s/m^2, Pr = 3.15.

ANALYSIS: To find the average coefficient for the outer tube surface, h_o, we need to evaluate h_i for the internal tube flow and U, the overall coefficient. From Eq. 11.5,

$$\frac{1}{UA} = \frac{1}{h_i A_i} + \frac{1}{h_o A_o} = \frac{1}{N_t \pi L}\left[\frac{1}{h_i D_i} + \frac{1}{h_o D_o}\right]$$

where N_t is the total number of tubes. Solving for h_o,

$$h_o = D_o^{-1}\left[(UA)^{-1} N_t \pi L - 1/h_i D_i\right]^{-1}. \quad (1)$$

Evaluate h_i from an appropriate correlation; begin by calculating the Reynolds number.

$$Re_{D,i} = \frac{4\,\dot{m}_h}{\pi D_i \mu} = \frac{4 \times 0.2\ kg/s}{\pi(0.020m)489 \times 10^{-6} N \cdot s/m^2} = 26{,}038.$$

Hence, flow is turbulent and since L >> D_i, the flow is likely to be fully developed. Use the Dittus-Boelter correlation with n = 0.3 since $T_s < T_m$, $Nu_D = 0.023\ Re_D^{4/5}\ Pr^{0.3}$

$$h_i = \frac{k}{D} Nu_D = \frac{0.650\ W/m \cdot K}{0.020m} \times 0.023(26{,}038)^{4/5}(3.15)^{0.3} = 3594\ W/m^2 \cdot K. \quad (2)$$

To evaluate UA, we need to employ the rate equation, written as

$$UA = q/F\Delta T_{\ell m,CF} \quad (3)$$

where $q = \dot{m}_h\ c_{p,h}(T_{h,i} - T_{h,o})$ = 0.2 kg/s × 4184 J/kg·K (87-27)°C = 50,208 W and $\Delta T_{\ell m,CF}$ = $[\Delta T_1 - \Delta T_2]/\ell n(\Delta T_1/\Delta T_2)$ = [(87 – 37) – (27 – 7)]°C/ ℓn [(87 – 37)/(27 – 7)] = 32.7°C. Find F ≈ 0.5 using Fig. 11S.1 with P = (27 – 87)/(7 – 87) = 0.75 and R = (7 – 37)/(27 – 87) = 0.50. Substituting numerical values in Eqs. (3) and (1), find

$$UA = 50{,}208\ W/0.5 \times 32.7°C = 3071\ W/K \quad (4)$$

$$h_o = (0.024m)^{-1}\left[(3071\ W/K)^{-1} \times 20 \times \pi \times 3m - 1/3594\ W/m^2 \cdot K \times 0.020m\right]^{-1} = 878\ W/m^2 \cdot K. \quad <$$

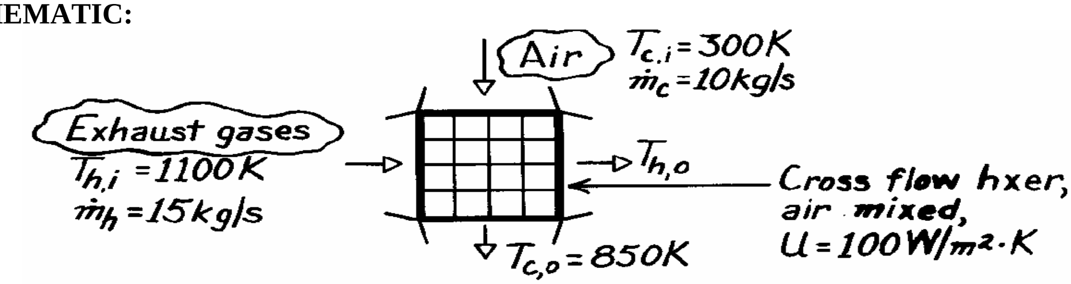
COMMENTS: Using the ε-NTU method: find C_h and C_c to obtain C_r = 0.5 and ε = 0.75. From Eq. 11.30b,c find NTU = 3.44 and UA = 2881 W/K.

PROBLEM 11S.10

KNOWN: Flow rates and inlet temperatures of exhaust gases and combustion air used in a cross-flow (one fluid mixed) heat exchanger. Overall heat transfer coefficient. Desired air outlet temperature.

FIND: Required heat exchanger surface area.

SCHEMATIC:



ASSUMPTIONS: (1) Steady-state conditions, (2) Negligible heat loss to surroundings, (3) Constant properties, (4) Gas properties are those of air.

PROPERTIES: *Table A-4*, Air ($\bar{T}_m \approx 700$ K, 1 atm): $c_p = 1075$ J/kg·K.

ANALYSIS: From Eqs. 11.6 and 11.7,

$$T_{h,o} = T_{h,i} - \frac{\dot{m}_c c_{p,c}}{\dot{m}_h c_{p,h}}\left(T_{c,o} - T_{c,i}\right) = 1100\text{K} - \frac{10 \text{ kg/s}}{15 \text{ kg/s}}(850 - 300)\text{K} = 733\text{K}.$$

From Eqs. 11.15, 11.17 and 11S.1,

$$\Delta T_{\ell m} = F\frac{\left(T_{h,i} - T_{c,o}\right) - \left(T_{h,o} - T_{c,i}\right)}{\ell n\left[\left(T_{h,i} - T_{c,o}\right)/\left(T_{h,o} - T_{c,i}\right)\right]} = F\frac{250 - 433}{\ell n(250/433)} = F \times 333\text{K}.$$

From Fig. 11S.4, with R = (300 – 850)/(733 – 1100) = 1.50 and P = (733 – 1100)/(300 – 1100) = 0.46, F ≈ 0.73. With

$$q = \dot{m}_h c_{p,h}\left(T_{h,i} - T_{h,o}\right) = 15\,\text{kg/s} \times 1075\,\text{J/kg}\cdot\text{K}(367\text{K}) = 5.92 \times 10^6\ \text{W}$$

it follows from Eq. 11.14 that

$$A = \frac{5.92 \times 10^6\ \text{W}}{100\,\text{W/m}^2 \cdot \text{K} \times 0.73(333\text{K})} = 243\,\text{m}^2.$$ <

