pedagogies (e.g., the Montessori and Reggio Emilia methods) the presumption that children are best served by highly customized instruction, and that standardized curricula are harmful to young people's self development. These ideas neatly reverse the ideal of uniform curricula common among educational leaders a century ago (Tyack 1974). While it is difficult to trace the causes of such a cultural shift definitively, it seems reasonable to posit that one driver of the change was the growing fascination with self actualization that characterized American culture in the 1960s and 1970s, and the simultaneous critiques of large bureaucratic institutions popular during this time (Bellah et al. 1985; Clecak 1983). Indeed, many early advocates of home education describe their effort as part of this broader cultural ferment (Stevens 2001). In any case, evidence from multiple studies suggests that the highly individualized instruction so valued by home schooling parents is becoming the presumed best practice in upper middle class households throughout North America (Lareau 2003; Davies et al. 2002).

Third, the emergence and endurance of home schooling is appropriately seen as part of the growing importance placed on parental choice in education generally. In the contemporary US, education is increasingly understood as a private good that families appropriately consume in the manner of their own discretion (Labaree 1997). A common corollary is the notion that educational services are best distributed through market mechanisms, which are thought to ideally match educational "products" with parents' and students' "preferences" (Chubb & Moe 1990). Within this market framework home schooling appears as but one of many potential options among which parents can choose as they see fit. The contrary idea that helped give rise to mass public schooling a century ago – namely, that education is a public good best distributed universally to all citizens – has become increasingly marginalized even while home education has moved toward the mainstream.

schools, charter

Amy Stuart Wells

In 1991, Minnesota passed the first charter school law in the United States, allowing state funds to support schools that operate autonomously from the public educational system. The charter school idea caught on quickly, with

40 states and the District of Columbia passing charter school laws between 1991 and 2006. By fall 2005, there were approximately 3,600 charter schools enrolling about 1 million students across the country.

The basic premise of charter school reform is to allow educators, parents, and/or entrepreneurs to receive per pupil funding to run schools that are exempt from many rules and regulations of the public system, including student assignment policies. Thus, charter schools not only have a great deal of autonomy in terms of their daily operations, they also have greater control over their enrollments than most public schools. They are schools of choice, enrolling students through an admissions process that often, but not always, involves a lottery. In exchange for this greater autonomy, charter schools are supposed to be held accountable for student outcomes. Each school's chartering agreement with one of various charter granting institutions – a school district, a state board of education, a state charter school board, or a university – describes its educational philosophy and goals. If a charter school fails to achieve these goals, the charter granting authority has the right to revoke the charter.

Beyond these similarities, each state charter school law is slightly different. Some laws are far more lenient than others in terms of the number of charters that can be granted or the number of charter school authorizing organizations. Furthermore, some states allow private schools to be converted into charter schools. Others allow charter schools to serve home schooling families or students who want to finish school via independent study. (These are known as non classroom based charter schools.) As a result of these differences in state laws, as well as demographic distinction in the K 12 populations, there is wide variation in the number of charter schools and their enrollments from one state to the next. For instance, in the 2005–6 school year, California claimed almost 600 charter schools serving about 200,000 students. In the same year, Mississippi had only one charter school serving 380 students.

In fact, charter school reform, as a national movement, is fairly lopsided, with only six states – Arizona, California, Florida, Michigan, Ohio, and Texas – housing nearly two thirds of the charter schools and students (see Ziebarth

et al. 2005). On the other end of the spectrum, 12 of the 40 states with charter school laws have fewer than 20 charter schools, accounting for only 3 percent of all the schools and less than 3 percent of all the students.

Thus, the popularity of charter schools is widespread but uneven, as different states and local officials embrace the reform to different degrees. This diversity across state and local lines also reflects the varied political roots of the charter school reform movement, as various supporters of charter schools jumped on the bandwagon for divergent reasons.

Charter school reform was born in the late 1980s and early 1990s, when there was growing frustration with many of the equity based policies of the 1960s and 1970s, particularly with programs such as school desegregation, compensatory education, and bilingual education, which were seen as overregulated. Policymakers were bent on trying to improve the quality of the overall educational system via an emphasis on higher educational standards – i.e., “excellence” – as well as an infusion of choice and competition.

The argument was that a rising tide would lift all boats and that both standards based accountability systems via systemic reform and a strong dose of market forces, namely competition and choice, would force all schools to respond to the needs of all students. All of this coincided with a growing demand for greater decentralization of educational governance and control. Charter school reform was in sync with all three of these efforts and is grounded in the ideology of each (see Wells et al. 2002).

CHARTER SCHOOL REFORM AFTER 15 YEARS: WHAT WE HAVE LEARNED

Despite charter school reform's political origins in both systemic reform and decentralization movements, in many ways it has been the free market advocates who have most directly shaped charter school policies. Given that 90 percent of the charter schools in the US exist in states with more deregulatory laws, much of the research on charter school reform conducted thus far provides insight into how effective the market model of school change is in the real world of schools and children. The results are not

optimistic, especially in light of the many claims attached to charter school reform at the birth of the movement. Proponents claimed that charter schools would promote achievement through their more autonomous structure. They also expected that charter schools would have greater accountability for student outcomes and public dollars, because of the possibility of losing their charter as a consequence of poor performance. Finally, charter school advocates claimed that these schools would provide choice for families and competition for public schools, improving the educational marketplace. Below, the research to date on each of these claims is summarized.

Student Achievement

Efforts to summarize and synthesize studies conducted on charter schools and student achievement have produced inconclusive but fairly negative results. In studies of national data and studies of specific state assessments, there is no evidence that charter schools are consistently outperforming regular public schools; in some cases, they are doing worse.

In Levin's (2005) review of the research on charter schools and student achievement, he concludes that although charter school advocates and opponents each choose particular studies that favor their points of view, overall there is no reliable pattern of difference between charter and public schools.

Another comprehensive review of the literature on charter schools and student achievement by Carnoy et al. (2005) examined separately those studies that drew upon the National Assessment of Educational Progress (NAEP) test scores across states and those that examined charter schools within the context of particular states by drawing on state test data. The vast majority of state level studies conclude that charter schools do not outperform public schools, even when charter schools have become well established. Carnoy et al. (2005) conclude that even when strong measures are used to control for selection bias, the effect on students of being in the charter schools appears to be negative.

Another review of literature on charter schools and student achievement by a more pro charter reform researcher demonstrates that

of 35 charter school achievement studies conducted since 2000, only 15 show positive results for charter schools (Hill 2005: 23). The 35 studies reviewed in this analysis include those conducted by politically conservative think tanks that are outspoken proponents of charter schools and vouchers.

Finally, a study conducted by the Rand Corporation (2003) found that in California, only the start up charter schools – those that, on average, over enroll white students – had slightly higher test scores than comparable public schools. Meanwhile, the charter schools that had been converted from regular public schools and enrolled a higher percentage of black and Latino students had test scores that were comparable to demographically similar public schools. And worse yet, the non classroom based charter schools – e.g., the online and independent study charter schools that enroll larger numbers of low income and/or low achieving students at a very low per pupil cost – had lower test scores than public schools with similar enrollments (see Wells & Holme 2005).

Accountability

As evidence mounts that current charter school laws have done little to improve student achievement, additional research suggests that they are rarely held accountable for student achievement. The lack of serious academic accountability for charter schools was documented in a US Department of Education study, which found that more than half of the charter school authorizers surveyed said they had difficulty closing charter schools that were failing. In fact, only 12 percent of those surveyed said they had ever revoked a charter or denied a renewal of a charter. And in those instances when an authorizer enforced a formal sanction, it was almost always due to financial problems with the charter school and rarely because of enforcement of the academic accountability provisions of the charter school laws (Finnigan et al. 2004).

Charter school reform in Dayton, Ohio, provides an example of the lack of academic accountability within the movement. Dayton experienced a proliferation of charter schools, despite evidence that the existing charter schools – many of which were operated by the

same management companies that were requesting the new charters – were performing at a lower level on state exams. A full 26 percent of students in Dayton are enrolled in charter schools, a much higher rate than in any other American city, but few of Dayton's charter schools perform better than its public schools (Dillon 2005).

In addition to the lack of academic accountability, there is also growing evidence that charter school reform opens the door for fraud and misappropriation of funds. In other words, public funding for these schools is deregulated to the degree that opportunists can make money at the public's expense. And while charter schools are more likely to be shut down because of fiscal as opposed to academic accountability issues, numerous examples of charter school closures suggest that it often takes a long time before fiscally questionable schools are closed (see Dillon 2004).

While solid research on charter school accountability – academic or fiscal – is lacking, there is no evidence that these publicly funded schools are being held *more* accountable than the regular public schools, especially in the states with the more deregulated charter school laws.

Choice and Competition

The claim that charter schools would provide students and parents with greater choice in education certainly speaks to the experiences of some of the students some of the time. Yet, research on charter school enrollments suggests that charter schools are more racially and socioeconomically segregated at the school level than the already highly segregated public schools. Further distinctions appear when researchers examine factors such as parent education and parental involvement.

Charter school proponents tout the fact that overall, when aggregated national data only are examined, charter schools serve a slightly higher percentage of students of color, if not more poor students. But more careful analyses of the data broken down by state, district, and surrounding communities demonstrate that charter schools disproportionately serve less disadvantaged students within their contexts. In other words, charter schools may well be located in

low income neighborhoods and enroll low income students of color, but oftentimes we see that the students enrolled in charter schools are less poor, have more involved and/or better educated parents, and are less likely to be labeled special needs or English language learners than their peers in nearby public schools. These data suggest that within each state, charter schools create more stratification at the school level (Cobb & Glass 1999; Fuller et al. 2003; Carnoy et al. 2005).

Furthermore, there are major differences across states in terms of the demographics of charter schools. In some states – especially Illinois, Ohio, and Michigan – charter school reform is a mostly urban reform designed to serve predominantly low income students of color. In other states, such as California, Arizona, and Colorado, it has appealed to a much wider range of people and communities, including many that are predominantly white and well off (Wells et al. 2000). Those states in which charter school minority enrollment is lower by more than 5 percent from the district enrollments house more charter schools overall than the states in which minority enrollment in charter schools is greater on average than district demographics by at least 5 percent (Ziebarth et al. 2005).

Roy and Mishel (2005) compare charter school demographics to the nearest public schools and demonstrate that in several states with the largest charter school enrollments, including Arizona, California, and Florida, charter schools enroll higher percentages of white students than their nearby public schools. They also find that charter schools in these states enroll a much lower percentage of students eligible for free or reduced price lunch than their nearby public schools.

Even when the racial/ethnic makeup of charter schools is similar to other nearby public schools, the students enrolled in charter schools are often “advantaged” in other ways. For instance, minority students attending charter schools in states where minority enrollment in charter schools is higher than in public schools tend to be socioeconomically advantaged compared to minority students in public schools (Carnoy et al. 2005). Of course, an argument could be made that even if the students enrolled in charter schools are slightly less

disadvantaged than those who attend nearby public schools, the mere fact that these public schools down the street operate within a competitive educational market means they will respond to the competition for students by improving. In reviewing this literature, Levin (2005) argues that the available results from a variety of charter school and voucher settings suggest only a modest competitive response by public schools at best.

Overall, there is little evidence that charter schools and the policies that create and support them have delivered on their promises of raising student achievement, making schools more accountable, or providing choices that the most disadvantaged students can take advantage of within a given community or context. Still, they remain a popular reform effort in great part because they are steeped in popular beliefs about the free market and competition. Researchers must continue to ask hard questions about whose interests are being served by this reform.

schools, common

Ann Owens

The rise of a common school system in nations around the world provides some evidence for a sociological theory of educational origins and expansion focused on socialization and social organization. While more functional arguments often point to the need for a well trained work force as the driving force in the rise of public education, a more sociological interpretation argues that modernizing countries, facing increased social differentiation, must transfer the socialization task from families to an institution like schools (Dreeben 1968). Another aspect of this argument is that with modernization, increased individualism also occurs, and a common school system is needed to promote national citizenship and induction into a general collectivity (Ramirez & Meyer 1980).

Current empirical evidence does not provide conclusive support for any one theory of why developing nations promote a free education system. However, in countries where this ideology of minimizing social differentiation and creating good citizens exists, this theory appears plausible. In France, for example, public education was first proposed by Enlightenment philosophers in the late 1700s in line with goals of universal citizenship and order (Alexander 2000). In the United States, common schools were established to provide a free,

state controlled education system for all citizens in line with the ideological goals of these theories. The creation of the common school system in the nineteenth century drew on the ideology of the developing republican government in that a republic depends on having a well educated and morally trained populace to direct the decisions of the government and monitor its actions. A free, state controlled education system would also alleviate political and social stratification based on education level by providing all citizens with equal opportunity to obtain a basic education, and therefore to exercise an equal vote in the new government and be competitive in the economy. Schooling became centrally controlled and organized and provided universal education.

THE NEED FOR COMMON SCHOOLS

The goal of socialization into one national collectivity was particularly salient for the US as it developed into an independent nation. In the US during the seventeenth and eighteenth centuries, education was the responsibility of parents and local communities. Demand for uniform, compulsory education grew from both pragmatic and ideological needs. First, citizens wanted a basic education to eliminate the disparate literacy levels between native colonists and British immigrants and between North and South; second, literacy was necessary to study the Bible, essential for salvation to Calvinists and Protestants; and finally, the growing economy in the colonies demanded the ability to read and do basic math for trading and planning purposes (Kaestle 1983). Availability and quality of schools, teachers, and curriculum were unregulated and unequal across towns and states, producing educational differences across regions. Low quality and limited availability of elementary schooling were reasons enough for the education system to be reformed; however, it was the political and ideological climate of the time that gave rise to the development of the common school system in the nineteenth century (Kaestle 1983; Tyack et al. 1987).

As the US government developed, political theorists began to see education as a key tool in maintaining the republican ideals on which the country was founded, with education acting as

“the fourth branch of government” (Tyack et al. 1987). The republican system of government depended on an enlightened general populace that understood what was in their best interest. Additionally, citizens needed to be well informed to be able to prevent some of the corruption that the Americans saw and eschewed in the European governments. Therefore, common education would serve as a training ground for citizens: citizens could be taught basic literacy and numeracy skills, but also receive “moral training” consistent with Protestant ideals and be informed on political and economic issues (Kaestle 1983, 2000). Further, with a country as big as America, republican government would not work without a well ordered population, and education was seen as a way to produce this orderly public. Common education would protect the government from having to act on an uninformed will, and also give the people power to protect themselves from a corrupt government. Education became a tool to distribute power more equitably among the populace.

In addition to maintaining republican goals, the common school system was seen as a way to reduce social and political stratification. At this time, the “haves” and “have nots” were distinguished by their levels of literacy and education, as education was necessary to be successful in trading and business and also necessary to be considered an appropriate choice for government office. Because there was no free school system, only those with money were able to send their children to school, and this system of education resulted in social reproduction wherein power stayed in the upper class. There were marked disparities in education by gender, race, nativity, and region. Women were rarely educated, nor were blacks or Native Americans. Northern states, New England in particular, had developed a more widespread system of education since the region was organized around highly populated towns compared with the less densely populated South (Kaestle 1983). European immigrants had often attended better schools in their home countries than were available to native colonists. Common schools were seen as a way to allow all citizens to have an equal chance to be qualified to hold positions of power, and education began to be seen as a mechanism for social mobility.

THE CREATION OF A COMMON SCHOOL SYSTEM

The earliest attempts to establish a common school system were by individual states, with New York, Massachusetts, and Connecticut leading the way. These early attempts often resulted in states using taxes from land or land grants to partially fund schools, but tuition was still charged to cover remaining expenses. From the late 1700s through the 1830s, the types of schools supported by state funds were not uniform; for example, New York state money went toward supporting existing private schools rather than supporting free schools (Ravitch 2000). In states where state funds were not allocated for education, particularly in the South, schools continued to be funded entirely by tuition payments, doing little to alleviate knowledge stratification among the classes. Apprenticeship and charity church education programs also existed.

In the early nineteenth century, the population and economy of America were booming, and these social changes helped pave the way for educational reform. While the economy prospered, the rewards to individuals were unequal, with the more educated generally being more successful. Also, with the population boom, America was experiencing higher rates of crime, a more diverse population, and more crowded cities. While the ideology of common schools had existed for some time, education now began to be seen as a pragmatic solution for decreasing stratification and cultural conflicts and maintaining social order. Schools could be designed as “factories” that could teach moral discipline (an increasingly popular movement in the early nineteenth century) and arm American citizens with basic education so that everyone had an equal chance for upward mobility in the thriving economy (Tyack et al. 1987). Also wanting to protect citizens’ power from the growing government, the public began to more vocally support the idea of a common school system, treating it as a necessity rather than rhetoric. The environment was ripe to implement reforms.

From the 1830s through the 1860s, reformers worked to pass legislation to establish a compulsory free schooling system. Two of the most prominent common schools reformers were

Henry Barnard and Horace Mann. In the late 1830s, each pushed through reforms in their respective state legislatures (Barnard in Connecticut, Mann in Massachusetts) similar to those being supported across the country and modeled after reforms in Europe. The basic demands of the common school supporters were that states should provide "free schooling, improved facilities, better classification, longer school years, better teacher training" (Kaestle 1983). Reformers also attempted to pull support from private schools by depicting them as non-republican institutions that reproduced social stratification, and states were encouraged to provide entirely free, high quality schools to reduce the appeal of private schools.

While the South considerably lagged behind the North in initiating changes, most states had established common schools by 1860. More students were attending school, and for longer periods of time. Schools became more highly organized, with a system of high schools serving as an umbrella under which to organize district schools. The concept of teacher training was debated, and the earliest education schools were set up, although few teachers attended them (Kaestle 1983). At the urging of reformer John Philbrick, schools were organized under a principal who had 10 to 12 usually female teachers. Major changes occurred with respect to centralizing control. In the early nineteenth century, schools were under the control of local community governments, which many argued allowed for inconsistent teaching and facilities standards. During the 1840s and 1850s, schools in most states were reorganized into larger districts and became state controlled and supervised. The office of school superintendent was created at the state level and was often combined with the secretary of state position. Schools became an organization run by this state superintendent, and large cities began to create school boards with officials elected by the public to work with the school leaders (Tyack 1974).

The reformers had made progress, but a minority in the population did not support the creation of a common school system. One major dispute was over the centralized control of schools as an organization. Some citizens felt that centralized control was too bureaucratic and would turn schools into a "mindless machine" directed by the state superintendent

(Tyack 1974). Also, a centralized school governing body could ignore local actors and regional and cultural differences (e.g., factory towns wanting more vocational education for their children), and individuals would not have a choice in how schools were run. However, supporters argued that centralized control would equalize school spending between rich and poor by providing free and regulated schools, and schools would also regulate discipline and offer all citizens the same basic curriculum. Political lines were drawn, with Democrats favoring local control of schooling and less government intervention and Whigs favoring state controlled systems and a more uniform training for all. Individual ethnic and religious groups wanted to keep elements of their culture and teachings in the school curriculum, and they too opposed state regulated schools and curricula. Eventually, the push for state controlled schools succeeded largely because of the strength of the republican rhetoric regarding the need for equal education and thus an equal voice for all, and because of the appeal of free, high quality schools open to everyone (Kaestle 1983).

The success of school reform required spending, and some citizens were reluctant to pay increased taxes. Some argued that common schooling supported by general taxation favored the rich. The working class resented having to pay the same taxes for schooling as people who could readily afford to send their children to private schools. These opponents of the free common schools argued that states should not require poor communities to support free schools if they were not able to. Additionally, those citizens who did not have children who were attending school resented having to pay education taxes. When higher taxation was proposed, poor communities rejected these proposals, while other communities felt compelled to support the ideals of common schools by paying what their superintendents required. Because of the economic boom in America, many states had sufficient funds to finance school initiatives, and increased taxation could be avoided. In states and communities that had fewer financial resources, ways to cut costs were proposed, including the hiring of female teachers, who, while not readily received or respected, were cheaper than male teachers. This early use of women as cheap labor, some argued, established

a gender hierarchy in education and other institutions that remains today (Kaestle 1983). By the 1870s, reformers were for the most part able to assuage opponents of tax supported schools by developing appropriate local tax formulas and by persuading the public that everyone benefited from a well educated populace because of the social order it facilitated, and therefore everyone should pay.

By the 1860s, a common school system had been set up in America with public access to state funded education under the control of state governments. Rural schools were still often heavily influenced by local taxpayers rather than state legislation, few teachers were properly trained, and disagreements over the curriculum and religion's place in it still persisted. However, the reformers had created a common school system based on ideology that still pervades the American educational system today. First, education for all is a republican ideal which allows everyone an equal chance; providing everyone with an equitable foundation will allow for social mobility for all racial, ethnic, and socioeconomic groups. Second, by centrally controlling education, equality and uniformity of instruction are guaranteed. This nascent common school system provided the foundation for the system of schooling that is in place today.

The origins of education systems vary across the world, and one factor in this variation is the ideological goals of each country. The economic system and degree of industrialization as well as the development of the nation state also influenced the rise of education systems around the world, but in countries where increasing social differentiation was seen as a threat to stability and where democratic ideals needed to be taught to a mass citizenry, common schools arose in part to serve these needs.

schools, magnet

Amy G. Langenkamp

Magnet schools are public schools defined by three principal characteristics: a distinctive curriculum or instructional approach, enrollment of students from outside the designated neighborhood attendance zones, and desegregation as their explicit purpose. Magnet schools have been used for desegregation since the mid 1970s. However, the concept of magnet schools is based on district specialty schools which have been present since the 1900s. Currently, there are two major national studies of magnet schools.

Blank et al. (1983) conducted a study in 1973 which found a significant increase in magnet schools since being accepted as a voluntary strategy for desegregating schools, from 14 to 138 districts during the first five years. Second, Steel and Levine conducted a nationally representative study of 600 multischool districts in

1992 and found magnet programs offered in at least 230 public school districts, serving 1.2 million students mostly in districts with a court ordered desegregation plan. Most magnet schools emphasize a particular subject area, and one fifth offer a distinctive instructional approach. Magnet schools are not homogeneous. Instead, magnet programs are offered at the elementary, middle, and high school level and function as Programs Within Schools (PWS) or whole school magnets (Steel & Levine 1994). For simplicity, PWS and whole school magnets will be referred to interchangeably unless otherwise indicated.

HISTORY AND DEVELOPMENT OF MAGNET SCHOOLS

The concept of magnet schools comes from district wide specialty schools such as the Bronx High School of Science in New York City. Magnet schools are also historically linked to school desegregation efforts. Court decisions of the civil rights era outlawed segregation in schooling and required school districts to produce racially mixed schools, such as the 1968 Supreme Court case of *Green v. Board of Education* in Virginia and *Swann v. Charlotte-Mecklenburg* in North Carolina (see Steel & Levine 1994 for a review). Faced with the challenge of integrating schools and whites' hesitancy to voluntarily transfer their children to majority minority schools, districts began forced busing. Violent protests and the exodus of many white families from the public and urban school system ensued (Meeks et al. 2000). Therefore, in 1975, magnet schools were allowed as a voluntary strategy for desegregation. Since that time, magnet schools' prevalence has grown enormously. In 1996, 85 percent of magnet schools were in court ordered districts (Steel & Levine 1994).

However, the connection of magnet schools to desegregation is only the initial reason for their growth in the US educational system. The report *A Nation at Risk* (1983) spurned education reform for more high quality and locally controlled public schools, the goal being to develop a stronger sense of community and increased parental involvement in their children's education (Steel & Levine 1994;

Gamoran 1996). In addition, federal funding has facilitated the growth of magnet schools.

Desegregation efforts have been funded principally through two federal programs, the Emergency School Aid Act (ESAA) from 1975 to 1981 and the Magnet School Assistance Program (MSAP), which began funding the start of new magnet programs or adding to current magnet programs in the mid 1980s. Funding from MSAP is conditional on schools' mission of reducing minority isolation, eliminating minority isolation, or preventing minority enrollment from rising above the district levels (Steel & Levine 1994). Funding for staff development, curriculum planning, supplies, and outreach contributed to 80 percent of the \$739 million spent between 1985 and 1991. Magnet programs are more extensive in districts that received MSAP funding; schools without funding have fewer outreach programs to recruit new students and provide limited transportation to students. MSAP funding affects the broader district as well. Districts without MSAP funding but with magnet programs can strip other public schools in that district of funding (Estes et al. 1990). For example, when compared to other public schools in the same district, magnet schools have additional staffing allowances, smaller classes, and more expenditure per pupil (Steel & Levine 1994).

PREVALENCE OF MAGNET SCHOOLS

Part of the difficulty in studying the effects of magnet schools, despite their increasing prevalence in urban school districts, is their heterogeneity. Typically, magnet schools have a distinctive curriculum, attract students from outside the neighborhood attendance zone, and have desegregation as their goal (Steel & Levine 1994). Fifty eight percent of magnet schools are in elementary schools and 38 percent are PWS magnets. Whole school magnets are more common in elementary schools while PWS magnets are more common in middle and secondary schools. Among magnets, instructional approaches are broken down as follows: 37 percent have an emphasis in a specific subject area, 27 percent offer a particular instructional approach, 14 percent have career vocational emphases, 12 percent are gifted and talented

magnets, and 11 percent have specific arts programs.

Even with their increase in urban districts, all schools in Steel and Levine's study maintain waiting lists for student attendance. To attract students to their schools, a typical district uses a variety of outreach strategies such as recruiting students from surrounding schools. Approximately one third of magnet schools are "dedicated" magnets, where there is no attendance zone and all students must choose to attend. The rest of the magnet schools have a neighborhood attendance zone and attract additional students from other attendance zones. Typically, those non dedicated magnets are comprised of white students attending magnet schools in minority neighborhoods (Steel & Levine 1994). About one third of magnet schools use program specific selection criteria; this practice is most common at gifted and talented magnet schools. In addition, the use of selection criteria is more common at magnet high schools.

Much of the research on magnet schools has been concerned with desegregating urban schools. Within magnet schools, the racial balance of students has been shown to differ from their schools' racial composition. For example, 71 percent of the students in PWS magnets are minority but only 61 percent of the students in the magnet program are minority (Steel & Levine 1994). In addition, magnet enrollment in white districts is predominantly minority, while minority district enrollment is predominantly white. Overall, most magnet schools are in predominantly minority urban school districts. Given this, researchers have debated the validity of magnet schools as true indications of desegregation. In addition, low income, special education, and limited English proficient students are underrepresented in magnet schools. Desegregation is a central theme for research on magnet schools: whether they contribute to desegregation efforts, if they increase educational quality in the district, and the types of magnets that are more or less successful in attaining these goals.

EMPIRICAL RESEARCH ON MAGNET SCHOOLS

Besides the two large reports referenced above, most empirical research on magnet schools

consists of district and school case studies. Partly, this is because the goals of desegregation for magnet schools are largely dependent on the type of magnet programs and minority trends of enrollment in a particular school or district. Many researchers find that tailoring magnet schools to needs of communities is more responsive to students' needs and makes a greater impact.

Much research on magnet schools involves the definition and measurement of desegregation. Desegregation can be measured by the simple racial composition of schools, which is often called a reduction of minority isolation. This is a prevalent measure for regional magnet schools. On the other hand, PWS magnets could "reduce isolation" at the school level but still have classrooms with very little interracial exposure (Estes et al. 1990).

Although most magnet schools' mission is desegregation, they are still voluntary. This creates a challenge for school districts. While court ordered magnet schools have been found to increase interracial exposure more effectively, these are also more likely to re-segregate once the court directive period has ended (Rossell 1990). Researchers have hypothesized why this might occur; magnet schools can only attract white students into minority areas if the district puts additional funds and a special curriculum into that school, whereas minority parents have been found to transfer their children to white schools categorically.

Concerning their quality, magnet schools have been found to offer a high quality of education, with higher levels of student achievement in certain areas (Gamoran 1996) and more teacher/student satisfaction with the learning environment (Estes et al. 1990). Magnet schools also improve the quality of education in their district by creating models of parent/school communication as well as raising the bar for non magnet schools to compete for students. At the same time, researchers conclude that magnet schools must be considered as separate entities from other public schools (Gamoran 1996). Minority students attending magnet schools are a selective group, with well informed parents and often passing an entrance exam. White students attending magnets often have parents who are dedicated to interracial exposure for their children. In addition, magnet

schools are typically better funded than other public schools.

Future research of magnet schools needs to be conducted, particularly research concerning the impact of magnet schools on long term desegregation efforts. Currently, there is a heavy reliance on magnet schools for efforts of desegregation. In addition, magnet schools are most widespread in urban districts, more often attracting white students into high quality magnet schools in the minority district than vice versa. This serves a relatively small percentage of students within the district (Estes et al. 1990; West 1994). To determine the impact of inter racial exposure on the problem of minority isolation and the race/ethnic achievement gap, research should focus on two aspects of magnet schools: for whole school magnets, comparing magnet schools to other schools in the same district, and for PWS magnets, comparing student performance of magnet students and non magnet students. Research examining equity of access for parents and students to other public school choice policies is relevant for the study of magnet schools as well (see Coleman et al. 1993 for an example).

Many scholars agree that magnet schools are high quality public schools with a targeted goal of reducing or eliminating minority isolation. They keep white students and students from higher socioeconomic groups in the public school system when they might otherwise opt for a private school. Perhaps most importantly, magnet schools use the goal of desegregation to enhance students' education through a diverse student body. Critique of magnet schools rarely focuses on their quality. Instead, researchers are concerned about magnet schools' ability to function as a broad based solution of school desegregation. Future research on magnet schools is needed in areas such as the local context of successful magnet schools, magnet schools' ubiquity in reaching the goal of desegregated public schools, and the extent to which student learning is improved.

schools, professional

Elizabeth McGhee Hassrick

Professional schools play an important role in socialization and stratification processes in modern societies. The credential process for professions, in which a person trains to become a legitimate practitioner, is currently dominated by universities. Universities established certification programs during the late 1800s, successfully outcompeting the guild based apprenticeships and mentorships of earlier centuries (Stevens 1983). Before World War II, most professional schools were located in elite

private universities, accessible only to the wealthy, but enrollment in professional schools dramatically increased post World War II, shifting participation from an elite arena to one more accessible across social class. Sociological researchers have explored the social and psychological effects of participation in professional schools (Becker et al. 1961; Hughes et al. 1973; Fox 1979), and sorting processes have been identified that influence the stratification of people from different classes, races, and genders as they seek to gain entrance and successfully complete professional school programs (Spaeth 1968; Spangler et al. 1978; Stolzenberg 1994; Schlee 2000). Much of the research about professional schools has been conducted within specific professions, in the service of practitioners. Cross disciplinary studies investigating the connections among professional schools, professions, and larger social processes have been neglected.

PROFESSIONALS IN TRAINING

Sociological evaluation of professional school programs began when enrollment dramatically increased during the late 1950s and early 1960s. Research debates over the role of professional students brought social and psychological considerations to the forefront. The Columbia group (Merton et al. 1957) argued that professional students were practitioners in training, participating in social processes and curricular content that prepared them for their future careers as professionals, able to “live up to the expectations of the professional role, long after they have left the sustaining value environment provided by the school” (p. 138). Such things as vague descriptions of expectations and clinical opportunities to observe physicians dealing with the inconsistencies of pharmaceutical outcomes and the experimental aspects of diagnosing provided medical students with exposure to the limits and uncertainties of their chosen profession (Fox 1979). The Chicago group (Becker et al. 1961) claimed that professional students gained mastery at being students, not professionals. Becker et al. focused their studies on the interactions students had with each other when faced with the day to day problem of being successful students. The conduct of

the “boys in white” was significantly shaped by situational constraints placed on students by institutions that emphasized their role as temporary and interchangeable subordinates. Both approaches were focused on socializing processes that occurred during professional school training.

PROFESSIONAL SCHOOLS AND SORTING PROCESSES

Educational processes greatly influence the positions people occupy in a stratified society. Determining what part professional schools play in the stratification process requires attention to the stages of participation (entry, progress through, and placement after completion) as well as to the differentiation found within as well as between professions and their related schools.

Enrollment

Modern stratification research has revealed that parents play a significant role in high school and college enrollment, but what about graduate schools? Studies on the effect that parents have on graduate school enrollment have produced mixed findings, once types of graduate schools were disaggregated. Parents were found to have no effect on student enrollment into MBA programs (Stolzenberg 1994) and little effect on master's programs. However, a strong parent effect was found for first professional and doctoral programs. The effect was indirect, related to student undergraduate institutions, academic performance, educational expectations, and career values. The academic achievement of students was determined as having a strong independent effect on enrollment in all kinds of professional studies. Students sometimes choose to enroll in a professional school, not to become a particular kind of professional but to maintain their lifestyle and social status. Schlee's (2000) study about law and business school choice found that students expressed ambiguity about a specific preference between law or business, and were most interested in being intellectually stimulated and maintaining their lifestyles and social status.

Achievement

Identifying the processes that influence achievement during professional school attendance has been a highly segregated project, implemented by each separate profession in the service of improving its own professional schools. Academic progress through law school has been shown to be affected by the concept of tokenism. When women were a small minority of the student body, factors such as role entrapment and social isolation had a negative effect on women's achievement (Spangler et al. 1978). More recent studies reveal a lessened effect on women enrolled in law schools after 1991, but a sustained negative effect on ethnic minorities (Clydesdale 2004) that diminishes achievements and increases academic differences between majority and minority groups. While research about law schools centers around issues of equity, business school critics struggle over the divide between research and practice. Recent business school critics complain of excessive "pure" research at the expense of messy multi-disciplinary practice (Zell 2005). More research about achievement across different professions is needed.

Placement

Placement after completion of professional school has been associated with prestige. Graduates from elite graduate programs win jobs with higher professional prestige. Each kind of professional work commands different levels of intraprofessional prestige. For example, the surgeon commands more professional respect than the family doctor, or the tax lawyer as compared with the labor lawyer. Abbott (1981) attributes the intraprofessional status hierarchy to the amount of "pure" professional work that each role demands, meaning, for example, that a surgeon is able to exclude more non medical tasks than the family doctor. In contrast, Heinz and Laumann (1982) assert that the status of different kinds of professional work is tied to the client base that pays for the work to be done. Corporate lawyers who negotiate complex legal contracts have high levels of intraprofessional prestige because their clients are wealthy. In

both formulations, generalists command less prestige within professions as compared with specialists. Professional schools reflect task and prestige hierarchies differently across professions. For example, in medical school, students compete for the chance to receive extended specialized training, whereas in law school, students from elite programs win placement in firms that practice specialized work that is considered more prestigious (Heinz & Laumann 1982). Graduates from prestigious law schools are more likely to be employed by elite firms with corporate clients, whereas "local" school graduates are more likely to have solo practices or be employed by small firms that serve individuals.

Differentiation

The differentiation found between professions impacts the status, quality, and quantity of professional schools. The number and types of colleges and their related professional training programs have diversified post World War II, and occupational categories have aligned themselves accordingly. Hughes et al. (1973) identified a task hierarchy where mundane and easily routinized tasks were relegated to various sub professions, for example, lab technicians, dental assistants, and paralegals. These trades are most often learned in vocational and two year community schools, whereas related professionals, such as dentists and lawyers, are trained in professional schools situated in four year universities. The resources necessary to establish and sustain professional schools at four year universities are related to the status and power of particular professions. Competition between occupations vying for secure professional standing has been understood both as a systemic process (Abbott 1988), where historically situated, interdependent professions combine, expand, change, and die, and as a market driven process (Larson 1977), where professions seek to monopolize markets to retain power. Sociologists have also sought to identify the essential features of professions, citing specialized knowledge, shared standards of practice, and strong service ethics (Freidson 1994) as characteristics of well established professions. Professions most aligned with the "ideal type" have the

greatest amount of public support. Research about how struggles between professions impact professional schools has been neglected.

In conclusion, professional schools remain the final frontier in educational research across school types. Most often, professional schools are grouped as a subcategory in higher education, but the close connection they share with the professions and the important role that they play in socialization and stratification processes in modern societies merit closer examination and theory development across professions. Research conducted within each profession regarding professional school performance does not provide the kind of analysis that will reveal how professional schools impact social processes.

schools, public

Ann Owens

For most nations, a free school system exists to provide all citizens with the basic skills needed to function successfully in society. Public schools teach basic literacy and numeracy skills and also socialize students into the incentive structure and power hierarchy of industry (Tyack 1974). From a functionalist perspective, many industrializing nations depended on workers with a basic education, requiring a universal system that could educate the workforce.

Industrialization also required more specialized workers, and highly organized public schools were necessary for advanced curricula and training. In addition to the pragmatic need for public education in maintaining an ordered society of viable workers, some nations' ideological goals also pervaded the creation and evolution of the education system. Public education is considered a tool for social mobility, a way for all children to obtain a common foundation for advancement, improvement, and success in society despite the background of their parents (Coleman & Hoffer 1987). Public schools teach a common curriculum and singular value system that allows students to effectively function in society and the economy. By equalizing the basic education all students receive, differences between community and family background characteristics can be minimized, alleviating stratification based on race/ethnicity or background resources. Education is also seen as fundamental investment in one's human capital (Becker 1993). Human capital is defined as investments one can make in oneself by pursuing training, knowledge accumulation, and health or medical care that will improve later well being and outcomes. The public school system provides a strong and universally available foundation for training and education, which serves as human capital that improves later financial gains and success.

Public schools do not have the same origins in all nations, however. The functional argument that industrialized nations drove the creation of schooling because of their need for educated workers does not ring true in places like Scotland, Prussia, France, and Japan, where schooling systems were developed before industrialization in those countries (Ramirez & Meyer 1980). Perhaps because of international pressure from the global community, many developing countries have also offered free and compulsory education to students from all social backgrounds, such as systems in Hong Kong, Malaysia, and even such highly stratified places as South Africa (Buchmann & Hannum 2001). Other empirical evidence points to the importance of a strong nation state in developing an education system; for example, the concurrent development of the education system and nation state in France and Prussia, although this theory does not hold in places such as

Britain and the US (Ramirez & Meyer 1980). While theories about the origins of a public education system have not converged around a singular conclusion, education is generally seen as a fundamental part of society, and its creation in various nations often coincides with the creation of other major institutions like government and the economy or in line with ideological goals of equality.

ORGANIZATIONAL CHANGES IN US PUBLIC SCHOOLS

Practical and ideological demands for free and compulsory schooling developed in the nineteenth century in many western countries. In the US, as in many European countries, societal changes of an economy increasingly dependent on industry and a booming population demanded an education system that could teach citizenship, social order, and standards for employment (Tyack 1974). Public education moved from being provided by families and churches to a highly organized, freely accessible system designed to prepare students for the modernizing world of work. In addition, a focus on social issues such as worker rights and equal wages also amplified the ideological debate on equal opportunity. Throughout the late nineteenth and twentieth centuries, movement toward free public education in the American school system was paralleled in other western countries, i.e., England (the Educational Act of 1870), France (the creation of the Republican schools), and Germany (whose eight year program of free schooling precedes most other countries, as it was established in the eighteenth century). The organization of public schools in the United States was tightened compared with the earlier common schools. Public schools needed to be reorganized to serve an increasingly stratified society, create effective workers, and to ensure that social control was maintained. Despite efforts by common school organizers in the late 1800s, disparities in curriculum, resources, and teacher training existed in schools. Public schools were to give all citizens an equal base in education, and therefore standards needed to be more uniformly established.

The main changes in the US public school system in the first half of the twentieth century

were with respect to control. Common schools were run by a superintendent and a large city school board. There was often conflict between the superintendent, viewed as a "professional" educator, and the members of the board, who were general citizens. The board and general public often saw the superintendent as a professional living off public tax money, and the superintendent saw a large, untrained, and meddling school board. In contrast to common school reformers, public school reformers argued for professionally controlled, more bureaucratically structured schools based on a science of education rather than community ideals. School boards were overhauled to be comprised of a small number of businessmen and professionals: schools were mimicking the organization of industry, where corporate board membership was entrusted only to the most highly qualified professionals. Schools now operated under a professionally trained superintendent, who, in conjunction with a professionally trained school board, advised and governed the school principal, who in turn oversaw teachers.

Aside from reorganization, progressive reformers were able to pass legislation mandating state standards for teachers with respect to training and hiring policy, thus increasing the professionalization of teaching as a profession, compulsory attendance, health and sanitation requirements, building standards, and regulated curricula like physical education (Tyack et al. 1987). Another change was the legal requirement of children to attend school, with parents eligible for punishment if their offspring were truant, emphasizing the organizational and socialization functions of public schools. Because of high costs for these reforms, new initiatives to supply federal aid to education were proposed in the late 1940s and early 1950s. Federal funding was often contested because of fears of centralization and disregard for local traditions or needs, and Catholic schools were outraged at the prospect of being cut out of funding, which would only serve public schools. To compromise, federal aid was offered to "federally impacted" communities whose schools were overcrowded because of an influx of federal workers; over the decades, increasing numbers of districts were able to qualify themselves as "federally impacted" to receive aid. However, the majority of funding still comes at the state and local level (Ravitch 1983).

CONTROVERSY AND REFORM IN US PUBLIC SCHOOLS

Several of the most controversial changes in public education have stemmed from the goals of social mobility and equal opportunity for all. The racial integration of schools is perhaps the most major and significant reform. In 1896, the *Plessy v. Ferguson* decision guaranteed "separate but equal" facilities for blacks and whites. However, equal education was rarely provided to blacks and whites in the first half of the twentieth century, when a dual school system existed wherein public funds, teacher training and pay, and facilities were far better for whites than blacks (Ravitch 1983). Along with the rising Civil Rights Movement and campaigns by the National Association for the Advancement of Colored People (NAACP), the *Brown v. Board of Education* decision in 1954 resulted in the Supreme Court declaring that separate schooling on the basis of race was inherently unequal. This decision set the stage for the slow and often opposed process of school integration.

Despite the legal sanctions, school integration happened very slowly and was examined in the Equality of Educational Opportunity Report, which was commissioned by the Civil Rights Act of 1964, and led by James S. Coleman (1966). The Coleman Report concluded that few schools were actually significantly racially diverse, and that family background and social composition of the school were more important predictors of academic success than school resources. This controversial report resulted in the idea that racial integration was key to academic success, and integration programs were developed which often involved busing lower resource or minority children to wealthier schools. This solution, however, led to further problems, with Coleman among others arguing that forced integration contributed to white flight, with white families leaving large urban districts that included lower resource families to create all white districts.

The equality of public schools has been examined again and again, on different bases. The establishment of Head Start preschool programs was influenced by research indicating that poor children were culturally or educationally "deficient" at the beginning of schooling.

Head Start was intended to be geared specifically toward the culture of impoverished children to give them not only academic preparation but also cultural skills to be competitive with middle class children. Head Start was partially funded by the 1965 passage of the Title I program of the Elementary and Secondary Education Act, which was designed to “meet the special educational needs of educationally deprived children” (Ravitch 1983: 159).

The 2001 No Child Left Behind (NCLB) Act signified the movement in educational reform toward accountability and standards testing. This movement draws on the ideology of schooling as a tool for social mobility and the pragmatic goal of readying all children for viable employment. By pushing for more stringent evaluations and standards, reformers are attempting to ensure that the quality of instruction between schools becomes more uniform, arming children with equal foundations. Standards testing provides an opportunity to gather data about students and schools, opening performance in public schools to parents, educational reformers, and policymakers. By closely evaluating students and identifying substandard teachers, NCLB attempts to strongly couple federal guidelines to curriculum and teaching to results, with consequences for schools who fail to improve test scores (i.e., requiring supplemental free tutoring and eventual reconstitution of a school that continually does not meet standards). Reform efforts have been constant since the establishment of an organized school system, with mixed results. However, the intention of the US public school system remains unchanged today: to provide all citizens with access to a basic education necessary for employment and success in society, and to provide equal opportunity for future advancement to all.

GLOBAL PATTERNS IN PUBLIC SCHOOL SYSTEMS

Public schools (often called state (in England) or free schools abroad) in other countries are similar in that they are government funded and offer free education for some compulsory length of time; however, systems across the globe vary with respect to degree of centralization or

decentralization of schooling and the existence of a national curriculum. France, for example, is considered to be highly centralized regarding curricula, but teaching methods are not strictly controlled (Alexander 2000). India is also fairly centralized, with policy changes and interventions occurring at the national level, although state and local governments influence some matters of expenditure and day to day functioning (Alexander 2000). In England, where the origins of the state school system occurred later than many other industrialized countries (not until the late nineteenth century), control of the public school system is in the hands of the central government, and schools and teachers have little autonomy (Alexander 2000). While national assessment standards, much like NCLB, are in place in England, the ideology of the English system does not reflect this centralization; since 2003, the focus has been on differences between children and serving individual needs, as outlined in the “Every Child Matters” green paper published by the Department for Education and Skills (2003). In contrast, Russia has moved toward a more decentralized system, focusing on an ideology of individualism and differentiation among students and developing a system (since the early 1990s) wherein the local government is responsible for financial, pedagogical, and professional development matters (Alexander 2000).

Most countries have established a national curriculum that is taught with little variation throughout districts. Language, mathematics, natural science, social science, the arts, and physical education are the subjects most often included in national curricula (Benavot et al. 1991). Regionally, there are some differences in the national curricula: for example, Latin American countries tend to spend less time on language instruction and more time on natural and social sciences, while countries in the Middle East or North Africa are more likely than other countries to include religious instruction in their national curricula (Benavot et al. 1991). Examining curricula globally, researchers have argued that stable patterns in curricula type can be seen across countries and over time, and that the rise and fall of certain curricula in different countries depend on the world political and historical climate at the time of their adoption,

rather than economic, political, or social factors at the national level (Kamens et al. 1996), implying that public education systems are moving toward a convergence around curricular choices. Public school systems around the world have responded to different reform movements as the national ideology, centralization of government power, and economic system have demanded, but the goal of providing free basic education for all citizens has persisted.

schools, religious

Jaap Dronkers

Religion and education have a long common history, dating back to prehistoric times. Religion and religious practices require structures for the preparation, initiation, and training of new members and of priests and teachers. For that reason, religious groups in premodern societies sooner or later took the responsibility of organizing the socialization of their new members and of their religious specialists. This does not mean that all education in premodern societies was organized by religious organizations. Non religious authorities, including kings, lords, cities, and guilds, organized a part of the socialization of the new societal members (for instance, warrior schools, apprenticeships, and academies for the training of bureaucrats), but in most premodern societies the major part of education outside the family was organized by or on behalf of religious organizations. One can argue that most schools in premodern societies were religious schools. Education was organized and financed by religious organizations, the content of education was controlled by religious authorities, and, in most cases, teachers were incorporated into these religious organizations, e.g., as monks or members of rank. This was true not only for schools at a basic level, but also for higher levels of education.

The transition from premodern to modern societies in Europe and North America between the sixteenth and nineteenth centuries led in most societies to a struggle between the state and the established church over the organization, financing, and content of education. This struggle was inspired by growing skepticism regarding religious teaching during the Enlightenment, by the increasing need for knowledge and skills not related to the needs of the

churches (growing technological sophistication, modern languages), and by the need of states, instead of a partly hostile church, to define the content of citizenship. It is important to note that this struggle between the state and the established churches took a different path in Anglo Saxon countries than in continental European societies (Archer 1984). In those European societies that were influenced by the French Revolution (including the United States), a legal and often constitutional separation between church and state was introduced at some point. Depending on the conditions of this separation and on the political parties involved, public and religious schools were allowed and sometimes partly or fully funded by the state. Although *de facto* separation between church and state emerged during the nineteenth century in many Anglo Saxon societies, with the exception of the United States, there was no constitutional separation between church and state in these societies. This made the distinction between public and private schools less clear. One consequence of the distinction between public and religious schools was the growing need of churches for the direct socialization of their new members, for which there had become less room in the public schools. Sunday schools, Qur'an schools, and the like emerged beginning in the nineteenth century in modern societies, but they were set up purely for religious socialization and no longer for the general education of their pupils. Although these institutions for religious socialization are often called schools, they should not be confused with religious schools, which are schools with mainly the same educational goals and programs as public schools, but which are organized and maintained by a private body that also has religious goals.

As a consequence of the struggle between the church and the state in many European societies, modern religious schools have different relations with the state. Within the educational systems of western industrial societies, schools can be roughly categorized on two dimensions. On the one hand, the issue is who makes decisions concerning the organization and curricula that schools provide; on the other hand, the source of funding for this education is key. In relation to the first issue, two types of religious

schools have emerged in most western countries. As a result of the struggle between the state and the established church, states have taken on the responsibility of organizing education. Here lies the root of public education that is fully governed and financed by public agencies (Archer 1984). At the same time, religious schools have been established or maintained by the efforts of churches and other religious institutions. However, it is important to note that non religious ideological and commercial organizations have also established private schools. Although schools of this type often still have to comply with government regulations to a certain extent, partly depending on the amount of financial support received from the government, the crucial decisions regarding the schools' affairs are made by private entities. Within this private sector, religious schools can again be classified as either government dependent or government independent by the extent to which they are subsidized by the state. Governmental subsidization of religious schools is secured by law in many countries, either in the constitution, as in The Netherlands and Germany, or in common law, as in France and Hungary. In many cases, this right results from claims of mostly religious groups to education based on the values and ideologies of the parents who are members of these groups and who are considered to be responsible for the way their children are raised. Alongside these religious government dependent schools, there exist in a number of countries, including Italy and the United States, religious schools that do not receive any government support. These schools finance themselves by means of pupil fees, donations, private sponsoring, and the like. Again, the two dimensions – governance and financing – cannot be considered to be completely independent of each other. When the amount of governmental financial support of private schools becomes larger, these governments will also demand a higher degree of influence on the programs that the schools offer. However, even schools that are completely independent financially will generally not be entirely free to determine the contents of their programs and will have to comply with minimal requirements on quality and safety. Moreover, the social context will also place constraints on schools' freedom. For

example, diplomas that meet generally accepted standards have become indispensable in modern societies.

Public and religious schools can be seen as the result of two different approaches to schooling. According to one point of view, schooling is an instrument of society as a whole (as represented by the central state) to prepare individuals for a life within society, independent of their social background, and in which religious convictions are considered to be a private matter. Public schools result from this point of view. The competing standpoint states that schools are an instrument not just of society but of parents and the social and cultural groups to which they belong. The aim of schooling according to this point of view is to offer young people an education that is in accordance with the religious way of life of their parents and their environment. Religious schools, more or less subsidized by the state, are the consequence of this approach (Coleman & Hoffer 1987; Godwin & Kemerer 2002).

Catholic schools are not the only examples of religious schools. Depending on the religious history and composition of a society, religious schools can also be Protestant, either related to a specific Protestant denomination (Lutheran, Evangelical, Baptist) or more general. The same holds for the *de facto* degree of orthodoxy of religious schools; it can be quite strong in some religious schools, while hardly existing in others. Religious schools are not only Christian. Depending on the history of a society, religious schools can also be Hindu, Islamic, Jewish, or other religions. "Parochial school" is therefore a misleading phrase, because it refers only to schools organized within the Catholic tradition. Despite the increasing irrelevance of church and religion in the everyday lives of most Europeans, religious schools have not dwindled. On the contrary, the religious school sector in societies with relatively religiously inactive populations is growing or is strongly overrepresented. This is true not only for societies that traditionally have had such schools, but also for those in which religious schools were abolished under communist regimes (Hungary, the new German Länder). One possible explanation is that the teachings of religious schools are generally more effective than those of public schools

because religious schools, although they no longer strive for the religious socialization of students, still try to attain other non cognitive goals, such as tolerance, social cooperation, and discipline, that are valued by unreligious parents. There also are other explanations for the rise of religious schools in the former communist societies, including distrust of the state as provider of collective goods like education, the lower effectiveness of public schools as a consequence of malfunctioning state bureaucracies, and a lower level of community building by parents and teachers around public schools than around religious schools.

Empirical evidence of the higher effectiveness of teaching in religious schools is increasing although not yet conclusive. Differences in school success and cognitive outcomes clearly exist between public and religious schools in modern societies on both sides of the Atlantic, but these differences are not very large and are not always found when comparing individual schools. However, these differences cannot be explained by the different social composition of the student populations or by other obvious social characteristics of pupils, parents, schools, or neighborhoods. Given the high level of state support for religious schools in European societies and the relatively low school fees, differences in school effectiveness of religious and non religious public schools cannot be explained by large financial contributions from parents whose children attend religious schools. In various continental European countries the law forbids large financial contributions from parents as a condition for obtaining state grants. Spending levels are mostly equal across the public and the state funded private school sectors because, in most cases, that is an essential element of the compromise between the state and the churches.

However, significant differences in non cognitive achievements, often the main argument for the existence of state funded religious schools, are hardly found in modern societies. There also exist a number of indications in multiple societies that children often attend religious schools for academic or social – not religious – reasons, whatever the policies of the schools. The two last points contradict the *raison d'être* of state funded religious schools,

because the right of parents to determine the moral and religious education of their children has always been more or less explicitly the basis of state recognition and funding of religious schools. The higher cognitive effectiveness of state funded religious schools also contradicts the *raison d'être* of religious schools, which maintain throughout that they do not want to compete with state schools for better academic outcomes.

The best explanation of the higher cognitive effectiveness of religious schools involves the different school climates in public and religious schools. A school climate (or culture) specifies different patterns of behavior for teachers and students. These patterns, which form the basis of a school climate, indicate shared beliefs about what students should learn, the proper norms of instruction, and how students and teachers should relate to each other. They affect the effectiveness of teaching and learning within schools and may also affect teacher morale, which can also influence teaching effectiveness. The school climate argument shows some resemblance to Coleman and Hoffer's social capital explanation (Coleman et al. 1982; Coleman & Hoffer 1987). They distinguish between two types of communities as related to schools: functional communities and value communities. The members of functional communities constitute a structural system of social interaction; they encounter each other in different kinds of social situations and know each other personally. In contrast, value communities are communities in which members (parents and teachers) share values and expectations regarding education but which are not functional communities; outside the school, there is no structural interaction or social network between the members. According to Coleman and Hoffer, functional communities like religious schools can be beneficial to their members because of the social capital they offer. Because there is interaction between parents inside and outside the religious school, norms can be maintained that create a stable and positive school climate, improving the pupils' scholastic achievement.

schools, single-sex

Cornelius Riordan

Single sex schools refer to education at the elementary, secondary, or post secondary level in which males or females attend school exclusively with members of their own sex. Alternatively, males and females may attend all classes separately even though they may be housed in the same facilities, a phenomenon referred to as a dual academy. A related though different phenomenon is single sex classes, whereby schools that are otherwise coeducational provide separate classes for males and/or females in selected subjects.

Most people take coeducation for granted. Typically, their own schooling has been coeducational; often, they have little awareness of single sex schools. Our political culture reinforces the taken for granted character of American coeducation. It implies that schools reflecting the variety of society exemplify what is best about democratic societies. Many people also take for granted that coeducation provides

equality of educational opportunity for women. Like racial and ethnic minorities, women have long been excluded from the educational process. Thus, many people regard coeducation as a major milestone in the pursuit of gender equality. Single sex education, by contrast, appears regressive.

Coeducation, however, began not because of any firm belief in its sound educational effect, but rather because of financial constraints (Riordan 1990). Historically, mixed sex schools were economically more efficient. In America, boys and girls have usually attended the same public schools. This practice originated with the "common" school. Of course, at one time throughout all society, only boys received an education. At other times, the only education for either boys or girls was single sex schooling, either public or private. Even today, single sex schooling remains the dominant form of school organization in many countries.

In most western, democratic countries, however, once mass and state supported public education had been established, it was clearly the exception for boys and girls to attend separate schools. By the end of the nineteenth century, coeducation was all but universal in American elementary and secondary public schools (Tyack & Hansot, 1990; Riordan 1990). Recently, however, there has been a resurgence of interest in single sex schools in western modern societies across the globe, both in the public and private sector (Riordan 2002).

EMPIRICAL RESEARCH ON SINGLE SEX SCHOOLS

There are very few formal reviews of the relative effects of single sex and coeducational schools or classrooms. Of course, all researchers have conducted their own literature reviews, but these are often incomplete. Moreover, research on single sex classrooms is not systematic or rigorous since there are many varied forms of this type of structure.

There are two exhaustive reviews of research on single sex schools. The first of these was conducted by Moore et al. (1992) for a US Department of Education report. This review concluded that the empirical evidence clearly

supported the proposition that single sex schools may produce positive outcomes, especially for young women. In the most recent and thorough review employing What Works Clearinghouse standards, Mael et al. (2005) concluded that the preponderance of studies supports the view that single sex schooling has positive benefits for both sexes in terms of both academic short term achievement and socioemotional development.

The academic and developmental consequences of attending single sex versus coeducational schools are typically insignificant for middle class or otherwise advantaged students (Riordan 1990). By contrast, the consequences appear to be significantly favorable for students who are historically or traditionally disadvantaged – minorities and/or low and working class and/or at risk students (Riordan 1990, 1994a; Salomone 2003). The major factor which conditions the strength of single sex effects is social class, and since class and race are inextricably linked, the effects are also conditioned by race, and sometimes by gender.

Specifically, disadvantaged students in single sex schools, compared to their counterparts in coeducational schools, have been shown to have higher achievement outcomes on standardized tests of mathematics, reading, science, and civics. They show higher levels of leadership behavior in school, do more homework, take a stronger course load, and have higher educational expectations. They also manifest higher levels of environmental control, more favorable attitudes towards school, and less sex role stereotyping. They acknowledge that their schools have higher levels of discipline and order and, not surprisingly, they have a less satisfactory social life than students in coeducational schools. In the long term, women who attended a girls' school continue to have higher test scores than women who attended coeducational schools (for an opposing conclusion, see Marsh 1989, 1991).

It is important to note, however, that single sex school effects are fairly robust even when social class or race is not partitioned. In their Catholic school study, Lee and Bryk (1986, 1989) analyzed the data by statistically controlling for social class, race, and other background characteristics and applied the results to students generally (assuming that there were no

differences in social class, race, or background variables). They found 65 of 74 separate dependent variable effects to be in favor of single sex schools. Thirty of 74 effects obtained an effect size (ES) of .18 or higher favoring single sex schools, equally distributed among boys and girls and the mean effect size was .13 favoring single sex schools.

The results for students attending women's colleges parallel and substantiate the secondary school results. They manifest higher levels of environmental control, greater satisfaction with school (though not social life), and they achieve higher occupational success despite the fact that there is no difference in educational achievement when compared to women who attended a coeducational college (Miller Bernal 2000; Riordan 1990, 1994b). This latter finding strongly suggests that their schooling has been of a higher quality since ultimately they have the same level of educational achievement as women attending coeducational schools. Amazingly, women who attend a women's college for even a single year and then transfer still obtain a significant gain in occupational success (Riordan 1994b).

These positive effects, however, are not universal. In a cross national study of four countries (Belgium, New Zealand, Thailand, and Japan), Baker et al. (1995) have shown that single sex schools do not have uniform and consistent effects. The effects appear to be limited to those national educational systems in which single sex schools are relatively rare. They argued that the rarity of a school type may enhance single sex effects under certain conditions. When single sex schools are rare in a country, the pro academic choice making by parents and students will result in a more selective student body who will bring with them a heightened degree of academic demands. In turn, rare school types are better able to *supply* the quality of schooling *demanded* by these more selective students. Being less normative, these schools are likely to possess greater autonomy.

Despite this array of positive effects, it is important to note that the most common finding in the systematic review by Mael and his colleagues (2005) was null or mixed results. The mixed results reflect the fact that often the effects are for females but not for males,

or for at risk students but not for middle class students. Furthermore, these significant effects for at risk students are small in comparison with the much larger effects of socioeconomic status and type of curriculum in a given school. This basic social science finding that school effects are small has been shown to be true since first identified in the famous Coleman Report, and data persistently confirm this educational fact over the past four decades (for a full review of studies, see Riordan 2004).

It is important also to emphasize that white middle class (or affluent) boys and girls do not suffer any loss by attending a single sex school (they are not better off in coeducational schools). Moreover, there does exist the possibility that they do acquire small gains that are undetectable. This is consistent with the large number of null effects noted above. There are, in fact, very few studies reporting more favorable results of any sort for students attending coeducational schools (see Mael et al. 2005).

As with most studies of school effects, the problem of "selection bias" always lurks in the shadows. All researchers acknowledge that students attending each type of school vary in a number of ways, including socioeconomic status, previous academic achievement, family structure, etc. And everyone agrees that it is critical to statistically control (and thereby equate) these preexisting characteristics in order to sort out the effects of the school from the effect of the home. Some researchers believe that the appropriate strategy is to control or equate exhaustively. Others argue that this strategy might control on some of the very characteristics that drive the entire success of single sex schools; namely, making a pro academic choice (see below).

WHY ARE SINGLE SEX SCHOOLS MORE EFFECTIVE THAN COEDUCATIONAL SCHOOLS?

There are at least a dozen theoretical rationales that provide support for the contention that single sex schools are more effective academically and developmentally than mixed sex schools, especially for minorities and at risk students. Single sex schools provide more

successful same sex teacher and student role models, more leadership opportunities, greater order and discipline, fewer social distractions to academic matters, and the choice of a single sex school is a pro academic choice. Students also gain advantages because of significant reductions in gender bias in both teaching and peer interaction, and via access to the entire curriculum. Single sex schools allow greater sensitivity to gender differences in learning, maturation, and school readiness. They provide safety from sexual harassment and sexual predatory behavior and have been shown to aid in spiritual and moral development.

IMPLICATIONS

Single sex schools are places where students go to learn; not to play, not to hassle teachers and other students, and not primarily to meet their friends and have fun. Aside from affluent middle class communities, private and alternative schools, coeducational schools are not all about academics. This has been noted often with alarm by respected and distinguished investigators across a variety of disciplines using a variety of methodologies (Goodlad 1984; Steinberg et al. 1996).

Given their rarity in western culture, single sex schools are likely to require pro academic choice that is made by parents and students. This choice sets into motion a set of relationships among teachers, parents, and students that emphasize academic and de-emphasize youth culture values, which as suggested above dominate coeducational schools. Thus, single sex schools provide a set of structural norms conducive to academic learning. This pro academic single sex school environment operates in concert and harmony with the choice making process that is made by students who attend single sex schools. In this regard, it is entirely different from a set of structures or programs that are put into place by educators. In single sex schools, the academic environment is normative in a true sociological sense. It is a set of rules established by the subjective reality (definitions) of participants which takes on an objective reality as a set of social structural norms. This idea is similar to that proposed by Bryk et al. (1993) of a "voluntary community" for public school

policy, which would resemble Catholic schools in every respect except for religion.

These academic definitions of school contradict the non academic definitions that students will otherwise bring to school and which come to constitute a youth culture. In effect, single sex schools mitigate the single largest obstacle which stands in the way of effective and equitable schooling, and it does this by using a fundamental sociological principle of how real social structures are created. Structures that are imposed and which contradict deeply cherished beliefs (regardless of how wrong headed and problematic they may be) will be rejected out of hand by any group with substantial power in numbers such as students in schools.

The challenge of effective and equitable schooling in the next century is to overcome the resistance and the recalcitrance of youth cultures in and out of the school. This is not a new problem and undoubtedly predates the modern school. But the intensity and the complexity of the problem is new, and it is the most important obstacle in schools today. Single sex schools provide an avenue for students to make a pro academic choice, thereby affirming their intrinsic agreement to work in the kind of environment that we identify as an effective and equitable school. Single sex schools should not be expected to correct the gender equity problems that exist in society and in coeducational schools. Moreover, students do not automatically do better in single sex schools. The important thing is the selection of a type of school that best suits each individual student.

Schumpeter, Joseph A. (1883–1950)

Yuichi Shionoya

Joseph Alois Schumpeter is generally acknowledged as one of the first rank economists of the twentieth century, along with John Maynard Keynes. Schumpeter was born in Teš', a small Moravian town in the Austro Hungarian Empire. (The town, once called by the Germans Triesch, today belongs to the Czech Republic.) His father, a textile manufacturer, died when Schumpeter was 4 years old. Blessed with opportunities owing to his mother's remarriage to a high ranking army officer, Schumpeter was able to enter the high society of the empire and was educated at the Theresianum in Vienna and at the University of Vienna.

Although Schumpeter's principal teachers were Eugen von Böhm Bawerk and Friedrich von Wieser, the major figures of the Austrian School of Economics, he was not accepted among the Austrian School because he was critical of its essentialism and psychologism. In his early academic years, he taught at a number of provincial universities (Czernowitz, Graz, and Bonn), and for a short period after World War I he held the posts of finance minister under the Austrian socialist government and of president of a private bank in Vienna. In 1932 Schumpeter moved to Harvard University, and stayed there until his death in 1950.

His outstanding distinction was his broad erudition, his wide ranging and large scale work, combining economic theory with history and sociology, and his grand vision of synthesizing conflicting schools of thought. His intellectual background primarily consisted of neoclassical economics (represented by Léon Walras), Karl Marx, and the German historical economics (represented by Gustav von Schmoller). His central concern was the formulation of the evolution of the capitalist economic system. When he explained the nature of his theory of economic development, he referred to Walras and Marx, to whom he had been indebted. According to him, Walras provided "a pure logic of the interdependence between economic

quantities,” and Marx “a vision of economic evolution as a distinct process generated by the economic system itself.” Schmoller taught him the method of approach to historical process in which all aspects of social life will change inter dependently.

The wide ranging work of Schumpeter can be interpreted as consisting of a system of substantive theory, i.e., (1) economic statics, (2) economic dynamics, and (3) economic sociology, and a system of metatheory, i.e., (4) the philosophy of science, (5) the history of science, and (6) the sociology of science, and is called a three layered, two structure approach to mind and society (Shionoya 1997). Substantive theory is addressed to society including economy, while metatheory is addressed to mind, knowledge, and theory including economics. The two systems are parallel in viewing the economy on the one hand and theory on the other from the viewpoint of, first, static structure, second, dynamic development, and third, their activities in a social context. They are linked together by the sociological dimension where economy and knowledge or mind and society are interrelated. The ambitious aim Schumpeter cherished throughout his academic life was a “comprehensive sociology,” an approach to social phenomena as a whole, which is supposed to be a synthesis of interaction between every single area and all others in a society. Its core idea is the *Soziologisierung* (sociologizing) of all social sciences. What he actually accomplished was the interaction of two sociologies, economic sociology and the sociology of science. Economic sociology is an analysis of the economy institutionally embedded in a society, and the sociology of economic knowledge concerns economic views (or the *Zeitgeist*) as social phenomena. Schumpeter’s two structure approach was intended to replace Marx’s social theory based on the economic interpretation of history concerning the relationship between the substructure and the superstructure of a society.

Schumpeter defined economic sociology as “a sort of generalized or typified or stylized economic history.” Economic sociology is the concept of an institution that can generalize, typify, or stylize the complexities of economic history. In his view, the concept of institution is intended to achieve the synthesis of theory and history in that, while it is a means of generalizing

historical events, it is limited due to its historical relativity and specificity. This is a compromise between the generality meant by theory and the individuality meant by history. He identified economic sociology as the fourth basic technique of economic analysis besides theory, statistics, and history.

His first book (Schumpeter 1908) covered the branches of economic statistics and the philosophy of science. While the book was a recapitulation of neoclassical economics on the line of the general equilibrium theory of Walras, it was essentially a methodological work that aimed to make a contribution to the solution of the *Methodenstreit* (debate on method) between theory and history in economics, or between Carl Menger and Gustav von Schmoller. Schumpeter ingeniously adapted the philosophy of science of Ernst Mach to economics and developed the methodology of instrumentalism.

Among his various accomplishments, his theory of economic development (Schumpeter 1926 [1912]) is best known. He defined economic development by reference to innovation (the cause of development), entrepreneurs (the carriers of development), and bank credit (the means of development). His concept of entrepreneur was a special case of the leader as the carrier of innovation in a wider area of social life. He also established an enduring reputation in his work on the history of economics (Schumpeter 1954). For him, the development of economy and society, on the one hand, and the development of thought and science, on the other, are two aspects of the same evolutionary process. Thus, economic dynamics and the history of science are the essential coordinates in the two structure approach to mind and society.

The general idea of Schumpeter’s economic sociology was first described in chapter 7 of the first edition of the development book. Although this chapter was eliminated in the second and subsequent editions, he kept the idea. Specifically, he developed a theory of social classes (Schumpeter 1927) that would serve as the crucial link between the concept of leadership in various areas of social life on the one hand, and the overall concept of civilization or the *Zeitgeist* on the other. In other words, social classes mediate the relationship between the economic and the non economic areas, between

the mind and society, or between economic sociology and the sociology of science. This idea, combined with the sociological investigation of the collapse of the tax state (Schumpeter 1918), was finally developed to *Capitalism, Socialism, and Democracy* (1942), in which he presented his famous thesis on the demise of capitalism as the result of its success. For Schumpeter, this does not mean pessimism from the perspective of a society as a whole because a locus of innovation and social leadership would shift from economic pursuits to other areas.

The relevance of Schumpeter's idea of economic sociology is its impact on the growth of institutional economics and evolutionary economics after World War II with a focus on innovation in technology, industry, and institution.

Schütz, Alfred (1899–1959)

John R. Hall

Alfred Schütz was best known for his work on the sociological approach known as *phenomenology*. His first book provided a critique of Max Weber's interpretive sociology of meaningful action. He subsequently wrote a series of phenomenologically inspired essays as well as a second book, *Structures of the Lifeworld*, with Thomas Luckmann. Over the years of his life and beyond, Schütz influenced diverse sociologists. Social phenomenology remains an important stream of sociology and Schütz's insights and the analysis that he advanced have percolated through wider currents. The discipline as a whole has become more "phenomenological" as a result, most notably through the social constructionist approach and emphases on the concepts of lived action and embodiment.

Born in Vienna as the only child of well-to-do Austrian Jewish parents, Schütz completed his gymnasium education there in 1917, and immediately served for a year and a half in the Austro-Hungarian Imperial Army on the Italian front. He returned to Vienna in 1918, where he pursued studies in law, the social sciences, and economics at the University of Vienna. He received a doctorate in law in 1921, and participated, both as a student and after, in intellectual circles that included economist Ludwig von Mises and Frederick von Hayek. He married Ilse Heim in 1926. In 1927 Schütz was appointed executive officer for Reitler, the Vienna-based international banking firm. In the years to come, he would continue to support his family and intellectual pursuits with one or another high-level "day job" in banking.

Schütz's initial intellectual interests in Vienna included economic theories of marginal utility, musicology (he played piano), language, and jokes. His core analytic pursuits emerged from his effort to criticize and ground the interpretive sociology of Weber, whom Schütz had heard lecture in Vienna in 1918. In the mid-1920s this ambition led him to Henri Bergson's writings. By the latter 1920s Schütz concluded that Bergson's *Time and Free Will* would not prove

an adequate point of departure for the philosophical theorization of social meaning, and he turned to the work of Edmund Husserl, whose analysis of the temporal flow of events as experienced in the mind itself became the basis of Schütz's critique of Weber. After this analysis was published in 1932 (later translated into English as *The Phenomenology of the Social World*), Schütz developed a close personal intellectual relationship with Husserl, visiting him occasionally in Freiburg up until Husserl's death in 1938.

In the shadow of Hitler's rise in Germany, other Jewish intellectuals emigrated from Austria beginning in the 1930s. Schütz himself was in Paris on business when the Nazi annexation of Austria took place on March 13, 1938. He worked to arrange the migration of his wife and children, and helped other Austrian intellectuals escape. On July 13, 1939, with war widely anticipated in France, Schütz and his family emigrated to New York. In the United States he aided other immigrants and worked with the US Bureau of Economic Warfare by providing economic analyses of Germany and Austria. He continued working with the Reitler firm in New York but, like a number of other European expatriates, began teaching on the Graduate Faculty of the New School for Social Research, where he became a full time professor in 1956. His health began to decline within only a few years, and he died on May 29, 1959 with his second major book still only in outline and draft form. Three volumes of his *Collected Papers* on philosophical, epistemological, and sociological topics were published posthumously, as was *Structures of the Lifeworld* (1973), completed by Thomas Luckmann on the basis of Schütz's schema.

In the political upheavals of his times, Schütz played his role as a citizen, even a world citizen. He was resolutely apolitical in his own work, however, and his phenomenological sociology contains no significant consideration of power and authority. Yet social phenomenology clearly has utility for political analysis, as fruitful extensions of Schütz's analysis of the "well informed citizen" have demonstrated. In the long term, Schütz's greatest legacy may be his critical analyses of modernity and its mediations of consciousness.

Schütz's central contributions to sociology are based on his development of a phenomenology of the social world. He came to this project through his engagement with Max Weber's methodology of *Verstehen*: analytically rigorous interpretive understanding of meaningful action. Schütz agreed with Weber that the human sciences both could and should employ *verstehende* analysis, since meaning is an intrinsic basis of action, and action is a core element constitutive of social phenomena. Weber used ideal types to describe meanings (e.g., inner worldly asceticism), social actions (e.g., rational action), and culturally inscribed patterns of social interaction (e.g., patrimonialism). Thus he could theoretically link action with broader social patterns and history – something that eluded numerous other theorists who either ignored meaning and action altogether, or analytically distinguished structure from action in ways that make meaning inaccessible.

Schütz praised Weber's achievements, but criticized his discussion of subjective meaning. For Schütz, Weber treated the problem of meaning from an *observer's* point of view without considering how meaning is constituted *subjectively*. Such a project would require an analysis of unfolding mental events of a social actor as a person – an Ego consciousness. Initially, Schütz sought such an account in Henri Bergson's idea of duration as the flow of conscious experience. But Edmund Husserl had a more richly developed account of consciousness and temporality. His "transcendental phenomenological reduction" sets aside ("brackets") the *contents* of cognition (e.g., an idea, visual image, or words) to examine the *acts* of consciousness by which contents are mediated in the flow of inner time. Drawing on transcendental phenomenology, Schütz characterized subjective meaning by connecting it to the flow of mental experience in (1) the vivid present, (2) its sedimentation in memory (and recollection), and (3) its anticipation of the future. Meaning thereby becomes located in specific acts of consciousness – pleasure, pain, nostalgia, remorse, anticipatory excitement or anxiety, and so forth. Out of an array of such possibilities, Schütz emphasized meaning associated with the "in order to motive" that imaginatively anticipates the future completion of a project, and the "because

motive” that an actor might deploy retrospectively to account for a given set of events. He demonstrated that the meanings a person gives to actions shift according to the actor’s temporal relation to them; that is, meanings of actions are not always “the same,” even for the actor herself. Weber’s typologies of meaning and action represent observers’ interpretations, whereas (various) subjective meanings themselves are situated within streams of unfolding individual consciousness.

Despite the power of transcendental phenomenology as the basis for understanding meaning, Schütz recognized its limitations as a basis for a phenomenology of the social world. Specifically, intersubjectivity – the social relation between an Ego and others in the vivid present – cannot be accounted for within the transcendental reduction, because the reduction deliberately brackets the content of any perceptions. The internal time consciousness that structures formations of meanings is a basic feature of the individual acting in the lifeworld, but the lifeworld – specific subjective meanings, other people, and cultural meanings – is only perceptible within a mundane “natural attitude” in which the individual does not doubt the “world given to me as being there,” and interprets the world on the basis of built up social and cultural frameworks of meaning (Schütz 1967: 43).

Building from his critique of Weber, Schütz (esp. 1962–6, 1970; Schütz & Luckmann 1972) concentrated on developing a mundane or lifeworldly phenomenology of the social world that would describe its transhistorical and transcultural structures. The result is a formal description of Ego consciousness, time, accents on reality, Others, intersubjectivity, meaning, horizons of life and death, and operations of meaningful action. These are described in terms of events of consciousness in relation to thematic issues that come to the fore, and motivational and interpretive structures of “relevance” that frame constructions of meaning.

Like Husserl, Schütz faced a basic difficulty: a transcendental phenomenological description must itself depend on socially based features of the lifeworld (e.g., language) available only within the natural attitude. Schütz came to terms with this dilemma by keying his phenomenology of the natural attitude to existential conditions of embodiment and historicity.

Critics of Schütz wonder whether his ego based phenomenology has any adequate basis for moving from consciousness to society, especially as a phenomenon *sui generis*. However, intersubjectivity is central to his analysis, and his phenomenology describes the epistemological status not only of Schütz’s own analyses but of actors’ typifications and knowledge more widely. It thus accounts for the situated character of meaning construction both for people in general and for observers with particular analytic interests (e.g., in social and other sciences, history, and other “finite provinces of meaning”) (Hall 1999: 16–19). In turn, Schütz’s more descriptive phenomenological essays on the character of particular types of actors and forms of interaction (e.g., the man on the street, the stranger, making music) are important in their own right. They also serve as exemplars of applied phenomenology (Hall 1977), and participant observation research demonstrates that Schütz’s critique of Weber can be extended to specify relationships between Weberian typifications of social structure and alternative constitutions of the lifeworld described in Schützian terms (Hall 1978).

Like certain other twentieth century social theorists (e.g., Vilfredo Pareto), Schütz has been underutilized relative to the power of his ideas. Nevertheless, his influence has been substantial, and the broad currents of sociology have moved in his direction. The major direct influences are telling. Schütz sought to engage the pragmatist interactionists. Talcott Parsons and Schütz engaged in a lively interaction, and Parsons’s student, Harold Garfinkel, drew on core Schützian ideas in his *Studies in Ethnomethodology*, which examines the actor’s situated methods of knowledge construction. John O’Neill (*Making Sense Together*, 1974) and Kurt Wolff (*Surrender and Catch*, 1976) also have built on everyday epistemology themes in Schütz’s work. Peter Berger and Thomas Luckmann centrally invoked Schütz in their pathbreaking book, *The Social Construction of Reality*. Pierre Bourdieu used a phenomenologically centered analysis of situated meanings in *Outline of a Theory of Practice* (1977) to challenge atemporal and ahistorical features of structuralism in its semiotic and social anthropological dispensations. And critical theorist Jürgen Habermas’s 1987 *Theory of Communicative Action, Volume 2* employed

Schütz's key concept of the lifeworld in describing the modern tendencies of rationalized systems to colonize and subordinate everyday social life by defining, circumscribing, and organizing its meaningful options.

More generally, after structural functionalism and systems theory reached their points of maximum influence in the 1960s, sociology has moved in a Schützian direction. Neither logical positivism nor a presuppositionless transcendental phenomenology holds up philosophically any more, and postfoundational social epistemologies, including the feminist epistemology of Dorothy Smith, as well as social studies of science, confront precisely the existential conditions of embodiment and knowledge that Schütz described. Although quantitative sociologists have rarely sought to accommodate social phenomenology in their research, a wide range of sociological theories – including those of a structuralist bent – now incorporate formulations about the social construction of reality. Explanatory and interpretive empirical work – both in historical sociology and using qualitative methods – also has become highly sensitive to the issue of multiple social realities and the play of situated meanings. Most generally, sociologists now typically want to specify mechanisms of social processes on the ground, rather than simply delineating abstract factors and their causal relationships to one another. All these developments are foreshadowed by the phenomenological sociology of Alfred Schütz. However, they do not yet consolidate a fully developed phenomenological analysis of society. Thus, Schütz's work remains an important resource in sociology, the full potential of which remains unrealized.

science

Ian Varcoe

Sociological frameworks used in the study of science move between two epistemological extremes. First, it is held that nature is recorded by science provided that the latter is in a fit state as a social institution to do so. Second, it is held that science is a social construction and in this sense in principle no different than any other part of culture.

If one is convinced of the first proposition, one's interest will be directed towards: the "goal" of science; the institutional norms that regulate the activity of the community of scientists; competition; the reward structure of science operating through "recognition" (citation practices, Nobel prizes, peer review); and similar topics. If one is convinced of the second proposition, one will be interested not so much in the institution and community of science, but rather in scientific knowledge and the question of how scientists reach a point where it can be said to have been "made." One will be interested in the "negotiation" through which a stable order of scientific objects is arrived at. In this "negotiation" there is included writing practices and the empirical study of "talk" (or discourse).

The great American sociologist Robert K. Merton was certain that science had social underpinnings. It was not the product of timeless individual curiosity. In its modern form – as understood by historians of science – it had its roots in seventeenth century European society. Twentieth century experience showed that it could be affected by political ideology (the Nazis’ “Aryan physics,” the Bolsheviks’ “bourgeois” versus “proletarian” science). In the West, however, science seemed to retain its “autonomy.” While located within capitalist society it was insulated from it, to a certain extent, by a set of distinctive norms the upholding of which cemented the community of scientists, and functioned to allow the pursuit of reliable (or certified) knowledge to go on. Priority disputes demonstrated how important recognition was to scientists as their only reward. Scientists are expected to share their findings, to subject the claims of others to rigorous critical tests, to be disinterested, and to judge claims not by persons but by universal criteria. Merton’s norms suffered from two basic criticisms: (1) empirically, the evidence for them actually working was thin; and (2) the suggestion was made that this was the “public face” of science, ritually evoked for public consumption and infinitely flexible as a rhetorical resource. Evidence showed that scientists were not open minded universalists. They condemned unconventional “science” without testing it and hung on to cherished ideas in the face of apparently disconfirming evidence. To his enduring credit Merton was concerned with the distinctiveness of science. He founded the sociology of science and initiated a program of research carried out mainly by American followers.

A second research tradition grew up in opposition to the Mertonian, known generically as the sociology of scientific knowledge. This movement was catalyzed by Thomas Kuhn’s *The Structure of Scientific Revolutions* (1962), which challenged the philosopher’s picture of science as demarcated by a method and put in its place a historical one in which scientists placed their faith in a paradigm and proceeded to solve fairly routine “puzzles” within it until such times as crisis set in and a “revolution” ensued consisting of a mass change of allegiances. Following this encouragement to create a realistic – in Kuhn’s case, a historical – rather

than a philosophical account of “science,” sociologists in Britain (based in Edinburgh University and other centers) issued manifestos declaring their intention to carry through Mannheim’s sociology of knowledge to its logical conclusion, not exempting scientific beliefs from its injunction to study the social bases of all beliefs (Mannheim, however, had equivocated over science and mathematics). The aim should be to open what Merton and his followers had left as a “black box”: why it was argued should sociological analysis halt at the threshold of scientists’ beliefs as if these could not be socially influenced (because *the* scientific method applied to Nature was assumed to be fully responsible for them). The sociology of scientific knowledge was avowedly relativist in its approach to scientific knowledge. Two broad schools are identifiable.

The first to appear was the “interests” approach. Owing to “interpretive flexibility,” replication is not a sure, decisive way to close down uncertainty about the “results” of experiments; and the closure which stabilizes “knowledge” is brought about by a range of social factors rather than something in the data: the struggle is to define the data (or the “phenomenon”). Numerous interview based case studies “showed” this.

To critics of this approach the idea that social interests cause interpretive behavior represents a failure to carry the “interpretive” perspective through to its full logical conclusion, namely that there is *only* interpretation in scientific life and social life generally. Causal analysis has no place anywhere. This point of view, inspired by the ethnomethodology of Harold Garfinkel, was backed up by the offering of an alternative: the ethnographic study of the laboratory through usually prolonged participant observation to see how science is “made” from the messy materials to be found therein. A second alternative was the analysis of scientists’ discourse to see the devices by which they sustain their sense of a reality “out there” and their own access to it, against their competitors. Both approaches call for a thoroughgoing reflexivity – more thoroughgoing than the interests approach, despite advocating it, practiced in reality. On this view, sociological analyses must be recognized as interpretations; they cannot be anything else.

These approaches came in the wake of the “strong program” in the sociology of science. It desired an approach that was symmetrical (as between “true” and “false” belief), causal, reflexive, and impartial. Arguably, interest type studies fail in full reflexivity (by claiming to be authoritative) and are not based on the empirical testing of deductive theory, but rather on the *post hoc* interpretation of the interview data. Interview material is used to construct a “story” of what was “really going on” in disputes (i.e., such material is taken at face value as a faithful account rather than rhetoric and some of it is favored over the rest by the sociologist as being closer than other parts to “what really happened”). Ethnographic study has also been criticized for failing to meet its own requirements: (1) by drawing on theory and thus not truly letting the discourse “speak” as far as possible without interpretation; (2) by having no way of recognizing the basis of differential authority in science, the *effect* of which the approach brings out; and (3) through acknowledging the role of rhetoric, allowing implicitly causal forces while denying them programmatically. It was noted that “forces outside of the laboratory” were drawn on to provide tacit explanations and that full blown discourse reductionism is as debilitating a dogma as the denial of language and social construction of reality, for here reality is collapsed into language.

To the discourse analyst the “interests” researcher can be seen applying empiricist *rhetoric* in claiming to provide a causal account of beliefs. Both approaches run into difficulties in that neither can in practice do entirely without reference to wider social realities beyond the research setting itself. The interests approach cannot examine these to a sufficiently high empirical standard (i.e., the rigorously high empirical standard it has set itself through the use of interviews and other forms of direct observation) and the ethnographic and discourse approaches find reference to these wider factors beyond the research setting simply unavoidable, although here again they cannot in practice be treated as the approach requires (i.e., as discourse). It might appear that both approaches, in being methodologically purist programmatically, are mirror reflections of the dogmatism about science that they reject, namely that it straightforwardly records nature. Strong

antidotes to naturalism were needed at the start of sociological research, but these commitments – while directing the focus of research – failed to permit the handling in full of the complexity of the phenomenon of science as a social enterprise.

In the twentieth century, particularly following 1945, “scientific research and development” became increasingly organized on a large scale. It attracted financial support from the state and consumed a significant proportion of GDP in the developed societies of the world. The pre war debate over whether science should be planned was settled willy nilly in terms of some form of planning following the Physicists’ War, which showed the indispensability of scientific investment to state power. Research and development became an institutional complex formed of the universities, industrial laboratories, and government research establishments. With state funding attention came to focus on a policy for science and technology. The institutions of organized science and science policy became an object of study and the latter began to be assessed by rational criteria. Recently, a theme in this assessment has been “science and the public,” the public understanding of science as a goal and a reality, and a “science for the people” with the regulation of science and technology came to the fore. Merton’s liberal view of science’s autonomy in democratic societies was not shared by J. D. Bernal, who between the two world wars argued that the benefits that science could bestow on humankind were not being realized. The direction of scientific research and the application of its results were being dictated by capitalism. A question raised by Bernal was whether a people’s science would be a different science from the one existing under capitalism. Analysts of the “social function of science” have divided on this issue, with some like Bernal (who later drew back from it) adopting a relativist position. The philosopher Herbert Marcuse took this position. Freed from existing relations of domination, human society would generate a new kind of science, different from the existing one, geared to emancipation. The alternative view to this one is that scientific knowledge is effectively neutral knowledge of nature, but the direction research takes and the uses fostered of results are influenced by the social, political, and economic relations of

capitalism. Profit and military needs dictate the use to which a basically neutral science is put. This view tends to share with Merton the belief that nature speaks through science (or to use a phrase of Norbert Elias's, that it is relatively more "object adequate" than say religion and magic; or as Ernst Gellner put it, science "works" in producing a powerful technology even though we cannot root it in a secure epistemology, ungrounded in society and history). It is critical of the sociology of scientific knowledge for its failure to connect its detailed case and ethnographic studies to the larger social structures in which science and technology have come to be embedded, and for its provisional relativist standpoint. The "interests" approach has so far mainly promised to establish connections between science and the wider society, while discourse analysts are engaged in a campaign to revolutionize sociology, making it an interpretive and reflexive discipline, so that it is difficult to see the categorical ground for any rapprochement. These, however, would find Marxist models, either of the use/abuse or "science as ideology" kind, empirically unsound, the tradition lacking a record of the scrupulous empirical inquiry needed to "read" science successfully in the locales where research is actually done. Micro versus macro and external versus internal analyses are divides that still tend to dog the social study of science.

Everyone in this field is agreed that science is a product in some form of social processes. "Science," however, is a contested terrain, academically and socially. Disciplinary boundaries are insecure and contestation takes place to define them. Social study of science today is an interdisciplinary area involving historians, philosophers, sociologists, and others, who often have indistinct, hybrid professional identities.

Science has become an arena of social contestation too, as the risk society thesis, postmodernism, and the sociology of expert knowledge have recently tended to confirm. Increasingly, experts confront other experts in the public domain where high consequence risks are debated before an often apprehensive and sometimes skeptical public. The authority of science appears to be in crisis, while its involvement in the reproduction of everyday life appears to grow. Everyday life appears increasingly hazardous, at least to those in the developed world

who face man made risks in which science and technology are implicated as cause and proffered aids to solutions. The social constructivist approach in the sociology of science is playing and has played a role in the study of "risk" (e.g., environmental and latterly social issues arising from the new genetics, to which Marx inspired sociology has also contributed).

Social movements such as the animal rights, environmental, and anti capitalist ones are preoccupied with "science issues," as formerly were the peace and socialist movements mainly from the 1960s onwards. Feminism, seen as scholarship, moreover, has been intensely preoccupied recently with the study of science. Its divisions can usefully be drawn parallel – but only partly so – to those familiar in the social studies of science. Broadly, a liberal feminism is concerned with and about the under representation of women in science and their position within a male dominated profession. A second strand is devoted to examining representations of women in science, historically and in contemporary terms, with particular attention having been given recently to *in vitro* fertilization and embryo research (the so called new reproductive technologies). A third approach mirroring in certain respects the sociology of scientific knowledge is epistemologically oriented. However, unlike the latter, it does make connections to the structural fact of gender relations and discrimination in the wider society, and it is not reflexive (applying its relativism consistently to itself). In this respect it resembles the idea of an emancipatory science yet to be born, found in places in the Marxian tradition.

This "standpoint feminism" raises the question of whether the science made by men is androcentric and oriented to domination of nature. It suggests that a feminine science would be likely to engage feeling, empathy, and listening as distinct from "cold," rational, detached observation. Such a science, it is suggested, subsumes its predecessor, completing knowledge in a higher synthesis. Against this view it is protested (1) that it may in fact be in the process of attempting to replace one gender biased approach with another; and (2) related to this, that, inconsistently, it applies its relativism to "male science" but not to itself. The negotiation which is such a central part of the findings of sociology of scientific knowledge studies does

not seem apparent in this approach. It may, it is suggested, be reifying the masculine and the feminine. There are other feminist approaches, however. These seek to avoid these alleged pit falls (e.g., postmodern feminism). There are also less uncompromising, more meliorist assessments of what currently constructed science might have to offer women that is of benefit to them.

The arena in which science is practiced, studied, and fought over today is not likely to change from its current divided, complex character in the immediate future. The certainties of the Enlightenment have indeed collapsed. The faultlines that divide research traditions continue to define those traditions as some what separate. Parallel positions can be found between them, dividing them internally but establishing wider sympathies (e.g., between anti relativist philosophers, Mertonians, and liberal feminists; between Marxists and standpoint feminists; and between postmodern feminists, ethnographers, discourse analysts, and postmodernists). Wider political commitments, which are themselves the distillation of political traditions, continue to affect attitudes towards science and the "social world." The question of the relation between them, and how it should be conceptualized, is still unresolved. As the boundary between research institute, university department, industrial laboratory, and defense establishment and the surrounding network of social relations – often extending globally – becomes ever more permeable, sociologists of science are forced to adopt ever more inventive methodologies. These transcend the entrenched positions of the past, pointing to a new flexibility, the beginnings of which are visible.

science, commercialization of

Daniel Lee Kleinman

Neither science based industry nor university involvement in commercially relevant science is a new phenomenon. In certain sectors, US firms employed scientists in the late nineteenth century, and examples of university–industry collaboration in the United States can be found in the early twentieth century. That said, the advent of the biotechnology industry in the late 1970s and 1980s prompted sustained policy and scholarly attention to the place of science in the economy.

The standard recent history of the commodification of science highlights several pieces of US legislation that analysts suggest altered the

landscape in which science is undertaken. Most prominent among these is the Bayh Dole Act of 1980. A central aim of this law was to encourage university–industry collaboration by permitting universities and small businesses to retain title to inventions produced with federal funding. Indeed, at the center of virtually all discussions of the commodification of science is the blurring boundary between academia and industry and the possibilities for transforming scientific research into marketable products.

Scholarly discussion of the commercialization of academic science can be divided into two waves. Early work focused on the threat to traditional academic norms of autonomy and openness posed by industry support for academic research and the array of university–industry relationships that flourished with the development of the biotechnology industry. Much of the early research was anecdotal and highlighted egregious cases of conflict of interest and industry pressure to keep academic research findings secret. During this period and subsequently, researchers have undertaken surveys in an effort to capture the extent to which traditional academic norms have been eroded by industry involvement in the university. This research has found academic scientists torn by conflicting pressures, but also shows that many factors besides connections to industry prompt scientists to restrict the flow of information (Blumenthal et al. 1986; Campbell et al. 2002).

If early research on the place of the academy in the knowledge economy focused on erosion of norms, the second wave has been more interested in understanding the social organization of the knowledge economy and the place of the university in it. Some such work explores networks of interdependence between industry and academic science (Powell 1998). Other scholarship suggests the emergence of a new mode of knowledge production in academia and industry that tends to be collaborative, non hierarchical, interdisciplinary, and organized through work teams and networks (Gibbons et al. 1994). Still other work sees a movement toward what the proponents call “academic capitalism” in which those university fields, departments, and faculty members who are closer to the market have greater access to resources and status than those further from the market (Slaughter & Leslie 1997). Finally, theorists of “asymmetrical con-

vergence” (Kleinman & Vallas 2001) contend that a process is underway in which the norms and practices characteristic of industry are increasingly, if unevenly, found in academia, while academic norms are in increasing and surprising ways found in science based industry.

science and culture

Daniel Breslau

Philosophers of the European Enlightenment defined science in opposition to culture or humanistic knowledge. Science was truth based

on verifiable observation and certain logical procedures, and thus stood opposed to all traditional beliefs. Francis Bacon, who initiated the philosophical tradition of elaborating “demarcation principles” to distinguish science from non science, differentiated science from all knowledge that is based on tradition and all humanistic knowledge, thus defining it in opposition to most of what we think of as pertaining to culture (Bacon 2001). Science was distinct from culture due to both its method, which followed transhistoric, universal rules, and its results.

The Enlightenment distinction between science and culture has been thoroughly eroded since the late twentieth century. It is one of the major transformations in western intellectual life that science and scientific knowledge are now legitimate objects of study for the human sciences.

While classical sociological writers provide some of the tools for the analysis of scientific knowledge, they observed the Enlightenment science/culture distinction, and only subjected the latter to sociological analysis. When supposedly scientific knowledge was subjected to a critical sociological gaze, as in the young Karl Marx’s critique of political economy, the term *ideology* allowed him to distinguish the object of his criticism from science. Durkheim and Mauss argued that systems for classifying the natural world originate in social classifications, but maintained that scientific knowledge, through the use of pure logic, had become independent of its socially based origins.

Twentieth century sociology of science refrained from sociological analysis of the content of scientific thought, taking as its task the description of the social conditions under which knowledge is liberated from social determinants. Joseph Ben David’s historical sociology of the role of the scientist examined the historical emergence and institutionalization of the scientist’s role, which Ben David assumed to be a necessary condition for supporting and motivating inquiry that would be interested solely in truth as such. After careful consideration of the possibility of social influences on the content of scientific knowledge, Ben David concluded that such influences were marginal at best, and that therefore “the possibilities for either an interactional or institutional sociology of the conceptual and theoretical contents of

science are extremely limited” (Ben David 1971).

Robert Merton’s functionalist analysis of science approached the same issues in a synchronic manner. Merton was interested in describing the particular features of the social subsystem of science that allowed for the continuous production of validated knowledge. Scientists internalize an ethos that enables them, or constrains them at pain of social sanction, to detach their scientific judgments from any personalistic social considerations (Merton 1973). Both Merton and Ben David were therefore describing the social determinants of the freedom of science from social determination.

While the functionalist sociology of science is neglected today, it should be credited with transposing the question of the basis of scientific efficacy from the rules of method to the social conditions under which it is practiced. It retained much of the traditional demarcation of science from culture, but restated the demarcation criteria in social, rather than moral, psychological, or methodological terms.

In the mid twentieth century a number of philosophical developments challenged the absolute divide between science and culture, suggesting that scientific knowledge is inseparable from a broader culture, which is specific to a social group and historical period. Wittgenstein’s arguments about the insufficiency of formal rules and the impossibility of drawing a necessary course of action from them without reference to a specific “form of life” demonstrated that the formalism of mathematics and logic do not free science from its broader cultural horizons. Quine, like Wittgenstein treating science as composed of linguistic elements, insisted on the dependence of observation on theoretical assumptions, and of hypotheses on a fabric of often unstated, often conventional, assumptions. Others, such as Michael Polanyi and Thomas Kuhn, attacked the assumption that scientific knowledge is independent of a specific historical, and cultural, context. Polanyi emphasized personal judgment based on *connoisseurship* and *tacit knowledge*, while Kuhn emphasized the dependence of scientific work on shared traditions of scientific communities. Both argued that these cultural dimensions were not obstacles to scientific knowledge, but were indeed among its necessary conditions.

Licensed by the new philosophical understanding, a number of sociologists of science located at the University of Edinburgh in the late 1970s initiated a program of theoretical statements and case studies that aimed to extend the sociology of knowledge to science. David Bloor's *Knowledge and Social Imagery* (1991) is the best known of these works. It is ironic that Bloor's work has been classified among so called postmodernist studies of science, since Bloor could not have been more explicit in his modernism, calling for a causal science of science. Bloor argued that the sociology of science harbored a contradiction, and a betrayal of a thoroughgoing social scientific treatment of science. Only false or rejected knowledge was assumed to have social causes and a sociological explanation, while validated knowledge was assumed to be caused only by the objects to which it refers. By subjecting only discarded knowledge, or error, to sociological analysis, and assuming that validated knowledge did not have social causes, the sociology of science was inconsistent, and engaged in explanations by final causes. Arguing that both rejected and validated knowledge should be explained in terms of the same kinds of causal antecedents, Bloor proposed a "strong program" for the sociology of science, also known as the sociology of scientific knowledge (SSK).

While the Edinburgh School did not elaborate a detailed sociological theory of scientific knowledge, the works of its adherents share what might be called a neo Mannheimian or conflict sociology of knowledge. Following Mannheim's "perspectival" method, the Edinburgh studies of scientific controversies relate opposed positions on scientific questions to opposed positions in a social structure, with opposed interests. For instance, Shapin's (1979) study of the phrenology controversy in early nineteenth century Edinburgh based its explanation on the opposed interests of the middle class proponents of phrenology and its opponents among the traditional academic elites. Opposed views on the structure of the brain and the interpretation of variation in human skulls were related to opposed interests in cultural authority.

While members of the Edinburgh School and SSK built their sociology of scientific knowledge around the classical tradition of the sociology of knowledge, with sources in Durkheim,

Marx, and Mannheim, others approached the question of science as the phenomenological question of the genesis of facts as such. While the SSK approach sought social explanations for given beliefs, these studies made the very existence of knowledge a problem for explanation. Also phenomenological in their methodology, researchers in what came to be called the laboratory studies approach sought to observe first hand the work involved in stabilizing scientific facts. Studies by Lynch (1979), Latour and Woolgar (1979), and Knorr Cetina (1981) treated facts, and indeed the existence of a taken for granted external reality, as tied to the instruments, procedures, and social arrangements of scientific work.

The most influential approach to emerge from this phenomenological tradition is that associated with Bruno Latour, Michel Callon, and John Law, and known as actor network theory. It begins with the principle of generalized symmetry articulated by Callon, by which one should not make an a priori metaphysical divide between humans and all other entities, attributing agency only to the former. There is no prior basis to presume that the social world is real while the natural world is constructed, any more than the opposite. To attempt to explain scientific knowledge in terms of social factors is to commit prematurely to a social realism. What is real and what is relative should be an outcome of the processes we examine. Actor network theory therefore allows for a proliferation of agents, which are all both constructed and constructing.

The objects of science, and indeed the world, are constructed through the linking of heterogeneous agencies in a network. All entities are located on a continuum from nebulous, poorly defined, controversial facts or artifacts to "black boxes," facts or artifacts that can be put to use without reference to the circumstances of their production. The difference between an incontrovertible fact and an uncertain claim is a function of the difference in the scope and strength of the network connections.

Actor network theory was presented as a comprehensive challenge to social science. It contained a principled rejection of the social explanation of scientific knowledge and of any explanatory priority of the social. The actor network theorists argued that there is no ground for an a priori distinction between the social and

the natural, and the presumption that the social can be used to explain the natural (as described by science). A sociological reduction of science would impose the product of the researcher's own network on an object in which the social is itself an outcome. It rejects an a priori distinction between science and culture, but not by collapsing science into culture. Rather, culture and science both refer to the mutual construction of the world through the elaboration of networks.

North American interactionist traditions have yielded yet another variant of sociological study of the content of science. With some sources in the "social worlds" research of symbolic interactionists such as Howard Becker and Anselm Strauss, scientific knowledge is here regarded as part of the local world that scientists construct. Sociologists such as Adele Clarke and Joan Fujimura applied this perspective, as it had been applied to work in cultural, industrial, and professional organizations, to the work of scientists. The work of scientists is then viewed as a process of negotiating a social order and its boundaries.

Philosophical challenges to the universality of scientific knowledge also resonated with feminist studies. While women's marginalization in scientific fields had been a topic of historical and sociological study, feminist research now argued that a historically specific form of gender domination was in fact built into scientific knowledge, and into the official definition of scientific method. Evelyn Fox Keller (1985) examined the history of the British Royal Society, and argued that the scientific method pioneered by Francis Bacon and his followers was based on a definition of masculinity. Male attributes of rationality, objectivity, and affective detachment were elaborated into the qualities of a scientist, with the use of an explicitly gendered metaphor. The relationship of the scientist to nature was described in terms of the male conquest of female sexuality. With this thesis of the gendered origins of scientific method, was the argument that a method based on detachment was in fact unnecessary, and was used to suppress equally valid ways of knowing, based on aptitudes more likely to be rooted in women's experience. The field of feminist epistemology has elaborated ways of knowing that are rooted in the experience and "standpoint" of women.

While there are now many approaches that treat science and scientific knowledge as cultural

endeavors, linked to the historically specific culture in which it is produced, these approaches as a whole have been the subject of continuing controversy. In a series of debates known as the science wars, some have objected to efforts to understand the content of science in terms of the culture and social structure of the society in which it is produced. Challenges to the independence of scientific truths from social and cultural conditioning have been regarded as challenges to science as such, and as relativistic (Gross & Levitt 1994).

science across cultures

Amanda Rees

Science is often thought of as a western invention, a way of thinking about the world that originated in Europe during the “Scientific Revolution,” and which proved to be such an effective means of manipulating nature that its techniques and practices were readily adopted by the rest of the world, once other societies had had the chance to consider science in action. However, this version of events depends on the assumption that science and technology are objective, culturally neutral, ahistorical, apolitical, and asocial elements in society. The reality, however, is rather more complicated. Rather than being a neutral aspect of relationships between different cultures, science has had an active role to play in intercultural engagement, both historically and at the present day. Rather than being the sole product of European ingenuity, science emerged out of the relationships that existed between Europe and the rest of the world; instead of simply being communicated to other societies as a more effective tool set for controlling the natural world, science was a key element in the processes whereby Europeans were able to dominate and to control other societies, both historically and at the present day.

There were at least two crucial historical contributions made by other societies to the European Scientific Revolution. The first was that made by Islamic scholars and natural philosophers. When the Roman Empire split into two halves in the third century CE, many if not most of the books and writings of the ancient Greek philosophers were lost to the western part of the empire, and remained so until the beginning of the European Renaissance. However, they were not lost to the eastern half, where they made crucial contributions to the self consciously Islamic society that grew up there after the death of Mohammed. Islamic scholars translated Greek natural philosophy into Arabic, creating a language of science for Islam, and developing cultures of Islamic natural philosophy, medicine, and mathematics that built on and expanded the knowledge acquired from the original Greek texts. When the works of

Aristotle, Euclid, Ptolemy, and others were rediscovered by Europeans, they were written not in Greek but in Arabic. The versions of Greek philosophy that were available to the scholars of the Renaissance were those that had been created by Islamic philosophers.

The second major contribution came several hundred years later, at the beginning of the nineteenth century. Science in Europe was in the early stages of professionalization, and increasingly, expeditions of scientific discovery were being sent around the world. They brought back specimens of plant, animal, and human life, measurements of temperature, height, and pressure, maps and histories – but rarely credited the local observers and informants from whence they had obtained these specimens and data. For example, Michael Bravo’s work on the “geographical gift” is based on the observation that huge areas of the globe were being mapped by a relatively small number of observers, and shows how many such maps were in fact drawn by local people at the behest of the “explorer.” Crucially, these voyages were not just voyages of scientific discovery, but were also closely tied to empire. They were conducted by the same men – colonial officials, military officers, naval captains, missionaries, and commercial speculators – who were at the same time building empires. Expeditions were used to claim sovereignty and to assess resources, and the voyages of ships such as *The Beagle* around the world were determined as much, if not more, by geopolitical and national issues as by purely scientific questions.

Sciences such as anthropology, medicine, geology, and natural history were deeply implicated in the imperial project. To survey the land and to record the distribution of plants and animals ultimately meant to assess an area’s natural resources with regard to future exploitation. The creation of the discipline of anthropology was inseparable from empire building, since anthropologists actively sought to link their work in with that done by nascent colonial administrators – learning more about how the societies of the colonized worked would improve the ability of the colonizers to govern them. The discipline of tropical medicine was invented to deal with the illnesses white people fell prey to in hot countries, and the offering and occasionally the withholding of medical aid and equipment became a critical element in

both the practice and rhetoric of empire. As such, in the postcolonial period, disciplines such as anthropology have had to seriously reconsider their place and role in public life.

However, the postcolonial period has also seen a reconsideration of the impact that science, medicine, and technology had on the colonized cultures. The work of the subaltern studies program (the work of Ranajit Guha and others) in relation to the history of the British in India has continuously demanded the recognition of the existence of a series of fundamentally different ways of perceiving the world, and this has been taken a step further by other postcolonial writers such as Homi Bhabha and Gyan Prakash. Prakash in particular has studied the use of science in colonial India, and has shown that the role of "science" as part of the civilizing mission of the British in India was not used in precisely the way the British administrators expected. Western science was explicitly used to educate sections of the Indian population, to make them more "western" in their outlook, through the establishment of museums, the deployment of periodic exhibitions, and so on. However, when Prakash examined the responses of the audience, it was possible to demonstrate that what was appropriated by these various Indian groups was no longer quite "science," and no longer quite "western," but had become much more ambivalent and chimeric in nature.

Currently, there are few extensive sociological studies of what could be called "postcolonial science," or science carried out in the developing world or by scientists from the developing world in the latter half of the twentieth century. More are desperately needed.

science, ethnographic studies of

Wenda K. Bauchspies

Ethnographies of science have their origins in the interdisciplinary field of science and technology studies (STS) that emerged out of the Civil Rights Movement, feminism, and environmentalism of the 1960s. STS research illustrates that science and technology are a human achievement, composed of actors, social systems, and social processes. Or, in other words, science and technology are social constructions created in a sociocultural framework with social institutions, actors, and networks, social practices, material culture, and worldviews. STS scholars use ethnographies of science to contextualize science, to study the culture of science, to provide alternative perspectives of science, and to help science and its publics to design new research questions, programs, and policies.

The 1970s saw the entrance of laboratory studies into the STS repertoire for analyzing the "institutional circumstances of scientific work," technical content, and the production of scientific knowledge (Knorr Cetina 1995: 140). In the laboratory, STS scholars studied "unfinished knowledge" or the process of knowledge creation. These early laboratory studies were done by Bruno Latour and Steve Woolgar (1979), Karen Knorr Cetina (1981), Michael Lynch (1985), and Michael Zenzen and Sal Restivo (1982). They represented

diverse methodological approaches from actor network theory to ethnomethodology and constructivism and showed the products of science to be cultural entities. Scientific knowledge was not simply “discovered” but was co created by the scientific practitioners and reconfigured within scientific practice. Ultimately, laboratory studies were able to explain how scientific knowledge production occurred in terms of social factors, and thus began the process of demystifying science.

The primary methodological tool of these early laboratory studies was fieldwork based participant observation, and David Hess (1997: 134) has named them the “first wave of ethnographic studies in STS.” This first generation of science ethnographers (mainly Europeans) focused primarily on the social processes that created objective, pure, neutral, descriptive science and the politics within the scientific community. Their work paved the way for the second wave of science ethnographers, who used social constructivism as a given to detail the cultural and political influences shaping knowledge and, thus, allowing the ethnographers and their work to contribute to and intervene in the dialogue of knowledge production (Hess 2001).

Sharon Traweek’s (1988) ethnographic and comparative study of a US high energy physics lab and a Japanese high energy physics lab symbolizes the shift from laboratory studies to a more complete ethnographic description of science that included actors, spaces, artifacts, descriptions of scientific practice, and the ethnographer’s reflections. More recent ethnographies of science (done primarily by American researchers) have followed in this genre while also addressing the roles of science and technology in the everyday/night world of not only scientists but also users, recipients, policy makers, activists, administrators, educators, and ethnographers. Recent STS ethnographic studies are moving beyond simply situating the ethnographer in the study and are seriously questioning how their theorizing might be applied or intervene in the process (Downey & Dumit 1997).

Medical anthropologist Rayna Rapp (1999) focused on the “geneticization of lives” through genetic counseling and technology that illustrated how the contemporary US reproductive process is embedded in language, religion,

ethnicity, class, gender, sexuality, age, and education. Her ethnography was structured not by chronology or ecology but by the technology as it moved through lived lives. She documented the ripples of genetic technology and the response and resolution of its passing. This form of ethnography highlighted the social spaces of reproductive technologies and the multiple, diverse, and varied perspectives that need to be considered within the culture of genetic science. These types of “findings” echo the roots of STS in 1960s social movements and contribute to the discussion and role of researcher and/or activist.

Another ethnographer of science, Joe Dumit (2004), focused on the virtual community of PET scans in US culture to create an “ethnography of images.” He “followed” the images from their inception in experimental design to “everyday notions of personhood.” Dumit’s work is a thick description of the images evolving in a crisscrossed space inhabited by actors from popular, forensic, activist, and neuroscience culture. It is a culture/artifact in creation, still being defined, that maps out gaps in expertise, knowledge, and consequences. Ethnographies of science are more than a description of a culture. They are an active contribution to the culture that the informants read, use, critique, and participate in. Laboratory studies and ethnographies of science have matured quickly into a dynamic tool that ethnographers are using to document culture and formulate applicable theory.

science and the measurement of risk

Claire Haggett

The definition and measurement of risks is controversial and much in debate, with risk assessments made by scientists often differing from those of the lay public. Scientific measurements are based on logic and rationality. They tend to ignore or invalidate lay understandings of risk, not taking into account social, experiential, or perceptual influences. However, sociological work has highlighted that responses to risk are governed by a huge number of

interrelated factors and have to be considered as part of the social context from which they arise. Lay people also have their own knowledge and expertise to draw upon when making assessments of the immanency and impact of any risk. It is not necessarily the case, therefore, that the public is being “irrational” in its decision making, but that it uses a different rationality to that of scientists. These differences can lead to conflicts over risks, and resistance from the public to the measurements, and subsequent recommendations, imposed upon them by scientific research.

Risk assessments carried out by scientists are based on technical rationality. Risks are determined by experts, founded on evidence and logic, and described in terms of statistical probabilities. Results are depicted as objective, universal, and value free. They are designed to improve decision making, and are presented as a means for human advancement. The focus is on identifying risks and people’s responses to them in order to build prescriptive models for their avoidance. Such prescriptions often note a divergence between the public fear of a risk and the actual incidence of the danger; the controversy over genetically modified foods is often cited as an example of where the risk does not warrant the public alarm caused by it. Indeed, scientific rationality about risks is intended to counter any public irrationality. The public is often considered to be unable to decide accurately and realistically about the existence and magnitude of the risks that it faces. It is deemed to use non scientific factors and base its judgments on emotions or misinformation. Scientific assessments may characterize the public as ignorantly or willfully disregarding the neutral, objectively derived facts, and there is often a focus therefore on how to overcome this ignorance – or how to act in spite of it. Reassurances may be given about the “real facts” of a risk, and attempts made to educate the public about its true likelihood. This is based on a view that educating people will win their support, and that if they knew the facts, they would behave accordingly – the “public deficit” model, whereby problems arise because people misunderstand or are unable to grasp the facts being presented to them. Any continued public concern is then often dismissed as hysteria or hype.

While scientific risk assessments are designed to make people appreciate the irrationality of their position, what they overlook is that people may simply be drawing on another form of rationality; one that is not any more or less irrational, but just different from that employed by scientists. This "sociocultural rationality" is based on experience, social values, and the social context in which an individual lives. Assessment of the impacts and implications of a risk are shaped by the circumstances in which that risk is anticipated. Moreover, rather than being ignorant of the methods and results of risk assessment, lay people may draw on their own expertise, definitions, and meanings, and use these to reflect upon the validity and credibility of the technical information they are given.

Debates and assessments of risk are rooted in the context from which they arise. It is not possible to separate the likelihood and impacts of any particular risk from the broader social situation and the everyday social reality in which they are experienced. For example, researchers examining the effects of pollution from petrochemical factories in the northeast of the UK found that people tolerated the discharge from the smoke stacks because the factories were an intrinsic part of the local community. They were the main source of employment and had been for several previous generations. The factories were central to the identity of the area, and had been the reason for the economic boom and prestige accorded to it. The impacts of the pollution were known about, accommodated for, and were adopted into patterns of life (see Phillimore & Moffatt 1999). The scientific risk assessments of the distribution and effects of the pollution did not reflect anything of the social context in which the risks of the emissions were perceived.

As well as the influence of the wider social context, people may also bring their own knowledge and experience to bear in assessing risks. The hierarchical scientific "top down" model of informing the public about the facts does not incorporate any notion of a two way relationship between people and scientists, or any negotiation between them. Sociological work, however, highlights the potential validity of a public response to a risk. Williams and Popay (1994) describe the situation in the town of Camelford in Cornwall, UK, where toxic substances were accidentally tipped into the local water

reservoir. Residents were concerned about both the short and long term risks to their health, but a committee of government scientists convened to look into the issue stated that chronic symptoms were not associated with the toxic dumping. However, in the light of continuing ill health, local residents continued to campaign for recognition of their claims, in what was to become a long running and contentious battle. At the heart of this dispute is the notion that the shared experiences that formed local knowledge could not be invalidated by reference to standards of objectivity derived from abstract scientific knowledge.

Considering local experience also highlights problems with the presumed universality of scientific assessments of risk. Technical information in any communications about risk is simplified in order for people to be able to understand it and to reassure them. While risk assessment and prediction may incorporate a great deal of uncertainty, this is rarely discussed in any public communications. However, understating any uncertainty can antagonize rather than reassure, and damage credibility when such standardization may not fit with normal experience. The invalidity of idealized and universal versions of "laboratory science" is highlighted when contrasted with "real world" experience and expertise. For example, Wynne (1989) documents differences between scientists' and farmers' knowledges in the aftermath of the Chernobyl accident. Concerns about the spread of radiation led to controversial restrictions being placed on farming practices and the movement and sale of livestock in the UK. However, the abstract knowledge applied by scientists in determining the levels of radiation and subsequent restrictions did not take account of local variations in the distribution of radiation, ignored local farming realities, and neglected the local knowledge and expert judgments of farmers. For the farmers, the supposedly universal scientific knowledge was out of touch with the practical reality and thus of no validity. It ignored factors that were obvious to them but invisible to outsiders, and made no attempt to accommodate (or even communicate with) their understandings and knowledge of the situation.

What universal risk assessments also overlook is that the nature of a risk affects the

response to it. Sociological research has documented increased public concern over risks perceived as unfamiliar, unfair, invisible, or involuntary. This is not necessarily "irrational," but rather highlights the contingent nature of risk assessment that technical analyses ignore. For example, people may accept risks many times greater if they are voluntarily assumed rather than forced upon them. Research has found that when people willingly engage in "risky behavior," they report greater knowledge, less fear, and more personal control over the risks. Examples include engaging in extreme sports, or taking recreational drugs. The imposition of a risk, as well as the perceived degree of risk and likelihood of danger, is an important factor, and people are therefore less likely to accept a risk imposed upon them, with consequences they have no control over. The outcry over safety on the railways is an example of this. Risk assessments based on rationality outline the statistical likelihood of being involved in a train crash or car accident, and the latter is much higher. But traveling by train means handing over the control and responsibility for the journey, and powerless passengers thus demand to be kept safe and free from risks.

Finally, differences in the definitions of risks relate to issues of trust in experts and scientific decision making. As well as any divergence between public and expert understanding of risks, the knowledge that the public receive from those experts is increasingly being met with skepticism. Accordingly therefore, individuals faced with a risk consider not only the probability of harm but also the credibility of whoever generates the information. The controversies over nuclear power, waste incinerators, and even renewable energy are all examples of this. Assurances from scientists and engineers that the noise from a windfarm will not disturb people living nearby, however authoritative and objective they seem, will be disregarded if the information is presented on behalf of the developer, or if it does not take into account the particular contingencies of the local area. Increasingly, scientific risk assessments are discounted and discredited by people who use their own knowledge and experience to determine the risks they face.

The disjuncture between scientists and lay assessment of risk has therefore led to increased

public resistance of both the procedures and results of expert measurement. Indeed, as discussed above, the notion of the division between local and scientific knowledge can be seen as part of a trend challenging scientific work more generally. Public resistance of technical assessment arises because people's experiences, meanings, and knowledges are not expressed in this definition; and are often ignored, ridiculed, and contradicted. When the control of the basis for which assessments about risk can be made is claimed by scientific experts, there may be little similarity between perceptions of risk embedded in lived experience and those based on ideals of rationality and logic. In the light of risk, divisions are opened up between lay and scientific knowledge and those who have access to and expertise of these seemingly opposing epistemologies. Scientific definitions tend to exclude those without access to the technical knowledge needed to understand them, and preclude any negotiation between experts and the public. They are intended to educate and inform, not empower, and are imposed upon a context in which they may be seen to have little validity. What sociology has done is to highlight the differing rationalities that scientists and lay people use in their risk assessments, and shown how conflicts arise because of these. Work in the tradition of the sociology of scientific knowledge (SSK) demonstrates that the "public deficit" model of understanding has little validity, and serves to problematize the public rather than the operation of science. Instead, a more symmetrical view of different knowledge and expertise is required.

science/non-science and boundary work

Yuri Jack Gómez Morales

The problem of demarcation – how to identify the unique and essential characteristics of science that distinguish it from other intellectual activities – has been addressed both as an analytical matter mainly by philosophers and epistemologists, and as a practical matter by sociologists and historians.

The philosophical quest for demarcating science has advanced along different avenues. It has been claimed that science is recognizable by its results, by its methods, and more often by the way in which statements claimed to be scientific are evaluated. Early in the twentieth century a philosophical school of thought known as logical positivism (the Vienna Circle) advanced an answer for demarcating science: demarcating science from religion and metaphysics was mainly a matter of semantics. Only statements about empirical observations are meaningful. Verification was then espoused as a safe criterion to decide whether or not one is dealing with a scientific statement. However, although any generalization can be tested by verification, it guarantees little, since the status of such generalizations is always uncertain, in that any follow-up observation may counter it.

Correcting verificationism, Popper's falsificationism starts by noticing that meaningfulness may not necessarily serve to demarcate science since a theory might well be meaningful without being scientific. By contrast, if the analysis starts by asserting under which conditions a theory can prove to be false (falsificationism), this serves better the quest for demarcating falsifiable scientific theories from unscientific (non-falsifiable) ones. Popper argued that scientific knowledge cannot be *proven* to be true; all that science can do is *disprove* theories. And to do so, criteria of refutation have to be laid down beforehand. Falsificationism is then an effort at producing instances which may counter a generalization. The failure to verify such instances, the failure to falsify a theory, generalization, or statement, gives credence to them as scientific. Alternatively, the failure to assess under which conditions the theory could be proved false is a clear sign of its unscientific nature.

But much that would be considered meaningful and useful in science is not necessarily falsifiable. Non-falsifiable statements have a role in scientific theories themselves, as in the case of cosmology, for example. If the acceptance or failure of scientific theories relied simply on falsification, no theory would ever survive long enough to be fruitful, as all theories contain anomalies. Besides, falsificationism does not provide a way to distinguish meaningful generalizations from meaningless ones. And more importantly, since falsificationism is based on factual propositions serving as instances to counter scientific claims, it implies a controversial observational theory. This last statement is the departure point of Lakatos's reassessment of falsificationism. The difficulties inherent in Popper's theory led Lakatos to propose a more subtle theory of falsification. His view, which he calls "sophisticated falsification" to distinguish it from Popper's, can be summarized thus: no experiment, experimental report, observational statement, or well-corroborated low-level falsifying hypothesis alone can lead to falsification. There is no falsification before the emergence of a better theory. Thus, Lakatos argued that no factual proposition can ever be proved by experiment; propositions can only be derived from other propositions, they cannot be derived from facts. Therefore, if factual propositions are unprovable then they are fallible, and if they are

fallible, clashes between theories and propositions are not falsifications but merely inconsistencies. Evaluation on Lakatos's view should be practiced, then, over a series of theories "in the long run" rather than one at a time. Both falsification and verification and the idea of a scientific method are useful demarcation criteria, but only within the temporal confines of an established scientific *paradigm*. This is a familiar line of argument associated with Kuhn, who went further than Lakatos in pointing out that sophisticated falsification sidesteps the fact that numerous preliminary decisions are involved in Lakatos's criteria. In order to decide whether a theory is indeed a better theory than another, scientists must, for example, decide which statement to make "unfalsifiable by fiat" and which not. Or dealing with a probabilistic theory, they must decide on a probability threshold below which statistical evidence will be held "inconsistent" with that theory; they have to decide what is going to be called "facts," "new facts," and so on.

Both Kuhn and Feyerabend's contributions to the problem of demarcation push it forward by opening up its subjective and sociohistorical dimension. Both argued that the sorts of decisions scientists take are made in the light of shared ideological commitments within a given paradigm. The questions of truth and falsity and correct or incorrect understanding are not uniquely empirical (as the analytical approach held) and many meaningful questions surrounding the problem cannot be settled this way.

Despite the fact that at the analytical level there is no full agreement on what it is that distinguishes science from other kinds of intellectual activities, at the practical level there are many examples of temporary and localized agreements about such a distinction, achieved on a daily basis in scientific practice. From academic curricula in schools and colleges to the design of public or private organizations for the funding and management of scientific research, from ideas of science and scientific practice disseminated throughout the news and media entertainment industries to the process of peer evaluation in specialized journals, the existence of tacit agreements on what is science accounts for practical decisions that must be taken in these various contexts: defining curricula content for a discipline, allocating resources for

research, announcing a new discovery, keeping the record of science, and even to tell someone a science fiction story involves a degree of tacit agreement on what science looks like. These practical dimensions of demarcation in science are what the notion boundary work attempts to describe. Boundary work is about an *ideological* style found in scientists' attempts to create a public image for science by contrasting it favorably to other intellectual or technical activities in order to advance their interests or resolve their inner strains (Gieryn 1983).

The capacity to create convincing distinctions between science and exemplars of non sciences or pseudo sciences serves a variety of goals pursued by scientists for the advancement of their professional careers: acquisition of intellectual authority and career opportunities as much as the denial of these resources to others (supposedly pseudo or non scientists), and the protection of the autonomy of scientific research from external interference.

From a boundary work standpoint, the authority of science is a result of its successful claim to autonomy, its expansion into areas previously claimed by others, and its successful rejection of other claimants to cognitive authority. Thus, boundary work comprises at least three kinds of strategies: expansion, expulsion, and the protection of autonomy. The work of expulsion operates when scientists seek to marginalize competing claims, to distinguish between orthodox and fringe, and to keep out specific social practices (e.g., magic, alchemy, witchcraft). Expansion occurs when scientists seek to extend their claim over areas previously claimed by others (e.g., religion, folk knowledge, craft expertise). Autonomy protection occurs when scientists seek to minimize interference in their domain by politicians or managers. On these grounds, cognitive authority turns out as the result, rather than the source, of successful boundary work and the novelty that this point of view brings to the fore is the extension of this argument from particular claims to scientific knowledge to the claims making surrounding the institution of science itself.

Because of the considerable material opportunities and professional advantages at stake, demarcating science is not merely an academic matter. Epistemologists and philosophers of science draw demarcations between types of

knowledge without mentioning that these demarcations mean borderlines between people. They construct hierarchies in the realm of knowledge without making explicit the claims of domination which can be based on them. They separate "true reality" from the merely phenomenal world of sensation and fantasy as if these differentiations were given by truth itself and not expressions of a social struggle about what the decisive facts are.

Boundary work has wider applications since expansion, monopolization, and protection of autonomy are generic features of professionalization. Thus, it is not surprising that the notion is useful for describing ideological demarcations of disciplines, specialties, or theoretical orientations within science as well. Content analysis of these ideologies suggests that science is not one single thing. Characteristics attributed to science vary widely depending upon the specific intellectual or professional activity designated as non science and the particular goals of the boundary work. The rich argumentative repertoire detected in scientific ideologies often results in inconsistency. In the public domain science is at once presented as theoretical and empirical, pure and applied, objective and subjective, exact and estimative, democratic and elitist, limitless and limited. These inconsistencies can be explained, however, when considering that scientists build boundaries according to the kind of obstacles they find in their pursuit of authority and resources. In their quest scientists may find themselves competing with each other and needing to erect boundaries that ground identical aims on different bases. By the same token, variability may result from a simultaneous pursuit of separate professional goals, each requiring a boundary to be built in a different way.

Boundary work, based as it is on relatively unstructured observation of relatively unstructured ideological activities, has been considered insufficient. Further scholarly work on this topic has focused attention on crucial and more structured activities performed by boundary workers. This is how boundary work – a notion initially formulated to explain how scientists maintain the boundaries of their community against threats to its cognitive authority – has found useful policy relevant applications. One example is studying the strategic demarcation

between political and scientific tasks in the advisory relationship between scientists and regulatory agencies. In this context, derivative notions such as boundary objects, boundary organizations, and even co production have been advanced. Boundary objects stand between different social worlds and they can be used by individuals within each world for specific purposes without losing their own identity as members of a specific community of practice. In some cases entire organizations can serve as boundary objects, as did many of the public interest organizations created by scientists in the mid twentieth century to facilitate political goals while protecting scientific ones (Guston 1999, 2001). Yet boundary organizations are also involved in co production, that is, the simultaneous production of knowledge and social order. Boundary organizations co produce society as they facilitate collaboration between scientists and nonscientists, and they create the combined scientific and social order through the generation of boundary objects (Jasanoff 1996; Bowker & Star 1999).

science and the precautionary principle

Saul Halfon

The precautionary principle is a regulatory approach, under conditions of scientific *uncertainty*, requiring that a new chemical or technology be regulated or banned until it is proven safe. This principle was developed in opposition to the dominant regulatory standard, which requires affirmative evidence of harm before regulatory action can be taken. These two approaches designate a central conflict in environmental and food regulation, particularly related to chemical release and use of genetically modified organisms.

Precautionary approaches to regulation have existed for much of the past century. For example, the United States Food and Drug Administration works on a precautionary model for drugs and food additives. Thus, pharmaceutical companies cannot market a drug in the United States until it is explicitly approved following affirmative evidence of safety.

Precaution as an explicit principle of policy making has more recent origins. It arose out of 1970s German environmental policy, particularly the *Vorsorgeprinzip* (foresight principle). In international regulation it was first codified in the 1984 First International Convention on Protection of the North Sea. Its most important articulation may be found in the Rio Declaration of the 1992 UN Conference on Environment

and Development, which states in Principle 15 that the “lack of full scientific certainty” should not prevent environmental protection. Other influential statements on precaution can be found in the 1998 “Wingspread Statement on the Precautionary Principle” and a 2000 “Communication from the Commission of the European Communities on the Precautionary Principle.” Several countries have explicitly endorsed the precautionary principle, most notably the European Union in the 1992 Treaty of Maastricht.

While naming an approach to scientific evidence, the precautionary principle is associated with a general orientation toward regulation that is directly counter to the “risk paradigm” or “sound science” approach. It is a crucial feature of what Martin Hajer calls the “ecological modernization” discourse coalition, and Joe Thornton treats it as part of the “ecological paradigm” of regulation, thus supporting a particular orientation toward scientific uncertainty, risk, expertise, proof, regulation, responsibility, public participation, and progress. As such, it is tied up with the politics of modernity and the culture wars: precaution is often favored by environmental, health, and consumer activists and advocates who support greater regulation; risk is often favored by corporations and free trade advocates who prefer minimal regulation.

Most proponents of precaution favor prevention rather than management (control and remediation) of pollution, are skeptical of scientific claims and standards in arenas of extreme complexity, respect democratic input as an important adjunct to technical knowledge, seek to regulate classes of phenomena rather than individual chemicals or products, question the assimilative capacity of the environment, prefer known to unknown risks, and would require proof of safety from the producer of a new product (often called a reversed onus of proof). They also favor Type I errors (false positives for harm) rather than Type II (false negatives).

By contrast, the risk paradigm generally takes a “command and control” approach to regulation, which focuses on defining “acceptable discharge” rates. This paradigm admits a relatively narrow set of quantifiable and measurable risks for consideration; that is, risks to human health and the environment rather than economic, cultural, or community risks. It thus

supports expert driven and technocratic modes of regulation. The refusal to regulate based on uncertain knowledge derives from a *positivist* stance toward science that buttresses their claim that this is the only “sound science” approach to regulation.

Proponents of precaution reject the “sound science”/“anti science” designation. Neither formulation is inherently more scientific than the other, although they do understand regulatory science differently – as either positivistic or as inherently uncertain. Precautionary approaches also tend to treat science policy as a science/politics hybrid, whereas risk based approaches appeal to the separation (purification) of science and politics into separate realms.

These paradigms are discursive packages rather than logical constructions, and as such can be reconstructed. Ongoing attempts at harmonizing these approaches seek to recombine various elements in a number of different ways. Some proponents of the precautionary principle fear that it will be coopted as it is thus separated from its historical entailments.

Both risk based and precautionary approaches have logical extremes, which would make the policy untenable in practice. Positive proof of harm is very rare, and thus an absolutist risk perspective effectively undermines regulation. Critics of risk based regulation claim that this is currently the case for persistent, bioaccumulative, and synergistic chemicals and those with complex or non linear modes of action in human and environmental systems. Ecosystem theories and theories of endocrine disruption in particular raise such concerns (the endocrine disruption hypothesis posits that many synthetic chemicals have powerful hormonal effects at extremely low doses). Likewise, positive proof of safety is very difficult, suggesting that no new chemical or genetically modified organism could be approved under precaution. Proponents of strong precaution suggest that most synthetic chemicals have historically proven harmful to human health and the environment, so such an approach is warranted. Critics suggest that this approach is completely untenable and would ultimately stall all innovation, costing many more lives than it would save. Most proponents of precaution reject such extremes, suggesting instead that precaution shifts the calculus of regulation rather than providing a

specific legal rule against innovation. Some suggest that precaution should be invoked only when there exists a *prima facie* case for the danger of a new substance and that priorities for precautionary regulation should be based on the degree of scientific uncertainty in combination with degrees of possible harm.

science, proof, and law

Stephen K. Sanderson

Science seeks to describe, explain, and predict features of the natural and social worlds. Scientists try to develop theories or explanations of

phenomena by means of producing bodies of empirical evidence that play a major role in determining whether theories are accepted, modified, or rejected. In general, scientists seek theories that are logically consistent, empirically testable, well supported by available empirical evidence (and not too severely contradicted by other available evidence), parsimonious or simple, and that continue to be a source of new ideas and lines of research. Scientists also generally seek to produce theories that yield a unified understanding of the phenomena they study. For example, Wilson (1998) talks of *consilience*, and some physical scientists claim they are moving very close to a “theory of everything” (Barrow 2001).

In the early decades of the twentieth century the Vienna Circle of logical positivists insisted that science consisted only of those propositions which could be verified by facts drawn from experience. However, Popper (1959) responded by arguing that theories could never be verified because a scientist can never possess all of the possible facts bearing on a theory. Popper’s solution to this problem was that the scientist had to proceed in a sort of reverse manner, by trying to *falsify* rather than verify a theory. In fact, for Popper, whether a theory was falsifiable or not was the line of demarcation between science and nonscience: science consists of falsifiable statements, and theories are retained so long as they survive these falsifying tests.

Popper recognized that a theory could rarely be falsified by a single disconfirming instance. There are degrees of falsification. In this regard, he spoke of the *corroboration* of theories. Theories are corroborated by being submitted to the most, and the most severe, falsifying efforts possible, and by withstanding them. But corroboration is not “truth.” It simply means that a theory is provisionally accepted pending further testing. Better theories are those that are logically stronger, that contain greater empirical content, that have greater explanatory and predictive capabilities, and that have been more severely tested. Any newly proposed theory should also be independently testable, have new and testable consequences, and must predict the existence of phenomena thus far unobserved. And, in the end, Popper admits *verification* back in, because he contends that, just as science would stagnate if it fails to

produce refutations, it would also stagnate if new theories failed to produce verifications (i.e., supportive evidence).

Popper’s philosophical model is not without its problems, yet his notion that no theory can ever really be “proved true” stands, as does his notion that statements that are unfalsifiable are not to be regarded as scientific. For Popper, science was perhaps the only epistemic activity in which errors can be identified and corrected over time (Harris 1979: 27). This is what allows science to progress toward greater *verisimilitude*, or increasingly accurate approximations to the truth.

Lakatos (1970) argued that Popper’s falsificationism was highly inconsistent with actual scientific practice and that it was so strict that it would make scientific advance impossible. Literally applied, Popper’s falsificationism would bring science to a halt because virtually every scientific theory that has ever been proposed has *anomalies*, or facts that are inconsistent with it. Indeed, Lakatos contended that every theory is born in an “ocean of anomalies,” and that scientists often retain theories for decades or even longer even though they know there are many inconsistencies.

However, Lakatos’s critique applies largely only to the very early Popper, who was a *naïve falsificationist*. Later, Popper became more nuanced in adopting a far less restrictive, or *sophisticated*, falsificationism in admitting degrees of falsification (or corroboration). Lakatos regarded sophisticated falsificationism as an improvement on naïve falsificationism, but thought it was still limited in the sense of conceiving of scientific testing as simply a comparison between a single theory and a body of evidence. What is needed is a three way comparison in which one not only compares a theory to evidence, but at the same time judges it *with respect to its main rivals*.

Moreover, Lakatos argued, it is not really theories that scientists test, but series of theories or research programs. Even if individual theories end up being decisively refuted, the research programs of which they are a part can still stand. Lakatos then went on to identify what he called theoretically progressive problem shifts. These are research programs that can explain everything their rivals explain, and at least some additional content. They can make

novel predictions not made by their rivals. Lakatos's own philosophical model of science he called the methodology of scientific research programs. Every research program contains a *negative heuristic* or "hard core" of fundamental assumptions or principles, around which scientists build a "protective belt" of auxiliary hypotheses. And it is the auxiliary hypotheses, rather than the hard core, that is subjected to empirical test.

There is also a *positive heuristic*, which consists of suggestions, hints, and insights that help the scientist to modify the protective belt in order to save the irrefutable hard core, and it is this positive heuristic that "saves the scientist from being confused by the ocean of anomalies" (Lakatos 1970: 135). The anomalies are acknowledged but temporarily shoved aside in hopes that they will eventually be shown to be explainable in the basic terms of the research program. Progress in science, for Lakatos, is therefore a matter of theoretically progressive research programs. However, progressive programs seldom last forever. They often become theoretically degenerating research programs, or programs in which too many (or too severe) anomalies accumulate that can no longer be explained away. Such a research program will then give way to one or more rivals that are theoretically progressive.

Following somewhat in the Lakatosian tradition is Laudan (1977), who agrees that science is a matter of evaluating research programs, and also that one can only evaluate them comparatively. However, Laudan points out that scientists do not consider only empirical evidence when evaluating theories. They also use conceptual problems, which may play at least as large a role in scientists' acceptance or rejection of the theories as empirical evidence. Moreover, scientists are rational to consider such conceptual problems if they have been a reliable guide to past knowledge. Conceptual problems are problems that arise from either the internal inconsistencies or ambiguities of a theory, or from conflicts between a theory and another theory (or non scientific doctrine) that is thought to be well founded.

One type of conceptual problem is methodological disputes. For example, Laudan avers that much of the opposition to psychoanalysis and psychological behaviorism turned

on methodological concerns, and many of the arguments over quantum mechanics also involved methodological questions. Another type of conceptual problem is worldviews, which are moral, theological, or ideological stances. Examples abound. After Darwin published *Origin of Species* in 1859, biologists fairly rapidly came to accept the reality of evolution, but there was great resistance to the mechanism he proposed to explain how evolution occurred – natural selection. This was because natural selection eliminated the concept of purpose, to which scientists were deeply attached as a worldview. It was only after about 1930 that an empirical foundation was developed that was capable of convincing scientists to abandon their entrenched concept of purpose and accept natural selection. Worldviews play a particularly crucial role in the acceptance or rejection of theories in the social sciences. For example, there has been great resistance to sociobiology, especially among sociologists, because it clashes with the entrenched Durkheimian worldview – "explain social facts only by relating them to other social facts" – and is seen as a threat to the discipline's identity. Sociobiology has also been resisted because it is widely viewed as promoting a conservative view of society, which clashes with sociologists' strong left leaning political views.

An important difference between Laudan on the one hand and Popper and Lakatos on the other concerns the debate over realism and anti realism. For Popper and Lakatos, who were scientific realists, science is truth seeking and is progressive in the sense of producing cumulative knowledge. Laudan, however, advocates antirealism, which means that, as Kuhn (1962) famously argued, science only solves puzzles or problems. Laudan emphasizes that in scientific change there is genuine progress (something Kuhn denied), but this change is not cumulative because new theories (or research traditions) cannot explain all of the phenomena explained by their predecessors. There are losses as well as gains when new research programs replace old ones.

In the 1970s there emerged a whole subfield of sociology, the sociology of scientific knowledge (SSK), which has grown and expanded by leaps and bounds. (For citations to the very large literature, see Laudan 1996: 183–209;

Kincaid 1996: 37–43; and several essays in Segerstrale 2000). Although its proponents vary in the degree to which they hold it, the essential premise is that the content of scientific knowledge is influenced much more by social and cultural factors than by canons of scientific rationality. This is one of the legacies of Kuhn. In addition to his argument that science is a problem solving rather than a truth seeking activity, Kuhn also contended that scientists operate within paradigms that are regularly overthrown by the advocates of rival paradigms, and that scientific progress only occurs *within* paradigms, not *between* them. Kuhn often spoke as if commitment to a paradigm is more a matter of group psychology or sociology rather than the rational weighing of evidence, and that paradigmatic change is much like a type of Gestalt switch. Many philosophers of science regard Kuhn's views as highly problematic because of what they see as their subjectivism and relativism.

More recently, science has come in for enormous criticism at the hands of postmodernists and other “antiscientists,” who regard science as undeserving of its epistemically privileged position and as just one way of knowing among others. This is one of the legacies of the “epistemological anarchism” of Feyerabend (1975), whose views were considerably more radical than Kuhn's. For Feyerabend, all modes of knowledge are essentially on the same plane, whether science or witchcraft, and thus his basic methodological rule was that there should be no methodological rules – “anything goes.” The postmodern attack on science has emphasized its alleged “Eurocentrism” and claimed that commitment to science as a superior epistemology is rooted in western cultural values rather than objective criteria (since, for postmodernism, there can be no such criteria). (For excellent summaries and commentaries, see Segerstrale 2000.) Those philosophers and sociologists who see science as a mere social construction seem to be engaged in a completely self refuting argument, since they do not “think *their own work* is only a social construction with no claim on evidence and truth as traditionally understood” (Kincaid 1996: 41).

Sociology is a very immature science, and most sociologists have an impoverished understanding of real science. For example, the

majority of sociologists study only one society (usually their own) and no general theories can be built on the basis of one case. (It would be like trying to build biological science by studying only penguins.) Many sociologists resolve the acrimonious debates among rival theoretical camps by settling for an eclectic position, but eclecticism as it is understood by sociologists is a strategy rarely if ever favored by natural scientists. Eclecticism violates the principle of parsimonious and highly unified explanation – one of the most fundamental of all scientific goals – and it makes the comparative evaluation of theories impossible (Sanderson 1987). Many sociologists who do highly quantitative survey research build unwieldy models that contain a large number of variables, but real science does not work that way. What results is a kind of “multivariate chaos” that is the antithesis of parsimonious explanation.

Sociology today lacks a highly cumulative body of knowledge, and there is very little agreement on key epistemological, methodological, and theoretical questions. Conceptual problems are particularly acute in sociology, especially in the form of political ideology and its role in settling theoretical debates. From the standpoint of the enormous successes of the natural sciences, sociology is an extremely immature discipline in terrible disarray. At the most general theoretical level, the vast majority of sociologists continue to adhere to the standard social science model, which assumes that human behavior is overwhelmingly determined by the social environment. However, this is a massively degenerating research program, for the accumulated anomalies are extreme. Sociologists cling to it for conceptual, not empirical, reasons.

Although the overall picture in sociology and social science more generally is not an impressive one, the social sciences do have some genuine research programs that may be regarded as at least mildly to moderately progressive. In anthropology, there is the cultural materialism of Harris (1979), which is coherent and unified and has made some impressive accomplishments. In psychology, anthropology, and to some extent sociology, there is a very coherent research program that now goes under the name of evolutionary psychology (Barkow et al. 1992; Crawford & Krebs 1998). Thus far it has proven to be a highly progressive research program.

A closely related research program in anthropology is evolutionary ecology (Smith & Winterhalder 1992). And in sociology a good example of a coherent research program is rational choice theory. This program has been attached to the study of early modern and modern states (Kiser et al. 1995), to the study of human sexuality (Posner 1992), and to numerous other substantive areas. There are also dependency and world system approaches to economic development, which have the merit of being research programs that have been subjected to extensive empirical testing, even though, unfortunately, the anomalies have become severe and in many ways these approaches are now degenerating programs (Sanderson 2005a). There is also the state centered approach to revolutions (Wickham Crowley 1992; Goldstone 1991; cf. Sanderson 2005b), which is something like a research program and seems to be a highly progressive one.

So the situation is by no means totally bleak. Natural scientists do not really need to study the history and philosophy of science, and few do. Indeed, scientists are often highly antagonistic toward philosophy of science. The reason natural scientists do not need philosophy of science is that they have a keen sense of what they are doing, and they generally do it extremely well. Social scientists, by contrast, very badly need to study the history and philosophy of science because they need to gain a much better understanding of how real science actually works and try to emulate it.

One major barrier to success in social science is the complexity and relative unpredictability of the phenomena being studied. The other major barrier is conceptual, and mainly ideological. Ideology is an enormous barrier to scientific objectivity, and indeed to the very practice of science at all. Sociologists and other social scientists can do nothing to alter the nature of the phenomena they study, but they are entirely free to embark along the path of objective social science if they choose to recommit themselves to doing so.

It should be clear that proof is not really possible in science, if by proof we mean "establishment with certainty." It has long been noted by philosophers of science of many stripes that theories will always be "underdetermined" by empirical evidence. (This is the famous Duhem-Quine underdetermination thesis, which has

often been used by postmodernists and other relativists to attack science. However, such conclusions are complete non sequiturs.) There is only disproof or, lacking that, provisional acceptance. Proof must be restricted to the domains of logic and mathematics. As for laws, these certainly exist in the physical sciences and to some extent in the biological sciences, but they rarely exist in the social sciences. Social scientists still have enough work to do to bring themselves up to minimal scientific standards. The development of widely agreed upon laws of social behavior, organization, and change are far off into the future.

science and public participation: the democratization of science

John Forrester

Thomas Jefferson, quoted in Fischer's *Citizens, Experts, and the Environment* (2001), said that wherever the people are well informed, they can be trusted with their own government. But, nowadays, who can claim to be well informed enough about science to govern it except the scientists themselves? In 1959, Sir Charles Snow put forward the thesis in the Rede Lecture that there was what amounted to an opposition between literary intellectualism at one end, and proficiency in the physical sciences at the other. Snow dated his realization of this

distinction to the 1930s. What we can say for certain is that there was a coming into common understanding that a reasonably well educated or cultured person could not, now, be expected to be normally able to comprehend both the sciences and the arts. This state of affairs is not by any means all the scientific community's fault, although science is guilty of creating, along with other forms of knowledge and understanding, elites. Elitism fosters disciplinization and subdisciplinization, and has given rise to mistrust and lack of understanding between the members of different disciplines and of science and scientists in general. The term "lay" was commonly used until the 1990s to describe those untutored in science, thus emphasizing the idea of a scientific priesthood or elite. For various reasons not dealt with here, this state of affairs is seen as being iniquitous, and so public participation in science, also known as public engagement in science, is seen as a means whereby that balance can be redressed.

This broad generalization of why science "needs" to be democratized hides several distinct rationales as to why the public should engage with science or vice versa. Before dealing with these rationales, there is one distinction that needs to be introduced: who or what "the public" or "publics" are engaging in or with. In many "western style" democracies, members of the public are engaging and being engaged in the governance of science, but not in knowledge creation itself. In contrast, in some continental European countries and in a few developing countries, citizen participation in science is seeing citizens more as co creators of new knowledge alongside traditional experts, new knowledge that is both "reliable" (after Gibbons 1999 – i.e., knowledge that is scientifically correct) and also "socially robust" (i.e., that overcomes the elitism of traditionally generated scientific knowledge). These two major dimensions to public engagement may be distinguished as public engagement *with* science on the one hand, and public engagement *in* science on the other. Stirling (2005) characterizes the first more exactly as "participation in the social appraisal of science and technology," while the other is also about knowledge production, as is illustrated by the title of the book *The New Production of Knowledge* published in 1994 by an international team of scholars including

Michael Gibbons and Peter Scott from the UK, Camille Limoges, Simon Schwartzmann, and Martin Trow from the Americas, and Helga Nowotny from continental Europe.

Since the end of World War II, there has been an almost logarithmic increase in the number of initiatives to open up new spaces for science and the public to interact. In 1985 in the UK, the Bodmer Report (see Miller 2001 for a fuller history) introduced the phrase “the Public Understanding of Science” (PUS) into the English language and also the idea that the public suffered from a deficit of knowledge about science. This thesis – that if only the public knew more about science and how it worked then they would be happier to allow science more funding, more control over science to scientists, and so on – can be seen to fit firmly into the dimension of public engagement with science. In the US during this period, science and scientists were engaged in a much more polarized debate sometimes referred to as the Science Wars (see Rose 1997), where the scientific elite defended itself against all critiques which it characterized as “anti science.” The Sociology of Scientific Knowledge (SSK) often found itself on the receiving end of attacks and rebuttals, particularly for its social constructionist stance. Yet, in the US, the American Association for the Advancement of Science (AAAS) has, over the years, had little more effect in generating public engagement in or with science than has its UK counterpart(s): the Royal Society, the Royal Institution, and the British Association for the Advancement of Science, who jointly formed the Committee on the Public Understanding of Science (CoPUS) after the Bodmer Report. The deficit model informed much of the early work of CoPUS and the AAAS. The deficit model, and projects based upon it, proved powerless to assist in improving science literacy.

SSK really did not engage with PUS as the former’s social constructionist thesis suggested that increasing scientific literacy was not going to serve any useful purpose except to science itself. UK SSK practitioners (see Irwin & Wynne 1996 for one collection of their works) were suggesting that science needed to be, at the very least, studied in context. Still using the terminology of elites, they made the argument

that “lay knowledge” should be considered alongside expert knowledge as epistemologically different but no less valid. The deficit model was moribund. However, the application of social constructionist ideas needs to be handled carefully, as while the governance and application of science – what Stirling called science’s “social appraisal” – is clearly open to public engagement and participation, the inclusion of the public’s (and publics’) knowledge in the creation of “new knowledge” is still a largely uncharted territory. Nonetheless, we have now moved from PUS to PEST (Public Engagement with Science and Technology), and PEST seems to be able to attract the interest of SSK practitioners and scientists alike. The UK Economic and Social Research Council has its *Science in Society* program, as does the Royal Society, CoPUS is to be reformed and renamed, and the influential House of Lords Select Committee on Science and Technology Third Report (2000) was entitled *Science and Society*. With the change from PUS to PEST, the mood has changed from edification to dialogue. Science is now expected to seek to democratize itself through engagement. The form that this engagement takes is still largely undecided.

In the last decade, many rationales have emerged for encouraging public participation, particularly with environmental policymaking spurs such as global climate change and, in particular, sustainable development (see Forrester 1999). Some have adopted the pragmatic argument that public involvement will assist with the effective implementation of policy; when members of the public are consulted and engaged with, they are more likely to lend their support to (or, at least, not oppose) science based policy measures. Others have argued that in democratic societies, people simply have a right to a participatory role. Further, the argument has been made that people may have access to knowledge that is unknown to experts; local people may themselves count as experts about their own localities. Such participative initiatives have been further spurred and legitimated by the participatory emphasis within Local Agenda 21. This was important in that it encouraged people to participate in the issues affecting their localities. Stirling (2005) has characterized these three rationales as:

- Normative democratic – in other words, the motive is the engagement. It is simply people's democratic right to be involved in decision making in society and in an increasingly technocratic society this involves increased involvement in science policy.
- Instrumental – this rationale is different in that it has a purpose related to an output or outcome. Citizens are engaged in order to change their behavior, or to inform the creation of new knowledge. PUS was clearly instrumental.
- Substantive – this is the most complex in that this rationale almost subsumes the other two, but at its most naïve it can be described that substantive engagement leads to a “better” decision. It can be argued that the move toward PEST sets the scene for substantive engagement to occur.

There will remain times when the public will be engaged “only” in the governance of science; engaged in making decisions about science funding, research priorities, and so on. There will also be times when what is required is engagement in the creation of new knowledge. The major methodological issues with science governance include: redefining the “norms” of science (after Merton's 1973 *The Sociology of Science*), deciding on the funding of science, the transparency of decision making within the governance of science and science research, and also the application of scientific knowledge (see Ziman 1996). Thus, this level of engagement concentrates upon science itself, its outworkings in the policy sphere. The major methodological concepts or issues involved in public engagement in the creation of [new] knowledge are to do with the nature of that knowledge itself – what the concept's authors call “mode 2 knowledge production” (Nowotny et al. 2001) – and where and how the conditions necessary for the growth of a “socially distributed expertise” (ibid.) may be fostered.

As science becomes increasingly answerable to a range of publics including both funders and users, sociology has begun to suggest that “new spaces” are needed to fulfill a new contractual arrangement between science and its primary constituency, society. Policymakers (see House of Lords *Science and Society* referred to above) warn against creating new institutions to

provide these spaces, instead emphasizing the need for trust and transparency in existing institutions. The focus, however, is on the need for transparency and trust; science still needs to reestablish relations of trust between science practitioners and members of different publics. One area where this is particularly critical is where science is deemed to suffer from a lack of certainty. The idea that under certain conditions of uncertainty (to wit, “post normal” science) there should be extended peer review was one put forward by Silvio Funtowicz and Jerry Ravetz in a series of papers (see Yearley et al. 2001 for a fuller exposition). They sought to develop a theoretical framework for understanding on what grounds and under what conditions the public should be involved. Put simply, they said that where the scientists had no firm evidence on what to base a decision, then the non scientist's view was just as valid, but they also made the point that where there were high “decision stakes” – in other words, when the outcome of the decision might impact upon a large number of people – then under those conditions the public too should have a voice. This framework was particularly influential in the 1990s. It has fed into the underlying PEST principle that science itself should no longer be controlled by a restricted corps of insiders.

One attempt to produce “mode 2 knowledge” was made by an interdisciplinary team of researchers from the UK (see Yearley et al. 2003) using a form of participatory mapping (see Cinderby & Forrester 2005): the idea was to create a common understanding as a basis to bring together the technological assessment or “evidence based knowledge” about local air quality with the experience and concerns of local stakeholders and residents. In the City of York (UK), local authority officers were sufficiently impressed with the technique that they supported the running of mapping groups to generate maps of local perceptions of problem areas (of air quality). A political decision was made to use these maps rather than those based on technical assessment alone in the designation of the city's air quality management area. Thus, it can be argued that the “new” knowledge superseded the technical assessment, but there is little evidence for this experience in York being replicated elsewhere in the UK, even in

this area of air quality, a “common good” where technical and “lay” understandings are so close. Thus it may be argued that, for the moment, the democratization of science is actually the democratization of the use – and governance – of science with little associated democratization of expertise.

science and religion

Steve Bruce

It is commonly held that the declining power and popularity of religion that we see in almost all modern industrial societies owes much to the rise of science; science and religion are competitors in a zero sum game, with the former being vastly more persuasive.

As US sociologist Robert Merton pointed out, many of the pioneering natural scientists in the seventeenth century (e.g., Robert Boyle) were pious men who saw their work as demonstrating the glory of God’s creation. Yet science has challenged what were once taken for granted elements of theistic belief systems (such as the idea that the earth was the center of creation and that God created the variety of life forms). In 1633 the Catholic Church tried, condemned, and imprisoned Galileo for continuing to promote the Copernican view that the earth moved around the sun after he had been instructed to desist. In the nineteenth century, leaders of the Church of England tried to refute the evolutionary theories of Charles Darwin and his followers. In the contemporary United States, conservative Protestants try to use the courts to force schools to give equal time to “creation science” as an alternative to naturalistic evolution.

This zero sum game view of the relationship between science and religion is largely misleading as an explanation of change. That many highly educated people whose standard of living depends very directly on natural science can continue to hold traditional supernaturalistic beliefs shows us that there are a number of ways

in which the disconfirming effect of science can be deflected. One successful way of responding is to rewrite theistic religious beliefs so that they accommodate new knowledge. In the second half of the nineteenth century, the mainstream Christian churches reconstructed their belief systems: heaven and hell were changed from being external realities to being psychological states. Heaven became a sense of contentment; hell became alienation, loneliness, and so on. Miracles were explained away. For example, events described in the Bible as miraculous (such as Noah's flood or the parting of the Red Sea) were taken to be misunderstandings of natural phenomena. Faith healing was explained not as divine intervention but as the workings of a placebo effect. By such trimming an omnipotent deity was preserved, not as an alternative to the causes of phenomena discovered by scientific explanation but as the author of the complex processes which natural science was discovering.

An alternative to rewriting the faith is to turn science against itself. Those who wish to continue to believe in divine creation, for example, can cite the Popperian view of the logic of scientific discovery to the effect that the findings of science are only ever hypothetical. In natural science properly understood, nothing is ever firmly proved to be the case. The cautious claim that our current state of knowledge is only the best we have at this point in time is, judo like, used to throw any scientific proposition that threatens religion.

More generally, the idea that scientific discoveries undermined religion requires that believers were aware of the conflict and of the weight of evidence behind the problematic findings. That may not often have been the case. Even in those societies with extensive compulsory schooling, very many people have little or no understanding of physics, chemistry, or medical science. For example, very many consumers of alternative medical therapies are unaware that they are implicitly subscribing to models of causation for which the best science offers no empirical support. It is difficult to see how homeopathy, with its central idea that a chemical agent can be so watered down that no trace of it can be detected and yet retain the ability to stimulate in the body a curative response, can be sustained within conventional notions of causation. Yet some trained medical scientists

use homeopathy and many patients seem satisfied that such cures are legitimately "scientific."

What this suggests is that while the battle between specific findings of natural scientific and religious ideas engaged the experts on each side, it probably played little part in the long term decline of religion. Too many people are simply unaware of the ideological clashes or were insulated by the sorts of rhetorical strategies listed above. To explain secularization, we must identify the social changes associated with industrialization that weakened the ability of ideological communities to reproduce themselves; the rise of individual freedom and the increase in social and cultural diversity are much more powerful agents of change than any particular naturalistic idea.

