most ordinary sociological studies, which identify correlations between socioeconomic background factors and various cultural practices and habits. Bourdieu, however, made a further claim. He claimed that in any society tastes are hierarchically ordered. This means that there is a legitimate taste in each society which gains its legitimacy from the very fact that other, lower echelons of society, the middle classes in particular, acknowledge its superiority by aspiring to acquire it and its visible symbols. A process of continuous social emulation reproduces both cultural distinctions and, by doing so, the different forms of capital. This process perpetually forces the upper classes to distinguish themselves from their social competitors by adopting new signs and symbols of excellence. One of the logical consequences of Bourdieu's analysis is that, as a result of the continuous process of making new distinctions, the taste of the upper classes tends to become more and more refined and exclusive. What we have here is, essentially, an aristocrat's taste. The cultural hero of early modernity, the dandy, is its true representative.

CLASS TASTE OR A VARIETY OF TASTES

Bourdieu's strong emphasis on the hierarchical and aristocratic nature of the ruling class taste is what has caused most reservations among sociologists toward his theoretical interpretations. The criticisms address concrete empirical and theoretical questions concerning his model. The dissenting empirical results can be explained both by different and rapidly changing socioeconomic conditions (most notably the democratization of educational opportunities) and by theoretical and methodological differences in the study designs.

An interesting question raised in recent studies is the emergence of a cultural omnivore. According to this idea – proposed by Peterson and Kern (1996) – what distinguishes the present cultural upper class from other classes is not the exclusiveness and refinement of its taste, but rather the very opposite, its inclusiveness. Peterson and Kern's studies of musical tastes

in Northern America revealed that the elite were omnivores – this was true above all of the economic elite graduating from business schools. They appreciated most or several musical genres almost indiscriminately, whereas social groups with less economic and cultural capital were much more restrictive in their tastes, with preferences such as country and western or gospel. Quite unexpectedly, business school graduates are the new cultural heroes.

Another interesting empirical observation to which Bourdieu paid very little attention in his own study are the distinctions according to gender. In virtually all subsequent empirical studies, gender differences seem to lie behind many distinctions in various fields of consumption and culture. They are particularly accentuated in the consumption of goods or in the practices of traditional high culture often associated with established cultural institutions, such as museums, art exhibitions and galleries, theatres, dance performances, etc. All have become leisure time activities for an increasingly female public. What is more important, they are practiced by women of various educational backgrounds, that is, not only by relatively well educated women but even by those in the middling positions. An equally clear distinction between the sexes can often be found, for instance, in eating practices and food tastes.

FUTURE DIRECTIONS

One of the interesting questions facing future research is to what extent does this validate the fact that by increasingly taking over such typically "highbrow" cultural practices women have really become a new cultural elite. Or, conversely, does this signify a general social and cultural degradation of these traditional genres and fields of "highbrow" culture? Or, finally, is it more likely, as suggested by some sociologists, that even though relatively clear cultural distinctions related to different taste preferences exist in present day societies, they are not in general or in the majority of cases hierarchically ordered? Women and men, or for that matter young people and old people, may just develop different tastes, but this practice does

not necessarily have to signify an eternal struggle over the determination of legitimate or good taste. Instead, we may have entered a state of societal development which is characterized by the emergence and coexistence of a number of different and equally good – or, if you like, bad – tastes. Social groups with similar lifestyles may just share a common taste without sharing anything else. Or, finally, as some sociologists claim, taste may have become more individualized and society more fragmented.

tatemae/honne

Jane Bachnik

Tatemae/honne distinguish between the world of social relations (surface reality) and the world of feelings (inner reality). *Tatemae* refers to formal principles or rules to which one is at least outwardly constrained, while *honne* conveys personal feelings or motives, which cannot be openly expressed due to *tatemae*. Rather than a discrepancy between a “false” exterior and “true” interior, *tatemae/honne* are better understood as conveying the existence of more than one kind of truth in social situations. Thus the “truth” of what is appropriate to say directly to others may be different from the “truth” in our hearts. Japanese cocoon their guests in *tatemae* so that a faux pas by a guest, even if it offends the host, will not be communicated directly in *tatemae*. Japanese accept that social communications may not correspond to personal feelings; moreover, they consider the surface reality to be just as “real” as the inner, private reality.

The words *tatemae/honne* came into frequent use only in the post war period, although the distinctions they characterize are found in literature as far back as the fourteenth century. *Tatemae* refers to the ridgepole (or main beam) in Japanese architecture, which supports the rest of the structure, and psychiatrist Takeo Doi considers the logic of *tatemae/honne* to be manifested in the relationship between the *tatemae* and the finished building. The *tatemae* is not the real aim of the builders, who construct the ridgepole in order to add the roof, walls, and floors that will constitute the completed building. Yet by the same token, it is impossible to complete the rest of the building unless the *tatemae* is raised first (Doi 1986). This logic privileges *tatemae* as the “core structure” of a building, which seems the opposite of its meaning as “surface reality.”

But this same logic links *tatemae* to its prime meaning of social conventions, such that *tatemae* supports the “structure” of social life much as the ridgepole supports the house. For example, the *tatemae* of the science fiction novel refers to the conventions for writing this kind of novel, which are created by a consensus that

can change over time. In its relationship to social conventions, *tatemae* always implies the existence of people in the background who assent to it, while at the same time keeping their own personal motives and opinions in *honne* (Doi 1986). Rather than being unique to Japan, *tatemae/honne* represent tensions between conforming to social conventions and giving expression to one's heartfelt desires – tensions between individual and society that are a fundamental part of social life everywhere.

In fact these same tensions are represented in a number of paired sets of terms, which include *omote* (“appearance,” “in front”) and *ura* (“behind the scenes,” “in back”). *Tatemae* is part of *omote* as official, public, and social, while *honne* is within *ura* as hidden, secret, and personal, and may also include what is publicly unacceptable or even illegal. Another set of terms, *uchi* (“inside,” “us,” “our group”) and *soto* (“outside,” “them”), is also linked to *tatemae/honne*, since *tatemae* constitutes the surface communication of *omote* presented to *soto* outsiders, while *honne* is expressed in the behind the scenes *ura* sphere of *uchi* insiders. *Tatemae/omote/soto* are always linked together, as are *honne/ura/uchi*.

The Japanese language also exhibits wide ranging distinctions manifested in formal/informal grammatical forms which parallel the distinctions contained in the double sets of terms. For example, communication of *soto/omote/tatemae* is characterized by choice of a formal register to express varying degrees of distance and deference through elaborated polite forms of speech. Communication of *uchi/ura/honne* is marked by choice of an informal register to express varying degrees of closeness (and some times intimacy) through highly contracted plain forms of speech. These distinctions permeate the entire language, since even single utterances, and certainly anything longer than two item exchanges, are marked by the use of register.

These language distinctions in tandem with the paired sets of terms indicate two distinct spheres in self and social life, which are nonetheless linked like two sides of a coin. Each sphere mutually defines and constitutes the other, in a way that actually mirrors the constitution of self and society. Thus *honne* exists only in relation to *tatemae*, and *tatemae* is constructed out of *honne*, which manipulates it from behind

the scenes. Consequently, the paired terms have been used as a basis for defining the organization of Japanese self and society. Takeo Doi (1986) developed the organization of a double sided Japanese self, based explicitly on *omote/ura* and *tatemae/honne*. Chie Nakane (1972) defined *uchi* as a basic and ubiquitous component of Japanese society. Bachnik and Quinn (1994) argued that the paired sets of terms form a theoretical basis for defining self, social life, and language, spelling out pragmatic and practice oriented perspectives.

Japanese society is distinctive in placing a high value on avoiding direct communication of *honne* problems, disagreements, and other “uncomfortable truths” in *tatemae*. Japanese are taught to sacrifice *honne* for the sake of *tatemae*, and are very skilled at keeping *honne* from “leaking” into *tatemae*. Yet *tatemae* can be seen as one of Japan’s “truly excellent features” (Kerr 2001), which infuses daily life in Japanese face to face communities with grace and calm. The emphasis placed on preserving *tatemae* over expressing *honne* can be regarded as self sacrifice for the sake of the greater social good (in this case the smooth functioning of social life).

But by the same token, should the sense of self service for a greater social good be distorted or lost, the results can be socially corrosive and dangerous. Many authors have noted that *tatemae/honne* distinctions are pervasive in Japanese large scale institutions, including those at the apex of power in government, big business, and politics. It is also noted that *tatemae/honne* have undergone a shift in meaning, so that *tatemae* now widely conveys falsity and emptiness, while *honne* is considered “true,” but tinged with dirtiness and corruption.

At the same time, a shift can be noted in the organization of *uchi/soto* when comparing small scale family organizations to large institutional organizations. This shift is exemplified by the constitution of *uchi*, which in family organizations consists of family members themselves (as “we,” “us,” “insiders”), making them privy to the realms of *ura* and *honne*. In contrast, in the government bureaucracy, for example, each government ministry is organized as an *uchi*, whose “inside” realms of *honne* and *ura* are accessible only to its own insider bureaucrats. The public is strictly *soto* to such a ministry and therefore privy only to *tatemae* communication.

Consequently, the inside operations and affairs of each ministry are kept opaque, and the hidden nature of *honne/ura* in these bureaucratic *uchi* gives rise to a circular process, whose aspects have been the focus of considerable research and investigative reporting in English. They include the fostering of dishonest and collusive practices in *uchi*; sabotaging of safety and regulatory procedures; and cosmetic accounting (*funshoku kessan*) to keep information about dishonest practices from reaching the *soto* public.

For example, bid rigging (*dango*) is pervasive in Japan, particularly in the construction industry, to whom the Construction Ministry channels the considerable funds allocated to public works construction. Ministry officials also participate in *dango* and have publicly defended bid rigging practices in 2005. *Dango* rests upon a tender system that is both fixed and closed, and such bidding inflates the project costs to the public by 30–50 percent. Crucial to carrying out *dango* is a practice known as *amakudari* (descent from heaven), in which bureaucrats from the ministry shift to high positions in industry or public agencies. *Amakudari*, in effect, creates an *uchi* conduit between the ministry and the firm or agency into which the bureaucrat descends. This allows that organization to create *uchi* ties with the ministry to create *dango* (and other *ura* practices) – through a *honne* motivation to maximize profits among themselves.

Such collusion is not limited to the Construction Ministry. In 1996 all of Japan's seven housing loan corporations (known as Jusen) went bankrupt with losses of eight trillion yen. Yet, even though over 90 percent of the loans extended by the Jusen were non performing by the early 1990s, and the Ministry of Finance knew this, the ministry failed to take any action. This was because six of the seven Jusen were run by *amakudari* directors from the Ministry of Finance, and so the ministry had no desire to "hurt its own," as one critic put it (Bowen 2003). Consequently, in the years before bankruptcy, the *amakudari* executives guided the banks in an elaborate shell game of accounting trickery that is highly developed in Japan. By the time the scandal became public in 1996, the public had to pay hundreds of billions of additional yen to clean up the mess (Kerr 2001).

During the 1990s a series of scandals circulated throughout the ministries, involving almost all of them. The scandals demonstrated the collusive processes outlined above, and one might expect the press to play an investigative role in breaking up such collusions. But since reporters can only get access to the news by being embedded in government attached press clubs, they also end up in collusion with the institutions in which they are embedded. The result is that the published news is largely *tatemae*.

The collusive relationships outlined above reveal a distinct – and pathological – inversion in the values of *tatemae/honne*, so that personal profiteering in *honne* takes precedence over self sacrifice for the greater social good in *tatemae*. Here the "good" has been transposed from the public, social good to a selfish, *uchi* good – "taking care of our own" – resulting in a huge variety of corrupt practices. This inversion of the government servant/public service relationship victimizes the public, who ultimately pay for the corruption – through wasted tax money which has created enormous fiscal deficits (and cuts in services), made pension funds insolvent, inflated construction costs, and created numerous safety hazards due to lack of effective regulation.

The kinds of collusive practices described above make it understandable how *tatemae* now connotes falsity and deceit, *honne* conveys dirtiness and dishonesty, and both *tatemae* and *honne* are held in low regard. The crucial question is whether the "excellent features" of *tatemae/honne* can be reclaimed, so that the corrupt and inverted relationship between bureaucrats and the public can be righted and self sacrifice for the social good take precedence over personal profiteering. These issues of bureaucratic corruption are of interest far beyond Japan, for they pervade today's world. Resolving them would strengthen Japanese democracy, by allowing the people to reclaim power from the bureaucracy and follow the constitution, which places sovereign power in their hands. These steps may also allow the people who produced the "economic miracle" to finally emerge from the quagmire of their 15 year slump.

taxes: progressive, proportional, and regressive

Christine A. Wernet

The generation of government revenue and the redistribution of income among the population are two central reasons for taxation (Davies 1986). Governments have used taxation as a means to generate revenue for centuries, and some governments have been using taxation as a means of resource reallocation since at least the 1800s. The three main types of taxation, progressive, proportional and regressive taxes, are outlined.

Progressive taxes are taxes that require those who earn more money to pay higher taxes. Personal income taxes in the US are progressive. For example, those who have a family income of \$100,000 or higher may pay as much as 29 percent of their total income in annual taxes, while those in the lowest income bracket, who may have a family income of \$10,000, pay approximately 4.6 percent of their total income

in annual taxes (Mishel et al. 1999). Proponents of progressive taxes argue that wealthy individuals have a moral obligation to society to pay higher taxes. Opponents argue that progressive income taxation has a negative effect on capital formation and economic growth.

Proportional taxes refer to taxes that equally burden all income groups in a society. Proportional taxes are sometimes referred to as a flat tax. For example, if a society had a proportional income tax of 15 percent, a family with an annual income of \$100,000 would pay \$15,000 a year in income taxes, while a family with an annual income of \$10,000 would pay \$1,500 a year in income taxes.

Regressive taxes burden lower income groups more than higher income groups. Less affluent individuals spend a higher proportion of their income on regressive taxes, such as sales taxes and excise taxes, than do more affluent individuals. For example, \$400 of sales tax is a much larger proportion of \$10,000 than it is of \$100,000. Sales tax is tax that is placed on all items that are sold: food, clothing, furniture, etc. Some states place a sales tax of, for example, 7 percent on all items sold. In this case, if an item is purchased for \$100 the individual will owe \$7 in sales tax to the government. Another regressive tax is the excise tax. Excise taxes are placed on certain items such as alcohol, tobacco, and gasoline. Excise taxes place a heavier burden on the poor than on the rich because excise taxes, like sales taxes, account for a larger proportion of their total income.

When all forms of taxation are considered, some countries, such as the US, actually have more income inequality after taxation than before (Devine 1983; Kerbo 2003). Therefore, while taxation does much to generate revenue for the government, it may do little to redistribute resources.

Taylorism

Harland Prechel

Taylorism was developed by Frederick Taylor in the 1880s. By the 1920s, together with other forms of scientific management, Taylorism was widely adopted in the US and other industrial societies. Taylor was raised in a prominent Philadelphia family, but rejected his parents' plans for a Harvard education and became an apprentice in a metal working plant. Later, he obtained a technical degree. Despite his career focus, Taylor retained the ideological bias of his upper class background that incorporated dimensions of socio Darwinism and utilitarianism. This doctrine provided the ideological context for Taylor's system of scientific management, which emphasized the idea that economic success is caused by superior abilities and those abilities can be learned.

Changes in the political legal arrangements in which business enterprises were embedded and the emergence of the modern corporation established the social structural context for implementing Taylorism. In the 1880s and 1890s, New Jersey and other states passed laws that made it easier for industrial firms to use the joint stock holding company. The embeddedness of industrial firms in these institutional arrangements permitted corporate consolidation, which created giant corporations by merging firms and incorporating them as subsidiary corporations (Prechel 2000). Attempts by capitalists to exercise more control over the labor

process in these corporations resulted in labor unrest, which was manifested as high rates of absenteeism, labor turnover, and strikes. In response to these historical contingencies, Taylor (1967) claimed there was a need for "greater national efficiency" and efficiency is best achieved through systematic management of people. He argued his system would reduce costs, increase efficiency, and appeal to workers' economic self interest. Taylor claimed that the increased efficiency from scientific management would result in high profits, which would permit capitalists to increase wages, thereby eliminating labor unrest and workers' desire to join unions.

The technical dimensions of Taylorism focused on the "one best way" to perform work. Taylor (1967) maintained that workers (1) retained knowledge over the production process, and (2) incorporated rest breaks into the production process (i.e., soldiering) that were so sophisticated and complex that capitalists and their foremen could not detect them. To increase control over the labor process, Taylor collected information from workers and located it in a centralized planning department where engineers used this information to establish rules to control the execution of each task by specifying how to complete it and the amount of required time to do it.

Drawing from the Marxian Hegelian conception of alienation, Braverman (1974) maintained that the separation of conception from execution in Taylorism dehumanizes the worker because it limits the opportunities for individuals to use their creative capacities. This separation occurs when engineers transform craft knowledge into work rules (i.e., bureaucratic controls) and machines (i.e., technical controls) (Edwards 1979). Although the centralization of knowledge also subordinated operating managers to centralized control, these managers retained a substantial degree of control over the managerial process during this historical period. Taylor also developed a reimbursement system that rewarded managers in relationship to their position in the hierarchical division of managerial labor.

There are several long term effects of Taylorism on class relations. First, the adoption of Taylorist ideology, which assumes that workers are inferior to managers, has been the source of

conflict between workers and managers. Second, the emergence of organizational hierarchies and the concomitant ideology of Taylorism encouraged managers and engineers to disregard workers' knowledge of the production process, which created obstacles to improving efficiency. Third, the reimbursement system initiated by Taylor contributed to inequality by establishing a system of pay differentials between managers and workers, which reached a historical high point in the late twentieth and early twenty first centuries.

teachers

Kristin Gordon

With over 3 million teachers working in the US public school system, teaching attracts considerable attention from sociologists. Many issues have been explored. Dominating the field are questions concerning teachers' roles, quality, professional status, training, gender composition, pay, staffing, and placement. Teachers play multiple roles in the educational process. First, teachers impart academic skills and knowledge (human capital). Second, teachers socialize children in the lifestyles, values, and cultures of society (cultural capital). The importance of the academic, social, and cultural dimensions of this work for children raises one

of the foremost questions in research on teachers: Does teacher quality matter? Early research studying the impact of teacher credentials and experience largely indicated that teacher quality did not consistently relate to student achievement. More recent exploration reveals that teacher preparation, particularly subject matter knowledge, does positively impact student achievement.

In addition to debates over teacher quality, the occupation is plagued by questionable professional status. In an effort to assert teacher professionalism, new models of teacher training have emerged. Historically, normal schools assumed responsibility for instruction in teaching theory and pedagogy. As teachers increasingly turned towards colleges and universities for training, substantive knowledge began dominating the curriculum. Today, reforms aimed at affirming teacher professionalism stress initial and ongoing training in subject area knowledge.

The gender composition of the occupation also contributes to its questionable professional status. Teaching in the US began as a male occupation. Around 1850, teaching became a predominantly female occupation and this pattern persists today. Despite the fact that teaching is a female dominated occupation, men are over represented in administrative positions. This occupational sex segregation reinforces the semi professional status and low pay of teaching. These factors are held partly responsible for the current staffing problems afflicting the occupation.

Recent research indicates that the US continues to have difficulty staffing classrooms with qualified teachers. Two possible causes of school staffing problems have been investigated: increased enrollments combined with high teacher retirement and teacher turnover. Recent research provides limited support for the notion that staffing problems are the result of increased enrollments and retirements. Rather, the evidence indicates that large numbers of teachers are leaving the occupation in response to problematic working conditions, specifically student discipline problems and insufficient administrative support. One consequence of these school staffing problems is the growing occurrence of out of field teaching. This phenomenon, in which a teacher does not possess a major or minor in their teaching field, is

particularly important for understanding teachers' careers, satisfaction, turnover, and student achievement.

Cross national research on teachers and teaching examine similar issues. Questions of teacher quality pervade educational reform in many national contexts. Recent data indicates that in many countries a large proportion of teachers are working without minimum qualifications. While concern over teacher quality appears in many nations' reform agendas, little research supports the contention that variation in teacher quality cross nationally explains national differences in student achievement.

Like the US, comparative studies reveal that many countries have trouble recruiting and retaining qualified teachers. This can be partially explained by teacher pay. While the salaries of experienced teachers studied by the Organization for Economic Cooperation and Development range from less than US\$10,000 in Poland and the Slovak Republic to US\$45,000 and more in Germany, Japan, Korea, Luxembourg, and Switzerland, there is agreement among teachers that teaching provides inadequate financial reward. Of those countries that share the US's staffing problems, the most frequent solutions include out of field teaching and increasing other teachers' workloads. Interestingly, staffing problems are not universal. Several nations, such as Greece and Korea, actually have an oversupply of teachers, which also introduces policy challenges.

Despite unique contexts, tremendous demands are being placed on teachers in their multiple roles. Debates about teacher quality, professional status, preparation, and placement persist. Continued sociological exploration of teachers and teaching is imperative for understanding these issues.

teaching and gender

Linda Grant and Linda Renzulli

The study of teachers and teaching has always been an important focus of sociology of education, but the analysis of links between teaching and gender has developed more recently. As Grant and Murray (1999) contend, K-12 teaching and postsecondary teaching are two different occupations and thus relationships between gender and teaching differ at each level. Other researchers have studied gender as it affects pedagogy and curriculum at all levels of schooling. Finally, some scholars, especially those working from a feminist perspective, have explored what students learn about gender in schooling, and how teachers – intentionally or not – affect the gender climates of educational institutions.

GENDER DISTRIBUTIONS IN THE TEACHING PROFESSION

Teaching is a classic example of an occupation that feminized. Today, about 75 percent of teachers in grades K 12 in the US are women. Similarly, in 11 of 20 OECD countries, women make up 70 percent or more of elementary teachers. Preschool teaching is also strongly woman dominated, with precise proportions hard to tabulate because few states license preschool teachers.

Women gained access to teaching in the late 1800s. Not until the 1920s in the US, and not until 1995 in OECD countries, did women represent 70 percent or more of teachers. The feminization of teaching occurred in part because with the growth of the middle class and formalization of schooling, teaching became a full time job. However, pay did not rise along with increased time demands. Thus, men left teaching in the US and internationally for better higher paying occupations, creating open positions that were relatively attractive for women.

As women entered the profession, the definition, role, and expectation for teachers' work changed. Contracts required that teachers be single women, and teaching was viewed as preparation for motherhood. Teachers' work was nevertheless controlled by male only school boards and administrators. As in other feminized occupations, women grew in numbers, but not in pay, power, or autonomy. More recently, pay and autonomy have increased, but pay remains low (Ingersoll 2001). In fact, as the rate of feminization increases in OECD countries, teacher salary seems to decrease.

Teaching became an avenue for upward mobility for farm and working class families and for black and white men and women. By the 1930s, however, most US teachers were middle class white women. Teaching in segregated schools was an important means of upward class mobility for African Americans. Under segregation, educated blacks' access to positions as teachers and administrators helped to establish a black middle class. When the *Brown v. Board of Education* decision ended legally mandated school segregation, many black educators lost their jobs, even when they were more qualified than their white counterparts. Blacks now make up less

than 8 percent of public school teachers, although about 17 percent of students are black. Black middle class women, and other educated minority youth, nowadays seek more lucrative careers.

At the postsecondary level, teaching remains a white *male* dominated profession. Women and persons of color have made only modest inroads into professor positions in recent decades in the US and in most other countries. Before the mid 1900s, white women in the US comprised only a small fraction of college faculty, concentrated primarily at women's colleges or in feminized disciplines such as home economics, education, or social work in coeducational institutions. Women's enrollments in PhD programs expanded dramatically in the late 1970s, and affirmative action policies adopted by colleges aided their entry into college teaching. By 2004, women were about one third of postsecondary faculty in the US, up from about 23 percent in 1974. In research intensive universities, women are only about 14 percent of full professors, but nearly 60 percent of lecturers and instructors (AAUP 2004). Women, however, are better represented across ranks at Historical Black Colleges and Universities (HBCUs) than in colleges generally (NCES 2004).

PAY GAPS

The heavily feminized occupation of preschool teaching is poorly paid, averaging lower hourly wages than bus drivers, secretaries, and practical nurses (Whitebook & Sakai 2004). K 12 teachers also earn relatively low wages, with women averaging only 90 percent of men's wages in 2000. In countries such as Japan and Turkey, where men are more numerous in the teaching ranks, teachers' salaries compare more favorably to the country's cost of living index than is the case in the US.

Several explanations have been offered about the gender gap in teachers' pay. One is the gender segregated composition of teaching staffs, with women more dominant in elementary grades where pay is low and men more numerous in secondary grades and administrative posts where wages are higher. Men are about three times more numerous among high school as among elementary teachers.

In addition, segregation in types of position within the hierarchy of teaching by gender also occurs (Cognard Black 2004). Men who enter teaching rise rapidly in status and often are tracked into administrative positions. In the US about 56 percent of principals are men, and male principals average three more years' experience than women counterparts. This contrasts sharply with the disadvantages to advancement that women often face in male dominated occupations, such as postsecondary teaching.

Gender differences in credentials also account for some of the pay gap. Male teachers are more likely to have advanced degrees, and they average more years of teaching experience than women. In addition, men are more likely to teach in unionized systems, and unions have been successful in raising teacher pay.

Women professors are more poorly paid than their men counterparts in US colleges and universities, with pay gaps even wider than at the K 12 level. In recent years women full professors have lost ground compared with men of similar ranks (AAUP 2004), but at lower ranks they have gained slightly, mostly as a result of wage stagnation for men. Among full professors, women's average salaries are 12 percent lower than men's. HBCUs show a different pattern. Although overall salaries at these institutions average only about 80 percent of college salaries generally, women and men of similar rank are closer to parity (NCES 2004).

Salary gaps reflect in part women's more recent entry into college teaching and consequent lesser seniority and their concentration into lower paid academic fields. Men have longer records of uninterrupted service and are in types of institutions with higher pay; for example, research universities rather than community colleges. Men also outnumber women in administrative positions. Women faculty are ghettoized into lower paid fields (e.g., English, foreign languages, or education rather than math, science, business, or law) (NSF 2004). Higher pay for the male dominated fields usually is justified by arguments that faculty in these disciplines have attractive job opportunities outside of academia. Nevertheless, with controls for rank, degree year, quality of degree, and employer type, margins of difference favor men (AAUP 2004).

Research has been inconsistent about whether men scholars have been more successful than women in publication and grant productivity, a major basis of salary awards in higher education. Earlier studies concentrated largely on natural scientists found productivity gaps favoring men, but more recent works suggest a convergence of publication and tenure rates, of women and men in fields such as sociology where women are not tokens (Hargens & Long 2002).

A comprehensive study of faculty shed light on subtle processes leading to gender inequities (MIT 1999). Women faculty recognized the negative impact of the gender climate on their careers and well being, but felt that complaints would be fruitless. Women faculty were underpaid relative to comparable men and systematically disadvantaged in areas such as teaching loads, assignment of laboratory and office space, access to mentoring and support, and sponsorship for awards and other special opportunities. Women faculty believed they did more mentoring than their male colleagues. Many had experienced sexual harassment, and women believed they would be seriously penalized for having a child or otherwise investing heavily in family.

GENDER AND PEDAGOGY

Few differences in teachers' pedagogical style by gender appear at either the K 12 or the postsecondary level. Where differences exist, they reflect the differential distributions of women and men across elementary and secondary teaching and their locations in different academic specialties using variable pedagogical approaches. Nevertheless, widespread concern that too few men are entering teaching and that male students in public schools in particular lack male role models has resulted in special programs to recruit men, especially men of color, into teaching. Gender differences in pedagogical style at the postsecondary level are more apparent in patterns of out of class mentoring and support than in classroom performance.

CURRICULUM AND GENDER CLIMATES

Studies have explored what is taught in schools about gender, in the formal curriculum and the

informal, or hidden, curriculum. Reports by American Association of University Women (AAUW 1992–2004) explore ways in which curriculum and gender climates of educational institutions can marginalize women. The reports critique formal curriculum for excluding or trivializing girls and women and for not addressing issues of particular significance to women's lives; for example, pay equity law, family leave policies, or women's health. Staffing patterns in public schools usually place men in positions of authority over women, modeling patriarchal systems for young learners. Furthermore, teachers do not necessarily create, but often tolerate, gender climates that are hostile to girls and women. The AAUW report has drawn criticism for failing to fully consider educational problems of boys and for blaming teachers for gender inequities that they have little power to influence. In many systems, teachers have proactively addressed gender equity issues via efforts to create gender equitable curricula and educational climates.

At the postsecondary level, studies of gender and teaching focus on whether women students face chilly climates in college classrooms, especially in male dominated fields such as math and science, and whether they have adequate opportunities for mentoring and sponsorship. Scholars have also explored harassment and other forms of sexual exploitation as they affect women faculty and students. Finally, a growing body of scholarship has examined whether or not women's scholarship is valued as much as men's in making hiring, tenure, promotion, and salary decisions in colleges and universities.

The impact of gender scholarship and feminist thought has been uneven across disciplines. Nevertheless, substantial change in the influence of women is evidenced by the rapid growth of women's and gender studies curricula, departments, and majors. Academic disciplines now include committees to monitor status of women, organizations of women scholars, and publication outlets for gender research. In sociology, the Sociologists for Women in Society and its affiliated journal, *Gender and Society*, are examples.

CONCLUSION

Gender affects teaching careers and advantages for men persist at all levels of education. Yet we

know little about why gender inequities persist in teaching, why men are reluctant to enter teaching (despite salary advantages), and why recruitment and retention of teachers of both genders is increasingly problematic. Possible links between these concerns and the feminization of teaching, its semi professional status, and the professionalization of the field have not been explored in theoretically sophisticated ways. At the postsecondary level, teaching may be threatened with deprofessionalization, just at a point when women comprise a significant presence.

Although studies in local contexts have established the importance of formal and informal curricula and gender climates for teachers and for students, these issues are rarely researched in national studies. We know more about the content of curricula and the characteristics of gender climates of educational institutions than about the long range impact on teachers and students. We lack a finely nuanced understanding of the role of teachers and educational institutions in reproducing or challenging gender stratification in society.

At the postsecondary level questions remain about how structural changes in colleges and universities will affect the status of women faculty and gender inclusive scholarship. Women's proportions of college enrollments at all levels continue to increase, and women are likely to make up larger shares of college teachers in the future. As colleges rely more heavily on part time, contingent workforces, men are leaving academia, and this trend is partly responsible for increasing proportions of women faculty in many disciplines. The implications of these changes are not yet clear.

teamwork

Michael A. West

Teams are a particular form of work group. They are groups of people who share responsibility for producing products or delivering services. They share overall work objectives and ideally have the necessary authority, autonomy, and resources to achieve these objectives. Team members are dependent on each other to achieve the objectives and therefore have to work closely, interdependently, and supportively to achieve the team's goals. Members have distinct and clear roles. Effective teams have as few members as necessary to perform the task and are ideally no larger than six to eight members. And the team is recognized by others in the

organization as a team. The team rather than the individual is increasingly considered the basic building block of organizations and team based working the modus operandi of organizations (West et al. 2003).

There are multiple types of teams in organizations: advice and involvement teams, e.g., management decision making committees, quality control (QC) circles, staff involvement teams; production and service teams, e.g., assembly teams; maintenance, construction, mining, and commercial airline teams; departmental teams; sales and health care teams; project and development teams, e.g., research teams, new product development teams, software development teams; action and negotiation teams, e.g., military combat units, surgical teams, and trade union negotiating teams.

Why work in teams? In many areas of endeavor, research has shown how team working can lead to greater efficiency or effectiveness. An analysis of the combined results of 131 studies of organizational change found that interventions with the largest effects upon financial performance were team development interventions or the creation of autonomous work teams (Macy & Izumi 1993). Applebaum and Batt (1994) reviewed 12 large scale surveys and 185 case studies of managerial practices. They concluded that team based working led to improvements in organizational performance on measures of both efficiency and quality. Similarly, Cotton (1993) reports on studies examining the effects of team working on productivity, satisfaction, and absenteeism. The author reviews 57 studies that report improvements on productivity, seven that found no change, and five that report productivity declines, following the implementation of self directed teams. Finally, studies in health care have repeatedly shown that better patient care is provided when health professionals work together in multidisciplinary teams.

THE HISTORY OF TEAM THEORY AND RESEARCH

The source of the stream of research on teams can be traced to the Hawthorne studies which established the importance of intergroup relations in organizations, the influences of teams on their members, and the importance

of informal groups in influencing work related behavior.

Two strands of thought about teams emerged in the 1960s and 1970s. The first focused on the whole team and examined unconscious phenomena in work teams (Bion 1961). Bion argued that teams developed "basic assumptions" in discussions of organizational culture, which could impede their effective functioning. These include basic assumptions of *dependence* (one of the team's members will look after the needs of the team and ensure its effectiveness); *pairing* (two team members will join together to produce a leader in some way, leading to a sense of messianic anticipation in the team); and *fight-flight* (the team meets to fight an enemy or run away, and is consequently unable to do any effective work). However, little research has been stimulated by this approach.

The second strand has led to considerably more theorizing and research internationally. The sociotechnical tradition proposed that social and task related outcomes can be optimized through appropriate task and work design – the well being of team members can be achieved in conjunction with team performance, through the joint optimization of the application of technology, organization, and the use of human resources.

In the last 20 years, there has been an altogether new emphasis amongst writers concerned with understanding work team effectiveness – the organizational context within which teams perform (Hackman 1990; Guzzo & Shea 1992). Hackman (1990), for example, has drawn attention to the influence of organizational reward, training, and information systems in influencing team effectiveness.

Guzzo and Shea developed a reciprocal model of team effectiveness. They argue that *outcome interdependence* among team members leads to higher team effectiveness. Outcome interdependence refers to the extent to which team members are dependent on each other to achieve organizational rewards such as recognition, career advancement, and financial rewards. *Task interdependence* moderates the relationship between outcome interdependence and effectiveness, because outcome interdependence can only lead to greater effectiveness if team members are required to work interdependently to get the job done. But the most significant element of the

model (theoretically) is the concept of *potency*, rather like self efficacy but at the team level characterized by a team sense of likely success and ability to meet challenges. This is a direct predictor of team effectiveness in the model. They extended this approach by proposing that potency best predicts team effectiveness in conjunction with three other factors – the alignment of team goals with organizational goals, organizational rewards for team accomplishments, and the availability of resources for teams.

Another model of team effectiveness has been developed from a focus on team reflexivity. West (1996) argues that most models of team performance tend to present static rather than dynamic processes, yet teams often change rapidly as a result of experience and member turnover, requiring repeated adaptation of communication and decision making processes. West proposes that what may best predict team effectiveness is an overarching factor influencing all aspects of team performance – team task reflexivity. He argues that teams are effective to the extent that they reflect upon their task objectives, strategies, processes, and environments and adapt these aspects of their functioning accordingly. In relation to the wider organizational environment, non reflexive teams will tend to comply unquestioningly with organizational demands and expectations; accept organizational limitations; fail to discuss or challenge organizational incompetence; communicate indebtedness and dependence on the organization; and rely heavily on organizational direction and reassurance. Reflexive teams, in contrast, are more likely to be agents of innovative change within the organization, developing ideas for new and improved products, services, or ways of working.

This brief account of some of the major theoretical approaches illustrates the move toward less descriptive models, which take into account organizational factors and reveal too that researchers are coming to terms with the inherent complexity and cloudiness of real teams in organizations.

TEAM EFFECTIVENESS

Much effort has been devoted to understanding the factors which promote team effectiveness. The thinking of most researchers has been

dominated by an input–process–output model, mainly because of its simplicity and utility. Inputs include the task of the team, team composition (size, functional and demographic diversity, tenure), and organizational context (such as culture, support for team working, structure). Some processes mediate the relationships between inputs and outputs such as participation mediating the effects of diversity upon innovation, while some inputs such as organizational context directly influence outputs. Processes include participation (influence over decision making, interactions, and information sharing), leadership, conflict, decision making, interteam processes, and reflexivity. Team outputs include productivity, innovation, team member well being, and team learning.

Inputs to Teams

The team task. The task a team performs is a fundamental influence on the work team, defining its structural, process, and functional requirements – who is in the team, what their roles are, how they should work together, and the nature and processes of the tasks they individually and collectively perform.

Dimensions for classifying task characteristics include task difficulty; solution multiplicity; intrinsic interest; cooperative requirement tasks which are unitary versus divisible, conjunctive, disjunctive, and additive; conflict versus cooperation elements; and conceptual versus behavioral components. These classification systems, developed by social psychologists, have not been fruitful for researchers exploring team performance and innovation in organizational settings, probably because such goals as producing television programs, battleground training, health care, product development, and providing financial services cannot be neatly categorized into discrete tasks and subtasks.

Sociotechnical systems theory (STST) provides a powerful framework for examining the effects of task design upon work team innovation. Sociotechnical systems theorists argue that autonomous work teams provide a structure through which the demands of the social and technical subsystems of an organization can be jointly optimized. The key to effective performance is then whether the work team can

control variation in quality and quantity of task performance at source. The joint optimization of the two subsystems is more likely when work teams have the following characteristics:

- The team is a relatively independent organizational unit that is responsible for a whole task.
- The tasks of members are related in content so that awareness of a common task is evoked and maintained and members are required to work interdependently.
- There is a “unity of product and organization,” i.e., the team has a complete task to perform and team members can “identify with their own product.”

The *task* characteristics that evoke “task orientation” or intrinsic motivation (and therefore innovation) according to STST are:

- completeness (i.e., whole tasks);
- varied demands;
- opportunities for social interaction;
- autonomy;
- opportunities for learning;
- development possibilities for the task.

Team composition. Team composition – used here to refer to the “mix” of members making up a team – has been examined in various ways. One examines the question of whether heterogeneity is advantageous to groups. The theoretical perspectives that have guided much of the research in this area include the attraction–selection–attrition model, similarity–attraction theory, and self categorization theory. A basic premise of all three is that we are attracted to those who are similar to us and thus organize, and evaluate, our social worlds accordingly. In the second line of research, it is assumed that heterogeneity is valuable but groups need to have the right mix of members. This approach questions which combination of roles, styles, or skills fits together particularly well and which types of people are needed within groups. Research in this area has tended to focus on heterogeneity in terms of demographic variables, skills, attitudes, cognitive ability, and, more recently, personality traits. Although much of the early research on group heterogeneity examined experimental laboratory based

groups, focus on “real world” groups has typified more recent research in this area.

Some studies suggest facilitative effects of heterogeneity on team performance. This pattern is most likely when the characteristics in question are skills or educational specialization. Strategic management initiatives appear more likely to be made by groups that were heterogeneous with respect to educational specialization. More recently, studies in health care suggest that the greater the number of professional groups represented in teams, the higher the levels of innovation in patient care. It might be that skill heterogeneity means that each group member is more likely to have non redundant – and, presumably, relevant – expertise to contribute to the team activities. Groups that include both diverse and overlapping knowledge domains and skills are particularly creative.

Some debate has surrounded the question of whether it is advantageous to have groups that are homogeneous or heterogeneous with respect to cognitive ability. Results of two recent meta analyses suggest that the relation between ability heterogeneity and performance may be somewhat complex. Based on these analyses, it appears that, in general, ability heterogeneity and performance are unrelated. Thus, there would seem little justification to select team members with a view to dispersing their cognitive ability levels.

Teams which are diverse in task related attributes are often diverse in relation to attributes inherent in the individual. These relation oriented characteristics can trigger stereotypes and prejudice which, via intergroup conflict (Hogg & Abrams 1988), can affect group processes and outcomes. For example, turnover rates are higher in groups that are heterogeneous with respect to age. Two studies that have examined ethnicity diversity in groups have suggested that the effects of diversity may change over time. Milliken and Martins (1996) suggested that ethnic diversity in groups can have negative effects on individual and group outcomes, primarily early in a group's life. Similarly, in one of the very few longitudinal studies in this area, Watson et al. (1993) reported that groups that were heterogeneous with respect to culture initially performed, on a series of business case exercises, more poorly than culturally homogeneous groups. As group members

gained experience with each other over time, however, performance difference between culturally homogeneous and heterogeneous groups largely disappeared.

Organizational supports. Various organizational contextual factors have been proposed as important in predicting team effectiveness. Reward systems, such as public recognition, preferred work assignments, and money, have long been known to provide motivation and affect performance, particularly when the rewards are contingent upon task achievement. Gladstein found that pay and recognition had an effect, especially upon the leader's behavior and the way the group structured itself. Hackman (1990) identified two contingencies: whether the rewards are administered to the group as a whole or to individuals, and whether the rewards provide incentives for collaboration or delegation of tasks to individuals (the former, in both cases, are associated with positive relationships between rewards and group effectiveness). Feedback is important for setting realistic goals and fostering high group commitment. In addition, high job satisfaction requires accurate feedback from both the task and other group members. However, group feedback can be difficult to provide to teams with either long cycles of work or one off projects. Limited empirical evidence suggests training is correlated with both self reported team effectiveness and managers' judgments of effectiveness.

Team Processes

The second major element of the input–process–output model is team processes. Among these, the most consistently important factor in determining team effectiveness is the existence of team goals or objectives (Guzzo & Shea 1992).

Objectives. The clarity or specificity of goals has also been shown to predict team performance outcomes. In order to combine efforts effectively, team members have to understand collectively what it is they are trying to achieve. Much research also indicates that involvement in goal setting fosters commitment to those goals and consequently better team performance.

Participation. The second factor of central theoretical and empirical concern in the study of team performance is the notion of participation.

Research on participation in decision making has a long history, revealing that participation tends to foster greater team effectiveness and commitment. When people participate in decision making through having influence, interacting with those involved in the change process, and sharing information, they tend to invest in the outcomes of those decisions and to offer ideas for new and improved ways of working. In Europe, schemes to increase participation have resulted in higher levels of innovation among industrial workers. At the organizational level, most writers concur that high centralization of decision making (low participation) inhibits innovation, although there is limited empirical evidence to support these views.

Task conflict. A central theme in the team work literatures is that divergent thinking and the management of competing perspectives are important processes in teamwork. Such processes are characteristic of task related team conflict and controversy. Tjosvold and colleagues have argued similarly that constructive controversy in teams improves the quality of decision making (Tjosvold 1991). Constructive controversy is characterized by full exploration of opposing opinions and frank analyses of task related issues. Constructive controversy occurs when decision makers believe they are in a cooperative team context where mutually beneficial goals are emphasized, rather than in a competitive context, where decision makers feel their personal competence is confirmed rather than questioned, and where they perceive processes of mutual influence rather than attempted dominance. Another perspective on conflict comes from minority influence theory. A number of researchers have shown that minority consistency of arguments over time is likely to lead to change in majority views in teams (Nemeth & Owens 1996). A homogeneous team in which minority dissent is suppressed will reduce creativity, innovation, individuality, and independence.

Outputs

The final component of the input–process–output model is outputs and this refers to team effectiveness or productivity, team innovation

(new and improved products, services, ways of working), team member well being and satisfaction, and team viability and attachment (the cohesion and commitment to the team shown by team members). This model continues to dominate in research but it is giving way to new concerns.

CURRENT AND FUTURE EMPHASES IN TEAM RESEARCH

The focus of research is increasingly turning toward an understanding of micro and macro processes hitherto neglected by researchers and theorists. The first is a concern with agreement within teams about their perceptions of team processes and outputs manifested in theorizing about team “mental models.” These refer to team members’ implicit and (to a greater or lesser extent) shared models of their team and its functioning as well as the wider environment with which the team engages (schema congruence and accuracy). High levels of congruence and accuracy are predicted to relate to team effectiveness. The methodological challenges of measuring shared mental models are yet to be overcome.

This concern is matched by a strong focus on trust, identity, and attachment in teams as factors that promote individual cooperation in teams (Korsgaard et al. 2003). Trust is defined as “the individual’s intention to accept vulnerability to the group based on the expectation that the group will act in a considerate and benevolent manner toward the individual” (Korsgaard et al. 2003: 116).

However, the most vigorous new developments in this area are likely to relate to research into team based organizations (Agarwal 2003). The study of work teams has developed rich understanding of social processes and performance in organizations (West et al. 2003) and the future for this area is immensely promising. The challenge now is to understand the functioning of team based organizations (or multi team systems) and how they can be structured and developed to maximize the benefits of this basic form of human functioning in modern, large, complex organizational settings. Moreover, as alliances and networks develop within

and between organizations, the spotlight of research is also exploring how teams can operate effectively across organizational boundaries (e.g., joint venture teams) and across networks to enable people to cooperate on tasks that no single organization can accomplish.

technological determinism

Alan Bryman

Technological determinism refers to the thesis that the path of social change is directly influenced by technological developments. As such the thesis ascribes agency to an inert object, namely technology, in human affairs and their development.

It is common to distinguish between hard and soft versions of the thesis. The hard version views technology as the sole determinant of social development, whereas the soft version depicts it as one among several other factors and as greatly implicated in the social circumstances out of which it arises. The soft version thus moderates the anti-determinist's dislike of

the ascription of agency to a thing and of the marginalizing of human intervention.

Nowadays, technological determinism is considered a discredited thesis about the nature of society. Few social scientists today would describe themselves as technological determinists without qualifying the description considerably. A lingering technological determinism can sometimes be discerned in approaches that seek to depict technology as both cause and effect (e.g., Hughes 1994).

Technological determinism was particularly influential in sociological studies of work and organizations. In the 1950s and 1960s, studies of work contexts like the automobile assembly line frequently construed the largely negative work attitudes of workers as directly produced by the technology with which they worked. The most sophisticated version of this approach can be discerned in Blauner (1964), where four different production technologies in US industry (craft, machine tending, assembly line, and process) were examined. Blauner showed that levels of work alienation varied systematically by the prevailing technology in the industries concerned. Another prominent study was Woodward's (1965) British investigation of technology in relation to organization structure. Woodward showed that structures varied by the prevailing technology of the organization in terms of characteristics like the flatness of the hierarchy. The suggestion that it was necessary to achieve a good fit between technology and organization structure was perceived as a corrective to the view that there could be universal laws of administration that could be applied without regard to an organization's special circumstances.

A number of problems with technological determinism have been identified. First, it is pointed out that a technology is designed with specific purposes and applications in mind, so that the "effects" that technological determinists claim to identify are in fact natural outcomes of how designers envisioned its purpose. Secondly, it is often observed that a technology can be implemented in several different ways, so that the supposed outcomes of its application are in fact the result of the ways in which it is introduced and executed (e.g., Buchanan & Boddy 1983). Third, technologies are interpretively flexible and as such can be construed in

different ways by those responsible for making them operational and by users (Grint & Woolgar 1997). Fourth, in the context of work situations, it is often pointed out that people bring to the workplace a variety of orientations that will also play a significant role in conditioning their work attitudes and behavior (e.g., Goldthorpe et al. 1968).

While technological determinism is frequently seen as outdated, it should not be replaced with the equally extreme view that technologies have no implications for human affairs, since technologies are responsible for constraining responses to them, as several writers have observed (e.g., Law 1992; Orlikowski 1992).

technological innovation

Polly S. Rizova

The topic of technological innovation has been fascinating generations of scholars, managers, and policymakers ever since Schumpeter's influential *Theory of Economic Development* (1934) appeared in English. In it, he compellingly argued that the survival of firms as well as that of society is dependent upon their ability to perpetually find new uses for the existing resources and to recombine the latter in novel ways. The economic and social changes in the western world, particularly after the Industrial Revolution, are attributed to a considerable degree to technological innovations.

At first addressed by economists, the topic has become of interest to an array of social science disciplines such as sociology, management science, industrial psychology, and the history of technology. Empirical research on the economic and social determinants and consequences of technological innovation surged in the 1980s and 1990s when leading scholarly journals devoted special issues to it: *Administrative Science Quarterly* (1990), *Strategic Management Journal* (1990), and the *Academy of Management Journal* (1996). *Social Studies of Science* was even more specific; in 1992 it published a symposium on "Failed Innovations."

Technological innovation is defined as a process which stretches from the origination to the development, implementation, and diffusion of new products or processes which have market and social value. Innovation is not to be identified with the act of scientific discovery or invention. The latter marks the very first occurrence of an *idea* for a novel product or process; the former encapsulates the deliberate *actions* of people from diverse organizational units – research and development (R&D), manufacturing, and marketing – to develop and to commercialize it. All through, it is ideas and knowledge that are sought, processed, and transmitted by both people and organizations. That is why technological innovation is conceived of as an information and knowledge processing activity which takes place in an organizational context and goes beyond the generation of a creative idea in the minds of single individuals.

In the years after World War II, a set view regarding what the force is behind technological innovation took prominence; namely, that scientific technical research is the single most important drive for innovation and, consequently, for economic development. Promulgated by Vannevar Bush in *Science: The Endless Frontier* (1945), it became known as the "linear model." This model was the framework used to inform all efforts to organize for successful innovation up to the 1980s. It rests on the assumption that innovation results from the application of science in a process which takes place through well defined sequential linear stages – scientific research, development, production, and marketing. Not only are the stages neatly defined, but so are their technical objectives and output. According to this understanding, innovation moves from one stage to the next after a successful completion of each stage's goals. Hence, by its nature, the model takes for granted that technological innovation springs from the new scientific knowledge and breakthroughs created in the first stage. Not surprisingly, research from this period addressed the link between science, scientific knowledge, and new technology. This view was also mirrored in the high level of government funding for university research and federal R&D laboratories.

An important shift in the contemporary understanding of technological innovation has been marked by the recognition of what technological innovation is *not* – namely, a linear process. Research in the 1980s demonstrated that although scientific research continues to be a viable source for innovations, the large majority of them began with a recognized market demand. It is often the case that a technological innovation is initiated at the stage located at the very end of the "linear model," from where it moves backward and forward throughout the rest. Hence, it involves nested goal formation and problem solving activities grounded in an iterative interaction between science, technology, and the market. The relative importance that scientific research and the market play in technological innovation, though, varies over time, with the size of a firm, and between, as well as within, industries. For instance, in *Forces of Production* (1984), David Noble shows that although the preponderance of innovations, as measured in absolute numbers, stemmed

from market driven competition, critical innovations such as supercomputers, integrated circuits, and the digital control of manufacturing were directly linked to government funded research. A reflection of this new way of looking at *why* and *how* innovation happens is the continuous search for design forms which are to respond to the need for coordination and information exchange between the multiple organizational divisions that take part in the innovation process.

The literature discusses four types of technological innovation. When the classification criterion is the locus of technological change, the differentiation is between *product* and *process* innovations. The former concerns any change to a firm's existing product or service portfolio; the latter refers to a change that the company introduces in the way a product is made or service is provided. More recent research has suggested that it is somewhat misleading to regard the two as completely independent from each other. Rather, as Utterback demonstrates in *Mastering the Dynamics of Innovation* (1994), they ought to be seen in an interrelated relationship in which their relative importance for the firm changes over time. Depending on the degree of technical change that is introduced to a final product or process when compared to the existing state of technology and the knowledge base, a distinction is made between *incremental* and *radical* technological innovations. *Incremental* innovation corresponds to a little departure from the currently existing and relied upon technical and scientific knowledge and practices; it only adds new features to an already existing product or process. In contrast, *radical* technological innovation involves a drastic departure from the existing technology, knowledge base, and practices; it is normally linked to a breakthrough in knowledge (e.g., the introduction of the airplane) (Damanpour 1998).

An important reason for distinguishing between radical and incremental innovation lies in the complexity of scientific knowledge that they draw upon and the degree of the predictability of the tasks associated with carrying out research and development. As a result, each imposes different requirements on staffing and organizing. For example, testing the conventional mechanical properties of batches of

commercial plastics is a highly predictable task. The complexity of a task refers to the requirement that knowledge must be drawn from multiple knowledge domains that are at most only loosely connected to one another. Complex tasks deal with ill structured, ambiguous technical circumstances that require assessment of the implications of multiple, and perhaps conflicting, knowledge domains to characterize them in terms of the actions needed. Simple tasks, on the other hand, deal with circumstances that are perceived to fall into the range of ordered experience, to conform to a well established paradigm. Integrating knowledge from medical practice, electronics, chemistry, and mechanical engineering to produce a concept for a medical magnetic resonance imaging device is a highly complex task. So too may be that of deciding which are the important characteristics of a plastic to test, while the selection of procedures to carry out routine tests is generally a simple task.

Technological innovation has been studied qualitatively and quantitatively at the level of the individual, the project, and the organization, as well as at the intra and interindustry levels. A wide array of topics has received coverage ranging from paradigm shifts, organizational learning, entrepreneurship, knowledge organizations, individual and organizational creativity, and, of course, how to organize for and succeed at innovation.

Much of the empirical research has been focused on structure and the investigation of the effect of the formal organization on the individual and firm behavior and outcomes. After decades of preoccupation with discovering the "one best way to organize," the contingency tradition, which developed in the 1960s, broke the old model. In this tradition, organizational structure is shaped by the nature of the technology and then in turn shapes the relationships between people in the work processes. In *The Management of Innovation* (1961), Burns and Stalker studied the relationship between a firm's innovativeness and organization design in 20 British electronics and rayon firms. They argued that *organic* (decentralized and less formalized) structures are conducive to technological innovation, particularly a radical one, as they are better able to respond rapidly to the ever changing environment, whereas *mechanistic*

(bureaucratic and highly formalized) organization forms tend to be innovation resistant. The literature on the management of technological innovation has examined various structural aspects and the conditions under which they affect the ability of individuals and organizations to innovate. Examples of those are: centralization, formalization, horizontal and vertical integration, and stage of industry development. The research informed by this tradition mostly relied on large surveys and statistical methodology to infer the effect of different structural arrangements on performance. Ultimately, it produced valuable insights and, much to the dissatisfaction of the managers of technology, one broad design rule: "*it all depends.*"

By the late 1970s, the structural contingency school was heavily criticized for focusing exclusively on the investigation of the formal structural attributes at the expense of neglecting the contribution of informal structures. This void has been filled by another structuralist approach – the social networks perspective. The origin of the social networks perspective can be traced to Simmel's (1950) work on dyads and triads, but it was Granovetter's (1985) seminal article that carved a prominent place in social research for the individuals and the social relations that they establish and maintain. Unlike the traditional structuralist approach which looks at performance as a function of the relationship between positions and people as *prescribed* by an organization chart, the social networks perspective seeks to capture the *actual* patterns of linkages and relations. It is based on the premise that the actors' behaviors and outcomes can be understood through the informal structural configurations (friendship, advice, and collegial networks) that they are a part of, and the positions they occupy within them (high or low respect, status and informal power). At the center of the social network analysis is an examination of the form and content of the stable patterns people develop in their relationships, as well as the effects these create.

The impact of social networks, their structural properties, and the social capital they create on outcomes has been investigated at multiple levels of analysis. This literature is replete with empirical evidence of the advantages that the informal structures offer over the formally prescribed rules and behaviors to

technological success (van de Ven 1986; Powell & Brantley 1992; Ibarra 1993). Informal structures have been shown to foster innovation through the creation of opportunities for learning, expanding on one's communication network and easing access to knowledge and information (Allen 1977; Tushman 1977).

Yet another influential stream of research on innovation, a qualitative one, came from the social constructivist perspective. In the 1980s it has been applied to scrutinize the production of scientific knowledge, technology, and technological innovation. The latter, according to this view, is not to be understood as a result of following the natural progression of technological development. Rather, it is seen as emerging from the constant interaction between technology and social processes. It is this interaction that explains how some innovations come to fruition and others do not, and why the same technologically sound projects could be funded under one type of social arrangement and abandoned under a different social cast. This literature gave us the insight that the same technologies could have different meanings to different people; thus, it addressed the question of *how* decisions on technology are reached and what role those who have interest in them play (Bijker et al. 1994).

Despite the impressive amount of empirical studies, the research on technological innovation is marked by inconsistent findings. Years of investigation and valuable contributions have not converged into a dominant theoretical perspective which incorporates the multiple streams of innovation research. This could be, at least, partially explained by the fact that innovation has been studied by researchers who represent a multitude of academic disciplines; their efforts and findings, though, are yet to be integrated. A systematic investigation designed to shed light on the phenomenon from more than a single theoretical perspective simultaneously is also lacking. Furthermore, there is a need for more studies which approach the understanding of innovation from a multilevel standpoint. The future research on technological innovation will need to address these issues.

technology, science, and culture

Noah Efron

It is because the sciences, especially the natural sciences, were for so long, and by so many, taken to be divorced from culture that their great interpenetration with culture remains surprising

and, in some circles, controversial. In recent decades, historians, sociologists, and anthropologists of science have documented many ways in which cultural influences have affected the development of the sciences, and in which sciences have left an imprint on seemingly far flung aspects of culture. This scholarship has been vigorously, sometimes viciously, disputed by scientists and others who still see the sciences as largely unswayed by the cultures in which they are practiced. In the 1990s, this dispute became commonly, if rather grandly, known as "the Science Wars."

It is difficult to characterize the relationships between science and culture because neither "science" nor "culture" is easily defined. "Science" typically refers to a set of practices aiming to uncover and formalize regularities in nature, and to the bodies of knowledge these practices produce. Since both the practices and the bodies of knowledge have varied by epoch, place, and discipline, however, any general characterization of science is partial and problematic. "Culture" too is a general term that has no universally accepted referent. Alfred Kroeber and Clyde Kluckhohn famously catalogued over 200 definitions of culture, including "the social legacy the individual acquires from his group," "a way of thinking, feeling, and believing," and "the storehouse of pooled learning." A recent United Nations declaration reckoned culture as the "set of distinctive spiritual, material, intellectual, and emotional features of society or a social group," and that it "encompasses, in addition to art and literature, lifestyles, ways of living together, value systems, traditions, and beliefs." The relationships between "science" and "culture," then, are relationships between hazy and ill grasped concepts.

Often, these relationships are viewed from one of two opposite directions. One concerns the impacts that culture has on science and technology, while the other concerns the influences of science and technology on culture. This crass division is problematic in the eyes of many because it assumes that "culture" and "science and technology" are fundamentally independent entities. For those who see science as a complex of human activities that are cultural from the ground up, the distinction between culture and science is misleading (making no more sense than similarly distinguishing

between, say, culture and music). Still, the notion that science and culture *are* fundamentally independent realms has a long history, and remains influential to this day. For this reason, at least, there is heuristic value in distinguishing between the place of culture in science, and that of science in culture, so long as the limitations of this distinction are acknowledged.

CULTURE IN SCIENCE AND TECHNOLOGY

The view that science is free from cultural influences was most rigorously (and influentially) formulated by a group of scientists and philosophers meeting regularly in 1920s Vienna. This "Vienna Circle," as it became known, included some of the greatest philosophers of the twentieth century – Rudolf Carnap, Karl Hempel, Moritz Schlick, and A. J. Ayer, to name a few – who developed a philosophy that became known as logical positivism, or logical empiricism. These philosophers saw in science the best exemplar of knowledge properly won. Science, as they saw it, ideally had two ways of ascertaining and verifying knowledge: direct observation and logic. No other source of knowledge (like tradition, intuition, or revelation) could be considered credible.

This view implied that good science is by its nature insusceptible to cultural influences, because it is a product solely of the logical manipulation of sense data. If the laws of nature are the same in New York and Nairobi, generating similar sense data, then the logical positivist view of science left no room for local culture to affect science. Indeed, in the view of many philosophers, scientists, and others who embraced this view, the greatest virtue of the scientific method was that it allowed flawed and subjective human beings to produce highly reliable, objective knowledge. As they saw it, science – unlike art, literature, philosophy, politics, couture, cuisine, and practically every other human endeavor – transcends human culture, a view that is sometimes called "scientific exceptionalism."

Though this image of scientific knowledge as uniquely divorced from the culture has retained currency in some circles to the present

day, its heyday was brief. In July 1931, a Soviet physicist named Boris Hessen delivered before the Second International Congress of the History of Science and Technology in Kensington, London, an address entitled "The Social and Economic Roots of Newton's *Principia*." In it, Hessen insisted that Newton's physics was influenced by class ideology and by the practical needs of moneyed Englishmen. These claims were embraced by some Marxist philosophers and scientists eager to see a link between early modern science and the culture of emerging capitalism, and they were rejected by many others for whom Hessen's paper was a crass attack on the intellectual purity of science. In 1935, Polish economist Henryk Grossman published in *Zeitschrift für Sozialforschung* a paper further developing Hessen's approach, called "The Social Foundations of Mechanistic Philosophy and Manufacture." In the same year, Ludwig Fleck argued in a book called *Genesis and Development of a Scientific Fact* that "thought styles" in medicine and science greatly influence even seemingly objective observations. One year later, American sociologist of science Robert K. Merton completed a Harvard dissertation entitled "Science, Technology, and Society in 17th Century England," tracing links between the rise of science and both Puritan ideology and contemporary economic circumstance. These works and other "externalist" accounts (so called because they attributed scientific development to factors outside science itself) challenged the positivist account of the advance of science, suggesting that cultural, social, political, and economic factors greatly affected science, even influencing the very content of scientific theories.

Partly in response to these challenges, in 1938 philosopher Hans Reichenbach distinguished between what he called the "context of discovery" in science, in which accident, human foibles, and social and cultural forces played a part, and the "context of justification," in which objective observation, logic, and reason alone determine which hypotheses are accepted and which are rejected. If cultural factors had any impact upon science at all, Reichenbach and the logical positivists insisted, it was limited to the messy and uninteresting "context of discovery." But over ensuing decades, historians, sociologists, and anthropologists continued to

describe cultural and social influences in almost every aspect of science. The most influential of these was Thomas Kuhn, who asserted in *The Structure of Scientific Revolutions* that science does not progress by amassing and correlating observations, but rather through sudden changes in fashion after which prior theories, and even data, acquire new meaning. Echoing Fleck, and drawing some inspiration from gestalt psychology, Kuhn argued that sense data themselves appear different to different researchers working from within different theoretical orientations. A Chinese acupuncturist and a Canadian cardiologist will see different symptoms in the same patient.

Kuhn's book inspired a great deal of research, some challenging his outlook, and some taking it much farther than Kuhn himself could endorse. Philosopher of science Paul Feyerabend concluded that science has no overarching method at all, and that in research "anything goes." Further, he declared in the 1975 introduction to the Chinese translation of his famous book *Against Method* that "First World science is one science among many." Different cultures produce different sciences. One of the most spirited efforts to describe the interpenetration of sciences and sociocultural factors was conceived at about this time in Edinburgh (and advanced by Barry Barnes, David Bloor, Donald MacKenzie, Steven Shapin, Andrew Pickering, and others) and called the "Strong Program." Its aim, according to Bloor, was to show that "it was not possible anymore to hold a vision of science as exempt from social influences." The accuracy or "truth" of a scientific theory can never be taken to explain its acceptance, Bloor and his colleagues insisted, because it is acceptance on the part of a scientific community that determines which theories are considered accurate and "true." Thus, it is not just "logic, rationality, and truth" that explain the progress of science, but also sociocultural negotiations within a scientific community. This view, embraced and expanded by a generation of historians, sociologists, and anthropologists of science, was developed into what became known as the "social constructivist" (or sometimes "social constructionist") view of science, which held that what is taken to be true among scientists reflects social consensus among them, and not bedrock facts about

nature. Scholars advocating the "social construction of technology" (SCOT) have similarly described how technologies do not evolve according to an inevitable logic of their own, but are constituted through ongoing negotiations between engineers, consumers, users, marketers, and others, and as a result reflect a mosaic of social and cultural assumptions.

In recent decades, feminist historians and philosophers of science like Evelyn Fox Keller and Donna Haraway have argued that cultural assumptions about gender greatly influence the production of scientific knowledge. Casual and commonplace sexist presumptions lead scientists to misrepresent women's physiology, psychology, and social roles, as well as to prefer certain sorts of scientific theories (reductive ones, for instance) over other sorts (holistic ones). More radically, Sandra Harding and other feminist scholars of science have argued that scientists' canons of epistemology – what they take to be knowledge and how they seek knowledge – are themselves conditioned in part by gender. In this view, often called "standpoint epistemology," what counts for evidence and argument may differ between female and male scientists. Other philosophers have emphasized that aesthetic considerations have greatly influenced which scientific theories have been accepted and which rejected. ("One can always make a theory, many theories, to account for known facts," wrote Nobel physicist George Thomson, "the test is aesthetic.") Still others have emphasized the impact of literary conventions on science, arguing that canons of literary coherence influence which scientific theories are accepted and which are rejected. Sociologist of science Karin Knorr Cetina has recently argued that scientific knowledge is mediated through varying "epistemic cultures, shaped by affinity, necessity, and historical coincidence." Taken together, sociologists, anthropologists, historians, and philosophers of science have, in the past 70 years, described how religion, politics, economics, class, gender, race, art, etiquette, and many other ambient aspects of culture and society have affected the process and products of science. Scholars have found traces of these influences in every facet of scientific practice: choice of subject to investigate, experimental design, observation, inference, analysis, publication, and more. These findings have been

embraced by many, probably most, scholars who study science, but they have remained a subject of acrimonious debate.

SCIENCE AND TECHNOLOGY IN CULTURE

Little (if anything at all) in modern, western culture remains untouched by science and technology. Science has long found a place in the arts, for instance. Science and scientists have been a recurring theme in modern literature, from John Donne's "The Anatomy of the World: The First Anniversary" and Molière's *The Learned Ladies* to Mary Shelley's *Frankenstein*, Sinclair Lewis's *Arrowsmith*, and on to recent generations' torrent of science fiction. Science has left imprints on centuries of painters and sculptors. Leon Battista Alberti acknowledged as much in his *On Painting* (1435), which applied classical optics and geometry to techniques for producing perspective on canvas. Leonardo da Vinci's painting reflects years of patient empirical study of the human form, as well as of physical and mechanical principles. Andreas Vesalius's *De Fabrica* (1543) was at once an anatomy atlas and a masterpiece of early modern artistic engraving. The tradition of artists consulting natural philosophers and scientists to perfect their craft continued unabated to the modern epoch when, for example, studies of vision carried out by researchers like Hermann von Helmholtz were eagerly devoured by early impressionists like Seurat, who acknowledged the crucial influence of science on his painting. A contemporary observed that a key to Picasso's work was his use of "geometric figures – of a geometry at the same time infinitesimal and cinematic." Around the same time, futurist painters like Giacomo Balla and Umberto Boccioni championed science, and especially technology, as the principal object of their art, calling for a moratorium on nudes, still lives, and other traditional artistic subjects and declaring that instead "we will sing the multicolored and polyphonic surf of revolutions in modern capitals; the nocturnal vibration of arsenals and docks beneath their glaring electric moons . . . factories hanging from the clouds by the threads of their smoke; . . . large breasted

locomotives bridled with long tubes, and the slippery flight of airplanes." More recently, "transgenic artists" and "bio artists" like Eduardo Kacs have adopted laboratory techniques as an artistic medium, asserting that "new technologies culturally mutate our perception of the human body from a naturally self regulated system to an artificially controlled and electronically transformed object." Kacs works in the medium of genetic modification, and he is not alone. In fact, for each of these examples, hundreds of similar examples can be adduced.

The influence of science upon music is, if anything, still more longstanding and deeply ingrained. Until modern times, music was itself considered a science (and was one of the mathematical sciences of the classical *quadrivium*, along with astronomy, geometry, and arithmetic). Until after the Renaissance, Boethius's sixth century *De musica* remained the most influential guide to music, advancing the notion that music expresses the same mathematical principles that govern the relations between all elements in the cosmos. Marin Mersenne investigated pitch in his physical inquiries (describing his findings in his 1636 *Harmonie universelle*), and Galileo Galilei, himself a lutenist of reputation, described his own empirical studies of the sounds produced by vibrating strings in his *Discourses Concerning Two New Sciences*. The relationship between physics and music remained intimate for subsequent centuries, for both scientists like d'Alembert, Bernoulli, Euler, Laplace, and Helmholtz and composers like Bach, Handel, Telemann, and Rameau. In the twentieth century, new technologies allowing sounds to be produced electronically and recorded greatly changed the nature of music. Electric pianos and guitars came into common use by mid century, finding their place alongside a great number of newly minted instruments, from the Theremin to the Moog synthesizer. By the final decades of the century, synthesized and computer generated compositions dominated much of both popular and avant garde music. In some cases, contemporary science was an immediate source of inspiration, as when Iannis Xenakis produced a series of compositions structured according to the kinetic theory of gases.

The impact of science and technology was greater still in newer cultural media like film

and television. These media would not exist at all without technological advances produced by modern science. Science and technology have in turn been constant themes in movies and television. From early movies like *Frankenstein* and *Dr. Jekyll and Mr. Hyde* to recent ones like *Contact* and *AI*, the cinema has constantly reflected on science and technology and their effect and meaning. So too has television, in dramas ranging from *Star Trek* to *Dark Angel*, and in hundreds of thousands of hours of science and nature documentaries broadcast over the six decades of the medium's existence. At the same time, advances in computer science have greatly expanded what is possible to depict on screen.

The influence of science on culture reaches well beyond the rarefied reaches of the arts. Historians have shown, for instance, how advances in bacteriology in the first half of the twentieth century changed conventional views of cleanliness, leading in time to a great increase in the time housewives devoted to housework. Advertisers enlisted science, pseudo science, and fake science to sell soft drinks, clothing, shampoo, baby formula, anti perspirant, and automobiles. A lab coated scientist soberly explaining the virtues of a product became one of the most recognizable images in western consumer culture.

Science has also helped fashion modern political culture. Friedrich Engels captured some thing crucial of Karl Marx's aspirations (if perhaps not his accomplishments) when he said of him in eulogy, "just as Darwin discovered the law of development of organic nature, so Marx discovered the law of development of human history." Throughout its century of growing and waning popularity, Marxism was presented by supporters as a "scientific" politics, its scientific nature warranting its validity and inevitability. In liberal societies, science played a different, though no less important, role as growing armies of economists, sociologists, engineers, and other "scientific experts" have been called upon to help fashion and evaluate every aspect of policy and administration. In a similar way, scientists now exercise great influence in the courts, serving as expert witnesses hired to persuade juries and judges of the veracity of facts, the credibility of litigants and witnesses, and the extent of damages.

SCIENCE, TECHNOLOGY, AND CULTURE

In the end, the complex relations between science and culture are not exhausted by canvasing how culture influences science and science influences culture. It is often the case, and more now than ever, that science and culture are indistinguishable, even in principle. Historian William Everdell has described how in the first years of the twentieth century many came to doubt the possibility of attaining true objectivity, a change that owed at once to the politics, economics, science, and art of the day, and ultimately changed each of these fields. "The belief in objectivity crumbled so that phenomenology and solipsism began to take over not only philosophy, but literature, politics, psychology and at last even physics" (Everdell 1997). More recently, the enormous attention paid to the impact of genetics on human character and behavior reflects a change in the very notion of what it means to be human, which is equally a product of scientific and cultural assumptions and has equally (and enormously) affected both the practice of science and the nature of the societies and cultures that produce science. In such cases, it is impossible to tease apart the mutual influences of science and culture, because the two are so tightly and diversely intertwined as to be inseparable. Many scholars today, expanding on the pioneering work of philosopher and anthropologist of science Bruno Latour, picture social and cultural artifacts, human actors, and natural objects as linked in a single "network." The identity of each element of the network is constituted, in varying degrees, by all other elements in the network. In Latour's system, it makes little sense to hypothesize social and cultural "influences" on science, or even about the "social construction" of scientific knowledge, because these formulations overlook the fact that society and nature (and the sciences that ostensibly study nature) are mutually constituted. This model, though not without problems, captures nicely the inextricability of science and culture.

telephone

Nicola Green

The telephone was developed in 1876, and alongside communication technologies such as the telegraph and steam based transportation systems, it was one of the key technologies that

contributed to the transformation of late nineteenth and early twentieth century western societies. The ability to transmit sound across long distances in real time was initially treated with either wonder or suspicion, but by the end of the twentieth century the telephone had become a taken for granted feature of everyday life in many parts of the western world. It is because of this ubiquity that sociologists have tended to neglect the telephone as a fundamentally social technology. More recently, however, sociologists have come to pay more attention to the extent of its significance in social communication, interpersonal interaction, social organization, and the regulation of social life.

The telephone was a technology that emerged from the era of industrialization, and the first means that sociologists have come to understand its sociological significance is by considering the technology in terms of its social and historical development. As a “new media” of its day, the telephone served to extend the social transformations of the industrial era, not by introducing entirely new social behaviors, but by providing new means to conduct familiar social practices, and prompting the revision of older forms of social organization in new settings. The telegraph and modern transportation systems had already transformed physical space and time by the late nineteenth century by, for example, collapsing distances and altering the perception of natural time and clock time, concentrating the tempo and reach of industrial production and consumption systems. The telephone extended these transformations by allowing communication to take place at a distance between commercial urban centers and businesses conducted from the newly emerging Victorian era suburbs, contributing to the spatial organization of the cities we see today.

The alteration of time and space in this way also enabled a revision of the boundaries between, for example, public and private life. Whereas one early use of the telephone was as a “broadcast” medium (one to many transmissions of, for example, public entertainments such as concerts), the telephone soon became an instrument wired into the homes of wealthy families in the US and Europe to facilitate one to one calls, thereby introducing a potential intrusion of the “public” sphere into the “private” life of the home. Whereas it was

initially envisaged by telephone companies that telephones in homes would primarily be used by the male head of household to conduct business, or (of secondary and later importance) be used by the female household manager to run the household more effectively, family members soon found the telephone could be used for communications beyond the economic life of the household, to maintain intimate social networks and relationships at a distance. The role of knowledgeable individuals and groups (whether "expert" or not) was therefore to negotiate and manage the revised boundaries of public good and domestic intimacy as framed by the technology.

The uneasy relationship between the public and the private as it was negotiated over the early history of the telephone highlights the central role that gender has played throughout the technology's history. With the disruption of familiar boundaries as telephones were introduced into homes, the roles of men and women with respect to the technology were also called into question. The telephone was originally conceived (along with other "electric" new technologies and media of the time) as a masculine technology, to be used primarily by (technically competent) men as heads of households, communities, and businesses for the public good and in the public sphere. With the development of larger centralized telephone exchanges serving a number of households and small communities, however, "operators" came to be employed to manage the calls to and from individual devices. As it gradually became accepted (through practice, legislation, and the organization of telephone provision) that the telephone could be used to facilitate all kinds of communications between both intimate relations and more distant associates, women operators were specifically enroled to facilitate telephone contact. Social communication and the maintenance of social networks and bonds was held to be a particularly feminine skill, and it was via these means that the association between the telephone and "talk" of all kinds was cemented, and over time in the domestic sphere came to be particularly associated with women and the emotional labor of social contact between family, friends, and social networks.

The management of revised boundaries of time and space, public and private, prompted

by wired, "landline" telephones also presented new dilemmas for the negotiation of interpersonal "presence" and "absence" in human communication. A second way that sociologists have investigated the importance of the telephone in social life is to focus on the technology particularly as a communications medium. Social interactionists in particular have examined the ways that social relationships are mediated, established, and maintained during telephone communications, both with those "co present" and not directly party to the communication, as well as those "telepresent" others with whom one is communicating at a distance. The ring of a telephone is a "summons" to communicative interaction (prompting some sociologists to ponder why, in contrast to most other communicative media, the telephone has no "off" switch – the summons is designed to be imperative). From this first summons, individuals may choose between a range of responses framed by normative contextual rules and procedures of interaction. In Goffman's terms, the instance of a phone call is a "stage" that needs to be managed via interactional strategies with respect to both co present and telepresent others. The normative procedures for taking a telephone call in private space where it might be overheard by intimate others conform to one set of rules, those for making a call in public space conform to another. In each case, individuals might develop strategies for deciding to make or take a call by negotiating the relative power of those co present and telepresent to demand attention and to establish the rules of conversation. The strategies will also include common rituals of negotiating identification, availability, and the purpose of the call. Of particular importance has been the evolution of normative rules and conversational rituals to establish interactional resources through which the relevance and sense of a telephone call can be understood. Goffman's notion of "footing" has been used to explain how mutual understanding and human "presence" are established and maintained when interlocutors are communicating at a distance.

Using conversation analysis, ethnomethodologists in particular have turned their attention to the contextually framed interactional skills used by members of a community in everyday telephone talk. Initially, ethnomethodologists

used recorded telephone conversations to investigate the social organization of telephone talk, mutual identification, turn taking, the achievement of communicative context, and the negotiation of talk content. Of particular interest has been the management of interaction given the absence of physical context. A range of studies have identified common features of telephone interaction, one of the most important of which is verbal exchanges that are paired in turn taking, one statement or question requiring a matched response. The opening sequences of telephone conversations will conventionally consist of normative telephone greetings, the identification of the caller and recognition, the inquiry as to well being, which all have their ritualized, common paired responses, framed with respect to context and the identity of the caller.

One important outcome of these studies was the recognition that the micro coordination of telephone talk and interactional norms differed across cultural contexts. A third way of understanding the sociological importance of the telephone has therefore been to examine comparatively the role, uses, and availability of the telephone across cultures, regions, nations, and internationally. Interactional studies have pointed out that conventional norms in telephone talk reflect deeper cultural differences in behavioral norms, the conventional rules of politeness, conversational norms in public spaces, turn taking, and informational requirements for mutual identification and recognition. Many of these studies have, however, concentrated on cultural differences within and between different nations and cultures in North America and Europe. This in itself points to a wider sociological phenomenon – that of globally unequal availability of a telecommunications infrastructure, and population access to associated technologies. This inequality has historically reflected the unequal division of resources between the developed and developing worlds – a number of sociologists have pointed out that the deployment and use of the landline telephone, especially when positioned in a domestic context, is a particularly western phenomenon. Despite its ubiquity in western settings, it was estimated at the turn of the millennium that around 70 per cent of the world's population had no direct access to a landline telephone. By concentrating on comparative research between western

nations, sociologists have sometimes neglected alternative configurations of people, cultural practices, and technologies that have evolved around telephony in non western settings, particularly community based and shared uses of telephones, its role in ritual, religious, and kinship practices, and its uses in the processes of both colonialism and development.

Access to telecommunications infrastructures has itself, however, again been transformed with further innovations in the configuration of telephony itself – in the form of wireless, mobile, or cellphone technology. Throughout the 1980s and 1990s, cellular telephony emerged as a key technological infrastructure in European and North American societies. The transmission of voice over distance no longer relied on fixed line telephone wires, but rather employed digital signals over radio waves. The devices to send and receive telephony signals were no longer bound to a single place such as the domestic household, and instead became the “hand set” or cellphone. This entailed a significant shift in telephone practices, as rather than being attached to a fixed geographical space, telephone devices instead became attached to particular persons and bodies. Via such means, telephony has become further individualized, and in the process, the mobile devices themselves became part of the consumption and commodity systems to an extent not previously seen. Telephone receivers could be highly personalized by, for example, changing the appearance of the hand set, and the devices not only carried voice calls, but incorporated address books and answering services more extensive than their fixed line predecessors, and featured “text messaging” – the ability to send short written rather than oral messages. More recently, mobile phones have also incorporated digital cameras (and the ability to exchange images), as well as hardware and software to support polyphonic “ringtones” and play digital audio files.

This mobilization of telephony has been extensive, most notably in Western Europe, where some countries' mobile phone subscription rates exceed 90 percent of the population. Because mobile telephony does not rely on a wired infrastructure, it has also overtaken subscription to fixed line telephony in some nations of the developing world. The extent of this change in telephony has led sociologists to

reevaluate the social relationships mediated by telephones, where those devices have become mobile.

As was the case with the fixed line telephone, the presence and use of telephones “on the move” has affected how the public and the private are negotiated in everyday life. Because mobile phones are significantly *personal* devices, they come to symbolize (through voice messaging, address books, and text messages) the social networks of which the individual is a part. At the same time, they are public by virtue of their use in shared spaces, whether those shared spaces are in the home or family relationship, or in collective spaces such as public transport. On the one hand, therefore, mobile phones can establish and maintain the private and personal as in the case, for example, where young people can bypass parental gatekeeping of the fixed line household phone to engage with their peers. On the other hand, mobile phones can both mediate and disrupt the public – when, for example, peers “gift” one another with text messages and images that can then be displayed to co present others to demonstrate participation in a telepresent social network, or when phones are used for voice calls in public space disrupting conventional behavioral norms. Similarly, gender is implicated in emerging norms of use, for example in the ways mobiles are used by women to manage their multiple responsibilities with respect to work, household, and extended family.

As was also the case with the fixed line telephone, the interactional norms governing use and behavior with respect to the mobile phone must be negotiated over time. The conversational norms with both co present and telepresent others are being rewritten as mobile phones become a more ubiquitous feature of everyday life. The “etiquette” of mobile phone use has been the subject of significant public debate, and continues to be so with the introduction of further features such as cameras that can readily be used across a range of social situations. Sociologists have begun to conduct ethnographies of a range of places and spaces to investigate these emerging norms, and to uncover the ways in which the mobile phone intervenes in social and communicative practices across a number of nations and cultures. They are investigating the historical significance of the mobile

with respect to the technological landscapes and social networks of which they are a part, and considering the organization, hierarchies, and power relations embedded in their production and consumption. As mobile and fixed line phones continue to converge with technologies such as the Internet, sociology now recognizes that in contemporary societies telephony has a central role in the technology and media landscape, and have adjusted their focus accordingly.

televangelism

William H. Swatos, Jr.

Initially an American phenomenon, televangelism refers to the use of television for Christian missionary outreach, of an evangelical fundamentalist type, usually incarnated in a single leadership figure, which became particularly prominent in the 1970s as a result of shifts in broadcasting policies regulated by the United States Federal Communications Commission (FCC) in 1960. Prior to that time, the FCC

required the commercial broadcast networks to donate a portion of their airtime to "public interest" use. A convenient way to do this was for the stations to cooperate with large, mainstream religious bodies to produce a variety of non confrontational, non sectarian programs that could fit within this category. This ended when the FCC in 1960 ruled that the stations could count commercial programming toward their public interest quotas. The effect was to open a new market, wherein profit interests could redefine the public interest within category limits. Hence, "religious interest" could be met by allowing the religious interests with the most money to have the available slots. This was greatly enhanced as more broadcast frequencies became more easily available. So was born the parallel religious institution of the "electronic church," with its most successful exponents eventually termed "televangelists."

As a part of media coverage of the growth in fundamentalist and evangelical churches in the United States during the 1970s and 1980s, one focus of attention became the concomitant expansion in the activities of religious broadcasters, especially the televangelist stars of Sunday morning. Eventual revelations of scandals involving sexual misconduct and/or financial misrepresentation by some of the best known television preachers, such as Jim Bakker and Jimmy Swaggart, served to fix popular gaze firmly on the operations of religious broadcasters. Unnuanced and even derisive reporting of these scandals also reinforced persistent stereotypes concerning the rather diverse ministries that jointly inhabit the airwaves. Chief among these is the impression that all religious broadcasters are money hungry opportunists, accountable to no higher authority, who promise miracles in order to lure huge numbers of the desperate and the gullible – and their financial contributions – away from the putatively sounder fellowship of mainline congregations or secular professional help.

A sociological account of televangelism is better constructed in aspects of the roles that broadcast ministers perform and the economic and organizational constraints within which they work. The electronic church, like other western institutions, is voluntaristic, diverse, market oriented, entrepreneurial, technologically advanced, and activated by vast amounts

of time and money. In the media market, there simply is no ministry without money. In a different sense than is normally intended, within broadcasting time is money – that is, time costs money. Thus, the head of a broadcast ministry, virtuous or not, must always preach with one eye glued to the financial bottom line and one foot planted a step ahead of his creditors. Hence the seeming obsession during religious broadcasts with talk of raising and spending money. Additionally, the very evangelistic nature of religious commitment among conservative Christians reinforces this entrepreneurial style. To their way of thinking, a faith that is not actively being passed on is a faith that is indolent and moribund. Not only is there a Christian imperative to extend the faith, but also a conviction that God has established a (hidden) time limit within which this must be done and that those who do not receive the Christian gospel are eternally lost. The logical conclusion to this line of thought is the incessant appeal for money to retire debts, maintain operations, and advance into the future.

The principal spokesperson for these appeals is the televangelist himself. Because very few current broadcast ministries are the projects of denominations, it is almost always an individual (most frequently the founder) who comes to embody the spirit of a religious program. He becomes the focal point for all that his ministry is and does; for all practical purposes, he *is* his organization. Televangelists are not above turning this condition around, however, and using it to cultivate loyalty among their followers. It is, after all, harder for people to trust an institution than a person, and even harder for them to endorse the worth of an abstract idea. So their gazes settle naturally on the profile of the preacher at center stage; hence, for example, viewers are much more likely to know *who* they watch among the televangelists than they are the actual name of his program.

Audience research shows that despite the sometimes outlandish claims of broadcast preachers themselves, the size of the regular audience for religious television in the United States is rather modest. It is dwarfed by the average ratings for the most popular talk shows and situation comedies on network television and its cable counterparts. The audience for religious television is also heavily concentrated

in Southern states, where religious convictions as a whole have greater salience than they do in the rest of the country; hence religious broadcasting may simply intensify already existing convictions rather than change alternative worldviews. Across the entire audience, furthermore, viewers are not ordinary unchurched, but are comparatively religious in the first place. Hence, there is little basis for a concern that religious television is substituting for worshiping with a congregation; the majority of viewers who are not otherwise religiously active are among the elderly, the immobile, and the chronically infirm, who would not swell the participatory ranks of congregants if televangelism were to cease.

television

Toby Miller

What is television? It is an object that is produced in a factory, then distributed physically (via transportation) and virtually (via advertising). At that point it transmogrifies into a fashion statement, a privileged (or damned) piece of furniture – a status symbol. Finally, it becomes outmoded junk, full of poisons and pollutants

in search of a dumping ground. In short, television has a physical existence, a history as an object of material production and consumption in addition to its renown as a site for making meaning. That renown is the focus of most sociological theory and research into the media.

Prior to the emergence of TV appliances and services, people fantasized about the transmission of image and sound across space. Richard Whittaker Hubbell made the point by publishing a book in 1942 entitled *4000 Years of Television*. The device even has its own patron saint, Clare of Assisi, a teen runaway from the thirteenth century who became the first Franciscan nun. She was canonized in 1958 for her bedridden vision of images from a midnight mass cast upon the wall, which Pius XII decided centuries later was the first broadcast. As TV proper came close to realization, it attracted intense critical speculation. Rudolf Arnheim's 1935 "Forecast of Television" predicted it would offer viewers simultaneous global experiences, transmitting railway disasters, professorial addresses, town meetings, boxing title fights, dance bands, carnivals, and aerial mountain views – a spectacular montage of Broadway and Vesuvius. A common vision would surpass the limitations of linguistic competence and interpretation. TV might even bring global peace with it, by showing spectators that "we are located as one among many." But this was no naïve welcome. Arnheim warned that "television is a new, hard test of our wisdom." The emergent medium's easy access to knowledge would either enrich or impoverish its viewers, manufacturing an informed public, vibrant and active, or an indolent audience, domesticated and passive (Arnheim 1969: 160–3). Two years after Arnheim, Barrett C. Kiesling (1937: 278) said "it is with fear and trembling that the author approaches the controversial subject of television." Such concerns about TV have never receded. They are the very stuff of sociology's inquiries into this bewildering device.

Like most sociological domains, the study of television is characterized by severe contestation over meanings and approaches, not least because its analysts "speak different languages, use different methods," and pursue "different questions" (Hartley 1999: 18). Broadly speaking, TV has given rise to three key topics:

- 1 Ownership and control: television's political economy.
- 2 Texts: its content.
- 3 Audiences: its public.

Within these categories lie several other divisions:

- 1 Approaches to ownership and control vary between neoliberal endorsements of limited regulation by the state, in the interests of guaranteeing market entry for new competitors, and Marxist critiques of the bourgeois media's agenda for discussing society.
- 2 Approaches to textuality vary between hermeneutic endeavors, which unearth the meaning of individual programs and link them to broader social formations and problems, and content analytic endeavors, which establish patterns across significant numbers of similar texts, rather than close readings of individual ones.
- 3 Approaches to audiences vary between social psychological attempts to validate correlations between watching TV and social conduct, and culturalist critiques of imported television threatening national culture.

There is an additional bifurcation between approaches favored by those working and/or trained in US social sciences versus the rest of the world. These relate to wider intellectual differences, but also to distinctive traditions of public policy. Like so many other areas of social life, TV is principally regarded as a means of profit through entertainment in the US and, historically at least, as a means of governance through information elsewhere. The first tradition focuses on audiences as consumers, the second as citizens. Pierre Bourdieu (1998: 48) refers to these rather graceless antinomies as "populist spontaneism and demagogic capitulation to popular tastes" versus "paternalistic pedagogic television." Neoliberal deregulation since the 1980s has privatized TV all over the globe under the sign of the US exemplar, but there continue to be theoretical, analytic, and political correlatives to this difference between the US and the rest.

Just as US sociology determinedly clings to a binary opposition between qualitative and

quantitative approaches, between impression and science, between commitment and truth, so it has hewed closely to methodological individualism in seeking to explain why people and television interact as they do, looking for links between TV and violence, misogyny, and educational attainment. Conversely, sociologists elsewhere worry less about such issues. They are more exercised by Hollywood's impact on their own countries' cultural expression. Global sociology is inclined to use critical terminology and methods that look at TV as a collective issue, rather than an individual one; a matter of interpretation and politics more than psychological impact. But there is in fact a link between the two anxieties.

In their different ways, each is an effects model, in that they assume television *does* things *to* people, that audience members are at risk of abjuring either interpersonal responsibility (in the US) or national culture (in the rest of the world). In Harold Garfinkel's (1992: 68) words, both models assume that the audience is a "cultural dope . . . acting in compliance with the common culture." Caricaturing people in this way clouds the actual "common sense rationalities . . . of here and now situations" they use. Most of the time that the television audience is invoked by sociologists, or by TV's critics and regulators, it is understood as just such a "dope"; for example, the assumption that "children are sitting victims; television bites them" (Schramm et al. 1961: 1).

The dope splits in two, in keeping with dominant audience models. The first appears in a *domestic* effects model, or DEM. Dominant in the US, and increasingly exported around the world, it is typically applied without consideration of place and is psychological. The DEM offers analysis and critique of education and civic order. It views television as a force that can either direct or pervert the audience. Entering young minds hypodermically, TV can both enable and imperil learning. It may also drive viewers to violence through aggressive and misogynistic images and narratives. The DEM is found at a variety of sites, including laboratories, clinics, prisons, schools, news papers, psychology journals, television stations' research and publicity departments, every day talk, program classification regulations, conference papers, parliamentary debates, and

state of our youth or state of our civil society moral panics. The DEM is embodied in the US media theatrics that ensue after mass school shootings, questioning the role of violent images (not hyper Protestantism, straight white masculinity, a risk society, or easy access to firearms) in creating violent people. The DEM also finds expression in content analysis, which has been put to a variety of sociological purposes. For example, a violence index has been created to compare the frequency and type of depictions of violence on US TV news and drama with actual crime statistics, and content analysis has also been applied to representations of gender and race.

The second means of constituting “dopes” is a *global* effects model, or GEM. The GEM, primarily utilized in non US discourse, is spatially specific and social. Whereas the DEM focuses on the cognition and emotion of individual human subjects, via observation and experimentation, the GEM looks to the knowledge of custom and patriotic feeling exhibited by populations, the grout of national culture. In place of psychology, it is concerned with politics. Television does not make you a well educated or an ill educated person, a wild or a self controlled one. Rather, it makes you a knowledgeable and loyal national subject, or a *naïf* who is ignorant of local tradition and history. Cultural belonging, not psychic wholeness, is the touchstone of the global effects model. Instead of measuring audience responses electronically or behaviorally, as its domestic counterpart does, the GEM interrogates the geopolitical origin of televisual texts and the themes and styles they embody, with particular attention to the putatively nation building genres of drama, news, sport, and current affairs. GEM adherents hold that local citizens should control TV, because their loyalty can be counted on in the event of war, while in the case of fiction, only locally sensitized producers will make narratives that are true to tradition and custom. The model is found in the discourses of cultural imperialism, everyday talk, broadcast and telecommunications policy, unions, international organizations, newspapers, heritage, cultural diplomacy, and post industrial service sector planning. In its manifestation as textual analysis, it interprets programs in ideological terms.

Both models have fundamental flaws. The DEM betrays all the disadvantages of ideal typical psychological reasoning. It relies on methodological individualism, thereby failing to account for cultural norms and politics, let alone the arcs of history and shifts in space that establish patterns of imagery and response inside TV coverage of politics, war, ideology, and discourse. Each massively costly test of media effects, based on, as the refrain goes, “a large university in the [US] mid West,” is countered by a similar experiment, with conflicting results. As politicians, grant givers, and jeremiad wielding pundits call for more and more research to prove that TV makes you stupid, violent, and apathetic (or the opposite), sociologists and others line up to indulge their contempt for popular culture and ordinary life and their rent seeking urge for grant money. The DEM never interrogates its own conditions of existence; namely, that governments and the media use it to account for social problems, and that TV’s capacity for private viewing troubles those authorities who desire surveillance of popular culture. As for the GEM, its concentration on national culture denies the potentially liberatory and pleasurable nature of different forms of television, forgets the internal differentiation of publics, valorizes frequently oppressive and/or unrepresentative local bourgeoisies in the name of maintaining and developing national televisual culture, and ignores the demographic realities of its “own” terrain.

Nevertheless, the DEM and the GEM continue unabated. From one side, Singer and Singer (2001: xv) argue that “psychophysiological and behavioral empirical studies beginning in the 1960s have pointed . . . to aggression as a learned response.” From the other side, García Canclini (2001: 1) notes that Latin Americans became “citizens through our relationship to Europe,” while warning that links to the US may “reduce us to consumers.”

In contradistinction to the DEM/GEM, a third tendency in sociology picks up on Garfinkel’s cultural dope insight. Endorsing the audience as active rather than passive, it constructs two other model audiences:

- 1 All powerful consumers (invented and loved by neoliberal policymakers, desired

and feared by corporations) who use TV like an appliance, choosing what they want from its programming.

- 2 All powerful interpreters (invented and loved by utopic sociologists and cultural critics, investigated and led by corporations) who use TV to bring pleasure and sense to their lives.

These models have a common origin. In lieu of citizen building, their logic is the construction and control of consumers. Instead of issuing the jeremiads of rat catching psy doomsayers, they claim that the TV audience is so clever and able that it makes its own meanings from programs, outwitting institutions of the state, academia, and capital that seek to measure and control it. Ownership patterns do not matter, because the industry is "wildly volatile," animated entirely by "the unpredictable choice of the audience" (De Vany 2004: 1, 140). The first approach demonstrates a mechanistic application of neoclassical economics. The second varies between social psychological tests of viewers' gratifications and a critical ethnography that engages cultural and social questions.

A summary of sociological approaches to television up to the present might look like Table 1.

And the future? What are we to make of digitally generated virtual actors (synthespians), desktop computers that produce and distribute expensive looking images, the New International Division of Cultural Labor's simultaneous production work on TV programs across the world, and broadband home video

access (Miller et al. 2005)? The rhetoric of the new media is inflected with the phenomenological awe of a precocious child who can be returned to Eden, healing the wounds of the modern as it magically reconciles public and private, labor and leisure, commerce and culture, citizenship and consumption. "Television is dead" (de Silva 2000) and the interactive web is the future. That may be. But it is worth remembering that television stations continue to multiply around the world, that TV is adapting to the use of Internet portals, and that the digital divide separating the poor from high technology is not changing. Two billion people in the world have never made a telephone call, let alone bought bookshelves on line.

In any event, the questions asked of television today illustrate its continued relevance. For example, leading bourgeois economist Jagdish Bhagwati (2002) is convinced that TV is partly to "blame" for global grassroots activism against globalization because television makes people identify with those suffering from capitalism, but has not led to rational action (i.e., support for the neoclassical economic policies he supports, which many would say caused the problem). Just a few pages further on in Bhagwati's essay, however, cable is suddenly a savior. There is no need to litigate against companies that pollute the environment, or impose sanctions on states that enslave children to become competitive in the global economy, because the rapid flow of information via the media ensures that "multinationals and their host governments cannot afford to alienate their constituencies"

(pp. 4, 6). The tie between the medium as a heaven and hell is as powerful as it was in Arnheim's forecast seven decades earlier.

We are perhaps witnessing a *transformation* of TV, rather than its demise. Television started in most countries as a *broadcast, national* medium dominated by the state. It is being transformed into a *cable and satellite, international* medium dominated by commerce, but still called "television." A TV like screen, located in domestic and public *spaces*, and transmitting signs from other *places*, will probably be the future.

In many ways, television has become an alembic for understanding society. There is intellectual and political value in utilizing the knowledge gained from sociology to assess this transformation and intervene in it, especially if we borrow from the right traditions. The three basic questions asked by students of the media – "Will this get me a job?" "Is television bad for you?" "How do we get that show back on?" – have direct links to the relationships between text and audience, as understood through ethnography and political economy. The respective answers are: "If you know who owns and regulates the media, you'll know how to apply"; "The answer depends on who is asking the question and why"; and "If you know how audiences are defined and counted and how genre functions, you'll be able to lobby for retention of your favorite programs."

In summary, analyzing television requires interrogating the manufacture and material history of TV sets; creation, commodification, governance, distribution, and interpretation of texts; global exchange of cultural and communications infrastructure and content; and economic rhetoric of communications policies. This can be done by combining political economy, ethnography, and textual analysis into a new critical sociology of TV.

terrorism

Douglas Kellner

The term terrorism derives from the Latin verb *terrere*, "to cause to tremble or quiver." It began to be used during the French Revolution, and especially after the fall of Robespierre and the "Reign of Terror," or simply "the Terror," in which enemies of the Revolution were subjected to imprisonment, torture, and

beheading, the first of many modern examples of state terrorism.

Over the past two centuries, terrorism has been a highly contested and volatile category. Those accused of terrorism are vilified as enemies of the state and social order, but many labeled “terrorists” insist that they are “freedom fighters,” strugglers for national liberation, or *mujaheddin* (holy warrior) or *fedayeen* (“prepared for martyrdom”), ready to die for righteous causes. Many decry terrorists’ indiscriminate violence against civilians, while other critics like Chomsky (1988) and Herman (1982) document state use of violence and terror against its perceived enemies.

During the nineteenth century, terrorism was frequently associated with anarchism. Russian anarchists and Narodniks (populists) advocated political terror and were responsible for assassinating Czar Alexander II, a frenzied milieu depicted by Fyodor Dostoevsky in his novel *The Possessed* (1913). Nationalist movements also began to use terrorism in anti colonial movements, such as the Irish Republican Brotherhood which carried out attacks in England in the name of Irish nationalism, or groups like the Internal Macedonian Revolutionary Organization which was driven by Slavic nationalism (Laquer 1998).

Sociologically, terrorist groups often recruit disaffected and alienated individuals, often motivated by strong ideologies like nationalism or religion to commit terrorist acts. These in turn generate societal fear and exacerbate conflicts and hatred within the social fabric.

During the twentieth century, oppositional political groups ranging from anarchists and nationalists on the left to fascists and the ultra right used political terror to promote their agendas, engaging in bombing, destroying property, political assassination, and other destructive action to attack the established order. Colonial national liberation movements spread throughout the globe, such as the Mau Mau group in Africa, the Palestinians in the Middle East, the Irish Republican Army in Britain, and the Basque liberation group ETA in Spain.

The term has also been associated in the twentieth century with indiscriminate or excessive use of state violence and has been leveled against actions of Nazi Germany, the Soviet Union, the United States, Israel, and other

countries. For instance, Chomsky (1988) and Herman (1982) document a wide range of US state terrorist actions in Southeast Asia, Africa, South America, and elsewhere, with Chomsky pointing out that the US is the only country that has ever been convicted of an international act of terrorism by the World Court, which condemned US acts against Nicaragua during the 1980s.

From the 1980s to the present, terrorists have constructed spectacles of terror to promote their causes, attack their adversaries, and gain worldwide publicity and attention. Terror spectacle has become an increasingly significant part of contemporary terrorism and various groups systematically use spectacles of terror to promote their agenda. Extravagant terrorist acts are thus orchestrated in part as media spectacles to gain worldwide attention, dramatize the issues of the terrorist groups involved, and achieve specific political objectives (Kellner 2003).

The hijacking of airplanes had been a standard terrorist activity, but the ante was significantly upped when, in 1970, the Popular Front for the Liberation of Palestine hijacked three western jetliners. The group forced the planes to land in the Jordanian desert, and then blew up the planes in an incident known as “Black September,” which was the topic of a Hollywood film. In 1972, Palestinian gunmen from the same movement stunned the world when they took Israeli athletes hostage at the Munich Olympic Games, producing another media spectacle turned into an academy award winning documentary film.

In 1975, an OPEC (Organization for Petroleum Exporting Countries) meeting was disrupted in Vienna, Austria when a terrorist group led by the notorious Carlos the Jackal entered, killing three people and wounding several in a chaotic shootout. Americans were targeted in a 1983 bombing in Beirut, Lebanon, in which 243 US servicemen were killed in a truck bombing orchestrated by a Shiite Muslim suicide bomber, which led the US to withdraw its troops from Lebanon. US tourists were victims in 1985 of Palestinians who seized the cruise ship *Achille Lauro*, when Leon Klinghoffer, 69, a disabled Jewish American, was killed and his body and wheelchair were thrown overboard. In June 1985, a double bombing of Air India jets originating from Canada attracted

global attention, as did a 1988 bombing of Pan Am Flight 103 over Lockerbie, Scotland.

In 1993, the World Trade Center was bombed in New York by Islamist terrorists linked to Osama bin Laden, providing a preview of the more spectacular September 11 aggression. An American born terrorist, Timothy McVeigh, bombed the Alfred P. Murrah Federal Building in Oklahoma City, killing 168 and wounding more than 500. Further, the bin Laden group assaulted US embassies in Africa in 1998 and a US destroyer harbored in Yemen in 2000.

Periodic IRA attacks in Britain continued, including a 1998 car bomb attack in Omagh, Northern Ireland that killed 29 and injured hundreds, creating great outrage. On September 11, 2001, terror attacks against the World Trade Center in New York and the Pentagon in Washington, DC became a global media spectacle (Kellner 2003). The September 11 terror spectacle was the most extravagant strike on US targets in its history and the first foreign attack on its territory since the war of 1812. The 9/11 attacks inaugurated a "war on terror" by the Bush administration and was the prelude to highly publicized terrorist bombings in London, Pakistan, Bali, and elsewhere, and Bush administration military interventions in Afghanistan and Iraq as "preemptive" actions in the "war on terror." Many critics accused the Bush administration of state technology in its invasion and occupation of Iraq.

Terrorism and terror war have thus become defining features of the twenty first century. Governments throughout the world have attempted to more precisely define and criminalize terrorism, while terrorist activities multiply. As weapons of destruction become more deadly and widespread, social divisions between haves and have nots multiply, and conflict rages throughout the world, terrorism will likely continue to be a major issue and problem of the present era.

text/hypertext

Gregory L. Ulmer

Hypertext refers to a network of nodes or lexias (units of content) connected non sequentially by links, forming a docuverse that includes users in a feedback loop, usually in a computer medium. The first description of hypertext as a concept was by Vannevar Bush, in an article entitled "As We May Think," published in the *Atlantic Monthly* in 1945. Bush imagined a machine desk called "memex" that could solve the problem of storage and retrieval created by the modern information explosion. Merging the functions of a library and a personal filing system, memex proposed to support and augment an associative indexing corresponding to the actual processes of human thought, memory, and imagination. Individuals researching the branching paths of information related to an inquiry would build trails of connections through the collective archive of recorded information, and these trails would be preserved, shared, and cross referenced, establishing possibly a new profession of knowledge "trailblazers."

Inspired by memex, Theodor Holm Nelson coined the term hypertext (and also hypermedia, to include multimedia) in 1965. "Such a system as the ELF (Evolutionary List File) actually ties in better than anything previously used with the actual processes by which thought is progressively organized, whether into stories or hypertext or library categories. Thus it may help integrate for human understanding bodies of material so diversely connected that they could not be untangled by the unaided mind" (Nelson 1989: 145). Nelson's vision, called the

Xanadu project (referring to the “magic place of literary memory” in Samuel Taylor Coleridge’s poem *Kubla Khan*), extended memex into a global archive in which users could write as well as read. Xanadu’s multiple styles of hypertext were at least partially realized in the greatest hypermedia system to date, the World Wide Web. Tim Berners Lee introduced the document description language HTML (hypertext markup language) in 1989 that made the Internet into a hypertext system. Even with the addition of the graphical browser, created by Marc Andreessen in 1993, however, the available equipment and its applications have not approached the full realization of the hypertext vision. Lev Manovich argued that the most important creators of the twentieth century are the people who invented the hypermedia tools, adding to the names already mentioned those of Douglas Englebart, who invented the mouse and windowed interface, Ivan Sutherland, whose Sketchpad was the first paint program, and J. C. R. Licklider, director of DARPA (Defense Advanced Research Projects Agency). All these figures made their contributions in the 1960s.

To appreciate the full potential of hypertext it is useful to place its development in the context of the concept of apparatus (social machine) commonly used in media studies. To say that hypertext is part of a new apparatus beginning to replace literacy helps avoid the fallacy of technological determinism. A language apparatus includes not only technology, but also institutional practices and human identity formation. It is possible to grasp what is happening in our time by analogy with the shift from orality to literacy in classical Greece, when Plato and Aristotle invented the institution of school, and the practices of alphabetic writing, including logic, method, and the category system of concepts (metaphysics) that eventually produced modern science. To have a term for the digital equivalent of literacy helps identify more easily the full range of inventions in progress across the dimensions of the apparatus. This neologism is “electracy,” combining “electricity” with the theory of “trace” used by Jacques Derrida to describe the operations of text (Ulmer 1989).

The beginnings of electracy as technology date from the 1830s, with the invention of

photography and Charles Babbage’s analytical engine, an information processor (never built) based on the punchcards of the Jacquard loom. The metaphor of “textile” in the root of “text” is worth noting in this context. The separate trajectories of these inventions converged finally in the graphical computer, making possible the mutual mapping between the culture of mass media entertainment operating through television and the culture of disciplinary science supported by the databases of information processors.

Hypertext is not only the result of a history of technology, but also the most recent manifestation of the ancient dream of a perfect or universal language. To deal with the information overload caused by manuscript culture, for example, medieval pedagogy promoted the art of memory. Mnemonic systems, associating real or imaginary settings and striking (violent or sexual) images with bodies of information, facilitated memorization in service of oratory. The practice led to attempts to build actual memory theaters, such as the one designed by Giulio Camillo in the 1530s. Large enough to be occupied by two people, the theater was a hypertextual organization (consisting of cross-referenced drawers filled with slips of writing) of the oeuvre of Cicero.

Mnemonic learning practices served several historical currents, including hermeticism and the trend leading from the search for a universal language to the creation of the encyclopedia in the Enlightenment. Jorge Luis Borges, whose story *The Garden of Forking Paths* (1941) is often mentioned as an allegory of hypertext design, drew upon this tradition of philosophical languages as a source for a number of seemingly bizarre ideas about writing and memory. The most influential fictional representation of what it might be like for an individual to think with complete access to the entire dynamic archive of collective information is William Gibson’s cyberpunk novel *Neuromancer*. In the two novels following *Neuromancer*, Gibson, who coined the term cyberspace, drew upon the event of possession in Haitian Vodun as a metaphor for this merger of individual and collective mind.

The key practical issue for those continuing to invent hypertext as an apparatus concerns the nature of the human–computer interface (HCI).

What remains to be invented is the electrate equivalent of logic, rhetoric, and poetics that allows people to be native users of a docuverse. The issue is foregrounded in Michael Joyce's *Afternoon* (1987), the first and still one of the most important examples of hypertext fiction. Composed in StorySpace, a hypertext authoring program developed by Joyce with Jay David Bolter and John B. Smith, *Afternoon* is a detective story in which the reader attempts to figure out the plot by navigating a complex set of nodes and links. The feeling of being lost in a maze reported by many readers of *Afternoon* may be extended to hypertext in general, in which reading is the exploration of an information space, whether in the mode of fiction, game, or encyclopedia. In this regard Espen Aarseth proposed as the two primary rhetorical figures of hypertext the tropes of aporia (impasse) and epiphany (revelation). The pleasure of navigation involves a eureka moment in which the user discovers how to continue the path productively. Aarseth also proposes the term "ergodic" to replace "narrative" to describe cybertexts in which the sequence through the lexias is different at each reading.

The labyrinth effect of hypertext makes explicit what was always implicit in the literate archive. Umberto Eco's study of semiotics clarifies that what hypertext embodies and renders tangible is nothing less than the dynamic, open, and infinite operation of meaning in process. Eco describes semiotics as a transition away from the logical categories of literate concepts generated by definition (semantics), to a new kind of category functioning through inference, having more to do with pragmatics. Since the meanings involved are interpretants, including the subjectivity of the individual, they take the form collectively of a labyrinth of the network or rhizomatic type, lacking both center and outside.

What are the practices that enable reading and writing in a labyrinthine docuverse? This is the fundamental active question of hypertext. Within the unifying framework of electracy it is possible to recognize that hypertext is being invented across the apparatus. The fact that hypertextual features are found in certain literary works such as *Tristram Shandy* (digression) or *Wuthering Heights* (nested points of view), not to mention *Finnegans Wake* (trace)

and other experimental works, is explained by the fact that the genealogy of hypermedia is social and cultural as well as technological. *Afternoon* is described as modernist in its aesthetics and postmodernist in its use of technical devices. Lev Manovich has shown that the practices of collage montage invented by the vanguard arts across the media, especially concentrated in the movements of the 1920s, have been designed into the interface controls of the software used to author in new media. Unfortunately, many artists experimenting with new media complain that the public have yet to internalize the equivalent rhetoric in their worldview, and continue to use as their default model of intelligibility the pop forms of mass entertainment.

The institutional practices appropriate for hypertext have at least been theorized, beginning in the same decade of the 1960s that produced the Xanadu project and the GUI tools, when a group of critics working in France formulated the poststructural theory of "text." When commentators claim that hypertext makes poststructuralism seem obvious, or that the Web is the laboratory for testing poststructural principles, they are referring to the writings of such figures as Roland Barthes, Julia Kristeva, and Jacques Derrida. The new meaning of "text" appearing in the 1960s was the culmination of the "linguistic turn" in the arts and letters disciplines going back to the beginnings of modernism in the nineteenth century. Meaning based on reference to an objective reality was replaced by signification emerging from the relationships among the elements of a system. Structuralism was the science of such systems. Poststructuralism took up the question of pragmatics, concerned with the experience of people within discourse.

Structuralism treated everything in culture as a language, thus doing for theory what the convergence of media in digital technology did for the equipment. The way was prepared for theorizing reading and writing as the traversal of a virtual world designed as a discourse. Roland Barthes (who introduced the term *lexia* to describe a unit of reading) devoted his entry on "text" for the *Encyclopaedie Universalis* to an exposition of Julia Kristeva's "semanalysis," which he said created an epistemological mutation by integrating linguistics and semiotics

with dialectical materialism and psychoanalysis. The old notion of a literary “work” as a unique bounded entity expressing the intentions of an individual author was replaced with the semiotic notion of text as an intertextual transformation of other texts. Kristeva introduced “intertext” to translate Mikhail Bakhtin’s “dialogical word” – the idea that every word is a crossroads of other words, opening onto the entire field of language, with meaning as an ideological struggle for possession of the field. Derrida’s “trace” expresses a similar idea that every sign carries the traces of all other signs.

The shift of identity experience in electracy is related to the “death of the author,” which Barthes reminds us is also the birth of the reader. Or, rather, text deconstructs the opposition between writer and reader, since what it names is not an inherent property of completed works, but a “productivity” of signification produced by the reader reworking the found materials of discourse. Text theatricalizes the encounter of the subject with language. “Subject” is not the person, but the identity position ideologically constructed in culture. The subject does not speak language, but is spoken by it. There is no position of critical distance outside the text, outside history or society, from which to judge events.

This loss of control over intention is compensated for by a new relationship of the subject immersed in discourse, which Barthes characterizes as “bliss.” Signification does not concern communication or message, but a new dimension of logic, of inference, which Barthes compares to Freud’s dreamwork (condensation and displacement). The technical, vanguard, and theoretical trajectories converge on this insight: the rhetoric of hypertext is precisely poetry (Bush’s associative thinking, or what Marcos Novak called liquid architecture). Poetry, or more generally the aesthetic operations observed in all varieties of creative thinking, contains the resources which it is the task of educators and designers today to translate into a “general electracy” that is to digital culture what general literacy is to print culture.

theology

Karl Gabriel

The modern conception of theology as both a faithful and rational or scientific way of talking about God dates from the Christian Middle Ages. Theology as a term is rooted in Greek philosophy, which consisted of three parts: the mythology of the gods, theology as a form of philosophy of nature, and political theology as a public cult. Christendom only reluctantly accepted the term. It is only from the twelfth century onwards that the term theology is commonly used for this science of Christian faith in contrast to the term philosophy. The late Middle Ages finds the term entirely accepted and it is even taken over by Martin Luther. In modern times it is especially used to distinguish between religious philosophy and religious studies on the one hand and Christian doctrine on the other.

Christian theology finds its roots in the biblical tradition. In its first phase since the second century, theology was dominated by the apologetical defense of faith from external attack as well as inner gnostic debate. Clement of

Alexandria and Origen developed the first conceptions of systematic knowledge and of an understanding of faith. From the thirteenth century a new prototype of theology as science of faith was established. The West and East developed differently, with western theology concerned with inner processes of systematization and rationalization, while the East was more liturgically and spiritually oriented. Furthermore, philosophy and theology in the West were separated, and challenged faith and science to bring forth their inner connection. Thomas Aquinas thought of God from the rational as well as the revelational points of view. The plurality of theologies was already apparent in the Middle Ages. Thus, scholastic theology with its tendencies to rationalize and intellectualize faith went hand in hand with forms of theology with ties to Augustinian Neoplatonic thinking or those which were more biblically or affectively oriented, such as the *devotio moderna*. Nominalism in the late Middle Ages came under the pressure of the medieval synthesis of faith and reason until it fell apart during the Reformation.

Modern western theology is marked by schism and conflict with modern society and culture. Reformation, due to the negation of scholastic theology, fell back on the Bible and on patristic theology, as well as trends of mysticism. For Luther, the object of theology was no longer the unity of faith and reason, but "the culpable and forlorn individual and the justification or saving God" (WA: 327). Modern trends in Protestant theology are marked either by the search for a connection with modern culture (e.g., the theology of the Enlightenment and liberal theology) or a stress on separation (e.g., Pietism and dialectical theology). At first, modern Catholic theology was anti Protestant and dominated by controversy. Neo Scholasticism, which was established in the nineteenth century, combined the critical debate with Protestantism with a separation towards modern culture and society. Approaches in liberal Catholic theology like the "Tübinger Schule" cannot convince or were clerically sentenced during the controversy over modernism. The struggle against modernism did not exclude inner processes of modernization in Catholic theology or in ecclesiastical structures.

Theology conceives of its modern form in processes of inner differentiation which follow the general development of society and science. When it began in the twelfth and thirteenth centuries it was still homogeneous in its interpretation of the Bible, reflection on faith, and introduction to religious practices. The beginnings of the separation of biblical and systematic theology reach back as far as the Middle Ages. In its function of thinking about faith, theology consists of three basic structures: historical, systematic, and practical science. Historical theology gained its modern form through the development of the historical critical method, which leads to tensions with systematic theology. Pastoral theology reacts to the modern differentiation of religion and society and helps establish practical theological disciplines which specialize in the practical role of the church in society. It is a specific part of modern theology that it reflects and copies the plurality of scientific approaches and disciplines. Today, theology signifies the connection between historical disciplines (contemporary history and exegesis of the Old and New Testament, church history), systematic disciplines (philosophy, fundamental theology, dogmatics, moral theology, social ethics), and practical disciplines (pastoral theology, liturgics, canon law, missionary science, religious education). The unity within the plurality of theologies is nowadays mainly expressed in the challenges it faces: the overcoming of confessional separation, the dialogue between religions, the variety of cultures, and the separation of the world into the poor and the rich. Theology is challenged to demonstrate the unity of the Christian promise of salvation and the culturality of Christian faith. It proves to be most fruitful where it succeeds in interpreting faith as part of a sociopolitical and cultural sphere with a view to its capability for experience and action. This is all the more clear in outlines of contextual theology developed across confessional boundaries, the best known of which are feminist theology, the theology of liberation, the theology of enculturation, and the theology of religions. In the sciences, theology nowadays appears to be an indispensable science of the cultural memory and a challenge to overcome the limitations of the modern understanding of science as a system of

hypothetical deductive propositions within interdisciplinary dialogue.

theoretical research programs

David G. Wagner

A theoretical research program has three components: a set of interrelated theories, a set of substantive and methodological working strategies used to generate and evaluate these theories, and a set of models for empirical investigation and analysis based on these theories. Theoretical research programs provide accounts of social phenomena as diverse as affect control, status

organization, network exchange, resource mobilization, revolution, and coalition formation in political action. Berger and Zelditch (1993, 2002) present detailed discussion and analysis of these and many other programs. Wagner (1984) discusses the source of the concept in the work of philosopher of science Imre Lakatos (1968, 1970) on scientific research programs.

Theoretical research programs are important to our understanding of how sociological knowledge grows. Programs are distinct from the broad, overarching meta theoretical strategies, such as functionalism and interactionism, which orient the construction of individual theories. Programs are more dynamic than strategies, the latter growing only very slowly and seldom in response to assessment of the theories that they generate. Programs are also distinct from individual theoretical arguments, or *unit theories*, such as Davis and Moore's theory of stratification or Lenski's theory of status crystallization. Although programs generally originate in a unit theory, they become much more complex as a network of interrelated theories emerges over time.

TYPES OF RELATIONS

The interrelation among theories in a program arises from a *core set* of key abstract concepts and assertions that are used in all the theories in the program. For example, the idea of an expectation state is central to the status characteristics program, the notion of a resource flow to the network exchange program. Over time these core ideas come to be used in a variety of different ways that expand our knowledge. Each of these ways represents a distinct pattern of the theoretical growth.

First, the ideas may be elaborated to provide a more detailed or specific account of the phenomenon under study. Theory T_2 is an *elaboration* of theory T_1 if it uses the same underlying core ideas to address a similar explanatory domain as T_1 , and is more comprehensive or specific or has better empirical grounding than T_1 . Usually, T_2 is intended to serve as a replacement for T_1 . Elaborations may expand the explanatory scope of a theory, formalize its structure, or enhance the empirical consequences of a theory and its corroboration.

For instance, a distributive justice theory that originally dealt only with situations involving quantity goods later expanded to deal with quality goods.

When combined with a few other new ideas, the core ideas may generate a new theory designed to explain different phenomena. T_2 is a *proliferant* of T_1 if it expands the core ideas (or adds new ones) to address a new explanatory domain or new theoretical problems in the domain of T_1 . In this case, both theories are likely to be viable and important explanatory tools, since they address different problems or phenomena. Proliferations significantly expand the range of sociological problems or phenomena to which a program's theories can be applied. For example, the concept of a source evaluator was added to expectation states theory to help explain how significant others affect actors' self evaluations and subsequent group behavior.

Sometimes two very closely related theories are developed from the same core ideas to develop more precise knowledge about how a process operates. T_1 and T_2 are *variants* of each other if they address the same or very similar explanatory domains, but propose slightly different mechanisms to account for how the process operates within that domain. Variants allow the theorist to consider and resolve small differences in understanding. Often, the result is a specification of different conditions under which each mechanism operates. For example, variant accounts of bargaining processes suggest that the use of threatening tactics either deters others from engaging in punitive behavior or leads to a spiral of conflicting threats that increases the likelihood of punitive behavior. Such variant theories may then be closely compared to determine which account provided the more effective explanation.

A superficially similar kind of relation appears when T_1 and T_2 use different sets of core ideas to address the same or overlapping explanatory domains. In this circumstance the theories are *competitors*. However, because of the significant differences in theoretical structure, it is often much more difficult to resolve explanatory differences between competitors than between variants. For example, one theory for the stabilization of mental illness invokes a labeling process, another focuses on psychophysiological

processes, and these have competed with each other without full resolution since they were first articulated in the 1960s.

Finally, ideas in one theory may be combined with ideas from another theory to provide a deeper or more complete account of phenomena or domains that previously were treated separately. Theory T_3 is an *integration* of T_1 and T_2 if it consolidates many of the ideas from the earlier theories, articulating ways in which they may be related. The manner in which integration is accomplished depends on the nature of the relation between T_1 and T_2 . If the integrated theories were variants, a common outcome is likely to be conditionalization. That is, T_1 is identified as operating under one set of conditions, T_2 under another set. Thus, when considering deterrence versus conflict spiral accounts of bargaining behavior, research has shown that deterrence occurs as long as the stakes in the bargaining remain relatively low. As the stakes increase, threat tactics prompt like responses, thereby generating the conditions for conflict spiral.

If T_1 and T_2 are proliferants, the integrating theory is likely to describe ways in which the different processes considered by the two earlier theories are interrelated. Accounts of the two processes may remain distinct, but connections between them are specified. For instance, reward expectations theory partially integrates status characteristics theory and the status value theory of distributive justice, the latter two theories previously having been proliferants. Reward expectations theory accomplishes this by specifying how expectations for task performance and expectations for reward allocation may form simultaneously in status situations.

Integrating competitors is most challenging. In this case the integrating theory usually must specify a new set of core ideas with which to describe the phenomena within its domain. Thus, Guillermina Jasso combined ideas from both multiple prior theories of distributive justice in developing her own. Key to her integration was the concept of a justice evaluation function, an idea that did not exist in either earlier theory.

Much more thorough accounts of the types of relation that may occur in theoretical research programs are available in Wagner (1984) and Wagner and Berger (1985). Those sources also

include detailed discussion and citation of relevant examples of each type.

WORKING STRATEGIES

Orienting strategies specify the fundamental aims and presuppositions that guide theoretical work. They provide an underlying ontology (what is to be seen as sociologically real) and an epistemology (how we know what is real). They also provide a substantive foundation of presuppositions about such issues as the nature of the actor, action, and the social order. Does the actor have agency? Is action rational? What is the relative importance of conflict and consensus in action? While orienting strategies provide the meta theoretical framework within which theoretical research programs may grow, they generally do not grow significantly or very rapidly, nor do they generally change in response to developments in the programs they frame.

There are, however, other elements of orienting strategies that do change and grow significantly in association with theoretical research programs. The directives of these *working strategies* are somewhat more specific and concrete than those of an overarching orienting strategy. Methodological working strategies provide concepts and principles dealing with the nature of the theory, the logic of inquiry, and the criteria for assessing theories. Herbert Blumer's proposal of a naturalistic method for investigating symbolic interaction is, for example, a methodological working strategy. Substantive working strategies provide concepts and principles specifying what properties of actors, action, and society are considered to be crucial for investigating social phenomena. They identify what kinds of problems are worth solving and what concepts and principles to use in solving them. Merton's proposals for functional analysis represent a substantive working strategy.

Working strategies play an important role in determining what the core ideas in a program should be, what questions should be addressed, and how they should be investigated. The answers generated constitute the different theories in a program. Methodological working strategies specify how these theories are to be constructed and what methodological tools are

to be employed in testing them. The foundational directives of orienting strategies provide the premises that justify working strategies; working strategies then specify more concretely how those premises can be realized.

Working strategies do not simply respond to broad foundational directives. They also respond to the success or failure of the elaborations, proliferants, variants, competitors, and integrations they stimulate. In fact, an articulation of at least some of the elements of a working strategy may only emerge gradually as theories in a program develop, broaden, and deepen understanding of the ideas under investigation. (For an illustration of this process, see the conceptualization of social interaction as a state organizing process in expectation states theory, in Berger et al. 1989, 1992). Thus, working strategies grow and change as a part of, and in concert with, the theories in the programs they guide.

MODELS

Another aspect of the development of theoretical research programs is associated with the implementation of theoretically based empirical models for research. Such models may include specifications of concrete instances of phenomena that can be modeled with the concepts and principles of theories in the program; they may specify conditions under which the model is expected to apply; they may identify observational techniques and procedures useful in applying the model; they may provide ways of interrelating elements from different theories in a program to deal with the complexity apparent in a particular application situation.

These are all issues of relevance in evaluating theoretical research programs. Models are central to evaluating the empirical adequacy of a program in representing specific social situations. They are also useful in specifying the range of situations and phenomena to which a program can be applied. Finally, models are essential in assessing how useful a program might be as a basis for intervention and change in specific social situations. (On the role of models in theory growth, see Berger & Zelditch 1998.)

MULTIDIMENSIONALITY OF THEORY GROWTH

Whether and how sociological knowledge is seen to grow thus depends on the unit of analysis chosen for considering the issue. A focus on the broad foundational orienting strategies of the discipline reveals very stable intellectual structures that change only very slowly (if at all) and without being particularly responsive to the fortunes of the theories generated from these strategies. A focus on individual theories yields only a consideration of changes in the empirical base for a static theoretical structure. And a focus on organizational and institutional properties like citation analyses and funding patterns reveals only growth in the social structures within which knowledge might occur, not the growth of knowledge itself.

A focus on theoretical research programs reveals *multiple* kinds and sources of growth. Knowledge grows through articulation and refinement of the working strategies that guide the construction of programs. Knowledge grows through the construction of new theories within programs. Elaborations, proliferants, variants, competitors, and integrations increase both the breadth of theoretical issues considered and the depth of understanding of those issues. Knowledge grows through assessments of the empirical adequacy and instrumental utility of the theory based models programs generate. A consideration of all of these patterns is necessary to fully understand how our sociological knowledge may be improved.

theory

Barry Markovsky

There are many different views in sociology about what theory is and what it should be. Many of these views are complementary, referring to different aspects of the process of theorizing, or to particular qualities that are more or less emphasized by different theorists. Some views are so disparate, however, as to be mutually incompatible, even while achieving legitimacy within mutually exclusive streams of sociological work. The purpose here is not to critically evaluate sociology's various theories and approaches, but rather to provide a short overview of some of the major strands of theoretical work. The approach will be to present several dimensions along which sociological theories have varied.

First, theories may be distinguished by major "schools," also known as approaches, frameworks, paradigms, metatheories, orientations, traditions, and by other labels as well. These

forms of theorizing tend to be relatively unstructured, open to interpretation, and immune to falsification – qualities that contrast markedly with the more parsimonious and rigorous products of formal theorizing. Some argue for reserving the term “theory” just for this more tightly constructed form, as this more clearly distinguishes statements that are considered to *embody* the theory from statements and discussions that are merely *about* the theory. Second, theories may be distinguished along a temporal dimension based upon when they first entered and impacted the discipline’s corpus of knowledge. A number of historians of sociology have attempted to rationalize the progression of the theories and schools, typically interpreting later developments as reactions against their immediate predecessors. Third, theories may be distinguished according to the extent to which they have been developed and evaluated with explicit reference to scientific standards. This dimension of evaluation should be important to sociology to the extent that its ultimate goal is to develop theories that are general, precise, and systematically evaluated in the empirical world. Finally, several additional properties will be considered that do not fit neatly into the above scheme.

SCHOOLS OF SOCIOLOGICAL THEORIZING

A small number of schools of sociological theorizing appear in virtually all textbooks on the subject. The remainder, a very much larger number (at least 70, judging by the 2005 edition of the *Encyclopedia of Social Theory*), range from near universal coverage to rarely seen in contemporary theory texts. This means that any review covering more than a handful of schools is invoking the personal tastes of the reviewer: there is no agreed upon metric for evaluating a school’s relative success or impact.

Conflict. Conflict theories focus on destabilizing factors such as social inequalities and social change. Karl Marx usually is credited with ushering in this orientation, with his emphasis on struggles between social classes with opposing interests, the emergence of collective consciousness among the oppressed, and the conditions for violent revolutionary change. Early versions

of the perspective were further articulated by Max Weber and Georg Simmel. Beginning in the late 1950s and extending through the 1970s, a succession of theorists extended and refined various strands of thought within the developing tradition. Ralf Dahrendorf, Lewis Coser, Jonathan Turner, and Randall Collins are among the more prominent. Each developed a critique of prior work, and each sought to integrate and streamline some of the disparate insights of his predecessors. The conflict approach since has evolved into other lines of work, e.g., neo Marxist theories, resource mobilization theory, theories of social revolutions, and breakdown theories of social movements.

Exchange. Social exchange theories reflect a kind of economic approach to social relations. As such, social actors (individuals or collectivities) are regarded as having individual interests that can be satisfied through exchanging goods, information, services – anything that others might accept in return for providing something of value. Many exchange theorists are further concerned with the larger social forces that bind together different interactants even as they pursue their individual interests. Roots of the exchange tradition in sociology can be found in the writings of Marx and Simmel. However, it was the more focused and explicit work of George Homans on behaviorist foundations, John Thibaut and Harold Kelley on rewards and costs in dyadic relationships, and Peter Blau on bridging to macro structures that really established this area’s identity by the 1960s. Richard Emerson and his collaborators subsequently developed a formal theory of power–dependence relations based on exchange principles, including an initial foray into social network relations. During this time, James Coleman, David Willer, and others also were developing exchange network theories addressing power, structural change, and other phenomena. Most theories of distributive justice and equity owe a debt to the exchange perspective, and more recent theorizing on group solidarity and commitment, legitimacy, and rational choice are offshoots of, or otherwise connected to, the exchange perspective.