COMMENTS: Using the effectiveness-NTU method, from Eq. 11.21

$$\varepsilon = \frac{T_{c,o} - T_{c,i}}{T_{h,i} - T_{c,i}} = \frac{(850 - 300)\text{K}}{(1100 - 300)\text{K}} = 0.688.$$

Hence, with $C_{mixed}/C_{unmixed} = C_c/C_h = 0.67$, Fig. 11.15 gives NTU ≈ 2.3. From Eq. 11.24,

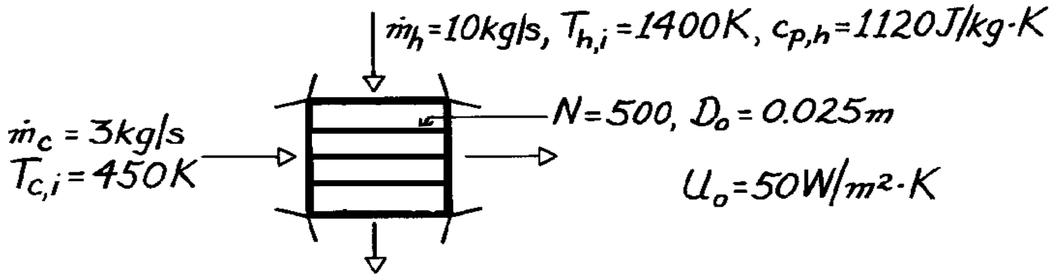
$$A = \text{NTU}\frac{C_{min}}{U} \approx 2.3\frac{10 \text{ kg/s} \times 1075 \text{ J/kg}\cdot\text{K}}{100 \text{ W/m}^2 \cdot \text{K}} \approx 247\,\text{m}^2.$$

PROBLEM 11S.11

KNOWN: Flow rate, specific heat and inlet temperature of gas in cross-flow heat exchanger. Flow rate and temperature of water which enters as saturated liquid and leaves as saturated vapor. Number of tubes, tube diameter and overall heat transfer coefficient.

FIND: Required tube length.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Constant gas specific heat.

PROPERTIES: *Table A-6*, Saturated Water, (T = 450 K): $h_{fg} = 2.024 \times 10^6$ J/kg.

ANALYSIS: The heat transfer rate can be found from considering the cold fluid,

$$q = \dot{m}_c h_{fg} = 3\text{ kg/s} \times 2.024 \times 10^6\text{ J/kg} = 6.072 \times 10^6\text{ W}$$

Then an energy balance on the hot fluid yields

$$T_{h,o} = T_{h,i} - q/\dot{m}_h c_{p,h} = 1400\text{ K} - 6.072 \times 10^6\text{ W}/10\text{ kg/s} \times 1120\text{ J/kg}\cdot\text{K} = 857.9\text{ K}$$

From Eqs. 11.15 and 11.17,

$$\Delta T_{lm,CF} = \frac{(T_{h,i} - T_{c,o}) - (T_{h,o} - T_{c,i})}{\ln\left[\left(T_{h,i} - T_{c,o}\right)/\left(T_{h,o} - T_{c,i}\right)\right]} = \frac{(1400 - 450)\text{ K} - (857.9 - 450)\text{ K}}{\ln\left[(1400 - 450)\text{ K}/(857.9 - 450)\text{ K}\right]} = 641\text{ K}$$

From Fig. 11S.4, with $P = (T_{c,o} - T_{c,i})/(T_{h,i} - T_{c,i}) = 0$, find $F = 1$, thus

$$A_o = q/U\Delta T_{lm,CF} = 6.072 \times 10^6\text{ W}/50\text{ W/m}^2\cdot\text{K} \times 641\text{ K} = 189\text{ m}^2$$

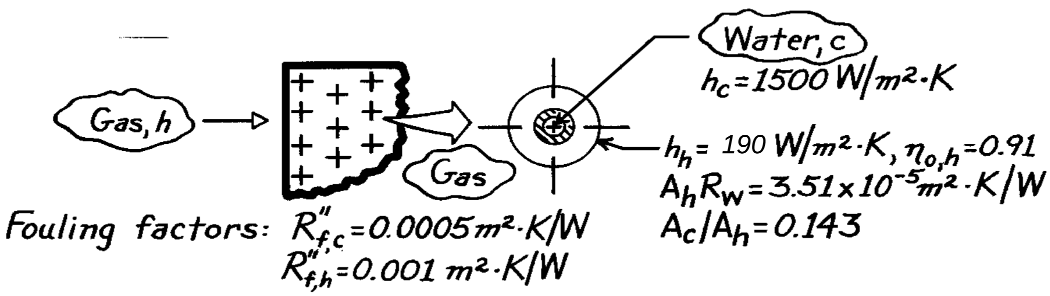
$$L = A_o/N\pi D_o = 189\text{ m}^2/500 \times \pi \times 0.025\text{ m} = 4.8\text{ m}$$ <

PROBLEM 11S.12

KNOWN: Compact heat exchanger (see Example 11S.2) after extended use has prescribed fouling factors on water and gas sides.

FIND: Gas-side overall heat transfer coefficient.

SCHEMATIC:



ASSUMPTIONS: (1) Heat transfer coefficients on the inside and outside (cold- and hot-sides) are the same as for the unfouled condition, (2) Temperature effectiveness of the finned hot side surface is the same as for the unfouled condition.

