Exactly this insight was the starting point for another challenge to the criticism of ideology. Some important Marxists like Gramsci and Lenin had called Marxism an ideology. In consequence, Marxists no longer had a privileged standpoint, but could only maintain one among many other perspectives on society. Karl Mannheim spelled out this paradox: the “hermeneutics of suspicion” (Paul Ricoeur) needs to be “totalized.” Every social theory is a potential ideology. Unfortunately, this totalization is self defeating. In order to call something an ideology, you need to claim that your own standpoint is valid. If you call everything an ideology, by implication you cannot call anything an ideology, because that applies to your own theory, too. Thus, Mannheim transformed ideology criticism into a less polemical sociological approach. This approach was as much influenced by Nietzsche’s perspectivism and Dilthey’s hermeneutics as it was by Marx. For Mannheim, the way social classes perceive society is necessarily influenced by their position in society. In order to understand an ideology or worldview right – without claiming that it is “false,” because there is nothing like the one, true picture of society – we need to relate it to this position in society. This is Mannheim’s “relationism,” which was very important for the modern sociology of knowledge, which moved ideology criticism from politics to science.

ideology, economy and

Edward G. Carmines and Michael W. Wagner

Two fundamental aspects of political life in advanced industrial democracies the world over are people's ideological preferences and their economic orientations. The interaction between these two factors helps organize citizens' value orientations and issue beliefs since there are several different ideological perspectives that people can have about the appropriate role for the involvement of government in managing a nation's economy. These distinctive ideological impulses range from extremely liberal (or "left") preferences favoring equality through more state control over the production, distribution, and pricing of a society's goods to extremely conservative (or "right") beliefs preferring individual freedom through allowing the market to control the production, distribution, and price decisions in a society.

The relationship between ideological preferences and economic orientations is important because they inform citizens' political choices and behavior. In order to understand how the dynamic and varying ways these concepts have been integrated in modern democracies, it is necessary to (1) define ideology and explain the general beliefs that make up important ideological perspectives; (2) define economy and describe various prominent economic systems; (3) illustrate the ways in which ideological preferences and economic orientations have commingled; (4) describe how issue preferences, other than economic, have further complicated

how citizens make political choices; and (5) compare the evolution of the interaction of ideology and economy in the United States to other advanced industrial democracies.

The sets of beliefs that people use to help organize their opinions on political issues are called ideologies. A great deal of research demonstrates that people often identify themselves as having some measure of either a liberal or conservative ideology. Generally speaking, liberals favor government intervention on political and economic problems, viewing change as progress, while conservatives often prefer the status quo over change and prefer a more limited government.

The differences between liberals and conservatives vary country by country. For example, in the United States, the public perceives only a modest difference between the Democratic Party and the Republican Party, with the Democrats generally representing American liberals and Republicans being the party of choice for most conservatives. On the other hand, French, British, and German people perceive sizable differences between the much larger numbers of political parties on each side of the ideological divide. Since the advanced industrial democracies of Europe have more political parties than the United States does, European parties vary widely on a liberal-conservative continuum, holding distinctly different, and sometimes more extreme, positions than the United States' two major parties.

Economics is the study of how a society produces and distributes its goods. There are various forms of economic systems, many of which are operating in contemporary political life. At the far right end of the economic spectrum is the pure capitalist system, where the market determines the pricing, production, and distribution of goods and services in a society while property is privately owned. This kind of capitalism is called "laissez faire" for the French term that loosely means "let the people do as they see fit." The government does not play any role in the economy in this kind of system, allowing the market to dictate a society's economic actions. There are no pure capitalist societies in the world.

At the other end of the ideological spectrum is the socialist system. A socialist economic system is one in which the means of production, distribution, property ownership, and price

controls are state run. Under a purely socialist system, it would be unjust for some people to own more property than others. Therefore, the government decides what a society needs, preventing individuals from having power over others.

In between these extremes lies the system of regulated capitalism that provides a capitalist economy generally protecting individuals from government encroachment and supporting private ownership while still allowing for government intervention designed to protect fair competition, individual rights, and other procedural guarantees. One prominent example of this economic middle ground began in the United States during the 1930s and was the inception of the New Deal.

The New Deal coalition is the classic case studied by scholars interested in how the interaction between ideological preferences and economic orientations influences political choices. What was remarkable about the American political landscape in the years following the first election of Franklin Delano Roosevelt to the presidency was that public opinion on nearly every issue that was salient to the American public revolved around people's answer to the question: "what is the proper role of government in providing for the general welfare of its citizenry?" At the New Deal's outset, the answer was largely class based.

In general, those of lower status and incomes, unskilled workers, northern blacks, Catholics, Jewish people, union members, urban residents, and southern whites became Democrats, favoring government support of progressive tax rates, the creation of a limited welfare state, and economic intervention. At the same time, the Republicans' coalition was a near mirror image of the Democrats' alliance. Upper and middle income earners, northern whites, non union families, non southerners, and rural residents preferred a more "laissez faire" attitude to government economic intervention. As such, the terms *liberal* and *conservative* became synonymous with one's position on the proper role of government in the economy.

This ideological alignment, based on citizens' preferences about the government's role in the economy, produced Democratic victories at the ballot box when elections were contested over New Deal economic and social welfare issues.

Of course, the debate over social welfare issues extended beyond the issue of government involvement in the economy, ranging over questions of whether or not the particular social goals of the New Deal were desirable for the United States.

The first hundred days of FDR's presidency brought swift changes to the way that the US government became involved in the American economy. During that time, the Securities and Exchange Commission reformed the banking system, the Civilian Conservation Corps, the Federal Emergency Relief Administration, and the Civil Works Administration provided relief to many of the 15 million Americans who were unemployed as a result of the Great Depression, and the Tennessee Valley Authority was created to address issues of flood control and public electric power. Later in Roosevelt's presidency, the Social Security Act was passed, providing the elderly with government financed income.

The political alignment of liberals favoring government intervention in the economy and conservatives favoring less government involvement dominated American politics for 30 years. However, as Edward G. Carmines and James A. Stimson (1989) argued in their book *Issue Evolution*, the introduction of racial issues transformed the American political system, adding a new dimension to the ideological divide. The 1964 presidential race between Democrat Lyndon Johnson and Republican Barry Goldwater introduced the idea of government involvement in issues of racial equality. While the major political parties had not taken consistent stands on racial issues during the New Deal's heyday, the 1964 election introduced Democrats as the party of racial liberalism and Republicans as the party of racial conservatism. While the conservative-liberal divide still existed, the coalitions that made them up began to change, complicating the clean economic ideological divide that existed before.

After becoming familiar with the parties' positions on racial issues, people began making political choices based on their ideological positions on race, in addition to the role of government in the economy. African Americans became, and continue to be, overwhelmingly Democratic, but southern whites gradually gravitated to the Republican Party. One long term result of this

shift is that the once powerful “Dixiecrat” wing of the Democratic Party has vanished from American politics. Racially liberal Republican members of Congress have similarly disappeared, even though many of them were central to passing civil rights legislation in the 1960s.

Further complicating matters in the United States, the introduction of the abortion issue to partisan politics in the 1970s and 1980s also began to influence ideological choices amongst elected officials and the electorate. Even though more Republicans than Democrats preferred abortion rights in the early 1970s, by the late 1980s Republicans had become the “pro life” conservative party on abortion while Democrats offered the more liberal “pro choice” position. The abortion issue is the most prominent of a new set of issues that are often referred to as “culture war” issues (such as women’s rights, gay rights, gun control, prayer in public school, and the death penalty). One of the most crucial distinctions between liberals and conservatives on the abortion issue and other cultural questions is people’s individual religiosity. The more evangelically religious an individual, the more likely he or she is to exhibit a conservative ideological perspective on cultural issues. Thus, the New Deal alignment of economic liberals and conservatives has been altered, but no similarly simple alignment has taken its place.

COMPARING EUROPEAN POSTMATERIALISM TO THE AMERICAN IDEOLOGICAL DIVIDE

The evolution in the United States from a purely economic divide to a more contemporary ideological landscape consisting of economic, racial, and cultural divisions seems unique when compared to the electorate’s ideological preferences in Europe’s advanced industrial democracies.

First, while the New Deal conflict provides a useful example regarding the impact of competing ideological orientations and economic preferences, many European nations have a much wider scope of conflict on the economic dimension of ideological conflict. For example, in his book *Citizen Politics*, Russell Dalton (2002) notes that in 1996, less than 40 percent of Americans believed that the government was

responsible for providing health care for the sick or a decent standard of living for the elderly, while more than 80 percent of the British and between 50 and 65 percent of Germans and the French supported such measures. Additionally, Europeans were much more likely to claim that the government should help reduce the income disparities between the rich and the poor. This more expansive scope of conflict is also treated differently in European nations than in the United States because of the significantly greater number of political parties European advanced industrial democracies have in comparison with the United States, which boasts only two major parties.

Second, and perhaps more importantly, Ronald Inglehart’s theory of postmaterialism, the leading account of cultural conflict in European advanced industrial democracies, provides a much different understanding of the role that economic preferences play in ideological orientations. The increasing affluence of the post war period, according to Inglehart, resulted in certain groups in the advanced industrial democracies of Europe focusing less of their attention on economic issues, or “material” goals, and more on non economic, value laden, or “postmaterial” matters. Thus, issues such as economic security and national defense, which tap into people’s underlying needs for safety and security, represent material goals. On the other hand, if a society is able to successfully meet material needs for a significant portion of its population, its citizens can shift their attention to higher order values such as personal freedom and participation; these represent postmaterial values.

Postmaterialism’s rise changes the nature of political conflict because it results in some parts of the working class shifting their political support to the right, while portions of the middle class move their political support to political parties on the left. In the end, according to Inglehart, the most meaningful basis of political conflict in western democracies (other than the United States) has come to be between materialists and postmaterialists, rather than between liberals and conservatives divided over economic issues.

Overall, the influence of material–postmaterial value priorities in American politics does not seem to help explain the growth of conflicts

over “culture war” issues during the past few decades. Still, the continuing passage of time and the occurrence of political change more generally require the further comparison of the evolution of the relationship between citizens’ ideological orientations and economic preferences for Americans, Europeans, and members of developing democracies across the globe.

ideology, sport and

Peter Millward

Sport and ideology refers to the way in which the former, as a distinct form of leisure activity, impacts upon the body of ideas which reflect the beliefs of a social group or political system. Indeed, the ideological capacity of sport can be considered so great that it may now be apt to rework Marx’s dictum, in that sport, rather than religion, might sensibly be considered to be the new opiate of the people. Unquestionably,

explicit links between sport and ideology have their roots in the work of the Frankfurt School thinker Theodor Adorno. In sum, Adorno argued that sport, like many other forms of popular culture, was a frivolous activity which reinforced the inequalities of the capitalist system and prohibited critical thought. At the heart of Adorno’s critique lay two defining principles: participant competition and the consumption of the sporting spectacle.

Addressing the first of these issues, Adorno argued that sport emitted dangerous social messages, which resonate with the sports playing proletariat. A given example is that sport is ultimately tied to “instrumental reason,” meaning that it serves a purpose of habituating those in subordinate social positions to the demands of material life. Therefore, Adorno’s indictment was specifically aimed at the means end rationality of bourgeois society, in that sport created the message that if the sports player worked/trained hard he or she would have more success. This was the ideological communication from the capitalist system. Building upon this, Adorno saw that the intrinsic value of sport was in permitting competition between members of the same social class, in that they risked physically damaging themselves and each other during participation. Adorno argued that this was a dystopian reality: members of the oppressed class should be galvanizing against the inherent power structures rather than indulging in masochism. Thus, in this sense, sport creates a false ideology in which instrumental reason is central, which carries a strong capitalist work ethic and hides the “real” bourgeois enemy.

However, the ideology which sport creates does not stop at sports competitors. Adorno saw that spectators offered remuneration for the privilege of watching competitive sport. Thus, Adorno and Horkheimer (1992) argued that sport, like much of popular culture, was part of the *culture industry*. They argued that sport, like the other institutions that create popular culture, was owned by members of the bourgeoisie but uncritically consumed by the proletariat masses. Taking the view that popular culture may numb the working class’s faculties of critical thought, Adorno and Horkheimer argued that the differences between the ideological propaganda of the Nazi party and key agents within popular culture

(including sport, music, cinema, and news print) were minimal. Indeed, popular cultural forms and Nazi propaganda were alike in lulling cultural consumers into a false sense of security and in the process limiting their ability to think critically. Essentially, the ideological message was that as long as the preoccupied proletariat had access to popular culture, they would not challenge the existing power structures.

Furthermore, the cultural industries have bourgeois owners who, for entry into sports events or access to the mediatized spectacle, charge fees for a unit of their product. Inevitably, like any profit making activity, this creates a surplus. Therefore, popular culture – including sport – pacifies the proletariat while producing a profit for the bourgeoisie. Indeed, Eco (1986) has voiced a similar opinion. Like Adorno and Horkheimer, he highlighted a belief that sport placates society by asking if it was “possible to have a revolution on a football Sunday?” With this, Eco suggested that sport – in this case football – negates the proletariat’s ability to think and act critically. Therefore, for Adorno, Horkheimer, and Eco, the only real sporting results are the continued oppression of those in subordinate positions and eventually an accommodation to monopolistic capitalism. What is more, these concerns were voiced long before the expansion of the global media, which has allowed the most popular sports events – such as English Premiership football and US NBA Championship basketball matches – to be broadcast worldwide, aiding the spread of global capitalism. In this sense, Adorno and Horkheimer’s condemnation was prophetic. Indeed, Adorno (1982) most succinctly summed up his concerns by arguing that “sport itself is not play but ritual in which the subjected celebrate their subjection,” and therefore clearly demonstrating the role sport plays in developing an ideology which favors existing power structures.

Thus, Adorno demonstrates the linkage between sport and the ideology of the capitalist system. However, Bero Rigauer (1981) points out that sport has also been utilized as an ideological tool by “state socialists”/“communists.” For instance, in the former USSR, the first socialist sports movement was organized by the state immediately after the revolution. Therefore, sport was used to create harmony

and practiced to promote the nation’s fitness during the Civil War (1917–20). This use of sport was markedly different from its uses in western capitalist systems, in that competitive sport was not featured. However, the practices were designed by Russian communist intellectuals in order to cultivate a social consciousness which could eliminate a range of social problems (such as alcoholism and illness). In this case, the ideological capacity of sport was utilized to manipulate the actions of the public, beyond capitalistic measures. Thus, using this form of ideology, sport can undeniably have a cohesive (as well as destructive) dimension that can (re)unite disparate societies.

However, the illustrated links between ideology and sport have been broadly one dimensional, relating to the way the economic or state power base conditions a public culture. Taking this route, Rigauer, Adorno, and Horkheimer do not look at subordination and empowerment beyond the macro political structures. Eco, on the other hand, pinpoints an additional criticism within the domain of sport participation. Eco argues that sport gives rise to a needless inequity, which separates those who demonstrate sporting aptitude from those who do not, deepening cultural inequality. Although Eco drenches his point with irony, it is clear that other forms of ideology exist beyond the parameters set by the named thinkers. Indeed, the late twentieth and early twenty first centuries have been characterized by the shift toward non class based new social movements. An agenda for future research which considers sport created ideology should be responsive to this, asking questions which relate to other forms of inequality in sport (and with links to the broader society). Such an agenda might, for example, specifically relate to issues of racism, xenophobia, gender, and sexuality, which pertain to both sporting and non sporting dimensions of contemporary society. Therefore, future scholarly research may focus on the various ideologies of inclusion and exclusion, building upon the impressive work of Back et al. (2001), Hargreaves (1994), and King (2003), among others.

idioculture

Tim Hallett

Idioculture is defined as “a system of knowledge, beliefs, behaviors, and customs shared by members of an interacting group to which members can refer and employ as the basis of further interaction” (Fine 1979: 734). Termed by Gary Alan Fine, idioculture respecifies the content of culture by focusing on the level of small groups and the social interactions therein. Developed before the sociology of culture gained popularity in the discipline and at a time in which macro, structural, political, and economic approaches were dominant and culture was seen as a vague, amorphous, fractured, “indescribable mist” (Fine 1979: 733), idioculture makes the culture concept useful by focusing on empirically observable group interactions as the locus of cultural creation. To regroup culture in group interactions, Fine draws from the symbolic interactionist tradition and research on group dynamics.

While the idioculture concept respecifies culture at the group level, it also identifies the process through which elements become a part of an idioculture. To become a part of an idioculture, an item must be Known, Useable, Functional, Appropriate, and Triggered (KUFAT). An item must be a part of a *known* pool of

background information. If the item is not known by at least two group members, it cannot become a stable basis of ongoing interaction. Though the focus of idioculture is local, the “known” criterion provides a link to broader social structural and cultural forces as they are experienced by group members. An item must also be *useable*, that is, it must be “mentionable in the context of group interaction,” (Fine 1979: 739). If the item violates the morals of a group or has taboo implications, it will not survive as a part of the idioculture. To become a part of idioculture, an item must also be *functional*: it must help the group to fulfill some need. Items that have no purpose in terms of group tasks or group emotions are unlikely to become a basis of ongoing interaction. An item must also be *appropriate*. An item is appropriate when it supports the status relations within the group. Items that are hostile to high status group members are censored, but items that are sponsored by high status members are likely to be incorporated into the idioculture. An item must also be *triggered*, it must “spark” group interactions, and triggers which are notable or unusual are most likely to become a part of the idioculture. The creation of idioculture through this five part process occurs via the interactions of group members.

The content of idioculture ranges from nick names and jokes to stories and rules of conduct. The concept was generated inductively from Fine's (1979, 1987) ethnographic study of little league baseball teams, but features prominently in all of his works, from his study of fantasy gaming to his recent observations of weather forecasting. Among the many examples that Fine gives is an informal rule created by a little league team prohibiting the eating of ice cream in the dugout during a game (Fine 1979: 743–4). The rule was triggered by an unexpected loss, during which a younger, non playing member ate an ice cream cone. The rule was drawn from a known background – the players knew that it was abnormal for a player in the “big leagues” to eat ice cream during a game. Likewise, the rule was useable because it did not deal with any childhood taboos. It was functional because it provided an emotional outlet while focusing the attention of the younger members and creating solidarity, and it was appropriate because it was enacted by high status members against the actions of a low status member. Though this

feature of the idioculture was created through this interactive process, it sets the terms for ongoing actions: it effectively ended the eating of ice cream for the rest of the season.

This process of idiocultural creation emphasizes the non random and therefore thoroughly sociological nature of culture. Different configurations of the five features explain how idioculture varies between different groups and how different forms appear and remain in different groups. That the “no ice cream” rule did not present itself in the idiocultures of other teams can be explained by the notable triggering (during a loss as opposed to a victory) and the status dynamics of the particular group.

The term idioculture is routinely referenced in the sociological literature as a synonym for small group culture. However, it is rare for researchers to engage the full KUFAT apparatus, perhaps due to an implicit methodological implication. Because idioculture is local in nature, it must be studied at the group level, and though the process of idiocultural creation is empirically observable, it requires detailed microsociological data collection and analysis. Though fieldwork is increasingly viewed as a legitimate method, many sociologists do not have the interest or inclination to engage in this labor.

While the term is used more frequently than the full concept, a number of studies capture the “spirit” of idioculture by emphasizing the connection between groups and culture. In his research on “creative genius,” Farrell (2001) debunks the image of solitary inspiration to show how groups such as the French Impressionists used friendship networks to form a “collaborative circle” that spawned creativity. Farrell presents a stage model of group creativity (formation, rebellion, quiet, creative work, collective action, separation, reunion) that is not unlike the KUFAT process. In their ethnographic studies of voluntary associations, Eliasoph and Lichterman (2003) propose a model of culture in which “group style” filters macro level collective representations down to the micro level of interaction. Eliasoph and Lichterman stress how the group style (composed of boundaries, bonds, and speech norms) mediates broader cultural categories, codes, and vocabularies, to make them useable in the context of everyday group life.

ie

Takami Kuwayama

In Japanese, *ie* means “house,” but it is often applied to a group of people residing in the same house to make a living together. This semantic shift is evident in the definitions given in the authoritative dictionary *Kojien* (5th edition, 1998): (1) a structure for residence; (2) a collectivity of people living in the same house; and (3) a kinship group with common ancestors and property handed down from generation to generation. The sociological and anthropological discussion of the *ie* is inevitably concerned with the last two meanings. The *ie* is widely regarded as Japan’s traditional family. There has been much controversy, however, about what it really is, particularly over the question of how the *ie* should be distinguished from the supposedly universal institution of family or

kazoku. (*Kazoku* is written in two Chinese characters, the first of which is the same as the character for *ie*). Furthermore, the *ie* has been used as a structural principle of larger organizations, including the entire Japanese nation, and, as such, it is central to the debate on Japan's national identity.

Putting aside the enormous variation within Japan, it is safe to characterize the *ie* as a 4P institution: patrilineal (tracing descent on the father's side), patrilocal (the bride moving into the groom's house after marriage), primogenital (house property being inherited by the eldest son), and patriarchal. There is general agreement that the structural core of the *ie* is the line of succession between the head and his successor. Succession has two different aspects: (1) accession to the headship and (2) inheritance of property. The *ie* headship is ordinarily passed on from father to eldest son, but many alternative strategies exist to maintain the group. For example, when there is no biological son to succeed within the *ie*, a son may be adopted from outside. The Japanese *ie* is distinguished from its Chinese or Korean or even Okinawan counterpart in that there is no strong feeling that the adopted son should be related to the head by blood. This fact correlates with the absence of a clear cut distinction between kin and non kin in traditional Japanese society. It is also related to the loose use of kinship terms in addressing non kin. As for inheritance, *ie* property is passed on to one child, usually to the eldest son by the rule of primogeniture. In some regions, however, it is inherited by the eldest daughter if she is a first child. In this particular case, the headship is ordinarily assumed by her husband who has been adopted into the *ie*. Occasionally, ultimogeniture is practiced – a custom commonly related to the *inkyō* (retirement) system, in which the senior couple set up a separate residence after abandoning the headship. Generally speaking, non inheriting children, including daughters, receive economic support from their parents when marrying out. In the case of a merchant *ie*, which incorporates unrelated employees as its members, branch shops are often set up for them, and they maintain fictive kinship relationships with the *ie* head. This custom supports the argument, to be explained later, that the *ie* is a corporate group, rather than a family, which functions as a managing body.

Many of the features mentioned above were found in the family system codified in the Civil Code of 1898, known as the “*ie seido*” (*ie* system). Because this Code was abolished after Japan's defeat in World War II, having been replaced in 1947 with a democratic civil code during the occupation period (1945–52), there is a widespread tendency to regard the *ie* as feudalistic and legally defunct. This tendency should be corrected in the light of two facts. First, as a social organization, the *ie* has developed over the long course of Japanese history, with its origin probably dating back to the twelfth century. It is not identical with that codified in 1898. Thus, the abolition of the Civil Code of 1898 does not automatically mean the demise of the *ie*. Second, legal changes do not bring about immediate changes in people's attitudes. The so called “*ie ishiki*” (*ie* consciousness) is weakening, but it persists and unexpectedly reveals itself on ceremonial occasions, such as weddings and funerals, often to the surprise of the people involved.

Among the many controversies over the identity of *ie*, that between Kizaemon Aruga and Seiichi Kitano deserves the closest attention. Aruga (also called “Ariga”), best known for his study of the *dozoku* (a federation of *ie* groups organized hierarchically with the *honke* [main *ie*] governing its *bunke* [branch *ie*]), maintained that the *ie* is a *seikatsu shudan* (life group). According to him, the *ie* is not simply a family or a kinship group. Rather, it consists of people, both kin and non kin, who live and work together to sustain themselves and, ultimately, to perpetuate the collectivity's *keifu* (genealogy). He further contended that the status of *ie* members is determined by their functional roles in maintaining the group and that positions within the *ie* may be filled by any competent person recruited from outside. Aruga thus considered the *ie* a task oriented residential unit (Aruga 1954, 1972). Kitano (1976) took exception to Aruga's functional view. Drawing on the theory of *shokazoku* (small family) formulated by Teizo Toda, founder of the Japanese sociology of family, he emphasized the emotional bond among family members. He argued that the family consists of only a small group of kinship members, centered on husband, wife, and children, who are affectively connected with each other. He therefore excluded people like servants, and severely

criticized Aruga, saying that the *ie* or the Japanese family as conceptualized by Aruga is essentially a *jigyō dantai* (enterprise group).

Significantly, it is the analogy between *ie* and enterprise group that was later adopted in analyzing the Japanese company, especially its commitment to the welfare of employees as persons rather than workers contracted to provide labor in exchange for wages. Known as “corporate familism,” this feature of the Japanese company has widely been regarded as a secret of Japan’s post war economic development.

The scholarly importance attached to the *ie* has eventually developed into what may be called the “*ie* model of Japanese society.” It is a part of the well known “group model,” in which the Japanese emphasis on the group is contrasted with western individualism. The *ie* model contains two major approaches: sociological and psychological. In the sociological approach, the *ie* is defined as the basic unit in Japanese society, and other large groups, such as the *dozoku*, the company, and even the entire nation, are considered structural extensions of the *ie*. Examples include concepts like “corporate familism,” “*ie* society,” and the “family state” (see below). In the psychological approach, the group orientation of the Japanese is highlighted. Attention is focused on the submission of the individual to the family will and the resultant suppression of personal needs and desires for the sake of the *ie*.

Chie Nakane, author of *Japanese Society* (1970), represents the sociological approach. In this influential book, Nakane argued that the idea of *ba*, “frame” or “field,” is pivotal in organizing groups in Japan. In her mind, *ba* refers to “a locality, an institution or a particular relationship which binds a set of individuals into one group” (p. 1), and it takes precedence over a member’s *shikaku* or attributes. Thus, being a member of a particular company is considered in Japan more important than being, for example, the president or a secretary of that company. In this idea is underscored the importance of group membership, as contrasted with individual achievement. Nakane maintained that the *ie* is the archetype of *ba*. The psychological approach, on the other hand, has extensively been used by American scholars. A classic example is found in Ruth Benedict’s *The Chrysanthemum and the Sword* (1946), in which she wrote:

“The claims of the family come before the claims of the individual. . . . Submission to the will of the family is demanded in the name of a supreme value in which, however onerous its requirements, all of them have a stake” (p. 55). In the United States, the argument that self sacrifice is demanded of the Japanese for the common good has repeatedly been made to date (e.g., Kondo 1990).

Since the Restoration of Meiji in 1868, the *ie* has often been represented as Japan’s national symbol. This representation is inseparable from that of the house or family, but it has transcended the original meaning to produce a broad discursive sphere in which different aspects of Japan are understood as manifestations of a single entity – the *ie*. A most dramatic example is that of the *kazoku kokka* (family state), a political ideology created by the authorities at the end of the nineteenth century, which worked as the country’s spiritual foundation until the end of World War II. The family state likened the entire Japanese nation to a huge *ie*, in which the relationship between the emperor and his subjects was compared to that between father and children, on the one hand, and between main *ie* and branch *ie*, on the other. From the first comparison was derived the notion that *chu* (loyalty to the emperor) was identical with *ko* (filial piety). From the second comparison was derived the belief that the emperor’s ancestors were genealogically related to those of his subjects. A sense of national unity, however fictitious, was thus fostered among the Japanese people. Through the moral training called *shushin*, Japanese schoolchildren were taught to serve the emperor faithfully, if necessary through the ultimate sacrifice of their lives. In *shushin*, self sacrifice for the sake of the *ie*, on which the nation was believed to be based, was praised as a great virtue, which was then contrasted with the supposed “vice” of western individualism.

Japan’s defeat in World War II put an end to the official ideology of family state. The notion persists, however, that the *ie* is a time honored tradition of Japan and that it should be defended from foreign encroachments. The current debate on the Japanese government’s proposal to install a *fufu betsu-sei* (two surname family) system, which would allow husband and wife to assume their own surnames, clearly

attests to this point. Article 24 of the Constitution of 1946 stipulates that the individual should be respected in family life and that husband and wife hold equal rights. Article 750 of the Civil Code of 1947 allows a married couple to assume the surname of either husband or wife in accordance with the agreement made at the time of marriage. In reality, however, women are required to change their surnames to those of their husbands upon marriage. In order to cope with a widespread sense of inequality among the ever growing number of working women, and also to comply with the international Convention on the Elimination of All Forms of Discrimination against Women, in the mid 1990s the Japanese government proposed to legalize the two surname family. This proposal immediately met strong opposition from nationalists, who vehemently maintained that it would only enhance the already individualistic trend among the Japanese whose moral fiber has, in their judgment, been destroyed by western values. Surprised by this reaction, the Japanese government has withdrawn the proposal. The debate continues, however, and it is difficult to predict the final outcome. Whatever the outcome may be, these issues demonstrate the vulnerability of the *ie* to political manipulation.

illness behavior

Ronald Angel

While the phrase health behavior refers to behaviors that individuals engage in to maintain health, the phrase illness behavior has been used to refer to the responses that individuals engage in after they become ill, presumably in an effort to get well. Many classic theoretical attempts to understand this process focused on what was conceived of as the illness career or the sick role. These theories (and later approaches) attempted to understand how an individual's perceptions, experience, and expression of symptoms, as well as their decisions concerning the appropriate course of action, are influenced by and interact with professional models of illness, provided primarily by physicians, to determine how the illness career is structured. Indeed, one of the most intriguing and important aspect of illness behavior models has to do with understanding compliance and the identification of those individual, cultural, and social factors that lead individuals to ignore or to follow medical advice.

As the populations of the developed world age and as chronic diseases such as obesity and its complications become more common, effective control requires long term compliance with regimens that include dietary changes, increased exercise, and proper medication use. In order to make profound changes in behavior and life style, the individual must come to view him or herself as sick and accept the proposition that the lifestyle changes and medical interventions prescribed will substantially lower the risk of further illness and functional decline. Similarly for HIV/AIDS, cancer, mental illness, or any other malady: the patient's response to intervention is determined by their own assessment of the medical advice provided. Even in an age in which medical authority is high, individuals continue to consult chiropractors, massage therapists, the practitioners of oriental medicine, herbalists, and many other non traditional healers. The uncertainty and ambiguity that surrounds so much of illness and its treatment leave a great deal of room for personal interpretation and evaluation.

The classic conceptions of illness behavior were largely functional and identified categories

of variables or factors that potentially influence the illness career. In most of these models, the response to illness usually begins with the recognition of symptoms or with a medical diagnosis in the absence of symptoms. The theories of Talcott Parsons (1975), Edward Suchman (1965), David Mechanic (1972), and others focus on the factors associated with the symptomatic individual's recognition and assessment of the severity and meaning of symptoms, as well as on those factors that determine the actions an individual takes in order to get well. Certain of these theories also dealt with society's expectations of the sick individual and the structure of the social roles that the ill individual occupies.

Suchman, for example, developed a theoretical model of the relationship between social and medical factors and related those to demographic and social group structure, including cultural orientation, in their impact on medical care use. Suchman identified several stages in the process of recognition and response to illness. At each stage the symptomatic individual engages in a cognitive process that is influenced by demographic and social group factors that leads him or her to reject a medical definition of the problem and postpone the acceptance of treatment, or to accept a medical explanation and comply with the prescribed treatment regimen. If the patient seeks medical advice and accepts its legitimacy, he or she assumes the sick role, the ultimate objective of which is recovery of one's health and functioning. Suchman observed that the probability of acceptance of a medical explanation for what is wrong with one is influenced by one's level of education and sophistication. Parochial individuals who are scientifically uninformed and who hold a popular view of healing tend to procrastinate, deny symptoms, and delay seeking medical attention longer than more cosmopolitan individuals who more readily accept their need for medical treatment. Suchman saw this theory providing important insight into the degree of congruence between physicians' subculture and belief systems and those of groups that adhered to more or less scientific or popular conceptions of illness and its treatment.

In subsequent years other theorists and researchers extended this tradition to focus specifically on the cognitive structures and

processes involved in the sick individual's response to illness and their relation to culture and the process of acculturation. Much of this research focused on the phenomenon of "somatization" – a clinical syndrome in which emotional and even social distress is expressed somatically – or on specific culturally defined syndromes such as "nervios" or "nerves" among Latinos (Kleinman 1986; Guarnaccia & Farias 1988). This theoretical tradition was motivated by the observation that in subjective experience individuals do not differentiate between their emotional and physical selves, but rather experience distress holistically. Modern scientific medicine and psychiatry differentiate between the physical and the mental for practical reasons, but most of humanity does not, and given the ambiguous nature of illness and treatment, emotional distress directly influences and accompanies physical illness. A large body of research has for years demonstrated that depression exacerbates the symptoms of physical diseases and increases suffering (Wells et al. 1989). A casual perusal of the Internet or journals such as *Psychosomatic Medicine* reveals many articles that demonstrate an association between depression and coronary artery disease, arthritis, chronic pain, and much more.

By now a rather large body of theoretically informed research has demonstrated that illness behavior relates to a process that is cognitively and socially quite complex. Leventhal (1986) and colleagues have elaborated such a cognitive model in relation to a number of specific conditions and to the degree and nature of compliance with prescribed treatments. Most of the research into illness behavior is based on surveys and more in depth anthropological and clinical inquiry. Surveys such as the Health and Nutrition Examination Survey ask questions about mental and physical symptoms, medical care use, self medications, etc., and they clearly demonstrate group differences in the level and structure of depressive affect and symptom reporting (Angel & Guarnaccia 1989). Although such data provide useful information on broad group differences it is beset by methodological problems related to self reports. Surveys are highly structured and offer little opportunity for deep or extensive probing. Indeed, the problems of language and communication plague

all illness behavior research, both because researcher and patient often do not speak the same language, and because of the fact that they have very different worldviews, as Suchman noted.

For the physician and for the social scientific or behavioral researcher, symptoms form much of the basis of assessment. Unlike signs, or the observable and objective evidence of disease, self reported symptoms reflect privileged information. The individual who is suffering is the only one with access to his or her internal subjective realm. Those cognitive and social factors that influence the expression of symptoms and the language one uses to talk about the self must be better understood by epidemiologists and social policy researchers, as well as physicians (Angel & Williams 2000). In recent years much more concern about measurement issues related to health matters has appeared (Stone et al. 2000). By now it is clear that self reported and subjective information is influenced by multiple factors, including those related to culture, education, and one's previous experience with illness (either one's own or someone else's), and much more (Angel & Thoits 1987).

Perhaps the complexity of the processes involved in illness behavior accounts for one of the practical weaknesses of this particular theoretical and research tradition. Although the theories posit useful associations between the mind and the body and the research demonstrates a clear association between depression and physical illness, neither the theories nor the research provide specific prescriptive insights into just who will engage in specific behaviors or who will comply with prescribed medical regimens. Certainly, it is of practical use to know that depression, anxiety disorder, and substance abuse are common in primary care and that the response to them is often inadequate. It is also useful to know that depressive affect is correlated with physical complaints, but it has been difficult to determine which patients are at highest risk.

Perhaps screening of primary care patients or better training of physicians and other health care professionals would increase the recognition of these problems, but just how they would be treated is not clear. The problem is seriously

compounded when the patients are recent immigrants with low acculturation levels or when they do not speak English. We understand the general aspects of illness behavior, but those insights have not been translated into practical applications. Knowing, for example, that poorly educated individuals of Latin extraction are, as a group, more likely to somatize and to employ culture bound expressions of distress does not allow us to identify which individuals of that group will do so. Individuals who share similar demographic and cultural characteristics can differ significantly in their personal response to illness. Indeed, the illness behavior tradition suffers from the shortcomings and offers the promises that Thoits (1995) identified in the area of the health outcomes of stress and coping. We know that some individuals cope better with specific stresses than others, but it is not often clear what gives them that capacity. It is clear that we need a better sense of the intervening factors that lead one individual to engage in one set of behaviors and another to deny. "Parochial" versus "cosmopolitan" orientations or the realization that individuals with a culturally traditional orientation are more likely to somatize and to delay seeking medical care are only general observations. They do not lend themselves to prescriptive statements, which is what practitioners often request of their more social scientific and anthropologically oriented colleagues.

Clearly, though, understanding the complex processes that fall into the very general category of illness behavior is important. Much of modern medicine and certainly the control of chronic disease involves changing the patient's conception of his or her personal vulnerabilities in order to bring about the appropriate behavioral changes. Understanding how and why individuals decide how to respond to symptoms or how they interpret medical advice requires that we go beyond the traditional models and employ the new insights of the cognitive sciences to understand how individuals frame illness vocabularies (Pelto & Pelto 1997). In order to move the understanding of illness behavior forward it will be necessary to employ the insights and techniques of the cognitive sciences in combination with more refined qualitative interviewing techniques. Brain imaging may

even lead to the identification of specific structures or processes associated with specific behaviors. At the very least we need some better sense of how complex medical information, or fairly burdensome medical recommendations such as advising a middle aged Mexican American man to alter his diet drastically, are interpreted. We also need a better understanding of the impact of family and local social structural factors on illness behavior. The dietary changes required to control a father's diabetes mean that the routines of the entire family may have to be altered and that one is required to reject local dietary traditions.

It would be impossible, of course, to end even a short entry on illness behavior without mention of the non cognitive, non psychological factors affecting individual behavior. Most of the traditional theories placed the symptom attention, evaluation, response process within a larger social and economic context. Rarely, though, was that context elaborated in detail. Yet we know that if one has few economic resources and no income, one is less likely to seek professional medical care or to comply with treatment and more likely to suffer adverse health consequences (Institute of Medicine 2002). One suspects that much of the impact of culture is really a reflection of social class. Of the over 40 million uninsured Americans a disproportionate number are African American and Hispanic. Mexican Americans who are concentrated in Texas (the state with the lowest rates of health care coverage for adults and children in the nation) are the most uninsured group in the nation (Angel et al. 2001). It is possible to attribute to culture or to low levels of acculturation effects that are, in fact, a result of the lack of social or economic resources. The cognitive processes that individuals engage in to decide whether or not to seek help or comply with prescribed regimens may well be quite rational and reflect reality. Clearly, illness behavior is a complex process with multiple explanatory layers. Since humans are not passive recipients of medical care though, and since the public's health generally depends on the collection of individual actions, understanding illness behavior in context remains a vitally important research initiative.

illness experience

Graham Scambler

The term illness experience refers to the ways in which people define and adjust to perceived interruptions to their health. It is conventional in medical sociology to distinguish between illness and disease. Illness refers to people's "lay" or subjective definitions of health problems, while disease refers to "professional" or objective definitions of health problems based on signs and symptoms. The value of this distinction is that it allows us to acknowledge that people can be ill without having a disease, and can have a disease without being ill (Freidson 1970).

For all its utility, the illness/disease dichotomy can also be misleading. First, it is evident that lay understandings of illness are typically informed by direct (e.g., communicated by doctors) or indirect (e.g., mediated by the Internet) representations of professional conceptions of disease. Less obviously, professional notions of disease do not emerge out of a cultural vacuum. Rather, they have their genesis in, often reflect, and must, if they are to retain their authority and legitimacy, continue to be seen to have their basis in the broader culture inhabited by prospective patients. Second, the dichotomy erroneously equates healing with allopathic medicine. There is strong evidence in North America, Europe, and elsewhere that people are turning increasingly to complementary or alternative practitioners to treat their health problems, and many of these healers reject the philosophy, theory, and practice of professional biomedicine. Arthur Kleinman's (1985) anthropological notion of the

"local health care system," comprising popular (self or lay care), folk, and professional sectors, neatly captures the complexity and subtlety of contemporary healing.

The research literature on the myriad but patterned ways in which people cope with the illness experience within their local health care systems can be broken down by theme. The first concerns how they come to see themselves as ill and their subsequent decision making regarding treatment and care. The second contextualizes these decisions in relation to the cultural norms that articulate morally appropriate and responsible behaviors around illness. The classical expression of these norms is Talcott Parsons's (1951) concept of the sick role, which establishes both rights and obligations attendant on illness in the US and kindred societies. The third theme focuses on the ongoing and negotiated relationships between ill people and their healers, typically, in the domain of research, doctors. The fourth concerns biomedical and other treatment regimes and, most conspicuously, those factors known to affect what has been variously called compliance, adherence, and, more recently, concordance. The fifth and final theme is the broadest: it covers how and with what results people accommodate to their illnesses. It is a theme usually identified as coping or adjustment/maladjustment, typically with chronic and disabling rather than acute conditions. The first two themes are dealt with in detail in other entries, so what follows concentrates on themes three, four, and five.

There is enormous variability in the manner in which illness intrudes on people. An illness with a dramatic impact may not indicate threatening disease. Similarly, life threatening disease can begin with uneventful symptomatology. A dizzy spell, faint, or blackout or two can either be rationalized away, as the product of fatigue or stress, or precipitate a consultation leading to a medical diagnosis of epilepsy. Medical labeling of this sort changes people: it "makes them into epileptics" (Scambler & Hopkins 1986). A diagnosis of multiple sclerosis typically occurs long after the individuals affected define themselves as ill, and often long after specialist doctors initiate testing. People are notoriously intolerant of uncertainty, particularly in the face of illness for which "lay

theories” seem inadequate. However, while people with epilepsy typically experience the biomedical termination of uncertainty as a set back (i.e., an unwanted stigmatizing identity has been foisted on them), those with multiple sclerosis, if not their kin, typically experience it as a relief (i.e., at last they can begin to make sense of what is happening).

Diagnoses of this type can lead to “biographical disruption” (Bury 1982), sometimes encompassing a “loss of self” (Charmaz 1983). Chronic symptoms like epilepsy or diseases like multiple sclerosis, diabetes, or rheumatoid arthritis require a rethinking or reordering of selves, goals, and priorities. Gareth Williams (1984) refers to such processes as “narrative reconstruction.” This may be self or other imposed. An individual with epilepsy, as it were incognito, may be affected more by “felt” than “enacted stigma”: he or she may suffer more from a sense of shame or fear of being stigmatized than from actual stigmatization or other forms of discrimination on the part of others (Scambler & Hopkins 1986; Scambler 2004). Someone with motor neuron disease, AIDS, or multiple sclerosis is more likely to be confronted with a stark and other imposed demand to reappraise his or her future.

The notion that people who are ill, acknowledge themselves as such, and seek professional help should recognize an obligation to comply with or adhere to appropriate medical counsel and regimens has been challenged, evidentially and in theory. It is known that compliance/adherence averages out at around 40 percent. The rationales people develop in relation to advice and medications bear testimony to the fact that they think for themselves and typically have multiple motivations and agendas. Freidson’s discernment of a “clash of perspectives” between doctors treating disease in their clinics and patients coping with illness in their day to day lives remains salient: the two parties can talk past each other.

Future research is likely to build on a topical concern with medical accountability and patient choice around illness. The concept of the “expert patient” has had a mixed reception, some heralding it as a device for co opting and limiting patient choice. In addition to continuing work on coping with illness, new challenges might be anticipated to the ubiquitous

presumption that all phenomena to which the label disease has been or might yet be attached, from diabetes to smoking to wrong body image, make either victims or irresponsible citizens of their bearers.

illness narrative

Lars Christer Hydén

Illness narratives are mostly thought of as sick people’s narratives about their illnesses and the effect on their lives. Illness narratives can also include the narratives of relatives about the effects the illnesses have had on their relationships with the sick people and on their own

lives. They often occur as oral narratives in everyday conversations with family, friends, and colleagues. They can also appear as written and published biographical or autobiographical accounts of illnesses or pathographies (Hawkins 1993). Both oral and written illness narratives help to configure and articulate experiences and events that change one's life and its prerequisite sites as a result of illness.

Research on the forms and functions of illness narratives expanded rapidly during the last decades of the twentieth century (Bury 2001). The medical sociologist Arthur Frank (1995) suggests that this interest has to do with ill persons in late modernity wanting to have their own suffering recognized in its individual particularity. Patients' illness narratives capture the individual's suffering in an everyday context, in contrast to the medical narratives that reflect the needs of the medical professions and institutions.

The research on illness narratives is marked by diversity in the theoretical perspectives and methods that are brought to bear on a variety of problems. The field covers interview studies of patient narratives of illnesses, as well as studies of the way narratives are used in the interaction between medical staff and patients.

Medical sociologists and anthropologists (among others) have attempted to understand suffering and illness as they are experienced by ill persons and how their daily lives are affected by illness – this in opposition to describing the illness from the perspective of the medical profession and institution. This approach has been conceptualized by Mishler (1984) as a conflict and struggle between the “voice of the life world” and the “voice of medicine.” Several researchers have tried to examine the “voice of the life world” in more detail and in that context used narrative both as an analytic and theoretical concept.

In what follows, three main areas of research will be discussed: illness narratives and identity, illness narrative and medical knowledge, and the functions of illness narratives. The first area is concerned with the ways individuals narratively reconstruct their identities in face of chronic illness. All types of illnesses affect the experience of continuity and inner coherence as it is called into question, perhaps becoming invalid altogether. Illness can be

experienced as a more or less external event that has intruded upon an ongoing life process. At first, the illness may seem to lack all connection with earlier events, and thus it ruptures not only the sense of continuity but also identity (Bury 1982; Williams, 1984).

Narratives offer an opportunity to knit together the split ends of life, to construct a new context and plot that encompasses both the illness event and surrounding life events and recreates a state of interrelatedness. Depicting illness in the form of narratives is also a way of contextualizing illness events and illness symptoms by bringing them together within a biographical context. By weaving the threads of illness events into the fabric of our personal lives, physical symptoms are transformed into aspects of our lives, and diagnoses and prognoses attain meaning within the framework of personal biography. Narrativizing illness enables other people to comment on the narrative and to offer new interpretations and suggestions. Thus, narratives serve as arenas or forums for presenting, discussing, and negotiating illness and how we relate to illness.

In the second area of research, the narrative is primarily *about* the illness; that is, the narrative conveys knowledge and ideas about illness (Kleinman 1988; Hunter 1991; Charon 2001). Examples are situations in which doctors and other professional care staff talk *about* the patient's illness. Several researchers emphasize the importance of the illness narrative as a means by which doctors acquire a more detailed clinical picture of the patient. The medical practitioner must become versed in the patient's narratives, not only in order to make a correct diagnosis, but also in order to propose a treatment program that is acceptable to the patient. Becoming acquainted with the patient's illness narratives also plays an important role in determining how the communication between doctor and patient develops (Clark & Mishler 1992) and how the patient experiences the information conveyed by the doctor. Charon (2001) has argued for the development of a “narrative medicine.” It is necessary for the doctor to learn the process of close, attentive listening to the patient in order to hear the patient's narrative questions, and to recognize that there are often no clear answers to these questions. Through emphatic listening a relationship is created that allows the

physician to arrive at a diagnosis, interpret physical findings, and involve the patient in obtaining effective care.

A third area of research is concerned with the *functions* narratives have in various contexts. One example of this is how narratives can be used as means of transforming individual experience into collective experience. Traditionally, illness narratives concern the *individual's* experience of illness. Several chronic illnesses (e.g., HIV/AIDS) pose the question of whether the narrative is able to *collectivize* the illness experience and ask what the social implications of illness are. An analysis of men who have been diagnosed as HIV positive, for example, shows how homosexual men reconstruct their identities and incorporate the cultural experiences of homosexuality into their life histories (Carricaburu & Pierret 1995). The illness experience is removed from the private sphere and becomes a part of an all encompassing political and social narrative and context. Through the narrative, the illness experience becomes a collective experience.

The study of illness narratives is a research area that is still growing. Important new areas focus on the way illness narratives are represented in various media like photos and film, and also the bodily enactment and performance of illness narratives in contrast to verbally performed narratives.

imagined communities

Paul R. Jones

Imagined communities is a term coined by Benedict Anderson (1983) in an influential book on the emergence and persistence of the nation. Anderson addresses a number of central sociological issues associated with belonging and cultural communities. A paradox of the modern age is that although many feel that the nation is our natural community, we do not know the vast majority of the other people who constitute this group. Indeed, Anderson famously defines the nation as *imagined* "because the members of even the smallest nation will never know most of their fellow members, meet them, or even hear of them, yet in the minds of each lives the image of their communion" (p. 6). The nation is defined as a *community* because "regardless of the actual inequality and exploitation that may prevail in each, the nation is always conceived as a deep, horizontal comradeship" (p. 7). Therefore, the concept of imagined community assumes that nations, national identities, and nationalism are socially constructed; "imagined" in this context then does not mean false, but instead points to the socio cognitive element in the construction of the nation.

Like many others working in this tradition, Anderson argues that culture is crucial to these constructions, placing major emphasis on the chance, yet highly dynamic, coincidence of the emergence of print culture and the development of industrial capitalism in the eighteenth and nineteenth centuries. Advances in printing technology, accompanied by increased literacy, allowed the concept of the nation to be disseminated through the media and through literature. The mass production of print also led to communication increasingly taking place within national linguistic boundaries and markets, allowing the emergent bourgeoisie to “imagine” themselves and to form new solidarities not based on family structures or religion. Indeed, the nation performs many of the integrative functions carried out by premodern religious cultural associations.

For Anderson then, the promise of the nation as an “imagined community” is both as a mechanism for social integration among strangers – a key concern for modern states – and a coherent narrative of progress based upon a constructed remembering and, just as importantly, a forgetting. The impression, albeit an illusion, is of a united group moving together through history and into a common future. In questioning how such narratives are constructed and maintained through culture, the concept of imagined community has become central to much sociological research on nationalism, ethnicity, and identity.

Imanishi, Kinji (1902–92)

Pamela J. Asquith

Kinji Imanishi was an ecologist, anthropologist, and founder of primatology in Japan. His basic view emphasized cooperation rather than competition in the natural world. This view held that “lifestyle partitioning” (*sumiwake*) among coexisting species explained the origin, or differentiation, of species. His concept of “species society” (*specia*) likewise focused on members of a species as a whole and their interactions with one another that maintain an equilibrium, rather than on the morphological differences and reproductive fitness of individual members of the species. He returned to these views many times in the course of his critiques of the predominance of natural selection theory to explain evolution.

Imanishi received a bachelor’s degree in 1928 from Kyoto University, specializing in entomology. He then turned to the relatively new discipline of ecology for graduate research, excited by the prospect of studying living organisms interacting with their natural environment. He received a Doctor of Science degree in 1940 from Kyoto University based on nearly 10 years of research on the ecology and taxonomy of mayfly larvae of various genera living in Japanese river torrents. In the next year he published his first and perhaps best known book, *Seibutsu no Sekai (The World of Living Things)*. This was a philosophical statement of his views on the origins and interactions of organisms with their environment and development of the biosphere. It was a pivotal book that related the views that had supported his biological work thus far, and out of which he developed most of his future ideas and projects. The book enjoyed several reprintings and was widely read by laypersons as well as scholars in Japan. English and German translations of the book were published in 2002 (Asquith et al. 2002; Wuthenow & Kurahara 2002).

As an undergraduate and graduate student he witnessed the considerable debate among western ecologists about the efficacy of natural selection theory to explain evolutionary

processes. He was to remain a lifelong “anti selectionist,” or critic of Darwinian and neo Darwinian evolution, though not of evolution itself.

His personal study notes and papers (dating from 1919 to 1980) reveal a probing, restless scholar with a huge capacity for synthesis and for fieldwork in several fields (Asquith 2004). From his student days he considered individual action upon the environment and recognition of the species society to be of paramount importance in understanding the life of living things. The idea of animals as active in selecting their own environments, rather than as passive organisms acted upon by chance, stemmed in part from migration studies among British ecologists. Charles Elton’s (1930) summary of factors likely to be important in evolution included, besides natural selection, sexual selection, “tradition” (or the transmission of learned behaviors between generations), the selection of the environment by individuals, and the spread of “indifferent” or non adaptive variations (that might be adaptive in another situation). A further reflection of the importance attached to sociality in determining biological outcomes was that social ecology in the 1920s and 1930s was considered to be a school within American sociology (Alihan 1938). Similarly, the well known *Animal Aggregations* (1931) by the University of Chicago’s W. C. Allee was subtitled *A Study in General Sociology*.

Part of what impelled Imanishi’s remarkably broad range of scientific interests was an accident of history. At every turn his research was cut off by world events, as he relates midway through his career (Imanishi 1966). He had planned a scientific expedition to Borneo to study orangutans during World War II, but conditions made that impossible. Instead, he went to Mongolia where he began field studies of the Mongol, a pastoral tribe. For this, he included study of the types of vegetation and its productivity on the Mongolian steppe as it formed the basis of the livelihood of the Mongol. In 1944 he became the first director of the Northwest Research Institute there. His studies in what would be called ecological anthropology found fruition many years later when one of his students founded the African Area Studies Research Institute at Kyoto University, which

conducts studies both of primates and of human ecology in Africa.

Imanishi left Mongolia in 1946 when the Institute was closed in the aftermath of the war. Shortly after his return to Japan he initiated various studies of naturalistic animal behavior, which soon became focused on Japanese macaques. Japanese primatology was founded through Imanishi and his students’ efforts in 1948. In 1950, at age 48, he became a lecturer in the Institute for Humanistic Studies at Kyoto University. In 1958 he traveled through Africa with his student Junichiro Itani to search for good field sites for studies of gorillas and chimpanzees. They also visited several pioneers of the developing primate studies centers in Europe and the United States. In 1959 he became Professor of Social Anthropology at Kyoto University. He also established the Laboratory of Physical Anthropology and in 1962 was appointed professor there too. After mandatory retirement from the Imperial University, he became Professor of Cultural Anthropology at Okayama University in 1965, and president of Gifu University in 1967, continuing actively to research and publish, particularly on evolution.

Imanishi’s extraordinarily broad and pioneering scholarly career was matched only by his mountaineering career and exploration (on which he also wrote prolifically). The latter was very much the basis for his inspirational example and popularity among the general public in Japan. He helped to found the still active Academic Alpine Club of Kyoto in 1931 and scaled over 2,000 peaks in Japan. During the early 1950s Imanishi led mountaineering expeditions to the Himalayas and his Japanese team was the first to ascend some of the peaks in the Annapurna range. His personal qualities and contributions were recognized twice by the Japanese government. In 1962 he was designated a “Person of Cultural Merit” and in 1979 he was named to the “Second Order of the Sacred Treasure.” Imanishi remained professionally active into his eighties. He died on June 15, 1992. Fifteen hundred people attended his funeral, including an envoy from the emperor.

Although Imanishi published comparatively few papers in English, the papers appear to mark turning points in the development of his ideas

and application to his researches. Very often he had published from one to several volumes in Japanese on major concepts that appeared in his English publications. Among these were papers on nomadism, development of the family, the evolution of personality, social behavior of primates, human and animal ecology, and, at the age of 82, a paper on his proposal for *shizengaku* (nature study) as a culmination of his efforts to dissolve disciplinary boundaries and mechanistic approaches to nature that he saw in the ever increasing specializations in science. Imanishi also found inspiration and a way to express his views in the writings of philosopher Kitarô Nishida (1870–1945). Nishida's view that every thing came from a single source and fit within a coherent whole was echoed in Imanishi's view of evolution and the current complexity of life. It is only up to us to find how the parts of the whole fit together. Imanishi set himself the task to try to understand the ecosystem shared by all organisms, living and non living.

Imanishi's influence extended far in the Japanese academy, even if it is sometimes only remembered by the most senior generations of scholars now. Those who accompanied him on his field researches and whom he sent on projects became professors, directors of institutes, and researchers in a great array of disciplines including anthropology, folklore studies, primatology, philosophy, ecology, and psychology. Imanishi referred to his human and animal studies as comparative sociological studies, and to his idea of the species society as a sociological concept. Critics of Imanishi's anti Darwinian views have suggested that these views were a reflection of his cultural and political viewpoint. However, his personal notes and papers reveal instead that he was in step with the debates surrounding natural selection theory – debates that only quieted after the modern evolutionary synthesis (bringing genetic bases to Darwin's theory) was formulated in the late 1930s. Imanishi was aware of all the advancements in genetic theory through the ensuing decades, but remained unconvinced by the priority of a single theory of evolution. The concept of species society is central to his views of the interconnectedness of things in nature. It is not just a conceptual construct, Imanishi noted, but it is an existent entity with an autonomous

nature, whose various individuals are continually contributing to the maintenance and perpetuation of the species society to which they belong. This shared life does not imply a conscious and active cooperation; rather, as the result of the interactive influences among individuals of the same species, a kind of continuous equilibrium results. The species society is a real entity in this world, or in other words, the world of species is a *social* phenomenon.

immigrant families

Karin Wall

Overall, the sociology of immigrant families represents a significant lacuna in the research on international migration. Although migratory flows have been interpreted as complex negotiations involving a diversity of actors including the individual, the family, social and kin networks, the market, and the state, other topics have polarized the attention of the social sciences. The political, demographic, and economic conditions of sending and receiving countries, on the one hand, and the patterns and corresponding consequences of migration movements for societies, in particular the survival or the elimination of ethnicity, on the other hand, have been the major concerns of classical migration research.

The neglect of the *immigrant family* is related to various factors. In the first place, sociologists underline the fact that immigrants were for a long time mostly workers and men. Women immigrants and children were few and only attracted attention when the intensity of family reunification, the settlement of families, and the integration problems of second generation migrants came to the forefront. Secondly, research shows that the feminization of migration and the diversification in women's patterns of migration have only recently become a noted trend. As Castles and Miller (1998) point out, women over the last decades became increasingly vital in all forms of migration in many regions and across the globe. Lastly, the linkages between sociology of the family and sociology of migration have been weak. The former has

focused on family change and organization in general rather than seeking to understand family trajectories and dynamics in the context of immigration. In contrast, gender studies have taken up the issue of migrant women and of women left behind more systematically, thus approaching the impact of immigration on family life from the perspective of women.

The invisibility of the family is, of course, relative. Indirectly, the immigrant family underpins many of the well known works on immigration, past and present. For example, Thomas and Znaniecki's *The Polish Peasant in Europe and America* (1918–20) analyzes the subjective experience and the integration of Polish immigrants – mostly young male workers but also married men who left families behind – by reference to the peasant family in Poland and to the maintenance of kinship ties, viewed as promoting adaptation, in the receiving country. The life stories also focus on the difficulties of the new nuclear families, labeled as *marriage groups* in order to distinguish them from traditional multigenerational families, in educating and controlling their children without the authority of the extended primary group. Changing family relationships and obligations, alongside the assertion of individualization in the host country, are thus a subtle but constant thread of interpretation woven into the analysis of the experiences of immigrant individuals.

In conceptual terms, immigrant families have been defined rather broadly as families that have one or more members who *moved from another country*: it may include only one member or both members of the couple (or a lone parent), and all, a few, or none of the children, as some may stay behind and others are born in the host country. A second approach is to define the immigrant family as one that relates to migration through a *variety of movements between countries*: some immigrate, some stay in the sending country, some come and go, others (children) go back temporarily. This type of *multilocal and multinational immigrant family* has become more frequent in a world of transnational mobility and communications. For labor immigrants, it is also stimulated by policies which are often restrictive in relation to family reunification and legalization. Members come or stay behind, remittances flow, and the family overarches two parts of the world, one rich, one poor. A third approach is to

define an immigrant family as one where every one in the family is an immigrant. This is the most restrictive definition and is probably less useful methodologically as fewer families meet this definition. Depending on the objectives of research, however, it is important to keep in mind the diversity in the criteria of definition as they are strongly related to the immigrant family's organization and identity.

The conceptual issue has not been high on the research agenda. Instead, research on migration and the family has traditionally worked along four main areas: the motivations of family migration; the forms of migration (how the family moves to another country); demographic trends; and the assimilation of immigrant families.

The decision to migrate is one of the oldest themes in migration research. Moving on from the simplistic idea of a push–pull model, research developed typologies which account for a variety of subjective and objective reasons, such as redundancy, poverty and hardship, aspirations based on the idea of searching for a better life, social rejection and political persecution, the wish to study or to specialize, starting a new life after divorce or single parenthood, the decision to marry or to obtain health care in another country, working for multinational firms or responding to offers for qualified labor in another country. All these reasons may apply to individuals or families, but immigrant families in mass migration have traditionally been linked to two motivational categories: hardship and the search for better life conditions.

Findings remind us, however, that family migration is a selective process and that the reasons leading up to the decision are frequently linked to other factors, such as close relatives who have already migrated – family networks stimulate and facilitate the migration process – or social contexts, such as the Caribbean or the Cape Verde islands, where, over the centuries, migration has acquired the quality of an all pervasive norm perceived as the only way of “making a life” (as L. Akesson describes it in her 2004 book of that title). Moreover, rather than searching for isolated motivations, research has emphasized that family immigration is linked to an ongoing *project* involving various aspects of family life: saving up, finding stable jobs in order to be able to build or buy a family

house, having children and giving them a better education and opportunities, helping elderly relatives in the home country, returning to the sending country with better living conditions (which may involve setting up a family business, buying farmland, or building a house in view of future retirement). The concept of a migration *project* has the advantage of underlining not only initial motivations but also the meanings of family immigration over time. These change and develop, depending, among other factors, on living conditions in the host country and on marital and parent–child relationships. Women from rural settings usually hesitate in returning after experiencing more egalitarian marital relationships and holding down full time jobs in the receiving society, whereas children often feel they belong to the host society where they were born or educated. As a result, parents may decide to return without adolescent or adult children, thus initiating a new coming and going between the countries. In summary, to understand family immigration as a *process* it is essential to analyze the migration project in time as well as the tensions and differing meanings of immigration within the family.

The forms of family migration have been roughly mapped out but inadequately analyzed concerning their impact on families. Family immigration is commonly associated either with *joint family* migration or a *man first* migration in which the male breadwinner arrives first and the family comes later (often referred to as *chain migration*). In the latter case, however, there may be various pathways into family immigration: the male worker, who may be married or single, arrives first, finds work and a home; if married, then the wife, with or without the children, comes later; if single, the worker either marries in the host country or returns home to find a wife. The impacts of the various *man first* forms of migration on the immigrant family may be quite diverse: for example, coping with marital separation entails a great deal of strain, but living with enforced separation from young children is highly stressful and leads to emotional and cultural tensions between parents and children. Other pathways may be mentioned: the male worker may form a new family in the receiving society while maintaining bonds with the family in the country of origin. On the other hand, single women, lone mothers, and wives

now frequently immigrate alone. In highly skilled couples, it is frequent for the wife to find a job first and for the husband to come later. In poor countries, unskilled single and divorced mothers are among the first to emigrate alone, often illegally, to work as domestic employees and health workers in order to improve the living conditions of children left behind with a grandmother. Unskilled lone working mothers may become lone mothers again in the receiving country, a situation often linked to immigrant lone parent poverty.

The demography of immigrant families has privileged the analysis of fertility, a research topic which has currently gained ground due to the policy issues surrounding aging populations in the receiving societies. Immigrant worker families have a high birth rate compared to the population of the countries they are living in. The migrants are young, and in the age group most likely to have children. They also come from countries where birth rates are high, although immigrant women tend to have lower fertility rates than comparable age groups in their home countries and that decrease over time. Analysis of immigrant family households has also shown that immigration stimulates the formation of extended horizontal families (young couples who lodge and support young relatives) rather than vertically extended families.

The permanence of ethnic minorities and the noted existence of female immigration and participation in the labor market led, in particular from the 1970s onwards, to more research on the assimilation and differing ethnicity of families and the children of immigrants (usually referred to as *second generation* immigrants). Regarding the process of assimilation, most research thinks in terms of a partial blending of cultures, with significant differences, nevertheless, according to the stronger or weaker ethnic contrasts (social, cultural, familial, racial) of the immigrant families in relation to the majority population group. Other theories have sought to go beyond the theory of assimilation or mutual acculturation. For example, Portes's notion of *segmented assimilation* (Rumbaut & Portes 2001) suggests that the children of immigrants assimilate to particular sectors of American society, with some becoming integrated into the majority middle class and others remaining in the inner city underclass. Rather than a mix of old

and new, this research shows that second generation migrants follow diverse trajectories into the receiving society.

Research related to immigrant families has thus centered essentially on the theoretical question of their integration or marginalization in the receiving societies, even if some work is also emerging on family dynamics. A recent study on the *reconciliation of work and family* in immigrant families in Europe showed that the first generation ones lack kin networks to support childcare as well as information on childcare facilities. Class and ethnic status cut across reconciliation strategies: skilled immigrant families resort to paid informal or formal care whereas unskilled labor families with low resources may have to manage by leaving young children alone, with other children, or taking them to work (Wall & São José 2004). Research on the dynamics of *mixed couples* has also been a recent topic of interest. Differences in culture, religion, and attitudes to family and gender roles often exacerbate the internal difficulties of married life (Barbara 1993).

Future directions in research, theory, and methodology are linked to the above mentioned development in the sociology of immigrant families. In methodological terms, systematic treatment of the typologies concerning motivations and forms of family immigration is needed if their impact is to be adequately understood. More emphasis on comparative work, across countries and different national origin groups, such as the research by Rumbaut and Portes (2001), is also to be expected in the context of continued and intense movements of families across the globe. On the other hand, diversification in research topics and theoretical approaches, considering the emphasis laid over the last decades on the paradigm of assimilation, represents an important challenge. Understanding patterns of marital, family, and intergenerational dynamics through the migration process may be one direction; stimulating linkages between gender studies, family studies, and migration research may be another pathway toward diversification.

immigration

Hans van Amersfoort

People have always been on the move. Some times they migrated over great distances, some times only a few miles, sometimes in regular circular movements in rhythm with the seasons, sometimes never to return to their place of departure. The study of such a general phenomenon requires a perspective from which to select the characteristics that we want to analyze. In studies on the micro level, the focus is primarily on individuals: the migrant's decision

whether to leave or to stay, his or her process of adaptation to the new environment, and so on. Sociologists, however, tend to concentrate on migration and its causes and consequences as a social phenomenon. The unit of analysis is not the individual migrant but the migration flow, not immigrants as individuals but immigrant populations and their characteristics. The volume of the migration flow, its demographic structure (e.g., only young males, whole families, etc.), and the homogeneity or heterogeneity of the immigrant population (the mix and levels of educational attainment) are all relevant variables for the description of immigration as a social phenomenon that cannot be studied at the individual level.

A second decision to be taken concerns the societal context of our field of study. Because migration is such a ubiquitous phenomenon, it has occurred and still occurs under very different circumstances. The world counts to date millions of people who have migrated of their own free will or who have been compelled to move by ethnic cleansing, civil wars, or natural disasters. The receiving societies differ fundamentally in nature and stability of state formation, to mention only one important characteristic. (Documentation of present day world migration is available at www.migrationinformation.org/GlobalData/.) A most important historical development impinging on migration processes has been the rise of the modern state, at least in the western world. The American and French revolutions signaled the birth of a state wherein government was legitimized not by patrimonial rights but by the will of the people. Government by the people for the people implied a distinction, between citizens and non citizens, between those who are part of the nation and those who are not. The amalgamation between government and people gave rise to the twin concept of the nation state. This modern state eclipsed in the course of a few centuries other institutions (notably the church) and became by far the most important institution regulating societal life. Especially after World War I, there was an increasing influence of the state on the labor market, in the field of housing, and with regard to education and medical care. The modern state became a welfare state and although there are differences between the western welfare states, they belong clearly to one family. With the rise of

the state as the dominant social institution, state borders became critical impediments for migration flows. The distinction between internal and external migration became accepted as a fundamental one for the analysis and assessment of migration processes. Neither geographical distance nor cultural differences between populations but state borders are at present the most relevant divides regulating human movements. Immigrants became defined as people settling in a country of which they are not citizens. Whereas in the nineteenth century the most important attribute of a citizen was the right to vote and to be eligible for public office, in the present day situation the most important attribute is the undisputed right of abode.

All welfare states have developed a three step system of migration regulation controlling entry, residence, and work. The states of the European Union, for instance, use the following categories in order to regulate migration: (1) nationals; (2) European nationals who have an agreed reciprocal right of residence and work; (3) foreigners, including (a) visitors: people who are supposed to stay only a limited period, sometimes subject to visa regulations but generally allowed to stay for a maximum of 3 months; (b) foreigners with a personal residence title, often tied to a job or function; (c) foreigners with a dependent residence title, such as children of legal residents; (4) (a) refugees: persons who are recognized as falling under the Geneva Refugee Convention; (b) asylum seekers: persons who claim to fall under the Geneva Convention, but whose claim is still under consideration.

Other welfare states use similar classifications to decide who is allowed to enter, reside, and work in the country. In all states migration control has become a political issue, often a very sensitive one, and studies about the regulation of migration and the links to other aspects of social traditions, definitions, and interests show a kaleidoscope of situations even within the category of welfare states, let alone in very different states such as the emirates around the Gulf (Cornelius et al. 1994; Brochmann & Hammar 1999). The definitions that look so clear on paper, for instance who is a refugee, in practice prove to be open to debate. The control of all visitors to prevent them overstaying their term and becoming illegal residents is virtually

impossible, and many an employer is happy to work with undocumented workers.

There are two different principles that guide the practical application of migration rules, as is already visible in the categories mentioned above. All western states have signed the Geneva Convention (1951) on refugees, as amended in New York (1967) and, for the countries of the European Union, refined in Dublin (1990). Whatever the practical definitions, the basic idea is clear: the ground for the right to enter, reside, and work in the country of immigration is based on the human rights of the refugee. The needs of the refugee immigrant supersede the interests of the immigration country. The consequence of this principle is that it is an open ended regulation, leaving the receiving states without any control over the number of entrants. No government is in practice prepared to accept this outcome. Hence, governments continuously modify the definitions and rules in order to contain the flows of these kinds of immigrants, without directly rejecting the treaties.

Implementation of the migration control mechanisms with regard to general immigrants depends on an evaluation of the following four aspects: (1) numerical consequences (does the country need more people?); (2) economic consequences (do the immigrants contribute to the economy or at least to certain sections of it?); (3) social consequences (what are the implications for the educational system, the costs of health care, the social housing program?); (4) cultural consequences (are the immigrants potentially people with strange and objectionable customs, with regard to women, for instance?). Leaving aside the special cases of spies, criminals, or international terrorists, these points determine the political discussions and policy measures with regard to immigration control. A distinction is made between good immigrants, who are expected to contribute to society, and unwanted immigrants, who are expected to become a burden rather than a boon. The last three factors converge in the more general question of whether the immigrants will ultimately be integrated into society.

The relation between immigrants and the host society, considered under various dimensions – assimilation, integration, incorporation – has been the main theme in the sociology of migration, especially in the United States. The

countries of the "New World" (US, Canada, Australia, New Zealand) had few doubts about the numerical aspects of migration, unlike European countries, with the notable exception of France. But the question of the role of immigrant populations in the society has always been on the agenda. Several ideologies and paradigms have played a role. It was soon clear that the massive immigration of the nineteenth century would change American society and that the immigrants would not all become white Anglo-Saxon Protestants. The idea that a homogeneous American culture would emerge from the mixture of cultures – American society as a gigantic melting pot – also proved to be too simple. Reality was more complex. Immigrants on the one hand became Americanized, but, on the other hand, they changed American society by introducing new religions, customs, and life styles. The great fears many Americans had about the immigration of Catholic Poles and Italians, not to mention East European Jews, proved unfounded. They did not become the average American, but they did become part of American life in the course of a few generations.

This last aspect, the temporal nature of immigrant assimilation, is emphasized in many studies by American scholars. Stanley Lieberman (1980) documented how, over a period of a hundred years, various immigrant populations found their way into American society, how separation and participation in central institutions (labor market, educational system) developed in a circular causation. Precisely because it is a complex process of several interlinked elements, immigrant integration is difficult to steer by policy measures. The first generation of an immigrant group, particularly if it is made up of a homogeneous, poorly educated population, is generally concentrated in neighborhoods where housing, schools, and public services are of inferior quality. This is clearly a consequence of their low incomes, which in turn result from restricted opportunities in the labor market. This lack of participation in society can also lead to low levels of achievement of the second generation in school. Factors that are positive in the short run (closeness to family or fellow countrymen, which reduces psychological tensions) may be negative when viewed from a longer time perspective. Still, however complicated the processes and whatever the variations in time

scale, regional factors, and other variables among various groups, the general conclusion has been that the immigrants adapted to American society and American society to them. It is precisely this overall conclusion that has been questioned by recent studies with regard to the present immigration situation.

The development of modern means of transportation and the globalization of the economy have resulted in unprecedented flows of people all around the world. Never before have there been so many travelers and migrants. This mobility raises the question of whether it is the numbers alone that have changed, or whether the new means of transportation and communication are contributing to the formation of new types of immigrant communities. Instead of the "classical immigrants" gradually shifting their orientation from the home to the host country, modern immigrants are supposed to remain oriented to the home culture. They are described as frequently traveling home, using television and websites to communicate among themselves, and adapting only partially, if at all, to the receiving society. They are not immigrants but transnationals. Such a general claim is difficult to prove or disprove, because first generation immigrants often have remained oriented to their homelands in many ways; on the other hand, maintaining contacts over long distances has undoubtedly become much easier. The question whether modern immigration is indeed different in nature, and therefore must have different consequences for the countries of immigration, is the subject of a recent study by Alba and Nee (2003). They summarize the classical American studies and scrutinize the evidence with regard to the assimilation of modern immigrant communities. They point out that an important aspect of modern assimilation is to be found in the rapid change in the economy and labor market. The American mainstream now looks different from the mainstream in the industrial era, but this is not to say that there is no mainstream and that immigrants are not assimilating to it.

During the past decades, western European states have also become immigration countries. Their situation in that respect has become similar to that of the classical immigration societies. Only France had, since the nineteenth century, already welcomed immigration as contributing

to the demographic strengthening of the nation. But France had, at the same time, always been confident that immigrants would become true French men and women in at most two generations. The centralized and strongly assimilative educational system would result in French citizens, whatever their surname or color. It is only during recent decades, when it became clear that the Muslim immigrants from North Africa were not assimilating in that way and remained recognizable communities, that immigration in France also became a sensitive issue. Were immigrants not threatening the integrity of the French Republic and becoming a source of cultural, if not political, separatism? As in other countries, the rise of international Islamic fundamentalist terror organizations has dominated the public discourse and greatly impeded an assessment of the role of immigrants in society. European countries other than France had no (recent) immigration tradition and had, on the contrary, regarded themselves as countries of emigration in the years after World War II. The UK and the Netherlands, as a legacy of their colonial past, had received postcolonial immigrants but regarded this as a historical accident, which would have no remaining consequences. It was only in the last quarter of the twentieth century that Western Europe realized that immigration was a permanent feature of its demographic and social development. In order to manage the immigration pressure that results from a fertility rate below replacement level in Europe and excessively youthful populations in other parts of the world, all European countries devised measures that aimed to keep the "good" immigrants in and the unwanted ones out. With the growth and further institutionalization of the European Union, the states of Western Europe try to arrive at a unified policy with regard to immigration. But a concept comparable to the American mainstream has as yet not emerged among these states, with historically different ideas of citizenship and different traditions with regard to the relation between public and private life.

immigration and language

Gillian Stevens and Jennifer M. Ortman

Languages are a means of communication, and provide access to cultural and social resources. The use of specific languages can also signify speakers' national and racial heritages. Because all but the very youngest migrants learn to speak in their country of origin, their language skills at the time of migration may not overlap with the language skills demanded in their country of destination. Any disparity between migrants' language skills and those of the receiving society results in a complex and multifaceted response involving individuals, communities, and societies. Individual level responses include language learning and language shift. Societal level responses to immigrants' languages may be formalized in policies governing the use of languages in various social domains. In a few cases, the languages themselves change.

LINGUISTIC ADAPTATION AND INCORPORATION

The language repertoires of societies and of their residents can shift in several ways when

immigrants enter a country. The languages introduced by immigrants can displace the languages spoken by the indigenous residents, as happened in the colonial US and in much of Latin America. More commonly, the immigrants are required to learn and use one or more new languages. The anticipatable difficulties associated with learning an additional language pressure prospective migrants to choose destinations in which their current language skills are useable. Migration streams thus form between countries that share a language, such as France and Morocco or the US and Canada. In spite of this selectivity, many migrants arrive in the receiving society without being conversant or literate in its major languages of communication.

Migrants who lack skills in a nation's dominant or official language(s) face formidable difficulties in adapting to their new society because the languages used by individuals in a society are laden with communicative, political, and cultural import. Migrants can encounter numerous communicative obstacles in major social arenas, and as a result often face diminished labor force prospects and other negative life outcomes. For example, poor oral and literacy skills in the destination country's dominant language(s) strongly depress occupational status and earnings among immigrant adults. In countries such as Germany and New Zealand, immigrants cannot become citizens without demonstrating proficiency in the country's official language. Moreover, the negative outcomes can persist into the next generation. For example, studies in a variety of countries, such as the US, Israel, and the Netherlands, show that children of migrants often encounter language based difficulties in school.

These negative outcomes pressure migrants and their children to learn the appropriate language(s). The first stage in the linguistic adaptation of immigrants is thus learning the society's dominant or official language(s). However, the political and social considerations dictating which languages migrants and their children should learn can be very complex, especially in multilingual societies. In Barcelona, Spain, for example, children of immigrants are pressed to learn three languages: Spanish (the national language), Catalan (a regional language), and English (as an international language).

In spite of the pressures to learn the society's dominant language(s), not all immigrants are equally successful. Research has identified a wide variety of factors associated with successful language acquisition among immigrants, but the most important factors are time, age at immigration, and education. In general, immigrants who have been in the country longer, who migrated in childhood, and who are more educated are more likely to be successful in learning a second (or higher order) language.

Sociologists generally interpret the strong positive association between length of residence in the host country and second language acquisition as the result of length of exposure to the opportunities and incentives to learn the language. The relationship may also reflect selection processes associated with return migration because migrants who are less motivated or less adept at learning the receiving country's major language are more likely to return to their country of origin. Sociologists attribute the strong and negative association between age at migration and second language acquisition as reflecting the participation of children in school, usually an intensive language learning environment. Many (but not all) sociolinguists interpret this association as reflecting the operation of maturational constraints (or critical periods), which result in children being able to learn a second language more successfully than adults.

The positive association between educational attainment and second language skills among immigrants also has several explanations. The costs associated with a continued reliance on a minority language, and thus the impetus for investment in second language proficiency, rise with educational attainment. Higher educational attainment among migrants may indicate exposure to, or formal instruction in, the language before arrival in the receiving country. Individuals with less education may have less practice exercising the cognitive skills required in learning a second language. Moreover, among very poorly educated adults, illiteracy in a first language impedes second language learning. Finally, it is possible that the causality is reversed and that migrants with better linguistic skills are better able to achieve more schooling.

Intergenerational language shift (or "mother tongue shift"), the next stage in the linguistic adaptation of immigrants and their families,

occurs when children learn only the society's dominant language(s) and do not learn their parent(s)' mother tongue. There are two ways to assess the extent of intergenerational mother tongue shift. The first is to directly compare children's language repertoires with those of their parents – an analytic approach that limits investigations to children living in the same household as their parents at the time the data are collected. Studies using this approach often show high rates of mother tongue shift between the first and later generations in countries such as the US or Australia. A second approach focuses on communal shift: the gradual substitution over an extended period of time of a minority or immigrant language with the society's dominant language.

The rapidity or extent of mother tongue shift (or conversely minority language maintenance) depends on numerous factors. The attributes of individuals, especially the parents, within immigrant families are particularly important because mother tongue shift presumes parents have learned and use the society's dominant language(s) with their children. Rates of mother tongue shift thus tend to be higher, for example, if parents are highly educated and have lived longer in the receiving country. Other considerations include the community and societal contexts. Rates of mother tongue shift tend to be lower (and levels of minority language maintenance higher) when the immigrant language communities are culturally cohesive, spatially concentrated, and larger in size. Societal considerations include the degree of tolerance of additional languages and the legal and social resources devoted to immigrant minority language populations and to minority language maintenance.

RECEPTION AND RESPONSE

The linguistic differences that historically mark immigrants as newcomers to a society include an inability to speak the society's dominant language(s) and fluency in some other language(s). Immigrants' language skills (or lack thereof) are easily observed by others and can therefore play an important role in the formation of attitudes and implementation of policies within the receiving society.

Immigrants' lack of proficiency in the society's dominant language(s) can be read as a reluctance to learn the language and thus a disinclination to participate in the society's cultural and political life. In extreme situations, lack of fluency in a dominant language is deemed a barrier to the integration of immigrants. In the 1910s, for example, when the "Americanization" movement held sway in the US, immigrants were herded into English language classes because they purportedly could not understand the ideals of the nation if articulated in any language other than English.

Even if fluent in the dominant language, fluency in an immigrant language can signify an individual's race, national origins, and status as an immigrant. The links between language skills and race, national origins, and nativity can incite xenophobia or nativism among the society's citizens. The use of an immigrant language can be viewed as evidence of continued affiliation with a racial or national origin group and in extreme cases can be seen as portending potential treachery, as happened with the use of German in the US during World War I. On occasion, the links between language skills and race have been enshrined in immigration policy and used to deny entry to prospective immigrants of certain races. During the first part of the twentieth century, for example, Australian immigration officials had the power to exclude any person who failed to pass a 50 word dictation test in *any* European language.

These types of responses can encourage governments to enact policies supporting or favoring the use of specific languages within a society. The policies are sometimes a response to languages introduced by recent immigrant groups. However, they sometimes seek to counteract the dominance of colonial languages, which were introduced by immigrants a century or more ago, by reviving or solidifying indigenous languages. Ironically, in many countries, the population prefers the colonial language. Hong Kong residents, for example, have resisted the recent attempt of the Chinese government to implement the use of Chinese rather than English as the medium of instruction in schools. South Africans prefer the use of English and Afrikaans in their schools and therefore strongly oppose the attempt of their government to revitalize

indigenous languages through a multicultural national language policy.

The government policies directed at contemporary migrants can concern the lack of skills in the country's dominant language(s) among prospective immigrants. Some countries, such as Canada and New Zealand, explicitly favor the entry of prospective migrants who demonstrate facility in the country's official language(s). Recent shifts in France's immigration policy require immigrants to sign an "integration contract" in which they agree to participate in language training and instruction on the values of French society in order to receive a ten year (rather than a one year) residence permit.

Government policies may also implicitly dictate the use of official or dominant languages in important social arenas such as schools, the judicial system, the health care system, the political system, or in the provision of social services. These policies often disproportionately affect immigrants and their children. But policies can also support immigrant or minority languages in important social arenas. These policies are often among the most complex and often contested. For example, there is an ongoing debate in the US on the relative merits of immersion, transitional bilingual, and immigrant language maintenance programs in schools.

LINGUISTIC SHIFT

When languages are "in contact" because two or more language groups share the same social space, sociologists generally concentrate on changes in what languages are spoken by migrants (or residents) and their descendants. However, the languages also can change, and new languages can emerge. For example, if the need (or opportunity) to communicate across language groups is very narrowly focused on trade or migrant labor, pidgin languages, which are restricted in vocabulary, can emerge. If learned by children, the pidgin becomes more complex because it is used within additional social domains, and is then often referred to as a Creole.

If a sizable number of migrants settle permanently in a receiving society, they can establish immigrant language communities. Because these communities are embedded in the larger society, the immigrants' language often

"borrows" words, or more rarely, elements of other linguistic structures, from the socially dominant language. A dominant language can also change. American English, for example, borrowed *kindergarten* from its early German immigrants, *shlick* from its early Yiddish immigrants, and *rodeo* and *macho* from its Mexican immigrants. Bilingual immigrants may also mix elements from the two languages in conversations, a phenomenon known as code switching.

Immigrants also often retain linguistic structures, especially phonological features, from their first language when speaking the society's dominant language. The result is often heard by linguistically naïve listeners as an accent. (Linguistic transference therefore aids the identification of immigrants as minority group members.) In some situations, a borrowed linguistic structure lingers into the linguistic repertoires of the immigrants' native born descendants. The result can be distinctive ethnic or geographically bounded dialectal communities sharing features such as the treatment of low back vowels among the Boston Irish and the /o/ fronting found among Philadelphians in the US.

immigration policy

Susan K. Brown and Frank D. Bean

Immigration policy specifies the laws and practices that allow persons to move permanently to other countries and petition for citizenship or to enter and stay for delimited lengths of time without the right to apply for citizenship. In developed countries, such policies include not only voluntary work and occupation based and family based migration but also the admission of refugees and the acceptance of asylum seekers. In its most comprehensive form, immigration policy not only involves the admission of immigrants, but also endeavors to coordinate labor needs with the control of migrant flows, affect international policies that might alleviate the need for some migration, and integrate newcomers into the socioeconomic fabric of the destination society. Immigration policies also often cover non immigrants, such as those who cross borders to travel, conduct business, work temporarily, visit, or study. Such policies also extend to the treatment of unauthorized immigrants, or those who enter a country without a visa or who overstay a visa, although the presence of such persons in the country does not directly result from admissions policies.

Immigration policies vary across countries, although relatively few countries receive many international migrants and have formal migration policies in place. Traditional migrant receiving countries such as the United States or Canada have tended to try to control who enters their borders through visa systems. Continental countries, such as Germany, that had not considered themselves migrant destinations despite decades of immigration, have tended over the years to control migration through residence and work permits, the parameters of which might become more favorable the longer

migrants stayed. While such distinctions of policy emphasis have blurred in recent years, policy conceptions between the traditional immigrant receiving countries still perceive of policy differently from new immigrant destinations.

Until the late nineteenth century, none of the major immigrant receiving countries sought to adopt laws and practices to regulate migration, nor did they mount substantial efforts to control the magnitude of immigrant flows. To a considerable extent, this owed to the relative absence of political forces compelling such restriction. Nativism was a relatively small cultural current in early nineteenth century America; most Americans at the time – as well as Canadians and Australians – understood that they needed to populate and settle their countries. After decades of flows of settlers, however, anti immigrant activity began to arise in the United States in the mid nineteenth century, first against Catholics, particularly the Irish but also the Germans; then against Asians, starting with the Chinese and moving on to Japanese and Filipinos; and then against all immigrants, particularly as immigrant flows were increasing from southern and eastern Europe.

By the late nineteenth century, the major immigrant receiving countries were beginning to restrict migration in response to anti immigrant sentiment. In the United States, the Chinese Exclusion Act of 1882 initiated an escalating series of limitations that culminated in the national quotas set in the Immigration Act of 1924. In Canada, legislation in 1895 barred those whose incapacities rendered them likely to become public charges, those with moral flaws, and those considered “racially and culturally unassimilable” (Lynch & Simon 2003). In 1923, Canada further prohibited most Chinese and other Asians. Meanwhile, Australia set up a dictation test in 1901, together with restrictions on public charges, the insane, prostitutes, and contract laborers. The dictation test – 50 words in any European language – effectively restricted immigration to Europeans.

THE GROWTH OF INTERNATIONAL MIGRATION

International migration (defined as legal movers from one country to another plus refugees and

asylees) grew in the latter part of the twentieth century. Although according to the United Nations it was only about 3 percent of the world's population in the year 2000, international migration has been rapidly increasing, with the global number of such migrants more than doubling in the latter third of the twentieth century. For example, the United Nations Population Division estimates a rise from 75 million to 175 million international migrants between 1965 and 2000. And the increase occurring over the last 15 years of this period (1985 to 2000) represents a rate of growth of more than 4 percent per year, more than two and a half times the 1.5 percent annual rate in overall population growth. Most of this in migration is concentrated in the developed countries, where international migrants make up almost 9 percent of the population overall. This proportion varies, from just over 1 percent in Japan to 21 percent in Australia to nearly 35 percent in Luxembourg as of 1997. Among the OECD countries, many of which have birth rates below replacement, immigrants account for about 65 percent of population growth.

Countries thus vary substantially in their concentrations of international migrants. Some nations, like the United States, have always been known as immigration countries (that is, as countries whose policies allow for substantial immigration). Others, like Japan and Spain, for example, have not. Still others, at least until recently, have not either seen themselves or been known as immigration countries even though they in fact have been or have become countries of immigration. Germany is a case in point. Like most developed countries in the world, Germany now receives migrants from elsewhere, either legally or "illegally." Most of the industrial countries of the world are now experiencing immigration, even though many have not yet come to view themselves as immigration countries. Certainly, the movement of peoples from country to country affects politics and economics both nationally and worldwide. Yet immigration policies often reflect these countries' ambivalence toward immigration. In 2004, Germany opted not to institute a point system to select immigrants with high levels of human capital but to maintain its recruitment ban (although with some limited exceptions for scientists, managers, and the self employed).

RECENT IMMIGRATION POLICY IN THE UNITED STATES

Because the United States receives by far the most immigrants of any country, US immigration policy deserves special mention. The immigration quotas of 1924, which curtailed immigration from Europe, were the culmination of 75 years of rising nativism. Four decades later, in the civil rights era, the Hart Celler Act lifted those quotas and established family reunification as the preeminent criterion for admission. By abolishing race and ethnic origin as grounds for exclusion, the act set good relations with recently independent Asian countries, but it also inaugurated an era of unforeseen expansion in immigration. While Canada and Europe contributed relatively few immigrants, more and more came from Asia and Latin America.

The end of the Bracero program for temporary workers from Mexico in 1964 also led to a major increase in unauthorized migration. The use of Mexicans as a source of labor was institutionalized throughout the Southwest, and demand for such labor was rising even as population growth in Mexico generated many more people than Mexico could employ. As the US economy slowed dramatically in the 1970s, even as the stream of immigrants picked up, debate grew on how to deal with the migration of low skilled workers, particularly those who were unauthorized. In 1986, Congress passed the Immigration Reform and Control Act (IRCA), which made it illegal to hire workers lacking appropriate documents, though this provision of the act has not been heavily enforced (Fix & Hill 1990). IRCA further made longtime unauthorized aliens and agricultural workers eligible for legalized status. The act also authorized spending \$4 billion for states' costs in providing public assistance, health care, and education for the newly legalized population; required states to verify that non citizens were eligible for welfare benefits; and expanded enforcement of the border patrol and inspections. Though the act did not succeed in curbing unauthorized migration, through 1994 it helped about 2 million unauthorized migrants become legal.

In 1990, a new Immigrant Act capped overall immigration for the first time since 1924 at

700,000 until 1994, and 675,000 thereafter, with unlimited visas for immediate relatives of US citizens. But the term “cap” is misleading, in that the cap exceeded the existing levels of family admissions and could be pierced under certain circumstances. The law also increased the number of visas for workers and shifted the preference toward skilled and professional labor. Furthermore, the act set up “diversity” visas for citizens of countries less likely to send immigrants to the United States.

In the aftermath of a backlash against immigrants that began in California, the United States began to emphasize border control and tripled its spending on border enforcement between 1993 and 2004. The Illegal Immigrant Reform and Immigrant Responsibility Act of 1996 further tightened US borders, particularly in the Southwest, and stiffened the penalties for smuggling, visa fraud, and illegal entry. The act, together with the welfare reform act of the same year, restricted the rights of non citizens to obtain federal means tested benefits, such as food stamps or Supplemental Security Income.

Mexican Immigration and US Policy

Special mention should also be made of Mexican migration, because Mexico has sent more legal immigrants to the United States between 1964 and 2004 than any other country, as well as the largest number of unauthorized migrants. The high profile of Mexican migration for US policy is relatively new. Until recently, Mexican migration, compared to that from other nations, was not particularly large and, in practice if not always in law, relatively unrestricted, with exceptions such as the repatriation of large numbers of Mexican migrants in the 1930s and again in 1954. Compared to the massive immigrations from Europe in the last half of the nineteenth century and the first decades of the twentieth century, Mexican immigration contributed only a small part of US population growth until recently. Its pre World War II peak occurred in the 1920s when the economic disruptions of the Mexican Revolution (1910–20) and the civil wars that followed led many Mexicans to migrate to the United States in search of jobs. In the 1920s,

459,000 Mexicans were registered as immigrating to the United States, equivalent to 3.2 per cent of the total Mexican population in 1921. These numbers of Mexican immigrants were not to be surpassed until the 1970s, but they were not exceptional. Several European countries, Italy, Germany, and the United Kingdom, contributed similar numbers of immigrants, while twice that number of immigrants came from Canada in the 1920s. Even Ireland, long past the peak of its contribution to US population growth, sent a higher proportion of its population as immigrants to the United States than did Mexico in these years. Some 5.2 per cent of the Irish population immigrated to the United States in the 1920s, despite the attainment of Irish independence that removed one of the major ostensible causes of Irish emigration.

Not only was Mexican migration not particularly voluminous, much of it was temporary in nature. Partly as a result, Mexican immigrants have had one of the lowest naturalization rates of any immigrant group. Census figures also suggest substantial emigration out of the United States by Mexican immigrants. While 728,000 Mexicans are recorded as immigrating to the United States between 1901 and 1930, the numbers of the Mexican born population in the US in 1930 amounted to 641,000, and these would have included many who had not documented their immigration. By 1950, the Mexican born in the census had dropped to 452,000, reflecting not only mortality and the low level of immigration after 1930, but also the forced repatriations of Mexicans in the 1930s. There are no satisfactory estimates of Mexican return migration to Mexico, but it is clear the amount of return migration has been quite high in virtually all years.

Unauthorized Mexican Migration

Mexican migrants to the United States until the 1960s were predominantly employed in types of work that were temporary and seasonal in nature. The rapid expansion of Californian agriculture depended on a seasonal labor force. So long as unauthorized Mexican migrants wished to return to Mexico, the arrangement suited both sides. Until the 1970s, most Mexican migrants did in fact wish to return;

but in the last three decades of the twentieth century, Mexican migration not only increased in volume, it also more and more involved longer term migration. A major reason for this shift toward permanent immigration was and continues to be the gradual erosion of the economic viability of small scale agriculture in Mexico, a change that has at once promoted migration to large metropolitan areas within Mexico and discouraged Mexican US migrants from returning to and investing in small town and rural Mexican villages and enterprises.

Because so much of Mexican migration has been unauthorized (i.e., occurring outside the framework of legal immigrant visas), US immigration policy has often given special policy attention to this type of migration. This reflects in part the United States' longstanding ambivalence about unauthorized labor migrants, particularly unauthorized migrants from Mexico. A good example of this ambivalence can be found in the now eliminated policy contradictions embedded in the so called "Texas proviso," a quirk of US immigration law for nearly 30 years which – until 1986 – made it legal to hire unauthorized workers (e.g., to employ them to take care of your lawn) but illegal to harbor them (e.g., to invite them into your home for a drink of water). Such anomalies have exemplified US policy approaches to unauthorized Mexican migration for several decades, practices that have repeatedly consisted of sporadic and highly public efforts to intercept unauthorized Mexican migrants as they cross the border into the United States (i.e., to "control the border") while "turning a blind eye" to migrants who enter via other means. Although messy and unseemly, this awkward mixture of *de jure* and *de facto* strategies served the interests of conflicting constituencies reasonably well. Agricultural and other employers of low skilled workers who tend to favor the easy entry of unauthorized migrants continued to benefit from a rather steady flow of workers, whereas citizens who worry about the social, cultural, economic, and legal implications of such migration have been able to take solace in at least periodic efforts at border enforcement.

That such largely ad hoc arrangements have not been entirely satisfactory is evident in the numerous legislative efforts of one kind or another mounted during the post war era to

curb such migration, usually attempts taking place after periods of high unemployment. One of these occurred in 1986 when Congress adopted the Immigration Reform and Control Act introducing civil and criminal penalties for hiring unauthorized workers. Another occurred in 1994, when Congress ratified the North American Free Trade Agreement (NAFTA), a treaty whose negotiation expressly avoided dealing with migration matters but whose political marketing widely promised that it would generate effective migration control through enhanced Mexican economic development. And in 1996, also following the economic recession of the early 1990s, Congress sought to reduce the attractiveness of migration by limiting immigrant access to social services.

Despite these legislative efforts, however, illegal migration to the United States has apparently not diminished, even though it has sometimes been temporarily reduced either by slowdowns in the economy or short term responses to legislative initiatives. This lack of abatement has caused many observers to argue that efforts at border control and enforcement are largely futile, that the pressures for entry into the countries of the world enjoying the strongest and most advanced economies are so great that border and migration control efforts inevitably fail (Cornelius et al. 2004). Others have argued that control policies, especially border enforcement emphases, are not merely ineffective but even counterproductive, at least in the case of Mexican unauthorized migration to the United States. Recent more strict enforcement policies have been argued to generate longer US stays on the part of circular migrants who might otherwise have remained in the country for shorter periods of time were it not for the fact that crossing the border had become more difficult. Whatever the case, the apparent persistence of migration under conditions of economic slowdowns and increased border enforcement raises new questions for future immigration policy research about the effectiveness of implicit and explicit policy efforts to control migration.

imperialism

Alberto Toscano

Imperialism designates the historical phenomenon whereby certain political entities have sought to exert control over and extract resources from others, whether through formal conquest, informal coercion, or a host of intermediate solutions (e.g., protectorates, alliances, occupations, and so on). It also denotes the multiple concepts or theories of imperialism, which continue to be the object of controversies that easily exceed the realm of academic debate, especially since “imperialist” still largely remains a term of reprobation. Initially coined to designate the existence and expansion of empires (from Ancient Rome to Napoleonic France), the notion of imperialism gained prominence in the late nineteenth century, when it came to identify the reality of European colonialism (from the British Raj to the “scramble for Africa”). The ensuing history of the concept registers a distinction between, on the one hand, purely political definitions of imperialism, which reduce it to an instance of power politics and foreground the issue of territorial gain, and,

on the other, socioeconomic analyses, which, while not discounting the significance of physical expansion, emphasize the underlying and often invisible causes of imperialist policies, thereby accounting for the influence of material factors on geopolitical decisions. The penchant for a given concept or theory of imperialism invariably determines which processes and events count as cases of imperialism, so that analytical definitions are here inseparable from historical judgments.

The acceleration in colonizing ventures during what Eric Hobsbawm has termed the “age of empire” gave rise to the first great debates on imperialism. At first, imperialism served to designate a policy of nationalist expansion and international competition. It was also marked by the sense of a European civilizing mission, the so called “white man’s burden.” The expansionist ideology was sustained by quasi vitalist ideas of the need for certain nations to expand politically, economically, and culturally (as testified, for instance, by some of Weber’s writings on Germany). Liberal opposition to imperialism attacked what it regarded as a jingoistic manipulation of mass sentiment for irrational ends or petty interests. In Schumpeter’s analysis, this led to a focus on the use of irrational and “objectless” nationalist tendencies to condition the popular masses, and to promoting a democratic free market polity that could sap the drives towards monopolization and hyper exploitation both at home and abroad. Where Schumpeter defined the causes of imperialism as primarily sociopolitical in character, Hobson’s *Imperialism* opened the way for its structural analysis as a necessary correlate of a particular socioeconomic order. While also highlighting the manufacture of expansionist consent against the very interests of the masses, Hobson contended that imperialism was driven by the needs of financial elites and monopolies which, failing to get sufficiently profitable returns on their investments in a saturated market constrained by the low purchasing power of workers, pushed for the forcible opening of overseas opportunities.