Functionalism. Functionalism (a.k.a. *structural functionalism*) dominated sociology for much of the period between 1930 and 1960. It regards social systems as consisting of differentiated,

interdependent substructures having corresponding functions that operate in a coordinated fashion to maintain the integrity of the system as a whole. The basic ideas were first inspired by analogies to living organisms. Many theorists in this area strove to identify a set of universal *requisite* functions that are essential for the survival of any system. Early theorists included Auguste Comte, Herbert Spencer, and Émile Durkheim. In the mid twentieth century, major figures included Robert K. Merton, who was best known for emphasizing the development of “theories of the middle range” (between grand and particularistic), and Talcott Parsons, known for his adaptation, goal attainment, integration, and latency (AGIL) model of system functions. Although functionalism lost its dominant status in sociology many years ago, its core ideas have continued to evolve and persist through several other lines of work such as human ecology, organizational ecology, neo-functionalism, evolutionary approaches, and others.

Interactionism. In contrast to the larger field’s primary concern with macro scale social phenomena, the interactionist tradition in sociology gives primacy to what we may call the *social individual*. Charles Horton Cooley’s work in the early 1900s on the emergence of self concepts out of social interaction proved to be seminal. George Herbert Mead became a leading figure in the 1930s and beyond by synthesizing earlier work and making theoretical connections between societal institutions, the social self, and the minds of human actors. Mead’s ideas were extended by theorists such as Jacob Moreno and Robert Park, both of whom emphasized the self–society connections inherent in the process of occupying social roles. While the core of this line of work came to be known as *symbolic interactionism*, branches instigated by the likes of Edmund Husserl, Alfred Schütz, Herbert Blumer, Manfred Kuhn, and others included phenomenology, ethnomethodology, self theories, role theories, identity theories, emotion theories, sociolinguistics, dramaturgical analysis, conversation analysis, and more. There have been numerous prominent contributors to these theoretical developments including Ralph Turner, Erving Goffman, Aaron Cicourel, Harold Garfinkel, Sheldon Stryker, Theodore Kemper, Randall

Collins, and others. Among the more interesting developments are several theories that go against the interactionist preference for discursive theorizing: David Heise’s affect control theory, Peter Burke’s identity control theory, and Joseph Berger’s expectation states theory are all formal theories with roots in interactionism. Each has survived systematic empirical testing and grown increasingly broad and precise over time.

Structuralism. As the label implies, structuralism is concerned with the ways that patterns among social objects determine social behavior. Within this rubric can be found a dizzying array of topics, levels of analysis, and styles of theorizing. Thus, the objects of investigation can range from patterns of individual cognitions to the patterns of political coalitions among nations. The field of structuralist theories was far simpler in the twentieth century when it emerged as a direct extension of certain strands within Marxist, Durkheimian, and Simmelian theorizing. Toward the middle of the century, however, the area experienced an infusion of disparate influences from the French social anthropologist Claude Lévi Strauss and his cognitive linguistic approach; from the British anthropologist Alfred Radcliffe Brown, who emphasized the reality of social structures rather than cognitive representations of them; and from the US by Moreno’s sociometry, Alex Bavelas’s communication network studies, balance theoretic approaches of Fritz Heider, Theodore Newcomb, Dorwin Cartwright, and Frank Harary, and Blau’s macrostructural theory. Today, the more recent approaches emerging from structuralist traditions hardly seem related at all: social network analysis, Pierre Bourdieu’s cultural conflict theory, Anthony Giddens’s structuration theory, and many others.

Others. The preceding represents only a small sample of schools of sociological theorizing, albeit a sample whose components have had profound impacts on the field. Many others have achieved at least some level of prominence, however. In addition to several schools or perspectives mentioned but not elaborated in the preceding paragraphs, members of another set receive relatively frequent mention in contemporary textbooks and websites. To characterize some of these briefly and in no particular order:

Critical theory is so named based on its critical stance toward modernity, culture, capitalism, or other properties of what at the time is contemporary society. *Ethnomethodology* examines methods by which actors develop a sense of social order and meaning. *Feminist theories* are concerned with examining and elevating the social, political, and economic status of women in society. *Postmodernism* offers non- and anti-scientific commentaries on conditions in post-industrial society. *Systems theories* focus on structures and dynamics constituted by social system components. *Neofunctionalism* offers postpositivist antidotes to some of the limitations of functionalism. *Neo Marxism* consists of twentieth century attempts to account for major problems in Marx's earlier theorizing.

In summary, it is evident that sociology has a great accumulation of schools and perspectives. An optimistic view might then be that there is a fantastic "database" of ideas from which to solve intellectual and social problems. A more pessimistic view is that most of the vast proliferation of ideas seem to wax and wane according to factors that have little to do with their precision, generality, parsimony, or communicability. A view that is both realistic and constructive might be that theorists may now focus less on the process of proliferating ideas, and more on the task of weeding out via careful logical and empirical analyses those which cannot demonstrate their merits. This means relegating many ideas strictly to "history of sociology" texts, despite whatever intellectual, political, or emotional appeal they may hold for however many contemporary adherents. Progressive fields improve systematically on their most promising theories and move beyond the rest.

HISTORIES OF SOCIOLOGICAL THEORIZING

There have been many attempts to trace the historical development of sociological theory, usually from a "classical" era in the mid nineteenth century to the present day. Most efforts interweave temporal and intellectual dimensions. That is, the publication dates of the works that are reviewed in any such reconstruction can be ordered along a timeline. Sometimes the timeline provides the backbone for the entire

review. Otherwise the timeline may be applied within but not across intellectual schools, for instance separately retracing the emergence of functionalism and interactionism via the appearance of publications associated with these respective areas. A third strategy has been to focus on one or more intellectual epochs, interpreting their development as resulting from the influences of contemporaneous intellectual endeavors and other factors. This exemplifies the application of sociology of knowledge to sociology itself: the objects of inquiry are sociological ideas and theories, with historians of the discipline offering speculations as to how empirical factors – prevailing social and political conditions, personal histories of the authors, received theories and perspectives of the day – instigated and shaped emerging schools of thought. Thus, the line between historical description and historical interpretation may blur – a bad thing if one is interested in the bald facts of sociology's history, but a good thing if one is interested in speculating on how sociology came to be the way it is today. Perhaps needless to say, there is high consensus on the temporal dimension of sociological theorizing, but less consensus on the intellectual dimensions that have shaped sociological theory.

The "sociological canon" – the authors whose seminal work is assigned in practically all sociological theory courses – includes Marx, Weber, and Durkheim. Their masterworks comprise sociology's body of *classical theory*, usually along with those of several of their contemporaries and near contemporaries whose selection tends to vary across writers. Classical theory is rife with big ideas and big aspirations. That the theorizing tended to manifest grandiose rhetoric and only selective empirical validation was and is perfectly forgivable: these were trailblazers in new territories.

Sociological theory produced within the current generation of scholars (roughly the last 25 years or so) is deemed *contemporary*. Theorizing that emerged in the years between the classical and contemporary periods also is often called contemporary, or else distinguished from contemporary theory by being called *modern*. In the brief sketches to follow, this period simply will be called *post classical*, distinct from work residing both in the classical canon and in the most recent decades.

Classical theorizing. The sociological literature cites more or less frequently a number of European scholars that made substantial contributions either during or directly preceded the classical period. In order of their birth years (1770 to 1864) and including those noted above, they were G. W. F. Hegel, Comte, Marx, Spencer, Vilfredo Pareto, Sigmund Freud, Thorstein Veblen, Durkheim, Simmel, Mead, and Weber. Most of these men were multidisciplinary in orientation. "Sociologist" was only beginning to develop its academic identity during these years, and the extent of its assimilation by these theorists correlates positively (though imperfectly) with their chronology. Without a doubt, later theorists were influenced by their contemporaries and predecessors, sometimes building on foundations laid by others, sometimes tearing them down, sometimes launching from them into new territories. Moreover, these theorists cited influences by numerous writers in other disciplines, and almost certainly were further affected by the prevailing states of science, culture, politics, economics, and other bodies of knowledge. Together they initiated, then eventually amassed, a body of scholarship that was sufficiently distinct from others in its substantive topics, value orientations, and level of discourse to warrant its unique name.

Post classical theorizing. For a half century after around 1920, sociology experienced an upsurge of activity and visibility. Along with the increasing number of sociologists came an intensification and proliferation of theorizing and debate, much of it operating in the shadow cast by functionalism, the era's dominant school. Some of this activity may be attributed to the rise of the critical theory school, led by Theodor Adorno, Max Horkheimer, and other continental scholars. However, the ascension of American sociology also occurred during this period, most famously (and chronologically) via the so called Chicago School (including W. I. Thomas, Florian Znaniecki, Park, Cooley, and Blumer), Harvard University (including Pitirim Sorokin, Parsons, and Homans), and Columbia University (including Merton, Paul Lazarsfeld, Daniel Bell, C. Wright Mills, and William J. Goode). Toward the latter part of this period, the aforementioned scholars and their intellectual offspring began to populate new departments of sociology. The resulting decline

in the hegemony of these influential programs did not reflect any decline in the production of sociological ideas, however. Every school of theorizing spawned multiple intellectual off spring, many of which have survived to the present.

Contemporary theorizing. The proliferation and diversification that characterized theorizing in the post classical era has only accelerated. This most recent phase in the development of sociological theorizing is the most difficult to portray, with many more theorists and would be theories arriving on the scene, and more complex relationships and influences among them. Textbooks from only five to ten years ago cite what then seemed to be burgeoning new trends that never really panned out. At best, feminist, postmodernist, agency-structure, and modernity approaches, to cite just a few, have achieved a sort of steady state as far as their impact on the "big picture" of sociological theory and research is concerned. Most of these impacts are far from discipline wide, and some already are shrinking.

Every approach, old and new, is important to some sociologists. Whereas there is near perfect consensus on the classical canon, however, and there is *some* consensus on what we may deem to be important post classical writings, there is nothing remotely approaching a consensus on important contemporary theorizing. Part of this state of affairs is attributable to the recency of the work. But if the past is any indication, it is more likely due to the sheer number of theoretical offerings being generated combined with the absence of any widely shared disciplinary norms for the evaluation and culling of sociological theorizing.

SCIENTIFIC VS. NON SCIENTIFIC THEORIZING

Sociology generally is considered to be a social *science*, but a significant proportion of its theorists, researchers, and practitioners operate in ways that are indifferent to scientific norms and practices, and a subset of its members is even overtly anti science. A central tenet of scientific fields is that research is oriented toward the development and evaluation of explicit, testable

theories. In this context, a theory is a set of general, parsimonious, logically related statements containing clearly defined terms, formulated to explain the broadest possible range of phenomena in the natural world. *Formal* theories reside at the most rigorous end of the theoretical spectrum. Authors of such theories pay special attention to the form of their theoretical arguments in the sense that they take care to (1) identify and define all of the theory's key terms, (2) identify all of the theory's key statements (which may be called axioms, assumptions, propositions, or by some other name), (3) ensure that their theoretical conclusions derive logically from the other key statements, and (4) distinguish statements that are *in* the theory from statements made *about* the theory. Many sociologists believe that formal theories are expressed in mathematical languages; however, this is not necessarily the case. The defined terms may be words, and the arguments may consist of linked declarative sentences for which *sentential logic* provides rules and methods used to check for logical correctness.

Scientists regard with skepticism theories that contain ambiguous terms or ambivalent statements, or that do not have a high degree of support gathered through systematic empirical testing. Ideally, scientific theories are public and collectively evaluated in the sense that informed proponents and informed critics all have the opportunity to check them against agreed upon standards of semantic clarity, logical integrity, and empirical verisimilitude. Science is progressive and self-correcting in the sense that its theories improve over time. This is largely due to the fact that scientists take it as their job to identify problems in theories – e.g., in their clarity, logic, or empirical support. It then becomes the job of a theory's proponents to solve the problems, lest the theory be discarded for a less flawed alternative. In this way, even while the work of individual scientists can be biased by values, politics, wishful thinking, or other factors in the short run, the long run effect of collective evaluation is theoretical improvement at the level of the scientific discipline.

Some sociologists would prefer to reserve the “theory” label only for the brand of theorizing just described, and use terms such as perspective, metatheory, orientation, framework, or ideology for writings that fail to satisfy

the foregoing definition for theory. This view is far from normative, however, and all manner of discursive, non-scientific products are referred to as theories in sociology. Some forms are self-consciously non-scientific, at the end of a spectrum opposite that of formal theories. Here, the explicit goal is not to create or evaluate theories as defined above. It may be, for example, to create rich descriptions of complex empirical phenomena, or to promote ideological or philosophical positions. For example, Marx's concept of *praxis* is often considered to be a component of Marxist theory, but is actually a prescription for revolutionary social action. In a similar way, while some contemporary feminist theories offer explanations for gender inequalities, others are explicit calls to political action. Even more confusing is that a given formulation may blend all three functions – explanatory, descriptive, ideological – and switch among them indiscriminately.

Much theorizing in sociology is non-scientific for yet another reason: the objects of discourse are not phenomena in the empirical world, but instead are other theoretical writings. Most theorists recognize this so that, for example, neofunctionalists who interpret the writings of Talcott Parsons would not claim to be doing science. Whereas the greater good of such activity may be incomprehensible from a scientific standpoint, nevertheless there is a sense in which the intellectual products of such activities grow and evolve, with the potential to discover previously unrealized nuances and insights. From a scientific standpoint, however, these activities fall short of cumulative theoretical development because the internal changes that occur as a result of discussion and debate are not governed by rules of logic and evidence. Factors such as writers' disciplinary status, personal charisma, or rhetorical skill may then produce an unwarranted degree of impact and acceptance of the theorizing they produce.

Arguably, the non-scientific label would also fit a highly *empiricist* form of research that may superficially appear to be scientific. In such work, rather than focusing on the evaluation of abstract and general theory, attention is focused solely on descriptions of observed relationships among indicators in specific data sets. Some times the descriptions may be highly quantitative, as would be the case with statistical

modeling; or they may be highly qualitative, e.g., “thick descriptions” of observed events in natural settings. Both forms of analysis may be invaluable in the process of theory development, particularly with respect to inducing plausible theoretical conjectures to be assessed later in more diverse empirical settings. Also, such observations may be deemed to be important for some non theoretical purpose, e.g., inferring practical solutions to problems associated with a particular empirical setting. Nevertheless, most scientists and philosophers of science now agree that observation and data analysis alone cannot sustain a science because they cannot “add up” to a theory without the aid of inductive leaps.

OTHER PROPERTIES OF SOCIOLOGICAL THEORIES

In addition to those discussed above, there are many other properties that a given sociological theory may possess or manifest to varying degrees. A selection of some of the most interesting and significant are mentioned below.

Programmatic structure. Although we may think of great theories as standing the test of time, successful theories tend to not stand still for long. As they are tested and refined, they evolve through stages as a consequence of modifications large and small. They may grow branches that address new classes of phenomena, and they may gain strength by integrating with other theories. The general term for both the ongoing theory building and theory testing activities, and for the resulting theoretical product, is *theory program* or *theoretical research program*. Philosopher of science Imre Lakatos was best known for exploring the dynamics of research programs, as well as the implications of conceptualizing theories as developing within programs.

Levels of analysis. To sociologists, “micro level theorizing” or “micro theorizing” implies a focus on the level of the individual person or small group, and often considers how they affect or are affected by phenomena at higher levels of analysis – social contexts, organizations, institutions, and so forth. “Macro theorizing” typically focuses on relationships among larger scale phenomena at higher levels of analysis, e.g.,

city level rates of crime as related to levels of urban poverty. Although macro theorists frequently make implicit assumptions about the capacities and proclivities of individuals, such links to the micro level generally are, at most, peripheral aspects of the macro theorizing. Traditionally, sociology is a macro theoretical discipline and so this is understandable. Since around the late 1980s, however, interest has increased in explicitly linking micro and macro levels by constructing *multilevel theories*.

Grounded theorizing. The method of grounded theorizing is used to arrive at a theory that is assured of being consistent with a set of observations. It is an inductive process in the sense that the specific observations in which the theory is “grounded” are used to stimulate the development of more abstract and general definitions and categories. Although this guarantees that the theory will conform to the given observations, it also becomes possible to “over fit” the theory, i.e., to tailor it too closely to particular nuances of the data at hand and so render it less likely to generalize beyond those data. Until a grounded theory is validated by systematic testing with a variety of methods, data sets, and phenomena not employed in its development, it is more accurate to consider it to be a form of empirical generalization.

Typologies. A typology is a framework for organizing concepts. As the name implies, it is concerned with different types or manifestations of the ideas it organizes. Thus, a simple one dimensional categorical typology of norms for the allocation of social rewards may include “need,” “equity,” and “equality.” A typological dimension also may be ordered, e.g., ranking degrees of national economic development by the labels “first world,” “second world,” and “third world.” Typologies also may have multiple dimensions. For instance, we could classify nations simultaneously along two dimensions: economic development (as just described) and form of government (monarchy, democracy, etc.). Frequently such typologies are presented in tabular form. Within each cell of the table may be either a general term for that particular cross classification (e.g., “Type C”), or an illustrative or exhaustive list of empirical referents (“Germany, New Zealand, Costa Rica”). Importantly, only a very broad definition of “theory” would include typology building as a

form of theorizing because typologies do not by themselves provide explanations or define the theoretical terms. Nevertheless, they can be a powerful theoretical tool by providing systematic refinements of theoretical terms that, in turn, promote finer grained explanations of the phenomena classified by the typology.

Propositional inventories. Some sociological articles and books offer lists of theoretical propositions highlighted in the body of the text or listed in an appendix. Such lists or inventories are intended to encapsulate the theoretical knowledge contained within the work. However, a list of propositions does not automatically constitute a theoretical knowledge. First, the propositions in a theory should be abstract, general statements linked to one another to form a logical system from which new statements may be derived. There is no such requirement for propositional inventories, and usually they are compiled without concern for the extent or pattern of their propositions' logical interrelatedness. Even so, a subset of propositions within an inventory could provide key components for a theory. Second, propositions in an inventory frequently vary in the extensiveness of the evidence upon which they are based, or in the care taken by the author in defining their terms.

Computer simulations. Although fundamentally they are nothing more than instruction sets, computer simulations (or *computational sociology*) have been adopted as a tool for expressing and logically examining theoretical statements. Just as statements in everyday language may range from particularistic and concrete to general and abstract, so may statements in computer programs depending upon how their terms are defined. When terms in program statements are defined abstractly, and the statements organized so as to model general phenomena and processes, simulations can function exactly like theories. In addition, computer simulation offers tools for automatic logic checking and dynamic analysis that are unparalleled in traditional methods.

theory construction

Murray Webster, Jr. and Barry Markovsky

In sociology, the term theory is used in a variety of ways, not all of which are mutually compatible. For present purposes we adopt a definition that is consistent with how the term is used by many sociologists, and by most scientists outside of our field: a *theory* is a set of explicit, abstract, general, logically related statements formulated to explain phenomena in the natural world. *Theory construction* is then the process of formulating and assembling components of theories into coherent wholes, or the process of revising and expanding theories in light of logical, semantic, and empirical analyses.

HISTORICAL DEVELOPMENT

Sociology's interest in theory construction arose quite suddenly in the 1960s, and tapered off relatively quickly thereafter. As one indicator of this pattern, all of the books that could be found on the subject of building sociological theories were located. None was published before 1960; 13 appeared between 1960 and 1975, seven between 1976 and 1990, and only one since – ironically, a collection of papers from a 1990 conference on the failure of formal theory to thrive in sociology. It is clear that sociology's interest in theory construction is less prominent now, as shown by decreasing numbers of didactic books and journal articles on the topic.

One possible reason for the decline in interest in the topic is that sociologists may be prone to embrace new approaches, only to move on to others as the glow of novelty fades. Also, advocates of the theory construction movement sometimes promoted differing, arcane, and even contradictory methods and rationales. We see two other influences as most significant, however. First, while relatively few sociologists would object to the goals of the theory construction movement (e.g., clear language and sound logic), approaching those goals entails hard work and discursive, informal theories are still the norm in sociology. Second, and

relatedly, the theory construction movement may have seemed to promise more than it delivered. Theories did not leap forward, full blown paradigms were not replaced, and sociological knowledge appeared to continue growing at a measured pace without the adoption of explicit theory construction methods. Disappointment led some to falsely caricature the movement, creating and then destroying “straw men.” Some reached the pessimistic conclusion that, because sociological theory has not advanced as they hoped, it may be impossible to build theory in our field (Cole 2001; for a more hopeful view, see Berger et al. 2005).

There is cause for optimism about sociology's future attention to theory construction issues. Interest in the subject has never disappeared and, over the course of decades, published work increasingly has attended to formal aspects of its underlying theories. It would not be surprising to see a resurgence of interest. This is because theory construction not only is a substantive topic, but also a body of *methods* that can improve theories *and* research, and bind the field more securely to the broader fabric of interdisciplinary knowledge.

ELEMENTS OF THEORIES

All theories are built from just a few basic elements. Different approaches to sociological theory building have emphasized some of these elements more than others, and sometimes elaborated them in ways that mask their simplicity. Nevertheless, theories boil down to just this: *terms* are used to build *statements*; statements are used to build *arguments*; and arguments apply under a set of *scope conditions*.

Terms

Ideally, every word or symbol in a theory is carefully chosen by the theorist to convey an idea or concept. Some terms may not be understood a priori the same way by all readers, however. To promote their clear communication to others, the theorist may assign to a term one or more conditions that must be satisfied in order for something to be considered an instance of it. For example: “*social power*: the capacity to

extract resources from another actor against the other's interests." Here, "social power" is a *defined term*. Having "the capacity to extract resources" along with it being "against the other's interests" are conditions of the *definition*. erms, so in any given theory the theorist will need to employ as a foundation some *primitive terms* whose meanings already are clear to the intended audience. A theory should have the minimum number of primitive terms and defined terms that are needed to communicate its claims to an intended audience.

Statements

Theories contain statements, each of which relates the states or values of one or more terms to the states or values of one or more other terms. For example, "The higher the parents' income, the more education is achieved by their children." A more famous example from another discipline: $e = mc^2$.

Arguments

Well constructed theories combine multiple statements and apply rules of logic to generate new statements. These are called arguments, and their component statements go by various names such as propositions, assumptions, premises, postulates, or axioms. The new statements they generate are called derivations, implications, conclusions, or theorems. Consider the above proposition on income and achievement, to which we add: "The more education a child receives, the higher his/her income upon entry into the workforce." Combining the two statements and applying basic logic, lets us conclude: "The higher the parents' income, the higher the child's income upon entry into the workforce." Note also how the two propositions *explain* the conclusion via the mediating effects of education.

Scope Conditions

Scope conditions are provisional statements that assert the conditions under which a theorist considers the theory to be applicable. Relatively few sociological theories identify scope

conditions as such, but nevertheless they are crucial because they provide guidance to researchers who are interested in testing or applying a theory.

PROPERTIES OF THEORIES

Inspiration for a theory can come from any where: observation, imagination, modifications to existing theories, and so on. Not all theories are created equal, however, and a variety of criteria exist that allow reasoned selections among alternative theories. In a word, such criteria help us to decide among theories on the basis of their *believability*. Some of these criteria are empirical, as when statistical methods are applied to help decide whether data confirm or refute hypotheses derived from a theory. Here we are most concerned with criteria pertaining to qualities that may be "built in" at the time the theory is constructed. Their goal is to promote accurate communication, rigorous testing, high accuracy, and broad applicability. They include the following: absence of contradictions, absence of ambivalence, abstractness, generality, precision, parsimony, and conditionality. We will describe each briefly.

- *Absence of contradictions.* If statements in a theory contradict one another (e.g., "If X, then Y" and "If X, then not Y," then the rules of logic dictate that the theory must be false. As such, it cannot fulfill its primary function of explaining phenomena.
- *Absence of ambivalence.* Ambivalent statements such as "If X, then maybe Y" are not themselves contradictory, but they allow other contradictory claims to coexist. In this case, "If X then Y" and "If X, then not Y" are both consistent with the ambivalent statement, but cannot coexist without creating a contradiction. Thus, ambivalence must be eliminated from theories.
- *Abstractness.* If a theory were *concrete* – the opposite of *abstract* – then it could explain only one particular phenomenon at a certain place and time. Abstractness ensures that theories have the potential to explain many phenomena in many times and places, including those that have yet to occur.

- *Generality.* This is a two pronged criterion. First, a general theory has numerous and varied applications to phenomena in the world. Second, a general theory has survived numerous and varied tests. It is important for a sociological theory to be capable of generating hypotheses about a wide variety of social phenomena, and just as important that the hypotheses survive empirical testing. If a theory has few applications, it will not be useful. If it has not survived tests, it lacks believability.
- *Precision.* A theory could be general, but also imprecise in the sense that it has survived many tests that were not especially stringent. For instance, predicting and verifying that "Group A existed longer than Group B" is not nearly as precise and informative as predicting and verifying that "Group A survived 3 years and 75 days; Group B survived 11 days."
- *Parsimony.* All else being equal, theories with fewer terms and statements are preferable to those having more terms and statements. This facilitates communication, as well as logical and empirical analysis of the theory.
- *Conditionality.* One of the qualities that distinguishes theories from descriptions of phenomena is the conditionality of theories. In particular, the core statements of theories assert how one concept is conditional on another: "If A, then B," or "The greater the X, the greater the Y," or even " $e = mc^2$." Conditional statements then combine to form theoretical arguments, from which new conditional statements may be derived and tested. In another sense, theories are also conditionalized by their use of scope conditions which express the conditions under which the theory is deemed to apply or not to apply.

Once the components of theories are assembled into a coherent whole, it becomes possible to compare them on each criterion. At present, there is no formula for adding up these qualities into something like an overall "believability index." However, the criteria are useful for thinking about ways to improve individual theories, or to compare multiple theories on particular dimensions when "all else is equal" or nearly so.

BUILDING INDUCTIVELY

In the social sciences, two different motivations account for much of the work that is done with theories. The first is the desire to understand a set of observations by developing a theory to explain them. The second is the wish to explore the untapped consequences of preexisting theory, seeking empirical tests and applications, and thereby evaluating the power of the theory. We refer to these general approaches as *inductive* and *deductive*, respectively. In this section we discuss the former, and then discuss the deductive approach in the next section.

Status characteristics theory (SCT, a.k.a. "the theory of status characteristics and expectation states") will illustrate the inductive aspects of theory construction. SCT's roots can be traced to 1950s research by Robert F. Bales on task focused, collectively oriented discussion groups. These so called Bales groups usually included 2–20 individuals, often college students who volunteered to participate. Through open discussions regarding a given problem or issue, groups typically arrived at collective decisions in 30–60 minutes. Members of the research team tallied their observations of such factors as who initiated contributions, the nature of those contributions, and to whom each was directed.

Early Bales group researchers observed four regularities:

- 1 There were participation inequalities. For instance, in 3 person groups, the highest, middle, and lowest participants initiated about 50 percent, 30 percent, and 20 percent of the group's contributions, respectively.
- 2 Group members' rates of initiating task relevant communications tended to correspond with their rates of receiving such communications from others.
- 3 Once inequalities emerged, typically they remained stable for the rest of the session, then reappeared in any subsequent interactions.
- 4 Individuals' ranks on participation rates tended to correspond with their ranks on all manner of perceived skills and influence.

Berger (1958) posited that these observed regularities are components of a social structure

that arises under certain task focused interaction conditions. He reasoned that the empirical regularities could be explained by *observable power and prestige orders* that emerge from underlying *performance expectation states* that are built up through the interaction process. The first published version of Berger's new theory came with a set of abstract and general scope conditions, among which were the requirements that group members are task focused and collectively oriented. Explicit propositions explained the process whereby performance expectations are formed and how expectations are transformed into the group power and prestige order.

While Berger's theory of performance expectations and behavior was subjected to tests in new situations, theorists also began to consider cases in which group members have preexisting status differences – a condition largely absent in Bales groups. For instance, juries are certainly task focused, collectively oriented groups. Unlike Bales groups, however, jurors typically vary by status characteristics such as age, gender, race, and occupation. What happens in such groups is that power and prestige orders emerge very quickly from initial encounters among members. When jurors choose a foreperson before they deliberate, they have minimal knowledge regarding one another's abilities. Nevertheless, they overwhelmingly favor someone with advantages on their society's status characteristics, such as a member of the racial majority with a high prestige occupation.

Research from a variety of sources confirms that groups with members differentiated on external status organize their internal power and prestige orders in a manner consistent with advantages the characteristic confers in the larger society. This occurs whether or not members' status characteristics are relevant to the group task. It seems that group members develop expectations for task performance by "importing" cultural beliefs regarding status advantages and disadvantages, and then infer specific skills to group members on that basis. These and many diverse cases became explainable by the SCT as it was extended to include explicit, testable propositions regarding links between status characteristics, performance expectations, and social behavior (Wagner & Berger 2002).

To summarize, the evolution of SCT implies a series of steps through which inductive theory building can transpire:

- 1 *List empirical generalizations.* In the case of SCT, a body of findings from prior research provided the raw material for the theoretical explanation.
- 2 *Formulate generalizations abstractly.* To build SCT, it was necessary to develop abstract concepts removed from particular studies and historical circumstances.
- 3 *Explain generalizations theoretically.* That is, additional general propositions are postulated with an eye toward combining them into a theoretical system that permits the focal generalizations to be deduced from others.
- 4 *Explicate scope conditions.* The purpose here is to demarcate classes of situations within which the general propositions should explain and predict phenomena of interest, and to distinguish these from situations in which the theory does not claim to provide explanations.
- 5 *Derive and test new consequences.* By deriving general statements and substituting empirical indicators for theoretical terms, it becomes possible to develop and conduct independent tests of the theory.
- 6 *Identify and conceptualize new applications.* Useful theories never stop developing. In this case, SCT was extended to incorporate predictions for situations of status heterogeneity as well as for the original equal status cases. SCT also has been extended and refined in a number of other ways, making it far deeper and broader than it was when first developed.

In all this work, there is an interplay of the empirical and the theoretical. The theorist attempts to explain some limited set of phenomena, develops an explanation, and conducts tests independent of the original observations that the theory was designed to explain. The tests may confirm theory, or they may refute it and stimulate modifications. The theorist searches for new applications and attempts to account for them with the theory, leading to new tests and modifications in an endless process of development.

BUILDING DEDUCTIVELY

We illustrate deductive theory building using Blau's (1977) *theory of inequality and heterogeneity*. Blau's original theory was entirely verbal, but later it was formalized by Skvoretz (1983) using an algebraic language. Blau began by considering two groups of different sizes. For convenience, we may think of them as groups of people, but the theory applies as well to any interacting units, whether human, animal, or computer simulated. To say there are two groups suggests there may be a differentiating basis (e.g., skin color or religion). Now suppose there is some interaction across the boundary between the groups, such as friendships or marriages. The theory's first task simply was to analyze how different relative group sizes affect cross boundary interactions.

If the two groups differ in size, and if interaction across the boundary is essentially random, one can deduce that an individual from the small group is more likely to interact with an individual from the large group than vice versa. For instance, suppose (1) the differentiating principle is skin color, (2) there are ten times as many in the larger group as in the smaller group, and (3) the interaction basis is friendship. If friendships form at random, then a much larger proportion of the small group (black) will have out group (white) friends than vice versa. Blau noted that this explained a lament he had heard among some of his egalitarian white friends who wished they had more black friends. They simply do not encounter enough potential out group friends in their daily interactions. That could only transpire if there were a high degree of cross group interaction and black individuals on average were willing to accept ten times as many friends as white individuals. For religion and marriage, the same relations hold. All else being equal, any randomly selected Jew in the US (about 3 percent of the population) has a higher chance of marrying a Christian (about 90 percent of the population) than does a randomly selected Christian of marrying a Jew. It is purely a "numbers effect," independent of other factors such as individual preferences for in group friends or spouses. After exploring consequences of the basic two group framework, Blau considered more complex situations by introducing preferences that biased

the random associations, hierarchical factors such as status differences, and intersecting bases of differentiation within and between groups.

In the Christian-Jew example, we know that interaction across groups is not random, and that it is not the case that 90 percent of Jews marry Christians. Interactions between and within groups tend to be biased by the shapes of social networks, and those networks tend to be connected more densely within groups than between them. Skvoretz (1983) took this into account when he formalized Blau's discursive theory using a kind of mathematics called *biased net theory*. He translated Blau's propositions into equations where the dependent or resultant variables were probabilities of in group associations, and the independent or causal variables were generalized, symbolic versions of factors identified by Blau. Skvoretz's version can claim several accomplishments. First, the formalized theory corrects some errors that are not obvious in the discursive theory. For instance, "salience" in the discursive theory is treated the same as "in group preference," whereas the formal theory demonstrates the utility of distinguishing the two concepts. Second, the formalized theory is more precise and thus more testable in its implications. Third, the formalized theory is more general, applicable to types of association beyond the friendships and marriages that Blau considered.

To review, this case of deductive theory building proceeded through these stages:

- 1 *Assert and explore general propositions.* Blau postulated that relative group sizes should affect intergroup associations in predictable ways, independent of all other factors. He explored the consequences of his theoretical propositions for cases of friendship and marriage formation.
- 2 *Explore new or modified propositions.* Further work explored the effects of additional factors in more complex situations, such as those with in group preferences, ordered differentiation, and cross cutting differentiation.
- 3 *Formalize.* Skvoretz's formalization revealed new and improved predictions, extended the theory's scope, and produced a more rigorous, general theory. Formalizing does not necessarily mean translating words into mathematical expressions, however.

Sentential logic and predicate logic are formalizations that can be applied to well constructed English sentences, and definitions of terms certainly can be written in carefully formulated prose. Formalization is best thought of as a process for improving discursive theory by sharpening the meanings of terms and the explicitness of arguments.

RECOMMENDATIONS

Once they are built, all good theories are deductive in the sense of having clearly stated propositions from which other statements logically follow. As well, most theories also are inductive in the sense that their propositions, and modifications to their propositions, typically began as conjectures and intuitive leaps. The inductive and deductive approaches we outlined have different emphases, but it is worth noting that any theory building enterprise can be improved by keeping in mind the following:

- 1 *Identify all significant terms.* Select primitive terms judiciously, and define the rest at a level of abstraction that will facilitate the construction of general propositions, useful links to empirical phenomena for tests and applications, and comprehension on the part of readers in the intended audience. There is an art to developing a theory's terminological system, along with much trial and error.
- 2 *Identify general propositions.* Be sure a reader can tell what the theory is arguing (i.e., what it assumes to be true, and what it concludes on the basis of those assumptions). Explicit terms and propositions facilitate logical and empirical analyses of a theory, and also facilitate its formalization.
- 3 *Identify scope conditions.* It is important for a theorist to place some limitations on the domain in which his or her theory will apply. For tests within its scope, confirmations increase the theory's believability, while disconfirmations diminish it. For tests conducted outside of a theory's scope,

neither confirmation nor disconfirmation can impact the theory. If scope conditions are not stated, then its author implicitly claims either that the theory applies everywhere to everything – an impossibility – or that he or she simply has not thought about the theory's limitations, making the theory highly vulnerable to failing tests in settings that the author may not ever have considered to be relevant.

- 4 *Conduct rigorous tests.* Building theories differs from punditry in the sense that the theorist who seeks out disconfirmations through well designed tests is more likely to home in on an accurate explanation than the theorist who only looks for confirmations. Rigorous tests are more likely than weak tests (or no tests) to identify areas where a theory can be improved. *Critical tests* evaluate conflicting hypotheses from competing theories and are thus especially valuable for the advancement of knowledge.
- 5 *Improve the theory.* Theories improve over time as they are refined and extended. Every element of a theory is subject to modification: terms can be sharpened to incorporate or exclude great swaths of empirical phenomena; scope conditions can be relaxed to permit broader application; propositions may be added to address new kinds of phenomena, and formalized to allow more precise explanations and hypotheses.

We began this entry by noting that theoretical knowledge, far from being mysterious, is actually how we understand the social world. What we *know* about social processes and social structures is exactly that which is embodied in our *theories* of social processes and social structures. Our knowledge is never completely valid and reliable, and it is always provisional, as tomorrow's tests and theoretical modifications alter what we think we know today. At the same time, these changes must be progressive. That is, today's knowledge should be more valid and reliable than it was, say, a few decades ago. And knowledge in a few decades (or sooner) should be better than today's. The more systematic our adoption and application of the tools of theory construction, the more efficiently our knowledge will improve.

theory and methods

Barry Markovsky

Theories organize and manipulate elements in a world of ideas. In contrast, *methods* organize and manipulate elements in the natural world, the world of concrete objects and events. Although *theory* has a variety of meanings in sociology, a definition that is both widely shared within the field and also consistent with the term's use in mainstream sciences is the following: a theory is a set of abstract, general, logically related statements formulated to explain phenomena in the natural world. The term *method* is commonly used two ways in

sociology: (1) a procedure enacted in the natural world for the purpose of yielding theoretically relevant observations; (2) an analysis of recorded observations that is intended to summarize or to make inferences about them. The first usage is loosely referred to as *research methods*. The second usage, *methods of data analysis*, encompasses our rather large palette of qualitative and quantitative techniques for working with empirical observations.

Countless books and journal articles have been published on topics in sociological theory and sociological methods over the years. However, there is relatively little information to be found on the details of their interface – the points of contact where correspondences are drawn between theories and the slices of the natural world to which they are intended to apply. This also reflects common practice: published research generally establishes relatively loose and intuitive linkages between theories and their empirical realizations. Sometimes the informality is appropriate, as when new theoretical ideas are being explored and there is uncertainty as to the specifics of their applicability to natural phenomena. Other times the lack of specificity can be highly problematic, such as when researcher A claims to have tested and falsified B's theory, but B contends that the theory was not intended to address the phenomena used in A's test. In general, the burden is on the theorist to clarify terms so that appropriate methods and analyses may be developed by others.

The theory–method interface is a crucial area of concern because, as social scientists, we are motivated to make our theories relevant to the natural world, either for the purpose of understanding it better or to intervene in sociological phenomena in desired ways. It is through our research methods and our methods of data analysis that we attempt to determine the degree of relevance of our theories to the phenomena that we seek to understand. This implies that there is an intimate relationship between theories and methods, but also that they are distinct spheres of operation, each with its own rules and standards. Without a doubt, sociological writings often obscure distinctions between theoretical statements and observation statements, and it may be difficult or even impossible to fully

prevent theories from coloring the observations that we make. However, to then presume that theory and method are indistinguishable in some inherent sense only leads to unwarranted confusion.

When developed without the benefit of strong connections to the natural world, the ories are no more valid than fantasies, and they deserve no better than highly provisional support. By the same token, when enacted without the benefit of clear theoretical purposes, methods are no more useful to us than undocumented snapshots of unfamiliar objects. Thus, theories rely on methods to make them believable, and methods rely on theories to give meaning to their products.

The interface of theory and methods – where elements in the theoretical realm connect to elements of the natural world – becomes most apparent when theories are written explicitly and succinctly, and their connections to objects in the natural world are rendered unequivocal. This is the ideal situation, and we will conclude by examining it in a bit more detail.

There are three essential components to the theory–methods connection: statements in the theory, statements about particular observations, and statements that link terms in the theory with specific observations. Their relationship is shown schematically in Figure 1.

Theories employ conditional statements, often called propositions or assumptions, to make general claims that can be subjected to scrutiny. An example appears in the upper half of the figure in the “theoretical world.” The statement may be read “If A, then B,” where A

and B are each simple declarative statements. For example, A may be “A group has a role structure” and B could be “A group has a system of rewards and punishments.” The conditional statement $A \rightarrow B$ asserts that if the first statement is true, then the second statement will be true as well.

To link theoretical propositions to the natural world, the terms in the propositions must be connected to actual empirical phenomena. The theoretical terms are abstract constructions (or “constructs”), not at all like descriptions of rich, complex objects in the natural world, but extremely useful from the standpoint of a theory: abstract terms are needed if the theory is to be *general* (i.e., applicable to a wide range of empirical cases). In the figure, each simple statement from the theory is connected to multiple concrete and specific referents in the natural world. For instance, a_1 may be “The Chess Club now active at Fairview High School has three elected positions” and b_1 could be “The Chess Club now active at Fairview High School has trophies for outstanding performance, and rescinds the membership of any member caught cheating.” There are also implicit linking statements: “‘The Chess Club now active at Fairview High School’ is an instance of ‘a group’” and “‘A combination of multiple elected and appointed positions’ is an instance of ‘a role structure.’” Now, having translated the theoretical statements into empirical statements, we can derive as many testable *hypotheses* as we have empirical instances (e.g., “If the Chess Club at Fairview High School has multiple elected and appointed positions, then it will have trophies for outstanding performance and rescind the membership of any member caught cheating”). Furthermore, a_2 , b_2 , a_3 , b_3 , and so on, can pertain to wildly different kinds of groups, rewards, etc.

Instructions for how to create these linking statements are supplied by the definitions of the theoretical terms; that is, the definitions for terms such “role structure,” “reward,” and “punishment” in the example above. This is why it is important for a theorist to define terms as clearly as possible. Failing to do so means that researchers will be uncertain as to the theory’s proper application, leaving it vulnerable to interpretations that its author never intended for it to cover. At the same time, definitions

Figure 1 The heart of the theory methods connection.

must be sufficiently open to interpretation so that the theory will be applicable to the widest possible range of cases. Thus, good theories strike a useful balance between specificity and generality.

Now that the theory can guide the choice of empirical indicators, research methods can be used to gather data, (e.g., through experiments, surveys, participant observation, text analysis, or other means – preferably more than one). The choice of research methods, in conjunction with the specific questions the researcher would like to answer, jointly guide the choice of methods for data analysis.

third world and postcolonial feminisms/subaltern

Marietta Morrissey

Sociological interest in feminism in the so called third world nations of Asia, Africa, and Latin America has been conditioned by disciplinary reactions and responses to larger theoretical transformations in the academy. The consequence has been a shift from liberal

feminist interpretations to more comprehensive understandings of the range of feminisms that have emerged in conditions of economic dependency, underdevelopment, and globalization. More recently, sociologists have begun to consider the complexity of women's positions and those of other powerless groups – the subaltern – through the lens of postcolonial studies.

THIRD WORLD FEMINISMS

Liberal Feminism: WID and GAD

Sociologists' initial contributions to our understanding of third world feminism coincided with the early stages of the sociological study of women more generally. Emphasizing occupational and educational inequality and gendered wage disparity, sociologists of the late 1970s and early 1980s assumed parallels between feminisms in the first and third worlds. Indeed, many women in poor countries aspired to higher levels of education and occupational achievement. Vibrant liberal feminist movements developed in many nations of the third world. Often led by western educated women from wealthy families, they encouraged women and girls to seek educational parity with men and success in the occupational and business sectors from which they had been excluded. Progressive women's groups and organizations recognized in traditional cultural norms and male inspired and dominated development strategies impediments to socioeconomic achievement by women (Boserup 1970).

International development and lending agencies encouraged liberal feminism by promoting Women in Development (WID) policies. Internationally funded economic development projects, particularly those emphasizing entrepreneurship, urged women's participation. Multilateral sponsors often required a WID component in project proposals. Many national governments adopted a similar approach. These practices remain in place today as development agencies recognize more fully women's roles in the production and marketing of crafts and food.

Academic and other critics of WID argued that separating women from families and community ties and the larger context of underdevelopment

misunderstands women's positions and thus has had little impact on women's educational or occupational statuses. Meanwhile, men have objected to the exclusive funding of women's business projects in some settings, claiming discrimination (Barriteau 2001). Thus, Gender and Development (GAD) initiatives were launched. They emphasize the relationship between the development process and gender relations and insist that neither men nor women be disadvantaged in nationally and internationally sponsored development projects.

Ultimately, the liberal feminist philosophy embodied in WID and GAD embraces only sectors of populations with access to basic resources. Larger populations of women have economic, health, and political concerns that have gradually come to the attention of scholars both within and outside the third world (Kandiyoti 1988). Researchers and theorists throughout the academy now generally acknowledge that western defined liberal feminism has little adaptability to women's concerns in third world nations. Indeed, the commonly cited distinctions among liberal, socialist, and radical feminisms deemed appropriate to first world countries do not accurately capture the reality of feminism in the third world.

National Feminisms

The most significant contributors to the redefinition of third world feminism have been activist and academic women working in national contexts. Themselves often from bourgeois backgrounds, they have had access to governmental organizations and NGOs working with the poor. The transmission and interpretation of the voices of low income and marginalized people broke conceptual barriers and allowed new definitions of third world feminist ideology and political movements to emerge. Representing many different disciplines with a strong affinity to sociology (particularly history, political science, and anthropology), academic work of the late 1980s and the 1990s on feminisms in the third world was often interdisciplinary and privileged the voices of the poor and disenfranchised over methodological issues and debates. No longer strictly or primarily sociological, studies of third world feminisms

from a social science view became part of a core of women's and gender studies literature.

Women's and gender studies caucuses and studies sections within Latin American, Caribbean, Asian, African, Middle Eastern, and other regionally focused organizations have provided important venues for the discussion and dispersal of the work of international feminists that together form interdisciplinary bodies of knowledge about third world women's positions and politics. Within sociology, *Gender and Society* has been an important vehicle for the education of sociologists in the US about work on feminism, women, and gender in third world settings. Of particular note are the literature reviews authored by third world feminist sociologists treating the state of women's and gender studies in their nations and regions (e.g., Ampofo et al. 2004).

POSTCOLONIAL FEMINISMS

Poststructural and Postcolonial Studies

While national scholars within third world nations redefined feminisms in ways pertinent to the social sciences, a parallel process was occurring in humanities disciplines. It began with a theoretical challenge to more traditional interpretive theories from proponents of poststructural approaches to literary and cultural interpretation. With their origins in linguistic theory, poststructural and postmodern critical and interpretive methods have called for the interrogation, deconstruction, and reinterpretation of representation in literature, art, and other cultural forms. Postcolonial theories have considered cultural representations produced in colonial and postcolonial settings. Third world feminist scholars (in particular, Spivak 1988, 1999) have expanded postcolonial theoretical categories in analyzing gender in postcolonial culture.

Postcolonial theories recognize the impact on third world nations of the historic termination of formal political and economic relations in the 1960s and 1970s. Indeed, decolonization was a product, albeit sometimes an indirect one, of third world social movements. However, much postcolonial analysis focuses on consciousness, culture, and ideology, rather than economic,

social, or political conditions and responses. Some postcolonial theorists (e.g. Bhabha) follow Foucault in examining the discourses and disciplines of culture and knowledge and the repressing forces internal to them. Bhabha's view, that it is in the interstices of colonial and national experiences that postcolonial culture lies, echoes anthropological work on liminal, syncretic, and other cross national and cross group cultural forms. This theoretical tendency complements sociological understandings of colonial and other forms of oppression (including gender) and their impacts on culture in the broadest sense. Others (e.g., Spivak) have been influenced by Said's (1979) efforts to uncover oppressive images and language in the colonizers' literary and cultural representations of the colonized. The latter approach has resonated in humanities disciplines, including postcolonial feminist cultural studies.

Sociological Contributions to Postcolonial Thought

Sociology has only slowly joined the poststructural critique of academic canons (Mirchandani 2005). The strength of hermeneutic and other anti positivist methodologies in sociology relative to many other disciplines has diminished the attraction of poststructural thought. Nevertheless, sociology has made an impact on indirect contributions to the elaboration of postcolonial theory. Moreover, the debates among sociological theorists about postmodernism as a historical epoch have had important implications for our understanding of globalization and its impacts on international feminisms.

Critical conceptualizations of third world economic development that incorporate understandings of bilateral dependence and global interdependence have been important in sociology since the 1970s. Sociologists James Petras (1973), Immanuel Wallerstein (1974), and others played pivotal roles in the elaboration of worldwide patterns of dependency and sectorally uneven development.

Equally important has been sociologists' reception to research and theory about the consciousness of the oppressed. The work of Franz Fanon (1961, 1967) and Albert Memmi (1965) on the complex intellectual and emotional effects

of colonialism – the mixed feelings of cultural inferiority, fear, and anger experienced by the colonized – contributed to sociological understandings of economic and political dependency and echoed issues raised by sociologists regarding other twentieth century conflicts. W. E. B. Du Bois (1903) wrote about the “dual consciousness” of African Americans, both oppressed by and subjugated by whites and at the same time conscious of oppression and resistant to it. Later, members of the Frankfurt School of European émigrés to the US, in particular Theodor Adorno, Erich Fromm, and Max Horkheimer, used the experiences of those terrorized and violated by the Nazi regime to explore further the duality of consciousnesses and cultures of subjugation and resistance and ideological responses.

Postcolonialism and Feminist Sociology

Feminist sociology has had a significant impact on the development of feminist postcolonialism. Patricia Hill Collins's book *Black Feminist Thought* (1990) has been widely cited in postcolonial feminist studies. Collins draws on the critical theory tradition and later standpoint theories such as that elaborated by Dorothy Smith (1989) to valorize the standpoints and situated group knowledge of African American women and to recognize the layers of oppression and hence knowledge that separate women by ethnicity, income, education, region, etc. Collins's work has thus been valuable in exploring a multiplicity and hierarchy of meanings in representations and in the daily consciousness, culture, and ideology of colonized groups.

Collins's contributions to third world and colonial feminisms go beyond the consideration of these topics within other nations to their discussion within the borders of wealthy nations. Immigrants and internally colonized ethnic minority groups are often termed third world people and their political and cultural ideologies (including gender politics) share dimensions with both the majority population and with other marginalized groups. Third world feminism in the US and other industrial countries shares the liminality and hybridity of feminisms in postcolonial nations. Moreover, the representation of ethnic minority women

in cultural works influenced by dominant groups within nations resembles in theme and form those treating women and gender relations in postcolonial nations.

Sociology and the Subaltern

Sociologists have long struggled with the problem of how research methodologies can allow us to hear, present, and interpret the voices of marginalized groups. American sociology's expansion of qualitative techniques beyond the ethnographic to include lengthy interviews and narrative analyses has coincided with the rise of gender studies in the field. Indeed, the concept of feminist methodology, which goes beyond the disciplinary confines of sociology, embodies a commitment to give voice to the powerless (DeVault 1999). At the same time, postcolonial literary and cultural studies have struggled with the challenge of giving means of expression to sectors of third world populations that are estranged from the means of cultural production and representation. The ways in which this problem has been conceptualized once again go back to theoretical work of broad significance to sociology.

From the late 1920s through the mid 1930s, imprisoned Italian political theorist and activist Antonio Gramsci produced a set of "note books" treating the difficult political problems of ideological hegemony, critical consciousness, and revolution. Published posthumously, Gramsci's *Prison Notebooks* (1991) are widely cited by neo Marxist academics eager to understand why objectively oppressed and subjugated classes have been unable to marshal forces to transform the class structure and in the case of fascist regimes seem in fact to embrace ideologies that run dramatically counter to their class interests. Gramsci's references to the subaltern have gained the attention of third world feminists and others trying to give visibility to the interests of marginalized groups.

"Subaltern" refers literally to a military officer rank below the highest levels, but is used more generally to mean subordinate groups. Gramsci wrote about two social categories of the subaltern: incipient challengers to traditional dominant classes and relatively powerless groups subject to constraining ideological

power. The Subaltern Studies Group of South Asian Historians followed Gramsci's lead in considering why Indian workers, peasants, and other "subaltern" groups did not emerge as revolutionary classes. The resulting emphasis on "history from below" has influenced and reinforced social science efforts to reveal and understand the ideology and culture of the powerless and the politically invisible. "Subaltern" has shifted meaning, however, as critical academic writing and postmodern and postcolonial feminists have argued that the conceptual and discursive meanings of Marxist and neo Marxist thought, including Gramsci's theorization of the subaltern, reproduce the binary and essentialist thinking that has limited third world women's political options. Spivak's (1988) article was particularly influential in moving the "subaltern" away from neo Marxism to a feminist epistemology that permits women to express unanticipated, untheorized thoughts, emotions and political strategies. Literary and cultural studies have since addressed the meanings of the expressions and representations of subaltern groups, and the implications of their exclusion from political and cultural platforms.

Sociologists have been notably absent in debate about the role of the subaltern per se, although issues of radical and revolutionary consciousness among workers, peasants, and other social groups have long been of interest in the discipline. In adhering to a fundamental disciplinary focus on social stratification and its elaboration in precisely defined social strata, sociologists may find the term subaltern imprecise both with reference to socioeconomic status and assumed group ideology, culture, and consciousness. Sociologists refer more frequently to "marginalized" groups, acknowledging more simply and exclusively an estrangement from economic and political power and privilege.

Globalization and Feminisms

Third world and postcolonial feminisms continue to command scholarly attention and inspire theoretical debate. However, changing economic conditions in rich and poor countries with increased globalization have generated an intense effort in the social sciences to understand women's changing positions.

Sociologists' recent collections on women in the third world (e.g., Blumberg et al. 1995) focus on women's roles in production and community based efforts to improve women's status.

Academic and policymakers' current discussions of globalization have to some extent supplanted the debates of the 1980s and 1990s about the meaning of late capitalism, postmodernism, and postcolonialism. Methodological and epistemological challenges to structuralist categorizations of cultural and historical change continue to engage feminist and other critical political theorists and activists. However, recent recognition of the breadth and depth of global interdependence has reinvigorated the scholarly quest to explicate the dynamics of global capitalism and the political spaces therein that allow for fundamental change. For third world women, whether in postcolonial or industrial settings, the feminist challenge is ever more complex as the interstices of the colonial and the national multiply and become less distinct.

Third world and postcolonial feminisms/subaltern present vital substantive, methodological, and political challenges and strategies of study that unite humanities and social science disciplines. Sociologists have taken a more prominent role in the interdisciplinary identification of third world women's economic, social, and political positions and interests in both postcolonial nations and in the US. The nearly century long debate within sociology about biases and inaccuracies produced by positivist derived methods and techniques and the continuing efforts of important subgroups within the field to reveal and valorize the voices of the marginalized has allowed the discipline to move in tandem with much of the postmodern critique of academic knowledge without joining fully in it. Postcolonial feminism has, in a similar way, engaged elements of sociological theory while accommodating a distinction between humanities disciplines' critical study of gendered cultural representation and social science efforts to understand gendered social relations.

Thomas, William I. (1863–1947)

Robert A. Stebbins

W. I. Thomas was born in Virginia and raised in a Protestant, rural, religious milieu. In 1884 he received his bachelor's degree from the University of Tennessee, and after two years of study in Germany followed by teaching English and sociology at Oberlin College, he joined in 1895 the new faculty in sociology at the University of Chicago. He had been among that department's first group of graduate students (he worked under Albion Small), starting in 1893 and receiving his doctorate in 1895. He remained at Chicago until 1918 when, for personal reasons, he retired. In 1923 Thomas returned to active teaching, now at the New School for Social Research, but his teaching was largely part time, for he preferred to mix teaching with research. Between 1930 and 1936 he went regularly to Sweden to work with the Social Science Institute at the University of Stockholm. He was appointed lecturer at Harvard University in 1936 and 1937, living in New Haven until his move to Berkeley, California, in 1939. He resided there as an independent researcher until his death in 1947.

Thomas is well known for his collaboration with Florian Znaniecki in *The Polish Peasant in Europe and America*, a five volume study published between 1918 and 1920. Other celebrated works include *The Unadjusted Girl* (1923) and, with Robert Park and Herbert Miller, *Old World Traits Transplanted* (1921). His reputation has lived on in sociology largely in the legacy he left symbolic interactionism in the theoretic sections of the *Polish Peasant*. The analytic framework of this study was based on the transformations in the personality and

social structure of the Polish peasant community as it moved to the US.

Thomas had an enduring interest in the pragmatic tradition in sociology, one center of which, at the time, was the University of Chicago. For him, sociology concentrated on human activities, wherein people demonstrated conscious control in developing art, religion, language, forms of government, and the like. More precisely, sociology looks at *attention*, the attitude that takes note of the outside world and then manipulates it. From this stance he wrote a great deal about attitudes and attention, later preferring to conceptualize both as *definition of the situation*. Crises in everyday life, be they large or small (e.g., upsetting a habit), bring people to define the situation in which they occur and then to act accordingly. Development and change in larger, abstract forms of structure and culture occur when many people define similar situations.

Today, Thomas is widely recognized as one of the founders of symbolic interactionism. A dictum from a work co authored with his wife, "if people define situations as real, they are real in their consequences" (Thomas & Thomas 1928: 571–2), is still frequently quoted.

time

Peter Clark

Time reckoning systems contain benchmarks that indicate the passing of time and durational expectancies with respect to sequences, rhythmic features, and periodicities. There is no social ordering without temporal ordering, yet time comprises more than the chronological use of calendar and clock time (CCT) with which most of the world associates it. There are also very significant frames of action calculated through the heterogeneous events located within natural and task based processes (Gurvitch 1964; Dubinskas 1988; Clark 1985; Bluedorne 2003). Time reckoning is a multilayered, hierarchical, contingent relationship between past, present, and future processes (Gurvitch 1964; Clark 1985; Harvey 1989; Adam 2004). The present is constituted through the differences between the remembered past and images of the future. One aim of an organization or society should be to establish an accessible, robust repertoire of temporal recipes and heuristics which enable the actionable interpretation of those future events that are located in emergent processes and flows.

It is from the processes, flows, cultures, and social structures that time reckoning frameworks are socially constructed. There are multiple, coexisting frameworks to choose from and choices are consequential. Individual competencies in self managing the different time reckoning situations are increasingly demanding. There has been a tendency to understate the times of consumption relative to the work times of the factory and the office (e.g., Thompson 1967; Harvey 1989). The temporality of "consuming for capitalism" is evident in the design of sports like American football, shopping at Wal Mart, engaging in mass tourism, eating slow food, or watching the media. The emergence of new social and non social processes associated with globalization depends upon and affords hybrid time reckoning systems.

Understanding temporal structuring and developing categories of temporality are central problems for practice and theory. Time is a key referential principle and its explication is required to understand the coordination and

synchronization within and between different segments of activity. Time and space are closely connected. Currently there is a rich vein of research, theorizing, and critical debate concerning the politics of time.

HOMOGENEOUS INSTRUMENTAL TIME AND EVENT BASED TEMPORALITY

The distinction between homogeneous instrumental systems of time reckoning and heterogeneous, event based reckoning is fundamental (Hassard 1996). Homogeneous time reckoning codes are represented by the calendar (e.g., week, month, year, 1917) and the clock (e.g., day, hour, minute). Calendars provide markers placed at equal standardized intervals derived from astronomical processes. A calendar expresses the rhythms of a society and suggests regularity. The calendar can be cyclical, as in the year when most societies celebrate the event of the "new year" but do so in contrasting ways. The calendar also provides a linear temporal structuring going backward into the past and forward into the future, as in utopian prophecy and scenario writing. Calendrical units are used reflectively to arrange past events, to plan the extended present, and to envisage different scenarios of the future. CCT is non reversible. So, 1066, 1776, and 1917 are in the past but 2020 is in the future. However, the imagining of different timescapes, including reversing time, is central to the modern and postmodern imagination and the cultural media. Linear event chains formed the basis for the emergence of historical consciousness about nature, especially geology (e.g., Darwin). The regularity of linear calendrical time was supplemented by the major innovation of narrative history and the imposition of determinate patterns (e.g., thesis, antithesis, synthesis). Calendrical time was and is used by powerful elites and their challengers to formulate linear chains of political events and to reveal anachronisms.

In Europe from the fourteenth to eighteenth centuries public clocks came to occupy a different role compared with China (Landes 1983). Christian monasteries, especially the Benedictines, established strict and exacting forms of temporal discipline which structured the day

very tightly. Christian bureaucracy initially structured everyday life in the emerging towns. New temporal structures were assembled around the ringing of bells and the display of public clocks. These were variously used to regulate the start and end of activities. Later this was extended to the increasing synchronization of activities within the towns. The escarpment movement clock required immense collective investment and struggle. The use of the clock to conquer space is illustrated by the mid eighteenth century development of a chronometer that could be used at sea to calculate the position of a ship relative to its intended trajectory. On land, from the eighteenth century onward the clock came to be used in the workplace by employers seeking to control work discipline. In England clock time was vigorously opposed and subverted by opposition by work groups in certain sectors (Thompson 1967). The Chinese used clocks for status and decoration throughout this period (Landes 1983). Homogeneous world times provided a global network which enabled high volume consumption.

CCT provides the framing to the world time of capitalism, travel, and trade in the twentieth century (Harvey 1989). CCT is a classificatory system of standardized, formalized units that can be added, subtracted, multiplied, divided, and arranged in linear and recurring patterns. CCT appears to be objective, authoritative, rational, and legitimate, yet CCT inscribes power at multiple levels. The regular units of CCT are tightly intertwined with use of money as medium of stored time. CCT enables planning, synchronizing, and coordinating activities by the state and by corporations.

Heterogeneous time reckoning contains clusters and sequences of events which are anchored in the duration of processes mainly known to local and specific groups of people of varying kinds: engineers and scientists. Events are contextual, directional, and irreversible. The units of event time tend to be pregnant with durational meanings like excitement, fear, and surprise. Scientists and engineers regularly use heterogeneous systems of reckoning (Dubinskas 1988). Marketing departments use event markers and intervals that are irregular and contingent yet have a patterning (Clark 1985).

Heterogeneous time reckoning is characterized by events as markers of intervals and by a heightened awareness of the durational aspects.

The big debate about time has been whether members of industrial and capitalist societies in the twenty first century use heterogeneous systems. Thompson (1967), in a seminal narrative about capitalism and work discipline, claimed that heterogeneous systems are displaced by homogeneous systems. However, as already indicated, industrialism and capitalism depend upon heterogeneous time reckoning. In practice, time reckoning is always multiple and diverse.

THEORETICAL LINEAGE

The agenda for time is contested. Gurvitch (1964) provides a stimulating history of time from Newton into the mid twentieth century. Abstract homogeneous time has been a dominating influence. Newton's (seventeenth century) universal framework, which was anchored in the metaphor of clock time, enabled the dualist separation of static and dynamic analyses. Dualism retained a powerful influence in sociology. Marx moved beyond descriptive chronologies based on calendrical time to construct a teleological, dialectical history of humankind as a journey toward a secular utopia. Marx focused on how capitalists equated homogeneous time units with the costs of production and opportunities for profit. The owners of firms translated units of time into money and commodified time. CCT became the framework in planning and controlling. The owners imposed clock based discipline, minimized porosity in the turnover time of financial capital, and replaced human time with technology. Weber sought to show a relationship between the measured work time of Taylorism, formal instrumental rationality, and the likelihood of disenchantment. Weber's historicism imposed ideal types on big structures and large processes. Gurvitch claimed that Weber's typological method was overly static and insufficiently processual.

The lineage of Newton and CCT was challenged in the early twentieth century. Bergson contended that the durational qualities of time

could not be understood within the temporality derived from Newtonian mechanics because social and biological processes were emergent. Therefore understanding flows, processes, and the future required a new ontology. Gurvitch provides a clear and relevant critique of Bergson's contribution. Durkheim stated that time, space, and causality are representations of collective life and are the solid frame that encloses all thought. Time is a serial order of experiences distinguishing the past, present, and future. The sequences can be cyclical (e.g., seasons), linear (e.g., birth to death), or open ended. Durkheim's attention to the durational features such as excitement highlighted the elements that distinguished sociology as an emerging discipline.

In the mid twentieth century Gurvitch sought to restate the sociology of time and history in terms of contingent processes, disjunctions, and a depthful ontology of places (Gurvitch 1964; Clark 1985). His spectrum of social times includes: the extent of continuity, contingency, and surprise; the pace of durations; and the relative influence of the past/present/future. An eightfold typology distinguishes levels in terms of surface or depth for different social formations (Harvey 1989: 224–5). Gurvitch, in contrast to Weber, proposed discontinuous typologies for specific periods and places.

The bold, complex approach of Gurvitch was displaced by Parsons's treatment of time in social systems. Parsons reinstated the dualism of static/dynamic from the Newtonian lineage and theorized time as an abstract objective framework. This complemented the new time geography, time budgets, and life cycle models. Time space geography records and maps the trajectories of individuals and cohorts during the day, week, and year as they move through particular spaces. This minimizes contingency and emphasizes chronic recursiveness about human activity (May & Thrift 2001). Time budgets are extensively used to audit activities in the typical day and week. They reveal consistent gender differences and significant differences between some nations. The life cycle model of birth, maturity, and death has become a temporal metaphor used to anticipate, justify, and explain the shifting changes to everyday

life. Commodities can have life cycles – and so can personal relationships.

Contemporary theory is being uneasily shaped by a blending of structuration theory (Giddens), casino capitalism (Harvey 1989), and dissipative structures. Giddens's sociology reconnected time with history whilst also subverting orthodox calendrical narratives. He adapted an objectified time and chronic recursiveness from time geography. Modernity became the capacity of historical narratives to provide reflexivity about custom and tradition so that existing time space is bracketed and scrutinized. The emergent future becomes the disrobing of the past of traditions. Innovation became routine. The relevance of time space distanciation cannot be overstated. Giddens provides a temporal tool kit for examining the stretching of corporations from local entities into massive global firms, of cities into regions, and of the state apparatus in the modern nation state. Giddens's treatment of temporal agency is much more rampant and controversial than in the alternatives to structuration. He contends that there has been a transformation into "late modernity" or "post traditional society" rather than a rupture from modernity. Giddens's theory of time provides a protective belt for otherwise unconnected studies in different disciplinary areas: organization theory, historical geography, and information systems (Bluedorne 2003). Harvey (1989), a critical geographer, contends that the temporal mechanisms of finance capitalism have been qualitatively transformed by the instantaneity of information technology to create casino capitalism. This rapid speeding up inserts new time frames on top of older, taken for granted time priorities and practices, causing personal disruption, high risk, and uncertainty. Finally, dissipative structures were theorized in modern science to conceptualize and explain the inner temporality of processes as continuous flows of becoming. Adam (2004) draws on this theory to argue that sociological theory needs to address the non social context and its future consequences for social processes. Dissipative structures confront and challenge "Giddens time," overturn the dualism of static/dynamic analyses, and promote attention to the multiple event trajectories located within all kinds of processes.

MULTIPLE TIMES

The combination of heterogeneous and homogeneous systems provides temporal orientation and ordering to everyday life and to the specialized activities of the state, religious organizations, science, corporations, and occupations. For example, in the multitude of different disciplines within a typical university, the times of contemporary physics still differ from those found in geology and both differ from those found in sociology or economics. Musical scores and orchestras had been a repository of controlled time, but these orderly conceptions have been complemented and confronted by a blooming of aesthetic temporalities in the humanities and the arts. Times are differently constructed, expended, and experienced in different strata in the same society. Regions may possess repertoires of times that enable or disable economic success. All these processes are pregnant with political conflicts and inequalities.

There are many highly abstract times. Eternal time constructs linear flows from the distant past into a glorious extended present. Italian fascism invoked the Roman Empire. A linear eternal orientation may be utopian or dystopian. Some religions link the past to a future state. The template of eternity underpins the aim of producing universal generalizations in the social sciences. Since the mid twentieth century there has been the routine and extensive development of temporally open, multistate models that are independent of any context. These start with an undesired state and move through progressive time to further states and arrive at the desired goal. The models provide an abstract, instrumental, multilinear conceptualization of processes such as the diffusion of innovations between nations. The intervals of time are sequential rather than simultaneous, yet irreversibility can be imagined as a game of comparisons and the auditing of performance. The discourse of tasks, events, milestones colonizes the temporal life of everyone. Families in Silicon Valley can coordinate their identities on a daily basis using handheld technologies.

In some theories of modernity it was mistakenly assumed that sacred religious time had been ousted as a major time setting authority

and replaced by the secular temporalities of science, the state, and commerce.

COMMODIFIED WORLD TIME: EXPERTS, CORPORATIONS, AND NATIONS

A market economy depends on and reproduces standardized, decontextualized, and commodified units of time. CCT provides a major discourse in capitalism to the coordination of technologies and labor discipline. The commodification of time and its separation from commodified space is an indicator of the role of the economy in capitalist societies. The market has been the route through which the work rhythms and temporal principles of corporations predominate. Time is experienced in everyday contexts through schedules of all kinds, calendars, deadlines, seasonal events, and project times. Even intimate moments like "quality time" seem scheduled. There are different temporal effects in the metropolitan centers like Los Angeles, Tokyo, and Frankfurt from those experienced in peripheries such as Nigeria producing raw materials or Kenya producing edible products. The metropolitan temporal flows instantiate the supply chains and networks that organize the spatial. The harvesting of flowers in Kenya is temporally orchestrated like a musical score to mesh with both the rate of expected sales in Europe and the fragile, aesthetic perishing of the flowers. A new discourse of flexible temporal principles is being imposed – "serving the consumer" – and contested.

Professional time experts, consultancies, and corporations are the leading edge of compressing and stretching time. They constantly use abstract representations to remove delays and waiting times when the financial return is low and the porosity is high. The evolution of the Gantt method of charting time lines and its inscription in software is very important. Gantt charts became a temporal boundary object in corporate power struggles (Yakura 2002). Time lines are graphical representations of tasks, events, and milestones. Gantt charts make abstract time visible to powerholders. Time experts orchestrate the temporality of urban spaces and search for places that can be more

deeply commodified, as in tourism around the Indian Ocean. They are the eyes of capitalist power (May & Thrift 2001) that reflexively search the world to compare practices and to construct sites for simulating novel practices. By enrolling and incentivizing innovation in information technology, they introduce mechanisms and organizational formations which tend to transform sticky processes into flows over vast distances. They develop software for the planning and surveillance of the use of resources in organizations. Time sequencing and synchronizing are embedded in expert systems like enterprise resource planning (ERP). These reduce the porosity of capital accumulation by envisaging the simultaneous actions and flows. A focus upon the cycle time of production can disrupt the total time from design to the consumer's purchase (Clark 1985).

Some corporations (e.g., Toyota) have developed capacities to stretch time through expert systems that embed capacities to design temporal structures which stretch across continents. Large organizations typically calculate an abstract temporal container expressing the aggregate volume of standardized time available to undertake a portfolio of activities over a given calendar period (Clark 1985; Hassard 1996; Bluedorne 2003). Large retailers are streamlining the purchasing function to speed up and control transactions whilst introducing barcode scanners and extending the panoptic gaze of the firm. The temporality is closer to that of super market than hospital.

Some nations, their corporations and their professions may be the source of time reckoning frameworks that are carried across large areas of the world. The key to analyzing the internal dynamics of the capitalist state is that revenue for the state is dependent upon processes of valorization which the state does not directly control. The state frames many of the new forms of temporal ordering through legislative actions (e.g., France). The temporal complexity within America is remarkable and consequential for the world. The spectrum ranges from the ordered times of American football and McDonald's to the event dominated temporal modularity associated with some West Coast communities and with the emergent segments of information technology. In twentieth century America, the

clock was used most extensively by influential specialist occupations specifically situated with a role in the temporal structuring of workplaces of all kinds, which to some extent occasionally structured home life as well (e.g., funerals). Many of the practices and technologies were commercially developed in and marketed around the world: from Gantt charts to systems of production and inventory control. Currently more over, time experts and firms specialize in "events" and in historicizing the past in a post modern history of the future. So, contrary to some views (e.g., Bluedorne 2003), there is a remarkable articulation between homogeneous and heterogeneous time reckoning in America. Celebratory and sacred times are evident in many social occasions.

TIME SPACE COMPRESSION AND THE POLITICS OF TIME

Critical theorists contend that in capitalism the political control of temporal structures by corporations has unfavorable consequences because we live in an extended present of time space compression and instantaneity. They contend that we are in an era when established expectations of what comes next are much less clear than in the past: it is a runaway world. If so, established temporal expectations are a poor guide to future navigation. Temporal relations may become so destabilized as a result of constant flux that they can provide little in the way of anchoring for social relations and place bound nostalgias. Time space compression means reducing the total cycle time of global financial capital accumulation by quickening the time from design to sale (Harvey 1989; May & Thrift 2001). The time to travel distances is reduced through increases in the speed of sending material goods, information, and people. Most of our electronic devices are dedicated to speeding things up. Commodified times relentlessly colonize and replace the social rhythms with greater speed of transactions. New forms of advertising create an aesthetic audiovisual economy of signs, brands, and logos which can be constantly upgraded. Consequently, the objectified qualities of how we represent the

world to ourselves are disrupted and this can lead to a tension between the speed of turnover and the capacity of societies to regenerate. Radically new forms of time disrupt linear homogeneous time with forms of project and event time that can be chaotic and volatile. There is discontinuity and there are new times (Gurvitch 1964). The experience of simultaneity and synchronized processes from the “electronic embrace” is complemented by new possibilities of asynchronicity in situations typified by a consensually grounded grammar. The time of mass production is replaced by mass customization and the opportunities for diversity.

time series

Robert M. Capraro

Time series analysis can be used in two general situations: (1) forecasting and (2) exploring the nature of some event represented by a set of points or observations, with both techniques serving the purpose for establishing theory that can, at some point, represent future events. Time series analyses are often used in business settings by forecasting stock, commodity, and product valuing. Time series is less often used in educational research; therefore, it is this perspective that will be used in all examples to contextualize possible research scenarios where time series analyses would be appropriate.

Among the myriad techniques subsumed by the term time series analyses are autocorrelation, trend, and seasonal variation, which all help in the quest to understand the underlying structure or the fit of a theoretical model. Just as with the general linear model, time series can handle single or multiple dependent variables. Some techniques for fitting a time series include Box Jenkins univariate and multivariate, and Holt Winters. The fit techniques, similar to the way classical measurement attempts to differentiate between true and unsystematic error score for each item, attempt to differentiate between data points that are and are not useful in helping to predict future events. Therefore, time series analyses incorporate procedures for dealing with these erroneous data points. Specifically, time series analyses make use of smoothing techniques; the approach to the smoothing differs, as well as the smoothing technique's susceptibility or ability to deal with “noise” or random unsystematic error. The smoothing techniques generally fit into one of two methods, consisting of averaging and exponential smoothing methods.

Generally, univariate time series refers to data that are recorded sequentially, at regular intervals, over some period of time. For example, a case for a univariate time series would be examining the impact of free/reduced lunch programs on school attendance patterns for low socioeconomic status as compared to the other students, for, say, 2 years. These time series data allow the researcher, depending on

sampling technique, to examine school attendance trends for these two groups based on their enrolment in the free/reduced lunch program. If trends were detected an additional time series analysis might be undertaken, one in which attendance patterns might help to identify trends in academic success or on high stakes tests. Currently, as with many statistical analyses, the minimal number of observation points is somewhat debated, but as a general rule of thumb, 50 observation points should suffice.

Two other general types of time series analyses, multivariate and interrupted time series, can be used when additional data points are available and related to the phenomena under investigation or when comparing the effects of an external event on the observations, respectively. From the example above, one might consider that the changes in attendance trends among the groups of interest might be due to other factors. In this case, a multivariate time series analysis might be reasonable and include other measures, such as classroom behavior management referrals, suspensions, or school climate measures such as parent volunteerism, teacher absenteeism, and phone calls to or from parents. When one is considering changes in programs or the impact of new programs, then an interrupted time series is applicable. The kindergarten through twelfth grade public education system provides a rich source of time series appropriate data. Many states hold textbook adoptions every 5 or 7 years. This change in textbooks allows one to consider student academic achievement in an interrupted time series that considers student performance before and after the change in textbooks. On the surface, this study is of marginal interest except if in changing textbooks a downward trend in student academic achievement was detected and this downward trend was predictable with each new adoption – some legislators may attempt to forgo the textbook adoption process for schools and opt for a single textbook. Again, referring to the original example, one might be interested in any of the above additional variables, but also want to consider the impact of new legislation influencing free/reduced lunch in conjunction with the inception of the Head Start legislation on school attendance, which represents an interrupted time series from before and after each of

the legislative actions. Interrupted time series allow one to consider the impact of some intervening variable on the phenomenon of interest. Often, interrupted time series make some use of retrospective data collection or the inclusion of extant data along with current data. However, the research question and paradigm should govern when and how to use any of the myriad varieties of time analyses.

RESEARCH PARADIGM

Time series can be useful when the researcher needs to be able to isolate the dependent variable from other exogenous variables. Therefore, it is necessary to find a design that allows for the control of variables that can function as threats to validity. When the researcher needs to interpret a dependent variable from some set of measured variables, why not simply use an experimental design? One option for measuring the outcomes of social interactions or programs is true experiments (Fishman & Weinberg 1992). In a true experiment, individuals are randomly assigned to either an experimental or a control group. The purpose for randomization is that it presumably controls for the effects of unmeasured variables, allowing the researcher to claim that the outcomes are the result of the intervention (i.e., not the result of unmeasured variables or quirky data) (Cook & Campbell 1979; Shadish et al. 2002). In the absence of random assignment or in non experimental situations, researchers attempt to control the effects of unmeasured variables on the outcome variable. However, in non experimental designs researchers cannot make causal statements regarding treatment results on the outcome variable. Researchers are limited to statements about linkages between the treatment and the outcome variable situated within the presence of other variables. In social science situations, non experimental designs can be more attractive than experimental designs because they are less costly, make retrospective longitudinal investigations possible, allow the use of extant secondary databases, and incorporate a reasonable control of extraneous variables. In time series analysis, aggregate data allow for the measuring of global changes, separate from other variables that can impact the outcome variable.

TIME SERIES ANALYTIC METHODS

Several different approaches are available for time series analyses. The time domain approach focuses on the correlation between immediately surrounding points in time by the dependence of the current values on past values. This modeling can be thought of as linear regressions of present values on past values generally considered as a useful forecasting tool. This approach is associated with autoregressive integrated moving average or ARIMA models. Conceptually, ARIMA handles data in the general form of time correlated events where one presumes that past values are predictive of future events. Just as multivariate analysis of variance better models real world events (Thompson 1991), multivariate time series can provide a better model by accounting for more than one input series through a multivariate ARIMA or transfer function.

The frequency domain approach focuses on periodicity and the idiosyncratic nature that can be explained by external factors. In social sciences or education one might be interested in monthly attendance patterns across rural, urban, and suburban schools or performance of students on minimal skills testing that occurs during various months across states.

Spectral analysis is often used to examine the various periods of interest in the data. This analytic method examines the variance associated with each interest period separately. This method often works well with long series or when the periods are clearly defined. For instance, the frequency domain approach seems to fit well with analyzing speech. Speech consists of clearly defined periods that can be analyzed by computer software to provide speech to text applications. However, in financial applications, one would want to know about summative trends for companies, financial indexes, and sector performance. Just as with education and social sciences, it is important to match what the time series analyst wants to know to the appropriate approach.

Conventionally, whichever approach one chooses the result is presented in graphical form with the *x axis* being time. There are three general forms for presenting the results. Continuous time series represent data collected

longitudinally, and observations could be made at any continuous point in time. Discrete time series use equally spaced points along the time continuum. The discrete nature for the data collection should be purposeful and intentional. Interrupted time series refers to examining related events before or after some intervening variable during the time series. While sampling technique is a non trivial issue, it is important to note that the sampling rate (frequency) can appreciably change the appearance of the representation of the data. Improper sampling can lead to distorted data, referred to as aliasing.

ANALYTIC DECISIONS AND STUDY FORTITUDE

Finally, in choosing a time series analysis it is important to keep some questions in mind: (1) How much data are required (for an interrupted time series) and how many baseline data points are needed? (2) How many schools/teachers/programs etc. are needed? (3) How large should subject pools be? (4) How many follow up years should be included in the analyses? These questions address factors influencing estimates of program impact. After the study is complete and these questions are considered in the design, it is important to consider impact. A simple way to represent the precision of a research design is its "minimum detectable effect." Intuitively, this is the smallest impact that has a good chance of being identified if it actually exists. The smaller the minimum detectable effect, the more precise the design. The first step in assessing the minimum detectable effect of a research design is to decide how impacts will be reported. However, the minimum detectable effect does not induct replicability of the observed effects. A popular way to determine effect that does infer replicability, especially for education research, is a measure called effect size. This is simply the impact in its original units (e.g., a scaled test score) divided by the standard deviation of the original measure for the population or sample of interest. Hence, effect sizes are measured in units of standard deviations. Thus, an effect size of 0.25 means a positive impact that is comparable in magnitude

to 0.25 standard deviations. An effect size of -0.40 means a negative impact that is comparable in magnitude to 0.40 standard deviations. Although judgments about whether a specific effect size is large or small are ultimately arbitrary, some guidelines do exist. Many researchers use the rule of thumb proposed by Cohen (1988), which suggests that effect sizes of roughly 0.20 be considered small, 0.50 be considered moderate, and 0.80 be considered large. Lipsey (1990) provides empirical support for this approach based on the distribution of 102 mean effect sizes obtained from 186 meta-analyses of treatment effectiveness studies, most of which are from education research. The bottom third of this distribution (small impacts) ranged from 0.00 to 0.32, the middle third (moderate impacts) ranged from 0.33 to 0.55, and the top third (large impacts) ranged from 0.56 to 1.26.

time-space

James Slevin

All social life is ordered over time and through space. However, when sociologists attend to the “situated” character of social life, they do not treat time space as simply the temporal and spatial environment of the phenomena they study. They see social life as not just being “in” time space, they see time space as central to all social interaction. The “situatedness” of social life involves time space as a constitutive feature in the construction and reconstruction of what people do and in the way they do things together. The ordering of social life comes about because social practices are routinely made to come together across time space as shared experiences. This binding of time space is expressed in the ways in which societies, institutions, and individuals organize time space.

Anthony Giddens draws attention to three features that need to be addressed by sociologists when seeking to understand the way in which social life is ordered across time space. The first involves the construction and reconstruction of regularized social interaction across time space through informed practices. Take, for example, the actions and interactions relating to the lending and borrowing of a library book. These are knowledgeable activities involving the understanding of a range of time space relations by both lenders and borrowers. A borrowed book has to be returned before the elapse of a specific time period and returned to a specific place in the library in order for it to be made available for the next person wishing to borrow it. The library staff gather and process information on the whereabouts of the books they have lent out and apply sanctions, where necessary, in order to secure their timely return.

The second feature involves the association of social interaction with purposefully designed spatial and temporal environments. Taking once again the example of a library book, such transactions are embedded in purposefully designed spatial and temporal settings for the storage, distribution, and collection of books. The design of a library building, the spacing of facilities for the storing of books, the catalog access points,

the information and administration desks, the reading rooms, etc., are all features integral to the spatial and temporal coordination of library transactions and are integral to what a library is.

The third feature involves the organizational mechanisms which are used to regulate the timing and spacing of social interaction. The lending and borrowing of a library book are organized by means of various time space organizing devices. A library will have specific opening hours. These may alter depending on which day of the week people wish to visit the library. The annual cycle of opening hours may include calendar dates when there are holiday closures. Other time space schedules, such as a library's borrowing and cataloging system, regulate the location of books, the total number of books borrowed, and the length of the borrowing period.

The development and use of information, communication, and transportation technology impact on all three of the features set out above. David Harvey's term "time space compression" describes the reduction of distance experienced through the decrease in the time taken, either to cross space physically by means of transportation, or symbolically by means of communication. People can, for example, use the Internet to access and consult cataloging systems of distant libraries which, due to their far off location, they would have never considered visiting physically. They can also increasingly download reading material digitally and so cancel out the need for physical transportation altogether. The use of the Internet also impacts on libraries as purposefully designed spatial and temporal settings. For example, library users may browse through books on a computer screen rather than in the open book stacks in a library building. Finally, Internet use impacts on the organizational mechanisms which are used to regulate the timing and spacing of library transactions. People can, for example, consult a library's cataloging system and download reading material even outside a library's opening hours. Moreover, material stored and distributed by a library in a digital form does not need to be returned to the library in order for it to be made available to others.

Time space compression allows for the stretching of social life across time space, a phenomenon that lies at the heart of one of the

most central transformative processes of our time: globalization. Tomlinson (1999) writes of "the 'proximity' that comes from the networking of social relations across large tracts of time space, causing distant events and powers to penetrate our local experience." However, as he makes clear, the compression of time space is not just about physical distance. It is also about social cultural distance.

Tocqueville, Alexis de (1805–59)

Sam Binkley

Born into a French aristocratic family in 1805, Alexis de Tocqueville was a French political theorist, sociologist, and cultural and historical commentator whose contributions are equally claimed by the disciplines of sociology, political science, American studies, and American history. In 1831, together with his colleague Gustave de Beaumont, Tocqueville embarked on a tour of the nascent American democracy in an

effort to understand the inner workings of the democratic spirit in the everyday lives and social institutions of the American people. On returning to France he wrote his famous two volume investigation, *Democracy in America* (1835). Tocqueville uncovered within American society a tension between democracy's conflicting imperatives: the egalitarian character of democratic societies, while successfully eliminating forms of despotism identified with feudalism, did not provide sufficient integration of the individual into the social fabric. Hence, democratization, if extended unchecked and in irresponsible ways, could produce excessive individualism (a term Tocqueville coined for this purpose), and ultimately new forms of despotism. In a comparison of the American and French experiences with democracy, Tocqueville pointed to the dangers posed by the French case, in which a sudden leveling of social hierarchies following the French Revolution eliminated the intermediary institutions that maintained the integration of individuals within the larger social fabric, leading to revolutionary despotism, a theme developed more completely in his other major work, *The Old Regime and the Revolution* (1856).

The American case, on the other hand, fostered voluntary democratic institutions which ensured local involvement and instructed in the methods and techniques of self rule. The American case, however, was possessed of the equally ominous threat of the "tyranny of the majority," or leveling and homogenizing of public opinion by the belief in the ultimate sovereignty of the views held by the greatest number. Tocqueville cited as an example the persecution of the editors of a Baltimore newspaper who, during the war of 1812, after voicing an unpopular view, were besieged by a mob of enraged locals, had their printing presses destroyed, and were jailed and ultimately killed. Tocqueville's assessment of such majoritarian absolutism contributed to later debates around mass society and twentieth century totalitarianism, conformity, and homogenization, and resonates with David Reisman's *The Lonely Crowd* (Reisman et al. 1950).

Tocqueville's legacy is still very much in dispute, particularly in debates around the welfare state, civic engagement, and democratic citizenship (Goldberg 2001). On the political right,

Tocqueville is cited as a critic of the tyranny of the welfare state and of public assistance as a means of redressing inequality. On the left he is taken up as an advocate of an active role for the state in offsetting the atomization of society through policies that enable associative engagement of individuals in democratic and community participation (Arato & Cohen 1992). Tocqueville's imprint is also visible in contemporary sociological concerns with declining social capital and the erosion of civic engagement in urban, mediated, and postmodern societies (Putnam 2000).

tolerance

Susanne Karstedt

In 1598, Henri IV King of France decreed the Edict of Nantes that proclaimed the principle of tolerance as guiding principle of the state, its administration, and the life of its citizens. The Edict of Nantes established the principle of tolerance in order to end civil strife and religious conflicts, and to enhance the safety of all

citizens, independent of their religious beliefs. Looking back over a period of more than 400 years, the Edict of Nantes is an astonishingly modern document. It granted equal access to the institutions of the state, public office, and educational institutions for all religious denominations, in particular for Protestants. As such, it is a document not only of the toleration of (religious) diversity, but also of the creation of those institutional safeguards and arrangements that underpin tolerance as a lived experience and practice of citizens.

Europe and the United States have been the seedbeds of tolerance, of the philosophical ideas on which it is founded, the legal and institutional framework where it is enshrined, and the education of citizens and their habits, through which tolerance becomes a lived experience. In Europe, tolerance emerged as a mechanism of internal conflict resolution during the period of religious wars and strife, and the Confederation of Warsaw (1573) is one of the earliest documents of (religious) tolerance guaranteed by the state. In the Middle Ages, cities like Toledo or Granada thrived on the established tolerance between Muslim, Christian, and Jewish citizens; Sarajevo is another of these notable examples, all from countries under Islamic occupation (Spain, Bosnia). It took nearly another 250 years after the Edict of Nantes for the principles and institutional foundations of religious tolerance to be firmly established in Europe in the nineteenth century. In this process Europe lagged behind the United States, which had adopted the ideas as well as the legal and institutional framework, had proclaimed religious tolerance in its Declaration of Independence, and guaranteed it in its Constitution. The European and American philosophers of the Enlightenment proclaimed toleration as the notion that all human beings are essentially the same, despite their religious and moral convictions, and that the beliefs of other races and civilizations are equal to those of Christianity. Tolerance emerged as a core concept and value in the formation of modernity and modern societies.

Tolerance is a concept which can only be defined in a negative way, and its essence is defined by the lack of action, social bonds, or emotions. It is not an expression of benevolence, but embodies a sense of disapproval. Tolerance

is the deliberate choice not to interfere with conducts and beliefs, lifestyles and behaviors, of which one disapproves. Tolerance is defined by passivity, not activity, and it is non reaction and non interference that characterize tolerant attitudes and behaviors. Tolerance means the absence, not presence, of strong emotions, and neither love nor hatred is comprised in the concept of tolerance. As such, tolerant attitudes and behaviors are situated between a positive and negative extreme; at its positive extreme, tolerance expressively includes respect for others, and acceptance and embracement of social diversity and individual difference. At its negative extreme, tolerance can be characterized by total neglect, disregard, ignorance, and avoidance of those individuals and groups who are different. The range covered by tolerance is reflected in thresholds, where behaviors and lifestyles of others are seen as threats to the social and moral order, and as such become "intolerable." How far tolerance can be stretched, and at what tipping points intolerance takes over, varies individually between groups and societies.

Tolerance owes its prominent role in the formation of modernity to its essential character as non interference. It is decisive for the cultural change from "passions to interests" (Hirschmann 1997 [1977]), which gave birth to modern capitalism. It constitutes the foundation for the development of universalistic and individualistic value patterns, and is essential for the development of the weak ties (Granovetter 1973) that are a defining feature of modern societies. Tolerance is embedded neither within those bonds of solidarity that develop between equals nor within groups, where tolerance of difference is not actually needed. Tolerance is, however, essential in the formation of links between different social groups, and facilitates the everyday interactions of their members. Tolerance is one of the foundations of the transformation from *Gemeinschaft* to *Gesellschaft* (Tönnies). Modern democracy and its "civic culture" (Almond & Verba 1963) are based on the lack of strong bonds and emotions, and tolerance is seen as an indispensable "underpinning of democracy" and cornerstone of civic culture (Sullivan & Transue 1999). The stability of modern democratic regimes is based on acceptance of the majority rule by the

minority, succession through elections with winners and losers, and peaceful negotiation of different interests between groups, as well as a specific attitudinal pattern amongst the citizenry that supports these institutions and makes them work.

Tolerance can only flourish where weak ties are strong. Weak ties need a certain level of trust and cohesion amongst the citizenry. Inglehart (1997) shows with data from the World Values Survey that generalized trust in others and tolerance of different and deviant lifestyles are highly correlated in his sample of 43 countries. In particular, generalized trust that links different ethnic groups increases tolerance of and the integration of ethnic minority groups (Jorgensen 2004; Uslaner 2004). Amongst the predictors of intolerance, perceived threat from all who are defined as "others" is an extremely potent, completely exogenous, and by far the most significant predictor of endangered tolerance (Gibson 1992; Sullivan & Transue 1999). This is mirrored by the individual dispositions and personality traits that are linked to intolerance. Adorno et al.'s *Authoritarian Personality* (1950) laid the foundations for an influential stream of research, which linked psychological insecurity and individual dogmatism to intolerance of "others" (Stouffer 1955; Gibson 1992; see Sullivan & Transue 1999). It has, however, proven to be difficult to establish that a "modal" and more authoritarian character is responsible for a higher or lower level of intolerance in a specific society. Rather than individual or collective dispositions, a specific social situation of anomie, felt insecurity, and perceived threats seems to combine into the significant social conditions conducive to intolerance, though these can be based on tradition and history (Gibson & Gouws 2003).

Consequently, transitional societies and emerging democracies seem to be in particular vulnerable to widespread intolerance and ethnic and religious strife, and more affected by resulting violent conflicts with ethnic minorities. The quest for "group rights" in the transition countries of Eastern and Central Europe has been made responsible for a decrease in tolerance and the revival of ethnic conflicts and boundaries, combined with increased violence (Offe 2002; Mann 2005). In divided societies like South Africa, perceived threats still loom large and

endanger tolerance and the building of democracy and civic culture (Gibson & Gouws 2003).

Contemporary societies and democracies put the tolerance and toleration of citizens to the test in new and different ways. They stress individualistic expression, individual autonomy, and identity, and citizens ask for the toleration of their own behavior and identity as much as they are asked to tolerate others. More autonomy and less restraint in behavior exercise the tolerance of citizens. As such, tolerance in modern societies encompasses a much broader spectrum of attitudinal and behavioral patterns than those related to political and/or religious affiliations. Citizens have to cope with new levels of ethnic and cultural diversity in contemporary societies due to the influx of ethnic minorities and immigrant groups, and their different ways of life. They experience increased levels of insecurity through crime and disorder in their neighborhoods and cities, or deep generational gaps between the lifestyles of younger and older generations in society. All this is perceived as threats to the existing "moral order" of groups and communities. Most recent developments indicate that religious affiliation in combination with ethnicity is perceived as a threat again, or that threats from crime become racialized (Frederico & Holmes 2005), thus pointing to highly differentiated patterns of tolerance and intolerance within different social groups. Tolerance has become precarious as citizens increasingly demand higher levels of personal and community security from the state, are increasingly willing to accept restrictions on civil liberties, are increasingly opting for populist solutions to such problems, and are more inclined toward punitiveness and less toward tolerance of deviance than before.

In responding to the challenges to tolerance in contemporary societies, political theory and philosophy have reconfigured the concept of tolerance in terms of liberalism, identity, and difference (Horton 1993; Walzer 1997; Horton & Mendus 1999; Shweder et al. 2002; Castiglione & McKinnon 2003; McKinnon & Castiglione 2003). Traditional notions of political and religious tolerance needed to be broadened in order to account for all aspects of the new forms of diversity in contemporary societies, and to relate them to the institutional framework of democracy, justice, and human

rights (Kymlicka & Opalski 2001). Beyond those mechanisms that citizens use to deal with the behavior, actions, and beliefs of “others” that they perceive as a threat to their “moral order,” citizens need to link with the institutions of society when they address them for support and help in dealing with such behaviors and the resulting social conflicts. The civic culture that engenders tolerance amongst citizens needs support from the institutions and associations of civil society, as well as strong democratic institutions. It is crucial in this process that freedom from insecurity and perceived threat is distributed equally, and that minorities as well as the majority are equally secure. The provision of security to all citizens by institutions as diverse as criminal justice and welfare is vital in ensuring and developing tolerance in societies. Contemporary societies need to find the balance between closely knit communities and diversity, stability, and disorder that shapes tolerance in all realms of life (Weissberg 1998).

Tönnies, Ferdinand (1855–1936)

Raymond M. Weinstein

Ferdinand Tönnies was born near Oldenswort, Germany, in the northern province of Schleswig Holstein. He came from a well to do farming family and grew up at a time when

Germany was expanding as a colonial empire and undergoing profound changes such as population growth, urbanization, and industrialization. Tönnies's oldest brother was involved in mercantile endeavors and thus he experienced the world of the peasant farmer as well as the town merchant. He received his doctorate in philosophy from the University of Tübingen in 1877, then returned to his native province, and later taught for over a half century as a private lecturer and professor at the University of Kiel.

Tönnies was interested in social philosophy and social science. His best known work was his first, *Gemeinschaft und Gesellschaft*, published in 1887. Translated into English as *Community and Society* (1957), this book on social change and modernization had a pioneering influence in the new discipline of sociology. Its later editions served to enhance Tönnies's reputation as an important social theorist. *Gemeinschaft* referred not so much to a geographic place as to a "community feeling," intimate and holistic relationships, and a common meeting of minds characteristic of people living in a village or small town. By contrast, Tönnies used *Gesellschaft* to describe the impersonal, limited, and contractual relationships people have in an urban industrial world, an "associational society." The two terms were meant to call attention to the dramatic shift occurring in the late nineteenth century in social groupings and interpersonal relations.

Tönnies believed all social relationships were governed by human will, the need to belong to groups or associate with others. He spoke of "natural will," the motivation for action derived from the temperament, character, or intellect of the individual. This will is typified by *Gemeinschaft* and is found in kinship groups, neighborhoods, and friendship circles. People are bound together by blood, locality, or common interest and naturally work together or help each other as an end in and for itself. Tönnies believed "rational will" is characteristic of *Gesellschaft*. People associate with one another as a means to an end, for economic or political gain in capitalist society, to rationally choose their associations for practical results rather than personal motives. Tönnies developed his concepts to be ideal types of historical relationships found in medieval or rural, as opposed to modern or urban, societies.

As a sociologist, Tönnies was ahead of his contemporaries – Durkheim and Weber in Europe and Cooley in the US – who likewise created dichotomies of the changing forces that bind people and different orientations guiding their actions. He was a prolific writer and made contributions to many areas of sociology, publishing over 900 works during his lifetime. In 1910 Tönnies wrote a philosophical treatise on Thomas Hobbes. In 1922 he produced a book about public opinion and research methods. The papers he considered most relevant were collected in three volumes from 1924 to 1929. In 1931 he published an introduction to sociology as a social science. His last book, *The Spirit of Modern Times*, appearing in 1935 shortly before his death, connected theoretically back to *Community and Society* a half century earlier.

Tönnies co founded the German Sociological Society and served as its president for several years. He came to America in 1904 to lecture at Harvard University. He was removed from his academic post at Kiel by the Nazis in 1933 because of his liberal ideas and public criticism of the regime. After the war, times changed and the father of sociology in Germany was honored by the creation of the Ferdinand Tönnies Gesellschaft at Kiel in 1956. The FTG sponsors research, journals, and conferences on sociological topics, and from 1998 published a 24 volume critical edition of Tönnies's complete works. Tönnies's first work, however, composed as a young man, turned out to be the one he would be most remembered for. His ideas continue to move, intellectually and emotionally, younger generations of scholars on both sides of the Atlantic. The German words *Gemeinschaft* and *Gesellschaft* are readily employed without translation by sociologists lecturing and writing in any language.

top management teams

Phyl Johnson and Steven W. Floyd

The top management team (TMT) literature concerns itself with the study of the most senior teams of executive directors in both private and public sector organizations. These teams are studied in terms of their makeup, their activities, and the extent to which either of these variables has a causal relationship with organizational performance. Top management teams are widely acknowledged to play a key role in organizational success and failure and, as such, generate significant research interest.

Although sharing some themes in common, the TMT literature does not normally include work that is interested in boards of directors and issues surrounding corporate governance. These literatures look at the next level up in organizational hierarchy where the decision making body is made up of directors that are internal (executive) and external (non executive) to the organization and are answerable to (or representative of) the owners of the business and other key stakeholders.

The TMT literature is tangential to other fields. As the most senior managers within the organization, it is the task of the membership of the TMT to both develop and lead the implementation of the strategy that organization is seeking to follow to achieve success. Therefore, both the leadership and strategic decision making literatures are relevant to and share common themes with the TMT literature.

Different perspectives have been used to explore the nature, role, and impact of TMTs.

One of the more widely known and recognized is the literature on the *demographic* profile (e.g., size, turnover, tenure, occupational background) of TMTs. In general, this research examines relationships between such variables and the organization's strategy or its financial performance. One of the causal mechanisms proposed to account for these relationships is the effect of demographic characteristics on the information processing capacity of the TMT. Thus, for example, Halebian and Finkelstein (1993) argue that larger TMTs have a greater degree of information processing capacity, that this leads to better strategic decisions, and thus, that the size of the TMT is positively associated with organizational performance. A similar line of causal reasoning connects the demographic characteristics of the TMT to its beliefs or knowledge base. Thus, for example, Michel and Hambrick (1992) argued that the more an organization's diversification posture relied on interdependence among business units, the more likely that operations, marketing, sales, and R&D would be represented in the functional backgrounds of TMT members. The most widely cited work within this genre is Hambrick and Mason's (1984) theoretical paper in which they outline both the rationale and the methodology for using demographic variables in the study of TMTs. This paper is usually recognized as launching this stream of research, which Hambrick and Mason call the "upper echelons perspective."

Another body of work that is focused on the TMT is the *strategic decision making* literature. One stream of debate and discussion within the strategic decision making literature breaks the decision making process into subtasks: scanning for strategic issues, interpreting these issues, and making a strategic choice. Here, the cognitive processes, biases, and routines of the members of the TMT are explored. For instance, one finding is that how strategists categorize a strategic issue influences strategic choice: when issues are categorized as threats, the decision is more likely to affect a significant change in strategy. Other researchers focus much more on the processes associated with strategic choice. One stream of work analyzes the comprehensiveness of strategic decision processes (Fredrickson 1984; Fredrickson & Mitchell 1984). A high degree of comprehensiveness means that the TMT pursues a more rational approach

to decision making, including the articulation of clear goals and the analysis of multiple alternatives, while a low degree of comprehensiveness means that decision making follows a more incremental pattern, involving a more limited comparison of a potential course of action against the status quo. Another body of work on TMT decision process examines the extent to which TMT members agree or disagree about strategic decisions, i.e., the extent of strategic consensus. Both the antecedents and outcomes of consensus have been explored (e.g., Dess 1987; Dess & Origer 1987; Woolridge & Floyd 1989; Dess & Priem 1995). Others focus on the manner in which the TMT interacts in the process of achieving agreement. Three modes of interaction are usually discussed: devil's advocacy, dialectical inquiry, and consensus building.

A more recent perspective on TMT decision making has sought to bring a finer grained understanding to the subject. Here a *cognitive lens* is used to explore how TMT members think about (Huff 1990) or make sense of (Weick 1995) the internal and external organizational environments and their role as strategists. The cognitive strategic groups literature would be an example (e.g., Porac et al. 1989; Reger & Huff 1993; Johnson et al. 1998). Here, researchers seek to account for strategic outcomes in terms of the way strategists think about the structure of their competitive environment.

So far the discussion of TMTs has been focused on the outcomes and nature of TMT activity and has been clearly aligned to the strategic decision making literature. However, there is a body of work within the TMT literature that is concerned less with the strategic nature of TMT activity per se than with the exploration of the *characteristics* of those who make it to the TMT. This is largely contingency based theorizing and moreover is more heavily focused on exploring the characteristics of those managers who make it to the CEO role rather than the executive suite generally. Norburn's (1989) study is an example of work that focuses on CEOs; he describes a set of psychological characteristics that predict CEO or director status.

There is a smaller literature that examines characteristics of individual TMT members, not in terms of who makes it to the top, but rather in terms of what happens to executives physically and psychologically when they

become members of the TMT. This literature is concerned with the causes and consequences of *executive health*.

Finally, there is a small literature that, encompassing all of the above and more, seeks to create a *typology* of TMTs. Often papers on this topic are designed for a practitioner as opposed to academic audience. Pitcher (1997) is a good example of work that is practically oriented and academically sound.

The primary methodological problem with studying the TMT has been access. That is, the upper echelons of organizations are comprised of powerful people who are not inclined to become objects of research. In the past, the preference has been to theorize using data that are in the public domain. Hence, the demographic methodology discussed at the outset has been used widely. However, the use of such *surrogate measures* (using demographic variables as a surrogate measure of TMT members' attitudes and beliefs) has been criticized (Lawrence 1997; Markoczy 1997) and calls have been issued for researchers to carry out more work that collects primary data from the TMT.

The issue of sensitivity and access remains, however. It is rare for a researcher to gain access to a TMT in order to observe members at work and ask them detailed questions about their activities. Balogun et al. (2003) argue that in order to induce such cooperation there must be a clear quid pro quo for the organization. Also, it is the responsibility of the researcher to have a meaningful contribution to offer the team (over and above feedback from the research itself). This sentiment is also echoed elsewhere in the management literature (Maclean & Macintosh 2002).

totalitarianism

Chamsy El Ojeili

Totalitarianism refers to a political system in which the people are completely or nearly completely dominated by an all embracing state. Totalitarianism is often said to involve the lack of independent social sectors, the non existence of rights and pluralism, and the eradication of politics. The concept is frequently viewed as differing from authoritarianism in a number of ways: being more ideological; involving the domination of a single political party; seeing pervasive state intervention at every level; and being a peculiarly twentieth century political form.

Totalitarianism is commonly deployed as a concept that encompasses both fascist and socialist social orders. Critics note that the concept thus deals with very different social formations and is of little analytical value. Although there are socialist accounts of totalitarianism (e.g., Franz Neumann, Claude Lefort, Cornelius Castoriadis, Agnes Heller), Marxists tend to be unhappy with the equation of the USSR with Nazi Germany, especially on account of what they see as clear socioeconomic divergences, viewing the concept as largely an expression of Cold War politics and as an inoculation against emancipatory change. Marxists have also criticized the idealism of attempts to trace the genesis of totalitarianism to thinkers such as Hegel

and Marx. They have insisted on the complicity of liberal democracies in totalitarianism – even charging that liberal democracies are themselves totalitarian – and some have insisted that the concept falsely implies the absence of conflict within these states. On the other hand, “totalitarianism” has been defended as a useful ideal type, and it has continued to have popular currency.

There have been a number of important contributions to the theory of totalitarianism. Friedrich and Brzezinski (1965) denoted six features of totalitarianism: an elaborate ideology which centers on a final, perfected humanity; a single mass party; a system of terror; near complete monopoly by the party of the means of mass communication; a near monopoly, too, over the use of weapons of armed combat; and central control of the economy. F. A. Hayek viewed totalitarianism as arising from planning and collectivism; Popper (1945) located the origins of the “closed society” in holism and in the “historicist” notion that history unfolds through knowable general laws towards an end point; and Talmon (1961) explored the beginnings of totalitarianism in the thought of Plato, Hegel, and Marx. Arendt (1951) underscored the role of imagined laws of history or nature, a frantic dynamism, terror, and ideology (separating people completely from reality); and she found precedents to, and conditions for, totalitarianism in imperialism, capitalism, and the superfluosity of the mass of people in industrial societies.

Although the term lost some of its intellectual appeal from the 1960s and the 1970s, it has gained something of a renewed currency in postmodernist discourse, which comes to echo the critical theory of the Frankfurt School. Here, an ethical turn has focused variously on the erasure of difference and otherness in totalizing, teleological narratives, on the coercive consequences of the rule of reason and science, and on the normalizing, even totalitarian, tendencies of modernity’s desire for order and transparency and its fear of ambivalence.

totemism

Gaetano Riccardo

The word totemism denotes in a broad sense the complex of beliefs concerning the existence of a sort of kinship between a human group, or a single individual, and an animal or a plant serving as an emblem of this link. This relationship implies a range of rituals and taboos, especially alimentary and sexual ones, which bind those who recognize themselves as members belonging to the same totem. The word itself, in the variant *totam*, was used in 1791 by the English traveler J. Long to designate the link of kinship and the worship of plants and animals by the Algonquin Indians of the Ojibwa, in Eastern North America. Although the term referred to the clan totem, Long used it to describe individual totemism, that is to say, the belief in the existence of a personal link between a person and an animal (more rarely a plant), which is considered as a guardian spirit.

In anthropology, the acceptance of the notion of totemism began in the late nineteenth

century and diminished at the beginning of the twentieth century. During this period scholars focused their attention especially on religious aspects of totemism, and they considered it principally as one of the most archaic forms of worship. So conceived, the idea of totemism achieved widespread fame and it was analyzed by various disciplines. Its introduction in the anthropological debate goes back to McLennan, who stressed how totemism was typified by three elements: fetishism, exogamy, and matrilineal descent. To these aspects Rivers would later add another, namely, prohibiting the group from eating the plant or the animal considered as a totem, except during certain ritual events.

While on the one hand the rapid increase of ethnographic data concerning totemism promoted their inclusion in great evolutionistic syntheses suggested by various authors, on the other it already heralded their superseding. The first important comparative exposition of known ethnographic data is due to Frazer's *Totemism and Exogamy* (1910), in which three different hypotheses concerning the origins of totemism are suggested. The first hypothesis states that the first form of totemism is the individual one, involving the idea that there is an external soul dwelling in animals and plants. The second hypothesis stresses the magical aspect of totemism, particularly expressed in its Australian variant. The third hypothesis stresses primitive humans' misunderstanding about the existence of a bond between sexuality and conception, with the consequent idea that the latter could depend on the action of an animal or vegetable spirit.

In Frazer's monumental work the arrangement of the collected ethnographic data concerning totemism aimed particularly to stress western modern rationality, in contrast to primitive thinking. One of the results of this approach was to hide a large variety of differences existing in the ethnographic data. The continuous decrease of this concern enabled scholars to stress how the variety of totemic phenomena was too wide to be ranged in a single typology. Research put forward by other scholars enabled them to identify very different phenomena, and when agreement was rare it was not easy to formulate universal hypotheses. Analogies began to be suggested with greater care, and with consideration of historical and geographical continuities and discontinuities.

Consequently, the age of major diffusion of the notion of totemism coincided with that of its major decline. In the year in which Frazer's monumental work appeared, another author, Goldenweiser (1910), stressed that it was misleading to include such different data as social organizations by clans, their being labeled by names of plants and animals, and, finally, the belief in a real or mystical relationship between clan members and a totemic species in a single institution. All these phenomena were not always equally present. Furthermore, in many cases they were independent of one another.

The evolutionistic approach to the problem of totemism did not necessarily presuppose the comparative method. It was sufficient to assume that totemism could be one of the most archaic forms of religion. Thus Durkheim (1912) was interested only in Australian totemism, which he claimed to be its most archaic form. According to Durkheim the totem is the main symbol of the society itself. In this way his analysis of totemism becomes an illustrative example of the inextricable link between the religious and the social. Durkheim's sociological approach was an alternative to a previous approach in which a psychological explanation concerning the creation of institutions and religious phenomena prevailed. The advance offered by this new approach was evident. Social phenomena were explained by the social itself and not by more or less imaginative conjectures about primitive thinking.

Although Durkheim's arguments were very incisive, the psychological approach to the study of totemism received a new impulse from the father of psychoanalysis, Sigmund Freud. In his work *Totem und Tabu* (*Totem and Taboo*) (1912), Freud tried to establish a parallelism between the two major prohibitions concerning totemism – alimentary and sexual – and the Oedipus complex. Ethnographic data were underestimated by him in favor of the Darwinian hypothesis concerning the prehistoric existence of the so called primitive horde. Freud supposed a social scenario in which there is not yet a form of exogamy and the whole group is ruled in a despotic way by a single man, the father, who is unable to control his instincts. This despotic father claims to be the only person who has access to the females of the group. Such an intolerable situation would have triggered a violent rebellion of the sons

against him. The youngest men killed the despotic father to devour him, and then they were racked with remorse. A sense of guilt for the crime committed led the sons to substitute the father with a symbolic figure, a totemic species. At the same time, the prohibition of sexual relationships with the females of the group, previously ordered by their despotic father, was spontaneously observed by them. This would be the reason for the appearance of totemism and exogamy as well.

Although in opposition to the arguments put forward by Durkheim, this purely psychological explanation of totemism formulated by Freud is to some extent similar because both authors share an evolutionistic and universalistic vision of cultural facts. A loss of interest in the notion of totemism began only when the evolutionistic perspective of analysis was abandoned. Until it was assumed as valid, the interest in totemism was assured by its presumed universalistic aspect, being considered as expressing a particular stage of human evolution. The fact that a particular and empirical form of totemism could not include any traits considered as an integral part of the totemic institution did not seem a problem. In any case, they were necessarily supposed to exist in a different stage of cultural evolution. So ethnographic evidence was considered important not so much for its local relevance as for expressing something considered as universal.

While Elkin was one of the last authors to assume that ethnographic analyses could still be developed in the direction of a more generalized interpretation of totemism, van Gennep (1920) was among the first authors to recognize that it could not be considered as a universal cultural phenomenon. This lack of universality of totemism was reasserted by some American anthropologists. Historical and relativistic methods of analyzing cultural facts gained ground in the United States. Authors such as Boas, Lowie, and Kroeber were very careful to stress the variety of ethnographic data. British functionalists such as Malinowski and above all Radcliffe Brown moved in an almost identical direction. In the latter's work particularly there are important suggestions concerning the tendency, typical of the most archaic societies, to change animals and plants into objects of worship able to ensure well being of the group.

A turning point toward the dissolution of the notion of totemism is represented by the publication of Lévi Strauss's famous book, *Le Totémisme aujourd'hui* (*Totemism Today*) (1962), in which the author speaks of "totemic illusion." He stresses that totemism does not correspond to a primitive form of religion but must be understood within the broader human tendency to classify everything in different species. According to Lévi Strauss, the core of totemism is represented not so much by a relationship between a group and a species as by the fact that this correspondence with different species is used to conceptualize the differences between the various human groups. Thus the specific nature of totemism would consist in enabling the representation of differences between human groups by resorting to analogies taken from the natural world. Totemism can be understood only on the basis that entire systems of differences, not single elements, are compared. Through totemism, relationships and differences among human groups are conceptualized by analogies with differences among species of animals and plants. According to Lévi Strauss, this would be the most important aspect of totemism. He supports his opinion through the statement that totemic species are useful for thinking and not for eating.

The analysis of totemism proposed by Lévi Strauss does not merely represent one opinion among others. It tries also to explain why the notion of totemism had an enduring life among anthropologists, despite its illusory character. According to Lévi Strauss, the idea of totemism was in a certain sense a sign of the ethnocentrism included in most anthropological works. To talk about totemism meant stressing the discord represented by a kind of thinking that assumed a confusion between natural and cultural spheres, considered quite different in western cultural tradition. Despite the rightness of these observations, the intellectualistic approach adopted by the French anthropologist in his analysis of totemism on the one hand effectively synthesizes the old fashioned debate concerning the idea of totemism, while on the other it seems to discourage possible alternative ways of research undertaken by other authors. Among these, those which focus their attention on the material and moral implications of totemistic practices assume a certain importance today.

A year before the publication of Lévi Strauss's book, Raoul and Laura Makarius (1961) resumed the argument concerning the relationship between totemism and exogamy and highlighted a possible "alimentary" origin of the marriage taboo among peoples composing a single group in which meals are shared. Furthermore, the remarks proposed by Valerio Valeri (1999) assume great importance with regard to the moral relevance of totemic taboos. Valeri highlights how the "phonological" approach adopted by Lévi Strauss does not allow us to appreciate the complexity of relationships between humans and animals, but merely focuses attention on less important aspects of totemism. Totemism constitutes a complex of phenomena reducible neither to an essence nor to a formalism in regard to which the conscious self representations of groups are considered as a trifling matter.

tracking

Kathryn S. Schiller

Tracking is the process of differentiating individuals' school experiences through the grouping of students for instructional purposes based on actual or assumed differences in academic development or interests. In theory, such practices can maximize learning by allowing instruction to be tailored to the needs of each classroom of students. In practice, the quality of instruction often varies dramatically based on the group level, such that low track students receive few learning opportunities while high track students are exposed to a rich and rigorous curriculum. When group placements are related to ascribed characteristics such as social class or ethnicity, tracking contributes to social stratification by perpetuating social inequality in not only individuals' current learning opportunities but also future educational and occupational attainment.

The terms *tracking*, *ability grouping*, and *streaming* are frequently used as synonyms. When distinctions are made, ability grouping usually refers to sorting of students in a given grade level into groups that progress through a common curriculum but at different speeds. In contrast, tracking usually refers to differences in students' academic programs, which differ in the topics covered based on the courses taken. Ability grouping is a more frequent practice in primary and elementary schools, while tracking is usually found in secondary schools.

Tracking is a feature of most modern school systems, although the process and extent of stratification and segregation vary dramatically. In the US during the late 1980s, many schools officially eliminated tracking (i.e., *detracked*) in response to political pressures to increase academic standards while reducing gaps in standardized test scores or educational attainment between genders and racial or ethnic groups. However, consistency in group placement across subjects and years indicates that *de facto* perpetuate social stratification in both the economic and health benefits related to higher levels of educational attainment.

DIMENSIONS OF TRACKING

In sociology, the conceptualization of tracking recognizes that classrooms are the technical core of schools in which students, teachers, and curricular materials combine to create learning environments that vary in quality and quantity of instruction. In addition, students' academic careers consist of series of classroom experiences spanning grade levels that often provide increasingly divergent educational experiences. While the operationalization of tracking varies, the concept in sociological research consistently refers to some aspect of a student's overall academic status at a particular point in time or over a relatively short period of time.

When used synonymously with ability grouping, students' track placement usually refers to their relative status in the academic hierarchy within a classroom or school. Within some elementary school classrooms, tracking occurs when the teacher sorts students into instructional groups based on perceived academic progress or ability. In other elementary schools, students are tracked when they are assigned to classrooms based on similar criteria. These groupings are usually given labels such as *low*, *average*, and *high* or *remedial*, *basic*, *regular*, and *advanced* to reflect relative rankings within the academic hierarchy. In general, most students are expected eventually to cover the same core topics and master a common set of basic skills, although the speed of progress or degree of mastery may differ. Group labels are used to reflect differences in difficulty of the instructional material to which students are exposed, which should build on their prior academic progress.

When referring to secondary schools, tracking is also operationalized as differences in academic programs traditionally described by schools or students as *vocational*, *general*, and *college preparatory*. While now mostly archaic, these terms are used to characterize the types or difficulty of courses students are expected to take based on whether they are expected to enter the workforce or attend college after high school. Students in the college preparatory track, for example, tend to take more academic courses such as advanced placement English,

physics, calculus, and foreign languages. In contrast, vocational students tend to take a large number of courses with direct occupational links, such as business English, drafting, book keeping, and commercial photography. General track students usually take a combination of less difficult academic courses, such as regular English, and elective courses that might also include one or two vocational courses. To the extent that students are being exposed to distinctly different sets of topics or subjects, self reported or school designated track can be a useful summary indicator of a student's general academic experiences during high school.

Since the late 1980s, however, sociologists have recognized that the traditional track labels fail to capture the great diversity of students' academic experiences in American high schools. By 1990, the relationship between sophomores' self reported track and level of mathematics course did not align consistently, such that knowing one type of classification increased the ability to predict the other by only 14 per cent (Stevenson et al. 1994). Several efforts have been made to develop finer grained measures of academic programs based on detailed analyses of the courses students take at a given time or overall during high school. These *course based* indicators of track usually use sophisticated statistical techniques to analyze students' high school transcripts. For example, Lucas (1999) developed his track indicators by a detailed mapping of course descriptions onto traditional track designations by taking into account both the level of difficulty and timing of when a student took a course. In this approach, for example, geometry is considered *elite college* track if taken as a freshman but *regular college* track if taken as a sophomore.

Other approaches to characterizing students' academic careers based on course taking during high school mostly abandon the concept of academic program. In one approach, clustering procedures are used to statistically identify *emergent* tracks based on constellations of course enrolments to which traditional labels may or may not be applied (e.g., Friedkin & Thomas 1997). The goal is to identify students who share similar educational experiences and positions within a particular school or a set of

schools without using an a priori classification system. Another approach focuses on indicators of students' progress through a proscribed curriculum by using indicators of whether a student took a given course in a given year and then statistically modeling changes between years to estimate trajectories through a normative sequence of courses (e.g., Schneider et al. 1998). These sequences are likely to be especially clear in high school mathematics due to the hierarchical and standardized nature of the curriculum in which mastery of a basic topic (e.g., functions) is usually required before attempting more advanced topics (e.g., geometry). This approach to characterizing students' academic status allows close examination of learning opportunity sequences, which are primarily a function of the structure and organization of a subject specific curriculum that link learning opportunities across time, even spanning levels of schooling.

While the comprehensive high school remains an institutionalized feature of American school systems, other countries often track students following a given academic program by placing them in the same school. For example, Germany has a three tiered system of secondary schools in which *Gymnasium* prepares students for higher education, *Realschule* prepare students for mid level occupations or careers, and *Hauptschule* provides a basic prevocational education. In Japan, students are admitted based on performance on entrance examinations to selective upper secondary schools, which have tight links to prestigious universities. Only a small portion of those students not intending to go to university attend technical upper secondary schools. Thus, tracking results from the sorting of students into secondary schools.

PROCESS OF SORTING STUDENTS

Tracking is of interest to sociologists as the product of schools' intentional sorting of students into courses or academic programs based on some observed or ascribed characteristic. On the most basic level, the availability of courses is determined by schools' master schedules, which specify which courses will be offered at what times. The master schedule thus constrains the possible combinations of courses students can

take in a given academic year. Within these constraints, assigning students to a selection of courses usually involves processes that consider a mixture of indicators for prior academic performance and individual preferences.

School officials begin the complex process of developing a master schedule for a given academic year in the spring of the prior year. Although they usually use previous years' schedules as templates, school officials must adjust for changes in staffing and student enrolments in light of available instructional resources (e.g., room space) and state regulations (e.g., curriculum and graduation requirements) (Delany 1991). For example, schools need to ensure they offer enough English or literature courses so that all students can meet most states' requirement that students complete 4 years of English to earn a high school diploma. However, a school may offer only one section of honors freshman English in order to free up a teacher for an English as a second language course to serve a growing number of immigrant students. When that honors course will be offered also depends on teacher availability and other courses being offered at the same time. Schools frequently make changes to their course schedules well into the academic year, as they continuously balance resource constraints with student demand.

While assignment policies can vary dramatically, most schools use several indicators of prior academic performance (such as grades or achievement test scores) in making course placement decisions. Turner (1960) described placement procedures that utilized performance on standardized assessments as *contest mobility systems*, in which individuals earn the right of entry into the elite. In contrast, more subjective criteria are used for making placement decisions in *sponsored mobility systems*, in which individuals with unusual qualities are singled out for special assistance. Sociologists have had heated debates over whether the US has more or less of a contest focused system than either Japan or Great Britain. This debate is the result of most school systems having features of both ideal type mobility systems, with some students earning placement in higher level courses and others being recruited to the academic elite.

Assignment systems, however, are rarely purely meritocratic due to limitations on the

availability of seats in a course and pressures from parents and students to change placements with which they disagree. For example, college educated parents may be so insistent that their children be given preference in assignment to the single honors English course being offered that other eligible students are prevented from enrolling in the class once it reaches capacity. Minority and lower class students often lack the social and academic resources to object or over turn undesirable track placements. This may partially account for the historical trend that minority and poor students are less likely to take college preparatory courses than equally talented white students or children of college educated parents.

ACADEMIC AND SOCIAL CONSEQUENCES

Whether official or *de facto*, tracking not only strongly influences learning and educational attainment, but also shapes the formation of friendships during high school and later occupational attainment and earnings. Organizational, individual, and societal factors influence the process of stratification of learning opportunities and academic outcomes related to course taking patterns.

Tracking clearly differentiates students' learning opportunities. In secondary schools, some are given academically challenging experiences preparing them for college, while others are relegated to classes with curriculum so diluted that they are caricatures of regular courses. Students in honors courses, especially in math and English, are generally exposed to higher quality learning environments in which they are expected to think critically and creativity is encouraged. In contrast, regular and basic courses often emphasize orderliness and regurgitation of facts and procedures. Conflict theorists such as Bowles and Gintis (1976) argue that these differences in curriculum reflect students' social origins and are one of the major mechanisms through which social stratification is perpetuated across generations. Lower track courses basically prepare working class children for menial jobs, while college track courses prepare the social elite's children for professional or managerial careers.

The distribution of academic rewards also differs across tracks and courses, with higher grades tending to be awarded in classes attended by students from more advantaged social backgrounds. Theoretically, grades reflect how well students meet their teachers' expectations of learning and behavior in a given course. Thus, differences between courses in the average grade awarded could reflect overall how well students in a given class met their teachers' expectations. However, grade inflation can result from parents pressuring teachers and schools to award higher grades in college preparatory courses to improve their chances of admission to competitive colleges and universities. Independent of students' individual achievements, these higher grades awarded in more advanced courses serve as public signals identifying the academic elite in a school.

Track placements also have long term effects on learning opportunities through what Kerckhoff (1993) described as *institutional inertia*, the consistency of placements across grade levels and schools created by organizational dependence on school records and prior placement decisions. The positional advantages gained from being placed in more advanced courses earlier in their careers helps academically elite students preserve their status even if they encounter difficulties in that or another course. Positional advantages also accrue from accumulation of prerequisites for later courses that signal to schools that a student was exposed to and gained the knowledge and skills thought necessary to progress. For example, taking algebra in middle school is intended to prepare students to take geometry as high school freshmen, although whether they get much exposure to algebra may be questionable. For these reasons, placement in a more basic course constrains access to advanced courses for even students who may later benefit from a more challenging curriculum. Thus, organizational signals concerning students' intellectual abilities and progress sent by prior course placements have lasting effects on their academic careers. When track mobility occurs, students are usually dropping down from a higher level course to a lower level one.

Finally, whether through direct intervention of parents or a more criterion based system, students' social backgrounds influence their

sorting into courses such that they tend to take classes with others similar to themselves. This social class segregation within schools may allow formation of micro communities with distinct norms and values relating to academic performance. Social capital developed in classes attended by large numbers of children with college educated parents is likely to create a classroom environment with high levels of academic pressure. Similarly, college educated parents may lobby for allocation of more qualified teachers and greater resources to the courses taken by their children. Thus, regardless of their own backgrounds, students are likely to benefit academically from attending classes with others from more advantaged social backgrounds.

tradition

Robert Tonkinson

"Tradition" connotes a body of values, beliefs, rules, and behavior patterns that is transmitted generationally by practice and word of mouth and is integral to socialization processes. The content of tradition is shared by a given group and has informational and moral components that concern the nature of things, right and wrong behavior, and unanswerable questions about life and death. Strong connotations of fixity, stability, and continuity are inherent in the notion of "tradition," as a benchmark or beacon guiding a society's body of daily behavior and providing justification for beliefs and practices. In relatively homogeneous small scale societies, where tradition is the only blue print for acceptable behavior, it is typically

unquestioned and, whatever its truth value, logicity, or consistency, may be regarded as sacred lore (Hunter & Whitten 1976).

Where orally transmitted, however, tradition is always open to variation, contestation, and change; it can also be adjusted, reworked, or reinterpreted to accommodate changing circumstances. Such lability gives the lie to tradition conceived as essentially fixed, immutable, and unchanging over time, and has attracted the attention of historians and anthropologists, particularly in recent decades. In an interesting convergence of focus, two edited volumes on the "construction" and "invention" of tradition appeared in the early 1980s. (Use of the more inflammatory term "invention" by anthropologists ceased after some widely publicized exchanges with indigenous people angered by the implication that they had fabricated their pasts; see Linnekin 1992; Lindstrom & White 1993; see also Turner 1997, on the "authenticity" of invented traditions.)

The first volume (Keesing & Tonkinson 1982) led to a burgeoning interest by anthropologists and others in cognate disciplines in the "politics of tradition." This work reflected the rise of new nationalisms in the Melanesian region that demanded new ways of imagining tradition (Lindstrom & White 1993). Known in Melanesian Tok Pisin lingua franca as *kastom*, semantically opposed to "modern" or "foreign," tradition became a rallying cry of pro independence movements. In an area famed for its cultural pluralism, the uses of "tradition" highlight the nature of political ideologies and the power of abstract symbols in disguising and mediating contradictions that potentially threaten broader unities (Keesing 1982). In much of Melanesia, the impact of Christianity had caused converts to devalue their traditions and dichotomize their past into a shameful pre European era of darkness and evil and the Christian era of goodness and light. This prior refiguring of the past was to cause considerable confusion in some areas when leaders of independence movements began invoking the uniqueness and strength of *kastom* (explicitly opposed to non indigenous European and Christian elements) in their rhetoric aimed at fostering a shared national identity and unity (Tonkinson 1982). Such appeals to tradition encouraged anthropologists to investigate the heuristic possibilities

inherent in tradition's seemingly paradoxical malleability.

Most contributors to the 1982 volume adopted a "cultural constructionist" approach, holding that tradition, like culture, is a contested field in which differently located groups struggle to establish and then reproduce their particular symbolic forms and constructions of meaning. Constructions of tradition are always, at some level, about the present, historically contingent, and oppositional (but not always dichotomous) between the western and the indigenous (Lindstrom & White 1993). This perspective inevitably encourages an analytical focus on class and power relations (cf. Keesing 1993), and has become a theoretical imperative for many anthropologists. Linnekin (1992) offers the strongest analytical overview available on the theory and politics of cultural constructionism, and of many anthropologists' unease about the deconstructionist excesses of postmodernism.

The second volume (Hobsbawm & Ranger 1983), by historians, was prompted by two factors: the ubiquity, in Europe and elsewhere, of "traditions" that in form and prominence seem ancient and timeless yet are often relatively recent in origin and are sometimes invented; and the contrast between modernity's unremitting innovation and change and people's attempts to structure elements within their societies as invariant and unchanging (Hobsbawm 1983). Historians are interested principally in the appearance and establishment of such traditions, as well as those that emerge within a brief and datable period yet are less readily traceable. In his Introduction, Hobsbawm defines "invented tradition" as "a set of practices, normally governed by overtly or tacitly accepted rules and of a ritual or symbolic nature, which seek to inculcate certain values and norms of behaviour by repetition, which automatically implies continuity with the past" (p. 1). Besides separating tradition from conventions and routines that are technological rather than ideological, he explicitly contrasts "custom," which is dominant in "traditional societies" and necessarily flexible, with "traditions," including invented ones, which typically stress invariance. Anthropologists have criticized this contrast as denying pre European contact dynamism, and as reminiscent of claims that such peoples are "without history" (Jolly & Thomas 1992). Hobsbawm suggests

that the seemingly most prevalent post Industrial Revolution invented tradition type is "those establishing or symbolizing social cohesion or the membership of groups, real or artificial communities."