ANALYSIS: The overall heat transfer coefficient follows from Eq. 11.1 as

$$\frac{1}{U_h A_h} = \frac{1}{(\eta_o h A)_c} + \frac{R''_{f,c}}{(\eta_o A)_c} + R_w + \frac{R''_{f,h}}{(\eta_o A)_h} + \frac{1}{(\eta_o h A)_h}$$

where R_w and R''_f are the wall resistance and fouling factors, respectively. Multiply both sides by A_h and recognizing that $\eta_{o,c} = 1$, obtain

$$\frac{1}{U_h} = \frac{1}{h_c (A_c/A_h)} + \frac{R''_{f,c}}{(A_c/A_h)} + A_h R_w + \frac{R''_{f,h}}{\eta_{o,h}} + \frac{1}{\eta_o h_h}.$$

Substitute numerical values from Example 11S.2 results (h_h, $\eta_{o,h}$, $A_h R_w$, A_c/A_h) and those from the problem statement $\left(R''_{f,h}, R''_{f,c}, h_c\right)$ to find,

$$\frac{1}{U_h} = \frac{1}{1500\ W/m^2\cdot K(0.143)}$$

$$+\frac{0.0005 m^2\cdot K/W}{(0.143)} + 3.51\times10^{-5}\ m^2\cdot K/W + \frac{0.001 m^2\cdot K/W}{0.91} + \frac{1}{0.91\times190\ W/m^2\cdot K}$$

$$\frac{1}{U_h} = \left(4.662\times10^{-3} + 3.497\times10^{-3} + 3.51\times10^{-5} + 1.099\times10^{-3} + 6.005\times10^{-3}\right) m^2\cdot K/W$$

$$U_h = 66.3\ W/m^2\cdot K.$$ <

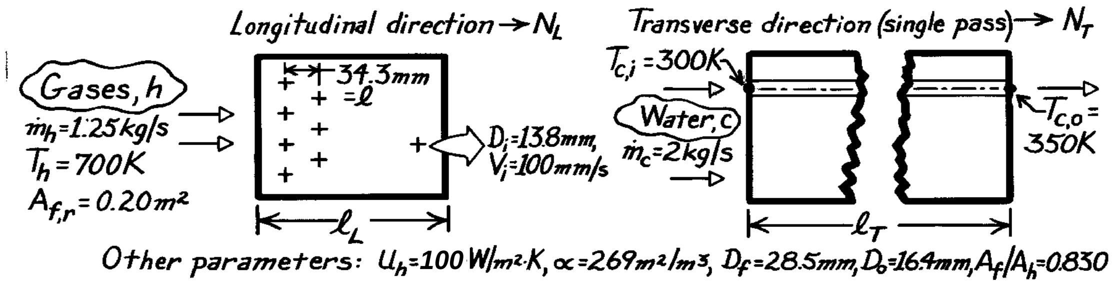
COMMENTS: For the unfouled condition, we found $U_h = 100\ W/m^2\cdot K$ from Example 11S.2. Note that the thermal resistance of the tube-fin material is negligible and that fouling has a significant effect, reducing U_h by 34%.

PROBLEM 11S.13

KNOWN: Compact heat exchanger with prescribed core geometry and operating parameters.

FIND: Required heat exchanger volume; number of tubes in the longitudinal and transverse directions, N_L and N_T; required tube length.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible heat loss to surroundings, (2) Single pass operation, (3) Gas properties are those of air.

PROPERTIES: *Table A-6*, Water ($\bar{T}_c$ = 325 K): ρ = 987.2 kg/m^3, c_p = 4182 J/kg·K; *Table A-4*, Air (Assume $T_{h,o} \approx$ 400 K, $\bar{T}_h \approx$ 550 K, 1 atm): c_p = 1040 J/kg·K.

ANALYSIS: To find the Hxer volume, first find A_h using the ε-NTU method. By definition,

$$V = A_h / \alpha \qquad \text{and} \qquad A_h = NTU \cdot C_{min} / U_h. \qquad (1,2)$$

Find the capacity rates, q, q_{max} and ε:

$$C_c = \dot{m}_c c_{p,c} = 2\ \text{kg/s} \times 4182\ \text{J/kg}\cdot\text{K} = 8364\ \text{W/K}$$

$$C_h = \dot{m}_h c_{p,h} = 1.25\ \text{kg/s} \times 1040\ \text{J/kg}\cdot\text{K} = 1300\ \text{W/K} \leftarrow C_{min}$$

Hence,

$$C_r = \frac{C_{min}}{C_{max}} = 0.155.$$

It follows that

$$\varepsilon = \frac{q}{q_{max}} = \frac{C_c\left(T_{c,o} - T_{c,i}\right)}{C_{min}\left(T_{h,i} - T_{c,i}\right)} = \frac{8364\ \text{W/K}\left(350 - 300\right)\text{K}}{1300\ \text{W/K}\left(700 - 300\right)\text{K}} = 0.804.$$

With ε = 0.804 and C_r = 0.155, find NTU ≈ 1.7 from Fig. 11.14 for a single-pass, cross flow Hxer with both fluids unmixed. Using Eqs. (2) and (1), find

$$A_h = 1.7 \times 1300\ \text{W/K} / 100\ \text{W/m}^2\cdot\text{K} = 22.1\text{m}^2$$

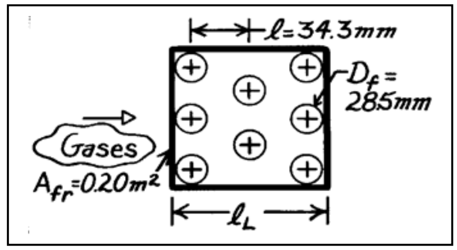
$$V = 23.7\,\text{m}^2 / 269\,\text{m}^2/\text{m}^3 = 0.082\,\text{m}^3.$$

Continued …..

PROBLEM 11S.13 (Cont.)

To determine the number of tubes in the longitudinal direction, consider the tubular arrangement in the sketch. The Hxer volume can be written as

$$V = A_{fr} \times \ell_L \qquad (3)$$



where

$$\ell_L = (N_L - 1)\ell + D_f \qquad (4)$$

and N_L is the number of tubes in the longitudinal direction. Combining Eqs. (3) and (4) and substituting numerical values, find

$$N_L = (V/A_{fr} - D_f)/\ell + 1 \qquad (5)$$

where D_f is the overall diameter of the finned tube, and

$$N_L = \left(0.082\,m^3/0.20\ m^2 - 0.0285m\right)/0.0343 + 1 = 12.1 \approx 13. \qquad <$$