But science does threaten religion in two rather subtle ways: it alters our images of the world and our images of ourselves. Religions assume that there is a supernatural realm: a world beyond the material. Although most modern scientists are careful not to stray beyond their competence and hence do not directly challenge such beliefs, the general assumption of the scientific community (and of the wider culture informed by it) is that the material world is to be understood in its own terms and that those terms are wide enough to encompass most of what interests us. For example, natural disasters are just that; they are not divine interventions. Personality defects are the result of biological or psychological, rather than spiritual, problems.

Science has also given us unprecedented technological power, which has two sorts of effects on religion. Firstly, the occasions for resort to religion have been much reduced. In pre industrial societies, appeal to God or the gods often provided the only response to uncertainty and risk. Without accurate weather forecasting and self righting boats, the best a fishing community could do to ensure the safe return of its crews was to pray and to placate a possibly wrathful God. When effective solutions to problems are devised, it is possible to continue in the old ways – to suppose that the chemical that will kill worms in sheep only works if we pray before we administer the dose – but it soon becomes apparent that the worm dose works as well for the ungodly as for the godly. In 1349, when the Black Death ravaged England, the national church instituted weeks of special

prayers and fasting. When AIDS (at first dubbed the “gay plague”) appeared in Britain in the early 1980s, the Church of England’s response was to call for the government to invest more money in scientific research. And the second response was more successful than the first: systematic research provided first the explanation for AIDS, and then the technology that allowed HIV positive people to live relatively normal lives. The rise of effective technologies reduces God from being omnipotent to being the much lesser “God of the gaps.” Gradually, the number and range of occasions on which people resort to religious activities to solve problems are reduced and the authority of the churches is correspondingly reduced. Religious authorities can no longer claim to validate all knowledge and are left with the much reduced role of safeguarding religious doctrine and trying to maintain control over sociomoral issues.

Technology has also produced a fundamental change in human self images. It is characteristic of most religions that they present humankind as tiny and powerless in the face of divine providence. Like the tormented Job of the Old Testament, people are expected to put up with whatever God or the gods inflict on them and hope that their obedience will eventually be rewarded, in some future life if not in this one. Although there is an obvious dark side to technology, it has made us considerably more powerful than we have ever been before. Instead of having to work within the natural world, we can hope to dominate it. A people that can extract oil from the depths of the North Sea and use it to vastly increase the comfort and lengths of our lives is a people of power and significance. Right or wrong, and for good or ill, we differ from our ancestors of the pre industrial world in being able to imagine ourselves masters of our fate.

science, social construction of

Lena Eriksson

In its simplest form, the claim that science is socially constructed means that there is no direct link between nature and our ideas about nature – the products of science are not themselves natural. This claim can be taken to mean different things and a distinction is often made between strong and weak interpretations of social constructivism. The stronger claim would not recognize an independent reality or materiality outside of our perceptions of it, or at least dismiss it as of no relevance as we cannot access it. This stance is, however, not a very common one. A weaker social constructivism tends to leave ontological queries to one side and instead focus on epistemological matters – how we gain knowledge about the world. What we count as knowledge is dependent on, and shaped by, the contexts in which it is created. Knowledge is thus made by people drawing on available cultural material, not preexisting facts in a world outside of human action, waiting to be uncovered.

The philosopher Ian Hacking has discussed and criticized different uses of the concept social construction. Hacking (1999) takes apart and analyzes the many and varying meanings of social construction. According to Hacking, the concept is routinely used in a way that makes it devoid of meaning. “The phrase has become code. If you use it favorably, you deem yourself rather radical. If you trash the phrase, you declare that you are rational, reasonable, and

respectable" (p. vii). Furthermore, the concept often comes with an inbuilt value judgment that implies that things should ideally be constructed differently.

When teasing out different meanings that different authors have given to social construction, Hacking found three main types: contingency, nominalism, and external reasons for stability (Sismondo 2004). The first kind of social constructivism essentially comes to mean that things could have been different – there was nothing inevitable about the current state of affairs and it was not determined by the nature of things. The second kind of social constructivism focuses on the politics of categories and points to how classifications are always human impositions rather than natural kinds. The third kind of social constructivism points to how stability and success in scientific theories are due to external, rather than evidential, reasons.

Whereas the idea of science and scientific knowledge as socially constructed can be traced to many a scholar, the very concept of social construction was introduced into mainstream social sciences by Peter L. Berger and Thomas Luckmann in their influential book *The Social Construction of Reality. A Treatise in the Sociology of Knowledge* (1966). In it, the authors combine ideas from Durkheim and Weber with perspectives from George Herbert Mead, to form a theory of social action. This theory would not only deal with plurality of knowledge and reality – for example what counts as knowledge in Borneo may make little sense in Bath and vice versa – but also study the ways in which realities are taken as known in human society. How is it that a concept such as gender is taken to be “natural” and “real” in every culture, while at the same time it is perceived and performed very differently in different cultures? Knowledge about the society in which we live is “a realization in the double sense of the word, in the sense of apprehending objectivated social reality, and in the sense of ongoingly producing this reality.” An objectivated social reality is a reality that is not “private” to the person who produced it, but accessed and shared by others. As humans we are continuously creating and recreating reality, and the role of the sociologist is to analyze the process of how reality is constructed, that is, how knowledge becomes institutionally established as real.

One way of understanding science as socially constructed is to point to obvious and “external” social factors, such as funding structures or political influences. These affect the way in which science develops; business interests can determine which projects are pursued, policy decisions can effectively close down entire avenues of research, and so on. The way in which research is institutionally organized is another much cited example of “external” social shaping of science – for example how heavy bureaucracy and strict disciplinary boundaries render the pursuit of trans disciplinary science difficult. Another variety of this brand of social constructivism is the argument that only scientific knowledge deemed to be “relevant” or interesting will be pursued. Social theorists such as Helen Longino and Evelyn Fox Keller have pointed to how male dominance in society in general, and in the scientific profession in particular, has resulted in certain kinds of scientific knowledge. The definition of scientific problems and framing of hypotheses come with an inbuilt gender bias. Male contraception is an under researched area because reproductive responsibilities are firmly placed with women in our society and it is thus assumed that it is the female body that is to be manipulated. Such social values are also reflected in the very methods that scientists will use – most human trials of medicines are performed on young men between 18 and 20 years of age. The generic “human” is thus a young man, whereas elderly women are the more likely consumers of the medicines that are being trialled.

Theorists such as Sandra Harding have argued that certain social positions – such as gender, race, or class – will render particular epistemological perspectives. A science conducted and shaped by black women would not contain the same knowledge as a science created by white men. What we call the collective body of knowledge in our society is really the knowledge of a dominant group – in this case men. This is not only due to “female” questions falling outside the framework of what is perceived to be “real science,” but because our entire view of knowledge is a (male) ideological construct. A Cartesian dualism such as body/mind is a construction built on the male experience of nature and culture as separate entities, as men tend to be free to engage in intellectual activity without

having to take responsibility for their own or others' bodies. The precondition for this male focus on matters intellectual is that women take care of the shopping, cooking, childrearing, laundry, cleaning, and other tasks that subsequently are not included in men's abstract conceptualizations of reality.

Other prominent feminist thinkers, notably Donna Haraway, instead view (scientific) knowledge as fragmented and physically anchored (but not necessarily the epistemological perspective of a particular social group). A knowing subject's perspective can always be located to a specific field – there is no objective “view from nowhere.” The arguments above differ both in their conceptualizations of the subject and of society, but have in common that they see scientific knowledge as dependent on the social frameworks in which they are produced. Science is not a neutral activity, but instead reflects institutional values.

Scientists tend to insist that their *way* of arriving at knowledge makes their claims more true and more valuable than other groups' knowledge claims (who arrived at their conclusions by different means and on different grounds). They argue that while it may be the case that certain types of knowledge – such as ideas about morality – are socially constructed, scientific knowledge should be exempt from such a mode of analysis. Scientific knowledge has a special authority and status because of the way in which we arrive at such knowledge. The “scientific method” – rigorous and systematic examination, testing, and replication – thus guarantees the veracity of scientific claims. “Truthfulness” is taken to mean that the claim in question is a direct representation of a reality that exists outside of, and independent from, our perceptions of it. A social constructivist view of science instead holds that scientific knowledge is as “social” as other types of knowledge.

A social constructivist perspective of science common in the field of science studies emphasizes the social influence at the very core of technical judgments. Scientific theories, it is argued, are always underdetermined by empirical data – there are a potentially infinite number of hypotheses that could serve to explain the same set of data. Despite this, scientists manage to “gel” around a limited number of possible explanations and eventually agree on

which one they consider to be true. This process of “truthmaking” is a social activity where the meaning of data is continuously being negotiated and renegotiated.

Sociologists of science have shown that scientific work in practice is rather more messy than in theory (Knorr Cetina 1981; Collins 1985; Fujimura 1988; Pickering 1992) and that data always require interpretation, that machines are continuously calibrated to generate information that “makes sense” (i.e., fits into a given frame of meaning), and that tests and models build on the assumption that the circumstances correspond precisely to “real world” circumstances. Furthermore, experiments routinely go wrong and scientists spend a substantial amount of their time attempting to discipline wayward material and tweak variables until they work (Knorr Cetina 1981; Latour & Woolgar 1986). The success of an experiment is determined by its outcome and thus measured against a host of prior assumptions about what “nature” looks like and whether the result at hand corresponds with that nature. If the result is deemed to fit into that framework it will eventually become a fact and taken to be not only a good model of nature, but part of nature itself.

Social constructivists of all extractions also tend to argue that the success of science in claiming to be the highest form of knowing in part rests on its ability to appear as though it lacks both temporal and spatial location. Harry Collins uses the metaphor of a ship in a bottle – once in place, science, like the ship, appears to have a timeless quality, as though it has always been there and always will be. The processes by which science and scientific knowledge are produced tend to disappear from later narratives when scientific “discoveries” or “facts” are presented. A scientific fact is like a ship in a bottle; it is near impossible to conceive of how the ship was ever outside the bottle, because the bottle neck is far too narrow for the ship to have been pressed through it. At one time it was, however, a mere pile of sticks outside the bottle (Collins 1985: preface). The mistake we make is to assume that the ship has always been a ship, and, in the case of science, that the fact has always been a fact.

Another common source of scientific authority is the notion of “objectivity.” The “human factor” – that is, the scientist(s) who produced

the knowledge – is made invisible, as are the circumstances under which the work was conducted. Porter (1992, 1995) has suggested that an inherently social relationship such as “trust” has taken the shape of objectivity by means of the apparent removal of individual, and therefore subjective, assessments. Porter (1995) argues that objectivity has nothing to do with truth and nature, but that it is instead the effort to exclude subjectivity – the “struggle against judgment.” As scientific communities are growing increasingly larger and span several continents, trust has to be achieved at a distance, without personal contact (Luhman 1979; Giddens 1989; Porter 1995). Trust relations, previously negotiated in direct interaction or via a personal contact, have been institutionalized – the checkpoints are no longer embodied in scientists but rather located in seemingly impersonal sets of procedures. One of the most successful examples of this is quantification, an almost ubiquitous feature in today’s natural sciences.

The interesting question to pursue is then – to speak with Berger and Luckmann – how knowledge becomes reality. Other theorists prefer not to speak of reality in such relativist terms, but still seek to study the genesis and development of facts. The task of the social scientist is to unpack so called black boxes (i.e., unproblematic givens that we no longer question) and analyze the processes that went before this fact, or set of facts, became taken for granted knowledge. In order to study how knowledge claims come to be established as facts, when they were once merely one of many competing theories, analysts need to go “upstream” and examine a time when these claims were more contentious (Latour 1987; Sismondo 2004). Latour and Woolgar (1986) show how an initially “nonsensical” statement gradually becomes a reasonable claim, to then be labeled “false,” only to retrieve its air of probability, to finally take on the status of a fact. This is done through a series of operations that aim to mobilize and “hook up” with other facts, scientists, and artifacts (Latour 1987).

So why is science a social construction, rather than just a construction? Woolgar has criticized the inherent asymmetry in the so called interest model, where scientific knowledge is explained by reference to social interests held by individual stakeholders or groups, but the social interests themselves are taken as

“real” and stable entities. Latour (2005) purports not to be a social constructivist, but “certainly a full blooded constructivist.” The first edition of Latour and Woolgar’s seminal work *Laboratory Life* had as its subtitle “the social construction of scientific facts,” which in the second edition was changed to merely “the construction of scientific facts.” According to Latour, an ideal subtitle would have read “the practical construction of scientific facts.” He has sought to clarify this position by arguing for a “constructivist realism.” The notion of construction must, according to Latour, be reconfigured altogether if science in action is to be understood. The trouble with the social constructivist view is that it builds on a false dualism – objects are taken to reside in nature, whereas subjects dwell only in society. Latour’s alternative actor network theory (ANT) is a materialist theory which puts “social” and “natural” on an equal footing – studying scientists’ practices should reconfigure what we traditionally think of as “social” just as much as it challenges our traditional views of “science” or “nature.” Latour does not want to talk about nature in the way it is commonly understood, but equally he does not want to talk of society. “Society” has been ruined by sociologists and social constructivists, as they have made sure that it has been purged of what Latour calls not objects, but “nonhumans.” If the social constructivist is to be believed, says Latour, only social relations exist in society. Furthermore, as nature is not awarded a reality status in its own right, but is simply a series of social inscriptions, the entire project becomes tautological. Latour thus disputes what he calls a dualist paradigm and seeks to avoid a subject–object distinction altogether. As “society” has become tainted, he prefers instead the notion of “collective.” This collective is extended to include nonhumans as well as humans. Latour’s society is constructed, but not socially constructed.

scientific knowledge, sociology of

Lena Eriksson

The sociology of scientific knowledge (SSK) is a field of sociology that started to take form in the early 1970s. Sociologists, historians, and philosophers who shared a common interest in

studying the social underpinnings of science took as a joint focus the very *content* of scientific knowledge. Previously, a division of labor had existed between philosophy and sociology. Philosophers' role was to analyze and define norms of science, discussing and drawing up demarcation criteria between science and non science. Sociologists were to study the structure of scientific institutions and provide explanations when science went wrong. Thus, the only type of knowledge qualifying for sociological attention was knowledge perceived to be somehow faulty. SSK, however, approached all scientific knowledge claims – regardless of whether they were held to be true or false – as material for sociological investigation (Bloor 1991 [1976]).

The intellectual roots of SSK are many and varied. Definite influences are philosophers and sociologists such as Weber, Durkheim, and Marx with their ideas about social construction, Wittgenstein's argument about the extension of rules, and Mannheim's writings about ideas as socially located. Later scholars, such as Robert Merton and Thomas Kuhn, are also recognized as predecessors to a field that started to take a more definite form with the publication of the Strong Program in the mid 1970s. The Strong Program was a programmatic statement from a transdisciplinary group of academics based at the University of Edinburgh, the so called Edinburgh School. It proposed that scientific knowledge should not be treated as a special case of knowledge, but instead be analyzed and explained in terms of its social origin and causes. A sociological account of the emergence of scientific knowledge should be causal, impartial, symmetrical, and reflexive.

Around the same time, a similar approach to the study of scientific knowledge was being developed elsewhere in Britain. EPOR, the Empirical Program of Relativism, formed the basis for the Bath School and was led by Harry Collins. As the name suggests, EPOR proposed that scientific knowledge production should be studied empirically and that a relativist approach should be taken to the object of study. It was, however, emphasized that the relativist stance should be deployed as a methodological tool and not necessarily reflect an ontological position. Sociological studies of science should demonstrate the “interpretive flexibility” of

knowledge claims, describe the institutional and network based mechanisms that would achieve “closure,” and, finally, connect such closure mechanisms to wider social and political structures.

One assumption underlying the SSK approach is summarized in the Duhem Quine hypothesis, which states that a theory always is underdetermined by data. No one theory can ever singularly explain a specific set of data; there are hypothetically an infinite number of theories that could be supported by the same data set. Therefore, a theory can never be tested on its own, and with reference to nature, e.g., the data themselves. Instead there tends to be a whole weave of interconnected assumptions being tried. The pertinent question for the sociology of scientific knowledge is that if the ories are underdetermined by data – that is, if “truth” cannot be determined by reference to nature – how is it that scientists still manage to gather around more or less stable theoretical constructs?

One commonly used model in SSK has been to analyze different positions in a given debate in terms of what wider interests they represent. Interests are invoked to explain how closure and consensus can be achieved in science despite the inherent potential for innumerable developments.

Interest explanations are often macrosocial and “interests” are, for example, the interests of the professional middle class in attaining or retaining moral and intellectual legitimacy for power and influence (Shapin 1975; Barnes & MacKenzie 1979), interests linked to investments in certain kinds of skills, models, or technologies (Fujimura 1988), or the interests of a professional group to claim or to maintain the cognitive authority over an issue or area (Gieryn & Figert 1986).

Stability can also be explained on a more microsocial level, as the result of negotiations between different scientists who achieve local agreement (Knorr Cetina 1981). Such a micro social approach represented a new trend in SSK, often known under the label of “laboratory studies.” In early SSK studies there had been a focus on scientific controversies. Typically, such analyses would encompass two or more competing “sides” of scientists arguing over a given theory or result. One of the perceived

methodological advantages of such an approach was that in times of contentious science, “normal” rules and practices in scientific every day life tend to be questioned and are thereby made visible to the analyst. The proponents of laboratory studies, conversely, wanted to study such “normal” scientific practice and the every day production of knowledge.

In 1979, Bruno Latour and Steve Woolgar published a landmark book called *Laboratory Life*, an ethnographic study of the Salk laboratory in San Diego. The authors took an anthropological approach to their objects of study and chose to “make the familiar strange,” thereby not taking anything for granted – so, for example, one of the drawings at the beginning of the book describes in detail the air conditioning system in the laboratory. Two years later, Karin Knorr Cetina published another important ethnographic study in which she described how successful laboratory work required a vast amount of “tinkering.” Like her French colleagues, Knorr Cetina noted the “messiness” of science in practice and how much of scientists’ time is spent making difficult objects behave properly so as to get a desired or acceptable outcome. Laboratory studies dispelled the popular belief that scientists go into the laboratory with a hypothesis to test, set up the experiment, test it, and then accept whichever result they get as the answer to their query. Instead, only certain kinds of outcomes will count as a “result” – most anomalies will fall under the category of experimental failings and only result in the scientist calibrating his or her equipment, or changing the parameters of the experiment.

During the 1980s, a new perspective gained ground among social scientists who studied science and technology. Actor network theory (ANT), developed by Michel Callon and Bruno Latour in Paris, and John Law in Britain, proposed that successful scientific work was a result of successful networks. ANT made no difference between science and technology, but instead used the term “technoscience.” To build a large, strong, and successful network, a given actor needs to enroll allies and translate their interests so that they aim toward the same, or a compatible, goal. In that respect, ANT networks and the activities of actors within them are similar to what one would traditionally think of as politicking. However, ANT networks

include not only human actors but also so called actants – non human objects or phenomena. Actants do not differ from their human counter parts in important ways – they, too, have interests and agency. Actants can be proteins, scallops, doorstops, or referendums, and any thing in between.

ANT thus took issue with the traditional SSK way of explaining the emergence and shape of natural science knowledge. Actor network theorists wanted to extend the concept of symmetry so as to include nature, a generalized or so called supersymmetry. There is, it was argued, an inherent asymmetry in the SSK approach because of its insistence on only allowing social explanations, thus imputing that the social world is more “real” than the natural world. Scientific knowledge is explained by reference to social interests, but the social interests themselves are taken as “real” and stable entities.

ANT also took a radically different approach to “interests.” With an actor network approach, interests are regarded as both cause and consequence. These co produced interests are both a resource that can be used when enrolling actors and a result of that enrollment activity. If one actor manages to translate the interests of others and thereby successfully align them, this transform and enroll strategy will increase the actor’s possibilities of creating and defining reality. This creates a self perpetuating movement, as the abilities to define and translate are co produced. An actor who successfully translates will gain ever more interpretive power. In Michel Callon’s famous study of the fishermen in St. Brieuc Bay, the question posed by the marine biologists – “How do scallops anchor?” – served to simultaneously translate the interests of the fishermen, the scientists, and the scallops, making it a question of survival for the scallops, of future livelihoods for the fishermen, and the pivotal question that needed to be answered – the obligatory passage point – in the scientists’ field of research (Callon 1986).

SSK critics of actor network theory have pointed to how agency appears to be unevenly distributed among actors and actants, in two different ways. Firstly, it appears that the initiative to network building always has to come from human actors. Secondly, it is the privilege of the analyst to decide which non human object will enjoy the role of “actant” – in Callon’s

St. Brieuc Bay study, only the scallops are assumed to have agency. The ships, test tubes, etc. are treated as “normal” objects.

Other critics have highlighted a focus on scientific “heroes” in ANT studies, a tendency to take rationality to be unproblematic and disconnected from cultural understandings of “rational,” and a failure to account for cultures or practices in their analyses. ANT was thus not unreservedly accepted into the realm of SSK, but provoked a long running debate on matters ontological, methodological, and epistemological – perhaps best summarized in the so called “chicken debate” between the Paris School, championed by Michel Callon and Bruno Latour, and the Bath School, represented by Harry Collins and Steve Yearley. Points of contention were, in particular, the role and status of actants and, thus, the role and status of “nature” versus “the social.”

Some 20 years after the emergence of the Strong Program, the field of SSK had grown in so many disparate directions that it no longer had its firm 1970s identity as one distinct perspective. Many other approaches, such as discourse analysis and symbolic interactionism, had gathered their own followings and developed discrete methodological tool kits and theoretical frameworks. In the present day, SSK has taken its place as one of many perspectives in the larger field of science studies.

Robert Merton's classic work in the 1950s posited, with the identification of the CUDOS norms of communism, universality, disinterestedness, and organized skepticism), but it is also a social activity in the respect that it plays an instrumental role in the construction of every day life.

Science is perhaps one of the most demarcated and professionalized human activities because it argues to have a different evidential basis for its knowledge claims. This evidential basis is largely the product of the scientific method that collects bits of information from the observation of a phenomenon in the form of induction, then operates in the deductive fashion by the creation of hypotheses to explain the phenomenon, the conducting of experiments in attempts to confirm and/or falsify the said hypotheses, and the building of a theory based on the results of experiments. Without elementary training and education in the fundamental aspects of science, the operations and products of the scientific community can become almost unintelligible to the outsider. This convolution is partly due to the increasing complexity of new specializations emergent within disciplines, coupled with the transformation of theories and the evolving nature of understanding. As a result, there is often a break, or chasm, between what the scientific community claims it is doing and what "the public" – those who find themselves outside of the scientific community – understand of the processes and products of science. Attempts at comprehending and explaining this break have become the work of sociologists, and other related fields of social science, who are interested in the public understanding of science (PUS).

Early quantitative surveys in the PUS found that there is "a tendency for better informed respondents to have a more positive general attitude towards science and scientists" (Durant et al. 1989). It was consequently argued that any public opposition to science and technology policies, decisions, and/or advancements was largely due to the fact that the public did not understand the arguments and reasoning behind the science in question. This view of the public understanding of science came to be known (largely by its critics) as the "deficit model" (Wynne 1991; Ziman 1991). Proponents of this deficit model of PUS feel that if the public were

scientific literacy and public understandings of science

Conor M. W. Douglas

Scientific literacy, and more so the public understanding of science, have recently become areas of study in their own right within the sociology of science and science and technology studies (STS). This emergence is partly due to the increased focus on science as an inherently social activity, but more specifically it is due to the mounting challenges that the scientific community has faced in dealing with this fact. Science is not only a social activity in that it is governed by a set of norms and values (as

simply better informed about science, then they would generally be more supportive of it. Glossing the work of Alan Gross, Sturgis and Allum (2004) put it like this: "in this formulation, it is the public that are assumed to be 'deficient' while science is 'sufficient' . . . lacking a proper understanding of the relevant facts, people fall back on mystical belief and irrational fears of the unknown."

Much focus in PUS has therefore been paid to one of the central problematics within the communication of information from scientists to the public: the role of the media. Based on the assumption that all information is mediated by the source from which it emanates, many of the investigators have taken up the media as a sight of examination and queried the effects that it may have on the public understanding of science. Some have argued that the media are responsible for misconstruing the message of the science and perpetuating misconceptions, while others have sought to explain the use of expert scientific testimony within the media.

Other central concerns in the PUS are the notion of "the public" as well as the notion of "science." Different people experience different aspects of science in very different ways, and thus studies that have made reference to "the public" as a homogeneous group, or ones which have tried to comprehend levels of understanding in "science" in general, have largely worked to cloud the picture of PUS. Consequently, much of the work carried out in the late twentieth and early twenty first centuries has focused on national contexts and case studies.

After considerable work done on the PUS in the West, more recent investigations have sought to open up the area of study to other countries and cultures that have traditionally been located outside of the dominant discourse. Such work includes a focus on PUS in ex Soviet countries, the contextualization of differences in PUS within European peripheral states, and international comparisons between PUS in oriental and western countries.

Not only have the more recent works been increasingly contextualized to specific national perspectives, but also much of the work done in PUS is case specific. Such investigations do not concentrate on the public understanding of science in general, but rather the public's understanding of a particular scientific advancement.

Examples include cases from around the world (e.g., East Asia, Oceania, Europe, and ex Soviet countries) and cut across technoscientific specializations (e.g., medical gene technology, genetically modified foods, nuclear sciences, and xenotransplantation). Traditional sociological categories such as gender, political affiliation, and socioeconomic status have also been areas of concentration within the PUS in an attempt to further contextualize "the public" within the PUS.

While the work carried out in the PUS is vast and diverse, some take for granted the assumption of the deficit model and continue to operate on the belief that a more informed public will necessarily lead to an increasing amount of support for scientific endeavors. Debate and controversy remain around this assumption of the deficit model, and contestation is not new to PUS, as it is an area of investigation that has altered and changed throughout the years.

In the early post war years in the US and the UK, the scientific community took very little interest in engaging the public with its processes, content, and (social) structure. Conversely, the popularization of science was high on the agenda for various social groups and institutions who worked in and around scientific areas, but as Lewenstein (1992) argues, this did not mean critical engagement with science as, "the term 'public understanding of science' became equated with 'public appreciation of the benefits that science provides to society.'" This era of science policy in 1940s and 1950s America is what Sarewitz (1996) has called the "myth of infinite benefit." Sarewitz's historical treatment shows how this myth posited that increasing state funding for scientific research would lead directly to increased public good and thus public support. Heavy state involvement in the promotion of science for the public good was championed by the likes of Vannevar Bush – the chief research adviser to President Roosevelt and one of the central figures in mobilizing science for use to the state and military, particularly during and after World War II. During this period new universities and research institutions were established, and existing ones witnessed an eruption in state funding for scientific activities. Dreams of flying cars and homes operated on nuclear energy filled the imaginations of the uncritical public until the 1960s.

In the US some attempts to gauge the concepts of scientific literacy (SL) and to distinguish them from PUS began around 1979 when social scientists working in these areas were commissioned to overhaul the *Science Indicators*. The goal of these social scientists was to

significantly expanded the scope of the surveys and begin to focus more attention on attitudes, knowledge measures, and expected participation measures for specific issues and controversies, such as nuclear power. Measures of policy preferences were expanded beyond spending preferences to specific regulatory areas. New measures concerning the individual's sources of scientific and technical information were added, allowing the formation of scales reflecting adult participation in informal science education activities. (Miller 1992)

In constructing this self professed "first measure of scientific literacy," Miller also created a construct to divide "the public" into subgroups:

individuals who report a high level of interest in science and technology policy issues and a sense of being very well informed about those issues (called the attentive public ...), those individuals who report a high level of interest in science and technology policy issues but who do not classify themselves as being very well informed about those issues (called the interested public), and those individuals who report that they are not very interested in science and technology policy issues (called the residual public). (Miller 1992)

In Britain, initiatives were taken up around the same time in an attempt to gauge the public's relationship with science. In 1985 the Bodmer report was published by the Royal Society, which called into question the degree of public support for science. As a response to the Bodmer report a body was established called the Committee for Public Understanding of Science (or COPUS) that was jointly founded by the Royal Society, the British Association, and the Royal Institution.

In both the US and the UK these reports, surveys, and indicators produced results that suggested that while there might be interest in science, knowledge about process and content was seriously lacking. In other words, findings suggested that the public was largely scientifically illiterate, which acted as the basis for the deficit model.

Predictably, the deficit model led to a major backlash from some of those within the constructivist school of STS and the social sciences more broadly who were interested in the PUS. The constructivists argued that it was shortsighted to assume that the public simply lacked an understanding of science, and it was rather that the public experienced science within their own specific social contexts and consequently sometimes chose to question the authority or validity of scientific claims (Wynne 1991). The debate boiled with such fervor and the research and interest in the area grew with such intensity that the journal *Public Understanding of Science* was created in 1992, dedicated solely to its namesake.

Constructivists and those supporters of the deficit model converge and diverge at interesting points within the PUS. For instance, both sides seem to agree that PUS entails an understanding of some of the formal content of science, the methods and processes of science, alongside a crucial third factor that differs for each party. For those of the deficit school this third factor is the "awareness of the impact of science and technology on individuals and society" (Miller 1992), whereas for constructivists like Wynne this third factor is the understanding of the "forms of institutional embedding, patronage and organizational control" of science (Wynne 1992). This third differing factor is paramount because in the constructivists' understanding the authority of science can legitimately be called into question.

According to constructivists like Wynne and Steven Yearley, scientific knowledge and expert claims are "always mediated by knowledge of the institutional arrangements under which expertise is authorized. Claims of expert knowledge are always contestable, depending on what one knows of the relevant institution" (Sturgis & Allum 2004, discussing Yearley). Consequently, the "scientific" advice of daily intake of "the four basic food groups" provided by the scientists from the American Food and Drug Association can be mediated by the knowledge that this institution has had a close working relationship with the National Dairy Council, and that years before the four basic food groups existed there were indeed twelve basic food groups in which dairy played a much smaller role (Haughton et al. 1987).

Constructivists assert that if a problem exists in the communication of science's content, processes, and structure, then the responsibility for the problem of PUS must swing both ways. This argument represents a flat rejection of the claim of the deficit model that the blame for the problem of PUS rests solely on the shoulders of the public (or even the media for that matter), and instead asserts that responsibility for the PUS must also be located within the scientific community.

Comprehending how the public integrates its knowledge about the "existing political culture of science and its social relations" (Wynne 1992) should not be taken for granted when analysts are attempting to gauge the public's understanding of science. Constructivists argue that it is not ignorance that leads the public to contest scientific claims and to be hesitant with support for the scientific community; rather, in some situations, scientific claims appear inconsistent, irrational, and/or contradictory to pre-existing knowledge. Some of the constructivists' reasons as to why a member of the public might choose to contest scientific knowledge are "when the reasoning behind the information is not made plain (often because of concerns about 'alarming' the public)"; "when it contradicts local experience (reassurance about safety when incidents have previously occurred)"; "when it is conveyed in unreasonable categorical terms (e.g., concerning the precise course of the envisaged emergency)"; and "when it seems to deny accepted social norms" (Wynne 1991).

For better or for worse, scientific literacy (SL) only enjoys a marginally more conceptual clarity than the PUS, which is perhaps counter intuitively due to its relatively lesser degree of treatment in the literature. Like most conceptual categories, including PUS, SL is a fluid and dynamic area of study, which "has changed somewhat over the years, moving from the ability to read and comprehend science related articles to its present emphasis on understanding and applying scientific principles to every day life" (Burns et al. 2003). Evidently, not only has the topic of SL changed over time, but it also has had to be broadened through time. As a consequence, nailing down a single contemporary definition for SL is also problematic. In accord with this position, academics such as B. S. P. Shen and later J. D. Miller (who has

been immersed in this area in one way or another for nearly three decades) have been forced to contextualize the concept of SL. For Shen (1975), SL was more clearly understood once broken into three subcategories: practical scientific literacy, civic scientific literacy, and cultural scientific literacy. Practical scientific literacy, he conceptualized, is the application of scientific concepts, skills, and ideas for the resolution of everyday and concrete problems. In this case practical scientific literacy might mean understanding the chemistry of how to balance the acidity/PH level in your garden, or pregnant parents being able to understand statistical significance and the concept of inheritance when the doctor explains an inheritable disease. Cultural scientific literacy, on the other hand, is the recognition of science as a major human achievement, and thus might entail a respectful understanding of the complexity of physical laws of gravity and engineering that landed humans on the moon.

Miller has taken pains to elaborate on the third of Shen's subcategories of scientific literacy: civic scientific literacy. Those who would be considered to exhibit civic scientific literacy would, for instance, be able to engage critically with the science content of a daily newspaper. This critical engagement would be done for constructive purposes so that the individual could more readily be involved in the processes by which science emerges within a democratic society. A good example of civic scientific literacy might be those people who constructively and open mindedly participated in the public debate over the integration of genetically modified foods in the UK in 2003. For Miller, civic scientific literacy involved not only the content dimension (i.e., being able to read and understand the science section of the newspaper or magazine), but also having an understanding of the process of scientific inquiry (i.e., construction of theory, hypothesis testing, and the experimental method), as well as some degree of understanding of the impact of science and technology on individuals and society (e.g., carbon emissions from automobiles get trapped within our atmosphere and lead to a greenhouse effect that warms our planet).

At the turn of the millennium the British House of Lords, a body firmly rooted outside of academic discourses, rather vaguely defined

the public understanding of science as “the shorthand term for all forms of outreach (in the UK) by the scientific community, or others on their behalf (e.g., science writers, museums, event organizers), to the public at large aimed at improving understanding” (Burns et al. 2003: 187). In the vast expanses of literature on the topic of PUS within academic discourses there exists no single clear cut definition. As one of the central commentators on the topic stated: “PUS is an ill defined area involving several different disciplinary perspectives” (Wynne 1995), including sociology, political science, science and technology studies, communication studies, and psychology, to name a few. SL does not present any clearer picture, as similar qualities have been used in its and PUS’s definitions, which include understanding science content, understanding methods of inquiry (or process), and understanding science as a social enterprise. Clearly, there is still much conceptual confusion around and between these terms. With that in mind, contestations over formless terms such as “the public” and “science,” and constructivist debate about the authority of science, have opened up the discourse within the PUS and moved it away from the rather vague definition offered by the British House of Lords. As science and technology continue to grow in terms of their pervasiveness in all aspects of society, PUS will surely continue to be a site of important academic discussion.

scientific models and simulations

Mikaela Sundberg

The term model is used in multiple ways in science and there are several different kinds of models. The most basic scientific models are material and conceptual analogues. They are copies that stand in for more opaque systems. Cloud chambers and cell cultures are examples of material models, whereas conceptual models are more abstract analogies that seek to render theories more comprehensible. Mathematical models are typically applications, approximations, or specifications of theories and principles that cannot be applied in their original form.

Computer simulations tend to be more obvious analogues than models, aptly characterized as virtual copies of systems. Simulations employ a generative mechanism to imitate the dynamic behavior of the underlying process that the simulations aim to represent. Simulation is an ambiguous term, but in all cases of scientific simulations they are based on some form of model. However, simulation models can be divided into two overall types, both of which tend to be used for representations of complex dynamics. The first type is based on mathematical models, which aim to represent established theoretical statements or physical laws. Simulations in physically based sciences usually exemplify this type of simulation. The second type of simulation model is based on simpler models, which consist of a few assumptions about leading mechanisms. This is generally the case in simulations of social phenomena using so called agent based models.

Although models and simulations are increasingly used in science, studies of them remain rare compared to the extensive studies of experiments that have taken place in the sociology of science since the 1970s. Models and simulations that represent the application of theoretical knowledge have also received less attention in the philosophy of science, where the traditional line of inquiry has mostly been in the theoretical domains.

From the perspective of the philosophy of science, models and simulations tend to be discussed in relation to theories. In the classic contribution *Models and Analogies in Science* (1966), Mary Hesse sees models as heuristically essential to the development and extension of theories, and also essential to the explanatory power of theories. However, the epistemological characteristics of models and simulations are less clear than those of theories. Models do not have the same epistemic tradition as theorizing and do not have transparent object domains. This is perhaps most significant in the case of simulations and it has thus been argued that simulation has its own epistemology (Winsberg 1999). In constructing simulation models, the theoretical structures are transformed into specific knowledge of systems and further into computational models that are implemented in a computer in the form of an algorithm. This is what makes simulations produce data sets. Because

simulation modeling produces these types of results, a standard for deciding whether the results are reliable is required. For this reason, results of simulations are often compared to observations. In this respect modeling and simulations share similar relations to experimentation as does theory. However, models and simulations are often seen in more pragmatic terms and therefore evaluated in relation to the purpose of modeling. This approach differs clearly from the epistemological view on theories, where theories are judged according to their being true or false.

A different way to approach modeling, not limited to epistemic questions such as the truth of models and how they should be verified, is to consider the instrumentality and autonomy of models. As partly dependent on theories and experiment, and partly independent, models can serve as bridges between theory and the world. This is suggested by Mary Morgan and Margaret Morrison in their influential book *Models as Mediators* (1999), where models are conceptualized as autonomous mediators. However, to only see models and simulations in the space between theories and the world assumes that theory and the world are stable entities, at the same time as it directs the attention toward a philosophical focus on what a model essentially is. From a sociological perspective, it is more appropriate to address the character of models in relation to the role that models and simulations play in scientific practice.

The characterization of the role of models and simulation models has often been based on the idea of models and simulation models as tools or objects for knowledge. The use of models and simulations as tools is most evident in applied science, where models are used to predict the development of various dynamic processes. Thus, in those cases where empirical data exist, the correspondence of outcomes with data becomes an important indicator of the performance of the model or simulation.

Because of their character as analogues, models and simulations can also themselves be studied the same way as natural systems are studied in empirical research. By acting as objects of knowledge in their own right, simulation models are explored to answer questions about how and why certain processes develop. In this situation, both the inner theoretical structure of the model

and how well its results correspond to data are important to the evaluation of the performance of the simulation model itself.

Some models and simulation models are constructed and used for only one of the above mentioned purposes. However, in principle, a particular simulation model can serve multiple purposes, depending on its role in practice and which questions it is being asked to address. Consequently, some models and simulations may serve as tools like technical artifacts or objects of knowledge depending on the setting where they are used.

Another line of research focuses on what people who model and simulate do, and how they work. While simulations can be described as both experimenting and theorizing depending on what aspects researchers talk about, the use of simulations as “virtual laboratories” in fact makes working with models very similar to experimenting (Dowling 1999). Models tend to integrate a broad range of ingredients such as, for example, metaphors, theoretical notions, and mathematical concepts and, not least from this point of view, the construction of models requires much experience and hard work (cf. Boumans 1999). In simulation modeling, questions related to the role of researchers are fundamental because the construction of simulation models and the interpretation of simulation results primarily depend on the researchers, their research areas, and their experience (Becker et al. 2005). In short, the role of human agency needs to be taken into account in developing the sociological understanding of how models and simulation models are constructed and used.

What appears as a particularly useful and important way to approach the practice of modeling and simulation is to acknowledge the materiality of modeling and simulations. Models are objects that have their own construction and ways of functioning that constrain interpretation and use (Knuuttila & Voutilainen 2003). What makes the materiality of simulation modeling even more evident is the transformation of a theoretical model into a computer program, and this intertwining is indeed a fundamental aspect to attend to in understanding simulation modeling practice (cf. Sundberg 2005).

However, further exploration is needed in terms of how the practices of modeling and

simulating can be conceived of in different ways rather than only in relation to theorizing and/or experimenting. In addition, an important question for future research concerns whether the concepts, metaphors, and methodologies developed on the basis of studies of experiments and experimental work can be successfully applied to and used in studies of modeling and simulations. For example, the participant observation approach, which has been the basis of many so called laboratory studies, is more difficult when studying modelers. Compared to the traditional work in a “wet laboratory,” it is more difficult for an observer to follow activities like writing equations or programming computers. To conclude, there is a growing but limited interest in, and knowledge of, the practices involved in modeling and simulations, but a more rigorous sociological approach remains to be developed.

scientific networks and invisible colleges

J. I. (Hans) Bakker

The notion that scientists and other scholars constitute a kind of community of scholars has frequently been asserted and discussed (Godfrey Smith 2003). The “invisible college” of natural philosophers is a seventeenth century idea (Price 1963). The phrasing is reminiscent of Adam Smith’s later “invisible hand,” except that the scientists are real persons and it is only the “colleges” that are sometimes invisible. It stems from Robert Boyle’s allusion to the importance to the founding of the Royal Society of Freemasons. An early driving force behind the society was Sir Robert Moray, a Mason who was not himself a natural philosopher (Lomas 2002). Jonathan Swift satirizes the Royal Society as “Laputa” in *Gulliver’s Travels* (Toulmin 1961), but the general consensus is that frequent communication among specialists is one of the hallmarks of modern science. A “scientometrics” approach makes it clear that the exponential growth in scientific fields and discoveries has resulted in various kinds of networks, including “networks of scientific papers” (Price 1986). It was only gradually over the course of the seventeenth century that the brief scientific paper replaced the book and Newton might well not have written his *Principia Mathematica* had there not been controversy about his papers on optics; “afterward he did not relish publication until it could take the [then] proper form of a finished book, treating the subject from beginning to end and meeting all conceivable objections and side arguments” (Price 1963: 64).

Of course, there have also been very visible ties among natural philosophers and scientists. Merton’s (1968) study of the origins of science stresses the close personal relationships among many of the members of the Royal Society in England. Whether they were aesthetically inclined Puritans or perhaps more hedonistic in their outlook (Feuer 1963), they were in any case part of the same collectivity. Other scientists across Europe corresponded with the Royal Society. When scholars sympathetic to logical positivism met at Harvard in 1939 they

articulated a concept of science as members of an illustrious community, but they were also individuals (Wilson 1999). Recent interest in network theory has prompted the idea of a scientific network.

The sociological study of science by early pioneers like Price (1963) and Merton (1968) has given way to science and technology in society (STS), a subdisciplinary field devoted to empirical research on the actual way in which research is carried out (Godfrey Smith 2003). Latour and Woolgar (1979) have studied the social construction of empirical findings in lab work. Sociological study of Nobel Prize winners in science indicates that those who study with Nobel Prize winners are themselves the most likely recipients of the Nobel Prize, presumably because they have first hand information about the cutting edge topics and techniques.

In hermeneutics the idea of a “hermeneutic circle” or “spiral” in science (Føllesdal 1994) is associated with “interaction between agents” and close ties among theorists and empirical researchers. In semiotics the notion of an interpretive community or network has been postulated as an aspect of Peirce’s (1998) more abstract notion of a recursive “interpretant.” Collins (1998) has stressed the general importance of networks. His theory holds that there is a “law of small numbers” and that the half a dozen or so major “philosophers” in any particular time and place are very likely to know one another. Each thinker searches for a niche. Full comprehension of the theory requires an understanding of the network of ties that cross over several generations.

Scientific networks are not just limited to physical or natural sciences. In classical and contemporary mathematics, statistics, arts, humanities, and social sciences the importance of such affiliations is sometimes made transparent through commemorative volumes. The *Festschrift* for Herbert Simon (Augier & March 2004) is a good example. The list of contributors reads like a “who’s who” of noteworthy thinkers on topics like bounded rationality (Arrow 2004) and “Hawkins Simon conditions” (Samuelson 2004). The history of economics is replete with cross fertilization within scientific networks, including the German Historical School that influenced Max Weber (Pearson 2002).

The analysis of science from the standpoint of its internal organizational structure in terms of

networks of affiliation and communication has not gone unchallenged. Steinmetz (2005) points out that emphasizing the idea of the scientific community as a kind of cultural system can lead to a failure to notice outside influences and forces. Moreover, the “communal” qualities of a network are not always a matter of egalitarian values; they often involve gate keeping and personality conflicts (Abbott 1999). There is a sense in which all those who can participate in a “culture” larger than that of a gathering and hunting community are part of a largely invisible network (Robbins 2005). At the same time, the existence of invisible colleges (of at most 100 or so members) also brings problems of cooperation within and among such communities (Price 1986). The question of “incommensurability” among invisible colleges holding different paradigmatic positions, even within recognized subdisciplinary fields, continues to interest a broad interdisciplinary group of scholars (Kuhn 2000). Once scientific theories have become widely accepted by members of a network they are then no longer as directly linked to a specific subset of all scientists and become the common property of “science” in general, often influencing individuals and groups who are working on quite different sets of empirical problems.

scientific norms/ counternorms

Stephen Turner

The classic sociological formulation of the “norms of science” was given by Robert K. Merton, in an article originally published as “A Note on Science and Democracy” (1942) and reprinted as “Science and Democratic Social Structure” in his *Social Theory and Social Structure* (1968 [1949, 1957]) and as “The Normative Structure of Science” in *The Sociology of Science* (1973). The formulation is sometimes known by its initials, CUDOS, which stands for the four norms: communism, universalism, disinterestedness, and organized skepticism. Merton’s representation of the normative character of science has proved to be one of the most enduring of all sociological analyses. It has been discussed at length by both critics, who proposed the concept of counternorms, and sympathizers, and in the late 1960s and early 1970s became emblematic of the “Mertonian” approach to the social study of science. Nor has it remained static. “Replication” is sometimes called the fifth norm. John Ziman suggested that “originality” be added as a norm, and in many recent explanations of the acronym CUDOS the O is used for originality.

THE ORIGINS OF THE NORMS

Merton wrote two papers on the norms of science, both concerned with a political problem: the autonomy of science. The first was “Science and the Social Order” (1938, in Merton 1973). This paper was presented during a period of intense political activity, a response to the political crisis over Nazi science, and in particular to the publication in the journal *Nature* of a translation of an article by J. Stark, originally published in Germany in a Nazi journal, that attacked “Jewish” science. This translation caused a large outcry at a time when scientists in Britain and the United States were largely supportive of peace in Europe, but recognized the threat of Nazism and were coming to recognize the threat that science in Germany would be forced to conform to Nazi

ideology. At the time of Merton’s first publication on this topic, there was a movement among scientists to respond to the Nazi threat to science politically. A series of resolutions and petitions was circulated, and scientists became politically active in defense of the autonomy of science, that is, the freedom of science from political control and direction (Kuznick 1987). The norms repeat ideas expressed in the petitions. The original title of the paper in which the CUDOS model appears, “Notes on Science and Democracy,” written during the war, reflected Merton’s anxiety over conflicts that might arise between science and religion that might be given political expression in democracies.

Merton’s paper was preceded in the sociological tradition by another deeply influential work, a speech by Max Weber entitled “Science as a Vocation.” Weber asks a question on behalf of the students who were the audience for his speech: how does one know that one has a calling for science? The answer is given in terms of the personal qualities that enable one to properly fulfill the role of the scientist (or scholar). Much of the essay is devoted to explaining the limitations of science, and that science cannot provide a worldview. Weber does not give a simple list of personal qualities but speaks of “the plain duty of intellectual integrity” (1946 [1921]: 155, cf. 146, 156), denounces the idea of “personality” in science (p. 137), and says that “the primary task of a useful teacher is to teach his students to recognize ‘inconvenient facts’” (p. 147). Weber’s comments may be compared to the list of virtues in the first of Merton’s papers, “Science and the Social Order.” Here, Merton’s list of the special virtues of scientists was “intellectual honesty, integrity, organized skepticism, disinterestedness, impersonality” (1973: 259).

Merton’s point about these virtues, however, was that they formed an “ethos.” This fact was relevant to the autonomy of science. Merton characterized “a liberal society” as one in which “integration derives primarily from the body of cultural norms toward which human activity is oriented” in contrast to a dictatorial structure, where integration is produced through formal organization and centralized social control (1973: 265). Science, because it was governed by an ethos, was already akin to “a liberal

society” and thus in effect already autonomous or self governed. The notion of *ethos* reappears in the more famous 1942 paper, but the list of virtues changes and the emphasis shifts to the norms of science understood primarily as external constraints, or, as Merton puts it, an “affectively toned complex of values and norms that is held to be binding on the man of science” (1973: 268–9), which the scientist is at least partly socialized into.

THE FOUR NORMS

The list of norms begins with universalism, which Merton explains in terms of “the canon that truth claims, whatever their sources, are to be subjected to preestablished impersonal criteria” (1973: 270). Acceptance of claims is not to be based on personal or social attributes of the claim maker, such as race, as the Nazis were encouraged to do by Stark (1938). Universalism is thus rooted in the impersonal character of science. Universalism is potentially a source of conflict with the larger society, particularly when the ethnocentrism of the larger society comes into conflict with science. But there are also cases in which the norm is breached by scientists, for example in wartime, when nationalism leads scientists to denounce the science of other nations for patriotic reasons, as occurred in World War I. Universalism also means that science should be open to talent, whatever the ethnic or status properties of the talented are. In this respect the values of science are similar to, and supported by, the values of democracy.

The second is communism. Merton says that the “substantive findings of science are a product of social collaboration and are assigned to the community. They constitute a common heritage in which the equity of the individual producer is severely limited” (1973: 273). The “property rights” of the scientist to his ideas are limited to that of recognition and esteem. Scientists compete for recognition and are consequently greatly concerned with priority claims about discoveries, a concern which reflects the importance of originality in science. But “the products of competition are communized” (1973: 274). Merton’s evidence for this norm includes the mild disapproval given to scientists

who fail to communicate their discoveries, and by the fact that scientists acknowledge “standing on the shoulders of giants.”

It is sometimes claimed that this norm has nothing to do with communism in the political sense, but this is not true. Merton was influenced by J. D. Bernal, a British scientist and communist who wrote an important book on the social character of science, in which he said that science was already a kind of communism, because scientists “have learned consciously to subordinate themselves to a common purpose without losing the individuality of their achievements,” that “each one knows that his work depends on that of his predecessors and colleagues, and that it can only reach its fruition through the work of his successors,” and because scientists understand the necessity of collaboration which they accept without the blind following of leaders (1939: 415–16). Bernal, like many of his contemporaries on the left, wrote about the “frustration of science,” the idea that capitalism was an obstacle to the application of science to human welfare. Merton alludes to these writings with the comment that the “communism of the scientific ethos is incompatible with the definition of technology as ‘private property’ in a capitalistic economy” (1973: 275), and notes that one response to the conflict by scientists has been to advocate socialism. His discussion of this and other conflicts produced by this norm points in the direction of his later discussions of the conflicting feelings or ambivalence which norms produce.

“Disinterestedness” is a feature of the professions in general that was important to Talcott Parsons, who related it to the dealings of professionals and clients. Merton observes that scientists do not have “clients” in this way, but do have the problem of fraud and the problem of pseudosciences. Merton observes that fraud is rare in science, and explains this, in a remarkable passage, by saying that “the activities of scientists are subject to rigorous policing, to a degree perhaps unparalleled in any other field of activity” as a result of the public and testable character of science (1973: 276). Socialized sentiment combines with this “rigorous policing” to make this norm especially stable.

Organized skepticism requires the “temporary suspension of judgment and the detached scrutiny of beliefs in terms of empirical and

logical criteria" (1973: 277). This is a source of potential friction with religion, and occurs especially when science extends into new topics previously covered by other institutions.

THE COUNTERNORMS AND THE CRITICS

The literature on the norms expanded in the 1950s, with various clarifications and additions, many of which related to the central fact of the passionate, personal commitment of scientists, one of the features of Weber's discussion of science that Merton had omitted. It loomed larger as a result of such influential works as Michael Polanyi's *Personal Knowledge* (1958). Bernard Barber (1952) had suggested that "emotional neutrality" was a separate norm and an important brake on the passions. But Merton and Barber moved away from this image of science. Merton noted that priority disputes were an example of the affective involvement of scientists with their own ideas, and Barber observed that the problem of resistance of scientists to discovery was intrinsic to science. This new view fit better with a functionalist account of science in which both the norms and the passions they contained were functional for science. But it also fit with Merton's developing sense that norms typically involved conflicting feelings or "ambivalence."

The idea that the norms had counternorms was developed by Ian Mitroff, whose study of elite moon scientists showed that tenacity in support of one's own idea was an accepted part of science and a condition for its progress. On the basis of this research, Mitroff proposed counternorms for each norm. The counternorm to organized skepticism, for example, was "organized dogmatism," which he formulated in this way: "The scientist must believe in his own findings with utter conviction while doubting those of others with all his worth" (Mitroff 1974: 592). Michael Mulkay expanded on this discussion, and turned it in a radically different direction. He argued that there were no strongly institutionalized norms of the Mertonian sort in science, and treated the Mertonian norms as an "ideology," asking what purposes this ideology served, suggesting that we understand science "not just as a community with special

professional concerns and with normative components appropriate to these concerns, but also as an interest group with a domineering elite and a justificatory ideology" (1976: 654).

This line of argument drove the discussion toward the question of whether the norms were applicable to the new situation of science, which was understood to be more commercialized and "private." The norms came to appear to some critics as the idealization of a previous form of science that systematically distorted the present understanding of science. New models of transdisciplinary research with specific practical goals also seemed to fit poorly with the norms, which now could be seen to relate primarily to competition for prestige in a disciplinary setting.

scientific productivity

SooHo Lee

Scientific productivity refers to the productivity of scientists in their research performance. In other words, the term concerns how much output scientists produce within a certain time period, or compared to the inputs that are utilized for the research. The major outputs from research are publications, patents, inventions, and product developments. However, especially in research institutions, productivity more directly refers to publication or publishing productivity since most research results are reported as forms of publication. Therefore, being “more or less productive” simply indicates that a scientist produces more or fewer publications than do others. Scholarly journal articles, books, conference papers, and monographs are included in publication counts. Among the publication forms, peer reviewed journal articles are most frequently used as a productivity measure.

Three different methods are used for counting publications: normal count (also called *standard* count), fractional count (also called *adjusted* count), and first author count (also called *straight* count). In normal count, each of the co authors is given full credit for the multi-authored publications regardless of how much each contributed to the publications. This counting method is most often used due to the convenience of data collection. However, inflating the number of publications is a major disadvantage. In contrast, in a fractional count, each publication is counted as one divided by the number of co authors. The main purpose of using fractional count is to remove an overestimation of normal count and estimate the individual contribution to a publication. But the process of fractional counting is very tedious since all the co authors are not always identified. First author count is another way to remove the

inflated credit by normal count and to determine the individual's major contribution to publications. This method only recognizes publications in which the individual has contributed as the main author.

While publication counts deal with the quantity of research performance, citation counts, on the other hand, address the quality of publications. It is often said that the more qualified the publication, the greater the number of citations. However, citation count is less frequently used for measuring productivity because it is not a direct output but shows the impact or influence of publications.

Since scientific productivity is of interest not only to academics but also for public policy in more recent times, what determines scientific productivity has been extensively studied in many disciplines. The literature identifies many determinants including psychological characteristics, demographic characteristics, environmental characteristics, cumulative advantages, and reinforcement. Psychological characteristics indicate that motivation, inner compulsion, capacity to work hard, cognitive and perceptual style, and work habits all affect the productivity of scientists significantly. It is almost always true that productive scientists have strong motivation and orientation for research.

Among the demographic characteristics, age is an important predictor for productivity. Early studies found that a productivity peak occurs in scientists' late thirties and early forties and thereafter declines steadily. By contrast, some recent studies identify another productivity peak around age 50. Although there are many different life cycle models of productivity, they should be interpreted appropriately in the context of a specific discipline. For example, the productivity cycle in physics is different from that in sociology. In most cases, scientists become less productive as they age, especially after 50. It is also often pointed out that the age effect is attributed to age and not to the possibility that older scientists have different attributes, values, or access to resources than younger members. Like age, gender is also an important variable affecting productivity difference. Early studies commonly pointed out that women tend to have somewhat lower publication rates than men. But more recent studies do not agree with this proposition, rather believing

that sex differences in publication productivity are negligible, with the exception of women with young children. In a similar vein, one recent study found that sex differences in the number of publications increase during the first decade of the career, but are reversed later in the career.

Environmental and organizational factors also play a significant role in determining scientific productivity. For example, prestigious institutions tend to have more research resources and many “star” scientists in more specific research fields. The advantages are likely to help their scientists to collaborate more easily with experts inside the organization and also to attract more joint research and research grants from outsiders. Especially when research projects require more expensive equipment and infrastructure (not only physical but also human capital), the institutional capacity and external supports significantly affect research performance.

Cumulative advantage and reinforcement theories explain the difference of scientific productivity among scientists by using a concept of “feedback” processes. They propose that prior exceptional performance is conducive to later performance. The ideas are largely based on Merton’s so called “Matthew effect” in science: once scientists receive recognition from their colleagues, they accrue additional advantages as they progress through their careers. The advantages typically begin with doctoral training in a prestigious department. The training, in turn, leads to a position in a major research university amply supplied with adequate resources for research. The initial appointment has a major impact on later productivity, and in turn, the prestige of second department and subsequent productivity. Cumulative advantage deals with resources and prestige of institutions, whereas reinforcement addresses the feedback one receives from successful publication of works, works being cited, and formal and informal praise from colleagues. Reinforcement theory typically explains that when scientists publish, the recognition they receive for the contribution stimulates further publication.

Although publication productivity measures scientists’ research performance efficiently, it still loses many aspects of scientists’ research performance. In particular, the outputs of teaching and mentoring as important research activities are often neglected in measuring scientific

productivity. So a better measurement needs to be developed to include broader aspects of scientific activity.

scientific racism

Jessica Blatt

Science has a long and fraught history of entanglement with the social myth of biological race. The modern sciences of biology and physical anthropology were founded on the conviction that racial difference was real, fundamental, and key to understanding the proper relationships between human groups. Advances in these very sciences, however, have shown that race is in no way an objective, natural category. While there are certainly biological differences among human populations, these differences are both relatively trivial and impossible to

map onto conventional racial divides. Genetic research, similarly, has yielded no statistically significant patterns of variation by race (Marks 2002). However, this is not a simple story of scientific progress, in which bad ideas are systematically displaced by better ones. The rise and (incomplete) retreat of scientific racism is an eminently political story.

In general terms, scientific racism is characterized by two central fallacies: a classificatory fallacy (race formalism) and a fallacy of reductionism and determinism in which complex phenomena such as intelligence or the capacity for self restraint are reified and explained as resulting straightforwardly from apparently simple causes, such as genes. Race formalism is the idea that humanity can be subdivided into groups that form "real," objective, natural units, sharing significant biological, and usually cultural and behavioral, characteristics. Originating in the rage for classification in Enlightenment science and philosophy, this idea reached a peak of scientific respectability in the decades around the turn of the twentieth century.

In *Systema Naturae* (1740), Carolus Linnaeus, the father of zoological classification, proposed four subdivisions of humankind: Americanus, Europaeus, Asiaticus, and Afer, or African. In a 1795 revision of his seminal work *On the Natural Variety of Mankind*, the German naturalist Johann Friedrich Blumenbach elaborated on this scheme, identifying five "races," the first and most perfect being, in his coinage, "Caucasian." Along with his invention of the Caucasian race, Blumenbach is remembered for introducing an explicit hierarchy into the Linnaean scheme. Nevertheless, Blumenbach recognized clearly that boundaries between races are artificial, and in fact his classification reflected the widely shared Enlightenment belief in the essential unity of humankind, with any variations explained in environmental terms.

As debates over slavery heightened during the nineteenth century, however, this view of humanity's natural history was rejected by many who argued that human races were in fact unrelated, hierarchically ranked species. Known as polygenesis or "multiple creations," this theory reached its height of popularity around the time of the American Civil War. Polygenetic theories spurred the collection of reams of physical data, particularly relating to skull size and form,

meant to define race differences. (This data and its uses have been effectively critiqued by Gould 1996.)

After the publication of Charles Darwin's *Origin of Species* (1859), polygenesis was largely displaced in scientific discourse by notions of races as groups sharing a common origin but occupying distinct rungs of an evolutionary ladder (though many scientists persisted in labeling these groups as separate species). The late decades of the nineteenth century saw intense interest both in using evolutionary frameworks to understand social reality and in racial classification specifically. (This was particularly so in the United States following the abandonment of Reconstruction era attempts to establish civic equality for freed slaves.) These trends were most prominently expressed in attempts to explain social hierarchy in terms of relative evolutionary fitness (social Darwinism, associated with Herbert Spencer), to measure and quantify racial difference (ethnology), and to reconstruct the evolutionary history of Europeans through study of living groups of "savages" (an enterprise known as the "comparative method").

Efforts to systematize racial classification, however, proved elusive. The 1911 *Report of the Dillingham Commission on Immigration to the US Senate* illustrates this difficulty. The report's "Dictionary of Races or Peoples" (even the title is indecisive) follows a racial classification recognizing 5 races, 6 "stocks," and 64 "peoples." At the same time, it acknowledges five distinct, competing schemes, proposing as few as 3 and as many as 29 races. However, the difficulty of imposing racial boundaries on human diversity, while it frustrated many biologists and physical anthropologists, did not by itself lead many to abandon the attempt. This required the confluence of external, political events with the efforts of scientific activists.

Throughout the nineteenth century, the physical characteristics of race were generally seen to be associated with behavioral characteristics as well, almost universally in ways that favored Europeans over other races, with "Negroes" or "Africans" at the bottom. The dissemination, just after the turn of the twentieth century, of Gregor Mendel's theories of heredity lent support to the idea that these behavioral traits were fixed, hereditary, and determined by what eventually came to be called "genes." These

reductionist and determinist notions fueled the American eugenics movement, which defended the regime of racial segregation and advocated (with considerable success) anti miscegenation laws, immigration restriction, and compulsory sterilization of the “unfit,” all in the name of racial purity and “betterment.” They were also linked to a series of attempts to quantify (and map the racial distribution of) human potential, as with the development of IQ and other mental tests. The emerging discipline of industrial relations also used racial classifications, attempting to determine which groups were best suited to particular kinds of work. To be sure, such ideas were not confined to the United States. Arguments about the biologically determined inferiority of non white groups figured in justifications of European colonialism broadly and helped to legitimize the regime of segregation that would come to be known as apartheid in South Africa, for instance.

Eugenics would see its most complete and horrific expression in Germany, where “race hygiene,” as the movement was known there, helped to justify the Holocaust. Nonetheless, American scientific racism was particularly virulent and influential. (The first compulsory sterilization law promulgated by the Nazi regime was in fact copied from a model drafted by American eugenicist Harry Laughlin.)

Widespread revulsion provoked by revelations of Nazi atrocities helped fuel an international reaction against scientific racism in the post World War II era. The United Nations Education, Scientific, and Cultural Organization (UNESCO) issued a series of “statements on race” signed by leading social and natural scientists beginning in 1950 (Montagu 1972). These statements, while not entirely unambiguous, were generally understood as a collective statement by the scientific community declaring racial doctrines to be harmful ideology without basis in natural science. They were the long delayed fruit of lobbying efforts by activist, anti racist scientists, led to a significant degree by anthropologist Franz Boas, to combat scientific racism (Barkan 1992). These efforts largely discredited scientific racism within the mainstream science and larger academic communities. More broadly, over the ensuing decades the US civil rights revolution and decolonization in Asia and Africa worked to delegitimize

popular racism to an extent, decreasing the appeal of scientific racism in and outside the academy.

Nevertheless, scientific racism is far from gone. Even in the immediate aftermath of the first UNESCO statements, white supremacists continued to try to turn racist theories to political advantage, for example in a series of lawsuits aimed at overturning *Brown v. Board of Education* (1954), the landmark Supreme Court decision outlawing racial segregation in American schools. More recently, a number of attempts to explain racial stratification in biological terms have surfaced since the 1980s, probably the best known of which is Richard Herrnstein and Charles Murray’s *The Bell Curve* (1994). While widely criticized and largely discredited within mainstream science, scientific racism continues to tap into widespread folk ideas about racial difference and hierarchy.

scientific revolution

J. I. (Hans) Bakker

To summarize the scientific revolution in one phrase: it was the time when a new way of studying the natural, physical world became widely accepted by a small "community of scholars," although not necessarily by nonscientists. But the specific status of that "new way" is hotly disputed and the precise historical steps involved in that development are extremely complex. Standard histories are those by Dampier (1966) and Cohen (2001). Cohen stresses the stages involved from initial creative insight to dissemination (orally or in letters, later on in print) and then widespread acceptance. For example, Descartes' theory of inertia of 1633 was held back when the Inquisition condemned Galileo's theological interpretations and Descartes decided it was not a good time to publish. In the seventeenth century there was a significant qualitative transformation in the approach to the study of natural philosophy and that major change is now often called the "scientific revolution," but it is clear that small scale "revolutions" took place before and have happened since. It was at that time that the transition from undifferentiated "astronomy/astrology" and "alchemy/chemistry" first really got under way. Moreover, great advances were made in mathematics. The story of the rise of modern science begins even earlier, however, with the Arab contacts with Greek science, and modern science eventually led to Enlightenment philosophy (Helleman & Bunch 1988: 58–188). Different natural philosophies changed at different rates and in different ways. For example, empirical and theoretical progress in astronomy and physics was different from progress in other physical sciences like chemistry (Goodman & Russell 1991: 387–414). However, it was between circa 1500 and 1800 that the distinction between true science and proto science or pseudo science (Shermer 2001: 22–65) became somewhat clearer. Many thinkers have seen the essence of the intellectual revolution as a leap beyond the tradition inherited from Aristotelianism and rationalism. But the notion that simple inductive empiricism, often identified with Francis Bacon's New "Organon" (*Novum*

organum) of 1620, is the basis of the scientific method has been rejected. It should be remembered that the introduction of Aristotle's *Organon* concerning "categories" and "interpretation," and his physics, astronomy, and biology transferred into Roman Catholic theology by Thomas Aquinas, was considered a radical step and indeed did open a window to the study of the actual order of nature and the universe (Funkenstein 1986). The idea of the importance of nuances of general theoretical assumptions concerning ontology and epistemology has been widely shared ever since the early 1960s, when Kuhn's (1970) history of paradigmatic changes in physical science became widely accepted. Indeed, the social sciences now also regularly use Kuhn's general theory of an oscillation between "normal science" and "paradigmatic revolutions." The link between Kuhn's theories and earlier views concerning a dialectic of reason – views primarily associated with Hegel's critique of Cartesian dualism (Russon 1991) – should be noted. However, the seventeenth century paradigmatic revolution associated with Descartes, Galileo, Copernicus, Kepler, von Helmont, and many others was extremely important, since it laid the foundation for what was considered to be true science for the next four centuries. Newton's laws of gravitational attraction, motion, and force (i.e., inverse square law) in the *Principia Mathematica* (1687 manuscript) led to British Newtonianism, which was widely exported throughout Europe (e.g., the Low Countries), but Cartesianism in France was a rival for many years (Russell 1991). In the eighteenth century botany and zoology became more systematic with the use of binomial nomenclature, although Linnaeus's theories of nature and of society were deeply flawed (Koerner 1999). It was only at the beginning of the twentieth century that a series of new ideas constituting a general change in worldviews made a radical shift in scientific thinking possible. Einstein's theory of relativity did not reject Newtonian mechanics, but did make it clear that Newton's assumptions about space and time were too limited and that a true explanation of gravity required postulating "space time." Similarly, discoveries in mathematics and statistics, particularly the invention of non Euclidean geometry, revolutionized science in the twentieth century in somewhat the same way they had

in earlier times (Newman 1956). The same can be said for Boolean and Fregean mathematical and symbolic logic (Bartley in Dodgson 1986: 3–42). Comte (1957) wrote that scientific thinking moves only gradually, but inevitably, from the study of distant objects, such as stars, to that which is closest to human life – society itself. His positivism had a profound impact on logical positivism and the quest for “consilience,” a unified general science of all of the natural world (Wilson 1998). In English the distinction between science and social science is more rigid than in many other languages. In German the term *Wissenschaft* encompasses not only physical and natural sciences, but also social sciences and other disciplines such as history and jurisprudence.

scientology

Peter B. Anderson

Scientology, or officially the “Church of Scientology,” was founded by adherents of Lafayette Ron Hubbard (1911–86) in 1954, but the movement behind Scientology dates back to Hubbard’s publication of the book *Dianetics: The Modern Science of Mental Health* in 1950. Dianetics was a therapeutic system which Hubbard claimed could cure psychosomatic illness. Dianetics can be described as an attack on what Hubbard considered to be the materialistic position of psychiatry. Hubbard stressed that he wanted to overcome the unspiritual therapeutic strategies he saw in psychiatry and to deliver the techniques for everyone to reach mental wholeness. In his anthropology, man is basically good and strives for survival of various collectives termed “dynamics,” in Dianetics from the individual level to that of humanity, and in Scientology he added further levels up to the “urge towards existence as infinity,” termed the “God Dynamic.”

Dianetics assumes that a person receives and stores impressions, the so called “engrams,” painful memories from this or earlier lives, leading an individual to irrational acts. The aim of Dianetics was that man should reach the state of “clear” – completely rational. The Dianetics therapy is based on “auditing,” which involves an auditor who listens to the statements of the “pre clear,” as the person in an auditing session is termed. Besides the principles underlining the early steps of the auditing, the contents up towards and above clear are not known to outsiders, as it is considered dangerous knowledge for people who have not acquired it through proper auditing.

After a number of conflicts – including conflicts with the established psychiatric and psychological therapeutic system – economic crisis, and the fact that he lost the copyright to his own book, Hubbard formed a new organization and the first Church of Scientology was founded in 1954. From an organizational point of view the Church of Scientology appears to be in contrast to Dianetics. Dianetics was loosely organized, public, and impossible to manage for Hubbard, whereas the Church of Scientology is hierarchical, with control systems making sure that all employees act in accordance with the wishes of the organization. This has been reshuffled and strengthened a number of times. The Sea Organization (Sea Org) was founded as an elite group of Scientologists committing themselves up to a billion years in 1967. In 1981 the religious activities were collected in the Church of Scientology International and since 1982 the religious activities have been overseen by the Religious Technology Center, which holds all the trade and service marks of Hubbard's work since his death.

The organizational development has been identified as one of the rare transformations from a so called cult to a sect. The cult consists of open minded seekers in a cultic milieu, whereas the sect claims to have a unique way of salvation which the adherents have to follow (Wallis 1977).

In its belief system, influences from theosophy, Eastern religions, and interplanetary activity can be seen, and Scientology emphasizes that members may sustain other religious memberships as well. As a consequence it is difficult to determine the exact number of Scientologists. In many countries Scientology does not keep central membership files, and beyond an active core many Scientologists have little or no contact with the church, even if they consider themselves Scientologists. World based estimates vary from about 1 million to the official figure of 8 million in 2004.

Hubbard's utilitarian ethics led him to investigate a number of social phenomena and based on his findings there are now separate organizations for the improvement of education (Association for Better Living and Education (ABLE) and Applied Scholastics) and drug habilitation (Narconon). Other organizations include the Way to Happiness Foundation, and the Citizens

Commission for Human Rights (CCHR). Apart from general human rights activities, the CCHR continues Hubbard's fight with the psychiatric system, where it tries to document abuses in medication and links to Nazi medicine.

Whereas social activities have been kept within the general frame of Scientology, there have recently been attempts to disseminate techniques to improve the situation of individuals beyond the lines of Scientology. This is a reaction to the events following the attack on the Twin Towers in New York in 2001. Scientology considers the "War against Terror" dangerous for humanity, and thinks that it has set the world on a course towards destruction. The attempt to disseminate techniques to improve individuals has been accompanied by a general recruitment campaign, to "clear the world."

Scientology's widespread activities have been difficult to fit into classificatory frameworks of health science, psychiatry, religion, and social activities in general. Scientology insists that auditing is a primary religious activity, and has faced problems being recognized as a full fledged religious body in countries (e.g., Great Britain) where religious activities are deemed to be collective. Many countries have allowed Scientology to register as a religious body due to the general religious content of the system (e.g., in the USA, Australia, Sweden, Germany). In some places the related social activities are considered religious, and in others charitable, independent of whether Scientology is recognized as a religious body in the country or not.

scientometrics

Yuri Jack Gómez Morales

Scientometrics is a methodological discipline and an administrative practice. In the first case, its major concern has been the identification of patterns of communication among scientists supporting theoretical models of cognitive and institutional development of science. In the second case, its concern is the identification of patterns in science and technology activities conceived as an input/output productive system. In both cases the identification of patterns is quantitative oriented and the interpretation of data has relied heavily on economic and sociological models and in recent times, on informational models, too.

SCIENTOMETRICS AS AN ADMINISTRATIVE PRACTICE

The integration of science and technology into national account systems became a necessity when the activity reached financial prominence after World War II. Science and technology activities constitute so large an enterprise that nowadays they employ hundreds of thousands of scientists and engineers all over the world, requiring significant proportions of GNP. Thus, countries have felt the need to render these activities accountable for scientists themselves, the general public, the state, and for those engaged in the administration, funding, and execution of science and technology activities.

The official history of scientometrics as an administrative practice often signals J. D. Bernal's *The Social Function of Science* (1939) as its inaugural work. Bernal's contribution set the quantitative study of scientific literature and personnel and the utilization of mathematical models as the foundations of objective examination and deliberation on science policy and management. Yet, as the developmental age that followed the war took off, scientometrics also began to be considered among the developmental sciences (Anderson & Buck 1980).

Due to its potential for empowering actors in controlling science and technology activities by scientific means, scientometrics developed greatly, in contrast with earlier and more encompassing proposals such as the *Science of Science* program proposed by Price (1964), which gradually went into decline. If this program once comprised the "history, philosophy, sociology, psychology, economics, political science, and operations research (etc.) of science, technology, medicine (etc.)," the development of scientometrics has been more decidedly oriented towards the making of metrics for the measurement of relevant social variables that would make possible the study of science and technology activities from the plethora of theoretical perspectives just mentioned.

Through quantification, scientometrics is at first glance prone to and easily integrated into economics, and through it to developmental policies for science and technology. Indeed, at different times economists have seen science, technology, or both (depending on the underlying model) as the missing factor or the key element explaining economic growth and socio-cultural development. In a broader sense, scientometrics as an administrative practice involves the construction and use of a wide range of measurements and models employed in prospective studies (i.e., the assessment of future trends in science and technology within plausible socioeconomic scenarios, in technical change studies, demographic studies on human resources for science and technology, technology choice, science and technology planning, and more recently, knowledge management within commercial and private organizations) (Tisdell 1981).

SCIENTOMETRICS AS A METHODOLOGICAL DISCIPLINE

As a methodological discipline scientometrics is conceived in a more restrictive sense limited to the study of scientific communication processes (Borgman 1990) and more often than not to the identification of quantitative patterns found in scientific literature. Despite the fact that there is no real agreement about this reduction of scientometrics to bibliometrics, nor about the identity between scientometrics and *informetrics* (Scientometrics 1994), from this bibliometric viewpoint scientometrics has been more often associated with the sociological understanding of science, both as a social system and as a socio technical network.

As regards the literature there is a clear set of contributions starting from the 1960s that might be grouped as belonging to scientometrics as a methodological discipline. One of the most significant is *Little Science, Big Science* published in 1963 by the physicist and historian of science Derek de Solla Price. The significance of this contribution is that it brought together previously published isolated results into an all encompassing model for the quantitative study of science based on its formal communication patterns. The three main problems this model addresses are the growth, structure, and consumption of scientific literature.

The logistic model of scientific growth states that if any sufficiently large segment of science is measured in any reasonable way, this measurement will show that at any time in history, science's rate of growth is proportional to its size, whatever the index chosen for measurement. In the first mathematical approach, the empirical law of growth (as Price named it) can be represented by an exponential function with a doubling period of about 10 to 15 years, depending on how stringent are the criteria used for defining the chosen index. It is evident that such sustained growth, starting in the sixteenth century, cannot continue indefinitely. Eventually, exponential growth will reach some limit, when the process must slacken and stop or, as a result of substantial contextual changes, science will undergo a redefinition so that further growth can be achieved. Price's exciting conclusions about the future of science once it reaches

saturation were not subject to further investigation or monitoring.

As to the structure of scientific production, the model resumed investigations undertaken as early as 1874 by Galton's inquiries into social elites developed in his *Hereditary Genius* (1884) and Lotka's empirical work on *The Frequency Distribution of Scientific Productivity* (1926). Having defined science in terms of the time series of scientific papers obeying a particularly fast pattern of growth, a further characterization of this growth can be made by showing that a relatively small and stable core of authors is responsible for a large fraction of scientific papers, and that the bulk of the population contributing the rest flows through rapidly.

Finally, the model integrates studies concerned with the consumption of scientific literature. Although Price was aware of its importance, it was the technical and conceptual contributions of Eugene Garfield (1955) that made possible the development of empirical research on this parameter. He introduced *citation indexing*, a method that revolutionized the way in which published knowledge (previously arranged by subject matter) was organized, using the relationships between documents established by authors themselves when referencing other papers. Garfield implemented this new form of bibliographical control using 1960s state of the art technology (computing) in order to process massive bibliographic data. Thus, by contrast to previous quantitative studies of the literature (including Price's) that were developed from the production side of the communication process using traditional bibliographic control, Garfield's development, which focused on the consumption side of the communication process, yielded an entirely new arena for bibliometrics whose results were consistent with Price's previous conclusions regarding the structure of scientific literature.

Scientometrics as a methodological discipline has developed many more important concepts and techniques, such as invisible colleges, the citation cycle, the Price Index, the co citation analysis, and the impact factor. However, the three notions of logistic growth, distribution of productivity, and citation of scientific literature constitute the heart of bibliometrics and have been the departure point of scientometrics as an

administrative practice, as any input/output analysis of science and technology takes into consideration bibliometrics as part of its battery of indicators.

Most interesting, however, are the interpretations and uses sociologists have made of bibliometrics. The very idea of bibliometrics as a specialty research method for the sociology of science is due to Merton and it was put into practice by his pupils when empirical investigations of the *normative structure of science* took off by the mid 1960s. At its outset the empirical program of the sociology of science focused on the problem of *stratification* within the social system of science (i.e., how to explain the social standing and value assigned to individuals within the community and the mechanism of social mobility within this community). Functionalists focused on the formal communication system of science – the scientific journals – as a privileged field for studying stratification, in as much as this system embodied, via peer reviewing, the complex of values and technical norms practiced by the scientific community when evaluating the originality, significance, and ultimately the quality of a contribution. Social standing within the community is then a result of rewards and other *cumulative advantages* conferred to a scientist on the basis of the significance of his or her contribution to the advancement of science and the fulfilment of the code of practice in achieving it. From this point of view, the basic reward a scientist may receive for his or her contribution is a citation to it. So it was that citation started to be considered as an indicator of scientific quality which, together with data on the productivity and growth of scientific literature, reveals a clear correlation between consumption, productivity, and social standing within the community. Moreover, soon after the introduction of the Science Citation Index, the range of applications of bibliometric data for the study of science was rapidly enhanced to include the history of scientific discoveries, cognitive maps of research fronts, and differentiated patterns of development among the sciences (natural and applied) and between these sciences and the humanities.

There is another bibliometric strand associated with actor network theory (Callon et al. 1986). According to this view, publishing scientific results is part of a more comprehensive

strategy scientists use in the social making of scientific facts. Indeed, publication is an important part of the strategy, for it is by that means that the socio technical network required for supporting a knowledge claim is constructed. Thus, if scientists' performance is guided by interests rather than values, the methodological question was to develop means for following those interests and their textual translations as they are performed in the scientific paper via referencing. The starting point of qualitative scientometrics is the indexicality of words like problems used by scientists in their texts. Actor network theorists focused on the way in which an author indexes a bibliographic reference within a line of argument that a paper develops. For analytical purposes, then, an article may be reduced to a network of powerful words that can be represented as a simple graph linking all of them. Each point on the graph represents a word, while a line indicates that the words linked in this way co occur in the article. The graph that summarizes an article can be read, like the original article, as a structured network of claimed equivalences. Such claimed equivalences between heterogeneous elements represent an author's strategy of translation. Thus, an author's socio technical network can be described to an extent through the equivalences and linkages between problems like words and through the measurement of the number of times such an equivalence appears in the total body of literature in which it might occur. The co word approach allows successful translations to be traced and distinguished. This visualization makes possible a departure from the network of textual translations to the network of socio technical problems, interests, and actors.

scripting theories

David Knapp Whittier

To articulate a sociological approach to human sexuality, William Simon and John Gagnon drew upon Kenneth Burke's dramatism and view that it is inappropriate and inaccurate to apply physical models to social phenomena. The "sexual script" concept (Gagnon & Simon 1973) summarizes their approach and their fullest articulation is known as "sexual scripting theory" (Simon & Gagnon 1986). The theory stresses three major areas of social life as significant for the production of sexuality: (1) cultural scenarios for sexuality, (2) interpersonal sexual scripting, and (3) intrapsychic sexual scripting. "Cultural scenarios" refers to definitions of and instructions for sex which can be

found in social institutions and cultural materials. "Interpersonal scripting" refers to the social arrangement of actual sexual interactions. "Intrapsychic scripting" refers to the activity and content of the mind, like sexual thoughts, fantasies, beliefs, and emotions. Sexual scripting analysis is the examination of the separate roles and interrelationships of these three areas of social life as they help produce sexuality.

Sexual scripting theory was built up out of the application of sociological ideas to sexuality. Gagnon and Simon's book, *Sexual Conduct: The Social Sources of Human Sexuality*, was revised and reissued in 2005. It is an important and prescient conceptualization predating Foucault's postmodernist position on sexuality and presaging queer theory approaches. Perhaps its greatest impact has been its conceptual theoretic contribution to the field – although it is rarely acknowledged. Even more rarely have empirical studies explicitly used sexual scripting theory.

When the theory has explicitly guided research the analyses have tended to emphasize one level only, most frequently that of cultural scenarios. For example, Laumann et al. (1994) correlate sociocultural contexts with sexual behaviors. Analyses which only match cultural scenarios with behaviors do not relate the mechanisms by which individuals acquire, and social life helps to create, sexuality. The attention to culture, interaction, and mind in sexual scripting theory is similar to that found in symbolic interactionism (Longmore 1998). However, there exists little work proclaiming guidance by both symbolic interactionism and sexual scripting theory. Only a couple of studies of interpersonal sexual interaction claim sexual scripting theory parentage (e.g., Escoffier 2003). Similarly, all but a few social psychological studies (e.g., Whittier & Melendez 2004) of sexuality embrace sexual scripting theory. Carr's (1999) cognitive sociology contribution notably implicates interrelationships of sexual scripting levels.

Sexual scripting theory also engages broad sociohistorical analysis and theorization of the self in pointing to a relationship between sexuality and modernity in helping to bring about individuation. Simultaneous specification of sexual change and forms at all three sexual scripting levels may require an extremely wide

range of data and substantial cross disciplinary abilities. The ambitiousness of this theory may deter use and even result in misunderstandings of it. Sexual scripting theory sincerely asks for depictions of the emergence of sociosexual facts like sexual intercourse and titillation. It is a bold framework for specifying how, in time and place, social life forms sexuality.

second demographic transition

Ron J. Lesthaeghe

The first or "classic" demographic transition refers to the historical declines in mortality and fertility, as witnessed from the eighteenth

century onward in several European populations, and continuing at present in most developing countries. The end point of the first demographic transition (FDT) was supposed to be an older stationary and stable population corresponding with replacement fertility (i.e., just over two children on average), zero population growth, and life expectancies higher than 70 years. As there would be an ultimate balance between deaths and births, there would be no "demographic" need for sustained immigration. Moreover, households in all parts of the world would converge toward the nuclear and conjugal types, composed of married couples and their offspring.

The second demographic transition (SDT), on the other hand, sees no such equilibrium as the end point. Rather, new developments bring sustained sub replacement fertility, a multitude of living arrangements other than marriage, the disconnection between marriage and procreation, and no stationary population. Instead, populations would face declining sizes if not complemented by new migrants (i.e., "replacement migration"), and they will also be much older than envisaged by the FDT as a result of lower fertility and additional gains in longevity. Migration streams will not be capable of stemming aging, but only stabilize population sizes. Nonetheless, the outcome is still the further growth of "multicultural societies." On the whole, the SDT brings new social challenges, including those associated with further aging, integration of immigrants and other cultures, less stability of households, and high levels of poverty or exclusion among certain household types (e.g., single persons of all ages, lone mothers).

HISTORY OF THE CONCEPT

The idea of a distinct phase stems directly from Philippe Ariès's analysis of the history of childhood and his paper on two successive motivations for low fertility (Ariès 1980). In his view, during the FDT, the decline in fertility was "unleashed by an enormous sentimental and financial investment in the child." Ariès refers to this as the "Child king era," and the fertility transition was carried by an altruistic investment in child quality. This motivation is no

longer the dominant one. Within the SDT, the motivation for parenthood is adult self realization, and the choice for just one particular lifestyle in competition with several others. The altruistic element focusing on offspring has weakened and the adult dyadic relationship has gained prominence instead.

The second element that sparked the SDT theory was the conviction that the cyclical fertility theory as formulated by Richard Easterlin would no longer hold and that sub replacement fertility was to become a structural, long term feature in western populations. In Easterlin's theory, small cohorts would have better employment opportunities and hence earlier marriage and higher fertility, whereas large cohorts would have worse economic life chances and display the opposite demographic responses. The cyclical reinforcement then stems from large cohorts of parents giving birth to small cohorts of children and vice versa. The SDT does not expect cyclical effects that would be strong enough to determine the fertility trend. Rather, it advances that other effects, both economic and cultural, have an overriding capacity in conditioning these trends.

The third element that conditioned the SDT theory is the major role given to the ideational factor and to the dynamics of cultural shift. The SDT theory fully recognizes the effects of macro level structural changes and of micro level economic calculus. As such it is not at odds with the core arguments of neoclassic economic reasoning. However, the SDT view does not consider these explanations as sufficient but merely as non redundant. By the same token, the cultural factors involved are non redundant elements and not sufficient ones. The SDT is therefore an "overarching" theory that spans both economic and sociological reasoning. And it does not do so by taking value orientations as endogenous or by considering culture as a form of addiction, but by treating ideational changes as exogenous influences that add stability to trends over and beyond economic fluctuations. The SDT furthermore links cultural shifts to dynamic processes of cohort succession, and to a recursive model of values based selection and individual values reorientation as a function of paths followed during the life course.

Fourth, a major stepping stone of the SDT theory has also been Abraham Maslow's theory

of changing needs. As populations become more wealthy and more educated, attention shifts away from needs associated with survival, security, and solidarity. Instead, greater weight is attached to individual self realization, recognition, grassroots democracy, and expressive work and education values. The SDT theory is therefore closely related to Ron Inglehart's concept of "postmaterialism" and its growing importance in political development. The direct consequence of this is that SDT also predicts that the typical demographic outcomes (sustained sub replacement fertility, growth of alternative living arrangements) are likely to emerge in non western societies that equally develop in the direction of capitalist economies, with multilevel democratic institutions, and greater accultuation of Maslowian "higher order needs."

FIRST DEMOGRAPHIC TRANSITION—SECOND DEMOGRAPHIC TRANSITION CONTRASTS

Having pointed out the intellectual origins of SDT, more attention can be given to the FDT–SDT contrast. Originally, SDT was viewed as the mere continuation of FDT, but such a "single transition" view obscures major differences of both a demographic and a social nature. The major contrasts have therefore been listed in Table 1.

Opposite Nuptiality Trends

The FDT transition in the West is characterized by the gradual weakening of the old Malthusian "preventive check" located in late and non universal marriage. Ages at first marriage are lowered and proportions marrying increased during the FDT. Furthermore, the areas where cohabitation and out of wedlock fertility had survived until the twentieth century, join the mainstream characterized by low illegitimacy and low incidence of unmarried partnerships. The earliest age at marriage is reached in the 1960s. Thereafter, all trends are reversed and rapidly so: ages at first marriage increase, more single persons start living alone or start to cohabit prior to marriage, long term cohabitation replaces marriage, and ultimately fertility outside marriage becomes much more frequent.

Table 1 Overview of demographic and societal characteristics respectively related to the FDT and SDT (Western Europe)

<i>FDT</i>	<i>SDT</i>
A. Marriage	
<ul style="list-style-type: none"> • Rise in proportions marrying, declining age at first marriage • Low or reduced cohabitation • Low divorce • High remarriage 	<ul style="list-style-type: none"> • Fall in proportions married, rise in age at first marriage • Rise in cohabitation (pre- and postmarital) • Rise in divorce, earlier divorce • Decline of remarriage following both divorce and widowhood
B. Fertility	
<ul style="list-style-type: none"> • Decline in marital fertility via reductions at older ages, lowering mean ages at first parenthood • Deficient contraception, parity failures • Declining illegitimate fertility • Low definitive childlessness among married couples 	<ul style="list-style-type: none"> • Further decline in fertility via postponement, increasing mean age at first parenthood, structural subreplacement fertility • Efficient contraception (exceptions in specific social groups) • Rising extra-marital fertility, parenthood within cohabitation • Rising definitive childlessness in unions
C. Societal background	
<ul style="list-style-type: none"> • Preoccupations with basic material needs: income, work conditions, housing, health, schooling, social security. Solidarity prime value • Rising memberships of political, civic, and community-oriented networks. Strengthening of social cohesion • Strong normative regulation by state and churches. First secularization wave, political and social “pillarization” • Segregated gender roles, familistic policies, embourgeoisement • Ordered life course transitions, prudent marriage and dominance of one single family model 	<ul style="list-style-type: none"> • Rise of “higher order” needs: individual autonomy, self-actualization, expressive work and socialization values, grassroots democracy, recognition. Tolerance prime value • Disengagement from civic and community-oriented networks, social capital shifts to expressive and affective types. Weakening of social cohesion • Retreat of the state, second secularization wave, sexual revolution, refusal of authority, political “depillarization” • Rising symmetry in gender roles, female economic autonomy • Flexible life course organization, multiple lifestyles, open future

A similar turnaround also takes place with respect to remarriage. During FDT, divorce (or widowhood) is often followed by remarriage, and even by continued childbearing. During SDT, post marital relationships are channelled into cohabitation or living apart together (LAT) relationships rather than remarriage. In parts of Central and in Eastern Europe, where the historical Malthusian late marriage pattern did not exist, SDT is equally characterized by a new trend toward later marriage and more cohabitation after 1990. Also, out of wedlock fertility now follows the western trend. Moreover, such features are now also emerging in the western part of Southern Europe (Italy, Malta, Spain, and especially Portugal).

Opposite Timing of Fertility

During FDT, fertility became increasingly confined to marriage, contraception mostly affected fertility at the older ages (stopping) and higher marriage durations, mean ages at parenthood declined, but childlessness among married couples remained low. There are examples of below replacement fertility during FDT, but these correspond to exceptional periods of deep economic crisis or war.

SDT starts in the 1960s with a multifaceted revolution. First, there was the contraceptive revolution with the introduction of hormonal contraception and far more efficient IUDs. Second, there was the sexual revolution, with

declining ages at first sexual intercourse. Third, there was the gender revolution that questioned the sole breadwinner household model and the gender division of labor that accompanied it. These three “revolutions” fit within the framework of an overall rejection of authority, the assertion of individual freedom of choice (autonomy), and an overhaul of the normative structure. The overall outcome of this with respect to fertility is postponement: mean ages at first parenthood rise again, opportunities for childbearing are lost due to higher divorce, the share of childless women increases, and higher parity births (4 +) become rare. The net result is structural and long term below replacement fertility.

Social Contrasts

With the exception of the very early fertility decline in France and a few other small European regions, much of FDT was an integral part of a development phase during which economic growth fostered material aspirations and improvements in material living conditions. The preoccupations of the 1860–1960 era were mainly concerned with increasing household real incomes, improving working and housing conditions, raising standards of health, improving human capital through mass education, and providing a safety net for all via the gradual construction of a social security system. In Europe, these goals were shared and promoted by all major democratic political parties, their organizations, and by churches as well. In this endeavor solidarity was a central concept. All such political or religious “pillars” had their views on the desirable evolution of the family. For the religious organizations, these views were based on the holiness of matrimony in the first place, but their defense of the closely knit conjugal family also stemmed from fears that urbanization and industrialization would lead to immorality and atheism. The secular pillars, such as socialist or liberal parties, equally saw the family as the cornerstone of society. Both moral and material uplifting would be served best by a sharp gender based division within the family: husbands assume their roles as devoted breadwinners and women as guardians of all quality related issues (order and neatness,

health, education, etc.). In other words, all religious and political factions – including the communist one – contributed to the “*embourgeoisement*” of the family.

SDT, on the other hand, is founded on the rise of the higher order needs. Once the basic material preoccupations are satisfied, further income growth and educational expansion jointly lead to the articulation of more existential and expressive needs. These are centered on a triad: *self actualization* in formulating goals, *individual autonomy* in choosing means, and claiming *recognition* for their realization. These issues emerge in a variety of domains, and this is why the SDT is related to such a broad array of indicators of ideational or cultural shift (Lesthaeghe and Surkyn 2004a). SDT occurs in tandem with the growth of “postmaterialism” (Inglehart 1990) and political or religious “depillarization” (Lesthaeghe & Moors 1995), the disengagement from civic, professional, or community oriented associations, a critical stand vis à vis all forms of authority, the stress on expressive values in socialization and in work, and, of course, a quest for far more egalitarian gender relations. Also at the individual level, the choices for new types of households (premarital single living, cohabitation, and parenthood within cohabitation) are all linked to such individualistic and non conformist value orientations in a great variety of spheres. Furthermore, these associations between household types and value orientations not only hold for Northern and Western Europe but, by now, equally for Southern, Central and Eastern Europe.

CRITICISMS

Several criticisms have been launched against the SDT view. First, some argue there is no “second” demographic transition, but just the continuation of a single one. Second, some suggest that SDT is typical only of Northwestern Europe. Third, SDT does not envisage a “new equilibrium” at the end, unlike the original FDT. In addition to these objections, others dislike the strong “cultural” interpretation. A reply to these criticisms argues that SDT correctly predicted the trends in Central, Eastern, and Southern Europe, and that all correlations

at the micro level between household type and value orientations emerge there as well.

secondary data analysis

Russell K. Schutt

Secondary data analysis is the method of using preexisting data in a different way or to answer a different research question than that intended by those who collected the data. The work of the secondary data analyst begins where the survey, experiment, or qualitative method that generates the data ends. The most common sources of data used in secondary analyses are social science surveys and data collected by government agencies, often with survey research methods, but it is also possible to reanalyze data that have been collected in experimental studies or with qualitative methods. Even reanalysis by researchers of data that they collected previously qualifies as secondary analysis if it is for a new purpose or in response to a methodological critique.

Secondary data analysis has been an important social science methodology since the earliest days of social research – Karl Marx reviewed government statistics in the Reading Room of the British Library; Émile Durkheim analyzed government records for his study of suicide rates. However, it is only with the advent of modern computers and, even more importantly, the Internet that secondary data analysis has become the most popular and accessible social research method. Literally thousands of large scale data sets are now available for the secondary data analyst, often with no more effort than the few commands required to download the data set; a number of important data sets can even be analyzed directly on the Web by users who lack their own statistical software.

There are many sources of data for secondary analysis within the United States and internationally. The most traditional source is data compiled by governmental units. The decennial population census by the US Bureau of the

Census is the single most important governmental data source, but many other data sets are collected by the Census and by other government agencies, including the US Census Bureau's Current Population Survey and its Survey of Manufactures or the Bureau of Labor Statistics' Consumer Expenditure Survey. These government data sets typically are quantitative; in fact, the term "statistics" – state istics – is derived from this type of data.

There are many other readily available sources: administrative data from hospitals, employers, and other institutions; records of transactions or other business conducted in government offices; both cross sectional and longitudinal social surveys conducted under many different auspices, ranging from university based researchers to international organizations like the Organization for Economic Development (OECD) (Hakim 1982: 6).

In the United States, the University of Michigan's Inter University Consortium for Political and Social Research (ICPSR) archives the most extensive collection of social science data sets outside of the federal government: more than 9,000 data sets from 130 countries, particularly from government units, social survey projects, and international organizations are made available online to individuals at more than 500 colleges and universities around the world that have joined ICPSR.

Far fewer qualitative data sets are available for secondary analysis, but the number is growing rapidly. The Human Relations Area Files at Yale University, established in 1949, currently contain over 800,000 pages of information on more than 365 different groups (HRAF 2005). More recently, multistudy qualitative archive projects have been developed by the Murray Research Center at Harvard's Radcliffe Institute for Advanced Study, and by the Economic and Social Data Service of the Universities of Sussex and Manchester in England, although these data sets are not available for direct public access. However, the ICPSR archives now include close to 100 data sets that have a qualitative component and the University of Southern Maine's Center for the Study of Lives makes life interview data available for reanalysis.

There are fundamental differences between a secondary and a primary analysis of social science data and there are unique challenges

faced by the secondary data analyst. What is most distinctive about the method of secondary data analysis is that it does not allow the progression from formulating a research question to designing specific methods that are best suited to answer that question. The secondary data analyst also cannot test and refine the methods to be used on the basis of preliminary feedback from the population or processes to be studied. Nor is it possible for the secondary data analyst to engage in the iterative process of making observations, developing concepts, making more observations, and refining the concepts that is the hallmark of much qualitative methodology.

These limitations of secondary data analysis mean that it may not be possible for a researcher to focus on the specific research question of original interest nor to use the most appropriate sampling or measurement approach for studying it. Secondary data analysis inevitably involves a tradeoff between the ease with which the research process can be initiated and the specific hypotheses that can be tested and methods that can be used. If the primary study was not designed to measure adequately a concept that is critical to the secondary analyst's hypothesis, the study may have to be abandoned until a more adequate source of data can be found. Alternatively, hypotheses or even the research question itself may be modified in order to match the analytic possibilities presented by the available data (Riedel 2000: 53).

Data quality is always a concern with secondary data, even when the data are collected by an official government agency. Government actions result at least in part from political processes that may not have as their first priority the design or maintenance of high quality data for social scientific analysis. For example, political opposition over the British Census's approach to recording ethnic origin led to changes in the 1991 Census that rendered its results inconsistent with prior years and that demonstrated the "tenuous relationship between enumeration [census] categories and possible social realities" (Fenton 1996: 155).

The basis for concern is much greater in research across national boundaries, because different data collection systems and definitions of key variables may have been used (Glover 1996). Census counts can be distorted by incorrect answers to census questions as well as by

inadequate coverage of the entire population (Rives & Serow 1988: 32–5).

Reanalyzing qualitative data collected by someone else also requires setting aside the interpretive research principle of letting the researcher's evolving understanding of a setting shape the focus of data collection efforts (Heaton 2004: 30–1). Instead, the secondary analyst of qualitative data must seek opportunities for testing new conceptualizations with the data already on hand as well as, when possible, by carrying on a dialogue with original researchers.

These problems can be lessened by seeking conscientiously to review data features and quality before deciding to develop an analysis of secondary data (Stewart & Kamins 1993: 17–31; Riedel 2000: 55–69) and then developing analysis plans that maximize the value of the available data. Replicating key analyses with alternative indicators of key concepts, testing for the stability of relationships across theoretically meaningful subsets of the data, and examining findings of comparable studies conducted with other data sets can each strengthen confidence in the findings of a secondary analysis.

In an environment in which so many important social science data sets are instantly available for reanalysis, the method of secondary data analysis should permit increasingly rapid refinement of social science knowledge, as new hypotheses can be tested and methodological disputes clarified, if not resolved, quickly. Both the necessary technology and the supportive ideologies required for this rapid refinement have spread throughout the world. Social science researchers now have the opportunity to take advantage of this methodology as well as the responsibility to carefully and publicly delineate and acknowledge the limitations of the method.

secondary groups

Patrick J. W. McGinty

A secondary group is a unique form of social group that tends to be formally organized or highly structured and based on predominantly impersonal or role based instrumental (task oriented) interactions that are of a nonpermanent nature. Examples of secondary groups include the impersonal relationship between salesclerk and customer in a department store; large lecture courses at popular universities; and complex organizations such as the American Sociological Association.

Despite its centrality in the sociological perspective and its being an omnipresent theme as well as an ongoing interest of sociologists in a

variety of forms, the concept of a secondary group is rather poorly conceptualized. This problematic status of the concept and its usage within the discipline is further conditioned by a unique confluence of understandings regarding the concept. First, it is deemed of central significance to the discipline, but is generally relegated to little more than a concept that students in "Introduction to Sociology" courses need only memorize and be able to identify. Second, the concept is widely understood in practice, and where it appears in the sociological literature it is consistently applied with little variation in meaning or definition. At the same time, however, the development and usage of the concept as a central concern in sociological research has declined significantly over time. Third, as a result, where the concept of secondary group is discussed in the contemporary sociological literature it is generally defined or treated only in relation to one or more sociological concepts – the most common referent concepts being community, social organization, and primary group.

This relational and yet dualistic conceptual definition and operationalization of secondary groups has its origins in the history of sociology and classical sociological theory. This is particularly evident in the historically and theoretically contextualized understanding of the relationship between community and society. It is common for the work of both Émile Durkheim and Georg Simmel (which sought to explicate the relationship between social groups and the organization of society) to be referenced in this context. However, it is the work of Charles Horton Cooley (1909) and Ferdinand Tönnies (1963) that continues to drive the historically and theoretically relational understanding of the concept.

In *Social Organization* (1909) Cooley provides in great detail the forms, functions, and attributes of the social units he called "primary groups." However, what Cooley did not do was develop a term for those social units which were not primary groups. Thus, the conventionally accepted set of attributes and characteristics of secondary groups were simply extrapolated from Cooley's understanding of primary groups. Or in other words, knowing what primary groups are, secondary groups by corollary must

be anything or everything that primary groups are not. Accordingly, it follows that for over a century sociologists have defined the concept of secondary group simply in relation to the associated (and similarly limited) conceptualization of primary group. To Cooley's credit, both his explicit definition of primary groups and the associated implicit definition of secondary groups have withstood the test of time. Ironically, Cooley's intent in *Social Organization* was to develop a processual and non dichotomous understanding of the relationship between community and social organization, the conceptualization of primary groups being only one aspect of the larger argument.

In addition, Ferdinand Tönnies's (1963) work regarding the dualistic conception of *Gemeinschaft* and *Gesellschaft* also sought to explain the relationship between community and social organization. Accordingly, Tönnies's explanations and assumptions regarding the forms, attributes, and characteristics of *Gesellschaften* – including but not limited to short term and impersonal relationships – have become closely associated with the conventional definition of secondary groups.

Despite the contemporary limitations regarding the conceptualization of secondary groups, there are a couple of theoretical developments that stand to alter significantly the manner in which secondary groups are conceptualized and defined. The more dramatic of the two developments is founded on a relational understanding of human interaction. Lyn H. Lofland (1989) reviews an extensive literature which shows how the emergent and informal but role based "unpersonal" relationship blurs the boundaries between forms of interactions generally shown as typical of both primary and secondary groups. However, in a more recent iteration, Lofland (1998) proposes an end to the unreflective use of the concept of secondary groups. Although suggesting that the ideal typical understanding of secondary groups does have its benefits, Lofland instead posits the need for a more dynamic set of concepts that can better capture the variety of forms of human relationships. Among the concepts Lofland proposes are the "fleeting relationship" (Davis 1959), "routinized relationships," "quasi primary relationships" (Stone 1954), and "intimate secondary relationships." The continued development of

these and similar insights stands to clarify as well as further our collective comparative understanding of social groups and their organization and processes.

Second, although still overwhelmingly understood in terms of the ideal typical conceptualizations similar to those now used, other practitioners are calling for the replacement of the concept of secondary groups with that of the seemingly more explanatory concept of "complex groups." Such a change in conceptual label seeks to shift explanatory focus of the concept from its current gaze – which highlights concerns such as the role and/or function of the social group – to that of the size, scope, and forms of relationships within the group and the associated forms of intergroup and intragroup relations. The underlying logic associated with this proposal is based on analyses of interaction networks. While it is the issue of complexity that drives this proposal for changing the conceptual label, it should be noted that such a change in conceptualization could provide greater theoretical synchronicity by narrowing the conceptual gap between our conventional understanding of secondary groups and micro/macro linkages, particularly with regard to one of the concepts' more widely accepted expressions: the complex organization (for the treatment of similar concerns in terms of weak and strong ties, see Granovetter 1973, 1983).

While the complex organization is one form of secondary group, it is the bureaucratically organized form of complex organization that is commonly held up as the classic epitome of the secondary group – being a large, impersonal organization based on a network of complex status relationships which maintains a set of instrumental goals and processes, and in which the length of individual associations varies. The expression of the bureaucratic organization as an ideal typical example of a secondary group should serve to heighten our awareness of the importance of the study of secondary groups. This same expression should then, by corollary, serve to heighten our sensitivity to the study of the variety of forms of human interaction and relations in contemporary social life. This is the case not only because of the increasing significance of secondary groups to our general social

welfare, but also because of their implicit relationship to the ever increasing growth and development of rationalized forms of organizing (Ritzer 2004), as well as expressions of individualism and unbridled self interest in human social life (for related but differing perspectives on the result of said forms of organizing, see also de Tocqueville 1966; Michels 1966).

secrecy

Laurence Moss

George Orwell's celebrated novel, *Nineteen Eighty Four*, presents a haunting and horrific account of how the thought police in a totalitarian world can monitor the private thoughts and uproot the deepest emotional sentiments held by individuals. Keeping secrets has become a capital offense. The "Party" has reduced the sphere of individual autonomy and privacy to practically nothing at all. According to Orwell, in this dystopia it became "intolerable [to the Party] that an erroneous thought should exist anywhere in the world, however secret and powerless it may be" and "in the eyes of the Party there was no distinction between the thought and the deed" (Orwell 2003 [1949]: 250, 263). Either one resulted in immediate arrest and eventual execution.

Orwell's prose frightens us because private thoughts and personal secrets are profoundly important to our sense of personhood and to the expression and development of human personality. A world without the possibility of personal secrets is a world that is intolerable.

SOCIOLOGY AND ECONOMICS

Orwell's world is not our world. Most people possess secrets about themselves that they intentionally prefer to keep to themselves and share with only a few. According to Miller, most of us fake things about our roles, our dispositions, emotions, our commitments, and even our entire identity. We intentionally persuade others about things that are simply not true (Miller 2003; see also Goffman 1963). The origins of these insights date back to the canonical writings in modern sociology and especially to the work of Georg Simmel (Ritzer 2000: 282–6).

According to Donald Levine, the nineteenth century sociologist Simmel was one of the earliest to advance the view that "sociology should describe the ideal types of forms of social interaction abstracted from their contents" (1971: lii). Simmel's search for the *forms of human interaction* and how they help illuminate the most interesting real life examples of people at

work and at play has earned him a reputation as one of the most insightful of the German sociologists at the start of the twentieth century.

In 1906, Simmel's "The Sociology of Secrecy and of Secret Societies" appeared in the *American Journal of Sociology* in which the phenomenon of the intentional misrepresentation of information by one individual or a group of individuals gives rise to the rituals and customs of the "secret society," such as the legendary Carbonari in Italy and the multitude of religious sects that spring up to practice a faith that the powerful state tries to stamp out. According to Simmel, "the secret society emerges everywhere as correlate of despotism and of police powers. This is true, not alone in political relations, but in the same way within the church, the school, and the family" (1906: 472). Simmel's idea that one strategy for coping with the demands and pressures of modern society involves camouflaging oneself with lies and falsehoods has spawned an enormously fertile field of analysis within modern sociology (cf. Goffman 1963; Bergmann 1993 [1987]).

Simmel pioneered several novel forms of analysis in the study of secrecy that still have influence today. For example, when an individual lies to another, that other person is not only deceived but also has a "misconception about the true intention of the person who [has told] the lie" (Simmel 1906: 445). These misconceptions are much less threatening to the persistence of the group in simple societies than they are in modern credit economies where the entire civilized structure is based on thousands of pre-suppositions about individuals and their intentions. A modern credit based economy in which money and its electronic forms permit myriad secret transactions right under the nose but out of the sight of the governing authorities has turned out to be an important and still unappreciated form of modern social life. The twenty first century terrorists finance their nefarious deeds by transferring funds from one currency area to the next and, as a result, the current "war on terror" is fought not only on the ground but also in the abstract financial world of electronic transfers and banking.

In modern business, "white collar crime" and the enormous magnitude of selected corporate crimes have become central to popular media reporting. At the heart of many of these

criminal enterprises is the notion of “secrecy” and the intentional presentation of false and misleading information, both to the victims and to many others. And so we can read Simmel as warning more about the potency of secrecy and dissimulation in modern complex financial network societies than in less developed and perhaps more primitive societies.

There is a geometry of social relations that we find in Simmel (Ritzer 2000: 268). As early as the seventeenth century, Thomas Hobbes recognized that groups of individuals who assemble for their defense against a threatening enemy need large numbers to succeed, but large numbers of individuals are prone to quarreling and intrigues as one individual faces off against another, revealing the antagonistic side of human nature. Certainly, after the danger of invasion has passed, their cohesion is apt to splinter and large numbers end up bickering, quarreling, and worse. Collective action would not succeed unless there were a strong central kingly power to keep the individual egos in check (Hobbes 1928 [1650]: 78–9). The idea that small groups of agents are capable of some forms of social action of which large groups are not resurfaced in Simmel’s writings more than two and half centuries later.

Simmel discussed the differences between the dyad and the triad and emphasized, as Hobbes had done, the importance of the “impact of numbers of people on the quality of interaction” (cf. Ritzer 2000: 268). With two individuals there is not much of a group structure to appreciate and study, but add merely a third individual and the structure and form of the interaction undergo fundamental change. For one thing, a genuine social structure finally comes into existence. Emergent structures are certainly present in the case with secrecy and secret dealings.

According to Simmel, in small groups it is difficult to keep and maintain secrets. Just about everyone is too close and there are repeated temptations to “slip” and tell all. In large groups, secrets can more easily emerge and be maintained. In large secret societies, a secret is shared by all members of the group but there is the constant tension “caused by the fact that the secret can be uncovered, or revealed, and thus the entire basis for the existence of the secret society can be eliminated” (Ritzer 2000: 283).

The contrast between secret keeping in small and large groups and the social structures that emerge somewhat spontaneously to improve the likelihood of success in secret keeping are grist for the mill of the sociologist. In his 1906 article, Simmel broke new ground when he carefully outlined the methods secret societies use to conceal their size and their leadership through the use of decentralized methods of information and control.

THE COSTS OF MAINTAINING SECRETS

It is a well established principle in the social sciences, and especially in economics, that the costs and difficulties of keeping *certain types of secrets* increase exponentially with the number of individuals sharing the secret. This is the large group problem that fascinated Simmel, but in economics seemingly opposite conclusions emerge.

Many business conspiracies to secretly set prices or restrict output, and in that way monopolize markets, fall apart of their own accord. This unraveling is quicker the larger the number of businesses trying to coordinate their business strategies. In the study of industrial organization and especially the study of cartels, it is often found that conspiracies to “fix” prices or rig contract competitions are often unraveled by dissenting members of the conspiracies who complain that their production quotas are unfair (i.e., “too low”). Former conspirators try to gain a private advantage for themselves by going their own way by only pretending to be a member of the cartel.

A different sort of problem may arise when one individual knows that one or more other individuals knows something important but may lie about it to the first individual. Some experts claim that this situation establishes the fundamental condition for secrecy itself. According to Ritzer, “secrecy is defined as the condition in which one person has the intention of hiding something while the other is seeking to reveal that which is being hidden” (Ritzer 2000: 282). Indeed, the holders of the non public information know that the others with whom they deal know that they know something they do not. In this way, a complicated strategic

problem of move and countermove begins. The subfield of economics known as “game theory” has gone a considerable distance investigating these forms of social interaction and the actual geometries involved.

For example, a physician knows whether his or her patient is mildly ill rather than seriously ill. Still, that doctor may prescribe additional expensive tests expecting the “kick back and special considerations” that may come his way from enriched colleagues who get paid to perform those unnecessary tests. This physician has a conflict of interest. He has been hired to diagnose and to heal. Instead, he lies and steals.

When the patient worries that he or she may be defrauded by the strategic use of “asymmetric information” by an unscrupulous expert, we have the conditions under which market structures evolve to permit the authentication of information and the creation of “good reputation.” The professions are often governed by emergent structures of “professional ethics and responsibility” that help dampen rapacious individual behavior that make up secrecy and lying to enhance fees and revenues. This was the claim of American sociologist Talcott Parsons in numerous writings (Parsons 1937). Modern sociologists often criticize economists for not considering the regulative role norms play compared with raw self interest.

When a number of persons share a secret, and keep that secret in absolute silence, we have another social phenomenon of special interest. Sociologist Eviatar Zerubavel summarizes what is known about silence and denial. His thesis follows the insights of Sigmund Freud and Carl Jung in psychology (Bok 1982: 8). Many jointly held secrets grow more difficult to keep over time. It is like an elephant in the room that the co conspirators ignore, but as a result the elephant keeps growing larger and larger until the secret can be bottled up no longer. The co conspirators suffer together in icy silence until all hell breaks loose and the elephant has shattered the conspiracy of silence. This phenomenon wreaks havoc on individual conscience and personality.

During the Nazi war against the Jews, there were homeowners living in close proximity to the death camps but no one discussed or even mentioned what everyone knew was going on over there right in front of their eyes. A “social

norm” emerged that limited what perceptions were permissible and what had to be ignored (Zerubavel 2006: 23). Other examples include child abuse in a family that is covered up by a shared secret held among family members.

LAW AND ECONOMICS

The common law defines a trade secret as any sort of formula or procedure that gives one seller a competitive advantage over another. For economists, a valuable trade secret means that one seller can score more profits than his or her rivals. Furthermore, it may allow that seller to price the product above its marginal cost of production, and that form of pricing results in “allocative inefficiency” in the sense that resources are not being allowed to move to what the market prices indicate are the most valued uses.

But allocative efficiency is not all that is important to economic welfare. The evidence suggests that regions are richer or poorer according to how much investment is taking place. While some of that investment is replacing worn out equipment and updating skills, other investment is part of entrepreneurialism and the creation of new products and services. That means a capitalist economy is constantly changing what is produced, how it is produced, and when it comes to the market in sometimes novel and unexpected ways. If the prospect of discovering a formula or recipe that will result in financial success is what motivates discovery and innovation, then a different type of efficiency argument can be made and has been made for “trade secrecy.” We speak of *dynamic efficiency* and identify this type of efficiency with the revolutionary and unexpected changes in the ways we work and live with one another. Many entrepreneurs and their backers try to maintain secrets so that they can generate “first mover” advantages before a large number of competitors get wind of the innovation and start to imitate and reduce the value of the secret.

In some specific cases, a trade secret might qualify for a patent award. The patent gives the owner the exclusive right to use his or her invention for a limited period of time. But not all information that is valuable in a market system is eligible for patent protection. Certain

secrets such as marketing methods, pricing for mulae, customer lists, and knowledge about supply chains unknown to competitors constitute valuable information that cannot be patented because it does not come within the “subject matter” of the patent system as set down by the legislature. In these instances, patenting is not an option at all. Keeping secrets is the only business option.

PROFESSIONAL MAGICIANS

It is a myth that magicians cherish their secrets and zealously guard them from prying eyes and public disclosure. Magicians are theatrical entertainers with their own associations and journals and increasingly receive academic attention and stature. If magicians were ever part of secret societies with Simmel like rituals of admission and inclusion, that is certainly no longer the case. Magicians are often erudite, scholarly, and instructive and they share their novel art in books, films, and seminars.

During the Vaudeville period in the history of the American theater, many magicians actually *patented* their major illusions. Since a patent requires that all the secrets that are necessary to the use and replication of the invention be disclosed, it is puzzling that magicians would actually patent their magicians' secrets. Of course, magicians did this not because they wanted to “keep the secret.” Instead, they wanted to monopolize the presentation of a magic illusion and have the legal right to prevent other magicians from replicating that illusion (Steinmeyer 2003: 73–113).

CONCLUSION

Secrecy is an intentional act that gives rise to many interesting social phenomena. It is consistent with individual autonomy and dynamic entrepreneurial capitalism. It is an area of sociology brought to our attention by the pioneering work of Georg Simmel and is today capable of spawning many areas of research and insightful analysis.

sect

William H. Swatos, Jr.

Although the term sect has played a role in both political sociology and the study of social movements at the hands of many Marxians as well as such early sociologists as LeBon, Sighele, Park, and Simmel, its primary continuing application has been among sociologists of religion in the context of church sect theory. The

dominance of this use has led to its virtual abandonment in other sociological subfields. In this context, a sect may be defined as a voluntary religious association whose members enter it as a result of a personal decision to join, which decision is then subject to confirmation by the existing members of the association. It contrasts with a church, whose members are said to be “born” into it, either by nationality or ongoing familial commitment.

In its many permutations and combinations as an explanation of religious organization and religiosity, church sect theory may be the most important middle range theory that the sociology of religion has to offer. It is also the case that, though termed church sect theory, a more accurate phrasing for actual usage of the construct would be sect church theory, since the preponderance of research and debate has been directed toward the sect type and changes that do or do not occur in religious organizations from sectarian origins into other sociological types.

Although the terms church and sect have a long heritage in the writings of church historians, credit for their first attachment to sociological concepts belongs to Max Weber. Their popularization among scholars of religion in the modern sense, however, was through ethicist H. Richard Niebuhr’s adaptation of the work of Weber’s sometime associate Ernst Troeltsch, himself a historical ethicist. To understand much of the debate and confusion in contemporary sociological usage, it is necessary to review how the concepts fit into Weber’s sociology of religion and how the Troeltsch–Niebuhr synthesis introduced corruptions into that use that impaired their analytical power.

WEBERIAN SOCIOLOGY AND TROELTSCHIAN ETHICS

Weber’s sociology is united by the overarching thematic element of the processes of the rationalization of action. Weber was attempting to answer the question of why the universal historical rationalization disenchantment process had come to fruition most completely in the Anglo American “spirit” of capitalism. As part of this project Weber wanted to employ an analytical method that would allow him to

maintain his commitment to the principle that sociology was a scientific discipline while dealing with historical data, wherein heretofore empathic *verstehende Soziologie* had failed to achieve conclusions that could in any way be compared to the accuracy of the experimental method. Weber’s answer was the comparative method using the tool of the ideal type: a hypothetically concrete reality, a mental construct based upon relevant empirical components, formed and explicitly delineated by the researcher to facilitate precise comparisons on specific points of interest. The conceptualizations of “church” and “sect,” like an inch in the measurement of length, serve to enable two or more religious organizations to be compared to each other. Church sect theory in Weber’s usage was not a standard *to* which religious organizations were compared but *by* which they were compared. The critical differentiating variable for Weber was “mode of membership” – whether the normal method of membership recruitment of the organization was by “birth” (church) or “decision” (sect).

In the transition from Weber to Troeltsch’s *The Social Teachings of the Christian Churches* (1912), the church sect typology underwent significant alterations. Troeltsch was not a social scientist but a theologian attempting to relate types of religious experiences with the varieties of social teachings to which they might be correlated. In doing so, he parted company with Weber’s work in two critical ways. First, he shifted the emphasis of the type from social organizational to behavioral. Second, he stressed the notion of “accommodation” or “compromise” as differentiating between the different religious styles. The first departure is most clearly seen in Troeltsch’s positing of *three* types of religious behavior: churchly, sectarian, and mystical. The third of these is now generally dropped from consideration by church sect theorists – in Weber’s work it occurs in a separate bipolar typology of behavioral orientation, namely that of asceticism mysticism. Nevertheless, the presence of the mystical type within Troeltsch’s formulation suggests that he was actually using the terms in a conceptually different operation from that to which church sect is usually put in organizational analysis. The “dichotomy” of church sect that has been attributed to Troeltsch must be understood

within both his three way scheme and the instrumental context of Weberian ideal typical method. Troeltsch shared with Weber primarily method, partially content, and peripherally project. Weber and Troeltsch were working on different, although related, questions. Troeltsch understood Weber's concept of the ideal type, capitalized on what Weber termed its "transient" nature, and hence reformulated the concepts of church, sect, and mysticism to work for his own purposes.

Subsequent church sect debates have largely been the result of an overemphasis upon the Weber–Troeltsch association that assumes that because the two men were colleagues (and even lived in the same building for a number of years) and Troeltsch used Weber's method and to some extent his content, the *intention* of Troeltsch's work was the same as Weber's, which it was not. What Troeltsch himself calls a "sociological formulation" of a theological question has been misidentified with Weber's attempt to solve a sociological problem. The difference between the two projects is clear in the critical distinguishing elements that form the focus for each one's work. Whereas Weber uses mode of membership, Troeltsch adopts accommodation or compromise. While mode of membership can be ascertained relatively directly, accommodation has a more mediated character: what is and is not accommodation is more perspectival. A theological rather than organizational – hence sociological – focus comes to frame the theory.

The basis for the shift in usage and concomitant confusion lies in the way in which the sect construct was introduced to the English speaking audience, with the corresponding void created in German scholarship as a result of the two world wars. The first major English language publication to use the types was the work of another sociologically inclined theological ethicist, Yale professor H. Richard Niebuhr's *The Social Sources of Denominationalism* (1929). Although at times possessed by a rather naïve evolutionism and narrow perspective, Niebuhr's work contributed a significant element that was lacking in earlier treatments. He used church and sect as poles of a continuum, rather than simply as discrete categories. Niebuhr did not merely classify groups in relation to their relative sect likeness or church likeness, but analyzed the dynamic process of

religious history as groups moved along this continuum. This approach found its down side, however, in that taken by itself it tended toward the reification of the types and the hypothetical continuum that he posited. It thus contained powerful seeds for church sect theory to grow into an evaluative device, quite outside the "value free" comparative sociological frame of reference in which it was conceived. Sect to church modeling not only turned the word order around, it also turned church sect theory from an analytical device to a quasi ethical evaluation. This disjuncture was compounded by the fact that Troeltsch's *Social Teachings* was translated in 1931, providing a kind of "classic" legitimation for Niebuhr's approach, whereas Weber's methodological work was not available in translation until 1949. Many of the subsequent difficulties that have attended church sect theory can be traced to the strange movements of this framework and its methodological base across the Atlantic.

ELABORATION, REACTION, AND REVISION

Subsequent elaborations of church sect theory have been clearly dependent upon the work of Troeltsch via Niebuhr. The original church sect dichotomy became generally interpreted as a continuum having a multicriteria basis for its analyses.

Howard Becker was the first American trained as a sociologist to use and extend church sect theory. Attempting to facilitate increased specificity, Becker delineated two types within each of the original two types, resulting in a cult sect denomination ecclesia model. In thus developing the typology, Becker abandoned the ideal type method for that of "abstract collectivities," ideal realities rather than constructs. J. Milton Yinger in his *Religion and the Struggle for Power* (1946) increased the limitations for specific points along the continuum, extending Becker's four types to six: cult, sect, established sect, class church/denomination, ecclesia, and universal church – the latter most clearly evidencing the increasingly theological focus of the usage.

Yinger subsequently went further in his specification, however, by subtyping sects in terms

of their relationship to the social order – whether they were accepting, avoiding, or aggressive. This development began a wave of interest in the sect type within church sect theorizing, with numerous writers offering contributions on the best way of treating this possibility, the most lasting of which is Bryan Wilson's "An Analysis of Sect Development" (1959). The results of this strategy were, on the one hand, to shift the focus of church sect theory away from *both* comparative and evaluative analyses toward a classificatory system of the bases and outcomes of religious organizational development in the wake of social systemic variables; and on the other hand, it invited a focus on religious movements that were relatively marginal to mainstream society, hence prepared the way for the emergence of the subfield within the sociology of religion known as New Religious Movements (NRMs) beginning in the 1970s.

An exception to this general tendency to focus on societally marginal religious organizations (first "sects," later "cults") was the publication in the *British Journal of Sociology* of a seminal essay by David Martin in 1962 simply titled "The Denomination." Although it did little to stem the tide of interest in marginal groups at the time, Martin's article would bear fruit in various ways in new typological formulations that appeared in the late 1970s. The action sociology models of both Roy Wallis and William H. Swatos, Jr., as well as the rational choice models of Rodney Stark and his colleagues, emphasize the importance of denominational religiosity as the typological alternative to sectarianism (and cultic forms).

On the heels of these developments also came criticism of the framework. A number of critics denounced the orientation as meaningless or, at best, woefully inadequate to systematic investigation of the empirical world. Church sect theorizing has been criticized as ambiguous and vague, lacking precise definitions, unsuited to tests for validity and reliability, merely descriptive rather than explanatory, less informative than other possible approaches, historically and geographically restricted, and unrelated to the rest of sociological theory. Despite all of these criticisms, however, the theoretical framework into which church sect has evolved has allowed a tremendous amount of data to be organized and reported.

In response to these criticisms, a number of scholars made revisions within the church sect framework, making it a more viable theoretical orientation for the sociological study of religion. Yinger, Wallis, Swatos, Paul Gustafson, and Roland Robertson, for example, have each suggested the value of an explicit visual scheme for modeling and analyses. Wilson, whose work on sects spanned over 40 years, came increasingly to accept a Weberian approach and was among the first to attempt to take aspects of sect analysis outside the orbit of Western religions and societies in his *Magic and the Millennium* (1973). Stark and colleagues have reached back into earlier empirical work by Glock and Stark to use pieces of church sect theorizing in their "rational choice" modeling, demonstrating that it is possible to tie the framework to large data sets.

NEO WEBERIAN ANALYSES

Particularly significant to the process of rethinking church sect theory was the work of Benton Johnson. As early as 1957, Johnson critiqued the Troeltschian approach to church sect. In subsequent work, he returned to Weber – not directly to Weber's discussion of church sect, but to his distinction between emissary and exemplary prophets. From this perspective, Johnson focuses upon the single universal variable property of a group's relationship to the social environment in which it exists. "Church" is employed as the polar type of *acceptance* of the social environment, whereas "sect" is the polar type of its *rejection*. Wilson thereafter also embraced "response to the world" as the principal basis for classification of sects in an ideal typical (rather than taxonomic) way. Johnson contends that the sociologist should strive toward the discovery of universal properties at a high level of generality that vary in such ways that typologies might be constructed. He sees "acceptance/rejection of the social environment" as a single variable around which empirical church sect distinctions may be grouped and asserts that this typological approach is superior to one that simply adds "types" as historical circumstances alter. These are in fact not types at all, in the Weberian sense, but categories. Johnson's work has significantly affected such

differing streams as Swatos's situationalism and the rational choice modeling of Stark and his colleagues.

Although Johnson's distinction possesses enormous advantages in terms of conceptual parsimony, its lack of integration of the historical differences in the various sociocultural systems in which religious organizations function produces potential difficulties in macrosociological analyses. Whereas the microsociologically based rational choice model focuses primarily on the effects of the organizational experience of the decision maker and only secondarily on the organization system component, a more culturally oriented analysis would note that different system contexts produce different styles of organizational response that cannot be entirely comprehended by a single universal variable component. Thus, Swatos cross cuts Johnson's acceptance-rejection dichotomy with the sociocultural system polarity of monopolism-pluralism. Following on the work of David Little, Swatos contends that the nature of the sociocultural system shapes the patterns of acceptance and rejection that become expressed in specific religious organizational forms and rationales. In related work, following leads from Martin and Wallis, Swatos has criticized the use of "cult" in Stark's church sect modeling; Swatos argues that from the Weberian point of view out of which church sect theorizing sprang, "cult" is properly contrasted to "order" as polar organizational manifestations of the mysticism-asceticism typology, rather than incorporated into church sect theory. Cults in turn have charismatic leaders, while orders have virtuosos. Patricia Wittberg's analysis of the dramatic decline of Roman Catholic religious orders in the western societies during the second half of the twentieth century, *The Rise and Fall of Catholic Religious Orders* (1994), particularly illustrates the appropriate use of the order/virtuoso combination and then deploys it within an explanatory structure that suggests the sociosystemic characteristics that lead not only to that decline but also to the corresponding rise of charismatic types of religious experiences and organizations.

Building on these foundations, Michael York's study of New Age and neopagan movements, *The Emerging Network* (1995), demonstrates the continued value of church sect

typologizing as a conceptual tool within a larger analytical framework through which these phenomena may also be studied profitably. The concept of *network* which York introduces in his work has been further elaborated by Hizuru Miki in a church sect schema as a polar type to *organization*. These advances facilitate both cross cultural comparisons and the analysis of both new religious movements and quasi religions, some of which have heretofore been treated under the now ideologically loaded concept of cult. Thus, church sect theorizing continues to be a part of ongoing sociological scholarship, well beyond its initial foundations, but also more closely linked in analytical style to those foundations than it was in the period from the 1930s to the 1970s.

secularization

Karel Dobbelaere

Secularization is a term used by sociologists to refer to a process by which the overarching and transcendent religious system of old is reduced in modern functionally differentiated societies to a subsystem alongside other subsystems, losing in this process its overarching claims over these other subsystems. This is the original meaning, but this process has consequences for the organizational and individual levels, which suggests that secularization needs to be analyzed on the societal (macro), the organizational (meso), and the individual (micro) levels.

The concept was introduced by Longueville in the negotiations that led to the Peace of Westphalia in 1648 when he used the term *séculariser* to describe the change in statute of certain ecclesiastical territories that were being added to Brandenburg as compensation for its territorial losses. The emergence of the term is linked to the notion *secularis* that had already been in use for centuries, not only to distinguish the secular from the sacred, but also especially to indicate the former's subordination to and dependence on the latter. However, the connotation associated with the term secularization has reversed this relationship: it expresses the advancing "emancipation" of the secular from the sacred. For the religious, however, it means rather the "confinement" of the religious to the religious sphere. The concept has a long history (which will not be analyzed here), and many authors have emphasized that it has always retained the ambiguous and consequently controversial meaning that it had from the start.

If the founding fathers rarely used the term, concepts and views related to theories of secularization were nonetheless canvassed, e.g., generalization and differentiation (Durkheim), and Weber (1920) used the term to typify the way in which, in the United States, membership in distinguished clubs and fraternal societies replaced membership of sects in guaranteeing moral rectitude and creditworthiness. Later generations of sociologists continued to employ the term, but attached different meanings to it (Shiner 1967). Not until the late 1960s and 1970s were several theories of secularization developed, most prominently by Berger (1967), Luckmann (1967), Wilson (1976), and Martin (1978). These theories subsequently led to discussions concerning their reliability and validity (e.g., Hammond 1985). In similar vein, others have suggested an alternative, i.e., rational choice theory (Young 1997), to explain the religious situation in the US, which they considered to be radically different from that of Europe, where secularization theory emerged. Finally, Tschannen and Dobbelaere have systematically analyzed the existing theories, since some discussions failed to scrutinize the ideas, levels of analysis, and arguments of those being criticized. Tschannen (1992) has suggested treating secularization theories as a paradigm and has described different "exemplars," or shared examples, typical of the paradigm. Dobbelaere (2002 [1981]) has stressed the need to differentiate the different levels of analysis one from another, suggesting convergences and divergences between existing theories. To describe the core of secularization theory, the different exemplars will be discussed here according to the levels of analysis.

THE MACRO LEVEL: SOCIETAL SECULARIZATION

Modern societies are primarily differentiated along functional lines that overlay the prior forms of segmentary and social class differentiation, and have developed different subsystems (e.g., economy, polity, science, family, and education). These subsystems are similar in the sense that society has equal need of them all, but dissimilar since each performs its own particular function (production and distribution of

goods and services; taking binding decisions; production of valid knowledge; procreation and mutual support; and teaching). Their functional autonomy depends of course on their communication with other functional systems and the environment. To guarantee these functions and to communicate with their environment, organizations (enterprises; political parties; research centers and academies; families; schools and universities) have been established (the meso level). Each of these organizations functions on the basis of its own medium (money; power; truth; love; information and know how) and according to the values of its subsystem and its specific norms.

Regarding religion, these organizations affirm their autonomy and reject religiously prescribed rules, i.e., the *autonomization* of the subsystems – e.g., the emancipation of education from ecclesiastical authority; the separation of church and state; the rejection of church prescriptions about birth control, abortion, and euthanasia; the decline of religious content in literature and arts; and the development of science as an autonomous secular perspective. Consequently, the religious influence is increasingly confined to the religious subsystem itself. Thus, the sociological explanation of societal secularization starts with the process of functional differentiation and the autonomization of the so called secular subsystems; as a consequence, religion becomes a subsystem alongside other subsystems, losing in this process its over arching claims over those other subsystems. On the global level, one could of course point to countries that are not secularized because “church and state” are not functionally differentiated – Iran, for example. But as Pace (1998) has pointed out, this is not typical of all Muslim countries; there are many where politics progressively asserts itself to form an independent sphere of action, which is the start of the secularization of these countries. In fact, societal secularization is only the particularization of the general process of functional differentiation in the religious subsystem and is a purely descriptive concept.

Berger and Luckmann stressed a consequence of the process of functional differentiation and the autonomization of the secular spheres, to wit, the *privatization of religion*. According to Luckmann (1967), the validity of

religious norms became restricted to its proper sphere, i.e., that of private life. Berger (1967) stressed the functionality of this for the maintenance of the highly rationalized order of modern economic and political institutions, the so called *public sphere*. This dichotomy, private/public, carries with it at least two shortcomings. First of all, it suggests that secularization was limited to the so called public sphere, which is incorrect: family life has also been secularized. This became very clear in the reactions of lay Catholics who objected to the rules enunciated in the papal encyclical *Humanae Vitae* (1968). Married couples rejected the claim of the church to define the goals of the family and to dictate the acceptable means by which these goals might be achieved. In other words, they defended the functional differentiation of family and religion. Secondly, it is the adoption in sociological discourse of ideological concepts used by liberals and socialists in the nineteenth century to legitimize functional differentiation and the autonomization of so called secular institutions: “religion is a private matter.”

It is clear that the private/public dichotomy is not a structural aspect of society. It is not a societal subsystem with institutionalized roles (professional versus public), as, for example, is the case in the economy (producers versus consumers), the educational system (teachers versus students), the polity (politicians versus voters), and the judicial system (magistrates and lawyers versus clients). It is, rather, a legitimizing conceptualization of the secular world, an ideological pair used in conflicts between opponents. For example, to defend their political, religious, or family options against possible sanctions and eventual dismissal by the management of Christian organizations, e.g., schools or hospitals, employees used this dichotomy if they failed to behave according to ecclesiastical rules in matters of family life, politics, or religion. They defended their private options, their private life, in what the managers of ecclesiastical organizations called the public sphere, since, according to the managers, these private options were publicly known. The outcome of such conflicts in court was that managers had to accept employees’ right to privacy. Of course, sociologists should study the use of this dichotomy in social discourse and conflicts, to analyze its strategic application by groups wanting to promote or to

retard the secularization of the social system. The private/public dichotomy is not a sociological conceptualization. In sociological discourse, this ideological pair might better be replaced by Habermas's (1982) conceptual dichotomy: system versus life world, used in a purely descriptive sense.

HOW ARE FUNCTIONALLY DIFFERENTIATED SOCIETIES INTEGRATED?

Pluralization, or the segmentary differentiation of the subsystem religion, was only possible, according to Parsons (1967), once the Christian ethic was institutionalized in the so called secular world: in other words, once the Christian ethic became *generalized*. Consequently, pluralization may not be considered an indicator of secularization – quite the contrary. However, the relationship is not unidirectional, since a growing pluralization may augment the necessity of generalization. Indeed, together with Bellah (1967), Parsons stressed the need for a civil religion which, to legitimize the system, overarches conventional religions. Martin (1978) suggests that when religion adapts to every status group through every variety of pulling sectarianism, then there is a need to preserve the unity of the nation by a national myth which represents a common denominator of all faiths: one nation under God. Indeed, civil religion generalizes the different notions of God present in the various denominations: the God of the Jews, Catholics, Unitarians, Calvinists, and so forth. National myths sacralize their prophets, martyrs, and historical places: they have their ritualistic expressions and may also use biblical archetypes (Bellah 1967). Such myths and legitimations are not always religious: civil religion is one possibility; there are also secular myths, such as the French myth based on *laïcité*, which legitimizes the French state, its schools and laws. One may also consider the need for secular laws overarching divergent, religiously inspired mores in religiously divided states.

How might the emergence of such a myth – religious or secular – be explained? Fenn (1978) has suggested that this is possible only when a society conceives of itself as a “nation,” as

“really real” – typical examples are the US, Japan, and France. On the other hand, the myth is rather seen as a cultural “fiction” to the extent that a society views itself as an arena for conflicting and cooperative activities of various classes, groups, corporation, and organizations. What explains the emergence of a “religious” rather than a “secular” myth, or vice versa, and what accounts for the secularization of a religious myth? For example, the “religious” civil religion of France, “la fille aînée de l'Église,” was progressively secularized after the French Revolution and anchored in *laïcité*. Another issue for inquiry is how and to what extent in certain countries a conventional religion may function as a civil religion in a religiously pluralistic society, and at what price, e.g., Anglicanism in England, Lutheranism in the Scandinavian countries, and Calvinism in the Netherlands. What degree of pluralism is congruent with a church fulfilling the role of civil religion?

Not all sociologists suggest that modern societies are integrated by common values, a point long since made by Durkheim. In a functionally differentiated society, the grip of the total societal system on the subsystems has changed, argues Luhmann (1977). A subsystem belongs to a societal system not because it is guided in its structural choices by requirements, values, and norms that apply to *all* subsystems. Integration is mediated by the fact that all subsystems are an inner societal environment for one another, they have to mutually accept one another's functions – which does not preclude “performances,” i.e., that a given subsystem intervenes in another subsystem if this subsystem is unable to solve some of its problems, as long as the intervening subsystem applies the values and norms of the subsystem in which it is intervening. Secondly, they have to prevent their own operations from producing insoluble problems in other subsystems, hence church leaders should not intervene in political elections by giving guidance to their flock about how to vote, since this would diminish the degree of functional differentiation. If such interventions are still acceptable in some countries, which was the case up to the 1980s in the Republic of Ireland and in Belgium until the 1950s, this would indicate a limitation of the differentiation of church and polity, and ipso

facto a lesser degree of secularization. However, the system cannot prevent private individuals from failing to differentiate some functions and, for example, voting according to their religious beliefs or choosing a school for their children appropriate to their religious views. A structural equivalent is, therefore, according to Luhmann (1977), built into the system to prevent the dedifferentiation of the system: the "Privatisierung des Entscheidens" (the individualization of decisions), which may cancel out some individual combinations by other combinations owing to the law of great numbers. This means that our societies function according to the principle of the *individualization* of decisions and actions, which implies that this principle is a *structural* component of modern societies. Publicity campaigns by industrial firms and political parties point to the individualization of decisions.

THE MESO LEVEL: ORGANIZATIONAL SECULARIZATION

The autonomization of the so called secular sub systems allowed the development of *functional rationality* within organizations. The economy lost its religious ethos (Weber). Goals and means were evaluated on a cost efficiency basis. This typical attitude implying observation, evaluation, calculation, and planning – which is based on a belief that the world is indeed calculable, controllable, and predictable – is not limited to the economic system. The political system was also rationalized, leaving little room for traditional and charismatic authority, as modern states developed their rational administration. Since these economic and political organizations needed ever greater numbers of people trained in science and rational techniques, the educational curriculum had to change. A scientific approach to the world and the teaching of technical knowledge increasingly replaced a religious literary formation. The development of scientifically based techniques also had its impact on the life world: domestic tasks became increasingly mechanized and computerized. Even the most intimate human behavior, sexuality, became governed by it. This is also the case with the so called *natural* method of birth control

proposed by the Catholic Church. It is based on the basal temperature of the woman registered when waking, which has to be plotted on a chart. On the basis of the temperature curve, the fertile and infertile periods can be calculated. Thus, it was on the basis of observation, calculation, and evaluation that sexual intercourse could be planned to prevent pregnancy. Another example in the field of sexuality was the Masters and Johnson research to "enhance" sexual pleasure. It was based on experimentation with couples and involved observation, calculation, and evaluation, by which means the researchers sought to produce guidelines to ensure and augment sexual pleasure: sexuality became a technique that could be improved by better performances according to the published "technical rules." The consequences of such developments were the *disenchantment* of the world and the *societalization* of the subsystems.

First, the disenchantment of the world. The growing propensity to consider the natural, material, social, and psychological world and the human body as calculable and human made, the result of controlled planning (e.g., in vitro fertilization and plastic surgery), engendered not only new roles but also new, basically rational and critical attitudes and a new cognition. Theses were replaced by hypotheses, the Bible by the encyclopedia, revelation by knowledge. According to Acquaviva (1979), this new cognition has been objectified in a new language that changed the image of reality, thus eliminating "pre logical," including religious, concepts. The mass media, using this new language, have radicalized this development and made it a social phenomenon. This suggests a possible impact of these changes on the micro level, i.e., the consciousness of the individual. Having internalized this new language, which produced a certain vision of the world, people may to some extent have lost the vision of a sacred reality. For example, when artificial insemination is discussed on television, technical interventions produce life and the issue is debated in a secular, technical language, reducing life's sacredness.

Second, it is in the systemic relations that societalization occurs, and these relationships became secondary: formal, segmented, utilitarian. By contrast, in the life world – family, friends, and social networks – primary relations

are still the binding force, they are personal, total, sympathetic, trustful, and considerate. The trend toward societalization or *Vergesellschaftung* is very clear in the distribution sector: neighborhood stores are increasingly replaced by large department stores, where interactions between customers and employees are limited to short, informative questions and exchanges of money for goods. Economic production developed large scale economic organizations in which Taylorism, which is based on the specialization of tasks and the elimination of unnecessary movement, was extensively applied. This innovation led to the development of the assembly line. The organized world is based on impersonal role relationships, the coordination of skills, and essentially formal and contractual patterns of behavior, in which personal virtue, as distinguished from role obligations, is of small consequence (Wilson 1982). In such systems, control is no longer based on morals and religion but has become impersonal, a matter of routine techniques and unknown officials – legal, technical, mechanized, computerized, and electronic – for example, speed control by unmanned cameras and video control in department stores. Thus religion has lost one of its important latent functions: as long as control was interpersonal, it was founded on religiously based mores and substantive values. In Wilson's view, there is another argument to explain why secularization is a concomitant of societalization: since religion offers redemption, which is personal, total, an indivisible ultimate that is not susceptible to rational techniques or cost efficiency criteria, it has to be offered in a "community" (Wilson 1976), and the *Vergesellschaftung* has destroyed communal life.

RELIGION ON THE MESO LEVEL

How did the organizations within the religious subsystem react to the secularization of the subsystems? The scientific approach to the world and the teaching of technical knowledge that replaced a religious literary formation in the schools distressed, for example, the leaders of the Seventh Day Adventist Church, who stimulated the expansion of their own religiously oriented educational network. In the Christian world, especially in the Catholic world, the

secularization of state schools, culture, and social life gave rise to the process of pillarization at the end of the nineteenth century. This was a deliberate attempt by the church to recover as much as possible of what was lost by secularization. It emerged in a context in which a separation was progressively being made – not only in principle but also structurally – between religion and other functional spheres, and to the extent that non Christians became a "fact," i.e., acquired real power to implement their secular views. The procedure for such recovery was the establishment of a multiplicity of organizations in which Catholics, *casu quo* Protestants, could be insulated from the secular environment – e.g., schools and universities, hospitals, old people's homes, youth and adult movements, cultural associations, sports clubs, mass media, trade unions, health insurance funds, and political parties. Pillarization was a defensive reaction and a typical process of segmented differentiation.

The emergence of new religious movements (NRMs) is related to the process of globalization and intercontinental mobility, and to the secularization that undermined the credibility of the "Christian collective consciousness." Pluralism had undermined its "objectivity," and the slowly perceived lack of impact of Christian religions on the societal level, expressed in the loss of its representatives' status and power, allowed exotic religions to improve their position on the religious market. Some NRMs, such as the Unification Church, the Family, and ISCON, wanted to resacralize the world and its institutions by bringing God back into the different groups operating in different subsystems such as the family, the economy, and even the polity. Wallis (1984) has called these "world rejecting new religions." However, the vast majority are of another type, "world affirming." They offer their members esoteric means for attaining immediate and automatic assertiveness, heightened spirituality, recovery, success, and a clear mind, e.g., Mahikari provides an "omitama" or amulet; transcendental meditation (TM) a personal mantra for meditation; Scientology auditing with an e meter; human potential movements offer therapies, encounter groups, or alternative health and spiritual centers.

Luckmann (1990) suggested that in many NRMs, the level of transcendence was lowered and has become "*this worldly*" or *mundane*. The

historical religions, to the contrary, are examples of "great transcendences," referring to something other than everyday reality, notwithstanding the fact that they were also involved in mundane or "this worldly" affairs. However, the reference was always transcendental, e.g., the incantations for healing, for success in examinations or work, or for "*une âme sœur*." Most world affirming NRMs appear to reach *only* the level of "intermediate transcendences." They bridge time and space and promote intersubjective communication, but remain at the immanent level of everyday reality. Consequently, some, like TM, claim to be spiritual rather than religious movements. Whether we call NRMs spiritual or religious is not important, what matters is that we register a change: the ultimate has become "this worldly." If one were to employ a substantive definition of religion, referring to transcendent beliefs and practices, to the super natural, many NRMs would not be considered as religions. Even when we use a functional definition of religion, we may come to the same conclusion. Luhmann (1977) stated that the problem of simultaneity of indefiniteness and certainty is the typical function of religion. Indeed, most of these world affirming new religions are not concerned with the problems of *simultaneity* of transcendence and immanence since they focus only on the immanent, on everyday life, on the secular. They have adapted to the secular world.

These mundane orientations of religion are not new. Berger (1967) and Luckmann (1967) have suggested that the higher church attendance in America compared to Europe might be explained by the mundane orientation of religion in America. Luckmann called it internal secularization, a radical inner change in American church religion: the secular ideas of the American Dream pervade church religion today. In asserting that American churches were themselves becoming highly secularized, these authors sought to reconcile empirical findings at the individual level, i.e., church attendance, which appeared to conflict with secularization theories, by pointing out changes at the organizational level, i.e., within the churches. The point of interest for our argument is that the idea of organizational secularization is not new: the concept of internal secularization was its predecessor.

SECULARIZATION AND LAICIZATION

The processes of societal and organizational secularization may be the consequence of a latent and/or a manifest process. In Belgium, pillarization was a reaction against a manifest policy, starting in the second part of the nineteenth century, by the radical liberal faction and, later, supported by the socialists to subvert the Catholic Church's control in matters of education, culture, and charity. This *manifest* process of secularization is called *laicization*. France is a very good example of the laicization of schools, and the 2005 law prohibiting ostentatious religious signs in state schools underlines this. Marx, Lenin, and the Marxist parties also propounded a deliberate policy of laicization of the state. According to Marx, the state that presupposes religion is not yet a real and genuine state, and even in his first articles in the *Rheinische Zeitung* he upheld the autonomy of politics. This position was later affirmed by Lenin and implemented in the USSR with the January 1918 decree on the separation of church from state and school from church. Other examples of the "logic of laicization," most typical of Catholic European societies, may be found in Champion (1993). In Belgium and the Netherlands, recent governments have laicized laws on life and death by legalizing abortion and depenalizing euthanasia, and they have extended marriage to homosexual couples, changing, according to a religious view, a so called God given law. These examples also clearly indicate that secularization is not a mechanical, evolutionary process but a consequence of divergent definitions, the outcome of which is dependent upon the balance of power. Such manifest conflicts do not occur only on the national level but may be situated on the city level and linked to so called secular issues such as homelessness and black neighborhood development, as pointed out in a study by Demerath and Williams (1992).

However, secularization may also be the result of a *latent* process. The secularization of the medical subsystem was a consequence of the development of medical science and professionalization: medical rationality reduced the place of religion. Even in Catholic hospitals, the organizational structure is based on medical specialisms and the development of administrative rationality, which marginalized religion

and, in the second half of the twentieth century, confined it to a small optional service – the chaplaincy. In Catholic schools, the professionalization of teachers stressed the scientific approach of the so called profane branches and reduced religion to a specific class, taught by a special teacher: it became one class among others. These are examples of a latent process of secularization: the secularization of Catholic hospitals and schools was the manifest purpose neither of medical doctors nor of teachers.

It is not only professionals who may secularize the world, as is evident from a study undertaken by Voyé (1998) on Christmas decorations in a Walloon village in Belgium. Isambert (1982) underscored the slide from the scriptural and liturgical basis of the nativity, which is oriented toward the incarnation and redemption, toward the Christ child. Indeed, the Christ child is placed at the center of familial Christmas celebrations and also in the decorations displayed by the city authorities. In this Walloon village, however, the decorations evoke a further sliding away: signboards several meters square, erected on lawns in front of houses and illuminated at night, represented Walt Disney cartoon characters. Here, Christmas is not only child oriented but, as Voyé rightfully underscores, with the Disney characters we are no longer in the realms of history but in a fairytale, peopled with fictive beings. These decorations convey implicitly the idea that Christmas is a marvelous fairytale, far removed from the original incarnation–redemption idea that the religious message of Christmas carries. By putting up these decorations, people latently secularize the Christian message.

THE MICRO LEVEL: INDIVIDUAL SECULARIZATION AND COMPARTMENTALIZATION

Luhmann's contention that the social structure is secularized but not the individual is controversial. Most sociologists will not challenge the first part, although some will question the second part. Berger, Davie, Martin, and Stark point out the religious fever in the United States, which is contested by other sociologists (e.g., Demerath 2001), and in the world, and

they reject the universal pattern of individual secularization, while accepting that Europe is to a large extent secularized on the micro level. For this reason they call Europe the exception, although Davie (2002) relativizes this by highlighting the persistence of religious beliefs and "religious sensitivity," and by referring to what she calls "vicarious religion": people drawing on religious capital at crucial times in their individual or collective lives, e.g., for the celebration of rites of passage. Her interpretation is based on data from the European Values Study referring, among other indicators, to belief in God. However, it may be remarked that the content of belief in God has greatly changed: the number of people believing in a "personal God" is shrinking and is replaced by a growing number of agnostics and persons believing in "a spirit or life force." Although sociological research in Belgium shows that a certain percentage of the unchurched still pray and define themselves as religious, a more detailed analysis reveals that, among those who have been at least two generations unchurched, fewer people define themselves as religious and fewer maintain a private practice than among the first generation unchurched. Does this not suggest that it is difficult to remain religious the longer one is severed from a religious congregation?

Recent qualitative research in Belgium has also revealed that for those unchurched persons and marginal church members who still ask for a religious rite of passage, the meaning of these rites has changed: it expresses for them more of a cultural and family tradition than a religious one. Hiernaux and Voyé led a study of Catholics in French speaking Belgium who intended to have a religious burial. The study revealed important changes. When Latin was used in ritual and hymns, the priest had the central role and used standardized formulae, which he knew and understood, creating a distance between daily life and the afterlife. Formerly, the ritual was centered on the life to come and the mystery surrounding it, whereas now the ritual centered upon the deceased: his life, loves, friendships, and accomplishments: the texts read and the songs and music played were chosen by the family with reference to the deceased. If religious texts and hymns were used, they were chosen to express the qualities of the deceased

and not because they refer to God. Quite often God was not brought in except in the rare sacramental words pronounced by the priest (Voyé 1998). Studying the motivations of the unchurched and marginal church members who had their children baptized, it was found that both the cultural tradition of the country and familial tradition were important elements in the motivation. By being baptized, the children would later be socialized in the basic values of their culture during the catechism preceding their first and solemn communion, and this was considered by parents to be important in giving their children a "good start." The evaluation of religious changes at the individual level as secularization is in fact based on a substantive definition of religion in reference to institutionalized religion. Researchers who question individual secularization use terms like religious sensitivity, spirituality, religious metamorphoses, or the changing contours of religious matters (for a discussion see Beckford 2003). On the micro level, secularization is here defined as declining religiosity and a change in motivation in the use of religious rites: from a traditional religious reference to a secularly motivated use.

How is such a decline in religiosity to be explained? There are no comparative studies between countries that allow us to link the mean degree of individual secularization to the level of societal secularization in these countries (Dobbelaere 2002 [1981]). Several other factors also play a role, including individualization as a *structural* component of modern societies, and migration and the mass media, which bring individuals in contact with other religions and undermine the taken for granted certainties of their own religion. Studies in the western world have highlighted religious bricolage resulting from individuals shopping on the religious market, as on other markets, and building their own meaning system (Dobbelaere et al. 2003). Pace (1998) has pointed out that in Muslim countries the conflict between country and city – the latter having created new social classes with different attitudes to religious traditions and a greater willingness to accept new choices and values – and emigration, which has affected the religion not only of emigrants but also of those who stay behind, as they compare themselves with their emigrated children, relatives, or friends, have had an impact on individual secularization.

However, on the micro level, secularization could also be defined as "*secularization of mind*" or *compartmentalization*: to what extent do people *think* in terms of separation of the religious subsystem and the juridical, educational, economic, family, scientific, medical, and political subsystems? In other words, do they think along the same lines as the secularized society is structured, i.e., that religion should *not* inform the so called profane subsystems, that these are autonomous and that any interference of religion in these subsystems should be eradicated and disallowed? In a study in Western and Central European countries, researchers were able to measure the degree of compartmentalization and to establish that the unchurched and members of the Protestant and Catholic churches with the lowest degree of church commitment think most in terms of compartmentalization (Billiet et al. 2003).

If researchers want to study the effect of societal secularization on individual secularization and on compartmentalization, then there should be international surveys that allow the measurement of these concepts in countries with different levels of societal secularization. Researchers should first establish the degree of societal secularization using a comprehensive *secularization index*. This will allow them to distinguish between countries according to their degree of societal secularization. Then they should be able to build an *individual secularization index* and a comprehensive *compartmentalization index*. Studying the association between societal secularization and compartmentalization, and between compartmentalization and individual secularization – defined as level of church commitment – should allow researchers to study the impact of societal changes on individual thinking and behavior.

In the United States an alternative theory to secularization, which was not considered applicable in the US context, was developed: rational choice theory (RCT). Are both theories mutually exclusive? RCT holds that a religious pluralistic situation may promote church commitment. This theory makes three important points (Young 1997). It postulates a *latent religiosity* on the demand side, which should become manifest by *active competition* between religious firms on the supply side. However, this is only possible in a *pluralistic religious situation*

where religious firms compete for customers, and to the extent that the supply side is not limited by state regulations, suppressing or subsidizing religions. Stated thus, RCT only works in states that are secularized on the societal level. State and religion should be deregulated to allow competition between religious firms; in the opposite case religious firms are "lazy," since there is no need for competition. Consequently, there is no opposition between secularization theory and RCT: both theories are complementary. Sociologists of religion should combine both theoretical approaches and integrate them (Dobbelaere 2002 [1981]).

segregation

Kristina Wolff

In 1906, W. E. B. Du Bois wrote that the “problem of the twentieth century is the problem of the Color Line” (Du Bois 1995: 42). This statement has come to represent the perpetual effects of racism in US society. It also is often used as a precursor to discussing the social phenomenon of segregation. While segregation in US society largely focuses on issues of race and ethnicity, it is more complex than this. Segregation is both the formal and informal separation of one group from another. Often this division is based on markers of difference, where race, ethnicity, gender, social class, sexual orientation, or religion is used as the foundation for justifying a split between groups and populations. The repercussions of these separations are vast, creating and supporting structural inequality within societies.

The most common form of segregation is *de facto*, which consists of divisions between groups of people in specific areas of their social lives such as in the workplace, housing, and schools. Historically, this often occurred as the result of immigration; people tend to move to where they know other people or where there is a population similar to them. The effects of this are visible today as many cities have neighborhoods that have large concentrations of people of the same ethnicity and/or religion. This type of segregation is shaped by a host of systemic influences such as nationwide discriminatory hiring policies and unfair practices in the banking, insurance, and real estate industries. Historically, these institutions practiced redlining, which determines what neighborhoods are not eligible for mortgages, loans, or other services due to their deteriorating conditions. Often these decisions were influenced by the religious, racial, ethnic, or gender characteristics of residents.