Despite ostensible differences in motivation and foci behind these two influential contributions to the literature on tradition, several interesting parallels can be discerned. There is a common interest in symbols and especially the power residing in them when they remain diffuse and undefined. Themes relating to appeals to history and tradition as legitimizing political action, such as resistance to colonial powers, and of reinforcing group cohesion also appear in both treatments. Related to this is another, stronger parallel: the process of nation building, wherein the emergence of new nation states worldwide and the growth of nationalism necessitate the creation and effective promulgation of symbols of shared identity and belonging, couching the recent, political, and cultural as timeless, "natural," and inevitable. Emergent national identities (informed by tradition) also take on value within the emerging global economic system by supporting tourism (people go to Scotland to see kilts and drink whisky, or to Vanuatu to see land dives and drink kava) as well as trade in localities and souvenirs.

Discussion and debate about the significance and uses of tradition have continued since the appearance of the two volumes just discussed. The topic has proved remarkably durable, engendering a multilayered body of knowledge about constructions of the past in contemporary societies (Tonkinson 1993). Social actors' received notions of tradition as the solid foundation that underpins customary behavior have been deemphasized in scholarly analyses in favor of conceptions of it as constantly subject to reinterpretation and rereading by each new generation of carriers, who construe their past in terms both of present perceptions and understandings and future hopes and needs (cf. Lindstrom 1982). Tradition becomes a model of past practices rather than a passively and unreflectively inherited legacy (Linnekin 1992). Heuristically, it is perhaps most usefully conceptualized as a resource, employed (or not employed) strategically by individuals and groups (Tonkinson 1993). As Lindstrom (1982) shows, *kastom* is subject to a range of

moral evaluations (or devaluations) by its carriers over time; it is understood by all as a symbol but no one can agree on its meaning, since understandings are embedded within rival groups and become part of competing political ideologies. A notable attribute of tradition is that it can be invoked just as effectively to manifest ethnocentrism and disunity, by emphasizing local differences and reinforcing boundaries, as it can when functioning as a political symbol of unity (in which case it is deliberately left vague and internally undifferentiated, so as to minimize its potentially divisive aspect). The consistent polarity of political uses of tradition between the grassroots, regional, and national levels of society suggests that different analytical strategies may be needed in each case (cf. Tonkinson 1993). In the last decade, the historical turn in anthropological theory has led scholars to attempt to contextualize the emergence of particular constructions of tradition within colonization, missionization, and post war "development" and in articulation with the global political economy (Lindstrom & White 1993).

traditional consumption city (Japan)

Yasushi Suzuki

“Traditional consumption city” is one of the categories introduced by Susumu Kurasawa (1968) in his typology of Japanese cities in the early 1960s. His typology emphasizes that the patterns of historical development of cities determine their distinctive social structures. The traditional consumption city refers to cities founded during the feudal era. A contrasting type is the industrial cities that developed

largely during the modernization that followed the Meiji Restoration of 1868. (For simplicity, the following description has been updated, although the typology remains essentially the same as Kurasawa’s original.)

The traditional consumption cities had, and many still have, castles that served as both the residence and offices for the feudal domain lords designated by the shogunate. In the Tokugawa era (1603–1867), those cities were financially sustained by tributes that were paid by the peasants of the domain and were inhabited by merchants and craftsmen who were largely dependent on the expenditures of the lords.

After the Meiji Restoration, some of these cities became the seats of prefectural governments. Kurasawa categorized the new prefectural seats as type A, other traditional consumption cities as type B. In type A, the prefectural governments provide a financial basis for the city. Other public agencies such as the prosecutor’s office, courts, Legal Affairs Bureau, and Land Transportation Offices are concentrated in type A cities, as well as private institutions such as banks, insurance, real estate, transportation, and trading companies. Thus, the type A traditional consumption city is characterized by relatively large numbers of upper middle class white collar workers. The type B cities, in contrast, are populated primarily by self employed merchants, small factory owners, and their employees. Most of these are locals who grew up in the city and surrounding rural areas.

Of course, even in the type A cities, small entrepreneurs are the majority in numbers, but the managerial, professional, and technical workers provide distinctive characteristics to the urban social structure. These workers are employed by large bureaucratic organizations, public or private, and relocate from city to city as a result of occupational promotion, although clerical and sales workers are usually recruited and promoted locally. Sendai, Kanazawa, and Fukuoka are good examples of the type A city; Hirosaki, Okazaki, and Kurashiki are examples of type B cities. Thus, the traditional consumption types are common among Japanese cities.

Kurasawa classified the industrial cities into three subgroups. First are small, light industrial cities (type C), some of which date back to traditional textile, ceramic, and knifemaking

towns. Then there are the heavy industrial cities based on modern industrial technologies for shipping, steel, chemical, electronic, and auto mobile manufacturing. These are divided into two different subcategories: one company towns such as Hitachi, Toyota, and Minamata (type D); and those with petrochemical complexes as in Yokkaichi, Kawasaki, and Mizushima (type E). Small industrial towns (type C) had flourished in the late nineteenth and early twentieth centuries, but generally declined by the late 1960s. Now these towns are typically populated by small factory owners, their employees, and small wholesale merchants. One company towns often developed in rural areas. Kamaishi city, for example, was a fishing village before the Kamaishi Iron Works was established in the late nineteenth century. Toyota city was an agricultural village before the Toyota Motors Corporation established its major plants there. The social composition of the one company town is simple, primarily consisting of the employees of the company, of course, including a handful of executives, managerial, professional, technical, and clerical employees, and a large number of blue collar workers. Typically, there are also a lot of subcontractors, merchants, and service workers. The social composition of the type E city is quite similar, but it is more complex and less visible, because there are many establishments of different large companies and the sheer size of the city is generally much larger.

Since the type D and E industrial cities have developed in the modern era, they have a purely modern industrial base, although native families may still hold estates and have some influence in the local politics. But most Japanese cities developed as traditional consumption types. Of course, they have modernized in various ways, attracting factories, universities, and tourists and developing airports, expressways, and the superexpress train lines and stations. The three largest metropolitan areas in Japan – Tokyo–Yokohama, Kyoto–Osaka–Kobe, and Nagoya – developed from this type and came to have comprehensive characteristics. In Kurasawa's typology, they are therefore placed in a special category – type M (metropolis). All three initially established their bases in the seventeenth century. As the seat of the Tokugawa shogunate, Edo (now Tokyo) established its primary functions as the center of political control.

Osaka was also formed during the Tokugawa period as the national commercial center, called "the kitchen of the world." Nagoya was simply a great castle town ruled by one of the top three Tokugawa related families. After the Meiji Restoration, Tokyo inherited its political functions from Edo, and grew to be the capital of the centralized imperial state. Osaka developed as a private commercial center, and Nagoya, a typical traditional consumption city located between the two, gradually developed manufacturing industries. By 1940, Tokyo, Osaka, and Nagoya had grown into great metropolises with populations of 7 million, 3 million, and 1 million people, respectively. During World War II, all three metropolises and many other major cities in Japan suffered heavy bombardment from the US military. However, the three metropolises had all rebuilt their industrial bases by 1955 and began to absorb huge amounts of labor from rural areas. A large number of suburban residential and industrial cities arose in the surrounding areas in the 1960s. Since 1965, deindustrialization and the shift to a service economy have been prominent in the central cities of the metropolitan areas.

Although Susumu Kurasawa's typology was originally published in 1960 and the descriptions presented here have been somewhat updated, globalization and the information technology revolution since the 1980s have dramatically affected the historical paths of cities and transformed urban social structures. Thus this typology might require further revision from the contemporary global perspective. The concept of the traditional consumption city nevertheless remains useful for illuminating the cumulative effect of historical heritage on urban structures.

traffic in women

Susan Hagood Lee

Traffic in women denotes the practice of transporting women away from their home to a distant location where they are coerced or forced into work or prostitution in slave-like conditions to the profit of their traffickers. Some 2–4 million women are trafficked annually. Women typically are lured into initial cooperation through the deceitful promise of employment at better wages than available in their home area. Traffickers target impoverished regions with few employment opportunities and transfer women to more affluent areas with a market for their labor or sexual services. Some victims are sold into trafficking by relatives or fellow villagers. Most fall prey to criminal organizations with extensive international networks which profit greatly from this lucrative trade. In many regions, legal businesses participate in trafficking under the guise of tourism or entertainment. States profit through taxes on these businesses, and corrupt officials benefit from bribes to protect the industry. In some areas, military installations and peacekeeping operations provide a customer base for trafficking. The international community has responded to trafficking with a Protocol calling on states to enact laws to criminalize all involvement in traffic in women. Heads of state have labeled this growing practice a new slave trade requiring concerted international action.

In a typical trafficking scenario, young women are recruited in their home region by agents who advertise plentiful jobs with high wages and good working conditions in another region. Advertised jobs include waitress, hostess, entertainer, dancer, model, restaurant worker, factory worker, maid, or nanny. The advertisements appeal to impoverished young women with few employment options in their home region due to poor economic development or lack of opportunities for women. The recruiting agents make the departure arrangements and obtain documents such as entertainment visas. The young women leave their home willingly in anticipation of a brighter economic future in which they will be able to contribute to the support of their impoverished families.

For many trafficked women, the journey is the first ever out of their home region.

Once at their destination, the recruiters turn the young women over to their new handler in exchange for a fee. The new handler often is a club or brothel owner who has placed an order for female workers with the recruiting agency. Sometimes the young women are presented with an employment contract in a foreign language which they must sign. The handler then takes custody of the women's legal documents and transports the women to a residence in which they are confined. The young women find themselves in an unfamiliar region, often in a foreign country. They lack possession of their legal documents and do not know the language or have any local contacts other than their traffickers. At this vulnerable point, they finally learn the real nature of their new work. They are told that they can leave only if they pay off their debts, including fees for visas, travel, food, shelter, and clothing. The employment contract is used as a seemingly legal document to coerce the young women into compliance. The women may be told that they can be arrested if they break their contract and attempt to leave. Since the police may be paid off by the club or brothel owners, this is not an idle threat.

Many trafficked women resist being prostituted. Sometimes drugs are used to placate the women and create a feeling of complicity in the criminal enterprise. Often, resistant women are severely beaten or gang raped to break their spirit. Sometimes cooperation is obtained by threatening the safety of the young woman's family. In poor regions, murders can be arranged cheaply, so such threats can be very effective. At other times, the traffickers may persuade the young women that prostitution is the quickest way to pay off their debts and regain their freedom.

There is no transparent accounting of the debts of trafficked women, however, and additional fees are added for ongoing expenses such as rent, clothing, and medical costs such as abortions. In the typical case, trafficked women never succeed in paying off the alleged debt until they become too old or too ill to be useful to the traffickers. Trafficked women are susceptible to HIV infection and AIDS as well as other sexually transmitted diseases. As their economic value diminishes, they suffer increasing abuse,

lack of nutrition, and sleep deprivation. Women's self esteem plummets with this disastrous turn in their lives. They fear the authorities and feel they cannot return home due to the stigma of prostitution. They lose any hope of economic betterment and realize they have lost their marriageability and chances for a normal life. They become depressed and unable to take action to help themselves. Even if they escape from their traffickers, the trauma of trafficking remains with them for a lifetime.

Many parties profit from trafficking. At the village level, women are sometimes sold by relatives or villagers whom they have angered by refusing a suit or divorcing a husband. Recruiting agents profit when they turn a young woman over to the customer who has placed an order. Transnational criminal networks such as the Russian Mafiya, Japanese Yakuza, and the Chinese Triads are involved in recruiting, transporting, and placing impoverished young women in cities where there is a market for sexual services. The CIA found that the Yakuza paid recruiters \$6,000 to \$10,000 per woman delivered to Japan. Unlike smuggling, where a person pays to be transported illegally, trafficking continues to pay the criminal syndicate long after the young woman is transported into the destination country. The CIA reported that Russian organized crime groups in Israel earn some \$1,000 to \$4,000 per woman per day. The profits from trafficking can then be used to finance other criminal activity such as corruption or terrorism. Trafficking in women is more profitable than other transnational crimes such as drug or arms trafficking, which do not offer ongoing income after transportation to their destination. Trafficking in women is less risky than drug or arms trafficking since there are fewer laws against trafficking in women. In many countries, trafficked women who come to the attention of the authorities are prosecuted for the crime of prostitution or expelled from the country as criminals themselves.

Legal businesses in the entertainment and tourism sectors sometimes participate in trafficking in women. Individual club owners or entertainment business associations place orders for women as entertainers or waitresses, paying recruitment fees or intermediary brokerage fees. Once hired, the women are pressured or coerced into prostitution roles in addition to

their legal waitress or dancer work. Tourism businesses such as hotels, travel agencies, and travel clubs profit from the market for sex tourism. States benefit from the taxes that such tourism and entertainment businesses render to the state treasury. Military bases fuel demand for prostitution and provide a magnet for trafficking activities. For instance, the Korea Special Tourism Association, an association of club owners near US military bases, imports impoverished women on entertainment visas to supply the military market. They charge participating clubs a brokerage fee for new recruits (Seol 2004). United Nations peacekeeping troops have contributed to the demand for prostitution, helping to create a lucrative market for traffickers. In Kosovo, UN and NATO troops constitute 20 percent of the prostitution market despite being only 2 percent of the population, according to an Amnesty International study. With the additional customers, a small scale prostitution network in Kosovo was transformed into a large scale industry run by criminal networks.

Trafficking takes place between poor regions with few employment opportunities and more affluent regions with a market for sexual services. The International Organization for Migration (IOM) reports that trafficking is growing most rapidly in Central and Eastern Europe and the former Soviet Union. The economic devastation in these regions following the collapse of the Soviet system has produced many young people desperate for employment and willing to risk migrating for work. Criminal enterprises in Moscow and Kiev transport women to countries such as the US, Germany, Japan, Thailand, and Israel, where markets exist for white prostitutes. Romanian and Moldavian women are trafficked to Asia, where their light skinned appearance makes them exotic compared to local women. Women from Kazakhstan and Kyrgyzstan are trafficked into Turkey and the Middle East.

In Asia, women from impoverished Bangladesh are trafficked to Pakistan. Rural Nepali women displaced by the Maoist rebellion are trafficked into the urban centers of India. Vietnamese and Cambodian women are trafficked to the more affluent countries of Thailand and Singapore. Korea has become both a sending country and a destination country.

Korean women are trafficked to Japan under the guise of entertainers, while Russian, Chinese, Philippine, and Central Asian women are trafficked to Korea to supply the military base towns.

In Africa, women are trafficked from Sub Saharan countries such as Ghana, Mali, and Benin to Nigeria and Libya, as well as to the western nations of Italy, Belgium, the Netherlands, and the US. African women are trafficked into the Middle East, lured by employment as domestic servants. President Obasanjo of Nigeria named international trafficking a new slave trade at a Nigeria conference on trafficking in 2000.

In Latin America, less data are available on trafficking. The IOM notes that trafficking takes place out of the war torn country of Columbia and that women are being trafficked from Latin America to the US and Southeast Asia.

Reliable figures as to the number of persons trafficked annually are hard to obtain, given the illegal nature of this activity. A 1999 CIA report estimated that some 700,000 to 2 million women and children are trafficked globally each year. The report estimated that 45,000 to 50,000 women and children are trafficked into the US annually, mostly from Southeast Asian countries. The United Nations has suggested that perhaps as many as 4 million persons are moved annually within or between countries for trafficking purposes. UN sources estimate that trafficking is a US\$5–7 billion operation annually. The ready demand for prostitution services and the ample supply of vulnerable impoverished women account for the profitability of this industry and its appeal to criminal networks.

The phenomenon of sex trafficking takes place at the intersection of poverty and international capitalist enterprises. Female sexuality is commodified and bought and sold on an international market to the highest bidder. The lack of economic development and employment opportunities for women in poor regions fuels the supply side of the equation. The commoditization of women's bodies as instruments of male pleasure contributes to the demand side of the market. Thus the structural context of poverty is coupled with the cultural devaluation of women in patriarchal societies. The AIDS epidemic has impacted the trafficking market

due to fears of contracting HIV from a prostitute and cultural beliefs concerning the curative and rejuvenating effect of sex with a virgin. The outcome has been to lower the age of women recruited in trafficking enterprises, with virgin girls fetching a higher price on the international prostitution market.

In 2000 the United Nations adopted a Protocol to Prevent, Suppress and Punish Trafficking in Persons, Especially Women and Children. The Protocol defines trafficking as the "recruitment, transportation, transfer, harboring or receipt of persons, by means of the threat or use of force or other forms of coercion, of abduction, of fraud, of deception, of the abuse of power or of a position of vulnerability or of the giving or receiving of payments or benefits to achieve the consent of a person having control over another person, for the purpose of exploitation." When a person under the age of 18 is recruited into prostitution, the Protocol considers it trafficking even when fraud and coercion are not involved. The Protocol considers consent to trafficking irrelevant, since consent is typically based on the deceitful exploitation of economic vulnerability. Under the terms of the Protocol, crossing an international border is not necessary to qualify as trafficking. Trafficked persons are seen as victims of crime to be protected and assisted, not criminals involved in prostitution. The Protocol requires states to facilitate and accept the return of trafficked persons to their country of origin. Repatriation should be voluntary and take victim safety into consideration.

The Protocol calls on signatories to enact national legislation in order to criminalize trafficking activities and offer assistance to victims. In response, the US enacted the Trafficking Victims Protection Act of 2000. It distinguishes between "severe" forms of trafficking (those involving fraud, force, or coercion) and sex trafficking (other sorts of commercial sexual activity). The Act mandates that severe trafficking be included in the annual State Department country reports on human rights, and it sets minimum standards for countries to meet in order to receive certain forms of assistance from the US. It provides for a new non immigrant visa category, a "T" visa, for victims of severe trafficking who would suffer extreme hardship upon removal from the US.

transcarceration

Robert Menzies

Commonly linked with the revisionist social control and new penology literatures of the 1980s and 1990s, transcarceration refers to the wide spread profusion of regulatory organizations, practices, authorities, and subjects across and beyond traditional boundaries of institutional governance in contemporary western societies.

The intellectual impetus for the transcarceration concept derived in large part from Michel Foucault's (1977) writings on the rise of the disciplinary society and "carceral archipelago"; from Andrew Scull's (1984) critique of conventional approaches to understanding community criminal justice and mental health initiatives; and from Stanley Cohen's (1985) analysis of late twentieth century "master patterns" of deviancy classification and punishment. From a range of disciplinary and substantive perspectives, theorists and researchers in the 1980s sought to account for the failings of the diversion, decarceration, rehabilitation, and reintegration schemes of the prior two decades – and of the post World War II liberal reconstructionist and civil libertarian political philosophies that these movements had embodied.

Transcarceration became both a metaphor and empirical yardstick for the unsettling paradox that state and civil projects aimed at downsizing control structures were in practice having precisely the opposite effect. Instead of disestablishing the old regimes, destructuring movements were generating hybrid systems of institutions, agencies, and programs which were multi sited, unbounded, virtually impossible to disentangle or evade, and widely dispersed through the contemporary landscape of the "punitive city" (Cohen 1985). In judicial, penal, psychiatric, welfare, and other arenas of human categorization and containment, traditional modernist dualisms between formal and informal, public and private, inside and outside, coercion and provision, were breaking down. Critical observers sought to explain how, having been freed from the oppressive regimes of prisons, asylums, and other exclusionary sites of confinement, untold thousands of citizens were finding themselves subject to new inclusionary modes of control which operated as appendages, not alternatives, to the systems they were supposed to eclipse.

An accumulating body of research showed how, with the proliferation of these "wider, stronger, and different nets" (Austin & Krisberg 1981), people and knowledge were circulating through jails, prisons, probation, parole and welfare offices, hospitals, clinics, halfway and boarding homes, the streets, and assorted other points of enclosure and transmission at ever accelerating rates. The grim consignment of

former patients and prisoners to lives of urban poverty, disease, drugs, and violence was disabusing even its most ardent exponents of the notion that decarceration was truly benefiting this burgeoning population of “conscript clientele” (Friedenberg 1975). Moreover, homelessness – the fate of so many deinstitutionalized people – was ascending into public consciousness as arguably the foremost domestic social problem of the 1980s. Concurrently, while James O’Connor’s “fiscal crisis of the state” (1973) might have initially triggered the closure of some public mental institutions (and many beds), the numbers of psychiatrized people continued to escalate as the average length of inpatient committals steadily declined; as mental health networks increasingly extended into general hospital wards, community clinics and the private sector; and as more and more patients faced the experience of being dumped destitute into inner cities only to be later rerouted into criminal contexts (a dynamic that persists into this new century). As for the penal realm, the decarceration era was ironically followed, in short order, by the unprecedented spasm of expansion that became the hallmark of neoconservative law and order programs through the 1980s and early 1990s, culminating in a combined jail and prison population of more than 2 million in the US alone.

By the 1980s, progressive scholars and activists were nearly united in acknowledging that the inclusionary agenda of destructuring and decentralization proponents had not only been ruinous in its own right, but had also sparked the punitive backlash and moral panics (Goode & Ben Yehuda 1994) that came to dominate late twentieth century penal politics. Socio legal scholars, radical criminologists, and anti psychiatrists, among others, came to recognize, in Stanley Cohen’s elegantly minimalist phrase, that “we blew it.” Accordingly, they set about rethinking some deeply held beliefs about the inherent benevolence and effectiveness of liberal policies and practices in corrections, mental health, and related fields. Moreover, the overarching constructs that had propelled the penal reform era of the 1960s and 1970s – the bifurcation of state and civil society, the public/private divide, the emphasis on individual autonomy and negative rights claims, the very ideas of decarceration and social control (the latter

subsequently described by Cohen (1985) as a Mickey Mouse concept) – were generally agreed to have lost their purchase. What was needed, in the eyes of many, was an utterly new “vision of social control.”

The transcarceration construct therefore emerged as a conceptual move toward the rehabilitation of social control theory, and the reworking of critical praxis in relation to this new hypermodern, pluralistic world of penalty. Among other aims, revisionist academics and practitioners sought to deinstitutionalize the analysis of control structures and cultures by adopting interdisciplinary, holistic, structurally informed, and materially grounded approaches to the study of social order. Such work is sensitive to the nuances, diversities, and contradictions of all regulatory practices; to the hierarchies of class, gender, race, ethnicity, sexuality, nationality, generation, and (dis)ability within which control and counter control strategies play out; to the daunting capacity of systems and officials to neutralize, subvert, and coopt even the most well conceived of reform efforts; and to the cascading (and often unanticipated and unintended) effects of progressive ventures.

The transcarceration construct in many ways prefigured, and continues to resonate through, the legion of writing that has multiplied over recent years within the fields of moral regulation, legal pluralism, and governmentality studies, and on topics as diverse as administrative criminology, actuarial justice, critical penology, the risk and surveillance societies, technologies and cultures of control, and governance of the self. Their variations notwithstanding, these contemporary works are conjoined by what is arguably the key idea yielded from the 1980s revisionist social control literature – namely, that a paradigmatic redrawing of territorial, legal, institutional, and discursive geographies has occurred in the sphere of human regulation, and that any contemporary reformist project must either engage with the actualities of these latterday transcarceral arrangements, or resign itself to failure.

transcription

Linda Skrla

Transcription is the process of converting recordings of social or communicative human interaction into written text. Transcribing audiotaped or videotaped speech acts, conversations, interviews, or other forms of human engagement might be considered to be a relatively simple task, largely a chore or a secretarial matter. After all, to transcribe, one need only write down what was said by the parties involved in the interaction.

The writing down of what was said, however, is viewed by researchers in a variety of fields (including linguistics, communication, psychology, sociology, anthropology, education, and nursing) as only part of the transcription task. In addition to *what* was said, transcription often involves attending to *how* things were said (timing, volume, emphasis, nonverbals), how they were *not* said (silences), and *where* they were said (context and environment).

Furthermore, opinions in various disciplines differ as to what the product of the process of transcription represents. In some instances, a transcript is viewed as a transparent, printed representation of the recorded interaction (a *hard copy*), and it becomes the actual data used for further analysis. Traditions in other fields position transcripts as mediated forms of the original data that are useful aids for analysis, but that never are considered to be identical to the audio or video recordings, which remain the original data and are the primary records for analysis. Other researchers view the transcription process as theory laden work that fundamentally alters the original data. Kvale (1996), for instance, argues that transcription is a form of translation because of the transcriptionist's key decision making role.

Numerous decisions must be made when a transcript is prepared, and various fields have developed sets of conventions to guide individual researchers engaged in the process. Opinions differ among fields as to whether the researcher should or must do his or her own transcription work or whether the task can be delegated to others. In either case, transcription conventions cover such considerations as page layout, placement of verbal and nonverbal information, timing (overlaps, pauses, silences), choice of orthographic, phonetic, or combined representation, discourse unit (utterance, proposition, or turn), and symbols. Research fields vary as to the existence of and fidelity to an accepted set of transcription conventions. Conversation analysis is an example of a field that has a widely used set of conventions, the Jeffersonian Transcription System, developed by Gail Jefferson. Examples of symbols from the Jeffersonian System are as follows:

1 Pauses (numbers in parentheses indicate in seconds and tenths of seconds the length of the interval)

J: When I was (0.6) oh five or six we moved

K: To your current house?

2 *Sound stretch (a colon indicates that the prior sound is prolonged; multiple colons indicate a more prolonged sound)*

A: I re:::ally didn't like it

3 *Emphasis (indicated by italics or underscoring; the larger the italics, the greater the stress)*

D: That one is mine

S: NO it is not either yours it's MINE

4 *Transcriptionist doubt (other than timings of intervals, items enclosed in single parentheses are in doubt)*

B: Who were you there to meet?

N: The same guy from the day before (Jeremy)

Standardized transcription conventions such as these have proved useful for handling, comparing, and sharing of language data. However, these conventions have come under criticism for what they do *not* do, such as representing participants' situated meanings, attending to researcher subjectivity, and acknowledging contextual factors. Mishler (1991) and others have argued for a view of transcription that acknowledges the fact that the process is both interpretive and constructive. In other words, exploration is needed of how researchers create representations in their transcripts that follow from their purposes, theories, and worldviews and how this process shapes and constrains subsequent interpretations derived from analysis of transcript data. Suggestions for how this might be accomplished have included calls for researchers to become more reflective about their transcription practices and for them to include discussions of transcription issues along with the presentation of their findings.

transgender, transvestism, and transsexualism

Dave King and Richard Ekins

Twenty years ago a sociological encyclopedia would not have included a separate entry featuring cross dressing or sex changing. The medicalization and pathologizing of these phenomena under such categorizations as transvestism, transsexualism, gender dysphoria, and intersex ensured that cross dressing and sex changing were considered, in the main, to be the domain of medicine and psychology. The small number of sociological studies relating to "transvestism" and "transsexualism" was considered to be a peripheral concern of historical sociology, the sociology of deviance, and feminism and gender studies. Only Garfinkel (1967) and Kessler and McKenna's *Gender: An Ethnomethodological Approach* (1978) provided a hint of the importance of transsexualism to the discipline of sociology.

This situation began to change in the mid 1980s, a development marked by the more wide spread use of the term “transgender” among “transvestites” and “transsexuals” themselves, and the establishment in 1986 of the world’s first “transgender archive” housed in a university sociology department. The sociological literature on the topic is still small, but much of sociological interest is to be found in the fields of social anthropology, lesbian and gay studies, women’s studies, and (especially in recent years) cultural studies. Most recently, transgender studies is emerging as a specialism in its own right.

The inclusion of an entry on transgender attests both to the greater visibility of transgender phenomena in contemporary society and to the greater interest shown in it by sociologists and other scholars in the arts and social sciences. However, before we trace the evolution of the term transgender, its various meanings and the social phenomena to which it relates, we must go back to the end of the nineteenth century and consider the emergence within medical discourses of what came to be known as transvestism and transsexualism. The immediate origins of contemporary Euro American conceptualizations of transgender are to be found in the latter half of the nineteenth century, a period which saw the beginning of what Foucault in his *History of Sexuality* (1979) terms the “medicalization of the sexually peculiar.” It was during this period that psychiatrists and other medical practitioners began to puzzle over the nature of people who reported that they felt like/dressed as/behaved like a person of the “opposite sex.” Such people were initially situated within the category of homosexuality or – in the then common terminology – “inversion,” but in the writings of Magnus Hirschfeld and Havelock Ellis a separate category emerged. The term transvestite was coined by Hirschfeld in 1910 to refer to those men who enjoyed behaving and dressing as women, or, indeed, wished to *be* women, and both he and Havelock Ellis (who preferred his own term, *eonism*) argued that this did not necessarily involve homosexuality. Neither Hirschfeld nor Ellis employed the then fashionable language of degeneracy or perversion, but they nevertheless viewed such people as anomalies to be explained within a medical framework. Edward Carpenter in 1911 translated

Hirschfeld’s term as “cross dressing,” a term which along with that of “cross dresser” has become popular in recent years, being seen to avoid the medical and erotic connotations with which “transvestite” has come to be associated.

Hirschfeld first used the term transsexual in 1923. The first “full” male to female (MTF) “sex change” operation (vaginoplasty, following castration and penile amputation) was performed in Berlin at Hirschfeld’s Institute for Sexual Science in 1931. However, it was not until the early 1950s following the widespread publicity given to the cases of Christine Jorgensen in America and Roberta Cowell in Britain (both MTF transsexuals) that the terminology of transsexualism was adopted to distinguish those seeking to “change sex” from those who were “content” to cross dress. During the 1960s “sex reassignment” began to be carried out on an experimental basis in some medical centers, partly due to its legitimization by John Money’s influential ideas on the development of gender. From that decade the professional literature on the topic began to grow rapidly. At this time the work of the US based German endocrinologist Harry Benjamin came to the fore. He argued that carefully selected transsexuals could benefit from “sex reassignment” procedures and for a number of years his *Transsexual Phenomena* (1966) was referred to as the transsexual’s Bible.

In the early 1970s the term gender dysphoria entered the literature and quickly became the preferred term used in the titles of medical conferences, associations, books, and articles. However, it was the term gender identity disorder that became enshrined in the official diagnostic nomenclature (American Psychiatric Association, 1973).

Although, within the medical literature, transvestites and transsexuals began to be differentiated from one another from the 1950s onwards, the subcultural groupings that emerged around the same time included both, at least until the early 1980s, when separate transsexual organizations began to consolidate. At the individual career level there was some slippage between the two categories and a more complex picture than that provided by transvestite/transsexual began to emerge.

The medical centers that began to experiment with sex reassignment during the 1960s provided opportunities for some sociologists to

encounter patients seeking such procedures. One such sociologist was Harold Garfinkel, whose *Studies in Ethnomethodology* with its germinal chapter on the transsexual "Agnes" was published in 1967. Garfinkel was interested, though, not in transsexualism (in fact Agnes was initially thought of as intersexed), but in how Agnes's experiences demonstrated the "rules" of doing gender. This approach to transsexuals continued in the work of Kessler and McKenna, among others.

Two other sociologists who were able to study transsexuals via the medical centers were Kando and Sulcov. Kando's *Sex Change* (1973) research began in 1968 and documented the transition of 17 MTF transsexuals who had received surgery at the University of Minnesota. Drawing heavily on the work of Erving Goffman, Kando reported how transsexuals dealt with issues of stigma and information management and how their identities were positioned in relation to the emergence of feminist critiques of traditional femininity. Sulcov, in an unpublished PhD thesis entitled "Transsexualism: Its Social Reality" (1973), focused on the construction of the category "transsexual" by both the medical profession and transsexuals themselves – a theme taken up by a number of later writers.

Other opportunities for research opened up during the 1960s as subcultural groups and organizations began to develop firstly in relation to transvestism and, later, transsexualism. An important figure here was the influential "trans" activist Virginia Prince, whose American organization the Foundation for Personal Identity Expression (for heterosexual transvestites) provided a model for many others around the world. Taylor Buckner carried out a survey of 262 members of Prince's organization for his Masters degree in 1964. Buckner's only publication on the topic contains some useful sociological material. However, the thrust of his article (appropriately published in the journal *Psychiatry*, 1970) was to provide an etiological theory of what he calls a "socially induced 'pathology'": an approach that by that time was out of favor within the discipline of sociology.

Two developments within sociology itself also shaped the approach to transgender phenomena in the mid 1960s. Firstly, there was the rise of the sociology of deviance and a general

interest in "alternative" lifestyles reflecting some thing of what was happening in Anglo American society at the time. This led in America to a number of empirical accounts of transvestites and transsexuals and their social worlds (e.g., Driscoll 1971; Feinbloom 1976). The second influential development was the (re)emergence of the women's movement and the interest in gender. The distinctions which writers such as John Money and Robert Stoller had drawn between sex and gender were enthusiastically embraced by some sociologists as demonstrations of the lack of a necessary link between gender roles and biological sex. Ann Oakley's influential *Sex, Gender and Society* (1972) drew on this literature and used transsexualism as a demonstration of the independence of sex and gender.

The new sociologists of deviance of the 1960s were generally "on the side" of many of the deviant groupings who were questioning conventional norms at that time. The norms and laws relating to such phenomena as homosexuality, drug use, and abortion were seen as oppressive instruments of power against which the deviant was rebelling. The rebels against gender norms, however, were feminists and, on the face of it, transvestites and transsexuals appeared to be embracing what feminism was questioning. While "radical drag" and "gender blending" were part of the gay liberation scene of the time, changing the content of what were beginning to be called "gender roles" was not what transvestism and transsexualism were about. However, some commentators did consider transvestites and transsexuals as "revolutionaries" who challenged the notion of ascribed gender in the sense that they broke the congruity between sex and gender. These ideas would not seem out of place alongside those of some of the queer theorists that we discuss below.

However, it was the work of Janice Raymond that dominated discussions of the political significance of transsexualism during the 1980s, when her particular style of radical feminism was in the ascendant. Raymond's *The Transsexual Empire* (1980) argues that transsexuals are among the victims of patriarchal society and its definitions of masculinity and femininity. The creation by the male medical profession of transsexualism and its "treatment" by means of sex change surgery obscures the political

and social sources of the “transsexual’s” suffering. Instead, “transsexuality” is conceptualized as an individual problem for which an individual solution is devised; the “real” problem – patriarchy – remains unaddressed. Moreover, Raymond sees MTF transsexuals and in particular those who identify as lesbian feminists as part of a masculine attempt to undermine feminism. Although Raymond’s book probably had little impact on what she called the “transsexual empire,” it was influential in some feminist circles. Riddell’s early and detailed critique of 1980 was not widely available until it was republished in 1996 (Ekins & King 1996) and, in line with the effect of radical feminism in other areas, most critics of Raymond’s position were intimidated into silence. Stone’s (1991) landmark riposte heralded a new era of transgender activism and theorization which drew heavily on postmodernism and the newly emerging queer theory. Since then, other critiques of Raymond’s work have been published (notably, Califia 1997).

Over the years a number of other empirical studies have appeared, mostly in America and the UK. Woodhouse (1989) reported on her research carried out from a feminist perspective into a small group of English male heterosexual transvestites and is unique for the attention given to their wives. Bolin (1988) followed a small group of North American transsexuals over a period of two years as they transformed their status from that of man to that of woman. In her use of the anthropological concept of liminality she anticipated one of the themes taken up in the theorizing of the 1990s. The first published sociological account from Australia was Perkins’s study of a group of transsexual prostitutes in Sydney, somewhat misleadingly entitled *The “Drag Queen” Scene* (1983). Lewins’s (1995) study focused on the social process of becoming a woman. This study was based upon interviews carried out in the early 1990s with over 50 MTF transsexuals attending a gender dysphoria clinic in Melbourne.

Rich in empirical data, Ekins’s (1997) study also contributed theoretically to exploring the interrelations between sex, sexuality, and gender; self, identity, and social world; and expert, member, and lay knowledge, as they develop over time. Using the methodology of grounded theory, Ekins developed the important conceptualization of “male femaling” which has major

ramifications for both the field of transgender and for the analysis of sex and gender more generally.

One theme within the sociology of deviance that was stimulated by the labeling theory of the 1960s was the study of the origins and applications of social labels. In this vein King (1993) sought to understand the nature of transvestism and transsexualism as social categories and documented how and why they have emerged, how they are applied, and their consequences. His work was based on a study of the medical literature, a large number of media reports, fieldwork with transsexuals and transvestites, and, most importantly, interviews with surgeons, psychiatrists, and psychologists and others working in this field. More recently, the historical work of Meyerowitz’s *How Sex Changed* (2002) has charted the emergence of transsexualism in America.

As we have seen, the terms transvestite and transsexual had emerged within a medical context and by the 1970s had become enshrined as diagnoses to designate what were seen as essentially pathological phenomena – gender identity disorders. Although used by transvestites and transsexuals themselves, the terms remained grounded in professional discourse. By the late 1980s some transvestites and transsexuals were beginning to use the term transgender in an inclusive, “umbrella” sense to encompass both identities. In due time other “gender variant” people (e.g., drag queens and kings and intersexed people) have come to be included within the umbrella term. By the early 1990s it became common to find references to the “transgender community,” although the use of the term has not been accepted by all. Although the term transgender has also entered medical and professional discourse (e.g., *International Journal of Transgenderism*), it nevertheless retains its essentially positive and non pathological meaning. By the mid 1990s Ekins and King (1996) were able to write of the “emerging field of transgender studies.” This was seen to encompass the personal experiences of transgendering, the different ways in which those experiences have become socially organized, the ways in which those experiences have been controlled principally by means of medicalization, and the various political issues raised by transgendering.

It is evident that the medical categories of transvestite and transsexual did not encompass the whole range of what we now think of as transgender phenomena. Although some of those who sought sex reassignment had been or were involved in female impersonation for entertainment purposes, the phenomenon of drag itself avoided the medical gaze. With the exception of Esther Newton's important ethnography (*Mother Camp*, 1972), drag also avoided the gaze of social scientists until the 1990s. Since then, Tewkesbury and Gagne and Schacht and Underwood have updated the story. Similarly, those people with physically intersexed conditions were absent from the social science literature with one notable exception – Foucault's study of *Herculine Barbin* (1980). Born females who "transgendered" were dealt with mainly in the literature on lesbianism. Little reference was made to the literature on transgenderism in non contemporary western cultures, except to point to the ubiquity of the phenomenon.

A number of these gaps in the literature have begun to be filled since the early 1990s. There is growth in the literature on "transgender" related phenomena in non western cultures. Most of this literature has focused on North American indigenous cultures (e.g., Fulton & Anderson 1992), although there is work on other cultures. Recently, there has been a surge of anthropological interest in transgender, principally in Southeast Asia and in South America (Kulick 1998). Some of this literature has focused on conceptions that have developed without the influence of western medicine, such as the idea of an institutionalized "third" gender or liminal gender space. Nevertheless, it is also evident that western discourses of transgenderism have been exported to many parts of the world and are usurping or are heavily influencing more traditional notions of gender and "transgender" phenomena.

Academic attention has also begun to focus on those people with intersexed conditions. This has been partly stimulated by the development of a more visible and vociferous intersex community. One of the main issues here has been to question the practice of surgically forcing intersexed infants into sexed categories where there is no medical need. Kessler (1998) discusses the ways in which intersex "transgressions" call into question the whole system of binary genders.

One option that was not covered by the medical categories of transvestism and transsexualism was the possibility of living as a member of the other sex without undergoing genital surgery. It was known, of course, that this was a route taken by many transgendered people. Indeed, for most female to male (FTM) transsexuals it has remained the only option because of the inability to surgically create a satisfactory penis. However, what was not considered was that this possibility – women with penises and men with vaginas – might be an acceptable status in its own right. Virginia Prince had argued consistently that transvestism was not about sexuality (the erotic) or sex (the body), but was about gender (the social). She argued that it was possible for a man to be a woman socially without altering the body – something which she herself has done since the late 1960s, when she began to refer to herself and others like her who lived as members of the other sex but without surgical interventions as "transgenderal" and, later, as "transgenderist." Prince explicitly distinguishes this group from transvestites and transsexuals.

Until the early 1990s FTMs and cross dressing females were not very much in evidence in either the literature or in the transgender movement. Since then, FTMs or, more accurately, "female bodied transpeople" to use Cromwell's (1999) term, have become a more visible feature of the transgender community and in fact have come to play key roles within that community and within transgender politics. They have also been prominent in the emergence of transgender theory. Judith Halberstam's *Female Masculinity* (1998) is a key work in this regard. More specifically, it is female bodied transpeople who have led the way in linking transgender to revolutionary socialism (Leslie Feinberg's *Transgender Warriors*, 1996); to radical body configurations and pansexualism (Del La Grace Volcano's *Sublime Mutations*, 2000); and to the beginnings of a hitherto neglected transgender approach to class, race, and masculinity (Halberstam 1998).

The rise in popularity of the term transgender has paralleled the rise in academia of queer theory, within which crossing the gender border is seen as subversive and transgressive. Much of this work falls outside the boundaries of sociology and is to be found within what has

come to be called cultural studies. This approach has been particularly influential with some trans activists and academics and raises radical questions about the binary and fixed nature of gender categories themselves. Especially influential was Judith Butler's work on gender as performativity. Also influential was Marjorie Garber's *Vested Interests* (1992), which drew on examples ranging across history, literature, film, photography, and popular and mass culture: from Shakespeare to Mark Twain and Oscar Wilde, through transsexual surgery and transvestite support groups, to Elvis Presley and Madonna, indicating the ubiquity of transgender phenomena. In a phrase echoed in a number of other writings she argued "transvestism is a space of possibility structuring and confounding culture: the disruptive element that intervenes, not just a category crisis of male and female, but a crisis of category itself" (p. 17).

It is within this context that the phenomenon of the "drag king" has emerged. The western world has been familiar with drag for a long time, but the term has most commonly been applied to men performing in women's clothes, although it has also been used to apply to women in men's clothes. Only recently though has the use of the suffix "king" emerged. Apparently beginning in the late 1980s with the term becoming more widespread through the 1990s, drag kings entered the academic literature with the publication of Halberstam's *Female Masculinity* (1998). Usually viewed through the lens of queer theory, drag kings are viewed not simply as the female counterparts to drag queens, but as a much more subversive phenomenon because of the mainstream view of masculinity as non performative.

Stone's (1991) article can also be seen to provide the starting point for the emergence of a postmodernist approach to transgender, which is now seen by some to be at the very cutting edge of debates about sex, sexuality, and gender. This approach has achieved a position of prominence in a number of recent contributions to cultural studies and queer theory. Stone's image of transsexuals as "outside the boundaries of gender" chimed in well with many of the themes in cultural studies and queer theory, and provided an approach that has been developed extensively in recent years. This idea points to the position of trans people as located

somewhere outside the spaces customarily occupied by men and women, as people who are beyond the laws of gender. The assumption that there are only two (opposite) genders, with their corresponding "masculinities" and "femininities," is opened up to scrutiny. Instead, it is suggested that there is the possibility of a "third" space outside the gender dichotomy to make sense of various gendered identities that transcend dimorphism. Within this approach the idea of permanent core identities and, for some, the idea of gender itself, disappear. The emphasis is on gender transience, fluidity, and performance, as in Kate Bornstein's *Gender Outlaw* (1994).

Despite this late modern/postmodern approach with its emphasis on diversity, fluidity, and moving beyond the rigidities of the binary gender divide and its celebration of new combinations of masculinity and femininity, for most, in the professional and transgender communities, as in society at large, the binary view of gender prevails.

transgression

Lauren Langman

Transgression, violating a formal rule and/or moral principle, crossing a boundary of acceptable conduct, or exceeding a social limit, is central to understanding social life in general and deviance in particular (Jenks 2003). Although there is no clear cut distinction between the criminal and moral, few societies ignore theft, while publicly breaking wind or picking one's nose is not usually punished as a criminal offense. At various moments, insanity, masturbation, homosexuality, and adultery have

been considered transgressions that have been deemed criminal and/or pathological. At some times, imputed transgressions such as witchcraft were harshly punished. A great deal of social history has concerned the attempts of competing groups to legislate morality – and most of these have been futile.

There are dialectical relations between what is deemed "normal" and what is "pathological" and hence constrained or isolated. Normative standards of right and wrong or good and evil are typically "contested terrains" with "policed boundaries" where powerful actors attempt to define "acceptable" action, thought, and belief. Yet indeed, establishing limits may itself foster the desire to transgress those limits because transgression can be "fun." How does society attempt to thwart transgression, and if that fails, how are transgressions punished? At the same time, how and why are some people impelled to transgress, and yet while transgressions are impelled by individual desire, notwithstanding, some transgressions elicit widespread revulsion, disgust, and outrage, even if they are not against the law?

A long history of thought has attempted to define "good" and "evil." While this has typically been the realm of religion, after the Enlightenment dethronement of faith it has been a concern of sociology. The nature of the "desirable" and "acceptable" ways of being and doing remain vital concerns. Today however, we are informed by the insights of Nietzsche, Durkheim, Freud, and Foucault, as well as Bataille, Bakhtin, Victor Turner, Mary Douglas, and many other scholars who have pondered the ways society constructs limits as well as desires to transgress.

Nietzsche (1989) was among the first to suggest that the "good," as kindness, charity, and humility, was typically an expression of the politics of *ressentiment* in which weak, petty, and banal people, typically majorities, imbued with a "slave mentality" of conformist subjugation, would attempt to stifle the "will to power" of the strong and noble, those who would transcend themselves. While Christian religion sustained servitude and the suppression of will, with modernity and the Death of God, "modern" forms of truth and power fostered the repression of will that in turn enfeebled the person and stunted his/her self fulfillment as an

Übermensch, the one who authentically transcended him/herself in overcoming the restraints of debilitating mediocrity and conformity. If that transcendence might require transgression, indeed cruelty and/or disdain of inferiors, then so be it. Transgression for Nietzsche challenges, overthrows, spoils, and questions the unquestionable (Jenks 2003: 81).

For Durkheim (1947 [1898]), society as a "moral order," expressed in its *conscience collective* (collective consciousness), depended on shared goals, values, norms, and beliefs, about words, deeds, and actions considered "normal," "right," and those considered "wrong," indeed "pathological," and subject to some kind of repressive sanction. This was evident in the laws that expressed the shared sentiments of tightly bound traditional societies or more diffuse modern societies. Such laws might be repressive or restitutive. Yet deviance was socially generated and inevitable in any society. The social structure fostered transgressions to periodically foster the collective outrage that would affirm the sanctity of norms through dramatic, emotion laden expiatory rituals. Even in a society of saints there must be sinners to affirm the rules among those untouched by the transgression and rekindle the solidarity of the society. Punishment brings the "decent people" together. But so too, at various moments such as festivals, episodic indulgence in the otherwise transgressive could celebrate norms and renew social bonds. At the same time, transgression can be a basis for social change as certain laws and norms are contested. At periods of social change marked by anomie, deviance becomes the basis for innovation and indeed, adaptation to new moral circumstances. What is considered transgressive in one era often becomes acceptable in another era and normative even later. Consider the changing notions of sexuality. At one time, masturbation, premarital sexuality (especially of women), and/or homosexuality were seen as psychopathology, criminality, or both.

In a similar vein, Mary Douglas (1966) has examined the relation of "purity" in which pollution, as transgression, threatens both elite power and the moral codes of a society. Thus certain kinds of people and/or actions must be kept separated, if not eradicated. Just as notions of ritual pollution safeguarded the traditional caste system of India by affirming social

boundaries, so too have various constructions of purity sustained certain class, race, or sex/gender boundaries. This can be seen in debates over immigration policies, gays in the military, and even the legality of gay marriage. Those who are "polluted" by virtue of their status or actions, often of a sexual nature, need to be excluded or isolated, lest their pollution "harm" the society as boundaries and norms are challenged.

Foucault, like Durkheim, looked at social structures. His concerns were the smaller institutional structures in which expertise was intertwined with power. He suggested that the construction of norms and definitions of transgression were not simply collective judgments, but indeed a reflection of localized institutional knowledge/power embedded within expert generated systems of meanings that define who and what is transgressive and prescribe the appropriate actions. Thus, for example, with the growth of rationality in European commerce, governance, and culture, self control and a methodical approach to everyday life became valued. The thoughts and behavior of the mad, the "unreasonable," the uncontrolled became stigmatized as "deviant." Thus as "madness" replaced leprosy as the socially required expression of deviance, psychiatry emerged as a system of knowledge/power whose "scientific" discourses "explained" insanity and prescribed its treatment, the "sequestration of unreason" in asylums (Foucault 1988 [1965]). In much the same way, Foucault argued that wardens and physicians possessed power/knowledge embedded in discursive practices that "explained" criminal or medical deviance, prescribed a remedy through their gaze and "expertise," and enhanced the power of expertise.

Similarly, for Jervis (1999), the transgressions of the modern are defined by demands of "purposive control and rationality in face of, if not contestation with the repressed other side, the irrational, uncontrolled otherness of the primitive, the insane, the woman and the debauchery of the carnival." The "otherness" of transgression is feared as it questions power. That "otherness" is not only feared but also desired and therefore tabooed, rendered disgusting to preserve the "purity" of rational yet repressed modernity.

Such inquiries raise questions about *how* the normative is socially constructed, defined, and

sustained and just *why* certain acts, beliefs, and thoughts are proper. In many cases, the transgressive has been punished by death, and often that death was the result of long, slow, painful, public torture. With modernity, transgression was more often punished by sequestration in institutions. Nevertheless, it is the society that creates experts who define and treat the socially generated transgression.

TRANSGRESSION AND DESIRE

As noted, transgression often involves sexuality. In the Victorian era, a “fallen” woman who lost her “virtue” was rendered an immoral outcast, not suitable for marriage. By the end of World War II, the majority of western women had become sexually active before marriage. Today, in the advanced countries, most unmarried youth are sexually active. Sexuality has a long history as a binary in opposition to culture. The construction of unbridled sexuality as transgressive and worthy of retribution was seen in the destruction of Sodom and Gomorrah as punishment for their sexual excesses. This set the tone for the Israelites’ opposition to the cultic religions of Baal and Ishtar in which temple prostitution was an essential part of fertility rituals. As an expression of nature, as passion, irrationality, and even death (orgasm as *la petite mort*), sexuality has stood opposed to order and control. This legacy informed Christianity, especially the teachings of Paul and later Augustine, and again in its conquests over paganism. When medieval Christianity became more tolerant of desire, Protestantism would reaffirm asceticism and denial.

The antagonism of civilization and desire, the binary of order versus passion, and the inherent tendency of desire to transgress limits were most clearly articulated by Freud; sexual and aggressive desires were the bases of motivation, while civilized society demanded restraint and control. Transgression presupposed desire, while taboos would prohibit gratifications that would render one dirty, polluted, and dangerous, and perhaps endanger the group. For Freud, the primary taboo was incest; the Oedipal desire of the boy for his mother was repressed or displaced due to the fear of castration as retaliation by the father. Taboo was one

of the earliest forms of conscience, internalized social controls of desire.

In much the same way, excreta became tabooed. Freud argued that civilization provided beauty, cleanliness, and order, aka an anal obsession. Civilization required limiting sexuality through rendering most erotic desires and/or their object(s) as tabooed and hence repressed. To ensure that people harmoniously worked together for the sake of collective adaptation, desire needed to be sublimated into work while libidinal aims (gratification) were inhibited so as to enable social ties. Yet such taboos fostered the very desires for transgression that they might thwart. But neither the desire nor the prohibition was likely to abate. However, the repression of desire, sustained by a punitive superego, held most transgressions in check, though the individual would suffer from his/her guilt.

Following Freud, while informed by Sade and Surrealism, Georges Bataille saw taboos on sex and violence rooted in the requirements of economic survival for the tribe. Bataille celebrated eroticism, sexuality purely for the sake of pleasure in the face of finitude – ultimately death. But at the same time, transgressions were ritualized violations of taboos such as in war, sacrifice, or the orgy. From what has been said, transgression is often a reflection of a desire for the tabooed, and indeed, desire is aroused because the act is “prohibited” and gratification rendered artificially scarce. In other words, if the society did not construct prohibitions, then people would not desire what is prohibited.

Finally, it must be noted that Freud and Marxists such as Wilhelm Reich, and later Herbert Marcuse, argued that sexual repression fostered the conformity required for workers in a capitalist system. But with the rapid expansion of consumer society after World War II, it became necessary to ease the restraints of repression so that people would spend rather than save money. One of the main ways impulse driven consumerism was encouraged was by linking it to sexuality – sex sells and the erosion of sexual constraints encourages the erosion of thrift and frugality. But society needed to “normalize” sexual transgression, thus it began to encourage fantasies of sexual fulfillment that would be obtained by consuming a particular commodity. Thus societies would tolerate the

premarital sexuality of consumers as a form of what Marcuse termed "repressive desublimation," encouraging seeming freedom in the service of domination. Yet as has been seen, the greater toleration of sexuality, straight or gay, has also rekindled a number of fundamentalist movements that would oppose toleration for what had heretofore been transgressive.

THE SEQUESTRATION OF TRANSGRESSION: SPATIAL AND TEMPORAL ISOLATION

As Foucault noted, asylum psychiatry sought to isolate unreason if it could not be transformed. In a similar way, societies provide marginal sites, zones of transition where transgression is tolerated. Victor Turner (1969) has argued that social structures foster "anti structures," marginal or liminal "in between" sites where transgressions are tolerated as long as they are isolated from the centers of the society.

In most societies, even those that are quite repressive, the transgressive that is strongly repressed will be desired. Yet perhaps because of that repression it can and will be available. Just as Victorianism fostered bordellos, and Prohibition fostered the "speakeasy," cultures provide encapsulated realms and sites where the otherwise prohibited finds toleration. Thus in certain eras, bordellos, gay bars, or S/M dungeons were sub rosa, hidden to most outsiders. Similarly, every major city in the world has regions where drugs and many kinds of sexual pleasures can be found, even when deemed criminal.

There are certain times that allow, if not encourage, transgression such as vacations and certain festivals. The prototypical time of transgression was carnival, the days before Easter; Bakhtin (1968) argued that the medieval carnival emerged as an episodic popular festival in which the grotesque and transgressive critiqued, through mocking, parody, and inversion, the repressive norms of the elites. In Breughel's *Battle Between Carnival and Lent* we see the joyous, rotund "king" of the carnival doing battle with the haggard, repressed Lent, just as we see the church next to the tavern. The peasants gathered together to drink, dance, and indulge what was otherwise prohibited; most of

these indulgences were bodily, especially erotic licentiousness and all manner of scatological excess. Carnival stood apart from everyday life, transgression was not just tolerated but celebrated. For Bakhtin, transgression embraced far more than sexuality. Carnival valorized the grotesque as a repudiation of elite aesthetic standards. Carnival was a critique of the elites, their lifestyles and seeming "superiority." On the one hand carnival could be seen as a form of resistance, but at the same time that resistance, displaced to the cultural realms, ultimately served to reproduce the political economy.

Bakhtin's work influenced a number of scholars such as Stallybrass and White (1986), and Presdee (2001). For Stallybrass and White, with the ascent of the trading classes and flourishing of coffeehouses, alcohol consumption dropped and fairs and carnivals waned. Presdee, more concerned with criminal transgressions, nevertheless argued that insofar as certain transgressions are labeled criminal, there are joys in such transgressions.

THE COMMODIFICATION OF TRANSGRESSION

In the contemporary era of globalized capitalism, the privatized hedonism of consumption has been universalized as the means of attaining the "goods life." Indeed, consumerism as an ideology, lifestyle, and basis for identity serves to sustain markets and assuage the discontents of the contemporary market based civilization. More specifically, in the current age, there are three major sources of discontent: (1) economic stagnation and the uncertainty of employment; (2) highly routinized, regulated, and often surveilled work; and (3) the emptiness and shallowness of most forms of "mass culture." Beneath the surface of such discontents lie deeper frustrations and anxieties over social fragmentation and attenuated social ties, problematic agency in an ever more controlled world, finding dignity and recognition, and finally, finding meaning in a world that seems ever more meaningless.

There are at least two reactions to these trends, fundamentalism and transgression, which indeed feed on each other. In the former case, the surrender of the self and subjugation to a higher "moral" authority provides integration

into a community of believers, empowerment through prayer and ritual, dignity through piety and purity, and clear cut meanings, rules, and regulations that disavow the transgressive. At the same time, for a great many people, the transgressive “compensates” for the adversities of modernity. Transgression exalts and rewards the self in its pursuit of hedonistic self indulgence. But further, transgressive means of assuaging the discontents of capitalism have themselves become commodified. Such modifications of transgression range from the shocking and grotesque realms of mass culture to transgressive subcultures and lifestyles of goths, punks, or hip hop. In these commodified transgressions, frustrations are allayed and discontent, anger, rage, and even ennui are contained by, while displaced from, the political economy. Much like the feudal carnival, adverse feelings are dissipated and potential disruption thwarted. Thus not only are discontents allayed, but capitalism finds profit in selling alternatives to its own mainstream and the system is reproduced.

CONCLUSION

Transgression, the crossing of often tabooed moral and frequently criminal boundaries, is not only a universal aspect of human societies but also a fruitful way of understanding how those societies construct and control deviant behaviors, while fostering the very deviance they abhor. In recent years, between the adversities of capitalism on the one hand, and the ever present need to expand the consumer economy on the other, we have seen the transgressive move from the margins to the mainstream. Whether we look at clothing/appearance, life styles, or musical styles, the boundaries of morality and the transgressive are quite fluid and variable. And while the embrace of the transgressive may cause many hardships, so too does transgression foster social change and, in the process, reveal much about the society.

transition from communism

Josephine E. Olson and Irene Hanson Frieze

“Transition from communism” refers to the historical process of moving from a centrally planned economy to a market oriented economy with a dominant private sector. In most cases it has also meant a transition from a totalitarian state to a democracy. Transitions have taken place in European and Central Asian countries formerly under Soviet domination and also in East Asian countries such as China and Vietnam. The transition period is largely associated with the 1990s, but China’s transition began in 1978, and transitions are far from complete in many countries. Discussion of the transition generally focuses on economic changes, but many political, legal, social, and psychological changes were also associated with the transition. The focus here is on the transitions in Central

and Eastern Europe, the former Yugoslavia, and the former Soviet Union.

Before the fall of the Berlin Wall in 1989 and the collapse of the Soviet Union in 1991, communist countries were centrally planned, with the government and cooperatives owning most means of production. Most communist economies emphasized heavy industry rather than services and consumer goods. Large factories and geographical specialization were common. Energy and transportation industries were often highly subsidized. International trade took place primarily among members of the Council for Mutual Economic Assistance (CMEA). Enterprises were controlled by strict administrative rather than financial constraints; managers had to meet the requirements of the central plan. A single state bank system served to meet the objectives of government economic plans.

All men and women of working age were expected to be employed outside the home, and unemployment was largely unknown. However, there were often provisions for lengthy maternal leaves for women. Services were provided for families, such as housing, government sponsored childcare centers, and meals at work. Governments provided retirement pensions for all workers, and retirement ages were often in the fifties. Employees received low wages, and wage differentials across jobs were low. By the 1980s, communist governments found they could not offer all the promised services. There were widespread shortages in consumer goods because of price controls, and consumer goods were often of poor quality.

With the breakup of the Soviet Union, Yugoslavia, and Czechoslovakia in the 1990s, there are now 27 transition countries. The German Democratic Republic merged with the Federal Republic of Germany in 1990 and its transition became an internal problem of Germany. The 27 countries are often classified into groups for analysis of the transition. The Baltic countries, Estonia, Latvia, and Lithuania, were part of the former Soviet Union after World War II. The Commonwealth of Independent States (CIS) includes the other countries of the Soviet Union: Armenia, Azerbaijan, Belarus, Georgia, Kazakhstan, the Kyrgyz Republic, Moldova, the Russian Federation, Tajikistan, Turkmenistan, Ukraine, and Uzbekistan. Five Central European countries (the Czech Republic, Hungary,

Poland, Slovakia, and Slovenia) joined the European Union in 2004 along with the Baltic countries. These eight countries are referred to as the Central Europe and Baltic (CEB) countries. The Southeast European (SEE) countries include the countries of the former Yugoslavia except Slovenia (Bosnia and Herzegovina, Croatia, the Former Yugoslav Republic (FYR) of Macedonia, and Serbia and Montenegro) as well as Albania, Bulgaria, and Romania. Bulgaria and Romania expect to join the European Union in 2007 and Croatia and FYR Macedonia are official candidates.

The massive requirements of the transition from communism were unprecedented in history; there were few guidelines to the best process. The following reforms were generally considered necessary to successfully complete the transition to a market economy. Macroeconomic stabilization was required to control inflation and prevent excessive government deficits. This required breaking up the single bank system into a central bank and numerous commercial and investment banks (allowing the entry of new banks). The central bank's responsibilities included limiting the growth of the money supply to control inflation. To avoid large government deficits, controls on government spending, tax reform, and strong tax collection methods needed to be put in place. The tax system had to be reformed so that the government could collect revenue from the private sector that was needed to finance its new responsibilities in a market oriented economy. Price and trade liberalization were needed so that domestic prices would reflect world prices and encourage efficient allocation of resources. Among other things, this meant the breakup of the CMEA trading bloc.

Hard budget constraints needed to be imposed on companies. This meant eliminating subsidies and non payment of taxes. Enterprises had to restructure, laying off workers and increasing productivity, to become profitable. Given outdated production methods and previous subsidies, many old enterprises were not viable in a global market and had to liquidate. Methods had to be found to transfer viable government owned enterprises to a competitive private sector. New businesses needed to be encouraged to increase output and absorb excess workers. Commercial banks needed to make loans based

on profit potential and eliminate non performing loans. A social safety net was required to deal with unemployment and poverty.

Legal and judicial systems and related institutions that would provide a level playing field in a market economy and enforce property rights had to be created. In retrospect, analysts believe that policymakers underestimated the importance of developing legal systems, particularly for the protection of property rights, and related institutions to the proper functioning of a market economy.

The transition in Europe and Central Asia turned out to be far more difficult than expected. The transition initially led to inflation as price controls were removed and as financial crises developed in some countries. There were dramatic drops in output and increased unemployment due to disruptions from the collapse of communist institutions, tight macroeconomic policies, and credit crunches. Although initial drops in output were anticipated, they were much larger than expected: an average fall of about 40 percent. The European Bank for Reconstruction and Development (EBRD) estimated that output fell on average until 1994 and did not begin to rise again until 1998.

Privatization of state owned enterprises took several forms. Small enterprises were transferred quickly and rather successfully to the private sector, primarily through local auctions. Large and medium sized state owned enterprises were handled in a variety of ways. Some countries such as Poland and Slovenia moved slowly to privatize state owned enterprises, but appointed supervisory boards to run them before privatization. Estonia and Hungary carefully sold off state enterprises to outside buyers, including foreign buyers. Some countries such as the Czech Republic, Lithuania, and Slovakia used voucher plans to quickly transfer ownership shares to most adult citizens. Russia and Ukraine privatized rapidly using primarily subsidized management buyouts. In retrospect, studies suggest that privatization to concentrated outside owners led to better restructuring; privatization to diffuse owners and to enterprise workers and managers often made things worse for restructuring than continued state ownership.

The 1990s were a time of extreme hardship for many people in the transition countries.

The World Bank (2002) estimated that 1 in 20 people in this region had incomes below one dollar per day in 1998 compared to only 1 in 60 in 1988. Aside from drops in output and employment, worsening distributions of income contributed to the growing poverty. Income distribution became more unequal in most countries, but CIS countries like Russia, Armenia, and the Kyrgyz Republic became among the most unequal in the world. War and civil strife in Armenia, Azerbaijan, Georgia, Moldova, and Tajikistan and in most of the states of the former Yugoslavia as well as financial crises, particularly the Russian crises of 1998, undermined the transition in many places. Ethnic and religious strife also hindered transition.

Most countries had shrinking social services and benefits. Fertility and marriage rates dropped, and in some CIS countries average life expectancy fell. There were serious psychological costs for many people due to the greater uncertainty about jobs, social disorientation, and declining standards of living. Value systems based on collectivism began to transform to more individualistic ones. Under communism, people relied on the state to guarantee them a job and to provide social benefits. With the transition, people were confronted with unemployment for the first time. Salaries for government workers were generally quite low, and the private sector, as it developed, provided higher paying but more demanding jobs. Younger workers, especially men, were most often sought for these new jobs. Women of childbearing age were often not hired, as companies sought to avoid paying maternity benefits. Young, attractive, unmarried women were often the most likely women to be hired and older women experienced the highest levels of unemployment.

The psychological changes resulting from the economic transition often included discontent with the changes. Public opinion surveys conducted in 1999 in the Czech Republic, Hungary, and Poland, three of the more successful transition countries, indicated that more people believed that the losses from the transition exceeded the gains than the reverse. Reactions were even more negative in other countries. But, some young adults have responded positively to the opportunities provided by the private sector and to the increased freedom of

political expression in some transition countries. A recent study showed some improvement since the mid 1990s in life satisfaction among residents of transition economies.

Although all the European and Central Asian countries initially suffered significant drops in output and other problems at the beginning of the transitions, there were enormous differences 15 years later. The EBRD (2005) estimated that output in 2004 was 126 percent of its 1989 level in the CEB countries, but only 92 percent in SEE countries and 81 percent in CIS countries. Output, however, has been growing in all countries since 2002 and it has been growing quite rapidly in some of the CIS countries. In 2003, half the countries still reported unemployment of 10 percent or more. The EBRD reported that inflation rates and government deficits were relatively low in 2005. The economic structure of transition countries has changed. Services have grown in relative importance while industry shrank in all countries and agriculture also shrank in the CIS countries. In 2005, the private sector accounted for more than 50 percent of output in all but Uzbekistan (45 percent), Belarus (25 percent), and Turkmenistan (25 percent). In many countries, this change was due to the rapid growth of new private businesses more than privatization of old state enterprises.

The EBRD has a set of transition indicators to track structural and institutional reforms in the transition countries as they move toward mature market economies. Most countries show significant progress in liberalizing prices, in liberalizing international trade and their exchange rate regimes, and in privatizing small scale enterprises. They are somewhat behind in large scale privatization and in banking reform and interest rate liberalization. They are still slower in the areas of governance and enterprise restructuring, infrastructure reform, reform in securities markets and non bank financial institutions, and competition (antitrust) policies. The countries that are the most advanced in reforms are the CEB countries, followed by Croatia, Bulgaria, and Romania. The countries that have made little or no progress in the transition are: Turkmenistan, which has only liberalized some prices and done some small scale privatization; Belarus; Uzbekistan; and Tajikistan.

It is not surprising that the CEB countries that have joined the European Union and those SEE countries that are in the process of joining the EU have made the most reforms. Many of these reforms are also required for membership in the European Union. In addition, the Central European countries tended to start with some initial advantages, such as relatively high per capita income, high levels of education, shorter times under communism, and proximity to the West. However, the Baltic countries, which were less advantaged initially, are now as advanced as the Central European countries.

transition economies

Rainhart Lang

Societies or economies in transition have been the focus of sociological research since the fall of the Berlin Wall in 1989, which symbolized the demise of the state socialist system. The term *transition economies* therefore applies mainly to post socialist countries in Central and Eastern Europe, and also in East Asia, despite its wider use in the economic or sociological literature.

The term *transition* is used to describe the process through which a society or economy introduces the institutional facets associated with advanced capitalist economies, such as

the legal system, ownership structures, institutions of financial and labor markets, the party system, and the institutions of the independent and democratic state. While the term *transition* is often restricted to a small time span of an economic change, or relates only to an economic view of post socialist societies, or describes the fixed result of the changes as *the* western type of a market economy or capitalism (Offe 1996), the term *transformation* has been more widely used in the sociological literature, especially in Europe, since the mid 1990s. The latter term covers a wider social process of fundamental political, economic, technological, and cultural change in structures and values, including all areas and levels of the society: organizations, the individual, and collective actors (Nee & Matthew 1996; Clark et al. 2001).

Transformation has been described as both managed and evolutionary, or self organized, this quality impinging upon the adjoining concept of “follow up modernization” (Grancelli 1995). In light of this interpretation, economic transition may be regarded as a temporal and spatial element within the wider transformation process in which new economic institutions are formed and established.

Taking into consideration such a broad view of transformational change, transformation might also be seen as an ongoing process also in those post socialist countries now entering

the EU. These nation states are still confronting processes of adaptation and change at various levels, including the adoption of societal institutions and values. The broader research agenda on radical social change in transformational societies or economies in transition is therefore concerned with various levels and processes in social change, as represented in Figure 1.

The traditional discourse on economic transition has focused mainly on the process of successful transfer and functioning of capitalist institutions such as labor markets, financial institutions, adequate ownership structures, and the privatization and economic restructuring of economic organizations. But as Clarke (1996) contended, “Although the process of privatization has transformed a stratum of office holders into a potential class of property owners, private property is not a sufficient condition for the constitution of a capitalist system of social production.” A wider perspective on transition economies has therefore demanded consideration of the impact of various other factors and phenomena such as national values, traditional cultures, political interests, and the strategies of individual and collective actors on the development of economic institutions, economic organizations, and economic actors in transforming societies. While American economic sociology has predominantly focused on change or continuity in workers’ control over the labor process

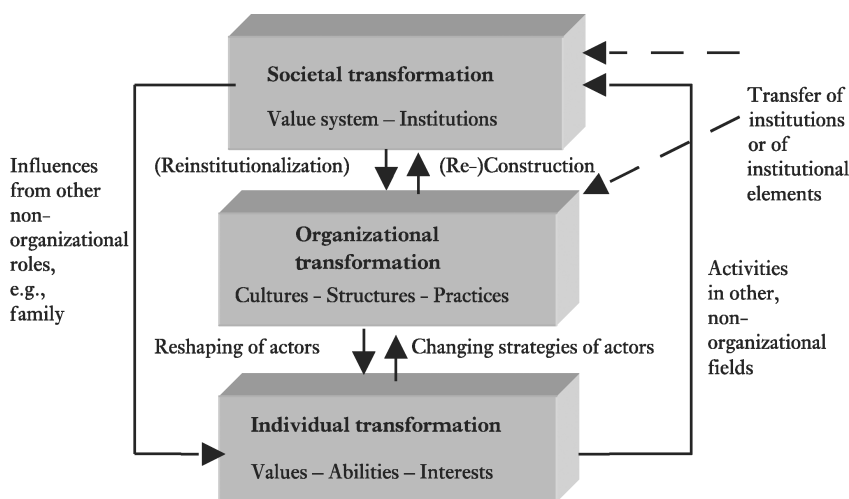

Figure 1 Levels and social aspects of transformation research in transition economies.

(Burawoy & Krotov 1992), on the transformation in income relations as a result of privatization attempts (Nee & Matthew 1996), on privatization and restructuring of enterprises (Stark 1996), and the emergence of new elites (Waldner 2003), the European debate has been much broader, and has manifested an interdisciplinary approach to transformation. The social aspects of economic transition that have been analyzed most frequently since the mid 1990s are delineated below.

At the societal level, *institution transfers vs. institution building*, or reinstitutionalization of social processes, has been at the center of research attempts, this including study of the conflicts between inherent values of the transferred institutions and the local national value systems. (Clarke 1996; Fligstein 1996; Grabher & Stark 1997; Stanojevic 2001; Wang 2001; Lang & Steger 2002; Bakacsi et al. 2002).

The development of new capitalist institutions in the transition economies, introduced with the massive financial and moral support of western institutions such as the World Bank or governmental advisers and consultants, led to difficulties and failure in the respective economies in the mid 1990s. It has transpired that the transferred institutions often did not fit with national cultures in the CEE countries (Bakacsi et al. 2002) or China (Wang 2001), as well as with the special requirements of transformational settings. The traditional national cultures, characterized by strong in group collectivism and high power distance, consolidated by the past system, differed in their core values from the transferred institutions, which exhibited individualistic "western" cultural norms. Moreover, different transition strategies could be observed, ranging from early shock therapy to an incremental change (Offe 1996).

At the same time, the imposed transfer of western institutions, supported by a tendency towards mimetic processes from inside the transition economies, finally led to inconsistency problems with the historical and cultural background of the local actors, as shown in various studies (e.g., Lang & Steger 2002). Older interests tended to convert the new institutions in ways that stabilized parts of the heritage, as for example shown by Stanojevic (2001) in the case of the transfer of the German system of industrial relations to Slovenia and Hungary. As a

result, the transition economies in CEE countries, as well as in post socialist Asian countries, have developed a new type of capitalism (Stark 1996; Wang 2001) or a special business system, which is characterized by a distinctive mixture between public and private enterprise, and with the strong influence of social networks and groups with particular interests that have underpinned economic activities and institutions (Fligstein 1996; Grabher & Stark 1997). The emergent or newly embedded institutions are the result of a "recombination" of properties (Stark 1996) based on the culture of the past and transformation experiences with the transferred institutions. While classical neoliberal theories were not able to explain these changes, evolutionary theory, network theory, and new institutional theory have been used more often in these studies (see Fligstein's 1996 claim for an integration of institutional theories).

At the level of organizations, the traditional focus of research has been on the privatization and restructuring of the old enterprises as well as the emergence of small private firms as the main forms of organizational transformation. The social aspects analyzed in the wider perspective of organizational transformation include cultural changes in (economic) organizations, and their enabling and limitation effects on economic activities (Burawoy & Krotov 1992), including the emergence and establishment of new practices as a result of "recombination" (Stark 1996; Grabher & Stark 1997) or "bricolage" (Clark et al. 2001). In addition, the interrelated processes of organizational and institutional learning, and their intended or unintended consequences for a co evolution of the newly established organizations and institutions, have been analyzed, to explain the various steps of adjustment and adaptation (Child & Czegledy 1996; Lieb Dóczy 2001). The results show that the core values of old organizations and local embeddedness play an important role for a successful organizational transformation, even in the case of a radical restructuring. The learning process in transformational settings could therefore be characterized as an explorative learning process beyond simple adaptive or exploitative learning.

At the level of individual (and collective) actors, the emergence and shape of new social groups of actors, especially entrepreneurs or

managers (Puffer et al. 2000; Steger & Lang 2003), and their influence on the development of new organizational forms, values, and the (re) construction of new institutions have formed an interesting field of transformation research. The results support the expectation of an elite reproduction instead of a radical change within the economic elite. The new owners, managers, or entrepreneurs of small businesses had mainly a management background in the old system, or belonged to distinctive social groupings. Since many of the old cadres, especially from the younger group of technocrats, have managed their individual transformation into the new capitalist system and have created new roles (Clark et al. 2001; Lang & Steger 2002; Waldner 2003), their values and experiences built the background for the new organizations. Not only the new managers but also the new social group of entrepreneurs differ therefore from their western counterparts with respect to values and preferred practices. Moreover, since they belong to informal social networks of different types, they also gain influence in the public sphere. As shown in early publications on transformation in CEE countries (e.g., Dittrich et al. 1995), powerful actors and their respective networks have to be seen as a central explanatory factor in transformation at societal level.

While in the early years of transformation research, surveys and statistics with questionable original data were used, the broader agenda of transformation research is now accompanied by a wider spectrum of research methods, wherein complex case studies and longitudinal type cases play an important role (Puffer et al. 2000; Clark et al. 2001; Clark & Michailova 2004). Even in the early years, statistics and surveys did not reflect the special influence of the informal "gray" market, the problematic state of official statistics, and the ability of the actors to produce a "good looking" surface picture ("social desirability" phenomena). A critical standpoint on the research methodology in transformation research has demonstrated that taking account of the important influence of third party agents such as translators, cultural interpreters, mixed research teams of insiders and outsiders, strangers, and indigenous researchers is helpful in overcoming partial "blindness," mistakes, and misinterpretations (Clark & Michailova 2004).

transition from school to work

Fabrizio Bernardi

Research on the transition from school to work focuses on the relationship between the level of education and the first job achieved upon entry into the labor market. This has traditionally been a central topic in social stratification and social mobility research. As such, the study of the transition from school to work has reflected the main theoretical positions that have dominated research on social stratification since the end of World War II. Under the influence of functionalist theory, the relationship between education and the first job has been studied in terms of the classical achievement/ascription dichotomy. Thus, scholars were mainly interested in establishing the relative weights of achieved and ascribed factors in the process of status achievement, in particular with regard to the first job. The key research question was whether or not access to better jobs was increasingly dependent on achieved factors, such as education, and less and less dependent on ascribed factors such as the characteristics of the family of origin. In the same period, economists developed the theory of human capital, which assumes that formal education increases individual productivity by providing the skills

and knowledge required for the most demanding occupations. According to this theory, individuals can improve their productivity by investing in their own education. Moreover, employers can dispose of perfect information about school leavers' productivity by considering their level of education. Thus, this theory predicts a direct relationship between level of education and quality of the first job achieved.

In opposition to both functionalist sociological theory and human capital theory, credentialist theory, developed in the 1970s, questioned the idea that education increases individual productivity at work. In this interpretation, educational certificates are credentials that certify membership in a given status group, i.e., groups that share a common culture, worldview, and values. While functionalist and human capital theories argued that school leavers are sorted into occupations on the basis of their merits and productivity, credentialist theory suggested that the process of the school to work transition is ruled by dominant status groups who define the educational requirements for a given occupation and, in this way, control and limit access to their privileged positions. The critique of the human capital assumption that education increases individual productivity is also the starting point of the signal theory of education that has been developed by both economists and sociologists. According to this theory, employers interpret education as a signal of the future trainability of applicants for a job vacancy. Although the level of education is not directly related to actual productivity, it reflects other individual traits such as commitment and social and communicative skills that are crucial for subsequent success at work. The important implication for the school to work transition is that, among other factors, the signaling capacity of educational qualifications is crucially dependent on the number of school leavers with a given level of qualification: as their number increases, the discriminatory information attached to the educational qualification decreases. If this is the case, one might expect the outcome of the school to work transition to depend to a greater extent on factors other than the mere level of education.

In more recent years, research on the transition from school to work has reflected and partly fostered a progressive shift from social

stratification and social mobility studies toward labor market sociology. This shift has come about with three interrelated epistemological, theoretical, and methodological changes. First of all, more effort has been made to specify the mechanisms underlying the school to work transition. Second, the importance of the institutional context in which the school to work transition is embedded has been acknowledged. Third, dynamic methods of analysis have been applied to study entry into the labor market, as opposed to the traditional cross sectional methods.

The first of these changes can be described as an attempt to move from a "variable sociology," mainly interested in establishing the patterns of association between independent and dependent variables, to a "mechanism sociology" that searches for the generative processes of social inequality. In the past, research on the school to work transition mainly focused on the net association of individual education and different measures of quality regarding the first job. In recent years, however, it has been recognized that, in order to address the questions "Who gets which job upon entry to work, and why?" one should account for the broader processes underlying the supply and demand side of the labor market and how they match. An explanation of the school to work transition should ideally consider the number and characteristics of school leavers (supply side), the availability of jobs with given characteristics (demand side), and, finally, the processes through which the school leavers achieve valuable information about job vacancies and the employers select employees from among the potential candidates for a job (matching processes).

This shift toward broader explanations of the process of entry into the labor market has also led to the acknowledgment of the importance of the institutional context in which the school to work transition is embedded. Thus, comparative research has highlighted institutional differences among countries or over time that might affect both the characteristics of the supply and the demand sides and the matching processes in the labor market and, thus, condition patterns of entry into the labor market. With regard to the characteristics of school leavers, a widely applied typology in research on the school to work transition distinguishes

between the level of *standardization* of educational provisions, the *stratification* of educational opportunities that characterizes different educational systems, and the level of *credential inflation*. More precisely, standardization refers to the degree to which the quality of education meets the standard in the country under consideration. What is important in this regard is whether curricula are nationally defined, whether teacher training is uniform, whether there is a national standardized examination system, and whether there is any large variation in funding across schools and universities. On the other hand, the concept of stratification points to the degree of separation of students into differentiated educational tracks and to the selection procedures occurring at early ages. Finally, credential inflation refers to the proportion of each cohort that gets to the highest level of the educational system. This last concept is important because it expresses the idea that the value of a certain educational qualification upon entry to the labor market depends on the number of school leavers with the same level of education. In general, it has been argued that, in countries with highly stratified and standardized educational systems and low educational inflation, educational returns upon entry into the labor market are on average higher than in other countries. This is because high levels of stratification and low credential inflation make it possible for employers to select among fewer applicants with clear cut distinctions in the qualifications. Moreover, higher levels of standardization make the signals provided by education more reliable. The empirical evidence provided by various cross national studies largely supports this type of argument.

With regard to the matching processes between school leavers and job vacancies, the study of the school to work transition has benefited from the insights of *network analysis*. The key research issue in this respect is if and how the process of entry into the labor market is facilitated by the circulation of valuable information on vacancies and job applicants through the network of relatives, friends, or simple acquaintances. Comparative studies have also focused on the nature and strength of the institutional linkages between the educational system and the labor market. In this respect, it has been argued that the school to work transition

is smoother and the relationship between the level and type of education and quality of the first job stronger in those countries where there are direct linkages or co linear linkages between the educational system and the occupational structure. *Direct linkages* exist in the dual system types of vocational training, such as the German and Danish ones, where employers and school jointly collaborate in providing training. An additional and rather exceptional case of strong linkage is the situation where the school acts directly as a job placement office, as in the case of Japan. *Co linear linkages* are found when there is strong congruence between training and certification provided in school and training or legal requirements for specific occupations in the labor market. For instance in the Netherlands, although there is little joint delivery of training by school and employers, there are a large number of occupations which require applicants to have taken training programs in the educational system before entry. Finally, where *no direct linkages* between school and work exist, as in the US, employers are not involved in any way in schooling and there is no formal congruence between training and certification provided by the educational system and training or legal requirements to access given occupations in the labor market.

Less attention has generally been paid to cross national differences on the demand side of the labor market that may potentially have severe consequences for the transition from school to work. Obtaining a good job after leaving school depends crucially on the availability of good jobs. In their most general form, demand side institutional differences that are particularly interesting for the school to work transition refer to cross national variation in the ratio of vacancies of highly skilled/unskilled jobs. All other conditions being equal, more highly educated people will have an advantage in terms of the quality of the job upon entry into the labor market if the demand for skilled jobs is high. Accordingly, the demand for skilled and unskilled labor will depend crucially on the productive system of a country and on the dominant market and organizational strategies of national firms. The political economy literature on the varieties of capitalism and production regimes might offer useful insights on national differences in the demand

for qualified workers for research on the school to work transition.

With regard to the most important methodological changes in this area of study, one might mention that in recent years the outcome of the transition from school to work has been conceived not only in terms of the quality of the first job achieved, but also considering the duration of the first job search. Thus, one aspect studied is how different indicators of educational achievement affect the speediness of the transition to work and how the duration of the job search itself influences the quality of its outcome. In this way, the intrinsic dynamic nature of the process under study has been fully acknowledged.

In sum, the study of the school to work transition has traditionally been a border area between economics and sociology. One might conclude that in the last decades the progressive broadening of the scope of analysis to include supply, demand, and matching processes, the acknowledgment that the process of entry into the labor market is embedded in different institutional contexts that might vary from one country to another, and, finally, the adoption of a longitudinal perspective have made the sociological contribution in this area most fruitful.

transnational and global feminisms

Manisha Desai

Transnational feminism refers both to the practices of women's movements around the world and to a theoretical perspective in which women theorize and strategize for women's rights and gender justice across national boundaries, work in collaboration with women from other countries, and frame their activism in terms that are both local and global. Thus, transnational feminism refers to the flow of ideas, issues, strategies, organizations, and activists across national boundaries. As practice it dates back to the mid and late nineteenth century when women activists from the US and Europe worked in collaboration around the abolitionist and suffrage movements in those countries, when women from colonizing countries such as England worked together with women in India and other colonies to advance women's rights, particularly suffrage and education, as well as when European women in the communist and socialist parties worked to develop women's organizations around the world on issues of women's economic rights (Rupp 1997). This earlier practice of transnational feminism was limited in several ways: the issues addressed were restricted to suffrage, education, and workers' rights; the nation state was still the center of activism; the flow of ideas, strategies, and activists was primarily, though not exclusively, from the North to the South; there were few international organizations, all of which were

hierarchical in nature; and the practice was neither widespread nor the dominant mode of feminism. While this practice continued, primarily in its communist and socialist manifestations, it was not until the 1970s when the United Nations declared 1975 as International Women's Year and 1975–85 as International Women's Decade and organized women's world conferences – in Mexico City in 1975, Copenhagen in 1980, Nairobi in 1985, and Beijing in 1995 – that the practice took off and has now become a dominant strategy of women's movements around the world.

As a theoretical perspective, it emerged in the US academy in the 1990s. It was a response to the critique of second wave, white, middle class feminism by women of color in the US and the "third world" and by poststructuralism and postcolonialism, as well as to women's solidarities across the world, forged as a result of women's participation in the UN's International Women's Decade and its four world conferences and preparatory national and regional meetings. The term "transnational feminism" was seldom used by the women's movements and international non government organizations (INGOs) until after the Beijing conference. Today it is widely used but remains contested by some Latin American feminists who are uncomfortable with the term. To them it is too reminiscent of transnational corporations.

Grewal and Kaplan (1994) and Mohanty (2002) were among the early framers of this academic discourse. Their articulation incorporated critiques of western feminisms and post modernism without jettisoning either. They underscored the need for feminist political practices that addressed the concerns of women around the world in their historic and particular relationships to multiple patriarchies as well as to international economic hegemonies. For a transnational feminist politics, they noted, feminists have to move beyond polarities, without ignoring the histories of unequal power relations that construct them, and build coalitions based on practices that women around the world develop to address the complex realities of their lives. Together, these local feminist practices could lead to transnational solidarities. This formulation of an intersectional analysis and transversal politics came to be defined as transnational feminism in the 1990s.

Such a transnational analytic focus developed not only in feminism but also in other areas of sociology, specifically social movements, gender, race, and sexuality studies, immigration, families, and organizations among others. This focus on the transnational was fueled by the pace of contemporary globalizations and information technology which enabled easy, quick, and reliable communication across national boundaries. Thus, the transnational analytic aim is to understand how the local – in terms of issues, identities, strategies, methods, targets of protest, and worldviews – becomes global and how global is evident in the local. Analysts assume that identities, networks, and communities are as likely to be global as local and that global dynamics and audiences constrain and facilitate local realities.

Transnational feminism became a privileged discourse in the 1990s in the academy at the same time that women's activists began to privilege transnational activism over local activism. In part, this reflects the common realities, of globalization and structural adjustment policies, that began to influence women's lives all around the world as well as the opportunities made possible by the communication technologies and the UN world conferences that enabled women to meet across national borders. Transnational feminist solidarities were being forged among women across national boundaries around several important sites: the UN conferences, specific local struggles, academic and policy research, and the global justice movements. Most analysts agree that the dominant protest repertoire of transnational activism includes education and mobilization, symbolic framing, and strategic use of information. Advocacy, lobbying, support, and direct action are secondary. Furthermore, the major targets of most transnational movements have been policy mechanisms of local, national, regional, and multilateral international institutions. Finally, while a lot of transnational activism is cyber based, it also involves travel to sites of protests and gatherings. Such a modality privileges educated, middle class activists over other movement activists and participants.

The four world conferences and accompanying NGO Forums were contentious events with women, not all of whom identified as feminists, from the South challenging Northern women's

conceptions of women's issues based solely on gender and sexuality and insisting on bringing in issues of development, nationalism, and neo colonialism. These differences among women began to be acknowledged and "solidarities of difference" were forged as they continued to meet over the decade and shared experiences of inequalities and struggles for justice. It was the 1985 conference in Nairobi that marked a shift from contention to solidarity and by the fourth conference in Beijing, women despite their differences had found a common language in the human rights framework. "Women's rights are human rights" emerged at the World Conference on Human Rights in Vienna in 1993 but became paradigmatic in Beijing. Thus, the UN conferences and then its specialized agency meetings, such as the Convention on Elimination of all Forms of Discrimination Against Women and the Committee on the Status of Women, became the prime sites of this new phase of transnational activism. Most women who attended the NGO Forums accompanying the UN conferences, which are for government delegations though increasingly many governments include activists and NGO members among their official delegates, were middle class educated women from INGOS, donors, academics, and activists. Grassroots women are present as well but most participate in their own Forum outside the main workshops in tents, sharing, performing, and selling handicrafts. Only women from the major INGOs and donors are involved in interacting with the official conferences. Thus, when feminists come together across borders around spaces like the UN conferences, they tend to reproduce inequalities among women and privilege women from the North and elite women from the South.

But transnational feminist politics is not limited to activism around the UN. As the burgeoning literature on transnational social movements shows, activists are coming together across national borders at various local levels for specific struggles such as coalitions against sweatshop labor, fair trade cooperatives, slum and shack dwellers' coalitions, anti privatization of water, and various other social justice movements. When grassroots activists and networks that involve community based organizations come together across borders for specific struggles,

while the tensions and contradictions persist, local women are able to negotiate and influence politics based on their knowledge and resources. Networks such as Women in Informal Economy Globalizing and Organizing (WIEGO) and Slum/Shack Dwellers International (SID) are composed of people affected directly in their homes and communities by the process of globalization, in partnership with NGOs and academic institutions (WIEGO is based at Harvard University) to gather data and to propose people centered solutions at international, institutional levels and to engage in local organizing. Such networks have been successful in changing perceptions about the poor and marginalized people and their right to participate in decisions that affect their lives as well as their abilities to generate solutions to their situations. Because such networks represent people and are accountable to them, they are more legitimate than other elite and middle class networks and NGOs that have no connections to the constituency on whose behalf they make claims.

Educated, middle class, and elite transnational feminist networks – DAWN, WIDE, WEDO, AWMR – however, have also played an important role in research, policy, and advocacy for women's rights (Moghadam 2005). They are an innovative feminist response, participatory and non hierarchical, and the most effective form of organizing in an era of globalization. They have been effective in generating new knowledge, influencing policies, and advocating on behalf of women's rights in many international institutions such as the UN, World Bank, and the IMF.

Both grassroots and middle class transnational feminist networks have also come together in the context of the global justice movement. The protests against corporate globalizations that began in Seattle in 1998 and continued through the end of the decade created new networks and led to the consolidation of the global justice movement. It was in the name of the global justice movement and as an alternative to the World Economic Forum in Davos, where leaders of corporate globalization meet, that the first World Social Forum (WSF) was called in January 2001 in Brazil (www.worldsocialforum.org). The WSF was organized as a democratic space for people from around the world to share their struggles and

reflect on alternatives. The language of the WSF stresses process and autonomy from state and parties. Feminists were active in the WSF from its inception and gender equality was stressed as one of the important aspects of global justice. Yet the first two WSF did not have as many sessions on gender, nor were women in prominent positions in the International Organizing Committee. To address this, feminists from Latin America, Asia, and Africa formed "Feminist Dialogues" in 2004 to engender the WSF and make it feminist in its focus, method, and participants.

Transnational feminism, both as practice and a theoretical framework, has several implications. As practice, the domination of transnational feminism has led to reproducing inequalities among activists, from the North versus South and also among activists from the South. Organizationally, it has privileged networks over other organizational structures, which has contradictory effects. On one hand, it enables communication and solidarity in a participatory manner across many boundaries. On the other hand, there is very little accountability and responsibility. Transnational feminism has also diverted resources from local to transnational level, and most importantly, because a lot of transnational activism has been around research, policy, and advocacy, the changes have been more discursive than redistributive. Transnational feminist movements have primarily succeeded at the level of discursive power. They have operated on the notion of discursive representation rather than political representation. Discursive representation has sought to be inclusive, open, and self reflexive. Such an emphasis is in part a reflection of feminists' ability to harness communicative rather than conventional power. Discourses have an empowering function and are an important site of resistance. But feminist discourses have not become hegemonic, they remain an alternative. And when discourses such as gender mainstreaming and women's human rights are taken up by states and international agencies, they tend to become depoliticized and have little impact on actual policy changes.

Theoretically, transnational feminism, and transnationalism in general, have raised issues of methodology. For example, what constitutes a social movement? Some analysts prefer to use

networks as the unit of analysis as it has become the organizational expression of transnational social movements, while others focus on methods used, i.e., social movements use contentious methods while NGOs and networks tend to use routine means of social change. Yet others use the concept of transnational activism instead of social movements. They define activism as political activities based on a conflict of interest that challenge or support power structures, that are carried out by non state actors, and that take place outside formal politics (Piper & Uhlin 2004). Such a move blurs distinctions between NGOs and social movements and indicates the difficulties of using categories like social movements that derive from state centered sociology for transnational politics.

These definitional issues have been central in the current analyses of women's movements as scholars have moved away from "global" or "international" feminist movements to transnational feminist practices and solidarities, debated the use of feminist versus women's movements, and lamented the NGOization of women's movements. These conceptual issues are important because they both construct movements even as they describe them and show a discomfort with the shift in political terrain that has not led to greater equality for women.

Despite these methodological issues, transnational feminism is here to stay both as a theoretical perspective and as practice. To be more effective as practice, transnational feminism will have to devise strategies with other mass movements – such as unions in the informal sector as well as export processing zones that can hold corporations accountable, enforce land redistribution policies, challenge agribusiness to sustainable land use, and promote fair trade economic alternatives and political quotas for women – that can redistribute resources and emancipate women.

transnational movements

Jackie Smith

Social movements emerged in tandem with modern nation states, as groups of people organized to resist new claims being made by national authorities (such as taxes or military conscription) or to advance their own claims that states provide a variety of public goods and services (such as education, health care, and various forms of financial assistance). Ongoing competition between authorities and

citizen challengers generated new structures – including parliaments, bills of rights, and bureaucratic checks and balances – to routinize public participation in national politics and to otherwise enhance the accountability of political leaders to citizenry (see, e.g., Tilly 1984; Markoff 1996). Today, as states increasingly turn to international political arenas to manage their economies and ecologies as well as other aspects of social life, we find that social movements are becoming increasingly transnational in their structure and focus.

Movements are assisted in their transnational organizing efforts by the same rapidly advancing technologies that have assisted in the expansion of a global economy. Relatively cheap airline tickets, more widely available telephone and Internet access, expanding use of English as a global working language, and a globalized mass media help enable people from more diverse classes and geographical origins to share information and cultivate cooperative relationships across huge distances. While transnational social movements were active in the nineteenth and early twentieth centuries promoting international peace, an end to slavery, and women's suffrage, activists in these movements were by and large from privileged backgrounds. Today's transnational activism, which has expanded rapidly since the 1970s and 1980s, involves those of far more modest means. That said, it is still true that many transnational (and other) movements are disproportionately middle class, since people with more and better education as well as time, skills, and resources are the most able to be involved in social movements. But social movement politics by its nature attempts to lower barriers and costs to popular political participation, and many activists seek to confront the inequities they find in their own structures and operations.

Transnational social movements are best seen as networks of actors that are organized at local, national, and international levels. Many include formal organizations that have constitutions, staff members, bank accounts, and boards of directors. Others are neighborhood or friendship groups who meet informally and irregularly and who support each other's work to promote social change. Individuals are also key players in all social movements, and in transnational movements we often find members of

government delegations to the United Nations playing key roles in social movements. For instance, governments like that of Mexico have long been supportive of international disarmament efforts, and that government's delegates have helped peace movement activists get access to information and increase their influence on official disarmament negotiations.

United Nations officials, such as those in the United Nations Human Rights Commission, are also frequently involved in supporting the work of the transnational human rights movement. Journalists and academics are also part of many movements, helping to popularize debates or to advance new analyses that can assist social movements. Webs of interpersonal and interorganizational connections help expand the flow of information to different actors within movements. Transnational events like United Nations conferences or transnational meetings of civil society groups have helped increase the strength and density of these network ties, and the increased frequency of these events in recent decades helps account for the rise of transnational movements.

Transnational movements have adopted a number of strategies to promote global change. They can work to advance new international agreements, such as the Convention to Ban Landmines or the International Criminal Court, or to block agreements such as those in the World Trade Organization. They can work to press individual governments to abide by international norms or to ratify treaties. And they can appeal to global institutions or norms in order to strengthen their leverage in national conflicts (see Smith et al. 1997). Margaret Keck and Kathryn Sikkink (1998) refer to the latter of these strategies as the "boomerang effect." They argue that when national political systems are repressive or restrictive, appeals to international norms or alliances can bring international pressure to bear on states, thereby altering the balance of power in national political contests. So when Argentine human rights activists mobilized their transnational networks, they introduced an additional cost (US military aid) to the government if it persisted in flouting international law. In short, transnational movements can and do affect both national and international political processes. Moreover, by shaping international treaties and by working

with international institutions, they help define the institutional arrangements of our global political system.

The major distinction of transnational movements is that they mobilize people across national boundaries around a shared aim. They help people define their interests and identities in ways that go beyond the traditional nation state borders. By facilitating routine communication between people from vastly different regions and cultures, they help enhance understanding and mutual trust while making international friendships more feasible and likely. A member of Amnesty International, for instance, will share more common interests and perspectives with AI members outside her own country than she will with many of her compatriots. Organizations generate their own internal cultures and identities. And because they generally oppose predominant cultural systems, social movement organizations have a particular need for creating supportive identities that can bind members together and support collective action even in the face of repression (see, e.g., Rupp 1997).

As they attempt to define new activist identities, transnational movements must overcome the considerable influence of the national state in defining people's primary allegiances and motivations. However, just as the processes of global economic integration help generate the technologies and other infrastructures that support transnational organizing, here too global processes help break down the monopolies states have on their citizens' loyalties. The globalization of the economy has meant that people's educational backgrounds are more similar, as are their professional lives and working conditions. Moreover, there are increasingly obvious connections between global forces, such as transnational corporations or international trade laws, and one's daily experiences and interests, and these provide important foundations for the creation of shared understandings and meanings outside the framework of traditional state boundaries. Indeed, overcoming differences in national perspectives may be far easier than overcoming other differences within movements (Moody 1997). In other words, we can see important foundations for the globalization of civil society to parallel the globalization of economic and political institutions.

Like all movements, transnational social movements seek to enhance their political influence by cultivating alliances with other groups. A longstanding divide exists between social movements organized around issues such as the environment or civil rights and those organized to promote the interests of labor (Waterman 2005). In many contexts, corporate interests seek to undermine alliance building by framing environmental struggles as contests between jobs or development and environmental conservation. Divisions between richer and poorer activists persist in many movements, as economic class shapes the day to day experiences and perspectives of people in important ways. Sometimes, however, transnational movements can help overcome class or caste divisions by providing a broader perspective on the divisions that might exist within a single country. Activists in transnational environmental groups, for instance, are motivated out of a concern for a particular policy, and they will work with any groups they think can help secure their aims. In contrast, within countries we often find that urban-rural divisions or even anti indigenous prejudices can impede alliance formation within nations. Thus, when the World Social Forum – an annual gathering of social movement and other actors seeking to democratize the global system – was held in Mumbai, Indian activists were forced to confront more directly the claims raised by low caste Dalit which drew wide and sympathetic attention from international delegates to the Forum.

While social movements address any number of different issues, many work more or less self consciously to affect the formal means by which citizens can both participate in policy debates and hold their elected leaders accountable for policy decisions. So movements for racial equality have generated laws to protect minority voting rights, and demonstrators protesting against military arms races have helped to advance new legal protections for all forms of public speech. In short, in the course of mobilizing around particular issues, movements help shape the laws and institutions of our democracies. This is exactly what has taken place in the international political arena. As groups mobilized to advocate human rights or to limit the use of military force, they have found themselves involved in the process of helping define the

role of citizens in institutions that were established by states.

Global political institutions such as the European Union and United Nations were formally organized by governments with little desire to see much in the way of citizen participation. International diplomacy was seen as “high politics” that needed to be removed from the pressures of what were seen as poorly informed and passionate citizenries. But because a government’s participation in any international organization generally required that their national legislature approve of the arrangement, governments were forced to yield some space for citizens’ involvement in these bodies. And since the establishment of both these institutions, we have seen efforts by movements to further expand citizen participation in global politics.

Nevertheless, a substantial “democratic deficit” remains, and many national delegates to international institutions are unelected and largely unaccountable to citizens. There are no political parties organizing constituencies beyond the national level. Many international negotiations remain secretive, and even national legislators are denied access to official meetings and documents. Because global institutions have an increasing impact on the policy decisions that affect us, this global democratic deficit has undermined the quality of democracy within nations as well. Some analysts speak of a “hollowing out” of national democracy in recent years as states delegate more of their authority to supranational institutions, privatize more of their services to the corporate sector, and delegate more distributional decisions to local authorities (see Markoff 2004). Thus, after years of growing transnational activism aimed at promoting international agreements for human rights, more equitable development, and environmental protections, more transnational movement groups are demanding global democracy as the twenty first century unfolds.

Another key emphasis of contemporary transnational movements is a call for a more balanced approach to global integration than policy makers have pursued thus far. Since the late 1970s, key players in global politics have emphasized the development of global markets, and they encouraged all countries to reduce tariffs and other measures that limit the flow

of goods and services across national borders. Increased global trade was thought to bring economic growth that would benefit all. Unfortunately, for many reasons this simple economic logic has not proved true, and along with unprecedented increases in global trade we find unprecedented concentrations of wealth amid persistent poverty and environmental degradation.

Beginning in the 1990s, many groups began working transnationally to challenge this predominant neoliberal model of economic globalization. They argued that many decisions should not be left to the “free” market, because markets only respond to those with wealth. And many social goods – such as a clean environment or public health – are not readily reduced to simple cost benefit calculations. These decisions, activists argue, require informed public debate and consultation. By the last meeting of the World Trade Organization in Seattle in 1999, transnational movements came together with national and local organizers to demand more accountable and less market oriented international policies. Activists were demanding a greater say in decisions about how our national and local economies (and politics) are organized, as they were finding that global institutions were squeezing out possibilities for citizen input into decisions about what kinds of industries operate in local communities, what protections states can (and more often cannot) enact to preserve their natural environments, and how educational, health, and other services are managed. So we see a sort of “clash of globalizations” pitting a global system driven by markets against a system of global governance where politics determines how public goods are managed and how conflicting interests are reconciled.

In sum, attention to transnational social movements helps us understand the political processes behind globalization. Because movements are working to connect localized citizens with global political processes, they provide the connective tissue that helps integrate our global polity. They are also part of complex processes of contestation that help define the structure of global institutions and the character of local, national, and global politics. By helping shape institutions, policies, and systems of meaning, they are important actors in the global system. By insisting that the global system be made more

open and accountable, transnational movements are essential for the preservation of democracy.

Studying transnational movements is difficult. One needs to have expertise in the politics and cultures of different countries, as well as an understanding of the global political system – which constitutes a unique “area study” of its own. Because of these complexities, most studies to date are case studies of how transnational activism affects a particular national context or of particular transnational campaigns or events. The *Global Civil Society Yearbook*, published annually since 2001, has sought to trace the evolution of globally organized social change efforts, and it provides useful information about trends in global organization and activism. Electronic newspaper records have allowed for large scale, comparative analyses of media coverage of movements. Key questions that emerge from analyses of transnational movements are: How have globalizing trends affected the ways people engage in politics? How do transnational forms of activism compare with national ones? How does participation in transnational activism vary across different countries? And, perhaps most importantly, what impacts do transnational movements have on global political and cultural change?

transnationalism

Larissa Remennick

The concept of transnationalism, described as an integral part of the globalization process, is becoming increasingly popular in social and political sciences (Glick Schiller et al. 1995; Guarnizo & Smith 1998; Portes et al. 1999). Originally coined in international economics to describe flows of capital and labor across national borders in the second half of the twentieth century, this concept was later applied to the study of international migration and ethnic diasporas. The transnational perspective became increasingly useful for exploring such issues as immigrant economic integration, identity, citizenship, and cultural retention. Transnationalism embraces a variety of multifaceted social relations that are both embedded in and transcend two or more nation states, cross cutting sociopolitical, territorial, and cultural borders. The ever increasing flows of people, goods, ideas, and images between various parts of the world enhance the blending of cultures and lifestyles and leads to the formation of “hyphenated” social and personal identities (Chinese American, Greek Australian, etc.).

Some authors argue that transnationalism may actually be a new name for an old phenomenon, in the sense that most big immigration

waves of the past were typified by ethnocultural retention and contacts with the homeland (Van Hear 1998; Guarnizo and Smith 1998). Indeed, historic studies of ethnic diasporas show that immigrants never fully severed their links with the country they left behind. Yet, due to technical and financial limitations of the time, for most migrants these links remained mainly in the sentimental and cultural realm, and were seldom expressed in active shuttle movement or communication across borders. Economic ties with countries of origin were typically limited to monetary remittances to family members. Although up to one quarter of transatlantic migrants of the late nineteenth and early twentieth centuries eventually returned to their homelands, the decision to repatriate was in fact another critical and irreversible choice to be made. Hence, for the majority of historic migrants, resettlement was an irreversible process always involving a dichotomy: stay or emigrate, or else stay or return (Jacobson 1995; Van Hear 1998).

In the late twentieth century efficient and relatively cheap means of communication and transportation (time and space compressing technologies) made this old dichotomy largely irrelevant. As Castells (1996) pointed out, new technologies have virtually created new patterns of social relations, or at least strongly reinforced preexisting tendencies. They allowed numerous diasporic immigrants to live in two or more countries at a time, by maintaining close physical and social links with their places of origin. Transnational activities and lifestyles became widely spread, embracing large numbers of people and playing a significant role in the economy, politics, and social life of both sending and receiving countries. Guarnizo and Smith (1998) introduced a useful distinction between the two types of transnationalism: "from above" and "from below." The former refers to institutionalized economic and political activities of multinational corporations and organizations such as the UN, Amnesty International, or Greenpeace, which set in motion a large scale global exchange of financial and human capital. On the other hand, the increasing role in these networks belongs to ordinary migrants – grassroots agents of transnationalism who run small businesses in their home countries, organize exchange of material (e.g., ethnic food) and

cultural goods (e.g., tours of folk artists) within the diaspora, pay regular visits to their birth place, and receive co ethnic guests. This is called a *transnational lifestyle*.

The migration experience in the context of a global society, where the constant exchange of people, products, and ideas is reinforced by global media networks, has attained a whole new quality. The full time loyalty to one country and one culture is no longer self evident: people may actually divide their physical presence, effort, and identity between several societies. Citizenship and political participation are also becoming bifocal or even multifocal, since some sending countries allow their expatriates to remain citizens, vote in national elections, and establish political movements. In this context, international migrants are becoming *transmigrants*, developing economic activities, enjoying cultural life, and keeping dense informal networks not only with their home country, but also with other national branches of their diaspora. The split of economic, social, and political loyalties among migrants, and gradual attenuation of loyalty to the nation state as such, is seen as problematic by some receiving countries (Glick Schiller et al. 1995; Guarnizo & Smith 1998). Yet some recent studies show that dual citizenship may in fact promote immigrants' legal and sociopolitical attachments to both their home and host countries, rather than reinforce so called postnationalism (Bloemraad 2004).

Most transnational networks in business, politics, communications, and culture organize along ethnic lines (i.e., include members of the same ethnic community spread between different locales on the map). Common language and cultural heritage are the key cementing factors for the *transnational diasporas* (Jacobson 1995; Van Hear 1998). In most cases, transnationals become bilingual and bicultural, but different communities may exhibit various degrees of cultural separatism versus acculturation in the host society. Over time, many immigrant groups develop cultural hybridism – the mix of the elements of their ethnic language and lifestyles with those adopted from the host culture. The most common expression of this trend is the formation of hybrid immigrant languages – Mexican English, Algerian French, Turkish German, etc. (Glick Schiller et al. 1995;

Guarnizo & Smith 1998; Van Hear 1998). In psychosocial terms, immigrant/transnational identity and personality become increasingly "elastic," if not "fluid," being constantly shaped and reshaped by multiple influences of the different societies migrants actually live in. Transnationals of today experience increasing difficulty in answering the questions, "Who are you? Where do you belong?" In that sense, transmigrant identity emerges as the epitome of postmodern identity (Giddens 1991; Guarnizo & Smith 1998). However exciting, a transnational lifestyle has its underside. While for many immigrants it may be a blessing, enabling them to enjoy the best of two (or more) worlds, for some others it virtually means living in limbo, or in a state of permanent uprooting.

transnationals

Ray Loveridge

The term transnational corporation (TNC) is often used interchangeably with that of multinational corporation (MNC) or multinational enterprise (MNE) to mean a firm that owns or controls income generating assets in more than one country. In the more exacting definition of Bartlett and Ghoshal (1989) the multinational organizational mode is described as one subset of the TNC (see below). Other transnational organizations include intergovernmental bodies such as the United Nations Organization (UNO) and International Monetary Fund (IMF), regulatory or standard setting agencies such as the Basle Group of Bankers, and a rapidly expanding group of "voluntary" associations known as non government organizations (NGOs). The focus here, however, will be on TNCs rather than these latter forms of cross national governance. In popular usage, the TNC is usually seen as being extremely large in terms of its level of employment, financial turnover, and ownership of assets. Indeed, it is usual to compare the turnover and assets of the top TNCs such as General Electric or Wal Mart with the gross domestic product of nation states. While not wishing to deny the vividness of this crude comparison, we should be aware of its analytical limitations in assessing both the relative resources of these institutions and the nature of their authority. Also, there is an increasing number of small firms that seek an international presence in order to provide their services across borders. In large part this has to do with the increasing appeal of so called "world standards" and global presence in purchasing a service or material product. Thus, the United Nations' (UNCTAD 2000) estimate of 45,000 parent TNCs existent in the mid 1990s is likely to have increased significantly over the ensuing decade and now includes many

little known startup firms that have local joint ventures or affiliates in several countries.

Trading organizations spanning territorial frontiers predate the modern nation state. Privately owned European corporations such as the East India Company and Hudson Bay Company played a major part in the establishment of overseas colonies of their parent nation from the seventeenth to nineteenth centuries (Hertner & Jones 1986). But the contemporary significance of TNCs can be traced to their varying contributions to the integration of global markets and, more controversially, to the possible convergent effects of “globalization” over the latter half of the twentieth century.

FOREIGN DIRECT INVESTMENT

In the mid 1980s the overall level of foreign direct investment (FDI) taking place between countries overtook that of exports and imports (Hirst & Thompson 1999). There was a major shift from the previously dominant pattern of entrepot trade in which western countries imported raw materials in order to manufacture finished goods for home consumption or for export. As Hirst and Thompson point out, FDI had actually reached a comparatively high level before World War I. However, the nature of foreign investment in the latter part of the twentieth century was fundamentally different from that of the earlier period. Earlier, FDI was largely composed of portfolio investment by European financiers in the material infrastructure of other countries. Today, it is most often carried out within the structure of a single TNC or its affiliates or associated partners in a cross national supply chain. Dicken (2003: 200–1) sees this temporal change as marking movement between an earlier mode of capitalist investment described by Marx as the circuit of commodity capital to one of finance capital and, most recently, to a global circuit of productive capital.

TNCS AND NATION STATES

Perhaps of equal analytical significance is the manner in which cross national transactions now often take place within an “internal market”

of bureaucratically structured relations between actors at different stages of the value adding chain. That is to say that the largest TNCs either exercise direct hierarchical control over operations performed in house or have a nodal position on global supply networks that enables them to shape outcomes according to managerial priorities rather than to short term movements in external prices (Dicken 2003: 17).

This shift in the nature of cross national transactions can be seen as changing the basis upon which national governments manage their economic balance of trade quite significantly. For example, the internal (transfer) value placed on a part manufactured component or product can be shaped by the desire of TNCs to minimize the amount of tax or tariff paid either to the country in which the exported component was produced or to the recipient importing country where it is to be finally assembled. The true cost of its original production may not be reflected in its “sale” price, and therefore in the national accounts of the supplying country.

In other respects also national governments often negotiate with TNCs from a position of greater or lesser dependency in a manner that has a direct effect on their domestic agenda. Where, as in, say, Nigeria, some 80 percent of capital investment and recorded national income derive from FDI, the local presence of TNCs is critical. Even in older economies such as that of the UK, up to 40 percent of local capital investment can derive from overseas. Indeed, some authors on business strategy see TNCs as becoming one of the most significant agencies of global governance (Ohmae 1995). Nation states are often seen to be competing with one another to obtain FDI in a “locational tournament.” For example, governments can offer advantageous low tax and/or low tariff regimes. Sometimes particular regions are designated as “export processing zones” (EPZ) with zero tariffs on materials imported simply for local processing and immediate reexport. In general, EPZs are designed to provide employment for low skilled labor. The attraction for the TNC is that of easy access to a cheap, stable, disciplined labor force (Froebel et al. 1980). In other cases the existence of a large potential consumer market that is best serviced “close to market,” such as exists in North America, Europe, and East Asia

(particularly China and India), attracts investment in the design and assembly of products to suit local tastes (Dicken 2003). For retail chains such as Wal Mart, Carrefour, and Tesco, as for professional service firms like financial accountants, a local presence is a prerequisite for delivery of their particular direct service.

The country's ability to attract so called "centers of excellence" (Cantwell & Santangelo 2000) or knowledge intensive plants such as R&D laboratories, which service the needs of the TNC throughout the world, is the ultimate prize. It has been described by one influential political theorist (Reich 1990) as the future "work of nations." By contrast, where the host country provides only extractive commodities such as mineral oil, metals, or precious stones, the processing of these materials can often be performed elsewhere unless the host state acts to prevent this and/or to reallocate investment income to the development of alternative sectors.

Some state governments consciously pursue a strategy of sponsoring "national champions" or locally based TNCs which occupy a significant place in global markets. The French government has, traditionally, been most overt in its pursuance of what is sometimes described as a "mercantilist" position. In practice, most governments tend to protect their "national interest" in important markets. In developing countries it has become part of conventional wisdom to attempt to create a hub of locally owned large business conglomerates from which to negotiate entry to world markets through joint ventures and learning alliances with more specialized TNCs from the developed world: Japan and South Korea are their models (Amsden 1989). Such government sponsored conglomerates are often seen as serving the dual function of "creating a local middle class" (Evans 1979).

TNC STRUCTURES AND STRATEGIES

From the viewpoint of the TNC acting as a "rational actor," a number of economic models have been put forward to explain its choice of strategy. These are put most succinctly in Dunning's (1980) "eclectic paradigm." The firm must first possess "ownership specific" advantages, particularly by comparison with local

producers. These may range from greater technological or managerial expertise to its more exotic reputation. Second, the firm must see advantage in keeping its capabilities within its own organization rather than licensing them or subcontracting them to a local supplier. This condition will evidently affect its willingness to share its knowledge with others, or even to allow local employees to appropriate this knowledge. Third, there must be location specific advantages of the kind described above to make the greater risk of overseas investment worthwhile. These can be expressed in terms of a variety of numerical indices such as geographical differences in labor productivity, wage costs, consumer tastes, sovereign (government) risk, and so on. Other models deployed by economists are modeled on sequential "learning" by the company through exporting or through the overseas assembly of product models that are considered outdated on the home market (see Vernon 1966 on the product cycle model). As markets have become increasingly open to global competition, such sequential models of overseas learning have become less applicable. For example, the Volkswagen Santana, produced in China since it was phased out in Germany in the 1970s, has recently been replaced by a range specifically designed for production in China. Perhaps more importantly, specialized producers of services for global supply chains, as well as so called dot.com website suppliers such as Amazon, target a cross national market from the outset, that is, they are global by design.

The analysis of the internal organizational structure of control within the TNC can, therefore, be seen as having an important significance for wider society in both its host and parent countries. Bartlett and Ghoshal (1989) summed prevailing wisdom on organizational form in a four part categorization of TNC control structure.

- The *global* company based on cost advantages through centralized control of a standardized product and production processes conducted in plants around the world. Examples include early US assembly plants such as automobiles and kitchen equipment. Nowadays, this mode is likely to be found among specialized component suppliers such as microchip producers.

- The *international* company that exploits the knowledge and design capabilities of head office through diffusion and local adaptation in local plants operating under close surveillance. Examples include most final assembly (original equipment) suppliers, but this also can include quasi professional services offering formulaic solutions such as management consultancy.
- The *multinational* company that seeks to meet the particular needs of local or regional markets and offers a wide mandate to local managers. Examples include retail chains, locally regulated professionals, or any close to market production.
- The *transnational* company in which head office is guided by the knowledge of local needs transmitted upwards by relatively autonomous local managers. It seeks to synthesize these experiences in a manner that allows lessons to be learned across diverse locations. Examples tend to be taken from among currently successful firms such as Unilever, GEC, and ABB, but in general Japanese firms are seen by most prescriptive writers as best in this process of “bottom up” learning.

A fifth mode, put forward by Hedlund (1986), is that of *heterarchy*. In this structural form, horizontal communication between overseas affiliates becomes a primary method of information passing, which may not involve going through head office. It is most likely that this will occur only where the passing of operational information can enhance immediate efficacy or avoid a crisis. But the widespread use of unmonitored email and chat rooms might well facilitate the emergence of such “communities of practice” in sectors such as oil drilling, logging, construction – or financial trading. In an exploratory study which combined case histories with a sample survey, Nohria and Ghoshal (1997) suggested that the most innovative TNCs were those that adopted a *differentiated network* approach in which affiliates were treated differently according to the “complexity” of their local context and the level of local “resources.”

As is suggested in the examples above, some analytic importance can be attached to the sector in which the TNC operates. But, equally,

this fivefold structural taxonomy has been treated by some writers as shaped by a temporally staged evolution from the export driven centralized organization to the dispersed and devolved structures of locally autonomous producers or servicers. On the other hand, the sheer size and internal complexity of its operations may be seen to trigger a devolution of authority. Other contingent factors can include those named by Nohria and Ghoshal (1997) as the contextual complexity and available capabilities to be found in the host country. Under the heading of “complexity” these authors subsume a widespread condition imposed by host governments that local affiliates must be partially owned and/or directed by local citizens. While intended to maintain some direct local control over the management of affiliate organization, these appointments can sometimes contribute to widespread accusations of corruption made against TNCs (Kaufmann 1999).

A different explanation is offered by cultural and institutional theorists adopting a more cognitive approach to strategic formulation. Perlmutter (1969) suggested that the values and interests of corporate elites encouraged one of four predispositions amongst TNC expatriate managers. These were ethnocentrism, polycentrism, regiocentrism, and geocentrism. Again, there is the suggestion that managers move along a learning curve from a home country dominance in thinking to a recognition of diversity in their local operations, moving toward greater rationalization across regions and, finally, to an integrated view of global strategy matching local capabilities. By contrast, comparative institutionalists such as Whitley (2003) tend to subscribe to the view that formal control structures within the TNC, including those determining job and career structures, are shaped more permanently by the back home institutions of the parent firm. In what has been the most cited study of managerial values carried out within a single TNC (IBM) in the 1970s, Hofstede (1980) discovered that what he described as “core work values” varied significantly across the 40 countries in which the study was conducted. Empirical evidence produced from a wide sample of TNCs by Harzing and Sorge (2003) suggested that whilst internal control structures appeared to be shaped by those of the parent country, strategic views on the external environment

held by TNC executives tend to converge on a pattern shaped by size of company and its sector or industry. Perhaps, then, it is not surprising that the more recent ethnographic work of D'Iribarne (1996) suggests the translation of centrally designed formal control structures can vary in different nationally and locally specific contexts, as can the enactment of "core work values."

HUMAN RESOURCE MANAGEMENT AND CIVIL RIGHTS

The study of human resource management (HRM) or employment practices within TNCs tends to dichotomize between a focus on expatriate management development and another on the workplace conditions of locally recruited operatives. Within these themes there are varying foci. The corporate career and personal needs of expatriate managers provides one set of prescriptive literatures, together with the desirability of a sensitivity toward local cultures (Dowling et al. 1994). Relationships with indigenous managers, particularly in the transfer of technical knowledge, are another more conflictual focus (Bhagat et al. 2002). What seems evident is that TNCs are generally likely to retain expatriates in a number of key functions, such as local financial executive or product development, whilst employing indigenous staff in other functions. Often this appears to be motivated by a desire to reduce salary costs and to satisfy the conditions imposed by the host government. However, over the close of the twentieth century it became evident that an emergent class of highly mobile executives was being appointed to senior positions within TNCs irrespective of nationality. Thus, a Brazilian was appointed to head the Japanese car manufacturer Nissan by its French shareholder, Renault. A US chief executive was externally recruited to the old German family owned firm of auto and electronic component suppliers, Robert Bosch, and so on.

Knowledge transfer also provides an important theme in the discussion of workplace practices. In the 1980s, research interest focused on the so called Japanization of work organization, in particular upon the adoption of teamworking

and the self regulation of quality standards within work groups in TNCs' affiliates across different national locations (Boyer et al. 1999). In the following decade, the emphasis tended to shift to the wider effects of rationalization undertaken within global supply chains, in particular to the effects of outsourcing low skilled work to low wage countries. In the early years of the present century, this movement spread to many routine office and sales functions of large western firms. This movement might be seen as confirming Reich's (1990) earlier notion of an emergent division of labor across relatively stable national systems in which "mature" economies rely on their capacity to produce knowledge workers ("symbolic analysts"). The response of labor unions in the West has been largely focused on obtaining better working conditions for TNC employees in developing countries with a view to equalizing employment opportunities for their local members in the parent company. However, the effect of cross national competition for low skilled jobs will inevitably bring about domestic tensions that may challenge the notion of a stable cross country division of labor (Storper 1997).

The role of the TNC in eroding boundaries to national markets has evidently been increasingly significant over the latter half of the twentieth century. In general, the literature is dichotomized into the managerially oriented study of organizational structures and strategies and that which describes and critiques the negative effects of the TNC as manifested in "globalization." There is a case for greater ethnographic study of the effect of TNCs on local communities in a manner that might provide a better qualitative understanding of both viewpoints. Most studies are conducted through questionnaires remotely designed and administered by western scholars to a sample of interested executives. Finally, it seems important to recognize that TNC strategies are bureaucratically conceived and can, given sufficient political will and understanding of their effects, be bureaucratically constrained.

transparency and global change

Burkart Holzner

The word “transparent” traditionally means the capacity of light to pass through clear glass so that one can see the things behind it. Transparency also means open, frank, candid, and true, as opposed to opaque or secret. Today, the concept “transparency” in sociology refers to the globally emerging value (and its derivative norms) of information disclosure and access. It asserts that all centers of authority have a “duty to disclose information” and that publics and citizens have a “right to know.” The value of transparency does not stand alone; it is part of information value systems that include also its counter values. Thus, the rules for openness are often circumscribed by norms limiting disclosure, such as secrecy, privacy, confidentiality, and others. There are obviously

many different kinds of information linked to these norms, such as personal data, public information, proprietary, and others. However, transparency norms are increasingly expected to be followed by governments, international agencies, professions, corporations, foundations, and civil society organizations.

Transparency as a value is historically recent. It had its origin early in the eighteenth century in Sweden's law of information freedom and later in the US Constitution. However, only in the last decades of the twentieth century were the corresponding norms adopted by states on a nearly global scale. Prior to the recent breakthroughs to create open access of information, most centers of authority relied on secrecy as a matter of course. The history of transparency is linked to the history of global change. The first major political impulses in this direction arose in the Protestant mobilization against corruption in the Catholic Church of the sixteenth century. Much later, in 1766, only Sweden established rules for information freedom. About a decade later, as the US declared independence and wrote its Constitution, free speech and the free flow of open information became novel, liberal institutions pointing in the direction of transparency. In the entire nineteenth century virtually no country adopted such values. The Scandinavian countries followed the example of Sweden only in the early twentieth century.

Starting slowly in the 1970s and more rapidly in the 1980s and the following decades, more and more countries adopted freedom of information laws. According to the Freedominfo.org *Global Survey: Freedom of Information and Access to Government Record Laws Around the World* (May 2004), 50 countries have adopted formal freedom of information acts, and another 30 countries are on their way to adopting such laws. There exists a similar growth in the number of countries that became electoral democracies: according to Freedominfo.org, in 1987 there were 66 democratic countries, but by 2001 there were 121.

Another innovation in the direction of transparency came from Sweden in 1809. It was the creation of the office of the national ombudsman. The ombudsman mediates between government and citizens, and serves to improve communications between them. The other

Scandinavian countries followed Sweden's lead only in the twentieth century. At the close of the 1980s there were 21 countries that had adopted the office. By 2000 there were 111. Indicators for transparency, such as freedom of information laws, electoral democracies, and the establishment of ombudsmen, show a rapidly rising tide of transparency in the last two decades of the twentieth century and beyond.

The number of countries adopting specific laws on transparency norms grew in the late 1990s and in the early twenty first century. These rules have affected almost all domains of power and influence, such as governments, corporations, accountants, lawyers, health professionals, foundations, and civil society organizations. In addition, many significant organizations find it advantageous to adopt transparency practices on a voluntary basis. Voluntary disclosure practices tend to enhance an organization's legitimacy and freedom from corruption. Further, the norms of transparency are spreading far beyond the countries that initiated them. This circumstance poses the challenge of developing internationally accepted specific transparency measures, for example in the accounting rules for financial disclosures across countries. The International Accounting Standards Board has adopted this challenge for its global profession. Similar "harmonization" of measures is evolving in health care, education, and many other professions.

Corruption is not compatible with transparency. Corruption in any rich or poor country is by now recognized as a grave danger to the public good and a threat to good governance in states and corporations. As late as the early 1990s many governments and international agencies did not consider corruption in other nations a cause for international intervention. It was assumed that the national sovereignty of even blatantly exploitative governments was an insurmountable barrier that provided immunity for the perpetrators. This changed when global anti corruption movements effectively challenged national sovereignty as a source of immunity for corrupt high officials and persuaded international agencies like the Organization for Economic Cooperation and Development (OECD), the World Bank, and many governments to establish international treaties inhibiting corruption and bribery. The largest

and most effective global civil society organization in this field is Transparency International, founded in 1993. It has expanded to become a worldwide network in approximately 80 countries, with a high level of influence in the domestic affairs of these countries, and in international agencies and governments. Transparency has become a major strategy in the effort to improve local as well as international governance.

The spread of transparency as a public value and the upsurge in national and international transparency norms is a very recent and rapidly growing phenomenon. Several increasingly global trends converged to produce the energy for the transparency phenomenon: the increase in global economic interdependence, the spread of demands for civil rights, and the arrival of breathtaking innovations in information technology. Economic interdependence also includes an increase in political interdependence: the demand for transparency soon became a necessity because global economic transactions require the availability of reliable economic and governmental information. Without this, trust at a distance across cultural barriers and boundaries would not be possible. The demands for transparency were a natural outgrowth of the movements for civil rights, women's rights, and consumer rights that started in the West and spread around the world, enhanced by the abolition of colonialism. Anti colonialism became a movement for autonomy in all former colonies. Initially, developing nations turned to nationalism; gradually, movements of responsible government and transparency are arising in many developing nations. In addition, the information revolution has made rapid communication and the creation of information infrastructures possible, and thereby made transparency technically viable in global change. This has a remarkable effect on the privacy of individuals: technology in the hands of governmental and commercial information systems produces comprehensive profiles of individuals, such as credit records, the value of homes, health data, and more. This development is also part of changing information value systems. It is very much in dispute.

The combination of global transformations, value changes, and the power of information and communication technology has created a historically new constellation of information

values. This constellation includes the transparency values of openness – autonomy, accountability, freedom of expression – as well as its counter values of secrecy and surveillance, with the value of privacy between them. The constellation of information values will have different profiles as perceptions of societal threats or security and general moral frameworks shift. Different interests of stakeholders virtually always lead to different interpretations of accessible information, inevitably provoking public debates.

Global change and intense interactions among regions and nations have given rise to novel border crossing solidarity formations. The treaties that established the European Union as a major power and supranational political institution are the most obvious example of such emerging transnational solidarities and of the way in which they are being achieved. The diverse transactions that are necessary beyond cultural and political boundaries have become a focus for creating trust building efforts. Valid transparency of important information is inevitably demanded in such situations. Trust at a distance is based on some form of certification of validity and reliability in the disclosed information. This form of trust at a distance is substantially different from “trust up close” among friends or relatives, or networks of shared commonalities. In fact, trust at a distance requires avoidance of conflicts of interest, cronyism, and insider privileges. Transparency requirements can actually limit or even destroy trust up close. It does need a relatively high degree of public information and formalization as against the friendly whisper.

The sources energizing the public demand for transparency are quite diverse, but they have converging effects. Colossal social upheavals, such as the defeat of Nazi Germany in World War II, have generated massive shifts in societies' moral frameworks. The crimes of the Holocaust and of criminal medical experiments on human subjects brought such outrage that massive reforms were called for by international publics. Certain transparency measures such as the establishment of “informed consent” rules were among the many changes that evolved from the catastrophe of the war. Bringing transparency to national histories became a necessity in order to establish justice for past governmental

crimes. Historical transparency has become a major factor in the countries in transition from authoritarianism to democracy, as in Germany, Japan, and in many countries more recently, such as South Africa and Argentina. Major sources of value changes also include lesser events such as scandals as value rational motives for reforms to adopt transparency. Scandals are very frequently drivers toward transparency – as in recent cases of corporate scandals in the US, or the scandals resulting from malfeasance in other professions such as accounting and medical research, or outright criminal acts on the part of prominent officials. Scandals call for repairs in the social rules and they often call for a shift of the socially accepted moral framework. Not infrequently, acts that were acceptable in the past become unacceptable later. Periods of legal remedial action often increase transparency in a more or less irreversible manner.