To determine the number of tubes in the transverse direction, compare the overall water flow rate $\dot{m}_c$ with that for a single tube, $\dot{m}_t$. That is,

$$\dot{m}_t = \rho_c A_t V_i \qquad (6)$$

where A_t is the tube inner cross-sectional area $\left(\pi D_i^2/4\right)$ and V_i the internal velocity. Hence,

$$N = \dot{m}_c/\dot{m}_t = (2\ kg/s)/987.2\ kg/m^3 \times \frac{\pi}{4}(0.0138\,m)^2 \times 0.100\ m/s = 135.4 \approx 135.$$

The total number of tubes required, N, is 135; the number in the transverse direction is

$$N_T = N/N_L = 135/13 = 10.4 \approx 11. \qquad <$$

To determine the water tube length, recognize that the total area (A_h), less that of the finned surfaces (A_f), will be that of the water tube surface area. That is,

$$A_h - A_f = \pi D_o \ell_T \cdot N.$$

From specification of the core geometry, we know $A_f/A_h = 0.830$; solve for ℓ_T to obtain

$$\ell_T = A_h(1 - A_f/A_h)/\pi D_o \cdot N \qquad (7)$$

$$\ell_T = 22.1 m^2 (1 - 0.830)/\pi(0.0164\,m) \times 135 = 0.54\,m. \qquad <$$

COMMENTS: In summary we find that

Total number of tubes, N ($N_T \times N_L$)	143
Tubes in longitudinal direction, N_L	13
Tubes in transverse direction, N_T	11

with a total surface area of 22.1 m^2. The length of the exchanger is

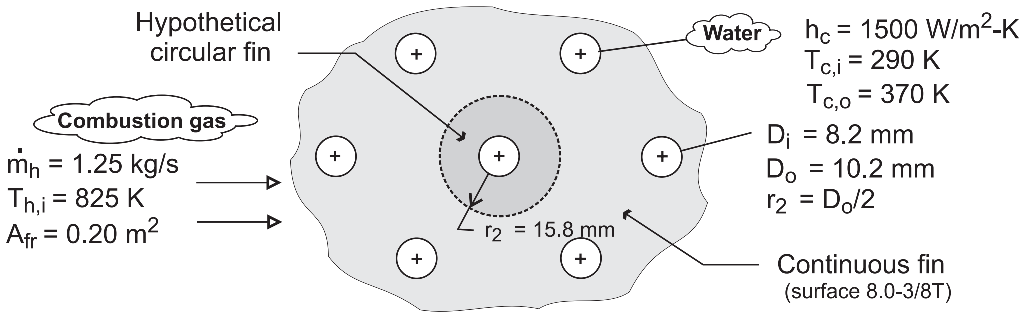
Length in longitudinal direction, ℓ_L	0.41 m
Length in transverse direction, ℓ_T	0.54 m.

PROBLEM 11S.14

KNOWN: Compact heat exchanger geometry, gas-side flow rate and inlet temperature, water-side convection coefficient, water flow rate, and water inlet and outlet temperatures.

FIND: Gas-side overall heat transfer coefficient. Required heat exchanger volume.

SCHEMATIC:



ASSUMPTIONS: (1) Gas has properties of atmospheric air at an assumed mean temperature of 700 K, (2) Negligible fouling, (3) Negligible heat exchange with the surroundings.

PROPERTIES: *Table A-1*, aluminum (T ≈ 300 K): k = 237 W/m·K. *Table A-4*, air (p = 1 atm, $\overline{T}$ = 700 K): c_p = 1075 J/kg·K, μ = 338.8 × 10^{-7} N·s/m^2, Pr = 0.695. *Table A-6*, water ($\overline{T}$ = 330 K): c_p = 4184 J/kg·K.

ANALYSIS: For the prescribed heat exchanger core,

$$\frac{1}{U_h} = \frac{1}{h_c\left(A_c / A_h\right)} + A_h R_w + \frac{1}{\eta_{o,h} h_h}$$

where

$$\frac{A_c}{A_h} \approx \frac{D_i}{D_o}\left(1 - \frac{A_{f,h}}{A_h}\right) = \frac{8.2}{10.2}(1 - 0.913) = 0.070$$

The product of A_h and the wall conduction resistance is

$$A_h R_w = \frac{\ln\left(D_o / D_i\right)}{2\pi k L / A_h} = \frac{D_i \ln\left(D_o / D_i\right)}{2k\left(A_c / A_h\right)} = \frac{0.0082\text{m} \times \ln(10.2/8.2)}{2 \times 237\,\text{W/m}\cdot\text{K}(0.070)} = 5.39 \times 10^{-5}\,\text{m}^2\cdot\text{K/W}$$

With a gas-side mass velocity of G = $\dot{m}_h / \sigma A_{fr}$ = 1.25 kg/s/0.534 × 0.20 m^2 = 11.7 kg/s·m^2,

$$Re = \frac{G D_h}{\mu} = \frac{11.7\ \text{kg/s}\cdot\text{m}^2 \times 0.00363\text{m}}{338.8 \times 10^{-7}\,\text{N}\cdot\text{s/m}^2} = 1254$$

and Fig. 11S.6 yields $j_H \approx 0.0096$. Hence,

$$h_h \approx \frac{0.0096\ G c_p}{Pr^{2/3}} = \frac{0.0096\left(11.7\ \text{kg/s}\cdot\text{m}^2\right)(1075\ \text{J/kg}\cdot\text{K})}{(0.695)^{2/3}} = 154\ \text{W/m}^2\cdot\text{K}$$

Continued …..