Segregation may also be *de jure* or required by law. Often these regulations determine access to public services and accommodations, housing, education, employment, and property ownership. Limits are placed on individuals’ rights to inheritance, ability to adopt children, or “who” they may marry. Examples of this

practice include “male only” jobs, the creation of the Jewish ghettos in Nazi Germany, the separation of Catholics and Protestants in Northern Ireland, miscegenation laws as well as barriers to same sex marriage in the United States. These formalized practices provide the foundation for *de facto* segregation. While some nations have eliminated *de jure* segregation, isolation and discrimination continue on informal levels.

Sociologists have focused on a variety of reasons why *de facto* segregation continues to exist in society. Conscious self segregation, such as residential segregation where groups of immigrants or lesbians and gays choose to live in the same geographical location, can foster a spirit of community while maintaining common cultural practices. However, residential segregation is heavily influenced by race/ethnicity and/or economic class. Early research, such as the work by Glazer and Moynihan, sought to understand the relationship of inequality with what they identified as ethnically organized neighborhoods in New York City (Glazer & Moynihan 1963). They concluded that as each group became more assimilated into US society, the less likely they were to face issues related to inequality. A limit to this research is Glazer and Moynihan’s treatment of people who are labeled “black” as an ethnic rather than racial group. The effects of race and racism play out differently than ethnicity in US society.

Scholarship by Wilson and by Massey and Denton represents two major debates surrounding segregation in US society. They have demonstrated that racism and classism, often perpetuated by segregation, are structural barriers to success (Massey & Denton 1993; Wilson 1987, 1991). Wilson recognizes the relationships of race and class in maintaining poverty, particularly in urban ghettos. His overarching conclusion is that due to structural economic issues such as loss of job opportunities, the flight of the middle class out of inner city neighborhoods, geographical location, and inadequate social policy reinforce segregation. Massey and Denton complement and challenge Wilson’s conclusions. While recognizing that economic opportunities and physical location contribute to the inability of the urban underclass, particularly impoverished black communities, to rise out of poverty, they demonstrate that residential

segregation is based on racial segregation. Inequality will continue as long as racism exists, creating barriers to adequate education, employment, and other services people need to have thriving communities.

Current research has shown that while society has become more integrated on some levels, inequality due to practices of segregation remains a significant factor in the areas of work, education, and health. Racial and ethnic groups, particularly blacks and Latinos/Chicanos, continue to have low high school and college graduation rates. Proportionally, they make up a larger percentage of people residing at the bottom of the economic ladder and black Americans have consistently higher mortality rates (Collins & Williams 1999; Charles 2003). This is heavily influenced by lack of access to adequate health care. Studies have also shown that residential segregation is increasing rather than decreasing.

Glazer and Moynihan's vision of integration based on assimilating into US society has not materialized due to a variety of factors including the strength of "isms," particularly racism, sexism, and heterosexism in society. Combined with classism and increasing economic disparity, social isolation is on the rise. While more whites are facing economic hardship, studies have shown that they continue to live in better neighborhoods than blacks who are at the same economic level. Research has shown that integration of neighborhoods, on race, ethnic, and economic class levels, significantly reduces crime and violence, improves academic performance and economic opportunities, and reduces bias and discriminatory practices.

seikatsu/seikatsusha

Wolfgang Seifert

Seikatsu and *seikatsusha* are expressions in colloquial Japanese as well as technical terms in the discipline of sociology. As the meaning of the words differs widely, depending on their usage, a translation into any western language is difficult, although a very basic translation of *seikatsu* would be "everyday life" and *seikatsusha* a person who pursues it. To understand the use of these terms in Japanese sociological research, one must know their historical background and intellectual context.

Seikatsu originates in classical Chinese texts and in ancient times had the meaning of "life/to live" or "existence/to exist." In modern times the word is most frequently used in the sense of "livelihood" or "everyday life," in contrast to

biological and physical aspects of life or its philosophical interpretations. Finally, the word *seikatsu* serves in an accentuated and positive sense as the fundamental category of an integrative science, developed in Japan and called *seikatsugaku* ("lifology").

Surprisingly, most Japanese encyclopedias and dictionaries of social sciences do not include the term *seikatsusha*, although its use is widespread nowadays. *Seikatsusha* also defies precise translation into a western language. Therefore, a whole range of meanings has to be kept in mind, reaching from "consumer" on the one hand to "a man, who actively organizes his own life" on the other hand. One of the rare definitions, coined in the 1970s after the first oil crisis, maintains: "*Seikatsusha* is used in the sense of an existence within which one is independent as an individual, freed from being a mere *company man*, not biased by rigid ideas of gender specific divisions of labor. A man who is concerned about global environmental problems as well as recycling, and being committed to local affairs and voluntary work" (Hamashima et al. 1997). In the early 1990s, *seikatsusha* became a fashionable word in politics and the media, but was often used without its critical implications. For instance, when the Japanese government announced its "Five Year Plan for Making Japan a Leading Nation with Regard to the Quality of Life" in 1992, it used *seikatsusha* almost synonymously with "consumer."

In addition, many words combined with *seikatsu* are used as specialist terms in sociology: *seikatsu jikan* = time use, *seikatsu kikai* = life chances (Dahrendorf), *seikatsu taido* = *Lebensführung* (Weber), *seikatsu no shitsu* = quality of life, *seikatsu sekai* = lifeworld/*Lebenswelt* (Husserl, Schütz, Habermas).

MAJOR DIMENSIONS OF SEIKATSU AND SEIKATSUSHA

In Japanese economic science the term *seikatsu* traditionally is related to consumption (*shōhi*); the consumer (*shōhisha* or *seikatsusha*) is seen in opposition to the producer. To cover theoretically and empirically the economic tasks and functions of everyday life, the subdiscipline of home economics (*kaseigaku*, *katei keizaigaku*) was developed. Furthermore, the attempt to

establish domestic science (*seikatsu kagaku*) is worth mentioning. Its subject is everyday life, basically covering all aspects of food, clothing, and housing. This interdisciplinary approach also includes sciences such as physics, chemistry, and biology.

Even before 1945 some scholars tried to separate the area of everyday life and material conditions of living from economics in order to establish it as a subject of sociological research. Kon Wajirō and sociologists who picked up his ideas rejected the understanding of *seikatsu* prevalent at the time (i.e., that everyday life was to be seen in relation to production). According to Kon, *seikatsu* is not limited to the reproduction of working power, but means the active shaping of one's conditions of life. The new interpretation of *seikatsu* led to a complete reversal of the emphasis put on life (*seikatsu*) and labor (*rôdô*) in research. The research object of the new interpretation was how people actively shaped their living conditions, such as food, clothing, and housing. Therefore, individual sources such as life histories and life documents are of prime importance for this kind of research.

Partly connected to this ethnographic approach and partly independent of it, the sociological concept of "life structure" (*seikatsu kôzô*) aims at specifically and systematically covering all spheres of the *seikatsusha*. While this concept is not yet fully established, what has to be done in research has been unanimously identified as follows: (1) research on life activities in relation to its material aspects; (2) grasping the outer shape of everyday life and its temporal and spatial structure; (3) including everyday social relations. When the Institute of Journalism and Communication Studies of Tokyo University started researching political consciousness and life consciousness (*seikatsu ishiki*) as early as 1959, the latter term covered (1) the interests in everyday life and the conditions supporting them; (2) lifestyle; and (3) consumers' consciousness. A second school in Japanese sociology that emerged around 1980 refers to the term "world of everyday life," as Schütz developed it following Husserl in his phenomenological sociology. Habermas's theorem of the *Lebenswelt* his *Theorie des kommunikativen Handelns* (Theory of Communicative Action, 1981) and its critical dimension of the "colonization of the lifeworld" were also employed.

From the early 1990s, political science started to analyze women's power in politics, partly based on Consumer Club Coops (*Seikatsu kurabu seikyō*). This new social movement and its political influence at regional levels are widely viewed as a symptom of a more mature stage of civil society in Japan.

Coping with everyday life demands a kind of pragmatist philosophy that is barely researched in academia. Intellectuals centering around the journal *Shisō no kagaku* after World War II realized the importance and potential of the "philosophy" of ordinary people, and tried to explore the thought and imagination of the common man.

INTELLECTUAL AND SOCIAL CONTEXT

Contemporary sociological research on *seikatsu* was stimulated by the three discourses on *Lebenskultur* (*seikatsu bunka*), consumer society (*shōhi shakai*), and new social movements (*shin shakai undō*).

In 1926 dramatist Kurata Hyakuzō used *seikatsusha* for the first time as an independent expression for man struggling for truth and peace of mind. In 1940 this religious coloring of *seikatsusha* was criticized by philosopher Miki Kiyoshi. Miki pointed out that the "cultural life," which had become gradually accepted in Japan after the opening of the country in 1853, was in fact western consumer culture. Miki instead advocated a "culture created by humans" – "life culture" (*seikatsu bunka*). This "ordinary culture" was rooted in the "language, food, social contacts, and customs" of Japan (i.e., in "our ancient traditions"). With this, Miki connected the idea of an "individual actively shaping his everyday life" (*seikatsusha*). Since then, Japanese intellectuals have been able to write on "low" culture or offer practical advice on coping with everyday life. Even before 1945, the architectural historian and sociologist influenced by ethnology, Kon Wajirō, began to record the everyday culture of his compatriots. According to Kon, *seikatsu* covers the four sectors of work, recreation, entertainment, and education, and therefore includes the whole of life activities. Kon related to an earlier criticism by welfare economist Kagoyama Takashi on the

restriction of those in work to their function as wage earning producers. In contrast, labor and social economist Ōkōchi Kazuo used the term *seikatsu* as the sector of reproduction of working power. He analyzed the connection between productivity and poverty, as well as reasons for fluctuations in living expenses.

Kon, on the other hand, focused on the concrete shape of everyday life and its changes in food, clothing, and housing. After 1945 he opposed the so called "modernist" theories which viewed the democratization of Japan as solely related to politics and law. He saw the range of possibilities offered by democracy in the organization of everyday life (*seikatsu no shikata*) and did not oppose the Japanese traditional lifestyle (*kurashikata*), but positively stressed its simplicity, plainness, and reason, and advocated integrating it into the changing environment of everyday life. The Japan Society for Lifology (*Nihon seikatsu gakkai*), founded in 1972, refers to Kon's concept of *seikatsujin*. Influenced by American pragmatism, after 1945 philosophers such as Kuno Osamu and Tsurumi Shunsuke felt compelled to study the "philosophy of ordinary people." In 1959 the journal *Shisō no kagaku* pointed out the importance of "nameless *seikatsusha*" (*mumei no seikatsusha*) for society. Such ideas later were integrated into the objectives of consumer cooperatives.

The discourse on the consumer society evolved in times of rapid economic growth and was started by Ōkuma Nobuyuki. As an economist, Ōkuma enhanced the appreciation of the term *seikatsusha* as early as 1940. According to him, economic sciences attributed all activities of preserving human life to the two sectors of production and consumption, while mainly focusing on matters of production. Consequently, the existence of human beings, as well, was subsumed merely under these two categories. Thus, we lost sight of our own "life activity" (*seikatsu*). Ōkuma's criticism of economic sciences was based on a new definition of *seikatsu* and *seikatsusha*: *seikatsusha* was not used as a synonym, but as a counterpart of consumer (*shōhisha*). As skepticism towards industrialism, mass production, and consumption emerged in the 1960s and 1970s, some scholars once again took up Ōkuma's concept of *seikatsu*.

In the 1960s and 1970s, political and social movements of a new type used the expression

seikatsusha in a positive sense, as well, and caused sociology and political science to broaden to some extent their analytical approach to society. The Citizens' Alliance for Peace in Vietnam (*Beheiren*) – active since 1965 – was based on a loose union of individuals, neither affiliated to political parties nor any other political organizations. Its participants considered themselves to be citizens (*shimin*) and “ordinary people” living in their personal circumstances (*seikatsu*), claiming a sphere of decision making which was autonomous from government and state. On the other hand, the new consumers' movements emerging from 1965 onwards tried to distance themselves from the previous consumers' cooperatives that had a large membership in Japan. They named themselves *Seikatsu kurabu seikyō* (literally, livelihood cooperatives; the translation “Consumers' Club Coops” slightly misses the meaning). These coops openly tried to gain political influence, to some extent succeeding in local and regional elections. In view of the globally widening gap between the rich and the poor they aimed ideologically at altering their lifestyle and organized the communal purchase of healthy food. To these, three goals were added: first, developing from a consumer (*shōhisha*) to an individual which actively shaped its everyday life (*seikatsusha*); second, establishing a political power independent from parties by freeing oneself from the conception of being an abstract national citizen (*kokumin*) by not electing representatives (*daihyōsha*) but deputies (*dairinin*); and third, connecting the “consumer” to the “productively shaping” being. Starting from this point, the political scientist Takabatake Michitoshi developed his idea of *seikatsusha citizen*. Thus, new perspectives for civil society in Japan were emphasized.

CURRENT DEVELOPMENTS

Today, research on the material circumstances (culture) of life (*seikatsu*) of the Japanese is multifaceted. Research on marketing and consumption examines the selling potential of certain products or services, as well as the behavior of the consumer. Numerous surveys are conducted on time budget and leisure behavior. On the other hand, education to conduct responsible

consumption and to strengthen the consumer's independence is attempted. Economic studies starting from the consumer's point of view are numerous.

Recently, works on the relation between social welfare and poverty that argue in favor of social politics based on economic reasoning have gained importance. The reason for this is that social cleavages have become more apparent and the problem of different life standards (*seikatsu suijun*) of different strata of society is being discussed again. New approaches to the relation of social security systems and *seikatsusha* are taken, and the relation between health and *seikatsusha* as wage earners is still being examined. Sociological works often relate to the concept of lifeworld, while many studies belong to the ethnographically influenced school of Kon. In political science and in sociology, the discourse on the perspectives for civil society in Japan is continuing. However, there seems to be a marked disillusionment with the potential of consumer goods associations, in particular the Consumers Club Coops, to change society in general (Hartmann 2003).

seken

Tomoko Kurihara

The Japanese script for *seken* combines the two Chinese characters meaning “world” (pronounced as either *yo* or *se*) with “space between” (pronounced as either *aida*, *ma*, *kan*, or *ken*). The core features of the concept are as follows. *Seken* refers to the appearance of the total network of social relations that surround an individual. It conveys the corresponding cultural norms and values that function to regulate social behavior, and hints at how such relations and behavior are maintained. *Seken* is thought to be a concept native to Japan that has existed since the seventh century. It corresponds roughly to *shakai*, the translated word for “society,” derived from the West, which came into circulation in the Meiji period (1898–1920) as western concepts, ideals, and values became popularized by politicians and intellectuals. “The public” is at times used as *seken*’s English equivalent. However, the two terms are by no means synonymous; a conceptual lacuna exists between “the public,” with its universalistic connotations, and *seken*, which, by comparison, when referring to one of its meanings – network – points rather more specifically to a social context or *aidagara*. Hamaguchi (1985) discerns how interrelations that constitute *aidagara* include encounters which are functional as well as unintentional and non transactional. Thus *seken* can be described as the sum of interrelations

as a result of the accumulation of subnetworks of *aidagara*.

A diagrammatic depiction of *seken* clearly embodies the two core features given above. The model represents the interrelations between individuals as a stratified concentric structure: the individual in the center, the people known to the individual (or friends, work colleagues, neighbors) in the adjacent ring, and people in society that the individual does not know (or strangers) in the outermost ring. *Seken* points to the body of people who fall in the mid region between the two. This model also accounts for the *breadth* of relations which surrounds the individual in everyday life; this mirrors a macro level reality that extensive networks sustain many aspects of Japanese social and economic life.

Seken is a relational term with a spatial reference, and the relation between the self and *seken* is ambiguous and precarious because the boundaries of the term are flexible, relatively arbitrary, and dependent on context. This situationally determined feature of *seken* poses three practical implications for its use. First, there is no singular or set way of identifying who – friends or strangers – fits these positions at any one time. For example, a particular individual, say, x san, might include another individual, y san, among the *seken* category on one occasion, but depending on how x san feels toward y san the following day, y san might no longer be considered *seken*. Second, the term *seken* does not necessarily correspond to a particular individual; it can also be applied, as in most cases, to refer to a group of individuals who are neither close nor other. In this way, *seken* is highly sensitive to the shifting positions of individuals within social interaction, and in *seken*, therefore, positioning is interchangeable and inconsistent. Third, the substance of *seken* can differ, dependent on sex, age, social origin, occupation, level of education, region, and marital status. The *seken* referent is therefore constituted either by the relations between these properties, each of which has its specific value, or by a single pertinent one.

Seken is a relational concept which entails a comparison between self and social norms and ideals in the context of daily practice. *Seken*’s presence regulates the thought and hence behavior of individuals which brings them in

alignment with society's standards. Japanese people on the whole take seriously the implications of deviating from *seken's* standards and they continually and minutely adjust the inconsistency arising between self and *seken*. The term *seken* is in frequent daily usage in contemporary Japan, where it can be experienced by the individual as an omnipresent force, constantly serving to judge and regulate behavior in a collectivist society. This sense is conveyed well by anthropologist Takie Sugiyama Lebra: "In parallel to the 'face' focused self, the *seken* other is equipped with its own 'eyes,' 'ears,' and 'mouth,' watching, hearing and gossiping about the self. This body metaphor contributes to the sense of immediacy and inescapability of the *seken's* presence" (Lebra 1992: 107).

As *seken* expresses a type of obligation and conformity to the group, it can be related to the dyadic concept of *tatemae* and *honme*, which mean, respectively, rules that are natural or proper, that have formed on the basis of group consensus, and, in spite of a display of conformity to the group, the individual's true intentions (see Doi 1986). *Tatemae* is also an essential technique in the presentation of the self. It is acquired by individuals through the learning and judging of social codes, thereby used to survive in society by reducing the potential for conflict. In this sense of technique *tatemae* differs from *seken*, which refers either to people or to a controlling force. Furthermore, insofar as *seken* indicates social norms which induce the conformity of individuals, the concept can be related to the western sociological and psychoanalytical notions of habitus, social fact/collective conscience, and the superego.

It is not entirely clear, even in practice, how the notion of *seken* operates: it is equally relevant to understand that the individual is somehow regulated by *seken* as much as the individual can regulate his or her own behavior in accordance to *seken's* standards. *Seken*, insofar as it can be construed as a disciplining force, can be interpreted as functioning similarly to the sociological concept of habitus (see Kurihara 2006). The concept of habitus is a "structuring structure" that shapes the practice of people at the level of the unconscious through a process of implicit pedagogy (Bourdieu 1977, 1990). Habitus is an internalized concept. The operation of

habitus and *seken* is similar in the way socially appropriate norms of conduct become internalized by individuals whereby their practice becomes shaped implicitly. Yet the difference between habitus and *seken* is that individuals are conscious of the presence and pressures of *seken* to a relatively greater extent than Pierre Bourdieu claims about habitus: *seken* seems to have a greater force of control. Furthermore, the boundary of the term habitus seems more stable than *seken*.

The concept of *seken* is often defined as being unique to Japanese society, but similar accounts of forces of control that regulate the body exist cross culturally. As discussed, it appears to fit descriptions of habitus, a French sociological concept, applied both to its provenance (Bourdieu 1984) and to Kabyle society (Bourdieu 1977, 1990). Marcel Mauss (1979 [1935]), who originally described habitus as an encultured bodily way of behaving, indeed intended the concept to apply cross culturally, and his examples of habitus were developed based around his observations of French and American society. Parallel examples of forces operating like *seken* are also found in ancient democratic Athenian society and in Victorian England. For example, Allen (2000) writes that the practice of naming and shaming, gossip, and the close scrutiny of others functioned in ancient Athens to keep people in their place. In the absence of any official punitive system possessing concrete techniques of control, order in Athenian society was produced by such discourses concerning punishment and the substance of the law. Discourse about order tended to have the desired ordering effect whereby such discourses functioned to perform an endless maintenance of distinctions, values, and meaning in society. In these examples, public opinion sanctions behavior.

Ultimately, *seken* refers to the relation between the individual and society. As *seken* regulates the behavior of individuals in relation to norms, an understanding of the way *seken* functions can be compared to the functioning of group norms and ideals outlined in Émile Durkheim's deterministic model of society, in his concept of social fact. To be precise, the relation between individual action and society is the object of theorization. For Durkheim, social facts, which consist of ways of thinking

and behaving, are coercive forces that penetrate the individual without the individual perceiving that they do. The social fact becomes part of the individual's thought and behavior in a way that transforms the individual by somehow tying him/her to the group by providing norms and ideals. By believing in the externality of social facts, Durkheim treated norms as properties of collectivities, which functioned to constrain. Combined with his view that social facts are moral phenomena, he explained how adherence to moral ideals incites action. By connecting the three spheres of morals, norms, and action, Durkheimian sociology offered an explanation for how sanctions/constraints regulate individuals' behavior.

At the level of an individual's psychic structure and processes, the psychoanalytic work of Sigmund Freud provides a comparable explanation of how *seken* regulates an individual's behavior. According to Freud's model, the repository of social norms within individuals called the superego functions by holding the individual's desires within the bounds set by society. The superego includes two subsystems: an ego ideal and conscience. The ego ideal is the child's conception of what his parents will approve; conscience is the child's conception of what his parents will condemn as morally bad. Both are assimilated by the child from examples and teachings provided by his parents. The ego ideal is learned through rewards; conscience is learned through punishments. Freud's explanation of how these social restraints become internalized to form the superego contain a European, middle class bias; however, it is possible to infer from this how the internal psychic process might work in adults when they are faced with social norms to which they should conform. In the case of *seken*, the role of the parents in Freud's model would pass on to the social body as a whole.

The theoretical proximity between *seken* and western sociological and psychological concepts – habitus, social fact, superego – would appear to illustrate the extent of commonality in the human condition. It is also clear that the concepts are by no means commensurate with one another due to inevitable cultural specificities rising from the regional scale of observation and conditions of analysis. Our understanding

of *seken* and similar phenomena would profit from a body of future research which applies in depth ethnographic methods to explore more comprehensively how *seken* works and impacts on individual daily lives in all spheres of social life.

self

Kathy Charmaz

The concept of self is simultaneously social and subjective; the self exists in social life. Common definitions of the self, however, accentuate its subjective side: all those qualities, attributes, values, feelings, and moral sentiments that a person assumes to be his or her own. The social sources of self make subjectivity possible because the person's experience of feelings, images, and interpretations emerges and takes on meaning through social interaction.

The concept of self lacks a coherent history; however, its intellectual antecedents appear throughout the history of philosophical and theological reflections about essential qualities comprising human nature and consciousness. A concept of self emerged in Renaissance European philosophy as transcending social and corporeal existence. As industrialization progressed, conceptions of the self became embedded in social life, rather than separate from it. The industrial age recast social relationships in new forms that vitiated prior assumptions. The classical theorists placed the self in society but did not explicitly theorize it. Marx theorized an inherently social conception of self without adopting a language of self. An implicitly theorized but explicitly social conception of self also emerged in Émile Durkheim's contrasting analyses of transformations wrought by the emerging industrial order.

A fundamental shift in the concept of self occurred when the early pragmatists resituated the self in ordinary experience. The pragmatists cut remaining ties to transcendental values and wove a *theoretical concept* of self from its social fabric. William James (1890) initiated a tradition of theorizing the self that has continued relevance today. He differentiated the "I," the self as subjective knower, from the "me," the object

of consciousness. James's concept of the "empirical self" developed in practical existence. For James, the number of a person's selves equaled the number of individuals who knew him or her. James contended that the self relied on its realization through experience and, moreover, brought communication into the forefront of theorizing the self. James viewed the self as inseparable from communication of its experience.

Charles Horton Cooley (1902) also emphasized communication and meanings of personal pronouns observed in everyday life. Building on James's empirical self, Cooley's concept of the "social self" brought the self into interaction. Cooley observed how children learn to distinguish between self and other, me and you, mine and yours. Moreover, Cooley brought sentiments and reflections into theorizing the self. In his concept of the "looking glass self," Cooley gave a central position to introspection and imagination: we first imagine how we appear to others; then, we imagine their judgment of our appearance, followed by "some sort of self feeling, such as pride or shame." Later textbook authors sometimes misunderstood Cooley's point here despite his emphasis that the judgment eliciting this self feeling is an "imputed sentiment," not a mechanical reflection.

George Herbert Mead (1929) criticized Cooley's introspective method as asocial and solipsistic; Mead believed that Cooley's view of self relied too heavily on biological explanations and gave too little attention to its fundamentally social nature. The criticisms of Cooley's concept of self that began with Mead continue to the present. Nonetheless, Cooley made sentiments central to the self and spawned a nascent sociology of emotions. Relationships between the self and emotions remain evident in Erving Goffman's (1956) analysis of embarrassment and mortification, Arlie Hochschild's (1983) portrayal of feeling rules and emotion management, Norman Denzin's (1987) analysis of the alcoholic self as living in a dis ease of emotions and time, and Thomas Scheff's (1990) argument that pride and shame are basic human emotions.

In the major statement of sociological theorizing of the self, George Herbert Mead (1934) advanced the most explicit theory of a socially structured reflexive self. Mead's social self is cognitive and embedded in communication. It

arises within and remains a part of interactional processes. For Mead, the self is both social process and social object. It is contingent upon “minded activity” that emanates from social existence. As we participate in social life, we learn to envision our group’s activities and to anticipate possible future actions – our own as well as other people’s. To accomplish this minded activity, we learn symbols, understand meanings, and converse with ourselves. Therefore, Mead and his intellectual descendants, Herbert Blumer and Anselm Strauss, argue that language plays a pivotal role in the development of self. Language gives us tools to view ourselves as objects for scrutiny. Through using language we invoke terms to make nuanced distinctions about ourselves as well as our worlds. We can envision, evaluate, and act toward ourselves as objects like we treat any other object. Furthermore, we mediate our responses during interaction because we can imagine the view of the other person.

Mead (1934) adopted James’s terms, the “I” and the “me,” to portray the self. The “I” is the creative part of the self that initiates action. It is spontaneous, immediate; the self enters the act without deliberation. The socialized “me” then monitors and directs the act because it assesses the “I” through a conversation with and about self. This conversation takes into account the internalized views and values of the group. Thus, the self is a social structure; it differs according to the social situation. Mead said that the situation calls forth a response from the self. More accurately, a situation calls forth *a* self because people’s varied situations lead to possessing different selves.

Mead wrested the concept of self from behaviorism. His concept of a social self counters portrayals of people as stimulus response creatures or as beings determined by social, cultural, or economic forces. Mead’s self develops in active response to what occurs around it. This response may consist of internalization, adaptation, innovation, or resistance. Much of social life is routine; however, when we reflect on new or problematic situations, we can choose how to respond, rather than react, to them. In short, Mead’s concepts of mind and self mean that we have agency: we can choose and control our actions.

Symbolic interactionist social psychology made the Meadian concept of self a cornerstone

of its perspective. As a result, symbolic interactionists kept the idea of an agentic self alive throughout mid century structural functionalist disciplinary dominance. The functionalist perspective ignored the self in favor of a static concept of roles and disregarded the interactive and interpretive features of socialization. More recently, theorizing about agency has brought interactionist conceptions of an acting, interpreting self into the mainstream of the discipline, although its pragmatist antecedents often go unrecognized (Maines 2001).

Throughout the later part of the twentieth century, Blumer’s (1969) Meadian view of the self and Goffman’s (1959) dramaturgical self sparked a vibrant dialogue about the self among symbolic interactionists and some structural social psychologists. Dramaturgical analysts view the self as constructed in action in response to concrete situations and settings in which people find themselves. Action, not individual reflection, becomes the distinguishing feature of self. Thus, dramaturgical analysts assume that what people do reveals more about their selves than what they say.

Erving Goffman (1959) observes that whenever we are in the real or imaginary presence of others, our behavior has social meaning and a promissory character. Subsequently, our actions express ourselves and give an impression of self to others, whether favorable or not. Goffman argues that people intend to bring about a certain impression of self. How we approach other people derives from the nature of the shared situation. Yet they realize that we try to make favorable impressions on others. Thus, our audience looks for cues we give off as well as what we say. Despite intentions and staged performances, social actors give off unwitting messages about self.

The dramaturgical perspective brings the occasion and its structure into theorizing the self. If the interaction order of the occasion produces selves, can the self be a unique personal possession of its holder? Might it not be a mask to cover a role? Learning the interaction order of an occasion requires only a minimal model of the actor – and self – who could behave sensibly in it.

The empirical study of the self has gained momentum over the past fifty years. Manfred H. Kuhn’s (1960) Twenty Statements Test

(TST) advanced the empirical study of the self by asking people to state how they see themselves. A major strength of the TST is that research participants give their own definitions of self without the researcher's preconceptions or suggestions imposed on them. A weakness is that the TST treats the self as stable attributes and does not take situations and processes into account.

The identity theorists have advanced connections between quantitative empirical studies and theoretical conceptions of the self. In Stryker's (1980; Stryker & Burke 2000) statement of the structural approach to identity theory, he asks how social structure affects the self and how the self affects social behavior. For identity theorists, the self is constituted by an organized set of identities (Burke 1980; Serpe 1987). Serpe's (1987) study of college freshmen supports the major premise of stability of self in identity theory and makes the significance of choice explicit. Serpe finds that identity change is expected in those identities in which choice is structurally possible. Burke (1980) not only emphasizes the relational aspect of identities, but also points out that their salience takes hierarchical form and that potential identities can motivate individuals. Burke calls for quantitative testing to measure the theoretical properties of identity, which he and Franzoi (1988) aim to do in their study of experiential situations. They used an innovative sampling method of signaling research participants with a timer to respond to a questionnaire about their direct experience, including their identities and roles. Burke and Franzoi found that how participants viewed their immediate situations shaped how they viewed themselves and, in turn, their behavior depended on how they viewed themselves.

Late twentieth century sociologists restored the self to its central place in theorizing. When using the term "self," however, they sometimes blur distinctions by reifying a single, static notion of self, rather than theorizing the multiplicity of selves and their processual nature. Following Mead, Viktor Gecas (1982) answers this problem. He distinguishes between the self as process from the self as stable structure, the self concept. Selves are built on processes; the stability of self concept is built on consistent processes; meanings about self last. Interaction processes constitute human existence. Thus the

self is continually in process. Yet human beings often display remarkable consistency of self over time. If the self is continually in process, why are selves not more mutable? People learn ways to define themselves. They take some things as mirroring their "real" selves, but do not claim their other enacted behaviors as reflecting them. Ralph Turner's (1976) notion of the self concept indicates why. Turner defines the self concept as an *organized* set of definitions of self, sentiments, values, and judgments, through which a person describes himself or herself. Enduring self concepts typically develop when people receive consistent responses from others. The self concept has boundaries, whether firm and impenetrable, or flaccid and permeable. Once a person's self has congealed into a self concept, it becomes more or less enduring.

The narrative turn of recent decades locates the self in stories people tell about themselves and how they tell them. The self becomes accomplished through active processes of self construction that entail rhetorical skills and occur within social contexts. Bjorklund (1998) shows how cultural discourse about the self speaks through autobiographies. Authors of autobiographies invoke historically and culturally situated vocabularies of the self to make sense of their lives and to present them to readers as moral performances.

Narrative analysts take literary forms as a point of departure and ask how people adopt and improvise on these forms. Thus their interests include plots, narrative coherence and logic, narrative sequence, composition of the story, and its specific content. Conversational analysts account for the production of self in the structure of ordinary conversations, but note that certain situations invite a self story and others require entitlement, negotiation, or cooperation for a story to ensue at all. They attend to the linguistic and interactional practices which make selves discernible in conversations. Both approaches foster placing primary focus on the texts in which discourse and conversation occur. Paradoxically then, these analysts may garner stories of the self produced under special conditions such as the research interview rather than those developed in everyday practices.

Most sociologists agree on the centrality of the self for understanding human existence, but views of its relative coherence and methods of

studying it remain contested. The postmodern self is tenuous, mobile, provisional, and fragmented. The self stands on shifting ground and thus shifts and becomes inconsistent, fragmented. Thus, contemporary life strips the self of its once coherent core and weakens the attachments on which this core was based. Despite its fragmented incoherence, these depictions of a postmodern self rely on a conception of society and cannot be divorced from it. Moreover, Gubrium and Holstein (1991; Holstein & Gubrium 1999) argue that if we reframe postmodern discourse and examine it empirically in everyday interpretive practices, then researchers can retrieve the concept of self for traditional sociological theory and research.

The concept of self in its many forms and varied emphases has inspired research that spans numerous substantive fields, such as occupations and professions, health and illness, aging, emotions, deviant behavior, race and ethnicity, and gender, as well as social psychology. These literatures contribute to an emphasis on development and change throughout the life course. Themes of reconstruction, development, and sometimes transformation of the adult self pervade studies of life changes, whether through experiencing losses or gains. Through these studies, sociologists have challenged assumptions of an asocial, reductionist, and static self. In sum, the self, and its attendant concepts, self image, self concept, and identity provide sharp tools to understand how, why, and when people develop, change, or retain a stable self throughout their lives.

self-concept

Scott Schieman

Sociological interest in the self concept, rooted in the early writings of Cooley and Mead, has evolved into a multifaceted quest to describe the connections between social contexts and personal functioning. In his classic work, *Conceiving the Self* (1979), Rosenberg defines the self concept as all of the thoughts and feelings that individuals maintain about the self as an object. Gecas and Burke (1995) have expanded on the definition: the self concept "is composed of various identities, attitudes, beliefs, values, motives, and experiences, along with their evaluative and affective components (e.g., self efficacy, self esteem), in terms of which individuals define themselves" (p. 42). These processes involve reflexivity and self awareness; that is, a level of consciousness or awareness about one's self that emerges from the distinctly human capacity to be an object and a subject to one's self.

A substantial core of the content of the self concept involves identities – the meanings that individuals attach to the self. Identities embody the answer to the question: "Who am I?" Often, but not always, identities are connected to the major institutionalized social roles of society such as "spouse," "parent," "worker," "student," "church member," "Muslim," and so on. In many respects, identity is the most "public" feature of the self concept because it typically describes one's place or membership in structural arrangements and social organization. At a social event, for example, individuals will ask each other about their work, their interests, their neighborhoods, and other pieces of information that typically peel back the layers of their identities. However, there may be a cost to the public nature of identities. Goffman illustrated the "spoiled identity" as socially undesirable or stigmatized aspects of the self concept. Spoiled identities contain discredited elements of the self concept that the individual is encouraged to conceal or "manage." Failure to do so often exacts social costs. Collectively, these ideas underscore the highly *social* nature of the self concept: other people have substantial influence

on the form, content, consequences, and revelation of the self concept.

Some of the most widely known research on the self concept has focused on its evaluative and affective components, especially self esteem and self efficacy. Self esteem is "the evaluation which the individual makes and customarily maintains with regard to himself or herself: it expresses an attitude of approval or disapproval toward oneself" (Rosenberg 1965: 5). Survey researchers have sought to measure self esteem with responses to statements that include: "I feel that I have a number of good qualities," "I feel that I'm a person of worth at least equal to others," "I am able to do things as well as most other people," "I take a positive attitude toward myself," and so on. By contrast, self efficacy – also referred to as the sense of mastery or personal control – involves the extent to which one feels in control of events and outcomes in everyday life. Measures of the sense of mastery ask about agreement or disagreement with statements like: "I have little control over the things that happen to me," "There is really no way I can solve some of the problems I have," "What happens to me in the future mostly depends on me," "I can do just about anything I really set my mind to," and so on. Sociologists are interested in mastery and self esteem for several reasons: because they are socially distributed, because their absence may erode well being, and because of their potential as psychosocial resources that help people avoid or manage stressors. That is, what groups have higher or lower levels of self esteem than others? How does a low sense of mastery influence psychological well being? And, do people who possess more favorable self evaluations have a different capacity to cope with the presence and consequences of stressful adversity?

The complexity of processes involving self dynamics has also provided researchers with terrain for theoretical and empirical developments about the self concept. For example, actors are often motivated to protect the self concept from external threats. In broader terms, an array of socialization forces and social structural arrangements shape the formation and content of the self concept; thus, it is a *social product*. In terms of self concept formation, the notion of personal or self investment evokes the

ideas of identity salience and the centrality of achieved statuses, such as education, for the emergence of positive self evaluations. Analyses of the structural determinants of personal qualities, especially with respect to achieved statuses and dimensions of social stratification, have a long tradition in sociology, from Marx's broad portrait of estranged labor to more specific occupational sources of alienation and powerlessness. Marx asserted that, although individuals may strive for self fulfillment, the physical quality and organization of many work environments can thwart self enhancement and lead to personal misery. Thus, Marx provides some of the earliest pieces of evidence about "structural social psychology" because he traced linkages among objective social economic conditions and the subjective, inner lives of individuals. Since then, sociologists of mental health and others have followed his efforts by documenting and describing the role of the self concept in the connections between structural strains and psychological distress. For example, a typical sequence of hypotheses about the distressing effects of poor work conditions is as follows: (1) poor work conditions elevate unfavorable self evaluations; (2) unfavorable self evaluations increase the risk for undesirable mental health outcomes; and (3) unfavorable self evaluations explain why poor work conditions increase the risk for undesirable mental health outcomes.

Building off the early sociological traditions of Marx, Cooley, and Mead, social stratification theory and research has sought to identify in detail the links between features of social structure (e.g., education, income, occupation, and work conditions) and self concepts. For example, individuals in higher status jobs with more authority and autonomy and more creative, stimulating, and challenging tasks tend to experience higher levels of self esteem and sense of mastery. Autonomous and non routine work, especially in higher status positions, reflects arrangements that contain greater chances for mobility and achievement. Such arrangements often include responsibility for vital operations that can shape the course and success of the organization. Individuals whose work has such qualities may feel more devoted to their jobs as a source of identity and feel a greater sense of

confidence, causal importance, and relevance. It may also enhance another evaluative aspect of the self concept: the sense of mattering. Individuals who feel a sense of mattering believe that their actions are acknowledged and relevant in the lives of other people. It is easy to understand the importance of mattering as a socially determined self evaluation by reflecting on the dreadful notion that one does not matter to any one or anything. Here, there are roots to other classical notions about the powerful effects of social integration versus social isolation – and their ultimate implications for the self concept.

In sum, the self concept reflects a multidimensional and complex set of processes that contain numerous overlapping parts. Sociological social psychology has sought to document and describe the ways that social contexts influence and are influenced by the self concept. Numerous domains of study of the self concept provide fertile grounds for advances in knowledge, including: the structure and organization of self conceptions; the internal dynamics of self concepts; the relationship between social structure and self conception; and the ways that self concepts influence the effects of social stressors on health and emotional well being. Long ago, Cooley and Mead laid the conceptual and theoretical groundwork for the sociological study of the self concept. More recently, Rosenberg (1992) asserted that "although the individual's view of himself may be internal, what he sees and feels when he thinks of himself is largely the product of social life" (p. 593). One of the main quests for sociological analyses of the self concept, then, continues to involve the documentation and description of the ways that fundamental sociological variables – especially those that designate one's location in the social structure – impress upon the self concept across the life course. While this "social product" side of analysis is critical, it is important to underscore the "social force" role of the self concept; that is, the ways that the self concept impresses upon social structures and arrangements.

self-control theory

Michael R. Gottfredson

Self control is a concept used by sociologists to explain differences among people in the frequency of engaging in a wide variety of acts that cause harm to others (Gottfredson & Hirschi 1990). It is defined as the tendency to avoid acts whose long term costs exceed their momentary advantages. The costs include penalties from institutions such as schools and the criminal justice system, the loss of affection from family and friends, loss of jobs and advancements in employment, and bodily injury and physical pain. Individuals with relatively high levels of self control tend to have low rates of crime, delinquency, and substance abuse because these behaviors entail potential long term costs. They tend to have relatively high rates of school and employment success and lasting interpersonal relationships.

In criminology, the concept of self control derives from the branch of sociological theories known as control theories. These theories are distinguished by the assumption that people are rational actors, seeking pleasure and avoiding pain. Basic human needs and desires are seen as fairly uniformly distributed among people (even if access to the means to satisfy these needs and desires is far from uniformly distributed). They include the desire for affection from others, material goods, and pleasurable physical and psychological experiences. In general, people pursue these wants in everyday life; controls are established by social groups (including parents, communities, and states) to channel the pursuit of these wants in ways that cause the least harm to others. Because these controls are exerted or not in the social environment, and because individuals experience different environments related to these controls, the extent to

which individuals are “free to deviate” varies. When these controls need always be present in the environment to be effective, they are often referred to as external or social controls. When the process of socialization during the early years of life establishes concern about others and the long term costs of behaviors, the form of control is referred to as self control.

The concept of self control was created to account for the fact that many delinquencies, crimes, and other problem behaviors seem to “go together” and therefore must have some thing in common. Behavioral research has consistently found that those who engage in high levels of delinquency, crime, and other social problems do not tend to specialize in the acts they commit. Interpersonal violence, stealing, drug use, accidents, and school misbehavior are commonly found in association. The acts associated with these problems all provide some immediate benefit for the actor (money, pleasure, the end of a troubling dispute), as do many other behaviors. But each also carries with it the possibility of harmful consequences to actor or to others. What is problematic for control theorists is not the idea that such acts may provide benefits to the actor, but rather that some people can disregard these benefits most of the time. Thus, self control theory is sometimes called a “restraint” theory or a theory that focuses on why people do not engage in crime and delinquency rather than why they do (Hirschi 1969). Self control theory does not focus on crime as defined by the legal system. Rather, self control theorists have argued that sociologists should create their own dependent variable for theories about crime and delinquency, drawn from empirical studies of what harmful behaviors seem to cluster together, regardless of the legal definitions present at any one time or legal system.

Self control theory is influenced by the observation that differences among people in the tendency to disregard long term costs appear to be established in childhood and, once established, tend to persist throughout life. Criminologists have long observed that the single best predictor of delinquency or crime is the prior history of delinquency or crime.

Self control theory begins with the assumption that human nature includes the general

tendency to pursue satisfaction of individual needs and desires. Left unregulated, the pursuit of these needs and desires causes inevitable conflict with others and, because of that, potentially harmful consequences to the actor. As a result, those who care about the child seek to train the child to restrict the pursuit of self interest by attending to the needs and wants of others. For self control theory, this process is what socialization entails. As the child develops, caregivers (parents, other relatives, friends and neighbors, and schools) sanction behavior harmful to others and harmful to the child. Children are taught to pay attention to the longer term consequences of their action. When a caring adult is present in the developing child’s environment, and takes an active role in socialization, high levels of self control are established and appear to become a fairly stable characteristic of the individual over the life course. But sometimes such early caregiving is not present in the child’s environment because an adult who cares about the long term interests of the child is not around or because the caregiver who is around lacks the skills necessary to create self control in the child. Furthermore, there are differences among groups and even nations in the level and duration of this socialization process. These differences are thought by control theory to produce the differences in levels of crime, violence, and other problem behaviors among individuals and communities and in different time periods.

Differences in self control are not the only cause of delinquency and crime according to this theory, but they consistently play an important role. Another feature of self control theory is a focus on the concept of opportunity as an additional cause of crime. Self control theory was influenced by developments in opportunity or routine activity theories which themselves focused attention on situational elements of crime as it typically occurs (Hindelang et al. 1978). This perspective studies the common features of delinquencies and crimes that occur, such as the times, places, and circumstances of crime, and attempts to infer how and why people interact with these features. These studies have suggested that crimes, delinquencies, and other problem behaviors do have many things in common. They seem to be overwhelmingly

opportunistic events, in the sense that they are not typically planned much in advance, but seem to happen as opportunities “present themselves.” Most often the delinquencies or crimes do not result in much gain for the offender – a little cash or stolen property, momentary excitement or fun, a temporary high, or a physical end to an argument. They tend to take place in the absence of “capable guardians” (Cohen & Felson 1979).

Self control theory assumes that differences among people in self control are also associated with the distribution of people in settings that vary in the opportunities for crime and delinquency. Thus, being among adolescent males in unsupervised settings, especially at night and in the presence of readily available drugs or alcohol, enhances opportunity for delinquency and is also a function of low self control. Similarly, persistence in school is a characteristic of those with higher levels of self control and also with reduced opportunities for delinquency. Throughout the life course, self control influences friend and family associations, employment patterns, and many other life experiences (essentially the opportunities for crime), which in turn are related to levels of crime and related behaviors.

Researchers have found self control theory to be a fruitful object of study. The theory has been applied to a wide variety of topics, ranging from white collar crime to genocide, and from motor vehicle accidents to victimization. Other research has focused on using the theory to help explain patterns in crime and delinquency, such as gender differences, peer effects, and between country variation in crime (for examples, see Britt & Gottfredson 2003; Hirschi & Gottfredson 1994). Most studies have found the measured level of self control to usefully predict the problem behavior under study. Internal to the theory, attention has focused on the proper measurement of self control, with some scholars finding attitudinal measures suitable and others preferring behavioral indicators.

Critics of self control theory have argued that the theory is merely a tautology, that it invokes an overly simplistic view of human nature, and that it is best regarded only as one form of social learning theory. Considerable debate has

centered on the assumption that, once established in early childhood, differences among people in self control are stable. Some theorists argue instead that there are important life experiences that can elevate the level of self control in adulthood, such as marriage. A persistent, but still very active, research dispute centers on the influence of peers on delinquency. Self control theory would predict that the correlation between the delinquency of an individual and the delinquency of his or her friends is due to the selection of friends and associates that is heavily influenced by self control and its determinants, whereas other perspectives argue that delinquent peers themselves cause delinquency to increase by supporting alternative norms or beliefs about the acceptability of delinquent conduct (for an excellent review of these issues, see Warr 2002).

The socialization idea in self control theory is itself subject to controversy and alternative explanations. That is, the view that people begin life similarly situated with respect to the imperative to seek self interest, and differ as adolescents largely as a consequence of differential socialization in childhood, is actively debated. Some argue that there are heritable predispositions that effect both variation in motivation for crime and amenability to socialization. Self control theory takes the position that the benefits of delinquencies and crimes are obvious and ubiquitous such that no special motivation or learning is required to explain why individuals may engage in them. Furthermore, the socialization required for self control is relatively easily achieved and is so effective that individual predispositions are likely to have minor effects in the generation of delinquency and crime. This debate will very likely shape future research and be increasingly active as techniques to establish predisposition and the studies necessary to examine the sources of self control are undertaken.

Self control theory has strong implications for public policies about delinquency and crime. Because the important causes of crime are thought to originate in early childhood, there is considerable promise in programs that focus resources for childcare among high risk populations. A body of research has been created showing that such programs do indeed

have important effects in reducing the level of delinquency and other problem behaviors and improving the life chances of children who otherwise would not benefit from self control (Greenwood 2002). On the other hand, the theory predicts that efforts to control crime by targeting adolescents or adults by policing and incarceration will be ineffective, since they inevitably come too late in the developmental process. As control theory predicts, the evidence appears to support the notion that variation in the practices of the criminal justice system has only negligible effects on individual criminal tendencies and on the crime rate over all (Gottfredson & Hirschi 2003).

self-determination

Daniele Conversi

Self-determination is a principle in international law that a people ought to be able to determine its own future and political status free from external interference. It hence embodies the right for all peoples to decide their own political, economic, and cultural development.

The principle was first implemented on European soil following the post World War I collapse of the dynastic Central European empires (Russian, Austro-Hungarian, and Ottoman). It was zealously fostered by the president of the United States, Woodrow Wilson (1856–1924), thus becoming the cornerstone for the entire post World War I order heralding the beginning of the “American century.” Accordingly, the boundaries of newly formed states had to be made congruent with “existing” ethnonational divisions. In order to achieve this goal, each self-determined unit had ideally to be conceived as an internally homogeneous entity. On the other hand, wherever possible, oppressed minorities should be granted the same right. Although the original idea was to establish a more stable world order, the effect was just the opposite, to increase European disorder, since all newly created entities included numerous minorities in their midst. The resulting convulsions became propitious for the consolidation of the United States as the hegemonic power at the global level.

Some of the new states, like Yugoslavia and Czechoslovakia (both established in 1918), lacked clear majorities. Subsequently, incipient fascist movements began to use this principle to exploit the presence of “stranded” minorities in what had suddenly become “foreign lands.” German, Italian, and Hungarian irredentists wished to apply the very Wilsonian principle of self-determination to their “unredeemed” kin minorities on strict nationality lines. They strove to reunite entire ethnic diasporas within their respective *Heimaten*.

Among other things, Woodrow Wilson’s 14 Points mandated that “the peoples of Austria-Hungary ... should be accorded the freest opportunity of autonomous development,” while the “nationalities ... under Turkish rule

should be assured an undoubted security of life and an absolutely unmolested opportunity of autonomous development." All these changes threatened to undo the tattered fabric of European and Ottoman pluri ethnic and multireligious societies, indeed, that is what they achieved.

Given the later rise of aggressive nationalism, particularly irredentism and Nazi fascism, the failure of this project was global in terms of international security, human rights, and the maintenance of peace. Like all attempts at "reordering the world" characteristic of totalitarian ideologies, it entailed tragic human costs, even though these had been largely unanticipated. However, while the Ottoman and Austro-Hungarian empires were being dissolved, Russia could save part of its territorial integrity by adopting the political praxis of Marxism-Leninism. The Constitution of the Soviet Union formally recognized the right to self-determination of its constituent Republics. This was a move initially envisioned by V. I. Lenin to capture the support of regional elites and hence assure the continuation of the "empire," although with a different name. Lenin had theorized about the need to use self-determination as an avenue to integrate the empire's nationalities into the new socialist order (Connor 1994 [1967]). But this legal principle was never fully put into practice due to the extremely centralized character of Soviet party politics.

After World War II, decolonization unleashed a second wave of self-determination claims, spreading the doctrine further. When the UN Charter was ratified in 1951, the signatories included a clause on the right of peoples to self-determination. Accordingly, all former colonies, that is, those which were already on the map prior to 1939, should be allowed to achieve sovereignty within their existing boundaries. Indeed, the doctrine of *uti possidetis* (from late Latin, "as you now possess") mandated that the states emerging from decolonization had to inherit the colonial administrative borders that existed at the time of independence. This term originally referred to a militaristic principle of international law allowing a belligerent to retain the captured territory it occupied at the termination of hostilities. In its decolonization form, the doctrine of *uti possidetis* was first applied in

Latin America in the 1820s when the Spanish empire began to crumble.

Imperial powers, emerging elites, and "realist" politicians wished to restrict the concept to existing colonial possessions and fiercely opposed its application to entire nationalities. In this way, fully fledged UN member governments could uphold the principle of "non-interference" in their internal affairs together with a strenuous defense of their state's territorial integrity. Their main rationale was provided by the supposed threat emanating from secessionist movements and epitomized by the ill-fated partition between India and Pakistan in 1947. But the major obstacle to a wider implementation of the principle was the Cold War's freeze on all conflicts beyond the logic of mutually opposed blocs. The unchallenged dogma was then that self-determination should never apply to ethnic groups or stateless nations. This consensus was only broken by the secession of Bangladesh (1971), when India succeeded in attracting the support of the international community. On the other hand, the Federation of Malaysia willingly allowed Singapore to secede in 1965. The right to self-determination is solemnly upheld by the United Nations Declaration on Human Rights (1970), the International Covenant on Economic, Social, and Cultural Rights (1966), and the International Covenant on Civil and Political Rights (1976).

A third wave of self-determination spread by the end of the Cold War, with German unification (1990), the breakup of former socialist "federations" (1990–3), and, finally, the independence of Eritrea (1993) and East Timor (1999). More recently, the concept has been used throughout the world by indigenous peoples, stateless nations, minorities, and sovereign states alike, but in a looser and more flexible way.

The principle of self-determination is rooted in British liberal thought, particularly in John Stuart Mill's idea of representative government (Connor 1994 [1967]). Mill notoriously argued that in a country which consists of several nationalities, free institutions of a representative government are "next to impossible" (Mill 1977 [1861]: 361). In this way, the door was left open for the advent of modern-day ethnic intolerance. The western liberal principle of "one nation, one state" deeply influenced Eastern European

political thought during the period of state building, just at a moment when German ethnicism and French Jacobinism were providing the inspiring models for national mobilization. Both liberals and Marxists had failed to deal with the issue of ethnic dissent because the European nation state provided the unique empirical referent for their political theories.

The principle indicates the aspiration of a group (the “self”) to freely “determine” its own political structure. But in order for the “self” to be “determined,” someone must first determine who the “self” is – or establish who are the people to be “determined.” The exercise of this right presupposes a previous process of “boundary definition” and “group recognition” (Conversi 1997). As Ivor Jennings (1956: 56) pointed out: “On the surface, it seemed reasonable: let the people decide. It was in fact ridiculous because the people cannot decide until somebody decides who are the people.” This is referred to as the concept’s paradoxical *indeterminacy* (Moore 1998). The principle remained often impossible to implement and, when attempted, it frequently led to further chaos and conflict.

The concept of self determination is often placed in opposition to that of *territorial integrity*, with which it is thought to be incompatible. However, self determination does not necessarily imply political separation, sovereignty, or secession. Many movements for national liberation, regional autonomy, and indigenous rights refer to self determination as a broad umbrella term which allows for a vast array of possibilities based on the recognition of collective rights. Calls for self determination can often be settled relatively easily with concessions of regional autonomy and/or cultural rights. Secession would work as a practical tool with high moral value if it could provide an avenue for ethnic or religious minorities to escape their persecution by dominant elites. However, the achievement of statehood through political separation does not always result in an improvement in either economic or human rights. Less drastic tools, short of independence, are available and can be implemented to address calls for self determination.

Contrary to self determination, *secession* is considered a capital sin in international politics. It is sternly resisted by states and governments

worldwide for obvious reasons. In the US its prejudicial connotation also derives from the negative myth of the Civil War, when 11 Southern states attempted to secede by forming the “Confederate States of America” (1861–5). This myth still reverberates in US foreign policy’s general hostility to secession. The initial refusal to recognize the independence of Slovenia and Croatia as they came under attack from the Yugoslav army (1991–2) and George Bush’s condemnation of Ukraine’s secessionist drive in 1990 stem both from *realpolitik* and from this anti secessionist legacy. However, this attitude was tempered by the US support for the independence of Estonia, Latvia, and Lithuania, which had been illegally annexed by the Soviet Union in 1943 as a consequence of the secret Hitler–Stalin Pact (Ribbentrop–Molotov Pact, August 23, 1939).

The right to self determination of peoples remains a cardinal principle in international law. On the one hand, denying this principle would flagrantly violate the companion principle of democracy – a contradiction disregarded in the early 1990s when the West failed to couple the two concepts as Yugoslavia disintegrated. On the other hand, the capacity of every people to take advantage of this concept is minimized by the unprecedented invasiveness of sweeping “external” forces, such as global law, consumerism, Americanization, and ecological disaster. The unbridled power of multinational companies often exceeds that of supposedly “sovereign” states. In an increasingly interdependent world, where megacorporations command greater resources than many single countries, the concept of self determination might become irrelevant for human development unless it can contain the most destructive aspects of globalization.

outcomes can also influence higher order ones. (Note that *identity* and *ideal self* are listed to acknowledge that self concept is composed of more than self esteem, but the former, and related concepts, are beyond the scope of this entry.)

Self may be defined sociologically as an organized and interactive system of thoughts, feelings, identities, and motives that (1) is born of self reflexivity and language, (2) people attribute to themselves, and (3) characterizes specific human beings. Psychologists tend to conceptualize the self as a set of cognitive representations indicating a person's personality traits, organized by linkages, across representations created by personal experience or biography. It is sometimes extended to include things besides trait attributes, such as social roles and even identities. In this case, the self is a cognitive structure incorporating such elements as intelligent, persistent, excitable, and truthful, or middle class, Jewish, female, and Canadian.

Self concept is how we imagine and perceive our self. It is inextricably tied to the "I-me" dialectic expounded by James and Mead. Self concept may be defined as the totality of an individual's thoughts and feelings about a particular object – his or her self. It includes cognition and emotion, since it is both an object of perception and reflection and an emotional response to those perceptions. As a product of its own objectification, self concept entails a particular person (i.e., subject, "knower," or

self-esteem, theories of

Timothy J. Owens

Self esteem refers to the overall positive or negative attitude an individual takes toward himself or herself. Understanding self esteem also requires awareness of related terms, especially *self* and *self concept*, along with an appreciation of their similarities and differences. Figure 1 illustrates how self, self concept, and self esteem are causally related, and the outcomes typically associated with self esteem. Although hierarchical in terms of abstractness and general causality, lower order concepts and

"I") figuratively standing outside himself or herself, and perceiving and reacting to the self as an object of consideration (i.e., object, the "known," or "me"). Accepting that the self may be both subject and object serves as the rationale for conducting studies of the self concept, and consequently self esteem.

Historically, theologians and philosophers were the first to delve into the nature of the self, that presumably quintessential characteristic of the human animal. Over the millennia, scholars have been acutely interested in such questions as: Who am *I*? What does *my* life mean? Am *I* a good person? Am *I* loved? Can *I* love? And what makes me, *me* and you, *you*? All of these questions imply a self, and self concept.

While philosophers and theologians still grapple with these questions, the bulk of contemporary research on the self is done by sociologists and psychologists. The key to the social science research perspective on the self is human reflexivity. This entails not only being able to view oneself as others might (self as object), but also labeling, categorizing, evaluating, and manipulating one's self (self as subject). Reflexivity hinges on language, whether emanating from a broader culture's written or non written language (e.g., Arabic and Ojibwe, respectively) or a subculture's argot (e.g., military idiom). In short, the reflexive self allows people to view themselves from a putatively external point of view, just as others do. Additionally, since the self can reflect back on itself, it is an integral part of many features we associate with being human: the ability to plan, worry about personal problems, ruminate about past actions, lament present circumstances, or envy others.

There are many theories of self esteem development in sociology. Most are embedded in symbolic interaction (especially labeling theory) and Festinger's theory of social comparisons. James presented the earliest social scientific formulation of self esteem. He regarded self esteem as a balancing act between an individual's perceptions of his or her success in some realm of life (e.g., sports) versus one's pretensions (i.e., aspirations) of success (e.g., wanting to be the top seeded tennis player in college sports). James used the equation $\text{Self esteem} = \frac{\text{Success}}{\text{Pretensions}}$ as illustration. Changing the numerator or denominator can increase or decrease self esteem. When aspirations

substantially outweigh perceived success, for example, the imbalance drives self esteem down.

Contemporary research on self esteem has been codified into four basic principles of self concept formation: reflected appraisals, social comparisons, self attributions, and psychological centrality. The principle of reflected appraisals is central to the symbolic interactionist's insistence that the self is a social product derived from the attitudes that others have toward one's self and that one eventually comes to see himself or herself as others do, à la Cooley's idea of the looking glass self and Mead's notion of role taking, both products of symbolic interaction. The contemporary literature recognizes three basic kinds of reflected appraisals or feedback. *Perceived selves* are the most important aspect of reflected appraisals for the self. Here, ego speculates on how he or she *believes* specific alters perceive him or her. One's *perception*, whether accurate or not, is the vital element. *Direct reflections* are the actual and direct responses that alter has toward ego, regardless of how subjectively ego perceives and thus assesses them. The *generalized other* is ego's composite sense of what others think of him or her.

Through social comparisons, people judge and evaluate themselves in comparison to particular individuals, groups, or social categories. The main function of this process, according to much contemporary research, is to test reality, especially when knowledge about oneself is ambiguous or uncertain. Two aspects of social comparisons are worth noting: criteria bases (i.e., superior/inferior, better/worse) and normative bases (i.e., deviance/conformity, same/different). Self attributions, the most intrinsically psychological of the four principles, hold that individuals draw conclusions about themselves (e.g., funny, popular, attractive, bookish) by observing their own behaviors, the outcomes they produce, and then making some kind of inference about themselves. Finally, psychological centrality, perhaps the most understudied of the four principles, holds that the self is an interrelated system of hierarchically organized components, with some identities and attributes being more important or more central to the self than others. Since psychological centrality is the weight or importance individuals assign to their various personal attributes, identities, and abilities, it serves to protect self esteem by pushing

potentially damaging self attributes and identities to the periphery of the self system, while holding enhancing attributes closer to the center.

Theories of self esteem as a *motive* hold that individuals desire to protect and if possible enhance their self concept. The motives of self esteem and self consistency are crucial in this regard. The self esteem motive goads individuals to think well of themselves. Many self theorists from James to the present regard this motive as universally dominant in the human motivational system. The self consistency motive asserts that people struggle to validate their self concepts, even when they are negative. To do otherwise requires revising one's self concept, a daunting task (Lecky 1951).

Self esteem is both a social product and a social force. As a social product, the social origins of the self concept and self esteem are investigated. It is taken axiomatically that the self arises out of society. Self esteem theory helps explain how this occurs. As a social force, self esteem serves as an important sociometer by which a population's general health and well being may be gauged. Self esteem has thus been linked to a variety of positive and negative outcomes, such as mental health and well being, prosocial behavior, participation in social movements, and deviant and risky behavior.

Self esteem may be usefully divided into two broad categories: specific self esteem and global self esteem. Each tends to be associated with different outcomes (see Fig. 1). Specific self esteem is tied to a person's roles, identities, activities, contexts, or attributes (e.g., academic, physical, social, moral, family). It is multifaceted and hierarchical, depending upon the importance one places on particular attributes. Global self esteem refers to overall characterizations of one's self as good or bad, worthy or worthless, acceptable or unacceptable, moral or immoral, likeable or dislikeable, and so on. It is imperative to recognize that global self esteem is a general portrayal of one's state or trait with respect to the self, without reference to an individual's particular roles, identities, or social contexts. A parallel viewpoint sees global self esteem as an amalgamation of one's many specific self esteems. Specific self esteem tends to predict behavioral outcomes (e.g., school grades) better than global self esteem, whereas global self esteem tends to

be more predictive of emotional and psychological outcomes (e.g., depression).

Attaining or maintaining high self esteem and avoiding low self esteem are perennial interests of social scientists and the lay public alike. People with high self esteem (HSE) possess self respect and feelings of worthiness. Aside from extremely arrogant HSE people, most possess other positive attributes such as humility and a willingness to acknowledge, though not dwell on, their personal faults and shortcomings. In contrast, people with very low self esteem (LSE) lack self respect and see only their faults, weaknesses, and unworthiness, coupled with a belief that they are seriously deficient people. In reality, very low LSE is fairly rare, probably no more than 15 percent of the population and perhaps much less. Most people have medium to high self esteem. Still, LSE is an important social problem. To have LSE is to live a life of misery. However painful and discomforting LSE may be, it is not a mental illness. Rather, it is a form of psychological distress characterized by such unpleasant subjective states as depressive affect, anxiety, general dissatisfaction with life, resentment, enmity, and suspicion.

Cognitively, self esteem theory and research shows that LSE people, in contrast to HSE people, tend to be more cynical, negative toward institutions, to harbor disapproving attitudes toward other persons and groups, and to be harshly critical of themselves. With these emotional and cognitive orientations, a LSE person's general approach to life is frequently twofold: avoid risk and a "moat" or defensive mentality. LSE people feel more threatened by others and believe personal failure or a misstep is right around the corner. Trying to avoid risk pushes LSE people into protective styles of life (in contrast to acquisitive styles) focusing on avoiding damage to one's feeling of self worth, regardless of how meager that may be. LSE people see their chief risks as interpersonal, thus making a moat mentality appealing. This allegorical barrier entails restricting interaction with others, marginalizing oneself in groups, being reticent about expressing one's thoughts and feelings about other people, actively concealing one's ideas and feelings, and putting up fronts or pretenses.

Investigating the origins of and consequences for high and low self esteem continues to be vigorously researched. To date, the vast majority

of research and theorizing on self esteem has been focused on children and adolescence. More research is needed on adult self esteem, especially as it relates to change and stability over the life course and the wide variety of adult roles and social contexts which influence and are influenced by self esteem. Specifying the link between macro structures and processes (i.e., social stratification, organizations and networks, and collective behavior) and self esteem awaits further sociological analysis. Accepting the truism that self and society are twin born also indicates the need for additional research on the reciprocal effects of self esteem and a variety of social problems.

self-fulfilling expectations

Alison J. Bianchi

A self fulfilling expectation (or as it is often referred to, a self fulfilling prophecy) is a person's anticipation about how a situation will end that prompts the person to behave in ways that cause the anticipated ending to come true. Individuals often have a sense that a situation's outcome is a foregone conclusion, even if the outcome is not necessarily inevitable. A person with this sense may be compelled to act in ways that encourage the presumed conclusion to happen in actuality. Hence, what the individual expects to occur often does occur because the individual has had a hand in producing the event. Thus, the self does indeed fulfill the promise of the expectation.

Consider, for instance, a professor in an engineering college who has very stereotypical views about the performance of males and females in his classes. He (wrongly) believes that men always perform better than women because they possess the genetic predisposition to be naturally better at mathematics. During this professor's classes, he tends to call on male students more than females; he non consciously grades males' exams more gently than females; and he spends more time with male students during office hours than with his female students. Due to these very biased behaviors, the male students get more academic attention and help while taking this professor's classes. Not surprisingly, the male students do tend to perform better than the female students in his courses. The professor expects them to perform better, and has had a hand in producing this outcome, despite his feelings that this is just the natural order of things!

Robert K. Merton first posited the concept of the self fulfilling expectation in 1948. He based this concept on the "Thomas theorem," named for W. I. Thomas. A summary of the Thomas theorem was: if an individual defines a situation as real, then it is real in its consequences. Merton reasoned that rather than relying completely on the objective elements presented by circumstances, persons often construct their own

meanings about a situation, and then respond to these subjective understandings. Actors' definitions of the situation also included notions about its outcome. Hence, if subjectively constructed expectations were part of actors' understandings of the situation, then they would play a role in how actors behaved. The actors' behavior would also influence the situation's objective outcome.

An interesting facet of self fulfilling expectations is that actors who experience them seldom consciously recognize their part in causing outcomes to occur. Instead, actors view situational conclusions as inevitable, and non consciously take steps to produce the inevitability. Another interesting facet of this phenomenon is the reaction of other persons to an actor's self fulfilling expectations. An actor's expectation of another person's behavior tends to educe that behavior from the other person, even if the expectation was erroneous. Thus, the other person's behaviors that are elicited by an actor's expectation will be interpreted as confirmation of the actor's definition of the situation and its concomitant outcome. The self fulfilling expectation is realized, yet again, as the focal actor's speculation about the other person's reaction to him or her comes true.

Merton believed that persons often had false definitions of the situation, and these false understandings evoked behavior that made the false conception come true. The classic example Merton used, for which he is often quoted, is the run on a bank. If rumors are spread that a bank is suffering from financial difficulties and will collapse, then those with savings in the bank may try to withdraw their money en masse, causing the bank to collapse in fact. Note how the original rumors about the bank's fragile pecuniary state may have been false; nonetheless, the resulting behavior of the bank customers fulfills the predictions of the gossip concerning the bank's financial health.

Sociologists have since disputed Merton's original conception of self fulfilling expectations. They have noted that an individual's anticipation of how a situation would end could not be truly false if it could in fact happen. Sociologists have theorized that the impetus behind the behavior that realizes the predicted outcome could be any understanding of the situation that the individual feels is real, and

could indeed become real, despite others' judgments of the anticipation as true or false.

Another aspect of Merton's discussion about self fulfilling expectations is their functionality for maintaining social inequalities through cultural beliefs. He asserts that cultural beliefs about who is and who should be the "haves" and "have nots" in a society must be shared and perpetuated to maintain social disparities. Members of a society who internalize these beliefs about the social order may behave as if they were true. Thus, Merton argued, the purpose of cultural beliefs regarding unequal distributions of power, status, or other valued social markers is to prod societal members into experiencing self fulfilling expectations.

Consider, again, the example of the biased engineering professor. How did he learn that women are not expected to do well in math oriented classes? He learned this from cultural stereotypes that women are not as adept at mathematics as men are. By internalizing these beliefs, the professor came to feel that women were less competent than men in the subject of engineering, and then he behaved as if women were, in fact, incompetent. If women then do perform less well in the professor's class, and this outcome is reproduced by many other biased professors, women may not obtain good jobs in this field, and probably will not rise to positions of influence in it; or, women may not get jobs in engineering at all. Thus, the disparity of power between men and women in engineering would be maintained by the mechanism of internalized cultural beliefs, and perpetuated by the poor performance of females experiencing the results of professors' self fulfilling expectations based on those beliefs. Note, too, that men in this discipline also experience the bias of professors' self fulfilling expectations, except the cultural beliefs about them are positive: professors may believe that men are good in math, and as a result the male students may receive more attention from these professors and do very well in college and in the field. Merton would have argued that it is no accident that men receive higher grades in engineering classes. The explanation for the phenomenon involves a cultural stereotype stimulating self fulfilling expectations.

Sociologists who have pondered the problems presented by self fulfilling expectations

include methodologists who specialize in causal modeling. One of the predicaments they face is the reaction of the population under study to their causal model. Researchers may formulate a cause and effect relation between variables measuring some aspect within a group. The research participants for whom this relation is hypothesized to hold may suspect, or even learn about, the posited relation. They may then take this relation into consideration when they act. As a result, the posited relation may be rendered false, since the group members may change the outcome of the situation. In other words, predictions of causal relations could themselves turn out to be a part of the interconnected social conditions that result in future outcomes. If these predictions factor into group members' subjective meanings of the situational outcome, and the group members disagree with the predictions, then these disagreements become beliefs about the situation, and could become self fulfilling expectations.

To provide an example of this dilemma, suppose citizens of a town are having a political race to elect the next mayor. Candidate A, a very handsome man, is running against candidate B, a very unattractive man. A sociologist studying the election suggests that gender is related to predicting the outcome in the race because females are more likely to vote for an attractive man than an unattractive one. The sociologist forecasts that candidate A will win the election. This forecast is based on her causal model that gender is related to voting behavior. The sociologist then publishes this supposition in the local newspaper. After reading about this, the women in the town become quite offended, feeling that the sociologist has portrayed them as focusing on shallow concerns about the candidates rather than the candidates' opinions about the issues. To prove that they are not superficial, the town's females overwhelmingly vote for candidate B, and the sociologist's causal relation is rendered false. The disagreement about the supposed portrayal of women by the sociologist becomes a belief about how the town's women should vote, and they in fact vote in this manner.

Another problem that self fulfilling expectations present for causal modeling has to do with the temporal ordering of causal and outcome variables. One of three necessary conditions for claiming causation between a cause and an

effect is that the cause must occur prior to the effect. For example, a researcher might posit that students' effort during the semester is one of the causes for getting a good grade at the end of the semester. This causal claim, that "effort is related to grades," would be acceptable as long as the sociologist made it clear that she was measuring effort during the course and prior to the assignment of grades at the end of the semester. In the case of a self fulfilling expectation, however, it is difficult to claim that the cause of the outcome clearly occurs prior to the outcome. The nature of a self fulfilling expectation is that an actor anticipates the outcome (or effect), behaves in a way to produce the outcome (the cause), and then the outcome is produced. In this chain of events, the anticipated effect becomes the real effect, with the cause being the mediating behavior. Without the anticipation of the effect, the real effect would not happen. And, in fact, the anticipated effect actually leads to the cause. Some would consider this phenomenon a violation of the temporal order condition required to claim causation. Therefore, when a self fulfilling expectation is modeled as a causal relation, researchers suggest that the person conceiving the model must declare it to be a weak causal claim.

In current sociological social psychological theories, self fulfilling expectations are rarely studied explicitly. An exception is a research program on the relation between expectations and attraction. More often, self fulfilling expectations are assumed to be operating as part of the process being explained. Two examples of this type of theory are status characteristics theory, a branch of expectation states theory, and stereotype threat theory. Both theories explain how cultural stereotypes affect performance, and use the concept of self fulfilling expectations to describe the group and individual level processes they examine.

In conclusion, despite this concept's recent relative neglect, it still has a great deal of potential to explain social behavior; there is much to gain, both theoretically and empirically, by incorporating the concept more rigorously into studies that attempt to tease out "processes" of interaction. Subjects ranging from interpersonal dynamics (e.g., couples' communications) to the persistence of discriminatory evaluations could benefit from using the concept, as

its theoretical versatility has yet to be fully realized.

self-fulfilling prophecy

Takako Nomi

The self fulfilling prophecy is the process by which one's expectations of other persons or groups lead those persons or groups to behave in ways that confirm those expectations. An influential and controversial idea in education,

the concept of the self fulfilling prophecy is used to illuminate the ways that teacher expectations influence students' behavioral and achievement outcomes. The self fulfilling prophecy predicts that positive teacher expectations lead to positive student outcomes, while negative expectations lead to negative student outcomes.

The term "self fulfilling prophecy" was coined in 1948 by Robert K. Merton, who drew upon W. I. Thomas's well known dictum: "if men define situations as real, they are real in their consequences" (see an excellent review by Wineberg 1987). The Thomas theorem suggests that the meanings of human actions are not inherent merely in their actions. Rather, people attribute meanings to those actions, and the meanings have consequences for future actions. Merton (1948) illustrated the concept with the example that a groundless rumor of a bank's insolvency could cause bankruptcy when enough customers believe in the rumor and rush to withdraw their deposits. The idea is simple: a false prediction could become true if it is widely believed to be true. Certainly, the self fulfilling prophecy is a unique social concept that has no application in the physical world. A false prediction about a hurricane does not bring gusty winds and torrential rain. However, the prediction of human actions may have a powerful effect on their outcomes.

At the micro level, the self fulfilling prophecy has theoretical roots in social phenomenology. The notion of the social construction of reality implies that reality is produced through social interactions among actors, who use symbols to interpret one another and assign meanings to perceptions and experiences. From this perspective, the self fulfilling prophecy is understood as reciprocal processes whereby cultural beliefs and human consciousness create and recreate social life.

At the macro level, self fulfilling prophecies serve the function of maintaining the existing social order and social relationships. Patterns of self fulfilling prophecies mirror structural arrangements in society as well as social beliefs that represent those structural arrangements. For example, social relationships between dominant and minority groups are defined and redefined through self fulfilling prophecies. Expectations for minority groups' behaviors are defined according to their social status, and

the interpretation of their behaviors by dominant groups justifies what is being defined.

The self fulfilling prophecy is also known as the Pygmalion effect after the publication in 1968 of *Pygmalion in the Classroom* by Richard Rosenthal, an educational psychologist at Harvard University, and Lenore Jacobson, an elementary school principal in South San Francisco. In 1964 they initiated an experiment in a low income elementary school where they created different teacher expectations and examined how such expectations influenced students' academic progress. At the beginning of the school year, an IQ test was administered and teachers were given false information about students' IQ scores. At the end of the school year, the IQ score gains were compared between students in experimental groups and those in control groups. Rosenthal and Jacobson found that students who were falsely identified as "spurters" – those who were predicted to "show an academic spurt" (Rosenthal & Jacobson 1968: 66) – made significantly greater gains in IQ scores than did those who were not so identified. Thus *Pygmalion* established a positive relationship between teacher expectations and students' intelligence, confirming the existence of the educational self fulfilling prophecy.

Soon after the publication of *Pygmalion*, Ray Rist (1970) began in 1967 to collect sociological data to test the self fulfilling prophecy in a ghetto school. By examining student-teacher interactions in an all black elementary school, Rist was able to answer questions about the mechanisms through which the self fulfilling prophecy in the classroom was manifested. One of the most striking findings in this study was that the teacher formed expectations during the first days of kindergarten. The teacher then assigned her students to three ability groups based on students' socioeconomic backgrounds, rather than their academic ability, and treated each ability group differently. She gave more freedom and encouragements to students in the highest ability group, but gave more criticisms and restrictions to students in the lowest ability group. Students in the highest ability group could get physically closer to the teacher than could students in the lowest ability group. Eventually, students in the highest ability group received more instruction and showed better

performance than did students in the lowest ability group.

Based on such observation, Rist (1970) described the self fulfilling prophecy in the classroom as a process of several steps. First, a teacher forms expectations about students' potential to achieve based on non academic factors. Then the teacher acts on these expectations and applies differential treatments. When the teacher's treatment is consistent, and if students do not resist, students will internalize and respond to the teacher in a way that confirms his/her expectations. Students' differential responses reinforce the teacher's differential treatment. The vicious cycle is then complete. Teacher expectations become "true" because the teacher acts as though they are true.

Both *Pygmalion* and Rist's ethnographic study sparked controversies during the years after their publication, as researchers searched for evidence to support or refute the prophecy. By the late 1980s, there were about 400 experiments and meta analyses on the self fulfilling prophecy in education. Critics have raised important issues about the validity of the tests and the lack of significant results beyond the second grade in the Pygmalion study, the lack of representativeness of Rist's study sample, and the leap from the classroom to the broader society in Rist's conclusions (Wineberg 1987). More importantly, many researchers failed to replicate the effect of self fulfilling prophecy. Such failure did not stop other researchers, policymakers, and the mass media from hailing these two major studies as providing a model for social science research and for teacher training. Educational self fulfilling prophecy even played a role in the courts' decisions over equity issues in education, including testing, desegregation, busing, and ability tracking (Wineburg 1987). More recently, the concept of the self fulfilling prophecy was applied to settings other than classrooms. These include work organizations, judicial settings, substance uses, delinquency, and health care, to name a few.

In the field of sociology of education, researchers have applied the concept to critique functionalist assumptions on the role of schools in social stratification. They challenged the earlier view that education is a meritocratic vehicle for social mobility and began to see schools as

institutions responsible for reproducing existing social inequalities. Since the publication in 1969 of James Coleman's report on the *Equality of Educational Opportunity*, which revealed greater achievement inequalities within schools than inequalities between schools, a focus has been placed on in school processes to understand how educational inequalities are created and reinforced. An area of research where educational self fulfilling prophecies are actively applied is in school organization. Sociologists have turned their attentions to ability grouping and tracking in K 12 schooling to examine if and how students' race and socioeconomic status affect student assignment to different ability groups or tracks, and how teacher expectations impact instructional practices in different ability groups or tracks, which, in turn, shape student learning. Students in different ability groups or tracks may be exposed to different hidden curricula and opportunities to learn, which mediate the relationship between teacher expectations and students' achievement outcomes. Another area of research related to the educational self fulfilling prophecy is the study of racial and gender stereotypes. This research seeks to better understand race and gender disparities in students' educational outcomes in post secondary levels. Most sociological findings support the notion of the educational self fulfilling prophecy in the US, as well as in other countries, including England, New Zealand, Australia, and South Korea, among others (Tauber 1997).

Today we have more information about the mediating mechanisms of the Pygmalion effect. A four factor theory (Rosenthal 1974) explains how teachers convey expectations to students in classrooms. These four factors are climate, feedback, input, and output. Climate refers to the tendency for the teacher to create a warm socio emotional climate, communicated both verbally and non verbally (e.g., smiling, nodding, and eye contacting), for high expectancy students but not for low expectancy students. Feedback refers to the tendency for the teacher to give more positive feedback to high expectancy students than to low expectancy students for the correctness or incorrectness of their responses. Input is the tendency for the teacher to teach more and harder curricula to higher expectancy students than to lower expectancy students.

Finally, output is the tendency for the teacher to encourage greater responsiveness from high expectancy students but not from low expectancy students. Teacher expectations are translated to student behavior in a two stage process. First, differential teacher expectations lead to differential teacher behavior. The teacher is likely to create a warmer climate, give more positive feedback, and display greater inputs and outputs for high expectancy students than for low expectancy students. Second, differential teacher behavior leads to differential student outcomes. Warm climate, positive feedback, and greater inputs and outputs lead to more positive student outcomes.

Not only is the study of the self fulfilling prophecy a good example of cross fertilization of academic disciplines, e.g., psychology and sociology, it is also a good example of how quantitative and qualitative methods are integrated. Rosenthal and Jacobson, as well as many other researchers, used experimental designs, whereas Rist applied ethnographic methods in his study. Rist's ethnography helps to advance the self fulfilling prophecy by illuminating the mechanism through which teacher expectations shaped learning opportunities. Both qualitative and quantitative studies have received methodological criticisms, however. Ethnographic studies were often based on observations in a small number of classrooms or schools and thus were criticized for non transferability of research results to other settings. Early replications of Rosenthal and Jacobson's experimental study also failed to confirm the findings of the Pygmalion effect. While these experimental studies also received methodological criticisms, such criticisms led researchers to investigate *why* these studies failed to observe the teacher expectancy effects. Later studies, using teacher interviews, revealed that the teacher did not believe the false information about students given by the experimenter when he/she already knew about the student. Meta analyses also supported the hypothesis that the timing of "expectancy induction" was critical for the formation of teacher expectation in experimental studies (Raudenbush 1984).

In the past 35 years, our knowledge about the self fulfilling prophecy has greatly increased. That said, more work is needed to recognize the positive force as well as the negative implication of the prophecy for education policies.

In the US, schoolteachers today are trained to avoid talking about problem students for fear of creating a self fulfilling prophecy. Similarly, school counselors' professional ethics emphasize the need to keep important student information confidential. This division of labor between teachers and school counselors leads to organizational secrecy, preventing school personnel from detecting and building a case regarding a troubled student. Outside of the US, we know relatively little about the self fulfilling prophecy and how it varies across countries. Cross national comparisons may illuminate how cultural beliefs about student ability influence the ways in which teachers form expectations, organize instruction, and adopt certain pedagogical practices. These factors may, in turn, affect the processes by which schools alter achievement inequalities. The investigation of such questions offers many directions for future fruitful research.

semi-domestication

Hiroyuki Torigoe and Yukiko Kada

The notion of semi domestication originated to refer to a kind of plant that is in between wild plants and domesticated crops and has been extended to refer to a particular mode of interaction between humans and animals. Botanists and archeologists have been very interested in semi cultivated plants for their potential to reveal origins. Anthropologists, in contrast, have begun to accumulate field data that show the usefulness of such plants to local communities. For example, research in a village in the foothills of the Himalayas has analyzed the use of a particular kind of grass root called *Namitoo* which grows in semi cultivated areas. Although there are wild roots growing in the same area, these semi domesticated roots grow larger in size and produce more seed roots. According to the anthropologist, the semi cultivated roots are "gathered" rather than "harvested," but in contrast to the cultivated roots that are planted in prepared fields, these semi domesticated roots do not grow as well under human control. It is also well known that in various regions of Asia, numerous semi cultivated plants are relied upon in times of pending famine.

Thus, in contrast to botanists and archeologists, anthropologists do not consider semi cultivated plants to be in a "developmental" process from wild to domesticated plants, but instead regard them as having their own specific cultural roles and meanings; they are good as they are (Matsui 1989). Among the positive meanings of semi cultivated plants is the fact that they require less work than fully domesticated plants. Although human societies cannot survive on semi cultivated plants alone, they add variety to the diet and are useful in times of scarcity.

These anthropological findings led Japanese environmental sociologists to explore the idea of semi domestication for clues to developing environmental policy. They have interpreted the phenomenon as evidence of the interaction between nature and humans. In Japan and other regions of Asia with high population densities, people often live in close proximity to mountains, rivers, and the sea. In such areas, attempting to preserve pristine “wilderness areas,” untouched by humans, as an ideal of environmental policy is unrealistic. This leads to accepting the fact that extracting numerous resources from forests, rivers, and the sea toward people’s basic subsistence is a prerequisite to conserving nature while making environmental policies effective and realistic.

Japanese environmental sociologists identified one of the motivations for utilizing semi domesticated plants without any substantial changes as nature conservation. Environmental sociologists have focused on two aspects of semi domesticated plant usage. One is ownership. For example, when someone plants bamboo, the ownership is clear and widely acknowledged in the community; but the bamboo will multiply each year without anyone’s care. Under these circumstances, researchers are interested in who has ownership rights to either use or dispose of the bamboo. Another question concerns ownership of lands or spaces where such plants grow. Semi cultivated plants often grow on riversides, in glades or vacant lots where ownership is ambiguous. Normally, however, there are hidden and shared community rules concerning these areas. By revealing these community rules, which are often closely related to the people’s involvement in nature and space, analysis of the ownership of semi cultivated plants is meaningful for developing environmental policies appropriate to each local community.

Extending from this research, a new field of study is emerging that considers the interactions between animals and humans from the perspective of semi domestication. Monkeys, wild boars, and deer, for example, live in close proximity to or in the community, and they are certainly influenced by humans; but people do not appear to have any intentions of fully domesticating these animals (and that may be impossible). Humans eat wild boar and deer, and may derive other benefits from monkeys

(some types of which are also eaten), but these animals might also inflict damage on crops. Studies that attempt to analyze these “give and take” interactions are being conducted by environmental sociologists and have something in common with the concept of life environmentalism developed in Japanese environmental sociology. This is a different approach to conventional ones that consider such animals simply as pests that can ruin crops as well as the natural environmental approach that attempts to minimize contact with these animals as much as possible in the interests of protecting nature.

semiotics

E. Valentine Daniel

From the perspective of one who surveys the ever shifting and ever expanding field of modern semiotics/semiotic, the long shadows of two dominant thinkers span the landscape: Charles Peirce and Ferdinand de Saussure. The history of the identification and use of signs as appropriate to certain culturally specified

domains of knowledge and practice is, however, far richer and deeper. Such a history has been traced to divination and medicine in ancient Mesopotamia, extending to philosophy as well as in Greek antiquity, and by the first century BCE to aesthetics and semantics in India (*Nyaya Sutra*). St. Augustine was the first thinker, however, to identify the sign (*signum*), in *De Doctrina Christiana* (ca. 397–426), as a universal that functions in any and all contexts where significance (including information and meaning) of any sort is communicated from one living being to another. That is, he proposed a point of view that enabled us to see things exclusively in terms of their signs' signifying function. By defining the sign, however, as "a thing, which, over and above the impression it makes on the senses, causes something else to come into thought as a consequence," he made sense perception into a necessary component of the sign. In its application, he chose to narrow the sign's compass even further, to sacramental theology. Both choices served to limit the full analytic power of the sign right through the Latin period and well into the Renaissance.

Augustine's definition excluded ideas from being signs because they were unavailable to sense perception. This unwarranted limitation troubled several post Augustinian Latin "semeioticians." Given the awesome power of tradition, even the most independent thinkers tried to accommodate Augustine by proposing several dichotomous sign types in which at least one half would represent continuity with tradition and only the other half, change. Fonseka, for instance, suggests distinctions such as formal vs. instrumental, conventional (social) vs. natural, internal vs. external, and mind dependent vs. mind independent signs. In the end he too is forced by tradition to concede that the first in each pair was not a sign as such, for to do otherwise would have gone against customary usage of the term, traceable not just to Augustine but to the Aristotelian dichotomies of substance and accident, *semeion* and *symbolon*, nature and culture. The Portuguese Dominican philosopher John of Painsot (1632) was the first to critique and systematize what Augustine had thematized, by removing the sense perception requirement from the sign's definition, thereby clearing the ground for a truly general semeiotic that included words

and ideas in its perspective. The message of Painsot's magnum opus was drowned in the Cartesian heralding of epistemological and solipsistic conundra that would keep modern philosophy preoccupied for another 300 years and more.

Some 58 years later, at the very end of his purported anti Cartesian *Essay Concerning Human Understanding* (1690), in which he made his case for empiricism, John Locke part hoped for, part prophesied, and part proposed a new field of inquiry called *semiotic*. In this "doctrine of signs" that he characterized as "aptly enough also, logic," we were invited to "consider the nature of signs, the mind makes use of for the understanding of things, or conveying knowledge to others." His *Essay* bequeathed us two ironies. Locke was totally unaware that an Iberian philosopher monk had already done his bidding the very year that he, Locke, was born. This was the first irony. Apart from giving it the name *semiotic*, he was also the first, in the non Latin world, to set the sign free from the tether of sense perception by which Augustine's definition had bound the sign. "For since the things, the mind contemplates are none of them, besides itself, present to the understanding," he argued, "'tis necessary that something else, as a sign or representation of the thing it considers, should be present to it." These he called *ideas*. Ideas were not directly available to the senses and needed "articulate sounds" to convey them to others, fit to be understood. Ideas and signs of ideas – words – could be "seen as the great instruments of knowledge" in which lay "the seeds of an overthrow" of his own purported anti Cartesian labor contained in the rest of the *Essay*. This was the second irony.

TWO TRADITIONS?

Locke's proposal lay idle from the seventeenth century until the American logician philosopher mathematician Charles Sanders Peirce picked up its charge in his writings from 1866 onward, in which he plumbed its depths and spanned its breadth to extents unimagined by Locke. Nevertheless, following Locke and in keeping with what he considered the "ethics of terminology," Peirce named his effort *semeiotic* (in keeping with its Greek origin, *semeion* for

“sign,” and emphatically preserving the diphthong “ei” of *semeion* in its pronunciation) and at times *semiotic*. Peirce’s writings on *semeiotic* are conspicuously and not so conspicuously distributed among the totality of his life’s work, an ever evolving architectonic philosophical system, which fills almost 100,000 (mostly unpublished) manuscript pages. A shift in philosophical fashions in the years following his death, the disarray in which his papers were found more than a decade later, the decision by the editors of his *Collected Papers* to publish his already published papers rather than select from among the unpublished versions of the same (which Peirce himself had considered better for not having had to be trimmed to suit various editors’ tastes), his not having had an academic position or students to disseminate his ideas, and his pithy style of writing had collectively conspired to put his work relatively out of reach of the average scholar and impenetrable to a novice, until quite recently.

Independently of both Peirce and Locke, the Swiss linguist Ferdinand de Saussure had determined to study the “life of signs in social life” and named his “new” science *semiology*. His ideas survived thanks to his students’ lecture notes, published posthumously in 1916 as *Cours de linguistique generale*. In contrast to Peirce’s writings, *Cours* had caught the attention of several leading linguists and “signophiles” of the twentieth century. As for nomenclature, in addition to *semiology*, *semeiotic*, and *semiotic* there were also available *significs*, *signology*, and *semiotics*. But the struggle for recognition was between *semiology* and *semiotics*, and *semiotics* won, as it were, the popular choice. Apart from their deliberated extension of their inquiries into extra linguistic sign systems and their choice of label to describe their work, most *semioticians* were *semiologist* by another name and the *Cours* remains their foundational text. Of the rest, *semeiotic* and *semiotic* were to become associated with those whose research followed, more or less, Peircean lines. Nevertheless, there is considerable cross over in choice of label, and, more rarely, mixing up of theoretical orientations. Many Peirceans use *semiotics* and non Peirceans *semiotic* (though more as an adjective than a noun) in their writings. *Semeiotic* is never used by Saussurians; and Peirceans who use this form do so in order to mark the difference of their

own approach to the sign in contradistinction to the Saussurians.

SAUSSURE AND SEMIOTICS

The rock upon which Saussure chose to build his *semiology* was *langue*. *Langue* is the linguistic system, which is but one component of *langage* (language or the language faculty). To get to and isolate *langue*, one strips away one half of each of two hierarchically ordered pairs that constitute language itself. The first half of language to go is diachrony (i.e., the history of a language) of the synchrony–diachrony dyad. The synchronic dimension of language – the structure of language at any given moment in time – consists of two aspects, *parole* (speech) and *langue*. Of these two, the one to be stripped away as irrelevant to the analysis of structural linguistics is *parole*: the idiosyncratic, contingent, pragmatic functions of language. *Langue* is an analytic construct, an abstraction from language as a means of explaining the regularities and typical patterns of a language that are normally hidden from the consciousness of individual speakers in a community that uses that language; it is not an ontological reality. And it is in *langue* that one locates the dynamo of not only the linguistic system, but also the generator of wider, non linguistic sign systems or *semiotics*, the sign. Structuralism, the earliest and the most ambitious extension of semiology into non linguistic systems of signs, goes even further by exploiting the dichotomy concealed within *langue* itself: paradigm and syntagm (also called the selective and combinatorial axes, respectively.) Lévi Straussian structuralists go on to disregard the syntagmatic dimension of *langue*, saving the paradigmatic dimension as the basis of structural analysis.

A linguistic sign, as defined by Saussure, is one and the same two sided phenomenon, a relationship that links an acoustic image and a concept, or a signifier and a signified. The link is not between a thing and its name, but between a concept and a sound pattern. The concept–sound pattern relationship is internal to language, internal to the mind, and is independent of external reality. Thus, the linguistic sign does not “stand for” an external world but construes it: a tree that is signified by the word “tree” is

not an actual tree, but the concept “tree.” Nor does a signifier “stand for” the signified but rather construes it. The signifier and the signified are “functives” that are co present or co occurrent albeit on different strata, the first more abstract than the second. In their respective strata they “exist” in a context of other signifiers and signifieds, respectively. Each is held together with and held apart from the other signifieds and signifiers in their respective strata by similarities and differences, which is what makes them part of a system or structure. Which signifier pairs with which signified is a matter of convention, arbitrary from an empirical point of view. How then is the external world brought into a relationship with the internal structure? The semiologically structured internal relationship of the signifier–signified analogically structures, organizes, and orients sign users to the flux of percepts they receive from the external world. This is a totally nominalistic view of both language and world.

There are many reasons why the semiological model of the sign – dyadic, non material, confined to a hermetically sealed system called language – came to assume paradigmatic power over semiotics generally. The foremost reason is structural and its reasoning unfolds more or less in the following manner. Only human beings have culture. Not all the features that constitute culture are, however, uniquely human. But language is uniquely human. What makes human language unique is *langue*. The linguistic sign is the defining element of *langue*. The defining feature of the linguistic sign is its binary structure, in which the elements of the dyad are held together by a relationship that is arbitrary or conventional (as opposed to natural). From this it is hypothesized that even though the uniquely human institution called culture is not identical to language, since its only assu redly human feature is language, the elementary form of culture must be structured along the lines of the elementary form of language, the linguistic or semiological sign.

The popularity of Saussurian *semiology* is made transparent by its inspiration of so many *semioticians* and schools of *semiotics*: Roman Jakobson of the Prague school of linguistics, Yuri Lotman of the Tartu Moscow school of semiotics and culture, the A. J. Greimas and lexicology, Louis Hjelmslev of the Danish

school of glossematics, and Roland Barthes the literary critic, who is best known for teaching us how to read literary and sociocultural texts semiologically. Some scholars see the Saussurian quest for the elementary structure of language as paralleling Durkheim’s quest for the elementary form of the religious life. There is no doubt, however, that Lévi Strauss (who introduced French structuralism into anthropology) self consciously patterned his quest for the elementary structure of kinship along Saussurian lines that converged with Durkheim’s quest for the elementary forms of the religious life. Indeed, the most successful application of the extension of the linguistic sign beyond linguistics was in French structuralism, which made its appearance around 1929, maturing into its most powerful and best known form in the anthropological writings of Lévi Strauss in the post war years. His pioneering application of Saussurian structuralism, read through Jakobson and N. S. Troubetzkoy’s phonology, to the study of kinship, mythology, and food had a profound effect on sociocultural anthropology. Structuralism spawned structuralist novelists like Alain Robbe Grillet. It provided new ways of rereading sociological classics such as the writings of Weber, Simmel, and Marx. Structural Marxism came into being mainly through the writings of Althusser in social theory and Sahlin in anthropology. Structuralism’s popularity spread to literary study and criticism and peaked in the late 1960s before it was gradually overshadowed by poststructuralism. The impress of the Saussurian sign, however, persists indelibly in both poststructuralism and postmodernism, not to mention the semiotic/semiotics of Kristeva and the post Freudian psychoanalysis of Lacan.

Among those who came to Saussure via Lévi Strauss, the most prominent was the philosopher Merleau Ponty, who believed that in structuralism he had found the way of resolving the subject–object impasse. The fact that even Saussure’s critics continue to base their own research on essentially Saussurian epistemology and assumptions is a further testimony to the compacted power of Saussure’s general theory of (even if mostly linguistic) signs. The Russian Marxist critic V. N. Volishinov, and those like Derrida, Eco or Jacobson, who consider Peirce to have had a deeper and keener understanding of *semiosis* than Saussure, in the

final analysis, despite their disclaimers, also remain Saussurians.

PEIRCE AND SEMEIOTIC

Robert Marty found 76 definitions of the sign in Peirce's published and unpublished writings; Alfred Lang found 12 more or its equivalents. Peirce defined and adjusted the definition of the sign to a range of contexts, a short list of which includes mathematics, logic, philosophy, pendulum experiments, chemistry, psychology, language, history, realism–nominalism debates, scholasticism, metaphysics, theories of mind, and discussions of truth. He bent his definitions for the benefit of his interlocutors and correspondents' comprehension. In his correspondences he discussed signs with his life long friend William James, with the like minded correspondent and exponent of *significs* Lady Welby, and with uncomprehending editors who wanted him to pitch his definitions to a general readership. He often obliged them with what he called "sops to Cerebrus," describing those Cartesians who were cognitively incapacitated by their mind/body dualism. For Peirce had a pan semeiotic view of the sign. The sign easily transgressed such dichotomies as mind/body, nature/culture, human/animal, and matter/spirit. The cosmos, for him, was perfused with signs. He considered thought as semeiotically active signs. He held that thought signs existed in crystals as much as they did in the brain; he considered the view of the mind being confined to the brain as far too nominalistic.

Many are the differences between Saussure and Peirce's concepts of the sign. One could begin with the fact that Saussure's is a dyadic sign, which originates in linguistics. The semeiotic sign is based on logic, and logic as semeiotic is a normative or formal science, in contrast to empirical sciences such as linguistics that Peirce classified as special sciences. As a formal science, semeiotic is concerned with the necessary conditions for what makes something a sign as such, with what bases one may determine its truth, and with the conditions that are required for the communication and growth of signs.

From the very start, Peirce determined that the sign was irreducibly triadic. The proof for the sign's triadicity he derived from logic,

mathematics, and phenomenology. With a certain amount of familiarity with a number of his scattered definitions of the *semeiotic* sign one could gradually build up one's understanding of it, by additions and refinements, until one comes nearer to grasping the sign in all its complexity that Peirce intended for us to grasp. After appreciating the fact that the sign is triadic, the first step would be to know that the first correlate of the triad is the *sign* (at times called the *representamen*), the second correlate is the *object*, and the third the *interpretant*. So the *semeiotic Sign* (upper case) is constituted by an irreducible triadic correlation in which a *sign* (lower case) stands for an *object* to an *interpretant*. The *sign* mediates the object and interpretant by representing the object to the interpretant; the object mediates the sign and the interpretant by grounding the sign; the interpretant mediates the sign and object by interpreting or translating the sign. Remove any one of the three correlates and the *Sign* as such will not be an actual *Sign*, but a mere potential sign.

It should be noted, however, that the *sign* represents the *object* to the *interpretant* only in "some respect or capacity" – not in every respect and capacity. The sign is not arbitrary and open. Peirce speaks of *signs* themselves having or not having the "fitness to represent" a given object. Such a fitness to represent a given object may be amply present, sparsely present, or not present at all in a sign, making it respectively quite appropriate, less appropriate, or inappropriate to represent the object in question. In other words, signs have built in limits to what they can and cannot represent or are likely or not likely to represent. What is being introduced here is the notion of a certain measure of motivation or tendency constitutive of the sign to represent something. Saussure denies such motivation, with a very few exceptions, to signs.

As for the *object*, Peirce tells us that it may be a:

single known existing thing or a thing believed formerly to have existed or expected to exist, or a collection of such things, or a known quality or relation or fact, which single object may be a collection, or a whole of parts, of it may have some other mode of being, such as an act permitted whose being does not prevent its negation from being equally permitted, or something of a general nature desired, required, or invariably found under certain general circumstances.

This is a wide understanding of an object indeed. The *semeiotic object* is of two types: *immediate* and *dynamic*. The *immediate object* is the *object* represented to us in the *sign* itself. The sentence "It is snowing downtown" will bring before my mind the idea that the word "snowing" represents. That idea or image is an *immediate object*. When one opens the window and sees cars coming from downtown with snow on them, then one sees the dynamic counterpart of the immediate object. The dynamic object is not necessarily a "real" or existing object. A "possible" one daydreams about can be the dynamic object that exerts an inner force in you that makes you seek for the possible. The same holds true for an idea. Insofar as it draws one towards it, it is *dynamic*. So an existent like a falling bookcase can be the *dynamic* counterpart of the warning that your friend shouts out ("Watch out! The bookcase!"), which would be the *immediate object*.

The *interpretant* is not the same as an *interpreter*, though an interpreter may be a species of interpretant. Peirce defines the *interpretant* as the "proper significate effect" of the sign on a third. At one point Peirce says that "a sign is not a sign unless it is translated into another sign in which it is more fully developed." In this case the translation or the meaning is the interpretant; it is the sign's "significate effect."

What is the motivating force of a sign based on? It is what Peirce calls the *ground*. The *ground* is the basis on which the sign "picks up" an object to represent. There are three common *grounds*. First, a *sign* may represent an *object* by virtue of the property or quality it shares with the object, or its similarity up to identity with the object. Such a *sign* is called an *icon*, provided there is an *interpretant* to interpret or be significantly affected by the representation of the object as such. When an icon is identical to an object, information is concealed rather than conveyed. Such is the case in protective coloration in nature where, for example, the color of a chameleon that is identical to that of its back ground is iconic; and so is the impeccable con artist. And as long as there is no interpretant to "read" the icon, it remains a potential sign. Second, when a *sign* represents an *object* on the grounds of its regular contiguity with the *object*, the sign is an *index* – again, assuming the

existence of an *interpretant*. Thus, the gathering darkness over the landscape indexes the setting of the sun to "something or somebody in some respect or capacity." Thus, to both human and beast, it would indicate the end of the day and the beginning of night. To an informed human being (a human being who is predisposed to interpret it one way rather than another) it could also signify the beginning of a solar eclipse, an omen, a god, an ancestor's presence. Whereas to most animals – inferring from their fixed response – it would appear that it indicates, as always, the day's end. Third, when a sign and object are related to each other by convention, the sign is a symbol – once more the existence of an interpretant is assumed. The cultural interpretation of an eclipse is such a symbol and so are most words. But some words, such as demonstratives (that! there! they! etc.), also known as *deictics* (from the Greek: to point), serve as indexes. Deictic indexes poke holes, as it were, through the symbolic cocoon or the hermetically sealed view of Language or linguistic signs as a world unto itself, attributed to Saussure, and touch the external, extralingual world or reality. For a "there!" to make sense, that has to be a there there. There are also iconic symbols such as metaphors and symbolic icons such as onomatopoeia. In fact, Peirce cautions us that, neither in nature nor in culture are there pure symbols, pure indexes, or pure icons. Every sign is a blend of all three, with one or more type being accentuated to the *interpretant*.

Despite his numerous attempts to fix the sign in a definition, Peirce's fundamental conception of semeiotic was that of "signing" activity or *semiosis* rather than the sign per se. This is evident in the following definition: "The *sign* is anything which determines something else (its *interpretant*) to refer to an object to which itself refers (its *object*) in the same way, the interpretant becoming a *sign* in turn, and so on *ad infinitum*." The sign so defined brings out the open and dynamic nature of sign activity or semiosis. Semiosis is the very life of the sign. When semiosis ceases, the sign either dies or goes into hibernation until an interpretant sign predisposed to receiving its representation of the object arrives. Thus, a potsherd from an antique goblet would "hibernate" until a knowledgeable archeologist finds it and is able to represent it as

a sign of an antique goblet to his student. She would, as the next interpretant sign along the chain of revived semeiosis who is fit to receive (by training) the representation, translate and communicate the object to yet another interpretant sign (her own students, say) as her professor's representation of the potsherd as representing the original goblet, which will then be represented to . . . *ad infinitum*.

The very structure of the semeiotic sign establishes it as fundamentally dialogic. If we were to anthropomorphize the three correlates of the Sign triad, *sign*, *object*, and *interpretant*, we could imagine a Mr. (S)ign's representation of Mrs. (O)bject to Mr. (I)nterpretant as being "determined by" – that is, constrained or delimited by – Mrs. (O)bject. And Mr. S "determines" Mr. (I) to represent Mrs. (O) "in the same way as" and "stand in the same relation to" Mrs. (O) as he, (Mr. (S)), himself had represented and stood in relation to Mrs. (O).

First, it is very unlikely that the Mrs. (O) that Mr. (S) represented to Mr. (I) is the Mrs. (O) as such, but rather, Mr. (S)'s Mrs. (O). In other words, no S(ign) is a *tabula rasa* upon which an O(bject) can impress or reproduce itself perfectly. Every S(ign) contains its own prior semeiotic genealogy and its attendant prejudices, and therefore the O(bject) represented will be the (S)ign's O(bject). For semeiosis to continue, Mr. (I) has a dual role to play: (1) he receives Mr. (S)'s Mrs. (O) in his role as Mr. I and (2) he represents what he has received, and in receiving inevitably modified, to Mr. I^a in his new role as Mr. S^a. It is equally unlikely that the Mrs. (O) whom Mr. (I) in his role as S^a will represent in his turn to another Interpretant, Mr. I^a, will be identical either to the Mrs. (O) prior to Mr. (S)'s representation of her or to the Mrs. (O) as represented to him by Mr. (S). That is, every "interpretant is an equivalent (not identical) or a more developed sign of the object" than the preceding sign. In other words, a subsequent interpretant sign need not necessarily be less revealing of the "original" object than an earlier sign of the same object. Rather, by having a greater interpretive fitness, and a more conducive interpretive context, be a more developed interpretant sign, providing us with greater knowledge of the said object than the earlier representation.

At the most abstract level there are three types of *interpretants*: the *immediate*, the *dynamic*, and the *final*. Peirce describes the *immediate interpretant* as "the immediate pertinent possible effect in its unanalyzed primitive entirety." A *dynamic interpretant* is the actual manifestation of a significant effect. And a *final interpretant* is the teleological growth of a sign that ends in an interrelated system of signs. The three *interpretants* that correspond in human experience to these abstract interpretants are the *emotional*, the *energetic*, and the *logical interpretants*. The feeling of *deja vous* would be an example of an *emotional interpretant*; the bodily reaction of one at whom the command "halt!" is barked out by a soldier after the declaration of a curfew would be an example of an *energetic interpretant*; and the habitualized mode of conditional reasoning such as "if the light turns red I will not cross the road" would be a *logical interpretant*. The *dynamic interpretant* does not possess meaning, it is a brute reaction; neither does an *emotional interpretant* that remains at the level of a mere feeling, before being put into words. A logical interpretant is meaningful. The path a river takes is a *final interpretant*: a habit carved into the earth. There are many other triadic sets of sign types and other triadic phenomena that one is likely to encounter in Peirce's writings. They are generated by the logic of Peirce's phenomenological categories of Firstness, Secondness, and Thirdness. In Peirce's semeiotic there are no impermeable or unmovable boundaries between internal and external, cultural and natural, mind and body, organic and inorganic that signs cannot cross and connect. Ecology is as amenable to semeiotic analysis as economics, music, or literature would be.

In semiology and semiotics there linger questions that have been at best inadequately answered and at worst not answered at all. How does the sound pattern/concept relationship take form in the mind of an individual or in the understanding of a speech community in the first place? How is the sign in one mind communicated in the first instance to another in the absence of the a priori of a shared language? Is incommensurability the only answer? How does the hermetically sealed internal linguistic sign precisely engage with the non linguistic external world and make such an engagement

warrantable and workable? Can we assign a truth value to any such engagement or is it all relative? How does a sign that is objectified in such an ideational abstraction have a bearing on concrete social intercourse (Voloshinov)? How does a synchronic structure theoretically accommodate both habit and change? (This question was most effectively posed by Bourdieu.) And finally, how does one account for the comparatively rapid and successful dissemination of semiology/semiotics in analyses of other domains of sociocultural life and how did it come to figure so much more prominently in so many disciplines than has semeiotic?

Other than the early discovery of Saussure's thoughts, the compactness and brilliant simplicity of his theory, the sparseness of his writings, the modesty of his aims, and the *Cours's* accessibility have facilitated its dispersal. Its inherent Cartesianism is hidebound with the Cartesian categories that are ubiquitous in the modern West and make his ideas easily assimilable. This is also why even self-professed anti-Cartesian warriors that one encounters in deconstruction, postmodernism, and poststructuralism are shot through with Cartesian thinking. Justifiably or not, both admirers and detractors of Saussurian semiology and semiotics are convinced that they understand Saussure well enough and therefore are ready and able to raise jugular snipping questions.

Most questions that are justified in semiotics are either anticipated and answered or become irrelevant in semeiotic. Peirce's semeiotic is non-dualist, incorrigibly diachronic, and inherently transdisciplinary. The semiological sign which is constrained only by convention can by convention be made free and available for redeployment in hermeneutic play. This is not so with the semeiotic sign, whose accountability to place, time, and purpose is far more exacting. For those wishing to understand Peirce, his voluminous writings and the state of disarray that his papers are in, however, create forbidding hurdles to scale. His project was anything but modest, and any topic that might engage the reader is spread out widely over time and contexts. His ideas grew and changed, and not always for the better. He aimed to connect the three large areas of his philosophy – realism, semeiotic, and pragmatism – with debatable success. This forces

anyone who wishes to explore only one area into exploring all of them, which is not a task for the hasty or the weak-willed. For these and similar reasons, Peirce scholars find themselves raising questions in one place only to find them already anticipated and answered elsewhere in his writings. Questions are posed but not from a place of confidence of having full control over his ideas; they are raised only for the sake of working through his texts for the answers, and sooner or later they do find them. Perusers of semeiotic tend to conclude prematurely that semiotics and semeiotic cover the same area of inquiry and then revert to the friendlier semiotics. Some make selective use of Peirce's ideas, as do Derrida and Deleuze, or stop short of accepting his semeiotic along with his realism, as does Eco, or are discouraged by the apparent anachronistic language and style of the author. Attempts to borrow from semeiotic into semiotic piecemeal either do not work or dangle like a graft that does not take. The conflation of semiotics and semeiotic is not helpful. As for whether the two approaches to the sign can be combined at all, the decision is split. French philosopher Gerard Deledalle denies such a possibility and discourages the search for one; but Joseph Lizska, an American philosopher, says that it is possible, arguing that Saussure's concept of value is the equivalent of Peirce's *logical interpretant*, thereby completing the incomplete *signifier–signified* dyad. But then, Peirce's sign and object are not the same at any level as the signifier and the signified. Despite these difficulties, much of Peirce's semeiotic has begun to make inroads into a range of fields and has even managed to introduce both complexity as well as simplifications into semiotics as well.

Peircean ideas entered sociology indirectly through Dewey, who was Peirce's student for a brief while, during which time he was introduced to Peircean pragmatism and logic, and would later modify these to suit his theoretical needs. The symbolic interactionism of George Herbert Mead had many semeiotic elements in it. C. Wright Mills was Mead's student and wrote in his dissertation a chapter each on James, Peirce, and Dewey. Charles Morris, another of Mead's students, and also part of the Chicago School's logical positivists, was the one who brought Peirce to center stage in his debate with

Dewey about the status of the “interpretant.” Morris, it is widely believed, misrepresented Peirce’s realist semeiotic by transforming it into a behaviorist theory of signs. More recently, Habermas and Apel have drawn heavily from Peirce for their own theories of pragmatism and communication. But, on the whole, relative to its sister discipline anthropology, sociology has been untouched by either semiotics or semeiotic, even though the writings of Bourdieu seem to have independently discovered some of Peirce’s seminal ideas, such as *habitus*.

separatism

Rutledge M. Dennis

The concept of separatism refers to the idea that racial, ethnic, cultural, religious, political, and linguistic differences, when accompanied by a legacy of oppression, exclusion, persecution, and discrimination, are justifications for groups to terminate their political and legal ties to other groups. Generally, the ultimate aim of the termination is the establishment or reestablishment of control over a specific territory in order to establish or reestablish sovereign control. The separatist claim is accompanied by intense feelings of rage, anger, hurt, and humiliation which often fuel the flames of revolts and revolutions. Above all, the claims of separatists are premised on a desire to erect an impenetrable social distance and barrier between themselves and the people, state, or territory against which they have grievances. We may distinguish between two general types of separatism: external separatism and internal separatism.

External separatism is rooted in the historical expansionism of nation states. As nation states expand and become imperial powers, they annex large areas which include diverse people, religions, and cultures. This process is seen in a review of ancient empires (Roman, Holy Roman), and the more recent empires (Ottoman, Russian, Austrian, Spanish, Portuguese, French, and British) from which contemporary nation states emerged in Europe, Asia, Africa, and the Middle East.

Empires are created when strong political, economic, and military powers wage war, and/or threaten, surrounding or distant political units. The resulting conquest often ends in the annexation of defeated nations, states, and societies, which then extends the political and military boundaries of the conquering power. This annexation process will include, against their will, numerous culturally, ethnically, and racially diverse groups. The imperial or colonial power is an external, distant, and occupying force because the gravitation of power lies not in the land or people occupied, but in the “mother country” or the political and economic center of the imperial power. The external separatist impulse, therefore, is the conquered

people's quest to reconnect or to sustain a loyalty to the myths and symbols of their past, real or imagined, and to validate a claim for their pre conquest independence. Even if they lacked complete independence prior to their colonial conquest, they now wish to assert such an independence. This desire for freedom and independence is even more overwhelming if a large number of the conquered people are old enough to have had the legacy of their way of life embedded in their social consciousness. For these reasons, the separatist desire is one of escaping foreign and external domination and to rebuff rule by the "other." In external separatism the separatist is engaged in a battle to separate and disconnect the interlocking external web of control, within which the imperial and colonial powers have engulfed a distant population. Though time (the 1920s as opposed to the 1950s and 1960s) and situational variables (world wars and regional wars) would be intervening factors in any discussion of the various empires and colonial countries mentioned earlier, the establishment of independent nations which greatly accelerated from the 1960s to the present era speaks volumes for the reasons this could not have been true in the period before 1960: prior to the 1960s many currently independent nations were integrated, partially or totally, within existing empires and colonial powers.

Internal separatism is the separatist impulse within groups occupying the same land mass, though they may occupy a special and recognizable region of the nation state or society where their relationship to the land is deeply rooted in their legends, myths, and history. In internal separatism, relations between the divergent groups traditionally alternate between harmony and conflict. The aspirations leading to a claim for internal separatism stem from the fact that the groups have different languages and cultural or religious backgrounds. More crucial to the separatist impulse, however, is the feeling, among the less dominant or smaller group, that it is the object of domination, discrimination, suppression, oppression, and persecution. Unlike the countries or areas of the world which successfully waged a war or negotiated their freedom, internal separatists are often less successful and many political entities are currently

engaged in a struggle to assert their freedom from a federation or nation state of which they are currently a part. There is often an ebb and flow in this internal separatist conflict and it may involve ultimately a case for total or partial separation from an existing nation state. Among this group one finds Kashmir, the Kurdish section of Iraq, Tibet, the Basque provinces, Kosovo in the greatly reduced Yugoslavia, the southern part of Sudan, Spanish Sahara, and the off and on position of Québec. We might also mention, though they differ from the others just mentioned, Wales and Scotland in Great Britain, in which there are periodic cries for independence, though very few will view this as a possibility. Finally, there are provinces and groups which opted for total or complete separation from countries within which they were the smaller and less dominant groups. In this category one finds Slovenia, Croatia, Bosnia Herzegovina, Serbia, and Macedonia, which separated from Yugoslavia. Estonia, Latvia, Lithuania, and Moldavia separated from the Soviet Union. There are also the countries which chose to become separate republics after the collapse of the Soviet Union. Then there was the peaceful separation of the Czechs and the Slovaks from Czechoslovakia, Eritrea's peaceful separation from Ethiopia, then the two countries' almost three year war to adjust their border boundaries, and the more recent independence of East Timor from Indonesia after a brief war.

In the United States the main separatist impulse was generated over the issue of slavery: the Southern desire to maintain and even extend slavery, and the Northern desire to limit and abolish the practice. Among African Americans the major separatist desire was created and sustained by Marcus Garvey from 1916 to the 1920s. Garvey's separatism entailed a version of Black Nationalism in which black Americans would emigrate to Africa. Though Garvey created a government in exile, with duly appointed cabinet members, a highly developed infrastructure, and purchased five ships to aid in the emigration, in the end he failed, and his movement died long before he did in England. Later, in the 1920s and 1930s, communists and socialists asserted that blacks in the South constituted a "nation within a nation" as an oppressed people. However, given the class position advocated

by both groups, and given the fact that blacks themselves did not rally behind that cause, separatism, which many blacks would have viewed as another form of segregation, was not considered a viable solution. In the 1950s and 1960s, the Nation of Islam sought to resurrect Garveyism, but instead of emigration their separatism called for the creation of a black nation within the seven Southern states with large black populations. There was no support among the black population for such a venture, especially as the massive Civil Rights Movement was slowly evolving at the time.

The separatist impulse presents an enormous challenge to nation states, especially democratic nation states, with diverse racial, ethnic, religious, and linguistic populations. The greatest challenge is that of creating the social and cultural institutions and organizations which will provide opportunities for groups to participate in the body politic and freely engage in cross racial, ethnic, cultural, and religious relationships in neighborhoods and communities, at work, in religious institutions, and in educational institutions. A test for democratic nations entails their ability to mix and blend and to incorporate divergent people and cultures. If this is possible, democratic and free societies would move toward constructing a new core culture. Lacking this, the separatist impulse will continue to loom large over the twenty first century just as it did over the twentieth.

sex-based wage gap and comparable worth

Juanita M. Firestone

An extensive body of empirical literature has addressed the issue of sex based wage differentials in the United States. The fact that this gap persists over time means that a large body of literature exists on the topic. Most recent research suggests that while the gap may vary based on a variety of factors including type of job, years of experience, economic sector, etc., sex based wage differences remain. Comparable worth is a process that is supposed to address the sex based wage gap by objectively comparing dissimilar jobs in order to determine relative worth to the objectives of a particular organization. The process involves a complex system of fine tuning an entire compensation structure. The information required to engage in comparable worth is considerable: jobs must be ranked according to the worth to the employer. This implies measuring the value of each job and calculating degrees of difference between the values of different jobs. Thus, if two jobs require equivalent levels of skill, education, responsibility, etc., the two should also have equivalent salaries.

Within this research tradition much attention has been paid to the impact of the sex composition of an occupation on the wages of men and women. Findings consistently report that lower hourly wages are associated with those occupations having a larger proportion of women. Many researchers contend that this difference in wages is based on discrimination rather than the actual contribution of the jobs to the goals and objectives of the organization. Comparable worth has been discussed as one means of addressing this problem, and narrowing, if not eliminating, wage disparity based on sex.

COMPARABLE WORTH AS A SOLUTION TO THE SEX BASED WAGE GAP

The phenomenon of sex based wage differentials is a fundamental and persistent social problem in the US and in countries around the world. Common approaches to studying the

problem are rooted in both sociological and economic research. Sociological explanations include socialization processes that dichotomize men's and women's roles and reward men for instrumental activities focused on accruing wealth, power, and status, and reward women for relational activities focused on providing love and care within family contexts. Economic explanations include human capital differences, rational choice, and organizational or bureaucratic theories of labor pattern formation. These efforts are further distinguished by their specialized focus on any of the following areas: the effects of job market competition, the systematic segregation of minorities and women into low paying jobs, the devaluation of female dominated professions, and within occupation wage discrimination. Depending on the focus of the explanation, the recommendations to solve the problem also differ widely. One such recommendation, which was more popular in the past, was a focus on comparable worth.

REASONS FOR THE SEX BASED WAGE GAP

Many economists argue that differences in wages are due to the fact that individuals may come to their job with greatly different talents/ability levels (human capital). These individuals typically oppose comparable worth because they contend that in a free labor market, fair wages will follow efficiency. Thus, differences in wages are attributed to the differences in human capital, which impact the efficiency with which an individual contributes to the organization's goals and objectives. Any differences in human capital obtained by men and women are then attributed to their individual choices, which are presumed to be free from constraints.

In any case, focusing exclusively on the economic analysis of the sex based wage gap disregards the historical and social context that could produce differences in choices by men and women. It seems clear that women's primary responsibility for housework and childcare affects the types of jobs many women prefer, since flexibility in terms of hours and turnover (entry/exit/re entry opportunities) can help women combine job and family responsibilities. Most agree that those occupations that are female typed are more flexible in terms of hours

and turnover. What is unclear is whether the flexibility associated with female typed jobs emerges because employers prefer to hire women in these jobs, or whether these jobs become female typed because of sex stereotyping. For example, women (and men) could be "guided" into certain jobs by social expectations about what is appropriate work. The processes used to guide women into female typed jobs might include implicit signals that women don't belong in men's jobs or explicit harassment or intimidation. In any event, as individuals we may have choices, but those choices do not occur in a vacuum, but occur within the complex social context in which we live.

CURRENT STATE OF RESEARCH

Among research focusing on wage differentials between men and women, most suggest that occupations with a larger proportion of women have lower hourly wages than those with a larger proportion of men. For example, studies that use data from the US Census detailed occupational categories as units of analysis have found that controlling for occupational characteristics (work demands, education level, supervisory capacity, etc.), occupations with a larger percentage of females have lower average hourly earnings. In other words, even with extensive controls for the amount of human capital an individual brings to the job included in the model, both men and women earn less if they work in a female dominated occupation.

Firm or organization specific studies also confirm that even after controlling for unique job skills, female jobs pay less. A few studies have documented that as the proportion of women increases over time in an occupation, the wages for men and women decrease, and that as the proportion of men increases, the wages for men and women increase. Results of this type of research have been unable to ascertain whether the change in the sex composition of the occupation impacted wages, or whether a change in wages altered the sex composition. Regardless, the data support the claims that (1) on average, women earn less than men, (2) men and women are segregated into different occupations, and (3) female typed occupations (sometimes referred to as pink collar jobs) earn lower wages.

On the one hand, there is support for the idea that men and women still have different types/levels of human capital. For example, men are more likely to have engineering and science degrees, and women are more likely to have degrees in elementary education and social work. On the other hand, evidence suggests that human capital and/or individual preferences cannot account for occupational segregation and the sex based wage gap. In fact, at the individual level we are likely to find enormous amounts of overlap in the abilities and preferences of men and women. It is also clear that the majority of female typed occupations reinforce stereotypical female traits such as nurturance and cooperation, suggesting that socialization processes impact occupational choices.

ARGUMENTS FOR AND AGAINST COMPARABLE WORTH

Opponents of comparable worth argue that implementing policies which focus on equalizing women's wages would be engaging in reverse discrimination against men. They further contend that it is an environment free from comparable worth that would allow women and men to choose jobs based on extrinsic factors such as pay and promotion and intrinsic factors such as challenge, variety, and compatibility with co workers. However, if women's wages were raised to a level where there would be no evidence of discrimination then the process would not discriminate against men.

In addition, opponents worry about the negative impact of holding over compensated wages (which are typically male dominated) frozen until pay equity adjustments and other increases (cost of living, etc.) create sex equity in wages. The argument is that comparable worth can be accomplished in theory, but is unlikely to work in practical applications. Proponents argue that comparable worth provides fairness in the job market by removing any residual discrimination, and that both men and women will benefit because neither men nor women would be guided into choosing jobs based on social stereotypes about what is acceptable. Finally, individuals would earn wages commensurate with the effort and value of their work, rather than the proportion of men and women who hold the job or the flexibility associated with a specific job.

CONCLUSION

The supply of labor is more than an economic process – it is also the result of sex based socialization. It seems unlikely that a vibrant and strong economy can exist if the labor market continues to undermine the productive contribution that women are capable of making. The issue is how to overcome the unfair and degrading practices of occupational segregation in which female typed jobs earn less primarily because the workers are women. Comparable worth is only one of several policies, which have been discussed as means to this goal. Since wage equity between men and women has not yet been attained, perhaps researchers should reinvestigate old ideas with new eyes and updated tools.

sex and crime

Ruth Triplett

Sex is one of the strongest correlates of crime. Researchers using a variety of ways of measuring crime find that females are less likely to be

involved in crime than males. Beyond the amount of crime, there is evidence that though there is some similarity in the types of crimes males and females commit, sex is related to the nature of offending as well. Despite the strength of the relationship of sex to crime, criminologists have historically ignored it, with a result that criminology's ability to explain this relationship is limited.

SEX AND THE EXTENT OF CRIME

Females are less likely to be involved in crime than males. Looking at data from the Uniform Crime Reports, clear evidence of this difference is readily seen. In 2000, for example, only 20 percent of all those arrested in the US were female. The rate of arrests for all crimes in 2000 was 9,752 out of 100,000 for males and 2,366 out of 100,000 for females.

The greater involvement in crime by males is consistent across time. Arrest data demonstrate that females offend at a rate across time that is consistently lower than that of males. This can be seen by a comparison of the percent of those arrested and the arrest rate for 2000 given above to that for 1965. The UCRs shows that in 1965, females accounted for 10 percent of all arrests and offended at a rate of 942 per 100,000. This is in comparison to males who, in 1965, accounted for 90 percent of all arrests and offended at a rate of 8,612 per 100,000.

Despite the consistent difference over time by sex, there is evidence that, in recent years, the involvement of females in crime is on the increase. In a careful analysis of arrest data from 1965 to 2000, Steffensmeier and Schwartz (2004) report that females moved from accounting for 10 percent of total arrests to 20 percent. At first glance these statistics might indicate the rise of a new "breed" of female offenders, but Steffensmeier and Schwartz's analysis reveals that this is not the truth. First, much of the increase in arrests for females overall was in minor property crimes, in particular larceny theft and fraud. Second, there are a number of crimes for which the female percent of arrests went down. For example, females accounted for 17 percent of all arrests for homicide in 1965 and 11 percent in 2000. Third, there has been a rise in the share of arrests for some violent crimes for

females. As Steffensmeier and Schwartz point out, the percent of arrests for aggravated assault and misdemeanor assault for females has risen. Between 1965 and 2000 the percent of female arrests for aggravated assault rose from 13 to 18 percent and for misdemeanor assault the percent rose from 9 to 20. The increase in some types of violent crime for females has raised the alarm among some. However, there is evidence that much of the increase in arrests for females for some violent crimes is caused more by a change in societal tolerance for these crimes than a real change in the behavior of females.

SEX AND THE NATURE OF CRIME

The relationship of sex to crime is found not only in the extent of offending but also in the nature of offending. Arrest data from the UCRs shows the difference is greatest in the violent and serious property crimes. For example, in 2000, females comprised only 11 percent of all those arrested in the US for homicide and 18 percent of those arrested for felony assault, while they accounted for 10 percent of all robbery arrests and 13 percent of all arrests for burglary. Females come closer to males in percent of arrests for minor property crimes, however. In 2000, females accounted for 33 percent of all larceny theft arrests and 48 percent of all arrests for embezzlement. The only crime for which females accounted for a greater percentage of arrests than males in 2000 was prostitution.

The difference in the nature of offending by sex is seen best in the difference between arrests for youths. Evidence suggests that the types of crime in which girls are involved are quite different from those of boys. Many of these differences parallel those between males and females overall: girls, like females overall, are much less likely to be involved in violent crimes. Arguably, the most significant feature of female involvement in juvenile crime, however, comes in the arrest rates for status offenses.

Status offenses are behaviors which are illegal for youths, but not for adults. They include such behaviors as running away from home, skipping school, violating curfews, the use of alcohol or tobacco, and incorrigibility. Since the development of the juvenile court, status offenses have been an important part of girls'

offending. Further, if we compare the nature of the offenses of female delinquents with those of males, it is clear that girls are considerably more likely to be arrested for status offenses. In 2000, for example, 21 percent of the arrests of females were for status offenses, while only 10 percent of the arrests of boys were in those categories. Girls comprised more than half of the arrests for running away from home (58 percent) – one of only two offenses recorded by the FBI for which females are more than half of the arrests (the other being prostitution).

Running away from home was, in fact, the third most likely offense for which girls were taken into custody in 2000 (larceny was the most common and “other offenses” were second). The top three offense categories for boys were “other offenses,” larceny, and drug abuse violations – running away ranks tenth in the arrest categories of boys in 2000. This difference in arrest rates for status offenses is striking because self report data suggests that boys and girls commit these offenses at similar rates. This strongly suggests that girls are more likely than boys to be arrested for behavior such as running away from home and incorrigibility.

There is also evidence that when they are arrested for status offenses, girls are likely to be dealt with more harshly than boys by the juvenile justice system. In spite of the fact that the 1974 Juvenile Justice and Delinquency Prevention Act specifically recommended the deinstitutionalization of status offenders, a significant number of girls continue to be sentenced to public or private juvenile institutions for these acts. In 1997, for example, 23 percent of all girls in residential placement within the justice system had a status offense as their most serious violation. Only 4 percent of boys in residential placement were there for status offenses. In 1997, almost half of the girls placed in private institutions were charged with status offenses, compared with 11 percent of privately placed boys. Overall, girls are a small minority of the juveniles in the US who are in residential placement (about 14 percent in 1997); however, they are quite close to a majority of youths who are incarcerated for status offenses. Clearly, the nature of the offenses that bring girls to a residential placement is different from that for boys. Girls are more likely to be institutionalized for a minor offense.

SEX AND CRIMINOLOGICAL THEORY

Despite its strength, historically, criminology has paid little attention to the relationship between sex and crime, spending much of its efforts focused on the criminality of males. In the 1960s, feminist criminologists began to develop a critique of mainstream criminology that focused on this neglect. They argue that, in the past, females have been neglected in the theory and research, and that when they are present they are viewed in a stereotyped manner. The result is that criminology has been, and continues to be, unable to explain why it is that males offend at such higher rates than females.

sex education

Debbie Epstein

The term sex education covers a multitude of approaches, meanings, and pedagogical strategies.

It is highly contextual, with localized cultures and understandings making significant differences both to the purposes and practices involved. It is also often highly politicized.

Sex education in both the UK and US has its origins in what Frank Mort (1987), among others, has termed the “medico moral” dis courses of the second half of the nineteenth century. However, as Pilcher (2005: 154) points out, the inclusion of sex education in the British school curriculum was controversial, since children were seen as simultaneously innocent and easily corruptible (a theme that has persisted into the twenty first century). Pilcher describes how serious concerns about the prevalence and spread of syphilis and gonorrhea, especially during World War I, propelled sex education into the school curriculum. The UK government subsequently began to provide funding for the National Council for Combating Venereal Disease (later the British Schools Hygiene Council) to carry out sex education in schools and also encouraged the introduction of lessons about sex hygiene and reproduction in biology lessons. This direct funding was with drawn and discretionary funding for sex education devolved to local education authorities in the late 1920s. Often, they chose not to provide such instruction, particularly after the Chief Medical Officer to the Board of Education questioned “whether direct class instruction in this subject is either advisable or practicable” (Board of Education 1930: 48).

World War II brought new moral panics about “dangerous ignorance” and the likelihood that sexual knowledge might be acquired in “ways which are likely to distort or degrade” (Board of Education 1943: 4). The 1950s marked a change in beginning to debate what the content of sex education should be rather than whether it should be taught at all. As Pilcher (2005: 160) points out, in the relatively short period between 1939 and 1956 sex had moved from a position of conspicuous absence in the health education curriculum to being rated as “the single most immediate problem” within it.

In the settler colonies (Australia, Canada, South Africa, and New Zealand), the development of sex education followed similar lines to those of the UK. Although little attention was paid to the formal education (let alone sex education) of indigenous people in these or

other colonies, there was a concern within the Colonial Office to prevent both “excessive breeding” by “natives” and “miscegenation.”

Similarly, in the United States, social purity activists in the nineteenth century called for women to teach their children about sex and argued for the introduction of sex education in schools in order to combat venereal disease in the early twentieth century. The actual introduction of sex or sex hygiene lessons into schools varied from state to state, depending to some extent on the relative strength of vice crusaders and social purity activists. While both these activist groups had the regulation of sexuality at the core of their campaigns (D’Emilio & Freedman 1988), they had very different approaches to this. Vice campaigners opposed sex education, believing that it would encourage “corruption” amongst the young. Social purity activists, in contrast, believed that the regulation of sexuality could best be achieved by the expansion of sex education (Irvine 2002).

Sex education curricula, practices, and theorizations in western Anglophone countries, as they have developed in the last years of the twentieth and first decade of the twenty first centuries, may be broadly divided into three categories:

- those taking, as their starting point, the promotion of sexual abstinence;
- those which, while not specifically promoting abstinence, nevertheless focus mainly on sexual reproduction and danger;
- more emergent approaches which are rooted in the sociological, psychological, and historical study of sexuality more generally.

The promotion of sexual abstinence (“abstinence only”) education is particularly strong in the US. The view underlying these approaches is that sex education is directly responsible for increases in sexual activity, the growth of sexually transmitted diseases, and an increasing number of unwanted teenage pregnancies. “Abstinence only” education avoids discussion of sex, sexual relationships, or contraception, focusing instead on the idea that sexual intercourse should be delayed until after marriage and, in some programs, getting young people to pledge that they will remain virgins until they marry. Strictly speaking, therefore, “abstinence only” education is not a form of

sex and relationships education at all (Sex Education Forum 2004). However “abstinence only” education has a long tradition and has been promoted in at least some US states for at least two decades. Despite this, there is no evidence that “abstinence only” education has the desired effects. Indeed, a number of researchers argue that it places young people at risk through their ignorance and the fact that if they expect to remain virgins, they are unlikely to be prepared to use contraception if and when they decide to become sexually active (Bearman & Bruckner 2001; Swann et al. 2003).

Despite the promotion of “abstinence only” education in the US, the dominant approach to sex education in most Anglophone countries is much more embedded in the teaching of sexual reproduction (e.g., in biology lessons) and the transmission of messages about danger and disease. Such approaches have been extensively described and critiqued by major theorists of sexuality and education. Michelle Fine (1988) was one of the first writers from a sociological perspective who engaged critically with sex education. Fine identified a number of discourses of sexuality in sex education lessons: “sexuality as violence,” “sexuality as victimization,” and “sexuality as individual morality” were the most common. She also identified a “discourse of desire,” which she found to be present only as a “whisper” – or even missing completely from sex education. Fine argues strongly that a language of desire is critical in allowing young women in particular to explore sexuality. She concludes that: “the absence of a discourse of desire, combined with the lack of analysis of the language of victimization, may actually retard the development of sexual subjectivity and responsibility in students” (Fine 1988: 49).

Research on sex education in the US (Trudell 1993), the UK (Thomson 1994; Measor et al. 2000), and Australia (Harrison & Hillier 1999) has shown that the mainstream approach to sex education in these (and other) places continues to focus mainly on sexual danger, moral imperatives, and sexual reproduction. With this fairly narrow focus this could be regarded as “sex education” in the strict sense. In this context, young people may be taught about the biology of sexual reproduction, the importance of, as the UK government stresses, “marriage for family life, stable and loving relationships” (DfEE

2000, 5: para. 9), and the dangers of pregnancy and sexually transmitted diseases. As Fine (1988) showed, this approach excludes discussion of pleasure or desire.

Peter Redman (1994) has suggested that we should differentiate between “sex education” and “sexuality education,” and proposed the development of the latter to supplant the former. Epstein et al. (2003) define sexuality as encompassing the “sexual cultures and sexual meanings [that] are constructed through a range of discursive practices across social institutions including schools” (p. 3), and argue that sexuality education in schools should be part of the humanities and social sciences curriculum rather than, as currently, included in biology and/or personal, social, and health education (in the UK), life skills education (in South Africa), or taught as a separate subject. They propose that young people should study the history and sociology of sexualities at different times and in different places, enabling them to question their own assumptions around, for example, heterosexuality, race and sexuality, and the stability of legitimated sexual forms.

Because sex education must be understood contextually, attention must also be paid to what happens in poor to middle income countries, especially those with severe problems due to the high prevalence of HIV/AIDS. There have been two primary approaches in these contexts. The first, as promoted particularly by supra and international organizations such as the World Bank and the OECD, sees education for women generally, and sex education in particular, as a means of limiting population growth in poor countries. This approach has been described as analogous to a “silver bullet” (Jeffery & Jeffery 1998; Jeffery & Basu 1996), which will act as a kind of contraceptive for women in these countries. Thus sex education in “developing” countries is often seen very instrumentally and, with its emphasis on biology and danger, is similar to the mainstream approach outlined above (see Pattman & Chege 2003).

Second, with the advent of the HIV/AIDS pandemic, there has been a further urgency added to the need for sex education and changing behavior in countries particularly affected by the virus. One of the key problems identified by those who are researching sex and HIV/AIDS education in the context of the

pandemic is that the burden of prevention of the spread of HIV/AIDS has, to a large extent, been placed on women. One of the key points made by such researchers is that any sex, sexuality, or HIV/AIDS education programs need to pay much greater attention to promoting gender equality if they are to have any chance of success (see, e.g., Abdool Karim et al. 2002; Unterhalter et al. 2002; Campbell 2003; Morrell 2003).

sex and gender

Barbara Ryan

Often confused or used as if the terms were the same, sex and gender are in actuality different designations of human behavior based on physical capabilities and social expectations.

Sex is related to the biological distinctions between males and females primarily found in relation to the reproductive functions of their bodies. Biological sex is usually stated as if there are two, and only two, distinct bodies: male and female. But, in fact, there are gradations between male and female accounting for at least five sexes (Fausto Sterling 1999). In the past called hermaphrodites, and today intersexual, these are people with a mixture of male and female genitalia. In addition, there are those who feel they are encased in a body of the wrong sex, some of whom take hormones and even undergo surgery to become transsexuals. Another classification is transgender, which is often used in the same way as the word transsexual, but also indicates people who cross the barrier of gender without physical change.

Sex is not a clear cut matter of chromosomes, hormones, and genitalia that produce females and males. All humans have hormones, such as estrogen and testosterone, but they are found in varying and changing levels (Fausto Sterling 1999; Kimmel 2004). Men as well as women have breasts. Some men have bigger breasts than some women and some men get breast cancer. Women have facial hair. Indeed, some women have more facial hair than some men.

Gender is a social definition of how to be or the ways of "being" considered appropriate for one's sex category. Because gender can be enacted in an infinite variety of ways, and indeed is, we know that gender is a social construction and, therefore, learned behavior.

Other terms closely related and often confused with sex/gender are sexual orientation and sexuality. Sexual orientation is descriptive of who you desire to have sexual relations with; that is, who is the object of your desire. Same sex desires indicate homosexuality; opposite sex desires indicate heterosexuality; sexual desire for both men and women indicates bisexuality (Ryan & DeMarco 2003).

Depending upon where and when you live, these classifications can affect your life in multiple ways. Thus, there is a long history, as well as ongoing processes, of differential treatment based upon one's sex, gender, and sexual orientation. What this leads to is privileged groups, those having access to the goods of society and those who are prohibited from such things. The casual dismissal of people who are different

from the powerful and dominant group carries with it a superior/inferior connotation that permeates every aspect of social life and, beyond that, can also lead to internalized oppression.

Most people live their lives with unquestioned assumptions about men and women based on an overemphasis of the role of biology in shaping human behavior (Rosenblum & Tavris 2000). This tendency is called biological reductionism (or essentialism) and is often justified as the work of nature or God. Although it is doubtful that Freud believed the differences between men and women were reducible to naturalistic thinking, the term he coined – "anatomy is destiny" – has been used as a justification for keeping women out of work deemed unfeminine (and typically higher paying) or to expect men to display masculine behavior at all times. Defining human designed categories as the result of biology or "intelligent design" is meant to remove that categorization from debate and, even further, to deny questioning of the concepts at all.

The fact is, the effects of social interaction on human behavior far override biological differences (Kimmel 2004). It is a western tendency, particularly American, to embrace a binary and biologically based perspective rather than one focusing on social forces as an understanding of how we think, talk, and otherwise behave and that this early determination is unchanging – that it is fixed for life. It is a belief that has been reinforced and promoted through the mass media, law, religion, and other social institutions.

For some time now, scholars, researchers, and activists have challenged perceived differences among people, such as race and gender. Research has shown a profound social influence on sex, gender, and sexuality (Connell 2000; Fenstermaker and West 2002; Glenn 1999; Seidman 2003). This new emphasis is a social constructionist perspective rooted in the understanding that reality is created in everyday interactions (Berger & Luckmann 1966). From a social construction perspective, differences among people emerge through interaction and the social processes of institutions such as religion, politics, economic positioning, and work relations.

Babies do not develop on their own into adult human beings. Socialization is the process

by which we learn the ways of society and our place in the social world. It is how we become "human." Society is around and within us. We learn from others how we are expected to live in our culture, our subcultures, and in accordance with our gender. That is, we are taught to have attitudes and behaviors based on our designation of male or female. Gendered messages are everywhere and constant, beginning with the family.

Family interactions are pivotal in the construction and the maintenance of gender ideologies and roles. As children grow, their agents of socialization broaden. They go to school and learn new ways of defining gender distinctiveness. They also begin interacting with peer groups that have an influence on their sense of self. This peer influence increases as the child progresses towards adolescence when the peer group becomes more powerful than family expectations.

A powerful influence on how gender is socially constructed comes from the mass media, particularly television. Gender socialization does not end with childhood; it continues throughout our life. Traditional stereotypes of men and women are perpetuated because women are still cast as younger, supportive counterparts to men, and older women are still the most underrepresented group (Gahahl et al. 2003). Likewise, movies provide scripts for how to live our lives while "doing gender." From the time of the earliest films, they have shown us the stereotypical gender roles we are meant to play on the stage of life.

Sex and gender are related yet distinctive terms, both heavily imbued with definitions, restrictions, privileges, and misconceptions based on the ways they have been socially constructed in different societies around the world. Sex, the biological component, is often used as a justification to privilege men over women. Gender, which has the widest and deepest applications, is often treated as if it were a biological condition rather than a social categorization that can and is used for placement in stratification systems.

sex panics

Benjamin Shepard

The concept of a sex panic builds on the idea of moral panic – a term first coined within British sociology and Stuart Hall's cultural studies. Sex panics are a distinct form of moral panic. The term moral panic builds on themes from American sociology of deviance, theories of collective behavior, social problems, French structuralist theory, and Frankfurt School social theory. Moral panics about youth have been assessed as studies of subcultures, while other inquiries have adopted social and psychological perspectives borrowed from disaster studies. As theorists grappled with the meanings of the AIDS epidemic and public policies aimed at alleviating

social problems, conceptions of moral panics overlapped with debates about “the under class.” A frequent theoretical approach to studying representations of moral panics about sexuality is to analyze “discourses” that regulate sexuality and demarcate hierarchies of what is and is not normal and moral, worthy and unworthy. Thus, panics have been analyzed from a range of different perspectives. In *Moral Panics*, a reader on moral panic as a “key idea” for sociological inquiry, Thompson (1998: 72) counsels: “It may be a sensible tactic to adopt insights from each of these in an eclectic manner or to combine them where appropriate, depending on the particular type of moral panic being studied.”

The first reference to the term moral panic was by sociologist Stanley Cohen in 1972. His point was that to the extent that cultural institutions draw parameters around deviance, they create moral panics. The process can be described through an escalating cycle. The cycle begins as a distinct group – perhaps a youth gang, gay men, or teenagers on welfare – engages in distinct acts, such as having sex in public or being on public assistance. These acts are viewed as a threat to traditional values and society at large. Once the threat is identified, it is presented in a highly charged, black and white manner in the media (Cohen 2002). This reduces the understanding of the complexity of the group or circumstances (Bourdieu 1998). From here, “right thinking” moral entrepreneurs such as state officials, police, social workers, bishops, psychologists, and other licensed experts establish diagnoses which pathologize and punish. These solutions tend to assert social control over activities and groups.

For Cohen, the moral panic scapegoat becomes a “folk devil” onto whom cultural anxieties are projected. Cohen focuses on the symbolic controls, the mythologies, and the labels at play as folk devils inspire widespread reaction. Thus, studies of panic consider the highly charged symbolic functions generating collective behavior, the stereotypes which from time to time inspire profound widespread hysteria.

Weeks (1985) suggests that the mechanics of these moral panics are quite familiar. They start with a threat from a youthful event or gathering. Those involved are stereotyped as demons; discourse about the threat escalates; this leads to

a simplified view of the problem and a draconian policy solution; anxiety wanes while the victims, the “folk devils,” are left to withstand often brutal legal penalties.

At its core, the concept of moral panic considers the role of political demonology: the labeling of opponents as threats to moral and social order. These are the folk devils Cohen describes. Stereotyping often has the effect of establishing power of one group over another group of people, in favor of a status quo. For this reason, people generally do not like to be categorized, labeled, or attributed with certain common characteristics. The process of being labeled limits freedom of movement and self-determination. Labeling is used to scapegoat – blame – and therefore control other people (Fisk 1993).

This process only escalates in the case of sexual panic. Historian Allan Bérubé suggests that the term sex panic refers to a moral crusade which results in “crackdowns on sexual outsiders” (Gaywave 1997). Duggan (1995) notes that such panics, red scares, and even witch hunts can be witnessed throughout countless chapters of US history. They are generally advanced by vocal interest groups with animosity toward cultural difference. In their most dangerous expression, these panics have been championed by crusaders hoping to establish one distinct brand of orthodoxy on the majority. These panics tend to deflect public discourse away from social problems involving race, sex, or poverty, which if addressed might shift social arrangements. Thus, panics can be understood as distractions.

For this reason activists have consistently sought to challenge these structures. By the mid 1980s, queer activists recognized that panic over the AIDS crisis impeded an effective response. From 1987 through the 1990s the AIDS Coalition to Unleash Power (ACT UP) enjoyed great success in its struggle against a panic over the AIDS epidemic. Much of the winning strategy involved the use of colorful, theatrical, playful, inventive, and aesthetic interventions which changed hearts and minds. Art critic and former ACT UP member Douglas Crimp suggests ACT UP’s work helped transform public discourse about the epidemic away from blame and hysteria toward a recognition that AIDS was a public health issue which

required an assertive government response (Takemoto 2003). Yet, panic was never far away.

In the summer of 1997 an ad hoc group of activists and scholars declared: *J'accuse*. They suggested that the policies of New York Mayor Rudy Giuliani's Quality of Life crusade fit a distinctively American political schema. The group noted this was not the first time government has advanced repressive policies around sexuality in the name of the larger public good. The group noted that since the ante bellum days of labor unrest and Anthony Comstock's social purity crusade (Gilfoyle 1992; Beisel 1997; Wagner 1997), attacks on sexuality have emerged within a distinct, recurrent pattern: morals are invoked; folk devils are found in gay people, prostitutes, and other sexual outsiders who function as scapegoats; and finally, a fantastical notion of social purity, which few live up to, is presented as a social norm. "Historians have come to call this pattern a 'sex panic,'" the group noted. Thus, they borrowed the term as the name for their group in order to highlight their view that with the mid 1990s effort to clean up New York City they were witnessing yet another sex panic (Crimp et al. 1997).

With that, SexPanic! was born. SexPanic! led the struggle against Giuliani's war on public sexual culture taking place under the auspices of his Quality of Life Crusade. Their work included a struggle against panic in private spaces where communities of sexual outsiders converge; it compared Giuliani's struggles with those of anti vice crusader Anthony Comstock. The group utilized a politics of play and pleasure to challenge structures of panic. These struggles can be understood as part of a lineage of protest against prohibition dating back to the days of the Temperance Movement (Wagner 1997).

The concept is useful in that it helps explain collective behavior – including periods of "hysteria," "red scares," and "prohibition." Yet Cohen (2002) is frank to acknowledge that just because something is stirred by irrational behavior does not necessarily mean it is a panic. Future research on the topic must work to make sense of these elements of collective behavior, which create panic. Hence, it must do more than name and acknowledge that panics exist. It must identify and highlight best practice approaches to combat periods of panic.

sex tourism

Susan L. Wortmann

Sex tourism is a multibillion dollar global industry wherein individuals (sex tourists) from industrialized, developed nations travel abroad with the distinct purpose of purchasing a variety of sexually associated services. Destinations vary, but most sex tourists seek the services of

individuals from developing nations. Sex tourists' travel and consumption, facilitated by technology and an unequal and increasingly interconnected world system, have raised the profitability of this industry to a historically unprecedented level. Blending global race, ethnicity, class, gender, and age inequalities with capitalist consumption, sex tourism creates and perpetuates a range of problems for sex workers and host countries. A growing body of interdisciplinary studies reveals a complex blend of exploitation and agency involved in sex tourism, the links between local and global, the need for inclusive and further study of homosexual, transgendered and bisexual, as well as heterosexual sex tourism, and the importance of understanding rather than stereotyping workers and experiences.

Worldwide, tourism itself is a major business. According to Williams (2002), 83 countries list tourism as one of their top five export categories. Economically vulnerable developing countries with exploitable resources often welcome the revenue that tourism brings. Indeed, because it can be a country's largest revenue source, there is also a tendency to uncritically associate all types of tourism with economic advancement. International organizations such as the World Bank and the International Money Fund (IMF) have provided loans for tourism as a mechanism to end poverty in developing nations. Many scholars question the impact of these loans, however, illustrating that because of devalued currencies, immigration, urbanization, and gendered labor markets, tourism is, especially for women of developing nations, a likely entry to service and sex work.

Fun, sun, adventure, and consumption of an affordable exotic Other are internationally associated with sex tourism's allure. This appeal is a commodity manufactured and maintained by technologies of developed countries. For example, foreign consumers have ready access to information and services from afar: through the Internet, chat rooms, e diaries, blogs, Internet promotional videos, and guidebooks. Readily accessible is advice on how to arrange a sex tour, how to bargain with submissive sex workers, best sites, and best workers. Some Internet sites allow tourists to arrange and customize complete packaged sex tours online. Importantly, sex tourists' destination countries have

little control over how their citizens are represented. For example, a number of sex trade brochures and magazines are produced in Europe. Additionally, cyberspace sites often feature stereotypical "sexy, willing, and submissive natives," and charter services advertise "exotic scenery" counterpoised against nearly naked bodies. Entire populations, in effect, become sexually commodified.

Air travel facilitates access to a number of developing countries with warm climates. While popular destinations include Thailand, the Philippines, the Dominican Republic, Costa Rica, and Brazil, sex tourism is not limited to locations in Southeast Asia and South America. Specific cities and regions are often associated with sex tourism, e.g., Holland's Amsterdam, Kenya's coast along the Indian Ocean, Cuba's Havana, and Thailand's Patpong region. While some locations have established cultural patterns of prostitution (for instance, brothels are traditional in Thailand), the influx of tourists looking specifically for sex associated services, along with developing nations' poverty and lack of jobs, have increased the local sex economy to a historic high. In some cases, this increase can be directly traced to deliberate intervention by governments and financial organizations. For instance, the sex trade in Thailand grew substantially during and after the Vietnam War when the governments of the US and Thailand negotiated a contract for American soldiers to be sent there for rest and relaxation (R&R). Both governments were thereby indirectly responsible for an increase in brothels.

While gay, lesbian, bisexual, transgendered, and heterosexual individuals engage in sex tourism as buyers and sellers, statistics and studies of the demography, psychology, experience, and motivations of tourists and workers are limited. Most, for example, explore the sex tourism of heterosexual middle/upper class males from industrialized nations such as Japan, Germany, or the US who seek young, submissive women for sex and companionship. The most commonly researched sex worker is a poor, young woman of color who has often migrated from a rural to an urban setting or to another country to support herself and/or her family. Accounts suggest that she may have found the sex trade much more lucrative than factory and domestic related trades, she may have found it the only

job available, or she may have been tricked or forced into sex work. Buyer and seller fantasy, according to many narratives, is an important industrial feature. Ethnographies reveal that, in addition to sex, some heterosexual male tourists seek submissive companionship, while some heterosexual women sex tourists seek romance or racialized exotic Others. Homosexual, bisexual, transgendered, and heterosexual sex workers alike appear to fantasize that their clients will offer more than money. For example, in overtly patriarchal countries, female sex workers may seek men who can provide them with more egalitarian gender relations, extended relationships, a visa that allows them to travel abroad, or even marriage. Gay sex workers appear to be motivated by gifts, money, promise of travel, and migration. Sexual identities are not necessarily stable among buyers and sellers – several accounts note that some male sex workers who service primarily men continue to have women as intimate partners, and that male tourists who are married to women purchase services from male and transgendered sex workers.

Sex tourism is credited with both the creation and intensification of micro and macro social problems including, but not limited to, violence against individuals (workers and tourists); disease and morbidity; child prostitution; and social/environmental destruction. Sex workers often suffer abuse and exploitation from clients, including refusal to wear condoms, physical or emotional violence, and failure to pay. They are likely to experience harassment by club operators and law enforcement. In most countries the sex trade is illegal and sex workers are unlikely to be legally protected. AIDS and sexually transmitted diseases (STDs) are prevalent and can impact buyer, seller, or future and present sex partners and children. Paradoxically, the threat of AIDS is reported to appeal to some sex tourists who regard it as adventure and high risk sport. Child prostitution, reported in many areas, has attracted international attention. International actions, such as passing legislation to make those who engage children as prostitutes liable abroad and in their own countries, may deflect attention and resources from adult workers and may make them scapegoats for the sex trade. Furthermore, all types of tourism

strain developing countries' environments, increase demands for natural resources, and produce additional pollution and waste.

Feminist scholars such as Enloe (1989) were instrumental in bringing academic attention to sex tourism. Interdisciplinary engagement has revealed a complex portrait of a range of issues that problematize earlier understandings of sex tourism as solely exploitative, that seek to broaden the focus to all types of workers and tourists, and that point to the importance of academics understanding their own positionality and tendency to "other" sex workers and tourists. Some challenge traditional definitions of sex tourism itself. For instance Ryan (2000) defines sex tourism merely as "sexual intercourse while away from home." Research emphases differ; some explore sex tourism on the macro level of global economic, social, and historical factors, while others emphasize the importance of inequalities of race, ethnicity, class, and gender separately, or together, and how these impact workers and tourists. Still others emphasize micro levels of interaction by stressing that the sex trade involves negotiation, agency, and opportunity for buyer and seller. Each of these conceptualizations impacts research emphases, findings, the resultant local and international policies, and, ultimately, the lives of individuals engaged in the global phenomenon of sex tourism.

sexism

Amy Lind

Sexism is discrimination on the basis of sex and/or gender. It occurs at various levels, from the individual to the institutional, and involves practices that promote gender based prejudice and stereotyping of social roles. Most commonly, sexism refers to inequalities that exist among men and women, particularly where women are treated as unequal or inferior to men. Like other forms of discrimination, sexism can occur through blatant or covert actions, including outright displays of hatred or disdain for an individual or group; the privileging of one gender over another; or tokenism, where, for example, a woman is hired only because she is a woman, rather than because of her skills and experience. How sexism plays out varies according to the social location of the individual or group

involved, particularly in regard to racial, ethnic, class, sexual, and/or religious background.

Beginning in the 1960s, sexism became a commonly used term by participants in second wave feminist movements in the US, Britain, Canada, and Europe and elsewhere. In the US, the National Organization for Women (NOW, co founded by Betty Friedan) fought for an Equal Rights Amendment (ERA) which, had it passed, would have provided full equality to men and women under the law. Affirmative action policies (a type of positive discrimination) also became an important strategy for reversing historical gender inequalities. In Britain, Europe, and other regions, legislation was proposed to end gender discrimination in the workplace, educational system, and political system. In the 1990s and 2000s many developing countries began to propose affirmative action policies to reverse gender discrimination as well (IWRAP 2005).

Beginning in the 1960s, US feminists organized widely against sex segregation in the labor market and workplace and introduced notions of unequal pay and comparable worth to address the unequal value assigned to “feminine” vs. “masculine” types of employment in US society (England 1992). Several studies address the gender wage gap in earnings among men and women; some break these figures down according to race/ethnicity (Jacobsen 1998). Comparable worth advocates have argued that increasing women's wages is not enough; rather, it is also necessary to rethink how certain types of jobs or employment sectors are viewed as “feminine” and therefore as inherently less economically worthy than those jobs viewed as “masculine.” For example, physicians, astronauts, and attorneys tend to be paid more than nurses, teachers, and secretaries (Lindsey 1997: 76). Men who provide administrative assistance are “office managers” whereas women are “secretaries.”