Social movements addressing such issues as government accountability, corporate malfeasance, environmental risks, and security problems invariably press for relevant information. They have become powerful sources for transparency demands within countries and globally. No one wants to deal with unknown risks from such sources as faulty products, environmental hazards, and government or corporate corruption. The structures for increasing the flow of information include legal provisions, such as freedom of information acts, ombudsmen, and court actions, market necessities, or the activities of civil society organizations such as the American Civil Liberty Union in the US and State Watch in the European Union.

There are further factors that encourage people to turn to transparency voluntarily. The information technology revolution has made it possible to generate and record information on such things as the value of real estate, the prices of goods, personal data, educational certificates, highway maps, sources of direction, and much more. This means that the historically prevailing condition of opacity – the absence of information about most things – is today shrinking. Many opportunities to use (and misuse) such information have opened up. Under these circumstances, the adoption of transparency can be an important advantage for individuals in visible positions, governments, and corporations. The rapid spread of governmental and corporate

codes of conduct is a function of this phenomenon. Corporate codes of conduct invariably emphasize the need for ethical conduct and transparency.

Very practical and matter of course transactions require transparency in markets. In all these various sources of transparency demands there is a need for certifying the validity of truth claims made by the information disclosing agency. The age of transparency, if we may call it that, is also an era of evaluation and certification, not only on the part of governmental regulators and in professional codes of ethics and their enforcement, but also by professional evaluation researchers in many fields of activity.

The social fact of transparency as a new globally relevant value also includes, of course, currents of resistance. Transparency was a child of the Enlightenment, but it is rapidly becoming a strategy for fighting corruption and authoritarianism in developing countries. These movements transcend civilizational boundaries and local cultural differences. The forms of transparency can vary, but transparency itself is always part of efforts that create open, democratic societies.

triangulation

Norman K. Denzin

Triangulation refers to the application and combination of several research methodologies in the study of the same phenomenon. The concept of triangulation, as in the action of making a triangle, may be traced to the Greeks and the origins of modern mathematics. Introduced in the social sciences in the 1950s (Campbell & Fiske 1959), heavily criticized in the 1980s (see Silverman 1985; Lincoln & Guba 1985; Guba & Lincoln 1989) and 1990s (Flick 2004), triangulation is a postpositivist methodological strategy. It has recently returned to favor as a new generation of scholars is drawn to a mixed, or multimethod, approach to social inquiry (Teddle & Tashakkori 2003).

When introduced in the social sciences the term functioned as a bridge between quantitative and qualitative epistemologies. It was seen as a way of helping qualitative researchers become more rigorous, perhaps allowing them to address a methodological inferiority associated with "a kind of stepchild complex" (Kamberelis & Dimitriadis 2004: 2). Advocates of mixed methods research argue that it allows them to answer questions that other methodologies taken alone cannot. Further, it provides "better inferences based on a greater diversity of divergent views" (Teddle & Tashakkori 2003: 14–15).

The use of multiple methods in an investigation so as to overcome the weaknesses or biases of a single method is sometimes called multiple operationalism. Indeed, triangulation has become a metaphor for methodological integration, of the postpositivist variety, in the social sciences. The metaphor evokes multiple meanings, including (1) a synonym for mixed method, multimethod, or mixed model designs (Teddle & Tashakkori 2003: 11, 14); (2) a method of validation; (3) the integration of

different mixed methods approaches; (4) combining quantitative and qualitative methodologies in the same study (Erzberger & Kelle 2003).

However, the history of the term, its uses and meanings, is not without contradictions. For example, some distinguish triangulation from those forms of multiple methods research which are informed by poststructuralism and cultural studies (Richardson 2000). In such projects "there are multiple standards for understanding the social world (epistemological relativism) . . . therefore diversity and contradictions should be incorporated within research accounts" (Spicer 2004: 298; see also Denzin 1989: 246). In contrast, Saukko (2003: 23) observes that the "classical aim of triangulation is to combine different kinds of material or methods to see whether they corroborate one another."

NEED FOR TRIANGULATION

Qualitative research is inherently multimethod in focus. However, the use of multiple methods, or triangulation, reflects an attempt to secure an in depth understanding of the phenomenon in question. Objective reality can never be captured. We only know a thing through its representations. Viewed thusly, critical or interpretive triangulation is not a tool or a strategy of validation, but an alternative to validation. The combination of multiple methodological practices, empirical materials, perspectives, and observers in a single study is best understood as a strategy which adds authenticity, trustworthiness, credibility, rigor, breadth, complexity, richness, and depth to any inquiry.

The social sciences, in varying degrees, use the following research methods and strategies: social surveys, experiments and quasi experiments, participant observation, critical performance ethnography, interviewing, case study and life history construction, grounded theory, action inquiry, testimony, unobtrusive methods, including archival materials, visual methods, autoethnography, focus groups, and discourse analysis. Each of these methods and strategies has inherent weaknesses, which range from an inability to enter realistically into the subject's life world in experiments and surveys, to the problems of reflecting change and process in unobtrusive methods, the attention to rival

interpretive factors in participant observation, to an excessive reliance on paper and pencil techniques in surveys and interviewing.

The realities to which sociological methods are fitted are not fixed. The social world is socially constructed and its meanings, to the observers and those observed, are constantly changing. As a consequence no single research method will ever capture all of the changing features of the social world under study. Each research method implies a different interpretation of the world and suggests different lines of action that the observer may take toward the research process. The meanings of methods are constantly changing, and each investigator brings different interpretations to bear upon the very research methods that are utilized. For those reasons, a productive search for sound interpretations of the social world employs triangulation strategies.

HERMENEUTICS OF INTERPRETATION

What is sought in triangulation is an interpretation that illuminates and reveals the subject matter in a thickly contextualized manner. A triangulated interpretation reflects the phenomenon as a process that is relational and interactive. The interpretation engulfs the subject matter, incorporating all of the understandings the researcher's diverse methods reveal about the phenomenon.

A hermeneutic interpretation does not remove the investigators from the study, but rather places them directly in the circle of interpretation. While it is commonplace in the social sciences to place the investigator outside the interpretive process, hence asking research methods to produce the interpretation that is sought, hermeneutic interpretation dictates that the circle of interpretation can never be avoided, but it must be entered the right way. Triangulation is the appropriate way of entering the circle of interpretation. The researcher is part of the interpretation.

TYPES AND STRATEGIES OF TRIANGULATION

While it is commonly assumed that triangulation is the use of multiple methods in the study

of the same phenomenon, this is only one form of the strategy. There are four basic types of triangulation: (1) data triangulation involving time, space, and persons; (2) investigator triangulation, which consists of the use of multiple rather than single observers; (3) theory triangulation, which consists of using more than one theoretical scheme in the interpretation of the phenomenon; (4) methodological triangulation, which involves using more than one method and may consist of within method or between method strategies. There is also multiple triangulation, where the researcher combines in one investigation multiple observers, theoretical perspectives, sources of data, and methodologies. Additional types of triangulation have been identified, including those labeled reflexive, structural, and multipurpose.

Critical or interpretive triangulation can be viewed as an alternative or incitement to traditional postpositivist forms of validation. Interpretive triangulation opens the space for conversations about how a text authorizes or legitimizes itself through the use of multiple voices and representational forms. These forms may act as catalysts to transgressive validities and to a politics of resistance (Lather 1993).

PROBLEMS IN DESIGNING MULTIPLE TRIANGULATED INVESTIGATIONS

There are at least four basic problems to be confronted in carrying out multiple triangulated research. These are (1) locating a common subject of analysis to which multiple methods, observers, and theories can be applied; (2) reconciling discrepant findings and interpretations; (3) novelty, or the location of a problem that has not been investigated before; and (4) restrictions of time and money.

The location of a common subject of analysis can only be resolved through a clear understanding of the question the investigator wishes to answer. Divergent and discrepant findings are to be expected. Each inspection of the phenomenon is likely to yield different pictures, images, and findings. Novel or new problems are often, upon inspection, not new, but merely manifestations of familiar topics previously examined from different perspectives and questions. Restrictions of time and money are the

least problematic, for if investigators are thoroughly committed to understanding a problem area they will persist in examining it even under difficult circumstances.

CRITICISMS OF TRIANGULATION

It must be noted that the method of triangulation is not without its critics. Several criticisms have been brought to bear upon the traditional treatments of the triangulation strategy.

Data Triangulation

Silverman (1985) has argued that a positivistic bias underlies the triangulation position and that this is most evident in the concept of data triangulation. He argued that a hypothesis testing orientation is present when authors argue that hypotheses that survive multiple tests contain more validity than those subjected to just one test. He also suggested that to assume that the same empirical unit can be measured more than once is inconsistent with the interactionist view of emergence and novelty in the field situation. If, as Silverman argued, all social action is situated and unique, then the same unit, behavior, or experience can never be observed twice. Each occurrence is unique. Patton (1980: 331) has correctly noted that the comparison of multiple data sources will "seldom lead to a single, totally consistent picture. It is best not to expect every thing to turn out the same."

Investigator Triangulation

No two investigators ever observe the same phenomenon in exactly the same way. Guba and Lincoln (1989: 307) suggest that it is a mistake to "expect corroboration of one investigator by another." The argument that greater reliability of observations can be obtained by using more than one observer is thus indefensible. This does not mean, however, that multiple observers or investigators should not be used. Douglas (1976) has suggested that team research (a similar term for the use of multiple observers) allows an investigator to gain multiple perspectives on a social situation. Members of a research team have a multiplier effect on

the research – each adds more than just his or her presence to the knowledge that is gained about the situation being studied.

Theory Triangulation

If facts are theory determined, then theoretical triangulation consists of using more than one theoretical scheme to interpret the phenomenon at hand. Seen thusly, this form of triangulation helps reveal complexity. However, Lincoln and Guba (1985: 307) argue: "The use of multiple theories as a triangulation technique seems to us to be both epistemologically unsound and empirically empty." They base this conclusion on the argument that facts are theory determined. Theoretical triangulation simply asks the researcher to be aware of the multiple ways in which the phenomenon may be interpreted. It does not demand, nor does it ask, that facts be consistent with two or more theories.

Methodological Triangulation

This strategy takes the position that single method studies are no longer defensible in the social sciences. The researcher using different methods should not expect findings generated by different methods to fall into a coherent picture. They will not, for each method yields a different picture and slice of reality. What is critical is that different pictures be allowed to emerge. Methodological triangulation allows this to happen.

Multiple Triangulation

Fielding and Fielding (1986) offered a critical interpretation of this strategy, arguing that multiple triangulation is the equivalent for research methods of correlation in data analysis. They both represent extreme forms of eclecticism. Further, they suggest that theoretic triangulation does not reduce bias, nor does methodological triangulation necessarily increase validity. If there is a case for triangulation, it is because we should combine theories and methods carefully and purposefully with the intention of adding breadth or depth to our analysis, but not for the purpose of pursuing "objective truth."

The goal of multiple triangulation is a fully grounded interpretive research approach. Objective reality will never be captured. In depth understanding, not validity, is sought in any interpretive study. Multiple triangulation should never be eclectic. It cannot, however, be meaningfully compared to correlation analysis in statistical studies.

ALTERNATIVE VALIDITIES

It is now understood that there are multiple forms of validity, many different ways of authorizing text and its arguments (Lather 1993; Saukko 2003: 18). These ways supplement, if not replace, triangulation as a preferred strategy of validation. Saukko (2003: 19–22) reviews three alternative validities. Dialogic validity asks how well a text captures the point of view of the person being studied. Deconstructive validity addresses a text's historicity, its hidden politics, and its underlying binary oppositions. Contextual validity asks how a text anchors itself in material reality, in concrete historical contexts, in the political economy of daily life. Each of these validities problematizes the positivist concept of a single truth. This opens the door for considering different ways of extending the logic of classic postpositivist triangulation.

ALTERNATIVE PARADIGMS FOR COMBINING METHODOLOGIES

Richardson (2000) disputes the concept of triangulation, asserting that the central image for qualitative inquiry is the crystal, or the prism, and not the triangle. Mixed genre texts, including performance texts, have more than three sides. Like crystals, montage in film, the jazz solo, or the pieces in a quilt, the mixed genre text can assume an infinite variety of shapes, substances, and transmutations. Crystals or prisms reflect externalities. They refract within themselves. This creates different colors and patterns, casting off in different directions.

Saukko, building on Richardson (2000), also challenges the classic postpositivist model of triangulation because the model presumes a fixed or semi fixed view of reality, and a view of methods as magnifying glasses that reflect or reveal this reality. The notion of prism works

well with dialogic and deconstructive validity. Like the prism, these validities draw attention to the multiple ways reality is constructed. Classic triangulation disappears under the prism model. Still, with its emphasis on fluid reality, the prism model gives too little attention to history and social context. Thus, Saukko advances a material semiotic perspective. This model looks at how material reality defracts rather than refracts vision. A defraction model shows how research is a material practice that "alters or creates reality" (Saukko 2003: 27). This visual defraction model is then compared to a participatory, dialogic model where multiple dialogues between multiple realities are created and encouraged. A dialogic framework attunes the researcher to the many different voices at work in a concrete situation. The scholar seeks out and incorporates multiple points of view in the research. This expands the egalitarian base of the project, and enhances its claims to strong objectivity; that is, to the commitment to take into account multiple perspectives (p. 29).

THE INCOMPATIBILITY THESIS

The incompatibility thesis disputes the key claim of triangulation, namely that methods and perspectives can be combined. The incompatibility thesis argues "compatibility between quantitative and qualitative methods is impossible due to incompatibility of the paradigms that underlie the methods" (Teddle & Tashakkori 2003: 14–15). The incompatibility argument potentially discredits triangulation as a research strategy. Under this scenario researchers who try to combine methods that are incompatible "are doomed to failure due to the inherent differences in the philosophies underlying them" (p. 19). Others disagree with this conclusion, and some contend that the incompatibility thesis has been largely discredited because researchers have demonstrated that it is possible to successfully use a mixed methods approach.

There are several schools of thought on this thesis, including the four identified by Teddle and Tashakkori: (1) the complementary strengths, mixed methods model; (2) the single paradigm mixed methods model; (3) the dialectical mixed methods model; and (4) the multiple paradigm mixed methods model.

Researchers using the complementary strengths, mixed methods model believe that the use of mixed methods is possible, but that the methods and their findings must be kept separate so that the strengths of each paradigm are maintained. Others argue that methods can be mixed because the paradigms are not pure anyway. In contrast, Morse (2003) warns that ad hoc mixing of methods can be a serious threat to validity. Single paradigm scholars (model 2) seek one paradigm to support their methodological preferences and critiques, for example connecting constructivism and qualitative methods. Pragmatists and transformative emancipatory action researchers posit a link between their model and mixed methods (Teddle & Tashakkori 2003: 20). Adherents of model (3), the dialectical model, assume that all paradigms (and methodologies) have something to offer and "that the use of multiple paradigms contributes to greater understanding" (Teddle & Tashakkori 2003: 22). Scholars in this group work back and forth between a variety of tension points, such as etic-emic, value neutrality-value committed.

In model (4), the multiple paradigm mixed methods model, several paradigms and mixed methods models are combined. It is argued that no single paradigm can apply to all designs or methods; that is, particular paradigms may work best with particular epistemologies and methodologies. "Several paradigms may serve as the framework for a triangulation design" (Teddle & Tashakkori 2003: 23). The multiple paradigm position acknowledges the fact that a complex, interconnected family of terms, concepts, and assumptions surrounds the term qualitative research. These include the traditions associated with postpositivism, postfoundationalism, poststructuralism, and the many qualitative research perspectives and/or methods connected to cultural and interpretive studies.

Clearly, multiple frameworks and understandings circulate in the discourses that define how multimethod approaches are to be taken up at this time in history.

CONCLUSION

Over the past four decades the discourse on triangulation, multiple operationalism, and

mixed method models has become quite complex and nuanced. This entry has attempted to present some of this complexity, some of its history. This is not a neat, linear history. Each decade has taken up triangulation and redefined it to meet perceived needs. The very term triangulation is unsettling and unruly. It disrupts and threatens the belief that reality in its complexities can ever be fully captured or faithfully represented.

Drawing again from Saukko (2003), bringing these different views of triangulation and multiperspectival research into play with one another, "holding them in creative tension with one another . . . cultivates multidimensional research and politics" (p. 32). There is no intention of arriving at a final, correct, enlightened view. The goal of multiple or critical triangulation is a fully grounded interpretive research project with an egalitarian base. Objective reality will never be captured. In depth understanding, the use of multiple validities, not a single validity, and a commitment to dialogue and strong objectivity are sought in any interpretive study.

tribalism

Susan R. Trencher

Tribalism refers to customs and beliefs transmitted and enacted in groups (tribes) sharing a common identity and in which centralized political organization and authority are absent. Academic and public references to tribalism have been expanded to refer to behaviors and beliefs associated with diverse populations, including those that share any one, or all, of the following: race, ethnicity, language, religion, ways of life, kinship, attitudes, worldview, and generation.

Sociological interest focuses on aspects of ethnicity and stratification.

In response to “degeneration theory” – a biblically derived idea that non state societies had degenerated from a previous civilized state – late nineteenth century anthropologists theorized tribal organization as the second stage of social and political formation in an evolutionary sequence moving from the simple to the complex (band, tribe, chiefdom, state). By the early 1900s, anthropologists discredited these theories and focused on patterns of tribal life to define and differentiate these groups from other social and political entities. Patterns included participation and belief in a way of life where social and political formations are composed of kin based groups associated with a constellation of societal traits, including non industrialized modes of subsistence, reciprocal modes of economic exchange, and common group ownership of natural resources. As groups, tribes consist of single populations or small communities living within a limited geographic range that can arrange themselves as a single entity for common purposes. Societal institutions, including economics, religion, and politics, are incorporated into the activities of everyday life. Political processes are significantly egalitarian and include power conferred as authority upon specific individuals on the basis of personal merit. Political positions are not permanent and decisions cannot be imposed by force or other systems of control. Tribes can exist within larger political entities, including states and nation states.

Changes in the use and meaning of tribalism in part reflect the ways in which members of societies living outside such systems seek to categorize and classify them, as well as the ways in which these populations, often pressed by outside interests, redefine and reassert ethnic, regional, and generational identity. Historically, the term tribe was derived from the Latin *tribus*, traced as a reference to the three original divisions of the Roman people 2,500 years ago. In translations of biblical texts into Latin (and later into English), *tribes* referred to the 12 subdivisions of the peoples of Israel constituted through common kinship and custom. By the late sixteenth century, references to tribalism extended to behaviors and beliefs of races and ethnic groups.

In the nineteenth century era of Western European expansion, tribalism took on significantly negative connotations as a reference to indigenous populations in non state societies viewed as inferior, which were to be “civilized” by colonialist regimes. This definition was widely extended to non western societies even where highly centralized states existed (e.g., the Aztecs). In the US, tribes were given legal status as autonomous political entities with inherent powers of self government by Chief Justice John Marshall (1831) as “domestic, dependent nations,” although they remained subject to the authority of the federal government.

In the early 1950s, tribalism was extended to refer to the behaviors of any group of people characterized by strong group loyalty to an array of characteristics and institutions, including attitudes, language, religion, social causes, political leanings, economic interests, race, and ethnicity. In the 1960s, references to tribalism became increasingly problematic and complex. In anthropology, experts in tribal societies argued that the term had become too ambiguous to be useful (Fried 1967; Helm 1967). Vail (1989) argued that while many academics in the US claimed that tribes did not exist and the term tribalism was a racist label imposed on non western populations, young Africans in emerging nations were asserting themselves as members of tribes and reasserting historical and existing regional and ethnic identities, as well as enmities between and among such groups. Emerging African governments used accusations of tribalism to denounce groups that objected to the position of the dominant party (Wiley 1981; Vail 1989). Wiley (1981, 1990) argued that group identity along ethnic lines was given positive meaning in western settings, but was referred to as tribal and negative in Africa, Latin America, and indigenous American populations, leading to misdirected foreign and social policies.

Since the 1990s there has been a resurgent use of tribalism in terms similar to those found in the period of colonialism and in the 1950s. In political science and in public rhetoric, Huntington (1993, 1996) has argued that tribalism based on ethnicity, religion, and/or language is the dangerous result of the end of the bipolar enmity of the Cold War. From this standpoint, tribalism is a negative reference to groups seen

as inferior and insular that resist and oppose other forms of organization and political authority claimed as legitimate and found in nation states and global systems.

trust

Karen S. Cook

A number of social theorists (e.g., Fukuyama 1995) argue that trust is somehow central to the production of social order in society. Trust fosters cooperative relations and lessens the need for monitoring and sanctioning. The strong argument that trust is *required* to produce cooperation, however, cannot be accurate since cooperation occurs in many settings in which there is very little trust. In such settings cooperation is secured by other mechanisms (Cook et al. 2005). In many instances these

mechanisms include reliable legal institutions that back property rights and contracts, as well as professional associations that monitor and sanction improper behavior and block the violation of trust relations (e.g., for physicians, lawyers, and others whose clients are often vulnerable).

Trust typically emerges when the parties involved have the opportunity to assess trust worthiness as they interact over time. In this sense trust is most likely to emerge in ongoing social relations in which there is a shadow of the future. It is much less likely (if at all) to emerge in settings in which the parties are strangers who will not encounter each other again. Cultural settings vary in the extent to which parties to an exchange are willing to take a risk on one another in the first instance of an exchange. In the trust literature, the term generalized trust is often used to indicate the extent to which individuals in a culture believe that "most people can be trusted," reflecting a relatively benign environment in which initial contacts are more often positive than negative. Where generalized trust is high, it is argued, exploitation tends to be lower; where it is low, the risks of exploitation are generally higher.

Adopting Hardin's (2002) encapsulated interest view of trust allows us to define trust primarily in relational terms. Actor A trusts actor B with respect to some particular matter(s) x, y, \dots, z when A believes that her interests are included in B's utility function, so that B values what A desires primarily because B wants to maintain a good relationship with A. Others have adopted a somewhat more general definition of trust as the belief that the trustee will not take advantage of a truster's vulnerability. If there is no risk or vulnerability there is no need for a trust relation to emerge between actors. To the extent that actor A perceives actor B as trustworthy, A is also much less likely to monitor B or to sanction B's negative behavior. It is this fact that leads to the argument that trust reduces transaction costs. Trust may also be essential when there is great risk of exploitation. Exploitation is especially likely when there is a power difference between the actors involved in the interaction.

Understanding trust has become a major enterprise in the social sciences in the past

decade, in part because of the changes in the fundamental nature of social relations as individuals in many cultures spend more time outside of the confines of family and small local communities. As Blau (2002) notes, life in large complex societies is very different from life in small isolated communities because in complex societies there has been a decline in the significance of the groups into which one is born, together with the growing significance of reciprocal social relations with relative strangers. Cook and Hardin (2001) refer to this changing circumstance as the move from communal norms of association and social control to networked forms of association and a reliance on other mechanisms of social control, including reliance on trust relations in networks. For social association, strangers in modern societies become "dependent on reciprocated choices," to use Blau's terms, in order to sustain social relations. This social change implies that the types of norms that control behavior in tight knit communities or small groups are not likely to be effective in the world of networked social relations.

In general a lack of mutual trust in a society makes collective undertakings difficult, if not impossible, since individuals cannot know if they engage in an action to benefit another that the action will be reciprocated. It is not only the problem of not knowing whom to trust, it is also the problem of having others not know they can trust you. The lack of mutual trust, Arrow (1974) points out, represents a distinct loss economically as well as a loss in the smooth running of the political system which requires the success of such collective undertakings. Mutual trust, however, cannot be produced on demand and is difficult to maintain even in close personal relations.

In the global era social contacts extend across regional and national boundaries in social networks defined by business, work, or travel connections and increasingly are maintained by more remote forms of communication, such as computer mediated interaction. Economic relations also extend far beyond face to face contacts. Many economic transactions are secured primarily by social relations or are embedded in social networks, sometimes including trust relations among business partners. As Arrow (1974)

notes, trust not only saves on transaction costs, it may also increase efficiency at the system level by reducing other costs, thereby increasing productivity. Arrow points out that many societies in which mutual trust is low are less developed economically, raising the question that Fukuyama (1995) addresses concerning the role of trust in the economic productivity of societies more broadly. The role of trust in Arrow's view is mainly in the production of public goods. When do individuals set aside their own personal interests to respond to the demands of their local community or even the larger society? This general question has also been addressed in a large experimental literature on social dilemmas (Cook & Cooper 2003). Issues of trust will remain central to theories of social order in the new world of broad ranging networked interactions and a global economy.

trustworthiness

J. Amos Hatch

Trustworthiness is a concept that constructivist qualitative researchers have used to establish criteria for judging the adequacy of their scholarly inquiries. Trustworthiness is roughly equivalent to the concept of validity in traditional quantitative research, and the genesis of its development is rooted in attempts by qualitative researchers in the early 1980s to find ways to legitimize their work and persuade others to take it seriously. Constructivist researchers think of trustworthiness as a system of checks and balances that take form in four criteria that reframe traditional, positivist elements of validity. *Credibility* is the constructivist criterion that parallels internal validity in the positivist paradigm; *transferability* parallels external validity; *dependability* stands in for reliability; and *confirmability* takes the place of objectivity. Along with the substitute criteria are corresponding empirical procedures (e.g., prolonged engagement, triangulation, and member checks) designed to affirm the adequacy of qualitative reports.

The term trustworthiness was first used in the context of qualitative research by Guba (1981). Guba contrasted criteria for adequacy between what he called rationalistic and naturalistic paradigms. He then introduced the criteria listed above and described a set of research techniques for enhancing the trustworthiness of naturalistic studies. In the same year, Guba and Lincoln (1981) published an elaboration of the same criteria and procedures. Over time, these authors have changed nomenclature, locating trustworthiness within the constructivist (not naturalistic) paradigm and contrasting their approach to positivist and postpositivist (not rationalistic or conventional) epistemological perspectives, but their descriptions of the trustworthiness concept and its purposes have remained constant (Guba & Lincoln 1994; Lincoln & Guba 2000).

Elements of trustworthiness and research techniques for improving the trustworthiness of naturalistic/constructivist studies are carefully described in Lincoln and Guba (1985). Building on their previous work, an entire

chapter is devoted to establishing trustworthiness in naturalistic research. A case is made for the importance of credibility, transferability, dependability, and confirmability as alternative criteria for establishing the merit of naturalistic studies, and research techniques for applying these criteria throughout the research process are detailed. Meeting the credibility criterion means demonstrating the “truth value” of the naturalistic inquiry by showing that multiple constructions of reality have been adequately represented and that the reconstructions of the researcher are credible to the constructors of the original realities. Lincoln and Guba suggest several research techniques designed to increase credibility: *prolonged engagement* (spending sufficient time in the field); *persistent observation* (bringing depth to the examination of salient elements); *triangulation* (using different data sources, methods, investigators, and theories); *peer debriefing* (exposing one’s research processes and findings to disinterested peers); *negative case analysis* (looking for alternative or disconfirming interpretations); *referential adequacy* (archiving portions of data for later comparison); and *member checks* (attaining feedback on research processes and results from those being studied).

Addressing the transferability criterion means providing enough information to potential users of research findings so that these individuals can make good decisions about the applicability of the findings to their own situations. Lincoln and Guba offer *thick description* as a technique for addressing transferability concerns. Adequately thick descriptions include sufficient contextual data so that readers can make their own determinations about how well the research settings match with other contexts in which the findings might be applied. Lincoln and Guba operationalize the trustworthiness criteria of dependability and confirmability in the form of an *inquiry audit*, including an *audit trail*. An inquiry audit can bolster a study’s dependability and confirmability by providing a careful analysis of the residue of records generated at all stages of the inquiry. The kinds of records that make up an audit trail include raw data, data analysis products, process notes, reflexive notes, and instrument development information. Lincoln and Guba conclude their description of research techniques by presenting *reflexive journal*

writing as a strategy that reaches across all of the criteria for enhancing trustworthiness. A reflexive journal should include a daily record of the logistical implementation of the study, a personal diary recording the researcher’s affective experiences, and a methodological log recounting decision processes as the study unfolds. Reflexive journaling and the research techniques associated with each criterion provide tools for increasing the trustworthiness of naturalistic studies.

The major contribution of the trustworthiness construct has been to provide qualitative researchers with an alternative perspective from which to consider issues of warrant that continue to trouble those operating outside the dominant discourse of positivism and quantitative research. In the 1980s, qualitative researchers were dismissed or even attacked for producing work that traditional researchers counted as “slipshod” or “touchy feely.” By identifying the elements of trustworthiness and applying the empirical strategies designed to accomplish them, qualitative scholars are able to make the case that their methods are legitimate. Even when the trustworthiness concept is not explicitly identified, its impact is evident in the frequency with which the strategies for accomplishing it are utilized in all kinds of qualitative reports. As qualitative inquiry has matured, the trustworthiness construct has been adapted to fit emerging research approaches under the qualitative umbrella. For example, Kincheloe and McLaren (1994) describe “critical trustworthiness,” Hatch and Wisniewski (1995) include trustworthiness among criteria for assessing narrative research, and Green (2000) points out the utility of trustworthiness for the evaluation of social programs. In the early twenty first century, qualitative research approaches are facing new threats as conservative political forces seek to return to narrow definitions of what constitutes “scientific” research (Erickson & Gutierrez 2000). Trustworthiness and adaptations of the procedures associated with achieving it continue to be important as qualitative research approaches seek to be acknowledged as legitimate.

Those who have critiqued the usefulness of the trustworthiness concept point out that it is more closely aligned with the assumptions of the positivist paradigm than many find

comfortable. In Guba and Lincoln's (1994: 114) own words, "although these criteria have been well received, their parallelism to positivist criteria makes them suspect." Others, who have moved past dividing research paradigms into binaries such as qualitative/quantitative or positivist/constructivist, argue that trustworthiness is not a good fit for evaluating qualitative research undertaken within alternative qualitative paradigms such as those embracing critical/feminist or poststructuralist epistemologies (Lincoln & Denzin 1994; Hatch 2002). Following this logic, seeking to establish trustworthiness remains a worthy goal for naturalistic researchers operating within the assumptions of the constructivist paradigm, but such an attempt would not make sense given the different worldviews that define paradigms other than constructivism.

Truth and Reconciliation Commissions

Kevin Avruch

Truth – or Truth and Reconciliation – Commissions are “bodies set up to investigate a past history of violations of human rights in a particular country – which can include violations by the military or other government forces or armed opposition forces” (Hayner 2002: 14). Such commissions focus on the past (usually on violations committed under a previous regime) and have strictly delimited mandates, both as to duration and what “counts” as violation. In the Chilean commission’s mandate, for example, only cases where victims actually died under torture were to be counted as human rights violations and investigated. The majority of commissions were established by executive order (less frequently by legislatures) of the new government. In the case of El Salvador, the United Nations established the commission, and it was (untypically) headed by non Salvadorans. In a few cases an NGO established the commission, as in Rwanda and earlier in South Africa by the African National Congress to investigate its own abuses. In legal terms, Truth Commissions are to be distinguished from “tribunals” or other more strictly judicial entities, such as War Crimes Commissions, since they do not possess the formal power to prosecute or otherwise render “justice” – an important point to be discussed below. In a few cases, Truth Commissions operate alongside tribunals (East Timor and Sierra Leone), or parallel to other judicial processes (Rwanda).

Since 1974 some 25 Truth Commissions have been established, about 10 each in Latin America (Bolivia, Argentina, Uruguay (twice), Chile, El Salvador, Ecuador, Guatemala, Peru, and Panama), and African countries (Uganda (twice), Zimbabwe, Chad, Rwanda, Burundi, South Africa, Nigeria, Sierra Leone, and Ghana). The remainder occurred in Nepal, Sri Lanka, Haiti, Yugoslavia, and East Timor. They typically complete their work within six months to two years. In a few cases the commissions were disbanded before their work was completed and reports issued (Bolivia and Ecuador), in other cases final reports were completed but never issued publicly (Zimbabwe, Uganda, Philippines), or were issued in severely censored versions (Haiti). By contrast, in South Africa's case the report published in 1998 received extremely wide distribution, and the work of the Commission itself was reported extensively by South African and international media. Argentina's report, issued in 1985, published under the title of *Nunca Mas* ("Never Again"), was widely read in Spanish, translated into English, and republished commercially in Britain and the US.

Such variation in final reporting characterizes other aspects of the commissions, in the scope of their work, the resources or legitimacy they command, and observers' judgments of their ultimate effectiveness or success. With regard to scope for example, a few of these commissions, most notably South Africa's, add the term "Reconciliation" to their title, pointing to wider ambitions in the area of post conflict peacebuilding, while in some other cases the search for "truth" defines the commission's mandate but the further task of "reconciliation" is intentionally left out (Yugoslavia). Yet even where the search for "truth" is highlighted in the commission's name and mandate, some of the commissions have been able to command wide recognition and respect for their relative impartiality and effectiveness (South Africa and Argentina), while others have been seen as more compromised (Chile's, where members of the old regime remained influential), as reluctant responses to international pressure (Uganda's 1974 commission), or merely as platforms to criticize the old regime and legitimize the new one (Chad).

The majority of commissions were established by newly emerging and often very fragile democracies – "transitional governments" in Kritz's (1995) term – which sought or were pressured to present a formal accounting of the violence and civil and human rights violations of the past. The emphasis here is on the production of an *account*. More difficult questions (political and moral ones) of *accountability* are less adequately addressed by these commissions (Minnow 1998; Rotberg & Thompson 2000). Such questions focus attention on the problem of *justice*, specifically on the ability of the commissions to "deliver" justice to victims by finding perpetrators formally guilty of their crimes and rendering some sort of appropriate punishment – *retributive justice*, in other words. Kritz (1995) and others have argued instead for forms of "transitional justice" appropriate to transitional regimes: less adjudicative, formal, and retributive, but in their lesser stringency and flexibility more able to help a new, fragile regime maneuver around the potential resistance posed by former elites and potential "spoilers," and thus achieve a measure of stability. This is the necessary political compromise some see built into the nature of the Truth Commission, especially if, as in the South African and several other cases, the commission lacks the power to prosecute but not effectively to grant amnesty. The question of amnesty granted perpetrators is among the most controversial aspects of these commissions' work.

Others, however, claim more far reaching goals and positive achievements for the commissions than retributive justice, delivered in court rooms or war crimes tribunals, can provide. Bishop Desmond Tutu (1999), for example, has argued that these commissions offer both victims and perpetrators another valid form of justice entirely, *restorative justice*, focused not upon penalty, punishment, and retribution, but upon recognizing harm, encouraging healing, and aiming for reconciliation. Proponents of restorative (or "reparative") justice are more likely to add the notion of "reconciliation" to that of "truth" as among the explicit goals of the commission, and to consider reconciliation, consisting minimally of "contrition" (on the part of the perpetrator) and "forgiveness" (on the victim's part), as crucial elements in the broader project of post conflict peacebuilding.

Whatever the hoary questions around the intersection of truth and justice, most observers and analysts agree that these commissions often do succeed in providing an authoritative and widely accepted record of what actually took place in the past, and giving to victims (and perhaps also to perpetrators; see Gobodo Madikizela 2003) a platform and a voice to recount their experience and express their pain and suffering. This is the “truth” part of the commissions’ work. In the South African Truth and Reconciliation Commission, such “narrative” or “personal” truths, emerging from testimonies, sought to ensure that individual acts of oppression could never be forgotten, and to create an indelible public memory and record of these events. Yet with respect to “truth” these commissions routinely operate in politically charged worlds that would make the most steadfast of academic postmodernists blush. And facts, even if publicly accepted, do not necessarily conduce to publicly accepted truths. The apartheid security forces and Latin American colonels and generals apparently believed that they were fighting communist subversion under emergency conditions that demanded extraordinary measures to protect national security; and many believe this today, even some among them who appeared before various commissions and admitted their acts and expressed regret for their victims and offered apologies to the survivors (Avruch & Vejarano 2001).

The final question surrounding the work of Truth Commissions has to do with how well change or transformation effected at the individual level of victim and perpetrator “transfers” to the national level and the larger project of national reconciliation. Advocates and critics argue about this, with the South African case often used by both parties in their arguments. But rigorous data are lacking, and claims to assessment are mainly still anecdotal. What can be said is that Truth and Reconciliation Commissions are part and parcel of the larger

project in the globalization of human rights and democratization. No one claims they are panaceas for the spread of human rights and democracy, but most of their supporters see them as relevant and appropriate, and not a few, as indispensable.

U

uncertainty

Jens Zinn

Uncertainty is characterized by cognitive and emotional elements. Uncertainty indicates unclear, ambiguous, or contradictory cognitive constructions, which cause feelings of uncertainty.

In sociology as well as economics, uncertainty is about expectations. It refers to the future and whether our expectations will be met and also to the present and our capacity to produce expectations. Typically, norms and institutions structure our expectations. They support clear and unambiguous notions and expectations even though they are always – to a certain degree – uncertain (Luhmann 1993). Sociological classics (e.g. by Durkheim, Gehlen, Parsons, and Erikson) see the destabilization of institutions and normative expectations caused by social change as something negative. The destabilization of expectations would produce feelings of uncertainty, and can even lead to an increase in suicides (Durkheim 2002 [1952]).

More recently, the term uncertainty became prominent in the discourse on reflexive modernization (Beck 1992; Giddens 1991) and the thesis of the risk society and institutional individualization (Beck 1992). A growing complexity, diversity, and instability would destabilize expectations, and awareness of lack of knowledge, especially regarding new risks (e.g., global warming, ozone layer depletion, nuclear contamination, genetically modified food) which cannot be calculated and rationally managed, would trigger feelings of uncertainty.

In economics uncertainty is distinguished from risk and ignorance. Whereas ignorance is what we cannot know, risk is understood as calculable and therefore manageable uncertainty.

When the “distribution of the outcomes of a group of instances is known (either through calculation a priori or from statistics of the past experience)” we call it risk. In the case of uncertainty “it is impossible to form a group of instances, because the situation dealt with is in a high degree unique” (Knight 1921). That does not mean that we know nothing about the future, but our knowledge is limited and our expectations therefore more or less certain.

Even though uncertainty is seen as a lack of controllability and therefore as negative, it is widely acknowledged that uncertainty is more the rule than the exception. Especially in entrepreneurial decision making, there is always a high degree of uncertainty involved because of novelty and unstable markets.

Recent developments in sociology and economics have fundamentally changed the perspective on uncertainty. Since it became evident that we often cannot transform uncertainty into certain expectations, growing interest has developed into how we can manage uncertainties as such. Therefore, new strategies beyond instrumental rationality have appeared (e.g., emotion, trust, fast and frugal heuristics, precaution), while the positive aspects of uncertainty, such as giving space for shaping the future, have been recognized (Zinn & Taylor Gooby 2006).

unemployment

Mikael Nordenmark

Unemployed persons comprise all those within the economically active population who are able and willing to work, and who are actively seeking jobs, but unable to find one. Unemployment and job loss affects millions of people every year throughout the world and the level of unemployment varies with economic conditions and other circumstances. The unemployment rate is expressed as a percentage of the total civilian labor force, where the latter includes both the unemployed and those with jobs (all those willing and able to work for pay).

Sociological unemployment research contributes to the understanding of the social and economic consequences of unemployment for individuals, family members, and others in the community. A majority of the studies have focused on the relationship between unemployment and mental health. The Great Depression of the 1930s generated some of the first studies of the effects of unemployment on the individual. Above all, it was the negative economic consequences of unemployment that were the focus, but their studies also indicated that unemployment affects individuals' social life, identity, and mental well being negatively (Jahoda et al. 1971; Bakke 1933).

As a consequence of the development of welfare states and welfare transfers, more recent unemployment research has concentrated on the psychosocial side of unemployment instead of the economic side. As with the investigations from the 1930s, most of these studies show that

the unemployed in general have poorer mental health than the employed. However, unemployment does not seem to have the same effect on everyone. The adverse effects of unemployment on mental well being have been found to be mediated by the individual's economic situation, work involvement, gender, social class, age, marital status, ethnicity, duration of unemployment, and previous unemployment experience.

There has been a debate on how the relationship between unemployment and mental health should be understood in causal terms. Does the level of mental well being cause unemployment or vice versa – is well being affected by the labor market situation? Longitudinal studies have shown that it is a question of both selection and effect. People with relatively poor mental health status run an increased risk of becoming unemployed, but also unemployment in itself has a negative impact on mental well being. However, most studies provide powerful evidence that unemployment causes, rather than merely results from, poor mental health (Gallie & Paugam 2000; Nordenmark & Strandh 1999; Warr 1987).

The most commonly used theoretical perspective for explaining the consequences of unemployment is the functionalistic approach developed by Maria Jahoda (1982). She looks at the consequences of unemployment in the light of the psychosocial meaning of employment. Jahoda maintains that employment, in addition to economic or the manifest functions, also has certain psychosocial functions (time structure, social contacts, participation in collective purpose, regular activity, status, and identity). It is the loss of these functions that is the main cause of poor mental well being among the unemployed.

One main critique of Jahoda's theory is that it sees all kinds of paid work as equally important for the individual's well being. Warr (1987) tries to solve this problem with his vitamin theory. According to the theory, there are vitamins that a human being needs for staying healthy and these can be consumed both in an unemployment, as well as in an employment, situation. Because the theory assumes that employment, and the loss of employment, can have different meanings for different individuals, it can

be used to explain mental health differences between categories of unemployed.

But perhaps the most serious critique of both Jahoda's theory about the latent functions of employment and of Warr's vitamin theory is the minimal role that the individual, or the actor, is assumed to play. These theories focus on how factors in the social environment affect individuals, rather than on how individuals experience, interpret, and act towards their social structure. This is what could be called a functionalistic perspective on the consequences of unemployment, and it has been criticized for instance by David Fryer (1986). In his agency theory, Fryer assumes that persons are active and motivated individuals who influence their environment and try to do their best to realize themselves. The effects of unemployment on mental health are then dependent on the degree to which the unemployment situation restricts agents from reaching what they see as desirable goals.

While Jahoda and Warr are criticized for overemphasizing the importance of the social structure, Fryer is often blamed for overemphasizing the role of the individual and not paying sufficient attention to the restrictions of the social environment. Therefore, there have been attempts to pay adequate attention to both individual and structural factors within one theory. In his status passage theory, Douglas Ezzy (1993) tries to integrate both structural factors and an acting agent. According to Ezzy, the level of mental well being among the unemployed is mainly decided by the individual's subjective interpretations of the objective social context.

In the light of previous unemployment research it is possible to distinguish two main dimensions of employment that structure the level of mental well being among the unemployed: the psychosocial and economic dimensions. In line with Ezzy's thoughts, the PEN model (*psychosocial and economic need for employment*) combines the psychosocial functions and agency perspectives into a conceptual model with which one can understand the interaction of these two needs. The model predicts that unemployed who have both a weak economic need and a weak psychosocial need for employment (for instance, unemployed living with a well paid partner and strongly involved in activities not directly connected to

employment) should not perceive unemployment as problematic and they may adapt relatively well to their new situation. On the other hand, the combination of both strong psychosocial and economic needs makes the likelihood of poor mental health higher (Nordenmark & Strandh 1999).

An important task for future unemployment research is to further analyze the diverse effects of unemployment in varying social and national settings, and to integrate research from the different social sciences. While unemployment research within the behavioral sciences has focused on mental health consequences, most economic research has analyzed causes of unemployment and employment. However, the only way to reach a deeper understanding of both the causes and consequences of unemployment is to combine economic research with research from the behavioral sciences.

unemployment as a social problem

Jutta Allmendinger and Wolfgang Ludwig Mayerhofer

All industrialized or post industrial societies consider themselves to be working societies. Work – or more precisely, *gainful* work – defines an individual's worth and status. It is for most people the main means of earning a living and frequently the prerequisite to be eligible for social security coverage. Therefore, unemployment is a principal social and political challenge – in particular since the mid 1970s, when most western countries experienced a marked increase in unemployment as a result of the so called first oil crisis. This followed an approximately 20 year period during which it was generally assumed that the interwar economic and labor market crisis was a thing of the past. Since then, the western industrial countries have tried, with varying success, to come to terms with the problem of unemployment. The post socialist economies – to varying degrees as well – are also hit by unemployment.

It is frequently alleged that unemployment results above all from regulatory interventions in the ("free") labor market, including overly generous social benefits. One cites as proof the relatively low unemployment rates in countries such as the US and Great Britain, which, in contrast to most European countries or Japan, have a weakly regulated labor market and residual social security systems, targeted mainly at the poor. Yet countries whose market regulations and/or social benefits are comparable to or even surpass this last mentioned group of countries (in many respects, this is true of the Scandinavian states) have also been very successful in fighting unemployment.

DEFINITIONS

The definitions and statistical measurement of unemployment differ in international comparison. To be counted as unemployed, an individual must have no or little gainful employment and seek paid work (which can also mean

more extensive work than previously). Many countries use the International Labor Organization definition of unemployment, which is based on surveys: an individual is considered unemployed who was not in *any* gainful employment during a specific reference week and who is actively seeking work. In other countries (e.g., Germany) unemployment is defined by a state agency, which counts as unemployed those who register with the Public Employment Service; these individuals, however, are allowed to be employed up to half of the standard working hours of a fully employed person. On the other hand, individuals without any employment at all who are not registered as unemployed (often because they are not entitled to unemployment compensation) are not counted as unemployed, no matter how hard they are seeking paid work. Unemployment *rates* also differ depending on the chosen reference standard. In some countries, this reference group includes all dependent employees; in most other countries, it also includes the self employed. For the purposes of international comparison, the OECD is trying to standardize national unemployment statistics.

Aside from official unemployment, measured in whatever form, one can assume the existence of so called discouraged workers (i.e., individuals who would like to pursue gainful employment, but have given up hope of finding employment and thus do not actively seek work). Frequently, individuals who participate in active labor market policy measures are not counted among the unemployed. Therefore, the actual extent of underemployment is generally higher than officially stated.

At the same time, it is important to keep in mind that for many people unemployment is a transitional phase. In fact, one can observe high labor market dynamics even in times of high unemployment; in most countries more (in some countries, far more) people become unemployed – and for the most part find work again – than corresponds to the average yearly stock of unemployed. The average duration of unemployment and the extent of long term unemployment (generally defined as unemployment lasting one year or longer), which may serve as an indicator of entrenched unemployment, show large differences in international comparison.

UNEMPLOYMENT AS A SOCIAL PROBLEM

In most countries, the unemployment of individuals with low education is markedly higher – generally by a factor of 2 to 4 – than that of highly qualified workers. Often, the unemployment of younger and older workers is also above average; in the case of the former, this is mainly due to high entry rates to unemployment, while the duration of unemployment is mostly average or even below average. Marked gender differences can be perceived above all in continental European countries, where women's unemployment is often significantly higher than men's, while there are hardly any gender differences in Anglo Saxon countries with their liberal labor markets or in the Scandinavian countries with their greater emphasis on gender equality. In most cases, ethnic and racial minorities suffer significantly higher unemployment rates than the native born majority.

Unemployment endangers the livelihood of the unemployed individual and, possibly, also that of his or her family. Regardless of the existence of the so called working poor, unemployment in many countries is the most important cause of poverty. Only in a few countries (mainly in the Scandinavian states) do social security systems largely compensate for the loss of income due to unemployment. Unemployment is also frequently associated with problems such as crime, right wing extremism, suicide, and illness.

Generally speaking, these effects increase with the duration of unemployment. Therefore, it is important to ask how long term unemployment may arise on the individual level, and theories of self reinforcement of unemployment are perhaps best suited for this task. One explanation refers to employers' behavior. If an individual has been unemployed for some time, employers may assume that this individual has already been "checked out" by other possible employers and been found to be wanting the necessary skills; therefore, the longer a person has been unemployed, the fewer job offers they may receive. Another theory associates unemployment with loss of human capital. The longer a person has been unemployed, the more they are barred from access to the latest

developments in their occupation. Besides, they may also lose more general skills such as perseverance or develop health problems.

Finally, the unemployed often have the least access to (re)training and further education, although they would need it most, for instance, if they have been working in a declining industry and would fare better if they were to switch to an occupation that offers better prospects for future developments.

Unemployment frequently results in negative consequences, even after having been overcome ("unemployment scarring"). These "scars," for example, can be a lower income, a slower rise in income, or increased occupational instability. It should be added that such consequences need not necessarily arise; for instance, if unemployment has been caused by a bad "match" between the skills offered by the unemployed and those required by the earlier job, this match may be better on the next job.

Another facet of self reinforcing unemployment is repeated unemployment. Many findings suggest that multiple unemployment in the past increases the risk of renewed unemployment. Frequently, however, the duration of the new unemployment is shorter (i.e., those affected more quickly find new work). Generally speaking, long term unemployment and repeated unemployment seem to be different phenomena. The former seems to have more to do with (possibly ascribed) individual "deficits" (low education, health problems, age) that make the individual unattractive for employers, the latter with the idiosyncrasies of certain industries or partial labor markets (Andreß 1989).

Persistent unemployment on the societal level is frequently associated with the concepts of underclass and exclusion. The term underclass was coined by Gunnar Myrdal and describes a social group that, because of its lack of access to steady employment, is even below the "working class" and thus cut off from mainstream society; in American inner city ghettos this tendency is exacerbated by spatial segregation (Wilson 1987). The term underclass, however, was also used by some social scientists to ascribe to people certain traits such as the inability to work due to a lack of skills or the unwillingness to work due to certain values and attitudes; its use in sociology is therefore controversial. The term

exclusion (of French origin) plays a bigger role in Europe, yet at the same time is less clearly defined. Partly it is used in the context of a belief, according to which unemployment by definition damages the “social contract” and destroys social cohesion, so that (re)integration into the labor market simultaneously restores social integration. In empirical research, exclusion is operationalized as the extent to which unemployment results in fewer social contacts and lower cultural and political participation (Gallie & Paugam 2000). In critical perspective, the term is used to indicate that contemporary capitalism offers fewer and fewer opportunities to participate socially, especially for the “less productive.”

Unemployment is also a political challenge. Those polled in surveys in the European Union most frequently cite unemployment as among the “most important problems facing their country” (with marked variations, depending largely on the level of unemployment in any given country). Enduring unemployment in particular – especially in countries where unemployment benefits are based on the contributions of the employed – poses a challenge to the viability of systems of social security. A labor market crisis in general raises demands for reducing the cost of the work factor by, among other things, lowering the non wage labor costs; yet high unemployment may necessitate an increase in social security contributions, unless one simply cuts unemployment benefits. More generally speaking, a situation of permanent austerity requires a “new politics of the welfare state” (Pierson 2001), which poses complex challenges for governments. It cannot be assumed, however, that the fight against unemployment has the highest priority everywhere (Korpi 2002); it can conflict with other goals such as price stability, and occasionally the fight against unemployment is undertaken rather as a form of symbolic politics.

It is in this context in particular that the unemployed run the risk of being confronted with “blaming the victim” attitudes on the part of political leaders. Based on a long tradition of distinguishing between the “deserving” and the “undeserving poor,” there are repeated attempts to put many unemployed in the latter category, by representing unemployment as

voluntary or as an expression of an aversion to work. According to modernized versions of such theses, unemployment is caused above all by overly generous social benefits, which raise the reservation wage of the unemployed above the actual level of productivity or to where the marginal returns of employment would be too small compared to unemployment compensation. If such arguments, which are geared to moral hazard, cannot be wholly dismissed, they fail to recognize the possible positive effects of unemployment benefits. If unemployment benefits are contingent upon continuous contributions, they provide an incentive for gainful employment, and in the case of actual unemployment, unemployment benefits can alleviate the pressure to have to accept the next best job offer and thus improve the match between job and skills (Gangl 2004). In addition, one also has to take into account the non monetary benefits of employment, such as social contacts or prestige, which make many people accept employment that has little or no marginal return from an economic point of view.

LABOR MARKET POLICIES

It is difficult to provide an exact definition of labor market policies, given that some countries distinguish between a policy of fighting unemployment and a policy of maintaining or raising employment and others do not. In the field of labor market policies in the narrow sense, that is, policies directed at the unemployed, there is usually a distinction between “passive” and “active” labor market policies. Passive labor market policy refers to unemployment compensation; active labor market policy denotes measures that help bring the unemployed back to work. These distinctions are not as clear cut as they may seem at first sight, since the cutting down of benefits, which has occurred in most countries during the past decades, often has been justified on account of providing more “incentives” for the unemployed to actively engage in seeking work. Indeed, “activation” of the unemployed has been a central feature of recent labor market policies; in the European Union, this term serves as a central guideline, but the reforms in the US, often referred to as

“workfare” (Peck 2001) (i.e., making welfare receipt conditional on being engaged in paid work), likewise can be understood as activation. It may be useful to distinguish between at least two types of activation policies (Torfing 1999; Barbier 2004). “Low end” activation is based on providing low benefits and making them strictly conditional on the unemployed’s efforts in seeking work and undergoing “work test” measures. “High end” activation, while not necessarily opposing a tighter grip on the unemployed, emphasizes training the unemployed and possibly also more state sponsored or subsidized jobs, at least on a temporary basis. Both types of activation seem to bear fruit, as is testified by the success of such divergent countries as Britain on the one hand and Sweden or Denmark on the other. Yet it must not be forgotten that reducing unemployment usually also involves fiscal, monetary, and other types of policies. The Netherlands, for instance, has been rather successful not only in reducing unemployment but also in increasing female labor market participation (even though to a large extent based on part time work) due to a mix of policies of wage moderation, increased flexibility, tax and welfare reform, and a shift of jobs towards private services (Visser & Hemerijck 1997).

FUTURE OF UNEMPLOYMENT

Unemployment is frequently explained by the transition of capitalist societies to post industrial and post Fordist economies. Technological changes lead to a continual rise in productivity, and economic growth in many countries lags behind the ensuing job decline, so that one frequently talks about “jobless growth.” Earlier hopes that the jobs lost in the producing sector would be regained in the service sector have not come true in a number of countries. Negative utopias such as Jeremy Rifkin’s *The End of Work* (1995) picture a world in which computers, robots, biotechnologies, and the like render human work nearly completely superfluous. Globalization has in recent years become another hotly debated topic; as capital becomes more and more mobile, cheap labor in Eastern Europe or Asia poses a threat to

employment in those countries hitherto considered as the leading nations.

Yet the most likely consequences of globalization are more complex; as some jobs are “exported,” new jobs are created that are necessary for firms to survive on international markets. Firms increasingly act as multinational or transnational enterprises and work is distributed over many countries and linked by computer networks. The outcomes of these developments for national labor markets (which still exist for a vast majority of workers, higher transnational mobility on the bottom and the top of the hierarchy of jobs notwithstanding) are less than clear cut and may vary considerably between countries.

Such variation is even more likely in the light of different production regimes and social models; it is not at all clear that the more “liberal” and uncoordinated economies that can be found in many countries of the Anglo Saxon world are superior to the coordinated market economies that prevail on the European continent (Freeman 1998; Soskice 1999). While unemployment in Europe is at high levels, it has rightly been pointed out that this is largely due to the problems of four major economies: Germany, France, Italy, and Spain. Most other countries fare substantially better. On the other hand, the drawbacks of (nearly) full employment in countries such as Britain and the US should not be neglected: high wage inequality, large numbers of “working poor,” and in the US a huge number of imprisoned adults, mostly black, who otherwise would raise the unemployment rate by about 2 percentage points (Western & Beckett 1999). Yet it is obvious that the European economies, based largely on medium and high skilled jobs, have to increase their investments in human capital substantially if they do not want to lose ground and if they want to maintain their higher levels of equality. Also, inclusion of women in the labor market is still lagging considerably behind many Western European countries. At the same time, it may be increasingly necessary to loosen the hitherto tight connection between paid work and entitlements to welfare benefits, as job insecurity most likely will continue to grow and episodes of unemployment will be part of the life course of many individuals for the coming decades.

uneven development

A. J. Jacobs

Uneven development refers to the inequitable spatial distribution of wealth and/or economic growth within a city, a metropolitan area, a nation state, or globally. The term also represents the simultaneous occurrence of economic and wealth expansion in one area accompanied by disinvestment and/or expanding poverty in another area. Urban scholars frequently have measured uneven development statistically, through an examination of the geographic distribution of income and employment within or among metropolitan regions, or by an analysis of changes in these and other variables among municipalities, over time. For example, Hill (1974) utilized zero order correlations to measure economic class and racial segregation by place within 127 American Metropolitan Statistical Areas. Jacobs (2003) compared the degree of place stratification in the Detroit and Nagoya Auto Regions by calculating the standard deviation divided by mean change in per capita income, population, and private employment in the two regions between 1969 and 2000 (i.e., the coefficient of variation) (see Jacobs 2005).

A prime case of interregional uneven development within a nation state was the large scale shift of industrial investment from the American Rustbelt (Northeastern and North Central US) to the American Sunbelt (Southeastern and Western US) that occurred during the 1970s and 1980s. A clear illustration of metropolitan uneven development has been the persistent post World War II out migration of population from American central cities to suburbia. In the case of the latter, many push and pull factors have contributed to these outcomes. The pull factors were fairly straightforward. The war,

combined with rapid economic growth in the US afterwards, created pent up demand for new housing in urban areas. However, in the early post war period, land in central cities was either unavailable or too expensive for the construction of new single family middle class residences. Therefore, Americans who dreamed of owning a home rather than renting, or owning a bigger and newer home with a backyard, were attracted to the open spaces and new housing in the suburbs. This phenomenon was supported by national monetary, tax, and infrastructure policies that made it possible for middle class families to receive secured, long term, low interest housing loans, and tax breaks for mortgage interest. It also made suburban locations greatly accessible to urban core employment centers through the construction and subsidizing of highways and water and sewer lines.

Unfortunately, the American dream was not open to everyone. Stated and latent national and local policies, such as those promulgated by the Federal Housing Administration (FHA), which recommended that banks only make loans in homogeneous areas, severely limited the housing opportunities of blacks, other minorities, and the poor. This served to exacerbate existing racial and class segregation in cities and metro areas; Gotham (2002) termed this racialized uneven development. It also allowed for the total abandonment of many inner city neighborhoods through restrictive covenants and bank redlining (e.g., the total refusal of banks to loan money in certain urban neighborhoods). The totality of these events dramatically heightened interracial animosity in the 1960s, especially in the industrial North. This served to accelerate central city white flight during the next decade. By the 1980s, hundreds of thousands of middle class jobs also had left for suburban green fields. The net result was rapid ex urban growth accompanied by massive fiscal shortages in the urban core, and place/spatial stratification by race, income, and educational and occupational status within many American metropolitan areas.

The academic literature on uneven development has been vast. Scholars of urban ecology were the first to conduct in depth studies examining the causes of spatial inequities. One of the most influential early twentieth century studies was Roderick McKenzie's *American Journal of*

Sociology essay, "The Concept of Dominance and World Organization" (1927). In this and other articles, McKenzie utilized biological metaphors to chronicle how human settlement patterns over time had led to a hierarchy of spatial locations. This system included the concentration of command and control activities in urban core areas, and the creation of specialized sub centers and subordinated periphery areas.

The Chicago School of urban ecology remained significant in the field of urban studies until the 1970s. Nevertheless, many of the most important studies of uneven development between the late 1950s and early 1970s focused on capitalism's impact on international inequities. In *Rich Lands and Poor*, Gunnar Myrdal argued that international place inequities were an inevitable social reality of modern capitalism, and that such unevenness naturally grew wider over time, as developed nations industrialized further, and investment and capital became more concentrated in these areas. In *Capitalism and Underdevelopment in Latin America*, André Gunder Frank argued that development and underdevelopment were like two sides of a coin. Drawing from the work of Paul Baran, he challenged the conventional economic thought of the time by claiming that global capitalism, rather than feudal backwardness, had been the primary cause of stagnation and poverty in certain nations and subnational regions, as well as metropolitan satellite polarization (developed-underdeveloped). Introducing dependency theory to North American scholarship, he maintained that uneven international and intranational outcomes were expected manifestations of metropolitan capitalist class extraction of surplus value from satellite labor.

While these studies and others were significant, perhaps the most important contributions to the discourse on uneven development during this period were those of Immanuel Wallerstein and Steve Hymer. Mirroring McKenzie, Wallerstein claimed that by the middle of the seventeenth century, capitalist development had already divided the world's territories into three unequal structural positions: core, semi periphery, and periphery. In his seminal piece, "The Multinational Corporation and the Law of Uneven Development" (1972), Hymer combined McKenzie's human ecology with Alfred Chandler's business organizational analysis to

explain the relationship between transnational corporations (TNCs or transnationals) and uneven spatial configurations (Hill & Feagin 1987). He argued that as a corporation evolved from a family firm to a TNC, territorial space was organized and reorganized locally and globally to reflect the internal organization of the firm. He suggested that like the nervous system in the body, political jurisdictions under the influence of TNCs became economically and socially dependent on such firms, rather than autonomous of them. This situation of dominance and subordination then served to both exacerbate social and economic divisions of labor and reproduce them on the spatial landscape.

It was the works of these two scholars that laid the foundation for the development of urban political economy. It has been this theory, whose advocates examine "the relationship between capitalism and urban organization on a global scale," which has been the dominant paradigm in the study of spatial inequities over the past 25 years (Hill & Feagin 1987). For example, the global/world cities hypothesis (to be discussed later) is an urban centered derivative of Wallerstein's world systems theory.

One other significant but under appreciated 1970s contribution to the discourse was Blue stone's (1972) article. Here he wrote that uneven development was inevitable in the American economic system. Over time, those who controlled resources would tend to invest and reinvest in products, geographical areas, and workers that promised them the most profitable return on their investment. Conversely, disinvestment would occur over time in products, places, and people that the dominant class believed offered them a relatively low return on their investment. Moreover, he claimed that uneven development was not restricted to industrial investment alone, but also was clearly evident in employment, education, training, and health care opportunities. This was because American political and business leaders had a vested interest in maintaining an unequal distribution of resources, as it disproportionately concentrated wealth and political influence within a small circle of power elites. Based on this evidence, similar to Myrdal, Bluestone concluded that the American political economic system inherently produced "continuous growth and relative prosperity" in affluent areas and segments of society, and

relative stagnation and impoverishment in declining areas and sectors, with the gap between the haves and have nots growing wider over time.

The 1980s represented the peak period for the study of American urban and metropolitan uneven development. For the most part, scholars maintained that American metropolitan unevenness was best understood as a long term process evolving out of the actions of economic and political elites operating within a complex context of global, national, and local political economic and social forces. In other words, they believed that America's particular forms of uneven development were deeply embedded within that nation's specific national and sub national contexts. As Smith (1988) claimed, this has been why the widespread and pronounced sprawling development, urban fiscal stress, residential segregation by class, and depopulation of inner city areas in the US have generally not been found in other advanced capitalist states.

While the urban scholarship of the 1980s focused a great deal on unevenness within and among metropolitan areas, the discourse since the early 1990s has centered on the degree to which globalization has had an impact on spatial unevenness. Extending Wallerstein's approach to the study of cities, global/world cities hypothesis theorists have argued that the continued globalization of the economic functions in modern industrial capitalism has created an international hierarchy/division of labor among cities and metropolitan areas. According to this view, expounded by John Friedmann, Saskia Sassen, and others, this hierarchy has served to expand inequities between core and periphery areas, between transnational elites and low skilled workers, and between dominant groups and racial minorities. In addition, it has led to an expansion of inner city ghettos, the development of a dual labor market within world cities, and to excessive rural-urban migration, and periphery-core immigration.

In contrast to global cities theorists, Richard Child Hill, Kuniko Fujita, and others propounding the nested city hypothesis have (re) asserted that national and local political economic contexts, rather than global capitalism, remain the decisive factors determining spatial configurations. Drawing from this approach, A.J. Jacobs claimed that over the past 30 years,

the US Federal Regulatory State's policies promoting fiercely competitive inter local relations, rather than inter local cooperation, have, in concert with subnational factors, served to accelerate suburban growth and central city hollowing in the Detroit Auto Region. Conversely, he argued that the reverse had been true in Japan, where national and subnational planning had fostered inter municipal collaboration, relatively balanced growth, and strong major cities in the that nation's auto region, Nagoya Tokai.

Over the next decade, cities and metropolitan areas will continue to dominate future research on uneven development. It is also clear that until a more integrated metatheory of spatial development becomes accepted, one which incorporates how the global, national, and local contexts all impact economic and social spatial patterns, the future scholarship on uneven development can be expected to teeter between global theories and embeddedness. Cross national comparative research should become a prominent method with which to both help settle this debate and shed light on a new metatheory.

unions

Judith Stepan Norris

Unions are collections of workers who join together for the purpose of defending their common interests as employees. In capitalist societies, union representation provides many workers with their only potential for meaningful input in their workplaces. These workers benefit from unions because employers alone possess legal rights and authority over their property (both land and machinery), and therefore any single worker has limited bargaining power vis-à-vis an employer. In the unionized workplace, the hegemony of capital is manifested in a regime of production based on collective bargaining agreements, which are reinforced by the state. Still, capital's control over the workforce is never complete. Workers struggle and negotiate with employers over the terms of the regime.

When workers organize into unions their representatives normally negotiate collective bargaining agreements with management, which codify the terms and conditions of the labor process. These agreements (or contracts) specify workers' wages, hours, benefits, and seniority and grievance systems, whether or not workers may strike, and whether or not the union cedes managerial prerogatives for a specified period. The managerial prerogatives clause is especially important since it either does or does not give to management the right to hire, fire, discipline, plan production, and change production processes, etc. When this clause is absent, these rights are open for negotiation, usually through the grievance procedure. The contract also specifies the number of union representatives within the workplace. These representatives are called union stewards or committeepersons. Union stewards inform workers of their rights and represent them in grievances against employers.

Contracts may place a total, conditional, or no prohibition against strikes during the term of the agreement. Conditional prohibitions specify situations in which a strike is allowable. Whereas many collective bargaining agreements signed between the 1930s and the early 1950s in the US did not include strike prohibitions, the more recent pattern is for them to be included in these agreements. Still, unions that sign collective bargaining agreements with total strike prohibitions may strike once their contracts expire. Alternatively, workers sometimes take matters into their own hands by conducting "wildcat" strikes, which occur without union authorization.

There are several types of unions. The two main types are craft (or vertical) and industrial (or horizontal) unions. Following the lead of the medieval guilds, the earliest trade unions tended to organize craft workers by their skills. To become a member of a craft union, a worker must be proficient in that craft, and workers are organized across workplaces. As industrialization progressed, a larger proportion of the workforce was employed in non and semi skilled positions. The industrial unions organized workers by industries (e.g., auto, rubber, steel) and sought to represent all the workers within a particular workplace.

Individual national (and international) unions (e.g., the United Mine Workers of America) normally belong to national umbrella organizations such as the American Federation of Labor (AFL) or the Congress of Industrial Organizations (CIO). The pejorative term "dual unionism" is reserved for instances when two unions (usually belonging to different umbrella organizations) simultaneously organize workers within a single industry or trade. Although the main stream US labor movement has considered dual unionism to be harmful, it may be associated with innovation and/or subsequent union growth. This was the case with the AFL's challenge to the Knights of Labor in the 1880s and with the CIO's challenge to the AFL in the 1930s.

Unionization rates vary over time, place, and industry. National rates of unionization vary from very low rates in the US and France to very high rates in the Scandinavian countries. The periods of increase in US union membership tend to coincide with the initiation of new and successful labor organizations, and the periods of decline have occurred as employment in highly unionized industries fell (especially when unions have not responded to the changing conditions). US union membership hit its peak during the 1950s, and has declined until the late 1990s, when the newly elected leadership of the American Federation of Labor Congress of Industrial Organizations (AFL CIO) began its emphasis on new organizing.

The level of democracy within unions has been an issue of heightened concern, especially during specific periods. The main charge is that unions tend to evolve into oligarchies that are unresponsive to workers' needs. Some researchers have pointed out that during certain periods, union democracy has been prevalent. So union democracy and oligarchy are "alternative possible paths of union development" (Stepan Norris & Zeitlin 2003).

Often, unions' efforts to organize workers were conducted in alliance with political parties. In Europe, unions tend to organize along industrial lines and to be affiliated with left of center political parties (some European countries also have had rival Christian, socialist, and/or communist unions). In the US there has been extensive involvement and interchange between

unions and political parties, but seldom any formal ties. Unions have both reacted to and influenced legislative change. In the early period of unionism, unions were prosecuted under existing and newly developed laws that served to control and/or eliminate them. Later, many such laws were repealed or modified. But considerable anti union legislation continues to exist. In the US the National Labor Relations (Wagner) Act of 1935 provided an important spur to union growth, while the 1947 Taft Hartley Act represented a severe setback for unions. In Great Britain the Combination Acts restricted and the Trade Union Act of 1871 liberalized labor laws.

Union organizing has been associated with conflict as well as a good deal of violence. Prior to the 1930s, US employers were given considerable leeway in protecting their property and often summoned the aid of state and federal troops to help. Taft and Ross's (1969) "grossly understated" estimate of US labor conflict casualties puts the death count at 700 and serious injuries at several thousand. They estimate that state and federal troops intervened in over 160 disputes. Although labor violence has decreased considerably over time, the US has had the most violent labor history of all industrialized nations.

urban

Vincent N. Parrillo

Urban is one of those deceptive concepts that seem simple to grasp yet have many layers of complexity that are subject to varying interpretations, depending on one's theoretical and analytical predisposition. Derived from the Latin word *urbanus* (meaning characteristic of, or pertaining to, the city), *urban* essentially holds that same connotation to most people.

Complicating that understanding, however, are varying criteria among the 228 countries with urban populations. These criteria include *administrative function* (a national or regional capital), *economic characteristics* (more than half the residents in non agricultural occupations), *functional nature* (existence of paved streets, water supply, sewerage, and electrical systems), and *population size or population density*. Administrative function is used solely in 89 countries and in combination with other criteria in an additional 20. Economic is one of several criteria in 27 countries, as is functional in 19 countries; functional is also used solely in 5 countries. Population size or density is the sole criterion in 46 countries and in combination in an additional 42. No definition exists in 24 countries, while in Guadeloupe, Hong Kong, Kuwait, Monaco, Nauru, and Singapore the entire population is designated as urban.

Such differences make cross national comparisons difficult. For example, the lower range limit for population of an urban area ranges from 200 in Iceland to 10,000 in Greece. A universal standard, say a midpoint from these two extremes of 5,000 inhabitants, would be inappropriate in populous countries such as China or India, where rural settlements with no urban attributes at all could easily contain such large numbers. Using each country's own

criteria, the Population Reference Bureau (2003) reported that 47 percent of the world's population was urban. Significant variations existed: Africa, 33 percent urban; Asia, 38 percent; Europe, 73 percent; Latin America and the Caribbean, 75 percent; North America, 79 percent. In Canada and the US the urban population was 79 percent, while in the United Kingdom it was 90 percent. The lowest urban population (5 percent) was in Rwanda, while the highest (100 percent) were in the six countries previously identified.

For centuries the contrast between the city and its surrounding region was simple: urban (the spatially defined city) and rural (everything else). From the eras of ancient and medieval societies with walled cities to the pre industrial cities of commerce, most people lived outside the city. A symbiotic relationship then existed between the city and its hinterland. The latter provided the necessary agricultural products for survival and the city supplied leadership, protection, advances in science and technology, arts and crafts products, and various other luxury items mostly of value only to city dwellers.

Sociology was born in Europe, a child of the industrial and urban revolutions that transformed human existence. As millions left the countryside and flocked to work in the urban factories, a new breed of social observer analyzed these altered forms of social organization. Although they thought the city could be a liberating force from "barbarism to civilization," Karl Marx and Friedrich Engels (1976) were among the first to describe the excesses of industrialization and appalling lifestyle of exploited urban workers.

In a seminal masterwork, *Gemeinschaft and Gesellschaft* (1887), German sociologist Ferdinand Tönnies – openly acknowledging Marx's influence – described the contrasting elements of urban and rural life from a cultural perspective. His concept of *Gemeinschaft* (community) characterized the small village and surrounding area in which people united by close ties of family and neighborhood shared traditional values and worked together for the common good. In contrast to this "we ness," *Gesellschaft* denoted the "me ness" of the city, where a future orientation among a heterogeneous population replaced tradition, leading Tönnies

to a pessimistic view of the city as characterized by disunity, rampant individualism, and selfishness, even hostility. This typology of *Gemeinschaft* and *Gesellschaft* had a lasting influence on other urban sociologists.

Émile Durkheim (1962) also had an enduring effect. His emphasis on contrasting social bonds offered another perspective on urban and rural distinctiveness. He suggested that urban social order rested on an *organic solidarity* in which individual differences, greater freedom, and choice thrive in a complex division of labor where inhabitants are interdependent. Rural life, on the other hand, is organized around *mechanical solidarity*, with social bonds constructed on likeness (common beliefs, customs, rituals, and symbols), where inhabitants are relatively self sufficient and not dependent on other groups to meet all of life's needs.

For the first half of the twentieth century other social scientists continued in this twofold typology. Their examinations of urban growth and development (urban ecology) – and of behavior, communities, economics, lifestyles, politics, and subcultures within an urban context (urbanism) – mostly rested on a spatial or geographic emphasis on the central city. From this perspective, they examined different variables and compared them to non urban areas. In the century's second half, however, changing settlement patterns and the evolution of a global economy reduced the analytical value of this simplistic urban–rural dichotomy.

The post World War II suburban boom in Europe, Japan, and the US initiated an exodus from cities and a growing preference for that lifestyle. At first, this intermediary along the urban–rural continuum was easily understood. Suburbs were mostly bedroom communities on the cities' outskirts, where inhabitants typically lived in one family houses, but worked, shopped, and enjoyed leisure activities in the city. By ringing the central cities, the suburbs reinforced the original conception of *urban* in a spatial context, and were essentially viewed as residential appendages to the cities.

Much as pre industrial cities had a mutual interdependence with the hinterland, initially so too did twentieth century cities and suburbs. That changed with the development of suburban office and industrial parks, shopping malls, megastores, hospitals, and places of worship.

As the suburbs became more self sufficient, the definition of *suburban* changed into that of a third entity, an alternative to *urban* and *rural*. Even so, larger cities continued to extend their sphere of influence beyond their boundaries, particularly in such areas as culture, fashion, media, professional sports, sightseeing, and tourism. *Metropolitan* is the term describing that extended area of urban influence, which the US Census Bureau calls *metropolitan statistical areas* (MSAs). The official US urban population thus includes not just those living in cities, but also those living elsewhere in *urbanized areas* with populations of 2,500 or more, as well as those living in *urbanized zones* (unincorporated communities of less than 2,500, but on the fringes of metropolitan areas). Metropolitan areas, with varying definitions, exist throughout the world.

Sometimes metropolitan areas overlap each other in their spheres of influence, creating what Jean Gottman (1961) popularized as a *megapolis*. His example was the region extending from Boston to Washington. The Census Bureau identifies 18 such regions in the US and calls them *consolidated metropolitan statistical areas* (or CMSAs).

Spurred by increasing affluence, transportation improvements, and advances in telecommunications that allowed for working from home, a new form of "urban" living became apparent in the 1980s: the exurb. An *exurb* is an upper middle class community in an outlying semi rural community, where highly educated professionals seek an escape from more congested urban, even suburban, locales. Typically, their residences are large, expensive homes on large, wooded lots. This blend of urban attributes among residents in a semi rural locale blurred the previous clarity of *urban* based on a spatial conceptualization.

Disparities in urban definitions and the blurring of urban and non urban elements led social scientists into new considerations. Some scholars prefer a theoretical approach, such as *convergence theory*, which argues that technology will lead cities and communities everywhere to develop similar organizational forms. Its counter theory is *divergence theory*, which posits that increasingly dissimilar organizational forms will emerge because of differences in the (1) cultural values and histories; (2) timing

and pace of urbanization; (3) form of government and planning approaches; and (4) hierarchy of countries in the global economy. Another perspective, *postmodern theory*, rests on the premise that cities develop in ways that are no longer rational or manageable according to the old logic of urban ecology. Instead, global capitalism serves as the underlying rationale for actions by increasingly fragmented urban power structures.

In fact, the still growing world economic system and ease of worldwide telecommunications serve as the basis for arguments by the "new urban sociologists" that *urban* now displays a global character and is an international process. The economic welfare and changes in cities more often result from causes existing beyond their boundaries. Moreover, both the physical form and social life of cities result less from "natural" processes and more from political and economic institutions at the national and international levels that shape urban life. Conflicts between labor and management or among diverse population segments also impact on the physical and social characteristics of cities. This interplay of global, national, regional, and local forces is an additional complicating factor in explaining what we mean by *urban*.

In the final analysis, *urban* remains subject to varying interpretations, with or without a spatial premise; with a local, regional, national, or global perspective; and with either a positive or negative emphasis. No matter what theoretical and conceptual approach one takes, the term nonetheless remains mostly suggestive of its Latin origins: that of particular qualities associated with people and patterns indeed found in cities.

urban community studies

Farrah Gafford

Urban community studies consist of a range of case studies, comparisons, and local analyses that explore the local cultures, relationships, interactions and identities. As cities in the US experienced rapid growth during the early twentieth century, sociologists speculated about how the interactions and relationships in these urban settings would be influenced by a swelling population, advanced technology, and a mounting flow of immigrants. With the population of urban centers like Chicago approaching a population of 2 million in the early 1900s, urban centers provided sociologists with an opportunity to examine how inhabitants would adjust to the growing populations and the diversity within these spaces. The result of these early inquiries would be the establishment of a premier American school of urban sociology and a long tradition of urban community studies in the field of sociology.

The intellectual roots of urban community studies can be traced to Tönnies's *Community and Society* (1887) and Durkheim's *The Division of Labor in Society* (1893). Tönnies contrasted the types of human interactions present in pre-industrial societies to interactions in industrialized societies. He argued the *Gemeinschaft* world is characterized by close knit ties among family, kin, and neighbors. In these cohesive

societies, individuals are very familiar with one another. However, in the modern *Gesellschaft* world of the city, relationships are based on self interest, and close knit relationships are replaced by work based and interest based relationships. Continuing this line of thought, Durkheim discussed the type of relationships in societies with a complex division of labor. He argued that in areas characterized by large populations and a highly specialized form of division of labor, solidarity was no longer based on common values, but rather dependence and a reliance on each other's skills. Durkheim described this type of solidarity as *organic solidarity*. In a society with organic solidarity, it becomes harder for individuals to create bonds with each other. As a result, individuals in these societies experienced feelings of alienation.

Tönnies and Durkheim's classic generalizations about the interactions in industrialized societies can be identified in our definitions and perceptions of urban communities today. While community can be viewed as a particular geographic location, the concept of community also assumes that certain types of relationships and social ties exist. With this in mind, scholars typically agree that social ties, interaction, and geographic location are the three essential components for defining community (Hillary 1955).

Over the course of time, Tönnies and Durkheim's ideas on the social relations in urban areas would influence American sociology. Sociologists from the Chicago School were responsible for some of the most prominent studies on urban community life in the US. Comparing the city to an ecological system, studies out of the Chicago School viewed the neighborhood as part of a larger system. Robert Park and Ernest Burgess's *The City* (1929) used concentric circle models to demonstrate the growth of urban areas. The concentric model illustrates the outward expansion of the city from the core or the central business district. Within the zones of urban growth are local districts or communities and these in turn are subdivided into smaller areas called neighborhoods. According to the concentric model, neighborhoods tend to develop according to the growth and development of the city.

Prominent works out of the Chicago School tradition like Harvey Zorbaugh's *The Gold Coast and Slum* (1929) suggested that the term

community could only be loosely applied to several of the neighborhoods. He argued that in respect to some of the subdivisions of this area, community only served as a geographical expression. Neighborhoods within the area lacked common traditions and feelings associated with traditional societies. Although the studies out of the Chicago tradition made great contributions to sociology, the school's heavy emphasis on the city and larger ecological forces minimized the role of individuals in creating solidarity or a sense of community within their own neighborhoods.

Years later, Herbert Gans's *The Urban Villagers* (1962) found that a close set of relationships could exist in so called urban slum neighborhoods. In a slum neighborhood in Boston, Gans observed the interconnectedness of peer groups (or the peer group society), institutions (community), and the out group or outside world of the residents. The area Gans described had a sense of cohesion or solidarity that was fostered through interactions with peer groups that included not only family or relatives but neighbors as well. Gerald Suttles's *The Social Order of the Slum* (1968) also depicted a form of community solidarity in an urban slum district. Suttles's observations of a Chicago neighborhood found that various ethnic groups were able to share social spaces and connect over the sense of shared space despite intergroup tensions. The sense of belonging to the same place allowed the residents to unite in response to outside threats from other neighborhoods.

Over the past two decades, urban community scholars have focused on the concentration of poverty in metropolitan areas. There is a growing body of literature that seeks to examine the role of neighborhood poverty on individual life chances. The neighborhood poverty literature attempts to understand the connection between neighborhood poverty and unemployment, crime, high school completion, and out of wedlock births. While neighborhood effect studies represent a growing concern in the field of urban community work, one of the challenges for those who study neighborhood effects revolves around the conceptualization and measurement of neighborhood.

A neighborhood is more than just a physical location or geographic space. Urban scholars are usually interested in the interactions and

social networks that take place within a particular geographic space, hence the interchangeable use of the terms neighborhood and community. Small and Newman (2001) suggest there are various dimensions to neighborhood, such as a set of institutions, cultures, social spaces, and networks that should all be taken into consideration when designing research on neighborhood effects. Without considering the multiple layers of the concept of neighborhood, it becomes increasingly hard to determine the effects of neighborhoods on individuals.

Researchers who study the effects of neighborhoods also have to consider how neighborhoods are measured in their studies. Census tracts do not always provide an adequate operational definition of neighborhood. One limitation of using census tracts to operationalize neighborhoods is that it does not account for residents' perceptions of neighborhood boundaries. Small and Newman (2001) argue a resident's perception of the neighborhood boundaries can act as a determinant of how a neighborhood affects a resident. One alternative to using census tract data in neighborhood research is to use neighborhood clusters or boundaries drawn by the research for the purpose of studying neighborhood effects.

While contributions of the neighborhood effect literature delineate a range of social problems associated with urban community life, other scholars have attempted to highlight the agency of residents in urban communities. Instead of viewing communities as simply "containers of poverty," this vein of work attempts to demonstrate how residents assign meaning to their communities and how they negotiate the use of public spaces in neighborhoods. In the text *Streetwise* (1990), Anderson argues that the social life in the inner city community consists of various rules and strategies for various interactions. He examines how residents in an urban community negotiate the use of public spaces. Anderson argues that individuals who are streetwise understand the rules of interaction for specific places within the community. Streetwise individuals know how to interpret gestures and body comportment of those within the community. The mutual respect and understanding of the rules of interaction ultimately contribute to a social order of community life. Anderson emphasizes that although negotiating

public space in the community helps to maintain a certain order, it does not totally alleviate the social problems in the urban communities.

Gotham and Brumley (2002) examined how public housing residents “use space” in order both to create and reject identities. While the physical spaces in the neighborhood did influence the actions of the residents, the authors also argue that residents actively create safe spaces, and hot spaces (dangerous spots in the community), through their interactions and actions with one another. Using safe spaces allows residents to create respectable identities and to disavow the negative identities associated with public housing residents.

One of the oldest and most preferred methods used to study urban communities is ethnographic field research. In order to study certain urban communities, sociologists may move into a neighborhood or participate in various neighborhood meetings and organizations. The use of this method can also be traced to the early days of the Chicago School. Park and his colleagues produced a number of ethnographic case studies of neighborhoods. Some of the ethnographic studies out of the Chicago School tradition include William Whyte’s *Street Corner Society* (1943) – which focused on life in an Italian American slum district in Boston – and Drake and Clayton’s *Black Metropolis* (1945), a study of Chicago’s black residential neighborhoods.

Contemporary urban community studies continue to draw on the Chicago School sociological tradition of ethnographic case studies of communities. Recent sociological works from Mary Pattillo McCoy and Maria Kefalas (2003) provide ethnographic accounts of life in urban communities. Pattillo McCoy’s *Black Picket Fences* (1999) examines the social organization of a black middle class neighborhood in Chicago. Over a 3 year period, she embedded herself in neighborhood life by coaching cheerleading, participating in church and neighborhood meetings, and working on local campaigns. Kefalas’s *Working Class Heroes* (2003) is based on her observations and extensive field notes of meetings and events in a Chicago working class community. She uses ethnographic accounts to demonstrate how race and class shape residents’ attachment to place.

Ethnographic studies have been useful in understanding the organization of certain

neighborhoods and the interactions among the residents in urban communities. However, urban ethnographers face a range of challenges while conducting field research. Although a researcher may reside in a neighborhood with the hopes of carrying out research, there is still the issue of gaining access to the community. In many cases, urban ethnographies require the assistance of a gatekeeper. Gatekeepers are individuals who can assist researchers in navigating the community and gaining additional contact within the community (Whyte 1997). In Whyte’s *Street Corner Society* (1943) his key informant, Doc, was responsible for introducing him to other contacts in the community and helping him to learn the ropes in the community. Kefalas (2003) also indicates that her gatekeepers introduced her to other members of the community and served as unofficial tour guides. She also acknowledges that information from her informants provided a “foundation” for her work. In addition to gaining access to the field, researchers who study urban communities are also challenged with the task of connecting their work to larger social scientific questions and concerns. Ethnographic studies of urban communities offer audiences vivid depictions of the lives of inhabitants, but thick descriptions and narratives alone will not advance the field of sociology. The data from these ethnographies should advance sociological knowledge by either generating theory or expanding existing theory.

Urban community scholars also rely on survey methods to test models of community participation and residents’ attachment to place. For instance, one of the most common models used to explain social interaction in communities is the systemic model put forth by Kasarda and Janowitz (1974). The systemic model suggests that length of residence is more important in predicting attachment to community than variables such as community size and density. Using survey data, the scholars provided support for the systemic model and rejected the linear development model that suggests that size and density are the primary factors that influence attachment to community. Guest (2000) addresses some of the limitations of the systemic model by considering the role of extra community relations in community attachment.

In addition to testing the models that explain the level of interaction within communities,

researchers have used survey studies to test the social disorganization of inner city neighborhoods. For example, Rankin and Quane (2000) use survey research to test the social isolation thesis by examining the importance of neighborhood characteristics on the networks and community participation of residents. Although survey research has been useful in developing and supporting community models, it can be difficult to find data sets that contain information on a variety of neighborhoods and information on both neighborhood characteristics and individuals (Ainsworth 2002).

Future community research will have to address a range of issues. Sociologists have already recast the community lost debate, or the argument that the tight knit associations and interactions among people in a geographic location are gradually eroding. As virtual communities become more prevalent feature of our society, urban community scholars will have to consider how urban communities will be affected by the occurrence of virtual communities. While virtual communities and cyberspace represent a new set of challenges for urban scholarship, some issues linger from previous decades. Urban community scholars are still faced with some of the similar issues that Park and his colleagues addressed over 60 years ago. Issues like immigration, swelling urban areas, and residential segregation are still features of the urban landscape. However, unlike their predecessors, urban scholars now have to tackle these issues in the context of globalization.

urban crime and violence

Walter S. DeKeseredy

Defining crime and violence is the subject of much debate. In fact, a review of the extant social scientific literature on these topics reveals a myriad of definitions. However, here, the focus is limited to illegal interpersonal behaviors that threaten people's social, economic, and physical well being. More specifically, the behaviors examined here are acts such as homicide, assault, robbery, theft, and drug dealing. While these harms affect both rural and urban communities, most of them occur in large metropolitan areas characterized by concentrated poverty and racial segregation (DeKeseredy et al. 2003).

Why are people who live in these neighborhoods at higher risk of committing and/or being victimized by crime? Not surprisingly, there are competing answers to this question. For example, heavily influenced by variants of Marxist thought, one group of scholars contends that lethal and non lethal crimes plaguing these disenfranchised communities are symptoms of the following factors: the rise of the "contingent" workforce; the outmigration of

people who can afford to leave poor urban communities; transnational corporations moving operations to developing countries to pay lower salaries; the "suburbanization" of employment; the implementation of high technology in work places; and the shift from a manufacturing to a service based economy (Massey & Denton 1993; Wilson 1996).

Another group of critical theorists argues that the above structural factors are, indeed, key predictors of urban crime, but asserts that it is a combination of these determinants and relative deprivation that motivate people to commit crimes, most of which are intra racial and intra class in nature (Young 1999). There are also sociologists driven by social disorganization theory who state that crime in socially and economically excluded neighborhoods is associated with an absence of collective efficacy. This concept refers to "mutual trust among neighbors combined with a willingness to intervene on the behalf of the common good, specifically to supervise children and maintain public order" (Sampson et al. 1998: 1). Generally, high crime rates are more likely to be located in urban neighborhoods characterized by anonymity, weak social ties with neighbors, and diminished control over people's behavior. However, collective efficacy does not completely mediate the relationship between a community's structural characteristics and crime. For example, Sampson et al. (1997) found that, after controlling for collective efficacy, concentrated disadvantage still exerted independent effects on violent crime.

Another widely read and cited perspective on the relationship between poverty and urban crime is culture of poverty theory. Developed by Oscar Lewis in 1966, this account is popular among and promoted by conservatives. Banfield (1974) is one well known culture of poverty theorist and he asserts that the values of poor and more affluent people are distinct. For Banfield, unlike more affluent people, the poor commit crime because they lack the discipline and moral fiber to avoid breaking the law if it means achieving short term gains. There are more recent culture of poverty theories and because they are well documented elsewhere, they are not reviewed here. Nevertheless, an important point to consider is that these perspectives fail to recognize that the poor and

affluent have the same goals and values. Both groups want to be happy, have jobs, decent standards of living, a warm and loving family, a safe neighborhood, and so on. However, only those near or at the top of the socioeconomic ladder have legitimate means of achieving the American Dream and its related status, which is why they are much less likely to engage in criminal forms of anti social behavior on the streets and elsewhere.

Of course, there are other theories of urban crime and violence and new ones are likely to be developed and tested in the near future. Further, those who study crime in urban communities use a variety of research methods to uncover rich qualitative and quantitative data on a wide variety of illegal activities. Still, there are major shortcomings in the extant empirical and theoretical literature on urban crime that must be overcome or minimized. For example, so far, most of the scholarly attention focuses on western industrialized nations and thus we know very little about urban crime in less developed societies (Crutchfield & Wadsworth 2003). Note, too, that there is a conspicuous absence of empirical and theoretical work on male to female intimate violence in poor and racially segregated communities, despite the fact that a few recent studies show that this is the most common form of criminal victimization experienced by women living in them (DeKeseredy & Renzetti 2004).

Another issue worth noting is that crime in public housing communities has received little sociological attention. In fact, to date, most of the information on violent and other offenses occurring in North American urban public housing communities is produced by journalists who portray crimes committed by and against those who live there as little more than "aberrations in an otherwise well functioning system" (Reiman 2001: 173). Fortunately, however, international scholarship on crime in public housing is starting to grow. Even so, most of this work is quantitative in nature and hence there is a major need for more rich ethnographic work on the contexts in which crimes in these impoverished social settings occur (Lab 2003).

Undoubtedly, these criticisms will be effectively addressed in the near future. Still, for those who directly and indirectly suffer from criminal victimization, the question of what is

to be done is much more important than the advancement of scholarship. Obviously, there are many prevention and control strategies currently in place, but most are simply aimed at “fixing poor people” (Crutchfield & Wadsworth 2003). Consider the massive expansion of the US prison population and major cutbacks to the welfare state. These policies, combined with the growing gap between the rich and poor, will only increase the amount of urban crime. Clearly, it is time for a new policy agenda. Rather than punishing the poor and minority populations, progressive scholars argue that we should strive to create stable quality employment, healthy public schools, a higher minimum wage, and other policies that reduce inequality and the anger and frustration it causes.

urban ecology

Michael J. White and Ann H. Kim

Urban ecology is the study of community structure and organization as manifest in cities and other relatively dense human settlements. Among its major topics, urban ecology is concerned with the patterns of urban community sorting and change by socioeconomic status, life cycle, and ethnicity, and with patterns of relations across systems of cities. Of particular concern is the dynamic evolution of cities and contrast in urban structure across time periods, societies, and urban scale. The notion of community is central to urban ecology; a premise of the ecological approach is that the aggregation of persons into communities has important implications for their life chances, for the behavior of groups, and for aggregate outcomes. A further aspect of community organization lies in its geographic manifestation, although a mere geographic reductionism would not accurately capture the theoretical or empirical approach of the ecological perspective.

A sub area of human ecology – a social science paradigm that seeks to understand the relationship between human organization and its environment, both in terms of physical setting and sustenance – the study of urban ecology has been interdisciplinary. Work in ecology has touched on sociology, demography, geography, economics, and anthropology, usually emphasizing the urban sectors of those disciplines. And at various times, human urban ecology has been more or less connected to biological ecology.

As Franklin Wilson argued, ecology is one of the oldest specializations within sociology and the intellectual roots of urban ecology can be found in the origins of sociology itself. For example, Émile Durkheim's *The Division of*

Labor in Society (1893) argued that modern societies are comprised of functionally interdependent units that are necessary for their survival and progress. As an explicit sociological approach, urban ecology is particularly associated with the Chicago School of sociology in the early twentieth century, even though the connection extends to a wide range of scholars and groups interested in cities and in population processes. The massive growth of cities at this time, fueled by the immigration of diverse origin populations, helped spur the interest in urban form and function, and hence urban ecology as a subject of interest.

These early thinkers attempted to establish a parallel for human behavior with the topic of ecology in biology to describe local biotic communities. Collections of organisms are seen as communities, and the membership and evolution of communities are seen in a framework of interdependence. Sociological approaches almost universally invoke notions of ecology that are at once aggregate, interdependent, and embedded in a spatial and environmental context. Thus, communities of plants and animals find their parallel in communities of human groups. Both approaches see competition for resources in a spatially delimited setting. A further aspect of the framework is the concept of sustenance, in which one considers the manner in which local organisms, here humans, are sustained by the environment and by organization.

Studies at this time of specific urban communities, such as Louis Wirth's *The Ghetto* (1928) and Harvey Zorbaugh's *The Gold Coast and the Slum* (1929), and of city form and subcommunities more generally, such as Robert Park, Ernest Burgess and Roderick McKenzie's *The City* (1925), offer key illustrations of early treatments by the Chicago School, also known as the classical position. Additional concern in this era was with land rents and gradients, which not only helped explain the distribution of social groups, but also connected to the evolving interest in urban economics.

These early notions of human ecology gave way to more statistically intensive and geographically driven analyses of human organization in urban physical space. Considerable analysis was devoted in the middle to late twentieth century to the dimensions of urban social

structure. These included extensive analyses of patterns of residential segregation, urban growth, and differentiation. The application of factor analysis, or "factorial ecology" in the nomenclature, identified life cycle, socioeconomic status, and ethnicity as key dimensions of urban ecological sorting.

The ecological approach then came under criticism from various quarters, the most notable early critic being Milla Alihan. The biological metaphor was seen as strained, limiting the crucial elements of human volition and cognition. Urban ecology was also at risk of appearing spatially deterministic and attention to the relative spatial position and mapping of social phenomena lent credence to the critique. Furthermore, ecological approaches were criticized methodologically, even generating a phrase, "the ecological fallacy," that has traversed into general social science parlance. The fallacy is the error of making inferences about individual behavior from analysis of phenomena at the aggregate level.

In the middle of the twentieth century, human (and hence urban) ecology received additional formulations, with perhaps the broadest theoretical treatment arising in Amos Hawley's *Human Ecology* (1950). This treatise emphasized the study of the community and the dynamic connections among individuals, human organization, and the environment. Around the same time the widely adopted POET framework came to the fore: Population, Organization, Environment, Technology. This POET paradigm is also part of the neoclassical or neo orthodox approach and it provides an intellectual rubric for organizing the thinking about urban phenomena and community processes within them.

Much work carried out from the mid twentieth century for the next several decades was ecological in approach, if not always explicit in name. While one stream of research concentrated on the internal structure of cities, another focused on systems of cities and the relationships among them. Analyses of residential segregation by ethnic and socioeconomic group, the relationship between urban economic base and population growth, and some international comparisons of internal urban structure all took place at this time. Similarly, analysis of metropolitan functional specialization, trade, and the

comparative growth of urban settlements were undertaken from an ecological vantage point.

These efforts were again followed by critiques from a variety of points, including Marxist and political economy perspectives. Both explicit and implicit criticisms suggested that the ecological approach missed several crucial elements in the study of urban development, structure, and change: the role of the state, local governments, and capital interests. At the same time, the combination of methodological concerns and the availability of microdata made the classic ecological style of aggregate analysis less attractive.

With the reemergence of concerns for urban issues generally and neighborhood issues specifically, various aspects of urban ecology achieved visibility or were reinvented in the late twentieth century. New data forms and methodological developments helped spur this turn. The wider concern for social exclusion, especially as it had a community or spatial manifestation, incorporated the ecological approach. The framework also continues to be relevant and widely used in the study of ethnic groups. In fact, the increasing ethnic diversification of high income societies provides increasing impetus for the ecological approach, as Park's adage that spatial distance reflects social distance is put to the test in new settings. Interest in residential integration and sorting still involves the analysis of community patterns of ethnic concentration. Moving beyond classical ecology as applied to ethnic and racial groups, contemporary treatments examine dynamic changes in residential environments, such as in residential attainment, where a minority or disadvantaged group achieves residential parity with members of the advantaged majority. Such work is an extension of classical concerns for the process of residential succession.

An additional research theme is the restructuring of urban areas in light of significant transportation, communication, and industrial transformations. Scholars have noted the trend for the spatial decentralization of urban growth (e.g., suburbanization and urban sprawl, land use patterns, and corporate activity). Where limitations in transportation and communications necessitated spatial proximity in the past, current technology, to some extent, liberates producers, suppliers, workers, and consumers

from this constraint. Regional factors, including policy variation and climate, may also play a role in shifting urban development. In this context, new urban forms and systems of inter urban hierarchy emerge.

A more methodological avenue of ecological investigation accompanies the exploitation of multi level or contextual data, in which individual data (microdata) is merged with characteristics of neighborhoods or a wider geographic area. Individual (person, household) behavior then, is taken to be predicted not only by individual traits, but also by characteristics of the local community. Indeed, the rapid development of the "neighborhood effects" literature, both substantively and methodologically, can be seen as a major intellectual current within sociology (Sampson et al. 2002), and this current taps directly into the central themes of urban ecology. Similarly, the broad interest in the problem of the macro micro link overlaps significantly with ecologists' interest in community, in multiple levels of aggregation, and in dynamic interchange. Such studies have examined the determinants of escaping distressed neighborhoods, the choice of new neighborhood as a function of its ethnic composition, community effects on child development and crime, and the role of neighborhood traits in determining health outcomes.

The multi level ecological approach is involved at a larger geographic scale, as well. The existence of social inequalities in health motivates a vein of research in which metropolitan income inequality is seen as playing a role in health outcomes such as infant and child mortality. Such studies have been carried out in some detail for the US. International comparisons also exist, where the "ecological" or aggregate measure is the level of inequality measured at the country level.

The predisposition of urban ecological analysis to spatial phenomena has made urban ecology readily receptive to the use of geographic information systems (GIS). More than merely mapping, GIS technology applied to urban ecology allows the analyst to redefine communities and networks, and to link micro to macro. Whereas social scientists were once bound by the community aggregation defined by others (such as a census agency's tract or ward boundaries), the availability of point coordinates

assigned to each person or housing unit, and to natural features and economic activities, would allow a more variegated and refined analysis of the relationship between human organization, sustenance activity, community, and territory. Tests for spatial autocorrelation, which examine the effect of proximity, further add to our toolkit for understanding urban structure and organization.

Such technological developments have stimulated a reconnection with biological ecology. Urban ecological analysis provides a framework for examining integrated human natural systems. Indeed, in several institutional and academic settings, the use of the phrases "urban ecology" and "human ecology" explicitly link human behavior to the biological environment. Here again human activity is seen as dynamic and community based, both influencing and influenced by its surrounding environment.

While urban ecology may be identified most clearly with American urban sociology and the Chicago School particularly, its adherents and manifestations are much broader. For example, it has been linked to the work of the French historian Fernand Braudel, who studied social system changes in the Mediterranean. It has been applied in analyses of urbanization in socialist countries as well as in the developing world. The paradigm was used to describe the somewhat inverted settlement patterns in Latin American cities. It has further found occasional expression in describing North African and European cities, where ethnic diversity had not yet achieved so clear a place in urban form. Still, the level of knowledge about urban ecology for settings outside of high income societies is less developed. It is far from certain that the models once applied to North America and Europe (and selected other locations) will apply so readily to other portions of world geography, especially to urban settings in developing countries. Yet themes of internal urban structure, geographical disparities in well being, and community change are relevant to all of these settings.

urban education

Alan R. Sadovnik

Urban education has been the subject of ongoing discussions in the US, with policies aimed at urban school improvement vigorously debated over the last 40 years. Since the 1960s, as cities became increasingly poor and populated by minority groups, urban schools have reflected the problems associated with poverty. Although rural and many suburban schools have similar problems, urban schools represent the most serious challenges. A significant percentage of urban schools have been labeled in need of improvement under federal No Child Left Behind (2002) guidelines, with large city school systems having dropout rates at or above 40 percent and student achievement well below 50 percent proficiency in mathematics and reading. Despite these alarming data, there are significant numbers of high performing urban

schools and a number of reform programs that show promise (Tractenberg et al. 2002).

As urban areas became increasingly poor and segregated, their school systems mirrored the problems of urban poverty, including low student achievement, high student mobility, high dropout rates, and high levels of school failure. Due to the concentration of poor and minority populations in urban areas, urban public schools have significantly higher proportions of low socioeconomic and minority students than their surrounding suburbs. Over the past four decades, affluent white families have either moved to the suburbs or sent their children to private schools. In 2003 the enrollments of some of the 12 largest city school districts in the US were overwhelmingly minority, with the percentage of white students ranging from a low of 5.2 percent in Detroit to a high of 16.4 percent in Philadelphia and the percentage of African American and Hispanic students combined ranging from a low of 73.4 percent in New York to a high of 92.9 percent in Detroit (Ladson Billings 2004).

Student achievement in urban schools mirrors the relationship between socioeconomic status (SES), race, ethnicity, and educational performance. Students from lower SES backgrounds have lower levels of academic attainment and achievement than students from higher SES backgrounds. African American and Hispanic students also have lower academic achievement than white and Asian American students. Given their high percentage of poor and African American and Hispanic students, urban schools reflect the achievement gaps that NCLB is designed to eliminate.

Since the 1960s the achievement gaps based on social class, race, ethnicity, and gender have been the focus of educational policy, especially in urban areas. These gaps include both group differences in achievement based on standardized tests and grades; attainment based on years of schooling, high school and college attendance and graduation and dropout rates and completion of honors and advanced placement courses; and opportunity based on access to qualified teachers, challenging curriculum placement in special education and investments in education, including state and local funding. The gaps include higher academic achievement by high income students compared to

low income students, white and Asian American students compared to African American and Hispanic students, even when controlling for socioeconomic level, and male students compared to female students. There have been some improvements since the 1960s, with the gender gap closing dramatically and in some cases with women outperforming men, and social class, race, and ethnic differences lessening until 1988. However, the social class, race, and ethnic achievement gap widened since 1988, despite continued educational policies aimed at reducing them (US Department of Education 2000).

The reasons for the differences in achievement are complex, including factors both outside and inside the schools. Rothstein (2004) argues that much of the achievement gap is due to factors related to poverty, such as inadequate housing, health care, and environmental problems, including lead paint and other toxins in the urban environment. Although this is the case, it is undoubtedly also true that factors within urban schools contribute to low achievement. These include unequal funding, unqualified teachers, low expectations and dumbed down curricula, and high turnover of teachers and principals.

With respect to investments, in 2001 the nation had an effective funding gap between highest and lowest poverty districts of \$1,256 per student, \$31,400 for a typical classroom of 25 students, and \$502,392 for a typical elementary school of 400 students. These gaps vary by state, with some such as Illinois, New York, and Pennsylvania having large gaps and some such as Delaware, Massachusetts, Minnesota, and New Jersey providing more funding to high poverty districts (Education Trust 2004). These funding gaps are most pronounced in large differences between urban and suburban districts. While some states, most notably New Jersey, have eliminated these differences through court intervention, children in most US cities receive considerably less funding than their suburban neighbors.

NCLB's requirement that all schools have highly qualified teachers in every classroom highlighted the problem of unqualified teachers in urban schools, many of whom were teaching out of their field of expertise. However, while most teachers meet the highly qualified standards of NCLB, the data indicate significant

numbers of classrooms staffed by teachers who are not highly qualified in the particular subject taught. This is the result of the practice called out of field teaching – teachers being assigned to teach subjects which do not match their training or education. This is a crucial practice because highly qualified teachers may actually become highly unqualified if they are assigned to teach subjects in which they have little training or education. At the secondary school level, about one fifth of classes in each of the core academic subjects (math, science, English, social studies) are taught by teachers who do not hold a teaching certificate in the subject taught. The data also show that urban schools, especially low income ones, have more out of field teaching than others.

Problems in staffing urban schools have less to do with teacher shortages and more to do with organizational issues inside schools. Principals often find it easier to hire unqualified teachers than qualified ones and the absence of status and professionalism and poor working conditions in teaching lead to high dropout rates in the first five years of teaching. Therefore, urban districts are constantly replacing teachers, which has significant consequences since it takes years to become an expert teacher. Rates of teacher attrition and misassignment are more prevalent in urban and high poverty schools (Ingersoll 1999, 2003). Ingersoll's research suggests that programs aimed at solving urban school staffing problems at the supply level through alternative teacher education programs such as Teach for America, the New York City Teaching Fellows Program, and New Jersey's Alternative Certification Program (all of which allow college graduates with majors in their teaching field to enter teaching without traditional certification through a college teacher education program) fail to address the organizational problems within schools that are responsible for high turnover rates.

Data from the Education Trust (2004) indicate that many urban schools do not have rigorous academic curricula for all of their students, often track a significant number into non academic programs, and have low expectations for success for a majority of their students. Bryk et al. (1993) argue that one of the reasons that urban parochial schools have higher academic achievement for low income

students of color is that these schools require a rigorous academic college preparatory curriculum for all of their students.

Despite these problems, there are also numerous examples of highly successful urban schools (Education Trust 2004). For example, in Newark, New Jersey, taken over by the New Jersey Department of Education in 1995 for, among other things, low student achievement, there are a number of district and public charter schools with high poverty and high minority populations that perform not only above the state averages, but also at the same levels as those in the highest socioeconomic districts (Barr 2004). Over the past 15 years a variety of educational policies have been implemented to replicate these schools and to improve urban schools. These include school finance litigation, comprehensive whole school reform programs, effective school models, school choice (including charter schools and private school vouchers), and state takeover of failing urban districts (Tractenberg et al. 2002).

These educational reforms have the potential to improve urban schools; however, by themselves they are limited in reducing the achievement gaps (Anyon 2005; Rothstein 2004) unless they also address the factors outside of schools responsible for educational inequalities. In addition to school based programs such as early childhood programs, summer programs, and after school programs, Rothstein (2004: 129–50) calls for economic programs to reduce income inequality and to create stable and affordable housing, and the expansion of school community clinics to provide health care and counseling. He also warns that although school finance suits are necessary to ensure that all children receive an adequate education, without addressing the economic forces outside of schools they will not be sufficient. Rothstein (a liberal) and Anyon (a radical) both conclude that school reform is necessary but insufficient to reduce the achievement gaps without broader social and economic policies aimed at reducing the effects of poverty.

These descriptions of US urban education and urban educational reforms are mirrored internationally. For example, research in the UK (Mortimore & Whitty 1999; Walford 1999; Power et al. 2001) indicates that students living in urban areas and disadvantaged minorities

achieve at lower levels than more affluent students. Mortimore and Whitty (1999) and Power et al. (2001) describe similar policies aimed at improving urban education and argue that although school reforms can make a difference, policies aimed at eradicating poverty must complement these. Whitty (1997), Walford (1999), Ladd (2002), and Plank and Sykes (2003) have examined the impact of school choice policies internationally to improve urban schools. Their research suggests that these policies have mixed success at best. Similar problems and policies have been described in Australia (Singh 2005) and numerous other countries (Cookson et al. 1992).

urban movements

Hans Pruijt

Urban movements are social movements through which citizens attempt to achieve some control over their urban environment. The urban environment comprises the built environment, the social fabric of the city, and the local political process.

An alternative current term is "urban social movements." Pickvance (2003) suggested that the term "urban movements" is to be preferred because it is more straightforward, analogous to "environmental movement" instead of "environmental social movement."

The sociological study of urban movements emerged in the aftermath of May 1968. Previously, urban sociology had tended to focus on community and social integration, at the expense of neglecting the political economy of urban development and conflicts of interest. One of the first to set out to fill this gap was Manuel Castells. In *The Urban Question* (1972) he presented a model of the dynamics of the urban system in which there was one single mechanism for structural change. He called this mechanism "urban social movements." Around the same time, citizens in many cities around the world were mobilizing in response to problems in the urban environment, which helped generate interest in the topic; a number of sociologists drew inspiration from their personal experience as participants in these mobilizations.

The urban movement literature shows a wide range of problems that citizens have responded to with collective action. A large section can be categorized under the heading of "collective consumption": housing shortages, growing discrepancies between rents and wages, landlords' neglect of maintenance – even up to the point of abandonment – and insufficient health care and education. In developing countries, shantytown dwellers face a lack of water supply, sewers, and electricity. A second set of action provoking problems is related to urban planning: displacement and destruction of beloved cityscapes. Finally, specific groups have mobilized around highly specific issues, such as squatters against anti squatter policies, property owners against proposed social housing and against property taxes, racist groups against migrants.

Urban movements tend to draw on a relatively stable set of familiar types of action. The action repertoires found in urban movements very much overlap with the action repertoires of other social movements. Some items, however, are specific for urban movements: the rent strike, squatting, and developing alternative spatial plans.

Organizational patterns can be bottom up or top down. Bottom up mobilization involves building networks of activists and occasional participants, the creation of committees, possibly formal organizations, newsletters, and neighborhood centers. An example in which substantial bottom up mobilization occurred was the 1970s Citizen Movement in Madrid. Top down mobilization occurs when political parties build local organizations, such as in the case of the land squatter movement of Santiago de Chile from 1965 to 1973, or when political groups try to take over or make use of a movement that started in a bottom up fashion. This occurred in the later stages of the Madrid Citizen Movement (examples from Castells 1983). Top down involvement of political groups or parties is often viewed as detrimental because it can entail a transformation into state oriented bureaucracy, and because it clashes with the prevalent ideal of self management (Castells 1983).

Often, urban movements exhibited a capacity for transcending social borders, such as through cross class mobilization. This has taken the shape of horizontal cooperation of participants from different class backgrounds (as in urban squatters' movements), or instead middle class activists (such as students) helping poor people (such as immigrant workers). Some urban movements, however, have been restricted in terms of the participants' ethnicity (such as black and Latino mobilizations in US cities in the 1960s and 1970s), class (e.g., rent strikes), or age (the Italian Social Centers Movement).

The relatively prominent role of women in urban movements – as far as social movements go that are not specific women's movements – has often been noted. An example is the 1922 tenants' protest in Veracruz, Mexico (Castells 1983). One explanation for this phenomenon points to the special role of women in collective consumption.

Protest goals are often clear and measurable, such as preventing a particular planned transformation in the built environment, ensuring that particular buildings are repaired instead of being abandoned, getting a street closed to through traffic, preventing the eviction of a building, or achieving a rent reduction. In studies of urban movements we tend to find ample

information on whether such goals have been attained. The resulting picture shows a mix of failure and success; it is evident that urban movements can have clear effects. The clearest are the effects of activists' victories in planning conflicts. In several cities (such as Amsterdam), the map shows the traces of urban highway construction projects that were abandoned in mid execution: a wide street, created as a stretch of urban highway after razing blocks left and right, stopped dead in a maze of ancient streets. Newly built houses or renovated buildings may be seen solidifying the protest movement's victory because the gap that they leave is only wide enough for a narrow street.

Beyond cancelation of individual construction projects we find wholesale transformations of urban planning, in a direction that more or less conforms to demands made by activists. An example is the influence that Castells (1983) ascribed to the Madrid Citizens Movement. Urban movements often are pre sentient of what later becomes accepted planning wisdom.

Ideally, claims about turns in urban history caused by protest are bolstered by an analysis of the decision making process and by an attempt to sort out movement influence from other factors, such as financial constraints.

Protesters' victories may be partial, such as a cap put on a rent increase instead of succeeding in preventing it completely, or being unable to prevent an eviction but instead securing rehousing. Also, there may be unintended effects, such as protests against eviction of squats leading to legalization. Some point to the risk that urban action can be self defeating: improvements in low income neighborhoods might attract gentrification, which forces the original inhabitants out of their neighborhood.

Some confusion exists as to whether urban movements should be seen as either instrumental movements or identity movements. The clarity in terms of goals that cases of urban protest often possess does not exist at the level of the movement. Movements do not need overarching goals, nor do they need a high level of organizational unification. Therefore, goals ascribed to urban movements tend to be somewhat arbitrary. For example, the same Dutch squatters' movement has been described by some as a "new social movement" or identity movement aiming

to create a new way of life, and by others, equally justifiably, as an instrumental movement fighting for affordable housing.

Urban movement studies tend to move beyond recording and explaining victories and defeats in individual cases of urban action and conflict. A question that has commanded much attention is the contribution that urban movements might make to social change. Castells, especially, has been involved in the search for a general theory. At first (e.g., in his 1972 book *The Urban Question*) he elaborated the idea that urban movements had a latent function in the class struggle. He stated that urban movements could only be significant for social change if they linked up with organizations involved in the class struggle in the sphere of production.

In a later attempt, Castells (1983) stated that the local focus of urban movements precludes transformation of production, communication, and government; the kind of social change that urban movements would be capable of producing is resistance to domination, or, in other words, changing the "urban meaning," resulting in "reactive utopias." Urban movements could achieve their maximum potential for social change (Castells reserved the title of urban *social* movement for this condition) when they were multi issue, pursuing all of the following three goals: (1) realizing collective consumption demands (such as those related to social housing) within a framework of promoting the city as a use value against commodification; (2) establishing and strengthening an autonomous cultural identity and promoting communication instead of "programmed one way information flows"; and (3) territorially based self management. Other criteria were explicit consciousness that active groups were part of a wider social movement, solidarity with other parts of the movement, expression of movement themes in the media, and – without giving up autonomy – the maintenance of links with professionals and political parties. Castells's model seems most fruitful when treated as an ideal type, i.e., as a conceptual tool for discussing similarities and differences between urban movements. Since the model does not include contextual variables and scarcely any action variables, not too much explanatory value is to be expected.

Rise, fall, and transformation of urban movements have been subject to analysis as well. In his early writings, Castells suggested that mobilization can be explained by the intensity of urban problems or the contradictions behind these. This stimulated other urban sociologists to identify contextual factors that play a role in mobilization, such as the extent to which citizens find themselves in a similar state of deprivation, whether or not it is a zero sum conflict (one neighborhood's gain is the other neighborhood's loss), and cleavages between tenants and owners or between those who are eligible for rehousing after renewal and those who are not. Insights from the general social movement literature, especially the political opportunity structure approach, apply here too: citizens mobilize in response to widening opportunities as cleavages within elites become manifest and new allies appear on the scene. Another relevant contextual variable is the extent to which urban managers succeed in redefining social issues as either individual or technical problems. Repression is an important factor everywhere, although most dramatically in developing countries where activists risk being murdered when they move against powerful interests (Corr 1999). Besides context, analyses of mobilization need to consider the strategies employed in the mobilization of resources such as influential sympathizers. The skills activists display in framing, i.e., verbalizing urban problems, identifying some one to blame, and proposing a solution, are important too.

Movements tend to have a life cycle; institutionalization (i.e., being channeled into a stable pattern based on formalized rules and laws) and cooptation (activists start performing some task at the request of the government) are often seen as the beginning of the end. It is an open question, however, whether institutionalization is inevitable. The introduction of conventional interaction such as consultation and negotiation does not imply that disruptive tactics necessarily disappear from the movement's action repertoire. Especially when disruptive tactics are part of the movement's identity (e.g., for a squatters' movement, squatting is both means and end) and when repression is moderate, they may remain part of the repertoire. Institutionalization and cooptation may cancel out the impulse toward change, but they may also offer

a way to secure the results of a movement's victory.

An emergent area of inquiry concerns the effect of structural regime change on urban movements. Post Fordist theory suggests that local governments increasingly feel contradictory pressures to decrease welfare bureaucracy and spending and, at the same time, to alleviate poverty. This results in a greater need to coopt urban movement groups, for example as managers of self help programs. Issues that prompt research and debate are whether activists should expect some influence in return for being coopted, because they perform an essential job, and whether cooptation of some movement groups means that new opportunities for radical groups emerge.

Some recent thinking deemphasizes the *local* focus of urban movements (Hamel et al. 2000). Indeed, we do find clear cases of urban movements that are both local and national or supranational, such as the youth movement that is involved in the creation of social centers, "Critical Mass" and "Reclaim the Streets." But more generally, the fact that urban mobilizations have appeared in at least nationwide wave patterns shows that influences beyond the local are relevant.

urban policy

Allan Cochrane

Urban policy actively shapes the ways in which people live in cities. As well as reflecting contemporary understandings of the role of cities in economic and social development, it also helps to create those understandings.

Definitions of urban policy are elusive in part because the term appears so self explanatory. It seems to be no more and no less than the sum of those policies that are intended to help cities or those living in them. Unfortunately, however, this commonsense approach is ultimately not very helpful – since most of us now live in urban areas of one sort or another, almost all public policy might be deemed to be urban policy. Assessing quite why one particular form of policy intervention attracts the sobriquet “urban” while another does not is more difficult than at first appears. Although there is a superficial continuity in the emphasis on “urban areas” rather than particular welfare client groups, the definition of the “urban” on which policy attention is focused has itself varied significantly, even if this has rarely been acknowledged by those making or implementing the policies.

The arrival of urban policy as a form of social policy in its own right (rather than an offshoot of urban planning or housing) can be located in the specific circumstances of the

US in the 1960s, in the context of the “War on Poverty” and the political demands of the increasingly urbanized African American population, which also found their expression in the urban riots or rebellions of the late 1960s. In this first incarnation it can be seen as a means of bringing previously excluded groups into the broader post war welfare settlement, even if still on rather different terms. And it was taken up in analogous ways in many other western countries (most obviously the UK). However, the development of urban policy from this starting point does not reflect a continuing process of learning with a clear and continuing set of aims and ambitions. On the contrary, it is “at least in western society, a chaotic conception” (Atkinson & Moon 1994: 20) because there has been no shared understanding of the “problem” around which policy might be defined.

There have been several quite distinctive attempts to find a means of defining urban policy that is capable of capturing and reflecting its full complexity. Some of its earliest analysts (e.g., Piven & Cloward 1972) saw its arrival in the US of the 1960s as a response to political pressure (whether expressed through the threat or reality of riots or the need to incorporate a rising black middle class) and the importance of such pressure in helping to generate urban policy, particularly in its early years, should not be dismissed. But the way in which it made its transatlantic migration (and has since gone on to become a global phenomenon) suggests that it is not enough to focus on its role as a response to popular pressures.

Another early explanation identified urban policy as an expression of the rise of a new political class: new professionals in government and academia seeking to stake their own position as an alternative policy elite, based around the rise of the social sciences and what has come to be called evidence based policymaking, rather than the traditional culture of the civil service or public bureaucracy (Marris & Rein 1972). This interpretation, too, has its attractions, since it fits well with the shift away from the traditional bureau professionalism of the Keynesian welfare state that has been widely recognized as a central feature of state restructuring since the 1970s. However, the extent to which urban policy can be closely identified

with the rise of a new professional class remains questionable, not least because that class has proved difficult to track or identify.

The emergence of urban policy in practice was accompanied by an explosion of critical theory which set out to place the new agenda in a wider context. At the core of this explosion were approaches that focused on issues of social reproduction, described as "collective consumption" by neo Marxists such as Manuel Castells. These approaches make it possible to identify a policy area that is not simply reducible to what is (confusingly and inconsistently) labeled "urban" in everyday speech or even the language used by new professionals. They also place the "urban" at the heart of political life and policy debate and the reshaping of contemporary welfare states. Castells (1977: 440) argued: "The essential problems regarding the urban are in fact bound up with the processes of 'collective consumption' or what Marxists call the organization of the collective means of reproduction of labor power." Since in this formulation the "urban" is itself defined by policy – the delivery of services and goods provided by or through the state to support the reproduction of labor power – core aspects of social policy are redefined as urban policy.

Unfortunately, one of the strengths of approaches that focus on collective or social reproduction is also a weakness, since, by identifying a separate sphere for the urban, they effectively exclude from consideration some of the policy initiatives that increasingly define the politics and shape the experience of life in urban areas. Many of the policies that would not be defined as urban in this sense help to define the experience of urban life (including policing and economic development, as well as transfer payments through the social security and benefits systems). Equally important, spending on some programs (such as education and health) might qualify as collective consumption, but they are generally only seen as urban when they are associated with specific area based initiatives.

If the debates of the 1970s focused on the role of the urban in processes of social reproduction, by the mid 1980s the emphasis had shifted dramatically. Now it was placed increasingly clearly on the role of cities in processes of

production, or on the realization of profits from real estate development. So, for example, in a powerful phrase, Logan and Molotch (1987) identify the city as a "growth machine." They argue: "*Local conflicts* over growth are central to the organization of cities ... not only the economic imperative of the larger system, but also the striving of *parochial actors* to make money" (p. viii).

In some important respects the insights of these theorists are helpful, particularly because they seem to fit with key aspects of today's actually existing urban policy. They are consistent with some of the policy shifts that have led to the identification of the "entrepreneurial" or the "competitive" city; that is, the policy approach that sees economic success as the necessary precondition for the well being (or welfare) of citizens rather than the existence of an extensive (social democratic) welfare state. For some, this understanding has come to form the basis of a critique; for others, it provided the basis of normative policymaking.

However, if Castells and others overemphasized the significance of cities as places of collective consumption, then this approach understates it. Because urban politics is understood through the drive to realize exchange value and generate profits from growth (through rising property values) or from the necessary relations associated with locally dependent business policy, aspects of urban policy that might be focused on other forms of social consumption (e.g., community) tend to be ruled out as irrelevant, or redefined as instrumental infrastructure. So, for example, the significance of urban policy as an attempt to control the disorderly and manage disordered spaces fits uneasily with a structural emphasis on growth as driver of urban policy. Similarly, while it might be possible to claim community based initiatives (and communitarian thinking) in terms that relate them to issues of production and the competitiveness of cities, the tension between a community based agenda and a more narrowly defined competitiveness oriented agenda is hard to ignore.

More recently, attempts have been made to position urban policy rather more explicitly within broader shifts in economy, public policy, and state restructuring. One aspect of this is

reflected in the major critique launched by those who see in its contemporary development and definition the working out of a global neo liberal agenda (Brenner & Theodore 2002). This approach invites us to understand urban policy as part of a wider process of change, while also positioning the city as an active agent in shaping that change. In this context, urban policy is seen to take on a key role in the reshaping of post war welfare states and the settlements associated with them. The rise and development of urban policy helped to shape (as well as reflect) the policy upheavals and state restructuring that characterized the fraying of the Keynesian welfare state and the unsettling of the political, economic, and welfare settlement implied by it. In its contemporary form(s) it begins to suggest the possibility of new political and welfare settlements, even if they remain highly provisional and contested.

The “urban” may often still be used as coded language for “welfare” (and black), but the rise of the “competitive” or “entrepreneurial” city powerfully illustrates the wider direction of change. Historically, the emphasis may have been on “inner cities” and those living in them, but now it is urban economies that are to be revitalized or restructured in order to make cities competitive and improve the economic well being of residents. Physical and commercial infrastructure is to be regenerated, making urban land economically productive once again, and there has also been a drive towards place marketing and cultural reimagination, so that cities can be made attractive to the “creative class.” Local neighborhoods are increasingly targeted either for community renewal (building social capital or community capacity) or for new forms of policing, where they cannot be relied on to police themselves effectively.

The rise of mega projects, the reimagination of cities as cultural centers, and “global cities” are as marked in Pacific Asia as in the US and Western Europe. In this context the nature of the urban “problem” is also interpreted differently – instead of a catalog of decline, which urban policy needs to reverse, in the new urban policy cities become potential (and actual) sources of growth and development. Even the “slums” of the new megacities in South America and Africa are now identified

by the World Bank as potential hotbeds of entrepreneurialism. There has been a broad shift away from a vision of the state as regulator of the market to one in which the state is defined as agent of the market, with an explicit policy focus on providing the infrastructure for profitable production rather than welfare support to those on the margins. It is within this context that cities are left to bargain and negotiate to achieve different outcomes for their populations.

urban political economy

Leonard Nevaréz

One of sociology's original and most fundamental questions is: how does the city shape social life? The answer provided by urban political economy is: as a mechanism in the accumulation of wealth, with all the power and inequality that results. "Political economy" generally refers to the scholarly paradigm that examines how material processes of production and exchange shape and are shaped by decisions made in economic and political institutions; with "urban," this concern centers around material production *of* and *within* cities. Since the 1970s, urban political economy has influenced the field of urban sociology, bringing insights from other disciplines – particularly social geography (with its conceptualization of social space and place) and political science (the focus on government and law) – while retaining sociology's social constructionist framework. Sociology provides an especially hospitable discipline for urban political economy's investigation of the ways in which the city's economic and political relations cohere and evolve across institutional, legal, and territorial domains.

Urban political economy emerged as a critique of the urban ecology paradigm, particularly the latter's explanation for the growth and structure of cities and regions. By emphasizing the spatial competition for resources by individuals, groups, and institutions, urban ecology has viewed political hierarchies, economic actors and laws, and other social institutions as expressions of more fundamental and pre conscious forces. Its corollary that city governments, local business elites, urban planners, or racist neighborhood associations, for example, are not the "real" agents of urban structure and relations had long struck a cadre of conflict oriented urban sociologists as a problematic denial of social power. By the 1950s and 1960s, urban ecology's inability to understand critically the problems of white flight and urban poverty in the US as well as urban and political unrest throughout the world created a breaking point for many urban sociologists. Consequently, a first generation of urban political economists began to emphasize the role of economic

structure and social power in explaining urban relations.

THE NEO MARXIAN TRADITION

Urban political economy updates the theoretical legacy of Karl Marx around the urban condition, a topic he did not address extensively in his nineteenth century writings. First, neo Marxians explained the city's evolution as structural expressions of *historical relations of production*. Beginning in the early twentieth century, their argument goes, industrial capitalists promoted the flight of manufacturing to the urban periphery and the growth of residential suburbs to advance their class interests in, respectively, avoiding the costs of aging and inflexible urban infrastructure and dispersing urban hotbeds of labor unrest. Industrialists promoted these interests in the political and cultural realms via federal policies and cultural sentiments promoting homeownership, suburban development, and the encouragement of growth in America's "Sunbelt" region (where the union tradition is much weaker than in the older "Rustbelt"). In urban sociology, these early neo Marxian claims appeared in the 1970s and 1980s alongside other intellectual agendas that, although not necessarily sharing the same conflict orientation, put urban class relations at the forefront of the field. Research on dual labor markets, immigrant entrepreneurs, ethnic niches, and related issues have all benefited from the neo Marxian insight that economic forces do not merely express social relations but in fact drive them as well. However, by emphasizing capitalism's causal role, this early urban political economy research in turn raised a question that casts doubt on urban sociology's disciplinary relevance: is the city merely a container for larger social forces?

A powerful rejection of that question began with a largely European cadre of neo Marxian scholars whose work integrated "urban" with "political economy" in new and compelling ways. First, British geographers starting with David Harvey explained how investment in land provided important functions for capitalism. Borrowing the idea of space as a "secondary circuit of capital" from French sociologist philosopher Henri Lefebvre (whose urban

writings at that time were mostly untranslated in English), Harvey contended that land and the built environment offer capital an important alternate site for investment when industrial investments soured. With this claim, Harvey reframed urban sociology's traditional interest for urban and regional development into a structural Marxist theory of *capital accumulation*. By assigning landed capitalists a distinct role vis à vis industrialists and financiers in the structural dynamics of capitalism, Harvey also established a new interest for the social role of landlords, developers, and other capitalists who profit from the built environment. Next, the Spanish born, French trained sociologist Manuel Castells theorized that the "urban" corresponds specifically to relations of *collective consumption*, those city based services, housing, and infrastructure provided by the state with which people reproduce their labor power. His claim particularly resonated in Western Europe and Latin America and launched a neo Marxian research agenda that examines urban politics, grassroots protest, and urban movements as expressions of class relations distinct from the capitalist-worker conflict usually emphasized by neo Marxians.