Hobson’s ideas were of great import for what is certainly the most read and influential tract on the subject, Lenin’s 1916 *Imperialism, the Highest Stage of Capitalism*. Compensating for the insufficient theorization of imperialism in

Marx’s own works, Lenin followed Hobson in seeing finance and monopoly capital as the key factor (a position also held by Hilferding and later by Baran, Sweezy, and Magdoff). In the midst of World War I, Lenin tried to understand that conflagration as an effect of the conflict between great capitalist powers, now held captive by increasingly parasitic financial oligarchies (this theory of imperialist conflict is juxtaposed with Kautsky’s theory of imperialist convergence, or “super imperialism”). This was, of course, a contradictory phenomenon, which saw both a seeming decay in the capitalist system as a whole, as well as an increase in the “socialization of production.” Importantly, Lenin also interpreted imperialism in a strategic political vein, and pushed for the formation of an anti imperialist front and the reconsideration of nationalism as a weapon against capitalism. Rosa Luxemburg, in her 1913 *The Accumulation of Capital*, also attempted to integrate a political critique of the age of empire with an economic analysis – founded on the idea of underconsumption and capitalism’s constant need to expand to non capitalist zones to create markets and realize surplus value. She also introduced the analysis of “militarism” both as an ideological tool and as a component (in the guise of the arms industry) of capital accumulation under conditions of imperialism, an analysis later expanded upon by Ernest Mandel in his *Late Capitalism*.

Marxist theories of imperialism – whose economic parameters have repeatedly come under attack by liberal economists and social theorists – grew in political significance and conceptual variety in the post war period, as they came face to face with the Cold War (especially in Vietnam, but also in terms of the vexing question of “communist imperialism”) and decolonization (which spawned neo Marxist theories of dependency and “modernization” *qua* products of imperialism). The ebb of theories of imperialism in the 1980s seemed terminal, especially as the analysis of the political economy of the world market came under the aegis of globalization theories. Even from the Left, namely in the theory of “Empire” as a new form of virtual, decentered capitalist sovereignty, the notion of imperialism appeared to be relegated to another era, when capitalism was still, to use Marx’s terms, in a phase of formal and not real

subsumption. Reaction to the work of Hardt and Negri paradoxically laid the ground for a renaissance in the theorization of imperialism, a renaissance that became all the more timely in the wake of the invasion and occupation of Iraq by the US and the UK in 2003. The justification of the war in terms of security and democracy, together with Iraq's massive oil resources, have inevitably spurred new attempts to link the economic and political aspects of imperialism. "Empire" is no longer used so much to designate a placeless system of power, and is frequently qualified as "American," leading to a renewal of the debate – prominent in the 1970s – over whether America's form of primarily non territorial economic power and influence should be defined as imperialism. David Harvey and Ellen M. Wood, two prominent Marxist theorists, have answered in the affirmative. The first, following Giovanni Arrighi, argues that the "new imperialism" must be understood in terms of two conjoined but irreducible logics: a territorial logic of political power and a molecular logic of capital accumulation. He thus regards the war as a means of securing American hegemony over energy resources and thus bolstering its increasingly labile standing in the world economy. Wood, in what is perhaps the boldest restatement yet of the theory of imperialism, defines capitalist imperialism – as opposed to previous empires of property (China, Rome) and empires of commerce (Arab Muslim, Venetian, Dutch) – in terms of the detachment of economic from political power. However, this economic power demands for its hegemony and expansion the presence of a system of multiple states, and the more globally integrated the system, the greater the tendency to the hegemony of one of these states (i.e., the American "empire") over the task of maintaining the capitalist system. Updating the methods of historical materialism, Wood thus returns to the key theme already broached by Luxemburg: the intimate correlation between capital accumulation, on the one hand, and expansionist or interventionist militarism, on the other. In historical terms, the study of imperialism has also been reinvigorated by an attention to its interaction with ecological factors, namely in Mike Davis's groundbreaking research on the murderous exacerbation of famines by imperial policies in his *Late Victorian Holocausts*.

implosion

Karen Bettez Halnon

French postmodernist critic Jean Baudrillard's theory of implosion is one of social entropy, wherein he asserts that a consumer age of information, media, and mass media has ushered in an accelerated and coercive hyperproduction of meaning and information to the "irrational" and "terroristic" extent that all meaning, knowledge, and subjectivity, and the "social" itself, are neutralized and ultimately collapse. All that is left, he says, is an imploding "mass," described dramatically as "an in vacuo aggregation of individual particles, refuse of the social and of media impulses; an opaque nebula whose growing density absorbs all the surrounding energy and light rays, to collapse finally under its own weight" (Baudrillard 1983: 3–4). In other words, amid ubiquitous and proliferating media generated information in a consumer society of simulacra and simulation, information ceases to be productive, in the sense of transformation of it by human

subjects. It is destructive energy, producing even more implosive density, more mass. Best and Kellner (1991: 121) further summarize Baudrillard's theory of implosion, a basic point of reference for postmodern theory: "The social thus disappears and with it distinctions implode between classes, political ideologies, cultural forms, and between media semiurgy and the real itself . . . Baudrillard is not only describing a series of implosions (that is, between politics and entertainment, capital and labour, or high and low culture) but is claiming that the society in its entirety is implosive."

Baudrillard claims that the only "imaginary referent" remaining in a world of simulacra and semiurgy are the non subject, non object "silent majorities," or the purely "crystal ball" statistical morbid remains of status groupings. The "singular function" of the silent majorities is to absorb all meaning, but not refract it. Stated otherwise, having "become bored and resentful of their constant bombardment with messages and the constant attempts to solicit them to buy, consume, work, vote, register an opinion, or participate in social life," the "masses thus become a sullen silent majority in which all meaning, messages, and solicitations implode as if sucked into a black hole" (Best & Kellner 1991: 121).

Baudrillard claims there is a "fantastic irony" in the muteness of the masses and their "exasperating endless conformity" (Baudrillard 1983: 33). While "at no time are the masses politically or historically engaged in a conscious manner" (p. 38), they have only one practice: a "collective retaliation," a "refusal to participate" (p. 14). Baudrillard says, for the inert, indifferent, passive masses, the only non conscious "strategic resistance" to the present phase of the system is that of a "refusal of meaning . . . the hyperconformist simulation of the very mechanisms of the system, which is a form of refusal and non reception" (p. 108). Forestalling any interpretation of the defiantly apolitical, he says, "the denial of meaning has no meaning" (pp. 40–1).

Explicitly challenging both critical theory and psychoanalytic interpretations that claim mystification or alienation, or that develop schemas aimed at liberating oppressed or repressed subjects, Baudrillard says that implosion "is inevitable, and every effort to save the principles of

reality, of accumulation, of universality, the principles of evolution which extol expanding systems, is archaic, regressive or nostalgic" (p. 60). In particular, with the death of human subjectivity and the "social," Baudrillard's theory of implosion declares the end of sociology and sociological inquiry. However, if it is any consolation, the continuity of an intellectual elite that thinks, acts, and interprets (aimlessly) outside or above "silent majorities" is implicit in Baudrillard's theory of implosion.

impression formation

Christopher D. Moore

Impression formation is the process by which individuals perceive, organize, and ultimately integrate information to form unified and coherent situated impressions of others. Internalized expectations for situated events condition what information individuals deem is important and worthy of their attention. Further, these expectations condition how individuals interpret this information. In face to face interaction, social cues including others' physical appearance,

verbal and non verbal behavior, and the social setting in which the exchange takes place combine with information in perceivers' memories to influence the ways in which they initially form impressions of others and themselves. These initial impressions serve as the basis for subsequent attributions.

Key findings regarding impression formation come from a variety of theoretical literatures. Most notable are social cognition theories, expectation states theory, and affect control theory. Specifically, research in social cognition provides explanations of general information gathering and processing, expectation states theory offers additional insights with regard to information integration, while affect control theory highlights the importance of affective meanings to the process of impression formation and provides a testable mathematical calculus designed to predict its outcomes.

PERCEIVING SOCIAL INFORMATION

Once raw information about a social object is gathered, it is organized and integrated to form a coherent conceptual impression of the social object. Cognitive limitations in our capacity to both perceive and process information affect the impressions we form about others. Specifically, we are limited in what we can pay attention to in a social situation, and we also rely on cognitive shortcuts to quickly and efficiently manage the information that we do gather. In addition to cognitive limitations, our social experiences serve to form preexisting expectations for events that affect the nature of information we notice and how we then interpret it.

Most people believe that first impressions are very important. Research in social cognition and related subfields extends this view by highlighting how the temporal ordering influences the processing of social information. For example, a concept related to the importance of first impressions is the *primacy effect*. The primacy effect is said to have occurred when individuals weight information acquired early in an interaction more than later information.

While the process of impression formation begins with perception, it is important to also consider that individuals' preexisting internalized expectations for how they expect events to

unfold serve to sensitize them to specific features of situations over others. The relative degree of attention given by an individual to a specific social object is a measure of that object's *salience* to that person. An object's salience also stems from the relationship between it and the social context. Specifically, any characteristic about a social object/person that provides an observer with a basis to differentiate it from other similar objects or others (however categorized) may make that characteristic more salient, and thus more likely to be usable as a cue for defining said object/person. For example, the relative height of another is less salient if the observer is of approximately the same height as the other who is being observed, or if said other is in a room populated by similarly statured individuals.

Once individuals form preliminary impressions about others, the evaluation of new information is often subject to the *confirmation bias*. This bias is in operation when individuals seek out or disproportionately favor new information that confirms their existing views. As interactions continue, new pieces of information that "fit" within the initially evoked schema are readily used to elaborate and bolster it, while potentially disconfirming information is treated with suspicion. The outcome of this process, through which individuals form general attitudes toward others by weighting the salience of new information more favorably if it matches what they already "know," is called the *halo effect*.

Alternatively, information that is "old" or sparse (e.g., not bolstered by subsequent readily available confirming information for extended periods of time) may be supplanted by new challenging information. Specifically, the "newness" of information may be such that it makes it more likely for it to earn the attention of observers simply because it is part of the immediate local situation. Thus, not only can early information be disproportionately weighted in terms of an individual's impression formations, but the most recent items of information – those that are freshest in one's mind – may also carry more than their "fair share" of weight with respect to impression formation. When this occurs, it is called the *recency effect*. These effects are difficult to self monitor and consciously control and they may be related to a wide range of other

biases such as ethnocentrism, groupthink, and self serving bias.

An illustration of how individuals form impressions of others is found in a classic research study conducted by Solomon Asch (1946). In this study, a number of people were shown a series of seven adjectives describing an unidentified person's personality characteristics. All conditions contained the following six adjectives – intelligent, skillful, industrious, determined, practical, and cautious – but varied on whether the seventh characteristic was either warm, cold, polite, or blunt. These adjectives represented the first (and only) pieces of information that the participants were given about the unidentified other. The participants were then asked to describe the person to which the list pertained by selecting from a list of other descriptors: generous, wise, happy, good natured, reliable, and important. The goal of this study was to see if individuals form organized impressions of others based on a combination of what they perceive and what they then assume to be likely given that information. Asch found that the participants who were shown lists containing the trait "warm" were more likely to rate the unidentified person as generous, happy, and good natured; whereas the participants who were shown the list containing the trait "cold" most often rated the unidentified person as stingy, unpopular, and unhappy. Further, when participants were shown either lists containing the traits "polite" or "blunt," their assessments of the unidentified person did not significantly differ. Asch concluded that hot and cold acted as *central organizing traits* with respect to how these individuals formulated their impressions of the unidentified person. These traits were especially important because they colored the participants' interpretation of other traits they also were shown such that the impressions they formed about the person the lists purportedly described were very different.

Individual traits are more than mere additive pieces of information; they are components that operate in relation to one another to form a gestalt picture of an individual. We do not perceive individuals as a collection of itemized traits, but rather these traits invoke images in their perceivers' minds of a complex assortment of meanings and expectations that then subsequently serves as the basis for further social

attributions. Asch referred to individuals' beliefs about how personality traits are related as *implicit personality theories*. These beliefs may also be thought of as trait schemas or personality stereotypes in that both of these terms also highlight the dynamic and abstract nature of these beliefs, as opposed to equating them only to a collection of specific traits.

ORGANIZING AND INTEGRATING SOCIAL INFORMATION

Expectation states theory provides a particularly useful and well supported explanation of how the social information is aggregated into organized subsets to form impressions of self and others (Berger et al. 1992). Specifically, to explain the effects of multiple and sometimes contradictory pieces of social information in situations, these researchers argue that all salient status information is combined for each actor to form an aggregated expectation state, with the difference between the focal actor's and others' aggregated expectation states representing the focal actor's expectation (dis)advantage. In other words, all salient information is organized into subsets analogous to person schemas, which then serve as the basis for the emergent status and influence arrangement of the group. Further, these researchers also demonstrate that an attenuation function operates with respect to additional pieces of supporting information such that at some point, for example, there is a diminishing independent effect for each additional piece of information favorable to group leaders' expected competence on their overall status in the group. Also, new information is likely to have a greater independent effect on status outcomes when presented in opposition to a field of contrary information than if it were presented alone.

Inconsistent information affects impressions in other ways. For example, changes in observers' evaluations of others may occur if they observe others behaving in ways that challenge their initial expectations for them. For example, if a presumably good and nice person behaves cruelly toward an also good but weaker other, an observer's evaluations of the first person in this case might be reassessed in light of this action unless the observer can somehow

otherwise justify the act. Such a justification may involve adjustments to the observer's definition of the action itself (e.g., it was not really that violent and hurtful after all), or perhaps to the observer's definition of the presumably "good but weaker other" (e.g., he actually deserved the treatment). Notice how each of these strategies involves the reassessment of some information, be it that which comes from the local situation or that which resides in the observer's memory. Also note that the schemas upon which the observer's expectations are based do not change; rather, adjustments are made with respect to "fit" between what she observes in the local situation and how she cognitively categorizes it.

Affect control theory (ACT) offers a mathematical formalization of the impression formation process that synthesizes elements of symbolic interactionism and role theory. Our understanding of the impression formation process owes much to ACT. According to ACT, individuals see themselves and the others around them as participating in situations by enacting social roles. Each person forms his or her definition of the situation by assigning an identity label to self and others after comparing the readily observable characteristics that each person possesses with internalized cultural expectations for what identities are appropriate given the setting they are in. ACT quantifies the affective definitions of these assigned labels on three dimensions: evaluation (goodness versus badness), potency (powerfulness versus powerlessness), and activity (liveliness versus passiveness). These dimensions have been shown to capture the culture specific sentiments that individual actors (A) form about self, behaviors (B), other social object/persons (O), and settings (S). The core ACT argument is that individual actors will try to create behaviors that maintain their symbolic meanings of A B O S situations. Once an individual has defined the setting and the actors/objects in it, cultural rules pertaining to these definitions provide the basis from which she can form expectations for the events (behaviors) that are likely to occur between herself and the others in the situation.

When the meanings of events interpreted from individuals' own localized experiences do not match those they anticipate, given their definition of the situation, ACT predicts they

will act to restore them. In particular, ACT researchers argue that social events create predictable changes in individual actors' feelings and impressions about the situation. The localized (transient) impressions individuals form in the context of situations are compared to their preexisting (fundamental) sentiments about the identities, behaviors, and setting that they are in. If events unfold such that individuals' experiences become out of line with their initial expectations for a situation, ACT predicts they will act to restore this balance. Importantly, ACT shows both how cognitive definitions of situations lead to impression formation, and how impressions from events can operate to maintain or change the definition of situations. Research in ACT has shown that this process applies to the meanings of the entire A B O S situation.

ACT researchers often utilize a computer program, INTERACT, that contains several culture specific dictionaries of sentiments and impression formation equations. This program automates the lengthy calculations involved in processing A B O S situations. Separate impression formation equations for the United States, Canada, and Japan are currently available. For investigations into other cultures for which sentiment dictionaries are available (such as Germany), the United States impression formation equations are generally used by default.

A number of assumptions are incorporated into the impression formation equations. One of these assumptions is that individuals' impressions tend to be stable. The *stability principle* states that once situational elements have been labeled and impressions about the evaluation, potency, and activity (EPA) of the A B O S elements have formed, those impressions tend to remain relatively stable and carry over into subsequent interactions. For example, the negative shift in the evaluation (E) dimension of an actor who does an evil deed, such as raping another, will be remembered by observers and cause them to continue to see the actor as bad after the event. When this principle is applied to the evaluation of actors' behavior, such as in the above example, it is called the *morality effect* (e.g., "good" or "bad" behaviors reflect evaluative "credits" or "demerits" toward actors' identities).

The *consistency principle* states that individuals tend to expect that the feelings they have about actors and their behaviors, or behaviors and targeted object persons, will be congruent. When events unfold that pair actors or object persons with inconsistently evaluated behaviors, observers tend to form corresponding negative impressions. For example, good actors are expected to perform good behaviors and good object persons are supposed to receive good treatment (and vice versa). Thus, if an actor behaves cruelly (bad) toward a nice (good) other, the actor violates the consistency principle and is then seen as less good (note that this negative evaluation is also reinforced by the morality effect). However, the consistency principle also yields some non intuitive predictions. For example, if a “bad” actor behaves generously toward a good and weak other, the actor may experience a marginally increased evaluation according to the morality effect, but the consistency principle suggests that the act may be seen as so out of character by observers that their subsequent suspicion of the actor may mitigate the otherwise positive evaluation from the behavior. In addition, actors who are seen as having much greater power over others are faced with a disincentive to actively use their power. Specifically, powerful actors who behave very powerfully toward weaker others appear as “bullies” and subsequently lose (possibly transfer) some of their perceived power. In other words, in order to maintain power, the consistency principle suggests that powerful actors should be sparing in their utilization of power. Further, if the evaluation (good versus bad) of a behavior is matched to the targeted object person, the consistency principle suggests that the actor, behavior, and object person will benefit from a slight increase in evaluation. On the other hand, when actors treat object persons in ways that are not consistent with their evaluation, the evaluation of the actor, behavior, and object person suffers a decrease. This effect seems to provide a global incentive for situated actors to “play by the normative rules” for the collective good (assuming that achieving a more positive evaluation operates as an incentive for most actors). Finally, a range of *congruency effects* further explains how specific pairs of different EPA dimensions combine to form impressions. For example, behaving nicely toward weaker others

will make actors seem merciful (more good), while behaving nicely toward more powerful others can make actors appear as flatterers (less good). Similarly, acting powerfully toward evil others will make actors seem righteous (more good), while acting “too” powerfully toward very nice others makes actors seem indecorous (less good).

The tendency of observers to accord more or less goodness to actors who behave in ways that result in an equilibrium state with respect to the evaluation and/or potency dimensions of all three core event elements (A B O) is called the *balance effect*. Using an equilibrium criterion consistent with cognitive balance theory, ACT posits that if the product of the combined valences (+/–) of an A B O structure is even (e.g., all three are + or any two are –), then the actor will be seen as more good. When applied to the evaluation (E) dimension of an A B O structure, this effect either reinforces or mitigates consistency effects based on evaluation (e.g., the effect enhances the consistency effect when object person is good and mitigates it when object person is bad). Also, when applied to the potency (P) dimension, the balance effect suggests that when powerful actors act potently toward powerful others, or when weak others act sheepishly toward similarly powerless others, they seem less nice. Interestingly, when powerful others direct potent acts toward weaker others, they and the targeted others seem more good (the latter reinforced by the consistency principle if the object person was not viewed as highly good beforehand) – but in doing so, powerful actors take the risk of losing some of their power (if the act is “too powerful”) according to the consistency principle.

income inequality, global

Glenn Firebaugh

Income inequality refers to the unequal distribution of income across units (usually individuals). *Global* income inequality refers to the unequal distribution of income across the world's citizens.

Global income inequality consists of income inequality across nations and income inequality within nations. Income inequality across nations, or *between nation income inequality*, refers to the unequal distribution of *average* income across nations. Income inequality within nations refers to the unequal distribution of income across individual units (individuals or households) within countries. Traditionally, sociologists have focused on within nation inequality: on why inequality is higher in some nations, on the consequences of high (and low) inequality, and on why inequality changes, where "change in income inequality" refers to change in the *ratios* of individuals' incomes. If everyone's income doubles, so an income of \$100 is boosted to \$200 and an income of \$1,000 is boosted

to \$2,000, inequality remains constant because the income ratio remains fixed at 10 to 1. Standard inequality measures, such as the Gini index, are based on the ratio concept of inequality (Allison 1978), and that is the concept of inequality used here.

Recently there has been a surge of interest in income inequality across nations, or between nation inequality. This new attention to between nation inequality reflects (1) a growing recognition that between nation inequality is the larger component of global income inequality; (2) more reliable data on national incomes; and (3) debate over whether between nation income inequality is now declining and, if so, whether the decline is steep enough to drive down global inequality as well.

First, with regard to between nation inequality as a component of global inequality, suppose we eliminated all inequality within countries by moving all incomes to the income mean within each country. How much global inequality would remain? The surprising answer is, "most of it." Because of huge income disparities between the world's richest and poorest regions, most global income inequality lies across countries, not within them (Goesling 2001).

The prominence of between nation inequality in today's world reflects profound spatial unevenness in income growth during the nineteenth century and first half of the twentieth century. During this period the world divided into three income camps as the industrializing West surged ahead economically and Asia and Africa lagged badly behind. Incomes in a middle group, consisting of most of Latin America and Eastern Europe (including the former Soviet Union), grew at roughly the world average. Because it was the richer regions that were growing faster, this unevenness in growth rates resulted in the massive inequality in income across regions and nations that we see today.

The legacy of the Industrial Revolution, then, is that of a world of much higher average income (Maddison 1995) much more unevenly distributed (Pritchett 1997). The growth in global inequality over this period was due entirely to growing inequality across countries since within nation income inequality declined over most of the period (Bourguignon & Morrisson 2002).

In recent decades, however, income inequality has declined across nations and increased in

the average nation, resulting in a “new geography” of global income inequality (Firebaugh 2003) where nationality is becoming less important in the determination of one’s income. There is little consensus on why inequality has increased recently in many nations (but not all nations); the reasons are complex and likely vary from country to country. By contrast, the major source of declining inequality across nations is clear (Firebaugh & Goesling 2004): faster than world average income growth in many of the world’s most populous poor nations in Asia. Although incomes continue to decline relatively (and in some instances absolutely) in many poor nations in Sub Saharan Africa, many more poor *individuals* live in poor nations where incomes are growing faster than the world average than in poor nations where incomes are growing slower than average. The result is declining income inequality across countries.

There is less consensus over the direction of the global trend since the global trend represents the net effect of two trends going in opposite directions. While some studies conclude that global inequality is declining because the decline across nations more than offsets the increase within nations (Firebaugh 2003: Table 11.1), others conclude that the global trend is indeterminate because some income series yield different results. The recent downward trend in between nation income inequality is steeper when one uses conventional national account (production) data than when one uses household survey data on consumption, and that can affect conclusions about the global trend. With regard to the within nation trend, estimates suffer from the lack of systematic data collection on income inequality for many nations, including some large nations. Aside from the problem of missing data, extant data are often inconsistent with regard to whether they are based on pre tax or post tax income, on whether the units are individuals or households, and on whether a probability sample was used.

The major challenge for future research on global inequality is data reliability. The measurement issues are pretty well settled: there is general consensus on how to measure income, and on how to measure and decompose income inequality. But our measurements and

decompositions are only as reliable as the data we input, and that is where much of the effort should be expended in future research on global income inequality.

income inequality and income mobility

Wout Ultee

Research on income inequality within the social sciences took off as a byproduct of income taxation. Lists were published showing how many tax paying units during a tax year had an income of a certain size. The distribution did not look like a bell shaped curve, but was skewed at the upper end. The description of the distribution by one parameter started with Vilfredo Pareto, and his results led to the hypothesis that this statistic was more or less the same for all times and places. Later results, using better measures like the Gini coefficient, found differences

between countries, leading to a hunt for explanations. Due to the efforts of the World Bank and the Luxemburg Income Study, quite comparable income inequality data for various countries are now available, so that hypotheses testing is possible.

Sociologists proposed basically two explanations for country level differences in income inequality. The first invokes economic factors, the second political ones. It has been held that in more economically developed countries income inequalities are smaller. Similarly, it has also been proposed that countries with a more peripheral (as opposed to central) place in the world economy have larger income inequalities. As to political factors, it has been maintained that in highly industrialized societies a long democratic history as well as a social democratic government, by way of various policies, have diminished income inequalities. Among these policies are progressive taxation, free secondary and tertiary education for all, and collective insurance against such matters as unemployment, work related disabilities, and old age.

By way of quite simple comparisons and more sophisticated statistical techniques, these hypotheses have generally proved their mettle. An important issue is exactly how income inequalities are measured and what hypotheses say about effects on this or that measure. According to some hypotheses, a democratic state is like Robin Hood: the state takes from the really rich and gives to the poorest of the poor. This hypothesis may be tested by using one measure of a country's income distribution, such as the Gini coefficient. Other theories take a closer look at what democracy is all about. If the members of a governing coalition wish to enrich themselves, they exclude the richest persons in a society from governing. So a redistribution from the rich to the rest will occur. But to exactly whom? Not only to the poorest of the poor, since the coalition governing a democratic state comprises at least 51 percent of the population, and the richest members of the coalition want a piece of the pie, too. Upon opposition from the poorest of the poor, the richest members of the coalition may threaten to blow up the coalition, leaving the poorest of the poor nothing at all. This is the theory of the strategic middle proposed by Gordon Tullock. If it is to be tested, an

overall measure for income inequality in a country (like the Gini coefficient) will not do. Data on the income share of, say, the poorest and the richest 10 percent and 20 percent of the population are also necessary. The Robin Hood hypothesis in its strongest form predicts that upon the introduction of democracy the income share of the two richest decile groups will go down, and the income share of the poorest deciles will go up, with the decrease of the former as large as the increase of the latter. The hypothesis of the strategic middle predicts a decrease for the richest deciles and an increase for the poorest deciles only if parties representing the interests of the poor are part of the governing coalition.

If some measure for the inequalities in income for all the households of a country does not change in the course of time, this of course does not mean that the income of all these households remained the same. It is not difficult to imagine that higher income inequality within a country goes together with more income mobility. Until recently, data on income mobility calculated over a longer time span were rare, but with the implementation of panel surveys by statistical agencies more data are becoming available. They mainly have been analyzed by economists.

Sociologists have studied data on intergenerational mobility along a scale of occupational status. Blau and Duncan (1967) examined data from the US and found a correlation between father and son's occupational status of 0.4 (with zero indicating no correlation and unity full correlation and the strongest possible determination of son's by father's occupational status). When reviewing Blau and Duncan's results, an economist suggested that occupational status as measured by sociologists is a reasonably good indicator of permanent income: not a person's income during one particular year, but a person's income calculated over a longer period. The interesting question is to what extent occupational correlations agree with data from long running income panels.

Earlier data from non representative samples in the US take single year earnings of fathers and sons, with father's earnings observed when the son was still in the parental home and son's earnings some decades after leaving it showing correlations below 0.2. Later studies used data from the Panel Study of Income

Dynamics, conducted annually since 1968 in the US. The data for father's earnings pertain to around 1970, with those for son's earnings around 1985. Age restrictions were applied so as to bypass the earnings of sons when they were under 30 years of age, when earnings supposedly are highly variable. This time the intergenerational correlation in single year earnings of fathers and sons was 0.3. Taking father's earnings not as a single year measure, but as the average of 5 years, increased the correlation to 0.4. Averaging son's earnings over 5 years too, the correlation approached 0.5. These findings on income mobility indicate that correlations between father and son's occupational status are not far off the mark and definitely not too high.

Apart from depicting the US as a much less mobile society than earlier income mobility data indicated, comparisons of US intergenerational income mobility data with those of other countries do not seem to show particularly low correlations for the US. Research on Finland and Sweden using 3 year annual average earnings for fathers and sons found correlations closer to 0.1 than to 0.2. Strict comparisons of a large number of countries remain a promise for the future, but it does seem that, for highly industrialized countries, low inequality in yearly income goes together with high income mobility.

index crime

Robert F. Meier

Index crimes are a series of eight crimes – murder and nonnegligent homicide, forcible rape, aggravated assault, robbery, burglary, larceny theft, motor vehicle theft, and arson – about which police agencies report to the Federal Bureau of Investigation (FBI). They have been an important source of information about crime for more than three quarters of a century. They are also an important part of a larger crime reporting program called the Uniform Crime Reports (UCR).

The UCR began in 1930 when police chiefs in various cities began to experience difficulties in keeping up with crime on a national basis. With greater use of the automobile in the 1920s, criminals were able to commit crimes over a larger geographic area. Offenders could commit a major crime in, say, Chicago in the morning, in Des Moines in the afternoon, and in Omaha that evening. Clearly, effective police efforts required more information about crime in other communities than had existed up to this time. In the late 1920s, the International Association of Chiefs of Police requested the FBI to serve as a collection agency for crime statistics. The plan was for police departments to send their information to the FBI which, in turn, would collate the information and publish the figures annually.

The UCR publishes its annual report, *Crime in the United States*, each year. The report contains information about crime for the preceding calendar year. Among the statistical information contained in the report is information about crimes known to the police, characteristics of persons who are arrested for those crimes, and data about police officers. The crime statistics are broken down into major geographic areas and specific jurisdictions (cities and counties) within states. The annual report

is largely a compilation of tables containing this information.

The UCR crime statistics are the result of a voluntary reporting system. No police department is *required* to submit information, but the great majority of all departments – state police, sheriff's offices, municipal police departments, federal police agencies, and even university and college campus police departments – do report their information for publication in the UCR. Police agencies covering about 94 percent of the population submit statistics on a monthly basis for the reporting system.

The FBI recognized that not all crimes could be included in the UCR, so they distinguished between two categories of offenses. The original Part I crimes were a list of seven offenses, all felonies that were thought to represent an “index” of crime in the US. For this reason, they are often referred to as the Index Crimes. The original index crimes were homicide, aggravated assault, forcible rape, robbery, burglary, larceny, and auto theft. In 1979 arson was added as an eighth index offense, although information in the UCR is still sketchy about this newest index crime, more than 20 years after it was added. The Part II offenses are a collection of about 27 offenses about which some but not all information is recorded. In terms of detailed information, the emphasis in the UCR is on the Part I or index crimes.

Murder and nonnegligent manslaughter is defined as the willful (nonnegligent) murder of one human being by another. As with the other index crimes, the determination of this crime is made by police investigation only, not other means (e.g., coroner, medical examiner).

Forcible rape, as defined by the UCR, is the carnal knowledge of a female forcibly and against her will. Neither assaults of male victims nor statutory rape cases are included.

Robbery is defined as taking or attempting to take anything of value from the care of another person through force or threat of force.

Aggravated assault is an unlawful attack by one person on another with the purpose of inflicting severe or aggravating injuries. Usually, such assaults involve a weapon. Also included in this crime are threats of severe injury.

Burglary is defined in the UCR as the unlawful entry into a structure for the purpose of committing a theft or felony. Actual theft is

not required and attempts are considered burglaries. Force is not required.

Larceny theft is defined as stealing property of another. There are many different kinds of thefts, such as shoplifting, purse snatching, and bicycle thefts. Specifically excluded from this crime category are embezzlement, confidence games, forgery, and worthless checks. Motor vehicle theft is also excluded since it is another index crime.

Motor vehicle theft is defined as the stealing of a motor vehicle or its parts. Included are thefts of cars, trucks, motorcycles, and buses. Specifically excluded are thefts of vehicles which do not intend to deprive owners of their vehicles permanently, such as joy riding.

Arson is defined as the willful burning of property with the intent to defraud. Arson is defined as the result of an investigation and those fires that are considered only suspicious are not included.

Surely, if one is interested only in characteristics of persons who are arrested, the UCR is the best single source for this information. Criminologists, however, are often more interested in the amount of real crime in the community, and in this regard the UCR is inadequate.

indigenous movements

David Anthony Tyee Clark

From the homelands of aboriginal peoples in Canada's Northwest Territories to indigenous territories in four Andean countries – Peru,

Ecuador, Bolivia, and Colombia – indigenous peoples have demanded self governing political institutions, asserted their rights to a greater measure of cultural self determination, and reacquired legal control over their own territories and resources. While throughout the Americas certain indigenous peoples have reestablished land ownership, gained official recognition of indigenous forms of government and justice, got elected to public office, and, in some cases, established independent regions, at the same time, others are losing their fragile control over lands, waters, and other resources, as well as their access to sacred sites. Market driven global processes, supported by state sponsored efforts often led by the United States, are deepening environmental deterioration and increasing poverty among natives, seriously deterring the possibility of sustainable indigenous societies and nations well into the future.

In response, indigenous peoples are continuing old fights as well as mounting new forms of resistance and grassroots mobilization. Throughout the Americas, indigenous peoples are resisting state violence and subtle coercion. While often concerned with defending recently reacquired autonomy, the political and economic conjuncture brought on by market oriented globalization has forced indigenous peoples to engage in new fights for survival.

The efforts of Indians in Latin America, for instance, have gained momentum in the last decade as government policies based on assimilation and paternalism are replaced with new approaches founded on participation and consensus building and a respect for the aspirations of indigenous peoples. In less than a decade, indigenous movements in Latin American countries have toppled two presidents and left their distinctive mark on parliaments, ministries, municipal governments, and even a vice presidency. There are nearly 50 million indigenous individuals among a total Latin American population of 400 million.

In some cases, governments have responded to indigenous movements with broad based state sponsored violence, such as in Ecuador in 1992 and 1994 where indigenous peoples constitute 3.5 million – 25 percent – of the total population. In Mexico, with 10 million indigenous, the Ejército Zapatista de Liberación

Nacional took up arms against the Mexican government in 1994 to demand access to the institutions of democracy and justice. As a result of their armed resistance that, along with other factors, destabilized the political system dominated since 1929 by the Institutional Revolutionary Party (PRI), in 2000 Mexico for the first time in over 70 years swore in a non PRI government.

In many cases, grassroots efforts have achieved success without bloodshed. For instance, the Aymara leader Víctor Hugo Cárdenas was Bolivian vice president from 1993 to 1997. Cárdenas has called on his allies to “go beyond legal and institutional changes and transform the entire culture surrounding policies on indigenous people, including the attitudes of national elites and bureaucracies.” In Brazil, indigenous peoples have worked with government leaders to set aside lands not as reservations where the government attempts to “civilize” hunters and gatherers, but where the government serves to keep loggers, gold miners, and other intruders out of indigenous lands.

Contemporary indigenous movements, appearing in response to unevenly institutionalized reforms, pose a serious challenge to emerging democracies. These movements have sparked political debates and constitutional reforms over community rights, territorial autonomy, and multi ethnic citizenry. Throughout the Americas – from Canada to Latin America – indigenous peoples remain as concerned as ever with safeguarding indigenous forms of government and governing, wresting control of resources away from states and state protected corporations, protecting sacred sites, and revitalizing indigenous languages and cultures.

Indigenous governments and governing. In Bolivia, for instance, indigenous peoples who make up 55 percent of the total population control 35 percent of the country’s municipalities – 311 in total. Local leaders set their own priorities and administer local financial resources. In the Mexican state of Oaxaca, residents of 412 of the state’s 570 municipalities chose their leaders in open assemblies of elders, rather than by ballot. The communities also run their own criminal justice systems. In the northern border state of Sonora, 33,000 Yaquis are represented by their own governor and council of elders, enforce their own laws, and exercise jurisdictional rights over

a 1,880 square mile territory in the southeast portion of the state.

Control of resources. In the United States, the Native American Rights Fund (NARF) is a non profit organization that provides legal representation and technical assistance to tribes, organizations, and individuals nationwide. In recent years on the Pine Ridge Reservation in South Dakota, for instance, NARF has supported the Oglala struggle with unsafe drinking water, crumbling sewage systems operating without EPA permits, and widespread pollution of primary streams which are both unregulated and unmonitored. A 1994 survey of 149 tribes conducted by the National Tribal Environmental Council for NARF revealed that tribes face an array of environmental problems. More than 75 tribes reported polluted or insufficient drinking water.

Sacred sites. For decades, a growing number of American Indians have been alarmed by the desecration and destruction of sacred sites and have advocated for increased protection. Dozens of sacred sites, including Dził Nchaa Si An in central Arizona and the home of the sacred deity Ma'l Oyattsik'i at Zuni Salt Lake in New Mexico, remain in 2005 the focus of ongoing struggles by indigenous activists and elders, as well as environmentalists and religious organizations concerned about protecting the spiritual welfare of indigenous peoples.

Indigenous languages and cultures. In the United States there is an "English Only" political movement that questions the value of teaching languages other than English, including indigenous languages. Identifying language loss among their greatest challenges, indigenous peoples have responded in a variety of ways. In Hawai'i, for instance, the 'Aha Punana Leo grew in 1983 from a pioneer group of language nest immersion preschools into a non profit Native Hawaiian family based 501(c)(3) tax exempt educational organization dedicated to reinstituting Hawaiian as a daily, living language.

Indigenous peoples of the Americas are not alone. Indigenous movements representing hope for the future are visible in Africa, Asia, and Europe, as well as among Pacific Island populations including those in Australia and New Zealand.

indigenous peoples

Thomas D. Hall and Joane Nagel

Throughout most of the nineteenth and twentieth centuries, scholars and policymakers predicted the disappearance of Native Americans and indigenous peoples in general (see Dippie 1982 for many examples). Global patterns of urbanization, industrialization, and resource extraction indeed have led to a reduction in the number of indigenous people living traditional lifestyles on ancestral lands. However, those who predicted the demise of indigenousness did not anticipate the global resurgence of indigenous consciousness, political mobilization, and cultural renewal of the past several decades (Wilmer 1993; Nagel 1996; Bodley 1994, 2003; Hall & Fenelon 2004). Indigenous groups in North and South America, Australia and New Zealand, Central Europe and Central Asia, Asia and Africa are making land claims,

petitioning for political rights, and demanding control of resources; many are doing so with remarkable success given their limited votes, money, or military capacity. To illustrate the resurgence in indigenous identities, communities, and cultures, after a brief discussion of terminology and the sociological significance of studying indigenous peoples, we focus here on contemporary demographic, economic, and political trends among Native Americans.

We use the term "indigenous" to refer to those peoples who either live or have lived within the past several centuries in nonstate societies, though virtually all indigenous communities are located within state societies. We note that the diversity of types of nonstate societies is far greater than the diversity of states. Attempts to organize this diversity have generated a plethora of terms: clans, bands, macro bands, tribelets, tribes, chiefdoms, segmentary lineages, etc. (see Chase Dunn & Hall 1997).

The term "tribe" is one of the most common designations for indigenous peoples, but it is also one of the most controversial because of its connotation of primitiveness and savagery. Despite its baggage, the term "tribe" has political utility for those peoples who inhabited North America before Europeans arrived, since the tribe–nation distinction often has been used politically to support or to deny autonomy or sovereignty for indigenous groups and because some indigenous communities informally and officially refer to themselves as tribes, though many have replaced "tribe" with "nation." Even "Native American" can be problematic, since legally, anyone born in the United States is a "native" [born] American. We use "indigenous" peoples or communities throughout this discussion, and for peoples indigenous to North America, we alternate among Native Americans, American Indians, native, or Indian.

When referring to a specific indigenous community, we use the name of the group, but we note that official names are political and historical constructions that do not necessarily reflect some prior, pristine indigeneity. For instance, there are the historical accidents of naming and the vagaries of spelling that stemmed from colonial powers' lack of clear understanding of indigenous languages. Sometimes a name derived from a derogatory term, while other changes mark indigenous peoples' efforts to reclaim their

name in their own language, such as Diné for Navajo, Ho Chunk for Winnebago, or Tohono O'odham for Papago.

Changes and disputes over indigenous peoples' names stem also from historical changes in group boundaries in response to internal processes or encounters with outsiders. In early contact periods with Europeans, North American native peoples often shared a broad sense of identity but were not ruled by any single social or political organization (Cornell 1988). The need for unified resistance to European, then American, encroachments led to the formation of socio political structures that encompassed new groupings of individuals and communities. Out of these alliances new names and identities emerged.

The modern organization of many historical indigenous cultures and communities has arisen, ironically, from efforts to destroy them, either by outright genocide, the devastations of disease, by assimilation into European societies, or by merger or amalgamation with other indigenous groups. At times these amalgamated communities were examples of "ethnogenesis," i.e., the creation of new ethnic groups whose contemporary names may or may not reflect their historical origins. In fact, a great deal of ethnographic and ethnohistorical research shows that the symbolic, demographic, and social boundaries of nonstate groups are extremely permeable (Brooks 2002). This suggests that the presumption of fixed, clear, rigid boundaries or borders is an artifact of contact with European states – the expectations of outsiders about the timeless nature of indigeneity and the needs of European and later postcolonial negotiators to identify "leaders" of native societies for purposes of treaty making and land acquisition.

Indigenous peoples are of special interests to sociology and to sociologists for several reasons. First, in the United States, the Americas, and in many other countries, indigenous peoples comprised the earliest human settlements and interactions with indigenous peoples by immigrant or colonial populations were important in shaping contemporary legal, cultural, political, economic, and social organization. In many countries indigenous peoples are central to national images of past and present and components of ethnically diverse national populations. Thus, despite their relatively small

numbers, they should be included in any general discussion of race or ethnicity, particularly since the historical treatment and contemporary status of native peoples are central to national questions of group rights, nation formation, justice, group formation, group transformation, and social change.

The study of indigenous peoples represents an invaluable opportunity for theory building and evaluation since indigenous peoples represent a wide variety of social structures that are not found among immigrant or settler groups. In the United States, the varieties of indigenous languages, kinship structures, political organization, or cultural formations present unique opportunities for understanding human pasts and presents. Further, since the founding of the United States, Native Americans have had a unique political and social relationship with the US government. They are the only ethnic community with legal rights connected directly to the federal government, rights that bypass county, city, and state governmental authority. This "government to government" tribal-federal relationship generates many politically and sociologically interesting interactions and exceptions that have led to controversies about gaming, Indian hunting and fishing rights, or the right to sell gasoline or tobacco on reservations without charging state taxes (see Bays & Foubert 2002).

Finally, consideration of indigenous peoples is vital to understanding long term social change and social evolution. On the one hand, omitting such groups biases the sample. On the other hand, it is erroneous to assume indigenous people, even those who live "traditionally," are models or "living artifacts" of earlier societies. Contemporary indigenous peoples have survived centuries, and in parts of Asia, millennia of contact and interaction with state societies. Their contemporary social structures have been shaped by their responses to those interactions. Ferguson and Whitehead (1992) caution against too much reliance on historical "first contact" accounts for information about change in indigenous societies. This is because intergroup contacts change both societies so profoundly that even the earliest first hand accounts must be approached with considerable skepticism. By the time a representative of a literate state society observes an indigenous group, typically

there already has been considerable prior contact and consequent social change. Thus, while first hand accounts can be useful, they cannot be presumed to be unbiased snapshots of the pre contact past. The rate of change resulting from intergroup contact in North America, for example, has led scholars to be cautious about assuming the accuracy of early nineteenth century depictions of western US tribes by Meriwether Lewis and William Clark (see Fenelon & Defender Wilson 2004).

CONTEMPORARY INDIGENOUS AMERICAN ISSUES AND TRENDS

The demography of indigenous peoples is another complex topic. First is the politics of numbers and their uses. Stiffarm and Lane (1992) argue that there is a tendency to underestimate the population of the Americas prior to European contact in order to minimize the decimation of the indigenous population. While estimates for the indigenous population of North American (US and Canada) range from 1 million to 30 million, Thornton (1987) argues for a figure in the neighborhood of 7 million, based on careful reconstruction of population densities, early population counts, and the effects of known epidemics. Native populations declined drastically, but not exclusively, from "old world" diseases. Native populations in the United States reached a nadir of about one quarter million around the turn of the twentieth century. Since then the Native American population has grown so that, at the beginning of the twenty first century, it is well over 2 million – between one third and one half of what it was in 1492. It is important to note that more than disease was involved in the depopulation of indigenous Americans; colonial and US land policies, population removals, and wars took on genocidal proportions and were major factors in the steep population decline.

Population recovery since World War II has been considerable: from 1960 to 1970 the number of Americans who reported their race to be "American Indian" in the US census grew 51 percent (from 523,591 to 792,730); from 1970 to 1980, the American Indian population grew faster, 72 percent (to 1,364,033); from 1980 to 1990, the American Indian population

increased 37 percent (to 1,878,285); and from 1990 to 2000, the American Indian population increased 26 percent (to 2,366,639). The increase is due to improved enumeration techniques, a decrease in death rates, and an increasingly willingness of individuals to identify themselves as Native American. Native Americans intermarry with other groups more than any other ethnic group, giving rise to three different categories of "Indians": (1) "American Indians," persons who claim to be Indian racially and have a specific tribal identification; (2) "American Indians of multiple ancestry," persons who claim to be Indian racially, but who have significant non Indian ancestry; and (3) "Americans of Indian descent," who do *not* claim to be Indian racially, but who report an Indian component in their background (Snipp 1986). This gives rise to questions about membership in Indian tribes and definitions of who is and is not "Indian" by tribal governments, federal officials, and Indian communities and individuals. The financial successes of some native communities (e.g., due to gaming or natural resources) makes identity an economic issue as well.

Urbanization, intermarriage, education, and increased participation in the paid labor force since World War II have spurred the most politically active period in American Indian history: formation of activist organizations such as the American Indian Movement and Women of All Red Nations, legal defense organizations such as Native American Rights Fund and Native Action, and lobbying groups such as National Congress of American Indians and National Tribal Chairmen's Association. These organizations comprised a backdrop and, in some cases, the infrastructure for Indian rights movements in cities and on reservations that took root and blossomed in the fertile political soil of the civil rights era in the US. Beginning in the 1960s, American Indians staged a variety of protest events: "fish ins" in the Pacific Northwest in the mid 1960s, the 19 month occupation of Alcatraz Island beginning in 1969, the 71 day siege at Wounded Knee on the Pine Ridge Reservation in South Dakota in 1973, the occupation of Camp Yellow Thunder in the Black Hills in the 1980s, and protests against Indian athletic mascots since the 1980s. Out of such protests and the legal battles they gave rise to came a new "self determination"

era in federal Indian policy. This opened the way to increased tribal control of budgets and decision making, to the development of tribally owned natural resources, to the establishment of casinos and gaming on tribal land, and to opportunities for self rule and economic development by Indian communities. These changes, in turn, have raised questions about how Native Americans fit into United States society.

In the twentieth century, access to wealth from mineral resources, gaming, and tourism has helped economic development on reservations and in American Indian communities. Although Snipp (1988) has shown that the differences between energy resource Indian nations and those without such resources tend to be minimal, gaming has brought profits and change to many native communities (Jorgensen 1998; Napoli 2002). A key problem facing Native American nations has been how to participate in economic development without undermining traditional Indian values (Cornell & Kalt 1992, 2005). The tension between development and tradition also are central to debates in many indigenous communities globally (Wilmer 1993; Gedicks 2001).

Economic development and the practice and preservation of traditional cultures are enmeshed in two important contemporary issues facing American Indians: the internal and external consequences of gaming as a strategy of economic development in Indian communities and non native interest in American Indian spiritual practices. Because of their special relationship with the US federal government, reservation governments are able to sponsor gaming, to sell gasoline and cigarettes without paying local and state taxes, and to sell other typically locally or state interdicted or regulated products such as fireworks. The growth of Indian casinos and the desire of non Indian governments and businesses to compete with Indian enterprises, which they see as having unfair tax advantages, has spawned social movements that are nominally anti gaming, but are often thinly disguised anti Indian movements. In some cases they reflect conflicts of interest among local non Indians, Indians, and local and state governments. Similar non Indian opposition has resulted from renewed Indian land claims (such as by the Passamaquoddies in Maine in the 1980s and the Oneidas in New York in the 1990s).

These controversies have heightened identity politics both within Native groups and between Native groups and the general population.

While American Indian gaming might be viewed negatively by some non Indians, American Indian religions and traditions (real or imagined) have attracted many non Indians. Some religions welcome, and indeed, seek to convert others and expand their membership. This generally is not the case with Native American spiritual leaders and practitioners. Non Indian appropriation of Indian spiritual traditions often is perceived by native people as theft – one in a long series of “Indian giving” by non Indians. The presence of charlatans and hucksters (a few of whom are of native ancestry) involved in assorted “new age” appropriations of Indian cultural elements lifted from their indigenous context has heightened the controversy (Churchill 1996).

The spread of new age and “world music” that uses elements and occasionally performers from various indigenous populations has spawned analogous controversies at a global level (Feld 1991). Not the least of the subcontroversies is that it is non Indian performers and producers who are making the large profits from the use of indigenous instruments, themes, music, and performances. Such controversies will not disappear quickly. They have, however, generated a new interest in relations with indigenous peoples and new attempts to reexamine the long, and often tawdry, history of Indian/non Indian relations.

individualism

Jens Zinn

Individualism emphasizes the importance of the individual, for example the individual's freedom, interests, rights, needs, or beliefs against the predominance of other institutions in regulating the individual's behavior, such as the state or the church. A range of theories in different societal domains contributes to the dissemination of individualistic ideas in society. In particular, economic and political liberalism are vehicles of individualism.

The term individualism was introduced by de Tocqueville. Even though he distinguished individualism from egotism, his distinction is essentially one of degree, but individualism would in the long run lead to "downright egotism."

A strong impact on the development of individualistic thinking in Western Europe can be traced to religion. The Reformation and the development of Protestantism indicated a shift to more individualistic thinking. This can be linked to Luther's claim that a personal relationship with God cannot be mediated by the interpretation of the church.

Another important contribution to individualistic thinking was given in economics by Adam Smith's development of a system of economic liberalism. He assumed that a simple system of

natural liberty and exchange of goods and services in free and competitive markets, with as few interventions by the state as possible, would best support societal development and welfare.

A growing political individualism became most influential with the French Revolution and the emphasis on individual rights, referring to the idea of natural justice in contrast to the absolutist state. Several of these developments came together in the bourgeois Enlightenment in the seventeenth and eighteenth centuries.

In Anglophone discourse there is a tendency to interpret individualism as egoistic and selfish behavior. For example, Bellah et al. (1985) prominently argued that the prevalence of individualistic behavior would destroy the moral integrity of American society, though this view was contested. More positively, individualism is interpreted in Beck's (1992) theorizing on the risk society. Here, *individualization* indicates liberation from traditional bonds. Thus, it opens up more options from which to choose, but at the same time forces people to choose.

Methodological individualism emphasizes that sociological phenomena can only be explained by the characteristics of individuals. It was developed in opposition to methodological collectivism or holism. For example, Durkheim justified a specific sociological contribution to the examination of the human being by claiming that social phenomena can only be explained socially, and thereby proposed a holistic approach.

Today, this fundamental contradiction is rather outdated. Sociologists are much more concerned with questions of how sociocultural and sociostructural factors on the one hand and individuals, their actions or characteristics, on the other hand, are mutually linked or constitute each other. Instead of stating extreme positions, today's research is more often engaged with how both aspects combine in social reality.

induction and observation in science

Andrew Tudor

One of the most persistent commonsense accounts of science is that in which scientists are understood systematically to assemble observations and arrive at reliable generalizations based upon them. Sometimes, wrongly, this simple inductive empiricist view is laid at the door of Francis Bacon (1561–1626) and dubbed “Baconian inductivism.” In fact, Bacon’s views were considerably more complex than this, but the hare that he set running – inductive inference as the heart of scientific method – has subsequently been pursued by all manner of hounds. The Scottish Enlightenment philosopher David Hume (1711–76) was preeminent among the early pursuers, and to this day “Hume’s problem” continues to preoccupy philosophy of science. In the mid twentieth century, there was a period when the seemingly more powerful hypothetico deductive model of scientific inquiry appeared to have run inductivism and Hume’s problem to exhaustion. However, it rapidly became apparent that the issues surrounding inductive inference had a peculiar capacity to reemerge from the coverts of deductive certainty, not least where the nature of observation itself was questioned. Into the space thus created have hastened newer, more relativistic epistemologies and, in full cry, the sociology of science.

Although Bacon was by no means a naïve inductivist, he did insist on the necessity of ridding the mind of certain kinds of preconceptions when examining the facts, so as to better discover the true workings of natural phenomena. In effect, then, the inferential process

moved from neutral observation to generalization unencumbered by misleading beliefs likely to obstruct proper knowledge. In its period this was a bold formulation, and one crucial to the subsequent development of natural philosophy into modern science. But it immediately raised difficulties for those eager to underwrite the legitimacy of scientific method in inductive terms. For while deductive reasoning had a lengthy logical pedigree, inductive inference was to prove far more slippery.

It was David Hume who presented the central problem of inductivism in its most influential form. In essence, the argument is simple: that however many instances we may find of a specific phenomenon, this gives us no reason in logic to expect that observed pattern to continue in the future. In other words, we have no justification for making any reliable inference from past evidence. Nor, of course, can we lay claim to probabilistic justification in as much as at the heart of the problem is the very unpredictability of the future in relation to past experience. The future will hold surprises. And against those who suggest, more pragmatically, that our past successes with this kind of inductive inference should lead us to expect success in the future, Hume levels the charge of circularity: attempting to justify inductive inference by inductively inferring future success from past instances of inductive inference itself.

Unsurprisingly, then, the difficulties consequent upon accepting inductive inference as *the* distinguishing feature of scientific method gave way by the mid twentieth century to more deductively inclined models of science. Rather than seeing science as founded on generalizations from data, these approaches afforded greater emphasis to the relative autonomy of theory. So, for example, variants of the hypothetico deductive model were little concerned with the grounds on which we actually arrived at our theories and generalizations. Their interest lay, rather, with deducing predictive hypotheses from theory which could then be subjected to (experimental) test. In strict versions – for example, Popperian falsificationism – the test could only falsify and not confirm (Hume’s problem again). But this, too, presented problems. Science clearly did not proceed on the basis of rigid, deductive tenets (let alone falsificationist ones), and at the heart of any process of

testing lay "observation" – which apparently relied upon some form of inductive inference from experience to the observation statements describing that experience. Since this would raise a variation of Hume's problem, deductivism was forced to recognize the unavoidably theory laden and conventional character of observation. The traditional logical positivist reliance on the distinction between theory language and observation language simply would not do. The language of observation was no less theoretical than the language of theory.

None of this, of course, dissolves the problem of inductive inference, if problem it is, for even if induction is not the defining element in so called scientific method it remains an important feature of actual scientific practice. Scientists make inductive inferences, albeit within a context of inquiry which also involves deduction, intuition, competition, and even sheer bloody mindedness. Accordingly, philosophers of science have continued to examine induction with a view to somehow resolving or bypassing the Humean difficulties. Within the pragmatist tradition, for example, Rescher (1980) has sought to reconceive inductive inference as essentially a kind of cognitive method, while others, such as Howson (2000), who retain more formal concerns, have leaned toward Bayesian probability theory as providing grounds for resolving at least some of Hume's problem(s). Such approaches are often illuminating about what kinds of presuppositions are involved in inductive practice, although their apparent goal of providing "justification" seems far less significant in a period which has come more fully to recognize the importance of sociological and psychological factors in scientific inquiry. Here, Collins's (1985: 145) "sociological resolution of the problem of induction" is interesting. By empirical examination of what he calls the "experimenters' regress," he seeks to show that the nature of experiments as "skillful practice" means that an attempted replication always leads to the necessity for yet further experimental tests to confirm the quality of each experiment in the chain. This regress can only be halted by contingent, collective decision. Observing, experimenting, and constituting "facts," then, are socially constructed achievements of human agents; they cannot, without loss, be rendered

as logically justified processes under the grand rubric of Inductive Scientific Method.

industrial relations

John Hogan and Peter Nolan

The material origins of industrial relations, both in practice and in research, can be traced to the movement from early to advanced capitalism. The rise of capitalism, centering on the purchase and sale of labor power, ushered in a new structure of relations between the direct producers and their controllers. Workers were brought together in centralized work stations and subjected to an authority relationship and hierarchical division of labor. The bosses had the right to hire and fire their charges, set their wages, and dictate the hours and intensity of

work. The detailed division of labor was entrenched and reinforced in the factories, thus rendering worker solidarity and collective organization difficult. But the unbridled authority of bosses eventually came to be challenged. Workers formed embryonic unions and relations between workers and their masters became increasingly fraught.

The study of industrial relations took its lead from these material developments in the workplace. It is no accident that the field of inquiry has been shaped by scholars operating from within the economies that have dominated the history of global capitalist development. The study of industrial relations is a predominantly Anglo Saxon discourse. Initially, scholars focused on processes of rule making and the elaboration of institutional arrangements to contain conflict. The formation, structure, and influence of unions dominated the early key texts, but researchers found that the character of workplace relations, employer practices, and the position of unions were strongly conditioned by the wider political economy and state interventions. Scholars in the United States took the lead.

In the 1920s and early 1930s, American unions suffered heavy membership losses and were marginalized by company sponsored unions. Yet, they proved to be successful in expanding their membership in the runup to and beyond World War II. While much of the success followed on from bitterly fought battles to build organization, notably in Minneapolis for the Teamsters and in Michigan amongst car workers, the position of US unions was bolstered by legislation introduced under Roosevelt's New Deal, in particular the Wagner Act, which legalized workers' rights of association, and the Social Security Act, which underpinned the emerging welfare state. But the changing balance of forces between employers, employees, and the unions proved difficult to capture in theory. By the late 1950s the dominant framework was the "systems" model, which treated industrial relations as a relatively autonomous subset of relations influenced by politics, the state, technology, and the economy (see Dunlop 1958; Kerr et al. 1960). Viewed as independent exogenous forces, these wider systematic variables were set apart conceptually from the processes and outcomes of the politics of

production. The possibility, for example, that the pace and impacts of technological advances may be conditioned by the division of labor and power struggles in the workplace was never considered. The approach thus attracted a vast critical literature that, *inter alia*, highlighted its intrinsic determinism and failure to unravel the complex, non linear connections and contradictions between the industrial relations "sub system" and broader political, economic, and technological forces.

Though initially influential in the UK, the systems approach was modified and adapted to take account of the particular patterns of workplace bargaining and the limited role of the state in directly shaping the pattern of industrial relations. The politics of pluralism dominated the mainstream literature that was primarily focused on institution building at workplace level. Like their American counterparts, the mainstream largely failed to unravel the complex connections between production politics and the particular historical trajectory of the UK economy, which by the early 1960s exhibited an entrenched pattern of low wages and low productivity. Criticized for overreliance on description, and for assuming that historical continuities would prevail over the forces of change, the mainstream, according to one critic (Crossley 1968), inclined toward a historicist method that blinded it to the contradictions and fragility of Britain's workplace institutions, including collective bargaining.

The late 1970s recoded the high tide of industrial relations in the Anglo Saxon countries. In the UK union membership peaked at over 13 million employees. But during the 1980s and 1990s successive Conservative governments promoted the view that industrial relations had become an irrelevant public policy area. Strikes were in decline, and major unions suffered heavy defeats in the face of a state sponsored employers' offensive. For many commentators, the defeat of the National Union of Mineworkers after a year long strike between 1984 and 1985 was the turning point in modern labor history. Rising levels of unemployment, which topped 3 million by the mid 1980s, and a series of draconian anti union laws sapped the capacity of unions to fight back and resist the degradation of working conditions that was legion across UK firms and industries.

In the United States, a new discourse – human resource management – focusing on the individual rather than collective employment relations captured the research agenda and led practitioners in the field of personnel and industrial relations to reinvent themselves. The administration led by Ronald Reagan was deeply hostile to the labor movement that had already been weakened by broader economic forces. Taking an unusually high profile in breaking the 1981 air traffic controllers' strike, Reagan was determined to promote a sea change in management practices, emphasize the primacy of the individual in the workplace, and denigrate established collective bargaining relations. Union membership and influence plummeted and have yet to recover, a malaise that brought forth a highly significant split in the peak trade union federation AFL CIO during 2005.

In continental Europe collective bargaining and the solidarity of trade unions across service and industrial sectors proved more enduring. Tensions were apparent, in the systems that evolved after 1945, but large employers accepted (sometimes reluctantly) their duties under the laws to negotiate and consult with the trade unions that represented their employees. Union membership levels remained high by comparison with the UK and the US, and the coverage of collective bargaining often approached levels in excess of 80 percent of the workforce. Despite the claims on behalf of the Anglo Saxon deregulated labor markets, the evidence revealed that the more regulated economies of Germany, Scandinavia, and Italy continued to thrive at the expense of the UK and US economies (Nolan 1994, 2004).

Employment patterns in continental Europe, it should be stressed, are not homogeneous. The panoply of institutional arrangements, both voluntary and statutory, that regulate the employment relationship vary considerably. Yet until quite recently many scholars counterpoised the industrial relations systems of the Anglo Saxon countries to a stylized model of highly regulated and highly unionized labor markets that embedded productivity inhibiting working practices. To be sure, in line with the traditions of social democracy that became embedded in many (but by no means all) European countries, institutional structures did evolve to protect the rights of workers in ways

that far exceeded the rights of British and American employees.

Yet it is crucial to be aware of the nuances of the employment systems in different European countries. In France, for example, a relatively small and divided union movement has kept alive a tradition of militancy, one capable of mobilizing beyond its immediate ranks, that has brought discipline to the practices of management. The principle of management prerogative has never been successfully embedded. In Germany union density rates are high, and workers retain considerable leverage over their terms and conditions of employment. A highly regulated system, to be sure, but it has succeeded in economic terms in delivering high levels of productivity and economic efficiency. It remains unique among the advanced economies in retaining a strong manufacturing sector. Further contrasts are provided by Spain, where unionism only took root after the death of Franco, and where a substantial proportion of the workforce is engaged in part time work, while in the former Soviet bloc, systems of industrial regulation and union formation are evidently in a state of flux.

The key conclusion is that countries within the European zone should be studied in their own terms and not be grouped under facile descriptions of a rigid and inefficient block of sclerotic economies burdened with high unemployment and low productivity growth rates.

The early evidence base for the study of industrial relations was forged in the last decades of the nineteenth century. Seminal contributions from the Webbs (1894, 1920) brought a new focus to the examination of the nature of employment, authority relations, and the position of wage labor that had not been attempted since Engels's study 50 years earlier, of the nature of employment in Halifax, Leeds, London, and Manchester (Engels 1993).

Writing in a period of growing tensions in major industries – railways, textiles, chemicals, and coal – and in the buildup to the General Strike of 1926, Sidney and Beatrice Webb laid the foundations for the modern study of industrial relations. Leading practitioners such as Montague Burton – who developed in Leeds the largest clothing factory in the world – commissioned independent research into the conditions of industrial peace. He funded three

Chairs at the Universities of Cambridge, Leeds, and Cardiff in the late 1920s to address the concerns of key businesses about achieving a degree of consensus on the shop floor. The incumbents of these Chairs brought pragmatic guidance to the key policymakers involved in employment relations, the practitioners in the expanding industries, and the growing trade union movement. The concept of partnership – a current public policy issue in the UK and continental Europe – had been anticipated by progressive employers and trade unions eager to establish negotiating rights in the factories in the third decade of the twentieth century. The situation in the US was far less hospitable and was not placed on a more constructive footing for at least two decades.

Industrial relations became an established source of public policy concern in the US and the UK in the 1960s. In the US the research led by economists (Lloyd Reynolds, Clark Kerr, and John Dunlop) took as a point of theoretical departure traditional neoclassical economics. But they invested their studies with an acute understanding of power relations in the work place and the pluralism of interactions between trade unions, government, and employers. Their research engaged with the orthodox notion that the anonymous forces of supply and demand dictated employment levels, rates of pay, and the position of different segments of the workforce within organizational hierarchies. Detailed studies of firms' internal labor markets (e.g., Ozanne 1968) revealed how imprecise a guide to the world of work the traditional economic axioms were (and still are). A beacon of light at a time of growing policy and theoretical conservatism, their work provided much of the impetus for the development of the academic study of industrial relations in Britain.

The research that ensued in Britain was driven by immediate policy questions focusing on rising strike levels, productivity deficits, and complex wage systems that were allegedly bringing manufacturing companies to a standstill. The challenge for researchers was to get behind the political rhetoric of the day. The lead was taken by a group of historians and social scientists committed to interdisciplinary policy research, collectively known as the "Oxford School." Led by Hugh Clegg, the group included academic practitioners (notably Alan

Flanders and Clegg) and historians of the labor movement (Alan Fox). Such was their political influence at this time, Clegg was asked by the then prime minister, Harold Wilson, to lead the 1965 Royal Commission on Industrial Relations. Notwithstanding the often inflated (sometimes inflammatory) claims of many writers who claimed to have detected a direct causal link between the UK's industrial relations and economic underperformance, no clear evidence was produced (see Nolan 1996 for an exposition of the debates).

Anecdotes were used by economists to support their accounts of the underlying institutional causes of productivity deficits with the ever more successful economies of continental Europe, but the economists rarely entered the factories and offices about which they had so much to say. Studies failed to demonstrate a clear causal link between the UK's economic underperformance and the pattern of industrial relations in firms and industries. Many commentators gave voice to the government's position that the established voluntary system of industrial relations in the UK had proved deleterious to economic performance, and that a regime change, involving restrictive legislation against the activities of trade unions, was required. As indicated below, there followed a sea change in the character of industrial relations.

The government was disturbed by the increasing incidence of strikes that were both unconstitutional (out of procedure) and unofficial (unauthorized by the leaders of the relevant unions). Sometimes referred to as "wildcat" strikes, because of their spontaneous character on the shop floor, these actions were particularly common in the ailing UK engineering industries. Coventry, Birmingham, and Liverpool were notable hotspots. In Leeds textiles and clothing featured prominently in the disputes stakes. Some commentators linked the strikes and the wage drift associated with the increasingly tight labor markets in the 1960s to loss of market share in international manufacturing markets.

Hugh Clegg commented thus:

Under employment of labour is one of the major scandals of the British economy. There may be few workers outside the newspaper

industry who are paid to do nothing at all, but throughout British industry there must be hundreds of thousands of workers who are paid to do nothing for a considerable part of their time ... Then there are the machines and changes in technology many of them in use in other countries which would be introduced here but for the limits placed by workers on their output. (Clegg 1964)

On the face of it this statement by Clegg represented a severe attack on the disruptive powers of the organized trade union movement in the UK, but he was also careful to include in his prescriptions the failures of management to do their jobs properly and efficiently. The Oxford School were ambivalent. Always committed to mutual disputes resolution in the workplace and to the limited role of legislators, Clegg and his colleagues espoused a program of reform that would engage all key parties: employers, workers, and their representatives to collective bargaining and the elaboration of new workplace procedures to minimize the damage that ensued from unbridled conflict.

The underlying philosophy was pluralism, the central idea that there were multiple stake holders in the workplace. The evidence that the Royal Commission assembled revealed that conflict was endemic in the workplace and that institution building was the best way of raising productivity and reducing strikes, absenteeism, and conflict. Their prognosis – most clearly registered in the Royal Commission Report – was that power should be shared through the elaboration of collective bargaining arrangements, that the emerging numbers of unpaid shop stewards in private and public sector organizations should be provided with facilities (office space, time off work for meetings) in order to resolve differences with management to avoid strikes and productivity damaging acts by both employers and employees.

Throughout this period in which academics worked hand in glove with policymakers in the UK and US, there were powerful dissenting voices. The most prominent scholar in the UK was Professor Vic Allen, a self proclaimed Marxist. The Oxford School ignored his contributions but failed to minimize their impact on successive generations of students of industrial relations that found in his work a refreshing challenge to the pluralist orthodoxy (Allen

1971). The argument, backed by careful empirical research, that workers and their employers had often differences that could not be reconciled by institution building as proposed by the 1968 Royal Commission was borne out by the severe conflicts of the 1970s.

The election of Mrs. Thatcher in the UK in 1979 signaled a major upheaval in the practice, perception, and study of industrial relations. The situation in the US was bleaker, with union membership plummeting and employers introducing tough measures to retard workers' "voice" (Freeman & Medoff 1984). The attack by the Thatcher government, through numerous legislative measures, effectively prevented unions from taking collective action at the work place. Set piece strikes in the steel, railway, and coal industries halted the threat of mass mobilization policies by workers as the government sought new legal powers to stem the tide of resistance to draconian closure and mass redundancy programs. No sector was protected.

The academic study of industrial relations suffered in line with the prevailing material conditions. The new advocates of human resource management seized upon the evidence of declining collective relations in the workplace and proclaimed a new regime change in which business would work with individuals to secure business success. Performance related pay, regular performance appraisals, teamworking, empowerment, and skill development programs were the new watchwords in a managerial vocabulary deployed to win the commitment of employees. Industrial relations researchers remained skeptical, arguing, somewhat complacently, that this was a fashion that would not endure.

The declining status of academic industrial relations was also a result of the failure of the mainstream to engage with other social science disciplines, notably economics. It ceded the terrain of debate – arguably the most politically charged debate in Europe, the US, and the UK – to economists who made bold claims with their blunt tools about the complex causal relations between conduct in the workplace and the performance of companies, industries, and national economies. They claimed that the terrain that had been occupied by students of the labor market, collective bargaining, and dispute resolution could be scrutinized with new techniques and data that would yield more

knowledge than the older tradition of micro empirical inquiry and ethnographic research.

The orientation in the new business schools that mushroomed in the US and UK, and to a lesser degree in continental Europe, promoted new vocabularies centered on leadership, self help, and unbridled individualism in pursuit of personal advancement in the organization. Collective solidarity among workers was consigned to history. Academics in the US developed a new institutional economics that broke with the public policy tradition of the "old" institutionalists (e.g., Kerr, Dunlop, and Reynolds) by elevating transaction costs, for example the costs of managing the employment relationship through an authority relationship as opposed to spot market hire and fire policies. Established research centers were closed or starved of resources. Indeed, in the UK, leading academics were accused of academic bias in favor of collective bargaining at a time when the government of the day was seeking to impose highly restrictive measures on the trade unions.

Did the state offensive against unionism produce new patterns of working and new management practices that redefined the landscape of industrial relations? The evidence for the UK suggests that the new hardline approach against collective bargaining and worker voice was counterproductive. It encouraged sloppy management systems and removed the incentive for employers to invest in new technologies and the up skilling of their employees. UK businesses pursued a longstanding tradition of competing in international markets with a low wage, poorly trained workforce. At the turn of the twentieth century, productivity levels in the UK remained significantly lower than in other European countries and the United States.

Industrial relations have become a major issue for public policy debate. The UK government has retreated from the draconian policies designed to marginalize collective relations in the workplace, in favor of a renewed attempt to generate the condition of industrial peace through institutional arrangements to generate partnership in the workplace. Current developments would have pleased Montague Burton. The attempt by policymakers and researchers to supplant the traditional issues that had for nearly 100 years formed the agenda for the practice and subject of industrial relations by

the rather vague and empirically ungrounded field of human resource management has failed (Nolan & O'Donnell 2003). Unions have begun to rebuild their activities in the UK with membership gains, and employers are increasingly keen to harness their influence in the workplace to bring forward much needed changes to secure productivity and innovation changes. Slowly and unevenly there is a creeping shift toward a more European model of employment relations and a retreat from the harsher climate of industrial relations that has characterized work experiences in the United States. There is an evolving agenda that will inevitably be shaped by the impacts of new information and communication technologies (ICT), global market shifts, and developments in the shape of organizations and production politics at workplace level.

The capacity of industrial relations researchers to engage with these unfolding transformations is demonstrated with explorations into the meaning and potential of the "information age." The analysis of the implications of ICTs, in particular the Internet, for the politics and processes of labor has generated a substantial literature. Debate has been driven by concern with finding ways of building more effective forms in the face of the widespread and global "crises" of trade unionism, while taking inspiration from the innovative countercoordination of workers who have already demonstrated the potentialities of new ICTs. In South Korea, for example, the Internet has been identified as central to the strategy of the Korean Confederation of Trade Unions to break free from clandestine status, while in the 1995–8 unofficial Liverpool dockers' dispute the Internet was used to generate the most widespread international simultaneous solidarity action the labor movement has ever witnessed (Carter et al. 2003).

Developments in union presence on the Internet, the routine use of electronic communications, and the sponsorship of practitioner and academic reflection upon the opportunities and "perils" provide clear indication of future possibilities (Hogan & Grieco 2000). There is now a widespread availability of communication technologies that can be utilized at relatively low and distributed cost and accessed in transit and from the home, with processing and storage capacities that are growing exponentially and which can be readily deployed for the receipt,

storage, auditing, manipulation, and broadcast of information globally. Through intervention into these communicative spaces visibility is greatly enhanced, allowing for the auditing of the performance of individuals and institutions (Hogan & Greene 2002). The retention of memories and traditions that hitherto had so easily been broken or lost is also placed within grasp as never before. This drive to innovation can challenge established power relations within trade unions but can also be internalized within labor institutions by the adoption of servicing and organizing facilities which specifically address the need to operate outside of the disciplinary constraints of hostile workplaces and which recognize that the captured market of the occupationally concentrated community is no more (Hogan & Nolan 2005).

industrial revolution

François Nielsen

The Industrial Revolution (IR) is the rapid increase in the use of machines powered by inanimate forms of energy (such as waterfalls, steam engines powered by coal, or electricity) that began in England in the later part of the eighteenth century. There are two perspectives on the scope of the subject. The IR may be viewed both as (1) a well defined historical episode, delimited in time and space, or (2) a much broader phase of sociocultural evolution that is

continuing to this day. In the first approach there is much agreement about the place (England) and time (the late 1700s). The year 1750 can be taken as a reasonable nominal date for the beginning of the IR (Nolan & Lenski 2004), although it might be considered early by some historians. The second approach is more encompassing, as it views the economic and social transformations of the nineteenth and twentieth centuries as all part of the unfolding of the IR.

A broad approach to the causes of the IR is to say that it is the result of the accumulation of technological information in agrarian societies of western Europe in the centuries that preceded the revolution (Nolan & Lenski 2004). Among these were innovations in shipbuilding and navigation that made possible transoceanic travel and the discovery of the New World. This event would contribute to increase trade activity, especially in the North Atlantic area, and infuse the European economy with large quantities of gold and silver. The resulting inflation favored the ascent of commercial classes relative to the landed aristocracy, and motivated the latter to try improving productivity of their land, spurring great progress in agricultural production. Another specific technological innovation was the mid fifteenth century invention of the printing press, which favored the spread of literacy and information in general and perhaps the rise of the rationalism associated with the Enlightenment. The printing press also facilitated the success of the Protestant Reformation, which was premised on direct access to sacred texts by believers. Much has been made of Max Weber's argument in *The Protestant Ethic and the Spirit of Capitalism* that the Protestant ethic of frugality and hard work facilitated the IR, but a major role of religion in the IR is unlikely in view of the fact that the earliest industrialized areas on the continent tended to be Catholic rather than Protestant (Delacroix & Nielsen 2001).

SHORT TERM CONSEQUENCES

Short term consequences of the IR are taken to be those that were already in evidence by, say, 1850.

Successive technological innovations in the late 1700s, especially in the textile industry,

led to the design of increasingly complex machines that became too heavy to be operated by muscle power alone. The factory system arose because of the need to organize work activities near machines connected to a central source of power, such as a water mill or later a steam engine. Factory based production had the additional advantages of permitting a more elaborate division of labor and closer supervision of the workers. Eventually there would be a corresponding decline in home based manufacturing production (the "putting out" or "cottage industry" system), although this consequence was not immediate.

Labor demand associated with the rise of factories exacerbated the influx of rural population to towns and cities. In the mid 1700s only 15 percent of the population of England lived in towns of 10,000 or more; this proportion increased to a quarter by 1800 and one half by 1840 (Weightman 2003: 77). Immediate consequences of rapid urbanization were crowding, pollution, disease, poverty, crime, and other social ills. Contributing to social disorganization was the uprooting of industrial workers and their families from kin based and traditional support networks in the countryside. Local town officials were overwhelmed and unable to cope with social problems on such an unprecedented scale (Nolan & Lenski 2004).

Although the issue of the short term impact of the IR on living standards is still controversial (Evans 2001), it is known that the first half of the nineteenth century was characterized by much economic instability and that many families were barely able to survive on low factory salaries, even with all members of the household employed (including children as young as 6) and despite long hours of work in often deplorable conditions. The obvious hardship of workers' lives made entirely reasonable Karl Marx's belief, shared by many contemporaries, that the development of capitalism would entail the progressive impoverishment of the proletariat, a prediction that turned out to be false in the long run.

LONG TERM DEVELOPMENTS

The entire way of life characteristic of modern industrial societies has its roots in the IR, and

thus can be viewed as a consequence of this historical episode. Some of the specific causal threads linking modern life to the IR can be distinguished.

Economy and Labor Force

Industrialization has transformed the predominant types of economic activity carried out by the population of industrial societies. The proportion of the labor force employed in the primary sector (extractive activities such as agriculture and mining) dwindled in most industrial societies from an overwhelming majority in 1750 to less than 5 percent by the close of the twentieth century. The secondary sector (manufacturing industries) rose to approximately a third of the labor force, reaching a maximum early in the second half of the twentieth century before declining in later decades. It is employment in the tertiary sector (services, or the production of intangible goods) that rose steadily throughout the course of industrialization, up to some three quarters of the labor force in many industrial societies today. These trends in the nature of work activities have radically changed the daily life and worldviews of members of industrial societies.

Industrialization began changing the nature of firms around 1850 with the spread of corporations based on the bureaucratic mode of organization, with a parallel decline in individually or family owned firms. One major advantage of the corporate form of organization, in which the firm is collectively owned by shareholders in the form of stock, was the principle of limited liability, a genuine legal innovation of the industrial era. Limited liability means that investors are risking only the amount invested in shares, rather than their entire assets, in the corporate venture. This allowed the spreading of risk and the consolidation of vast amounts of capital. Corporations were run on bureaucratic principles, including the assignment of positions on the basis of competence acquired through education and training. This development coincided with the increasingly systematic application of science to industrial production. The resulting demand for skills, from the elementary (literacy) to the most sophisticated (such as

engineering or legal), must have contributed to the spread of education, although other factors such as national rivalries may have been at work. Most industrial societies had extensive systems of primary education by the late 1800s, often with compulsory attendance laws. Systems of mass secondary and tertiary (college level) education involving large proportions of the corresponding age cohorts did not develop until the second half of the twentieth century, however.

An inherent feature of capitalism is the tendency to growth in the average size of firms and industrial concentration, resulting in the domination of an industrial sector by one firm (a situation of *monopoly*) or a few (*oligopoly*). The mechanism of industrial concentration is based on economies of scale, which imply that a firm producing more units can reduce production costs by further subdividing fixed costs (such as costs of machinery, product development, and advertising). An initial market share advantage thus permits reducing production costs, and capturing an even larger market share. This autocatalytic process ("snowball effect") inevitably leads to increase in the size of firms and industrial concentration, a trend that was already evident in the late 1800s. As corporations grew in size and complexity they became increasingly controlled by the appointed executives (who had the expertise needed to run the organization) as opposed to the stockholders.

Demography, Family, and the Role of Women

Industrializing societies (with some exceptions such as France) experienced the *demographic transition* which is marked by a decline in the death rate followed by a delayed decline in the birth rate. The decline in deaths was due to improved food distribution facilitated by better transportation networks in the form of canals and railroads, better sanitation such as sewers and water treatment systems, and other public health measures such as vaccination. The decline in birth rate was due to a decline in the desire for large families more than improvements in birth control technology; the phenomenon is still somewhat mysterious. During the demographic transition, as the decline in births lagged behind the decline in deaths,

industrializing societies experienced a phase of rapid population growth.

Rising productivity of labor combined with tapering population growth at the conclusion of the demographic transition eventually produced a remarkable rise in living standards for a majority of the population of industrial societies, refuting the trend of impoverishment prophesied by Marx.

Declining birth rates entailed much smaller families. The trend was dramatic: of British couples married around 1860, 63 percent had five children or more; of those married around 1925, only 12 percent did (Nolan & Lenski 2004: 281). Smaller family size reduced demands on women in the household, facilitated employment of women outside the home, and contributed to make women (and individuals in general) increasingly independent from the family.

With the decline in family farms and home based industry the household ceased to be the principal unit of production. In a parallel trend the family lost a number of its traditional functions, including caring for the sick and the elderly, part of the socialization of children, and even food preparation; these activities were taken over by specialized organizations such as hospitals, retirement homes, schools, and makers of frozen dinners. Raising children, their early socialization, and the provision of emotional support for members have remained important functions of the family in industrial societies. The development of labor saving machines for household tasks during the twentieth century further freed women for outside employment.

Greater independence from the family due to employment opportunities for women and the economic safety net provided in some measure by most industrial societies cannot be unrelated to the secular increase in divorce rate (a trend also marked by major upward and downward swings) that affected most industrial societies.

Ideology and Politics

In the ideological realm industrialization witnessed the emergence of new secular ideologies, including free market capitalism (Smith 1976 [1776]), and socialism in two principal flavors:

democratic and revolutionary. The polity was transformed by the remarkably steady progression of *democratic republicanism* or *mass democracy*, i.e., a system of government where political decisions are made by representatives elected by the entire citizenry. Using franchise or electoral turnout as an indicator, it appears that democracy has increased steadily from the early 1800s, only temporarily interrupted by the fascist takeovers of the 1920s and 1930s (Flora 1983; Nolan & Lenski 2004). The democratic trend can also be seen in the passage of successive legislative milestones such as universal male voting, women suffrage, or Jewish emancipation (Davies 1998).

Another political trend was growing support for democratic socialism in many industrial countries, often with the support of working class organizations such as trade unions. Social democratic parties have achieved many of the goals of socialism, collectively referred to as the welfare state. These goals include social security, state pension systems, unemployment compensation, national health care, free education at all levels, family allowances, subsidized childcare, and so on. The extent to which the welfare state has been achieved varies considerably among modern industrial nations, being less developed in the US than in most European countries (Esping Andersen 1990).

The development of the welfare state and other government activities has produced massive increases in the size of government in all industrial societies, whether size is measured as number of employees or as government share of gross domestic product. "Big government" is strongly correlated with the development of the welfare state (e.g., Nolan & Lenski 2004: 233).

Fewer people in industrial societies today attend religious services or believe in God. The decline in traditional religious beliefs has been less marked in the US, a particularity attributed variously to the historical salience of religion in the country's origins, the variety of denominations and resulting competition for members (resulting in a more "efficient" recruitment of believers), or the relative failure of socialist ideologies in the US (Lipset & Marks 2000). It is possible that the trend of religious skepticism is partly independent of

industrialization per se, having deeper and independent roots in the Enlightenment.

The World System

In the international context the rapid increase in production beginning with the IR in industrializing areas of Europe (and later the US and Japan) initiated an unprecedented rise in overall world inequality, as the income gap kept widening between industrial and non industrial nations for more than two centuries (Firebaugh 2003). The resulting development gap, and the associated imbalance in military technology and power, may well have provided the conditions for the phase of territorial expansion of industrial nations from about 1860 to the eve of World War I that has been called *imperialism* or *colonialism* (Chirot 1986). This historical episode set the stage for the current phase of globalization (increasing trade and interactions of all kinds) affecting societies within the world system.

INDUSTRIAL OR POST INDUSTRIAL SOCIETY

Some authors argue that the transformations taking place at the turn of the twenty first century are so profound that societies affected by them deserve the new name of *post industrial* societies. The post industrial type of society is deemed different from the industrial one in that it is based on the production of services rather than manufactured goods, the processing of information rather than material objects (Bell 1976). Others, such as Nolan and Lenski (2004), prefer to view these recent trends as part of a later phase of the IR. In that view, advanced industrial societies today are experiencing the continuation of the IR rather than moving toward a radically different post industrial stage. Both views certainly have merits; analyzing today's social trajectories does not require choosing any particular terminology.

industrialization

Michael Indergaard

Industrialization is the process by which an economy shifts from an agricultural to a manufacturing base during a period of sustained change and growth, eventually creating a higher standard of living. Sociology's founders were keenly interested in the causes, correlates, and consequences of industrialization, which they considered a major development in the broader social transformation producing modern society.

For much of the twentieth century, however, broad analyses by classical sociologists such as Marx and Weber were overshadowed by narrow accounts featuring technology or efficiency. Sociologists often deferred to economic historians, accepting determinist narratives of a singular path of industrialization marked by a flurry of new gadgets, energy sources, and processes unleashed by *laissez faire* policies. Sociologists drew on miscellaneous concepts and observations to compile profiles of industrial society featuring traits such as a division of labor, rationalization, the systematic application of science, urbanization, increased life expectancy, literacy, higher standards of living, and democracy. More recently, the humbling of western industry by newly industrialized countries (NICs) has led sociologists to examine how interactions of political, cultural, and economic factors in different contexts produce multiple paths of industrialization.

A key influence on discussion of industrialization was Adam Smith's notion that more specialization in the division of labor, though it had negative effects on workers, is more efficient and inevitably increases a nation's wealth if the state adopts a *laissez faire* stance. Another was provided by French writers in the early 1800s who spoke of an Industrial Revolution, citing parallels between technological changes in manufacturing and the French Revolution. Engels drew on various romantic currents in exposing the conditions that the Industrial Revolution imposed on the English working class. In *Capital* (1867), Marx placed the Industrial Revolution in the historical development of the capitalist mode of production, arguing that the detailed division of labor abetted the introduction of machinery which subordinated and replaced workers. Social progress, he asserted, awaited an overthrow of capitalist class relations and the detailed division of labor. Victorian reformers, alarmed by the revolutionary critiques and growing urban poverty, embraced Toynbee's romantic denouncement of the Industrial Revolution which, ironically, echoed Engels: it established the idea among economic historians that industrialization occurred through rapid technological change causing social catastrophe (Coleman 1992).

Most sociologists rejected Marx's radicalism, preferring interpretations of industrialization

compatible with reformist positions. They were attracted to Durkheim's argument that the division of labor had temporarily made social solidarity problematic and to Weber's early work on the Protestant ethic, touted as the culturalist answer to Marx's materialism. Discussions of industrialization largely ignored Marx's dialectical conception of history and the comprehensive analysis that Weber later developed of how cultural, political, and economic factors interacted to produce rational capitalism.

The reform inclination in the early twentieth century was particularly evident among American sociologists who, having agreed to stay out of turf claimed by economists, focused on social aspects of industrial society. The Chicago School organized around the study of social problems and forms of organization in industrial cities, while a broad subspecialty – industrial sociology – drew on institutional economics and human relations theories to explore relations and groups in industrial organizations and workplaces. Over time, industry sociology expanded to examine additional issues such as development, occupations, stratification, organizations, and labor markets before such topics were hived off by a host of emerging subspecialties in the discipline.

A new movement in economic history injected optimism into discussions of industrialization during the twentieth century, celebrating the Industrial Revolution's technological achievements (e.g., use of coal, the steam engine, the spinning jenny); it reinforced the idea that the British case defined a general path of industrialization. The Great Depression, fascism, and the Soviet Union's industrialization temporarily raised doubts about the one path thesis. Free market accounts of industrialization also were challenged by Polanyi's argument that ideology and state interventions set the ground for industrialization and for unregulated markets themselves. However, the World War II triumph restored confidence in the US that industrializing countries would converge around a common path. Some economists advised that multiple paths were possible, but many sociologists embraced Rostow's modernization thesis that all developing societies would have to pass through five stages of development, with industrialization representing the takeoff stage. Similarly, industrial sociologists

endorsed a convergence thesis proposing that functional imperatives of industrialization required societies to develop certain traits – e.g., an extended division of labor, separation of family and enterprise, and rational forms of calculation and investments. They added that industrialization would encourage secularization, social mobility, and democracy.

In the 1960s and 1970s, a new wave in economic history attacked the Industrial Revolution metaphor, using macroeconomic trends (e.g., growth in national income, growth and sectoral composition of the labor force) to argue that industrialization had been a gradual process. Achievement partisans, however, depicted the Industrial Revolution in ever more heroic terms, comparing it to the development of agriculture, monotheism, and even language. They bolstered their position, drawing on Schumpeter's claim that each long wave of growth was propelled by a distinctive set of innovations (Coleman 1992). Dominant accounts of industrialization also came under fire from the left. Neo Marxians revisited western industrialization, arguing that its capitalist nature accounted for the calamities it inflicted on working people. Labor process studies showed how social control agendas drove efforts in factories to subdivide work and deskill workers. Dependency and world systems theorists proposed that the development of poor nations was distorted or constrained by unequal relations with advanced nations.

In the 1970s and 1980s, the rise of state guided industrial powers in East Asia, crisis in western industry, and promotion of free markets by Anglo American neoliberals brought a sea change in studies of industrialization. Debates about flexible industrial systems and new global divisions of labor produced evidence that industrialization had taken multiple paths in the past as well as the present. Seeking an alternative to technology/efficiency explanations, a new economic sociology spearheaded a return to broad examinations of industrialization. Piore and Sabel's (1984) study of the triumph of mass production over craft production inspired a large body of work. They argued that political conflicts and competing visions influenced the path that industrialization takes in different nations and the respective capacities that result

(e.g., the flexibility of Japanese manufacturing). Institutionalists also cited political and cultural factors in challenging Alfred Chandler's argument that the industrial corporation gained the form that it did (modeled on railroad administration) because it was the most efficient way to coordinate a large number of geographically dispersed workers.

A second debate concerned the rise of Japan and the East Asian NICs (South Korea, Taiwan, Hong Kong, Singapore). Economists attributed their international competitiveness to free trade policies which gave them access to foreign capital and technology while exposing them to market discipline. In contrast, proponents of the developmental state model argued that a distinctive set of policies gave East Asian NICs an advantage in overcoming the internal obstacles that late industrializers face. As was the case with Japan earlier, an initial lack of capacity for innovation in products and processes forced late industrializers (e.g., Brazil, Turkey, India, Mexico, South Korea, Taiwan) to enter the global economy through emulation of foreign technology and reliance on cheap labor and tariffs. Developmental states allowed East Asian NICs to complete and develop beyond this initial stage much more quickly than other NICs. The developmental state devises national strategies, encourages the formation of business groups, and guides capital into targeted sectors. It also exercises discipline over business (e.g., performance standards) as a condition for subsidies, encouraging firms to excel in making incremental improvements and enabling entire segments to move into higher value sectors (Amsden 1989). A second explanation (Gereffi 1994) for varying paths of industrialization among NICs stresses the different positions that their chief industries hold in new global divisions of labor. State strategies still matter, but are constrained by the dynamics of product cycles and by the structures of different kinds of international commodity chains dominated by multinational corporations. A third model stresses the hybrid nature of post socialist development, a notion that is especially relevant for the case of China – an avowed practitioner of market socialism that is often considered an avatar of global market forces but also resembles a developmental state.

The post industrial society thesis deems the recent decline in manufacturing in western nations to reflect a transition to a knowledge based service economy. However, the credibility of the term post industrial depends on how industrialization is defined. If one considers industrialization to be the rationalization of economic activities, as does Ritzer's McDonaldization thesis, then the standardization of work routines and the homogenization of products and consumption that one sees in a fast food restaurant imply that industrialization continues in the service sector. Other work suggests that the development of information technology represents the industrialization of information. Mokyr (2002) proposes that sustained growth in both the First and Second Industrial Revolutions was due to the broadening of the knowledge base. He raises the possibility that the increasing accessibility of scientific knowledge due to computers may have initiated a Third Industrial Revolution. Synthesizing the literature on industrialization in the past and present, Castells (2000) advises that we are undergoing an Information Technology Revolution based on the application of knowledge and information back to the very process of generating knowledge and information.

The term industrialization seems more the product of mythmaking and list making than a coherent theoretical program. In the reductionist manner in which economics addresses the term, industrialization means so little; in sociology it has come to mean so much. After nearly two centuries of use, basic definitional and methodological issues remain unsettled. When can a nation be deemed to be industrialized? At what point does the process begin? Can industrialization be distinguished from a stage of capitalism or the process of rationalization? What social structures, institutions, and processes are as essential for industrialization as technology and how should we understand their interplay? Should the unit of study be the nation state or some global segment?

Given industrialization's correlation with basic indicators of well being, it is important to determine what can still be expected in cases where industrialization has stalled or never really started. That problem is becoming more complex and daunting as the industrialization

of developing nations is increasingly structured by their links to global networks of production and information technology.

inequalities in marriage

Constance Shehan and Susan Cody

Women and men typically experience different rights and responsibilities in marriage, in spite of widespread beliefs in marital equality. These differences led sociologist Jesse Bernard (1972) to coin the phrase "his and her marriages." Gender based patterns of marital inequality have existed historically in the US and other western nations, though they have declined somewhat in recent decades, and they persist in other parts of the globe, as well. For various reasons, which will be outlined below, there are systematic gender differences in the amount and type of domestic labor and family care performed by spouses, in power and authority in marital decision making, in access to and control over household resources, and likelihood of experiencing severe injury as a result of spousal violence. Gender based inequalities continue after divorce, characterizing property settlements and custody arrangements as well as the relative economic circumstances of former spouses.

INEQUALITIES IN THE DIVISION OF HOUSEHOLD LABOR

Studies of the division of household labor conducted over the past 40 years have shown that women allocate considerably more time each week than men to various household tasks and family care even when they are employed outside their homes. Today, women typically devote about 19 hours, and men about 10 hours, to housework each week (Bianchi et al. 2000). The types of household tasks performed by women and men also differ. Men tend to do those that are more flexibly scheduled and at least somewhat discretionary, whereas women perform routine and repetitive labor that must be performed on a regular basis (Hochschild 1989).

In terms of childcare, fathers are more likely to spend time with children in recreational activities while mothers allocate considerable time to basic "maintenance" chores. The gender based patterns of family care are even more pronounced when it comes to elderly relatives. Nearly all the work that is done for ill or dependent elderly

people in private homes is done by women. British researchers estimate that the ratio of time women and men spend in elder care approaches 19 to 1 (Abel 1986). Even in households where time allocated to household tasks and family care by spouses is similar, wives perform an "executive" function, monitoring family needs and ensuring that they are met in a timely and effective fashion. This may mean hiring and supervising outside help, in which case wives are likely to use their own salaries to pay for the costs of the auxiliary help. As a result, women spend more of their time in various types of labor and have less time for leisure and sleep. Among married couples with infants, women work an extra day, or 24 hours more per week than their husbands (Rexroat & Shehan 1987).

INEQUALITIES IN POWER AND DECISION MAKING

Marital power can be defined as one spouse's ability to impose his or her will on another, which can mean forcing the other spouse to act in certain ways or accept a specific "definition of reality" as one's own (Aulette 2002). Alternative explanations for the balance of marital power emphasize individual traits or abilities such as one partner's greater size or strength, greater knowledge or expertise, control over socioeconomic resources, or superior communication skills. Thus, the balance of power swings to the stronger spouse or the one who contributes more money and status. When decisions are contested, the partner with the greater interest in or knowledge about the issue may have greater say in the final outcome. Or, in some cases, the more persuasive partner may win out. These bases of marital power often favor husbands insofar as men, on average, are larger and stronger and earn higher wages than their wives. Gender differences in communication styles in which men tend to control the course of conversations by talking more, interrupting more, and vetoing topics, may also swing decision making power to husbands. One of the most important bases of power in marriage is patriarchal authority: legitimate authority bestowed on men to act as the heads of their families and/or households. Patriarchy is institutionalized in religious customs and governmental policies.

In many cultures, women's secondary status is linked to social systems which connect kinship and patriarchy. In such societies, social relations, including those within families, are influenced by traditional views of women and men. Kin groups are built around male headship. Traditions of patrilinealism and patrilocality have restricted women's choices inside and outside the home (Lerner 1987). In recent years, however, extended families have become less common around the globe. While this change has been bemoaned by some as a loss of tradition and family ties, it is also linked to greater freedom for women.

Today, in most western societies, patriarchal authority in families and households does not have the same influence it once had, but it still exists and in certain segments of American society it continues to be strongly supported. Evangelical Christians, for instance, often adhere to patriarchal authority, as do other religious subcultures such as the Hasidic Jews, the Old Order Amish, and to a lesser extent, the Mormons. Some ethnic and nationality groups in the US also adhere fairly closely to a patriarchal ideology. These include people who have recently emigrated from the traditionally patriarchal cultures of the Middle East, Africa, Latin America, and Asia. African American and Latino populations have cultural elements that support patriarchy, although other aspects of their lives (such as the need for women to be employed) may counterbalance the traditional view of male dominance.

Patriarchy is also built into civil laws. In a very real sense, American state and federal governments create a hidden marriage contract through laws, administrative rulings, and court decisions. This contract defines the rights, responsibilities, and obligations of married persons and is based on traditional assumptions about the roles of husbands and wives which grew out of English common law. Any person who marries is agreeing to conform to any and all conditions of the hidden contract (Stetson 1991). Primary among these assumptions are the following: husbands are the heads of their households; husbands are responsible for the economic support of their wives and children; and wives are responsible for domestic services and childcare. Under the common law tradition, husbands had the right to decide where they and

their families would live. They were also given control of the family's economic resources, including the wife's property and possessions at the time of their marriage. When a wife was employed under these conditions, her husband was entitled to her wages.

INEQUALITIES IN THE LIKELIHOOD OF INTIMATE PARTNER VIOLENCE

While men are more likely than women to be victims of reported violence in our society, they are considerably less likely to be victims of intimate partner violence. If women are violently assaulted, their assailant is most likely a husband or boyfriend. When women are assaulted, they are more likely to be injured if they have an intimate relationship with the perpetrator. Bureau of Justice statistics reveal the extent of the gender difference: roughly 7.5 women and 1.4 men in every 1,000 are victims of crimes with intimate perpetrators. Feminist scholars argue that gender inequality and the oppression of women are the central features of violence in families. Historically, there have been norms and laws that condone violence against women. In the nineteenth century, for example, many states had laws specifically approving of wife beating. Battering is a reflection of the inequality between women and men and is a conscious strategy used by men to control women and to maintain the system of gender inequality.

In 1993 the United Nations adopted the Declaration on the Elimination of Violence Against Women. UNIFEM, the branch of the United Nations which deals with women's issues, has focused its attention on the global epidemic of violence against women and girls, especially violence that occurs within families (Sev'er & Yurdakul 2006). Because of the strong preference for sons, girls face a high risk of violence beginning at or before birth. Parents may use practices such as sex selective abortion or infanticide to increase their chances for a son (Ravindran 1986). Worldwide, millions of girls have been victimized by a practice known as female genital mutilation (FGM). This cultural practice involves some combination of procedures ranging from partial to total removal of the clitoris and/or sewing together the external genitalia, often under very harsh and unhygienic conditions. It is used to ensure the virginity of

girls, thereby increasing their opportunities for marriage (World Health Organization 1995).