In relation to this, sociologists have also addressed how sexism is inherent in language: in the structure of language and in everyday communication. They have pointed out how male pronouns are used to define all of humanity, as in the phrases, “all men are created equal,” “we need the right man for the job,” and “we live in a manmade society.” Just as “man” is assumed to refer to both men and

women, “he” is assumed to refer to “she.” Similarly, many titles and occupations are biased toward men, as in “businessmen,” “newsmen,” or “mailmen,” despite the fact that women work in these professions (Lindsey 1997). Advocates of gender equality have worked to create more gender neutral language and one may now hear references to “business people,” “news reporters,” and “mail carriers.” Scholars have also pointed out how, in everyday communication, informal exchanges, gossip, or jokes may reproduce stereotypical gender roles and identities. Verbal sexual harassment at work or on the street is one example of this.

Sexism has been challenged in the courts in many countries, as in the case of the US with the passage of the 1972 Educational Amendment to the Civil Rights Act. Typically referred to as Title IX, this legislation mandated that schools, colleges, and universities that received public funds must provide equality in funding for male and female students at all levels. This allowed female students equal opportunity in their academic pursuits and athletic activities for the first time in history. Gender based affirmative action policies, based on the racial model proposed originally by civil rights leaders, were introduced in the early 1970s, particularly in the areas of employment and education to ensure that women “enjoyed the same opportunities for promotions, salary increases, career advancement, school admissions, scholarships, and financial aid” as men (Brunner 2005). An example of positive discrimination, these policies were seen as temporary and remedial rather than permanent. During the 1990s, critics challenged the constitutionality of gender based and race based affirmative action policies in the courts, arguing that they were a form of reverse discrimination. Defenders contend that such policies are necessary in societies where gender (and racial) inequality is institutionalized and ongoing. Discrimination against women, sometimes referred to as sexual discrimination in legal discourse, is now illegal in many countries, although these laws are difficult to uphold. The United Nations Convention on the Elimination of All Forms of Discrimination against Women (CEDAW), adopted in 1979 by the UN General Assembly, urged governments around the world to adopt legislation that promotes gender equality. As of

2005, 90 percent (180 member countries) have ratified the Convention.

The definition of sexism has changed over time, reflecting contemporary sociological debates on sex vs. gender and nature vs. nurture. During the early stage of second wave feminism, sexism was typically defined as unequal treatment on the basis of sex. Later social theorists emphasized gender, rather than sex, as the appropriate level of analysis, since, they argued, discrimination is based on cultural, rather than biological, difference (Lorber 1994). Some went even further to argue that how a given society defines sex difference in human anatomy is also a product of culture and not a predetermined, natural given.

To the extent that sexism is based on the assumption that there are essential differences between men and women (be they biologically or culturally based), then it is an *essentialist* notion. Postmodern scholars have emphasized how individuals of both dominant and marginalized groups reproduce sexism, pointing out, for example, that women themselves reinforce structures of domination by engaging in sexist jokes and competing unfairly with other women. While the nature–nurture debates continue, many feminist scholars would continue to agree that the social context, rather than any assumed biological difference between men and women, is crucial to understanding how and why women are viewed as the “weaker sex” and therefore subject to sexism.

Critics have argued that sex/gender difference does not imply sex/gender discrimination per se, and that by blaming men, feminists are promoting reverse sexism. Other critics argue that sexism alone is not enough to understand gender based discrimination, particularly for non European, non white women; rather, one needs to assess gender inequality in conjunction with, for example, racial, ethnic, sexual, or class inequality (Collins 1998). Most feminist scholars would agree that the most pervasive type of sexism is that which continues to exist in people’s belief systems and cultural attitudes – beliefs and attitudes which cannot be changed immediately through legislation.

sexual citizenship

David T. Evans

All sociological analyses of human sexualities contain implications of differential social exclusion, and social movements such as Gay Liberation, feminism, and Queer activism fight for sexual "rights" employing the rhetoric of equality. However, only in the last decade have such issues been explicitly theorized and researched under the rubric of sexual citizenship, focusing on the political, legal, and economic construction of sexualities through the institutionalized principles and processes of heteronormative

liberal democratic citizenship, though precisely how has remained open to considerable disagreement.

In earlier micro and middle range sociological accounts, hegemonic heterosexism was invariably acknowledged, but as an implicit ideological, rather than explicitly structural, dominant presence. Discussion and analysis of the patterned discriminatory consequences of hegemonic heterosexism on aspects of mundane citizenship, such as taxation, life insurance, health care provision, home ownership, inheritance rights, conditions of employment, use of "public" and "private" spaces, etc., were thereby absent. Given the institutionalization of the family as the natural "dominant regime of (heterosexual) truth" (Mort 1980), these omissions were unsurprising and unrecognized. As one result, the early sociology of sexuality commenced its critiques of naturalist explanations by responding to the latter's focus on discrete forms of "deviance" requiring explanation, as heteronormative forms did not. During the 1980s the impact of postmodernist and "queer" perspectives further discouraged macro analysis of sexualities deemed to be increasingly fragmented, fluid, and unstable. However, during the same decade, citizenship in general excited new social scientific interest. The conceptual and interpretive origins and disagreements in sociological accounts of sexual citizenship derive from these differences in academic and political provenance, at the heart of which reside contested accounts of late modernity and citizenship in general.

Citizenship has had a sustained presence in British sociology due to the lasting influence of Marshall's (1950) classic account of civil, political, and social rights, the development of the modern British welfare state as part of post World War II regeneration and, since the 1950s, the growing impact of conditions of "disorganized" capitalism: fragmentation of economic interest groups with greater industrial flexibility in economies increasingly consumption driven; breakdown of neo corporatist state regulation; growing contradictions between state and capital; growth of new, seemingly fragmented and discrete, social movements, and active citizens as reflexive consumers. "Capital, culture, technology and politics merely came together to roam beyond the regulatory power

of the national state" (Urry 2000), which of necessity retreated from moralist to causalist principles. Rather than appraising sexual behaviors as "immoral" and interfering in the private lives of citizens "to seek to enhance any particular pattern of behavior," the law became primarily concerned with proven deleterious effects on "victims," the preservation of "public order and decency," protection of the citizen from "public" offense and injury (Wolfenden 1957), and the restriction of tolerated sexual deviance to "private" spaces. This reformulation of regulatory principles inevitably impinged on those of citizenship. While justifications for partial or complete citizenship exclusion are to be found in classic accounts such as Marshall's (1950) specification that social rights include "all . . . rights which accrue from the fundamental right to share to the full in the social heritage and to the life of a civilized being according to the standards prevailing in the society," their implicit heteronormative (dis) qualifications remained largely unrecognized and unaddressed until post Wolfenden legal reformulations began to have a concrete impact.

Under these new social conditions of disorganized capitalism, the citizenship space in civil society opened up between criminality (sexual murder, rape, pedophilia, etc.) and heteronormativity became occupied by conditionally "legal" but relatively differentiated "immoral" and thus partial sexual citizens, with their own specific rights and duties, which in turn underpinned the development of associated niche markets of leisure and lifestyle consumption. Inevitably, traditional forms of governance were strained by the structural disjunction between growing amoral market pressures on such "private" urban sexual spaces and "moral" state authority, leading to heightened pressure on key normative distinctions such as "morality," "legality," "public," and "private." By the 1980s this underlying disjunction resulted in a political hiatus in which New Right free market liberalism encouraged the expansion and expression of "private" sexual lifestyles, amid strident reaffirmations of family values in the face of AIDS, child sex abuse, and other moral panics.

Liberal democratic citizenship had apparently reached a breaking point, but the crisis was "resolved" in Britain by the Citizen's Charter (HMSO 1991), which gave due regard

to citizens' "privacy," "dignity," and diverse "cultural beliefs," still exemplified by such references to "citizens, especially as parents." The citizenship balance shifted from welfare rights and the relationship between individual, community, and state, to rights of informed choice by autonomous individuals as consumers. Rather than citizenship being conditional on conformity to "standards prevailing in the society," it became "that set of practices (juridical, political, economic, and cultural) which define a person as a competent member of society, and which as a consequence shape the flow of resources to persons and social groups" (Turner 1993a), competence being defined as responsible self regulation. Liberal democratic citizenship was thus revitalized as an "inclusive" status regardless of class, ethnic, gender, and sexual difference, in which competent "legal" but "immoral" minorities regulated themselves into forms of "privacy," but still leaving the "ideal citizen" as a married, white, male, heterosexual property owner.

Only during the early 1990s did mainstream academic discourses begin to acknowledge this economization and sexualization of citizenship, hesitantly noting, for example, that some citizenship tensions "appear to be centered around . . . the struggle for homosexual rights" (Turner 1993a). Homosexual and lesbian citizenship has dominated subsequent sexual citizenship concerns, though other forms of citizenship tension, conflict, and even chaos have emerged concerning the citizenship status of, for instance, sex workers and their clients, users of pornography, transsexuals, children, claimants for access to reproductive technologies, surrogacy and adoption, sex tourists, and unmarried heterosexual partners.

The sociology of sexual citizenship emerged out of the political and intellectual hiatus of this period. It did so through two perspectives which, despite common and complementary elements, differ markedly in their basic conceptualizations. Both agree that citizenship rights are not "natural" and inalienable," but forged out of social activities built into notions of community and identity. Their disagreements hinge on the always vexed relationship between dominant power structures and actor sovereignty, disputes over the extent to which dominant political and economic forms have become increasingly

compromised, and the state's adaptive capacity to sustain fundamental heterosexist patriarchal principles and practices of citizenship despite ostensibly making "liberal" concessions, by enforcing differential forms of unequal and partial sexual citizenship.

Though not always using the term, Plummer (1992, 2003), Giddens (1992), and Weeks (1998) explore alternative "pure" and "intimate" forms of sexual citizenship, outside the civil, political, and social dimensions of convention. In contrast, Evans (1993) concentrates on a materialist exploration of the inherent heterosexism of conventional citizenship, and on the increasingly overt sociosexual consequences of late modern reformulations, and these analytical distinctions are reflected in their different political prognoses.

Plummer (1992) hailed the emergence of the "culture of sexual citizenship" out of the 1980s "uncertainty over politics": the rise and decline of the New Right, failure of socialism, the rise of new utopian social movements, etc. He asked: "where does the lesbian and gay politics which flourishes in the latter part of the twentieth century in the Western world sit in all this end of century change?" The tone is of optimism and empowerment of diverse sexual citizens beyond traditional formal citizenship control, enabling "a radical, pluralistic, democratic, contingent, participatory politics of human life choices and difference . . . in the making" (Plummer 2003). While older sexual minorities discoursed in terms of civil, political, and social rights, this new regime is distinguished by the emergence of a fourth citizenship dimension: intimate citizenship, manifest through new communities of discourse, sexual stories and identities, diverse alternative rights and responsibilities, pleasures, bodies, visibility, and relationships. "Such stories play a prominent role in understanding the workings of the political and moral life of late modern societies . . . and carry potential for the radical transformation of the social order" (Plummer 2003). This new "culture of sexual citizenship" is dependent on new cultural intermediaries (mass media, advertising, Internet technologies, markets for "symbolic goods," etc.), which facilitate "imagining," "vocalizing," and "invention" of identities and cultures of shared problems. Similarly, Giddens (1992) refers to the emergence of "pure relationships,"

sexual relationships based on equal vulnerability, mutual trust and respect, "relationships of social and economic equality." For Weeks (1998), the "sexual citizen" "could be anyone . . . (who) exists or . . . wants to come into being – because of the new primacy given to sexual subjectivity in the contemporary world.

In contrast to this culturalist emphasis, Evans (1993), drawing on similar symptoms of 1980s political crisis, concentrates on the crisis management of the late modern state to maintain its "moral" authority through reformulations of heteronormative citizenship to incorporate and depoliticize "competent" sexual and other "partial" citizens, through the extension of single issue "rights" (fetishized as "equal"), while using examples of sexual "incompetence" to reaffirm dominant heterosexist values. Given "disorganized" conditions, it is acknowledged that periodic crises in governance enable the emergence of intimate alternative claims on citizenship, but these in turn are defused through further citizenship readjustments. Thus, while for Plummer (1992) "'rights' campaigns around 'being gay' and 'lesbian' have had some remarkable payoffs in the western world . . . (in which) being gay and lesbian . . . has become a positive experience bringing no more problems than any other way of living and loving," for Evans such claims demonstrate how effectively bourgeois citizenship adapts and incorporates, as evidenced by the extent to which sexual political movements "now talk in the language of citizenship – rather than of liberation as in an earlier generation" (Richardson 2000). Thus, new forms of sexual citizenship, behind the rhetorical facade of "liberty" and "equality," provide the means whereby the state fragments, neutralizes, and distracts sexual dissidence to sustain and protect its own "moral authority" and the greater capitalist and heteronormative good.

Disagreements at the heart of both versions extend to a range of key structural and political elements. While sexual communities exist as central to the emergence and sustenance of intimate citizenship, for structuralists they are fetishized "communities," riven by internal divisions of class, ethnicity, age, and gender, etc. Numerous studies of the differential impact of HIV and AIDS on "the gay community" reveal deep inequalities between such constituencies and access to sexual health care, information, and

treatment. Uncritical references to “the gay community” thus in effect sustain the gay political dominance of white middle class males. Further more, “gay” media, advertising, and consumption of “symbolic goods” reflect not empowered intimate citizenship, but effective consumer exploitation and self regulatory cultural and structural ghettoization.

Despite these fundamental disagreements, ultimately these two approaches do provide complementary perspectives on the macro dynamic structuration of sexualities in late modernity, facilitating detailed comparative research and analysis, not only in sociology but in such cognate disciplines as political theory, geography, and social policy. The strengths of the paradigm are many: hitherto discrete sexualities are grounded in the same material conditions of disorganized capitalism; all aspects of conventionally desexualized citizenship rights and duties are revealed as heteronormatively discriminating between sexually differentiated populations; and perhaps most important of all, hegemonic heteronormativity itself, so often left as an all powerful but nebulous organizing principle, is revealed in all its concrete complexity, inconsistency, and duplicity.

Inevitably, areas of tension, uneven development, and omission remain. Culturalist perspectives can underemphasize or even ignore the importance of materialist influences on the construction of sexualities. Structuralism can be too reductionist and (given its primary focus on formal citizenship principles and processes) can give less attention to sexual constituencies ignored by the latter. Corrective responses have been forthcoming, however, with, for example, an expansive literature on distinctive forms of lesbian citizenship ranging from the gendered general (because all citizenship formulations ignore structural processes of gendered power) to the politically specific: “Why should we attempt to further rights within a system whose very operation depends on logic that defines lesbians as ‘deviant outsiders’ in order to confirm the ‘normality’ of heterosexuality?” (Jackson 1996–7).

Reference here to “further rights” highlights the need for sexual citizenship studies to resist fragmentation into specific “equal rights” such as “same sex marriage” and thus lose sight of the wider citizenship context. Same sex

marriage may initially be a dissident challenge, but it is the first step of incorporation into citizenship compliance with heteronormative standards of “husband”/“wife” gendered roles, “monogamy,” economic interdependence, and, however achieved, “parenthood,” which leaves the “dominant regime of truth” intact. Similarly, advocations of “queering” the state from within – in education, adoption, fostering, and health care, etc. – are effectively neutralized by institutional practice. Meanwhile, with the institutionalization of rights through the United Nations charter and the European Court of Human Rights, attention now moves to “transnational” arenas of sexual citizenship, in which, however, current evidence suggests, the “right to family life” still takes precedence over all others.

sexual cultures in Africa

Suzanne Leclerc Madlala

Sexual cultures throughout the world comprise the socially and culturally created experience of human sexuality, including shared norms, values, beliefs, attitudes, and knowledges that shape and give meaning to behaviors related to sex. In Africa, a continent that is exceedingly diverse, patterns of sexual culture can be expected to exhibit considerable variation. In terms of religion, language, culture, topography, climate, economy, and governance, Africa presents a rich tapestry of distinctive ways of life. While Islamic cultures predominate in the semi tropical and desert regions north of the Sahara, extending southwards along both the east and west coasts, Christianity pervades in much of the forest and savannah regions south of the Sahara. Life in most all African societies today resonates with an infusion of traditions derived from these major religions plus more indigenous aspects of culture such as animism and matrilineal descent (western and central Africa), or ancestor honoring and patrilineal descent (eastern and southern Africa). The large cattle keeping pastoral societies of the east and south such as the Masai, Buganda, Shona, and Zulu present a stark contrast to the much smaller agricultural and foraging societies that inhabit the central rainforest belt. Africa is also home to the San people (often termed Bushmen), one of the world's longest surviving hunter gathering groups. Perhaps what is most common to all these societies is their rapid integration into national

cash economies and global networks of trade and industry. Modern scholarship on African sexual cultures gives recognition to the great diversity of Africa and seeks to accurately reflect this diversity through empirically grounded studies of people's experiences of sexuality.

As a specific area of academic inquiry, the study of African sexual cultures is fairly recent. In many of the early writings by western explorers, missionaries, colonial administrators, and academics, descriptions of particular aspects of sexual culture were most often alluded to with reference to marriage and kinship (e.g., Radcliffe Brown & Forde 1950). Thus, a major point of departure for modern scholars is the previous silencing of African subjectivity during the colonial encounter followed by the employment of tropes of excess, unrestrained carnality, irrationality, and violence when describing African sexuality. In addition to perpetuating negative stereotypes, much of the previous literature did little to portray the variegated nature of the African continent and its people. Thus, while studies by McClintock (1995), Stoler (2002), and Nagel (2003) have contributed much to our understanding of the intersections between African sexual cultures and the historic experience of oppression, erstwhile representations of a "hypersexed" African and persistent ignorance of the continent's diversity continue to dog the study of this important topic.

NEW DIMENSIONS

How are sex and sexuality played out, performed, constituted, interrogated, and reconfigured in the context of a modernizing Africa? How have the legacies of colonialism, Christianity, Islam, and apartheid as well as the ongoing effects of poverty, civil war, and racism contributed to the construction of sexual cultures and the norms that guide sexual relations? What is the impact of globalization on sexual identities and people's ideas and behaviors related to sex? These are amongst the most significant questions guiding contemporary studies of African sexual cultures. A major approach to the topic involves the application of modern theoretical frameworks such as gender and "queer" theory to issues that have long been of interest to scholars of African culture more generally, for

example bridewealth, wife inheritance, polygamy, and customary systems of power and authority. Of recent significance is a collection of works dedicated to exploring sexuality in the context of Africa edited by Signe Arnfred (2004) entitled *Rethinking African Sexualities*. Various contributors to this volume explore a range of contemporary sexualities and the multiple ways in which they are being addressed. Included is work by Haram that examines the meanings that women attach to "survival sex," which involves having children with several men and maintaining sexual relationships with them as a way to meet their own and their children's material needs. Using the term "polyandrous motherhood" (as theorized by Guyer in the mid 1990s), Haram raises a perennial question of the applicability and universality of western derived notions such as prostitution.

Of particular theoretical importance to the study of African sexual cultures are two opposing arguments. Firstly, that traditional African arrangements of sexuality and gender have allowed for a far richer diversity than is suggested by western terms of sexual identity; and secondly, that traditional African morality did not allow for sexualities beyond heterosexuality. Lending support to the first argument are scholars such as Amadiume (1987), Teunis (1996), Murray and Roscoe (1998), and more recently Tamale (2003) and Wieringa (2005). Teunis's description of the *gordjiguene* of Senegal, literally translated as man woman, reveals a long acceptance of "feminine" men who have sex with other men and today are referred to as homosexual. For the *gordjiguene* the label of homosexual is too limited and misleading. There is a way of life that betrays a certain institutionalized bisexuality with the concurrent maintenance of heterosexual identity. Blackwood and Wieringa (1999) have reported similar examples of flexible sexualities from across the continent. Others, such as Zimbabwean President Robert Mugabe, continue to argue that homosexuality and anything other than peno vaginal intercourse are the imported practices of western decadence and inherently "un-African." Yet, ongoing research consistently suggests otherwise. What appears to be a long history of cultural tolerance for multifarious and unfixed sexualities is currently at odds in

many African states with conservative public discourses and "denialism" about alternative sexualities. According to Reddy (2004), this discordant situation encourages homophobia and the silencing of local voices on matters of sex. While modern constitutional laws in many African countries provide for freedom of expression and protection from sexual discrimination, present day same sex relationships are often denounced and not uncommonly subject to acts of violence. Political sensitivities around issues related to sex are doubtless a factor in both the paucity of African scholars writing about sexual cultures and a result of that same paucity. Increased participation by African scholars in the study of and reporting on the continent's sexual cultures should help to obviate some of the prevailing inconsistencies, stereotypes, and sexual prejudices that currently exist.

AIDS AND DEMOCRACY

The entrenchment of the HIV/AIDS pandemic and the consolidation of democratic systems across the continent over the past few decades have given a certain urgency to the topic of sexual cultures and have informed the nature of much recent research. Work by Schoeph (1991), Ankomah (1992), Caldwell et al. (1992), McGrath et al. (1993), and Orubuloye et al. (1993) amongst others defined a subfield of African studies in gender and AIDS during the early phases of the pandemic. Analyzing how hegemonic sexual cultures tend to lend support for various forms of sexual discrimination, or how such cultures (especially those where marriage customarily entails a large bridewealth) tend to subordinate women and contribute to their vulnerability to HIV infection, emerged as crucial areas of study in the 1990s. Ongoing debates around practices such as female circumcision which persists in many African Islamic societies continue to point up the tensions between tradition and modern democratic notions of gender and sexual rights (Shell Duncan & Hemlund 2000). A recent collection of work edited by Ouzgane and Morrell entitled *African Masculinities* (2005) highlights the need for more research on social constructions of manliness and the role these play in the

production of sexual cultures. A contribution here by Silberschmidt demonstrates how shrinking employment opportunities for East African men in the past two decades, accelerated by structural adjustment programs, have eroded men's ability to be breadwinners and contributed to increased violence toward women and multipartnered casual sex. These behaviors in turn have had, and continue to have, a direct bearing on the consistently high rates of HIV/AIDS in that part of the world. Morgan and Wieringa's (2005) work on female same sex practices addresses the issue of applying universal norms of freedom, human rights, and sexual identity to societies with very different social and cultural structures from those which produced dominant constructs such as "gay" or "lesbian." These authors consider the institutionalized practice of women marriages amongst groups where the continuity of the patrilineage and royal statuses are of prime concern. In these societies (reported to be customary in some 40 African societies), women paid bridewealth for another woman who was expected to bear children as heirs to the bloodline of the female husband. While various scholars have suggested different sociological reasons for women marriages in Africa (e.g., Herskovits 1937; Amadiume 1987), it is only recently that scholars such as Morgan and Wieringa (2005) have attempted to discern elements of sexual attraction or other qualities that would invoke a western understanding of lesbianism.

GLOBALIZATION

According to Altman (2001), a leading scholar on the impact of globalization on sexual cultures, many non western societies including those in Africa can expect to see the rapid emergence of new "hybridities," that is, where old forms of acting out sexuality increasingly coexist with new imported identities. Amongst younger, better educated, and more urbanized African women, there is an emerging lesbian identity with links to global movements and networks. In societies long familiar with customs such as women marriage, a major dimension of current research involves discerning the extent, if any, new globalized forms of sexuality are rooted or shaped by past local practices.

The sexual cultures of all human societies are based on complex norms, values, and moral codes. Traditionally in many African societies, notions of respect, restraint, and avoidance were key notions related to sexual behavior. As African societies have become more modernized and increasingly subjected to the forces of globalization with greater exposure to foreign media, traditional ways of regulating sexuality have declined while new forms of sexual behavior and norms have arisen. In South Africa for example, the practice of older age mates instructing youth on how to avoid pregnancies through the use of non penetrative "thigh sex" known as *ukumetsha* amongst the Xhosa and *uku soma* amongst the Zulu virtually disappeared by the 1950s with increasing Christianization and rapid urbanization (Delius & Glaser 2002). Scholars have argued that contemporary patterns of sexual culture in Africa that often include multipartnered casual sex, high levels of sexual violence, teenage pregnancy, and HIV/AIDS are not so much a result of traditional permissiveness as a result of the breakdown of traditional norms and regulations surrounding sex (e.g., Standing & Kisekka 1989; Ahlberg 1994). Reflecting on the rapid pace of change in the developing world, Altman (2001) reminds us that for many people sexual desire coexists with a "desire for modernity," that is, a desire to be part of the affluence and freedom associated with images of the rich world. With reference to Africa, Leclerc Madlala (2003) suggests that one way to understand contemporary practices of "transactional sex" or sex for gifts exchanges is as an "updated" version of "survival sex," with the new pressures of consumerism having replaced the former pressures of survival in communities with growing wealth and growing wealth disparities.

As the study of African sexual cultures expands, there is an increasing awareness of the need for more sensitive, ethically sound, and accurate methodologies for collecting data on one of the most private and complex of all human behaviors. The future direction of study on this topic will be shaped by efforts to develop these methodologies along with theories that more accurately explain the linkages between sexual behaviors and the economic, material, social, cultural, and political forces that are active in the environment. With increasing intellectual input by African scholars, it is likely

that there will emerge more Afrocentric perspectives to challenge not only dominant discourses and current interpretations of sexual desire and performance, but also the structural conditions that play a role in promoting sexual practices that have dire consequences in the context of AIDS. In many ways we are just beginning to gain knowledge on the vast array of sexual cultures and subcultures in Africa; those that once existed, those that currently exist, and those that are still in the making.

sexual cultures in Asia

Travis S. K. Kong

Sexual cultures in Asia refer to the ways of sexual life – the shared beliefs, values, meanings, and practices – that are common to members of Asian societies.

The sexual cultures of a society refer to its sexual belief systems, usually stemming from folktales, myths, and religions, which provide a framework for what we should think and how we should feel and behave in terms of sexuality. These sexual belief systems in turn give impetus to the forming of a hierarchy of sexual value systems that define what is sexually right or wrong, normal or pathological, honorable or shameful. Sexual belief and value systems, governed by sexual norms and manifested in customs and laws, are shared meanings and practices that are common to different segments of a society and historical periods. Different sexual cultures exist within a society and change over time.

Sexual cultures in Asia refer to many different and somewhat conflicting sexual value systems, as Asia is not a unified entity but a collective term that refers to many countries with divergent and even contradictory social, cultural, economic, and political values and systems.

Studies on sexuality are relatively a new area in sociology. Studies of Asian sexuality have been limited as sociologists have focused overwhelmingly on Anglo European countries. As anthropologists have the tradition of studying “other” cultures (with the earliest studies having been based mainly on travel reports from missionaries, traders, and seamen), anthropological texts and ethnographic materials provide some discussion of non western sexuality. Early key scholars such as Bronislaw Malinowski, Ruth Benedict, and Margaret Mead touched upon the issues of gender and sexuality.

With the affirmation of gender and sexuality studies by feminists and gay and lesbian scholars, the rise of postcolonialism, and the growing force of Asian (diasporic) academics, studies on non western sexual cultures, including Asia, are now being taken seriously (e.g., Herdt 1997; Jackson & Cook 1999; Altman 2001; Ruth 2002). The scholars who carried out these studies tend to charge former scholars with being

Eurocentric, pointing to the fact that they exoticized/erotized the “other” and overemphasized such “differences” between Asian and European cultures as sexual “excess,” “promiscuity,” largely ritualized or visible homosexuality and transgenderism, and so forth. They also point out that the sex/gender system in Asia seems to be different from the systems found in Anglo European countries, in that terms such as male/female, man/woman, or masculine/feminine are not easily distinguished in Asia and are believed to be a modern invention, heavily influenced by western biological and medical discourses. Thus, studies of gender, sex, and sexuality in Asia tend to show a picture that does not necessarily reflect Anglo European knowledge.

Recent studies on modern sexual cultures in Asia, as part of studies on Asian cultures and modernity, usually focus on various factors such as colonial histories (if any), traditions and religions, the growing affluence of most Asian countries, and the (de)colonialization strategies of the states, which play crucial roles in shaping ideas about gender, sex, and sexuality and which liberate or regulate possible forms of sexual expression (e.g., on dating, romance, premarital sex, virginity, abortion, divorce, birth control, homosexuality, pornography, prostitution) under the whole process of globalization and decolonization. They also focus on how the emergence of new sexual identities, cultures, and communities simultaneously shapes and reshapes the social life of a particular country or even the global processes of change. Common features of Asian sexual cultures seem to be an interplay or coexistence of indigenous sexual traditions with post modern western aestheticism, rhetoric, and outlooks.

CHANGES IN MARRIAGE, LOVE, AND SEXUALITY

It is argued that traditional Asian sexual cultures were largely governed by patriarchic structures (rituals, religions, family) that legitimized the power of men (e.g., polygamy or a lineage structure organized around fathers and sons in China, South Korea, Japan) and marginalized women in various ways such as female infanticide (China, India), footbinding (China), chastity

(wife burning, *Sati*, in India; chastity shrines in China), reproduction, birth control, and so forth. This discourse of dominance seems to have been less prevalent in Southeast Asia (where women tended to attain a higher status) and has been challenged by other studies that emphasize the subversive power of females (e.g., chastity – abstaining from (re)marriage could be read as female control of sexuality, independence, or hidden lesbianism) (e.g., Ong & Peletz 1995; Manderson & Jolly 1997).

The modern capitalist era has witnessed a profound transformation in the spheres of sexuality and intimacy in Asia, whereby traditional sexual values and practices coexist with modern sexual thoughts of individualism and libertarianism.

The monogamous marriage that is based on personal choice, love, and fulfillment has gradually become the norm, overtaking the traditional arranged marriage which was based on social and economic considerations, although arranged marriages are still practiced in South Asian countries such as India, Pakistan, Bangladesh, and Sri Lanka. There is an increasing variety of traditional extended family patterns such as non marital cohabitation, voluntary childlessness, never married singlehood, stepfamilies, and single parenthood, which in turn might lead to problems in caring for the young, the old, and the sick.

Although the traditional gender split in which men are regarded as breadwinners and women as housewives is still maintained in poor countries or in poor/rural regions of a country (e.g., China, India), it has also been challenged as women have become better educated and have come to participate in the job market, especially in developed countries (e.g., Hong Kong, Singapore, Taiwan). Economic achievements and individualistic libertarian ideas have given women a large degree of freedom to create their sexual spaces. Sexual relations between men and women have shifted, and egalitarianism between the sexes seems to have emerged with regard to initiating sex, demanding sexual satisfaction including orgasms, and in patterns of marital, extramarital, and post marital sex.

The state still has strong control over issues involving sexuality (e.g., the one child policy in China), but there has been a liberalization in attitudes toward such issues as birth control,

abortion, divorce, premarital sex, cohabitation, and homosexuality. Sex and love are increasingly commercialized or commodified. Commercial establishments that facilitate sexual or intimate liaisons (e.g., bars and clubs, massage parlors, saunas, sex shops, dating services, prostitution, etc.) are abundant, which legitimates sex as a domain of pleasure in contrast with the family as the confined site for intimacy.

HOMOSEXUALITY

The dominant discourse describing modern Asian homosexuality tends to assume that most countries in Asia had a longstanding tradition of tolerating men who had desired other men (lesbianism has always been underrepresented). The stories of *yu tao* (the peach remainder) and *tuan hsiu* (the cut sleeve) were two famous euphemisms among the literati for male homosexuality (*nanse*, *nangfeng*) in Chinese history, dating back to as early as the Zhou period (1122?–256 BCE) (Hinsch 1990). Likewise, Buddhist monasteries and samurai societies (*Shudo*, a young samurai who is befriended by an older man) were believed to be centers for homosexual activities (*nanshoku*) in ancient Japan from the medieval period to the end of the nineteenth century (Leupp 1995).

Social or religious systems of thought such as Confucianism, Taoism, Buddhism, and Hinduism, which are prevalent in most Asian countries, are not concerned with the gender of sexual activity or the object of sexual desire, and thus do not strongly condemn homosexuality in the way that Abrahamic religions (e.g., Christianity) do. As a result, traditional Asian literature does not generally refer to same gender desire as an innate essence (indicating an identity) but rather as an action, tendency, or preference. Correspondingly, a man who engaged in homosexual acts did not cause much trouble so long as he conformed to or did not challenge the patriarchal family (lineage) structure (e.g., by getting married and bearing children). Homosociality, or same sex friendships, were largely condoned.

Civic religions and customs tend to encourage sexual and gender ambivalence. In some countries, the presence of a “third gender” is evident. For example, a *hijra* (in India) is a person who is

born biologically male or born with ambiguous genitalia but identifies himself as belonging to a "third sex," "neither man nor woman," although he usually picks up a female gender identity. Or in Thailand, a male to female transgendered person is called a *katheoy* (or lady boy). Likewise, *bakla* and *bantut* are terms referring to a transgendered person in the Philippines, with the corresponding terms being *banci* in Java and *waria* in Indonesia. The case of Asian homosexuality thus provides a new understanding of the debate over essentialism/constructionism that raged throughout the 1980s in the West.

This relatively tolerated homosexual tradition seemed to come to an end with the advent of modernity and colonialism. For example, homosexual activities in Hong Kong and India were tolerated prior to British colonization but then became a criminal act after the introduction of British laws and legal codes. While male homosexual acts were decriminalized in Hong Kong in 1991, India still has penal laws against homosexual acts.

The present situation regarding homosexuality in Asia seems to be a mixture of state intervention (which can be reflected through penal sanctions against anal sex), large visible and commercial gay scenes (bars, clubs, saunas, etc.), annual gay pride walks or festivals (e.g., South Korea, Bangkok, Manila, Tokyo, Taipei, Phnom Penh, Nepal), and the rise of gay and lesbian organizations.

Countries that have laws penalizing homosexuality include India, Bangladesh, Pakistan, Sri Lanka, Nepal, Malaysia, and Singapore, while countries such as China, Taiwan, Hong Kong, Japan (some cities), South Korea, Thailand, Indonesia, and Cambodia have decriminalized homosexual acts. The legal status of homosexuality does not necessarily refer to a fair or positive attitude from the government. For example, although male homosexuality is not illegal in China, gay men and lesbians are easily arrested (and charged with hooliganism) and gay bars and clubs are frequently raided.

Studies tend to suggest that national political and cultural characteristics play a crucial role in the creation of modern gay and lesbian identities and in the development of national lesbian and gay movements (Adam et al. 1999). Although many modern Asian countries refer

to homosexuals as gays and lesbians, each country seems to have its own terms of reference. The creation of a new sexual self is not necessarily a repetition of the gay and lesbian liberation movement in the West. Non politicized identities and non political social interactions seem to be dominant in Asian countries. It seems that gay identities have been reconciled within a family oriented culture and that gay rights have been subsumed under the notion of social harmony. Coming out is not a common way of asserting one's gayness, and desires do not seem to be framed in terms of political interests. There has been a division between personal identity and community politics (e.g., Jackson 1995, on Thailand; Kong 2002, on Hong Kong; McLelland 2000, on Japan).

Moreover, the scale and activities of gay and lesbian organizations depend very much on their economic resources and the political situation in a specific country. Some of these organizations have been quite shortlived. Although gay and lesbian groups in Asia tend to be more inward looking and to focus on the building of identity, some (e.g., Hong Kong, Taiwan) take on a more visible and confrontational approach to fighting against discrimination and for human rights (e.g., same sex marriages).

Popular culture has, on the one hand, created a discourse about homosexuality that presents a biased or one dimensional image of gay men and lesbians (e.g., gay men as sissy fashion queens and lesbians as tough women). On the other hand, it has led to the making of many movies (e.g., *Wedding Banquet*, 1992; *Happy Together*, 1997; *Iron Ladies*, 2001; *Arisan!*, 2003) that directly address the issue of homosexual love, which can be seen from the various lesbian and gay film festivals that are held in Asia (e.g., Hong Kong, Thailand, Tokyo, the Philippines).

Recent studies have not just examined the dynamics between straight and gay communities, but have also discussed the diversity within the gay and lesbian communities, in which differences and marginalization can occur along the lines of gender, class, race, age, and body (Kong 2004), and the Internet as a new way for gay men and lesbians (especially young people and those who live in a homophobic Asian society) to identify one another through sexuality, language, and values (Berry et al. 2003).

THE SEX TRADE

The sex industry is an important economic sector in most countries of Asia. It not only provides sexual services to local people, but also attracts foreign tourists from western and nearby countries.

Sex work can broadly refer to any exchange of sex for money, with or without sexual contact, from striptease shows, live performances, peep shows, telephone sex, sex shops, pornography, and prostitution. Sex work in Asia takes many different forms, ranging from the "standard" forms such as street prostitution, brothels, saunas, and massage parlors to bars and nightclubs. Particular forms can also be found in certain countries. For example, in Taiwan betel nut beauties refer to young girls who dress in fancy clothes, sit in a glass booth, and sell betel nuts to lorry and truck drivers. Live shows in Thailand refer to women injecting objects in their vaginas. And in South Korea, Filipino women work in military bases.

In Asia, the legal status of prostitution varies from one country to another. For example, prostitution is illegal in Vietnam, Indonesia, Japan, and Korea, but not in Hong Kong, Macao, and Singapore (only legal in designated red light areas). However, the legality of prostitution does not necessarily mean that sex workers in those countries receive better treatment. For example, although prostitution is illegal in Japan, female sex workers are rarely prosecuted, while in Hong Kong, prostitution is legal but sex workers are usually arrested for committing other crimes (e.g., soliciting in a public place for "immoral" purposes). There are many loopholes in the law as well as different interpretations of the law which usually discriminate against workers rather than clients or other parties. The punishments for sex workers usually range from being put in jail (e.g., Indonesia), being forced to join labor camps (e.g., China), simply being punished by having to stand up for hours (e.g., Macao), being deported back to one's place of origin if the worker is a foreigner, and/or being fined (Zi Teng & AMRC 2001).

Women who engage in prostitution should be seen not as a unified entity but as a highly stratified group of women whose life experiences vary greatly according to their income, the amount of control and autonomy they have

over their work, their impact on the community, and so on. These women differ in age, education, marital status, race, and ethnicity.

The overwhelming reason why women enter prostitution seems to be economic, i.e., they simply need money for their own survival, for their parents and/or their own families, to help their siblings to pay tuition fees, to pay debts that may have been incurred by misfortunes in the family or by a husband addicted to drugs or gambling, and so forth. However, studies also show that some of these women also use prostitution as a way to escape from their families, from unhappy marriages, abusive husbands, and to gain sexual pleasure, economic freedom, and independence. Moreover, there are many women who are forced to engage in prostitution (e.g., women who have been trafficked or under age girls who are beaten up, raped, and locked up by pimps and/or owners of brothels), but there are also women who choose to work in prostitution (e.g., Wang 2002; Ho 2003). This reflects the feminist debate on prostitution, which centers around the issue of the sexual victim (e.g., Catharine MacKinnon, Andrea Dworkin) versus the sexual agent (e.g., Annie Sprinkle, Pat Califia) with the focal point being choice, consent, and autonomy (see Chapkis 1997).

Child prostitution and the trafficking of children and/or women have received a great deal of attention from academics as well as policy makers. Mobility is a salient feature of the sex industry in Asia which can occur internally (from rural areas to big cities) or externally (to other countries). The sex industry in most Asian countries is a mixture of local and transient migrant workers, forming a "circuit of desire." Although sex workers suffer from many forms of legal discrimination and societal prejudice, a large scale, visible, and confrontational labor movement is rare. A notable example is when the Taiwanese government decided to abolish licensed sex workers in 1997, and sex workers and supporters protested for days.

Male prostitution is understudied in both Anglo European and Asian countries (Aggleton 1999). Male prostitution also takes many different forms such as hustling in public places, working in bars and clubs and in massage parlors, and providing escort services. Male prostitution complicates the debate on prostitution:

male prostitution (serving women) challenges that it is the woman – as a customer – who holds economic power and pays for her own pleasure. Male prostitution (serving men) poses a greater challenge as it recognizes the inequalities among members of the same gender, reinforces the logic of desire and consumption, and upsets the egalitarian ideal of the gay liberation movement (Kong 2005).

HIV/AIDS

HIV/AIDS has spread in Asia in diverse ways. It seems to be most extensive in Cambodia, Myanmar, Thailand, and parts of India, while there has been a sharp increase in China, Indonesia, Nepal, and Vietnam; although Bangladesh, Laos, and the Philippines have reported some of the lowest HIV rates in the world. As Asia comprises nearly 60 percent of the world's population, the epidemic in Asia has huge implications for the globe (www.unaids.org).

In contrast to Africa, where the major route of transmission is through casual heterosexual relationships, the key risk populations in Asia include drug users who inject drugs, men who have sex with men, sex workers and their clients, and the immediate sexual partners of these three populations. In Asia, the HIV epidemic has tended to be multiple and interrelated in nature. For example, drug users might make use of commercial sex services or even sell sex, sex workers may use drugs, and men who have sex with men may also visit female sex workers.

Tackling HIV/AIDS seems to be an urgent issue for most governments, but the problem is difficult to combat as it is not just a medical disease but a social problem involving issues of social stigma, morality, and control. Although ignorance or lack of knowledge might be a significant reason for HIV infection especially in poor countries, sexual cultures and values seem to be far more important in influencing safer sex practices than the transmission of information or even the availability of condoms.

For example, drug users who inject drugs play an important role in the spread of the virus in many countries (e.g., China, Vietnam, and Malaysia). However, in certain parts of China, drug users have been known to deliberately inject infected blood into themselves in order

to avoid being admitted to reeducation centers for drug users. Men who have sex with men (MSM) are a largely ignored group in certain countries (e.g., India, China) that do not officially recognize the existence of such people. Most sex workers might be serious about using condoms with their clients but are ambivalent about using them with their non paid affective partners, with whom they might not be in a monogamous relationship. Unprotected penetrative sex in the context of an affective relationship has a significant symbolic meaning for sex workers.

sexual cultures in Latin America

Salvador Vidal Ortiz

A definition of “sexual cultures in Latin America” necessarily rests on a series of assumptions that need to be unpacked, thereby offering productive ways of thinking about what “sexual cultures in Latin America” means – and how to empirically engage with them in related research. First, the notion of “Latin America” is based on the disparate unification of many

countries (from the rest of the Americas) through a perceived cultural homogeneity that ignores language variability, rival historical relations, economic and political differences, and national distinctions (including nationalistic discourses of difference between many of these countries). As well, Latin Americanist and ethnographic scholars debate what fits within the notion of “Latin America,” since there are often a variety of linguistic, geographic, and political reasons given in such scholarship to exclude or include nations or regions, as exemplified by the challenges in placing or excluding countries like Puerto Rico, Brazil, Spain, the English speaking Caribbean, and even the Southern cone.

The second assumption is that using “Latin American” negates the relationship between Latin Americans in Latin America, Latin Americans in the US, and US Latinos, and it inherently erases racialization processes for those that migrate to the US. Third, like any other definitions containing the word “culture,” it presupposes anthropological colonization strategies that situate such culture in oppositional frameworks. And last, the framing of “sexual cultures” in Latin America (often meaning “not here”) presupposes a distinction between some of the theoretical frameworks through which social scientists understand culture and regions all over the world, which is often using the US as a referent. Views of gender and sexuality systems that are not US or western based tend to be labeled as premodern (Decena 2004), without in turn exploring how in US or western contexts alternative ways of looking at the gender/sexuality relationship are taking place within these borders, whether by Latinos or *United States* alike. Linked to this last assumption is a bias: framing sexual cultures, like any other framing of cultural elements, has the potential to foreground a culturalist argument that hides political economic relations between countries and regions in other parts of the world facing similar relations to that of “Latin American” countries – a key example is the Pacific Islands and their relationship to US militarization and colonialism to countries like Puerto Rico (Vidal Ortiz 2004). As well, it ignores how the US is as much a Latin American region as any other country, given the demographics of US society.

These assumptions notwithstanding, the available social science literature today does provide several crucial issues inherent in this scholarship's currency. Issues like how sex, gender, and sexuality are conceptualized in "Latin America," HIV/AIDS (Carrillo 2002), sex tourism (Cantú 2002), the impact of Latin Americans' migration to the US (and the migration back and forth between rural and urban contexts in Latin American countries, and between those countries and the US) (Decena 2004; Peña 2005), ideas about bisexuality in Latin American culture (Cantú 1999), and heterosexual sexuality research discussions (González López 2005) are important and central to such scholarship. For reasons of space, the discussion here focuses only on the sex/gender system implicit in Latin American studies (including masculinity and sexuality studies), sex tourism, and finally migration and sexuality.

SEX/GENDER AND POWER

Most of the "sexual cultures" scholarship in Latin American societies engages the relationship between sex(uality) and gender, namely, the assumption that links gendered expectations to that of oppositional sexual acts and identifications (Almaguer 1993; Guzmán 2006). Almaguer (1993) argued that unlike western countries, where sexuality and gender are distinct aspects of the "self" enacted through different vectors, in Mexico, and by extension Mexican families and in other Latin American countries, the distinction of gender and sexuality has been notoriously marked by an understanding of the (male) actors' positioning in sexual activity. Succinctly, a heterosexual man is still considered such in the event of having sex with another man, if he is the *activo*, relegating the homosexual stigma to the penetrated, or *pasivo* person (see also Lancaster 1992; Carrier 1995; Murray 1995). It has been this system, linked as it is to the inequalities faced by women, that many scholars have discussed as *machismo* in Latin American societies. Further sociological and anthropological writings have expanded and contested Almaguer's work, stating how this is simplifying Anglo sexualities, noting how sexual identity and sexual behavior do not have to be congruent (Cantú 2002), that this typology ignores the

mutual influence of migration (Carrier 1995), and that indeed partial sexual identities emerge out of this *activo/pasivo* notion, and are "part and parcel of the culture itself" (Guzmán 1997: 217), and not merely an incision or segment of political movements.

Specific anthropological research has tackled the question of how sexuality and gender apply to other countries, regions, or different configurations of culture, such as *travestis* in Brazil (Kulick 1998). Kulick notes that research before his looked at homosexual roles in Latin America, and such research has perceived a relationship to sexuality and gender, but, he qualifies, has mistakenly conflated sex and gender, thus not theorizing those links to cultural understandings of the interplay of sexuality, gender, and sex. As Guzmán (1997) and Kulick (1998) have both argued (in the US and in Brazil), the "man/non man" categorization of sexuality and gender offers us possibilities to reconceptualize the relationship between sexuality and gender, sexual desire, and notions of sexual actors in gendered terms. (Using this "man/non man" categorization helps understand the relationship of homosexual men and all women into what may be understood as "sexual minorities.") Research by these two scholars has suggested that the "man/non man" categorization through terms such as *mayate*, *bugarrón*, *loca*, or *travestí* offer possibilities to reconceptualize the relationship between sexuality and gender.

In addition, as Guzmán (2006) has recently suggested, racial difference might be interpreted in the US as different sexual identificatory practices among "Latin American" "sexual minorities." Notions of "Latin American" identities are often used as a foundation to "racially" distinguish between North Americans and "Latin Americans." (Even though "Latinos" are ethnicized in US society, these frameworks create a difference in racialized terms [Urciuoli 1996], as will be seen in the sex tourism section.) As recently discussed by Lancaster (2005), this difference of *homology* (fusing the sexual activity of men with men into a homosexual identity, supposedly common in US society) and *heterology* (a consideration not only of the sexual actors, but also of the acts themselves and how those are read in gendered ways, credited to Latin Americans) is then discussed as "sexual culture." While these differences are "intriguing"

anthropologically speaking, if we are not careful, we are only one step away from claiming them as oppositional to those of US culture, reifying the meaning of culture altogether.

Taking this literature in general, comparisons between Latin America and the US indicate that these sexualities and sexual cultures are more complex than previously argued. As well, the relationship between sex and gender as theorized until now greatly misses women, and lesbians in particular (for a recent, refreshing exception offering a great history of lesbian organizing in Latin America, refer to Mogrovejo 2005), and, to a lesser extent, transgender, transsexual, and *travesti* Latin Americans in Latin America or the US.

SEX TOURISM

Sexual tourism feeds into this US/Latin American opposition often posed by social scientists. Countries like Cuba, Puerto Rico, Mexico, Panama, Colombia, the Dominican Republic, and Brazil are considered sex tourist destinations by foreigners (Perlongher 1999; La Fountain Stokes 2002; Hill 2004). This sex tourism exists in great part due to local economic needs and individual obligations to one's family. Herein the issue of seeking, for instance, gay male tourists by non self identified gay men is recurrent in the literature. (While there is limitation to migrate outside of these Latin American countries, Parker 1999 and Agustín 2003 have discussed the migration of Latin American sex workers to Europe.)

Because of notions of hypersexualized "Latin American" women and men, many of these destinations flourish in terms of their local supply of sex workers. And because many of these countries have a hybrid racial classification (and offer various African, Asian, and indigenous phenotypical readings of race), often a sexualized racialization takes place where those tourists have an idea of racial difference that is highly eroticized. Add to that mix the reading of heterosexually identified men who have sex with men and there is a significant system of sexual racial difference that feeds in those oppositions – both by the tourists and by the locals. Another significant element is the international debt in

which many of these countries are involved, and the often lower socioeconomic and educational status of sex workers, forcing a serious class distinction to exist between a European or US tourist whose money will be exchanged and the cost of a sex worker that will be a fraction of the type of escort and sex work services in many US cities (see Perlongher 1999; Hill 2004).

SEXUAL MIGRATION AND SEXUAL IDENTITY

In social scientific literature, terms like *sexual migration* (see, e.g., Carrillo 2004) help us to understand the seemingly strong pool of "sexual minorities" that come to the US for support and a space that presumably is missing in their Latin American country of origin. This notion of sexual migration, however, begins in the US. "Canonical" works on "gay and lesbian" migration have argued for the formation of such enclaves as a departure from an oppressive home to a more open space where communities have formed (D'Emilio 1983; Rubin 1993 [1984]). An assumed rupture from one's family of origin was the basis for massive migratory patterns that created "gay cities" all over the US. Rubin's and D'Emilio's work has been critiqued for its inability to address the supposedly "better" place – the urban center (Cantú 1999; Decena 2004; Guzmán 2006). This sexual migration has also been discussed internationally – in this particular case, Latin America – where it depends on linearly articulated ideas of oppression of "gays" that migrate from rural to urban places, and it uses the notion of a Latin American tight familial control as its axis. Decena, for instance, in his work on Dominican homosexual men and migration, brings out the capitalist tendencies of such scholarship in opposing a "gay" identity and lack of familial ties when he states that: "the sexually liberated capital is exciting and attractive because it allows one to break away from the bonds of patriarchal family relations" (2004: 4). Cantú's work is also helpful: he signaled that a similar "urban" migration to that of gays and lesbians of European descent was taking place, by homosexual Mexican men – in his research,

from Mexico to metropolitan areas in Southern California. Cantú troubles the relationship between political economy and culturalist arguments by asking: "If the literature on the social construction of a Western gay identity is correct in linking sexual identities to capitalist development, then why should our understanding of sexual identities in the 'developing world' give primacy to culture and divorce it from political economy?" (2002: 141). His answer is that among US scholars, and specifically in the anthropological literature cited by Almaguer, "culture became the mechanism that reified difference and reproduced the imagined distance of 'the others' in academic discourse itself." Additional answers to these questions are also being currently produced by a number of academic scholars.

Other terms have furthered this notion of migration caused by sexual oppression; in particular, the concept of the *sexile* (coined by Guzmán 1997) serves us well in recognizing the trajectory of "sexual minorities" who have left their countries of origin *because of* their sexuality and/or atypical gendered behavior. "Sexual migration" and "sexile" both indicate an interplay between culture, sexual agency, identity, and transnational flows, but say little about the economic and social characteristics of life in Latin American society, or the reasons for seeking to move to the US (or Europe for that matter – see, e.g., Pichardo Galán 2003). Even though it may seem logical to think that most migration by "sexual minorities" from Latin America involves travel to the US because of their sexual identity, no evidence can support this as a central reason for migrating. Instead, economic factors continue to be a leading reason for the migration of "sexual minorities" (see, e.g., Cantú 1999). To complicate matters somewhat, whereas in US social movements and identity politics the lesbian, gay, bisexual, and transgender (LGBT) acronym is representative of different, if related, "sexual minorities," scholars and lay folk outside such a community (and outside the US) might simply locate all within the same category: *gay*. Whatever "gay" means, it often means "non man," where man is understood as heterosexual and with a particular (hegemonic) masculinity. We see an increasing exportation of human rights based on

neatly defined categories in the advocacy for political asylum for gay, lesbian, bisexual, and transgender identified people (refer to the work by Cantú 2005; Miller 2005; Randazzo 2005), partly in order to sustain a dichotomy that establishes the US as a more developed and accepting society.

CONCLUSION

Unfortunately, sexuality research tends to focus on Mexico, and then attempts are made to generalize such findings to the rest of Latin America. In addition, the abundant research on gender/sexuality and race conducted in Brazil focusing on *travestis* (Kulick 1998) and sex/gender and masculinities (Parker 1999) is often utilized to compare Latino US based populations to Latin American ones. This is, we have been told, because in the "American" imaginary, "Latin Americans" are simply just like each other. But perhaps that perception actually covers another one: some groups under that "Latino" or "Latin American" umbrella are much more exotic, or those sexualities are labeled much more based on gender constructs in premodern societies, or inadvertently converted into sexual machines, in some places than others. Thus this sexualized racialization is selective in terms of how gendered it is: some may see people from countries such as Brazil as ultra masculine and heterosexually identified, and simultaneously see men from Mexico as smaller and more feminized. Sexual desire may follow the racialization at hand. In this sense, "Latin American" itself is a construct that does no justice to the sexual variability within those countries – nor to the consumption of those sexual actors in "Latin America." Instead of oppositional cultural arrangements where "Latin American" is simply read culturally – not in terms of racialization – a newer analysis may hold a conversation with such scientific frameworks and force them to acknowledge alternative analyses besides binary systems.

sexual cultures in Russia

Dan Healey

Russia's hybrid condition, combining European and Asian geography, cultures, and histories, makes it a complex national tradition to study, and sexuality in Russia reflects that complexity. At the same time, the country's often violent historical experience and its significant divergence from the familiar currents of European religious, cultural, and intellectual life have marked Russian approaches to sexuality.

The leading religion of the Great Russian ethnic majority is the Russian Orthodox faith, and this church's conception of sexuality was inherited from Byzantium during Christianization in the tenth century. Orthodoxy distinguished itself from western Christianity by an extremely ascetic view of human sexuality, denying the sanctity of sexual intercourse even between married partners, and hailing celibate marriage as the purest form of conjugal life. Proclaimed frequently, but seldom adhered to, the wholesale rejection of (or call to sublimation of) sexuality is an enduring feature of Russian intellectual life, characteristic of thinkers as diverse as Leo Tolstoy and Vladimir Lenin. If sexuality was to be suppressed for the benefit of the soul in the opinion of generations of Orthodox confessors and sermon writers, by the nineteenth century radicals and socialists believed the energy diverted from sexuality could be channeled into political action.

Until Stalin's first Five Year Plan (declared fulfilled in four years, 1928–32), about 80 percent of Russian society consisted of peasants. Peasant sexual culture had both Christian and pre-Christian elements, a reflection of the weak influence of Orthodoxy in a vast and poor country. Thus the Orthodox wedding ceremony and

all its rituals formed a key stage in the lives of virtually all peasants, yet the courtship rituals that led up to it encouraged sexual intimacy with prospective partners and even with the wider peer group. Information about sex might be suppressed in formal public speech, especially religious discourse, but peasants shared jokes, songs, and limericks (*chastushki*) that gave the genitals ribald personalities and celebrated the comedy and pathos of human sexuality. Obscene, sex-themed speech in elaborate and linguistically productive formulations (a sublanguage of Russian known as *mat*) offered young men the opportunity to entertain peers and compete for attention while establishing their masculine credentials. Crude prints (*lubki*) and chap books recording sexual images and stories were in circulation by the early nineteenth century, Russia's peasant version of the beginnings of a modern pornography.

Scholarly study of Russian sexuality began in the second half of the nineteenth century with medical, legal, and ethnographic works. Inquiry focused on peasant customs and legal concepts regarding marriage and the family, on the medicolegal understanding of sexual crime, and on the medical policing of legalized prostitution. Gynecologists defining sexual maturity conducted massive surveys of the onset of first menstruation in various ethnic groups. Doctors investigated and deplored the early marriage patterns of the "primitive" peoples of Imperial Russia's south and eastern periphery, an internal Orient.

Nihilists and socialists developed a stringent critique of Russian middle class mores, supposedly derivative of Western European bourgeois capitalist values. An alternative tradition of "fictional marriage" (to liberate intelligentsia women from oppressive parents), of "free love" (unchained from property and religion), and a demanding cult of sublimation for the good of the coming revolution grew up. Jealousy in personal relations was seen as petty bourgeois selfishness. These values were projected by gentry and middle class intellectuals on to a romanticized "politically conscious" proletariat. Liberals absorbed much of this alternative tradition and added to it with a focus on the emancipation of women from legal and professional restraints, and campaigns to end regulated prostitution.

Most public discussion about sexuality, until the 1905 Revolution brought an end to censorship, took place in the form of literary fiction. Tolstoy's story of adultery and murder, "Kreutzer Sonata" (1891), set the pattern: a tale initially banned by the censor circulated in educated society and aroused passionate debate about the nature of sexuality inside and beyond marriage. After 1905 an explosion of discourse about sexualities erupted. Sexological terminology acquired extensive purchase on public consciousness, and not only in the urban, educated population, as cheap novels and newspapers proliferated and a commercial leisure culture used sensational sexual themes to sell publications. Soviet commentators later viewed the era from 1905 to 1917 as a "decadent" period when quickening capitalism animated a deplorably sexualized bourgeois public culture. It was a moment when new voices emerged: Mikhail A. Kuzmin's *Wings* (1906) celebrated a young man's acceptance of his homosexuality in an unapologetically optimistic key that was unique in European literature, and Lidiia Zinov'eva Annibal's *Thirty Three Monsters* (1907) explicitly portrayed lesbian love, albeit with less optimism and more French inspired "decadent" gloom. Mikhail Artsybashev's bleak novel of ideas, *Sanin* (1907), depicted a generation disillusioned by the failed revolution and turning instead to predatory sexuality. Russia's emerging cinema explored sexual themes with enthusiasm, especially in the films of Evgenii Bauer. The year 1905 also accelerated the development of scholarly sexology in Russia, with surveys of student sexual behavior (especially that of Moscow medical expert M. A. Chlenov, published in 1909), psychiatric theorizing about the origins of perversion, and a deepening commitment to sexual "enlightenment" among educators in military and civilian life.

Between 1914 and 1921, war, revolution, and civil war brought death, famine, and violence that disrupted family ties, sent 2 million "bourgeois" Russians into emigration, and established the world's first anti capitalist state, Soviet Russia (later united with republics on the old imperial periphery as the Union of Soviet Socialist Republics, 1922). Revolutionary Bolshevik (communist) legislation secularizing marriage and greatly relaxing divorce (1918, 1926), legalizing abortion on demand

(1920), and decriminalizing sodomy (1922, 1926) seemed to fulfill the radical dream of love unchained from constraints of religion, property, and petty bourgeois prejudice. A People's Commissariat (ministry) of Health was inaugurated, with Bolshevik physician Nikolai Semashko at its head. As the key state patron of medical research, he encouraged the development of a socialist sexology under the revealing rubric of "social hygiene." Sexological knowledge would serve the building of socialism by offering scientific solutions to humanity's most perplexing difficulties. Such nostrums were hailed internationally by reformers like Germany's Magnus Hirschfeld; communist parties in Europe and elsewhere paraded their sex radicalism as a component of the march to social revolution. Official prescriptions at home, however, favored a profoundly rationalist program of sublimation, deferral, and sexual enlightenment that owed much to the pre-revolutionary radical credo putting politics before the personal.

Nevertheless, during the mixed economy era of the New Economic Policy (1921–8), Semashko was by no means the sole manager of sexual discourse. Private doctors published sex advice pamphlets, hot-headed Communist Party youth and women's leaders debated the meaning of sexual revolution avidly, psychiatrists and criminologists explored some of Soviet society's sexual underworlds, and literature and cinema continued to probe the "accursed questions" of sexual life in a revolutionary setting. The Bolsheviks' chief exponent of radical sexual revolution, Aleksandra Kollontai, published theoretical and literary portraits of the new sexual freedom and its positive and negative consequences. Non-party novelists succeeded in publishing gritty fiction about the sex problem that aroused consternation in the conservative ruling elite. "Free love" became a tag that acquired a negative, "petty bourgeois" political value, often tied to oppositionist inclinations more generally. Leader of the Communist Party Vladimir Lenin branded the so-called "glass of water theory" (the notion that under socialism sexual desire would be slaked as easily and naturally as thirst) "antisocial" and "un-Marxist." Sexual atrocities later in the 1920s aroused revulsion at the persistent street-level attitude that women who refused sexual favors were

indulging in “petty bourgeois” prejudices; the rape of a young student by a gang of “conscious” workers and young communists in Leningrad in 1926 was Russia’s first modern sex scandal. In the face of the negative consequences of sexual revolution, communists, the inheritors of Russia’s nineteenth century radical ethos, continued to preach restraint for the good of the cause and a scientific approach to all sexual activity, while calling for increasingly stern punishment for irresponsible sexual behavior.

The roots of a Stalinist approach to sexual questions thus predated Joseph Stalin’s consolidation of power (1929) and the launch of the first Five Year Plans. The 1930s saw the end of any remaining state sponsorship for sexual radicalism. Official attempts to articulate a sexual value system emphasizing stability of heterosexual family relations and parental responsibility for offspring gathered pace during the decade. Male–male sexual relations were recriminalized in 1934, apparently in response to secret police observation of male prostitution and fears that the “caste like nature” of homosexual circles would facilitate espionage. The Party made conservative, patriarchal pronouncements about the psychology of married life, a topic previously evaded as unworthy of ideologists’ attention. As war approached, the regime worried about the birthrate and banned abortion in 1936, while divorce was simultaneously made much less accessible. Birth control devices were removed from sale by a secret decree. Literature and cinema, now under the ideological control of “socialist realism,” promoted fecundity and made a striking attempt to revive feminine makeup and hairstyles, fashion and allure, all previously marked as “degenerate” and “capitalist” but now revalued as appropriate for a prosperous socialist way of life. Science was starved of funds to investigate what ought to come naturally in a well organized socialist society; thus sexological studies came to a virtual standstill, not to be revived until Stalin’s death in 1953.

The Great Patriotic War (1941–5) resulted in the loss of 27 million Soviet lives, and an enduring gender imbalance, with 10 percent more women than men in the population well into the 1960s. After the war as soldiers returned from the front, sexually transmitted disease was a major concern. The abortion ban was

proving difficult to enforce as restive doctors argued behind closed doors against having to denounce women who tried to terminate their own pregnancies. Measures to increase the birthrate included a “bachelor tax” on less prolific couples and unmarried persons of fertile age. Censorship made sexual topics even more taboo than they had been in the 1930s. Pent up expectations for reform, the pressures of reconstruction and famine (1946–7), and worker migration in search of better working conditions regardless of the state penalties fueled a volatile social context. Stalin’s successors legalized abortion on demand in 1955 and opened public debate on the “sexual question” (marriage, women’s roles at home and at work, morality, sex education). Ruler Nikita Khrushchev’s housing reforms gave the majority of urban households a flat with its own front door, an innovation that increased privacy and created intimate settings for the development of both officially approved domestic heterosexual monogamy and less orthodox arrangements.

Research on sexuality in the late Soviet era was characterized by a plumbing and mechanics functionality that evaded questions of psychology, tabooed pleasure as a goal in itself, and confined the study of sex to branches of gynecology, urology, and endocrinology. The discipline of “sexual pathology” (*seksopatologiya*) acquired independent status by promising medical fixes for technical problems (frigidity, infertility, impotence). As Igor Kon explains, there was no need for a Soviet sexology since mature socialism provided the material conditions in which nature was free to assert an unproblematic heterosexual normality; only the abnormal, the deviant, and the perverse needed scientific attention. Medical or sociological interest in “normal” sexuality was regarded in academic circles as prurient and unsound. Much of the Soviet trained medical and academic establishment retains this view, and even today sex counselors in the Russian Federation call themselves “*seksopatologi*,” i.e., sexual pathologists.

Despite this rather bleak picture, less orthodox approaches to sexuality appeared in the “era of stagnation” (1965–85) associated with the rule of Leonid Brezhnev. Freudian psychology made a limited revival after half a century of official suppression. Some jurists called for the decriminalization of sodomy, citing examples

from the socialist satellite regimes. Neuroendocrinologist Aron Belkin, the father of the Soviet sex change operation, began working on transsexual patients in his Moscow clinic. He also began "correcting" the sex of intersex patients, who often journeyed from the far corners of the Soviet Union seeking help. His work was greatly influenced by developments not only in socialist countries but also in the US and other capitalist states. Attention to the diverse international sources of sexological knowledge was also evident in the sexual pathology textbooks of G. S. Vasilchenko (1977, 1983). During Mikhail Gorbachev's reforming tenure (1985–91) and the collapse of communist rule, even more liberal approaches to the study of sexuality emerged. The leader of this tendency was and remains Igor Kon, a member of the Russian Academy of Sciences, whose training was not as a "*seksopatolog*" but in philosophy and sociology. Kon's work has promoted ideas that remain very much at odds with the medical mainstream: Scandinavian style sex education, an acceptance of teenage sexuality as normal and healthy (a view denied by vociferous Russian experts in a host of disciplines), a relaxed attitude toward same sex relations, and a view of human sexuality predicated on the individual's rights rather than on the demands of the nation state.

Beyond medicine, Russian sexuality studies have developed impressively in history, sociology, and other humanistic disciplines long suppressed or distorted by Marxist–Leninist ideology. The Boris Yeltsin Russian presidency (1991–9) saw the establishment of new liberal universities and the adaptation of some older ones to liberal humanist scholarly traditions. The opening of previously sequestered library and archival collections resulted in a wave of new publications of documents, reprints of pre revolutionary monographs, and new studies of tabooed topics like pornography and swearing. Natalia Pushkareva's (1999) work on medieval Russian sexual culture, A. L. Toporkov's (1995, 1996) document collections of Russian erotic folklore and essay collection on pornography (with M. Levitt 1991) demonstrate how historians of sexuality are freer to explore the topic and to collaborate with foreign Russianists as well. There has been a mini boom in gay and lesbian historical studies, of varying quality; the

most influential single work is an anecdotal guide to the gay history of St. Petersburg by a curator under the pseudonym Konstantin K. Rotikov (1998). Prostitution under tsar and commissar has found its historians.

Sociological explorations of contemporary sexualities are well advanced, and apply methodologies previously impossible for Soviet academic researchers, such as interviews about intimate relations, and discourse analysis of sexual memoirs and of the mass media. A noteworthy trend has been the rapid translation of canonical feminist and queer texts into Russian and their reflection, adaptation, and rejection in the work of a generation of younger scholars. Two monographs on hazing culture and sexuality in the Russian army (2002, 2003) show that even this conservative national institution cannot resist scrutiny of its sexual secrets; in fact, these studies hint at a return to a pre revolutionary tendency for the tsarist army to license the new sexological discourses of the late nineteenth century to resolve problems of cadet education. Recent collections of essays from the European University of St. Petersburg (2001, 2002) demonstrate the range of work typical of post Soviet sociology with its exploration of the Soviet legacy of "official and unofficial norms" of sexual culture, of youth sexuality, of sexuality among disabled people, of women's alienation from their bodies and from pleasure, and of methodological dilemmas associated with the study of sexuality. The most ambitious critical work shows a healthy skepticism for models received from canonical western texts and a questioning of the ways in which they might be applied to Russia's specific historical and social experience. While politically a conservative nationalism remains on the ascendant and the sexual liberalization associated with Igor Kon and the Yeltsin years is in the shade, academic studies of sexuality are likely to prosper if only because a large cohort of energetic scholars now work in this field in Russia's universities.

sexual cultures in Scandinavia

Jan Lofstrom

Scandinavia as a social and cultural entity comprises the Nordic countries – Denmark, Sweden, Norway, Iceland, and Finland – plus the autonomous territories of Greenland and the Faroe Islands, which belong to Denmark, and the Åland Islands, which are part of Finland. The social and cultural distinctions of the countries notwithstanding, it is often justified to consider them in aggregate. For example, in terms of prevailing values and ideals the Nordic societies are more secularized and less traditional than most other western societies, and values pertaining to "self expression" (tolerance, post materialist values, etc.) are also relatively speaking very prominent in Nordic societies (Inglehart & Baker 2000). This has a bearing on various issues of sexual life and sexual norms.

The Nordic countries have often been regarded as in the global vanguard in endorsing and promoting gender equality and progressive sexual politics. There are good grounds for this view, though it is clear also that in the Nordic countries a lot of work still remains to be done on these issues. They have also been seen as paradigmatic welfare states, where the public power (state, municipality) provides extensive public social security schemes plus education and health care services to the citizens on a universalist basis. The liberalist critique argues that the Nordic style welfare state has intruded too much into citizens' private lives, but the counter argument has been that the interventions of public power can be conducive to the sociopsychological well being of individual citizens, including the delicate area of sexuality.

One of the outcomes of the Nordic welfare state ideology has been women's improved access to social and economic independence. This, naturally, also impinges on the form that sexual cultures have in these societies. From a global perspective the women in Scandinavia have been well represented in politics, higher education, and full time paid labor. The reasons for this are varied and include for example

the cultural notions of gender that have accommodated the idea of female active subjectivity. These notions are a legacy of a rural cultural mode that survived in Finland and in Norway for example well into the twentieth century. Women's large scale participation in paid labor entails a degree of economic independence from male breadwinners, be they husbands or kinsmen; thus it is likely to support also female sexual subjectivity. Moreover, welfare state policies such as provision of extensive child daycare and parental leave have also often aimed to help women be better able to combine motherhood and career. This applies to single mothers in particular, whose poverty rate has been low in global comparison, largely because of a supportive social policy which indicates an absence of social stigma for single mothers.

Like single motherhood, cohabitation, abortion, and divorce generally lack any social stigma in contemporary Nordic societies. Pre marital sex is not an issue and a clear majority of people choose to live in a marriage like arrangement before they marry – if they marry at all. Living as a single has become all the more common in the last 10–15 years, and also in these cases it is mostly taken for granted that the single (if not a senior citizen) has long term or casual intimate relations. The divorce rate is fairly high, but divorce is often followed by a new marriage or cohabitation and it does not usually entail public opprobrium or other social costs. Some may deplore this as a “decline of the family,” but in fact family like formations clearly still have a strong appeal – it is only that they have become highly varied (e.g., registered partnerships). This can be seen as a vindication of the late modern pure relationships that Anthony Giddens outlined in *The Transformations of Intimacy* (1992): the norm of unbreakable marital ties has faded, in Scandinavia perhaps more than elsewhere in the West. The safety nets provided by the welfare state have probably made it more feasible for individuals (women in particular) to discontinue unsatisfying relationships and to consider, for example, cohabiting or single parenting as real options in life. It is also worth emphasizing that – the reality of frequent divorces and “serial monogamy” notwithstanding – the ideal of lifelong relationships has endured in younger

generations, and marital fidelity may now rank somewhat higher than a few decades ago as an ideal.

In the Nordic welfare state ideology there has often been at least an implicit equation between individual citizens' sexual health and national well being. The memorandum that a state committee prepared on “questions of sexuality” in Sweden in 1936 put it very clearly: in modern society sexuality would serve not only as a spring of personal pleasure, but would also propel the progress of society generally. The memorandum embodies the kind of ideal of social engineering that Sweden has often been considered to exemplify, but which has also existed in the other Nordic welfare state regimes – the ideal of a society designed according to rationalist scientific principles for the good of all citizens. The aspiration to benign social engineering has been visible, for example, in family planning and in sexual education.

One of the key texts in shaping the policy of family planning in Scandinavia (and also more widely) is the 1934 *Kris i befolkningsfrågan* (Crisis in the Population Issue) by the Swedish social scientists Alva and Gunnar Myrdal. In the long run this positive interest in issues of procreation and sexuality has generated arrangements like the provision of public marital advice services and sex education in schools. Indeed, institutionalized sex education has been one of the hallmarks of Nordic sexual politics, compulsory sex education being often part of the school curriculum. Here as well the aim has been to promote the social sexual health of individuals and society in tandem, recognizing that children mature sexually at an earlier age than before. Against the argument that extensive sex education is an invitation to early sexual experimentation, the Nordic experience rather suggests that professional sex education, including information on contraception, is conducive to adolescent sexual health and well being (e.g., there are comparatively low rates of teenage pregnancy and abortion). There are, however, distinctions between the Nordic countries that modify this picture and would need to be explained in more detail; for example, in Norway, the rate of teenage abortions has been much higher than elsewhere in Scandinavia.

Issues of contraception, sex education, and adolescent sexuality and abortion have thus been of little concern in Nordic societies in the last few decades. Likewise, both attitudes and legislation regarding the sexual content of films and other cultural products are very liberal. Pornography is easily available to (adult) consumers, the major exception being child pornography, which is banned by law. This overall sexual permissiveness notwithstanding, there has been discussion on the potential problems of pornography and prostitution from the perspective of gender equality, most notably in Sweden where there is in fact a law (since 1999) against sex purchase (i.e., buying sexual services). The rationale is that prostitution might be best curtailed by way of reducing demand for it. The efficacy of the law can not yet be assessed.

The status of sexual minorities, most notably homosexuals, is often considered to be one of the hallmarks of Nordic sexual liberalism. In fact, homosexual relations were decriminalized in some European states in the nineteenth century, whereas the first Nordic countries to take that step were Denmark–Iceland (1930) and Sweden (1944), whereas Finland (1971) and Norway (1972) followed much later. In the last 20–30 years, however, Nordic societies have been at the forefront of expanding institutional rights for gays and lesbians, for example in legislating against discrimination on sexual grounds and in introducing registered partnership laws (“gay marriages”). The laws on registered partnership conferred on lesbian and gay couples a legal status similar to that of married and cohabiting heterosexual couples, with the exception of not being allowed to adopt children. Parental rights remained a differential line between “first class” and “second class” citizens when heterosexual and non heterosexual life styles in other respects were set on equal terms in civil law. However, this difference has partly disappeared in more recent legislation (e.g., in Sweden since 2003). The registered partnership laws seem to show that the “modern homosexual” has lost most symbolic power as the paradigmatic social misfit, yet it would be an overstatement to say that gays and lesbians – and transsexuals – are always treated on an equal basis in everyday encounters. One can argue that the early introduction of partnership laws in the Nordic countries was an offspring of the welfare

state doctrine of social equality, rather than any “gay friendly” sentiments as such. It is noteworthy that some gay and lesbian critics have regarded the partnership laws as a token gesture that opens up the empty institution of marriage to homosexuals and allows them to be as ordinary as straight people, whereas the heterosexual patterns of lifestyle and intimate relations have become similar to what used to be the modern homosexual form of existence, as sociologist Henning Bech has called it.

The Nordic countries have been ethnically, linguistically, and religiously homogeneous societies until recently; it was in the 1960s that Denmark and Sweden began to receive greater numbers of non European immigrants, and in Norway and Finland similar developments have taken place even more recently. The ensuing cultural diversity has also entailed an increasing variety of sexual cultures in society, and on some occasions the cultural distinctions have resulted in frictions. The pattern of gender relations and male and female social roles in Scandinavian societies may often look bewildering not only to non- but also to western observers, and the norms and practices of family arrangements and sex relations in the migrant groups sometimes stand in stark contrast to those prevailing in Nordic cultures. Such differences are present in any multicultural society of course, but what is perhaps characteristic of Nordic societies is that historically there is a powerful thrust toward cultural assimilation that does not easily allow much space to sub cultural communities and cultural enclaves. Whether we speak of migrants or lesbians and gays, it is also a demographic fact that Scandinavian societies are small in population. Consequently, any “subgroups” within society are also small; hence, the preconditions for discrete sexual (sub)cultures are limited from the outset.

sexual deviance

Richard Temksbury

Sexual deviance, and what is defined as sexually deviant, is culturally and historically specific. This concept refers to behaviors that involve individuals seeking erotic gratification through means that are considered odd, different, or unacceptable to either most or influential persons in one's community. As with most forms of deviance, sexual deviance is something that is defined differently by persons of different backgrounds, beliefs, morals, and locations. However, sexual deviance is also an idea about which most persons hold very strong views, and react in stigmatizing and ostracizing ways.

Sexual deviance is a term that refers to behavior that has a sexual aspect to it and is considered a violation of either general societal norms or the expectations and/or limits of behavior for specific cultural settings. Defining some sexually oriented behavior as deviant means that the action meets at least one (or a combination) of four criteria: (1) degree of consent, (2) the nature of the persons/objects involved in the action, (3) the actual action and body parts involved, or (4) the setting in

which the behavior is performed. Generally speaking, sexual behavior that is not fully consensual by all persons involved is considered deviant. Rape and exhibitionism (where the persons to whom sexual images are presented are unwilling recipients) are obvious examples of sexual deviance defined by degree of consent. Sexual behavior with children, animals, or "odd" objects (vegetables, firearms, kitchen appliances, etc.) would be considered deviant by most people because such persons and objects are not generally considered sexual. When we speak of sexual deviance based on the action or body parts involved as the defining elements we could think of individuals who receive sexual gratification from violence, setting fires, wearing opposite gender clothing, or even for some people, masturbation. This category would also include sexual acts that include body parts not typically considered sexual, such as individuals' feet, ears, or noses. Finally, some settings, such as a courtroom, church, or an open field in a public park would be thought of by most people as inappropriate for sexual activities. Therefore, sexual acts performed in these locations (regardless of how "normal" the acts may be) would be considered deviant, simply because of where they were performed.

It is important to keep in mind that sexual deviance, as with all types of deviance, is not usually something that is inherently "wrong." Instead, sexual deviance is so determined by one of two approaches, both based on social conditions. The easier to see of these two approaches is the idea of statistical definitions. This means that sexual behaviors in which only a minority of persons engages would be considered deviant. In this view, behaviors in which a majority of persons participate would be normative, and those actions that only a "few" people do would be "different" (i.e., deviant). A more purely sociological approach to defining sexual deviance is to focus on the ways that society members react and respond to particular acts. In this approach, when others learn of an individual's sexual activities with farm animals and react by showing their distaste for the act and stigmatization of the persons involved, we know that sex with farm animals is considered deviant.

Sexual deviance includes behaviors that are deemed to be violations of all degrees of social

norms. Some sexually deviant behavior is a violation of only regular social expectations/norms. This would include premarital sex, sexual activities performed on one's desk at work, or perhaps the exchange of money for sexual acts. Other forms of sexual deviance would be considered violations of social mores; a more is a strong social norm that is usually considered to carry with it a moral aspect. Examples of sexual deviance that violate morally infused, strong social norms would be sexual activities between a supervisor and an employee when the employee is told their job may depend on their "consent," homosexual activities, and the exchange of sexual behavior for illegal drugs. Taboos are our strongest form of social norms and indicate activities that are so extreme that people may have a hard time even imagining that such actions ever occur. Sexual deviance that is a violation of social taboos might include sex with children, sex in a church, or sexually sadistic acts where individuals are forced to endure humiliation, extreme pain, or serious injury/death.

What this clearly points to is the fact that it can be difficult at times to define what is and is not sexual deviance. Individuals have different moral standards based on different cultures and subcultures that may vary in their views of acceptable and unacceptable sexual behaviors, and whether one has/does participate in certain activities will also influence their views and definitions. From the examples given above, it is easy to see that while we may refer to the exchange of sexual acts for money or drugs as deviant, clearly a significant number of persons do such actions. And many such persons do not necessarily see their actions as "deviant." Others with strong moral and religious beliefs might say sexual activities between same sex persons are wrong (and therefore deviant). However, many other persons (both those who do and do not engage in same sex sexual activities) do not hold moral or religious objections to such actions. Similarly, some people may believe that it is wrong to engage in sexual acts with persons to whom they are not legally married, while others may in fact believe that it is acceptable, important, or even imperative to become sexually experienced and skilled prior to marrying. This example can be clearly seen

in the beliefs and practices of many tribal societies where individuals are expected to enter into marriage with a high level of sexual skill/experience. Other cultures, obviously, do not condone such approaches.

And, finally, it is also important to recognize that definitions (and responses to) sexual deviance may change and vary over time. Consider, for example, the widespread changes in definitions of sexual deviance in the last fifty years. In the mid twentieth century issues such as premarital sex, homosexuality, oral genital contact, and even masturbation were considered extremely deviant, and rarely spoken of. Today, television shows, popular magazines, the Internet, and many persons' everyday conversations are filled with graphic, humorous, and clearly endorsing references to such previously "deviant" forms of sexual behavior. Or some acts that at one point in time may have been considered normative and expected may evolve to being seen as deviant. A good example here is the idea of marital rape. For most of known history, at least in western societies, wives were not viewed as having the right or ability to say no to sexual advances/requests from their husbands. A man who desired to have sex with his wife could, and often did, force her to do sexual acts. However, as an outgrowth of the feminist movement in the mid to late twentieth century, such actions have come to be viewed as wrong, and in many jurisdictions even illegal. Historical shifts occur in both directions, moving some acts out of the category of deviance and shifting others toward a designation as deviant.

Research documenting and explaining sexual deviance is something that is not overly abundant. Most of the research related to sexual deviance has come from the psychological or psychiatric perspectives. This body of research takes for granted that the behaviors and actors being studied are deviant, and seeks to identify both a cause/motivator for the behavior, and ways to intervene and either control or eliminate the behavior. In part, this can be explained by the fact that psychologists and psychiatrists tend to conduct their research with individuals who are either in therapy/treatment seeking to change their behaviors or who have been compelled to participate in therapy/treatment (often

as a result of legal processing). Sociological research on sexual deviance is available, but is not as numerous or readily available as that coming from psychologists and psychiatrists. Sociologists, with a focus on understanding the experiences, supporting social structures, and both contributing factors and experienced consequences of sexual deviance, tend to conduct their research with participants in sexual deviance in the free world, often in the environments where the sexual deviance is performed. Sociologists are less inclined than many psychologists and psychiatrists to study sexual deviance because the qualitative nature of such work takes the researcher to places they may not wish to frequent. As a result, many sociologists – even those who specialize in the study of deviant behavior – choose not to do research on sexual deviance.

Speaking in a sociological sense, we can think of sexual deviance as constituting three main varieties of deviance: normal, sociological, and pathological. These designations, like those discussed above, are also fluid and can introduce controversy over where a particular type of behavior may best fit. However, as analytic tools, thinking of sexual deviance as normal, sociological, or pathological can help to better understand if/how, when, where, by whom, and even why certain aspects of sexual behavior are defined as deviant and others are not.

Normal sexual deviance is sexual behavior that is relatively common, although not something that is widely discussed, acknowledged, or admitted. In fact, according to statistical ways of defining deviance, many acts that would be considered normal sexual deviance would not be deviant – a majority of society members may in fact engage in some normal sexual deviance behaviors. Some types of normal sexual deviance may be viewed as positive by many/some people – such as abstinence – yet also be widely considered deviant. These tend to be behaviors that are individually based and do not have any type of supportive social structure or organization associated with them. This is a key factor distinguishing normal sexual deviance from that which is sociologically defined.

Sociological sexual deviance includes behaviors that violate some type of social norms, but is associated with some variety of social group, structure, or organization that endorses,

practices, encourages (at least for members), and therefore sustains activities. Pornography, prostitution, and swinging are examples of sociological sexual deviance. Each has recognizable groups and organizations (or corporations) that promote and keep the activity going. Sustaining the activity may mean active recruitment/marketing for new participants and social support for encouraging individuals already involved to remain involved.

Pathological forms of sexual deviance are those that come to mind most quickly and easily, and that would be likely to most easily produce widespread agreement about the deviance of the acts. Pathological sexual deviance is illegal in nature (usually) and is associated with imposing harm on others. The participants of this type of deviance are seen as psychologically challenged. Examples of pathological forms of sexual deviance include sexual violence, pedophilia, and incest.

Clearly, definitions of sexual deviance vary, and may include a wide range of behaviors. Sexual behavior is largely unknown, but when it is known and deemed deviant many forms of sexual deviance are likely to cause an individual to retreat into hiding. However, when “outed,” these individuals are likely to be stigmatized. Obviously, as a social construct, definitions of sexual deviance are powerful and important forces in the structure and process of social settings and groups.

sexual harassment

Kathrin Zippel

Sexual harassment refers to unwelcome sexual advances, requests for sexual favors, or other forms of unwanted attention of a sexual nature, in a workplace or elsewhere. Legal definitions distinguish between *quid pro quo* sexual harassment, where putting up with these behaviors is a condition of work, and behaviors that create an intimidating, offensive, hostile environment for the victim. Its forms can be physical, verbal, gestural, visual, or graphic. Behaviors that can be perceived as sexual harassment include unwelcome (sexual) jokes, remarks with sexual connotations or about private lives, gossip, repeated requests to go out, and any form of unwanted touching or invasion of personal space, as well as sexual advances or assault.

The overwhelming majority of victims are women; adolescent and young workers especially report sexual harassment experiences. Perpetrators are most often individual men or groups of men. Men, in particular those who are financially vulnerable, can experience sexual harassment as well (Uggen & Blackstone 2004). Same sex harassment has also received attention, in particular, gender and sexual harassment among men.

Besides consequences such as loss of a job or not being promoted, victims experience psychological effects. Reactions cover a range of emotional and physical responses, including confusion, discomfort, anxiety, anger, and stress. Cultural representations of sexual harassment, however, often suggest an innocent flirt gone wrong, or that victims "asked" for it by dress or behavior. These representations may depict victims as revengeful, tapping into cultural repertoires similar to those around sexual violence.

Empirical research on the prevalence of the phenomenon has faced several methodological difficulties, partly because of its conceptualization, since the experience of sexual harassment depends on contextual factors. It usually includes related behaviors and several events, and hence is a dynamic or process rather than an isolated occurrence. Surveys have been

conducted using the Sexual Experiences Questionnaire (SEQ) developed by Louise Fitzgerald and her colleagues; however, these studies tend to rely on self reports, which raises the problem of subjective versus objective measures, including underreporting.

In the 1970s, second wave feminists in the US criticized the social, legal, and cultural norms of behaviors and organizational practices concerning men's sexual advances toward women and the unwanted eroticization and sexualization of relationships in the workplace and elsewhere. Feminists questioned the conditions under which women "consent" to these behaviors in the context of unequal power relations.

While US law has defined sexual harassment primarily as discrimination based on sex at work and in education, sexual harassment also occurs between people in other hierarchical positions, for example, in the unequal power relationships between doctor and patient, psychologist and client, landlord and tenant, or between colleagues/peers.

Feminist theories view sexual harassment primarily as rooted in unequal gender relations and the abuse of power of men over women. Sexual harassment is the product of a gender system that maintains a dominant, (hetero)normative form of masculinity. In this view, sexual harassment is a problem because of different "sex roles," or assumptions about male sexual aggression and female passivity, that spill over into the workplace.

Organizational theories view sexual harassment as a problem perpetuated through gendered organizational and institutional structures. For example, the occupational status of the victim and supervisory authority of the perpetrator influence the perceptions and interpretations of sexual harassment. Women's lower status at work, sex segregation, gender gaps in authority, and other organizational factors contribute to and are perpetuated by sexual harassment.

Sociolegal and political approaches explore the relationship between emerging sexual harassment laws and individual and societal perceptions, for example, by asking questions about legal consciousness, sensitivity to gender issues, and interpretations of sexual harassment.

The experiences, interpretations, and perceptions of sexual harassment vary not only

by gender but also by age, social class, and race. Research has recently begun to examine cross national differences in individual, organizational, social, political, and legal interpretations of sexual harassment. For example, in several European countries sexual harassment is considered in the context of bullying, mobbing, or moral harassment, as a violation of workers' dignity or a form of violence against women.

sexual health

Laura M. Carpenter

Sexual health is both a lay expression and a technical term defined in national and international legal and public policy documents. As employed by social scientists, sexual health generally refers to a state of physical and emotional well being in which an individual enjoys freedom from sexually related disease, dysfunction, coercion, and shame, and thus the ability to enjoy and act on her or his sexual feelings.

The concept is widely used in the United States, Canada, Australia, Europe, and Latin America.

Although scholars and policymakers have treated sexuality as a public health issue since the mid 1800s, few sociologists explicitly used the expression “sexual health” to describe their work before the mid 1990s (many still do not). In fact, the formal definition of sexual health dates only to 1975, when the World Health Organization (WHO) convened an international panel of human sexuality experts for the purpose of addressing a perceived shortage of sexuality educators and research opportunities. At that time, the youth counterculture, second wave feminist, gay rights, and women's health movements were helping to transform understandings of gender, sexuality, and health in the West. Previously, reproductive health and sexual health had been treated as a single issue, with the emphasis on reproduction; the advent of highly effective contraceptives, along with increasing secularization and social acceptance of nonmarital sexuality in many societies, made a sharper distinction possible.

The 1975 WHO panel delineated the basic elements of sexual health as the “right to sexual information and . . . pleasure,” the “capacity to . . . control sexual and reproductive behaviour,” “freedom from . . . psychological factors inhibiting sexual response and . . . relationship,” and “freedom from organic disorders, diseases, and deficiencies that interfere with sexual and reproductive functions.” This definition bears the imprint of the WHO's 1946 definition of health as “a state of complete physical, mental, and social well being and not merely the absence of disease or infirmity.” It represents a fundamentally social rather than strictly biomedical understanding of sexual health, going beyond a narrow focus on disease, physiology, and reproduction to consider the social contexts in which sexual feelings and activity occur.

Pleasure, agency, and freedom from physiological and psychological disorders have been central components of all subsequent major definitions of sexual health. These elements also appear in lay definitions, as when the (US) Boston Women's Health Collective's *New Our Bodies, Ourselves* (1984) glossed sexual health as “a physical and emotional state of well being that allows us to enjoy and act on our sexual feelings.”

Definitions of sexual health have since evolved in response to broad social trends. In 1987, during a period marked by intense debate over social diversity and cultural relativism, the WHO Regional Office for Europe released a report (*Concepts on Sexual Health: Report on a Working Group*) contending that the culturally and temporally contingent nature of sexual health precluded a universal definition. The authors' concern that a single definition could be used to label some individuals or behaviors as unhealthy has informed subsequent definitions, which have recognized the importance of factors such as religion, age, disabilities, socioeconomic status, and sexual identity.

In the early 1990s an international coalition of women's health and development NGOs emerged as a major force in a series of population and development conferences sponsored by the United Nations. Coalition members were concerned with a broad range of issues related to sexuality, health, and human rights, including preventing mass rape and female genital mutilation (FGM) and ensuring women's ability to control their fertility, choice of partners, and sexual identity. The coalition succeeded in placing sexual health, framed as an aspect of reproductive health, on the international policy agenda and incorporating it into such documents as the 1994 International Conference of Population and Development (ICPD) Program of Action. The 1990s also saw a concerted effort to frame health as a human right and the development of the concept of sexual rights. Efforts to incorporate sexual health and sexual rights into international law and policy have consistently met with vigorous opposition by a Vatican led alliance of religious/moral conservative governments and organizations.

The exact relationship between sexual health, reproductive health, and sexual rights is contested. ICPD delegates found it politically expedient to categorize sexual health as an aspect of the less controversial reproductive health. Other influential reports, such as that produced by the 1995 (US) National Commission of Adolescent Sexual Health, treat reproductive health as a component of sexual health. Definitions of sexual rights typically include access to sexual and reproductive health care and sexuality education as well as sexual and reproductive autonomy, bodily integrity, and the pursuit of sexual

pleasure. The link between sexual health and sexual rights was made explicit in a 2000 joint report by the Pan American Health Organization (PAHO) and WHO (*Promotion of Sexual Health: Recommendations for Action*), written largely by Latin American sexologists: "Since protection of health is a basic human right, it follows that sexual health involves sexual rights." These widely publicized conferences contributed to a dramatic increase in the number of sociologists and demographers framing their research in terms of "sexual health."

In 2002, the WHO issued a revised definition of sexual health as "a state of physical, emotional, mental, and social well being related to sexuality . . . Sexual health requires a positive and respectful approach to sexuality and sexual relationships, as well as the possibility of having pleasurable and safe sexual experiences, free of coercion, discrimination, and violence." The task force further declared that the attainment of sexual health depended on having the "sexual rights of all persons . . . respected, protected, and fulfilled."

National governments have also sought to define and incorporate sexual health into public policy. In 1999 and 2001, respectively, the Canadian and US governments, prompted by a host of similar concerns – including population aging; increasing social diversity; health and social welfare system restructuring; new reproductive technologies; and "unacceptably high" levels of sexually transmitted infections (STIs), infertility, sexual violence, and teen pregnancy – issued reports addressing sexual health. Health Canada's *Report from Consultations on a Framework for Sexual and Reproductive Health* and the US Surgeon General David Satcher's *The Surgeon General's Call to Action to Promote Sexual Health and Responsible Sexual Behavior* both explicitly acknowledged the importance of sexual health to children and older adults (previous definitions imply reproductive age adults) and stressed the need for sexual responsibility at the individual and community levels (the latter referring to ensuring community members' access to sexuality education and health services and freedom from discrimination and violence). By contrast, a 2001 report from the British Department of Health (*National Strategy for Sexual Health and HIV*), produced as part of a wider health

system reform initiative, construed sexual health in relatively narrow terms, reiterating the basic tenets of previous definitions, but focusing chiefly on reproductive issues and the prevention of HIV/STIs and unintended pregnancy, and avoiding reference to responsibility and pleasure. That said, the British framework resembles its Canadian counterpart in treating sexual health as a fundamental human right, whereas the US guidelines tend to frame it as an individual choice – a difference consistent with broader cultural tendencies.

The social trends that have influenced definitions of sexual health have also shaped the nature of sociological research. Historically, due to prevailing codes of morality, beliefs about the purpose of sex, and understandings of social problems, most studies of sexual health topics focused on married couples of reproductive age or heterosexual adolescents (whose sexuality is presumed to be problematic). Furthermore, although definitions of sexual health are nominally gender neutral, in practice the bulk of research on sexual health has centered on women – largely due to the physiology of pregnancy, gendered assumptions about family responsibilities, and the sexual double standard. For much of the twentieth century, studies tended to focus either on white middle class people – typically cast as paragons of health and normalcy – or on economically disadvantaged people and/or members of racial/ethnic minorities, frequently framed as deviant or unhealthy. Study populations have become increasingly socially diverse since the 1970s, with scholars paying more attention to the effects of intersecting identities from the 1990s onward.

Despite the broad range of issues encompassed by leading definitions of sexual health, in practice, the vast majority of academic research on the topic focuses on STIs (including HIV/AIDS) and reproductive health. In developed nations, male and female sexual dysfunction are also common subjects; in the developing world, FGM and sexual violence are frequently studied. Researchers' preoccupation with the negative aspects of sexual health may stem from worldwide cultural and political difficulties in agreeing on a common definition of positive sexual health. With the advent of globalization, sociologists interested in sexual health have

become increasingly aware of the need for a global approach to many sexual health issues, such as the relationship of global sex tourism to STI transmission.

Early sociological work on sexual health topics was generally motivated by concern with family and population dynamics. Approaches to many issues changed markedly starting in the 1970s, as second wave feminism gave rise to new understandings of sexuality and gender, inspired the increasingly global women's health movement, and influenced two generations of feminist sociologists to direct attention to gender, sexuality, and bodies. From the 1930s onward, sociologists studied "sexual adjustment" – encompassing compatibility in sexual desire, preferred activities, and frigidity/impotence – as an aspect of "marital adjustment" or emotional well being in marriage. The term "sexual adjustment" has largely fallen out of favor, and studies now consider these issues among same sex and cohabiting couples and attend more closely to power and gendered expectations. Sociology's rich tradition of research on reproductive health and politics like wise began to cover new territory in the 1970s, especially the critical policy issues of childbirth, episiotomy, abortion rights, and menopause. Feminists, along with gay rights activists, have also helped to direct scholarly attention to stranger, acquaintance, and marital rape and rape culture, as well as sexuality related hate crimes.

As scholarly interest in masculinity expanded from the 1990s onward, researchers have increasingly recognized the importance of attending to men's sexual health, beyond sexual dysfunction, both in its own right and in terms of its effects on female and male partners. Major foci to date include men's role in reproduction and birth control, STI transmission, male infertility, and sexual violence.

Gay rights activism, the increasing visibility of lesbian/gay people, and an increasing number of openly lesbian/gay sociologists have also influenced sexual health research agendas. Prior to the 1974 removal of homosexuality from the American Psychiatric Association's *DSM III*, sexual desire for and contact with same sex partners was largely studied as a sign of mental illness. Research addressing the relationship of sexual health to sexual identity/orientation has burgeoned since. The emergence of HIV/AIDS

in 1982 prompted extensive research on gay men's sexual health, albeit much of it narrowly focused on HIV/AIDS. Lesbians' sexual health has received less attention because lesbians have not been a major risk group for HIV; however, sociologists have recently begun to explore lesbian and bisexual women's use of sexual health services. Research on social factors affecting the transmission, prevention, and diagnosis of STIs other than HIV/AIDS has continued throughout this era, with several recent studies offering compelling analyses of the ways gender and race intersect to shape the experience of living with, and seeking treatment for, STIs.

The aging of western populations, along with the unprecedented growth and deregulation of the pharmaceutical industry that began in the 1990s, have prompted increasing attention to sexual health after the menopause/climacteric. Analyses of the social causes and effects of sexual dysfunction – an umbrella term including erectile dysfunction (formerly called impotence) and premature ejaculation in men and dyspareunia (painful intercourse), sexual aversion, and lack of desire in men and women (formerly called frigidity, in women) – have proliferated since the 1970s, due to new understandings of sexuality as essential to human happiness. From the late 1990s onward, researchers have charted the increasing medicalization of male and female sexual dysfunction and the pharmaceutical industry's role in setting research and treatment agendas. Over the same period, increasing scholarly interest in the lives of people with chronic illnesses and physical and mental disabilities has prompted a small but growing body of research on the sexual health of women and men with disabilities and/or chronic medical conditions.

Other aspects of sexual health examined by sociologists include:

- Sexual pleasure and desire, other than as related to dysfunction. Such research is relatively rare, especially among youth and people past reproductive age, and is seldom framed in terms of sexual health.
- Formal and informal sexuality education and the politics surrounding it. Comparisons of European and US approaches to sexual health education are especially interesting.
- The medical treatment of people born intersexed, especially genital surgery, as well as lay and medical opposition to that treatment.

Sociological studies of sexual health employ both quantitative and qualitative methods, with the former being somewhat more common, especially for issues deemed relevant to public health. By and large, research on sexual health is subject to the same methodological difficulties as research on sexuality in general (e.g., study participants' desire for privacy). However, the social and political climate in which scholars work may pose additional challenges. For example, since the late 1980s, conservative governments and grassroots organizations in the US and Britain have sought to impede and censor sexuality research by reducing and restricting funding and interfering in already funded projects. In fact, the increasing popularity of the term "sexual health" may reflect an attempt by researchers worldwide to circumvent conservative opposition, under the assumption that research on sexuality is more likely to be deemed justifiable if it concerns health. Sociopolitical factors may also affect the implementation of public policy grounded in social scientific research. In the US, for example, conservative presidential administrations have overseen the removal of accurate contraception information from official websites and the promotion of "only abstinence until marriage" sexual health education programs, despite evidence of their ineffectiveness. Policies in one nation may have global effects, as in the case of legislation forbidding international population programs that receive US funds from mentioning abortion.

sexual identities

Ken Plummer

The term identity is derived from the Latin root *idem*, implying sameness and continuity, and helps to provide a sense of who we are and of who other people are. It serves as a crucial bridge in social life between human beings and wider cultures; it implies a sense of meaning and a sense of categorization and differentiation; and it marks out differences – between ourselves and others. The idea of identity speaks of locating a person within a personal and social category. It suggests answer to the question “who am I?” placing one's self and life within a framework of past (what kind of person I was and how I became it), of present (of who I am now), and future (guiding the sense of who one will be and how one is different from others). Sexual and gendered identities help to locate people within sexual and gender cultural frameworks.

In some (usually more traditional) societies, identities are often assumed (they may be ascribed) and there is little debate about the nature of identities. Gender and sexuality may

be taken for granted as a given identity. In other societies (usually modern ones prone to individualism), just who one is becomes a greater problem, and there is much discussion on the nature, origins, and impact of different kinds of identities. Some suggest that identities are more or less fixed and given from within – they are essentialist. They serve as an inner core of who one is. Much of biological, psychological, and psychotherapeutic thought is of this kind. Others suggest that identities themselves are historically and socially contingent, and that they are hence socially constructed. In this latter sense, people have to invent who they are – there is no inner core. Much of Meadian interactionist thought is of this kind. The analysis of identities covers a wide range of concerns from gender and sexual identities to ethnic identities, from occupational to nationalistic identities. Very often there are “hierarchies of identity” with master identities becoming key and conflicts being developed between them.

In recent times, with the emergence of post modern culture, identities have increasingly come to be seen as highly unstable and precarious. For theorists like Anthony Giddens, Ulrich Beck, and Zygmunt Bauman, identities are destabilized and have to be worked at. Giddens, in his *Modernity and Self Identity* (1991), suggests that identity becomes part of a “politics of life style” which has emerged to ask “how should we live?” in a post traditional order and against the backdrop of existential questions. Lifestyle choice is increasingly important in the constitution of identity and daily activity. “Reflexively organized life planning becomes a central feature of the structuring of self identity” (Giddens 1991: 5); self identity is “the self as reflexively understood by the person in terms of her or his biography” (p. 53). For Bauman, “if the *modern* ‘problem of identity’ was how to construct an identity and keep it solid and stable, the *postmodern* ‘problem of identity’ is primarily how to avoid fixation and keep the options open” (1996: 18). Kenneth Gergen (1991) depicts a journey which he describes as “from the Romantic (via the Modern) to the Postmodern.” For him, the post modern means “the very concept of personal essences is thrown in doubt.” The source of this change is “the technologies of social saturation”

(low tech and hi tech), leading to a “multi phrenic condition” and new patterns of relationships (“fractional,” “microwave,” etc.). All of this could mean that lifestyle choices have to be made around gender (how to be a man, what kind of man, how to see oneself as a man), or as a sexual being (how to be gay, how to identify oneself, etc.).

LESBIAN AND GAY IDENTITY

Ever since its arrival in academia during the 1970s, lesbian and gay studies have been haunted by the identity problem (Plummer 1981). From early studies such as Carol Warren’s *Identity and Community in the Gay World* (1974) and Barbara Ponse’s *Identities in the Lesbian World* (1978), through Richard Troiden’s *Gay and Lesbian Identity* (1988) and William H. DuBay’s (neglected) *Gay Identity: The Self Under Ban* (1987), the themes of classification and identity have been extremely prominent. In the now voluminous and magisterial compendiums, textbooks, readers, and handbooks that have been reproduced for lesbian and gay studies, identity always plays a prominent part. And articles on the field continue to multiply, though nowadays usually with increasing complexity. Without doubt, it has consistently been one of the big themes for understanding “lesbian and gay lives” historically, comparatively, and contemporaneously.

Broadly, research on gay identity has highlighted six questions:

- 1 What is the nature of the lesbian and gay identity? – the essentialist/phenomenalist question.
- 2 How did the identity of lesbian and gay emerge? – the historical question.
- 3 How do people come to acquire the lesbian/gay identity? – the question of stages and processes.
- 4 How do people manage the lesbian and gay identity? – the coming out/outing/passing problem.
- 5 How is the identity changing?
- 6 What are the political uses of lesbian and gay identities? – which highlights the politics of identity and the issue of citizenship rights.

This concern with identities is all part of a wider zeal to classify and order our identities and sexualities. In all this earlier work, there was a clear tendency to locate a fairly clear gay identity and a fairly identifiable pattern of coming out through stages (the popular coming out models of the 1970s and 1980s). It was usually linked to a community – identities became the bridge between the gay or lesbian person and the gay or lesbian community. Over time, the notions of identity became more complex as stage models of identity were challenged, variations of ethnicity and sexualities were confronted, and a politics of identity was developed. In all of this, boundaries were clearly being drawn, but in complex ways.

During the 1970s, a social science literature emerged which suggested the processes in which a person came to build up different kinds of sexual identity. These writings often delineated stages. Plummer (1975) suggested the stages of sensitization, signification, subculturalization, and stabilization. Troiden (1988) extends this and suggests a similar model: sensitization, identity confusion, assumption of a gay identity for oneself, and commitment to homosexuality as a way of life. Vivienne Cass (1979) suggested five movements: identity confusion, identity comparison, identity tolerance, identity acceptance, and identity pride. Nowadays, such models are seen as perhaps having relevance for the 1960s and the 1970s when homosexuality was heavily stigmatized; however, these days younger people are experiencing much more flexible ways of relating to the category of homosexual.

From at least the 1960s the idea of “coming out” became more and more significant as an aspect of gay and lesbian identity construction. Coming out has multiple meanings. In the earlier twentieth century, Delaney suggests that it seems to have meant “having one’s first major homosexual experience.” Subsequently, it meant primarily self identification as homosexual. But toward the end of the twentieth century it came increasingly to mean disclosing who one is to family, friends, and indeed the wider world. In 1970, Barry Dank suggested how central this process was. Likewise, the gay and lesbian movement of the 1970s saw “coming out” as a political act: the making of homosexuality into a public event became a major force for change.

Times have changed. Ritch C. Savin Williams suggests in the early twenty first century there has been much greater complexity and variability in the complex process of gay identity formation. He suggests a much wider range of terms available within which to locate oneself, with many refusing, resisting, and modifying sexual identity labels.

THE POLITICS OF IDENTITY AND ITS CRITICS

Identity politics became increasingly prominent from the late 1960s onwards, and is particularly associated with ethnic and religious minorities as well as with feminist and lesbian and gay movements. There is a clear move here from a class based politics to a broader set of alliances. Experiences such as those of black, gay, or women's oppression become highlighted as the focus for creating a separate group identity – as blacks, gays, or feminists. By the 1980s it became clear that many sexual and gender identities were coming to be political categories. With reminiscences of Marx's dictum of a class becoming a class in itself – of the rise of political identity – and the model of black consciousness and black identity becoming more and more an issue, increasingly both the women's movement and the gay and lesbian movement came to center around a pivotal (and usually essentialized) identity. Indeed, without such identities becoming extant, much of the politics of the new social movements would not be possible.

A telling article by Steven Epstein (1985) on ethnic identity and gay identity suggested the parallel between black identity as a political and personal tool, and the gay identity as working in similar ways. The gay community, and indeed contemporary gay politics, require a clear identity around which to mobilize. This has remained the case for the vast majority of gays and lesbians since that time: there is a clear and strong identity. The notion of gay identity of true lesbians not only brought clarity to (an often unclear) life, it also firmly focused on a politics and galvanized action.

What was happening, though it may not have been clearly seen initially, was the development of a politics of identity. Gay identity became a

political tactic. It also allowed rights to be attached to the identity. The new social movements (NSMs) have consistently been seen as generating a politics of identity which claims recognition as one of its main goals – collective, public, and political identities.

But there have also been a number of counter movements to this. First, critics suggest that actual sexual or gender identities are themselves much more complex than such simple terms suggest. Whilst we used to have rather simple terms of "passive" or "active" gays and "butch" and "femme" lesbians, increasingly these have become fragmented into many kinds: lesbian boys and male lesbians (Zita 1998), MSM (men who have sex with men), "female masculinity" (Halberstam 1998), or the range of "intersex" and "trans" identities (Preves 2003) – as well as broader ones such as "LGBT" (lesbian, gay, bisexual, and transgender identities). In general, though, critics suggest that the categories have oversimplified – even stereotyped and essentialized – complex experiences. Sexual and gender identities, for example, lie at the intersections of many other axes: ethnicity, nationality, age, disablement. These can readily hyphenate identities into "Asian gay identity" or "working class, Native American lesbian identity."

Second, critics suggest that postmodern times have brought very different and largely unstable identities, as we have seen above: there is no fixed way of being sexual or gendered. They critique identity, and suggest instead that it is much more fluid, often characterized by narratives (Holstein & Gubrium 2000), seriality, performativity (Salih & Butler 2004), and hybridity. Stuart Hall (1997) talks of the diasporic experience as defined not "by essence or purity, but by the recognition of a necessary heterogeneity and diversity; by a conception of identity which lives with and through, not despite, difference; by *hybridity*."

QUEERING IDENTITY

"Gay identity," then, like all other identities, can presume too much. It is indeed usually an essentialist idea and cannot begin to capture the full complexities of what we might provisionally sense as "same sex experience," which may be youthful or old, black or white, disabled or

non disabled, to engage in just a few of the most simplistic variations. So our notions of identities from which we speak have to become more varied, pluralized, and open than this, whilst indeed having to acknowledge some kind of continuities and boundaries (except in the most extreme, transgressive, and postmodern cases). Fixed clear voices seem now to have become weakened, identities ebb and flow, and voices now speak from a multiplicity of shifting and unsettled positions, constructing diverse narratives (stories of the lives of our lives) (Holstein & Gubrium 2000). These voices are always in dialogic process, and people speaking from various identities and positions may well find that these have to shift in the very processes of argumentation. But they cannot speak at all if they do not recognize the categories, however humbling and inadequate they may be. We need what might be called a *thin essentialism*. We need our identities, even as we change and modify them on a daily basis, and they are surely part of the continuing politics of citizenship. (And at times there may even be a need to “risk essentialism” to sense a strong, shared “we.”)

These more radical tendencies in identity theory have since the late 1980s (in North America, largely as a humanities/multicultural based response to a more limited social psychological approach classically found in “lesbian and gay studies” as indicated above) been linked to “queer.” “Queer” is most definitely meant to take us beyond the boundaries and borders of heteronormativity. The roots of queer theory (if not the term) are usually seen to lie in the work of Eve Kosofsky Sedgwick in *Epistemology of the Closet* (1990). She argues that the central classifying device of the nineteenth and twentieth centuries – the overarching borders of society – is composed of the hetero/homo binary divide: “many of the major nodes of thought and knowledge in twentieth century Western culture as a whole are structured – indeed fractured – by a chronic, now endemic crisis of homo/heterosexual definition, indicatively male, dating from the end of the nineteenth century” (1990: 1).

Identity is thus seriously questioned. Like wise, Judith Butler’s *Gender Trouble* (1979) is interested in deconstructing the sex/gender divide (and hence less concerned with the deconstruction of the homo/heterosexual

binary). For Butler, there can be no claim to any essential gender: it is all “performative,” slippery, unfixed. If there is a heart to queer theory, then, it must be seen as a *radical stance around sexuality and gender that denies any fixed categories and seeks to subvert any tendencies toward normality within its study*. Queer theory, then, is a stance in which sexual categories are seen to be open, fluid, and non fixed: both the boundaries of heterosexual/homosexual identities and sex/gender identities are challenged. Indeed, categories such as gay, lesbian, and heterosexual identity become “deconstructed.” There is a decentering of identity.

Whether we can live with deconstructed identities in the future remains to be seen.

sexual markets, commodification, and consumption

Ken Plummer

Modern sexualities have become constituted through massive markets. Consumption has become a key social characteristic of the late twentieth century (see Robert Bocock's *Consumption*, 1993), and in parts of the world we are "born to shop." Consumption has played a growing role in the lives of individuals around the (wealthier) world, and one aspect of this is the deep and pervasive ways in which human sexualities have come to be marketed, commodified, distributed, and consumed across the world. In contrast with what Foucault, in the first volume of *The History of Sexuality*, called *ars erotica* (and the presumed spontaneity of sex though influenced by religion), contemporary sexualities are structured increasingly in global

capitalist markets (Altman 2000). This is no minor observation, although it is a much neglected one.

In one sense there is little new about this. There are several long term historical institutions which have regulated sex through economic mechanisms. Prostitution, for example, has – rightly or wrongly – been commonly called the "oldest profession" and involved the financial supply of and demand for sex, among much else. In the twentieth century, this wider "sex industry" involves many workers and could properly be seen as an aspect of the sociology of work. Thus there are

business owners and investors, independent contractors and non-sexual employees (waiters, cashiers, guards, drivers, accountants, lawyers, doctors) and middlemen who facilitate business processes (some travel agents, guides, estate agents, matrimonial agents, newspaper and magazine editors, Internet entrepreneurs). Sites involved include bars, restaurants, cabarets, clubs, brothels, discotheques, saunas, massage parlors, sex shops with private booths, motels, flats, dungeons for bondage and domination, Internet sites, cinemas and anywhere that sex is offered for sale on an occasional basis such as stag (men only) and hen (women only) events, shipboard activities or modeling parties. Products and services included erotic phone lines, escort and matrimonial services, films and videos, souvenirs, toys, clothes, equipment and live and virtual spectacles via web cameras. (Agustin 2005)

Likewise, many marital arrangements – from the bride dowry to family inheritance – are not new and have involved the regulation of sexuality through monetary means. But these have not typically involved the turning of sex into commoditized markets, such as "mail order brides" (Constable 2003), as is found today.

The contemporary ecology of sexual markets suggests looking at the workings of five major interlocking markets through which sexuality is consumed. These are:

- 1 The sale of sexualized corporeal bodies, in many versions of real live sex acts (Chapkis 1997): "prostitution" and sex work, trafficking of bodies, stripping, table dancing/lap dancing (Frank 2002), sex tourism (Ryan & Hall 2001), and sex parties. "Real sex" is on sale. Much of this is global, and

in rich/first world countries large numbers of men are purchasers of sex.

- 2 The sale of sexualized representations, through images and texts – in erotica, pornography, and Internet messaging. Not only is there a huge industry of pornography for men (straight and gay), but there are also now substantial markets for women. The widespread nature of this has been called the “pornographication” of culture (McNair 2002).
- 3 The sale of sexualized objects: most prominent here are “sex toys,” from S/M costumes, nitrate inhalants (“Poppers”), and whips/harnesses to dildos, vibrators, inflated blowup dolls, and lingerie, organized through shops like Ann Summers (Storr 2004). Parties are organized; the “circuit party” organizes sex parties (usually gay) on a national and international scale (e.g., Westhaver 2005).
- 4 The sale of sexualized technologies: much of sex is also marketed through medical aids, from Viagra to contraceptives and transgender surgery, as well as cosmetic surgery (Haiken 1997).
- 5 The sale of sexualized relationships, including marriage (such as mail order brides), and meeting places, such as gay bars (Chasin 2000; Sender 2005), singles bars, or indeed almost any bar which can facilitate sexual relationships. Likewise, relationships can become subject to expensive therapy and standardized self help books which can sell, for example, the 12 steps needed for a perfect relationship. Increasingly, relationships can be found in the marketplaces of cyberspace.

Some of these markets involve the explicit and direct selling of sex; others are more covert and indirect. Thus, the most conspicuous consumption is through direct markets where sex itself is the direct commodity for sale. By contrast, covert or indirect markets are those which use sexualities to sell something else – the massive worlds of advertising, entertainment, and sport are often sold through their sexual iconography. Thus stars from singers (Elvis Presley, Madonna) to film stars (Valentino in the 1920s to Tom Cruise) and sports stars (George Best to David Beckham) command

large sums while extracting “desires” from their audiences. Many objects are also sold that depend on an erotic connection: perfumes, clothes, holidays, music, dance, and so on, are linked to sex.

There is a landscape of erotica as a background to everyday life through film, television, advertising, video, and pop music – and indeed, even the city becomes a sexualized space. Web sites, too, can provide online sexual pleasures, all neatly coded and organized according to a catalogue that transcends Krafft Ebing’s wilder taxonomies where consumers may find just what they desire, order and pay for it online, and subsequently meet their desires. It often parallels the McDonaldization of society (Ritzer 2004) as the McDonaldization of sexuality, being rendered rational, calculable, efficient, and predictable.

Sexual markets also span across the whole life cycle. Children enter systems of consumption and sexuality, even if they are not clear about them. Adolescents become saturated with sexual consumption, in the process developing desires of all kinds. In later life, the daily routines of sexual markets are unmistakable.

Tim Edwards in *Contradictions of Consumption* (1996) has suggested five fundamental meanings of consumption to consumers. These ideas are indicative of what could be developed in relation to sexuality. The first sees the consumer as king: sexual consumption indicates a kind of victor over the producer and retailer. The second sees sexual consumers as victims – as cultural dopes who cannot help but be persuaded about the latest sexual fashions. Third is the sexual consumer as criminal: the purchasing of illegal goods, and the many markets that sell sex against the law. Fourth is the anti sexual consumer: someone who ostensibly rejects the increased dehumanization and crass commercialism of the consumer world. This type of consumer may turn to alternative and more spontaneous versions of sexuality (although paradoxically, such sexualities are also often sold in therapeutic markets, for example). Finally, the sexual consumer may also be a voyeur or pleasure seeker: a *flâneur* engaging with the proliferating erotic environment of images.

Consumption usually plays a symbolic role and may help to establish group boundaries, such as between men and women, gay and

straight. It is not surprising that much of sexual consumption is linked to matters of gender: what it is to be a sexy man, or a sexy woman. There is growing research that suggests that what the symbols and culture propose for the sexuality of women are different from those for male sexuality. Thus women's consumption of sexuality and their desires can be shaped by the media: television's *Sex and the City*, advertising, women's magazines, websites, pop music, and, of course, fashion. Some feminists have argued this plays a key role for women and men. Notably, this is bound up with bringing back sexuality for women – sometimes a domesticated version, sometimes as an overstated self expression (women become “self made,” autoerotic, choosing sexual display, seeking breakthrough sexual pleasure), as being desired, being sexy, feeling empowered (Storr 2004). Others see it as a sad reflection of shopping. The body is increasingly objectified, sex acts are more and more open to being sold, allied goods like underwear become sexualized, and the entire body is reconstructed as thin and beautiful through expensive cosmetic surgeries.

The commodification of sexuality, then, is seen as a rapidly expanding (and expensive) global market. Sexual consumption suggests the widespread growth of sexual pleasure and its accessibility where sex becomes “liberated.” By contrast, sexual consumption may also be seen as a mechanism of dehumanization and disenchantment, a multibillion dollar industry which provides huge profits for organized crime, medical empires, and commercial companies that trade in a wide array of “sex.” Desires are turned into markets and shaped and reinforced by them.

sexual politics

Matthew Waites

“Sexual politics” refers to the contestation of power relations with respect to sex, gender, and sexuality. The concept originates in the

second wave feminist movement which emerged in the late 1960s and 1970s in western societies. Its definitive textual origin is Kate Millett's *Sexual Politics*, first published in 1970, one of the founding works of the emerging women's liberation movement which provided a social and political analysis of "patriarchy" – the social system of rule by men. For Millett, "sexual politics" expressed the idea that "sex is a status category with political implications," and this implied challenging the distinction between public and private which reproduced inequality between men and women by consigning concerns about sex and sexuality to a non political private realm. The concept is now widely used in academia and in popular culture to refer to a range of struggles over sex, gender, and sexuality, although the scope and implications of sexual politics remain highly contested.

The idea of sexual politics was revolutionary for sociology. Power relations between men and women which had previously been interpreted as the appropriate expression of biological differences (e.g., in the work of Talcott Parsons) were acknowledged as the products of society, history, and culture, and hence as politically accountable. Feminists sought to distinguish sex, understood as biological difference, from gender, understood as socially defined – as in Ann Oakley's *Sex, Gender, and Society* (1972). Gradually, knowledge generated in feminist social movements began to challenge sociological orthodoxy.

One of the central concerns of Millett's *Sexual Politics* was with power and domination in relation to sexual activity itself, and indeed Millett argued that "coitus" "may serve as a model of sexual politics on an individual or personal plane." However, "sexual politics" as a phrase used in mainstream politics and culture sometimes became associated first and foremost with a focus on power inequalities relating to biological sex and gender rather than sexuality. During the 1970s, the emerging sociology of "sexual divisions" sometimes continued to neglect sexuality in its focus on work and the family. Sexual politics tended to imply that the politics of gender could be equated with the politics of socially defined relationships between two biologically given sexes. This assumption has more recently been challenged, however, in the context of developing technologies of body modification and surgery, by radical

transgender theorists and poststructuralist feminist theorist Judith Butler (1990), whose contestation of conceptions of sex as presocial and immutable defines what she now describes as the "new gender politics" (2004). Sexual politics today, then, has become a concept used to describe a wide variety of forms of intellectual work, social movement activity, and cultural politics contesting sex, gender, and sexuality by women, men, and transgender people, lesbian, gay, and bisexual people, queer people and heterosexual people, sadomasochists, pedophiles, anti pornography campaigners, and many others.

Sexual politics politicized sociology with respect to gender and sexuality. Yet sexual politics also challenged traditional conceptions of the scope of politics as a discipline, pushing its research beyond the institutions of government and the public sphere to interrogate power structured relationships in "private" life. Sexual politics thus tended to suggest the necessity of interdisciplinary analysis, yet political sociology – preoccupied with sophology and the sociology of government institutions – was initially ill equipped to serve as a forum for the necessary cross fertilization. Over time, however, the idea of sexual politics has fostered interdisciplinary scholarship, and recently has contributed to the reinvention of political sociology as a more open and innovative field (Nash 1999).

Feminism in the United States, and to a lesser extent in the West more generally, became divided by "sex wars" between radical feminists and self defined "pro sex" feminists during the late 1970s and 1980s. Pornography was a central issue, for example in the radical feminist analysis of patriarchal oppression produced by Catharine MacKinnon and Andrea Dworkin (cf. Dworkin 1981); but such analyses were rejected by other "pro sex"/"anti censorship" feminists such as Carole Vance, who organized the Barnard conference on female sexuality in 1982 in response, placing greater emphasis on possibilities for women's sexual pleasure within heterosexuality (Vance 1992). Feminists remain divided over issues such as pornography and prostitution.

If, as is widely agreed among sociologists, the emergence of gay liberation and women's liberation movements from the late 1960s marked an important new phase in sexual politics, then

it can be argued that contemporary sexual politics has again entered a new phase during the 1990s and in the new millennium. In the developed world, feminism has achieved a fundamental shift from the assumed model of the heterosexual nuclear family with a male “bread winner” and corresponding gender norms of femininity and masculinity, to a situation in which it is assumed to be legitimate for both male and female partners in heterosexual relationships to engage in paid employment, and where diverse heterosexual masculinities and femininities are more acceptable, though still policed. Gay and lesbian movements have achieved a shift from a world structured by “the closet,” as suggested by Eve Sedgwick in *Epistemology of the Closet* (1990) – one of the founding texts of “queer theory” (see below) – to a world now moving *Beyond the Closet* – the title of a study published in 2004 by US sociologist Steven Seidman. Transgender people have also experienced a significant shift toward public visibility and toleration, accompanied in some states by crucial legal reforms granting recognition of a change of gender, such as the 2004 Gender Recognition Act in the United Kingdom, though the state continues to institutionalize problematic forms of medicalization (e.g., the Act makes provision for “gender recognition” to be granted to individuals only where they are determined by a “Gender Recognition Panel” to have experienced “gender dysphoria” according to a report from a registered medical practitioner or psychologist; and also to be “living in the other gender” with the intention to continue doing so until death. In certain respects, such laws thus legally entrench, rather than destabilize, biomedical and binary conceptions of sex and gender).

Overall there have been significant changes, but contemporary developments do not suggest the future direction of social and political change will necessarily continue to be defined by the advance of these movements. Contemporary sexual politics in western states is marked, for example, by the emergence of men’s movements campaigning on issues such as fathers’ rights, which have a relationship to feminism that is frequently hostile. The contemporary cultural politics of sexuality has shifted profoundly, particularly in youth culture.

The issue of children’s relationship to sexuality has come increasingly to the fore. Pedophile organizations and movements were able to emerge in the 1970s liberal climate in many western states to argue for the legitimacy of consensual relationships between adults and children. But with child sexual abuse emerging as a major public issue since the 1980s, such organizations and movements have increasingly gone underground. Libertarian critics such as Judith Levine in *Harmful to Minors* (2002) now warn of “the perils of protecting children from sex,” emphasizing instead the need for sex education and openness. In this context, “age of consent” laws regulating young people’s sexual behavior are increasingly subject to international comparison and contestation (Waites 2005).

The early 1990s witnessed the emergence of “queer politics,” and relatedly “queer theory,” in western states. “Queer” is a profoundly contested label: for some, queer has simply served as a rhetorically assertive synonym for “gay” or “gay, lesbian, and bisexual,” but for others “queer” is fundamentally associated with a project of destabilizing the prevailing heterosexual/homosexual dichotomy. Queer theory is characterized by the influence of the French poststructuralist Michel Foucault, and associated above all with a challenge to “heteronormativity.” Such a politics is critical of what is perceived as the liberal assimilationist politics of prominent lesbian and gay organizations discerned in demands for “lesbian and gay marriage” and “gays in the military” (see Warner 1999).

Meanwhile, in the “developing” world sexual politics is equally dynamic and fraught with conflict. In India, for example, where conceptions of national identity are structured by gendered signifiers such as “Mother India,” Chetan Bhatt has discussed how women nevertheless obtain forms of political agency within Hindu nationalist movements. In Zimbabwe, as Oliver Phillips has documented, homosexuality has become politicized and labeled as an un-African “white man’s disease” by President Robert Mugabe in the context of postcolonial struggles over national identity; and research by Jacqui Alexander has discerned similar postcolonial dynamics in the Caribbean (for extracts from all these, see Weeks et al. 2003).

Probably more than any other factor, HIV/AIDS has played a huge role in transforming global sexual politics, forcing governments to address the most intimate areas of people's lives, and challenging deeply embedded cultural and religious traditions. Responses to HIV/AIDS have been analyzed in the context of globalization, with attention to the political economy of the crisis (Altman 2001). Research such as that of Ros Petchesky and the International Reproductive Rights Research Action Group demonstrates that the battles of sexual politics remain to be fought in much of the world, particularly Africa, but also criticizes the imposition of prescribed western agendas and solutions (Petchesky & Judd 1998).

sexual practices

Stephen K. Sanderson

Sexual practices have varied widely across time and space. In the broadest terms, societies are either *sex positive* or *sex negative*, with the majority the former (Bullough 1976). The Trobriand Islanders of Melanesia were described by Malinowski as unusually sexually permissive. Sex life may begin for young boys as early as age 10 and for young girls as early as age 6. Polynesian societies were also renowned for their high levels of sexual permissiveness. For example, among the ancient Hawaiians, "a little girl's clitoris was stretched and lengthened through oral stimulation. The penis received similar treatment so as to enhance its beauty and prepare it for sexual enjoyment later in life" (de Waal 2005: 107).

Homosexual relationships have also been common in a number of preliterate (and in modern) societies. In some North American Indian societies, a man known as a *berdache* dressed as a woman, performed women's roles, and engaged in sexual relations with other men, all with social approval. Other societies (e.g., India, Polynesia, Oman) have had the local equivalent of a *berdache*. Among the Azande of the Sudan, man-boy homosexual relations were common, and institutionalized homosexuality has been widespread throughout Melanesia. For example, among the Etoro of New Guinea, men and young boys sleep together in men's houses, and man-boy homosexual relations are common.

In agrarian civilizations, outside of western civilization, with its sex negative Judeo-Christian tradition, sexual permissiveness has usually far exceeded restrictiveness. The Greeks were a fairly permissive culture, and are famed for their institutionalized form of homosexuality between older men and young boys. India was perhaps the most sex positive of all the historical agrarian civilizations. Hindus thought that women enjoyed sex at least as much as men, and a wide range of sexual practices was considered acceptable. The Chinese were also quite open about sex and had a form of man-boy homosexuality that resembled the Greek pattern (Bullough 1976), and the same was true in Japan (Leupp 1995).

Freud and the Freudians dominated the study of human sexuality for many years. For Freud, sex was an overpowering biological drive that was repressed by society in varying ways and degrees. The Freudian tradition was kept alive in altered form by such thinkers as Reich and Marcuse. Kinsey emerged onto the scene in the late 1940s, and Masters and Johnson in the 1960s. Their work had little theory and has been referred to as a kind of "radical empiricism" (Brake 1982).

The currently dominant approach to explaining sexual practices seems to be *social constructionism*, which downplays the biological nature of humans and emphasizes that sexual practices are socially and culturally created. Among the earliest sociologists to take this approach, specifically in the form of symbolic interactionism, were John Gagnon and William Simon, as well as Ken Plummer. Social constructionists oppose "essentialism," or the notion that sexuality is largely a matter of biologically pre-given drives. For the constructionists, sexual practices are less biologically given than determined by society through complex webs of social interaction and social definition. Gagnon and Simon emphasized the importance of "sexual scripts"; for them, sexual conduct "is acquired and assembled in human interaction, judged and performed in specific cultural and historical worlds" (Gagnon 1977: 2). And, as Plummer tells us, "Sexuality has no meaning other than that given to it in social situations. Thus the forms and the contents of sexual meanings are another cultural variable, and why certain

meanings are learnt and not others is problematic" (1982: 233).

Outside the symbolic interactionist tradition, social constructionist views of sexuality start with Foucault (1978). Foucault not only challenged biological essentialism, but also linked sex with power. Foucault was particularly interested in the development of a new science of sexuality in the nineteenth century, which he saw as part of the rise of a "disciplinary society" in which the state was increasingly trying to bring its citizens under control. Knowledge of sexuality was central to this control (Seidman 2003). Social constructionists in the Foucauldian tradition include Jeffrey Weeks and Steven Seidman. In Seidman's words, "We are born with bodies, but it is society that determines which parts of the body and which pleasures and acts are sexual. Also, the classification of sex acts into good and bad or acceptable and illicit is today understood as a product of social power: the dominant sexual norms express the beliefs of the dominant social groups" (2003: 39).

The leading alternative to social constructionism today is the *Darwinian* approach of sociobiologists and evolutionary psychologists. Donald Symons (1979), for example, has sought to show how Darwinian sexual selection has acted on human sexual desires by looking in particular at universal or extremely widespread sexual attitudes and practices. He points to such things as the overwhelming tendency of males everywhere to be aroused by visual sexual stimuli; to the apparently universal desire of men to mate with younger females; to copulation as primarily a service provided by females to males; and to the universal desire of males for a wide variety of sexual partners. Such preferences, when acted upon, help males to achieve higher levels of reproductive success than would be possible by a preference for older, less fecund females, or by being indifferent to the sight of naked females. Research in the Darwinian evolutionary tradition has also emphasized the widespread existence of sexual jealousy in both males and females. For males, sexual jealousy is seen as a way to avoid having one's mate inseminated by another man, whereas for females it is a way of holding onto mates who otherwise might abandon them for other females (Buss

2000). The Darwinian approach has made little headway in sociology, but it has been highly influential in psychology and anthropology (cf. Sanderson 2001: 177–94).

Two other recent approaches to human sexuality are Collins's (2004) interaction ritual theory and Posner's (1992) rational choice theory. Collins argues that sexual practices can best be understood as Goffmanian interaction rituals. If humans are hard wired for anything it is "for the kinds of pleasure in emotional entrainment and rhythmic synchronization that make humans pursuers of interaction rituals" (2004: 227). Posner's rational choice theory is based on the notion that "the balance of private costs and private benefits determines the relative frequency of different sexual practices" (1992: 116). For example, in societies in which there is a high ratio of men to available women, opportunistic homosexuality and prostitution will be more frequent than in societies with an approximately equal ratio of men to available women.

The study of sexual practices has become an especially vigorous subfield of sociology, but is also of great interest to psychologists, anthropologists, and even historians. Despite major theoretical disputes, there has been a great deal of progress in this subfield and continued progress is likely to be both substantial and rapid.

sexual violence and rape

Liz Kelly

Rape attracted limited attention across the social sciences and humanities until it emerged as a key issue for feminists in the early 1970s. Most scholarship on the subject dates from this time, with the highest concentration appearing during the 1970s and 1980s. The first sociological study – Menachim Amir's *Patterns in Forcible Rape* (1971) – addressed the victimology of rape. But it, along with most previous work, was subjected to intense feminist critique, including in Susan Brownmiller's prescient *Against Our Will* (1975), which, in "giving rape its history," explored rape two decades before it became widely recognized. Rape was relatively invisible in feminist, policy, and research agendas during the 1990s outside the context of war/conflict. As we enter the twenty first century, shoots of renewed interest are evident with a series of books and major research reports addressing theory (Cahill 2001), reporting and belief (Jordan 2004), rape in diverse contexts (Barstow 2002), and prevalence and attrition (Kelly et al. 2005).

CONTESTED CONCEPTS

Defining sexual violence and rape continues to vex social scientists, legal scholars, and practitioners, as debates about the boundary between consent and non consent remain unresolved. The undisputed criminal status of rape lends the definitional issue a strong legal component, made more complex by the presence internationally of at least three competing conceptual frames: rape as forcible intercourse; rape as intercourse without consent; rape as intercourse in coercive circumstances. Albeit somewhat minor differences, they have significant implications for “what counts” in prevalence research and the evidential requirements to prove a case in court: in both instances, the requirement of force constitutes the narrowest definition. Alongside these foundational matters have been additional questions, including: whether all forms of penetration should be included; whether men can be raped; and whether rape is possible in marriage. Reformed legal definitions have tended to expand to encompass men and other forms of penetration, with the most contested issue remaining marital rape. Whether and how far legal definitions are echoed in research, not to mention shared by those experiencing unwanted sex, are recurring themes in empirical studies and commentaries. A key challenge from research has been to expand the concept of “real rape” (Estrich 1987), and feminist theorists (see, e.g., MacKinnon 1989) have problematized the consent/non consent binary, suggesting continuities or, in one formulation, a continuum (Kelly 1987) of non consent, only part of which is criminalized.

The issue of language has also proved thorny, with some seeking to reframe the issue as a crime of violence, replacing the word rape with “sexual assault,” narrower and wider meanings of the word rape, and some using “sexual violence” to frame all forms of violence against women (Kelly 1987), while others limit its reach to explicitly sexualized assaults. How to refer to those who have been raped is also contested, with the term “victim” widely criticized yet remaining a legal status where crimes are reported, and “survivor,” whilst preferred, taking on an increasingly therapeutic meaning.

FROM UNUSUAL TO EVERYDAY MATTERS

The wellspring for the creation of a knowledge base on rape was (re)discovery within feminist praxis of how often women and girls had had sex against their will. The critically important concepts of “silencing” and “naming” emerged from the practices of consciousness raising and public “speakouts,” practices which have strong correlates in the emphasis in feminist epistemology on qualitative approaches, on enabling and recording personal accounts in sociology and criminology, and on “reclaiming” testimonies (and activism) from the past through historical research (see, e.g., Kumar 1993; Sommerville 2004).

Viewed in retrospect, many early feminist texts reproduced the “deviant” construction of rapists. However, as feminist discourse became more nuanced, connections between rape and the construction of heterosexuality, masculinity, and femininity were increasingly explored (MacKinnon 1989; Lees 1993), and the limited progress made in terms of young women’s belief in their right and ability to say no to unwanted sex documented (Holland et al. 1997). This issue has taken on even more profound implications as new research from Africa, and especially South Africa, demonstrates how difficult it is for women to negotiate safe sex in cultural contexts where force and coercion are commonplace and HIV infection an ever present risk (Jewkes & Abrahams 2000). Brutalization through conflict has been increasingly addressed as a context in which levels of sexual violence increase, even at times encouraged by combatants (Barstow 2002). These studies highlight the continuing barriers to achieving the feminist goals of sexual freedom/agency for many women. However, rape research and more optimistic postmodern feminism do connect through the theoretical and material importance given to concepts and practices of sexual autonomy and its most recent variant, sexual sovereignty. Increasingly, legal reform attempts to build sexual offense statutes around these foundations for adults (see, e.g., recent legislation in South Africa and England and Wales). Law professor Stephen Schulhofer (1998: 9, 132) points out that a premise of the

right to sexual autonomy problematizes behaviors currently outside the reach of criminal law.

[The law] still refuses to outlaw coercion and abuses of trust which prevent a woman from deciding freely whether to choose or refuse a sexual relationship. And when she does refuse, the law still fails to ensure that her clearly expressed preferences will be honoured and enforced. . . . Conduct that forces a person to choose between her sexual autonomy and any of her other legally protected entitlements rights to property, to privacy, and to reputation is by definition improper; it deserves to be treated as a serious criminal offence.

A more specific theoretical and practical literature has emerged within sociolegal studies, and especially feminist jurisprudence, exploring the content, success, and, all too often, failures of legal reform (Rowland 2004). The courtroom has proved a rich resource for exploring the social construction of rape, heterosexuality, and gender (Matoesian 1993; Ehrlich 2001), and rape law, with its unique evidential requirements, is a paradigmatic example of the "hidden gender of law" (Graycar & Morgan 2002). Within these detailed explorations are unresolved debates as to whether emphasizing the sexual element in the name and construction of rape is a form of essentialism, whether it is a unique form of crime/assault, and most recently through notions of embodiment, whether law can ever recognize and address the sexualized elements and harms involved (Cahill 2001).

PREVALENCE, CONTEXTS, AND RESPONSES

Empirical research on rape began documenting its nature, contexts, and consequences, moving on to assess incidence and responses, especially by the criminal justice system. More recently, evaluative research has focused on rape crisis groups, Sexual Assault Referral Centers, and innovations such as forensic nursing. The knowledge base overall, and with respect to prevalence, is considerably weaker than that on domestic violence or sexual abuse in childhood (Hagerman White 2001). Women's heightened fear of crime is in large part connected to fear of sexual attack in the public sphere; this

"phenomenology of fear" (Cahill 2001) was documented in the 1980s in many studies on women's safety.

Most women experience the fear of rape as a nagging, gnawing sense that something awful could happen, and angst that keeps them from doing things they want and need to do, or from doing them at the time or in the way they might otherwise do. Women's fear of rape is a sense that they must always be on guard, vigilant and alert, a feeling that causes a woman to tighten with anxiety if someone is walking too closely behind her, especially at night. (Gordon & Riger 1989: 2)

Similar constraints only pertain for men and boys if they are located in contexts where sexual assault is rife, such as prison or living on the street.

Methodological innovation has been primarily through the development of surveys of violence against women, and the recognition that not using the term "rape" and providing more than one route into more detailed questions on assaults increased disclosure. US college students have high reporting rates for victimization and perpetration (Schwartz 1997). The Canadian Violence Against Women Survey (Johnson & Sacco 1995) heralded what has been termed the "third generation" of prevalence research (Walby & Myhill 2001), although many who have drawn on it subsequently have entirely excluded or limited the questions on sexual assault, prioritizing the more popular/acknowledged issue of domestic violence. Using telephone interviews, a national random sample of 12,300 women took part. The key findings with respect to sexual assault were: over a third had been sexually assaulted; for almost 60 percent this involved more than one assault; four in five (81 percent) were committed by known men; only 6 percent (1 in 19) were reported to the police (in comparison, a quarter of those who had experienced domestic violence reported at least one incident). These data raise critical issues about the perception of rape as a single, discrete event. The only recent prevalence study to include male and female respondents took place in the US and reported prevalence rates for rape of 17.6 percent for women and 3 percent for men (Tjaden & Thoennes 1998).

The extent of unwanted sex that prevalence research revealed, especially within samples of US college students, led to several widely reported challenges, disputing the methods and analysis and referring to the findings as “advocacy numbers” (Gilbert 1991). An unfortunate legacy has been the inaccurate, but preferred, media concept of “date rape.” Interestingly, surveys on male rape, using the same methodological tools, are seldom berated for “biased” findings and are more likely to meet comments as to the extent of underreporting.

The conventional orthodoxy about differential rates – both over time and across societies – of reported and recorded rapes has been that they reflect levels of (dis)trust in agencies and the state, rather than differences in levels of rape across societies. Some emerging data suggest more complex processes may be at play: for example, the very different societies of Australia, South Africa, and Sweden having high reporting rates per head of population. The Swedish data are especially intriguing since Sweden invariably heads global indexes on gender equality, suggesting that sexual (and domestic) violence does not decrease automatically as women’s employment and political representation increase. Two recent studies (see Regan & Kelly 2003) revealed variable reporting patterns over time across Europe. The latter revealed at least three patterns: year on year increases for two decades across the UK and Scandinavia; flatter levels across the German speaking countries; and sharp declines for many Central and Eastern European countries during the 1990s. Whilst some observations can be confidently made – such as the obvious impact of decreased capacity of, and trust in, state infrastructures in Central and Eastern Europe in the 1990s – more complex methodologies and theorization are needed to explain the variations in Western Europe.

Few contemporary studies explore questions central in early studies – the experiential realities of rape and/or its short and long term consequences (Kelly 1987) – and interest in the possibility of avoiding rape (Bart & O’Brien 1985) has also waned. In their place is a more therapeutic, “self help” literature drawing heavily on psychological work on trauma and the practices initially developed in women’s groups. Of particular interest, and in contrast

to the above, is philosophy professor Susan Brison’s (2002) reflection on her own experience of rape and how it changed not just her own sense of self, but her philosophical understanding of the self. In a rewarding combination of testimony and intellectual engagement, she echoes Judith Herman in noting the critical importance of the simultaneous disconnections from one’s body, place in world, and relationships to others. For her, reconnecting to others and the embodied practice of women’s self defense (Seith & Kelly 2003) were critical in her remaking of her self.

TAKING STOCK, MOVING ON

From a marginal issue, the topic of rape has had an uneven intellectual trajectory over the last three decades. A number of substantive studies have established that it is much more common than previously thought, happens primarily in the context of routine interactions, and is more mundane than the media preoccupations and representations imply. In the research literature there are now detailed studies of rape in varying contexts, such as marriage, confinement in prison, mental hospital, or other residential setting, and coercive/deceptive sexual encounters with a range of professionals/authority figures, including therapists and religious leaders (Schwartz 1997). There are also emerging discussions of the ways in which culture and context can affect the meaning and consequences of sexual violence, such as in the context of codes of honor.

The stereotype of “real rape” (Estel 1998) continues to undermine the intent underpinning legal reform. More recent attention to the attrition process reveals rates of prosecution and conviction are falling (Kelly et al. 2005). Thus, as the profile of reported rapes comes to more accurately reflect the realities established in social research, fewer and fewer cases result in a conviction. For example, in England and Wales in the mid 1970s, one in three reported rapes resulted in a conviction; in 2003, the conviction rate dropped to an all time low of 1 in 19 (Kelly et al. 2005).

Whilst statute and theory may have moved on, attitudes and practices with respect to female and male sexuality retain many of the

elements that prompted initial feminist critique. The dominant heterosexual culture continues to be one in which young women's ambivalence and uncertainty are viewed by young men as a challenge to be overcome, and women's sexual autonomy – not to mention sexual pleasure – is secondary. Thus the conditions in which coercive sex is commonplace are reproduced (Holland et al. 1997). Whilst young women undoubtedly aspire to be sexual subjects, and like their forefathers do resist sexual coercion, the context in which they act continues to be defined through powerful and essentialist notions of men's needs and desires. Whilst young women have greater space for action, some of these freedoms – such as being alone in public spaces, drinking alcohol – can be used to question their credibility should they be assaulted.

New challenges are evident in the emergence of attrition data, especially concerns about the failure of the criminal justice system to deal effectively with rape between persons who know each other. In this context the application of restorative justice practices (in particular the dropping of a criminal charge where the acts and harms are admitted) – currently being experimented with in South Australia and Tucson, Arizona – raises complex questions. Support from service users for “proactive” follow up by agencies questions a number of orthodoxies in feminist practice that require more detailed research. In addition, how perpetrators/rapists are categorized and understood deserves revisiting, especially whether it is appropriate to refer to men who have met their victim only hours before the assault as “acquaintances.” Does someone buying you a drink constitute “consensual contact”? Perhaps the context in which rapists target has changed with contemporary gender and sexual mores. The street and public places may simply be less successful “hunting” grounds for predatory men than clubs and pubs: and the latter may also provide a foundation for the most effective defense should they ever be charged – consent.

sexualities, cities and

David Bell

As part of a broader investigation of the connections between sexuality and space, researchers in a number of disciplines have explored the relationship between particular sexual practices and identities and urban space – either at a generic level or in terms of particular cities around the world. There are a number of intersecting strands to this work. First, there is research that explores the cultural construction of the city – the city as it is imagined and portrayed in popular culture – and that investigates how this construction shapes possibilities and limitations

for sexual practices and identities. For example, in terms of western gay male practices and identities, Kath Weston (1995) shows how US metropolitan centers were (and still are) constructed as places more open to male homosexuality, stimulating “the great gay migration” in the post war United States. For other groups labeled as “deviant” the city may also be constructed positively, in terms either of its liberal atmosphere or of the possibility of anonymity. But this association can lead to the city itself being considered “deviant” or dangerous, and therefore as an unsafe place. This connection is forcefully articulated in relation to two issues: prostitution and (sexually transmitted) disease (STD). In nineteenth century England, for example, moral panics about prostitution centered on city streets as danger zones, and moral regulation served to limit women’s access to urban public space. In terms of disease, similar moral panics over STDs, most notably HIV/AIDS, have brought about policies to “clean up” parts of the city associated with certain sexual practices – perhaps most famously in New York City during Mayor Giuliani’s administration.

A second important area of work is concerned with ideas about spaces within the city. In the first half of the twentieth century, researchers in the Chicago School of Urban Sociology investigated the urban geography of non normative sexualities, mapping the varied “sex zones” used by different groups (Heap 2003). Later work also used the tools of urban ethnography to research the practices of “deviant” sexual cultures – most controversially in Laud Humphries’s *Tearoom Trade: Impersonal Sex in Public Places* (1975), which utilized covert techniques in a study of male same sex activity in public toilets. One issue both the Chicago researchers and Humphries discussed that has continued to be central to research on the city’s sexual spaces is the distinction between public space and private space. Private space – usually thought to exist in the home – is often constructed as the only appropriate space for sexual expression. In contrast, public space is subject to intense scrutiny and regulation, and anything other than the “safest” forms of heteronormative sexual expression may be subject to formal or informal policing. This powerful divide has led to public space being seen as a crucial battleground in

struggles over sexual politics. Some gay rights groups, for example, argue for the right to express their sexuality in public, staging protests to highlight discrimination. Moreover, the safety of the domestic home might not provide opportunities for sexual expression, if that expression is considered taboo within the moral economy of the family or household, so other spaces become centers of sexual practice and identity, including commercial spaces such as bars and clubs, and public spaces such as parks and streets. In the case of western gay male culture, for example, public spaces have historically played an important role, offering opportunities for men to meet away from the regulatory gaze of home and family – a role they continue to play today in western and non western cities.

Related to the issue of public and private space comes the broader question of the politics of space. Access to space in the city is regulated in all kinds of ways, making claims on space an important political tactic. For marginalized sexual minorities, the symbolic and material claiming of space has been a central component of rights struggles. From the temporary claiming of space in a protest march to the permanent establishment of residential or commercial spaces, there are many manifestations of this aspect of the relationship between cities and sexualities. Some critics argue that *all* space is fundamentally constructed and coded as hetero sexual, and that there are also normative “genderings” of space; these dominant codings and orderings of space limit possibilities for women and for sexual minorities. However, spaces of resistance to the dominant order can be carved out, and although some are highly ephemeral, others can become more permanently rooted in the city. In some large western cities, for example, particular neighborhoods have come to be associated with lesbian and gay communities – either as places where gay bars and clubs are concentrated, as in Manchester’s gay village, or where there is a marked residential concentration of lesbian and gay households, supported by gay owned or “gay friendly” services, as in the Castro district in San Francisco. Other sexual minorities are not equally able to make such claims on cityspace, and have been unable (or unwilling) to develop neighborhoods or villages of their own. Nevertheless, districts like the

Castro have historically been very important, in terms of making the lesbian and gay community visible, and also politically powerful (at least as regards local politics).

While claims on space in cities have been seen as important political markers, the spaces claimed are themselves seen by some people as contradictory. Marking out one neighborhood as “gay,” for example, implicitly marks all other neighborhoods as “straight.” Residential concentration also ghettoizes those who live there, and excludes those who do not. A visible gay neighborhood might be attractive not only to gay men and lesbians, but also to homophobic “queer bashers,” or may be subject to excessive policing and regulation. Nevertheless, gay neighborhoods or villages have developed in a large number of cities (although their scale and scope vary considerably); in some cities this development has been encouraged by policy makers, especially since the so called pink economy came to their attention. According to pink economy discourse, gay men (in particular) are affluent and like to spend their sizable disposable incomes on high status lifestyle commodities. Attracting these high spenders into the city therefore promises financial dividends. While the pink economy has been thoroughly debunked as an overhyped myth, there is still considerable commercial interest in some sexual minorities, gay men in particular – though this is considerably less than the commercial interest shown in heterosexuality.

The development of gay spaces in cities is only one of the many relationships between cities and sexualities. As Pat Califia famously wrote in *Public Sex: The Culture of Radical Sex* (1994), echoing the foundational work of the Chicago School, the city is a patchwork of “sex zones,” some legitimate and dominant, others constructed as deviant or marginal. Considerable work has focused on exploring these sex zones, revealing the complex sexual ecology of the city. Part of that complexity comes from acknowledging specificity – moving away from generic discussions of “The City” to explore how particular sexualities relate to particular cities and cityspaces. This kind of attention to specificity has been tremendously important in highlighting that very different sexual spaces and cultures exist in different cities (and parts of cities); each city has its own map of sex zones.

While studies of the sexual life of cities have to date been dominated by work on large metropolitan cities and by a focus on particular sexual identities and communities – mostly homosexual – important work is increasingly exploring smaller cities (not to mention the rural) and other types of sexual expression, identity, community, and politics. One area of neglect has been an explicit and sustained investigation of the relationships between heterosexuality and the city – while there has been lots of work on gender, there has been much less explicitly about sexuality in this regard.

An area of growing interest and importance, in terms of more specific and situated studies of the relationship between cities and sexualities, concerns cities outside the contemporary West. Different times and different places have produced very different interconnections between urban space and sexual cultures. Historical studies, such as those collected in Higgs's *Queer Sites: Gay Urban Histories Since 1600* (1999), have much to teach us about these interconnections in the past, revealing long forgotten urban sexual habits and habitats. Studies outside the West also reveal a multiplicity of distinct relationships between cities and sexualities, often in spite of the supposedly homogenizing forces of globalization. The study of globalization in relation to sexuality is also important for bringing issues of movement into focus: cities are spaces of flows, where people, goods, ideas, and images intersect as they circuit the globe. There is a growing interest in sexuality and movement, whether temporary or permanent, forced or elective. Rather than totalizing and fixing "The City" in space and time, therefore, work on cities and sexualities must necessarily be pluralistic, reflecting the full diversity of cities and sexualities.

sexualities and consumption

Yvette Taylor

Sexuality and consumption are interlinked in powerful and significant ways, perhaps even more so in contemporary, even "postmodern," times, shaping various material and subjective possibilities and impossibilities, as sexuality is displayed and regulated via consumption. Consumption refers to a wide variety of spending patterns and behaviors and is typically equated with "choice"; what we choose to buy, where and when, and how we choose to use purchasable commodities, ranging from mundane everyday goods and services to extravagant "one off" specials, which seemingly reinforce the uniqueness of our own individual consumer choice. Crane (2000) explores fashion and its various and shifting meanings, symbolically, culturally, and economically, across time and place, drawing on data from England, France, and the United States. Crane claims that class has become a less salient aspect of identity, with less effect upon clothing practices, consumption, and signification, which she describes as a shift from classed practices to those based around "life styles." The concept of "subcultural" affiliation is invoked as a way of capturing the proliferation of clothing styles and choices, which, it is claimed, mark the changes from industrial class based societies to "postmodern," "post industrial" societies. The manifestations of class and gender are seemingly replaced by an erasure of fixed hierarchies, a blurring of certainty which these categories once represented, and a diffusion of meaning across and between other axes of "difference," particularly that of sexuality.

Yet to consume also implies a potential restriction in terms of what is being offered and to whom. Other market activities, such as employment, leisure activities, and citizenship, are related to consumption insofar as these afford possibilities for participating in certain markets, create and foreground certain "choices," while restricting and regulating individuals within multiple social domains. Heterosexuality is privileged, even expected, within many consumer spheres, but lesbian, gay, and bisexual sexualities are also increasingly affecting, and indeed affected by, marketization, as the notion of a ready, waiting, and willing "pink pound" implies (Chasin 2000; Hennessy 2000).

Sexuality, as an innately private and individual concern, has been interrogated and problematized by many feminist researchers, who have revealed its profoundly social and public regulation. While there has been longstanding attention to compulsory heterosexuality, as socially structured and institutionalized, others point to the increasing complexity, even fluidity, of sexual practices, identities, and regimes. The dichotomy existing around materialist versus queer conceptualizations of sexuality is strongly expressed through polarized critiques of sexuality and consumption (Jackson 2001). Here sexualities become either cynically commodified and thus inseparable from interconnecting inequalities, such as gender and class, or exist as evidence of potentiality and (market) possibility, affording diverse sexualities much cultural visibility.

Whether thought of as a resource or as a constraint, an equalizing force or a divisive battleground, it is difficult to ignore the ever increasing spaces of sexual consumption, as manifest in the media (McRobbie 2004), in commercialized scene spaces, and even in the realm of citizenship. The interconnection between sexuality and consumption provides for a series of inclusions and exclusions, in the market and in the state itself, which has been a dominant theme in the literature on sexuality studies.

Chasin uncovers the linkage between the development of the "lesbian and gay movement" in the US and the growth of lesbian and gay "niche markets" that promise inclusion into the marketplace and the nation itself – but at a price. Within her account, social recognition is dependent on ability to consume as

identity becomes branded, commodified, and consumed. Lesbians and gays are integrated, even assimilated, as consumers rather than as citizens. Money then represents the prerequisite for participation as well as the boundary. Chasin's catchy (and cutting) title *Selling Out* conveys notions of failure and possible fraudulence, hinting at the ways in which sexual identities have been depoliticized, as they become only another consumer possibility. The skepticism aired resonates with many other critiques (Warner 1993; Hennessy 2000). Many theorists have examined consumption in relation to the construction and reconstruction of identity; Warner (1993) looks at the pivotal role of the market in the construction of queer sexualities and notes its exclusionary tendencies. Here the "institutions of culture building" are market mediated and include bars, discos, newspapers, magazines, phone lines, resorts, and urban commercial districts, which are only accessible to those with the requisite social, cultural, and economic capital (Bourdieu 1984; Skeggs 1999, 2001).

While popular discourses on the "pink pound" signal a new, consumer based potential inclusion, many researchers have highlighted entrenched and compounded inequalities within this. Seemingly celebratory discourses on lesbians' and gay men's spending power invoke what Binnie (2004) describes as the "myth of the pink economy," which compounds the idea of a "special," even privileged, group who can more than afford their rights: here rights are equated entirely with spending power, which is a highly gendered phenomenon. Lesbians have rarely been addressed as consumers, which may be set to change as they are identified as potentially profitable, whether that is in terms of "new" leisure pursuits, fostered by improving incomes, or in the commercialization of, for example, civil partnerships. Nearly half of the countries in the European Union offer some legal recognition to same sex couples, ranging from full civil marriage to domestic partnerships. An array of legal and commercial services has sprung up in response to this demand.

As sexuality becomes marketed and commodified as a "lifestyle option," many note that not all lifestyles are equally visible or validated. Similarly, the existence of commercialized scene spaces, thought of as refuges and "safe spaces"

for sexual minorities, is not unproblematic and various theorists have given attention to inequalities operating within such commercialized space. Skeggs (1999, 2001) has shown that inequalities operate within leisure space, controlling entitlements to that space and affecting the appropriate "performance" (Taylor 2007b). Appearance in particular becomes the mechanism for inclusion and exclusion; a resource through which claims for legitimacy and entitlement are made whereby sexuality, gender, and class affect embodied presentations and a sense of entitlement versus a sense of exclusion. Having the money can buy access – having the right clothes, right style, and taste can indicate that entitlement to be there – but displaying sexual identity, and receiving affirmation, may require unaffordable presentations. Hennessy (2000) has critiqued discourses of consumer choice and the necessity to display a "designer identity" given that it may only be accessible to those materially poised to occupy the position, those with the ability and opportunities to engage in lesbian or gay male "chic."