THE NEO WEBERIAN TRADITION

If Marx gives urban political economy its concern for the structural dynamics of capitalism, Max Weber's legacy provides the conceptual vocabulary with which to understand social power and human agency. This is underscored by the curious fact that for Marx, the notion of a "ruling class" is somewhat a contradiction in terms. Governance involves political processes that, to have theoretical integrity, must not be entirely determined by other social realms; yet Marx famously gave little credence to politics' autonomy from material relations of production. Consequently, structural Marxists like Harvey had no vocabulary with which to understand urban power and political contingency apart from the structural determination and historical conjunctures of the economy.

Reasserting its intellectual relevance, the American school of urban sociology reintroduced the neo Weberian question, "Who governs the city?" posed previously within political

science during the 1950s and 1960s. In this earlier *community power* debate, Floyd Hunter and other proponents of the elitist perspective argued that a core group of private urban elites regularly and successfully promote their interests through city hall. Rejecting this claim, Robert Dahl and other advocates of a pluralist perspective countered that private interest groups may prevail on certain issues, but not consistently enough to dominate urban politics. Eventually, the community power debates reached an impasse over inconclusive findings as well as theoretical and methodological differences. By the 1970s, as urban political economists studied the ways in which cities generate wealth for capitalists, it became clear with hindsight that neither side in the community power debate had theorized the material interests of the city's power holders in a substantial way.

Consequently, urban political economists adapted neo Weberian premises to the neo Marxian problematic and identified the social production of urban space – that is, *city building* – as the institution that organizes the material interests and galvanizes the political dominance of urban elites. This means that urban governance is not confined within urban governments; just as important are the private decisions made by place based entrepreneurs and businesses to make money. Harvey Molotch crystallized this idea with his theory of the *growth machine*, a territorially defined coalition of urban elites from across public, private, and civic sectors that promotes growth in order to advance its common interests in intensifying land based exchange values (higher rents for developers and landlords, increasing tax revenues for local governments, new readers for local newspapers, more ratepayers for utilities, more jobs for local trade unions, and so on). With his colleague John Logan, Molotch identified the class relations and political stakes underlying the growth machine, asserting that the exchange value interests of growth machines invariably portend environmental impacts, infrastructure strain, fiscal constraints on public services, and other material conflicts with the use value interests of residents. For urban sociologists, the growth machine theory transcended the earlier community power debate by identifying urban growth as the consensus agenda (which elitists emphasized) underlying the overt conflicts and

political factions of city hall (which pluralists emphasized).

Contemporary research on urban power has further developed the insights of growth machine theory, which did not theorize in detail on how urban elites engage the political realm, under what conditions they cooperate with one another (in fact, urban elites may be divided by vested interests in different parts of the city or different kinds of growth), or how effective they are in attracting urban growth and achieving political hegemony. These issues have been taken up by urban regime theory, a school of urban political science that has influenced urban political economy since the late 1980s. An *urban regime* is the set of formal and informal arrangements that makes urban governance by a public-private coalition possible. As Clarence Stone has explained, urban regimes vary by the agendas that their participants pursue; some are radically progressive, while others simply maintain the political status quo. However, the most frequently observed type is the development regime enacted by pro growth elites, although for reasons that go beyond the shared interests of the growth machine. Just as importantly, actors in the development regime most effectively marshal and share the political benefits, business opportunities, and other "selective incentives" that enforce cooperation and prevent dissent within their public-private coalition.

NEW PATTERNS OF URBAN RESTRUCTURING

Since the 1980s, urban political economy has developed in large part as a response to the dramatic shifts in economies, politics, population, and settlement associated with *urban restructuring*. This concept has pushed urban political economists to identify what is qualitatively new and significant about capitalism's transformations of the city. For example, the globalization of traditional American industry, on the one hand, merely demonstrates at a larger scale structural dynamics that spurred the growth of the American Sunbelt decades earlier: industrial capital's vulnerability to site specific labor costs and labor control, and its benefits from geographically uneven development. On the other hand, the technological and organizational

innovations that made globalization possible have generated unanticipated economic, spatial, and social outcomes.

In her *global city* thesis, Saskia Sassen explained how the financial capitals of New York, London, and Tokyo have assumed new centrality in the coordination of transnational corporate (TNC) activity. This is not because these global cities attract TNC headquarters, many of which have in fact left major cities, but instead because they concentrate the social networks of smaller financial and advanced business service firms that oversee, respectively, the capital investments and legal organizational management needed by TNCs. Sassen's insight that geography, markets, and networks assume a coordinating role formerly contained within corporate bureaucracy parallels a larger theory about the geography of "flexible accumulation." Rejecting the popular wisdom that place no longer matters in globalization, this theory documents the central function of *flexible industrial districts* in industries where skilled labor, entrepreneurial companies, and specialized support systems cluster, such as Silicon Valley (technology), Hollywood (film), Paris (high fashion), and the "Third Italy" (textiles).

Amidst the global context of capital mobility and job flight, these and other economically vibrant cities and regions in fact witness economic polarization and social inequality, due to economic growth as well as stagnation. For instance, well paid workers in booming technical, cultural, and creative industries create new demand for consumer services that employ low skill labor. Also, some creative industries remain competitive by relying on local sweatshops (endemic in fashion centers like New York or Los Angeles) or other informal enterprises. Manuel Castells and John Mollenkopf have described the subsequent urban structure with their idea of the *dual city*. In its more glamorous half, new professionals revitalize once staid urban economies, gentrify abandoned neighborhoods, and stimulate the growth of coffeeshops, bistros, bars, and other high end consumer services. In its less affluent half, working classes become less secure with the exodus of manufacturing and other activities that once created decent paying union jobs, while new immigrants leap over older ethnic and racial groups to manage and fill the low paying service and

sweatshop jobs, or to sell goods on the street in informal economies.

Theoretically, globalization underscores how the dynamics of growth and decline extend beyond the scale of any one city, region, or even nation. Not surprisingly, urban restructuring has thus challenged urban political economy's models of human agency. On the one hand, the structural context in which growth coalitions operate has always been "global" to some extent, as companies choose a location from a variety of places, and places' competitive advantages are influenced by non local factors like state budgets, national federal mandates, and interest rates. On the other hand, capital investment and urban growth increasingly materialize in a decentralized, market form. At least in the new economy's industrial clusters, the decisions that bring growth are made by a number of actors too large for any growth coalition to sway effectively with conventional lobbying. As urban political economy keeps abreast of the structural changes associated with urban restructuring, the paradigm's practitioners continue to reevaluate what constitutes the "political." Does the neo Weberian focus on political institutions' legitimacy, interest groups' pressure politics, and coalitional power plays still have explanatory value in this era of urban restructuring? If so, just how much, and at what scale does it explain?

urban poverty

David J. Harding

While a technical definition of the urban poor includes those individuals in families with incomes below the federal poverty line who live in metropolitan areas, most research on urban poverty focuses on racial and ethnic minorities living in segregated, high poverty neighborhoods in central cities. The study of urban poverty lies at the intersection of several sociological fields, including race and ethnicity, immigration, stratification, and urban sociology. As a predominantly problem oriented field, urban poverty research attempts to understand the roots of urban dilemmas such as crime and delinquency, single motherhood, unemployment, and low levels of education, often drawing theoretical concepts from other areas of sociology such as social capital, networks, and culture. The causes and consequences of spatially concentrated poverty and the intergenerational transmission of poverty are also frequent subjects of inquiry. A recurring debate in this field is whether income inadequacy causes problem behavior or whether problem behavior causes income inadequacy.

The study of urban poverty dates back to the founding of sociology as a discipline in the US with W. E. B. Du Bois's *The Philadelphia Negro*, first published in 1899. Du Bois developed the theoretical ideas that remain important to this day, including the connection between spatial isolation and social exclusion. Sociologists of the Chicago School largely viewed urban poverty as a temporary stage in the incorporation of immigrant groups from abroad and of migrants from rural areas. High population turnover, lack

of material resources, and ethnic heterogeneity lead to the breakdown of social control in immigrant receiving neighborhoods, creating higher rates of crime and delinquency. Through processes of neighborhood invasion and succession, they argued, ethnic groups moving upward in economic status also move from crowded, poor, central city neighborhoods through a series of concentric zones to progressively better off areas further from the central city.

The Great Migration, which brought Southern blacks to Northern and Western cities in great numbers between the two world wars and after World War II, challenged the Chicago School model of invasion and succession, as urban blacks were blocked from the economic and spatial advancement previously experienced by white ethnic groups. Focus shifted to understanding the intergenerational transmission of poverty. Some scholars emphasized structural constraints while others argued for cultural explanations, particularly the development of a culture of poverty, characterized by the intergenerational transmission of norms disparaging education and two parent families and encouraging crime. In response to the controversial Moynihan report, which argued that matriarchal family structures found in black communities were destructive, researchers began to train attention on the adaptive characteristics of black families and their resilience in the face of racial discrimination, segregation, and economic subjugation. Conservative scholars objected that these accounts ignored the more powerful and perverse incentives of the welfare system that, they suggested, encouraged out of wedlock childbearing, single parent households, and persistent unemployment.

The demographics of poverty shifted dramatically over the course of the twentieth century. Improvements in social security and other government programs for the elderly made urban poverty less of a problem among the elderly, while the spread of single parent families made urban poverty more of a problem among unmarried mothers and their children, the so called feminization of poverty.

With the publication of *The Truly Disadvantaged* (1986), William Julius Wilson refocused attention on the spatial or neighborhood context of urban poverty. Wilson argued that the black urban poor were doubly disadvantaged by both

their individual poverty and their residence in concentrated poverty neighborhoods. Advances in civil rights in the 1960s had made it possible for middle class blacks to move out of inner city ghetto neighborhoods in the 1970s, leaving the poor behind. At the same time, the decline of the manufacturing economy had led to chronic unemployment and underemployment among working class males, especially blacks. Wilson argued that an underclass emerged, a concentrated population characterized by single motherhood, poverty, joblessness, high school dropouts, and participation in the underground economy. Because of its spatial isolation, this population came to be socially isolated from mainstream society, and in the presence of economic deprivation, came to develop cultural practices that diverged from the mainstream. Though Wilson (1997) would later rename this group the ghetto poor and call special attention to the importance of joblessness, the emphasis on neighborhoods remained.

Wilson's work reinvigorated the study of urban poverty as researchers challenged his claims about the rise of concentrated poverty neighborhoods and tested his hypotheses about the consequences of neighborhood poverty for individuals. Massey and Denton (1993) charged Wilson with ignoring the role of racial segregation in magnifying the consequences of economic segregation, and Quillian (1999) later showed that though middle class blacks were able to leave ghetto neighborhoods, their new neighborhoods quickly resegregated as whites left. Scholars argued that the decline of manufacturing was important only in the industrial cities of the North, where manufacturing jobs paid well and where blacks were well integrated into the manufacturing workforce (Jargowsky 1997). Others challenged Wilson's emphasis on joblessness and pointed toward the large numbers of working poor in disadvantaged neighborhoods, for whom poverty is the result of low wages rather than unemployment (Newman 1999).

One strand of current research investigates the consequences of neighborhood disadvantage for individual residents. Residents of disadvantaged neighborhoods generally have higher rates of school dropouts, teenage pregnancy, single parent families, unemployment, crime and delinquency, and other problems, net of

differences in observed family and individual characteristics. While there is some question as to whether these differences are the product of unobserved differences between residents of advantaged and disadvantaged neighborhoods, results from mobility experiments and from sophisticated methodological techniques designed to deal with this selection bias have convinced most scholars that neighborhood effects are real. Debate continues, however, on their magnitude relative to other influences.

Attention subsequently turned to understanding the social processes that create neighborhood effects. Jencks and Mayer (1990) suggest four mechanisms by which neighborhood poverty might influence adolescents: relative deprivation, exposure to negative peer influences, collective socialization by neighborhood adults, and formal institutions, which distribute material resources and effect contact with non neighborhood adults. A social control perspective highlights the ability of neighborhood residents to control behavior in the neighborhood, both through informal sanctions and monitoring and through the acquisition of institutional resources such as police protection. Sampson et al. (1997) show that collective efficacy, or "social cohesion among neighbors combined with their willingness to intervene on behalf of the common good," mediates the relationship between neighborhood structural disadvantages and public disorder and crime.

A second strand of current research seeks to understand the causes of high rates of out of wedlock and teenage childbearing among the urban poor. Three explanations have emerged for out of wedlock childbearing, though to date there is not enough evidence to adjudicate between them (Small & Newman 2001). The male marriageable pool hypothesis holds that a shortage of economically attractive mates leads poor urban women to eschew marriage. The slavery hypothesis holds that the institution of slavery damaged gender relations among African Americans, leading to fewer permanent marital unions among them. A third hypothesis holds that out of wedlock childbearing has become more acceptable in society as a whole, and that the behavior of the urban poor reflects this new normative environment. Edin and Kefalas (2006) argue that poor urban women actually hold marriage and childbearing in such

high regard that they delay or avoid marriage when success is uncertain. Coupled with a belief that motherhood is the most important social role a woman can perform, these cultural understandings of marriage lead to high rates of out of wedlock childbearing among the urban poor.

Three explanations have also been offered for the higher rates of teenage childbearing among the urban poor (Small & Newman 2001). The peer culture hypothesis holds that among the urban poor, early sexual activity and early childbearing are a source of status among peers (Anderson 1999). The weathering hypothesis holds that early childbearing is a rational response to the deteriorating health of urban poor women as they age, making the teen years the optimal period for healthy childbearing. Finally, the poverty of relationships hypothesis holds that teenage girls have children to compensate for a lack of other meaningful social relationships and for lack of prospects for finding rewarding work.

As research continues, the study of urban poverty faces a number of methodological and theoretical challenges. First, today's urban poor are quite heterogeneous. For example, while most of the research focus has been on African Americans, Latinos now make up the largest minority group in the US, and Latinos and other immigrants have become an important and understudied segment of the urban poor. Indeed, the Latino paradox – higher rates of poverty but fewer negative outcomes among Latinos – raises fundamental questions about the roles of structure and culture. Second, while social isolation has been used theoretically to understand the consequences of urban poverty, we have only begun to understand how the urban poor are socially isolated or socially connected to others. Third, understanding the dynamics and consequences of high poverty urban neighborhoods requires new methods and new data for measuring the social and cultural characteristics of these neighborhoods, beyond the structural measures provided by the decennial Census. While methods for measuring the characteristics of urban neighborhoods are being developed, further data are needed to take advantage of these methods.

These three concerns highlight two important weaknesses in the current literature on

urban poverty. One is the lack of attention to the mechanisms or social processes by which poverty and poor urban neighborhoods have their effects, including the potential for heterogeneity in mechanisms across neighborhoods. A second weakness is a lack of attention to culture and to individual agency in understanding the causes and consequences of urban poverty. To have an impact, macro level structural forces such as joblessness or neighborhood disadvantage must affect individual behavior through decision making processes and cultural or cognitive understandings. While most urban poverty researchers continue to talk in terms of norms and values, the sociology of culture has moved toward a more cognitive view of culture that emphasizes cultural repertoires, strategies of action, frames, cultural capital, and boundary making. Poverty researchers are increasingly questioning current theories of urban space and investigating the strategies the urban poor use to challenge their marginality. Gotham & Brumley (2002) use ethnographic field observations and interviews with public housing residents to argue that the urban poor use space to provide a measure of security and protection, to designate and avoid areas of criminality and drug activity, and to challenge or support the redevelopment of public housing (see also Gotham 2003).

Finally, recent work on urban poverty has expanded into other domains. Health outcomes such as low birth weight, mental health, and disease have been shown to be related to individual and neighborhood disadvantage. Using new statistical techniques that assess the impact of a neighborhood's location within the urban context, researchers have also begun to investigate the importance of neighborhood spatial context.

urban renewal and redevelopment

Gregory J. Crowley

The built environment deteriorates with the passage of time and the stresses of use and neglect. Unemployment, poverty, shortages of affordable housing, health epidemics, and transportation

problems often accompany physical decay in modern cities. Attempts to relieve these social problems through the maintenance, rehabilitation, and rebuilding of the physical environment are known as urban redevelopment.

European governments implemented the first large scale urban redevelopment projects in the nineteenth century. Louis Napoleon Bonaparte of France led the way with his massive renovation of Paris that began in 1853. Thousands of residents were displaced by the creation of a system of wide boulevards that "pierced" diagonally through dense, older neighborhoods of the city. Another wave of urban redevelopment began after World War II. In Europe, government acquisition and demolition of properties played a major role in the rebuilding of cities destroyed by war. Cities in North America meanwhile embarked on their first major effort at demolition and rehabilitation of the built environment. Title II of the 1949 Federal Housing Act, known as "urban renewal," responded to a very different problem: the long term trend of suburbanization that threatened the stability of the central city.

The sociology of redevelopment in the US grew out of attempts to explain population dispersal and corresponding urban distress. Urban ecology, a leading perspective, explains population shifts in terms of "succession." Competition for scarce resources causes some subspecies to replace, or "succeed," others in a habitat. According to the logic of succession, middle class whites and blacks moved from central cities in the twentieth century simply because technological changes in transportation allowed them to adopt the higher standard of living promised by suburban areas.

Other scholars have criticized urban ecology for overlooking how social inequalities and power relations are structured in the form of the built environment. Neo Marxist theory emphasizes that capitalist firms change location not only to accommodate upgraded physical plant, but also to control labor conflict. Gordon (1978) used US Census data to show that manufacturing employment in the "rings" increased at more than twice the rate of centers of industrial cities beginning in the 1890s. The change occurred amid a steady increase in labor strife and well before the technological innovations that would later transform the organization of

work and domestic life. According to Gordon, executives at the turn of the century moved their plants to the suburbs mainly to avoid labor union activity, which was concentrated in central cities.

A third approach is urban political economy, which is critical of both ecology and neo Marxism for discounting the social and political context in which demographic changes occur. Political economy views territorial shifts in population as a result of urban governing coalitions that shape zoning, transportation, taxation, housing, and other policies affecting patterns of land use and migration within a territory. From the political economy perspective, metropolitan "sprawl" is caused by more than just a demand for high quality housing on the urban periphery. Urban governing coalitions promoting uncontrolled growth are certainly influential in many cities, but in others "smart growth" advocates attempt to direct new development into existing neighborhoods. Among the policy tools they use are loan programs, tax credits for historic preservation, growth controls, and transportation planning.

Understood as a process, redevelopment involves the mobilization of substantial resources controlled by state as well as non governmental actors. Community development corporations, tax increment financing (TIF), eminent domain, tax exempt bonds, human capital, and social trust are some of the many resources commonly involved in attempts to improve distressed neighborhoods. Valued resources may be controlled by real estate owners, financial institutions, developers, neighborhood residents, historic preservationists, or environmental groups. Sociological studies of redevelopment tend to revolve around questions relating to how the composition and dynamics of urban governing coalitions influence strategies of redevelopment.

In the 1950s and 1960s community power researchers visited cities across North America in search of data revealing who influences redevelopment and other local policies. In his pioneering study of decision makers in 1950s Atlanta, Floyd Hunter (1953) answered these questions by documenting who in the community held the greatest reputation for political influence. He identified some 13 leaders, mainly corporate executives, reputed to control important decisions in the city's urban renewal

program. Many of Hunter's followers found in other cities the same pattern of corporate business dominance in physical rebuilding projects. Other scholars found "coalitional" power structures such that business elites who initiated urban renewal were less influential in formalizing and implementing specific projects. Still others found multiple competing factions in the community, which caused redevelopment to be neglected for a lack of leadership and common purpose.

Critics of Hunter's "reputational" method charged that it is impossible to determine who actually exercises influence over specific decisions by asking people who they believe has power. Just because business elites have reputations for power does not mean they will be united on all redevelopment issues or even have the time to examine them in sufficient depth to take a position. An alternative is the decision making approach, developed by Edward Banfield (1961) and Robert Dahl (1961) in their case studies of community power in Chicago and New Haven, Connecticut, respectively. Actual rather than potential control over specific public issues is the topic of decision making analysis.

When combined with reputational analysis, decision making has tended to produce more complete explanations of community power by showing the limitations imposed on elites by underlying community divisions. According to Banfield, a small group of corporate executives advocated federal urban renewal in Chicago, but they had to expend considerable political capital persuading other elites, who stood little to gain by the demolition of downtown, to go along with their 100 acre Fort Dearborn clearance and renewal project. The implementation of redevelopment, Banfield concluded, is often compromised by limitations in the stocks of political capital of elites who promote them. Similarly, Dahl attributed the success of urban renewal in New Haven as a result of the quality of New Haven's leadership. Mayor Lee and his urban renewal staff were distinguished in their ability to shape their proposals according to what they believed interest groups and voters in New Haven could be expected to support or reject.

Community power researchers were for the most part unconcerned with the impact of

redevelopment on the lives of residents in project areas or on the cultural and economic vitality of the city as a whole. They examined land use decisions mainly to demonstrate methods for measuring the distribution of community power. Other critically minded scholars attacked national urban renewal after a decade of post war slum clearance had demolished thousands of affordable housing units without replacement. The most celebrated among these critics was Jane Jacobs. In her *Death and Life of Great American Cities* (1961) Jacobs outlined a theory of urban planning that illustrated how physical features of older, mixed use neighborhoods – the sidewalks, parks, and corner stores – configure informal social contacts that ensure the safety and vitality of cities. Older, "blighted" neighborhoods in city after city were demolished for the purpose of upgrading them to accommodate high rise luxury apartments, offices, and large government buildings such as Government Center in the West End of Boston.

In the last section of his classic book *Urban Villagers* (1962), Herbert Gans described how destruction of the built environment caused by urban renewal disrupted relationships among neighbors and extended families in Boston's Italian West End. Gans introduced the important distinction, overlooked by local planners, between a slum and a low rent district. The West End definitely fell into the latter category, according to Gans, which benefited greatly the working class families residing there. Gans's work influenced a generation of urban planners to be skeptical towards the view that older neighborhoods must be demolished in order to be saved.

By the 1970s a growing body of research validated earlier criticisms of urban renewal. Most of this work was done by scholars versed in neo Marxist and political economy literature. They used case methods to develop theories of how class interests – especially those of corporate business and real estate – influence government intervention in the physical redevelopment of cities. Susan S. Fainstein and colleagues (1986) have studied dozens of American and European cities this way. Much government intervention, they argue, is geared toward large scale real estate projects such as the building of stadia and convention centers,

and the redevelopment of older warehousing and retailing districts. Prevailing forms of public support for these projects contribute little to the welfare of existing residents and businesses, even if the new development actually increases commercial activity in the city. Eminent domain authority is used to displace low income residents and small businesses from project areas, developer subsidies and tax increment financing increase the tax burden of city residents, and rezoning of neighborhoods for large scale projects can create unwanted traffic and noise, while undermining community identity.

Economic competition between cities also affects the redevelopment process. In his influential book *City Limits* (1981), Paul Peterson presented a theory of why some cities outperform others in the competition for mobile capital and skilled labor. The book became popular in the Reagan era of deep cuts in federal funding to cities and growing competition for private capital. Economic growth and urban redevelopment became the most important local policy arenas in which competition between cities was played out. Local officials must work to raise the value of taxable properties in order to finance public schools, transportation, parks, and other services. For declining municipalities, this means trapping mobile capital in place. As a city attracts investment from the outside, according to the argument, its government performs better and its quality of life rises in comparison to other places. Peterson overlooked the question of who gains and who loses in the struggle for urban growth. In his view, some urban dwellers would necessarily suffer from redevelopment along the lines pointed out by political economists. But the sacrifices of some would repay in the prosperity of the city as a whole.

Current sociological accounts of the distribution of benefits and costs of redevelopment owe much to urban regime theory, a perspective created by scholars familiar with neo Marxist, political economy, and city limits literature, but unsatisfied with their simplified views on coalition building and conflict management. Fundamental to regime theory is the concept of the city as a "growth machine" (Molotch 1976) made up of property owners, realtors, mortgage bankers, and others who profit from

the intensification of land use. Landed interests are among the most active members in the local polity, and their highest political priority is to create the right conditions for outside investment, which leads to economic growth. This may include low taxes, quality municipal services, a productive and inexpensive labor force, and minimal regulations on business. In the American political economy a division of labor exists between the state, which holds legal authority to act on behalf of all citizens, and the market, where productive assets are owned and controlled. Making and carrying out important policies related to economic growth and redevelopment thus requires the blending of resources from both sectors and the effective management of ensuing conflicts from within and without. Accordingly, the form of local government intervention in land use largely reflects who is incorporated into decision making and by what formal and informal arrangements decisions are reached.

The regime perspective reflects a more complex and changing reality of urban redevelopment than earlier approaches. It states that one cannot decide in the abstract whether or not large scale or government led urban redevelopment is a good or bad thing for the community as a whole or its individual members. Much depends on the nature of governing arrangements and the kinds of "solutions sets" that have evolved for dealing with urban distress. When arts organizations are represented in urban regimes, they shift land use strategies toward "mixed use" projects and the rehabilitation of older buildings, along the lines of Jane Jacobs's recommendations. Affordable housing advocates represented in regimes in Boston, San Francisco, and other places have created "linkage" policies, whereby downtown redevelopment projects are assessed a fee to help finance construction or rehabilitation of low and moderate income housing. Other policies and types of regime exist, to the good or ill of the cities they govern. To be sure, in local redevelopment there remains a strong "systematic bias," as regime theorist Clarence Stone (1989) calls it, towards corporate business interests. As long as productive assets, which create wealth and employment in a commercial republic, remain in private hands, government will

seek them as primary partners in urban governance.

Over the past century the physical decline of cities has corresponded more and more with patterns of socioeconomic distress. In the name of relieving distress, officials have facilitated redevelopment of the built environment. At times, government action has contributed to greater decline and distress, such as occurred with federal urban renewal. More often, redevelopment projects have mixed results. Understanding the institutions and coalition forms most conducive to more sustainable growth that meets the needs of all urban residents remains a high priority agenda for future research.

urban revolution

Kevin Fox Gotham

The urban revolution refers to the emergence of urban life and the concomitant transformation of human settlements from simple agrarian based systems to complex and hierarchical systems of manufacturing and trade. The term also refers to the present era of metropolitan or megalopolis growth, the development of exurbs, and the explosion of primate or mega cities. Archeologist V. Gordon Childe coined the term *urban revolution* to explain the series of stages in the development of cities that preceded the Industrial Revolution of the nineteenth century. For Childe, the first revolution – the “Agricultural Revolution” – occurred when hunting and gathering societies mastered the skill of food production and began to live in stable and sedentary groups. The second revolution – the “Urban Revolution” – began during the fourth and third millennia BCE in the civilizations of Mesopotamia and the Near East. The urban revolution ushered in a new era of population growth, complex urban development, and the development of such institutions as the bureaucratic state, warfare, architecture, and writing. For Henri Lefebvre (2003), the urban revolution not only signifies a long historical shift from an agricultural to an industrial to an urban world, but also refers to a shift in the internal organization of the city, from the political city of pre-medieval times to the mercantile, then industrial, city to the present phase, where the “urban” becomes a global trend. Today, many scholars use the term urban revolution to connote profound changes in the social organization of societies, but they disagree over the conceptualization, causes, and trajectory of the change.

One major point of debate focuses on issues of conceptualization and addresses questions about when, where, and why the first cities arose. In his oft-cited essay “The Urban Revolution,” Childe (1950) described the features of early

communities in Mesopotamia that marked the beginning of urban settlements. First, a key feature of the first cities was their immense population size, up to 20,000 residents, and their dense geographic concentration. A second major feature was the production of an agricultural surplus. This important development spearheaded several other changes, including the establishment of specialized groups such as craftsmen, transport workers, merchants, officials, and priests. Third, farmers and peasants gradually came under the control of the city through a system of taxation to support government activity, including standing armies. Fourth, the financing and construction of large public works, and other monuments and temples, came to "symbolize the concentration of the social surplus." Fifth, the production of agricultural surplus created problems over the allocation and control of wealth, leading to the emergence of social stratification. Priests, military leaders, and other elites formed a "ruling class" that exempted themselves from physical labor and pursued "intellectual tasks." Sixth, to control and regulate the growth of surplus, the ruling classes invented systems of recording, numerical calculation, and writing. Seventh, the first cities were the birthplaces of modern science, as the invention of writing "enabled the leisured clerks to proceed to the elaboration of exact and predictive sciences – arithmetic, geometry, and astronomy." Eighth, the specialization of labor gave "a new direction to artistic expression" by providing a cultural foundation for artists and craftspeople to cultivate sophisticated styles and traditions. Ninth, the concentration of surplus helped encourage and expand trade, a development that led to "the importation of raw material, needed for industry or cult and not available locally." Tenth, membership in the community was no longer based on kinship but on residence.

Childe's thesis was highly controversial when it was published and the causes and nature of the urban revolution remain hotly debated. On the one hand, Childe offered a powerful theory of urbanization based on the specialization of work, the differentiation of the division of labor, and the interdependence of skills and tasks. These social relations provide the basis for the development of modern industrial societies. On the other hand, scholars have argued that

Childe's thesis embraces a macro evolutionary orientation that ignores the diversity of human settlements around the world. Others have maintained that Childe's theory employs an overly deterministic view of urbanization that downplays the important role of culture in development of complex societies. One major criticism is that Childe's thesis is tautological and employs functionalistic assumptions to legitimate its arguments. It is not clear, for example, if the specialized division of labor promoted the early development of cities, or if the social complexity of cities encouraged the growth of a differentiated division of labor. It is also not clear if urbanization was the result or the cause of changes in the social relations of production and technological innovations.

These problems flow into a second point of debate, the periodization and trajectories of the urban revolution. Evidence from archeologists and sociologists suggests that urban development is discontinuous and contingent. While Childe argued that a precondition of cities is an agricultural surplus, others have suggested that human control over rivers and mastery of irrigation led to the development of cities. Other critics such as Jane Jacobs argued that early commercial centers such as those in Catal Hyuk in present day Turkey developed as centers of trade in the absence of agricultural surplus. Anthropologists have long maintained that ancient civilizations in North America developed complex and sophisticated systems of trade and commerce along the Mississippi River without knowledge of farming. One of the oldest cities, Jericho, had a thriving urban culture based on trade and crafts production over four millennia ago, many centuries before the development of agricultural surplus in the region. In short, Childe's thesis suggests an interpretation of early urbanization in Mesopotamian cities. Its generalizability to other regions and time periods remains in question. Still, Childe's ideas offer an incisive and poignant perspective which generations of scholars have utilized to understand the historical development of human societies.

Third, scholars argue that there is not one urban revolution but several. A "Second Urban Revolution," for example, began about 1750 as the Industrial Revolution generated rapid urban growth in Europe. The economy, physical form,

and culture of cities changed dramatically as feudal power broke down and trade and travel increased. Increasing size, density, and diversity of cities combined with the growth of commerce to make urban life more rational, anonymous, and depersonalized. Since about 1950, a “Third Urban Revolution” has been occurring in less developed countries, where most of the world’s largest cities are located. The increasing number of primate or mega cities of more than 8 million inhabitants illustrates profound demographic and population trends of the past century. In 1950, only two cities, London and New York, were that size. In 1975, there were 11 mega cities, including 6 in the industrialized countries. In 1995, there were 23 total, with 17 in the developing countries. In 2015, the projected number of mega cities is 36, with 30 of them in the developing world and most in Asia. In short, the urban revolution is a global trend that is taking place at different speeds on different continents. Any convincing attempt to understand and explain these important changes has to offer a coherent conceptualization of urban revolution; an account of causal logic; a clear set of propositions about historical periodization; a specification of impacts; and a sound explanation about the trajectory of the process itself.

urban–rural population movements

Michael J. White

The movement of the population between rural and urban areas is both a major consequence and a major determinant of social change. From a sociological vantage point, this movement offers potential for significant transformation in sending and receiving communities alike, as various types of individuals (differentiated by age, sex, education, ethnicity, etc.) are added and subtracted from the community. For the individual, the relocation may bring attendant challenges, even as it brings new opportunities. Within the research community, the study of urban–rural population movement would be seen as a subdivision within the broader study of internal migration, urbanization, population redistribution, or migrant adjustment.

From a simple demographic point of view, migration forms one of the basic components of population change, and along with fertility and mortality, determines the growth of populations. Historically, the redistribution of persons between urban and rural regions has been driven mostly by changes in economic opportunity, although policy interventions, shifts in region political fortunes, ethnic relations, environmental stress, and other sweeping societal changes also provoke movement. While for decades, even centuries, the preponderant direction of net population shift was from rural to urban areas, this broad characterization overlooks some important counterflows and other more short term movement that may not fit the stylized pattern. In more recent decades high income societies, already highly urbanized, have seen something closer to equilibrium in rural–urban population flows.

DEFINITION OF MOBILITY AND THE CLASSIFICATION OF TERRITORY

Under most conventional definitions, rural–urban population movement occurs when an individual changes “usual place of residence” from a location classified as rural to another

classified as urban. This definition, and all the measures that follow from it, rests crucially on aspects of space and time that determine residence, territory, and the interval over which geographical mobility takes place. In general, urban territory is relatively high in population density, often bounded within a separate administrative structure, and linked to non agricultural production.

This simple urban–rural dichotomy is still used widely in national and international statistical compendia, and also in other social science applications, yet it is problematic. The definition of urban has resisted codification. No consistent definition of urban (and hence, rural) has been adopted by national governments (NRC 2003). A survey of contemporary practice found wide variation in thresholds and the balance between administrative and more functional classifications, with less than a quarter of countries using strict population size and density criteria (NRC 2003: 132). Typically, settlements over 2,000 or 5,000 persons are classified as urban, depending also on administrative considerations. (For the recent country specific list, see UN 2004: ch. 7.)

An alternative to the simple dichotomy is to identify “urban agglomerations.” According to the recent UN compendium, the definition “usually incorporates the population in a city or town plus that in the suburban areas lying outside of but being adjacent to the city boundaries” (UN 2004: 111). The classification of territory as metropolitan helps address the shortcoming of the rural–urban dichotomy, but many classifications do not capture relocations across the wide range of scale of settlements. Many tabulations and presentations of data still abide by a simple dichotomous cutoff. In general, as urban territory is classified and reclassified, the categories of population residence and movement are also determined.

Time matters, too. The notion of a relatively permanent change in usual place of residence eliminates temporary and seasonal movement. In high income societies seasonal movement for reasons of climate and temporary job relocation are often missed in the study of population movements. In developing societies much short term movement related to seasonality of agriculture and managing economic risk is absent from official statistics. Rural–urban

population movement may be more likely to be missed in such circumstances.

CONTRIBUTION OF POPULATION MOVEMENT TO URBAN–RURAL BALANCE

Rural–urban migration contributes substantially, but not always overwhelmingly, to urban growth. The scale of the contribution of population movement to overall urban growth depends critically on the relative size (stock) of the urban and rural populations initially, and the relative rates of natural increase in the two sectors. In a typical circumstance that begins as predominantly rural, the contribution of rural–urban migration flow is likely to be quite high initially and then decline over time as the rural stock is depleted and the urban stock incremented. One careful empirical examination of urbanization in developing settings calculated that migration (and reclassification of territory) contributed about 40 percent of urban growth in recent decades in developing countries (Chen et al. 1998). Rural–urban migration generally contributes more to city growth in lower fertility settings (US, Europe, China) than in high fertility settings (Sub Saharan Africa). Many high income and industrialized societies already have a large urban population. Thus, modest increases in urban–rural migration rates or declines in rural–urban migration rates could shift the net flow in the direction of rural areas.

OVERVIEW OF RURAL–URBAN POPULATION MOVEMENT TRENDS

For much of the twentieth century, the predominant pattern of population change in industrializing societies was urbanization (i.e., an increasing share of the population classified as urban). The UN projects that the world will become majority urban by 2007 and 61 percent urban by 2030 (UN 2004), up from 29 percent urban in 1950. While much of the shift in the net balance of population is due to rural–urban migration, reclassification of territory usually works to further augment the urban population over time, as settlements pass the definitional threshold to become urban.

Counter urbanization, by contrast, is a decline in the share of population residing in cities and suburban territory. This reverse trend was noted in the US in the 1970s, and then in Europe and other industrialized societies. While it is correct to characterize the trend as a movement to lower density settlements, counter urbanization had several manifestations. Some movement was to exurban areas outside of the formal boundaries of urban agglomerations, some to more remote communities, and some was to smaller places within the urban hierarchy. In fact, from the 1970s through 1990s, several high income societies experienced competing trends of urbanization, counter urbanization, suburbanization, and continued selective rural depopulation. The US is illustrative, where the net population flow between non metropolitan to metropolitan territory fluctuated over these decades. As societies move into spatial equilibrium, and as the social distinctions between urban and rural become blurred, such fluctuations are more likely.

DETERMINANTS OF RURAL-URBAN POPULATION MOVEMENT

Economic opportunity has long been the driver of population movement. During much of the nineteenth and twentieth centuries in contemporary high income societies, migration was preponderantly from rural to urban areas, as industrialization generated labor demand in cities, and gains in agricultural productivity freed labor from the farms. The movement to the cities is still underway in a variety of middle and low income nations. China, during its late twentieth century economic transformation, provided a telling example as the fraction of the population living in urban areas increased steadily, augmented by a steady flow of both authorized and unauthorized migrants from the countryside. In high income economies as factors of production became less tied to geographic place, the pull of cities and their suburbs lessened, and so did the migratory flow to these central locations. In developed societies urban populations grew modestly in absolute terms and levels of urbanization increased by only a few percentage points during the decades of the late twentieth century (UN 2004).

At the level of the individual migrant, the economic underpinnings of relocation are borne out. Surveys asking individual migrants directly about their reasons for moving repeatedly indicate that the greater the distance, the more likely the move is linked to employment opportunity. These reasons tend to hold in both low income and high income societies, but in technologically advanced societies with dispersed employment opportunities, rural-urban and urban-rural population movement may involve a mixture of work and family reasons as life cycle changes drive both. For example, retirees often seek out lower cost housing and natural amenities, which are factors that generally favor smaller cities or rural areas.

In developing countries, the gender composition of the migration stream may vary with time, as primary migrants of one sex later reunify with family members who follow. Family and kinship related reasons (marriage markets linked to rural origin social networks, return to a natal village for childbirth) may also generate counter streams. Finally, sharp swings in economic and political stability may provide further impetus for movement between rural and urban areas.

SOCIAL CONSEQUENCES OF MIGRATION

Adaptation to the new setting of the city has long been of interest in the study of rural-urban migration. For destination cities, there is a parallel concern with the ways in which the influx changes community composition and social processes. Less attention has been paid to the adaptation of individuals and places in the urban-rural counter stream or those people and places that have been left behind by the migratory flow. A large sociological literature in the early twentieth century grappled with the consequences of the increasing scale of urban living and the social heterogeneity introduced by the influx of migrants from the countryside and, in some cases, from other nations. Ernest Burgess, Georg Simmel, Robert Park, and Louis Wirth, among others, examined these issues.

Migration generally benefits the migrant household economically. Some theories posit the development of a dual sector urban economy,

with migrants relegated to an informal sector of long term low wage employment. Nevertheless, one recent assessment concluded that even amid substantial variation in individual outcomes, rural–urban migrants attain improved earnings that compare to urban natives after a period of adjustment (NRC 2003: 353).

Urban living is associated with changes in various sorts of behavior (declining fertility, a shift in health exposure regime) and the access to new sorts of resources (schools, sanitation). The direct effects of urban living certainly exist, but were likely overstated by some early observers. Most intriguing for the sociologist is the manner in which social interactions may shift in urban areas. Various processes of diffusion of new ideas and the development of sub communities are possible when large numbers of new individuals are introduced into a dense heterogeneous environment.

Rural–urban migration also leaves people behind, and moreover, connects origin and destination communities. Social science has produced far less information about the consequences of migration for origin communities. What is known from examination of the composition of the migration streams is that origin communities tend to lose young adults, the more educated, and those with the most portable skills. Often, such departures are also differential by gender and ethnic group. There is reason to think that selective migration may have some adverse implications for those left behind, but a return flow of remittances and reduced labor market competition for remaining rural jobs may partly compensate for the outflow.

CURRENT DEVELOPMENTS

Several aspects of rural–urban population movement remain poorly understood. In some cases, this is due to the fact that this phenomenon is relatively new. In other cases, it is due to the fact that data collection or scholarly analysis is insufficient to shed light on the issue. Changes in transportation, communication, information technology, and associated economic incentives have made transnational rural–urban migration more extensive and more visible. There is international movement that is also rural–urban:

Southern European guestworkers flowing to major cities of Northern Europe; francophone African migrants to Paris; farmers in Central Mexico leaving for the Southwestern US. Circular, seasonal, and temporary migration has occupied the attention of migration scholars for some time. Such mobility is highly prevalent, and of significant economic and social impact, in some societies. Much of the time in cities is spent in economic activity with wages saved or remitted to the home family and community. At the same time, the absences – which may range from forays of several days to sojourns of several months – may bring the stress that comes with familial discontinuities.

Some new thinking on this topic considers contextual conditions. Migration offers a potential household strategy for managing risk and uncertainty, especially in agricultural regions. By sending some household members to the city, the household can spread its risks across the economic fortunes of agricultural and non agricultural sectors. Notably, such household behavior can generate seasonal and circular migratory flows. Interest in the migration development paradox stems from the observation that, contrary to expectation, migration out of impoverished rural communities is often quite low, and actually rises with community socioeconomic level. Some posit that this paradox of lower migration propensity in the face of potentially greater wage gains stems from the absolute lack of resources available to support mobility in the poor communities. This deserves greater examination, and certainly begs the question of how community context helps inaugurate, sustain, and terminate migration flows.

Some of the methodological and theoretical trends in sociology are likely to have particular benefit for the study of rural–urban population movement and other forms of population redistribution. The increasing prevalence of longitudinal data, the technological gains enabling the collection and storage of detailed geographically referenced data, and the growing attention to contextual effects all point to innovations in the future.

urban space

Adalberto Agiurre

It is not an easy task to provide a definition of urban space because such a definition must consider the social parameters of its constituent parts: urban and space. The difficulty of defining urban space is enhanced if one considers that urban space is an artifact of urbanization – a social process that describes the manner in which cities grow and societies become more complex. For example, a synergistic perspective of space situates the location of “urban” as an outcome of social and institutional forces associated with urbanization. In contrast, a

structural perspective of space identifies “urban” as the product of social structures and relationships that typify urbanization. Combining the synergistic and structural perspectives results in the identification of social features associated with urban space: (1) diversity of social roles and relationships, and (2) institutional arrangements and social networks necessary for efficient social order. No matter which perspective one adopts, one thing is clear: urban space is a dynamic aspect of urbanization. Urban space involves synergistic and structural aspects.

From a synergistic perspective, urbanization is fueled by population growth and institutional expansion. In a simplistic scenario, in order for urbanization to occur, people must come together in large enough numbers that they are situated in a space that makes them noticeably different from less populated human groupings. In addition, the social diversity of the people situated in the same space promotes a form of social interaction characterized by formal role relationships rather than intimate or informal (e.g., familial) role relationships. That is, as a population increases its numbers within the same space it becomes necessary for the maintenance of social order that diversity within the population be characterized by formal role relationships (*Gesellschaft*) rather than informal role relations (*Gemeinschaft*). One might say that a distinction emerges between highly populated space (urban) and less populated space (rural).

The aggregation of people within the same space serves as a social force that brings together persons with diverse lifestyles and work ethics. In most cases people migrated to the same space because of shared interests or shared expectations regarding lifestyles and work ethics. Interestingly, social contact between persons in the population sharing the same space enhances the social diversity of the population by increasing familiarity with different lifestyles and work ethics. In turn, the diversity of lifestyles and work ethics necessitates the development of institutional structures for their expression; for example, churches for religious expression and a labor market for demonstrating a work ethic.

At the institutional level, situating a large number of persons with a diversity of lifestyles and work ethics within the same space required the centralization of social life. The dynamic

aspect of increased social contact between persons required the development of formal relationships between persons and institutions. For persons situated within the same space to be able to express their lifestyle and work ethic in an efficient manner required the formation of institutional structures for the performance of diverse lifestyles and work ethics. In particular, centralization was necessary for the efficient operation of institutional structures focused on coordinating the delivery of services vital to the expression of lifestyles and work ethics.

For example, in order to promote the efficient expression of social life, economic organizations such as banks and labor markets developed in order to provide a network of services that utilized labor, raw materials, and capital. The network of services, in turn, centralized the production of services that met the needs of a growing population. As such, a large and growing population, coupled with an institutional structure designed to promote centralization and social efficiency, created a context for defining urban space: the situating of a large number of persons with diverse lifestyles and work ethics in space nested within an institutional structure that promotes centralization and social efficiency. From a commonsense point of view, urban space is often regarded as a rudimentary definition for the city.

Given the preceding definition of urban space one must not assume that it is a twentieth century or twenty first century phenomenon. Large urban centers or urban spaces can be identified in the history of societies in the world system. According to some estimates, the city of Babylon had almost a million residents at the height of its social development. Similarly, Rome had almost half a million residents at its peak, while London had about a million residents by the early 1800s. All three cities or urban spaces were characterized by a large population of residents and the operation of institutional structures for promoting social efficiency in a diverse population (e.g., collection of taxes, distribution of raw materials, and the production of work).

The institutional structures that centralized social life in an efficient manner resulted in an outcome that one finds today. As the number of persons sharing the same space intensified, so did the diversification of lifestyles and work

ethics. In particular, the centralization of social life resulted in the hierarchical arrangement of persons based on lifestyle and work ethic. That is, class differences became visible and served to partition urban space. The partition of urban space made it possible to observe how persons sharing the same space associated with each other along class lines.

For example, in early nineteenth century Parisian society the aristocracy and growing bourgeoisie moved to the margins of the city to escape the increasing numbers of the "popular classes" in Paris. The access to capital and valued resources enjoyed by the upper and middle classes allowed them to situate themselves on the margin of urban space. In a sense, access to capital or valued resources served as a social force to extend the boundaries of urban space into rural space. As a result, what is often referred to as a suburb – space adjacent to or on the periphery of urban space – took rudimentary expression as the ability of persons with capital to differentiate themselves by class from persons subject to the homogenizing effects of the "popular class" on persons sharing the same urban space.

One finds in American society a similar phenomenon in the twenty first century. The increasing perception that urban space is pregnant with social problems such as crime, homelessness, and poverty has resulted in persons and families fleeing to space located on the periphery or within traveling distance of urban space. During the 1970s and early 1980s in the US, moving from urban space to the suburb was often characterized as "white flight" because it was a movement that was mostly driven by white persons and families. These were white persons and families that had accumulated equity in their homes located in urban space that permitted them to sell their homes and buy new larger homes in the suburbs. (Unfortunately, most of those left behind in urban space were racial and ethnic minorities who did not own their homes, thus resulting in the racialization of the suburbs.) Ironically, in some cases the number of persons and families moving from urban space to the suburbs was so drastic that suburbs became mirror images of the urban space persons and families were fleeing. The suburbs have become so much like urban space that persons and families are moving into rural areas,

resulting in “suburbs of the suburbs,” or what population experts refer to as exurbs.

Interestingly, as persons and families moved from urban to suburban space, the uses of public space have come into question. Who is entitled to occupy public space? In urban centers, the poor and homeless have been identified as targets for city redevelopment projects. For example, redevelopment policies have been used by cities to implement “eminent domain” practices to remove older homes, often occupied by the elderly on fixed incomes, to make room for upscale townhouses or condominiums that appeal to young people and families, especially those with white collar or professional occupations. Redevelopment policies have been designed by cities that establish vagrancy zones in downtown areas that make loitering on public walkways a misdemeanor – a strategic tool for criminalizing the homeless in downtown areas. As a result, city redevelopment practices seek to remove the poor and homeless from public space not so much to “clean up” the city, but so as to create an attractive locale for bringing back the capital that left the city when persons and families moved to the suburbs.

In the suburbs the fight is over how to allocate public space to parks and recreation areas versus businesses and commercial interests. For example, many of the suburbs’ residents commute to work in urban centers. In order to develop a system of services that meet the needs of growing suburbs, city councils in the suburbs have courted businesses, especially manufacturers, to relocate to the suburbs in order to generate sales tax revenue and jobs, thus keeping residents in the suburbs and improving their quality of life by providing jobs that do not require commuting. The push for attracting businesses, however, comes at a cost to residents. Public space that has been designated for recreational use is used as a carrot by city councils to attract businesses. As a result, public space in the suburb is a contest between resource used by people versus economic benefits for businesses.

In summary, if one considers the social construction of population centers, one might say that urban space is typified by what is called a “city.” A city is a collection of people and institutional structures that promote the efficient interaction between persons and place. Urban space has often increased in population to the

point that it serves as a synergistic force for the social construction of the suburb. Ironically, suburbs have decided that the only means for their survival is to mirror urban areas – formal social relationships and complex institutional arrangements. In turn, the suburb has served as a synergistic force to create its own alter ego, the exurb. As a result, the rapid growth of suburban populations makes it difficult to exclude the suburb from consideration as urban space because it is a product and catalyst for the social construction of urban space. It is possible to consider the rise of the suburb as an extension of urban space that seeks to accommodate the expression of increasing diversity in lifestyles and work ethics. It is not clear, however, how increasing racial and ethnic diversity in the US population will shape the synergistic link between urban and suburban space. Ironically, what urban and suburban spaces have in common is the transformation of public space into contested terrain.

urban tourism

Richard Lloyd

Urban tourism refers to the consumption of city spectacles (such as architecture, monuments, and parks) and cultural amenities (such as museums, restaurants, and performances) by visitors. Studying urban tourism requires taking seriously leisure activities and transient populations, features of the city that much of past urban theory declines to address. However, a number of developments in recent decades have led tourism to assume a larger place in urban scholarship. As industrial manufacturing deserts dense urban areas, entertainment plays an expanded role in many city economies. Leisure and consumption for some means work and profits for others. The attraction and accommodation of visitors has become a central concern for public and private city elites. The sizable but fleeting population of visitors to the city has a surprising influence over local politics, investment choices, and the built environment.

The label "tourist" frequently evokes pejorative connotations, which color not only popular but also scholarly representations. While crude stereotypes of the tourist suggest a plodding brute oblivious to all but the most obvious and pre-packaged attractions of the urban landscape, the leisure activity of tourism in fact contains a wide range of consumption activities and orientations toward the city. Moreover, the "business or pleasure" distinction obscures the fact that many trips are multi purpose, with business travelers also shopping, visiting museums, and dining out. Susan Fainstein and Dennis Judd advocate the use of the term visitor rather than tourist, and see tourism as a particular mode of activity in which visitors engage. Especially today, even permanent residents may at times

use aspects of their own cities "as if tourists," consuming its spectacular, exotic, and heterogeneous amenities (Lloyd & Clark 2001).

Cities have long been privileged destinations for visitors as well as sites of residence. The ancient city was a destination for pilgrims, merchants, political envoys, and adventurers, some of whom produced accounts of the exotic spectacles they encountered. The industrial revolution led to rapid growth in the permanent populations of large European and US cities during the nineteenth and early twentieth centuries. During the industrial epoch large cities remained spaces of spectacle and a multitude of entertainments. In the prototypical industrial city of Chicago, for example, city elites were not satisfied merely being hog butcher to the world, actively seeking to enhance the city's cultural image and attract visitors by launching the Columbian exposition of 1892 (in which the Ferris Wheel was introduced).

Still, the sociological study of the city, grounded in the massive growth of urban areas coinciding with the industrial revolution, has traditionally treated tourism peripherally if at all. The last half century, however, has brought significant change. Industry has increasingly declined in the older cities of the US and other developed nations, enhanced technologies of transportation and communication have made travel far more convenient and widely available, and the aesthetic and experiential dimensions of consumption have come to play an arguably much greater role in the global economy. Fast growing cities like Las Vegas and Orlando feature economies primarily organized around tourism and consumption. For old and new cities, the active production of spectacle and consumption opportunities is now a crucial feature of the political economy. In this case, tourism can no longer be a tertiary concern for urban theory.

In the 1980s, newly popular theories of post modernism took the lead in examining the city as a site of spectacle and consumption. Focusing on the signifying qualities of the material landscape, thinkers such as Umberto Eco, Jean Baudrillard, and Mark Gottdeiner direct considerable attention to tourist destinations like the Las Vegas strip and Disneyland. The post modern tendency to emphasize the transient and the ephemeral in social life likewise results

in considerable attention to the spaces and activities of tourists. In this light it is unsurprising that Frederic Jameson identifies Los Angeles's Bonaventure Hotel as the signature space of "postmodernism in the city." While these approaches have been influential, the mostly semiotic method employed in them is dissatisfying for many sociologists.

Disneyland and Las Vegas remain potent models that inform the study of the post industrial city as an object of consumption. Many theorists advance the notion that the city itself is increasingly constructed as a theme park in order to entice consumers. These approaches, which can be called the "Disneyfication" or "theme park" models of urban tourism (Sorkin 1992; Hannigan 1998; Bryman 2004), emphasize homogenizing tendencies in large cities, as tourist spaces come to look much the same from one city to the next. They focus on the injection of large scale developments such as sports stadiums, convention halls, and shopping malls into formerly decaying areas. Baltimore's Inner Harbor and Chicago's Navy Pier are signature spaces of this style of redevelopment in the US. These spaces of consumption tend to be highly segregated from the rest of the city and the everyday activity of residents. Hence, Judd (1999) identifies the construction of "tourist bubbles," districts that organize tourist activity in a highly regimented fashion while actively excluding undesirable elements.

The success of Disneyfied tourist entertainment is more uneven than these approaches usually anticipate, and themed entertainment venues like Planet Hollywood and the Rainforest Café routinely failed during the 1990s. Critics like Michael Sorkin (1992) decry the "inauthenticity" of themed spaces; what is increasingly clear is that tourists themselves often wish to consume what they perceive to be authentic attractions within a city. Rather than the homogenization of the urban landscape that Disneyfication anticipates, these attractions derive from specific aspects of local identity. Many cities combine large scale theme developments with more "indigenous" cultural attractions. Grazian (2003) shows that tourists search for authenticity in entertainments such as the Blues in Memphis and Chicago, or country music in Nashville. Local venues strategize to satisfy these expectations, producing what

MacCannell (1999) identifies as "staged authenticity." Often, tourists practice multiple styles of consumption, in Chicago visiting obligatory attractions like Navy Pier, the Sears Tower Observation Deck, and the splendid shopping of the Miracle Mile, while also attempting to locate the "real" Chicago in smoky Blues clubs "off the beaten path."

Indeed, the attraction of cities for tourists derives from both the breadth and the depth of urban culture. Breadth signals the diversity of attractions that center city districts are uniquely poised to offer, which can include professional sports, museums of various sorts, high, low, and middlebrow theater, musical performances, and an exceptionally wide range of dining and shopping opportunities. Depth refers to the cumulative nature of a city's identity (Suttles 1984), the resonance that attaches to particular aspects of the built environment and local culture. These include landmarks like the Eiffel Tower, the Golden Gate Bridge, or the Empire State Building. Tourists may experience Yankee Stadium as pleasantly haunted by the ghosts of Ruth and Mantle and the streets of Greenwich Village by past generations of storied bohemians. Thus, while some popular tourist destinations such as Orlando and Las Vegas are constituted almost entirely by prefabricated entertainments, and revel in the absence of depth, many others are valued for a place identity that emerges from distinct and varied histories.

At a more mundane but equally important level, cities contain essential infrastructure, achieved through a balance of public and private investment, which enables them to accommodate large numbers of visitors. Such infrastructure includes airports, convention centers, and significant amounts of lodging. Conventions are major vehicles for attracting visitors, and in these cases corporate expense accounts underwrite consumption in restaurants and other entertainment venues. Just as Chicago competed to win the Columbian Exposition near the end of the nineteenth century, entering the twenty first century urban boosters are locked in competition for major conventions as well as other high profile, visitor attracting events such as the Olympics or the Super Bowl.

Local boosters argue that new tourist attractions generate multiplier effects that will improve

the tax base and benefit permanent residents. Actual results have been uneven. While the entertainment economy of large cities implies a substantial workforce, the service jobs created are often far less promising than the manufacturing jobs that they replace, representing a mostly disorganized sector of cleaning personnel, kitchen staff, ticket takers, and the like. Casino gaming, a strategy for attracting tourist dollars recently turned to by the most economically desperate urban districts, including downtown Detroit and Gary, appears to produce particularly dubious effects for the local quality of life of poor residents.

The costs and benefits of tourist enterprises promise to be important objects of both theoretical and policy analyses in coming years. In the wake of the 2001 attack on the World Trade Center, security has emerged as another key factor in the regulation of city visitors that will bear considerable scrutiny. Long ignored, the relationship between cities and their visitors has become a core concern in contemporary urban theory.

urban way of life (East Asia)

Yasushi Suzuki

Among the various definitions of the “urban way of life” in Japanese social science, Susumu Kurasawa’s (1987) definition is most widely accepted in sociology. “Way of life” here refers to a way of coping with common and collective problems in the community. A “rural way of life” is characterized by a strong capacity of residents’ households to deal with common problems and their dependence on the mutual aid systems of laypeople in coping with collective problems. In contrast, the “urban way of life” is characterized by the low ability of households to sustain themselves, and their consequential dependence on the specialized systems of experts and professional institutions.

Kurasawa examined several classic arguments in modern sociology on the issue, such as Sorokin and Zimmerman’s (1929) urban–rural dichotomy, Simmel’s (1951) analyses of urban life, Wirth’s (1938) urbanism as a way of life, as well as Tadashi Fukutake’s (1952) and Eitaro Suzuki’s (1957) definitions of rural and urban communities. Kurasawa then identified the core of the urban way of life as the specialized systems of professional institutions in urban communities. His argument focuses on occupational diversity, social differentiation, division of labor,

and nodal institutions which have been identified as the structural characteristics of urban life, and he excluded from the conception individual and psychological traits such as secondary contacts, superficial and temporary relationships, rationality, impersonality, and alienation. In sum, Kurasawa argued that specialized systems of professional institutions are distinctive traits of urban social organizations. He also proposed his own definition of the city: it is a relatively large, dense settlement of non agricultural residents in a society at a given time.

While concentrating on defining the city and the urban way of life, Kurasawa's theoretical framework remains unclear. He may have considered the "urban way of life" to be an independent variable that affects both the ecological traits of cities and the social and psychological traits. Or perhaps he considered the "urban way of life" to be an intermediate variable between the two. Either way, his focus was on the concept of the "urban way of life" itself. Treating the concepts of professional and mutual aid systems as a dichotomy, he argued that the professional systems should be complemented by mutual aid systems even in urban settings (Kurasawa 1988). In effect, this can be used as an analytical framework for describing urban problems.

In the late 1960s and 1970s, suburbanization produced many new problems in urban Japan, such as a deficiency in infrastructures. Kennichi Miyamoto, one of the leading urban economists in Japan, argued that since the "urban way of life" includes concentration of population, commodity consumption, and collective consumption (i.e., public facilities such as water supply and sewerage systems, streets, parks, and schools), contemporary urban problems were distinctively characterized by the deficiencies in the means of collective consumption (Miyamoto 1980).

Another issue associated with them is the creation of local urban communities. Citizen's movements and public policymakers addressing urban problems advocated the creation of communities in cities. Kurasawa, as we have seen, recommended that local communities should play a significant role in providing mutual aid systems within the urban way of life.

Defining the urban way of life in terms of the reliance on specialized systems of professional

institutions thus implies that most urban problems result from expert systems. They may be caused by the deficiency of collective goods provided by governments or by excessive dependency on goods and services provided by markets. Local communities may complement the specialized systems and help alleviate the associated problems. This view remains limited, however, to the consumption sphere, as does Miyamoto's "urban way of life" (and Manuel Castells's similar arguments on "collective consumption"). More recently, specialized systems have been reconsidered in relation to the problems of trust and the risks of the "abstract systems" of modern societies (Giddens 1990). The conception of the "urban way of life" in terms of specialized systems may obtain further significance if it is connected to an analysis of the broader consequences of specialization on modern mental life, as with Simmel's argument in the early twentieth century.

urbanism, subcultural theory of

Charles R. Tittle

Claude Fischer's (1975, 1995) urban theory is designed to explain how and why social relationships vary by size of population in settlements. According to the theory, urban life is bifurcated into public and private domains. In the public domain social relationships are typically superficial because people are usually interacting with others whom they do not know personally and may not see again. Such interactions are based mainly on the obvious roles people are playing at the time, such as bus rider, store clerk or customer, and pedestrian. Thus, the public domain, which varies directly with the size of the population, is characterized by anonymity, impersonality, tolerance, and lack of social bonding with others.

However, urbanites, even those in settlements with very large populations, have private lives characterized by interpersonal networks of friends, associates, and family, just as do people in smaller settlements. In addition, urbanites are more likely to be involved in other private networks with people who share interests that are somewhat uncommon and often unconventional. Through interaction concerning those peculiar interests, people within such networks develop distinct norms, a particular set of meanings and legitimations, status systems, and other social characteristics that distinguish them as *subcultures*. Thus, in their private worlds, urbanites are no less socially bonded interpersonally than people in other places and, in addition, they

are more likely to be involved in subcultural networks.

Cities promote subcultural formation because their large populations make it more likely that a number of people will share a given interest even though it may be statistically rare or unconventional. Moreover, the freedom implied by an anonymous, impersonal, tolerant public domain permits urbanites with peculiar interests to locate each other and interact sufficiently to produce subcultures. Fischer uses the term *critical mass* to refer to a situation where there are enough people with similar but unusual interests to form a subculture. The larger the city, the greater the number of critical masses and the larger the likelihood of subcultures of many types.

Because so many and so many different kinds of subcultures blossom and grow in cities, urban dwellers become more tolerant of the peculiar behaviors or interests that various subcultural affiliates embrace. In addition, subcultural affiliation provides supportive networks, distinct normative expectations, and social controls to encourage those who participate in them to embrace the behaviors around which the subcultures are oriented. Since many of those subcultures are concerned with unconventional or unacceptable things from the point of view of the wider normative context, their participants are likely to exhibit enhanced rates of deviant behavior. As a result, the larger the settlement, the higher the rates of misbehavior, including criminal behavior.

Hence, in a rather straightforward way, subcultural theory also implies a connection between changes in population and crime rates. As the size of a population increases, the critical mass for any given specialized interest also goes up, as do the critical masses for larger numbers and varieties of interests. Growing populations will therefore have enhanced chances of developing criminal subcultures as well as elevated chances of greater diversity in kinds of subcultures, especially unusual ones. Urban subcultures may facilitate innovation and diffusion of new ideas as well as promote conventionality or unacceptable behavior, so they also help distinguish cities as inspirational places for cultural change.

Fischer's theory has been especially important because it helped resolve contradictions between earlier urban theories. For example,

Wirth (1969) portrayed the city as a place of social isolation with consequent ineffective social control and high likelihood of social pathologies. Additionally, Gans (1962) had contended that urban social relationships and behavioral patterns were entirely the result of the socio demographic characteristics of their residents without urban contexts themselves having any causal effects. Fischer's account borrows from each, but it also adds a unique subcultural element.

However, because part of the theory concerns supra individual, ecological level phenomena that are hard to measure with city wide data, the complete theory has not been thoroughly tested. The evidence does seem consistent with the notion that urban dwellers maintain inter personal and familial ties while simultaneously occupying a public world of relative (though not as extreme as earlier accounts suggest) indifference, that many kinds of subcultures do thrive in cities, and that those who are affiliated with such subcultures are more likely to engage in the peculiar behaviors they promote. However, it has not yet been established that cities are the birthplaces or the most nurturing contexts for all subcultures and it is not yet clear whether modern communication systems, particularly the Internet, render cities less relevant to sub cultural formation or the behaviors presumably generated by them.

urbanism/urban culture

Joanna Hadjicostandi

"With a year old son and a husband who traveled several days a week, she knew she wanted something more than a neighborhood. She wanted a community" (Richards 2005: 64).

"Urbanism" refers to the distinctive social and cultural patterns that develop in cities. "City," "urban site," "urban society," and "urbanization" are often used to refer to the physical structures as well as the social activities in an urban society. Cities have always been key sites for transcultural connections such as local and long distance trade and the transmission of innovations. They further have been the centers where political and economic power relations are instituted and maintained. Within urban centers multiple cultures develop, interact, and create social change.

Urbanism is not a monolithic term, but one that is complex, multifaceted, and centrally placed in history.

When discussing urbanism, Deitrick and Ellis (2004: 427-8) present a long list of key patterns that dominate urban areas. The first pattern they refer to is the creation of metropolitan regions that are composed of a structured hierarchy of cities, towns, villages, and neighborhoods. They recognize patterns revitalizing city centers with interconnected streets that are friendly to pedestrians and cyclists. They further argue that there is a very careful placement of unaesthetic structures such as garages and parking spaces with a transit oriented development. Well designed buildings and gathering places along with high quality parks and conservation lands are used to define and connect neighborhoods and districts. Finally, there is respect for local history and regional character in new architectural development. This can be particularly observed in neighborhoods that retain the character of their traditional inhabitants. Thus, we have Little Italy in the North End in Boston, or Chinatown in the middle of New York City and San Francisco, Astoria in New York, Soho in London, and so on. Interestingly, the nature of those neighborhoods and how they are viewed by the population have tremendous historical and ethnic/racial significance. For instance, visiting

Chinatown or Little Italy is a night out on the town as opposed to visiting Roxbury, a low income, economically depressed, black dominated neighborhood in Boston.

Others claim that urbanism is a cluster of variables. Cowgill (2004) defines a city as a permanent settlement within the larger territory occupied by a society considered home by a significant number of residents whose activities, roles, practices, experiences, identities, and attitudes differ significantly from those of other members of the society who identify most closely with "rural" lands outside such settlements. Beyond the structure of the city, he theorized about individuals and their practices, interests, and emotions; the extent to which the first cities were deliberately created rather than merely emerging as byproducts of increasing sociopolitical complexity; the internal structure of cities and the interplay of top down planning and bottom up self organization; social, economic, and political relations between cities and their hinterlands; interactions of cities with their physical environments; and the difficult "city state" concept.

GLOBALIZATION AND URBANISM

The city is a place where people typically lead in economic and technological developments as well as artistic and intellectual experiments. Foreigners and endogenous extramodal cultural elements contribute to the creative potential of these innovations.

Migration patterns have changed dramatically in the past two to three decades due to many socioeconomic and political changes that have occurred globally. The new waves of migrants stem from many Asian and African countries, as well as from Central and Eastern Europe and South and Central America. The great numbers of migrants from such diverse backgrounds and differences in lifestyle, with heterogeneous habits, food, clothing, music, film, dance, and literature, have instigated a shift of research focus in race, class, ethnicity, age, and gender. They have also become involved in the construction of new political spaces that cross conventional boundaries between nations and ethnic groups.

RACIAL SEGREGATION AND URBANISM

Although urbanism involves different patterns of cohabitation between groups, some kind of segregation exists almost in every city.

For example, most North American cities remain deeply segregated by race, economic status, or ethnic affinity. Although overt racism has decreased over the last 30 years, racial segregation continues to be a persistent feature of North American cities. Economic segregation continues, sometimes acting as a proxy for racial segregation, strengthened by ideologies justifying "neighborhood protection." Ethnic enclaves persist as protective way stations for recent immigrants as well as distinctive and valued urban neighborhoods.

A host of other problems, such as the lack of both public services and private enterprise in inner city black, Hispanic/Latino, or Chinese neighborhoods, have persisted in part because of this segregation. The challenge today is to address the legacy of nearly a century of institutional practices that supported racial and ethnic ghettos deep in our urban demography. Specifically, the practices of mortgage lenders and property insurers may have done more to shape housing patterns than bald racism ever did (Squires 1999).

In 1989, Urban Institute researchers found that the dual housing markets are perpetuated by racial steering, insurance decisions, and other forms of disparate treatment of minorities such as concentrating public housing in central city locations and financing highways to facilitate suburban development. Dismantling cities' dual housing markets will require appropriate political strategies that address the structural causes.

GENTRIFICATION

N. Smith (2002) uses several events in New York in the late 1990s to launch two central arguments about the changing relationship between neoliberal urbanism and so called globalization. First, much as the neoliberal state becomes a consummate agent of – rather than a regulator of – the market, the new revanchist urbanism that replaces liberal urban policy in

cities of the advanced capitalist world increasingly expresses the impulses of capitalist production rather than social reproduction. As globalization bespeaks a rescaling of the global, the scale of the urban is recast. The true global cities may be the rapidly growing metropolitan economies of Asia, Latin America, and (to a lesser extent) Africa, as much as the command centers of Europe, North America, and Japan. Second, the process of gentrification, which initially emerged as a sporadic, quaint, and local anomaly in the housing markets of some command center cities, is now thoroughly generalized as an urban strategy that takes over from liberal urban policy. No longer isolated or restricted to Europe, North America, or Oceania, the impulse behind gentrification is now generalized; its incidence is global, and it is densely connected into the circuits of global capital and cultural circulation. What connects these two arguments is the shift from an urban scale defined according to the conditions of social reproduction to one in which the investment of productive capital holds definitive precedence.

URBAN CULTURES/NEW URBAN PLANNING MOVEMENT

The new urbanism, a movement in urban town planning that developed in the late 1980s and early 1990s, is built on the belief that physical environments really matter and shape people's lives in ways they might not recognize. The principle of new urbanism is to erect fabricated "small towns" with an increased density of friendly residential neighborhoods, and all the facilities within walking (or skipping) radius of their home.

The objective is to facilitate everyday social interaction through the strategic design of public and private spaces, creating the sense of real neighborhoods. Traditional neighborhoods wove people together in economic interdependence, allowing for residents as well as most professionals to be deeply involved in the local society.

The most notorious new urbanism development is the Disney owned Celebration in Florida. Unveiled in 1994, this \$2.5 billion project nestled on 4,900 acres a mere 5 miles south of

Walt Disney World is the new urbanism embodiment of Walt Disney's utopian vision of an ideal planned community.

Ladera Ranch, an Orange County, California, development, is designed to mix homes, neighborhood shops, and jobs to get away from the developing individualism (Richards 2005). Houses are set close to the street and to each other, and are equipped with front porches to encourage social interaction, while banishing garages to the back. The community also employs six salaried event planners who organize at least a dozen functions a year, from harvest festivals to holiday lighting celebrations to garage sales to movies in the park. Residents are also linked around the clock on their own intranet system, Ladera Life, where message boards, chat rooms, and activity schedules are always accessible. Such innovations attempt to make people the moving force in the life of a neighborhood. Ladera embraces its mission with such intensity that residents joke that they are living on a stationary cruise ship. There are some who think that the intensive communitarian social engineering that distinguishes Ladera or other communities like it may ultimately work against it. Nicolaides insists that too much planning can thwart natural community involvement, which has to grow organically over time to be real.

Another distinctive urban engineering project is Ave Maria, Florida. This intentional community, founded by pizza entrepreneur Tom Monaghan, is the expression of a community comprehensively embracing and enforcing the religious values of Roman Catholicism.

Another example of new urbanism is the creation of urban cultural parks, which was inspired by a Lowell park development (www.braypapers.com/new.html). There, planners found that the powerful architectural and urban artifacts of the industrial era could be used to transform a city where everything was perceived to be dull into a city where everything is interesting. New life was given to century old mill buildings and canals through adaptive uses. Urban cultural parks represent a major leap from the nineteenth century concept of the park as a retreat or escape from the city. In an urban cultural park, the entire urban landscape, with its amalgam of cultural and natural resources, becomes the "park,"

which serves as a unifying force, helping the city develop an integrated, resource based planning effort that addresses the goals of preservation, education, recreation, and economic development.

ARCHITECTURE, ART, AND SOCIAL CONDITION

KATARXIS is a website (luciensteil.tripod.com/katarxis/) dedicated exclusively to a new traditional architecture and urbanism that incorporates a reevaluation of the many world cultures in cities and includes the heritages of the West and the East. Another artistic development is the creation of murals in cities, honoring cultural backgrounds, political beliefs, anger, love, despair, or hope.

J. S. Smith (2002) analyzes the Hispanic urban experience as a window through which an intense attachment to rural places of origin can be examined. Hispanics, like Greeks, Italians, Polish, or Irish immigrants, have a deep attachment to the village of their family's roots. This is quite visible in the way they structure their lives and cultures in the new urban setting. It is not unusual to witness people sipping their coffee under a grapevine, just as they did in their Greek village, in a small street in Allston, Massachusetts. Similarly, Hispanics show their attachment to the rural village ideal in beautiful murals painted on neighborhood walls or the desire to be buried in the town of origin. Rural based, intensely local music and other kinds of public art frequently mark the territory of an urban ethnic enclave. The murals remind urban dwelling Hispanics of their cultural roots, reinforcing cultural identity and giving them feelings of comfort, security, belonging, and continuity with a long cherished historical tradition. These are physical and cultural features that are documented, but each also connotes a whole range of broader psychological and spiritual life, much as rural landscape always has.

COMMUNITY ORGANIZING

Community organizing has always been crucial in developing social movements, whether these

are in response to lack of government funding and support (Stoecker & Vakil 2000) or in objection to immigration policy proposals.

Organizing has been particularly powerful among the youth in most countries. Throughout the 1960s, most countries globally witnessed youth movements. The student uprising in Athens, Greece, is a good example of change in the country's political power. On November 14, 1973, students at the National Technical University of Athens (also known as "Athens Polytechnic" or *Polytechnion*) went on strike and started protesting against the regime of the colonels. There was no response to their demands, so the students barricaded themselves in and built a radio station that broadcast across Athens. Soon thousands of workers, citizens, and youngsters joined them, which marked the beginning of the end of the regime.

Generally in the 1960s, youth desired to crack the many codes that maintained sexual, social, racial, and political oppressions. Student revolts were connected with movements of rebellion in a number of sexual, social, racial, and political spheres. The intellectual resources came from writers and theorists such as Mao in the Cultural Revolution, Marcuse on sexuality, one dimensional man, art and socialism, and feminism. Alternative collective lifestyles were proposed, encompassing popular music forms, drug use, and living in environmentally friendly ways.

Today, two youth movements and cultures can be mentioned as examples. The first is hip hop, evolving in the US in the late 1970s and 1980s, exerting an ever stronger global influence. The code it cracked was that of complacency and passivity, which had socialized successive urban youth cultures into accepting unemployment and racial and ethnic oppression. The code it proposed in its place was a mixture of rap, music, dance, and graffiti. Oppressed ethnic/racial identities are celebrated by marginalized communities by challenging majoritarian aesthetic authority. This self assertion includes redefinition of language, and radical challenges to liberal and conservative social norms. The intellectual roots are in an indigenous people's aesthetic rebellion against Eurocentric Caribbean colonial authorities. It began with Caribbean artists such as King Stitt and Kool Herc, and developed its alternative

code through American pop artists such as Snoop Dogg and Ice Cube.

The second example is that of the development of new communities through the Internet. These communities overcome the limits of space and time upon communication. Resources develop organically on the basis of its users' interests, practices, and intentions. Users do not necessarily intend a reproduction of the norms that dominate in face to face communication. There are, however, a number of parallels, as in the email practice where messages are designed to *flame* and *insult* their recipients. This is paralleled by the face to face version of the open, raised voice argument where the intention is to provoke and bully the other party (Dobson 2002).

Cowan (2005) also presents popular music associated with urban culture, with entries on The Clash, Dancing in the Streets, and hip hop among others. The promiscuous mingling in the book of higher and lower culture, of professional jargon and street slang, is rather like real life that documents social change in the making.

urbanization

Anthony M. Orum

Urbanization refers to the process whereby ever larger numbers of people migrate to and establish residence in relatively dense areas of population. It is a phenomenon that has existed throughout the ages, from ancient times to the present. Large numbers of people have gathered and created urban sites in places like ancient Rome and Cairo as well as in ancient Peking in China. Yet, in recent times, the process of urbanization has gained increasing momentum and with it greater attention as well. Today, more than half of the world's population live in what are considered urban places, and demographers project that by the year 2050 much of the world's population will reside in them.

If urbanization were simply about large numbers of people living in dense residential settlements, it would hold little interest for sociologists. In fact, it is about considerably more. One of the questions posed about urbanization has to do with the reasons why people move into urban areas. What, in particular, draws people into urban areas and, once there, why do they remain? Even more importantly, what happens to people and to their lives as human beings once they move into the compact spaces of urban areas? These are questions that have prompted some of the most interesting and perceptive of sociological writings.

For many sociologists, life in the metropolis constitutes the essence of what societies are all about. If one can understand, for example, the nature of communities as they form in cities,

some would argue, then one can develop a good grasp of those elements that help people to bond with one another, in general. Others would point out, too, that a study of the lives of people in these dense and compact settlements provides great insight into such central sociological issues as the nature of social inequality and the roots of social conflict.

Urbanization thus is something that holds great interest for sociologists and the theories they develop about the way the world works. The first of the major sociological theorists to write about urbanization and its connections to social life was the German social theorist, Georg Simmel. He saw in the nature of urbanization and the growth of the modern metropolis elements that were characteristic not merely of cities, but of the broader development and change unfolding in the modern world. Simmel insisted that the modern city compelled people to treat one another in an indifferent and cool manner. People did not relate to one another as intimates, for example, but rather in an instrumental and calculating fashion: what can you do for me, in effect, rather than let us get to know one another better. This sense of rational calculation and its effects on the lives of people in large urban areas were pervasive throughout city life, Simmel argued, as the result of the emergence of these major centers of population: it shaped the character of society in the metropolis and it demanded that people adapt to its dictates and constraints. Life was swift in the city, relations transitory, and people were compelled to adapt to it by taking a new mental attitude.

Simmel, in effect, set the tone for much of the sociological writing about cities and urbanization over the course of the next several decades. His ideas, coupled with somewhat parallel ideas in the writings of thinkers such as Ferdinand Tönnies, became the building blocks for how others would come to think of urbanization and the metropolis. The next major perspective on urbanization and urban areas, in fact, came from a scholar who helped to create the Chicago School of sociology, Louis Wirth. Wirth, in effect, synthesized many of the key insights of Simmel in a work that would become perhaps the most famous essay about the urban condition in the twentieth century, "Urbanism as a Way of Life." Wirth insisted that the pace of life in the city forced people to deal with one

another in an impersonal fashion. People tended to become anonymous in the city; as a result, this influenced their own sense of comfort and security. The city, because of its size and the pace of its life, could become a place that helped to produce various forms of social disorganization, including divorce and crime. Urbanization also placed people into new relationships with one another, the effect being to undermine or to deemphasize the intimacy they had found in smaller places. Moreover, the city also gave birth to new and singular social developments, among them a range of new organizations, such as voluntary associations, not to say also new business groups. In effect, Wirth formalized and extended the basic insights of Simmel, creating both a sociological and a social psychological portrait of the city – a portrait that would remain in place for many decades and provide both an inspiration and a foil for subsequent sociological research.

Other writers and researchers from the Chicago School, among them Park and Burgess, helped to embellish and to flesh out this vision of what urbanization and cities were all about. The Chicago School, in effect, became that branch of sociology that would be devoted to understanding, interpreting, and even seeking remedies for the urban condition created in the modern world. The Chicago School sociologists turned to questions of immigration, for example, because of the great numbers of immigrants that began to enter cities like Chicago at the turn of the twentieth century. Park also turned to other issues, including race and race relations. Drawing on the work of plant ecologists, he developed notions about how immigrants and natives adapt to one another as they come into contact. The foremost theory of race relations during the twentieth century – the theory of assimilation – originated in the work of Park, from his own insights and views gleaned from his and his students' studies of urbanization and the city.

Eventually, the ideas and research of Park and Burgess and their students would become known as the school of human ecology. Taking their inspiration from plant ecologists, they used concepts of population, conflict, and change to talk broadly about what happens when urban areas are created, and as different social groups come into contact with one another. They

believed that urbanization necessarily implied tension and conflict, and that such conflict came about because social groups, possessed of different national origins and often different cultures, competed for scarce resources (in particular, land and space) in the city. The city itself seemed to be animated by some basic underlying forces. They argued, for example, that land values at the center of the city were the highest across the metropolis because the land there was the most prized, especially by business. These initial insights were later turned into a sophisticated and complicated theory of people and space by Hawley (1950).

For a long while, these ideas about the city – its impersonality, its conflict between different population groups, and its underlying population dynamics – remained at the forefront of sociological research into cities and urbanization. Then, in the 1970s, these ideas were challenged sharply by a new school of social theory about urban areas and urbanization, that of the neo Marxists. Central writers like Castells and Harvey argued that the conflict and change within cities – the various social changes that accompanied the process of urbanization – were the result not of some underlying features of urbanization *per se*, but rather of the growth and development of modern capitalism. It was capitalism – its inequalities and its tensions between the rich and the poor – that should be held to account for the underside of urbanization, they insisted. With such general assertions as these, then, Castells and Harvey, along with French social theorist Henri Lefebvre, introduced a fresh set of ideas into the thinking and writing about urban areas.

Today, it is the writings of this latter group of social thinkers, and others who share their basic orientation, that tend to dominate research and thinking about urbanization. Issues of poverty and inequality, in particular, seem to have emerged across the world as the world itself has become increasingly urbanized. New and compelling questions arise: How will the new comers be treated within urban areas? Are conflict and poverty forever inevitable features of urban growth? And why is poverty persistent, especially among some groups of new immigrants to the city, but not among others?

In recent years scholars have begun to rethink the way they conceive both of cities

and of the broader process of urbanization. Lefebvre urged students of urbanization to turn their attention to urban areas as spaces, and to investigate the way such spaces were created. In particular, he insisted that the broader social forces of modern capitalism have much to do with the configuration and arrangement of spaces in the city. Thus, for example, the nature of work and the way that people must travel to work helps to account not only for the development of transportation routes and modes of transportation, but also for the nature of social life and the sites of residential settlements in urban areas.

Other scholars have taken up such themes and pushed them in new directions. David Harvey, for example, is particularly intent on uncovering the ways in which inequalities emerge in the spaces of cities. His ambition, among other things, has been to show how cities are constantly made and destroyed, a process that is a result, he argues, of the broader processes of capitalism that are devoted, in essence, to the creation of profit. The spaces and sites of cities thus become the pawns for capitalist enterprises: new buildings arise and others disappear because of the constant search for profit and its rise and fall over time. Sharon Zukin has explored these themes even further, noting the ways in which certain spaces of the city have been remade once the older industrial enterprises created during the early part of the twentieth century declined. Zukin also borrows from the work of Joseph Schumpeter, noting how the "creative destruction" of urban areas – the dismantling of old houses, for example, and the creation of new mansions in their place – is emblematic of the growth of market forces in cities, but also of the decline of cities as special places for the lives of human beings.

We tend to think of urbanization and the sites it creates as "places." In recent years, more and more attention has been devoted to how people develop an attachment to the places of cities, and why such an attachment emerges as a key element in their lives. Anthropologists, historians, and philosophers have begun to create a new, broader perspective on the city that emphasizes it as a "place" – a specific site in social space where people regularly gather. The growth of this new view of urbanization and urban areas is somewhat ironic at this time, given that new

global forces are playing such a large and impressive part in driving urbanization and in reshaping urban areas.

One of the prominent themes in recent research deals with the forces that promote the growth and development of cities. When scholars such as those of the Chicago School wrote about the growth of urban areas in the past, they most often were concerned about the specific local factors that brought migrants into the city. Naturally, the most important of such factors, both to sociologists and to other scholars, were economic ones: the history of American and European cities in the nineteenth century, for example, provided ample evidence of the ways in which booming industries and new jobs, not to mention the right kind of civic leadership, provided just the right incentives for people to move into cities.

Today, however, the local has become global. Individual cities, and the attraction they hold for new migrants, must compete not only with other cities in their own immediate regions and surroundings, but also with cities worldwide. Moreover, there is a new stratification system that has emerged among cities. Sassen (2001) has argued that some cities have become global forces, their economic structures and enterprises so powerful that their decisions can actually override those of national governments. When taken to its broadest conclusion, this sense of the significance of global forces suggests that broad economic movements can have an impact on urbanization across the world: people will tend to migrate from the poorer places to the richer ones, and those movements no longer are dictated simply by local forces, or even national governments, but rather are the work of major economic firms and the movement of capital across the world.

The original sociologists of urbanization and urban areas, Simmel and Park, for example, observed the migration of people into cities and the emergence of new forms of life and activity there. Among the things they found were forms of class stratification within the city: in central areas they were the places where the dominant financial enterprises were found; nearby were warehouses where the goods of manufacturing were located; within this area and adjacent to it were the new ethnic villages that emerged, along with the growth of a

substantial working class; in the outer areas of cities would be found the wealthier residents – those people who could afford to commute into the city on a regular basis. This was essentially the pattern uncovered in America of space and the distribution of wealth. In other nations, such as France, spatial inequalities took somewhat different forms: the poorer immigrants would settle in the outskirts of cities, with the central parts of such cities still reserved for the wealthier residents. And in Latin American and African countries there was a similar pattern of class segregation that would emerge: in such instances, the relatively well off people in the cities themselves were surrounded by thousands of poor people who lived their lives in shacks and poverty.

Today, a century after many modern cities were formed, social and economic inequalities remain intact. Poor people continue to live apart from rich ones, whether they reside in the inner cities or on their outskirts. Major sociological attention has been devoted to this phenomenon – of poverty and spatial inequalities – over the course of the past two decades, driven initially by the powerful writings of William Julius Wilson on the American underclass. Cities continue to be spatially segregated, and sociologists seek to understand the nature of such segregation better. Poverty has been understood not to be a transitory state for many people, but rather it persists, especially for African Americans. As cities become the destination of ever growing numbers of immigrants, the poor among them (e.g., Mexicans in the US, Turks in Germany, Africans in the Netherlands), the story of race and inequality seems to be repeating the same tales of hardship and dislocation that happened to black Americans. Two major arguments now compete to explain this recurrent phenomenon of race and poverty: (1) that the roots of poverty are primarily economic, born of an inability of people in urban areas either to find high paying jobs or, given limited education, to qualify for them; (2) that the problem of race and poverty is even more pernicious, and that racism is a phenomenon that does not easily disappear, but rather influences the ways in which poor people are treated in many urban areas of the world.

The early sociologists of urbanization, it could be argued, seemed to think that the city

itself created a space in which new forms of social life and a new kind environment would emerge, and that these elements would reshape the character of life. What the research and findings of recent work on urbanization, poverty, and despair now show us is that there are indeed broader and more intractable forces at work in shaping urban areas – and that unless human beings work collectively to eliminate such elements as racism or the class segregation of cities, the lives of the poor and the rich will continue to exist as worlds apart. Urbanization, we now realize, is not simply a broad impersonal fact of modern life, but it is something that people and social forces create – and thus it is something that can be changed as well.

use-value

Rob Beamish

Marx begins *Capital* with an analysis of the use value of the commodity, suggesting, perhaps, that all useful concrete things have use values – but that is incorrect and the distinction, fine as it might seem, between the utility of a thing and the use value of a commodity is important. First, not every useful thing is a commodity, although every commodity, except one, is a useful thing. There are many things in the world around us – some may have no apparent use and others have known utility. As a thing – of utility or non utility – it is a concrete object with qualitatively distinct, physical properties; it is part of the natural order; it may have uses but it does not have use value. Use value inheres only in a commodity and the difference between utility and use value indicates the significant social dimension of a commodity.

The use value of a commodity appears to be the same as the utility of a non commodity thing. As use value, a commodity is also a qualitatively distinct, concrete object that can satisfy human want directly in consumption or indirectly as material in further production. Like all useful things, commodity uses are discovered in history and many have standard measures appropriate to their use – yards of linen, kilograms of steel.

Use value differentiates a commodity from things found in nature or procured or produced by private labor for personal use because the commodity is secured or produced to enter into a social relation of exchange. It enters exchange as a qualitatively distinct, concrete object – giving it physical utility or use – which simultaneously contains a quantity of socially necessary, abstract labor – giving it value (hence, use value). A use value's qualitatively concrete form determines its use and also constitutes the material embodiment of wealth that is congealed within it as a quantitatively comparable social substance – units of abstract, socially necessary labor time. A use value's form is concrete; its substance is social and abstract. The use values of commodities constitute a special branch of commercial knowledge that focuses on their concrete utility and their abstract value.

One use value is unique – it is not a thing but the capacity to do work within a social relation of exchange. The capacity to do work in general has no use value even though it has ontological significance and is important in one's private activities. However, as a qualitatively unique, concrete capacity, engaged in social labor – labor that will be congealed in a product that will enter the social relations of exchange – the capacity to labor has a concretely human form and a quantitatively comparable, abstract, social substance (the value required to restore the capacity to labor after a period of expenditure). Labor power is a unique use value because it can, under given conditions of social production, produce more abstract value than necessary to replace it. This unique use value is the source of surplus value.

utopia

David W. Lovell

Utopia is a type of imaginary ideal society. It generally takes a literary form, but it plays a role in social and political thought. From being playful, “utopian” has become a term of opprobrium, warning that a proposed scheme for improvement is not just impossible, it is perfidious. For there is a wide range of (different and often incompatible) notions of what is “ideal,” and attempting to realize one person's dream may become another's nightmare.

As with many concepts that have a long history, “utopia” has no agreed definition. Invented by Sir Thomas More for his book

Utopia, published in 1516, More's neologism was a play on the Greek words for "good place" and "no place." Thus began a tradition of writing about ideal societies, though ideal societies themselves were not new.

The diversity among what are commonly called "utopias" is vast. They include: Plato's *Republic*, a hierarchical society exemplifying justice; More's *Utopia*, an island on which communal ownership, material security, and the obligation to work were key features; Tommaso Campanella's *City of the Sun* (1602), a city built in seven concentric circles, with citizens dedicated to knowledge; Francis Bacon's *New Atlantis* (1627), a society run by scientists; utopias by Enlightenment thinkers such as the Abbé de Mably, Morelly, and Denis Diderot; socialist utopias of the early nineteenth century sketched by Charles Fourier, Étienne Cabet, and others; and (at the time) very popular utopias, based loosely on Marxism, in Edward Bellamy's *Looking Backward* (1888) and William Morris's contrasting *News from Nowhere* (1891).

Most utopias take the form of literary representations of ideal societies. Indeed, Kumar (1991b: 25) argues that what makes "utopia" distinctive is that it is a novel. In literature utopia should be distinguished from futuristic genres such as science fiction, where the technology may be extraordinary but the social relations are conventional (or even medieval). Nevertheless, as literature, utopia is unsatisfying because it abolishes the friction and opposition needed for character and plot development.

Utopia, however, is not just a type of literature, for it normally includes some plans that have been associated with social and political projects. Nor should it simply be equated with the notion of an ideal society, though it often is (Manuel & Manuel 1979). "Ideal society" is too broad, encompassing other worldly places such as "Heaven," or legends of a "Golden Age," or "Arcadia," or "Paradise." It also includes the "Land of Cockaigne" and similar dreams of extravagance and excess, and the Millennium, a vision of apocalyptic deliverance popular with some religions.

What sets "utopia" apart from other ideal societies is that in utopia human nature is not drastically altered: it is an imperfect society where social controls and discipline eliminate

disharmony (Davis 1981). Utopias accept a basic problem of social life: the scarcity that arises from our wants constantly outstripping our attempts to satisfy them. Thus, utopian institutions are designed to deal with the results of potential social conflicts that arise from this problem. "The utopian idealizes not man nor nature but organization" (Davis 1984: 9). While utopia relies on a malleable, and even perfectible, humanity (Kumar 1991a: 29), it is not a final, perfect state – an important distinction (Passmore 1970).

"Utopia" has meant different things to different people, and different things at different times. This is not so surprising, since our imagination – on which utopias must draw, at least in part – is historically conditioned. At its simplest, we might thus say that earlier utopias are technologically simple, while more recent utopias are high tech. Levitas (1990: 7) emphasizes this historical point in her argument that utopia is best considered as a "desire for a better way of living and being." Particular utopias tell us something about the conditions under which people live, because they show us what desires their historical circumstances generate but do not fulfill. Recent developments in utopian thinking, for example, have reflected changing social concerns: Callenbach's *Ecotopia* (1990) is an ecological utopia, while Piercy's *Woman on the Edge of Time* (1977) is a feminist utopia.

It is nevertheless difficult to link too closely the appearance and characteristics of particular utopias with their historical contexts, and utopias exhibit a number of recurring themes. From the time of Plato, many utopias have proposed common ownership, or stressed the evils of private property. Many rely upon benevolent despots or kings (in More's *Utopia*, the ruler Utopus laid down ideal laws 900 years previously). Some invoke rule by enlightened elites (the "guardians" in Plato's *Republic*; scientists and industrialists in Saint Simon's *New Industrial World*), and have a class system based on social function. But the most important common feature of utopias is their stress on social harmony, order, and a strong sense of community. Many of them therefore have the characteristics (both good and bad) of what Ferdinand Tönnies called *Gemeinschaft*, an organic community with face to face social relations.

What, then, have utopias looked like? Most have an elaborate system of rules, along with punishments for disobedience (Campanella's strict punishments, including community executions, are extreme, but even More was generous in this department). Most, however, devote very little attention to the community's processes of rule making in response to changing circumstances because of an implicit assumption that the social organization is static and thus that rules, once established, will not need to be changed. Politics as a dynamic process of peacefully reconciling different interests does not exist. Relations between utopia's inhabitants have not until recent times been envisaged as equal, but as conforming to a natural or functional hierarchy of roles, for the root of social disorder is never inequality as such, but rather the rejection of inequality. Some utopians have pushed their preference for order to the point of insisting on a particular architecture, as with Campanella's geometric patterns and Fourier's functional *phalanstères*. Children are sometimes reared in individual families, or more often by the community. How the citizens of utopia spend their daily lives depends largely on when the utopia was written, for many conventional matters (including gender relations and workplace issues) are unseen and unquestioned. This becomes particularly important in the wake of industrialization, when utopias can either be industrial or bucolic.

Even if utopias implicitly embody a critique of their host society by addressing unfulfilled desires, very few are written to generate movements for social change, or to inspire the creation of experimental settlements. More's *Utopia* was published in Latin, and was thus inaccessible to the vast majority of his countrymen. Linking utopias to revolutionary movements is actually a post Enlightenment phenomenon (Rose 1987: 36). Furthermore, the socialist and religious traditions – Cabet, Victor Considérant, the Fourierists and Saint Simonians, on the one hand, and the Quakers on the other – began to establish experimental communities to implement their visions. The stress on community as mutual dependence even extended, in the Saint Simonian experimental community at Ménilmontant in the 1830s, to being compelled by virtue of the design of clothes to assist one

another to dress. Many of these communities were created in the United States, perhaps because of its relative openness (Holloway 1966). One of the longest lived was the Oneida Community (1848–81) in New York State, founded on religious doctrines developed by John Noyes. But Australia too – somewhat surprisingly, given its reputation as a “social laboratory” in the late nineteenth century – spawned a well known utopian, William Lane. Lane established “New Australia” in Paraguay in 1893, a short lived attempt at a socialist colony.

Experimental utopias have consistently dashed the expectations they raised. Begun with enthusiasm and sometimes in the face of great hardship, they display that mix of virtue and vice, communal spirit and individualism, and sacrifice and selfishness that is characteristic of societies in general. Physically isolating themselves from the corrupting influence of society also meant that such communities tended to turn inwards and ultimately devour themselves. However far people travel, they cannot escape their social relations. As for social cement, experimental utopias have been united (at least for a time) by allegiance to a charismatic leader, or by a sense of mission, whether social or religious. In literary utopias, there is a sense that fellow feeling will be the mainspring of community, and that the inhabitants will recognize the justice of its arrangements, however they are described.

Is Marx's vision a utopia? Given his emphatic critique of the “utopian socialists” in the *Communist Manifesto*, and Engels's determined contrast between socialism, utopian and scientific, it is often (understandably) assumed that Marxism is not utopian. Marx was, first of all, an analyst and critic of capitalism. But the contrast that he and Engels sought to draw between themselves and their socialist competitors was chiefly a difference over means, not ends. The Saint Simonians, Fourier, Cabet, and others of their ilk were indeed naïve about class struggle and industrial development, about the power of the state, about the chances for successful utopian settlements, and about the power of moral example for social change. Yet their goals were very similar to those of Marx: social harmony and material security.

Marx's critique of alienation and his expectation of its transcendence is central to understanding his utopia, even if the concept "alienation" was overshadowed in his later work by the language and methods of political economy. Like other utopias, the triumph over alienation means the end of politics: the rule over men, according to Marx, will be replaced by the administration of things. But Marx understood the limitations of literary representations of ideal societies, so he refused to write "recipes for cookshops of the future" and left his vision open ended. Beilharz (1992) has argued that socialists, in response to Marx's diverse assumptions about the future (whether human fulfillment will be found in labor, or in leisure, in harmony with nature or in subduing nature), have constructed a range of competing visions with quite different political consequences.

It is not surprising that some have questioned the possibility of a utopian reign of harmony, community, and security. With the attempt to implement a communist utopia in Russia after 1917, which imposed murderous uniformity on the masses and privileged the new rulers, "utopia" became sullied by association. It was dogged by "dystopias," literary attempts to describe the malign effects on human beings (particularly individuals) of the imposition of the ideal rules of some utopias, drawing strongly on the contrast between rulers and ruled. This tradition began with Yevgeny Zamyatin's *We* (1920), and went on with Aldous Huxley's *Brave New World* (1932), but achieved its greatest influence with George Orwell's *Nineteen Eighty Four* (1949).

One of utopia's functions is social criticism. But the line between utopia and other kinds of social theory is not clear cut. It has been described as a "mobilizing myth" to change society by Karl Mannheim (1936), though Mannheim distinguishes it from "wishful thinking," by which he meant most of what are usually called utopias. Bauman (1976) champions socialism as an "active utopia" because it challenges people to bring about a better world. Geras (1999: 43) has promoted the virtues of a "maximum utopia," insofar as it encourages people to reflect on social life. Utopias mix critique, projections, hopes, and desires in a variety of ways, not all of them considered positive. Indeed, opinion is split over whether utopia

is valuable or dangerous. Oscar Wilde said that "a map of the world which does not include Utopia is not worth even glancing at, for it leaves out the one country at which Humanity is always landing," yet respected thinkers have condemned "utopia" as the source of totalitarianism in the modern world (Kateb 1963).

Utopias nowadays are not written with much confidence, yet they remain an important way of reflecting on society. We should not disparage utopian thinking as mere escapism, nor lightly dismiss utopias. They help us to think beyond the everyday, the mundane, and the routine, and encourage us to question what is possible in human affairs. For we are inclined to confuse the possible with the familiar. For all its value, however, there seems to be a limit to how much utopian thinking is able to contribute to illuminating the complexity of social existence. The fundamental issues – whether they concern how to reconcile the individual and the community, who is to rule, how to prevent bad rulers from doing harm, or how to distribute scarce goods justly – are caricatured by those who envisage simple formulae, fixed rules, or an ultimate value. As a novel, utopia can have thought provoking effects; as a program for social renovation, it is insufficient.

V

validity, qualitative

Patti Lather

Validity is not just one of many issues in science but the crux of the issue: the claims of science to a certain privilege in terms of authoritative knowledge. How scientific knowledge is made credible is, hence, a longstanding issue. If one looks at validity as a social construction, one sees how the very calculus of credibility of what is deemed “good science,” the very determination of warrants of validity, has shifted across time, place, and various fields.

In the contemporary moment, the crisis of legitimation occurring across knowledge systems is registered in a cacophony of postpositivism, non foundationalism, kinds of realism and post realism, warranted assertability, logics of inquiry, construct validity, carefully controlled inference, objectivism, situational validity, and Cronbachian insights regarding the decay of generalizations. As a result, discourse practices of validity in qualitative research exemplify a proliferation of available framings in terms of the legitimation of knowledge, particularly the power and political dimensions of the issue of demarcation.

Various turns have characterized research in the human sciences over the last few decades, shifts that are not so much linear as multiple, simultaneous, and interruptive. It is as if the critiques of truth in Nietzsche, self presence in Freud, referential language in Saussure, and metaphysics in Heidegger were finally coming home to roost in the social sciences. Across this dizzying array of in movement shifts, these turns challenge the “view from nowhere” and the traditional foundations of knowledge that continue to undergird so much of contemporary research. The following outlines twentieth century turns

toward epistemological indeterminacy in order to underscore contemporary interest in situatedness, perspective, relationality, narrative, poesis, and blurred genres. It then surveys across the field of social inquiry in terms of the variety of available discourses of validity in order to delineate the weakening of any “one best way approach” to validity.

EPISTEMIC INDETERMINACY AND THE WEAKENING OF HOMOGENEOUS STANDARDS

In exploring the work of science in an era of blurred genres, validity is a “limit question” of research, one that repeatedly resurfaces, one that can be neither avoided nor resolved. Within a context of epistemic anti foundationalism, validity is about much more than the limits of objectivity: “It bores into the essence of science itself” (Kerlinger 1986: 432). What follows argues in a Foucauldian manner that validity be situated as practices toward spaces of constructed visibility and incitements to see which constitute power/knowledge. This post epistemic focus decenters validity as about epistemological guarantees and shifts it into practices that are situated, multiple, partial, endlessly deferred, a reflexive validity interested in how discourse does its work.

From a post epistemic focus, validity is a boundary line for what is acceptable and not acceptable in research. Validity is, in short, power, the power to determine the demarcation between science and not science. Such a post epistemic focus shifts the validity question in some interesting directions. Some argue for dismissing validity altogether as too much about the continuation of positivist ideals. Others worry that qualitative work that fails to provide systematic depth analysis and analytic rigor

threatens the fragile legitimacy that qualitative research has established and holds it to a scientific accounting. This is made most obvious in recent moves by the federal government to warrant experimental design as the “gold standard” for good science.

In contrast, Pam Moss, writing out of psycho-metrics and assessment, argues that all social science research is under theoretic pressure in terms of foundational assumptions. Moss (1996) argues for a reflexive complementarity between varied approaches to the social sciences in order to think reflexivity about our taken for granted practices and perspectives. Moss sees a reciprocity of accountability in this purposeful engagement across paradigmatic assumptions and her expansion of validity echoes Mishler’s (1990) argument that the “problem” of validity is about deep theoretical issues that technical solutions cannot begin to address. Ever since Cronbach and Meehl’s (1955) essay on the problems with construct validity in psychological testing, validity has been the problem, not the solution. Various post positivist efforts have been made to resolve the problem, from the naturalistic and constructivist paradigms of Lincoln and Guba that dominated the early discourse of qualitative research to discourse theory, ethnographic authority, critical, feminist, and race based paradigms and more recent poststructuralisms. Some efforts toward validity in qualitative research remain deeply inscribed in a correspondence model of truth and assumptions of transparent narration, while others attempt validity practices that take into account the crisis of representation. And some call for new imaginaries altogether, where validity is as much about the play of difference as the repetition of sameness. Rather than exhausting the problem, all exemplify how the effort to answer the problem of validity is always partial, situated, temporary.

The following traces these provisional “solutions” as an effort to displace normative criteria of quality. Normative criteria posit themselves as universal and attempt to regulate “best way” procedures, whereas socially grounded criteria are situated, relational, temporal/historical. Unlike standardized regulatory criteria, such criteria move away from compelling conviction to some essence and toward contextually relevant practices that both disrupt referential logic and shift orientation from the object to the

relations of its perception, to its situation of address and reception.

COUNTERPRACTICES OF AUTHORITY: FROM QUALITY CRITERIA TO SOCIAL PRACTICES

Just a decade ago, Lincoln and Guba’s delineation of validity served as a sort of mantra across qualitative work in the social sciences. This evidences the importance of a validity discourse appropriate to qualitative research, but most interesting is how Guba and Lincoln’s early delineation worked in unanticipated ways to undercut representational logic and spawn increasingly post epistemic practices of validity. This section traces the movement of their thinking across a decade of validity formulations. To set the stage for this, the first layer in the story of validity in qualitative research is the standard story from the side of positivism.

Whereas the criteria for the credibility of quantitative research are based on the validity and reliability of instruments and internal validity, in qualitative research the primary criterion is the credibility of the study. Credibility is defined as the extent to which the data, data analysis, and conclusions are believable and trustworthy as based on a set of standard practices. Markers of credibility include triangulation, the use of different methods, samples of people and/or times and places. Reliability is the fit between what occurs and what is recorded, and is established by: detailed fieldnotes, a team approach, participant confirmation of accuracy of observations, mechanized recording of data (tape recorders, videotapes, photographs), use of participant quotations, and an active search for discrepant data. Internal validity refers to the match between researchers’ categories and interpretations and what is actually true. It is claimed via prolonged engagement, thick description, thorough delineation of research process, and unobtrusive entry and participation in the setting. Finally, external validity shifts from generalizability based on sampling to reader assessment of transferability.

While this treatment of generalization evidences some attention to post positivist assumptions, the preceding is grounded in the sort of scientificity that is at issue here. Guba and

Lincoln (1989), for example, argue that internal validity, as an assessment of the degree of isomorphism between a study's findings and the real world, cannot have meaning as a criterion in a paradigm that rejects a realist ontology. Additionally, external validity or generalizability has little meaning if realities are multiple and constructed. Erickson's (1986) idea of "particularizability" seems more useful: documenting particular cases with "thick" description, so that the reader can determine the degree of "transferability." Most interesting in this standard treatment of validity in qualitative research is the rather unremarked work of the concept of "transferability." Displacing a validity of correspondence with a focus on the terms of address, of reception, shifts orientation to the reader who determines the degree to which a study is "transferable" to his or her own context of interest.

The next layer in the story of validity is a standard treatment of validity from the side of post positivism.

Michael Patton's *Qualitative Evaluation and Research Methods* (1990 [1980]) was one of the most widely used texts prior to the bestselling *Handbook of Qualitative Research* (Denzin & Lincoln 2000 [1994]). Patton elaborates on methodical reporting of systematic procedures of data collection and analysis. Particularly concerned about researcher effects, he cautions against the sort of self importance that often leads to overrating this problem. The key is that reducing distortions is based on "empathic neutrality," a kind of impartiality that works to minimize researcher effect while recognizing that "the data inevitably represent perspective rather than absolute truth" (p. 475). In delineating legitimating practices, Patton surveys across the most frequently noted figures: Lincoln and Guba and Miles and Huberman on specific validity practices; LeCompte and Goetz and Kirk and Miller on reliability and validity; Michael Scriven on rethinking objectivity; Denzin on triangulation; Peshkin on subjectivity as a resource; and Cronbach on generalizability. The basic assumptions of this canonical discourse on validity in qualitative research can be traced by unpacking the work of, arguably, the central figures in the validity debates in qualitative research, Guba and Lincoln.

In the summary chart in *Naturalistic Inquiry* (1985), Lincoln and Guba summarize the techniques for establishing trustworthiness as (1) credibility (prolonged engagement and persistent observation; triangulation of sources, methods, and investigators; peer debriefing; negative case analysis; referential adequacy; and member checks); (2) transferability via thick description; (3) dependability and confirmability via an audit trail; and (4) the reflexive journal (p. 328). Each practice is more or less developed, with the member check positioned as the most crucial technique. This involves taking back to the participants what you have learned from them and can range from a minimalist "transcript check" to a more involved reaction to a preliminary analysis to a maximal feedback loop in regards to the final write up. All are offered in the hopes of working against prescription and orthodoxy.

By 1989, Guba and Lincoln had moved to a delineation of three different approaches: parallel or quasi foundational criteria, now called trustworthy criteria; the nature of the hermeneutic process itself; and a new set of non foundational criteria, termed the authenticity criteria. The parallel criteria map onto the 1985 formulation, but they are more clearly located in a post realist ontology, for example, triangulation is deemphasized as "too positivist" in its assumptions of "unchanging phenomena" (p. 240). "The hermeneutic process as its own quality control" argues the difficulty of falsity because of the interactive, dialogic nature of the research process. The most noteworthy feature of the authenticity criteria is the break with more traditional methodological criteria into criteria that blur the line between ethics and validity. Termed *fairness* and *ontological, educative, catalytic*, and *tactical authenticity*, the criteria are about balancing viewpoints, encouraging the learning of both researcher and researched, sharing knowledge democratically, and fostering social action. The emphasis here is the move of validity from a set of epistemic concepts to a space of relational practices in situated contexts of inquiry.

By 1995, Lincoln shifted fully into an anti foundational discourse interested in research as relational and fostering of action and social justice. Quality criteria are posited as fluid and emergent, with a focus on criteria that collapse the distinction between rigor and ethics.

Tracing both the history and the rationale for the continued importance of rigor criteria, Lincoln notes her continued use of the parallel foundationalist criteria with her doctoral students as a place to begin. She then delineates emerging criteria that, while all relational, are differently aware of the exclusionary function of quality criteria and the inevitability of partial and incomplete standpoints. Regarding the latter, “detachment and author objectivity” become “barriers to quality, not insurance of having achieved it,” as she urges researchers to “come clean” about their own stances (p. 280). Epistemology is situated as an ethical issue, and objectivism is displaced by linking research as a community project to social action. Key practices are delineated: the use of multiple voices, reflexivity regarding the relationships and contradictions of research processes, reciprocity, sacredness, and sharing royalties as a way to address the cultural and economic capital that academics make out of the lives of others. This includes movement toward action inquiry. The interest here is the move beyond the search for uniform criteria toward criteria that emerge as a natural consequence of the inquiry effort. This is a call for a profusion of situated validities, immanent validities, within the context of a particular inquiry.

Seeing validity as an apparatus of betterment, as a cure for what ails us, Lincoln’s panegyric contrasts starkly with Scheurich (1996) who, rather than pay tribute, deconstructs “the masks of validity.” Across both positivism and post positivism, Scheurich organizes discourses of validity into three categories. The first, *originary validity*, translates conventional science concerns into post positivism, for example Lincoln and Guba’s parallel criteria. *Successor validity* recasts the concepts that arose in opposition to conventional notions of science, for example the concept of catalytic validity that grows out of advocacy research or “research as praxis” (Lather 1986a, b). Finally, *interrogated validity* deconstructs the policing function of validity, for example Cherryholmes’s argument that construct validity is “of and about power” (1988: 450). Scheurich argues that to the extent discourse practices of validity are about policing the borders between “the accepted from the not true or the unaccepted or the not yet accepted” (1996: 5), they are

“imperial” in allowing the same and disallowing the different. At the heart of the western knowledge project, Scheurich writes, is this “Same/Other power binary” (p. 6) that is more about “Eating the Other” (quoting bell hooks) than it is about increasing knowledge. “Validity practices are unconscious instantiations of a western philosophical . . . dualism” (p. 8) that is not about individual conscious intentions but about the western “civilizational project, an imperial project” (p. 7). To undermine this dualism, he urges new imaginaries of validity that both unmask dualisms and celebrate polyphony and difference, the shifting complexities of truth as multiply perspectival.

As a possibility, Scheurich unpacks Lather’s (1993) delineation of transgressive validities – ironic, paralogical, rhizomatic, and situated/embodied/voluptuous. All unsettle truth regimes, implode controlling codes, and work against the constraints of authority. All foreground the insufficiencies of language and the production of meaning effects, foster differences and heterogeneity, put conventional discursive procedures under erasure, and embody a situated, partial, positioned, explicit tentativeness. All anticipate a politics that desires both justice and the unknown, generate new locally determined norms of understanding, and proliferate open ended and context sensitive criteria that enact practices of engagement and self reflexivity. All bring ethics and epistemology together. Intended to “incite” the proliferation of validity discourse practices, this effort leaves Scheurich unsatisfied, however, still worried about the capacity of “our restless civilizational immodesty” to reappear with new masks in its continuing absorption of the other into the same (1996: 10). Turning to the accelerating proliferation of marginalized voices, he calls for “a Bakhtinian dialogic carnival, a loud clamor of a polyphonic, open, tumultuous, subversive conversation on validity” (p. 10). Here validity has moved from a discourse about *quality* as normative to a discourse of *relational practices* that evokes an epistemic disruption, a transgression of set forms.

This exemplifies how validity is being used to further change the terms of the legitimation of knowledge beyond discrete methods and toward the social uses of the knowledge we

construct. Across shifts in episteme and the consequent weakening of homogeneous standards and the proliferation of counterpractices of authority in qualitative research, the intelligibility and availability of alternative discourse practices of validity work to loosen positivism and suggest the critical potential of validity to put under theoretic pressure the claims of scientificity.

validity, quantitative

Karen Lahm

The term validity can be defined and explained in a plethora of ways. In quantitative research, validity is most commonly discussed when a researcher is developing measures of variables or concepts to put on a survey or use in an experiment, etc. Specifically, validity is synonymous with accuracy in that a valid measure is one that is actually or in reality measuring the concept or variable that it is supposed to be measuring. For example, say a researcher needed to develop a measure for the variable IQ (Intelligence Quotient). So the researcher decides that he is going to ask his sample to get on a scale and weigh themselves in pounds. Such a measure of IQ (body weight in pounds) would be an invalid measure of one's intelligence because in reality body weight tells us nothing about one's IQ. A more valid measure of one's intelligence would be to give an IQ test and compute IQs from the answers gathered on the test.

In order to ensure validity, researchers strive to meet several criteria when they create their measures of concepts and/or variables. First, they try to ensure that their measure has face validity. Face validity provides a check to see if "on its face" or literally it is a measure appropriate for a concept. The example above lacks face validity because in reality body weight does not tell us anything about how intelligent one is. A second criterion for assessing measures is content validity. This suggests that a measure must cover a range of meanings for a given concept or variable. For example, if a researcher wanted to measure someone's criminality, he would not just ask them about how many times

they shoplifted. He would have to ask them about all types of criminal behavior (i.e., from shoplifting to violent crime) in order to cover the entire range of the variable. Third is criterion related or predictive validity. Predictive validity assesses whether or not a measure can adequately predict the future behavior or outcome that it is supposed to. For example, many researchers believe that SAT/ACT scores are good measures of college success because they have a high degree of predictive validity. SAT/ACT tests are standardized college entrance exams taken by high school students in America. The purpose of these exams is to test whether or not a high school student has learned what they needed to be successful in college. Thus, the higher one's score on these exams the more likely it is one will be successful in college (at least, that is what the testing services say). Predictive validity can be established through regression analysis. One can use the value and sign of a correlation coefficient (Pearson's r) as an indicator of predictive validity of the independent variable upon the dependent variable.

The fourth criterion for creating valid measures is construct validity. Construct validity ensures that one's measure "fits" within the theoretical system examined in the research. For example, in the field of criminology, social disorganization theory suggests that neighborhoods or cities with high levels of disorganization (i.e., poverty, ethnic heterogeneity, high population turnover) have less social control and thus more crime. Let us say a researcher came up with some measures of these concepts and went out and gathered some data on them. This researcher, through his data analysis, found that in his sample of cities higher levels of social disorganization led to more social control and less crime. These findings are opposite to what research in this area typically indicates, so he should go back and check the validity of his measures of variables because his finding does not jibe with what the theory suggests. It is important to note that some measures meet all of these criteria for validity, while some measures do not. Also, one measure is not universally valid in all times and places.

Once valid measures are created it is also important for a researcher to ensure both internal and external validity. Both internal and external validity most often come into question

within the field of experimental research; however, their importance encompasses all scientific endeavors. In most scientific research the goal is to establish causal connections between concepts or variables. One step in establishing cause is to ensure internal validity. Internal validity refers to the degree to which the researcher eliminates or controls for confounding variables in the study. For example, let us say a researcher wanted to establish that attending a study session will increase test score. In this example, there are many confounding variables that could be influencing test scores besides attendance at a review session. For instance, maybe the students studied more outside of the review session, maybe they got lots of sleep the night before the exam, maybe they ate healthier in the weeks leading up to the exam and were more alert.

To ensure more internal validity, the researcher could do several things, like add a control group or a group of students who did not have the exam and see how their scores compared to the experimental group who received the study session. The researcher could also have given a pre test to examine scores both before and after the study session. The researcher would also want to make sure students were randomly assigned to both the experimental and control groups, so that it was not only the smart students that attended the review session. Moreover, the researcher would also want to make sure that the control group and experimental group do not have contact with one another. He would want to make sure no one drops out of the study. He would also want to make sure the pre test and post test are the same instruments and that there are no other review sessions or outside study groups being offered to either set of participants.

Also important is external validity. It refers to the degree to which the results of an experiment can be generalized to the rest of the population. Think of this as the universality of your findings. Can your findings apply to other people at other places at other times? Some ways to ensure external validity is to randomly select experimental and control groups from the general population. Also, one should replicate their study in a variety of settings, times, etc. These techniques may help to ensure the generalizability of one's findings to the larger population.

value

Rob Beamish

Value and theories of value might begin in economics but they have significant sociological importance. As with economics, two divergent conceptions of value dominate sociological thought: an objective, intrinsic, production centered theory versus a subjective, consumption focused conception of value – best represented in Marx and Simmel's works, respectively. Marx's systematic presentation of value's form and substance in *Capital* critically extended Adam Smith, David Ricardo, and other political economists' labor theory of value, while Simmel developed the sociological importance of subjective conceptions of value that began with political economist Jacques Turgot and William Jevons and the Austrian School developed with theories of marginal utility, value, and price.

Theories of value extend back at least to Aristotle and the social production of value and its social significance reach back to points in history when humankind lived in primitive communal groupings and the unit of production and consumption coincided. Group members worked collectively to meet their material needs and wants. Labor was communal and the communal product was shared. Products of labor were considered only for their concrete

utility, with no conception of value (abstract or concrete; subjective or objective).

Production above the material wants of the group and periodic interchange created the conditions for intermittent and then ongoing exchange between groups or communities and later within them. Surplus production allowed the social relations of primitive commodity exchange to emerge and a social division of labor between and within groups developed. As production was directed to both communal wants and social exchange, production changed from concrete, primitive communal to communal social and a separation of abstract and concrete labor within the commodity arose.

The form of communal life remained a kin, tribal, or communal group or village, but the substance of the social relations among members within production became increasingly mediated as exchange was introduced and expanded. Exchange created a social relation between the qualitatively unique concrete labors of commodities requiring their comparison as abstract, quantitatively comparable labors. Exchange also introduced mediate social relations between production and consumption. Exchange created the value form and labor created its substance. The form and substance of value permitted class division to develop and the accumulation of abstract wealth – value.

In his critique of classical political economy, Marx used Hegel's dialectic of quantity and quality, general and specific, form and content, and form and substance to analytically synthetically, rather than historically, present an objectively based labor theory of value that would expose the underlying dynamic of exploitation within capitalist production and serve as the departure point for a synthetically based comprehension of capitalism's totality. Marx argued that beneath a commodity's qualitative, concrete appearance there are abstract, quantitatively comparable units of socially useful, socially necessary, simple, abstract labor. This objective substance of value pertains to all commodities, including the "capacity for work" or the labor power workers sell to capital in the labor market. In return for the full and fair exchange of the value of their labor power, workers contract themselves to work a specific period of time at certain levels of productivity, under particular conditions. Due to labor power's unique nature, in

the course of a workday it can produce commodities with a total value that is greater than the value substance of labor power itself – creating a surplus of value (or surplus value). The key contradiction in capitalist production is that workers, receiving full value for their ability to do work, can still generate a surplus which maintains and builds the social relations of production that confront them, appropriate the social surplus, and exploit them. As Hegel began the *Phenomenology* with the single, simple category of sense certainty, and its immediate contradictions, to build an increasingly complex conception of human reason's totality, Marx established the objective substance of value as his departure point for an increasingly synthetic analysis of the contradictions of capitalist production, circulation, and then the system as a whole.

While value was not as central to Simmel's sociology as it was to Marx's critique of political economy, Simmel's discussions of value stem directly from his sociological perspective, illustrate his approach to understanding social phenomena, and represent a key "culturalist" critique of historical materialism. Simmel's conception of value stemmed from his interest in money as one of many potential, heuristic concepts that sociologists could use to formulate understandings of social relationships. Simmel explored the ways in which money – one of the more important and highly complex cultural forms of social interaction – was a form in and through which particular types of social interaction occurred and how that interaction held broader social and historical implications.

Individual subjects, Simmel argued, assess and attach value or values to objects to overcome the physical distance and separation between them and the objects of their interest. In exchange processes, people assess their own relationship to an object as well as others' expectations to arrive at a particular, subjectively established value of the object – expressed or made concrete in the money form. Value, through the money form, is objectified; value becomes a "cultural objectivation." Unlike Marx, any labor substance to value is inconsequential. Value is a cultural product; it is produced through subjective understanding and assessment and, most significantly, stems from and further develops a particular worldview.

The calculation of value creates and reinforces a cultural form that seeks uniformity within diversity, rationality from within affective attachment, and individuation through interaction. Value, and its expression in money, establishes an economic rationality that progressively expands into a broader, more encompassing instrumental rationality. Like Weber, Simmel saw, through value and money, the increasing domination of a rational, instrumental approach to social relationships.

Despite their differences over value, Marx and Simmel's analyses led to similar concern with alienation in commodity based societies. Similarly, value served as a key departure point for more complex, comprehensive social analyses.

values

Giuseppe Giordan

Values represent beliefs and ideals which form the basis for choices and preferences, both at an individual and collective level. Generally speaking, a value is defined as that which is "good" and which is desired and is able to make one happy. Such long lasting and immaterial ideas regard both current conduct and one's ultimate objective in life: they are different from simple interests, which are not particularly characterized by duration, and also from moral laws,

which indicate what is the “right thing to do.” Values propose a certain lifestyle and “how to be” rather than purely concrete rules of behavior.

The utilization of the concept in sociology has been the object of lively debate owing to the difficulty of clearly defining what is meant by values. Sociologists often stress how difficult it is to provide a definition that is usable in empirical research and they underline the relativity and subjectivity of the definition itself. However, all researchers highlight the connection between values, social structure, and actual behaviour of social subjects. Hechter et al. (1993) identify some difficulties in the study of values: (1) they are not visible; (2) there are no theories capable of satisfactorily explaining the connection between values and behaviors both at individual and collective levels (and besides we lack theories explaining how values are formed); (3) they are not easily measurable.

Values are not to be confused with attitudes, norms, and needs or with the peculiarities of personal traits (Hitlin Piliavin 2004). Values are centered on ideals; hence, they have an abstract role in building self identity, while attitudes directly refer to the actual behavior of individuals. Compared to norms, then, values are perceived by individuals not as imposed from outside, but rather as outcomes of free personal choice. In addition, while needs refer to the biological sphere, values highlight the various cultural responses that can be given to such needs. The need for food or sex meets different responses according to the values of the different cultures where such needs are felt. Values also differ from traits because traits refer to the actual fixed aspects of personality, while values are abstract judgment criteria constantly inclined towards self transcendentalism.

Empirical research on values emphasizes how their origin can be traced to a heterogeneous multiplicity of factors such as biology (genus, race, ethnicity) and the various characteristics of the social structure to which the individual belongs (e.g., literacy level, occupation, professed religion, social class, family). The concept of values is found in various cognitive spheres and there is a multiplicity of definitions which vary according to the point of reference, be it economics, philosophy, psychology, or sociology, all of which offer significant contributions

to a more complete understanding of the concept.

ECONOMICS AND PHILOSOPHY

In the field of economics a value may be defined as that which defines two interconnected but different prospects: on the one hand, the characteristic of a good is that it may be exchanged for other goods (“exchange value”); on the other hand, all the characteristics which enable any given good to satisfy the multiple needs of humankind are defined as “use value.” The definition of the concept of value from an economic perspective is extremely important, as it has significant consequences in the sociocultural and psychological spheres: values also are conditioned by subjective, not objective evaluation and are identifiable and comprehensible in relation to a specific historical period and particular circumstances and therefore do not have an absolute or eternal character.

This dialectical relationship between the absoluteness of values and the relativism of historical perspective constitutes the heart of the philosophical debate that directly connects concepts of value to that which is good: this provides the reference for the objectives of life and the moral dimension of life. In classical philosophy (particularly Stoicism) the concept of values is explained in a subjective sense and defines the object of ethically good choices. Nietzsche, however, dramatically changed such philosophical reflection in both social and cultural terms at the end of the nineteenth century. His explicit proposal was to radically overthrow the order of traditional values which were based on metaphysics, logic, morals, and religion: all these values were identified principally by the Christian tradition, based on renouncement and asceticism. Nietzsche opposed to them the “vital values” centered on the free expression of the will of man.

From a phenomenological perspective, Max Scheler underlined the “objective” character of values and highlighted absoluteness and eternity: these may be grasped not only via the intellect but also intuitively via the emotional experience of the conscience. Scheler suggested a hierarchy of values, among which are values of the senses (pleasure is contrasted

with displeasure), vital values, spiritual values (legal, aesthetic, cognitive) and finally the supreme value of holiness. For Scheler, the ultimate foundation of values is the discovery of the unitary principle of love. Nicolai Hartmann also underlined the original emotional characteristic of values and interpreted this concept in a rigorously realistic manner: the perception of values may vary and may be completely absent, but values exist independently of subjective conscience.

It is easy to see how the foregoing influences the perception and the role that values play in the construction of identity: this process develops as a result of the need for certainty provided by secure and reliable points of reference and also as a result of the relativity of different situations and different historical periods.

VALUES AND IDENTITY

Values are found at the crossroads between different fields of cognizance, particularly evident when one takes into consideration their roles in the construction of identity, both at a personal and at a collective level. The theme of values is significant for in depth study of the complex relationship between the individual and the society and culture to which they belong, thus highlighting a nexus of interrelationships (the contribution of psychology, anthropology, and sociology are of particular importance). In addition to needs and attitudes, values constitute fundamental psychic contents: while needs "push" us into action, values "attract" our project making capacity. Thus, we are not made only to satisfy physical needs, but also to face risks and uncertainty in the search for and attainment of new goals and ideals.

Values have a specific function at the heart of one's mentality: they provide identity and they are traction elements of the entire mental apparatus. In other words not only do values unify the diverse components of "I," but they also push the individual to greater realization in the search for a positive identity. One's aim of surpassing the limits of the simple and every day gives meaning to life. This search for the meaning of life provides one with free choice in spite of continual clashes with the conditions of

one's own situation. Although the search is highly personal, the values of the individual are part of their social and cultural context. From a sociocultural point of view, values constitute a specific element of every culture: they are closely linked to the symbols, laws, and rituals which regulate the various dimensions of collective life. Thus, it is clear that values have the function of uniting individual and social praxis; it is this unity which coherently guarantees the link between the individual and society. From a sociological point of view, it is the complex mechanism of the transfer of values from one generation to another which constitutes the socialization process, within which the interaction between society and the individual and thus various aspects of culture become important for the individual.

Seen from the perspective of the social sciences, values do not concern the dimension of absoluteness and transcendence of the philosophical context, but are linked to precise historical, geographical, and social contexts related to various economic, political, and religious structures. The anthropologist Clyde Kluckhohn (1951) defined three fundamental dimensions of values. The entire emotional dimension underlines the profound link between values and the emotions of the subject. The intensity of this link depends on the degree of interiorization of the system of values within any given society. The cognitive dimension is where values implicate the consciousness and the capacity of rational justification on the part of the individual. Kluckhohn then underlines the selective function played by values: these are the criteria by which the subject judges, selects, and orders different behavior and the various ways of thinking which make up their social context: thus, values are fundamental in orienting social behavior.

VALUES AND SOCIAL CHANGE

The sociocultural approach to the topic of values relates to the phenomenon of social change. Knowing all the values which guarantee cohesion and guide the development of a social system is decisive for the comprehension of factors which have moved traditional society

to modern and postmodern society. It suffices to reflect on the value of progress, which is comprehended as a permanent innovation that ought to guarantee the development of humanity to ever improving conditions, and has been the tool used to back the change from traditional to modern society. In addition to progress, modernity is characterized by the affirmation of the individual's freedom of choice, which democracy must guarantee.

The contemporary situation can be characterized by what Inglehart (1977) defined as the "silent revolution": he referred to American and western society in general and underlined the fact that since 1945 society has been moving away from general values. Although the process is slow and gradual, there has been a move away from "materialistic values" to "post materialistic values" in the last few decades. In the past importance was given to physical and economic security; now, however, growing importance is given to the sense of belonging, self realization, and intellectual and aesthetic satisfaction. Although post materialists do not deny the importance of material issues in life, they emphasize quality of life, safeguarding the environment, and freedom of expression. Subjective quality of life and subjective well being are no longer expressed purely in economic terms.

Bellah et al. (1985) connect the search for happiness with the attainment of increasingly elevated levels of freedom. Individualism seems to be the characteristic trait of American and western society in general: the need to establish personal freedom and the search for success in economic terms as spurred on by the spirit of personal initiative and creativity, however, tend to isolate members of a community and thus often create discrimination.

"CRISIS OF VALUES" AND THE CHALLENGE OF CULTURAL PLURALISM

The rapid and profound changes which have touched society and culture in recent years have resulted in widespread discomfort, both for individuals and for collective life. Technological innovation encroaches upon the origins

of life; interpersonal relations are based increasingly on emotions and temporariness; wide spread emigration results in the cohabitation of different customs and traditions in the same territory – all often create difficulties between peers and between different generations. An increasingly accentuated diversity in lifestyles results in the questioning of consolidated traditions, which were, until recently, accepted as unquestionable and eternal.