Cross cultural studies indicate that wife beating is the most common form of family violence (World Health Organization 1995). Estimates of the incidence of wife abuse are conservative, due to shame and guilt on the part of victims, lack of legal recourse, and fear of partner retaliation. In recent years, extreme forms of violence against wives have been exposed. In India, for example, wives are expected to express deep gratitude for selection into marriage and to show deference to husbands and other family members. Bride burnings may result from a wife's alleged infidelity or a family's inability to pay the dowry in full to the husband.

In recent years, honor killings have been publicized in such nations as Pakistan, Egypt, and Turkey (Sev'er and Yurdakul 2006). Such countries have a strong tradition of family based patriarchy and may customarily mandate complete control over women's social, reproductive, and economic lives. In Turkey, for example, wives have virtually no rights to property, and their sexual behavior continues to be controlled even after a legal separation has been granted. Wives are not protected against marital rape unless they sustain a serious and obvious physical injury. Furthermore, law enforcement officials continue to hold very traditional ideas about sexual assault, believing that women provoke such crimes in most cases.

EQUALITARIAN MARRIAGES

Despite the prevalence of traditional or patriarchal marriages, it does appear that some couples today are attempting to create and maintain what has been described as egalitarian or "peer marriages." Greater awareness of gender inequalities, changing gender roles, as well as the need for two wage earners, has prompted some couples to consider a more equitable type of intimate relating. Clearly, the inequalities associated with marriage have been a major source of marital dissatisfaction in the past. Couples who maintain or who perceive that they maintain equity in their relationships express higher levels of marital satisfaction. Sociologists have coined the term peer marriage to refer to relationships that are built on *equity* (i.e., each

partner gives to the relationship in the same proportion that she or he receives) and *equality* (i.e., each partner has equal status and is equally responsible for emotional, economic, and household duties). Peer marriages are difficult to achieve and maintain, however, due to the overwhelming acceptance and established traditions of patriarchal marriage. Couples who strive for egalitarianism are viewed with suspicion, disbelief, or hostility (Blumstein & Schwartz 1983). Not surprisingly, women are often the first to initiate or express a preference for peer marriage (Schwartz 1994), although feminist ideology is not often cited as the reason. More often, wives cite the desire for more shared parenting as their primary motivation. Peer marriages remain quite rare (Risman 1998).

Peer marriages have four important characteristics: a nearly equal division of household labor and childcare; equal influence over important decisions; equal control over the family money; and equal consideration given to both partners' work in family decision making.

inequality and the city

James R. Elliott and Timothy J. Haney

Urban sociology emerged from the fertile ground of US cities during the early 1900s as a means of understanding social problems and the processes that produce them. Central to the field's conceptualization and analysis of these social problems was, and remains, the idea of inequality, defined loosely as the uneven distribution of social resources and actors relative to one another. As such, the term "inequality and the city" is best understood as a conceptual umbrella that spans a broad range of subtopics and research traditions within urban sociology, rather than as a single subfield in its own right. For heuristic purposes, we can organize this material into two subject matters: inequality *among* cities and inequality *within* cities.

INEQUALITY AMONG CITIES

Research on inequality among cities focuses on how cities emerge and develop through interaction with other places, that is, as connected

nodes within a more expansive trade and settlement system. Early attempts to understand the nature of this system emphasized the hierarchical, or unequal, distribution of cities by size and economic function within national regions, attempting to explain why, for example, Chicago became a more dominant city than Dubuque.

This research tradition traces to the 1930s, when German geographer Walter Christaller (1966 [1933]) advanced two theoretical propositions: first, a positive correlation exists between the importance of a city's economic functions and its population size; second, cities tend to "space" themselves such that those of similar size and economic importance do not cut into each other's market area. From these two propositions, Christaller developed a theory of urban hierarchy in which a few "super" cities generate market control over a larger number of middle order cities, which in turn generate market control over an even larger number of lower order cities, which themselves generate market control over surrounding rural hinterlands. The result is an even, orderly, and unequal system of cities, with those at the top gaining demographically and economically from those beneath them.

Subsequent research has challenged the assumptions and deductive logic of Christaller's theory, but it has not displaced the idea of urban hierarchy. Most recently this idea has resurfaced prominently in the "global city" literature, which investigates how new processes of global trade are redefining the roles that major cities play in the world system. This line of investigation can be traced to the early 1900s, when Robert McKenzie (1927), an original member of the Chicago School of Sociology, advanced a global perspective on urban structure and change in which he argued that social development brings with it increasing specialization of parts and greater centralization of "coordination and control" functions over time. It follows, McKenzie reasoned, that similar processes would bring growing inequality among places around the world, with most settlements becoming increasingly specialized and subordinate to a few cities where these "coordination and control" functions would concentrate.

Today's literature on "global cities" advances a similar theme but also contends that today's

world economy has changed radically over recent decades as multinational corporations have seized the reins of increasingly far flung financial and production operations. These developments have reduced the systemic importance of cities that serve merely as political capitals and increased the systemic importance of cities that act as strategic command posts for global business. According to Saskia Sassen (1991), these developments have produced a new breed of global city, which functions in four ways that distinguish it from the past: (1) as a highly concentrated and influential node in the organization of the world economy; (2) as a strategic site for the location of sophisticated business services, which have replaced manufacturing as the leading engine of economic development; (3) as a production and innovation site for this new sector; and (4) as a place where corporations go to buy and sell these sophisticated business services – accounting, advertising, legal counsel, information management, and the like. Sassen's central point is that global control is not an inevitable byproduct of economic globalization; rather, it must be produced, and this production occurs in global cities.

According to many observers, these developments have changed not only the urban hierarchy but also the social structure of cities at its top (e.g., New York, Los Angeles, Tokyo, London). This line of research contends that the growth and development of today's "command and control" functions in global cities polarize job opportunities in the local labor market. The result is a large sector of highly skilled, well paid, corporate professionals and a large sector of less skilled, poorly paid, non professionals that serve the new elite as maids, janitors, dry cleaners, nannies, private security, restaurant help, and the like. This polarization tends to push working class natives out of global cities, attract low skill immigrant labor, and reproduce, locally, forms of extreme inequality that these cities help to maintain on a global scale.

INEQUALITY WITHIN CITIES

These issues move us from viewing cities as nodes in a larger system to viewing the city as a system itself. This tradition traces to the early

years of the Chicago School (1910s–1920s), when US cities were booming and flush with European immigrants from all regions. Prejudice and discrimination against Poles, Italians, and Irish were high and often bitter during this period, followed later by the great migration of Southern, rural African Americans to the same urban centers, generating new ethnic divisions. From this turbulent context emerged a rich tradition of research on ethnic, racial, and class inequalities in the city.

Anchoring this tradition is the ecological premise that social and spatial distance correlate positively in the city, such that groups with higher status will seek to remove themselves spatially, as well as socially, from those with lower status. This premise identifies segregation, especially residential segregation, as the chief mechanism behind durable inequality in the city. Early research within this tradition produced rich cultural studies of ethnic urban neighborhoods created by this segregation, capped intellectually by Louis Wirth's (1928) classic study of Jews in *The Ghetto*. By mid century, however, with immigration restrictions in place and European assimilation on course, scholars began steadily shifting their attention from the vibrant lives of ethnic villages to the dramatic segregation of whites and blacks across metropolitan space. This issue erupted onto the front pages in the late 1960s, when racial unrest from Watts to Detroit to Newark shook US cities and white consciousness.

Efforts to understand this unrest pointed squarely to racial segregation of whites and blacks in big cities and the disadvantages and frustrations that this segregation created for African Americans. Central to this literature was John Kain's (1968) "spatial mismatch" hypothesis, which continues to inspire research to this day. Stripped to the bone, the spatial mismatch hypothesis advances two claims: first, proximity to jobs increases odds of employment and reduces commuting costs; second, African Americans tend to live farther than whites from available jobs as a result of residential segregation and emergent patterns of suburbanization. As a result, African Americans as a group tend to have higher employment costs and lower job prospects than otherwise equal whites, leading to higher rates of joblessness and underemployment. In his study of data from the 1950s, Kain

estimated that residential segregation cost African American workers as many as 9,000 jobs in Detroit and 24,000 jobs in Chicago.

A decade later William Julius Wilson (1978) tweaked this idea in his influential book, *The Declining Significance of Race*, when he argued that US society was entering a new era during the 1970s in which class, more than race, now determined the life chances of African Americans. Wilson rooted this claim in the growth of college educated blacks in professional occupations beginning in the late 1960s. For them, and their white counterparts, Wilson claimed, class position, not race, would define their place in the stratification system. The fate of less educated blacks, however, would differ radically. Wilson later argued in *The Truly Disadvantaged* (1987) that as the black middle class grew, it would exercise its new racial freedom and move from established inner city neighborhoods, leaving behind an impoverished "urban underclass" that lacked the skills, job opportunities, and social resources needed to succeed in today's urban economy. The result, Wilson claimed, was not only poor people but also disorganized communities that suffered from their eroding class, not racial, status.

This line of argument generated a great deal of debate in urban studies, with perhaps the most prominent critique coming from Douglas Massey and Nancy Denton (1993) in their book *American Apartheid*. In this and subsequent work, the authors argue that recent shifts in the urban economy away from manufacturing toward professional services have been uniquely detrimental to African Americans because they have joined with racial segregation to produce extreme concentrations of poverty that expose poor blacks to remarkably harsh and disadvantaged neighborhood environments. At stake in the ensuing debate with Wilson was whether race and class could ever truly be viewed as separate causes of urban inequality and what the answer implied for policy efforts to redress this inequality. For Wilson, class specific actions that avoided the stigma of racial politics were best – higher educational standards, better teacher development, more school funding, public child care and parental leave, universal health care, school to work programs, job centers, public employment programs, and the like. For Massey, these laudable efforts would have to be

accompanied by race specific remedies to reduce discrimination and expand opportunities for African Americans specifically, who remain by far the most segregated group in US cities.

By the late 1990s, immigration began to push the intellectual pendulum back from concerns over black/white segregation to concerns over immigrant adjustment and its role in reshaping racial, ethnic, and class inequalities in cities. Central to this literature is the question of how millions of less educated immigrants can enter the same urban environments that failed less educated African Americans and succeed, growing in number. The current answer, while still evolving, seems to run roughly as follows. Less educated immigrants are willing to take jobs that less educated natives will not due to the stigma that these jobs carry in US society. Immigrants who accept these stigmatized jobs, in turn, help friends and relatives move to the area to take similar jobs. The result is an ethnically organized economy for less educated workers, wherein racial and ethnic groups not only tend to live apart from one another but also work apart in labor markets regulated as much by ethnic networks as by market forces. Whether these developments constitute "success" for less educated immigrants is open to question, but scholars have already begun to talk of a new "immigrant underclass" that, despite its steady employment and dense job networks, finds itself living and working in substandard conditions that appear difficult to escape.

A related concern in this area is whether immigration and its urban concentration have increased the difficulties facing less educated African Americans. Sometimes referred to as the "immigrant competition" hypothesis, this question has generated much debate but mixed results. On the one hand, economists and social demographers, who generally expect immigration to harm the wages and employment opportunities of blacks due to open markets, have found little evidence to this effect. On the other hand, sociologists working from a "new economic sociology" framework, who generally assume that immigrant networks minimize competition with blacks, have found evidence of a negative effect of immigration on African Americans' job prospects. The argument here is that urban blacks have trouble finding decent jobs not because they lack the necessary education

and experience but because immigration has divided urban labor markets along ethnic lines, reducing job opportunities for natives, especially less skilled African Americans. Where these and related intellectual traditions on inequality and the city lead next remains for future researchers to decide.

inequality/stratification, gender

Michele Adams

Gender stratification refers to the level of inequality in society based on gender, the social characteristics associated with sex. Specifically, gender stratification refers to the differential ability of men and women to access society's

resources and to receive its privileges. As gender stratification increases, so does the level of gender inequality, reflecting greater differences between men's and women's access to power. Because historically men have garnered greater social power, gender inequality has systematically disadvantaged women. Gender inequality is complicated, moreover, by the intersection of gender with race/ethnicity, social class, age, and sexuality. That is, every individual, categorized as either male or female, also falls somewhere within a matrix of domination that includes these other dimensions (Collins 1991).

Original applications of the terms sex and gender tended to confuse the two, which were often used interchangeably. More recently, most sociologists have begun to distinguish between them, agreeing that the terms should apply to different, but related, concepts. While sex is defined in terms of biology and the reproductive organs one is born with, gender is typically seen in more social terms, as society's idea of how people should be, based on their biological sex. Gender, that is, is socially constructed to reflect society's expectations about how men and women should act, dress, move, and comport themselves in the context of everyday social interaction.

Under what conditions did gender inequality originate and under what conditions has it been maintained? Early answers to this question drew on biological differences between men and women and their associated reproductive functions to posit a "natural" division of labor between the two. Accordingly, men were seen as having evolved from hunters to family bread winners and providers, with women as child bearing, childrearing, and domestic experts. More sophisticated study of premodern societies, however, has discredited many of these assumptions, pointing to more diversity and fluidity in men's and women's roles than a natural division of labor could explain.

As more nuanced information emerged from research on early societies, perspectives on the origin of gender inequality became more complex. Two main explanatory approaches surfaced from these later analyses, one economic and the other political. One early economic perspective came from Friedrich Engels's book, *The Origins of the Family, Private Property and the State* (1884). Although some of his assumptions

are now recognized as incorrect, he was accurate in suggesting that early societies were more gender egalitarian than later ones, based on the latter's accumulation of material surplus. Social theorists (Blumberg 1978; Huber & Spitze 1983; Chafetz 1990) have proposed varying economic perspectives on the origin of gender inequality, taking account of labor conditions, the kinship system, and larger social politics. Generally, economic perspectives on gender stratification suggest that a high demand for women's labor, combined with kinship systems that promote inheritance through the maternal line and residence with female kin, promotes women's economic power and reduces gender inequality. Increased gender equality is evidenced in women's greater control over their fertility, choice of marriage partners, sexuality, and greater authority in the home and local politics.

Political perspectives on the origins of gender stratification examine how military situations and the organization of the state affect the relative power of men and women. One political theory of gender stratification evaluates ways by which control of weaponry, overall military situation, and social stratification and economic surplus affect inequality (Collins 1975). This perspective suggests that gender stratification increases as fighting and weapons are increasingly monopolized by men, and economic surplus and class stratification are high. Under these conditions, women are controlled as sexual property.

The industrial revolution reduced the importance of sex differences in maintaining the gendered division of labor. Machines replaced muscle power, and men's brawn became less significant as a source of energy. By the beginning of the twentieth century, bottle sterilization techniques freed women from the necessity of breastfeeding with its associated time and schedule demands. Over the course of the twentieth century, the invention of the birth control pill and other reliable contraceptive methods allowed women greater control over their reproduction, giving them relative freedom to move into the paid workforce in increasing numbers. According to the *Statistical Abstract of the United States, 2004-2005*, by the end of the century, nearly 60 percent of women aged 25 or older, many mothers of young children, worked in the paid labor force. This is a trend, moreover, that

shows little sign of abating. The sheer volume of women now doing paid work has, to a significant degree, lowered the level of gender inequality in the workplace.

The women's movement has been instrumental in reducing gender inequality. In the US, the first wave of the movement emerged in the mid nineteenth century as a reaction to women's lack of power in both the public and private spheres. Elizabeth Cady Stanton and Susan B. Anthony are well known as initiators of the movement, which ultimately turned its sights toward women's suffrage. After gaining the vote in 1920, the women's movement in the US became relatively inactive for the next 50 years, only to reemerge in the 1970s. This second wave of feminism reinvigorated the quest for women's empowerment in marriage and family and sought to equalize women's involvement and opportunity in institutions such as the labor force, education, law, and politics. While the struggle for women's equality is far from over, second wave feminism was able to mobilize many women (and men) on behalf of women's rights, overturning a number of institutionalized inequities embedded in law and promoting women's involvement in professional occupations and politics at the highest levels.

Nevertheless, both in the US and globally, women continue to be negatively affected by gender stratification. Although inroads have been made, gender persists as a core organizing structure around which inequality is arranged. In the workplace, occupations remain gender segregated overall, with "women's work" providing lower pay, fewer benefits, and less security than "men's work," even if comparable in form or content. At home, women continue to shoulder the lion's share of household labor, childcare, and domestic responsibility, even when employed in the paid labor force. These trends, moreover, extend globally, such that while women now constitute over a third of the world's labor force, they also, according to the Population Crisis Committee (1988), constitute 70 percent of the world's poor.

In the US, education is one area in which women have made substantial gains. In 1970, women comprised roughly 42 percent of under graduate college enrolment; by 2001, that figure had risen to approximately 56 percent, a trend that is projected to continue (Peter & Horn

2005). Similarly, women today are awarded the majority of bachelors degrees (57 percent). Less change has occurred in the areas in which men and women earn their degrees and the earnings realized from them. In 2001, men predominated in business and engineering programs, as they did in 1980, while women have continued to earn more degrees than men in education, the health professions, and psychology. Moreover, the gender wage gap for bachelors degree recipients employed full time one year after graduation actually increased between 1994 and 2001. In 1994, these women earned 84 percent of what these men earned; in 2001, women's earnings had dropped to 83 percent of men's earnings (Peter & Horn 2005).

Women have made less educational progress elsewhere in the world. A gender gap in education persists in much of the developing world, where women's enrolment lags behind men's enrolment at all educational levels. Nevertheless, research continues to demonstrate the importance of women's education, which is positively related to beneficial national outcomes such as economic growth, greater life expectancy, and improved functioning of political processes (Hill & King 1995).

Where women are denied education and other rights, their health tends to suffer. For instance, lack of access to information on preventing HIV/AIDS has contributed to women's increased susceptibility to this devastating disease. According to the UNAIDS report "Women, Girls, HIV and AIDS" (2004), of those infected with HIV worldwide, 47 percent are women; in Sub Saharan Africa, that figure has risen to 57 percent. Besides lack of education, the spread of HIV/AIDS among women has been linked to their restricted access to employment, property ownership, and other rights, as well as their vulnerability to violence.

Violence against women continues to be a major problem, reflecting the extent of gender inequality worldwide. Domestic violence perpetrated against women by their intimate partners has become an issue of international concern, occurring in all countries and across all social, economic, religious, and cultural groups. Stranger rape has become a weapon of war, and women in war zones are habitually subject to sexual assault by their captors both during and after conflict. In some countries such as in Africa,

women ranging in age from infancy to maturity are subjected by custom to genital mutilation. This practice, condemned by international groups, reflects the second class citizenship of women and related attempts to regulate their sexuality. By the same token, constraints on women's ability to control their own sexuality and reproduction have historically been a hall mark of societies with high levels of gender stratification. Lack of access to safe methods of birth control and information regarding family planning and other reproductive options continues to plague women in a number of developing countries (Pillai & Wang 1999).

The following theoretical perspectives are among those invoked to explain the persistence of gender inequality. Sociobiological explanations suggest that the gendered division of labor is based on biological differences between men and women. The greater physical power of men, these theories suggest, leads to economic and political power. Women's reproductive functions, on the other hand, leave them vulnerable, dependent on men for protection and support, and without social power. Sociobiological explanations have been criticized for ignoring relevant cultural and social factors that affect the balance of power between men and women.

Structural functionalism peaked in the US in the 1950s with the theorizing of Talcott Parsons. Reflecting the powerful pro family sentiment that characterized this era, structural functionalists promoted the complementarity of gendered roles for men and women, particularly in the context of the family. Men were instrumental, rational, goal oriented, and unemotional, and their associated role involved acting as family breadwinner. Women were expressive, emotional, and nurturing, and, as a result, were expected to stay home, tend the hearth, and raise the children. Because of the economic aspect of the breadwinner role, men were valued more highly than women, whose family role involved no monetary benefit. Adherence to the structural functionalist notion of gender roles thus institutionalized gender stratification and inequality as a functional imperative of family life. Today, structural functionalism receives little academic support, as it, too, omits questions of power.

Conflict theory is another perspective that may be used to explain gender stratification.

In this account, issues of power do come into play, with gender inequality explained as resulting from the unequal distribution of resources and power between men and women. Men's institutionalized and superior access to resources keeps them in control, while women, who have less access to valued resources, are obliged to submit.

Feminist theory is a version of conflict theory, suggesting that the unequal distribution of resources, control, and power is intentionally (if subconsciously) exercised by men to dominate women. Women are at the center of feminist theory and patriarchy is represented as the social system that supports men's domination of women. The goal of feminist theory is to move beyond theory to actively reduce gender inequality in society and in women's everyday lives.

In some arenas, gender stratification appears to be declining; in others, it does not. Evidence of the former comes in the form of men's increasing participation in household labor and childcare, once thought to be exclusively women's work. Evidence of the latter can be seen in the intractability of the gender wage gap and the glass ceiling that women bump up against in the paid labor force. Moreover, while men are, in fact, sharing more labor in the home, most of the increase can be explained by women who do less rather than by men who do substantially more. Nevertheless, as women continue to press for equality and men recognize the benefits that shared parenting and involved partnering have for them, gender equality is more likely than not to become the norm rather than the exception.

inequality, wealth

Nico Wilterdink

In all human societies beyond a certain minimum size, material possessions (such as land, animals, houses, tools, and consumption goods) are distributed unequally among individuals and groups. Insofar as these possessions have a monetary or exchange value, this unequal distribution can be described as inequality of wealth. Besides, and related to, income inequality, wealth inequality is an aspect of economic inequality which in turn is a dimension of social

inequality in the wide sense. *Wealth* can be defined as the monetary value of the sum total of assets or goods belonging to a certain unit. This unit may vary from a national society (national wealth) to an individual person (individual wealth). *Personal wealth* is the wealth owned by an individual person or a consumption unit consisting of more than one person (a household or family). *Wealth inequality* is usually understood as the unequal distribution of personal wealth in a society.

Wealth gives the owner certain advantages; in other words, it has functions for the owner. These functions vary with the relative amount of wealth, its composition (the specific goods that make up the wealth), and its institutional context (including laws of property). In general terms, three economic or material functions can be distinguished: wealth is a source of (1) income (profits, interest, rent, dividend as well as capital gains), (2) material comfort and consumption (the ownership of a house and various durable consumption goods), and (3) material security. This latter function is particularly important when collective arrangements that guarantee some minimum income (pension rights, life insurances, social insurance, welfare payments) are lacking. Personal wealth can also have wider functions for its owners: it is a basis of (4) relative freedom and autonomy, (5) status, and (6) power. It contributes to individual freedom to the extent that it widens the scope of alternatives in consumption and leisure, and gives the possibility to postpone work, or not to work at all. In most stratified societies in the past, the very wealthy were a leisure class that distinguished itself by its freedom from physical labor. Wealth is also a source of status. Large wealth holders may impress others by showing their possessions (a big house, a large piece of land, expensive jewelry, etc.) or obliging others by their generosity and material help. This may also contribute to power. More directly, wealth is a basis of power when it enables the owner to make other people work for him (as employees, servants, or even slaves). And it may be helpful in acquiring wider political power, for example, as a basis for financing an election campaign. Finally, personal wealth is (7) an important vehicle for keeping privileges within the family as it is

transferred to the next generation through inheritance. On all these accounts, wealth inequality is at the basis of, and connected to, various dimensions of social inequality.

In the course of human history, wealth inequality tended to increase with the growing size and complexity of societies. In larger agrarian societies, most arable land was typically owned by only a tiny fraction of the population. This landed aristocracy not only derived the bulk of its income from the land, but also had political rights and privileges with respect to those who tilled the land, the dependent peasantry. With commercialization and monetarization and the advance of capitalism, starting in Western Europe in the late Middle Ages, these "feudal" relations gradually disappeared, and property became more sharply differentiated from political power. It is only under these modern conditions that wealth inequality can be assessed with some degree of accuracy.

Several empirical studies have attempted to assess the degree of wealth inequality in a given society and trends over time on the basis of tax data. Most studies have been undertaken by economists and economic historians. Lindert (2000: 181) calculated on the basis of estate duty data that the wealthiest 1 percent of households in England and Wales in 1670 held 48.9 percent of total personal wealth; in 1700 this share had declined to 39.3 percent, but since then it rose to 43.6 percent in 1740, 54.9 percent in 1810, and 61.1 percent in 1870. These figures thus indicate a high and, for the period 1700–1875, rising inequality. A high concentration of wealth was also found in the city of Amsterdam, Holland, in the seventeenth century, where the richest 1 percent of families held 41 percent of total taxable wealth in 1631 and 45 percent in 1674 (Soltow & van Zanden 1998: 38). Less inequality has been found for the US in the nineteenth century, although here too wealth inequality tended to increase, the share of the top 1 percent of households rising, according to one estimate, from 21 percent in 1810 to 31 percent in 1900 (Schneider 2004: 29, Table 3.10).

For the twentieth century and beyond, more data and estimates are available. Table 1 summarizes findings on trends in three countries: the UK, the US, and Sweden.

Table 1 Share of top 1%/5% of wealth-holders in total personal wealth in the UK, the US, and Sweden, 1911–2000

<i>Year</i>	<i>UK</i>	<i>US</i>	<i>Sweden</i>
1911–13	69/87		
1920–2		37/	50/77
1929–30	58/79	44/	47/74
1935			42/70
1938–9	55/77	36/	
1949–51	47/74	27/	33/60
1960	34/60		
1969–70	30/54	31/	23/46
1975			17/38
1979–80	20/43	21/	
1983			21
1990–2	18/35	34/	
2000	22/42		

Several conclusions can be drawn from the figures in this table as well as the outcomes of studies on other countries:

- 1 The degree of inequality in the distribution of personal wealth is much higher than that of income. The shares of the top 1 percent or 5 percent in total personal wealth are normally more than twice the shares of the top 1 percent or 5 percent in total disposable income.
- 2 During the first three quarters of the twentieth century, wealth inequality in western countries tended to diminish, though this tendency was much less clear and outspoken for the US than for the UK and Sweden. The same trend has been observed for several other western countries as well, such as France, Belgium, (West) Germany, Canada, and the Netherlands.
- 3 Since the last 15–25 years of the twentieth century, this trend stopped or even reversed: wealth inequality increased in many western societies.

These developments more or less correspond, and are related, to trends in income inequality. In order to assess their sociological significance, one has to connect them to other social developments: the long run growth of national wealth; the increasing significance of collective wealth, such as pension funds and government owned assets; and the development of welfare

state arrangements that give a certain degree of material security and are, in this respect, a functional alternative to personal wealth. The tendency of decreasing personal wealth inequality, particularly in the period from about 1930 to 1975, went hand in hand with equalizing tendencies in other respects: decreasing income inequalities and the development and expansion of collective arrangements for material security, including pension rights and state guaranteed social insurances. The inclusion of pension rights in the distribution of wealth among individuals or households results in a lower degree of wealth inequality. The ongoing expansion of pension funds alleviates to some extent the tendency of growing personal wealth inequality since the last few decades of the twentieth century. On the other hand, this tendency is reinforced by other trends in the direction of more inequality: growing income differences and declining levels of state regulated transfer incomes.

Economic explanations of wealth distribution usually start with individuals. Basic determinants of individual wealth are: earned (non property) income, the savings rate, age, returns on wealth (property income and capital gains), and inheritance. The larger the differences in these respects, the larger the resulting wealth inequality. Several factors explain why wealth inequality is much higher than income inequality. First, there is a strong positive correlation between income and savings rate. High income groups save more not only in absolute terms, but also proportionally. Low income groups often spend more than they get, and as a consequence their wealth amounts to zero or is even negative. Whereas households cannot survive for long with a zero or negative income (unless they are very wealthy!), they can do without wealth (apart from some basic consumption goods). Secondly, the accumulation of wealth on the basis of savings on current income takes time; therefore, older age groups are on average wealthier than younger ones, and the differences within the older age groups are larger. A third factor is the cumulative interaction between income and wealth which is particularly important in the creation of new fortunes. In a capitalist market, one or a few entrepreneurs get a competitive advantage in new expanding branches; high profits are made

that can be reinvested and lead to a strong upward appreciation of the invested capital.

In the course of the twentieth century, labor incomes (wages and salaries) in western societies increased in absolute terms and relative to capital incomes: this explains, to some extent, why wealth inequality tended to diminish. Through savings on wages, small wealth was created that brought some redistribution in favor of formerly "propertyless" wage earners. A more specific factor, related to this, was the spread of home ownership. The introduction of new or higher taxes on wealth and income from wealth and/or wealth transfers (particularly inheritances) may also have contributed to some leveling in the distribution of wealth. Short term changes in wealth inequality are connected to differential capital gains, especially fluctuations on the stock market: since shares and bonds are highly concentrated among large wealth holders, a booming stock market leads to increasing wealth inequality, a recession on the other hand to decreasing inequality. This partly explains why wealth inequality increased in many western countries from the 1980s when stock prices started to rise more strongly and steadily than in previous years. A more general explanation is that returns on capital increased relative to average wages and wage incomes became more unequal. Moreover, in several countries tax reforms were initiated that were particularly advantageous for the well to do.

These explanations can be given a more sociological twist by relating factors of production to social groups or classes and conceiving the relations between these groups in terms of power and interdependence. The growth of wage income relative to capital income resulting in decreasing wealth inequality can be regarded as the manifestation of a shift in the power relation between (large) capital owners and workers (manual and non manual, on different levels) in favor of the latter, which was in turn connected to processes of industrialization, urbanization, and democratization. In the last decades of the twentieth century, on the other hand, processes of deindustrialization and globalization contributed to the weakening power position of organized labor in relation to corporations and their shareholders, which may help to explain the growth of income and wealth inequality.

infant, child, and maternal health and mortality

Michelle J. Hindin and Britta Mullany

According to the World Health Organization (WHO), health is a state of "complete physical, mental, and social well being and not merely the absence of disease or infirmity." The health status of a population, including that of infants, children, and mothers, has traditionally been summarized via mortality. An infant death is defined as a death under the age of 1; the standard indicator used to measure infant death is the "infant mortality rate," equal to the number of infant deaths under the age of 1 per 1,000 live births in a given year. A child death is a death of a child under the age of 5; the "under 5 mortality rate" refers to the number of deaths of children under age 5 per 1,000 live births in a given year. Given the multiple periods of risk related to a pregnancy, the definition of maternal mortality is more complex. A maternal death is one which occurs while "pregnant or within 42 days of the termination of pregnancy, irrespective of the duration and the site of the pregnancy, from any cause related to or aggravated by the pregnancy or its management but

not from accidental or incidental causes” (WHO 1948). The “maternal mortality ratio” is the most frequently used indicator to measure maternal deaths and is defined as the number of women who die as a result of complications of pregnancy or childbearing in a given year per 100,000 live births in that year.

INEQUALITIES IN INFANT, CHILD, AND MATERNAL HEALTH AND MORTALITY

The death of an infant or child is considerably more likely in a developing country as compared to more developed settings. According to data from 2003–4, almost 11 million child deaths occur annually – approximately 8 million of these deaths occur in the first year of life. The first 28 days of life (also known as the neonatal period) represent the period of greatest risk with approximately 4 million deaths worldwide occurring during this time. With average under 5 mortality rates of 89/1,000 live births for the developing world and 120/1,000 for the world’s poorest countries, and 8/1,000 for high income countries, a child’s risk of dying before his or her fifth birthday is at least 11 times higher in developing countries than in developed countries. The majority of child deaths around the world occur in Sub Saharan Africa and South Asia. High child mortality is strongly linked to high fertility rates, which in turn increases risks of maternal, infant, and child death; this cycle, known as the replacement effect, suggests that a decline in infant and child death rates is a necessary precursor for a decline in fertility.

In the scope of public health, maternal mortality is the health risk for which the largest divide exists between the developed and the developing world. Approximately 515,000 maternal deaths occur worldwide each year, 99 percent of which are in developing countries; consequently, a woman’s risk of dying from pregnancy related complications is 45 times higher in the developing versus the developed world. While the maternal mortality ratio (MMR) in the developed world is 12/100,000 live births, the MMR in the developing world is 440/100,000, with the highest risks being found in Sub Saharan Africa and South Asia. For each

woman who dies due to complications of pregnancy or childbearing, an estimated 30 women are afflicted with chronic disease, disability, or physical injury resulting from pregnancy related complications. The death of a mother can have dire ramifications on a family, particularly in the developing country context. In addition to the loss of the primary caregiver and of a productive worker, the risk of death for her children under the age of 5 is doubled (in some cases, even tripled).

THE CAUSES OF INFANT, CHILD, AND MATERNAL HEALTH AND MORTALITY

The causes of infant and child mortality vary substantially in developed versus developing countries. The major causes of infant and child death in the developing world include neonatal causes (including birth asphyxia and low birth weight), diarrhea, pneumonia, malaria, measles, and AIDS. As societies become more advanced, the leading causes of infant and child death shift toward congenital anomalies, preterm related disorders, sudden infant death syndrome, and others.

The direct causes of maternal death are unpredictable and often occur within hours or days after delivery. Globally, hemorrhage, sepsis/infection, and pregnancy induced hypertension are the leading causes of maternal mortality. Other prominent causes of maternal death, particularly in developing countries, include obstructed labor and complications of unsafe abortion. Ectopic pregnancies result in a small proportion of maternal deaths in more industrialized countries as well.

The vast inequities in risk between higher income and lower income countries are one of the most striking elements about infant, child, and maternal survival. Similar gaps in infant, child, and maternal mortality are increasingly being seen between wealthy and poor communities within most countries of the world. While the direct medical causes of maternal, child, or infant death can be roughly outlined as above, it is exceedingly difficult to divide the direct cause of a death from the individual, social, economic, and cultural factors that precede and impact that medical condition and its management.

As related to child survival, for example, recent research has indicated that the predominant underlying cause of the majority of global child deaths, including deaths attributed to diarrhea, pneumonia, malaria, and measles, is malnutrition, which itself is the consequence of numerous factors.

In an effort to simplify these complexities, Figure 1 presents a conceptual framework of infant, child, and maternal mortality. The framework depicts some of the pathways through which distal determinants, such as socioeconomic conditions and cultural factors, can influence more intermediate health determinants, such as hygiene and sanitation practices and in turn contamination of water or food, which subsequently impact infant, child, and maternal survival via proximate mechanisms (or actual causes of death), such as undernutrition or infectious disease.

The socioeconomic, cultural, and political context of a population is crucial in understanding patterns of health in that setting. These background factors set the stage for individual, household, and community wide factors that ultimately influence health outcomes by acting through maternal and/or environmental pathways. Poverty, for example, is perhaps the most common underlying factor that both "increases exposure and reduces resistance to disease, a synergy that contributes to the wide inequities" in infant and child health, as well as maternal health (Victora et al. 2003). In addition, risks to health are frequently compounded by the reduced utilization of and access to health services often found in poorer communities. The WHO and UNICEF have, for example, described maternal mortality as "a litmus test of the status of women, their access to health care and the adequacy of the health care system in responding to their needs" (WHO/UNICEF 1996).

Individual, household/familial, and community factors can play an important role in influencing the utilization of health care, which can ultimately impact health outcomes. A woman who wishes to seek health care for a condition but who has no decision making power in her household may, for instance, suffer the repercussions of being denied access to household finances to seek care by her husband or other family member. Other social factors acting at the household level, such as domestic violence

toward pregnant women, can also have serious repercussions both on a woman's health and on the health of her child(ren). Worldwide, as many as 25 percent of women are physically or sexually abused during pregnancy, usually by an intimate partner. Women who have experienced violence are more likely to delay seeking antenatal care; more likely to experience sexually transmitted infections, bleeding during pregnancy, and unwanted or mistimed pregnancies; less likely to gain sufficient weight; and more likely to experience a miscarriage, abortion, premature labor, fetal distress, and low birth weight infant.

Factors influenced by distal determinants but ultimately specific to the mother impact the survival of both her and her children. For instance, short intervals between pregnancies increase the risk of pregnancy complications, with children born three to five years after a previous birth having a greater chance of survival compared to children born less than two years after a previous birth.

Background factors, such as household sanitation, can also impact exposure risks to disease through contaminated air, water, or food, and increased insect and parasite vector transmission. As a result of distal determinants operating via these intermediate environmental factors, children in poor settings are more likely to experience malnourishment and have lower resistance to infectious diseases. Similarly, women in such settings are more likely to experience poor maternal nutrition and infections during pregnancy, which in turn increases their risk of giving birth to a low birth weight baby, who is susceptible to undernutrition and disease.

Each of these points along the pathways, as illustrated in Figure 1, represents potential points for health promotion interventions, in the form of both prevention activities (e.g., improved access to water and sanitation, immunizations for pregnant women and children) and curative activities (e.g., improved access to health facilities, oral rehydration treatment for diarrhea). The reduction of infant, child, and maternal mortality must thus be achieved through a multitiered approach that addresses underlying factors (e.g., poverty, education, sociocultural aspects), intermediate causes (e.g., environmental contamination, short birth intervals), proximate causes (e.g., malnutrition, disease), and the population equitable introduction

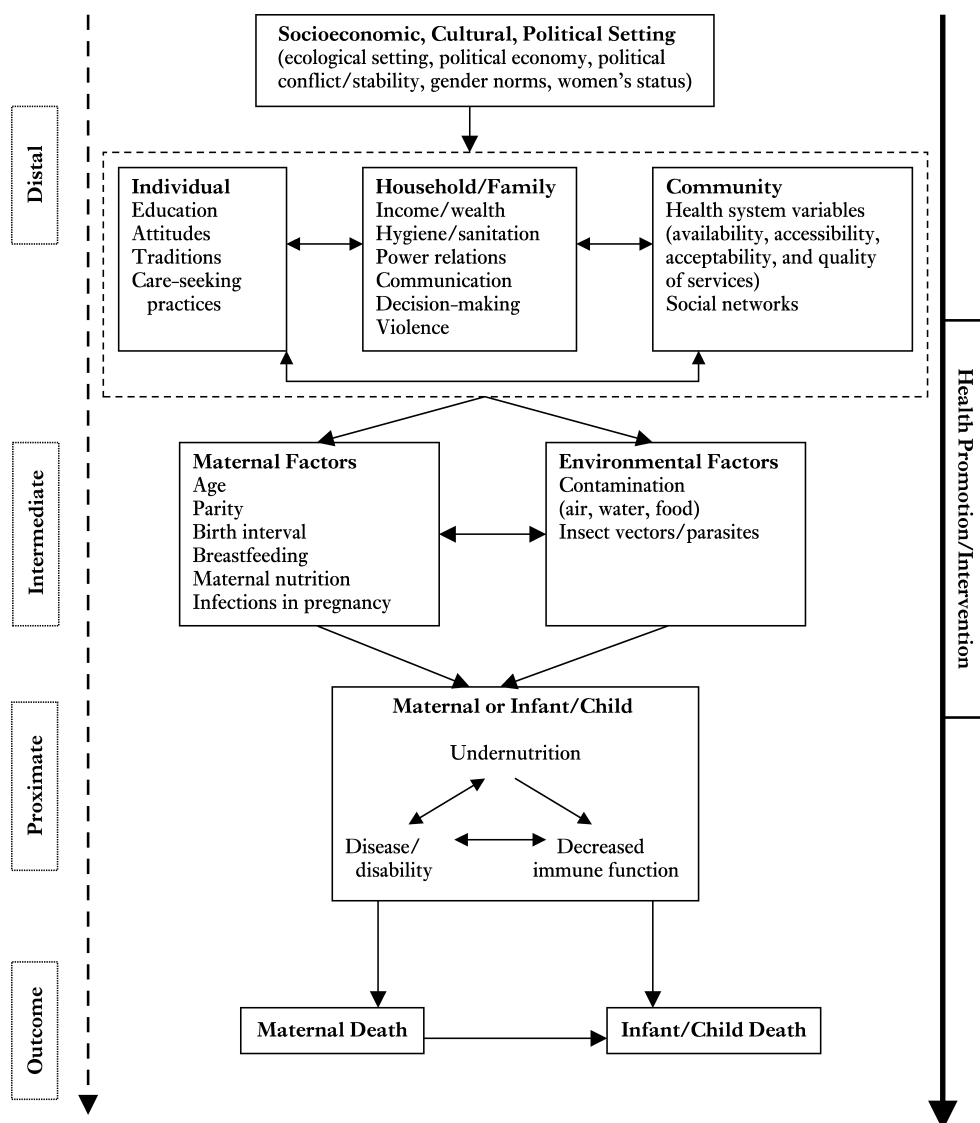

Figure 1 Conceptual framework of infant, child, and maternal health and mortality.

and monitoring of health promotion/disease prevention interventions (e.g., skilled attendance at birth, basic neonatal care, immunizations).

POLICY

The last two decades of the twentieth century witnessed an increased recognition of the important health needs and risks of women

and children globally. Figure 2 depicts an outline of the significant events impacting infant, child, and maternal health from the late 1970s to the present.

Numerous programs have been launched over recent years aimed at promoting infant and child health. In 1982, UNICEF, in collaboration with several other large international institutions, launched the Child Survival Revolution. In this initiative, reducing infant and child mortality

1976–1985	United Nations Decade for Women
1979	United Nations adopted the Convention on the Elimination of All Forms of Discrimination Against Women (CEDAW)
1982	UNICEF launched the Child Survival Revolution
1987	Safe Motherhood Initiative launched, Nairobi
1989	The convention on the rights of the child was adopted by the UN
1990	World Summit for Children and the Declaration on the Survival, Protection, and Development of Children
1992	Integrated Management of Childhood Illness (IMCI) Strategy by WHO and UNICEF began
1994	International Conference on Population and Development, Cairo
1995	The Fourth World Conference on Women: Action for Equality, Development, and Peace (including rights of girl-child), Beijing
1996	Generic guidelines for IMCI completed
2000	UN Millennium Goals launched through the United Nations Millennium Declaration
2000	Special Session of the UN General Assembly Women 2000: Gender Equality, Development, and Peace for the twenty-first century
2002	UN General Assembly Special Session on Children
2004	WHO strategy on Reproductive Health and Resolution on the Family

Source: www.un.org/esa/coordination/ecosoc/puc.htm (accessed August 5, 2004).

Figure 2 Timeline of recent significant events in maternal, child, and infant health.

was highlighted as an instrumental step along the journey of a country's development, and four low cost interventions were singled out in an effort to reduce infant and child mortality. The acronym GOBI was used to summarize these four interventions (growth monitoring, oral rehydration therapy, breastfeeding, and immunization). Approximately a decade later, UNICEF and WHO introduced a new strategy named the Integrated Management of Childhood Illness (IMCI). Also aimed at reducing early childhood morbidity and death, the IMCI emphasized management of childhood illnesses with proper nutrition and immunization and improvement of service delivery at the household, community, and referral levels.

The launch of the Safe Motherhood Initiative (SMI) in 1987 represented an important commitment to maternal health, in the form of a partnership between WHO, the United Nations, the World Bank, and numerous governments and institutions. The primary aim of the SMI is to reduce maternal morbidity and mortality by encouraging the adoption of a number of maternal health promotion strategies (including family planning, post abortion care, antenatal care, skilled assistance during child birth, essential obstetric care, and adolescent reproductive health care).

An important perspective that has been gaining strength in maternal and child health movements has been an emphasis on human rights. The WHO estimates that 88–98 percent of maternal deaths are avoidable, and several international human rights committees consider the failure to address preventable causes of maternal death as being a violation of human rights. The Committee on the Elimination of Discrimination Against Women was one of the leading groups to clearly state this in its recommendations. Similar stances have been taken in relation to children; a shift toward viewing children as complete individuals has been crucial in framing their health rights as human rights, particularly in cases such as protection from sex trafficking of female children.

METHODOLOGICAL ISSUES

There are several methodological issues that arise for measuring infant, child, and maternal mortality. In the majority of settings where mortality risks run the highest, vital statistics registration systems are weak, and access to and utilization of health services are too low to provide accurate population estimates. Poor vital registration systems found in many settings lead

to less than a full account of all births and deaths. Household surveys are often used; however, the relatively rare occurrence of death (particularly for maternal mortality) necessitates unusually large sample sizes, and consequently requires substantial financial and logistical inputs.

The calculation of infant, child, and maternal death rates can fall prey to seasonal effects; since many risk factors (e.g., malnutrition) and diseases (e.g., malaria) can change considerably throughout the seasons of a given year, caution must be exercised in surmising rates from data collected only in certain segments of a calendar year. Similarly, rapid shifts in fertility trends can result in misleading conclusions regarding maternal, infant, and child death rates.

There are specific issues that arise when measuring infant and child mortality, with data quality issues being the most prevalent. Members of a population most at risk for having a child death (e.g., individuals without a home or living in extreme poverty, migrant or conflict affected communities) are also the most likely to be underrepresented in a vital events registration system; this problem is particularly problematic in developing country settings. Issues of underreporting and misclassification of mortality can be found for all ages of infant and child death, but are especially problematic for newborns. Beginning at the time of delivery, for instance, the correct identification of a live birth versus a stillbirth can be difficult. Though live births are used in the denominator for measuring rates of infant and child mortality, newborn infants who are born alive but die shortly (e.g., 1 minute) after birth may not be counted as live births, thereby underestimating the infant mortality rate. The timing of a death, or age at which a child dies, can be susceptible to both numerical rounding biases (i.e., respondents round up or down to the nearest age) and recall biases (i.e., respondents miscalculate the timing of the event). Retrospective recall difficulties can also result in misclassification of cause of infant or child death. In addition, child deaths are often the cause of sequential or concurrent illnesses, a factor that is important in ascertaining cause specific risks to infant and child health. Greater efforts must therefore be made in correctly classifying a single cause of

death, or multiple causes of death, allowing for the possibilities of co occurrence of diseases or synergy in causes of death.

Assessing the levels of maternal mortality is also difficult since there are issues of measurement, misclassification, and underreporting. Despite being the most frequently cited indicator for measuring maternal mortality, the MMR has a number of weaknesses. The MMR uses live births in the denominator, although a sizable proportion of women each year experience (and survive) pregnancies that do not result in live births. Therefore, the MMR actually inflates the risk of maternal death. In addition, women die from pregnancy related complications in the absence of a live birth, particularly women who experience unsafe abortions.

There are a number of alternatives to the MMR. Since most women become pregnant more than once in their lives, a more accurate measurement of maternal risk would take into account the lifetime risk of maternal death as a cumulative measure inclusive of fertility rates and the risk of dying from pregnancy related causes. For instance, maternal mortality risk could be calculated per 100,000 pregnancies, rather than 100,000 live births; however, the near impossibility of counting the number of pregnancies makes this calculation unrealistic. The maternal mortality rate (number of maternal deaths in a given time period, usually one year, per 100,000 women of reproductive age) may better capture the risks introduced by exposure through fertility. The indirect sisterhood method of estimating maternal mortality relies on reports from the respondents of household surveys about pregnancy related deaths among their sisters. This method, however, is costly since maternal mortality is relatively rare and therefore requires a very large sample size to obtain accurate population estimates. The WHO, UNICEF, and UNFPA have developed adjusted estimates of MMR that attempt to correct for underreporting and misclassification of maternal deaths.

Regardless of which estimation method is used to calculate maternal mortality, all methods are prone to misclassification bias and underreporting. Some examples of this include: the pregnancy status of a woman may be unknown at the time of her death; there may be fear or stigma preventing the report of an

abortion related, miscarriage related, or other maternal death; or the medical cause of death may be unknown. Given these difficulties, proxy process indicators are used as monitoring tools. The “benchmark” proxy indicator promoted by UNICEF, WHO, and UNFPA is the percentage of all births attended by skilled health workers, including doctors, nurses, or midwives. These figures are often highly correlated with maternal mortality, are cost effective, and easier to measure.

Data availability and quality are dependent on adequate funding. Several maternal health issues in particular are more sensitive to political shifts in resource allocation; data availability and quality are subsequently affected. Specifically, contraception, abortion, and comprehensive sex education, all of which influence women’s reproductive health status, are particularly prone to political tides; the controversial aspects of these issues often manifest themselves in restrictions, terms, and/or conditions from funders of maternal health services. A paradoxical cycle of inadequate funding, followed by reduced availability of reliable data, is created; the less reliable data collected on these sensitive issues, the less funding that will be devoted to their improvement. There is a need for increased and improved event surveillance systems, as well as additional and stronger data concerning the identification of risk factors and the pathways between those risk factors and health outcomes, that will ultimately lead to more effective, affordable, and appropriate interventions for infant, child, and maternal health.

The sustained improvement of infant, child, and maternal health has faced major setbacks, and will inevitably continue to do so. Populations in crisis, such as those being persecuted, or those living or fleeing from war torn or natural disaster stricken areas, face greatly magnified health risks. The international community must learn to better address the health needs of these populations, including their amplified health risks as well as the often accompanying reduction or destruction of health infrastructure in such communities.

Perhaps the most prominent setback on the global stage has been the HIV/AIDS epidemic. Women account for almost half of the 40 million people living with HIV worldwide.

In the hardest hit regions, most notably Sub Saharan Africa, women make up the majority of people living with HIV, and maternal to child transmission of the virus is a major problem. Approximately 6 million children worldwide have been infected with HIV since the start of the pandemic, and access to the means of preventing vertical transmission from mother to child remains severely limited in many countries. In a 2004 call to action, several United Nations branches stated that in order to slow the spread of the epidemic and mitigate its consequences, the “triple threats” of gender inequality, poverty, and HIV/AIDS must be addressed.

FUTURE DIRECTIONS

A new set of benchmarks and policies may improve the global situation for infant, child, and maternal health. There is a growing focus on the significance of educating and empowering women, both for the sake of women themselves and for the overall health of their families. In 2000, the United Nations implemented a series of Millennium Development Goals, pledged to be met by all 191 United Nations member states. The third goal highlights the recognition of the importance of women’s education by pledging to “eliminate gender disparity in primary and secondary education preferably by 2005, and at all levels by 2015.” As more educated women enter the labor force, new infant, child, and maternal health issues will arise, creating the need for improved policies for women workers and workers with families. The International Labor Organization has played an active role in creating minimum standards for maternity leave, workers who are breastfeeding, and the needs of working families.

To improve infant, child, and maternal health, researchers, policymakers, and public health practitioners must go beyond the direct causes of death. The framework presented here attempts to capture social and contextual inputs that have traditionally been excluded or deemphasized in many health models and frameworks. Models need to consider a range of factors from the sociopolitical context to the power dynamics between couples to better understand the causes of infant, child, and maternal health and mortality. In addition, there is a critical need

for research on improving strategies of health delivery systems and coverage of public health campaigns. Exploring multiple levels of influence on individual outcomes is required for increased understanding and prevention of mortality. In addition, a fundamental priority must be the improvement of surveillance and monitoring systems. The lack of high quality population representative data presents a major barrier to the development and implementation of more appropriate health promotion policies, particularly in developing country settings.

infertility

Arthur L. Greil

Infertility is a term used by medical professionals to refer to the physical inability to conceive a child or to successfully carry a child to term. Demographers typically employ the word "sub fecundity" to describe this inability to have desired children. Some demographers use "infertility" to mean childlessness, regardless of childbearing intentions or contraception practices, but others utilize the term more narrowly and in conformity with popular and general sociological usage to refer to a woman's inability to give birth in the absence of contraception.

Although infertility must necessarily manifest itself in the female partner, the man or the woman or both may have the reproductive impairment. A specific male factor is identified in from 20 percent to 40 percent of those cases where a cause can be found. Since a major cause of infertility is female tubal factors related to reproductive tract infections (RTIs) spread through heterosexual intercourse, it is likely that men contribute to infertility in more than half of all infertile couples. It is thus ironic that, in many parts of the world, infertility is considered to be a "woman's problem."

Medical practitioners generally differentiate between "primary infertility," a situation in which an infertile woman has not had any pregnancies, and "secondary infertility," in which infertility has been preceded by at least one pregnancy. Demographers, epidemiologists, and other sociologists more often use these terms to refer to live births rather than pregnancies, using the term "primary infertility" to mean involuntary childlessness and the term "secondary infertility" to denote infertility experienced by couples who already have at least one biological child.

Most medical professionals consider a couple to be infertile if they have failed to conceive after 12 months of unprotected intercourse, reasoning that 90 percent of non-contracepting women will conceive within a year. This definition has been used by the National Survey of Family Growth (NSFG) in the United States and by researchers in the Netherlands, Norway,

and other industrialized societies (Schmidt & Münster 1995). The World Health Organization (WHO) considers a couple to be infertile if they have experienced two years of unprotected intercourse (after which time 95 percent of non contracepting women will have conceived), and some demographers have used longer intervals of either five or seven years (Larsen 2000). When self reports are used to measure infertility, individuals are considered to be infertile if they state that it would be difficult or impossible for them to conceive a child. NSFG's definition of "impaired fecundity" combines medical considerations with self reports (Chandra & Stephen 1998). Most studies of the social and psychological consequences of infertility utilize clinic samples, implicitly defining the infertile as those who are concerned enough about their fecundity to present themselves for treatment.

INCIDENCE

Various problems of methodology and data availability make it impossible to determine the incidence of infertility throughout the world with precision. The lack of consistent operational definitions of infertility makes it difficult to determine the numerator in an infertility rate with any confidence. But there is also uncertainty about the denominator, as no agreement exists with regard to who should be considered "at risk" for infertility. There are no agreed upon upper and lower age limits for fertility; nor is there agreement about how to deal with women who have not "tested" their infertility by attempting to have children. Not all countries conduct population surveys based on random samples, and those that do employ various methodologies. Finally, many factors influence the accuracy of reporting, and there is no reason to assume that these factors will be consistent from one survey to another (Schmidt & Münster 1995).

Somewhere between 8 and 12 percent of couples or between 50 and 80 million people worldwide are affected by infertility (Inhorn 2002). Lifetime prevalence rates are probably considerably higher; it is likely that 20 to 40 percent of couples in any given society have been affected by infertility at some point in their lives (Schmidt & Münster 1995). There are wide

variations in the incidence of infertility from society to society and from region to region and ethnic group to ethnic group within societies. Infertility is particularly prevalent in Sub Saharan Africa, to the extent that demographers often refer to a "Central African Infertility Belt." This higher rate is probably due to the higher incidence of RTIs. Secondary infertility appears to account for somewhat more than half of all cases of infertility in the industrialized world and is even more common in Sub Saharan Africa.

SOCIAL AND CULTURAL CONTEXT

While infertility is clearly of interest to demographers, the study of infertility also has interest for sociologists interested in gender, help seeking behavior, health care institutions, self identity, and subjective well being. Infertility is a health problem which can have far reaching effects on life satisfaction, well being, and psychological adjustment, especially for women. In societies throughout the world, parenthood is seen as an integral part of the transition to adult status. Because of the great importance attached to the childbearing and parenting roles, women often experience infertility as a catastrophic role failure, which can come to permeate every aspect of life (Sandelowski 1993).

Most research on the social and emotional impact of infertility has been marred by a reliance on clinic based samples of treatment seekers. Because many infertile couples do not seek treatment, this makes it difficult to generalize findings to all infertile couples and confounds the consequences of fertility status, treatment seeking, and treatment itself. Descriptive and ethnographic studies have generally concluded infertility is a stressful experience that leads to psychological distress, feelings of social isolation, perceived stigma, and stressed relationships. The findings of quantitative studies using control groups have been more equivocal. In a review of the literature, Greil (1997) concludes that most well designed studies find that the infertile are more distressed than the non infertile, but not in a clinically significant way. McQuillan et al. (2003) conclude that infertility distress is found primarily among infertile

women who remain childless. Most of the large body of research on the relationship between infertility and gender has found that women and men experience infertility differently, with women generally reporting greater distress.

Recently published ethnographic work (Inhorn & van Balen 2002) suggests that stigma and suffering of infertility may be more pronounced in developing societies, where parenting is culturally mandatory and where alternative roles for women may be less available. Infertility is both more common and more stigmatizing in many of the societies where fertility rates are highest and population pressures are greatest. Marcia Inhorn describes a "fertility-infertility dialectic," in which fear of infertility results in behaviors that lead both to high fertility rates and a high incidence of infertility. While infertility is seldom considered to be an important public health problem in societies where overpopulation is deemed to be the more serious problem, it may well be that controlling fertility rates will depend on dealing with women's concerns about *infertility*.

TREATMENT

From 30 to 70 percent of infertile women in industrialized societies report that they have been to a physician or a clinic to seek treatment (Schmidt & Münster 1995). Treatment seeking rates among industrialized countries appear to vary with access to health care, with treatment rates higher in societies with universal or near universal health care coverage. Women with primary infertility are approximately twice as likely as those with secondary infertility to seek treatment. While reproductive impairments are actually more common among minority groups and those with lower incomes, whites and those with higher incomes are most likely to seek treatment. Many American women who are infertile according to the medical definition do not self identify as infertile and therefore do not pursue treatment.

Increased media coverage in recent years has given the impression that the incidence of infertility has been rising dramatically in industrialized societies. In fact, this is not the case. It is, however, true that the number of *childless* infertile couples has been increasing in the

industrialized societies. Since female fertility declines with increasing age, the current trend in industrialized societies toward delayed child bearing means that a larger percentage of infertile couples than before are childless when they discover their infertility.

While the proportion of infertile women in industrialized societies has remained stable, the proportion of infertile women who have decided to seek medical treatment has increased dramatically in recent years in industrialized societies. Office visits for men have remained at virtually the same level as before. The trend toward delayed childbearing has meant that many women now discover their infertility at an older age when less time remains on the "biological clock." The advent of birth control technology may have given the infertile a stronger sense that conception is something that can be conquered via technology. Increased demand for medical services may also be related to the decreasing availability of non medical solutions to the problem of involuntary childlessness, such as adoption.

Advances in medical treatment, including but not limited to such advanced reproductive technologies (ARTs) as *in vitro* fertilization (IVF) and intra cytoplasmic sperm injection (ICSI), and the media attention that have surrounded them have contributed to a strengthening of the sense in developing societies that infertility is something that can be brought under control and that seeking medical treatment is the most appropriate response. A decline in the fertility rate has resulted in a drop in demand for obstetrical services in industrialized societies; when the supply of obstetricians exceeds the demand, gynecologists may be inclined to pay more attention to other kinds of services. Physicians may also have been encouraged to devote increased attention to infertility by the increased prestige that has come to infertility as a specialty as a result of publicity surrounding ARTs.

Treatment of infertility is often expensive, time consuming, and invasive. The infertile often find that treatment regimens assume a central importance in their lives. The fact that reproductive technology has made the hope for a child more realistic can make infertility even harder to accept and can lead the infertile, especially infertile women, to become very

treatment oriented. A group of scholars influenced by feminist concerns has argued that overreliance on ARTs reinforces the notion of mandatory motherhood and reinforces traditional gender roles and patriarchal ideologies. Increasing reliance on ARTs has resulted in a dramatic rise in multiple births.

Demand for infertility treatment from both biomedical and traditional healers is quite strong in developing societies. For example, infertility is said to be the leading reason for gynecological visits in Nigeria. Clinics that offer IVF and other ARTs exist throughout the world, but access to them is typically limited to the wealthy. It is in the developing world, where demand for infertility services is greatest, that access to infertility treatment in general is most limited.

Areas where further research is needed include patterns of sociocultural variations in the experience of infertility; lay conceptions of infertility; help seeking behavior; long term consequences of infertility; and the socioeconomic context of infertility treatment.

infidelity and marital affairs

Kaeren Harrison

Infidelity is about being emotionally or sexually unfaithful. It is closely equated with non monogamy, and as such is usually examined in the context of marriage. However, as constructions of marriage have changed since the middle of the twentieth century, the meanings attached to infidelity (or unfaithfulness, betrayal, or disloyalty) are no longer associated so exclusively with marriage. Awareness – and direct experience – of the fragility of marriage is high, ensuring that marriage is no longer uncritically perceived as a monogamous lifelong relationship. This is reflected in the popularity of prenuptial contracts, civil ceremonies, and the sharing of “relationship aspirations” rather than traditional marriage vows.

In his analysis of *The Transformation of Intimacy* (1992), Anthony Giddens provides a theoretical reappraisal of the nature of contemporary marital and partner commitment which is particularly interesting in the context of examining infidelity. In it, he describes the emergence of “confluent love,” a form of intimacy based on mutual self disclosure. The essence of confluent love lies in its contingency; couples construct a relationship of mutual trust and commitment alongside the knowledge that their relationship might not last for ever. The relationship will only last for as long as each member finds it emotionally and sexually

fulfilling. Moreover, within confluent love, sexual exclusivity may or may not be significant, depending on the understandings negotiated by the couple.

Such views about transformations in the character of commitment in marriage and marriage-like relationships carry implications for understandings of infidelity. Of itself, a movement towards confluent love does not necessarily indicate that infidelity within partnerships is more acceptable than it once was. Indeed, it can be argued that monogamy (albeit serial rather than lifelong) remains a highly salient marker of commitment and stability in relationships because of the additional emphasis now placed on personal compatibility and long term satisfaction (Allan & Harrison 2002). Nevertheless, the recognition that individuals have a right, and perhaps a responsibility, to seek fulfilment within their personal relationships, creates a cultural climate in which the exploration and development of new relationships is socially more acceptable than it once was.

Popular discourses around infidelity reflect these complexities. The terms “having an affair” or “becoming involved (or intimate) with someone else” carry different meanings and emotional overtones from “committing adultery” or “engaging in extramarital sex.” The first two expressions convey greater tolerance and therefore a more ambiguous and muted moral message; the second two expressions retain a strong sense of social disapproval. In other words, responses to infidelity are shaped by the current understandings of marriage in the society and the social circle in question. Expressing this point slightly differently, the “rules” against infidelity are applied more readily to some people, and some groups, at some times, than others. An obvious example of this is the degree to which husbands’ and wives’ extramarital affairs have been understood very differently, with men’s infidelity being condoned more readily than women’s.

Attention must also be paid to the social or cultural variables that influence an individual’s behavior. In agricultural societies, for example, marriage and kinship – with their associated land rights – represent the key structures around which social and economic organization is built. Under these conditions, it is likely that infidelity would be seen as a threat to the social

order as well as to the marital relationship, and would be condemned through a range of religious, moral, and social sanctions. Even today, there are some fundamentalist Muslim countries where infidelity may be punished by death. Cross culturally, infidelity is the most frequently cited reason for divorce, and actual – or suspected – infidelity (usually on the part of the woman) is a primary cause of domestic violence and spousal homicide. These last two points, of course, indicate that for some women engaging in an affair carries very different risks and repercussions than it does for men, and therefore we should be cautious of an analysis of infidelity that is gender free.

However, recent research in Britain (Lawson 1988; Reibstein & Richards 1992; Wellings et al. 1994) has suggested that the incidence of affairs is increasing, and that behavior by men and women is converging. There is some evidence that many (or even most) men and women admit to having at least one affair in their first marriages (Lake & Hills 1979), indicating a move away from stereotypically gendered understandings of affairs based on “double standards,” and suggesting a more complex understanding of sexuality, fidelity, and commitment where women’s and men’s needs are not highly differentiated. And yet both men and women in social attitude surveys in Britain and the US demonstrate continued disapproval of extramarital sexual relationships, with the percentage of people saying that such relationships were “always” or “mostly” wrong consistently being over 80 percent (Scott 1998). This would suggest that there is significant dissonance between what individuals feel their relationship practices should be like, and what they actually are like, making it increasingly difficult for people to make sense of affairs within the context of shifting normative frameworks.

Nevertheless, affairs – whether within heterosexual marriages or other forms of exclusive partnerships – are clearly important life events for those who have them. Unfortunately, despite the significance of affairs, there has been very little empirical research undertaken. This is a curious omission, given that sexual matters are now discussed far more openly and when there is greater ambiguity around the moral status of affairs. The recent resurgence of interest in family diversity and family practices has

generated a lot of research on or about divorce, family dissolution and reordering, remarriage and, more recently, stepfamilies. However, little attention has been paid to the part that affairs might play in the process of marital breakdown and the character of new domestic arrangements. In other words, there would seem to be some disparity between the predominance of affairs on the one hand and the extent to which they have been studied academically on the other.

Among the reasons for the lack of sociological research into infidelity and marital affairs are the methodological issues and problems associated with the topic. Conducting research on issues of sex and secrecy raises serious ethical considerations, while the sheer variety of affairs makes any generalization difficult. This is a point that has been made by a number of authors who have investigated the broad nature of affairs and their consequences (Duncombe et al. 2004). Passion, transgression, secrecy and lies, betrayal, power, emotion work, identity construction, and gossip as a means of social control are common themes in Duncombe et al.'s edited collection, demonstrating the complex set of issues that face people who engage in affairs. There are few clues, however, as to why individuals might engage in affairs in the first place. Research is still in its early stages, but affairs tend to occur at different stages of marriage, possibly for different reasons. Early on, where partners have already engaged in premarital sex with others; after childbirth, when marital satisfaction dwindles; in early middle age, when individuals seek reassurance that they remain attractive; and in later years, when an affair may end an otherwise "empty" marriage. Men's affairs tend to cut across class, age, and marital status, whereas married women have markedly fewer relationships with young single men – a reflection, perhaps, of older men's greater resources and freedom, compared with women's "social depreciation" with age.

While the individuals involved (directly and indirectly) in affairs are important, it should also be remembered that these relationships develop, endure, and sometimes end within a wider complex of interacting forces. In other words, the patterns and pathways of affairs are framed within a societal context. The form affairs take, their importance in people's lives,

the extent to which they are "allowed" to continue, and whether they are condemned or condoned, are all shaped by broader social and economic influences. The sociological study of how affairs are constructed at different historical points in time, among different social groups, would certainly contribute to an increased understanding of institutions and practices such as marriage, sexuality, morality, and gender relations.

information and resource processing paradigm

Koichi Hasegawa

Tamito Yoshida's notion of the information and resource processing paradigm was influenced by information theory, particularly Norbert Wiener's *Cybernetics* (1948). At first,

Wiener was reluctant to relate his idea of cybernetic control to the social sciences, but he later came to apply the negative feedback process – the most basic principle of the cybernetic control mechanism – to organic bodies, human beings, and human society. The basic idea of Yoshida's (1990) general systems theory evolved from Wiener's work through the generalizing of his logic. His central hypothesis comprises the following.

The natural world is divided into "non controlled nature," "inorganic nature" such as the universe, and "controlled nature." Controlled nature is composed of "organic nature" controlled by "genetic information" and "human nature" controlled by "cultural information." From Yoshida's "evolutionist" perspective, any natural system, including that of plants, animals, human beings, and any level of society, has the common basic structure of an "information and resource processing system." This means that any controlled system is "the system of resources and resource processing" controlled by "information and information processing." In this context, "information" and "resources" are defined in very broad and abstract terms. For instance, cherry blossoms only bloom when the temperature is higher than 20 degrees, hence they are controlled by temperature, by information. Similarly, human action involves a highly complicated process of information and resource processing. Human actions are controlled by a wide variety of cultural and social information such as language, signs, symbols, norms, and values. When we drive a car and come to a red signal, we press on the brake pedal. In this case, our behavior is controlled by the red signal, traffic rules, orders from cranial nerves and so on.

The structure of such systems is always configured by elements and patterns of information processing and resource processing. This structure is also controlled by information and information processing, such as norms and values. In family life, we can observe a pattern of action among family members (e.g., the sharing of housework, talking, the communal eating of meals, and so on). Social system is a "social information and resource processing system among two and more actors, including individuals and collectivities. Social resources are divided into material, informational, human,

and relational resources. Material resources include energy and energy resources. Money, influence, political power, love, and prestige are examples of relational resources.

Yoshida's ideas led to the development of his theory of the self organizing system. An organic "information and resource processing system" is also a self organizing system, with a built in mechanism for structural change, so that when the performance of the system falls below a socially accepted level it has the potential to structurally change so as to increase its performance level. In cases where the system is performing adequately, it then remains stable and is able to maintain that performance level.

information society

Hugh Mackay

The information society is a key way in which contemporary social transformation is conceived. Used commonly by policymakers, journalists, and futurists as well as sociologists, the notion encompasses a diversity of arguments which have in common that they see information, and information technology (IT), as at the heart of the burgeoning social order. Greater volumes of data are being communicated by a fast growing range of technologies, with profound social consequences for nearly every aspect of social life. On the basis of the growth of information flows and technologies, information society theorists argue that the changes underway represent not just quantitative but qualitative social change – transforming almost

every realm of social life, including households, communities, education, health, work, surveillance, democracy, and identities. Together, these changes are seen as constituting a new form of society, comparable to the shift from an agrarian to an industrial society. Rather than tightly defined, the scope of information society debates ranges widely and overlaps with other approaches to understanding contemporary social change. Other terms ("post industrial society," "knowledge society," and "network society") carry similar and often overlapping meanings; while for some social theorists, different labels ("late modernity," "postmodernity," or "globalization") better characterize contemporary social transformations. Even those who focus on the "information society" use the term to refer to different social processes.

Information society theorists can be broadly categorized in terms of those who see technology as the driving force behind the change, versus those who see social factors as shaping technology and history. This debate, technological determinism versus "the social shaping of technology," lies at the heart of the sociology of technology. While sociologists have been concerned to refute technological determinism, countering the common, everyday way of conceiving of the relationship of technology to society, much work on the information society remains at least implicitly technologically determinist, while in the sociology of technology there is a growing interest in the constraining capacity of technology. Another key issue in the debate is whether and when quantitative changes (e.g., increasing flows of information, a larger information sector of the economy, or growing levels of ownership of IT devices) constitute qualitative change (the emergence of a new form of society, even an "IT revolution"). In other words, there is a debate about whether the situation is radically different from the past, or merely the continuation of long running phenomena or tendencies. A further distinction is between optimists and pessimists, on which count the debate is remarkably polarized: for some (notably Daniel Bell), the information society is a progressive development, characterized by greater freedom and fulfillment, whereas others (Herbert Schiller, Jürgen Habermas, Nicholas Garnham, Frank Webster) point to the continuation or exacerbation of long running

inequalities and patterns of control. Some contributors to the debate, and not just those in fiction and futurism, are normative in their writing, slipping into a mode of endorsing the changes that they identify as underway. Different theorists focus on different strands of the debate, notably the growth of technology, the transformation of the economy, the changing nature of work, new patterns of connection across time and space, and the coming to the fore of mediated culture. Contributors to the debate include economists (e.g., Fritz Machlup), geographers (e.g., David Harvey), planners (e.g., Manuel Castells), and cultural theorists (e.g., Mark Poster) as well as sociologists (e.g., Daniel Bell). The debate can be reviewed by considering the work of two key contributors to the field, Bell (who comes to the information society by identifying an information economy) and Castells (who provides a broad ranging recent account of the information society).

The information society debate has its origins in the work of Daniel Bell, who has provided one of its most detailed accounts. Generally, he wrote about "post industrial society," but in some of his later work he refers to the "information society," and the distinction matters little to him. Bell argued that western economies had deindustrialized, by which he meant that they had a declining percentage of the workforce working in the manufacturing sector and growing employment in the service and information sectors. Figure 1 shows clearly the transformation which lies at the heart of his thesis.

Bell describes a "march through the sectors," from agrarian through industrial to post industrial, or information, society. The shift of manufacturing to China and the growth of call center employment are obvious contemporary manifestations of the changes to which he is referring. For Bell, pre industrial society is characterized by muscle power, industrial society by machinery, and post industrial society by information. The post industrial society is about not only the transition to a service economy, but also the growth of scientific knowledge, which now drives history as never before.

Bell's thesis is rooted in, and draws heavily on, the empirical work of two economists, Fritz Machlup and Marc Porat. Machlup found that the knowledge industries between 1947 and

1958 expanded at a compound growth rate of 10.6 percent per annum, and thus established the high degree to which the US economy was dependent on its knowledge workforce. Machlup's definition of knowledge was his own subjective interpretation, Alistair Duff refers to this work as "riddled with errors," and Bell acknowledges that Machlup's data were "somewhat unsatisfactory." Nonetheless, there has been a dramatic growth in the use of codified knowledge which is transmitted systematically to others, and production and organization have become increasingly dependent on such knowledge. For Bell, knowledge has replaced labor as the source of added value, supplanting capital and labor as the central variable of society. Whether knowledge has *replaced* labor, or merely transformed it – perhaps increasing the skills required of the workforce – is debatable. Bell also used Porat's examination of the proportion of economic activity that can be attributed to information activities. Porat concluded that nearly 50 percent of the GNP and more than 50 percent of wages and salaries in the US in 1967 derived from the production, processing, and distribution of information goods and services.

Thus, Bell's analysis depends on definitions of "knowledge" and "service sector" and on the relationship between these and other sectors and occupations. There is considerable

debate about such categorizations, and about how the processes are (or are not) related. Cleaning, transport, and accountancy, for example, might be classified as "services" if they are bought in, but "manufacturing" if they are undertaken in house. In other words, divisions into service and manufacturing can be unreliable or even meaningless. In his work there is some confusion about, and sometimes conflation of, knowledge and service work. Like futurists, but rather unusually for a sociologist, Bell is happy to play the role of social forecaster, presenting his vision of the future: his work moves readily from analysis to prognostication and even to prescription. He is remarkably optimistic, seeing the post industrial society as one in which everyone will enjoy access to the world's traditions of art, music, and literature. Post industrial society means the rise of professional work, professionals are oriented towards their clients, and society becomes transformed into a more caring, communal society. Education, care, public interest, and the environment, he wrote in the 1970s, become more important than restricted concerns to maximize the return on capital.

Finally, while Bell's analysis fuses data and argument about the economy, employment, and knowledge, underlying his work is a clear technological determinism. He epitomizes the information society literature by according to

Figure 1 Four-sector aggregation of the US workforce, 1860–1980.
Source: Bureau of Labor Statistics, cited by Bell (1980: 521).

technology a central role in social change: technological innovation is seen as resulting in social change. By contrast, sociologists of technology reject the notion that technology is somehow outside society and that technological change causes social change. Rather, they have been concerned to explore how particular social formations *give rise to* (or shape) the development of specific technologies (MacKenzie & Wajcman 1999).

Castells's work on the "network society" provides a more recent account, again at a macro level, of contemporary, global, social transformation. His concern is to provide a cross cultural theory of economy and society in the information age, specifically in relation to an emerging new social structure. While Castells uses a different term, his work resonates with the tenor of information society debates. Like Bell, Castells documents the demise of traditional, labor intensive forms of industry and their replacement by flexible production. His account fuses the transformation of capitalism (notably, the growth of globalization) with changing patterns and forms of identity. He argues that, with the rise of the informational mode of development, we are witnessing the emergence of a new socioeconomic paradigm, one with information processing at its core. For Castells, the issue is not information as such, but the "informational society" – the "specific form of social organization in which information generation, processing, and transmission become the fundamental sources of productivity and power, because of the technological conditions" (Castells 1996: 21).

In other words, the issue is not simply that information is central to production, but that it permeates society. In the informational economy, networks are the new social morphology. Organizations are transforming from bureaucracies to network enterprises, responding to information flows, with economic activity organized by means of fluid project teams. Economic activity becomes spatially dispersed but globally integrated, reducing the strategic significance of place, but enhancing the strategic role of major cities. Networks are composed of interconnected nodes – places where information does not merely flow, but is collated, analyzed, and acted on. Thus, New York, Paris, Tokyo, and London are inhabited by a

managerial class with a cosmopolitan lifestyle, extensive networks around the world, frequent air travel, and using exotic restaurants. In contrast with earlier time space arrangements, there is in terms of flows no distance between nodes on the same network. In other words, geographical distance is irrelevant to connection and communication. So there are fundamental changes to the nature of time and space, with time compressed and almost annihilated; and space shifting to the space of flows: places continue to be the focus of everyday life, rooting culture and transmitting history, but they are overlaid by flows. The network of flows is crucial to domination and change in society: interconnected, global, capitalist networks organize economic activity using IT and are the main sources of power in society. The power of flows in the networks prevails over the flow of power – which might be read as some kind of "flow determinism." The Internet and computer mediated communication are seen as transforming the fabric of society – though Castells explicitly rejects technological determinism.

The other main strands of Castells's argument are about identity and culture. The transformation of economies has been accompanied by the decline of traditional, class based forms of association, particularly the labor movement. At the same time, state power has been eroded and new forms of collective resistance have emerged, notably feminism and environmentalism. The explosion of electronic media, specifically the development and growth of segmented audiences and interactivity, means the growth of "customized cottages" (as opposed to a global village) and a culture of "real virtuality." Although he acknowledges growing inequality, social exclusion, and polarization, Castells, rather like Bell, sees at least the possibility of a positive future, of new forms of communication and the network society offering democratizing possibilities.

While Bell focuses his analysis very much on the economy, and Castells provides a remarkably wide ranging account, the work of these two key analysts of the information society addresses what can be seen as the four core themes of the information society, or of information society debates. First is the new patterning of work and inequality. This includes debates informed by Bell regarding the decline

of manufacturing in western economies, and the growth of information and service sectors; the deskilling debate and the restructuring of work; and the growth of e commerce. It also includes debates about the growing gulf between the rich and the poor, and social exclusion – the “digital divide.” There is debate about the extent to which lack of access to information is a cause, rather than merely a reflection, of social exclusion.

Second is time space reconfiguration, compression, or convergence – different authors use different terms. The shrinking of time and space, examined by Castells, is facilitated by instantaneous electronic communication. Globalization and digital information networks lie at the heart of information society debates. Some invoke McLuhan’s notion of the global village and develop this in relation to the Internet, and a large and growing body of literature examines Internet communities, for example those of national diasporas. Multi channel television and global television flows are key components of global cultural communication. The erosions of boundaries between home and work and public and private are other aspects of time space reconfiguration.

Third is the huge growth of cultural activities, institutions, and practices. Culture has become increasingly significant in contemporary society, and with new ICTs the means to produce, circulate, and exchange culture has expanded enormously. The media and communications industries have a huge economic significance today, paralleling that of physical plant in the industrial era. Far from simply a matter of business and flow, culture connects closely with the constitution of subjectivity, with identity.

Fourth, there is a set of issues about the transformation of state power and democracy – with the growth of technologies of surveillance. Behavior in public space is routinely observed and recorded on video, while computer systems map personal movements, conversations, email traffic, consumption patterns, networks, and social activities. At the same time, democracy is facilitated by the capacity for many to many communication (as opposed to the broadcasting model of one to many) and the increasing accessibility of growing amounts of information, with the development of the Internet. New patterns of communication across time and space

enhance communication possibilities, and state control of the media is challenged by new technologies – satellite but especially the Internet – that easily cross national borders.

The notion of the information society has been highly influential in policy studies, notably in Japan, the EU, and the UN. From the end of the 1980s the EU identified the information society as a policy objective. It was seen that information and communication technology (ICT) could be harnessed to generate economic growth and to promote social cohesion. EU information society policies have their origins in economic policies to maintain competitive advantage, policies that followed the deregulation of state telecommunications in the 1980s. The Delors Report (1993) proposed a Task Force on European Information Infrastructures, which led to the Bangemann Report (1994) *Europe and the Global Information Infrastructure*. This referred to the spread of ICTs as a “new industrial revolution,” and advocated financing the revolution through public private partnerships. The Bangemann Report led to the Action Plan (1994), which has been revised subsequently but which remains the basis of the EU’s information society policies. These have focused very much on IT infrastructure, encouraging businesses to get online and governments to deliver services electronically. At the same time as focusing on neoliberal economic development, there is a concern with social cohesion – in that policies focus, too, on the digital divide. The tenor of the EU information society discourse is both technologically determinist and highly positive, with reports routinely extolling the benefits of IT – at home and work, and in education and leisure.

There are important UN policies, which have focused on social exclusion and the digital divide. The World Summit on the Information Society, with its second phase in Tunis in 2005, was convened to set the global agenda, to build consensus between stakeholder groups (governments, civil society groups, NGOs, and corporations), and to develop an action plan (with target goals for 2015). The UN sees ICTs and access to information and knowledge as central to achieving development goals, and of value in resolving conflicts and attaining world peace.

The information society remains a term very much in vogue three decades after its

formulation. In part because of its breadth, it is a malleable concept or debate. It continues to resonate because of the growing plethora of ICTs and their considerable significance in everyday social life. In turn, this has led to take up by policymakers, making the information society an important area in which sociological debate connects with public policy. Research councils have responded to this connection with publicly funded research programs. In methodological terms, the field has been characterized by heterogeneity, with a prominent strand – that shows no sign of abating – that focuses on quantifying the information society.

information technology

David Lyon

Information technology (IT) is generally taken to be a technical system for storing, transmitting, or processing information. As such it could refer to the paper documents and files of a bureaucratic organization, or even to hieroglyphs on rocks in the ancient world. While such broad meanings remind us of the larger context of human interaction with information, in the twenty first century IT usually refers to electronically based systems that draw upon a combination of computing power and telecommunications. Indeed, IT is now central to many systems that are increasingly integrated, producing a fusion of what was once referred to separately as electronic media and information and communication technologies.

INTELLECTUAL AND SOCIAL CONTEXT

IT may be thought of by some computer scientists as a merely technical matter, but in fact a very good case can be made that such are relatively trivial. In the real world IT is the product of economic, political, social, and cultural contexts and choices, as well as technical knowledge, that shape its development and use. In these contexts the shaping and consequences of IT are far from trivial.

The changes that occurred in IT production and use between the start and the close of the twentieth century are nothing short of astonishing. While paper based bureaucracies dominated the means of organizational practice at the start of the century, digital ones dominated them by the end, even though the “paperless office” never materialized as promised. But not only this – the ways in which production, education, administration, entertainment, travel, and other activities were done were transformed in large part through their interactions with and increasing dependence on IT. Today, for the vast majority in the global North, everyday life is unimaginable without a range of IT based systems, tools, and gadgets, some of which – like call centers or smart refrigerators – were almost unheard of in the 1980s.

One crucial change was the convergence of telecommunications with computing power. Joining telecommunications with computing enabled many aspects of the taken for granted world that many in the global North now inhabit – of instant remote interactions with computers, credit and debit cards, computer controlled machine tools, cell phones, and iPods.

By the end of the twentieth century, IT was integrated with all aspects of modern life, such that many started to speak of an information age based on new forms of work and employment, a new global economy, a spatial division of labor, and a general sense of contracting space and accelerating time – as opposed to the industrial age ushered in by the Victorians a century before. And IT also ceased to be thought of as an “external” factor. It had become embedded in countless processes, practices, systems, and devices.

MAJOR SOCIAL DIMENSIONS

At the largest scale, IT must be seen as one dimension of modernity. IT is now a major contributor to the distinctive character of contemporary modernity and, in social science, to the debate over how modernity is transforming itself in the twenty first century. If in early modern times a strong motif was reliance on science and technology as a vital determinant

of “progress,” one could argue that the emphasis shifted decisively from “science” to “technology” during the twentieth century. While dependence on science is still demonstrably constitutive of today’s modernity, it has in some ways been folded into technology, such that terms like technological society have far more popular resonance than scientific society. The term technoscience captures some of this folding.

More specifically, IT is implicated in a number of social, cultural, and political economic changes that are referred to variously as late modernity or postmodernity, or are considered under the rubric of globalization. Alongside the shift towards consumption and consumer capitalism (Slater 1997), reliance on communication and IT has helped to reconfigure some of the central institutions of social life and to change the contours of modernity (Lyon 1999) in the global North and to a lesser extent and some times in different ways in parts of the global South. The very notion of global mobility of information, persons, goods, images, services, wastes, and entertainment – basic to any globalization thesis – is fundamentally enabled by IT. And equally the shift towards more fluid social relations (Bauman 2000) associated with the postmodern can only be understood in terms of remote connections and instant communication based on IT.

IT affects many aspects of social, political, economic, and cultural life, though not always in ways foreseen by the pundits and marketers. This is why serious sociological analysis is so vital for grasping the realities of change. Whether in military, workplace, domestic, or entertainment spheres, IT is increasingly a *sine qua non* (Webster 2004) of organization and practice, so it is worth exploring as a major theme of contemporary social analysis. This may involve examining ways that IT extends human capacities, but also looking at how IT may be implicated in actual alterations in social life (Gane 2004). And none of this may be adequately considered without seeing how IT is implicated in regimes of power, whether within labor processes, bureaucratic organization, or policing and state control. IT is intrinsically bound up with contemporary regimes of governance (Rose 1999).

SOCIAL RESEARCH ON IT

IT is an enabling technology that experienced – and is still experiencing – exponential growth just because it is basic to so many major processes of production and consumption. It started with a focus on microelectronics and now has to be considered in relation to the wholesale convergence and integration of many different media. The growth may be jerky at times, but the overall pattern is of steady expansion. IT is now a major economic player with huge ramifications in every area. IT is also a crucial enabler for globalization (whatever it means) and thus implicated in current developments.

The treatment of IT in the social sciences began as a fairly minor subfield, but it is now seen as one of the major areas for social science research. Four phases may be distinguished in its development. The first was what might be termed popular IT, and this first appeared under the rubric of the microelectronics revolution or the information technology revolution. These studies were very focused on the amazing capabilities and potential of these technologies to bring about “social transformations” of various kinds. While such studies rightly recognized the epochal character of IT, far too much stress was placed on what the technologies themselves would achieve and equally too much optimism was expressed about their benign character. However, such studies also stimulated serious critique (Webster & Robins 1986; Mosco 1996), which served to move the debate forward.

A second phase might be called IT studies in which workplace organization, government administration, and other areas such as “virtual communities” were examined in terms of the mediation of relationships by IT. This empirical contribution has produced a number of treatments of lasting value. A third phase, inspired largely by French theory, could be called post structuralist IT studies, and these make much of the diverse contributions by Baudrillard and Lyotard. Later on, studies in the Foucauldian tradition and from authors such as Deleuze also became significant. Lastly, what might be called critical IT studies constitutes a fourth phase (and of course these “phases” overlap considerably with each other – they are neither historically nor conceptually independent). Such critical studies began by attacking the

technological determinism of early popular accounts of “IT and society,” but also made solid contributions of their own by stressing the political economy and the gendered and racialized developments of IT.

From the 1980s onward research councils in North America and Europe began to recognize the importance of IT and this was reflected in funding for studies of the social dimensions of electronically mediated relationships of all kinds. After the advent of the World Wide Web in the early 1990s, for example, the UK Economic and Social Research Council set up a multi million pound initiative under the title “Virtual Society?” Similar work has been pursued in the US and Canada. Such developments tend to encourage empirical research and, with the late twentieth century trend towards radical economic restructuring, they also tend to be tied more tightly to the competitiveness of the country in question (hence the Canadian Social Sciences and Research Council funding for work on “Knowledge Based Economies” and then the “Initiative on the New Economy”).

CURRENT EMPHASES

Classic work in social scientific treatments of IT was done by precursors in the field such as Canadians Harold Adams Innis and his student Marshall McLuhan, along with the philosopher George Grant (Kroker 1984). These and several others were also influenced by earlier and more general work on technology by Jacques Ellul and Martin Heidegger. One could say that Innis’s work was the most doggedly empirical, even though he was to originate the important “bias of communication” perspective (Innis 1962). McLuhan’s was less tied to political economy and attuned more to the cultural changes associated with new media in general, while Grant provided a deeper critique based in relational and ethical perspectives. These could be compared and contrasted with Ellul’s searing attack on mere “technique” (that loses sight of what he argued are more significant goals of human activity, such as peace and justice) or Heidegger’s argument that technology is not correctly understood as a “tool” or “means,” but as a way of interacting with reality (and is not necessarily entirely under human control).

The most significant early sociological treatment of IT came from Daniel Bell, whose work still stands as a milestone in our comprehension of the social dimensions of what he called post industrial society (Bell 1974). By examining carefully the occupational structure, Bell's "social forecast" proposed that "industrial society" – which it should be recalled was the standard sociological description of contemporary social relations for several decades in the twentieth century – was slowly but surely being replaced by something else. And among other things, a new kind of reliance upon organized technical knowledge was at the heart of this putative shift. In Bell's own work, and then in the work of others, the negative descriptor was soon exchanged for the more commonplace term "information society," a concept that retains its salience in the early twenty first century.

More recently, however, the large scale comparative studies of Manuel Castells (2000) under the general title of the *Information Age* have become the standard and the foil for analysis of the social aspects of IT. Castells's work is similar to Bell's in that he seeks some structural explanations for what he takes to be epochal shifts in economy, polity, and society, but different in several respects, too. Unlike Bell, Castells does not imagine that the US provides the model for "information society" or, as he calls it, "network society." Castells provides some comparative analyses of IT development in different societies, beginning with alterations in urban infrastructure – his interest was in "global cities" – but also examining new social and political movements whose existence and activities depend on the availability of IT, and new forms of criminality and social exclusion appearing in information societies (see also Stalder 2005).

During the last part of the twentieth century and into the present century IT studies proliferated into a number of constituent sub fields. In addition to the macro level studies of the information society, other distinct areas emerged. Internet studies became important in its own right (e.g., Jones 1999; Wellman & Haythornthwaite 2002), although this field is likely to change shape somewhat as other kinds of media (such as wireless cell phones) are integrated with Internet access. Science, technology,

and society (STS) perspectives are also important in this field and combined with "information science" approaches have produced important studies such as Brown and Duguid's (2000) work on the "social life of information." This in turn relates to work done in organization studies and management information systems.

As noted above, IT is also studied in relation to globalization studies and in terms of divisions of access (digital divides) that may be socioeconomic but also associated with race and ethnicity and with gender (Wajcman 1991). IT studies are also implicated in surveillance studies and in the analysis of contemporary governance. Most strikingly, since the attacks of 9/11 and subsequent attacks in Madrid and London, IT companies have been competing for contracts with governments to upgrade security arrangements, especially at borders and within policing and intelligence services. The ideals of "convergence" and "integration" of systems and departments have never been as prominent as in the current quests for interoperability and for networked anti terror techniques.

ANALYSIS AND CRITIQUE

The social analysis of IT does not of course take place in a philosophical or ethical vacuum. As with all social theory, explanations of processes, systems, and change inevitably refer to some kinds of valuing, to normative critique or at the most basic level, to views of the "good society" or its opposite. Rather than attempt the impossible, to purge theory of such features, it makes more sense to acknowledge the particular kinds of arguments being made and to debate the consequences of taking a specific stance. With regard to macro level theories of the information society this is particularly evident, not least because some early studies seemed intent on optimistic forecasts of general human benefit in the wake of the new technologies. But it is also, though less obviously, true of STS, organization studies, and of studies of IT and social divisions.

A sociological understanding of IT cannot but notice the role of cultural factors in IT development. The ideas of information society or cyberspace are replete with mythical or even

“sublime” characteristics (Mosco 2004). They relate to the supposedly beneficent effects of IT in their capacity to make life easier, more peaceful, or even to transcend the limitations of the body. Unfortunately, while there are of course labor saving devices associated with IT, and while some quests for social justice are indeed facilitated by IT and some IT based innovations (e.g., word processing) may be useful “prosthetic” extensions to the human body, IT in the real world is as caught up in the contradictions and struggles of social life as anything else.

But there is a further problem here. Those accounts of IT that gloss unavoidable aspects of the “real world” also distract attention from the questions of ethics and politics that responsible treatments of IT will always raise (even though these in themselves go beyond the purview of sociology; see Robins 1995, or, for another perspective, Lash 2001). Thus, while it is the case, for example, that globalization in all its manifestations is facilitated by IT, all the debates over globalization – who benefits, how distance “dies,” where sweatshops and waste dumps are located, how superpower hegemony is maintained – thus also implicate IT. And as IT applications do not simply “appear” but are sought and developed for particular purposes, the argument that IT is a “neutral” technology and it is “how it is used” that matters is shown to be not only unsociological and hollow but also dangerous.

IT is today wrapped with the packaging of global consumerism, although it is also basic to the military systems that ultimately back up what appears to be a world of “free choices.” That efficiency and productivity may be enhanced using IT is not questioned, but what might be worth questioning is whether these represent primary goals of social, economic, and political life. As Weber observed a century ago, the “demands of the day” make a significant call on sociology “as a vocation” (Gerth & Mills 1946). He argued strenuously against turning sociology into a vocation for “demagogues,” but he also bemoaned the demise of seeing sociological work in the light of larger purposes and of politics and ethics. This is as true of the sociology of IT as the studies of bureaucracy or of comparative religion that Weber undertook.

FUTURE DIRECTIONS

The sociological analysis of IT is likely to continue for a long time to come, even though the discrete term IT may disappear as the technologies are increasingly embedded in systems and products. At a basic economic level, knowledge based work, which accounts for a growing proportion of GDP in many countries around the world (including now, significantly, China and India), is highly dependent on IT. In every productive sector, IT makes an important difference and understanding this is in part a sociological issue. But IT is also involved in the ways that services, travel, education, and entertainment are organized, not to mention life in the domestic sphere. It is hard to think of an area of social life studies by sociologists in which IT has no impact.

IT is also implicated in several very significant current trends, especially those towards the safety state and the security economy. As concerns about terrorism have been added to the already existing issues of the so called risk society (Ericson & Haggerty 1997), security and surveillance will continue to play a prominent role in social, economic, and political life. The security economy is now a sector in its own right and commands massive markets, especially in the global North. These markets are frequently involved in dedicated surveillance technologies of various kinds and also in redeploying technologies developed in one area (consumer marketing in particular) for security purposes. Intelligence services, for example, in the quest for identifying potential terrorists, now use data mining tools invented for profiling consumers (Lyon 2003).

Social theories of IT are proliferating, but some key threads are likely to stand the test of time. Firstly, political economy perspectives that locate IT developments in the power relations of capitalist countries serve as a reminder that whatever the micro level changes and how ever genuine improvements are made in human welfare, there is a constant tendency that IT will be developed in ways that benefit some groups at the expense of others. Secondly, technology studies look at the ways in which artifacts themselves are produced and how they interact with systems and users. This reminds us of the contingency of IT developments. Thirdly, the

kinds of theory associated with particular aspects of IT development – in relation to race and ethnicity, gender, age, ability, access, and region – will continue to be important for the social understanding of IT. Fourthly, postmodern and poststructural theories (e.g., from Bau drillard, Foucault, and Deleuze) are likely to continue to stimulate new ways of thinking about IT as simulation, as discourse, or as assemblage.

Information technology has in some ways become as basic to social life as industrial organization was in the twentieth century. It thus warrants a commensurate degree of sociological attention that is clear, careful, and ethically critical.

infotainment

Lauren Langman

The twentieth century, with its new forms of mass production and mass media, gave rise to what has been called consumer society, a world largely concerned with personal gratifications and desirable selfhood gained through consuming goods and experiences. An essential part of this new “amusement society” has been a focus

on entertainment from watching television sit coms to attending sport events, various rock concerts, or the symphony. As mass mediated entertainment became a growing industry, there was a proliferation of cable programming and cable news outlets, greater fragmentation of audiences, and a growing concentration of ownership. Thus the gathering of "hard news," reports of breaking events of war and peace, prosperity and poverty, leadership, public affairs, or investigations of crimes became highly expensive, producing little revenue and ever less audience share. These various factors led to the erosion of barriers between reporting "hard news" and the production of "soft news" combining information and entertainment to produce "infotainment," pleasantries about people, places, or events which provide the viewer with an agreeable form of entertainment "that is unrelated to public affairs or policy, and is typically more sensational, more personality or celebrity oriented, less time bound (meaning that the traditional journalistic norm of "timeliness" does not apply), and more incident based than hard news" (Patterson 2001).

Thus we have seen that whether in print, radio, or television, almost half of the "news" now concerns such things as celebrity revelations – often conducted by celebrity journalists, in which the private thoughts of a Britney Spears on sex, diets, and clothes are far more entertaining than how changing tax codes more directly impact people. Various human interest stories, sensationalist tabloid journalism, life style, personal finances, or the paranormal, what has been called "eye candy," pleasurable to view, have now become one of the main sources of information about the "world," or rather the world that many citizens inhabit, a world without war, hunger, poverty, or pollution, but filled with information about the loves and marriage of celebrities, their affairs and divorces, and how they decorate their homes. Clinton's *affaire* Monica, from first revelation to published memoirs, garnered far more interest than his record on jobs, taxes, or the former Yugoslavia. While "infotainment" seems an aspect of television, it has also impacted much of print journalism, as for example *USA Today* reducing the vast complexities of events to a

paragraph or so. To maintain or increase readership, many respectable newspapers have included more tabloid "infotainment" and have moved closer to *National Enquirer* like reports on aliens in the government and monsters feeding on pollution.

It should also be noted that a great deal of talk radio and television that purports to be news and news commentary, generally presented by strong, charismatic "personalities," has become a channel for conservative viewpoints. While people like Rush Limbaugh, Don Imus, or Bill O'Reilly may very well be witty and entertaining, much of what they report is not just biased or distorted but blatantly wrong, and viewers/listeners are unlikely to have access to more accurate reportage. "Infotainment," whether celebrities' lives, UFOs, wonder diets, or most political talk shows, is however more than simply amusing; it is part of a much larger set of processes that have encouraged personal gratifications at the cost of public concerns and thus serves to erode democratic governance. This becomes most evident when celebrities become politicians and political news is entertainment, whether it involves Cicciolina the Italian porn star, Ronald Reagan, or Arnold Schwarzenegger. As the Frankfurt scholars suggested, the "culture industries" serve an important conservative ideological function by reproducing the status quo and hiding its inequalities, injustices, and costs in human suffering.

in-groups and out-groups

Michael J. McCallion

An in group is a social unit an individual belongs to, interacts with, and shares a sense of "we ness" with. An out group, on the other hand, is a social unit or group of people that an individual neither belongs to nor identifies with. The construction and maintenance of boundaries (physical or symbolic) are the primary ways by which groups establish what it means to be "in" and, by contrast, what it means to be "out." The basis of in group identity, then, is socially constructed through symbolic markers (boundaries) such as narratives, creeds, rituals, and social practices. Moreover, sociologists view such boundaries along a continuum of permeability (open) and impermeability (closed), which influences group member entrance and exit processes. In group identity, in other words, is always an ongoing achievement in which group boundaries are collectively generated, affirmed, maintained, and employed to mark differences between insiders and outsiders (Hadden & Lester 1978).

In his classic study of folkways, William Graham Sumner (1906) articulated the enduring notions of in groups and out groups and the dialectical relation between them. Sumner stressed the negative reciprocity between in groups and out groups, especially in the context of conflict over scarce resources. In an environment of scarcity, Sumner argued, individuals need to band together to compete with other groups for survival. Without such conflict and scarcity, neither strong in group attachment nor out group hostility would occur, as Sherif and Sherif (1953) have confirmed in their work on intergroup behavior.

Indeed, Muzafer Sherif and his associates (1961) conducted various intergroup studies, in particular their classic field group study of 11 and 12 year old boys. In stage one of their study, the researchers took a group of boys to summer camp and divided them into two groups, each group residing in its own cabin. Eventually two cohesive groups formed, with one group calling itself the Rattlers and the

other the Eagles. In stage two, the groups engaged in competitive sporting activities, which soon gave way to name calling, accusations, fighting, and raiding of cabins, involving some structural damage. At this point the researchers discovered that negative stereotyping had developed toward the out group, while in group solidarity increased. Moreover, it was concluded that the social variable increasing each group's cohesiveness was threats toward the out group. In stage three, the researchers attempted to unite the groups through various common social events, but the intergroup conflict continued. It was not until the two groups had to work together to accomplish common goals (all pushing their broken down truck up a hill) that conflict decreased and cooperation ensued, leading to Sherif's hypothesis that conflict arose from mutually incompatible goals and cooperation from pursuing common goals.