With $r_{2c} = r_2 + t/2 = 15.8$ mm + 0.330 mm/2 = 15.97 mm, $r_{2c}/r_1 = 15.97/5.1 = 3.13$, $L = r_2 - r_1 = 10.7$ mm, $L_c = L + t/2 = 10.87$ mm = 0.0109m, $A_p = L_c t = 3.59 \times 10^{-6}$ m^2, and $L_c^{3/2}(h_h/kA_p)^{1/2} = 0.484$, Fig. 3.20 yields $\eta_f \approx 0.77$. Hence,

$$\eta_{o,h} = 1 - \frac{A_f}{A}(1-\eta_f) = 1 - 0.913(1-0.77) = 0.790$$

$$U_h^{-1} = \left(1500\ \text{W/m}^2\cdot\text{K} \times 0.07\right)^{-1} + 5.39\times10^{-5}\text{m}^2\cdot\text{K/W} + \left(0.79\times154\ \text{W/m}^2\cdot\text{K}\right)^{-1} = 0.0183\,\text{m}^2\cdot\text{K/W}$$

$$U_h = 56.2\ \text{W/m}^2\cdot\text{K}$$ <

With $q = Cc\,(T_{c,o} - T_{c,i}) = 4184$ W/K × 80 K = 3.35×10^5 W, $q_{max} = C_{min}(T_{h,i} - T_{c,i}) = 1344$ W/K × 535 K = 7.19×10^5 W, $\varepsilon = 0.466$ and $C_r = 0.321$. From Figure 11.14, we then obtain NTU ≈ 0.65. The required gas-side surface area is then

$$A_h = \frac{NTU \times C_{min}}{U_h} = \frac{0.65\times1344\ \text{W/K}}{56.2\ \text{W/m}^2\cdot\text{K}} = 15.5\ \text{m}^2$$

With $\alpha = 587$ m^2/m^3, the required volume is

$$V = \frac{A_h}{\alpha} = \frac{15.5\,\text{m}^2}{587\,\text{m}^2/\text{m}^3} = 0.026\,\text{m}^3$$ <

COMMENTS: (1) Although U_h is small and A_h larger for the continuous fins than for the circular fins of Example 11.6, the much larger value of α renders the volume requirement smaller.

(2) The heat exchanger length is $L = V/A_{fr} = 0.132$ m, and the number of tube rows is

$$N_L \approx \frac{L}{S_L} + 1 = 7$$

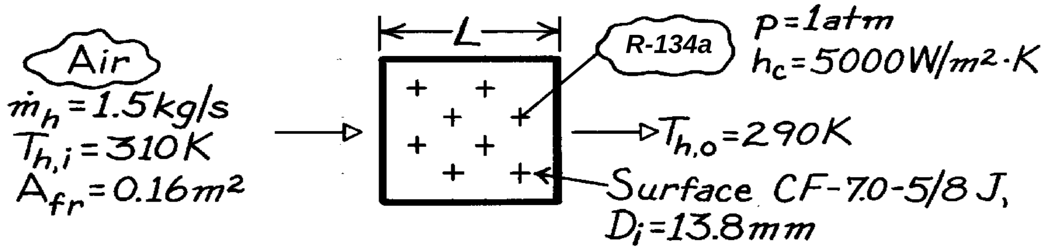
(3) The hypothetical fin radius ($r_2 = 15.8$ mm) was estimated to be the arithmetic mean of one-half the center-to-center spacing between one tube and its six neighbors.

PROBLEM 11S.15

KNOWN: Cooling coil geometry. Air flow rate and inlet and outlet temperatures. Refrigerant-134a pressure and convection coefficient.

FIND: Required number of tube rows.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible fouling, (2) Constant properties, (3) Negligible heat loss to surroundings.

PROPERTIES: *Table A-4*, Air ($\bar{T}_h$ = 300 K, 1 atm): c_p = 1007 J/kg·K, $\mu = 184.6 \times 10^{-7}$ N·s/m^2, k = 0.0263 W/m·K, Pr = 0.707; *Table A-5*, Sat. R-134a (1 atm): $T_{sat} = T_c$ = 247 K, h_{fg} = 217 kJ/kg.

ANALYSIS: The required number of tube rows is

$$N_L = (L - D_f)/S_L + 1$$

where

$$L = V/A_{fr} \qquad V = A_h/\alpha \qquad A_h = NTU\left(C_{min}/U_h\right)$$

$$1/U_h = 1/h_c\left(A_c/A_h\right) + A_h R_w + 1/\eta_{o,h} h_h.$$

From Ex. 11S.2, (A_c/A_h) = 0.143 and $A_h R_w = 3.51 \times 10^{-5}$ m^2·K/W. With

$$G = \frac{\dot{m}_h}{\sigma A_{fr}} = \frac{1.50 \text{ kg/s}}{0.449 \times 0.16 \text{ m}^2} = 20.9 \text{ kg/s} \cdot \text{m}^2$$

$$Re = \frac{GD_h}{\mu} = \frac{20.9 \text{ kg/s} \cdot \text{m}^2 \times 6.68 \times 10^{-3} \text{ m}}{184.6 \times 10^{-7} \text{ N} \cdot \text{s/m}^2} = 7563$$

and Fig. 11S.5 gives $j_H \approx 0.0068$. Hence,

$$h_h = j_h \frac{Gc_p}{Pr^{2/3}} = 0.0068 \frac{20.9 \text{ kg/s} \cdot \text{m}^2 \times 1007 \text{ J/kg} \cdot \text{K}}{(0.707)^{2/3}} = 180 \text{ W/m}^2 \cdot \text{K}.$$

With L_c = 6.18 mm and $A_p = 1.57 \times 10^{-6}$ m^2 from Ex. 11S.5, $L_c^{3/2}\left(h_h/kA_p\right)^{1/2}$ = 0.338 and, from Fig. 3.20, $\eta_f \approx 0.89$ for r_{2c}/r_1 = 1.75. Hence, as in Ex. 11S.5, $\eta_{o,h}$ = 0.91 and

$$1/U_h = 1/\left(5000 \text{ W/m}^2 \cdot \text{K}\right) 0.143 + 3.51 \times 10^{-5} \text{ m}^2 \cdot \text{K/W} + 1/\left(0.91 \times 180 \text{ W/m}^2 \cdot \text{K}\right)$$

$$U_h = 133 \text{ W/m}^2 \cdot \text{K}.$$

Continued …..

PROBLEM 11S.15 (Cont.)