This has been defined as the crisis of values, an expression which is not easy to define precisely unless one refers to the disorientation caused by the speed of change and the construction of identity and daily life in modern to postmodern society. The crisis of values principally signifies the need to underline the profound change in the process of legitimization of values. This legitimization is no longer to be found in the certainty of institutions and within the law, but is instead based upon individual freedom of choice and a desire for self realization. No longer is there obedience to a unique authority of tradition, but rather there is social recognition of the multiplicity of values. In addition, the crisis of values refers to a new "range of values" which may be adopted both by various societies and by individuals: these options are not always easy to match and reconcile with a common point of reference. Thus, the crisis of values is not a disappearance of values, but is rather the result of their excessive, incoherent, and often contradictory proliferation.

A result of social complexity is the creation of diverse possibilities in the composition of values and social change. These positions may be schematically recapitulated in fundamentalist and relativist models, as well as by the possibilities offered by cultural pluralism. The fundamentalist model (often, but not always, inspired by religious legitimization) aims to safeguard eternity and the immutability of values, negating the possibility of interaction with the concrete social and cultural context of the values themselves. The relativist conception stresses the radical freedom of the individual in the construction of personal values, as far as (in its extreme form) the affirmation of the impossibility of human kind's recognition of the foundation of good and evil.

The outlook of cultural pluralism aims at safeguarding the diversity of different cultural concepts through the legitimization of their very diversity. Surpassing an ethnocentric vision (which encompasses the belief that one's own cultural values are superior to those of other cultures) opens up one's system of values to comparison and relations with other cultural systems and values. Cultural diversity is now the biggest challenge for the construction of social systems which are able to guarantee the free expression of the values of individuals and the community to which they belong.

values: global

Dusko Sekulic

Social values are relatively abstract and generalized standards or principles of what the individuals in a society consider good and desirable. Equality, justice, and freedom are examples of such values. They are the basis for creating evaluative criteria for judging concrete social behavior as good or bad, desirable or despicable, acceptable or unacceptable. Values are the source of concrete prescription for behavior in practical situations of everyday life. Where the general value is equality, the norms of teacher impartiality or the presumption of innocence in courts are concrete norms derived from the abstract value.

There are two important points to be made regarding values and their role in understanding social life. First, society is partially constituted through values and the study of sociology is the study of values. Society can usually tolerate highly diverse attitudes, but it requires some degree of homogeneity and consistency in the values held by people. This provides a commonality of shared values, which shape social and political consensus. To what extent shared values are a necessary precondition for society to survive is a hotly debated issue in sociology. In Parsonsian sociology, social order depends on the existence of such general and shared values. They are regarded as legitimate and binding, and act as standards by which particular actions are selected. The linkage of social and personality systems is achieved by the internalization of values through socialization processes. The critique states that functionalism overemphasizes the importance of shared values in maintaining social order. Conflict theorists would argue that socialization, and the maintenance of common values, hides the underlying interests of those in power to preserve the existing order. The emphasis on the value of homogeneity underestimates the human capability to handle contradictions or simply to compartmentalize them.

Second, as much as society is partially constituted through values, it is also observed that the contents of values vary tremendously. All ethical and religious systems claim universal

validity of the values they profess. The empirical reality is that none of these values is universally accepted, and values prevailing in different societies do not reflect some universal value system characterizing humanity.

The practical reaction to this empirical fact can vary between ethnocentrism, the practice of judging another culture and its values by the standards of one's own culture and values, to cultural relativism, the practice of evaluating value systems by their own standards. Both positions have tremendous ethical and moral consequences. What are the standards that allow the ethnocentrist to claim superiority of his/her values? For cultural relativists, the moral dilemma stems from the fact that if almost any kind of behavior is normative and accepted somewhere in the world, does that mean every thing is equally right? Sociology, not being a normative science, does not provide answers to these normative questions. But there are several approaches within sociology that are preoccupied with the question of global or universal values.

We divide these approaches into three broad groups. The first tries to detect some common values derived from human nature in general. The widely used approach of this type is that of sociobiology. The second approach is based on comparative social psychology, which claims that some universal value structures can be discovered. Here we must emphasize that universal structure does not mean universal value *content*, but the universal *structure* of value systems. The third approach tries to detect shifts toward acceptance of some global values as a result of social change and globalization processes.

Sociobiology starts from the assumptions that values are at least partly rooted in our biological nature. If that is the case, our common "biological" human nature gives basis to some common universal tendencies. If altruistic behavior can be derived from inclusive fitness, then the positive values connected to such behavior, including universal positive evaluation and the great significance that is attached to kinship bonds, can be derived from our biological nature (van den Berghe 1979). The maintenance of values in populations could therefore be explained by a combination of biological and cultural mechanisms (Cavalli Sforza & Feldman 1981).

The second approach claims that there is a universal structure of human values, and that comparative research can discover such universal structures. Although the emphasis and frequency of particular values differ among societies, the underlying structure is the same and can be applied in every society. One such approach can be found in the work of Schwartz (1992, 1994). He developed empirically a schematic representation of what he finds to be an almost universal structure of human values. It is comprised of two higher order dimensions of values, and motivational types of values derived from the higher order values. The two higher order dimensions are openness to change versus conservation, and self enhancement versus self transcendence.

The first dimension indicates the degree to which individuals are motivated to engage in independent action and are willing to challenge themselves for both intellectual and emotional realization. The second dimension reflects the distinction between values oriented toward the pursuit of self interest and values related to a concern for the welfare of others. Within these two general dimensions, ten motivational value types could be distinguished. These ten values are hedonism, power, achievement, stimulation, self direction, universalism, benevolence, conformity, tradition, and security. Schwartz also adds spirituality, which can be differentiated in some, but not all, of his comparative samples. Adjacent values share motivational emphases. Achievement and hedonism both focus on self centered satisfaction, and power and achievement focus on social superiority and esteem.

Schwartz has found that the system of values is essentially the same worldwide. Initially his samples were limited to Western Europe, but recently his modified method replicated the structure in the Far East and South America (Schwartz 2004). Schwartz goes a step further and reports that there is a "surprisingly widespread consensus regarding the hierarchical order of values" across probed societies. Benevolence is most often ranked first, followed by self direction, universalism, security, conformity, achievement, hedonism, stimulation, tradition, and power. Values on the top and bottom of the scale are ranked most consistently, with the middle of the scale much less so.

Hofstede (2001) made a comparative study of values based on analysis of 117,000 IBM employees worldwide. He grouped societies together based on five value dimensions obtained using factor analysis. The dimensions are power distance (acceptance of inequality), uncertainty avoidance, individualism/collectivism, masculinity/femininity, and long versus short time orientations. The individualism/collectivism dichotomy is a widely researched topic within the comparative perspective. In this tradition, the individualistic cultures of the West are contrasted with the collectivistic cultures of the East and Latin America (Triandis 1995; Kagitcibasi 1997).

The third approach starts from analyzing the impact of broadly defined modernization processes, especially those of globalization, on value changes. It is a universally accepted truism that changes in social conditions of life produce changes in values, as values influence acceptance of certain material practices. Diffusion as a more benign form of variable producing change, and subjugation of one society by another as a more malignant form, all produce changes in values.

In the social sciences, a new concept, globalization, is used to describe supposedly historically unique phenomena of ever increasing flows of goods, information, and people. Will a homogeneous global culture and a universal value system be the consequence of such a trend? Is it true that the areas of the world, and the social groups more enmeshed in globalizing processes, are developing more universalistic values? The most comprehensive theory originating from this framework is Inglehart's theory of value change. His analysis is based on the World Value Surveys that have been collected in regular five year waves starting in 1981, and on the Euro Barometer surveys that started in the 1970s. The main conclusion from his research is that a phenomenon, which he calls the "post modern shift," is occurring.

This shift should be put into the framework of broad historical and economic changes that influence value changes. Inglehart is very careful to emphasize reciprocal causal linkages between economy, culture, and politics. Economic change, cultural change, and political change are linked in a coherent pattern and the postmodern shift is part of that broad pattern.

The modernization process resulted in increasing emphasis on individual economic achievement, and this emphasis on individual success made modernization possible, as described by Max Weber.

This shift toward materialistic priorities entailed the acceptance of social mobility and a deemphasis on communal obligations. The main ingredient of the postmodern shift is that the value of economic achievement as the top priority is giving way to an increasing emphasis on the quality of life. In a major part of the world, the disciplined, self denying, and achievement oriented values and norms of industrial society are yielding to increasingly broad latitude for individual choice of lifestyles and individual self expression. The shift from "materialist" values, emphasizing economic and physical security, to "post materialist" values, emphasizing individual self expression and quality of life concerns, are the key elements of occurring change.

This shift in the dominant values of modern society springs from the fact that there is a fundamental difference between growing up with an awareness that survival is precarious and growing up with the feeling that one's survival can be taken for granted. The origin of the shift is rooted in the economic miracles that occurred first in Western Europe and North America, and later in East Asia and then in Southeast Asia. Coupled with the safety net of the modern welfare state, this has produced unprecedented high levels of economic security.

This new security shifted the authority away from both religion and the state to the individual, with an increasing focus on individual concerns such as friends and leisure. The root cause of the postmodern shift has been the gradual withering away of value systems that emerged under conditions of scarcity, and the spread of security values among a growing segment of the public of these societies.

This change in the direction of a domination of post materialist values does appear as a gradual process. It takes place as the younger generation replaces the older in the adult population of society. This is the consequence of the socialization hypothesis introduced into sociology by Mannheim's famous essay on generations. The main idea is that one's basic values reflect the conditions that prevailed during one's pre adult

years. Those raised under conditions of unprecedented security can tolerate more ambiguity and are less in need of rigid rules. In accordance with the principles of diminishing marginal utility in economic theory and Maslow's concept of a need hierarchy in psychology, subjective well being and quality of life become higher priorities than economic growth.

Materialist/post materialist value priorities are, according to Inglehart, only one component of the much broader configuration of values constituting the postmodern dimension. This dimension has proven to be remarkably robust over time and it is comprised of two clear clusters of statements ranked by respondents. The post materialist statements clustering together deal with less impersonal society, more say in job, more say in government, ideas counting more than money, and freedom of speech. Opposites of these are materialist statements clustered in the opposite direction. They deal with a strong defense force, fighting rising prices, fighting against crime, maintaining order, economic growth, and maintaining stable economy. This clustering shows stability in a large number of surveys around the world with the gradual emergence of the domination of post materialist values in the youngest generations of the highly developed societies. Inglehart's interpretation is not in the sense of the life cycle, but as a cohort effect. That means that a global hierarchy of values in the developed societies is changing with important consequences for politics, culture, and society in general (Inglehart 1977, 1990, 1997; Inglehart & Baker 2000).

Two great shifts documented on the basis of the World Value Surveys are the rise of more egalitarian values and attitudes toward the roles of women and men. Generation comparisons suggest that post industrial societies have experienced a parallel liberalization of moral values toward sexuality among younger generations, and as this generation is replacing the older, the global shift will occur (Inglehart & Norris 2003). The second area is the most empirically founded support for the secularization thesis (Norris & Inglehart 2004).

Finally, we are faced with the dilemma of the presumed universal nature of the values of modernity. Here, the empirical and normative dimensions are intertwined, and it is very difficult to separate one from the other. To what

extent are the values of democracy, human rights, individual rights, and children's rights empirical expressions of the changes that are happening in the social structures of modern and postmodern globalizing societies? Or to what extent are they simply a reflection of the ideological goals of dominant sectors of the most modernized parts of highly developed societies? Are individual human rights the expression of the "natural" rights of all individuals reflecting some basic values deeply rooted in human nature? Do human rights reflect human nature in the same way as Adam Smith claimed that the existence of the market reflects "man's propensity to barter, truck and exchange one thing for another"?

If that is true, then as the market is the institution best suited to human nature, so the same can be said for political democracy of the western type. Is human nature an empirical fact or a construction of the ideological mind? Is the fact that these rights are trampled in so many societies just the result of bad institutions? Would their removal and replacement with the "normal" democratic institutions establish the "natural, order of things," with the sanctity of the individual as the dominant societal value? Or to use another perspective, is the insistence on Asian values just the ideologized defense of Asian authoritarian regimes or a genuine defense of the endangered principal values of traditional culture confronted with the imperial domination of the West?

variables

VARIABLES AND CASES

Variables (indicators, items) are an important concept in methods of social research and epistemology. A variable is a superordinated attribute, characteristic, or finding that exists in at least two distinct subordinated categories (classes, groups, units of measurement, values). Cases (individuals) can differ – vary – on the variable concerning the category they belong to. Variables thus are used to classify cases. Very

often, cases are persons as members of an organization, a region, a nation, etc. Note that in statistical terminology “individuals” and “persons” are not the same. Instead, many different types of cases can be conceptualized. Some examples are given in Table 1.

These cases can be assigned to categories of variables. For example, if John Smith was an American man voting for the Republicans and favoring tax cuts, he could be ascribed the attribute “male” on the variable “gender,” “American” on the variable “nationality,” “Republican” on the variable “preferred political party,” and “in favor of tax cuts” on the variable “attitude towards tax cuts.” Following the same logic, the film *Titanic* could be referred to the category “1997” on the variable “production year,” “PG 13” on the variable “rating,” and “11” on the variable “number of Oscars won.” Similarly, any type of case can be assigned to categories of variables.

Applying this principle, all cases of a sample or population can be allocated to variables. Categories should be mutually exclusive, meaning that any individual can only be allocated to one category. They should also be exhaustive (i.e., each individual should be assignable to one category). If for some reason one does not know what category a case belongs to, this is called missing data or missing value.

All cases assigned to the same category count as “the same” (concerning this variable). If two cases are allotted to different categories, they are regarded as being dissimilar. For example, the films *Titanic* and *10 Things I Hate About You* are of the same rating (PG 13), but differ concerning the number of Oscars they won and the year they were released.

VARIABLES AND MEASUREMENT

Although both qualitative and quantitative research use the principle of variables in the sense that cases are classified, the concept is more important in standardized research, especially in survey research, as it links questionnaires and statistics: each question in a questionnaire (usually) can be considered as one variable, each possible answer to a question as a category (value). Some researchers reserve the term “item” for lists of similar questions

with the same response spectrum. Using a coding system, the answers given have to be coded (i.e., they have to be transformed into figures in order to make them processible by statistics). Here, the problem of measurement arises (i.e., the verbal responses have to be correctly transferred into numbers without distorting their meaning). Defining a concept in a way that it can be measured is called operationalization.

Measurement is especially difficult in international comparative research as respondents might mean completely different things using the same concepts. For example, the German word *fremd* could mean “foreign,” “alien,” “strange,” or “external” in English.

Correct measurement is important, as any statistical procedure assumes that data are free from distortion. One can only achieve valid results if this assumption is true. On the other hand, these methods are very efficient because they can investigate the relation between variables independent of context. Univariate statistics describe the distribution of one variable, bivariate statistics analyze the relation between two variables, and multivariate statistics model the relation between three or more variables. Typically, one distinguishes dependent, independent, and intervening variables for statistical analysis. However, Abbott (2001) has criticized variable centered analysis methods because researchers using them tend to forget that not variables but human beings are acting. The latter are formalized in survey research as cases.

TYPES OF VARIABLES

One of the factors influencing which statistical analysis procedures are allowed and how results may be interpreted is variable type. There are multiple ways of classifying types of variables. First, variables can be classified by the number and discernibility of their categories (see Table 2).

Secondly, variables can differ concerning the level of analysis (level of aggregation) of the cases concerned. Researchers can study individuals (e.g., persons or single newspaper articles): (1) variables can describe these individuals' genuine characteristics; (2) relational variables describe a case's interrelationship to other cases (e.g., “Jim (case 1) is married to Jill (case 2)”; (3) contextual variables capture a case's embeddedness in a collective (e.g., “Jim (case) lives in the US (aggregate)”).

Researchers can also examine collectives (aggregates, higher levels of analysis) (e.g., countries). These collectives can be regarded as individual cases themselves, but they also consist of individuals of lower analysis levels. Global (integral) variables are variables describing characteristics genuine to the aggregate (e.g., western countries could be allocated to the variable “Welfare Regime” as “Liberal,” “Conservative,” “Social Democratic,” “Familistic,” or “Post Socialist”). Analytical (aggregative) variables have to be calculated from variables measuring characteristics of lower level cases

Table 2 Classification of variables by characteristics of categories

<i>Type of variable</i>	<i>Characteristics of categories</i>	<i>Example</i>	
		<i>Variable</i>	<i>Categories/ Values</i>
Binary variable (Dummy variable)	Two categories with clear boundaries that should be coded with “1” and “0”	Gender	Male Female
Discrete and polytomous	More than two (but finite number of) categories with clear boundaries	Continent	Africa, America, Asia, Europe, Australia
Continuous	Large (often infinite) number of categories that make the boundaries between categories hard to distinguish	Income in US \$	Any value from 0 to an infinite number

Table 3 Classification of variables by level of measurement

<i>Measurement level</i>	<i>Variable type</i>	<i>Characteristics of categories</i>	<i>Example</i>	
			<i>Variable</i>	<i>Categories/ Values</i>
<div>Low ↑ ↓ High</div>	Categorical variable (Index, Nominal variable, Qualitative variable)	Categories are just different, but there is no rank between categories	Gender	Male Female
	Ordinal variable (Dimension, scale in the narrow sense)	Additionally, categories can be ranked	Attitude toward tax cuts	Completely agree Partly agree Partly disagree Completely disagree
	Metric variable (variable of interval scale)	Additionally, the distance between any two adjacent categories is the same	IQ	Any value from about 80 to about 180
	Variable of ratio scale	Additionally, a true point of zero exists	Number of children	Any value from 0 to about 20

(e.g., a country’s “unemployment rate” has to be calculated from dividing the number of unemployed by the number of persons fit for work in the country). Structural variables are calculated from information on the relation between lower level cases (e.g., “strength of local networks” could be measured by dividing the number of existing contacts between local actors by the number of all theoretically possible contacts).

Thirdly, variables differ in level of measurement (scale in the broader sense); that is, on the question how categories can be arranged (see Table 3). The higher the scale type, the

more severe are the measurement rules, but the more statistical methods are allowed as well.

Fourthly, variables differ on how they can be operationalized. Manifest variables can be observed and measured directly. For example, a person’s size can be assessed by using a tape line and ascribing the number reading on the scale to the person (e.g., 1.67m). In contrast, latent variables cannot be directly observed (e.g., conservatism could be measured by a person’s attitude toward many political issues. Special methods, such as factor analysis, can be used to reconstruct latent variables, which are some times also called dimensions or scales.

Fifthly, for some variables, individual values can be interpreted directly, without knowing other cases' values (e.g., if "size" is measured in meters and a person is "1.67m," one can imagine how tall this person is). In contrast, for other variables, one needs to know the whole range of values to assess the meaning of a single case's value. For example, if "size" is measured by the categories "short" – "medium" – "tall," and a person is classified as "tall," it makes a big difference if this person lives in the US or China. In the US a "tall" person is probably at least 1.80m, while in China a person might be called "tall" if she were 1.60m, which would probably be categorized as "short" in the US.

variables, control

Hung En Sung

Control variables are variables included in multivariate analyses to identify spurious associations. In assessing whether X is associated with

Y , it is important to examine whether the covariation between them persists after the effects of other variables on this association are removed (McClendon 2002). Here, "control" means to hold constant. A variable is controlled when its influence on the other variables in the model is held constant.

In laboratory experiments a variable Z can be controlled by setting a fixed value for it and observing the relationships between X and Y for that fixed value. The experiment can then be repeated at other fixed values of Z to see whether the same results occur. However, in most social science research, values of variables such as race, education, age, and income cannot usually be manipulated before obtaining the data. In correlational studies the portion of the association between X and Y that is caused by variation in Z can be removed by comparing only cases with equal or similar values of Z at a time. A spurious relationship exists between X and Y if both variables are dependent on Z , so that the association between X and Y disappears when Z is controlled (see Fig. 1).

Informed and methodological application of control variables is crucial to the advancement of scientific knowledge. Social research establishes causal claims by demonstrating temporally ordered covariation of variables and by discrediting alternative explanations as implausible (Sobel 1995). For example, earlier studies reported an inverse relationship between levels of female government officials and levels of corruption and urged countries to raise the number of women in public offices to fight corruption (see Fig. 2). But replications that included measures of liberal democracy (e.g., independent judiciary, freedom of the press, and universal suffrage) as control variables found that when forced into the same model, the effects of gender on corruption became statistically insignificant, whereas liberal democracy remained a very

powerful predictor (Sung 2003). The inclusion of the right control variables prompted the discovery that the observed association between gender and corruption was largely spurious and mainly caused by a political system that promoted both gender equality and better governance (see Fig. 3).

It is not always theoretically evident which variables should be controlled in multivariate analysis. Researchers should thus develop a thorough knowledge of the theory and previous work relating to their field of research so that one will be more likely to recognize possible spurious relationships and to control relevant variables, thus not giving too much importance to an observed bivariate statistical association.

variables, dependent

Ernest T. Goetz

Research involves identification and description of characteristics of organisms, objects, events, and locations. When these characteristics can take on different values (e.g., when they differ between people or from one time to another for the same person), they are referred to as *variables*. The variables involved in any particular research study are determined by the interests and intentions of the researcher. Much research focuses on the relationships between variables, particularly *causal relationships*. In such research, *dependent variables* are the presumed outcomes or effects of *independent variables*. In research about causal relationships, measurement (i.e., systematic assignment of numerical values to variables) of the dependent variable (or multiple dependent variables) is used to determine if the independent variable had the hypothesized effect or predicted relationship. For example, people's income might be measured to see if it is dependent on or predicted by their occupation. Their occupation, in turn, might be measured to see if it is dependent on or predicted by their education level. Thus, depending on the focus of a study or model, the same variable may function as a dependent variable or independent variable (Pedhazur & Schmelkin 1991).

Note also that income, occupation, and education level differ in the type of *measurement*

(i.e., “assignment of numbers to aspects of objects or events according to one or another rule or convention”) (Stevens 1968: 850) they represent and the information they convey. A commonly used system for classifying variables in this regard was developed by Stevens (1951, 1958). It should be noted at the outset that this analysis can be applied to variables serving different roles in a research design, statistical analysis, or theoretical model. Stevens identified four *scales of measurement*, which can be ordered from least to most informative or mathematically sophisticated. At the lowest level are *nominal scales*, in which different categories (e.g., male, female; Democrat, Republican; dentist, electrician) are arbitrarily assigned different numerical values. Note that the numbers so assigned (e.g., male = 1, female = 2) convey no information other than category membership (e.g., the values shown above do not indicate that females have more or less of anything than males). *Ordinal scales* convey information about relative degrees or amounts. They are constructed by assigning numbers to indicate rank ordering based on an attribute of interest (e.g., education levels might be ordered as follows: high school diploma, associate’s degree, bachelor’s degree, master’s degree, doctoral degree; also Stevens’s scales of measurement). The numbers assigned in an ordinal scale communicate relationships of less than/greater than, but tell you nothing about the magnitude of the differences. Thus, the number of years required or the amount of knowledge gained between a high school diploma and an associate’s degree may not be the same as that involved in progressing from a master’s degree to a doctoral degree. In *interval scales* (e.g., Fahrenheit and Celsius temperatures, calendar dates in years), differences between the numbers assigned to observations indicate the distance or interval between them on the dimension of interest and are invariant across the measurement scale. Thus, the difference in temperature between 37° and 42° Fahrenheit is the same as the difference between 79° and 84° Fahrenheit. However, it is not the case that 84° Fahrenheit is twice as hot as 42° Fahrenheit. Such statements can only be made for *ratio scales*, which have a true or absolute zero (e.g., Calvin temperatures, number of children, income in dollars).

The nature of the measurement constrains the statistical procedures that can be used to summarize data. According to Stevens (1958), the only permissible statistical operations for nominal scales are tabulation of the number of cases of each category and identification of the most frequent category (mode). Interval scales permit the identification of the median and percentiles and the calculation of rank order correlations. It is only with interval and ratio level scales that one can appropriately calculate a mean, standard deviation, and product moment correlation. Thus, there is a strong pull to interpret data in the social sciences as representing interval scale measurement when a more conservative ordinal interpretation might be more appropriate (e.g., rating scale data, standardized test scores).

In interpreting the information provided by measurement of dependent variables, it is also essential to consider their *reliability* and *validity*. Reliability refers to the accuracy or precision of the scores, that is, the extent to which they are free from error. Validity, on the other hand, refers to the appropriateness and utility of the interpretation of data derived via measurement procedures (Cronbach 1971). Although data must be reliable in order to permit valid interpretations, misguided or erroneous interpretations of reliable data also are possible. Thus, reliability is necessary but not sufficient for validity. Depending on the intended purpose of the interpretation, different approaches to gauging validity are possible. *Content validation* entails an examination of the appropriateness of the types of items included in an assessment to the domain being measured. Thus, a test of high school algebra should include items appropriate for that content area and level of instruction, and a survey of views on a president’s performance should include questions covering the major issues of the day. *Criterion related* validation is accomplished by examining the relationship between the measure whose validity is being assessed and some criterial outcome or measure. For example, the criterion related validity of a measure of an incumbent president’s popularity as a predictor of his or her reelection might be assessed by examining the ability of a poll of the president’s approval rating before an election to predict the outcome of the election. More generally, criterion related validity is measured via

correlation between the measure in question and the criterial measure. For example, the criterion related validity of exit polls in a presidential election might be tested by correlating exit polls with final vote counts in a sample of precincts. *Construct validation* is less straightforward. The term *construct* refers to human attributes such as knowledge, beliefs, attitudes, and opinions that are of theoretical importance to social scientists. Pedhazur and Schmelkin (1991) described construct validation as a never ending process that involves careful attention to the definition of the concept, item content, measurement procedures and scoring procedures, and internal structure analysis. Although concept validation is complex, it is essential to ensuring the validity of many measures such as surveys and tests as indices of the attributes they are intended to measure.

Finally, it is important to note that the operationalization of the dependent variable can play an important role in determining the size of the effect observed for the dependent variable. Wilson and Lipsey (2001) synthesized the results of 319 meta analyses encompassing 16,525 studies of psychological treatments (primarily in mental health and education) and found that study methods, which included type of design, method quality, and operationalization of dependent variables, accounted for nearly as much of the variance in outcomes of these studies as the nature of the treatments, with operationalization of the dependent variables being one of the most important aspects of study methods.

variables, independent

Ernest T. Goetz

Research involves identification and description of characteristics of organisms, objects, events, and locations. When these characteristics can take on different values (e.g., when they differ between people or from one time to another for the same person), they are referred to as *variables*. The variables involved in any particular research study are determined by the interests and intentions of the researcher. Much research focuses on the relationships between variables, particularly *causal relationships*. In such research, *independent variables* are the presumed causes whose effects are measured via changes in the value of *dependent variables*. Independent variables are temporally or theoretically prior to (and therefore independent of) dependent variables. For example, the manner in which the prosecutor and defense attorney present their closing arguments to a jury precedes the jury's deliberations and verdict, and so may influence them. Thus, various aspects of the closing arguments might be viewed as independent variables. According to Cohen et al. (2003), there are four requirements for the treatment of a variable *X* as a cause (or independent variable) of variable *Y* (the effect or dependent variable):

- 1 *X* precedes *Y* in time (temporal precedence).
- 2 Some mechanism whereby this causal effect operates can be posited (causal mechanism).

- 3 A change in the value of X is accompanied by a change in the value of Y on the average (association).
- 4 The effects of X on Y can be isolated from the effects of other potential variables on Y (non spuriousness or lack of confounders).

It is important to note that (3) above entails a probabilistic view of causality, which is at the core of causal research in the social sciences (Pearl 2000). Thus, a change in the independent variable is likely to be associated with a change in the dependent variable, but the occurrence, direction, and size of the change may differ from one individual or occasion to the next. In social science research, the probabilistic nature of causal relationships is compensated by the use of multiple observations.

Evidence of the causal relationship between independent variables and dependent variables is strongest in experimental research, which has long been held as the “gold standard” in the study of causality and sometimes anointed as “the scientific method.” The causal interpretation of relationships between variables in non experimental research is gaining increased acceptance and legitimacy (e.g., Cohen et al. 2003), although some authors still caution against causal interpretations of non experimental research and advocate the use of the term *predictor variable* in place of *independent variable* in such research (e.g., Brewer 2000).

In a prototypical experiment, causal relationships are tested by manipulating the independent variable (or variables) while keeping other factors constant (i.e., controlled). For example, the effect of hydrochloric acid on iron could be studied under laboratory conditions designed to eliminate the potential effects of other chemical agents or physical conditions (e.g., temperature, air pressure). Although this level of control is seldom if ever possible in social science research, researchers attempt to control or account for other potentially confounding variables. Thus, one might study the effect of mode of presentation of an argument in a study in which other potentially confounding variables (e.g., sex and age of the audience) are controlled by matching or by statistical procedures (e.g., removal of associated variance through *regression*).

In non experimental research, support for causal relationships is provided through tests of association, preferably by testing *a priori* causal models. Naturally occurring variation in the independent variable (or variables) is measured (that is, the independent variable is not manipulated), and its predictive value is tested after controlling or accounting for potential confounds. Although it is not possible to eliminate all potential confounds, judicious selection of control variables can help to minimize the problem. Thus, the effect of the sex of an audience member on response to a given form of argument might be studied by having men and women of the same age and education level listen to the same presentation. Research, both experimental and non experimental, can also explore the effects of more than one independent variable, and measure outcomes in terms of more than one dependent variable. Further, a fuller understanding of the relationship between independent and dependent variables may require consideration of *moderator variables*, which influence the relationship between independent and dependent variables, and *mediator variables*, which elaborate the relationship between independent and dependent variables through the specification of intervening processes or states in the causal process.

As Pedhazur and Schmelkin (1991) point out, the same independent variable can be manipulated in one study and non manipulated in another study. For example, sex is a non manipulated variable in the examples presented above, but it would be a manipulated variable in an experiment where male and female “attorneys” presented the same argument to different audiences. Further, the same variable can be an independent variable in one study and a dependent variable in another study. Thus, sex would be a dependent variable in a test of a drug whose intended effect was to increase the likelihood of giving birth to a female or male child.

Like dependent variables, variation in independent variables takes several forms. If one were to study the effect of a drug, one might compare various levels of dosage of the drug, or one might compare its effects to those of other drugs. In the first instance, variation is said to be *continuous* or quantitative; in the latter, variation is said to be *categorical* or qualitative. Statistical procedures have been developed that are

particularly appropriate to each type of independent variable: effects of categorical independent variables typically are assessed through *analysis of variance* and its variants (e.g., multivariate analysis of variance), while effects of continuous independent variables typically are assessed via regression and its variants (e.g., *multivariate* and *multiple regression*). There are also statistical techniques that are compatible with both categorical and continuous regression (e.g., *analysis of covariance*, *semantic equation modeling*). Some times researchers take continuous independent variables (e.g., age) and reduce them to categorical data by dichotomization. One common form of dichotomization is the median split, in which values above the median are lumped together in one group, while those below are lumped into another. By ignoring variation within these artificially constructed groups, dichotomization results in a loss of information, which makes the outcomes of statistical analyses less informative and reliable (Cohen 1983; MacCallum et al. 2002).

variance

Ernest T. Goetz

Variability is one of the key characteristics of a set of scores. Measures of variability are used to provide an indication of the extent to which characteristics of people (e.g., income, education), events (e.g., attendance at concerts), or things (e.g., capacity of concert venues) differ from one another. Of the statistical indices of variability (e.g., range, semi interquartile range), the variance and standard deviation are the only ones that reflect the exact value of each score. In this respect, they are analogous to the mean, the measure of centrality from which they are derived. For this reason, the variance and standard deviation are the measures of variability used in parametric statistics (e.g., analysis of variance (ANOVA), correlation, general linear modeling, hierarchical linear modeling, regression and regression analysis, structural equation modeling).

The variance and standard deviation depict variability of a set of scores in terms of their distances from the mean, or deviation scores. A deviation score is computed by subtracting the mean of the set of scores from the score. Therefore, like the mean, deviation scores can only be computed for interval scales (e.g., Fahrenheit or Celsius temperatures) or ratio scales (e.g., height, weight, Kelvin temperatures), in which differences between scores are meaningful and consistent. Because of the way that deviation scores are defined and computed, the sum of the deviation scores is zero for all sets of scores. Therefore, the average deviation score (which also is zero by definition) is of no value as a measure of variability. This difficulty is overcome by squaring the deviation scores.

To illustrate, suppose we were to count the number of books high school students were carrying in their backpacks. A list of five students and the number of books in their backpacks is presented in the first two columns of Table 1. The mean number of books being carried by these students is six (i.e., $30/5 = 6$). The deviation scores for each student (i.e., number of books they are carrying minus the mean number of books, six in this case) are shown in column three. As previously noted, these add up to zero

Table 1

<i>Student</i>	<i>Score</i>	<i>Score</i>	<i>Mean</i>	<i>(Score - Mean)²</i>
Júan	12		6	36
Laurie	1		5	25
Ronghua	9		3	9
Tufan	5		1	1
Yolanda	3		3	9
Total	30		0	80

with an average of zero, as they would for any set of scores.

In descriptive statistics, in which you are interested in characterizing the set of scores that you have, the variance is found dividing the sum of the squared deviation scores (shown in the final column) by the number of scores in the set, or $80/5 = 16$ for our example. However, in inferential statistics, in which you want to *estimate* the variability of a large set of scores of interest (i.e., population) from some smaller set of scores that are available (i.e., sample), this approach systematically underestimates the variance of the population. To correct for this bias, the sum of the squared deviation scores is divided by the number of scores minus one, or $80/4 = 20$ in the present case. It should be noted that inferences about a population based on a sample of scores are most valid when they are based on a random sample of scores in which each member of the population (e.g., all US high school students) has an equal chance of being selected. Further, as sample size increases, so does the accuracy of the inferences that can be drawn regarding the population.

Since calculation of the variance yields a metric in which the unit of measurement is squared and sometimes interpretable (e.g., books squared), variability is most often reported in terms of the standard deviation. The standard deviation is found by taking the square root of the variance, which brings the number back to the original unit of measurement. In our example, if the set of scores were the population of interest, the standard deviation would be $\sqrt{16} = 4$. If the set of scores were a sample that was being used to make inferences about a larger population of scores, the standard deviation

would be $\sqrt{20} = 4.47$ (note that the disparity between the results of the two computational formulas decreases as sample size increases).

Thus, the standard deviation can be viewed as a modified average deviation score, adjusted to accommodate for the fact that the sum of the deviation scores is always zero. In our example, the variability of the number of books as measured by the standard deviation (4.47) is quite large compared to the mean number of books (6), assuming that the five students are a random sample of all the students in the high school. However, given the fact that our sample of students is small, the accuracy of our estimates would be limited, resulting in wide confidence intervals, or range of values in which the population parameters (i.e., statistics descriptive of the full set of scores of interest, here the average number of books carried in the backpacks of all US high school students) might be expected to fall.

It is important to note, however, that variance is more than just an intermediate step on the road to the calculation of the standard deviation. Directly or with modifications, it is used in the description and estimation of the relationships between two or more variables. For example, the strength of the relationship between two interval or ratio scales (e.g., height and weight) is measured using the *Pearson product moment correlation*, or Pearson *r*. The Pearson *r* is calculated using the variance of the two sets of scores and their covariance, which is an analogue of variance in which the deviation score of one variable is multiplied by the deviation score of the second variable for each observation in the data set (e.g., Margot's height and weight). The proportion of variance accounted for by one or more variables is a metric of effect size that is commonly used in inferential statistics.

Veblen, Thorstein (1857–1929)

Matthias Zick Varul

Thorstein Veblen, US economist and social theorist, argued for an evolutionary institutionalist approach to social development. History is a non teleological process in which, by quasi Darwinian selection, institutions survive according to their fit with the current “state of the industrial arts.” Inert institutions inhibit further technological progress beyond the state they are adapted to facilitate. In this context, Veblen developed the theory of latecomer advantages and technological borrowing.

Veblen sees two driving motivational forces in the development of technology and institutions. The first, more primordial, is the *instinct of workmanship*, which motivates cooperative productive work for the good of the community. Having been dominant in a peaceful, egalitarian, and matriarchal *age of savagery*, it has been subdued by the second motive, the *predatory instinct*, seeking competitive advantage for the individual at the cost of others in a warlike and patriarchal *barbaric age*. In this setting, a non productive leisure class dominates the productive industrial classes of farmers, workers, craftsmen, and technicians.

This dominance is perpetuated in modern capitalism, although in a pacified form. Cultural dominance lies with a leisure class of rentiers and absentee owners and industry is dominated by a managerially active business class. While industrial workers and particularly engineers

adhere to the logic of production and efficiency, the business class follows the logic of profit, often fueling industrial innovation, but frequently also sabotaging efficiency and technological progress where doing so enhances monetary outcomes.

Widely seen as Veblen’s sociologically most significant achievement is the analysis of consumerism in his *Theory of the Leisure Class*. With the ability to waste being the principal determinant in class structure, the leisure class engages in conspicuous leisure and consumption to assert their social position. The sole utility of the goods thus consumed lies not in their capacity to satisfy any substantive need but in their capacity to demonstrate spending power and habitual abstention from productive work. Ascending groups try to *emulate* upper class habits of consumption and leisure. This sets off a dynamics of consumer good innovation as the emulated upper classes, in order to keep ahead of the runners up, constantly have to refine their *pecuniary canons of taste*. Those innovations then will trickle down to lower classes in a cascade of competitive emulation inspired by *invidious comparison*.

verstehen

Larry Ray

Usually translated as “understanding,” the concept of *verstehen* has become part of a critique of positivist approaches to the social sciences. Associated with the sociology of Max Weber, *verstehen* derives from the hermeneutic critique of positivism that emerged in German universities in the 1880s and 1890s that gave rise to a dispute over method in the social sciences (*Methodenstreit*). *Verstehen* refers to understanding the meaning of action from the actor’s point of view. It is entering into the shoes of the other, and adopting this research stance requires treating the actor as a subject, rather than an object of one’s observations. It also implies that unlike objects in the natural world, human actors are not simply the product of causal forces. Individuals are seen to create the world by organizing their own understanding of it and giving it meaning. To do research on actors without taking into account the meanings they attribute to their actions or environment is to treat them like objects (Drislane and Parkinson 2002).

Wilhelm Dilthey’s sociology provided a more elaborated method of understanding than Weber’s. Based on the view that since sociologists participate in the cultural worlds of those they study it is possible to gain a kind of inner understanding of social life that is impossible in the natural sciences, Dilthey distinguished several levels of understanding. The most formal level of understanding is based on signs and symbols, which make mental content intelligible but reveal nothing about the inner mental life of the subject. Then there is direct understanding – recognizing a symbol *as* something, which involves decoding the communication of expressions, gestures, and actions, or, say, the meaning of a sentence or mathematical expression. This infers intention from observation of action – so if we see someone hitting a nail with a hammer we might infer what their intention might be; similarly, we recognize certain facial expressions as indicating grief or happiness. Further, there are “higher” levels of understanding involving empathy and reexperiencing, which involve projecting oneself into a text or form of life and appropriating it on the basis of shared

experience. For example, to share the experience of poetic love one must have loved, to imagine suffering one must have suffered, and so on. Then on the basis of empathy arises the “highest” form of understanding, where one recreates or relives the process of cultural production. This occurs in *reverse order* to the sequence of events, and moves from the completed product or event back to the context and intentions that inspired it.

The procedure of placing oneself within the worldview of frames of meaning of contemporary or historical actors is crucial to making sense and thereby explaining social actions and outcomes. We are surrounded by Roman ruins, cathedrals, and summer castles, as Dilthey put it, fragments of the history of mind that can be understood only by interpretive techniques grounded in the life process of individuals.

This empathetic approach to social inquiry, it is argued, finds no analogy in the methods of the natural sciences, but aims to reconstruct the relationship between expressions and meanings and intentions of actors (Dilthey 1986). Its objective is less to explain the world and more to understand and reconstruct meaning to regain the lost unity of the act of creation of texts, cultures, artworks, institutions, and historical events. In this sense, as Delanty (1997) argues, hermeneutics had a more conservative orientation than positivism. Whereas the latter arose in the context of revolt against the authority of tradition and political absolutism, hermeneutics has tended to value community, be uncritical of social institutions, and ignore power relations. However, understanding is resolutely universalistic in its assumption that a common (and therefore comprehensible) humanity underlies all processes of cultural and historical creation.

Weber’s use of the method of *verstehen* attempts to reconcile interpretation of action with causal explanation in a way that establishes an interaction between the two. So causal explanations must have adequacy on the level of meaning, while meanings themselves may constitute causes. One of the most systematic uses of this method by Weber is in *The Protestant Ethic and the Spirit of Capitalism* where he supplements structural and economic accounts of the origin of capitalism in Europe with empathetic reconstruction of the worldview of

seventeenth century Calvinist and other Protestant groups. He argues that Calvinist belief in predestination, which precluded achieving salvation through good works, provoked “an unprecedented inner loneliness” and search for signs of salvation. Through attempting to resolve this paradox the theological quest for evidence of divine grace was transposed into the worldly but ascetic pursuit of capital accumulation, success in which was interpreted by Calvinists as signaling divine selection. What this example illustrates is that only through empathetic reconstruction of actors’ meanings is it possible to explain critical events like the growth of capitalism.

However, the use of *verstehen* is open to criticism. First, critics have argued that this is not a distinct method, but an elaboration of what all social actors do routinely in everyday life. Secondly, there is no way of validating *verstehende* interpretations since they cannot be tested against replicable evidence. Thirdly, it is claimed that interpretation of meanings adds no new knowledge and by definition recycles what is already known about society. Fourthly, *verstehen* is at best a source of hypotheses that then require testing against evidence. Fifthly, it is accused of over emphasizing meaning at the expense of material structures and unintended consequences of actions. To some extent these criticisms focus on *verstehen* as a form of introspection or imaginative reconstruction of meanings rather than as a systematic dialogue with a range of social materials – texts, archives, conversations, worldviews, and cultural artifacts – in which suggested interpretations can be “tested” with reference to the extent that they open up new layers of understanding.

Viagra

Meika Loe

Viagra is a blood circulation drug (the first in its drug class as a PDE5 inhibitor) prescribed to treat erectile dysfunction. This drug, marketed by Pfizer Pharmaceuticals and approved by the FDA in 1998, has been widely cited for its record breaking sales and its “blockbuster” status. Specifically, Viagra set records as the fastest selling drug in America, and netted over a billion dollars in its first year. Viagra was the first FDA approved oral therapy for sexual dysfunction. After five years of consistent sales, competitors Levitra and Cialis (also PDE5 inhibitors) have entered the market, claiming to work faster and for longer periods of time. The financial success of Viagra has helped to construct and finance research and product development in sexual medicine.

Sociologists have treated the Viagra phenomenon as an opportunity to analyze the social construction of medicine, masculinity, sexuality, marketing, and aging. Viagra, when read as a social artifact of our times, is emblematic of changing social realities in the twenty first century. In sum, Viagra exemplifies the medicalization of social problems at a time when biomedicine is hegemonic, with increasing jurisdiction over areas of life not previously medicalized.

Viagra reflects the emergence of the pharmaceutical era, in which the increasingly consolidated pharmaceutical industry is the most profitable industry in America, with “unprecedented levels of control” over medical education, drug regulation, research, marketing, and advocacy. Viagra reveals the merging of science and capitalism in the pharmaceutical era, as

medical researchers and experts are increasingly affiliated with this industry. Viagra was also one of the first drugs to be marketed directly to consumers, after the ban on DTC advertisements was lifted in 1997. In the pharmaceutical era, drugs such as Viagra can be used as tools for the construction of personhood and idealized identities. In this way, the Viagra phenomenon heralds the commodification of sexuality and masculinity. The male body becomes an important new site for medicalization and marketing. Sexuality is increasingly a site for biomedical intervention, and Viagra represents the McDonaldization of sex in a culture that emphasizes efficiency and a quick fix mentality. Finally, as more products emerge to "treat" symptoms of aging, Viagra will be remembered as one of the first blockbuster drugs marketed to an aging populace, with senator and war veteran Bob Dole as its spokesperson. More recently, sexual medicine is marketed to a wider demographic in terms of age, ethnicity, and gender.

Viagra's debut is a perfect opportunity to examine the construction of social norms, ideals, and expectations, particularly because it renders visible and influences many taken for granted social assumptions about sex, aging, gender, and medicine. For example, since Viagra's debut, "normal sex" in America is more and more narrowly defined and difficult to achieve. Then again, normal sex is a seeming requirement for normal personhood. More recently, we have heard that "normal" for women means sexually desirous, easily aroused, fully lubricated, and orgasmic. With such elevated standards, normal sex in the Viagra era likely requires medical or pharmaceutical intervention.

victimization

Tancy J. Vandecar Burdin

Victimization is the action of victimizing, or fact of being victimized (Viano 1976). Until a variety of factors converged during the 1960s, individual victims were not always given much attention by the criminal justice system. During this time, the women's movement began to address the victim blaming often seen with sexually violent crimes. Child abuse as a societal problem was also coming to the attention of local and state leaders. Finally, rapidly growing crime rates between 1960 and 1980 brought greater scrutiny to the criminal justice system, in part through President Johnson's 1967 Commission report. Victimization was one focus of this report. The culmination of these factors began the discussion about the victim's role in the criminal justice process, what services should be provided to victims, and data gathering about victimization in the US (Doerner & Lab 1995).

The 1980s were an active time in the history of victims' rights. In 1981 President Reagan established the Annual National Victims of Crime Week in April and in the following year he created the President's Task Force on Victims of Crime, which developed a series of recommendations regarding several victims' issues (Davis & Henley 1990). The 1983 Omnibus Victim/Witness Protection Act addressed the rights of victims and witnesses of federal crimes. The Act stated that victims should not be subjected to intimidation by the offender, have the right to be consulted about possible plea bargains, and can provide victim impact

statements for sentencing consideration. Many states have followed the federal example by allowing the same protections for victims (Doerner & Lab 1995).

The 1984 Victims of Crime Act (VOCA) established the Crime Victims Fund of \$100 million to help provide grants to victim assistance and compensation programs (Doerner & Lab 1995). In fiscal year 2002, VOCA provided over \$93 million in victim compensation funds to the states (OVC 2003). The Office for Victims of Crime (OVC), established in 1988, now provides management for the fund, which is maintained by fines and other monies collected from federal offenders (Doerner & Lab 1995; OVC 2004). The OVC also provides training and education about victims, supports projects to improve victims' rights and services, and maintains and distributes a variety of publications about victim issues.

Information about victimization in the US can be found in a variety of sources. The Uniform Crime Report (UCR) collects crime information from law enforcement agencies throughout the country and is managed by the Federal Bureau of Investigation. The UCR collects data on crimes known to the police in two categories: personal and property offenses. Personal offenses include the violent crimes of murder, forcible rape, robbery, and aggravated assault. Property offenses include burglary, larceny, motor vehicle theft, and arson. While the UCR provides a way for law enforcement to consistently report crime data from year to year and locality to locality, there is very little information about the victim or offender (if the offender is never arrested). Also, the UCR can only report crimes made known to the police (Doerner & Lab 1995). Property crimes are more numerous than violent crimes and crime rates have generally been declining since the early 1990s. The number of violent crimes decreased 25.6 percent from 1994 to 2003. Property crimes decreased 14 percent during the same period. In 2003, about 1.38 million violent crimes were known to the police, compared to 10.44 million property crimes. This translates to 475 violent crimes per 100,000 people and 3,588 property crimes per 100,000 (FBI 2004).

The National Crime Survey (NCS) began in 1972 with a sample of 72,000 households. Each member within the household over the age of

12 was interviewed. The household remained in the sample for three years and was contacted every six months during that time. Each member was interviewed to obtain individual victimization data and one member was selected to give information about crimes committed against the household. However, this one person may not have knowledge of all crimes committed against the household (Doerner & Lab 1995). Several revisions to the NCS beginning in 1979 led to changing the name of the instrument to the National Crime Victimization Survey (NCVS). Changes included changes to the screening questions, the addition of supplemental special topic questions, and allowing for the use of the telephone to conduct interviews after the initial data gathering session were implemented. In 1992, the NCVS was further revised to capture more extensive data on rape, sexual assault, intimate partner violence, and vandalism. The NCVS now collects victimization data on rape, sexual assault, robbery, aggravated and simple assault, purse snatching/pocket picking, household burglary, motor vehicle theft, theft, intimate partner violence, and vandalism (Bureau of Justice Statistics 2002).

The percentage of households experiencing a property or violent crime as defined by the NCVS has been declining since 1994. In 2002, about 15 percent of 110.3 million US households experienced one of the NCVS measured crimes. This compares to 25 percent of households in 1994. Three percent of households in 2002 experienced a violent crime and 13 percent experienced a property crime. Theft and simple assault were the two most common offenses within each category (Bureau of Justice Statistics 2004). In terms of individual victimizations, there were about 5.5 million personal crime victimizations (this includes the violent crimes and purse snatching) in 2002. Property crime victimizations numbered about 17.5 million (Bureau of Justice Statistics 2003).

Certain demographic factors are associated with greater risks of victimization. The risk of victimization decreases with age after peaking in the 16–24 age group. The elderly (ages 65 and older) have much lower victimization rates than younger individuals (Laub 1990). Men in general are more likely to experience a violent crime than are women. Men experienced

crimes of violence at a rate of 25.5 per 1,000 persons aged 12 or older compared to 20.8 per 1,000 for women in 2002. Women are more likely to experience rape or sexual assault than are men (1.8 victimizations per 1,000 compared to 0.3 per 1,000, respectively, in 2002), as well as simple assault with minor injury (4.2 victimizations per 1,000 compared to 3.6 per 1,000, respectively). Blacks are also more likely to experience crimes of violence than other minorities and whites. Blacks had a violent crime victimization rate of 27.9 per 1,000 persons aged 12 or older in 2002, compared to 22.8 per 1,000 for whites and 14.7 for other minorities. Blacks are slightly less likely than whites to experience simple assault (14.6 victimizations per 1,000 in 2002, compared to 15.9 for whites) (Bureau of Justice Statistics 2003).

However, demographics alone cannot fully explain victimization and criminal behavior. Theories of victimization began in the 1940s with Hans von Hentig and his theory of victim-perpetrator interaction. Von Hentig observed that victims often contributed to their victimization by somehow provoking the offender or by putting themselves in situations that would make them prone to criminal acts. Ezzat Fattah stressed the link between victimization and offending and argued that the criminal act as a whole needs to be examined because of the interaction of the victim and offender. Victims can be offenders and vice versa (Adler et al. 2004).

Hindelang, Gottfredson, and Garofalo developed the lifestyle theory of crime in 1978. Changing gender roles (women working outside the home) and work schedules means that people live different lifestyles, spend varying amounts of time in public, and interact with different kinds of people. This theory is based on several propositions, including that increased time spent with non family members and in public places increases the chances for victimization. "Variations in lifestyle affect the number of victimization risks that a person experiences" (Adler et al. 2004: 223).

The lifestyle theory of crime is very similar to the routine activities approach to explaining criminal behavior and victimization. Cohen and Felson argue that a crime can only occur when there is a likely offender, a suitable target, no other person present to somehow prevent the

crime ("capable guardian"), and no "personal handler" to control the likely offender. If all of these factors come together spatially then the potential for criminal perpetration is high. Through the routine activities of everyday life – such as going to work or school, participating in recreational activities, and so on – potential victims can come into contact with potential offenders. And if no capable guardians or personal handlers are present, the chances increase that a criminal act will occur.

video games

Greig de Peuter

Video games are played via a dedicated console connected to a television (e.g., Sony's Play Station) and computer games are played on a personal computer, or PC. These two forms of digital play comprise a lucrative sector of the global entertainment complex, an immersive, simulation based interactive medium, a high profile domain of youth oriented popular culture, and a preferred leisure activity for millions of media consumers. Emerging early in the new millennium, game studies is the field of multi disciplinary scholarship devoted to the analysis of video and computer games.

The origins of digital play lie in the US military–university complex. Cold War era technologies that were intended to combat the “socialist threat” and to boost industrial productivity were turned upside down – from work to play – when, in 1962, student hackers at Massachusetts Institute of Technology created *Space war!*, one of the first computer games. This breakthrough was harnessed in the 1970s by Atari, the US corporation that led the transformation of digital play into a cultural industry. A harbinger of the “information society,” the spread of video arcades and the launch of the first home based consoles in the 1980s saw interactive entertainment suffuse cultural space, commodify “free time,” and prepare many young people for the digital age.

Combining audacious marketing campaigns and innovative game design, two video game companies with roots in Japan – Nintendo and Sega – significantly expanded the gaming audience in the late 1980s and early 1990s. Giants of information capitalism Sony and Microsoft entered the business in the mid 1990s, perceiving Internet ready game consoles as a vessel for the delivery of diverse digitalized media content into homes. Gaming meanwhile became a pre dominant use of PCs, driven especially by hardcore players of modem linked games. In the first decade of the 2000s, digital play further saturated virtual space and everyday life, with the rise of “massively multiplayer” online games and mobile phone games.

Generating higher revenues than the movie box office, video and computer games are a burgeoning cultural industry. The video game side of the industry has typically featured only three console manufacturers (i.e., Microsoft, Nintendo, Sony), an oligopolistic industrial structure that makes brand marketing aggressive. Every four years or so an upgraded generation of consoles is released, galvanizing a new cycle of game production and consumption. Increasingly hit driven, the software side of the industry has two arms: *development* involves the technical and creative labor of making games, a process that can require 50 people, nearly three years, and up to \$200 million; *publishing* involves the financing and marketing of games, a sector in which ownership is highly concentrated. The computer game side of the industry is more separately organized, because proprietary licensing agreements do not restrict what software can be made for a PC.

Kline et al. (2003) argue that the interactive entertainment industry exemplifies the technological, cultural, and marketing dynamics of production and consumption in post Fordism: perpetual innovation, intellectual property, immaterial labor, cybernetic marketing, synergistic promotion, and “experiential” commodities whose value is rapidly exhausted. Transnationally organized, the largest games companies are headquartered in the US, Europe, or Japan, but manufacturing is frequently outsourced to countries such as China and Mexico – also the emerging consumer markets for games. Games corporations deepen the global digital divide by hyper exploiting manufacturing labor, while they also contribute (driven by the compulsion of market expansion) to the formation of a world spanning game audience.

The nascent field of game studies is evolving a vocabulary and an approach through which to examine games and gaming. Scholars variously emphasize that video and computer games are storytelling media (Murray 2004), narrative spaces (Jenkins 2004), and a new art form (Poole 2000). Others deconstruct the semiotics of games, looking at how the representation in game worlds of, for example, gender and violence, reproduce hegemonic ideologies and power relations. Still others emphasize the non representational dimension of games,

specifically “game mechanics,” or the programmed set of rules and freedoms that establish the parameters of “gameplay.” The precise qualities of this medium vary widely across the diversity of game genres (e.g., first person shooter, puzzle, role playing, sports).

Surrounding digital play is a multifaceted gamer culture. The militaristic roots of interactive entertainment and consumer research led game design have etched into the culture of digital play a symbolic subjective nexus of “militarized masculinity” (Kline et al. 2003: 246–68). Game culture is, moreover, thoroughly promotionalized. Games companies have constructed a dense web of promotional media, from magazines to online forums, that not only advertises games but also monitors players’ criticisms and creative proposals; that information is fed back into the game design process, closing the loop between game production and consumption. Games are further integrated into the cross promotional weave of popular culture via synergistic marketing (Kinder 1991). There is, however, also a bottom up, participatory gamer culture, with hackers, culture jammers, artists, and activists altering the content of existing games and creating new ones through various “modification” techniques, from laying female “skins” over male avatars to “patching” anti war messages into military themed online games.

Future research on video and computer games will need to develop in three directions: (1) media theory, to grasp the particularity of this new medium, the grammar of game design, and the nature of gamers’ experience of interactivity, simulation, and virtuality; (2) political economy, to examine the cultural consequences of the game sector’s concentrated ownership structure and high intensity marketing, the intellectual property battle between game companies and game piracy, and the relation between the games sector and the military; and (3) cultural studies, to inquire into the creative labor of game development, the ideological content of game narratives, and the active agency of gamers in both the commercial and the bottom up culture of digital play.

violence

Trutz von Trotha

Violence is a form of power, of the “ability of human beings to prevail over forces which are directed against them” (Popitz 1999: 22). It is really power in action, “action power,” as Popitz says, a way of action, above all of harm, based on the power physically and materially to hurt other creatures or to be harmed. It is determined by the boundless relation of human beings with violence: the motivations for violence are so varied and numerous that they cannot be exhausted by any list. No genetic program limits the violent behavior of humans

to certain situations. Anyone can become a perpetrator and no one and almost nothing, neither human nor anything else, whatever category, is safe from victimization. Violence means to kill, to harm, to destroy, to rob, and to expel. These are the five basic forms of violence. All varieties of violence are variants and hybrids of these forms.

Among the basic forms of violence, killing stands out especially. It represents the extreme limit of violence. There is no unlimited progressive grading of violence. With killing there is *absolute* violence, an extreme limit of all social conflict, the end of dominance, power, and even sociation. As power over life and death, absolute violence is the experiential area for the idea of complete power, the source of absolute impotence, and the starting point for unlimited violent fantasies of immeasurable destruction and safe omnipotence – just as in the case of suicide, absolute violence is the source of absolute freedom. Deadly action power constitutes the antinomy of absolute power and the fact that all power of human beings over one another is imperfect. Both can become the trigger for fundamental legitimations: for the god like superiority of the killer and for unconditional opposition. The all powerful ruler is surrounded by those who attempt an assassination or a coup, become martyrs, or free themselves from the ruler's absolute power by committing suicide. They all definitively limit the power of death of the ruler. Absolute violence is present in all other forms of violence, whether openly or latently. Violence is action power within the experiential realm of the unsurpassable act of killing. These special characteristics differentiate killing from all other forms of violence.

Non lethal, physical violence is action power which leads to the deliberate physical harm of others or directly threatens this – ranging from the slap to sexual rape, from “police arrest” to torture. Unlike killing it can be graded. It is a form of sociation by way of the subordination and concretization of the other and the space of unlimited victim fantasies, in which all that is possible in powerless torment, despair, and humiliation is anticipated. In this sense physical violence belongs to the realm of lack of freedom, even when it is companion to the overthrow of more or less unfree political and social orders. As concerns the victim, the act of

killing is pure action power. Consequently, “binding action power” (Popitz 1999: 47), which creates lasting instances of power and relations of domination, is in the case of killing only for the survivors. By contrast, physical violence can become binding action power both for others and for those who are struck by physical violence.

Absolute violence and physical violence are both aimed immediately at the body, at the natural vulnerability and mortality of human beings. Therefore, notions and ideas of natural superiority and inferiority are typically associated with these forms of power – in the direct assault on the essential nature of human beings, absolute and physical violence seem to be a part of nature itself. Together with the threat of death and violence, they both as a rule stand at the beginning and end of centralized rule and of the state in particular. At the same time they are included among the most reliable guarantees for domination and its institutions of political and administrative rule.

Destructive violence and robbery are aimed at materially damaging others. It is a question of the property of others. If destructive violence – ranging from vandalism, the numerous strategies of anti guerrilla struggle, and the “fight against terrorism” to a scorched earth policy and carpet bombing – is the deliberate physical destruction of the property of others, then the armed robber or mugger, plunderer or raider uses or threatens to resort to physical violence when stealing others (e.g., slave raids) or when depriving them of their material goods. Unlike the case of destruction, which may indirectly lead to the acquisition of the property of others or of a territory, robbery is an immediate source of enrichment.

Expulsion, especially as a collective act, is typically accompanied by all the forms of violence mentioned hereto, and may be considerably determined by the aim of enrichment. Unlike robbery, it is a case of membership – the violent or threatened violent exclusion of people beyond the physical boundaries of a social unit. In expulsion, the protagonist forces others to abandon their “house and home,” their physical living space, whether it is a building, a neighborhood, or even a state territory. As in the case of killing, expulsion is notice to quit a society; however, unlike killing, this notice to

quit is not absolute and is therefore in principle reversible.

Death and physical suffering, destruction of house and home, abduction, kidnapping and material loss, flight and loss of country and home town are, together with all the psychic, mental, emotional, social, and symbolic harms which always accompany them, the physical and material wounds which violence imposes. The five basic forms of violent action power are the essential and non extendable core of the concept of violence. The core consists of the fact that violence is not a structure but an act of power, typically and particularly in the case of collective violence combined with other forms of violence. Death, complete power, complete impotence, and physical harm throw a shadow on all forms of violence.

In the lengthy discussion which is still going on today about the concept of violence, on the one hand the long tradition of political philosophy is continued in which power and violence are seen as opposites (Arendt 1970). On the other hand, the signification of the concept of violence has either been covered over by other more general concepts or extended to become unrecognizable. Together with the concept of aggression developed in ethology and above all in psychology, the concepts of structural, cultural, and symbolic violence have proved themselves to be the longest lasting and most successful, and have been joined also by the concept of psychic violence (Nunner Winkler 2004). Analytically, the problematic nature of these concepts lies in the fact that the connection to the above named forms of violence is lost. As a result, the sharp distinction between the numerous forms of inequalities, stigmatizations, and processes of exclusion and psychic mistreatment are lost. This emphasizes all the more the fact that the concept of violence is in particular evaluatively and normatively loaded, that it lies at the heart of the constitutive need for legitimation by power and violence, that it is an important part of legitimation discourse in political and social struggles and moral crusades, and that the idea of what violence *is* is historically interculturally and intraculturally highly variable.

In general, in sociological theory until very recently violence and especially war were neglected. Violence is one of the preferred topics

of the sociology of deviance, criminality, and social problems. The latter and the sociological mainstream research into violence are first and foremost *aetiological* research into violence and have a close link to cycles and fashions of the discourses of violence and social and criminal policy. They investigate the conditions under which violence is more likely to occur, whereby the explanation for violent criminality as individual behavior and its aggregation in the form of rates of crime are foregrounded. In the sociological aetiology of violence the main emphasis is on sociostructural and institutional relations and macrosociological processes of change. Anomie, poverty, social segregation, and marginalization belong here; social groups and subcultures, social opportunity structures, family relations, socialization, and education processes no less so than general social processes of economization, individualization, and social disintegration. Among the most influential theories in which violent crimes are topicalized as one of the many forms of criminality are the unchanged continuations of classical sociology, such as anomie theory, the theory of legitimate and illegitimate opportunity structures, and the theory of subcultures. In the 1980s and 1990s control theories – where not so much criminal behavior as conformity is seen to require explanation – and the macrosociological theory of individualization and social disintegration attracted a lot of attention. With the rise of neoliberal economic policy and its driving force in the field of criminal policy, aetiological theories and research were challenged by utilitarian theory on the basis of the general theory of rational choice, which understands criminal behavior to be the result of a cost benefit calculation. However, its reliability is treated with some skepticism. This is particularly true in the case of violent crime (Albrecht 2003).

An impressive number of analytical dimensions have shown themselves to be fertile, ranging from learning processes within the family and peer group to the transformation of whole political systems, societies, and cultures. They reflect the change in prominent incidences of violence, such as the change in public discourse about violence. Included here is the rise in civil wars, violent ethnic conflicts, terrorism, and (especially in Europe) right wing extremist violence, as well as the “rise of the victim,” where

the traditional focus on the perpetrator has been abandoned in favor of the victim of violence. An enormous amount of literature has been published about violence towards children, in heterosexual partnerships, against gays, lesbians, bisexual, and transsexual victims, in the family, at school, at work, and in road incidents. The gender theory of violence is one of the most politically influential and one of the most interesting discourses for the theory of violence and attempts to provide an answer for the fact that three quarters to 99 percent of those suspected of having committed violent crimes are men: violence is primarily a male phenomenon. With the theory of patriarchy, men's studies, and gender focused socialization theories, gender theory has taken a prominent place in the theory of violence and research into it. However, insofar as the one neglects the homosocial dimension of male violence, the others are primarily deficit theories of male violence, and attention is increasingly focused on the double distinction and dominance logic of doing masculinity: masculinity and violent masculinity in particular are established by men who set themselves apart from women, as well as from other men (Meuser 2002).

All in all, there arises from this diverse research the picture of a present in which violence is not only omnipresent but in western societies (not least as a result of scholarship and social movements) is also perceived to be all pervasive. As political violence, violence seems to have given up its utopian revolutionary character and can hardly be linked with a demanding western concept of politics. On the contrary, it asserts the claims of identity, belonging, and exclusion and is used as a strategy for escalation in the pursuit of power and recognition. It is a seismograph for growing social inequalities, especially as far as the segregation of the job market and housing are concerned. It is "individualized" insofar as, on the one hand, it displays the loss of social bonding forces, and on the other, the extremely varied extent of individual ways of coping with social problems. It is, however, mainly a violence which is anchored in extremely multifaceted social conditions and processes and consequently contradicts all the more the "thematization traps" (Heitmeyer & Hagan 2003) into which science and public discourse regularly

fall: the pitfalls of "reinterpretation" (i.e., of framing violence as an individual or social pathology or as a biological, genetic deficiency), the pitfalls of reductionism, "inflation," "moralization," and "scandalization," and the latter's uneven sister, the "normality trap."

In addition to the many levels of analysis, a pluralism of methods and a lively pleasure in experimentation and methodical imagination (which happened with the Chicago School at the beginning of sociology and of the sociology of deviance and crime in particular) are now enjoying a new heyday (Heitmeyer & Hagan 2003). In quantitative research the analysis of criminal statistics and research by means of questionnaires remains dominant. In the context of the former, the historical comparative research of criminal statistics is particularly relevant (Thome 2004). In Europe they show a U shaped curve for homicide: a clear decline in the homicide rate from the fifteenth century to the middle of the twentieth century, followed by another rise since the 1960s, which would appear to be long term. The theories of Elias (2000) compete with those of Durkheim (1951, 1957) as the most appropriate explanation for this development. Elias traced the process of civilization to the relationship between the state monopoly of violence, growing interdependence, corresponding control by others, and self control. While Durkheim saw the civilizing force in the complex differentiation and individualism of modern society, he also had a clear vision of the anomic side of the latter, which is taken up by the current prominent theories of individualization and disorganization. The use of questionnaires has continued, especially in the field of research into hidden crime, in spite of numerous methodological hurdles, including the over or underestimation of violent criminality as a result of too small chance random samplings.

Qualitative methods of all kinds are predominantly used where little is known of the environments and cultural connections of the violent actors, either as individuals or as a collective, and for the reconstruction and analysis of subjective and collective meanings of violence, the way of life of violent protagonists, and the processes of violent interaction. An ethnography of violence has developed here for which ethnographic journalism (Buford 1991) and especially

war reporting play an important role – it is still one of the most difficult and yet most banal methodological problems of research into violence that the immediate, academic observation of violence rarely occurs and is limited to a few forms and contexts. The Milgram experiment is a striking example of this: it still offers rich insights today (Blass 2000) and at the same time raises far reaching ethical research questions.

As for the future development of violence and its discourses, six circumstances deserve particular attention: the decline of the state, the rise of terrorism and asymmetrical war, the multiplication of basic conflicts of belonging, the increasing connection between religion and violence, the pleasure in violence, and the triumphant advance of the victim. Nowadays it seems that the triumph – anchored in colonialism – of the modern western state, characterized by the monopoly of violence, in many parts of the world is rather more formal than substantial. The modern state as welfare state is under pressure even in western societies. Violence, which arises from the many precarious forms of statehood, and which is connected with the decline of the state, its transformations, and accompanying inequalities underlines the fact that the sociological problem of violence is again to be conceptualized as it was analyzed by Thomas Hobbes, Arendt, and Popitz: as a problem of order which violence both endangers and creates and guarantees, and is therefore not exclusively the domain of specialized sociologists, as is the case with the sociology of crime or of social problems. The problem of violence lies at the heart of general sociology and in particular of the sociology of power. The sociology of violence is an intercultural, comparative, historical, and political sociology of the “forms of order of violence” (Hanser & von Trotha 2002). It is a sociology of institutions, rules, meanings, perceptions, and emotional patterns, which determine how societies and cultures deal with human violence; the most important and significant among them are the political systems of rule which, as Hobbes and other political philosophers have argued, are answers to the question how people can protect themselves from violence.

They are at the same time cause as well as product of the decline of the state and

increasingly determine the appearance of and the discourses about violence (Schwab Trapp 2002): basic conflicts of belonging where – in the shape of ethnic, religious, and racist conflicts – membership is denied and groups of people, determined by category, are violently excluded, raped, and destroyed (Wimmer et al. 2004), terrorism, and asymmetric war (Münkler 2002). With the war in the Balkans and the 9/11 attacks on the World Trade Center and the Pentagon, war has returned to Europe and the territory of the US. This has given rise to a rapid increase in research into and publications about these phenomena. It has led the sociology of war to gain a certain and hitherto unknown momentum, and contrary to the aetiological mainstream analysis of violence sociologists and anthropologists have begun to highlight that violence is not a structure but a process of interaction and escalation (Elwert et al. 1999). This is particularly true of the sociology of the asymmetric war, which in the shadow of atomic and conventional war (which itself has developed a historically incomparable potential for destruction) has become the main form of war with the greatest losses, chiefly among the civilian population. The rise of the asymmetric war has hardly foreseeable consequences for international order, foreign and domestic policy, law, and the constitution of the societies concerned. The latter include developments toward the disappearance of the traditional modern division between war and crime, and the commercialization of war.

The growing link between religion and war can be seen in many violent and war like conflicts – the conflict between Israel and Palestine, the global small war of al Qaeda, and the legitimization of preemptive war by means of Christian fundamentalist missions and eschatologies by evangelical movements in the US (Armstrong 2000). It will probably pose the greatest challenge for international order, policy, culture, and society, as well as for sociology. In Europe and in sociology rooted in the modern European world, where modernization equals secularization, it is particularly difficult to face up to this challenge theoretically and empirically.

What is almost as inaccessible for this western self image is the return of pleasure in violence. Violence is action and like sexuality it is the epitome of sensual experience – the pleasure of emotion, excitement, and physical

experience, the immediacy of the moment, an escape out of the mundane into the freedom of power and the now, the appetite of youthful masculinity and of action. The pleasure in violence is a powerful element of any social order. Elias's theory of civilization is one of the most influential, contemporary social scientific theories about such pleasure. It is a sociology of power arguing that by means of the monopoly of violence and the extended chain of actions made possible by it, the pleasure in violence is removed from the members of the modern state in their daily lives; it is "civilized." However, opposing developments are too evident to enable the analysis of Elias to be continued. In asymmetrical wars and violent, ethnic, and religious conflicts, the pleasure in violence has become a cult of unchained cruelty. Even in western states the pleasure in violence is still present in various forms: in the subcultures of misery and every day violent criminality in the French "quartiers d'exil" (Dubet & Lapeyronnie 1992), in the inner city areas of the American equivalent, in networks of organized crime, the subcultures of prostitution and child pornography, the youth subcultures of the German "Skins," "Hools," or "Autonomous" and their soulmates in other European and non European countries. These phenomena are only the most obvious. They require a phenomenology and ethnography of violence. In the German speaking sociology of violence, such a debate is being held between "mainstreamers" and "innovators" (Imbusch 2004).

The rise of the culture of the victim goes together with a rise in the discourse of the victim, in which empathy and identification with the victim are self evident. The fact remains that the culture of the victim nowadays is becoming increasingly a source for the legitimization of violence, revenge, and extensive claims to security. The world of armed conflict is determined by a discourse pattern of accusation and self pity; the more irreconcilable, the more demanding and righteous it is, the more violent the action power becomes. The everyday, political side of this discourse is a discourse of criminalization, punishment, and revenge by the actual or potential victims of violence (Waldmann 2003). It is directed at "security" – above all at the *sense* of security – and against all actual or potential "perpetrators of violence" that can be

imagined by the fertile imaginations of the victims. Its protagonists are a mixed bunch whose social space extends from workers to academics, from police associations and political parties to the society for the protection of minors, workers in women's safe houses, and feminist movements. Its "successes" have radically changed the reality of North American criminal law in particular: the merciless execution of the death penalty, a policy of incarceration which has meant an all time high rate of imprisonment in the US, the return of public humiliation, and the ritual exclusion of sex offenders (Wacquant 1999). While Europe has until now largely opted out of this development, the discourse of the victim in connection with the problems of dramatically increasing social inequalities and social exclusions, of terrorism and organized crime, has however provided influential justification for the dissolution of classic legal principles. Once again it makes the Janus face of violence only too clear: it looks upon order and disorder; and in the face of order it can become a threatening grimace.

violence among athletes

Kevin Young

Aspects of violence among athletes, including behaviors encompassed within the rules as well as outside the rules of sport, have traditionally been condoned in many settings as "part of the game." This is witnessed in the way that aggressive, high risk, or injurious practices that would be socially and/or legally intolerable apart from sports are encouraged and expected to occur in connection with sports. Further, in many countries, sport is immersed in fervent *cultures* of aggression that may serve to compromise participant safety and limit the possibility of change. Such cultures may also have influenced sport scholarship, since sociologists have paid far less attention to violence among athletes than to violence among fans.

Most sociologists agree that while there is no single cause of violence among athletes, understanding the phenomenon requires examining socialization processes associated with many sports and, indeed, with the institution of sport in general, where athletes learn from an early age that behaviors such as hitting and being hit, and conceiving of violence as a vehicle to resolve conflicts (Coakley 1989), are acceptable and easily rationalized. Combined with an emphasis in many commercialized sports on heroic values, physical dominance, and winning at all costs, thinking and behaving aggressively is simply part of the learning that individuals and groups undertake in sport. Violence among athletes is one outgrowth of this learning.

Several typologies of player violence exist, but one of the most popular and useful comes from Canadian Michael Smith (1983), who classified violence among athletes into four

categories, the first two being relatively legitimate and the last two relatively illegitimate in the eyes of sports organizations and the authorities. *Brutal body contact* includes ordinary occurrences such as tackles, blocks, and body checks – acts that can be found within the official rules of many sports, and to which most would agree that consent is given or implied. *Borderline violence* involves acts prohibited by the official rules of a given sport but occur routinely and are more or less accepted by persons connected with the game (e.g., the fist fight in ice hockey). These actions carry potential for causing injury as well as prompting further violence between players – such as, in ice hockey, the bench clearing brawl. Historically speaking, sanctions imposed by sports leagues and administrators for borderline violence have been light and often tokenistic. *Quasi criminal violence* violates the formal rules of a given sport, the law of the land, and, to a significant degree, the informal norms of players. This type of violence usually results in serious injury that precipitates considerable official and public attention. Quasi criminal violence in ice hockey may include practices such as dangerous stick work, which can cause severe injury, and which often elicit in-house suspensions and fines. Finally, *criminal violence* includes behaviors so seriously and obviously outside the boundaries of acceptability for sport and the wider community that they are handled as exceptional, and possibly unlawful, from the outset. Consequently, it becomes possible to conceive of violence among athletes as sports “crime” (Young 2002). In depth assessments of how sports violence and sports injury cases are adjudicated by the courts, and the sorts of legal defenses available to prosecuted athletes, have been advanced in a number of countries (Harrow 1980; Gardiner et al. 1998; Young 2004).

Smith’s sociolegal approach is useful, but it has two limitations. First, prompted by shifting scales of public and legal tolerance since approximately the 1970s, there has been some “collapsing” of his categories. For example, incidents considered ten years ago as “quasi criminal” or even “borderline” violence may today be brought before the courts and scrutinized seriously under law as “criminal” sports violence. In this connection, while Smith’s typology addresses the important sociological

question of the “legitimacy of violence” – that is, the legitimation/delegitimation process with regard to what is perceived as acceptable violence and what is not (Ball Rokeach 1971) – it requires updating to fit a dynamic sociolegal climate (Young 2004).

Second, Smith’s typology overlooks the way in which aspects of violence among athletes may result from gender processes. Feminist work on sport and gender (Bryson 1987; Theberge 1997) allows us to understand male tolerance of risk and injury linked to aggression and violence in sport as a constituting process enhancing masculine or subcultural identity. In this respect, playing sport in a hyperaggressive way and causing or incurring injury are means of establishing positive status and career success in the form of reputational and/or material benefits. How strongly hegemonic codes of masculinity insert themselves into different sports and sports cultures varies, but it is clear that numerous sports contain “patriarchal dividends” (Connell 1995: 79) for males who are willing to “sacrifice their body” in violent ways in order to win. However, research on the masculinization of player violence is complicated by the fact that studies demonstrate that many female athletes also revere risk and the use of aggression (Rail 1992; Young & White 1995; Theberge 1997). Female involvement in high risk, aggressive, and violent sport values thus suggests that sport socialization may be more important than gender socialization but, on this important question, far more research is needed.

A trend toward the assessment of “sports related violence” in its broader context is evident in the way that sociologists have recently expanded their conception of “violence among athletes” to encompass actions away from the field of play. Included here are “rape cultures” that pervade locker rooms, abusive initiation (“hazing”) practices, and athletes (professional and amateur) involved in domestic violence, partner abuse, as well as crimes of violence in the wider community. Such cases have not traditionally been viewed as “violence among athletes,” but clearly, they are potentially abusive, injurious, or otherwise unlawful practices, performed with some consistency by athletes, that cannot easily be separated from the sports process and that only begin to make sense when the socially embedded character of sport is

closely examined. Strong gender effects are visible here too, for while female athletes certainly participate in disturbing hazing rituals (Bryshun & Young 1999), it is clear that athletes involved in misogynist locker room cultures (Curry 1991) and acts of domestic violence and "street crimes" are predominantly male (Crosset et al. 1995; Benedict & Klein 1997). Fascinating questions of the interface between hegemonic sports codes (competition, winning, dominance, etc.), hypermasculinity, poverty, and race are thus raised but remain, to this point, largely unanswered.

The literature on violence among athletes is not new, but it remains limited. First and most importantly, sociologists have not exercised care in definitional and conceptual matters. *Aggression*, which most people would accept is a normative (though not necessarily agreeable) feature of many sports, is not the same thing as *violence* itself, which is often vaguely conceived of as the "unwanted" version of the sorts of aggressive behaviors and attitudes many sports simply require. Unraveling such definitional quandaries is important, though this is admittedly complicated by varied sport specific traditions where the definition of "wanted" and "unwanted" behavior is concerned.

After a hiatus in the late 1980s and early 1990s, sociolegal work on the relationship between sports violence and the law is being revitalized. Cross cultural comparisons of official responses to violence among athletes have not been made available to date. From a burgeoning literature, we know something about the relationship between violence, injury, and pain, but more information is needed. Because the bulk of this research has focused on the experiences of men, studies of risk taking, physicality, and injury among girls and women are again required, especially in light of evidence from some countries that, as opportunities open up, females are increasingly turning to aggressive, traditionally male defined sports such as rugby, ice hockey, boxing, and martial arts.

After years of research on the sports violence/media nexus, an impressive body of material has been amassed on coverage styles, but the question of "media effects" remains prickly, and the ways that audiences deconstruct and are impacted by mediated sports violence remain uncertain.

Finally, very little is known about forms of *sports related violence* that occur away from the field of play – the involvement of athletes, as victims or offenders, in practices such as hazing, abuse, and street crime. A recent shift by sociologists of sport in this direction, coupled with increasing media attention to and public awareness of athletes behaving badly, will expand knowledge of these additional dimensions of violence among athletes.

violence among fans

Kevin Young

Multiple definitions of fan violence exist in the sociology of sport. Some are limited to specific behaviors, such as hand to hand fighting or acts of vandalism, or to violence committed in the context of a particular sport, whereas others are more expansive. Because research shows that the phenomenon is diverse, the latter definitional approach is more useful. Therefore, *violence among fans* is best understood as involving direct or indirect acts of physical violence by sports spectators, at or away from the sports arena, that result in injury to persons or damage to property.

Unlike acts of violence among athletes, violence among fans elicits anxious responses from the authorities and often is closely policed. The occurrence of numerous injurious, and several deadly, crowd episodes has sensitized the public and social controllers to the need for careful regulation of sports crowds. In many countries fan violence is seen as a serious social problem, and strict measures, including new laws, have been introduced (Young 2000, 2002). Fans of British and European soccer have certainly

gained notoriety for their violent rituals and practices, but, in fact, violent crowd disturbances occur regularly worldwide. Many sports have been affected, some more consistently than others, and some perhaps more surprising than others. These include, but are not restricted to, baseball, cricket, ice hockey, boxing, horse racing, basketball, American and Canadian football, rugby, and, of course, soccer. It is equally apparent that violence among sports fans has a long history (Guttmann 1986).

Most sociological research has focused on forms and causes of British soccer hooliganism. In step with a popular, but not necessarily accurate (Dunning et al. 1988), perception that hooliganism began in the 1960s and 1970s, and with several tragic episodes resulting in multiple injuries and deaths at soccer games, especially in the 1980s, the literature expanded rapidly during this period, though it has diminished of late. The debates between scholars on this issue have been complex and occasionally fractious, but certain strands within this research may be identified.

One of the initial explanations of hooliganism was social psychological. Building on Tiger’s (1969) controversial study of aggression among *Men in Groups*, and on presumptions of the “need” for male bonding, Peter Marsh et al. (1978) developed the “Ritual of Soccer Violence Thesis” following observations at Oxford United Football Club. Employing a so called “ethogenic method” to explore the organization and motives of hooligan fans from an insider’s point of view, Marsh et al. conceptualized aggression as a means of controlling the social world in the process of achieving certain outcomes. Therefore, fan violence at soccer matches was viewed as a cultural adaptation to the working class environment for male British adolescents – a “ritual of teenage aggro.” The contention that hooliganism is largely a ritualistic “fantasy” of violence has been severely criticized, especially for failing to explain the regularity of serious injuries at soccer games, and offering superficial explanations of the social class background of participants. There *are* ritualistic elements to soccer “aggro” in Britain and elsewhere (for instance, many of the crowd chants and gestures, and even aspects of intergroup provocation, are certainly ritualistic), but to argue that the essence of hooliganism is ritualistic, and that

actual violence seldom occurs, raises doubts about the potential of this approach, particularly when hooligan encounters have been widely reported, routinely injurious, and occasionally fatal.

In the 1970s and 1980s, Marxist criminologist Ian Taylor (1971, 1987) offered a macrosociological and class sensitive account of soccer hooliganism. For him, hooliganism was associated with two different phases in the development of the British game and of British society more generally. First, Taylor looked historically to the emergence of soccer in working class communities, and to the disruptive effects of commercialization on the game. Commercialization, he argued, fractured a formerly rich "soccer subculture" that weaved its way through such communities. Practices such as the invasion of playing fields and vandalism were interpreted as attempts by the remnants of this subculture to reclaim a game that had become increasingly removed from its control. In the 1980s, and clearly moved by the tragic events of the 1985 Bradford fire and Heysel Stadium riot, as well as the 1989 Hillsborough Stadium crush which resulted in the deaths of dozens of innocent lives (Young 2000), Taylor revised portions of his earlier thesis to argue that contemporary manifestations of soccer hooliganism could better be understood if placed against crises of the British state. Specifically, he argued that increasing dislocation within working class communities and the development of an "upper" working class jingoism (or "Little Englanderism") during the tenure of Prime Minister Margaret Thatcher's Conservative rule exacerbated Britain's hooliganism problem, and helped fuel a long sequence of xenophobically violent exchanges between fans of English club teams and of the English national team abroad and those of teams from other countries.

While sensitive to questions of history and social class, Taylor's work has been criticized for "romanticizing" any real "control" working class fans may ever have exerted over the game during its early phases, for ignoring very early "hooligan" encounters (during, for instance, the early twentieth century and alleged "soccer consciousness" phase), and for misidentifying the majority of hooligan fans as "upper" (and thus more affluent and resourceful) working class. The fact that Taylor's ideas, while

provocative, were never based on any acknowledged empirical protocol has not helped their durability, though his attempts to offer a form of "social deprivation thesis" have certainly influenced subsequent North American accounts of fan violence (Young 2002).

Taylor's Marxist views on dynamic class culture and on the development of the British game were echoed at approximately the same time by several writers at the Center for Contemporary Cultural Studies at Birmingham University, England where, once again, soccer hooliganism was viewed as a reaction by working class males to commercializing processes, such as the increasing presentation of soccer as a market commodity, emerging in what had traditionally been construed as "the people's game." Examining deep structural changes in working class communities, Clarke (1978) and others added a strong subcultural/ethnographic component to their class analysis, allowing them to explain the presence in the 1960s and 1970s hooligan "phases" of flamboyant skinhead groups combining traditional working class values (such as the fierce defense of local and national identities, and love of football) with interests in commercial youth style. Relating soccer hooliganism to the context of a culture in flux is a helpful framework of analysis, and the sociohistorical approaches of Taylor, Clarke, and others certainly offer considerably more explanatory insight into a complex social problem than the microsociological ventures of Marsh et al. However, as with Taylor's early work, Clarke and colleagues actually produced little concrete evidence to support the argument that hooliganism was a response to changing working class traditions and values. Stability of working class social relations in an allegedly "hooligan free" past (i.e., in the pre 1960 era) is a view that both parties tended to assume too uncritically – this, again, has not gone unnoticed by critics.

A group of sociologists at the University of Leicester (Dunning et al. 1988) have been interested to examine the "social roots" of British soccer hooliganism. Unlike Marsh and Taylor, however, the Eliasian/figurational work of the Leicester group is grounded in extensive comparisons of the phenomenon in its past and present contexts. Principally, Dunning and his colleagues argue that aggressive standards of behavior displayed by soccer hooligans are

directly influenced by the social conditions and values inherent in the class cultural background of those involved.

A predominant theme of their work, and one which represents a direct counterpoint to Taylor's "Little England" thesis, is that hooligan groups are largely comprised of individuals from the roughest and lowest (rather than "upper") sectors of the working classes. They argue that the hooligan's relatively deprived social condition is instrumental in the production and reproduction of normative modes of behavior, including strong emphases on notions of territory, male dominance, and physicality. It is precisely the reproduction of this social condition that is seen to lead to the development of a specific violent masculine style manifested regularly in the context of soccer. Notions of dynamic territoriality are also offered which allow the Leicester researchers to account for the shifting allegiances of fan support (and thus shifting expressions of fan violence) at local, regional, and international levels. While there are several unique features to the ideas of the Leicester "School," perhaps the most important is the adoption of a long term Eliasian view regarding the development of soccer hooliganism, which allows them to demonstrate that forms of spectator disorder have existed for over a century. The Leicester research has been heavily influential in Britain and internationally, both within the academy and with policymakers.

As comprehensive as these four approaches are, they do not represent the full spectrum of work available on fan violence in the UK. Other studies which have contributed to the "hooligan debate" include, but are not limited to, Murray's (1984) social history of religious sectarianism in Scottish football, Robins's (1984) accounts of the intersections between soccer violence and the popular cultural interests of young British men, and studies of soccer, violence, and gender in Ireland (Bairner 1995).

This impressive volume of research on soccer hooliganism has not been matched elsewhere, despite the known existence of problems with violence among sports fans. In North America, for instance, where there is clear evidence of fan disorders (Young 2002), remarkably little sociological work has been tendered. The work that does exist is neither as thorough nor as theorized as the British work. Notwithstanding several

notable attempts (Smith 1983) to explain North American fan violence in terms of its social causes, there seems to be a general reluctance on the part of researchers to take the phenomenon seriously, and far more work is needed. Indeed, despite the fact that the bulk of the research on violence among fans relates to transatlantic contexts and experiences, many countries where organized sport is played and valued have recorded problems with fan violence at one time or another. Regrettably, however, the research, and especially that portion of it written in or translated into English, remains slim, and there are no clear ways of classifying or categorizing this work into thematic "schools" or coherent bodies of theory.

Janet Lever's (1983) work on fan violence associated with Brazilian soccer set an early marker for the international research. Using a structural functionalist approach, Lever sought to show how sport in South America can represent both unifying and divisive properties – unifying in the sense that it may enhance community awareness and loyalty, but divisive because it underlines social class distinctions. Fan violence, she argues, is but one side effect of failed attempts by the Brazilian authorities to deal with poverty and such class distinctions – soccer stadiums have often been used as a venue for the expression of class conflict such as missile throwing from the "poorer" stadium sections into the "richer" sections. Arguably, Lever's functionalist approach cannot easily account for these tensions and her study is now outdated, but it nevertheless represents groundbreaking sociological work on fan violence in South America. A more contemporary account of fan violence in this context may be found in Archetti and Romero (1994).

By now, most serious students of sports violence understand that the argument that soccer hooliganism is a "British Disease" is a myth. In their early figurational studies, Williams et al. (1984) unearthed over 70 reports of fan violence at soccer games in 30 different countries in which English fans were not involved between 1904 and 1983. Slightly later, Williams and Goldberg (1989: 7) identified numerous cases of hooliganism where English fans were, in fact, the "victims of foreign hooliganism" rather than the assailants. Today, cases of fan violence in diverse international contexts are routinely

reported in the popular media and over the Internet.

Notwithstanding cultural variance in the nature and extent of fan violence, evidence indicates that soccer hooliganism expanded throughout the 1980s in a number of European countries. A considerable European research literature also emerged at this time. Greece, France, Spain, Belgium, Austria, Sweden, the Netherlands, Germany, and Italy are among countries known to have experienced significant problems with soccer hooliganism (Young 2000: 389). In many of these locations, fan violence has been shown to intersect with far right wing politics and racist ideologies, demonstrating a clear sociological link between problems in sport and those in the wider society.

While care must always be taken to differentiate between injuries caused by intentional fan violence and those caused by "accidental" crowd surges or stampedes prompted by such things as over ticketing, negligent policing, or stadium collapses, in terms of total numbers of injuries and fatalities, some of the most serious cases of injurious and fatal fan episodes have occurred in South and Central American locations. For example, a by now well known riot broke out at the National Stadium in Lima, Peru in May 1964, resulting in over 300 deaths, and in another notorious case of soccer related violence, a so called "Soccer War" lasting several days was waged between Honduras and El Salvador in the summer of 1969 following a game played between the two countries. More recently, 83 people were killed and over 150 others injured in a stampede linked to the distribution of forged tickets at a 1996 World Cup qualifying game held in Guatemala City (Young 2000: 389).

Violence among sports fans is a multidimensional and complex topic that has generated a huge volume of research on matters such as causes, manifestations and responses, and media coverage, but this research shows serious imbalances. For example, while there seems little doubt that the most substantial and rigorously theorized body of work in this area has examined forms and causes of British soccer hooliganism, relatively little is known about fan violence in other parts of the world. Again, this is true of North America, for instance, where the phenomenon is acknowledged by

sports organizations and authorities alike, but where, with only a few exceptions, much of what we know comes from descriptive and often less than reliable media accounts (Young 2002).

The portion of the research on fan violence summarized here underlines the importance of approaching the topic in ways that respect a historically informed sociology of cultural practices like sport. Culture is important because the often heterogeneous manifestations and meanings of fan violence develop in distinct ways in distinct places, as we can see from the varied manner in which fans from European countries differentially aggress at soccer games (Williams & Goldberg 1989). History is important because these manifestations and meanings always emerge from prior social arrangements, as the work of the Leicester School ably demonstrates. And, a sociology of fan violence is critical because, far from existing in a vacuum, the actions and practices of unruly sports fans coexist relationally with wider social institutions and processes, as can be witnessed by the deeply gendered character of fan violence, which remains a predominantly male activity. Again, cultural differences exist in this regard.

Finally, part of the complexity of explaining fan violence concerns the methodological fact that it is not easy to study. As with other aspects of crime and social "deviance," while outlining the main behavioral components of the phenomenon is relatively uncomplicated (we know how fan violence is *done*), detailing its causes, extent, and nature is not. This is particularly the case where fan violence is not restricted to one sport or one level of sport (Young 2002). Understanding the causes, extent/nature, and motives and meanings of fan violence requires careful and committed research that must overcome familiar problems of access, "entry," and reliability. To this point, the British research stands out as that body of work that has most consistently tackled these dilemmas, but the continued existence of violence among fans in other countries surely means that others must follow suit in due course.

violent crime

Rosemary Gartner

In popular discourse, violent crime is the intentional, malicious physical injury of one person by another, with assault, rape, and murder being obvious and apparently uncontroversial examples. In legal discourse, violent crime is behavior that leads to particular legal procedures and is thereby legally sanctionable. Here violent crime is constituted by legal reactions, not by characteristics inherent in behaviors or people. Legal definitions may appear precise and objective, but because they are created and applied through social and political processes, legally defined violent crime is historically and socially constructed. Social scientists acknowledge this but typically rely on legal definitions to delimit the violent acts they study (Jackman 2002).

Documenting and explaining the distribution of violent crime across time, place, and persons are the major tasks of those who study it. Most nations and sub national jurisdictions compile reports on crimes known to police, which include information on accused, victim, and incident characteristics. There are two principal limitations to these official statistics. First, because legal definitions of even serious crimes vary across time and place, official statistics may not accurately measure differences in the prevalence of violent behaviors across societies or over time. Second, because characteristics of the legal agencies that collect information on crime influence how acts are interpreted and reported, official statistics do not accurately measure levels of violent crime even within a single society. Some violent acts that fit legal definitions are subject to criminal enforcement less often than others. For example, in most nations, well under half of physical and sexual assaults are reported to police (Nieuwebeerta 2002). Since authorities learn about violent crime primarily from the public, popular views on the seriousness of particular violent acts, as well as perceptions of the legitimacy of legal officials, also influence which acts are reported. Official statistics on violent crime therefore underrepresent its true prevalence.

Unofficial data sources, such as general population surveys, avoid some of these problems by

providing information on violent crimes not known to officials. Victimization and self report surveys, which ask people about their violent victimization and/or offending over a specified period, yield higher estimates of the prevalence of violent crime than do official statistics. Victimization surveys also show that the likelihood that violent crimes will become known to officials depends partly on their severity, as well as on characteristics of victims, offenders, and the relationships between them. However, because victimization and self report surveys rely on the honesty, memory, and perceptions of respondents, they have their own limitations and biases.

Is there more violent crime today than in the past? The most reliable historical evidence comes from Western Europe and North America, where trends over the last six or seven centuries have been downward, albeit punctuated by short term crime waves (Eisner 2003). This decline reversed somewhat in North America and Western Europe in the 1970s and in Eastern Europe in the 1980s, when violent crime rates rose dramatically. Nevertheless, interpersonal violence has become a much less customary part of daily life over the long term.

Are some societies more prone to violent crimes? Data from victimization surveys and public health records suggest that rates of lethal violence vary greatly, even among similar societies (Nieuwbeerta 2002). For example, homicide rates are about three times higher in the US than in Canada and four times higher in Venezuela than Chile. Countries in Northern Africa and the Middle East appear to have lower rates of serious interpersonal violence, as do many Asian countries. Interestingly, rates of sub lethal and lethal violence do not correlate highly: countries with high homicide rates do not consistently have high rates of assault and robbery (Zimring & Hawkins 1997).

What social processes, conditions, or policies affect rates of violent crime? The centuries long decline in violence in the West was likely due to the expansion of state powers, the Protestant Reformation, and the rise of modern individualism (Eisner 2003). In contemporary societies, homicide rates are higher where inequalities in income and wealth are greater and where there are few restrictions on the

ownership and use of firearms. Some of the factors commonly thought to affect violent crime (e.g., urbanization, unemployment, or the death penalty) do not, in fact, appear to do so.

Are some people more likely to be involved in violence? Serious violent crimes tend to be the domain of young, economically disadvantaged males virtually everywhere (Reiss & Roth 1993). Most violent offenders have criminal records, but few specialize in violence. Victims of violent crime, with the exception of rape victims, generally share many characteristics with their victimizers (i.e., they also tend to be young, economically disadvantaged males). Females are more likely to be victims than offenders; most female victims are attacked by males they are related to or are intimately involved with. A substantial proportion of violent crimes occurs among relatives or persons well known to each other, though this proportion is smaller in the US than other countries, and has been declining.

Most sociological explanations of violent crime focus on one of three levels of analysis: the individual, the situational, or the structural cultural (Sampson & Lauritsen 1994). Individual level analyses look for characteristics that predispose or fail to discourage people from violence. Situational approaches attend to the context and processes immediately surrounding violent events, such as the nature of the interaction among participants and the presence of weapons or bystanders. Structural cultural approaches look at broader social forces, processes, and value systems shaping violent motivations and opportunities.

Most sociological research on violent crime has focused on interpersonal violence among individuals. But with recent changes in global politics and governance, sociologists are now confronted with violent behaviors, such as terrorist acts and war crimes, that present both challenges to traditional methods and theories, as well as opportunities for evaluating accepted knowledge about violent crime.

virtual sports

Michael Atkinson

Virtual sports are symbolic representations of embodied, expressive, and “real world” athletic experiences. These sports can involve complete “out of body” practices wherein participants “play” a sport without exerting their bodies in a traditionally athletic way (i.e., a sports video game), or more embodied performances involving physical activity in a simulated sports environment (i.e., athletic movement in a modified sports setting like a cyclists’ wind tunnel). Centrally, virtual sports involve human beings as either real or represented athletes in a technologically enhanced setting. Although certain ludic activities might be considered representations of sport (e.g., “touch” football, “pick up” ice hockey, or go kart racing), virtual sports are those that place either embodied or computer generated athletes in simulated sports spaces.

Virtual sport has, by and large, escaped sociological scrutiny. Nevertheless, three types of virtual sport are ripe for investigation. First, and perhaps most commonly, virtual sports

abound in home and arcade video games. Through the advent of home entertainment systems in the 1970s and 1980s such as Atari, Intellivision, Collecovision, and Vectrex, sports video games became a staple of both popular and youth cultures in North America. From the 1980s onward, game players have competed in virtual sports ranging from hockey to basketball to hunting to skateboarding. Indeed, one of the very first video games commercially marketed in the US, Pong, resembled a crude form of table tennis. Since then, digitally refined and interactively dynamic computer systems such as Sega, Nintendo, Odyssey, Play Station, and X Box have enabled consumers to play practically every mainstream western sport. Sports games presently account for approximately 20 per cent of video game sales in North America, the world’s largest gaming market, grossing US\$8 billion yearly (Lieberman 2003).

Second, virtual sports enthusiasts now have access to physically interactive video games. For example, players may literally “step into” virtual golf courses. A person stands on an Astro turf tee box holding an electronically sensed golf club, and swings at a virtual ball. A simulated ball instantaneously appears on a large video screen situated several feet in front of the tee box, and flies down the virtual course according to the celerity and spin at which it had been virtually struck. Individuals may play an entire round of golf on the machine, selecting from any number of professional courses. People may also use similar machines (for a cost of US\$10–100) to drive virtual race cars, bat against virtual Major League Baseball pitchers, shoot virtual basketballs, ride virtual race horses, or even paddle virtual kayaks.

Third, simulated sports environments may be utilized as training tools for elite athletes. Virtual training machines carefully monitor and strictly control the effort levels of athletes in order to study and help improve their physical abilities. For example, swimmers are often placed in “current tanks” to scientifically evaluate the efficiency of their strokes and pinpoint $\dot{V}O_2(\max)$ rates. Elite level ice hockey players’ skating strides are technically studied in laboratories by using treadmills with simulated ice surfaces. Professional cyclists straddle stationary racing bikes in wind rooms and “peddle through” virtual rides that appear on video

screens in front of them; twisting and turning when they go through turns, and exerting effort when tackling hills.

The ascendance of virtual sport over the past 30 years points to how a host of "sociogenic" (Elias 1994) shifts within western cultures have altered our understandings of embodied athleticism. First, virtual sports are of increasing importance at a time in which both amateur and professional sports are intensely commercialized. Sociologists of sport suggest that, particularly in western nations with state sponsored, rigidly institutionalized and professional sports cultures, the entire sporting experience is fragmented into market commodities, including sport simulations that allow users to become more actively involved fans. As sport is consumed as a popular culture commodity, sports organizations profit by aggressively tapping home entertainment/gaming markets. Many global and national sports organizations license and/or package virtual game experiences for consumers, allowing them to create fantasy leagues and manipulate player performance at the push of a button or thrust of a joystick.

Second, athletic contests are globally promoted as contexts of social "mimesis" (Elias & Dunning 1986) by sports marketers. Audiences are sold virtual sport as symbols of emotionally charged and risky, yet rule bound, scenarios of physically intense competition. Because of the openness of the aggression, struggle, and toughness in sports, they provide a type of "exciting significance" for audiences. Virtual sports games highlight and exaggerate the taken for granted physicality and mimesis inherent in both mainstream and alternative sports. Extreme hitting, bloodletting, brutal tackling, and flamboyant injuries, for example, are common in virtual sports games. Rules are broken without penalty, virtual players do not experience the catastrophic effects of rough play, and users receive reward incentives within games for the number of on field hits levied or styles of aggressive play mastered.

Third, the booming popularity of virtual sports games should be contextualized against what postmodern sociologists like Baudrillard (1983) refer to as the "simulation" of social reality. Virtual sports games, for instance, create hyper representations of embodied athleticism

and transform social constructions of "real" sport for users. The games not only mimic what actually occurs in sport, they now partially define what audiences expect from embodied sports. Virtual games may also be more accessible forms of sport for many users, as one can play dozens of sports regardless of physical fitness level. Furthermore, one is granted an unprecedented agency to mold the contours and parameters of an athletic contest at whim (i.e., players involved, physical settings, length of competitions, speed of games, and rule structures). Comparatively, for athletes who are "plugged into" virtual sports machines, simulated sports fields allow for incredible physical exertion without many of the physical dangers inherent in competition. Therefore, performance evaluating or rehabilitating sports machines generate simulated contexts of performance so that athletes may become "swifter, higher, and stronger" during competition.

Fourth, virtual sports underscore how machines and bodies cybernetically intersect in western cultures. Donna Haraway (1991) noted, some time ago, that the postmodern era is one in which corporeality is increasingly breeched by technology. For Haraway and others, it is difficult to conceive of any social activity, including a full gamut of sports performances, that has evaded technological improvement, innovation, control, and monitoring. When individuals are able to kick a soccer ball, catch a baseball, throw a javelin, or perform a ski jump by tapping a computer button or moving the body expressively in a "sports like motion" in front of video sensors, one cannot overlook how athleticism is deeply tied to computer technology.

Fifth, the prominence of virtual sports reflects emergent cultural preferences for stationary, home based digital entertainment. Virtual sports participation through video game play jibes with athletically inactive North American lifestyles. Virtual sports fit nicely into the social "sit down" lifestyles widely attributed to long school or work days, poor dietary practices, and exposure to computers as everyday tools. Troublingly, at a time when physical passivity in the leisure sphere and overall obesity rates are on the rise in North America, and as physical education programs are disappearing from educational curricula at all institutional levels, virtual games are a primary form of sports

participation for “growing” populations of North Americans (Clocksin et al. 2002).

Extant theoretical deconstructions of virtual sports are narrow in both scope and content. The bulk of the limited empirical research on virtual sports addresses how exposure to aggressive sports games is correlated with aggressive interpersonal behaviors (Bensley & Van Eenwyk 2001). Virtual sports are especially targeted in the contemporary moral panic about youth deviance and the consumption of violent video games. Using a blend of social psychological, behavioral, and sociobiological theories, researchers argue that virtual sports games desensitize users to extreme violence and confound users’ understanding of real world aggression. Yet despite nearly three decades of concentrated empirical research on youth violence and video game play, there is no consensus among social scientists that virtual sports play a causal role in any category of criminal or otherwise assaultive behavior.

Second, political economists study virtual sports as vacuous cultural commodities. Authors including Postigo (2003) weave a pastiche of Marxist, cultural studies, and post industrial theories to evidence how virtual sports have little use value but great exchange value among youth groups. Virtual sports alienate users from embodied athletic experiences and diminish the socially interactive aspects of competitive sport. As critics of virtual sport, political economists contend that athletes, teams, and leagues utilize video games as vehicles for crassly soliciting fan investment into athletics. Furthermore, they argue, virtual sports like video games discourage the first hand experience of athleticism in sport, and motivate individuals to participate passively via video interface.

Third, sociologists of sport employ post modernist theories to examine the impacts of computer technology on athlete training, performance, and rehabilitation. Sociologists including Debra Shogan (1999) study athletes’ bodies as fragmented, technologically invaded, and subject to penetration/improvement at the hands of therapists, doctors, and trainers. Athletes, as the subjects and targets of medical knowledge bases, are strategically crafted into cybernetic entities that resemble carefully engineered machines rather than embodied agents. Virtual sport machines used in athletic training or in

recreational leisure pursuits blur the boundaries between “natural” human performance and artificially engineered, hyperreal athletics. The postmodern athlete is one whose performance is carefully mapped, dissected, analyzed, predicted, and monitored by a full spectrum of computer systems.

Existing research on virtual sports explores only a small range of data collection techniques and strategies. Social experiments, self report surveys, content analysis, and to a lesser extent interviewing, are the main methods structuring empirical investigations of virtual sports and their cultural significance. Dominant research questions tend to focus on popular sports video games played, the impact of virtual sports on fan communities, and the significance of virtual sports for improving real world athletic performance.

Future research on virtual sports should encourage methodological diversity. At present, the population of virtual sports enthusiasts is not well defined, nor is the social significance of virtual sports across cultural lifestyles sufficiently probed. This is largely due to the methodological targeting of certain populations of “home system” game players (typically, young males from the middle class), online players (a similar population as home system players), or elite level athletes. We must determine, in the broadest sense, what groups participate in virtual sport, which have access to virtual sport, and how they are intersubjectively defined as socially meaningful. In particular, questions pertaining to users’ interpretive constructions of virtual sports should be pursued via qualitative methods. More exploratory and in depth ethnographic methods (i.e., participant observation, visual ethnography, or auto ethnography) might be tapped with greater fervor in this process.

Substantively, future research should venture beyond “game play aggression” hypotheses and cyborg case studies. Dominant approaches to the study of virtual sports highlight the solitary, anti social, and disembodied natures of game play for participants. Resultantly, we know very little about the socially integrative function of virtual sports or their creative insertion into everyday group practices. Particular attention might be given to online, multi user, “real time” sports gaming. Through the advent of online MUDs (Multi User Domains), MOOs (MUD

Object Oriented systems), and other forms of computer mediated communication (CMC), virtual sports enthusiasts cooperatively interact within digital game worlds. Online virtual sport spaces are relationship building and socially organizing contexts wherein individuals socially interface through shared games. Sport specific online leagues form through the efforts of hundreds or even thousands of participants scattered across the world. As part of studying ongoing globalization processes in sports worlds, sociologists might inspect how the innovation of online, virtual sports cultures erodes traditional time/space social barriers.

Future research on virtual sport should also examine potential ethical problems accompanying the increased reliance on computer technologies in athletics. For example, sociologists should question: Are virtual sport technologies available to all elite athletes, and if not, is this a source of stratification among them? Are unfair advantages created for athletes who access the premier virtual training and rehabilitation technologies? Does the adoption of virtual sport in training stress the science of athletic performance over its humanistic elements? Does video game play discourage rigorous physical activity and athleticism? Are youth cultures persuaded to consume sport in commodity form, and not as athletes? What role does virtual sport hold in the thickening of westerners' waistlines? Do online virtual sports actually facilitate community building and social interchange in ways embodied sports involvements do not?

W

war

Wolfgang Knobl

To find an uncontested definition of war is an almost impossible task. Although definitions characterizing wars as major and oftentimes longlasting conflicts between political groups (especially states or nation states) and carried out by armed forces seem to be useful and convincing at first sight, they are not without problems. The difficulty lies not so much in the vagueness of terms like “major conflict” (how many injured or dead people make a war?) or “longlasting conflict” (there were certainly wars in history that lasted decades; how ever, can there be wars that last only hours?). The real problem with such definitions is the close link between war and the state. This link is a nuisance for those social scientists who – as social anthropologists or historians – have to deal with conflicts in areas or periods without states. And it is an obstacle for sociologists and political scientists who deal with contemporary conflicts in regions where once existing states have vanished as sovereign political units and where a variety of groups use their potential of violence in an often gruesome way. Is this form of mass violence to be called “war”? Or is it another type of conflict? Thus, the problem of definition is on the agenda again.

Although analyses of war (and peace) are probably as old as historiography, *systematic* research into this topic did not start before the European Enlightenment. This research, however, focused much more on the conditions of peace than on the realities of war: with clearly normative intentions, philosophers from Thomas Hobbes to Jean Jacques Rousseau and Immanuel Kant reflected on the possibilities of *preventing* war. It was only after that period that

a first analysis of war *as dynamic process* was published, Carl von Clausewitz’s famous and posthumously published treatise *On War* (1832). Clausewitz interpreted war as a continuation of politics by other means, but he never regarded war as a process planned and carried out exclusively by rational actors. On the contrary, Clausewitz framed war with his “trinitarian formula,” arguing that war has to be seen as an intersection of actions of governments, populations, and military commanders, actions that are motivated by rationality, but also by hatred and hostility and by daring calculations of chances.

The publication date of Clausewitz’s treatise ironically coincided with the beginning of sociology since it was exactly around that time that Auguste Comte wrote his *Cours de la philosophie positive*—“ironically,” because Comte already seemed to belong to a completely different world; whereas Clausewitz’s thinking was deeply shaped by the experience of the Revolutionary and Napoleonic Wars, Comte’s writings were impregnated by the liberal belief in continuous progress toward a peaceful and rational society. It was Comte who argued that history can be divided into three periods, a theological, a metaphysical, and a scientific era, the last one Comte’s own period dominated by a scientific spirit that in the end will eradicate all militaristic ambitions and adventures. Thus, Comte formulated a thesis that became a kind of premise for the majority of sociologists in the second half of the nineteenth and twentieth centuries, the liberal thesis of a strict incompatibility between war and industrial society. According to this thesis, war is some kind of archaic and disappearing relic that therefore does not need to be analyzed in much detail, a point – though somewhat transformed – ironically shared by socialists and Marxists alike, since they also expected the end of war, at

least within the historical stage of socialism. It is revealing that both liberal and socialist theorists of imperialism (Hobson and Schumpeter; Lenin and Luxemburg) were much more interested in the political or economic causes of imperialist wars, not in war itself and its consequences.

Thus, within the early phase of the history of the discipline, it is difficult to find sociologists seriously and systematically analyzing war – precisely because of this liberal (and socialist) premise. True, in Max Weber's huge oeuvre one will always find scattered though certainly interesting hints at the consequences of warfare for societal development. But it is also true that most of the other founding fathers of sociology were rather quiet on that subject. It was only during World War I that Émile Durkheim, Georg Simmel, or George Herbert Mead were more or less forced to write something about war, but the pieces they published were definitely not at the heart of the ideas for which they became famous. Werner Sombart's well known book *Krieg und Kapitalismus* (*War and Capitalism*, 1913), in which he sketched war's positive economic effects on the economy of early modern Europe, remained an exception.

Interestingly, the sociological neglect of matters of war did not really change that much with the coming of the two world wars: World War II and its aftermath saw the establishment of military sociology in the United States and the publication of Samuel Stouffer's marvelous *The American Soldier*, but – strangely enough – this alone did not put war on the sociological agenda: although one of the four volumes of Stouffer's multivolume work described and theorized "combat experience" and thus one of the central topics of war, the other volumes focused much more on the military as an institution and thus laid the groundwork for military sociology as a subdiscipline which above all analyzes organizational structures and problems of armed forces. War was only a side aspect of this research program. Thus, only some isolated figures shouldered the task of analyzing war and its societal consequences, notably Emil Lederer during World War I, Hans Speier just before and during World War II, and Stanislaw Andreski, Raymond Aron, and Morris Janowitz in the three decades after 1945.

It was not until the rise of historical sociology in the late 1970s and the coming of a new world order after the collapse of the Soviet Empire that war, and especially *the consequences of war*, really began to be theorized in a systematic way by closely connected groups of researchers. Starting with Theda Skocpol's *States and Social Revolutions* (1979), the debate focused very much on how European modernity was shaped by the impact of wars. Whereas Skocpol had argued that especially the French and the Russian Revolutions and their outcomes can only be understood by focusing on international contexts, and particularly on the crises of state administrations weakened by longlasting or lost wars, others emphasized how the modern state and its monopoly of violence were the result of violent interstate conflicts: it was only by constant warfare that large state bureaucracies were built in Europe, bureaucracies for the purpose of extracting resources out of civil society in order to finance large standing armies. Even the rise of democracy and welfare states historically seemed to be closely connected with war since suffering populations could organize and successfully demand suffrage and social rights (see Porter 1994). And, last but not least, war was also linked to internal repression since the militarization of societies as a consequence of war sometimes led to ethnic cleansing or even genocide (Shaw 2003).

However, this kind of historical sociological research also made clear that war is not a homogeneous variable since different kinds of war have very different effects. Even within the context of the nineteenth and twentieth centuries at least four types of war are to be distinguished: (1) interstate wars between neighboring or competing nations; (2) colonial wars in which mostly European expeditionary forces usually defeated indigenous groups and populations in various parts of the world; (3) civil wars between established state apparatuses and rebels; and (4) wars of national liberation against mostly European colonial powers, a type of war that only came into being after 1945.

The common feature of all these types of war is that a more or less powerful state is at least on one side of the conflict. But what about major conflicts in which states are missing? As

indicated above, this increasingly becomes a problem for researchers specialized in some regions of the contemporary world where states have ceased to exist – but not mass violence. The debate on state failure and state breakdown that had started at the beginning of the 1980s and focused very much on some African and Latin American regions had a huge impact on war research as well. Some analysts have begun to talk about so called “new wars” (Kaldor 1999) that usually take place in spaces where the state monopoly of violence has vanished and where various types of combatants – armed bandits, ethnic groups, parts of former state elites, etc. – are violently fighting for resources. These conflicts – so the argument goes – are not shaped by clearly defined ideological or political goals any longer as, for example, the wars of liberation in the period of decolonization. On the contrary, this type of war is almost exclusively dependent on its own peculiar economy (Jean & Rufin 1996) since in the era of globalization combatants are able to use resources brought in by humanitarian organizations and ethnic and other groups living abroad. Since aid and transfer payments usually continue for a long time, these “new wars” can last a long time as well, wars in which clear cut demarcations between combatants and civilians can no longer be detected and in which so called child soldiers as well as private military firms play a significant role.

As these troubled spots and spaces and their “new wars” are often seen as major threats to either particular western states or to the world community as a whole, the number of military interventions by mostly western states (or UN forces) has dramatically increased since the end of the 1990s. Thus, one of the latest trends within social science research is the focus on these interventions. In contrast to former periods, the high tech warfare of western states often does not seem to affect western civilian populations very much and does not even risk the lives of western soldiers – but does often lead to many casualties among the population of those regions where western armed forces strike (see Shaw’s term “risk transfer war”). It remains to be seen, however, whether warfare really does not have much effect on the homefront of (western) democratic societies,

since wars – even those fought in faraway places and without many body bags coming home – do always restructure the domestic political scene. That research, however, has only recently started (see Merom 2003).

Ward, Lester Frank (1841–1913)

Michael R. Hill

Lester Frank Ward, a man of modest origins born in Joliet, Illinois, was a major architect of American sociology. Prior to Ward's election to the first presidency (1906–7) of the American Sociological Society (ASS, now the American Sociological Association), academic sociology in the US had no independent national disciplinary organization save the unifying voice of the *American Journal of Sociology*, then edited by Albion W. Small at the University of Chicago. The ASS, under Lester Ward's pioneering and able leadership, catapulted sociology into the American intellectual and academic mainstream.

Following horrific service in the Union army during the US Civil War (Ward was seriously wounded, the details of which are found in *Young Ward's Diary*), he earned his undergraduate degree from Columbian University (now George Washington University) in 1869 and won a master's degree, in botany, in 1871. Like the interdisciplinarian Roscoe Pound, who later excelled in botany, law, and sociology, Ward was a formally trained botanist and a self-taught, pioneering sociologist. Working as a paleobotanist in various government offices, including the US Geological Survey, Ward privately developed his systematic analyses of human society and, like several early sociologists, personally underwrote the publication of his books. Ward's major works include: *Dynamic Sociology* (1883), *The Psychic Factors of Civilization* (1893), *Outlines of Sociology* (1898), *Pure Sociology* (1903),

and *Applied Sociology* (1906). His six volume *Glimpses of the Cosmos* (1913) is replete with autobiographical commentary on the origins of his voluminous writings.

Ward's early books and his 1895 contribution of a seminal article on "The Place of Sociology among Sciences" to the inaugural issue of the *American Journal of Sociology* (AJS) demonstrate his leadership at the forefront of sociological thinking. From 1900 to 1903, Ward presided over the international Institut de Sociologie, foreshadowing his subsequent role as president of the ASS. In 1906, Ward achieved a formal academic post, as Professor of Sociology in Brown University.

Ward's interest in Darwinism, notions of systemic "synergy," his concept of "gyneco-centrism," and his advocacy of civilization's progressive "telic" forces allied him in promoting many of the same intellectual trajectories advocated by sociologists Edward A. Ross and Charlotte Perkins Gilman.

Ward died on April 18, 1913. His papers, manuscripts, and professional files repose in multiple locations, including the following major depositories: Smithsonian Institution Archives; Brown University Archives; George Washington University Archives and Special Collections; and the Manuscripts Division of the Library of Congress.

waste, excess, and second-hand consumption

Nicky Gregson

Waste is a quotidian facet of all societies. All societies discard things; all societies have to deal with what remains of things, from human and animal bodies to vegetable peelings; and all societies are shaped through value regimes which acknowledge waste and/or rubbish as a category, albeit that they vary considerably in their determination of what exactly might befit this category, in how much matter is placed in this category, and what they do with it. While disciplines such as archeology and anthropology and interdisciplinary fields such as material culture have long recognized the disclosing capacities of waste, and while others (notably cultural studies) have begun to explore its metaphorical purchase, sociology largely has left waste alone (O'Brien 1999). This silence is unlikely to remain, for theoretical and empirical reasons. Together with its close theoretical referent excess, waste poses questions which go to the heart of current sociological debates about materiality and mobility, about reflexivity and subjectivities, and about commodity exchange. Waste has begun to be good to think through and not just about. But waste itself matters, increasingly. What happens to the remains of things, and what should happen to them, is now at the forefront of political debate, globally, nationally, and locally. Rubbish defines us: it places us in the world and our relation to it discloses key social divisions, inequalities, and distinctions.

Waste's absence from the sociological frame has in no small measure been bound up with the frequent identification of waste matter with acts of disposal. Seen thus, waste is located as the end point in the commodity chain; as matter whose utility to networks of producers and consumers has been lost and which is therefore open to disposal. As a consequence, waste is cast in trajectories that position it within socio technical waste management systems that are more commonly the academic

preserve of engineers and environmentalists rather than social scientists. This is critical. Waste management systems separate waste matter from sites of production and consumption. They carry matter away from households, for example through the medium of containers such as bins and skips, and they remove them from processing plants, for instance in sealed drums and road tankers. As such, waste management systems render waste as matter out of sight, beyond everyday fields of vision and beyond the sociological frame. Waste management is constituted as a practice not for public display; as known of yet not widely known about, and as a process that discloses considerable ambivalence. In leaving waste alone, sociology has been both acknowledging these ambivalences and acknowledging disciplinary boundaries.

Recent work in sociology and more broadly within the social sciences, however, has begun to turn the mirror to waste. This is discernable in both empirical work on consumption and everyday life and in theoretical writings on consumption.

WASTE, CONSUMPTION, AND EVERYDAY LIFE

Susan Strasser's (1999) study of the history of trash in the US positions waste and disposal as an effect of mass production and mass consumption. For Strasser, manufactured obsolescence, shaped through the imperatives of fashion and technological change, is a post 1950s phenomenon; one in which the ready availability of replacements combines with discourses of disposal to render throwing away the no longer wanted or needed, and not just the worn out, a routine, easy act of convenience. Strasser shows this development to be predicated upon the rise of public health discourses in the US in the late nineteenth century, to relate to changes in municipal trash collection services, and to changes in the design of house interiors, notably the reduction in available space for storage in both apartment and suburban dwelling structures. However, she also argues that these changes constitute a transformation in people's relationships to objects. For much of human history, she argues, this has been a relationship of stewardship, in which

practices of caring for things, repair, handing down, and making do run parallel with the art of bricolage. Citing quilt making, "turning" articles of clothing, and rug making as emblematic of this sense of stewardship, she goes on to argue that mass production and mass consumption have brought about a far more ephemeral relation to things. Indeed, Strasser argues that the second half of the twentieth century ushered in a period in which the mantra of convenience, cleanliness, and disposability was regarded as the positive to stewardship's negative.

There are clear parallels between Strasser's work in the US and that of Shove and Chappells and Shove in the UK. Liz Shove (2003) highlights the importance of comfort, cleanliness, and convenience to understandings of key practices of contemporary consumption in the UK, but it is in her work with Chappells (Chappells & Shove 1999) that she addresses the importance of waste management systems directly, arguing that the changing technologies of household waste management disclose the changing meanings of household waste. Beginning with eighteenth century asphalt privies and moving through to early twentieth century metal bins, and thence to a late twentieth century combination of "wheelie bins" (garbage bins with wheels) and recycling bins, Chappells and Shove argue that these technologies are indicative of changing boundaries between the public and private management of waste. Although the advent of wheelie bin technology is considered to have increased the amount of household waste being disposed of, sorting and separating waste matter for disposal through kerbside recycling schemes is argued to have instigated a growing sense of collective responsibility around waste matter and its management. At the same time, recycling activities highlight the importance of a rather different sense of stewardship to that discussed by Strasser, one that goes beyond caring for things to connect practices of reuse and recycling to a stewardship of the planet and to arguments regarding sustainable futures.

Contemporaneous with the above work is the plethora of recent work on second hand exchange and consumption. Addressing a number of sites of second hand exchange and consumption

(including car boot sales and charity shops), Gregson and Crewe (2003) have highlighted the poverty of commodity chain analyses which identify first cycle retail as the end point of concern, emphasizing instead how value is recursively created in acts of second hand exchange and not just produced through value regimes (Thompson 1979). At the same time, Clarke (2000) through her work on nearly new sales has shown the importance of moral economies of mothers. In both sets of work many of Strasser's arguments about stewardship reappear: practices of handing down and handing around, of care and of bricolage are shown not to have disappeared but to have been recast. Moreover, as Gregson and Crewe suggest, the proliferation of sites of second hand exchange, both face to face and virtual, not only works to reinstate the possibility of reuse, but also establishes hierarchies in sites of second hand exchange and works to defer the declarations of rubbish value that waste depends upon. Placing lots on eBay, doing a car boot or garage sale, taking worn and/or unwanted items of clothing or books to the local charity shop are all acts which, at least in part, seek to extend the economic and social life of things by placing them in conditions that allow for their revaluation. Furthermore, such sites of exchange connect with international economies in second hand goods. So that which remains unsold in several of these arenas may be sold on to intermediaries and displaced geographically to places which provide the conditions for their potential revaluation, usually in the third world. Clothing provides one of the best examples of this process, with unwanted garments from the UK and US traveling to Zambia to be reworked as a hybrid fashion (Tranberg Hansen 2000), but there are others too, notably mobile phones, spectacles, and computers.

Research on second hand exchange and consumption has not only extended understandings of the commodity chain and the complexities of value, but also highlights how acts of disposal are not necessarily acts of waste making. Developments within the waste management industry itself also warn against the easy, yet erroneous, identification of disposal with waste. Waste economies per se constitute a huge tertiary sector, spanning everything from the

handling of the most hazardous by products of the nuclear and chemical industries, to clinical (body related) waste and household discards. Within this, waste minimization through the expansion in markets for recyclables is a particular growth area, and likely to expand considerably within the European Union in the next decade. Fleeces from plastic, pencils from drinks vending machine cups, pens from computer printers, and mouse mats from recycled car tires are just a few examples of the expanding market in recyclables alongside more ubiquitous generic products such as recycled paper. Indeed, selling provenance is now not just a geographical matter but a material one too, as manufacturers proclaim a previous material configuration to their products either alongside or in place of a supply chain that appeals to both transparency and fair trade. "I used to be a car tyre" and "We used to be plastic cups" are just two of the logos that feature in the advertising of a UK based design company specializing in recyclables. Note that this is not just working with previous histories as consumer objects: these things also have an identity, they are "I's" and "We's." As such, these examples point to the way in which an ethics of care can be mobilized within discourses of recycling. Going beyond stewardship of the planet notions of sustainability, this is a custodial relation that mobilizes anthropomorphism, and one that simultaneously points to a flatter ontology of humans and things akin to that encountered within actant network theory (ANT).

Most recent empirical work in this field positions discussions of waste within debates about value and the commodity form, while paying attention also to the arguments of Appadurai (1986) and Kopytoff (1986) regarding the social life of things. Theoretical work on waste, however, regards waste as a category, integral to the ordering of both self and society and to the ordering of society through consumption.

WASTE, ORDER, AND EXCESS

It was Mary Douglas's key text *Purity and Danger* (1966) which first drew attention to the social significance of societies' ridding of certain sorts of waste matter. She highlighted the

centrality of expulsion and disposal to social classification, specifically to both the constitution of boundaries and the making of social order. Of particular significance here is the placing out, either on or beyond the margins, of matter deemed to be troublesome, particularly the symbolically polluting or contaminating by products of human bodies. Similarly, Gail Hawkins (2001) regards the passage of waste matter, and specifically its spatial separation from the body, as central to the ordering of self, maintaining the boundary between what is deemed to be self and what is not. In so doing, this process is regarded as providing the conditions for the renewal of the self through acts of loss. In this and in later work, Hawkins connects this more phenomenological sense of being with waste to theories of subjectivity and to garbage, in what is an explicit attempt to constitute an ethics of waste. Taking as one of her starting points the various "Don't litter" invocations evidenced in many environmental campaigns in the US, Europe, Australia, and New Zealand during the 1990s, Hawkins argues that such imploring works with a Foucauldian sense of an (un)disciplined self. Campaigns such as these are argued to highlight a self who is unable to regulate its actions in the interests of social and environmental order. Moving on, Hawkins outlines how the complexities of dealing with and putting out the garbage are an endless cycle of ritual and repetition dominated by time consuming acts of classification and sorting in which self surveillance and self scrutiny are at a premium. The self here is reflexively made in and through relations with waste. But this is also a self made in and through relations to others, as forged through technologies of waste management. This is a maneuver which takes Hawkins initially in the direction of Foucault's later writings on subjectivity and technologies of the self, through the governmentality literature, and thence to Deleuze and Connolly. Keen to move away from an ethics of waste which highlights normative moralities such as the Reduce-Reuse-Recycle mantra, and which promote recycling as virtue added disposal, Hawkins attempts to explore Connolly's politics of disturbance to create different, more uncertain and provisional ways of living and being with waste (Hawkins 2003). In a move which both echoes and reverses the

discourses identified in Dominic Laporte's groundbreaking *History of Shit* (2002), this takes Hawkins to what many would surely regard as an alternative, utopian world of living with shit and without drains; to a world which turns upside down modernist notions of civilization, in which shit remains within the domestic sphere, rather than being transported away, unsmelt and hidden via extensive networks of underground drains and sewers.

Although far from prominent in theoretical writing on the sociology of consumption, in which desire and distinction have figured centrally, waste has had a presence, even in the earliest writings. Frow (2003) for example, highlights how in one of the formative early texts on consumption, Thorstein Veblen pinpointed the capacity to be wasteful as critical to the sumptuary systems of nineteenth century capitalism, alongside the more commonly emphasized ownership of desired consumer objects. Frow emphasizes that Veblen saw the conspicuous wasting of time, and not just the wasting of desired things, as central to aristocratic notions of leisure, and therefore to the development of a theory of the leisure class. Waste's metaphoric power has been harnessed more recently, notably in relation to debates about organizations within the late twentieth and early twenty first centuries. Richard Sennett, for example, in *The Corrosion of Character* (1998), has emphasized how waste and specifically waste reduction and minimization are held up as metaphorical markers of creativity within the contemporary workplace. Although written nearly a century apart, both Veblen and Sennett's readings begin to touch on waste's relation to excess. For Veblen, this is construed in relation to an absolute need for humans to consume, which profligate acts of consumption exceed. Sennett, however, points to how excess in the workplace is identified with excess labor capacity and operational inefficiencies, and how the elimination of excess is regarded as imperative to the emergence of leaner, more flexible, and more competitive organizations. It is, however, in the work of the French philosopher Georges Bataille that the connections between waste, excess, and consumption are most fully explored.

In *The Accursed Share* (2002), Georges Bataille begins to develop a work of general economy which centers on the importance of

consumption rather than production and which locates the expenditure of wealth, or the surplus, as at the heart of consumption in all societies. Although these arguments are connected to some rather opaque comments about energy and resources, it is the surplus which is "the accursed share" of Bataille's title, and it is this which he argues must be expended, given away, lost, or destroyed by all societies. According to Bataille, then, the surplus – the excess – must of necessity be wasted. This theoretical position is one which is grounded in sacrifice and the gift economy of the potlatch, and not in the utility of commodity exchange. Although several commentators have highlighted the almost wilful disregard of historical evidence in Bataille's writings on both sacrifice and potlatch, the theoretical significance of both to an understanding of waste as excess is considerable. Both practices are concerned with managing the surplus and both appropriate objects (often including sentient beings) from the utility of productive consumption to arenas of conspicuous wasting. However, as others have remarked, as important to both sacrifice and potlatch is the cultural work performed by both practices and the social transformations wrought through these rituals. Sacrifice, then, is not just about wasting. Neither is it simply a devotional ritual to a divine being, but it is about a reaffirmation of a transcendent force.