In recent decades, much social research has confirmed Sumner's basic principle that conflict between groups often tends not to weaken, but rather to strengthen, groups internally. In other words, in group favoritism and out group negativity are strongly related, with some research (Tajfel 1982) finding that the mere categorization of people into groups can lead to increased attraction of in group members and devaluation of out group members. Ralph Dahrendorf (1964: 58) argues even more strongly that "it appears to be a general law that human groups react to external pressure by increased internal coherence." Even before Dahrendorf, however, Lewis Coser published a classic book, *The Functions of Social Conflict* (1956), which argued that intergroup conflict clarifies boundaries, strengthens in group identity, increases unity and participation, and strengthens ideological solidarity within conflicted groups. Social scientists continue to observe these principles at work in a variety of settings, from ethnic relations (Gerard 1985) to military organizations (Elliot 1986). In particular, many studies in social psychology have confirmed the theory that out group conflict builds in group solidarity (e.g., Fisher 1993). Also, many studies in anthropology, psychology, and political science support these findings, with Stein (1976), in reviewing this literature, concluding: "In sum, then, there is a clear convergence in the literature in both

the specific studies and in the various disciplines, that suggests that external conflict does increase internal cohesion."

Although research continues to confirm the findings that external conflict increases in group solidarity, other research has found that mere categorization (Karp et al. 1993) or conflict (Allport 1954) are not key or absolutely necessary for the creation or maintenance of in group solidarity and cohesion. Kollock (1998), reviewing this literature, writes that "it is the belief in future reciprocal exchanges between members . . . that moderates the temptation to defect and encourages cooperation. The expectation of in group reciprocity seems to serve as a very deep heuristic that shapes our strategic decisions." Allport (1954) also found that attachment to one's in group does not require conflict or hostility toward out groups, which stands in contrast to the inherited wisdom of Sumner's work. Allport postulated, for instance, that in groups are psychologically primary, in the sense that familiarity, attachment, and preference for one's in group comes prior to development of attitudes toward specific out groups. Moreover, he notes, in group love can be compatible with a range of attitudes toward corresponding out groups, including mild positivity and indifference or intense disdain and hatred. The bonds of in group solidarity, in other words, are not necessarily based on conflict/hostility toward outsiders or born of altruism via categorization of individuals into out groups and in groups, but rather, in many instances, in group solidarity arises from the practices and beliefs in the interdependencies of group members and expectations of reciprocity among the members.

insecurity and fear of crime

Philippe Robert

Insecurity and fear of crime are expressions designating the apprehension elicited by crime and, by extension, the field of research devoted to studying it.

In the United States, research on fear of crime took off following a study by a presidential commission on crime in the mid 1960s (President's Commission 1967), which tackled the problem of measuring crime from a new perspective. Growing doubts about the adequacy of

police statistics at the time encouraged a search for non institutional tools based on general population surveys. This led Joseph Bidermann, Philip Ennis, and Al Reiss, Jr. to invent the victimization survey. However, when people in a sample were questioned about their fear in addition to any victimizations they had suffered, the two measures turned out not to coincide that well: some victims were not very frightened, some non victims were nonetheless fearful. Fear of crime thus gradually came to be singled out as an object of research. Even before this American tradition had taken hold in Europe, British sociologists had approached this research field from another angle: they had termed "moral panic" the excessive alarm elicited either by fights between youth gangs in holiday resorts (Cohen 1973) or by muggings (Hall et al. 1981). Elsewhere, sociologists or political scientists interested in local occurrences had studied rumors, such as reports that girls had been abducted by shopkeepers in one French city, or local signs of insecurity, the explanation for which was sought in the living conditions and social relations of insecure groups. The gradual reception of the American research tradition on fear of crime finally unified these different European strands to some extent.

Some subtle differences do exist, however, as evidenced in the terms used. North Americans tend to speak of fear of crime, whereas in Europe insecurity is increasingly becoming the accepted term, not only in German (*Unsicherheit*) and French (*insécurité* or *sentiment d'insécurité*), but also in European English. The two expressions are not exactly equivalent: recourse to one or the other may indicate, at least implicitly, differing conceptions.

Be that as it may, irrespective of whether we speak of fear of crime or insecurity, these expressions have become a part of the language of sociology because of the realization that apprehension is not a simple reflection of the risk incurred or of previous experience of victimization. Insecurity or fear of crime has become an object of research because it is felt to be *excessive*; attempts are made to dispel or to explain this apparent enigma. At the same time, these expressions continue to be used in public debate, and belong primarily to the language of the mass media and politics. Their conceptual coherence is faulty and sociologists may

consider whether research would not do better to replace them with more homogeneous objects of study.

The two main trends in research on insecurity and fear of crime may now be described. First, explaining why apprehension exceeds actual risk or experience has led to work exploring three themes. It may be claimed that insecurity is not so much caused by the intensity of the threat of crime to which one is exposed, or by one's experience as victim, but rather, that it results from media messages that unduly magnify crime. One may also wonder whether insecurity is not fed by disorder rather than by crime per se. Finally, the extent of apprehension may be adjusted by considering differences in exposure to risk or the greater vulnerability of some individuals.

Since apprehension of crime seems disproportionate in comparison with offenses actually committed, it seems common sense to accuse media coverage. The media everywhere devote a great deal of time and space to crime generally, as is readily observed, and most importantly, they mainly publicize the most spectacular and most frightening crimes, especially violent crime. The media, then, offer a dramatized image of criminality. Quite naturally, the media are deemed responsible for the gap between crime and the fear it elicits. Offending is good for filling up news columns, it is spectacular, in short, it helps to sell the media. Moreover, it is in the interests of certain other actors to feed the press, radio, and television with dramatic, fear inducing information about crime: politicians play on fear as a vote getting device or as a way of diverting public attention from more complex social problems such as unemployment; the police use it as an argument to support their demands for greater resources and to point up the importance of their work, sometimes even to silence criticism about their poor relationship with the public; lastly, some moral entrepreneurs find arguments to back their demands for greater repression, while pressure groups try to discredit some minorities by putting the blame for crime on them. As a sales gimmick, insecurity may serve a number of causes (Warr 2000).

However true all this may be, empirical research yields only lukewarm support for this commonsense argument. As usual, the message

delivered by the mass media is easy to observe, but its impact is much more difficult to determine. It is very tempting to assume that what is delivered is received. On further reflection, however, this assumption is not very solid: it leads to the postulate that the target of media messages is like putty, passively molded by it. A handful of studies do come to the conclusion that media messages on crime are instrumental in producing insecurity. However, some have been subjected to serious methodological criticism that sheds doubt on their conclusions, whereas many other studies are unable to establish any definite causal relationship.

As a rule, the available research tends rather to reject the media's ability to create fear of crime out of nothing. It indicates that a media message suggesting a threat to security is only received as such if it corroborates some personal experience felt as security threatening, or if it encounters a preexisting concern with security. If it falls on such fertile ground it may nourish insecurity, especially when people are subjected to constant media hype, particularly since people who are most sensitive to insecurity also tend to revel most in such alarmist messages. This may create a sort of vicious circle: people who are sensitive to insecurity problems welcome any corroboration provided by the authoritative media. Not only does the message then feed insecurity, it also legitimates it: this is not some personal whim, it is invested with the authority of the TV news program. But perhaps the influence of the media on insecurity stems mostly from the ability of mass communications to provide cognitive patterns, to give a definite shape to feelings of insecurity, its causes (*parental abdication* or *an overliberal justice system*), and the proper remedies (*zero tolerance*), thus furnishing ready made frames of reference.

Whereas the mass media's responsibility in creating feelings of insecurity must be qualified, conversely, their enormous influence on political personnel should not be underestimated. It may be that political leaders' experience of their own sensitivity leads them to point an accusing finger at the media at regular intervals.

The discrepancy between the risk of crime and the fear it elicits has propelled research in a second direction, which ascribes feelings of

insecurity to incivility rather than to crime, on the basis of Wilson and Kelling's (1982) article on broken windows. When signs of social disorder (e.g., drunkenness, youth gangs, harassment on the streets, drug dealing) and of physical disorder (e.g., vandalism, abandoned buildings, buildup of garbage and refuse) are allowed to accumulate in an area, the mechanisms of informal control are undermined, the housing market collapses, families who are able to leave move away to avoid being stigmatized by a neighborhood that is pulled into a downward spiral of disintegration, and feelings of insecurity prosper. The overview conducted by Skogan (1990) for the US conclusively marked the development of this type of research. The fact remains, however, that the underlying explanatory model may not be the same for those who think that incivility encourages crime, those for whom it primarily increases perception of crime (as is the case for LaGrange et al. 1992), and those who feel that it produces insecurity directly (e.g., Hale et al. 1994), the other possibility being that incivility affects both crime and fear simultaneously.

Another avenue of research has tried to correct the poor correlation between the extent of crime and the fear it elicits. In 1979, Balkin drew attention to the effect of exposure to risk: retirees and housewives who express great apprehension are less irrational than it would seem. Their risk of victimization should be correlated with their exposure, much less frequent than, for instance, a young man who goes out every evening; it is therefore greater than at first apparent. Stafford and Galle (1984) were the first to do empirical work in this direction. However, the Balkin effect can only work for street crime, not for housebreaking, burglary, or violence between intimates, which often have enormous repercussions. Many other factors operate in the same direction – differences in vulnerability, for instance. The prospect of being jostled is much more serious for an elderly man than for a youth of 20: any broken bone will heal rapidly in the latter's case, whereas the former risks permanent invalidity. The same is true of what Ferraro (1995) calls the *shadow effect* of fear of rape on women's fear of crime: behind any threatening situation lurks the far more terrifying risk of sexual violence.

However rich the three research currents outlined here, the fact remains that none has succeeded in completely dispelling the enigma of insecurity, and this legitimates the other broad area of research on insecurity and fear of crime. Are we dealing with a coherent social object, or do these labels, used in public debate, conceal more complex phenomena?

Many writers have attempted to break down the categories of fear of crime and insecurity in order to reach more consistent ones. Young Rifai, for example: as early as 1979 she made distinctions between general concern, at either a national or a local level, evaluation of actual risk in one's own neighborhood, and assessment of the probability of personally being a victim of a specific offense. The distinction between *fear* and *concern*, suggested by Furstenberg in 1971 (and adopted since in various forms – such as *concrete fear* and *formless fear* in the 1980 Figgie Report, and by a great many researchers) has finally prevailed. It is one thing to fear crime for oneself or one's loved ones, and quite another to view it as a serious societal problem. One may of course be both fearful and concerned, but the number of cases in which this is not true is sufficient to demonstrate the analytic cogency of this distinction. Although they may merge in some people, fear and concern are not driven by the same mechanism.

Fear for oneself and one's loved ones seems to be a kind of anticipation of a risk, hence its good correlation with local indicators of crime, be they police statistics or victimization rates, or with experience of victimization. To produce fear, however, the perception of danger combines with subjective feelings of vulnerability. The latter may depend either on physical causes, such as age or sex, or on living conditions. To take one example, some French studies show that people who are financially unable to leave their derelict urban area are particularly prone to fear crime, which they could only escape by moving out (Peretti Watel 2000). Concern seems to be less concrete, less tied to a personal situation. It views insecurity as a social problem rather than a personal risk, and therefore seems to be relatively insensitive to variations in actual risk or personal victimization. It is apparently linked less to vulnerability with respect to crime than to apprehensiveness

about societal transformations, which makes people relatively intolerant of crime, viewed as a sign of disorder.

These distinctions help us to understand why the link between insecurity and the risk of crime or personal experience of victimization seems to vary with the form – concrete or abstract – of the question posed. Another point is that it is easier to apply a single indicator to the measurement of concern than to fear, which is both local and fragmented: in the same population, during the same investigation, scores and profiles may differ considerably depending on whether the question has to do with fear at night on the streets, at home, in different kinds of public transportation, or for one's children. Conversely, concern does not seem to be a black or white variable: there is a whole range of types, from people for whom security is an obsession to the relatively unconcerned, and including the strongly concerned.

Although the distinction was first made in the US, many observers have pointed out that North American research seems to deal increasingly with fear, whereas European research, although encompassing fewer studies, is directed at both facets of insecurity. The difference in vocabulary on either side of the Atlantic definitely reflects diverging scholarly orientations.

Be that as it may, scholarly interest in insecurity or fear of crime is part of a deep seated change in ways of thinking about crime. Traditionally, interest focused on the extent of crime and its control, and even more specifically on offenders and what should be done with them. The main question then was: what should be done with that fringe of hardened repeat offenders who seem impervious to dissuasion by the law and the criminal justice system? Should they be rehabilitated when possible, and eliminated when not? The emphasis on insecurity places us within a conception in which crime is perceived as a mass risk, the harmful effects of which must be controlled while limiting the costs of public policies. The central variable is no longer the criminal as much as feelings about or experience of crime.

This change of emphasis seems to go along with the firm belief – carefully hidden but deeply rooted – among political leaders that public policies pertaining to security are mainly played

out on the symbolic register, through statements of intention and the impact of calculated announcements. Perhaps this should be interpreted as reflecting a degree of powerlessness. Certainly, one of the bases of the nation state is its claim to protect the security of people and their property. But concrete fears must be handled by local arrangements involving a number of protagonists, and these are difficult for national level officials to comprehend. (Conversely, local governments are increasingly using security as an argument to attract people to their city or region.) As for concern with security, it may well turn out to be a bottomless pit: a government can prove its inclination for law and order, but have greater difficulty making the future less uncertain.

This juncture is stimulating for the development of research, for which the strong demand for knowledge is beneficial. But it also puts a tremendous onus on it, as is always the case when a subject of sociological research develops out of a controversial area of public debate, in which the very terms used are, in themselves, one element of the debate. Research on insecurity and fear of crime will continue to accumulate at a rapid pace; its fruitfulness, however, will depend on the ability of sociologists to call into question the obvious, immediate nature of the very formulations suggested by those who sponsor their work.

institution

Christoph Henning

An institution is the fixing of stereotyped social interactions in the form of rules. In most cases these rules are made explicit and there are sanctioning mechanisms behind them. Yet sometimes these characteristics are absent, for example when people adhere to such rules simply because they feel urged to act in this way. An institution does not need to be a large organization. The largest institutions known are states or multinational organizations like the United Nations, yet there are also much smaller institutions, as for example marriage or monthly meetings of a group at a certain pub. Therefore, institutionalization is not a matter of size.

The term institution has become quite popular in the neo institutional economics of Oliver Williamson and D. C. North. Their use of the term has recently spread back into sociology, in spite of the fact that it refers only to “constraints” on individual utility maximizing behavior due to the fact that there are always others trying to do the same thing. It categorizes institutions in terms of the transaction costs people save if they agree to cooperate with others. In this individualistic perspective, the essentially social character of institutions is omitted from the start. That does not matter much for economics, but this conception is of little use for sociology. Sociological concepts of institutions, institutionalization, and institutional change have in fact influenced economics in the first place. An institution can determine what appears to the individual as a “utility” or an obligation. So if one starts from institutions, one can explain individual behavior, rather than the other way round. This is what the sociological concept of institution is aiming at.

The first sociologist to use the term was Herbert Spencer. He described society as an organism. Accordingly, for him institutions were society’s “organs.” He distinguished six different types of social institutions: those related to the family, politics, religion, the economy, ceremonies, and professions. Another naturalistic approach was developed by Bronislaw Malinowski, who started with the needs of the individual. The function of a social institution is to fulfill basic needs of a group. On this basis, higher or second order needs may develop which also call for satisfaction. This leads to a distinction between primary institutions, which can be legitimated with reference to nature, and secondary institutions, which must be legitimated with reference to culture. Here, institutions appear as the “concrete isolates of organized behavior” in which groups of people satisfy their needs together.

There is another tradition in social theory that starts not with nature but with ideas. Sometimes institutions enact power over the behavior of individuals even where it is against their interests. This cannot be explained by need alone, and there must be other sources of institutional credibility. For Émile Durkheim, who described sociology as the “science of institutions,” these sources were the collective patterns of thought. They are as solid as physical objects for the socialized individual. But where does this normative and symbolic surplus come from? Following Maurice Hauriou (1865–1929), institutions are centered around a leading idea (*idée directrice*). This idea is shared by every member of a group and therefore constitutes institutions like law or the state. In order to provide continuity, this idea needs to be incorporated and personalized. Talcott Parsons further developed this approach: for him, too, society is based on norms and values. Yet in the Parsonian tradition, the term institution almost disappeared behind the more fundamental concept of the social “system.”

A third way of dealing with institutions tries to combine the natural and the symbolic factors. For the German anthropologist Arnold Gehlen (1904–76), institutions are necessary in order to give directions to human beings. Compared to lower animals, human instincts are reduced. Yet social life without directions

would lead to a Hobbesian war of all against all. Institutions therefore reduce complexity: they limit the possibilities to act. In so doing they not only fulfill the basic needs in a certain culturally fixed way, they also supply cultural meaning to all things, providing a “meaning of life.” On the basis of this “background satisfaction,” new possibilities appear which constitute the second order freedom of cultivated man. This philosophical approach was taken up by the seminal work of Berger and Luckmann, *The Social Construction of Reality* (1966). Their work integrates different approaches into a general theory of institutionalization. Following them, social interaction becomes institutionalized when typified behavioral patterns crystallize into role models that are known to all or most members of society. Such models can last for generations. Therefore, their internalization (the counterpart of institutionalization) requires certain narratives in order to legitimize these institutions. Institutions do not necessarily need to become “total,” as Goffman described in examples like prisons. The dimension of legitimation allows for an institutional adaptation to new challenges. For this reason, institutional analysis is not confined to finding formal organizational structures and necessities. It also needs to investigate the culture of an institution, which includes the legitimizing narratives as well as the informal narratives that allow for institutional continuity and institutional change.

Institutional economics has stressed the importance of institutional settings as restrictions on individual economic action. Economic sociology has reacted to this recent trend by showing that much more is at stake. Institutions matter even more than institutional economics admits. Economic action is always embedded in broader cultural and political settings. The market itself is an institution that needs regulation. This starts with a central bank that physically provides money, interest rates, loans, exchange rates, and so on; and it has cultural implications, as, for example, the issue of which “goods” should be allowed to be traded at all. Should there be markets for human organs and genetic codes? This is a question that is dealt with in ethical, political, and juridical institutions. The main object of economic analysis is the market. But there are

social institutions at work long before a market evolves. Therefore, the sociology of institutions is more relevant today than ever.

institutional review boards and sociological research

Zoe Blumberg Corwin and William G. Tierney

Institutional review boards (IRBs) are charged with ensuring the rights of volunteers who participate in research conducted through a university. Originally conceived after World War II to deter possible abuses in biomedical research, human subject review has expanded to research in the social sciences. The role of IRBs in research is not without controversy, especially as it pertains to sociological studies. Tension between IRBs and researchers centers on how the two parties interpret what constitutes

research and the effects of IRB regulation on research in general.

ORIGINS AND HISTORY

During the Nuremberg War Crime Trials after World War II, news of abusive biomedical experiments conducted by the Nazis drew attention to the importance of establishing ethical parameters for conducting research. The Nuremberg Code (1947) expanded on earlier directives issued by the Prussian government to protect the welfare of research subjects, including obtaining consent from participants in medical experiments. The much publicized Code outlined a broad protocol for judging the ethics and actions of scientists who performed biomedical research on human subjects, was intended for the international community, and served as the prototype for subsequent IRB regulations in the US.

The first major effort to establish IRBs at universities across the country and to articulate IRB guidelines occurred in 1974 when the US government created the National Commission for the Protection of Human Subjects of Biomedical and Behavioral Research. The commission was charged to determine the various distinctions between biomedical and behavioral research, establish a way to assess the risks and benefits of conducting research, outline the guidelines for subject selection, and define the boundaries of informed consent. The Commission's central policy document, the Belmont Report (1979), outlined guidelines for the Commission at the federal level and for individual IRBs at the institutional level. The report clarified distinctions between research and practice, identified three ethical principles intended to guide the protection of human subjects, and discussed the application of the three principles. The authors of the report intentionally utilized generalized language, thus leaving room for interpretations of details up to individual IRBs at each institution, a point with implications discussed below.

By 1991, oversight for human subjects policy in the US had been transferred to the Department of Health and Human Services which, in conjunction with 16 other federal departments, drafted what is commonly referred to as the

Common Rule (45 CFR 46.111). The Common Rule expanded on earlier regulations and required that universities create IRBs if their researchers desire to access government funding for investigations. Many universities, however, have expanded IRB jurisdiction to cover all research activities with human subjects regardless of funding sources. The expanded IRB role is most likely due to increasing university concerns of being sued over improper research protocols and methods.

In 2001 the American Association of University Professors wrote a critical response to the Common Rule outlining concerns of social scientists over governmental regulations on research, questioning the constraints that IRBs potentially place on academic freedom, and studying the applications of governmental regulations on social science research. In particular, the document offered suggestions for improving how IRBs address qualitative research which comprises approximately 25 percent of all research reviewed by IRBs. The AAUP document underscored the challenge of interpreting IRB guidelines given the broad definitions articulated in the Belmont Report (AAUP 2001).

IRBs are not exclusive to the US. US IRBs provide protections for subjects participating in foreign research conducted by US researchers and many countries employ their own system of human subject protections within their universities. International IRBs are structured around similar issues to IRBs in the US, yet the details of implementation vary in nuanced ways. For example, in the Netherlands, social scientists are exempt from undergoing IRB review unless their research poses clear physical or psychological duress on subjects (Bosk & DeVries 2004), and Canadian IRBs differ slightly in how they define "minimal risk" and "human subjects" (Center for Advanced Study 2005). Debates entertained by IRBs and researchers in the international community are reflective of those that occur in the US.

JURISDICTION

IRBs are responsible for translating federal, state, and local regulations into institutional practice. As such, IRBs are mandated to

approve, require modifications, or disprove of research activities related to human subjects and funded by federal resources. As noted, numerous universities now require all research, irrespective of funding source or researcher, to receive IRB approval. For example, any graduate student who writes a master's thesis or a dissertation must receive IRB approval. A recent study by the NIH found that few proposed studies were rejected by IRBs, but that approximately 80 percent required changes (AAUP 2001). The authority of IRBs is governed by principles outlined in the Belmont Report, but also is determined by the composition of IRBs, interpretation of exemptions and regulations, and treatment of informed consent. Most large institutions host separate medical and social behavioral IRBs. According to the Common Rule, IRBs must have at least five members, ideally from diverse backgrounds with respect to race, class, and gender, but also from various academic disciplines. Because the majority of IRB members come from biomedical fields, it is especially important for sociological researchers that IRBs are comprised of individuals who understand the nuances of social scientific work. If an IRB is faced with evaluating a proposal where no one is familiar with the research, experts are allowed to be consulted and participate in the review.

IRBs are guided by the three ethical principles outlined in the Belmont Report: (1) respect for persons, (2) beneficence, and (3) justice. Respect for persons emphasizes that individuals should be recognized as autonomous and treated with dignity and that persons with diminished autonomy (e.g., persons with certain types of mental illness, persons with restricted liberty such as prisoners) deserve special protections. The implications of this principle pertain to supplying participants with adequate information about the research project and ensuring voluntary participation. Beneficence requires researchers to do no harm and to maximize the possibility for benefits and minimize possible risks to subjects. The application of beneficence involves weighing the risks and benefits of each particular project. The third principle, justice, obliges researchers to distribute the benefits and burdens of research equitably. This principle relates to fair sample selection for the subject individually, but also

as a member of a social, racial, sexual, or ethnic group. The Tuskegee syphilis study of 1940, where rural African American men were used as research subjects and deprived of effective treatment, even though the disease affected a much wider population, is an example of how a specific population can be unfairly burdened through a selective sample.

Especially important to sociological researchers are the six concepts of exemption pertaining to social science research. They are (1) research in education settings on instructional techniques, curricula, or classroom management methods; (2) research involving the use of educational tests, survey procedures, interview procedures, or observation of public behavior, unless the subject can be identified and disclosure of the subject's responses could put the individual at risk of criminal or civil liability or could damage the subject's financial standing, employability, or reputation; (3) research involving elected or appointed officials or candidates for public office; (4) studies using existing data, documents, or records, as long as these resources are publicly available or the human subject cannot be identified; (5) studies of public benefit or service programs; and (6) research focusing on consumer consumption of food and the taste and quality of food (AAUP 2001). These categories are exempt because they are believed to exhibit minimal risk. However, what qualifies as exempt is also open for interpretation by university specific IRBs.

The majority of IRBs require written proof of informed consent to participate in research. Consent forms outline the study parameters, possible risks, and benefits of participating in the project, and require a signature from the research subject. Requiring written consent can pose problems for qualitative researchers in particular and at times must be negotiated with the institution's IRB. For example, the American Anthropological Association (2004) has argued that in some cases having research subjects sign a consent form can be alienating and even deter an individual from participating in a study. Examples of this include research with vulnerable populations such as individuals with stigmatizing illnesses (e.g., HIV/AIDS), or individuals who perform illegal activities (e.g., sex work, garment workers without immigration documents), or individuals who do not

believe in signing government documents (e.g., *curanderos* – medicinal healers – from rural Mexico). Other issues arise, particularly in the field of education, if non research activities, such as course evaluations, are conflated with exempt research. The Internet poses new challenges for obtaining informed consent, as researchers increasingly use email and chat rooms as sites for data collection. Still, researchers contend that obtaining consent should be a meaningful activity because it reflects the essence of individual autonomy (Brody 2001).

MAJOR DEBATES

Given the original purposes of IRBs, how well does institutional review fare with regard to sociological research? Despite the value they place on ethical conduct in research, sociological researchers are often at odds with the IRB process. On the one hand, IRBs have the potential to share resources and expertise with scholars, as well as highlight the importance of reflexivity in research. Yet researchers also complain that vague definitions and varying interpretations of research pose unique challenges to sociological work, that applying a biomedical model to social science research is ineffective, and that the implementation of IRB review inhibits academic freedom and restricts productivity. Further, many scholars perceive IRBs as increasingly more concerned with the protection of the university from lawsuits than with the protection of human subjects.

The amorphous character of definitions presented in the Belmont Report is particularly problematic for sociological researchers. For example, the report defines research as an activity designed to “test hypotheses, permit conclusions to be drawn, and thereby to develop or contribute to generalizable knowledge (expressed, for example, in theories, principles and statements of relationships).” This definition has perplexed social scientists who do not purport to test hypotheses or produce generalizable findings, but still are required to submit their proposed studies to their IRB for review. Also troubling for sociological researchers is the definition of the human subject as “a living individual about whom an investigator (whether professional or student) conducting research obtains (1) data

through intervention or interaction with the individual, or (2) identifiable private information.” The terms “intervention,” “interaction,” and “private information” can be interpreted in different ways. Even measuring the costs and benefits of a research project is subject to interpretation. IRBs, for example, can determine that while the benefits of a research study are reasonable in relation to the risks imposed on subjects, the benefits with respect to new knowledge are not substantial and thereby deny approval or request modifications to the study. Here the interpretation of what constitutes knowledge is open for interpretation and strongly influenced by the composition of IRB members. As discussed below, how an IRB interprets the Belmont Report’s definitions has significant ramifications for various types of sociological research.

In principle and in practicality, many researchers from the field of sociology voice concerns over the fact that IRB regulations derive from a biomedical model. Since the goals of sociological research as well as the methods often vary from biomedical research, this paradox poses problems for sociological researchers, especially for those who conduct qualitative studies. The examples of oral histories, ethnographies, and case studies illustrate the complexity of the inconsistency.

In 2003, after discussion with the American Historical Society, the federal government determined that oral histories do not constitute research and consequently are not subject to IRB review. Historians had voiced concern over how IRBs had been interpreting regulations intended for biomedical researchers which were “unsuited” to historical methods (Brainard 2003). The association argued that oral histories do not attempt to add to “generalizable knowledge” and that historians aim to describe a specific past and therefore do not need to undergo IRB review (Ritchie & Shopes 2003). At the core of this ruling was the interpretation of what it means to do research. While historians applauded the decision, they are now faced with the mixed message that what they do is not considered research. Consequently, a side effect of the loose interpretation of research is that it created a larger chasm between academic disciplines.

Unlike with oral histories, the American Anthropological Association (AAA) determined

that ethnographies qualify as research, but should be evaluated on a case by case manner due to their often complex nature. In many cases, ethnographers are unable to articulate hypotheses and procedures formally prior to beginning data collection due to the dynamic nature of the method. In a 2004 statement on IRBs and ethnography, the AAA (2004) pointed out that, due to the fact that ethnographic research is based on cultivating trusting relationships over time, IRBs need to recognize that consent is a changing and ongoing process. The AAA stressed the need to evaluate the socio-cultural environment of each research project in order to adequately assess risk. It is likely that most ethnographies will be classified as low risk since it is fairly simple to withdraw participation. A major area of contention for the AAA with regards to IRBs is the documentation of consent as discussed above, but also considering the intrusion that research paraphernalia (consent forms, tape recorders, writing pads, pencils, and pens) can have on securing trust with an interviewee.

The position of case studies is less clear. Some scholars argue that case studies aim to contribute to generalizable knowledge, can cause risk to participants, and thus are subject to IRB review; others argue that case studies do not rely on "systematic investigation" and generally invoke little risk and therefore should not be classified as research. How the IRB interprets research determines how case studies should be treated.

A practical result of this confusion is a logjam with regard to the approval process. The interpretation of IRB "rules" varies from campus to campus, and with different committees on the same campus. What was approved last year, or even last semester, may not gain approval this year. Graduate students, in particular, have faced delays in conducting research in large part because no one is certain how to proceed, so that everything needs to be reviewed by a committee. Even if the process were optimal, the result can be remarkably inefficient.

For many institutions, IRB review extends not just to research but into the classroom. Sociological scholars have emphasized the risk that increased surveillance, more rigid regulations, and emphasis on the institution over the individual place on academic freedom. Again, efforts to translate biomedical approaches to sociological research fuel the complexity of

ensuring academic freedom. Increased attention to human subjects as a result of biomedical failures, scrutiny of classroom teaching, and questions about what constitutes "evidence and scientific inquiry serve as fodder for limits on academic freedom" (Lincoln & Tierney 2004). It is suggested that this is partly because IRBs focus on research *plans* instead of potential publications, a method that works for biomedical research but has a complicated application to sociological work, since researchers often do not know what they will publish until the research is complete.

Debates in journal articles, conference papers, and online discussions suggest that IRBs have the potential to stifle innovations in research by discouraging research with populations who might appear to pose high risks to IRBs, slowing down the research process, and assuming a "one size fits all" model for nuanced types of sociological studies (AAUP 2001). Delays in IRB approval adversely affect the actual production of scholarship, as well as the perceptions about how to design future research. Lincoln and Tierney (2004) point out that a growing reluctance to approve research with children as well as restrictions on reflexive research contribute to self censorship on the part of researchers.

Concern has been expressed over burdening researchers with too much regulation and paper work, a situation complicated by IRBs who are sometimes ignorant about sociological research methods (Pritchard 2002). At the same time, attention has turned to resisting "mission creep," or the inability of IRBs to cope with increased workloads caused by a misplaced focus on procedure over ethical issues (Center for Advanced Study 2005). Negative perceptions and experiences with IRBs have also been shown to demoralize faculty and students (Pritchard 2002). Graduate students witness the frustration experienced by their professors and opt to do research that they perceive will receive expedited or exempt review.

FUTURE

One solution to promoting understanding of sociological research is to ensure that members of sociology departments are represented on IRBs and that biomedical members are educated

as to the nuances of sociological research. More in depth understandings of the types of risks involved in sociological research can expand the potential for exempt review as well as lessen the number of required changes to research design. Other recommendations include sending research proposals to an IRB representative in home departments before submitting the document for review, thus decreasing the potential for an IRB member to misinterpret study goals or methods.

Kahn and Mastroianni (2002) pose an important question: How do we move from a culture of compliance to a culture of conscience? There are a host of innovative approaches to educating researchers about the IRB process. Universities now offer online certification for individuals conducting federal research, specialized journals highlight the continually changing issues facing IRBs, and online chat rooms provide a forum for discussing issues pertinent to IRB review (see www.irbforum.com). National conferences have also created venues for discussing the parameters of IRBs (American Sociological Association in 2005; Center for Advanced Study at the University of Illinois in 2003; Social and Behavioral Sciences Working Group in Human Research Protections in 2003). Graduate research seminars can incorporate sections on IRB review.

Given the public attention afforded to instances of university neglect of research volunteers and increasing concern of universities to protect themselves from lawsuits, it is unlikely that IRB regulations will relax in the future. In fact, trends in the last ten years indicate that IRBs have become more rigid. Consequently, it is critical that researchers continue to express vigilance over infringements on academic freedom and the adverse effects of IRB review on innovation in research. This can partially be facilitated through supporting sociological studies on how IRBs function (DeVries 2005). Continued dialogue and debate is productive not only at the institutional level, but in national forums as well.

institutional theory, new

Chris Carter and Stewart Clegg

Emerging from the sociology of education in the 1970s, new institutional theory (NIT) has become one of the foremost positions within the mainstream of American management studies. It seeks to explain the ways in which institutions are created, sustained, and diffused. NIT's antecedents lay in the institutional theorizing of writers such as Philip Selznick a generation before. Adherents of NIT are keen to draw a distinction between "new" and "old" institutionalism. While old institutionalism emphasized politics and the role of conflict, NIT took legitimacy as its master concept. The old institutionalism focused on the existence of a negotiated order between different interest groups, while in its place NIT sought to understand the way in which the quest for legitimacy is a driving force behind the isomorphism of organizations. NIT is interested in understanding the means through which the socially constructed external environment enters the organization by "creating the lens through which actors view the world and the very categories of structure, action, and thought" (Powell & DiMaggio 1991).

Works by Meyer and Rowan (1977) and DiMaggio and Powell (1983) are generally held up as foundational or seminal statements of NIT. Constituting the two branches of NIT, they remain widely cited to this day. Meyer and Rowan examined why particular phenomena became institutionalized; that is, why certain forms were repeatedly enacted over time. Exploring the use of budgeting in the loosely institutionalized setting of a university, they argued that it came to play a more important

role because of the increasing need for university authorities to portray their actions to external agencies as following some form of "rationality." Their analysis highlights that such rationality is often a mere rhetorical veneer – an image existing only in a ceremonial and symbolic form – which might well be decoupled from what actually happens in the organization. Building on these insights, Suchman argues that this leaves three strategies open to organizational actors: (1) they ignore the actual performance of an initiative and choose to concentrate on celebrating the ceremonial aspects of the initiative; (2) they criticize and display cynicism towards the initiative, acknowledging that its results are problematic; (3) they champion reform of the initiative, thereby drawing a distinction between the troubled present and a more successful future.

The DiMaggio and Powell branch of NIT seeks to understand why it is that organizations are increasingly coming to resemble each other. They argue that this process of isomorphism is driven by the necessity of being seen to be legitimate in the eyes of important stakeholders, which, following Berger and Luckman, they see as an intersubjective process of social construction. DiMaggio and Powell identify coercive, normative, and mimetic dimensions of isomorphism. Coercive isomorphism, as the name suggests, occurs where an organization is compelled to institutionalize a particular policy, such as adopt an employment law or a tax standard. Coercive isomorphism is often found in global supply chains, where one powerful buyer coerces other parts of the supply chain to adopt a particular initiative or technology. Normative isomorphism refers to institutions adopting similar initiatives because they are regarded as constituting professional "best practice." The MBA qualification can be construed as a transmission mechanism for notions of best practice in management. The drive for legitimacy on these three dimensions increasingly leads organizations to resemble each other, at least superficially.

In management studies, contrary to their intentions, DiMaggio and Powell's concept of mimetic isomorphism has become by far the most widely used and tested of the three types of institutional isomorphism (Mizruchi & Fein 1999). It is this concept that underpins much of

the burgeoning research in management fashion. According to this perspective, management fashions are ephemeral and are adopted by organizations seeking to demonstrate that they are in symphony with the spirit of the zeitgeist. In the adoption of an initiative, some organizations are regarded as being fashion leaders, on the catwalk at the leading shows, as it were, amidst a blaze of positive publicity, while others follow more slowly, less as *fashionistas* and more as diffusionists, as fashion gradually trickles and distills down to the high street (Mazza & Alvarez 2000). After a few years, a fashion becomes *démodé*, leaving the organizational scene without an institutional trace. There is little empirical doubt that management fashion has become a feature of the organizational world. Some researchers (Mizruchi & Fein 1999) have suggested this is not the sole reason for the popularity of mimetic isomorphism. Its uncontroversial content – dealing with mimicry instead of power and conflict – make it perfect for making contributions to conservative American management journals. Thus, NIT has undergone a series of translations as it has entered the canon of management. These translations have taken it far from the initial work of DiMaggio and Powell and Meyer and Rowan.

NIT has been criticized for its weakness in being able to explain organizational change. As a social theory it has difficulty in explaining how change occurs. NIT's departure from old institutionalism marked a downplaying of power and politics, which means that, as a theory, it has little to say about conflict or hegemony. Similarly, NIT falls silent on agency. There have been recent calls to reintroduce agency into institutional analysis, a challenge that is being addressed by the emerging institutional entrepreneurship community.

Despite its limitations, NIT remains a popular position and it has the capacity to help understand aspects of the intersubjective relationship between an organization and its field (Powell & DiMaggio 1991). It can help us understand the adoption of innovations (Mazza & Alvarez 2000), long term shifts in organization fields (Fligstein 1991), and variation among nation states, an issue that is also addressed by the closely related societal effects school (Maurice et al. 1980). Indeed, with the latter we may say that a separate European New

Institutional School, more attuned to the classical sociological concerns of power, has been established. However, lacking the citational impact of the leading US journals, because of its European provenance, its impact has been less influential. Indeed, in an ironical way, this serves as a final example of institutional theory at work: those theories that become most easily institutionalized are those that are seen to have been published in what are regarded, by a hegemonic system dominated by US scholarship, in the most legitimate journals. Needless to say, these are those sourced in the US rather than elsewhere.

institutionalism

Paul Ingram

There are many definitions of institution in sociology. Most of them are subsumed in the following: institutions are persistent social facts that regulate social behavior. "Persistent" indicates the role of institutions in stabilizing social life. "Social facts" capture the idea that institutions are the product of interaction and association and that they exist externally to individuals. "Regulate social behavior" represents that institutions sanction certain forms of social behavior and discourage others.

According to this definition, most targets of sociological study qualify as institutions. At a minimum, organizations, the state, social norms, laws, cultural values, and socially constructed knowledge are, or are enlivened by, institutions, and each of these has been the focus of one or more variants of institutional argument. Indeed, Durkheim (1982: 59) defined sociology as "the science of institutions, their genesis and their functioning." There is really no question among sociologists that institutions matter for social life. Instead, sociological institutionalism is directed at questions of which institutions matter most, how they impact individual behavior, and how they emerge and change.

INSTITUTIONAL FORMS AND FORMS OF INSTITUTIONALISM

There are a number of variants of institutionalism based on different emphases on these three issues. One way to organize these is along two dimensions that identify the social structures with which the institutions are most closely associated. A public/private dimension identifies the subjects of the institution. Public institutions apply to all members of a nation, culture, or general sphere of interaction such as an industry, whereas private institutions apply to recognized members of an exclusive social structure, such as a group or an organization. A centralized/decentralized dimension refers to the source of institutional authority. Centralized institutions are those created and enforced by some designated agent, whereas

decentralized institutions are emergent, and responsibility for their enforcement is diffuse. Archetypes of the four major forms of institutions identified by these two dimensions are laws (public-centralized), cultural values (public-decentralized), organizational rules (private-centralized), and social norms (private-decentralized). The social structures that house these institutional forms are, respectively, states, civil society, organizations, and networks.

Public-Decentralized: Culture, Values, and Civil Society

The public-decentralized quadrant is currently the most active in sociology, represented by the "new institutional" school that emerged in the late 1970s and closely associated with Stanford University (it is sometimes labeled the "Stanford School"). The seminal article was Meyer and Rowan (1977), which argued that many formal organizations implement structures that are consistent with widespread societal beliefs about legitimate approaches to organizing, and not necessarily a response to the task demands the organization faces. Organizing in this way can bring the organization resources, which are often dependent on legitimate action. However, it is not the conscious pursuit of the rewards of legitimacy that motivates action in this form of institutionalism. Rather, action here is more preconscious than calculative, based on the actor's socially constructed cognitions about their role and the expectations it entails (Berger & Luckmann 1967). This cognitive approach is a defining feature of this form of institutionalism.

The role of legitimacy as a mechanism for the new institutional school leads naturally to the question, "where does legitimacy come from?" The most common argument is that legitimacy is a function of frequency of occurrence, with a practice or structure becoming more cognitively familiar, and therefore more legitimate as it becomes more common, to the point where it may be sufficiently endemic as to be "taken for granted." The most compelling empirical evidence of this process comes from organizational ecology's theory of density dependence, which argues that an organizational form becomes more legitimate as a function of the number of organizations that employ it. The results of

dozens of analyses of organizational founding and failure are seen as supporting that theory (e.g., Carroll & Hannan 1999).

Legitimacy based institutionalism often examines the impact of institutional influence on organizations. The ultimate source of institutional influence from this perspective, however, is the concept of propriety inherent in civil society. Organizations are seen not generally as the source of institutional influence, but rather as a manifestation of it. Organizations stabilize the institutional environment by giving ideas a structural representation, which in turn reinforces them and facilitates their transition to taken for granted status. Although organizations are most often the target of institutional influence, an appealing element of this theory is that other social actors may be similarly affected. Some of the most exciting empirical applications of this form of institutionalism have examined states as the unit of analysis, identifying how they are subject to internationally embedded sentiments as to what types of activities are appropriate for a state (Meyer et al. 1997).

Within countries, pressure from institutions is not equal in all sectors of society. The relative importance of the legitimacy of organizational practices, as opposed to their direct implications for the organization's ability to achieve its goals, is greater in sectors that are more public. Consequently, studies on the structures of educational and health care organizations, and government offices, are among the most prominent in this literature. The literature is least compelling when it seeks to explain organizational features such as the marketing strategies of for profit enterprises that cannot be clearly linked to ideas of propriety. This is not to say that this literature has nothing to say about the strategies and structures of for profit organizations, however. There are a number of important studies on the processes by which organizational structures that represent societal values, particularly regarding labor relations and the role of women and minorities within organizations, become institutionalized among for profit firms. A particularly interesting example in this line is Dobbin and Sutton (1998), which argues that the US federal government relied on its influence over the process of legitimation to affect a shift in employment rights that it did not

have the administrative capacity to force on organizations.

Private-Decentralized: Interorganizational Ties and Group Norms

An influential paper by DiMaggio and Powell (1991) forges a bridge between public-decentralized and private-decentralized institutions, and between the legitimacy based new institutionalism and its more realist ancestors. DiMaggio and Powell examine the tendency for organizations within a field of interaction to employ the same structures, practices, and procedures. Partly, they complement legitimacy based institutional arguments by more precisely specifying the mechanisms by which ideals enter organizations, for example, through the influence of the professions. They also recognize more direct mechanisms of interorganizational influence, particularly the possibility that a powerful organization may coerce others that are dependent on it. Whereas the Stanford School sees institutions mainly as preconscious influences on cognition, the concept of coercive isomorphism is consistent with the idea that organizations may promote or adopt certain practices due to more conscious calculations regarding their costs and benefits to the organization's goals and to important interorganizational relationships. This idea connects firmly to what is called the "old institutionalism" in organizational sociology, represented famously by Selznick's (1949) classic study of the Tennessee Valley Authority (TVA). Selznick shows how, in its attempt to maintain control and sustain itself, the TVA became infused with the values of powerful constituents in its environment, coming to represent and pursue their values and interests at the cost of the TVA's original goals. As with the new institutionalism, the old institutionalism characterizes organizations as laden with external ideals, even when they are not needed or even helpful for achieving the organization's operational goals. The difference is the logic of action, which for the old institutionalists derives ultimately from utilitarian pursuits of organizations and their participants. Norms may be internalized in this view, but their origins are in the interests and values of the participants of a social system, and

they are associated with regulatory rewards and punishments which are an important part of their influence (Parsons 1990).

Selznick and other old institutionalists are categorized as examining private institutions because organizations are not unavoidably subject to the influence of their interaction partners in the way that they are to the law or to public perceptions of legitimacy. At the same time, these institutions are decentralized because there is nothing official about the authority for influence among interdependent organizations. No bank is designated, for example, to encourage cooperative organizations to adopt capitalist organizing principles (a common empirical example of an ideal that leads to interorganizational coercion). Based on the behavioral constraints that emerge from voluntary association, the old institutionalism of organizational theory can be seen as comparable, at a higher level of social aggregation, to the norms of social groups. Indeed, the literature on social norms represents most of the sociology relevant to private-decentralized institutions.

Much of what sociologists know about normative control derives from social exchange theory. A fundamental work here is Homans (1950), which presents a number of insightful cases that show the micro processes through which the benefits that members derive from groups become the basis for the group's control over them. More recently, researchers have used more formal models to show that norms can align individual and group interests by encouraging individuals to contribute to collective goods (e.g., Coleman 1990). Norms are of obvious sociological interest in their own right, but they are also important for understanding the operation of the most significant social structures. In particular, research on private-decentralized institutions is being used in economic sociology to better specify just how social networks that connect individuals, organizations, and states affect the behavior of those actors.

Private-Centralized: Bureaucracy and Organizational Rules

The third category of institutions, private-centralized, is based on the role played by organizations and organizational rules as the *source* (as

opposed to the target) of institutional influence. The targets of private-centralized institutions are the participants in the organization, which may be individuals or other organizations in the case of a supra organization such as a trade association. Attention to organizational policies and bureaucracy as determinants of individual behavior is the foundation of organizational theory. The foundational argument here is Weber's (1947) illustration of how authority may derive from the rules of bureaucracy. Merton (1957) contributed a potent essay on the micro mechanisms by which bureaucratic rules grip participants, even to the point where they may sometimes inhibit the pursuit of the organization's goals. Subsequently, contingency theorists built theories that indicate which combinations of formal organizing principles are best to encourage particular behaviors from participants. Currently, the attention to private-centralized institutions from sociologists is low. Part of the reason is the success of new institutional arguments which have alerted analysts to the symbolic implications of formal organizational structures, rather than their direct influence on behavior. Private-centralized institutions are, however, the subject of a vibrant literature in organizational economics, one that borrows from and influences sociology. Williamson (1985) and others operating under the banner of "transaction cost economics" argue that formal organization and other institutional forms, notably the market, may be more or less effective for governance depending on characteristics of the transactions in question.

Public-Centralized: The State

The fourth category, public-centralized institutions, represents the state and the laws and policies it implements. Institutional arguments regarding the state's impact on the economy can be categorized into four broad types. First, the state is a fundamental source of the institutions that smooth exchange by helping citizens to make credible commitments (Campbell & Lindberg 1990; North 1990). This role of the state is particularly prominent in recent accounts of the transition from state socialism, where the costly absence of property rights, contract law, and the regulation of financial

markets becomes starkly apparent. Second, the pattern of economic behavior within a state depends on whether the state can commit to not “bailing out” subjects when they struggle. If not, subjects may be diverted from productive activity toward efforts to “hold up” the state for subsidies. Third, subjects’ willingness to invest in long term projects will depend on whether the state has the checks and safeguards to resist appropriating subjects’ wealth. Fourth, the state may affect the distribution of power and wealth, between rich and poor, between suppliers and consumers, or between rival organizational forms. Dobbin’s (1994) comparison of the development of anti trust institutions in France, the UK, and the US is an important example of the state’s distributional influence. Beyond these direct effects of the state on the economy, institutionalists such as Skocpol (1985) have also theorized as to the source of the state’s strength. Following Weber, they highlight bureaucracy as a key source of the state’s capacity to implement policy, but they also consider the state’s autonomy from other actors in society.

FUTURE DIRECTIONS FOR THEORY

The various institutionalisms all struggle with two questions: “how are different types of institutions interdependent?” and “how do institutions change?” The first question has become a pressing problem partly because of the pattern of development of institutionalism as a field of inquiry. Different schools of institutionalism have tended to focus on one kind of institution, typically arguing for its supremacy as an influence on behavior and slighting the relevance of other institutional forms. Nevertheless, some of the most exciting institutional arguments highlight the fact that the functioning of one institutional form, such as state regulation, depends on other institutions, such as norms derived from social cohesion. Indeed, Durkheim makes this claim in the preface to the second edition of *The Division of Labor in Society* (1984: liv), where he calls a modern state that governs unorganized individuals “a veritable sociological monstrosity” and claims “[a] nation cannot be maintained unless, between the state and individuals, a whole range of secondary

groups are interposed.” The dependence of the state on other institutional forms makes for an even larger place for sociology among disciplinary approaches to institutionalism.

Kindred interdependencies exist between other institutional forms. As Homans’s (1950) reanalysis of the bank wiring room indicates, organizational rules may be frustrated by opposition norms among the participants. In part interdependence between institutional forms occurs because actors are almost always subject to various institutions – an individual in the US is subject to the law, the policies of an employing organization, the norms of friendship groups, and the values of culture. More than merely acting simultaneously on the same targets, however, different institutions may interact with and enable each other. For example, Fligstein (2001) presents an economic sociological account of markets that emphasizes that a range of different institutions, including property rights, rules of exchange, governance structures, and conceptions of control, are jointly necessary to make a market.

The second and most pressing challenge for all forms of institutionalism is to explain the origin and change of institutions. As institutions stabilize social structure and constrain behavior, it is perhaps unsurprising that theories say more about the persistence of institutions than their change. Furthermore, the arguments about institutional change that do exist emphasize incremental change processes in which the past weighs heavily. For the Stanford School, the key mechanism is diffusion, whereby a practice moves from actor to actor, gaining the momentum of legitimacy on the way (DiMaggio & Powell 1991). Other institutional schools highlight path dependence as a mechanism of institutional change (e.g., North 1990). Neither of these approaches accounts for the discontinuities in institutional trajectories which are perhaps the key moments of institutionalized life, or which institutions will be created in the first place. A promising development that targets such discontinuities is the combination of institutionalism with social movement theories. This approach sees institutional entrepreneurs playing a key role of motivating and organizing others to affect institutional change. To do so, they may broker between social sites and institutional ideas and frame potential institutions

in ways that appeal to preexisting institutions. Furthermore, elements of the institutional framework may be reconstructed into new institutions in a form of bricolage. This approach therefore combines most extant institutional theories, recognizing that institutions affect individual interest but require collective consent, and that institutional change depends on preexisting institutions but may sometimes involve a turning point that shifts the institutional trajectory.

intellectual property

Chris Rojek

Any form of literature, science, music, film, or computer program can be protected by copyright to prevent third parties from making copies without written permission. Copyright is the law of authorship and dates back to the Statute of Anne (1709) passed in England to protect the rights of authors and publishers from piracy. The law has been progressively elaborated in Europe and North America to grant copyright for a fixed term to the estate of deceased authors and protect authors from the violation of their rights through new technologies of reproduction and exchange. However, the balance between the rights of authors and freedom of information is a delicate one and is regularly subject to legal challenge. In the US the First Amendment, which guarantees free speech and a free press, has been used by litigants as the basis to contest the reach of copyright.

The issue has escalated in legal and popular culture as new electronic technologies of reproduction and file sharing, such as the photocopier, home audiotape, videotape machines, and computers, have become available. The First Amendment raises the issue of "fair use" through private educational and leisure practices, news reporting, comment, and criticism. The exchange of information and opinions in education and the press would be violated by an over zealous application of copyright principles. In 1994 the US Supreme Court ruled that "transformative use," which alters the original to create a new work, through interpretation and parody, is acceptable. The ruling had wide spread ramifications for hip hop, rap, and other forms of new music which employ sampling technology. The landmark case on this issue is *Acuff Rose Music v. 2 Live Crew* (1991). In 1965 Acuff Rose Music acquired the rights to the song *Oh Pretty Woman* from its writers, the pop star Roy Orbison and William Dees. In 1990 the controversial rap group 2 Live Crew recorded its own version of the song without seeking copyright clearance. Acuff Rose sued for infringement of its copyright. The Trial Court ruled that while 2 Live Crew had indeed infringed copyright, their version of the song constituted parody rather than imitation. It upheld the right of 2 Live Crew to engage in parody without legal constraint. However, the question of when "fair use" becomes "literary larceny" is extremely thorny and is obviously open to conflicting aesthetic judgments.

The Internet vastly increases the flow of data exchange and creates unprecedented challenges for policing and the application of copyright. Without a commercially viable system of monitoring file exchange, the integrity of copyright relies on the probity of Internet users. In the late 1990s the development of peer to peer (P2P) file exchange systems such as *Napster* seriously eroded the market share of record companies. This provoked a protracted and as yet unresolved series of legal disputes between P2P providers and copyright holders. The development of legal, fee based download systems such as the *Apple Music Store* has been a partial solution to the problem. But it has not eliminated illegal file exchange. Broadband technology will exacerbate the problem by allowing more information to be downloaded

at faster speeds, making the downloading of full length feature films and computer programs as quick and easy as downloading a 3 minute pop single.

intelligence tests

Aaron M. Pallas

Intelligence is a concept whose meaning has been fashioned by the discipline of psychology. Psychologists view intelligence as a set of mental abilities that are inferred from an individual's performance on an intelligence test. In defining intelligence as one or more abilities, psychologists seek to demarcate it from the accumulation of specific knowledge to which only some individuals are exposed. In this view, intelligence is a broad cognitive capacity that, though often correlated with the acquisition of specific knowledge, is conceptually distinct from it.

In emphasizing intelligence as a quality of individual cognition, psychologists differentiate it from other individual qualities, such as personality, character, social skills, and physical abilities. Such qualities may be highly valued by a society, and those who possess them may have different life chances than those who do

not; but because they are not cognitive skills, they are not acknowledged by most scholars as forms of intelligence. The prevailing view of intelligence as an attribute of the individual also does not admit the more social view of cognition that sees human cognition as distributed across a group of individuals in a particular social setting, who use tools and artifacts to represent knowledge (Hutchins 1995).

Intelligence can be characterized as a hierarchical set of cognitive abilities, with Carroll's (1993) representation of three levels of mental abilities the most widely cited. At the lowest level are highly specific skills represented by performance on specific tests. One well known intelligence test, the WAIS III (1997), has 14 specific tests, ranging from digit span (in which the examinee repeats an orally presented sequence of numbers either forwards or backwards) to picture completion (in which an examinee must identify what is missing from a color picture of a common object or setting). These specific tests are distinct in the sense that performance on one does not perfectly predict performance on another. But individuals may perform better on some clusters of these specific tests than on others, and the correlations among scores on such tests can be accounted for by a smaller number of factors than the original number of tests. Carroll (1993), in an exhaustive study of the correlations among mental test scores, concluded that there are eight factors that can adequately represent the clusters: broad visual perception, broad auditory perception, broad retrieval ability, broad cognitive speediness, processing speed, general memory and learning, crystallized intelligence, and fluid intelligence.

As was true for performance on specific tests, performance on one of these factors does not perfectly predict performance on another, indicating that the factors are distinct. But individuals who score highly on one factor are more likely to score highly on others, with the average intercorrelation among factors about .70 (Deary 2001). Carroll (1993) concluded that most of the variation among individuals on these eight factors could be accounted for by one general factor, which has historically been referred to as *g*, or general intelligence. Because *g* is abstracted from performance on a great many tests, it is often described as a context free measure of

general reasoning or problem solving ability, and as the ability to comprehend and respond to complexity in one's environment.

Modern intelligence tests typically are constructed to have an overall mean of 100 and a standard deviation of about 15, and the distribution of scores within many populations assumes the shape of a bell curve, with about two thirds of the scores clustered between 85 and 115, and fewer than 5 percent of the scores either below 70 or above 130. In the US, individuals identified as African American have historically scored on average about 15 points below those identified as white, an average group difference that parallels the gap observed on a variety of tests of educational achievement. The average black-white difference in IQ test scores cannot be explained by a simple form of cultural bias, as the differences are observed on tasks that appear to require little knowledge of white middle class culture as well as those that are "culturally loaded" (Jencks 1998). Nor can the black-white test score difference be easily attributed to the lower socioeconomic status of blacks, as substantial differences are observed even when blacks and whites are matched on measurable social and economic characteristics (Phillips et al. 1998). Unmeasured social differences between blacks and whites may be important, but they are not yet an adequate explanation for the black-white difference in IQ test scores.

There is little question that performance on intelligence tests is a function of both genes and environment. Heritability, an attribute of a population of individuals at a particular historical moment, refers to the extent to which variation in individual intelligence scores is due to differences among individuals in their genes and environments. A heritability estimate of zero indicates that all of the variation among individual test scores is due to differences in those individuals' environments. A heritability estimate of one indicates that all of the variation among individual test scores is due to differences in those individuals' genes. Although scientists are not yet able to identify the specific genes associated with particular cognitive abilities, the shared genetic heritage of monozygotic ("identical") and dizygotic ("fraternal") twins provides some purchase on the relative influence of genes and environment. Within middle class white populations in western

societies, heritability estimates typically range from .50 to .70 (Cianciolo & Sternberg 2004).

Heritability estimates tell us little about the origins of a particular individual's cognitive abilities. In part this is because heritability is defined in relation to a population, not to an individual. But it would be difficult to summarize the mix of genetic and environmental influences in a single number, as individuals experience remarkably different social environments, due to both their social locations in society (Gottfredson 2000) and the unique experiences of individuals within the same general social location or the same family (Gottfredson 1997; Deary 2001). Moreover, individuals have the capacity both to select themselves into new environments and to modify the environments in which they are situated, and these adaptations may be more easily negotiated by individuals with greater cognitive ability.

Some scholars have succumbed to the temptation to link the average black–white difference in IQ scores to the high heritability of intelligence within the middle class white population, suggesting that the origins of the black–white gap in intelligence scores are genetic (Herrnstein & Murray 1994). There is to date little empirical support for this view (Neisser et al. 1996). The existing evidence on black–white differences does not rely on a biological or genetic basis for racial classification, but rather a social basis, individuals' self reports. Hence, the observed score difference represents a mixture of social and biological influences (Gottfredson 1997). Moreover, it is widely recognized that the magnitude of the heritability of a trait within a population, such as US blacks, does not imply a similar magnitude of its heritability between populations.

Individuals who score higher on intelligence tests have differing profiles of adult social and economic success than do those who score lower. Intelligence test scores are correlated with educational attainment, job performance, and income, and with the likelihood of delinquent behavior and incarceration. A functional interpretation of these associations is that they reflect the complexity of the modern world, in which only those with advanced cognitive skills can successfully navigate their environments over sustained periods of the life course. It is a logical fallacy, however, to conclude that the

advantages enjoyed by people with high IQ test scores are a necessary, and hence natural, feature of modern society. The impact of individual differences in IQ test scores on adult success is expressed within a system of structured social inequality, in which social origins either open or close the doors to opportunity (Fischer et al. 1996). Differences among individuals are real, but their impact can be magnified or muted by the political choices a society makes. Under the current institutional arrangements, individual differences in measured cognitive ability do matter, and perhaps increasingly so.

interaction

Dirk vom Lehn

“Interaction” describes particular kinds of social relationship that are different from, but constitutive of, groups, organizations, and networks. Interaction occurs when two or more participants are in each other’s perceptual range and orient to each other through their action and activity. It ends when the participants dissolve their mutual orientation and leave the social situation.

Sociological research only gradually recognized the significance of social interaction. It initially focused on groups and organized relationships before progressively finding that temporary bound social relationships are critical to understanding the emergence and organization of more persistent forms of relationship. Georg Simmel was one of the first sociologists to mark the difference between relatively persistent social relationships such as groups and fleeting social encounters such as the mutual exchange of glances. He differentiates various “forms of interaction” and demonstrates their significance for social life. Simmel’s work has been of great importance for the development of sociological approaches to understanding interaction, in particular symbolic interactionism and conversation analysis.

George Herbert Mead argues that the emergence of interaction is grounded in the fact that people’s actions function as social stimuli that affect a reaction of the other. He differentiates interaction mediated by gestures and symbolic interaction. The former, a “conversation of gestures,” is relatively primitive and unreliable. Mead famously compares it to a “dog fight.” Symbolic interaction uses “significant symbols” like language that stimulate the same reaction in the actor and the other. It provides the basis for

people’s ability “to take the role of the other” and align each other’s actions. Mead’s work provides the intellectual basis for the emergence of symbolic interactionism (Mead 1934).

In light of these theories, early twentieth century sociology began to take seriously interaction as a “social fact.” *Functionalist approaches* investigate interaction as social system integrated by a common set of cultural symbols and norms that ensure people orient to situations in the same way (Parsons 1951). In recent years, Talcott Parsons’s approach has been updated by Niklas Luhmann, who opposes social theories based on a consensus about meanings and values. He views social systems as *communication systems* that have developed specific mechanisms to organize their communication processes. Society’s subsystems, such as politics or economy, organize their communication processes by virtue of generalized media such as power or money; they are autonomous from the co presence of participants. Contrarily, the emergence of interaction systems relies on the co presence of multiple participants who orient to each other’s actions (Luhmann 1995). Systems theory remains relatively underdeveloped with regard to the social organization of interaction systems.

Exchange theory focuses on the individual and the “rationale” for his or her decision to engage in interaction. George Caspar Homans argues that interaction emerges because the actor who is a rational decision maker anticipates to maximize his or her rewards by virtue of the exchange. He begins to develop psychological principles and rules that support the actor’s decision to engage in exchanges (Homans 1961). Peter Blau has further developed exchange theory by linking it to contemporary theories concerned with social structure. He explores the relation between rational actions and the emergence of social structures (Blau 1964). In a related way, Richard Emerson investigates the origin of *exchange networks* by focusing on the exchange of valuable resources between parties (Emerson 1974).

Although there had been a growing sociological concern with interaction since the 1940s, relatively little research was undertaken to explore the process of interaction. Robert Bales’s *Interaction Process Analysis* (1976) addresses this gap in research. IPA focuses on

group activities that are undertaken to achieve a goal shared between group members. It provides quantitative methods through which people's actions are recorded and analyzed. The analysis reveals the phases of the activity a group is involved in and the different roles of the group members in the activity. In recent years, IPA has been further developed as a tool (Symlog) for people to enhance their effectiveness in group activities. IPA has been very influential in particular for small group research.

Symbolic interactionism was developed in opposition to functionalist approaches. In drawing on Mead's work, Herbert Blumer, who coined the term symbolic interactionism, considers "society as symbolic interaction" (Blumer 1969). He argues that society and its norms and values do not predefine how people act and interact. However, people act in situations according to the meaning these situations have for them. The "definition of the situation" is produced in interaction with others. Hence, symbolic interactionist research is particularly interested in the interpretive processes by virtue of which participants negotiate the definition of the situation.

Blumer's theoretical work has initiated the emergence of the Chicago School, which produced a large body of ethnographic studies tackling topics such as social problems, race relations, and industrial relations (Everett C. Hughes, Howard S. Becker). In recent years, sociologists like Mitchell Duneier have taken up the Chicago School's work and produced intriguing ethnographies of race relations (*Slim's Table*, 1992) or street vendors (*Sidewalk*, 1992). Ethnographies are not the only way in which symbolic interactionism developed. The Iowa School evolved a very different approach to further Mead and Blumer's concepts. Its work was initially interested in developing "scientific methods" to explore the structure of the self (Manford Kuhn). From the mid 1960s, Carl Couch and his colleagues introduced experimental methods to develop "a set of universal social principles" explaining how social units such as dyads and triads coordinate their activities (Couch & Hintz 1975). There also is a large body of research related to symbolic interactionism that explores how phenomena that are often viewed to be cognitive or material rather than social feature in interaction. For example,

investigations have been undertaken concerned with emotion and affect (Norman Denzin), the human body (Kathy Charmaz), or with the role of non human objects in interaction (Joseph Cohen; Susan Leigh Star and Geoffrey Bowker).

Erving Goffman's famous work on *The Presentation of Self in Everyday Life* (1959) is often discussed in the context of debates in symbolic interactionism. Yet, it forms part of a research tradition that uses the "theater metaphor" for the inquiry of social life. His essay refers to Kenneth Burke's "dramatism," which explores the relationships between the act, the agent, the scene, agency, and the purpose of action ("dramatic pentad"). Goffman's "dramaturgical approach" explores how these relationships play out in social interaction and investigates the techniques participants employ to manage the impression others have of them. It has been very influential in sociological research and occasioned a wide range of ethnographic research concerned, for example, with the presentation of self of politicians and management gurus.

Goffman's investigations also draw on developments in human anthropology and cognate disciplines. Whilst sociology was still debating the significance of social interaction as a phenomenon, human anthropologists and ethologists (Heini Hediger; Irenaeus Eibl-Eibesfeldt) were long engaged in exploring the social production of culture. Gregory Bateson used film recordings to reveal the social organization of action and interaction. In light of Bateson's observations and related developments in other disciplines, a new communication theory emerged that conceived communication to be a "multichannel system." Researchers began to dissect the different communication channels to reveal the organization of their elements. Investigations have been undertaken to uncover the elements of language (Edward Sapir), the ways in which the meaning of utterances is influenced by the tone of voice, pitch, volume, and other paralinguistic cues, and bodily communication such as gestures and facial expressions (Michael Argyle, Paul Ekman, Adam Kendon; see Scherer et al. 1982).

These developments have initiated investigations that explore other aspects of human interaction and communication. Ray Birdwhistell (1970) uses film recordings to dissect the

elements of body movement in concerted activities. Edward Hall (1966) investigates people's spatial behavior and experience of space. He conceives spatial behavior as a "language" by virtue of which people structure the social space in which they act and interact ("proxemics"). Hall's work provides the basis for inquiries into the spatial organization in conversations (Robert Sommer) or the use of personal space in public places. In the 1960s and early 1970s, Albert E. Scheflen (1972) explored how communicative systems such as psychotherapeutic encounters are structured and generate meaning by virtue of neatly organized verbal and bodily actions ("context analysis").

Goffman and later Adam Kendon (1990) drew on the observations made by the aforementioned investigations. They explored how through spatial and bodily behavior participants organize "relations in public" (Goffman 1971) and "focused" and "unfocused interaction" (Goffman 1963). These inquiries in the social organization of actions and activities reveal how participants bodily orient to each other and how they can shift the focus of an activity by virtue of changes in their bodily positions, postures, and gestures (Juergen Streeck). They reveal how people organize and structure their activities in social situations by virtue of body movements. Studies of people's spatial and bodily conduct in interaction have made important contributions to our understanding of interaction. However, they neglect how participants' talk is coordinated with their bodily conduct in interaction.

The development of *ethnomethodology* by Harold Garfinkel has been the beginning of a program of research that led to new developments in exploring how social interaction emerges from participants' actions and activities. Ethnomethodology aims to reveal the practices and reasoning that underlie people's action and interaction. Garfinkel investigates the *in situ* "indexical" character of interaction. The indexicality of people's practices and reasoning leads to the insight that the context of action is not predefined and stable, as symbolic interactionists may argue, but that action is "doubly contextual in being both context shaped and context renewing" (Heritage 1984).

In light of Garfinkel's *Studies in Ethnomethodology* (1967), Harvey Sacks and colleagues

developed *conversation analysis* as a methodological framework to explore how language is used in practice. Conversation analysis employs audio recordings as principal data to investigate in detail the organization of brief fragments of talk. The original work by Harvey Sacks, Emanuel Schegloff, Gail Jefferson, and others has principally been concerned with talk as an institution in its own right. This work reveals how participants attend to each other's utterances moment by moment and begin to unpack the *sequential* organization of talk in interaction. They show how interactional encounters are opened and closed as well as how participants deal with interactional problems that arise in conversations. Key to the understanding of the organization of talk are "social mechanisms," such as adjacency pairs, repairs, and the like, that participants draw on in interaction. These mechanisms are independent from participants' cognitive disposition and motivation, institutional arrangements, and material constraints (Sacks 1974, 1992). In recent years, a body of research has emerged that expands the conversation analytic perspective. It explores how talk and its analysis are embedded in culture (Michael Moerman), how institutional arrangements influence the organization of "talk at work" (Paul Drew and John Heritage), and how participants orient to institutional settings and situations.

Various researchers have recently begun to augment the disembodied concept of interaction that pervades conversation analysis by exploring how the body and aspects of the material environment feature in interaction. They draw on Simmel and Goffman's work and use the analytic and methodological framework provided by ethnomethodology and conversation analysis to investigate how participants socially organize their talk and bodily conduct in social situations. The principal data of these investigations are audio/video recordings of naturally occurring social interaction. They employ the analytic and methodological framework of ethnomethodology and conversation analysis to explore the interactional and sequential production of talk and bodily conduct. They reveal how minute bodily movements such as a shift in gaze direction or the turn of a head can influence the way in which an interactional sequence develops. They demonstrate that speaking and hearing

are closely intertwined activities. In speaking, the bodily actions of the hearer play a significant part in the way in which the talk is produced (Goodwin 1981). The observations and findings of these video based studies of interaction provide the basis for a growing body of research concerned with the ways in which participants socially and sequentially organize their actions and activities in a variety of workplaces. The emerging field of *workplace studies* (Luff et al. 2000) reveals the social and sequential organization of work that involves the use of highly complex technologies in control rooms of urban transport systems, air traffic control, operating theaters, and news production. Workplace studies explore how participants orient to and embed objects and artifacts, such as paper documents, computer screens, or large displays, in the interactional production of work. They examine how participants produce a "reciprocity of perspectives" (Alfred Schutz) with regard to objects and artifacts, tools and technologies (Suchman 1987; Heath & Luff 2000). They also investigate the ways in which the human body becomes the focus of interaction. For example, in medical encounters, anesthesia, or surgical procedures, participants produce the status of the body as acting and feeling subject or inanimate object in and through social interaction. In recent years, related work has been undertaken in museums and galleries exploring how participants orient to and make sense of exhibits and exhibitions in interaction (Heath & vom Lehn 2004).

The development of video based field studies that explore social interaction in material environments reflects a growing sociological interest in "materiality." Bruno Latour, Michel Callon, John Law, and others who have recently developed actor network theory (ANT) have put the object and materiality firmly on the agenda of sociological debate. They argue for a fundamental rethink of the relationship between the social and the material. They ascribe objects the status of "actants" and explore how they participate in social situations. The body of research in ANT has been very influential in social studies of science (Latour 1987; Law 1991).

Recent technological developments challenge a fundamental principle of social interaction, namely, the physical co presence of

participants in social situations. Novel computer technologies seem to provide participants with sufficient resources to organize their action and activities "just like" in situations of co presence. A large body of research has emerged in disciplines cognate to sociology, such as computer supported cooperative work (CSCW), which explore interaction across distributed locations. They illuminate the difficulties of designers who try to create situations of "virtual presence" and of participants who attempt to organize their actions with others who are "in range" but not bodily present in a social situation. The exploration of distributed work has helped to reinvigorate the interest of sociologists in undertaking research on the social organization of interaction. However, it also has brought to the fore the tension between concepts of "interaction" used in the information and computer sciences and those developed in sociology, the former relying on a separation of "sender" and "receiver," the latter maintaining the particular social characteristics of interaction. The coming years will show whether sociology will be able to further develop its theories and methods to grasp the new forms of interaction emerging in light of the current technological revolution.

interaction order

Mark D. Jacobs

The interaction order, as conceived by Erving Goffman, is constructed around systems of enabling conventions that – without recourse to social contract or social consensus, as often assumed – provide a basis of social order. The interaction order, Goffman insists, is a substantive domain in its own right, engendered by social situations, interactions in which at least two actors are co bodily present. That is, against the claims of either micro or macrosociological reductionism, Goffman insists on the analytical distinctness of the interaction order from both the underlying language games and conversational protocols of ethnomethodologists and the various overarching systems of macrostructuralists. For his part, Goffman dismisses the claim that macrostructural properties are epiphenomenal to the interaction order. The influence of Goffman's formulation extends even to theorists who reject the primacy of his analytic focus, as well as to those who embrace different characterizations of interactional dynamics.

As Goffman (1983) explains in his summative statement about the interaction order, enabling conventions arise as techniques of social management of the personal risks – both bodily and self expressive – inherent in interpersonal interaction. These conventions “can be viewed . . . in the sense of the ground rules of a game” (p. 5); they are the shared base of cognitive and moral presuppositions that make interaction possible. Not merely tact but tact about tact (Goffman 1959) is one such convention; deference is another. By instructive contrast with the macrosociologist Edward Shils (under whose tutelage Goffman first studied

deference), who declared: "Deference . . . is a way of expressing an assessment of the self and others with respect to 'macrosocial' properties" (1975: 277), Goffman analyzes deference "as a means through which this self is established . . . Deference and demeanor practices must be institutionalized so that the individual will be able to project a viable, sacred self and stay in the game on a proper ritual basis" (1967: 91).

As a theoretical construct, the interaction order is a Simmelian Durkheimian hybrid. Goffman recapitulates Simmel's "The Problem of Sociology" (which famously declares: "Society exists where a number of individuals enter into interaction") (Simmel 1959a: 314), not only in its basic conception, but also in its methodological prescription: "The trick, of course, is to differently conceptualize these effects, great or small, so that what they share can be extracted and analyzed, and so that the forms of social life they derive from can be pieced out and cataloged sociologically, allowing what is intrinsic to interactional life to be exposed thereby" (Goffman 1983: 3).

He echoes Simmel's "How is Society Possible" (1959b) in declaring: "at the very center of interaction life is the cognitive relation we have with those present before us, without which relationship our activity, behavioral and verbal, could not be meaningfully organized" (Goffman 1983: 4). He explicitly draws on Durkheim in his assertion that enabling conventions are essentially symbolic and ritual. And he hearkens to Durkheim's analysis of the *corroborée* in *The Elementary Forms of the Religious Life* (1995) in his discussion of those intense ceremonials in the interaction order that have consequences for macrostructures.

In its relatively short career, the concept of the interaction order has already spawned a rich and variegated tradition. The concept animates such classic monographs as Schwartz's *Queuing and Waiting* (1975), which focuses on a paradigmatic form of the interaction order, and Fine's *With the Boys* (1987), which traces the emergence of "idiocultures" in primary groups involved in Little League Baseball. This tradition even encompasses theories that challenge the analytic distinctness of the interaction order: the macrosociological theories of Giddens (1984), for example, in which the interaction order cements the "duality of structure," as well

as the microsociological theories of Collins (2004), in which structural transformations derive their energies from interaction rituals.

intergenerational conflict

Merril Silverstein

Intergenerational conflict refers to the collective tension, strain, and antagonism between older and younger generations over what constitutes the fair distribution of public resources

across age groups. Intergenerational conflict is most often invoked in the context of the generational equity debate, an ongoing public dialogue about the cost and fairness of entitlement programs for the older population. One of the opening salvos in the debate over generational equity was the observation that the well being of older and younger Americans diverged over the third quarter of the twentieth century as a result of public policies that favored older adults and lifted them out of poverty (Preston 1984). The popular press concluded from this that older adults had gained at the expense of younger adults, and it was not uncommon in the 1980s and 1990s for the elderly to be portrayed as a leisure class of affluent retirees unfairly benefiting from the taxes paid by a struggling working age population.

Anxiety about the future viability of public programs for the aged has been on the rise, particularly among younger generations, driven by fears of population aging and consequent growth in the dependency ratio – a measure of the size of the working age population relative to the retired population. Trends in population aging converged with national and international pressures to shrink government spending, raising fundamental questions about the nature of society's collective obligation to the elderly and the rights of older citizens to public benefits.

Economists, in particular, framed the issue of generational equity as a competition for limited resources in a zero sum game between the young and the old. Using an approach known now as "generational accounting," they discussed how the financing of entitlement programs for the aged (Social Security, Medicare, and other government programs that use age to determine eligibility) was unfair to the younger generation that would ultimately pay the bill (Longman 1987). The public and scholarly debates that ensued opened the door to questioning the deservingness of older people as an entitled group, the inviolability of the contract between generations that began with the New Deal, and the wisdom of sustaining entitlement programs in their current form when the baby boom generation reaches old age. The "sacred cow" of the Social Security program was sacred no more, as conservative politicians began using the older population as a scapegoat to further

their political agenda of shrinking the size of government (Binstock 1983).

The central tenet of generational accounting – that there are winners and losers in the competition between generations – was met with swift resistance by many social scientists. There was little evidence suggesting that generations were in conflict. Not only was public support for Social Security and Medicare programs very strong across all age groups, some research found that support for these programs was stronger among younger adults than it was among the elderly (Logan & Spitze 1995). In addition, when public opinion about various government programs was charted over time, entitlement programs serving older adults were the ones least likely to lose support. Thus, the slight declines observed in support for Social Security tended more to be the product of strengthening overall preferences for fiscal restraint and smaller government than of generational conflict. Scholars advocated for decoupling the fortunes of the young and the old, attributing them to unique historical processes. Where older people benefited from public programs initiated through the second half of the twentieth century, children were disadvantaged over this same period by family and economic change, such as the increase in single parent families and the decline in real wages due to economic restructuring.

Social scientists discovered that the public's attitudes toward entitlement programs were more complex than could be measured on a single metric. Several orthogonal dimensions were identified: (1) perceptions about the legitimacy and social value of entitlement programs for the elderly; and (2) concerns over the cost of such programs. Thus, it is possible to support programs for the elderly while at the same time expressing concern over their costs. What explains the public's support for entitlement programs is the norm of reciprocity – the notion that older people previously contributed into the system and now deserve to be supported as an earned right. This argument has been extended to include the older population's earlier contribution to post war economic expansion.

The principle of *generational justice* was brought into the scholarly debate to represent the moral dimension of public policy that emphasizes responsibility for older citizens as

a collective duty. If reciprocity were relied upon as the sole underlying principle guiding intergenerational transfers, then older generations that presided over a particularly weak economy for most of their working lives would produce a moral hazard. This makes public programs all the more important, for they compel even the most reluctant contributors to make state mediated transfers to the older generation.

One of the most compelling arguments against the existence of widespread intergenerational conflict is that younger and older adults are interdependent with each other within family lineages – what is known as the *interdependence of generations perspective*. Thus, individuals simultaneously occupy several types of generational positions: welfare generation as represented by age group or birth cohort at the macro level, and family generation as represented by position in the family lineage at the micro level (Attias Donfut & Arber 1999). Resources that flow upward from later to earlier born cohorts through government transfer programs are then balanced against the sizable downward flow of resources from older parents to adult children in the form of inter vivo transfers, bequests, and childcare. This circular flow of support builds solidarity across generations and suggests that obligations between welfare generations and family generations are not competing but complementary with each other. Whether intergenerational conflict continues to be minimal will hinge on how changes in public policies and family commitments alter the integrity of this implicit contract across generations.

intergenerational mobility: core model of social fluidity

Richard Breen

The analysis of intergenerational social mobility is usually carried out using log linear or log multiplicative statistical models applied to a contingency table which cross classifies individuals' current class (usually called "class destination") with the class in which they were brought up ("class origin"). An important distinction is between absolute and relative mobility (sometimes called "social fluidity"). Absolute mobility refers to the distribution of cases in the mobility table. Social fluidity refers to the inequality between individuals from different classes in their chances of coming to occupy one rather than another destination class. It is captured by odds ratios which are measured as the proportion of cases that originate in class A and are found in destination class X rather than class Y, divided by the proportion of cases from origin class B which are found in destination X rather than Y. An odds ratio of one indicates

that the chances of being in destination class X rather than in Y are the same for those originating in both A and B, while an odds ratio greater than one shows that those born in A are more likely than those born in B to be in X rather than Y, and conversely for an odds ratio less than one. An important feature of odds ratios is that they are unaffected by any scalar multiplication of one or more rows and/or columns of a table: thus, inequalities in access to particular class destinations can be compared across mobility tables, despite the fact that they differ in their distributions of origins and destinations.

One of the most widely reported findings of mobility research is that differences between mobility tables (when these tables represent, for example, sexes or ethnic groups in a given country, different time points within the same country, different countries, and so on) in the distribution of cases in the mobility table (i.e., absolute mobility) are overwhelmingly shaped by differences in the marginal distributions of origins and destinations rather than differences in social fluidity (Erikson & Goldthorpe 1992: 213–14). Despite this, by far the greater amount of research has been devoted to social fluidity – possibly because fluidity captures, in a very obvious way, inequality in the competition for more, rather than less, desirable destination class positions.

SOCIAL FLUIDITY IN LOG LINEAR AND LOG MULTIPLICATIVE MODELS

Assume that the mobility table has I rows (origin classes) and J columns (destination classes), indexed by $i = 1, \dots, I$ and $j = 1, \dots, J$ respectively. Because mobility tables are usually square, $I = J$. F_{ij} is the logarithm of the expected (under the model) frequency in the ij^{th} cell of the table and this is a function of a constant term, λ ; an effect associated with being in the i^{th} row (i.e., coming from the i^{th} origin class), λ_i^O ; an effect associated with being in the j^{th} column (destination class), λ_j^D ; and the effect, on the ij^{th} cell, of the association between origins and destinations, λ_{ij}^{OD} . That is:

$$F_{ij} = \lambda + \lambda_i^O + \lambda_j^D + \lambda_{ij}^{OD}, \text{ for all} \\ i = 1, \dots, I; \quad j = 1, \dots, J$$

The association between origins and destinations is captured in the λ_{ij}^{OD} terms which are functions of the logarithm of the odds ratios (the log odds ratios) in the table. A maximum of $(I - 1) \times (J - 1)$ such terms can be estimated (because this is the number of independent odds ratios in a table), and doing this would yield a model that exactly fitted the data. However, rather than fit all the association parameters we would like to reduce this to a few interpretable parameters which represent some underlying social processes that structure the pattern of fluidity. Such a set of parameters we will call a model of fluidity. How well a particular model reproduces the data (its “goodness of fit”) is assessed by comparing the frequencies expected under the model with the observed data and several measures based on this comparison are widely used. A large number of models of social fluidity have been proposed: examples include Hout’s (1984) “status, autonomy, and training” (SAT) model; Breen and Whelan’s (1992) “agriculture, hierarchy, and property” (AHP) model; and the model developed by Jonsson and Mills in 1993. But Erikson and Goldthorpe’s (1992) “core model” of social fluidity is the most widely used such model.

When we make comparisons of social fluidity between two or more mobility tables we are interested in whether the pattern of fluidity (or, equivalently, the odds ratios) differs significantly across the tables. In other words, is there more or less inequality in some tables compared with others? When comparing fluidity across tables, we must specify the manner in which the parameters of the chosen model of fluidity differ between them. In this way, we hope to gain insight into exactly where and how the fluidity regime varies.

CORE MODEL OF SOCIAL FLUIDITY

In 1975, Featherman, Jones, and Hauser put forward the FJH hypothesis: “the genotypical pattern of mobility (circulation mobility [i.e., social fluidity]) in industrial societies with a market economy and a nuclear family system is basically the same” (Featherman et al. 1975: 340). Since then many publications have been devoted to testing this hypothesis, the majority of which have found support for it (most

notably, Erikson & Goldthorpe 1992), though with some influential exceptions (Ganzeboom et al. 1989; Breen 2004).

The FJH hypothesis refers to a “genotypical pattern” of fluidity, and Erikson and Goldthorpe (1987a, 1987b, 1992) developed the “core model of social fluidity” as an attempt to characterize this genotypical pattern. Having done this, they could test whether the purported pattern was indeed the same in industrial societies with a market economy and nuclear family system. The data that they used comprise mobility tables having seven classes of both origin and destination, defined according to the Goldthorpe or “EGP” (Erikson, Goldthorpe, and Portocarero) class schema (for details, see Erikson & Goldthorpe 1992: ch. 2). The seven classes are denoted by Roman numerals as follows:

- 1 Classes I+II: professionals, administrators and officials; managers
- 2 Class III: routine non manual employees
- 3 Class IVab: small proprietors and artisans
- 4 Class IVc: farmers
- 5 Classes V+VI: technicians, supervisors, and skilled manual workers
- 6 Class VIIa: semi and unskilled workers not in agriculture
- 7 Class VIIb: semi and unskilled workers in agriculture

Erikson and Goldthorpe developed the core model as a theoretically informed account of the fluidity patterns of England and France (which were taken as the two nations whose fluidity patterns most closely corresponded to some putative common pattern). The model consists of eight components, usually expressed through a set of eight matrices, in each of which the cells of the table are assigned to one of two categories. These rows and columns of the matrices are ordered according to the ordering of origin and destination classes as they are listed above.

The first element of social fluidity in the core model concerns hierarchical movement; and in the first dimension of this (called HI1) the value 2 indicates movement between three ordered (from most to least desirable) groups of classes: (a) class I+II; (b) classes III, IVab and c, and V+VI; and (c) VIIa and b. (Erikson and Goldthorpe (1992: 46, 124) treat class IVc

(farmers) as lying at the lowest hierarchical level (c) in class origins, but at the second level (b) in destinations.) In other words, the value 2 is assigned to cells of the mobility table which indicate an origin in one group but a destination in another. The value 1 is applied to cells in the same group in both origins and destinations:

```

1 2 2 2 2 2 2
2 1 1 1 1 2 2
2 1 1 1 1 2 2
2 2 2 2 2 1 1
2 1 1 1 1 2 2
2 2 2 2 2 1 1
2 2 2 2 2 1 1

```

Another matrix, called HI2, is defined distinguishing movement across two levels:

```

1 1 1 1 1 2 2
1 1 1 1 1 1 1
1 1 1 1 1 1 1
2 1 1 1 1 1 1
1 1 1 1 1 1 1
2 1 1 1 1 1 1
2 1 1 1 1 1 1

```

Here the value 2 is applied to cells with an origin in a class in group (a) and a destination in a class in group (c), and vice versa. This element of the model thus distinguishes “long range” mobility (as opposed to the short range mobility captured by HI1).

The second component concerns the inheritance of class position; that is, the tendency for men to enter the same class as their father – a tendency which is more marked in some classes than in others. The first inheritance matrix, IN1, distinguishes cells in which origin and destination are in the same class:

```

2 1 1 1 1 1 1
1 2 1 1 1 1 1
1 1 2 1 1 1 1
1 1 1 2 1 1 1
1 1 1 1 2 1 1
1 1 1 1 1 2 1
1 1 1 1 1 1 2

```

The second inheritance matrix, IN2, distinguishes three classes in which inheritance is more pronounced than elsewhere: these are classes I+II, IVab, and IVc:

```

2 1 1 1 1 1 1
1 1 1 1 1 1 1
1 1 2 1 1 1 1
1 1 1 2 1 1 1
1 1 1 1 1 1 1
1 1 1 1 1 1 1
1 1 1 1 1 1 1
1 1 1 1 1 1 1

```

The final inheritance matrix, IN3, reserves a single distinction for farmers (IVc), among whom class inheritance is particularly strong:

```

1 1 1 1 1 1 1
1 1 1 1 1 1 1
1 1 1 1 1 1 1
1 1 1 2 1 1 1
1 1 1 1 1 1 1
1 1 1 1 1 1 1
1 1 1 1 1 1 1
1 1 1 1 1 1 1

```

The third aspect of the core model is a single matrix, SE, that defines barriers to movement between the agricultural and non agricultural sectors. Thus, all cells with agricultural origins (classes IVc and VIIb) and non agricultural destinations, and vice versa, are assigned the value 2:

```

1 1 1 2 1 1 2
1 1 1 2 1 1 2
1 1 1 2 1 1 2
2 2 2 1 2 2 1
1 1 1 2 1 1 2
1 1 1 2 1 1 2
2 2 2 1 2 2 1

```

The final component of the model is two affinity matrices. The first, AF1, identifies movement between classes I+II and VIIb and assigns the value 2 to these cells:

```

1 1 1 1 1 1 2
1 1 1 1 1 1 1
1 1 1 1 1 1 1
1 1 1 1 1 1 1
1 1 1 1 1 1 1
1 1 1 1 1 1 1
2 1 1 1 1 1 1

```

while AF2 identifies reciprocal movement between I+II and III; between IVab and IVc; and between V+VI and VIIa; and non reciprocal movement from IVc to VIIa and from VIIb to VIIa:

```

1 2 2 1 1 1 1
2 1 1 1 1 1 1
2 1 1 2 1 1 1
1 1 2 1 1 2 1
1 1 1 1 1 2 1
1 1 1 1 2 1 1
1 1 1 1 1 2 1

```

In the case of AF1, movement between I+II and VIIb is thought to be particularly unlikely (even over and above the hierarchy, inheritance, and sectoral effects already included), whereas the movements captured in AF2 are thought to be especially likely.

The model is derived from a number of propositions about the factors shaping inequality in mobility chances (for a full explanation, see Erikson & Goldthorpe 1987a). Because hierarchical movements are assumed to be more difficult than non hierarchical ones, both HI1 and HI2 should have negative values. The inheritance effects, by contrast, should all be positive, while the sector effect, since it captures the difficulty of moving between the two sectors, should be negative. Of the affinity effects, AF1 should be negative (it captures a “disaffinity”) and AF2 positive. Some of the parameters of the core model are to be interpreted incrementally. For instance, the relative likelihood of long distance mobility is captured by the sum of the coefficients for HI1 and HI2, rather than by HI2 alone. HI2, in fact, tells us the degree to which long range mobility is more difficult than short range. In the same way, the propensity to inheritance of class IVc is given by IN1 plus IN2 plus IN3. So IN3 itself measures the “extra” inheritance observed among farmers compared with classes I+II and IVab.

Erikson and Goldthorpe (1992: 173) argue that the FJH thesis requires, as the first criterion for its support, that a model of fluidity (in this case the “core model” of fluidity) should provide a reasonable fit to the data. But they find that the core model with the same parameter values for all countries in their sample does not provide an adequate fit to the data: in other words, there is statistically significant variation between countries in the parameters of the model. Allowing such variation, the model fits the data much better, and Erikson and Goldthorpe take the success of this as supporting the FJH hypothesis:

"We can at least maintain that . . . the . . . effects that our model comprises do tend to operate cross nationally in the way anticipated, even if with differing strengths" (Erikson and Goldthorpe 1992: 174). Nevertheless, even allowing the parameters of the core model to differ between countries, they still find that everywhere except England and France, some adjustments have to be made to the core model itself in order successfully to capture national variations in fluidity. These are sometimes called the national variants of the core model. The adjustments are of two kinds. In some cases the existing matrices are redefined: so, for example, when applied to the West German data, IN2 assigns immobility in class I+II to level 1, rather than 2. That is, there is no tendency for class inheritance to be higher here than in any other class. In other cases, additional affinity matrices were included. So, in Hungary, an additional matrix, called AFX, captures the tendency for movement from the class of farmers, IVc, to the class of agricultural workers, VIIb.

CONCLUSIONS

The core model is nowadays very widely used (see, for example, the essays in Breen 2004) and its fit to empirical has often been adequate, and in some cases, good. The main reason for this is that it succeeds in capturing the features evident in most mobility tables, namely the tendency for clustering on some cells of the main diagonal of the table (inheritance effects), and the inequality that derives from a hierarchical ordering of the classes. But these features are common to almost all models of fluidity: indeed, given a number of mobility tables, it is usually quite difficult to decide which of a set of models is to be preferred because none provides an unequivocal best fit to all the tables. If there can be said to be any core features of fluidity it is the tendency for clustering on the diagonal and the hierarchical component. The latter can be modeled in various ways, and, indeed, Erikson and Goldthorpe's approach here is idiosyncratic, with most analysts preferring a simple scaling of the origins and destinations according to the mean prestige or mean income of the occupations that make up each class. Nevertheless, a model which only fits inheritance and hierarchical effects is unlikely

to fit any mobility table. The claims of the core model then rest on having found other processes (instantiated in the se and af terms) that are common to all fluidity regimes. Unfortunately, the need to introduce national variants of the model, which mainly modify the se and af terms, somewhat undermines that claim. As Sorenson (1992: 309) remarks: "*any* mobility regime can be represented as *some* core model with national variants."

The major weakness of the core model is that the effects hypothesized to shape fluidity are all operationalized as binary contrasts or "dummy variables" (on the other hand, this may also help to account for the model's popularity, since one requires no more than the mobility table itself in order to employ it). The alternative is to express log odds ratios as proportional to differences in scores on measured variables, and several other models of fluidity adopt this approach (e.g., Hout 1984; Breen & Whelan 1992; see also Breen & Whelan 1994). To illustrate: we might express the log odds ratios capturing hierarchical inequality as proportional to the difference in the mean earnings of the origin and destination classes involved in the comparison. Clearly, the choice of explanatory variables should follow from some hypothesized mechanisms rooted in individual action and interaction, and, in fact, the use of explanatory variables inevitably pushes mobility research away from a concentration on tabular data and towards analyses using data on individuals (Logan 1983; Breen 1994) which test hypotheses about the processes that shape individual mobility trajectories and account for the variation among them. A move in this direction would do much to advance the study of social fluidity both theoretically and empirically.

intergenerational mobility: methods of analysis

Ruud Luijkx

This entry comprises an analysis of intergenerational mobility, and in particular mobility tables, in which parents' and children's positions are cross classified. These positions

can refer to the level of educational achievement, earnings, occupational position, religious denomination, social class, and so on. Intergenerational class mobility (social mobility) involves the class of the family in which respondents lived when young (the *origin* class), and their current class position (the *destination* class).

The analysis of social mobility has a long tradition within sociology and largely evolved within the context of the International Sociological Association's Research Committee 28 on Social Stratification and Mobility. Elaborate overviews of the results of the different "generations" of social mobility research have been published (Ganzeboom et al. 1991; Treiman & Ganzeboom 2000; Breen & Jonsson 2005).

DISTINGUISHING SOCIAL CLASSES

Usually, the origin class in an intergenerational mobility table is related to the occupational position fathers held when respondents were between 12 and 16 years of age, and the destination class is related to the *current* occupational position of respondents, although sometimes destination refers to the first occupation held. A typical age selection for respondents is between 25 and 64 years of age. How many categories do the origin and destination class have? Looking at the history of social mobility analysis, a whole range of social class variables has been used. Very crude classifications that only distinguished farm, manual, and non manual occupations were used in early analyses (see, e.g., Lipset & Zetterberg 1959). Sometimes, for manual and non manual occupations, a further distinction was made into an upper and a lower category. This five category classification used to be standard in the United States and has been used as the basis for further refinements, leading to a seventeenfold categorization (Blau & Duncan 1967; Featherman & Hauser 1978). Another, now dominant, categorization is the Goldthorpe or EG(P) (Erikson, Goldthorpe, and Portocarero) class schema (Erikson & Goldthorpe 1992). To construct these more refined class schemes, detailed occupational information and information on the self employment and supervising status of people holding the occupational positions is essential (Ganzeboom & Treiman 1996).

The criteria used to aggregate occupations into social classes are in many cases more pragmatic than theoretical, but classifications can be evaluated in terms of both homogeneity and structure. *Homogeneity* refers to the extent that, within an aggregate of occupations (social class), there are no barriers between any origin occupation and any destination occupation. *Structure* refers to pattern and strength of the barriers between origin and destination classes. These barriers should be similar for the occupations constituting the classes. When disaggregated information is available, the assumption that class boundaries (barriers) are in agreement with the requirements of homogeneity and structure is testable.

The following list makes use of the seven class version of the Goldthorpe class schema:

- 1 Classes I + II: professionals, administrators and officials, managers.
- 2 Class III: routine non manual employees.
- 3 Class IVab: small proprietors and artisans.
- 4 Class IVc: farmers.
- 5 Class V + VI: technicians, supervisors, and skilled manual workers.
- 6 Class VIIa: semi and unskilled workers not in agriculture.
- 7 Class VIIb: semi and unskilled workers in agriculture.

Table 1 presents an intergenerational mobility table based on data used by Breen and Luijkx (2004). The table is an “average” table based on 89 mobility tables for men from France, Germany, Great Britain, Hungary,

Ireland, the Netherlands, Poland, and Sweden between 1970 and 2000. The number of cases in the table is rescaled for reasons of exposition from more than 250,000 to 1,000.

We distinguish origin O with subscript i and destination D with subscript j . Let $\{f_{ij}\}$ ($i = 1, \dots, I; j = 1, \dots, J$) be the observed frequencies for each cell (i, j) in the $I \times J$ mobility table of origin by destination (in this case $I = J = 7$); f_{ij} is the observed number of people with origin i and destination j . The observed row totals are designated by f_{i+} , the observed column totals by f_{+j} , and the grand total by f_{++} or N .

MEASURING ABSOLUTE MOBILITY

Using the data in Table 1, we can compute measures of absolute mobility. We observe that 340 out of 1,000 men are in the same class as their fathers. In other words, 34.0 percent of the men are immobile and thus the mobility rate in the table is 66.0 percent. The mobility rate (or gross change) depends on the number of classes being distinguished, as can be seen from Table 2. In Table 2, we combine the seven classes into three: (1) I + II, (2) III, IVab, IVc, and V + VI, and (3) VIIa and VIIb. Based on these data, we now conclude that 50.8 percent ($9.5 + 33.3 + 8.0$) of the people are immobile and that the mobility rate is 49.2 percent. Within the mobile, we can distinguish those who are upwardly mobile, going from (3) to (1) or (2) and from (2) to (1) – in total 31.2 percent; and those who are downwardly mobile, going from (1) to (2) or (3) and from

Table 1 A mobility table

<i>O(origin)</i>	<i>D(destination)</i>							<i>Total</i>
	<i>I + II</i>	<i>III</i>	<i>IVab</i>	<i>IVc</i>	<i>V + VI</i>	<i>VIIa</i>	<i>VIIb</i>	
I + II	95	14	9	1	24	11	1	155
III	26	9	4	1	16	8	1	65
IVab	28	9	18	1	21	13	1	91
IVc	25	9	10	55	40	40	11	190
V + VI	67	21	16	1	102	44	2	253
VIIa	38	16	11	2	70	53	3	193
VIIb	5	3	2	2	17	16	8	53
Total	284	81	70	63	290	185	27	1,000

Table 2 A mobility table (percentages)

<i>Origin</i>	<i>Destination</i>			<i>Total</i>
	<i>(1)</i>	<i>(2)</i>	<i>(3)</i>	
(1)	9.5	4.8	1.2	15.5
(2)	14.6	33.3	12.0	59.9
(3)	4.3	12.3	8.0	24.6
Total	28.4	50.4	21.2	100.0

(2) to (3) – in total 18.0 percent. It is clear from these results that upward mobility is more typical for the last part of the twentieth century than downward mobility.