Scene spaces are increasingly becoming leisure spaces of consumption, where the claiming of a lesbian or gay identity is no longer necessary to "consume" such leisure space, but where the "intrusion" of a heterosexual presence into scene space is still far from unproblematic. Such intrusion, like the commercial scene space itself, appears to be highly gendered. Drawing upon longitudinal ethnographic research (1997) and research on violence, sexuality, and space in the UK, Skeggs (1999, 2001) highlights the contrast and tensions existing in scene spaces between a group of white working class heterosexual women, whose identity is based on "disidentification" (from being working class), and a group of lesbians who form their identity through visibility, recognition, and territorialization. Skeggs suggests that heterosexual working class women enter commercialized scene venues in order to be safe from the male gaze, while their straight presence, or "lesbian masquerades," have negative consequences for others, namely lesbians and gay men.

Queer theory has been associated with the pursuit of a queer lifestyle, an "aestheticization of daily life" constructed through a "post modern consumer ethic" (Hennessy 2000).

Fraser (1999) argues that queer theory's stance on visibility and recognition further marks a connection between identity and aesthetics, whereby queer becomes a brand name, an identity project assuming the form of aesthetic, consumer based lifestyles (Featherstone 1991). The queer body, in displaying and signifying, is, from a queer perspective, seen to bestow a political value (Butler 1993). But within this are important ramifications for escalating class inequality, given that appearance can be another signifier upon which to denigrate working class bodies and tastes, in which they (again) become "flawed consumers" who cannot pay and display in "proper," "tasteful" ways (Bourdieu 1984; Bauman 1998; Skeggs 1999, 2001). Aesthetics, and identity constructed via consumption of cultural goods, may mark the self as tasteful, authentic, and thus entitled (for example, to occupy queer space), or it may exclude and mark as wrong, unentitled, and inauthentic. When considering intersections between consumption and sexuality, materialist feminists would suggest that it has been difficult to fully utilize and appropriate the theoretical readings of queer. Although Judith Butler may usefully illuminate aspects of the operation of queer identity, this reading of performance and performativity may mean little to the everyday enactment of sexuality.

In contrast, Roseneil (2000) charts the cultural valorizing of the queer in popular culture, fashion, magazines, and television, which is taken as evidence of the "aspirational status of queer" rather than as the class exclusive "aestheticization of everyday life," which materialist thought would name as a perpetuation and extension of current inequalities (Fraser 1999). Culturally, there is a proliferation of films and literature where femininity is fetishized and naturalized as objects of female desire (McRobbie 2004), while women can now choose the commodities and costumes from which to perform femininity, as part of their repertoire of self identification. The burden faced is one of "having it all" whereby having it all, good career and good sex, becomes an imperative rather than a "choice." Pic 'n' mix relationships and "identity umbrellas" become necessities in building an experienced, endlessly adaptable, and refashioned self and multisexualism another sought after and purchasable

commodity. "Meterosexual" is becoming a new buzzword, apparently describing urban, fashion conscious men who are not afraid to express an interest in fashion or beauty, areas typically thought of as the preserve of women and gay men. Nonetheless, multiplicity or "meterosexuality" does not necessarily translate into equality, and again choices are not equally available or validated on the (sexual) market. As one form of (male) sexuality is celebrated, other forms of (female) sexuality are problematized as excessive and simply wrong.

Romanticized representations seeking to reaffirm traditional femininity exist alongside representations that problematize and pathologize women's sexual behavior, appearance in public, especially leisure, space, and their uptake of a "laddish" drinking culture as resolutely "unfeminine" (McRobbie 2000; Harris 2004). A classed polarization between new celebratory (white and middle class) femininities and sorrowful, pitiful, and excessive working class sexuality, embodied in the pathological representations of the "teen mum," is articulated in the literature. Celebrations and denigrations of "new" femininity are challenged and resisted by the realization that gender, class, and sexual inequalities remain embedded within economic and social structures, something which materialist feminist approaches have been adept at highlighting.

Many feminist writers have explored young women's consumption of lifestyle magazines. McRobbie (2000) argues that contemporary femininity and masculinity are being reappraised with representations of sexuality now breaching traditional gendered boundaries of acceptance, whereas Tyler (2004) claims such "resources" bring managerial imperatives, such as efficiency and effectiveness, which must be incorporated into self management of sexuality. Sexual pleasure may well be subject to rationalization, through a process of sexual "modernization," whereby issues of efficiency and outcome again come to the fore in the "sexual mode of production." Tyler (2004) maintains that the focus on and overinvestment in "good sex," weighted toward success, entitlement, and mobility, deflects attention away from gendered inequalities, such as women's continued familial dependence and exploitation in family and work realms, potentially separating out

interconnections between sexuality, gender, and the household, emphasized in feminist research.

The restructuring of flexible global capitalism offers new research directions. Binnie (2004) unravels the links between sexuality, the nation state, and globalization, critiquing previous studies for their heteronormative assumptions and attentions and instead choosing to "queer" globalization, providing a queer perspective on the subject. The prevalence of class inequalities contests the link between globalization and inevitable and progressive mobility, movement, and liberation. Not only are there enduring citizenship and immigration restrictions, perhaps felt less by the monogamous, high earning couple, but the process of transnational movement is itself a highly gendered phenomenon. Maybe, as Binnie (2004) claims, we are all "sex tourists," tourism being a sexualized process, but gay men's tourism is often particularly problematized and pathologized as overtly, and deviantly, sexual. Thus a crucial reminder against collapsing important material and subjective differences and inequalities is highlighted in theorizing sexualities and consumption.

sexualities and culture wars

Glenn Lucke

The term "culture wars" came to prominence in the early 1990s, referring to conflicts in US society over abortion, religion in schools, acceptance of homosexuals, pornography, the

judiciary, and the arts. Many of the flashpoints in the culture war derive from competing cultural assumptions about the body, particularly various aspects of sexuality. Activists in the culture war struggle to define what Americans believe a human to be and how human life is to be rightly ordered.

The origin of the term traces to German Chancellor Otto von Bismarck, who used *kulturkampf* in 1878 to launch a values campaign against Catholic and Jewish minorities in newly united Germany. Sociologist James Davison Hunter (1991, 1994) appropriated the concept as a tool for understanding the nature of contemporary cultural conflict in the US. In Hunter's work, culture wars concerns the activities of loosely clustered groups of elite knowledge workers who seek to impose their competing understandings of reality – both the way things are and the way things ought to be – on the rest of society.

Hunter's theory reflects the confluence of several strands of classical sociological theory, particularly the synthesis of Weber and Durkheim forged by Peter Berger (1967) regarding the sociology of knowledge and the sociology of religion. Humans construct reality in their social relations and productions, and this constructed reality becomes internalized "knowledge." Berger's key contribution was the concept of plausibility structures, social groups in which humans are embedded, that govern which ideas we find plausible or implausible. Thus, while humans experience reality as taken for granted, it is in fact socially constructed by the plausibility structures people inhabit.

Which social constructions will dominate society? Whose ideas and values will become plausible for the most people? These questions introduce the issue of power that is largely absent from Berger's synthesis. Thus, Hunter's culture wars theory also draws upon the insights of conflict sociology in the Marxist tradition to understand how power structures and relations affect the social construction of reality. In particular Hunter uses the work of Italian Marxist Antonio Gramsci, whose work in the sociology of knowledge contributed the idea of knowledge workers (elites) who have a disproportionate role in supplying the ruling ideas of a society. If in Marx's day the bourgeoisie were the ruling class

by dint of their ownership of the means of production, Gramsci realized that knowledge workers were increasingly the ruling class by dint of their credentials and their relationship to the production of knowledge.

Hunter applies this understanding of elites as knowledge workers in trying to make sense of conflict in the US in the late twentieth century. Hunter notes that the old cultural cleavages – Christian versus Jew, Protestant versus Roman Catholic – no longer hold sway. In the contests over abortion, gay sexuality, and religion in the public sphere, he detects a realignment that has taken place as Christian and Jewish, Protestant and Roman Catholic elites form new, competing alliances. These new alliances of elites cut across the previous historic cultural cleavages.

The sociological questions of what has changed and why led to Hunter's signal (and much disputed) insight: that underneath the public contests about different aspects of sexuality are deep structures of moral authority. On the surface the conflict appears to be political: conservative versus liberal. Hunter contends that below the surface the knowledge worker activists generally cluster toward two poles: the orthodox and the progressives. The worldview of the orthodox moral universe is based on commitment to an external transcendent Being and the worldview of the progressives entails a tendency to recast values and historic faiths in light of prevailing cultural assumptions. While multitudes of viable positions exist between the two poles, Hunter suggests that many elites involved in contests over culture generally share either the orthodox or the progressive moral orientation. Those associated with the orthodox impulse include conservative Protestants, conservative Roman Catholics, and Orthodox Jews. Those associated with the progressive impulse include liberal Protestants, liberal Roman Catholics, Reform Jews, and secularists.

Debates between orthodox and progressive elites over aspects of sexuality, particularly abortion, homosexuality, sex education in schools, and pornography, generate significant controversy. The orthodox broadly enunciate principles found in their understanding of a Supreme Being, sacred texts, and historical church/synagogue teaching. These traditionalist religious perspectives largely militate against gay marriage and abortion rights, seeing the progressive

efforts as assaults on the nature of the family and a moral society. The progressives contend that the freedoms guaranteed by the US Constitution, not to mention enlightened thinking generally, mean extending full civil rights to gays and lesbians and maintaining a woman's right to choose in dealing with a pregnancy. Because these arguments are rooted in ultimate concerns, Hunter's account suggests that the competing elite knowledge workers do not appear to share much common ground. Given the stakes – defining how Americans will order society – the activists resort to inflamed rhetoric and power politics in a winner take all mentality.

Though Hunter's culture wars theory focused on elite knowledge workers and explicitly denied that most everyday Americans were involved in contests over culture, soon the media became fascinated with the notion that average citizens were combatants in the war. The perception that average Americans were caught up in the culture war was crystallized by a speech at the 1992 Republican National Convention by former presidential candidate Patrick Buchanan. He declared, "There is a religious war going on in our country for the soul of America. It is a cultural war, as critical to the kind of nation we will one day be as was the Cold War itself."

Increasingly, the media came to understand culture wars to refer to the opinions and/or values of everyday Americans. This impelled social scientists to investigate this notion as well as Hunter's claim that the cleavage was between two poles of moral authority. Three significant criticisms of the culture wars thesis emerged from various research initiatives: (1) public opinion really is not very polarized; (2) the orthodox/progressive dichotomy is too simplistic to account for the diversity of positions in contested culture; (3) the metaphor of "war" is overstated, sensationalistic, and thus inappropriate.

DiMaggio et al. (1996) use data from the National Election Survey and the General Social Survey (1972–94) to interrogate the notion that American public opinion is polarized. They find no increased polarization in American public opinion since the 1970s. Examination of between group and within group variance showed surprising convergence of opinion on most issues. The one exception to this was the

central battleground of abortion, where opinion was polarized along the lines of the culture war concept.

Another project (Smith et al. 1997) engaged 128 evangelicals in two hour in depth qualitative interviews. Smith's team found that most evangelicals are oblivious to a host of culture war terms, issues, and personalities. Those respondents who were aware either believe such contests are wrong headed or the respondents indicate that aspects of both orthodox and progressive positions/reasoning appeal to them.

Alan Wolfe's *One Nation After All* (1999) depends on 200 qualitative interviews and he finds that most middle class Americans not only are not culture wars combatants, but also they believe much in common with other middle class people. However, Wolfe agrees with the culture wars theory with respect to elite knowledge workers.

The culture wars thesis appeared to suffer cracks under the weight of these and other critiques. However, the 2000 presidential electoral map revived media discussion of culture wars. The election, so close that it came down to a few hundred votes in Florida, revealed a significant divide among the Red states (Bush supporters) and Blue states (Gore supporters). For the most part the Blue areas of electoral strength were in the vast population centers on the West and East coasts, with other centers near the Great Lakes. Bush's strongest support came from the South and Midwest, and predominantly suburbs, small towns, and rural areas. Election survey data revealed that the most robust variable for predicting voting behavior in Red and Blue states was frequency of church attendance: those who were most religious overwhelmingly voted Republican and those with the highest indicators for secularity voted overwhelmingly for Democrats.

However, social scientists began to point out that the presidential electoral results did not map onto cultural divides neatly or consistently. For example, politically liberal states like Massachusetts contain significant numbers of "orthodox" citizens, particularly Roman Catholics. Outside of a handful of states on either side, the rest of the states tilted Red or Blue by a small margin. Morris Fiorina et al. (2004) conducted an exhaustive review of the

culture wars literature, available polling data, and election returns to demonstrate that the US was emphatically not polarized. Fiorina's findings show that Americans are clearly divided, but *closely divided*. The largest cluster of citizenry lay near the middle, with a combination of orthodox and progressivist views. Fiorina contends that if a culture war means a polarized or polarizing public, then the culture wars thesis is false.

Culture war proponents point to 2004 as exemplary of the cultural conflict between orthodox and progressive activists. Not only were moral values the top issue cited by voters in the 2004 presidential election, but also issues of sexuality dominated the news. First, the Massachusetts Supreme Court and later the City of San Francisco legalized gay marriage for the first time, and hundreds of couples took advantage of their new right. Traditionalists swung into action, proposing a marriage amendment to the Constitution that would permanently ensure that marriage was between a man and a woman. Eleven states had similar amendments to their state constitutions on the ballot and the pro traditional marriage side prevailed in all 11. Further, the Congress passed and the president signed a law that banned "partial birth abortion."

How does one make sense of the non polarized opinion findings, yet still make sense of the remarkable cultural and political ferment in 2004 over sexuality battles? Most sociologists concur with Hunter's original statement that average citizens are not involved in these fights. A powerful minority of credentialed elites, many (but not all) of whom fit the generalizations about orthodox and progressive moral authority, are the key actors. Furthermore, where there is disagreement on most cultural issues, the divide is not large, except on sexuality issues like abortion and homosexuality. Some commentators see the common ground in popular opinion, coupled with the basic acceptance of abortion and increasing acceptance of homosexuality, as evidence that the progressives won the culture war a long time ago. In this view the skirmishes in which the orthodox prevail are last gasps of the once vibrant traditional culture.

The methodology used to examine the culture wars thesis has unfortunately mostly

focused on popular opinion, when the thesis explicitly specified that elite knowledge workers were the combatants. Furthermore, most of the popular opinion research employs data sets collected for other projects. While sophisticated techniques (DiMaggio et al. 1996) can improve the utility of the existing data sets, the best way forward would be a research design that operationalized the culture wars thesis directly. Smith et al. (1997) did test moral questions directly, but their qualitative interviews with ordinary evangelicals did not test credentialed elites. A survey of knowledge workers in culture producing institutions, coupled with in depth qualitative interviews of the same, would allow sociologists to explore the moral universe of these elites and ways in which moral authority impacts their work on cultural issues.

sexuality

Ann Cronin

A variety of different approaches to understanding sexuality have emerged over the last 150 years. One way of categorizing these approaches is to distinguish between essentialist and social constructionist models of sexuality. Essentialism prioritizes a biological explanation for sexuality and hence limits its definition of sexuality to the individual expression of human desire and pleasure. In contrast, social constructionism prioritizes the relationship between the individual and society to show that the meaning attached to sexuality is embedded in specific historical, political, and social practices. Attention is paid to the culturally and socially diverse ways in which sexual desires, practices, identities, and attitudes are conceptualized, categorized, deployed, and ultimately regulated through the social institutions and practices of different societies. Although sociology's historical silence on sexuality served to reinforce an essentialist and normative understanding of sexuality, contemporary sociologists of sexuality, while acknowledging the importance of biology, produce socially situated accounts of sexuality. Furthermore, sociology offers a critical analysis of essentialism. A diverse range of approaches are used to account for the social organization of sexuality, including the sociology of homosexuality, feminist understandings of sexuality, queer theory, and an examination of the relationship between masculinity and sexuality. While each approach highlights different aspects of the debate on sexuality, there are many similarities and connections between the different perspectives. Furthermore, attention is paid to the interaction of sexual identity with other salient social identities, such as gender, race and ethnicity, class, age, and nationality.

HISTORY OF SEXUALITY

The social construction of sexual identity based on a dichotomy of heterosexuality and homosexuality can be traced to processes that began in the nineteenth century. Foucault's (1979)

historical account of the social construction of sexuality in modern western societies challenges essentialist conceptualizations of sex and sexual identity as transhistorical and stable categories. Foucault argues that since the eighteenth century the discursive invention of sexuality as a biological instinct has resulted in individuals and populations becoming subject to a new form of power: biopower, which assumes that sexuality is the key to understanding an individual's health, pathology, and identity. Initially directed at population control through the development of statistics and demography, the development of sexology – the science of sexuality – in the nineteenth century led to a separation of the “medicine of sex” from the “medicine of the body,” which resulted in the construction and administration of scientifically based therapies. Within these therapeutic discourses, sex denoted the sexual act, while sexuality symbolized the true essence – the core identity – of the individual. Furthermore, distortion or perversion of the natural sexual instinct would lead to sexual abnormality and deviance. The task of sexology became one of developing schemes and categories of anomalies and perversions that were, in turn, applied to people's identities. Thus, for the first time, sexual behavior was discursively constructed to represent the true nature and identity of an individual. Same sex sexual behavior was indicative of a homosexual identity; opposite sex sexual behavior was indicative of a heterosexual identity. For Foucault, this resulted in the connection of the body, the new human sciences, and the demands for regulation and surveillance, so that power and pleasure (knowledge and sex) meshed with each other. Within this, homosexuality was regarded as a perversion, thus legitimating its regulation and surveillance, whether overtly as in the case of legal sanctions against male homosexuality, or covertly as in the invisibility of lesbianism and the promotion of marriage and motherhood.

While the sexologists favored a biological explanation for sexuality, it was Freud's psychoanalytic theory of sexual development that led to the psychological construction of different sexual identities in the first half of the twentieth century. Freud proposed a sequential systematic model, in which an individual progresses from an initial bisexuality, or polymorphous sexuality, in early childhood through to the development of

mature sexuality, which is viewed as the achievement of a stable heterosexual identity. Within this, homosexuality is viewed as a temporary stage of development (usually occurring during adolescence) on the path toward heterosexuality. This implies that those who identify as homosexual in adulthood have “fixated” on an early and hence immature phase of sexual development; alternatively, they have, due to psychological disturbance, “regressed” to this early phase of sexual development. Either way, homosexuality is located within a discourse of deviance, psychopathology, and illness.

SOCIOLOGY OF HOMOSEXUALITY

In 1948 Alfred Kinsey and his colleagues published *Sexual Behavior in the Human Male* and in 1953 *Sexual Behavior in the Human Female*. Kinsey's large scale study of human sexual behavior highlighted the discrepancy between the number of people who engage in same sex behavior and the number who identify as homosexual. Kinsey developed a six point continuum designed to encompass a variety of sexual behavior and feelings, ranging from exclusively heterosexual (1) to exclusively homosexual (6). In between are a range of feelings and behaviors that cannot be categorized as either exclusively heterosexual or homosexual, with bisexuality, a desire for both sexes, somewhere in the middle. Kinsey argued that individuals move between categories throughout their life, thus rendering invalid the use of discrete sexual identities. For Kinsey, the development of an exclusive homosexual identity was the outcome of society's rejection of the homosexual.

The birth of the Gay Liberation and Black Liberation movements, alongside the reemergence of the Women's Movement, in the 1960s signaled both a new form of political action and protest and provided the political stimulus for the academic research of oppressed groups in society (Plummer 1981). The Kinsey Reports and the development of the labeling perspective provided the theoretical catalyst for a sociology of sexuality, although initially it was focused mainly on sexual deviance, with a particular interest in prostitution and homosexuality.

Although Kinsey was a zoologist, his work resonates with sociologists using labeling theory

and symbolic interactionism to challenge essentialist normative explanations of homosexuality. Starting from the premise that all sexual behavior is socially constructed, sociologists suggest that people who engage in same sex behavior are labeled deviant due to the reactions of a hostile society; thus there is nothing intrinsically deviant about a homosexual identity.

McIntosh (1968) stated that the very concept of homosexuality as an individual condition should come under sociological scrutiny because labeling an individual "homosexual" acts as a form of social control. Firstly, it acts as a deterrent for possible newcomers and secondly, it acts as a device to segregate and reinforce difference in those identified as deviant, thus leading to the formation of a homosexual subculture, with its own rules, norms, and values. While not without its critics, McIntosh's work is generally regarded as a landmark in sociology for its introduction of the "homosexual category," which served as a basis for further work.

Gagnon and Simon (1973), broadening the debate to a general discussion on sexuality, used the concept of sexual scripts to explore how people internalize the sexual norms and values of society. The sociology of homosexuality, while remaining on the margins of the discipline, has made a major contribution to the understanding of the social organization of homosexual identity, culture, and community.

GENDER AND SEXUALITY

While feminism represents a diverse body of theory, radical feminist theorists have concentrated on the relationship between sex, gender, and sexuality to argue that women's sexuality and their reproductive capabilities are controlled and regulated by men through a system of patriarchy. Sex refers to the biological differences between women and men, while gender refers to the social construction of male and female roles. Although the two are interlinked, sex was regarded by early radical feminists as a biological given and hence unalterable. However, gender, the social meaning of femaleness and maleness, ensures the continuation of a patriarchal sex/gender system, which is reliant on male supremacy. Fundamental to this is the construction of a naturalized, passive,

female heterosexuality in opposition to an active male heterosexuality. Radical feminism deconstructs this "natural" relationship and through the slogan the "personal is political" highlights the relationship between women's personal lives and the patriarchal society they inhabit.

Both lesbianism and heterosexuality are theorized as political institutions aimed at regulating women's sexuality and contributing to their subordination. While for some feminists this ensures the continuation of unequal gender relations, others argue that sexuality actually constitutes gender; thus it should be viewed as a singular concept where the subordination of women is eroticized in sexuality. However, this neglects other forms of male power that are not expressed through sexuality.

Faderman (1985) examines the relationship between the nineteenth century sexological constructions of lesbianism as pathological with the demands of an emergent Women's Movement; while Rich (1980) argues that the compulsory nature of heterosexuality ensures that men retain their physical, economic, and emotional control over women. For feminists like Rich and Faderman, the institution of heterosexuality is dependent upon ensuring that the experiences of lesbians either remain invisible or are associated with disease and illness, thus limiting women's identification with this category. Feminists argue that the development of scientific theory and practice was used to maintain existing gender relations and deny women access to the public world. Rich proposes a new definition of lesbian existence: a lesbian continuum encompassing a wide range of women identified experience, which moves beyond the clinical definition to deepen and broaden lesbian experience. Through deconstructing divisive labels of sexuality, women can unite to fight for women's liberation, regardless of the sex of the person they choose to have sexual relationships with.

The radical feminist understanding of sexuality sparked fierce debate among feminists, leading to the "sex wars" between "pro sex" feminists who regarded radical feminists as being both essentialist in thinking and anti sex. Lesbians argued that radical feminist theory desexualized lesbian relationships or impeded the formation of lesbian identity and community building; other feminists questioned the distinction between sex and gender. Some argue that

heterosexuality is a “political regime” based on an artificial biologically based distinction between women and men, and is oppressive to both women and homosexuals. This analysis undermines the traditional understanding of the category of sex as being biologically defined and hence immutable and enables the examination of how sex difference contributes to the existing social order. Essentialist categories of woman, man, heterosexual, and homosexual are reconfigured as political categories to become critical sites of gender deconstruction.

While radical feminism urges all women to become lesbians in order to fight male domination, recent feminist work has argued that being heterosexual does not automatically mean women are being complicit in their own oppression. Some distinguish between the institution of heterosexuality and heterosexuality as individual practice and identity, in which women are able to operate agency and control. This distinction between the levels of structure and agency enables women to identify as heterosexual yet resist the institution of heterosexuality.

Partly as a result of both feminist and gay writing, some male sociologists have begun to examine the social construction of masculinity and its links to the social organization of sexuality. While diverse in its exploration of masculinity, a key focus has been the examination of the relationship between power and masculinity, which has been theorized under the concept of “hegemonic masculinity” and the related concepts of “subordinated” and “complicit” masculinities. Heterosexuality is regarded as being central to hegemonic masculinity, while homosexuality is regarded as being a subordinate masculinity.

QUEER THEORY

Queer theory emerged in the US in the 1980s, due firstly to the emergence of new political movements such as Queer Nation and ACT UP, which initially developed in response to the failure of the right wing American government to respond appropriately to the emerging AIDS epidemic; and secondly, the development of lesbian and gay studies programs in humanities departments. Epstein (1994) notes the following uses of the term: a linguistic

reclamation; a gesture signaling anti assimilationist politics; a politics of provocation in which liberal boundaries are contested; reference to a more fully “co sexual” politics between women and men; a way of moving beyond homosexuality/heterosexuality. That is, it is inclusive of all sexualities opposed to heteronormativity. Queer theory signals a social constructionist politics, which is characterized by a resistance to all sexual labels and categories; instead, it argues that there exists a fluidity of sexual expression.

Initially regarded with suspicion by sociology, partly due to its poststructuralist origins, sociologists have begun to examine the benefits of a mutually interactive relationship between queer theory and sociology (Seidman 1997). While sociology has concentrated on the construction of homosexual identities and communities, queer theory, through the work of Foucault and Derrida, has developed a radical agenda that concentrates on the dynamic relationship between the dualism homosexuality/heterosexuality. By focusing on the importance of this relationship it is possible to remove the sociological study of homosexuality from the “deviant ghetto” and permit a sociological examination of the heteronormative nature of all knowledge and social structures. Heteronormativity refers to the way in which the social organization of western societies is predicated on the belief that heterosexuality is biologically, psychologically, and sociologically superior to other forms of sexuality. Thus, heterosexuality does not simply refer to opposite sex relationships but represents an axis of power and dominant mode for conducting intimate relationships, which in turn is linked to ideas concerning gender appropriate sexual behavior. Heteronormativity as ideology and normative principle dominates both the legal system and the cultural system, thus legitimating differential treatment of those who stand outside of the heterosexual regime. The concept of heteronormativity increases our understanding of both the structural disadvantages of those who stand outside the heterosexual regime and the way in which institutionalized heterosexuality limits and constrains those who identify as heterosexual.

A theoretical concern with the borders that exist between sexual identities and communities has resulted in the deconstruction of all sexual identities, including politicized ones. For

example, while recognizing that the very construction of the homosexual enabled the struggle for civil rights, claiming the label homosexual simultaneously reinforces the centrality of heterosexuality. This makes it impossible to locate oneself “outside” of dominant discourses, for to define oneself as standing outside the sexual norm means first placing oneself within dominant definitions of sexuality. Thus, many queer theorists examine how claiming a homosexual identity contributes to reinforcing the hetero/homo split (Namaste 1994).

Queer theory does not attempt to move beyond this “double bind” in current conceptions of sexuality. Instead, it concentrates on the creation, regulation, and resistance of sexual borders to show that sexuality and power are present in all aspects of social life and structures. Queer theory and practice signal important theoretical shifts, resulting in a critical distancing from the terms lesbian and gay; the term queer has become a catalyst for people disaffected by earlier work on sexual identity, which homogenized the experiences and interests of lesbian and gay men and assumed that sexual identity is both visible and static. Queer theory’s poststructuralist approach challenges the foundationalist assumptions present in existing understandings of identity and uses this as a basis to question current notions of sexual identity, leading to a rejection of unifying concepts and an increasing emphasis on difference and plurality.

THEORY AND PRACTICE

Explanations for sexuality, whether they are biological, psychological, or sociological in origin, have a direct consequence on the way in which individuals understand and practice their own sexuality, as well as the laws, regulations, norms, and values that govern gender appropriate sexual behavior. The stigmatization of homosexuality and its association with disease and deviance in the first half of the twentieth century had a detrimental effect on people who found themselves attracted to members of the same sex, a situation that was exacerbated by the social and legal sanctions surrounding same sex lifestyles. In the UK, despite nearly two decades of active campaigning, the decriminalization of private homosexual acts between two men over the age

of 21 did not occur until 1967. This was reduced to 18 in 1994 and finally achieved parity with the age of consent for heterosexuals (16) in 2001. Same sex behavior between women has never been criminalized in the UK. Globally, lesbian and gay men have been subjected to both formal and informal discrimination in the workplace, educational institutions, military establishments, and health care, as well as being denied the benefits and rights accorded to heterosexual individuals. While there has been local or national reform over the last 30 years, many countries still discriminate against homosexual behavior and in some places it remains punishable by imprisonment or death. Likewise, while feminist campaigns have partially succeeded in exposing the complex relationship between gender and sexuality, women in many parts of the world remain in a subordinate position to men, and this is enacted either through the legal system or through the informal rules and regulations that govern the practice of sexuality. This includes the double sexual standard that still operates in many parts of the world, the high incidence of sexual violence against women, and sexual harassment in the workplace. Sociological interest in sexuality has helped to expose the discrimination and stigma faced by homosexuals, as well as providing a broader analysis of the social organization of sexuality in society.

sexuality and the law

Leslie J. Moran

Reference to sexuality in the day to day operation of the law is coterminous with the emergence of sexuality as a category in the wider society. However, its explicit appearance in the official texts of law such as constitutions, codes of law, and statutes is relatively recent. For example, some of the most familiar legal terms associated with sexuality (e.g., buggery, sodomy, and indecency), phrases such as age of consent, or other key legal terms (e.g., justice, equity, marriage, spouse, parent, contract, libel, slander, property interest, and the right to privacy) make no explicit reference to sexuality. Sexuality is read into these legal concepts. An example of the emergence of sexuality as a legal term of art is the phrase sexual orientation. This phrase made its first formal appearance in the official texts of law in 1973.

One sign of an awareness of the pervasive significance of sexuality in the law is reflected

in the move away from a preoccupation with criminal law in particular sexual offenses and the emergence of a more expansive exploration of sexuality across a wide range of areas of law, from property relations to access to fertility treatment, from taxation to hate crime, from domestic violence to international law, from the regulation of kinship to the regulation of business. Long dominated by work focusing on law in anglophone western liberal democratic states the agenda is expanding to include wider national and international contexts. For example, Carl Stychin and Didi Herman's edited collection *Sexuality in the Legal Arena* (2000) includes work on law in South Africa and Zimbabwe and studies of sexuality in international laws such as the European Convention of Human Rights and the UN's International Convention on Civil and Political Rights. Robert Wintermute and Mads Andenaes's edited collection *Legal Recognition of Same Sex Partnership: A Study of National, European and International Law* (2001) includes essays that explore the impact of sexuality in the legal regulation of kinship relations in a wide range of national contexts (e.g., France, Germany, the Netherlands, Brazil, South Africa), as well as through a consideration of international law.

A search of electronic legal literature data bases such as Hein online for material dealing with sexuality reveals that this body of work is dominated by material focusing on lesbian and gay sexualities. A much smaller body of work appears to focus on heterosexuality, with little appearing to examine bisexuality in a legal context (Moran 2006). Exploration of work on heterosexuality and the law reveals that much of that work focuses on lesbian and gay sexualities. For example, in Alison Young's *Femininity in Dissent* (1990), which studies the criminalization of female anti nuclear protesters at Greenham Common in the UK, heterosexuality appears in an exploration of the media and criminal justice representation of the women protesters as lesbians. Andrew Sharpe's monograph *Transgender Jurisprudence: Dysphoric Bodies of Law* (2002) engages with heterosexuality in a series of judgments from the UK, Australia, and the US concerned with the struggle for legal recognition of transgender claims to establish their gender identity. A key finding of his analysis is the importance of heterosexuality in the

jurisprudence of transgender and central to that heterosexuality is homosexuality and homophobia. Janet Halley's pioneering studies of the US Supreme Court decision of *Bowers vs. Hardwick* (1986) dealing with the constitutionality of state prohibition of consensual sex between adult males offers some of the best work using techniques of deconstruction to examine the constitution of heterosexuality through homosexuality as "other" (Halley 1993).

The dominance of work on gay and lesbian sexualities in studies of sexuality and the law is far from being a state of affairs unique to work on sexuality in law. As Jonathan Katz notes in his study *The Invention of Heterosexuality* (1995: 12), "talk of heterosexuality so often and so easily glides off into talk of homosexuality, leaving heterosexuality – once again – forgotten." Here Katz points to the difficulties of making heterosexuality as the norm an object of critical inquiry. But as Kitzinger and Wilkinson suggest in the introduction to their edited collection *Heterosexuality: A Feminist and Psychology Reader* (1993), the norm of heterosexuality is always present while, at the same time, it is that which most resists appearance. Work on gay and lesbian sexualities in law not only explores these particular sexualities in law, but also offers the most sustained scholarship on heterosexuality to date in that field. A key component of this work is its engagement with the nature, form, effects, and institutions of heterosexuality. Terms in this work that point to the relationship between heterosexuality and these other sexualities include homophobia, heterosexism, and more recently heteronormativity. However, the danger remains that through the focus on "lesbian" or "gay," critical reflection on "heterosexuality" may slip out of the frame. The challenge is to keep both the norm and the exception in the frame of analysis in order to expose and critique the (re)production of sexuality in law.

Scholarship on sexuality and law may take many different forms. The dominant mode of legal scholarship is known by the phrase "the black letter tradition." While it is an approach to law that has its roots in the western legal method, it also has wider global significance. The methodological preoccupation is with the language of the official texts of law and with an exposition of the "true" meaning of these texts.

Formally, this "truth" can only be established by reference to other official texts of law. These texts range from constitutions and other founding texts of the nation state, such as a bill of rights, to legislation that flows from these founding texts. The latter may take the form of pieces of legislation, either created from time to time or introduced as codes of law offering a single catalog of the rules. In addition to establishing the true meaning of the language of law scholarship within, the black letter tradition also offers commentaries on the text of law: discovering meanings that appear to be formally absent from the text, finding endless consistencies and continuities of meaning, and explaining distinctions. This is a mode of legal scholarship that represents itself as being hermetically sealed from other scholarly disciplines and intimately associated with professional training for lawyers and formally devoid of politics. The methodology of this tradition of scholarship has been used to promote as well as deny legal recognition based upon a person's sexuality. Robert Wintermute's *Sexual Orientation and Human Rights: The United States Constitution, the European Convention and the Canadian Charter* (1995) is a good example of this type of legal scholarship. Wintermute offers an analysis of various legal terms such as equality, sexual orientation, and sex discrimination in several jurisdictional settings, including the US, Canada, and Australia. He explores the judicial interpretation given to these terms with a view to determining which legal category may best promote civil and human rights.

Other schools of legal scholarship (law in context, the law and society movement, socio legal studies, critical legal studies, law and culture, legal history) and law related scholarship such as criminology draw upon a wider range of methodologies, mainly (but not exclusively) associated with the social sciences and have a more interdisciplinary approach. They include a more expansive approach to legal phenomena, an interest in the wider operation of law in different institutional and everyday locations, and an explicit interest in the interface between law and economics, politics, psychology and the social, and cultural dimensions of law. The interdisciplinary dimensions of this work also draw attention to the fact that the study of law is not the exclusive preserve of legal studies,

but may also be found in scholarship in other disciplines such as history, politics, psychology, literature, sociology, cultural studies, and so on (Moran 2002).

Davina Cooper's monograph *Sexing the City: Lesbian and Gay Politics Within the Activist State* (1994) provides a good example of work focusing on sexual politics in local government in the UK. Aileen Stein's *The Stranger Next Door: The Story of a Small Community's Battle Over Sex, Faith and Civil Rights* (2001) is a study of sexual politics in a small community in the Northwest of the US. This study explores sexuality and the law by way of the daily activities of individuals, in their relations with the central or local state and private institutions and in their everyday interpersonal interactions. Other work, such as Stephen Tomsen's *Hatred, Murder and Male Honour: Anti Homosexual Homicides in New South Wales, 1980–2000* (2002), with its roots in criminological scholarship, explores sexuality through a study of police data on gay related murder and examines not only the causes of violence in this context, but also the context in which it takes place, challenging a range of heterosexist assumptions that inform understandings of the nature of murder and the processes of investigation and criminal prosecution. Studies of the representation of law, laws, and legality in high and popular cultural contexts such as fine art, literature, music, film, television, video games, and so on are a new context in which work on sexuality in law has begun to emerge. Didi Herman's study, "Juliet and Juliet Would Be More My Cup of Tea": Sexuality, Law and Popular Culture" published in a collection of essays, *Law and Popular Culture* (2004), edited by Michael Freeman, explores the governance and regulation of sexuality in and through popular culture, in this instance television.

Some legal scholarship explores sexuality by reference to theories of law drawing upon a wide range of philosophical and metaphysical traditions. Here law is taken to be a repository of the founding ideals of human society, of its ethical and moral substratum. Morris Kaplan's study *Sexual Justice* (1997) is an example of this type of scholarship, using the work of philosophers such as Hegel, and Nietzsche and the more recent scholarship of Judith Butler to examine a range of legal issues

concerning sexuality. Nicholas Bamforth's *Sexuality, Morals and Justice* (1997) offers a sustained analysis of sexual equality by particular reference to moral philosophy. Ruthann Robson's *When Sappho Goes to Law School* (1998) draws extensively on the insights of feminist scholarship.

Some of the most exciting work on sexuality and the law is scholarship informed by queer theory, exploring the materiality of sexuality and challenging the essentializing dimensions of sexual identity politics in law. At best, queer theory offers a multidisciplinary set of tools drawing upon poststructuralist and post-Marxist political theory and cultural and literary studies. Margaret Davis's essay "Queer Property, Queer Persons: Self Ownership and Beyond" (1999) is a brilliant example of the potential of queer theory. Her essay explores the nature of sexual identity by way of an analysis of themes of personality and property. Her work exemplifies queer theory's ability to expose the fundamental instability of what appear to be fixed categories of sexuality and to challenge and disrupt the sexual and gender hierarchies through which heterosexuality is given shape and form. Her analysis provides an example of work that challenges identity as the essence, core, or foundation of the subject. She reveals not only how deeply embedded these ideas are in western legal culture, but also how identity is implicated in and draws upon other fundamental legal ideas which might seem to be remote from it, such as property. Another important dimension of this essay is the way Davis explores the limits of queer theory, in particular the way it has rapidly been transformed from a technique of radical and progressive critique into just another (albeit new) identity category.

Other work drawing upon queer theory and its poststructuralist sources includes Carl Sty chin's *Law's Desire* (1995), which offers a series of case studies of sexual politics in US legal disputes and one of the first engagements with queer theory in legal studies. Leslie Moran's *The Homosexual(ity) of Law* (1996) and Derek McGhee's *Homosexuality, Law and Resistance* (2001) offer a poststructuralist analysis of sexual identity in law, this time in the context of English law, developing a Foucauldian analysis. The former also has a strong historical focus

and engages with the criminological literature on deviance and sexuality.

A different but related line of critical engagement within current legal studies of sexuality has focused on critiques of identity politics as "a politics of recognition." Susan Boyd's (1999) feminist inspired work offers an example of legal scholarship exploring the challenge to identity politics raised by the "politics of redistribution." Her work also questions the point of departure that sets recognition and redistribution as two categories that are in a relation of either/or. Her exploration of these issues takes place in relation to debates within feminism and the politics of kinship recognition, more specifically struggles over women's rights in heterosexual and lesbian domestic relations.

The problematic reification of identity categories is another theme to be found in current work on sexuality in law. Here the concern focuses on the totalizing assumptions at work in sexual identity in general and "lesbian" or "gay" in particular as separate, distinct, and complete categories. Current work has examined the interface between sexuality and gender, race and ethnicity (Moran 2006). The impact of class, age, and disability on sexuality in law remains a neglected area of study. A new and exciting development has been an exploration of these issues in a postcolonial context (Kapur 1999; Hiu 2004).

Much remains to be explored, as the study of sexuality and the law is in its infancy. More research specifically examining the heterosexual norm needs to be undertaken in all contexts. In other respects, the future direction of research will in part be influenced by the context and location in which the research is being undertaken. For example, in several African states the preoccupation remains the impact of the criminal law, and sexual offenses in particular, on the lives of citizens and the absence of any civil and human rights relating to sexuality. In many western capitalist democracies sexuality in the arena of civil and human rights remains a dominant and still expanding theme. Sexuality in the context of kinship relations is another popular emphasis that is likely to grow in importance. In locations in which sexual citizenship has become more of a reality, studies of the impact of these changes not only upon the lives of individuals but on all aspects of society

will be important. As these reforms take effect, new agendas for empirical and critical work that explore the impact of these changes will emerge. For example, Shane Phelan's *Sexual Strangers: Gays, Lesbians and the Dilemmas of Citizenship* (2001) explores some of the problems associated with the emerging concept of sexual citizenship. Leslie Moran and Beverly Skeggs's *Sexuality and the Politics of Violence and Safety* (2004) explores some of the more troubling aspects of the sexual politics of criminal justice responses to the pervasive and damaging effects of sexual violence.

Another emerging agenda focuses on sexuality and law in a global context. One dimension of this is the global spread of sexual politics in relation to law. Carl Stychin's *Nation by Rights* (1998) and *Governing Sexuality: The Changing Politics of Citizenship and Law Reform* (2003) begin an exploration of the globalization of sexual politics and the impact of sexuality on civil and human rights in both national and international contexts. A second dimension of this global turn is the emergence of a body of work on sexuality in law that brings new theoretical insights into play, such as work influenced by postcolonial scholarship (Kapur 1999).

While the work on sexuality and law is methodologically diverse, much work remains preoccupied with the analysis of texts. While the type of texts is now more diverse (ranging from media reports of legal activities, to law reports and case files, to literature and film), work that has a strong empirical focus using both quantitative and qualitative methods or ethnographic work is less common. More empirical work needs to be undertaken to examine the rapidly changing sexual landscape of law and legal relations.

sexuality, masculinity and

Rebecca F. Plante and Michael S. Kimmel

Nowhere in our intimate lives is there greater expression of gender difference than in our sexual relationships. "She" may make love "just like a woman," as Bob Dylan famously sang, but "he" would make love just like a man. Though we often think that sexual orientation is the great dividing line in our sexual expression – that being gay or straight is all we need to know about a person's sexuality – the evidence points decisively the other way, toward an understanding that gender, not sexual orientation, is the dividing line along which sexual expression, desire, and experience is organized. Gay men and straight men think and act in sexually similar ways, as do lesbians and straight women. In that sense, sexually speaking, gay men and lesbians are *gender* conformists.

How do we explain the different sexualities of women and men? How different are men's and women's sexualities? Have men's sexualities changed over the last 100 years?

BEYOND BIOLOGY

Many people believe that the differences between male and female sexuality are the simple reflection of biological differences. Some point to different evolutionary imperatives, brain chemistry and organization, or endocrine differences to explain these differences. And while these are no doubt important, biological differences tend to *assume* the very questions we might seek to answer. For example, hormone levels may influence the intensity of the sex drive, but they do not predict its direction or the object of sexual desire. Evolutionary imperatives can be just as easily employed to find the opposite of contemporary US stereotypes. And biological models assume a uniformity *among* males and *among* females that is illusory; indeed, the really interesting variations are among women and among men, not small, sometimes barely perceptible, average differences between women and men.

To sociologists, sexuality is less the product of these biological drives and more a set of experiences constructed within a social, cultural, and historical context. Sex has a history and it varies not only between women and men, but across cultures and over time, and over the life course. Sexual identities and sexual behaviors occur within these sociocultural parameters, and normative constraints and cultural expectations guide the individual experience and expression of sexual life. Most significantly, sexuality is constructed through the lens of gender. We tend to believe that sexual expression is gender expression; we imagine that gay men and lesbians are gender nonconformists.

THEORIES OF SEXUAL DEVELOPMENT

There are several explanations of how men learn hegemonic expectations; these theories could ostensibly be applied to most cultures. Gagnon and Simon's theory of *sexual scripting* argues that cultural, subcultural, and interpersonal standards for sexual and gendered conduct are socially constructed. Ideas about proper conduct and attitudes are gathered from prescriptive and proscriptive "scripts," the shoulds, ought to's, and don'ts of sexuality.

Social learning theory suggests that sexuality is learned through observation, modeling, and positive and negative reinforcement. So men's sexuality would be learned by observing models (family, friends, and mass mediated images) and coming to understand which behaviors and attitudes are culturally rewarded. This is in direct contrast to sociobiological theories, which posit that behavior is hormonal, innate, or essential. Therefore, men's sexuality would be ordained by non social sources. This view contributes to the belief that men's sexuality is natural, simple, and easy to decipher.

Psychoanalytic theories, derived from Freud, argue that sexuality is a major force, or drive (*libido*), and that the ego functions to translate social mores for the irrational, pleasure seeking id. Ego strength is the ability of the ego to channel sexual energies (sublimation) and redirect them toward culturally constructive outlets. These theories would suggest that the social elements of sexuality and gender are created from or result from the natural aspects of biologically based sex.

However, most sociologists would agree that western societies privilege binary, dichotomized, gendered roles and distinctions; the sexual arena is an ideal place in which to exemplify and magnify differences. Research suggests that in the West and in much of the rest of the world, action, autonomy, competition, and aggression are thought to be desirable masculine qualities. When these values are linked to beliefs about biology, the groundwork is laid for the creation of masculine sexuality that expects men to take the initiative, be aggressive, and be knowledgeable.

SEXUALITY AND GENDER INEQUALITY

Theories of sexuality must not only account for the differences between women and men, and the variations among women and among men, but also must explain sexual and gender inequality. In addition to other predictors of social inequality (age, race, class, ethnicity), gender and sexual orientation provide both the grounding for identity and the basis for inequality.

Patriarchy, which refers to a society in which social power rests mostly in men's hands, can

create a gender hierarchy in which men dominate or exploit women. The cultural value attributed to assertive, initiating, knowledgeable men is consequential. Rape, sexual assault, and child molestation are the darkest aspects of patriarchy, sexism, and gender inequities. Regardless of sexual orientation, men are expected to take charge and direct the action and interaction (but especially in heterosexual contexts). Certainly, in popular culture, men's sexuality is thought to be driven by efficient and irresistible forces and therefore resistant to social control.

Homophobia, defined as the fear of anyone or anything defined as gay or lesbian, is implicated in the construction of masculine sexuality. Conceptually, it can be better understood as a complex element of patriarchy and sexism, combined with hatred and fear of homosexuality. Homophobia disables intimacy for men. Masculine sexuality is organized around the underlying belief that women are inferior to men. The unfortunate misperception that gay equals feminine can result in the "sexual prejudice" that to be gay is to be "less than a man" (Herek 2005). Thus, some men's sexuality appears to be primarily organized around behavior and attitudes that prove heterosexuality. Many men suffer from the sociocultural contradictions of increasingly masculinized sexuality, which encourages risky and emotionally circumscribed interactions. Active pursuit of heterosexual and overt sexual prowess confer status, particularly for young men.

ELEMENTS OF THE MASCULINE SEXUAL SCRIPT

With genitalia outside the body, men can feel as if their emotions and sexualities are wholly *externalized*, suggests Gergen (2001). In this way, bodies become mechanized, tool like, exemplified by the occasional practice of referring to the phallus as an object (e.g., "The little head thinks for the big head," implying that phallic "behavior and logic" supersedes the brain). This can enhance a disjuncture for mind, body, feelings, and fantasies. Language and slang highlight this, such as "Little General," "love torpedo," "Herman the One Eyed German," and "Woodrow." The crucial element of masculine sexuality is the penis, a

visible and thus formidable symbol of *desire* and arousal. Men are expected to separate emotion from sexual action.

The mind/body separation, along with expectations of assertiveness and aggressiveness, can combine in volatile ways. Some men (and women) engage in “recreational” and/or risky sex. Recreational sex often requires a mind/body split so that feelings of intimacy, love, and tenderness can be dissociated from sexual encounters. This requires its participants to believe that sex is “just sex,” and can be pleasantly enjoyed without emotional fallout, dashed expectations, and differences in participants’ perceptions.

Sexuality for men has long included visual and written representations of people, positions, and practices, dating back to Greek and Roman eras. Pornography – materials that are sexually explicit and intended to cause sexual arousal – serves to eroticize particular cultural stories about sexualities. In modern western pornography men are depicted as powerful, lusty, sexual initiators with enormous phalluses that always perform reliably.

With the phallus as the largely undisputed focus of men’s sexuality, sociocultural scripts assert that it is natural for the penis to be the main “tool” of men’s sexuality. The corollary is that coitus (penile vaginal intercourse) is the most natural sexual behavior. Coitus is “real sex,” the only valid way to achieve pleasure. This taken for granted notion also reinforces the dominance of heterosexuality. This limits the cultural acceptance of non genital and some times solo forms of expression, though masculine sexuality includes many such examples, including watching erotic dancing (stripping), going to sex/swing clubs, and many bondage/dominance (or sado/masochism) activities.

Men are expected to master their bodies and sexualities. A spoof of the *Joy of Sex* (a popular sex how to manual) depicted men as the workers of sex, wearing hard hats and wielding jackhammers (McConnachie 1974). The “job” of sex asserts that sex is performative, an opportunity for men to demonstrate their prowess. (Thus, men experience “performance anxiety” when they “can’t get the job done.”) Men are especially responsible for controlling all aspects of heterosex, from flirtation and first meeting to foreplay and everything else. Combined with

the seemingly overt nature of his desire (symbolized by an erection), a man is particularly expected to labor to arouse his female partners, whose desire is thought to be more hidden and mysterious.

Masculine sexuality, as natural and organic, is thought to encompass more knowledge of sex than does feminine sexuality. Men “naturally” know not only how to control their own orgasms but also their partners’. The taxonomy of what the *Diagnostic and Statistical Manual* (1994) calls *male sexual dysfunction* includes at least two orgasm related issues: premature ejaculation and male orgasmic disorder (formerly “retarded ejaculation”). Both diagnoses rely on vague perceptions of what “normal” orgasm and ejaculation should be like – that it should be happening at just the right time. Masculine sexuality requires a man to be in control of his body at all times, moderating his arousal and responses so that he can orchestrate pleasure for his partner and/or display his skill.

Diagnoses of sexual dysfunction are not limited to orgasm issues – *erectile dysfunction* (ED) has powerful resonance for most men. The global market for erectile dysfunction pharmaceuticals is about US\$3 billion. Given the expectation that masculine sexuality is focused on the penis and heterosexual coitus, it requires an erection under a man’s control. ED challenges the belief that men’s bodies are purely external, devoid of contextual, relational, or health related influences. The popularity of erection control measures, including drugs, pumps, and implants, is testimony to the taken for granted assumptions that underlie masculine sexuality.

Masculine sexuality is especially thought to be subject to “the heat of the moment,” a powerful force of libido and desire that inhibits rationality and planning ahead. Lust and desire combine with the cultural belief that sex should be spontaneous and powerful, in the moment, and free from restrictions imposed by prophylaxis and contraception. Heterosexually active men can counteract the heat of the moment by reassuring themselves, independently of specific sexual encounters, that female partners use contraception. This logic supports the argument that condoms interfere with the lusty, spur of the moment impulses thought to be the most natural aspect of sex.

“Normative” male sexuality is therefore non relational, objectifying, and phallocentric, more prone to various paraphilia, multiple partners, recreational sexuality, and a strict separation of sex and love. Normative male sexuality is thus an expression of gender inequality, a mechanism for its reproduction, rather than a resistance to it. Happily, as with all such normative constructions, norms are more fungible in practice, and individual men still have large latitude in negotiating and developing different (and individual) sexual expressions.

Long perceived as major sources of social, political, economic, and even esoteric power, sexuality and religion are logical partners for sociological study. Although each is individually the subject of a significant subfield within sociology, in combination they have received less scholarly attention to date than they are due. Nevertheless, there is a significant body of work already in place on their many and varied connections – enough to point innovators in several fruitful directions. The key connections between these two powerful social institutions

lie in religious ritual, social structure and social control, and boundary creation and maintenance.

RITUALS

Although much of the study of religion has focused on belief, to individual members of a religion practice is often most central. This holds especially true in the context of sexuality, which is generally practiced – or not – depending on the teachings of a religious group and the practitioner's position within that group.

Most salacious, though least common overall, are religious rites that involve sexual practice in some central way. Though many minority religious groups have been falsely accused of such ritual activity as part of attempts to discredit them, religions also exist that do make ritual use of human sexuality. In some cases these ritual practices are well within the social norm. Some cultures, for example, include sexual practices in their rites of passage from childhood to adulthood. It is worth noting that interpretations of such practices vary enormously; thus, sexual rites of passage are generally not viewed (primarily, at least) as a source of sexual pleasure but rather as a symbolically important part of social role transformation.

Socially normative sexual rites may also function metaphorically, on the time honored esoteric principle that activities in the microcosm are echoed in the macrocosm. Some ancient Mediterranean cultures practiced a form of so called “temple prostitution,” in which a practitioner had sexual intercourse with a deity in the form of that deity's earthly representative – usually a priestess. Such intercourse, again, was not (primarily) for pleasure, and it was sometimes more symbolic than physical. Its purpose, rather, was to strengthen the bond between worshippers (or an entire people) and their deity, to encourage the fertility of the land, or to reenact a creation story. Within more esoteric traditions, such as Kabbalah (medieval Jewish mysticism), the sexual union of a married couple was interpreted as uniting the male and female aspects of the divine.

Other ritual uses of sexuality are intentionally transgressive. Perhaps the best known (and the most misunderstood) of these in the West today

is Tantra, a set of religious beliefs and practices that arose in India as early as the seventh century CE and eventually came to influence sectors of Hinduism, Buddhism, and Jainism (White 2003). Over the course of the past century western esotericists have imported aspects of a fairly garbled understanding of Tantra into their own mystical teachings and marketed the result as “sex magic,” “Tantra,” or “Tantric sex” (Urban 2004). In its South Asian context, however, the sexual aspects of Tantra are but one part of a larger structure in which direct contravention of social norms is held to be the key to advanced religious practice.

More common than sexual rituals are ritual restrictions on and purifications of sexuality. These include the restrictions on sexual practices and practitioners so famously analyzed by Mary Douglas in *Purity and Danger* (1966). Many religions consider sexual activity and often sexual fluids to be extremely powerful; some interpret this power as a kind of pollution and some as a source of ritual power, whereas others see it simply as a potential source of interference in the ritual. Since religions concerned with pollution are usually also concerned with purity, special sexual regulations for religious practitioners are quite common. These may include engaging in purifying practices before religious rituals if one has had sexual intercourse, menstruated, touched one’s genitals, given birth, masturbated, had nocturnal emissions, or, at the extreme, even thought about sex.

A number of important rituals regulate sexuality in the broader culture as well as within a religion. Marital rites are nearly ubiquitous, and often represent the social and religious sanction of sexuality between the people being married. Most religions treat sex within marriage and sex outside of marriage differently (such treatment also varies significantly by gender), and most see at least some forms of sexual activity as beneficial. A few, however, view human sexuality as a detriment to spiritual advancement, and enjoin either temporary or permanent celibacy on their most devout practitioners. Some, such as certain branches of Christianity, connect sexuality to evil, whereas others, such as renunciant strains of Hinduism and Buddhism, see it as a weakening of one’s spiritual powers (Hinduism) or an

unnecessary tie to an illusory and oppressive material world (Buddhism). A number of religions consider either women or (more commonly) men to be better suited to abstinence and therefore to advanced spiritual development; religion thus becomes an important determinant and carrier of gender roles as well as attitudes toward sexuality.

SOCIAL STRUCTURE AND SOCIAL CONTROL

Because religion concerns itself with ultimate reality, it is especially well suited as an agent of social control, but also as a locus for the deconstruction and reconstruction of the social order. Religious beliefs and practices shape sexual practices, beliefs, roles, identities, and norms; in essence, they are a key factor in the social construction of desire. Consider, for example, the stringent restrictions placed by many branches of Buddhism on contact between a nun or monk and a member of the opposite sex – or even, in the case of monks, certain types of men (Faure 1998). Catholic monastic orders warn against “special friendships” between members of the same sex; Orthodox Jewish synagogues and Muslim mosques keep the sexes separate; and many religions expect “modest” dress (however defined) during religious ritual. Each of these examples constructs desire implicitly, and suggests that sexuality and religion, while not necessarily enemies, are not quite compatible.

On the other hand, religion can also provide a site for powerful challenges to an existing social sexual order. The symbolic deployment of the *hijab*, or headscarf, by Muslim women is one example of this. Worn in different styles – or not at all – depending on the country, the culture, and the individual woman, the polysemic *hijab* has come to represent simultaneously male repression, anti imperialism, sensible fashion, and a feminist rejection of the male gaze. Other forms of social resistance that bring sexuality and religion together include new religious movements that experiment with sexual norms and family structure. In the US in the nineteenth century a flurry of new religious movements included the Shakers (founded in

the eighteenth century), who practiced celibacy and lived in sex segregated communal settings; the Church of Jesus Christ of Latter Day Saints, which experimented with polygyny for several decades; and the Oneida Perfectionists, who practiced *coitus interruptus* as a form of birth control, experimented with eugenics, and considered non procreative, heterosexual intercourse between members of the community to be a beneficial form of social interaction. Mid twentieth century new religious movements in the US included The Family (Children of God), who practiced for a number of years an evangelical method known as “flirty fishing”: using sex (usually between a female member and a male potential convert) as a recruitment tool.

An equally contested intersection of religion and sexuality is that of same sex eroticism – particularly gay, lesbian, or bisexual identity – and the Abrahamic religions of Judaism, Christianity, and Islam. The status of same sex eroticism in these religions has varied both across gender and over time. With contemporary western understandings of sexual orientation came a medicalized approach that removed same sex eroticism from religious discourse. As scientific and public opinion shifted during the 1960s and 1970s, homosexuality returned to being an important subject of moral and therefore religious concern. Simultaneously, self identified gay, lesbian, and bisexual Christians and Jews began organizing their own religious communities and demanding inclusion in heterosexually dominated organizations (Wilcox 2003). In response, efforts to resist the deconstruction and reconstruction of “tradition” have come not only from conservative, heterosexual dominated organizations but also from a new set of organizations often run by self identified “former homosexuals”: the ex gay movement, which argues that people with same sex desires can be healed or can at least learn to live “as God wants them to” – that is, in procreative, opposite sex marriages (Moon 2004).

In a number of societies sexual and gender norms are closely intertwined, with deviation from expected gender roles – especially on the part of men – implying an accompanying deviation from expected sexual roles. In most cases this has little to do with religion, but especially

in cultures where religion is diffuse, there is often overlap. Early Muslim cultures, for example, knew of *mukhannathun*, “effeminate men,” some of whom were associated with passive homosexuality, and this association strengthened in later centuries, though not without significant social and religious stigma (Rowson 1991; Murray & Roscoe 1997). In India, when a man assumes the identity of a *hijra*, he becomes a member of a third sex known to be sexually attracted to men but to live as women. Once a part of royal courts, *hijras* today are considered auspicious, especially on the occasion of a wedding or a birth, but are also social outcasts. Western cultures, lacking an auspicious model of gender crossing or same sex eroticism in their own dominant religion, have tended to romanticize the *hijras* in recent years while forgetting the social stigma and often the poverty that attends their lives (Nanda 1990). Also romanticized, as well as appropriated and misunderstood, is the “two spirit” person in indigenous North American cultures. Dubbed “berdache” (a derogatory term meaning male prostitute) by white anthropologists, two spirit people in traditional cultures adopted the gender roles of the opposite sex and were referred to by a variety of terms in their respective cultures. Some indigenous traditions recognized this phenomenon only in the male born, while several recognized it in those born female as well, and many did not recognize it at all. In some cultures a two spirit person would also adopt the sexual role normative to the opposite sex, pairing with a same sex but opposite gender partner; in other cases the expected pairing for a two spirit person was heterosexual (but homo gender). Furthermore, while some indigenous traditions assigned a special religious status to the two spirit person, this was not nearly as ubiquitous as contemporary gay and lesbian cultures have often implied. Today, traditional two spirit identities appear to be relatively rare, although there is a pan Indian two spirit movement that includes both the same sex attracted and the gender diverse (Jacobs et al. 1997).

In addition to sexual orientation, other forms of sexual identity may also be combined with religion. In religions where celibacy marks an advanced practitioner, the absence of sexual

practice may itself be an important identity factor. Conservative Christian teens may find a part of their identity in the True Love Waits movement, which encourages celibacy until marriage. And as Hardacre (1997) and Underwood (1999) have convincingly demonstrated, a spate of tabloid articles and spiritualists' advertisements about "spirit attacks" from aborted fetuses may have played a complex role in women's identity negotiations amid changing gender norms and sexual standards in Japan during the 1980s. Marriage also brings up a number of identity issues surrounding religion and sexuality. The most prominent in most western countries at the moment may be the legalization and religious recognition of same sex marriage, but questions of religious inter marriage and spousal conversion have been of concern in a number of religions for quite some time.

The topic of same sex marriage points to the intersection of religion, sexuality, and politics – three social spheres whose overlap is particularly explosive and contested. Political organizing by religious groups in the US has increasingly focused on sexuality issues since the 1960s. Conservative religious movements were appalled by the 1973 Supreme Court decision in *Roe v. Wade*, which legalized abortion. Liberalization of divorce laws, the legalization and public availability of a variety of contraceptives, the decriminalization and demedicalization of homosexuality, sex education in public schools, pornography, and prostitution have all been issues that have drawn religious conservatives in the US and elsewhere to band together for political purposes. Religious liberals have also organized in recent years; one interesting example in the US is Soulforce, which uses direct action tactics to protest policies that discriminate against lesbians, gay men, bisexuals, and transgendered people in religious groups. Also of concern globally is the rise of religious nationalism as a powerful political force, of which more below.

BOUNDARIES

Sexuality and politics intersect not only in secular spheres but also within religious organizations – and that intersection is increasingly

global. As women, lesbians, gay men, and bisexuals demand inclusion and rise to leadership positions within an increasing number of religious groups, those groups with international membership are forced to grapple with questions of human sexuality whose answers are often culturally bound. Further complications are introduced by the recent history of western colonialism and the ongoing tensions of postcolonial and neocolonial relationships. Within Buddhism, debates over women's roles and sometimes over same sex eroticism have been furthered by the differing perspectives of a growing population of western converts (some of whom are themselves religious leaders) and Buddhist leaders in historically Buddhist countries. The situation is even more complicated in the Anglican Communion, which began to evangelize in the southern hemisphere during British colonial rule and now includes a sizable and thus highly politically influential number of bishops from Africa and Southeast Asia. At recent conferences of the Anglican Communion, the ordination and episcopate of women, gay men, and lesbians have been central – and divisive – issues on the agenda (Rubenstein 2004).

Religion and sexuality played important roles in the formation of individual, group, national, and international boundaries long before gay and lesbian ordination, or even women's ordination, became a central topic of religious discussion. The creation and violation of personal sexual boundaries becomes a religious issue not only when religions are responsible for defining those boundaries, but also when religious leaders use their power and prestige to gain illicit sexual access to followers. Since both sexual harassment and rape are crimes of power, it stands to reason that some religious leaders, like other figures whose social standing is relatively unassailable, would be prone to such abuse. Examples abound across religions and time periods: medieval Japanese Buddhist texts praise the "love of boys," and describe not only secret communication codes between monks and novices but also strategies for coerced sex (Faure 1998). And despite the veneration of the female consort in South Asian Tantric texts, in practice the sexual rituals of Tantra can sometimes be more exploitive than enlightening for the women involved.

In 2002 sexual abuse scandals shook the Roman Catholic Church in the US. Of particular interest in this case are not only the allegations of sexual abuse, but also the intense interest of the media in sexual abuse committed on boys by celibate priests. A century and a half earlier, non Catholics in the US had been horrified and titillated by false reports that Catholic priests were abusing young girls; that contemporary allegations of abuse of women, and allegations against religious leaders outside Catholicism (i.e., non celibate leaders), fail to capture the public imagination in the same way says far more about sexual and religious preoccupations in the US than it does about the Catholic Church. Further analysis of representations of Catholicism and of the Vatican's draconian, homophobic response to the scandals would be immensely fruitful (Jordan 2003).

Religion and sexuality have conspired in the creation of boundaries and the construction of Others in ways that fundamentally shape the processes of colonialism, decolonization, and globalization. At the height of European colonialism many branches of Christianity worked hand in hand with colonial powers, not only accompanying military forces or in some cases paving the way through their evangelistic efforts, but also providing part of the justification for colonialism through their constructions of colonized peoples as religiously – and therefore culturally and intellectually – inferior. Important here is the religious and, later, academic construction of colonized peoples through sexual and gendered metaphors and stereotypes. A central aspect of missionary work in many colonies was the socialization of converts and schoolchildren into European sexual norms – a process that was integral to Christianization – and colonial laws often directly forbade sexual or related practices of which Christians of the period disapproved.

As countries around the world gained independence from European colonial powers, another important sexual and often religious symbol came to the fore: the use of the human body, and especially the bodies of women, as a metaphor for the nation (Friedland 2002). Religious nationalists in some former colonies decry western fashions for women (even as some nationalist men themselves sport western clothing) and insist on the careful control of women's

sexual behavior as a way of regaining and maintaining the country's strength (impregnability?) and independence. A classic example of this phenomenon is the rhetoric produced by both India and Pakistan (but especially India) in the wake of widespread kidnappings and sexual violence following the partition of India in 1947 (Menon 1998). In the US, too, sexual and religious imagery intertwine in national metaphors. A particularly instructive case is the aftermath of the September 11 attacks. "God Bless America" became a frantically repeated invocation while news reports bemoaned the "traumatic penetration" of the country and conservative Protestant leader Jerry Falwell blamed abortion doctors, feminists, and homosexuals for the attacks.

Under conditions of globalization, the cultural tensions that arise between immigrant communities and their hosts also link religion and sexuality. Concerns over western sexual mores and sexual identities sometimes attend the immigration of westerners into non western countries, and every immigrant community struggles some way with the differences in (often religiously based) sexual morality between the home culture and the host culture. Several European countries have recently become embroiled in what could be called "Muslim panics," fearing conservative Muslim influences on their societies and political systems. Many of those anxieties center around stereotypical perceptions of Islamic sexual and gender norms, driven in part (like some colonial sexual laws) by intense scrutiny of fairly rare events: in this case, especially "honor killings" and acid attacks directed against women believed to be threatening the family's honor, generally through a violation of strictly conservative sexual and gender norms. Some non Muslim Europeans use the brush of honor killings to tar all of Islam, forgetting that, like any other world religion, Islam is widely culturally diverse. Sexualized Muslim panics are only the most recent case in which gender, religion, sexuality, globalization, and postcolonial/neocolonial dynamics intertwine; religion and sexuality are so often integrated that a complete analysis of either often requires attention to both.

sexuality research: ethics

Maira Carmody

Sexuality research and sex research differ in a number of important ways. Sex research focuses on the mechanics of sex and is dominated by biomedical discourses and most often framed from an "objective" stance. Sexuality research, on the other hand, recognizes power relations between women and men, between heterosexual and homosexual, and between cultures, and therefore is inherently political (Connell & Dowsett 1993). Sexuality and the research of sexuality are embedded in cultural and historical contexts. Both are embodied experiences that consider the complex dynamic meanings and activities, cultural signs, politics, and ethics that impact on its realization or repression.

Power relations are embedded in every aspect of sexuality research. As Denzin in *The Research Act* (1989) has argued, when sociologists do research they inevitably take sides for or against particular values, political bodies, and society at large. This argument includes sexuality researchers, who focus on the most intimate aspects of people's lives. Within the divergent research traditions of sociology there are a number of approaches that reflect particular forms of knowledge about sexuality and ethics. These include functionalists such as Talcott Parsons, symbolic interactionists such as Gagnon and Simon, and Plummer, feminist theorists as diverse as Dworkin and Rubin, masculinity theorists such as Connell, and poststructuralist theorists such as Foucault. While each of these perspectives varies in how it conceptualizes sexuality and gender, they all reflect particular configurations of values, ethics, and society. How sexuality researchers frame their research projects will be influenced by their commitment to or rejection of these or other social theories.

Ethical considerations include the way the research question is constructed, the topic to be studied, and the people or issue being explored, the biography and relations among researchers, the values of the funding body and other actors, and the methodology chosen by the researcher. Laud Humphreys was strongly criticized for the use of deception in his methodology when following up men who engage in

impersonal sex. Ethics also includes which individuals or groups are excluded from research and whether they represent marginal or more powerful groups. Lee, reviewing research on sensitive topics, highlights how sexuality researchers may experience "stigma contagion," coming to share the stigma associated with those being studied. Citing a range of authors, he highlights how researchers may experience stereotypical expectations about sex researchers or have their work and their advancement in the academy trivialized or seen as marginal to mainstream disciplines. Sexuality research therefore raises a diversity of ethical challenges for researchers in this field.

There are several ways that sexuality researchers can seek guidance to resolve research ethics. The benchmarks for guiding research with humans has a long history within medical sciences after the Nuremberg trials. Increasingly, social sciences are paying attention to this issue. Reference to codes of ethical practice such as those of the British Sociological Association (2002) or the American Sociological Association (1999) may provide a general overview. However, much of the academic surveillance of research is carried out by university ethics committees or internal review boards (US). It appears to vary significantly between disciplines, universities, and countries. The overriding concern in deciding what is ethical research is the balance between perceived harm to an individual involved in a research project and the perceived benefits to the individual and society in general. While as a guiding principle this is worthy, the operation of this principle can create particular difficulties for sexuality researchers. As Beck in *The Risk Society* (1992) has indicated, western societies are increasingly focused around a discourse of risk and risk management. When this is combined with ethics committees dominated by a positivist and biomedical model, sexuality researchers often find worthy projects questioned. This may include challenging the "objectivity" of qualitative methodology and sampling "bias" when sexual cultures or networks are the focus of study. Regulation may extend to a focus on reporting adverse impacts of research on participants rather than balanced reporting on both positive and negative outcomes. Underpinning these challenges is the conflict between different research paradigms or attempts to silence the voices of sexual minorities through assumptions

of heteronormativity and institutionalized homophobia or sexism. These challenges and how sexuality researchers and ethics committees resolve them will significantly impact on the kind of research that gets funded and the construction of knowledge. A risk management model of research, while possibly protecting individual institutions against future litigation, does little to help sexuality researchers in developing transparent ethical research practices.

There is danger in researchers feeling that all the ethical issues have been dealt with once ethics committee approval is obtained. Codes of practice assume a fixed position and deny the dynamic nature of research and a conception of ethics where meanings are subject to negotiation and redefinition. However, ethical issues confront researchers in a number of areas, including relationships in the field, informed consent, use of the Internet, representation of data, and support for researchers.

Boundaries between the researcher and the researched may be blurred when exploring sexual cultures if the researcher is a member of that culture. This occurs in many aspects of sexuality research and is a continuing issue in HIV research. Disclosing personal details to enhance a connection with an informant could result in either feeling vulnerable or being exposed to harm. The erotic subjectivity of anthropologists in the cultures they study is explored in depth in an edited collection by Kulick and Wilson (1995). Interestingly, they had great difficulty finding heterosexual male anthropologists who were willing to write about how they resolve the ethics of these contacts. Feminist critiques of research have challenged the gender blindness of much research and some have argued for attempting to equalize the power relationships as a framework for shared political struggle. This can present ethical difficulties when researchers universalize the meaning of gender and how this relates to sexuality for other women within their own or other cultures.

Regulation of sexuality research may vary between institutional settings and countries and can raise significant risks of the researcher imposing first world research processes and interpretation of findings in a less developed setting. Sensitivity to cross cultural differences may be acknowledged intellectually by research teams, but this may not provide ethical guidance

in relation to personal and research relationships with participants. It may also result in a failure to recognize the ways in which sexuality and sex practices are understood in these settings and may "spoil the field" for future research efforts. There are positive and negative possibilities of participant observation in a range of settings where sex occurs, for example, if a researcher is investigating sex work, commercial sex venues, or sadomasochism (SM) communities. What ethical code do they call on to guide their relationships with other people in the setting or their own behavior? The risks are significant, not only physically but also professionally if not handled well, as Harry Wolcott recounts in *Sneaky Kid and its Aftermath* (2002).

Gaining informed consent from research participants is central to ethical research to ensure there is no coercion and that participants understand the meaning of consent. Some ethics bodies require written consent, but this can raise particular dilemmas for sexuality researchers. Participant observation research is a case in point. It may not be appropriate to pull out a consent form in a sex venue or when interviewing sex workers or young homeless people. In situations where people are justifiably suspicious of authority figures or "outsiders," the demand for written consent may work against gaining important knowledge from informants. Longitudinal studies may also present other dilemmas. Consent given at the beginning of a project may need to be revisited further into the project as participants' circumstances or researchers change.

Sexuality research using the Internet extends ethical issues into the virtual world. As this is a relatively new domain for sexuality research, there are to date only limited guidelines to assist researchers. Given the anonymity of cyberspace, it may be that respondents are less cautious in this context than in a face to face setting. Consent is complex in this setting and there needs to be a mechanism to ensure who is actually consenting and some way to verify their "identity." Privacy issues may also need to be addressed given the problems of computer hacking and software sharing programs. The Internet may provide increased opportunities for researching individuals and groups who may be hard to recruit, for example, same sex attracted young people or groups with specific

fetishes. Research with under age young people is often contentious. Yet important research with young people about sexuality could significantly add to community knowledge and lead to improvement in services targeted to their needs. However, fears of the sexual exploitation of children and young people make this an area that many ethics committees are reluctant to support without parental approval (Binik et al. 1999).

The interpretation of data and their dissemination raises another set of challenges for all researchers, including those in the field of sexuality. Decisions about what methodology will be chosen to analyze data not only impact on the rigor of the project but also highlight "the crisis of representation" facing all social science. Ethical decisions are reflected in the choice of theoretical approach, which part of the data to include and exclude, and what interpretation is made of findings. Postmodern approaches have challenged the "truth" claims of positivist research. This suggests the need to be very transparent about the partial nature of the stories told and to locate findings from the point of view of the "historically and culturally situated individual."

Sexuality researchers enter the field from a range of disciplines, including sociology, anthropology, criminology, psychology, history, cultural studies, and political science. The interdisciplinary nature of current sexuality research means that researchers often come to the issue with a range of expectations and experiences shaped by age, gender, sexuality, culture background, and (dis)ability. Their disciplinary background may provide some frameworks for guiding their behavior in relation to sexuality research. Research teams may provide an important context for ethical issues to be debated and resolved. However, many researchers work alone, or may be inexperienced or a long way from their home base. In addition, even experienced researchers may find themselves facing ethical and personal difficulties once the research project has commenced. While most ethics committees are focused on ensuring no harm is done to research participants and ensuring they have phone numbers for counseling or follow up support, there is less formal acknowledgment of the need to prevent harm to researchers. This is relevant

during fieldwork or afterwards when findings are published and they may come under intense scrutiny from disaffected individuals or organizations. Developing mechanisms of support during fieldwork, including debriefing and after the completion of projects, is fundamental to ethical research practice and necessary for new and inexperienced researchers, including postgraduates.

The development of ethical practice in relation to sexuality research requires a much more dynamic and complex process than a purely regulatory approach. The sensitive and intimate nature of sexuality research and the multiple sites and cultural contexts in which it is carried out suggest the need to encourage ethical subjectivity in researchers. Central to this would be a focus on reflexivity. Ethical subjects, following Michel Foucault, *Ethics: The Essential Works*, reflect on how we constitute ourselves as moral subjects of our own actions, and essential to this subjectivity is caring for others. Jeffrey Weeks proposes a sexual ethics based on radical pluralism. This approach moves away from an absolutist model of ethics. Instead, it suggests ethics need to be developed based on the social production of sexualities and the complex ways in which they are embedded in diverse power relations. Zygmunt Bauman (1993) argues for a postmodern ethics in which there is a greater awareness of making ethical choices in every part of life and the profoundly ambivalent nature of these choices. Plummer (2001) argues for a much clearer discussion of these issues amongst researchers that does not always rely on abstract principles but takes seriously the stories researchers provide of their own situated ethical problems and decision making.

sexuality research: history

Lesley A. Hall

Research on sexuality began as a complex and interdisciplinary endeavor. Although it was, like so many of today's fields, a product of the nineteenth century belief in the power of rational scientific investigation, it was very much a latecomer. F. H. A. Marshall commented in his 1910 synthesis, *The Physiology of Reproduction*, that physiologists had made comprehensive studies of all other bodily functions, but reproduction had not been the object of sustained research. Marshall was thus obliged to bring together scraps of evidence from diverse sources, from anthropology via medicine to animal husbandry. Research on sexuality was similarly affected by a scarcity of materials and taboos against investigation, and the threat of prosecution for publication.

The lack of institutional and financial support, and the general unacceptability of the subject, meant that large projects using the research protocols emerging in medicine and the social sciences were an impossibility. Thus research into sexuality initially tended to be based in the analysis of phenomena brought to the investigator's attention (cases encountered by doctors, legal trials, self observation, reports from friends and colleagues, letters from readers), and the

collation of evidence gleaned from a wide variety of fields – history, literature, medicine, and the growing field of anthropology and ethnography. Theories might be engendered from impressionistic, limited, biased, and unrepresentative empirical materials. The subject was marginalized and stigmatized and did not lead to any of the usual professional rewards. Such research, therefore, was most often conducted by those who had some kind of personal motivation to pursue it.

The wider roots of the desire to investigate sexuality were several. The rise in urbanization and consequent opportunities for social mobility had led to the breakdown of traditional forms of control over sexual behavior. Prostitution was on a larger scale and much more visible in such conurbations. They also enabled previously isolated individuals, such as men who desired other men, to meet one another and to create subcultures based on identity. Darwin's theories of the role of sexual selection in evolution provided an important legitimating as well as analytical device for thinking about the subject. Venereal diseases were widespread and incurable. The rise of a social purity movement aimed at improving both the morality and the health of society made powerful representations for the benefits of talking about sexual matters rather than concealing them under a cloak of taboo. To provide proper knowledge of the workings of the body required that these should be understood, with healthy scientific information replacing old wives' tales and furtive smut. A developing women's movement destabilized accepted ideas about marriage and sexual morality and current notions of gender. All these elements were turning sexuality into something with social, rather than purely individual, resonances, while undermining assumptions about "the natural."

PRELIMINARY APPROACHES

Initially, specific problems were considered more or less in isolation. Concern over prostitution, and its concomitant of sexually transmitted diseases, led to interest in how and why women became prostitutes. Facilitated by the existing French system of regulation, sanitarian Jean Baptiste Parent Duchâtelet made a study of Parisian prostitutes, based on incarcerated

women registered with the police, excluding casual and clandestine prostitution and the higher echelons. This major study was not published until after the author's death (1836). The British surgeon William Acton, in his own work on the subject (1858), deplored the fact that, because of both the differing organization of the trade and greater moral prudery, such a detailed study could not be undertaken in Britain. The American Abraham Flexner, in *Prostitution in Europe* (1919), revealed that covert, clandestine, and casual prostitution flourished even in countries which imposed regulatory systems of control and medical inspection.

Such studies were undertaken by men and focused on women, or a particular class of women, as a "problem," on whom they could turn a scientific and pathologizing gaze. The idea that the consumer of prostitution might also be a problem to be addressed was only raised later in the nineteenth century, by the feminist wing of the developing social purity movement, in a political, not merely moral, critique of social acceptance of male promiscuity. However, as studies on the subject continued to comment into the final decades of the twentieth century, the male purchaser of sexual services remained shadowy.

A rather different situation pertained in the case of men defined by the term coined by the Hungarian Kertebeny in 1869, "homosexual." While there were sporadic medical reports on cases involving men desiring other men, and a medico forensic literature on "sodomy," the debate on homosexuality was generated, initially, by men trying to understand their own stigmatized desires, in many countries subject to brutal criminal penalties. Among the resources drawn upon were changing scientific understandings of the body and of anatomical development. The pioneering figure Karl Heinrich Ulrichs, initially under the pseudonym "Numa Numantius" and then in his own name, published a series of monographs on same sex love in which he posited a theory of gender inversion (the female psyche in the male body, and vice versa) of congenital origin. He endeavored to gain medical allies, and influenced later work by the psychiatrists Richard von Krafft Ebing and Carl Westphal, although he considered that their views were distorted by seeing an undue proportion of criminal or insane, rather than healthily

functioning, homosexuals, leading merely to replacing concepts of homosexuality as sin or crime with a disease model.

While the evolution of ideas about the homosexual was a major concern in discussions of sexual "deviation" in the late nineteenth century, and has been the main focus of scholarship in the area, other phenomena which could not be assimilated to a post Darwinian evolutionary model of the role of sexual selection in reproduction were also analyzed. French psychologist Alfred Binet invented the term "fetishism," given more extensive currency by Krafft Ebing, who himself defined "sadism" and "masochism." Oosterhuis in *Stepchildren of Nature* (2000) reveals a significant subgroup of male masochists among Krafft Ebing's patients and informants. A group generally marginal to these discussions was women (possibly because being a woman was already considered deviant or at least problematic). There was some discussion of the lesbian, though there were far fewer cases reported in the growing literature on homosexuality, but "masochism" was seen as innate to the female nature and thus only a problem when it manifested in men.

THE FIELD DEVELOPS

Around the turn of the nineteenth and twentieth centuries several writers began to pull together the various strands within which sexual matters were being analyzed – the public health and morality concern with prostitution and venereal diseases, the legal and medical debates on homosexuality, concerns over marriage and reproduction (inflected by the theory of eugenics adumbrated by Darwin's cousin Francis Galton), anthropological reports on other cultures, arguments for the desirability of general sexual enlightenment, medical cases, historical data – into broader syntheses. A leading figure in this new development was the British doctor and literary figure Havelock Ellis, who between 1897 and 1927 produced his massive seven volume study, *Studies in the Psychology of Sex*, the first volume of which, *Sexual Inversion*, was prosecuted for obscenity, a traumatic event leading Ellis to have the rest of the series published in the US. Although Magnus Hirschfeld began as a homosexual rights activist anxious to repeal

or moderate the German laws on the subject, over his lengthy career as researcher, educator, and campaigner his copious writings covered a much wider range of sexual issues. He also created connections between isolated individuals in different countries working in the field by establishing journals, setting up an Institute for Sexual Science in Berlin (destroyed by the Nazis in 1933), and facilitating international networks through holding congresses. Iwan Bloch took a similar broad and deep view, in particular emphasizing the importance of historical understanding. Such figures laid a necessary foundation for further work by synthesizing materials from a diversity of sources to establish a picture of what was known about sexuality. A very different approach to the study of sex, emphasizing the depths of the psyche rather than the broad sweep of societies in time and space, was that evolved by Sigmund Freud and the early psychoanalytic movement. Freud made the significant observation that understanding the process by which heterosexuality developed was just as problematic as discovering the "cause" of homosexuality and that the relation between desire and its object was by no means a given.

Well behind investigation into the other endocrine secretions, work was undertaken on the sex hormones. The topic had been cast into some disrepute as a result of the Franco-American Brown Sequard's sensationalized "rejuvenation" treatments of the 1890s, and respectability was further compromised by similar promises from Steinach and Voronoff in the interwar years. For several decades research remained predicated on the assumption that gender specific ovarian and testicular hormones influenced sexual identity and functioning: this was discovered not to be the case by the late 1920s. With the development of biochemical assaying techniques, research moved into the realm of chemists in the laboratory – a degree of removal from the messy processes of the body and direct connection with sexual functioning which doubtless influenced the increasing scientific respectability of the field and its access to resources, but also led to a loss of connection with research into sex within its social context.

In the United States, the issues vigorously debated and discussed within American sex radical and reform movements of the mid nineteenth century had been, if not silenced,

seriously muffled by the rise of the movement for aggressive censorship of sexual materials embodied in Anthony Comstock. Thus initiatives such as Clelia Mosher's 1890s survey of women's experiences of and attitudes toward sex, unpublished until the 1970s, had no influence and established no tradition. For several decades Robert Latou Dickinson privately accumulated detailed information on the patients in his gynecological practice, including drawings (later photographs) of their genital anatomy. Prince A. Morrow brought European debates on the venereal disease (VD) problem and the ineffectuality of policing prostitutes to the US and tied these in to concerns over marriage. Research became legitimized by the arguments of improving marriage and reducing disease: studying what went wrong with sexual lives would assist in working out how to ensure things went right. A number of surveys were undertaken and several published: G. V. Hamilton's *A Research in Marriage* (1929), Katharine Bement Davies's *Factors in the Sex Life of 2200 Women* (1929), Robert L. Dickinson and Lura Beam's *A Thousand Marriages* (1931) and *The Single Woman* (1934).

It was in this context of the concept of strengthening marriage through better understanding of sex that Alfred Kinsey was able to inaugurate his mammoth enterprise of research into the sexual life of the human male and female. Focusing on behaviors rather than on emotions or attitudes, he collected a huge amount of material through face to face interviews with unprecedentedly huge numbers of men and women. The fruits of his researches were published as *Sexual Behavior in the Human Male* (1953) and *Sexual Behavior in the Human Female* (1953). There remained questions about how representative they were, a factor of which Kinsey was well aware. He tried to obtain 100 percent responses from any group or community studied, made particular attempts to gain access to groups that might otherwise be underrepresented, and designated certain areas as necessitating future research projects. Kinsey's work remains controversial, but also still profoundly influential.

Kinsey and his team undertook, among other things, some direct study of sexual intercourse, but the researchers who fully broke this final

barrier were William Masters and Virginia Johnson, who undertook extensive mapping of the processes of arousal and satisfaction using human participants in the laboratory, assisted by technological developments. Their work has been critiqued for its attempt to ignore context and social aspects of sexual interaction by selecting specifically for participants who were capable of functioning in the laboratory milieu, and, in the case of women, were readily orgasmic, and on this basis creating a one size fits all model of the process of arousal, orgasm, and resolution.

Research into sexuality followed a path from the specific to the very general synthesis, succeeded by a branching out into new separate paths concentrating on distinct aspects (the physiological, the social, the psychological). Lack of coordination between different approaches has remained a problem.

sexuality research: methods

Julia A. Ericksen and Eugene P. Ericksen

As Kinsey and others discovered to their cost, sex research is fraught with problems for researchers and must be managed carefully. In the US, Congress has cut or threatened the funding in recent decades for two national surveys of sexual behavior: a study of massage parlor workers and a study of sexual risk taking, among other topics. And those who publish research invite trouble, as the University of Minnesota Press found when it published Judith Levine's *Harmful to Minors*.

Although researchers have been concerned about this problem for over 100 years, Kinsey was the first to discuss it explicitly. Worried about guarding the confidentiality of the thousands of respondents who agreed to share their sex histories, he trained his hand-picked interviewers to learn the questions and write the answers in carefully guarded code, and he kept locks on all the materials in his institute. Even so, in 1954, when Congress investigated the Rockefeller Foundation to punish it for opposing the House Un-American Activities Committee, the only issue raised was their funding of Kinsey's research. As a result, the funding ceased.

While sociologists argue that we become sexual just like we become anything else, those who engage in sexuality research recognize that their work differs from that of others, for the reasons outlined above. These researchers have

responded to the perceived dangers by careful management. Many sociologists of sexuality write theoretical articles, or use small numbers of qualitative interviews with carefully selected volunteer respondents, or undertake historical research using texts as their data source. Such studies cannot usually be generalized to the population of interest. Researchers who undertake quantitative work justify their carefully picked topics by citing compelling social reasons.

In addition, researchers have ignored methodological problems associated with asking sensitive questions for fear of inviting criticism discrediting their results. For example, there has been an enormous amount of research on voting behavior in the United States in response to the difficult problems associated with getting an accurate account of the vote and with predicting who will vote and how in forthcoming elections. Until recently, there has been no comparable body of research on sexual behavior surveys.

In the last decade or so the picture has changed, and major research centers have begun to undertake methodological research on sex surveys. In spite of Foucault's declaration that talk about sex led to self-policing, not to liberation, and even in the face of much discourse intended to control sexuality, most would agree that attitudes towards sexuality are more liberal and facilitate more open discussion of sexual behavior than previously. Surveys are one kind of open discussion about sex. In addition, the devastation caused by AIDS has provided ample justification for prying into the private lives of individuals.

Much of this research has been undertaken in the United States, and this is the focus of our discussion. However, a few examples of important research elsewhere should be mentioned. Here too, much of the impetus has been HIV transmission. When Congress cut the funding for a national survey of adults, the researchers at the University of Chicago were able to field a survey without support from the Robert Wood Johnson Foundation, but it was much smaller than originally planned. When the British government cut the funding for a similar survey, the Wellcome Foundation funded a large national survey and a decade later the government funded a repeat. From the beginning, one of

the researchers, Kaye Wellings, took an interest in data quality. A major research focus was behavioral change over time, so she used a series of techniques to ascertain whether reported changes in socially disapproved of behavior between 1990 and 2000 resulted from actual behavioral change. And at the Australian Research Centre in Sex, Health and Society, researchers interested in HIV transmission have explored such topics as how to measure sexual behavior in high risk venues and the validity of self reported condom use.

What follows is a brief description of some American research on some of the problems identified in sex surveys, and examples of attempts to solve these problems.

SELECTING THE POPULATION TO INTERVIEW

Kinsey refused to use probability sampling, even after its efficacy was explained to him, because he believed he could not interview respondents who were not volunteers and because he did not understand that the greatest variety was not the same as a representation of the population. Researchers now understand and use modern sampling techniques with great success. Survey response rates have declined as a result of caller ID and increased consumer weariness over telephone abuses, but they are not higher on sex surveys than other surveys. For example, the Chicago survey (the National Health and Social Life Survey) undertaken by Edward Laumann and colleagues at the National Opinion Research Center (NORC) in 1992, reported a 79 percent response rate, which compares favorably with between 75 percent and 79 percent for NORC's General Social Survey (GSS).

There are still major sampling issues, particularly in the lack of a national probability sample of men who have sex with men, because it is difficult and time consuming to sample rare populations, especially when the selection factor concerns behavior that is not always admitted to.

PROBLEMS WITH THE INTERVIEW

Several interviewing problems continue to challenge researchers. Kinsey believed erroneously

that respondents would be more willing to unburden themselves to middle class white men with "non ethnic" names. Today, most interviewers are women, and most experts regard women as better interviewers than men. With sex surveys, however, some argue that accuracy improves with interviewers of the same gender as respondents, particularly when asking about sensitive topics such as rape or anal intercourse. When AIDS first appeared, surveyors of gay men argued that self identified gay male interviewers were more successful than women or heterosexual men.

The mere presence of an interviewer may affect response accuracy. When Laumann and colleagues (1994) asked respondents for the number of lifetime sexual partners, women reported an average of 3 male partners and men an average of 12 female. Both of these averages cannot be correct. One problem with asking this question is that it places a burden on respondents. For people with many partners, this question is difficult to answer. They may estimate rather than enumerate, particularly given interview time constraints. Those who enumerate may forget some partners, especially when constrained to give an answer quickly. Brown and Sinclair (1999) asked college students their total number of sexual partners, and then asked how the number was derived. When men and women used the same technique the distribution of number of partners was similar by gender, but enumeration produced lower tallies than estimation and men were more likely to estimate than women. Thus the authors concluded that the difference in results is not a product of intentional deception.

Not all researchers agree. Many recognize that reputational issues for men and women push the genders in opposite directions, such that some men deliberately overestimate their lifetime sexual partners and some women deliberately underestimate. If so, the more a respondent feels anonymous and unknown to even the interviewer, the more accurate the data should be. This was shown by Tourangeau and Smith (1996) in a comparison of computer assisted personal interviewing with computer assisted self administered interviewing. Men using self administered questionnaires reported fewer sexual partners than men listening to interviewers, and women reported more.

QUESTIONNAIRE DESIGN

Researchers recognize that respondents have to complete a number of tasks in answering a question. In addition to the issues of retrieval discussed above, they must comprehend the question. Since questions about sexual behavior are not part of everyday polite conversation, there may not be general agreement about the word meaning. When Bill Clinton stated that oral/genital sex did not constitute "having sex," about half the American population agreed with him. Furthermore, there are social class and educational variations in sexual terminology. Kinsey realized that less well educated respondents would not understand "masturbation," so he used terms like "jerk off" instead. However, since "jerk off" would offend the better educated, he used masturbation where he deemed it appropriate.

Researchers today want to use the same words for all because wording changes affect answers, but problems of comprehension remain. Lauermann et al. (1994) approached the masturbation problem with a written definition: "By masturbation, we mean self sex or self stimulation, that is, stimulating your genitals (sex organs) to the point of arousal but not necessarily to orgasm or climax." Thus, in order not to offend by using "jerk off," they used several difficult words, one of which even got its own additional definition. And those who cannot understand such terms tend to be demographically concentrated. Binson and Catania found that although only 4 percent and 5 percent, respectively, said they had difficulty understanding "vaginal intercourse" and "anal intercourse," 20 percent and 25 percent of those with less than 12 years of schooling reported difficulty.

With sensitive questions, researchers may list alternative responses to a question so that the respondent can pick a category rather than reveal their actual answer. However, when social desirability is an issue, respondents may pick one of the central categories, on the grounds that this is going to appear average or normal. And the respondents may not volunteer information needed to understand their responses. For example, opinion questions on controversial topics may not record strength of the opinion. Schuman and Presser (1996) showed the importance of this in a study of

attitudes towards abortion. In the GSS most respondents (58 percent) favored legal abortion for married women, but those opposing this right were much more likely to consider it to be a very important issue (49 percent) than those in favor (21 percent). In a follow up study, 65 percent said they agreed with abortion on demand in the early months of pregnancy, but 70 percent of those opposed described their views as very strong or extremely strong, compared to only 25 percent of those in favor. Finally, almost 20 percent of women against abortion on demand had given money and/or written a letter for the cause, compared to just over 5 percent of those in favor. Even though most Americans support a woman's right to choose, activists are to be found substantially in the opposition.

Finally, researchers are sometimes unclear as to the question they want answering. When Kinsey asked questions about homosexuality, he asked about desire as well as about behavior because he assumed some people wanted to engage in same gender sex but lacked the courage to act on their desires. Based on the result of these questions he placed each respondent on his scale from 0 (exclusively heterosexual) to 6 (exclusively homosexual). He assumed that desire could be added to behavior to provide an estimate of "natural" homoerotic behavior in a non repressive society. Laumann and colleagues asked separate questions about behavior, about desire, and about identity and found differences in the incidence and distribution of each. Identity – that is, self identifying as gay, lesbian, or bisexual – proved less frequent than the report of same gender desire or behavior. Just over 10 percent of men and slightly fewer women reported any same gender sexual activity or interest. Of these, only one quarter of the men and 15 percent of the women reported same gender desire, behavior, and identity. Most women reported only desire, with some reporting desire and behavior and some reporting only behavior. The pattern was the same for the men, although men were less likely to report only desire and more likely to report only behavior. This becomes important when we consider that in studying AIDS, we should want to know which men have sex with other men, not which men consider themselves to be gay.

DATA ANALYSIS

Researchers now understand that their biases can influence the outcome of their data analysis, and they use sophisticated data analysis techniques to be more certain of their conclusions. Yet the questions they ask of the data reveal a point of view. Laumann and colleagues were careful to present their findings as evidence of the conservative nature of American sexual behavior, pointing out, for example, that the modal number of lifetime sexual partners was one and that married individuals reported the highest rates of sexual satisfaction. In doing so, they chose to emphasize the conservative sexual behavior of the majority of Americans instead of the libidinous minority. This was reassuring to researchers who had been accused of attempting to promote sexual hedonism in Americans by normalizing extreme behavior.

This brief description of modern practice suggests that a history of sexual behavior surveys is a history of the growing sophistication of researchers and the increasing certainty of their conclusions. In order for this to be the case, researchers would have to be neutral observers of sexual behavior, an unlikely proposition in a world where no one escapes pressure to monitor personal sexual standards and desires. In addition, sexual behavior would be independent of history and culture, and questions such as the proportion of gays in the population would be technical, not political, and they would not be historically specific. While survey improvements have produced more accurate reflections of historical moments, surveys do not divulge universal truths, only those relative to their time and place.

Surveys teach us not only about sexual behavior in America and elsewhere, but also about the beliefs shaping sexual behavior, and about the concerns driving researchers to ask questions. And as survey practice has improved, the ensuing descriptions of sexual practice not only provide a behavioral control, but they also normalize the desires of those who learn there are others like them.

sexuality and sport

Caroline Fusco

Michel Foucault (1978), one of the most influential historians of sexuality, argued that sex and sexuality became a pivot for the organization and control of life in the modern world, and that sex and sexuality are increasingly central to human affairs to the extent that much of contemporary life has been organized around these concepts.

Although the relation between sexuality and sport serves as a central structure for body/identity/gender meanings, sexuality was

a neglected area of inquiry in sports studies until the mid 1990s. Sport has long been a site for the reproduction of difference, particularly the naturalization of sexual differences, but sexuality occupied a somewhat “absent presence” in sport sociological research until the late 1980s, when sports sociologists explicitly addressed this topic. Since that time, scholars in the sociology of sport have figured prominently in the critique of historical and cultural forms of sexuality and the ways that sport serves as a site for constructing and policing sexualities and both reproducing and resisting heterosexism and the heterosexualization of sport related forms (Birrell & Cole 1994).

Although there are many sexual orientations (heterosexual, homosexual, bisexual, transgendered, transsexual, queer, etc.), the study of sexuality in physical education and sport has been characterized by the assumption that “sexuality” is non normative; that is, the study of sexuality and sport has historically (and some times in the contemporary moment) been understood as the study of homosexuality or other “deviant” sexualities and sport. Such an approach assumes that heterosexuals do not have “a sexuality,” and it has interfered with developing a fuller theoretical and empirical understanding of sexuality and sport.

Prior to the late 1980s, research on sport and sexuality was primarily framed within a socio-psychological framework and focused on the role conflict that women athletes experienced while participating in sports and the strategies they used to cope with the contradictions that arose between competing in sport – historically and socially constructed as a masculine practice – and their feminine gender role. Critics argued that all of this social psychologically oriented scholarship was based on the faulty assumptions that all women athletes were heterosexual, and that “feminine” always implied heterosexuality. These assumptions led researchers to overlook the experiences of women athletes who did not define themselves as heterosexual and identified as gay or lesbian. Lesbianism was thereby erased from women’s sports. This “conspiracy of silence” meant that lesbian athletes were ignored, shunned, and constrained to remain invisible in sports, and the lesbian label was used to intimidate lesbians and heterosexual

women. As a result, attempts by women athletes to challenge socially constructed gender relations in sport were undermined and sports continued to valorize heterosexuality.

Feminist theorists in the 1990s disrupted the conspiracy of silence by exposing homophobia in women’s sport and physical education, and making visible the experiences of athletes, coaches, and physical education teachers who identified as gay or lesbian. Research identified the heterosexual and homophobic discrimination inherent in women’s sports and validated a proliferation of accounts from lesbian athletes, coaches, and physical education teachers in North American schools that revealed how they are demonized and the identity management strategies they must use to survive and resist systemic discrimination (Fusco 1998). Historical research has documented longstanding tensions between lesbians and heterosexual women in sport, and demonstrated that the institutionalization of homophobia in sport and physical education is grounded in sexology discourses popularized in the 1930s (Cahn 1994): these discourses heterosexualized women’s physical activity by identifying beauty, sexual attractiveness, and male companionship as necessary affirmations of womanhood.

No single theory has informed scholarly work on sexuality and sport. Theoretical and methodological diversity has led to multiple questions about sexuality and sport. A combination of qualitative research strategies, surveys, and in depth interviews has been used to present rich and often painful descriptions of the multiple realities of lesbians in sport. Theoretically, much of the early work on sexuality was based on liberal or radical feminist perspectives. *Liberal feminists* reported the oppression lesbians experienced; documented their feelings of being threatened, silenced, and excluded; and suggested that lesbian athletes, like other women athletes, wanted only to play and be recognized as athletes, not as lesbians. *Radical feminists* continue to critique this approach because it depoliticizes sport at the same time that it reproduces heterosexuality, gender normativity, and patriarchy in women’s sport. Radical feminists document the links among sport, sexuality, and gender politics and make explicit the relationship between individual discriminatory

behavior and institutionalized homophobia and heterosexism, which they argue maintains traditional gender roles, and bolsters masculinity while maintaining male privilege and control in sport. Most radical feminist scholars use a social constructionist framework (where sexuality is interpreted as socially and historically contingent) rather than an essentialist one (where sexuality is interpreted as a phenomenon common to all humans of every culture and time), and focus on the voices of lesbian athletes and their stories of oppression, silence, and marginalization. This approach has been informative, but it often ignores stories of lesbian agency, disruption, and radical resistance to the systemic heteronormativity of the sports world.

While the lesbian experience in sport has been thoroughly examined, little attention is paid to the experiences of gay men in sports. Pronger's *The Arena of Masculinity* (1990) remains the most comprehensive and theoretically rigorous examination of homosexuality in sport. Pronger reveals that the presumed masculine and heterosexual world of sport is also a potentially homoerotic world for gay men. Yet, because sport is an arena where male aggression and violence is encouraged, this homoerotic potential is stifled and violently suppressed. Masculinity in sports is solidified through the marginalization of homosexuality, which is vilified and mocked in songs and "drag" performances, while heterosexuality is confirmed in locker room banter that glorifies "heterosexual conquest." While silence surrounds lesbians in women's sport, there is near complete denial about the presence of gay men in sport. The pervasive expectation that male athletes are heterosexual makes it almost impossible for gay men to come out in sports, and legitimizes threats of homophobic violence. The assumption that gay men do not participate in aggressive male sports confirms the two sex/gender classification system, which codes lesbians as masculine and gay men as effeminate. Therefore, men who compete in aesthetic sports are denigrated and labeled as gay, and this has led to a remasculinizing of these sports by emphasizing strength and power.

The two strands of theorizing that have emerged from initial investigations of homosexuality in sports are (1) sport as a site for reproducing aggressive hyper heterosexual masculinity

(Messner & Sabo 1994; Burstyn 1999) and (2) the erotic potential of men's sports and the ways that homophobia regulates the homosocial heterosexual milieu of men's sports and prevents them from slipping into homoeroticism (Pronger 1999).

Contemporary theorizing about gender, sex, sexuality, and sport demonstrates an increasing awareness and application of postmodern, poststructuralist, queer, postcolonial, and cultural geography theories to the study of sexuality and sport. Although each of these "new" theories provides a unique approach to the study of sexuality and sport, all of them are based on possibilities for rethinking sexuality and sport. Scholars using them are interested in the social, historical, and political discourses that produce sexuality and the ways that sexuality has consistently been marked as white, middle class, and able bodied. Liberal interpretations of sexuality as an essential, monolithic, homogeneous or fixed identity category are widely discounted as more scholars focus their attention on the intersectionality of gender, sexuality, race, and class (Collins 2004). Poststructuralists in sport studies deconstruct the discourses that organize sexuality, the body, and the sex/gender dimorphic system. Queer theorists explore the borders of sexual identities, communities, and politics and how categories such as heterosexual, gay, lesbian, and queer emerge, while also working to destabilize and disrupt the heterosexual/homosexual binary. While earlier scholarship incorporated certain epistemological and ontological assumptions about the categories "lesbian," "gay" and "heterosexual," queer theorists now question these essentialisms and suggest that all sexual identities are continually performed. According to Butler (2004), a democratic sexual society requires that people *undo gender*. While it is now recognized that a universal "homosexual" identity does not exist, early studies in the sociology of sport, which examined "lesbian" and "homosexual" experiences in sport, provided an important step in the analysis of sexuality and sport. They served as strategic and anti oppressive scholarship that brought the experiences of lesbian and gay athletes out of the sports closet.

More recently, scholars using cultural geography have examined how heteronormative

spaces of sport are a determinant of homosexual experiences. This research demonstrates that normative sport spaces can be disrupted through lesbian and gay presence. Scholars have particularly focused on the Gay Games as a potential site for queer disruption, despite some concern that the forces of commodity have coopted and normalized them. Likewise, recent decisions by the International Olympic Committee (IOC) to allow transsexual athletes to compete in the Olympic Games have garnered the attention of sports sociologists. The IOC's decision appears to acknowledge the continuum of sexualities espoused by queer theorists, and might be heralded as a move forward in human rights in relation to sexuality and sport. However, scholars are closely examining the regulations and requirements concerning transsexual athletes with respect to how this discourse remains embedded in the two sex/gender classification system. While the IOC appears to be recognizing transsexuals' rights to participate, scholars are skeptical that these policies will disrupt heterosexualized international sports.

While the homoerotic potential of men's sport has been explored, there is relatively little work on the homoerotic potential in women's sport. This is not surprising given that women are usually represented as objects of desire rather than desiring subjects. Overall, scholarship on lesbians and sport has de eroticized lesbian desire by presenting a non threatening image of lesbians to promote full inclusion as athletes and coaches. However, scholars increasingly recognize that this approach misses an important opportunity to challenge the constant affirmation and production of heterosexual desire in women's sports. At the same time, queer theorists call for new approaches that celebrate the body and acknowledge that sport is inherently erotic and sexual. However, sport as a cultural and social institution has set limits on the body and its desires and established boundaries that close off the possibility for pleasure and erotic desire (Pronger 1999). Scholars are exploring how these boundaries can be disrupted to create a physical culture in which Eros, rather than rationality, is celebrated. Currently, they are aware that the sexual objectification of women in sports; the sexual harassment of women, girls, and young boys in

sport; the shame associated with homosexual abuse in men's sport; and the use of sexual games in ritualistic team hazing have been profiled in the media in ways that make people fearful of sexuality and the sexual and erotic potential of sport.

Despite the contentiousness of these issues, researchers continue to analyze the ways in which all forms of sexuality and gendered performances can be celebrated in sport in ways that do not ethically exploit, oppress, or cause harm to other beings.

Shadow Work (Ivan Illich)

Nicholas DeMaria Harney

Shadow Work (1981), written by the polymath ex Catholic priest Ivan Illich (1926–2002), critiques what Illich sees as the contrived structures of desire present in modern commodity intensive society. Shadow work refers to the “unpaid servitude” modern people tolerate to satisfy the desires that experts suggest they need. *Shadow Work* extends his earlier critiques of the way institutions and professions in the modern industrialized world dehumanize by creating needs and controlling the satisfaction of those needs. In a series of polemical books written in the 1970s, Illich argued that there was a tendency for institutions to develop in ways opposite to their original intent. For example, in *Deschooling Society* (1973) he argued that contemporary educational practices discouraged learning, and in *Medical Nemesis* (1976) care was neglected by the organizational imperatives of medical experts and institutions. He developed the principle of counterproductivity to label the transformation of a potentially positive ideal into a negative institutional arrangement because of the undesired externalities that came with the process of institutionalization. Illich was concerned with how technological advancement and “development” might work to destroy convivial human relationships, the human spirit, and the environment. In addition to critiquing modern institutions, experts, and expert knowledge, Illich critiqued the commodification of activities, transforming, for example, knowledge and learning into a possession rather than a way of being in the world.

Shadow Work followed on from *Towards a History of Needs* (1977) to evaluate how powerful groups created a “radical monopoly” over the satisfaction of human needs that these professionals defined for the public. *Shadow Work* connects the historical development of the commodification of speech by the standardization of a mother tongue at the expense of vernacular language and the destruction of the real, experiential learning inherent in everyday

communication and speech with the emergence of a shadow economy. The professionalization of language for Illich opens up a realm of unpaid contributions that people make to manage society at the expense of vernacular domains, domains of subsistence and mutual self help. This shadow work includes students cramming for exams, housework, commuting to work, shopping, and the myriad ways people prepare for, consume, and comply with professionally mediated services.

Illich’s critique of the modern commodity intensive society’s substitution of exchange values for use values echoes Marx, Carlyle, and Polanyi in that he argues against any sense of the market or scarcity as “natural,” rather that they are the result of choices. For him, commodity intensive societies transfer people’s autonomy and independence to rights guaranteed by techniques, tools, and arrangements offered by professionals and the desires they create for society. To combat this alienation, Illich suggests that people develop “vernacular values” based on reciprocity outside the market, subsistence, pragmatic restraint, conviviality, and autonomy to use technology and organize society to encourage greater liberty. Perhaps because much of Illich’s work is polemical and he draws on a remarkable range of sources, he is not much cited today. Nevertheless, his work has relevance for the hypermediatized twenty first century and contemporary research on non monetized and non commodified spaces in the globalizing world.

Shariati, Ali (1933–77)

Bryan S. Turner

Born in Mazinan, a desert village in the north eastern province of Iran, Ali Shariati was a leading Iranian sociologist and Muslim intellectual, who published a number of influential books and a great volume of lectures, talks, and occasional articles. He contributed to the sociology of religion, but apart from his *On the Sociology of Islam* (1980a), his work is not widely known in western social science.

Shariati, who was greatly influenced by his father, a scholar and religious teacher, attended a teacher's training college and came into contact with young people from poor social backgrounds. As a student he became active in the nationalist movement of Mohammad Mossadeq, and, having received his bachelor's degree in 1959 from Mashhad University, he pursued graduate study in France, receiving his doctorate from the Sorbonne in 1964. On returning to Iran, he was briefly imprisoned on charges relating to his political activities in France. He began teaching at Mashhad University as an assistant professor of Islamic history, where his original interpretations of problems facing Muslim societies gained him a wide student audience. In 1967 at the invitation of Ayatollah Motahhari, he transferred to Tehran where he lectured at the Housseiniye Ershad Religious Institute, attracting even larger audiences. He was again imprisoned but popular and international pressure eventually secured his release in 1975. He remained, however, under close surveillance by SAVAK (the Iranian Security Agency). Shariati had many enemies but he was supported by Ayatollah Khomeini, and consequently he had a significant impact on the

Iranian Revolution. Because his movements were severely restricted, he migrated to England, but he was found dead in his apartment three weeks later in June 1977. It was generally assumed that he had been murdered by SAVAK agents (Rahnema 2004).

Along with Ayatollah Khomeini and Ayatollah Motahhari, Shariati was one of the principal architects of Islamic revolutionary thought as a direct response to the ideology of modernity, and as a challenge to the modernization policies of the Pahlavi dynasty (Chehabi 1990). During the reign of Mohammad Reza Pahlavi (1941–79), the overwhelming ambition to suppress communism meant that there was relative tolerance of Islamic discourse. In the 20 years before the Islamic Revolution, Islamic associations flourished among intellectual groups, and the urban population tripled and religious societies among the urban poor provided an important political network.

Shariati was intellectually influenced by both Marxism and radical Shi'ite theology. He was a critic of modernization, which he believed was a sinister means of seducing non western communities into modernity. In order to export their own commodities, western powers have to destroy the self sufficient domestic economy of traditional societies, and hence western modernity destroys traditional patterns of consumption. Although there are many critics of western imperialism, Shariati developed a deep and sophisticated understanding of the alienation of the self, or in his terms the "emptying" of the self, in which consumerism under neocolonial conditions brings about the eradication of cultural traditions and produces the authenticity of the self.

Shariati placed a substantial emphasis on the revolutionary role of intellectuals in defending culture against western consumerism, but he also criticized them for their distance from the mass of the population. In his book *Fatimah is Fatimah* (1971), he supported intellectuals in their quest for freedom and equality for the masses, but he condemned them for departing from their traditional religious roots, excoriating them for becoming "modernized pseudo intellectuals." In his *The Intellectual and his Responsibility in Society* (1972), Shariati rejected secularism as a philosophy of the intellectual

class, because religion, outside the West, is a bulwark against imperialism. Although the West had achieved modernity as a result of the Enlightenment, each society must find its own enlightenment in terms of its own culture and tradition. The West had imposed the Enlightenment without respect for the integrity of other cultures and its universalism had become a form of cultural imperialism. Intellectuals had to recognize the problem of living in what Shariati called a “dual society” in which only a small elite became modernized, leaving the mass of society in a state of poverty and disempowerment. For Shariati in *Whence Do We Begin?* (1975), only the religiously motivated intellectuals could bridge the gap between the educated, secularized elite and the masses.

The analysis of the self and subjectivity was central to Shariati's philosophy (Vahdat 2002). Shariati's sociotheology exhibited a tension between insisting that human free will is the defining characteristic of humanity and arguing that human subjectivity presupposes submission to God. Shariati tried to solve this dilemma by interpreting human existence as a journey away from material existence to a spiritual life. Humans are alienated in nature rather than from nature, and the spiritual life requires the radical subordination of the body to a spiritual purpose. The natural body is a “desolate abode” or a prison from which human beings must escape in order to realize their true essence. Contempt for the body is a precondition of the journey toward authentic subjectivity. Shariati recognized that this solution would always be partial and that human existence was a perennial conflict between autonomy and submission that he described as a condition of human bewilderment.

While Shariati was critical of Marx's sociology in his *Marxism and Other Western Fallacies* (1980b), he also borrowed extensively from Marx's vocabulary to describe this human bewilderment. Shariati was, like Marx, opposed to the liberal notion of individualism, and emphasized collective, not individual, agency. Islam recognized the agency of the mass of ordinary people, and Shariati developed the revolutionary proposition that the voice of the people is God. It was through this revolutionary theology that he came to affirm the needs of the “disempowered” – the mass of the population who suffered directly

from colonial exploitation and marginalization. It was to the salvation of the disempowered and the cancelation of the forces of oppression that the message of the Qur'an was directed. Although Shariati emphasized the moral responsibility of the individual, the revolutionary role of Islam, the political responsibility of the intellectual, and the sovereignty of the people, he did not in his major political text, *Community and Leadership* (1979), advocate popular democracy, but instead he adumbrated the role of the charismatic imam who is neither elected nor selected.

Shariati's thought was a major intellectual contribution to one of the most significant revolutions of modern times. The originality of his thought was to combine existentialism, Marxism, and Islamic thought to produce a comprehensive criticism of western imperialism. Shariati developed a normative critique of modernization that emphasized the negative consequences of consumerism on an agrarian society under the control of an authoritarian government.

Shintoism

Tsuyoshi Nakano

Although there is no widely accepted definition of Shintoism even among Japanese scholars, the term could be defined tentatively as a Japanese traditional religious system based on so called "Shinto." Shinto is generally believed to be indigenous to Japan. The term was coined by the combination of two words from Chinese – *shin*, originally from the Chinese character for "divine beings" or "gods" (*shen*), and *to*, originally from "way" (*tao*). Therefore, the literal meaning is "the way of the gods," which corresponds to the native Japanese reading of the term, *kami no michi*, or *kannagara no michi*. The term Shinto (*kami no michi*) first appeared in *Nihon shoki* (Chronicles of Japan compiled 720 CE), together with the term "Buddha's law," *hotoke no minori*. This was done in order to consciously designate traditional forms of worship of the emperor, which were inherited from ancestors, as these related to *kami* (god or gods; the same character as *shin*) and not to Buddhism. This indicates the large influence that rivalry with Buddhism had in the creation of the Shinto tradition from the outset.

Nevertheless, there are various theories concerning the establishment of Shintoism as a relatively independent religious system. One suggests the establishment of a centralized system of governance based on the legal codes of ancient Japan in the seventh or eighth century (Inoue 1998), and another holds that the idea of Shinto as an independent religion scarcely existed before the Meiji Restoration (Hardacre 1989). In any case, the Shinto tradition became an important religious source that was connected to agricultural rituals and festivals at the community level, and rites of passage at the personal level. Shinto is understood to have been a major religious and cultural influence that has provided a unique value orientation for the Japanese people. Therefore, in order to understand the divergent and yet uniquely Japanese sensitivities, attitudes, and mentalities of people and communities, a recognition and understanding of Shinto is essential.

According to statistics compiled every year by the Division of Religious Affairs of the

Japanese Ministry of Education and Science based on reports from each religious body, at the end of 2001 the number of religious corporations (officially certificated and registered under Japanese law) related to Shinto was about 85,000, 46.7 percent of the total figure (Buddhist temples numbered over 77,000, 42.5 percent of the total; Christian churches 4,337, 2.4 percent of the total). Shinto adherents accounted for about 106,000,000, i.e., 49.7 percent, of the total number of religious adherents in Japan (Buddhists 95,000,000, 44.5 percent; Christians 1,800,000, 0.4 percent). The total number of religious adherents was twice that of the actual population of Japan, which means that most people are counted twice, by a Shinto shrine and by a Buddhist temple in each area. This kind of mixing of Shinto and Buddhist religious traditions is indicative of the traditional religious life of many Japanese people.

The National Police Agency also reported that nearly 90,000,000 Japanese visited a shrine on New Year's Day in 2004. According to more detailed public opinion surveys conducted by scholars and various newspapers, the percentage of respondents who said they visited a shrine on New Year's Day was 56 percent in 1979 and 61.7 percent in 1994. However, the rate of those who "believe" in Shinto was only 3.3 percent in 1979 (*Yomiuri Press*), and 4.4 percent in 1995 (*Fiji Press*). This indicates that Shinto in general is a religion of participation in traditional rituals and festivals at shrines, and is not a religion that constitutes an articulated system of beliefs, doctrine, and ethics.

The shrine (*jinja*) precinct is a sacred area with a gate (*torii*), ablution area, and sacred buildings, including the main sanctuary, which houses the symbol of the *kami* (*shintai*) and a worship area (*haiden*). At special times through the year, shrines become the focal point for community festivals (*matsuri*), which are held according to the tradition of each shrine in honor of its own *kami*. Nevertheless, there are also many common festivals, such as the Spring Festival (*Haru matsuri*), Autumn Festival (*Aki matsuri*), and the like. As individual rites of passage, family members sometimes visit the local shrine. After birth, for example, an infant is taken to the local shrine in order to be acknowledged and celebrated as a new member of the village or the community by its tutelary

deity (or the local guardian god). Further celebrations include the Seven, Five, and Three Festival (*Shichigosan*), at which boys of 5 years of age and girls of 3 and 7 years of age are brought to the shrine. In addition, marriage rites are performed at shrines, though they are becoming less popular among the younger generation. Shinto is a “this worldly” religion in the sense that it is interested in tangible benefits which will promote life in the human world.

The origin of basic forms of Shinto worship of gods is obscure. There is no founder, no sacred scriptures, nor any fixed system of doctrine. Instead, Shinto seems to originate from simple worship of *kami* (gods), with rituals developing when people began to settle down to grow rice in the Yayoi era from 300 BCE to 250 CE. At least by the early historical period (third century CE), the clan (*uji*) system formed a certain ancestral worship, which was worship and rituals performed for gods of personal clans (*ujigami*). People also believed in other spiritual powers and beings which had the *kami* nature. Some *kami* were connected to specific geographical areas or lands; others were believed to reside within living beings and phenomena such as the sun, the moon, mountains, trees, thunder, fire, and wind. This religious culture was based on a kind of animism that prevailed in various parts of the world since ancient times. Shamans and diviners were regarded as important figures in operating and controlling these divine powers. The imperial (*tenno*) clan eventually gained power over other clans, especially in terms of rites and festivals that were connected with rice growing. Its supremacy could be attributed to a kind of shamanistic power, and following the famous work of Sir James Frazer, Japanese anthropologists agree that the Japanese emperor could be regarded as a shaman king or “priest king” in origin.

Although each clan continued to maintain its own forms of ancestor worship and myths of origin, as the imperial clan gained greater supremacy its myths also gained ascendancy. These provided the dominant motifs into which the myths of the other clans were integrated. By the eighth century, these myths were collected and edited as two well known volumes, *Kojiki* (Records of Ancient Matters)

of 712 CE and the above mentioned *Nihon shoki*. These volumes laid important foundations for various ideas and themes of the cosmological view in Shinto. The universe was divided into three levels: the Plain of High Heaven (*Takama ga hara*); this Manifested World on the Earth (*Nakatsu kuni*); and the Netherworld (*Yomotsu kuni*). Moreover, beliefs in the creation of the world by *Izanagi* (male *kami*) and *Izanami* (female *kami*), the dominance of the sun goddess *Amaterasu Omikami* and the descent of the imperial line from *Amaterasu*, and in forces of life, fertility, pollution, and purification were established. The basic Shinto practices, dances, and chanting of *norito* (prayers) were formed in accordance with these myths as well. While the details of these themes are unique, they share a common structure with other typologies found in the Andromeda, Perseus, Oedipus, and Orpheus myths from ancient Greek mythology.

These records also indicate the hegemonic position of *Amaterasu Omikami*, and the myth that the imperial line directly descended from the sun goddess gradually became prominent. In addition, although the indigenous nature of Shintoism is often emphasized, it is obvious that Shintoism has transformed and hybridized with other religious traditions throughout history. This was particularly evident with its amalgamation with Buddhism and Confucianism, which became the ideology that legitimized the ruling of Japanese feudal societies by the imperial family. According to *Nihon shoki* and other sources, Buddhism was first officially introduced from Korea in the sixth century CE, and Empress Suiko declared she would adopt Buddhism as the principle of governing the country in 593. This was partly because it was regarded as having magical religious powers that would help govern the people and guard the nation. In this process of introduction, opposition, and amalgamation with Buddhism, Shinto itself became conscious of its own originality and tried to describe and develop its myths, forms of ritual, and certain doctrinal themes. The making of Shintoism as a religious system in Japan was formed through this process.

At the folk or community level, this syncretism is deeper and more intricate. In festivals and celebrations in traditional villages, a

division of religious functions developed, with Buddhist temples usually taking charge of rituals relating to death such as funerals, while Shinto shrines were responsible for festivals, rites of passage, and agricultural rituals.

In spite of the National Seclusion policy in the Edo period (1603–1867), knowledge and information about western scholarship and science gradually filtered into Japan, especially after 1720 when Tokugawa Yoshimune (the shogun) lifted the ban on the importation of foreign books. By the early nineteenth century, Dutch studies (*rangaku*) and western studies (*yogaku*) were widely read throughout Japan.

At the beginning of the nineteenth century, as the School of National Learning (*Kokugaku*) emerged and then developed into Revival Shinto (*Fukko Shinto*), Shintoism was given more social importance not as a religion but rather as a political ideology. In the works of Hirata Atsutane, who emphasized a return to Shinto's original traditions, most religions such as Buddhism and Christianity were thought of as foreign. He and his contemporaries sought to discover an "original" Japanese religious tradition. As some of their ideas derived from other religious traditions, however, "original" tradition in this context should be understood as a result of cultural contact with other traditions and not as a purely original Japanese idea. Revival Shinto asserted that Shinto should return to its former position as the fundamental principle guiding the nation. Nevertheless, Revival Shinto can be seen as an expression of, or a reaction to, a cultural and colonial crisis brought about by the increasing influence of the West. This laid the foundation of a sweeping conservative anti foreign movement, which gathered under the slogan "revere the emperor, expel the barbarians" (*sonno joi*).

By the Meiji Restoration in 1868, the Tokugawa shogunate was dismantled and replaced with a limited representative and monarch system under the Meiji Constitution (promulgated in 1889). Japan began building a modern nation state partly to counter the colonizing threat posed by the West. The state's involvement in Shinto affairs increased and the formation of so called State Shinto began. State Shinto was in a sense different from Shinto as it had originally developed. Although it included aspects of Shinto mythology and

incorporated Shinto institutions and practices, the newly established Meiji government essentially invented State Shinto as a means to legitimize governmental authority and unify the people. The government incorporated all Shintoist rituals and observances and ordered all citizens to observe them, thus utilizing Shinto ceremonial events to promote nationalism. Thus State Shinto was a type of new national religion introduced by the government after the Meiji Restoration. However, the government itself did not regard State Shinto as a religion but as the Japanese "national cult" – one that included religious ideology and rituals and surpassed all other religions.

In addition, the qualifications of the emperor as head of state and his rights as sovereign did not have their source in the Constitution, although the form of government was a kind of constitutional monarchy according to its provisions (Chap. 1, Art. 4). The Imperial Precept on the Promulgation of the Constitution declared: "The rights of sovereignty of the State, We have inherited from Our Ancestors." It was stressed that these rights had been derived neither from the people nor from the Constitution, but from an institutional charisma of a "lineal succession unbroken for ages eternal." Moreover, the stipulation in Article 3 of the Constitution that "the emperor is sacred and inviolable" granted the emperor a sacred, transcendental character. Thus the emperor possessed a mystical authority as a kind of divine king, or as the highest priest of the state, as well as possessing secular powers as sovereign of the state and as supreme commander of the military forces.

This politico religious ideology was derived from an extreme interpretation of Shinto mythology, according to which the emperor was regarded as having descended from the supreme ancestral deity, the sun goddess *Ama terasu*, and was regarded as its manifest deity (*Akitsu kami*). This idea was based on, first, the assertion that the emperor, the land, and the people of Japan constituted one sacred invisible entity, and second, a system of related teachings, Shinto institutions, practices, and rites known as State Shinto, or National Shinto as it was called by the Allied Powers (Bunce 1948), or, as designated by W. P. Woodard (1972), a national cult.

Thus, the structure of the Japanese state as a whole was signified mystically or religiously by the ideology of the emperor system, and the government sought unification of the people in the nation and sought to control even their everyday religious life by utilizing this mystic ideology through State Shinto.

SHINTOISM SINCE 1945

On August 15, 1945, the Japanese government accepted the Potsdam Declaration of the Allied Powers and surrendered unconditionally. This defeat in World War II and the reform of the whole Japanese society through the Occupation by the Allied Powers led to radical changes in Japanese religions, especially in Shinto and its relation to the state.

The first directive relating to reform of the religious system, issued by the Supreme Commander for the Allied Powers (SCAP), was the so called Civil Liberties Directive of October 4, 1945. In order to realize the objectives of freedom of thought, speech, religion, assembly, and respect for fundamental human rights, it required the abrogation and immediate suspension of the operation of all provisions of laws establishing or maintaining restrictions on those rights. However, the more important directive was the so called Shinto Directive of December 15, 1945, which ordered clearly and in a shocking way the "abolition of State Shinto" and the "complete separation of religion and state."

The purpose of this directive was clear, namely, "to separate religion from the state, to prevent misuse of religion for political ends, and to put all religions, faith, and creeds upon exactly the same legal basis, entitled precisely to the same opportunities and protection." It forbade "affiliation with the government and the propagation and dissemination of militaristic and ultra nationalistic ideology not only to Shinto but to followers of all religions, faiths, sects, creeds, or philosophies" (Shinto Directive, Article 2a). It therefore forbade "the sponsorship, support, perpetuation, control and dissemination of Shinto" by the state, abolished the Shrine Board (*Jing'in*) of the Ministry of Home Affairs, which was the representative agency of State Shinto within the administrative

structure of the government, and prohibited all Shinto education and rites in educational institutions supported wholly or in part by public funds, the attendance of public officials in shrine worship or any other Shinto observances, and the use in official writings of terms with State Shinto, militaristic, and ultra nationalistic connotations. In short, this meant in a very direct way the abolition of State Shinto and the disestablishment of state religion.

According to the policy, the Peace Preservation Law, in accordance with which many leaders of new religions had been thrown into prison during the war, was abrogated. The Religious Organizations Law (*Shukyo dantai ho*), which had been another instrument designed to restrict religious freedom, was replaced by the Religious Juridical Persons Ordinance (*Shukyo hojin rei*, Imperial Ordinance No. 719), promulgated on December 28, 1945. This ordinance set out working rules for the free establishment of religious corporations by mere registration with the appropriate government body. The laws obstructing religious freedom of religious groups were abolished, and by the amendments of this ordinance on February 2, 1946, even Shrine Shinto, now separated from the state and liberated from its control, was given the opportunity of continuing its existence as an ordinary religious corporation. Thus "equality of all religions before the law," which was one of the objectives of the Shinto Directive, became a reality. Finally, on November 3, 1946, the new Constitution of Japan was promulgated, coming into effect on May 3 of the following year. It codified "freedom of religion" and "separation of religion and state" in Articles 20 and 89.

The reform of the religious system by the Occupation administration effected great changes in Japanese society and religion. First of all, it brought about secularization of the Japanese state. Although the imperial system was retained, the emperor was no longer the head of the state nor the source of legitimacy for political rule, but was now regarded as a symbol of the unity of the whole nation. The new Constitution became the source of law and authority. For the first time, Japan became a constitutional democracy. The religious or mystical character of the state was disposed of, and

freedom of religion was established as a “basic human right.” In this free and democratic society, Shintoism continues to exist in several different forms:

- 1 Shinto of the Imperial Household (*Koshitsu Shinto*) focuses on rites for the spirits of imperial ancestors and is observed at imperial institutions. It is distinguished from other forms of Shinto partly because the emperor himself performs its ceremonies, and partly because it is believed that it retains the most archaic style of Shinto worship. But this Shinto is not open to the public.
- 2 Shrine Shinto (*Jinja Shinto*) is presently the form of Shinto that embraces the vast majority of Shinto shrines and adherents in Japan, administered by the Association of Shinto Shrines (Jinja Honcho). It is the most popular system of Shintoism now in Japan, which is upheld in a great many and varied local shrines with seasonal rituals and festivals held in honor of kami. It continues to emphasize the traditionally close relationship between Shinto and Japanese life and the need for national regeneration.
- 3 Sect Shinto (*Kyoha Shinto*) refers to 13 religious organizations which originated from new Shinto movements that arose from the social and economic distress toward the end of the Tokugawa period and the beginning of the Meiji period. They were mostly founded by charismatic figures and promised worldly benefits, such as wealth, success in life, and cures for sickness. Because the Meiji government did not want to incorporate these groups into the structure of State Shinto, it created a new classification of Sect Shinto, eventually recognizing them as offshoots of the mainstream Shinto tradition. Groups such as Kurozumi kyo, Fuso kyo, Ontake kyo, Konko kyo, and Tenri kyo belong to this category.
- 4 Folk Shinto (*Minkan Shinto*) is a designation for the wide ranging groups of superstitious, magico religious rites and practices of the common people, embracing conceptions of spirits and souls, good and evil kami, divination of lucky or evil direction, and unlucky days. Folk Shinto does not

stand in opposition to Shrine Shinto or Sect Shinto but might be considered as the substratum of those more organized forms.

PROBLEMS INVOLVING SHINTOISM

The post war reforms established the principles of freedom of religion and the separation of religion and state. These principles have been widely accepted, for people remember how freedom was suppressed under State Shinto before and during the war. But with regard to their interpretation, questions have arisen as to whether “separation” is an absolute or relative term, to be understood as an end in itself or as a means of affirming religious freedom. There are a number of issues concerning the relationship between the state and religion, especially relating to Shintoism, in the post war period.

State Support for and Official Worship at the Yasukuni Shrine

Before and during World War II, the Yasukuni shrine was an important national institution particularly for promoting hero worship and strengthening the fighting spirit of the nation. Enshrined within it are the spirits of many soldiers who died in war for the emperor or for the state since the Meiji period. Occupation policies dictated that the shrine be stripped of its militaristic elements and completely separated from the state. Consequently, the Yasukuni shrine was forced to sever its ties with the state yet it continued to exist on the same legal basis as other religious bodies, as one religious organization among others.

But with the peace treaty and the restoration of independence at the end of the Occupation in April 1952, a movement calling for state support to reestablish a special status for the Yasukuni shrine began. By the end of 1974 a bill supporting public funding of the shrine had been submitted unsuccessfully to the Diet on five separate occasions. Proponents of the movement eventually changed their strategy, and they began to lobby for the emperor and state officials to worship (*sanpai*) at the shrine in their

official capacity, for foreign envoys to pay their respects, and for representatives of the Self Defense Forces to offer formal worship there. In these and other ways, proponents sought to give people the impression that the shrine was already a *de facto* public institution, that is, a religious institution with special ties to the state. It was in this context that the movement for "official visits" (*koshiki sanpai*) emerged.

The event that particularly drew people's attention to the issues occurred on August 15, 1975, the thirtieth anniversary of the end of the Pacific War, when the then Prime Minister Miki Takeo visited the Yasukuni shrine. Although some of his predecessors had visited the shrine while in office, this visit was especially important as it highlighted two crucial issues: (1) whether it constituted a religious action by a government official that violated the Constitution, and (2) the complex problem of evaluating the war. Prime Minister Miki emphasized that he visited the shrine in a private capacity, but it is undeniable that his action opened the way for subsequent official visits. Thus it was that a later prime minister, Nakasone Yasuhiro, who was emphasizing the "end of the post war period," made the first official visit to the shrine on August 15, 1985. He signed the register as "Prime Minister of the Cabinet" and made a donation of 30,000 yen from public funds.

Nakasone's visit provoked an unexpectedly strong barrage of protests from China and other Asian countries, and official visits to the shrine ceased for a time. However, Prime Minister Junichiro Koizumi reestablished this practice again on August 13, 2001, and since then has visited each year. Needless to say, a loud chorus of criticism against these visits arose from many Japanese people as well as other Asian countries, especially from China and Korea. It was even judged to be unconstitutional by the Fukuoka district court on April 7, 2004.

Although these visits ignited disputes over the distinction between the prime minister as a public figure or a private citizen and whether donations to the shrine's coffers constituted a religious act or were simply a matter of conventional etiquette, the more pressing issue is whether these visits give preferential treatment to one religion over others and serve to accord the shrine the status of a national institution. Moreover, these actions by leading conservative

politicians are closely associated with the rise of religious nationalism in Japan, particularly when the Japanese Self Defense Forces were being sent to Iraq and other areas.

The Emperor and Shinto Rituals

The post war system that assigned a purely symbolic status to the emperor gave rise to yet another type of debate and lawsuit. In connection with the mourning service (*taiso*) held for Emperor Showa on February 24, 1989, questions arose as to the degree to which this ought to be a state ceremony. In order to forestall constitutional misgivings, it was finally decided that the *Taiso no gi*, a Shinto service of mourning for the emperor, would be carried out as an Imperial Household ceremony, but that the *Taiso no rei*, a separate Shinto rite, would be carried out as a secular state ceremony. A similar division was employed on November 12, 1990 when the new emperor's *Sokui no rei*, or Enthronement Ceremony, was handled as a state ceremony and the subsequent *Daijosai*, or Great Food Offering, as a private ceremony based on the Shinto of the Imperial Household. The central question in all these matters was the extent to which a rite could be a state ceremony without violating the principle of separation of religion and state.

A closely related question giving rise to intense debate was whether the *Daijosai* should be paid for with private funds from the Imperial Household's internal budget (*naiteihi*) or with public funds from the Imperial Palace budget (*kyuteihi*). The government, recognizing the religious character of this rite, decided that it would be an Imperial Household ceremony. But the government also recognized the "public character" of this rite and chose to use public funds from the Imperial Palace budget. This decision struck a balance between upholders of tradition, who wanted it to be a state ceremony, and public opinion, which called for strict application of the principle of separation of religion and state.

There are many other lawsuits that contest allegedly unconstitutional action on the basis of the principle of separation of religion and state. Most of these lawsuits, however, have to do with issues that grew out of pre war and

wartime State Shinto. One issue concerns the extent to which a religious organization is autonomous and the extent to which it is subject to judiciary intervention. The lawsuits mentioned above show clearly that the principle of separation of religion and state introduced by the Occupation has not taken firm root in Japan, and has yet to find a harmonious balance with traditional Japanese culture.

shopping

Sharon Zukin

As the public face of consumption, shopping includes an array of social, economic, and cultural activities connected with consumers' selection and procurement of goods and services. In contrast to consumption, which, historically, is synonymous with satisfaction of basic biological needs, shopping is a distinctly modern ensemble of actions, perceptions, and emotions. Shopping develops in a money economy, on a sophisticated industrial base, along with the integration of local places into larger markets providing a range of innovative, and often exotic, product choices. Choice is, indeed, a keyword of shopping, for the process of identifying needed or desired products and selecting among them magnifies the role of individual decision making and taste. But collective norms and pressures are equally important. Whether the parameters of a man's, a woman's, or, increasingly, a child's shopping are set by money, access to information, or the example set by their peers, shopping expresses both individual desires and collective dreams.

Since Walter Benjamin (1999) wrote about the Parisian arcades, or mid block shopping galleries, of the 1840s, social and cultural theorists have understood shopping to be an experience that envelops individuals in dreams of commodities. The physical sensation of being surrounded by goods, with their evocation of exoticism and novelty, suppresses criticism or rebellion; the design of the shopping space is calculated to impress and overwhelm. But

shopping also provides an experience of sociality – being together with other people – in an apparently public space. Although the main point of shopping is to make purchases for individual use, families and friends do shop together, and age or peer groups meet – and examine each other – in shopping spaces. Shopping for necessities expresses solidarities among family members (especially mother and child) and intimate friends, while shopping in a local community – even among strangers – strengthens bonds of interdependence and place identity. But shopping also poses an implicit conflict. Increasingly under non local, standardized, corporate control, shopping creates a public sphere in which consumers struggle to create an experience that they, themselves, value (Zukin 2004).

Only recently have scholars paid attention to shopping as a serious form of social action. Aside from marketing studies about what people buy and how they respond to the layout of stores, few researchers have suggested an institutional theory of how shopping develops, how it relates to both economy and culture, and how shoppers integrate their shopping experiences with overall ideology.

HISTORY OF SHOPPING

The earliest shopping dates back to ancient empires, when the density of residents, division of labor, and economic surplus in towns enabled them to establish marketplaces for exchanging the products of local farmers, urban artisans and craftspeople, and long distance traders. Merchants gradually became a separate occupation from either traders or craftspeople; they kept a fixed stall at the market and, eventually, an indoor shop. After centuries of providing a limited range and number of products, some merchants used the emerging industrial system of mass production and access to bank credit to offer many different kinds of merchandise under one roof. Like the increasingly complex organization of the state, the nineteenth century department store integrated a variety of specialized functions, and offered shoppers a world of goods.

Historically, shoppers have gone out to markets or stores, and come into direct contact

with displays of goods to buy, as well as with merchants and other shoppers. But since the mid nineteenth century, technological innovations, often supported by the state, have made it possible to view goods or images of goods at home, purchase them, and arrange for their delivery, all without going out in public. Beginning in the 1870s in the United States and Western Europe, mail order catalogs connected retailers and warehouses in cities at the hub of transportation networks with consumers who lived in remote rural areas. Although individual entrepreneurs established these companies, and were closely linked to both manufacturers and banks, they depended on the state run postal service to ship catalogs and on the railroads to transport goods. In the early 1900s regular parcel post deliveries throughout the USA encouraged the expansion of the mail order business, while the widespread use of telephones enabled shoppers to place orders by calling, rather than visiting, local stores. By the 1970s, another pair of innovations – bank issued credit cards and toll free “800” telephone numbers – set loose an explosion of long distance shopping, although it also increased consumer debt. And, by the 1990s, the diffusion of personal computers and public access to the World Wide Web allowed shoppers and stores to form a truly virtual, global market.

Even with “bricks and mortar” stores, the diffusion of automobile ownership and the construction of roads and highways during the twentieth century decentralized shopping as never before. Cars permitted shoppers to travel longer distances and transport a larger number of purchases on each shopping trip. Because new, post World War II homes had modern refrigerators and roomy kitchen cabinets, shoppers were freed from the necessity of daily provisioning. By the same token, most postwar housing was built in suburbs that were zoned only for residences, which made shoppers dependent on automobile transportation for weekly shopping trips. These trips became family outings, and although they offered relief from the monotony and lack of public interaction that were typical of suburban life, they subjected family members to the routinization of supermarkets, chain stores, and ever larger shopping malls. Malls became, in effect, the most widely used public space in suburbs – even though they were privately owned and

controlled, separated from streets by parking lots, and usually located in places accessible only by car.

Just as stores are compelled to respond to shoppers' changing needs and wants, so they also respond to rising costs of labor. For this reason, the clerks who served shoppers in traditional stores were gradually replaced, from the early 1900s, with self service. Although steady customers in exclusive stores may still expect to be served by a salesperson who keeps track of their preferences, shoppers in most stores see all the merchandise displayed on shelves, racks, or counters before their eyes, feel and try on products without either help or interference from the staff, and carry their intended purchases, themselves, to central checkout lines. In some ways this makes shopping a more democratic experience, but it results in shoppers' frustration when they can't find what they want or need information. Transparent packaging, universal bar codes, and automation have also helped to reduce stores' labor costs while further routinizing the shopping experience.

TYPES OF STORES

From the earliest times, marketplaces have been bazaars of commercial display, theaters of social interaction, and even carnivals of transgression where men and women assume roles that may be unrelated to their everyday lives. Partly this reflects the magic that one perceives in desired objects to transform our lives, and partly it reflects the magic of a special place – the market – where strangers mingle, exchange information, and seek entertainment. By the late nineteenth century, the more carnivalesque or raucous aspects of markets had been tamed; not only did most shopping occur indoors, in stores, but corporate ownership, policing, and a greater number of middle class women shoppers contributed to a more rigorous, though implicit, regime of social control. At the same time, the emergence of fixed prices, introduced by F. W. Woolworth's five and dime stores, eliminated the need to bargain and, in a sense, defined modern shopping. Elements of older market places nonetheless survived in specific forms: public or farmers' markets, flea markets, and fairs.

During the nineteenth century, department stores, five and dimes, and mail order catalogs created paradigmatic forms of shopping. Each brought an unprecedented array of products to large numbers of consumers and made shopping something of a universal experience. Unlike previous kinds of stores, including general or country stores, from which rural residents – mainly farmers – bought supplies, department stores, five and dimes, and mail order catalogs catered to all social classes and ethnic groups, and treated them entirely as consumers rather than as producers. But the face to face interaction in stores did enforce social distinctions – often with terrible cruelty. Before the civil rights laws of the 1960s, department stores, especially in the South of the United States, would not permit black shoppers to try on clothes, and five and dimes restricted seats at their lunch counters to whites. Even now, salespeople in high status stores may snub men and women of lower social classes. To avoid these everyday kinds of discrimination, some shoppers have always preferred to use mail order catalogs or, these days, they shop on the Internet.

From the late nineteenth century, department stores expanded, modernized, and democratized the sense of luxury that shoppers had earlier experienced in small, custom shops and arcades (Leach 1993). They were the first big, multi floor stores, and were usually located in the busy centers of cities' commercial districts, close to mass transit lines. Department stores borrowed theatrical techniques to heighten the aesthetic and emotional experience of shopping, dramatizing both window and interior displays with electric lights, colorful décor, mannequins, and tableaux. They also sought the collaboration of art museums in devising model rooms and special exhibitions. Not only were department stores visual feasts, they also kept shoppers in motion. Escalators brought them up to less traveled departments, giving them a view of merchandise on each floor as they passed by. And in some department stores, shoppers descended to a "bargain basement" where especially low priced goods were sold.

Department stores established special amenities to welcome women shoppers and to keep them longer in the store – from non alcoholic tearooms and spacious rest rooms to fashion shows and infants' clothing departments. While

women pressed for greater independence and the right to vote, department stores offered them a safe public space that they could use without being accompanied by men. This was especially important for women of the middle and upper classes.

The feeling of being surrounded by goods that could be bought and owned played to shoppers' imaginations. But if department stores were "dream worlds," as Rosalind Williams (1982) calls them, they relied on a strict, hierarchical business organization, with well paid male merchants and managers at the top and low paid, usually female sales clerks and African American elevator operators at the bottom (Benson 1986). The five and dime store reproduced the same hierarchy – and the same dream like experience – for an even broader public of shoppers. Five and dimes featured products that rich as well as poor could buy, all displayed on counters, and all priced at only five or ten cents. These stores helped to create the age of mass consumption for everyone.

The patterns set by department stores and five and dimes were expanded in the twentieth century by supermarkets, which sold many different kinds of food, as well as other goods, under one roof, and shopping centers, which featured an array of specialty shops as well as one or two department stores. By 1960, most Americans regularly drove to shop in these large places that were dominated by national chains, rather than walking to traditional, individually owned, local or corner stores.

During the 1950s, however, a new kind of store altered the shopping experience. To capture shoppers who were concerned about inflation, discount stores offered no frills displays, few services or amenities, and guaranteed lower than usual prices. Dedicated, at first, to only a single category of merchandise – often, household appliances and electronics goods – discount stores soon branched out to include a wide range of products. Wal Mart, which emerged by the 1990s as the largest, most successful discount chain, and, eventually, the largest private employer in the world, built upon the model of both the supermarket and the five and dime. Wal Mart stores charged "low prices always" by holding their expenses down and pushing suppliers to do the same. For the first 20 years, discount stores sold only generic or no name

brands, until Wal Mart changed its strategy and offered nationally advertised brands at very low prices, often because these products were manufactured by low wage workers in China. This shift changed the shopping experience, bringing rich and middle class shoppers into the discount store alongside Wal Mart's middle income base, and made "aspirational" shopping for brand name goods accessible to people of modest means. It is no wonder Wal Mart expanded rapidly through the United States and into Mexico and China, though not without provoking serious complaints about its labor and environmental practices.

In the 1960s a different type of new, small store catered to an emerging group of teenage and young adult consumers. Copied from shops in London and Paris, *boutiques* soon spread to the United States and around the world. In contrast to department and discount stores, boutiques sold only a small range of products, beginning with fashion, and used these products to set out a definite, style conscious point of view. Some boutiques specialized in the expensive clothing of a single, famous, international designer – and were among the first multinational chain stores. But many more boutiques just concentrated on a single kind of product or style, and were especially attractive to the young. During these years of cultural ferment, shopping became a vehicle for differentiating age groups and developing and diffusing "life style," at least in the form of commodities that could be grouped together to suggest a common approach to life. Not just buying the products, but shopping in different kinds of stores became a form of peer groups' self expression.

Reflecting the needs of consumer products companies rather than of consumers, another kind of store – the branded store, selling the various product lines of a single corporation – emerged during the 1980s. The model was set by The Gap, a national chain of moderate price jeans and T shirt shops, which, since the 1960s, had sold products of different suppliers under the manufacturers' labels. A corporate makeover defined a coherent visual identity for Gap stores, and unified all products that they sold under The Gap's own label. At the same time, the chain revised contracts with suppliers, so that all goods sold at The Gap were now identified with the chain rather than with independent

or competing producers. Other stores followed The Gap's example, with Nike developing some of the most elaborate stores to showcase their athletic shoes, clothing, and equipment. Shopping then became an experience of communing with a specific brand, because of either the reputation of its products and designers, or the magic of its name.

Viewing individual consumers as the center of shopping focuses attention on need, desire, and identity as wellsprings of the willingness to shop. Yet every aspect of shopping – from places where people shop and displays of goods to buy, to the status cues of advertisements and the convenience of easy financial credit – is calculated to appeal. Abundance, novelty, low prices, and exclusive styles lure shoppers to loosen their self control and engage in shopping more (Underhill 1999). Branding and creating an emotional experience in the store are bids to get shoppers' loyalty. From stores' and manufacturers' point of view, there is profit to be gained by prolonging shoppers' stay in a "buying mode." For this reason, modern retailers continually develop new amenities and amass a larger assortment of merchandise to engage shoppers and keep them involved. This is the strategy of every shopping site, from activity filled malls to "sticky" retail websites. If shopping is reputed to be an entertainment experience, or promoted as a way of saving time, it is nonetheless exhausting, requires an increasing amount of attention, and intrudes into the privacy of our home. It intrudes as well into public spaces like art museums and Internet search engines, that have been, until recently, a refuge from creeping commodification.

SHOPPING AS A CULTURAL FIELD

Clearly, shopping is more than just an economic exchange of goods, and different from an individual effort to find commodities that express identity, achieve a higher status, or satisfy desire. It is really a cultural field in Pierre Bourdieu's sense (Ferguson 1998), including a range of cultural texts and social institutions. This cultural field is the interface between production and consumption, which helps to create both producers and consumers. Although the shopping experience centers on specific kinds

of stores (or websites), where goods are displayed and bought, the entire field translates the product cycles of manufacturers, messages in magazines and advertisements, and credit policies of states and banks into individual cultural practices. Consumer guidebooks and product reviews play an important mediating role because they present authoritative judgments that legitimize and set rules for shopping, voicing the rational as well as the aesthetic values shoppers pursue. The individual is both socialized to shop and socialized by the activities, places, and texts that make up shopping.

Shopping, then, brings together the micro level construction of individual identity and the macro level development of modernity. This suggests future research focusing on questions that have already emerged about the modern public sphere: implications of shoppers' mobility and fascination with commodities; the uses of shopping in different societies to exclude social groups from, or create common access to, public space; the integration of shopping into rituals of solidarity in families, communities, and localities. As an attitude toward goods that, in a rich society, often emphasizes sensual pleasure and escape from everyday concerns, shopping is often interpreted as a behavior of excess, showing a lack of self control bordering on narcissism. But this judgment neglects the anxiety that accompanies many shoppers' choices: keeping within the rigid limits of a budget, finding a comfortable store, and making the *right* choice.

Psychologists report that an abundance of choices – of products, services, and means of consumption – increases shoppers' anxiety (Schwartz 2004). For sociologists, the issue of choice should suggest research focusing on how the public is formed by the social practices of stores and by the consumer guides and magazines that play the role of cultural intermediaries, as well as on how public policies in a shopping culture are formulated and received.

shopping malls

Lauren Langman

The shopping mall is one of the most important social locations and symbols of contemporary consumer society and its cornucopia of goods. It is typically a “self contained” social environment with an assembly of stores and shops, carts and kiosks, and surely various eateries located in food courts. Shopping malls are the points of intersection between a vast globalized system where the production of highly advertised goods is distributed to individual consumers. They are sites of practices that mediate between the globalized factories and stores that sell the merchandise and individual interactions and identities that are today

ever more dependent on the consumption of “branded” goods (Klein 1999).

Insofar as mall shopping is more frequent than church attendance in the United States and consumerism has taken on a religious hue, malls have often been termed “temples of consumption” (Kowinski 1985). As special places apart from the “ordinary world,” people celebrate the “superior power” of the globalized commodity system through rituals of consumption that affirm their identities and lifestyles, as they pursue beliefs that the “goods life” offers access to simulated heavens on earth.

HISTORY

From the earliest prehistoric times, people have traded goods with each other. With the rise of permanent settlements and merchant and artisan classes, certain times and social places were designated for trade, such as fairs, markets, and celebrations, making commerce spatially situated. Village squares and marketplaces were places where people might not only trade goods, but also exchange socially relevant information (aka gossip). Traditional markets were as much concerned with maintaining social ties and relationships as commerce.

This pattern of trade began to change after the Crusades, when silks, spices, and porcelain from the East became more readily available to Europe. When Marco Polo returned with tales of the Middle Kingdom, as trade with the Levant (Eastern Mediterranean) began to flourish, a series of events would lead to one of the most significant social transformations in history: the rise of a rational, industrial, market society that would culminate in a now globalized, capitalist modernity.

In the Paris of 1822, following industrialization and urbanization, arcades (covered passages of shops) came into being. Glass roofs create a new permutation of the “built environment”: protection from the weather. Arcades catered primarily to the growing affluent middle classes and created what Benjamin (1999) called “phantasmagorias” of commodities. These new “dream worlds of the city” became backgrounds for the urban dandy with the conspicuous

leisure to stroll through the city, and create the new experiences of urban life.

Later in the nineteenth century, throughout Europe, with a growing middle class working in urban centers and mass transportation improvements, came the department store, with its vast collections of goods from fashions to household items. The latest fashions were elegantly displayed on mannequins. Magnificent “rooms” of furniture were displayed with careful attention to the new forms of electric lights, colors, and arrangements (Leach 1989).

Following World War II, shopping malls began to sprout up throughout the US. Although some malls had been built in the 1920s, with the federally financed expressway system, stores went to the suburbs, where the people were. There were four central features of the new shopping malls: (1) huge parking lots, (2) established department stores became “anchors” for the mall, (3) many tried to develop a particular theme to make them “different” from other malls and make customers feel special shopping there, and (4) malls were private property that attempted to recreate nostalgic forms of “main streets” replete with casual interactions.

With globalization fostering certain kinds of urban based jobs in finance, law, etc., there came the gentrification of many cities and their transformation into shopping/entertainment centers in the late twentieth century. High rise urban malls began to emerge, such as Water Tower Place in Chicago. Concurrently, mega malls such as the Edmonton Mall and the Mall of America were on the rise. Further, malls are now likely not only to consist of shops, but some may also have casinos, movie theaters, chapels, amusement parks, nightclubs, or even hotels for those who might travel long distances just to shop at some of the hundreds of stores – most of which are available everywhere.

SOCIOLOGY OF THE MALL

It is often surprising that there has been very little sociological research and theory about shopping malls and mall specific behavior. One of the first sociologists to study malls was Gottdiener (2001), whose work influenced many other sociologists, such as Crawford (1992), Ritzer (1999), and Zukin (2004).

Functions of Malls

Malls are primarily places where consumer goods made anywhere in the world can be distributed to people according to their social locations (real and imagined) and membership in particular cultures of taste, fashion, and sophistication – aspects of what Bourdieu has called “distinction.” Almost two thirds of the goods sold in the US are purchased at malls.

There are two faces of mall functions: social and design. Mall design functions to disguise the exchange relation of producer and consumer by stimulating consumer fantasies (Gottdiener 2001). Malls are designed to lead consumers to walk through sequences of small and anchor stores, arranged on the basis of consumer behavior studies. Halls and fancy atriums are meant to add the leisure of a mall visit to support consumption maximization. In order to create symbolic differences between malls selling more or less the same goods, they are often “themed,” given an overall motif connoting luxury, nostalgia or perhaps high tech fantasy (Gottdiener 2001). With the added symbolism provided by themes, malls now are not only about production and distribution, but also other phenomena related to goods and services: advertising, marketing, sales, individual taste, style, fashion (Ritzer 1999: 6). Despite their goal to be “different,” the motifs that are considered “successful” in attracting customers to the malls are often repeated in other malls.

Malls as Social Locations

Perhaps the Arcades Project of Benjamin (1999) remains the most comprehensive classical attempt to frame the roofed passages as a new site of consumption with new modes of experiencing oneself and others. To Kowinski (1985), malls were spiritual places. Gottdiener emphasized the extent to which malls were exemplars of produced spaces that became essential moments of consumer society, exemplars of “theming,” the creation of a coherent ambience in which symbolic differences attempt to give place a special leitmotif, and in turn loyalty to a specific place of consumption and location for the realization of the consumer based self. For Ritzer (1999), malls, as “cathedrals of

consumption,” were places where the rationality of modernity was masked by a “re enchantment of the world” to encourage consumption.

Some malls attempt to simulate public spaces for community events. For example, Christmas celebrations in shopping malls are typical, and may perhaps encourage some more shopping as well. Some malls encourage visits at Halloween by suggesting they are considered safer to do trick or treating for children rather than knocking on the door of a stranger’s house (Chin 2001). Meanwhile, the parents may happen to buy things. People wandering about in malls are perceived more positively compared to those in outdoor public spaces, since the “controlled environment” of the mall is absent from the actual downtown urban space. This keeps out “unwanted people” and/or political ideas.

Shopping Mall Selfhood

Malls are the places that can be seen as sites where consumerism “colonizes the lifeworld of the self.” One can buy the accoutrements of identity to fashion a “fantastic” subjectivity, including modes of gratifying self presentations and appearances that awaken an often moribund self, and incorporation of one into consumption based subcultures (Langman 1992), especially in a “branded” world when a “brand” is a *synecdoche* for a distinct, albeit imaginary identity and lifestyle (Klein 1999). Chin’s (2001) study found that the consumer sphere in shopping malls is an almost imaginary world for African American girls from poor families, distracting them from threat and victimization from men and their childhood vulnerability at home. Malls are the places for subjective doing, being, and becoming, serving functional, existential, and imaginary purposes for the realization of consumer based selfhood, often satisfying “needs” that are fostered by media based programming and advertisement. “Being in the mall,” a fundamental ontological moment, results in being seen as a consumer and confirmed as one who can and does shop. For some people, being recognized as one who can and does buy an RL or DKNY jacket or a Rolex watch is often the best experience they have. The amount of money spent in the mall to buy is influenced by the degree of exposure to the consumer culture and limitations of buying power.

SOCIOLOGICAL RESEARCH OF MALLS

How do people experience malls? Although the research is often impressionistic rather than systematic, it has been suggested that malls provide an adventurous rush of new experiences; there is a feeling of leisurely “timelessness” where people seem not to be in a hurry. They give a cosmopolitan feeling of being somewhere “special” rather than in a kind of fortress. An important topic has been the extent to which malls as private properties are used as “public places,” alternatives to schools or city centers, yet security guards often exclude political actions such as leafleting or petitioning and thus act to constrain free speech.