A further recent theoretical development considers the connections between waste, disposal, and consumption, but without reference to excess. Kevin Hetherington (2004) disrupts the associations drawn frequently between waste and disposal. He argues that waste's lack of dynamism makes it a problematic category, and that disposal is best regarded not as an end point in consumption, but as constitutive of consumption as a social and ethical act. Hetherington begins his paper by critiquing Douglas's work, maintaining that in establishing the placement out of troublesome matter as a binary (there: not here), she misses how social order is always uncertain, provisional, and constantly open to being remade. In contrast, and drawing on the work of both Munro and Hertz, Hetherington argues that disposal is a constant act of placing absences through conduits of disposal. Attics, wardrobes, drawers, and even fridges are all argued to provide gaps between presence and absence, and to allow for questions

of value to be considered. Making a case for the importance of absence within sociological thinking, and hinging this to non linear ways of thinking about time and space characteristic of non representational work, Hetherington argues that the presence of the trace works to ensure that disposal is never a finished business. Instead, our lives are haunted by ghostly presences and absent presences. Disposal is the means through which we manage our social relations, through absence.

FUTURE DIRECTIONS

Recent theoretical and empirical work on waste has been proceeding in parallel universes, and there are some notable points of difference between authors. At the same time as there are clear differences between theorists, so too are there differences between theorists and those whose concerns are more empirical. Few of those conducting empirical research on waste, for example, would concur with Hetherington's argument that waste is an end point, or with his assertion that waste is unhelpful to think through given its lack of dynamism, a position supported by Bataille's emphasis on the exuberant qualities of waste as excess. Furthermore, waste matter is the stuff of value creation and its handling, even the location and manner of its handling, is a "frontline" governance activity. Increasingly, empirical research in this field is moving to address practices of divestment, ridding, and loss as these relate to things, and the transformations of waste. Its theoretical points of reference center on ideas of transience, durability, and materiality, and emphasize the traces in things and the depths to things. In such work it is the matter of matter which starts to matter. To paraphrase Laporte, shit is ... shit, and its qualities as such really do matter. Future sociological work on waste is likely to confront the materiality of waste, and not just content itself with thinking through it.

weak ties (strength of)

D. B. Tindall and Todd E. Malinick

Weak ties are relationships between individuals marked by relatively low intensity and emotional closeness. By contrast, strong ties are relationships that involve high levels of intensity and emotional closeness. The importance of weak ties to a variety of sociological phenomena has been most influentially articulated by Mark Granovetter (1973) in one of the best cited articles in sociology, "The Strength of Weak Ties" (SWT).

Granovetter argues that most people intuitively expect strong ties to generally be more important than weak ties, because those to whom we are closely tied are more motivated to help us, and are also more likely to be stronger sources of social influence and social support. However, basing his argument on principles of social psychology, Granovetter argues that weak ties are – paradoxically – more important for a variety of phenomena, from helping people obtain a job, to the diffusion of ideas and innovations, to facilitating collective action. Granovetter also argues that insights provided by the "strength of weak ties" principle have implications for understanding the linkages between the micro and macro levels of social reality. His insights about the importance of weak ties have, in part, motivated a variety of methodological endeavors such as operationalizing tie strength, developing techniques to accurately estimate

network size, assessing the accuracy of respondents' recall of ties, and the development of network sampling methods.

Granovetter utilizes network graphs to illustrate his theoretical insights. In one graph there are two egos of interest, A and B. Their set of friends is represented as $S = C, D, E, F, G, H$. All of the individuals in the set S have ties to either A or B. Granovetter argues that the stronger the tie between A and B, the larger the proportion of individuals in S to whom they will both be tied (connected by either a strong or weak tie). Granovetter predicts that the overlap will be least when the tie between A and B is absent, it will be greatest when the tie between A and B is strong, and it will be intermediate when the tie between A and B is weak.

Next, Granovetter introduces the notion of the forbidden triad. This is a set of three individuals in which A and B are strongly linked, A has a strong tie to a friend C, but the tie between C and B is absent. Granovetter argues that due to pressures on the actors to maintain balanced relationships with their alters (as articulated by Heider's balance theory), this type of triad is very unlikely to occur. In elaborating the application of this idea to larger social networks, Granovetter introduces the concept of a bridge. A bridge is a line in a network which provides the only path between two points (see Fig. 1). He also distinguishes between more narrowly defined "bridges" (as described previously) and "local bridges," the latter being a line in a graph that provides the only local path between two points. Granovetter notes that

Figure 1 Simplified diagram of Granovetter's concept of a bridging tie. Points depict nodes, or individuals, and lines depict relations. The solid lines represent strong ties and the dashed line represents a weak bridging tie.

bridges are theoretically important to diffusion processes.

Granovetter argues that if, as theory suggests, the "forbidden triad" is absent, then it is unlikely that a strong tie will ever serve as a bridge. A strong tie can be a bridge only if neither ego has any other strong ties. This is unlikely in a social network. However, this constraint does not apply to weak ties. Weak ties are not automatically bridges, but according to Granovetter *all bridges are weak ties*. Granovetter asserts that in large networks it is unlikely that a specific tie provides the only path between two points, but local bridges may be functionally important. The significance of weak ties is that those which are local bridges create more and shorter paths. Consequently, whatever is to be disseminated can reach a larger number of people and cross greater social distance when it is diffused through weak ties rather than through strong ones.

Based on the notion of the "forbidden triad," Granovetter reasons that strong ties should tend to be people who not only know one another, but also have few contacts not tied to ego as well. An ego's weak ties in general, by contrast, will not be tied to one another but will tend to be tied to individuals not tied to ego. Granovetter posits that indirect contacts are typically reached through ties in this weak tie sector; and such ties are of importance not only in ego's manipulation of networks, but also in that they are the conduits through which ideas, influences, or information socially distant from alters may reach ego. The fewer indirect contacts ego has, the more restricted she will be in terms of knowledge of the world beyond her own friendship circle. In a later article, Granovetter (1983: 208) clarified his argument by asserting that "only *bridging* weak ties are of special value to individuals; the significance of weak ties is that they are far more likely to be bridges than are strong ties."

In his SWT article, and a related book, Granovetter goes on to describe the results of a study he undertook examining the role contacts play in helping an individual to get a job amongst recent professional, technical, and managerial job changers in a suburb of Boston. In his study, the majority of jobs were obtained through weak ties.

Granovetter's SWT insights have spawned substantial work on the relationship between the tie strength between egos and contacts and job search outcomes, though there has been some variation in findings regarding the role and importance of weak ties. Some reasons for these varied results are: that measures of tie strength have varied; there may be differential effects for different types of outcomes (any job offer versus level of position of job offered versus salary offered); and there may be differential effects for different types of occupations/sectors of the economy. Other relevant factors may include whether or not the job is a "first job," and there may be different patterns in nation states with different socioeconomic and political conditions (see Lin et al. 1981; Montgomery 1992).

Granovetter's SWT insights also have implications for collective action at both the whole network and egocentric network levels. Granovetter has argued that at the level of whole networks, weak ties are important because they are more likely (than strong ties) to serve as bridges between otherwise isolated cliques in a community.

It is also worth considering the weak/strong tie distinction and its implications for collective action from the ego network perspective. Granovetter argues that at the level of egocentric networks, weak ties are important because they are more likely (than strong ties) to provide novel information (e.g., about social movement activities). McAdam (1986) distinguishes between high risk cost (hrc) activism (e.g., activities that entail potential physical risks to the individual, or that are costly in terms of time and money) and low risk cost (lrc) activism. He then relates the risks and costs involved in activism to tie strength and ideological commitment, and cites empirical evidence which suggests that prior ties to a recruiting agent are the most powerful predictor of recruitment to low risk activism. McAdam points out, however, that ideological commitment to low risk activism does not have to be high in order for individuals to participate. For instance, if an ego is asked to participate in a low risk cost demonstration for a seemingly worthwhile cause, low amounts of social pressure from weak ties (e.g., from acquaintances at work or school) might be

enough to tip the cost/benefit ratio in the direction of participating. In contrast to hrc activism, McAdam suggests that under conditions of hrc activism, strong ties are more important (than weak ties). One reason for this is that strong ties are much more likely to provide social support, and under conditions of hrc this may be crucial for participation (Tindall 2002).

Various definitions of tie strength between individuals have been developed, many of which overlap; these include: (1) felt closeness (e.g., emotional closeness); (2) frequency of contact (how frequently ego communicates with alter); (3) duration (the length of time the relationship has persisted); (4) role definition (e.g., using ties to "acquaintances" to indicate weak ties and ties to "close friends" and/or "immediate family members" to indicate strong ties); (5) reciprocation (reciprocal identification as a strong tie, or reciprocation of a particular type of exchange); (6) volume and type of exchanges; (7) multiplexity (being related through multiple ties of different content); (8) social homogeneity (social similarity); (9) ordinal rank of intimate ties; and (10) network overlap (ego and alter share members of their personal networks).

According to Granovetter (1973: 1361), the strength of an interpersonal tie is a combination of the amount of time, emotional intensity, intimacy, and reciprocal services that characterize the tie. Marsden and Campbell (1984) have provided a thorough conceptual and empirical review of the notion of tie strength. They argue that a distinction should be made between *indicators* and *predictors* of tie strength. Indicators are components of tie strength (e.g., closeness as a measure of the intensity of a relationship). Predictors, by contrast, are aspects of relationships that are associated with tie strength but are not components of it (e.g., role relationships such as neighbor or co worker statuses that arise out of interactions based on particular foci). Based on an analysis of empirical data, Marsden and Campbell (1984) concluded that closeness (the measure of the emotional intensity of a tie) is the best indicator of tie strength (among those available to them in their study).

These definitions primarily apply to ties between individuals. Additional definitions have been developed regarding ties amongst

groups. For instance, when an officer of company A sits on the boards of companies B and C, there is a strong link between A and B, and a strong link between A and C, but also a weak tie between B and C. In the former two cases the interlock is direct and thus strong, and in the latter it is incidental and thus weak (Granovetter 1983). Powell (1990) has looked at ties relative to interorganizational structure and views tie strength as a function of several factors in addition to those already mentioned, including trust, complementarity, accommodation, indebtedness, collaboration, and history. However, while the concept of tie strength has been incorporated into analyses examining relationships amongst larger social units (e.g., companies), it is unclear whether the logic of Granovetter's SWT argument applies to such relationships, as his arguments are rooted in balance theory and relationships amongst individuals.

Somewhat surprisingly given the importance of tie strength in the sociological literature, there has been relatively little methodological work done on refining the conceptualization and measurement of tie strength. Further, most of the effort on conceptualizing tie strength has focused on ties between individuals. Less attention has been given to conceptualizing the strength of ties linking larger social units (e.g., organizations, corporations, nation states).

The SWT argument is implicitly connected to a number of substantive and theoretical problems in sociology; some of these include "small world studies," network sampling, estimating personal network size, techniques for assessing and improving the accuracy of responses, and understanding the creation of weak ties.

Small world studies have examined social cohesion, the extent to which individuals are integrated into society, and the social distance that exists between pairs of individuals and/or different social groups. Understanding the prevalence of weak ties and the roles that bridging weak ties play in society is crucial to understanding cohesion/social distance.

In order to describe the structure of weak and strong ties in large bounded populations, one needs to be able to sample such populations because, amongst other reasons, it is impractical to collect network information on large

populations. Granovetter has also contributed to research in this area, as have others.

Being able to describe the potential effects of weak ties on outcomes for individuals is predicated on having a good estimate for how many weak ties an individual has in the first place. A variety of techniques have been developed for eliciting responses about ties, including *name rosters*, *name generators*, and *position generators*. Researchers have also worked at trying to assess the accuracy of respondents' reports of the number of ties they have and have developed techniques for the accuracy of recall and for improving recall of forgotten alters.

Finally, understanding the differential creation of weak ties is crucial for understanding their effects. Research has shown that social structures produce foci where individuals with similar social characteristics tend to meet and form ties. Researchers have examined tie strength in the context of patterned tie formation in communities and in voluntary organizations.

wealth

Claudia W. Scholz and Juanita M. Firestone

Wealth is defined as assets held by an individual or household. These assets may include financial wealth such as savings accounts, stocks, or bonds as well as property such as the family home, farm, or business. Some estimates of household wealth also include consumer durables such as vehicles and refrigerators.

Wealth is an important dimension of stratification because property can be passed down from generation to generation. Families use accumulated assets or savings to bridge interruptions in income, preventing downward social mobility. In spite of its importance, sociologists tend to leave wealth out of their measures of socioeconomic status, because of the difficulties in obtaining valid and reliable data on household assets. Using the data that are available, sociologists and economists have determined that in American society, the distribution of wealth is far more unequal than the distribution of income. The US exhibits the highest levels of wealth inequality in the developed world.

For economists, wealth represents forgone consumption – income that is saved rather than being spent on daily necessities or consumer desires. It is important to note that not all individuals are equally able to save. The accumulation of assets is extremely difficult for the working poor because nearly all of their income goes to fulfill daily needs and because their needs are not subsidized by their employer through medical or childcare benefits.

Recent economic indicators suggest that more and more American families are having trouble saving a portion of their incomes. Net household liabilities have exceeded net asset accumulation in the United States since 1999, which means

that Americans are not only failing to accumulate wealth, they are also accumulating personal debt at unprecedented rates. Households that have seen an increase in net worth over the past few years have benefited from rising home values and stock prices rather than increasing personal savings rates. Some research indicates that US households in the bottom quintile have no wealth at all, and a large portion of these have negative wealth (i.e., debt).

Throughout the history of the United States, government initiatives have sought to encourage the acquisition of wealth by American households. These programs have enabled many families to secure homeownership and save for retirement. Unfortunately, many of these government subsidies have benefited native born white families far more than other groups, resulting in a large wealth gap patterned by race and ethnicity. For example, on average, African American households possess only 8 cents in wealth for every dollar possessed by white families. This disparity persists, even though the income gap between African American and white households has shrunk. African American households are also more likely to possess wealth in the form of residential property than in a more liquid form such as stocks or bonds. Recently, providers of social services have begun to address these disparities in wealth by implementing asset based poverty reduction programs that help low income families secure homes and save for education and retirement.

Weber, Max (1864–1920)

John Drysdale

German sociologist Max Weber, the first child of Max Weber, Sr., and Helene Fallenstein Weber, was born in Erfurt, Thuringia, April 21, 1864. When Max was 5 years old the family moved to Berlin, where Max, Sr., an attorney, became active in both municipal and national politics, and following German unification served as a member of the *Reichstag*, 1872–84. During these heady years the Weber household was often visited by leading politicians and professors. While the conversations of frequent guests provided much stimulation for the young Weber, there is no doubt that the most important and formative influence on him was provided by his mother, a devout Protestant, spiritually sensitive, ethically concerned and active, and intellectually curious.

Weber studied history, economics, philosophy, and law at the universities of Heidelberg, Göttingen, and Berlin. Along the way he completed his military training for an officer's commission. By 1889 he was awarded a doctorate *magna cum laude* with a dissertation on medieval commercial partnerships, and completed his legal training, entitling him to serve briefly as a junior barrister (*Referendar*) in Berlin. In his choice of Heidelberg for undergraduate study as well as in his study of law, the young Weber was following in the footsteps of his father. However, he eventually decided to pursue an academic career. In 1893 he married a distant cousin, Marianne Schnitger, who was to become perhaps his most important intellectual companion. The following year he accepted an appointment as professor of economics at Freiburg. Weber began to attract wide attention with his inaugural public lecture, "The National State and Economic Policy," given in May 1895. This address was a testament to Weber's economic nationalism and, when it was published, sparked a controversy over Weber's claim that economic policy was the servant of the national state. In 1896 he was lured to Heidelberg to take the professorial chair in political economy previously held by Karl Knies, one of his former teachers.

Just as he appeared to be settling into a promising academic career, Weber suffered a psychological breakdown in 1897, unable to resume scholarly work until 1902. His attempts to return to classroom lectures were unsuccessful, however, leading him to forsake his professorial salary and appointment. His breakdown is thought to have been occasioned by a serious altercation with his father during a parental visit in Heidelberg in the summer of 1897. His father died several weeks later without their becoming reconciled.

Having resumed scholarly writing in 1903, Max ventured to extend his activities and responsibilities to editing a journal and to professional travel. In 1904 Max and Marianne traveled as part of a delegation of German academics to represent their country at the World Exposition in St. Louis, Missouri, where he lectured on rural society and economy in Germany. The couple spent several weeks traveling around several regions of the US, visiting relatives, sightseeing, and pursuing contacts with various academics and social leaders (e.g., Booker T. Washington and W. E. B. Du Bois).

In the same year, Weber assumed the lead editorial responsibilities for the major social science journal of the time, *Archiv für Sozialwissenschaft und Sozialpolitik* (Archives for Social Science and Social Policy). He also completed work begun the previous year on a pair of extended essays under the title “The Protestant Ethic and the ‘Spirit’ of Capitalism.” From this point on to the end of his life he maintained an intense pace of scholarly work. Over the next few years he wrote several essays on methodological problems, replied to critics of his work on Protestantism, wrote further on religious sects in North America, conducted research and wrote about the psychophysics of industrial work and about agrarian conditions in ancient society. Beyond these topics he found time to contribute to public exchanges on various topics, including conditions of academic freedom in German universities and the status of women in employment. With the incipient revolution against the tsar in Russia, Weber learned Russian well enough to keep up with events in Russian newspapers and journals. He also published his political sociological analyses of current conditions in Russia in the wake of the 1905 revolution.

In 1910 he joined with his brother, Alfred, and a few other colleagues, including Robert Michels, Georg Simmel, Ferdinand Tönnies, and Ernst Troeltsch, to establish the German Sociological Society. Having begun his career in the study and practice of law and the academic appointments at both Freiburg and Heidelberg as a political economist, he began to identify himself also as a sociologist in the last decade of his life. The common thread in all three of these identities was his interest in the historical dimensions of social and cultural phenomena, including legal, political, economic, and religious spheres.

With the outbreak of war, Weber served for a brief time as an administrator for a military hospital in Heidelberg. Even during the war he continued to work on multiple research and writing projects. One of these, published after his death, became known as *Economy and Society*, part of a large scale handbook series in the social sciences. A second project became his largest body of work, his comparative studies of what he called “world religions,” again published posthumously under the rubric of the “economic ethic of world religions,” better known in the English speaking world as his sociology of religion.

Toward the end of his life, Weber again tried to resume university teaching. He taught a summer course in Vienna in 1918 before accepting an appointment to the chair of political economy at Munich for the academic year 1919–20. Here he lectured on economic history and sociology, among other subjects. He completed revisions to “The Protestant Ethic and the ‘Spirit’ of Capitalism,” but was still working on other revisions for the first volume of his multi volume series on the economic ethic of the world religions when he became ill with influenza in early June 1920. He succumbed to pneumonia at his home in Munich on June 14.

EARLY WORK AND VISION OF THE SOCIAL SCIENCES

Weber’s earliest projects were historical and empirical. On the historical side were his doctoral and habilitation dissertations, the first on the history of commercial partnerships in medieval Europe (1889), the second on agrarian

Roman economic history (1891). Each won accolades from his professors and attention from scholars. Weber's foray into empirical and quantitative research began as early as 1892 with his participation in a large scale survey of East Prussian agricultural conditions sponsored by the *Verein für Sozialpolitik* (Association for Social Policy) with a focus on conditions of rural labor. Weber joined the study in midstream but contributed significantly to the interpretation of the empirical findings. This work was related to the emerging fields of agricultural economics and rural sociology. Among other things Weber concentrated on the policy implications of the transition from patriarchal agrarian social and economic structures and traditional attitudes to more modern and rational entrepreneurial forms and practices associated with emergent capitalism. Also, the study of agricultural labor represented for Weber a shift away from legal toward economic perspectives.

Between 1903 and 1908 Weber published several so called "methodological" essays in which he addressed a wide range of questions concerning the goals, subject matter, and methods of the social sciences. The most famous of these essays was "'Objectivity' in Social Science and Social Policy," published in 1904 as Weber was assuming the co editorship of the influential journal *Archiv für Sozialwissenschaft und Sozialpolitik*. He sketched his vision of the social sciences as grounded in cognitive interests that are in part historical and in part theoretical, and as seeking relevance to questions of value and contemporary social policy.

Weber's extended discussion of concept formation focused on his notion of "ideal type" concepts. Ideal types are conceptual instruments that seek to represent the most relevant aspects of a given object (e.g., "city," "patriarchy," "capitalism") for purposes of social scientific inquiry. They are formed as deliberate constructs through a process of selection, abstraction, and idealization. Ideal type concepts aim to be useful rather than descriptive, for they are not intended to represent actual phenomena. Weber maintained that they were in fact indispensable for purposes of inquiry and clear exposition. Moreover, ideal types are well suited to a vision of social science concerned with representing the cultural significance and value oriented aspects of social phenomena

within the context of historically oriented causal inquiries. When it is forgotten that social scientific concepts of phenomena and processes are mere constructs, the result is the fallacy of *reification* with respect to objects (e.g., the view that "rationality" is real) or to processes (e.g., the view that "rationalization" is a real force). On similar grounds Weber was distrustful of both organicism (e.g., the view that collectivities as such are real) and evolutionism (e.g., the view that processes of change are lawlike, real forces moving in any single direction) as found in the nineteenth century sociological positivism of Comte and Spencer. Weber's position with respect to these issues has been variously characterized as methodological individualism, atomism, and nominalism.

WEBER'S RESEARCH PROGRAM: TWO MACROSOCIOLOGICAL STUDIES

Weber came to identify his work with the field of sociology relatively late in his career and only through a circuitous route that began with his training in law and proceeded through his early academic work in economic history and political economy. Initially skeptical of Comte and Spencer's sociology, in the last decade of his life Weber participated in the German Sociological Society and began to identify his work with sociology. His sociology was largely historical and comparative, a valuable complement to the historical study of economics, politics, and religion. His greatest substantive contributions to sociology were associated with two great macro sociological projects that occupied most of the last decade of his life.

Economy and Society in World Historical Perspective

Weber's first major project became known as "Economy and Society." This title actually was assigned to Weber's incomplete contribution to a multi volume series that was to include works from many social scientists under Weber's general editorship. The large scale project *Outline of Social Economics* was planned around 1910 and occupied a great deal of Weber's time and labor for the rest of his life. At the time of his death, his own contribution consisted of two

unfinished sets of manuscripts. The longer one, published as Part Two of *Economy and Society*, was written mostly between 1910 and 1914. A more compressed manuscript, published as Part One, was written in his last years. Following his death in 1920, his editors, chiefly Marianne Weber, had to decipher Weber's intentions regarding the inclusion and arrangement of these fragmentary manuscripts.

The book *Economy and Society*, although lacking in rigorous internal order and coherence, nevertheless represents an enormous achievement of encyclopedic scholarship with a global reach. Guenther Roth has called it a kind of "sociologist's world history." Its conceptual and theoretical foundations were first outlined in published form in Weber's 1913 essay "Some Categories of Interpretive Sociology." There he sketched a vision of an "interpretive" sociology that included both the interpretive understanding and the causal explanation of intelligible human conduct. "Social action" was treated as the core of human social life. This type of conduct has two chief characteristics. First, it is undertaken by an individual actor on the basis of a subjectively intended meaning. Second, it is oriented toward the behavior of other people. Such conduct is amenable to intelligible explanation despite varying degrees of rationality and familiarity in terms of an observer's experience. As Weber put it: one "need not be Caesar to understand Caesar." Any social action has both subjective meaning and objective conditions, both of which are important in sociological explanation. Weber's dualistic conception of social action can be understood as a synthesis of two scholarly traditions or paradigms: hermeneutics, which emphasized the understanding of meaning, and positivism, which focused on the causal explanation of empirically observable conditions.

Part of the opening chapter, "Basic Sociological Terms," in Part One of *Economy and Society*, includes Weber's extended treatment of social action as the basic conceptual building block for the interpretation of human conduct. There he develops a typology of social action in the form of a series of "ideal types." The types of action are delineated, first, in terms of a distinction between rational and non rational action, where "rational" refers to more or less conscious consideration of one's action as a way

of achieving a given end. Rational social action can be of two types: *instrumentally rational*, in which there is calculation of the choice of means to achieve a chosen purpose, and *value rational*, in which the calculation is limited to the possible means to be undertaken to pursue a value treated as an end in itself. Non rational action also displays two main types: *emotional affectual*, in which action is determined by immediate emotions toward someone or something without pausing to calculate choices in terms of relations of means to ends or likely consequences, and *traditional* action, in which action is guided by ingrained habituation, and may involve little consciousness, much less calculation. Weber intended the typology to provide value free concepts by which observers could interpret actions of people in virtually any kind of social context. In real life most, if not all, social action represents some mixture of these types. Traditional, or habitual, action is very common in all societies, as is emotional affectual action. Though perhaps less common, the rational types of action exhibit more individual mastery or self control over one's conduct, and imply also the possibility of taking responsibility for the values and consequences associated with individual conduct.

Consistent with the aims of a comprehensive reference work, much of Part One of *Economy and Society* presents a broad array of relatively abstract typologies, ranging from types of social action and social relationships to organizations, institutional structures, and social stratification. Also in line with the multidisciplinary reach of the work are typologies of economic and political action and structures. In general, Weber's procedure is, first, to stipulate a definition of a given concept as an "ideal" or "pure type," and then to provide illustrations and commentary based on historical and comparative research. The best known and most widely used of the dozens of typologies in Part One is Weber's threefold typology of political authority or legitimate domination (*Herrschaft*). *Rational legal authority* rests on a belief in the legality of a framework of enacted rules by which rulers are selected and by which they govern. Constitutional republican forms of government and parliamentary democracies exemplify rational legal authority. *Traditional authority* rests on a belief in the time honored sanctity of traditions.

Traditional leaders are chosen in accordance with inherited, unwritten rules and are obeyed on account of their traditional status. They often rule by personal loyalty based on either kinship or common upbringing. Among the types of traditional rulership Weber mentions gerontocracy, patriarchalism, and patrimonialism. Finally, *charismatic authority* rests on a belief in the special, even divine or superhuman, qualities (sanctity, heroism, exemplary character) of a person to rule, apart from inherited traditions or laws. Obedience is owed to the person and commands of the individual leader on the basis of personal *charisma* (literally, “gift of grace”), which may include magical powers or a record of heroic achievements in the hunt or in war. Charismatic rule may be involved to a greater or lesser degree in religious, military, and political contexts. Weber seems to have adopted the concept of charisma, modeled on the case of Jesus Christ, and extended it to apply to non religious contexts, for example, Alexander the Great and Napoleon.

In the second part of *Economy and Society* Weber elaborates his well known and highly influential concept of *bureaucracy*. Although bureaucracies existed in one form or another in ancient and non western contexts, such as Confucian China and Hindu India, Weber was interested primarily in the role of bureaucracy in modern western societies. In its purest form bureaucracy exhibits the following characteristics: a hierarchical organization of offices (official functions) is governed by laws or administrative regulations; each office has a specific and limited jurisdiction within which it has the authority to carry out its specialized activities; appointment to official positions requires technical qualifications and training; staff members are typically employees who regard their jobs as careers, but they do not own the resources or “means of production” associated with their offices; and official rules, decisions, and actions are recorded in writing and maintained on file as part of the organization.

In Weber’s view the development of bureaucratic forms of organization in the modern West was part of a marked trend toward *bureaucratization* across a broad range of institutions. Bureaucracy came to epitomize the modern national state in its legal system, and in its military and civilian administrative (e.g., civil service)

structures and procedures. The state was not alone, however, as a site of bureaucratic organization and control. Bureaucracy, which had arisen early on in the context of church organization, was adopted as the most efficient means of organizing work and decision making in economic units such as corporations and banks, educational institutions such as academies and universities, and other public services such as hospitals, transportation, and communications.

While bureaucracy was not a modern invention, nor exclusive to the western world, it became greatly elaborated within modern western institutions, especially in the government of modern national states. Weber regarded bureaucracy as particularly consonant with the rational legal type of political domination, also increasingly typical of western modernity. All the designated properties of bureaucracy, especially its governance of action by impersonal standards and systematic procedures, its organization of work activities in the name of efficiency, and its codification of rules and records, were harmonious with rational legal domination as opposed to governance based on personal loyalties to either traditional or charismatic rule.

Bureaucratization – the development and spread of bureaucracy – in turn, is conceived by Weber as part of a historical process of *rationalization*, which is the extension of various types of rationality. Bureaucracy represents *formal*, as opposed to *substantive*, *rationality*, given the character of bureaucracy as merely an instrument or tool which can serve virtually any set of (substantive) ends or purposes. That is, the rationality of bureaucracy is limited to its form rather than the aims or purposes of any particular organization. Weber envisioned the extension of rationalization in part through the growth of bureaucracy in ever widening sectors of society.

Bureaucracy cannot be judged to be completely good or bad in its consequences either for individuals or for the society as a whole. On the one hand, bureaucracy represents the most efficient form of organization for the achievement of a broad range of human purposes and values. For instance, the development of capitalism, which Weber termed “that most fateful power in our modern life,” has been greatly facilitated by bureaucracy with respect to the internal organization of economic enterprises and in

the environment in which these enterprises function (e.g., financial and governmental organizations) by providing for calculability. Indeed, in all the arenas of modern life, bureaucratic apparatuses enable the most efficient possible means for the achievement of complex tasks. On the other hand, bureaucracy has its costs and even irrational consequences. For one, the actions of bureaucratic staff are highly constrained by the framework of impersonal, abstract rules, and the personalities and attitudes of the staff tend to become habituated to the impersonal, emotionally indifferent patterns of behavior in the bureaucracy. The individual bureaucrat is reduced to the status of a small cog in a large and complex machine, prescriptively devoid of any exhibition of love, hate, or any other emotion or value commitment. At the societal level, the existence and intensity of value diversity and conflict are exacerbated by the very efficiency of organizations devoted to fundamentally different and perhaps incompatible goals such as capital versus labor, and public versus private interests.

Bureaucracy is only one of 16 chapters in more than a thousand pages of Part Two of *Economy and Society*. Three other chapters have been published separately as books and have achieved classic status in their own right: *The Sociology of Religion*, *The Sociology of Law*, and *The City*. Of these topics, religion most concerned Weber during his last years, although he never treated it in isolation from other institutions and spheres of life. It is also the topic that most obviously connects *Economy and Society* with his other major substantive project, discussed next.

The Comparative Studies of Civilizations: The “Economic Ethic of World Religions”

Weber’s second major project was conceived under the rubric of “the economic ethic of the world religions.” Massive in scope, this study focused on each of several “world religions,” including Confucianism, Taoism, Buddhism, Hinduism, ancient Judaism, Islam, and Christianity. (The treatment of the latter two religions was left incomplete upon his death.) The focus on religion as indicated in the titles of the component parts (e.g., *The Religion of China*,

The Religion of India) was misleadingly narrow. In actuality these were comparative civilizational studies, showing how religion is implicated in all the major spheres of society and culture in each case.

The design as well as the execution of Weber’s research program, culminating in this comparative historical project on major civilizations *cum* world religions, developed in stages over the last two decades of his life. The starting point can be traced to his renowned study of the relation of the Protestant ethic to the “spirit” of modern capitalism, dating from 1904–5.

The Protestant Ethic and the Spirit of Capitalism

In this earliest stage of his research Weber was interested in ascertaining the contribution made by a set of religious beliefs and practices to the development of the specific form of modern (“rational”) capitalism as found in Western Europe and the US. What marked this modern form of capitalism as new was especially the emphasis on the systematic organization of work done by laborers hired on a formally free market, and enterprises devoted to the pursuit of increasing profit without the constraints of traditionalism. Here as elsewhere in his work Weber recognized that there had been other prior forms of capitalism in Europe as well as non western capitalistic forms and practices. Likewise, he acknowledged that the rise of capitalism as a specific economic system in modern Europe had many causes, both material and cultural. His central problem here was, first and primarily, to explain the rise, not of capitalism as a system, but of the peculiar “spirit” (ethos, mentality) of this new economic system, and second, to show how this new ethos made specific contributions to the intensive growth of modern capitalism in its most crucial stages, especially in the eighteenth and nineteenth centuries. Hence, the problems he addressed were complex, yet circumscribed, as were his hypotheses, lines of argument, interpretations of evidence, and conclusions. This is not to say that his arguments were free of ambiguities, nor that the evidence he marshaled was completely convincing.

What was the new “spirit” of capitalism that Weber took as the object of his inquiry? He

described it as an ethic, albeit a secular one, lacking immediate religious foundation or reference, yet prescribing as a moral duty the pursuit of earning more and more money as an end in itself. Whether as an entrepreneur, independent craftsman, or laborer, an individual is obliged to make the acquisition of money from their occupation the center of their life. At the same time, the individual is also duty bound not to pursue wealth in order to spend money for the enjoyment of luxury or leisure. The acquisition of wealth is its own reward. Waste of time or money is admonished; frugality, reinvestment, and credit worthiness are virtues. Although the historical origins of this distinctly modern frame of mind are unclear, Weber believed that this new positive moral outlook on the acquisition of money had emerged in America and Western Europe by the eighteenth century. One of the surprising claims is that Weber's spirit of capitalism grew and flourished largely independently of the system of capitalism itself. Weber acknowledges that Benjamin Franklin, though a great exemplar of the new spirit, did not fit the model of the modern capitalist, nor was capitalism very advanced in its development in Franklin's America. This fact of the independent origin of the capitalist spirit, however, served Weber's view that it was not an ideology springing from the economic system that was its rationale, as Marxism might have posited. However, if the modern spirit of capitalism was not a product of the form or system of capitalism, the question becomes all the more urgent: What were the sources of this new attitude toward the acquisition of wealth, an attitude that became, as Weber put it, a leading principle of capitalism?

In his search for the historical origins of capitalism's modern spirit, Weber took as his point of departure the contemporary controversies over the respective orientations of Roman Catholics and Protestants toward capitalistic economic activities. In this context it had been noted as a matter of empirical fact that Protestants were more likely than Catholics to be involved in the more innovative and technically skilled types of capitalistic activity and at the same time were more likely to pursue the patterns of training and education appropriate for such work. Likewise, they tended to be more prosperous than their more tradition bound

Catholic counterparts. The attempts to explain these differences were the stuff of wide ranging if unproductive controversies at the time Weber himself began to take up the questions.

As Weber probed the possible sources of the differences he found them to lie in the early history of Protestantism. First, Luther and Lutheranism made key contributions, particularly in advancing the idea that worldly economic activities in pursuit of a livelihood were worthy "vocations," thereby providing enterprise and work with moral sanction. This, Weber reasoned, provided the impetus for individuals to devote themselves to worldly economic activity to a greater extent than in circumstances where tradition had dictated that work was either morally neutral or even evil, albeit necessary for economic sustenance. Second, Calvin and Calvinism provided additional, crucial incentives to work unstintingly in one's economic vocation. Here, Weber's line of argument about the connections between religious beliefs and economic activities becomes intricate and turns on the paradox of unintended consequences.

The central doctrine of original Calvinism was the belief in the predestination of one's soul to ultimate salvation or damnation, a fate that the individual believer could neither know nor change. This harsh doctrine was later moderated by pastoral interpretation (e.g., by the seventeenth century English minister, Richard Baxter) to alleviate the anxieties of believers tormented by their lack of knowledge concerning their personal salvation. Individuals were admonished to avoid self doubt regarding their status as members of the elect on the grounds that such doubts could be the work of the devil. Moreover, the best way to gain and sustain self assurance of one's salvation was to work tirelessly in one's earthly vocation. Thus, the only possible relief from the psychological isolation of salvation anxiety was to work assiduously and single mindedly in one's chosen economic vocation.

In Weber's interpretation the significant result of following this kind of religious counsel was the production of a new *this worldly rational asceticism* – "this worldly" in that the consequences were visible purely in the mundane world of work; *rational* in that the individual assumed self conscious control over their actions and life course; *ascetic* in that self discipline and

avoidance of temptations (idleness, pleasure, materialism) through complete devotion to labor came to dominate everyday life. With some variations this Calvinist asceticism permeated several other Protestant sects by the eighteenth century: Pietism, Methodism, and the Baptist sects, including Baptists, Mennonites, and Quakers, as well as Congregationalists and various independent sects.

According to Weber, this Protestant asceticism connected with the secular spirit of capitalism exemplified by Benjamin Franklin in the late eighteenth century. The exact nature of the linkage has been the subject of much dispute among Weber's interpreters and critics. Was Protestant asceticism the cause and capitalism's spirit the effect? Or was it mere parallelism, consonance, consistency, or "elective affinity" between the two? Or was it a case of historical metamorphosis, transformation, or secularization from the Protestant ethic to the later spirit of capitalism? Regardless of the exact nature of the connection between the religious ethic and the secular spirit, the potential economic consequences are easy to discern: employers and workers thoroughly dedicated to the program of capitalistic enterprise unfettered by the distractions of the world outside the factory, the workshop, or the firm. To the extent that Calvinism actually had these effects, they were clearly and paradoxically the unintended consequences of the religious doctrines and interpretations. Moreover, the contribution of Protestant asceticism in providing moral legitimacy and meaning to participation in modern capitalistic enterprises, however important in the crucial early stages of modern capitalism, began to fade into irrelevance during the nineteenth century. Capitalism had freed itself from religious and ethical moorings. By the early twentieth century the motivation to work had devolved into a mere compulsion in order to support an ever more prosperous and materialistic lifestyle, a compulsion likened by Weber to a "steel hard casing."

Economic Ethic of World Religions

If modern capitalism and its spirit were spurred initially by Protestant asceticism, and given that capitalism flourished in Western Europe, Britain, and North America as never before and as

nowhere else, the question became how to explain the relative lack of such capitalistic development in other times and places. In order to address this question Weber devised and partially executed a large scale study of civilizations, especially those of China, India, and the ancient Near East, a study that occupied much of his time during the last several years of his life. Of the multi volume work *Collected Essays on the Sociology of Religion*, he managed to complete only the first volume, which began with a revised version of the essay on the Protestant ethic, and included his essay on Protestant sects in America, his substantial study of Confucianism and Taoism, and finally an important essay on how various life spheres become differentiated from religion and from one another – "Intermediate Reflections: Religious Rejections of the World and their Directions." Further volumes were to include his studies of Hinduism, Buddhism, ancient Judaism, Islam, and early Christianity.

In each of these studies Weber examined a wide range of material and structural factors that in other times and places tended to retard a "rational" form of capitalism as it developed in the modern West. He reserved his central focus, however, for the role of the various religions, especially through the kinds of "economic ethic" they promulgated. In spite of significant differences among them they all lacked the kind of "this worldly rational asceticism" found in the modern West. Lacking this frame of mind and pattern of life inspired by the ideal of being God's instrument in, though not of, the world, none of the other world religions was in a position to support an ascetic, but energetic, spirit of rational capitalism.

RECEPTION AND LEGACY

In late 1917 Weber delivered a public lecture on "Science as a Vocation" at the University of Munich. This was followed in early 1919 by his lecture on "Politics as a Vocation" delivered at the same venue. The common theme of the two lectures was the importance of self renunciation involved in devoting one's life to either scholarship or politics. In both cases, however, the ascetic element was accompanied by a humanistic commitment to the values underlying the

pursuit of knowledge and public responsibility. In the lecture on science Weber was returning to a theme about which he had frequently spoken and written: the complex relation of values to science. On the one hand, scientist scholars are obliged to restrain their own value judgments from biasing inquiry. On the other hand, the problems of inquiry should be selected and constructed so as to make relevant contributions not only to knowledge but to social policy formation as well. In the lecture on politics, Weber distinguished between two “ethics” as alternative models of political leadership: the “ethic of conviction” by which leadership is based on the pursuit of an ultimate value as a “cause,” and the “ethic of responsibility” in which the emphasis is on taking responsibility for the consequences of decisions and actions. Weber clearly advocated the latter.

By the last stage of his career Weber had achieved a national reputation both for his scholarship and his politics. World War I had ended in Germany’s defeat, and Weber had assumed an advisory role to the defeated military and civilian authorities. As Germans looked forward to what became known as the Weimar Republic as the successor to the fallen *Kaiserreich* there was even some talk of Weber becoming a political leader. That possibility was cut short by his death in the early days of the new republic.

While Weber was widely recognized in Germany as a scholar and public figure, his work was not yet well known outside the country. None of his works had been translated into English prior to his death. Not until 1930 was *The Protestant Ethic* translated by Talcott Parsons. A complete English edition of *Economy and Society* had to wait until 1968. Even today it is still difficult to evaluate Weber’s reception and legacy. This is partly due to the fact that his work and perspective consistently transcended the boundaries of any single social science discipline of his time or ours. Thus, in addition to being claimed as a leading founder of twentieth-century sociology and a major contributor to modern political science, public administration, and political theory, he has been recognized for significant contributions to the fields of economic history, historical jurisprudence, the study of ancient civilizations (most especially Rome and the Near East), and the comparative study of religions. He was a historian who

became a sociologist, a sociologist who remained an economist, a serious student of ancient society who contributed significantly to the understanding of modern western culture, its distinctiveness, and its development. He was equally captivated by the study of economics and religion, of material and ideal factors, of social structure and individual action. In sociology his contributions are recognized especially in the areas of law, religion, and the economy; in the study of social stratification, political, urban, and rural sociology, and the sociology of culture. In terms of the method and general conception of sociology, Weber insisted that social action is the conceptual foundation of our understanding of societal structures. Insofar as action carries meaning it is intelligible through the use of *Verstehen* (understanding) in the context of interaction and of sociological observation. As important as action is, Weber gave even more attention to what he called order and to what sociologists later came to view as social structure. Action and structure, for Weber, interact in complex loops, with structure emanating either directly or indirectly as a result of action, yet with subsequent action both enabled and constrained by existing structure. Weber is rightly regarded as the founder of structural sociology (stratification, institutions) as well as the sociology of action.

Weber’s influence, already enormous, is likely to increase. Not all of Weber’s writings have yet been translated into English or Japanese, the two major languages for the reception and study of his writings. Nor is the end yet in sight to the monumental project of collecting, editing, and publishing all Weber’s surviving writings and correspondence, the *Max Weber Gesamtausgabe*.

In preparation for the 14th World Congress of Sociology in Montreal in 1998, the International Sociological Association surveyed its members around the world to determine the most influential books written by sociologists in the twentieth century. Weber’s *Economy and Society* was selected as the most influential book of the past century, followed not far behind by his *Protestant Ethic and the Spirit of Capitalism* (ranked fourth). Weber was also chosen as the most influential author of the twentieth century by both male and female sociologists among the 455 respondents to the survey. Given the broad

sweep of Weber's historical comparative sociology and the recent and planned publications of Weber's works in German, English, Japanese, Chinese, and other languages, his legacy is likely to increase in global influence.

welfare dependency and welfare underuse

Hartley Dean

Welfare dependency is a term that refers to the use that people make of publicly provided cash benefits (sometimes called cash transfers) or human services. Welfare underuse is the term applied when people who are entitled to publicly provided benefits and services fail to take them up.

WELFARE DEPENDENCY

Welfare dependency, therefore, is a feature of advanced industrial societies with developed welfare states, whose citizens enjoy specific "social" rights (e.g., to social security, health care, social support, and education). The premise on which the advocates of state welfare provision promoted its development was that, as the social division of labor in society becomes more complex, the "states of dependency" that arise at various points in the human life course can be defined and recognized as collective responsibilities (Titmuss 2001: 64). However, the social policymakers who fashioned the modern welfare states of the post World War II era were often "reluctant collectivists" (George & Wilding 1985). They may have favored guaranteed basic minimum provision by the state, but they also wanted people to depend on income from paid employment on the one hand and on support from their families on the other. Welfare states have developed in different ways in different parts of the capitalist world, and while social democratic welfare states (e.g., Sweden) have sustained relatively high levels of state welfare dependency, liberal (e.g., the US) and conservative (e.g., Germany) welfare states have tended to discourage it in favor of labor market or family dependency, respectively (Esping Andersen 1990).

Since the 1970s, the idea of welfare dependency has become increasingly contested as support for state welfare provision has declined. Economic globalization, it was claimed, put welfare state spending under pressure (because it was alleged to make national economies uncompetitive); social and demographic changes in western societies placed what some regarded as unsustainable demands on welfare states (for example, because of population aging, and because of rising numbers of lone parent households); and the political rise of the New Right presented a wholesale challenge to the legitimacy of state welfare dependency. Despite this, where people depend on state education, contributory state pension schemes, or health care provision, these have by and large retained popular and political support, but cash benefits for people of working age and public housing provision by and large have not. In some countries – particularly the US – the term welfare has been associated specifically with means tested

or income related social assistance for the poorest and has acquired a distinctly pejorative connotation (Fraser 1997). Just as the Poor Law regimes that had preceded the development of modern welfare states had deliberately stigmatized the undeserving poor, dependency on the state for income and/or housing and for certain kinds of social support entailed an inherently and increasingly stigmatized status.

Theorists of the New Right (e.g., Murray 1984) claimed that the perpetuation of welfare dependency undermines society by eroding individual responsibility and that it discourages people from sustaining themselves through employment and/or within their families. Earlier anthropological studies had suggested that urban slums in various parts of the world exhibited a culture of poverty that was transmitted from generation to generation. Now, it was claimed, the welfare state was breeding a culture of idleness, irresponsibility, and dependency and was contributing to the creation in many developed western societies of an "underclass." Unemployment and lone parenthood were blamed on the ready availability of cash benefits and public housing which acted as disincentives to self sufficiency and economic independence on the one hand and to marriage and family life on the other.

Critics of this thesis have drawn upon evidence that people who depend on cash benefits from the state exhibit no signs of a culture of dependency: on the contrary, they tend to subscribe to the same values, aspirations, and prejudices as does mainstream society (Dean & Taylor Gooby 1992). It has been argued that we are witnessing a form of "dependency fetishism" that obscures our understanding of the interdependency that characterizes human society. Popular and political discourse tends perversely to regard our dependency on employment and within families as "independence," but uniquely to problematize state welfare dependency.

When one considers the total value of all the benefits and services citizens in developed countries typically receive from the welfare state, most of this is likely to have been self financed through the various taxes and social security contributions that they will have paid in the course of their lifetimes (Falkingham & Hills 1995). The availability of new forms of longitudinal social data enables us to consider the dynamics of poverty, and to see that for

many unemployed people and lone parents who claim cash benefits provided by the state, their dependency is likely to be a relatively short lived and not necessarily an enduring experience (Leisering & Walker 1998).

WELFARE UNDERUSE

Welfare underuse is in substantial part, but by no means solely, attributable to the stigma often associated with welfare dependency. It is important to distinguish between the underuse of cash benefits, transfers, or their equivalent in kind (e.g., food stamps or food cards) and the underuse of public or social services.

The underuse of cash benefits provision is often referred to as a failure of benefits "take up." A considerable body of research on benefits take up was conducted in the 1970s and 1980s (for an overview, see Craig 1991). It is widely recognized that conditional means tested benefits or social assistance schemes have much lower rates of take up than universal or contributory benefit schemes (under which citizens may have an automatic entitlement or an entitlement based in social insurance contributions). This was attributed by researchers to the sense of stigma that may attach to claiming such benefits, to ignorance on the part of potential claimants, and/or to the administrative complexity of the schemes. The research drew either upon psychological models, which assume a set of behavioral thresholds that potential claimants must overcome, or econometric models, which assume that potential claimants weigh up the utilities and disutilities associated with claiming their entitlements. Subsequent comparative research, however, has informed an "interactive model" of take up that looks at multi level influences at the scheme or systemic level, at the administrative level, and at the level of the claimant or client (Oorschott 1995). This sociological approach emphasizes both the structural features of welfare systems and the consequences that may flow, for example, from the behavior of administrators, bureaucrats, and caseworkers, who may develop informal methods to ration access to welfare provision.

The underuse of public services may similarly result from structural and administrative features of those services. Of particular concern

is the differential use of services by different social classes or minority groups. Certain kinds of public services, such as health care and education, may be more extensively used and provide greater benefits to middle class families than to the poorest families who need them the most (Le Grand 1982). One of the most spectacular failures of many modern welfare states is reflected in the fact that benefits of advances in medical science and health technologies have been so unequally distributed (Wilkinson 1996). Even in countries with a universal national health service (e.g., the UK) people from lower socioeconomic classes and/or from minority ethnic groups experience significantly higher mortality and morbidity rates and make less use of health services than people from higher socioeconomic classes and from the white population. The reasons for this are complex. They reflect the extent to which inequalities in income may be translated more generally into inequalities in life chances and inequalities of power. But they also reflect some of the subtle ways in which public service providers may discriminate against, or be culturally insensitive to, particular groups in society.

The majority of the population in developed capitalist welfare states will during particular stages of their life course depend upon or make use of publicly provided or state financed health, education, and welfare services. That is a measure of the level of a country's "social development." Social policymakers and sociologists may, however, be concerned about whether, by whom, and why dependency upon such provision becomes excessive; or conversely about whether, by whom, and why such provision may be underused.

welfare fraud

Siegfried Lamnek and Ralf Ottermann

Sociologists define *fraud* as any deception the intended outcomes of which are knowingly in breach of norms (of honesty, reciprocity, solidarity, etc.), and define *deception* as any intentional non disclosure and/or misrepresentation of relevant information, which is to make others behave in a way they would not if they were well informed (Ottermann 2000). Many frauds do not violate laws and/or are considered relatively harmless. But some frauds are regarded not just as unfair or illegitimate, but also as illegal acts of deception. Such is *welfare fraud*, committed in order to obtain unauthorized benefits, which is seen as a violation of statute, as an offense against the rules that regulate the welfare system. In legal terms,

welfare fraud (benefit fraud, public assistance fraud) is defined as making a false or misleading statement or committing an act intended to mislead, misrepresent, conceal, or withhold facts concerning the eligibility for public assistance, which is determined, for instance, by (dis)information of the current marital status, household composition, employment status, income, receipt of monetary and in kind gifts, bank accounts, and other resources of the claimants or clients. Welfare fraud is committed when persons make false statements, and/or misrepresent facts, or when (changed) situations are not reported to the departments of social services, in order to obtain public funds for which the beneficiaries would not otherwise be eligible. Labeled a crime, welfare fraud can result in imprisonment, probation, repayment, recoupment, or becoming ineligible for assistance for a certain length of time.

Welfare fraud is socially perceived as an illegal as well as an immoral act of deception and treated as a *social problem* in public discourse. In contrast to similar offenses against the state and its welfare system, such as minor tax evasion or illicit work ("moonlighting," "doing something on the side"), welfare fraud is easily scandalized and stigmatized by opinion leaders and moral entrepreneurs, since it is often seen as an "underclass fraud" and as such as a behavior of already otherwise stigmatized minorities predominantly problematized and combatted by the "moralizing upper and middle classes" and the "legislating political elites" (social scientists included). Welfare cheats have few defenses since nearly all the circumstances of their lives are under public scrutiny and they carry a "moral taint" as persons unable – if not unwilling – to earn a living (Barker et al. 1990). Thus, people who intend and commit welfare fraud have to face and to deal with the fact of extraordinary *social control*. But even if they try, they will be less successful in doing stigma management than illicit workers and tax evaders, and this in spite of the fact that the latter are often perceived as doing the greater harm to the public purse (Schäfer 2002). Despite the relatively low costs caused by welfare fraud to the public purse, an outraged public opinion – fueled by mass media campaigns and pronouncements by politicians – led to the establishment of relatively expensive anti fraud

squads specialized in the detection and prosecution of welfare cheats (Pemberton 1990). This raises doubts whether the latter makes sense fiscally in regard to the former (Matt & Cook 1993). Moreover, the public (mis)perception of welfare fraud is often (mis)used as a justification of tax evasion and welfare cuts, and vice versa. However, there has to be a welfare system for people to commit welfare fraud, and people have to appear needy: they have to meet certain criteria, such as poverty and helplessness and/or a basic willingness to work, in order to at least seem eligible for public assistance (Lamnek et al. 2000).

The welfare state was originally not designed just for the poor; instead, it should prevent all people from becoming too poor and deprived, and hence becoming a risk for social order and cohesion. It was supposed to offer social protection for everyone, even though people depending on welfare should not be better off than self-sufficient laborers, therefore relying on deterrence and the stigmatization of (potential) welfare recipients as a way of policing the boundaries. However, social welfare has shifted back towards minimum provision of the poor and the stigmatization of welfare recipients (Spicker 2002). The policy of holding down support for the poor and unemployed is supposed to minimize the incentives to claim benefits and remain on welfare unnecessarily and to maximize the willingness to work for the purpose of self-sufficiency, thereby protecting laborers' dividends of conformity with the central rules of the *occupational society*. Welfare policy can then be seen as a form of social control which creates social values (e.g., the value of work) and shapes social identities (e.g., as deserving or not) and relationships (e.g., between taxpayers and the poor) (Raftopoulou 2004). But the policy of minimal provision plus financial cuts in the name of work has the unanticipated consequence of making illicit work while claiming benefit ("doing the double") more attractive – even for the employers of welfare cheats and contrasting with the stereotype that people on welfare usually are unwilling to work. The real issue is that legal employment opportunities ("proper jobs") to make a living are especially rare and declining for the less qualified, trained, and educated "reserve army of cheap labor" (Evason & Woods 1995).

In public discourses welfare cheats are often (mis)used as scapegoats for structural problems of social change and for unemployment in modern developed societies. Challenges (e.g., resulting from the mobility of global players or demographic aging) have limited the resources available to the welfare state, while at the same time increasing the extent and magnitude of welfare needs. Especially during economic recession, when financial resources are short and governments intend to redress budgetary deficits, the connection between socioeconomic positions and prospects on the one hand and people's attitudes towards welfare on the other hand is becoming obvious. The perceived (in)efficiency, (un)fairness and/or (il)legitimacy of the welfare system induces (non)compliance with the system and, as a result, (in)tolerance of welfare fraud, tax evasion, and moonlighting. The extent of compliance with the system, the degree of tolerance of fraudulent practices, and the tendency to minimize versus dramatize fraudulent behavior in public discourses correspond to differing conceptions of *distributive justice*. According to the principles of distributive justice, people believe that goods and burdens in a society should be fairly distributed. The principle of achievement or contribution contrasts with the principles of equality and neediness. Ideas of individual responsibility, minimal taxes and entitlements, private provision, and self-help partly collide with notions of welfare. In public opinion, a social policy of minimal support and welfare cuts seem the more legitimate the more welfare is associated with fraud, abuse, social irresponsibility, laziness, waste of public funds, tax burdens, and welfare costs. Politicians claim lean welfarism as an appropriate method to divide the deserving from the non-deserving. However, minimum welfare and maximum control of the welfare recipients also reduce the chances of the really needy escaping from welfare dependency. This in sum may lead to resentments against the system and the willingness to cheat it for socioeconomic reasons. These varying conceptions of distributive justice on attitudes towards the welfare state correlate with socioeconomic positions and prospects, risks, strains, aims, and claims. People use conceptions of distributive justice to legitimate welfare fraud. They can "blame the system," for instance, as "being rigged" and/or "fostering

social injustices.” In contrast, it is easier to scandalize welfare fraud when it is seen as “part of the system” (e.g., as a symptom of so called “welfarization”). When people are convinced that fraudulent behavior (welfare fraud, tax evasion, and illicit work) is widespread, they prepare themselves for such a behavior, which is, in the first place, to increase or keep their own socioeconomic resources (Lamnek & Luedtke 1999).

Public discourses of welfare fraud (e.g., its rise and fall as a social problem) are a subject of *discourse analyses* and historical and comparative sociology. In contrast to official statistics which mainly deliver the results of the (selective processes brought about by the) social control of welfare fraud, *social surveys* provide more valid data concerning intra and intercultural differences in the public opinion of welfare fraud, as well as its incidences. *Self reports*, focused *group discussions*, and *interviews* display the perspectives and motives of the cheats and their patterns of interpretation of the situation(s) and corresponding neutralizations of social norms (which lower the anticipated moral costs of deviant/delinquent behavior). *Life history approaches* give insight into so called de shaming processes (which reduce the costs of self and peer imposed punishment and stigmatization, and therefore, for example, explain, opportunity structures notwithstanding, why welfare cheats tend to engage or to be involved in further “criminality”), while *case studies*, *field observations*, and *ethnographic research* expose the impact of social milieus, such as differential associations and processes of (the offenders’) social learning and informal patterns of the agencies of (formal) social control. The combination of qualitative and quantitative methods seems to be the best practice for exploring the macro social and micro social dimensions of welfare fraud, as well as for generating and testing theories along the macro–micro–macro link.

As far as welfare fraud as a *deviant/delinquent behavior* is concerned – as a social action which makes sense to (potential) offenders – sociologists have found that anticipated threats and rewards through informal sanctions have greater effects on people’s behavior than anticipated threats and rewards through formal sanctions. Internal self control, the clear versus bad conscience which is anticipated, is – as far as social

norms have been internalized and cannot be neutralized – more important than the anticipated external social control. The anticipation of other people’s perceptions of one’s own actions is the more crucial the less is the social distance. Thus, besides the threat of legal sanctions and the feelings of guilt that individuals might impose upon themselves when they offend their own conscience by engaging in behaviors they consider morally wrong, there is also the threat of shame, embarrassment, and social disapproval that individuals might experience when they violate norms which people they value support (Yaniv 1998). Sociologists investigated the comparative deterrence effect of formal and informal sanctions (i.e., the perceived certainty and severity of legal punishment on the one hand and the anticipated peer imposed punishments on the other hand) and found that, apart from past criminal involvement, which plays a significant social biographical role in so called de shaming processes, informal sanctions have a greater effect on welfare fraud than formal sanctions. Only such persons who have nothing to lose (e.g., being chronically short of money and de shamed since already marginalized and stigmatized as “on welfare”) are out of control. Thus, people have to be socially included, not excluded, if society is really interested in diminishing “underclass fraud.” If full employment turns out to be a social fiction, we will be in need of a change in social policy and therefore in need of sociological thought.

welfare regimes

Stephan Lessenich

Thinking in terms of "regimes" and "regime types" has become popular in comparative welfare research since the late 1980s. Originally stemming from international relations studies (Krasner 1983), the "regime" concept has been discovered for and adapted to welfare state research mainly by Danish sociologist Gøsta Esping Andersen, who used it in his seminal work on *The Three Worlds of Welfare Capitalism* to institutional nexus of work and welfare in advanced capitalist societies. Building on a welfare regime's capacity to reduce the market dependency of individuals ("decommodification"), its implications for the structure of social inequality ("stratification"), and the relative importance of state, market, and the family (or households) in the production of social welfare, Esping Andersen claimed that the modern welfare state comes in three ideal typical

variants: the "liberal," the "conservative," and the "social democratic" model. The great advance for welfare research brought about by this regime typology is twofold. On the one hand, the "three worlds" constitute a suitable tool for bringing order into the complex "real world" of welfare capitalism. On the other hand, and when it comes to specify the differences between advanced welfare states, the concept of welfare regimes focuses not simply on social expenditure data but on the qualitative aspects of welfare state policies, i.e., on the welfare state's relevance as a means of ordering social relations according to specific ideological convictions and normative principles. According to Esping Andersen, the relative weight of "liberal," "conservative," and/or "social democratic" convictions and principles in different national welfare regimes today depends on the power resources with which the respective social movements were able to engage in the "democratic class struggle" (Korpi 1983) around the welfare state, its emergence and its design, in the late nineteenth and early twentieth centuries.

Esping Andersen's "regime approach" has been the object of broad conceptual, methodological, and empirical criticism and, at the same time, guiding principle of much of the comparative research on social policy and the welfare state over the last 15 years. While the first wave of critique concentrated on the question of whether and how individual cases (i.e., national welfare states) could be subsumed to one (or another) of the three regime types, subsequent work focused on amending, extending, and transposing Esping Andersen's "holy trinity." Whereas some authors discovered alternative institutional models of linking work and welfare in Southern Europe, the Antipodes, or the emerging welfare states of Central and Eastern Europe, others contrasted Esping Andersen's male biased "decommodification regimes" with more gender sensitive "care regimes." In *Social Foundations of Postindustrial Economies* (1999), the author of *The Three Worlds of Welfare Capitalism* assumed part of that criticism, emphasizing the different welfare regimes' capacity of "defamiliarization" (i.e., of exonerating individuals from family burdens) and reformulating his regime types as different ("residual," "corporatist," or "universalistic") "models of solidarity." In any case, the ultimately academic

and futile struggle about whether there are three, four, or n “worlds of welfare” out there eventually has been settled. The future of the concept of welfare regimes lies in further analyses of the interplay (and possible “elective affinities”) between Esping Andersen’s “worlds of welfare” and different “varieties of capitalism” and, above all, in in depth case studies of the changing nature of national welfare regimes in times of accelerating social change, permanent economic austerity, and, not least, growing political transnationalization as it is most prominently reflected in the European integration process. In fact, this is where today the comparative study of welfare regimes may again, as back in the 1980s, profit from research on international regimes and their effects on policymaking and social agency.

welfare state

Markus Gangl

The essence of the modern welfare state lies in its institutional commitment to reconcile equity issues with the efficient operation of economic markets in industrial and post industrial capitalist societies. As capitalism institutionally relies on the free competition of autonomous individual agents in exchange markets to achieve economic efficiency, but meets with real world economies exhibiting an unequal distribution of wealth holdings, economies of scale in production, significant transaction costs, and imperfect information regarding prices and preferences, the unfettered operation of economic forces is likely to result in anything but an egalitarian distribution of economic well being in a society. As an institutional antidote, modern welfare states have developed various policy instruments to realign the distributional outcomes of the market with broader social objectives of governments and their constituencies – and hence, the welfare state has rightly come to be seen as institutionally expressing and preserving social solidarity in highly complex societies made up of socially as well as economically highly heterogeneous populations.

WELFARE STATE INSTITUTIONS

Historically, the foundations of the modern welfare state emerged in late nineteenth century Europe when governments responded to social upheaval generated by the transition to full fledged industrial economies. From the introduction of public health and pension insurance in Bismarckian Germany in the 1880s onwards, governments began – partly in response to dramatic social change itself, partly to check the

threat of a growing labor movement – to recognize the need to establish institutional mechanisms to guarantee that the broad majority of the population, especially the working class, would actually participate in economic growth generated by technological progress and an intensified transition to the capitalist mode of production. However, whereas the origins of welfare states have been in the social integration of the working class, welfare states have considerably expanded their scope and objectives, and have much refined their policy instruments over much of the twentieth century.

Nowadays, modern welfare states in fact consist of a broad array of institutions, policies, and programs aiming to secure adequate standards of living, broadly defined, for an encompassing majority of the population in industrialized societies. In consequence, welfare state institutions today comprise poverty relief through social assistance programs, social insurance against old age, ill health, job related accidents or unemployment, family policies through child benefits, childcare subsidies, and parental leave schemes, service provision in the form of job counseling, public employment offices, public childcare facilities or public systems of care for the elderly, public housing, and often extensive social worker services. Moreover, these welfare state programs, narrowly defined, have become embedded in systems of public education at the primary, secondary, and tertiary level of education, extensive public regulation of markets, extensive judiciary systems, systems of public policies to conserve the environmental bases of affluent industrial societies, and, last but not least, a tax system raising the financial means necessary to fund these various instruments of government intervention.

Clearly, existing real world welfare states differ significantly in both the level and range of welfare state commitments across the industrialized world. Encompassing welfare states and a respectively significant role of the state in social stratification as well as economic markets has been a hallmark of European societies. Due to strong labor movements and a long history of social democratic governance, Scandinavian countries, notably Sweden, feature particularly extensive welfare states that provide encompassing transfer systems compensating for social hardships, extensive public services to families

and the elderly, as well as a significant public sector providing these. As demonstrated by the historical experience of continental European countries like France or Germany, welfare state development was also spurred by Catholic social thought and dominantly Christian democratic politics, although resulting welfare states are typically more bent toward regulation, prefer social insurance to universal transfer systems, and are weaker on public service provision than their Scandinavian counterparts. In comparison, welfare programs are much less generous, and hence the role of the state in social stratification much more limited, in the United States, Britain, Australia, and New Zealand after the reforms of the 1980s, but also in most post communist countries of Eastern Europe.

ECONOMIC EFFECTS

Whatever the precise institutional arrangements, i.e., the specific national welfare mix institutionally balancing responsibilities and rights of families, markets, and government in any given society, there can be little doubt about the fact that the above policy instruments may constitute a veritable government intervention into private households' decisions on economic and social affairs. By providing transfers to compensate for social risk, governments deliberately alter the nexus between market incomes and household standard of livings, governments deliberately alter price structures by providing services and by subsidizing childrearing or education, governments deliberately alter households' market power by providing information, legal services, and regulation, and, last but not least, governments typically set up progressive tax systems to fund their services disproportionately through revenue generated from the well off as well as from prospering firms and sectors. As these and other effects are likely to significantly affect the structure of economic incentives and constraints, welfare states are equally likely to engender significant economic consequences in terms of both economic behavior of individuals and households at the micro level and with respect to societies' larger macro economic prospects – in fact, soliciting respective economic effects may well be considered, after all, the whole point of establishing welfare

state institutions. Given that welfare state institutions often fundamentally affect societies' economic structure, it is hardly surprising to find the empirical magnitude as well as the normative desirability of respective effects a matter of much social science discourse as well as public debate. To survey some of the key arguments and results, we address welfare state effects with respect to distributional outcomes, allocation, economic capabilities, and macroeconomic efficiency below, although this hardly provides an exhaustive list of total welfare state impact on the structure of advanced industrial societies.

Redistribution

To most, the welfare state simply is redistribution. Evidently, by providing income support to the needy and by funding these transfers through progressive taxes, welfare states succeed in redistributing income from the wealthy to the poor and hence contribute to alleviating relative poverty and to provide for minimally acceptable standards of living for practically the full population in the industrial world. To obtain empirical estimates of welfare states' redistributive impact, social scientists typically rely on data on household equivalent income, thus measuring standards of living by household income adjusted for household size. Defining (relative) poverty as standards of living falling below a threshold of 50 percent the national median household equivalent income, data from the cross nationally comparable Luxembourg

Income Study compiled in Table 1 indicate both generally low poverty levels in advanced industrial societies and a significant role played by the welfare state in bringing this about. In a country like Sweden, poverty rates measured for market incomes alone amount to about 15 percent, yet taking into account welfare state taxes and transfers, less than 5 percent of all households remain below the 50 percent poverty line. Apparently, much the same holds true for other European countries as well, whereas the United States clearly stands out for its weakly developed welfare state showing but little redistributive impact.

Furthermore, Table 1 also shows that welfare state redistribution extends well beyond the low income strata. Using the Gini coefficient – a measure ranging from 0 (perfect equality, i.e., everyone enjoying the same standard of living) to 100 (perfect inequality, i.e., all income earned by a single household) – to indicate the extent of overall income inequality in a given society, Table 1 again points to a significant reduction in income inequality due to welfare state efforts. Clearly, anti poverty transfers have their share in this as well, yet more detailed analyses make it plain that transfers to the non poor population like child benefits and particularly social insurance payments to the unemployed, the ill, and (although not included in the data of Table 1) the elderly are integral to welfare states' redistributive efforts in the population at large. As this points out, reducing the welfare state to mere anti poverty transfers would be to severely misrepresent its redistributive role: in

Table 1 Poverty and income in equality in western countries (working-age households only), 1980s–1990s

particular, as social insurance seeks to protect households against income losses from adverse events, welfare states deliberately redistribute incomes to non poor households temporarily hit by income shocks in order to promote economic security and consumption smoothing over the life cycle. Accordingly, both pro poor redistribution through targeted transfers and redistribution over the life cycle through social insurance are decisive for the redistributive impact of the welfare state.

Allocation

Against the significant role of the welfare state in reducing economic inequality, social scientists have wondered whether these redistributive efforts might not generate negative side effects on the economic behavior of individuals and households. Most prominently, neoclassical economics asserts that high tax loads required to fund extensive welfare programs generate work disincentives or, at least, incentives to evade taxes by the high income households expected to fund the welfare state. Similarly, mainstream economic theory expects transfer programs like social assistance or unemployment benefits to create significant work disincentives among those actually receiving transfers since many low income households may hardly hope to command much higher market wages than what they might expect to receive from transfer programs.

Empirically, however, respective effects on work disincentives are typically found to be rather weak in general – labor force participation rates in the universalist Swedish welfare model, for example, are on a par with those in the United States, where a weak welfare state might be considered to induce the least significant distortions of economic incentives. In part this negative evidence might be related to the fact that work has intrinsic value to most people, that industrial economies successfully continue to maintain appropriate work norms, that workers are willing to pay payroll taxes that are seen as insurance premiums, or it might be the case that institutional provisions like job search requirements, minimum entitlement periods, and other qualifying conditions actually prevent transfer recipients from exploiting benefit systems.

On the other hand, many European welfare states clearly have been facing issues of high influx of older workers into unemployment or disability benefit systems as a form of early retirement, so that potential problems with work disincentives induced by welfare state programs are not easily to be dismissed at least for specific subgroups of workers.

What is also missing from the standard economic account of the relationship between welfare states and the allocation of economic effort, however, is the fact that welfare states might actually generate positive allocative impact that might act to counterbalance any presumed disincentive effects. In fact, tying transfer benefits to contribution records may induce workers to seek employment in the legal sector of the economy in order to qualify for benefits later on, thus implicitly also broadening the welfare state's tax base. Moreover, welfare states will alter the structure of the economy itself where, as perhaps most clearly to be seen in the case of women's labor force participation, welfare state provision of care and other social services increases demand for, and at least helps to build, a formal market for services and thus women's labor. Obviously, this in the very least implies a redistribution of employment and earnings opportunities in favor of women.

Capabilities

Efforts to systematically enhance the economic potential of individuals and households may in fact be seen as a constituent element of modern welfare states that is strangely absent from most discussions of the economic role of the welfare state in economics. Quite obviously, however, systems of public education are more than likely to improve access to training and skills, especially among lower class youth. Similarly, job counseling and retraining programs offered to displaced workers or disadvantaged youth represent veritable welfare state investment in worker human capital unlikely to be undertaken by either employers or workers themselves. Finally, anti discrimination laws and similar labor market regulation requiring equal treatment of different worker groups may have promoted economic opportunities for women and

minority workers. Again, these efforts to strengthen individual and household earnings power will counter potential disincentive effects of the welfare state and will generally contribute to a redistribution of labor market, i.e., income chances in the population.

Macroeconomic Efficiency

The strain between various and potentially counteracting economic effects of the welfare state is equally evident in work on welfare state effects on overall macroeconomic efficiency and growth. Clearly, macroeconomic efficiency is all important to welfare states committed to provide high standards of living to a broad majority of the national population. Against this background, neoclassical economics has once again nurtured doubts about the macroeconomic viability of extensive welfare states that would reduce incentives to save and invest and hence undermine societies' long term economic prospects. In fact, economists have compiled consistent empirical evidence from cross national research on post war economic growth that indicates a potential Achilles' heel of the welfare state: in general, countries that spent most on transfers and government consumption already back in the 1960s indeed incurred lower average growth rates up to the late 1990s.

However, economic research is also crystal clear that successful welfare states do have the means to prevent their own demise and that the key recipe to sustain extensive welfare systems is to maintain a balance between redistribution and investment in education and training. The same economic research indicating growth inhibiting effects of transfers and government size consistently points out that societies exhibiting more highly educated workforces are those that have been seeing significantly above average growth prospects over the post war period due to the intensified technological change thus induced. Facing intensified economic progress and globalization partly spurred by its own success, the welfare state of the twenty first century may thus, ironically enough, be very much in the same position as during its inception: on the one hand, the welfare state entails a significant redistribution of resources that threatens to create negative economic externalities, and, on the other hand, it is the very same redistribution

of economic capacities that legitimizes and thus indeed makes it possible to fully exploit the economic potential of a capitalist economy.

welfare state, retrenchment of

Olli E. Kangas

Retrenchment of the welfare state pertains to various cost containment efforts that governments have tried to introduce. Retrenchment has taken different forms in different countries and different policy areas. It can include cuts in generosity and increasing qualification conditions to make benefits less universal and restrict the number of recipients. Also, changes in the form of financing can be used. In many countries financial responsibilities have been transferred to individuals themselves. The state has limited its role and citizens have more responsibility for their own welfare. The naming of the policies varies. Sometimes retrenchment is used synonymously with cutting, rolling back, restructuring, reforming, recasting, recalibrating, and dismantling the welfare state.

The "crisis" of the welfare state is as long as the history of the welfare state. When the very first social policy programs were introduced 100 years ago there were worries about the overly excessive public spending that would hamper economic growth and erode individual morality and the competitiveness of the country. Thus, the theme is nothing new, but there have been fluctuations in policy priorities.

The oil crises of the 1970s changed the prevailing socioeconomic doctrine and more vociferous voices were raised against public spending, and public social spending in particular. The welfare state was seen as too costly and impossible to sustain. "A vicious spiral" metaphor obtained the upper hand. Influential international organizations warned against cost expansion caused by deteriorating economic growth rates, generous welfare provisions, and aging populations. It was anticipated that these factors would increase public expenditure, especially spending on pensions, to economically unsustainable levels. As a consequence, many countries introduced a series of austerity measures to reverse the development and adapt social policies to the immediate crisis and in the longer run to disarm the "pension bomb" triggered by demographic changes.

The changing economic and political climate also changed the sociological research agenda. Up to the early 1980s, analyses of the causes of the growth of the welfare state gave way to studies revolving around retrenchment. In that sense, Flora's huge comparative research project *Growth to Limits* (1987) was an omen. The welfare state had (seemingly) grown to its limits.

Just as Esping Andersen's *Three Worlds of Welfare Capitalism* (1990) launched an avalanche of studies on welfare state typologies and explanations of them, Pierson's *Dismantling the Welfare State?* (1994) inaugurated a new era of retrenchment studies in which welfare cuts (not improvements) were in focus. Consequently, a shift in explanatory factors took place. Previously, a power resource approach emphasizing the role of politics had been successfully used to explain country specific variations in welfare benefits, but gradually neo institutionalism and various forms of structural functionalist explanations (referring to globalization and demographic pressures) gained ground.

The political discourses that emphasize the decisive role of economic and demographic variables and constraints caused by globalization are not that novel. The old structural functionalism was revitalized after a period of stagnation in the 1980s and early 1990s. The new argument in the new politics of welfare was that policy goals had changed. Instead of seeking credit for improvement of the citizens' well being, governments in their retrenchment policies must try to avoid blame and to minimize political costs (Pierson 1994). In its blame avoidance politics a government has two devices at its disposal. It can obfuscate and make things too difficult for the general public to understand (e.g., mathematical formulas to calculate pensions are such a device). And there is the so called grandfather/mother clause that leaves current recipients intact but introduces cuts in future benefits. Again, the pension area is the best example.

Sociological retrenchment studies lean toward institutionalism and path dependent explanations. Here the argument goes that once established, social policy institutions have their own impact on possibilities to cut these institutions. The welfare state was changed from explanandum to explanans. On the one hand, clients of social policy constitute influential

pressure groups that politicians must take into consideration when deliberating about cuts in benefits. The central political question is blame avoidance (i.e., how to avoid punishment from the electorate). On the other hand, the welfare state itself has become an institution that has strong feedback loops to politics. Due to the impact of these loops, some schemes are easier to change, whereas others have stronger institutional inertia. One important stream in the retrenchment discourse has dealt with the degree of inertia. The idea that underpins this is that previous decisions constrain future options. Institutions are put on a specific track which creates path dependency.

The degree of path dependency varies between welfare state programs and regimes. Pension programs are the best example of a scheme that is difficult to change. In the pension area the state has given individuals certain promises that extend to 30 or 50 years in the future. Therefore, most pension reforms must be incremental to give individuals possibilities to adapt themselves to the new situation.

Historical analyses show that state corporatist programs – programs administrated on a bi- or tripartite basis either between social partners or between partners and the state and financed through social security contributions – are harder to change than, for example, schemes that are based on pure political administration and tax financing. In the former case social partners usually have a number of institutional veto points at which to reject any cuts proposed by the government. Moreover, insurance contributions paid by employees create a feeling that they have paid for the benefits, whereas the link between general taxes and benefits is more obscure and taxes do not create a basis for strong claim rights.

Institutional approaches are often divided into two or three variants. In rational choice institutionalism emphasis is on political actors who in their self interested rent seeking react/act in the institutional surroundings that the welfare state creates, whereas historical institutionalists are more interested in how, for example, the welfare state as such constructs interests and formulates actors' images of their interests. The most constructivist variant, sociological institutionalism, employs discourses and

consequently the politics of retrenchment is much more about discursive or ideological struggles over the right to give interpretation to "reality." From time to time the hegemonic interpretations are changed, which leads to changes in welfare policies. The shift from Keynesianism to monetarism is an example of a paradigmatic shift in the mode of thinking that in turn changes politics.

An important theme in the retrenchment debate concerns the possibilities for changing the existing welfare state. For structuralists, power resource sociologists, and sociological institutionalists, the answer is rather easy. Changes take place when structural preconditions, political constellations, and policy paradigms are changed. Path dependency and institutional stickiness may cause some problems in explaining change. A handy solution that adopts elements of all the above mentioned approaches is to say that welfare institutions (notably pensions) enjoy long periods of stability, but occasionally the stability is punctuated by crises – be they changes in structural, political, or discursive contexts or combinations of such factors – that may bring pathbreaking changes. The new path is then followed up to the next punctuation point. The problem in this kind of retrenchment discussion is that a pathbreaking change is supposed to be abrupt. However, many fundamental changes may go unnoticed and be based on non decisions: small scale adjustments can ultimately alter the whole system, including the underlying ideology of the responsibilities of the state vis à vis the market and the individual. To make the picture a bit more complicated, the severity of retrenchment depends on the indicator we look at. A change in the basic ideology (e.g., from means testing to universalism) may not yield better benefits to the clients. Social spending figures may give a totally different picture of the impacts of retrenchment policies than indicators of social rights. Moreover, consequences of cuts in terms of poverty and social exclusion/inclusion will be visible after a time lag of decades, which means that sociologists will also wrestle with these questions in the future. Perhaps, then, the strong western bias in welfare state retrenchment discourse will be changed and social policy debates will deal much more

with the distribution of resources in a global perspective.

whiteness

Howard Winant

Like water to the proverbial fish, whiteness has been largely invisible in the “modern world system” of European creation. This invisibility is somewhat unique among the racial categories. The uniqueness does not consist of the “normalization” of whiteness: the idea that whiteness is the “default” racial status, that whites are “just people” who “don’t have a race.” Nor does its uniqueness consist in the

“transparency” of whiteness: the way in which whiteness is taken for granted in the world’s powerful countries and thus not seen, like water by the fish. In many places, especially where one racially defined group predominates, that group’s raciality is relatively invisible. Think of much of Africa, Han China, or Yamato Japan.

No, the uniqueness of whiteness’s invisibility lies in the contradictions therein: while whiteness partakes of normality and transparency, it is also dominant, insistently so. And it is also beleaguered, nervous, defensive. These qualities in turn belie claims for the “normality” of whiteness, the default status of the concept.

Whiteness can hardly be hidden in a social system based on racial domination, one in which races are necessarily relational matters. White supremacy has never gone unresisted, for one thing, so whites (colonists, settlers, planters, etc.) have always had to “circle the wagons”: they had to theorize whiteness, defend its “purity,” and justify their rule. They had to take up their “White Man’s Burden,” carry out their “*Mission Civilisatrice*,” fulfill their “Manifest Destiny.”

From the early days of conquest and slavery, from the early phases of European empire building right down to the present, there has been white unease about the very white supremacy employed to organize and justify European rule. “What if. . . , what if. . . ”

Resistance. What if the blacks, the natives, the kaffirs, the wogs, rose up against us? (Indeed, they often have done so.) What if they treated us as we have treated them? In white horror at the Haitian revolution, at Sepoy, at the Mau Mau, at Nat Turner, at the revolt of the Muslim Malês of Bahia in 1835, at the putative barbarity of the Algerian revolution (and in endless other instances), we see the inner fears and guilt that accompany white rule.

Migration. How can we keep ourselves from being “swamped” by the “rising tide of color”? Lothrop Stoddard (1920) and Madison Grant’s (1916) bestsellers contemplated with dread the declining fortunes of European rule, conceiving whiteness as a fortress, a laager, besieged by the lesser breeds who sought to immigrate, to overrun the “advanced” outposts of civilization, to drag down all the higher accomplishments of Europe

and its avatars. North American nativism of course preceded their panicky alarms by more than a century (Higham 1955). Mrs. Thatcher revived the “swamping” metaphor in her campaigns, and it continues to thrive under the careful tending of Le Pen, Haider, Fini, Tom Tancredo, and many other politicians in every white dominated metropole in the world.

Sexual purity. Miscegenation is a threat to whiteness authored by whites, notably white men, themselves. “Carnal knowledge and imperial power” (and slavocratic power too) have always gone together, as Stoler (2002) has most effectively demonstrated. Danger, race mixing ahead! Rape and concubinage, the problematic and ambiguous identities of mixed race offspring, the thrill of desire for the racialized “other,” and the constant risk that whites will “go native” (Torgovnick 1991) have always represented a risk to white purity, and thus white identity itself.

So despite numerous claims of universality, racelessness, and “colorblindness” (Bonilla Silva 2003), whiteness is not only still present but also racially particular in its own right. “White” is a racial category, and “whites” something of a racial group, of course partaking of huge variation across space and time. But what is “whiteness,” anyway?

In much radical literature, largely recent but not without precedent, whiteness is portrayed entirely in the negative: as the explicit absence of “color,” of raciality. Whiteness substitutes for class consciousness, subverting it by racially linking rulers and ruled. The social fact of *not* being black, *not* being “of color,” is seen as its essential quality. Ignatiev (1995), Lott (1993), Roediger (1991), and others have advanced this analysis, drawing to various degrees on Du Bois’s account in *Black Reconstruction* (1935) of the “psychological wage” derived by the North American white worker from the choice of racial rather than class identity. Whiteness arises as if to say, “I may be poor and exploited, but at least I’m white.” Morgan’s (1975) history of Virginia colonialism takes a similar view.

Other currents dispute this view at least in part, noting the problematic and partial character of the “achievement” of whiteness by many European immigrants (Jacobson 1998) and the weird reversals of white supremacist obsessions

with purity and beleagueredness that echo in such arguments. Some have argued that “white trash” is itself a distinct racial category, pointing to the persecution of the supposedly “feeble minded” during the heyday of eugenics, and the continuing contempt expressed for the white poor today (Wray & Newitz 1997). But the most telling objection to the idea that whiteness is a purely negative racial category, and hence something that could be “abolished,” is the recognition that racial identity is relational in character. However socially constructed the creation and perpetuation of racial identities may have been, these identities can no more be discontinued than can such other similarly situated human attributes that we now see as fundamental: gender, class, and nation, for example.

Beyond this, racialization is notoriously synthetic and absorptive. In forging its whiteness, Europe incorporated a great many of the characteristics of those over whom it ruled, imparting to them in turn many of its own qualities: not only resources, not only migrants, not only diseases, not only gametes, flowed in both directions across various racial divides, but so too did language, technology, and knowledge, both sacred and profane.

Thus the chief distinction between the racial category of whiteness and other racial designations is not some supposedly all encompassing negativity of white identity; indeed, the claim that whiteness is merely the “absence of color” is quite questionable. Rather, the concept’s problematic nature stems from its continuing (if often flexible and today often disavowed) involvement with domination. To adapt Lincoln’s formulation: whiteness cannot forever endure half asserting itself, and half denying itself. A whiteness that abandoned its ambivalent claims to “colorblindness” (another way of reclaiming invisibility) and that recognized that its gestation and development, right down to the present, have been tainted by “unfair gains, unjust enrichments, and unearned advantages” (Lipsitz 1998), could perhaps redeem itself by breaking decisively with that history. Could whiteness not be reinvented by such means as practical measures of redistribution and thoroughgoing racial democratization? After all, there have been many anti racist whites; from where did their motivations arise? Might not

white people yet achieve admission to a pluralist global community that acknowledged racial difference but refused racially based stratification or hierarchy? Since history has not ended, the final judgment on such questions has yet to be made.

widowhood

Kate Davidson

There has been a slow but discernible increase in sociological interest in the experience of widowhood in later life in the last three decades of the twentieth century, which has come about as a result of two major western world trends: demography and feminism. People are living longer, and as a result of a decrease in birth rates, the proportion of older people in the population is steadily increasing. For example, in the UK, the 2001 census data revealed that 48 percent of women compared to 17 percent of men over the age of 65 were widowed. Second wave feminism's imperative has been to examine women's experiences and circumstances, and to reflect on what societal norms and values inform meaning and self conceptualization in relation to being female. Gradually now, feminism is addressing the issue of aging. The conjunction of these two trends has seen the steady emergence, particularly in North America, of sociological study of widowhood as experienced by women (Lopata 1996).

However, minimal sociological attention has been paid to the lives of widowed men, primarily because of their relative invisibility, both numerically and in welfare distribution statistics. The research there has been on widowers has principally focused on the health outcomes and psychological disorientation caused by an anticipated disjunction: a husband does not expect to predecease his wife. Nevertheless, the issue of "who suffers more," widowers or widows, is shown to be contentious. Parkes and Weiss in their *Recovery from Bereavement* (1983), which looked at widows and widowers across all ages, revealed that both widowed men and women were found to have lower psychological well being

than their married counterparts. Health status and social networks were major predictors of psychological well being. Among women, close female friends contributed more to psychological well being than family contact, while among men, family contact was more important.

In the Netherlands, Stevens (1995) examined the well being and living conditions of older widows and widowers in order to establish gender differences in adaptation to conjugal loss. Her results indicated that there were remarkable similarities in the reported well being of the respondents. Availability of resources such as income, education, and freedom from limiting disability advantaged the widowers, but widows benefited from the support of close female friends and neighbors as well as adult children. Few significant differences were found in the reported personal relationship needs, although the relational patterns were different: the women tended to have more "emotionally intimate" female friends. The men were content with male friends for "sociability," but also wished for a cross gender romantic relationship. The men, Stevens discovered, derived satisfaction from the presence of new partners or partner like relationships and tended to depend more on adult children than did the widows. She found that while widowed women were disadvantaged regarding income, education, and health resources, they reported similar life satisfaction to the widowed men. She concluded that this was because women had been socialized into greater flexibility and adaptability over the life course. This helped them with the major change brought about by widowhood and mediated the instrumental disadvantages.

Early research on spousal bereavement (almost exclusively for women) conceptualized widowhood as "role loss" and "role exit." Bereavement was analyzed in terms of role change from wife to widow, which in turn considered a widow to be a "roleless wife," who lacked any duties towards others in the social system. Widowhood was viewed as *involuntary disengagement* and as such the individual was thought to be rendered powerless. These disengagement theories have contributed to the literature which views widowhood as a totally negative state. The literature does not highlight whether this process is the same or different for widowers since the male identity is differently

socially structured. The primary social role of a man is not husband and father, his sense of self identity is derived from his occupational status rather than his marital status.

The death of a spouse is a devastating experience for the vast majority of people, but the consequential adaptation from "we" to "I" is substantially different for men and women. Later sociological theory such as that explored by Anthony Giddens in *Modernity and Self Identity* (1994) permits us to reconceptualize loss in terms of ontological security, which takes into consideration adaptation as a *process* mediated by age, gender, culture, and social capital. In doing so, we can contextualize these older people's experience within a life course perspective, the outcome of which is not always unrelentingly depressing. Indeed, some widows express a sense of liberation and personal development after the loss of their husband. The few studies carried out on widowers indicate that it is the loss of the person whose care allowed them independence, and the need to take on the role as self carer, that requires psychological and social adjustment (Bennett et al. 2003). Men therefore rarely view widowhood as a time of freedom. Depending upon age, health, and financial status – that is, the younger, fitter, and richer they are – the more likely they are to seek cross gender companionship, with (preferably) or without sexual relations. Contrary to received wisdom, older widowers' main motive for seeking a new partnership is not to have instrumental help from a housekeeper, but to assuage the loneliness they feel at the death of the most central person in their life. It is ironic that the men, socialized into independence and autonomy, seem to be less psychologically prepared to cope with aloneness.

Williams, Raymond (1921–88)

Tony Bennett

Born in 1921 in Wales, Raymond Williams was educated at Cambridge and, after wartime military service and an initial academic position in Oxford's Extra Mural Delegacy, returned there on a permanent basis as Lecturer in English in 1961, subsequently becoming Professor of Drama in 1974.

A lifelong socialist, Williams was an active member of the Labour Party and a key figure in the British new left. These and his other political involvements – in the Campaign for Nuclear Disarmament (CND), for example – provided the horizon for his intellectual work. This took varied forms. A moderately successful novelist, Williams was much in demand as a political and cultural commentator and he wrote a number of specialist studies on specific literary and dramatic genres.

His most enduring impact, however, was a theoretical one focused on new ways of thinking about the relationships between culture and society that have had considerable influence on debates in sociology and, for cultural studies, remain of foundational significance.

Developed initially in *Culture and Society* (1958) and *The Long Revolution* (1961), Williams's central accomplishment was to dispute, and provide an alternative to, the terms in which the relations between culture and society had been debated in British social thought in the nineteenth and early twentieth centuries. Reviewing the writings of Samuel Taylor Coleridge, John Ruskin, Matthew Arnold, T. S. Eliot, and others, Williams took issue with their sense of culture as an elite standard of perfection that had to be defended against the deadening influence of the masses, a view that informed the literary criticism of Williams's contemporary, F. R. Leavis.

Objecting that there are no masses, only different ways of seeing people as masses, Williams challenged this tradition of thought on two main grounds. First, drawing on the anthropological concept of culture proposed by Edward Burnett Tylor in his *Primitive Culture* (1871), Williams argued that any socially viable contemporary understanding of culture had to concern itself not only with the selective tradition of high artistic and intellectual culture but also with the beliefs, customs, and traditions – the everyday ways of life – of different social classes and groups.

His second contention was that such ways of life should not be studied in isolation from each other. Analysis should rather encompass the whole set of relations that organized the interactions between ways of life. Williams attributed to these a patterned complexity which – in a term whose exact meaning has proved elusive – he called the “structure of feeling” characterizing a particular period or society. The early work of the Birmingham School in cultural studies was profoundly shaped by its engagements with these aspects of Williams's work and the more empirically developed traditions of subcultural analysis coming out of American sociology (Hall & Jefferson 1976).

Williams's work took a different direction in the 1970s, mainly as a consequence of his exposure to the continental tradition of “western Marxism” that *New Left Review* made widely available in English translation. His intellectual engagement with European Marxism bore its most distinctive fruit in *Marxism and Literature* (1977) in which, while committing to a Marxist position, he also sought to reform it.

In earlier work, Williams had distanced himself from the Marxist formulations of the relations between culture and society that were then available to him. In *Marxism and Literature*, the influence of Antonio Gramsci, Lucien Goldman, and others led to a more favorable reading of Marxist thought on the condition that its understanding of the relations between culture and society be detached from the determinist implications of the base/superstructure metaphor. The result was a distinctive formulation of the relative autonomy of culture which Williams fashioned into a probing account of the role of materialism in Marxist thought – issues he returned to in *Problems in Materialism and Culture* (1980).

Other key texts include *The Country and the City* (1973), a commanding overview of the representation of the relations between rural and urban social life in British literature and social thought, and *Television: Technology and Cultural Form* (1974) which, in rebutting determinist accounts of the relations between media technologies and society and discussing the significance of flow in the organization of the television text, had a long term influence on the development of television studies. *Keywords* (1976) made an original contribution to public scholarship in its historical survey of the key terms in the English vocabulary of the relations between culture and society.

Williams died in 1988, shortly after retiring. While he remained intellectually active to the end – *The Politics of Modernism* (1989) was published posthumously – his later work spoke less centrally to changing political concerns. For Williams, the key point of social reference for discussing culture was always class. His work therefore yielded little purchase on the increasingly important questions regarding gender, sexuality, and culture that feminist thought had placed on the agenda. The exclusively national and white British framework of this thought was also incapable of addressing questions of race and ethnicity – an aspect of his legacy that Paul Gilroy (1987) drew attention to.

There are several critical commentaries on Williams's life and work and one biography (Inglis 1995). Williams, however, had always made commentary on his life a part of his work in a manner that was and remains distinctive. His interviews with the editors of *New Left Review*, published as *Politics and Letters* (1979), are still the most absorbing manifestation and portrayal of this interweaving of life and work.

Wollstonecraft, Mary (1759–97)

Cynthia Siemsen

Mary Wollstonecraft has been widely regarded at least since the 1970s as the first feminist thinker of consequence on women's sociopolitical condition. The label "feminist" is perhaps a misnomer considering the historical context of her life and the relative youth of the term. However, if the litmus test for feminist thought is opposition to gender hierarchy, acceptance that gender is socially constructed, and belief that women as a social group need collective action to bring about equality, Mary Wollstonecraft is a proto feminist thinker. Her writings appear on the shelves of literature, political philosophy, and women's studies. Wollstonecraft's life is also the subject in its own right of psychology, anthropology, and literature. However, the consideration of her contribution to classical sociological thought is more recent. Wollstonecraft's theoretical absence is not a reflection on her sociological contributions; rather, it symbolizes the patriarchal nature of society when sociology as a discipline emerged, and the everyday reality of most societies throughout history, including our own.

The statement that social theory cannot be disentangled from the life and historical moment of the thinker takes on great meaning when applied to Mary Wollstonecraft. Her biography reads like the plot of a great tragedy: berated daughter, servant, vilified political writer, at times suicidal lover, briefly happy wife,

and early death from the complications of child birth which delivered a great gothic novelist. The tendency to emphasize “Wollstonecraft, the subject” over “Wollstonecraft, the social thinker” is difficult to resist. However, Wollstonecraft’s biography informed her thought and her theory influenced her life. But Wollstonecraft’s theory goes beyond the particulars of her life to expose the gendered power relations of larger social institutions.

Wollstonecraft was born in the crowded East End of London. She was the second child of seven, and oldest daughter to a ne’er do well farmer who was a violent alcoholic and who beat his wife. Wollstonecraft recollected that she slept on the landing outside her parents’ bed room in the event she should have to protect her mother from her father’s abuse. Wollstonecraft (1798) remembered her father as a tyrant and her mother as his willing victim. She was continually reminded of the status difference between herself and her parents’ firstborn son. Although she remained bitter toward her brother, and the institution of inheritance, later in life Wollstonecraft grew to appreciate poverty’s odd benefits. Wollstonecraft reasoned that, had she led the sheltered social existence of her middle class female counterparts, she may have developed physical and mental inadequacies fostered by patriarchal environments.

Wollstonecraft fled her parents’ house at 19 years to pursue a life of economic independence from men. Through service to moneyed women, Wollstonecraft became convinced that middle class women’s inadequacies grew from their dependencies upon husbands, which were supported by the spirit and letter of English law. A married woman legally could not own property in her own name; furthermore, as subservient to her husband, she had no legal control over her own children. Divorce was nearly impossible.

Wollstonecraft was for the most part self taught. During her early years of independence, she combined her talents with those of her friend Fanny Blood, and opened a school for girls. Although the school folded following Blood’s death due to complications of child birth, the endeavor led Wollstonecraft to write her first work for money. *Thoughts on the Education of Daughters* (1787) stressed the power of women to cultivate their minds through education and reason, in order to realize independence

and virtue. While her first piece was less than original – a frequent criticism of Wollstonecraft (Sapiro 1992) – *Thoughts* reflected Wollstonecraft’s later preoccupation with outcomes of blind obedience, whether within the family or within the state.

Wollstonecraft wrote *Mary: A Fiction* (1788) the following year. The now 27 year old governess depicted a young woman who was belittled by her parents and forced to educate herself as a means of survival. The novel closes by reflecting on a “world where there is neither marrying, nor giving in marriage.” Obviously, *Mary* is not pure fiction, but it demonstrates Wollstonecraft’s potential for radical thought.

By the end of 1787, Wollstonecraft adopted the identity of a professional writer with the aid of the Dissenting publisher Joseph Johnson. Wollstonecraft joined Johnson’s political circle that included British poet and painter William Blake, American Revolutionary Thomas Paine, British political theorist William Godwin, and moral philosopher Richard Price. Wollstonecraft’s first great work would not be published until 1790; in the interim she became a frequent book reviewer for Johnson’s *Analytical Review*. Of note is her critique of Rousseau’s *Confessions*.

The Vindication of the Rights of Men (1790) was the first of many responses to Edmund Burke’s *Reflections on the Revolution in France* (1790), the most famous being Thomas Paine’s *The Rights of Man*. With the falling of the Bastille in 1789, England was thrust into a controversy over human rights. Burke declared that the principles of the French Revolution might prove the ruin of France (and perhaps England) if liberty and equality prevailed. Burke conceived those institutions threatened by the revolution – the monarchy, class distinctions, inheritance, and property – as the basis of social order. Without them society might revert to its previous brutish state where innate human passions ran rampant.

Less than a month after *Reflections* was published, Wollstonecraft dashed off her heated response that synthesized her ideas with those of Locke, Rousseau, and Richard Price. Wollstonecraft’s *The Vindication of the Rights of Men* was considered rude (especially after she revealed her identity), rushed, and emotionally personal. Despite its anger, *Rights of Men* has

been described as “one of the most sophisticated essays on political argument and political psychology of her day” (Sapiro 1992: 24–5). Wollstonecraft (1790) followed Locke in defining rights as God given to “such a degree of liberty, civil and religious, as is compatible with the liberty of every other individual with whom he is united in a social compact” (pp. 7–8). Following Rousseau, liberty in civil society was only an ideal that obscures the reality of private property. For Wollstonecraft, human rights were rational rights; they were inherited at birth by humans, as rational creatures; rational rights cannot be undermined by tradition or other social institutions. She criticized Burke’s view of human malice present at birth. For Wollstonecraft (1790), “children are born ignorant, [consequently] innocent” (p. 72). Following Price, morality was not an instinct; it existed in the sphere of human reason. Wollstonecraft ridiculed Burke for supporting the aristocracy and class distinctions; she instead stressed the bad effects of privilege on the person, for “the respect paid to rank and fortune damps every generous purpose of the soul” (p. 52). Wollstonecraft argued that upper class women were only half human, their biggest concern being to please men.

However, *The Vindication of the Rights of Woman* (1792) was the first place she identified – in today’s words – women as an oppressed group, crossing class lines. In it she set forth two theoretical propositions. First, she argued that the absolute monarchism of her day was tied to four institutions: the aristocracy, military, church, and most of all, the patriarchal family. Second, true freedom for all human beings (i.e., economic, political, and intellectual) would never exist as long as women and men were not equals. Wollstonecraft repeatedly asserted the right of women to prove their equality through enlarged opportunities (e.g., education) and independence from men. However, its more sociological reading is that just as the tyranny of men injures the character of women, so the tyranny of government harms its people.

By the end of 1792 Wollstonecraft had traveled to France to witness the revolution first hand. In a departure from liberal thought, Wollstonecraft grappled with power and domination in *An Historical and Moral View of the*

Origin and Progress of the French Revolution (1794), addressing both the political violence of the *ancien régime* and the violence of the Terror she witnessed. Wollstonecraft’s years in France are most often linked to her romantic liaison with American writer and entrepreneur Gilbert Imlay. By the end of 1793 France and England were at war and British expatriates were being arrested in France. Wollstonecraft sought protection at the American Embassy by registering as the “wife” of Imlay. Although they never married, Imlay fathered Wollstonecraft’s first daughter, Fanny, and was the impetus behind *Letters Written during a Short Residence in Sweden, Norway, and Denmark* (1796).

Imlay lost interest in Wollstonecraft after Fanny’s birth, plunging her into a deep depression. Todd (2000: 279–80) writes: “She took no comfort from the stern words in *The Rights of Woman* about the stupidity of women who put their trust in romantic hopes.” The knowledge of Imlay’s interest in other women led to Wollstonecraft’s first suicide attempt. To help her recover, Imlay sent Wollstonecraft (and Fanny) to Scandinavia as his business agent – a lost cargo ship needed recovery.

Wollstonecraft’s last great work began as part of a new genre, the travelogue; it also lapses into a memoir of a troubled woman struggling to find peace of mind. (Wollstonecraft did not achieve peace of mind on her travels to Scandinavia. Her affair with Imlay ended only after another suicide attempt.) However, it was also a treatise on society and human nature. Wollstonecraft’s consciousness of power’s oppressive nature was keener than ever. She witnessed the tyranny of Denmark against its weaker neighbors, men over women, and found power’s root in private property. Observing convicts on a road one day she reflected that the gold keys of the nearby noblemen were a greater disgrace than the prisoners’ chains. Whether a person was the aristocrat or the prisoner, they would feel the ill effects of the same unjust society at the level of their characters.

One of *A Short Residence*’s readers was William Godwin, who wrote: “if ever there was a book calculated to make a man in love with its author, this appears to me to be the book” (Ferguson & Todd 1984: 89). Wollstonecraft and Godwin’s intellectual and love relationship

was short lived. After learning of Wollstonecraft's pregnancy they chose to marry despite their public statements on the evils of the marriage contract as an artificial bond. While pregnant, Wollstonecraft was in the process of writing a novel she would never finish. At 38 years of age, Wollstonecraft died from complications after childbirth. Her infant, Mary Godwin Shelley, survived and went on to write *Frankenstein*. Although she never completed *The Wrongs of Woman, or Maria* (1798), in that work Wollstonecraft gave her most radical statement of the relationship between patriarchy, the state, and the family. She argued that the family represents a small commonwealth of the state, and that a husband is not only its patriarch, but also its police.

What earns Mary Wollstonecraft a place of prominence in pre sociological philosophy is her early articulation of micro and macro levels of analysis. On the one hand, she describes social environmental influences on the formation of the gendered self. Wollstonecraft's analysis also extends beyond her personal experience and close observation of gender roles of her day; she also demonstrates the tie between gender and power in the relations of dominance and subordination within social institutions such as the aristocracy, military, church, and family.

womanism

April L. Few

In 1983, Alice Walker contrasted Afrocentrism, black feminism, and white feminism using the term *womanist* to render a critique of possibilities for women and men who felt ostracized by the mainstream women's movement in the United States. Walker's much cited phrase, "Womanist is to feminist as purple is to lavender," reflects this comparison. Walker derived the term womanist from the Southern black folk expression of mothers to female children, "You acting womanish." Womanish girls and women "act out in outrageous, courageous, and willful ways." They are free from traditional conventions that limit white women's experience and relating. Walker stated that womanish girls and women want to know more and in greater depth than what was considered good for them. They

are “responsible, in charge, and serious” when relating to themselves and the world.

In her classic essay “In Search of Our Mothers’ Gardens,” Walker describes womanism as being rooted in black women’s particular history of racial and gender oppression in the United States. Yet, womanists are “traditionally universalists.” Womanism is a gender progressive worldview that emerges from black women’s unique history, is accessible primarily to black women yet also extends beyond women of African descent, as evidenced in the works of other multi ethnic feminists. Therefore, womanism is a pluralist vision of black empowerment and consciousness. Because it is a pluralist vision, womanism requires both women and men to be aware of the nature of gendered inequalities and to share a commitment to work toward social change.

Walker (1983) describes a womanist as many things. A womanist “loves herself . . . regardless.” She is a black feminist or feminist of color who is “committed to the survival and wholeness of an entire people, both male and female.” A womanist prefers women’s culture and has an appreciation for women’s flexibility and the strengths to negotiate adversity. Yet, a critique of womanism is that it does not address inter racial cooperation among women. She loves the spirit of black women and the struggle to confront and to overcome. Walker (1983: xi) also describes a womanist as “a woman who loves women, sexually and/or nonsexually.” The writings of many womanists are rather silent about this aspect of Walker’s womanism. As black feminist Barbara Smith suspects, this omission may speak to either ambivalence or homophobia in black communities.

Other scholars have described womanism similarly. Geneva Smitherman defined a womanist as an African American woman who is rooted in the black community and committed to the development of herself and the entire community. Jannette Taylor stated that the word “womanist” incorporates the complexity of experience for black women and that the framework allows the experiences to be shared through the language and principles of black communities. Delores Williams believed that womanism reflects Afrocentric cultural codes. These codes are female centered and relate to the conditions, meanings, and values that have

emerged from black women’s activities in their communities. In “Some Implications of Womanist Theory,” Sherley Anne Williams (1986) argued that womanist theory is especially accessible to black men because, while it calls for feminist discussions of black women’s texts and for critiques of black androcentrism, womanism places black psychic health as a primary objective. In 1994, Layli Phillips and Barbara McCaskill created the scholarly journal *The Womanist: Womanist Theory and Research* to demonstrate the interdisciplinary, intercultural, and international nature of womanist perspectives in the academy and to feature womanist grounded pedagogical and theoretical articles, creative writing, and art of black women.

In the late 1980s, black female theologians began to incorporate race and gender critiques into theology. Walker’s definition of womanism has played a significant role in raising consciousness among female seminarians regarding the moral agency of black women scholars, particularly and initially active members in the Academy of Religion and the Society of Biblical Literature who sought to create analytical frameworks to advance theoretically black women’s religious discourse. Womanism has been used by black women theologians to challenge and critique religious traditions and ecclesiastical political processes. Womanist theologians also have sought to clarify women centered aspects of biblical studies, church history, systematic theology, and social ethics. Katie Cannon’s *Black Womanist Ethics* (1988), Jacquelyn Grant’s *White Women’s Christ and Black Women’s Jesus* (1989), Delores S. Williams’s *Sisters in the Wilderness: The Challenge of Womanist God Talk* (1993), Emilie Townes’s *A Troubling in My Soul: Womanist Perspectives on Evil and Suffering* (1993), and Cheryl Kirk Duggan’s *Exorcizing Evil: A Womanist Perspective on the Spirituals* (1997) are significant Christian womanist texts that center the essence of black feminism in Protestant theology. Even Christian womanist self help books such as Renita Weems’s *Just a Sister Away: A Womanist Vision of Women’s Relationship in the Bible* and *I Asked for Intimacy: Stories of Blessings, Betrayals, and Birthings* (1993) have been published to extend womanism’s reach beyond the academy and seminary.

Some womanists like Clenora Hudson Weems (1993) argue that the feminist–womanist

tie should be separated by locating womanism in the words of Sojourner Truth (i.e., *Ain't I A Woman*) and Afrocentric cultural values. Africana womanism is this theoretical framework. Hudson Weems identified the characteristics of Africana womanism as self naming, self defining, role flexibility, family centeredness, struggling alongside men against multiple oppressions, adaptability, black sisterhood, wholeness, authenticity, strength, male compatibility, respect for self, others, and elders, recognition, ambition, mothering, nurturing, and spirituality. Hudson Weems believes that mainstream white feminism was too self centered or female centered with its focus on self realization and personal gratification. Africana womanists, on the other hand, are family centered and community centered, interested in collective outcomes and group achievement. It should be noted that although Africana womanists see sexism as an important problem, some do not see sexism as an objective more important than fighting racism. This perspective on sexism reflects the nationalist roots of womanism and is another critique of womanism.

women, economy and

Elizabeth Esterchild

Women's position in the economy and their general well being in all other spheres of life depend heavily on the type of society in which they reside. All societies have a complex division

of labor by sex. In some, men's and women's tasks are not differentially evaluated and rewarded; in others differential evaluation is so strong that men receive the lion's share of property, material goods, and rights and privileges while women become the property of men and their work and work products are controlled by men. Societies differ because of alternative modes of organization of the productive forces and the subsequent differences in the parts played by the two sexes in these economic arrangements. Gerhard Lenski (1966) described six different types of societies based on the level of technology of the primary means of production, while gender scholars (Dunn et al. 1999) filled in the distinct implications for women.

In the earliest foraging and simple horticultural societies, women's contributions to food, clothing, and shelter ensured respect for them, as families depended on women's work for survival. Meanwhile, men garnered a bit more prestige because they hunted for the highly prized meat and distributed it outside the family. Material inequality was almost unknown because redistribution norms prevailed and each member of society had access to the means of production (Lenski 1966).

When the steel tipped hoe was introduced, societies were able to produce a surplus. People in these new, advanced horticultural societies demanded more land; both warfare and trading with other societies became widespread. Only men and eventually only certain men could participate in the military and the emerging governing class. The expectation that men would accumulate possessions replaced redistribution norms, and material inequality increased greatly (Lenski 1966). Women's lives and work became more and more subordinated to men's desires, and although a few were able to set themselves apart by being excellent traders or wives of high ranking men, the huge majority were completely occupied with producing more warriors, feeding their families, and working to produce surplus that was placed in the hands of men (Chafetz 1986). These changes in the economic structure and the division of labor had profound negative effects on women's status. A double standard of sexuality emerged, divorce was virtually impossible to obtain, and women were eventually viewed as property. Daughters could be traded as brides for military alliances;

wives, including sometimes multiple wives, were used to promote the husbands' interests. Women became interchangeable; women who were stolen or captured from other societies could be incorporated to produce more heirs and perform the same work for which wives were responsible. It is likely that the first patriarchal bargains were struck in this type of society. In the bargain, women, albeit reluctantly, traded their work to their husbands in return for the protection husbands provided.

The introduction of another mode of production – plow agriculture with several associated increases in level of technology – simply accelerated all these trends. A larger military and political apparatus appeared, and distinctions among ranks increased. The emergence of propertied classes coincided with a huge increase in the amount of material inequality. The elite class was made up of the highest status people from the military, the state, and the propertied classes; all were in a position to benefit from the labor of a large peasant class, a smaller artisan class, and sometimes a large number of slaves (Lenski 1966). As hereditary inequality solidified, women's status increasingly depended on the status of their fathers and husbands. More important, women of the elite classes were not allowed to participate in the military, the state with its expanding bureaucracy, or to own significant property. Elite women were unable, then, to directly reap the rewards associated with high status. Middle class women had plenty of duties to perform. They and peasant women – the bulk of the population – saw their work devalued in part because it did not produce anything for the market. Women were still responsible for feeding their families, so they labored in large gardens and with small animals, but they were denied access to the major means of production: the oxen and the plow. As a result, women's status deteriorated and an ideology of inferiority developed which carried over into industrial society (Chafetz 1986).

In the United States, ideological changes that accompanied the move to industrialization fueled the fires of classism, racism, and sexism. Capitalist employers were happy to fan the flames to keep the fires burning. They propagated the ideas that "real men" did not have a wife employed for pay, that woman's place was in the home, and that a good wife is one who can

make her husband look good by spending his money very wisely. In this way, employers had a large number of men who worked very hard, who were well cared for by their wives, and whose wives were seduced to become a market for consumer goods. As well, employers kept the labor market segmented into many distinct occupational niches and hired different categories of people in each. They did their best to forestall the formation of unions, while unions were not always willing to incorporate women into their organization. Many workers at different levels opposed hiring of minority women and men as well as white women in "their" jobs, thus helping perpetuate job segregation.

In the United States, at the beginning of the 1900s, male workers demanded a family wage, and employers were happy to push the twin myths that men were being paid a wage large enough to support a family and that women were only working until marriage or to supplement their husbands' income so they did not need a living wage (Charles & Grusky 2004). Over the course of the twentieth century, these ideas eroded somewhat as more and more women acquired an education and moved into the labor force. At mid century, unmarried women had been employed for quite some time, as had divorced and poor married women. Married women with high school age children joined the labor market after World War II, and beginning in the 1970s, more and more middle class women with preschool or school age children entered the labor market. Their fortunes were limited, however, as unequal pay scales continued, and women were crowded into relatively low paying clerical, service, and factory jobs. Most employed women were now doing a double shift, both working to feed their families and taking care of the emotional and physical needs of their husbands and children (Charles & Grusky 2004).

Moreover, as health care improved and people lived much longer, women were often faced with being the primary caretaker for their elderly parents or for their husbands' elderly relatives. Indeed, it was not uncommon to see women caught among the triple roles of raising their own children, caring for elderly parents, and keeping their own careers up and running. As employers recognized the need to keep women committed to working for them, some

began offering support for childcare, flexible working hours, and more generous family leave policies. Other women adapted by working part time or part year, but such strategies left them ineligible for even pro rated benefits (Reskin 1998; Gregory et al. 1999). Truly meaningful part time jobs that allow both husbands and wives to meet family needs as well as have some time to enjoy their lives are still very few in number.

Today, the United States, Japan, and some European nations have moved into a post industrial phase in which few workers actually produce goods but provide services instead (Lenski 1966; Charles & Grusky 2004). Automation and other technological advances free many workers – both women and men – from the factory but leave their future uncertain because of the loss of steady, relatively well paying blue collar jobs (Sernau 2006). Many production jobs moved overseas where employers are free from government taxes and restrictions and can employ an ever ready supply of laborers who work for low pay and few benefits. These shifts have left some men employed at high end jobs that pay well, but pushed more downward on the pay scale. In these early years of the new century, it appears that the market for women workers is becoming bifurcated as well.

Currently, around the world there is enormous variability in women's economic participation. The many so called developing societies result from the imposition and then the throwing off of colonial rule. Historically, colonizers exploited native people for natural resources and for labor. Today as well, third world societies supply a market for some goods and cheap, throwaway laborers for production. The debilitating effects of colonization disrupted traditional family and cultural practices, frequently drew men away from their households to work, and left women to fend for themselves. Women in these traditional societies often lose rights to the land and hence face great difficulty in growing food for their children and elders (Sernau 2006). Today, a few women in these societies are gaining an education and moving into white collar positions in urban labor markets. Many more are forced by circumstances to work in the informal sector as housemaids, selling food or handmade objects on street corners, or as day

laborers. In most instances, their work is unacknowledged in computations of the gross national product and largely unregulated.

In post industrial societies, government policies designed to remedy employment discrimination often meet extreme resistance fueled by misunderstandings among the public and serious obstacles from employers who do not want to yield control over their business practices. The combined forces of anti discrimination laws and remedies, affirmative action regulations, and comparable worth campaigns are far from eliminating the deleterious effects of employment discrimination on white women or minority people of either sex (Reskin 1998).

Employees are reluctant to bring charges under anti discrimination laws and thereby risk their jobs. Class action suits have won major concessions from a handful of large companies in the United States; in the European Union, however, only individuals can contest instances of discrimination (Gregory et al. 1999). Affirmative action policies require employers to exert concerted efforts to ensure equal opportunities before choosing workers. They require employers to actively seek out women and minority applicants and make sure that they are not lumped into a limited array of job categories. Affirmative action requires quotas and time tables *only in those extremely rare cases* when employers have systematically and obviously discriminated against potential employees and have repeatedly failed to adjust their practices to more equitable arrangements (Reskin 1998).

Comparable worth policies offer a solution to the enduring problem that occupations in which women frequently work are often undervalued and underpaid. Because sex segregation of work is likely to endure for generations to come, advocates recommend a complete reevaluation of the demands and contributions of all job categories and gradually raising the pay of each undervalued occupation until pay equity is achieved. Despite the federal Equal Pay Act, comparable worth has most often been implemented – at least partially – in state and municipal employment rather than in private employment (Reskin 1998; Kahn & Figart 1999).

Contemporary women are rarely found in the ranks of the elite wealthholders but are more than numerous among the poor, especially those who are single and the mothers of small

children. Older women, especially those who are widowed, are most likely to have to depend on social security payments to subsist. Mean while, middle and working class couples typically find it necessary to have both wife and husband employed regardless of the ages and stages of the children and despite the fact that one or both draw relatively high wages. Improvements in the economic position of women await major changes in ideological patterns and in the institutional structure of work.

women, information technology and (Asia)

Helen Johnson

New information and communication technologies (ICT) challenge and have the potential to promote change in women's social status and socioeconomic opportunities in various ways. Some sociologists argue that innovative ICT embody the key characteristics required to provide women with effective opportunities to participate in mainstream economic activities in Asian societies, others that ICT are yet another tool of masculinized social, economic, and political power that is merely perpetuating gender differentiation.

"Asia" cannot be fully defined but the term is a useful shorthand to describe the array of countries whose economies now engage with ICT. "Asia" can encompass Japan, Singapore, and South Korea as three of the world's most technologically developed nations. Asian countries in general hold leading positions in the ICT arena, and nations such as India are sites for technology industries and practices that add significantly to the region's economies, societies, and cultures. While "women" cannot be considered a homogeneous group, "gender" is one of the major ways that humans organize their lives. Many Asian sociologists link ICT to

the analytical prism of "gender" to add detail to the social practices that imbricate ICT usage, examine the ways these may be shaped by gendered and cross cultural difference, assess the potential for marginalization of some social groups via ICT innovation, and add to current debates in the Asia Pacific region surrounding the development of social policies that address issues of social marginalization caused by ICT.

Female Internet use in Asia continues to increase, with women, in 2001, in South Korea comprising 45 percent of the online population, in Hong Kong 44 percent, and in Singapore and Taiwan 42 percent and 41 percent, respectively. Furthermore, women themselves are appraising the benefits of ICT. Previous international research on gender and ICT has focused on the participation of women in computer science as a profession; issues of access analyzed through the prisms of race, class, and gender; the diversity of social interactions on the Internet and their potential for the constitution of multiple identities; the gendering of information systems; and issues of sexual harassment and online pornography. Further studies argue that feminist historical analyses illuminate a range of concepts and actions missing from mainstream social studies of technology and highlight women's active use of the Internet for social change, support networks, and self expression. Others consider how gender is a factor online via experimentation with identity, and how the Internet can be a transformative space where gender categories are reconfigured. Haraway (1985, 1997) has theorized how traditional and innovative media have reconfigured social possibilities for bodies, technologies, and gender. Consalvo and Paasonen have critiqued the ways that technologically neutral or determinist positions do not question the social structures and cultures enveloping new media nor the social differences such as age, caste, class, and nationality that exist between women. Joshi's (1997) edited collection questions the potential for new ICT to expand the gender gap and/or to create more democratic environments in "Asian" nation states.

Analyses of the gendered access to and use of the Internet in the United States have stirred debate about whether the Internet perpetuates regressive social structures or enables progressive female agency in Asian nation states (see,

for Japan, Aoshima 1993; Kanai 1993; Kurano 1993; Hirose 1997; and for other nation states in Asia, Joshi 1997). They also detail the time and financial constraints that hinder women's access and argue that providing access to cyber empowerment is fundamental. Gan (1997) asserts that the gender marking of technology as a male domain has been transferred to the Internet via gender coded societal conditions in Singapore and, despite the government's vigorous program to place technology in the hands of all citizens, social attitudes about women's roles and capabilities must also change. Lumby (1997) notes that technological literacy has been defined against women's skills, and questions about whether the Internet is yet another tool of masculinized social, economic, and political power are deemed vital. Ang (2001) and Tan (1991) explore how researchers ignore, to their loss, how local peoples invoke different gendered perceptions to further their interests. And researchers such as Gupta and Singh (1994) and Hobart (1993) detail how geographical information systems (GIS), as computer programs for mapping definitive geographical identifications which can be linked to information databases about local peoples, have been critiqued for privileging spatial coordinates at the expense of incorporating and understanding poetry and performance as important components of local and indigenous communities' knowledge.

The ways in which ICT may change modes of thinking as well as practices have also been examined. Wong (2000) shows how new technology changes not only material reality but also the ways people think about reality, explores social relations and attitudes to cyberspace and the Internet, styles of interaction with new ICTs and perceived possibilities of identity formation, and argues that cyberspace not only connotes the possibility of transcending one's body but also provides a utopian space for transcendence to a higher state of being. Deconstructing the images and language used to describe cyberspace, Wong notes that most users are ambivalent, with attitudes spinning between idealism, cynicism, and indifference. Wong also explores how language is styled by the influences of the Internet as it becomes interwoven throughout society, and the appeal of the Net for adolescents in terms of relative

empowerment, word games, and flaming for entertainment. Of significance is her presentation of the Japanese Industrial Standard (JIS) character, its use to subvert ASCII text's globalism, and its development of a different range of emotions to express Japanese sentiments. Razak (1997) explores changes to modes of thinking via an index to Malay women's social consciousness, ascertaining how media technologies act to reinforce women's concepts of identity. She notes that improvements in women's consciousness of their rights and responsibilities are occurring and that women are receiving greater media coverage of their familial contributions and their broader social achievements.

Information literacy is examined via Amin's (1997) proposal that ICT may have a different meaning within the context of a "developing" nation such as Bangladesh, in that it must include older technologies such as fax and telephones. She suggests that ICT has a liberating potential in giving women the ability to choose from a wider range of occupations. While Amin's analysis does not take into consideration how class issues may impact on education and access, Joshi (2004) does discuss the difficulties of ensuring that a range of people participate in digitally empowered development in India and focuses particularly on the ways in which women's issues such as health, health education, and access to means of communication evolve. Rajesh (2002) also examines the potential for social disadvantage that is exacerbated by technological development, concentrating on issues of access, whereas Bhatnagare and Schware (1999) examine how ICTs are forming a significant component of rural development. Cheuk (2000) explores information literacy in the workplace via a user centered approach, considers common strategies that are exhibited by people in a group, and the diverse strategies of each individual adopted at different times, in order to gain a holistic understanding of information literacy and thence to improve education in this area.

Current research focuses on how women specifically engage with ICTs across cultures in Asia, the problems of access that face socially disadvantaged sectors of the region's many constituent communities, and the potential impact of technology on local peoples, particularly in relation to the loss or ignorance of local knowledge.

women, religion and

Sally K. Gallagher

Women's religious commitments, ideals, and involvement are increasingly of interest to sociologists within both the sociology of religion and other fields. While early research on religion focused on the origins, functions, meaning, and measurement of religion, the past few decades have witnessed a burgeoning interest in women's spirituality, the involvement of women within religious institutions, and religiously based women's social movements. Part of this shift is the result of the growth of gender

studies within sociology, as well as increased religious pluralism and expression across the religious landscape.

Women's involvement in religion varies depending on whether we are considering personal beliefs and practices or institutional affiliation and leadership. Some scholars have been critical of women's marginalization within religious institutions. Some critics, such as theologian Mary Daly, argue that women's historic exclusion from positions of leadership and authority within western religious traditions is evidence that the Judeo Christian tradition itself is inherently patriarchal and oppressive and should be abandoned in favor of non patriarchal feminist spiritualities. The recent growth of neo pagan (Neitz 2000), goddess worship, and other forms of feminist spirituality suggest that some women are moving away from traditional western religious institutions because they do not adequately meet their needs or provide the kind of overarching moral narrative that gives meaning to women's lives.

Others, however, argue that religion itself (especially western Christianity) is not inherently oppressive to women, but that the gender egalitarian teachings of these traditions and the historical involvement of women as leaders, teachers, and writers have been minimized for political and economic reasons. Thus, within both the Roman Catholic Church and evangelical Protestantism, for example, feminist organizations have emerged in an effort to restore more gender equitable practices and beliefs. Christians for Biblical Equality, the Evangelical and Ecumenical Women's Caucus, and the Women's Ordination Conference are examples of organizations that seek to advance feminist goals within conservative Protestant and Roman Catholic churches. Countering these are a number of conservative organizations and institutions that promote "traditional gender roles" in which women's nurturing is seen as a natural complement to men's responsibilities as leaders, protectors, and providers within both family and the church (Concerned Women for America and the Council on Biblical Manhood and Womanhood are two such examples). Although less and less willing to describe these relationships as one of women's submission and men's leadership, the model these groups promote is nevertheless one in which men have final

decision making authority and spiritual responsibility for family life. The abuses of this power have led to an increase of scholarship on links between religious teaching on women's submission and domestic abuse (Kroegeer & Nason Clark 2001).

Sociology of religion has also explored the dimensions of women's leadership as clergy and lay leaders within the church. Adair Lummis, Nancy Ammerman, and Paula Nesbitt are examples of scholars who have written on the struggles of women in positions of leadership within conservative denominations and traditions and the organizational barriers women face as effective clergy.

What the above research highlights is how women's connections to religious institutions vary based on underlying ideas about the nature of masculinity and femininity themselves. The teachings of some religious institutions and traditions are that women and men are essentially different, and because of those differences should be differently involved in religious worship, teaching, and leadership. Orthodox Judaism, Roman Catholicism, Eastern Orthodoxy, Islam, and many conservative Protestant denominations are examples of religious traditions in which specific leadership positions and responsibilities are reserved for men. Within some of these traditions, religious ritual and family responsibilities are also gendered – with women and men being seen as having separate practices and obligations inside and outside the household.

Not all theologically conservative religions, however, are necessarily or uniformly conservative when it comes to the place of women in religious life. The past decade has seen a movement away from debates over androgyny and hierarchy toward a growing emphasis on complementarity and ideological egalitarianism. Both those who argue that there are essential gender differences and those who argue for gender equality have moved toward a pragmatically egalitarian approach in which symbolic offices and authority may remain limited to women, but women's increasing opportunities to teach, lead, and participate in institutional religious life are paralleled by greater emphasis on men's responsibility to become more involved in everyday family life as husbands and fathers (Gallagher 2003; Bartkowski 2004; Wilcox 2004).

In terms of personal religious life, sociologists of religion have been particularly interested in the appeal of conservative religious traditions to women and the articulation of religion and family life. Rather than focusing on women's institutional involvement, this body of research explores the personal benefits women find in religious observance. Recent studies of conservative Protestants (Manning 1999; Bartkowski 2001; Gallagher 2003), Pentecostals (Griffith 1997; Brasher 1998), Latter Day Saints (Beaman 2001), and newly Orthodox Jewish women (Davidman 1991; Manning 1999) have all made the case that women find personal satisfaction, growth, community, and family support through religious life. Small group participation, prayer services, and family rituals are particularly important in creating a sense of community and care for women within these traditions.

women in science

Anne Kerr

The history and present status of women in science are of interest to sociologists because of the longstanding disparities in women's and men's relative rank and levels of productivity in science, but also because of the male domination of the sciences as a whole. A range of psychological, structural, and cultural explanations have been developed to explain these circumstances and a whole plethora of initiatives and schemes have been implemented to redress the gender imbalance within science. Disparities nevertheless remain and their entrenchment is the subject of continued theoretical and empirical debate.

Women have not always been a minority within science. As Carolyn Merchant has demonstrated, the scientific revolution was premised upon the formal exclusion of women from the new institutions of science. Wise women and midwives were persecuted and "well born" women intellectuals were confined to the home as the division between public and private life intensified. At the same time, dichotomies between mind and nature, reason and feeling, and male and female hardened. Great women scientists like Christine de Pizan (1365–ca. 1430) and Laura Bassi (1711–78) were nevertheless rediscovered in the 1970s as second wave feminists took up their predecessors' quest to show that women can do science just as well as men. They also concentrated their attention on the barriers to women's achievement in science, spawning a rich and diverse literature on the history and culture of science at a time when women were entering science

at a rapid pace. As Schiebinger notes, by 1995, 23 percent of US scientists and engineers were women. Yet it also became apparent that women's fortunes in science wax and wane according to the political and economic climate as well as the development of scientific institutions. Progression is far from linear.

There are copious amounts of empirical evidence to demonstrate that girls excel in science in the right context but that women drop out of science at each and every significant transition throughout the typical scientific career. Women are more likely to be found in low status, insecure jobs, and to devote themselves to the least valued aspects of academic life, particularly teaching. This means that their record of research fund raising is not as good as men's and, relatedly, their publication rates and their promotional prospects are worse. The glass ceiling has become something of a cliché but there is no doubt that it is very real. The proportion of female professors in the sciences is minuscule, and the rate of increase is far lower than the increases in women gaining PhDs in the sciences.

As Mary Frank Fox has convincingly argued, the organizational context of science is fundamental to these gender inequalities. Women are least likely to succeed in organizational contexts where the criteria of evaluation and assessment are informal and subjective. In environments where their contribution is not actively encouraged, they participate less in policy discussions and collaborative enterprises. The individualistic culture of some science departments means that graduate education in particular is essentially "privatized" and it is in this type of environment that implicit norms of masculinity flourish, and those who "look like" those currently in positions of authority are privileged. What Knorr Cetina has called the "epistemic culture" of science, sustained in part through the secrecy and informality of many peer review mechanisms, privileges already established scholars and those like them, and marginalizes female and other minority groups as "the other."

Women's domestic situation is also crucial to their success in science. The long hours culture of science does not suit women's double burden of paid work and unpaid domestic labor.

The widespread and entrenched cultural belief that women have prime responsibility for child care and the tendency for a woman's career to take second place to that of her husband are other obvious contributory factors. On a more positive note, women's marriages also give them access to different networks of influence, and it seems that women who are married to other scientists are more successful than their counterparts.

Of course there is a burgeoning industry of psychological research and pseudo scientific speculation in the wider culture which offers reductionist and essentialist explanations of women's lack of success in science. Differences in women's and men's patterns of speech, sociability, cognitive processing, visual-spatial ability, and levels of aggression have all been deployed to explain women's underrepresentation in science. These have been convincingly debunked by proponents of the "gender similarity hypothesis," whose meta analyses have shown that women and men are more alike than they are different, except in a few largely inconsequential characteristics like the ability to throw objects long distances. As authors such as Janet Shibley Hyde have pointed out, there is a high cost to the prevailing cultural emphasis on gender difference, as it undermines women's sense of their ability to succeed in the workplace (and men's sense of their ability to nurture). Low expectations of girls' and women's mathematical ability and scientific prowess undermine their confidence and perpetuate inequalities. In short, stereotypes matter.