Outflow and Inflow Percentages

Using outflow and inflow percentages, one can answer the question of where people in a certain class are going and where they come from. Outflow percentages are defined as f_{ij}/f_{i+} and

give the conditional distribution of destinations for each origin. They are used to answer the question of how likely it is that people from a certain origin will go to the different destinations. On the other hand, inflow percentages are defined as f_{ij}/f_{+j} and answer the question of which origins members are distributed from. Outflow and inflow percentages are presented in Tables 3a and 3b.

From the inflow percentages (Table 3b), we can conclude that origin matters. The origin distributions for the different classes differ, e.g., 87.3 percent of farmers are recruited from

Table 3a Outflow percentages

	<i>Destination</i>							
<i>Origin</i>	<i>I + II</i>	<i>III</i>	<i>IVab</i>	<i>IVc</i>	<i>V + VI</i>	<i>VIIa</i>	<i>VIIb</i>	<i>Total</i>
I + II	61.3	9.0	5.8	0.7	15.5	7.1	0.7	100.0
III	40.0	13.9	6.2	1.5	24.6	12.3	1.5	100.0
IVab	30.8	9.9	19.8	1.1	23.1	14.3	1.1	100.0
IVc	13.2	4.7	5.3	29.0	21.1	21.1	5.8	100.0
V + VI	26.5	8.3	6.3	0.4	40.3	17.4	0.8	100.0
VIIa	19.7	8.3	5.7	1.0	36.3	27.5	1.6	100.0
VIIb	9.4	5.7	3.8	3.8	32.1	30.2	15.1	100.0
Total	28.4	8.1	7.0	6.3	29.0	18.5	2.7	100.0

Table 3b Inflow percentages

[illegible]

a farmers' background, whereas only 33.5 per cent of the people in class I + II are recruited from that class. However, when we look at Table 3a, we see that 29.0 percent of the people with a farmers' background become farmers themselves, but that 61.3 percent of the people with an origin in class I + II end up in that same class. An explanation for this can be derived from the column and row totals in Tables 3a and 3b, respectively: Class I + II expanded from 15.5 percent in the origin distribution to 28.4 percent in the destination distribution, while the relative size of the farmer class declined from 19.0 to 6.3 percent. This brings us to the dissimilarity index.

Dissimilarity Index

If we look upon the class distribution of destinations as an opportunity structure, we can say that economic and demographic changes in society contribute to the dissimilarity between the contemporary opportunity structure, i.e., the destinations, and the class origins of current workers. Looking at Table 1, it is evident that the decline in agricultural jobs is balanced by an increase in non manual positions. A summary measure of these countervailing changes is the index of dissimilarity between the distribution of origins and the distribution of destinations:

$$\Delta = \sum_{i=1}^I \frac{|f_{i+} - f_{+i}|}{2N}$$

Δ is a measure of net change. It does not take into account the actual gross flows in the mobility table, only the net outcome of all flows. can be interpreted as the minimal proportion of people who have to be reclassified to make the origin and destination distributions identical (for Table 1 this is 0.182). Above we saw that the gross change (mobility rate) was 0.660. A high mobility rate results if the destination distribution differs substantially from the origin distribution or if origins and destinations are statistically independent, that is, if the conditional distributions of destinations are the same for all origins. A low mobility rate results if there is a similarity of origin and destination distribution *and* if the association between

origin and destination is strong. In the analysis of mobility, these two elements have to be separated: mobility due to dissimilar marginal distributions of origins and destinations (known as structural mobility) and mobility due to association between origins and destinations.

MEASURING RELATIVE MOBILITY

Mobility can also be described in terms of odds ratios. It is possible to compute many odds ratios from an $I \times J$ table, but the association in the complete table can be fully described by the odds ratios of a basic set of subtables: the 2×2 subtables formed from adjacent rows and adjacent columns. There are $(I - 1) \times (J - 1)$ basic subtables. The formula for the (adjacent) odds ratios is:

$$\theta_{ij} = \frac{f_{ij}/f_{i(j+1)}}{f_{(i+1)j}/f_{(i+1)(j+1)}}$$

In Table 4 this basic set is presented for the data from Table 1.

Goldthorpe (1980: 77) described odds ratios as indicating how unequal the outcomes are of competitions between persons of different origins to achieve or avoid certain jobs. For example, in Table 1, 95 men with origin I + II go to class I + II and 14 go to class III. The odds of going to class I + II instead of class III from origin I + II is $95/14 = 6.79$. For people from class III background, this figure is $26/9 = 2.89$. Although men from both origins are more likely to end up in class I + II instead of class III, the odds are 2.35 ($6.79/2.89$) times greater for men from origin I + II than for men from origin III. Were the odds for both origins equal, the odds ratio would have equaled one.

If all the odds ratios in the table are equal to one, we can speak of perfect mobility, i.e., destinations do not depend on origins. It is clear from the pattern in Table 4 that the odds ratios in the diagonal cells are much higher than the other ones, indicating that the propensity for men to stay in their own class is much higher than moving to another class.

An important feature of the odds ratio is that it is not dependent on the marginals: when all frequencies in a certain row or column are

multiplied by a constant, the odds ratios remain the same. This property is useful in the case of stratified samples: the odds ratios are not sensitive to an over or underrepresentation of a certain category. Even more important is the fact that it makes comparison of the origin–destination association possible between tables with different marginal distributions. This origin–destination association or relative mobility is also known as social fluidity.

Log Linear Models to Constrain the Odds Ratio Patterns

The full set of contiguous odds ratios (Table 4) constitutes a complete account of the association pattern, the so called saturated model or unconstrained association model. Log linear models are used to constrain the odds ratios in the saturated model to a more parsimonious set in order to find a sociologically more meaningful and statistically more powerful account of the data. We define the following log linear model:

$$\ln F_{ij} = \lambda + \lambda_i^O + \lambda_j^D + \lambda_{ij}^{OD}, \quad \text{for all} \\ i = 1, \dots, I; j = 1, \dots, J$$

where F_{ij} is the (under the model) expected frequency in the ij th cell of the table; λ is the grand mean; λ_i^O and λ_j^D are the one variable effects pertaining to the origin and destination; and λ_{ij}^{OD} is the origin–destination association. Identifying restrictions on the parameters have to be defined. As fit measures, the conventional log likelihood ratio χ^2 statistic (L^2), and the BIC statistic (Raftery 1986) are mostly used.

Which patterns of social fluidity can be modeled using log linear analysis? The simplest

pattern would be the one with no origin–destination association, the already presented perfect mobility model (in that case all $\lambda_{ij}^{OD} = 0$). But such a model does not fit our data well ($L^2 = 336.9$; $df = 36$). A next model is that of quasi perfect mobility. It assumes that people have a higher propensity to stay in their own class than moving to other classes (and that this propensity is different for each class), but that for people who are mobile, there is perfect mobility. We display this model as a matrix showing which association parameters of the model affect which cell of the table:

2	1	1	1	1	1	1
1	3	1	1	1	1	1
1	1	4	1	1	1	1
1	1	1	5	1	1	1
1	1	1	1	6	1	1
1	1	1	1	1	7	1
1	1	1	1	1	1	8

This model fits the data much better, but is still not statistically significant ($L^2 = 65.4$; $df = 29$). The highest immobility parameter belongs to class IVc (farmers), followed by VIIb (agricultural workers) and IVab (self employed). Another pattern that improves the fit of the model further is the core model of social fluidity.

Scaled Association Models

Scaled association models have turned out to be very useful for summarizing relative mobility

Table 4 Odds ratios for the mobility table

Origin	Destination					
	(I + II):III	III:IVab	IVab:IVc	IVc:(V + VI)	(V + VI):VIIa	VIIa:VIIb
(I + II):III	2.35	0.69	2.25	0.67	1.09	1.38
III:IVab	0.93	4.50	0.22	1.31	1.24	0.62
IVab:IVc	1.12	0.56	99.00	0.03	1.62	3.58
IVc:(V + VI)	0.87	0.69	0.01	140.25	0.43	0.17
(V + VI):VIIa	1.34	0.90	2.91	0.34	1.76	1.25
VIIa:VIIb	1.43	0.97	5.50	0.24	1.24	8.83

(Goodman 1979). The “starting” point is the very restricted uniform association model that assumes all contiguous associations in a table to be identical: $\ln \theta_{ij} = \varphi$. This model uses one parameter to characterize all odds ratios in a table, which is parsimonious but also often too restrictive (in these data, $L^2 = 224.7$; $df = 35$). The stringent assumption can be meaningfully relaxed in three ways:

- 1 By including diagonal density parameters that represent within class immobility over and above the association.
- 2 By scaling the distances between the row (μ_i) and column (ν_j) categories: $\ln \theta_{ij} = \varphi(\mu_{i+1} - \mu_i)(\nu_{j+1} - \nu_j)$; the category scalings μ_i and ν_j can be interpreted as measures of distance between or similarity among social categories with respect to the mobility chances. If categories are identically scaled ($\mu_1 = \mu_2$), this suggests that they can be regarded as a single social class. If the scalings are very different, this implies not only that mobility between the classes is extremely difficult, but also that they have very different mobility exchanges with other classes.
- 3 As a useful special restriction in this model we can introduce equal scalings for origins and destinations: $\mu_i = \nu_i$.

This model is known as the Goodman–Hauser model after its principal inventors (Goodman 1979; Hauser 1984). This model yields a very good fit to the data ($L^2 = 12.0$; $df = 23$). In Table 5 we present the scaling and immobility parameters.

Although not equidistant, we see from the scaling measures that the distance between the classes is ordered except for the farmers (IVc), who are better placed between unskilled manual workers (VIIa) and agricultural workers (VIIb). The immobility data show that inheritance is strong not only for farmers (IVc) and

the self employed (IVab), but also for the service class (I + II).

In the Goodman–Hauser model the distance between the classes is estimated. An attractive alternative is the measured variable approach in which known characteristics are used as scalings for the classes. In Hout’s (1984) SAT model, he scales origins and destinations using socioeconomic status (S), on the job autonomy (A), and specialized training (T). Breen and Whelan’s (1994) AHP model scales origins and destinations with origin and destination specific measures for agriculture (A), hierarchy (H), and property (P).

COMPARATIVE ANALYSIS

The measures presented here for absolute mobility can also be used to compare the level of absolute mobility between countries and periods. An important prerequisite is that tables are comparable (of same dimension and using similar class categories). Dissimilarity indices can be computed to compare origin and destination distributions between tables, and in this way divergence or convergence between countries and periods can be assessed (see, e.g., Breen & Luijckx 2004).

For the comparative analysis of relative mobility, log linear models are extremely well suited. To compare tables, we need to extend the log linear model defined earlier:

$$\ln F_{ijk} = \lambda + \lambda_i^O + \lambda_j^D + \lambda_k^T + \lambda_{ik}^{OT} + \lambda_{jk}^{DT} + \lambda_{ij}^{OD} + \lambda_{ijk}^{ODT},$$

for all $i = 1, \dots, I$; $j = 1, \dots, J$; $k = 1, \dots, K$

We now have an additional one variable effect (λ_k^T) pertaining to the table totals, two additional two variable effects ($\lambda_{ik}^{OT}, \lambda_{jk}^{DT}$) pertaining to the origin and destination distributions for the

Table 5 Parameters for the Goodman–Hauser model

Class	I + II	III	IVab	IVc	V + VI	VIIa	VIIb
Scaling	0.48	0.35	0.23	0.38	0.08	0.11	0.66
Immobility	0.69	0.21	1.13	2.82	0.41	0.21	0.20

distinct tables, and an additional three variable effect (λ_{ijk}^{ODT}) pertaining to the variation in origin–destination association in the different tables.

Let us think of T as a number of tables from different periods within one country, although it could also be tables from different countries or a combination of periods and countries (the model can also be further extended to take period and country into account as distinct variables). A first model is the constant social fluidity (CnSF) model that assumes no variation in the odds ratios OD across the tables (all $\lambda_{ijk}^{ODT} = 0$). Erikson and Goldthorpe (1992) and Xie (1992) have proposed an elaboration of the CnSF model to test for trends, the UniDiff (uniform difference) or log multiplicative layer effect model. UniDiff takes an intermediate position between CnSF (same pattern and strength of association in all tables) and the saturated model (different pattern and different strength of association for all tables) by using as a constraint that the set of odds ratios in one table differs from the set of odds ratios in the next table only by a log multiplicative scaling factor: $\ln \theta_{ijk} = \beta_k * \ln \theta_{ij}$, where $\beta_1 = 1$ by convention. In this case $\ln \theta_{ij}$ refers to the set of log odds ratios in the first table.

The UniDiff model does not model the pattern of mobility in the tables, but simple extensions to do so can be made by elaborating on the scaled association model presented earlier: $\ln \theta_{ijk} = \varphi_k(\mu_{i+1} - \mu_i)(\nu_{j+1} - \nu_j)$. In this model, scalings μ_i and ν_j are assumed to be equal across tables and the association φ_k is allowed to differ (in a similar way as β_k in the UniDiff model). Both β_k and φ_k can be constrained linearly or curvilinearly.

General statistical programs like SPSS, SAS, and STATA can be used to estimate most of the models presented here. To estimate the log multiplicative scaled association and UniDiff models, specialized programs such as LEM (Vermunt 1997) are more appropriate.

Although published more than 20 years ago, Hout's *Mobility Tables* (1983) is still one of the more comprehensive introductions to the log linear analysis of mobility tables. A more recent work in which both substantive and methodological aspects of mobility analysis are presented is the collection of country papers in

Breen (2004), which also includes a comparative analysis of eight nations over three decades.

intergenerational relationships and exchanges

Timothy J. Biblarz, Vern L. Bengtson, and Merrill Silverstein

The study of intergenerational relationships and exchange is about the structure and process of sharing that occurs in the linked lives of grandparents, parents, and children (and some times extended kin) as they move along the life course. Like the discipline of sociology, this subfield emerged in the wake of rapid industrialization, urbanization, and expansion of the state's role in families (e.g., the education of children and caring for the elderly), and is concerned with how these major social changes altered extended family ties, the role of grandparents, and parent-child relationships. Midtown researchers in the 1920s, for example,

observed challenges to parental control as children's individualistic aspirations began to compete with family obligations. In the US, parents' relationships with children have since shifted from an emphasis on obedience and strict conformity to developing children's autonomy and independence. In Japan, South Korea, and other countries, the significance of filial piety seems to be diminishing, raising new questions about who should care for the old and young.

The study of intergenerational relationships and exchange has been guided by two questions. The first involves intergenerational transmission: what do families transmit from one generation to the next, how do processes of intergenerational transmission occur, and why? Sizable correlations have been found, for example, between the social class position of parents and that eventually held by children (the intergenerational reproduction of inequality), and between parents' and children's religious and political values, occupations, family behavior (e.g., propensity to divorce), health related behavior (e.g., smoking), and other statuses, values, and behaviors. The family environment (as against genetic) component of intergenerational inheritance has been variously explained by patterns of parental investment in children (economic theory), children modeling their parents (learning theory), and levels of affect in the parent-child relationship (attachment theory). Research is just beginning to explore transmission across multiple generations, as in the case of grandparental influence on grandchildren, prompted in part by positive trends in the health, longevity, and socioeconomic status of older generations.

The second question involves how intergenerational relationships and exchange contribute to (or detract from) the well being of individual family members. Under what circumstances do relationships and exchange provide members psychological and material well being, a haven in a heartless world, or leave them in the cold? The concern most often has been with the well being of society's two dependent populations, elders and children, although the well being of the "sandwiched" generation has also received attention. A key feature is the study of caregiving, and of the timing and spacing of transfers up and down the intergenerational ladder

over the life course. The core resources given altruistically or exchanged reciprocally that are most frequently studied include time and involvement, money, assets and goods, and love, affection, and intimacy, in part because these have proven essential to individual well being.

Trends from the 1960s to the present – most notably, increases in divorce, maternal employment, nonmarital childbearing, and cohabitation – have stirred volumes of new research on consequences for parent–child relationships, child development and well being, and intergenerational exchange. New research shows that the quality of early parent–child relationships is consequential years later, when aging parents may need help from adult children, or vice versa. Some studies show that fathers who divorce while their children are young, for example, get less from their children in old age. The role of grandparents in contributing to the well being of grandchildren, particularly in the context of divorce and other stressors, is becoming an important focus of research.

While intergenerational relationships and exchange are studied in a variety of social science disciplines, the sociological approach has at least three key features. First, it pays attention to how patterns of intergenerational relationships and exchange are affected by the social contexts (neighborhoods, employment sites, economic conditions, and so on) in which families, and family members, are embedded. For example, a number of studies have shown that bad jobs make good parenting more difficult to achieve. The experiences and lessons learned in extra family environments get brought into families, influencing family relationships and exchange.

Second, the life course perspective is often used as a framework for studying intergenerational relationships. It draws attention to the unique alignment of age or life stage (e.g., the nature of exchanges between parents and children will vary depending on whether children are in infancy, childhood, adolescence, or adulthood) and history (e.g., relationships will be colored both by the period under which family members came of age and the current climate), with an eye toward how individual development and primary relationships at the micro level

are affected by local, regional, national, and even global events. The life course approach is inherently longitudinal, viewing intergenerational relationships as beginning at birth and moving through old age, and sequential, where earlier intergenerational events and transitions along the life course will have essential implications for later ones.

Third, rooted in the expansion of the division of labor and population heterogeneity that accompanied modernization, sociology has become markedly attentive to the consequences of social inequalities – hierarchies based on the intersecting dimensions of education, occupation, economic status, age, race, ethnicity, nativity and immigration status, gender, sexual orientation, and family background. This “race, class, gender” approach has become an important component of studies of intergenerational relationships. Do class, race, and ethnicity, for example, shape the way parents raise children and adult children care for aging parents? Some evidence suggests that, controlling for resources, African American and Latino adults in the US are more likely to provide assistance to their parents, and that race, class, and gender shape the way parents raise their children.

Since its origin was in the disruptions of major social changes, this subfield traditionally has been concerned with family decline – the possibility that intergenerational relationships have weakened and exchanges have diminished. To date, the fear of intergenerational decline has been stronger than the empirical evidence. Even at the height of the apparent generation gap in the US – the 1960s – relatively high levels of shared values and bonds between family members were observed, and the vast majority of caregiving today continues to be provided by family members. Recent work has also shown that employment has not led to significant decline in the amount of time mothers spend with children. To be sure, at the beginning of the twenty first century, intergenerational relationships and exchanges are more diverse and complicated than ever before, but remain crucially important to the well being of individuals and society.

international gender division of labor

Christine E. Bose

World systems theorists were among the first to use the concept of an international division of labor by illustrating how the production of goods and services for “core” or more developed countries relied on the material resources of “peripheral” or developing nations (Wallerstein 1974). Their work describes the changing

political and economic relationships among nations over the last six centuries, beginning with the period of colonization when Western European nations took possession of other countries in order to gain access to their raw materials such as sugar, coffee, gold, silver, or labor sold into slavery. By the middle of the twentieth century most of those colonies had gained their political freedom and titular control over their own resources, but were never able to break away from their economic dependence on highly industrialized countries.

In the twentieth century a new process called global or economic restructuring created a new form of international division of labor between the developed countries (now labeled the global North, a term replacing the old Cold War label “First World”) and the developing nations (now called the global South, which replaced the concept of a “Third World”). Beginning in the 1970s, in order to lessen production costs and enabled by improvements in information and production technologies, US, Japanese, and Western European corporations began to “off shore” some of their production processes to the global South, often moving to export processing zones (EPZs) within these countries, which are defined as industrial zones that provide manufacturing infrastructure, tax reductions, low labor costs, lax environmental regulations, and other incentives. As a result of this worldwide economic restructuring, much basic manufacturing and heavy industrial production were relocated to developing nations, while corporate headquarters, service work, and final product finishing stayed in developed nations. This process was initially referred to as the growth of the global assembly line or the global factory (Kamel 1990). Instead of taking raw material resources from their former colonies, transnational corporations (TNCs) based in the global North rely on residents of the global South to provide inexpensive labor for factories now located in developing countries.

In addition, international development or funding agencies such as the International Monetary Fund and the World Bank influence global South economies when they loan money to poor and developing nations, because loans are tied to required austerity measures known as structural adjustment programs (SAPs). SAPs require the debtor countries to reduce

government expenditures on social services and increase production for export, rather than supporting independent local businesses that produce for local consumption, in order to earn more foreign currency to pay back these loans. An important byproduct of these two factors – TNCs relocating production overseas and structural adjustment programs – is that developing economies are indirectly controlled by transnational corporations and/or funding agencies located in developed nations, thus reinforcing a new international division of labor.

This international division of labor is profoundly gendered in many ways. Mies et al. (1988) observed there has been an international trend towards the “housewifization” of all labor – an interesting term that incorporates several aspects of the relationship between paid work and women’s unpaid work at home. First, paid work is becoming increasingly feminized, with new jobs in the service sector drawing more on women’s than men’s labor. Indeed, some of women’s traditional white and pink collar jobs, such as data entry or telephone call in work, are now being sent to workers in developing countries, especially to English speaking, former British colony nations (Freeman 2000).

Second, paid work is increasingly organized like women’s housework, with jobs that require flexible schedules and are occupationally segregated. Such “flexibilization” of the world economy refers to the growth of part time, temporary, or seasonal employment. In developed countries, this process is most visible in the growth of the service sector. In developing economies flexibilization usually refers to the need for families to have multiple income sources based on subsistence farming, vending, or other forms of self employment, and perhaps some formal paid work.

Third, many of these jobs, like market trading, factory outwork, or off the books childcare, are found in the informal sector of the global economy that is rapidly expanding but, like housework, is not regulated by national labor laws. Therefore, increasing “informalization” of work often accompanies flexibilization.

Fifth, since women’s traditional tasks are stereotyped as unskilled (although they are not), companies or individual employers can more easily pay less and provide less job security.

In other words, economic restructuring and the international division of paid labor created new jobs that have many of the characteristics of women’s paid work and unpaid carework and housework, which is not surprising since women are the source of new labor in most countries worldwide.

Recent scholarship by Parreñas (2000), Hondagneu Sotello and Avila (1997), and others illustrates that there also is an international division of reproductive or carework labor. This occurs when women from developing countries migrate internationally to more developed ones to perform paid carework for other women, then use their earnings to hire someone back home (often a rural to urban migrant or another family member) to take care of their own families. Parreñas (2000) argues that this labor chain, transferring white women’s domestic and reproductive labor to women of color from developing nations, creates an international system of racial stratification in reproductive work and makes temporary overseas “contract workers” into a new export commodity for some developing countries.

While the international division of labor continues to change forms, one of the constant features is its gendered and raced nature.

Internet

James Slevin

The Internet is a global network of interconnected computer hardware and software systems, making possible the storage, retrieval, circulation, and processing of information and communication across time and space. From a sociological perspective, the Internet is not synonymous with a global information machine as it is in some popular accounts. A sociological account encompasses the constituent Internet technologies and attends to these as social phenomena. It also includes the information and other content which is produced, transmitted, and received by individuals and organizations using the Internet. Finally, a sociological account of the Internet includes the socially and historically structured contexts and processes in which the production, transmission, and reception of information and communication are embedded.

Consider the simple act of writing and sending an email over the Internet. What can we say from a sociological perspective about communicating in this way? We could start by pointing out that communicating by email is not just an alternative way of producing and distributing information. It involves us in a complexity of new forms of action and interaction that stretch across the world. In order to send an email, we need to have access to technologies that allow us to store, process, and send information over the Internet. The resources we are able to muster in respect of communicating and in respect of accessing and distributing information over the Internet are not uniformly spread. Moreover, using these technologies is a skilled performance demanding particular capabilities, for example, knowing how to work a computer, knowing how to address an email, and knowing how to attach other items like photographs, if we so wish.

Sending an email is also embedded in various kinds of interlocking institutional arrangements. Sending email from a private Internet connection at home is different from sending an email from an office or from an Internet café. At home, we might need to negotiate time spent on the computer with others in our household who might also wish to use it. In an office, we might be restricted in sending private emails which are not strictly related to our work. In an Internet café, we might be paying for Internet access by the minute, feel uncomfortable because other people can read our screens, and leave as soon as we have finished our coffee. The circumstances of the recipient of our email may also be relevant to the process of sending it. It's no good sending an email and expecting a direct response if the recipient is away on holiday or is normally asleep at that time of day. The situated social contexts of both the sender and recipient also interlock with institutional arrangements that are instantiated in what happens online. Sending an email from an Internet café, for example, may involve us using the online services of a distant Internet provider. Such arrangements also enable and restrict communication and the accessing and distributing of information.

Finally, the content of an email also involves us in new forms of action and interaction and is constructed and organized differently from communication by letter, phone, or in face to face exchange. The content of email messages mostly does not display the same formalities that letters do. In such a situation where we want to communicate a complicated message which could easily be misunderstood, we might prefer to use a phone or meet face to face rather than communicate by email. Moreover, the choice to send a message by email rather than using a different means of communication is already an act that may be considered socially meaningful by a recipient. Sending highly consequential information via email, for example, may seem insensitive to a recipient's feelings and interests.

Email is only one of a baffling variety of available Internet applications. The World Wide Web, newsgroups, instant messenger systems, Virtual Learning Environments, to name but a few others, can all be approached from a similar sociological perspective.

The Internet deserves the attention of sociologists for three major reasons. First, the Internet facilitates a reorganization of information and social relationships across time and space. As such, its development and use have intended and unintended consequences for human social life, groups, and societies that need to be studied and understood. Second, in investigating and understanding the complex subject matter of sociology, the Internet is an important tool for collecting data and for accessing information relevant to such an endeavor. Third, the Internet deserves the attention of sociologists because it expands the opportunities for circulating research findings and for supporting critical reflection, learning, and debate. However, in staking out the relevance of the Internet for sociology, we need to be aware that as a social phenomenon, it is an expression of the radical interconnection of people, organizations, different sectors of society, and the problems that we take up for study. In this way, studying the Internet involves shifts and linkages to perspectives that might traditionally have been considered to lie beyond the disciplinary boundaries of sociology. A comprehensive understanding of the Internet can only be developed jointly, from a multidisciplinary approach.

Fundamental to a sociological account of the Internet is that its development and use are not accidental to a set of complex and contradictory changes that are taking place in our world today. As such, the Internet is in the midst of some of our most severe and exciting challenges. The world we live in is becoming increasingly globalized. As a global communication network, the Internet is transforming the complex relationships between local activities and interaction across distance. The world we live in confronts us with new opportunities and dilemmas as the certainties afforded by tradition, authority, and nature no longer direct our lives in the way that they once did. The Internet radicalizes this process by placing "horizontal" forms of communications center stage, by allowing the questioning and blurring over of authority, and by allowing the reordering and expansion of the built environment. The world we live in is increasingly reflexive and saturated with information. As a technology of communication, the Internet transforms our information environments by facilitating global attentiveness,

visibility, and questioning. Moreover, as a technology of communication, the Internet does not simply impact on this set of complex and contradictory changes; it contributes to the construction, mediation, and disclosure of what these transformations are.

Globalization, detraditionalization, and the intensification of social reflexivity force themselves as major themes into all sorts of Internet topics addressed by sociological research. In connecting these themes to the topics they study, sociologists are concerned with a range of questions that follow from the challenges we face. First, to what extent is the Internet facilitating an advance in intelligent relationships between individuals, groups, and organizations arranged through dialogue rather than domination and violence? Second, how might the Internet empower individuals, groups, and organizations to make things happen rather than to have things happen to them in the context of overall goals and interests? Third, in what way does the Internet offer a new basis for solidarity and strategic alliances, bringing together in association individuals, groups, and organizations who were previously socially and geographically far apart? Fourth, in what way might the Internet open up new opportunities for limiting damage and conflict as new communication networks allow individuals, groups, and organizations to cross paths with others whose views differ from their own? In dealing with these questions, sociologists may opt to emphasize the communicational, political, economic, and normative aspects of the Internet and its use, or a combination of these.

In spite of all the excitement generated by the Internet over recent years, we would not be far off the mark if we were to conclude that it remains only poorly understood. Many debates about the social impact of the Internet have involved opposing sides taking almost completely contradictory views about its significance in modern life. On the one hand, we find the Internet radicals who claim that we are at the dawn of a new era of opportunity in which we can live our lives on the screen. On the other, we find the Internet skeptics, who warn of the onset of a terrible nightmare in which many people will find themselves disconnected and irrelevant to the important things that go on in their world. Sometimes optimistic and pessimistic views are raised by one and the same person.

While we might rejoice at the idea that people hold different opinions, this kind of understanding of an important communication medium is not at all satisfactory given the severity of the challenges that we face, both on the level of world society and institutions and on the level of our personal lives. Why is our understanding of the Internet so poor? More importantly, what can sociologists do about it?

Some commentators point to a lack of adequate research into the Internet and yet others to the sheer pace of social and technical change which they claim has overtaken us. The problem, however, also goes deeper than this. We urgently need to find concepts and frameworks that can be placed in the service of developing a more critical understanding of the Internet and we must continue to remain critical of what we may find.

A great deal of early knowledge of the Internet had an anecdotal and descriptive quality about it. As the sophistication of Internet studies advanced, research began to slot into an already growing interest in communication via the computer. Studies of computer mediated communication and "cyberculture" developed from this and were taken up by researchers from diverse disciplinary backgrounds. This resulted in the research area becoming highly fragmented with different disciplines declaring different parts of it to be their own. While narrowly defined disciplinary approaches still exist today, Internet research has become increasingly multidisciplinary.

Another problem with early research is related to the use of the term "new media" to refer to technologies like the Internet. This was conveniently taken by some to mean that they could begin their understanding of the Internet with a fresh start without critically referring to existing theories and to existing media. Some commentators even claimed that media convergence would result in the new media swallowing up or replacing the old. Today, we are far more sensitized to the way in which the Internet reconfigures different media and the contrasting ways in which it reconfigures our information and communication environment.

The biggest shift in the treatment of the Internet, however, is that early research tended to focus on what was happening on the Net. Internet culture was understood to be an online

phenomenon quite divorced from the social contexts within which, and by virtue of which, it was produced and received. There is now a growing realization that the Internet is not incidental to our lives but fundamental to the way we live now. This has resulted in far more comprehensive studies looking at the way in which the Internet enmeshes with the cultural transformations associated with the rise of modern societies and a far greater awareness of the situated and cultural contexts of its use.

With the Internet so centrally involved in the shakeup of our institutions, organizations, and our individual lives, the research topics addressed by sociologists are bounded only by the limits of their imagination. While the following list does not exhaust all possibilities, it contains some of the topics that sociological research has addressed.

- 1 The history of Internet related technologies. The history of the Internet is only beginning to be written. Many early accounts hardly progress beyond the construction of time lines setting out important events without explaining why these came about or what they mean. More advanced approaches show the Internet not to be a sudden invention, governed solely by conditions internal to its own technological development. Instead, they argue that all Internet related innovations are fundamentally social and their meaning, together with their meaningful use, is grounded in social contexts. The Internet is the result of tensionful, contradictory technical and social conditions and the consequences of its use are no less so.
- 2 Self identity and everyday life. Globalization and detraditionalization mean that individuals face more opportunities in constructing their own lives than once was the case. Who we are, what we do, and how we do things together is increasingly mediated and fed by information and communication technologies. Sociological studies attempt to unravel the involvement of the Internet in transforming the nature of the self, experience, and communication in everyday life. Sociologists are sensitive to ways in which the Internet is furthering individual autonomy but also to ways in which the Internet might adversely affect individuals

by excluding them from its use or by involving them in problems of compulsion, addiction, and self harm.

- 3 Networking and community. The turmoil of our modern world has resulted in the break down of traditional strategies for organizing solidarity. Critical awareness of this social disintegration is accompanied by a renewed interest in community. Online communication opens up vast opportunities for human interaction and association across time and space. Communities facilitated by the Internet often consist of individuals related to each other in terms of practice rather than proximity. There are worries, however, that new forms of human association using the Internet are undermining solidarity still further with individuals becoming increasingly disengaged from meaningful face to face relationships.
- 4 Organizations, business, and institutions. Modern organizations exist by virtue of the informed practices of their members. Internet technology has permeated all forms of organization in the form of intranets for their internal communication, extranets for their communication with other organizations, and the Internet for their external communication. Using these networks, some organizations have become more open and informed resulting from a decentralization of organizational authority, a shift toward supportive and facilitative leadership, a focus on knowledge sharing, horizontal communication, teamwork and empowerment, and a blurring of traditional organizational boundaries, for example, where individuals work from home and on the move. However, using these networks, organizations can also become highly centralized, hierarchical, inaccessible, exclusive, and fundamentalist rather than cosmopolitan in their outlook.
- 5 Publicness and democracy. The Internet is creating new opportunities and burdens as regards mediating visibility and making information available to others. Sociologists are interested in how the Internet is impacting on the public sphere, redefining freedom of expression and discussion. The new global information environment is a powerful democratizing force. Democratic institutions are being transformed under pressure of highly reflexive citizenries who are increasingly organizing themselves internationally.
- 6 Social movements and civil society. The rise of various social movements oriented toward challenges traditional democratic institutions have failed to cope with has snapped together with the new opportunities offered by the Internet. The civil rights movements, the feminist movements, the ecological and anti nuclear movements, and the gay and lesbian movements, to name but a few, are all reinvigorating civil society, empowered by the Internet. For sociologists, their struggle for visibility, campaigns, and use of information technology have become important topics of study.
- 7 Globalization and the digital divide. Globalization is an inherent feature of our modern world and raises many questions and difficulties. We increasingly live in one world where globalized communication is relevant to all our lives. Yet the consequences of globalized communication are highly contradictory and most of the world's population is excluded from using it.
- 8 Regulation. New forms of policy and regulation are being researched, developed, and implemented affecting Internet access and content, stimulating economic development, promoting diversity, pluralism, and the deconcentration of power, and regulating the connections with other media.
- 9 Research and social theory. Sociologists have also attended to questions regarding Internet research and whether this demands new theoretical frameworks and research methodologies.

Sociological projects in these areas are set to continue and new projects will arise. Some will acquire new significance and urgency. None the more so than in the area of e learning. Successful intervention in our world today is increasingly governed by decisions made on the basis of knowledge and competence which is revisable or can be rendered outdated in an instant. The Internet is set to play a key role in facilitating the building and rebuilding of knowledge and skills, at any time and in any place, and is already contributing to the

refashioning of education, its institutions, and the way we learn.

As the radical interconnectedness afforded by the Internet propels its users into an increasingly challenging reality of cultural differences, people and organizations will increasingly cross paths with others whose views and interests may differ from their own. How people and organizations can best negotiate such a complexity of experiences will demand significant attention from sociologists.

There is also a growing awareness of the environmental impact of global communication systems. The Internet already consumes a vast amount of energy and produces a vast amount of waste. In this respect, as with other global technological systems of our times, the Internet only works because most of the world's population is excluded from using it. This poses tremendous challenges for finding ways of dealing with the digital divide.

New technological developments also call for new developments in sociological perspectives and imagination. Not only people but also technological systems, even ones we do not normally associate with communication and the Internet, will increasingly become interconnected. Our lives and the contexts in which we work and live will become ever more saturated with information which will create new demands for processing information and archiving it. Social problems and problems specifically related to the Internet will become more interconnected and complex. In meeting these challenges, sociologists will increasingly find themselves working with others across disciplines in a world acutely aware of the limitations of their expertise. In all of this, it is the sociologist's responsibility to contribute to understanding the ways in which technologies like the Internet are being used, to reflect critically on our complex world, to gain a better understanding of it, and to intervene in it the best we can.

Internet medicine

Michael Hardey

The engagement of medicine with information and communications technologies (ICTs) can be traced to the early part of the twentieth century when attempts were made to send X ray images through the phone lines. By the 1970s, the desire to overcome the constraints distance imposed on contact between clinicians had produced a new specialist area of practice labeled "telemedicine." Since the emergence of

the Internet, telemedicine has come to denote medical practices that use, for example, email, teleconferencing, and remote diagnosis. As Giddens (1991) notes, scientific disciplines in advanced modernity generate ever more subdisciplines. Consequently, specializations have emerged organized around telepsychiatry, tele-neurology, teleorthopedics, medical informatics, and so forth. Despite this differentiation, a useful distinction can now be made between telemedicine and what is known as e health. This recognizes the Internet as a key driver in the new "information age" where the "electronic" flows of information and capital form the "new economy" of the twenty first century (Castells 2001). The prefix "e" has since become attached to activities that use the Internet to make interactive links between producers and consumers, so that together with e commerce the category e health has quickly become established. It can be defined sociologically as involving theoretically grounded and empirically informed attempts to understand the dynamic, emergent, and pluralistic nature of knowledge about health and illness that is mediated by the Internet. From this, four key themes that continue to frame research and debates within e health are evident.

The first theme involves what might be termed the "quality debate," which has been significant since the initial use of the Internet to provide consumers with health information. It reflects the open, dynamic, global, and potentially anonymous nature of the media where the status of the providers of information and the veracity of material that is published may not be clear. To put it simply, the key issue in medical circles is whether information published on the Internet puts consumers at risk. Consequently, a range of organizations has emerged to provide "kite marks" which are awarded to Internet sites that only display reliable biomedical information. Such systems necessarily dismiss complementary and alternative (CAM) approaches to health that are not open to clear scientific verification.

The second theme is concerned with how individuals perceive and use information published on the Internet. Drawing on work by Anthony Giddens and others, it has been argued that people make sense of the choices that confront them in the information age through a

reflexive engagement with diverse forms and sources of information. This involves the careful and rational discovery and assessment of information about health that offers to improve or shape aspects of individual lives. This highlights concerns about how medical treatments including drugs can be purchased or treatments entered into through the Internet in a way that escapes national regulations. For example, spam email advertising Viagra is widespread but there is no guarantee that the drugs purchased through ICTs will resemble those available through medical prescriptions. Similarly, how do consumers know that a doctor who offers email consultation is really what he or she purports to be? Trust is, as Parsons's (1991 [1951]) model of the sick role noted, central to the doctor-patient relationship. The third theme is therefore concerned with the way well informed patients may transform this relationship (Hardey 1999). Reflecting broader aspects of the consumer society, the doctor-patient relationship is becoming democratized and one that is often better regarded as a partnership than an unequal encounter between expert and passive consumer.

Finally, the interactive nature of the Internet enables people to become producers as well as consumers of information. Research into news groups and similar peer to peer spaces have revealed how they are used to share information and experiences about illnesses. Whether the topic is "fatness," asthma, or any other health related issue, it is possible to find newsgroups where individuals can post questions and offer advice to others. What has been called "wired self help" has in effect opened up a global network of people with whom experiences can be shared that in the past was limited by sociability within geographically bound communities and families (Burrows & Nettleton 2002). There are also many web pages and blogs constructed by those who have experienced sometimes rare conditions and who want to share information in a global forum. Chronic illness may therefore not be such an isolating experience as it was in the past and people may come together to advocate new forms of treatment or call for more medical resources (Hardey 2004). Furthermore, those with "sick" bodies may leave them behind and interact on an equal basis with others in the disembodied digital domain of the Internet.

The Internet represents a challenge to established social research. Research has to capture the dynamic nature of the medium and often needs to embrace the local and global aspect of both users and the information that is published. This may involve the use of ICTs to generate data from, for example, email based questionnaires or interactive interviews. Furthermore, the analysis of Internet resources may involve text, images, and languages other than English despite its domination of the Internet. Much work needs to be done on how CAM is represented and consumed through ICTs. The “digital divide” remains an important policy and research concern as unequal access to ICTs may further disadvantage the poor, who suffer disproportionately from chronic illness. Finally, we are only beginning to recognize how the Internet may be used to address the inequalities in health between people who live in the first and third worlds.

interpersonal relationships

Terri L. Orbach

In any relationship, two participants are interdependent, where the behavior of each affects the outcomes of the other. Additionally, the individuals interact with each other in a series of interactions that are interrelated and affect each other. Individuals form many different kinds of relationships with other people, some of which are intimate and close (e.g., parent–child, spouse–spouse, friendships) and others which are not intimate and close (e.g., neighbor, teacher–student). Most of the research on interpersonal relationships has focused on those relationships that are close, intimate, and have high interdependence. In an influential book, Kelley and colleagues (1983) define a close relationship as one that is strong, frequent, and with diverse interdependence that lasts over a considerable period of time. In sociology, although the classic distinction between primary and secondary relationships has been expanded in the public realm (fleeting, routinized, quasi-primary, and intimate secondary relationships), these close relationships (as described above) also can be categorized as primary groups, which provide support and nurture and socialize individuals to the norms of society.

The concept of relationship historically has had a central and significant place in sociology. Some of the founding sociologists, such as Simmel and Marx, were concerned with attraction and interpersonal relationship issues. Even particular types of relationships and relationship processes – such as courtship, marriage, and parent–child relationships – have always been important to how and what sociologists study. For example, sociologists have been particularly interested in research on marriage and the family, specifically the structural and

demographic correlates of these relations (e.g., Bernard 1972).

HISTORICAL CONTEXT

In the 1960s the initial focus of interpersonal relationship research was on the interpersonal attraction process, primarily between strangers meeting for the first time, rather than on the relationships themselves that might develop as a result of attraction. This research developed primarily out of mate selection studies first begun by family sociologists in the 1930s and 1940s (Burgess & Cottrell 1939). Attraction typically is conceptualized as an attitude toward another consisting of feelings, cognitions, and behaviors and can be negative and/or positive in nature. Most of the early research on the interpersonal attraction process relied on self report measures to assess the factors that lead a person (P) to be attracted to another person (O). For example, the bogus stranger paradigm (Byrne 1971) asked respondents (typically, young college students) to rate how much they were attracted to another person after being presented with minimal information about this other person. In these paradigms, respondents were actually participating in an experiment, where the information presented to respondents was manipulated, and the other persons were typically hypothetical others. Walster, Berscheid, and their colleagues (e.g., Walster et al. 1966) also conducted numerous "get acquainted interaction" studies in which real respondents were matched with each other and given the opportunity to interact, after which they self reported their attraction to each other.

In the 1980s researchers turned their attention to the more intense sentiments and phenomena that occur within actual interpersonal relationships, and to the social context of various kinds of specific relationships. Although attraction was important, maybe even necessary for P (person) and O (other) to begin an interpersonal relationship, the majority of research started to focus on the "pulse" or quality of these interpersonal relationships and its link to processes inside (e.g., cognitions, depression, physical health) and outside (e.g., work satisfaction, financial strain, family cohesiveness) the individual. In addition, researchers began to examine the influence of factors in P (person)

(e.g., depression) and O (other) (e.g., physical attractiveness), along with the combination of those factors (P and O) (e.g., conflict, similarity) on the likelihood that P and O will stay in the relationship and are happy with it.

NEW DIRECTIONS IN RESEARCH

Even more recently, relationships have received considerable attention in sociology and the other social sciences. An examination of the research since 1980 illuminates several themes. First, an expanding and significant body of literature demonstrates that interpersonal relationships are vital and important to the physical and mental health of individuals. Studies show (House et al. 2003) that individuals are likely to suffer from depression, anxiety, ill health, and other physical problems if they lack interpersonal relationships of high quantity and quality. The interesting finding here is that quality and quantity of relationships are critical for individuals' overall health and well being.

Second, the current research emphasizes specific relational processes that are relevant at various stages of the life course of a relationship. This literature tends to be organized according to relationship type and focuses on factors that are important to the development of a relationship (attraction, similarity, background factors), the maintenance of a relationship (communication, conflict, family interference and support), and the dissolution of a relationship (legal factors, effects on children, adjustment). There also is strong evidence to suggest that what factors predict divorce or dissolution of a relationship differ depending on the life course stage of the *relationship*. The age or life course stage of the *individual* also has been found to be relevant to what relational processes are important to individuals' evaluations of the relationship (relationship quality). Further, the recent emphasis on the life course of both relationship and individual has focused scholarly attention on the importance of making conceptual distinctions between (1) the intent to maintain a relationship (e.g., commitment) (see Johnson 1991), (2) personal evaluations within a relationship as perceived by individuals (relationship quality), and (3) the status of the relationship (relationship stability) (Veroff et al. 1997).

A third new direction in relationship research has been to concentrate on making the dyad the unit of analysis rather than the individual (Couch 1992). This change is both methodological and conceptual and has become an important contribution to the literature on relationships. Relationship scholars now find it important to collect information from both members of the dyad, rather than only one member, and assess how these reports may differentially affect the well being and stability of the relationship (Duck 1990).

Fourth, given the prominence of symbolic interactionism in sociology (e.g., Mead 1934), another new direction of relationship research has been to apply symbolic interactionist concepts to the study of relationship well being and stability (Burke & Cast 1997). The self is created out of the interactions and feedback from others, and the relational context is even more salient for how individuals view themselves. Further, to understand how adults define and describe themselves to others, relationship scholars turn directly to the context and status of their relationships.

The fifth new direction in relationship research has been to examine the construction of meaning within relationships for relationship quality and stability (Orbuch et al. 1993). In these studies, there is an acknowledgment that individuals may construct meanings of their relationship, based on the social context of that relationship and individual, which in turn has significant influence on individuals' evaluations and status of those relationships. Many relationship scholars now ask couples/dyads (separately or jointly) to use a narrative or account as stories technique to gain a better understanding of individuals' meanings of their relationship and relational processes over time (for a review, see Orbuch 1997). This technique allows individuals to have a "voice" in their reports about their relationships and permits variations in reports as a result of the "sociocultural ecology" within which the relationship is embedded. This approach also recognizes that these stories formulate, control, predict, and shape individuals' relational experiences over time.

Sixth, the larger environment and structural conditions that can be harmful or beneficial for a couple's well being have been examined. Relationship scholars have begun to link these

"sociocultural ecologies," or what sociologists term the norms, cultural meanings, settings, circumstances, or people outside the relationship, to relationship quality and stability. One specific contextual factor that has received a great deal of attention lately is social networks, or the link between the relationship and people outside the dyad. Specifically, relationship scholars have been interested in the influence of social networks of family and friends on the stability and quality of relationships (for a review, see Felmlee & Sprecher 2000). The majority of this research looks at how social networks can be a potential source of support or reduction of stress for couples, but this direct link has been challenged and revised by many (Kessler et al. 1995). The general notion that social networks are linked to the internal pulse of the relationship was first examined by Bott (1971).

Another important contextual factor that has received attention recently is the context of race/ethnicity for interpersonal relationships (McLoyd et al. 2000). Relationship scholars have begun to highlight the similarities and differences between and within various racial/ethnic groups. Recent studies find that both cultural and structural factors may affect relational processes differentially among various ethnic groups (Orbuch et al. 2002).

CONCLUSIONS AND FUTURE DIRECTIONS

The field of interpersonal relationships has a strong history and vibrant theoretical foundation in the discipline of sociology. Critical to sociological ideas and theories is the notion that individuals interact with others and that these interactions are interrelated and affect each other. Further, the topic of interpersonal relationships is the perfect arena to understand and illuminate many underlying sociological processes and concepts (e.g., development of self, culture, social networks, commitment, and emotions) that are critical to the discipline.

The study of interpersonal relationships is not yet the focus of an organized subspecialty in sociology, as it is in psychology and communication studies. Yet the research questions that have been asked about interpersonal relationships,

whether in the past or present, are not inherently more psychological than sociological. It is imperative that sociologists continue to expand research on the topic of interpersonal relationships (Felmlee & Sprecher 2000). For sociologists, the list of questions is still very expansive and the research possibilities are endless.

interracial unions

Alison Roberts

Interracial unions refer to romantic relationships between people of different racial categories. Generally, the term indicates married (and hence, heterosexual) status, as it is more feasible to identify and carry out social research on this population than non married, non cohabiting, and/or same sex interracial couples. Sociological inquiry of racial intermarriage stems from the study of assimilation and understanding the social evolution of societies with significant immigration. Researchers employ both qualitative and quantitative methods to study interracial unions: a macro level perspective involves examining demographic data to identify cultural patterns, and a micro level approach focuses on the cultural meaning – derived from social interaction – of an interracial relationship to the couple and to their family, friends, and community. In recent years

more attention has been devoted to the study of the identity of the offspring of interracial unions, but the study of interracial marriage remains sociologically relevant – the rate of interracial marriages can be an indicator of levels of proximity or distance across racial lines, tolerance or prejudice of different groups, and the malleability of the boundaries of racial categories. Interracial unions are studied by sociologists with an interest in racial and ethnic relations as well as those interested in the family.

Sociologists use the metaphor of the “marriage market” to analyze how people select their spouses: individuals will look for the most desirable partner they can attract given the resources available to them. This model explains why many married couples share similar characteristics such as educational background and socioeconomic status. However, individuals may compensate for any “mismatching” by providing each other with resources that the other does not possess. This status exchange hypothesis explains that members of higher status groups could be inclined to marry members of lower status groups if the individuals with the lower status could offer a resource to offset that lower status. In his 1941 article “Intermarriage and the Social Structure: Fact and Theory,” Merton argued that racial minorities could compensate for their lower racial status with a higher socioeconomic position. Much of the research conducted on interracial marriages has focused on an exchange of racial status for socioeconomic status.

Sociologists who study racial and ethnic relations use assimilation theories to address immigrants’ ability to adapt to the new environment and to integrate with other racial and ethnic groups. Milton Gordon established several stages of assimilation that explained what outcomes we can expect if immigrants adapt to and become part of their new culture. One such outcome would be marital assimilation, indicated by significant intermarriage between ethnic and racial groups. Over time, intermarriage among white, European American ethnic groups became quite commonplace, but that trend has not been replicated in the rate of interracial unions. Historical conditions such as colonialism and slavery are determinants of how interracial marriages are perceived within a society. Indeed, many states and nations legislated and

enforced sanctions against interracial unions. In South Africa, interracial marriages were not entirely uncommon until the Prohibition of Mixed Marriages Act of 1949 and the Immorality Act of 1950 effectively outlawed interracial unions. Today interracial marriages remain rare occurrences even with the repeal of apartheid-induced racial laws in the late 1980s. In the United States, some states forbade interracial marriage up until 1967, when the Supreme Court overturned the last anti miscegenation laws in the case of *Loving v. Virginia*.

A few trends characterize interracial marriages in the United States. Since 1967 the rate of interracial marriages has increased exponentially, and demographic trends and cultural patterns indicate that this rate will continue to increase in the same direction. However, the growing number of interracial unions does not bear out proportionately among racial groups. The amount of research on interracial marriages between blacks and whites belies the fact that these unions make up a very small percentage of interracial marriages overall. Interracial marriages among blacks remain relatively uncommon, especially when compared with the rates of interracial marriage among Asians, Latinos, and American Indians. Younger generations find interracial unions more acceptable: researchers find that interracial marriages are more common among newer immigrant groups from Asian and Latin American countries, particularly among the young, native born population.

Qualitative analyses indicate that interracial couples face an array of challenges as a consequence of their decision to “cross the color line” in their selection of a spouse. Public opinion of interracial unions is much more favorable than it has ever been, but many people tend to be less accepting when an immediate family member chooses to date or marry interracially. Interracial couples may deal with strained relations with their families and perhaps even estrangement. They must also contend with a worldview that posits race as an essential quality, not a socially constructed element of a person’s identity. They may find themselves defending their relationship in ways other couples are never called on to do. Finally, their own ideas about race may be tested – they may witness privilege and/or racism in new ways.

Research on interracial unions would be well served if the literature based on both demographic and qualitative approaches was synthesized. As new immigration patterns take shape, the world becomes more diverse, and racial boundaries continue to shift, it will be important for those studying interracial unions to employ innovative perspectives. In an increasingly global society, the field would benefit from a cross cultural and cross national examination of interracial unions.

intersectionality

Cynthia Fabrizio Pelak

Most gender scholars agree that to understand historical and contemporary gender relations one must be attentive to how race, class, and

other systems of power intersect with gender. The general consensus around intersectionality has emerged from an evolving interdisciplinary body of theory and practice that emphasizes the simultaneity of oppressions, the interlocking systems of inequalities, and the multiplicity of gendered social locations. Legal scholar Kimberlé Crenshaw (1989, 1991) was one of the first to use the term intersectionality to draw attention to the marginalization of black women's experiences within single axis frameworks of anti discrimination laws, feminist theories, and anti racist politics. Sociologist Patricia Hill Collins (2000: 18) defines intersectionality as "particular forms of intersecting oppressions, for example, intersections of race and gender, or of sexuality and nation." She goes on to say: "intersectional paradigms remind us that oppression cannot be reduced to one fundamental type, and that oppressions work together in producing injustice." Intersectionality has its roots in numerous intellectual traditions, such as socialist feminism, race and ethnic studies, and postcolonial feminisms. The various identifiers of the projects in which intersectionality is central – black feminism, womanism, multiracial feminism, third world feminism, postcolonial feminism, indigenous feminism, and multicultural feminism – suggest divergent origins and analytical foci. In this entry, the term intersectionality is used to refer broadly to scholarship that uses theoretical approaches that foreground interlocking systems of inequality. Special attention is given to the contributions of scholars who were instrumental in developing the intersectionality perspective, namely black women intellectuals from North America and women of color scholars from the "third world."

An intersectionality framework is attentive to multiple levels of analyses: individual, inter-racial, institutional, cultural, and structural. Individuals are seen as occupying multiple and often contradictory status positions as well as being embedded in institutional, cultural, or structural contexts that are multidimensional and fluid. By focusing on how systems of inequality are cross cutting rather than operating in isolation from one another, intersectionality draws attention to differences among women (or among men) rather than simply differences between women and men. Beyond recognizing differences, this tradition understands systems of

oppression as grounded in relational power differentials. Men's domination is thus related to (and dependent upon) women's subordination and the status of poor women of color is related to (and dependent upon) the status of affluent white women. Using a multi lens approach or a race/gender/class approach allows researchers to understand consequential power differentials among women as well as those between women and men. Hence, this framework can help explain why women's common structural location as women is not sufficient for mobilization against gender inequalities.

Theorizing around intersectionality is directly rooted in the practical concerns of building diverse grassroots coalitions of women (and men) to fight against gender and other oppressions. Like feminist studies, the work on intersectionality did not develop in the rarefied atmosphere of academia, but among collectivities of people who sought to understand and change the systems of oppression called racism, patriarchy, and class exploitation (Collins 2000). To elucidate this framework, five basic assertions common to intersectionality approaches are identified (Baca Zinn & Thornton Dill 1996). They include the conceptualization of gender and race as structures and not simply individual traits, the rejection of an *a priori* assumption that women constitute a unified category, the existence of interlocking systems of inequality and oppression, the recognition of the interplay of social structure and human agency, and the necessity for historically specific, local analyses to understand interlocking inequalities.

CONCEPTUALIZATION OF GENDER AND RACE

Within intersectionality paradigms, gender and race are not simply conceptualized as a social characteristic of an individual, but are understood as structures, discourses, or sets of enduring relations that operate at multiple levels in connection with other structures, such as class, sexuality, and nationality. There is general agreement among social theorists that gender and race are social constructions rather than predetermined, transhistorical, biological or natural phenomena. The changing meanings of

gender and racial categories across time and place substantiate the fluid, social character of gender and race. Omi and Winant (1994) conceptualize race as an ever changing complex of meanings that signifies and symbolizes sociopolitical conflicts and interests rather than a fixed, concrete, objective, or natural attribute. Likewise, scholars drawing on an intersectionality approach reject essentialist notions of gender and argue that sexed bodies do not exist outside of the social (Ferber 1998). Harding (1991: 79) explicates such a conceptualization within an intersectionality framework by claiming "there are no gender relations *per se*, but only gender relations as constructed by and between classes, races, and cultures."

ANALYTICAL CATEGORY OF WOMEN

Another basic assertion of gender scholars working within this framework is that the category of "women" is not assumed to be a homogeneous, unified group of individuals who experience a common oppression. The analytical category of "women" is not assumed prior to an investigation. As Mohanty et al. (1991: 58) argue, "sisterhood cannot be assumed on the basis of gender; it must be forged in concrete historical and political practice and analysis." Within an intersectionality framework, women's shared structural location as women is not sufficient for understanding their experiences of inequality.

INTERLOCKING SYSTEMS OF INEQUALITIES

A central component of intersectionality is the linkages of individual experiences with social structures. An intersectionality perspective assumes that individuals' lives are embedded within and affected by interlocking systems of inequalities, such as those based on race, gender, class, and sexuality. Individuals occupy multiple and often contradictory status positions that simultaneously advantage and disadvantage their lives. Collins (2000) identifies the interlocking systems of inequalities as a "matrix of domination," which is a model of interlocking rather than additive connections between inequalities and statuses. The notion of a matrix

of domination is a criticism of the construction of binary oppositions of oppressed/oppressor or black/white; it rejects the “either/or” dichotomy while embracing a “both/and” position. Individuals can be simultaneously privileged and disadvantaged.

The notion of interlocking inequalities operates at two distinct analytical levels. At a macro level the concept refers to the connections between institutional and organizational structures of race, class, and gender. For example, the paid labor market is structured such that women of different racial and class backgrounds are differentially situated in the hierarchy of jobs. The labor market is thus simultaneously structured upon gender, race, and class hierarchies. The notion of interlocking oppressions at the micro level refers to how interactions between individuals and groups are shaped simultaneously by race, gender, and class structures. For example, the interactions between a female domestic worker and her employer are often shaped by unequal race and class statuses. At both levels of analysis, gender relations and inequalities cross cut other systems of power rather than operating in isolation. A woman’s gendered experiences are always framed in the context of her racial and class locations. Therefore, gender relations and gender inequalities are best examined simultaneously through lenses of race, class, and other systems of inequality. Using this multi lens approach or the notion of the matrix of domination allows researchers to (1) ground scholarship on gender in the histories of racism, classism, imperialism, and nationalism; (2) highlight how status positions are relational such that positions of privilege and disadvantage are connected; and (3) understand consequential differences among women (or among men) rather than simply differences between women and men.

HUMAN AGENCY

Intersectionality also highlights the interplay between social structures and human agency. The importance of recognizing the interplay of social structures and human agency is that it allows for the possibility of social change. Scholars employing an intersectionality approach critique scholarship that overemphasizes the

powerlessness of women and only represents women as victims, exploited, and dependent on men. Mohanty et al. (1991: 56), for example, criticize the research produced by western scholars that represent “third world” women as ignorant, poor, uneducated, tradition bound, domestic, or family oriented, rather than agents of their own identity.

Intersectionality theorists tend to focus on the strategies of creative resistance that women employ to survive and thrive in oppressive situations. Social science scholarship typically focuses on overt, public political activity, while scholars drawing on intersectionality foreground the less visible politicized activities that are taken up by subordinated groups. For example, Berger’s (2004) study of women of color with HIV/AIDS highlights how multiply stigmatized women develop a public voice and facilitate their political participation by drawing on resources rarely associated with political participation. Berger’s work demonstrates that political resistance need not be formal or institutionalized. Collins (2000) recognizes two interdependent forms of black women’s social activism: the subtle undermining of institutions through the creation of female spheres of influence within existing structures of oppression when direct confrontation is neither possible nor preferred, and the institutional transformation consisting of direct challenges in the form of trade unions, boycotts, sit ins, marches, etc. By shifting our understanding of power relations based on a hierarchical, vertical model to a more fluid model of interrelatedness, intersectionality theorists argue that we can begin to analyze the dynamics of domination and resistance in new ways.

HISTORICALLY SPECIFIC AND LOCAL ANALYSES

The basic assumptions of intersectionality necessitate the need for historically specific, local analyses that allow for the specification of the complexities of particular modes of structured power relations. It is through such analyses that theoretical categories can be generated from within the context being analyzed. Intersectionality scholars reject universalizing and ahistorical approaches that try to explain,

for example, patriarchal organization for all places at all times. The call for historically specific, local analyses also demands that researchers not impose a specific ideological or universal theoretical formula to interpret their findings. Postcolonial feminists, for example, offer a strong critique of the tendency of western feminists to interpret and judge "third world" women's activism through a western feminist or "first world" framework rather than indigenous understandings and definitions of feminist activism (Mama 1995). What is transgressive in one sociopolitical context may take on an entirely different meaning in another sociopolitical context.

Two early works that were influential in the development of an intersectionality approach are Angela Davis's book *Women, Race, and Class* (1981) and *This Bridge Called My Back* (1983) edited by Moraga and Anzaldúa. Both of these texts center on the experiences of women of color to theorize differences among women and encourage alliances across racial, ethnic, class, sexual, and national boundaries. Davis (1981) addresses topics ranging from womanhood and the legacy of slavery, race and class dynamics of the early nineteenth century women's movement in the US, rape and sexual assault, reproductive rights, and the politics of housework. Moraga and Anzaldúa (1983) grapple with the complexities of race, class, culture, homophobia, revolutionary politics, immigration, and motherhood through the voices of Chicana, black, Asian, Native, and third world women.

Another more recent exemplar of an intersectionality approach is Abby Ferber's book *White Man Falling* (1998). Ferber employs an intersectionality perspective to understand how the white supremacy movement articulates white male identity. Her analysis demonstrates that to fully appreciate the complexities of white supremacist identity one must explicate how race, gender, class, sexuality, family, religion, and nation intersect within the white supremacy movement.

The body of scholarship that builds upon insights of intersectionality is vast, diverse, and goes well beyond gender studies. Although there may be significant theoretical, methodological, and epistemological differences within this evolving interdisciplinary body of theory and practice, the thread that ties them together

is the appreciation for the simultaneity of oppressions, the interlocking systems of inequalities, and the multiplicity of social locations. Even when intersectionality is not named or pioneering intersectionality scholars are not given credit for their ideas, the impact of this perspective has been deep and lasting.

intersexuality

Laura M. Moore

Intersex refers to a variety of inborn conditions whereby an individual's sexual or reproductive anatomy varies from social expectations about "normal" male or female anatomy. Because the standards are arbitrary, "intersex" is not a discrete category – what counts as intersex depends upon who's counting. That said, about 1/2,000 babies is born with obvious enough differences to come to medical attention. This biological variation creates direct challenges to binary constructs of sex and gender and to the cultural institutional systems designed around assumptions that discrete sex categories naturally yield complementary gender roles and heterosexuality.

The medical treatment of intersexual infants in contemporary western cultures was first highlighted in Suzanne Kessler's (1990) publication, "The Medical Construction of Gender: Case Management of Intersexed Infants." This psychosocial theory presumes intersexuals must be normalized into one of two possible categories, male or female, so they can develop appropriate gender identities and meet society's gender role expectations. Hence, biological sex is forced to conform to socially constructed gender. Deconstruction analysis has revealed several sexist and heterosexist gender stereotypes embedded in the standard medical protocol, which prioritizes males' ability to penetrate and females' ability to procreate (Dreger 1998; Fausto Sterling 1999). Among some gender theorists and scholars, intersexuality has become intertwined in nature versus nurture debates as well as identity politics arguments regarding the existence of an essential versus a socially constructed self (Turner 1999).

The most common surgeries performed on children with intersex conditions are removal of clitoral tissue and enlargement of the vagina. Though medical management of intersex drew the attention of media and the academy at the same time as African genital cutting, these parties have been largely unable to equate female genital cutting in Africa with clitoral surgeries in contemporary western culture (Chase 2002).

Individuals with intersex conditions entered the arena of gender and sexual identity politics with the formation of the Intersex Society of North America (ISNA) in 1993. Building on strategies employed by gender and sexual minority rights movements of the late twentieth century, ISNA members have demanded an end to cosmetic genital surgery on infants, noting the absence of empirical evidence supporting the practice and ethical, medical, and human rights concerns (Chase 2003; see also the ISNA website, www.isna.org). Sex assignment at birth has critical legal and social implications including marital rights, certain constitutional protections, military service, athletic program participation, and leadership opportunities in religious organizations. People with intersex argue the existing medical treatment protocol must be changed to reduce the shame and secrecy around their condition and to allow people with "ambiguous genitalia" the right to make their own decisions about plastic surgeries.

intersubjectivity

Paul T. Munroe

Intersubjectivity refers to a shared perception of reality between or among two or more individuals. The term has been important in many aspects of sociology, from positivist and post-positivist research methods to studies of the lived experiences of individuals by ethno-methodologists and feminist scholars.

The term presupposes that we, as human beings, cannot know reality except through our own senses: sight, hearing, smell, taste, or tactile feeling. Accordingly, each individual's reality is necessarily subjective. We may extend and refine those senses through measuring devices such as telescopes, scales, cameras, and myriad other technologies, but ultimately each person's understanding of reality is individually subjective. One cannot see "blue" except through one's own senses. With social reality, we have even less certainty. It is easier to know that the sky is blue than it is to know that "James likes me."

However, most individuals also understand that we cannot change reality simply by thinking. Reality has an "obdurate" character (Turner & Boynes 2002). If one were to wake up and decide that "blue" is "yellow," it would be clear that one could not effect this change and make it real for many others. This is a duality of truths that presents a problem for people interested in studying how people live their lives; neither objectivity nor subjectivity is sufficient to explain the life experiences of the individual. Intersubjectivity is an intermediate position that sociologists use to solve this problem. We propose that the best people can, and often do, achieve is a common understanding of what is going on.

A related line of theorizing is work on the duality of agency and structure. As Giddens

(1984) and Sewell (1992) argue convincingly, "actions," willed behaviors of free individuals, often follow and reproduce a given "structure," rules and patterns set in the external environment, even though actors have a choice to not do these acts. Part of what happens is that people perceive certain behaviors as normal, and if not compulsory, at least expected. Structure is thus enacted in everyday behavior. This enactment of structure could not happen without intersubjectivity.

INTERSUBJECTIVE TESTABILITY

Philosophers of science (Feigl 1953; Popper 1959) and social scientists (Cohen 1989) have used intersubjectivity, or often intersubjective testability, to discuss the day-to-day operations of a relatively successful science of human behavior. There is no way to know objectively the meaning of a particular behavior. Nor is there a way deterministically (with certainty) to predict that one process follows another every time, without fail. However, regularities do occur. Patterns of social behavior are often repeated; they can be observed to happen in similar ways in many instances, and these observations can be documented.

Since this is true, social science should be able to explain and predict, with better than chance results, the outcomes of certain situations based on some initial information and a theory of how things work. The concept of intersubjective testability is one answer to the question "how?" People in a particular field of study come to agree first on the rules of evidence. They obtain specialized training in order to be able to conduct tests of "knowledge claims" (Feigl 1953; Cohen 1989) about the regularities of patterns of behavior. Understanding is facilitated by clear definitions and precision in the theory, and by transparency in the research methods. Since the rules of evidence are agreed upon, different scientists looking at the same information can agree on its meaning. Social scientists obtain intersubjectivity on the results of a particular piece of research.

It is a value judgment on the part of people who share this view of social science that this intersubjectively tested knowledge, though short of perfectly certain or objective knowledge, is

far better than many of its alternatives, such as intuition, tradition, "common sense," or guessing. Specialists trained in a certain field of science thus are and should be treated as authorities on how to evaluate knowledge claims in the field they dedicate their lives to studying. The knowledge that is generated through this rigorous process will be better and more reliable than knowledge produced through less systematic methods.

INTERSUBJECTIVITY IN EVERYDAY LIFE

In a quite different vein, phenomenologists (e.g., Schütz 1967) and ethnomethodologists (e.g., Garfinkel 1967) have used the term intersubjectivity to refer to the understandings people come to share in their everyday lives. Once again, the term presupposes that objectivity is not possible in human understanding. Here an emphasis is placed on the malleability of meaning, especially social meaning, and it is stressed that differences of subjective views are ubiquitous. Intersubjectivity in this context refers to the shared perspectives people sometimes actually achieve, and often assume they have achieved. People take for granted that reality is in fact obdurate. They may realize at times that there is no way objectively to know what is "real." But for day to day activity, this is treated as unimportant. People operate as if reality is knowable, as if people similar to themselves see things the same way, and that if reasonable people discuss matters, they will probably come to the same conclusions.

This assumption of intersubjectivity can become problematic when the reality of differences between people's expectations and interpretations becomes apparent. Garfinkel (1967) has pointed out that intersubjectivity is most visible, and its importance is highlighted, when it is violated. When taken for granted behaviors do not occur, or unexpected behaviors do occur, they call into question assumptions about reality. The resulting breakdown in intersubjectivity can be most unsettling. This line of work has led to an often repeated phrase among social constructionists that "reality is negotiated."

FEMINIST CONTRIBUTIONS TO INTERSUBJECTIVITY

Feminist scholars (see Lengermann & Niebrugge 1995) have pointed out that there are important aspects of power that are involved with intersubjectivity in interaction. Low power actors are often required to share the perspectives of high power actors, coming to an intersubjective agreement on "what you want, what you think, what you do." High power actors are often afforded the right to concern themselves with "what I want, think, and need."

One kind of relation of power that qualitative researchers engage in is the interview setting. If researchers are more interested in what they want to know from their interviewees, they may miss the opportunity to learn what the interviewees want them to know. As a value statement, some qualitative researchers who wish to study human behavior from a feminist perspective claim that they should attempt to achieve an intersubjective view with their interviewees.

INTERSUBJECTIVITY IN THERAPEUTIC INTERACTIONS

Mitchell (2000) identifies four levels or modes of interaction which can be studied in a therapeutic situation: behavioral, in which relatively smooth interactions are facilitated by patterned, habitual repertoires of activities; primitive emotional, in which people's affect states transfer from one person to another – one person's anger invokes another's fear, one person's sadness makes another sad; self oriented, in which the other person is thought of as a characteristic other in relation to the self (how does this person see me, what kind of person is this, and what is my role in this situation); and finally at the most useful and highest functioning level, intersubjectivity, in which two people are reacting in a genuine fashion to each other's conscious, willful, meaningful interactions. These modes of interaction hold much promise for the future study of interpersonal behavior in many other circumstances.

intertextuality

Matt Hills

The concept of intertextuality has been significant within a range of theoretical debates (Orr 2003). Though often assumed to be a matter of one text directly citing or quoting material from another, intertextuality has also been theorized as underpinning the general condition of textuality itself. As French structuralist Julia

Kristeva (1969) argues: “Every text takes shape as a mosaic of citations.” This has become a crucial concept in structuralist attacks on the authority of the author (Barthes 1977; Allen 2000). It is argued that language and textuality, as structuring systems, should form the proper objects of analysis, and not authorial agency.

Intertextuality’s importance has not been restricted to structuralist debates, for it has also played a key role in definitions of the postmodern condition (Jameson 1985; Allen 2000). In Fredric Jameson’s influential account, a specific type of intertextuality – thought of as a form of imitation – characterizes postmodernism: “Pastiche is . . . the imitation of a peculiar or unique style . . . but it is a neutral practice of such mimicry . . . Pastiche is blank parody” (Jameson 1985: 114). Here, intertextuality becomes an endemic social and cultural condition in postmodernism: signs, codes, and texts are subject to constant repetition, without any sense of “parody” as a critical or reflexive discourse. Instead, styles and texts are seemingly reiterated and re-represented, cut adrift from their original contexts and endlessly recombined as “pastiche.”

However, this criticism lacks sociological context itself. Writers such as Collins (1989) and Lash (1990) have engaged more precisely with the sociology of “postmodern” intertextuality. Collins (1989) analyses how “inter-textual arenas” operate in genre fiction, suggesting that authors and texts can position themselves in relation to their generic predecessors. Thus, texts such as detective fictions may bid for “literary” value by linking themselves to literary discourse, while others may seek deliberately to “mix” discourses, combining “High Art” and pop cultural intertextualities so as to destabilize the cultural authority of the former, rather than simply deploying its cultural and social prestige. Moving this debate on, Lash (1990) argues that the wide-ranging intertextuality of postmodern culture may simply reflect the distinctive “cultural capital” of new middle class groups of consumers – those who are able to spot many popular and elite cultural references. Indeed, we could go so far as to suggest that types of intertextuality carry “intertextual cultural capital” (Hills 2005): they specifically target educated, specialized, and highly media-literate audiences.

intervention studies

Robert F. Boruch

Intervention studies address one or more of the following five kinds of questions:

- 1 What is the nature and severity of problems to which an intervention is directed or may be directed, and what is the evidence of the problem?
- 2 How and how well is the intervention deployed, and what is the evidence for this?
- 3 Does the intervention work? Which intervention works better? And what is the evidence?
- 4 What are the cost-effect relationships among interventions, and what is the evidence?
- 5 What interventions work, or not, based on what cumulative evidence from repeated studies?

The phrase intervention studies is commonly used in epidemiology and medical research to refer to questions of the third kind (i.e., studies

of the effects of health related interventions). The phrase has also become common in prevention research, work on learning disabilities and behavioral disorders, and in other areas. Variations on the phrase are frequently in the context of studies of effects of interventions *other* than health related ones. For instance, intervention studies “covers questions, posed in different academic disciplines and government agencies, that are also addressed under the rubrics of ‘evaluation,’ ‘prevention research,’ and ‘randomized controlled trials’” (social experiments) (Rossi et al. 2004; see also Boruch 1997).

Questions of the third kind, on intervention effects, receive most attention then in what follows. The others are handled as precursors to or successors of this basic class of question. The interventions at issue vary with the problem’s character and context. Across the social sciences, these can include *practices*, such as providing conventional welfare, police, or health services. They may include *programs* designed to provide better or more specialized services to individuals, organizations, or geopolitical jurisdictions. And at the broadest level, interventions may be construed as macro level *policy* in welfare, environment, education, and other arenas.

In addressing the first question, on nature and severity of the problem, evidence may be generated by probability sample surveys of those people or organizations at risk, administrative records of service organizations, and ethnographic (street level) research. Each method, for instance, has been exploited to estimate the size of homeless populations in various cities, and the number and kinds of victims of crime. In health oriented sociology and epidemiology, such studies include work to estimate incidence and prevalence of events such as injuries and survival rates. Good understanding of needs is usually a precursor to developing an intervention that could address the need, and is a precursor to testing the intervention’s effects.

Theory drives the choice of what variables ought to be measured. In considering teenage pregnancy, for instance, one might focus on girls, or boys, or both, depending on one’s theory about the problem or one’s theoretical construal of the phenomenon in different cultures and countries.

At least for studies based on sample surveys, government statistical agencies and professional

organizations have developed standards for judging the quality of the studies and their results. See, for instance, the standards enunciated by the US Census Bureau, as well as those for the UK, China, Sweden, Canada, and others.

The second question, on deployment of the intervention, falls under the rubrics of implementation studies, process research, and program monitoring, depending on the academic discipline and agency responsible for generating an evidential answer. Sociological theory might inform one's choices about what to measure and how (e.g., measuring social capital in the context of education interventions such as private versus public schools). Typically, the evidence to answer the question stems from performance indicators that permit one to judge progress of relevant agencies or the adequacy of the intervention services. Less often, the evidence may be generated through periodic surveys of clients' or customers' satisfaction with the intervention service, for instance. Anthropological studies may also be used to generate hypotheses and ideas about the character of service and delivery from the points of view of service recipients or other stakeholders in the process.

In health care, for example, studies that address the second question often aim to learn whether government or other professional guidelines for health care of the elderly (say) are operationalized in hospital or other care settings. Finding that fewer than half the guidelines are implemented well is important. Understanding whether, how, and how well particular interventions can be deployed in different settings is no easy matter. The need to understand has led to the production of systematic reviews of evidence on the topic, such as Fixsen et al. (2005), and to new peer reviewed journals such as www.implementationsciences.com that cover new empirical work on how to deploy or not. For a new intervention, deeper questions hinge on whether it has been implemented with fidelity in a trial and how need for fidelity and need for flexibility in adaption can be balanced in larger scale trials and in eventual deployment of the intervention beyond the trials.

The third question, on relative effects of interventions, invites attention to randomized

controlled trials that produce the least equivocal evidence possible about whether one intervention is better than another or better than the ambient service or system (Boruch 1997). In these trials, individuals, organizations, or geopolitical jurisdictions are randomly assigned to each different intervention, including a control (ambient conditions). Well run randomized trials generate a statistically unbiased effect of the interventions' relative effects and a legitimate statistical statement of one's confidence in the results. Put in other words, a trial's product is a fair comparison that takes into account chance variation in individual and institutional behavior.

In the US, for instance, randomized trials have been conducted to test the effect of programs that move poor people from high to low poverty areas. These Moving to Opportunity trials (Gibson Davis & Duncan 2005) include anthropological work on processes and people. Mexico's Progreso randomized trial was preceded by statistical work on severity of the school dropout problem in rural areas and informed by anthropological research on its nature and the intervention process. Villages were randomly assigned to an income support program or to control conditions to learn whether the program was effective in reducing a chronically high rate of school dropout (Parker & Teruel 2005).

Large scale studies in which entire organizations or entities are randomly allocated to different interventions are often called cluster randomized trials, or group randomized trials, or place randomized trials, depending on the disciplinary context. Prevention researchers further distinguish between efficacy trials and effectiveness trials (Flay et al. 2005). Efficacy trials are well controlled and depend on experts and their collaborators to deploy an intervention in contexts that are well understood, with measures of outcome whose reliability is controlled, and so on. The effectiveness trials are mounted later, in environments that are real world in the sense that the interventions may not be delivered as they ought to be, the measures of outcome are not as reliable, and so on. The interest in generating better evidence on effectiveness through such trials has led to the creation of specialized peer reviewed journals in which trial results and issues can be reported. These

include the *Journal of Experimental Criminology* and www.trialsjournal.com.

When randomized trials are not ethical or feasible, evidence on what intervention works may be generated through quasi experiments or through statistical model based approaches. These are common in sociology and other social sciences. Quasi experiments and observational studies produce more equivocal (i.e., potentially biased) estimates of effect than randomized trials.

Generally, these approaches try to approximate a randomized trial by using statistical methods to equate groups or to construct groups that are similar apart from the intervention. The methods and the independent variables used vary depending on the domain. The statistical approaches in the model based approaches include propensity scores, selection models, structural models, instrumental variables, and other techniques that try to approximate the results of randomized trials.

Comparing the results of randomized controlled trials against quasi experiments or observational studies on the same intervention is important for several reasons. Randomized trials ensure unbiased estimates of effect, but they are often more difficult to carry out than a quasi experiment. The quasi experiment may be easier to carry out, but does not provide the same level of assurance of unbiased estimates and instead relies on more assumptions. If the results of using each approach are similar, or lead to the same policy decisions, one might then opt for quasi experiments. Empirical comparisons of the results of each suggest, however, that results often do differ and neither the magnitude nor the direction differences are predictable. The discrepancies have been explored through reviews of intervention studies in health (Deeks et al. 2003), employment and training (Glazerman et al. 2003), education and economic development (Rawlings 2005), and other areas. Identifying specific domains in which the nonrandomized intervention studies are dependable is crucial for science and for building better evidence based policy.

Some professional societies and government organizations have developed standards for reporting based on studies of the effects of interventions. The standards have been constructed

to ensure that the relevant evidence is presented completely and uniformly. In health care, for instance, the international CONSORT statement has been a model for reports on randomized controlled trials (Mohrer et al. 2001; Campbell et al. 2004). Analogous efforts have been made to ensure uniform reporting on quasi experimental (nonrandomized) trials, notably TREND.

Standards for judging the trustworthiness of evidence from studies on the effects of interventions have also been developed. The international Society for Prevention Research, for instance, issued guidelines that distinguish between evidence on efficacy trials and effectiveness trials and also handles evidence on whether effective programs can be disseminated (Flay et al. 2005).

In education, substance abuse, and mental health, government agencies have developed systems for screening evidence from studies of the effects of the interventions. In the US, the Institute for Education Sciences put high priority on randomized trials, and put only certain quasi experimental designs in second place. It eliminated many other study designs as a basis for dependable evidence. The Substance Abuse and Mental Health Administration (SAMSHA) sponsors the National Register of Exemplary Programs and Practices (NREPP) to assist people in identifying model programs that have been identified on the basis of quality of evidence, including randomized trials (www.modelprograms.samsha.gov). In crime and delinquency, Blueprints screens evidence and identifies model programs.

Addressing the fourth question, involving cost effectiveness of different interventions, usually presumes evidence for answers to the first three questions. Few peer reviewed journals that report on trustworthy studies of the effects of interventions also report on the intervention costs, however. Accountants, finance people, and economists can then add value beyond the first three questions addressed in intervention studies. Guidelines on the conduct of cost effectiveness analyses of interventions have been developed for various substantive areas of study (National Institute of Drug Abuse 1999; on prevention and treatment, Levin & McEwan 2001; in education, Rossi et al. 2004).

The cumulation of results of studies of an intervention's effects and the analysis of this assembly of studies are important to science, of course. Systematic reviews of intervention studies of effect have developed remarkably since the 1990s. The scientific rubrics for development in this area include meta analysis and systematic reviews, each of which emphasizes the quality of the evidence. The QUOROM Group in health research standards reports on meta analyses of randomized trials (Moher et al. 1999). As yet, analogous guidelines have not yet been developed for the educational, social welfare, and criminological areas.

Beginning in 1993 the international Cochrane Collaboration (www.cochrane.org) in health has led the way in generating uniform, systematic, high quality reviews of assemblies of studies on effectiveness of interventions. The international Campbell Collaboration (www.campbellcollaboration.org), Cochrane's younger sibling, focuses on social welfare, crime and justice, and education. The Cochrane Collaboration has produced over 1,500 systematic reviews since 1993. The topics range from effectiveness of psychosocial development interventions such as multi systemic therapy, to summarizing efforts to manage colitis, heart disease, and other illness. Both the Cochrane Collaboration and the Campbell Collaboration have developed world wide accessible registers of randomized trials. In this respect, the organizations compile information that addresses a variation on questions of the third kind in the context of intervention studies – What works? Or works better? – based on fair evidence.

interviewing, structured, unstructured, and postmodern

Andrea Fontana

Interviewing is a methodology based on asking questions in order to gain information from the respondent. The interview may be structured, unstructured, and postmodern. Structured interview seeks information with an emphasis on measurement, unstructured interview stresses understanding the world of the respondent, and postmodern interview focuses on the negotiated interaction between interviewer and respondent.

DEVELOPMENT

Interviewing first became popular in clinical diagnosing and in counseling; later, it was used in psychological testing. Charles Booth (1902–3) is credited with introducing interviewing to sociology, by embarking on a survey of social and economic conditions in London. Others followed, both in England and the US. Among the most notable early interview projects were Du Bois's (1899) study of Philadelphia and the Lynds' (1929, 1937) studies of Middletown.

During World War II the impetus of interviewing was magnified by large scale interviews of American military personnel, some of which were directed by Samuel Stouffer and titled *The American Soldier*. In the 1950s, interviewing in the form of quantitative research moved into academia and dominated it for the next three decades. Some of the most notable proponents of this methodology were Paul Lazarsfeld and Robert K. Merton at the Bureau of Applied Social Research at Columbia University, Harry Field at the National Opinion Research Center in Denver and later in Chicago, and Rensis Likert with the Survey Research Center at the University of Michigan.

There were other developments in interviewing. Opinion polling was popularized by George Gallup; the documentary method focused on respondents' attitudes, and was initially used

by W. I. Thomas and Florian Znaniecki; unstructured interviewing, often coupled with ethnographic research, was originally used by researchers at the Chicago School of sociology. Focus group interviewing moved from marketing to sociology and was employed both in quantitative and qualitative research. Oral history and creative interviewing were based on multiple, very lengthy interview sessions with the respondent. More recently, postmodern approaches have brought heightened attention to the negotiated collaboration in interviews between interviewer and respondents and the dynamics of gendered interviewing.

STRUCTURED INTERVIEWING

Telephone interviews, face to face interviews, and interviews associated with survey research are included in this category. Structured interviews make an effort to standardize both the instrument (the interview questions) and the interviewer. The questions posed are generally preestablished, provide a limited number of possible responses, and leave little room for variations. This approach makes it possible to numerically code each response a priori. The interviewer attempts to remain as neutral as possible and to treat each interview in exactly the same manner. The same questions are read in the same sequence to all respondents; explanations to be given to the respondents are prepared in advance by the supervisor and the interviewer should not deviate from them or try to interpret the meaning of any question. The interviewer must ensure that no one interrupts the interview or tries to answer for the respondent. The interviewer should not attempt to influence any answer or show agreement or disagreement in regard to any answers. The interviewer must never deviate from the preestablished questions and their exact wording. These efforts aim at minimizing errors and leaving little room for chance.

However, three types of problems arise in structured interviewing. Firstly, the task itself: the close ended nature of the questions limits the breadth of the answers. Secondly, the interviewers: they do not in fact remain neutral but are influenced by the nature of the context and the variations among respondents. Additionally,

the interviewers have been found to change the wording of questions. Thirdly, the respondents: there is an assumption that respondents will answer truthfully and rationally and will not let emotions or any personal agenda affect their answers.

FOCUS GROUP INTERVIEWING

Focus group interviews are basically a qualitative method; an interviewer/moderator assembles a small group of respondents in a conference room or similar setting in order to gather their collective opinions of the subject under study. The moderator directs the interaction among respondents and his or her approach can vary from very structured to completely unstructured, depending on the purpose of the interview.

Focus group interviewing originated in market research in order to collect consumers' opinions of various products. Sociologists use focus group interviewing for different purposes. Most common is to use the interview as an exploratory tool to fine tune research topics or to pretest survey research structured questions. The interview can also be used for triangulation purposes to support and validate another method, either quantitative or qualitative. Finally, focus group interviews can be used as the sole basis of data gathering, often to elicit the respondents' recall of an event they all witnessed, such as a disaster or a celebration.

Focus group interviewers must possess skills similar to those of individual interviewers. Addressing a group, however, presents additional problems. The interviewer must ensure that all respondents are participating in the process and no one is dominating the interaction; also, the interviewer should be aware of the possibility of "group think." Focus groups are popular since they provide an alternative or addition to both qualitative and quantitative research methods and are relatively easy to assemble and fairly inexpensive.

UNSTRUCTURED INTERVIEWING

Unstructured interviewing, also called in depth interviewing, is an open ended methodological

technique. The interviewer has a general idea about the topics of research but does not use any structured questions or formal approach to interviewing. There is no effort to ask the same questions of all respondents or to quantify the responses. The focus of this type of interviewing is to *understand* the way of life of the respondents and the meaning they themselves attribute to the events. We present three types of unstructured interviewing: traditional, oral history, and creative interviewing.

Traditional Interviewing

Traditional unstructured interviewing is often used in conjunction with ethnographic field work and follows the same techniques. The interviewer has to *access the setting* of the group being studied, whether that be a welfare office or a massage parlor. Sometimes the study focuses on no group per se, as when studying homeless persons on the streets, and *entrée* must be negotiated anew with every individual. Next, the interviewer must make efforts to *understand the language and culture* of the respondents. Cultural anthropologists at times had to rely on interpreters, with perhaps disastrous misunderstanding of the cultural mores (Freeman 1983). Sociologists studying a subculture, such as physicians, also need to gain understanding of the language used. In addition, they must familiarize themselves with the cultural nuances of the group, such as not to ride a British bike while studying the Hell's Angels (Thompson 1985). *Locating an informant* is the next move. It is valuable to befriend a marginal member of the group under study with whom the interviewer can check the veracity of information being received by the others. *Gaining trust* and *establishing rapport* are next; the respondents must feel at ease and trust the interviewer or they will freeze them out, withhold information, or lie. Trust and rapport take time to achieve and are easy to lose, just by a wrong decision. Finally, the interviewer must find an inconspicuous way to collect information, ranging from debriefing oneself every night into a tape recorder to surreptitiously writing fieldnotes on toilet paper in a rest room.

This type of unstructured interviewing is still somewhat formal in its step by step

approach and its attempt to find checks and balances in an effort to “scientize” the study. Interpreting the information received is also problematic. Since there is no close ended questionnaire, the researcher finds there is a great deal of what often seems disconnected information and has to decide what to use and what not to use. There is also a tendency, as in structured interviewing, to view the interviewer as “invisible” while in fact who is doing the interviewing has a great influence on the interaction and results.

Oral History

Oral history is a very old approach to interviewing. It is based on lengthy, often multiple interviews with members of a specific group, such as a Native American tribe or elderly people in a chronic care facility. Its goal is to capture the daily forms of life of the group under study through the recollection of its members. Oral histories are not always published, but transcripts can be found in libraries – memories of a past waiting for someone to bring them back to life.

Creative Interviewing

Oral history straddles anthropology and sociology, while creative interviewing is more germane to sociology. Douglas (1985) coined this approach and it shares with oral history a technique based on multiple, lengthy, unstructured interviews with single respondents. Douglas’s approach is more skeptical, raising doubts about the veracity of the respondents and suggesting techniques to help pry the “truth” from them. The interviewer should become close to the respondents and share with them facets of their own life in a sort of confidential *quid pro quo*.

POSTMODERN INTERVIEWING

Postmodern informed researchers in both anthropology and sociology (Marcus & Fischer 1986) moved away from scientific claims about fieldwork and unstructured interviewing.

Instead, they are reflexive about the role and influence of the interviewer in their interaction with respondents. They suggest ways to minimize if not eliminate this influence, by increasing quotations from the actual, untouched statements of the respondents. Also, postmodern interviewers use a *polyphonic* approach, using multiple voices of respondents with minimal intrusion by the interviewer. The interviewer became visible, actively drawn out in the reporting, to help inform the readers about the possible biases and gendered, social, and contextual distortions created by whom ever, wherever, and whenever the interview occurred.

We present two types of postmodern informed interviewing: gendered interview and active interview.

Gendered Interviewing

There has been a pervasive tendency in traditional interviewing, whether structured or unstructured, to be paternalistic. It was not uncommon (in cultural anthropology) to give women researchers “temporary male status” to allow them to access settings and to talk to people with whom women would not otherwise be allowed to interact. The influence of gender in interviewing has been traditionally overlooked. Postmodern interviewers accuse traditional interviewers of ignoring gender differences in order to maintain the pretension of value free and neutral research. Yet, as Denzin (1997) and other postmodern sociologists hold, interviews take place in a culturally paternalistic society where gender differences do matter.

In gendered interviews the interviewer must share herself with the respondent to gain her intimacy. Gendered interviewing is committed to maintaining the integrity of the phenomena studied and presenting the viewpoint of respondents. Yet this is not a ruse, as in creative interviewing, to get more information. Instead, the interviewer throws asunder pretenses of value neutrality and becomes an advocate for the women (or other oppressed individuals, such as African Americans or gay groups) being studied. It is reminiscent of C. W. Mills’s ameliorative sociology.

Some have pointed out that there may be times when the researcher does not see things eye to eye with the group studied and advocacy becomes very problematic. Others have confessed that the “sharedness” between interviewer and respondent is artificial, since it is still the researcher who has the power of producing a text from the interview. Edwards and Mauthern (2002) feel that rather than pretend that differences between interviewer and respondents have been overcome, they should be pointed out, as they cannot be eliminated.

Active Interviewing

Holstein and Gubrium (1995) coined the term active interviewing to refer to the fact that interviews are actively negotiated accomplishments between the interviewer and the respondent. The two (or more) individuals actively collaborate in creating a text in a unique situation and a specific setting. According to Holstein and Gubrium, traditional interviews of all types stress too much the data gathered in the interview, regardless of how they were collected. The interviewer should also pay much closer attention to the latter, the ways in which data were collected – by whom, where, how, in what circumstances, and any other element that may have influenced the data. This approach is a very reflexive one, which rejects the notion that we merely gather data in interviews and use refined techniques to improve the quality of those data. Here the interview is a cooperative, negotiated text, created in the interaction and dependent upon it and the individuals involved.

Reporting Interviews

Postmodern interviewers are also experimenting with new modes of reporting their findings. Rather than mimicking the sparse language of science as do traditional sociologists, postmodern reports at times take the form of performances, plays, introspective recounting, and even poetry. The intent is to provide a more immediate and colorful picture for the readers, who can hopefully be more attracted to sociology and gain a better empathetic understanding

through the immediacy of the new reporting techniques.

Limits of Postmodern Interviewing

Postmodern interviewers have met with criticism from traditional interviewers. The question “but is it sociology?” has been repeatedly asked and not satisfactorily answered. Also, assuming that it is sociology, how does postmodern interviewing submit to the standard criteria of sociology, such as verifiability and replicability? Furthermore, how do sociologists judge the merits of the poetry or performance? Were these arbiters to judge them by literary standards they would fall very short; no other standards have thus far been suggested.

ELECTRONIC INTERVIEWING

A new development in interviewing is through electronic outlets, especially the Internet. Given the tremendous expansion of home computers this means of interviewing allows access to a huge population. The technique costs little and can have a very speedy response. Of course, there is no face to face or even voice to voice contact, so we are faced with a “virtual interviewing” with almost no checks and balances of who the respondent really is and the veracity of their statements. Currently, electronic interviewing tends to rely on questionnaires, but some are already exploring the world of chat rooms (Markham 1998) and delving into the fabricated realities and online lifestyles of virtual online selves.

ETHICAL ISSUES

Since the objects of inquiry in interviewing are human beings, there must be ethical considerations in their regards. All interviewers would agree to grant the respondents rights to informed consent, anonymity, and protection from harm. Much of structured and unstructured interviewing research has no stake per se in the world of the respondents, albeit at times social policy may arise from the findings of some studies. Postmodern interviewers aim for

advocacy for oppressed and underserved individuals and groups whom they study, thus moving away from the traditional sociological goal of value neutrality and objectivity.

Another important ethical consideration is the relation and degree of involvement between researcher and respondents. Whyte (1943) has recently been accused (by Boelen 1992) of misrepresenting and exploiting his respondents, especially his closest informant, Doc. Having casual sexual relations with some of the respondents (as admitted by Goode 2002) certainly goes beyond the ethical involvement between interviewer and respondent.

Interviewing is a very varied methodology, but it ought to be, since human beings are very complex and find themselves in a myriad of different vicissitudes. Each and every subtype of interviewing should be able to get to some kind of answer, to reach some life description from the respondents. This is the goal: not just asking questions, but being able to get answers – meaningful answers.

intimacy

Lynn Jamieson

What is imagined by “intimacy” as a quality of relationships is often associated with particular ways of behaving (Davis 1973). Intimacy is sometimes defined narrowly to mean the familiarity resulting from close association. In this sense, domestic life across much of the life course in all societies is intimate. Living arrangements that involve sharing domestic space, a “hearth and home,” the caring activities associated with bearing and raising children, and other forms of routinely giving or receiving physical care necessarily provide familiarity and privileged knowledge. Sometimes the term “intimacy” is also used even more narrowly to refer to sexual familiarity with another person. In everyday current usage, intimacy is often presumed to involve more than close association and familiarity, for example, also involving strong emotional attachments such as love. However, in both popular and academic commentaries, intimacy is increasingly understood as representing a very particular form of “closeness” and being “special” to another person founded on self disclosure. This self disclosing or self expressing intimacy is characterized by knowledge and understanding of inner selves.

Privileged knowledge gained through close physical association is not a sufficient condition to ensure this type of intimacy. People living side by side can feel trapped together as strangers who know nothing of each other's inner worlds.

Studying how people generate and sustain intimacy leaves open the issue of what types of intimate relationships (sexual relationships, couple, kin, specific family relationships, friendship) are significant to people in different times and places. Popular and academic commentators of trends in affluent "western" societies make a range of claims and counterclaims about the nature of intimacy, its meaning and significance in everyday lives, and patterns of social change. These include claims that a focus on private intimacy has helped displace civic and community engagement, that individualized forms of intimacy have undermined conventional "family values," and counterclaims of heightened equality and democracy spreading from personal life to other domains.

"Self disclosing intimacy" as an element of "good" couple, family, and, ultimately, friendship relationships has had widespread endorsement among the growing ranks of relationship experts, psychologists, psychiatrists, psychotherapists, and sexual counselors. This view point was increasingly marketed and advertised in the late twentieth century through a range of cultural products advocating talking and listening, sharing your thoughts, showing your feelings to achieve and maintain a "good relationship," often privileging self expression over more practical forms of "love and care." Advocates of "self disclosing intimacy" claim participants in conversations of mutual self revelation create a quality of relationship more intense than the knowing and understanding that can be gathered without such dialogue. Sexual intimacy may play a part, but for some advocates of this type of intimacy it is neither a necessary nor a sufficient condition, as an intimacy of inner selves is conceived as possible without an intimacy of bodies. However, if, as some theorists have argued, sexuality has come to be seen in western cultures as expressive of the very essence of the self, then sexual familiarity inevitably enhances the intimacy generated by verbal self disclosures.

Academics across a range of disciplines have provided metacommentary on this cultural turn

to "self disclosing intimacy," generating both pessimistic and optimistic analysis of changes in intimate relationships. An influential optimistic analysis was produced by British sociologist Anthony Giddens in *The Transformation of Intimacy* (1992). Giddens argued that a qualitative shift in intimacy began to occur in the late twentieth century. In this period, the faster pace of social change and heightened awareness of risk and uncertainty meant that conventional ways of doing things, including "being a family" and constructing gender and sexual identities, were increasingly open to reworking, as people became more self conscious of being makers of their own "narrative of the self." In this climate, Giddens argued, people increasingly sought "self disclosing intimacy" to anchor themselves in one or more particularly intense personal relationships. Relationships became more fragile, only lasting as long as they provided mutual satisfaction, but they were also potentially more satisfactory, equal, and democratic. Sex was no longer harnessed to set scripts; instead couples negotiated their own rules of sexual conduct on a "what we enjoy" basis. Although people continued to choose long term intimate relationships, including marriage like relationships and parenting relationships, diversity in styles of personal life inevitably also blossomed.

There has been continued discussion of whether and why women's relationships appear to involve more "self disclosing intimacy" than men's (Duncombe & Marsden 1995). Some psychological and psychoanalytic accounts map this to the function of mothering and mother-child relationships. Historically produced gendered cultural discourses, together with inequalities in social constraints and opportunities, are also widely cited in the literature. Similarly, there are discussions of differences by social class, ethnicity, age, and life course stage in patterns of intimacy. Giddens suggested that women, and particularly lesbians and young women, were at the vanguard of his alleged transformation of intimacy: women because previous conventions and social conditions have made them more skilled at "doing intimacy"; women in same sex relationships because they are less constrained by any prior script that suggests a particular division of labor; and young women because they have the most to gain in more equal

and democratic relationships. The work of some feminist commentators has suggested that Giddens has underestimated the persistence of gender inequality (Jamieson 1999) and the ideological strength of a conventional heterosexual culture (Berlant 1997). Berlant argued in her analysis of US culture that the ideologies and institutions of heterosexual intimacy have provided support to a reactionary status quo by encouraging citizens to take refuge from the confusions of capitalism and politics. However, Giddens's argument also finds support among those who believe they are identifying a growing number of instances of people constructing intimate relationships outside of the "heteronorm" (Roseneil & Budgeon 2004).