A number of research agendas have looked at specific features of malls, such as the impact of total closed circuit television (CCTV) surveillance as a disciplinary practice. Similarly, a topic that has warranted much attention has been the patterns of inclusion and exclusion. Malls generally don’t want certain kinds of people: the poor, the unemployed (thought to be there not to buy but to steal), or the political. Those who are just likely to congregate and not buy much – aka teenage mall rats seeking hangouts – are observed closely or directed to inferior merchandise. Yet, at the same time, they are the primary consumers of certain kinds of fashions, music, videos, etc.

Most research on malls has been done by developers and marketers studying the demographics and psychographics of a potential consumer base. For example, Weiss (1988) has shown how American consumer patterns readily differ by zip codes, where people live. There are some 40 or more clusters of shoppers, some, like “young suburbia,” are more likely to shop in malls than the more affluent, more educated, more urban “money and brains” or “new bohemians.” Similarly, a great deal of marketing research has attempted to look at sales in terms of store location within the mall, store design, product placement, and even such things as lighting, scent, and the fashions of the sales staff as they impact consumers.

Malls present major challenges for social research, not the least of which is because of the many ways they can be studied, their historical evolution, impact on land use, class reproduction, job creation, or semiotic analyses of

their design, décor, and ambience. Much less has been charted about malls as sites for social practices. Ethnographic studies typically require a stable population; mall shoppers typically come and go.

Some elites criticize the banality and commercialization of malls, yet consumption of various goods can and does provide some people with various pleasures, such as incorporation into peer groups – especially for the many people who do work that is both necessary and undesirable (“shadow work”). Malls provide realms where shopping is fun and buying or using goods provides valorized identities with agency and creativity.

FUTURE OF MALLS

In the past decade, the dominance of the mall as the primary site for the distribution of mass produced goods has faced at least two major challenges. Foregrounded by the growing inequality and wage stagnation, the stand alone “big box” superstores like Wal Mart and Costco and Target have been growing rapidly. While such stores do not have as wide a range of goods and brands, they do offer “savings” on quantity purchases. The other threat to the mall has been the proliferation of “virtual malls” on the Internet. Most of the products available at the mall can be purchased online and often for less cost in time and money than going to the mall.

In order for malls to continue to stay in business, they will need to offer activities that cannot be easily done at home, as when movie theaters came to malls to take advantage of the empty parking lots in the evenings. Malls will need to offer people a lot more than goods to be able to sell them goods. For example, Edmonton Mall and the Mall of America include a number of amusements, such as rides for kiddies and sophisticated restaurants for parents. However, to expect malls to become full community and activity centers is probably asking too much considering their ability to exclude people, activities, and ideas. In a globalized world, the mall serves a central role in mediating advertising, fostering consumerism, and socializing the “emotion rules” and modes of experiencing the consumer self and the world.

shushin koyo

Ross Mouer

Literally translated as “end of life employment,” *shushin koyo* is commonly rendered as “lifetime employment.” The term has often been used out of context to refer to a practice

of hiring employees at a young age and then continuously employing them until they die. This usage is associated with an emphasis on mutual commitment between the employer and the employee within a paternalistic framework. Some have argued that the employment relationship came out of the traditional sense of loyalty associated with the *samurai* in service to his master and the reciprocal obligations of the overlord to his retainers. Other factors commonly mentioned as supporting such a commitment at work include Japan's bureaucratic tradition in state run enterprises, the interests of management in retaining skilled employees, and the need felt by many ordinary Japanese males after Japan's defeat in the Pacific War to reorient their strong sense of identity which had previously revolved around the nation state.

More sanguine observers and ordinary Japanese have thought of *shushin koyo* in more practical terms as referring rather loosely to long term or career employment. Labor turn over in Japan has been significant throughout the post war period, and few think of *shushin koyo* as an actual practice, although many are cognizant that overall levels of labor mobility among Japanese firms may be lower than in many other industrialized economies (such as in America or Australia). They too will know that it is much lower in Japan's large firms than in its smaller ones. It has also been accepted that Japan's large firms have traditionally been better able to absorb the effects of economic downturns and to subsidize a certain degree of redundancy in such situations. Smaller firms have never had that margin and have had to behave in an economically more rationalistic manner. Nevertheless, recession and the further globalization of Japan's economy combined in the 1990s to increase the pressure on Japan's large firms to trim their workforce; some large firms went bankrupt and many others moved quickly to downsize and reduce fixed labor costs as a component of their overall operating costs. The unemployment rate in Japan rose from around 2.5 in the late 1980s to over 5 percent by 2000.

Debate about the actual practice of *shushin koyo* aside, many have argued that its greater importance has been as an ideal for many Japanese. Regardless of whether or not workers stayed with their firm for longer periods than workers in other countries, many argued that

the crux of the matter lies in understanding the cultural and social context in which employers would not unreasonably dismiss employees. The commitment on the part of the employer was reinforced in at least two ways. One was in the realization and belief that poverty was a serious issue in Japan immediately after the war when a consensus seemed to emerge that each standard household should be able to have at least one secure breadwinner. The other was that the shift from age to seniority as a criterion determining wages or salaries made sense if long term employment was assured.

Long term employment guarantees have tended to go hand in hand with the institutionalization of salary systems for most regular (male) employees. This tended to fix wage costs regardless of hours worked up to a point, an approach which tended to put pressure on many firms that struggled during recessionary times, and this was certainly the case since the 1990s.

It should be noted that the commitment to maintain employment for a household head did not necessarily extend to other members of the household. Before the mid to late 1980s, Japanese women were often encouraged or even pressured to resign upon marriage, or upon reaching an arbitrary age (such as 30 or 31). The practice of hiring offspring (sons or daughters) varied, but the principle in most firms offering *shushin koyo* guarantees was that entry to the firm would be based on some notion of competitively demonstrated merit. Finally, employment associated with the *shushin koyo* guarantee was to begin immediately after graduation and extend to age 55 in most firms, an age not too far removed from the average life expectancy in the late 1940s and early 1950s.

As a set of cultural expectations, the notion of *shushin koyo* was central to the emergence in the 1960s of Japan's *sarariman* (salaried employee) as the key element in the formation of a new social class, and to the concomitant development of the mass culture associated with Japan having a broadly based middle class that initially spread across blue and white collar employment in Japan's large firms, and then came to include those employed in medium sized and smaller firms (for more on Japan's middle class at that time see Vogel 1963). The stability for families that flowed from the *shushin koyo* guarantee fueled homeownership, successive waves of

consumerism, and the materialism associated with the new lifestyle. As a way of life, the *sarari man* lifestyle incorporated a kind of womb to tomb tradeoff. For the *sarariman*'s offspring this involved a commitment to doing their best at school and in a series of entrance examinations (*juken benkyo*). For many students this meant extra tuition in *juku* (private schools offering supplementary instruction) or *yobiko* (preparatory schools). For the cohort it meant over time a growing percentage of students attending private high schools and tertiary institutions. The pressure on students to start their salaried careers on the highest possible wage age trajectory in the best possible firm reflected a credentialism which has over time led to decreasing intergenerational mobility and the reproduction of social class in contemporary Japan as described by Sato (2000) and others.

To obtain greater productivity at the firm level, management has over time developed a number of techniques to remove redundant employees. Most important is the fact that promotion has been more tightly linked to performance based criteria in ways that determine the trajectory that each employee's age wage curve follows. However, the major means of regulating fixed labor costs have been natural attrition through the fixed retirement age (known as *teinen*) and the freedom to decide the number of new graduates to be hired as replacements each April. In recent years there has been a tendency to hire fewer graduates as regular employees for *shushin koyo* type positions and an increased reliance on part time employees, freelancers, dispatched workers, and subcontractors. The move away from the idealized patterns of long term employment has been reinforced by the movement of educated and otherwise skilled women into traditionally male domains, a reconstituting of career paths owing to equal employment opportunity legislation, the influx of migrant workers, multiculturalization, and the overall diversification of lifestyles (and hence the needs and motivations of employees). Taken together, these changes are altering the notion of *shushin koyo* as the dominant cultural practice associated with employment for male household heads.

One final issue connected to *shushin koyo* as a practice tied to a clear idea of *teinen* has been the rapid aging of the population, with the

proportion of the population aged 65 and older increasing from 5.3 percent in 1955 to 17.3 percent in 2000. During the 1970s and 1980s this was partially accommodated in large firms by gradually moving the fixed retirement age up from 55 to 60. Since then many firms have introduced or formalized schemes for "rehiring" employees who had officially retired. Many also have informal means of redeploying retired employees in subsidiaries or subcontracting firms. While this often accommodated the needs of better performing employees, those whose performance was below average often had to struggle as pensioners. Pension schemes are varied and complex, a factor adding anxiety to many Japanese employees over the decade preceding retirement. At the beginning of the twenty first century many ideas are being discussed with regard to the financing of pensions and to their availability. One is to postpone access to pensions until a later age. Although this needs to be coupled to thinking about the fixed retirement age, it should be noted that by international standards a large percent of the Japanese population aged over 65 is still working. In 2000, 34.1 percent of Japanese men aged 65 and over (and 14.4 percent of women) were working. This compared with 16.9 and 9.1 percent in the US, 3.7 and 1.8 percent in France, and 10.7 and 2.8 percent in Italy (Japan Institute of Labor 2002: 17). At the same time, the increasing casualization of work in Japan is likely to see a growing disparity in retirement between (1) those who have been in the privileged *shushin koyo* sector as regular (male) employees in Japan's large established firms and enjoy the benefit of having a substantial component of their pension coming from a firm linked private fund and (2) those who rely heavily on the state funded component of their pensions.

sibling relationships during old age

Ingrid Arnet Connidis

A growing interest in old siblings reflects the potential increase in their importance at a time when union dissolution is high and birth rates low. For many subjects, a definition merely begins the story. In the case of older siblings, defining the term and exploring different types of sibship remain compelling research challenges. Traditional definitions refer to the category of full siblings, related to one another through two biological parents. This restrictive definition excludes those who are half siblings (related through one shared biological parent), adopted siblings (related through legal adoption), and step siblings (related to one another through subsequent marriages of one or both biological or adoptive parents). In earlier times, acquiring step siblings typically occurred after the death of one parent and subsequent remarriage of the other. Now, step siblings are more likely to result from the remarriage of one or both parents following divorce. For most old persons today, these categories cover the vast majority of siblings; the future will bring an even broader array of adult sibling types in the wake of more marriage like unions that also produce children.

Relatively little research concerns old siblings in their own right, but in recent decades research on siblings has finally extended beyond childhood. The bulk of studies tend to be psychological or developmental (Cicirelli 1995); to focus on university aged adults; to address assumed traits of sibling relationships such as rivalry; or, when extended into middle

age, to explore siblings largely in the context of caring for their parents rather than their direct relationships with one another. The variety of research on adult siblings, including cohort comparisons, suggests a general portrait of change in sibling ties over the life course and of a significant tie in later life.

The sibling bond is unique in the contradictory expectations that it include the obligations of family membership but, as a tie between relative peers, it should also be relatively voluntary (Allan 1977). This makes siblings an ideal relationship for exploring the *ambivalence* that characterizes family relationships at both the sociological and psychological levels (Connidis & McMullin 2002). Exploring sibling ties benefits from and in turn helps to extend the theoretical constructs of the life course and ambivalence (Walker et al. in press).

Sibling ties are very active in youth, then go through a period of relative dormancy, and eventually resurface once long term relationships are established or disbanded, children are raised, and paid work is either stabilized or left behind, sometimes through job loss but usually through retirement. On the way to this more active phase in sibling relationships, various life transitions may rekindle bonds between siblings, as they reach out to and for one another. Life changes such as the illness or death of parents and other family members, divorce, widowhood, remarriage, and relocation nearby, often heighten sibling contact and support. Research on the negotiation of the sibling tie in the context of caring for a parent, particularly one without a partner, indicates the dynamics of family life and its interplay with larger social forces (Matthews 2002). Structured social relations based on gender, age, class, race, ethnicity, and sexual orientation play themselves out and are evident in studies *across* families (families of different races, classes, and ethnic background negotiate sibling ties differently) and *within* families (gender and sexual orientation influence the respective positions of siblings in the family network, including their relative responsibilities for particular obligations).

Even during times of relative inactivity as measured by contact, emotional closeness persists in the shared memories and reflections of siblings. The observed significance of reminiscence on old age adds a unique quality and value

to sibling ties – typically the relationship that endures the longest in most of our lives. Women and single and childless persons have particularly involved sibling ties. Those who have fewer alternative attachments do not simply rely more heavily on their siblings; indications are that they also invest more heavily in them, directly as siblings and less directly as aunts and uncles (Connidis 2001). This means that older persons who have a sister or a single or a childless sibling are also more likely to sustain more active sibling relationships.

The greater involvement of sisters than brothers can be linked to both demographic trends and social structure. Because they live longer, women are more likely to either enjoy or require the company of someone other than a partner. This difference in availability is reinforced by socially constructed gender relations in which age remains a liability for old women who are interested in an intimate relationship (many are not). The stronger sister connections are also reinforced by a stronger culture of caring among women than men that is a further instance of socially structured gender relations.

An area of study that is likely to further our understanding of sibling ties particularly and family ties more generally is the extent to which divisions based on class occur *within* families when siblings are adults and no longer assume the same class position by virtue of their shared childhood. In the case of old persons, a related research question concerns the effect of timing – when sibling ties are acquired – on the long term relationship between brothers and sisters. As well, many adults form close bonds with their partners' siblings that carry into old age; thus, siblings in law and their equivalent are important sibling types about whom we need to learn more.

sibling ties

Melanie Mauthner

Sibling ties are some of the most widespread and enduring intimate relationships. Located at the border of kinship and friendship, the sociology of siblings largely centers on childhood and old age, rivalry and social support. The role of sibling ties at other stages of the life course – youth and adulthood – and in relation to other topics such as mental illness, substance abuse, disability, and domestic violence (Sanders 2004) is neglected. Principally explored from an adult carer perspective and a policy and professional agenda rather than through a sociological lens, sibling ties are little understood. Exceptions include schooling, fostering, and adoption decisions, where the importance of sibling ties is recognized. Yet they continue to be viewed in relation to parent–child bonds rather than as relationships in their own right.

Until the 1980s the sociology of siblings was influenced by ideas from developmental psychology. Sibling ties were explored through a behavioral and cognitive lens with incest, eating disorders, aggression, and educational achievement as dominant themes. Other angles that characterized the field were the intensity and effects of sibling ties. Links between these elements and parental neglect and the endurance

of sibling ties over time received a lot of attention. As a sphere of social interaction, support, and as a network even, empirical work was in its infancy until sociologists began to explore meanings of different types of adult sibling ties (Allan 1977).

Numerous factors account for sociological neglect of sibling ties until the 1980s. One was the preeminence in family studies of issues connected to marriage, reproduction, and parenting rather than to intimacy more generally, including lesbian/gay ties, friendship, and sibship. A second factor was the pervasive emphasis on the child as individual and on the mother-child bond rather than on the child as a member of a generational sibling group. Third, psychoanalytic notions of envy and the trauma of displacement after the birth of a sibling made it difficult to challenge either the rivalry or the deviance discourses (Coles 2003). Indeed, these continue to influence everyday understandings of hostility and misbehavior as perceived in sibling ties. A fourth factor was the absence of siblings' own narratives about what it means to be a sister or brother. This invisibility mirrored that of previously marginalized relationships in studies of domestic life among stepfamilies and non heterosexual households. Fifth, there was a tendency to ignore sibling ties as constitutive of power relations and caring practices and socializing in themselves. In retrospect this silence appears ethnocentric for overlooking kin arrangements based on lateral rather than vertical connections.

Gradually, researchers instigated cross disciplinary dialogues that placed sibling ties in social life firmly on the map (Zukow 1989). Attention shifted to social context, intra household links, life events, and concepts such as negotiation and reciprocity. By the 1990s sociologists influenced by social constructionist and feminist perspectives started to investigate siblings as a social group (Walker et al. 2005). They examined the intrinsic value of their ties across the life course in order to understand patterns of transnational migration, family employment, and gendered identity. Ethnographies of sibling life and a sibling standpoint emerged (Song 1999; Mauthner 2002) as sociologists explored changing forms of intimacy in relation to residency, shared history, and belonging to familial cultures and ethnic communities.

There has been little sociological research on sibling ties, especially across the life course. Sibling ties now form part of sociological inquiry into the social relations of intimacy, care, and identity; no longer are they merely of concern in relation to instances of "clinical adaptation" (Lamb and Sutton Smith 1982). For the topic of sibling sociology to grow, there is a need for a broader range of issues to be addressed and for more diverse theories and methodologies to be used, particularly more qualitative and longitudinal approaches. There is a need to investigate the complexity of the ties, the components of their longevity, and how they shape identity in psychic life. New interdisciplinary work attempts to define multiple meanings of "sibling," of sameness and difference, agency and interdependence, and of continuity and change by drawing on psychoanalysis, post structuralism, and cultural geography.

A priority is to establish how competing discourses of rivalry, deviance, and care coexist in forming contested meanings of sibling ties. Other directions and topics ripe for investigation include more work exploring generational and historical dimensions, socio legal aspects of sibling partnership and citizenship rights, sibling representations in popular culture, sibling experiences of asylum and resettlement, and memories of mental illness, adoption, and fostering. Sibling sociology is likely to encompass work on sibling identities shaped by previously overlooked sociodemographic variables such as ethnicity, class, and dis/ability. Greater methodological diversity will reveal the particularity and cultural specificity of sibling ties rather than their universal attributes. More research employing ethnography, memory work, and biographical methods will be useful. Thus, a new body of work documenting psychosocial elements of sibling ties for understanding identity and intimacy will emerge.

sick role

Andrew C. Twaddle

The sick role was a formulation by Talcott Parsons that posited four institutionalized behavioral expectations that attached to people defined as "sick." For about three decades, from the early 1950s to about 1980, it was the central focus of many sociologists who studied medical care. It received a large amount of criticism as well as uncritical use and became passé when Parsons's theory fell out of favor and sociology turned toward a more critical and conflict oriented approach to theorizing.

On the surface, it is quite simple and straightforward.

- 1 Sick people are expected to be *exempt from normal role obligations*. That exemption is limited and conditional. It is limited in the sense that one cannot claim exemption beyond some limit on one's own authority. At some point the right to exemption will have to be legitimated by someone with authority. It is conditional on the obligations of the sick role being fulfilled and by the "nature and severity of the condition."
- 2 Sick people are expected to be "*not responsible*" for their condition in the sense that they cannot get well by an act of motivation alone. The sick person "needs help" and has a claim on the larger community for care. It is important, in the light of subsequent criticisms, to note that this right does not attach to the onset of the condition, but to its continuation. Even if the condition arose because of the actions of the affected person, she still needs treatment to recover.
- 3 Sick people are expected to be motivated toward recovery, to *want to get well*. This expectation is an obligation that is one of the conditions for the two rights just noted. If the sick person seems to be motivated by secondary gain, the legitimacy of the two rights may be rescinded. They may become defined as not entitled to care or exemption from expectations attached to "normal" people.
- 4 Sick people are expected to *seek and cooperate with technically competent help*. This obligation limits the rights of the first two expectations, in part by being evidence of meeting the obligation of the third one. At some point, varying with the "nature and severity of the condition," sick people need the legitimation of a competent treatment agent in order to continue being entitled to care and to exemptions from normal expectations. In the light of subsequent criticisms, it is important to note that Parsons did not say that the "competent treatment agent" had to be a physician, but that physicians were the most commonly used.

There are some important contexts that are vital for understanding the sick role and which, when not taken into account, have led to considerable misunderstanding of the concept. First, the sick role applies only to those defined as sick, making it important to differentiate sickness from the related concepts of disease and illness on the one hand and other forms of "deviant behavior" on the other. Second, it was developed as a small part of Parsons's life's work, an attempt to generate a "general theory of action" under an "action frame of reference" that would unify the social sciences.

DISEASE, ILLNESS, AND SICKNESS

Sickness is a social identity, a defined incapacity for normal socially expected task and role performance. It is related to, but not the same as, disease, which is a physiological malfunction – an infection, mechanical breakdown, or degeneration resulting in reduced capacity and/or life expectancy. Nor is it the same as illness, a subjective feeling of health based on body state perceptions and/or feelings of competence. Disease has an organic basis, illness is social psychological, but sickness is distinctively sociological.

Many critics have held that the sick role is more attuned to acute disease and not very appropriate for chronic disease (e.g., diabetes), on the grounds that the third expectation could not apply to people who are by definition not going to recover. Nor would it apply to trivial diseases (e.g., common cold) that do not result in professional consultations, stigmatized diseases (e.g., addiction, STDs, some mental illness) in which people are held responsible for their condition, or various permanent legitimate roles (sickly, handicapped, mentally retarded, etc.). If the focus is on incapacity as a source of nonconformity, disease and illness become contextual triggering and bargaining events. Distinctions between acute and chronic become less salient. At the same time, many characteristics of the “nature and severity” of the condition, including prognosis and the specific incapacities of individual cases, have been shown to modify behavioral expectations.

It is of at least passing interest that the biographical beginning of Parsons’s work on the sick role, in addition to having an admired physician brother, was his own diagnosis with diabetes, a chronic disease.

ACTION FRAME OF REFERENCE

The sick role was a small part of Parsons’s attempt to build a general theory of action. The most immediate context was, on one hand, his approach to the problem of social deviance and social control, which differentiated motivated and unmotivated deviance; crime and sickness as alternative forms of deviance; punishment and therapy as alternative responses to

deviance; and the criminal justice system and the medical care system as alternative systems of social control. In this context, the sick role was an illustration of how sick people were different from criminals. Sickness was a designation for the condition where people deviate from social norms not because they “want to” but because they “can’t help it.” They lack the capacity for conformity and “need help, not punishment” to come into compliance.

Another important context was Parsons’s concern with the modernization of societies along five axes he called pattern variables. He accepted the general view of sociological theorists that the rise of the business community was the hallmark of capitalism and the modern era. However, he posited that at the same time business was coming to dominance, the professions were rising to prominence. While they were also harbingers of modern society, they were distinct from business interests.

Professions and business were held to be similar with respect to the pattern variables except for one that distinguished self interest and collectivity interest. Here business was seen as self interested, while the professions manifested collectivity interest. Physicians were the prototype profession. Patients, and by extension clients of other professions, were people with problems they could not definitively identify or solve, hence they were dependent upon others with both expert knowledge and control of the means of treatment. In this state, they were vulnerable to exploitation and required a relationship in which they could trust the professional to work in their interest toward the collective goal of effecting a cure, if possible, or stabilization and control if cure were not an option. This was in stark contrast to the competitive *caveat emptor* ethos of business.

A third theoretical concern (much less developed with reference to the sick role) was the delineation of essential requirements for the continuity of societies, the “functional imperatives.” Here Parsons held that maintaining, at some level, a healthy population was required for needed tasks and roles to be performed. It was hence important to make provision for some way of bringing sick people back to a capacity level that made the work of the society possible.

Most of the sociologists and others concerned with health, sickness, and medical care were

(and are) more interested in variations within societies than in the characteristics of societies as global entities. Considerable documentation accumulated that the behavior of symptomatic and sick people varies along social class and ethnic lines and is strongly influenced by interaction patterns in families, neighborhoods, work settings, and friendship groups. From this work came an empirically based critique of the sick role along several lines; most important was that the concept did not focus on questions of core importance to most sociologists.

Another important dimension of the criticisms was the observation that most disease and illness episodes are relatively minor and self limiting. Only a small minority ever comes to medical attention. Instead, people treat themselves, generating in the US a huge over the counter trade in remedies. In addition, many people use what is now called alternative medicine. The sick role was seen as too focused on the physician and the medical encounter.

The emphasis in the sick role formulation on the helplessness of the patient and her or his dependence on the physician for knowledge, skill, and access to resources was seen as underplaying the agency of patients. Interactions involved in the treatment of chronic disease are less likely to follow an activity-passivity model and more likely to be of a guidance-cooperation or mutual participation type. The one kind of patient most likely to be passively dependent, the critically "ill" in the intensive care unit, has seldom been studied.

It is worth noting that most studies of sickness behavior have been done on hospitalized low income patients in the subsidized services of general hospitals. These are the conditions that maximize the social status and power differentials between physicians and patients, probably skewing the research toward the most insecure and deferential patients. If studies were done on the "gold coast" private services or in private medical receptions, we might see a different set of expectations operating (or not).

Work on sickness behavior has changed toward patient decision making, using variants of the sickness career model which treats the sick role expectations as a set of parameters around which considerable variation is expected and incorporates other models, such as the health beliefs model and the concept of illness

behavior. It is an example of macro micro theorizing.

People whose health status is in question interact with others who reflect the sick role expectations through the filters of their own social class and ethnic identities, as well as their specific relationship with the afflicted individual. A process of consultation and negotiation takes place around a series of questions that frame the career of the sick person: whether a change from "normal" has taken place; whether that change is significant; whether help is needed; the type of help needed; the treatment agent to be consulted; and the nature and degree of "cooperation" with treatment recommendations. With such an approach, it is possible to document the rich variety of human response to symptoms while understanding the structural impact of class and ethnicity and retaining the important insights of the sick role formulation.

In the last 30 years or so attention in medical sociology has shifted away from the social psychology of sickness and toward a focus on medical care systems and social conflict. The study of sickness, however, remains both theoretically and practically important and the sick role is still a meaningful framework for a part of that study.

significant others

Erica Owens

Significant others are those persons who are of sufficient importance in an individual's life to affect the individual's emotions, behavior, and sense of self. While in common parlance "significant other" has come to designate a romantic partner, sociologists' broader use of the term would include other relations such as family members and close friends or mentors. Through interactions with significant others, and perceptions of their responses to one's behavior, an individual gains a sense of who he or she is, and comes to understand how to act in a given context and role. Self concept is based largely on our perceptions – whether accurate or not – of who we are in the eyes of those whose opinions matter to us.

The term "significant other" was coined by Harry Stack Sullivan, who identified significant

others as those who directly socialize the person to whom they are significant. Sullivan (1940) and George Herbert Mead (1967) suggest that socialization relies upon a person's considering the other's view of himself or herself as important. Having positive feelings toward another will greatly increase the chances that this person will become significant, and thus serve as a reference for belief and behavior.

Mead was among the first to recognize the role of important others in the development and maintenance of identity. According to Mead, there is no inherent or core self present at birth. Rather, the self is a social product that develops in stages through the process of social interaction. The key to this process is the ability to take the role of the other party in an interaction, or picture what the other might do, think, or say within a given context. Taking the role of the other allows a person to make behavioral choices based upon these perceived responses, and thereby attempt to influence how he or she is perceived by others.

Very young children are incapable of this form of projection. Their first forays into social interaction involve simple imitation of others, without an understanding of the mechanics of the relationship between themselves and these others. As children develop greater understanding of the world around them, they enter the play stage of role taking behavior. During this stage a child has the ability to take the role of significant others, generally parents or caregivers. The young child has sufficient experience with these others, and sufficient emotional investment in their reactions to him or her, to make the cognitive leap required in playacting "mommy" or "daddy." To a casual observer, such play might seem unimportant. However, when a child pretends to be daddy and cautions a stuffed toy that if the toy is naughty it will be punished, this child is demonstrating the knowledge that under certain circumstances (naughty behavior) a given other (daddy) will likely react in a predictable way (punishment).

This process of understanding important others and applying this understanding to guide one's behavior is not without its dangers. The very importance of significant others magnifies the impact of their reactions toward the individual. For instance, Wiley (2003) suggests that parents who do not provide sufficient emotional

support to the infant during identity development may do lasting damage to the integrity of the adult sense of self. Primary socialization is accomplished through a child's interactions with adults closest to him or her. The quality of this interaction will have lasting impact on whether the world is seen as a safe and welcoming place.

Parents who provide adequate support during the earliest stages of identity development provide a stronger basis for the perception of self, but continuing support from later significant others will be necessary for the individual to maintain self esteem. The production of a positive self concept, or a preferred self, is an ongoing project requiring the cooperation of others. Thus, the constant implicit threat that approval from significant others may be withdrawn helps to moderate behavior.

Deviance, or the violation of social norms, is discouraged partly by this threat of loss of significant others' approval. Whether the result is decreased or increased adherence to the norms of the larger culture depends upon the normative orientations of those others a person is trying to please. According to control theory, a person working to maintain close ties to people who adhere to conventional norms will be less likely to engage in behaviors that violate said norms. Conversely, differential association suggests that a person who wants to please significant others who engage in and approve of a form of deviance will be more likely to engage in deviance themselves. For instance, stealing may be discouraged ("If I got caught shoplifting my mom would kill me!") or encouraged ("Everyone in the gang is expected to shoplift, so I had better") depending in part upon the values held by significant others.

Tamotsu Shibutani (1962) explains this process further, through his discussion of reference groups and their function in social control. Reference groups are audiences for actions, even if the group being referenced is not physically represented through a member or members present to see the action. Every actor has a number of reference groups that serve as controls for behavior because the actor will try "to maintain or enhance his standing" in front of these groups (p. 132). Unfortunately, it may be difficult or impossible for a person to meet all of the behavioral norms of various competing groups. As people tend to conform to norms of those

groups they find most compelling, and significant others tend to serve as representatives for reference groups, the closeness and sentiment felt between significant others greatly increases their influence over individual behavior.

The relationship between an individual and the persons he or she considers to be significant others is often, but not always, reciprocal. Husband and wife share a relationship that is reciprocally significant, as do mother and child. Each can reasonably be considered significant to the other. However, some relationships may be significant for one party and much less significant, or nonexistent, for the other. A popular coach may be a significant other for a large number of college athletes, none of whom need be individually significant to the coach in return.

signs

J. I. (Hans) Bakker

The term "sign" is used in semiotics and hermeneutics as an umbrella (portmanteau) word covering all forms of gestures, ciphers, tokens,

marks, indices, and symbols that convey human meaning. There have been many philosophical views expressed in the study of human meaning construction. Some thinkers trace the beginning of human cognition by the earliest *Homo sapiens* to the use of signs. The earliest religious thinkers emphasized some supernatural indicators of the true nature of reality; they understood "signs" in nature as messages. This led to necromancy and other forms of divination. The Chinese *Yi Ching* was initially based on the reading of tortoise shells. Victory in battle was often seen as a sign of the whim of the gods or of God's pleasure in ancient times. That which was not understood directly had to be fathomed on the basis of conjecture. Greek physicians utilized somatic signs to diagnose disease. They called this process semeiosis.

The idea of semiotic signs has gradually been extended to cover more and more features of reality. At the same time, secularization since the Scientific Revolution and the Enlightenment has made the notion that signs come from supernatural forces less acceptable. Classicist and theologian Friederich Schleiermacher utilized hermeneutics to translate and interpret both Plato and the Bible. He discovered that the way he carried out exegesis was no different for the pagan, secular texts than for the Christian, sacred texts. Hence, he postulated the possibility of a *general* hermeneutics. This idea was further developed by Wilhelm Dilthey, who thought of hermeneutics as a way of developing a "critique of historical reason" that would supplement Kant's three critiques. Dilthey's approach helped to provide a philosophical foundation for non positivistic social sciences based on the study of human beings as moral and ethical actors whose outlooks and motivations could be understood (*Geisteswissenschaften* which used *Verstehen*). We can understand human actors because we ourselves are human, even though we may need to bridge a chasm of time or space (e.g., China in the tenth century). All human signs are human creations and therefore can be understood by human beings.

But hermeneutics lacked a more general epistemological foundation. That came with the work of Charles Sanders Peirce, founder of pragmatism and pragmaticism, considered by some to be the greatest American philosopher.

Peirce emphasized the way in which signs mediate between that which is being represented and that which is interpreted. While few follow Peirce's detailed arguments to the letter, the general thrust of Peirce's critique of Cartesian dualism makes it abundantly clear that an epistemology which focuses on the individual "subject" as an interpreter of "objects" is severely misleading. Peirce's correction of Descartes's epistemology parallels Einstein's extension of Newton's physics. For many practical purposes it is sufficient to simply think in terms of the subject's comprehension of time and space; but, for universal laws of physics, such as the law of gravity, such a limited framework will not do. Similarly, for many purposes a Cartesian dualism is adequate. It was important for the Scientific Revolution of the seventeenth century because the independent Cartesian subject looking through a microscope, eyeglass, or a telescope replaced argument based on the authority of the Roman Catholic Church's Thomist dogma. But a still wider perspective on human knowledge can be gained by questioning the "objectivity" of empirical observations based on inductive data gathering. A broader approach to knowledge requires a more sophisticated epistemology, one that includes an emphasis on the way in which a "sign" of some sort will always mediate between subject and object. Moreover, the isolated individual never exists in reality but only as a thought experiment (*Gedanken experiment*). In reality all scientific understanding is based on communities of scholars (Cohen 2001).

By extension, the same is even true of every day, commonsense reality, although we are usually not fully aware of it. We do not see the world; we only interpret stimuli with the aid of signs. Peirce had a complex typology of signs but the most important for sociology are icons, indices, and symbols. Icons are very specific images, such as those used on computer screens to indicate the location of a software application. Indices are signs which point to a more abstract level of reality. All descriptive statistics and statistical measures of association and correlation are indices. The most complex type of human sign is the symbol. A symbol can have many different meanings, depending on the context. George Herbert Mead's concept of

the “significant symbol” is an echo of Peirce’s general theory of signs. A symbol can only be significant to those who have learned to interpret it. It is very easy to misunderstand symbols. When a Roman Catholic sees a dove on a stained glass window he or she knows it represents the Holy Spirit; but the same Catholic seeing a swastika on a Buddha may not know that it represents good fortune. The Buddhist, in turn, may have no idea of the meaning of the dove. Our classification schemes and typologies are often highly symbolic even though we tend to assume that they are purely analytical and descriptive. This has led some philosophers (e.g., Wittgenstein) to argue that the real meaning of a sign is in its use, but others dispute that claim. To understand a “text” more clearly, we have to have an initial “vague notion” of what the key terms mean (Eco 1999: 275–9). That is, due to “intertextuality” we cannot escape a certain degree of circularity in examining signs.

The idea that we comprehend the world according to our “definition of the situation” can be extended to include the neo Kantian notion that we perceive the world through a priori categories of understanding. Simmel took that one step further and argued that all a priors are cultural. Today we would say that we are socialized into a culture. But the further specification of the true significance of any culturally constructed sign requires some awareness of the contextual mediating function of that sign. Theories put forward by Ferdinand de Saussure and C. S. Peirce have been further developed by other semioticians. But the key ingredient is awareness of the universal function in all human representation and communication of the sign. While theorists may differ concerning the precise operationalization of the concept of the sign, there has been considerable attention paid to signs in models of the process of semiosis by such divergent thinkers as Victoria Lady Welby, Mikhail Bakhtin, Charles W. Morris, Thomas S. Sebeok, Ferruccio Rossi Landi, and Umberto Eco (Petrilli & Ponzio 2005).

Simmel, Georg (1858–1918)

Russell Kelly

Georg Simmel was born in Berlin on March 1, 1858 and died in Strasbourg in Alsace on September 26, 1918. He is generally recognized as an important sociological writer and teacher in Europe around 1900. He is less well recognized as an important philosopher of the same period. While he was a friend and contemporary of the German sociologist Max Weber, he was also a colleague and fellow teacher with the eminent philosopher Wilhelm Dilthey. Among the students and correspondents influenced by Simmel, four major figures in American sociology attended his lectures in Berlin: Albion Small, later head of department at the University of Chicago and founding editor of the *American Journal of Sociology*, George Herbert Mead, University of Chicago philosopher, W. I. Thomas, Chicago sociologist, and Robert Park, founder of the US research tradition known best as ethnography. In the famous “Green Book,” *The Introduction to Sociology*, of 1921, Park and Burgess included more separate contributions from Simmel than from any other European sociologist. Simmel’s influence from

his teaching and his published papers on the development of sociology in the USA cannot be underestimated. Only his exclusion from Talcott Parsons's seminal *Structure of Social Action* cast a shadow for the period 1937 into the early 1960s. Since sociologists of the stature of Erving Goffman, Lewis Coser, and Kurt Wolff reclaimed Simmel's sociological work during the 1960s, his influence has been extended to virtually every area of the sociological spectrum.

FAMILY, BACKGROUND, AND CAREER

Simmel was born the youngest of seven children into a family of renowned chocolate makers, Felix & Sarotti. His father Ewald died in 1874 when Simmel was aged 16. His mother, Flora Bodenstern, was officially *Hausfrau* (housewife) to her seven children. Georg married Gertrud Kinel (aka as the author, Luise Enckendorff) in 1890 and his son Hans was born a year later. His daughter Angela was born in 1904 to his relationship with his student and colleague Gertrud Kantorowicz, writer and art historian.

Although born into a Jewish family, the Simmels had converted to Evangelical Protestantism. This was not unusual among the aspiring middle and upper middle classes of respectable Prussian and Austro-Hungarian Imperial society in the nineteenth century. Access to state employment, social and professional contacts, and any form of royal patronage were all severely restricted if a person was officially Jewish. Many "modern" Jewish families took this option in Vienna, Budapest, Prague and, of course, Berlin. This is particularly relevant in Simmel's biography, as many subsequent writers have attributed his lack of recognition in Germany in his lifetime to anti-Semitism (Wolff 1950). This may not necessarily have been the case. During World War I, for example, Simmel abandoned all religious belief and any claim to a religious status.

After his father's death, Simmel's upbringing passed to the control of Julius Friedlander, a family friend and music publisher. After completing his *abitur* or college matriculation in Berlin in 1876, Simmel proceeded to study history and philosophy, and later art history, at the King Frederick William University in Berlin. Although usually described as the Berlin

University, this royal connection is particularly relevant to the son of a Jewish family. Had Simmel's Jewish background been that significant, his student career could not have been so successful. He studied history with Droysen and Mommsen, psychology with Lazarus, ethnology with Bastian, and history of philosophy with Zeller – all renowned professors of their day. In 1881, aged 23, Simmel publicly defended his first dissertation (*ordinarius*) on Kant's physical monadology (theory of substances). The success of his dissertation gave him the right to proceed to prepare his second dissertation (*habilitation*) and a requirement (and right) to teach in the department of philosophy while doing so. This dissertation was titled *On the Relationship between Ethical Ideals and the Logical and Aesthetic*. His degree was awarded on January 16, 1885.

His teaching included titles like Ethics, New Philosophical Theory, Sociology, and Social Psychology. As *Privatdozent* (associate lecturer), Simmel was paid according to the attendances at his lectures across the year, and on the balance of registered students and paying guests. His attractive style, performance, and topical content, directed towards his public rather than the registered students, maintained a regular audience of 150–200 between 1885 and 1898. Linked to his wife's daytime *salon* and his at-home tutorials, Simmel's courses became increasingly fashionable among Berlin intellectuals and their foreign visitors. Several notable sociologists of the next generation attended his lectures and tutorials. Americans on the post-graduation European tour and roving students from Eastern and Western Europe spread his influence and brought his ideas back to the USA or took them to their own country. His popularity and earnings, although not substantial, were the envy of some of his fellows and colleagues and were the source of some resentment.

Frequent attempts were made by Professor Wilhelm Dilthey and his colleagues in the philosophy department to sponsor Simmel for appointment to a full professorship. It is important to note that although universities sponsored faculty, professorships were awarded by the Prussian state and ministers were influenced in their decisions by external as well as internal pressures. The only concession was in 1900 when Simmel was awarded his

ausserordentlicher (Extraordinary) professorship. This allowed him to continue teaching and to use the title, but fell short of the full status of a professor who could recruit and supervise post graduate students.

There are two explanations for his exclusion. One suggests that a reference from Schaefer describing “an Israelite through and through, in his external appearance, in his bearing and in his mode of thought” (Frisby 1992) was influential with its clearly racist substance. Equally, however, Schaefer and others were jealous and critical of his popularity as diminishing the status of his science and heavily critical of Simmel as a representative of the emerging discipline of sociology. The personal attack (and Dilthey’s defensive references) were directed at sociology, at its radical and revolutionary potential, at its un- or anti positivist, anti empirical, and anti scientific potential in Simmel’s hands. His flamboyant appeal to foreigners and to women in attracting lecture audiences further weakened the case for Simmel as a serious academic.

Subsequent attempts to find him recognition outside of Berlin and Prussia, especially by his friend and colleague Max Weber, always stalled on the failure to secure promotion in Berlin. He was rejected for a second chair at Heidelberg and for the smaller university at Griefswald, although he was awarded a honorary doctorate in politics from Freiburg in 1911. Finally, in 1914, he was granted his full professorship at the University of Strasbourg, aged 56. Dissatisfied and unfulfilled, his health and his motivation went into rapid decline and he died of liver cancer in September 1918.

SOCIOLOGY OF KNOWLEDGE: *ERKENNTNISSETHEORIE*

Simmel’s importance to sociology lies in his answer to his own question. “How is *gesellschaft*?” was one of his first sociological essays and became the first chapter in his *Soziologie* (1908). He argued that sociology was not a science but more a method or methodology for exploring the ongoing and continuous processes of *socialization*, or what would be described today as *social interaction*. The data of social life were drawn from other disciplines like *Volkspsychologie* – a social and anthropological psychology –

and economics. Sociology’s task was to use this data to describe and explain the processes of *sociation*. Simmel sought within these processes for the essentials of sociology, *formen*, or for the core of his formal sociology. All people in all societies interact and the forms of that interaction can be categorized. Simmel saw the task of his sociology as identifying the categories or types of interactions. This concept comes very close to the notion of “ideal type” associated with Simmel’s friend and colleague, Max Weber.

Formen

Formen or *Lebensformen* are descriptions of processes of *sociation*, which allow the processes to be divided into types or categories. One example, for Simmel, was superordination and subordination, where his examples ranged from the simple leader and follower in a small nomadic or tribal group to the processes that made some relations between monarchs or princes and their people stable and some unstable. These *formen* become features of the work of others. One of the most fundamental of interactional processes still at the core of modern sociology is W. I. Thomas’s “definition of the situation.” Erving Goffman describes processes for self and identity management. Lewis Coser offers *social conflict* as another of the forms identified by Simmel under the heading of competition and conflict. But Simmel’s notion of “Form” also has philosophical implications, as it is a “representation” expressed through and appearing in the interaction between persons, in intersubjectivity. More individual and interpersonal phenomena are identified as forms by Simmel, like jealousy or distrust. Jörg Bergmann (1993) followed the guide in his example of “secrecy,” the form that underlies his studies of *klatsch* or gossip.

Form can best be recognized by the task it performs. Identifying forms involved Simmel in an extensive range of articles and papers. Each piece is in a sense a demonstration of the method at work, being a reflection on whatever the topic happened to be. How is society possible? What does art or culture do? Why is the family indispensable? Why is conflict between rich and poor inevitable? This same approach was introduced by Robert Park and W. I. Thomas as the ground for the work of the Chicago School in the 1920s

and 1930s, from the early journalistic period through participant observation studies, to the more formal ethnographies of the 1960s to 1990s. It is also the style adopted by the more radical and experimental methods to be found in Harold Garfinkel's ethnomethodology, in the unique style of Erving Goffman, and in the widening array of projects listed under the heading qualitative research. Simmel's corpus is a set of demonstrations of *forms* that outlines the potential promised by the new science of sociology, unrestrained by commitments to set theories, methods, or perspectives. He opened avenues of inquiry that would take sociology more than a century to explore (Frisby 1992).

Dyad and Triad

One particular concept and focus originating in Simmel's work is the dyad (*Zweierverbindung* – literally, two hanging or binding together) and the triad (*Verbindung zu dreien* – three associating). Dyad and triad are translations that lose another important feature – the dynamic and processual nature of these forms. The dyad is unique as the only form that cannot exist without either of the two members whose associating is the pairing. For example, I cannot have an argument with myself, nor sustain that argument if the other party leaves and I become acutely embarrassed as I shout at the receding back of my opponent, drawing the attention of complete strangers.

Triads or larger groups can establish and continue their existence as a form with a constantly changing or revolving membership. New members can join while others leave or come and go. A discussion in a bar can continue all evening, long after the original group who set the topic up have left. A local soccer game can change personnel several times without interruption, but one, alone, cannot continue a game of chess. Simmel applies these notions in both directions, explaining the persistence of groups, large and small, on the one hand, while examining the internal features, stability, and fragility of monogamous marriage, on the other. Describing the dyadic form and the actions or behavior that constitute, maintain, and sustain it was fundamental to the development of not only sociology, but also psychology, and was the

origin of the discipline that is now social psychology.

Social Differentiation

From Karl Marx onward, the agenda for sociology had been set to account for processes of social change and revolution that rested on structures of social and economic inequality. Émile Durkheim and Max Weber, following Herbert Spencer and Social Darwinism, were seeking alternative explanations of order, stability or managed change, and how to achieve progress through evolution and development. Simmel's radical alternative to both these streams was to reject theories of social inequality or difference as a given structure imposed on the powerless by the powerful, or on the peasants by the landowners, or by princes on their subjects. Instead, he argues for social difference as a form describing exchanges between individuals, the totality appearing as a fixed structure. Changing the social interactions between individuals could radically transform what had previously looked like a fixed social structure. Marx, Durkheim, and Weber took it for granted that society existed and could be studied as a whole or in the constituent parts that they identified: actions, structures and systems, social classes, or social facts. Only Simmel started from the individual in interaction and "built" society from the bottom up. It was probably this radical individualism that opponents and critics saw as revolutionary and dangerous in Simmel's writing and teaching and in the development of sociology, and which led to his lack of promotion in the university.

Superordination and Subordination

In searching for a form in social interaction, Simmel identified the relation of leader and follower as occurring in many known societies. His description notes that there cannot be a leader without followers and that it follows from this that the leader, even in a relation of domination and coercion, still depends upon the dominated or subordinated for the relation to maintain. The follower is as essential to the existence of the interaction as is the leader for that *form* of interaction to sustain itself.

He examines all the logical variations of the relationship, concluding that the universality of the *form*, for example, would make socialism – where relations of inequality had been overwhelmed and absolute equality imposed – both idealistic and unstable, even impossible.

Conflict

Simmel argued that the analysis of conflict had moved on from that of the simplistic two class conflicts of Karl Marx into the much more complex environment that was modern work in the modern city. The original relationship between early societies who had no other form of communication, interaction, or exchange had been war, direct physical conflict. More modern conflict relationships were institutionalized in contests between lawyers in courts. This brought to conflict two new dimensions. First, conflict was now bedded in a system of rules, norms, and laws that regulated conflict situations (e.g., rules of engagement in the Gulf War, Geneva Conventions on Human Rights, and International Courts). Second, conflict was a normal, expected phase or stage in any process of interaction, which could be resolved by the parties without destroying the relationship.

Lebensanschauung

Simmel's last major work, *Lebensanschauung* (Life reflections), was published after his death. It has never been translated into English, probably because few sociologists felt it merited such attention. Simmel's return in this book to the individual in interaction as "self," as an aggregate process of the *forms* of sociation in which the individual engages, presages much of the fundamental work in philosophy and the emerging discipline of sociology. George Herbert Mead takes up the same themes from William James and, like Simmel, from Bergson in his lectures that became *Mind, Self and Society*. Martin Heidegger attributes some of the fundamental themes of his phenomenological philosophy to *Lebensanschauung*. Alfred Schutz and Aron Gurwitsch take the same starting points for *Phenomenology of the Social World* and *Studies in Phenomenology and Psychology*. Although Simmel is rarely quoted in the history of the

concept of *self*, it would not be unfair to attribute the origins of the sociological version of the concept to these writings.

Otherwise, the book is a book of its times. Simmel had moved to Strasbourg, had doubts about his lack of fame as a leading sociologist, returned to philosophy, and begun to shift his position on supporting Germany's role in World War I. He abandoned all religious belief and was increasingly disillusioned with his student group, depleted by military service and with his colleagues at the university. The book reflects the spirit of pessimism that was to prove important to Germany's undoing as the twentieth century progressed. In the post World War II spirit of optimism that marked the explosion of sociology in the 1960s, the *Lebensanschauung* was thus properly neglected and overlooked. With the refocus in the new millennium on micro sociological processes, the book might receive the examination and detailed review that it warrants, if only to ensure historical accuracy.

OVERVIEW

Simmel was probably not the greatest sociologist of his generation. That tribute ought to go to Max Weber or Émile Durkheim. Nor can we claim that Simmel's writings are still key texts for the modern student. What can be said is that few sociologists at work today do not owe some methodological or theoretical debt which traces its origin back to *Soziologie*. The methodological stream known as qualitative research in sociology and across the range of social sciences was first promoted and demonstrated by Simmel in his teachings and writings. The focus on deviance, the outsider, and the stranger as they characterize urban and city life underwrite streams of work in urban sociology, the sociology of deviance, and the sociology of mental illness and its treatment. Micro sociology, however its proponents might reject the label, symbolic interaction, sociology in the natural attitude or setting – all find their initial steps in Simmel's lectures and papers. Currently, the most profound debt is from cultural studies, where the attention of sociologists turns to fashion, art, sculpture, music, and performance set in the modern or postmodern world, following Simmel's early lead.

simulacra and simulation

Lauren Langman

For a number of sociologists, media theorists, and social critics, the current era, with its global market, advanced technologies, mass media and digital information, and the all present marketing of goods and politics, must be seen

as radically different from the industrial age of machine based mass production. One of the central technological innovations of the industrial era was the capturing of visual images, sounds, and later media with both sound and picture. From the earliest photos, to records, and later movies and television, we have seen and heard endless reproductions. But, today, many argue that we live in a "postmodern" age dominated by an endless number of spectacular images, most of which are simulations, copies without an original source, imitations where the original never existed. With the proliferation of simulations, created images serve less to reproduce the reality that was seen or heard than to create various images that in turn create a new "reality" and new kinds of meanings. The "reality" of today, a world of fantastic dreams and images, is said to be largely a product of advertisers, marketers, and political consultants. They are the ones who create and disseminate the spectacles and simulations of "hyperreality." At some point in the late twentieth century, the prevalence of artificial images, staged events, and socially constructed "realities" had become so prevalent as to be considered "normal," "natural," and hardly worth more than a yawn. In retrospect, we might now call our times the age of simulation.

With the emergence of symbolic capacities and the intentional production of various grunts, groans, and sounds – distinct words – signifiers came to represent things, what was signified. Language, according to Saussure, was a system of signs through which the spoken word represented different kinds of objects, actions, and experiences. For most of history, communication has attempted to describe or "re present" reality, or at least a particular version of reality ranging from the nature of the world, religious cosmologies, histories and law, and granary records to aesthetic expressions of one's self, desires, and meanings. Printing, mass literacy, and, more recently, mass produced and mediated representations in newspapers, magazines, radio, film, and television transformed the way people experienced themselves and their world.

Classical social theory emerged before the mechanical reproduction of images and the proliferation of mass media. Marx had noted the importance of ideology in distorting and

mystifying ruling class interests to reproduce capitalist societies. Similarly, the fantastic nature of the “commodity form” hid the actual reality of class relationships. Weber saw the importance of written records for bureaucracies – the typical organizations of modern governments and, indeed, most formal organizations. But neither anticipated the world transformative properties of mass media on politics and consumption.

The neo Marxist Frankfurt School argued that mass media distorted and disguised reality to serve the interests of political elites. It argued that emotionally gratifying Nazi propaganda consisted of an endless barrage of spectacular images and simplistic slogans that mobilized support for Hitler. Meanwhile, denigrating images demonized the Jews, who were blamed by Hitler for Germany’s problems as the Nazis promised retribution.

After the crises of 1939 that led to World War II, capitalism required expanding new markets. Consumer goods would provide that market – but the work ethic and frugality needed to be tempered in order to foster consumerism as a lifestyle. Thus consumer capitalism required the existence not only of affordable goods, but also of consumers who constantly “needed” to buy things. There was an increased role for advertising and marketing that moved from describing products to creating images in order to colonize consciousness and socialize people to buy commodities that provided meanings and gratifying, lifestyle based identities. In the illusory world of crafted images, “authenticity” became a commodity to sustain consumerism.

The Frankfurt School then argued that the “culture industry” not only sold mass mediated entertainment as a profitable commodity, but also fostered “one dimensional” thought that dulled the capacity for critical reason. Dulled reason led people to accept the socially constructed versions of reality crafted by elite commercial interests or political elites. The “culture industry” provided escapism to distract people from important social issues; the shallowness of consumerism or the hypocrisy of political leaders was disguised. But for many scholars, critical theory was a “snobbish” expression of a cultural elitism that basked in pessimism.

The next generation of media/culture theorists, Guy Debord, Jean Baudrillard, Paul Virilio,

and Umberto Eco, might be called the “simulationists.” They claimed that we now live in a world where mass mediated communication and the mass production of simulations, fakes, and replicas do not so much represent and/or ideologically distort reality as “create” a new order of reality, a spectacular “hyperreality” based on images, simulations, and mythologies that have no connection with actual reality. Nor does this simulated reality hide “truth” behind appearances; rather, there are no “truths” other than the simulated images that now dominate our culture.

The French Situationists, a group of avant garde Marxists, anarchists, and libertarians, were influenced by Dada and Surrealism. Debord (1977 [1967]) became their most elegant spokesman. They felt that the Soviet models of revolution and vision of society were deeply flawed and irrelevant to a consumer society dominated by endless spectacles. They argued that by the late 1950s we lived in a world characterized by continuous spectacle, extraordinary images and events that were systematically produced. Radio, television, film, music, industrial arts, fashions, athletic events, and festivals had become an all powerful, hegemonic system sustaining elite privilege and rendering workers placid through consumption. Extraordinary representations mediated reality and the relations between people. For Debord, the spectacle had become an all pervasive aspect of modern life, but this world of images served to justify the nature of capitalist society and ignore the “more fundamental” issue of how goods were produced – typically by exploited workers. For most people, the images of the new consumer society were its truth, while its “realities” of exploitation and domination were ignored. The spectacular images had displaced underlying realities and served to sustain the system.

The endless images and meanings of consumer society engendered “pseudo needs” to consume, which, much like the drudgery of work under capitalism, fostered alienation and in turn powerlessness and passivity. The fetish of the commodity form now colonized everyday life; subjective experiences were imitations of experience. Being “human” became equated with buying and “having” things, and “having” was transformed into appearances. The domination of appearances, what seemed plausible or even

true, isolated the present from history and maintained the status quo as an eternal today (Cubitt 2000). The spectacle had become the new form of domination.

The Situationists influenced the then young Jean Baudrillard, a neo Marxist sociologist concerned with signification and consumption. But in 1972 he broke with the Marxism that he saw as a critique of now outmoded modern, capitalist, industrial production. He saw this as irrelevant to the new, postmodern, “semiurgical” society, one based on semiotics, the production and interpretations of meanings in which acts and objects served as “signs” that have relationships to each other to produce “texts.” For Baudrillard (1994), this new order of seduction by images was increasingly based on simulation where simulacra preceded and created “hyper reality” rather than representing reality – accurately or otherwise. The “real” has imploded and been replaced by codes of reality. “The simulator’s model offers us ‘all the signs of the real’ without its vicissitudes” (Baudrillard 1994). Producers of signs such as advertisers, politicians, or film stars attempt to manipulate the public by controlling the interpretive frameworks – the code. The code is an overarching mode of sign organization that influences the “correct” or widely accepted interpretation (Gottdiener 2001). The simulations or the model have become the determinant of the perception, experience, and understanding of the contemporary world.

Semiotics and simulation have displaced political economy in the postmodern era, in which there are no more “actual” events; only media events are significant. For example, wars now exist only to the extent that they are televised images of war. Charts or radar screens supplant actual blood, death, destruction, pain, and suffering. “Public opinion” has become more “real” than the people who offer it. Individuals have become simulations of self modeled after mass mediated images, films, and ads that are articulated in spectacular self presentations dependent on consumer products that convey the right images and meanings (Langman 1992). The masses are bombarded by images (simulations) and signs (simulacra) that encourage them to buy, vote, work, or play, but eventually they become apathetic (i.e., cynical) (Hawk n.d.). People are no longer concerned with knowing

the truth – the image is sufficient. This creates a world in which consumerism leads to the “goods life.” Congenial, photogenic, yet often inept leaders are elected, disastrous policies appear brilliant, while a public exposed to thousands and thousands of media images shows little concern or outrage.

Virilio’s (1986 [1977]) analysis of modern culture emphasized the history of warfare and the importance of speed in moving men, material, and information. The growing speed of media, from messenger delivered notes to watching events unfold on television, or today emails and IMs that cross the globe, has led to a growing disconnection between images and the realities they would represent. This has, in turn, led to lapses in objectivity as well as subjectivity. Indeed, the speed of the succession of ephemeral images, without mass, bulk, or truth, has led to the erosion of freedom.

For Eco (1986 [1967]), “hyperreality” is the dominant trope of our age. His view of hyperreality is much like the spectacle for Debord and simulation for Baudrillard. Like them, he was one of the earliest writers to note the proliferation of the artificial, the fake, the imitation, and the replica as the new reality, the new “hyperreality” that was especially evident in Disneyland, Los Angeles, and Las Vegas, primary realms of recreations and themed environments that produce something better than the real. The US was seen as a land of fake history, fake art, fake nature, and fake cities where imitations do not so much reproduce reality as create a “better version” of a history without oppression, art without flaws, jungles without danger, and cities without crime, dirt, or even actual people. The Disney imitations of Main Streets, castles, (animatronic) people, animals, and monsters stand as the prototypic expression of an artificial realm of replicas. In the magical realms of Disney, fantasies are mass produced. This new theme park version of “hyperreality” can be seen in cities like Los Angeles, itself a center for the production of simulation. But the ultimate in simulation must be Las Vegas with its simulations of Egypt, Paris, Italy, and New York (Gottdiener 2001).

For Eco, the defining characteristic of our age is the emptiness of communication, perhaps best seen in the banter of sportscasters who engage in idle chatter for hours on end, who talk without

there being anything to talk about. Such banter is without content or meaning – a total waste. But this style of form without substance has become the dominant trope of advertising, entertainment, and politics. Indeed, as Baudrillard suggested, there has been an implosion and the boundaries between these realms have withered.

To be sure, simulations, fantastic themes, and imaginary motifs in the service of consumerism may well provide corporations with profits by providing people with a myriad of gratifications. So too can simulation sustain political power. But there is a dark side to the proliferation of simulation – its celebrations of consumerism promise a gratifying identity, lifestyle, and even a reality that is always elusive. In the case of politics, often onerous policies can gain mass support. The use of radio and movies for propagandistic political purposes was essential to the rise of Hitler and support for his aggressive policies. Today, with television as the primary means through which most people are informed about the world, the ominous side of simulation and its capacity to dissimulate and misinform is greatly increased. Television, with its primary emphasis on the rapidly changing visual image, is especially well suited for entertainment. It does not so much represent reality as inform opinions. News and political information take the form of entertaining political spectacles and simulations. This is a major danger to freedom and democracy because of the passivity of viewing in general, the absence of counterfactual information, and the domination of the news programs by escapist distractions (Edelman 1987; Kellner 1992). With television's endless simulations and its creations of hyperreal worlds, there is a dulling of critical reasoning that fosters passivity at best, and cynicism at worst. Indeed, many question whether a free media and informed public can exist in the current world. All too often, it seems that the simulation and its realities are preferred.

A long tradition of intellectual work has been critical of representations that do not represent but instead distort and hide. Perhaps this began with Plato's critique of painting as an inferior form of representation. But in our current world, we might note that critics from the right such as Ortega, the left such as Adorno, or a democratic centrist such as Postman, have each

in their own way been critical of the ways in which media images not only seduce, but also offer massive distortions of the actual ways the world functions by providing illusory utopias whose locations in hyperreality serve the powerful who remain in control of the realities of political economy.

simulation and virtuality

Sean Cubitt

The term *simulation* and its cognate *simulacrum* have a venerable history as the Latin translations of the Platonic *eidolon*. This is a copy of a

copy, exemplified in Plato's *Republic* by a painting of a bed: the carpenter's bed is a copy of the Ideal; the painter's a copy of the carpenter's, and so at a distant remove from the reality of the Idea. The term *virtual* is almost as ancient, traceable to the Aristotelian distinction between potential and actual: the future is a field of infinite potential until it is realized, at which point it trades its potentiality for actuality. Both terms have double usages in contemporary social science, as theoretical tools and as descriptions of specific methods, both associated with computer modeling.

Simulation theory is most closely associated with French sociologist Jean Baudrillard. From his early work on consumerism to his first major books, *The Mirror of Production* (1973) and *Symbolic Exchange and Death* (1976), Baudrillard voiced the despair of his generation with the betrayal of the political movements of 1968. Drawing on the situationist Guy Debord's theory of the spectacle and on the renegade surrealist Georges Bataille's notion of symbolic economies, Baudrillard began to query the reality of an increasingly mediated world. Rather than a composite formation of individual or class actors, society was a self-replicating Code, a homeostatic system. In the most frequently cited statement of his position in mid-career he wrote of the simulacrum's four historical phases:

- it is the reflection of a profound reality;
- it masks and denatures a profound reality;
- it masks the *absence* of a profound reality;
- it has no relation to any reality whatsoever:
- it is its own pure simulacrum.

(Baudrillard 1994: 6)

By contrast with postmodern theorists of difference, Baudrillard's later work insists on a new historical condition of homogeneity from which the possibility of historical change has been eradicated: "The perfect crime is that of an unconditional realization of the world by the actualization of all data, the transformation of all our acts and all events into pure information: in short, the final solution, the resolution of the world ahead of time by the cloning of reality and the extermination of the real by its double" (Baudrillard 1996: 25). "Realization" and "actualization" indicate the Aristotelian roots of the later Baudrillard. The world as

material, and therefore as potential, has been lost in favor of an actual world composed of its transcription into data. And as data, the world acts as a homeostatic system realized "ahead of time," that is, before it could fulfill whatever other potentialities lay latent in it to evolve historically into something truly different.

Although, through its debt to Debord, simulation theory has roots in Marxism, and perhaps especially the Hegelian Marxism of Lukács, it is itself an anti-Marxism. Skeptical, even scathing, of the consumer society, Baudrillard nonetheless holds out no hope for social action to change the world. This is in part because social classes have been supplanted by their mediation in polling, leaving only silence and apathy as appropriate political strategies; and in part because, he claims, the traditional workplace core of Marxist organization has ceased to produce. Factories no longer manufacture goods, and social movements no longer seek to close them down or seize them. Instead, political groups seek to keep factories open and functioning, not for what they make, but so that they can provide jobs. People work in order to work, not to make things or to provide services. To claim a "right to work" is equivalent to demanding a "right to leisure," and both are equally simulations whose purpose is simply to reproduce the consumers of signs. Production itself, the core of Marx's *Capital*, has ceased to exist.

Other authors with an interest in simulation have shared this distrust of Marxism, especially the variants prevalent in 1968. Umberto Eco was a rigorous critic of the Italian Red Brigades as well as an ironic critic of North American consumerism in his *Faith in Fakes: Travels in Hyperreality* (1986). Urban planner and historian of warfare Paul Virilio, through his involvement with Henri Lefebvre, was a major participant in the May events in Paris in 1968, but in his career as essayist has increasingly expressed his distrust of the contemporary world in terms of radical Catholicism. Simulation theory has been particularly influential in media and leisure studies and in scholarship on contemporary warfare. It has found itself especially vulnerable to charges of monoculturalism, cultural pessimism, and an overly absolute periodization through which to distinguish the contemporary world from previous history.

The same cannot be said for the second usage of the term *simulation* in contemporary sociology, where it refers to the practice of modeling future scenarios through the use of computer programs such as geographical information systems. Typical uses consist of employing very large databases of past geographical, economic, and demographic trends from which skilled programmers can extrapolate likely future scenarios based on shifting key variables. This type of automated futurological social science is, indeed, the kind of activity which Baudrillard singles out for attention in *The Perfect Crime* as practice which reconfigures society as pure information, thus robbing it of its reality. The conflict arises over two key disagreements. Firstly, Baudrillard is a constructionist who believes that the datum is not given, while empirical social science believes that interpretation is epiphenomenal. Secondly, simulation theory is an extreme variant on the theory of representation, according to which no representation is adequate to the reality to which it refers: in the theory of representation, this results in partial representations which are open to bias, prone to agenda setting, and ideological. Simulation theory sees the inadequacy as absolute: representation depends on the absence of the represented, and thus overrides and obliterates the reality it refers to. Simulation as modeling, however, recognizes partiality as experimental tolerances or degrees of accuracy.

The term *virtuality* is often confused with simulation, especially in contexts where both are aligned with the less definite concept of hyper reality. It refers both to computer generated quasi realities and to the philosophical concept of potential existence. Although the word has attained general currency through its evocation of any connection to digital media, technically it refers to immersive systems capable of generating the illusion that the user is occupying a space which is in fact entirely or largely computer generated. Such systems include head mounted displays, virtual environments with or without 3D enhanced goggles or screens, and increasingly the domain of theme park rides. Because theme parks and other wholly designed environments (such as Forest Lawn cemetery and at least some heritage centers) are also emblematic topics in simulation theory, the confusion is unsurprising. Howard Rheingold's *Virtual Reality* (1991) and Michael Heim's *Metaphysics*

of Virtual Reality (1993) and *Virtual Realism* (1998) presented immersive audiovisual media as pathways to enlightenment. In a key essay responding to such claims, roboticist Simon Penny (1994) asserted that virtual reality systems were the fulfillment of the European Enlightenment's dream of perfected individualism in a normalized Cartesian space. Although scientific and artistic experiments with immersive media continue, research now focuses on augmented reality, in which wearable computers allow data to be mapped over real world perception, while the expected mass market in the games sector has been overtaken by the rise of network and mobile gaming as the major growth engine for the industry.

Outside research and educational and aesthetic uses, virtuality's main presence in the early twenty first century is in mass spectacle. Thus the term is applied to such phenomena as Disneyland and similar theme parks, especially attractions whose spectacle, volume, and physical movement is sufficient to overwhelm participants, to IMAX and OMNIMAX theatrical screens, to the most lavish live theater, and to such urban phenomena as Las Vegas and downtown Tokyo. For the most part these spectacular venues involve participation in crowds rather than individuated interfaces, and confused spatial orientation rather than the Cartesianism of immersive technologies. For authors like Norman Klein (*The Vatican to Vegas: A History of Special Effects*, 2004) and Angela Ndalanis (*Neo Baroque Aesthetics and Contemporary Entertainment*, 2004), the virtuality of immersive leisure technologies no longer appears as the precursor to new rationalist enlightenment, but as the heir to the European baroque's sensuous mysticism and celebration of power. In both instances, however, what can be discerned is a movement from the domination of nature to escape from it, both as environment and as human nature. Slavoj Žižek in *The Plague of Fantasies* (1997) sees this occurring on at least three levels: immersive virtual realities put "real" reality into question; biotechnologies and other real world applications undermine the givenness of external reality; and the role play of network mediated communities disintegrates the reality and givenness of the self. This opens for Žižek two possible futures: a catastrophe in which the informational double of the world is lost and

with it the function of the Other in the construction of desire and symbolization; and a utopia in which all symbolic conflicts, chief among them wars, are played out in virtual space with no real casualties at all. Either route might result in the redemption of real life from its own vanishing. At this juncture Žižek's virtuality appears to approximate Baudrillard's understanding of the stakes of simulation, but without Baudrillard's nihilistic reworking of Leibniz (i.e., why is there nothing rather than something?).

A similarly optimistic usage of "virtuality" derives from French philosopher Gilles Deleuze, a professed anti Hegelian rather than an anti Marxist (in contrast to the profoundly Hegelian Žižek). Defining the term in *Difference and Repetition*, another book from 1968, Deleuze uses a phenomenological example that comes close to his later readings of C. S. Peirce: the confused yet distinctive sounds of the sea. Such sounds are composed of differential relations among singularities, unique events, but are not yet distinguished as separate sounds. Such sensations are virtual as opposed to identified and distinguished sounds, which become actual in the process of becoming objects of perception. The virtual-actual opposition applied to social relations implies an atomistic field of differences, relationships, and points of singularity where they intersect to form, among other things, individual sensoria, all of which constitute a virtual domain of potentiality. The actualization of one specific potential deprives the virtual plane of its other possibilities, but also generates further potentialities, further virtuality. The concept seems close to both Ernst Bloch's conception of the future as not yet existing, and to the idea of natality outlined in Hannah Arendt's introduction to her *The Human Condition* (1958).

The term has been taken up by numerous social thinkers. Hardt and Negri devote a chapter of *Empire* (2000) to the concept of virtualities as the desires of the multitudes and their productive capacity to transform them into reality. Thus defined, the virtual is both the affective motivation and the power to act "beyond measure," that is, outside the political and economic structures of dominance. Equally insistent that this virtual power is material and anti dialectical, they assert the virtual as the boundless creativity of being. A similar use

appears in Luce Irigaray's concept of the virtual feminine, for example in *Sexes et parentés* (1987), where the project of becoming feminine is asserted to be an open ended process of creation. This concept has been linked with Deleuze's virtuality in the work of Rosi Braidotti, for whom "Sexual difference, from being a boundary marker, has become a threshold for the elaboration and the expression of multiple differences, which extend beyond gender but also beyond the human" (Braidotti 2002: 261). Such virtual gender is at once immanent and embodied, singular but constitutionally articulated with multiple social relations. Like Baudrillard's simulation, such conceptualizations of virtuality deny that differences constitute a dialectic, and to that extent almost all simulation and virtuality theorists share a general anti Hegelian or anti Marxist stance, insisting on the fluidity of becoming rather than the mechanisms of conflict. Ironically, however, for two terms so frequently confused, simulation theory is strongly pessimistic and anti realist (though practical simulation is both future oriented and empiricist), while virtuality theory is equally strongly optimistic (although practical virtual reality is open to criticisms of nostalgic reconstruction of Enlightenment ideals).

situationists

Alberto Toscano

The situationists were a collective of anti-capitalist thinkers, active from the late 1950s to the early 1970s, who theorized the alienated character of modern consumer society and its revolutionary overcoming. Plagued throughout its history by splits and expulsions, the Situationist International (SI) was formed in 1957 from a number of tiny avant garde groups, including the Lettrist International and the Movement for an Imaginist Bauhaus. The SI published an eponymous journal from 1958 to 1969. Best known for its widespread cultural influence (from Baudrillard to punk rock) and role in the Paris events of May 1968, the SI counted among its ranks the Danish painter Asger Jorn, the Belgian writer Raoul Vaneigem, and the English art historian T. J. Clark. Its chief theorist was Guy Debord.

Undertaking a fierce critique of what they defined as the colonization of everyday life by capitalism, the situationists saw themselves as overcoming the limitations of the avant gardes of Dadaism and Surrealism. Their name derives from the idea that capitalist culture could only be undermined through a deliberate practice – simultaneously aesthetic and political – of “constructing situations”: “games of events” and “unitary ambiances” that would rupture the alienation or separation of the modern day worker/consumer from his authentic desires and potentials, terminating his subjection to what Debord termed “the humanism of the commodity.”

The project of constructing situations was both urbanistic and semiotic. In conjunction with Henri Lefebvre, whom they later denounced for his reformism, the situationists attacked the deadening effects of modernist urbanism and architecture, exemplified by Le Corbusier. They sought to counter this modernist planning of social life with the “psychogeographical” practice of *dérive*, a methodical practice of drifting through the fragmented space of the modern metropolis, experimenting with the city’s effects on the behavior and desires of individuals. The ultimate horizon of such a practice was a “unitary urbanism” that would try to reactivate

the sedimented potentials of the city and create spatial experiences freed from the domination of commodities. At the level of signs, the situationists advocated *détournement*, the subversive usage of the materials of capitalist culture. This was epitomized in the irreverent use of comic strips to communicate revolutionary messages during May ’68. These strategies were linked, especially in the work of Vaneigem, to a politicization of pleasure and play as anti-systemic practices.

Relying heavily on Hegel, Feuerbach, the early Marx, and Lukács, Debord’s *The Society of the Spectacle* (1995) proposed to update the categories of ideology critique to confront the novelty of advanced capitalism. Debord argued that the hegemony of capital over life had become virtually total, as capital was accumulated not just in the guise of material commodities but in that of “spectacles.” According to Debord, the social relations underlying such spectacles were alienated in a manner far more severe than the one envisaged by Marx’s account of commodity fetishism.

In his discussions of consumption and celebrity, Debord showed how capitalism can appear as an autonomous domain, both production and the image of that production. The spectacle – both as a sector of capitalism (the “media”) and as the totality of alienated social relations – signals not just the subordination of men to the dictates of political economy, but also the simultaneous justification of such a state of affairs. In the spectacle, life itself vanishes into its separate or independent representation and capitalism perpetually celebrates its own existence. Even the most revolutionary of practices (situationist ones included) can be “recuperated” and made functional to the perpetuation of alienated life.

Reflecting more specifically on the geopolitical situation, Debord interpreted the Cold War as the complicit juxtaposition of a bureaucratic “concentrated spectacle” in the East and a consumerist “diffuse spectacle” in the West, and foresaw, on the eve of the collapse of historical communism, their unification in an “integrated spectacle.” This diagnosis was linked to the situationists’ virulent opposition not just to the Leninist and Stalinist visions of the party, but also to a host of revolutionary trends, from Maoism to third worldism. Abhorring any

notion of politics that would trade autonomy for representation (or for charismatic leadership), the situationists pledged allegiance to the tradition of workers' councils, which they regarded as the only form of organization that would not merely repeat or displace the alienation instituted by the spectacle.

The situationists' theory of contemporary society was accompanied by a bleak estimation of the human sciences. From urbanism to political science, from psychology to sociology, the situationists viewed the activity of such compartmentalized academic disciplines as, at best, a form of passivity deriving from the separation of intellectual from manual labor, and, at worst, a willful collusion with the reign of the spectacular economy. Though the situationists did make ample usage of notions originating in the human sciences, including sociology, it was only to the extent that such notions could be enlisted in a practical critique of alienation. Their aim was to identify those forms of life capable of breaking through the cultural "decomposition" and increasing "proletarianization" that affected the contemporary world. It is in this sense that the situationists focused, for instance, on the ambivalent role of leisure in contemporary society and the emergence of violent and unmediated forms of contestation (e.g., the Watts Riots of 1965). The goal was to accelerate the collapse of capitalism, not merely to interpret it. Or, as they put it in the SI editorial "Critique of Urbanism" (1961): "to envisage in terms of aggressivity what for sociology is neutral."

In line with Debord's frequent references to Machiavelli and Clausewitz, the thinking of the situationists, who repeatedly refused any fixed doctrine of "situationism," is best understood as a *strategic* critique rather than as any kind of dispassionate social analysis. The situationists sought to locate the faultlines in the ensemble of capitalist social relations and outline modes of living capable of constructing new, antagonistic desires that would resist their atomization and representation.

slavery

Rodney Coates

Perhaps the oldest form of human oppression is that of slavery. Slavery, with its roots in antiquity (e.g., Egypt, Babylon, Assyria, Israel, and Greece), is defined as the forced labor of one group by another. The institution of slavery, where the slave was considered merely a piece of animate property or chattel, was first developed by the Greeks. Brutality, to include whipping, humiliation, and alienation, has been part of slavery from its inception. Slaves, stripped of their human dignity and title, were forced to abandon their family, culture, and personhood, as another owned their very being. Women, doubly exploited, were subject to sexual exploitation where they could be forced into prostitution or to submit to the sexual demands of their masters or their guests. Slaves during these periods, often accorded higher status, could be

adopted and become legal heirs of the masters. Typically, these slaves were vested with special duties owing to their unique talents (such as teachers, actors, fighters, etc.). The modern system of slavery, a direct result of European imperialistic expansion, provided even harsher levels and degrees of exploitation, humiliation, and degradation.

The modern slave system beginning with the start of the Atlantic slave trade preserved many of the earlier exploitative conditions while creating unique variations of its own. Similar practices included the dehumanization and degradation of the slave in order to preserve order. Hence there were attempts to strip the slave of his identity, culture, and history, slaves were reduced to things (chattel property), and they were required to observe ritualistic etiquette and politically correct behaviors. These practices further served to reinforce the hegemonic structures of control and power. Modern slavery differed significantly in that it created race and racism to justify the institution. Slaves, not complacent, formed extensive networks of rebellion that greatly aided their attempts to revolt, escape, and contest the system.

The primary goal of modern slavery was to create a hyperexploitative system benefiting the master class. This institution is deemed hyperexploitative for it rested on the exclusive control of and the capacity to exhaust the total labor capacity of the slave. Hence, the average life expectancy of a slave was typically set at no more than 30 years of age. All of the produce, intellectual, physical, and even issue, were deemed to be the rightful property of the master. Death, escape, and the rarely utilized emancipation of the slave were the only release from this hyperexploitation. The fact that racial identity was integral to the system increased the likelihood that all persons of color, regardless of status (i.e., born free, emancipated, or escaped), were continually paranoid. Such paranoia was frequently manipulated (formally by race specific laws, bands of disgruntled whites, or caprice) to ensure continued servile behavior of both free and non free. Hence, slavery as a total institution shrouded persons of color regardless of status.

What few realize, when contemplating slavery, is the damage done to white and other forms

of labor. Essentially slavery, with its capacity to hyperexploit labor, displaced other forms of labor where it was in competition. Those of lower class position, but in the same racial caste as the dominant master class, found their positions tenuously dependent upon the good will of the master class. That is to say, their labor value was unduly suppressed by the cheaper labor value supplied by the master class. In those areas where there was a shortage of slave labor, the value of lower class white labor was lowered. Racism, in these situations, served to offset the lower value of lower class white labor both psychologically and socially. Therefore, the slave could be humiliated, brutalized, and displaced by the lowliest of white workers. Inappropriate etiquette or politically incorrect behavior on the part of the slave could result in beatings, maiming, or even summary execution. Alternatively, in those situations where labor was in surplus, then white labor was actually displaced. Such displacement only aggravated the racial divide, while those white laborers forced to relocate tended to reproduce racial exclusionary or bifurcated labor systems wherever they settled. Racism, based upon these racial exclusions, far outlasted the system of hyperexploitation that produced them.

Sexual exploitation within slavery served multiple functions to include the sadistic pleasure of the master class, increased profit owing to issue produced, and of course the further humiliation of the slave.

Within the Americas three distinct slave systems developed. The distinctions between these systems derive from different cultural, political, and economic realities. These different realities, for want of a better terminology, are best described as those under the Spanish, French, and English sphere of influence. The major distinctions between these four slave systems had to do with the form of contact situation that prevailed. The most significant reasons for the differences among the European colonies have to do with the American Revolution among the English, and the influence of the Catholic Church among both the French and the Spanish. We shall briefly describe these three systems.

Spanish imperialist goals, fueled by vague and overly hyped claims of rivers and temples

of gold, led to the first official European “settlements” in the Americas. These settlements, whose primary goal was to extract the claimed riches as fast as possible, soon led to disappointment as no rivers or temples of gold were found. Columbus and his men, undaunted, began to kidnap, imprison, ransom, and enslave the natives in their attempt to secure the illusive gold. Failing in this, the Spanish – still believing in hordes of gold just waiting for the plunder – sent more and more conquistadors to search out the prizes. With time, the only prize identified was the lush soils of the Amazon – and the Spanish colonial experience began. Maximization of exploitative goals led to, first, the enslavement of Native Americans, and later the importation of African slaves. The period of Spanish conquest, from 1519 to 1523, was characterized by extraordinary brutality and cruelty and decimated the indigenous population. Starting with a population of just over 4.5 million in 1519, the native population declined to 3.3 million in 1570 and to 1.3 million in 1646. The primary culprits for these declines were small pox and typhus, wars of extermination, forced labor, brutal work conditions in the mines and on the plantations, tribute taxes, and cultural genocide. The decimation of the native labor force increased the demands for alternative labor sources. These alternative labor sources were soon supplied by the Dutch and Spanish merchants in the form of the African slave. The Spanish, with no intent on permanent settlement, did not encourage large numbers of Spanish women to immigrate. Thus, the gender imbalance increased the likelihood of sexual exploitation, prostitution, and the creolization of the population. Under rare circumstances, the Catholic Church stepped in and insisted upon the formalization of these unions in the guise of marriage. With time, the societies that came into being reflected these blended racial origins, generated by slavery, of Spanish, Natives, and Africans.

The French, eager to fill Napoleon’s treasure chest and pay out mounting royal debt, entered the Americas with the express desire to maximize profits through trade. Their efforts in the Americas, centering in the Caribbean, Mid South and West, brought them into immediate contact with the Native Americans. Almost

from the start, they established rather friendly relationships. As with the Spanish, the French soon realized that their profits could be greatly enhanced with the creation of a colonial presence, and hence more permanent agricultural communities were established. In order to maximize these efforts, the French relied more and more heavily upon the African as the chief source of exploitable labor. Owing to the shortage of French women, again there was a heightened tendency to sexually exploit the African and Native American women. Thus prostitution, rape, and sexual abuse were often the result. Some of this sexual abuse was masked under the guise of formal marriages, which also served to provide access to greater resources among the indigenous population, legitimacy among the growing Creole population, and stability for the growing social structure.

The English, under the guise of freedom, initially promoted their imperialist expansion on the backs of lower class Europeans. It is important to point out that among the English, the first group to experience slavery was not the Africans but the Irish. English rulers, beginning with Queen Elizabeth and continuing through Cromwell and King James, in a systematic attempt to destroy the Irish people and their culture forced several thousand Irish into slavery in the Americas. Thousands of other Europeans, similarly positioned at the bottom of European society, were forced to serve masters in this land of the free. Of interest is the fact that before African slavery was normalized, these individuals were collectively viewed as slaves. With the advent of African slavery, these slaves found their status significantly altered as they now became defined as servants. Still with the further passage of time, lower status Europeans were allowed entry into the racial caste of whiteness. Whiteness accorded its participants the ability to discriminate against non whites, hence we note the birth not only of racism but also of a racialized hierarchy. Both racism and this racialized hierarchy were functional in maintaining control over the slavocracy that later developed.

slurs (racial/ethnic)

John Moland, Jr.

A racial or ethnic slur is a remark or statement designed to defame, vilify, belittle, and insult members of a racial or ethnic group, usually by those who are not members of that racial or ethnic group (Rodale 1986: 1125). Examples of racial and ethnic slurs include expressions such as "miserly jew," "gook," "jap," "red savage," "mongrel," "half breed," "sambo," "spook," "nigger," "coon," and "kike."

Racial and ethnic slurs reflect the attitudes and beliefs of individuals and groups, on both conscious and unconscious levels, to make another group, generally a group with less power, the target of the slurs. For this reason, there is for both the user and the target of the slurs a variety of psychological, emotional, and behavioral actions and counteractions. The choice of words used, and the force with which they are used, mirror the degree of animosity the users of the slurs will have toward the groups that are the targets of the slurs. Such slurs traditionally have meanings in the ideological underpinnings that buttress such slurs, for behind the use of slurs one would find beliefs in the biological, cultural, and moral inferiority of the victims of the slurs. Consequently, slurs

are used to ascribe attributes of moral weakness, intellectual and academic weakness, and physical and behavioral peculiarities to members of the racial or ethnic group.

Historically, racial slurs used by white Americans toward black Americans depict black Americans as emotionally and intellectually immature, morally degenerate, and not being fully human. This can be seen in arguments used in the defense of slavery and segregation after the Civil War. Slurs against blacks were used in the sermons of white ministers, the speeches of politicians, and the writings of academicians to describe blacks in a very negative manner so as to justify the status quo. For example, the following slur appeared in the *Baptist Courier* of June 22, 1899: "The native African is a born liar and thief" (Owens 1971: 79). Senator Theodore G. Bilbo, a white supremacist and lay minister, was outspoken as a public official in his use of slurs to express his strong concern for maintaining segregation and "the purity of white blood." The intensity of his resentment of black Americans was demonstrated by the slur used in the title of his book, *Separation or Mongrelization* (1947). Table 1 presents examples of words used in expressing slurs against black Americans in the religious sermons, political speeches, and academic writings of white Americans.

From the perspective of *symbolic interaction*, the slur words provide qualitative data for examining the direct and indirect semantic differentials and far ranging implications in the use of the slur. Each slur word generates a dichotomy of mutually exclusive characteristics for blacks and whites, with an implied logic and a possible course of action for the user of the slur as well as for those who are the targets of the slur. The slur, therefore, functions as a tool for the formulation of ideas, emotions, and actions toward those to whom the slur is applied. From this perspective, slurs provide an outlet for expressing emotions with the potential of serving as a rallying call to action. When the slur is used to describe an individual or group in strong negative terms, giving expression to feelings of hatred, then the slur symbolizes and arouses negative images, feelings, and emotions which the user assigns to the racial or ethnic background of those involved. When these negative qualities are intensely and saliently impressed

upon the mind of the user, they become deeply internalized in the user's conduct and personal identity. The intense saliency of these features and the descriptive characteristic of the slur determine the nature and extent of interaction of the slur user with members of the targeted racial or ethnic group. The affective content of racial and ethnic slurs for the user include verbalized ideas, beliefs, and emotions. This constitutes part of the social psychological process which allows the user to maintain a coherent and meaningful view of the self and others in the context of the user's belief system, ideological perspective, and self interest. In this sense, slurs demonstrate the power of words.

Racial slurs, as verbalized expressions of racist beliefs, result in the user constructing a circular logic in which social relations and interactions of blacks and whites are perceived only from a racist perspective of black inferiority and white superiority. By addressing and interpreting reality through slurs, social relations and group interaction are consequently limited and restricted to a linguistic framework that serves the vested interests of the user, which may be direct and/or indirect in its psychological, monetary, or other advantages for the user.

From the *social conflict* perspective, racial and ethnic slurs can be seen as mechanisms for

expressing aggression toward an out group through slandering, labeling, stigmatizing, and verbally "cutting to pieces" those of the ethnic and racial out group. In this manner, the slur serves as an instrument or process for releasing aggressive hostility in in group/out group conflict situations. Such hostility is expressed in the use of slurs in anti racial and anti ethnic jokes (Middleton & Moland 1959: 61). The frequent use of racial and ethnic slurs in the rhetoric of institutional leaders and other members of the in group creates in their minds and in the minds of listeners an almost permanent fixation of negative images of those in the racial or ethnic out group. The stigma and label assigned to the out group precede and dominate any contact or relationship in group members have with those of the racial or ethnic out group. This brings into play the *social control function* of slurs for in group members. For example, white in group members are aware of the slur "nigger lover" and the ridicule and rejection that one would experience if seen in frequent association with black Americans. In this manner, the slur serves a social control function by exerting strong pressure for conformity with conventional racial norms while promoting in group solidarity. Finally, an important function of slurs for members of the racial or ethnic in group (the users) is

that of creating and reinforcing a sense of solidarity and intimacy within the group. It also provides the individual using the slur a sense of social approval and bonding with in group members.

Small, Albion W. (1854–1926)

Joyce E. Williams

Albion W. Small is known more for discipline building in sociology than for contributions to sociological theory. He established the first department of sociology at the University of Chicago and served as its head from 1892 to 1924, and in that role influenced several generations of American sociologists. In 1895 he established the discipline's first professional journal, the *American Journal of Sociology*. He helped to found the American Sociological Society in 1905 and served two terms as its president. As with most of the first generation of sociologists in the US, Small's formal training was in philosophy and theology, but studies in Germany turned his attention to economics and interest theory. All of his work reflects an overarching concern with ethical interests. Small wrote and spoke about methodology, but not as we know it today. His own methodology was largely historical, economic, and political analysis. Nor did he clearly distinguish theory from methods. In his "Fifty Years of Sociology" (1916) under the subheading of theory, Small wrote about years of "wrestling about methods" along with the search for a single, theoretical explanation of society.

Influenced by Gustav Ratzenhofer and Ludwig Gumplowicz in Germany, Small's major contribution to sociological theory was his conceptualization of the social process, seen as developing, adjusting, and satisfying human interests. He viewed society as a process of social conflict, ultimately transformed by socialization and cooperative behaviors (Barnes 1948). His sociology was a classification of human interests and their significance in the social process, which he saw as a struggle of interest groups even though he believed strongly in solidarity. Small's text *General Sociology* (1905) focused on human interests and the social process, but made as many contributions to economics and political science as to sociology.

Small's writings reflect his struggle with cooperation and conflict. He taught a course on "The Conflict of Classes" and wrote *Between Eras: From Capitalism to Democracy* (1913),

contextualizing class conflict in the rise of capitalism. Small's goal for sociology was to supply a secular theology for industrial capitalism. He combined a Marxian economic ethic with Christian social ethics, advocating a kind of Christian socialism based on rigorous empiricism. He saw subordination of self to society as the highest form of individual altruism. Much of his work was an attempt to unify character and social structure in an integration of self and society (Vidich & Lyman 1985). He provided a transition between systematizers such as Comte, Spencer, and Ward and subsequent generations of specialists. For Small, sociology provided the basis for an intelligent and efficient control of the social process and progressive improvement of human culture and social institutions. All of his work was about understanding the social process as a whole and about utilization of that process for social betterment.

Smith, Adam (1723–90)

D. A. Reisman

Adam Smith was born on June 5, 1723 in Kirkcaldy, a quiet fishing village north of Edinburgh. His father (whom he never knew) had been a Comptroller of Customs. He studied moral philosophy at the University of

Glasgow, where his teacher, Francis Hutcheson, was emphasizing “the greatest happiness of the greatest number” even in the shadow of John Knox and Scottish Puritanism. Smith then spent six years at Oxford as a Snell Scholar. A crisis of faith, possibly brought on by an exposure to the epistemological skepticism of David Hume, led him to abandon his plan to become a clergyman.

Returning to Scotland in 1748, Smith lectured on literature (student notes from his course have been published as *Lectures on Rhetoric and Belles Lettres*) and from 1751–63 was Professor of Moral Philosophy at the University of Glasgow. His *Theory of Moral Sentiments* appeared in 1759. In it he argues that there is a social consensus on right and wrong which the sensitive social actor both absorbs and replicates. His theory of the “impartial spectator” who serves as the sounding board recalls the later ideas of G. H. Mead, while his appeal to “sympathy” or empathy that give the individual a way into others’ feelings and thoughts looks forward to Weber on *Verstehen*.

Smith spent the years 1754–6 accompanying the young Duke of Buccleuch on his “grand tour” to Paris, Toulouse, Geneva, and other centers of European culture and thought. Smith met the French *philosophes* (including Turgot, Helvétius, and Rousseau) and also absorbed the great lesson of Physiocratic economics that the whole is an interdependent and a nature driven circular flow. France in the last years of the *ancien régime* must have been an object lesson to him of how liberty could be suppressed by the Bastille, economical statesmanship by Versailles, and optimal allocation by tariffs and taxes.

Smith spent the next 10 years, in receipt of a pension from the Duke, doing research in Kirkcaldy. It was then that he wrote his great work, *An Inquiry into the Nature and Causes of the Wealth of Nations*. Published in 1776, it was an immediate success. It seemed to be defending the “invisible hand” of the free market against Mercantilist politicians and incompetent bureaucrats (including, significantly, the corporate hierarchy that Weber, Schumpeter, and Galbraith were to hold in high esteem) and to be saying that the instinctual drive to “truck, barter, and exchange” would be enough to produce rising living standards for all classes even without a Poor Law or a social welfare net.

Smith anticipates Marx in that he formulates a labor theory of value, implies that the class antagonisms of post feudal industrialism would be based around the inputs of labor and capital, and demonstrates that the division of labor in the modern production line system leaves the worker debased and alienated, “stupid and ignorant.” His insights into conspicuous consumption resemble those of Veblen on the proof of status. They also demonstrate that he was envisaging a meritocratic, mobile society in which ascription would be challenged by achievement and the landed aristocracy would become increasingly irrelevant in a rapidly growing commercial society.

In 1778 Smith was appointed a Comptroller of Customs. He died in Edinburgh on July 17, 1790, aged 67, and is buried in the Canongate churchyard.

smoking

Jason Hughes

The word smoking has widely come to mean “consuming tobacco,” and yet throughout history other substances – such as opium, cannabis, phencyclidine (PCP), and crack cocaine – have been smoked as a principal mode of their consumption. Equally, tobacco has been consumed in a multitude of ways other than through

smoking. For example, prior to contact with Columbus, indigenous peoples of the Americas had variously chewed, snuffed (tobacco powder up the nostrils), drunk (tobacco juice), licked (applying tobacco resin to the gums and teeth), topically applied (to the skin), ocularly absorbed, and anally injected tobacco (Wilbert 1987). What we refer to as smoking should be understood first and foremost as a historically diverse set of practices surrounding the use of a range of drugs which, at various stages, did not necessarily involve the practice of smoking itself. That said, smoking today, as in pre Columbian America, is by far the most widespread mode of consuming tobacco: the term refers to a phenomenon that has come to have enormous social, cultural, and economic significance. What follows is a broad and brief account of the sociocultural development of smoking divided into three main “stages”: pre Columbian smoking; modern smoking; and contemporary smoking. This focus on developments at the most general level serves to highlight the emergence of key themes in cultural uses and associations relating to the practice: a transition from understandings and uses of smoking as a practice to “lose control” and “escape normality” toward those in which smoking increasingly came to be used as a means of self control and to return to “normality.”

Sociocultural understandings and uses of tobacco among the indigenous peoples of the Americas in the pre Columbian period varied considerably. However, characteristically, smoking held enormous spiritual significance; was highly ritualized; and involved more pronounced effects than those we would associate with present day cigarette smoking. In formal ceremonial use, particularly shamanistic ritual, the strains and species of tobacco used and the practices surrounding consumption were such that smoking was capable of inducing hallucinogenic trances (Wilbert 1987: 134–6). Smoking was understood to offer a mode of transportation into the spiritual world through such altered states of consciousness; and in doing so it played a central role in indigenous American healing practices. Smoking marked many formal occasions: it was used to cement alliances between peoples, to symbolize peace, and to finalize agreements. Even recreational smoking was highly ritualized and involved the consumption of considerably stronger species and

varieties than those associated with contemporary patterns.

The indigenous American esteem for tobacco smoking as a medical remedy was adopted by “modern” users – i.e., post contact European smokers between the sixteenth and nineteenth centuries – with great enthusiasm. Some leading physicians of the time hailed tobacco as a panacea: a remedy for a range of ailments, from toothache to “cancer.” While only the mildest and, to early Europeans, most palatable strains and species of tobacco were brought back from the “New World,” even these, relative to those commonly in use today, were considerably more capable of producing intoxication. Indeed, concerns were expressed at the time that smoking, like drinking, may make workers unfit for labor (Brandt 1990). The practice rapidly became popular across Europe and had spread to many parts of Asia, Africa, and beyond by the end of the sixteenth century. Sociocultural uses and associations rapidly shifted from medical to recreational, and numerous treatises concerning the “abuse” of tobacco were written by physicians of the time who sought to retain tobacco as a medical remedy, rather than a drug of vice and the dissolute lifestyle with which it had by then come to be associated. Elite groups in European societies came to regard smoking as vulgar as it became “common.” Following the French court in its capacity as a model setting center for European upper classes, such groups switched from smoking to snuffing to distance themselves from what they considered to be their social inferiors. The practice of snuffing subsequently spread to all levels of society.

Contemporary patterns are epitomized by the resurgence of smoking, first in the spread of cigar smoking amongst affluent groups, and then through the emergence of the cigarette as a popular mode of consumption from the nineteenth century onwards. Smoking a cigarette, compared with indigenous American or even early European pipe smoking, involved relatively milder and more ambiguous effects. In part predicated upon such changes in its uses and effects, smoking came to be understood as a “psychological tool,” a means to return one to normal from a range of dysphoric states linked to emotional arousal or underarousal. Compared to the ritualized and ceremonial use of tobacco of pre Columbian smokers, and to a lesser

degree the practices associated with “modern” smokers, “contemporary” smokers increasingly came to *individualize* the effects and functions of tobacco such that it could be used and understood as a means of self control. The rise of cigarettes is also linked to processes involving the mass consumerization and feminization of smoking. Indeed, in the early twentieth century cigarettes became a symbol of women’s emancipation – an association seized upon by tobacco companies of the time. Issues relating to the gender and class dynamics of smoking, health inequalities, and the marketing activities of tobacco corporations remain a topic of considerable sociological interest (see, e.g., Graham & Blackburn 1998; Pampel 2002). Also, particularly since the publication of findings from high profile epidemiological studies in the 1950s and 1960s which linked tobacco consumption to fatal diseases, smoking has become increasingly *medicalized* – both understandings of smoking and, arguably, experiences of smoking and being a smoker; it has attained the status of an addictive disease in itself (Hughes 2003).

Thus, in short, the sociocultural development of smoking can be summarized as involving over the long term a series of interrelated shifts: from smoking to “lose control” toward smoking as a means of self control, from ritualized smoking to more individualized smoking, from understandings of smoking as a panacea to its current status as a pandemic.

SOCCER

Richard Giulianotti and Dominic Malcolm

The game of association football, also known as soccer, involves two competing teams of 11 players. The players attempt to maneuver the football into the opposing team's goal, using any part of the body except the hands and arms. Only the goalkeeper is permitted to handle the ball, and then only within the penalty area surrounding the goal. The winning team scores most goals over a set time period, usually 90 minutes.

Association football is to be distinguished from those "football" codes that allow general ball handling and arm tackling, notably "American football," Australian Rules football, rugby union, and rugby league. Football is sometimes known as the "simplest game": its 17 basic laws and minimal equipment (a ball) ensure that games may be improvised and played in informal settings.

Football is the world's most popular team sport in participant and spectator numbers. The global governing body, the Fédération Internationale de Football Association (FIFA), estimated in 2000 that there are 250 million registered players, and over 1.4 billion people interested in football; a combined worldwide television audience of 35–40 billion watches football's premier tournament, the World Cup finals, played on a quadrennial basis. At the time of writing, FIFA boasts 205 member states, more than the 191 members of the United

Nations, and, as a global organization, eclipsed only by the International Amateur Athletics Federation (IAAF) with 211 members.

Different kinds of football related games have been played across the world, notably in China in the second century BCE and in medieval Tuscany. However, football developed into its modern form in Britain in the nineteenth century. "Folk football" games had been played in towns and villages since before medieval times, according to local customs and with few definite rules. In the early nineteenth century, industrialization, urbanization, and legal prohibitions restricted folk football but the game was taken up in English public schools and universities, partly as a mechanism for instilling discipline into pupils. The status rivalry between Rugby and Eton public schools was central to the initial codification of the separate and distinct forms of the game in the 1840s. These subsequently became rugby football and association football (of which American football, Canadian football, and Australian Rules football are subsequent refinements). In the 1840s, the "Cambridge rules" of football were established and applied, and in 1863 the game's rules were formally codified and printed and the (English) Football Association was formed. As the title of soccer's international federation indicates, to most of the world the game is known as football (or a local translation of the word, e.g., *Fussball* in German, *fútbol* in Spanish) rather than soccer. The word soccer is thought to have originated in the late nineteenth century at Oxford University, being a corruption of the term "association," and referring to a specific way of playing football, distinct particularly from rugby football.

The social and institutional aspects of football's global spread are of sociological interest. Football's international diffusion between the 1860s and 1914 was largely dependent upon British trade and educational influence overseas. In Europe, British migrant workers would form teams and attract challenges from local sides; or young local men would return from their education or peregrinations in Britain with a ball and rulebook to teach the game to their compatriots. In Latin America, British engineers, railway workers, sailors, teachers, and pupils were largely responsible for introducing local people to football. A similar story arises in Africa, though

British soldiers also introduced football in occupied territories such as modern day Nigeria and South Africa. Thus football became more firmly established in the “informal” British Empire (and where the game was introduced by working and merchant class colonizers), in contrast with other British sports like cricket and rugby, which became popular in those countries formally subject to British imperial rule (and where sports were introduced by colonizers who were public school educated and held elite administrative roles in the host societies). Football was thus probably seen by non British peoples as more “neutral” culturally, less compromised by imperialistic mores, as well as the most materially accessible form of modern sport.

Football associations were established in most nations in Europe and Latin America to oversee the game’s organization. Notably in South America, these associations gradually shook off British influence, as a reflection of growing national pride and political autonomy. Driven particularly by the French, FIFA was founded by European associations in 1904, and continental governing bodies slowly followed: CONMEBOL in South America in 1916; UEFA in Europe, and AFC in Asia in 1954; CAF in Africa in 1957; CONCACAF in 1961; and the OFC for Oceania in 1965. Continental confederations organize tournaments and represent their members’ interests inside FIFA. In true modernist style, the national football associations remain the basic political units within football’s governance.

There are six dimensions of football that have attracted particular sociological interest: cultural differentiation; governance and politics; the cultural politics of race and gender; commodification; violence and hooliganism; and internationalism.

CULTURAL DIFFERENTIATION

Cultural differentiation falls into three broad domains:

- 1 Football is marked globally by intense club and supporter rivalries. At local level, particularly in major cities, heated “derby” fixtures arise, e.g., Boca Juniors versus River Plate in Buenos Aires. There are also

strong regional rivalries, e.g., Bayern Munich versus Ruhr teams in Germany, or teams from north and south Italy; and major international rivalries, e.g., Brazil versus Argentina, England versus Scotland, Germany versus Holland. These rivalries habitually reflect and energize underlying intercommunal senses of cultural opposition and enmity. Allegiance to particular clubs and nations enables supporters to construct strong collective identities vis à vis these “others.”

- 2 Neo Durkheimians would argue that football has contributed substantially to modern nation building, especially in large or ethnically diverse developing nations like Brazil, Cameroon, and Nigeria. National electronic media allow citizens in remote regions to listen to or watch their “national” team in major international tournaments, so heightening cultural nationalism.
- 3 The globalization of football provides numerous illustrations of cultural “glocalization,” whereby particular senses of cultural distinctiveness are constructed and expressed through the game. Particular clubs and nations establish favored playing styles or specific ways of administering their business. Each supporter community constructs particular “traditions” regarding its heroic players or the specific history of the club, thereby differentiating that club from its rivals.

GOVERNANCE

Governance falls into three broad domains:

- 1 Football’s governing bodies undergo critical sociological scrutiny, notably regarding power struggles and corrupt practice. Major struggles have arisen between European and Latin American football officials over the control of FIFA, amidst substantial accusations regarding bribery and vote fixing. The close ties between television networks and Latin American football associations have also attracted analysis.
- 2 Neo Marxists argued that political elites have exploited football to germinate populist

domestic support for oppressive regimes, notably among military juntas in Latin America and in the old Soviet bloc nations. These arguments too readily assume that performers and audiences can be duped by popular culture into supporting iniquitous regimes.

- 3 Sociologists in the UK have focused on the commercialization or "commodification" of football since the early 1990s. Particular attention has been paid to fan attempts to democratize club governance, such as through formation of independent supporters' associations or the more recent advent of "supporter trusts" that have gained control of some clubs. Greater awareness has arisen of alternative models of club governance in part through increasing public knowledge of the international game.

CULTURAL POLITICS OF RACE AND GENDER

Two general issues arise, regarding formal exclusion and cultural expressions of racism and sexism.

Historically, most nations have formally excluded non white players from white controlled football clubs and leagues. Even in polyethnic Brazil, non white players were excluded until one club in Rio recruited blacks with great success in the 1920s. Post war migration and African national independence have helped in the long term to secure anti racism measures in FIFA and to promote non white players in Europe.

Football has tended to provide a key space for the construction of particular forms of masculinity, thus women have always been excluded from full participation as players and officials. Whilst national and international women's football tournaments have been established since the 1970s, most notably in North America, and women's attendance at professional fixtures has risen in most parts of the world, in few instances do women make up over a quarter of football spectators. What advances have been made are driven partly by commercial motives, as football related businesses tap new markets.

Overt and covert forms of cultural racism have gained greater analysis over the past 30 years. Overt racism is demonstrated through, for example, club refusals to sign players of particular ethnicity. Anti racism campaigns have been inspired by top black players, and have been subsequently backed by football's governing bodies. Covert racism, such as not selecting non whites for key playing positions, can be highlighted statistically but such actions are harder to contest in individual cases.

Overt sexism remains very evident, as masculine football cultures tend to deploy derogatory and objectifying language regarding women and gay men. Covert sexism continues in the highly gendered stratification of employees within sports institutions.

COMMODIFICATION

Four particular issues arise here.

- 1 Up to the 1930s, many European and Latin American football nations experienced hegemonic struggles over professionalization (i.e., the direct payment of players and coaches). More aristocratic and traditionalist forces favored player amateurism, partly to minimize or prevent mass participation and partly in attempts to retain control over the game. Business minded football officials and marginalized social groups favored professionalism, eventually defeating the public school influenced defenders of amateurism in the context of late twentieth century capitalism.
- 2 More generalized concerns remain regarding social exclusion and alienation as germinated by football's increasing commercialization. Many social justice issues arise, e.g., higher admission prices may exclude poor but dedicated supporters; running football institutions as businesses may disenfranchise supporters politically from "their" game; high prices for football equipment or renting playing fields may alienate many and reduce young people's participation in the game; and inflated player salaries may sour the social relations between fans and players. What is perhaps most surprising is that it is only in the last 15 years that companies have

come to recognize the huge and inelastic demand for football, and sought to exploit this for economic gain.

- 3 Concerns have increasingly been voiced about the influence wielded by the media and corporations. Many argue that growing media control has led to fixtures being arranged to suit television viewers rather than fans who watch matches live, and that the media have also developed a particular kind of presentation which trivializes and spectacularizes football and thus detracts from aspects perceived to be the basis of the traditional appeal of the game. Allegations have even been made that sponsors now influence playing matters, most notably concerning Ronaldo's appearance for Brazil in the 1998 World Cup Final, and the role of Adidas in David Beckham's move from Manchester United to Real Madrid in 2003.
- 4 Intensified economic and cultural globalization generates major debates over neoliberalism within world football. The game is marked by intensified and unregulated flows in people (especially players), capital, media images, and commodities (notably merchandise). The largest and richest European markets come to dominate the world's leading football resources (notably top players), and can effectively corral the greatest corporate revenues and most numerous fans (that is, merchandise consumers) worldwide. These widening inequalities in world football are reinforced by the imposition of more general neoliberal policies in the developing world, resulting in the impoverishment of sporting clubs and leagues in Latin America and Africa.

VIOLENCE AND HOOLIGANISM

Violence and hooliganism fall into three broad domains.

- 1 "Football hooliganism" relates to a complex and culturally diverse phenomenon which in many instances is deeply rooted historically. For example, in Northern Europe, self-defining "hooligan" groups develop distinct subcultures characterized by the

pursuit of status seeking fights with similar fans that follow opposing teams. In Southern Europe and Latin America, fan violence is associated with "militant" supporters, known as *ultras* or *barras bravas*, who engage in culturally distinctive rituals of support.

- 2 The state contributes crucially to the construction of "hooliganism" through the (often violent) imposition of "security" in and around stadiums, and through juridical attempts to label and legally punish "hooligans."
- 3 Some football subcultures have ties to paramilitary movements and military conflicts. The Yugoslav civil war in the early 1990s involved several units drawn from football supporter organizations. Other violent conflicts with strong football connections have arisen in Nigeria, Mauritius, and the "Soccer War" between Honduras and El Salvador in 1969. More symbolically, fans of Glasgow's two leading teams, Celtic and Rangers, sing anthems that celebrate paramilitary movements in Northern Ireland.

INTERNATIONALISM

Internationalism falls into three main domains.

- 1 "Naïve internationalism" celebrates football's functionality in bringing peoples and nations together, promoting intercultural understanding and social harmony. This argument tends to ignore the historical evidence of conflict and violence within sport.
- 2 A "pragmatic internationalism" adopts a practical, social policy orientation toward football, notably in the developing world. Football is seen as having a positive practical function in the positive resocialization of traumatized peoples, such as former child soldiers in West Africa, and in helping to build peaceful social contact between warring communities, such as in Bosnia or Rwanda.
- 3 An emerging human rights perspective examines how the organization of sports like football in the developing world has impinged upon the personal liberties and freedoms of young people in particular. For example, coaches may enter into psychologically and

physically abusive relations with young players, in part by demanding long hours of labor from these child athletes.

Inevitably, these six sociological themes have received varied treatments by scholars from different nations and continents. In Britain, football hooliganism has been a major topic since the 1970s, with European nations (notably Italy and France) following in the early 1990s. In Scotland, religious sectarianism between supporters provokes a recurring debate. Whereas in England hostile debates between the advocates of various approaches have arisen, notably over explanations of violence in football, closer disciplinary ties exist between historians, sociologists, and anthropologists in many European nations (notably in Scandinavia, Italy, France, and Germany).

Since the early 1990s in the UK, the intensified commodification of football has received both critical and sympathetic sociological comments; the role of media corporations in advancing this process has attracted particular attention. Questions of social exclusion in football have focused particularly on ethnic minorities and, to a lesser extent, women in England.

In Latin America, anthropologists played the founding role in the social scientific study of football. Four major investigative questions have been apparent. First, how does football relate to distinctive national, cultural, and "racial" identities, particularly given the diasporic movements of players to Europe? Second, what "function" has football played in sustaining military juntas and *caudillo* style politicians? Third, through the strong influence of Gramscian theory in Latin American sociology, how do football and other popular cultural forms encapsulate the resistant identities of marginalized communities? Fourth, how might Latin American football's endemic corruption be exposed and replaced by more transparent, democratic forms of governance?

Overall, the sociological analysis of football faces several methodological problems. A lack of systematic international collaborative research is still apparent, notably among many UK based writers. Geopolitical and linguistic divisions remain between many sociologists, commonly separating Anglophone researchers, continental Europeans (North and South), and Latin

Americans. European football researchers, such as those publishing in German and French, have shown stronger commitments to international dialogue, reflecting their greater empirical and conceptual grasp of globalization processes.

Three particular, substantive issues within football remain underexamined by sociologists. First, we require serious ethnographic studies of professional football clubs, although gaining access and funding to conduct such research is certainly problematic. Second, we need a proper sociological treatment of the technical and aesthetic aspects of football. Third, we require an adequate, cross cultural analysis of the relationship between elite and grassroots football with particular attention to access and participation.

social accountability and governance

Crawford Spence and Chris Carter

Recent accounting scandals such as Enron, Parmalat, and WorldCom have concentrated attention on the accountability and governance of corporations. Social accounting has been described and critiqued from a variety of positions, ranging from right wing neoliberal critiques all the way through to Marxist and deep green critiques. The different positions taken on the desirability or otherwise of social accounting can be understood by considering the type of change that each theorist advocates. The majority of writing and work in the area has come from those who see social accounting as a means of bringing about evolutionary change in capitalism.

WHAT IS SOCIAL ACCOUNTING?

Social contractarian perspective: evolutionary change. Social accounting is generally understood as an attempt to investigate organizations more broadly. By scrutinizing the impact of the activities of organizations, social accountants seek to highlight the wider social and environmental costs of their operations. The rationale underpinning this approach is that corporations have a wider responsibility than merely making profits for shareholders. Social accounting has similarly been described as an "attempt to deconstruct conventional accounting, expose

some of its more unpleasant characteristics and offer new accountings predicated on values wider than making rich managers and shareholders even richer" (Bebbington et al. 1999). The key master concept underpinning social accounting is *accountability*. Whereas conventional accounting (allegedly) serves to make an organization accountable to its financial owners, social accounting seeks to discharge accountability to other stakeholders. These are groups that are influenced by or can influence the social, environmental, and economic impacts of an organization (Gray et al. 1996). The principal argument behind accountability is that stakeholders have a *right* to information regarding the social and environmental effects of corporate economic activity. These rights to information may be enshrined in law, may appear in quasi legal or voluntary codes of conduct, or may be moral in nature (Gray et al. 1996).

Enhanced corporate accountability would ultimately require companies to temper their relentless pursuit of profit and competitiveness by considering their interactions with a wider constituency of stakeholder groups. Indeed, the rendering transparent of an organization does not set the parameters to the vision of the social accounting project. Gray (2005) has argued that social and environmental accounts are an essential precondition to a healthy and functioning democracy, warning that the absence of such accounts leaves society relatively powerless when compared with the power of modern day corporations. Thus something must happen once the accountability has been discharged. There is a radical intention in the social accounting project. The explicit intention is to increase democracy, but not necessarily as an end in itself. Underlying social accounting is a concern with the social dislocations and environmental degradation caused by organizations in advanced capitalism. Increased accountability, although morally desirable in itself, is also seen as a means to move toward a more socially and environmentally benign order.

Neoliberalism: radical change (right wing). Critiques of social accounting emanate from a variety of theoretical positions. However, it has been very rare for those on the right to engage in the social accounting debate at all. One must return to Benston (1982) to find a critique of social accounting from a right wing position.

On a practical note, Benston suggests that the measurement of "externalities" is problematic and therefore cannot be relied upon. Notwithstanding the practical considerations put forward by Benston (1982, 1984) and the logical inconsistencies therein (Schreuder & Ramanathan 1984), his arguments are primarily ideological: the primary responsibility of management is to shareholders and social accounting would impose unnecessary costs upon them. In any case, other stakeholders such as employees, customers, and creditors, Benston (1982) argues, are well served already by voluntary management reports. Social accounting may be useful with respect to corporate governance, exposing fraudulent dealings and misuses of shareholder assets by management. He holds that even the cost of an accounting standard would likely exceed the benefits to shareholders (see Benston 1984). As such, "the responsibility of accountants would be best served by their forbearance from social accounting" (Benston 1982).

Expedients: marginal change. Moving away from a radical right wing position, another conception of what social accounting is and what it may do is offered by Parker (1986). Parker falls into what Gray et al. (1996) refer to as the "expedient" camp. Parker notes that social accounting means different things to different people. To "corporate defenders," it is a means of defense against critics of the corporation. To "corporate critics," it provides a constraint upon socially irresponsible behavior and a positive motivation for the corporation to act in a socially responsible manner. Parker argues that standards could moderate and regulate the competing purposes of these groups, i.e., allow corporations to manage their image whilst restricting reporting bias and thereby facilitating a more informed and protected society. Whilst those of radical left wing persuasions would be horrified by the former, Parker sees the use of social accounting as an image enhancer as something that is actually good, as long as it is accompanied by the provision of substantive social accounting information. Although informed by a "suspicion of powerful private interests" (Parker 1991: 32), Parker's view emanates from an acceptance of the current essential structure of capitalist society (see Parker 1991: 27).

Marxian critique: radical change (left wing). As long as one accepts the need for a more

sociodemocratic form of system, Benston's and Parker's views do little to disturb the rationale for social accounting. More shaking critiques of social accounting come from those theorists that put social justice (however this is defined; e.g., Puxty, 1986, 1991; Tinker et al. 1991) and ecological sustainability (e.g., Maunders & Burritt 1991) at the heart of their analysis. The essence of Tinker et al.'s position is that a better accounting can only come about after a change in structural conditions. The structure of society, and of capitalism in particular, is such that social accounting will be captured by vested interest groups and used to mask those vested interests. These structural inequalities, argue Tinker et al., are overlooked by Gray et al. by virtue of their commitment to pluralist thinking and "middle ground theorizing." The middle ground is characterized by Tinker et al. as concerned with "what is pragmatic and socially acceptable; not what is socially just, scientifically rational, or likely to rectify social ills arising from waste, exploitation, extravagance, disadvantage or coercion" (1991: 29).

Tinker et al. explain how the history of social accounting shows the middle ground shifting in specific directions, in response to definite social conflicts and struggles. This swaying in the tide minimizes and mystifies the structural inequalities of contemporary capitalism (1991: 36). Social accounting thus serves a political quietism function which "mask(s) the affinities of many right wing positions and middle of the road research" (p. 37). Gray et al.'s middle of the road approach is therefore rejected. The middle ground is contested and unstable and Gray et al. refuse to examine the basic contradictions of the social system that cause this instability; Gray et al.'s approach has not been shown to be productive, Tinker et al. argue, and "the political quietism implicit in their viewpoint is empirically unsubstantiated" (1991: 47).

As an alternative, Tinker et al. advocate a critical accounting that speaks about social antagonisms and structural inequalities. The examples given by Tinker et al. are recasts of the accounting records provided by firms in terms of, in one case, the role that a mining company played in colonial exploitation and, in another, an analysis of General Motors' use of their annual reports as ideological weapons.

If there is any role for social accounting from a Marxist viewpoint, then one infers that it would be through external social audits. These are social accounts prepared about an organization by people outside of that organization. Examples of this particular type of social accounting are evident in the work of Social Audit Ltd. (see Medawar 1976) in the 1970s who, without the cooperation of the organizations whom they were auditing, constructed a series of detailed exposés of the social and environmental impacts of those organizations in the UK. In a similar vein, though with a much more Marxist slant, Counter Information Services compiled a series of *Counter Reports* of large multinational organizations in the 1970s (see Gray et al. 1987 for examples of these). Similar exercises have been carried out recently by Christian Aid and Friends of the Earth, who have produced “alternative” versions of social accounts of organizations such as Shell and Exxon.

Tinker et al.’s (1991) critique emanates from a view of society that focuses on conflict and power struggles. A similar viewpoint on social accounting is reached by Puxty (1986, 1991), who, following Habermas, argues that it owes its very existence to the needs of the powerful within society (1986: 103). This “capture” of social accounting is inevitable given the non pluralistic makeup of society. Society has dominant interests. Social accounting does not dissolve these power relationships, as its proponents hope it might, but reenforces them: “Accounting is part of a system of distorted communication that reflects the social system. Any extension of accounting through the processes of that system can thus be no more than an extension of that systematic distortion” (Puxty 1986: 108). Puxty repeats these views through a later article where he “reject(s) the possibility of progress of society through current pluralist institutions, and corporate social information that might be generated through them” (1991: 41).

Deep green critique: radical change (ecological). Maunders and Burritt (1991) take a deep green perspective when considering how to account for the environment. They argue that any attempt to solve ecological problems through an accounting that is an extension of conventional accounting may be doomed to failure. This is because of the neoclassical ideological foundations on

which conventional accounting rests: selfishness of maximizing individual utility; contrived consumer demand (wants over needs); and anthropocentrism. It is argued by Maunders and Burritt that a much more radical accounting is needed that actively challenges these cultural values.

These “radical” critiques variously place notions of social justice (Puxty 1986, 1991; Tinker et al. 1991; Cooper 1992) or environmental sustainability (Maunders & Burritt 1991) and/or Mother Earth (Cooper 1992) at the heart of their analyses. What is common to each of them is that they see social accounting, at least corporate *self* reporting, as not a mere irrelevance but something that could actually exacerbate ecological problems and further entrench social inequality. Social accounting hides and disguises deeper structural inequalities that must be critiqued and transcended. As such, corporate social accounting is counterproductive. In seeking to disempower corporations, it actually seeks to bolster the interests of corporations. If there is any place for social accounting, then it must be through externally produced social audits. The problem, argues Lehman (1999, 2001), is in according a privileged status to corporations as the agents of change. Gray et al. seek to put corporations at the center of their theorizing as the entity that prepares the social/environmental analysis of its own operations. The radical left wing critique curiously comes to the same opinion on social accounting as the radical right wing critique. In Cooper’s ecofeminist (and Marxist) critique of environmental accounting, she concludes that “in the present symbolic order accountants should not attempt to account for the environment” (1992: 37).

In the wake of accounting scandals and increasing concern over the environmental sustainability of the current economic orthodoxy, social accounting is likely to figure more widely in policy and academic debates. The contours of the debate on social accounting are currently configured around the responsibilities of corporations and the limits of reformist pluralism in the wake of corporate power.

social capital

Rosalind Edwards

Social capital is a concept broadly referring to the ways people connect through social networks, common values within these networks such as trust and reciprocity, and how this constitutes a resource that equates to a kind of capital. Different theorists emphasize slightly different features within this broad definition.

Some perspectives pose social capital as a distinct form of “public good,” embodied in civic engagement and having knock on effects for democracy and economic prosperity. Putnam (2000) points to local communities in which a predominance of work poor families and/or ethnic diversity has eroded positive social capital in favor of negative forms. Fukuyama (1995) argues that engagement in the private and voluntary sectors enhances economic prosperity, whereas strong kinship allegiances crowd out other economically beneficial social connections. Thus different forms of social capital are identified. Putnam highlights self sustaining voluntary associations as generating the “bridging” form of social capital that enables people to “get ahead” – horizontal trust and reciprocal connections between people from different walks of life – as opposed to the “bonding” social capital among homogeneous people that allows them only to “get by.” Woolcock (1998)

has also added the notion of vertical “linking” social capital with formal organizations, with the state facilitating new local partnership networks.

Other work sees the family as a wellspring of social capital. Coleman (1988) argues that the family is where children have their human capital (notably, educational success) developed and are socialized into the norms, values, and sanctions of society. He argues that this nurturance is inherent in the structure of family relationships, which then affects the nature of local communities, and that social capital building is hindered where parents are “absent,” as in lone mother or dual earner families.

Another perspective highlights social capital as intertwined with other capital assets: economic, cultural, and symbolic. These are transmitted and reproduced over time, within social groups and across generations, sustaining class privilege and power (Bourdieu 1986). Dominant social capital processes are seen as also having a “dark side,” marginalizing or confining people on the basis of their ethnicity, gender, and age (Portes 1998; Morrow 1999; Molyneux 2002).

While engagement with the concept of social capital as a theoretical concept and policy instrument has been welcomed as signaling a shift towards engagement with social processes (Woolcock 1998; Schuller et al. 2000), there is some concern that this is occurring in a simplistic manner and is suffused with liberal economic rationality (Fine 2000). Other criticisms of the concept include the lack of consensus over its definition and hence difficulties in measuring it (Morrow 1999; Molyneux 2002), and the tautological nature of many conceptions of social capital processes (Portes 1998).

social capital and education

Rafael Santana and Barbara Schneider

The concept of social capital has been widely used in educational research. However, researchers have yet to come to an agreement over what constitutes social capital and what its effects are on educational and other social outcomes. There are at least two distinct theories of social capital commonly used by educational researchers. The first, by James S. Coleman, conceptualizes social capital as the relational ties among individuals within a closed functional community (Coleman & Hoffer 1987; Coleman 1988, 1990). This perspective highlights the benefits of membership within a social system and emphasizes the functional form of social capital. The second, by

French sociologist Pierre Bourdieu, also emphasizes the interconnectedness of individuals within a social system but additionally highlights members' access to institutional resources as well as their consumptive behaviors that enable them to reproduce other forms of capital (Bourdieu 1986).

Coleman (1988) distinguishes social capital from human and economic capital by arguing that social capital is obtained through the relational ties of individuals in a social system, whereas human capital is increased through education and training, and economic capital is accrued through the reinvestment of capital for profit. Intangible, social capital is an abstract resource that actors use to facilitate certain actions that lead to productive outcomes (Coleman 1988). Social capital inheres in the relations among actors and is not lodged within any single individual but rather develops out of sustained interactions among actors.

Properties of social capital include (1) the degree of closure or interconnectedness of ties within a social network and (2) the density of social ties among its members. Coleman argues that a high degree of network closure enhances communication among members, thus strengthening ties. The density of social ties also facilitates the articulation of mutual expectations and obligations for network membership, which allows members to discern whether others are fulfilling their agreed upon obligations. Shared norms, expectations, mutual obligations, and effective sanctions serve to strengthen social ties and give rise to another form of social capital, trustworthiness. Network members are regarded as trustworthy when they fulfill their obligations to others within the network. Networks characterized by high levels of trustworthiness are those in which members enforce agreed upon norms through sanctioning unacceptable behavior.

For example, parents can draw on the social resources available within the network to monitor their children's behavior. The closure of the network and the density of the ties among parents and other adults in the network encourage the flow of information about their children's activities. If a child misbehaves in the presence of other adults in the community, they can be trusted to notify the child's parent of the child's behavior with the expectation that such

misbehavior will be prevented by the parent in the future.

Offering an alternative perspective on social capital, Bourdieu argues that network collectivity is maintained through investment strategies that strengthen and ensure the durability of relationships binding individuals to each other. These investments and exchanges occur through ceremonies, ritualized meetings, and other social activities (Bourdieu 1986: 250). To Bourdieu, social capital is used to accrue advantages which are ascribed to social networks by virtue of their position within a social structure rather than from the inherent qualities of the relationships between individuals within the network. In contrast to Coleman, Bourdieu views social capital within the context of social stratification and reproduction, underscoring the benefits afforded to individuals located differentially within the social structure. As Portes (1998: 3) notes, Bourdieu's treatment of social capital is "instrumental, focusing on the benefits accruing to individuals by virtue of participation in groups and on the deliberate construction of sociability for the purpose of creating this resource."

Bourdieu defines social capital both as the social ties between individuals and the sum of resources that are available as a result of those ties. He suggests that actors operate within a social hierarchy, and individuals at varying positions in the social hierarchy will differ in their associated networks and in their access to social capital. For example, individuals of low social status may have ties primarily to other individuals of low status who can contribute only limited resources to the relationship. He notes, however, that individuals can increase their access to social capital by expanding their network of social relationships to others outside the primary network. This point is also developed by Granovetter (1973) and Burt (1992), who suggest that weak social ties within the network's structural configuration allow for greater individual mobility and more diverse channels for information and resources within and between networks.

Educational research more closely aligned with Coleman's conception of social capital tends to identify the productive, or positive, outcomes associated with increasing social capital within a social system, such as raising children's educational expectations, achievement,

and attainment. On the other hand, scholars whose work relies more on Bourdieu's articulation of social capital emphasize the social structural implications of differential access to and use of social capital in reproducing inequalities in society.

SOCIAL CAPITAL THEORY AND ITS APPLICATION IN EDUCATIONAL RESEARCH

Educational researchers have examined both the various functions and forms of social capital within schools and its influence on student outcomes (i.e., achievement, attainment, and aspirations). According to Stanton Salazar and Dornbusch (1995), institutional agents, such as counselors, teachers, and other students, are gatekeepers of resources and opportunities within schools, and students with access to these institutional agents are at a distinct advantage. Stanton Salazar and Dornbusch report that Mexican American students with ties to institutional agents experience changes in their educational aspirations and expectations. Measuring social capital as the number of ties (strong and weak) students have with institutional agents (school, family, and non family ties), they suggest that students may increase access to more diverse networks through strong and weak ties by maintaining Spanish use within the school. They conclude that bilingualism plays a prominent role in determining access to social capital for Mexican American students because they experience network advantages in accessing institutional support not available to Spanish dominant immigrant students and English dominant working class students.

Maintaining one's own culture may increase the strength of ties within an ethnically or culturally determined network; however, assimilating into institutions such as schools may be necessary to develop weak ties to the institutional agents who offer guidance for academic success. For example, Portes (1998) argues that immigrants can adapt to mainstream culture while retaining positive aspects of their country of origin. He challenges the view that complete assimilation is the optimal mode of adaptation for upward social mobility in an English dominated, nationalist environment.

Although high concentrations of black and Hispanic students within urban centers have been suggested to create a negative "culture of poverty" effect on achievement, Goldsmith (2004) finds that, in racially segregated schools, denser, more cohesive ties among students and teachers lead to higher educational expectations among Mexican American students than in schools that are more ethnically mixed or mostly white. Additionally, while agreeing with Coleman's (1988) suggestion that being in a single parent family negatively affects students' achievement, Pong (1998) finds that social capital can counteract the negative effect of non intact families on mathematics and reading achievement. In schools with high concentrations of students from single parent families and stepfamilies, dense networks between single parents counteract the negative effects of these family forms on student achievement.

Scholars have taken an organizational perspective to explore the function that social capital plays in facilitating professional development among teachers. For example, Frank et al. (2004) argue that social capital within schools promotes the diffusion of teaching innovations between teachers and administrators. By observing and interacting with other teaching professionals, teachers and administrators are pressured to improve their pedagogical practices and also more easily benefit from the expertise of their colleagues. Frank et al. find that "change agents," that is, teachers who have already adopted new pedagogical techniques, should participate in local social capital processes that are related to the implementation of educational innovations and reforms. The authors recommend that change agents spend some of their professional development time interacting with other organizational members in order to share skills or cultivate new expertise.

Coleman (1988; Coleman & Hoffer 1987) argues that close relations between parents and students within the school produce increased student achievement. However, scholars have reexamined Coleman's work on the direct and positive effect that intergenerational closure has on student outcomes and found different results. Examining intergenerational closure among parents in public and private schools, Morgan and Sorenson find a negative association of closure with mathematics achievement,

despite dense friendship networks. However, public schools characterized by closure among students, teachers, parents, and administrators were shown to positively affect student math achievement.

Trust between teachers, parents, and students is one of the most fundamental forms of social capital. Bryk and Schneider (2002) argue that within the school community, individuals are interconnected through a set of mutual dependencies which make them vulnerable to sanctions from other community members. Therefore, school members build relational trust in order to ameliorate the uncertainty that arises from their mutual vulnerability to each other. Relational trust, therefore, is derived from discerning the intentionality and discrete interactions that individuals have with each other in the community. Schools characterized by high levels of relational trust are much more likely to experience sustained improvement in student academic achievement, and teachers and administrators in these schools are likely to be more committed to students' learning.

Similarly, Goddard (2003) connects trust worthiness to both the structural and functional forms of social capital. Trust, measured as the relational networks that connect parents and community members, was found to have a significant, positive effect on students' likelihood of passing high stakes standardized tests. These trusting relationships were supported by norms that encourage learning within the school environment. Trust has also been found to be a key element in the development of leadership within schools. The relationships between teachers, administrators, and instruction specialists act as sources from which teachers obtain professional development and assistance. When developing leadership within the school, teachers can draw on trusting relationships with administrators and other teachers as sources of professional assistance. Trust, therefore, acts as a fundamental institutional resource for enhancing student learning and developing teacher professionalism.

Other research has examined the dynamic aspects of social ties and the ways in which these ties are mobilized for the achievement of goals (i.e., functional specificity; see Sandefur & Laumann 1998; Kim & Schneider 2006). Within schools, parents and teachers activate network

connections to "broker" for their students. For example, Lareau (2003) demonstrates the different techniques employed by lower and middle class families in an attempt to improve student learning. These techniques vary by class and race, and produce both positive and negative student outcomes. Lareau finds that middle class parents use a technique of concerted cultivation in order to foster their children's talents in leisure and academic activities. Working class and poor parents, on the other hand, do not engage in this concerted cultivation, and instead trust the expertise and knowledge of educational professionals in directing their children's educational trajectories.

CRITIQUES OF SOCIAL CAPITAL IN SCHOOL RESEARCH: SUBSTANTIVE AND METHODOLOGICAL

Recent applications of social capital theory suggest that the formation of strong ties does not always have positive effects and can constrain the actions of network members (Portes & Sensenbrenner 1993). Intergenerational closure, for example, may promote normative behavior such as childrearing practices among working families (Parcel & Menaghan 1994), but it may also have a negative impact by inhibiting actions that could be beneficial, such as low resource parents interacting frequently with their children's teacher. In other words, one form of social capital that works for a certain type of result may not work for other outcomes. Accordingly, Portes (1998: 15) identifies four negative consequences of social capital. Specifically regarding educational outcomes, strong norms may foster an environment of lowered expectations and behavior (defined as a downward leveling of norms).

Other scholars have also examined the deleterious effect of the negative or counterfeit social capital that teachers create with students. For example, though finding that positive student-teacher relations tend to positively affect student achievement, Ream (2003) concludes that teachers who cultivate and nurture social relations in the classroom for the sole purpose of maintaining classroom harmony do so at the expense of academic content. This negative social capital is epitomized by a teacher who excuses rather

than sanctions misbehavior in order to maintain the already close relationship with a student. Although fostering positive relationships between teachers and students, this type of "defensive teaching" ultimately undermines academic achievement and serves to negatively affect academic progress.

Finally, research using social capital as a predictor of social outcomes has largely been descriptive and correlational rather than causal; causal links between social capital and its outcomes have been only weakly established. Some scholars, however, have attempted to remedy this lack of scientifically rigorous research by isolating the effects of social capital within the family on student academic achievement. Schneider and Coleman (1993) also look within the family and treat parental participation, family composition, maternal employment, and family activities as indicators of social capital. Characterizing social capital as a resource that facilitates action, these authors treat parental efforts and interventions in their child's schooling as positive influences in student learning. Despite the deficiencies in its use and definition, social capital continues to be a useful analytic concept for understanding relational ties and how they promote norms, sanctions, and trust between parents, students, teachers, and administrators.

social capital and health

Craig B. Little

Social capital, according to the most widely accepted definition, refers to “features of social life – networks, norms and trust – that enable participants to act together more effectively to pursue shared objectives” (Putnam 1996: 56). Communities characterized by high levels of social capital have been hypothesized to benefit from lower crime rates, higher educational achievement, greater economic growth, and better health. Social capital generally incorporates the much older concepts of civic virtue and social cohesion. Research linking social cohesion and health dates back at least a century to Durkheim who demonstrated that populations with higher social integration have lower rates of suicide. Social theorists whose work serves as the foundation for the present interest in social capital include Pierre Bourdieu, James Coleman, and Robert Putnam. The appearance of social capital as a key word in research articles is relatively infrequent prior to 1980 and has grown enormously since the mid 1990s.

The core elements of social capital include measures of civic and social engagement (group memberships, political participation such as voting, community voluntarism, and time spent with friends) and indicators of trust (such as an agreement on a survey with the statement “Most people can be trusted”). The health indicators with which social capital has been shown to be correlated include both mortality data (infant mortality or life expectancy, for example) and morbidity statistics for various specific diseases. Assessments of the research evidence range from claims that the correlation is consistent and robust (Kawachi et al. 1997; Putnam 2000: 327) to reviews or studies that suggest that the relationship is both modest and variable among specific health indicators (Kennelly et al. 2003; Pearce & Davey Smith 2003; Morgan & Swann 2004).

The specific mechanisms to account for the relationship between social capital and health status remain to be established. One possible explanation is that people embedded in more intense social networks have greater access to money, transportation, home care, or other

tangible assets that improve their health status or illness outcomes. Another is that people who are more socially isolated are more likely to engage in damaging health habits such as smoking, drinking, or overeating. It may also be the case that the social connections and supports inherent in social capital trigger physiological responses that buffer stress and, possibly, even stimulate a person’s disease fighting immune system. Recent evidence suggests that social capital, broadly defined as the quality of social relations, may mediate the relationship between inequality and health status (Marmot 2004: 188; Wilkinson 2005: 125). In this hypothesis, as social inequality increases in a society, the reservoir of social capital decreases, which, in turn, negatively affects people’s health.

Broad agreement exists that research on the relationship between social capital and health is only at its beginning. Work to create greater conceptual clarity and more precise operational measures of social capital is necessary and continuing. Likewise, there is a need to search for evidence linking findings from large scale epidemiological studies at the level of countries or states with the results from studies at the community and individual levels.

social change

Dusko Sekulic

Change can be defined as a "succession of events which produce over time a modification or replacement of particular patterns or units by other novel ones." Sociology as a discipline emerged in the middle of the nineteenth century as an attempt to explain not only the great waves of change sweeping Europe in the form of industrialization and democratization, but also the observed gap between European and colonized societies.

BASIC QUESTIONS

Whether something is changing or not depends on the perspective from which we observe. Recurrent fluctuations of prices or the unemployment rate do not change the nature of the market system; on the other hand, one of the characteristics of the market is constant push for changes in products, technologies, and social relations. How the market functions, the dominant actors, and the mediums of exchange evolve dramatically. However, from the more abstract perspective, we can argue that since capitalism emerged, it has not essentially changed, because its crucial regulatory institution, the free market, remains unchanged.

The second diagnosis of change or stability depends on the theoretical approach used to explain the causal mechanisms operating on the observed unit of analysis. Classical sociology was not only preoccupied with the explanation of the uniqueness of observed change,

for example the rise of capitalism in the West, but was also grounded on the assumption that some general principles and mechanisms producing all observed changes could be discovered. For Comte, such principles were the development of knowledge and ideas, for Marx, dialectics of productive forces and productive relationships, and for Lenski, development of technological capacities.

The third is the question of the tipping point. Is the change from 50 percent to 51 percent of employment in the service sector enough of a turning point that we can argue a new type of society (a post industrial one) has emerged (Bell 1973)? Or at what point has the modern era ended and the postmodern arisen if we want to believe in the postmodernists' claim that we are living in a new "post modern" era? At which point in time do the changes in the 1920s (the introduction of the assembly line, the application of "Taylorism") indicate the emergence of a new "Fordist" system (Kumar 1995)?

THEORIES OF SOCIAL CHANGE

Theoretical approaches to the question of macrosocietal change can be divided into two broad groups. In the first are theories starting from the assumption that underlying principles, general laws of social change, could be discovered. Although they differ in the acceptance of directionality or nonlinearity of change, they have in common the belief of "basic principles." On the other hand, we have theories rejecting this assumption and trying to explain particular historical events or configurations of factors characterizing group of events like revolutions or empires.

The first group of theories is based on the idea of evolution. According to that approach, the general mechanism of historical change can be described as going through certain stages driven by some inherent forces. These stages are the expression of some basic principle and are pointing in a certain direction. For Comte, societies go through three stages: a theological military, a metaphysical judicial, and a scientific industrial stage. This "law of the three stages" obviously reflects the prevailing thought of the time, because similar formulations can be

found earlier in Vico's *New Science* (1725): the age of Gods, the age of heroes, and the age of men.

In the two "discourses" Turgot presented at the Sorbonne in 1750, we can find the theory of three stages: religious, metaphysical, and scientific. In general, human development can be understood using the paradigm of growth; it is characterized by slow advancements from a less to a more developed state (Meek 1973). Similar formulations could be found in Saint Simon. In his *Letters from an Inhabitant of Geneva*, he formulated the Law of Three Stages, later misappropriated and announced by Comte as an original discovery. According to this law, the nature of ideas determines and limits social arrangements.

Karl Marx can also be classified within the frames of classical evolutionary thinking. His evolutionism was of a particular kind, with class conflict being the main force producing change. This conflict perspective influenced later development of historical sociology, which is no longer based on evolutionist ideas. For Marx the mode of production of material life determines the general character of the social, political, and spiritual processes of life. It is not the consciousness of men that determines their being; on the contrary, it is their social being that determines their consciousness.

At a certain stage of their development, the material forces of production in society come into conflict with the existing relations of production. The stages of development are "primitive communism," slavery, feudalism, capitalism, and communism, with socialism as its first phase. This progression model was derived mostly from the analysis of European history. When Marx looked at other parts of the world, he introduced significant changes to it. For example, in the analysis of Asia, he introduced the concept of the "Asiatic mode of production." Its long duration derives from its "presupposition that the individual does not become independent vis à vis the commune; that there is a self sustaining circle of production, unity of agriculture and manufacture" (Marx 1973 [1857–8]: 491).

Another subgroup of evolutionary theories is based on the idea of close resemblance of biological and social evolution. Herbert Spencer developed an evolutionary scheme for

explaining historical change. The evolution of society can be understood by comparing it to the growth of an organism. Both increase in size and in structure, from a few like parts to numerous interrelated unlike parts: "matter passes from an indefinite, incoherent homogeneity to a definite, coherent heterogeneity" (Spencer 1964 [1862]: 394).

Spencer was the first to systematically use the concept of differentiation that became a key idea in evolutionary and functionalist theories. Social differentiation refers to a process whereby sets of activities performed by one social institution become split up among different institutions. Differentiation represents an increasing specialization of the parts of a society. For Spencer, differentiation was a necessary accompaniment of the growth in size of both biological and social aggregates.

Following Spencer, Émile Durkheim held that increasing dynamic density, the number of people in interaction with one another, is critical in determining social change. As dynamic density increases, societies are segmented into similar units that combine to form larger units. Such primitive, segmented societies are characterized by strong mechanical solidarity based on common belief and consensus. As societies industrialize and urbanize and become more complex, the increased division of labor destroys mechanical solidarity and moral integration. A new form of order arises on the basis of organic solidarity. This comprises the interdependence of economic ties arising out of differentiation and specialization within the modern economy, a new network of occupational associations such as guilds and professional associations that link individuals to the state, and the emergence within these associations of collectively created moral restraints on egoism.

Durkheim's evolutionism is clearly visible from his introductory explanations in *Elementary Forms of the Religious Life*: "Everytime we undertake to explain something human, taken at a given moment in history – be it religious belief, a moral precept, a legal principle, an esthetic style, or an economic system – it is necessary to go back to its most primitive and simple form, to try to account for the characterization by which it was marked at that time, and then to show how it developed and became

complicated little by little, and how it became that which it is at the moment in question" (Durkheim 1947 [1912]: 3). In choosing the religion of Australian Aborigines, Durkheim assumed that he was studying religion in its most primitive and simple form. By studying the visible components, the culture and rites of primitive religion, he was able to analyze things that, in modern religions, are hidden by their complexity. Of course, underlying this scheme is an evolutionary assumption of the development of religion from simple to complex forms.

For both Spencer and Durkheim, the main mechanism producing social change is increased population density and the differentiation of society that follows. They both envisioned social change as leading to more complex social forms, but they rejected the idea that development goes through predetermined stages.

Modern evolutionary theory is less rigid in interpreting the stages of history. Nolan and Lenski in *Human Societies: An Introduction to Macrosociology* (1999) based their explanation of social change on the increased technological capacities of societies. New technologies of material production, as of information processing, send ripples of change through all aspects of social life. The evolution of societies is not predetermined but some general evolutionary patterns can be detected. Agrarian states are transformed into industrial societies but not the other way around. Lenski acknowledges that reversals are possible, but they are usually a consequence of some external cataclysm.

Cataclysmic events and environmental degradation are the topics of the evolutionary theory of Jarred Diamond. In his book *Collapse* (2005), he traces a fundamental pattern of catastrophe occurring when societies squander their resources, or ignore the signals of environmental degradation. Environmental damage, climate change, rapid population growth, unstable trade partners, and pressure from enemies are all factors producing the demise of societies. The indeterminate nature of new evolutionary theory is shown in Diamond with cases of societies that were able to find solutions for the same problems and persisted as a consequence. In his earlier work *Guns, Germs, and Steel* (1998), he shows how inequality among societies and subjugation of one society by others are rooted

in differing natural resources available to different people.

The second approach intertwined with evolutionism is functionalism. It regards change as the adaptation of a social system to its environment by the process of differentiation and increasing structural complexity. Society is viewed as a complex and interconnected pattern of functions, and change is explained as an equilibrium phenomenon of the constant search for equilibrium. The dominant system structure is taken as the fixed point of reference against which other structures or latent consequences are seen as potentially disruptive. This means that deviance and strains of various kinds are residual in the model. They are not given full fledged status as integral parts of the system as in the conflict model of social change. In response to the widespread critique of functionalism as static and not taking into account social change, Parsons developed in the 1960s his theory of sociocultural evolution in *Societies, Evolutionary and Comparative Perspective* (1966) and *The System of Modern Societies* (1971). Parsons's embrace of evolutionism read as repudiation of his statements from 1937: "Who now reads Spencer? . . . Spencer is dead" (Parsons 1949 [1937]: 3). For Parsons, evolution has a multi dimensional character. Differentiation, the major Spencerian scheme, is the basic, although not the only, dimension of it. In Parsons's scheme, it is complemented by adaptive upgrading, cumulative learning leading to the establishment of ever more intelligent technologies and ever more comprehensive and deeper scientific knowledge.

Through evolutionary processes, societies move from a system of ascription to one of achievement. Groups excluded from contributing to the system must be freed for inclusion. A wider array of skills and abilities is needed to handle increased complexities. Higher stages of evolution are characterized by value generalization. The system of cultural ideas is increasingly abstracted from their concrete context of a particular place and time and is thus better able to serve as a measure of legitimation and criticism of any particular norm, institution, or action. Evolution, for Parsons, proceeds through a variety of cycles, but no general process affects all societies equally. Some societies may foster evolution, whereas others may be pervaded by

internal conflicts or environmental constraints that impede the evolutionary process or even lead to the deterioration of the system. Although Parsons conceived evolution as occurring in stages (primitive, intermediate, and modern societies), he carefully avoided the impression of creating a unilinear theory of stages. For Parsons, evolution is not a linear process, although broad levels of advancement can be detected on a very abstract level with considerable variability of types.

The most sophisticated use of the structural differentiation concept in explaining social change is by Shlomo Eisenstadt (1964). His understanding of social change is based on the usage of concepts like "differentiated institutions," "crystalized roles," or "cultural orientations." In spite of this general approach for Eisenstadt, the direction and nature of change are not universal or explained by general principles and first causes. Change is always tied to concrete circumstances as defined within a particular society. Structural functional analysis is the only device for discovering particular historical configurations. Although his whole work is preoccupied with social change, the nature of change is most systematically analyzed in *Revolution and the Transformation of Societies* (1978).

The third group of theories emphasizes the cycles of growth and decay. The roots of this approach are in the works of philosophers like Arnold Toynbee and Oswald Spengler. The four volumes of *Social and Cultural Dynamics* (1937–41) by Pitirim Sorokin are a sociological version of philosophers' cyclical analysis. He saw societies oscillating among three different types of mentalities; sensate, ideational, and idealistic. The first type emphasizes the role of senses in comprehending reality, the second more transcendental or religious principles, and the idealistic type combines the two principles. Change is produced by the internal logic of these systems, which push their mode of thinking until it reaches its end point and the system is transformed into another form.

The main position of modern historical sociology, which is regarded here as the fourth major type of general theory, is that there can be no single explanation for all the important transitions in human history. "History is informative to the degree that things are not instances of general categories, but are instead

the product of causally connected series of events that produce unique configurations in each thing" (Stinchcombe 1978: ix). Historical changes must be located in their particular historical and cultural context and the main method used is historical comparison (Calhoun 1995, 1998). Max Weber was an important pioneer of this approach. He sees historical change as a concatenation of unique events and unrepeatable complexities. The rise of large scale capitalism is the result of a series of combinations of conditions that had to occur together. This makes world history and major changes like capitalism the result of configurations of events so rare as to appear accidental. Weber's *Protestant Ethic and the Spirit of Capitalism* is very often interpreted as a simple causal statement that Protestantism caused the rise of capitalism in the West. De facto it is a much more complicated argument where Protestantism is only the last intensification of one of the chains of factors leading to capitalism.

Important contemporary work in that tradition includes Barrington Moore's *The Social Origins of Dictatorship and Democracy* (1966), which analyzes historical conditions producing dictatorships or democracies. There are three basic routes of change: the first is when feudal landowners become capitalist and ally themselves with the bourgeoisie. This route is most likely to produce democracy. When landowners enter capitalist markets but keep peasants on land, they increase their exploitation and enter into an alliance with state bureaucracy. This path leads to a fascist state. The final route is when landowners became absentee owners, which produces conflict and peasant revolts, mass mobilization, and social revolutions in different forms.

Theda Skocpol in *States and Social Revolutions* (1979) argues that revolutionary situations are the result of the emergence of politico-military crises of the state resulting usually from military defeats in the international arena. State collapse is the result of a fiscal/administrative crisis of the state, conflicts within the ruling elite, and popular revolt. The same line of thinking is developed in the geopolitical theory of historical change of Randall Collins developed in *Weberian Sociological Theory* (1986) and *Macrohistory* (1999). His main explanatory variable is the success of the state in the

international arena. Internal legitimacy and external power prestige are connected.

social change and causal analysis

Paul Bernard

Causal analysis means researching the processes through which causes produce their effects. This is particularly complex in the social sciences, which face challenges that do not affect the natural sciences (see Bernard with Boucher 2005). First, *social relations* are the real concern of the social sciences; variables can only indirectly represent these social relations through a characterization of the actors and objects involved in them (age, gender, or class categories, for instance, interacting in employment, family, or educational trajectories). Second, social relations are shaped in *historically* irreversible ways, at the microsocial level as well as at the meso level of institutions or at the macro level of societies. Finally, human actions depend on complex *intentions*; these largely have to be imputed when survey based, quantitative variables are used, while they are explored more directly through qualitative, open ended methods (see Bernard 1993 for a detailed discussion of how causal analysis can readily be used with both quantitative and qualitative types of data and methods).

Adapting causal analysis to these challenges in the social sciences means reformulating its basic rules. We cannot be looking for a set of necessary conditions which together form a sufficient condition for the effect to emerge; we are rather engaged in the invention of a usable *causal heuristics*. As Figure 1 indicates, the classic expression of causal rules reflects their use in the natural sciences (and to some extent in the more nomothetic of the social sciences, such as neoclassical economics and psychology), where quantities and general laws prevail. But in the more idiographic of the social sciences (such as sociology or political science), the reformulation of these rules as heuristic causality brings new meaning to the enterprise of linking causes to effects through processes.

First, researchers must identify *regularities*, quantitative or otherwise, involving the alleged “cause” and “effect”; there should be a discernible pattern linking them. Second, these

The three rules of classical causal analysis	The three corresponding rules of causal heuristics
Finding a statistically significant association between the alleged cause and effect	Observing regularities in the relation between the alleged cause and effect

regularities have to be checked systematically as to the contexts in which they prevail (or fail to appear). This is where relevant *control* variables are introduced, revealing such patterns as the following: both alleged cause and consequence depend on a common, antecedent “cause”; an intermediate variable serves as a “causal” conduit between alleged cause and consequence; and so called interaction effects, where the pattern of relation between alleged cause and consequence changes under various conditions specified by the control variable.

Finally, and this is the most important rule, the researcher has to come up with a *narrative*, a telling of the story of the processes through which the cause (or causes) engenders effects, under certain specified conditions. These three steps are obviously iterative: researchers go back and forth, trying to inductively make the theoretical sense of increasingly rich empirical patterns, and checking the theoretical implications of these interpretations against an ever broadening set of empirical findings (generalization); this was admirably explained by Arthur Stinchcombe (1968). Variables and their relations thus provide us with stenographic traces of social relations as they unfold through time; variables are markers for individual and collective actors and events upstream, which causally shape events, and indeed actors, downstream.

The narrative is of course key to how causal heuristics can meet the challenges of sociological analysis. Causal interpretations do rest on observed regularities and ambient conditions as

indexed by control variables; but the focus of these interpretations should be on interacting individual actors, who shape their future in the midst of constraints and opportunities offered by their past. This shaping takes place in various contexts, at the micro, meso, and macro levels, in which actors are involved at specific historical junctures, according to their birth cohort. This view of human life, based on the increasingly widespread notion of *life course* (Marshall & Mueller 2002), brings together social relations, history, and intentionality.

To illustrate the uses of causal heuristics in the study of social change, two questions will be examined in more detail below. First, how do welfare regimes affect the life course of individuals? By welfare regimes, much more is meant than a simple collection of social policies; they designate the broad set of resilient institutional arrangements through which markets, states, families, and communities divide up among themselves and organize the work of producing and distributing well being. Second, how do regimes themselves come about and change over time, partly under the influence of the mobilization of actors experiencing different trajectories?

REGIMES, LIFE CHANCES, AND THE LIFE COURSE

In a very influential book, Gösta Esping Andersen (1990) proposed a categorization of advanced capitalist societies into three types

of institutional arrangements. These welfare regimes were: the social democratic regime, in the Nordic countries, in which the emphasis is on equality, giving the state a considerable role in sustaining universal social rights; the liberal regime, primarily in Anglo Saxon countries, in which the liberty of economic actors is put forward, making markets the key institution and confining states to a more remedial role; and the conservative regime, in most Western European countries, in which the principle of solidarity dominates, with social insurance schemes often based on occupational categories and family affiliations.

The specific contours of such typologies and the labeling of welfare regimes have been intensely debated; some even argue that advanced societies are so different from one another in this respect that their situation can hardly be summarized in such a way. The issue of producing and distributing well being is indeed closely related to that of social inequalities, and each society comes to grips with it in its own specific way, in the course of its history. This being said, typologies can be useful comparative tools under two conditions (Arts & Gelissen 2002). First, they must not be "sacralized": they are only meant to represent essential features, and to reveal the forest rather than the myriad individual trees. In fact, it is against the backdrop of broad types that the individual features of each society will stand out. Second, a typology is only helpful if it can be used to do something else. The question thus arises of whether welfare regimes have any consequences for the life chances and the life course of individuals.

There are abundant examples that they do. Welfare regimes are even drawing attention outside the circle of specialists in social policies as such. Health researchers such as Navarro and Shi (2001), for instance, examine the impact of the major policy traditions during the period 1945–80 (social democratic, Christian democratic, liberal, and ex fascist, another set of labels for similar clusters of countries) in four areas: the main determinants of income inequalities, the level of public expenditures and health care benefits coverage, public support of services to families, and the level of population health as measured by infant mortality rates. The results indicate that countries more committed to redistributive and full employment

policies, such as the social democratic, were generally more successful in improving the health of populations, and without loss of economic efficiency. An implicit causal chain is obviously evoked here, involving the level of inequality, social programs, and the resulting level of health.

Welfare regimes also have an impact on an issue of long standing in sociology, that of social mobility. DiPrete (2003) argues that the traditional comparative analysis of occupational mobility may not accurately describe cross national differences in living standards changes over the life course. For one thing, occupational position may no longer be an appropriate index of belonging to a social class, in these times of contingent jobs and of individualization of trajectories. Moreover, industrial nations differ in the extent of labor force participation by women, stability of working hours, stability of households, and state tax and transfer policies, all factors that contribute to determining how well individuals will fare over their lifetime. Studies of living standards mobility in the liberal US, in conservative Germany, and in social democratic Sweden indeed reveal much greater similarity between the countries than do traditional studies of male occupational mobility, where the flexibility of the American society was featured. Note that the new factors brought to bear on the issue of the life course by DiPrete all reflect the influence of welfare regimes: this is obvious for taxes and transfers, but regimes also influence – as shown below – labor force participation, especially for women, the stability of professional careers, and indirectly the stability of families and households.

While both of these studies provide valuable narratives, they essentially rest their case on the broad association between regimes and typical life chances. Hicks and Kenworthy (2003) use more systematic causal modeling. They first apply factor analysis to 20 broad indicators of social policies in order to characterize 18 countries over the 1980s and 1990s. They can thus identify two dimensions along which these countries' policies differ: a "progressive liberalism" axis, characterized at its positive end by extensive, universal, and homogeneous benefits, active labor market policy, and government employment and gender egalitarian family policies; and second, a "traditional conservatism"

axis featuring occupational and status based differentiations of social insurance programs and specialized income security programs for civil servants, as well as generous and longlasting unemployment benefits, reliance on heavy tax burdens for employers, and extensions of union collective bargaining coverage. These two factors are then used in regression analysis as predictors of aggregate national socioeconomic outcomes. Progressive liberalism leads to income redistribution and greater gender equality in the labor market, while traditional conservatism leads to a weakened employment performance.

What can be learned from these three studies (and many others that could have been cited)? Encompassing macrostructures like welfare regimes clearly influence changes experienced by individuals in their lives, for instance in their health, in the evolution of their living standards, and in their chances of access to jobs, with gender differences playing a significant role. This finding in turn raises a new causal issue: where do welfare regimes come from?

HOW DO REGIMES COME ABOUT AND CHANGE?

As mentioned earlier, regimes correspond to the broad set of institutional arrangements through which markets, states, families, and communities divide up among themselves the production and distribution of well being. They would not be regimes if they were not broad and resilient, and even self reproducing. Such stability would seem to offer limited opportunities for the study of social change. But upon reflection, this is not necessarily so: explaining stability requires attention to the processes at play in preserving existing arrangements, just as explaining change requires attention to the processes at play to disrupt and transform them.