With $C_{min}/C_{max} = 0$ and $C_{min} = \dot{m}_h c_{p,h} = 1511$ W/K,

$$\varepsilon = \frac{q}{q_{max}} = \frac{C_h\left(T_{h,i} - T_{h,o}\right)}{C_h\left(T_{h,i} - T_{c,i}\right)} = \frac{20\ \text{K}}{67\ \text{K}} = 0.317$$

$$\text{NTU} = -\ln(1-\varepsilon) = 0.382$$

and

$$A_h = \text{NTU}\frac{C_{min}}{U_h} = 0.382\frac{1511\ \text{W/K}}{133\ \text{W/m}^2\cdot\text{K}} = 4.34\,\text{m}^2.$$

Hence,

$$L = \frac{A_h}{\alpha A_{fr}} = \frac{4.34\,\text{m}^2}{\left(269\ \text{m}^2/\text{m}^3\right)0.16\,\text{m}^2} = 0.101\,\text{m}$$

and

$$N_L = \frac{L - D_f}{S_L} + 1 = \frac{0.0723}{0.0343\,\text{m}} + 1 = 3.1.$$

Hence, three or more rows must be used. <

COMMENTS: For the prescribed operating conditions, the heat rate would be

$$q = C_h\left(T_{h,i} - T_{h,o}\right) = 1511\ \text{W/K}\left(20\ \text{K}\right) = 30,220\ \text{W}.$$

If R-134a enters the tubes as saturated liquid, a flow rate of at least

$$\dot{m}_c = \frac{q}{h_{fg}} = \frac{30,220\ \text{W}}{217,000\ \text{J/kg}} = 0.139\ \text{kg/s}$$

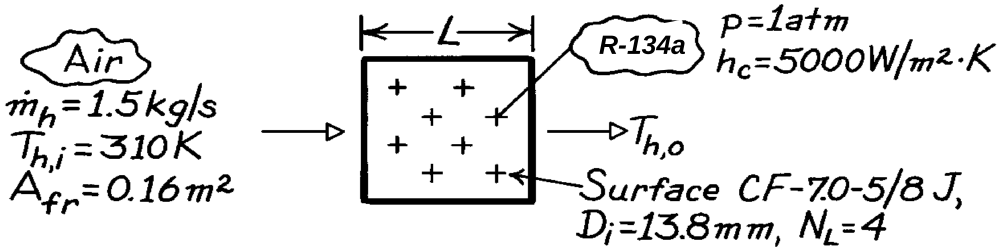
would be needed to maintain saturated conditions in the tubes.

PROBLEM 11S.16

KNOWN: Cooling coil geometry. Air flow rate and inlet temperature. R-134a pressure and convection coefficient.

FIND: Air outlet temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible fouling, (2) Constant properties, (3) Negligible heat loss to surroundings.

PROPERTIES: *Table A-4*, Air ($\bar{T}_h \approx 300$ K, 1 atm): c_p = 1007 J/kg·K, $\mu = 184.6 \times 10^{-7}$ N·s/m^2, k = 0.0263 W/m·K, Pr = 0.707; *Table A-5*, Sat. R-134a (1 atm): $T_{sat} = T_c$ = 247 K, h_{fg} = 217 kJ/kg.

ANALYSIS: To obtain the air outlet temperature, we must first obtain the heat rate from the ε-NTU method. To find A_h, first find the heat exchanger length,

$$L \approx (N_L - 1)S_L + D_f = 3(0.0343\,m) + 0.0285\,m = 0.131\,m.$$

Hence,

$$V = A_{fr}L = 0.16\,m^2(0.131\,m) = 0.021\,m^3$$

$$A_h = \alpha V = \left(269\,m^2/m^3\right)0.021\,m^3 = 5.65\,m^2.$$

The overall coefficient is

$$\frac{1}{U_h} = \frac{1}{h_c(A_c/A_h)} + A_h R_w + \frac{1}{\eta_{o,h} h_h}$$

where Ex. 11S.2 yields $(A_c/A_h) = 0.143$ and $A_h R_w = 3.51 \times 10^{-5}$ m^2·K/W. With

$$G = \frac{\dot{m}_h}{\sigma A_{fr}} = \frac{1.50\ kg/s}{0.449 \times 0.16\ m^2} = 20.9\ kg/s\cdot m^2$$

$$Re = \frac{GD_h}{\mu} = \frac{20.9\ kg/s\cdot m^2 \times 6.68\times10^{-3}\,m}{184.6\times10^{-7}\ N\cdot s/m^2} = 7563.$$

Fig. 11S.5 gives $j_H \approx 0.0068$. Hence,

$$h_h = j_h \frac{Gc_p}{Pr^{2/3}} = 0.0068 \frac{20.9\ kg/s\cdot m^2 \times 1007\ J/kg\cdot K}{(0.707)^{2/3}}$$

$$h_h = 180\ W/m^2\cdot K.$$

Continued …..

PROBLEM 11S.16 (Cont.)

With L_c = 6.18 mm and $A_p = 1.57 \times 10^{-6}\ m^2$ from Ex. 11S.2, $L_c^{3/2}\left(h_h / kA_p\right)^{1/2}$ = 0.338 and, from Fig. 3.20, $\eta_f \approx 0.89$ for $r_{2c}/r_1 = 1.75$. Hence, as in Ex. 11S.2, $\eta_{o,h} = 0.91$ and

$$\frac{1}{U_h} = \frac{1}{\left(5000\ W/m^2 \cdot K\right)0.143} + 3.51 \times 10^{-5}\ m^2 \cdot K/W + \frac{1}{0.91\left(180\ W/m^2 \cdot K\right)}$$

$$U_h = 133\ W/m^2 \cdot K.$$

With

$$C_{min} = C_h = \dot{m}_h c_{p,h} = 1.5\ kg/s\left(1007\ J/kg \cdot K\right) = 1511\ W/K$$

$$NTU = \frac{U_h A_h}{C_{min}} = \frac{133\ W/m^2 \cdot K \times 5.65\, m^2}{1511\ W/K} = 0.497.$$

With $C_{min}/C_{max} = 0$, Eq. 11.35a yields

$$\varepsilon = 1 - \exp\left(-NTU\right) = 1 - \exp\left(-0.497\right) = 0.392.$$

Hence,

$$q = \varepsilon q_{max} = \varepsilon C_{min}\left(T_{h,i} - T_{c,i}\right) = 0.392\left(1511\ W/K\right)63\ K$$

$$q = 37,200\ W.$$

The air outlet temperature is

$$T_{h,o} = T_{h,i} - \frac{q}{C_h} = 310\ K - \frac{37,200\ W}{1511\ W/K} = 285\ K. \quad <$$