Whereas Giddens's account suggested that cultural emphasis on "disclosing intimacy" is matched by positive social change in the everyday lives of men and women, there are many more pessimistic visions of what is happening to intimacy in this period of "postmodernity." According to a number of academic commentators, either intimacy has become attenuated (rather than more intense) or its intensity is of little social worth. Unrestrained market forces and mass consumer cultures are accused of promoting a self-obsessive, self-isolating, or competitive individualism which renders people incapable of sustaining meaningful intimate relationships. As one commentator puts it, concern to be sincere and responsible is replaced with worry about being true to one's self (Miztal 2000). Social scientists from a range of contexts have developed variations of this argument, sometimes in tandem with debate about "social capital" and concern that private intimacy supplants or undermines "community." Well-known examples include Bauman (2003) and Sennett (1998). This is also a longstanding subtheme in the work of Hochschild (2003; see also Bellah et al. 1985).

High rates of relationship breakdown, the associated disruption of wider social networks, and concerns, particularly in Europe and North America, about juggling family and work clearly do indicate strains in intimate life. However, detailed research on how people conduct specific intimate relationships commonly identifies strenuous efforts to create "good relationships" and to put children and "family" first, although generally it is women who continue to play the

larger part in sustaining these intimate relationships. Much of the empirical research demonstrates neither self-obsession nor the primacy of "self-disclosing intimacy." In a review of research on couple relationships, sexual relationships, parent-child relationships, and friendship relationships, Jamieson (1998) concluded that the evidence demonstrated a wider repertoire of intimacy than "disclosing intimacy." The relationships people described as "good" relationships were often neither equal nor democratic. Moreover, equal relationships were sustained by more than "disclosing intimacy." For example, couples who had worked hard to have fair divisions of labor typically negotiated mutual practical care that did more to sustain their sense of intimacy than self-disclosure. As Vogler asserts, perhaps "not all intimacies are affairs of the self" (2000: 48; see also Holland et al. 2003). This is not, however, to deny the significance of "self-disclosing intimacy" in popular culture, or its discursive power to influence everyday perceptions of how to do intimacy.

differently than unmarried couples who live together. The public nature of unions is also evident in attitude surveys that show general agreement about a gendered division of labor within marriage. The distinction between private and public unions is less useful than might appear at first. Private aspects of couples' relationships are, at least in part, a function of the laws, policies, norms, and economic organization of the public world. For instance, the relative wages of men and women may affect the timing of marriage and the kind of person some one marries. Social norms affect how husbands and wives divide household labor and childcare. Policies that change how difficult it is to divorce may also alter the quality of relationships within marriage. When divorce is less costly, spouses invest less in their relationship and pursue more of their own interests than when divorce is more difficult.

intimate union formation and dissolution

Judith A. Seltzer

Ten years ago studies of couple relationships emphasized marriage formation and dissolution (both separation and divorce). Marriage is still the dominant heterosexual couple relationship, but increases in rates of nonmarital cohabitation, the growing recognition of couple relationships between individuals who do not live together, sometimes called LAT (Living Apart Together) couples, and same sex unions have broadened the area of inquiry to include these other unions as well. A benefit of the broader perspective is that it allows for comparisons between marriage and less institutionalized relationships, such as cohabitation, to assess effects of social context and laws on couples' well being.

Research on unions often distinguishes between unions as private, intimate relationships and unions as public phenomena that are a result of laws, policies, and social norms about the rights and obligations of members of the couple. Examples of the latter are tax policies and inheritance laws that treat married couples

TRENDS

The US has seen an increase in the age at which couples marry. In 2003, half of US men were married by the time they reached age 27.1, an increase since 1970 of nearly 4 years. For women, the increase in median age at marriage to 25.3 was even greater, 4.4 years (US Bureau of the Census 2004). During this period, sex outside of marriage became more acceptable, rates of marital separation and divorce rose and then stabilized at high rates, and nonmarital cohabitation became much more common before and after marriage. By the late 1990s about half of first marriages ended in separation or divorce (some who end marriages do not formally divorce); and over half of first marriages were preceded by cohabitation. The probability of marital dissolution has been relatively stable for the past 20 years, although crude divorce rates have stabilized and even declined slightly for some subgroups. Late marriage and high divorce rates do not mean that individuals have stopped pairing off. Individuals still form couples and live together outside of marriage. Although rates of cohabitation have continued to rise, the increase in cohabitation has not compensated for the rise in age at marriage. That is, rates of union formation, where unions include marriage and nonmarital cohabitation,

are still lower today despite the increase in cohabitation.

Within the US there are substantial class and race/ethnic differences in rates of union formation and dissolution. Men and women who have more secure economic prospects are more likely to marry than those who are economically disadvantaged. African Americans are much less likely to marry than are whites. This race difference cannot be explained fully by racial differences in economic characteristics. Marital dissolution is also more common among those with less education and among African Americans, as compared to whites. These disparities in separation and divorce appear to be widening over time.

Trends in union formation and dissolution in Western European countries are similar in several ways to those in the US. Age at marriage has risen and nonmarital unions, sometimes called consensual unions, have become increasingly common since the 1970s. Rates of divorce have also increased in most European countries. The combination of delayed or nonmarriage, increasing consensual unions, and high rates of marital instability support the claim that marriage has become less attractive compared to alternative arrangements.

ECONOMIC AND CULTURAL EXPLANATIONS

There are two broad categories of explanations for these trends and differentials: cultural change and changes in economic opportunities. Cultural explanations argue that changes in unions occurred because of a broad shift toward individualistic and egalitarian values. Some trace this ideological shift to the Protestant Reformation, while others identify a qualitative change toward the middle of the twentieth century, sometimes called the Second Demographic Transition. The rise in individualism fostered investment in personal goals which sometimes conflicted with marital goals, and resulted in delayed marriage and increases in marital dissolution. At the same time, a growing concern with equality between women and men fostered increases in women's education and labor force participation, contributing to declines in the number of children couples have. Without the

responsibility for children, individual spouses have less investment in their marriage and find divorce less costly. The driving force in these explanations, however, is changes in values.

Economic explanations for changes in marriage emphasize the rise in opportunities for wage labor, expansion of educational opportunities, and the relative wages of women and men. These theories argue that marriage and other unions are the result of cost benefit calculations about whether the benefits of being married (or divorced) are greater than alternatives, such as being single or cohabiting. Delayed marriage and higher rates of marital dissolution occur because women have greater economic independence outside of marriage than they had earlier in the twentieth century. This interpretation derives from the "new home economics" theory advanced by Gary Becker and is consistent with Talcott Parsons's view of the family in which there are gains to specialization in marriage. In these theories, both husband and wife are better off when one (typically the husband), who has higher earning potential, specializes in market work and the other (typically the wife) specializes in housework and childcare. When women's earning potential increases, the gains to marriage are relatively smaller, and divorce rates rise.

Empirical evidence for the theories emphasizing women's economic opportunities is mixed. Several patterns suggest this explanation cannot on its own account for trends and differentials in union formation and dissolution. For example, US women with higher education and earnings are more likely to marry than women with lower earning potential. Education also reduces women's chances of divorce in the US. There is also some evidence that the education disparity in rates of marital dissolution has increased recently.

A second variant of economic interpretations focuses on men's economic prospects and security. According to this view, marriage in western societies has long been an economic arrangement, a prerequisite for which was that the couple must have sufficient economic resources to live independently from their parents. Even today, men's economic resources and potential earnings are an important predictor of marriage. In this view, marriage is delayed or foregone when men have difficulty establishing

themselves in the labor market and earning a family wage, that is, among those who are less educated and minority group members. New research in this area, however, suggests that for recent cohorts both women's and men's earning potentials affect who marries and the kind of person they marry.

Although cultural and economic explanations for changes in unions are often posited as competing interpretations, efforts to compare them typically demonstrate that neither is sufficient on its own to explain either temporal or cross sectional variation in union patterns. It is more likely that both ideological and economic factors contributed to changes in the formation and dissolution of marriage.

PRIVATE RELATIONSHIPS AND THE MARRIAGE MARKET

In the US the popular notion of finding a spouse is that two people fall in love and then marry. That marriage depends on more than love is evident from data on assortative mating, or the extent to which spouses resemble each other on social and demographic characteristics. Husbands and wives are very likely to have the same racial identification. They are also likely to be similar in the amount of schooling they have completed. In addition, spouses are likely to come from similar religious backgrounds, but religious intermarriage has been increasing in the US. Couples who are cohabiting are somewhat less homogamous or similar than married couples. This is probably in part because cohabitation is a period when individuals are evaluating whether or not they are a good match for each other, and in part because the social norms about what constitutes an appropriate marriage partner are different from those governing other unions. Members of cohabiting couples who are more similar have a greater likelihood of marrying. Marriages between more similar spouses are also more stable and less likely to end in divorce.

Similarities between spouses' or partners' characteristics are the result of a matching process in which each person seeks the best partner who will also have him or her. Social scientists sometimes describe the process of spouse selection as a marriage market. This analogy assumes that spouses find each other through an

exchange process. The actors in marriage markets differ across cultures. Although in the US the potential spouses themselves are the primary actors, in some cultures matches are formed by kin groups seeking alliances with each other for political reasons or to protect property, and in other settings parents themselves or a third party matchmaker bring a couple together.

Marriage markets also differ in the characteristics considered desirable in a potential spouse. For instance, in a secular society in which technical skills are highly valued, finding a highly educated spouse may be more important than marrying someone who is of the same religion. In the US, religious homogamy has declined at the same time educational homogamy has increased. There may also be gender differences in the characteristics desired in a spouse. If the roles of husband and wife differ, as in the Parsonian breadwinner-homemaker model of middle class marriage, then the marital division of labor dictates that men with higher earning potential and women who are attractive and emotionally supportive would be highly sought after on the marriage market. Men's attractiveness and women's earning potential would be relatively less important compared to the characteristics that help fulfill the gendered role requirements of marriage.

Finally, marriage markets are also constrained by formal rules about who is an appropriate marriage partner (e.g., whether or not first cousins are allowed to marry; and whether racial intermarriage was permitted under previous US state laws governing marriage). Informal aspects of social organization also affect marriage market outcomes. Daily interaction between persons of the same race or education level in neighborhoods, schools, and work settings increases the likelihood of homogamous unions. By choosing where to live or where to send their children to school, families indirectly affect children's later decisions about whom to marry.

DELAY IN MARRIAGE AS AN EXTENDED SEARCH FOR A SPOUSE

Finding a spouse takes longer when it is unclear whether or not potential spouses have the desired characteristics. Physical appearance is easy to observe at a young age, but signs that

someone will have a successful career or earn a lot of money are not apparent until individuals are older and have finished school and started working. That age is correlated with characteristics that matter on the marriage market is an insight that can be used to interpret the trend in age at marriage for US women and men. In the mid twentieth century both women and men married at younger ages than they do today, in part because men completed schooling earlier and entered paid work at younger ages, thus revealing their potential as a breadwinner at younger ages. With the growth in demand for more highly educated workers, determining whether a potential husband would be a good economic provider takes longer as men (and women) stay in school longer and delay the age at which they marry. At the same time, the women's movement and improvements in women's economic opportunities increased the value to potential husbands of wives' earning potential. Uncertainty about women's economic potential when they are young also contributes to the rise in age at marriage, and probably accounts for the even greater rate of increase in women's age at marriage than men's. Much, but not all, of the delay in marriage in the US is compensated for by the increase in cohabitation before marriage. Living together before marriage is one way that couples learn more about whether a potential partner would be an appropriate spouse, even if couples do not consciously decide to cohabit as a step on the way to marriage.

Even with late marriage, there is still uncertainty about whether a potential spouse is a good match. Individuals change after marriage, sometimes in ways that make them more compatible and sometimes in ways that are unexpected. When individuals change in ways that are not anticipated (e.g., if a person is wrong about what kind of person their spouse will become or if one of the partners loses a job) these unexpected disruptions may increase the chance that the marriage will dissolve. The rise in US divorce rates in the 1960s and 1970s might be explained by unanticipated changes in spouses' expectations about each other's gender role obligations in marriage associated with the women's movement and women's greater labor market opportunities and by decreasing costs of dissolving unsatisfactory matches.

FUTURE RESEARCH

Many theories about the formation and dissolution of intimate unions claim that unions depend on individuals' assessments of the relative benefits of being in the relationship as compared to an alternative. When cohabitation is rare, it is likely that the alternative to marriage is being single. When cohabitation is more widely accepted, there may be two alternatives to marriage: being single or cohabiting. New research should investigate the conditions that affect the alternatives individuals weigh in deciding whether, when, and with whom to form (or dissolve) a union.

Another productive area for new research is how individuals form expectations about potential partners' future characteristics (e.g., whether they will be good economic providers or good parents). It is especially important to learn more about the role of uncertainty in making decisions about unions and the degree to which individuals actually think of themselves as making a decision.

The challenge of designing studies that fully take into account the range of potential partners who might form a union, that is, the full marriage market, is a longstanding problem in studies of union formation and dissolution. Research that considers only unions or matches that have already been formed excludes important information about the alternatives or failed matches.

Finally, research on unions typically assumes that the partners or spouses co reside, and that when the union dissolves, the partners no longer live together. Co residence is important, but it is not the only dimension of intimacy and enduring ties that matters for couple relationships. Couples who are deeply committed to each other and their relationship may live apart (LAT relationships), and those who live together may not think of themselves as being in an enduring or satisfying relationship. Learning more about the continuum of relationships and the conditions under which they involve co residence will shed new light on the meaning and effects of contemporary unions.

invasion-succession

Barrett A. Lee

Invasion succession (hereafter IS) has enjoyed considerable popularity among social scientists as a framework for understanding community change. In its simplest form, IS refers to the replacement of one population group or land use by another within a particular geographical environment. Due to mounting awareness of the complexities surrounding the process of change, however, the IS model no longer occupies the status of conventional wisdom that it did throughout much of the last century.

The historical roots of IS can be traced to the work of sociologists at the University of Chicago in the 1920s and 1930s. Borrowing ideas from plant and animal ecology, Park (1952), McKenzie (1968), and their colleagues stressed unfettered competition for valued resources (such as a desirable location or housing) as the driving force behind IS. Competition was believed to spur a natural, orderly, and irreversible transition from an equilibrium stage dominated by the incumbent group to a new equilibrium dominated by the “invading” group. According to the Chicago sociologists, the notion of passage through a sequence of stages could be helpful for depicting social change along multiple dimensions – demographic, cultural, economic – and across settings ranging from the local to the global.

Despite the Chicago School's broad view, the scope of IS has narrowed substantially over subsequent decades of empirical usage. Well before

World War II, IS research had already begun to focus on residential phenomena, including the settlement patterns of ethnic immigrants and shifts in community socioeconomic status. The meaning of IS became even more restricted after 1950. Studies by the Duncans (1957) and the Taeubers (1969) applied the term to a specific type of change in neighborhood racial composition: from white to African American occupancy. These studies defined additional stages (e.g., penetration, consolidation) in the IS process and spelled out the population dynamics that could produce an increase in the percentage of black residents. They also identified the conditions under which IS was likely to occur.

Many investigations conducted from the 1950s through the 1970s emphasized the pace and inevitability of white to black transition. Racial change was thought to proceed at a gradual rate until the representation of African Americans in an area reached some vague "tipping point." Once the area tipped, whites were deemed more likely to move out, leaving vacancies to be filled by black home seekers eager for better housing and neighborhoods. The result of such "white flight" was accelerated change and, ultimately, resegregation. Put differently, this common version of the IS model precludes stable integration, black to white change, or other racial residential outcomes.

Recent scholarship has challenged the model on several fronts. One weakness is its overly descriptive character: IS predicts what should happen to a community over time but fails to explain why. In response to this weakness, students of racial change have devoted increased attention to decision making – by both households and institutional actors – as an important explanatory mechanism (Hartmann 1993). Shifting racial composition can be seen as the cumulation of numerous household level decisions to move out of, stay put in, or move into a given neighborhood. These decisions involve more than the ability to compete successfully for residential position, as implied by the IS model. Household members may take into account their own racial preferences, how they think residents from other racial groups will respond to them, perceived correlates of a neighborhood's racial mix (safety, school quality,

property values, etc.), and what kind of future they anticipate for the neighborhood.

Household decision making is further influenced by a wide range of institutions ignored in IS research. Those institutional actors participating directly in the housing market tend to be key. Real estate agents, for example, have used "blockbusting" tactics to encourage panic selling on the part of white homeowners, speeding white to black change (Gotham 2002). Current evidence indicates that African Americans continue to receive less information and assistance from agents at all stages of the home seeking process and are "steered" to certain types of areas (Yinger 1995). Lenders and insurers have also been shown to engage in discriminatory behavior. Similarly, local government policies and the efforts of residents' associations can constrain or facilitate household mobility decisions and thus modify the process of racial transition.

Beyond its explanatory deficiencies, the IS model seems out of step with certain kinds of community change. Gentrification, occasionally labeled "reverse" succession, offers a case in point. Since the 1970s, middle class renovation of older housing in inner city areas has typically been accompanied by an increasing (rather than decreasing) percentage of white residents and upward (rather than downward) socioeconomic movement. Another trend, the rise of multi ethnic neighborhoods, defies the two group logic of IS. With Latino and Asian populations growing rapidly across the metropolitan US, new trajectories of change are pushing more neighborhoods in the direction of greater diversity while reducing the number of all white and all black areas (Fasensfest et al. 2004). The IS prediction that African Americans will completely replace whites once they enter a neighborhood is less accurate now than in the past.

Multi ethnic patterns of change highlight the significance of the larger context in which neighborhoods are embedded. Immigration policies and flows at the national level fuel these patterns, disproportionately affecting neighborhoods in "gateway" metropolises such as Los Angeles and New York. Variation across metropolitan settings in housing construction activity can have consequences for neighborhood change

as well. When new housing units are occupied, the older vacated units become available, stimulating moves by members of different groups into and out of established residential areas in domino like fashion.

The IS model appears to have worked best when a distinctive set of forces – notably, pervasive discrimination against an expanding African American population – made selected neighborhoods in Midwestern and Northeastern cities vulnerable to dramatic white to black transitions. In hindsight, the historical and place specific nature of the model is apparent. So are more fundamental shortcomings. To fully comprehend how communities evolve, one must be able to explain differences in the direction, pace, and magnitude of change on several dimensions, including but not limited to racial ethnic composition. An adequate explanation must also incorporate causal factors operating at the social psychological, household, institutional, and contextual levels. In its most common form, IS fails to satisfy these criteria.

investigative poetics

Stephen Hartnett

In his Beat inflected manifesto, *Investigative Poetry*, Edward Sanders (1976) argued that “the essence of investigative poetry” is to create “lines of lyric beauty [that] descend from data clusters,” hence both seducing and empowering readers with “a melodic blizzard of data fragments.” As illustrated in *America*, his epic collection of data fragment strewn poems, Sanders (2000) hoped to merge poetry with the pedagogical imperative to teach his readers their national history and the political goal of empowering them to re-enliven the great traditions of activism and artistry celebrated in his poems. By interweaving the emotional power of poetry with the pedagogical power of historical scholarship and the political power of fighting for social justice, Sanders’s *America* embodies the theory explored in his *Investigative Poetry*, thus providing a model for writing layered, historically dense, yet beautiful, political poems (Bernstein 1990; Monroe 1996; Hartnett & Engels 2005).

While Sanders’s version of investigative poetry is focused on US national history, other practitioners of the art have sought to write in a comparative, international mode. For example, Carolyn Forché’s *The Country Between Us* (1981) shuttles between the US and El Salvador, where she was both witness to and participant in the nasty wars launched by presidents Reagan and Carter against supposed leftists. Peter Dale Scott’s *Coming to Jakarta: A Poem about Terror* (1988) fulfills a similar role, oscillating back and forth between US political intrigue and the CIA sponsored coup that brought Suharto to power in Indonesia and that led in 1965 and 1966 to the killing of half a million alleged communists (Blum 1995). For both Forché and Scott, witnesses propelled to chronicle terrible

acts of violence while still honoring the aesthetic joys of poetry, investigative poetry can say what cannot otherwise be said, it can cut through stultifying genre expectations to interlace personal horror and historical fact, first hand reports and philosophical flights of fancy.

Investigative poetry is more than just the expression of front line reporting in poetic forms, however, for the works cited above by Sanders, Forché, and Scott also offer compelling meditations on the role of poetry as a survival mechanism in an age of mass produced terror (Hartnett 1999; Kaplan 2006). As argued by Terrence Des Pres (1986) in a roundtable discussion on the possibilities of political poetry, “we turn where we can for sustenance, and some of us take poetry seriously in exactly this way,” as a daily practice of making meaning. From this perspective, investigative poetry offers not only a creative vehicle for offering political criticism, but also a heuristic model of *how to live*, of how to take a critical stance against what Des Pres calls “empires in endless conflict” while not giving in to despair or quietude, all the while maintaining a daily commitment to producing art (see Hartnett 2003).

For example, after chronicling the horrors of the US aided genocide in Indonesia, the closing section of Scott’s *Coming to Jakarta* advises readers to cherish the small moments that make each day precious:

As for those of us
who are lucky enough
not to sit hypnotized
our hands on the steering wheel
which seems to have detached itself
from the speeding vehicle
it is our job to say
relax trust
spend more time with your children
things can only go
a little better
if you do not hang on so hard.

For Scott, investigative poetry includes ventures not only into international intrigue and bloody political crises, but also into the micro logical mechanics of daily life. This inward turn is framed, of course, as part of a political response to empire, as an experiment in living an ethical life in the shadow of so much plenty

earned largely through the mass produced pain of so many others (Scott 1992, 2000; Hartnett 2006).

Whereas Sanders’s work concerns US history, and whereas Forché’s and Scott’s contributions explore international political intrigue, a third major strand of investigative poetry includes work clumped loosely around a notion of ethnographic or anthropological poetry. Of the early practitioners of this genre, Jerome Rothenberg and Gary Snyder are perhaps the best known. The term *ethnopoetics* was coined in 1967 by Jerome Rothenberg and Dennis Tedlock and gained prominence via the work of *Alcheringa*, a magazine Rothenberg and Tedlock founded in 1970 (Statement of Intention 1970). Merging a fascination with premodern and developing cultures with a stinging rebuke of western modernity, ethnopoetics offered ecologically sensitive, culturally comparativist poems full of both wonder and anger (Rothenberg & Rothenberg 1983; Prattis 1985; Rothenberg 1990).

For example, Snyder’s *Turtle Island* (1974) moves from a celebration of the Anasazi, a Native American tribe living in the sun drenched Southwest, to “The Call of the Wild,” a bitter poem attacking “All these Americans up in special cities in the sky / Dumping poisons and explosives.” Published amid the war in Vietnam, this clear reference to the saturation bombings sanctioned by President Nixon invites readers to think about the deep historical connections among Indian genocide, environmental destruction, and the butchery under way in the name of defeating communism. By thinking in this multi temporal manner, by holding the Anasazi and the Vietnamese in one’s mind at the same time, Snyder gains historical and political leverage for his claim in “Tomorrow’s Song” that “The USA slowly lost its mandate / in the middle and later twentieth century / it never gave the mountains and rivers, / trees and animals, / a vote. / all the people turned away from it.” Reading these lines in light of another set of US triggered wars in Afghanistan and Iraq, one is struck by the commonsensical argument that there is an intimate relation between the violence used to demolish nature and the violence used to murder our fellow humans. Indeed, in the face of the well oiled machinery of death that slaughtered the Indians, that

murdered millions of Vietnamese, that leveled Afghanistan and Iraq, and that has left a world wide trail of ecological destruction in its path, one is struck by how relevant and powerful this poem feels 32 years after its first publication.

A fourth strain of investigative poetry builds upon the early work of ethnopoetics, yet infuses it with a stronger sense of anthropological depth. For example, consider Ivan Brady's masterful *The Time at Darwin's Reef* (2003). Whereas the ethnopoets mentioned above dabbled in studies of ancient and other non western cultures – sometimes veering close to what could be called nostalgia or naïve Orientalism – Brady is an accomplished anthropologist who has studied Pacific Island cultures for over 25 years, meaning Brady's poems bristle with a lifetime of research and personal experience. As evidence of the book's remarkably broad sense of time and place, *Darwin's Reef* closes with an alphabetical "Place List" and a chronological "Date List," both of which include information relevant to the other. For example, the Place List begins with "Abaiang Island, February 14, 1840," closes with "USMCRD, San Diego, California, August 27, 1958," and includes 60 other place/time entries sandwiched in between. Readers recognize from glancing through the Place List and Date List that *Darwin's Reef* addresses the long history of naval conquest, beginning for the purposes of this book in the South Pacific during the 1840s, culminating in the world's largest floating arms depot, San Diego, during the late 1950s, and wreaking havoc on all the places in between. The Place List and Date List thus function as semiotic machines of imaginative yet historically grounded suggestions, producing juxtapositions, layerings, and clues meant to lead the reader on geographic and temporal journeys through the wreckage of colonialism (see Brady 2000).

As in Snyder's *Turtle Island*, "Time" at Darwin's Reef is less linear than in traditional historical writings and more like the twisting, reverberating, ecological, and even spiritual forms it often takes in folklore. For example, in the poem that names the book, "The Time at Darwin's Reef" – located with the place and date listings that preface each poem as "Playa de la Muerte, South Pacific, July 4, 1969" – Brady conveys time as "High Time, 1:05 p.m.,

Fiji time" (local clock time), as "Time to Get Down" (from the Cessna flying overhead), as "Island Time" (the deep ecological time of natural change), as "Copy Time in the coral" (the movements of coral reproduction as seen in "ejaculating rocks"), as "Magic Time," and so on, in a dizzying multiplication of possible times, most of them rooted not in western notions of clocks, but rather in the natural temporal forms of tides, seasons, and life cycles. Taken together, these layered "times" indicate a spiritual sense of completeness, of multiplicities woven into an organic whole, of ecological centeredness.

Lest readers assume that Brady's gorgeous experiments in temporal confusions lapse into political complacency, "Proem for the Queen of Spain" layers such temporal dislocations against spatial and political fragments, hence creating a sense of bitter poetic judgment. The bulk of the piece is a letter (fictional but true to its historical moment) from Fernando Junipero Dominguez, written in "New Spain" (Mexico) in 1539, in which the writer thanks the queen for bringing to his people "the Embrace of the Mission and the Love of God, Amen." The letter demonstrates how colonized peoples internalized oppression, in this case in the form of bowing to a foreign god brought to the New World by a foreign empire. The endmatter following the poem provides multiple historical references on the history of Dominguez, so the poem fulfills the pedagogical function of both seducing readers to think historically and then leading them to the necessary information to pursue their own further readings. Tucked within the letter, however, Brady offers expletive laced commands from US troops who shout at Vietnamese peasants: "Nam fuckin' xuong dat! Lie the fuck down! Or y'all gonna fuckin' die!" Much like Snyder's juxtaposing of the Anasazi against Nixon's saturation bombing of Vietnamese peasants, Brady's insertion of dialogue from US soldiers within a 1539 letter to the queen of Spain illustrates a sense of continuity linking the Spanish invasion of Mexico to the US invasion of Vietnam. Against the deeply satisfying ecological times of "Time at Darwin's Reef," then, "Proem for the Queen of Spain" offers a chilling sense of *imperial time*, of the looping repetitive horrors of conquest.

Although attempts to define a genre are doomed to failure and inevitably invite a cascade of counter arguments, refutations, and modifications, readings of Sanders, Forché, Scott, Rothenberg, Snyder, and Brady suggest that investigative poetry exhibits these characteristics:

- An attempt to supplement poetic imagery with evidence won through scholarly research, with the hope that merging art and archive makes our poetry more worldly and our politics more personal.
- An attempt to use reference matter not only to support political arguments but also as a tool to provide readers with additional information and empowerment.
- An attempt to problematize the self by studying the complex interactions among individuals and their political contexts, hence witnessing both the fracturing of the self and the deep implication of the author in the cultural and political systems that he or she examines.
- An attempt to problematize politics by witnessing the ways social structures are embodied as lived experience, hence adding to political criticism ethnographic, phenomenological, and existential components.
- An attempt to situate these questions about self and society within larger historical narratives, thereby offering poems that function as genealogical critiques of power.
- An attempt to produce poems that take a multi perspectival approach, not by celebrating or criticizing one or two voices but by building a constellation of multiple voices in conversation.
- A deep faith in the power of commitment, meaning that to write an investigative poetry of witness the poet must put himself or herself in harm's way and function not only as an observer of political crises but also as a participant in them.

Islam

Khaled Fouad Allam

The birth of Islam coincided with radical change in the anthropological and sociocultural situation of Arab populations which, in about the seventh century CE, had already been affected by strong social tensions and by a number of important religious upheavals. If pre Islamic societies are generally to be considered as polytheistic, the presence, since the beginnings of Islam, of important Christian and Hebrew communities must not be understated and from which elements of the Koran are taken. This “new” religion, Islam – whose etymology means “peace” but also “submission” in the sense of humankind’s devotion to God’s word – not only changed the extant religious language, but also deeply modified the social and anthropological structures of the peoples of the Arab peninsula. In analyzing the structures of Islamic societies it is clear how such an event resulted from the demand for change in a social universe – the tribal and clan world – which claimed to be structured differently from the extant one, and which was crossed by deep tensions and crises.

According to Islamic tradition, God chose a man, Mohammad, who through the angel Gabriel’s revelation (or *tanzil*, which means Word descent) would become God’s messenger and prophet. The God of Abraham reveals definitively in the Word, the recitation of which corresponds to the term *Qur’an* in Arabic, the language that, according to the Koran, God chose because of its “clarity.” This point represents an essential element in the definition of Islamic identity: the new religious conscience of Islam involves a linguistic and semantic

specificity represented by the Arab language. In this way, signs and symbols define the whole religious universe of Islam and they are the foundations of Islamic dogma, the *I’gaz al qur’an* (the inimitability of the Koran): “If all the humans and all the Jinns banded together in order to produce a Qur’an like this, they could never produce anything like it, no matter how much assistance they lent one another” (Koran, Surah XVII, verse 88).

The notion of inimitability refers to the notions of fascination and amazement: the divine language interrogates man, as the creator asks him to witness the eternity of his mystery (*gaib*) and the mystery of creation. An essential element of Islamic theology is the mystery behind the revelation of God, who does not allow man to attain such knowledge. Divine revelation in Islam is inseparable from “God’s messenger” or *rasul*, Mohammad’s path, which is divided into two phases, each corresponding to a collection of Surahs (chapters) of the Koran. The first phase, from the beginning of the revelation until 622, is called the Meccan period: it reflects the image of a solitary man, marginalized from Meccan society because of the revelation. The Meccan Surahs of this first period deal with a deeply spiritual, eschatological Islam – an Islam which could be referred to as being an interior Islam. In the second period, from 622 to 632, a change in the function of the Koran’s message occurs: Islam appears and develops in Medina, where the first Muslim community is born and where individual religious identity becomes collective. The cycle of the revelation continues in Medina and the Prophet Mohammad dies in 632, leaving a society in the making.

The Koran’s text, composed of 114 Surahs, is present in the memory of the Prophet’s companions (the first four caliphs) and in the community’s memory, but it is not yet structured, given that their culture is based on oral traditions and not the written word. This explains the reason for the great disagreements behind the authenticity of some verses and forms of transliteration. In fact, any passage which passes from oral to written form creates a filter that has consequences for an orally revealed religion.

The present text of the Koran, comprising 114 chapters, was codified during the age of caliph Utman (d. 656). His decision to arrive

at a definitive version of the text intended to stop the violent polemics which the two different approaches to text created, due to the diverging views on Islam and its social structure. Sources for the contention were founded on issues of Arabic grammar. Two schools arose: the Bassora school and the Baghdad school. This implied two different ways to expound the revealed Word: one more closed, the other more open. Utman, to avoid disputes, opted for the more conservative system.

In the Koran, the order of chapters does not follow the chronological sequence of their revelation. Except for the first Surah, *Al Fatiha* ("the opening") that is Meccan, all the initial Surahs are from the Medina period, in that they essentially define the social organization of Islam and its ethical and juridical principles. Some scholars affirm that the historical sequence of the Surahs is inverted because they have been ordered beginning with the longer ones and ending with the shorter ones. Others affirm that this has to be interpreted as an accent on the Medina Surahs – those that refer to a specificity of Islam, the primacy of the community over the individual, a primacy that is historically defined in Medina and becomes the social archetype of the Muslim world.

In effect, Islamic identity is founded not only on the historically defined experience of the Medina community, but also, and essentially, on the prophetic function. The Prophet Muhammad embodies two roles in Islam. He is the messenger of God, whose Word he receives to transmit to the community, and he also represents the image of the perfect man (*insan kamil*), symbol of charismatic authority that is expressed through history, and therefore in a social construction consequent to the sacred experience of revelation. He is the archetype, the model which should inspire every Muslim community.

The first historical experience of Islam is that of Medina: it represents the collective memory for the entire Muslim world. In this way history becomes tradition (*Summa*) and creates an individual and collective model for the whole community. From the outset, this passage in history involves a structural crux: if an initial historical experience is to be reproduced perpetually, Islam can no longer be empowered by history. Therefore, with the death of its

Prophet, profound disagreements arose regarding Islam's developments throughout history; the controversy between Sunnis and Shiites has its roots in the function of the Prophet. For the Sunnis, the cycle of prophecy concludes definitively with Muhammad's death. To subscribe to a historical perspective means to reproduce the founding elements of Islam, the categories and the interpretive patterns elaborated by the Prophet, since they are considered sufficient to preserve the social and religious elements of a community.

For the Shiites, on the contrary, the cycle of prophecy does not end, but continues throughout history. Islam has to be experienced permanently, in order to preserve a vital link between the sacred and the historical experience of its community. In the Shiite tradition, such continuity is made possible by prophetic descent, by the genealogical filiations which have their beginnings with Ali, cousin and son in law of the Prophet: in fact, the Shiite *faith witness* mentions Muhammad alongside Ali.

These deep differences in the interpretive grid configure the Islamic universe into different dimensions and into contrasting anthropological and juridical patterns. In Islam, two perceptions of the connection between society and religious identity have developed. They correspond to different ways of interpreting the concept of authority. For the Shiites, the collective memory of Islam is kept alive, since the prophetic descent ensures the continuity of interpretation. The caliph is the principal figure of authority because it is he who maintains the interpretation of the Koran; the prophetic tradition does not conclude with the death of Muhammad, but it is continually enriched through the succession of the *imams*, interpreters of Islam in its historical development. For the Sunnis, on the contrary, the historical cycle of interpretation concludes with the death of the Prophet in 632; Muslim society disposes of a definitively fixed pattern that can and must only repeat itself in following cycles of history.

Such deep disagreements produced a political and a theological divorce, since – according to the Shiite perspective – the caliphate had been usurped by the Sunnis. While Sunni Islamic theology is based upon a series of dogmas, Shiite Islamic theology is founded on the combination of the spiritual dimension and its

achievement in history. While for the Shiites there is an uninterrupted investment in history with the sacred, for the Sunnis these two areas are distinct from one another and are always susceptible to conflict. For example, radical Islamism springs from the refusal of a historical investment in the interpretation of the Koran.

Sociologically, Sunni Islamism adapted to the cultural and cognitive contexts of the different peoples it encountered within its history, through the formulation of a legal system and not of a theology. Up to the present there are four schools of juridical interpretation: the Malikite, the Hanbalite, the Hanafite, and the Shafiite. Each of them extends over a wide area of the Muslim world. For example, the Malikite school is present in the Maghreb region and the Hanbalite school extends over the Middle West area (Mashreq), whereas the Hanbalite and Shafiite schools are in the areas of the so called peripheral Islam (Central Asia, the Balkans, the Indian subcontinent, etc). Not only do these schools differ from each other in their juridical characteristics, but each of them also defines a specific approach to the Koran's exegesis, since each adopts a particular speculative methodology about the juridical corpus, varying from maximalist to minimalist interpretations.

There are four methods of reasoning in the formulation of the law in Sunni Islamism: *igma* (consent); *qiyas* (analogy); *ray* (personal opinion); and *igthad* (interpretation), which provides an essentially closed praxis. The identity of a Sunni Muslim is not only founded upon the Koran and the prophetic tradition, but also upon his belonging to a certain juridical school which conditions his whole existence, from birth to death, through rites and religious praxis.

From the late Middle Ages, the European approach to Islam has been functional to the relation between religious identity and territory. The expansion of Islam in the Mediterranean basin has been interpreted in terms of competition between two patterns of medieval intelligibility, that is to say in terms of the different conceptions of truth, connected to revelation in the two sacred texts (the Koran and the Christian gospels). Intellectual and theological debates attempted to ascertain which of them held the truth.

Until the beginning of the twentieth century the interpreting grid of the Islamic phenomenon was based upon the more relevant historical events or changes. The birth of a wide Islamic empire in the heart of the Mediterranean has been the object of various interpretations, in particular the thesis of two prominent historians, the medievalist Henri Pirenne and the founder of the *Annales* school, Fernand Braudel. Pirenne affirmed that what distinguishes Islam from Christianity – and what corresponds to Islam's strategy of conquering new territories – is that Islam never integrates into other cultures, but always remains unchanged. Studying the texts of the Councils in Muslim Spain, Pirenne points out that the church had to translate its Latin texts into Arabic because Arabic was so widespread. His explanation is that the Muslim conquest implied an extension of its religious and sociocultural pattern. Pirenne places this specificity of Islam in opposition with the conquest of the Germans who, on the contrary, integrated and embraced the linguistic, cultural, and religious patterns of the people they conquered and who converted therefore to Christianity. Pirenne considers the fact that Islam never integrates a specificity of the religion, because he maintains that Muslim identity has a territorial character: Islam exists anywhere Muslims live.

The *Annales* school reflects a more complex position, in which religious matters are defined on the basis of material relations. From this point of view, the expansion of Middle Age empires has to be interpreted in relation to the exchange of goods and the control of maritime routes, which determines the logic of power and rule. If this logic is maintained until a certain date, then this is a consequence of the material, that is, economic characteristics of the period. In effect, the decline of the Muslim world historically coincides with the loss of control of the new trade routes. This happened in the sixteenth century, when trade moved from the Mediterranean to the Atlantic. In this case religious identity just seals the means of production and the consequent power relations of the period.

The nineteenth century and the first half of the twentieth saw the development of orientalism. This doctrine is considered as constitutive

of a phenomenology of Islamic elements, such as the corpus of founding texts, the production of Muslim jurisprudence, the Arab language and its idioms, and the literature and the history of great dynasties. But orientalism certainly lacked the material history of the Muslim world, providing for it a series of interpreting grids, in the same way that the historical method did in the development of the western world. In fact, in Islam's historiography, the lack of a history of peoples is evident, since a history of dynasties and power has prevailed.

The conceptual frame of orientalism that provided a comprehensive and organic picture of Islam gradually crumbled in the face of the felt necessity to decodify those societies into a structural approach. A new approach to these societies was shaped in the field of social and cultural anthropology, where in fact more relevant methodological changes appeared. In the 1950s scholars like Jacques Berque, Jean Paul Charnay, Germaine Tillon, and Clifford Geertz opened a new approach to Islam through structuralist research. They analyzed the kinship system and local economies; they conducted sociolinguistic studies of dialects; they began to analyze production in the Muslim world and its relations with territory. In this way they got over the issues that blocked these societies into rigid and decontextualized frames.

During the last few decades the consequences of decolonization together with the phenomenon of acculturation in Muslim countries have amplified the crisis and the re-Islamization of society, through the forming of religious parties and of a symbolic universe reintroducing religious order in socialization processes (veils for women, beards for men, etc.). Political science and sociology have analyzed all these changes. The phenomenon of Islamic terrorism, the geopolitical changes consequent to the Afghan crisis and the two Gulf wars, together with the question of the development of an Islamic Diaspora, both in the USA and in Europe, have raised the question of a public space for Islam in democratic western societies.

The role of sociologists and political analysts has therefore become relevant in providing a comprehensive frame for the great changes in Islam's progress. For example, scholars underline the deep fracture (*fitna*) afflicting contemporary Islam, dividing those who embrace a

close relation between Islam and political order, and those who embrace a change of Islam in private life. The works of Gilles Kepel, Olivier Roy, and Jocelyne Cesari tend to demonstrate the complexity of the changes and conflicts in progress in Islam and in its relations with the West.

A multi disciplinary approach to Islam in the social sciences gives an account of the present complexities and of the phenomena still in progress within Muslim societies. Such an approach is shared by many Muslim scholars, such as the anthropologist Abdellah Hamoudi, the philosopher Mohammed Arkoun, the political analyst Ghassan Salamé, the sociologist Leila Babès, and the historians Abdessalam Cheddadi and Abdellah Laroui. In all these studies the traits of contemporary Muslim societies are evident in the relationship between reality and change. Scholars have to face the difficulty of formulating appropriate interpreting grids to describe an ever changing reality. In studying and analyzing reality there is always a risk of using analytical frames which are surpassed by the constant transformation of reality, and of not having a conceptual frame that can account for reality and change.

The doctrine of orientalism has undergone a crisis because it fixed a method of study of those societies which did not take into consideration their transformation. Today, in the social sciences, the risk persists of fixing an immutable frame for Muslim societies by affirming that "Islam is . . ." The wording should probably be changed from Islam to Muslims, that is to say, those who live Islam.

The prospects for research on Islam and Muslim societies involve more than a shift towards field analyses, starting by singling out groups and segments of society, since collective identity tends today to shift toward individual identity. All this is related to the new forms of organization and structure of Muslim societies. What needs to be defined today is the Islamic Diaspora and Islamic nationalism, and what are the political procedures structuring Islam into political patterns like those of Morocco or Turkey. What should be analyzed is the crisis that is political Islam, as in Algeria. Finally, the crisis of contemporary Islam should be evaluated, in which the central questions troubling the Muslim world are the construction of a

democratic space and the acknowledgment of human rights – the rights of the individual and religious freedom. Studying these questions society by society and country by country, the social sciences could provide a new framework that emphasizes the magnitude of the crisis, but also the significance of the changes that Islamic societies are already undergoing.

Islamic sexual culture

Hammed Shahidian

Delineating criteria for "Islamic sexuality" appears impossible because there exist no uniform codes for sexual behavior or relations. There are in fact many Islamic *sexualities*. Even so, one may deduce certain (relative) constants in sexual ideology. Islam considers sexual desire a natural aspect of human relationship and dissociates sexuality from guilt. In the Qur'an, just as plants and animals are created "in pairs, two and two" (13:3), humans are created with a mate. Several Qur'anic verses (2:183–7; 4:1; 53:45) refer to mating as a divine design for making a harmonious family, a microcosm of the society wherein people can lead a peaceful life. Thus, sexuality in Islam is in nature heterosexual, with women being men's "tilth"; men are instructed to enter their "fields" as they please (2:223). Islamic sexuality reflects gender power hierarchy. Men are active and on top; women, boys, slaves, servants, and maids passive and at the bottom.

Having recognized the legitimacy of sexual desire, and having limited the legitimate outlet for sexual satisfaction to the marital bed, Islam promotes marriage (*nikâh*) at the earliest possible time. Yet in reality early marriage is not

always possible. Marriage elevates intercourse from an act of lust to a sacred task and marks the boundaries of legitimate and illegitimate sexual liaisons. Marriage is an obligation of all believers. The restriction of sex to the marital bed – at least in theory – creates strict sexual and moral codes: *he* ought to display his manliness and *she*, her chastity. Any deviation is tantamount to anarchy and a revolt against God.

Islamic sexuality is ultimately procreational. The objective of lovemaking is not satisfying bodily desire but performing a divine mission (56:59). A quest for family “harmony” and raising healthy and virtuous children brings a couple together. Even when not resulting in procreation, marital intercourse performs its sacred mission by functioning as an antidote against the temptation of fornication.

Though these ideological “constants” are routinely negotiated and redefined in social practice, they are nonetheless significant in defining “normal” sexuality and how individuals must manage their sexual desires. Sexuality is intimately linked to religion, family law, and politics. The most blatant example is the Shari’ah based notion of *tamkin*, according to which being financially provided for by her husband obligates a woman to live where he chooses and to serve him – including sexually – as he desires (unless his demands contradict the Shari’ah). States often regulate private erotic expressions to accord with the religiously defined “appropriate” sexuality and conservative moral standards. Deviation from sexual norms can be easily attributed to conspiracy with foreign powers to undermine religion and state.

Unequal power within the family severely compromises women’s rights to consent and inextricably ties sexuality to violence. Passage to manhood involves rituals of violence (e.g., circumcision and conscription) that entail subordination of women. Circumcision or military training abuses inflict pain upon young men, yet this pain is celebrated and revered as a precondition to manhood. Crimes of honor, punishment for adultery (death by stoning), and female genital mutilation – neither of the latter prescribed by the Qur’an – are other manifestations of violence and sexuality.

Nationalist and modernization projects have drawn middle and upper class women into the public sphere, but they have also reemphasized

women’s maternal responsibility and have valorized them as symbols of nation and tradition, leading to new measures of control over female sexuality. In Turkey, for instance, women’s chastity (*iffet*) was a component of the Kemalist reconstruction of Turkish identity. In many Middle Eastern countries, a female student’s chastity is a prerequisite for entitlement to formal education. Often, even married women cannot attend day classes in high school; they are required to enroll in evening classes with older students if they wish to continue their education.

According to Islamist ideologues, women stand at the vanguard of foreign intervention. Women are also the most significant bastion against external powers. Capitalizing on the perceived western threat to Islam and the Middle East, Islamist movements have promoted restrictive definitions of female gender roles and sexuality by assigning to women the task of preserving “authentic” culture. Traditions have been revived and invented. *Hejâb* (the Islamic dress code) has been referred to as the “flag” of Islam. Weakened customs such as *mut’a* (temporary marriage) have been reinforced (e.g., in Iran), and in some cases (e.g., Pakistan under President Zia) rape has been redefined as a form of *zinâ* (adultery).

Despite conservative tides, sexual ideologies and practices have undergone some changes. Emerging voices have addressed sexuality, especially restrictions on female sexuality, as a human rights issue. Feminists have attempted to move sexuality away from the sphere of metaphysical rules and place them in the context of social relationships. Progressive political movements are moving away from the belief that sexuality (and women’s rights) concerns only the bourgeoisie. Evidence from a number of Islamic societies suggests that many youths are experiencing premarital sex. Though most women in Islamic countries marry, postponing marriage, even never marrying, is gaining gradual acceptance. Homosexuals are also slowly asserting their identities as gays and lesbians.

Studies of sexuality in Islamic cultures have been rather limited. There is a need for investigating the actual sexual behavior of the population, changes in attitude toward sex, and emerging sexualities. It is also pivotal to closely scrutinize classical and contemporary treatises

on sexuality, paying attention not just to the text's overall message, but also to its underlying images, vocabularies, and assumptions.

J

James, William (1842–1910)

Frank J. Page

William James was the son of a theologian and brother of the novelist Henry James. He taught psychology and philosophy at Harvard University. His *Principles of Psychology* (1890) is the foundation of modern psychology. An annotated version, *On Psychology: Briefer Course*, was published in 1892. Other major works include *The Will to Believe* (1897), *Human Immortality* (1898), *The Varieties of Religious Experience* (1902), *Pragmatism* (1907), and *The Meaning of Truth* (1909). Along with Charles S. Peirce, Charles H. Cooley, and John Dewey, he was instrumental in establishing American pragmatism. This intellectual tradition has been an influential framework for symbolic interactionism, US educational practices, and many epistemological issues. James's conceptions of psychology, consciousness, cognition, self, self-esteem, stream of consciousness, and habit have a profound relevance for many sociological assumptions regarding the nature of society and its influence on human conduct.

As defined by James, psychology deals with consciousness, cognition, emotion, motivation, and conduct, all of which must be understood within the context of nature and evolution. His psychology rejects dualism, an ancient and prevalent assumption that asserts that mind (cognition and soul) and body are distinct and separate entities. James replaces dualism with parallelism, which posits that mind and body are linked through the central nervous system, and that there is a uniform correlation between thought and underlying physiological processes. In effect, cognition is made possible by

the brain and central nervous system, an axiom central to modern psychology.

In harmony with his parallelism and modern evolutionary theory, James's psychology is predicated upon psychological functionalism, which asserts that the mind, consciousness, memory, and cognition are evolved traits that exist because they promote human survival. According to this paradigm, consciousness and the self awareness it facilitates are made possible by the central nervous system and exist because of their adaptive value.

James describes the central nervous system as a biological machine that receives sense impressions and discharges reactions that promote survival of the organism. The biological principle that drives this process is homeostasis, the tendency of organisms to seek stability and respond in ways that will promote survival. In accord with this principle, humans are directed by sensations registered in the central nervous system. Accordingly, human behavior will tend toward those activities that are pleasurable and avoid those that are painful, because they promote survival. However, according to James, humans are not merely reactive organisms directed by biological instincts and drives. In humans, responses and interactions between the individual and the environment are mediated by consciousness.

According to James's concept of consciousness, early in childhood and forever after, many of the sense impressions that guide human conduct are mediated by and attached to signs and symbols that, as categories of thought, can be stored in memory and called to the forefront of consciousness. Through learning, people acquire these categories from society. In cognition, through the processes of association and disassociation, these categories facilitate discrimination, whereby people can categorize and differentiate between different objects and

actions, and use this information to make decisions and choices. People think, perceive, and act on the basis of these categories, and it is not only the ability to discriminate that is made possible by categories, but also the sensations associated with categories that direct human thought and conduct.

In his analysis of consciousness, James describes the link between signs and sensations as “apperception.” This physiological connection between signs and sensations is the mechanism by which signs and symbols direct human conduct. The sensory images that direct human conduct are “anticipatory images.” These images and categories of thought enable people to anticipate the probable sensations associated with certain acts and objects, and thereby direct human conduct in ways that are generally beneficial to the individual and the species.

The concept of apperception is a core concept in James’s model of consciousness. Several functions and implications are connected to this concept. First, apperception allows the cognitive processes of association and discrimination to be directed by sensations, however subtle, that occur when an individual thinks and interacts with the environment. Second, apperception is an incipient conception of sentiment, a key concept in Cooley’s later conceptions of self and society. Third, apperception is intrinsic to James’s principle of “ideo motivation,” which asserts that sensations associated with signs and symbols stored in the mind influence cognition in ways that direct and motivate conduct. Finally, apperception is a crucial component of James’s concept of a “figured reality,” which, like Peirce’s concept of symbolic realism, posits that people can store signs and symbols that represent reality in their minds and use them for thinking, anticipating, and generally directing their conduct. This principle is central to later studies of cognition and symbolic interactionism.

James’s principle of a figured reality is a central tenet in his functionalist model of consciousness. As such, it is also an important element in the American pragmatist conception of instrumental knowledge wherein knowledge is defined as information that guides human actions in a way that is useful and instrumental to well being and survival. As conceptualized

by James, all knowledge is composed of signs and symbols that are necessarily associated with sensations; this conception of knowledge also has implications for theories of meaning. Most importantly, if categories of thought are associated with sensation, meaning is not simply a matter of ascertaining what words refer to, but also a question regarding how acts and different ideas and things make people feel. Following this principle, acts and things that are meaningful are generally associated with certain pleasant and positive feelings, while those that are deemed meaningless are associated with bad and unpleasant feelings or no feelings at all. This principle, wherein knowledge is associated with a feeling state, underlies James’s analysis of depression and the “sick soul.”

A major tenet in James’s conception of consciousness is the proposition that consciousness should always be conceptualized as something that is constantly changing, yet continuous, “a stream of consciousness.” The validity of this concept is supported by the fact that, in accordance with James’s principles, people do have the capacity for memory, cognition, learning, forgetting, habit, and the use of language to represent self and reality, all of which make consciousness and self awareness a stable yet fluid experience. In *Principles of Psychology*, James carefully delineates these many capacities, their complex interrelationships, and the human qualities they facilitate. His analysis culminates with his depiction of the adaptive nature of habit which functions to simplify movements, conserve energy, limit fatigue, and allow people to multitask and become habituated to social norms. Accordingly, habit is not only personally empowering but also the “great flywheel of society,” a notion that has considerable relevance for sociological conceptions of social control and order.

James’s complex model of consciousness and human nature postulates that humans are evolved, sentient, cognitive, self aware beings prone to habit and capable of learning, discrimination, and willful activity. However, the capstone of his psychology is his definition of self, and the related conceptions of the soul, will, motivation, and mental illness. As defined by James, self is composed of the “I and the Me.” The I is the knower, thinker, and therefore the subject. The Me is that which empirically

can be known by the knower about the knower as object. Basically, the knower is the consciousness and the changeable memory made possible by the central nervous system, where as the Me is that which comes to be known about the knower through consciousness and awareness.

For analytical purposes, James divides the Me (that which can be known) into the Material Me, the Social Me, and the Spiritual Me. Each Me is important because, as known by the I, through the process of self appreciation (evaluation), it may arouse instincts, feelings, and emotions that motivate and direct conduct. More specifically, if self appraisal indicates that the self, be it the material, social, or spiritual aspect of self, is successful and secure, a person will experience self complacency, and keep doing what he or she has been doing, or not doing. On the other hand, if self appraisal leads to the conclusion that some aspect of the self is deficient or threatened, it will arouse instincts, emotions, and feelings that will generate self seeking and self preserving actions that attempt to remedy the problem by changing the self or the situation. Finally, if self appraisal leads to a sense of hopelessness, the individual may experience lethargy, angst, depression, denial, and suicidal tendencies.

Because they are crucial aspects of the self that guide behavior, James carefully conceptualizes each aspect of the Me. The Material Me or self is not only the physical bodily self, but also anything that a person can identify with. This may include family, friends, pets, lovers, houses, cars, a career, an art form, or a particular locality. However, in that the human body necessarily has the most direct connection with self, it is the innermost if not most important aspect of the material self. When threatened, as a matter of self striving and self preservation, strong instincts and emotions such as rage and anger will be automatically elicited.

In conceptualizing the Social Me, James delineates that part of the self that is aware of and responds to the expectations, influence, importance, and dependency on other people and groups. In many ways, his analysis of the Social Me adumbrates the conception of the “Me” that was developed by George Herbert Mead and later incorporated into symbolic

interactionism. It also foreshadows what sociologists now describe as the social self, role playing, situated identities, role conflict, and what Goffman later described as “impression management.” That James saw the Social Me and social motivation as powerful is evident in his description of the American worship of success as a “Bitch Goddess” that creates workaholics.

James defines the Spiritual Me as that part of the self that, in being aware of itself as a thinking, feeling, acting creature, can ultimately deem life itself to be good, bad, meaningful, or meaningless. As a matter of self striving, it is the spiritual self that directs conduct in terms of acquired intellectual, moral, religious, and philosophical beliefs and aspirations. However, while the spiritual self is an important and often dominant aspect of self, decisions are not always made by the spiritual self, but rather by that aspect of self that at a particular moment is the most engaged or threatened. When physical survival is at stake, the material self may predominate and overrule the social and spiritual self, a proposition that indirectly underscores the dangers of severe social disorganization and the moral importance of social order.

The Me(s) in James’s model of self is an important organizing concept, because, in harmony with his functionalism and parallelism, as a matter of self striving (self protection), it responds when threatened. Consequently, when faced with a threat of injury or death, the Material Me, through instinct and emotion, strives for physical survival. When social rank is threatened, the Social Me, knowing of its dependence upon other people, strives for recognition as a means of security. When confronted with threats to cherished beliefs and values, the Spiritual Me attempts to direct conduct in terms of ideals and morals. Conceptually, each Me is an abstraction representing different aspects of the self as known by the I (the knower) that function as sources of motivation and direction.

James augments his analysis of the self and the motivation that springs from self awareness with his mathematical formula for self esteem (Self esteem = Success/Pretenses to Success). According to this formula, a person’s self esteem level and the motivation that follows from it will be a function of the ratio of that person’s actual success divided by his or her

aspirations to success. When formulated in this ratio, self esteem is low when a person has many aspirations to success and few actual successes, and high when a person has many successes and few aspirations. As a result, self esteem can be heightened by success or by lowering aspirations for success. Charles Cooley and many modern theorists elaborated this concept.

A related and important, but often overlooked, principle regarding consciousness, motivation, and conduct developed by James that bespeaks his principle of ideomotority asserts that people will act on the basis of that image or idea that comes to the forefront of consciousness. According to this principle, whether or not a particular idea comes to the forefront of consciousness and thereby becomes a matter for thought and discrimination and a means of directing conduct will be a function of the intensity of the sensations associated with that particular idea or image. Due to apperception, all are accompanied by sensations, and James divides the ideas and images that compose consciousness into two types, those associated with instincts and drives, and those drawn from society. The values and beliefs drawn from society are “emotion laden ideas.” Paralleling Freud’s discussion of the superego, James underscores how as part of the spiritual self these ideas direct conduct in prosocial ways. However, he notes that because instincts are associated with survival, they are also associated with strong sensations, and that when survival is at stake, an idea associated with an instinct, be it hunger, thirst, sex, or fear, may dominate consciousness and cognition and preempt the Social and Spiritual Me, and lead to conduct that is asocial and amoral.

According to James, consciousness is composed of ideas about the world and the self. Whether or not a particular idea or image will dominate consciousness and become the basis of cognition, perception, and motivation will be influenced by the strength of the sensations associated with it, the relative influence of instinct, society, the proper functioning of the central nervous system and the self, and the situation at hand. Consciousness, cognition, and the self are influenced by a variety of factors, but people think, make decisions, and act on the basis of intention and will. For

James, “will” or “will power,” rather than being an amorphous metaphysical concept, is simply the individual’s conscious attempt to keep certain ideas at the forefront of consciousness and thereby control her or his conduct. As to the issue of “free will,” James’s parallelism and functionalism, along with his conception of the self, implicitly imply that will is constrained by the functioning or dysfunctioning of the central nervous system and the nature, development, and health of the self.

While it does not often get the attention that the I, the Me, and self esteem receive, James’s concept of Soul is crucially important because it is the Soul that facilitates the interaction of the I and the Me. As defined by James, the Soul is that part of the I (the knower and thinker) that, as part of the stream of consciousness, functions as an ongoing, combining medium that allows for change and growth while maintaining continuity and a consistent sense of identity and self. While this concept is somewhat vague, it necessarily refers to the capacity of the individual to feel, know, learn, develop, and change. This ability to change yet maintain a continuous sense of identity is made possible by memory, learning, cognition, sensation, and, most importantly, the human use of language, all of which allow people to acquire new understandings of themselves and the world they live in, and selectively discard and forget older, inappropriate views. In terms of James’s parallelism and functionalism, this is made possible by the central nervous system and the self awareness that consciousness affords. However, as emphasized by James, the central nervous system, the Me(s), the Soul, and consciousness are subject to illness and aberrations that may lead to mental illness and human suffering.

In *Principles of Psychology*, James analyzes abnormal behavior in terms of mutations and multiplications of the self. These aberrations may be caused by alterations of memory brought about by changes, defects, or damage to the central nervous system or alterations in the material, social, and spiritual aspects of self. As conceptualized, a malady, be it a psychological problem that arises from a physiological deficit or a purely psychological problem associated with a damaged, threatened, or overreactive self,

may lead to depression, insane delusions, alternating selves, mediumships or possessions, and false memories.

In *Varieties of Religious Experience*, James describes pathologies associated with the "sick soul" and the "divided self." These illnesses are driven by conditions where, in some individuals, the I's knowledge of the world gives rise to an awareness of inevitable suffering and the demise of self. This knowledge challenges and undermines the religious and philosophical ideas held by the spiritual self that give meaning and purpose to existence. As a result, the Soul, perceiving its own suffering and demise, is pained and sick. In addition, the self is divided and conflicted because the Spiritual Me is at a loss to provide direction to the Social Me and the Material Me which, without direction, may conflict with one another. In response, people may suffer neurosis, hopelessness, depression, and sadness, and some will search other religions and philosophies for more comforting beliefs that, in some cases, may relieve their anguish and give them a sense of being "reborn."

Japanese-style management

Ross Mouer

Japanese style management (JSM) (*nihonteki kei ei*) is a loosely defined term used to indicate the way employees are managed in firms and other organizations in Japan. Accordingly, its meaning changes as micro economic realities change. At the same time, the term is used to distinguish from management practices in Japan more generally (*nihon no kei ei* or *nihon ni okeru kei ei*) to those employment practices that are alleged to be uniquely Japanese (*nihonteki*) and to have a peculiarly Japanese cultural imprint. Using the term to indicate the packaged set of practices which are described below, many acknowledge that what they refer to exists mainly in Japan's large firms. In this context, JSM was popularly used in the 1970s to delineate a number of interrelated practices demarcating the way work was organized in Japan (or at least in Japan's largest firms) from how it was conceived elsewhere.

The practices initially receiving attention were lifetime employment, seniority wages, and enterprise unionism. These came to be known as the three pillars, the three sacred treasures, or the three sacred emblems of industrial relations in Japan. Although the cultural uniqueness of each has been challenged, some have argued that it is the overall mix as an integrated system that has been unique. The belief that these practices were unique to Japan was bolstered by references to other phenomena alleged to be outcomes of the unique features: Japan's low levels of industrial disputes (reflecting a high value placed on social consensus), long hours worked in Japan (as part of a special culturally ordained work ethic), the provision of certain types of company welfare such as employee housing (emanating from familial and paternalistic orientations found in Japan's traditional agricultural communities), and lower labor turnover (reflecting an innate sense of loyalty to the company as a primary group; i.e., a surrogate family). In its second report on industrial relations in Japan in 1977, an OECD

study team indicated that the three pillars were “kept in place” by a fourth: Japan’s cultural values. Underpinning the three structures were a traditionally Japanese predilection for verticality in human relationships (e.g., seniority), for being part of a group (e.g., long term employment), and for consensual relationships (e.g., enterprise unionism). By the 1970s these cultural features had come to be codified in academic accounts of nearly every aspect of Japanese society – a paradigmatic approach or viewpoint which came to be known as *nihonjinron*. This kind of cultural essentialism view came to dominate much of the Learn from Japan boom of the late 1970s and the 1980s.

The structures mentioned above were initially seen as part of an overall system of industrial relations that produced few strikes, wage restraint, and high levels of motivation as major factors facilitating Japan’s rapid growth in the 1960s and 1970s. However, the literature about JSM shifted attention downward from the societal level and macroeconomic outcomes to the microeconomic concerns associated with employment relations in the firm. To some extent this shift reflected a general change in interest in the field internationally from the way tripartite frameworks for labor–management relations came to be institutionalized to a much more multi dimensional mapping of employment relations and human resource management. Despite this shift, many in the field continued to assume that the industrial relations system in Japan was largely the sum of the HRM practices found in each Japanese firm. At this level the model was developed further to highlight “uniquely Japanese” approaches such as widespread bottom up consultation (e.g., *nemawashi*, the memo system known as *ringi seido*), spontaneous and voluntary quality control circles, internal labor markets, joint labor–management consultations, the absence of a strong militant class orientation in ritualized conflicts such as the Spring Wage Offensive (the annual round of 6–8 weeks each spring when unions put forth their wage demands and settlements are negotiated between labor and management), and the highly integrated production systems which utilized large numbers of firms linked together to form enterprise groupings known as *keiretsukigyo*.

In the 1970s numerous scholars sought to codify the linkages between *nihonjinron* and *nihonteki kei ei* (Ogishima 1984). In the late 1950s the anthropologist Abegglen coined the term “lifetime employment” to describe what he perceived to be a peculiar feature of management practices at the firms he studied in Japan. In the next decade Hazama (1963) began the codification by which he and others sought to link aspects of JSM to cultural underpinnings. However, it was in the 1970s that those foundations came to be seen as uniquely Japanese (and not just remnants from a tradition associated with all pre industrial societies). As a kind of postmodern outcome, the Japanese firm was seen as being able to maintain a delicate balance between the push for greater social justice (as seen in the demands of left wing unions) and the efforts of management (with the cooperation of business unions) to obtain greater efficiency. Nakayama (1974) wrote about a system generating true efficiency (*honrai no noritsu*) by combining an emphasis on economic rationality (*noritsu*) with an emphasis on fairness (*kosei*). For Tsuda (1977), the terms were cooperative community (*kyodo seikatsutai*), rationality (*gorisei*), and consensus (*goi*); for Hazama (1971), group oriented labor–management relations (*shudanteki roshi kankei*), profit seeking (*eiri no tsuikyū*), and continuity of the company (*kaisha no eizoku*); for Iwata (1977), the formative principles of Japanese management (*nihonteki kei ei no hensei genri*), organizational demands (*soshiki no yōkyū*), and the demands of individual employees (*kojin no yōkyū*). In hindsight an increased awareness of how the institutions associated with JSM were born out of the immediate post war years, the shift in the balance of power first to unions and then back to management, and the ongoing ideological battle between Cold War camps has helped those interested in JSM to see how it was produced out of a peculiar historical milieu in which the tensions between capitalist and socialist views worked themselves out in the context of successful economic resurgence and the efforts to reestablish positive assertions of national identity.

In the 1980s debate revolved around the exportability of JSM, with many questions raised about the exportability of the cultural

proclivities commonly associated with work organization in Japan. In the process the culturalist view was undermined by a growing acknowledgment that JSM practices were found primarily in Japan's large firms. Nevertheless, although firms with over 500 employees accounted for only 12 percent of the labor force in 1975 (and only 8.9 percent in 1999) (Mouer & Kawanishi 2004: 119), it was asserted by many that the model's significance was less in its prevalence as an actual reality and more in its role as an ideal to which many in the Japanese workforce aspired. Myth or not, the fact remains that notions of *nihonteki kei ei* and the entire set of *emic* terms used to describe components of JSM have become important as a Japanese vocabulary for talking about work organization in Japan.

In the 1980s western managers, unionists, and academics made a concerted effort to find out more about JSM. Managers motivated by the desire to acquire a new kind of competitive advantage traveled to Japan to discover the secrets of JSM and to find "quick fix" solutions. Unionists, however, came to feel the pressure of certain anti union tactics which were seen as being characteristic of some Japanese investment in their own countries. Some of these views were captured in North America in the film *Gung ho*. The efforts of these practitioners tended to shift attention back from the alleged essence of Japanese culture to the more easily observed concrete structures that could more easily be implemented in their own societies. By the early 1990s the literature had come to provide a more comprehensive view highlighting a number of structural features central to the functioning of JSM. Outside Japan a debate developed between those who saw JSM primarily in cultural terms as a post Fordist phenomenon and those who saw it more in structural terms as an ultra Fordist approach.

The structuralists paid attention to the very complex system of delayed wage payments and the importance of performance linked criteria which markedly differentiated the age wage (seniority) trajectories on which individual employees found themselves. Just in time systems (which had been contrasted with more costly just in case systems) were introduced without the full realization that the costs saved by the final assembling plants with reduced

stocks of parts had not been removed from the overall production process, but had rather been simply shifted further down through the production process, a situation reflected in continuing firm size differentials in working conditions. Other ways in which internal and external labor markets were segmented – especially in terms of employment status and the distinction between regular employees and a huge range of non regular employees – also came to be seen as integral to how the "Japanese system" of integrated production actually functioned. The use of excessive regulation and an opaque performance management system have also been mentioned as factors goading workers to work long hours and to accept assignments which physically removed them from being involved in their family on a day to day basis. These facets came to be documented by Kumazawa (1994, 1997) and by many others from the late 1980s onwards. Further to these correctives were studies showing that many Japanese firms governed by JSM were actually not very efficiently run; privatized public enterprises (from the Japan National Railways in the early 1980s to national universities at the end of the 1990s), retailers, and many financial institutions provide ready examples.

Mouer and Kawanishi (2004) argue that JSM needs to be understood in a broader social context in which choices at work have been fairly limited for many Japanese employees, including those in large firms. The absence of adequate safety nets for unemployment and the segmented approach to providing health insurance and pensions require all employees to think very carefully about choices which increase the risk that they might experience some form of downward intragenerational mobility as they are shifted out of Japan's more privileged labor markets and into its less attractive ones. Since the turn of the century a good deal has been written about widening income differentials and the difficulty of achieving intra and intergenerational upward mobility (e.g., Sato 2000). Changes in the power relationship between peak organizations representing labor and management markedly affect the likelihood of progressive legislation being introduced to affect social welfare.

In recent years, however, Japan's affluence and a relatively high standard of living have altered the relationship between labor and management in the labor market. Fewer Japanese

are willing to labor in jobs characterized by the 3 Ds (i.e., that are dirty, demanding, and dangerous) – or the 3 Ks in Japanese) (*kitanai*, *kitsui*, and *kiken*). Parasite singles (young persons in their late twenties and in their thirties who have not left home and continue to enjoy free accommodation at their parents' expense while working for good wages, as described in Yamada 1999) are less prone to seek "privileged employment" at all costs, and the number of *furitaa* (freelance casuals) has increased significantly over the 1990s. Widespread questioning of gender derived segmentation has opened up the work place to greater competition. These changes only add to doubts about the uniqueness of JSM (*nihonteki kei ei*), and in this sense JSM (*nihon ni okeru kei ei*) will continue to be characterized by change and be difficult to capture in its entirety as managers use Japanese structural elements to respond to the spread of global standards. While the workers will continue to be guided by a strong sense of self interest, the spread of multicultural thinking is likely to encourage variety in those responses. Over time new vocabularies for describing JSM are bound to emerge as perceptions and realities change, and as different conditions of possibility come to shape the environment in which work is performed in Japan.

Jehovah's Witnesses

Massimo Introvigne

Rodney Stark and Laurence Iannaccone (1997) noted that, despite their millions of members, until recently Jehovah's Witnesses failed to attract the attention of most sociologists of religion (Beckford 1975 is one of the rare book length studies). The difficult access to their international archives was a factor, together with a general underevaluation of non mainline Christian groups by certain sociologists. In the 1990s and 2000s, however, the situation changed. Sociologists became interested in testing on such a large group hypotheses about the relative success of different religious movements, cognitive dissonance, routinization of charisma, and mainstreaming of once marginal religions, while a new Witnesses leadership was ready to cooperate.

The Jehovah's Witnesses are the largest among a group of several religious movements that claim the heritage of Pastor Charles Taze Russell (1852–1916). Born in Pittsburgh, Pennsylvania, Russell became involved in theological

controversies within the American Adventist movement, which had predicted the end of the world for the year 1844 based on numerical speculations drawn from the Bible. After 1844, Adventists divided into several competing groups. Those who renounced any further date setting eventually became the Seventh Day Adventists, a large international denomination. Some of those who would still calculate prophetic dates focused their hopes on the year 1874, and constituted a loosely organized movement. After the new disappointment, the young Russell emerged as one of the leaders of those who had placed their hopes in 1874. Russell both predicted the end of the world as we know it for the year 1914 and shifted his focus on teachings other than prophetic date setting.

In 1878, Russell separated himself from other factions of the movement and started editing a magazine, *Zion's Watch Tower and Herald of Christ's Presence*, which is still published today as *The Watchtower*. Russell's followers were known simply as Bible Students, but in 1884 the preacher formally established an organization known as the Zion's Watch Tower Society, later the Watch Tower Bible and Tract Society. Russell's ideas involved the denial of Trinity (Jesus Christ was regarded as God's first creature). He also preached conditionalism, a rejection of the traditional view of the immortality of the soul. These doctrines would later seem highly heterodox to mainline Christians. In the late nineteenth century, however, they were shared by quite a few preachers. Russell's notable success (almost all his books sold millions of copies) did not come so much from the alleged revolutionary character of his teachings as from the fact that they were perceived as being in continuity with, if not part of, mainline Christianity. This confirmed to later social science that new religious movements, in order to gain a large following, should exhibit only a moderate discontinuity with respect to mainline religion.

The prophetic failure of 1914 did not stop the movement's progress. The Bible Students, however, were radical Christian pacifists, who adamantly refused to be drafted and to fight in war. In several countries they were arrested in significant numbers. In this climate, the election as president of the Watch Tower Society of Joseph Franklin Rutherford (1869–1942) was

not welcome by everybody, and several schismatic groups separated from the mainline movement, although all these splinter organizations remained quite small.

Not only did Rutherford promote speculations about a new date for the end of the world, 1925, he also transformed the loose network of Russell's times into a strongly centralized organization, changing its name in 1931 into the current one of Jehovah's Witnesses. With a peculiar and abrasive populist rhetoric, Rutherford consistently attacked organized religion, politics, and big business as "rackets" and corrupt monopolies up to no good. Although Rutherford would be later criticized for his early and, in retrospect, naïve attempt in 1933 to contact the Nazi regime and present a positive image of the German Jehovah's Witnesses, such contacts quickly failed and the Witnesses were severely persecuted in Nazi Germany, as in Fascist Italy and Communist Russia. Several hundred died in Nazi concentration camps.

Nathan Homer Knorr (1905–77) succeeded Rutherford in 1942. Again, the transition from one president to the next took place during a world war. The 115,000 active Witnesses, still committed to radical pacifism, were again experiencing difficult times in most countries of the world. Presiding over the Witnesses in an era that was now suspicious of charismatic leadership, Knorr struggled to depersonalize the movement's hierarchy and almost consciously organized a sustained routinization of charisma within the group. Articles in the Witnesses' magazines and books were now published anonymously, concluding a process initiated during the Rutherford era. Although still emphasizing the Witnesses as the only authorized organization representing the Lord's true church in the world, the style became less abrasive than it had been during the Rutherford administration. Missionary endeavors, now much more systematically organized, became the top priority.

At Knorr's death in 1977, the movement had grown to more than 2 million "publishers" (i.e., Witnesses engaged in the active "field service" of proselytization, mostly conducted by systematically visiting all homes in a given neighborhood) and more than 5 million participants to the memorial of the Lord's Supper, the only yearly "liturgy" of the movement. This difference emphasizes the problem in assessing the

number of Jehovah's Witnesses statistically. While the Witnesses themselves would count only the "publishers" as members in full standing, adherents of other denominations are not counted by taking into account only those active in missionary enterprises. Participants in the yearly memorial offer a statistical assessment closer to how members of other religious organizations are normally counted, although it is true that the yearly memorial is occasionally attended also by friends and sympathizers. On the other hand, it is also true that the traditional Christian slogan "every member is a missionary" is taken much more literally by the Witnesses than by most other Christian denominations, and everybody is encouraged to devote a substantial amount of time to missionary endeavors. Although the effectiveness of the systematic door to door strategy has been called into question, sociologists have noted that the internal effects of the effort in reinforcing the members' identity and commitment are almost as important as its external success (see Beckford 1975).

A new prophetic enthusiasm seized the movement before 1975, a date regarded by many Witnesses as a likely end of this world. The disappointment many Witnesses experienced created several difficulties and energized an oppositional movement which received considerable media attention but in fact involved only a limited, if vocal, number of former members. The fact that the Witnesses survived prophetic failures in 1914, 1925, and 1975 has been regarded by some sociologists as a confirmation of the theory of cognitive dissonance as applied by Festinger et al. (1956) to instances "when prophecy fails." In order to avoid admitting their previous gullibility, members reinforce their missionary efforts and, by persuading others, re persuade themselves. The theory would predict that, counterintuitively, movements can grow rather than enter into a crisis after a prophetic failure. More recently, however, others have argued that cognitive dissonance has very little to do with Witnesses' reactions to prophetic disconfirmation. First of all, in the immediate aftermath of failed date setting, Witnesses *lost* members, and started growing again only after years of painful reorganization (Singelenberg 1989). On the other hand, prophecy in fact only fails for the

outsiders; from the point of view of the movement itself, prophecy does not fail but is regarded as having come true at other levels: perhaps *a* world, rather than *the* world, has ended, or the prophecy needs to be understood differently (Melton 1985).

In 1995 *The Watchtower* announced a "new point of view" on prophetic date setting, still regarding the end of the world as we know it as quite near, but discouraging members from calculating precise dates. This evolution, as it did for Seventh Day Adventists one century earlier, had the gradual effect of reducing the "other worldliness" of the Witnesses, facilitating their further evolution toward the religious mainline. International expansion resumed (with more than 15 million participants at the yearly memorial in 2004), and the bureaucratization process continued. In 1976 the Witnesses started adopting a rotating presidency among the members of the governing body, the spiritual presiding body of the organization, thus further deemphasizing the presidency's charisma which had been so crucial in the Russell and Rutherford eras. In October 2000, after Milton Henschel (1920–2003) had succeeded Frederick Franz (1893–1992) as president of the Watch Tower Society, all members of the governing body voluntarily stepped aside from the board of directors of that Society, thus separating the spiritual from the administrative governance of the Witnesses.

In the late 1990s, renewed discrimination in countries such as Russia and France (where the Witnesses were involved in campaigns against so called "cults" and "sects") led to what Pauline Côté and James Richardson (2001: 14) called a "deformation" or "reconfiguration" of the group's relationships with the external world. The two sociologists believe that external pressure, including persecution and legal harassment, may cause important changes in religious organizations. In other words, even when groups successfully resist pressure, how exactly they resisted may involve significant internal changes. In the cases of the Jehovah's Witnesses, Côté and Richardson report a first phase of "disciplined litigation" during and immediately after the Rutherford era. In the face of sustained legal discrimination, prominent Witnesses leader and lawyer Hayden Cooper Covington (1911–79) both reacted through any

available legal means, and counseled the Witnesses to avoid the most abrasive slogans against “big business,” politics, and other religions, which would not have fared well in courts of law. The introduction of “theocratic tact” showed how legal strategy contributed to mainstreaming the Witnesses after World War II (Zygmunt 1977).

However, after they had scored important victories before the US Supreme Court and other jurisdictions, the Witnesses did not continue with the “disciplined litigation” strategy and even appeared concerned not to lose their distinctiveness. Similar processes of backing off from what may be perceived as a too rapid integration into the religious mainstream have been described by Mauss (1994) with respect to the Mormons, and defined as “retrenchment.” These retrenchment strategies may be very successful in terms of church growth because, as Stark and Iannaccone (1997: 152–3) have argued precisely with reference to Jehovah’s Witnesses, keeping the “strict” features of the group may both reduce the number of free riders and make a movement more attractive to the large conservative niche of the religious market.

In the case of the Witnesses, a certain retrenchment in the 1960s involved the closing in 1963 of the movement’s in house legal office, which had served as an important tool for contacts with religious liberty advocates and other religious groups, although limited to legal issues rather than involving ecumenical dialogue. However, renewed attacks led to the reopening of the legal office in 1981 and the emergence in the 1990s of a new strategy that Côté and Richardson (2001: 11) have defined as “vigilant litigation.” Court cases are now used to prove to opponents, the media, and the members themselves that the Witnesses’ lifestyle should no longer be regarded as marginal or controversial but is part of the mainline, although their theology remains unique. Law and the courts have thus been consciously used as a vehicle for moving toward the mainstream, although the results in countries like Russia or France remain quite uncertain.

Jevons, William (1835–82)

Milan Zafirovski

William Stanley Jevons is best known as an early influential British neoclassical and utilitarian economist mostly influenced by and developing Benthamite utilitarianism (Schumpeter 1991). More precisely, he is renowned among economists as one of the founders (alongside Carl Menger and Leon Walras) of marginalism or marginal utility theory (during the 1870s) as what economist sociologist Schumpeter (1954) describes as a Copernican Revolution in economics (for more on Jevons as an economist, see Mosselmans & White 2000). Overall, his sociologically minded disciple Philip Wicksteed (1905) describes Jevons as “one of the most

powerful, bold, and original thinkers” in economics. While virtually unknown or neglected among sociologists, curiously enough, Jevons can probably be credited (Swedberg 2003) with inventing the term economic sociology (in the second 1879 edition of his main work, the *Theory of Political Economy*), though not the idea or concept. The idea of economic sociology is already contained or germane in Comte, especially his notion of social economy, as a branch of sociology distinguished from orthodox economics, and of the “economy of real society” subject to “sociological research.”

Specifically, Jevons (1965) suggests “it is only by subdivision, by recognizing a branch of Economic Sociology, together possibly with two or three other branches of statistical, jural, or social science, that we can rescue our [economic] science from its confused state.” He adds that economics (also called political economy) is in such a “chaotic state” owing to the need of subdividing a “too extensive sphere of knowledge,” with economic sociology being one of the results of this subdivision. Hence, Jevons considers economic sociology not only a field of sociology, but also a branch of economics, alongside, for example, the mathematical theory of economics, systematic and descriptive economics, fiscal science, and others, as do similarly some later economists (e.g., Schumpeter 1954). In turn, he treats economics as a “branch of the social sciences,” by implication of sociology understood as such a general science. Thus, Jevons (1965) states that the so called new historical branch of social science, and implicitly economics, “is doubtless a portion of what Herbert Spencer calls Sociology.” At this juncture, he adopts an apparent Spencerian or evolutionary definition of sociology as the “Science of the Evolution of Social Relations.” Notably, Jevons defines economics by analogy to the Spencerian definition of sociology or in evolutionary terms, as “a science of the development of economic forms and relations.” Further, he implies that economics as defined is “one branch of Mr. Spencer’s Sociology,” an implication also suggested by his followers Wicksteed and Edgeworth. Wicksteed (1933), noting that Jevons followed Comte “to erect a hierarchy of science,” places economic science among the “branches of sociological study” and even urges

that “economics must be the handmaid of sociology.” Similarly, Edgeworth (1967) describes Jevons’s marginal utility economics as the “most sublime branch” of sociology in Comte’s sense.

The Jevonian definitions of economics and sociology also yield an implicit Spencerian or evolutionary definition of Jevons’s economic sociology as the study of the “development of economic forms and relations” in interrelation to and within the general “evolution of social relations.” Thus understood, Jevons’s economic sociology is a neoclassical economist’s attempt at integration of economics and sociology, thus anticipating similar efforts by some sociologists (e.g., Parsons & Smelser 1956). Another implicit definition of economic sociology is found in Jevons’s (1866) alternative, utilitarian hedonistic specification of the “field of inquiry” of economics, deemed a “hedonic science,” as consisting only of the “relations of ordinary pleasures and pains,” or a “calculus of pleasure and pain” (Schumpeter 1991), and not of “all human motives.” Viewing this field as “wide enough,” he states “there are motives nearly always present with us, arising from conscience, compassion, or from some moral or religious source, which [economics] cannot and does not pretend to treat. These will remain to us as outstanding and disturbing forces; they must be treated, if at all, by other appropriate branches of knowledge” (Jevons 1866). By implication, one of these latter appropriate branches of knowledge is, as Jevons himself suggests in his later writings, economic sociology, thereby implicitly defined as the study of the relations of utilitarian hedonistic motivation to other human motives as “disturbing forces” or, in Weber’s words, material and ideal values/interests alike. Negatively, Jevons’s statement, by denying that economics deals with “all human motives” and excluding non economic factors from its field as “disturbing forces,” does not suggest what has come to be known as the economic approach to “all human behavior” or rational choice theory. Positively, the statement in essence adopts and elaborates on Mill’s earlier view that most “disturbing causes” do not belong to the domain of economics but to “some other science,” specifically what he proposes as the “science of social economy” as an anticipation or equivalent of

Jevons's economic sociology (a proposal that also implies no rational choice theory).

The main part of Jevons's economic sociology is the sociology of the market, just as the (marginalist) theory of markets, value, and prices is the key element of his pure economics. One implied element of Jevons's sociology of the market is the observed impact of non economic factors such as bargaining power and asymmetrical knowledge or information on market transactions. This is what he essentially suggests by observing that often market transactions "must be settled upon other than strictly economic grounds [supply and demand]" (Jevons 1965), specifically on bargaining and by implication power relations (an observation approvingly cited by his prominent marginalist disciple, Francis Edgeworth). In turn, Jevons predicts that the outcome of bargaining will "greatly depend on the comparative amount of knowledge of each other's position and needs which either bargainer may possess or manage to obtain in the course of the transaction" (i.e., simply, asymmetrical or private information as a particular ("soft") facet or source of differential power and domination). He therefore implies that the bargaining outcome such as the market price will be ultimately determined by what Weber calls power constellations, specifically economic domination "by virtue of a constellation of interests," and contemporary sociologists term differential positional power. Consequently, Jevons (1965) suggests "indeterminate bargains of this kind are best arranged by an arbitrator or third party," including political and other extraneous parties like government.

This indicates a second, related element of Jevons's sociology of the market: the role of political factors in markets. For illustration, he observes that the so called political intelligence of the moment often affects "prospective" supply or demand (i.e., speculation) and its bearing on market equilibrium (Jevons 1965). A third element of Jevons's sociology of the market and economic sociology overall involves the influence of institutions on markets and the economy. For example, he notes the "hedonic bearing of our social institutions" (Jevons 1881), and thus suggests institutional influences

on market economic behavior, including pursuit of pleasure or maximizing utility. Notably, he recognizes that non economic institutions have such a hedonic economic impact in virtue of their contribution to human wants or material (and other) well being which he considers (like Adam Smith) the "sole object of all industry" (Jevons 1965).

In sum, while mostly unknown and overlooked among sociologists, Jevons is potentially interesting and intriguing for them on account of his proposal of economic sociology, thus formally contributing to the adoption and development, even within economics, of a classical sociological idea and field.

Johnson, Charles Spurgeon (1893–1956)

Mary Jo Deegan

African American race relations authority and academic administrator Charles Spurgeon Johnson was born in Bristol, Virginia on July 24, 1893. The grandson of a slave and the son of a Baptist minister, Johnson was inspired by religious ideals and a commitment to end social inequality. He graduated from Wayland Academy and studied at Virginia Union University, both in Richmond, Virginia. He completed a BA in sociology from the University of Chicago in 1917. After America entered World War I, he enlisted in the army. He returned to the university in 1919 and began his graduate studies with Robert Ezra Park.

In the summer of 1919 a major race riot occurred in Chicago, and the Chicago Commission on Race Relations, under the auspices of the Chicago Urban League, began to investigate the conditions leading up to it. Johnson directed this research from 1919 to 1921. In 1922 the commission published *The Negro in Chicago*, wherein Johnson made significant contributions.

In 1921 he moved to New York to direct research for the National Urban League. From 1923 to 1928 he edited their magazine, *Opportunity*, an important publishing outlet during the Harlem Renaissance. It influenced the careers of many artists including Langston Hughes, Zora Neale Hurston, and Arnaud Bontemps.

In 1929 Johnson moved to Nashville, Tennessee, where he chaired the social sciences department at Fisk University. He hired colleagues formerly associated with the Chicago School of Sociology, including Horace Cayton, E. Franklin Frazier, and Park after the latter's retirement from the University of Chicago.

Johnson's books *The Negro in American Civilization* (1930), *Shadow of the Plantation* (1934), and *The Negro College Graduate* (1936) emphasized the importance of scientific, objective goals to collect and interpret empirical data. Education was a major source for social change to obtain social equality. Johnson documented institutionalized discrimination in these books

but rarely commented upon it or supported explicit reforms.

During World War II, Johnson shifted his conservative politics by openly attacking segregation. He published *The Monthly Summary*, which provided information on race relations throughout the country. In 1943 his work on segregation influenced Gunnar Myrdal's *An American Dilemma* (1944). In 1944, Johnson began annual Race Relations Institutes (RRI), attended by national leaders. Johnson became the first black president of Fisk University in 1946, a position he held until 1956.

National Association for the Advancement of Colored People (NAACP) attorney Thurgood Marshall often addressed the RRI in the 1950s and Johnson provided him with sociological data and interpretations that Marshall used in his legal briefs for *Brown v. Board of Education* (1954). This landmark decision eliminated the legal justification for "separate but equal" public facilities and set in motion many public protests in the later Civil Rights Movement.

By the late 1940s Johnson was appointed to several powerful positions: as a United States delegate to UNESCO (1946–7), a member of the Fulbright Board of Foreign Scholarships (1947–54), and a delegate to the Assembly of the World Council of Churches (1948). His balance between "objective" social science and a more critical, change oriented stance helped Johnson obtain philanthropic funds, create a Southern center for studying racial injustice, and develop a global network supporting black artists.

On October 27, 1956, Johnson died suddenly in Louisville, Kentucky of a heart attack. He was mourned by educational, sociological, and political leaders who recognized his contributions to all these fields.

jōmin

Takami Kuwayama

Jōmin is a central concept in Kunio Yanagita's research into Japanese folklore. Yanagita (1875–1962), founder of Japanese folklore studies or folkloristics, invented this term by combining two characters – *jo* (also pronounced *tsune*), used either as a noun or a modifier, meaning “usual,” “ordinary,” “average,” or “conventional,” and *min*, a noun meaning “people.” *Jōmin* thus means “common people” as distinguished from both elites in the ruling class and people placed at the bottom of society, including outcasts. No proper equivalent is found in European languages, but its meaning is close to that of the German *Volk* or the English “folk.”

The importance attached to the study of *jōmin* in Yanagita's research may be explained in terms of his theory of history. Defining folkloristics as a historical science, Yanagita contended that orthodox historiography, using almost exclusively written documents as data, merely recorded the lives of great individuals and dramatic events. Commoners, who made up the majority of the population, were described as the anonymous masses without emotion and character, if described at all. Dissatisfied with this practice, Yanagita placed *jōmin* at the center of historical inquiry. He also proposed new methods for studying history. Instead of doing archival research, he conducted fieldwork. Yanagita reasoned that, since Japan modernized relatively late, premodern manners and customs were still practiced among the commoners. Even if they were no longer practiced, they could be reconstructed, Yanagita thought, from the memory of living people. Thus, he extensively used interviews, in addition to the observations of actual behavior, as a tool of investigation into the past. In Yanagita's mind, history did not refer to past events, but rather the past within the present. In today's terminology, he wrote the “social history” of the Japanese people at large, using the ethnographic methods that were developed in the early twentieth century.

There is agreement among Japanese folklorists that *jōmin* embody Japan's folk culture. Put another way, ordinary people are understood as active agents of historical development, not as

passive subjects, who, with their own will, observe and pass on tradition from generation to generation. There is, however, some ambiguity as to the exact meaning of *jōmin* because Yanagita neither defined it precisely nor used it consistently, as was often the case with other concepts he proposed. Despite his admiration for science, Yanagita was essentially a man of letters, whose influence derived more from his literary talent than from his scientific achievement. Among later generations of scholars, therefore, there has been much debate about the meaning and the significance of *jōmin* for folklore research. Even today, it continues to be debated, with new interpretations presented from various fields.

One of the best interpretations has been presented by Ajio Fukuta, Japan's leading folklorist. Fukuta examined the frequencies of Yanagita's use of “*jōmin*,” as well as its meanings, in his voluminous works. Having found that Yanagita's usages had changed over time, Fukuta classified them into three periods: (1) from the 1910s to the 1920s; (2) around the mid 1930s; and (3) after the 1940s. In the first period, when Yanagita first made his name as a governmental bureaucrat and later, after his resignation, as a pioneer in folkloristics, *jōmin* was used to mean peasants who had settled in a particular community located on flat land, as contrasted with non peasants, such as hunters, wood turners, and some sorts of religious practitioners, who moved from community to community in the mountains. In the second period, when Yanagita's scholarship fully developed, *jōmin* meant not simply peasants but “ordinary peasants,” excluding the hereditary upper class peasants who owned massive land and thus dominated local politics. Fukuta's interpretation is based on Yanagita's classic statement, made in his 1935 book *Kyodo Seikatsu no Kenkyūho* (*Methods in the Study of Local Community Life*), that *jōmin* were found in between the upper and the lower classes of people in a farming community, the former pointing to the hereditary ruling class, and the latter pointing to people engaged in specialized occupations, such as smiths, coopers, and itinerant priests. These people refused to settle in one community. In the last period, when Yanagita's research interest shifted from the study of local customs to that of Japan's national culture, *jōmin*'s meaning

was extended to include the entire Japanese population, even the emperor. In Yanagita's observation, some aspects of ordinary people's life, rituals in particular, closely resembled those of the imperial family – hence the unity of the Japanese nation.

After Yanagita's death in 1962, much of the debate on *jōmin* focused on the extended usage just mentioned. Central to the debate was the question of whether *jōmin* constituted a specific category of people who really existed at a particular time and place or, by contrast, an abstract category comprising the entire Japanese people across time and space. Fukuta supported the former position, regarding *jōmin* mainly as *honhyakusho* (independent peasants), who, in the Tokugawa period, possessed their own land and house, as well as their descendants, who were believed to embody their ancestors' traditions in modern times. He thus objected to Yanagita's attempt to make *jōmin* an all embracing category. Many folklorists supported Yanagita, however, and interpreted *jōmin* as meaning not only the Japanese people, but also the totality of their way of life. In their hands, *jōmin* became almost synonymous with Japanese culture – a view that later came to be called “*jōmin* as a cultural concept.”

This identification of *jōmin* with Japanese culture aroused much controversy among historians. Historians directed their criticisms toward the folklorists' indifference to the time frame, which, according to the former, was derived from the latter's supposition of the “supertemporal nature” of *jōmin*. This concept was so named after the folklorists' assertion that *jōmin* was a transgenerational category. Indeed, the aforementioned “*jōmin* as a cultural concept” was divorced from a specific time frame, hence unable to indicate when particular customs were practiced – a criticism similar to that of “essentialism” in today's scholarship. Another criticism made by historians, especially those in the Marxist camp, was concerned with the folklorists' indifference to class, which derived from the supposed “superclass nature” of *jōmin*. Given Yanagita's view that *jōmin* included the emperor, this was only expected. All in all, the idea of *jōmin* has the same weaknesses as the anthropological notion of culture: both tend to be essentialist and gloss over internal differences and conflict.

Fukuta's approach, by contrast, is free from such ambiguities. It represents what has come to be called “*jōmin* as a substantial concept.” This concept, however, has a different set of problems. For one thing, the proportion of the people Fukuta identified as *jōmin* (i.e., independent peasants in Tokugawa times and their descendants) has significantly diminished in post war Japan as a result of urbanization and industrialization. Since *jōmin* is a pivotal concept in Japanese folkloristics, this demographic change implies the loss of the discipline's *raison d'être*. At least, the dramatic social change that has occurred since the end of World War II has made it necessary to reconsider the folklorists' customary emphasis on peasant culture. Some scholars, most notably Noboru Miyata, have tried to solve this problem by developing new fields, such as “urban folkloristics.” For another, the attempt to restrict the meaning of *jōmin* to a narrowly defined group of people will eventually direct the researchers' attention away from the folk customs practiced outside that category. Accordingly, the scope of research will be considerably diminished, and folkloristics may lose its popularity among readers at large.

Despite his familiarity with western scholarship, Yanagita seldom mentioned the literature he had consulted in producing his voluminous works. This omission was probably intentional. Yanagita was convinced that folkloristics would only prosper in a country like Japan, where the old and the new coexisted, and that western scholars would sooner or later be forced to reexamine their findings in light of the Japanese research. Yanagita wanted to be the leader, if not the founder, of the world community of folklorists. Considering the passive role Japanese academics conventionally played in the international community, his ambition was exceptional. However, Yanagita's failure to properly acknowledge his intellectual debt has brought about unfortunate results among his followers – the difficulty of assessing his achievement in the global context and the subsequent isolation of Japanese folkloristics from western scholarship, which occupies a central place in the “academic world system” (Kuwayama 2004). Thus, it is unclear if Yanagita's concept of *jōmin*, around which his scholarship developed, has any connection with, for example, the Annales School of French social history, which

developed at about the same time. The task of clarifying the “western roots” of Yanagita still remains to be done.

journaling, reflexive

Valerie J. Janesick

Journal writing as a reflexive research activity has been called reflexive journaling by many sociologists and researchers in training. It has been most used by qualitative researchers in the social sciences and other fields since these professionals are seeking to describe a given social setting or a person's life history in its entirety. Qualitative research has a long history of its own which includes discussion of the techniques of the qualitative researcher. Reflexive journaling has been one of the most described and often used techniques (Janesick 2004). It has proven to be an effective tool for understanding the processes of qualitative research more fully, as well as the experiences,

mindsets, biases, and emotional states of the researcher.

Many researchers advocate the use of a reflexive journal at various points in the research project timeline. To begin with, a journal is a remarkable tool for any researcher to use to reflect upon the methods of a given work in progress, including how and when certain techniques are used in the study. Likewise, it is a good idea to track the thinking processes of the researcher and participants in a study. In fact, writing a reflexive journal on the role of the researcher in any given qualitative project is an effective means to describe and explain research thought processes. Often qualitative researchers are criticized for not explaining exactly how they conducted a study. The reflexive journal writing of a researcher is one device that assists in developing a record of how a study was designed, why certain techniques were selected, and subsequent ethical issues that evolved in the study. A researcher may track in a journal the daily workings of the study. For example, did the participants change an interview appointment? How did this subsequently affect the flow of the study? Did a serious ethical issue emerge from the conduct of the study? If so, how was this described, explained, and resolved? These and other such questions are a few examples of the types of prompts for the writer. In addition this emphasizes the importance of keeping a reflexive journal throughout the entire qualitative research project.

If one checks recent dissertations completed and catalogued on Dissertation Abstracts International, it is easy to see that many recent dissertations include the use of a reflexive journal. The inclusion of the use of the reflexive journal as part of the data collection procedure indicates, to some extent, the credibility of this technique. But, conversely, does it not also act as a source of credibility and validity for the overall project? As a research technique, the reflexive journal is user friendly and often instills a sense of confidence in beginning researchers and a sense of accomplishment in experienced researchers. Many researchers verify that the use of a reflexive journal makes the challenge of interviewing, observations, and taking fieldnotes much more fluid. Researchers who use the reflexive journal often become more reflective persons and better writers. Writing

in a journal every day instills a habit of mind which can only help in the writing of the final research report.

In beginning the reflexive journal, regardless of the project, it is always useful to supply all the basic descriptive data in each entry. Information such as the date, time, place, participants, and any other descriptive information should be registered in order to provide accuracy in reporting later in the study. Especially in long term qualitative projects, the specific evidence which locates members and activities of the project can become most useful in the final analysis and interpretation of the research findings. Now let us turn to the history of the reflexive journal and the creation of a reflexive journal, which are also critical aspects of the journaling process.

Journal writing began from a need to tell a story. Famous journal writers throughout history have provided us with eminent examples and various categories of journals (Progoff 1992). Some types of journal writing can be viewed from the perspective of chronicler, traveler, creator, apologist, confessor, or prisoner, as Mallon (1995) describes. No matter what orientation taken by the reflexive journal writer, it is generally agreed that reflexive journal writing is utilized for providing clarity, organizing one's thoughts and feelings, and for achieving understanding. Thus the social science researcher has a valuable tool in reflexive journal writing.

While journal writing has its seeds in psychology, sociology, and history, one can rely on understanding the use of the journal from social psychology and the symbolic interactionists. In addition, what Denzin (1989) calls "interpretive interactionism" is a useful tool for understanding the reflexive journal. Symbolic interactionists have historically argued that we all give meaning to the symbols we encounter in interacting with one another. Interpretive interactionists go a step further in that the act of interpretation is a communication act with one or more interactors. For the journal writer, one is interacting with one's self in a sense.

Basically, the art of journal writing and subsequent interpretations of journal writing produce meaning and understanding which are shaped by genre, the narrative form used, and personal cultural and paradigmatic conventions

of the writer, who is either the researcher, participant, and/or co researcher. As Progoff (1992) notes, journal writing is ultimately a way of getting feedback from ourselves. In so doing, it enables us to experience in a full and open ended way the movement of our lives as a whole and the meaning that follows from reflecting on that movement.