Saint Arnaud and Bernard (2003) used an approach similar to Hicks and Kenworthy's, but they compared indicators for two time periods, the mid 1980s and the mid 1990s. They found that, for that interval at least, the clustering of advanced societies into regimes endured, in spite of the mounting pressures of globalization, which would hypothetically tend to dissolve the differences by making generous

welfare states fiscally unsustainable. In their search for an explanation of this resilience, they divided their indicators into three sets, concerning policies, outcomes, and civic participation (such as newspaper readership, voting, union membership, and trust). The same clusters of countries emerged in all three sets; this suggests that regimes, once established, so dominate the economic, social, and political scenes of the various countries that they give the same "texture" to their social situations, to their government programs, and to the civic commitment of their citizens. Why? Probably because policies influence outcomes, which in turn shape social and political mobilization, through civic literacy (Milner 2002); such mobilizations then lead to further confirmation of policy orientations and thus to the resilience of regimes. For instance, egalitarian policies would be confirmed and reinforced by a competent and mobilized citizenry, while the less egalitarian policies and situations of liberal countries would lead to less effective mobilizations in favor of policy changes.

This narrative of the processes linking policies, outcomes, and participation, while informative, is not being tested here with a specific causal analysis. Huber and Stephens (2001) take up that task in an impressive comparative effort that spans 18 advanced countries and 35 years of time series data; qualitative historical analysis is also called upon in about half of the cases, in order to confirm and enrich the interpretations coming out of quantitative modeling.

Their main thesis is that while the welfare state expanded during the 1960s and 1970s, it had to retrench in the 1980s and 1990s when austerity became the order of the day. Besides increasing economic pressures in the second period – in contrast with the continuing expansion in the first – two major factors were at play during the whole period: the political forces that dominated government, especially if they had sufficient time to put a strong imprint on the policies of the various countries, and the institutional structure, which can help or hinder discontinuities in policy directions.

The first factor is the more interesting from a causally narrative point of view. Huber and Stephens find that long term government incumbency of social democratic parties, committed to equality and solidarity, leads to the

construction of generous welfare states, with substantial entitlements, significant emphasis on the provision of public services – rather than only transfers – and redistribution through the tax and transfer system. Christian democratic parties, when they predominate, call for the support of all social classes, and this leads to substantive welfare expenditures. But they compete with the social democrats on the basis of religious appeal, and thus put forward the conciliation of various interests, not equality and redistribution. And their view of subsidiarity, where well being is produced at the lowest possible level (families, then local communities, and only residually at the state level), restricts the expansion of publicly delivered services.

Why does long incumbency make such a difference? Not only because it allows a party in power to change many policies, but also because it changes the policy agenda and the policy scene themselves. According to Huber and Stephens, there is first a ratchet effect, such that the center of gravity of the policy agenda is shifted, and indeed defined in terms of the preferences embodied in previous policy innovations. Moreover, expectations are transformed, and certain policy alternatives that social actors might otherwise have found attractive are no longer considered by them. Opportunities are also foreclosed or opened by previous policy choices, sometimes to such a point that some political players are no longer present on the scene (for instance, employers of low paid workers are absent in a country that has long had a high minimum wage). Finally, ideological hegemony sets in and makes an impression on the political ideas of most social classes.

One particular idea which has taken shape, and indeed redefined the agenda in social democratic countries, involves the labor force participation of women. Huber and Stephens point to the fact that the feminist movement, in alliance with unions and the labor movement, pushed for social and labor policies that would help women balance earning and caring roles. This has allowed an increasing number of women to join the labor force, thus further increasing their influence on the political scene, in a cycle of mutual reinforcement between policies and outcomes. The result is the development of services which at once help women participate, provide them with jobs in the

public service that are better than would be the case in private services (though not as good as men's), and help increase the overall level of education and health in the population.

When they turn to the period of retrenchment of the welfare state, Huber and Stephens show that social democratic rule and Christian democratic rule cannot produce, in the 1980s and 1990s, the sort of growth in government expenditures that prevailed in the previous two decades. They may not be paying enough attention, however, to an emerging pattern which they themselves have pointed out in other parts of their analysis: while overall revenues and expenditures no longer grow, public services may well do, and they are particularly important to women's labor force participation because they help the family care for dependents.

RETRENCHMENT OR RECONFIGURATION: FROM WELFARE REGIMES TO SOCIAL REGIMES

In still unpublished research, Bernard and Boucher (2005) extend the method of factor analyzing indicators of policies and outcomes to a broader set of dimensions and to more recent years (spanning the 1990s up to the early 2000s). They emphasize policies and outcomes having to do with services as well as transfers, and with the production of a healthy, well educated, and work ready population as well as with the coverage of traditional social risks.

The first factor in the analysis reveals an activation dimension, where policies are all aimed at making as many people as possible, and in particular women, active and productive in the labor market, with good health, basic education, and professional training. The second factor corresponds to a passive, welfare transfer dimension: programs essentially try to cover the risks of the many people who are unemployed, especially in the long run, or retiring early, voluntarily or not; and few women participate in the labor market.

At first sight, passive and active programs would seem to be polar opposites on a single dimension. But there is a third possibility: liberal countries tend to have fewer social programs of either kind. Indeed, the analysis reveals a growing competition between three models. First,

a social democratic one, where programs are oriented toward high social investments, which are expensive but paid for by a population that participates heavily in the labor market. Second, a liberal model where labor market participation is also high, but without a substantial level of social investment: in fact, the dearth of social programs forces a large proportion of the population into employment, with those who can afford appropriate education and health care faring much better than those who can only rely on lean public services and transfer programs. Finally, continental Europe is at the crossroads, with fiscally unsustainable welfare programs that are not clearly oriented toward increasing labor market activity. The way this third group of countries evolves will pretty much decide the fate of the "European social model," and determine whether welfare regimes will generally retrench or be reconfigured.

One interesting aspect of this research that also surfaced, but not as explicitly, in the work of Hicks and Kenworthy, and in that of Huber and Stephens, is that welfare regimes no longer concern only welfare and traditional social risks. The redefinition of gender roles has become part of the reconfiguration of welfare regimes, and the latter are increasingly seen as part of production regimes, that is, of how capitalist societies manage, in diverse ways, their economy as well as their social problems. Research increasingly reveals the existence of "social regimes," where all dimensions of society and the economy become relevant to one another and must somehow, through clashes and debates, assume some coherence and become sustainable.

CONCLUSION

Causal analysis of social change is about determining and narrating how the macro structures of society shape the life chances and the life course of individuals. It is also about examining how broad social categories of individuals sharing a common fate can imagine and fight for changes in the organization of society, for instance in their welfare regimes. The causal analysis of comparative international data allows researchers to identify the contours of such regimes, to examine their effects on individuals,

and to identify the actors, institutions, ideas, and processes involved in their reproduction and in their transformation. Causal analysis guides us, empirically and theoretically, in examining how, as C. Wright Mills (1976 [1959]) put it, biographies and history interact.

social change: the contributions of S. N. Eisenstadt

Eliezer Ben Rafael and Yitzhak Sternberg

Social change is a major focus of S. N. Eisenstadt's sociological work. It runs as a thread that binds together many of his works, from his earliest studies on absorption of immigrants (1952) and empires (1963), through his explorations in Axial civilizations (see, e.g., 1986), up to his later works about multiple modernities (among others, 2003). A recurring theme in Eisenstadt's work is his emphasis on endemic factors – in built tensions, contradictions, conflicts, and antinomies – as accounting for changes in, and transformations of, the social reality. In early formulations of this perspective, he already states that innovation and change are not external to institutional systems. They are aspects of the process of institutionalization and the working of social institutions (Eisenstadt 1965, 1968, 1970). He carries on this principle of dialectical transformation to his analyses of the dynamics of civilizations and modernity, which indeed once led Robert Bellah to describe Eisenstadt as a “non Marxist Marxist.”

From this standpoint, Eisenstadt elaborates typologies of social changes according to their scopes and impacts. He speaks of macro socio-historical, civilizational, and epochal transformations, differentiating them from more restricted intra epochal and intracivilizational changes. When he focuses on epochal transformations, he draws the distinction between major sociohistorical breakthroughs and secondary

breakthroughs. Reflecting on Jaspers (1953), Eisenstadt argues that a major breakthrough in human history was the crystallization of Axial Age civilizations from 500 BCE to the first century of the Christian era. This worldwide transformation, he says, constituted some of the utmost breakthroughs in history, the central aspect of which was the surfacing of new ontological conceptions of a gulch between the transcendental and the mundane (Eisenstadt 2001: 1916). A most significant aspect of the dynamics of Axial civilizations was their potentiality to generate further internal transformations – i.e., secondary breakthroughs. Accordingly, the main outcome of one of the Axial civilizations in Western Europe was the development of modernity which, from there, was to expand and encompass the world (Eisenstadt 2001: 1918).

In comparison, Eisenstadt sees the great revolutions – such as the English Civil War, the American and French revolutions, and later the Russian and Chinese ones – as intra epochal and less dramatic transformations. These revolutions, he contends, by no means constitute major processes of change, whether in premodern or modern times (Eisenstadt 1992: 397). Eisenstadt's unique contribution to the study of these revolutions is their understanding as part of the social transformations of epochal changes and dynamics, which incorporates them in his general civilizational analysis. The “kernels” of these revolutions, from this point of view, can already be found in the basic characteristics of Axial civilizations, and more specifically, in the ideological and structural components of their political process. However, it is only with early modernity (the chronology of which differs in different societies) that these dynamics generated revolutionary processes and that affinities tended to concretize between political developments pertaining to the Axial civilizations and the ideological and organizational forces embedded in revolutions (Eisenstadt 1992: 394).

On the other hand, a radical change like the Meiji Restoration of 1868 in Japan cannot be seen, according to Eisenstadt, as such a revolution, since appropriate historical civilizational kernels were lacking to the extent that, historically, Japan does not belong to an Axial Age civilization. More specifically, this analysis is grounded in the observation that in Japan, one could not find any autonomous religious order,

group of intellectuals, or political party that formulated, and fought on behalf of, a universal utopian vision. This absence of such essential ingredients makes all the difference between the Meiji Ishin and the great revolutions. In practical terms, the Meiji Restoration was intended to bring about the reconstruction of the Japanese nation, and did not raise any universalistic claim requiring propagation outside Japan (Eisenstadt 1992: 396, 390).

This linking of the concept of civilization with epochal transformations, and hence with a sociohistorical periodization, represents an important contribution to both social change theory and civilizational analysis (Arnason 2001). In this respect, this approach differs from other perspectives on civilization such as, among others, Fernand Braudel's (1980) spatial synchronic analysis, which emphasizes long term continuity; or the "classical" civilizational analyses, like Oswald Spengler's (1945) and Arnold Toynbee's (1965), which tend to evince recurring cyclical stages. Eisenstadt, in contrast, privileges a temporal diachronic analysis that sets emphasis on sociohistorical epochal make overs of civilizations. In this he also differs from approaches like Norbert Elias's (1994) that focus on sociohistorical, long term civilizing processes; instead, he emphasizes discontinuities and divisions as accounting for the generation of new phases of development.

Hence, Eisenstadt's approach to the question of directionality in macro sociohistorical transformations cannot be understood as evolutionist. Although his civilizational analysis is prone to delineate vast periodic stages, it is clearly distinguishable from a linear evolutionist approach in the vein illustrated by Rostow (1960). Against evolutionary aspects in functionalism, Eisenstadt argued that considerable social changes do not always lead to greater differentiation between institutional spheres and developments. Transformations that, at first glance, delineate what might be thought of as "similar stages" of institutional development may be leading to divergent horizons (Eisenstadt 2003: 6–7). Eisenstadt insists on the multiplicity and variety that both Axial civilizations and modernity may adopt, side by side with their common characteristics (see also Tiryakian 2005). In brief, he calls attention to potential convergence as well as divergence. Above all,

he opposes evolutionary teleological approaches that overstate directionality toward convergence, such as Parsons's (1964) thesis on "evolutionary universals in society" or Fukuyama's (1992) vision of an "end of history."

As a derivative of his basic approach that underlines the importance of human agency and creativity, Eisenstadt contributes his own view regarding the "bearers" and initiators of social change by highlighting the crucial role of elites. Accordingly, for instance, the development and crystallization of Axial civilizations were made possible, in Eisenstadt's comprehension, only thanks to the emergence of a new type of elite that deeply differed from those that dominated pre Axial Age civilizations. This new kind of elite consisted of individuals who were independent enough, intellectually, to elaborate and propose new cultural and social orientations, which they derived from new ontological conceptions (Eisenstadt 2001: 1917).

Though at a different level of analysis, this preoccupation with the influential in relation to social change was already present in Eisenstadt's early work about the absorption of new immigrants in Israel, where he insisted on the importance of elites in the construction of trust and solidarity (Eisenstadt 2003: 3). All in all, he contends, it is those groups that evince a high level of internal solidarity and trust that are best able to adjust in situations of change; elites, he pursues, play here a major role, not only in the building of cohesiveness within collectives but also in connecting this process with commitments to broader institutional and societal frameworks. This example shows how far Eisenstadt valorizes elites in connection with social change, and, moreover, that, in his mind, the very notion of social change is not bound exclusively to conflictual contexts. Change may also be bound to the building of social cohesion and it then much depends on the action of elites. Focusing on elites, and not on social classes, to be sure enables Eisenstadt to develop a more open explanatory framework for the appreciation of social change (see Eisenstadt with Currlaru 1971). This, however, does not mean that Eisenstadt can be identified, in this respect, with an elite theoretician like Vilfredo Pareto (1963), who emphasizes recurring ahistorical cycles emanating from inter elite and intra elite conflicts. Eisenstadt's own underscoring of the

importance of elites to social change remains bound to the specification of the social context of change and the historical processes wherein it takes place.

All in all, Eisenstadt's thought regarding the dynamics of social change, especially in relation to the study of civilizations and modernity, is best grasped through the concept of "program" (see also Boudon 1986, 2005). These dynamics that are grounded in basic characteristics, tensions, and antinomies inherent to the social order trace out paths of development and outcomes that cannot be known *a priori* and remain open to a variety of alternate trajectories. This scheme, in its general formulation, rejects any form of historical determinism and, on purpose, remains less specific than major alternate perspectives. In this latter respect, one may mention as examples the overwhelming weight granted to the relations of production and class structures in Marxism or to technology and productivity in the similarly close "technologist productionist" model (see Kerr et al. 1962). In both these approaches, changes in key factors of the social structure account for changes in all other areas of social activity. In contrast, Eisenstadt, who by no means ignores the factors evinced by those outlooks, stresses the possibility that additional areas of activity also play an autonomous role in societal development.

In particular, his civilizational analyses attach much attention to the transformative potential of culture, and especially to the circulation of ideas and perceptions of the social order and, relatedly, to the confrontation of alternative intellectual and ideological horizons. Thus, for example, he insists on the impact, in the emergence and institutionalization of Axial Age civilizations, of new ontological conceptions that elaborated on chasms between transcendental and mundane orders (Eisenstadt 2001). In another example, where he compares the dynamics of Axial (China and Europe) and a non Axial (Japan) civilizations, he insists on the significance of the combination of ideological elements and their institutional settings in the occurrence of political revolutionary processes in the former cases, while in the latter case there was a lack in universalistic missionary visions that can be traced back to its historical experience (Eisenstadt 1992: 395). Furthermore, the

"kernel" of great revolutions can be found only in Axial civilizations where the ontology of salvation was turned toward the mundane world – at least partially. In civilizations where the notion of salvation referred exclusively to the "other world," it is doubtful that the political arena might constitute a scene for struggles conveying a revolutionary significance (Eisenstadt 1992: 395).

This openness of perspective is the rule regarding all topics investigated by Eisenstadt – youth cultures, empires, systems of social stratification, revolutions, historical civilizations, or the Israeli society. It is particularly salient in his work on modernity, where he elaborates an alternative approach to more closed models. Through the autonomy of action this perspective endows to men and women in their relation to society and the world, modernity sets people in a stance of reflexivity to their acts and goals. It opens the way to new behaviors and understandings of the social order as well as to new tensions and conflicts. On the other hand, modernity, it is also Eisenstadt's contention, does not collide head on with religion and premodern traditions in every area of activity and regarding any topic of reflection. Modernity brings about radical changes in lifestyles and new challenges that may oppose religious and traditional patterns and premises, and require from them new formulations and expressions. It does not, however, necessarily combat them on essential existential questions or regarding symbolic aspects of collective endeavors. Hence, changes attached to the expansion of modernity may be derived from and be implemented through different, if not divergent, understandings of modernity, revealing the lasting traces of particular cultures, religious systems, and legacies. It is in the context, among other significant circumstances, of the diversity of such premodern traditions and the potential diversity of their influences on societies' turn to modernity that Eisenstadt speaks of the contemporary world in terms of multiple modernities. By this notion he means that contemporary modern or modernizing settings differ from each other not only by the forms that modernity takes on everywhere, but also according to foci, kinds and degrees of tensions that are endemic to those societies' experience. This opens the discussion of modernity to the widest range of possibilities, and it

is as such that it definitely belongs, in a prominent place, to the comparative sociological literature of modernity.

In forging this view of modernity, Eisenstadt actually follows in the footsteps of both Marx (see Tucker 1978) and Weber (see Gerth & Mills 1948): he is close to the former when he focuses on social change as generated by dialectical processes endemic to social reality; he is closer to the latter when he sees social change in a broad comparative perspective where culture and views of the world do play a crucial role in the development of society. Moreover, and again like the founding fathers of sociology, Eisenstadt as well is by no means *neutral* toward the object of his investigations. One cannot mistake his liberal pluralist outlook when, for example, he opposes “destructive” and “constructive” tendencies of modernity, nor when he contrasts totalistic and pluralistic societal arrangements of sociocultural divisions (see also Dahrendorf 2005). Eisenstadt stands here firmly on the ground of Weber, Durkheim, and Marx, for whom value judgments and a priori convictions never hindered scientific achievements but, on the contrary, induced them to study and re study the reality of society and the trends of its transformation (see Ben Rafael & Sternberg 2003).

And, indeed, in this immense work that is Shmuel Eisenstadt's, the concept of social change holds the role of pivotal axis; it derives from, and concretizes the very openness of, his sociological perspective.

social change, Southeast Asia

Charles Hirschman and Jennifer Edwards

Southeast Asia consists of the 11 countries that lie between the Indian subcontinent and China. On the mainland of Southeast Asia are Myanmar (Burma), Thailand, Laos, Cambodia, and Vietnam. Insular Southeast Asia includes Indonesia, the Philippines, Brunei, Malaysia, and Singapore and most recently East Timor. While most of Malaysia (Peninsular Malaysia) is on the mainland, it is usually considered part of insular Southeast Asia because the Malay population (the majority ethnic population of Malaysia) shares a common language and religion with much of the Indonesian population. The city state of Singapore (on an island connected by a mile long causeway to Peninsular Malaysia) was historically part of Malaysia, but because of its unique ethnic composition (three quarters of the population is of Chinese origin) it is more similar to East Asia than Southeast Asia.

While there are some common geographical and cultural features, diversity is the hallmark of the region. Incredible indigenous cultural

variation has been overlaid with centuries of contact, trade, migration, and cultural exchange from within the region and from other parts of Asia, and for the past 500 years from Europe (for general overviews of the region, see Osborne 1997; Somers Heidhues 2000; Shamsul 2001; Wertheim 1968). The common characteristic of mainland Southeast Asia is Buddhism, although there are very significant variations across and within countries. Islam is the majority religion in Indonesia, Brunei, and Malaysia, and there are significant minority Muslim populations in Singapore, southern Thailand, and the southern Philippines. Christianity is the major religion of the Philippines, and there are small Christian minorities throughout the region. Hinduism is the major religion in Bali, an island in Indonesia, and among the Indian minority populations of Malaysia and Singapore. The lowlands of both mainland and insular Southeast Asia tend to be densely settled, and wet (irrigated) rice agriculture is the predominant feature of the countryside. Rural areas are knitted together with small and medium size market towns. The major metropolitan areas of the region (Jakarta, Bangkok, Singapore, Manila, Rangoon, Kuala Lumpur, Ho Chi Minh City) are typically port cities or located along major rivers. Many of these towns and cities have significant Chinese minorities (often intermarried with the local population) that play an important role in commerce. Every country has remote highland and mountainous regions which are often populated by ethnic minorities.

In terms of land area, population size, and cultural and linguistic diversity, Southeast Asia is comparable to Europe. By the year 2000 the population of Southeast Asia exceeded 500 million – about 8 percent of the world's total. Indonesia is the fifth most populous country in the world, while the oil rich sultanate of Brunei (located on the island of Borneo) is one of the smallest. The other large countries of the region, Thailand, Vietnam, and the Philippines, are more populous than all European countries except for Russia and Germany. The sea (South China Sea, the Indian and Pacific Oceans) surrounds much of the region, especially the immense Indonesian and Filipino archipelagos. While the sea can be a barrier, the ocean and the rivers of the region are avenues that have fostered local and long distance trade throughout

history. The same oceans can also be cruelly destructive forces, as evidenced by the enormous loss of life and of entire communities from the December 2004 Indian Ocean tsunami.

POLITICAL HISTORY

The contemporary political divisions of the region are largely a product of European imperialism, especially of the nineteenth century. Prior to European intervention, there were great regional civilizations – both agrarian states and maritime empires that waxed and waned over the centuries. The remains of temple complexes at Angkor (in Cambodia) and Pagan (in Burma) rival the architectural achievements of any pre-modern world civilization. Early western observers of the city of Melaka (a fifteenth century maritime empire centered on the west coast of the Malayan peninsula) described it as more magnificent than any contemporary European city. These early polities were founded on intensive rice cultivation with complex irrigation systems and/or the dominance of regional and long distance trade. The region has also been deeply influenced by contacts with the great civilizations of India and China. The cultural influences from outside have invariably been transformed into distinctive local forms in different Southeast Asian contexts. The ease of movement throughout the region seems to have shaped cultures that easily absorbed new ideas, immigrants, and a tolerance for diversity.

European influence began in the sixteenth century with the appearance of Portuguese and Spanish naval forces, followed by the arrival of the Dutch in the seventeenth century, and then by the British and French. In the early centuries of contact, European powers were able to dominate the seas and thereby limit the expansion of Southeast Asian polities, but rarely penetrated very far inland from their coastal trading cities. All of Southeast Asia was transformed, however, in the nineteenth century, as the industrial revolution in the West stimulated demand for mineral and agricultural products around the globe. New economic organizations of plantations, mines, and markets led to large scale migration of people and capital to frontier areas and to the cities of Southeast Asia. There was an accompanying flurry of imperialist wars to grab

land, people, and potential resources. In a series of expansions, the British conquered the area of present day Myanmar (Burma) and Malaysia, the Dutch completed their conquest of the East Indies (now Indonesia), and the French took the areas that formed their Indochina empire (present day Vietnam, Cambodia, and Laos). At the turn of the twentieth century, the United States defeated nationalist forces to take control of the Philippines just as the Spanish empire was crumbling. Siam (Thailand) was the only indigenous Southeast Asian state to escape the grip of colonialism.

The political history of the region has not been stable or evolutionary. As western countries moved toward more democratic social and political institutions over the first decades of the twentieth centuries, the colonists (British, Dutch, American, and French) constructed authoritarian dependencies in the tropics based on export economies and racial ideologies. Although there were stirrings of nationalist sentiment during the first half of the twentieth century, it was only after World War II that the nationalist forces were strong enough and the international environment favorable enough to bring political independence to the region. The critical turning point was the Japanese conquest and occupation of Southeast Asia from 1942 to 1945, which permanently shattered the myth of European superiority. The colonial powers returned after World War II, but encountered popular nationalist movements that demanded the end of colonialism.

Independence was negotiated peacefully by the Americans in the Philippines and the British in Burma and Malaysia, but nationalist forces had to wage wars of independence against the Dutch in Indonesia (1945–50) and against France in Vietnam (1945–54). The interplay of nationalist struggles, class conflicts, and East–West Cold War rivalry had a marked influence on political developments in the region. In almost every country there were radical and communist movements that held the allegiance of significant sectors of the population. In several cases, communist parties were part of the nationalist movement, but then departed (or were driven out of) the political arena as domestic and international tensions escalated. Vietnam was unique in that the nationalist movement was led by communists. After the French were

defeated in 1954 and agreed to grant independence to Vietnam, the United States intervened to set up a noncommunist Vietnam state in the southern region of the country. After another 20 years of war and a million casualties, Vietnam was finally united as an independent state in 1975. Following 1975, tensions between the socialist states (Vietnam, Cambodia, and Laos) and the rest of the region were the major focus of international relations in the region, but by the late 1990s these rivalries had subsided.

Domestic political developments within individual countries of the region have been no less dramatic. Governments have oscillated between authoritarian and democratic forms with no clear linear trend. Behind the headlines of military coups, regional wars for autonomy, and “managed” elections, have been the complex political struggles among various contending groups defined by class, region, ethnicity, and kinship. These struggles have ranged from civil war to fairly open elections. Large scale violence is not the norm, but massacres in Indonesia, Cambodia, and East Timor have been among the worst of such episodes in modern times. Popular civil protests against ruling elites in the Philippines and Burma have had significant domestic and international reverberations. Neither academic scholarship nor political reporting has offered broad empirical generalizations or convincing interpretations of the postwar political change in Southeast Asia.

Evolutionary – and sometimes revolutionary – social change continued throughout much of Southeast Asia in the 1980s and 1990s. After the collapse of the Soviet Union, the socialist countries in the region, including Vietnam, Cambodia, and Laos, moved rapidly toward more market driven economies. Several other countries in the region experienced major political movements that led to changes in national leadership. The “people power” movement led to the end of the Marcos regime in the Philippines and a return of regular elections. Nonviolent mass street protests ended the string of military coups in Thailand and ushered in an era of open democratic governance. Popular protests also forced the end of the Suharto regime in 1998 and brought the first free elections in 45 years in Indonesia. The military junta continues to rule Burma in the early years of

the twenty first century, but few expect it to last for many more years. Even in Malaysia and Singapore, perhaps the most stable countries in the region, change was in the air, when after several decades of rule, first Lee Kwan Yew in Singapore and then Mahathir Mohamed in Malaysia handed over power to appointed successors. After many years of instability, Cambodia experienced consecutive peaceful elections in 1998 and 2003.

The 1990s also witnessed the creation of the new state of East Timor. After a long history of political repression by Indonesia, the people of East Timor voted for independence in a UN supervised referendum in 1999. After a period of brutal retaliatory violence from Indonesian sponsored militias, East Timor was granted international recognition as an independent state in 2002.

SOCIOECONOMIC CHANGE

Southeast Asia has been one of the most economically dynamic regions in the developing world. Economic change has been accompanied by many other attributes of modernization, including the widespread availability of education, modern transportation, and the mass media during the post Independence era. This is most evident for the original ASEAN (Association of Southeast Asian Nations) countries of Thailand, Malaysia, Singapore, Indonesia, Philippines, and Brunei (admitted in 1984). Several of these countries are often identified as second tier Asian tigers (following the earlier model of the rapidly developing countries of South Korea, Taiwan, Hong Kong, and Singapore). Progress has been slower in the remaining Southeast Asian countries of Vietnam, Myanmar (Burma), Laos, and Cambodia, which were admitted to ASEAN in the 1990s.

Many indicators of development in Southeast Asia, including very low levels of mortality and almost universal secondary schooling, are approaching the prevailing standards of developed countries. Demographic research has revealed very rapid declines in fertility in several Southeast Asian countries, particularly in Singapore, Thailand, Malaysia, and Indonesia. If the current pace of decline continues,

replacement level fertility (two children per woman) should be reached in the near future (Hirschman & Guest 1990).

At the same time, however, there is wide variation within the region and within some countries on all of these indicators. Life expectancy varies by over 20 years across some of the ASEAN countries, with a low of 55 years in Laos and a high of 82 in Singapore. While Singapore and Malaysia are competing for high tech industry jobs, the majority of the population in Burma and Laos remains in subsistence agriculture.

The reasons for the success of some countries and economic stagnation in others are a matter of dispute. The East Asian model of state sponsored export industrialization is widely discussed in policy and academic circles, but the parallels between East Asian and Southeast Asian economic development strategies are still a matter of considerable uncertainty. Although market driven capitalism is part of the story, the role of the governments in managing their economies has also been integral to economic development in the region. What is striking about economic development in the region is the degree to which it has been carried out by fairly authoritarian states. The relationship between democracy and economic growth and development, argued to go hand in hand by modernization theorists, seemed to be challenged by the experience of Southeast Asian tigers towards the end of the twentieth century, but much research is left to be done on the causes and consequences of economic development and modernization in the region.

For much of the 1990s, most of Southeast Asia experienced rapid economic growth and the development of a middle class population whose growing social and political influence has been widely discussed in the research literature (McVey 1992; Girling 1996; Embong 2001). For example, the reform political movements in Thailand, Indonesia, and Malaysia are thought to be one manifestation of the increasing role of the new middle class. The period of very rapid economic growth was halted in late 1997 by the "Asian economic crisis" that hit the region, and Thailand, Malaysia, and Indonesia in particular. The causes of the crisis are the subject of much debate, with the role of "crony

capitalism" and highly speculative financial markets widely considered to be important contributing factors.

Despite the economic crisis of the late 1990s, economic growth has resumed in the region, even for some of the poorer countries like Laos. Assuming that current socioeconomic trends continue, several countries in the region will probably follow Japan, Korea, and Taiwan along the path of development in the early decades of the twenty first century.

SOCIOLOGICAL RESEARCH

Scholarship on Southeast Asia has often reached beyond the boundaries of the region to influence debates over social science concepts, theory, and models. Perhaps most influential has been the work on Indonesia by anthropologist Clifford Geertz. His evocative concepts of the "theatre state," "thick description," and "agricultural involution" have stimulated debate and research in several social science disciplines, including sociology. His model of agricultural involution (Geertz 1968) has been one of the most provocative developments in scholarship on Indonesia over the last generation. A strikingly bold thesis, agricultural involution is an attempt to explain how Java became one of the most densely settled populations in the world within a traditional agricultural economy. To address this question, Geertz presents an ecological interpretation of the evolution (involution) of Javanese social structure in the face of rapid population growth and Dutch colonialism within the constraints (and possibilities) of wet rice economy. The colonial system prevented industrialization and the development of an indigenous entrepreneurial class. The traditional rice economy, however, could absorb a larger population because additional labor inputs in the maintenance of irrigation facilities, water control, weeding, and harvesting yielded marginal increments in rice production. Over the decades, this refinement of traditional production technology (involution) led to an increasing rigidification of traditional Javanese culture that discouraged innovation and any efforts at social change – therefore reinforcing the structural limits of the colonial system. Even after independence

when structural limits were lifted, the legacy of the past, as reflected in Javanese culture, remained.

Geertz's thesis remains highly controversial and many of its components have been confronted with negative evidence (for a review of the debate, see White 1983; Geertz 1984). For example, Geertz deemphasized social class divisions with his interpretation of "shared poverty" as the traditional social strategy. Most research has shown significant inequality of landholding and other socioeconomic dimensions in Javanese villages, although it is not clear if inequality is permanently perpetuated between families across generations. Even accepting many of the criticisms, agricultural involution is a seminal sociological model that should serve to generate empirical research on the historical development of Asian societies.

Moral Economy

A classic question in social science concerns the causes of revolution or rebellion. Neither Marxian theory, which emphasizes exploitation, nor relative deprivation theory seem to be satisfactory models to explain the occurrence of revolutions or rebellions. The most sophisticated sociological theory of peasant rebellion is based upon historical materials from Burma and Vietnam by political scientist James Scott (1976). Scott argues that peasants only rebel when their normative expectations of a minimum subsistence level are not met. These conditions are more likely to occur when capitalist market relations and colonial states erode traditional social structures and the reciprocal obligations of peasants and their patrons.

In a more recent study based upon fieldwork in a rural Malaysian village, Scott (1985) examines how class antagonisms are displayed in everyday life. Given that rebellion is a very rare event in most societies, Scott calls attention to political, social, and linguistic behaviors (weapons of the weak) that reveal the depth of antipathy and potential social conflict, but do not risk violent reaction from the state and powerful elites. In these two books and related publications, Scott has provided original interpretations of peasant political behavior in Southeast Asia and set a research agenda for

scholars of other world regions and, more generally, the development of social theory.

Status of Women

In addition to the theoretical concepts mentioned above, empirical generalizations have arisen from studies of Southeast Asian societies that have relevance far beyond the region. Empirically, the most common cultural characteristic across the region is the relatively high status of women in Southeast Asian societies, especially when compared to East Asia and South Asia. While women still face many social and cultural obstacles in Southeast Asia, the situation appears much different than the patriarchal societies of other Asian societies and the model of traditional female domesticity of many western societies. While there are a few matrilineal societies in the region, Southeast Asian kinship systems are typically bilateral, with equal importance attached to the husband's and wife's families. The patrilocal custom of an obligatory residence of a newly married couple with or near the groom's family is largely absent in Southeast Asia. The residence of young couples after marriage seems to be largely a matter of choice or dependent on the relative economic opportunities. There is no strong sex preference for children in Southeast Asia, and both girl and boy children are highly valued. Divorce, often initiated by wives, was part of the cultural fabric of several Southeast Asian societies, including Malaysia, Indonesia, and Thailand (Hirschman & Teerawichitchainan 2003).

The relatively positive status of women is also evident in earlier times. Historian Anthony Reid (1988: 146–72) reports that early European observers were struck by the active role of women in economic and political affairs in Southeast Asia. Traditional folklore also suggested that women play an active role in courtship and that female sexual expectations were as important as men's.

At present, women seem to be well represented in schools, universities, and in employment in all modern sectors of the economy in almost every country of Southeast Asia. There is only a modest scholarly literature on the higher status of women in Southeast Asia (Andaya 2001; Van Esterik 1982), and few efforts have

been made to explain the links between traditional roles of women as productive workers in the rural rice economy and their relative ease of entry into the modern sector, particularly in manufacturing industries such as textiles. The impact of modernization and economic development on gender relations and on the status of women are important topics for future scholarship.

Cultural Pluralism

Cultural pluralism has been the focus of both historical and contemporary research on Southeast Asia. Historically, one of the defining features of the region was the relatively easy absorption of peoples, ideas, and cultural practices from elsewhere. In the twentieth century, however, assimilation into Southeast Asian societies became more difficult with the creation of political and social barriers. Some of the key sources of ethnic and religious conflict in the region are illuminated in Chirot and Reid's (1997) collection of essays that compare the experiences of the Chinese in Southeast Asia with those of Jews in Central Europe. The implications of religious and ethnic diversity in the region for democratization have also garnered scholarly attention (e.g., Hefner 2001).

In particular, the relationship between politics and Islam is a topic of growing regional research interest with implications far beyond the region. Even with their majority Muslim populations, Indonesia and Malaysia have managed to maintain relatively secular states in spite of challenges from opposition parties that espouse religiously oriented politics. Hefner (2000) challenges the widely asserted stereotype that democracy is unable to flourish in the presence of Islam.

CONCLUSION

A generation or two ago there was intense discussion and debate over the question of whether Southeast Asia was a region in more than a geographic sense. The question has pretty much been settled by historical and contemporary research (Wolters 1999; Reid 2003). In spite of the great political, economic, and sociocultural diversity in the region, there are many common cultural, political, and social forms. The similarity of family systems and the status

of women throughout Southeast Asia suggest common historical and cultural roots among all the peoples of the region. The long history of migration from other regions, the ecological, cultural, and social differences between lowland and upland peoples, as well as the presence of linguistic and religious pluralism, have created multi ethnic societies in every country in the region. Colonialism created many divisions that affected variations in the political and economic developments of Southeast Asian countries during the twentieth century. The study of these processes of modernization and social changes in politics, family structure, ethnic relations, and other social spheres makes Southeast Asia an extraordinarily interesting sociological laboratory for comparative research.

social cognition

Chandra Mukerji

Studies of social cognition attempt to explain how thought or cognitive problem solving takes place in groups. While scholars generally agree that learning can be a collective activity, many

are reluctant to accept that thinking itself could have a social dimension. Psychologists and cognitive scientists tend to consider thought as an internal brain activity. Sociologists generally avoid the problem by focusing on social behavior. When sociologists look at consciousness, they generally study how internal psychological processes have been shaped by external social demands. Media scholars examine patterns of persuasion, and political sociologists look at ideology and hegemonic practices. All agree that collective life proceeds through the mind as well as the body, but few consider social cognition or how thinking might take place through interaction (Scribner & Cole 1974; Longino 1990; Hutchins 1995; Turnbull 2000; Rosenthal 2003).

Scholars doing work in the sociology of scientific knowledge (SSK) have been the exception. Conducting fieldwork in laboratories, they have repeatedly found that ideas emerge through interaction. Researchers talk to one another about what they are seeing and how they understand their data (Bloor 1990; Longino 1990; Knorr Cetina 1999). Their thinking takes place in conversation and this fact is documented in the long list of authors in many scientific publications.

The problem for those interested in social cognition is to define the more general conditions under which such activity takes place (Latour 1993; Rosenthal 2003; Mukerji 2006). Ed Hutchins (1995), an anthropologist working in cognitive science, has been a leader in this field. He explains that social cognition can take place even when individuals are alone. He asks us to imagine a student sitting at a desk, doing a math problem. There is paper on the desk and a pencil in the student's hand. Where, Hutchins asks, is the thinking going on? The simple answer is in the brain. The student absorbs the problem, solves it internally, and puts the result onto the paper. But Hutchins argues that the calculations in fact take place on the paper as well as in the brain. The student uses cultural symbols to do the problem, and manipulates them in culturally prescribed ways, using techniques designed for pencil and paper. Many math problems are impossible to solve without writing them down. So, Hutchins argues, the thought is *both* in the brain and in the material world. The brain learns to do what the culture says can be done on paper, and the problem is

solved where collective and individual life meet – at the desk or in the school room. The brain is not an autonomous source of ideas, but rather another part of the human anatomy that is trained to fit a culture. Just as people learn ways of walking, forms of sexuality, emotional states, languages, and work skills, so they also learn ways of thinking. And they practice them with others. The brain itself is trained as children grow to adulthood by the physical and cultural environment in which they are raised. Individual thought is not so individual after all.

Hutchins (1995) argues that collective forms of problem solving are even more evident in group life, and he demonstrates this in a series of studies of navigation. When pilots fly planes or sailors take their ship to sea, they routinely rely on the knowledge and cognitive skills of others. They enroll maps, gauges, observations, and instruments into the enterprise, forming what Latour has called “networks of people and things.” The Pacific Islanders that Hutchins first studied, who navigate their canoes over long distances out of sight of land, determine their course collectively, watching the patterns of waves, tracking stars, watching for birds, and looking for currents in the color of the water. The measures are too diverse for any one individual to monitor effectively, so they work together to navigate the Pacific. US naval vessels with all their instruments also require distributed cognition. To determine a course, some sailors look at sonar screens while others follow wave and wind data or monitor the speed of the engine. These different but comparable actors similarly use multiple measures to solve problems of navigation, and use talk to integrate the information in useful ways.

Turnbull (2000) studies other instances and techniques of collective cognition. Like Hutchins, Turnbull is interested in the cognitive practices of indigenous people, focusing his attention on aboriginal groups in Australia. But he also studies western cartography and building practices. For example, he looks at the use of templates by medieval masons in building cathedrals. They could reproduce arches of a similar form without having to make novel measurements. With the templates, cathedrals that were erected over centuries gained continuity of form because new masons worked with the same cognitive tools as their predecessors. Turnbull looks

at maps in a similar way. Cultures may have such different mapping systems that one cannot translate information easily from one to another, but within their culture, maps help coordinate thought and sustain ways of life over time.

Mukerji (2006) also looks at social cognition and indigenous intelligence, but as part of his torical sociology of early state power. She studies the construction of the Canal du Midi, one of the first navigational canals to make extensive use of locks. She is particularly interested in a group of indigenous women engineers who lived in the Pyrenees in the seventeenth century. They managed some of the most sophisticated waterworks of the period in these remote mountains where Roman settlers once built baths. Their skills in hydraulic engineering were derived from Roman precedents, but their provenance had been forgotten. The hydraulic techniques no longer served public baths, but public laundries. Because their skills were honed against the difficult landscape of the mountains, these indigenous workers had the very rare ability to cut contours with precision, and carry water over vast distances in rough country. Because of these abilities, they were employed as laborers on the Canal du Midi. They participated in a system of distributed problem solving with military engineers, academics, and artisans.

According to Longino (1990), the reluctance to see cognition as social is grounded on the philosophical assumptions of Descartes and his followers that for centuries privileged the individual knower in the pursuit of truth. Descartes defined outside influences as a source of confusion to anyone seeking knowledge. He argued that authorities can proffer illusions rather than point to the truth, so thinking independently is necessary for the pursuit of knowledge. Longino breaks with this tradition and makes a philosophical argument in favor of social epistemology, using the laboratory from SSK as her guide. She argues that group problem solving can be just as progressive as individual thought. Individuals as well as groups can cultivate illusions, but in fact, she says, the shared professional skepticism of scientists is a better means of dispelling than individual contemplation.

This position is compatible with what the developmental psychologists Scribner and Cole (1974) have argued about culture and learning. Following the precepts of the Russian

psychologist Vygotsky, they contend that learning is a social activity, not simply a natural capacity of human brains. Literacy effects are not just abilities acquired in learning to decode and write messages, but rather effects of the schooling in which literacy is acquired. Rote memory and recitation may constitute literacy, but they do not produce the same kind of cognitive skills as critical reading. The reflexivity that psychologists usually associate with learning to read is really the product of the ways that texts are presented and interrogated in western societies. The collective practices of schools and families produce forms of consciousness that are social, not individual. Scribner and Cole argue that texts and other inscriptions are cognitive tools. They can be (but are not necessarily) used as intellectual scaffolding for developing higher forms of reasoning. Schools tell pupils how to understand and use these tools, and produce cultural forms of collective reasoning.

The notion of cognitive tools has proven particularly effective in interpreting the collective patterns of cognition in science. Scientific instruments constitute another type of cognitive tool that not only allows people to think in new ways, but to approach problems in similar fashions. Where the same instruments are used in multiple fields of study, they help to fashion a common way of working and thinking. Research that is very specialized can nonetheless contribute to collective shifts in knowledge because scientists share cognitive tools: not only types of measurements, but also mathematical models, or logics of research.

Hutchins, Cole, and researchers in the SSK tradition tend to focus on face to face interaction where people learn from one another or learn in tandem, but Mukerji, studying the Canal du Midi, also looks at how the state in this period cultivated and organized intelligence, using cognitive advantages to augment their institutional power. Military engineers, academics, and civil engineers were all cultivated and patronized by the royal treasury, and were obliged to serve on the king's projects. They came to the Canal du Midi when they were told to do so, combining their different expertise acquired as creatures of the state. The resulting social intelligence was a political asset, and used to improve the infrastructure of the kingdom.

Occupations have their own forms of intelligence that can be cultivated in seclusion or used in coordination with others. Large scale organizations such as corporations or governments combine and use them in precise ways. The American sailors described by Hutchins, navigating navy vessels at sea, have duties defined by the naval hierarchy. Their skills are a product of this system, and so are their practices of collaborating. They are trained to help navigate collectively and to have the distinct skills needed for the job. Bureaucracies are not just socially rational systems of offices, but means for managing and exploiting human intelligence.

Currently, those who study social cognition do not question whether such a thing exists or not. The evidence for it seems strong. But it is still difficult to differentiate a pattern of *social* thought from a chain of command. In the former, group members share their ideas and find common solutions to problems together. In the latter, information is fed from the bottom to the people at the top, who do the thinking. More research is needed to make more precise descriptions of this. And more precise theories are needed to distinguish social cognition or distributed thought from other patterns of solving problems.

What is most intriguing in current research are the efforts to clarify what difference it makes that human beings can talk with one another and stabilize common understandings of things. Clearly, groups can sometimes accomplish through distributed cognition what individuals could not do on their own. The question is when and how this capacity is employed and how much of social life is founded on this ability.

social comparison theory

Monica K. Miller and David Flores

Comparisons with other people play a significant role in social life, as they provide meaning and self-relevant knowledge. How people view their own circumstances, abilities, and behaviors varies according to the types of social comparisons they make. Although in his seminal work Leon Festinger (1954) did not offer a precise definition of social comparison, it is generally conceptualized as the process of thinking about the self in relation to other people. Individuals frequently make social comparisons because no objective comparison information is available; however, when both social and objective information is available, people are often more influenced by social information, as it is frequently more diagnostic than objective information. Further, many researchers believe that comparisons may be with real or imagined others, and do not require personal contact or conscious thought. Comparisons can also be made between one's own social group and another social group. Although comparison information can be encountered naturally in one's environment, most research has studied the types of comparisons that participants seek out intentionally.

There are many motivations for seeking social comparison information. First, comparisons

provide information for self-evaluation. In situations lacking objective standards, people often look to similar others as an indicator of how well one has performed. For example, students often want to know how their test score ranks among their classmates' scores. Second, social comparison can serve self-improvement purposes, as is the case of younger children comparing themselves with older children when learning new tasks. A third goal is self-enhancement, which allows one to feel better about the self through comparison with someone who is worse off. Social comparisons are also made to inform future behavior. Customers at a bar observe other customers tipping the bartender, and take this as a cue that they should do the same. Finally, individuals seek comparisons out of a desire to affiliate with or gather information about others.

In order to achieve the goal of the comparison, individuals can be selective in their choice of a comparison target and strategic in their interpreting, distorting, or disregarding comparison information. Additionally, the presence of varying goals may lead to different types of comparisons. For example, cancer patients typically compare their coping and health with those less fortunate (i.e., a downward comparison), promoting a need for positive self-evaluation. However, patients also seek interactions with patients who are doing better than the self (i.e., an upward comparison), promoting the need for self-improvement.

Social comparisons evoke a variety of behavioral, cognitive, and affective reactions. Such reactions are largely thought to be brought about by a threat to the self-image, a sense of injustice, or some other uncomfortable state that results from a comparison. For instance, a worker who learns that he gets paid more than another worker can justify this inequity by either working harder or by reasoning that his work is more difficult than that of the lower-paid worker. This example indicates that people often can choose between behavioral and cognitive responses.

Affective responses have also been intensely studied. In general, a comparison with someone whose abilities, performance, or attributes are superior produces more negative affect and lower self-esteem than does a comparison with someone who is inferior. This is overly simplistic, however, and several caveats to this effect

warrant consideration. First, in order to cause negative affect, a comparison domain must be important to one's self image. Abraham Tesser's (1988) self evaluation maintenance (SEM) model suggests that people want to maintain positive beliefs about themselves, and comparisons with superior others can have two different effects on self views. SEM suggests that when a comparison other outperforms the self in a domain that is *not* relevant to one's self image, the individual is not threatened and the comparison actually augments self evaluation. In such a case the individual may feel proud to be close to someone who has performed so well. Alternatively, if the comparison other outperforms the self in a domain that *is* relevant to one's self image, the individual is more likely to experience negative affect. Consequently, one option for an outperformed individual to reduce the threat of an unfavorable evaluation is to diminish the relevance of the comparison domain to his self image.

Second, Tesser's SEM model suggests that the similarity of the comparison other to the self can affect one's reaction to a comparison. Before making a social comparison, individuals often consider the relevance of the other's situation to their own. Individuals favor comparisons with others who are members of their gender and in group. This suggests that one way to avoid a negative social comparison is to alter the perceived similarity of the comparison other. By rationalizing that the comparison other is different from the self in some important way, the threat of being outperformed is reduced.

A third caveat is the perception of control that a person feels over the evaluative domain. In situations in which individuals feel a great amount of control, an upward comparison may actually lead to positive affect, as the comparison indicates that better outcomes are attainable. This is the case of cancer patients seeking companionship with patients who have recovered. If individuals feel that they have the ability to change their situation, these feelings of self efficacy are likely to increase performance; however, without the perceived ability to change the situation, a person is likely to feel helpless.

The diversity of motivations, reactions to, and characterizations of social comparison has led researchers to employ a variety of methods in their study of the topic. There are three

general methodological approaches to social comparison research (Wood 1996). The selection approach concerns what information is sought out for use in comparisons; the reaction approach focuses on the impact of provided social information; the narration approach concentrates on participants' reports about what information they use in their everyday lives.

The selection approach examines the processes involved in seeking social information. People often appear to select comparison others who are generally similar on some relevant factor, such as age or gender, though there are instances when a dissimilar other may be seen as most informative, such as when a person believes similar others may share one's own biases. As discussed earlier, an individual's motivations for making the comparison can influence selection of the comparison other. If multiple options for comparison are available, a person will strategically select a comparison other that helps reach the goal of the comparison, and might even construct a hypothetical other for comparison.

In order to study how individuals select a comparison other, researchers have employed a number of different methods. In the rank order paradigm, participants are given their relative standing (e.g., they ranked third out of seven) and are then given the opportunity to see the score associated with other ranks. Typically, participants will first ask to see the extreme scores, and then ask to see the score associated with the ranks immediately above their own. Another approach provides the opportunity for participants to examine more than just the score the comparison other achieved; for example, participants have the chance to see the actual answers that other participants gave on their tests. Researchers measure how many of the other participants' tests the participant chooses to view. A final selection research method is the affiliation paradigm, which gives participants in a stressful situation the option of affiliating with fellow participants or non participants. The choice to affiliate with other participants is seen as an interest in comparing reactions to the situation.

In addition to studying how participants select a comparison other, researchers also study how participants react to comparisons with others. In the reaction approach, social

comparison is manipulated as the independent variable, and researchers assess the effects of social information on participants. Social comparisons can affect such variables as mood, jealousy, self esteem, self evaluation, and performance. Additionally, researchers study reactions to social information that is received during the course of participants' everyday lives. In such studies, some dimension of the social environment is correlated with an outcome measure. For example, students use social comparison information such as their class ranking to shape their career goals.

The final method of study, the narrative approach, concentrates on participants' descriptions and reports of comparisons made in everyday life. Methods used include asking participants to record their comparisons in a diary, directly asking participants about comparisons they make, and observing comparisons people make spontaneously during conversations.

Given the variety of responses, methods, and measurements involved with social comparisons, it is not surprising that the topic is marked by a number of controversies. One main disagreement involves what exactly constitutes a social comparison. Traditionalists assert that only a comparison with a specific person with whom one has had personal contact qualifies as a social comparison. An opposing view proposes that personal contact is not a necessary condition, and that any social information, including information about hypothetical and fictional comparison others, qualifies as social comparison.

Another debate involves whether a comparison must change an individual's self evaluation to be rightfully considered a social comparison. Some researchers argue that a change in self evaluation is a key criterion of a true social comparison, while others contend that this prerequisite excludes many phenomena that should justifiably be included. This latter view asserts that comparisons should not be defined in terms of effect, but rather social comparison occurs any time an individual is involved in the process of thinking about social information in relation to the self, regardless of consequences.

A large portion of the social comparison research has measured the selection of information by participants, thus treating comparison as a deliberate act. The question has been raised, however, as to whether social comparison is

always intentional. Some researchers have proposed that, because people constantly face information about others, they may at times be forced to compare themselves to others, regardless of whether they desire to do so. Thus, comparisons may be encountered rather than selected. It has also been asserted that comparisons may sometimes be unconscious, suggesting that people may not be fully aware of some comparisons they make or the effects of these comparisons.

Social comparison research is also marked by controversy surrounding methodological issues. Some research methods require participants to report comparisons they make, and some researchers have questioned whether people can adequately do so. For example, people might make comparisons automatically, or may not be entirely aware of the steps taken in their comparison processes, thereby distorting self reports. Furthermore, social comparison measures may be marked by social desirability effects, as participants might not admit to making social comparisons that violate norms or have unfavorable implications. Given the diversity that characterizes the processes of social comparison and the broad expanse of topics that it implicates, the fact that research in the field is marked by a number of issues of contention comes as no surprise.

Since its inception, social comparison has affected a diverse range of areas, including equity, affiliation, and social interaction. It has been used in a variety of fields including social psychology, clinical psychology, cognitive psychology, personality psychology, and sociology. Its wide ranging application is evident in current research trends, including studies of marital and life satisfaction, and the eating behaviors and body image of adolescent girls. Researchers continue to apply social comparison theory to new topic areas, leading to an ever expanding diversity of literature in the area.

social control

Darin Weinberg

The concept of social control entered the lexicon of academic sociology in the early twentieth century. It was articulated first in the pioneering work of Edward A. Ross, and then, a short time later, by a handful of some of the most distinguished figures in the early history of American sociology, including Ernest Burgess, Charles Horton Cooley, Robert Park, and W. I. Thomas. These scholars took a rather expansive view of the matter, suggesting the study of social control covered the sum total of institutions and practices by which societies regulate themselves. Concerned as it was with the great variety of social mechanisms that maintain social order in the widest sense, the earliest sociological research on social control was sometimes difficult to distinguish from efforts to define modern society as such or to specify the proper subject matter of sociology as a whole. While this broadly encompassing view of the concept's reach has sometimes been criticized, these sociologists cannot be held solely responsible for having cast the concept so generally. For in formulating their arguments regarding the meaning and importance of the concept of social control, these early American sociologists

were responding to a much more established tradition of European social thought concerning the fundamental causes of social order in modern societies.

The conceptual problem of social order is usually traced to the English social philosopher Thomas Hobbes. Hobbes asked how individual human actors, guided by nothing but their own self interests, might cohere in the form of an orderly, law abiding society. His answer was that obedience to the law was a result of the self interested human actor coming to recognize the poor prospects of his or her own survival in a lawless world. Precisely because we possess a natural instinct toward self preservation, people produce and obey an absolute sovereign (whose sole right it is to set and enforce the law). Many have since argued that Hobbes formulated this argument in fear of the political upheaval occurring in Britain at the time he wrote and with a concern to give philosophical justification to a monarchy intent on violently subduing republican political revolt. Later social philosophers like John Locke argued, contra Hobbes, that human nature is not wholly selfish and that there is no need for the state to repress its free expression. However, as feudal Europe gave way to the industrial, American, and French revolutions it became progressively clearer to the social thinkers of the day that, quite regardless of the arguments of philosophers, the social order Hobbes defended was inevitably disintegrating. The classic sociological works of figures like Marx, Durkheim, and Weber can be understood as efforts to explain the nature of the new social order that was replacing feudalism and a specification of how this new social order cohered. Hence, for Marx, modern society cohered around what he called the capitalist mode of production; for Durkheim, it cohered due to the interdependencies introduced by a complex division of labor; for Weber, it cohered due to the emergence of large scale institutions like the bureaucratic state and modern market. For these social theorists, the orderly maintenance of complex modern societies was to be explained largely as the result of their fundamental structural properties rather than the deliberate designs of the actors who comprise them.

While Edward Ross and his American followers embraced the classic European preoccupation with the question of how social order is

maintained in complex modern societies, they distanced themselves from the structural explanations on offer from the likes of Marx, Weber, and Durkheim to posit an approach more grounded in the agency of social actors. For them, the question of social order, or social control, was a question of how modern societies might influence their members to see their own individual self interests as more or less compatible with the collective interests of their society. Hence, the question of social control was precisely the question of how modern societies might remain orderly through the rational force of persuasion, rather than the brute force or coercion condoned by Hobbes. This question became fused rather early on with questions concerning the social problems of the city in what became known as the Chicago School of urban sociology. Early Chicago School sociologists believed the traditional forms of social control found in small towns and villages broke down in the city. While they shared this premise with European theorists like Ferdinand Tönnies, they differed in their desire to keep their research firmly grounded in the empirical world. Thus, whereas Tönnies was happy to make broad generalizations regarding premodern and modern societies, proponents of the Chicago School found too much variety and nuance both in the past and the present to remain comfortable with Tönnies's famous dichotomy between *Gemeinschaft* and *Gesellschaft*. Chicago School scholar Louis Wirth, for example, called for a more precise empirical attention to three variables that he felt distinguished cities that suffered comparatively more social problems from those that suffered less: population size, density, and heterogeneity. Wirth argued that as each of these increases, the close personal relationships found in smaller communities decrease. Because urban life is comparatively anonymous, big city dwellers do not feel bound to honor each other, nor to sanction each other for breaking the law. This causes both increased social disorder and a need to delegate the work of social control to professionals in place of the self policing community found in small towns. Because they cannot be as ubiquitous, professional agents of social control cannot be as effective in maintaining social order as is fuller community participation in this effort. Similar arguments were made by W. I. Thomas in

defense of his influential theory linking what he called social disorganization, various urban social problems, and the breakdown of social control.

The early Chicago School's understanding of social control remains important to this day. However, it has been refined and rivaled by a variety of other approaches that bear discussion. In the first instance, one must note the important work done by C. Everett Hughes and his students on occupations and, more precisely, occupational socialization. Hughes departed from the emphasis early Chicago School researchers gave to the relationship between complex differentiated societies and social disorganization. Theorists like Wirth and Thomas tended to highlight the effective social controls small groups exercised over their members and the breakdown of these controls as groups grew larger. Hughes and his students noted that many of the mechanisms of social control one finds in smaller groups like families and villages were also operative in occupational groups. This insight served to introduce a higher level of empirical refinement into research concerning the non coercive social control mechanisms at work in larger social groups and usefully to blur the line between what Cooley had called primary and secondary groups.

A somewhat higher level of theoretical refinement was introduced into the study of social control by Talcott Parsons and his students. Parsons argued that large scale differentiated societies generate any number of mechanisms by which to manage the inevitable role strains and ambivalences introduced by the complexity of modern life. Parsons's structural functionalist approach maintained the early Chicago School's optimistic understanding of social control as the necessary work societies do upon themselves to sustain themselves. This line of theoretical development was radicalized considerably by ethnomethodology. Ethnomethodologists have sought to transform some of Parsons's theoretical premises regarding the regulative work that societies do upon themselves into questions for empirical inquiry. For example, in his famous "breaching experiments," Harold Garfinkel sent his students out into the world with instructions to deliberately disrupt the taken for granted meanings at work in various ordinary interactions. These experiments inaugurated

a tradition of research that has revealed just how resilient, resourceful, and creative social actors can be when called upon to manage the diverse episodes of social disorder they encounter in the conduct of their everyday lives. Ethnomethodologists have discovered a vast collection of interactional techniques by which social control is exercised in both formal and informal social settings, ranging from laboratories to family dinners. This research has effectively demonstrated that social control should not be conceptualized as a set of intermittent interventions into our everyday lives, so much as a routine, pervasive, and indispensable feature of them. While remarkably different in their respective approaches to research, the emphases of Hughes, Parsons, and ethnomethodology are aligned insofar as they each remain decidedly focused on the collectively orchestrated aspects of social control and its role in creating and maintaining consensus, equilibrium, and collaborative activity. They are not as concerned to demonstrate how social control figures in the exercise of coercion and exploitation.

Conflict theories of social control have been vehemently opposed to the claims that social control can either be defined in contrast to coercive control or that it could ever reflect the freely achieved consensus of society as a whole. In place of the idea that social groups regulate themselves in pursuit of their collective interests, conflict theorists insist that modern societies are never as integrated or as harmonious as this imagery suggests. Because subgroups within society will inevitably hold different beliefs about what kinds of things merit regulation, actual social control efforts can never reflect the beliefs of everyone. Hence, social control will always entail more powerful factions within society regulating less powerful factions, not in the collective interest but in their own self interest. Various research agendas emphasizing the coercive and self interested dimensions of social control became prominent in the 1950s and 1960s. One such agenda, broadly known as labeling theory, was popularized by sociologists like Howard Becker, Erving Goffman, and Edwin Lemert. In expounding the labeling approach, Lemert, for example, wrote that while older studies of social control had "tended to rest heavily upon the idea that

deviance leads to social control, I have come to believe that the reverse idea (i.e., social control leads to deviance) is equally tenable and the potentially richer premise for studying deviance in modern society" (Lemert 1967: ix). According to labeling theorists, it is misleading to distinguish "social disorder" or "deviance" from the particular definitions of these concepts provided by specific agents of social control. This is because the activities of agents of social control like the courts, medical clinics, mental hospitals, and police forces are very often not only *responsive* to deviance, but actually define as deviance (and as meriting social control) activities that in other societies may not be seen as deviance at all. Hence, labeling theorists have argued that activities like drug use and homosexuality come to be seen as matters deserving of social control less because of breakdowns in social order than by virtue of the definitional or "labeling" activities of what Becker dubbed "moral entrepreneurs" and other elite members of society with a stake in seeing certain activities condemned and/or curtailed. The labeling perspective also highlights the negative consequences that can flow from labeling itself. For example, the idea of "secondary deviance" was devised to signal the fact that people labeled as particular kinds of deviants may come to be socialized by agents of social control to adopt roles attendant to the labels they have received. Thus labeled as a criminal or as learning disabled, for example, people might begin to adopt dysfunctional habits associated with these labels simply by virtue of the fact they have been so labeled.

The labeling perspective tended to highlight the stake had by particular professional groups or moral entrepreneurs in defining certain behaviors as deviant and subjecting them to social controls. This rather diffuse sense of the sources of various campaigns of social control was ultimately challenged by other conflict theorists who placed greater emphasis on centralized forms of power in modern societies, like the state and/or a relatively integrated dominant class. For these theorists, social control was still more nefarious than had been suggested by labeling theorists. Social control was now seen not just to impose the moral sentiments of one faction of society upon another, but to subdue class conflict and/or to facilitate the exploitation

of the weak by the strong. Such research came in a variety of guises, but they all shared a much more sustained interest in macro structural histories of modern societies. While some researchers focused on the nostalgic yearnings of a cultural elite whose power and authority were declining in the aftermath of industrialization, most took a more orthodox Marxist view of things. According to Marxist conflict theorists, social control is best understood as a collection of measures undertaken in the interests of the dominant economic class. This can include efforts to secure their ever accumulating wealth through the use of evermore sophisticated police forces and carceral institutions; efforts to politically debilitate the working class through legislation restricting organized labor; the use of educational institutions and other approaches to disciplining the working class in order to make them at once less threatening to commerce and better suited to the labor needs of the dominant class; or efforts to diffuse the animosity and revolutionary potentials of the working class through mass cultural fare that serves to distract and pacify them and/or concessions in the form of state administered health and social welfare provisions. In short, social control is seen as a multifaceted project formulated and orchestrated by the economically powerful (or their hired minions) to ensure their retention of power and often to accumulate more.

While opposed to the reductionism evident in some Marxist analyses, the work of Michel Foucault has made immensely important contributions to our critical understanding of social control by refining our understanding of power. Marxist theorists of social control have very often been profoundly critical of the state and the multitude of other agencies through which the dominant economic class seeks to legitimate its putative stranglehold on the working class. But they have tended to preserve a distinction between the exercise of power and the exercise of knowledge. Whereas they have held that the use of power to control people is inevitably coercive, until Foucault, most Marxist theorists remained committed to the notion that the use of knowledge, or truth, to control people is non coercive. Appeals to truth are appeals to the better nature of human beings, to their faculties of reason, and their amenability to influence

through genuine persuasion rather than coercive control. According to Foucault, this conception of the relationship between power and knowledge is highly problematic because it fails to appreciate the extent to which power, when it is exercised efficiently, is seductive rather than coercive. Foucault insisted that power is not merely repressive, but eminently productive, and that evidence of its repressive tendencies must be interpreted in light of the positive goals that it has prioritized over that which it has repressed. When it is most effective, social control is impossible to distinguish from self control because those who are controlled are complicit in the control that is exercised over them and do not resist. Repression, then, ought only very rarely to be seen as an end in itself rather than a necessary cost of pursuing some putatively greater good. Moreover, power is not opposed to truth, but intimately connected to it. Foucault argued that all power is attended by a regime of truth through which its goals are formulated, and the means of achieving those goals are strategically devised and refined. This, for Foucault, was as true for science as it was for the military campaigns of powerful empires or for any other exercise of power. Finally, power and knowledge, or as Foucault wrote, power/knowledge, can be found in virtually any concrete regime of disciplined activity. In other words, the reality of power/knowledge is to be found in the endless actual practices in and for which it is summoned, consolidated, and developed. Foucault and his followers have called attention to the fusion of power and knowledge in such instances as the development of correctional facilities, formal educational institutions, the rise of professional military service, the development and rationalization of clinical expertise, public health measures, and, more broadly, the transformation of feudal courts into bureaucratic states. To highlight their role in the accomplishment of social control, Foucault referred to these various regimes as instances of what he called "governmentality," which he defined as "the conduct of conduct." For Foucault, while governmentality was certainly a form of social control exercised by governments, the scope of this concept also extended to wherever the "conduct of conduct" became an observable practice. It is something that

bosses do with employees, parents do with children, teachers do with students, and that we as individuals do with our selves – as when we diet.

Toward the end of his life, Foucault's appreciation of the extent to which we as individuals play an active, rather than passive, role in the social control that is exercised over us was increasing. Of course, he remained cognizant of the fact that we are very deeply embedded in, and affected by, historically enduring regimes of power/knowledge of which we are often scarcely aware. However, he became more interested in the fact that our lives are projects that we ourselves do, at some level, craft and steer according to our own visions of the good. While these visions are by no means uninfluenced by our sociohistorical circumstances, they do not for that cease to be our own. Moreover, the forces by which we are socially controlled are not immune to our efforts to exert some influence upon them – modest though these efforts may often be. Rather than resigning himself to the notion that our collective fates must inevitably be coerced, Foucault seemed to be moving in the direction of the early Chicago School theorists of social control, who remained cautious and critical but, nonetheless, hopeful that the regulation of society could, in principle, be accomplished democratically and compassionately rather than coercively and exploitatively. And, along with many other contemporary students of social control, he was resolutely convinced that, while necessary as such, the regulation of society is, at present, considerably more coercive and exploitative than it has to be.

Social Darwinism

Bernd Weiler

Social Darwinism, a highly controversial and protean term, refers to the application of concepts and ideas to the social world which are allegedly derived from Charles Darwin's theory of evolution. Despite the fact that the so called founding fathers of sociology tried to establish the autonomy of their discipline, the often unconscious reliance upon biological concepts and the interpretation of the social order as the outcome of a natural process were pervasive traits of late nineteenth and early twentieth century social science. The term Social Darwinism first came into usage in the late 1870s and early 1880s and is, in its classic phase, commonly – and as some would immediately object wrongly – associated with such diverse theorists as Spencer and Bagehot in Great Britain, Sumner and Fiske in the US, Gumplovicz and Ratzel in Austria, Lombroso, Ferri, and Nicotro in Italy, Broca, Topinard,

and Lapouge in France, and Hellwald, Woltmann, Ploetz, and Ammon in Germany.

Modern historiographical debates about Social Darwinism, which date back especially to Hofstadter's seminal work *Social Darwinism in American Thought* (1944), have focused primarily on the question of the precise definition of the term and concomitantly on who should be classified as a Social Darwinist. Closely linked to this definitional issue are the methodological questions of the unit of analysis in Social Darwinism, as well as the overall significance and ideological connotations of Social Darwinism at the fin de siècle. Research has further revolved around the origins of Social Darwinism and the historical linkage between Darwinism and Social Darwinism. Finally, there remains the contentious issue whether, and in what form, the Social Darwinist tradition is still alive today.

Regarding the definitional issue of Social Darwinism, a term more often used in his historiographical research than in the primary sources (Hodgson 2004), a "generalist" and a "restrictionist" approach can be analytically distinguished (Crook 1996). In the generalist definition, which corresponds more closely to the standard textbook accounts, Social Darwinism refers to the use of evolutionary, developmental, or progressivist ideas clothed in Darwinian terminology when analyzing social inequality. For the generalists, to classify somebody as a Social Darwinist it is not necessary for the person to explicitly rely upon the theory proposed by Darwin in his main works, *The Origin of Species* and *The Descent of Man* (1871). In contrast to this broad definition, the restrictionists argue that the mere rhetorical use of catchphrases and metaphors such as "struggle for existence," "natural selection," "survival of the fittest," and "adaptation" does not make a social theorist a Social Darwinist. According to the restrictionists, the label should be reserved for those turn of the century thinkers who consciously and explicitly applied the central elements of Darwin's composite theory to the analysis of social life. In this narrow understanding of the term, Spencer, the arch Social Darwinist of the generalists, is classified as a Social Lamarckist because he, like many of his contemporaries, believed in the inheritance of acquired characteristics and also because he equated, contrary to Darwin, evolution with directed progress.

Neither would the Polish born sociologist Gumpłowicz qualify as a Social Darwinist because he explicitly rejected the transference of biological concepts to the field of sociology and was also a declared adherent of Agassiz's theory of the immutability of species. One might argue, however, that by opposing the categories of Social Darwinism and Social Lamarckism, one does not capture the complex web of actual interrelationships that existed between the two currents of sociobiological thought around 1900. It also needs to be emphasized that when Social Darwinists applied the idea of natural selection to social life, they seldom defined the unit of analysis in a precise manner. Not only did the elements in the "struggle for existence" range from individuals fighting each other to rival families, ranks, classes, societies, nations, and races, but also the analysis often shifted from one unit to the next. Furthermore, the units of analysis in Social Darwinist thought vary accordingly from biological, to economic, to cultural, and to political entities.

Intimately linked with these definitional issues is the question of the overall significance and the ideological connotations of Social Darwinism as an intellectual and a policy movement around 1900. Whereas the "orthodox" historiographical school of Social Darwinism, led by Hofstadter, argued that in America Social Darwinism was the dominant intellectual current of the Gilded Age, transcending the boundaries of academia and exerting a strong influence on business and politics, the "revisionist" school, based upon a narrower definition of the term and represented especially by Bannister, claimed that the significance of Social Darwinism as an intellectual movement had been greatly exaggerated (Bannister 1988; Hawkins 1998). Furthermore, whereas the orthodox school had linked Social Darwinism to conservative and liberal ideologies, the revisionist school emphasized the ideological use made of Darwin by the collectivist oriented Left. From an ideological point of view Darwin's theory, despite emphasizing nature over nurture, has in fact proved to be quite multivalent, lending support to such diverse policy movements as liberal laissez faire economics, protectionism, restricted immigration, imperialism, Left and Right eugenics, etc.

Research on the intellectual sources of Social Darwinism and on the relationship between Darwinism and Social Darwinism has shown that key elements of Social Darwinism, such as the Malthusian idea of a “struggle for existence,” the idea of evolution, and the notion of a “survival of the fittest” (a phrase coined by Spencer several years before the publication of the *Origin*), predate Darwin’s biology. In this context it has been argued that not only is Darwin’s metaphorical language thoroughly Victorian, but also his whole theory represents – as Marx wrote to Engels in the early 1860s and Nietzsche in *The Gay Science* (1882) had already sarcastically noted – the transference of the experiences of the overcrowded, British industrial lower middle class into the realm of biology. According to this line of reasoning, Darwin’s biological theory was able to exert a considerable influence on social thought because it was social in its origin and nature. The historical context of discovery, however, does not enable us to judge the validity of Darwinism or Social Darwinism. It should also be emphasized that as Darwin’s evolutionary theory changed in the wake of the so called Modern Synthesis, the complex relationship between Darwinism and modern social analysis needs to be reconsidered and recontextualized.

Social Darwinism, a polemical label that according to Bannister had been used from the beginning to denounce one’s opponent, fell into disrepute after World War II because of its alleged connection to the ideology of National Socialism and Fascism. Reflecting upon the fact that such diverse intellectual and policy movements as the ethological work of people like Lorenz and Morris in the 1960s, Wilson’s sociobiology and Dawkins’s work on the *Selfish Gene* in the 1970s, Reaganomics and Thatcherite politics in the 1980s, Herrnstein and Murray’s *Bell Curve*, and Pinker’s evolutionary psychology in the 1990s have all been labeled or stigmatized as Social Darwinist, the ambiguity and ideological multivalence of the term still seem to prevail.

social dilemmas

Jane Sell

A social dilemma is any setting in which there is a conflict between individual short term incentives and overall group incentives. Social dilemmas are pervasive and appear in all levels

of interaction, from small face to face interactions to large scale global situations. The study of social dilemmas is prominent in all of the social sciences, and investigations have involved all types of methods ranging from case studies to experiments. Common examples of social dilemmas include the provision of public goods such as public education and international treaties and the maintenance of resources such as fisheries and other ecosystems.

There are many categorizations of social dilemmas. An important distinction is between a two person (or actor) dilemma and multiperson dilemmas, termed *N* person dilemmas. Other distinctions relate to the timing and structure of the incentives, and the relationship between cooperation (and the reverse of cooperation, defection) and group gains.

Two statements often used to frame the issues surrounding social dilemmas are Mancur Olson's *The Logic of Collective Action* (1965) and Garret Hardin's "The Tragedy of the Commons" (1968). Olson's book concerns public goods while Hardin's article addresses common property resources. Because both types of problems have an incentive structure that pits individual against group interest, they are considered social dilemmas; however, there are social psychological differences between the public good problem, which involves "giving up" individual resources for the group good, and the resource good problem of establishing individual restraint from using the resource.

Social dilemmas are often discussed in contradistinction to market settings. In market settings, exchanges occur because there are different preferences (revealed by the actor's behavior by observing what she gives up to consume the good). In perfectly competitive systems, the law of demand (*ceteris paribus*, the lower the price, the higher the demand) and the law of supply (*ceteris paribus*, the higher the price, the greater the supply) interact to yield an equilibrium. In this equilibrium, a profit maximizing firm will produce the output for which price is equal to the marginal cost.

However, such market mechanisms are not present in social dilemmas. The basic reason they do not exist is that most social dilemmas are characterized by non excludability: no member of the group can be excluded from consuming the good. Regardless of whether an

individual actor has contributed, he or she is able to use the good. So, for example, regardless of whether individuals have helped a civil rights movement, they accrue benefits from the movement's gain. Or regardless of whether a nation practices sustainable development, it benefits from other nations' adherence to sustainable practices. It is not a market phenomenon that enables the exclusion of those who have not contributed.

From the perspective of game theory, a rational choice heuristic often employed in economics, social dilemmas and the basic principle of non excludability create a particular dominant strategy. A dominant strategy is a strategy that is the best rational, individual strategy no matter what choices other actors make. So in most social dilemmas, the dominant strategy is to consume, but not contribute. In other words, it is individually rational to "free ride" on others' contributions or sacrifices. However, if all actors are engaging in the same calculations, nobody will contribute and the good or resource will not survive. The civil rights movement will fail; sustainability will never be reached.

Given the incentive problems that are defining properties of social dilemmas, when are cooperation and solution of social dilemmas possible? We know that social dilemmas are sometimes solved. Examples include extraordinarily successful instances of the Zanjas irrigation communities in the Philippines (first documented in 1630), cited by Ostrom (1990). On the other hand, there are many social dilemmas that have not been solved and have led to disastrous consequences. Examples include cases of genocide, and destruction of fragile ecosystems such as the Tigris-Euphrates alluvial salt marsh.

SOLUTIONS

What conditions are most likely to lead to solution of social dilemmas? Game theorists have concentrated on formal solutions that invoke mathematics involved in expected utility arguments. One very important formulation has been the folk theorem. The folk theorem (so called because it was a generally understood idea) posits a whole range of history contingent strategies that allow for cooperation if, at some point, it is the case that an actor's cost

of contributing exceeds the cost of contribution and the discount rate is sufficiently large such that contributing remains an individually rational strategy. From this point of view, social dilemmas can be solved rationally, although it is difficult to predict exactly how. That is, the folk theorem does not rule out many possibilities.

Many solutions to social dilemmas involve changing the basic structure of the dilemma and thereby affecting incentives. Such solutions include factors such as punishment mechanisms for not cooperating (one class of which includes "trigger strategies"), and incentives for cooperating.

Individual level factors such as social motivation have been investigated and it has been demonstrated that some people, and indeed some cultures, appear more or less oriented toward cooperation (see Kopelman et al. 2002).

Other solutions to social dilemmas have focused on "social" factors, that is, factors affected by group interaction. Some of these solutions add additional costs or benefits that are social. So, for example, punishments might include the "loss of face" or shame for not cooperating. Incentives might include the acquisition of a positive reputation or honor that is bestowed upon the family. Two very powerful such factors are social identity and trust. Social identity is the sense of "we ness" that accompanies shared significant social categories that indicate some extent of common fate. Trust is a more diffuse property, which may or may not relate to social identity, but does entail a sense of predictability of others' actions. If an actor trusts others to cooperate, and so acts on that basis, the original incentives of the social dilemma can be transformed and the dilemma solved.

Finally, there is the recognition that even if all the incentive problems associated with social dilemmas are solved, issues related to coordination remain. Clearly, coordination problems can sabotage the successful resolution of a dilemma. Ostrom (1990, 1998) details an interest in coordination by her attention to the "nested" nature of organizations or stakeholders. Communication lines among different levels of government must be clear and open. Local autonomy enables the tailoring of principles to the particular circumstances.

With such a tremendous range of interest in social dilemmas, it would seem that research accumulation would be apparent. But, it is an irony that literature on cooperation sometimes lacks cooperation. This is not a matter of obstinacy, but relates to issues of different assumptions, methods, and theories. For example, rich case study analyses are not often integrated into the formal, deductive analyses of game theory. A particularly promising suggestion for integration is the emphasis upon institutional rules and how such rules change the structure of the dilemmas and the strategies for their solution. These rules are most often used in political science, but they offer a framework by which to both conceptualize issues in a formal, mathematical sense and organize vast arrays of rich, in depth data.

social disorganization theory

Barbara D. Warner

Social disorganization theory provides an explanation of the variation in crime rates among neighborhoods. It assumes that the basis of criminal behavior lies largely within the structural and cultural conditions of the neighborhood. Socially disorganized neighborhoods are defined as those not having the capacity to regulate behaviors and activities that are inconsistent with neighborhood values. This capacity to regulate behaviors is referred to as the level of social control. Recent social disorganization theory has particularly emphasized neighborhood levels of informal social control.

Social disorganization theory was originally developed by Clifford Shaw and Henry McKay in their book *Juvenile Delinquency and Urban Areas* (1942, revised 1969). In studying the distribution of delinquency among different areas of Chicago in the early 1900s, Shaw and McKay noticed several patterns. First, delinquency rates decreased as one moved from the center of the city outward. Second, a large proportion of “neighborhoods” (square mile areas) that had high rates of delinquency in 1900 continued to have high rates 30 years later. This was particularly remarkable because many of those neighborhoods had undergone tremendous ethnic change during that time period. Further, they found that neighborhoods with high levels of delinquency also had high levels of other problems such as adult crime, truancy, tuberculosis, and infant mortality.

Their approach to understanding variations in crime rates among neighborhoods was based on an ecological model that argued that distinctive features emerged in areas as a result of

ecological differentiation arising from the growth of the city. As an end product of the process of city growth, areas within the city become differentiated in terms of physical, social, economic, and cultural conditions. Their research examined these characteristics in relation to rates of delinquency. The characteristics they found to be related to rates of delinquency were physical status (population increase or decrease), economic status (percentage of families on relief, median rental, home ownership), and population composition (percentage of foreign born and African American families). Specifically, areas with decreasing population, low economic status, and higher percentages of foreign born and African Americans were associated with higher rates of delinquency.

In explaining these relationships Shaw and McKay argued that low economic status, high levels of ethnic heterogeneity, and decreasing population led to a breakdown in the community’s ability to articulate and reach shared goals. In turn, this led to weakened institutions (e.g., schools, family, and church) and therefore weakened informal social control. The inability of the community to informally control criminal behavior allowed for the development of a criminal subculture which, through cultural transmission or differential association, then led to increased rates of crime. To address these issues, Shaw and McKay argued for creating neighborhood programs carried out by local residents that would strengthen and unify the constructive aspects of community life.

From the 1940s through the 1960s there were several empirical tests of social disorganization theory that were, at least in part, supportive of the theory. However, there was also a growing recognition of problems in empirically testing social disorganization theory. These problems included the fact that studies examining social disorganization theory used official measures of crime (such as court records or arrest rates), and official measures of crime were argued to be biased in a way that would be consistent with the theory. For example, police may be more likely to make arrests in poor or ethnically diverse neighborhoods than they would in middle class or all white neighborhoods, leading to the appearance of higher rates of crime in the poorer or ethnically diverse neighborhoods. Hence, arrest rates were argued

to be more likely to be reflective of police behavior than actual levels of crime. Second, it became increasingly clear that the main theoretical concept, social disorganization, was not measured separately from crime rates. Therefore, the main concept in the theory was not really being examined. Empirical tests only measured the extent to which measures of poverty, ethnic diversity, and residential mobility were related to crime, not whether the process or mechanism through which these factors were related was social disorganization.

Not until the 1980s was there systematic progress in addressing these issues. Arguably the most important study in the revitalization of social disorganization theory at the end of the twentieth century was one done by Sampson and Groves (1989). Previous to this study the intervening process of social disorganization that is hypothesized to link the community characteristics of poverty, residential mobility, and racial/ethnic heterogeneity to crime rates had not been empirically examined with a sufficiently large sample of neighborhoods to allow for reliable aggregate level multivariate analysis. Using data from the British crime survey, Sampson and Groves conceptualize social disorganization as the inability to bring about informal social control due to weak informal (kinship and friendship networks) and formal (organizational) associational ties. In this study they examine measures of social disorganization distinct from crime measures and use an unofficial measure of crime rates – specifically, victimization rates. The results of this study showed that low levels of both friendship networks and organizational participation, as well as the inability to supervise youth peer groups, were significantly related to rates of crime. Further, these intervening measures of social disorganization mediated much of the effect of the community structural characteristics (socioeconomic status, residential mobility, ethnic heterogeneity, and family disruption) on crime rates. This focus on friendship networks and associational ties as the basis for informal social control became known as the systemic model of social disorganization theory.

Since this time the concept of social disorganization has continued to be a fertile area of research, focusing on the differential capacity of communities to carry out informal social

control, the different mechanisms of informal social control, and the different neighborhood structures that make informal social control possible. Some researchers have examined the structure and nature of friendship networks within neighborhoods as a necessary foundation for informal social control. Others have focused directly on levels of informal social control as defined by neighbors' willingness to intervene in inappropriate neighborhood behavior, or neighbors' levels of surveillance and guardianship within the neighborhood. Still other research has examined the impact of the absence of institutional resources, such as recreational facilities, or the presence of negative institutions, such as drinking establishments, on the ability of neighborhoods to exercise social control. More recently, Sampson et al. (1997) have developed a broader concept that combines the level of mutual trust among neighbors and their willingness to intervene as the mechanism necessary to bring about lower crime rates. They refer to this as collective efficacy.

While research within the systemic model has mainly focused on ties *within* the neighborhood, other researchers have addressed ties to external groups or institutions. The systemic perspective on neighborhoods views neighborhood structure as being comprised of private, parochial, and public ties. Private ties refer to intimate or kinship relationships. Parochial ties refer to friendship ties that are less intimate than private ties. These may be neighbors who participate in local organizations together or who occasionally discuss neighborhood or other issues. Both private and parochial ties refer to networks within the neighborhood. Ties within neighborhoods are viewed as essential for transmitting both expectations regarding appropriate behavior and informal sanctions when norms are violated. Public ties refer to linkages to persons, groups, or organizations, such as the police or other municipal organizations, external to the neighborhood, that can be activated to secure resources or services that affect the community's regulatory capacity. Public ties have been viewed as important mechanisms for neighborhoods to use to influence political decisions that may negatively impact on the community. For example, disadvantaged neighborhoods may be chosen for the placement of a variety of programs, such as drug treatment programs, needle

exchanges, community correction facilities, or new public housing projects that may be viewed as having the potential to further destabilize the community. To the extent that neighborhoods are able to cultivate ties with public and private agencies or groups outside of their neighborhood, they may be better able to ward off decisions such as these, as well as acquire resources to remove abandoned or condemned buildings, clean up litter strewn recreational areas, and remove prostitution hot spots or drug dealers. A study by Velez in *Criminology* (2001) finds public ties to decrease victimization, and further, that this relationship is most pronounced in disadvantaged neighborhoods.

Most of the current research examining social disorganization theory has focused on the structural aspects of social disorganization discussed above, and little attention has been paid to the cultural issues. However, with a growing number of ethnographic studies pointing to characteristics of oppositional or "street" culture in high crime inner city neighborhoods (e.g., Anderson 1999), more attention is turning to the potential role of neighborhood culture in a social disorganization model. In Shaw and McKay's original social disorganization model, culture had a prominent role. Shaw and McKay recognized the role of culture in terms of the variability among neighborhoods in the presence of delinquency values. Neighborhoods in which delinquent values were present provided conflicting value systems for youth and were viewed as an important motivation for criminal behavior. However, Kornhauser (1978) argued convincingly that such a cultural deviance model was inconsistent with the overall assumptions of a social control model of social disorganization theory. Nonetheless, Kornhauser did suggest that while the content of values did not vary across neighborhoods, the *strength* of those values within communities did vary. She referred to this as the attenuation of cultural values. This idea of attenuated culture has recently been examined by Warner (2003). Findings from this study suggest that neighborhood social ties increase cultural strength and cultural strength increases informal social control.

The availability of statistical packages that allow researchers to analyze multilevel and causal models has further enhanced the development of social disorganization theory. Because

social disorganization theory argues that the roots of crime are within the neighborhood context itself and not simply the result of the types of individuals that comprise the neighborhood, multilevel models allowing for the examination of both aggregate and individual level effects have become important tools in contemporary examinations of social disorganization theory. Similarly, because there are several posited processes through which community characteristics such as poverty, residential mobility, and ethnic heterogeneity affect crime rates, explicitly modeling the causal process, using structural equation models, has become important.

Community level studies of crime based in social disorganization theory are continuing to produce new insight into the causes and solutions to both property and violent crime. One of the biggest puzzles remaining from a social disorganization perspective is why neighborhood poverty or disadvantage continues to directly influence crime rates. While some of the effect of disadvantage is mediated by measures of social disorganization, most research also finds that a significant direct effect of disadvantage on crime remains. This finding suggests that there may be other neighborhood processes influencing crime rates that are not yet completely understood or effectively measured.

social distance

Joyce E. Williams

Use of the concept of social distance dates back to Georg Simmel's discussion of the stranger in his *Soziologie* (1923). According to Simmel, the stranger represents the union of newness and remoteness as he moves out of one social circle and strives for acceptance in another. Robert Park (1924) popularized the concept of social distance as the grades and degrees of understanding and intimacy that characterize personal and social relations. Social distance is based on social norms that differentiate individuals and groups on the basis of race/ethnicity, age, sex, social class, religion, and nationality. The greater the social distance between individuals and groups, the less they influence each other.

It was Emory Bogardus (1925) who operationalized and measured social distance by first asking over 200 participants their willingness to admit members of 39 different racial and ethnic groups to the following: close kinship by marriage, as fellow club members, as neighbors, as workers in their same occupation, to citizenship in their country, as visitors only to their country, and as persons to be excluded from their country. The Bogardus Social Distance Scale is largely synonymous with the concept today. The scale is unidimensional and cumulative, assuming that at the highest level of acceptance the respondent would admit members of the designated group to all steps below that level. Although social scientists have applied variations of the social distance scale to social classes, and religious, occupational, and other groups for over three quarters of a century, it has proved a reliable measure of the

level of acceptance of one racial/ethnic group by another (Schaefer 2004). There is, however, some question as to whether it measures group status or social intimacy.

According to Bogardus, social nearness originates in favorable experiences and farness in unfavorable experiences. There is, of course, circularity in this logic: acceptance of members of another group is likely because of favorable experiences that are more likely to originate in social nearness as opposed to social farness. The concept of social distance subsumes individual characteristics in the characteristics of their group. Social nearness or farness originates with either a lack of knowledge, resulting in prejudice, about the group in question, or with knowledge that the group differs from your own in some identifiable way, such as appearance, beliefs, or behaviors. Both ignorance of a group or knowledge of their differences holds the potential for social conflict. Poole (1927) was the first to distinguish between social distance and personal distance, thereby offering an explanation of how individuals become "exceptions" to their groups. Social distance is dictated by social norms. Personal distance as in acquaintances, friendships, and love, on the other hand, is limited only by the possibilities of association between individuals or individuals and groups. While social or personal distance may not explain conflict, both can account for misunderstandings and ignorance that give rise to interpersonal and intergroup conflicts as well as social problems.

social embeddedness of economic action

Enzo Mingione and Simone Ghezzi

The concept of embeddedness expresses the notion that social actors exist within relational, institutional, and cultural contexts and cannot be seen as atomized decision makers maximizing their own utilities. Embeddedness approaches prioritize the different conditions within which social action takes place. They challenge the utilitarian, “undersocialized,” neoclassical position, and the functional “oversocialized” position (where social conditions exist a priori to behaviors). The concept of embeddedness is based on several assumptions about society: the actor is not an atomized individual; immediate utility cannot explain the full meaning of social relations; logics underlying the formation of institutions and their norms of behavior cannot be removed from the contexts of social interaction within which these institutions exist; convergent trends of transformation result in diverse processes of adaptation, which evolve from specific social, cultural, and cognitive configurations.

These assumptions are present in Weberian approaches (methodological individualism) and become criteria for the ideal type reconstruction of the meaning of individual action. They are also present in structural approaches concerned with the dynamics of logics governing social behavior.

The concept of embeddedness that followed from the work of Polanyi (1944, 1957) was revisited by Mark Granovetter (1985) and has ever since been at the center of the theoretical and methodological debates within the so called “new economic sociology” (Swedberg 1997, 2003). At the core of this approach a number of important contributions illustrate the importance of social networks, social capital, the

diversity of cultural and cognitive elements, and the social construction of markets (Burt 1992; Nee & Ingram 1998; Zelizer 1988, 1994).

DURKHEIM'S CONTRIBUTION: SOCIAL TIES, INSTITUTIONS, SOCIALIZATION

Even though it was Polanyi who introduced the term embeddedness, tools for analyzing the contextual diversity of social action were already present in classic works, especially those of Durkheim and Weber. The former theorizes the relevance of social ties and socialization processes; the latter brings into relief the tensions characterizing the processes of rationalization. Both conceive of the actor not as a utilitarian and atomized *homo oeconomicus*, but as a subject inserted in diversified networks and institutional contexts, the very subject matter of sociological analysis.

For Durkheim, the advent of modern industrial society is accompanied by a profound transformation in the ties that characterize social life. The increasing and more complex division of labor, industrialization, and urbanization progressively weakens ties of mechanical solidarity that regulate cooperation in the small and stable communities typical of the pre industrial era. Durkheim opposes the idea that ties in modern society are the inevitable outcome of fragmented and diversified self interests. The mechanical interplay of interests leads to conflict and anomie, to the breakup of society, and to the loss of opportunities for cooperation. Organic solidarity is therefore a relation of cooperation socially built upon an institutional process regulated by norms and rules within which the modern nation state and labor organizations play a key role. This perspective may lead to an oversocialized position, but at the same time it may provide insights into the way in which social ties generate the institutional regulation of behaviors characteristic of different situations of embeddedness. Durkheim's contribution, to view socialization processes as a matrix of the different conditions of embeddedness, stems from this latter direction. Rules regulating social interaction are transmitted through learning, which takes place in situations of persistent diversity and ongoing change. Such situations determine not only new economic and

technological opportunities, and consequently new regulative necessities, but also allow for different levels of individual freedom to next generation cohorts.

MAX WEBER: PROCESS OF RATIONALIZATION AS A MATRIX OF DIVERSITY

To Weber, the interpretation of modern society relies on two linchpins: the notion of methodological individualism based on the motives of individual action; and the idea that modernity is characterized by complex processes of rationalization, which points to the increasing importance of rational action. Weber does not assume that social action is performed by atomized individuals maximizing utility, but rather by persons influenced by their social networks, specific habits and traditions, by shared values and culture. The diversity of social contexts produces substantial variations in “the interest of the actors as themselves are aware of them” (Weber 1978: 30). It is from this concern with diversity that Weber’s contribution to the notion of embeddedness can be drawn.

Weber singled out two different forms of social interaction affecting social behavior in different ways: one form comes into being when two or more actors are related by a shared sense of membership in a delimited social group (the community); the second arises when actors share common interests (the association). Rationalization does not entail the extinction of community ties (*Vergemeinschaftung*), but it sets off an ongoing transformation of these same ties which inevitably cause tensions with associative relations (*Vergesellschaftung*). In particular, the pervasiveness of instrumental rationality is at odds with traditional habits. Change, therefore, does not lead to a uniform process of utilitarian individualism, but is the effect of variable forms of adaptation. Such forms constitute the main basis upon which the notion of embeddedness can be closely examined.

Weber’s second major contribution regards the tensions present within rationalization processes, particularly between formal rationality and substantive rationality. The former pertains to market exchange and immediate utility, the latter may be seen as the foundation of

redistributive logics. While rational behavior emerges from the tense interplay of these two forms of rationality, values determine the need for institutional regulation, the priority of the public good over the individual’s immediate benefit.

“Formal and substantive rationality, no matter by what standard the latter is measured, are always in principle separate things, no matter that in many (and under certain very artificial assumptions even in all) cases they may coincide empirically” (Weber 1978: 108). Here, Weber indicates an important tool to empirically analyze the diversity present in the processes of social construction of regulative institutions.

The Protestant Ethic and the Spirit of Capitalism may be read as a pioneering work on sociocultural embeddedness. Weber notes how typical capitalist behavior – profit orientation and emphasis on the importance of professional *beruf* (calling) – can only develop and extend in favorable cultural contexts fashioned by the Protestant ethic. Therefore, he reaffirms the idea that *homo oeconomicus* is not an atomized individual removed from his or her own cultural context, but rather that different sociocultural configurations (familial, ethnic, local, and religious conditions in which any individual is socialized) keep a decisive influence in orienting his or her social behavior.

POLANYI: PROCESS OF DISEMBEDDEDNESS AND REEMBEDDEDNESS

Polanyi argues that the diffusion of market based relations is a socially disruptive process. The notion of embeddedness may thus be used to understand the logics underlying the formation and transformation of social institutions in contexts of market exchange. In market relations immediate self interest prevails over other relationships, causing diversified processes of disembeddedness – as economic relations bring about social disruption – and concomitant processes of reembeddedness (i.e., new forms of regulation).

Polyani’s historical approach in *The Great Transformation* (1944) denounces the disruptive effects of *laissez faire* and emphasizes how serious tensions run through modern society.

Countermeasures (i.e., new regulative institutions) are established to keep at bay the negative impact of the diffusion of market relations. In particular, needs for new regulative principles occur in relation to the fictitious commodities – labor, land, and money – which are organized in self regulating markets. For this very reason they are incompatible with social life and yet “essential to a market economy” (p. 73). It follows that capitalist societies, built upon commodification processes, are characterized by a double movement of disembeddedness and reembeddedness (the necessity to produce new social regulation in the markets of fictitious commodities). *The Great Transformation* does not contain a theoretical/methodological model to carry out sociological analysis on the various manifestations of embeddedness. Polanyi (1957), however, does outline a procedure employing the conceptual tools of anthropology, which is subsequently used to develop a sociological theory of embeddedness.

Polanyi identifies three types of exchange relations: reciprocity, redistribution, and market exchange. Reciprocal and redistributive exchanges are meaningful only in so much as they are conceived of as part of the social order. They express two diverse logics of social organization comprised of specific meanings and contents in different cultural and historical settings. The logic of reciprocity is built upon the collective interests of small groups with strong and close ties, defined as community relationships in sociological terms. In this form of exchange, rules favoring the reproduction of the social group prevail over the immediate self interest of the individual. By contrast, the logic of redistribution stems from membership in a wider community and its internal power relations. In this setting of stable, hierarchically organized, and politically legitimated social relations resources are extracted from some individuals to benefit others.

At an abstract level market exchange is not compatible with society – the efficiency of competitive behavior occurs among atomized actors who are not enmeshed in social relations – and therefore appears to be guided by a universal logic devoid of social substance. Reciprocity and redistribution are viewed as embedded, while the market is disembedded. The problem of embeddedness in modern society is to explain

how it is possible to reconcile a growing number of market based interactions with social order. If at the abstract level it is possible to hypothesize an interactive phenomenon which exists outside of any form of social organization, in reality systematic market exchanges cannot take place outside a favorable social context.

According to Polanyi the three different logics of exchange – present always in different combinations – provide society with needed institutions, and therefore with the various configurations of embeddedness. The disembeddedness resulting from increasing individualism constitutes the driving force in ongoing transformations affecting all social institutions: those founded on reciprocity (i.e., household, kinship), those based on redistributive principles (such as the expansion of welfare programs), and those which make the markets of fictitious commodities more compatible with society. The outcomes of this process vary according to the dynamic interaction at work in different historical, cultural, and cognitive contexts.

The notion of tensions singled out by Weber and Polanyi makes it more difficult to implement interpretive parameters, yet sociology should not retreat from such a challenge. The construction of institutions governing modern societies is understood as a contextual double movement – much more difficult to construe in terms of utility and immediate functionality. The disruption of sociality caused by growing individualism and the concomitant reconstruction of social ties to limit individualism itself explains the chronically unstable equilibrium of modern society.

SOCIAL CONSTRUCTION OF DIFFERENCES: INNOVATION AND PATH DEPENDENCY

The approaches based on embeddedness show how it is possible to interpret market based societies without employing the reductive and asocial parameter of utilitarianism. It is true that utilitarian logics provide the easiest access to the atomized dimension of the individual, but these are socially meaningless because utilitarian behavior cannot occur without the current presence of institutions, norms, and culture in society. Polanyi's critique of the

self regulating market, and Weber's idea of permanent tensions between formal rationality and tradition, and between formal and substantive rationality, stress this precisely.

In conclusion, an example regarding labor regulation serves to clarify embeddedness approaches. The market sets wages based on the competitive relation between the supply of the workforce and the demand of the employers within a logic of labor productivity. However, linking wages to productivity presents insurmountable difficulties when considering workers' social life. Their needs change because their life cycle and material condition change as well. For example, a working couple with small children inevitably goes through a concomitant decrease in productivity and an increase in social needs. Resorting to market self regulation is not an effective solution: if the employer were to provide parental leave as well as a wage increase to the new parents, the company's competitiveness would be compromised and its future threatened. As a response to this problem, changes have occurred within the household through the devising of new strategies of adaptation; in addition, new forms of social protection have been introduced, such as the state regulation of parental leaves and childcare services.

The market, constrained by its own logic of competitiveness, cannot solve the labor disputes that are generated within it. Such disputes are being dealt with by the arrangement of adapting mechanisms, based on cooperative logics among which we may single out reciprocity (the family) and redistribution (the welfare state). The market enters the process of reembeddedness by mobilizing logics that allow for the stability of cooperation (consider the establishment of day care programs provided by firms).

The process of adaptation changes across societies, even though they undergo similar pressures and economic trends. One of the steps suggested here to highlight the different conditions of embeddedness is path dependency analysis, that is, a historical selective process within which some embedded conditions are transformed into specific configurations of development.

Returning to the previous childcare example – as Esping Andersen (1990) shows in his analysis of the different worlds of welfare

capitalism – along different historical routes some social contexts develop a greater number of universal public services, whereas others give more importance to the private sector, and others more often resort to family care and to social network solidarity. Cultural and social diversity may be a source of social action or its very limitation. Adaptation continues to modify the various starting conditions through paths where choices and opportunities are given neither by individual utility nor by pre-determined social institutions.

Path dependency suggests the historicized dimension of social analysis. The translation of such a historical dimension into research procedures is quite complex, yet essential. If the actor is not viewed as an atomized individual, he or she must therefore be located into different social, cultural, and cognitive contexts, which are the outcome of diversified historical processes of chance, innovation, and adaptation.

social epidemiology

James House

Social epidemiology lies at the intersection between the traditionally biomedical field of epidemiology, which is concerned with understanding the distribution, spread, and determinants of disease in populations, and the parts of sociology and other social sciences concerned with understanding the role of social factors, forces, and processes in the epidemiology of health and illness of individuals and populations (Syme 2001). As a field, social epidemiology has been largely created over the past half century by the combined efforts of persons trained in sociology and related social sciences to study the nature, etiology, and course of physical and mental health and illness in human populations. In some cases, they ended up more as epidemiologists than sociologists (e.g., Leonard Syme and Saxon Graham). There were also a number of pioneering physician epidemiologists, mostly from England and the British Commonwealth (e.g., John Cassel, Michael Marmot, and Mervyn Susser) who recognized the importance of incorporating psychosocial factors into the epidemiology of human health and illness.

The result has been the development and growth of a major new and vibrant interdisciplinary field and the transformation of scientific and popular understanding of the nature of determinants of physical health and illness. From a hegemonic paradigm that, for about a

century through the 1950s, viewed physical health as largely a function of biomedical factors, physical health and illness are now understood by both scientists and lay persons as equally or more a function of social, psychological, and behavioral factors. Early understanding (e.g., Freudian) of mental health and illness as being as much or more psychosocial as biomedical in nature, contributed importantly to the development of the social epidemiology of physical health and illness. Mental health epidemiology and treatment, in contrast, have headed in a more biological direction.

The 1950s have been aptly described as the high water mark of the medical profession's dominance of the health care system and the preeminence of the biomedical paradigm of physical health and illness which had developed out of the great discoveries in bacteriology of the nineteenth century (Mishler 1981). Faith in biomedical science and practice was fueled by a sense of triumph in the development of vaccines, antibiotics, and other prophylactic agents, from antiseptics to pesticides to prevent or treat, and even virtually eradicate, many forms of previously fatal or highly debilitating infectious diseases, capped by the dramatic conquest of polio in the 1950s.

Even then, however, this biomedical dominance was already being challenged by several developments. First, as the prevalence and impact of infectious diseases waned, chronic diseases such as cardiovascular disease and cancer increased to "epidemic" proportions, virtually halting, from the mid 1950s to the early 1970s, the long term increase in life expectancy in Western Europe and the US that had continued almost unabated since the eighteenth century. In contrast to most infectious diseases, the newly epidemic chronic diseases were produced by the interplay of multiple contingent "risk factors," no one of which was generally either necessary or sufficient to produce disease (House 2002). Initially, these risk factors were biomedical in nature (i.e., blood pressure, cholesterol), but they soon became environmental, behavioral, and psychosocial in nature.

Using methods similar to those used to identify biomedical risk factors, most notably the prospective cohort study, first health behaviors and lifestyles (from smoking to immoderate consumption of food and alcohol to lack of

physical activity), then the Type A or coronary prone behavior pattern, and then a broad range of psychosocial factors – social relationships and supports, acute (or life event) and chronic stress, and psychological disposition, such as control/mastery/self efficacy and anger/hostility – were shown to be consequential risk factors for morbidity and mortality from a wide range of causes (House 2002). Just over 40 years ago cigarette smoking was identified, on the basis of prospective epidemiological studies and laboratory research on animals, as a major risk factor for cancers of the lung and other sites, as well as for cardiovascular disease (DHEW 1964). Within 20 more years, Berkman and Breslow's (1983) analyses of the Alameda County Study, which Breslow had initiated in the early 1960s, combined with other research to expand the list of behavioral risk factors for health to include not only smoking, but also low levels of physical activity and immoderate levels of drinking alcoholic beverages and of food consumption/weight. The Alameda County Study also produced the first modern epidemiological evidence that lack of social relationships and support could be as risky as a cause of mortality as cigarette smoking, a finding repeatedly confirmed and generalized over the last two decades (House et al. 1988; Berkman and Glass 2000).

In the seminal decades of the 1960s through the 1980s, the identification by Friedman and Rosenman (1974) of the Type A behavior pattern and its certification by the National Heart, Lung, and Blood Institute (Review Panel 1981) as a risk factor for coronary artery disease like smoking, high blood pressure, and cholesterol, was of major importance in legitimating social epidemiology in NIH and the broader biomedical arena. Subsequently, dispositional anger and hostility have been identified as the key toxic ingredient of the broader Type A pattern (Smith 2001), and has joined a number of other psychological dispositions such as self efficacy/mastery/control, optimism/pessimism, and depressive affect as potential consequential risk factors (House 2002).

Parallel to these developments in psychosocial risk factor epidemiology were two others that reinforced the importance of psychosocial factors, and hence social epidemiology, in understanding patterns of individual and especially population health. McKeown (1976) initiated a

field of research showing that even the dramatic reduction in infectious diseases and consequent increases in life expectancy of the mid eighteenth to early twentieth centuries occurred prior to, and hence could not be due to, the development of the germ theory of disease or its application in preventive vaccination or pharmacologic therapy. Rather, the bulk of the dramatic growth in human population and life expectancy over the period was attributable to broad patterns of economic development and attendant improvements in public health, nutrition, clothing, housing, and sanitation (Bengtsson 2001). Finally, the development of stress and adaptation theory in physiology (e.g., Cannon and Selye), psychology (e.g., Lazarus), and sociology and related social sciences (e.g., Levine and Scotch), along with subsequent developments in psychoneuroimmunology, provided explanations of how psychosocial risk factors got "under the skin" to cause physical illness and even death (House 2002; Taylor et al. 1997).

By the late 1980s, social epidemiology was increasingly well established within and between the biomedical and social sciences, focusing increasingly on uncovering new psychosocial risk factors and showing how interventions could be used to modify these risk factors and hence improve health. But social epidemiology and psychosocial risk factors to health also came increasingly to share in the problems of biomedical and environmental risk factors epidemiology: tendencies to proliferate disparate and scattered risk factors, each with small to modest effects and often a limited or disputable evidentiary base.

Over the last two decades, psychosocial risk factor epidemiology has come to be overshadowed and also positively transformed by a reemergent social epidemiology of socioeconomic and racial/ethnic disparities in health. The Black Report in England startled many in the early 1980s by showing that despite the operation of the National Health Service for a quarter of a century, occupational class difference in mortality and life expectancy had not diminished and had perhaps even increased in England and Wales between the late 1940s and mid 1970s (Black et al. 1982). This finding stimulated similar research and findings and a broader rediscovery of the strength and

persistence of socioeconomic and also racial/ethnic disparities in health in the US, UK, and many other developed and developing countries.

These disparities generally outstripped those due to any single or small set of risk factors, reflecting the powerful tendency for the more health damaging aspects or levels of almost any social, psychological, behavioral, and even biomedical risk factor to be more prevalent among disadvantaged socioeconomic and racial groups, even as the major disease threats to health and risk factors for them varied over historical time and social space. Socioeconomic and racial/ethnic health disparities prior to the mid twentieth century were largely a product of differential exposure and susceptibility to infectious disease due to poorer nutrition, clothing, housing, sanitation, and other conditions of life and work. But as chronic diseases supplanted infectious diseases as the leading causes of morbidity and mortality by the later twentieth century, socioeconomic and racial/ethnic disparities in health came to be a function of differential experience of and exposure to these diseases and their risk factors. Indeed, over the course of the twentieth century, the increasingly leading cause of death – cardiovascular disease – and the major risk factor for it as well as cancer – cigarette smoking – went from being more prevalent and incident in the advantaged socioeconomic and racial/ethnic groups in the early twentieth century to being more incident and prevalent in less advantaged socioeconomic and racial/ethnic groups by the end of the century. Thus, socioeconomic and racial/ethnic stratification appear to operate as a fundamental cause or determinant of health via their influence on the experience of and exposure to virtually any and all risk factors for health in the past, present, or future (Link & Phelan 1995; House & Williams 2001).

In the first decade of the twenty first century, understanding and hence alleviating socioeconomic and racial disparities in health has been identified as one of the (arguably *the*) most important goals for public health policy and research, and the most promising avenue for achieving continued improvement in overall population health (DHHS 2000). The most advantaged portions of the human population, both within and across societies, are increasingly

approaching the biological limits of life expectancy and health, or what James Fries has termed the “compression” of mortality and morbidity against the biological limits of the human life span. Hence, the greatest opportunities for improving population health lie in bringing the health of the broad lower range of the population in terms of socioeconomic position and race/ethnicity increasingly closer to the biological optimum that the more advantaged are already starting to realize. In the case of the US, reducing socioeconomic and racial/ethnic disparities in health is also the necessary route to reversing the nation’s declining relative position in the world in terms of population health indicators such as life expectancy and infant mortality.

Understanding the processes and mechanisms that generate socioeconomic and racial/ethnic health disparities and social and economic policy, as much or more than health policy, will be central to alleviating such disparities. The increased focus on such disparities is also essential to developing a more integrative causal theory of the determinants and consequences of psychosocial risk factors for health. Major challenges at this point, both theoretically and methodologically, are (1) to better understand the causal priorities and interconnections of socioeconomic position (SEP), race/ethnicity, and other major sociodemographic factors such as gender and age, with respect to each other and to health (e.g., how much of the cause flow is from SEP to health or vice versa, or how much of racial/ethnic and differences in health are a function of differences of SEP); (2) to delineate the social, psychological, behavioral, and biomedical processes and pathways linking SEP and race/ethnicity (and also gender and age) to health; and (3) understanding how all these factors and processes are influenced by broader social contexts, forces, and policies. Multilevel, life course, longitudinal studies and methods will be central to all of these goals.

Thus, only a half century from its inception, social epidemiology has become increasingly central to broader health research and policy. All of this represents in many ways merely a reaffirmation, though on a much firmer conceptual, theoretical, and empirical base, of Rudolf Virchow’s mid nineteenth century insight that “Medicine is a social science, and politics

nothing but medicine on a grand scale." Social epidemiological research and theory have come a long way since Virchow, and even from their more modern roots in the mid twentieth century. They will be essential to twenty first century efforts toward understanding and improving individual and population health and reducing social disparities in health.

social epistemology

Steve Fuller

Social epistemology uses the resources of history and the social sciences to address normative questions surrounding the organization of knowledge processes and products. It seeks to provide guidance on how and what we should know on the basis of how and what we actually know. The subject matter corresponds to what John Dewey called "the conduct of inquiry" and what may appear today as an abstract form of science policy. Social epistemology advances beyond other theories of knowledge by taking seriously that knowledge is produced by agents who are not merely individually embodied but

also collectively embedded in certain specifiable relationships that extend over large chunks of space and time.

The need for social epistemology is captured by an interdisciplinary gap between philosophy and sociology: philosophical theories of knowledge have tended to stress normative approaches without considering their empirical realizability or political consequences. Sociological theories suffer the reverse problem of capturing the empirical and ideological character of knowledge, but typically without offering guidance on how knowledge policy should be conducted; hence the debilitating sense of “relativism” traditionally associated with the sociology of knowledge. Social epistemology aims to consolidate the strengths and eliminate the weaknesses of these two approaches.

The phrase “social epistemology” was coined in the 1960s by the US library scientist Jesse Shera to name a field concerned with the “architecture of knowledge” in both its theoretical and practical senses, ranging from the organization of the sciences to the design of libraries and information retrieval systems. By the 1970s, in response to academia’s complicity in the emergence of the “military industrial complex,” social epistemology was traveling under the banner of “critical science” (Ravetz 1971).

However, 1987 marks the introduction of the phrase into philosophy, as the title of a special issue of the revamped logical positivist journal *Synthese*, and the start of the first journal in the field, founded by Steve Fuller. That Anglo American analytic philosophy – rather than a continental European school – formally introduced “social epistemology” is telling. Accounts of knowledge in the European traditions already presupposed a social dimension, which would have made “social epistemology” superfluous. From the nineteenth century onward, epistemologies descended from French positivism and German idealism have consistently stressed the systematic and collective character of knowledge. In contrast, Anglo American philosophy has remained wedded to the individual – be it Cartesian or Darwinian – as the paradigm case of the knower. In this context, “social epistemology” is explicitly designed to redress the balance.

Social epistemologies may be compared in terms of the presumptive answers they provide to the following research questions:

- Are the norms of inquiry autonomous from the norms governing the rest of society?
- Is there anything more to a “form of inquiry” than the manner in which inquirers are arranged?
- Do truth and the other normative aims of science remain unchanged as particular forms of inquiry come and go?
- Is there anything more to “the problem of knowledge” than a matter of *whose* actions are licensed on the basis of *which* claims made under *what* circumstances?
- Is the social character of knowledge reducible to the aggregated beliefs of some group of individuals?
- Is social epistemology’s purview limited to the identification of mechanisms and institutions that meet conceptually satisfying definitions of knowledge?

Social epistemologists inclined toward positive answers to these questions remain close to the Cartesian starting point of classical epistemology, which focuses on the individual’s orientation to the truth. They rely sparingly on historical and social scientific findings, unless these are reasonably seen as part of the individual’s stock of common knowledge, which is sometimes dignified as “folk epistemology” (e.g., Kitcher 1993; Goldman 1999). In contrast, social epistemologists inclined toward negative answers are more open to interdisciplinary and empirical approaches, often with the intention of making individuals sufficiently aware of the social context of their knowledge production that they revise their modes of inquiry altogether. An example would be to take to heart science’s historic claim to universality by treating greater race, class, and/or gender inclusiveness in the community of inquirers as itself indicative of greater objectivity (Longino 1990; Harding 1991).

As the last example suggests, social epistemology does not deny the desirability of at least some of the classical ideals of epistemology. However, these ideals remain empty words without some clear strategy for overcoming the obstacles that block their successful institutionalization. Nowadays this sociological problem is perhaps most acute with respect to the autonomy of inquiry, given the openness of universities to extramural forces. Here social

epistemology, under the influence of analytic philosophy, rightly upholds positivist strictures about the need to operationalize, proceduralize, and standardize key concepts that might otherwise have no clear meaning whatsoever.

social exchange theory

Michael J. Lovaglia

Social exchange theory is an influential approach to the study of society, generating much recent research. Rather than a theory that explains precisely the nature of some social phenomenon, social exchange theory is an orienting strategy or perspective that shapes the way exchange researchers develop theories and conduct research (social conflict theory is another example of an orienting strategy). From the perspective of social exchange theory, society can be characterized as an exchange system in which social interaction consists of trade in valued resources. Resources exchanged can include any combination of consumable goods,

money, affection, attention, and perhaps most basically, information.

Early work that established the importance of exchange for developing social structure came from cultural anthropology that investigated patterns of exchange and gift rituals in tribal societies. The prototypical example is Bronislaw Malinowski's 1922 ethnography *Argonauts of the Western Pacific*, which documented a circular pattern of exchange (the Kula ring) among residents of a string of Pacific islands. Patterns of social exchange were proposed to enhance social solidarity and reduce intergroup conflict.

The increasing influence of social exchange theory in the twentieth century parallels the rise of utilitarian microeconomics as an explanatory framework for social development. Both approaches assume that individuals behave in ways they find rewarding. Whereas economics focuses on the exchange of goods for money in markets of equally positioned actors who have no history of previous exchanges, social exchange focuses on exchange more generally in networks of actors who may have quite different social positions and who have the opportunity to exchange with each other repeatedly. Rational choice theory has developed within sociology as a theoretical approach to individual decision making related to social exchange theory but more heavily influenced by microeconomics.

In seeking to explain the relationships between individuals and groups, social exchange theory sits between sociological and psychological approaches. An emphasis on the relationships between individuals, and ultimately how patterns of those relationships affect outcomes, allows social exchange theory to address more macro level sociological concerns. In particular, patterns of exchange relations constitute networks; thus social exchange theory has contributed to social network analysis and led to network exchange theory.

George Homans published *Social Behavior: Its Elementary Forms* in 1961, presenting a theory grounded in social exchange that is capable of explaining specific social phenomena and predicting outcomes of social interaction. Homans's theory blended ideas from behaviorist psychology and microeconomics to create foundational assumptions that could be used to generate predictions. Rewards, for example, are assumed to

increase behavior while the marginal utility of increasing rewards declines due to satiation. Through the 1990s, Louis Gray, Irving Tallman and their colleagues have continued research on individual decision making using a behaviorist approach with the development of their cost equalization model.

Homans's behaviorist approach was criticized for the basic tautology that resulted in his theory: individuals are predicted to behave in ways that result in reward, but what individuals find rewarding is determined by how they behave. Moreover, Homans's espousal of methodological individualism as the proper means of studying society was resisted by many sociologists. He argued that social structure consisted of patterns of individual behavior; thus the study of society could be reduced to the study of individual behavior. Peter Blau's *Exchange and Power in Social Life* (published a few years after Homans's book) advocated the social exchange approach to develop a more macro theory of society.

In 1962, Richard Emerson's power dependence theory continued to use behaviorist psychological principles of reward and satiation, but added ideas from John Thibaut and Harold Kelley's *The Social Psychology of Groups* about the social advantages conferred by access to alternative individuals capable of supplying valued resources. This new emphasis on exchange *relationships* was the sociological dimension that furthered theoretical progress. Emerson's theory established *power* (to acquire resources) as a central concern of social exchange theory. Power dependence theory proposed that power differences result from exchange in two ways: (1) through individual decision making as one actor placing more value on the rewards of an exchange relationship than does another, and (2) through a pattern of social relationships that gives one exchange partner greater access to alternative sources of reward.

In proposing social structure as an important source of power in exchange relationships, Emerson obviated the tautology inherent in using the internal values of individuals to explain their behavior. Instead, researchers could examine aspects of social structure that determine the distribution of resources in an exchange network. Rapid development of

sociological theory and research on social exchange followed the 1972 publication of Emerson's article on social exchange in networks. Since then, the development of social exchange theory has been carried out in research programs that coordinate theoretical advance with empirical research supporting its validity.

Karen Cook, Toshio Yamagishi, and their colleagues continued Emerson's research program to investigate patterns of exchange relations in networks that determine the distribution of power among network positions. By systematically analyzing differences in relationships among positions and experimental tests of those analyses, Cook et al. (1983) discovered that more central positions in an exchange network were not necessarily advantaged, but could be either high power or low power depending on their direct and indirect connections to other positions. Their later work established trust in exchange relationships as a major area of research (Yamagishi, Cook, & Watabe 1998).

Markovsky et al. (1988) developed an algorithm to determine the power of positions in exchange networks of any size and shape. Network exchange theory uses graph theory techniques to count relationships as paths leading away from each position to quantify each position's power as a graph theoretic power index (GPI) number. Later, with John Skvoretz, Michael Lovaglia, and others, network exchange theory continued to develop through a systematic program of theoretical development and experimental research. Two qualitatively different types of power were identified in exchange networks: strong power as quantified by the GPI, and a self limiting variety of weak power that can be quantified by analyzing probabilities that individual positions will be included in an exchange (Markovsky et al. 1993). In 1995, network exchange theory researchers used the resistance equation from David Willer's elementary theory to transform probabilities of inclusion into exact predictions of the resources that different positions could acquire from exchange.

Beginning in the 1980s, Linda Molm has developed exchange theory to encompass coercion. Her research investigates reciprocal exchange as opposed to the negotiated exchanges often studied by network exchange researchers. In negotiated exchange, two individuals agree

to trade one commodity for another. The assumption is that both parties gain from the transaction. No negotiation occurs in reciprocal exchange; instead, one party rewards or punishes another who then has the opportunity to reciprocate. Molm's (1997) statement of the theory and its supporting research proposes that punishment is more likely to be used when power differences are great and when rewards are used unjustly or ineffectively. These and other propositions of the theory are well supported by experimental research.

Edward J. Lawler developed a non zero sum conception of power that continues to advance social exchange research. He proposed that to study power effectively, it is important to assess the total power of both individuals in an exchange relationship, as well as the relative advantage that one individual has over another. During the 1980s his work with Samuel Bacharach used a social exchange approach to investigate conflict resolution in negotiation and bargaining. Central to this approach is the idea that social exchange can reduce conflict. During the 1990s he developed a theory of relational cohesion. Working with Jeongkoo Yoon, he proposed and validated through experimental research that ongoing exchange relations can increase positive emotional bonds and thus social solidarity between exchange partners, but only to the extent that exchanges were perceived as equal. Large power differences reduced the emotional benefits of exchange relationships.

Research on social exchange continues to flourish. Social theories are influential in the discipline to the extent that they generate important research questions that are then answered through empirical investigation. For example, a longstanding question for social theory involves the intentionality of power use. Does the use of social power require that individual actors intend to use it? Willer and Skvoretz (1997) answered that question when they discovered that a passive actor in an exchange network, one who only accepts the best offer available but who makes no attempt to improve it, is capable of exercising as much power as one who actively seeks to maximize resources at others' expense. That is, the social power produced by the structure of an exchange network is independent of the intentions of those who occupy

network positions. Social exchange theory is an influential research area because it continues to raise important questions and generate research capable of answering them.

social exclusion

Hilary Silver

Social exclusion is a rupturing of the social bond. It is a process of declining participation, access, and solidarity. At the societal level, it reflects inadequate social cohesion or integration. At the individual level, it refers to the incapacity to participate in normatively expected social activities and to build meaningful social relations.

The idea of social exclusion originated in France. It has many affinities with French Republican thought, especially the concepts of solidarity and the social bond. Its sociological pedigree is clearly Durkheimian, as Levitas (2000) has noted. However, the concept is also adumbrated in Georg Simmel's *The Stranger*, Norbert Elias's *The Established and the Outsiders*, *Stigma*, and Howard Becker's *Outsiders*. Social exclusion may also be conceived in terms of Max Weber's concepts of status groups and social closure.

Despite the concept's novelty and ambiguity, definitions of social exclusion abound. They vary by national context and sociological paradigm. Some scholars refer to an inability to exercise the social rights of citizenship, including the right to a decent standard of living. These approaches see social exclusion as synonymous with poverty and deprivation, and thus as an aspect of social stratification. Other approaches, especially in Britain, emphasize the importance of individual choice, for a person cannot be excluded if inclusion is accessible, but undersired. These perspectives emphasize exclusion from opportunities and thus conceive of the concept as one similar to discrimination. However, the original meaning of social exclusion stresses social distance, marginalization, and inadequate integration.

Social exclusion is most frequently defined in contrast to poverty. It is a relational rather than a redistributive idea. Although poverty can lead to social exclusion, as well as the reverse, one can easily imagine rich members of excluded groups. Thus, it is not strictly a question of insufficient material resources. As Touraine (1991) put it, exclusion is an issue of being in or out, rather than up or down. Because

exclusion is about broken relationships, there are always two parties to consider: the excluders as well as the excluded.

Exclusion is also multi dimensional, combining economic and social deprivation. However, analysts differ on whether exclusion is always a cumulative process of multiple, interrelated disadvantages. The UK's Social Exclusion Unit defines exclusion as "a shorthand label for what can happen when individuals or areas suffer from a combination of linked problems." Emphasizing joined up social problems, especially when spatially concentrated, resonates with the idea of an "underclass." This is even more the case when, as Vlemminckx and Berghman (2001) claim, exclusion implies entrapment or intergenerational transmission.

Certainly, research confirms that exclusion along one dimension may increase the risks of exclusion along other dimensions, but very few people are totally excluded from all social relations at once. There are many more people who are socially excluded in some respects than there are people excluded in all respects. Indeed, it is virtually impossible for human beings to exist totally outside societal influences.

Social exclusion may be considered as both a condition and a process, although it is most frequently treated in dynamic terms. Castel (1991), for example, eschews the term exclusion, preferring the notion of *disaffiliation*. Paugam (1991), another French sociologist, refers to a process of *social disqualification*. These authors consider exclusion along a continuum, with intermediate steps of vulnerability or precariousness.

There are many mechanisms of social exclusion: extermination, exile, abandonment, ostracism, shaming, marginalization, segregation, discrimination. Sometimes, even social assistance can produce exclusion. In general, groups deliberately use exclusion as a means of social control and boundary maintenance. It reinforces internal solidarity and may allow insiders to monopolize resources.

Although most scholars agree that social exclusion is multi dimensional and has different forms in different social contexts, there is little consensus over what are the most important dimensions of social exclusion. Studies have so far examined the dimensions that are easiest to measure with available data. This has first and

foremost meant extending poverty and unemployment indicators to take account of time and place. A. B. Atkinson, a British economist, proposed the initial exclusion measures for the European Union, most of which consisted of income and joblessness indicators (Atkinson et al. 2002). In the second EU Joint Inclusion Report these indicators were accompanied with education and health measures.

However, several sociological studies, especially in the UK, have tackled other social and political dimensions of exclusion. For example, Gordon et al. (2000) conducted a new *Poverty and Social Exclusion in Britain* survey for the Joseph Rowntree Foundation specifically for this purpose. In addition to income poverty and material deprivation, exclusion from the labor market and from public services, they examined four aspects of exclusion from social relations: socializing, social isolation, social support, and civic engagement. The researchers identified these aspects directly by asking Britons themselves what they considered "normal" social activities, whether they experienced constraints upon participating in them, and, if so, the nature of those obstacles. This and other studies (see Hills et al. 2002) reveal that income distribution and unemployment are weakly associated with sociability and community participation. Gallie and Paugam's (2000) research suggests material deprivation may even be positively related to social relations in Southern Europe.

The dimensions of social exclusion receiving the most recent attention concern the recognition and rights of racial and ethnic groups, especially of immigrants. This emphasis is largely due to the adoption of the 2000 EU "Racial Directive" on equal treatment irrespective of racial and ethnic origin, and the EQUAL program to fight labor market discrimination. In 2005 the British Council of Brussels and other agencies released a European Civic Citizenship and Inclusion Index that uses uniform indicators to gauge the extent to which immigrants to a country have rights and obligations comparable to EU citizens. While these attempts to measure social dimensions of exclusion are important advances, many cultural, political, and social aspects of life lack good indicators. The Joint Report on Social Inclusion called for more attention to neglected types of disadvantage,

such as access to the Internet, housing, transportation, continuing education, and language acquisition. Further methodological advances are expected in the future.

Social exclusion has expanded its meaning over time to encompass more social problems and disadvantaged groups. In France, when the term originated in the 1960s, a group of "Social Catholics," especially the ATD Fourth World movement headed by Father Joseph Wresinski, used the term to refer to the extremely poor of affluent and less developed countries living in the slums. In the 1970s, when René Lenoir (1974) used the term, the socially excluded referred to the handicapped, substance abusers, juvenile delinquents, and deviant groups. In the 1980s, as unemployment rose after the Oil Shocks, the term applied to youth and older unskilled workers whom deindustrialization displaced. As long term joblessness, homelessness, and racism all became issues in the next two decades, they added yet more complexity to the meaning of social exclusion. A coalition of social movements concerned with these many issues demanded action, leading to France's anti exclusion laws enacted in 1988, 1998, and 2005.

In the 1990s the European Union adopted the term. Leaders passed resolutions to fight social exclusion as part of the European Social Model, one that weds economic growth with job creation and social cohesion. Since 2001, member states of the EU have produced National Action Plans for social inclusion submitted to Brussels for coordination in a Joint Inclusion Report. The European Union will shortly consider the fight for social inclusion in the larger context of social protection. Already in 2005, the Joint Report on Social Protection and Social Inclusion coupled national progress reports on inclusion with benchmarks on pensions. The next Joint Report will further streamline the monitoring process, adding medical and other dimensions. As the EU expands from 15 to 25 members, new issues of social exclusion are likely to arise, such as discrimination against the Roma (gypsies) in Central and Eastern Europe. In sum, Brussels will probably determine the direction of the study of social exclusion for the near future.

Interest in social exclusion has expanded beyond Europe, although so far the concept

has not caught on in the US. International agencies working in less developed countries have found the concept useful for studying the challenges of integration in pluri ethnic societies, caste structures, religious cleavages, and indigenous peoples' rights. UN agencies and international development banks have funded programs to promote social inclusion in the global South.

Thus, political and policy considerations have been as important as sociological interests to the development of social exclusion as a subject of study. For example, Giddens (2000) discussed "social exclusion" in his book on *The Third Way* just as Tony Blair was adopting the idea. Esping Andersen referred to the challenges of social exclusion in his 2002 book, *Why We Need a New Welfare State*. And France's full fledged National Observatory for the Study of Social Exclusion produces annual research reports for the government.

Programs to fight social exclusion ideally take a comprehensive approach, progressively tackling multiple problems and tailoring solutions to a person's particular combination of needs. Solutions usually entail the participation of the excluded in their own inclusion. The European Social Funds have co funded local projects that help rebuild social relations and "reinsert" excluded people in socially useful activities. These projects might include working in a subsidized job, taking a training course, or renovating housing for the homeless. They may not lift someone out of poverty, but they do reknit the social bond. Inclusion does not rely only on having a paid job in a for profit business.

Finally, there are many critiques of the idea of social exclusion. Central among them is the argument that it distracts attention from social inequality and class conflict. The excluded have a wide range of problems and do not share interests that might cement them into a political force. In addition, inclusion is usually a euphemism for rejoining the labor force. Other critics point out the lack of a theory that identifies the causes and consequences of exclusion. There is not a zero sum relationship in which greater exclusion means less inclusion. Rather, both processes are interrelated and can occur simultaneously. These and many other controversies will ensure the further development

of the concept of social exclusion in the years to come.

social fact

Donald A. Nielsen

The concept of social fact was defined by the French sociologist Émile Durkheim, in his book on the *Rules of Sociological Method* (1982), as ways of feeling, thinking, and acting external to and exercising constraint over the individual. Durkheim's emphasis on social facts was part of his critique of psychological theories of human behavior and society. The concept of social fact is identified with Durkheim and his school, but is also relevant to the understanding of any social theory which views society as an objective reality apart from the individuals composing it. Such approaches can be distinguished from the theoretical perspectives of such figures as Weber, Mead, and others who emphasize social action, interaction, or individual definitions of reality.

According to Durkheim, social facts are collective phenomena and, as such, make up the distinctive subject matter of sociology. Social facts can be embodied in social institutions, such as religions, political forms, kinship structures, or legal codes. There are also more diffuse social facts; for example, mass behavior of crowds and the collective trends identifiable in statistical rates of social phenomena such as suicide and crime. Institutions are an especially central concern of sociology as a social science. Durkheim insisted that social facts should be treated as things. They are realities in their own right, with their own laws of organization, apart from the ways these facts might appear to the individual's consciousness. Durkheim thought that sociology would have no distinctive subject matter if society itself did not exist as an objective reality. Thus, sociology and psychology represent independent levels of analysis.

In *Suicide* (1897) Durkheim studied suicide rates as measurable manifestations of prior social facts. He argued that suicide rates were correlated with differing social circumstances and created a theory of four social causes of suicide, two of them endemic to modern society. Egoistic suicide emerged from a lack of integration of the individual into social groups, especially

the family, the religious group, and the political community. Since familial, religious, and political ties were weakening in modern society, egoism was the most frequent contemporary cause of suicide. He suggested that the reintegration of the individual into society might be performed by strengthening the role of occupational or professional groups.

Anomic suicide resulted from the failure of another class of social facts, namely social norms, to regulate the individual's desires. It occurred especially during fluctuating economic circumstances, but could emerge in any setting where the individual's existing standards of conduct and expectations were radically disrupted. Durkheim emphasized that such social causes operated independently from the individual incidence of suicide and represented a level of social facts which could be understood only through a new science of sociology.

Durkheim and his school studied a wide range of social facts, including family and kinship, the division of labor, religion and magic, and the categories of human understanding such as time, space, and the person. Their emphasis on the factual character of society led Durkheim and his followers to examine what they called the social substratum of groups and the collective representations, or the collective psychology, shared by the average members of society. The former class of social facts, social morphology, was especially central to their work and involved the study of the number, distribution, and social organization of populations in space and over time. In this way, the Durkheimians combined the disciplines of geography, history, and demography into a holistic sociological analysis of the social substructure. Maurice Halbwachs focused especially on social morphology, although each member of the school, including Durkheim, adopted this approach to the study of social phenomena.

For example, Durkheim argued that the causes of changes in social facts must be located in historically antecedent social phenomena. In *The Division of Labor in Society* (1893) he examined the transformation of societies from mechanical to organic solidarity. Mechanical solidarity was based on a strong collective consciousness and organized around segmental groups, primarily extended kinship structures.

The result was a society based on the similarity among its individual members and social units. Organic solidarity was rooted in mutual interdependence of activities in the division of labor, where the collective consciousness became less strong and, thus, there appeared a greater individuation of thought and conduct. The cause of the change from mechanical to organic solidarity was found in social morphology; in particular, an increase in the overall population volume, an increase in society's material density (i.e., the number of people in a given territory), and an increased moral or dynamic density (i.e., communication and interaction among groups).

In a related study, *Seasonal Variations in Eskimo Society* (1904–5), Marcel Mauss used a similar approach. He found that major changes in religious ritual, law, family organization, economic life, and other features of Eskimo society resulted from the seasonal variation of population concentration and dispersion and their concomitant effects on moral density. Durkheim and Mauss argued, in their study of *Primitive Classification* (1901–2), that the main categories of thought and classification of objects in primitive societies reflected the social organization of those societies and should be understood apart from the individual's psychology. In his study of "The Preeminence of the Right Hand" (1909), Robert Hertz argued that the higher cultural value placed on the right hand was rooted in social and religious definitions of the sacred versus the profane, rather than in any biological asymmetry. Hertz's study laid the foundation for a growing literature on dual systems of classification which, in turn, gave an impetus to structuralist theories of culture and society.

Other social theories outside the Durkheimian orbit have also emphasized the role of objective social conditions or social facts. Marxist social theorists have focused on the ways in which forces and social relations of production confront individuals as objective conditions of existence. Marx argued that individuals make history, but do so under conditions independent of their individual wills. For Marx, social existence determines consciousness. Individuals are primarily to be seen as representatives of social classes or personifications of objective

economic forces. When Marx does discuss social action, he emphasizes the role of collective actors in history, namely social classes like the bourgeoisie or the proletariat. This tension between objective factual conditions and collective voluntary action presented dilemmas for later Marxists.

A variety of functionalist and structuralist approaches have emerged from this early emphasis on the factual quality of social existence. Although Talcott Parsons's early study *The Structure of Social Action* (1937) developed an action frame of reference, he soon developed a macro sociological, structural, and functional theory which muted his earlier emphasis on actors and social action. For example, in *The Social System* (1951) Parsons developed a general theory of social systems which focused on four basic functions which all social systems, including whole societies, needed to perform in order to continue as going concerns (i.e., adaptation to environment, goal attainment, social integration, cultural pattern maintenance). Parsons examined the interchanges among institutions (e.g., economy, polity, household, school, law, etc.) serving these functions and used this strategy to build increasingly inclusive theoretical systems, ones which could be applied to concrete sociological questions. For instance, in *Economy and Society* (1956) Parsons and Neil Smelser analyzed the economy as a social system and examined its internal organization along with its relations with other non economic systems, while in *Family, Socialization and Interaction Process* (1955), Parsons and several collaborators discussed the family as a social system, including its structure of instrumental and integrative roles. On related grounds, Kingsley Davis and Wilbert Moore argued for the functional necessity of social stratification, while other functionalists such as Robert K. Merton turned to the study of social structures and their consequences. Merton distinguished between the manifest (i.e., intended and foreseen) and latent (i.e., unintended and unforeseen) functions of social arrangements. Merton's approach allowed him to examine various social phenomena of the "middle range" (e.g., conflict, bureaucracy, reference groups) which often slipped through the more holistic and systematic functionalism of Parsons.

More recent French social thought has produced a number of variations on Durkheim's sociological objectivism. These include Lévi Strauss's structural anthropology, the historical work of the *Annales* school, especially Braudel and his followers, Foucault's investigations, and the theorizing of Althusser. Lévi Strauss created structural theories of kinship, myth, and culture by combining structural linguistics with ideas drawn from the Durkheim school, Marx, and Freud. His theories pitted structure against history and argued for the centrality of enduring structures of human cognitive and social organization. Human expressions and the actions of individuals were best seen as variants operating within the confines of established social and cultural structures. The second generation of *Annales* historians such as Fernand Braudel pursued a similar agenda by rejecting the study of history in terms of actors and events and emphasizing structures of the *longue durée*, including such things as enduring socioeconomic and civilizational structures and even geography and climate. This approach is most fully captured in Braudel's work on *The Mediterranean* (1949), but is also found in the work of such *Annales* figures as Immanuel Le Roy Ladurie, who has suggested that the study of the economic and social impact of slow climatic changes opens up the possibility of a "history without people" (in this connection, it is worth recalling that Durkheim rejected the idea that climate had an impact on suicide rates). Michel Foucault's work also diminishes the role of the individual subject. His studies of madness, the clinic, the prison, and changing systems of knowledge reject the search for causal sequences rooted in the actions of individuals or groups and, instead, view actors and their actions as instantiations of the words and deeds made possible by the reigning discourses. These structuralist tendencies are perhaps most fully expressed in Louis Althusser's work. He rejects Marx's early humanistic writings in favor of his later, more objectivist scientific work, and ends by forging a structural theory of society where human agency is entirely eliminated and social change occurs through a process of internal contradictions within dynamic socioeconomic, political, and legal structures.

The emphasis on social facts in sociology is generally opposed by thinkers who see human

agency as central to our understanding of society. This latter group includes Max Weber's social action theory, the symbolic interactionist theory of Herbert Blumer, the phenomenological perspective of Alfred Schutz, and several related perspectives. For example, Weber's work rests on the principle of "methodological individualism," where objective social processes can in principle be reduced to the actions and interactions of individuals. In a similar vein, symbolic interactionists see society as a process and not an object. Schutz attempts to build scientific concepts about society by starting with the taken for granted conceptualizations of individual actors. There have been efforts by such figures as Peter Berger and Thomas Luckmann, Anthony Giddens, and Pierre Bourdieu to synthesize the positivist, objectivist study of social facts derived from the Durkheimian, Marxian, structuralist, functionalist, and related traditions with the study of social action, interaction, and agency. However, these efforts have not always been fully successful in doing justice to both the objective social reality of economy, society, and culture as well as the equally robust reality of individual social action, interaction, and response. This dilemma is probably inherent to sociology as a social and human science.

social identity theory

Peter L. Callero

Social identity theory offers a social psychological explanation of intergroup prejudice, discrimination, and conflict. Its origins lie in the work of Henri Tajfel (Tajfel & Turner 1979) and his associates who have been instrumental in the development of a distinctly European approach to psychology. This approach is broadly concerned with the relationship between self and society. For Tajfel, the key to understanding prejudice, discrimination, and intergroup conflict is found in an individual's social identity as defined by group membership. Social identity theory rejects explanations based on individual defects of physiology, personality, or attitude. In this regard, it represents a challenge to more traditional psychological theories and has generated nascent interest among sociologists. Tajfel's experimental findings on group affiliation and personal bias were first published in the 1960s and, since then, social identity theory has generated an immense body of empirical research in support of its basic hypotheses. Over the years, social identity theory has been elaborated and extended to encompass issues of group leadership, organizational psychology, deviance, and political action. Today, social identity theory stands as one of the most influential theoretical perspectives within psychological social psychology.

MINIMAL GROUP PARADIGM

The empirical starting point for understanding social identity theory is found in a series of laboratory experiments that have come to be known as the minimal group paradigm. The objective in this early research was to identify the minimal conditions required to produce favoritism toward one group and discrimination against another. In the minimal group design, subjects are randomly assigned to one of two groups that they believe were established on the basis of a trivial preliminary test (e.g., whether one underestimated or overestimated the number of dots on a screen). The conditions are such that there is no history or prior knowledge

of the group or of other group members, there is no interaction among or between group members, other group members cannot be heard or seen, no competition of any sort is ever established, and the only differentiating factor is the perception that there are two distinct groups. Results from studies using the minimal group paradigm consistently show favoritism toward one's own group and bias against another group (usually measured in terms of reward distribution to group members and member attitudes toward the in group and the out group). Thus, on the basis of a purely cognitive discrimination of groups as defined by simple category distinctions, the seeds of intergroup conflict are sown. Variations on the minimal group design have ruled out the effect of perceived similarity among group members and various other methodological artifacts. For Tajfel and his colleagues, the findings show that the mere categorization into groups can produce a distinctly consequential social identity, and that social identity based upon group membership is the psychological foundation of intergroup conflict. At the same time, Tajfel was quick to emphasize that the findings should not be interpreted to mean that material conditions, historical structures, and cultural traditions do not affect real world conflict. In fact, these sociological forces are the context within which social identity operates.

SOCIAL IDENTITY

Social identity refers to an individual's subjective understanding of group membership. It is a cognitive category that includes emotional and evaluative associations. Social identity can be as simple and fleeting as a label employed in a psychology experiment or as complex and encompassing as national, religious, or ethnic affiliations. Unlike the symbolic interactionist tradition in sociology where self, identity, and personhood are seen as inherently social at all levels, social identity theory argues that group identity is formed psychologically and in opposition to one's personal identity.

In other words, the psychology of group behavior is assumed to be qualitatively different from the psychology of interpersonal behavior. While this ontological distinction provides

social identity theory with the conceptual language needed to understand prejudice, discrimination, and conflict as ordinary, adaptive, and functional interactions of group behavior, critics have argued that it has led to the adoption of an overly restricted understanding of the social dimension of identity. Because social identity is seen as the cognitive mechanism that makes group behavior possible, understanding the motivations, contextual contingencies, and cognitive structures associated with the psychology of *groupness* has been a major focus of research.

As noted above, an enormous body of empirical research has found that an individual's commitment to a group is associated with positive bias toward the group, or in group favoritism. In addition, the same expansive body of research finds that in group favoritism is often associated with out group bias such that members of other groups tend to be viewed in a stereotypical manner. In other words, the salience of a social identity (psychological commitment to a group) leads to prejudice, discrimination, and conflict between groups. But of course these basic associations are not universal. Not all group commitments for all individuals lead to the same type of bias. Perhaps the most valuable contribution of social identity theory is that it provides a framework for predicting when and how group bias occurs. The effects are highly contingent and so the explanations can be quite detailed and complex, but three major factors affecting the process are the salience of particular social identities, the objective features of a particular situation, and the individual's beliefs about the group.

When group membership in the form of a social identity is psychologically salient, it is said to affect perception, cognition, and behavior; predictions that have received substantial empirical support. But according to social identity theory, the salience of a group identity should not be viewed as a transsituational quality of the person. Rather, it is a process whereby specific social identities come to define the self in particular social contexts. Some social settings will allow for a fit between social identity categories stored in memory and the perception of self in relation to other group members. Categories that have optimal fit, and maximize

meaning for the actor, will become salient. For example, in a setting where groups are in conflict over financial resources, such as a collective bargaining table or a picket line, we would expect a worker's union identity to be salient. This in turn would be associated with positive generalizations about union members and negative generalizations regarding management. But even in this rather straightforward and simple example, the outcome is not determined since individual belief structures also intervene.

According to social identity theory, the two belief structures most important for understanding intergroup relations are those that address social mobility and social change. Importantly, these two beliefs are related in that they are said to represent different ends of a single continuum. An individual who believes in social mobility thinks that it is possible to achieve positive social regard by moving from one group of relatively low status to another of relatively higher status. This belief is based on the assumption of a relatively free and unrestricted social structure. In contrast, a belief in social change rests on the idea that positive improvement in one's social standing requires action as a group member. It is in effect a rejection of free and independent agency in favor of a more collective approach to changing the position of one's group. Because of its emphasis on solidarity with other group members, this end of the continuum is seen as corresponding to the psychological salience of a social identity.

MOTIVATION AND SELF CATEGORIZATION

At its core, the social identity approach to group conflict is built upon the energizing forces of specific psychological motives. These include a motivation to enhance self esteem, a motivation to maintain a distinct social identity, and a motivation to reduce uncertainty. Thus, it is hypothesized that the fundamental drive to achieve a favorable view of self leads individuals to associate with groups that will enhance self regard. But since this cannot be achieved unless the group is recognizably distinct and clearly associated with positive sentiment, individuals are also motivated to affiliate with

groups that offer *positive distinctiveness*. More over, as actors attempt to define and clarify knowledge about self and others, they are also driven by a need to reduce uncertainty. The cognitive processes associated with categorizing self and other are in turn viewed as effective strategies for reducing uncertainty. Although various hypotheses and contingencies linked to these motives have been studied at length, empirical support for the self esteem motives has been mixed. This has contributed in part to a significant shift in emphasis over the last 20 years toward greater interest in developing the cognitive dimension of social identity theory.

During the 1980s Jon Turner and his colleagues (Turner et al. 1987) initiated the development of self categorization theory as an extension and elaboration of social identity theory. Self categorization theory addresses more specifically the cognitive structures and processes that define social identity and the psychology of group affiliation and commitment. For example, a key concept in self categorization theory is that of *prototypicality*, or the degree to which a category member is representative of the category as a whole. A cognitive prototype is an actor's mental representation of the core defining attributes of a group. Research suggests that this is usually constructed from qualities of exemplary members, either through a disembodied ideal type or an actual group member who comes close to the imagined ideal. These stereotyped images are stored in memory and are altered in the social context of group comparison in order to enhance meaning. For example, under the principle of *metacontrast*, attributes of the prototype will change so as to maximize the difference between the in group and the out group. In this way, the self categorization process functions to induce group solidarity, encourage social identity salience, and reduce self uncertainty by establishing shared beliefs through group membership.

SOCIOLOGICAL CONTRIBUTIONS

The distinguishing contribution of social identity theory is its explanation of the psychological foundations of intergroup prejudice, discrimination, and conflict. By assuming an ontological

break between interpersonal and group psychology, social identity theory departs from the more reductionist approaches to intergroup behavior. Since the 1980s social identity theory has seen tremendous growth and influence and must now be considered one of the most dominant theoretical perspectives in psychology. Nevertheless, at this point in time its standing among sociologists remains relatively weak. This is a partial consequence of institutional barriers, but it also reflects more basic epistemological differences between social psychologists in the two scholarly traditions. Because social identity theory assumes an ontologically independent person acting as either an individual or as a group member, its ability to provide an accounting of fundamental sociological processes is limited. Thus, the emergence of selfhood and identity from interpersonal interaction is not addressed within social identity theory, and historically situated macro forces of political economy, colonialism, and cultural imperialism can enter only as details of a specific situation. To the extent that social identity theory continues to rely primarily on laboratory experimentation focused on discovering and describing cognitive processes, it will unlikely develop a larger following among sociologists. Should, however, it begin to link these processes more directly with actual group conflict in real world settings, it has the potential to contribute to interdisciplinary cross fertilization.

social indicators

Kenneth C. Land

Social indicators are statistical time series “used to monitor the social system, helping to identify changes and to guide intervention to alter the course of social change” (Ferriss 1988: 601). Examples are unemployment rates, crime rates, estimates of life expectancy, health status indices such as the average number of “healthy” days (or days without activity limitations) in the past month for a specific population, school enrollment rates, average achievement scores on a standardized test, rates of voting in elections, and measures of subjective well being such as how satisfied individuals are with life as a whole. In addition to these specific indicators, recent work has led to the development of summary indices that combine a number of specific indicators into composite measures of the quality of life or well being for a society as a whole or for specific segments or subunits thereof.

Associated with the term social indicators is a field of research that cuts across several social science disciplines (Land 1983). Three broad questions about social indicators are addressed here:

- Where did the field of social indicators come from? What is the historical development and intellectual history of social indicators?
- Can different categories of social indicators be distinguished? What are the major types?
- How are social indicators used? What are the functions of social indicators?

HISTORICAL DEVELOPMENTS

Social Indicators in the 1960s

The term *social indicators* was born and given its initial meaning in an attempt, undertaken in the early 1960s by the American Academy of Arts and Sciences for the National Aeronautics and Space Administration, to detect and anticipate the nature and magnitude of the second order consequences of the space program, specifically the effort to launch a manned space flight to the moon and back, for American society. Frustrated by the lack of sufficient data to detect such effects and the absence of a systematic conceptual framework and methodology for analysis, some of those involved in the Academy project attempted to develop a system of social indicators – statistics, statistical series, and other forms of evidence – with which to detect and anticipate social change as well as to evaluate specific programs and determine their impact. The results of this part of the Academy project were published in a volume (Bauer 1966) bearing the title *Social Indicators*.

The appearance of this volume was not an isolated event. Several other influential publications commented on the lack of a system for charting social change and advocated that the US government establish a “system of social accounts” that would facilitate a cost-benefit analysis of more than the market related aspects of society already indexed by the National Income and Product Accounts (Land 1983). The need for social indicators also was emphasized by the publication of the 101 page *Toward a Social Report* (US Department of Health, Education, and Welfare 1969) on the last day of Lyndon B. Johnson’s administration in 1969. Conceived of as a prototypical counterpart to the annual economic reports of the president, each of its seven chapters addressed major issues in an important area of social concern (health and illness; social mobility; the physical environment; income and poverty; public order and safety; learning, science, and art; and participation and alienation) and provided an assessment of prevalent conditions. In addition, the document firmly established the link of social indicators to the idea of systematic reporting on social issues for the purpose of public enlightenment.

Generally speaking, the sharp impulse of interest in social indicators in the 1960s grew out of the movement toward collection and organization of national social, economic, and demographic data that began in western societies during the seventeenth and eighteenth centuries and accelerated in the twentieth century. The work of sociologist William F. Ogburn and his collaborators at the University of Chicago in the 1930s and 1940s on the theory and measurement of social change is more proximate and sociologically germane. As chairman of President Herbert Hoover's Research Committee on Social Trends, Ogburn supervised production of the two volume *Recent Social Trends* (1933), a pathbreaking contribution to social reporting. Ogburn's ideas about the measurement of social change influenced several of his students – notably Albert D. Biderman, Otis Dudley Duncan, Albert J. Reiss, Jr., and Eleanor Bernert Sheldon, who played major roles in the emergence and development of the field of social indicators in the 1960s and 1970s.

Social Indicators in the 1970s and 1980s

At the end of the 1960s, the enthusiasm for social indicators was sufficiently strong and broad based for Duncan (1969) to write of the existence of a Social Indicators Movement. In the early 1970s, this led to numerous developments, including the establishing in 1972, with National Science Foundation support, of the Social Science Research Council Center for Coordination of Research on Social Indicators in Washington, DC; research efforts to define and develop a methodology for the measurement of indicators of subjective well being as measures of the quality of life (Campbell et al. 1976); the commencement of a US federal government series of comprehensive social indicators books of charts, tables, and limited analyses; the initiation of several continuing data series based on periodic sample surveys of the national population, such as the annual National Opinion Research Center's (NORC's) General Social Survey or the Bureau of Justice Statistics' annual National Crime Victimization Survey; the publication in 1974 of the first volume of the international journal *Social Indicators Research*; and the spread of social indicators/social reporting to numerous other nations

and international agencies, such as the United Nations and the Organization for Economic Cooperation and Development.

In contrast to the 1970s, social indicators activities slowed in the 1980s, as funding cuts or non renewals led to the closing of the Center for Coordination of Research on Social Indicators, the discontinuation of related work at several international agencies, the termination of government sponsored social indicators reports in some countries, including the United States, and the reduction of statistical efforts to monitor various aspects of society. Several explanations have been given for this turnabout. Certainly, politics and the state of national economies in the early 1980s are among the most identifiable proximate causes. Administrations that came to power in the United States and elsewhere based decisions more on a "conservative ideology" and less on current social data than had been the case earlier. And faltering economies producing large government budget deficits provided the incentive to make funding cuts. In addition, however, there was a perceived lack of demonstrated usefulness of social indicators in public policymaking. This was due, in part, to an overly simplistic view of how and under what conditions knowledge influences policy, a topic treated more fully below in discussions of uses of social indicators.

Social Indicators in the 1990s and 2000s

The 1980s ended with the question of "Whatever Happened to Social Indicators?" and the conclusion that the field had faded away. But, shortly after this conclusion was articulated, interest in social indicators revived and the field has been in an expansionary phase since the mid 1990s.

A key part in this expansion is a development that became vividly apparent in the 1990s: the widespread political, popular, and theoretical appeal of the quality of life (QOL) concept. This concept emerged and became part of the Social Indicators Movement in the late 1960s and early 1970s as doubts were raised in the highly developed western industrial societies about economic growth as the major goal of societal progress. The "social costs" of economic growth were cited, and there was increasing doubt about whether "more" should be

equated with “better.” The QOL concept which resulted from this discussion was posed as an alternative to the more and more questionable concept of the affluent society and entered discussions of social policy and politics as a new, but more complex, multidimensional goal.

As a goal of social and economic policy, QOL encompasses all (or at least many) domains of life and subsumes, in addition to individual material and immaterial well being, such collective values as freedom, justice, and the guarantee of natural conditions of life for present and future generations. The social scientific and policy uses of the QOL notion have been paralleled in the private sector by the widespread use and popularity of numerous rankings – based on weighted scales of multiple domains of well being – of the “best” places to live, work, do business, play, etc., be they cities, states, regions, or nations.

The theoretical appeal of the QOL concept as an integrating notion in the social sciences and related disciplines is, in part, due to the perceived importance of measuring individuals’ subjective assessments of their satisfaction with various life domains and with life as a whole. For instance, during the last two decades of the twentieth century, QOL became a concept that bridged the discipline of marketing research and strategic business policy with social indicators. Marketing is an important social force – with far reaching direct and indirect impacts on the prevailing QOL in a society – through consumer satisfaction and its impact on satisfaction with life as a whole. The intersection of marketing research with social indicators through the QOL concept led to the organization in the mid 1990s of the multidisciplinary International Society for Quality of Life Studies (for more information, visit www.isqols.org).

Another key development occurred in the field of social indicators in the 1990s and 2000s: the field entered a new era of the construction of composite or summary social indicators. Often these indices attempt to summarize indicators (objective and/or subjective) of a number of domains of life into a single index of the quality of life for the population or society as a whole or for some significant segment thereof (e.g., children and youth, the elderly, racial and minority groups, cities, states, or regions within the nation, etc.). They thus attempt to answer one

of the original questions motivating the Social Indicators Movement: how are we doing overall in terms of the quality of life? With respect to our past? With respect to other comparable units (e.g., cities, states, regions, nations)? Many of the pioneers of the Social Indicators Movement in the 1960s and 1970s felt that the database as well as the theoretical foundations were not sufficient at that time for the development of composite indices and that efforts should, instead, be concentrated on conducting basic research on social indicators and the measurement of the quality of life and the development of a richer social database.

Since the 1960s, however, there has been a tremendous increase in the richness of social data available for many societies. There also has been an accumulation of studies and theoretical developments with respect to subjective well being and quality of life studies. This has encouraged a new generation of social indicators researchers to return to the task of composite index construction. Some examples: (1) at the level of the broadest possible comparisons of nations with respect to the overall quality of life, the Human Development Index (United Nations Development Program 2004); (2) at the level of comparisons at the national level over time in the United States, the Fordham Index of Social Health (Miringoff & Miringoff 1999); and (3) for a specific subpopulation, the Child Well Being Index developed by Land et al. (2001). The field of social indicators and quality of life research probably will see several decades of such index construction and competition among various indices – with a corresponding need for careful assessments to determine which indices have substantive validity for which populations in the assessment of the quality of life and its changes over time and social space.

TYPES OF INDICATORS

Policy/Welfare/Criterion Indicators

Based on the premise that social indicators should relate directly to social policymaking considerations, an early definition by economist Mancur Olson, the principal author of *Toward a Social Report*, characterized a social indicator

as a “statistic of direct normative interest which facilitates concise, comprehensive and balance judgments about the condition of major aspects of a society” (US Department of Health, Education, and Welfare 1969: 97). Olson went on to state that such an indicator is, in all cases, a direct measure of welfare and is subject to the interpretation that if it changes in the “right” direction, while other things remain equal, things have gotten better, or people are better off. Accordingly, by this definition, statistics on the number of doctors or police officers could not be social indicators, whereas figures on health or crime rates could be.

In the language of policy analysis, social indicators are “target” or “output” or “outcome” or “end value” or “criteria” variables, toward changes in which some public policy (program, project) is directed. Such a use of social indicators requires that (1) society agrees about what needs improving; (2) it is possible to decide unambiguously what “getting better” means; and (3) it is meaningful to aggregate the indicators to the level of aggregation at which the policy is defined.

In recognition of the fact that various other meanings have been attached to the term social indicators, the tendency among recent authors is to use a somewhat different terminology for the class of indicators identified by Olson. For instance, Land (1983) termed this the class of *normative welfare indicators*. Building on the Olson approach, MacRae (1985: 5) defined *policy indicators* as “measures of those variables that are to be included in a broadly policy relevant system of public statistics.”

Life Satisfaction and/or Happiness Indicators

Another class of social indicators has its roots in the work of Campbell et al. (1976), who argued that the direct monitoring of key social psychological states (attitudes, expectations, feelings, aspirations, and values) in the population is necessary for an understanding of social change and the quality of life. In this approach, social indicators seek to measure psychological satisfaction, happiness, and life fulfillment by using survey research instruments that ascertain the subjective reality in which people live. The result may aptly be termed *life satisfaction, subjective well being, or happiness indicators*.