COMMENTS: If R-134a enters the tubes as saturated liquid, a flow rate of at least

$$\dot{m}_c = \frac{q}{h_{fg}} = \frac{37,200\ W}{217,000\ J/kg} = 0.171\ kg/s$$

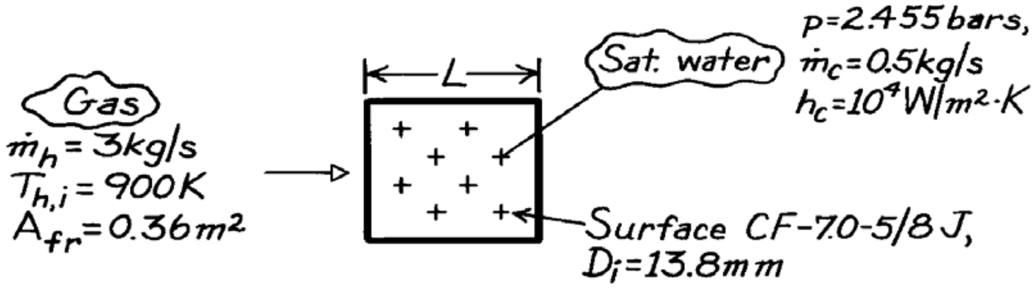
would be needed to maintain saturated conditions in the tubes.

PROBLEM 11S.17

KNOWN: Cooling coil geometry. Gas flow rate and inlet temperature. Water pressure, flow rate and convection coefficient.

FIND: Required number of tube rows.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible fouling, (2) Constant properties, (3) Negligible heat loss to surroundings.

PROPERTIES: *Table A-4*, Air ($\bar{T}_h \approx 725$ K, 1 atm): $c_p = 1081$ J/kg·K, $\mu = 346.7 \times 10^{-7}$ N·s/m^2, k = 0.0536 W/m·K, Pr = 0.698; *Table A-6*, Sat. water (2.455 bar): $T_{sat} = T_c = 400$ K, $h_{fg} = 2183$ kJ/kg.

ANALYSIS: The required number of tube rows is

$$N_L = \frac{L - D_f}{S_L} + 1$$

where

$$L = \frac{V}{A_{fr}} \qquad V = \frac{A_h}{\alpha} \qquad A_h = NTU\frac{C_{min}}{U_h}$$

$$\frac{1}{U_h} = \frac{1}{h_c\left(A_c / A_h\right)} + A_h R_w + \frac{1}{\eta_{o,h} h_h}.$$

From Ex. 11S.2, $(A_c/A_h) \approx 0.143$ and

$$A_h R_w = \frac{D_i \ln\left(D_o / D_i\right)}{2k\left(A_c / A_h\right)} = \frac{\left(0.0138\,m\right)\ln\left(16.4/13.8\right)}{2\left(15\ W/m \cdot K\right)\left(0.143\right)} = 5.55 \times 10^{-4}\,m^2 \cdot K/W.$$

With

$$G = \frac{\dot{m}_h}{\sigma A_{fr}} = \frac{3.0\ kg/s}{0.449 \times 0.36\,m^2} = 18.6\ kg/s \cdot m^2$$

$$Re = \frac{GD_h}{\mu} = \frac{18.6\ kg/s \cdot m^2 \times 6.68 \times 10^{-3}\,m}{346.7 \times 10^{-7}\ N \cdot s/m^2} = 3576$$

and Fig. 11.16S.5 gives $j_h \approx 0.009$. Hence,

$$h_h = j_h \frac{Gc_p}{Pr^{2/3}} = 0.009\frac{18.6\ kg/s \cdot m^2 \times 1081\ J/kg \cdot K}{\left(0.698\right)^{2/3}} = 230\ W/m^2 \cdot K.$$

Continued …..

PROBLEM 11S.17 (Cont.)

With $r_{2c}/r_1 = 1.75$, $L_c = 6.18$ mm and $A_p = 1.57 \times 10^{-6}\ m^2$ from Ex. 11.6, $L_c^{3/2}\left(h_h / kA_p\right)^{1/2} = 1.52$ and Fig. 3.20 gives $\eta_f \approx 0.40$. Hence,

$$\eta_{o,h} = 1 - \frac{A_f}{A}\left(1-\eta_f\right) = 1 - 0.83\left(1-0.4\right) = 0.50.$$

Hence,

$$\frac{1}{U_h} = \frac{1}{\left(10^4\ W/m^2\cdot K\right)0.143} + 5.55\times10^{-4}\ m^2\cdot K/W + \frac{1}{0.50\left(230\ W/m^2\cdot K\right)}$$

$$U_h = 100.5\ W/m^2\cdot K.$$

With

$$q = \dot{m}_c h_{fg} = 0.5\ kg/s\left(2.183\times10^6\ J/kg\right) = 1.092\times10^6\ W$$

$$C_{min} = C_h = 3.0\ kg/s\left(1081\ J/kg\cdot K\right) = 3243\ W/K$$

$$q_{max} = C_{min}\left(T_{h,i} - T_{c,i}\right) = 3243\ W/K\left(500\ K\right) = 1.622\times10^6\ W$$

find

$$\varepsilon = \frac{q}{q_{max}} = \frac{1.092\times10^6\ W}{1.622\times10^6\ W} = 0.674.$$

From Eq. 11.35b

$$NTU = -\ln\left(1-\varepsilon\right) = -\ln\left(1-0.674\right) = 1.121.$$

Hence,

$$A_h = NTU\frac{C_{min}}{U_h} = 1.121\frac{3243\ W/K}{100.5\ W/m^2\cdot K} = 36.17\ m^2$$

$$L = \frac{A_h}{A_{fr}\alpha} = \frac{36.17\ m^2}{0.36\ m^2\left(269\ m^2/m^3\right)} = 0.373\ m$$

$$N_L = \frac{L - D_f}{S_L} + 1 = \frac{373 - 28.5}{34.3} + 1 = 11.06 \approx 11. \quad <$$