One might ask, why should one invest the time in journal writing? Journal writing allows one to reflect, to dig deeper into the heart of the words, beliefs, and behaviors we describe in our journals. The act of writing down one's thoughts will allow for stepping into one's inner mind and reaching further for clarity and interpretations of the behaviors, beliefs, and words we write. Journal writing also allows for training the writer as a researcher in writing about a research project in progress. The journal becomes a tool for training the research instrument, the person. Since qualitative social science relies heavily on the researcher as research instrument, journal writing can only assist researchers in reaching their goals in any given project.

Judaism

Abraham D. Lavender

Judaism is one of the world's oldest religions, characterized by a belief in one God (monotheism), a belief that the Torah is the source of divine knowledge and law, and that the Jews,

because the Torah was given to them after other peoples turned it down, have an obligation to be a light unto the world. The Torah is also referred to as the holy scriptures. It is the first five books (Genesis, Exodus, Leviticus, Numbers, and Deuteronomy) of what Christians refer to as the Old Testament. In Hebrew, the word *Torah* means “teaching.” In a larger sense the Torah consists not only of the five books, but includes all of Jewish tradition. The belief in monotheism is affirmed in the Shema, the first line and essence of which comes from Deuteronomy 6:4, and is translated as “Hear, O Israel, the Lord our God, the Lord is One.” Judaism does not claim to be the only true religion, but rather teaches that there are different ways of reaching God.

Some sources define Judaism as the religion of the Jews, but this then raises the question of how to define Jews. The definition has changed throughout history, and continues to change even until today. This situation exists largely because Jews also have been considered a race, an ethnic group, a culture, a civilization, or a nation. Today, a person born of a Jewish mother is considered Jewish even if he or she does not practice Judaism, unless there is a deliberate rejection of Judaism. Reform and Reconstructionist Judaism accept a child born of either a Jewish mother or father if the child is raised to accept Judaism. But until about 2,000 years ago the religion followed the father instead of the mother. In Israel today the issue of who is a Jew continues to be a hotly debated topic which changes according to the internal political situation and influences from the Diaspora.

Abraham (ca. 1600 BCE) is considered the first patriarch and the founder of Judaism. He was born and raised in Ur (present day Iraq), and after rejecting the idols of his culture and accepting the belief in monotheism, he migrated to Canaan. As with much of ancient history, researchers today question whether this is legend or fact, or a mixture of both, but Abraham is viewed as the founder of Judaism.

The initials used above, BCE, refer to Before the Common Era, and CE refers to the Common Era. They frequently are used by Jews instead of BC and AD, which are based on the birth and death of Jesus, and hence are viewed by some as Christian markers. However, the years are the same as in the Christian (Gregorian) calendar,

so that one could, for example, say 2007 CE, which would be the same as AD 2007. However, within the Jewish community, and with Jewish calendars, the years differ, and one does not use any initials after the year. Because Judaism, like Islam, the Chinese culture, and others, uses a lunar calendar instead of a fixed calendar, the Jewish year does not begin on January 1, but on the Jewish holiday, Rosh Hashanah (“the head of the year”), which usually occurs in September or early October. The Jewish calendar adds 3,761 years to the Christian calendar, so that, for example, the Christian year of 2000–2001 was the Jewish year of 5760–5761. Judaism uses this system to date the beginning of the world with Adam and Eve. Abraham, and the beginning of Judaism, go back only about 3,600 or 3,700 years, but the Jewish calendar goes back 1,946 years before Abraham. The number of years is based on the 19 generations listed inclusively from Adam to Abraham (Abram) in Genesis 5:3–32 and Genesis 11:10–26. The Jewish day begins at sundown instead of at midnight.

While all of the Torah is very important to Judaism, the Ten Commandments (Exodus 20:1–17), revealed to Moses at Mount Sinai in the thirteenth century BCE, are viewed in Judaism as the basis of all legislation. About two centuries after Moses, King David (1010–970 BCE) made Jerusalem the center of the government and of Judaism. David’s son Solomon built the first Temple, making Jerusalem the physical center of worship for Jews. But the strengthening of Jerusalem strained relations with the tribes outside of Jerusalem, leading to major effects on the future of Judaism.

Like most religions, Judaism has changed over time and has developed divisions with different definitions, degrees of traditionalism, and practices. The first major division was in 721 BCE when the ten northern tribes, known as Israel, were conquered by the Assyrians and sent into exile (becoming known as the Lost Tribes), while the two southern tribes, known as Judah and centered in Jerusalem, continued. In 2 Kings 17:7 it is said that Israel fell because “the people of Israel had sinned against the Lord their God.” But in 586 BCE Judah also fell, victim of the large Babylonian Empire to the east. Solomon’s Temple was destroyed and much of the population, especially much of the religious leadership, was deported to Babylonia.

Large numbers also went to Egypt. But only a few decades later, in 538 BCE, under new Babylonian leadership, Jews were allowed to return to Jerusalem. Some stayed in Babylonia and some returned. The exile was interpreted as punishment for sins, and the return was interpreted as God's forgiveness for the sins.

The Temple was rebuilt in Jerusalem (completed in 516 BCE) and referred to as the Second Temple. Rebuilding a Jewish life was not easy, but eventually Judah was reestablished with Judaism at its center and the Temple playing a major role. The Greek empire was the next threat to Judaism, partly by ruling over Judah, but also by presenting other perspectives and "hedonistic" philosophies. After 198 BCE the Seleucids ruled Jerusalem, banned the practice of Judaism, and raised an altar to Zeus in the Temple. In 165 BCE the Maccabees, a Jewish group, won independence for Judah and reestablished Judaism. Two groups arose during this period: the Pharisees, who maintained the Torah and the Oral Law and tried to adapt Judaism to new conditions, and the Sadducees, an aristocratic group who rejected the Oral Law and interpreted the Pentateuch (Genesis, Exodus, Leviticus, Numbers, and Deuteronomy) literally. Although they were frequently dominant in Temple worship, they disappeared as a group with the destruction of the Second Temple in 70 CE. Oral Law is the authoritative interpretation of the Written Law (the Pentateuch), and traditionally is considered as being given to Moses at Mount Sinai along with the Written Law.

The destruction of the Second Temple resulted from Roman rule. Religious conflict was dominant in Israel, partly leading to a weakened condition, and by 47 BCE Israel was ruled by the Roman Empire. This defeat brought great soul searching, many individuals claimed to be the promised Messiah who would bring peace (Jesus, a rabbi, appeared in this context), and conflicts between religious groups were frequent. There were Jewish revolts against the Romans, and as a result in 70 CE the Second Temple was destroyed. In 135 CE a second revolt was crushed and most Jews were exiled from Israel.

Even by the end of the first century of the Common Era, shortly after the life of Jesus, the

world Jewish population was about 7 million, with about 2.5 million in Israel and almost two thirds in the Diaspora, especially in Egypt, Syria, Greece, Rome, and Babylonia. With a Temple no longer existing as the major center of Judaism, and with nearly all Jews expelled from Israel in 135 CE, the worship of Judaism would undergo major changes. Over a million Jews had been killed during the revolts in Israel, including rabbis and other scholars, and many yeshivot (Jewish academies) had been destroyed. A religious need existed. Rabbinic Judaism, which emphasized interpretations by rabbis, would become dominant. The synagogue increased in importance, becoming the focus of Jewish communal life. Because nearly all Jews were now in Diaspora, living in many countries, many interpretations of how to believe in and practice Judaism developed. The Babylonian Talmud was developed between the early third and late fifth centuries CE. It consists of Jewish history and customs, and interpretations of Jewish law. The less accepted Jerusalem Talmud was completed around the fifth century CE. Halakhah refers to the legal part of the Talmudic and later Jewish literature, including Oral Law, and is the traditionally accepted interpretation of the Written Law.

From a cultural perspective, Jews today are classified as Sephardic or Ashkenazic. Sephardic comes from the Hebrew word referring to Spain, and Sephardic Jews in a restricted sense are those Jews from Spain or Portugal. However, the term frequently is used also to refer to Jews from the Near East, the Middle East, North Africa, and a few other locations. A more correct terminology is to refer to Jews from the Eastern world as Mizrahim, *mizrahi* meaning "eastern" in Hebrew. Ashkenazi comes from the Hebrew word for Germany, but like Sephardi, has been extended to cover a much larger area. It includes all of Europe except a few areas such as Spain and Portugal, and in a larger sense, generally refers to those Jews who have lived in Christian lands. Jews lived in many of these areas long before the areas became Christian. By contrast, most Sephardim have lived in Islamic or Muslim lands since the advent of Islam in the seventh century, although most of these areas, such as Iran,

Iraq, the Middle East, and North Africa, had sizable Sephardic populations long before the areas became Islamic.

Sephardim, living mostly in Islamic lands, were not treated as equals but generally were not treated as badly as the Ashkenazim (*im* is the masculine plural, and *ot* the feminine, in Hebrew). Sephardim were more likely to interact with the non Jewish populations, whereas Ashkenazim, facing more oppression, were less likely to interact with non Jews. Ashkenazim generally maintained Yiddish, that is, Hebrew mixed with German or other European languages, as their major language. Sephardim from Spain maintained Ladino, Hebrew mixed with Spanish, to a limited degree, and in some other areas maintained Hebrew mixed with the local language, such as Judeo Persian. But Sephardim or Mizrahim largely spoke the language of the country. In all Arab countries Arabic remained the vernacular of the Jews to the present time, and a voluminous literature in Arabic was produced by Jews. Largely because of the interaction, or lack thereof, with non Jewish neighbors, Sephardim and Ashkenazim developed different responses to discrimination and persecution. Ashkenazim have been more likely to approach persecution from a martyr perspective, whereas Sephardim have been more likely to temporarily adjust themselves to the demands of the oppressive society (some times converting to the dominant religion, with a secret maintenance of Judaism) with the expectation of being able to return to Judaism at a later date. Maimonides (1135–1204), a very famous rabbi, philosopher, and physician who was born in Spain, fled to Morocco to escape persecution, and spent most of his life in Egypt, taught this perspective. Some indications are that his family followed this perspective.

In 1170 there were 1,400,000 Sephardim in the world, and only 100,000 Ashkenazim, Sephardim comprising 93.3 percent of world Jewry. World trade patterns shifted, some countries underwent difficult times, and by 1700 there were 2 million Jews in the world, evenly divided between Ashkenazim and Sephardim. In the next 200 years the Ashkenazim, largely in Eastern Europe, continued an explosive growth while the Sephardim declined. In 1900 there were 9,550,000 Ashkenazim and

only 950,000 Sephardim, Ashkenazim comprising 90.5 percent of world Jewry.

Largely because of different experiences of Jews living in diverse areas, as well as the influences of modernization, Judaism historically has had religious divisions and movements. In the Common Era, the Karaites appeared in the Middle East in the early eighth century, and rejected the Talmudic and Rabbinic traditions. Kabbalah, emphasizing Jewish mysticism, became more important around the twelfth century. By the sixteenth century, Jerusalem, Safed, Tiberias, and Hebron were centers of Jewish mysticism in Israel. Shabbetai Zevi came out of Turkey in the seventeenth century, claimed to be the Messiah, and got a large following, but eventually converted to Islam under pressure. Hasidism arose in Eastern Europe in the eighteenth century as a pietist religious and social movement, emphasizing devotion of the masses rather than Talmudic learning for a few. The Haskalah, a modernization and Enlightenment approach to Judaism, arose in Germany, Italy, and Western Europe in general in the 1770s.

Today, there are several major branches of Judaism, which differ in their beliefs and practices. In most Ashkenazi areas the two main divisions are Orthodox, or Traditional, Judaism, and Liberal, or Progressive, Judaism. Orthodox Judaism accepts the totality of Judaism as based on the Torah, Oral Laws, and commentary, and requires a strong degree of traditional belief and daily observance. It is divided into Modern Orthodox and Traditional Orthodox. Liberal Judaism has made more adjustments with modern societies and is less demanding in both beliefs and practices.

The US, whose Jewish population is over 90 percent Ashkenazi, developed a threefold division of Orthodox, Conservative, and Reform Judaism, largely because of migration patterns which were not experienced in other countries. Although Sephardic Jews founded the US Jewish community in 1654 and remained the cultural elite until the 1700s, the first sizable Jewish population was established in the early and middle 1800s by German Jews. They usually had been influenced by Haskalah before migrating. Reform Judaism had begun in Germany and was brought to the US. In the 1880s large numbers of Jews began migrating to

the US from Eastern Europe, which mostly had not yet experienced the Haskalah. Hence, they usually brought Orthodoxy with them. Many felt that Orthodoxy was too traditional for the US, which was much different from Eastern Europe, but many also felt that Reform Judaism had given up too much tradition. So a middle ground, Conservative Judaism, developed. Conservatism agrees with Orthodoxy in many beliefs, but is closer to Reform in practices. A fourth branch of Judaism in the US, Reconstructionism, views Judaism as an evolving religious civilization and follows some modern practices, such as ordination of women. Sephardic Jews did not follow this migration pattern to the US, and hence did not divide into either Reform or Conservative Judaism. Sephardic Judaism is Orthodox, but because it represents all Sephardim with various degrees of traditionalism and modernization, it tends to be more flexible than Ashkenazi Orthodoxy.

In contemporary Israel, because of political alignments within the Knesset (Israel's parliament), Orthodoxy (mostly of the Ashkenazi perspective) has been the arbiter of religious and cultural disagreements. This includes the question of who is a Jew, and has led to major conflicts between traditional and non traditional Jews. A large number of Israeli Jews are secular rather than religious. Reform and Conservative Judaism have made some progress in Israel, but progress has been limited because of insufficient political power. The Masorti movement, founded in 1979, is the umbrella for Conservative Jews in Israel.

Judaism has several major holidays and a number of minor holidays. Most important are Rosh Hashanah, Jewish new year, and Yom Kippur, the Day of Atonement. Rosh Hashanah begins a 10 day period of repentance that ends with Yom Kippur, the holiest day of the Jewish year. As noted, both occur in September or October. Other major Jewish holidays are a reflection of Judaism's long religious and cultural history, including persecutions and victories. Purim (February–March) is a joyful holiday that celebrates the victory of the Jews over a plot to destroy them in ancient Persia. Pesach, or Passover (March–April) is a celebration of the Jewish escape from slavery in ancient Egypt in the thirteenth century BCE. Sukkot (September–October) is a joyful festival

symbolized by booths (*sukkot*) which represent the huts which Jews lived in during the years in the wilderness during their return from Egyptian slavery. Sukkot is celebrated for 7 days and nights and concludes with Simchat Torah, a joyful holiday which celebrates the completion of the annual reading of the Torah and the beginning of a new cycle. Hanukkah (usually December) lasts for 8 days and celebrates the victory of the Maccabees over the Seleucid oppression in 165 BCE. Historically, Hanukkah was a relatively minor holiday, but it has become more important in Christian countries partly to offset Christmas so that Jewish children do not feel left out.

Judaism has several life cycle events beginning with circumcision (*brit milah*) for a male Jewish child on the eighth day after birth. This is to renew the covenant between Abraham and God (Genesis 17:9–13). When a child is 13 years of age, a rite of passage into adulthood is celebrated: bar mitzvah for the male and bat mitzvah for the female. In the US and some other places in recent decades, these ceremonies have become expensive celebrations for some youths. Bat mitzvahs, traditionally not celebrated as much as bar mitzvahs, have increased in importance in recent decades to lessen the gender gap. Marriage and death, as in most religions, also have special religious ceremonies.

Intermarriage of Jews with non Jews has become very common in a number of places, including the US, in the last few decades. This reflects the extent to which Jews have been accepted in larger societies, but it also is a numerical threat to the Jewish community because of the tendency of children of intermarried couples to merge into the larger society. Assimilating often is easier than maintaining a separate identity. Some non Jews who marry Jews convert to Judaism, but overall intermarriage is a numerical loss to the Jewish community.

At the same time that Judaism is losing people to intermarriage, there are two groups of people who are returning to Judaism. In the Americas, thousands of descendants of Jews who left Judaism during the Spanish Inquisition (especially 1391 to 1492) are returning to a Jewish identity. This is found especially in the Southwestern US, but is evident in most areas with large numbers of Hispanics, such as

California, Miami, Florida, and New York City. Some descendants of the Lost Tribes of Israel, exiled by the Assyrians in 721 BCE, also are returning to Judaism. Some, especially from India, have returned to Israel to live. Black Jews from Ethiopia also have returned to Israel in large numbers, undergoing conversion once in Israel. Among all these returnee groups, there is a desire, so far unfulfilled, for a return ceremony rather than a conversion ceremony.

The belief that Jews are a race has been held by most non Jews and some Jews until recent decades, and historically has been used as an excuse for major anti Semitic actions. The Crusades, the Inquisition in Spain and Portugal, the pogroms (mob attacks on Jews, often for fun) in Eastern Europe, and the Holocaust all have had various degrees of racial, religious, and social reasons for anti Semitism. The racial dimension has often been the most severe, especially during the Holocaust. It was the pogroms in Russia which gave impetus to the First Aliyah in 1881–2 and began the large scale return of Jews to Israel as part of the Zionist movement. In recent decades the concept of race has decreased in importance and more attention has been put on genetic (DNA) clusters. There is a Middle Eastern genetic base shared by about two thirds of Jews in the world, and the closest genetic relatives of Jews as a group are other Middle Eastern groups such as Palestinians, Syrians, and Lebanese.

Recent studies conclude that there are about 13 million (12,950,000) Jews in the world today, with 60.7 percent (7,856,000) in the Diaspora and 39.3 percent (5,094,000) in Israel. The Americas account for 46.9 percent (6,071,100) of world Jewry, with the US alone accounting for 40.9 percent (5,300,000). This has decreased in the last few decades, largely because of intermarriage and loss of children to Judaism. In the Americas, other than the US, the largest populations are in Canada (370,500), Argentina (187,000), Brazil (97,000), and Mexico (40,000).

Hashoah (the Holocaust) killed about 6,000,000 Jews – 37 percent of all world Jewry – mostly in Europe. Until then, 60 percent of world Jewry lived in Europe. Now, Europe has only 12.0 percent (1,550,800) of world Jewry. The three largest populations are found in France (498,000), of whom many are post 1948

exiles from Morocco, Algeria, and other North African countries, the United Kingdom (300,000), and Germany (108,000), most of whom are immigrants from Eastern Europe. Next in size in Europe are Russia (252,000), Ukraine (95,000), Hungary (50,000), Belgium (31,400), the Netherlands (30,000), Italy (29,000), and Belarus (23,000). In the 1990s about 900,000 Jews left the former Soviet Union and moved to Israel. Iran, Iraq, and North African countries historically had large Jewish populations, but most of these Jews (about 870,000) left in the 15 years after 1948 because of hostility against them after Israel's independence in 1948 and the rise of Islamic based nationalism in North Africa. About 600,000 moved to Israel, and today about half of the population of Israel is Sephardi or Mizrahi.

The above figures, given annually in the American Jewish Year Book, are estimates and include people who identify as Jewish, whether or not they are active followers of, or even believers in, Judaism. Once again, the definition of who is a Jew includes a mixture of religious and cultural identities, and, for countries where anti Semitism persists, racial components.

juvenile delinquency

Jeff Maahs

Juvenile delinquency refers to behaviors of children and adolescents that violate the legal code. Some jurisdictions further distinguish "delinquent offenses," those that violate criminal law, from "status offenses" (e.g., curfew violation, truancy) that apply only to minors. The legal status of "juvenile delinquent" is relatively new. The concept of delinquency is rooted, however, in an ancient debate over when children can form criminal intent and bear criminal responsibility for their actions, and whether/how they should be officially sanctioned. Some of the earliest written legal codes make distinctions in the punishments available for children and adult offenders. By the seventeenth century, English common law adopted a classification system where children under 8 years of age were immune from criminal prosecution. For youth aged 8 to 13 years, the state had the burden of proving that the youth possessed criminal intent (Butts & Mitchell 2000). In the United States, Progressive era reformers went a step further and created an entirely new system to respond to juvenile offenders. The first juvenile court, created in Cook County, Illinois in 1899 and modeled thereafter by other states, was markedly different from criminal courts. The new court was quasi civil and informal in nature, and under the doctrine of *parens patriae* (the state as parent), aspired to act in the best

interests of the child. The new philosophy and procedures required a new language. Thus, rather than finding juveniles guilty of a criminal offense and sentencing them to a sanction, youths were "adjudicated delinquent" and received a suitable "disposition."

The issues of criminal responsibility and age appropriate responses to juvenile offending remain unresolved, as evidenced by wide variation in statutes defining juvenile delinquency across the United States. For example, the upper age limit for juvenile court jurisdictions ranges from 15 to 18 years. Additionally, many states have statutes that allow, for various reasons (e.g., seriousness of offense, prior juvenile offenses), youth to be waived to criminal court.

Aside from legal considerations and the formal response to juvenile misconduct, juvenile delinquency occupies a central position in the study of criminal behavior. This position is well justified for a number of reasons, chief among them the prevalence of juvenile offending. In the United States, juveniles aged 13–17 years make up only 6 percent of the population, yet account for roughly 30 percent of all arrests for Uniform Crime Reporting (UCR) index offenses. A plot of arrest rates versus age yields an "age-crime curve" that indicates offending rates peak during adolescence (around age 16 for property offenses, and age 18 for violent offenses) and diminish soon thereafter.

Unsurprisingly therefore, the major theoretical paradigms explaining crime, including social control theory (Hirschi 1969), social learning theory (Sutherland 1947), strain theory (Merton 1938), and labeling theory (Becker 1963), are derived from theories of juvenile delinquency. In the 1960s, several "subculture" theories evolved solely to explain the existence and nature of delinquent gangs (see, e.g., Cohen 1955). Although some of these theories extend to account for adult offending, most focus explicitly on concepts (school experience, peer groups, parenting) that are germane to adolescence. More recently, juvenile delinquency interests criminologists for another reason – its ability to predict future criminal behavior.

Studies (using both self report and official data) of cohorts of children indicate that a small minority of children (roughly 6 percent) account for a large portion (over 50 percent) of the delinquency in that cohort. Further,

delinquency, and even non delinquent behavior problems (e.g., severe, age inappropriate temper tantrums, conduct disorder), are robust predictors of future criminal behavior. A major goal of developmental or life course criminology is to explain why antisocial behavior is stable over time. Some theorists argue that stability is due to a trait (impulsivity, low self control) that is stable from early childhood onward. Others contend that delinquency itself has effects on the environment (school performance, peer and parent relationships) that mortgage the child's future prospects and narrow options for change. While this debate remains unsettled, there is some agreement with regards to other correlates of juvenile delinquency.

Gender is among the most agreed upon correlate of crime. Regardless of how delinquency is measured (e.g., arrest data, self report, victimization data), males are much more likely to engage in most forms of delinquency than females. The data are more ambiguous for social class and race. In the United States, official data (and some victimization data) indicate moderate to strong relationships between delinquency, class, and race, whereas self report data often indicate weak or nonexistent associations. This may be due to police or court bias, or to differences in the nature of offenses measured by self report and official data. Aside from gender, the most empirically supported individual level correlates include socialization markers (parental supervision and discipline, parent-child bond), and the influence of delinquent peers. At the macro level, social disorganization theorists focus on neighborhood characteristics (high

poverty, high residential mobility) conducive to delinquency. Sampson and Groves (1989), using data from the British Crime Survey, found that delinquency is more likely in neighborhoods where these ecological characteristics impede a neighborhood's ability to informally supervise and control youth.

K

key informant

Jon H. Rieger

The term key informant is generally associated, though not exclusively, with qualitative research in which a researcher employs interviewing of knowledgeable participants as an important part of the method of investigation. During the often extended period of fieldwork that such research requires, a particular subject may become an especially useful source of information, be repeatedly interviewed, and thus earn designation as a key informant. It is not unusual in field research that at any particular time an investigator might have several informants who could be identified as performing in that role. Key informants can extend the investigator's reach in situations where he or she has not been, or cannot be a direct observer, and they can illuminate the meanings of behavior that the researcher does not understand. They can also serve as a check on the information obtained from other informants.

Varying circumstances may determine who actually ends up serving as a key informant. Sometimes a person becomes a key informant by merit of playing an important role in the social setting being studied. If the researcher is studying an organization, for example, a key informant might turn out to be that person who occupies a central structural position or who may be situated strategically in the communication network within the organization. An individual in such a position is likely to be unusually knowledgeable about the organization and its internal dynamics and may function as a gatekeeper. This circumstance can make his or her cooperation critically important to the success of the research. Properly cultivated, that person may serve not only as a key

informant, but may also function as a potential sponsor and guide.

Another kind of subject who might become a key informant would be an individual who has long experience with the phenomenon being studied: veteran participants are likely to be rich repositories of information. Long term participants in a particular setting potentially provide not only a wealth of useful information but can also bring perspective to their accounts. Researchers tend to be acutely sensitive to those circumstances which may indicate that a particular subject has special or extensive knowledge and may therefore make special recruitment efforts to secure his or her service in that role. Classic studies by Whyte (1955) and Liebow (1967) demonstrate the successful utilization of key informants by social researchers in field settings.

Who will be a key informant is not always predictable, for as often as not, the person who fulfills that role emerges as the research is ongoing. While the researcher may have good reasons to surmise that certain individuals will become key informants, this is not always the way things turn out in field situations. A person who may be desirable as a potential informant may be, for various reasons, insufficiently accessible to the researcher. Issues of trust can interfere with development of the researcher–informant relationship, or there may arise simple conflicts of personality or temperament. Moreover, key informants may shift as the research is ongoing: different phases or aspects of the research may call forth different individuals who can serve as key informants.

The researcher must exercise some care in the choice and employment of informants and in reliance on any of them as key sources. For example, experienced field researchers are generally wary of subjects who present themselves early and enthusiastically to outsiders. Such

individuals may actually be marginal or isolated within their own group. Uncritical use of these subjects may yield information of little value and interfere with gaining access to more reliable sources. The value of a key informant may also be adversely affected by his or her limitations as an observer, or lack of reportorial articulateness or sensitivity. To combat such problems some field researchers have even suggested that key informants be given training for their roles (Pelto & Pelto 1978).

Other perils accompany reliance on key informants. They may harbor unacknowledged biases or be driven by their own private agendas. Alternatively, key informants may distort, embellish, or exaggerate their accounts in an attempt to provide what they believe the researcher wants to hear. On the other hand, informants may willfully falsify or invent information. Chagnon (1977), for example, spent most of his initial field time being systematically lied to by supposed key informants among the Yanomamo Indians in South America, and it took 5 months of effort before he was able to connect with even a single source in the tribe that he could trust, and nearly a year to find a second informant to confirm the accounts of the first.

The value of informants in social research was well recognized at a fairly early stage in the evolution of contemporary research methodology and a substantial literature began to develop on the topic, especially in the 1950s. By the late 1960s virtually every aspect of the potentials and limitations of informant interviews had been pretty thoroughly explored. The basic insights into the use of informants generally, and key informants in particular, date to this classic literature. The value of this approach as a component of a robust social research methodology has thus been well established for several generations, and it has become a fairly standardized part of contemporary methods training (e.g., Warren & Karner 2005). In recent decades, the use of key informants has become a very common procedure in evaluation research, so much so that in some venues it has acquired more formal recognition as the “key informant method.”

Khaldun, Ibn (732–808 AH/1332–1406)

Syed Farid Alatas

Walī al Dīn 'Abd al Rahman ibn Muhammad ibn Khaldun al Tunisi al Hadhrami was born in Tunis on 1 Ramadan of the Muslim year into an Arab family which originated from the Hadhramaut, Yemen and subsequently settled in Seville at the beginning of the Arab conquest of Spain. His ancestors left Spain for North Africa after the Reconquista and settled in Tunis in the seventh/thirteenth century. Ibn Khaldun was a scholar, teacher, and judge but is best known from the nineteenth century as

the founder of historiography and sociology. Ibn Khaldun received a customary education in the traditional sciences, after which he held posts in various courts in North Africa and Spain. After a number of unsuccessful stints in office he withdrew into seclusion to write his *Muqaddimah*, a prolegomenon to the study of history that was completed in 1378 and which introduces what he believed to be a new science he called *'ilm al 'umran al bashari* (science of civilization) or *'ilm al ijtimā' al insani* (science of human society). Ibn Khaldun's chief works are the *Kitab al 'Ibar wa Dīwan al Muḥtadā' wa al Khabar fi Ayyam al 'Arab wa al 'Ajam wa al Barbar wa man Asar ahum min Dhawī al Sultan al Akbar* (*Book of Examples and the Collection of Origins of the History of the Arabs and Berbers*); *Muqaddimah* (*Prolegomenon*); *Lubab al Muḥassal fi usul al dīn* (*The Resumé of the Compendium in the Fundamentals of Religion*), being his summary of Fakhr al Dīn al Rāzī's *Compendium of the Sciences of the Ancients and Moderns*; and his autobiography, *Al Ta'rīf bi Ibn Khaldun wa Rihlatuhu Gharban wa Sharqan* (*Biography of Ibn Khaldun and His Travels East and West*).

Ibn Khaldun lived during the period of the political fragmentation and cultural decline of the Arab Muslim world. The picture of chaos and disintegration that Ibn Khaldun grew up with must have influenced the development of his thought. His central concern was the explanation of the rise and decline of states and societies and he believed that he had discovered an original method for this purpose. In fact, his own classification of the major known fields of knowledge cultivated up to his time shows that his science of human society was unknown. The first category, that of the traditional sciences (*al 'ulum al naqliyya*), refers to sciences associated with revealed knowledge, while the second category, that of the rational sciences (*al 'ulum al 'aqliyya*), refers to sciences which arise from the human capacity for reason, sense perception, and observation (ibn Khaldun 1981 [1378]: 435–7, 478). Neither ibn Khaldun's nor earlier classifications of the sciences include *'ilm al 'umran al bashari* or *'ilm al ijtimā' al insani*.

Ibn Khaldun's *Muqaddimah* is a prolegomenon to his larger historical work on the Arabs and Berbers, the *Kitab al 'Ibar*. He begins the

Muqaddimah by problematizing the study of history, suggesting that the only way to distinguish true from false reports and to ascertain the probability and possibility of events is the investigation of human society (ibn Khaldun 1981 [1378]: 38 [1967: I.77]). It is this investigation that he refers to as *'ilm al 'umran al bashari* (science of civilization) or *'ilm al ijtimā' al insani* (science of human society), which may also be translated as sociology. Ibn Khaldun made the distinction between the outer forms (*zahir*) and the inner meaning (*batin*) of history (ibn Khaldun 1981 [1378]: 1 [1967: I.6]). The outer forms consist of facts and reports while the inner meaning refers to explanations of cause and effect. The new science, therefore, is presented by ibn Khaldun as a tool for the study of history and is directed to uncovering the inner meaning of history. The new field of inquiry consists of the following areas: (1) society (*'umran*) in general and its divisions; (2) Bedouin society (*al 'umran al badawa*), tribal societies (*qabail*), and primitive peoples (*al wahshiyyah*); (3) the state (*al dawlah*), royal (*mulk*) and caliphate (*khi lafah*) authority; (4) sedentary society (*al 'umran al hadharah*), cities; and (5) the crafts, ways of making a living, occupations. These areas roughly approximate, in the language of the modern social sciences, human or social ecology, rural sociology, political sociology, urban sociology, and the sociology of work. The brief introduction to Ibn Khaldun's sociology that follows looks at the empirical and theoretical aspects of his work.

Empirically, ibn Khaldun's interest was in the study of the rise and fall of the various North African states. This begins with theorizing the differences in social organization between nomadic (*al 'umran al badawa*) and sedentary societies (*'umran hadharah*). Fundamental to his theory is the concept of *'asabiyyah* society with a strong *'asabiyyah* could establish domination over one with a weak *'asabiyyah* (ibn Khaldun 1981 [1378]: 139, 154 [1967: I.284, 313]). In this context, *'asabiyyah* refers to the feeling of solidarity among the members of a group that is derived from the knowledge that they share a common descent. Because of superior *'asabiyyah* among the Bedouin, they could defeat sedentary people in urban areas and establish their own dynasties. Having done so, they became set in the urban ways of life

and experienced great diminution in their *'asabiyyah*. With this went their military strength and their ability to rule.

There are at least two general ways in which *'asabiyyah* declines. One is where the second generation of tribesmen who founded the dynasty experience a change “from the desert attitude to sedentary culture, from privation to luxury, from a state in which everybody shared in the glory to one in which one man claims all the glory for himself while the others are too lazy to strive for (glory), and from proud superiority to humble subservience. Thus, the vigour of group feeling is broken to some extent.” By the third generation *'asabiyyah* disappears completely (ibn Khaldun 1981 [1378]: 171 [1967: I.352]). This left them vulnerable to attack by fresh supplies of pre urban Bedouins with stronger *'asabiyyah* who replaced the weaker urbanized ones. And so the cycle repeats itself.

Another distinct way in which *'asabiyyah* declines is when the “ruler gains complete control over his people, claims royal authority all for himself, excluding them; and prevents them from trying to have a share in it” (ibn Khaldun 1981 [1378]: 175 [1967: I.353]). In other words, when a tribal group establishes a dynasty and its authority becomes legitimate, the ruler can dispense with *'asabiyyah*. The ascendant ruler then rules with the help not of his own people, but of those other tribal groups who have become his clients.

The social cohesion expressed by the concept of *'asabiyyah* is only partly derived from agnatic ties in tribal social organizations. While all tribal groups have stronger or weaker *'asabiyyahs* based on kinship, religion can also bring about such social cohesion, as was the case with the Arabs who needed Islam in order to subordinate themselves and unite as a social organization. But beyond this social psychological aspect of *'asabiyyah*, there are its material manifestations. *'Asabiyyah* refers to the authority that is wielded by the leader that derives, in addition, from his material standing as a result of profits from trade and appropriation from raiding activities. For ibn Khaldun, then, *'asabiyyah* referred to (1) kinship ties, (2) a socially cohesive religion such as Islam that provided a shared idiom legitimizing the leader's aspirations for power and authority, and

(3) the strength of the leader derived from trade, booty, pillage, and conquest.

Ibn Khaldun resigned himself to the eternal repetition of the cycle. He did not foresee developments that would lead to the elimination of the cycle. This happened with the Ottomans, the Qajar dynasty in Iran, and the state in the Yemen. The cycle ceased to be in operation when the basis of state power was no longer tribal. In Ibn Khaldun's world, ordinary folk were caught between the oppressive policies and conduct of a royal authority on one hand, and the other the prospects of conquest by bloodthirsty tribesmen led by a religious leader bent on destruction of the existing order.

Underlying the above substantive concerns is ibn Khaldun's interest in elaborating a new science of society. An understanding of the relationships among the state and society, group feeling or solidarity, and the question of the end of society requires an application of Aristotle's four types of causes, the formal, material, efficient, and final cause (Mahdi 1957: ch. 5). Understanding the inner meaning of history is to know the nature of society, which in turn requires the study of its causes. The causes are what gives society its constitution (material cause), its definition (formal cause), the motive forces of society (efficient cause), and society's end (final cause) (Mahdi 1957: 233–4, 253, 270). The material cause or the “substratum” of society is identified by ibn Khaldun as the constituent elements of society such as economic life and urban institutions (Mahdi 1957: 234). What gives definition to society, the formal cause, is the organizing ability of the state (Mahdi 1957: 235). But the material and formal causes are united by an efficient cause, solidarity or group feeling (*'asabiyyah*), which is the primary factor effecting societal change (Mahdi 1957: 253–4, 261). As society has a goal or end, the final cause also enters into the analysis. The end is the common good, for the sake of which the society, state, and solidarity (the material, formal, and efficient causes) exercise their causality (Mahdi 1957: 270). The above can be said to be the elements of ibn Khaldun's general sociology, applicable to all types of societies, nomadic or sedentary, feudal or prebendal, Muslim or non Muslim.

There are numerous works on ibn Khaldun's life and thought, including an autobiography. There are not many modern biographies of ibn Khaldun, but a well known one was authored by an early Egyptian sociologist, Muhammad Abdullah Enan, and is available in both the Arabic original and English translation (1941, 1953). Ibn Khaldun has been widely written on in the Arab and Muslim world as a precursor of modern sociology. Well known examples are 'Abd al 'Aziz 'Izzat's thesis in 1932 entitled *Ibn Khaldun et sa science sociale* supervised by Fauconnier and Maunier in France (Roussillon 1992: 56 n48) and another work comparing ibn Khaldun and Émile Durkheim ('Izzat 1952). Ali Abd al Wahid Wafi undertook a comparative study of ibn Khaldun and Auguste Comte (1951) and wrote a much cited work on ibn Khaldun as the founder of sociology (1962).

Ibn Khaldun has been recognized as a founder of sociology by earlier generations of sociologists (Kremer 1879; Flint 1893: 158ff.; Gumpłowicz 1928 [1899]: 90–114; Maunier 1913; Oppenheimer 1922–35: II.173ff., IV.251ff.; Ortega y Gasset 1976–8 [1934]). Becker and Barnes in their *Social Thought from Lore to Science*, first published in 1938, devote many pages to a discussion of the ideas of ibn Khaldun, recognizing that he was the first to apply modern like ideas in historical sociology.

However, this degree of recognition has not been accorded to ibn Khaldun in contemporary teaching and the writing of the history of sociology. A neo Khaldunian sociology has yet to be developed. There has always been little interest in developing his ideas, combining them with concepts derived from modern sociology, and applying theoretical frameworks derived from his thought to historical and empirical realities.

There have been few works which have gone beyond the mere comparison of some ideas and concepts in ibn Khaldun with those of modern western scholars toward the theoretical integration of his theory into a framework that employs some of the tools of modern social science (Gellner 1981; Lacoste 1984; Carre 1988; Alatas 1993).

kindergarten

Valerie E. Lee and David T. Burkam

The idea of a kindergarten originated in 1840, after the German educationalist Friedrich Froebel opened a Play and Activity Institute for children between the ages of 3 and 7 to develop their mental, social, and emotional faculties. The term is now used in many parts of the world for the initial stages of a child's classroom schooling. In some countries kindergarten is part of the formal school system, but in others it usually refers to preschool or day care programs. In France and Germany such programs are separate from the schools and are often run by churches and local community groups. In India, Mexico, and the US kindergarten programs are available through both public and private schools.

Many aspects of children's education in kindergarten are important in a sociological context. However, the discussion here is restricted to a few important issues about kindergarten in the US: (1) differences in children's social and cognitive status as they begin their formal schooling in kindergarten; (2) how these social and cognitive differences map onto the quality of the schools where they experience kindergarten; and (3) how differences in children's cognitive growth in kindergarten are associated with whether their experiences are in full day or half day programs.

When US children should begin their formal schooling, and what the nature of that schooling should be, has been debated for almost two

centuries (Ramey & Campbell 1991; Pianta & Cox 1999). Although the availability of publicly funded preschool education (including Head Start) is far from universal and is typically restricted to low income children, virtually all US children now attend kindergarten. Despite its universality, the nature of the optimal kindergarten experience is widely debated among educators, early childhood specialists, parents, and researchers (Vecchiotti 2001). Since the 1960s, experts have called for more than "self directed play." Among early childhood experts, "early intervention" typically refers to activities that include both play and academics.

Children neither begin nor end their education on an equal footing. Although kindergarten is where virtually all US children begin their formal schooling, many have early and informal schooling experiences in preschool, Head Start, or childcare (Olsen & Zigler 1989). Although all children enter kindergarten at close to the same age (typically, 5 years old), there is great variation in their cognitive and social skills as they start school (Alexander & Entwisle 1988; Ramey & Campbell 1991; Duncan et al. 1998; Pianta & Cox 1999). Moreover, cognitive and social status are typically associated with family background and race/ethnicity (Jencks & Phillips 1998). Using data from the current and nationally representative US Department of Education's Early Childhood Longitudinal Study, Kindergarten Cohort (ECLS K), Lee and Burkam (2002) reported substantial differences in young children's test scores in literacy and mathematics by race, ethnicity, and socioeconomic status (SES) as they begin kindergarten.

Such substantial cognitive and social differences among children as they begin school present a serious conundrum. On the one hand, school is seen by the broader society as the location where social inequalities should be reduced. Advantages and disadvantages that children experience at home should not determine what happens to them in school. Rather, school is a place where children should have equal chances to make the most of their potential. On the other hand, schools often tailor children's educational activities to their perceived potential (or cognitive status), which would increase rather than equalize social

differences. Kindergarten is where this conundrum about the proper role of schooling in either equalizing or magnifying cognitive and social differences begins.

Researchers and policymakers agree that social background factors are associated with school success. Moreover, research findings are consistent that social stratification in educational outcomes increases as children move through school. However, there is less agreement about the causes of increasingly stratified outcomes. One explanation for growing inequality is that children's educational experiences are differentiated as early as kindergarten – through reading groups, special education placement, and retention (Alexander & Entwisle 1988). Many educators see such differential experiences as appropriate responses to the cognitive and behavioral differences children bring to kindergarten. Such differentiation extends through elementary school through ability grouping, special education, and gifted and talented programs. They are well recognized by high school, through tracking, advanced placement, and the like.

Another explanation for increases in socially based cognitive differences relates to the schools children attend, although this link has typically been assumed rather than subjected to empirical scrutiny. The association between background and school quality means that disadvantages derived from the lack of home resources that might stimulate cognitive growth are frequently reinforced by a lack of school resources (both financial and human). The low resource base of such schools constrains their ability to compensate for poor children's weak preparation.

Lee and Burkam (2002) used ECLS K to explore the link between young children's social background, defined by race/ethnicity and socioeconomic status (particularly poverty or economic need) and the quality of the schools where they attend kindergarten. School quality was broadly defined with a wide array of measures. Although background factors were not equally strongly associated with all measures of school quality, the patterns of association were strikingly consistent. Black, Hispanic, and lower SES children begin school at kindergarten in systematically lower quality elementary schools than their more advantaged and white counterparts. Whether defined by less favorable

social contexts, larger kindergarten classes, less outreach to smooth the transition to first grade, less well prepared and experienced teachers, less positive attitudes among teachers, fewer school resources, or poor neighborhood and school conditions, the least advantaged US children were shown to begin their formal schooling in consistently lower quality schools.

The consistency of these findings across aspects of school quality very different from one another was both striking and troubling. The least advantaged children in the US, who also begin their formal schooling at a substantial cognitive disadvantage, are systematically mapped into the nation's worst schools. Moreover, there is a strong association between the type of communities where schools are located (large or medium city, suburbs, small town, or rural area) and the quality of their public schools. The lowest quality schools are in large cities; the highest quality schools are located in the suburbs, where the most affluent citizens reside. Those findings translate into a sobering conclusion: children who need the best schooling actually start their education in the nation's worst public schools.

As kindergarten attendance has moved toward universality, pressure has mounted among policymakers to increase the cognitive demands made on kindergarten students. One way to accomplish this is to keep children in school longer. Several demographic and sociocultural factors explain the growing implementation of full day kindergarten. The proportion of working mothers with children under 6 is increasing; over 60 percent of these mothers are now in the workforce. Moreover, for growing numbers of children, rather than their first school experience, kindergarten fits into a continuum routinely beginning with childcare and/or a pre kindergarten or preschool experience and moves through elementary school (Olsen & Zigler 1989). Since the mid 1970s more and more children under 5 have attended preschool programs: private or public preschools, Head Start, or childcare. Proponents of full day kindergarten believe that, as a result of their childcare and preschool experiences, children are ready for more demanding and cognitively oriented educational programs. Recent scientific, technological, and economic developments

have thrust the importance of academic success, especially in literacy and numeracy, into the forefront of social discourse. Public and political forces collectively impose enormous pressures on schools to focus on children's academic achievement, and this focus begins earlier and earlier.

Full day kindergarten advocates suggest that a longer school day provides educational support that ensures a productive beginning school experience and increases the chances of future school success, particularly for poor children. The growing diversity among kindergarten children's racial, ethnic, cultural, social, economic, and linguistic backgrounds challenges educators to serve children well in increasingly complex classrooms. Full day advocates suggest numerous advantages of a longer kindergarten day: (1) it allows teachers more opportunity to assess children's educational needs and individualize instruction; (2) it makes small group learning experiences more feasible; (3) it engages children in a broader range of learning experiences; (4) it provides opportunities for in depth exploration of a curriculum; (5) it provides opportunities for closer teacher-parent relationships; and (6) it benefits working parents.

Not all educators, researchers, and parents favor full day kindergarten. Detractors argue that children in full day programs risk stress and fatigue due to the long day. However, research reveals that children attending full day kindergarten demonstrate less frustration than children in half day programs and do not show evidence of fatigue (Elicker & Mathur 1997). Others argue that full day kindergarten increases the chance that children will be expected to achieve and perform beyond their developmental capabilities (Olsen & Zigler 1989).

Full day programs in public schools enroll less advantaged children (those whose families are lower SES and/or minority). Full day programs are more common in public schools located in large US cities, which enroll less affluent and more minority children (Lee & Burkam 2002). A logical explanation for these trends focuses on public efforts to induce social equity. Despite the higher cost of operating full day kindergarten programs, their implementation may have a compensatory purpose. Schools with disadvantaged populations are able to offer

such programs because Title 1 funds (US federal money that assists schools with high numbers or percentages of poor children to ensure that all children meet academic achievement standards) could cover the added costs.

Although the relative impact of full day and half day kindergarten programs has been subjected to considerable empirical scrutiny, the quality of this research base is not strong. Many such studies are quite dated; many have weak research designs. Although some studies explore affective outcomes, most focus on cognitive performance. In general, research findings favor full day (or extended day) kindergarten over half day programs for academic performance. Further, some studies suggest that full day kindergarten is especially effective for socially and educationally disadvantaged children (Elicker & Mathur 1997). Whereas some studies document long term benefits of full day kindergarten, others report no long term effects. No study demonstrates academic advantages for children in half day kindergarten.

A recent study improved on the extant research based on this topic in several ways (Lee et al. 2001). First, it used current and representative samples from ECLS K. Second, it made use of more appropriate multilevel analysis methods. Third, its conclusions were located within policies that consider costs and benefits of full day programs. Although kindergarten is now close to universal in the US, only about half (55 percent) of schools offer kindergarten exclusively in a full day format. Full day programs are more common both in private schools and as compensatory programs (i.e., in inner city schools enrolling high proportions of low income and minority children).

Findings of the study strongly favored full day programs, with between school advantages of almost one standard deviation on gains over the kindergarten year in both literacy and mathematics achievement. This translated into over a month's learning advantage in both subjects. Although the time spent in school was twice as long in full day than half day kindergartens, the time spent on academic instruction was not double. Asking whether the benefits are worth the cost, the authors concluded that they are. Although costs for moving to full day programs include doubling the numbers of kindergarten teachers and increasing classroom space,

the benefits in academic terms are substantial, with potential long term benefits of less remediation or retention. Evaluations of educational interventions, particularly at the national level, have seldom reported cognitive advantages this large.

Although offering kindergarten to all in the educational landscape of the US is no longer contested, there is considerably less agreement about the nature of the optimal kindergarten experience. Further research is needed to determine the ideal length of the kindergarten day, and how much of children's kindergarten experiences should focus on academics and how much should be devoted to play and socialization. In addition, numerous equity issues need to be addressed through careful investigations into whether children's academic experiences in kindergarten should be tailored to their cognitive status at entry, and whether full day kindergarten should be an aspect of compensatory education, so that only low income and/or low performing children have access to such programs at public expense. As the first formal educational setting that virtually all US children experience, ongoing research needs to provide an understanding of how children's academic and social experiences in kindergarten lay the groundwork for their educational trajectories.

King, Martin Luther (1929–68)

John H. Stanfield

Dr. Martin Luther King, Jr., was not only an internationally renowned civil rights leader, but was also a public sociologist par excellence. King was born into a family and local community of socially involved ministers, deeply dedicated to issues of racial justice, in Atlanta, Georgia. His father was the pastor of Ebenezer Baptist Church, located in the now famous Auburn Avenue black community in Atlanta, who along with peers such as the Rev. William Borders, pastor of the Wheat Street Baptist Church, and John Dobbs, informally called the Mayor of Sweet Auburn, created a community culture that was highly critical of the racial status quo. It was in the Auburn Avenue community that King developed his lifelong commitment to social justice that would become refined as he was educated and went through the experiences of being a leader of a powerful social movement. This is important to keep in

mind since often, while analyzing the contributions of King, it has been common to forget, or to undervalue, the influences of his community of origin. It was here that he was exposed, at an early age, to highly educated black men who took bold public stances against the racial oppression of their day.

His time at Morehouse College as an undergraduate (1944–8) coincided with the most influential years of Benjamin E. Mays, the institution's president, who was a practical theologian and public sociologist who published what was considered to be, for many years, the seminal text on the sociology of the black church. Mays, who was appointed as Morehouse president in the early 1940s, transformed this remarkable liberal arts college for black men into a sociological learning community teaching social justice and egalitarian values which permeated the culture of the campus and were reinforced by Mays's mandatory Tuesday Chapel talks to Morehouse men. Besides the leadership of Mays, the ideas and insights of Walter Chivers, the longtime chair of the Morehouse department of sociology in which he majored, had a profound influence on King. Chivers was the chief black community researcher for Arthur Raper's (1933) *The Tragedy of Lynching*, 1 of public sociological activist research in the South. From the 1940s until the late 1960s, when he retired, Chivers directed the Morehouse Family Institute, which sponsored annual conferences designed to translate academic knowledge about family issues for black community members who would be invited to these campus events. Chivers's approach would have a profound influence on how King subsequently valued the capacity of sociology as a discipline to bring about social transformation.

King would learn as well the importance of careful empirical sociological research from spending a summer working as a research assistant for the Afro Caribbean Quaker sociologist Ira de A. Reid, who was on the Atlanta University Center faculty for a brief time. It should be mentioned that the reflective sociological reasoning typical of the culture of Morehouse College also involved the department of religion, which included professors such as S. M. Williams, who encouraged Morehouse students not only to study religious ideas, but also to be active in addressing questions of social

inequality in a Jim Crow society. King's profound ethical and sociological critiques of race in American society, such as *The Letter from Birmingham Jail* and his "I Have a Dream" speech, were shaped by an older Morehouse professor, Howard Thurman, who was a theologian with a strong sociological imagination, as best seen in his book *Jesus and the Disinherited* (1949). (While Thurman was dean of Boston University's Marsh Chapel, he would introduce King, then a doctoral student, to the ideas of Gandhi.)

Thus, wherever King turned in the Morehouse curriculum there was the emphasis on thinking sociologically to promote the public good of racial justice. Surviving papers from King's Morehouse and Crozier Seminary days reveal a young man with a keen sociological approach to theology and community justice issues. This pattern would continue in his sermons, which also tended to have a deep reflective sociological focus. That King identified himself as a sociologist can be seen in his willingness to write prefaces to sociological texts such as Daniel Thompson's (1963) classical study of the black leadership class. He also wrote at least one essay on the use of the behavioral sciences in efforts to transform communities and societies. King's first book, *Stride Towards Freedom* (1958), was a personal ethnographic account of the origins and development of the 1955 Montgomery Bus Boycott, which is still a seminal handbook on how to organize a local social movement. It also includes one of the first sociological discussions about non violence as a means to achieve what would be eventually called restorative justice. Lastly, when King went to Stockholm in 1964, one of the people he most wanted to see was Gunnar Myrdal, the Swedish economist whose monumental *An American Dilemma* (1944) had greatly influenced his views on race as a social and moral problem in the US.

King's leadership of the Southern Christian Leadership Conference during the 1960s, like his command over the Montgomery Bus Boycott during the mid 1950s, demonstrated his skills as an applied public sociologist. His capacity to manage men and women with strong personalities and his extraordinary ability to delegate authority as a self effacing leader were amazing. He was also a master of the media

during an age in which television was beginning to become the dominant force in mass communications. If it were not for King's skill at dealing with the media, as well as his political acumen, his movement would not have been nearly as effective as it was. When King was assassinated in Memphis in 1968, he was being increasingly criticized, as his movement began to falter outside the South and due to his opposition to the Vietnam War. Also, as indicated in his 1964 Nobel Peace Prize lecture, he was beginning to turn, at least since the early 1960s, to economic questions, which made many traditional supporters of his movement, including those in the media, increasingly uncomfortable. That is to say, he began to inch closer to the perspectives of emerging Black Power leaders who were advocating black economic empowerment.

King's ability to take academically challenging theological and sociological ideas and translate them effectively for mass appeal made him a most unusual example of what a public sociologist does, and for whom. Nevertheless, the most distinctive dimension of King's sociology was his integration of spiritual and interfaith concerns into his social analysis of racial problems and other important issues during his time, such as poverty and war. His sermons, lectures, and books have fascinating illustrations of how his spiritual values are intertwined with his astute sociological analyses. In doing this, King's approach provides a model for those sociologists interested in the ethical and spiritual dimensions of human experiences, and an example for those theologians wishing to understand the sociological context for religious studies.

Kinsey, Alfred (1892–1956)

Ken Plummer

Alfred Kinsey was not by training a sociologist, but a biologist (specializing in the taxonomy of gall wasps) at Indiana University, Bloomington. Believing there was a need for a course about marriage and sexual behavior, in 1938 he was concerned to find little data on which to base such study. According to one small study at that time, some 96 percent of young Americans did not know the word masturbation and many thought it was a form of insanity. In general there was widespread ignorance, and he decided to conduct his own study of the sexual behavior of the American female and male during the 1930s to 1950s – most prominently as *The Sexual Behavior of the Human Male* (1948) and *The Sexual Behavior of the Human Female* (1953), and after his death, less well known studies such as *Sex Offenders* (1965). Ultimately providing some 18,000 life stories of individuals (many of whom he interviewed himself), it was largely taxonomic – a “social book keeping” exercise showing who does what with whom, where, when, and how often. Using the interviews, he and his colleagues asked around 300 questions. When published, his work was a large statistical and scientific study, but curiously it became a national bestseller and played a prominent role in shaping US cultural life in the later part of the twentieth century (Reumann 2005).

His work was largely atheoretical, but his data showed dramatically how sexual behavior was related to social forces. (The theoretical

implications were later drawn out by John Gagnon and William Simon, especially in their theory of social scripting.)

For Kinsey, matters such as social class, age, marriage, urban living, and religion seriously shaped social patterns of sexual behavior. His work documented significant differences between men and women, noting that “the range of variation in the female far exceeds the range of variation in the male” (Kinsey et al. 1953: 537–8; see tables in vol. 2), as well as across social classes. He also showed a wide range of variant sexual behavior; for example, finding very high rates of extramarital and premarital sex, high rates of masturbation, curiously high rates of zoophilia, and most famously of all very high rates of homosexual behavior. He found much higher rates of participation in homosexual acts than previously thought, and invented the heterosexual–homosexual continuum with a point scale ranging from “exclusively homosexual” (Kinsey 6) through to “exclusively heterosexual” (Kinsey 0) (Kinsey et al. 1953: 470).

Among his other major contributions was the refinement of interview research tools – a major appendix on research strategy is included in the first volume and it became required reading for many students of sociology during the 1950s and 1960s. His interviews required great sensitivity in eliciting material, and his sample depended upon volunteers. It remains one of the most detailed large sample studies to date, though it depended upon volunteers and did not use random sampling.

Kinsey’s work has been much criticized. Apart from many moralists who condemned his work as obscene, there were others (such as Lionel Trilling) who argued that the focus on sexual behavior – of measuring who does what to whom, where, and when – managed to reduce sex to orgasm counting while robbing it of meaningful humanity. The importance of love was minimized (but Kinsey argued that this was not measurable and this was his concern). Radical (or anti libertarian) feminists came to criticize it for its tacit celebration of male power, for its emphasis on pleasure while ignoring the danger of sexuality, and for the violence often perpetrated upon women. (Although many also argued that it made women’s hitherto neglected and denied sexuality much more active and visible.) Sociologists were later very critical of

its methodology: it did not employ a random probability sample but depended on volunteers, and hence, although large, the sample was seen as very biased. Further, the sample was not representative, and the interviews were not very accurate.

But others have seen it as a trailblazing study. For its time, the study was actually a remarkable methodological achievement, not least due to Kinsey’s pioneering, single minded efforts. In time, not only did it come to inspire many subsequent empirical works on human sexual behavior, but sociologists eventually became part of a team of researchers and helped the research take both a more theoretical (sexual scripting) and therapeutic turn. Robinson (1976) suggested that the key contribution of Kinsey’s work was its impact on society: it rendered sexuality more democratic and generated an “ideology of tolerance” around sexuality that has now permeated culture. This, in turn, was built “on Kinsey’s discovery of the remarkable variety of human experience.” Kinsey also established the Kinsey Institute (formally known as the Kinsey Institute for Research in Sex, Gender, and Reproduction), which exists to this day in Bloomington, Indiana. Part of its work became therapeutic training for practitioners, and as such it played a prominent role in the development of sex therapy and sexology, though it has often been under continuing critiques.

Kinsey’s own life has been the subject of both biography (Jones 1970; Gathorne Hardy 1998) and film. He may have looked the picture of conservative America (complete with his bow tie): he was “happily married” and his work took on the mantle of objectivity and respectability. But as recent writing has shown, Kinsey and his colleagues were in fact “sexual enthusiasts,” very accepting of a wide range of sexual diversities, and implicitly very critical of the moralism that dominated US sexual mores. He was ultimately attacked as a communist out to destroy the family and he became depressed – dying in ignominy of a heart attack at the age of 62. He was never to know his profound influence in making people aware of sexual issues, and in trailblazing the field of sexology and sex research. His work has played a major role in the development both of the study of sexuality as a serious area and in creating a very different sexual culture.

kinship

Graham Allan

The study of kinship tends to be associated more closely with social anthropology than with sociology. In large part, this is a consequence of anthropologists frequently studying societies in which social and economic organization was premised to a great extent on the obligations and responsibilities that kin had towards one another. Consequently, understanding the kinship system operating in such a society provided the anthropologist with a means of revealing the society's dominant structural characteristics. In contrast, sociologists focused more on industrial societies in which family and kinship solidarities, while of consequence, were far less central to the overall organization of social and economic life. Indeed, often, family relationships were understood to be of declining significance

within western societies. Like the collapse of community, the decline of kinship solidarities was understood as a necessary consequence of the economic specialization and bureaucratic rationalization associated with modernity and industrial development.

In focusing on kinship systems anthropologists are concerned with specifying the principles which underlie the dominant forms of kinship behavior, commitments, and solidarities occurring within the society they are studying. They examine such issues as who is recognized as kin; what the boundaries of kinship are; what the social and economic consequences of particular kinship positions are; whether some categories of kin (e.g., patrilineal or matrilineal kin) are privileged over others; how kinship groups operate to protect their economic interests; and the like. Such questions about the kinship system as a system can also be asked of western societies, even while recognizing that kinship is structurally of less importance in these societies. Indeed, in many ways, the long history of moral panics and polemical debates concerning the state of contemporary family life can be recognized as essentially debates about the character of the contemporary kinship system in the society in question.

Historically, the sociologist who has been most influential in analyses of western kinship systems is Talcott Parsons (1949, 1955). His argument, building on the work of earlier European social theorists, was that the family and kinship system emergent in developed industrial societies could best be characterized as a *nuclear family* system. This form of kinship system, according to Parsons, was best suited (i.e., functionally most compatible) to meet the economic requirements of industrial societies. The essence of the nuclear family system is that each individual's primary obligations are defined as being to his or her nuclear family of spouse/partner and dependent children. Parsons argues that the absence of extensive kinship obligations outside the nuclear family facilitates mobility among the labor force and limits the extent to which kinship obligations potentially undermine dominant organizational requirements for fair and equal treatment. Other sociologists, in particular W. J. Goode in his book *World Revolution and Family Patterns* (1964), developed Parsons's ideas further by attempting to demonstrate that a wide range of

contemporary societies were merging towards a common nuclear family system.

In evaluating Parsons's views of kinship, it is important to recognize that his concept of structural isolation does not equate with either social isolation or an absence of all obligations. What it does assert is that responsibilities to nuclear family members are prioritized over obligations to other kin. In other words, the argument is that within the dominant kinship system a relatively strong boundary is drawn between nuclear family members and other kin. Other writers have queried how strong this boundary really is. Litwak and his associates in particular emphasized the important role that other family members outside the nuclear family household play in sustaining social life (see Harris 1983). Certainly, there is now ample evidence that in industrial societies primary kin – mothers, fathers, sons, daughters, siblings – generally remain significant throughout a person's life, and not just when they reside together as a nuclear family. Typically, though not invariably, these kin act as resources for one another, being part of an individual's personal support network for coping with different contingencies.

Thus, while a person's primary responsibilities are usually to their spouse/partner and dependent children, there remains a continuing solidarity with other kin. In particular, a parent's concern for children does not end when the child becomes adult, and few adult children have no sense of commitment to their parents. Yet importantly, this solidarity is *permissive* rather than *obligatory* (Allan 1979). That is, within most western societies, the "rules" of kinship are not tightly framed. Typically, neither the law nor custom specifies how relationships with non nuclear kin should be ordered. Instead, there is a relative freedom for individuals to work out or "negotiate" how their kinship relationships should be patterned. Within this, of course, some groups or subcultures have stronger social regulation of kinship relations than others. For example, many migrant minority groups, especially those with a specific religious commitment, draw on kinship as a means of coping in a foreign and sometimes hostile environment, of advancing their economic interests, and of protecting and celebrating their culture.

The extent to which forms of negotiation occur between kin has been highlighted in

Finch and Mason's (1993) research in Britain. They were concerned with the nature of kinship obligation in general, but more specifically with how families determine who provides support to elderly parents as they become more infirm. Their argument is that kinship obligations and responsibilities are not culturally specified – they do not follow "a preordained set of social rules." Rather, in any particular instance, a process of "negotiation" occurs through which decisions come to be made. Importantly, such negotiation does not occur in isolation, but is framed by the biographical development of the relationships in question. In other words, previous kinship behavior, as well as knowledge of the personalities and commitments of those involved, form part of the context in which the negotiation occurs. Moreover, Finch and Mason (1993) highlight three different modes of negotiation that can occur. These are: *open discussions*, *clear intentions*, and *non decisions*. As the name implies, the first is where two or more kin openly discuss and negotiate potential responses to the issue in question. The second is where a particular individual decides on a course of action and conveys this to other kin involved without really allowing any wider discussion. The final category, non decisions, arises where, because of the circumstances of those involved, a particular course of action emerges as "obvious" to all without any explicit decision taking ever occurring.

The importance of Finch and Mason's analysis is that it highlights the role of agency as well as structure in kin behavior. While there are clear patterns in the ways kin behave toward one another (e.g., in the greater likelihood of daughters rather than sons providing parents with personal care in later old age) there is also a great deal of variation. As an illustration, there is solidarity between siblings, but the ways in which that solidarity is expressed vary depending on the circumstances of the siblings, their other commitments, and the history of their relationship. So too there can be diversity in who is regarded as kin, which kinship ties are honored, and what activities and topics of conversation are seen as relevant within different kin relationships. Furthermore, all these matters are liable to change over time as people's circumstances alter. Thus, within contemporary western society, kinship position does not

of itself determine how people behave towards their kin or the responsibilities they feel.

The variation there is in people's attitudes and behavior towards kin has been compounded over the last 30 years by significant changes in patterns of family formation and dissolution. Most obviously, there has been the substantial growth in divorce and remarriage. Of themselves, these raise questions about the categorization and meaning of kinship. For example, are ex spouses categorized as kin? Under what circumstances? When, if at all, are their kin categorized as kin? Similarly, to what degree and under what circumstances does a stepparent or a stepchild become kin? Are they likely to be so regarded without co residence? Equally, what are the kinship consequences of cohabitation, a pattern of partnership which is becoming increasingly common? When do cohabitantes come to be regarded as kin, either by their partner or by their partner's other kin? Such questions do not have clear cut answers; there is a relative absence of kinship "rules" governing these matters. Instead, the nature of the relationships which develop and the extent to which they are understood as operating within a kinship frame are emergent, and in this sense "negotiated" in line with Finch and Mason's (1993) arguments.

One other important property of kinship is worth noting. As implied above, kinship is not just about individual relationships. The collective element of kinship is central to understanding kinship behavior. That is, kinship is a network of relationships in which each tie is influenced by, and in turn influences, the others. The effective boundaries of the network vary for different people, over time and for different contents. But typically news, information, and gossip flow readily through the network, with some individuals acting as "kin keepers." For example, mothers often play a key role in passing news on to their children and facilitating contact at times of family ceremonial. In part it is because kinship operates as a network that a focus on negotiation is so useful for understanding kinship processes. Similarly, the issues raised above concerning when new partners come to be regarded as kin or whether stepparents are kin are not solely individual issues. In part, what matters is whether others in the kinship network regard

them as "family," too. In many ways it is the network properties of kinship that distinguish it most clearly from other personal ties and which encourage the "diffuse, enduring solidarity" which Schneider (1968) defines as characteristic of American kinship – and by implication other western kinship.

Kitsuse, John I. (1923–2003)

Axel Groenemeyer

John I. Kitsuse was one of the premier and most influential contributors to the social constructionist movement from the 1960s, which changed the way sociologists approached the

study of social problems, normality, deviance, and control. Born a second generation Japanese American in California, Kitsuse was imprisoned in an internment camp for one year during World War II. He earned his bachelor's degree from Boston University and his master's and PhD from UCLA before he became professor of sociology at Northwestern University in 1958. From 1974 until 1991 he was professor of sociology at University of California San Diego. He served as president of the Society for the Study of Social Problems from 1978 to 1979. He died in California.

Kitsuse started his academic career with contributions on migration and social integration, especially of Japanese migrants in the US (Broom & Kitsuse 1955, 1956), and with research on education and the school system in the US (Chandler et al. 1962; Cicourel & Kitsuse 1963). However, he is primarily known as one of the founding fathers of the labeling approach to deviant behavior in the 1960s and for his contributions to the perspective of constructivism on social problems from the 1970s on.

The basic methodological and epistemological perspective of Kitsuse could best be described with a story, written at the beginning of his book *Constructing the Social* (Sarbin & Kitsuse 1994). Three referees are involved in a discussion. The first one, a self confident realist, argued that he would punish every foul according to the rules of the game. The second one, more cautious and influenced by the perspective of symbolic interaction, answered: "I only punish the fouls as and how I see them." After that, the third one, a convinced constructivist, stated: "There will only be a foul when I punish it." There is no doubt that Kitsuse, at least after the early 1960s, followed the perspective of the third referee. Even if the basic ideas of the then so called labeling approach had been developed long before by Tannenbaum (1938) and Lemert (1951), this radical subjectivism and relativism had not become convincing before the 1960s, with its political and intellectual climate of political mobilization for civil rights and other social movements, and the criminalizing reactions of the state. The reactions of agencies of social control and their consequences in the construction of deviant labels and careers, the scrutinizing of basic and commonly held categories of deviance and

conformity, and the opening of sociology to the perspectives of "underdogs" became the main interests of a whole generation of sociologists and constituted the base for a fundamental criticism of the supremacy of structural functionalism in sociology and of positivist criminology, which had always been interested only in the individual pathologies of offenders.

Among the "fathers" of this new approach of the sociology of deviance – sometimes called the New Chicago School from California (David Matza, Sheldon L. Messinger, Howard B. Becker, Aaron V. Cicourel, Erving Goffman, Edwin M. Lemert, Harold Garfinkel) – Kitsuse was one of the first to formulate this research program in a radical way (Kitsuse 1962, 1964; Kitsuse & Cicourel 1963). Whereas this new perspective had been popularized by the work of Howard Becker (1963), who had been influenced more by Everett C. Hughes and Edwin H. Sutherland and the theory of learning, and by Erving Goffman's (1963) analysis of stigma and identity development, Kitsuse had already use a constructivist perspective (even if it had not been so named at this time).

Although the labeling approach very often has been linked to symbolic interaction, ethno methodology, or phenomenology, it never developed a consistent theory. This has not only been a major criticism of the perspective from outside its ranks, but also by Kitsuse (1975) himself. However, against its critics (e.g., Gove 1975), he insisted on the methodological position that the process of labeling could not be reduced to another cause of deviance among others. In this, he followed the line of argumentation developed in the classic text of Kitsuse and Cicourel (1963). The objective of this analysis was not the dismantling of measurement problems of official statistics on crime, but to show that these statistics are basically *not* statistics of crime. Instead, they have to be seen as a representation of the activities of the agencies of social control. In this formulation there are no measurement problems of crime in official statistics because they do not measure criminal activities. Unlike Becker (1963) and Lemert (1951), Kitsuse insists there will only be a criminal offense if and when this label is successfully applied. From this perspective the idea of undetected crime does not make any sense. As a consequence the only interesting issue in

the sociology of deviance and crime has to be the processes by which deviant labels are constructed and applied to certain categories of behavior and people. Deviant behavior cannot be explained by existing social norms, but must be analyzed as the activities of social control.

Even if the labeling perspective of Kitsuse had not been named constructivist, its central arguments certainly followed this idea and laid the groundwork for the more theoretical formulations that – since the publication of *Constructing Social Problems* (Spector & Kitsuse 1977) – dominated the sociology of social problems, at least in the US. This book, which was an elaboration of ideas published previously (Kitsuse & Spector 1973, 1975; Spector & Kitsuse 1973), defined the field of social problems from a new perspective. Social problems were no longer rooted in social structures and social change as in theories of social disorganization, anomie, and social pathology, but had to be analyzed as “activities of individuals or groups making assertions of grievances and claims with respect to some putative conditions” (Spector & Kitsuse 1977: 75). “Claims making activities” now constitute the basic research question, and very often the perspective of reconstructing the establishment of specific issues as problematic in public discourses is seen as the only legitimate and characteristic research question in the sociology of social problems.

Criticisms about inconsistencies in his argumentation (for not having followed the methodological perspective of constructivism consistently) (Woolgar & Pawluch 1985) led Kitsuse to reformulate this perspective in a more linguistic form of discourse analysis (Ibarra & Kitsuse 1993). Whereas in *Constructing Social Problems* the main focus of analysis was on activities and collective actors that define issues as social problems on the public agenda, now social problems should be analyzed as cognitive structures – “vernacular constituents” – of texts and narratives. With this “linguistic turn” any reference to the real world of social conditions and actors was dismissed from the sociology of social problems: they are just a special game of rhetoric and counter rhetoric. The role of sociological knowledge is reduced to that of developing convincing narratives that could offer some new perspectives. The central criterion for the validity of these narratives

is not a somehow constructed correspondence with some social reality, but its coherence and dramatic structure (Sarbin and Kitsuse 1994). In principle, sociologists become storytellers like any other collective actor in society, perhaps with the difference that sociologists tell stories about the stories of other storytellers. As a consequence, one could ask whether this should still be called sociology, but in the perspective of his radical constructivism Kitsuse left this question open.

knowledge

Steve Fuller

Knowledge is relevant to sociology as the principle that social relations can be organized in terms of the differential access that members have to a common reality.

Until the late eighteenth century, Plato's *Republic* epitomized the role of knowledge as a static principle of social stratification. However, the Enlightenment introduced a more dynamic conception, whereby different forms of knowledge could be ordered according to the degree of freedom permitted to their possessors. An individual or a society might then pass through these stages in a process of development. Thus, thinkers as otherwise diverse as Hegel, Comte, and Mill came to associate progress with the extension of knowledge to more people.

However, this dynamic conception of knowledge produced a paradox: the distribution of knowledge and the production of power seem to trade off against each other. The more we know, the less it matters. Knowledge only

seems to beget power if relatively few people enjoy it. The distinctly sociological response to this paradox was to jettison Plato's original idea that a single vision of reality needs to be the basis for knowledge. This response, popularly associated with philosophical relativism, asserts simply that different forms of knowledge are appropriate to the needs and wants of their possessors.

The history of the sociology of knowledge is a tale of two traditions, French and German. Both came to fruition in the period 1890–1930. They are based on the proximity of knowers in space and time, respectively. Thus, the French tradition focused on how people of different origins who are concentrated in one space over time acquire a common mindset, whereas the German tradition focused on how people dispersed over a wide space retain a common mindset by virtue of having been born at roughly the same time.

The French tradition, exemplified by Lucien Lévy Bruhl and Émile Durkheim, regarded sustained interpersonal contact as the means by which a “collective consciousness” is forged and maintained. Both took tribal rituals as the paradigmatic site for the formation of this sort of consciousness, whereby emotional energy is translated into such cognitively significant artifacts as sacred texts and canonical procedures.

In contrast, the German tradition, exemplified by Wilhelm Dilthey and Karl Mannheim, was influenced more by history – indeed, historicism – than anthropology. Instead of looking at how the physical environment, including artifacts, constrains cognitive development, the German tradition focused on the overall world view exhibited by an array of texts produced by people who marched through time together, a “generational cohort.”

Common to both the French and German traditions was the assumption that knowledge is constituted as acts of collective resistance to the environment. The exact nature of the resistance is explainable by the spatiotemporal arrangement of the people concerned. Thus, a Durkheimian might show how religious rituals enable the faithful to escape the limitations of their material conditions and stand up to potential oppressors, while a Mannheimian might show how a persistent ideology enables the

experience of a particular generation to define the parameters of policy for the entire society. In both cases, the sociology of knowledge is meant to complement, not replace, the psychology of normal thought processes through which individuals adapt to a world that is largely not of their own making. Berger and Luckmann's *The Social Construction of Reality* (1967) eclectically mixes French and German traditions.

The addition of scientific knowledge as a potential object of inquiry complicated matters. Among the classical sociologists, Vilfredo Pareto was very clear about the "non logical" status of the forms of knowledge eligible for sociological scrutiny. He declared that rationality is self explanatory as the path of least resistance between ends and means, while sociology is needed to explain the friction of bias and error that usually gets in the way. The "rational choice" paradigm in the social sciences retains this perspective today. It was also how positivistic philosophers divided the intellectual labor between the epistemology and the sociology of knowledge. They presumed that science would always fall on the rational side of the divide, and hence not require special sociological treatment. Mannheim himself justified the presumption on reflexive grounds: sociology could not be trusted to study knowledge scientifically unless it was systematically immune to the kinds of frictions Pareto identified.

This general line of reasoning was overturned in the late 1970s by the self styled sociology of scientific knowledge (Bloor 1976). It posed an empirical and a conceptual challenge to Mannheim's strictures. The empirical challenge lay in the irony that sociology seemed to have a mystified understanding of the form of knowledge it aspired to be. For example, Robert Merton's famous account of the normative structure of science had been based largely on the methodological pronouncements of distinguished scientists and philosophers. This was like constructing a sociology of religion solely out of the writings of theologians and priests. Consequently, the last quarter century has witnessed an efflorescence of studies applying some German but mainly French approaches to the sociology of knowledge to the understanding of science. As had been the case with religion, much of this work on science has been

"demystifying" and hence a source of discomfort to professional scientists and philosophers of science.

The conceptual challenge pertained to the definition of science used to infer that it is necessarily a rational activity. Might not a religion or a political party also appear "rational," especially if evaluated in terms of its own goals? Conversely, were scientists judged in terms of all the consequences of their activities, both intended and unintended, might they not appear as "irrational" as priests and politicians? How, then, should the socially and ecologically transformative, sometimes even destructive, character of science be taken into any overall assessment of its "rationality." This challenge has been taken up most directly by "social epistemology" (Fuller 1988), which attempts to reconstruct a normative order for science in light of this socially expanded sense of consequences.

Perhaps the biggest challenge facing the sociology of knowledge today is science's tendency to become embedded in the technological structure of society as "technoscience" (Latour 1987). Under the circumstances, science's character as a form of knowledge is reduced to its sheer capacity to increase the possessor's sphere of action. Such a reduction characterizes the definition of "knowledge" used by sociologists who argue that we live in "knowledge societies" (Stehr 1994). For them, knowledge is a commodity traded in many markets by many producers. In this emerging political economy, institutions traditionally dedicated to the pursuit of knowledge (e.g., universities) no longer enjoy any special advantage.

knowledge management

John Sillince

Knowledge management seeks to increase organizational capability to use knowledge as a source of competitive advantage. The field has risen to prominence along with the “knowledge worker,” who is someone who does work which involves knowledge which is socially complex, causally ambiguous, and tacit. Relevant theories include social capital theory and the resource based view of the firm. Practitioner approaches to knowledge management emphasize ways of creating, diffusing, using, and evaluating knowledge.

Strategy researchers attempt to create statements about the link between industry structure and firm performance in order to deliver guidance to leaders of firms. This guidance advocates either selection of an appropriate formula for changing industry structure, or diversification into more profitable industries. However, the value of such guidance is undermined by its key assumption of interfirm homogeneity – all firms can implement such strategies. An emerging theory of the resource based view (RBV) of the firm and of sustainable competitive advantage implies that such strategies are not able to protect the firm against imitation or substitution. This has led to the rise in importance of theories of business strategy which privilege resources such as knowledge which are socially complex, tacit, and causally ambiguous.

Socially complex resources are routines and skills which, because of their relational nature, are difficult to imitate or substitute. Knowledge is a socially complex resource because its creation and use depend on networks of relationships and because it is collectively owned. Much

work in organizations is done in interaction with others, where the knowledge is created and used collaboratively rather than in isolation, and for this reason where it is difficult to disentangle what each person knows individually from the collectively generated knowledge. Other work is done in networks of friends and contacts who inform each other of opportunities, send warnings, and answer questions. The value of knowledge within social networks often depends on its surprise value. Such knowledge tends to come from “weak ties” – distant rather than near relationships. Networks also can act as passage ways for accessing information. Through “weak ties” and “friends of friends” network members can gain privileged access to information and opportunities. In order to explicate such properties of networks and communities a theory of social capital has developed. Social capital theory argues that there are intangible goods such as knowledge, trust, goodwill, and reputation which animate social networks, constitute social structure, and facilitate the actions of individuals. It has been argued that organizations have advantages over markets for the development and use of social capital. This is because organizations are able to protect secrets and to create a trustful working environment better than markets. Such a view places knowledge as a central element within the organizational community, which concerns itself with the creation of new knowledge by means of combination and exchange of previous knowledge.

Causally ambiguous resources are ones which cannot be easily identified as inputs to performance improvements and so do not help competitors who wish to learn why a firm is so successful. However, the assumption is that organization members are sufficiently able to identify the value of those resources. Knowledge is a causally ambiguous resource because how firms do things is not just a question of procedures, policies, and routines. There are also experience, degree of care and heedfulness, cooperativeness and collective confidence which also facilitate the use to which knowledge is put and which help to improve business performance.

Tacit resources are implicit and therefore uncodifiable and so are again difficult to copy. Knowledge is a tacit resource because it is used and exchanged in language and interaction,

where context cues and conversational sequence provide implicit information about the meaning of what is said. Even when written down, there is meaning to be gained by reading "between the lines."

Recent times have seen theoretical developments in how organization members are seen and how they see themselves in terms of a greater emphasis on knowledge. More educational qualifications and training, more reliance on an empowered, flexible workforce which is able to take the initiative, together with a shift from manufacturing into services, have all led to a greater emphasis on the intellectual content of work. These forces have all been behind the rise of the term "knowledge worker."

The simplest definition of knowledge worker is someone who does work which involves knowledge which is socially complex, causally ambiguous, and tacit. Many attempts have been made to measure "intellectual capital," which is defined as the knowledge dimension of social capital. Simple methods include a focus on observable and tangible assets such as patents and routines. However, this misses out many intangibles and any serious attempt to measure intellectual capital would need to take account of these. Intellectual capital is structurally embedded in the organization because the individual's knowledge is enriched and applied in a specific context created by the organization. That context includes routines, equipment, and people. Intellectual capital is relationally embedded in the organization because the individual's knowledge is enriched and applied in relationships with others. Knowledge is therefore partly a function of who one knows and what relationships one has with them. However, those relationships are only partly influenced by the organization – they may span across organizational boundaries. Intellectual capital is also influenced by cultural and cognitive factors such as inertia, cognitive bias, curiosity, and motivation.

Many employees now have responsibilities which are difficult to track and control and therefore employees are increasingly difficult to motivate. Employees with complex responsibilities are valuable because the tasks they perform would take some time to teach to a replacement, who may not be as good anyway. Employees are increasingly disloyal to their

company, despite attempts by companies to develop "strong cultures." They are therefore free to leave and join other organizations. Old fashioned, heavy handed control methods may backfire in such cases, as the knowledge held by such workers "walks out the door."

The slimming down of workforces as a quick and simple method of economic stabilization in times of market difficulties has led to gaps in knowledge, or to gaps in organizational methods for handling knowledge. These gaps have added to the perceived importance of knowledge. If knowledge workers make up the organizational brain, removing whole levels of the hierarchy is analogous to small parts of the brain dying in a stroke, with its effect on dislocation of the organizational memory. Just as in the case of stroke in an individual, organizational memory may recover over time if there are suitable recovery practices.

The search for non imitable organizational capabilities in line with resource based theory of the firm has increased the importance of organizational identity. Organizational identity is "who we are as an organization." It increases one's sense of belonging, commitment, and identification. To conceive of knowledge as an individual competence misses the potential for linking individual knowledge to organizational identification. Instead, conceiving of organizational identity as the collective meaning of knowledge creation ensures that individual members feel part of a common activity, and discourages them from individualistic, alienated, and opportunistic means of gaining compensation. This is all to say that such management messages avoid drawing attention to individual competencies and instead draw attention to organization level capabilities.

The view of knowledge in relation to organizational processes which has been most influential with practitioners has been the mechanistic view that there are different, separable processes. These are creation, diffusion, use, and evaluation of knowledge.

The realization that the creation of explicit knowledge can be measured whereas the creation of tacit knowledge cannot, and that the tacitness of knowledge prevents free transfer between a firm's workers, has led to at least two very different responses. One approach, of great appeal to practitioners, and influenced by a

mechanistic view of knowledge, has been to suggest that tacit knowledge should be transformed into explicit knowledge rather like changing base metal into gold. This approach centers upon the transformations possible between tacit and explicit knowledge. These transformations are explicit to explicit (socialization), tacit to explicit (externalization), tacit to tacit (combination), and explicit to tacit (internalization). This classification has been linked to steps of learning. However, few empirical tests have been carried out of these ideas, perhaps because of the intractability of tacit knowledge.

The other approach to the creation of knowledge more favored by academic researchers has been to investigate tacit knowledge as a sociological phenomenon. For example, language is a rich field of investigation because much of the information contained in interactions is situated and context dependent. Another example is social networks in which knowledge is understood and evaluated as part of social relationships – the intellectual content of a piece of information may be less influential in its being believed compared to whether the source is liked or trusted. Another example is activity theory, which argues that knowledge is embedded in – and therefore inextricable from – tasks or, more precisely, interdependencies between tasks, “tools,” and people.

The desire to measure and therefore control knowledge may be a misguided objective. The crucial question here is whether the control of knowledge leads to over standardization. Individuals have their own “craft” ways of doing things, whereas organizational interest is furthered by standardization. Knowledge is continuously created by economic activity, and attempts to standardize too much may eradicate any novelties that eventually become sources of a firm’s uniqueness. Over standardization may also lead to the creation of routines which can be imitated by competitors.

The diffusion of knowledge has been investigated intensively for some years. Starting from the simple electricity analogy that knowledge starts from a source and eventually, despite resistance, reaches a destination or target, the field has changed considerably. The transfer of knowledge depends upon the target’s ability to handle or understand it: its “absorptive capacity.” Thus, a new industrial process will more

likely be taken up by another company if it has scientists and technologists who understand it, and if it has industrial processes which can turn it into valuable products. The barrier may not only be in terms of understanding the content of the knowledge to be transferred. It may also be a question of the cultural gulf which exists between the sending and receiving organization – a difficulty experienced by many multinationals. The idea of absorptive capacity has been generalized to say that the target must be treated carefully by the source in order to facilitate diffusion. For example, Edison bought up a gas company and designed electric lamps of similar dimness to gas lamps in order first to overcome the resistance of monopoly gas suppliers, and secondly to adapt to consumers’ expectations of dimness. Only later did electric lights increase in brightness when the idea of the electric light had been accepted. This is an example of the value of institutional theory in understanding knowledge diffusion.

Institutional theory states that much organizational action is caused not by instrumental or rational objectives, but instead takes on the values or prescriptions contained in institutional rules. Organizations adopt many rational seeming procedures and techniques not because they make members more knowledgeable about what they are doing, but just in order to be seen to be following methods accepted by other organizations. It may be that a lot of the value of knowledge, and of knowledge workers, may be of this institutional kind. That is, knowledge may often be valued because it provides the organization with legitimacy rather than because it makes things work better or faster.

When looked at in this way, knowledge becomes a political good, which adds to an organization’s reputation and which is useful to specific professional groups in their attempts to increase their status and power. Historical studies have been undertaken of companies which have shown that the status and power of professional groups have changed markedly. In the early twentieth century, manufacturing and production engineering were the most powerful professionals. Since then there has been a rise in both the finance and the marketing functions, as companies have come to realize that scarce resources in their environment, first of finance and then of consumer demand,

give precedence to people who have knowledge about such scarce resources.

One dimension of knowledge management of interest to practitioners is the extent to which the creation, diffusion, use, and evaluation of knowledge can be facilitated by information and communication technology, and how much it is facilitated by human resource management by creating a cultural environment which encourages information sharing and knowledge creation. Technology offers several tools, but requires cultural support to be fully effective. Intranets enable organizations to share back ground information such as procedures and policies and to make this information available on an as needed basis. But intranets depend upon individuals adding information for others to read. Databases which contain organization members' area of specialization enable members to contact the most suitable person to help them solve their problem. But members may refuse to give the time requested to solve a problem, especially if the organization rewards individuals narrowly according to specific targets. Or members may refuse to share their knowledge because they do not wish to lose their indispensability and the power associated with it. Project diaries which chronicle surprises and problems surmounted are valuable sources of advice for the project teams that follow. But often project teams are too busy to fill in the diary, or members wish to hide mistakes. Multinationals spawn huge numbers of projects in each unit and subsidiary. These projects often duplicate each other in different regions or departments. Databases of projects and their main features enable members to avoid such duplication. But such databases also threaten team budgets and so often teams refuse to add their own project's details. Such databases also cross regional boundaries and so threaten the independence of regional units.

Where such methods have been systematized they therefore require a centralized system directing their use. An example is the use of Rapid Action for Process Improvement Deployment (RAPID) at all Ford's car factories as a method of publicizing new process improvements between plants. However, it is important that local subsidiaries have sufficient freedom to develop their own solutions to problems if they wish, because markets and regulations may vary

considerably between subsidiaries. Finding the right balance is partly judging the product as global (oil), nearly global (cars), or national (insurance). It is also a matter of giving regions the choice of getting the diffused and reused idea cheaply or the local solution at full cost.

These examples show the importance of the human factors involved in technology use with regard to knowledge management. Knowledge management is therefore as much an area of concern for human resource management as it is for information technology. The main aim of such policies is to encourage information sharing. One approach is to create a "strong culture," that is, a strong identification with the organization, a positive organizational identity. This is not just a job for a communications department, because what members consider their organization to be will affect, for example, how they train new recruits, how they deal with customers, and how they check quality. Another approach is to use rewards of both money and recognition. Most consultancy firms, in which knowledge sharing is vital, give their consultants high basic salaries so that doing "good citizen" activities such as sharing information with others does not lead to loss of the consultant's income. Consultancy firms which do not do this have problems motivating their staff to cooperate enough to share information. Directly rewarding specific actions such as how much an individual writes is difficult because it may be quality rather than quantity that counts. The best situation is when reputation as an expert is its own reward.

Behind all questions of effective knowledge management is the existence or nonexistence of trust in working relationships. After all, this is the advantage of organizations rather than markets as methods of creating economic value. Some organizations have trust and some do not. Inside most companies there exist departmental feuds, scapegoating, blame shifting, and ruthless competition for promotion. Trust takes time to build up. Trust exists between identifiable individuals. It is based on perceived good will to be likely to promise something and also on competence to do what the person promises to do. But there is also such a thing as institutional trust, where being from a certain company or department or region or nationality gives a person a guaranteed trustworthiness

even when we do not know that person. Because of the growing importance of knowledge and therefore of information sharing, trust is also growing in importance. It is one of the fundamental qualitative features of organizational climate. Because it is impossible to acquire imitatively it is a potent source of competitive advantage.

Several routines have gained prominence as methods of facilitating knowledge sharing. One is the Peer Assist scheme at BP. When a difficult decision arises (e.g., when a new oil rig has to be started involving risky investment) the person who is responsible calls for experts to come to a meeting to give their views. This is resourced by the sending units on the argument that the visiting experts gain by picking up new experience and new credits on their CVs. Although conflicts between strangers might develop, it seems that the need of experts to get invited to such meetings leads them to control their level of criticism. Another routine is the Asset Consulting Team approach at Chevron, where if you have a problem, you go and visit a specialized internal consulting unit.

Most practitioners recognize knowledge management as talking about and spreading "best practice." One problem is that this year's best practice becomes last year's bad practice. Spreading best practice may also result in sharing ignorance. These problems occur when knowledge management becomes concerned merely with diffusion and not with creation of new knowledge.

knowledge societies

Nico Stehr

The transformation of modern societies into knowledge societies continues to be based, as was the case for industrial society, on changes in the structure of the economies of advanced societies. Economic capital – or, more precisely, the source of economic growth and value adding activities – increasingly relies on knowledge. The transformation of the structures of the modern economy by knowledge as a productive force constitutes the “material” basis and justification for designating advanced modern society as a knowledge society. The significance of knowledge grows in all spheres of life and in all social institutions of modern society. The historical emergence of knowledge societies represents not a revolutionary development, but rather a gradual process during which the defining characteristics of society change and new traits emerge. Until recently, modern society was conceived primarily in terms of property and labor. While the traditional attributes of labor and property certainly have not disappeared entirely, a new principle, “knowledge,” has been added which, to an extent, challenges as well as transforms property and labor as the constitutive mechanisms of society.

Knowledge may be defined as a *capacity for action*. This definition indicates that implementation of knowledge is open, that it is dependent on or is embedded within the context of

specific social, economic, and intellectual conditions. Knowledge is a peculiar entity with properties unlike those of commodities or of secrets, for example. Knowledge exists in objectified and embodied forms. If sold, it enters other domains – and yet it remains within the domain of its producer. Unlike money, property rights, and symbolic attributes such as titles, knowledge cannot be transmitted instantaneously. Its acquisition takes time and often is based on intermediary cognitive capacities and skills. Despite its reputation, knowledge is virtually never uncontested. Scientific and technical knowledge is uniquely important in modern social systems because it produces incremental capacities for social and economic action that may be “privately appropriated,” at least temporarily. Knowledge has of course always had a major function in social life. Social groups, social situations, social interaction, and social roles all depend on, and are mediated by, knowledge. Power, too, has frequently been based on knowledge advantages, not merely on physical strength.

The emergence of knowledge societies signals first and foremost a radical transformation in the structure of the economy. What changes are the dynamics of the supply and demand for primary products or raw materials; the dependence of employment on production; the importance of the manufacturing sector that processes primary products; the role of manual labor and the social organization of work; the role of international trade in manufactured goods and services; the function of time and place in production and of the nature of the limits to economic growth. The common denominator of the changing economic structure is a shift away from an economy driven and governed by *material* inputs into the productive process and its organization, toward an economy in which the transformations of productive and distributive processes are increasingly determined by symbolic or knowledge based inputs.

The transformation of modern societies into knowledge has profound consequences aside from those that pertain to its economic structure. One of the more remarkable consequences is the extent to which modern societies become fragile societies. Modern societies tend to be fragile from the viewpoint of those large and once dominant social institutions that find it

increasingly difficult to impose their will on all of society. From the perspective of small groups and social movements more uncoupled from the influence of the traditional large scale social institutions, however, modern societies are not more fragile, in the first instance. For such groups and social movements, the social transformations underway mean a distinct gain in their relative influence and participation, even if typically mainly in their ability to resist, delay, and alter the objectives of the larger institutions.

Knowledge societies (to adopt a phrase from Adam Ferguson) are the results of human action, but often not of deliberate human design. They emerge as adaptations to persistent but evolving needs and changing circumstances of human conduct.

Modern societies are also increasingly vulnerable entities. More specifically, the economy, the communication and traffic systems are vulnerable to malfunctions of self imposed practices typically designed to avoid breakdowns. Modern infrastructures and technological regimes are subject to accidents, including large scale disasters as the result of fortuitous, unanticipated human action, to non marginal or extreme natural events that may dramatically undermine the taken for granted routines of everyday life in modern societies, and to deliberate sabotage.

Present day social systems may be seen to be fragile and vulnerable entities in yet another sense. Such fragility results from the conduct as well as the deployment of artifacts designed to stabilize, routinize, and delimit social action (e.g., the so called “computer trap” or, more generally, the unintended outcomes of intentional social action). In the process of evermore deeply embedding computers into the social fabric of society, that is, redesigning and reengineering large scale social and socio technical systems in order to manage the complexities of modern society, novel risks and vulnerabilities are created.

The fragility of modern societies is a unique condition. Societies are fragile because individuals are capable, within certain established rules, of asserting their own interests by opposing or resisting the (not too long ago) almost unassailable monopoly of truth of major societal institutions. That is to say, legitimate cultural

practices based on the enlargement and diffusion of knowledge enable a much larger segment of society effectively to oppose power configurations that turned out or are apprehended to be tenuous and brittle.

Among the major but widely invisible social innovations in modern society is the immense growth of the "civil society" sector. This sector provides an organized basis through which citizens can exercise individual initiative in the private pursuit of public purposes. One is therefore able to interpret the considerable enlargement of the informal economy, but also corruption and the growth of wealth in modern society, as well as increasing but typically unsuccessful efforts to police these spheres, as evidence of the diverse as well as expanded capacity of individuals, households, and small groups to take advantage of and benefit from contexts in which the degree of social control exercised by larger (legitimate) social institutions has diminished considerably.

The future of modern society no longer mimics the past to the extent to which this has been the case. History will increasingly be full of unanticipated incertitudes, peculiar reversals, and proliferating surprises, and we will have to cope with the ever greater speed of significantly compressed events. The changing agendas of social, political, and economic life as the result of our growing capacity to make history will also place inordinate demands on our mental capacities and social resources.

knowledge, sociology of

E. Doyle McCarthy

The sociology of knowledge examines the social and group origin of ideas, arguing that the entire "ideational realm" ("knowledges," ideas, ideologies, mentalities) develops within the context of a society's groups and institutions. Its ideas address broad sociological questions about the extent and limits of social and group influence through an examination of the social and cultural foundations of cognition and perception. Despite significant changes over time, classical and contemporary studies in the sociology of knowledge share a common theme: the social foundations of thought. Ideas, concepts, and belief systems share an intrinsic sociality explained by the contexts in which they emerge.

From its origins in German sociology in the 1920s, sociology of knowledge has assumed that ideas (knowledge) emerge out of and are determined by the social contexts and positions (structural locations) of their proponents. Its major premise is that the entire ideational realm is functionally related to sociohistorical reality. According to its framers, *Wissenssoziologie* was developed as an empirical and historical method for resolving the conflicts of ideologies in Weimar Germany that followed the political and social revolutions of the late nineteenth and early twentieth centuries, conflicts grounded in competing worldviews and directed by intellectual and political elites. Outlined in early statements by Max Scheler and Karl Mannheim, the new discipline reflected the intellectual needs of an era, to bring both rationality and objectivity to bear on the problems of intellectual and ideological confusion. It was in this sense that the sociology of knowledge has been described as a discipline that reflected a new way of understanding "knowledge" within a modern and ideologically pluralistic setting. The approach defines a new "situation" (Mannheim 1936), summarily described as "modernity," a world where "knowledge" and "truth" have many faces. What we believe that we *know* varies with the cognitive operations of human minds and these vary by community, class, culture, nation, generation, and so forth.

Contemporary sociology of knowledge addresses a related but different set of concerns than those posed by its founders, and its subject matter extends beyond the problem of relativism and the social location of ideas and ideologies. Prominent among its current themes are the “local” features of knowledges and the study of their functions in everyday life. This redirection of the field from the study of conflicting ideologies to the study of the tacit and taken for granted understandings of everyday life can be characterized as a shift from concerns with the truth status of ideas and ideologies to the concerns of a cultural “sociology of meaning.” These changes also represent a movement away from a study of the ideological functions of elites and intellectuals to conceptions of knowledges as discursive (cultural) forms and as part of the entire range of symbolic and signifying systems operating in a society.

The term sociology of knowledge (*Wissenssoziologie*) was first used in 1924 and 1925 by Scheler (1980) and Mannheim (1952). From its inception, it described a field of inquiry closely linked to problems of European philosophy and historicism, particularly the nineteenth century German philosophical interest in problems surrounding relativism that were linked to the legacies of Karl Marx, Friedrich Nietzsche, and the historicists, whose cultural philosophy of worldviews (*Weltanschauungsphilosophie*) was influential in German social science from the 1890s to the 1930s.

For Scheler (1980), who offered the first systematic outline of the discipline, the *forms* of mental acts, through which knowledge is gained, are always conditioned by the structure of society. For this reason, sociology of knowledge is foundational to all specialized studies of culture and to metaphysics. While Scheler’s original essays provoked commentary and debate, it was Mannheim’s formulation of the discipline in *Ideology and Utopia* that defined the subject matter of the field for years to come. Those who offered their own sociologies of knowledge, including Talcott Parsons (1961) and Robert K. Merton (1957), defined their positions relative to Mannheim’s arguments concerning ideology, utopia, and relationism.

Mannheim’s treatise begins with a review and critique of Marxism and proceeds toward a

theory of ideology in the broader sense: the mental structure in its totality as it appears in different currents of thought and across different social groups. This “total conception of ideology” examines thought on the structural level, allowing the same object to take on different (group) aspects. This understanding of ideology refers to a person’s, group’s, or society’s way of conceiving things situated within particular historical and social settings. Like ideologies, “utopias” arise out of particular social and political conditions, but are distinguished by their opposition to the prevailing order. Utopias are the embodiment of “wish images” in collective actions that shatter and transform social worlds. Both concepts form part of Mannheim’s broad design for a critical but nonevaluative treatment of “ideology,” one that supersedes the sociohistorical determinism and relativism of Marxism while moving toward a “relationist” notion of truth. From an analysis of the various and competing social positions of ideologists and utopians, a kind of “truth” emerges that is grounded in the conditions of intellectual objectivity and detachment from the social conditions that more directly determine ideas. *Ideology and Utopia* established the criteria for a valid knowledge, albeit a *relational* knowledge, of sociohistorical processes. More important, it raised the problems surrounding the historicity of thought and did this within the newly emerging academic discourse of sociology. In the process, it gave legitimacy to a new set of methodological issues involving the problems of objectivity and truth for the sciences and the humanities.