This approach led to many methodological studies exploring the utility of various survey and analytic techniques for mapping individuals’ feelings of satisfaction with numbers aspects (“domains”) of their experiences. These studies examine domains ranging from the highly specific (house, family, etc.) to the global (life as a whole). A large number of other studies and applications of these concepts and techniques have appeared over the past three decades and continue to appear – one or more studies of subjective well being indicators can be found in almost any issue of the journal *Social Indicators Research* and the *Journal of Happiness Studies*.

The principle that the link between objective conditions and subjective well being (defined in terms of response to sample survey or interview questions about happiness or satisfaction with life as a whole) is sometimes paradoxical and therefore that subjective as well as objective states should be monitored is well established in the social indicators literature. However, numerous studies of the measurement and psychodynamics of subjective well being over the past three decades have led to a better understanding of this construct. While research continues and it would be incorrect to say that the debates have been settled, it appears that this construct may have both *traitlike* (i.e., a durable psychological condition that differs among individuals and contributes to stability over time and consistency across situations) and *statelike* (i.e., a condition that is reactive to situational differences and thus potentially amenable to influence by social context and public policies) properties.

With respect to the statelike properties of subjective well being, Davis (1984) used an accumulated sample from several years of NORC General Social Surveys to document the responsiveness of happiness with life as a whole to (1) “new money” (recent changes in respondents’ financial status as opposed to current income level), (2) “an old man/lady” (being married or having an intimate living partner), and (3) “two’s company” (a household size of two as compared to living alone or families of three or more). Numerous other studies have found additional factors that are more or less strongly associated with variations in subjective well being. But the relevance of intimate living conditions/family status almost always is

replicated. The connection of subjective well being to income levels has been a particularly intriguing problem for social indicators researchers ever since Easterlin's (1973) finding that income differences between nations predicted national differences in happiness but that the association of happiness with income within countries was much weaker. Easterlin's study has stimulated a large literature on the relationship of income to subjective well being; for a recent review of this research literature, see Diener and Biswas Diener (2002). Suffice it to say that the last word is not in on this subject and that the theoretical and applied importance of the relationship will continue to be a focus of research interest.

Descriptive Social Indicators

Building on the Ogburn legacy of research on social trends, a third approach to social indicators focuses on social measurements and analyses designed to improve our understanding of what the main features of society are, how they interrelate, and how these features and their relationships change. This produces *descriptive social indicators* – indices of the state of society and changes taking place therein. Although descriptive social indicators may be more or less directly (causally) related to the well being goals of public policies or programs and thus include policy or criterion indicators, they are not limited to such uses. For instance, in the area of health, descriptive indicators might include preventive indicators such as the percent of the population that does not smoke cigarettes, as well as criterion indicators such as the number of days of activity limitations in the past month or an index of self reported satisfaction with health.

The various statistical forms that descriptive social indicators can take were described by Land (1983). These can be ordered by degree of abstraction from those that require only one or two data series and little processing (e.g., an age specific death rate) to those that involve more complicated processing into a single composite or summary index (e.g., years of life expectancy at age x , years of active or disability free life expectancy at age x). Descriptive social indicators can be formulated at any of these levels of abstraction. Moreover, these

indicators can, at least in principle, be organized into demographic or time budget based systems of social accounts.

FUNCTIONS OF INDICATORS

The Enlightenment Function

The Social Indicators Movement was motivated by the principle that it is important to *monitor changes over time* in a broad range of social phenomena that extend beyond the traditional economic indicators and that include *indicators of quality of life*. Many organized actors in contemporary society – including government agencies, organizations and activists interested in social change programs, scholars, and marketing researchers interested in market development and product innovations – monitor indicators in which they have a vested interest and want to see increase or decline (Ferriss 1988).

A second principle that has been part of the Social Indicators Movement from the outset is that a critically important role of social indicators in contemporary democratic societies is *public enlightenment through social reporting*. In brief, modern democracies require social reporting to describe social trends, explain why an indicator series behaves as it does and how this knowledge affects interpretation, and highlight important relationships among series.

It also is important to document the consequences that are reasonably attributable to changes in a series. This includes the systematic use of social indicators to *forecast trends in social conditions and/or turning points therein*. To be sure, the area of projection or forecasting is filled with uncertainties. Techniques range from the naïve extrapolation of recent trends to futuristic scenario construction to complicated model building with regression, time series, or stochastic process techniques. Demands for the anticipation of the future (at a minimum, for the description of “what will happen if present trends continue”), for foresight and forward thinking in the public and private sectors, and for the assessment of critical trends appear to be an intrinsic part of contemporary post industrial societies. Thus, it is prudent to expect that the “anticipation” task will become an increasingly

important part of the enlightenment function of social indicators.

As the decades of the 1990s and 2000s unfolded, the model of a comprehensive national social report in the tradition pioneered by Ogburn and Olson clearly had faltered in the United States, at least in the sense of federal government sponsorship and/or production. But the key ideas of monitoring, reporting, and forecasting were evident to greater or lesser extents in the production of continuing, periodic subject matter specific publications by various federal agencies, including *Science Indicators* (published by the National Science Foundation), *The Condition of Education* (published by the Department of Education), the *Report to the Nation on Crime and Justice* (published by the Department of Justice), and numerous Bureau of the Census publications. Special topics involving groups of federal agencies also receive attention from time to time. For instance, the Federal Interagency Forum on Child and Family Statistics began in 1997 an annual publication on *America's Children: Key National Indicators of Well Being*. In addition, the United States has numerous private research organizations, policy institutes, and scholars that continue to produce reports, monographs, and books interpreting social trends and developments in various areas of social concern.

In contrast to the situation in the United States, comprehensive social reports/social indicators compendiums continue to be published periodically in several other countries. Examples are the *Datenreport* series published biannually since 1983 by the Federal Republic of Germany, the *Social and Cultural Report* published biannually by the Social and Cultural Planning Office of The Netherlands, and *Australian Social Trends* published annually by the Australian Bureau of Statistics. Citations and summary reviews of these and other social indicators/social reports publications can be found in the quarterly newsletter and review of social reports, *SINET: Social Indicators Network News* (for access, see www.soc.duke.edu/resources/sinet/index.html).

The difference in the organization of social indicators/reporting work in the United States as compared to that in other countries is in part attributable to the lack of a central statistical office responsible for the coordination of all

government statistical activities in the former. More generally, it is indicative of the fact that, despite the invention of the ideas of social indicators and comprehensive social reporting in the United States, the nation has lagged in their institutionalization. Whether a new round of legislative effort will eventually create the necessary institutional base remains to be seen.

The Policy Analysis Function

Policy analysts distinguish various ways of guiding or affecting public policy, including *problem definition*, *policy choice and evaluation of alternatives*, and *program monitoring* (MacRae 1985). The social reporting/public enlightenment approach to social indicators centers around the first of these, namely, the use of social indicators in problem definition and the framing of the terms of policy discourse. Indeed, studies of the actual use of social indicators suggest that this is precisely the manner in which they have affected public action. But policy analysts from Olson to MacRae always have hoped for more from social indicators, namely, the shaping of public policy and planning through the policy choice process.

Land and Ferriss (2002) noted that the following *model for directed social change* emerged during the 1990s concerning policy uses of social indicators in such areas as health, education, and the welfare of children and youth in the United States:

- *Identify trends in criterion indicators*, the direction or rate of change of which should be changed.
- *Gather together intelligence* from experiments, field research, or theory that suggests what should be done to bring about the desired change.
- *Launch a decentralized program to effect change in specific criterion indicators* by specific amounts, to be attained by a target date.
- *Monitor progress* by periodically assessing trends on the specific indicators, modifying strategies as needed.
- As initial goals are reached, *set new goals* for continued progress.

Land and Ferriss (2002) developed a more complete articulation of this scheme in the

form of a sociological model that accommodates both the enlightenment and policy analysis functions of social indicators. They noted that identifying such goals and setting about altering their direction or rate of change is a process called *telesis*, which means “progress that is intelligently planned and directed; the attainment of the desired ends by the application of intelligent human effort to the means.” The further development and application of this conceptual framework may provide the foundations for the policy analytic use of social indicators in the future.

social influence

Lisa Rashotte

Social influence is defined as change in an individual’s thoughts, feelings, attitudes, or behaviors that results from interaction with another individual or a group. Social influence is distinct from conformity, power, and authority. Conformity occurs when an individual *expresses* a particular opinion or behavior in order to fit in to a given situation or to meet the expectations of a given other, though he does not necessarily hold that opinion or believe that the behavior is appropriate. Power is the ability to *force or coerce* a particular way by controlling her outcomes. Authority is power that is believed to be *legitimate* (rather than coercive) by those who are subjected to it.

Social influence, however, is the process by which individuals make *real* changes to their feelings and behaviors as a result of interaction with others who are perceived to be similar, desirable, or expert. People adjust their beliefs with respect to others to whom they feel similar in accordance with psychological principles such as balance. Individuals are also influenced by the majority: when a large portion of an individual’s referent social group holds a particular attitude, it is likely that the individual will adopt it as well. Additionally, individuals may

change an opinion under the influence of another who is perceived to be an expert in the matter at hand.

French and Raven (1959) provided an early formalization of the concept of social influence in their discussion of the bases of social power. For French and Raven, agents of change included not just individuals and groups, but also norms and roles. They viewed social influence as the outcome of the exertion of social power from one of five bases: reward power, coercive power, legitimate power, expert power, or referent power. A change in *reported* opinion or attitude (conformity) was considered an instance of social influence whether or not it represented a true private change.

French and Raven's original research was concerned with situations in which a supervisor influences a worker in a work situation. Subsequent scholarship has examined a wide variety of other social interactions, including families, classrooms, doctors and their patients, salespeople and customers, political figures, and dating couples. Work settings also continue to be a prominent topic for studies of social influence.

Since 1959, scholars have distinguished true social influence from forced public acceptance and from changes based on reward or coercive power. Social researchers are still concerned with public compliance, reward power, and coercive power, but those concerns are differentiated from social influence studies. Current research on social influence generally uses experimental methodology and tends to fall into five main areas: (1) minority influence in group settings, (2) research on persuasion, (3) dynamic social impact theory, (4) a structural approach to social influence, and (5) social influence in expectation states theory. Each is discussed below.

Minority influence is said to occur when a minority subgroup attempts to change the majority. For example, teachers often influence their students' beliefs, and political and religious leaders frequently influence the behavior of their followers. While some previous research has characterized the process of social influence as the majority riding roughshod over the minority, many scholars interested in minority influence believe that every member of a group can influence others, at least to some degree. Studies have found this to be particularly true

when the minority group is consistent in what it presents to the majority.

In addition, the presence of minority groups within a larger group often leads to more creative thinking and better overall solutions on group tasks. Nemeth and Kwan (1987) demonstrated this in a study of four person groups working on a creativity task. Individuals were given information that a majority (3 of 3) or a minority (1 of 3) of the other group members had come up with a novel response to the task at hand. Those who were in the minority condition actually produced more correct solutions to the task, indicating the strong effect of minority viewpoints.

Current research on persuasion, broadly defined as change in attitudes or beliefs based on information received from others, focuses on written or spoken messages sent from source to recipient. This research operates on the assumption that individuals process messages carefully whenever they are motivated and able to do so. Two types of theories dominate modern persuasion research: the elaboration likelihood model and heuristic systemic models.

The elaboration likelihood model developed by Cacioppo, Petty, and Stoltenberg (1985) has been used most frequently (and very effectively) in therapeutic and counseling settings. It states that the amount and nature of thinking that a person does about a message will affect the kind of persuasion that the message produces. Aspects of the persuasion situation that have been shown to be important for this model include source, message, recipient, affect, channel, and context. Of particular importance is the degree to which the recipient views the message's issue as relevant to himself. This model has demonstrated its utility in persuading various people to make various types of healthier choices (e.g., cancer patients, those at risk from HIV/AIDS, teens at risk from tobacco use, etc.).

Heuristic systemic models propose that argument strength will be most effective in persuading an individual when she is motivated and able to attend to the message (the "systemic" route). When the target individual is not motivated or is unable to attend carefully, persuasion will take place through more indirect means (the "heuristic" route), such as nonverbal cues or source credibility. Persuasion that takes place

via the systemic route will be relatively permanent and enduring; persuasion through the heuristic route is more likely to be temporary.

Broader than persuasion, social impact theory, as developed primarily by Bibb Latane (1981), forms the basis for an active line of inquiry today called dynamic social impact theory. Social impact means any of the number of changes that might occur in an individual (physiological, cognitive, emotional, or behavioral) due to the presence or action of others, who are real, imagined, or implied. Social impact theory proposes that the impact of any information source is a function of three factors: the number of others who make up that source, their immediacy (i.e., closeness), and their strength (i.e., salience or power). Impact also may be attenuated by impediments to the operation of any of the three factors.

Dynamic social impact theory (Latane 1996) uses these ideas about social impact to describe and predict the diffusion of beliefs through social systems. In this view, social structure is the result of individuals influencing each other in a dynamic and iterative way. The likelihood of being influenced by someone nearby, rather than far away, (the *immediacy* factor noted above) produces localized cultures of beliefs within communication networks. This process can lead initially randomly distributed attitudes and beliefs to become clustered or correlated; less popular beliefs become consolidated into minority subcultures. Dynamic social impact theory views society as a self organizing complex system in which individuals interact and impact each others' beliefs.

Like dynamic social impact theory, the structural approach to social influence examines interpersonal influence that occurs within a larger network of influences. In this larger network, attitudes and opinions of individuals are reflections of the attitudes and opinions of their referent others. Interpersonal influence is seen as a basis of individuals' socialization and identity. Social influence is seen as the process by which a group of actors will weigh and then integrate the opinions of significant others within the context of social structural constraints. The structure determines the initial positions of group members and the network and weight of interpersonal influences within the group.

Social influence network theory, as described by Friedkin (1998), has its roots in work by social psychologists and mathematicians, including French. The formal theory involves a two stage weighted averaging of influential opinions. Actors start out with their own initial opinions on some matter. At each stage, then, actors form a "norm" opinion which is a weighted average of the other opinions in the group. Actors then modify their own opinion in response to this norm, forming a new opinion which is a weighted average of their initial opinion and the network norm. This theory utilizes mathematical models and quantifications to measure the process of social influence.

Expectation states theory provides another formal treatment of social influence. Rooted in the work of Bales (1950), which found inequalities in the amount of influence group members had over one another, researchers in this tradition have developed systematic models predicting the relative influence of task oriented actors in group settings. Bales discovered that even when group members were equal on status at the beginning of the group session, some members would end up being more influential than others. The group would develop a hierarchy based on the behavior of the group members. When group members were initially unequal in status, inequalities would be imported to the group from the larger society such that, for example, age or sex or race would structure a hierarchy of influence.

Expectation states theory, as described in Berger et al. (1980), was originally proposed as an explanation for Bales's finding that groups of status equals would develop inequalities in influence. According to the theory, group members develop expectations about the future task performance of all group members, including themselves. Once developed, these expectations guide the group interaction. In fact, expectations both guide and are maintained by the interaction. Those group members for whom the highest expectations are held will be the most influential in the group's interactions.

Research in the expectation states tradition has developed into a burgeoning area within sociological social psychology. Scholars are continuing to expand the theory both theoretically and substantively. On the theoretical side, developments include the status characteristics

branch, work on status creation, ideas about status interventions, and many others. More substantive or applied work has been conducted using expectation states approaches to social influence in settings such as classrooms, jury rooms, and the workplace. Status characteristics that produce influence have been identified and extensively studied, including sex, race, sexual orientation, and physical attractiveness.

Future work will need to integrate these approaches of minority influence, persuasion, social impact, the structure of social influence, and expectation states. While each approach has produced worthwhile knowledge thus far, a general model of social influence will need to incorporate group structures, the characteristics of the individuals in those structures, and the distribution of characteristics into majority and minority components.

social integration and inclusion

Rainer Strobl

Social integration refers to the interrelation of elements in a social system. The term social system is used in a broad sense here. It describes a social unit with a relatively stable order that establishes a border between itself and its environment. In this sense groups, organizations, or even whole nation states are examples of social systems. Traditionally, actors who are members of a social unit are regarded as the elements of a social system. However, in sociological works like Luhmann's *Social Systems* (1995) the elements are conceived more abstractly as actions or communications. This theoretical development reflects a social development of increasing functional differentiation and individualization with more demanding conditions for the coordination of the elements in a social system. In tribal societies the interrelation of elements is quasi natural. It is granted by clear expectations in strict kinship systems. But already feudal societies need elaborate catalogues of rights and duties, albeit these are conceived as God given and the individual is confronted with a clear set of norms in his social environment. With increasing functional differentiation in modern societies there is a decreasing involvement of actors as whole persons with all their abilities and social and psychological needs in a single social system. As a result, social integration is no longer self evident and becomes both a social and a theoretical problem.

The pioneer in the study of social integration, Durkheim (1970) presents two ways for

linking up elements of a social system and thus two types of social integration. On the one hand, his concept of mechanical solidarity stresses the traditional coordination of the elements in a social system through common values and beliefs. It implies tendencies common to all members of the society and the urge to conform to a "collective conscience." On the other hand, his concept of organic solidarity emphasizes a new form of integration through interdependence. It refers to the division of labor and the necessary cooperation of specialists. These two types of social integration are also known as normative and functional integration. Although Parsons (1967) approves of Durkheim's distinction between mechanical and organic solidarity, normative integration plays the dominant role in his work. It even encompasses functional integration and comes close to the notion of social order, which is a normative order in Parsons's theory. Although mechanical solidarity and organic solidarity are conceived as in Durkheim's work, Parsons emphasizes that organic solidarity also depends on common values and on norms of property, contract, market relations, etc. But unlike the norms of mechanical solidarity, these norms only set a framework for actors who then follow their individual interests. Apart from the mentioned two types of social integration there is another way of relating elements of a social system yet to be discussed: *conflict*. Georg Simmel demonstrated in "The Sociology of Conflict" (1903) that actors can be intensively linked by conflict. As soon as one gets involved in an escalating conflict more and more remarks and actions of the opponent become relevant in terms of intended discrimination or harm and are integrated into the system. Contrary to common belief, conflicts are social systems with a high degree of social integration. Thus, the opposite of social integration is not conflict but social disintegration. Conflicts arise if communication and interaction chains do not simply stop and disintegrate after the acknowledgment of a controversy, but begin to revolve around this controversy. Consequently, one has to acknowledge that there can be both too much and too little social integration.

Social integration has been discussed as being close to the general issue of social order. An additional aspect is how an element

becomes part of an existing social system. In this connection *assimilation* and *inclusion* can be regarded as modes of incorporating new elements. Assimilation refers to the possibility of becoming a member of a social unit by the acceptance and adoption of a given normative system. In this way the assimilation concept is traditionally used in migration literature. In Gordon's (1964) well known assimilation model the process starts with cultural and behavioral adaptation which opens access to cliques, clubs, and institutions on primary group level and the possibility of intermarriage. According to Gordon, this should lead to identification with the host society and finally to an absence of prejudice, discrimination, and value and power conflicts. However, Gordon concedes that a certain phase may continue indefinitely and thus the final state may never be reached. Conforming to important normative standards of cliques, clubs, and institutions on primary group level thus may grant access to functionally unspecific social systems and may fulfill the social and psychological needs of a person, but they cannot guarantee access to good jobs or good education in modern societies. In other words, assimilation refers to the sphere of the lifeworld. It involves the whole person who becomes a member of a group or community. Consequently, the person will be defined as a member of this group or community and her freedom to act will be restricted according to the normative system of this social unit. In this connection we can concede that once access is obtained there may start processes of negotiating social norms. Therefore, assimilation need not be conceived as a unidirectional process where (in the end) the minority has become a copy of the majority. But at least there is the idea of a cultural nucleus that has to be accepted (Alba & Nee 2003).

As in modern societies integration into the sphere of the lifeworld does not automatically lead to participation in function systems like the economy, science, the educational system, or the justice system, there has to be a mechanism for participation in these systems. This mechanism is called inclusion. *Inclusion* means that specific competences and actions of a person are relevant for a social system. Accordingly, no individual is completely integrated into only one function system (Luhmann 1995). The adoption of specific cultural norms

is not a precondition for inclusion. Sometimes it is even the violation of norms that facilitates inclusion. An example is rap music. Some famous rap musicians violate diverse cultural and even legal norms. However, this behavior helps to make them relevant for the music industry and to include them into the economic system. The freedom for the individual to violate norms in some social areas and nevertheless be included in function systems is a result of the fact that only specific roles of an individual, or more precisely, only particular actions and communications contribute to the processing of a function system. For the economic system, it is the crucial question if someone can pay or not, for the justice system it is the difference between right and wrong, for science it is the difference between true and false, etc. Of course, the basic norms of the particular function system have to be accepted (e.g., the norms of property and contract in economy or theoretical and methodological standards in science). However, some one from abroad can be an important business partner without accepting the moral or cultural standards of the country and someone who is disrespectful towards his wife can have valuable scientific insights. The necessary condition for relevance in a function system is the availability of the respective media, such as money, knowledge, power, etc. On the other hand, a lack of money, knowledge, or power prevents inclusion in the particular system and implies the danger of exclusion from all function systems. People in this situation (e.g., illegal immigrants, the homeless) are not relevant as taxpayers, consumers, or voters and are reduced to social problems or completely lost from sight.

As participation in function systems is essential in modern societies, there are instruments to improve the abilities and resources of disadvantaged and excluded individuals. In particular, the institutions of the welfare state can be conceived as means to safeguard against exclusion and to reinclude the excluded. Efforts to integrate migrants – improvement of legal status, language courses, financial support, etc. – also aim at the chances of inclusion. Assimilation, on the other hand, cannot be achieved by institutional actors because they typically address a person in the specific role of a client. However, the change of cultural habits and personal convictions would involve the whole person.

Therefore, this is beyond their capability. It may not even be desirable to support a strong commitment to family, friends or the local, religious, or ethnic community. This form of social integration may for example prevent a person from moving to another town for a job or from attending a university and thus turn out as an obstacle to inclusion. Therefore, to improve inclusion it may be necessary to loosen social integration into primary groups and to support normative disintegration to a certain degree. On the other hand, a strong commitment to the demands of the function systems and a neglect of the lifeworld may lead to dissatisfaction, emotional problems, or even psychosomatic symptoms. As function systems dominate modern societies, there are reasons for complaints about the colonization of lifeworlds. However, as Weber pointed out in *Economy and Society* (1968), integration into a group or a community can also go along with oppression and the restriction of chances in life. In traditional societies, those who are not willing or who are not able to conform to the norms of the family and the community often have to face massive sanctions. In this respect inclusion as a new form of social integration means more freedom for the individual. But in contrast to the clear cut normative environment of traditional societies and groups, inclusion also means participation in different social systems with heterogeneous demands. In modern societies the individual is not undivided in the Latin meaning of the word, but divided into different roles and only specific actions and communications are relevant for the function systems and are included into their processing. From the perspective of the individual, there are no ready made solutions for the integration of the included and excluded facets of his personality into a meaningful identity, as from the perspective of society there is no master scheme for the integration of the different subsystems into a consistent whole. Under these circumstances, assimilation to the rigid but clear norms of ethnic, religious, or political fundamentalism can become a tempting alternative. It will be a challenging task for future research to analyze the possibilities and risks for a compromise between the demands of lifeworld and function systems and for a balance between assimilation and inclusion.

social justice, theories of

Karen A. Hegtvædt

Justice, in its many guises, is a fundamental principle ensuring order in social groups ranging from small, intimate circles of friends to large, diverse societies. Its counterpart, injustice, arises when expectations about distributions, procedures, or interactions are unmet. Such unmet expectations stimulate the potential

for change, both trivial and profound. *Distributive justice* pertains to the fairness of the allocation of rewards or burdens to a circle of recipients. *Procedural justice* captures the fairness of the means by which distributions are made. *Interactional justice* refers to fairness in the treatment of individuals within a group. These formal definitions, however, beg the fact that what individuals perceive as fair is subjective. That subjectivity pervades the two general approaches of the sociological study of justice.

One approach analyzes the social injustices wrought by income inequality, racism, sexism, etc. Theories about differences between groups based on income, skin color, gender, etc. are addressed elsewhere in this encyclopedia. Such perspectives focus on the origins and consequences of the differences, and implicitly raise the specter of injustice in considering fairness of the distribution of resources to each group and the treatment of group members based on their (subjectively devalued or presumed inferior) characteristics. In a related vein, debates over the distribution of societal goods (e.g., health care, jobs, housing) and societal burdens (e.g., hazardous wastes, taxes) to different groups in society also constitute issues of social justice. Social movements, while caused by many factors and requiring resources and organization, may rally individuals with cries of injustice and signal changes to redress injustice.

The second approach, which is largely the focus of this entry, examines the intersection of individuals' objective circumstances, their perceived realities, and their behaviors in order to grasp what people believe is just and how they respond to perceived injustices. In pursuing this second approach, social psychologists have developed theoretical frameworks and cumulated empirical results to explain distributive, procedural, and interactional justice issues more broadly. Such explanations, in turn, may inform the study of social injustices.

DISTRIBUTIVE JUSTICE

Theoretical perspectives on distributive justice address in various ways three key questions: What is justice? Why do people differentially perceive injustice? How do people respond to

perceived injustice? Most theoretical approaches focus singularly on one of these questions. Guillermina Jasso (2001), however, offers a theoretical framework for justice analysis that includes the building blocks to address all of the key questions.

Jasso identifies the following as abstract components of determining what is just: the observer, who makes judgments about justice, and the rewardees, who are recipients of whatever is being distributed (observers may also be rewardees). The theory focuses on the observer's beliefs about the just reward and its application to the rewardees, given their characteristics. The application results in a just reward function which, when summed over rewardees, ensures the just reward distribution.

Combining these abstract building blocks reflects prior theorizing on distribution rules and allocation preferences (e.g., Leventhal et al. 1980). Distribution rules specify how outcome levels should correspond with individual characteristics (i.e., just reward functions). Three basic principles are equality, equity, and needs. Distinct from the others, the equality principle ignores individual characteristics, focusing instead on the equality of outcomes. The equity principle assumes that contributions, status, effort, etc. constitute inputs that entitle actors to commensurate levels of rewards. Equity also typically implies a comparison of outcome to input ratios across individuals. The needs principle likewise emphasizes commensurability with outcomes.

Leventhal et al.'s expectancy value perspective argues that various motivations (e.g., self interest, fairness, expedience) coupled with expectations about which principle enhances the likelihood of achieving differentially valued goals (e.g., group harmony, productivity, group welfare) predict distribution rule preference. Although the theoretical framework recognizes different motivations, what is preferred shapes what individuals believe to be fair or, in Jasso's terms, the observer's beliefs about the just reward. The theory allows that situational circumstances do affect underlying motivations and the value of goals. For example, conditions emphasizing impartiality, attention to the welfare of others, emphasis on a currently blatantly unfair distribution, open discussion

of distribution principles, and/or politeness typically produce distribution preferences that differ from those associated with self interest. Thus individuals' own concerns and circumstances influence what they believe to be just.

Recognition of variation in the social positioning of individuals is one means to explain why people differentially perceive injustice. Indeed, there tends to be an egocentric bias in what people believe is just, although situational factors (e.g., role demands, concern for others) and individual characteristics (e.g., gender, specific belief systems) may attenuate it (Hegtvedt & Markovsky 1995). In addition to objective circumstances and personal motivations, actors' subjective evaluations of what is just stem from perceptions about a given situation and comparisons invoked.

A number of empirical studies attempt to address how beliefs and perceptions affect evaluations of injustice. Drawing from attribution theory and notions about cognitive processing, individuals are more likely to weigh internally caused inputs (e.g., effort, ability), which are under the control of an actor, as a more suitable basis for deriving an equitable distribution than externally caused inputs. Schema about pay levels and pay processes also provide a standard for assessing justice.

Such standards are a form of non social comparisons, but may stem from prior social comparisons. Early theoretical work in the expectation states tradition (Berger et al. 1972) highlighted the importance of both the status value of outcomes (not simply their consumatory value) as well as various types of comparisons. This status value formulation argues that people develop stereotyped ideas of how social characteristics go with particular rewards. These ideas constitute referential structures. Thus, when an individual assesses his or her reward level or outcome/input ratio, the comparison may be to that of another individual (i.e., a local comparison) or to that inherent in a referential structure representing what people with the given characteristics generally get. The latter comparison puts individual rewards into a broader perspective and raises the possibility of the combination of comparisons. Other comparisons include those to one's past (internal comparisons) or between one's group and another group.

Jasso (1980) captures mathematically the potential for variation in the magnitude of perceived injustice (i.e., degrees of under and overreward) stemming theoretically from differences in cognitions and comparisons. The justice evaluation (J) represents the observer's judgment that someone (including self) is justly or unjustly rewarded. The formula for J defines the justice evaluation in terms of the comparison between the actual reward received and the amount considered just, which implicitly stems from the observer's motivations, perceptions, and comparisons, as discussed above. The formula includes a numerical coefficient that designates the reward as a good or as a bad, and that allows the transformation of the experience of the justice evaluation into an expressed evaluation. An array of observer–rewardee justice evaluations may create a matrix or index to capture the overall injustice in a group or society. Such an array may also distinguish variation in the experience of injustice, bolstering the subjectivity of the evaluation.

Evaluations of injustice are likely to engender emotional, psychological, and behavioral reactions. Adams' (1965) classic formulation of equity theory specifies non mathematically how individuals are likely to respond to perceived injustice, while Jasso's (2001) more recent statement offers a mathematical approach. Adams suggested that individuals who feel unjustly treated are likely to feel distress, and as self-interested actors are likely to be motivated to eliminate unpleasant feelings and restore justice in the least costly manner. Homans elaborated on the concept of distress, arguing that underrewarded actors are likely to feel anger while overrewarded ones may feel guilt. Although cumulated studies document the anger responses, the guilt response remains more equivocal. Likewise, research tends to support Adams's behavioral strategies for restoring equity (e.g., increasing inputs if overrewarded, increasing outcomes if underrewarded), but few studies address psychological mechanisms (e.g., cognitively altering the value of inputs and outcomes) or compare the conditions under which one strategy or another will be chosen. Adams's formulation is focused on individual level reactions, while Jasso's further allows for the possibility of collective reactions.

Most theorizing and research in distributive justice pertains to individual level phenomena, largely because it is individuals who assess whether or not injustice has occurred. As a result, perceptions of justice are sometimes confounded with feelings of deservingness and, ironically, equated with assessments of self-interest. Yet, as philosophical treatises on justice and the implicit moral underpinnings of social psychological approaches suggest, distributive justice ensures more than the welfare of an individual. Rather, it engenders beliefs that a fair distribution will benefit the collectivity more broadly by upholding consensual values and suppressing bias. The emphasis on the group, while somewhat lost in considerations of distributive justice, is the cornerstone of the key theoretical approaches to procedural and interactional justice.

PROCEDURAL AND INTERACTIONAL JUSTICE

Although the three key questions characterizing distributive justice research also apply to procedural justice, the development of this area is marked chronologically by several classic contributions. Thibaut and Walker (1975) first drew attention to the notion of procedural justice in the legal context. They argued that people are concerned about the procedures involved in decision making, especially in conflict situations, because they affect outcome levels. Certain rules could ensure procedural justice (Leventhal et al. 1980): (1) consistency of procedures across persons; (2) suppression of bias; (3) accuracy of information; (4) mechanisms to correct bad decisions; (5) representativeness of the participants to a decision; and (6) ethicality of standards. Lind and Tyler (1988), however, documented that adherence to such rules is important to people independent of outcome levels and in a variety of contexts. As an alternative to Thibaut and Walker's "instrumental" approach to fair procedures, they offered a group value approach that has become the theoretical touchstone for both procedural and interactional justice, especially in the area of organizational research.

The group value approach assumes that people want to be valued members of their group

and that they look to procedures within the group to provide them with information about their position in the group. To the extent that authorities employ fair procedural rules, such as giving individuals the opportunity to voice their concerns prior to a decision (e.g., allowing representativeness), they are likely to feel valued by the group. The use of fair procedures, moreover, solidifies the group structure and values, enhancing individuals' pride in their group. In addition, authorities who treat their subordinates in a trusting, respectful, and unbiased fashion are likely to be viewed as procedurally fair. In effect, Tyler and Lind (1992) recognize two forms of procedural justice: (1) the rules underlying the process of decision making; and (2) the polite and dignified treatment of members of the group. Some researchers (Bies & Moag 1986) contend that the second constitutes a unique form: interactional justice.

Regardless of the labeling, a great deal of research specifies what rules appear to be procedurally fair, the relationship between procedural and distributive justice, and the implications of procedural injustice (see Tyler et al. 1997). Research indicates that people perceive rules such as consistency and representativeness as key to ensuring procedural justice. Also important to procedural justice evaluations are the reasons certain procedures are invoked. Providing a rationale for a decision allows evaluators to make more accurate attributions and demonstrates respect for their ability to understand why authorities made a certain decision.

Lind and Tyler (1988) emphasize the importance of procedures for understanding evaluations of distributive justice as well. Individuals are more likely to tolerate unfair or low outcomes if the procedures by which they were produced are perceived as fair. Two theoretical frameworks detail why this is so. Folger's (1986) referent cognition theory suggests that when people receive an unfair outcome, they examine the procedures or "instrumentalities" responsible for their outcomes. Comparisons between what actually happened and what could have happened (the referent cognitions) affect the perceived severity of the distributive injustice. Also relying upon cognitions, van den Bos et al. (2001) argue that people use whatever information they have to substitute for information

that might be more relevant but is missing (e.g., other people's levels of rewards). Their "fairness heuristic theory" argues that procedural information provides an individual with knowledge of his or her value to the group, which in turn underlies feelings of inclusion that affect acceptance or rejection of outcomes. When people have more information on outcomes upon which to make their distributive justice evaluations, they are less likely to rely upon procedural information. Thus it is in the absence of information that individuals use procedures as a heuristic.

Because of the importance of procedures in and of themselves, however, the group value model specifies reactions to procedural injustice or, more generally, the implications of procedural unfairness. Like reactions to distributive injustice, individuals who perceive procedural injustice may feel angry and dissatisfied, as well as develop a dislike toward the perpetrators of the injustice. Procedural unfairness also threatens compliance with rules and with authorities in a variety of settings. For example, in dealing with law enforcement officers, individuals are more likely to comply with their requests if they are treated in a polite, respectful manner. In organizational settings, procedural justice is likely to enhance organizational commitment and organizational citizenship behaviors (Colquitt et al. 2001). The forays of procedural justice researchers into more applied areas reinforce the role of basic theory in understanding issues of social justice.

RELEVANCE OF THEORIES TO SOCIAL JUSTICE

Although varying in levels of abstract and underlying theoretical assumptions (e.g., self interest versus group value), the individual level theories of distributive, procedural, and interactional justice may inform the study of social justice issues such as income inequality, racism, sexism, etc. Indeed, in the past, many studies have focused on the fairness of distribution of income or privileges across groups (Hegtvedt & Markovsky 1995). People in western societies tend to view inequality as fair by focusing on the importance of individual contributions.

This perception varies cross nationally, however, depending upon strength of beliefs in the capitalistic economic system in comparison to beliefs in a welfare state. Similarly, justice theory has been brought to bear upon gender issues such as the fairness of the division of labor in the household. Like the role of belief systems in understanding perceptions of income inequality, gender roles attitudes tend to affect tolerance of inequality in the household division of labor. Understanding the ways in which people assess whether procedures or outcomes are fair or unfair may provide a basis for resolving conflicts occurring between different cultural and ethnic groups, especially as the demographics of these groups shift.

Theories of justice in social psychology have long assumed consensus on what is just or simply ignored the implications of different perceptions of injustice. However, as social injustices illustrate, such consensus is often illusive and the consequences profound for some groups. Several areas of research stemming from basic theoretical frameworks may contribute to a means to resolve social injustices. First, examination of social categorization processes and perceptions of similarity and dissimilarity may help to define the moral communities to which justice principles apply. Second, an understanding of the different interests and beliefs of groups may inform the likelihood and nature of conflict between groups (or individuals) and the potential role of a more general sense of justice (not simply justified self interest) in resolving competing claims. And third, a shift away from the typical predictions of what the disadvantaged are likely to perceive, feel, and do toward determining when people who benefit from current societal procedures and distributions are likely to step beyond their own self interests may inform understanding of social change and ultimately create a more consensual notion of justice.

social learning theory

Laura Auf der Heide

Social learning theory was developed in the 1950s by Albert Bandura as a direct response to strict behaviorism as a means for explaining how individuals learn about their social worlds. Instead of solely examining the result of the outside environment on individual behavior, social learning theory is concerned with the reciprocal influence of environmental cues on an individual's behavior and the impact of the individual's behavior on the environment. In addition, social learning theory places an emphasis on individuals' cognitive processes as they decide upon future courses of action. Thus, social learning theory takes a middle ground position between social psychological theories that stress either environmental or internal cognitive processes as the sole component of learning.

BEHAVIORISM

Social learning theory posits that people learn about their social worlds in two distinct ways. First, following in the tradition of behaviorism, individuals learn through direct experience with their environments, and the rewards and consequences that follow. Behaviorism espouses a phenomenon known as operant conditioning. In essence, through operant conditioning, behaviorists believe they can predict the future probability of behavior based on two types of contingency effects associated with a particular behavior. *Reinforcement contingencies* encourage an individual to keep repeating a task. *Punishment contingencies* serve to diminish a particular behavior. Similar to theories of social exchange and rational choice, behaviorism and social learning theory assume that individuals attempt to maximize their rewards and avoid punishments. For example, Carrie may learn that hitting her brother Bill is unacceptable when she is punished by her mother for that act. According to predictions of operant conditioning, Carrie should stop hitting Bill to avoid the negative sanction (punishment contingency). Similarly, Carrie might learn that

putting her clothes in the hamper is good when her mother praises her for that act. Here we would expect Carrie to keep putting her clothes in the hamper in order to continue receiving praise (reinforcement contingency). Numerous experimental studies have shown that behavior can be effectively increased or decreased through the use of different contingencies.

OBSERVATIONAL LEARNING AND MODELING

In addition to recognizing the importance of direct experience on learning, social learning theory also stresses the importance of observational learning, or modeling, the actions of others. Social learning theory posits that individuals do not have to experience consequences directly to determine the value of a particular action if they have been able to observe the consequences somebody else has received for it. Thus, in reference to the first example above, if Carrie watches her older sister Margaret get in trouble for hitting Bill, she will learn that hitting Bill has negative consequences without experiencing the negative consequences for her self. Given this information, Carrie will likely not hit Bill in the future unless the reward for hurting him is greater than the punishment she receives from her mother. In reference to the second example, if Carrie sees Margaret get rewarded for putting her clothes in the hamper, she may model Margaret's behavior and put *her* clothes in the hamper to get a reward.

The concept of modeling is intrinsic to the discussion of observational learning. Whenever we learn by observing someone else's rewards/consequences, that person becomes a model for that behavior, whether we choose to reenact that behavior ourselves or not. In the above examples, Margaret served as Carrie's model. Bandura (1973) proposes that there are four necessary conditions for observational learning and modeling. *Attentional processes* highlight the importance of an individual's awareness of a model performing an activity. Thus, mere exposure to the model is not enough for an individual to learn from the model's behavior; one must also pay attention to the behavior. *Retention processes* refer to the individual's capacity for long term memory of a model's

behavior. It is a necessary component of the learning process that an individual be able to reproduce the model's behavior even when the model is not physically present; one primary way of retaining the learned behavior is through rehearsal. *Motor reproduction processes* occur when an individual enacts what she has learned. However, Bandura stresses that individuals can learn particular behaviors without having acted them out themselves. For instance, Carrie learned that hitting Bill had consequences for Margaret without having to hit Bill herself. Finally, *reinforcement and motivational processes* are integral to observational learning. Although individuals learn behavior from others, they are less likely to enact the behavior themselves if they have seen others get punished for the behavior. These four conditions specify *when* individuals are likely to learn from others. However, there are three conditions under which individuals may be more or less likely to imitate a model once these four conditions have been fulfilled.

DETERMINANTS OF MODELING

Bandura has identified three determinants that affect whether an individual will model what she has learned. First, the model's characteristics matter. Social learning theory recognizes that an individual's status, power, and competence at a task will greatly impact whether others choose to model her. This perspective has been developed formally as expectation states theory. In our society, people assume that individuals with high status, power, or competence must know the correct way of doing things; thus, social learning theory would predict that individuals with these characteristics will be modeled more often. Second, the attributes of the individual learning from the model (or the observer) determine whether she will be more likely to model the behavior. Research has demonstrated that those who lack confidence, have low self-esteem, and are more dependent are more often rewarded for imitating high status people. Indeed, the status, power, and competence of the observer likely interact with the characteristics of the model to determine imitation: a low status person will be more likely to model a

high status person than the other way around. For example, research has shown that children model adults, but adults do not model children, a lower status group. In addition to status characteristics, research shows that those who are more open to learning through modeling often obtain the greatest gains when learning new skills (Bandura 1977). Third, as mentioned above, the response categories associated with a model's behavior directly influence whether an observer imitates that behavior. This is especially true when an individual sees a model get rewarded or punished for a particular action. However, when a model receives a neutral response for her actions, or an observer is unsure of the response consequences for an action, then the observer will be more likely to focus on the status of the model when determining her future course of action. Thus, an observer will more likely imitate a high status over a low status model if she does not know the outcomes of the model's actions. Observers tend to continue imitating models as long as they receive rewards for that action. If they start obtaining bad reactions for their actions, then they will seek out a new model.

Adding observational learning to behaviorism's focus on operant conditioning was a great advance for social learning theory. However, both direct and observational learning still emphasize the environment when predicting the behaviors of individuals. Social learning theory extends this to include individual cognitions as part of the learning process. Given the assumption that individuals desire to maximize rewards and minimize punishments, social learning theory posits that they learn to regulate themselves in order to obtain desired rewards. Social learning theory holds that when observing the response consequences of others, individuals begin to understand the future consequences of various actions they could take. This knowledge, gained through observation of the environment, allows individuals to plan what actions will allow them to obtain desired rewards extrinsically, as well as influence them to intrinsically motivate themselves to achieve external rewards. Over the long term, research has shown that individuals are more influenced by intrinsic than extrinsic rewards (Bandura 1977).

APPLICATIONS OF SOCIAL LEARNING THEORY

Within sociology, social learning theory has been applied primarily to the socialization process, aggression, and deviance. As already detailed, social learning theory can be usefully applied to examine how children learn about their social worlds. Through processes of imitation and conditioning, children learn how to speak, how to interact with others, and how to adopt the norms and values of society. Some sociological research has attempted to extend social learning theory to learning across the life course, in such diverse areas as organizational behavior and social movements.

Perhaps in its most famous application, Bandura utilized social learning theory to study aggression. In contrast to the evolutionary perspective on aggression, which roots aggression in the individual's biological makeup and psychological functioning, and the frustration-aggression hypothesis, which posits that individuals behave aggressively when they encounter a stimulus that psychologically frustrates them, social learning theory examines how the *external* son's aggressiveness. In a series of well known experiments, Bandura (1965) showed that children who watched models behave aggressively towards a blown up Bobo doll were more likely to imitate the behavior when the model received a reward or a neutral response for the aggression. However, children who watched the model receive a punishment were statistically less likely to imitate the model's behavior. As a result of these experiments, Bandura concluded that the aggression individuals evidence in the present is directly contingent upon the amount of aggression they have learned in the past. Furthermore, Bandura posits that observational learning is more important than operant conditioning when children learn aggression. Social learning theory's views on aggression have been used to support claims that violence in multimedia outlets, especially movies, television, and video games, leads children to become more aggressive. This perspective has become more popular in the wake of children's violence in schools in the late 1990s.

Social learning theory has also been usefully applied in sociology to the study of crime and deviance in the form of the theory of differential

association (Akers 1977). Akers's theory has four parts, two of which directly originate with social learning theory. First, the theory proposes that people associate with different groups (i.e., have differential association with groups), and as a result become exposed to the norms and values of those groups. Second, the groups with whom we choose to interact also provide us with significant definitions, symbols, and meanings. Most important to deviance, groups espouse definitions either favorable or unfavorable to delinquency. Third, like social learning theory, the theory of differential association predicts that individuals will engage in deviant acts if they receive positive reinforcement for them, and desist if they are punished for committing them. Most of the time, individuals will persist in deviant acts if the group reinforces that behavior. Finally, individuals imitate the behavior of individuals in their group, based on the three contingencies to modeling behavior specified above. Thus, if we see members of our group being delinquent, we see them receive positive rewards for that behavior, and they are high status in our eyes, we will be likely to imitate the deviant behavior. Although differential association was created specifically to explain deviant behavior, it could be usefully applied to most situations involving socialization to a particular group.

Classical tests of social learning theory, including Bandura's studies on aggression, employed experimental methodologies. However, more recent work using the social learning theory paradigm has successfully utilized survey instruments and interviews in an attempt to explain theoretical principles. Given social learning theory's attention to both individual and environmental phenomena, it is uniquely suited to explaining multiple facets of human behavior.

social movement organizations

Elizabeth A. Armstrong and Tim Bartley

Social movements organize people, resources, and ideas for social change. Many do this through formal organizations, and most sociologists recognize the social movement organization (SMO) as a key factor in the study of movements. SMOs can be defined as formal organizations that take the collective pursuit of social change as a primary goal. This concept is trickier than it may initially seem, since it relies on two concepts that are themselves difficult to define. Scholars generally define social movements as contentious forms of collective action operating at least partly outside institutionalized politics. Yet scholars disagree about how significant the desired change needs to be and what it means to work outside of institutionalized politics. Common definitions of organizations – as goal directed, boundary maintaining, and rule governed groups – are somewhat less contentious.

Many social movement groups, both past and present, are clearly identifiable as SMOs – for example, the Student Non Violent Coordinating Committee (SNCC), War Resisters League, Greenpeace, United Students Against Sweatshops, the National Gay and Lesbian Task Force, and many others. Other groups, however, are more ambiguous. Some groups

are insufficiently organized or change oriented to be considered SMOs. For instance, Gay Liberation Fronts existed in many US cities in the early 1970s, but it is unclear if they ever cohered into formal organizations. In contrast, the AFL CIO is highly organized, but at some points it has perhaps been too entrenched in “normal politics” to fit standard definitions of an SMO. Sociologists have not hit upon a simple formula for deciding what is and is not an SMO. In practice, they have often drawn on lay understandings – that is, treating a group as an SMO if its participants see themselves as building an organization that participates in a movement.

Organizations have not always been central to social movement research. Early theories saw mass activity as rooted in social *disorganization*. Studies of crowd behavior and mid century “mass society” theories treated collective action as the result of alienation, social isolation, and authoritarian tendencies. Similarly, “strain theory” argued that social movements were caused by structural shifts that produced social disintegration and the breakdown of existing organizational and institutional structures.

The Civil Rights Movement had a profound impact on the study of social movements. Sociologists' sympathies with the movement contributed to the rise of theories that treated activism as rational political activity requiring resources and organization instead of irrational, spontaneous collective behavior. This shift moved SMOs to the center of the analysis, carried by two influential theories – resource mobilization and political process. Resource mobilization theory developed in part as a response to the professionalization of social movements in the later years of the Civil Rights Movement. McCarthy and Zald (1977) argued that the rise and fall of movements is best explained by the resources available for building and maintaining organizations, not by grievances, which were seen as relatively constant. The resource mobilization paradigm, more than any other approach, put the structure and strength of SMOs at the center of the analysis. Political process theory also drew attention to organizations, viewing social movements as “politics by other means” for those excluded from the formal polity (McAdam 1982). Researchers in this tradition have shown not

only that political opportunities shape mobilization, but also that grassroots organizational infrastructures are critical, as illustrated by the important role that black churches and colleges played in the Civil Rights Movement.

Syntheses of resource mobilization and political process approaches solidified the SMO as a key focus of research. While the SMO was a novel focus in the early days of resource mobilization theory, it now occupies a central place in the sociology of movements.

INTERNAL DYNAMICS OF SMOs

Most research on the internal dynamics of SMOs engages with one of two strong theories of voluntary organizations. One strand focuses on Robert Michels's "iron law of oligarchy" (Michels 1962 [1911]), which argues that organizations inevitably evolve from democratic governance toward control by elites, from radical goals toward moderate ones, and from broad agendas for social change toward narrow dictates of organizational maintenance. Michels's critique of oligarchy inspired some new left and feminist activists in the 1960s to experiment with informal and anti bureaucratic organizational forms, but these experiments often created new organizational problems. Freeman (1972) warned against a "tyranny of structure lessness" in which power coalesces in the hands of the few even in groups with little formal structure. Researchers and activists continue to puzzle over the conditions under which the iron law of oligarchy applies and how movements can subvert this process.

Michels's theory also inspired debates about the efficiency of formal organization – particularly hierarchical and bureaucratic organization – and its effects on movement outcomes. While Piven and Cloward (1979) suggested that formal organization depresses mass mobilization, Gamson (1975) argued that bureaucracy can help movements achieve their goals. This debate posed the question in a limited way: only two organizational forms were considered (bureaucracy versus no bureaucracy) and it was assumed that organizational forms were simply vehicles for achieving particular goals. Other research has moved past these limitations. Polletta (2002) argues that participatory democracy

within SMOs is politically effective under particular conditions. Participatory democracy has three main benefits: it builds group solidarity, enhances the development of innovative tactics, and develops leadership skills. Thus, participatory democracy works when costs of participation are high, the environment is uncertain, or when there are few people with developed leadership skills.

A second strand of research on the internal dynamics of SMOs responds to Olson's (1965) influential statement on the problem of "free riding" in voluntary organizations. Olson argued that since self interested individuals will tend to free ride on the efforts of others, voluntary organizations will be doomed to failure unless they can provide excludable benefits (selective incentives) to their members. Sociologists have shown that organizations can also generate mobilization through "solidary" incentives, social networks, or the formation of a "critical mass." These studies have shed light on the determinants of movement participation, and have reminded social movement scholars that organization is a problem and a process, not merely a structure to be taken for granted.

ENVIRONMENTS AND FIELDS OF SMOs

Scholars have developed several ways of thinking about how SMOs rely on broader environments. Resource mobilization theorists see the provision or withholding of resources – funding, space, staff, technical expertise, equipment – as the primary way environments affect the emergence, form, development, and survival of SMOs. SMOs are more likely to be founded, survive, grow, and achieve their objectives in resource rich environments, and to struggle in resource poor environments. Political process scholars have focused on how the structure of political opportunities shapes the formation, growth, survival, and success of SMOs. Specifically, they have shown that the state and other elite groups enable and constrain SMOs by providing positive opportunities for some kinds of organizations and establishing legal prohibitions against other kinds – typically, those with politically radical or otherwise undesirable ideologies or strategies. As a legitimate source

of rules about what kinds of organizations are legal and will receive benefits from the state (i.e., tax exemption), the state effectively “channels” SMOs. Pressures from the state can also lead SMOs to become more bureaucratic, as tax breaks and governmental funding are often available only to organizations that can demonstrate that their internal structure is acceptable to the state. Institutional theory provides a third way to think about the relationship between SMOs and environments. Neo institutionalists argue that SMOs, like other kinds of organizations, tend to adopt organizational forms that are culturally legitimate and taken for granted as appropriate.

Scholars have also expanded the focus to consider the structure and evolution of entire “fields” or “populations” of SMOs and the consequences for social movement outcomes. Influenced by population ecology theory, some social movement scholars have analyzed the interacting forces that cause populations of SMOs to grow or decline. Minkoff (1999) shows how SMOs constitute the environment for one another, such that the fate and impact of a particular SMO depends partially on its position within a population or field organization. SMOs in a field may compete for resources, cooperate on social movement actions, develop a division of labor, or provide resources and other forms of support to each other. The conditions under which cooperation or competition prevails are not fully understood.

Examination of the structure and evolution of movement fields has also shed light on the consequences of movement diversification. It has often been assumed that ideological differences in a social movement field reflect a lack of unity and thus indicate movement weakness. Yet ideological and functional diversity may enable movements to appeal to a larger constituency and to respond effectively to complex and rapidly changing political environments. Diversity in social movement fields also enables movements to benefit from “radical flank effects” and may even generate useful strategic innovation.

BEYOND THE SMO

Research organized around the concept of the SMO has generated insight into the problem of

how actors coordinate collective action. However, scholars have also found that the process of organizing a social movement is not fully captured by a focus on SMOs. The study of SMOs (as a noun) is only a part of the larger project of understanding social movement organization (as a process). Several strands of social movement scholarship shift the SMO out of the center of the analysis.

A cultural turn in social movement scholarship has reinvigorated interest in *why* people organize. While resource mobilization and political process approaches treated grievances as relatively unproblematic, cultural approaches argue that movements cannot be understood without attention to discourse, framing, and the crystallization of collective identities. This perspective sees SMOs as a site of the cultural work of movements – framing and building collective identities.

Clemens (1997) demonstrated that it is not just the quantity of organization that assists a movement; qualitative variation in organizational form also matters for the success of movements. Scholars have also emphasized that organizational forms are often selected not merely because of their perceived efficiency, but because of activists’ ideological commitments or taken for granted assumptions.

The move beyond SMOs is also informed by the recognition that social movement activity is sometimes coordinated through networks, rather than or in addition to organizations. What we recognize as a social movement may actually be an extensive advocacy network, featuring SMOs but also including highly professionalized advocacy organizations, governmental or intergovernmental actors, and individual policy entrepreneurs. Some activists have adopted decentralized networks as an organizing principle, eschewing more traditional organizational vehicles. In the environmental movement, for instance, groups like EarthFirst!, the Rainforest Action Network, and the Indigenous Environmental Network all embrace a network model, albeit in varying ways and degrees.

Finally, scholars beyond the subfield of social movements have realized that the processes identified and described by social movement scholars are evident in other arenas of social life. Theories developed to explain SMOs are sometimes applied to other types of organizations,

including businesses, industry associations, and universities. A synthesis of “social movements and organizational theory” (Davis et al. 2005) represents a deeper dialogue between these two subfields, which has the potential to generate new insights into the processes of organizing for change.

social movements

James M. Jasper

Although scholarly definitions vary, common usage portrays social movements as sustained and intentional efforts to foster or retard social changes, primarily outside the normal institutional channels encouraged by authorities. *Sustained* implies that movements differ from single events such as riots or rallies. Their persistence often allows them to develop formal organizations, but they may also operate through informal social networks. *Intentional* links movements to culture and strategy: people have ideas about what they want and how to get it, ideas that are filtered through culture as well as psychology. Movements have purposes, even when these have to do with transforming members themselves (as in many religious movements) rather than the world outside the movement. *Foster or retard*: although many scholars have a Whiggish tendency to view movements as progressive, dismissing regressive efforts as countermovements, this distinction seems arbitrary and unsustainable (not to mention the unfortunate effect that different tools are then used to analyze the two types). *Non institutional* distinguishes movements from political parties and interest groups that are a more regular part of many political systems, even though movements frequently create these other entities and often maintain close relationships to them. Most movements today deploy some tactics within mainstream institutions, and non institutional protest is itself often quite institutionalized. Unsurprisingly, each of these claims about social movements has been subject to controversy and differences in emphasis.

UNDERSTANDING DISCONTENT

Theories of discontent have always reflected the historical forms protest was taking at the time, as well as each writer's own sympathies and political participation. In seventeenth and eighteenth century Europe, the collective expression of discontent was primarily understood through the lens of legitimate sovereignty. Economic and social dimensions of the emerging nation state were not yet distinguished from the political, so protest both took the form of and was seen as a political act. The concept of the social movement was not yet possible. Contract theory, a primarily normative discourse, allowed thinkers such as Hobbes to argue against the legitimacy of most resistance to the state, and others such as Locke to defend revolutionary action in the face of predatory rulers. Thinkers of the time hardly noticed the activities of the lower classes.

With accelerated urbanization in the nineteenth century, European intellectuals increasingly took alarm at the regular rebellions of artisans, developing the concept of the mob to explain and disparage them. Crowds came to be seen as a form of madness that caused individuals to act differently than they would when alone – a view crystallized by Gustave Le Bon in the 1890s. Although based on little empirical research, the crowd image remained vital to a number of thinkers in the early twentieth century, including Durkheim, Freud, Weber, and Parsons. Only revolutionaries such as Marx viewed urban mobs favorably, wrongly insisting that they were part of the proletariat who would usher in a just society in the form of socialism (instead, most were the old working class of artisans whose way of life was disappearing).

More sophisticated versions of crowd theory appeared in the mid twentieth century, largely in response to communism and fascism. Until the late 1960s, the dominant view of protest overemphasized the non institutional dimension, lumping movements together with fads, panics, and other collective behavior. Explicitly or implicitly, crowds remained the heart of this vision: the kernel on which other forms of collective behavior were somehow built. Most analysts, drawing from Le Bon, feared crowds and movements and portrayed them pejoratively, although occasional interactionists pointed to

their creativity instead (in a fruitful tradition stretching from Robert Park to Ralph Turner and Lewis Killian, and on through recent theorists such as David Snow and John Lofland). How movements were sustained and what were their goals received less attention, and only occasionally did theorists link movements to social change.

Suddenly everything changed. In the mid 1960s, social movements were everywhere, populated no longer by a dangerous working class but by familiar middle class faces. In retrospect we can see various roots of this new activism: the emergence of a British and later an American new left; increasing international attention to the US Civil Rights Movement especially after the student sit ins of 1960; the 1964 confrontation that spawned the Berkeley free speech movement; anti colonial movements and revolutions around the globe. Theories soon appeared that were sympathetic to protestors.

An organizational or structural paradigm, steeped in Marxism, dominated research from the 1970s to the late 1990s, highlighting the sustained dimension of movements by portraying them as linked to the core political and economic institutions and cleavages of society. No longer grouped with fads, social movements were now nearly indistinguishable from political parties. They were thought to reflect deep structural interests, especially class but also gender, race, and (eventually) sexual preference. Structural assumptions discouraged the asking of "why" questions, as a desire for change or inclusion was assumed. So although movements were recognized as purposive, their purposes were taken for granted rather than empirically investigated. Attitudes and grievances assumed to be ever present were dismissed as causal factors of any importance. The essential question about movements was how they could overcome repression, especially by the state, in order to further their (already existing) interests. They were seen as insurgents or challengers, outsiders trying to gain entry into existing polities. (Scholars disappointed by the failure of most movements of the 1960s focused naturally on the structural constraints that they had faced.)

An American version of the new paradigm emphasized finances, often mobilized by paid, professional activists. Organizations require financial support, and the easiest way to attract

this is by appealing to the privileged in society. Another is by gathering small donations from a large number of sympathizers, especially through direct mail. In the 1960s, a large social movement sector developed, with well developed techniques for gathering funds, organizing shows of public support, and pressuring legislators (McCarthy & Zald 1977). These developments suggested a model of movements as similar to firms in markets, competing with one another for funds, members, and attention. This research tradition is often referred to as resource mobilization due to its emphasis on funding.

Another version of the structural paradigm focused on interactions between movements and the state, on the assumption that the state was usually the opponent as well as judge (under the Marxist assumption that states are instruments of the ruling class). Often dubbed "political process," this tradition emphasized the need for elite allies, cracks in state repression, state crises, and other windows of opportunity in the political environment. This perspective especially fit (because it was largely derived from) the study of European labor and American civil rights movements: efforts at inclusion by well defined groups that lasted for decades. In Europe a more comparative version developed, highlighting ongoing state structures (Kriesi et al. 1995). Despite its healthy focus on a movement's external environment, this approach modeled that environment as a structure (open or closed, for example) rather than an arena of diverse strategic players, as relationships rather than interactions.

Alain Touraine and his many students crafted a different version of the structural paradigm, linking contemporary movements to social structure instead of concentrating on organizational forms. Whereas the central conflict of industrial societies, Touraine (1978) argued, pitted labor against capital in a struggle over the distribution of material goods, post industrial societies saw conflicts over cultural understandings, especially the direction in which society's increasing self control would take it. The technocrats of capital and government sought profit and efficiency, while protestors saw these as mere means to the deeper ends of cultural identities and political rights. Touraine's vision helped scholars recognize the

significance of new movements such as ecology, feminism, or gay rights, invisible under traditional structural models. More recently, Touraine has admitted that Europe and the United States have become new kinds of capitalist societies more than the post industrial societies he had prophesied. The technocrats won.

Alongside these macrosocial visions there emerged a more individualistic view of movements which were redefined accordingly as collective action. Rooted in neoclassical micro economic theory, Mancur Olson (1965) and others cast doubt on the sustainability of movements, precisely by emphasizing the intentions of potential participants whose rationality consisted of constantly calculating whether to participate based on costs and benefits to themselves as individuals. Olson left little room for the attractions of collective solidarity and other incentives besides material benefits. As others have filled in some of these gaps, deriving solutions to the free rider problem, the rational choice approach has become less and less distinct. Many of the solutions are the organizational challenges emphasized by the mobilization and process traditions.

At the turn of the millennium, the structural, Tourainian, and rational choice approaches faced deep problems, and appeared in articles most often as whipping boys for proffered alternatives. The main lacuna of all three was an inattention to cultural meanings, the socially constructed purposes and identities of social movement groups. Even Touraine, who emphasized struggles over cultural meanings rather than material rewards, too often derived those meanings from his theory of historical change rather than empirically from the movements themselves.

Accordingly, beginning in the late 1980s, considerable research and theory addressed the cultural dimensions of movements. Two concepts, frames and collective identity, dominated these efforts. David Snow, Rob Benson, and a series of collaborators did the most to theorize the nature of rhetorical frames, especially those used by activists to recruit others to their cause.

Inspired by identity politics in the United States, in the 1990s the concept of collective identity was increasingly used to get at cultural meanings not already covered by frames. At first, collective identities were seen as a

mobilizing rhetoric built upon a structural position or discrimination, a form of cognitive liberation (McAdam 1982). Individuals imagined themselves members of some larger community, in whose name they acted. Only later was it realized that movements themselves can foster identities without any preexisting structural similarities – and identities can even form around movements, specific tactics such as non violence, or particular organizations (Jasper 1997). It also took time for scholars to recognize that emotional solidarities are just as important to identities as cognitive categories are.

Clearly and narrowly defined, frames and identities are important tools in our conceptual repertoire for understanding social movements, but there are additional ways to get at meanings (Jasper 1997; Goodwin & Jasper 2006). Analyses of ritual or of media coverage draw on well established fields of anthropology and media studies. Narrative has also become popular, as stories are an important part of meetings and self images in social movements. Although traditional narrative theory emphasizes the structuring plots of stories, others highlight the social context of storytelling. Rhetoric, which takes off from this latter point, highlights the interplay of orator and audience, building in not only interaction but intention and emotion. Like framing, naming is a key part of making sense of the world and of persuading others.

Emotions are a central component of culture, playing a role in all social movements. Basic affects like love and hate can pull a movement together or tear it apart. Reactive emotions such as anger, fear, and shock provide raw materials that organizers must transform into moral indignation. Moods such as resignation or cynicism can discourage recruits, just as those of confidence or exhilaration can attract them perhaps through the interaction rituals Collins (2001) describes. Emotions even figure in the outcomes of movements, which frequently aim to transform sensibilities such as compassion or justice.

EMERGENCE

The initial stirrings of a social movement are poorly understood. Given the sensibilities, ideas, values, and allegiances mixed together

in different population segments, how does necessarily limited attention come to be focused on one set of issues rather than others? A new worthy event or death of a loved one may shock people into attention. The zeitgeist may shift slightly, in an enormously complex way, bringing attention and sympathy to new arenas. News coverage also influences our emotional and moral attention. Typically, a small network of would be leaders manages to set aside their normal lives to craft appeals to these under standings to recruit like minded others (or they may be movement professionals whose work is to stimulate protest). Little is known about the first stirrings of a movement.

In contrast, extensive research has examined how individuals are recruited to an emerging or ongoing movement. Early arguments, focusing on individual psychology, had suggested that alienated, insecure, or dogmatic individuals joined social movements. The structural paradigm dismissed such speculation in favor of factors like biographical availability: the lack of spouse, children, or demanding jobs that frees people for the time commitment of participation. But the most important factor in explaining who joins and who does not may be whether the potential recruit already knows someone in the movement. In many movements, a majority of participants are recruited this way (Snow et al. 1980). In a process Anthony Oberschall dubbed bloc recruitment, entire networks can be coopted for new purposes, such as the fundamentalist congregations that became part of the movement to stop the Equal Rights Amendment for American women.

Researchers also turned their attention to the messages transmitted across networks, in other words the cultural aspects of recruitment. Snow and his co authors suggested that recruiters and potential participants had to align their frames to achieve a common definition of a problem and prescription for solving it, with Snow and Benford (1992: 137) defining a frame as an interpretive schema that simplifies and condenses the world out there by selectively punctuating and encoding objects, situations, events, experiences, and sequences of actions within one's present or past environment. Although originally used to focus on the strategic and rhetorical interaction between organizers and recruits, frames have more often and

less usefully been analyzed as static bundles of meanings that either work or do not work.

Recruitment requires more than cognitive agreement between organizers and their audiences. At least as important are the moral visions and emotions that propel people into action. Fear and anger must be transformed into indignation and outrage. Moral shocks are one way that people are drawn into action: when they learn something about the world that outrages them, discovering that the world is not as they had thought (Jasper 1997). The shock may come from a public event such as *Roe v. Wade* or from private sources like the death of a child through corporate negligence. These shocks can be so strong that people seek out protest groups even in the absence of social network ties. Emotions are an essential component of culture, and culture is an essential part of recruitment, whether it operates through social networks or other media.

In addition to people (both leaders and followers), an emerging movement usually needs some infrastructure to carry out its activities. It requires basic means of communication and transportation: a bullhorn to address a large crowd, a fax machine or Internet access to reach supporters, carpools to get people to a rally. It may also need a large meeting room. Financial support allows organizers to purchase what they need. In what was perhaps the high water mark of mobilization theory, Morris (1984) demonstrated the many contributions that black churches and other institutions made to the American Civil Rights Movement, from networks of preachers throughout the South and beyond to meeting halls in which ideas could be aired. Churches also provided cultural meanings, for instance Bible stories and religious songs, that could be used to convey the movement's message to a wide variety of Southern blacks.

In the late twentieth century, transnational social movements and their organizations spread rapidly in a world of globally improving communication and transportation (Keck & Sikkink 1998). It was hard to understand these international networks through the structural paradigm's focus on preexisting interests in a relatively homogeneous and well networked population. This new work on globalization

also portrays a world of many different kinds of players – local, national, and international non governmental organizations (NGOs), assorted state agencies, international institutions such as the United Nations or International Monetary Fund, diverse funding sources, various kinds of publics in complex interaction. Some perceive a shift in conflicts from institutions whose members are nation states (World Bank, World Trade Organization, UN) to a more participatory public sphere of NGOs that cooperate directly as well as through the older organizations. The exchange of information and ideas lies at the heart of these newer networks.

DYNAMICS

But what do movements do? Tilly (1978) suggests that a society contains a repertoire of collective action, from which protestors inevitably draw, depending on local senses of justice, the daily routines and social organization of the participants, their prior experience with collective action, and the repression they are likely to face. Most social movements in a society will conduct the same activities, since that is what they have learned to do through trial and error. New tactics, outside the repertoire, may take opponents and authorities by surprise, but protestors themselves may bungle them due to lack of experience and know how. At the extreme, those who face extreme surveillance and few legal rights are restricted to weapons of the weak such as sabotage, pilfering, poaching, or even jokes and gossip (Scott 1985).

The organizational forms which movements adopt have attracted much attention, perhaps because they are central to a structural paradigm. Piven and Cloward (1977) dissented from the common view that protest groups should accumulate resources, suggesting instead that these distract attention from the best strategy of downtrodden groups, radical insurgency and disruption. An organization, they warn, can all too easily begin to view its own perpetuation and expansion as goals alongside its original purpose. Others have countered that professionalized organizations can stimulate grassroots activity, and that they can allow movement ideas

to survive long periods when they are out of favor. Jasper (2004) prefers to see the building of a stable protest organization as a dilemma, with risks and benefits to both doing it and not doing it.

What kind of organization to construct is another important strategic choice. Drawing on institutional theory, Clemens (1993) shows that organizational form is itself a message, presumably for both members and outsiders. In the American labor movement of the 1890s, fraternal forms of organizing downplayed economic interests and political confrontation, while more military forms like Coxey's Army elicited violent repression. Organizational forms, like other tactical choices, are a fundamental part of shaping a collective identity.

Most protest groups contain rival factions, which may have different goals or different tastes in tactics (Jasper 1997). Factions may develop as newcomers join a movement, demanding internal as well as external changes. Movements may grow more radical because new recruits want more action, or have identities based on being radical, although the structural account emphasizes rebuffs by the state as the key source of radicalization. Radical flanks can have advantages as well as disadvantages. Radical actions and ideas attract media attention, and some times garner quick concessions from opponents or authorities. Among disadvantages, foremost is the possibility that radicals will pull an organization or movement apart or that it will attract repression fatal to the cause.

Less research has addressed other features of what movements actually do on a daily basis: how they make decisions about tactics, seek allies, struggle with factions and unruly individuals, and balance their appeals to a number of different audiences. The structural emphasis on external allies and resources left little theoretical space to see how insurgents actually operated, especially when they had few resources. (Although Touraine, by bringing together representatives of different factions in a movement, was able to recreate their internal conflicts in his "sociological interventions.") Even the poorest can often generate internal resources, and most try to accumulate whatever resources they lack at the beginning of a conflict. Even without money and the resources it buys,

protestors can still be creative, doing things that catch their opponents off guard or take advantage of legal and political opportunities.

In a critique of classic research on organizing, Ganz (2000) derived a number of factors that made the United Farm Workers more inventive than its predecessors and rivals. These include leaders with diverse experience, salient local knowledge, personal commitment, diverse network ties (including strong ties to constituencies), and a diverse tactical repertoire. Organizations, Ganz found, were more creative when they had regular meetings open to diverse perspectives and with the authority to make decisions, had diverse resources (especially flowing up from the constituency itself), and were accountable to each other but also their constituencies. Democratic or entrepreneurial selection of leaders worked better than more bureaucratic processes.

Under the influence of recent theories of agency, organizations can be seen as strategic players in fields of conflict with a range of other players, rather than reified as a movement facing either the state or a political environment. That environment is recognized as a farrago of friends, foes, bystanders, regulators, and others, each with its own goals, means, and internal conflicts. States and movements are both fanciful metaphors covering a variety of players. A more strategic perspective has the potential to explore the boundaries between movements and other political phenomena, finding both similarities and differences across institutional spheres.

In this strategic perspective Jasper (2004) highlights the choices that individuals and groups face by naming a range of dilemmas confronting movements, indeed all strategic players. Naughty or Nice, for example, gets at the diverse effects of disruption or violence, which are often widely unpopular but may inspire a panicked response and yield a quick victory. In the Extension Dilemma, organizers must decide how large a coalition or group to build: bigger ones have more resources at their disposal, but often at the expense of a consensus around goals or a clear collective identity. An emphasis on tradeoffs or choices like these is one way to insist on the agency of social movements even in the face of structural constraints.

EFFECTS

The effects of movements on policy, society, and culture have always interested scholars, as they provide much of the inspiration for studying movements in the first place. Scholars frequently exaggerate the impact of the movements they have spent so much time studying, especially as there are so many definitions and types of success to which to turn. Research in this area has also tended to have a normative flavor, as Whiggish scholars seek sources of progressive social change.

Gamson (1975) pointed to two forms of success: benefits for a movement's constituency and recognition for the protest group itself. The latter was based on a structural image of challengers attempting to gain access to a polity closed to them. An impact on public policy is the central or ultimate goal of many movements, but this effect is often hard to observe because politicians frequently deny it even while they sometimes advance a movement's goals. And indeed, a movement's effect is often to sensitize other actors in a political arena. Kriesi et al. (1995: 212) list internal impacts of identity and organization, and external impacts of four types: procedural, substantive, structural, and sensitizing.

Many factors determine a movement's influence. Rochon (1990: 108) lists size, novelty, and militancy, oddly ignoring resources. Size matters because it may affect resources, but also because in democracies protestors are also voters. Novelty gains media attention and discomfits opponents. Militancy, for instance violence and disruption, may also catch opponents and authorities off guard, but it runs the risk that the latter will organize a repressive strategy capable of suppressing the movement. This is Jasper's Naughty or Nice dilemma. Militancy, like most risky strategies, generally succeeds when a goal can be attained quickly and irreversibly.

All strategic choices can have ramifications. Social movements borrow heavily from each other, not least because activists often move from one to another. This is one reason that movements so often appear in waves, as a frame or tactic proves useful to a number of them. (Although the stronger concept of a cycle, in which one stage leads to the next, seems to have

overreached the evidence.) Elisabeth Clemens showed that the early women's movement, by choosing one form of organization rather than another, often inspired changes in government as well. These groups introduced organizational logics from one sphere of life into another, inserting economic, charitable, and fraternal models into politics, and thereby helping to create today's pattern of interest group politics. New tactics spread rapidly.

Even when social movements have little impact on the world around them, they almost always affect their own members. A number of scholars have traced the consequences of participation in protestors' later lives, especially those active in the 1960s. Far from growing more conservative as they aged, this generation has maintained left leaning sympathies and a well documented inclination toward activism.

METHODS OF RESEARCH

Most studies of social movements, whether quantitative or qualitative, have been case studies. As with those who do area studies, scholars of movements must devote enormous time to mastering the diverse phenomena that comprise any social movement, usually composed of many diverse groups, different kinds of members, various kinds of tactics and events, interactions with a number of other strategic players, and so on. On the positive side, there is frequently a ready audience for reports on the many social movements that help compose our political landscape. On the negative, the same case is often used to develop new theories and concepts as well as to try them out empirically. For instance, every scholar who has written about political opportunities has discovered a different list of them, making it hard to discern the scope conditions of any of them.

Some scholars have tried to avoid this difficulty by looking at events instead of movements. Originally deployed in the study of riots, the use of events as units of analysis was especially helpful in the historical understanding of strikes and other contentious events for which newspaper reports but not richer information were available. Waves of events are useful for seeing the main product of organizing efforts, and for relating these activities to

other political variables. The strength of this approach lies in tracking developments over time and checking correlations of protest with other variables such as unemployment or grain prices, but it remains largely wedded to news paper accounts.

Protest events are hardly the only unit to be studied. Individuals can be interviewed in depth or randomly surveyed. Researchers can participate themselves, gaining introspective insights not otherwise available and which may be the most effective means for understanding emotions and some strategic choices. Organizations can be studied through a variety of methods, and the interplay of organizations is especially amenable to comparative analysis. Other methods are available for examining networks of individuals or organizations. All of the above can be studied through historical archives as well as contemporary means of gathering data. Computer simulations have also been used to test a number of impressions about movement organization. Gamson (1992) used focus groups to powerfully show the raw cultural materials available for organizing, the commonsense understandings that are as important as media framings of events. Fortunately, the study of social movements has proven open to a variety of techniques rather than being wedded to any kind of methodological purity (Klandermans & Staggenborg 2002).

To conclude, research into social movements shifts focus as movements themselves develop. Nineteenth century riots inspired crowd theories. After mid twentieth century battles with fascism and communism, western analysts turned to mass society theories to explain political movements they feared. In the 1960s, sympathy for middle class movements, especially of students who would later become academics, encouraged portraits of protestors as rational. A number of culturally oriented movements in the 1970s, often labeled new social movements to contrast them with the labor movement, helped to spawn cultural theories. Global networks of activists have inspired globally oriented theories. Future transformations will no doubt give us new portrayals and theories that we cannot yet imagine.

social movements, biographical consequences of

Silke Roth

Personal and biographical effects belong to the unintended consequences of social movements. Participation in social movements changes people's lives, while social movements aim at social change (or its prevention), and even affect the lives of those who did not get involved in movements and countermovements.

A biographical perspective on social movements makes clear that social change and personal change are inextricably linked.

Biographical consequences of social movements can be observed at the micro, meso, and macro levels. The effects at the micro level concern the impact of movement participation on activists' life courses, the individual level of participants in movement activities. As numerous studies show, activists tend to remain committed to social change goals they pursue in social movements and that this commitment has significant effects in their work lives, political attitudes, and personal relationships (Evans 1979; Andrews 1991). Based on research on participants of the New Left, Giugni (2004: 494) summarizes the effects as follows: the former activists continue to hold leftist attitudes, define themselves as "liberal" and "radical," and remain active in social movements and other forms of political activity. They tend to be concentrated in teaching and other "helping" professions, have lower incomes than their age peers, and are more likely to have experienced an episodic or non traditional work history. Furthermore, they are more likely to have divorced, married later, or remained single than their age peers. In addition, gender differences can be observed. For example, the participation in the Freedom Summer campaign of 1964 had different impacts on male and female life courses. Compared to their peers, male volunteers had jobs with less stability, prestige, and income, while female volunteers were less likely to be married or have children than their peers (McAdam 1992). Andrews (1991) found that lifelong commitment to socialism gave interviewees a purpose in life.

At the meso level, biographical consequences concern how social movements and movement organizations are shaped by the membership. Activists develop *tastes for tactics* (Jasper 1997), which have an impact on the participation in social movements and movement organizations as well as on the tactics employed and coalitions and networks formed. Roth (2003) argued that activists form bridging organizations in order to reconcile competing political identities that evolved in political socialization processes through the participation of social movements. Activists often move from one movement to the other and contribute to diffusion of strategies,

tactics, and frames and engage in coalition building (Whittier 2004). The biographies of activists account for generational change in social movements and social movement organizations. Evans (1979) described how the women's movement emerged out of the Civil Rights Movement; Whittier (2004) discusses how movements influence each other, for example through spillover processes.

The consequences at the macro level concern the impact of social movements on the general population, for example changing norms with respect to education, employment, or marital status. Economic and demographic factors, as well as the social movements of the 1960s and 1970s, led to the transformation from a materialist to a post materialist value system and changes in the life course. Consciousness raising groups, as part of the women's movement, not only changed the self definitions and worldviews of the participating women but also transformed society. McAdam (1999) argues that the links between the social movements of the 1960s and 1970s and the changes in life course patterns constitute a three stage process. Initially, only activists reject normal life course trajectories in favor of alternatives like cohabitation, childlessness, and unstable work. In the second stage, the alternative lifestyle spreads to college campuses and countercultural neighborhoods, and finally, in the third stage, reaches young people in general.

The analysis of political generations can combine micro, meso, and macro levels of the biographical consequences of social movements. A biographical perspective on historical processes, cycles of protest, and political opportunity structures draws the attention to political generations (Mannheim 1952; Braungart & Braungart 1985) which share historical moments and process the past in a specific manner. Those active in the West German student movement of the 1960s as well as those active in the peaceful revolution of 1989 see their activism as a response to the involvement of their parents in National Socialism.

Giugni (2004) provides a critical assessment of the methodological shortcomings of the study of biographical consequences of social movements. Typically, the studies employed small samples which were non representative and focused mostly on New Left activists. Further

problems include lack of control groups, small numbers of participants, and samples drawn from narrow geographical areas. In addition, often only a single point in time was measured. In order to disentangle aging or life cycle effects, cohort or generational effects, and period effects, panel designs should be employed. While aging and life cycle effects refer to various stages (youth, middle age, and old age) and different phases (education, work/career, marriage, parenthood) in one's life course, cohort and generational effects encompass sharing the experience of a historical event which has shaped this age group (e.g., World War II or the 1960s). Surveying the same group at various points in time (panel study) makes it possible to distinguish between the effects of a stage in one's life course and being born into a specific cohort or generation.

Biographical methods are especially well suited to studying the biographical impact of social movements at all three levels since they make it possible to study the process character of social action. Compared to other strategies of studying contentious politics, the life history method can assess subjective constructions and objective processes as well as developments in the private and public spheres and how they are interrelated. Life histories allow an understanding of individual developments as well as group phenomena and capture movement ideology, movement counterculture, organizational stories, and the dynamics of small networks. Instead of providing static images, life stories offer insight into processes (Della Porta 1992). Life histories enable the analysis of the sequences and patterning of life events and thereby contribute to a better understanding of the causes and effects of political affiliation as well as the interaction between the crystallization of consciousness and the mobilization of action, and social structures and networks that nourish (or fail to nourish) activist identities and beliefs during periods of political inactivity (Blee 1996: 687). Life histories provide a context for understanding the fluctuation and transient character of movement participation. Membership in a social movement organization is one practice within the trajectory of the life course; it has been preceded by former and parallel memberships and activities; it parallels developments in family and work careers. A life history

approach promises to contribute to a better understanding of the social construction of the history, collective identity, alignment with social movements, and conceptualization of social movement organizations from the perspective of the membership (Della Porta 1992).

Since the mid 1990s, social movement research has seen an increasing integration of various research paradigms as well as a renewed interest in culture and emotions. Furthermore, research on revolutions and social movements has become more integrated. Globalization processes have affected theory formation by challenging North American and Western European experiences as paradigmatic. A perspective on the biographical consequences of social movements emphasizes that activists migrate from one movement to another and sustain multiple memberships over time. On the individual level, this points to processes of political socialization; on the organizational and movement level, this points to social movement interaction and diffusion processes (Roth 2003). Frames, strategies, and repertoires of action are transported from one movement to another through overlapping memberships and coalitions (Whittier 2004). Seidman (1999) explains the fact that gender issues became prominent in South Africa's democratic transition due to the fact that South Africans visiting Europe and North America either as students or exiles were often introduced to new feminist ideas. When they returned to South Africa, the exiles introduced feminist ideas in the democratic struggle, challenging earlier assumptions about women's role in politics. A focus on biographies of social movement activists contributes to a better understanding of social movement participation and development as well as to the analysis of diffusion processes.

social movements, leadership in

Judith Stepan Norris and Ben Lind

Social movement leaders act and make decisions on behalf of the movements they represent and therefore wield influence on the

movement's trajectory. In this light, early scholarship addressed how leaders' personal qualities affect the character and actions of their movements. Mills (1971) notably identified union leader characteristics as telling of the distinctions between the American Federation of Labor and the Congress of Industrial Organizations. Stepan Norris and Zeitlin (2003) extended this line of research by documenting the differential success of communist and non communist leaders in collective bargaining accomplishments, union democracy, and attention to minority and women's rights. Similarly, Ganz (2000) partially credited the successful unionization of California's farm workers (1960s–1970s) to the personal biographies, networks, and repertoires of leaders in the United Farm Workers Union.

Social movements provide leaders with selective incentives, and scholars have examined how they matter. McCarthy and Zald (1977) consider paid versus voluntary service as well as positions that provide career building experience versus those that do not. Traditionally, positions that provide both salary and career experience are considered to be *professional* as opposed to *nonprofessional* leadership positions (Staggenborg 1988). Students of social movements have similarly categorized leaders according to their relationships with adherents of their respective social movements. Morris and Staggenborg (2004) proposed four types of movement leaders: (1) official title bearing leaders of social movement organizations; (2) leadership team members who work with and advise top leaders (resembling McCarthy and Zald's definition of a cadre); (3) bridge leaders – movement activists who provide an intermediary between the top leadership and mass potential constituents and adherents (see Robnett 1996); and (4) local organizers who mobilize relatively small communities, but lack direct communication with top movement leaders. Kretschmer and Meyer (2005) identify a “platform leader” who maintains her position by clearly articulating a distinct position within a larger social movement.

Although much of the research focuses on how leaders affect social movements, some emphasize a more dialectical approach. Ganz (2000), for instance, proposed a model whereby leaders' biographies, personal networks, and

collective action repertoires influence the strategic capacity and therefore the applied strategy of a movement. If their strategy utilizes effective and appropriate timing, targets, and tactics, it will produce successful outcomes for the movement that result in greater environmental effects – altering the biographies, networks, and repertoires of future movement leaders. McCarthy and Zald (1977) hypothesize that social movements that acquire increased funding have a tendency to procure professional leaders, who in turn are more likely to favor institutional tactics, coalition work, and formalization of their movement organizations. They also tend to avoid initiating new movements and introducing novel tactics when compared to social movements led by nonprofessionals (Staggenborg 1988).

In light of telling case studies regarding leadership in movements, most scholars acknowledge this topic remains under theorized and in need of further research.

social movements, networks and

Mario Diani

Since the interest in social movements started to develop in the 1960s, networks have been analyzed from two main perspectives. On the one hand, they have been treated as important facilitators of individuals' decisions to become involved in collective action, in the context of the debate inspired by Mancur Olson's seminal work on *The Logic of Collective Action*. On the other hand, analysts have looked at social movement networks as the structure of the links between the multiplicity of organizations and individual activists, committed to a certain cause. From this perspective, movement networks have been treated as the consequence, rather than the precondition, of collective action, a specific instance of the broader processes through which actors modify social structures through agency. More specifically, looking at the configuration of movement networks has provided observers with a clue to grasp the logics by which movement actors choose their partners, thus generating broader and complex organizational fields.

In their most basic sense, social networks consist of sets of nodes, linked by some form of relationship, and delimited by some specific criteria. Analysts of social movement networks have mostly used as nodes either the individuals mobilizing or sympathizing with a certain cause, or subscribing to certain alternative life styles, or the organizations promoting collective action on such issues and/or encouraging alternative cultural practices. They have looked at both direct and indirect ties. Direct ties are present when two nodes are directly linked in explicit interaction and interdependence – e.g., two activists who know each other personally,

or two organizations that jointly promote a rally. Indirect ties are assumed to exist between two nodes when they share some relevant activity or resource – e.g., interest in certain issues or in the same campaigns – yet without any face to face interaction.

Defining the boundaries of a social movement – i.e., classifying certain actors or events as part of a social movement dynamic or not – has proved most problematic. Many social movement analysts associate with a given movement all organizations sharing an interest in certain issues (e.g., the environment, or women's rights) or all organizations willing to adopt disruptive tactics, regardless of whether they are actually linked to each other. Others include in a movement only those nodes actually connected by some kind of relation. In particular, social movements have been conceived as the processes through which informal networks between a multiplicity of actors, sharing a collective identity, and engaged in social and/or political conflict, are built and reproduced. Identity plays a crucial role here as it connects actors to longer term collective projects, thus making their relation different from that between actors engaged in purely instrumental coalitions.

In the beginning, social movement analysts mostly focused on the role of social networks as predictors of individual participation in collective action. Even in the early 1970s, many still regarded movement participants as individuals lacking a proper social integration, following the disruption of routine social arrangements brought about by radical processes of change and modernization. Interest in the link between social networks and movement participation developed precisely to challenge that assumption. By the 1980s, the notion that social movement participants are usually well integrated in dense systems of social relationships, that prior social ties operate as a basis for movement recruitment, and that established social settings are the locus of movement emergence, had become one of the most established findings in social movement research.

Social movement activists and sympathizers are usually linked through both “private” and “public” ties well before collective action develops. Personal friends, relatives, colleagues, and neighbors may all affect individual

decisions to become involved in a movement; so may people who share with prospective participants some kind of collective engagement, such as previous or current participation in other movement activities, political or social organizations, or public bodies. Individuals may also be linked through indirect ties, generated by their joint involvement in specific activities and/or events, yet without any face to face interaction. These may range from participation in the same political or social activities and/or organizations, to involvement in the same subcultures or countercultures.

The impact of individual networks on individual participation has been tested in reference to different dependent variables. These have included presence or absence of participation; participation in specific types of activities (e.g., in conservation or political ecology groups); the continuation of participation over time; and the levels of risk associated with participation. Networks may provide opportunities for action through the circulation of information about ongoing activities, existing organizations, people to contact, and a reduction of the practical costs attached to participation. They may be the source of social pressure on prospective participants ("if you go, I will go too"), although cross pressures are also possible, and so are people participating precisely because they expect others not to do anything. Networks may facilitate the development of cognitive skills and competences, and/or provide the context for the socialization of individuals to specific sets of values. They may also represent the locus for the development of strong emotional feelings.

It is disputed whether direct or indirect ties should operate differently, although in general social pressure is more likely to be exerted through direct links, while socialization to values or cognitive skills may also originate from involvement in similar organizational settings, regardless of strong involvement with specific individuals. Whether strong or weak ties should matter most is also a matter of debate: one would expect strong ties to matter more in the case of high risk activities, but weak ties may facilitate the contacts between a movement organization and a constituency with more moderate or at least diversified orientations, and/or the diffusion or the spread of a movement campaign.

Another important illustration of the networks-movements connections is the view of movements as complex fields of interactions between multiple actors. This had already been noticed in the 1970s by scholars interested in subcultural and countercultural dynamics as well as in interorganizational relationships. However, this perspective has gained momentum since the 1980s, in parallel with the growing success of the network concept as a key to make sense of contemporary society, beyond classic dichotomies such as that between bureaucracy and markets, and with the renewed interest in agency in social theory. The spread of transnational contention and coalition building has further emphasized the interest in movement networks. All this has translated into growing attention to both interorganizational fields and subcultural and countercultural communities.

Looking at interorganizational fields reflects the fact that it is actually very difficult to think of movements as consisting of one organization. When this happens, as in the instances of the Bolshevik party in Russia or the National Socialist party in Germany, it usually means that the transition from movement to organization is complete. Movements indeed consist of multiple instances of interorganizational collaboration on campaigns of different intensity and scope. Direct ties between movement organizations include most prominently the exchange of information and the pooling of mobilization resources; indirect ties cover a broad range of possibilities, from shared personnel to joint participation in specific actions and/or events, from exposure to the same media, especially computer mediated media, to shared linkages to third parties (whether private or public organizations).

Sometimes, relationships between groups and organizations are recurrent to the point that one can think, for a given social movement, of a distinctive "alliance structure" and "oppositional structure"; at other times this does not happen and ad hoc shifting coalition networks prevail. It is important to recognize the difference between a pure coalition, driven by instrumental principles, and a movement network. In both cases, networks facilitate the mobilization and allocation of resources across an organizational field, the negotiation of agreed goals, and the production and circulation of information.

However, it is the presence of a shared identity which qualifies a movement network vis à vis a coalition network, and draws its boundaries. As identity is not a given trait but is the product of incessant negotiations between social actors, which often involves ideological conflicts, movement boundaries are rarely stable. Their instability is also reflected in movement networks' internal segmentation, even though this may also depend on principles of division of labor or the diversity in issue agendas between different organizations.

At the same time, social movements, especially but not exclusively those challenging moral values and dominant cultural codes, also have a strong subcultural and countercultural dimension. Individual networks represent the backbone of broader social movement communities, where interpersonal ties involve the sharing of distinctive lifestyles or of broader cultural models. While social movement scholars have studied them mostly in reference to "new" social movements (e.g., gay and lesbian subcultures, alternative scenes, radical intellectual milieus), working class communities continue to attract considerable attention from social historians and historical sociologists. To say the least, communitarian ties strengthen the identity and solidarity among movement activists and sympathizers. At the same time, though, they provide the specific locus of social conflict in those cases where the challenge is eminently on the symbolic side, where, in other words, at stake are mainly the definition of identities and the preservation of opportunities for the enactment of alternative lifestyles.

Thinking on networks and movements is likely to evolve along at least three lines. First, social scientists need to extend their conception of nodes in movement networks to objects other than individuals or organizations. In particular, protest events should be treated as network nodes. The whole idea of protest cycles presupposes interdependence between events, and so do the techniques of event history analysis increasingly used in this area of inquiry. The application of a network perspective could generate important insights on the innumerable mechanisms whereby events become linked to a social movement process. Organizations operate as ties by promoting and/or participating in multiple events; individual activists operate in

the same way; events may also be linked through symbolic means, e.g., by narratives that underline continuity between what would otherwise be largely independent and disconnected episodes of social conflict.

The time dimension should also be introduced more explicitly into the analysis of movement networks. Most studies of networks are based on data collected at one single point in time. More information is needed on how movement networks evolve over time, and how those changes affect patterns of collective action at large. Unfortunately, the data necessary to do those analyses are hard to locate, as systematic archives of social movement activity are rare. Nonetheless, some remarkable studies have indeed drawn upon archival records. Court records are another important source of network data, and have been used to account for recruitment to contemporary terrorist groups as well as for the traits of historical examples of contention. Newspaper reports offer a possible alternative, which has not been extensively explored yet. If data obtained in this way were confirmed to be a valid measure of actual ties, this would represent a major step forward toward network analysis of movements over long time spans.

Finally, research on networks and movements has increasingly explored the impact of virtual links, in particular those originating from computer mediated communication, on collective action processes. The main question is whether "virtual," computer mediated ties may replace "real" ties in the generation not only of the practical opportunities, but also of the shared understandings and – most important – the mutual trust which have consistently been identified as important facilitators of collective action. Available evidence is too sparse to be conclusive, and much more work is required to achieve conclusions that are at least as sound as those achieved, for all their limitations, in the study of the link between movement activity and "real" social networks.

social movements, nonviolent

Kurt Schock

Nonviolent social movements rely primarily upon methods of nonviolent action to promote change. Although most social movements concerned with personal transformation, lifestyle, and culture are nonviolent, those concerned with political, social, and economic change that directly challenge the interests of the elite may be violent, nonviolent, or a combination of

the two. The focus here is on social movements that directly challenge elite interests, and that do so – by choice or due to limited options – only or primarily through methods of nonviolent action, such as protest demonstrations, marches, boycotts, strikes, and civil disobedience. Of course, any social movement that directly challenges the interests of the elite, whether it is nonviolent or violent, may be met with violence.

Nonviolent action methods are actions that do not involve physical violence or the threat of physical force against human beings and that involve collective action in the pursuit of political, social, or economic objectives. Nonviolent action occurs through (1) acts of omission, whereby people refuse to perform acts expected by norms, custom, law, or decree; (2) acts of commission, whereby people perform acts which they do not usually perform, are not expected by norms or customs to perform, or are forbidden by law or decree to perform; or (3) a combination of the two (Sharp 1973). These methods bring political, economic, social, emotional, or moral pressure to bear in the wielding of power in contentious interactions between collective actors (Sharp 1973, 1990; McCarthy 1990, 1997). Rather than viewing nonviolent action as one half of a rigid violent–nonviolent dichotomy, nonviolent action may be better understood as a set of methods with special features that differ from both violent resistance and institutional politics, as well as from “everyday forms of resistance” (McCarthy 1990; Schock 2005).

Although nonviolent action has been used in struggles against oppression throughout history, it was Mohandas Gandhi who was most influential in identifying nonviolence as a unique phenomenon with power different from and greater than that of violence, and developing the first comprehensive theory and praxis of nonviolent resistance. Gandhi’s philosophy and praxis of *satyagraha*, developed in the first half of the twentieth century, prescribes nonviolent action in which people refuse to cooperate with laws and social relations perceived to be unjust and willingly suffer the consequences of noncooperation and civil disobedience. Along with noncooperation, *satyagraha* involves constructive programs, that is, building just, decentralized, non coercive,

and democratic social relations autonomous from state and market forces.

Over the course of the twentieth century, methods of nonviolent action became a deliberate tool for social and political change, being transformed from a largely ad hoc strategy – based on either moral or religious principles, or a lack of violent alternatives – to a conscious, reflective method of struggle. There was a shift from informal and unorganized nonviolent struggle to formal and organized nonviolent struggle as expressed through social movements. By the end of the twentieth century nonviolent action became a modular and global method for challenging oppression.

Major episodes of twentieth century nonviolent resistance include the Gandhi led movement that challenged British rule in India (1919–47) and the Civil Rights Movement led by Martin Luther King, Jr. that challenged racial discrimination in the US South (1955–68). Various “waves” of nonviolent social movements include a series of civic strikes against dictatorships in Latin America (1931–61); numerous protest movements in more developed countries in the late 1960s – exemplified by the student and anti Vietnam War movements in the US and Australia, and the student led insurrection in France in 1968; and a wave of “unarmed insurrections” throughout the “second” and “third” worlds from 1978 into the twenty first century that challenged nondemocratic regimes, including those in Iran, South Africa, Chile, the Philippines, Indonesia, Nepal, Burma, China, and Ukraine. Nonviolent social movements, beginning with the Solidarity movement in Poland in the early 1980s, contributed to the toppling of communist regimes in Eastern Europe. Moreover, these struggles contributed to the breakup of the Soviet empire and the end of the Cold War.

Various issue related social movements have been almost exclusively nonviolent. Throughout the twentieth century women’s movements have fundamentally been concerned with the advocacy of nonviolent methods and social relations. Women’s movements have adopted nonviolent action as both a tactical choice and a framing element, and have cultivated a social critique of violence – from domestic violence to war (Costain 2000). Labor movements in industrialized countries have historically depended on

methods of noncooperation, especially the strike, to force concessions from capitalists and the state. The “new social movements” that emerged in western industrialized countries after World War II, such as the environmental and peace movements, have been almost exclusively nonviolent. Indigenous people’s movements throughout the world have also been primarily nonviolent.

Many of the *violent* social movements of the twentieth century involved struggles for control of the state apparatus and/or struggles for self determination, national liberation, or separatism. Although such conflicts will continue into the twenty first century, many twenty first century social movements have the goal of expanding democratic relations rather than controlling territory or the state – a goal that may be better attained through methods of nonviolent action than through violence.

The beginning of the twenty first century witnessed the emergence of a “movement of movements” implementing methods of nonviolent action to expand global civil society and struggle for social justice. Globalization from below and global justice movements have relied almost entirely on nonviolent action in their struggles against state and corporate driven globalization. Throughout the Global South, land struggles have emerged that implement nonviolent action to promote a more equitable distribution of land and sustainable development. Potential growth areas for nonviolent social movements in the twenty first century include challenging polyarchic or quasi democratic relations and “manufactured consent,” and promoting economic democracy throughout the world.

CHARACTERISTICS

Methods of resistance implemented by nonviolent social movements fall into three classes: protest and persuasion, noncooperation, and nonviolent intervention (Sharp 1973). Methods of protest and persuasion are symbolic expressions with communicative content intended to persuade the opponent, expose the opponent’s illegitimacy, provide social visibility to unjust relations, illustrate the extent of dissatisfaction throughout a population, educate the

public and third parties or catalyze their support, and overcome fear and acquiescence. These methods are often the crucibles in which frames are elaborated and disseminated, solidarity is forged, and people are mobilized to participate in other methods of nonviolent action. These methods do not consist of the use of reason, discussion, or persuasion *exclusive of* direct contentious action. They include actions such as protest demonstrations, marches, rallies, public speeches, symbolic public acts, vigils, and political funerals.

Methods of noncooperation involve the deliberate withdrawal, restriction, or defiance of expected participation or cooperation. While these methods may have symbolic significance, they are also intended to disrupt the status quo and undermine the opponent's power, resources, and legitimacy. These methods may be social, economic, or political. Social noncooperation involves the refusal to carry out normal social relations, such as social boycotts, social ostracism, student strikes, stayaways, and offering sanctuary to dissidents. Economic noncooperation involves the suspension of existing economic relationships or the refusal to initiate new ones, such as labor strikes or slowdowns, economic boycotts, refusal to pay rent, debts, interest, or taxes, and the collective withdrawal of bank deposits. Political noncooperation involves the refusal to continue usual forms of political participation or obedience. A common type of political noncooperation is civil disobedience (i.e., the open and deliberate violation of laws or orders for a political purpose), such as the publication of banned newspapers or pamphlets, and the refusal to participate in the military or obey orders of state agents.

Methods of nonviolent intervention are acts of interposition intended directly to disrupt continued subjugation or to develop alternatives to oppressive relations. Examples range from sit ins, pickets, nonviolent obstructions, nonviolent sabotage, land occupations, and paralyzing transportation to developing alternative markets and creating parallel institutions during the course of contentious struggles. These methods can be subdivided into two types. *Disruptive* nonviolent intervention upsets or destroys normal or established social relations. *Creative* nonviolent intervention forges autonomous social relations (Burrowes 1996). Creative

nonviolent intervention is significant because in struggles against oppression it is not only necessary to reject participating in oppressive relations, it is also necessary to engage in positive action to build alternatives; that is, to implement constructive programs and parallel structures. The two types of nonviolent intervention are mutually supporting and reinforcing: while disruptive nonviolent intervention (and noncooperation) drains power from the oppressors, creative nonviolent intervention generates power among the oppressed.

Nonviolent social movements may produce change through various mechanisms, including conversion, accommodation, nonviolent coercion, and disintegration (Sharp 1973, 1990). Conversion occurs when the opponent, as a result of nonviolent action by challengers, adopts the challenger's point of view and concedes to its goals. Conversion may occur through reason and argumentation, or as a result of changes in the emotions, beliefs, attitudes, or morality of the oppressors. The likelihood of conversion increases the less the social distance there is between the oppressors and the oppressed. However, if the oppressors view challengers as outside of their moral order or as inferior, then they are more likely to be indifferent. Thus, gender, race, ethnicity, religion, and language may be characteristics that form the basis of dehumanizing ideologies that decrease the likelihood of conversion. In addition to social distance, physical distance or a lack of communication between the oppressors and the oppressed may also inhibit conversion. Conversion is commonly (mis)understood as the only way or the main way in which nonviolent action produces change.

Through accommodation the oppressor grants concessions to the challengers, even though it is not converted to the challenger's point of view, is not forced to concede by the challenger's actions, and has the capacity to continue the struggle. An oppressor may accommodate a challenge when it perceives that the costs of ignoring or repressing are greater than the costs of giving in to some or all of its demands, views it as more of a nuisance than a threat, or calculates that by giving in to some or all of the challenger's demands the movement will be coopted thus preempting a more broad based movement. While "coercion" is often associated with violence, coercion can also be

affected through nonviolent pressure. Through nonviolent coercion, change is achieved against the oppressor's will as a result of the challenger successfully and nonviolently undermining its power, legitimacy, and ability to control the situation. Nonviolent coercion may promote change in one of three ways: (1) the challenge becomes too widespread to be controlled through repression, (2) the oppressor loses its willingness to repress, or (3) the movement's implementation of nonviolent action creates situations whereby it is too disruptive for the opponent to function without significant alterations in its policies or structure.

Disintegration occurs when the opponent breaks down in the face of widespread nonviolent resistance. That is, the challenge undermines the sources of the opponent's power to such an extent that there is no longer any effective institutional body to challenge or resist.

TYPES

Conceptual, if not empirical, distinctions can be made between social movements that implement nonviolent action as a matter of principle and those that implement it for pragmatic reasons. Participants in principled or conscientious nonviolent social movements view nonviolence as a way of life and usually hold religious or ethical beliefs that prohibit using violence against others in most or all situations. In contrast, participants in pragmatic nonviolent social movements perceive nonviolent action as the most expedient method for promoting change. Nonviolence is viewed as a means for prosecuting conflicts and not necessarily as a lifestyle. Since conflict is viewed as a relationship of incompatible interests, conversion of the opponent's views is not expected, therefore other mechanisms of change come into play. The goal of these movements is to limit the opponent's options or undermine its power in order to promote change (Stiehm 1968; Burrowes 1996).

Distinctions can also be made between *reformist* and *revolutionary* nonviolent social movements. In reformist nonviolent social movements, particular policies are perceived as the cause of or the solution for social problems. Movements of this type tend to implement short to medium term campaigns aimed

at changing public policies within the existing political framework. Moreover, these movements do not usually involve constructive programs. In contrast, revolutionary nonviolent social movements are guided by a structural analysis, and aim to change the basic structures of society. Particular campaigns, which may have a short to medium term time frame, are conducted within the context of a long term revolutionary vision and involve the implementation of constructive programs (Burrowes 1996).

The cross classification of the principled pragmatic dimension with the reformist revolutionary dimension provides four types of nonviolent social movements: pragmatic reform, principled reform, pragmatic revolutionary, and principled revolutionary. These categories are broadly descriptive rather than definitive and are not mutually exclusive (Burrowes 1996). Examples of pragmatic reform movements include anti nuclear and environmental movements in developed countries that target government and corporate policies. An example of a principled reform movement is the American Civil Rights Movement that incorporated a religious perspective in its challenge to particular policies that upheld racial discrimination. Examples of pragmatic revolutionary movements include the Eastern European revolutions of 1989 and the Palestinian Intifada (1987–90) that used nonviolent methods against Israeli domination and occupation. An example of a principled revolutionary movement is Gandhi's struggle in India directed at liberation from British rule and the development of constructive programs aimed to fundamentally transform social relations.

UNDERSTANDING NONVIOLENT SOCIAL MOVEMENTS

A number of interrelated areas exist where research and theory building would increase our understanding of nonviolent social movements: (1) correcting misconceptions about nonviolent action; (2) rethinking history from a perspective of nonviolent struggle and understanding the processes by which violence has been glorified throughout history; (3) reconceptualizing political power; (4) developing theories

of nonviolent revolution; and (5) theorizing the role of agency and strategy in nonviolent resistance.

First, the ability to understand and explain the dynamics of nonviolent social movements has suffered from numerous misconceptions about nonviolent action. Some of these misconceptions include the inability to differentiate nonviolent action from inaction or passive resistance; the view that nonviolent action involves only actions that are legal or institutionalized; the view that nonviolent action is a middle class or bourgeois method for social change and that it can only produce moderate change; and the view that nonviolent action works solely in democratic contexts and is ineffective in nondemocracies. For social scientific research on nonviolent social movements to proceed it is essential that these and other misconceptions about nonviolent action be identified and corrected (Schock 2003).

Second, while nonviolent action has been used throughout history, it has received much less attention, relative to the exercise of violence, by social scientists, historians, politicians, and the media. An important task for research on nonviolent social movements is to rethink history from a nonviolent perspective (Sharp 1973; Wink 1992; Schell 2003). In addition to uncovering the history of nonviolent action, social scientists must also explain why violence has been glorified throughout history. This would entail an attempt to understand the "myth of redemptive violence" (Wink 1992), the "mythology of terror" (Ackerman & DuVall 2000), and the glorification of violence in national myths and the socialization processes through which they are perpetuated.

Third, correcting misconceptions about nonviolent action and uncovering the history of nonviolent resistance will lead to a reconceptualization of the sources of political power. Schell (2003) makes a useful distinction between coercive power and cooperative power. Coercive power springs from the threat or use of violence, is based on fear, and flows downward from the state by virtue of its command of the instruments of violence. Cooperative power arises from the action in concert of people who willingly agree with one another. It flows upward from the consent, support, and nonviolent activity of the people. While most political theory has

assumed that violence, or coercive power, is the final arbiter in politics, the increasing use and effectiveness of nonviolent struggle has led to a questioning of this traditional assumption.

Fourth, the failure to understand the power and role of nonviolent action in political change in the past has led to the failure to predict and understand nonviolent political change in the present. In fact, it has been argued that we lack social scientific theories of nonviolent revolution (Schell 2003). According to most social scientists, violence is one of the defining features of revolutions. Yet violence has historically been much more prevalent during the consolidation of power than in the toppling of the old regime or in the revolutionary transfer of power, and the consolidation of the new order does not necessarily have to be violent. Social scientists need to theorize more adequately the role of human agency and strategy in nonviolent social movements. Social scientists have tended to emphasize structural theories of social movements and revolution. While useful, these theories may overlook the crucial role of agency, strategy, and tactics in promoting social change. Useful starting points include the works of Ackerman and Kruegler (1994), which delineate principles of strategic nonviolent conflict, and Schock (2005), which identifies attributes of nonviolent social movements that facilitate their resilience in repressive contexts and increase their leverage.

social movements, participatory democracy in

Francesca Polletta

Participatory democracy refers to an organizational form in which decision making is decentralized, non hierarchical, and consensus oriented. It can be contrasted with bureaucracy,

in which decision making is centralized, hierarchical, and based on a formal division of labor, as well as with majority vote. Participatory democratic organizations have been a prominent feature of many progressive movements, including radical pacifism, the Civil Rights Movement, the new left, feminism, environmentalism, anti nuclear activism, and the anti corporate globalization movement.

Participatory democratic organizations today claim a diverse lineage, with precursors in ancient Athenian democracy, the New England town hall, Quaker meetings, and Spanish Civil War affinity groups. The term itself was popularized in 1962 by the new left group Students for a Democratic Society (SDS). SDS leaders intended participatory democracy to describe a polity in which citizens were involved in public policymaking, not a mode of organizational decision making. However, at the time, decision making within SDS itself was collectivist and consensus oriented, this despite the group's formal reliance on parliamentary procedure. The same was true of the militant civil rights group the Student Non Violent Coordinating Committee (SNCC). For thousands of activists, participatory democracy soon became an organizational ethos. "Collectives" run on participatory democratic principles proliferated in the radical feminist and anti war movements of the late 1960s (Rothschild 2000; Polletta 2002).

By the end of the decade, many young activists perceived the political system as intransigent, and they turned to building alternative schools, health centers, food coops, and publishing guilds, thus contributing to an enduring cooperative movement (Rothschild & Whitt 1986). With the rise of the anti nuclear movement in Europe and the United States in the late 1970s, activists put participatory democratic movement organizations to use once again in overtly challenging the state, developing institutions of "affinity groups" and "spokescouncils" to coordinate mass actions involving thousands of people. More recently, participatory democratic forms have been prominent in the anti corporate globalization and global justice movements (Polletta 2002).

For sociologists writing about the surge of collectivist organizations in the 1960s, the participatory democratic impulse reflected a youthful

repudiation of authority that was at odds with the demands of effective political reform. Participatory democratic organizations were conceptualized as “expressive” or “redemptive” in contrast to their “instrumental” and “adversary” bureaucratic counterparts (Breines 1989). Since then, many scholars have instead adopted Breines’s (1989) view of participatory democracy as animated by a *prefigurative* impulse. By enacting within the movement itself values of radical equality, freedom, and community, activists have sought to bring into being a society marked by those values. Far from anti political, participatory democracy has been an attempt to transform what counts as politics.

Still, most scholars have seen participatory democracies as fragile. And indeed, some of the most famous participatory democratic movement groups, such as SDS, numerous feminist collectives, and the anti nuclear Clamshell Alliance, collapsed after explosive internal battles about organizational decision making. However, scholars have disagreed about the source of participatory democracy’s fragility. One popular explanation centers on the form’s inefficiency. Consensus decision making takes time; decentralized administration creates problems of coordination; and a minimal division of labor sacrifices the benefits of expertise. These inefficiencies are manageable in an organization that is small or has little opportunity for political impact. But when participatory democratic groups grow in size or political stature and therefore face new demands for coordination and funding, such inefficiencies become intolerable. The result is often a battle between political pragmatists, who are willing to adopt a more centralized and hierarchical organizational structure, and purists who refuse such reforms. Ultimately, either groups bureaucratize, as did many feminist organizations in the 1970s and 1980s, or they collapse.

This account neglects the fact that participatory democracy can be efficient. Multiple lines of input facilitate tactical innovation; decentralized organization allows movements to tailor programs to local contexts; and rotating leadership can maximize political learning (see Rothschild 2000 on the instrumental benefits of collectivist forms in for profit organizations). Moreover, the battles that have racked

participatory democratic groups have usually centered not on the inefficiency of the form but on the group’s failure to live up to its professed egalitarianism. In line with this insight, some scholars have argued that participatory democracy’s vulnerability is its inequity rather than its inefficiency. Michels (1958 [1915]) maintained that democratic organizations inevitably developed oligarchical structures as those occupying positions based on their expertise acquired a stake in retaining their positions. Participatory democrats refuse those imperatives and privilege democracy over expertise. That only means that the hierarchies are informal, scholars in this vein argue. The result is what Freeman (1973) calls the “tyranny of structurelessness,” in which the elimination of formal structures of authority only makes it easier for informal cliques to rule freely. When members shut out of decision making protest their marginalization, an organizational crisis is likely since participatory democracy provides no mechanisms for holding leaders formally accountable.

A third perspective holds that as long as members’ interests are fundamentally congruent, they are unlikely to object to disparities in informal influence (Mansbridge 1983). But when members’ interests conflict, which is likely to occur in all but the most homogeneous of groups, the consensus based decision making characteristic of participatory democratic organizations offers no way of adjudicating those conflicts. If minorities are not coerced to agree with the majority, then a stalemate is likely. After a series of such stalemates, an organizational crisis may ensue.

Although these explanations for participatory democracy’s fragility have been advanced separately, one can imagine that one may be more applicable than the others depending on the circumstances, or that two or even all three dynamics may operate at the same time. For example, an influx of new members may increase organizational inefficiencies at the same time as it creates new conflicts of interest and heightens newcomers’ perception of veterans as a controlling elite. But the three explanations also assume that there is a single form of participatory democracy across movements and historical eras. An alternative perspective holds

that groups have enacted commitments to radical democracy, equality, even consensus, in very different ways. For example, Polletta (2002) argues that participatory democratic groups in the pacifist, civil rights, new left, and feminist movements of the 1950s and 1960s drew deliberative norms from relationships of friendship, religious fellowship, and tutelage. The familiarity of those interactional styles made participatory democracy fairly easy to practice but also made for distinctive organizational challenges. For example, groups that styled their democracies on friendship were more likely to encounter crises after an influx of new members than were groups that styled their democracies on religious fellowship, since the latter were more comfortable with an informal probationary period for new members. In a study of three anti-toxics groups, Lichterman (1996) found that one group solicited members' input round robin style for every decision, while another consistently deferred to the group's leader. Yet, both groups said that they made their decisions by consensus. Different versions of participatory democracy may reflect distinctive political traditions, modes of religious engagement, professional styles of collaboration, or class based norms.

These kinds of institutional influences on how democratic commitments are enacted exist alongside the pressures exercised by funders and governmental agencies to shape what participatory democratic organizations look like. Funders often require explicit job descriptions and assessment criteria (Matthews 1994). The Internal Revenue Service's complex standards for retaining tax exempt status push organizations to hire legal and financial experts (McCarthy et al. 1991). The accreditation groups that evaluate organizations' suitability for philanthropic funding encourage them to create conventional boards of directors (McCarthy et al. 1991). The result is that very few movement organizations today resemble anything like a pure form of participatory democracy (Bordt 1997). Instead, a hierarchy of offices is sometimes combined with informal consultation across levels, or decisions are divided into those requiring consensus and those not requiring it, and so on (Iannello 1992). Some research suggests that these hybrid organizations have been effective

in maximizing the tactical innovation and solidarity associated with participatory democracy while avoiding the form's inefficiencies, inequities, and potential for stalemate. Even groups whose commitment to consensus based decision making is paramount tend to accept supermajorities rather than unanimity for contentious decisions and they use a range of formal mechanisms unknown to 1960s participatory democrats, such as time limits on discussions and facilitators.

Several lines of research on participatory democratic organizations are promising. Rather than looking for the fundamental flaw in participatory democracy as an organizational form, several scholars have sought instead to identify the institutional conditions in which participatory democracies are likely to proliferate (Rothschild & Whitt 1986). Another valuable approach has been to identify the tasks that are furthered or impeded by particular organizational forms, tasks such as raising funds, innovating tactically, sustaining coalitions, and ensuring decision makers' accountability (Staggenborg 1989).

A third area of promising research concerns the impacts of participatory democratic organizational forms. During historical periods or institutional arenas in which participatory democratic organizations are prominent, do they make inroads into the repertoire of institutionalized organizational forms? For example, Rothschild (2000) argues that widespread public support for workplace democracy reflects the popular valorization of terms such as "voice" and "empowerment" by the social justice movements of the 1960s and 1970s. What are the conditions in which particular versions of participatory democracy diffuse across movements? Some evidence suggests that a popular perception of participatory democracy as white and middle class may make it less appealing to activists of color and working class activists (Polletta 2005). Finally, we know little about whether participatory democratic organizations exist in conservative movements and, if they do, if they are animated by goals other than prefigurative ones.

social movements, political consequences of

Edwin Amenta and Neal Caren

Scholars have increasingly turned their attention to the political or state related consequences of social movements. Making sense of the state related consequences raises specific and difficult conceptual and theoretical issues. Conceptually speaking, scholars have to address the meaning of "success" or "influence" for challengers. Theoretically, scholars need to address what, beyond some degree of mobilization and basically plausible claims making, matters in explaining the state related impacts of challengers. In comparison to mobilizing supporters, fashioning identities among them, or achieving recognition from targets, most macropolitical consequences of challengers are not as directly related to the efforts expended by challengers.

In designating the consequences of social movements, Gamson's (1990 [1975]) two types of success have been influential. Gamson considers success in new advantages, his first type, as meaning whether a challenger's goals or claims were mainly realized. Yet Gamson's concept of new advantages places limits on the consideration of possible impacts of challenges. It may be possible, notably, for a challenger to fail to achieve its stated program – and thus be deemed a failure – but still to win substantial new advantages for its constituents. This is especially likely for challengers with far reaching goals. There may also be unintended consequences that influence beneficiary groups, and challengers may do worse than fail.

To address some of these issues, other scholars start with an alternative based on the concept of *collective goods*, or group wise advantages or disadvantages from which non participants in a challenge cannot be easily excluded (Olson 1965). Collective goods can be material, such as categorical social spending programs, but can also be less tangible, such as new ways to refer to members of a group. Social movement organizations almost invariably claim to represent a group extending beyond the leaders and adherents of the organization and most make demands that would provide collective benefits

to that larger group (Tilly 1999). According to the collective benefit standard, a challenger can have considerable impact even when it fails to achieve what it is seeking. It also can address the possibility that challengers would have negative consequences or negligible ones, such as achieving a program that did not realize its intended effect to benefit constituents (Amenta 2006). Scholars working from this standard tend to refer to the consequences or impacts of social movements rather than successes or failures. From this perspective, the greatest sort of impact is the one that provides a group, not necessarily organizations representing that group, continuing leverage over political processes. These sorts of gains are usually at a structural or systemic level of state processes and are a kind of metacollective benefit, as they increase the productivity of all future collective action of the group. Gains in the democratization of state processes are perhaps the most important that social movements can influence.

Most collective action, however, is aimed at a more medium level – major changes in policy and the bureaucratic enforcement and implementation of that policy. Once enacted and enforced with bureaucratic means, categorical social spending programs, notably, provide benefits in such a manner (Amenta 2006). The beneficiaries gain rights of entitlement to the benefits, and legal changes and bureaucratic reinforcement of such laws help to ensure the routine maintenance of such collective benefits. Under these circumstances, the issue is privileged in politics, is effectively removed from the political agenda, and the political system becomes biased in favor of the group. A bureaucracy would have to be targeted and altered, if not captured, or new legislation would have to be passed rescinding benefits – a process that becomes more difficult as time passes as bureaucracies are reinforced and people organize their lives around the programs. Regulatory bureaucracies that are products of challenger mobilizations may push on their own to advance mandates in the absence of new legislation, as in the case of state labor commissions or in affirmative action. Through their policies, states can ratify or attempt to undermine potential collective identities or help to create new ones, sometimes on purpose, often inadvertently. Dividing

the process of creating new laws containing collective benefits into the agenda setting, legislative content, passage, and implementation of legislation simplifies analysis and also makes it easier to judge the impact of challengers.

Gamson's second type of success, the "acceptance" (1990 [1975]) or "representation" (Cress & Snow 2000) achieved by challenging organizations, can also be related systematically back to states and collective benefits. To the extent that state action recognizing challenging organizations influences their form or resources, it also influences their potential to gain future collective benefits. Gamson's idea of acceptance may, however, be too broadly drawn to capture the sorts of representation sought by challengers attempting to influence democratic states. More important and plausible for state oriented challengers is a version of Gamson's "inclusion," which would amount to the placing of challengers in state positions through election or appointment. Challengers can provide candidates for office or can stand as representatives of new political parties. As is the case for other, better politically situated groups, it is possible for social movement organizations to capture bureaucracies and run them in favor of their constituency. By gaining representation in legislative offices and bureaucracies, challengers can influence policies throughout the process, including placing programs on the agenda, helping to specify their content, aiding their passage, and supporting their enforcement. Movements may also attempt to gain recognition for altered or new movement organizations, which might include political parties, political lobbying, or educational organizations. Collective action may be intended to win or may result in winning higher order rights through the state that advantage a group in its conflicts with other groups (Tarrow 1998). Labor movements, notably, often focus on the state to ensure rights to organize and engage in collective bargaining with businesses and business associations, and the state may be used as a fulcrum in transnational protest. Challengers blocked in one country may appeal to sympathetic organizations in others.

There are four main arguments designed to explain the impact of social movements on states. The first argument is that whatever aids

a group's mobilization will lead to its making gains, as mobilization of various sorts will aid movements in whatever they do (McCarthy & Zald 2002). The mobilization of various resources is needed to engage in collective action, which is designed and expected to bring a certain amount of collective benefits. This line of argumentation is consistent with rational choice discussions of collective action problems, in that they view the main issue for social movements as overcoming free rider disincentives to participation (Olson 1965). The ability to mobilize different sorts of resources is key for the impact of movements and mobilization of resources and membership has been shown to influence some state related consequences in different research (McCarthy & Zald 2002). However, mobilization seems to be a necessary condition to have influence over states, as there seems to be no connection between size of a mobilized challenger and gaining new benefits (Kitschelt 1986; Gamson 1990 [1975]).

Second, specific strategies and goals of collective action and forms of challenger organization are more likely to produce influence. Gamson (1990 [1975]) found notably that limited goals, the use of "constraints," selective incentives, and bureaucratic forms of organization were more likely to produce new advantages. In contrast, goals and strategies aiming at "displacement" – in which a movement seeks to destroy or replace its opponent – were likely to fail. Others have advanced Gamson's argument about the importance of organization in social movement success by focusing on the sorts of social movement organizations likely to produce gains. It has been argued that resourceful movement infrastructures led to gains in policy implementation (Andrews 2001) and that innovative organizational forms can lead to gains for challengers and transformations of political institutions (Clemens 1997). Singled out for special attention are claims making and framing. Cress and Snow (2000) argue notably that for a challenger to have an impact, it is necessary for it to employ resonant "prognostic" and "diagnostic" frames; to gain results, challengers need to identify problems and pose credible solutions to those problems that play to state actors and other third parties as well as to be able to mobilize participants.

A third argument attempts to take into account contextual influences by claiming that once a challenger is mobilized, the main thing influencing its impact is the political context or "opportunity structure." This line of argumentation has both systemic and dynamic components to it, and sometimes it is also argued that systemic political contexts greatly influence or determine the strategies of challengers. Kriesi and his colleagues (1995) take the most systemic view, arguing that the openness and capacity of states largely determine whether a state related movement will have influence. When states have both inclusive strategies and strong capacities, challengers are most likely to achieve "proactive" impacts. Under weak states, by contrast, reactive impacts are more probable, as the state lacks the capacity to implement policies (see also Kitschelt 1986).

The more overarching arguments have been criticized, however, on the grounds that all manner of social movements with different strategies have developed within similar countries (Dalton 1995) and that within any country differences in impacts have varied over time. Arguments regarding systemic political contexts have also been criticized on the grounds that they take a too abstract view of states and political opportunity structures. Notably, focusing on the overall openness of politics and strength of states ignores conceptual and theoretical developments in political sociology literatures that have addressed the influence of politics and states in more fine grained ways. Important factors include the polity structure, the democratization of state institutions, electoral rules and procedures, and state policies. These aspects of states influence forms of challenger representation, as well as the tactics of challengers. These arguments tend to drop the weak/strong state and open/closed polity dichotomies and refer to specific aspects of polity and political actors.

The centralization and division of power between each branch of government also has an impact on social movement organizations (Amenta 2006). An autonomous court system with veto power over the legislative branch, for example, may lead to an emphasis on legal mobilizations, which may shift focus away from more mass based protests. Multiple points of access are a two edged sword, however, as they also

provide multiple points of veto. The level of democracy has important consequences for the forms that mobilization will take. Specifically, the greater the exclusion from the democratic process, the more likely non institutional forms of protest will take place. Electoral rules may have the greatest impact on the relationship between social movements and the party system. Winner take all systems, such as in the US, discourage the formation and legitimacy of new political parties. Initiative and referendum procedures increase the likelihood that organizations will be single focused. In addition, states can also provide a variety of resources for specific social movements that can vary from concrete items to legitimacy.

On the dynamic side, the political opportunity argument focuses on alterations in political conditions that improve the productivity of collective action of challengers. In their study of farm workers' mobilization and collective action, Jenkins and Perrow (1977) found that changes in the political context influenced their growth and impact, through the rise to power of favorable political regimes and through the support of liberal organizations like organized labor. In his study of the Civil Rights Movement, McAdam (1982) argued that favorable political conditions were necessary for its gains – which were based on tactical innovations. In short, according to the strongest form of this argument, mobilized challengers have impacts largely because they engage in collective action at the right time. This argumentation has suffered, however, in comparison with the systemic view of political contexts in being able to specify what constitutes a favorable context. The main candidates – polity openness, instability of elite alliances, the presence of elite allies for challengers, declines in capacities and propensities for repression – are drawn so widely as to be difficult to operationalize.

Finally, many scholars have developed different political mediation models of social movement consequences, which build on arguments concerning strategy, organizational form, and political contexts (Amenta et al. 1992; Skocpol 1992; Amenta 2006). The basic point of this argument is that the collective action of challengers is politically mediated. In a democratic political system, mobilizing relatively large numbers

of committed people is probably necessary to winning new collective benefits for those otherwise underrepresented in politics. So, too, are making plausible claims regarding the worthiness of the group and the usefulness of its program. Yet challengers' action is more likely to produce results when institutional political actors see benefit in aiding the group that the challenger represents. To secure new benefits, challengers will typically need help or complementary action from like minded state actors, including elected officials, appointed officials, or state civil servants. And so challengers need to engage in collective action that changes the calculations of relevant institutional political actors, and challengers need to adopt organizational forms that fit political circumstances.

Political mediation arguments do not identify individual organizational forms, strategies, or long term or short term political contexts that will always or usually help challengers to win collective benefits. Instead the idea is that certain organizational forms and collective action strategies will be more productive in some political contexts rather than others. In her examination of organized groups throughout US history, Skocpol (1992) argues that to have influence the forms of challengers and other mass based interest organizations need to fit the divided nature of the American political context, a systemic condition. US organizations need to have a wide geographical presence to influence Congress, which is based on district representation. The most extensive discussion of this sort suggests that challengers need to moderate strategies and forms to address political circumstances. The standard distinction between disruptive and assimilative strategies is dropped in favor of addressing variations in assertiveness of action (Amenta 2006), with assertive meaning the use of increasingly strong sanctions, something akin to Gamson's "constraints." If the political regime is supportive and the domestic bureaucrats are professionalized and supportive, limited protest based mainly on the evidence of mobilization is likely to be sufficient to provide increased collective benefits. By contrast, achieving collective benefits through public policy is likely to be more difficult if neither a supportive regime nor administrative authority exists.

Although this understanding of the political context is a dynamic one that takes into account changes in political contexts, it can also be related back to systemic and structural characteristics of political systems, notably political institutional conditions that make the establishment of a reform oriented regime or bureaucratic capacities difficult. When the regime is opposed to the challenger or sees no benefit in adding its beneficiary group to its coalition and when state bureaucracies in the area are hostile or absent, the sorts of limited protest listed above are likely to be ignored or have a limited effect. As political circumstances become more difficult, more assertive or bolder collective action is required to produce collective benefits. Sanctions in assertive institutional collective action threaten to increase or decrease the likelihood of gaining or keeping something valuable to political actors – often positions – or to take over their functions or prerogatives. The institutional collective action of challengers works largely by mobilizing large numbers of people behind a course of activity, often one with electoral implications. This collective action may be designed to convince the general public of the justice of the cause and influence elected and appointed officials in that manner, but may also demonstrate to these officials that a large segment of the electorate is willing to vote or engage in other political activity mainly on the basis of a single key issue.

social movements, recruitment to

Steven E. Barkan and Steven F. Cohn

Social movements have long been an important basis of political participation in democracies and have achieved major political, social, and cultural changes. Although the influence of social movements depends largely on their ability to recruit members, it is by no means obvious why people choose to participate in them.

This question has been termed "the free rider problem." As Mancur Olson's (1965) analysis indicates, people have limited time and energy and must choose to spend these resources in ways that most benefit themselves. Individuals join social movements because they believe that the movement's goals, if implemented, would yield significant benefits to themselves and/or to the attainment of values they cherish. Although these benefits motivate participation, there is an additional problem. If a movement has few participants, people desiring these benefits might believe that the movement could not succeed unless they joined the movement. Thus, joining the movement might represent a rational investment of their time, energy, and, often, money. However, if a movement already has a large number of participants, then it is unlikely that one more person's joining the movement would increase its chances of success. In that case, why would additional people join? If the movement is successful, they, along with the participants, would enjoy the fruits of this success; they would have gained all the benefits of participation without spending their own scarce resources of time and energy. In that case, they could use these resources to gain other benefits for themselves, while "free riding" on the efforts of those already participating.

One possible response to this free rider problem is that people who join social movements do not rationally calculate the costs and benefits of their joining. Analyses of social movements in the late nineteenth and early twentieth centuries indeed assumed that social movements were not rational enterprises and that those who joined them were, in fact, acting on the

basis of irrational impulses. The most prominent proponent of this view, Gustave Le Bon (1897), a French theorist, said that people joined movements because they succumbed to crowd emotions and lost their ability to resist unconscious instincts. This general belief informed views of social movements well into the twentieth century, as these views stressed that movements represented an emotional and relatively unorganized response to a breakdown in social norms and social organization. Individuals were said to be attracted to movements because they were lonely and alienated owing to weak social ties and hence sought in movements a sense of belonging they otherwise lacked.

In recent years this non rational model of social movements has fallen into disfavor. Social movements are now viewed as rational enterprises in pursuit of many kinds of political, social, and cultural changes, and their members are viewed as rational individuals favoring such changes. However, the success of recent efforts to demonstrate the rationality of social movement participants has reemphasized the importance of addressing the free rider problem: if these people are rational, why do they participate at all? The contemporary literature on social movement recruitment and participation tries to answer this question.

Its dominant response derives from analogous work in complex and voluntary organizations, including labor unions. Organizations generally offer several types of resources to motivate recruitment and higher levels of participation after recruitment. These include (1) *coercion*; (2) *utilitarian incentives* such as paid income in work organizations and discounts for various goods and services in voluntary organizations; (3) *normative* (or *purposive*) *incentives* that appeal to the values, concerns, and ideologies of individuals and, in social movements, lead people to identify with a movement's goals and to believe that the movement is capable of achieving its goals; and (4) *social* (or *solidary*) *incentives* that make participation socially rewarding in terms of friendships and other personal contacts. Because social movement organizations (SMOs), like other voluntary organizations, typically lack the first two types of incentives, they must rely heavily on the latter two types to induce people to join them and to motivate higher levels of participation after joining.

In these respects, normative and social incentives act as *selective incentives* to induce self interested people to devote time and energy to participation rather than to other potentially rewarding activities. An additional category of *organizational incentives* that lead people to feel a sense of belonging to the movement is also thought to be important for levels of post recruitment participation.

In contrast to many types of voluntary organizations, normative incentives in social movements depend heavily on the movement's (or its SMOs') political ideologies and beliefs. These cognitions include the movement's grievances, goals, and strategies for change. Individuals whose own ideologies and beliefs are congruent with those of the movement are more likely to join it. In addition to these movement specific ideologies, more general cognitions may also influence decisions to join. These include a liberal versus conservative belief system, a feeling of political efficacy, and religious ideologies. Movements and organizations that are liberal tend to attract liberal individuals, while those that are conservative tend to attract conservative individuals. People who are politically efficacious, that is, who believe that citizen participation generally, and their own particularly, can make a difference, are more likely to join than those who are politically alienated. Social movements and SMOs with a religious basis for their activities attract members whose religious beliefs coincide with those of the movement or SMO.

In all these respects, a movement's set of ideologies is thought to be an important, necessary condition for recruiting members, but it is far from a sufficient condition. The reason for this is simple: many more people agree with a movement's goals and other ideologies than ever participate in the movement or help it in any other way. This recognition has led the contemporary social movement literature to stress the importance of social incentives. In this view, people join movements because they have pre existing friendship and organizational ties that induce them to join. For example, agreeing to some friends' request to join them in a protest wins their appreciation, while declining their request may win their displeasure. In this respect, recruitment into social movements is no different from the many other activities in

which social ties play an important role. Accordingly, a host of studies find that individuals with preexisting ties to movement members will be more likely to join a movement than those with fewer or no such ties. These ties appear to be especially important for recruitment into high risk activism like the Freedom Rides in the US South that were a hallmark of the Civil Rights Movement in the 1960s. By challenging the earlier, non rational model's assumption that social movements attract lonely and alienated individuals, the emphasis in contemporary work on friendship and organizational networks reinforces the rationality of social movement participation.

Turning to post recruitment participation, individuals who develop friendships after joining a movement or SMO tend to exhibit higher levels of participation than those with fewer or no such friendships. In this regard, SMOs with a national membership face particular problems because their members are geographically isolated and usually have little contact with each other or with the national organization. To deal with this situation, some national organizations have developed a "federated" structure involving many local chapters. Because these chapters enable interaction and friendships among members who live near each other, they enhance commitment to the organization itself and promote higher levels of participation on its behalf.

Organizational incentives are the final type of resource offered by SMOs and are thought to be especially important for post recruitment participation. These incentives take two forms, perceptions and communication. Members have various perceptions of their SMO. A first perception, *legitimacy*, involves members' willingness to trust SMO leaders and to support their decisions, even if the members might disagree with some of these decisions. Those with higher levels of perceived legitimacy are more likely to exhibit higher levels of post recruitment participation. A second perception involves members' beliefs in the *effectiveness* of their SMO. Post recruitment participation is generally higher among members who perceive stronger effectiveness. A final perception concerns members' *commitment*, including their sense of belonging, to their SMO and movement. Members who are more committed also exhibit higher levels of post recruitment participation.

Communication with SMO leaders and staff also matters. In particular, members who are contacted more often by their SMO's leaders and staff or otherwise communicate with them are also thought to exhibit higher levels of post recruitment participation than members with less or no such communication.

Future work on recruitment should address at least three problems in the literature. The first problem concerns potential deficiencies in the studies of recruitment. An ideal study would be predictive and would study a random sample of adults, predicting which factors would lead some of them to join a particular social movement. Because only a small proportion of adults become members of any given social movement, such a study would need an extremely large sample to have any statistical validity and would be astronomically expensive. Because of this, studies of social movement recruitment are limited in scope. Some studies are retrospective, asking current participants why they initially chose to participate. Results from these studies depend upon the assumption that current participants can accurately remember and will accurately report why they started to participate, and these studies often have no adequate control group of non participants. Other studies are predictive but only in a limited context: for example, they study who among a set of people in a particular locality who favor the goals of a social movement rally actually choose to participate in the rally. As these difficulties suggest, the recruitment literature would benefit from better designed studies, but, because of the nature of recruitment into social movements, such studies are difficult to devise.

A second problem in the recruitment literature concerns the many types of social movements. Many typologies of movements exist, but a common typology divides them, based on their goals, into political or social reform movements, religious movements, self help movements, and cultural movements. Within each category there are many types of specific movements that have existed in many different nations and localities within nations and across many different decades and centuries. Although many studies of recruitment exist, they do not begin to match in number the sheer quantity of movements, and additional work on unstudied movements may shed new light on the dynamics of recruitment.

Finally, studies of recruitment obviously imply that one is being recruited into something. But what is this something? What does it mean to be a member of a social movement? If someone takes part in just one protest on behalf of a social movement, is that person a member of that movement? As this question suggests, people do not usually sign up for a movement in the way they sign up for many other activities. To compound this problem, some SMOs are organized in a very formal manner, with clear membership rolls and criteria for membership, while others are organized much more loosely, with unclear criteria for membership and only a loose understanding, if that, of who their members are. In the most informal SMOs, members may literally come and go, and it is not at all easy to identify their members. The lack of a clear understanding in movements and SMOs, and thus in the recruitment literature, of what it means to be a member confounds efforts to achieve a comprehensive understanding of recruitment, however important such an understanding is for the study of social movements.

social movements, relative deprivation and

Mikaila Mariel Lemonik Arthur

The relative deprivation model aims to explain individuals' decisions to join or start social movements and is based on a certain set of psychological ideas (Gurr 1970). Relative deprivation itself refers to "the gap between what one has and what one expects" (Brusch 1996), particularly in comparison to some specific reference group. The concept of relative deprivation has its roots in the early "frustration-aggression hypothesis" of John Dollard, which suggested that when individuals respond to frustration and do not receive a response that relieves their frustration, such individuals will respond with aggression. Relative deprivation has been used as the mechanism to explain where this frustration emerges from.

Analysts of relative deprivation have specified a variety of dimensions of deprivation that individuals may experience. These include *aspirational deprivation*, or having increasing aspirations that are not realized; *decremental deprivation*, or when expectations are stable but available resources are declining; and *progressive deprivation*, or improvement in general social, economic, or power conditions which is followed by a sudden reversal of these trends. In general, in order to experience relative deprivation, an individual must not only experience desire, but also feel that she or he has a right to gain access to the sought after resources. In addition, she or he must experience a perception that the likelihood of one's access's being blocked is quite high. The contradiction between this feeling of entitlement and this feeling of stymied progress forms a type of cognitive dissonance (Morrison 1971) which becomes

activated through the appearance of a *structural strain* (McPhail 1971).

While many theorists of relative deprivation have confined their analysis to exploring when relative deprivation emerges and what form it takes, some have gone further to specify a mechanism whereby relative deprivation leads to collective action. The combination of feelings of relative deprivation with structural strain as noted above can lead individuals to come to see the sources of the blockages to their aspirations as *structural* blockages. Therefore, these individuals are led to seek structural solutions by working together as part of a similarly situated group – in other words, a social movement.

More sophisticated relative deprivation analyses include deprivation along with other factors, such as the balance of power between parties or resource mobilization. For instance, Korpi (1974) suggested that it is not only how deprived a group feels in terms of power resources that matters, it is also the rate of change in access to these resources relative to other groups, and that of the three types of deprivation, only progressive deprivation is likely to lead to situations of conflict. Similarly, Tilly (1973), while not writing specifically in the relative deprivation school, notes that violent collective action is particularly likely both when a group is gaining power relative to others and when they are losing it. Miller et al. (1977) propose another instance in which the experience of relative deprivation is likely to matter: in the case of uncertainty about the future. They note that only certain disaster is more frustrating than uncertainty. More specifically, models based on the notion of relative deprivation have been used to explain when revolution does and does not occur, how religious movements or cults come into being, and the timing of urban race riots.

The empirical evidence used to demonstrate relative deprivation is usually socioeconomic in nature and collected on aggregate levels, such as census data, even though deprivation itself is an individual experience. In addition, more recent empirical research has had difficulty confirming the usefulness of relative deprivation models. For instance, relative deprivation may be able to explain some small part of the variation in riots, but it is unable to explain why the majority of individuals who face relative

deprivation do not act on this fact. However, even some analysts who are not fully impressed by the relative deprivation approach point to the likelihood that individual members of social movement organizations may talk about their reasons for forming or joining the movement in terms that can be conceived of as relative deprivation (Wallis 1975). Others have criticized the relative deprivation model because it cannot be tested empirically without some sort of evidence of feelings of deprivation prior to the collective action episode (Kent 1982). The model, therefore, is less commonly employed in sociological analyses of social movements today, though it continues to prove popular among psychologists.

social movements, repression of

Jennifer Earl

The repression of social movements refers to attempts by groups, individuals, or state actors (e.g., militaries, national police, and local police) to increase the costs associated with social movement participation or otherwise limit social movement activity. Commonly studied forms of repression include police action at public protest events, such as arrests and police violence, military suppression of protest events, "disappearances" of activists, arrests and/or imprisonment of social movement participants, infiltration of social movements by government informants, covert counterintelligence programs against social movement organizations and participants, restrictions of free speech and assembly, assaults on human rights, and murders of social movement activists, among other tactics.

Recognizing that the above examples represent a wide variety of ways to suppress or control protest and social movements, scholars have sought to distinguish between different types of repressive actions. Two common distinctions that have been made are between overt and covert repression and between coercive repression and channeling. Researchers make these kinds of distinctions because they suspect that the dynamics and consequences of repression may differ depending on the kind of repressive tactic deployed.

The distinction between overt and covert is based on visibility of the repressive acts (or, at least, how visible they are intended to be). For instance, the Federal Bureau of Investigation (FBI) ran a series of covert counterintelligence programs against selected social movements from 1956 to 1971 in the United States. These programs used methods such as tapping phone

lines, examining mail, and burglarizing dwellings and offices to gather information that was meant to affect the ability of social movements to survive and/or deploy certain tactics, without the public recognizing that the FBI was targeting these groups. In contrast to these covert tactics, other repressive actions are meant to be publicly visible (i.e., overt). An example of overt repression was the Chinese government's actions at Tiananmen Square in 1989, where the government used military tanks to crush protesters and move crowds.

The distinction between coercion and channeling is also important. Coercion involves violence, harassment, and surveillance while channeling occurs when laws, policies, or actions reward protest movements for using certain kinds of tactics (typically, more institutional and/or non violent tactics) while discouraging others (typically, more radical, non institutional, or violent tactics). Coercive repression is well known: the tanks in Tiananmen Square, South American death squads, and murders of civil rights activists in the US are all examples of coercive repression. In contrast, channeling focuses on the proverbial carrots that can lure protesters toward certain tactics and/or goals as well as the proverbial sticks that push protesters away from certain tactics and/or goals. For example, some have argued that US tax laws on non profit status encourage social movement organizations to take more institutional action and less political action. If social movement organizations were to organize the use of violent tactics for political ends, for instance, their tax exempt status could be threatened. Thus, social movements are channeled toward more conventional and less political action by the US tax code. Another well studied example of channeling involves donations to social movement organizations. Some scholars have argued that philanthropists encourage moderate protest and discourage radical protest by funding moderate social movement organizations and defunding organizations that radicalize. Although empirical research suggests that funding can be reactive, scholars have not confirmed the extent to which defunding, in particular, actually occurs.

A less frequently invoked distinction between different kinds of repression involves who is "doing" the repression. The bulk of research

on the repression of social movements has focused on the role of state actors (e.g., militaries, national police, and local police). However, this should not suggest that there are not important theoretical differences between state actors, nor should it suggest that private groups and/or individuals never repress social movements. Militaries charged with repression in authoritarian states are likely to differ from local police agencies, with respect to both how they distribute repression and the types of repressive actions they employ. In contrast to state action, groups such as the Ku Klux Klan (KKK), White Citizens Councils, universities, corporations, and the philanthropists discussed above have all been implicated in the repression of social movements. The KKK, for example, engaged in coercive repression against civil rights activists, and corporations have employed private security agents to disrupt strikes.

All three of these distinctions between various types of repression – covert versus overt, coercive versus channeling, and private versus public actors – are important because they bear on two fundamental questions that scholars have raised about repression: (1) how can researchers explain the level and types of repressive actions taken against different activists and social movements? and (2) how can researchers explain the consequences, or effects, of repression on activists and social movements?

EXPLAINING THE LEVEL OR TYPE OF REPRESSION

The vast majority of research that casts repression as a dependent variable has focused on explaining the level of particular types of repression without discussing tradeoffs between different types of repression. For instance, scholars may separately attempt to explain the number of protests at which police will be present, the number of political murders, or the severity of restrictions on free speech or free association in a country, but they have much less frequently examined how an increase in the severity of free speech and free association restrictions might affect the rate of political murders in the same country.

Scholars interested in explaining the prevalence, level, or severity of a particular type

of repression tend to focus on a small set of causal explanations. The most widely researched and supported explanation is often referred to as a "threat" model of repression because it predicts that the more threatening a social movement, a social movement organization, or a protest activity is to the government and government elites, the more likely or severe repressive action will be. Because the emphasis is on threats to regimes, this approach has largely been used to explain repressive acts by governments or actors closely connected to the state.

Scholars working within a threat perspective have differed in whether they consider objective threats or subjective threats to be most important. Scholars who emphasize objective threats to a regime have been referred to as "realists" or "realists." Other scholars argue that governments and political elites do not always recognize existing threats, may misinterpret a non threat as threatening, or may otherwise exaggerate or downplay objective threats. Scholars emphasizing the subjectivity of threats refer to the process by which states and/or political elites recognize and/or construct threats as "threat perception."

Whether concerned with objective or subjective threats, a range of particular factors has been identified as objectively threatening, or likely to be perceived as threatening, including: the mobilization of large numbers of social movement supporters and participants, the use of radical or violent protest tactics, and the embrace of radical or transformative ideologies, to list a few.

In addition to a threat model of repression, others primarily interested in repressive actions by states have argued that states are opportunists. That is, since scholars believe that states are interested in suppressing all challengers, weak challengers that appear vulnerable to repression will quickly become targets of repressive action. Weakness could be indicated by a range of characteristics, such as the social composition of social movement supports and/or the level of resources a social movement has available.

Still others have attempted to explain the level or severity of repression with reference to the organizations and actors that are charged with carrying out repressive acts. For instance,

recent research on the FBI's covert counter intelligence programs in the 1960s and 1970s suggests that the organizational structure and decision making processes of the FBI influenced what groups were targeted for action, the tactics that were used against targeted groups, and the extent to which different groups were consistently and heavily repressed. Others have made similar arguments about organizational and institutional characteristics of police forces in explaining police action at protest events.

In contrast to these approaches, which view repression as an outcome of some directional causal process, others have argued for a more emergent view of repression. Specifically, some researchers interested in processes of interaction between insurgents and authorities argue that general explanations of repression are problematic because many repressive outcomes are actually the result of situational interactions and thus cannot be predicted (e.g., police interact with protesters and out of that interaction emerges a police response to protesters).

Other scholars interested in interactions between activists and repressive agents have understood interaction to be less about situational interactions and more about the relationships over time between authorities and insurgents. Framing the interaction between authorities and insurgents as a predator-prey situation, these students of social movements have argued that causal consistencies may exist. Methodological techniques, such as biological predator-prey statistical models, allow these researchers to statistically diagnose feedback processes between authorities and insurgents. For instance, a general version of one of these models would specify that the actions of repressive agents at Time 1 affect some movement characteristic at Time 2, which in turn affects the actions of repressive agents at Time 3. Some researchers have expanded these techniques to consider how repressive actors, movements, and countermovements interact over time and thereby affect the rate and/or severity of repression.

THE EFFECTS OF REPRESSIVE ACTION

Quite aside from the question of how to explain repression, or changes in repressive levels over

time, researchers have also engaged a second major research question on repression: what are the effects of repression on activists and social movements? Most of the research in this area has focused on the effects of repression on either the level of social movement activity or the tactics deployed by social movements.

Before discussing theories about the effects of repression, it is important to understand how this debate is related to major theories on social movements. Some interest in the effects of repression on the level of social movement participation has been generated by the connection of repression to arguments surrounding "political opportunities." In the political process approach to explaining social movement emergence, mobilization, and success, repression is thought to represent one type of political opportunity. Political opportunities are critical to political process theory because the theory's fundamental proposition is that favorable political opportunities have a direct (or curvilinear, according to some) relationship with movement emergence, movement mobilization, and movement success.

One could further specify, differentiating between stable and volatile political opportunities. Stable opportunities are often defined as being structural, and hence are called political opportunity structures (POS). Repressive capacities or structural controls on repressive agents (e.g., constitutional limitations on police power) are seen by some scholars as POS. Volatile opportunities vary over time and may be less structural. The prevalence of state repression at a given moment is often referred to as being a component of volatile political opportunities.

Political process theorists argue that repression dampens social movement mobilization and may encourage the use of more institutional, and less violent, social movement tactics. Sometimes framed as increasing the costs of movement participation, or the costs of deploying a particular tactic, the claim is that repression reduces the number of individuals willing to engage in protest at all, or at least the number of individuals willing to use particular protest tactics. Others interested in rational choice models of collective action, but not in political process or political opportunities, have agreed with this cost based argument, suggest ing that repression raises the costs of activism

and thus should reduce the overall amount of activism.

While supportive evidence of this claim has been found, evidence has also been found suggesting that repression radicalizes social movement participants. Thus, instead of diminishing protest or deterring the use of particularly aggressive tactics, many scholars have argued that repression encourages further protest and the use of non institutional tactics.

Still other scholars have sought to reconcile these seemingly divergent empirical findings by arguing the repression has a curvilinear (or, alternatively, an inverted U) relationship to movement participation and the use of confrontational tactics. For instance, if there was no repression, such a society might be so open to change that protest would be unnecessary. At the same time, if a society was under authoritarian control, the costs for activism might be exorbitant. Under this logic, one would expect protest where moderate repression is found, represented by an inverted U relationship between repression and protest. This dizzying array of theoretical arguments is matched by a similarly large array of discordant findings: empirical evidence exists for direct, inverse, curvilinear, inverted U, and null effects of repression on movement mobilization and tactical deployment. Thus, despite significant scholarly effort, substantial discord about the effects of repression still exists.

social movements, strain and breakdown theories of

Steven M. Buechler

Strain and breakdown theories seek to explain the causes of collective behavior and social movements. They implicitly presume that when social institutions are stable, collective behavior is unlikely. It is when institutions undergo strain or breakdown that the resulting social disorganization and decreased social control are more likely to foster collective behavior in the form of fads, crazes, riots, rebellions, movements, and revolutions.

The classical sociological spokesperson for this approach is Émile Durkheim, who diagnosed modern society as insufficiently integrated and subject to grave dangers of anomie and egoism. Put differently, chronic strains and acute breakdowns in social order could foster many types of antisocial behavior, including suicide (Durkheim 1951 [1897]). European crowd theorists then seized on notions of strain and breakdown to explain both the emergence and the stereotypically excessive and irrational nature of crowd behavior. Robert Park transplanted this perspective to the United States in

the early twentieth century and laid the foundation for the collective behavior tradition.

Herbert Blumer definitively established collective behavior as a major subfield in US sociology. His work (Blumer 1951) posited strong links between strain or breakdown and a distinctive conception of collective behavior (including crowds, masses, publics, and movements) that emphasized its spontaneous, contagious, excitable, and often irrational character. Turner and Killian (1987) further developed this approach by analyzing emergent norms in collective behavior.

Several other variations of the collective behavior tradition emerged in the 1950s and early 1960s. Relative deprivation theory interpreted strain as a social psychological condition of cognitive dissonance that motivated collective behavior. Structural functionalists proposed an elaborate multistage model in which structural strain was a crucial factor facilitating the emergence of many different forms of collective behavior (Smelser 1962). Mass society theorists saw strain deriving from the lack of intermediate social groupings that fostered alienation, which in turn motivated participation in collective behavior.

From European origins in the 1890s through US sociology in the 1960s, strain and breakdown provided the preeminent explanations of the emergence of collective behavior and social movements. However, critics argued that this tradition viewed collective behavior in a distinctly negative way. While there were more differences between theorists than the critics acknowledged, the charge was that the tradition as a whole viewed collective behavior as irrational, disorganized, emotional outbursts that spread through contagion and threatened social order. This broad challenge was accompanied by more specific criticisms of strain and breakdown theories as too vague, not necessary, or not sufficient to explain collective behavior. These criticisms were part of a major paradigm shift prompted by the protests of the 1960s, the politics of younger sociologists, and their unwillingness to analyze these protests in the unfavorable terms of collective behavior theory.

Proponents of the new resource mobilization paradigm in the 1970s and early 1980s argued that the collective behavior tradition involved a priori, negative judgments of such behavior;

that collective behavior was too broad a category to be intellectually viable; that social movements required a different analysis than more fleeting forms of collective behavior; that movements were often rational, organized, enduring, and legitimate responses to injustice; and that movements were better explained in political than psychologically reductionist terms.

These critiques also rested on empirical investigation. Studies of 1960s urban riots found strain and breakdown theories to be vague and psychologistic, to obscure the political dimensions of these riots, to deny rational and strategic aspects of riots as a political tactic, and to obscure the actual roots of the associated violence. Work on European collective action also argued that violence is better seen as an interactive product of relations between authorities and protesters, and that protesters often act in a rational, purposive, political fashion when choosing tactics. In explanatory terms, these critics argued that the degree of solidarity among contenders is a much more precise predictor of the episodic nature of collective action than vague notions of strain and breakdown. These critics concluded that breakdown theories are logically and empirically flawed and that solidarity theories are universally preferable (Tilly et al. 1975).

Until the mid 1970s, strain and breakdown theories were still the prevailing explanation of collective behavior. Less than a decade later, they had all but disappeared with the paradigm shift from collective behavior to resource mobilization, and the consequent marginalization of strain and breakdown explanations.

Despite their marginalization, strain and breakdown theories persisted around the edges of this new subfield. One example may be found in studies of revolution. Working outside the mainstream resource mobilization paradigm, Goldstone (1991) identified similar dynamics in revolutions in the modern world involving state breakdown, revolutionary contention, and state rebuilding. State breakdown involves a conjunction of state fiscal distress, elite alienation and conflict, and high mobilization potential among the general populace. In this interactive model, all three elements must be present if a full revolutionary challenge is to unfold. The background causes of state breakdown are historically specific, but often involve

demographic growth and population shifts which put new pressure on state resources (Goldstone 1991). Goldstone concludes that state breakdowns from 1500 to 1850 resulted from population growth which overwhelmed agrarian bureaucratic states and prompted fiscal instability, intra elite conflicts, and popular unrest. In its emphasis on deterministic background factors and external variables, Goldstone's model is closer to the collective behavior tradition's emphasis on strain and breakdown explanations than it is to the more movement centered resource mobilization model.

Another example of the persistence of strain and breakdown approaches is Piven and Cloward's (1992) argument that social structures normally limit opportunities for protest and diminish its force when it does occur. Thus, it is social breakdowns in society's regulatory capacity and everyday routines that provide rare but potent opportunities for mass defiance. But breakdown is not enough; people must also see their deprivations as unjust and mutable. Such insights are only likely when social distress is high or institutions are obviously malfunctioning. Societal breakdown thus not only disrupts regulatory capacity and everyday routines, it also raises consciousness about alternative social arrangements. Piven and Cloward (1992) further argue that strain and breakdown are especially critical for explaining non normative protest in the form of mass defiance; the latter is a more basic challenge to power since it not merely pursues a specific agenda but does so in a way that challenges elite rule making. The distinction is critical to the debate: breakdown is not a necessary precondition of normative group action but it is a precondition of collective protest, riot, and rebellion.

A final example of the persistence of breakdown theories is a recent specification that links breakdown and the quotidian nature of social life (Snow et al. 1998). The latter refers to taken for granted practices and routines that comprise habitual social action, alongside routinized expectations and the suspension of doubt about the social world and one's role within it. Disruptions of the quotidian make routine action problematic and undermine the natural attitude. This specification of breakdown dynamics can be combined with solidarity explanations since it is not the associational

ties between people that break down but rather their taken for granted practices and beliefs. These three very different examples illustrate the persistence of strain and breakdown theories despite their marginalization by the resource mobilization perspective. For further examples, see Useem (1998).

While strain and breakdown theories have persisted in these ways, it can also be argued that they have actually returned to mainstream social movement theory under a new nomenclature (Buechler 2004). There is considerable conceptual overlap between what collective behavior theorists mean by strain or breakdown and what resource mobilization theorists mean by opportunity. What obscures this equation is the valuational bias of each set of concepts. The terms "strain" and "breakdown" inherently connote negative, problematic conditions to be prevented, avoided, or repaired. As these terms functioned in the collective behavior paradigm, they conveyed deeply embedded negative judgments about the appropriateness of collective behavior. And as Useem (1998) recently observed, breakdown theorists to this day are more likely to see social control in a positive light and protester action in a negative light. Thus, it was not just breakdown as a causal mechanism that provoked the ire of critics; it was also the halo of negative judgments that drew their fire.

The concept of opportunity was tailor made for this debate. It provided the transvaluation sought by critics that allowed them to paint collective action in a positive light. In contrast to "breakdown," "opportunity" inherently signifies something to be sought, desired, seized, enjoyed, valued, and maximized. In addition, it preserved a way of talking about changes in background conditions that facilitate collective action. By substituting opportunity for breakdown, resource mobilization and political process theorists retained a powerful explanation for collective action while reversing the valuations placed on that action.

This concept has now found its place in social movement theory in a theoretical synthesis of political opportunities, mobilizing structures, and framing processes. While opportunity and breakdown are not the same thing, they do the same work in their respective theoretical traditions. Both refer to external, variable processes