COMMENTS: The gas outlet temperature is

$$T_{h,o} = T_{h,i} - \frac{q}{C_{min}} = 900\ K - \frac{1.092\times10^6\ W}{3243\ W/K} = 564\ K.$$

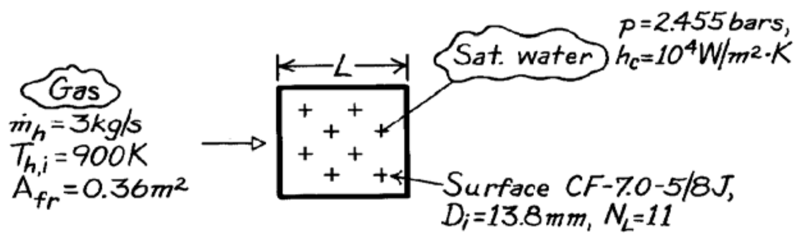
Hence $\overline{T}_h$ = (900 K + 564 K)/2 = 732 K is in good agreement with the assumed value.

PROBLEM 11S.18

KNOWN: Cooling coil geometry. Gas flow rate and inlet temperature. Water pressure and convection coefficient.

FIND: Gas outlet temperature.

SCHEMATIC:



ASSUMPTIONS: (1) Negligible fouling, (2) Constant properties, (3) Negligible heat loss to surroundings.

PROPERTIES: *Table A-4*, Air ($\bar{T}_h \approx 725$ K, 1 atm): c_p = 1081 J/kg·K, $\mu = 346.7 \times 10^{-7}$ N·s/m², k = 0.0536 W/m·K, Pr = 0.698; *Table A-6*, Sat. water (2.455 bar): $T_{sat} = T_c = 400$ K, h_{fg} = 2183 kJ/kg.

ANALYSIS: To obtain $T_{h,o}$, first obtain q from the ε-NTU method. To determine NTU, A_h must be found from knowledge of L.

$$L \approx (N_L - 1)S_L + D_f = 10(0.0343\,\text{m}) + 0.0285\,\text{m} = 0.372\,\text{m}.$$

Hence,

$$V = A_{fr}L = 0.36\,\text{m}^2(0.372\,\text{m}) = 0.134\,\text{m}^3$$

$$A_h = \alpha V = \left(269\,\text{m}^2/\text{m}^3\right)0.134\,\text{m}^3 = 36.05\,\text{m}^2.$$

The overall coefficient is

$$\frac{1}{U_h} = \frac{1}{h_c(A_c/A_h)} + A_h R_w + \frac{1}{\eta_{o,h} h_h}.$$

From Ex. 11S.2, $(A_c/A_h) \approx 0.143$ and

$$A_h R_w = \frac{D_i \ln(D_o/D_i)}{2k(A_c/A_h)} = \frac{(0.0138\,\text{m})\ln(16.4/13.8)}{2(15\text{ W/m}\cdot\text{K})(0.143)} = 5.55\times10^{-4}\,\text{m}^2\cdot\text{K/W}.$$

With

$$G = \frac{\dot{m}_h}{\sigma A_{fr}} = \frac{3.0\text{ kg/s}}{0.449\times0.36\,\text{m}^2} = 18.6\text{ kg/s}\cdot\text{m}^2$$

$$Re = \frac{GD_h}{\mu} = \frac{18.6\text{ kg/s}\cdot\text{m}^2\times6.68\times10^{-3}\,\text{m}}{346.7\times10^{-7}\,\text{N}\cdot\text{s/m}^2} = 3576$$

and Fig. 11S.5 gives $j_H \approx 0.009$. Hence,

Continued …..

PROBLEM 11S.18 (Cont.)

$$h_h = j_h \frac{Gc_p}{Pr^{2/3}} = 0.009 \frac{18.6\ kg/s \cdot m^2 \times 1081\ J/kg \cdot K}{(0.698)^{2/3}}$$

$$h_h = 230\ W/m^2 \cdot K.$$

With $r_{2c}/r_1 = 1.75$, $L_c = 6.18$ mm and $A_p = 1.57 \times 10^{-6}\ m^2$ from Ex. 11.6, $L_c^{3/2}\left(h_h / kA_p\right)^{1/2} = 1.52$ and Fig. 3.20 gives $\eta_f \approx 0.40$. Hence,

$$\eta_{o,h} = 1 - \frac{A_f}{A}(1 - \eta_f) = 1 - 0.83(1 - 0.4) = 0.50.$$

Hence,

$$\frac{1}{U_h} = \frac{1}{\left(10^4\ W/m^2 \cdot K\right)0.143} + 5.55 \times 10^{-4}\ m^2 \cdot K/W + \frac{1}{0.50\left(230\ W/m^2 \cdot K\right)}$$

$$U_h = 100.5\ W/m^2 \cdot K.$$

With

$$C_{min} = C_h = 3\ kg/s\left(1081\ J/kg \cdot K\right) = 3243\ W/K$$

$$NTU = \frac{U_h A_h}{C_{min}} = \frac{100.5\ W/m^2 \cdot K\left(36.05\, m^2\right)}{3243\ W/K} = 1.117.$$

Since $C_{min}/C_{max} = 0$, Eq. 11.35a gives

$$\varepsilon = 1 - \exp(-NTU) = 1 - \exp(-1.117) = 0.673.$$

Hence,

$$q = \varepsilon C_{min}\left(T_{h,i} - T_{c,i}\right) = 0.673\left(3243\ W/K\right)\left(500\ K\right) = 1.091 \times 10^6\ W$$

and

$$T_{h,o} = T_{h,i} - \frac{q}{C_{min}} = 900\ K - \frac{1.091 \times 10^6\ W}{3243\ W/K} = 564\ K. \quad <$$

COMMENTS: (1) The assumption of $\overline{T}_h = 725$ K is good.

(2) If water enters the tubes as saturated liquid, a flow rate of at least

$$\dot{m}_c = \frac{q}{h_{fg}} = \frac{1.091 \times 10^6\ W}{2.183 \times 10^6\ J/kg} = 0.50\ kg/s$$

would be need to maintain saturated conditions in the tubes.