Western thought is underpinned by hierarchical binaries or dualisms, for example, mind/body, culture/nature, masculine/feminine, active/passive, to name but a few. Within this framework, "woman" is associated with terms such as passive, responsive, and inferior. These are constructed in opposition to "man," described as active, aggressive/predatory, and superior. The cultural investment in binarization, particularly between the two sexes, also produces heterosexuality as the only normative form of desire and privileges so called masculine values and experiences over so called feminine. With respect to sexuality, Luce Irigaray, in *This Sex Which is Not One* (1985), argues that western culture has persistently negated or repressed those modes of sexual experience that may be specific to women and which do not fit with masculinist assumptions about women's sexuality.

Western knowledge about human sexuality prior to the nineteenth century has been largely attributed to the Greeks. The framing of women's sexuality as inferior to men's sexuality can be found in the works of early philosophers such as Plato and Aristotle, as well as Galen, the influential second century physician and theorist. Plato, for example, popularized the idea that a "wandering (inactive) uterus" causes female hysteria in women who do not bear children. While Galen accepted the Aristotelian thesis that a woman is like a man, but lower in the hierarchy of being, he disputed Plato's idea of the wandering uterus (Tuana 1993). Women's genitals, Galen argued, were like those of men

but found inside the body. This was explained by “arrested development” and supported Aristotle’s idea that woman is “less perfect” than or a “misbegotten” man. Galen’s thesis that women’s sexuality was similar, although inferior, to men’s sexuality remained popular well into the eighteenth century. With respect to hysteria, it is worth noting that this became increasingly medicalized from the seventeenth century onwards. By the nineteenth century, it had become the source of attribution for myriad ailments and symptoms supposedly associated with “woman” and firmly connected with women’s sexuality (Ussher 1997).

In *Making Sex: Body and Gender from the Greeks to Freud* (1990), Thomas Laqueur argues that it was only from the late eighteenth century that “sex as we know it” was invented. Until this period, he argues, a “one sex” model of sexual difference dominated western medico-biological thought. The shift to a “two sex” model was the result of social, political, and economic changes in the late eighteenth century rather than scientific developments. These created the context in which sexual differences needed to be articulated to support shifting gender arrangements. Although women were no longer seen as inverted replicas of men, the association of women’s bodies and sexuality as reproductive and nurturing, as opposed to sexual and passionate, was reinforced. The anatomical and physiological differences between males and females were thus used to reproduce assumptions about the nature of “heterosexuality,” positioning men as more active, stronger, superior, women as weaker, passive, and inferior, and positioning penile vaginal penetration as “natural” and central to all conceptions of human sexuality (Potts 2002).

Sexology, the “scientific study” of sexuality, was first constituted as an object of medical and scientific knowledge in the nineteenth century. Two of its pioneers, Richard von Krafft Ebing (*Psychopathia Sexualis*, 1886) and Havelock Ellis (*Studies in the Psychology of Sex*, 1913), drew on biological and evolutionary understandings of sexuality which continued to endorse the inevitability of male domination and female submission. They equated sex and gender and saw male and female sexuality as fundamentally opposed. Although Ellis supported the possibility and importance of female genital pleasure,

he nonetheless saw women as creatures weakened by their reproductive biology, since the “worm” or menstruation “gnaws periodically at the roots of life” (Segal 1994). Furthermore, women’s sexual activity was seen as being primarily for reproductive purposes. Although it was given a more autonomous existence in the writings of Ellis, it still required a man to initiate and release it. Thus, while some saw Ellis as promoting a liberal shift away from the sexual repression of Victorian times, Margaret Jackson (1987), for example, argues that his theories eroticized the oppression of women.

In the mid twentieth century, sexologist Alfred Kinsey argued that a liberal, as opposed to repressive, attitude to sexuality was necessary for men and women to be more effective sexual partners. His aim was to promote better understanding between men and women and increase women’s orgasmic satisfaction (Segal 1994). As a zoologist, Kinsey framed sex as a straightforward biological function and a purely physical phenomenon. His reports on male and female sexuality detailed what people actually did sexually and hence challenged popular sexual norms. For example, Kinsey and his colleagues, in *Sexual Behavior in the Human Female* (1953), found that almost a quarter of women had extramarital sexual relations, 3 percent of the female population were homosexual, and there were high rates of premarital sex among women and men. Kinsey also challenged the notion of female frigidity by indicating high rates of sexual responsiveness among women. In opposition to Freud, he reported that the clitoris was the main site of sexual responsiveness. In fact, he claimed the vaginal orgasm was a physiological impossibility and criticized Freud and others for projecting male constructs of sexuality onto women (Irvine 2002). Furthermore, Kinsey challenged the idea that masturbation was a dangerous sexual practice and argued that it was the best way for women to reach orgasm. While Kinsey’s work was seen by some as opening up more “positive” attitudes to sex by countering gendered sexual norms of the period, others argued his emphasis on the power of the male drive perpetuated the positioning of males as agents and females as passive recipients of the sexual act (Potts 2002). Furthermore, Kinsey’s refusal to acknowledge the significance of ethical, social, or emotional factors in the study of sexuality,

and his use of a biologically deterministic theory of sexuality, supported the common assumptions about women's sexuality he was attempting to disrupt.

The popularization of sexological research, in particular the notions that women "enjoy" sexual intercourse and that orgasms are the sign of that enjoyment, reinforce what Paula Nicolson (1993) calls the coital and orgasmic imperatives. The coital imperative asserts that penile vaginal intercourse is a "natural" and "normal" activity, while the orgasmic imperative posits that all sexual activity culminates in orgasm. Nicolson (1994) argues that these imperatives provide clear definitions of pleasure for women to adhere to, in spite of Kinsey's claim that orgasm through intercourse is not necessarily common for women, or Shere Hite's assertion, in *The Hite Report: A Nationwide Study of Female Sexuality* (1977), that this is not what most women themselves see as constituting pleasure. This also set the scene for the medicalization of "female sexual dysfunction" by prescribing what constitutes "normal" and hence "abnormal" female sexual function/experience (see below).

The medico biological, psychological, and sexological approaches which dominated eighteenth to mid twentieth century theorizing and research on women's sexuality drew on "sexual essentialism," that is, the notion that sex "is a natural force . . . eternally unchanging, asocial and transhistorical" (Rubin 1984). Feminist anthropologist Gayle Rubin argued that sexual essentialism is a fixed phenomenon in the West, but that the domination of sexual knowledge by disciplines such as medicine and sexology reinforced this essentialism. Within such a framework, sex was "a property of individuals [residing] in their hormones or their psyches" and having "no history and no significant social determinants."

Over the past few decades, essentialist understandings of women's sexuality have been increasingly challenged. For example, while many feminist approaches have pointed to the social construction of sexuality, these have produced tensions with feminist approaches informed by essentialist understandings. Nonetheless, since the first wave of feminism in the nineteenth century, the issue of women's sexuality has been central to feminist theorizing and research. For example, prior to the emergence of the "human

sexuality" of the medical experts, nineteenth century feminists began to discuss questions that would later be categorized under "sexual politics." The attempt to politicize sex and gender relations was carried out indirectly through discussions of prostitution and the double standard (Valverde 1985). With the rise of second wave feminism in the late 1960s and early 1970s, feminists challenged what were defined as "male dominated" or "patriarchal" understandings of women's sexuality and assumptions about heterosexuality. For many feminists, heterosexual relations were seen as detrimental to women and implicit in women's subordination. The feminist slogan, "the personal is political," is often thought to refer primarily to bringing women's sexuality out into the open and exposing it as a major domain for the deployment and exercise of domination (Tiefer 1995).

Over the past decades, much feminist theorizing and debate about women's sexuality can be considered in terms of the title of Carol Vance's edited volume, *Pleasure and Danger: Exploring Female Sexuality* (1984), a collection of papers presented at the Feminist Conference at Barnard College in 1982. Vance explains that the conference attempted to explore the ambiguous and complex relationship between sexual pleasure and danger in women's lives and feminist theory. In part, this was a response to a focus on "sexual pessimism" or the "dangers" of sexuality for women.

Some of the "dangers" of heterosexual sex for women, for example, were highlighted in what was referred to as the lesbian-heterosexual split. This occurred in the women's movement in the 1970s. Lesbianism was first defined as central for women in the struggle against male dominance. Then, with the framing of heterosexuality as an eroticized institution through which male supremacy is maintained, came the assertion that heterosexual women were "sleeping with the enemy." Thus lesbianism became almost a "categorical imperative" for feminists (Faderman, cited in Segal 1994). What was referred to as "political lesbianism" entailed a significant theoretical revision in feminist thinking about women's sexuality, as well as behavioral changes (Segal 1994). However, this focus on the dangers of heterosexuality for women drew on, as well as reinforced, more essentialized understandings of *differences* between

men's and women's sexuality. Women's sexuality was framed as gentle, nurturing, and loving, in opposition to an aggressive and dominating male sexuality.

This situation was intensified in the 1970s and 1980s when feminist theorizing about women's sexuality became inseparable from theorizing men's violence against women. For example, Susan Brownmiller, in *Against Our Will* (1975), focuses on rape as the primary means by which men have kept women subordinate throughout history. Here, sexuality is seen as the fundamental source of men's oppression of women. The work of Catharine MacKinnon (e.g., *Feminism Unmodified: Discourses of Life and Law*, 1987) and Andrea Dworkin (*Pornography: Men Possessing Women*, 1979, and *Intercourse*, 1987) on pornography has been hugely influential in perpetuating the idea that heterosexual sex is coercive, violating, and disempowering for women. MacKinnon and Dworkin targeted the pioneers of sexology and their descendants for entrenching women's oppression by encouraging them to speak about pleasure in heterosexual relations, an encounter in which, they argue, women are inevitably positioned as subordinate (Segal 1994). Once again, this radical feminist theorizing drew on essentialist understandings of men's and women's sexuality as fundamentally different and neglected historical and sociological analyses in favor of naturalistic assumptions about what sexuality "really is" (Valverde 1985). This also worked to silence the voices of heterosexual women/feminists about their sexual lives and pleasures.

Much feminist theorizing in the 1980s and 1990s draws on the work of Michel Foucault, and poststructuralism more broadly, to explore the ways in which sexuality is constructed in discourse. Lynne Segal (1994) and Stevi Jackson (2003), for example, critique phallogocentric and essentialist models of women's sexual pleasure as "eroticized submission," in particular the way in which these denied agency to heterosexual women (seen as either misguided victims or dupes). While acknowledging the "dangers" in heterosexual relationships, such as sexual coercion and sexual violence, much feminist theorizing has focused on the discursive construction of heterosex and the diversity of heterosexual experiences and bodily

contacts. This includes a focus on women's sexual agency. Queer theory has also influenced contemporary understandings of sexuality and facilitated a shift to exploring the diversity and fluidity of sexual identities, preferences, practices, and meanings.

However, attention to the dangers of sexuality for women also remains a central component of theorizing and research. In the new millennium, sexual violence against women, from domestic violence to rape and the more recent "date rape," is prevalent. Recent work attempts to explore the complex ways in which normative understandings of heterosexuality and women's sexuality provide the "cultural scaffolding" (Gavey 2005) for rape and sexual violence against women. Attention to the location of discourses about sexuality within specific socio-historical contexts and the ways in which individuals are positioned within, and negotiate with, normative discourses underpins much contemporary research. Gavey (2005), for example, works to unsettle rigid gender binaries around both active desiring sexuality and physical aggression, as well as those around the possibilities of victimization. She advocates a transformation of the cultural conditions of possibility for gendered ways of being sexual and "aggressive."

Other contemporary feminist ways to "re-corporeograph" women's sexuality (Potts 2002) include decentralizing the penis, disrupting the masculine (active)/feminine (passive) dichotomy, and promoting the autonomous female sexual subject. Examples of such reframings include: rethinking heterosexual intercourse in terms of engulfment or embracement of the man's penis by the woman's active vagina, thinking in terms of the "phallic woman" or destabilizing impressions of female bodies as vulnerable interiorized spaces and eroticizing the "receptive" male, and promoting active female sexuality through attention to the "female ejaculation" (Bell 1991).

Challenging understandings of what constitutes normative heterosex, for example the coital and orgasmic imperatives, is therefore a central endeavor in much critical theorizing and research on women's sexuality. This extends to the recent critiques of the medicalization of women's sexuality. Since the 1990s there has been an increasing focus on women's sexual

problems, located primarily within medical and sexological frameworks. Female sexual dysfunction, as a sexual disorder, was “made” in the late 1990s and is routinely reported to affect around 40 percent of women (despite serious concerns about this figure by sex researchers). “Female sexual dysfunction” refers to women’s sexual difficulties with arousal, penile vaginal penetration, and orgasm and promotes a specific norm of sexually correct genital performance. The necessary ingredients for “successful” sexual experience are desire (vaguely indicated as being “for sex”), genital arousal, a timely orgasm, and the ability to enjoy vaginal penetration (Tiefer 2001). On the one hand, there is acknowledgment of women’s new sexual agency and rights, yet on the other hand, the medical model ignores the non medical nature of sexual problems and difficulties, in spite of women repeatedly telling researchers that these are their primary areas of sexual distress. Tiefer argues that the medical model promotes the idea that all women want the same thing out of sex, with routine orgasmic genital function as the center piece and physical manifestations as the main source of difficulty. It tells women there is something wrong with them whenever they experience a pattern of sexual desire, arousal, or orgasm defined by experts as “abnormal.”

The escalating medicalization of women’s sexuality provoked Leonore Tiefer (2001) to think about a “new view” of women’s sexual problems. Tiefer, together with a grassroots group of feminist social scientists, sex educators, therapists, sex researchers, physicians, and activists, developed the Campaign for a New View of Women’s Sexual Problems. In contrast to the medical model, the “new view” emphasizes sexual diversity, social context, education, empowerment, and attention to the ways in which sexual norms are constructed. It is hoped this “new view” will influence sexuality theory, research, and education.

women's empowerment

Denise A. Copelton

Women's empowerment is a central concern of the women's movement. It refers to the general process through which women gain knowledge about the structures that oppress them, and seek to alter the power imbalances in society. Bookman and Morgen (1988: 4) define empowerment broadly as the "process aimed at consolidating, maintaining, or changing the nature and distribution of power in a particular cultural context" that can range from "acts of individual resistance to mass political mobilizations." Given women's diverse experiences of inequality, women's empowerment has been partially achieved through a variety of strategies and within a number of different historical, institutional, and cultural contexts. For example, in the first wave of the women's movement in the US, women's empowerment was linked explicitly to political power in the form of voting rights. In the second wave, women's empowerment was linked to such issues as reproductive rights, workplace rights, freedom from men's violence, and furthering women's political rights and legal protections through the Equal Rights Amendment (ERA). Not all of these issues were successful, however, as the ERA never passed into law, violence against women continues, and reproductive rights are not shared equally by all women. Nevertheless, that large numbers of women demanded changes to the unequal institutional arrangements in politics, law, medicine, and intimate relationships illustrates the process of women's empowerment. Though the concept and process of women's empowerment is far reaching and factors into all areas of women's lives, the discussion below focuses on those

areas of women's lives in which the concept of empowerment has taken center stage. These include second wave US feminist organizing; women, sports, and self defense; women's health care; and women and development.

In the US, women's empowerment figured especially prominently in the second wave women's liberation movement of the late 1960s and 1970s and took the form of consciousness raising groups. As practiced by second wave feminist groups, consciousness raising is quite similar to the development of a sociological imagination, which allows its possessor to reframe her problems as collective rather than individual, as emanating from political or institutional structures rather than personal failings. The multistep process of consciousness raising began with sharing personal experiences with other women, connecting those experiences with larger institutional forces, and linking all of the above to larger theories of oppression and privilege (Ferree & Hess 1995). The process often facilitated a "click" experience or epiphany and politicized a large number of women as they collectively reframed their personal experiences as the result of institutionalized sexism and gender discrimination. The feminist slogan "The personal is political" resonated strongly with this overall process of consciousness raising. However, not all women wanted to press for political and institutional change. Some second wave feminist organizations' use of consciousness raising as a tool of empowerment functioned more like a self help "rap" session or feminist support group than as a collective strategy to press for societal change. In some groups, the process of consciousness raising never progressed to its final phase – that of facilitating political activism. Instead, some consciousness raising groups functioned merely as psychological support groups or self help groups, places where women could receive support from other women as they attempted to make changes in their personal lives.

In the 1970s, the women's health movement emerged out of second wave feminist organizing in the US. Feminist critics charged that medicine in general and physicians in particular mystified women's bodies and argued that if physicians shared information about women's bodies at all, they did so in complicated scientific terms which rendered such information

inaccessible to most women without a medical background. The medicalization of childbirth came in for special scrutiny as feminists argued that the medical treatment of childbirth placed control over this natural process entirely in the hands of medical experts, leaving childbearing women powerless to determine the course of their own care. Activists in both the feminist and childbirth reform movements believed that women must be empowered to wrest control away from physicians and reconceptualize health care to minimize power differentials between providers and patients, or as they were increasingly called, clients. Thus, women's empowerment in health care would come, they argued, through sharing medical information with women and leveling the power differentials embedded in the traditional doctor–patient relationship. A host of second wave publications such as *Our Bodies, Ourselves* and *How to Stay Out of the Gynecologist's Office* intended to make medical information accessible to women and empower women to take charge of their own health.

Feminist women's health centers, in particular, took seriously the goal of women's empowerment. Jan Thomas (2000) notes that feminist health centers empower women patients through three principal mechanisms. First, instead of merely providing care to women, these centers aim to educate and inform clients about their own health and health care options so women clients can become active participants in their own care. Second, feminist centers seek to break down institutional barriers to care by reducing the physical and social distance between clients and providers, increasing the average length of provider–client interaction, and by becoming visible in the local community. Finally, centers seek to treat all clients with dignity and respect. Thomas (2000: 144) writes that empowerment “takes place over time through the mutual sharing of information, knowledge, and skills” and “culminates in a woman's active control of her health care.”

The concept of women's empowerment has also factored heavily in arguments for women's sports and self defense courses. Title IX of the Educational Amendments Act of 1972 banned sex discrimination in US schools, including school sports programs. Passage of Title IX was seen as a victory for girls not only because

it banned school based sex discrimination of all sorts, but also because it required schools to offer girls opportunities for sports participation that were equal to those of boys. Advocates for girls' and women's sports argued that sports empower girls and women by improving self esteem, developing positive body images, offering a sense of accomplishment, and promoting self confidence, which then may translate into higher grades and standardized test scores, lower high school dropout rates, and higher college attendance rates. In other words, participation in sports empowers girls to develop greater confidence in their own abilities and thereby challenge gender stereotypes and power imbalances in societal institutions.

Advocates of self defense training for women and girls argue that self defense can prevent women's victimization by strengthening their physical and psychological capacity to resist male violence. By teaching women basic martial arts techniques, feminist self defense courses empower women to resist traditional gender role socialization that encourages passivity, and to develop instead both the self confidence and physical skills necessary to resist and flee an assailant. About the impact of women's physical development through sports, Roth and Basow (2004: 262) write, “as our bodies are transformed, so are our minds.” Women's participation in sport and feminist self defense, these scholars argue, therefore empowers women to contest traditional assumptions concerning the frailty of women and women's bodies and thereby challenge the power dynamics embedded in traditional gender roles that leave women susceptible to potential male violence.

Recently, the concept of women's empowerment has factored heavily in development discourse and practice, particularly among non government organizations (NGOs). One of the ways that women's empowerment is currently being pursued in developing countries is through micro credit lending. Historically, development programs focused on women only as a means of controlling fertility. Programs promoting women's education were thus often justified with reference to the lower fertility rates these programs would facilitate. Focusing almost exclusively on familial roles, such development programs typically ignored women's economic roles and rarely promoted women's

well being for its own sake. Development policies and programs also typically construed women as in need of aid or welfare, rather than as in need of sustainable income generating projects, despite the fact that many studies showed that women were often the main income earners within their households. However, since the mid 1970s development discourse and policy have increasingly recognized that women's equity in developing nations is tied to their income generating activities. Recognition that rural women earned a livelihood from a variety of economic activities besides waged labor led the Grameen Bank of Bangladesh to organize micro credit lending schemes aimed at poor women. NGOs and other private funders have adopted the model of micro lending in part, because of the higher loan repayment rates associated with micro lending compared to other credit schemes aimed at the poor.

Research examining the impact of micro lending on women's empowerment has found mixed results. Because micro lending is primarily concerned with women's economic position, providing credit to enterprising women who might not otherwise qualify for credit, its results have largely expanded women's economic resources while leaving untouched other sources of gender inequality. Offering micro credit to women in developing nations does not always result in women's control of economic resources. Thus, if women's empowerment means control over resources, increased self reliance, greater independent decision making, and shared decision making with men, then micro lending has been only partially successful.

women's health

Diane S. Shinberg

Women's health encompasses physical, emotional, and social health and well being associated with female reproductive and sexual development over the life cycle, or any medical condition more common among women. The sociology of women's health includes the study of gendered politics within medicine, medical training, doctor-patient interactions, self care, illness behavior, and health care utilization. Women's health can be more broadly construed to include the relationships between gender inequality (gender as a social institution) and health, even among men.

The pervasiveness of biological essentialism, the ideological emphasis on biology as *the* explanation for apparent differences between men and women, is one reason women's health is such a broad and dynamic area of sociological study. Gender inequality – the social constraint, devaluation, and oppression of women – historically has been justified on the basis that the female sex status is frail with respect to anatomy, physiology, hormones, development, sex, procreation, and, most recently, genes. The use of biomedical authority in theories regarding the fundamental differences between the sexes supports the pervasive belief in women's biologic vulnerability as “the weaker sex.” Such ideology has had social consequences, for example, as manifest in barring women from pursuing higher education because intellectual activities supposedly would divert the flow of blood to the brain from the uterus, leading to uterine atrophy, decreased fertility, and even barrenness. More recently, hormonal fluctuations associated with menstruation, premenstrual syndrome, post partum depression, and menopause are cited as causes of mental imbalance and unpredictability which prevent women from holding the reins of power in political and corporate offices.

DEMOGRAPHY AND EPIDEMIOLOGY OF WOMEN'S HEALTH

In post demographic transition societies women on average live longer than men. Mortality declines and gains in life expectancy were most substantial, especially among women, in the early to mid twentieth century, a trend related to declines in maternal and infant mortality. According to the National Center for Health Statistics for 2002 in the US, total female life expectancies at birth, at age 60, and at age 85 were 79.9, 83.5, and 92 years versus 74.7, 80.3, and 90.9 for males, respectively.

Despite a so called female physiological advantage in terms of survival, women apparently experience more sickness and ill health than men, contributing to a so called gender paradox in health where “women are sicker, but men die quicker.” However, this generalization is overly simplistic; indeed, careful

assessments reveal a more complex story about excess female sickness when specific aspects and definitions of health are considered. While women tend toward higher levels of overall physical illness, disability days, and health care utilization, men experience more life threatening ailments such as heart disease, respiratory disease, and cancer. Despite Americans' mistaken belief that female specific illnesses such as breast cancer are the leading cause of death among women, men and women die from largely the same set of causes, such as heart disease.

Biomedical approaches to sex differences in health and illness emphasize the portion of gender differences in morbidity attributable to female reproductive problems or to physiological differences between males and females that contribute to different rates of disease processes and aging among men and women. Although biophysiology may contribute to static sex differences in morbidity and mortality, it may be unlikely that such differences, per se, account for change in gender differences in health and death over time.

By contrast, sociomedical approaches to gender disparities in health consider social constructionism and gender role theories. Gender differences in material circumstances, social roles, social support, and lifestyle explain historical change in and gender patterning of health and mortality. People's social roles and characteristics are related to their health, and those roles that women tend to hold more than men may be important in explaining gender disparities in health. These acquired risks (e.g., low socioeconomic status, non employment, parenting, care giving, and certain health habits) decrease health status. Compositional gender differences in these acquired risks contribute to gender differences in health that favor men. Secondly, the social construction of gender roles is related to health in that traditional feminine role obligations are more compatible with illness behavior and sick role incumbency than traditionally masculine roles. Reproductive role obligations, such as nurturing and care giving, requires cognizance of the nutritional and behavioral requirements of others, and an awareness of what constitutes normal (versus deviant, sick, or out of the ordinary) behaviors and needs of other family members. Such responsibilities

may foster sensitivity to sickness and may foster adoption of health promoting behavior on one's own behalf and on behalf of others, and women tend to be the primary agent for health within the family. Finally, sociomedical approaches suggest gendered artifacts of health reporting behavior, help seeking behavior, and recall and response rates may contribute to measured gendered differences in subjective health.

ILLNESS BEHAVIOR, HEALTH CARE UTILIZATION, AND MEDICALIZATION

In general, women go to the doctor more than men, with rates of physician visits overall 40 per cent higher among women compared to men. According to the National Center for Health Statistics, among 25–44 year olds, women go to the doctor twice as often as men. Men seek preventive health care half as frequently as women do.

There is an apparent congruity between emphasized femininity and the sick role, with these associations influencing illness behaviors, such as help seeking. By contrast, an incongruity between hegemonic masculinity and sick role behavior is manifest among health lifestyles in which masculinity supports risk taking and negative health behaviors such as drinking, smoking, low seatbelt use, and health care avoidance. Men are twice as likely as women to have had no health care visits in the past 12 months and are three times as likely as women to have had no health care contacts whatsoever during a three year period.

Perhaps the predominant sociological focus on women's health has been the medicalization of the female life cycle. Medicalization refers to the process through which aspects of life fall under the purview of medicine and come to be defined as medical problems or illnesses. As women are more often patients than men, women's lives may be more easily subject to medicalization; for example, menstruation, premenstrual syndrome (PMS), pregnancy, birth, breast feeding, infertility, and menopause have all become medicalized to some degree with respect to medical language and to medical practice.

While the medicalization of birth in the US was strongly associated with the rise of medicine as a profession and medical control over the use of forceps in the early twentieth century, the medicalization of pregnancy is a more recent and ongoing process. Through technological advancements (e.g., sonograms, amniocentesis) and legal and insurance constraints (e.g., managed care and malpractice insurance), the definition of what is considered as a "high risk" pregnancy has expanded so that more technological interventions are brought to bear upon the pregnant and laboring woman (Rothman 2000). Infertility, once considered a social problem for unfortunate couples, is highly medicalized since 1978 and the birth of Louise Brown, the first "test tube baby" or child conceived as a result of *in vitro* fertilization. Although healthy birth rates resulting from hi tech assisted reproductive technologies remain modest, many private health insurance plans now cover some assisted reproduction trials. Other examples of medicalization research in women's health include Anne Figert's study of the politics of defining PMS as a medical and psychological disorder and Margaret Lock's research on the divergent medicalization of menopause in the US and Japan. With respect to medicalized language, Emily Martin has detailed how biomedical textbooks employ gendered language to describe gamete production, conception, menstruation, and menopause.

GENDER AND THE INSTITUTION OF MEDICINE

As feminism enhanced women's entry into medical fields, more women have access to medical schools today (nearly half of medical students are women). However, while about a quarter of doctors in the US are women, nursing remains a female dominated occupation; about 95 percent of nurses are women. Gender stratification operates at all levels within these fields: women who become doctors tend to specialize in pediatrics, family practice, and obstetrics/gynecology at higher rates than male doctors. Within more exclusive branches of medicine, such as advanced surgical specialties, women's representation remains scant. Overall,

male doctors earn more than female doctors, while female doctors are more likely to be salaried and less likely to be self employed than their male counterparts. Among full time physicians, women tend to work somewhat shorter hours than men, although total office hours spent with patients are similar. However, female physicians tend to spend slightly more time (about 2 minutes longer) with patients and thus tend to see fewer patients than male doctors. Given the gender distribution among doctors, nurses, and patients, the predominant dyads within medicine (doctor–patient and doctor–nurse) are gendered as well as hierarchical. Thus, medical settings have contributed to studies of dominance, authority, and gender (Fisher 1988).

The heightened inclusion of women in the profession of medicine has contributed attention to the differential treatment of women as second class patients relative to men and to the exceptional treatment of women as patients who receive excessive intervention. It is important to remember that differential and/or exceptional treatment of women as patients is not necessarily the result of overt discrimination. The gender system is strongly related to ideas about illness, etiology, and treatment. In the example of heart disease, McKinlay (1996) identified patient, provider, health system, and technological influences on the gendered detection of illness.

WOMEN'S HEALTH MOVEMENT, POLICY, AND SCHOLARSHIP

The last decades of the twentieth century were a dynamic period for women's health scholarship and activism. The modern women's health movement not only changed the US health care system but also applied the important sociological concepts of authority, deviance, labeling, and medicalization to resist stigma associated with being female.

The successes of the women's health movement in the 1970s buoyed larger movements in self help and consumerist health care. For example, activists concerned about coercive female sterilization practices against poor women, women of color, and Medicaid recipients fought for informed consent protocols for

such procedures. The National Women's Health Network lobbied the US Food and Drug Administration (FDA) to provide more information to women who opted to take contraceptive birth control pills; thus, the Pill became the first prescription drug in the US to include a mandatory patient package insert which disclosed potential side effects.

Pressure from groups outside medicine and from growing cohorts of women scientists, including doctors, forced a change in the way biomedicine was conducted and organized in the US. For decades, women were routinely excluded from clinical trials due to concerns over chemical exposures and reproductive vulnerabilities. Many medications had not been tested on women and thus physicians were on their own in prescribing dosages and assessing drug interactions. However, in 1990 the National Institutes of Health founded an Office of Research on Women to oversee the systematic inclusion of women in clinical studies. This development may be seen as an example of medicine's growing reliance on evidence based approaches to the clinical treatment of patients.

Just as sociology has shifted from a consideration of the sociology of women to the sociology of gender, the meaning of women's health is expanding to include gender and health. This provides opportunities to configure women's health to include many aspects of interlocking systems of domination, (e.g., race, class, sexuality, age, etc.) and to address ways in which gender as a social institution influences health. Other important influences within sociology include research on the sociology of the body and on aging and the life course.

The sociology of women's health will need to better understand the renewed interest of biomedicine in sex specific biology (Wizemann & Pardue 2001). Future developments in gender and health will address the continuation of medicalization, with new opportunities for gender based case comparisons (e.g., sexual dysfunction); the intersections of gender, disability, and the body; and gendered life course trajectories in health practices and outcomes.

women's movements

Carol Mueller

Women's movements arise from the gendered social constructions that have accompanied the biological differences between male and female. Because social distinctions based on gender are the most basic forms of human differentiation, they pervade social life. Throughout history, across classes, ethnicity, nationality, sexuality, and religious groupings, the gendered division of labor has been associated with differential roles, rewards, and with an associated politics. That is, the political processes by which rules are made and valued objects and services are distributed have institutionalized gender differences since the beginning of human history. In only rare circumstances have these differences not been associated with the subordination of

women. Traditional systems of political thought, supported by most religions, have relegated women to a secondary status. Thus, the potential beneficiaries of "women's movements" conceivably encompass more than half of humanity throughout history.

Yet women are also divided by all of the other social distinctions and sources of subordination to which the human experience gives rise. These distinctions are characterized variously in terms of "multiculturalism," "intersectionality," and, for the last few years, the all embracing language of "human rights." Women's differences present both obstacles to mobilization and a multiplicity of competing claims characterized in terms of identity struggles (Hobson 2003). Others, however, argue that the resolution of differences occurs in an ongoing process of negotiation in specific sociopolitical contexts within which no long term historic actor is forged (Stephen 1997: 275-9). This perspective could help account for the periodic societal amnesia regarding the collective struggles associated with women's movements. Negotiating and defining who "women" are in terms of their competing identities, nature of subordination, and associated claims constitute some of the major processes of women's movements (see, for instance, Hobson 2003; Regar 2006).

We should also recognize that not all of women's mobilizations are full blown social movements. In fact, many are local campaigns restricted to neighborhood or community. Most of these remain local, such as the neighborhood groups that Naples describes in the New York area during the 1960s War on Poverty. Historically, the most famous of the shortlived women's protests was the October 1789 march on Versailles to protest increases in the price of bread, one of the defining *journées* of the French Revolution. Other local mobilizations by women have become national and then internationally modeled by other women. Such was the case with the Mothers (and Grandmothers) of the Plaza de Mayo in Buenos Aires in the late 1970s and the 1980s. The mothers' protests on behalf of their disappeared children were taken up by mothers throughout Latin America (Stephen 1997). In these cases, women were bound together by their identities as "mothers of the disappeared." Women in Black offer another example where gender alone is a binding identity. Their

signature protests against violence and warfare originated among Palestinian and Israeli women and then spread to Serbia and Ireland, and are now found all over Europe and North America.

FEMINISM AND WOMEN'S MOVEMENTS

To speak of "women's" movements, however, requires attention to the distinction between movements made up of women as a constituency or organizational strategy and those movements in which the empowerment of women is both a goal and source of theoretical and ideological negotiation and contestation, that is, "feminist" movements (Ferree & Mueller 2004). The distinction is that between an organizational or identity choice of female membership that may or may not be feminist and a mobilization that is based in ideology, framing, cultural discourse, and practices concerned with women's subordination, potentially made up of men as well as women. Women's movements take action on behalf of home and family as well as supporting principles like peace and justice as the responsibility of women in their roles as wives and mothers. Most of the short term mobilizations of women described above are of this nature.

Women's mobilizations can become feminist and vice versa, as when women in the anti slavery movement of the early nineteenth century became the founders of the US suffrage movement (Flexner 1959). The recent origins of feminism in the US began with women who felt they had received second class treatment in the Civil Rights Movement and the new left of the 1960s. Similarly, Lynn Stephen notes that "Latin American women's activism ... often combines a commitment to basic material survival for women and their families with direct or indirect challenges to women's subordination to men" (1997: 267). For the sake of consistency, in the following discussion, the term "feminist" will be used to designate those movements concerned with rectifying women's subordination despite the fact that their goals are frequently much broader.

Although feminist mobilizations are always concerned with the subordination or self actualization of women, the elasticity of that

definition has led to enormous variety in feminist movements. The term itself is a product of intellectual discourse in late nineteenth century France, but the "woman question" had been a matter of public concern in Europe since the sixteenth century among literate men and women. To emphasize ideas as the defining characteristic of a feminist movement is only to recognize a historic fact. As Karen Offen notes in her history of European feminism, "an expanding body of feminist criticism in print precedes by centuries the development of the women's groups which do begin to form, from 1789 on" (2000: 25). Like most of the social movements associated with modernity, feminist movements were also empowered by the spread of literacy and a print culture (Tarrow 1998). As Offen points out, the Enlightenment was as much about the "woman question" as it was about citizenship, democracy, science, and the authority of reason.

Among women and men who might be considered feminists, there have been many schools of thought on the subordination of women that have continuously served as major sources of ideological and political conflict. Despite this diversity, the most consistent division globally and historically has been between liberal and socialist feminisms. Prior to 1848, it seemed that socialists and feminists were pursuing the same goals, but after mid century, an intense rivalry developed in Europe that was echoed in most parts of the world where both systems of thought fought for dominance. Pre Marxist socialist visionaries on both sides of the Atlantic supported egalitarian utopias with communalized family systems like the Owenites in England and the Oneida Community in upper New York state. By the last half of the century, however, August Bebel, Friedrich Engels, Karl Marx's daughter, and Clara Zetkin made it clear that class had political primacy over sex in socialist thinking (Offen 2000). These differences have influenced positions on protective labor legislation, prostitution, state support for mothers, and, most importantly, the question of whether women's subordination is a result of capitalism or some more universal relationship between men and women.

The pervasive socialist/liberal difference between feminists is still found, for instance, in Raka Ray's (1999) comparison of feminist

organizing in Bombay and Calcutta; in European and North American feminists' responses to neoliberal political and social restructuring (Banaszak et al. 2003); and in Latin American women's responses to authoritarian governments, where the Zapatista rebellion in Chiapas shows the closest approximation to revolutionary socialist practice (Stephen 1997). In the US and Canada, with weak traditions of socialism, feminist union women such as the Women of Steel described by Fonow (2003) have, nevertheless, begun to make significant progress in building international coalitions.

MODES OF MOBILIZATION AND MOVEMENT LONGEVITY

As one of the major social movements developing in the modern period, feminist movements have, to some extent, shared the same repertoire of collective action (Tarrow 1998) as labor, environment, male suffrage, and other "rights" movements. While feminists' mobilizing structures may have been located in beauty shops, garden clubs, churches, and neighborhood groups rather than taverns, sporting events, and men's clubs, to some extent the resulting repertoires were similar despite the relative absence of violence, or of strikes and revolutionary attempts to take over the state. If we look back at the women's suffrage movements of the nineteenth and early twentieth centuries, we see a very similar repertoire of mass meetings, petitions, demonstrations, and electoral campaigns that were associated with the birth of other social movements attempting to influence the state. The ultimate success of these movements is also credited to the formal organizations that coordinated national campaigns over decades and across large distances.

At the same time, nineteenth century feminists challenged cultural norms and values through a more symbolic and discursive repertoire associated today with "new social movements" (Melucci 1989). "Bloomer girls" defied the strictures of women's clothing as well as Victorian sensibilities (Flexner 1959). Among other radical challenges to nineteenth century culture was the call for free love and the end of marriage by leaders of the National Suffrage Association, echoing the programs of communal

utopians early in the century. While these claims sprang from the center of equal rights/liberal feminism in the United States, Engels and other socialists were making similar attacks on the institution of marriage as "legalized prostitution" in Europe.

A similar combination of cultural and political repertoires has characterized the more recent phase of feminist mobilization. The US feminist movement has, in fact, been primarily identified in terms of an equal rights branch engaged with the state (Costain 1992) and a women's liberation branch which has challenged basic cultural assumptions. The former has had its program institutionalized through legislation, court decisions, lobbying, formal organizations, electoral campaigns, and the increasing support of women in electoral and administrative offices. The latter branch of the movement achieves long term influence through the creation of women's studies programs in colleges and universities, performance art, books, journals, and music, book stores, coffee shops, and entire communities of feminists. The impressive success of Eve Ensler's *Vagina Monologues* has demonstrated how performance art can serve as a venue for consciousness raising. As Katzenstein (1998) points out, this distinction in repertoires exists even in the "unobtrusive" mobilizations of feminists within highly structured, patriarchal institutions like the US military and the Catholic Church.

Like most long running international movements, feminists have gone through periods of highly public mobilization followed by "abeyance" periods (Rupp & Taylor 1987). When the public visibility of the movement is lost, low profile organizations, networks, and communities can sustain the ideologies, framing, and collective memory of the movement. In Europe and North America, this periodicity or cycle of protest (Tarrow 1998) has been characterized in several ways. The most common is the "wave" analogy in terms of first and second waves, with younger scholars pointing to a third wave since the mid 1990s. The first wave, from the mid nineteenth century until after World War I, is associated with the campaign for women's suffrage, although the movement actually had a much broader agenda. The second wave is associated with the 1960s and, in terms of equal rights, the creation of the State

Commissions on the Status of Women leading to the formation of the National Organization for Women and a host of legislation for women, including the Equal Rights Amendment (Costain 1992). On the cultural side, women's liberation groups engaged in street theater against the Miss America Contest in Atlantic City, released mice at the New York Marriage Fair, and hexed Wall Street. While these "waves" span decades, Whittier (1995) points out that "generations" of feminists can change identities, claims, and repertoires as often as every few years in highly mobile grassroots organizations. Beginning in the 1990s, a "third" wave has been widely debated in terms of how much current feminist issues and practices are discontinuous from earlier mobilizations (see Reger 2006). These discussions are so pervasive that there are increasing arguments for other metaphors.

Regardless of the analogy, what seems very clear is that these transformative moments redefining the relationship of women to men and to society have historically been quickly suppressed by countermovements that reestablished women's traditional subordination. This was true until women gained a firm foothold in the polity through suffrage movements of the late nineteenth and twentieth centuries. Offen (2000) describes such a process of French movement and countermovement occurring repeatedly in 1789, 1830, 1848, and 1871. Institutionalized access to the polity has been a necessary, but not sufficient, condition for achieving cumulative gains toward eliminating women's subordination.

At the local level, periodicity and protest cycles are strongly influenced by sociopolitical conditions and the rise of countermovements. Globally, however, war and depression have played the primary role in suppressing transnational communication, travel, conferences, and organizational development (Ferree & Mueller 2004). Although the major effect of both world wars of the twentieth century was the suppression of women's international mobilization, as was the Cold War, all three conflagrations led to the creation of institutions that furthered global feminist movements. The League of Nations, the Organization of American States, the United Nations, and the decade of international conferences that followed the collapse of

the Soviet Union all served as targets of feminists' mobilizations, as forums for debates on differences in women's subordination North and South, and, eventually, as sources of both resources and legitimation.

A GLOBAL MOVEMENT?

By the time European powers encircled the globe with their empires in the nineteenth century, some of the ideas associated with feminism had become embedded in the larger cultural package of "modernity" (Kandiyoti 1991). Indigenous leaders in the European colonies some times entertained these ideas along with other modern systems of thought as a way of coming to terms with the imperial powers. Thus, attacks on footbinding in China, *sati* in India, and female circumcision in East Africa were largely campaigns sponsored by coalitions of western missionaries and modernizing local leaders with support from information campaigns aimed at European audiences of men as well as women (Keck & Sikkink 1998). As nationalist movements led to the overthrow of colonial powers in the twentieth century, feminist ideas were in danger of being attacked for their association with western imperialism and discredited "modern" ideas (Kandiyoti 1991). Similarly, when the Soviet system collapsed late in the twentieth century, ideas about women's equal participation in politics and the paid labor force were discredited in many countries of Eastern Europe because of their association with an imposed Soviet style socialism (Jacquette & Wolchik 1998). Despite these setbacks, both liberal equal rights and socialist interpretations of feminism have circled the globe.

In the late nineteenth century, railways and steamships increased the opportunities for travel, and international postal networks enhanced the opportunities for building transnational networks. The World Expositions held in Paris, London, and Chicago provided opportunities for feminists to hold their own parallel congresses, much as women have done in the late twentieth century during international UN conferences. With the Second International of 1889, socialists identified a common platform with class oppression given preference over the subordination of women as an accepted political

priority. The first wave of feminist mobilization in the late nineteenth century led to the creation of international organizations that merged women's concerns for peace and the end of poverty with feminist concerns about women's subordination. In a series of meetings before and after World War I, conferences were held to bring international attention to all of these issues and to create mechanisms for pursuing these aims between conferences.

In a surprising historic parallel, the late twentieth century saw comparable international expansions in opportunities for communication, travel, and networking. Air flights became increasingly affordable. By the end of the century, the Internet provided instant access to the far corners of the globe. Organizationally, the creation of the Commission on the Status of Women (CSW) within the United Nations gave feminists their initial entrée into the major governmental body with international legitimacy (see Meyer & Prügl 1999). From their beach head in CSW, feminists were successful in lobbying for an International Women's Year (IWY) conference in Mexico City for 1975 which became a starting point for a series of global conferences that brought together an increasing number of governmental representatives and movement organizers. In preparation and in response to these conferences, women's organizations flourished. Feminists also took their agenda(s) to UN conferences on the environment (Rio, 1983), human rights (Vienna, 1993), and population (Cairo, 1994). By the time of the UN conference for women in Beijing (1995), estimates placed the number of official and unofficial participants at 30,000 to 40,000 – the largest gathering of women in world history. Despite this impressive showing of global feminism as historic actor, the global face of the movement has received scant notice from the mainstream media.

Early in the twenty first century, the Internet was alive with debates over whether, when, and where further UN conferences for women should be held. Organizers feared the counter movement taking shape in the alliance between the Vatican and representatives from Muslim countries that appeared in Cairo and again at the Beijing Conference that would be reinforced by delegations appointed by conservative administrations in Australia, the United States,

and other western countries. Countermovements, however, have occurred as frequently as the feminist movements they oppose. There seems little likelihood that either feminists or their opposition will disappear in the coming century.

work, sociology of

Melissa Bonstead Bruns

Work is typically described as the activities involved in the production of goods and services. The sociology of work, then, involves the systematic study of the interrelationship between the people and institutions associated with the production of goods and services. The general heading of the sociology of work subsumes many topics, which can be separated roughly into individual level approaches and structural level approaches. Individual level approaches treat the individual as the unit of analysis and typically focus on ascribed characteristics such as gender, race, and age. They also commonly address achieved characteristics such as education, promotion, compensation, and other labor force outcomes. Individual level approaches may also examine the impact of work over time by looking at the life course or career trajectory of individuals.

The units of analysis of structural level approaches range from jobs, to occupations, to industries, and may even focus on the individual *within* the larger structure. Common topics addressed under a structural rubric include occupational structures, internal labor markets (ILMs), bureaucracies, unionization, skills, professions, and globalization. Overlapping these two approaches is work on particular occupations or areas of employment, and work on public policy issues related to the labor market, such as affirmative action, comparable worth, welfare to work programs, and the welfare state in general.

Over the course of its evolution, the sociology of work has diverged into three separate subfields. One still goes by the name sociology of work, and the other two are industrial sociology and formal organizations. The sociology of work encompasses three main theoretical movements. The first spanned the years roughly between 1920 and 1950. It was rooted in the Chicago School of sociology and was strongly influenced by symbolic interaction and the pioneering work of Everett Hughes. His and other early approaches had a primarily micro focus and addressed the issues of worker culture and interpersonal relations, especially with regard to workplace problems.

The next two decades saw the field turning its focus from a symbolic interactionist concern for individual issues to a more structural focus where the individual worker was viewed as an actor constrained by various organizational impediments. Critics of this structural approach argued that it lost sight of the worker as a purposeful agent, with structure supplanting self-determination. At the same time, research shifted from primarily qualitative to heavily quantitative, in part to increase generalizability of research findings. As such, multivariate analysis became the norm. On the theoretical side, sociological theories such as structural functionalism, social conflict theory, neo-Marxist theory, and systems theory heavily influenced the research during this time. Arguably, the most significant work of this period is Blau and Duncan's *The American Occupational Structure* (1967), which mapped the factors that contribute to an individual's success, such as personal achievement and family background. By situating individuals within a status ranked occupational structure, Blau and Duncan systematically measured social placement while laying the groundwork for studying social mobility.

The third and most current movement emphasizes a synthesis of work done at the individual and structural levels. Two dominant subspecialties and countless other minor subspecialties are situated in this most recent movement. The first of the dominant subspecialties has its roots in Marx's *Capital* and was ignited by Harry Braverman (1974). Braverman introduced the idea of *labor process* to describe how capitalists have degraded the organization of work, leading to the homogenization of

workers. Though other theorists have criticized Braverman's work, it reinvigorated the Marxist influence on the sociology of work and led to future studies on worker organization and resistance, worker satisfaction, the role of the state, deskilling, and the role of class in the workplace.

The second dominant subspecialty examines various work structures, such as occupational structures, industries, and firms, and incorporates them into individual level models of inequality focusing on such issues as income and segregation. This *new structuralist* approach owes much to Averitt (1968). The new structuralists viewed work structures as segmented; thus, analysis focused on how work structures divide the economy, labor market, and labor force and on the inequalities inherent in these divisions. For example, dual labor market theorists such as Doeringer and Piore (1971) highlighted the existence of two distinct labor markets. The *primary labor market* is where the "good" jobs are: those with high wages, unions, good benefits, international markets, and, most importantly, internal labor markets. *Secondary labor markets* are marked by jobs that offer lower wages, are not unionized, have few if any benefits, and little opportunity for advancement. Current structuralist approaches have moved beyond the simplistic dualist approach in favor of more sophisticated models of segmentation.

Much of the current research in the area of sociology of work involves inequality. Researchers apply various theories to phenomena such as segregation (by job, occupation, firm, and industry), the wage gap, advancement and mobility, and problems stemming from disparate treatment and disparate impact. Ascribed characteristics such as race, ethnicity, age, and others are the keys to understanding inequality in the labor process, though inequality based on sex and gender is the most heavily researched.

Researchers interested in gender inequality largely concentrate on segregation and the wage gap. Occupational segregation has been the subject of a great deal of research as women tend to be crowded into a small number of traditionally female occupations such as nursing, teaching, clerical work, and other fields commonly associated with caregiving, service, or relating with others. Men, on the other hand, tend to be concentrated in engineering, architecture, protective services (e.g., police and fire fighters), skilled

craftwork, construction, mechanical repair, and other fields seen as requiring instrumental action, supervisory skills, physical strength, and analytical abilities. Explanations for occupational segregation vary. Individual explanations point to prevailing gender roles and gender role socialization to explain occupational choices made by men and women. However, a valid counterargument to this claim is that strong social pressures to bear the primary burden of child and household duties, the fear of disparate treatment in the workplace, and actual disparate treatment and disparate impact in the workplace constrain women's choices. Structural explanations examine how various work structures function to keep men and women in different fields. Segmented labor market theorists argue, for example, that statistical discrimination on the part of employers leads to a tendency to view women as less productive and subsequently leads to a funneling of women into "bad" jobs and men into "good" jobs. Even when women enter the firms where the good jobs are located, structural theorists argue that structures such as internal labor markets are often segregated as well.

The bulk of the research done on gender differences at work involves the wage gap. Though the size of the gap varies according to hours worked, career stage, age of worker, and human capital investments, a gap persists nonetheless. Again, the individual level explanations focus on worker choice and the tendency of women to choose lower wage options, often as a result of perceived family and household obligations. Structural explanations look to the gender structuring of occupations, the crowding of women into certain occupations, and the devaluation of skills commonly associated with women. This type of structural explanation has spurred interest in comparable worth (pay equity) policies. Comparable worth policies seek to assign equal rewards to men and women in positions that are comparable on the basis of skills, responsibilities, working conditions, and effort (England 1992). Researchers attribute the recent trends in the reduction of the wage gap between men and women more to the decline in wages for men as a result of changes to the occupational structure and the loss of high paying manufacturing positions than to significant gains made by women.

Occupational segregation and inequalities in labor force outcomes such as wages and

promotion also affect individuals who are members of racial or ethnic subpopulations. Minorities are disproportionately concentrated in peripheral firms, in low wage, low prestige positions, with little opportunity for advancement. Discrimination in the hiring process, educational inequalities, concentration effects, and class differences also factor heavily into the inequalities faced by racial and ethnic subpopulations.

The relationship between work and family is closely related to, and often overlaps, issues of gender and work. A reciprocal relationship exists between family life and work life; as for most families, changes in one lead to changes in the other. The impact of family life on the work experience differs for men and women, especially with regard to labor force outcomes such as income. This became especially apparent as the number of dual earner households surpassed the number of households following a more traditional division of labor. Some researchers have argued that men receive a wage premium for getting married and having children, while women receive a wage penalty, and that women retain the primary responsibility for the bulk of domestic work even when they work full time outside the home. However, factors such as social class, level of acceptance for egalitarian ideals, level of education, timing of marriage and family within one's career, and differences in earnings and occupational status between partners may temper these differences. Researchers also see the family-work connection as relevant to level of productivity, career advancement and aspirations, and individual well being and mental health.

Workers are increasingly feeling the effects of a global economy. Patterns of global communication, global migration, and global trade have led to numerous cross cultural studies of work along with research on the implications of a global economy. Extreme concentrations of power in the hands of a few multinational corporations and the rise of free trade zones where environmental and human rights concerns have been on the rise have led to a resurgence in worker organization and solidarity. Hence, much work in the field has concentrated on worker rights and collectivization.

Sociologists of work regard many of the problems associated with increased globalization as

a result of unevenness in the process of industrialization, which has led to vast wealth and power differences cross nationally. Three theories seek to explain this phenomenon. First, modernization theory purports that societies evolve through predictable stages of development and industrialization according to their own internal dynamics, which include technological advances and patterns of consumption. Second, dependency theory challenges modernization theory, claiming instead that, within the global economy, more developed countries place less developed countries in a position of dependency. Third and most recently, world systems theory also challenges modernization theory by rejecting the notion that nations evolve in a singular predictable pattern. Instead, it views the global economy as a system of interdependent parts where trade relations function to reproduce existing power differences.

The growth of the service economy and the impact of technology on the world of work and the economy have also taken center stage in recent years. One theoretical approach to these shifts in the organization of work is optimistic in that it sees a move toward a service economy as part of a natural economic process. Thus, theorists predict that changes in technology will improve the quality of work and work life for workers. A second and more pessimistic approach sees changes in the economy as heightening the inequality between skilled and unskilled workers, with technology leading to deskilling or even supplanting the worker.

Researchers expect much of the future growth in the field of the sociology of work to be in continued globalization, increased technological advances, and a continuing evolution of the structure of work and the growth in the service economy. As long as inequality in labor market outcomes exists, however, research will continue on gender, race, and the family, as well as other research programs addressing inequality. Future research will also likely continue the current trend of increasing methodological sophistication, as the quantitative methods currently employed in the field have become increasingly complex. Additionally, researchers recently have called for more integration and cooperation with other disciplines and specialties such as economics, economic sociology, industrial psychology, and others.

workplace diversity

Stella Nkomo

Workplace diversity appears to have a rather short history as a field in organization studies if one locates its emergence only within contemporary scholarship (Nkomo & Cox 1996). Issues that commonly fall within the study of workplace diversity have always existed. Yet, early conceptualizations of organizations were rooted in universalistic approaches that largely ignored race, ethnicity, gender, culture, sexuality, and other social identities (e.g., Clegg 1990). Race

and gender in organizations gained some attention after the passage of equal employment legislation in the United States during the 1970s as well as in the UK. This work appeared under the rubric of women in management and in studies of the effects of affirmative action and workplace discrimination (for a review see Cox & Nkomo 1990).

Substantive attention to workplace diversity in organizations is attributed primarily to the publication of *Workforce 2000* (Johnson & Packer 1987). This report forecasted a radical increase in the number of women and racial/ethnic minorities entering the United States workforce. It seems this forecast was largely on target although some changes in the profile of the workforce were unforeseen, including an increase in the number of workers with disabilities and growing religious diversity. Women constitute 48 percent of the United States workforce. By 2020, 32 percent of the US labor force is projected to be ethnic minorities, and four of every ten people entering the workforce from 1998 to 2008 will be members of minority groups. Hispanics are now the largest minority group in the United States, surpassing African Americans.

The authors of *Workforce 2000* urged organizations and decision makers to identify ways to "manage" this growing diversity (Nkomo & Cox 1996). Consequently, the field was initially practitioner driven with scholarly attention lagging. Some would argue this accounts for the frequently lodged criticism that much of the literature on workforce diversity is atheoretical (Nkomo & Cox 1996; Cassell & Biswas 2000). However, in the last ten years, the research on workplace diversity has escalated (Ragins & Gonzalez 2003).

The conceptualization of and research on workforce diversity has largely emanated from North America, primarily the United States. Consequently, much of the extant literature represents a perspective rooted in the social and political history of the United States. More recently, the topic of workplace diversity has gained currency in Europe (e.g., Dick & Cassell 2002; Maxwell et al. 2003; Point & Singh 2003), with its growing immigrant population from Asia, Africa, and the Caribbean, as well as in other regions of the world, including Africa, Australia, and New Zealand (e.g., Jones et al. 2000; Nyambegera 2002; Hartel 2004).

Defining the concept of diversity remains problematic. Some scholars take a narrow approach, focusing on what has been referred to as surface level diversity or visible immutable identities (e.g., race, gender, age, ethnicity). Still others argue for a more expansive definition that encompasses surface as well as deep level diversity (Harrison et al. 1998). The latter refers to personality, attitudes, values, and beliefs. Another classification scheme uses demographic diversity, which is similar to surface level diversity, and job related diversity, which is defined as experiences, skills, and functional work responsibilities. Although the categorizations may differ, there appears to be a trend toward broader definitions of workplace diversity rather than narrow ones. Broader definitions suggest workplace diversity should focus on all the ways individuals differ from one another. Nkomo and Cox (1996: 339) argued that despite the level of disagreement over what constitutes diversity, the concept of identity is at the core of understanding workplace diversity in organizations. They suggest diversity refers to identities based on membership in social and demographic groups, and how differences in identities affect social relations in organizations.

A number of theoretical perspectives have been utilized to study workplace diversity. Most often, scholars have turned to the rich body of theory on intergroup relations. Social identity theory, embedded intergroup theory, and organization demography have been the dominant theoretical perspectives for examining workplace diversity. Generally, these perspectives focus on the effects and consequences of diversity in organizations. Research utilizing social identity theory typically examines the categorization processes that create in group and out group memberships, resulting in one's own group being more highly valued. This body of work suggests that social identification and related processes produce both negative and positive effects in organizations. Some studies have shown that diverse work groups make better decisions than homogeneous groups, while other results suggest diverse work groups evoke greater conflict and less cohesiveness (Ragins & Gonzalez 2003). The solution to managing diversity in the workplace within a social identity framework is a reduction in the salience of group boundaries.

While social identity theory is largely a cognitive theory, scholars examining workplace diversity have also sought to identify specific contextual influences on categorization processes. For example, contextual factors such as intergroup competition, faultlines, and ongoing within group interaction are seen as important predictors of the saliency of group boundaries (Lau & Murnighan 1998). Scholars have also acknowledged the influence of two way or reciprocal identification processes between organizational/work group members as well as the realization that members of any given social group or category vary in the extent to which identity group membership is a central and salient aspect of their overall self concept (Hogg & Terry 2000).

Alderfer and Smith (1982) developed embedded intergroup theory specifically for understanding identity group memberships within an organizational setting. Their theory posits that two types of groups exist within organizations: identity groups and organization groups. Their theory can also be seen as another way of classifying the content of workplace identities in organizations. An identity group is defined as a group whose members share similar biological or demographic characteristics such as sex or race. An organization group is viewed as one in which members share common organization positions or equivalent work experiences. A person's identity in an organization is composed of their group memberships as well as organization group membership. Alderfer and Smith (1982) propose complex interactions among these identities. For example, they argue that conflicts and tensions arise when the two identities are mirror societal positions. For example, often there may be a correlation between identity group membership and organization membership that reflects broader societal patterns. In the United States and in many countries, leadership and management positions tend to be dominated by heterosexual white males. The theory suggests workplace diversity in organizations requires an understanding of identity group membership, organization membership, as well as the broader societal context in which those relations are embedded. Much of the research on race and ethnicity in organizations has relied heavily on embedded intergroup relations theory to

demonstrate how attitudes toward minorities and their structural position in the broader society affect the workplace experiences (e.g., Bell & Nkomo 2001).

Organizational demography focuses on the causes, consequences, or distribution of employees in an organization (Tsui & Gutek 1999). Scholars studying workplace diversity have utilized organizational demography theory to focus primarily on the group identities of age, tenure, education, and functional background. However, Tsui and Gutek (1999: 15) emphasize that diversity and demography are not the same. They argue that demography experts focus on understanding the meaning of demographic diversity and analyzing the effects of such diversity on individuals, groups, and organizations. Their interest is not in prescribing action or change but in explanation. Demographic analysis employs three approaches to uncover the effects of demographic differences: categorical demography, composition demography, and relational demography. Categorical research focuses on the effects of an individual's demographic characteristics on work related behavior and attitudes. Composition demography is concerned with the effects of demographic compositions of work units and organizations on individuals or groups. Relational demography focuses on social relationships between an individual and the group with respect. The interest is in effects of the difference in the individual's demographic attributes and those of the other members in the group. For example, the situation of a lone female manager in a top management team is argued to be different from being a female in a top management team comprised mainly of females (Tsui & Gutek 1999). An important assumption of demography theory is equivalence among all types of diversity. The interest is in the effects of relative heterogeneity and homogeneity rather than the subjective meaning of the demographic identity (Ragins & Gonzalez 2003).

Recently, a more critical analysis of workplace diversity has emerged from critical management and postmodern theories. This work problematizes the very concept of diversity and its assumptions, particularly the discourse of diversity (Dick & Cassell 2002; Zanonni & Janssens 2003). Scholars have analyzed diversity as a rewriting project that overlooks the issue of

inequality of power among groups in the work force (Linnehan & Konrad 1999) as well as viewing it as an effort to obscure the need for attention to issues of discrimination and oppression. Zanonni and Janssens (2003) analyzed the texts on diversity produced in 25 interviews with Flemish human resource (HR) managers from a critical discourse analysis and rhetorical perspective. They found that HR managers' diversity discourses reflect existing managerial practices. Similarly, Kelly and Dobbin (1998) argue equal employment opportunity/affirmative action specialists, primarily in the United States, retheorized anti discrimination and affirmative action practices as diversity management to make them more digestible and to ensure their institutional positions. Other scholars argue that the extant literature promotes an essentialist understanding of people and their identities (De los Reyes 2000). There is also work demonstrating the ways in which workplaces are fundamentally gendered and racialized (Fletcher 2001).

A review of the trajectory of the extant scholarship on workplace diversity reveals a great deal about its nature. Initial research was dominated by the question of how to manage workplace diversity and its effects. Scholars focused on research to uncover the effects of diversity and how organizations should manage diverse work groups. An implicit assumption was that diversity is a problem to be managed. Diversity was also assumed to reside in "others," not within dominant group members. Valuing diversity became the next dominant theme. Efforts were made to change the view of diversity from being a problem to a positive feature in workplaces and to make a business case for workplace diversity. Some scholars have attempted to empirically measure the effects of workplace diversity on the bottom line. Richard (2000) tested the effects of racial diversity on firm performance but did not find direct effects. Instead, racial diversity combined with business strategy to have a positive effect on performance. However, most of the literature advocating the valuing of diversity has been prescriptive. Thomas and Ely (1996) argued for the adoption of an "integration and learning" paradigm for workplace diversity. This approach seeks to incorporate diversity throughout the organization, vertically and horizontally, inclusive of the nature of the

organization's approach to processes, strategy, and work. According to Thomas and Ely under this paradigm, cultural differences among organization members are recognized as sources of skill and insight that can have a direct impact on the organization's core tasks.

The current trajectory suggests a questioning mode. On one hand critical management and postmodern approaches question the very ontology, essence, and aims of workplace diversity (Zanoni & Janssens 2003). At the same time, there is an evident broadening in the level of complexity in the study of workplace diversity within scholarship from a positivist and functional orientation. More attention is being given to the context in which diversity effects may occur as well as recognizing that individuals have multiple identities, not a singular identity. Others question whether enough attention has been paid to the effects of religious diversity, sexual orientation, disability, and class (Ragins & Gonzalez 2003). Despite the volume of research generated over the past ten years, clearly there remain a number of pertinent complex issues and unanswered questions. Not least among them is the persistence of discrimination, racism, sexism, and homophobia as well as continued inequality in the workplace. Ragins and Gonzalez (2003) noted that doing research on workplace diversity requires traversing a slippery slope. Yet, it is clear that there is still much research needed to understand the meaning, effects, and consequences of workplace diversity as well as how best to address the stubborn issues of inequality.

world conflict

Gordon Fellman

Fights of one kind or another show up in archaeological and anthropological studies of early societies as well as later ones. Usually limited to ritualized encounters, these conflicts seem more like sport than anything else; two

groups of men fight, the action ending when someone is hurt.

If war means using weapons deliberately to kill, in order to gain food, booty, land, honor, or other prizes, then war appears to start 12,000–15,000 years ago, probably around the time of the onset of agriculture and the settled communities that accompanied it. Surely the idea of taking food and other things from people who have them would occur to people more than once. Fighting strategies and weapons developed early on, as did the killing of civilians as well as warriors.

Historians can tell us about wars among and within tribes, city states, empires, and nations. What qualifies, though, as a world conflict? Here it is suggested that a world conflict must involve at least three continents and have an outcome with serious effects in much of the world. World War I mainly involved Western Europe and the United States. By contrast, World War II included the Pacific, Asia, Africa, Europe, and North America. It concluded with the end of most of colonialism that had flourished for up to two centuries; the Cold War, which lasted almost half a century; escalation in the deadliness of weapons systems; and the spread of “free market” economics, liberal democracy, and totalitarianism to places that had known little of these ideologies and practices before.

World conflicts can be examined in terms of at least four dimensions: economic, political, religious, and social psychological. It will not do to seek the “cause” of a given war. Nazism, for example, is a consequence of the humiliation of Germany in the Versailles Treaty marking the end of World War I, but it also reflects on the dire straits the Great Depression brought to much of the West, the romance of German nationalism, and the social psychology of the relationship between a charismatic demagogue and almost an entire people.

“World conflicts” do not mean only war in the traditional sense. In the twenty first century, “terrorism” has emerged as a variant on traditional war and a central form of world conflict. “Terrorism” has been applied recently to non state violence directed at civilians and combatants in contests of will, power, and systems. “Terrorism” can also include organized

violence against civilians no matter where it comes from. Hence, nations bombing civilians under any circumstances can qualify as "state terrorists," as distinct from "extra state terrorists" all the way from organized movements to ad hoc suicide bombers.

In the twenty first century, terrorism is the most dramatic and overtly war like form of world conflict. Globalization is another. Whatever its multiple meanings, globalization brings about major conflicts between employers and workers, whether those fired in a developed country to save a company money or those working for low wages in less developed countries.

Another aspect of globalization based world conflict is between forces wishing to preserve the planet in healthy ways and those wishing to disrupt and even destroy delicate resource systems for profit. This includes damage in the ways resources are extracted and the use of fossil fuels in manufacturing and in transporting resources and goods over much of the world. These are all aspects of economy based world conflicts.

Politically based world conflicts are between political systems vying for dominance. The Cold War was partly about western capitalism and the so called communist alternative wanting to eliminate each other, but also between societies with at least a partially democratic underlay and those with totalitarian cores. The Cold War organized and stabilized world conflict from 1945 to 1989, when the Soviet Union disintegrated. The end of the Cold War represents a crisis in the nation state and the secularism that most often has accompanied it in the West. Before the great nation state period began in the eighteenth century, ethnic/national and religious identifications were paramount in much of the world. Part of the accomplishment of the secular nation state as defined, for example, by France and the United States in the eighteenth century was that national identity and politics edged aside ethnic and religious identities.

Major western nations developed somewhat democratic institutions along with capitalist economic systems. These two factors combined with industrialization to produce unprecedented goods, trade, and wealth. And also great disparities between the rich and the poor.

With the end of colonialism and imperialism, which were fundamental to the development of liberal democracy and capitalism, world conflict came to be defined as conflict between nations' policies that favored manufacturers, traders, and bankers and the peoples whose resources, economies, and lives were disrupted, controlled, and even ruined by them. As industrialization grew, so did the exploitation of child and female labor, urban crowding, slums, poverty, disease, violence, prostitution, and family breakdown. Thus world conflict was defined heavily by the differences in interests between elites who ran economic and political systems and the majority of people who did not benefit very much from the elites' policies and actions.

Objections to this state of affairs were articulated most forcefully by Karl Marx, who foresaw the brutalities of capitalism as a necessary precondition for liberation from them in the form of a successor society that would allow comfort and fulfillment for all people rather than primarily elites. Marx warned that Russia would ruin his ideas if it tried to implement them, as it had barely entered capitalist industrialization, the full development of which, according to Marx, was necessary before the true human liberation of socialism and communism could proceed.

It was Lenin who decided that communism could skip the full development of capitalism. Whatever the outrages and failures of the effort he set in motion, it at least maintained itself for hundreds of millions of people as an image of an eventually more humane alternative to capitalism. But between its own internal problems and pressures against it from outside, the Soviet alternative collapsed near the end of the twentieth century. This supposedly left the US as the surviving, triumphant system, but that was not exactly the way much of the world experienced the outcome of the Cold War. Even as the Soviet system ended, the seemingly triumphant American system hit some great snags. Its elites assumed that the US was now free to act as it wished in the world. It could take what it wanted on its own terms and could make wars with impunity.

This condition did not, though, sit well with vast numbers of people in the world and even in the US. The collapse of the Soviet

alternative and the mistrust and loathing of US efforts in much of the world provoked massive repudiation of both systems and widespread reversion to ethnic and religious identifications.

In the new century, world conflicts take forms other than traditional wars. One finds ethnicities (e.g., Hutus and Tutsis in East Africa) and religions (e.g., Catholics and Protestants in Northern Ireland), and combinations of religions and ethnicities (e.g., Sinhalese and Tamils in Sri Lanka, Israelis and Palestinians in the Middle East) pitted against each other. These conflicts blend anger over differences in wealth and control with belief in one's own group's legitimacy and the illegitimacy of its opponent.

The second current form of violent world conflict is terrorist movements against nation states. Some see this form of conflict as based on totalitarian commitments of one party versus democratic political commitments of the other.

The liberal hope of endless economic growth, increasingly fair distribution of goods and services, democratic political institutions, and the privacy of religious commitments and behavior seems to have run up against vast objections and rejections. The totalitarian alternative appeared in major force in Leninism/Stalinism, Nazism, and Maoism in the twentieth century, and appears to be gaining force in Islamism and some forms of Judaism and Christianity in the twenty first century. These movements and their ethnic nationalist counterparts appear to represent, individually and collectively, a rejection of relativism, "progress," electoral democracy, and the separation of religion and state.

The advertised freedoms of the market and democratic systems seem less and less attractive to more and more people. How can we explain this? At least two approaches come to mind. One harks back to a post World War II social science classic, *The Authoritarian Personality* (1950), by Theodor Adorno and three other European refugees. The authors set themselves the task of understanding not so much the rise of Hitler as the willingness of most Germans to support him. Adorno et al. found that the "authoritarian personality" harbors an "intolerance of ambiguity." They saw the contrasting term, "tolerance of ambiguity," as characterizing the "democratic personality," which they obviously preferred.

Certain kinds of leaders can provide a community feeling, a sense of bonding with similar others that appears to be lacking in the modern world of free market economics and pseudo democratic politics ("pseudo" because few if any "democracies" realize very fully the potential of the democratic ideal; money interests, media that seem more intent on keeping the lid on things than informing the electorate, cynical manipulations of emotions and information, and other forces operate to undermine the true potential of democracy). The yearning for strong leadership and absolute, unambiguous declarations about the world suggests a yearning for community which modernism seems to undermine. It also suggests that in some peoples at some times, emotional needs are not congruent with rational needs. For example, the needs for adequate shelter, food, employment, education, and health care do not necessarily define people's approaches to political choices.

The part of the brain that deals with emotions is older and more primitive than the part dealing with reason. Feelings are, of course, far stronger and more dominating for the first several years of life than is reason, and it is completely likely that the salience of feelings is never really abandoned. Rather, it becomes disguised and channeled into institutional behavior.

Young children rely on the authority and approval of parents they often experience as perfectly strong, caring, loving, and wise. Around age 6 or 7, the awareness dawns that parents are not perfect at all. This is a crucial moment, for societies intuitively understand that disillusionment with the imperfect parent does not lead the child to discard the wish for the parent previously idealized. Society offers metaphors, usually religious and national, for those ideal parents lost. The "perfect parent" is a cult figure or God or Nazism or Communism or Islamism, or fundamentalist Christian, Jewish, Hindu, or other clergy or secular national leaders.

At the heart of this are two compelling questions that absolute authority answers for the willing follower. One is, what am I to do with my love, which is so insistent and strong that it impels me way beyond the family in which I first learned its pleasures and centrality? The second question is, what am I to do with my anger, which is so insistent and strong that it

impels me way beyond the family in which I first learned it in its numerous manifestations?

Absolute leaders instruct their followers to love certain people and hate the rest. Such leaders take upon themselves the judgmental capacity and conscience of the followers. They say in effect, you do not need to bother yourself making judgments about good and bad, right and wrong, life and death. I will relieve you of those complex, painful decisions and reduce it all to easy contrasts and slogans. This will simplify your life while giving me the absolute power that every child dreams of but gives up fairly early on. I will speak to that child in you that wished to be omnipotent and also that child in you that wished for the perfect and all knowing parent. You will love the people I tell you to love and hate and even kill those I tell you to oppose.

And here we get to the least studied crucial issue in human behavior in our time: anger (which includes such manifestations as rage, wrath, hatred, loathing, fury, vilification, and much more). Like all emotions, anger originates in the self's predisposition to feel that emotion and in real experiences that draw it out. Children commonly are so consumed with anger that it frightens them as well as the adults who witness and feel it.

With loving, accepting care on the part of adults, children's anger can be accepted, understood, and contained. More commonly, though, the anger is not fully accepted, not completely understood, and not adequately contained. The child who has this experience, and most people have had it, is left with a field of metal rods representing numerous experiences of unfulfilled anger. Culture offers what amount to magnets that fly over those fields of anger rods and pull them swiftly to the magnet. In a racist society, culture says, take that free floating anger and use it against people whose skin color is different from yours. Or gender. Or nationality. Or religion. Or sexual orientation. Or anything else that offers an opportunity to attach anger to something and let it out there, even though it does not actually originate or belong there.

What conflict does on the world scale is to galvanize endless and countless rods of anger to the magnets of racism, nationalism, religious

superiority, and so forth, "opposition structures" that capture that free floating hatred and use it to accomplish domination, vilification, exploitation, and war. Certain leaders with excessive tendencies in this direction engage their own anger to organize and perpetuate opposition structures and encourage followers, who have their own reservoirs of anger, to join them in the enterprise.

When this anger is organized into structures that exploit economically and humiliate politically, we find the major alternative, in explaining terrorism, to the anti modernist one. This interpretation identifies terrorism as a form of war made by the weak against the strong, in retaliation for economic exploitations and political humiliations. Note that the anti modernist interpretation assumes war to the finish as the only solution. This other interpretation offers an entirely different view and hope.

Conflict at its base draws on anger in two forms: proactive and reactive. Those who ruin other cultures, tear out their resources, force their populations into cities and degradation, and put profit above the well being of humans, communities, and the environment are people who, in addition to making money, proactively find outlets for their anger. They do not act from malice or sadistic design so much as unacknowledged inner pressures they cannot identify and which they fear to face. "Acting out" those inner pressures is far easier and more familiar than facing them and working to overcome them.

The "structural violence" of domination, exploitation, and humiliation – all operating normatively through economic and political institutions, among others – often draws on physical violence in order to coerce the victims of political and economic strategies of domination to submit to the more powerful party. Familiar with violence as the objects of it, the victims turn to violence in reaction to it. Reactive anger – likely that of the bulk of terrorists in the world at this time – is a response to the proactive anger of someone else.

But there is an option, slowly working its way into the public consciousness of our species, which is non violent conflict resolution. This is ethically the most recent and most humane alternative to violence in world conflicts. In the recent period, its exponents and practitioners

trace a line from Thoreau through Gandhi, Martin Luther King, Jr., the Dalai Lama, Thich Nhat Hanh, and Aung Sang Suu Kii, among others.

If those who lead peoples into violent conflict draw on their followers' reservoirs of hatred – call them “war leaders” – the major and recent alternative leaders – “peace leaders” – draw on their followers' unfulfilled yearnings for peace, community, kindness, and love. These are as natural and fundamental human needs and desires as those for vengeance, hatred, and killing. But they speak to less raw, unsocialized parts of our selves, which it appears are harder to provoke and manipulate than the others. It is more difficult to bond with people than to separate from and oppose them. Those who would end violent conflict in the world need to recognize and take into account this deep, painful, but potentially liberating reality.

The ending of violent conflicts depends also on extending awareness of the true history of peace. In 1905, popular movements in Norway and Sweden forced two governments to withdraw troops massed at their shared border and ready for war. After the breakup of the Soviet Union, almost all its components moved to other forms of government and economy without violence. At the turn of the twenty-first century, long time conflicts in Northern Ireland and Sri Lanka were on the verge, at last, of non-violent resolution. Numerous projects bring Israelis and Palestinians together in non-violent encounters that point toward peace.

There appears to be a dialectical process between old war customs and new peace visions and practices. Peace visions in this era must include the needs of all people on the planet for environmental health and safety, vibrant and viable communities and societies, and productive, fulfilling lives in relationship with others and the planet.

Organizations and movements that promote peace number in the thousands or tens of thousands throughout the world. They are less developed, disseminated, and experienced than organizations and movements promoting and practicing war, but they are clearly in motion. If they gain the momentum they need to banish

war to the history books, we will still face a slew of grave conflicts that will require inventiveness, patience, and determination to solve satisfactorily. There is no greater challenge to those concerned about the nature and fate of world conflict.

writing as method

Elizabeth Adams St.Pierre

Writing as a method of inquiry refers to a research practice of foregrounding and investigating how researchers construct knowledge about people, themselves, and the world by writing. This concept, introduced by Laurel Richardson (2000 [1994]) and developed by Elizabeth St. Pierre (Richardson & St. Pierre 2005) and others, brings the idea that writing is thinking from the humanities to the social sciences.

Writers have always used writing to help them think about their lives and their work, but that function of writing has seldom been taken advantage of in that area of social science research that mimics research in the natural sciences by assuming that language can describe reality. However, after the linguistic turn, the crisis of legitimation, and the crisis of representation, many social science researchers no longer assume that language is transparent and can simply mirror or represent reality; rather, they understand that language helps to create reality. Writing is therefore not an objectifying practice or a mopping up activity at the end of a research project but a creative practice used throughout to make sense of lives and culture, to theorize, and to produce knowledge.

Since the Enlightenment, writing has been divided into two kinds: literary and scientific. Literature has traditionally been associated with personal expression, rhetoric, physicality, emotions, and subjectivity. Science writing is associated with facts, the truth, reality, rationality, and objectivity. Literature is soft and suspect; science writing is hard and true. Enlightenment thinkers such as René Descartes and Francis Bacon set up binary oppositions – mind/body, objective/subjective, fact/fiction – in which the first term is privileged and scientific. The scientific method assumes that the rational mind can divorce itself from its irrational body and produce true knowledge employing criteria of exactitude, rigor, and systematicity. In this scenario, mathematics is the perfect language, supposedly pure and uncontaminated by the inexactitude, imprecision, and precariousness of everyday life. Science is thus above life, and

science writing should reflect the same detachment, rationality, and control.

Of course, such a neat division of writing, and the world (scientific and non scientific), was never entirely successful, and events of the twentieth century, in particular, brought into question the idea that the knowledge produced by science could cure the problems of human kind. Indeed, the sometimes disastrous effects of an objective, rational science brought the entire enterprise into question after the atrocities of World Wars I and II, Algeria, and Vietnam. The social movements of the 1960s and 1970s demanded that science – both social and natural science – be taken to task for its complicity in perpetuating poverty, racism, sexism, homophobia, ageism, and so forth. Texts encouraging a mind–body connection resisted Descartes's 300 year old theory and doubted that the mind and body had ever been separate. Scholars began to move out of their own fields, blurring disciplinary boundaries, as they sought different methods to use to produce different knowledge that might allow different possibilities for living. The “soft” social sciences began to claim the status of the natural sciences, no longer content to be called underdeveloped natural sciences or pre scientific. Physicists began writing for popular audiences, and social science writers began using the genres of the humanities.

Social scientists have always represented their work in words and written texts; however, after the blurring of the genres, forms of representation such as drama and film were increasingly used to report scientific knowledge. Form constrains content, and different genres of writing encourage different thinking and produce different knowledge. No particular genre of writing is superior to another; each has possibilities and limits. Though a conventional scientific research report modeled after that of the natural sciences has been privileged for some time in the social sciences, science does not require a particular genre. A poem can convey as much meaning (and a different meaning) as an academic essay. In fact, to learn as much as they can about their topic, researchers might write up data from a single project using a variety of forms – personal narrative, expository essay, autobiography, fiction, and poetry – in order to engage those data in more and more complex ways, thereby complicating the making of

meaning and illustrating the very partial and fragile nature of the work we call science.

Researchers who have special talents have indeed experimented with alternative forms of representation, including poetry, drama, auto ethnography, fiction, performance texts, poly vocal texts, hypertext, readers' theater, comedy and satire, visual presentations, mixed genres, and even painting and dance. Social scientists concerned with disseminating their work widely often write very different texts about the same project for different audiences.

The tenuous relation between language and meaning that emerges from postmodern theories of the last half of the twentieth century is central to the idea that writing is a method of inquiry. In *Of Grammatology* (1967), Jacques Derrida explained that language cannot contain and fix meaning. He theorized the concepts *différance* and *writing under erasure* to explain that meaning escapes language and so is always deferred. "Word and thing or thought never in fact become one" (Spivak 1974: lvii). When we write under erasure, we let go of meaning at the moment we introduce it. As a result, meaning cannot be a portable property that words can carry from one person to another, and language cannot "represent" the world.

Postmodern discourses differ from the interpretive discourses used in conventional social science inquiry that assume there is a deep, hidden, prelinguistic meaning that can be found and brought to discourse. If there is no mimetic link between a deep (or transcendental) Truth and a particular instantiation, then the copy theory of truth upon which some theories of representation are structured cannot hold. Post modernism, after the linguistic turn, suggests that interpretation is not the discovery of meaning but the introduction of meaning. Because of this, writers can never control readers' interpretations since there is always an excess of meaning as people bring their own lived experiences to the texts they read. Writing, then, is not a neutral activity of expression that simply matches word to world. It becomes a task of responsibility as researchers create people, practices, and cultures in the texts they write.

Researchers also collect data in the texts they write, so writing can be a *method of data collection*. Researchers write throughout the research process as they document their day to day

activities, their impressions of events, their formal interviews and informal conversations with participants, and their formal and informal observations. Some of these data are conventional – data from formal interviews and observations, for example, that are textualized in interview transcripts and fieldnotes. These are official data that are described in social science textbooks.

Other data are transgressive (St.Pierre 1997) and may include memories of the past and the future, dreams, sensualities, emotions, the words of other scholars, the novel just read, a neighbor's comment. These data are found in every study, though their presence and importance are seldom acknowledged. Writers can not simply erase these transgressive data from their minds and bodies as they think and write about the more conventional data in their interview transcripts and fieldnotes. They bring the richness of their lives to their research. Thus, different researchers studying the same topic think with different conventional and transgressive data and necessarily produce different knowledge. There is no separation between the knower and the known in the work, and the unique positioning of the researcher is valued. *Bias* is not thinkable in this structure, but that does not mean that one does not discriminate among representations, that "anything goes." It means that readers develop more complex ideas of what good research is. Validity is not dismissed but constantly reworked as appropriate.

Since writing is thinking it can also be a *method of data analysis*. Writing allows us to think things we might not have thought by thinking alone. Writing takes us places we might not have gone if we had not written. We must think in order to write the next word, the next sentence, the next theory. An idea simply thought may seem brilliant until it is written. A brilliant unthought idea may appear as we write. Writing forces us to textualize the rigorous confusion of our thinking, and that work is analysis. This analysis is much more complicated than what is usually called data analysis – positivist practices of coding data, sorting it into categories that are grouped into themes that become section headings in an outline that organizes writing in advance of writing. Those practices ignore the work of writing as thinking, as analysis. They assume that writing only

documents what is already known. Using writing as a method of inquiry, however – as a method of data collection and data analysis – acknowledges and builds into the research process the generative work of writing.

The linguistic turn that recognized that meaning (the Truth) about people and culture could not be captured and closed off in language led to the crises of representation and legitimation that recognized that meaning (truth) is always partial, situated, contingent, inaccurate, and, thus, dangerous to some extent. The resulting burden of authorship led to the ethical turn that recognized that researchers' texts do not capture truth but produce it. Leery of writing texts that might misrepresent or even harm participants, social science researchers began to ask different questions about their work. Instead of asking "What does [marriage, race, subjectivity] mean?" they posed questions such as those Paul Bové (1990: 54) asked about discourse: "How does discourse function? Where is it to be found? How does it get produced and regulated? What are its social effects? How does it exist?"

From these questions comes a different question about writing: "What else might writing do except mean?" Some researchers, particularly postmodern researchers, have begun to question whether the goal of social science research should even be representation (the goal of interpretivism), and they are increasingly hesitant to get to the bottom of meaning, to gratify the interpretive entitlement of readers to *know* their participants. They are no longer willing to write comfort texts with rich, thick descriptions that provide easy access to and lay bare people's lives, whether exotic or ordinary. Their writing does not encourage an uncomplicated and sentimental identification that erases the difference of the Other. Rather, they shift the focus from their participants to the topic of their research – marriage, race, subjectivity – using conventional and transgressive data to theorize without deliv-
 ering anyone or any place in authentic, more adequate, persuasive representations. People and lives are no longer the epistemological end of

the study – objects that can be known – but provocateurs – lines of flight that lead else where. This elsewhere is the promise of writing as a method of inquiry, of discovery, of coming and going, of movement past what is known.

This kind of post representational work can be accomplished in any genre, but it requires that we understand writing differently. Writing becomes a field of play in which we are always unprepared to make meaning, and whatever meaning we make will always come too late to rescue us. Nevertheless, we write because we know that, in writing, anything can happen – and will. Like other writers, we may produce knowledge that will change the world.

xenophobia

Paul R. Jones

Derived from the Greek words *xeno*, meaning “foreigner,” “stranger,” or “guest,” and *phobia*, meaning fear, xenophobia literally refers to a phobic attitude toward foreigners. However, “phobia” in this context is not meant in the clinical sense but rather refers to a part of the network of racist ideologies predicated on discriminatory discourse and practice. Xenophobia is thus a term that describes fear or prejudice with respect to something or someone perceived as “foreign” or “other.” As such, xenophobia is an exclusionary logic whose focus is primarily cultural, being directed toward those artifacts or cultural expressions considered somehow “different.” As with all discriminatory ideologies, xenophobia constructs a hierarchical order of people and cultures.

As xenophobia both maintains and constructs such social and cultural boundaries, it can entail a deliberate or unconscious misrecognition of other cultures. Indeed, the designation of certain attributes to other cultures expresses power in itself, as meanings can be imposed on one group by a more dominant group. Given this broad definition, xenophobia could be generalized to a wide range of social situations, but primarily it operates as an ideological basis for nationalism (when such discourses devalue and stigmatize the cultures of other nations) and for related anti immigrant discourses. Accordingly, xenophobia underpins much of the ideology of right wing political parties that emphasize cultural difference and perpetrate the myth of cultural incompatibility. By framing their arguments in terms of real or imagined cultural

differences, radical right populist parties have increasingly used xenophobic discourse to “legitimate” their racist policies.

Some commentators have suggested the existence of “xeno racism,” a confluence between xenophobia and racism, which is not only directed at black and minority ethnic groups and individuals but also is a “xenophobia that bears all the marks of the old racism, except that it is not colour coded” (Sivanandan 2001: 2). The displacement of poor white populations forced to seek asylum has shifted the focus of right wing political parties toward these dispossessed communities; the concept of “xeno racism” is useful for analyzing the growing racism in popular media and political discourses directed toward white people seeking asylum. Xenophobia is an important concept for sociologists and political theorists researching how such categorizations of the “other” are constructed and subsequently stigmatized or devalued.

Y

Yanagita, Kunio (1875–1962)

Takami Kuwayama

Kunio Yanagita is widely regarded as the founder of Japanese folklore studies or folkloristics. His influence transcended disciplinary boundaries and was felt in many other fields, including sociology and anthropology. Even today, he continues to be discussed, both inside and outside academic circles. Although little known outside East Asia, Yanagita is indisputably one of the intellectual giants of the modern world.

PERSONAL HISTORY

Yanagita was the sixth son of a poor family in the village of Tsujikawa, Shintō Province, known today as Kanzaki, Hyōgo Prefecture. His father made a living by teaching Chinese classics as a private tutor. Until he was adopted by the Yanagita family at the age of 27, he carried his father's surname, Matsuoka. In 1887, when Kunio was 13 years old, he moved to Ibaraki Prefecture, located northeast of Tokyo, where his brother practiced medicine. Three years later, in 1890, Kunio moved to central Tokyo to receive higher education, but his major interest at that time was literature. He thus joined a literary circle to study poems and became acquainted with some young talented men of letters. Yanagita maintained throughout his young adulthood a keen interest in literature, but eventually studied agricultural policy at the School of Law, Tokyo Imperial University. In 1900, soon after graduation, he found his first job as a bureaucrat in the Department of Agriculture and Commerce.

Having been adopted by a prestigious family in the next year, Kunio Yanagita assumed some important governmental posts, which culminated in 1914 in the appointment as chief secretary in the House of Peers. During office, Yanagita wrote articles about Japanese agriculture, in which he emphasized the need to implement structural reform, but his proposals were turned down. Discouraged, he gradually developed an interest in Japan's folk customs, and visited remote places in the countryside. His field trips resulted in the production of some pioneering books on Japanese folklore. It was about this time that he read James Frazer's *Golden Bough*.

In 1919, at the age of 45, Yanagita put an end to his career as a bureaucrat and started writing for *Asahi Shinbun*, Japan's leading newspaper. Soon afterwards, he was dispatched to Europe as Japan's delegate to the League of Nations. He took advantage of this opportunity to attend lectures at Geneva University. Yanagita was an avid reader of books published in Europe, being well versed in the latest scholarship there. In the early 1930s he resigned from all his public posts to devote himself to the study of folklore. Despite his reputation, he only occasionally taught at universities because he was convinced that folkloristics would only flourish when researchers lived side by side with *jomin* (ordinary people). He thus kept his distance from professional scholars, organizing instead nationwide networks of independent researchers. Many of his lectures on folklore were given for these researchers at his house in Tokyo. Besides his specialty, Yanagita distinguished himself as a public intellectual who addressed a variety of social issues. In 1951 he was awarded the Order of Cultural Merit, the highest honor to be bestowed on Japanese academics. After his death in 1962, his numerous books and articles were compiled in the form of *zenshu* (complete works), the latest version of which began to be

published in 1997. This version, when completed, will comprise a total of 38 volumes, each containing no fewer than 600 printed pages.

JAPANESE FOLKLORISTICS

To appreciate Yanagita's scholarship, some major characteristics of Japanese folkloristics should be mentioned first. In Japan, folkloristics and ethnology, now better known as social or cultural anthropology, have developed as twin disciplines since the late nineteenth century. This contrasts with Great Britain and the US, where the two fields have separate histories, except at the beginning. The Japanese situation is related to the relatively late modernization of the country. In Japan's countryside, researchers from the cities discovered many old manners and customs comparable to those found by western ethnologists in "primitive" society. Japanese intellectuals found a foreign culture within their own country. This discovery led Japanese folklorists to study a wider range of topics than their counterparts in the English speaking countries. Generally, in Great Britain and the US, the scope of research tends to focus on folktales, ballads, legends, and so forth, whereas in Japan topics like social structure and ideology are also explored. Thus, Japanese folkloristics may best be understood as the anthropological study of Japan by the Japanese. It is a typical example of what Takami Kuwayama (2004) called native anthropology.

THEORY AND METHODOLOGY

Folkloristics as a Historical Science

Yanagita regarded his discipline as a historical science. He criticized orthodox historiography of his time for two major reasons. First, it was concerned almost exclusively with the lives of great individuals and dramatic events. It revealed very little of commoners' history. Second, orthodox historiography reconstructed the past by using only written documents as data. As long as this methodology was followed, Yanagita thought, it was impossible to explore the folk traditions that had been passed on for generations without being recorded. He thus

proposed to gather data by doing fieldwork. More specifically, he devised ethnographic methods in which researchers interviewed people about their customs, both past and present. The rationale was that, because Japan modernized relatively late, old customs were still practiced in everyday life, so that thinking about the past was tantamount to thinking about the present. For Yanagita, history referred to the past within the present. Yanagita maintained that language contained the history of ideas and things, and he thus paid particular attention to the analysis of the words and phrases actually used during the interviews. There is, therefore, much etymological discussion in his writings. In today's terminology, Yanagita tried to write the social history of the Japanese people at large. One major difference, though, between Yanagita and today's social historians is that Yanagita aimed at discovering the general *pattern* of history. Put another way, he was interested in discovering the possible "laws" governing the changes that had occurred in ordinary people's lives. The history he wrote is often called *ikkai sei no nai rekishi* (history without unique events).

Folklore Research by Natives for Natives

Yanagita explained the fundamentals of his methodology in *Minkan Denshoron* (On Popular Tradition) and *Kyodo Seikatsu no Kenkyūho* (Methods in the Study of Local Community Life), published in 1934 and 1935, respectively. He classified the objects of folklore research into three categories: (1) material culture; (2) verbal art; and (3) mentalities. The first is a translation of *yukei bunka* (literally, culture that has a form), which includes the following: habitat; clothing; food; transportation; labor; villages; family and kinship; funerals; annual events; religious festivals; and children's games and toys. According to Yanagita, these merely scratch the surface of a folk culture, and even travelers can study them. The second category, *genjo geijutsu* (literally, language and art), comprises the following: new words; new expressions; proverbs; riddles; prayers; children's language; songs and ballads; and narratives, folktales, and legends. This category is concerned with audible phenomena, which are more complex than the first because understanding them requires language

competence, but they are still not particularly deep. The third category is a translation of *shin'igensho* (literally, psychosemantic phenomena), which roughly corresponds to mentalities in the sense of the term used by the Annales School of French history. It consists of knowledge, life skills, and purposes of life. Yanagita was convinced that only compatriots or natives could fully understand the mentalities of their people. Thus, he excluded foreigners from the study of mentalities. For Yanagita, folkloristics was *jisei no gaku* (science for self reflection).

Yanagita's model of research is similar to that of Bronislaw Malinowski's. In *Argonauts of the Western Pacific* (1922), Malinowski classified ethnographic research into three parts in ascending order of complexity: (1) the organization of the tribe and the anatomy of its culture; (2) daily life and ordinary behavior; and (3) the native mind. There is, however, a definitive difference between the two scholars. As noted above, Yanagita considered it practically impossible for non natives to understand the native mind, whereas Malinowski had no doubt concerning their ability to grasp it. If anything, Malinowski argued that natives were so absorbed in the details of everyday life that they could not observe themselves objectively. He further contended that the natives lacked the intellectual capacity to study their own culture, so that it must be studied and represented by professionally trained outsiders – western anthropologists.

There are both merits and demerits in these contrasting views. Yanagita's position, on the one hand, regards natives in the non western world as active agents of research into their culture. They are considered knowledge producers in their own right, rather than passive objects of research. In the age of colonialism, when the natives were denigrated as "primitive" and "uncivilized," Yanagita's view was innovative. On the other hand, it underestimates the ability of trained outsiders to investigate foreign cultures. It even generates a blinkered nationalism that excludes foreigners from the study of one's own country. By contrast, Malinowski's position encourages cultural research by qualified outsiders, but, in the name of science, it tends to elevate their status to the final judges on the cultures they are studying – a point criticized by many native intellectuals engaged in indigenous rights movements today.

Concentric Area Theory

One of the best known theories presented by Yanagita is called *shukenron*, which, for lack of suitable translations, is rendered here as concentric area theory. Proposed in his 1930 book *Kagyuko* (On Snails), this theory first divides Japan into many blocks, which are then arranged to form concentric circles, with Kyoto, Japan's ancient capital, at the center. Based on the premise that new ideas and things develop at the center/urban, concentric area theory holds that new forms of culture will gradually spread toward the periphery/rural, replacing the old with the new in the process of diffusion. Thus, according to Yanagita, customs more commonly practiced on the periphery at the time of investigation are older than those practiced at the center.

This theory grew out of Yanagita's research on dialects. The example he used was that of the snail, for which many different terms exist in Japan. Having collected hundreds of local terms, Yanagita drew a lexical map and demonstrated that, as they moved away from the capital city, snails were called, in descending order of proximity to the center, *dedemushi*, *maimai*, *katatsumuri*, *tsuburi*, and *namekuji*. (These terms were prototypes from which similar local terms had been derived.) Particularly interesting was the case of *namekuji*, which Yanagita considered the oldest term for the snail. In standard Japanese, *namekuji* means slug, but Yanagita discovered that, in many remote areas, slugs were lexically indistinguishable from snails. Significantly, these areas were usually located both at the southwestern and the northeastern frontiers of the country. This discovery was later named the correspondence of outlying areas, which Yanagita interpreted as indicating that the center's influence had not yet penetrated through the peripheral areas. The implication was that the periphery was not yet "civilized," and that it would eventually be assimilated into the center as civilization spread. In this way, Yanagita turned spatial differences (i.e., different terminologies used in different parts of Japan) into temporal differences (i.e., different stages of civilization or "progress" in which these areas were supposedly placed). Yanagita also maintained that his language analysis could also be applied to cultural analysis in general.

In western scholarship, this conversion of space into time, technically known as comparative method, is a distinctive feature of the nineteenth century social evolutionism represented by, among the most notable, Edward Tylor and Lewis Morgan.

A major problem of concentric area theory is the assumption that Japan constitutes a single national community. Without this assumption, it would have been impossible for Yanagita to contend that new customs had first developed at the center/urban and then spread gradually toward the periphery/rural. Concentric area theory would only apply on the assumption that Japan is a homogeneous nation, with a powerful centralized government situated at the geographical core. At least, it does not fully consider the possibility of external influences, such as prolonged contact with other people, which could have prevented the unchecked flow of culture. In today's critical theory, which emphasizes the multiplicity of cultural experience, Yanagita's theses have been much criticized for having overlooked Japan's internal diversity. It should be noted, however, that, in the early stage of his career, Yanagita enthusiastically studied minority groups, such as hunters and wood turners in the mountains. He in fact hypothesized that these people were genealogically separate from Japan's majority group, rice cultivating peasants on flat land. This hypothesis, however, was later discarded by Yanagita himself and fell into oblivion as his interest shifted to the study of Japan's national culture.

Another problem of concentric area theory is the neglect of Hokkaido, located at the northern end of the Japanese archipelago. Indeed, Yanagita left out Hokkaido from the lexical map of the snail mentioned above without giving any reason. Throughout his career, Yanagita paid only scant attention to Hokkaido, probably because it was (and still is) strongly associated with Ainu people. By contrast, Yanagita had been fascinated with Okinawa, Japan's southernmost island, since he was young. He even regarded it as the archetype of Japan. In his last book, *Kaijo no Michi* (Ocean Routes) (1961), he asserted that the ancestors of the Japanese people had first migrated from southern China to Okinawa, sailing on the Japan Current, in order to seek out porcelain shells, and then moved further north to mainland Japan, where they

had eventually settled as rice cultivators. This theory has only partially been supported by later archeological research, but illuminates how Yanagita assumed contrasting attitudes toward Okinawa and Hokkaido.

PROSPECTS FOR FUTURE RESEARCH

Despite such problems, there is no doubt that Yanagita was an intellectual giant whose influence continues to be felt today. Among his legacies that have yet to be fully explored, the idea of *sekai minzokugaku* or global folkloristics deserves special attention. Presented in *Minkan Denshoron* (1935), this idea has long been neglected for complex reasons. Recently, however, a new interpretation has been proposed (Kuwayama 2004), which holds that Yanagita originally conceived of global folkloristics as an international forum for dialogue, in which researchers from around the world could exchange ideas without privileging one or a few leading countries. In this new interpretation, global folkloristics is understood as an assemblage of different "national folkloristics" practiced in different parts of the world: it reflects Yanagita's strong desire to make folkloristics a global discipline without sacrificing each country's scholarly tradition. If the ideal of global folkloristics is realized, it will promote the study of one's own culture by natives, who have long been treated as no more than "research assistants" for the "real" researchers from the West.

youth/adolescence

Sue Heath

Youth and adolescence are terms which are often used interchangeably to refer to a phase of the life course between childhood and adulthood, yet are often positioned as contrasting approaches within academic discourse. Sociologists use the term youth to refer to a socially constructed life phase which is not only culturally specific, but which is also the product of particular historical conjunctures. Within this approach, youth is broadly construed as a collective experience which is shaped by social structures, age specific institutions, and societal expectations. In contrast, the term adolescence emphasizes processes of individual social and/or physiological and psychological development and as such is much more closely associated with the disciplines of developmental psychology and clinical medicine. Within this approach the phase between childhood and adulthood is often equated with puberty, and is represented as a time marked by experimentation and emotional storm and stress. Classic theorists of adolescence include G. Stanley Hall (1844–1924) and Erik H. Erikson (1902–94).

CONCEPTUALIZING YOUTH

There are a number of different approaches to the sociological conceptualization of youth. An approach which has been particularly influential in recent years defines youth as a period of *transition*, emphasizing young people's movement through key transitional stages towards the

attainment of adulthood. Writing from a Northern European perspective in his book *Youth and Social Policy* (1995), Coles, for example, focuses on three key transitions: the transition from school to work, from the family of origin to a family of destination, and from the parental house to a house of one's own. The assumption of linear progression that underpins this model has attracted criticism in recent years. It is further argued that the model is rendered obsolete by the increasingly widespread deferral of some of the traditional markers of adulthood and the increased visibility of alternative life styles which challenge the assumed desirability of attainment in these areas.

An alternative approach focuses on youth as a *relational* concept, which derives its existence and its meaning from its relationship to the concept of adulthood. This approach foregrounds and critiques the relative powerlessness of young people in relation to the world of adults, regardless of how adulthood may be defined over time and across different cultures. Wyn and White (1997), for example, argue that "if youth is the state of 'becoming,' adulthood is the 'arrival.' At the same time, youth is also 'not adult,' a deficit of the adult state" (p. 11). The concepts of both youth and adolescence thus can be employed to legitimate the differential treatment of younger people, and to justify adult intervention in their lives. As Griffin (1993) argues, this tends to result in the portrayal of young people in one of two ways: as either *victims* of social problems or as *perpetrators* of those same problems. Both portrayals serve to marginalize them in relation to adults.

A third approach focuses more on the political economy of youth, regarding youth as a period defined by the various *age related legal strictures* – including social policies – that regulate young people's lives. Phil Mizen (2004) has argued, for example, that "the simple fact of possessing a certain biological age brings with it differential access to social power, while age also provides the means through which young people are brought into a more or less common relationship with many of the central institutions of modern life" (p. 9). This approach, then, is closely related to the notion of youth as a relational concept. However, it places particular emphasis on the political underpinnings of the concept, and foregrounds the significance

of age as a means by which full citizenship is denied.

Youth is a culturally specific concept. Access to age related citizenship rights, for example, or social norms regarding key transitional stages, varies hugely across different societies and across different cultures and regions within specific societies (Brown et al. 2002). The prevalence of young people among the global population of street people, sweated laborers, sex workers, and militia powerfully underlines this point. Conceptualizations of youth are also historically specific. For example, it is often argued that the emergence of youth as a category which is separate and distinct from adulthood and childhood has tended to occur in parallel with processes of industrialization, in order to serve the needs of emergent capitalism.

DISTINCT TRADITIONS WITHIN THE SOCIOLOGY OF YOUTH

Earlier conceptualizations of youth within Europe and North America were strongly influenced by the *functionalist* theories of writers such as Talcott Parsons and, slightly later, Shmuel N. Eisenstadt. Within functionalist accounts, the period of youth serves as a means of facilitating the smooth transition from the particularistic values of the family of origin to the normative values of broader society. Youth culture plays a key role in facilitating this movement, although the exact nature of a young person's cultural affiliation is rendered theoretically irrelevant by the primary role of youth culture in ensuring the maintenance of social order. In contrast, the writings of Karl Mannheim on *youth and generation* point to the historically significant role of younger generations. Mannheim defined generation in terms of groups of individuals who, by belonging to the same birth cohort, share a common "generation location" in relation to key social and historical circumstances, and it is this common location that shapes their attitudes and actions as a distinct generation. While nonetheless arguing that some generations are noted more for their contribution to the status quo, Mannheim recognized the agency of young people by arguing that certain generations are very much in the vanguard of social change, whether for good or ill.

The *cultural studies tradition* within youth research originated in the work of the Chicago School in the first half of the twentieth century. Classic ethnographies such as Thrasher's *The Gang* (1927) and Foote Whyte's *Street Corner Society* (1943) highlighted the impact of urbanization in producing the stigmatized category of deviant youth. In the period following World War II, a more overtly political perspective on youth culture emerged. The Centre for Contemporary Cultural Studies (CCCS) at the University of Birmingham defined the field in terms of a class based critique of young people's roles as consumers and producers of mass and ghetto cultures. The classic CCCS collection *Resistance Through Rituals* (1976) contended that youth subcultures represented an attempt by working class young people both to give meaning to, and to solve, the "working class problematic," namely, their marginalization from hegemonic middle class society. Through studying a variety of colorful youth subcultures, it was concluded that such allegiances nonetheless represented "imaginary solutions" to this problematic and served to reinforce the alienation of working class youth.

Over time, the original CCCS position has attracted considerable criticism, including accusations of over interpreting the significance of "style" and of over emphasizing the place of leisure in young people's lives. The relative invisibility of young women in their accounts also generated a strong feminist critique. More recent work within the cultural studies tradition has attempted to address these criticisms, and has also moved beyond the earlier focus on social class. In the UK, key writers in the field use the language of "post subculture," "scenes," and "tribes" to argue that class is no longer of relevance to an understanding of contemporary manifestations of youth culture (Bennett & Kahn Harris 2004), although this is a contested position. Similarly, in the US there is greater focus on the diversity of youth cultures and a concern to explore the formation of cultural identity, particularly in relation to ethnic identity and hybrid youth cultures (Lee & Zhou 2004).

The *youth transitions tradition* has emerged as another influential strand within the sociology of youth over the last two decades, particularly in Northern Europe and Australasia. Transitions researchers have pointed to the disruption of

relatively safe and predictable transitional routes and their replacement by *fractured* and *extended transitions* to adulthood, especially in the economic sphere. The transitions tradition is also distinctive for its focus on the impact of social class, gender, and ethnicity on young people's life chances and, more recently, its engagement with debates concerning social exclusion, social capital, and the putative youth underclass. The approach has, however, been criticized for overemphasizing the impact of social structure and for adopting an over deterministic approach to understanding young people's lives.

More recently, Ulrich Beck's *individualization thesis* has been utilized by transitions researchers and others seeking to understand the experiences of young adults in "late modernity." In *Risk Society* (1992), Beck argues that there is an increasing tendency for young people to "write their own biographies" in a world characterized by rising levels of risk and bewildering choice. However, while the proliferation of individualized biographies might suggest that class, ethnicity, and gender are no longer determinants of young people's life chances, and have encouraged younger generations to feel that they are no longer constrained by these factors, critics argue that the old indicators nonetheless remain firmly in place. In *Young People and Social Change* (1997), Furlong and Cartmel refer to this paradox as "the epistemological fallacy of late modernity." This has led some youth researchers to distinguish between "normal" and "choice" biographies, the former marked by continuity with gender divergent "traditional" working class transitional routes and the latter marked by the emergence of gender convergent destandardized pathways among well educated and/or affluent young adults (du Bois Reymond 1998).

CURRENT THEMES AND METHODOLOGICAL CONCERNS

The subject matter of sociological youth research is wide ranging, with few aspects of young people's lives left unexplored by contemporary researchers. Certain themes, such as youth culture and leisure, education and work, and health related behaviors, are perennial concerns. More recent topics of interest have

included social space, globalization, new technologies, consumption and lifestyle, intimacy and sexuality and, as more overarching concerns, identity and subjectivity. A broader conceptual debate relates to the (re)definition of youth in late modernity and the blurring of the boundaries of childhood, youth, and adulthood among younger generations (see for example Cote's *Arrested Adulthood*, 2000, and Dwyer and Wyn's *Youth, Education and Risk*, 2001). The theme of youth (in) crisis is also common in youth research in many parts of the world. This is often a racialized debate, highlighting the pathologization of racial identity (see, for example, Giroux's *Fugitive Cultures*, 1996). There is also a strong gender dimension to the youth crisis debate, focusing on the global trend towards rising levels of academic achievement among young women and associated claims of a contemporary "crisis of masculinity."

In exploring these themes, youth sociologists have traditionally drawn upon a wide variety of methods for researching young people's lives, ranging from detailed ethnographic studies through to large scale national and subnational cohort studies. Recent developments include the adoption of narrative and auto/biographical interviewing techniques by many youth researchers, and the increasing use of visual methods, including photo elicitation, video diaries, and spatial mapping techniques. This in part reflects a desire to use research methods which are deemed to have an intrinsic appeal to young people. There is also a growing emphasis on qualitative longitudinal research, and some moves towards greater inclusiveness in terms of sampling, incorporating groups who are often sidelined in mainstream youth research, such as young lesbians and gay men, disabled young people, students, young people from socially privileged backgrounds, and young people from rural areas. Finally, participatory youth research – youth research *for* and *by* young people – is becoming more common, and has been a particularly useful vehicle for giving voice to some of these excluded groups.

youth sport

Paul De Knop and Marc Theeboom

Youth is defined for the purposes of this discussion as youngsters between 6 and 18 years. Sport means all sport activities practiced outside the physical education curriculum. Consequently, school sport as extra curricular activity is also included.

With the start of the Sport for All movement in the 1960s and 1970s, this period can be characterized as the years of growth for sport. Youth sport at that time was mainly an activity for adolescents and pre adolescents that took place in sports clubs or during extra curricular training at school. Now the age to begin participating in youth sport has decreased to 7 years or even younger. This policy of attracting younger children to become involved in organized sport is based not on pedagogical objectives but on those related to "survival." Sports clubs want to

remain in the market because their economic existence is threatened.

Sport has become a very popular leisuretime activity among youth. In most countries, at least 50 percent of all children in their early teens are active in various sports. Most of these activities take place in a sports club or during extra curricular training at school. More boys than girls are active in sports. Sports segregate the sexes as few other phenomena do. Boys and girls seldom take part in sports together.

Some of the most common youth sports globally are soccer among boys and swimming among both boys and girls. Among activities outside a sports club, jogging, cycling, and walking are the most popular. The most common sports are almost always universal. There are hardly any popular sports in a country that are played in that specific country alone. Sport has thus become international, not least with the help of television, with rules for performance that are understood by almost all individuals regardless of nationality and language.

The most common motives for taking part in sports are characterized by intrinsic values such as enjoyment and social aspects. These motives are more common than success in competition and better performance. Middle class children are overrepresented in organized youth sport. Membership of sports clubs is strongly related to gender, social class, and family situation.

Since the 1970s there have been important changes in sport and ideas about childhood and psychosocial development. The general value systems and norms in many societies have undergone significant transformations, and traditions and traditional social networks in local districts have been weakened. The way families have been individualized has led to less rigid authority structures, and a number of commercial and educational "adjustments" have taken place. Because of these changes, young people are more directed toward creating their own identities. Also, greater emphasis is placed on the role of institutions involved in leisuretime activities, to offer coherent experiences and guidance for the formation of identity among young people. Schultz Jørgensen and colleagues (1986) suggested that the time of youth has become a waiting period for the formation of a psychosocial identity. Sport plays a major role in this formation of identity.

The following trends in youth sport are noticeable.

- 1 The number of opportunities for youth sport participation have increased substantially since the early 1990s, and youth sports have become more specialized and differentiated at the same time as performance demands have increased.
- 2 Sport has become institutionalized. Traditional sports, such as team sports, are not played spontaneously to the same extent as before. In some countries spontaneous, informally organized sports have almost disappeared. Children's knowledge about and performance in sport have been more differentiated, and the extent and intensity of physical activity have become more varied. Two extreme groups of children can be identified today. In one group, children train intensively several times a week, some every day. In the other group, children are not physically active at all during their leisure time. As a result, physical capacity and sports skills vary considerably between children.
- 3 During recent decades more children have entered organized sport. Differences between boys and girls as regards both extent and trends have decreased, mainly because girls' sports habits have come to resemble those of boys. This trend is most common in Nordic countries, although it also exists in countries where there are increased opportunities for girls to participate in organized sports programs.
- 4 While the flow to organized sport seemed to have stopped and even diminished in many countries, activities in commercial training centers where there is an emphasis on systematic training and skill development have increased. What is significant about these centers is that, although possibilities for making social contacts exist, there are no far reaching obligations. Youngsters can come and go as they please and are not dependent on parents' engagement.
- 5 There has been a professionalization of sports delivery, including a need for quality assessment and control in organized sports programs.
- 6 There is an increased adaptation of rules, equipment, and competitive forms to

children's developmental stages and physical abilities.

- 7 Sports organizations have started to develop schemes to specifically attract young people to their sports.
- 8 There are an increasing number of initiatives in which organized sports are provided for youth at risk.

Problems in youth sports have received a great deal of attention in research. A dropout problem among teenagers, especially among girls, is reported in many countries. During adolescence there is a decrease in the number of participants. Interest in organized sports seems to have reached a breakpoint in many countries and is now even declining.

Youth sports have been shaped to a large extent by adult sports, and adult norms and values predominate. For example, rules for team sports are similar for adults and young children. In addition, youth sport often contains only specialized activities with sport specific training.

Youth sport has become more serious and less playful. Children are not allowed to play to the same extent as before. This problem increases with the decreasing age of participants. Youth sports have become heavily organized. Different sports compete for children's interest, resulting in a focus on increasingly younger children becoming members of sports clubs.

Youth sport participation is far from democratized as involvement is related to children's age and gender as well as their parents' socioeconomic status. Many children are dependent on their parents for financial and logistical support, for example transportation. Often, a certain economic standard is a prerequisite for participation.

Ethical questions in youth sport have been raised in many countries. In order for sport to serve educational purposes for youth, the following principles have been formulated: (1) rules and regulations should be followed; (2) respect should be shown to other players and officials; (3) participants should demand the same from themselves as from others; and (4) participants should display a sense of justice and be loyal and generous.

Western competitive sports have developed in the direction of a greater emphasis on the

importance of winning. This development can also be noticed in youth sport and can be regarded as a threat for the child orientation of sport. It is also reported from several countries that qualified youth sports leaders are hard to find. There is a heavy dependency on volunteers, which creates a high turnover and inconsistent quality of leadership and coaching.

Other problems also exist. For example, there is a need for effective cooperation between sports clubs, schools, and municipalities. The most successful programs have been those in which different actors have worked in partnership to make better provision of sporting opportunities for young people. Furthermore, the number of sports injuries among children and adolescents has been increasing in all nations where medical data are available.

In light of these problems, several policy recommendations have been made for youth sports programs. Some of these are listed below.

- One of the main objectives of a future policy for youth sport should be to increase quality from a pedagogical point of view. Such a policy needs to focus on the following topics: developing a cooperative approach to the provision of youth sport instead of "competition" between the different organizations; ensuring youth sports coaches have appropriate pedagogical qualifications; setting up specific youth sports coaching programs; persuading parents that informal play during childhood is more important than formal sports participation; promoting sport for youth with an emphasis on enjoyment and its social aspects; and scientifically evaluating the effectiveness of sports promotional campaigns.
- Sports among children must be made more accessible and should be offered close to residential areas. There should be greater possibilities for all children to try different sports, and better conditions should be created for varied physical activities.
- The intrinsic values of youth sports (play and learning) must have priority at all times.
- Training must be individualized and rich in variations. Firmly controlled and formalized training can be counterproductive. Sports clubs should aim to develop talent in the

best way possible instead of trying to find new talent. Selection and specialization of individuals should not be made before they have reached their teens. Distinct variations in the maturing process among youth make any early prognoses of success in later years very uncertain.

- A child's relation to sports and to her own body as well as the experience of her own physical ability are the result of learning motor skills. But sport is also a question of learning norms and values related to behavior and lifestyle. Children are socialized into sports and thus also into the value system of sports. Youth sport is one of the most important environments for socialization. Sports must therefore also be valued as such and given due significance in children's lives and development. Sport is perhaps the most important norm setter, second only to family and school. On the strength of its range and importance, sport must mediate and recreate essential values for the continued existence of a particular culture. In other words, it has a reproducing function. Therefore, it is vital that sport follow a sound ethical code. Also, in youth sport, leaders' personal characteristics and behavior are highly important.
- One of the greatest challenges facing youth sport is the development of a cooperative and coordinated approach by schools and clubs with the aim of offering sports as an educational environment for all children that enables them to develop at their own speed and according to their own interests.
- Quality improvement or quality control will need to become essential elements of sports policy with a focus on encouraging quality awareness, developing quality standards, measuring instruments and remedial techniques, and monitoring through research and transfer of knowledge.

In conclusion, youth sport can serve many purposes. It can be a meaningful activity for many children and give them a lifelong interest in physical activity as an important part of a healthy way of life and as a source of pleasure and relaxation. It can also form future elite sportsmen and women and become a means for self realization and success for young people who have a talent for sports. For many children,

sports are also an important environment for socialization and they play a vital role in the reproduction of culture. However, given the recent developments outlined above, many steps still need to be taken in order for youth sports to fulfill any of these aims in an optimal way.

Zimbardo Prison Experiment

Markus Kemmelmeier

Social psychologist Phillip Zimbardo (b. 1933) conducted a well known prison study known as the Stanford Prison Experiment. Funded by the US Navy to investigate conflict in military prisons, Zimbardo and his graduate students, Craig Haney and W. Curtis Banks, rejected the idea that the personality characteristics of prisoners and guards in the prison system were primarily responsible for conflicts as they occurred in the prison system. Broadly consistent with Goffman's (1961) concept of a total institution, Zimbardo and his team identified individual anonymity and loss of identity as the most prominent characteristics of prisons, which Zimbardo's (1970) deindividuation theory linked to antisocial behavior. Without room for individual identities, Zimbardo and colleagues reasoned that the social roles of prisoner and guard would be the dominant influence on behavior and allow participants to behave in ways that would otherwise be unimaginable to them.

Zimbardo and his team of researchers used newspaper ads to recruit volunteers to participate in a two week long "prison simulation" in exchange for payment of \$15 per day. From 75 applicants, researchers selected 24 young men, predominantly white and middle class (21 active participants and 3 alternates), whom pretests showed to be healthy, normal, and well adjusted. Through the toss of a coin, participants were randomly assigned to the role of prisoner or guard. Zimbardo assumed the role of "superintendent," an undergraduate research assistant played the role of "warden," and Zimbardo's graduate students

were "psychological counselors." The involvement of an ex convict consultant in planning and running the prison simulation ensured its realism. The prison was physically located in the remodeled basement of the psychology department at Stanford University. It included a small closet used as solitary confinement facility, quarters for the prison staff, as well as an interview testing room, which was also used for "parole" meetings. The mock prison was equipped with hidden video and audio recording equipment, allowing subsequent analysis of much of the activity that occurred.

The prison study began on August 14, 1971 with a guard orientation establishing the prison hierarchy and its procedures. The 11 guards were dressed in khaki military style uniforms and dark sunglasses to provide a sense of anonymity. They were also given whistles and night sticks as symbols of power. Guards were to work in eight hour shifts, but would otherwise pursue their normal lives outside of the study. Over the course of the study, many volunteered extra hours without additional pay. Guards received no formal training, but were allowed to run the prison in whatever way they wished, with the only stipulation being that physical violence would not be tolerated.

Having secured the cooperation of the Palo Alto Police Department, on August 15 Zimbardo had real police officers arrest the 10 prisoner participants at their residences. The alleged charges were burglary or armed robbery. After having been advised of their legal rights, prisoners were ferried off to the police station, where they were booked, fingerprinted, and had their mugshots taken. After a brief period in a police holding cell, prisoners were blindfolded and brought to the "Stanford County Prison," where they were stripped naked, deloused by the guards (using a deodorant spray), and then had their blindfolds removed. (Prisoners were

never aware that they were in a university building.) As their only piece of clothing, they were given a pair of rubber sandals and a "Muslim smock," onto which their prisoner number was sewn. No underwear was issued. Prisoners also received a nylon stocking cap to further conceal any distinctive features. Three prisoners were housed to a cell, with no personal belongings allowed, and prisoners were only referred to by their number. All procedures were aimed at fostering a sense of anonymity and humiliation, a sentiment reinforced by a lock and chain that prisoners wore around their ankles as a constant reminder of their oppressed state.

The study quickly devolved into a situation of great hostility and open tension, in which prisoners and guards quickly absorbed their respective roles. After a relatively uneventful first day of the study, on the second day many prisoners revolted against the degrading conditions by ripping off their prisoner numbers and barricading themselves in their cells. Without intervention from the research staff, the guards successfully crushed the riot by imposing harsh punishment that included stripping prisoners naked, solitary confinement, withholding of meals, and withholding of blankets and pillows, physical exercise, and various arbitrary activities. The guards further divided the prisoners by pitting "good," privileged cells against "bad" cells, and leading the latter to suspect that there were informers among them. In doing so, the guards affirmed the power and authority associated with their roles as well as a sense of unity against the prisoners. The subsequent harassment on the part of the guards and staff caused serious emotional disturbance in one of the ringleaders of the rebellion, Prisoner #8612. Because they had not anticipated the intensity of the interactions and reactions, initially Zimbardo and his colleagues did not give in to #8612's request to be released, but instead tried to recruit him as a "snitch." Although the prisoner was released later on the same day, the rumor persisted that prisoners would not be released under any circumstances.

Over the course of the following days, the guards' behavior became increasingly sadistic and abusive. Regular prisoner lineups, originally instituted as administrative procedures to familiarize prisoners with their number, devolved into hour long ordeals. Food and even going to the

bathroom turned into privileges that could be granted and withheld. Mattresses and bedding were removed from the "bad" cells, forcing prisoners to sleep on the concrete floor. Prisoners were forced to clean the toilet with their bare hands or were forced to stand naked in front of the guards. Occasional admonishments on the part of the psychological counselors to refrain from certain actions had limited effects, partly because the guards rejected any interference with the exercise of their "duty." Because surveillance was limited, some abusive behavior and even mild physical violence occurred outside of the supervision of the research staff.

Prisoners showed varied reactions to the abuse including "extreme emotional depression, crying, rage and acute anxiety" (Haney et al. 1973: 81). Disorganized thinking and uncontrollable emotional outbursts were common. Some sought to avoid punishment by becoming model prisoners and "zombie like" following guards' orders. A total of five prisoners had to be released, including one prisoner who experienced a sudden rash upon hearing that his request for early parole had been denied by a parole board consisting of secretaries and graduate students and chaired by Zimbardo's ex convict consultant. Zimbardo initially denied the sick prisoner's request to be released, on suspicions that he was faking illness to "con" his way out of the prison.

Following the failed revolt, the only resistance against the oppressive regime of the guards came from Prisoner #416, who joined the experiment as a replacement. In light of the terrible conditions, Prisoner #416 went on a hunger strike, which resulted in his being put in solitary confinement for several hours. The guards offered prisoners the choice to either give up their blankets and have #416 released, or keep their blankets and have #416 stay overnight in solitary confinement. Viewing #416 as a troublemaker, all prisoners decided to keep their blankets. (Upon the researchers' intervention, #416 was returned to his cell.)

The oppressive reality of the prison simulation was underscored by the fact that a visitor familiar with penal environments, who came to see the prisoners during Visitors' Night, described prisoners' reactions as those typical of first time offenders. A public defender who visited the prison in its final phase testified to

the similarity of the mindset and behavior of the prisoners to real inmates. Additional evidence showed that prisoners had internalized their roles. On the fifth day of the study, Zimbardo offered the remaining five prisoners a deal to lose all their pay in exchange for “parole,” and most prisoners accepted. When all parole requests were turned down, none of the prisoners requested to be released, suggesting that they believed that the only way out was to receive parole or go “crazy,” as all other previously released prisoners. In retrospect #416 commented: “It was a prison to me. I don’t regard it as an experiment or a simulation. It was a prison run by psychologists instead of run by the state.”

Zimbardo admits that he, as well as others on his staff, was increasingly absorbed by his role in the experiment, and failed to recognize its inhumanity. For instance, on the fourth day, rumors of an impending prison break had him enter a Stanford undergraduate student into the experiment in order to spy on the other prisoners. Zimbardo’s request to the Palo Alto Police Department to avert the outbreak by transferring his prisoners to a more secure detention facility was turned down. Zimbardo recalls being angry and disgusted at this lack of professional cooperation.

Originally scheduled for a period of two weeks, the experiment was ended after 6 days with the arrival of Christine Maslach, who had been asked to conduct interviews. As a social psychologist unrelated to the study, she objected to the horrifying conditions of the mock prison and convinced Zimbardo to terminate the study. Prisoners expressed great relief, whereas many guards were disappointed. Zimbardo notes that roughly 100 individuals had visited or participated, yet not one had challenged its legitimacy.

Results of this experiment illustrate the potential power of social contexts in shaping human behavior. The fulfillment of social roles within a closed social system overwhelmed individual moral intentions and standards. With preexisting personality difference providing no value in predicting the behavior of prisoners and guards, Zimbardo and colleagues concluded that the roles assigned to individuals within evil social systems are able to turn good people to evil. This idea was consistent with Stanley Milgram’s (1974) famous obedience research. Milgram found that most participants

in the role of a subordinate followed the orders of a legitimate authority, even when aware that doing so would likely cause the death of an innocent person. As a result of their research, Zimbardo and Haney have become vocal advocates of prison reform and frequent commentators on prisoner abuse, like that suffered at the Abu Ghraib prison at the hands of American military.

Even though the Stanford Prison Experiment had been approved by Stanford’s Human Subjects Review Board, it represented an ethical fiasco. All participants signed consent forms agreeing to have some of their civil rights temporarily suspended, but they were unable to anticipate the harm to which they would be subjected. Further, Zimbardo and his team were unable to anticipate the prison dynamics and, by aligning themselves with the guards in running the prison, failed to protect the human rights of the prisoners. Consequentially, this study has led to a tightening of regulations and practices in protecting human research participants.

Various criticisms have been leveled against this experiment. Some critics argued that prisoners and guards were only acting out familiar stereotypes of prisoners and guards. Zimbardo contends that it was role playing initially, but that participants internalized their roles over the course of the study – a notion which is supported by most participants and documented in the movie *Quiet Rage*. Other criticism concerns the nature of the data and the fact that documentation of the study was incomplete and often anecdotal, with conclusions often being drawn subjectively. Audio and video recording was focused on more spectacular events that confirmed the expected effects of anonymity and social roles, but did not document existing differences in the behavior of guards. Much of the documentation focused on the cruellest guard nicknamed “John Wayne,” with little attention devoted to much kinder guards. Further, it is unclear to what extent the simulation reflected actual conditions at prisons where this level of anonymity and humiliation is uncommon. Lastly, because the study was never replicated, the generality of its findings is unclear.

In 2002, social psychologists Steven Reicher and Alex Haslam, in conjunction with the BBC, set up a prison simulation study, which differed in many important aspects from the Stanford

Prison Experiment. Among other things, this research used an on average older and more diverse set of participants while allowing a much greater degree of experimental control and documentation. Results of this study differed dramatically, for instance, in that no prisoner abuse occurred.

The Stanford Prison Experiment inspired the novel *Black Box* by Mario Giordano, which was made into the German feature film *Das Experiment* directed by Oliver Hirschbiegel.

Znaniecki, Florian (1882–1958)

Robert A. Stebbins

Florian Znaniecki was born to a well-to-do Polish family living in Russian-occupied territory. His active support of Polish nationalism resulted in his dismissal from the University of Warsaw and an extended stay abroad. He studied at the University of Geneva and the Sorbonne. He later returned, this time to the University of Cracow, receiving his doctorate there in 1910. While helping Poles to migrate he met W. I. Thomas, who in 1914 invited Znaniecki to join him at the University of Chicago. Shortly thereafter the two began work on the famous five-volume study *The Polish Peasant in Europe and America*, published between 1918 and 1920. Znaniecki taught at Columbia University (1916–17), at the University of Chicago (1917–19), and in 1920, following Polish independence, became professor of philosophy at the new University of Poznań. Here he helped to establish sociology, founded the Polish Institute of Sociology, in 1929 and launched a Polish sociological journal. Following the conquest of Poland in World War II, he was invited to Columbia University (1939). In 1941 he went as professor of sociology to the University of Illinois, retiring from there in 1951. Before his death in 1958, he was elected president of the American Sociological Society (1955).

Znaniecki, with W. I. Thomas and others, is often singled out as one of the founders of symbolic interactionism, primarily for his work in the theoretic sections of the *Polish Peasant*. Still, one of the best discussions of definition of the situation is found in his *Cultural Sciences: Their Origin and Development* (1952). Znaniecki's other books tackle different subjects, as in *The Method of Sociology* (1934) where he argues that we must avoid regarding the static and dynamic sides of society as mutually exclusive perspectives. In *The Social Role of the Man of Knowledge* (1940) he examines the scholar from the perspective of the sociology of knowledge.

In *The Method of Sociology* Znaniecki moves away from symbolic interactionism toward

sociological functionalism. By abstracting, generalizing, and then expanding on Pareto's concept of system, Znaniecki makes a unique contribution to sociology: social life is a *plurality* rather, that sociology must determine whether a particular system is included in a larger system and whether the particular system encompasses one or more smaller systems (Martindale 1981: 460–1). Sociology's task is to analyze causal relations within systems and then move from there to a more inclusive picture of comprehensive changes. In *The Social Role of the Man of Knowledge*, though in many ways influenced by symbolic interactionism, Znaniecki also treats culture as a system of knowledge. Participation in this system is determined by people's activities enacted through roles linked in social systems.

Znaniecki died at work, in the sense that he left upon his death an unfinished manuscript entitled "Systematic Sociology." It was published posthumously in 1965 as *Social Relations and Social Roles*. It includes a complete list of his works, compiled by his daughter, Helena Z. Lopata.

Select Bibliography

The select bibliography is meant to be a partial listing of the most cited works from the entries in this encyclopedia. It is *not* intended to be a comprehensive list of the most widely cited or influential books in the field. While ideally these two lists would overlap, this is not necessarily the case. Every attempt has been made to include cited works from the full spectrum of areas and topics represented in these volumes.