Despite the many criticisms of *Ideology and Utopia*, the work received wide attention and appreciation inside and outside the social sciences where the problems posed by relativism continued to attract the attention of those working in the sciences and the humanities. While reviews of the work focused on its failure to overcome relativism and Mannheim’s excessive reliance on the Marxist conception of ideology, Mannheim’s book provoked discussion and commentary in the decades after its publication.

Werner Stark’s *The Sociology of Knowledge* (1991) prompted a major advancement and redirection of the field. It argued for the

embedding of sociology of knowledge within the larger field of cultural sociology. Stark's book clarified the principal themes of earlier writers, especially sociologists, who had addressed the problem of the social element in thinking. He also intended it to serve as an introduction to the field that would prepare the way for a detailed and comprehensive history of the sociology of knowledge and its most significant ideas: theories of ideology of Marx and Mannheim; philosophical speculations of the neo-Kantians Heinrich Rickert and Max Weber; views of the German phenomenological school of the 1920s, especially Scheler. Stark's strongest affinity was with Scheler's struggle to reconcile the antithetical claims of idealism and materialism, and his view of the sociology of knowledge as the foundation for a knowledge of "eternal values." The sociology of knowledge is concerned with the "social determination of knowledge," not with the problem of ideology. This distinction is an indispensable precondition of the sociology of knowledge. It directs attention to the study of mental life as grounded in social and historical conditions, granting to "social determination" a depth that the theory of ideology does not accomplish. While the theory of ideology will always play a vital role in sociology and the history of ideas, it remains outside the principal concerns of the sociology of knowledge.

Berger and Luckmann's *The Social Construction of Reality* (1966) advanced a sociology of knowledge that was compatible with the view of sociology as a humanistic discipline and the notion that "human reality" is a "socially constructed reality." The work moved the field further away from theoretical knowledge or ideas and toward the (pre theoretical) knowledge that social actors draw from in everyday life. Their treatise also redirected the traditional theory of social determination of ideas by social realities: social reality itself is a *construct*. It integrated the perspectives of classical European social thought (Marx, Durkheim, Weber) with the social psychology of the American pragmatist philosopher George Herbert Mead, thereby advancing Mead's social psychology as a theoretical complement to European sociology of knowledge (see Curtis & Petras 1970; Remmling 1973). What the authors proposed was that knowledge and social reality exist in a

reciprocal or dialectical relationship of mutual constitution. This work placed the sociology of knowledge on a new footing whose focus was the broad range of signifying systems that form and communicate the realm of social realities. Since its introduction, the idea of a "constructed reality" has summarized a number of concerns of writers in the sciences and humanities that may be described as the *problem of meaning* and the use of philosophical, literary, and historical approaches to study its social construction. Berger and Luckmann's treatise subsumed knowledges within a framework of interpretation, a *hermeneutics* that was decidedly cultural and semiotic, concerned with the symbolic and signifying operations of knowledges.

More recently, the "new sociology of knowledge" (Swidler & Ardit 1994; McCarthy 1996) can be seen as part of this larger movement in the social sciences, distinguished by a turn away from materialism and social structure toward semiotic theories that focus on the ways in which a society's meanings are communicated and reproduced. Swidler and Ardit (1994) focus on how social organizations (e.g., the media) order knowledges, rather than examining social locations and group interests. In light of new theories of social power and practice (Michel Foucault and Pierre Bourdieu), they also examine how knowledges maintain social hierarchies and how techniques of power are simultaneously and historically linked to knowledges. They join others in pointing out that newer theories of power, gender, and knowledge depart from the economic, class, and institutional focus of the classical sociology of knowledge.

Proponents of the new sociology of knowledge do not claim that the subfield has been entirely superseded by newer work in sociology and cultural studies. However, they note that the new sociology of knowledge is not a unified field, an argument also advanced by earlier writers who treated the sociology of knowledge as a "frame of reference" rather than a body of theory in its own right (Curtis & Petras 1970: 1; cf. Remmling 1973).

Two overriding factors can account for the persistence of a broad approach to knowledges. First, the propositions of Scheler, Mannheim, and other early writers in this field (e.g., in the US, works by Florian Znaniecki, C. Wright Mills, and Edward Shils) today serve as working

propositions for a range of social scientists as well as for specialists in other disciplines, including the subfields of the history of ideas, social psychology, social studies of science, feminist theories, and cultural studies. For this reason, a sociology of knowledge perspective – concerning group life and mind – has been incorporated into the many subfields of sociology as well as sister disciplines from anthropology to history. Furthermore, as long as knowledges are understood as preeminently cultural phenomena, the more likely it is that the sociology of knowledge will be seen as a broadly inclusive set of theories and studies rather than a subfield with a distinct subject matter. Knowledges are no longer confined to the domain of “superstructure.” They operate across the full extent of society, from the realm of everyday affairs to the institutions of law, politics, art, and religion, to the various sites and fields where knowledges are produced. The new sociology of knowledge examines the observable properties of knowledges in texts, modes of communication, and forms of speech within specific institutional settings.

Komarovsky, Mirra (1905–99)

Vicky M. MacLean

Mirra Komarovsky's research, teaching, and advocacy on behalf of women mark her as a pioneer in the sociology of gender and feminist scholarship. She was the second woman to serve as president of the American Sociological Association, thus furthering opportunities for women in the profession of sociology. Major contributions to sociology include her critique of the Parsonian functionalist perspective on gender roles, research on women's education and changing feminine identities, and the study of men and masculinity. Komarovsky's research focused on the nature of conflict and strains in gender roles during periods of uneven social change. Her 1953 book *Women in the Modern World: Their Education and Their Dilemma* anticipated Betty Freidan's *The Feminine Mystique* by more than a decade. Methodological contributions include refining the use of the qualitative case study method using in depth interviewing and synthesizing sociological schedules and surveys with psychological tests of personality and gender.

Born to a Jewish family in Russia in 1905, Komarovsky migrated with her family from Baku to the United States in 1921, fleeing anti-Semitism and Bolshevik attempts to eradicate the middle class. Her childhood education in Russia was primarily from private tutors. In the United States Mirra's family initially

settled in Wichita, Kansas where she graduated from Wichita High School. Then in 1922 her father moved the family to Brooklyn, New York to provide greater educational and career opportunities for Mirra. She took her bachelor's degree at Barnard College, majoring in economics and sociology. Komarovsky received the Caroline Durer Fellowship for graduate studies, taught as an instructor at Skidmore College, and then pursued her master's degree at Columbia University, writing her thesis under the direction of William Ogburn. Upon accepting a research associate position at the International Institute for Social Research, Komarovsky began graduate work for her doctorate under the direction of Paul Lazarsfeld, and returned to Barnard to teach (Reinharz 1989, 1991; Rieder 1999). Her dissertation, *The Unemployed Man and His Family* (1940), was a continuation of Max Horkheimer's *Studien über Autorität und Familie* (1936). Using the case study method, Komarovsky studied 59 skilled worker families receiving government relief during the Depression. The study revealed that unemployment led to a deterioration of men's personalities, undermined their household authority, and affected marital satisfaction. A man's loss of status was experienced more in relation to his wife than his young children, but his status and authority over adolescent children suffered most.

Central to Komarovsky's scholarship were the objectives of identifying the functional significance of sex roles, their cultural contradictions, and prospects for social change. Whereas the dominant functionalist perspective emphasized the integrating functions of a sexual division of labor in maintaining a system's equilibrium, Komarovsky emphasized role strains and conflicts. Focusing on these dysfunctional aspects of sex roles, she emphasized the important relationship between men's changing roles (particularly in sharing domestic responsibilities) and women's emancipation. "Cultural Contradictions and Sex Roles," published in the *American Journal of Sociology* in 1946, launched four decades of research on the changing gender role attitudes of women entering an elite women's college and the dilemmas college women faced due to competing gender role expectations. This research culminated in *Women in College: Shaping New Feminine*

Identities (1985). Prominent influences on Komarovsky's work were Ogburn's cultural lag theory and Merton's role theory. She conceptualized role conflicts and strains as emerging from the discontinuities created by differential rates of change in norms, attitudes, and institutional arrangements. *Women in the Modern World* (1953) addressed post World War II anti feminist charges that colleges neglected the special functions of women in society. Critiquing biological and psychological theories of gender differences, Komarovsky offered a sociological explanation of the dilemmas faced by women. The foremost contradiction was in the competing expectations of the "traditional" feminine role and the "modern" role, the latter emphasizing women's intellectual and professional development. Whether a woman chose homemaking or to combine domestic and paid work, she was likely to experience internal conflicts and dissatisfactions. Komarovsky argued for social changes allowing men and women to reach their full potentials, advocating for women's employment in non traditional fields, men's sharing in family responsibilities, and wider availability of quality childcare.

Women in the Modern World emphasized strategies employed by college educated women in the 1940s to address gender role strains; for example, "think smart and act dumb" was an adaptive strategy used to protect male egos. In contrast, *Women in College* (1985) emphasized the growing complexities of shifting gender roles and competing expectations from family, institutional, and peer influences in the 1980s. Based on a longitudinal study of 240 Barnard freshman women, the study traced the school's influences on changes in gender role attitudes, career aspirations, and lifestyle preferences for marriage and motherhood. Over time, women were found to gain an increasing commitment to combining careers and family, became more certain in their career choices, and an increasing proportion were committed to sustaining uninterrupted full time careers. In *Women in College* Komarovsky also examined outside factors that shaped women's career orientations, including the quality of their parents' marital relationships, mothers' satisfactions with the homemaker role, and mother-daughter relationships.

Blue Collar Marriage (1962) is Komarovsky's study of stable working class marriages based

on in depth interviews with 58 couples living in "Glenton," a mill town located in a major metropolitan area. Working class, native born white Protestant couples, under the age of 40, with no more than a high school education and at least one child, were interviewed. Marital satisfaction based on discrepancies between ideals and reality was examined. Certain discrepancies in marriage were found to be easily tolerated by couples while others led to dissatisfaction. High conformity between values and behaviors sometimes led to strains and stresses as opposed to greater satisfaction in marriage. The cultural lag between modern conceptions of companionate marriage and the means for achieving personal intimacy was the basis of dissatisfaction in marriage, particularly for high school educated women who had high expectations for personal intimacy. Although working class couples experienced a minimal level of work–family role conflicts, they lacked intimate communication and self disclosure. Ironically, a consensus of values about sex roles among traditional couples led to frustrations in the form of social isolation and emotional disengagement, particularly for the men. Komarovsky concluded that traditional values were problematic for couples in a society that could no longer accommodate a rigid sexual division of labor. The absence of economic and social rewards generally increased social isolation, creating a drab and narrowly circumscribed life for blue collar families.

Not only did Komarovsky study female gender roles, but a number of her studies addressed men and masculinity, paving the way for contemporary work on hegemonic, alternative, and intersecting masculinities. In *Dilemmas of Masculinity: A Study of College Youth* (1976), Komarovsky found that men are not unlike women in the dilemmas they face in meeting role expectations, and in balancing cultural contradictions and role ambiguities. Using a sample of 62 senior males from Columbia University, Komarovsky examined masculine role strains resulting primarily from incongruity between the ideals of egalitarian relationships on the one hand, and men's personal preferences for masculine privileges in relationships on the other. The cultural revolution of the 1960s resulted in changes in male attitudes; for example, men expected their

wives to work, but retained traditional views that work should not interfere with the primary roles of mother and wife. Role strains, defined as the perceived or latent difficulty in fulfilling role expectations, and/or the low rewards for role conformity, were analyzed in several spheres of men's lives. Stresses in the sexual sphere included anxieties surrounding virginal status, sexual performance, and guilt associated with sex outside of marriage (e.g., potential pregnancy, sexual exploitation, and infidelity). Strains and stresses related to future work roles were prominent, particularly those surrounding choosing and achieving career goals. Similarly, men's desires for emotional independence from parents created stresses in their family relationships due to their economic dependence. Unsatisfactory father–son relationships were more common than mother–son relationships and had consequences for men's abilities to handle role strains and to disclose their emotions in heterosexual relationships. In relations with women (apart from sex), power and emotional disclosure were the primary sources of role strain. Of particular importance were men's feelings of inadequacy in obtaining ideal masculine leadership or dominance, assertiveness, and, to a lesser degree, intellectual superiority. Komarovsky developed a theoretical typology of role strain: ambiguity in role expectations; incongruity between individual and society in role conformity; insufficiency of resources to fulfill role expectations; low rewards for role conformity; latent and manifest conflicts in role conformity; and overload of role obligations.

In her American Sociological Association "Presidential Address: Some Problems in Role Analysis" (1973), published in the *American Sociological Review*, Komarovsky addressed the most common criticisms of social structural role analysis by using illustrations from her own and other's research. To the criticism that role analysis obscures and neglects individuality, presenting as it were an "oversocialized" view of humans lacking in spontaneity or self agency, Komarovsky highlighted the importance of integrating psychological variables into sociological research. In particular, she promoted understanding the social situational origins of psychological ambivalence as these become embedded in the structure of social statuses and roles. To the criticism that role

analysis places too much emphasis on role conformity and stability, Komarovsky illustrated from her own analyses of *Blue Collar Marriage Dilemmas of Masculinity* the ways in which role conformity can become problematic in times of social change, creating conflict and disorganization. In “The Concept of Social Role Revisited” (1992), Komarovsky specifically took up the criticisms of some feminists that the concept of social role is too limited in the sociological study of gender. Critics have argued, for instance, that the concept of sex role is too closely linked to biology and neglects the social construction of gender (p. 301). The use of the concept of “gender” or “gender roles,” argued Komarovsky, is preferred to “sex roles” but this preferred language and clarification of definition does not undermine the utility of social role or gender role analyses. Others, such as Barrie Thorne, have stated that the language of roles is deeply embedded in functionalism with its emphases on “consensus, stability, and continuity” (p. 303). Komarovsky (1992) responded that although Parsonian sociology placed emphasis on the functional integration of differentiated instrumental (male) and expressive (female) roles in the family, for others interested in women’s problems the concept of social role locates “disensus, discontinuity, and change” (p. 303). Komarovsky concluded that while new conceptualizations of gender are important for illuminating selected aspects of gender, the new approaches are not all inclusive, and complement rather than undermine social role analysis.

“Some Reflections on the Feminist Scholarship in Sociology,” published in the *Annual Review* in 1991, provides a retrospective look at the important contributions of feminist scholarship to sociology and is an indication of Komarovsky’s continued involvement in the discipline. The article addresses how the women’s movement of the 1960s influenced the feminist critique of sociology and the important contributions of feminist precursors (writing between the 1930s and 1960) to the “new feminist scholarship.” The feminist critique, she argued, identified lacunae in knowledge, revealed distortions embedded in the traditional theoretical interpretations, and raised new questions for research. The new scholarship was particularly important in revealing the malleability of

personality and its responsiveness to social structural opportunity, the strong sex typing of occupations and resistance to women’s work integration, and the importance of reconceptualizing work to include both paid and unpaid activities. While this early work took a “minimalist” approach to gender differences in personality traits that too often were used to legitimize women’s subordination, later work attempted to revalue women’s traditional activities and feminine traits, thus challenging the bias in the value system of the dominant group.

Komarovsky’s affiliation with Barnard College spanned three quarters of a century from her undergraduate years through her retirement. In personal interviews Komarovsky indicated that she experienced both personal and professional obstacles to fulfilling her potential as a sociologist, not receiving interpersonal or institutional support for her work until later in her career (Reinharz 1989, 1991). As a student she was discouraged from becoming a professional sociologist, instructed by her mentor, Ogburn, that her desire to teach was unrealistic for a woman, a foreigner, and a Jew. On the Barnard faculty, from 1935 to 1946, she did not advance beyond the level of assistant professor. An administrative change in the late 1940s, however, brought her promotions and the support needed to advance professionally. She served as chair of the Barnard Department of Sociology for 17 years and returned to teach and to serve as the director of Women’s Studies after her retirement in 1970. For her years of service and accomplishments at Barnard, Komarovsky received the Emily Gregory Award for teaching excellence and the Distinguished Alumnae Award, Medal of Distinction. Her accomplishments in the profession included serving as: vice president (1949) and president (1955) of the Eastern Sociological Association, a member of the Council of the American Sociological Association (1966–9), associate editor of the *American Sociological Review*, and president of the American Sociological Association (1972–3) (Reinharz 1989, 1991; Rieder 1999).

Kondratieff cycles

Immanuel Wallerstein

It is an elementary truism that no phenomena are absolutely stable. Whatever we measure in the real world shows fluctuations, whether we are speaking of basic economic phenomena (such as prices, production, employment, or investment), politico military phenomena (such as wars, free trade policies, or geopolitical arrangements), or cultural phenomena (such as puritanical mores or family patterns). The question is always whether we can ascertain the existence of any kind of rules or systemic pressures that govern the ups and downs of phenomena, including the explanation of the fluctuations and their timing and frequency.

The most readily observed fluctuations are those that affect the income levels of a population. We refer popularly to such ups and downs as prosperity and bad times. It is therefore no surprise that social scientists have been trying to explain such cyclical happenings for at least two centuries. As long as a large proportion of the population was engaged in agricultural production, the distinction between good harvest years and bad ones was of great importance to almost everyone, since the fluctuations promptly affected the prices and distribution of the products and therefore the ability of ordinary people to survive.

When industrial production became a larger percentage of total production, it became clear that there were fluctuations in the rates of profit of entrepreneurs, and therefore of production and employment, and this had immediate implications for public policy. Some scholars were beginning to measure such fluctuations at the beginning of the nineteenth century. Cyclical phenomena of varying lengths began to be observed, recorded, and eventually predicted. It was towards the middle of the nineteenth century that analysts began to talk of waves (A + B phases) that were 50–60 years in length. It is waves of this length that we now refer to as Kondratieff cycles.

Kondratieff cycles are named after Nikolai Kondratieff, a Russian economist whose classic work on such cycles was published in 1925. Kondratieff was not the first person to write about such waves, but his name became attached to them. Kondratieff observed price cycles in some major industrial countries, beginning in the late eighteenth century. His choice of starting date was no accident since, by the time he was writing, the late eighteenth century was also commonly given as the date of the industrial revolution.

Economists speak of a number of other shorter economic cycles named after their original analysts: the Kitchin cycle (40 months), the Juglar cycle (8–10 years), and the Kuznets cycle (15–20 years). They are explained variously. More economists are willing to accept the existence of these shorter cycles than are willing to give credence to the existence of Kondratieff cycles. Nonetheless, Kondratieff cycles have a wide, distinguished, and intellectually very varied set of proponents. Among

economists the most prominent was no doubt Joseph Schumpeter in his book *Business Cycles*, who is primarily responsible for labeling these cycles with Kondratieff's name. The concept found strong supporters among Marxist economists (Helphand, van Gelderen, de Wolff, Trotsky, Mandel) but just as strong opponents (probably a larger group). It also found strong support among non and anti Marxist economists (Dupriez, Hansen, Rostow, Forrester, Mensch) but just as strong opponents (probably again a larger group).

If one turns to economic historians, one finds a very large group (e.g., Simiand, Braudel) who describe Kondratieff waves without using that name for earlier periods – the sixteenth to eighteenth centuries, and for some beginning much earlier. And then there is a group of political scientists and sociologists who find such cycles in the political and cultural arenas (again, often without using that name). Some see these cycles as linked to wars, some as linked to the rise and fall of hegemonic powers. Some find even longer economic cycles, to which Cameron (1973) gave the name of “logistics” because of their S shape.

The critics of Kondratieff cycles point to inconsistencies among proponents concerning the dating and argue that the statistical evidence is inadequate, and often conclude with name calling (“science fiction,” according to Paul Samuelson). The debates among the proponents are more substantive and have to do with the underlying explanation of the cyclical patterns and a secondary debate about how, once in the B phase, the system ever renews an expansionary phase.

If one looks at Kondratieff's classic work one notices immediately that all the data are about a very few countries (England, France, the US, and Germany). Only one graph and chart are comparative; all the rest are about either England or France. The earliest data are for 1780. The data deal with prices, wages, foreign trade turnover, and production of raw materials. Kondratieff does note, however, that the rising phase seems to have more social upheavals (revolutions, wars). His basic explanation of the start of a cycle is the possibility of profitable investment in “new basic productive forces” (Kondratieff 1984: 104). It is Schumpeter who took what was no more than empirical data in Kondratieff and

turned it into a theory. Schumpeter made two basic additions to the description Kondratieff had made. First, he argued that the three described forms of waves – the Kitchin, the Juglar, and the Kondratieff – fitted within each other: “It is possible to count off, historically as well as statistically, six Juglars to a Kondratieff and three Kitchens to a Juglar – not as an average but in every individual case” (Schumpeter 1939 I: 174–5).

The second change was to shift from a two stage model of a long wave (prosperity and recession, or A and B) to a four stage model, which he named prosperity, recession, depression, and revival. The four stages were bracketed at each end by equilibrium. This allowed Schumpeter to locate temporally the process of innovation (something for him quite distinct from invention), which he defined as “the setting up of a new production function” (p. 87). He called it “the outstanding fact in the economic history of capitalist society” (p. 86). It is spurred by the third phase (depression) and bears fruit in the fourth phase (revival) and accounts for the return to equilibrium and prosperity.

The Schumpeterian emphasis on innovation as the explanation of the long waves and the reason why they are a fundamental feature of a capitalist world has given rise to one entire school of Kondratieff theorizing, which was revived when the world system entered a Kondratieff B phase in the 1970s. Whereas the innovation school tends to emphasize the self regenerating capacities of capitalist entrepreneurs (they innovate when they can no longer make profits on the basis of previous products), the class conflict school of Kondratieff theorists insists that regeneration is a political process. Renewal of capital accumulation requires capitalists to “increase the rate of surplus value and to foster deterioration of general working conditions for the working class” (Mandel 1980: 46). Their capacity to do this depends on the latter's “capacity to mount resistance and counterattack” (p. 47). Hence, the upswing depends on a dialectic between objective and subjective factors, “in which the subjective factors are characterized by relative autonomy” (p. 49).

In a sense, both the innovation school and the class conflict school see a decline in the rate of profit inherent in the capitalist process as accounting for the downturns. For Schumpeter,

it is the inevitable speculative overreach, when there is prosperity and profits are high, which leads to excessive credit to producers who are not sufficiently efficient. For Mandel, it is essentially the expansion of production beyond the possibilities of buyers in the market. For both the innovation and the class conflict schools the downturns are inevitable, and the question really is what permits the upturns. Suter (1992) adds evidence that national debt cycles are linked to the downturn phase.

There are of course some analysts, such as Rostow (1978), who see the downturns as the result of the fact that "investment decisions tend to be determined by current indicators of profitability rather than by rational long range assessments" (p. 307). There is here the implicit suggestion that these decisions are irrational "mistakes," mistakes that might be corrected by greater wisdom. And indeed, it is clear that, in the last 50 years, central banks and world financial institutions have frequently undertaken measures in order to dampen cyclical behavior, which has no doubt affected the process somewhat.

While the innovation school looks primarily at the economic arena (indeed, primarily at the level of entrepreneurial activity), the class conflict school tries to effectuate a "dialectic" between the economic (objective) processes and the political or class conflict (subjective) processes. However, there are analysts who wish to turn our attention primarily to the political arena, and indeed to the geopolitical arena of the relations between states and the existence of "hegemonic powers" or "leadership cycles." These analysts tend to speak of "long cycles" rather than of "Kondratieff cycles" and these cycles turn out in general to be longer than those of Kondratieff.

Wars – to be more exact, world wars – play a central role in these analyses of grand political long cycles. Modelski (1987) traced over five centuries of such cycles, seeing them as having four phases: global war (ending with a victor or leader), world power (or world peace led by the victor), delegitimation (or decline of the leader), and deconcentration (lack of order and presence of a strong challenger to the leader). He suggested that in these conflicts the "continental" powers lose out to the "oceanic" powers. He saw this as "the major rhythm of the modern

world" (p. 34), in which the result of the global war is the key decision.

The political long cycle group shares one characteristic with the economic historians who speak of A and B phases. They agree that the processes they are describing go back at least to the sixteenth century, and are not a product merely of the so called industrial revolution, often dated as beginning in the last decades of the eighteenth century (and which was the temporal foundation of Kondratieff's original discussion). So, be it noted, does Schumpeter.

There have been attempts to blend the discussion about Kondratieff cycles and political long cycles, using the longer time frame. Goldstein (1988) sought to "integrate" virtually all the emphases into a complex theoretical model which includes six "basic two way causality relationships . . . portrayed as negative feedback loops with time delays [whose] primary relationship is between production and war" (p. 277). Wallerstein (1983) saw two separate cycles in the workings of the modern world system. One is the cycle of hegemony, in which the achievement of temporary hegemony is rooted in the ability of one state to command simultaneous primacy in production, trade, and finance. The other is the Kondratieff cycle which relates to the achievement of temporary quasi monopolies in leading industries (Wallerstein 2004: 30–2). In both cases, the maximal positions (hegemony, quasi monopoly with its concomitant maximal capital accumulation) are self liquidating, which takes the form of long cycles with four phases.

It has been remarked that the popularity of theorizing about Kondratieffs is correlated with whether the world system is in an A or a B phase. People living in A phases seem to dislike long wave theorizing because it suggests that the A phase is not eternal, whereas people living in B phases seem to like such theorizing, since it suggests that the B phase will come to an end.

The literature on Kondratieff cycles and on "long cycles" is extensive. It has always been controversial. Indeed, few hypotheses about the modern world or about capitalism as a system seem to arouse as much negative passion among its opponents. One has to ask the question why. There seem to be several major

arguments against the existence of Kondratieff cycles. One is a debate about the quality of the data put forward in its favor. This is of course a perfectly legitimate debate. But it is doubtful that the quality of the data is significantly weaker than that for any other hypothesis that deals with macrophenomena over long historical time.

The second is that the hypothesis is mechanistic, in that it suggests exact time parameters for the presumed phases of the cycles. But this is simply unfair, since all proponents explicitly state that the timing is only approximate and has varied from cycle to cycle. Indeed, proponents of the Kondratieff cycles argue among themselves constantly about the dating one wishes to assign to various cycles.

The heart of the debate involves two issues. One is whether there are any general rules governing large scale social phenomena. The school of social scientists whose emphases are exclusively idiographic of course reject this. But so do social scientists whose epistemology is reductionist, emphasizing microphenomena and rejecting the idea of emergent properties. The second issue is among those who are willing to accept the existence of large scale generalizations, but are quite unhappy about the policy implications of Kondratieff cycles. For some, they suggest that a Whig interpretation of history is unsustainable since the structures of the modern world provide constantly for “downturns.” For others, it is the opposite. They see Kondratieffs as minimizing the element of agency and the possibilities of basic transformation of the existing system.

It is clear that the debate about Kondratieffs hides other, more important debates about the understanding of large scale social processes and the historical development of the modern world. These questions will never be resolved at the level of the existence or non existence of Kondratieff cycles, but must be tackled directly. In the meantime, there is a significant group of historical social scientists who are trying to add evidence and clarify theoretically their observations about macro fluctuations in the real world.

Krafft-Ebing, Richard von (1840–1902)

Ken Plummer

Richard von Krafft Ebing was an influential Viennese psychiatrist who invented a massive taxonomy of non procreative sexual classifications in his influential text, *Psychopathia Sexualis with specific reference to the Antipathy Sexual Instinct: A Medico Forensic Study* (1886). Never a sociologist, he gathered some 1,500 “clinical” case studies, developing a simplified version of life stories/autobiography as a tool for gathering unique subjective worlds of sexuality which could then be placed in the public domain (Plummer 1995). Many were

introduced – in a fairly random way – as newly discovered medical perversions and disorders such as masochism, fetishism, necrophilia, sadism, inversion, and even heterosexuality – combining, for example, a wide range of case studies from men who were attracted to handkerchief boys with detailed case studies of necrophiliac murders. It was the first book of its kind and played a very significant social role in bringing to recognition an array of diverse sexualities. Much of this is discussed very critically in Foucault's key work, *The History of Sexuality* (1978), where Krafft Ebing is implicitly seen as a key figure in creating the sexual confessional, the medical construction of sexual perversion, and the contemporary organization of sexual discourses. For Foucault's influential work, Krafft Ebing was a theorist of the Victorian "repressive hypotheses."

Initially, Krafft Ebing theorized homosexuality as a degenerate inherited trait (although it can be caused by masturbation or debauchery), and his work was very significant in establishing the ideas that homosexuals were specific kinds of people, that their state was a sickness, and that cure may well be possible. As such, it could seem that Krafft Ebing was a conservative regulator of sexuality. In fact, he was a sympathetic liberal doctor who was concerned with the ways in which many sexual deviations had become criminalized, seeing them as unjust. He was influential on both Havelock Ellis and Sigmund Freud, even though they both rejected his theory. Putting his work in context, his study must be seen as one strand of late nineteenth century thinking in which sexuality was becoming separated out from its procreative function. The sexual impulse was no longer seen as dominated by the reproductive instinct, and could indeed be linked to pleasure and personal fulfillment. Many of the so called perversions were part of this wider pleasure and desire (Oosterhuis 2000).

Psychopathia Sexualis was first published in 1886 and went through 12 editions. It was published in English in 1892, although much of the sexual language was left in a medicalized scientific form – "written in Latin" – to prevent the titillation of non medical readers, who were largely excluded from reading it. By the final edition he was much more critical of his own ideas

of morbidity and degeneracy, but he did not live to see his own critique published. In the end, his work offered a humanistic account of wide spread human sexual differences.

Kuhn, Thomas and scientific paradigms

Ron Stanfield and Mary Wrenn

Thomas S. Kuhn (1922–96) was born in Cincinnati, Ohio, and attended Harvard University. After graduating with a bachelor's degree in physics, Kuhn worked for the US government during World War II, then returned to Harvard for graduate study in physics. Having entertained an interest in philosophy since his undergraduate days, Kuhn agreed to teach a newly developed history of science class as part of his graduate work. As a result, in the last stages of his doctoral program, he decided to change his field to the history of science, a change which allowed him an entrée into the study of philosophy by focusing on the philosophical implications of change within a discipline. Kuhn continued down this intellectual pathway,

dedicating much of his professional academic career to the study of the history of science, and was especially intrigued by the shifting of *gestalts* within a discipline through time.

Although Kuhn's work focused almost exclusively on change within the natural sciences, it is perhaps in the social sciences that Kuhn's work made the deepest impact and where it continues to resonate today. Kuhn's emphasis on the social construction of a body of scientific knowledge appealed to social scientists who had long suffered in comparison to formal precision and elegance of the natural sciences. By seeming to emphasize consensus over rigor, Kuhn supported the scientific claim of social studies. He also opened the door to the study of the sociology of science through his work on the influence of cognitive values upon what is considered acceptable science, what Kuhn refers to as *normal science*, within any particular discipline.

Kuhn's most recognized and enduring work is *The Structure of Scientific Revolutions*. In *Structure*, Kuhn describes a process of a discipline's articulation or extension of a given developmental path up to the point at which that path no longer is able to furnish or resolve interesting problems. This crisis of normal science provokes extraordinary science and the possibility of scientific revolution in which the basic paradigm of a discipline is changed. A paradigm is a worldview, a set of implicit and explicit guides or examples defining the world and the questions and methods for analyzing the world.

The basic stages of Kuhn's scientific revolution or history of science paradigm are the following: pre paradigm; normal science; crisis and, possibly, extraordinary science; and normal science again after the crisis is resolved. The pre paradigm stage is characterized by the existence of several competing schools of thought, each offering a potential paradigm, none of which is persuasive enough to gain the (near) universal acceptance associated with normal science. There is a lack of direction as to what research should be done and as to the appropriate methods for doing it. Each competing group tends to seize upon a set of problems, facts, and methods. Published works take the form of extensive treatises that define and justify the scope and method of the research.

When one or a synthesis of the competing schools begins to attract ever larger shares of

practitioners, the transition to normal or mature science begins. Paradigms gain this acceptance by being considered more capable of solving a set of problems that have come to be accepted as the most important. The transition to normal science is marked by a withering away of competing schools, caused by conversion of old adherents, lack of recruits from a new generation, or simply defining out of the science the diehards who refuse to convert.

The discipline also is given a narrower, more rigid definition. This more rigid definition changes the nature of scientific publications, as general books (except textbooks) are replaced by shorter articles or research reports that assume prior knowledge of the paradigm on the part of the reader. The textbook tradition also arises. Textbooks generally include only that past scientific work relevant to the current paradigm. This creates the accumulated knowledge illusion of a science, since past scientists are seen as sharing the same worldview, that is, as studying the same puzzles, data, and phenomena as current scientists, albeit somewhat less adroitly. Students learn from texts, not by using original sources. The discipline grows more insular, with its own standards and communications system increasingly separated from the lay public. Indeed, scientific revolutions tend to become invisible because of the textbook tradition.

Normal science is achieved when the discipline more or less universally accepts the dominant paradigm, which then directs the practitioner as to the key questions and appropriate methods of normal research. Normal science encompasses a period of paradigm articulation involving the manipulation of fact and theory to expand the scope and precision and to resolve the ambiguities of the paradigm. Significantly, normal science is characterized by a lack of intent to uncover phenomenal or theoretical novelties. The accepted paradigm defines the appropriate problems to pursue and the procedures to be used for this pursuit, and it guarantees that solutions to the problems can be found by using these procedures. Normal science involves puzzle solving. When an experiment fails to produce the anticipated result, the puzzle solver, not the puzzle (paradigm), is considered inadequate. This point is important because scientific revolutions are rejections of paradigms that do not make good their guarantees. Normal science

is thus characterized by a period of relative quiescence, but this should not be interpreted as an equilibrium or static period. Normal science features calm and orderly cumulative change; it is not an equilibrium situation to be disturbed only by exogenous happenstance. As an articulation or day to day working out of the directions given by a paradigmatic axial structure, normal science itself sows the seeds for a period of storm, crisis, and redirection.

A situation of crisis occurs with the interruption of the normal science pattern. The existence of one or several anomalies marks the first stage of such a crisis. An anomaly is a violation of expectation or failure of a set of paradigm puzzles to come out right. As such, an anomaly may be associated with conflicting experimental or empirical discoveries or with an insistent theoretical ambiguity that defies resolution by paradigm articulation. An anomaly may not lead to crisis; it may exist and be recognized but be considered peripheral. Or the paradigm may be adjusted to resolve the anomaly. To evoke a crisis, an anomaly must question explicit, fundamental generalizations of the paradigm; be important to the solution of a pressing practical problem; or involve a long history of persistently defying resolution within the paradigm. When, for these or other reasons, an anomaly becomes recognized as more than merely a difficult problem, the transition to crisis and extraordinary science has begun. More attention is afforded the anomaly, and it may come to be recognized as the subject matter of the discipline.

The period of extraordinary science is similar in many ways to the pre paradigm state. There occurs a relaxation of the rules of normal science, which results in more speculative, random research. Increasingly divergent articulations occur, which may involve the formation of schools of thought. This pattern often leads to an increase in discoveries and a shift to philosophical analyses or explicit methodological debates on the rules of the paradigm. In essence, then, a state of flux exists in which the discipline searches for a new departure by reconsidering data, questioning structural institutions, evaluating received doctrine, and the like. The state of flux which occurs during extraordinary science is necessary but not sufficient to invoke a battle of paradigms. The period of

extraordinary science ends in one of three ways. The anomaly may be resolved finally by normal science; the anomaly may resist all offered approaches, in which case the discipline accepts it as insoluble given the state of the art; or a new paradigm may emerge and a battle for its acceptance ensues. In the last case, the ascension to dominance of a new paradigm is, of course, the consummation of a scientific revolution.

The paradigm battle occurs when dissenting opinion is molded into a synthetic paradigm that can be used to challenge the extant conventional wisdom. The challenge to conventional opinion is weakened by the existence of several dissenting schools, each insisting on its own doctrinal integrity and expending vital energy to do so. The true testing in a science occurs within the paradigm battle. Normal science does not involve testing the paradigm with fact. It is a process of matching fact and theory with the burden of failure resting upon the tool user, not the tool. Testing occurs in the paradigm battle when competing paradigms are tested for their ability to gain the allegiance of the discipline. This testing cannot be done precisely by proof either of the falsifiability criterion or of the probability of accurate prediction types, since competing paradigms are incommensurate. That is, holding different worldviews, standards, delineations of the science, and connotations of terminology, practitioners with different paradigms cannot agree on an objective operational test of the paradigms. The testing and conversion process is one of persuasion. Frequently members of the old generation remain unpersuaded and either are defined out of the discipline or manage to stave off conversion of the discipline until their deaths.

There are three principal persuasive arguments for a new paradigm: that it is capable of resolving the crisis producing anomaly; that it permits the admission of new phenomena inadmissible under the old paradigm; and that it is aesthetically more pleasing, neater, more suitable, or simpler than the old paradigm. More generally, Kuhn notes that to gain acceptance the new paradigm must be seen as preserving most or all of the problem solving capacity of the old paradigm while offering additional capacity of its own. Of course its chances for success increase with the amount of importance that can be attached to this additional capacity. Although

the new paradigm retains the problem solving capacity of the old, the new paradigm is not simply a cumulative process of attaching a new layer to the old foundation. Rather, it is the social construction of a new foundation involving new fundamental laws, generalizations, and behavioral functions; often new methods and applications; and a redefinition of the character and standards of the science. It is because of this marked deviation from the previously established paradigm that the new paradigm arises in the minds of one or a few individuals whose research is usually concentrated in the anomaly area, and who generally are young or new to the discipline and therefore have less invested in the propagation of the old paradigm. Indeed, the new paradigm is a change in worldview to such an extent that the world itself is changed. The perception and cognition of data and even the data to be collected are redefined.

Kuhn's work indicates the importance of social structure in any discussion of a scientific community. For example, a clear picture of socialization or acculturation emerges from the discussion of the intergenerational process of recruitment and accreditation. Paradigm discipline to sustain an integral core of fundamental problems and methods is a social process. The most visible aspect of this process is the structure and function of a penalty-reward and status system in the discipline's hierarchy of journals, departments, and associational offices of function and sinecure. There is also the tacit knowledge aspect in that the members of a science have internalized shared commitments, values, and research guides that remain tacit in a period of normality. Their existence, however, can be recognized consciously and their content deliberately scrutinized in periods of crisis and extraordinary science. The hierarchy of departments, journals, and associations may also be subject to critical scrutiny in such times.

In discussing normal science as a puzzle solving activity, Kuhn notes that the paradigm, and not society, defines the scope and method of a science, but this is not to say that paradigm shifts within a science occur in complete autonomy and that the wider society or social structure bears no influence upon paradigmatic change. Given the subjective character of paradigm acceptance, any social forces that play upon an investigator's sense of self and

sense of collegiality may play a role. Kuhn cites nationality as an example of an external criterion that could influence the rate of change within a discipline. Darwinism, Kuhn notes, ascended to normal science before its adaptation in other countries. As well, an individual scientist's values and norms influence the disciplinary choices made. As such, both shared and personal criteria figure into the decision making process and work to determine the openness with which paradigm changes might be greeted and the type and degree of change which the individual practitioner will tolerate. The degree of influence by these external values is directly correlated with the degree of upheaval generated by the paradigm battle internal to the discipline. Subjective values thus rise to guide the individual and fill the lacuna left by the conflation or absence of objective rule criteria. In the interest of maintaining "objective science," the part played by an individual's values and norms is generally unacknowledged in the evolution of a science. Moreover, Kuhn points out that in understanding the ascension to dominance of a new paradigm, reference must be made not only to the shared criteria of the scientists who chose the new paradigm, but also to those points on which they differ.

Kuhn's work has had enormous influence not only in the history and philosophy of science but also in the language of everyday life. His emphasis on the social construction of science is part of a general movement, dating at least to Marx, toward a sociology of knowing. If a unification of scientific knowledge is in the offing near term, it will likely build upon this growing concern with the process of human cognition.

Kurauchi, Kazuta (1896–1988)

Kenji Kosaka

Kazuta Kurauchi was born in Okayama Prefecture in Japan. His father was the head teacher of Chinese classics at Kojokan, which was a local private school specializing in Chinese literature studies. From his early days, Kurauchi was greatly influenced by both Keiken Sakata, the famous scholar who owned and managed the school he attended, and his father.

Kurauchi graduated from the Faculty of Letters at the then Tokyo Imperial University – now Tokyo University – where he studied sociology under Tongo Takebe, who was a follower and proponent of Comtean sociology. As sociology was not yet a well developed academic discipline in Japan, Kurauchi also studied history, literature, and philosophy, all of which combined to give a much broader perspective to his sociological work. Thus, although a sociologist, he was also well versed in classical Chinese and western (particularly German and French, but also English and Italian) and Japanese literature studies, both classical and contemporary. This wide intellectual background informed his sociological studies, and distinguished him from other Japanese

sociologists, both those who were his contemporaries and those who came after him.

After graduation, Kurauchi was employed by the Ministry of Education to research educational matters in Japan, but continued his sociological studies with colleagues at the Tokyo Society of Sociological Study. He also taught at various universities as a part time instructor at this time. Eventually he moved into teaching as full time academic work, becoming a faculty member at Kyushu University (1933–46), Osaka University (1948–60), Kwansei Gakuin University (1960–7), and Otemon University (1967–74). He was granted a doctoral degree in sociology for his book *Bunka Shakaigaku* (*Sociology of Culture*), written in 1943.

Among his other major works are the books *Bunka to Kyoiku* (*Culture and Education*, 1948), *Shakaigakubu Gairon* (*Outline of Sociology*, 1953), and *Shakaigaku – Zohoban* (*Sociology, Enlarged Edition*, 1966), which, with his many academic papers, are all included in his *Collected Papers* (1976–84). Kurauchi served as president of the Kansai Sociological Association (1956–60), and was a member of the Science Council of Japan from 1960 to 1963. He died at his home in Osaka Municipal Prefecture on July 6, 1988, having actively written about and explored new sociological research areas of study until the very end of his life.

Kurauchi was a creative scholar who lived in the Meiji era and who attempted to integrate western and Japanese philosophy, having first studied and learned Comtean sociology from Takebe, but later becoming inclined toward the sociological thinking of Tarde and Georg Simmel. His graduation thesis was “Considerations on the Causes of the Decline of Societies.” He was later also influenced by the strong currents in German sociology, particularly by phenomenology and the sociologies of culture and knowledge. The research interest which sustained his work was in the “social” dimension of society and sociology as an academic discipline.

In 1922, a new movement emerged at Tokyo Imperial University among the younger sociologists. This movement sought to absorb the new waves of European sociology that had developed while Japanese scholars had been isolated due to World War I. *Tokyo Shakaigaku Kenkyukai* (Tokyo Society of Sociological

Study) was formed in 1924 by Hisatoshi Tanabe (a committed French sociologist being a follower of both Durkheim and Tarde), Kurauchi, and Takashi Akiba (well known for his studies of ethnic groups in Korea and in China) in order to promote this new movement. Although Kurauchi was committed to phenomenological sociology, Japanese sociology as a whole became more diverse and more independent in the years following the formation of the Tokyo Society of Sociological Study.

Kurauchi's principal influences were Simmel, Kracauer, Husserl, Vierkandt, Tönnies, Scheler, Litt, Geiger, and Mannheim, all of whom are considered phenomenological sociologists. Following study and research methods developed by this prominent group of sociologists, Kurauchi attempted to have a clearer understanding of the essence of "society" in the lived experiences of the self as an individual. Theodor Litt was perhaps the most influential phenomenological sociologist on Kurauchi's sociology. It was Litt's insights into lived space and the conceptualization of the essence of society in terms of the reciprocity of perspectives that most affected Kurauchi's sociological thinking. Kurauchi applied Litt's insights to both the spatial and temporal perspectives. Other prominent sociologists greatly influenced Kurauchi, such as Durkheim, Tarde, Gurwitsch, and other French sociologists. No multiplication of names of people who influenced Kurauchi's intellectual odyssey, however, would be sufficient.

Kurauchi is known as a pioneer in three areas of sociological study and research in Japan: the sociology of education, cultural sociology, and theoretical sociology. Among his major contributions was the development of unique and creative theories and concepts of sociological thought from a phenomenological perspective. His creativity and innovativeness can be seen in the sociological analytical framework and in the uniquely coined sociological concepts and terms he developed. He considered society to be a whole that contains many subjects. This whole is experienced by each individual subject, rather than by the whole subjectivity. The contemplation of society must be considered from three points: the wholeness of society, individuals, and the many varied relations that hold between and among individuals.

The experience of society is always defined in terms of time and place, where three group types can be distinguished according to the lived experience of individuals: preceding group (*Vorgruppe*), present group (*Jetztgruppe*), and subsequent or succeeding group (*Nachgruppe*). Preceding group is defined as a social group which exists prior to a given nation state, and which is involved in the transformation process of that nation state from within, with the collective energy of a social group being retained. An example is tribal groups, on whose allegiance a given nation state is based, these groups existing prior to the creation or construction of the state system, and maintaining their group allegiances after the system is formed. Such groups are often agitating elements in the state system, and there is always the possibility that these groups may withdraw from that system.

Present groups are those necessary for the construction or creation of the nation state system. Bureaucratic groups and military groups are prime examples of this group type in that they play important roles – as far as formal roles are concerned – in sustaining the state as such. However, as concerns their informal roles, these groups can easily deviate from normative standards set by the state. Since such groups are deeply connected to the state system, having been instrumental in the creation of the state system, they can also have great effects on social changes (e.g., in a coup d'état). Succeeding groups emerge after the creation or construction of the state system has been initiated, and are created or recreated by the system itself. These groups may become discontented with the state system, in which case they may also become agents of revolutionary change through their resistance to the system.

These notions of society were quite original to Kurauchi, although he got the idea from the work of early Chinese and Japanese historians such as Su Dongpo (1036–1101) and Rai Sanyo (1780–1832). Kurauchi combined the three group type model with a fourfold schema to fully develop his own theory of societal change – which he called *ri ho say may* – by integrating various sociological insights, both eastern and western. Society in its totality and societal change can be analyzed, he claimed, by reference to *ri* (law), *ho* (norm), *say* (current), and *may* (destiny), as shown in Figure 1.

	Universal	Particular
Ultra-societal	law (<i>ri</i> ; <i>Gesetz</i>)	destiny (<i>may</i> ; <i>Geschick</i>)
Societal	norm (<i>ho</i> ; <i>Norm</i>)	current (<i>say</i> ; <i>Strom</i>)

Figure 1 Societal change.

In the conceptual schema in Figure 1, *ri* refers to “external” general laws that serve to regulate societies and events and manage the thinking, actions, and behavior of humans. Our individual lives are also determined by *may* in that we cannot choose when, where, or with what socio-economic status we are born. *Ho* refers to societies’ “internal” laws and institutions, whereas *say* represents more transient entities such as social currents, fads, mobs, and public opinion. In Kurauchi’s theoretical thinking, *ri* and *ho* are much more stable than *may* and *say*. All these terms originated in eastern or Oriental literature, but are readily translatable into terms clearly understood in western philosophy.

Kurauchi uses this fourfold typological schema to explain various social phenomena; even the architecture of a house, seen from Kurauchi’s sociological perspective, can be interpreted using the four concepts. A house in Kurauchi’s conceptual schema is a representation of material culture, it being a creation and adaptation of humans in the midst of their natural surroundings (*ri*). The house embodies human values (*ho*), and is a reflection of a variety of manners that show social currents (*say*). The house, consisting of three major components – roof, wall, and floor – is also a place where someone happens to live (*may*). The natural environment coupled with the human need to protect oneself from possible violent assault by outsiders, for example, together determine different housing styles, which reflect different cultures and ways of thinking and behaving (e.g., eastern/Oriental and western/Occidental, modern and premodern, etc.).

Kurauchi uses this same explanatory schema to illustrate, for example, how elements of Confucianism have affected modernization and the development of democracy in Japanese society, how the history of a society is to be analyzed in general terms, and how religion is formed and transformed during historical processes. Thus, Kurauchi’s fourfold schema provides a

powerful interpretive framework in sociology. Kurauchi’s culture and his original social analyses reminded him of early literature, both eastern and western. At the same time, the opposite occurred: he was provided with useful clues or hints to formulating sociological concepts and theories by recalling early literature. For Kurauchi, even the past can be classified into three types. First there is the “age of direct contemporaries,” secondly “the age of direct transmission of tradition,” and lastly “the age of indirect records and literature.” This further utilization of Kurauchi’s conceptual and theoretical framework was suggested to him by Chun Gin, a Chinese scholar of the Gong Yang school at the end of the Qing dynasty. This typology was also easily linked to the concepts of *Vorwelt* (world of predecessors), *Umwelt* (fellow men in direct experiences), *Mitwelt* (world of contemporaries), and *Folgemwelt* (world of successors), which were developed by Alfred Schütz.

Kurauchi applied his unique phenomenological perspective to the interpretation of numerous historical events as well as cultural and artistic works. The *I Ching*, for example, remained one of his longstanding academic interests. *Doroumi koki*, which was an orally constructed legend in Japan of the creation of humans, describes the philosophy of Miki Nakayama (1798–1887), the founder of the Shinto sect named *Tenri kyo*. Kurauchi reinterpreted *Doroumi koki* as an elaborate philosophy for ordinary people based on both the *I Ching* and his own sociological perspectives.

The legend known as *Doroumi koki* begins by describing how humans were created. Gods of (the) sun and (the) moon looked down upon *doroumi* (muddy sea), only to find loaches. The gods soon grew tired of looking at this monotonous scenery and decided to create humans. Kurauchi interprets this as an embodiment of *K’un* (ground), represented as loaches in *doroumi* and gods in *Ch’ien* (heaven), a combination of

the two trigrams of *ying* and *yang* which, he says, imply the production or creation of some thing – in this case, humans.

Other phenomena can be interpreted in terms of a combination of two out of eight trigrams. A seemingly ridiculous legend, involving a variety of fish and reptiles, such as tortoises, eels, glo befish, plaice, flatfish, black snakes, and killer whales, is now codified as representing three layers of humans, animals, and vegetables. Furthermore, in the process of that codification the legend acquires a deep sociological interpretation. This analysis thus recalls Aristotelian anthropology and Lévi Straussian structuralism as well as Chinese and Japanese philosophy. No other sociologist, Japanese or otherwise, can compete with Kurauchi's analysis explaining the entire discourse of *Doroumi koki*.

Kurauchi's sociology may very well be characterized as an attempt to integrate sociology with its western origins into the social thought and literature of the eastern/Oriental and Asian experiences. In 1974 Kurauchi stated,

[I am] dissatisfied with the situation where Japanese sociologists view sociology as an imported science subservient to the authority of Western scholars, while lessons from Chinese and Japanese classical and contemporary works are ignored. It is unnaturally dogmatic that we do not investigate that literature and continue to treat it as irrelevant. This is a cultural tragedy. ("Sociology and I," in *Collected Papers*, V.456)

Kurauchi never once mentioned or spoke of "globalization" in the sense in which the term

was used at about the end of the twentieth century. The three group model discussed above may well reflect the world system in the 1960s as Kurauchi viewed it. However, Kurauchi's ideas and theories will never become outdated since they are concerned deeply with the fundamental structures and processes of the lived experiences of humans, and with society. Kurauchi's ideas, concepts, and theoretical explanations, analyses, and interpretations are readily applicable to any society at any level of discussion or analysis, and at any time. The many newly emerging difficult tasks, and the turmoil which gives rise to an urgency of confronting those tasks in the twenty first century, can be readily addressed by carefully looking at and applying Kurauchi's general theoretical schema.

L

labeling

Thomas Calhoun and Mark Konty

In the sociology of deviance the concept of labeling is used in two interrelated ways. One involves the labeling of people as *deviants*. When people are so labeled, they are judged to be deviant by some standard and the label has important sociological and psychological consequences. The other is the labeling of actions as *deviance*. When actions are labeled as such, there tends to be an actual or assumed non normative behavior, and that reaction reflects the feeling and attitude of a person or group toward that behavior.

Although functionalism and conflict theory contributed to the labeling concept, it is most firmly rooted in symbolic interactionism. As suggested by symbolic interactionism, people and their behavior are labeled deviant via social interaction with others, and the feedback we receive from those interactions structures our view of ourselves. In effect, labeling behavior as deviant constitutes and defines its deviant status, and, as a result, the person so labeled experiences the consequences of being labeled deviant.

LABELING PEOPLE AS DEVIANTS

Deviant labels are *negative*. Frank Tannenbaum (1938) was the first sociologist to argue that society creates criminals by “dramatizing the evil” of the offender. The person is “defined,” “identified,” “segregated,” and made “conscious and self conscious” of his or her failings. The label identifies the negative character of the offender.

Deviant labeling produces negative *reactions*. Edwin Lemert (1951) made a conceptual distinction between primary and secondary deviance. Primary deviance is norm violating behavior that goes undetected by others and consequently escapes being labeled deviant. This type of deviation does not affect the individual’s social relationships or self concept. Secondary deviance, however, is known to others and provokes negative “societal response.” Lemert was not concerned with what prompted people to commit the deviant act in the first place, but was interested in how the negative responses to deviance shaped future behavior. A person may commit rule breaking acts, but with no response from others the individual simply carries on as before. A person, then, is not a deviant unless others respond in a negative way to the person’s behavior.

Deviant labeling depends upon *social relationships*. All labels emerge from social relationships. These negative reactions ascribe negative characteristics to the individual. These reactions, however, are not the same for all kinds of people. Instead, as Howard Becker (1963) observed, some individuals are more likely to be labeled deviant than others, even when the same rule is broken. The likelihood of being labeled deviant, however, depends on the relationship between one person and others. Generally, the greater the difference in power and status between the two parties, the more likely one is labeled deviant by the other. Also, the more distant the relationship, the more likely labeling is to occur. Thus, labeling is more likely to occur among strangers than among friends and family members.

Deviant labels are *noxious*, an “undesired differentness” (Goffman 1963: 5). They tend to threaten or destroy the labeled person’s career, social position, and relationship with friends, acquaintances, and others. As a result,

people generally try to avoid deviant labels and they use various strategies to manage the situation to avoid the label. Erving Goffman (1963) draws a distinction between people who are "discredited" (already stigmatized) and "discreditable" (may be stigmatized at any time) and suggests some of the ways that each manages the situation to avoid the noxious effects of the deviant label.

Deviant labels make *social interaction difficult*. Generally, people prefer to interact with others who are more like them. The deviant label lets us know that the deviant is not like us, seems to oppose our values, or has different tastes and preferences. We consequently feel uncomfortable interacting with the deviant person. Moreover, interacting with deviants carries the risk of guilt by association or what Goffman (1963) called "courtesy stigma," whereby conventional people are labeled deviant simply because they associate with a deviant. As a consequence, conventional people tend to steer clear of the deviant.

Another effect on social interaction occurs when the rule breakers are shamed for their behavior. According to John Braithwaite (1989), shaming takes one of two forms, each with different consequences. In "disintegrative" shaming the rule breaker is stigmatized and rejected by the group, resulting in the likelihood of further deviance. "Reintegrative" shaming, on the other hand, involves showing compassion and understanding for the rule breaker while simultaneously making him feel shame for his behavior. The result is the likelihood that deviance will desist. The effect of labeling on social interaction thus depends upon the type of shaming practiced by the group.

Deviant labels tend to produce *deviant self concepts*. In symbolic interactionism, the self is a product of social interaction. If the interaction involves a person being labeled as a deviant, that person is likely to develop a deviant self concept. The altered self concept in turn affects future outcomes. This can occur even if the individual has done nothing wrong.

William Chambliss (1973) demonstrated that not only does social status affect who gets labeled, but that this difference also affects the self concepts accordingly. The "Roughnecks" came from the community's lower social strata. They engaged in some petty larceny and

occasionally fought with each other. The community labeled them as the town troublemakers. The "Saints" were members of the community's upper social strata. They were actually more deviant than the Roughnecks, not only because they committed more deviant acts but also because their deviant acts were more serious and harmful. These boys were nonetheless considered upstanding members of the community, and when they were caught breaking rules, the behavior was excused as "boys being boys." Following high school graduation the Saints did better than the Roughnecks. The Saints became the respectable citizens they were projected to be, while the Roughnecks continued a life of petty crime and low paying jobs. The only exception was two Roughneck boys who went away to college on athletic scholarships. Free from the negative feedback of the deviant label, they developed positive, successful self concepts. They returned to their home community and occupied the same positions as the Saints. This reveals a situation where two groups of youth, both engaged in delinquency, had very different outcomes because their social statuses determined how their behavior was reacted to, and those reactions shaped the boys' futures in different ways.

LABELING BEHAVIOR AS DEVIANCE

Becker (1963) observed, "deviant behavior is behavior that people so label." This seems to be stating the obvious, but this subjective, or reactive, definition of deviance opened the door for new analytical and theoretical insights in the study of deviance. Analytically, this definition of deviance allows researchers to set aside their own judgments of right and wrong and instead focus on the judgments and consequent reactions of the society being observed. Theoretically, this definition calls attention to the role of power in defining behavior as deviant.

How can we know what is regarded as deviant in a society? Becker analyzed several approaches and found each wanting. One approach is to calculate some statistical mean and use that as a standard of what is "normal," but this may or may not actually fit what the society considers desirable or deviant. Some typical behaviors (e.g., lying) are quite common

but still considered deviant. Some atypical behaviors (e.g., eating pancakes for lunch) are not considered deviant at all. Another approach is to determine if a behavior is harmful to the individual or society, but there is often little consensus as to what is harmful or not. The approach with the most intuitive appeal is to simply ask what the rules are or look for some absolute moral code (e.g., the Bible) which the group references. In complex societies, however, people reference many different groups, each under different rules, and figuring out which rules apply at what time and in which setting makes analysis difficult, if at all possible. On top of all this is the fact that some formal rules are rarely enforced while other informal rules carry more weight. How could the observer know what is deviant and what is not? The answer, Becker contended, is that the observer can know deviance by how people react to an individual's behavior. If they react negatively, he reasoned, then the act must be deviant.

Some critics question the moral validity of this approach. They argue deviants are unusual, deviance is harmful, and the moral code is absolute rather than relative. Deviance is an objective phenomenon, they conclude, not a product of social construction. Unfortunately, this approach is analytically useless and doesn't reflect empirical reality. To the researcher, it doesn't matter what *should* be deviant, but rather what *is* regarded as deviant in a particular society. Simply observing the world around us tells us that definitions of deviance do vary across groups, time, and space.

The labeling, reactive definition provides a parsimonious solution to the problem of defining a phenomenon with so much variance. People don't react negatively if they believe a behavior is positive, so if there is a negative reaction, there must have been a negative behavior in the eye of the observer. Of course, this definition also includes people who may have actually done nothing wrong, but are still labeled deviant, what Becker called the "falsely accused." There is a problem, though, with this reactive definition. It may include the subjective view of deviance as *positive*, which runs counter to most sociologists' assumption that deviance is always negative (Heckert & Heckert 2002).

A key utility of the reactive definition of deviance is that it allows sociologists to examine the role of power in defining deviant and normative behavior. A normative definition of deviance, which regards deviance as a norm violation, says nothing about where the norms came from or why the norm violation does not have the same consequences for different categories of people. The more power and resources a social category commands, the greater is its capacity to resist being labeled as deviant and the more impact its definitions of deviance have. More powerful social sectors of the society are more likely than less powerful sectors to have their definitions of deviance valorized and institutionalized. Taken collectively, the more influence a social category has, the more likely its views on right and wrong will have influence on the educational curriculum, the content of the media, political discourse, and the actions and policies of the criminal justice system.

AN ASSESSMENT OF LABELING THEORY

The labeling *process* is distinct from labeling *theory*. The process of labeling, a process that takes place in all societies and all times, has manifestations and consequences that are distinct from any theoretical claims made by labeling theorists. Labeling theory can be critiqued independent of the phenomena observed during the labeling process. As a theory, labeling can be both dependent and independent variable. Labeling theorists have attempted to explain why certain people are more likely to be labeled than others, taking labels as result dependent upon other factors. Substantial evidence indicates that factors like power and status differences, resources, social distance, and visibility affect the likelihood that a label will be applied. Labeling theorists also posit that labels have their own independent effects on social interaction, self concepts, and behavior.

Over the years a number of criticisms have been leveled at labeling as an independent variable. The most common is the charge that the labeling perspective does not explain initial acts of deviance, as it only explains deviance after the behavior has been detected and the label

applied. But supporters of the labeling theory counter that the theory is not intended to explain initial deviance but instead secondary, continued, or repeated deviance as a result of the societal responses to initial deviance. However, research has yielded mixed results on the presumed validity of the theory. Labeling by friends, family, and other informal social agents has strong effects on self concepts (Matsueda 1992), while labels from the criminal justice system and other formal social control agencies seem to have weak or no effects on individual's self concepts (Akers & Sellers 2004).

labeling theory

Ross Matsueda

Unlike most theories of crime and deviance, which emphasize the causes of deviant behavior, labeling theories focus on society's reaction to crime and deviance. Labeling theorists argue that society's reaction to deviance is fundamental for three reasons. First, individuals who are labeled as deviant by society often become stigmatized and isolated from society, leading them into a deviant lifestyle. Second, the very definition of deviance lies not in the objective behavior of "deviants," but in powerful groups' ability to define and label the behavior of the powerless as deviant or criminal. Thus, deviance is socially constructed. Third, society's reaction to deviance provides positive functions for society by defining the boundary between deviant and conventional behavior and by reaffirming social solidarity.

LABELING, STIGMA, AND DEVIANCE AMPLIFICATION

Labeling theory argues that initial acts of child misbehavior are harmless acts of primary deviance; if left alone, children would mature out of misbehavior. While the children define such acts as "play" or "mischief," the adult community defines them as "bad" or "evil." The community, which includes parents, teachers, and juvenile justice officials, labels the acts as "delinquent," and the child as "bad" or "evil," in need of treatment or reform. The label, in turn, affects the self image of the child, who comes to internalize the label, which produces more deviance, and more labeling. This escalating process of labeling can even tuate in the youth caught up in the legal system, stigmatized by society, isolated from conventional groups, and left with a deviant self image. The result can be a self fulfilling prophecy, as an otherwise conforming child fulfills the prophecy of the initial labeling of harmless acts, through deviance amplification (Matsueda 1992).

Lemert (1951) used the term primary deviance to refer to harmless initial acts of deviance, and secondary deviance to refer to deviance resulting from the negative effects of labeling. Labeling theorists have identified many examples of secondary deviance. For example, because of the stigma of their arrest records, ex prisoners have difficulty getting jobs, finding affordable housing in good neighborhoods, and finding noncriminal companions, all of which impedes reentry into conventional society. Mental patients institutionalized in mental hospitals are stripped of their identities and forced to adapt to a custodial environment, which can hamper their attempts to recover. The poor are sometimes labeled as lazy and slothful, which can undermine their self esteem and attempts to secure and maintain jobs.

These propositions of labeling theory led to policy changes in the 1970s. In juvenile justice, non intervention policies were introduced to remove youth from the tangle of juvenile corrections and community treatment. In mental health, deinstitutionalization and mainstreaming were adopted to move non chronic mental patients into the community. Such policies resulted in some successes, but also unanticipated consequences, such as widening the net of community controls of juveniles and increasing the ranks of mentally ill in the homeless population. Thus, the policies were no panacea for the complex problems addressed.

SOCIAL CONSTRUCTION, POLITICAL POWER, AND THE DEFINITION OF DEVIANCE

Perhaps more than any other theory of deviance, labeling theory takes seriously a social constructionist view. Rather than assuming that deviance and crime are objective behaviors "out there" to be discovered, labeling theorists argue that deviance is socially constructed through an institutional process involving politics and the legal system, and an interactional process involving the powerful applying of labels to the powerless. As a social construction, then, deviance is relative to a given society and

historical period. Out of the nearly limitless variety of human acts, societies settle on a small range of acts to label as deviant; most entail harm to others, but some entail little harm. The relativity of deviance is underscored by labeling theorists' definition of deviance.

In contrast to the usual definitions of deviance (or crime) as behavior violating social norms (or criminal laws), most labeling theorists adopt a "labeling definition of deviance," in which deviance is a label or status conferred by a social audience. Deviance, then, is not a behavior but a label: "The deviant is one to whom that label has successfully been applied; deviant behavior is behavior that people so label" (Becker 1963). When introduced, this definition created confusion, as critics argued that, taken literally, the definition excludes the possibility of actual deviant behavior, independent of whether or not it is labeled. Becker (1973) responded by saying the entire process of creating rules, violating rules, and labeling violators constitutes labeling: "Social groups create deviance by making the rules whose infraction constitutes deviance, and by applying those rules to outsiders." Such a definition spawned studies of the entire process, beginning with rule creation.

A hallmark of labeling theory is the observation that labels are not distributed equally in society, but rather are disproportionately applied to the powerless, the disadvantaged, and the poor. This begins with the creation of rules that define deviance. Labeling theorists argued that generally the powerful succeed in creating rules and laws outlawing behavior that violates their self interests. Thus, rule creation is a result of group conflict in society, in which the powerful have a distinct advantage. Becker (1963) showed how moral entrepreneurs, typically drawn from the ranks of the middle and upper classes, create moral crusades by mobilizing disparate interest groups to outlaw behaviors that violate their common interest. Classic examples include the Marihuana Tax Act, prohibition, sexual psychopath laws, and the creation of the juvenile court.

Labeling theorists also maintain that once laws are passed they tend to be enforced by the justice system in unfair ways, again more likely to single out the less powerful for the same behavior.

At the extreme, some theorists claimed that everyone commits crimes, but only a select few – including minorities, the poor, and the powerless – are arrested and incarcerated. Finally, an offshoot of labeling theory, termed the medicalization of deviance perspective, showed how the powerful medical profession increasingly succeeds in defining deviance as a medical problem or illness requiring treatment by licensed medical professionals. Once the deviant act is medicalized, other approaches to explaining, treating, and policymaking are ignored.

POSITIVE FUNCTIONS OF DEVIANCE

Building on the works of Durkheim and Mead, Erikson (1962, 1966) examined the positive functions of labeling for society. Durkheim (1964) argued that punishment of criminals served two functions. First, by punishing criminals with outrage and passion, society reaffirms the moral order – including the values, beliefs, and morals that bind society together – threatened by criminals' transgressions. Second, by punishing criminals, society draws a line between moral and immoral conduct, which is necessary because what constitutes crime and deviance is relative to a given society. Durkheim argued that in a "society of saints," trivial deviations – which we would consider merely "bad taste" – would be punished to reaffirm the moral order. Mead (1918) maintained that punishment allows members of society to express impulses of hostility and outrage, which creates a strong emotional identification with conventional society and feelings of anger at the criminal.

Erikson notes that labeling, such as imprisonment or hospitalization, does not reform or cure the deviant (the manifest function), but instead stigmatizes and segregates the deviant, resulting in a self-fulfilling prophecy in which deviants return to their deviant ways. Erikson concludes that labeling serves the latent function of maintaining a pool of deviants for defining moral boundaries and reaffirming social solidarity. He studied the Salem witch trials and showed how Puritans expressed their emotional hysteria by condemning witches and labeling them sinners and agents of the devil,

which reduced tensions and factions among Puritans, Quakers, and other sects.

CRITICISMS AND PROMISING NEW DIRECTIONS

In the 1970s labeling theory achieved prominence as a major theory of deviance; through the 1980s it was subjected to several major critiques; by the 1990s, new theoretical developments emerged. Critiques came from disparate sources. Conflict and Marxist criminologists argued that labeling theory's analysis of rule creation and enforcement was rudimentary and ignored the contradictions of capitalism, which are revealed by a Marxist critique of capitalist social relations. Positivist criminologists, who advocate using scientific principles to study crime, argued that actual deviance did exist, the concept of secondary deviance was bankrupt, and labels were not disproportionately applied in society, when controlling for actual behavior.

Three recent developments in labeling theory have addressed the positivist critique by responding to Becker's (1973) call for an interactionist theory of all aspects of deviance, including primary deviance, labeling, and secondary deviance. Link and his colleagues (1989) have developed a modified labeling theory of mental illness in which a community's tolerance of mental illness colors how mental patients cope with the stigma of official labeling by treatment agencies. Depending on whether the community discriminates and devalues mental patients, the patient either minimizes the stigma by enlightening others, hides the treatment history, or withdraws from prejudicial groups.

Braithwaite (1989) developed a theory of shame and reintegration, in which he argues that labeling can have both positive and negative effects on future behavior. When offenders are severely punished, they are stigmatized as an outcast, cut off from conventional groups, and are likely to turn to subcultures, which ensnarls them in a web of criminality. In contrast, when offenders are publicly shamed by the community expressing disapproval, but then reintegrated into society, the stigmatizing effects of labeling will not lead to secondary deviance. Reintegrative shaming is most effective in communitarian societies like Japan, in which members are

intertwined in each other's lives, making shaming and reintegration likely and successful.

Matsueda (1992) and his colleagues (Heimer & Matsueda 1994) used Mead's theory of role taking and social cognition to develop a theory of both primary and secondary deviance, termed differential social control. In problematic situations in which habitual behavior is blocked, individuals take the role of others, form a self as an object from the standpoint of others, and consider alternate solutions to problems from the standpoint of others. This cognitive process links the self and social groups to behavioral decisions: the self is a reflection of appraisals made by significant others, including reference groups. They find support for a causal chain, in which labeling by others influences future delinquency by altering reflected appraisals.

In sum, labeling theory has shaped how we view deviance and crime in society by underscoring the importance of society's reactions to deviance, analyzing political power and deviant labels, and showing how labeling can amplify deviance. Left for dead in the 1980s by some researchers, labeling theory is enjoying a revival by researchers responding to Becker's (1973) call for an interactionist theory of all aspects of deviance, including primary deviance, labeling, and secondary deviance.

labor/labor power

Rob Beamish

While establishing their materialist position, Marx and Engels argued that one may distinguish humankind from other biological entities by consciousness, religion, or whatever else one chose, but humankind fundamentally distinguished itself from animals and other living organisms when it began to produce its means of life. Labor, they argued, is an eternal, naturally imposed condition of human life, common to all forms of society. Finally, Marx and Engels noted, while producing its means of life, humankind indirectly produces the material conditions for its ongoing existence.

Two decades later, Marx again stressed labor's ontological nature and importance. In *Capital*, Marx distinguished labor "in general" from labor involved in "the valorization process." The latter is a particular sociohistorical form of labor that produces commodities that are sold in the market and functions as the source of surplus value. Labor in general is the general form of labor through which materials from the natural world are appropriated and converted to products that directly or indirectly meet human needs and wants. Labor in general actualizes the fundamental interchange between humankind and nature through which humankind engages with nature, changes

its understanding of nature, and influences its own character. More than 130 years of scholarship in the physical, biological, and social sciences have refined, but not fundamentally altered, Marx's position on labor's ontological character.

Humankind is directly part of the material order of nature and inescapably bound to its laws (e.g., gravity, mitosis and meiosis, aging). As living creatures, there are specific material needs which we must meet (e.g., we must metabolize oxygen, water, protein, and caloric energy to live), but they are not all met immediately and directly. Through time and the evolutionary processes of the material order, the human order became dirempted or alienated from the material order. Whereas the material order of nature is direct, concrete, and thingly, the human order is concurrently immediate and mediate, concrete and abstract, and objective and subjective. Labor in general is the activity through which humankind indirectly or mediately engages with the material order and draws upon the concrete and abstract aspects of its being to create and recreate its existence.

It was Marx's 1844 critique of Hegel's *Phenomenology* that led to his deepest and most perceptive analyses of labor as the material, ontological basis to human life. Read through Marx's emerging materialist position, Hegel's conception correctly emphasized the creative aspects of labor, but limited it to the self-conscious mind. For Marx, human self-development stemmed from labor that was simultaneously concrete and abstract. Through labor, a material object is created which is separate from the producer as he or she externalizes an idea in a material form. This object stands "opposite" and outside the producer, but it simultaneously remains a part of him or her insofar as it represents the culmination of his or her creative activity. Subject to the laws of the material order – including humankind's material being – labor is an activity that is simultaneously objective and subjective because in producing an object – in the creation and externalization of an idea – the producer also gains subjective knowledge that did not exist before production began. Ontologically, labor is a concrete process that is inescapably creative. The mediate relation of humankind to the material order interposes,

through the labor process, a grid of culture between humankind and the natural order.

If labor is the eternal, naturally imposed condition of human life, labor power is the eternal, active, mediating capacity and force between humankind and the material order. Living labor, Marx argued in *Capital*, is the fire that infuses energy into raw materials, tools, and machinery, and turns them from moribund objects into newly formed products that can meet human needs and wants through consumption.

The notion of labor power originates in Adam Smith's *Wealth of Nations*, where he attributed the "productive powers" of labor to the division of labor. Noting the conception of "productive faculties" in one of his 1844 study notebooks, Marx refocused the term when wrestling with the question of what a worker actually brings to the production process. Marx argued that labor was brought to the marketplace as a potential. The living worker represented and carried an ability (or abilities) and the capacity to engage in labor – the product that was of ultimate interest to the capitalist purchaser. While Marx used several terms in his early work, he tended to use labor power in his later works to describe the capacity or commodity that the worker brought to the valorization process, but labor power always represented a complex conception of potential, ability, power, and force which brought life to the material order in the concurrently concrete and abstract, objective and subjective, immediate and mediate process of labor.

In class societies, labor power is the sole source of value creation. Because labor power is a capacity, the purchaser pays only as much as is required for the worker – the bearer of this potential – to meet his or her socially determined needs to reproduce him or herself and return to work day after day. The expenditure of labor power produces more value than the replacement value of labor power, giving rise to surplus value. As a result, labor power is the unique source of surplus value. The identification of labor power as the source of surplus in societies of social labor, in general and capitalist society in particular, was among Marx's most significant discoveries.

labor–management relations

Casten von Otter

The study of labor–management relations (LMR) refers to the rules and policies which govern and organize employment, how these are established and implemented, and how they affect the needs and interests of employees and employers. LMR has implications for the organization of work as well as economic policy. Focus gradually has broadened from the formation and operation of national and local institutions and collective bargaining to strategic human resource policies. Most recently a multi level agenda has formed, following new needs for regulation in world trade, in the extended European Union, and in former communist and newly industrialized countries.

The freedom of collective bargaining is an important instrument of citizenship in a democracy, as expressed by the UN Declaration of Human Rights and the International Labor Organization's statement of core labor standards. Based on a norm of accommodation of interests, LMR eases the burden placed on parliamentary institutions. Respect for the freedom of association for all workers is generally seen as a prerequisite for a sustainable system of free trade.

To sociology, LMR is a momentous arena in which a political order intersects with the market system, which affects social differentiation, the distribution of social and economic welfare, and numerous other social dimensions in which sociologists take great interest. The field is important, as well, to many other disciplines – economics (labor economics), management science, political science, labor law, and social history. Industrial (or labor) relations was established as an academic discipline in the US in the early twentieth century. LMR is unusually rich in interdisciplinary theories, as well as international comparative studies. Its academic history is marked by strong ideological and normative commitments and the evident inputs to theorizing from political ideologies as well as the social sciences.

Two analytical paradigms have dominated the field. The traditional industrial relations systems perspective as laid out by John Dunlop is focused on the governance of work. Conflicts of interest between employees and management are seen as legitimate and often structural in origin. The favored vehicle for conflict resolution is collective bargaining (ultimately backed by the right to strike and lock out) and regulated procedures for arbitration. Legislation is a useful instrument to be applied, however, mostly when self determination by the parties has failed. While this theoretical perspective does not preclude accommodation of interests at the individual level, it maintains the importance of a collective regulatory framework that establishes a countervailing force against unfettered market forces and unilateral decisions of the employer. The industrial relations perspective has been criticized for being too top down, for disregarding workplace practices, and (initially) lacking in agency theory.

The other perspective is personnel or human resource management (HRM) and is underpinned by application of behavioral science (human relations theory) to organizational design. Corporate culture is important in integrating the employees with the aims and long term objectives of the firm. Thus, wage systems and benefit schemes should be molded, not only to fulfill a contractual obligation, but also as proactive instruments to promote skills and beneficial attitudes and actions. New human resource policies are related to the increased

pressure to compete in terms of speed, innovation, customization, etc. Conflicts and power relations are played down, as both parties supposedly have a strong interest in maintaining a consensual culture. HRM schemes have been controversial for their alleged use to foster complacent attitudes and to shift focus from trade union relations to personnel policy. More recently, the two fields are becoming integrated, as policies associated with HRM are introduced into collective agreements in Europe and the US.

HISTORY

Labor relations as a theme evolved out of the social problems that became evident during the industrial revolution. In all countries a period of social struggle preceded the resolution of labor conflict in institutional forms, bearing witness to the strong adversarial potential of unregulated LMR. In the words of Marx, workers were treated like commodities and should organize to overthrow the capitalist system. Sidney and Beatrice Webb inspired the reformist labor movement, favoring the improvement of LMR through legislated labor standards and collective bargaining, which ultimately could lead to industrial democracy. The basic idea – then and to this day – is to take wages, benefits, safety, and security standards out of economic competition. Germany under Bismarck pioneered legislation in health and safety, unemployment and workers' compensation insurance, retirement benefits, etc. Social model institutions for LMR or utopian communities such as those established by Robert Owen or Henry Ford served to demonstrate the viability of more human policies, but failed for different reasons in the long run.

J. R. Commons laid the foundation of the academic theory of industrial relations and the vocational practice in the US. The New Deal took his ideas further and established a national industrial relations framework with the National Labor Relations Act and the Fair Labor Standards Act, etc., which set an example to many countries. Since then the formal structure has expanded in scope, detail, and complexity.

During the politically radical 1970s attention was drawn to industrial democracy and new

less alienating models of work. The thinking owed inspiration both to the Webbs and to Japanese management, and to experiments with work organization by the Tavistock Institute (sociotechnical theory), especially in Norway and Sweden, which tackled issues such as employee participation in cross functional learning, innovation, and quality. After a century of progressive evolution of workers' rights through collective bargaining and legislation, the trajectory for these approaches to LMR seemed to decline in the 1980s.

INSTITUTIONS OF LMR

There are three main processes of employment regulation: legal enactment, collective bargaining, and unilateral regulation confirmed by the individual when accepting his or her employment contract. LMR regimes involve a mix of substantive and procedural matters, but beneath them all are two parties in asymmetric positions, trying to make the most of their relative positions. Notions of interests, fairness, and effectiveness are profoundly important, within the action frame of reference. There is across nations a wide variety of arrangements, a mix of public and private, firm specific, state and tripartite forms, reflecting particular national experiences, attitudes, and key political relationships, etc.

National clusters of LMR regimes have been identified as the European model, which is the more encompassing, and the Anglo American, which is more minimalist. Some argue that there is more than one path to competitive advantage, and speak of the former as "coordinated" and the latter as "liberal market economies." Defining characteristics of the coordinated model are a combination of multi employer bargaining, legal enforceability, and the practice of extension (of collective agreements), as well as provisions for information and consultation.

Few dispute the need for some government legislation in defining rules for collective bargaining and labor conflicts and establishing core standards (e.g., prohibiting forced and child labor, and more recently discrimination, sexual harassment, etc.). Issues regulated variably by law or contract or in combination include minimum wages, working hours, holidays, sick

leave, dismissals, and redundancy and supplementary benefit schemes. Health plans, severance pay, unemployment insurance, pension plans, etc. are in some countries general entitlements, in others mediated through collective agreements or not at all. Issues of worker participation can similarly be regulated to give the workers – either as employees or through a trade union – representation on corporate boards, in work councils, or similar entities. An active labor market policy, assisting in the relocation and training of workers, is in most countries an integral part of the industrial relations system, seen as instrumental in obtaining compliance with structural economic change from the unions.

Over the years the general tendency has been for bargaining to become less differentiated between the private and public sectors, salaried and waged workers, etc. A prominent feature when comparing Europe, the US, and the leading Asian economies is the persistent high degree of interest in organization among workers and employers in Western Europe. In the US union membership is considerably lower than in most of Europe, and the peak level organizations command little authority. Employers' organizations are strong in Europe, barely feature in the US, and are weak in Japan.

The effectiveness of a union as negotiator and political lobbyist depends on its ability to command the loyalty of its members in mobilizing for action and respect for collective agreements. This makes internal governance and strategic leadership of unions of basic interest. Unions hold different views on how far they should allow themselves to be involved with government and management. Positions taken vis à vis employee stock ownership plans, quality circles, and productivity programs reflect varying deliberations and political inclinations (e.g., communist, social democratic, or catholic).

Union membership as percent of the active labor force was at its peak in most western countries in the 1970s. Only in a few mainly Northern European countries is a majority of the workforce engaged in trade unions. In countries such as the US, the UK, Australia, France, and Italy membership has declined by two thirds or more. Countries with stable density have legislation that favors membership.

In the last few decades US managers have been actively anti union, while in Europe the focus has been on new arrangements rather than derecognition of unions. Non union representation does not exclude workers' consultation. Many multinational corporations which are non union have developed systems for employee regulation and representation as part of their personnel policy. The rules are then determined unilaterally and can be altered at management's discretion.

ENCOMPASSING REGIMES

Fundamental to the role of collective bargaining as theorized by the economist Mancur Olson is the degree of coordination in encompassing units. Where there is peak level bargaining and trade unions have a near total coverage of the community, they need to take into account wage, price, and employment effects, which induce restraint and concern for inflation. While under disintegrated bargaining, where the beneficial results are concentrated in the members and the negative impact is dispersed, the union will disregard inflationary and other external effects.

This line of reasoning is the rationale for neo corporatist arrangements, such as a government led incomes policy. Most such schemes were eliminated in the neoliberal ascendancy of the 1980s. However, there has been an unexpected revival of "social pacts" as instruments for preparing for global competitiveness and the EMU (the European currency). In these, reform of LMR and wage moderation, labor market flexibility, and revised welfare provisions hold a key role.

European integration has prompted a multi level system of governance, introducing a supranational level and encouraging resort to decentralization within national systems. The effects of harmonizing social standards in the Euro zone need to take into account the vast regional economic differences in the expanded community. Compared to the US, labor market mobility remains much lower in Europe, for obvious cultural and traditional reasons.

All of the Western European countries, except the UK, are characterized by an inclusive structure of multi employer bargaining.

The impact of collective bargaining only vaguely reflects the density of union membership. Most countries hold statutory extension provisions by which the terms of the collective agreement are extended throughout a sector or country. A consequence is that there is little correlation in Europe between trade union membership (on average below 50 percent) and coverage by collective agreement (around 80 percent). In the UK and Ireland by contrast, collective agreements are voluntary and enforceable by law only if the parties are agreed. Collective bargaining in the US never covered more than about a third of the labor market, but collective agreements are intensively developed to cover a wide range of issues. Some agreements have ramifications outside their constituency as a benchmark for non union firms. This might explain why many Americans (between 40–50 percent) think favorably of unions, although fewer than 10 percent are members.

A NEW PARADIGM?

Over the last few decades momentous events have transformed the field of LMR practice and research. Inflexible markets were blamed for the stalled growth of the old industrialized countries in the 1970s, in comparison to rapidly developing economies in Asia. New global product markets created strong competitive pressures. In response, employers and a new range of neoclassical economists called for the deconstruction of LMR to reassert management authority and enhance flexibility.

Deregulation of the economy has left both parties with less room for contingent accommodation. Workers' bargaining power has suffered threefold because of the new international mobility of capital, technology driven vertical disintegration into global production networks, and monetary policy upholding an equilibrium level of unemployment (two or three times the previous full employment level). International dispersion of work enables employers to evade existing labor regulation and makes a unified workers' front more difficult.

With the macroeconomic policy shift in the 1980s from demand to supply side economics, industrial relations' effects took center stage in the economic policy discourse. The neoliberal

transformation process began in the US and the UK, and was followed by many other countries, including New Zealand, Australia, and many of the East European countries. Most of the emerging market economies in Asia and Latin America have a liberal market model, when LMR is not coercively regulated by the state.

The Reagan and Thatcher governments set out fundamentally to reform the industrial relations system and curb militant unionism and a mounting number of strikes, irregularities inside unions, and fierce labor-management disputes, plus inflationary pressure from wages. The Anglo American axis was formed around a shift in policy towards more pro individualism, private ordering, and free markets, and against collectivism and regulation of markets. Union immunities were reduced, strikes restricted, etc. The protection of workers in the UK was replaced by a legislative approach (traditionally condemned by the unions) to discrimination, unfair dismissal, and the like. The procedure continued under the subsequent Labour government, which introduced the first ever minimum wage law.

The blow to the unions also affected industrial relations research to the degree that it was symbiotic with the bipartisan structure. The situation eventually led to invigorated interest in workplace practices and HRM. Several facets of the scheme, such as flattened organizational hierarchy, gain sharing, and extensive communication, could be incorporated into and controlled under the participative management doctrine. In Scandinavia, where new laws on codetermination had been enacted in the mid 1970s, the basic principles had entered collective agreements, with clauses that gave the local union a say in their implementation.

MANAGEMENT PRACTICES

Alternative ways of thinking about LMR have long existed along lines parallel to the collective bargaining framework. Japanese (and to a degree Northern European) unions have for more than a generation acted on the presumption that there is a close link between high productivity, employment, and wages. The human relations theory associated with Elton Mayo is part of the legacy in these countries, as well as in American

business schools. The focus in the 1990s on competitive advantage and industrial reengineering was evoked by globalization and deregulation, and brought emphasis to a strategic approach to employment management. The classic works of sociologists and psychologists like Argyris, Herzberg, McGregor, and Whyte guided the link to integration of LMR with business strategy.

In the deregulated market firms typically pay lower or more differentiated wages and they utilize work systems and employment contracts that are more flexible. Some exploit nonstandard employment arrangements that shift economic risks onto the workforce. However, work and employment are not changing as fast as may have been expected, and are unlikely to do so. Work is not disappearing. Surveys indicate that labor force participation and hours of work have remained stable in the OECD area. People are highly committed to work. The evidence on workforce changes (e.g., with regard to tenure, training, and wage inequality) is mainly with in occupations, indicating that there is an increasing diversity in workforce and individualized remuneration. Organizations are using a variety of skills in cross functional teams, and there has been a drastic reduction in management and supervisory jobs. Managers become coaches and workers are expected to act more on their own commitment. Voluntary quits have declined, so have perceptions of job security. Dual career patterns make work and family decisions highly interdependent. Union membership continues its long term decline, even though significant innovations are made in union-management relations. Taken together, the changes have exerted a profound effect on explicit and implicit employment contracts and conditions of employment.

The bulk of surveys indicate strong pressure in all countries for numerical and functional flexibility, but also that environmental factors impinge in systematic ways on how work structures evolve – though they are not deterministic. A study by the ILO (Auer & Cazes 2003) suggests that stable employment relationships are in fact quite resilient. Arguments in favor of unconditional flexibility miss the fact that with high turnover human and organizational capital may be eroded. In Japan, policies are still geared towards employment maintenance and

thus social protection is low, while in Denmark the opposite is the case. When social protection outside the firm is kept at a high standard even though job security is low, workers perceive a lower degree of insecurity compared to the opposite situation.

FUTURE DIRECTIONS

The study of LMR, although relevant to innumerable disciplines, is held together by the existence of a politically urgent real life problem. Where the field has lost its central policy relevance, so has the demand for a multidisciplinary research community, as analyzed by Kaufman (2004). The need for systematic theories of LMR, however, has not disappeared, resulting in claims to new interesting research combinations.

Labor-management relations are deeply embedded in sociopolitical traditions and narratives, pointing to their relevance for the discourses of cross national institution building and “varieties of capitalism.” Human resource management has emerged intellectually stronger by infusing some industrial relations thinking. Monitoring of welfare effects under deregulation has become increasingly rewarding for sociological analysis. Finally, globalizing trade and production defines a distinctly international and challenging research agenda, where the basic assumption upon which organized labor has acted for well over 150 years – “to take wages out competition” – has met with some challenging complications. The western bias, which has prevailed throughout history in this field, might be approaching the end.

labor markets

Anne Fearfull

In principle a labor market is the primary method of allocating people to paid work, of whatever nature, within capitalist economies/societies. Within capitalism, the separation of the producer of a good or service from the means of its production has rendered a situation where labor power (that is, the capacity of a person to work) has become a commodity to be bought and sold. In theory both buyers and sellers of labor power are free to choose from or to whom they would like to buy or sell. Thus, the “market” can be represented as an efficient, voluntary mechanism of exchange wherein the economic rules of efficiency, perfect competition, and supply and demand apply, and equilibrium will be achieved. From such a perspective market imperfections (or disequilibria) when they occur do so because interest groups within a market are, for example, able to strengthen their position, restrict entry to their group, or force pay changes. Actions or events such as these are regarded essentially as “glitches” and, over time, theory suggests, equilibrium will be reached.

From a general picture of labor markets within the context provided, we can hone our examination by considering the notion of both external and internal labor markets. The model of the dual labor market developed by Doeringer and Piore (1971) introduced the idea of the primary and secondary sectors. The primary sector represents core skill areas for which employers were prepared to pay higher levels of wages and provide better employment terms and conditions as a means of ensuring as far as possible a secure, committed, and competitive labor force. By contrast, workers in the secondary sector would not expect to have so secure a position. Indeed, it is this sector which facilitates flexibility for employers, as workers within this context would tend to have contracts based on, for example, seasonal requirements or part time availability of or for work. Within this sector would be subcontracted workers or even businesses, and significant levels of labor turnover would be both expected and tolerated. This pattern of duality has been further popularized through the model of the flexible firm proposed by Atkinson (1984). This model proposed a range of flexibilities for operationalization by employers, including numerical, functional, and financial. The basis of this proposal was the employment of distinct core and secondary workforces, the latter, in extreme cases, attracting so called “zero hour” contracts. The agreement for people working under such a contractual term would be that they had no fixed hours or times of work, but would be called upon as and when the employer required their services.

From a sociological perspective, focus is placed upon the relationship between those groups within the labor market and within individual workplaces and occupations. Broadly speaking there is a rejection of the economists’ notion of market efficiency. The basis of this alternative position is the inequitable nature of the employment relationship. The root of such inequity is firmly planted in the nature of capitalism and the dispossession of workers from the means of production, of either goods or services, including their lack of ownership of raw materials, tools, and places of production.

Attempts have been made by labor to manage the ensuing competition within labor markets. Some of these attempts have driven

wedges between the different sectors within the labor force. Trades unions and other employee associations engage in collective bargaining to influence pay and conditions for their constituencies. Social closure has been one method used by trades unions to limit competition by restricting access to particular jobs to their members alone. While this is no longer an option for trades unions following the outlawing of closed shops, it remains a means by which professional bodies establish and maintain their power within their sectors. This is achieved by their ability to devise and establish systems of practice and codes of ethics within their fields of work and to have these formally recognized through the gaining of chartered status. Similarly, buyers of labor power (i.e., employers) have effected their own methods of managing labor markets and some of these have been addressed above in the outline of the dual market and its associated models.

The points suggested so far suggest that, while we might be able to form a neat definition of the term labor markets, and indeed we frequently see variations on such definitions in dictionaries and textbooks, the practice of and experience within them are far from neat. There are a number of reasons for this, some of which have already been outlined. By expanding upon those outlines we can appreciate the complexity of labor markets and the extent to which competition within them is anything but "perfect." If we take Littler's (1985: 3) position that "differences in labor market status help to create (or reinforce) different orientations to work," then we begin to gain greater insight into the nature of variations and experiences of labor within the labor market in general, and within specific labor markets in particular. Although not an exhaustive list, status markers include, being:

- Professionally qualified
- Trade qualified
- Skilled
- Unskilled
- Male
- Female
- A full time employee
- A part time employee
- Experienced
- Relatively inexperienced
- A school leaver

- From an ethnic minority group
- Already employed
- Unemployed

To explore the sociology of labor markets further we can use examples from the above. Beginning with young people entering the labor market we can consider the notions of structure and agency and the important interplay between these factors in that context. The socialization of individuals plays an enormous role in mediating our perception of agency since it heightens our awareness of the choices which can or cannot be made, as the case might be or might be perceived. It is clear that agency is affected by structures in place which might limit choice, and also by the extent to which individuals (in this case young people) are aware of the opportunities available to them and the contexts in which they might exercise their agency. Giddens's (1984) theory of structuration recognizes the inextricable link between structure and agency. However, while critically we can appreciate the boundaries placed upon people and their choices as a result of structures at the levels of both society and organization, we might also appreciate how structures enable opportunities to be formed and a context in which choices can be made.

The issue of class and class consciousness is particularly relevant when considering structuration and labor markets. This is especially so within the context of young people newly entering the labor market. The extent to which they are conscious of their "place" or "level" within the structure of society, and the degree to which they see this as determining the occupational choices they are able to make, may lead to lack of development and/or realization of their aspirations. Family support is also central to the developing aspirations of young people entering or preparing to enter the labor market.

If we consider the unemployed and their relation to labor markets we can see other levels of complexity. Attempting to re enter a labor market from a position of unemployment, the unemployed are often met with difficult and sometimes insurmountable barriers. To some extent this is due to our often implicit understanding of the latent functions of work (Jahoda 1982). These functions are the socio psychological factors rendered as a result of

being employed; for example, having an imposed time structure to one's day; having social relationships beyond those formed within the family unit; having a sense of purpose; and the development of identity. For those people becoming unemployed, these positive, essentially unintended consequences of work can fade quickly as one begins to doubt oneself and one's contribution to both society and family. Long term unemployment, or a situation where one has never been employed, can have more extensive and significant implications, as such a situation can be regarded as rendering a person work incapacitated. Such incapacitation is with regard to skill levels and changes in skill requirements due to technological advancements, but just as importantly, with regard to the sociopsychological implications of unemployment.

Gershuny (1994) demonstrated the severity of the sociological and psychological implications of unemployment. So severe are they, in fact, that they might render people's potential participation in any labor market extremely difficult; due to the traditionally tighter tie between men and work, this can be particularly debilitating for men, as their sense of identity diminishes. Thus, the notion of a reserve army of unemployed people ready, willing, and able to be called back into the labor market when required might be regarded as nonsensical. Amid severely high levels of unemployment in the UK in the 1980s, an alternative perspective emerged whereby the notion of the Protestant work ethic, central to the functioning of western labor markets, was questioned as appropriate and proposals made to replace or amend it with the "usefulness ethic." This view is typified by Robertson (1985), who proposed an "ownwork agenda," the basis of which would move us away from employment where our working time is controlled through labor markets, to a system in which people would take control of the use of their own time. As we know, this proposal did not come into being. And yet we have seen an increasing interest in alternative lifestyles as people seek to effect improved work-life balance.

Using another example from our labor market groups above, we can examine the dynamic between women and labor markets. The dual role of women within society as both

economically active and having primary responsibility for social reproduction renders their role or potential role within labor markets as problematic, both for themselves and for potential employers. The ensuing gender stereotyping and female subordination in the sexual division of labor prevails even today and in spite of legislation designed and introduced to outlaw inequities in access, opportunity, and pay. Women's particular place within, or displacement from, labor markets was discussed by Lewis (1988) when outlining past law which "denied women access to property and political rights." From a radical feminist perspective, the dominance of men in both legal and political environments and the fact that education was withheld from women until the late nineteenth century provides insight into the roles taken up by women, or aspired to by them, within the labor market in general. In this regard, we can reiterate Littler's suggestion, cited above, about the creation or reinforcement of orientations to work in the light of the nature of the gender relationship within both labor markets and society in general.

Over the past two decades feminist writers have extended the debate about the opportunities available to women and the degree to which they have been seriously curtailed by the patriarchal nature of western society. Cockburn (1987), for example, considered the level of discrimination apparent in training opportunities. The gendered nature of both occupational and job segregation has been considered by a range of authors (Crompton & Sanderson 1990; Reskin & Roos 1990; Cockburn 1991; Boterro 1992). These writers argue that such segregation is a result of practices within both employing organizations and the nature of societal organization, each of which is considered as being patriarchal. Extending this type of argument, Reskin and Roos (1990) illustrated the advantaged position with regard to job and occupational opportunities, as well as pay, enjoyed by white men, in general, over men of color and all women. Using an American focus, they provided a historical context for the inequitable distribution of workplace participation for men and women on the basis of gendering, race, and ethnicity. Again, the importance of the domestic sphere is emphasized as a means of shaping job and pay equity through raising the

issues of aspirations and orientations of people entering the labor market and even targeting particular labor markets.

Extending the notion of inequalities for people within labor markets, we can draw further on the questions of race and ethnicity. The issues faced by ethnic minority people in the labor market are more complex than for indigenous populations. As Jenkins (1986) has shown, ethnic minority people in general face discriminatory processes due to potential employers' sensitivity around the extent to which people from such groups would "fit in" within an existing workforce. This notion of "acceptability" therefore extends requirements beyond those of a person's technical "suitability" for a post, which is a determinant for most people's employment. Thus, in spite of legislation introduced both nationally and internationally over the past three decades or so, we can consider notions of institutional racism (Macpherson 1999) as being a considerable threat to multi ethnic workforces within organizations and the equitable treatment of ethnic minority groups within more widely defined labor markets. For ethnic minority women, any such circumstances are exacerbated further. Facing multiple roles in excess of those faced by many women in general in both internal and external labor and primary and secondary markets, ethnic minority women find their career aspirations challenged by stereotyping in relation to their sociocultural and religious affiliations, as well as those in relation to perceptions of their roles within family and community life (Kamenou 2002).

Although we have not considered each one of the labor market status markers listed above, we have developed an ongoing theme which challenges the dominant economic perspective on labor markets, including the notion that buyers and sellers of labor power are free to choose to whom they would like to buy from or sell to. From the perspective taken here, we can see that the concept of the efficient market, perfect competition, and the achievement of equilibrium is highly questionable. A more realistic position recognizes market imperfections, or disequilibrium, and that they emerge because of the varying strengths of the numerous interest groups.

labor movement

Rick Fantasia and Kim Voss

The labor movement is a broad, multidimensional social formation that is generated from the social structures of work and industry in a society. It may comprise both legally recognized and formally sanctioned institutions (like trade unions, political parties, and works councils) as well as less formal groupings of workers and their allies (industrial actions, organizations of strike supporters, dissident movements within unions, cultural forms, etc.). Labor movements operate at the intersection of economic practice, civil society, and the state. They are more or less firmly institutionalized in any given society in any given historical period, and can be partly characterized by the extent to which extra institutional practices are permitted and have been incorporated into the routine operations of industrial and labor relations. The social and organizational composition of a labor movement as well as the degree to which its practices have been institutionalized are thus two important analytical axes through which the social logic of a labor movement can be discerned.

Having been born in and by the industrial order, the labor movements of the most developed capitalist societies generally took on their characteristic appearance over the course of the nineteenth century, with political parties and trade unions being the most prevalent organizational forms. Contrary to conventional wisdom, in its formative decades the US labor movement was not a particularly exceptional case relative to other industrial societies, although the arc of its trajectory would become increasingly distinctive later on. Thus, just as in England and France, two countries whose socioeconomic development was roughly comparable to the

United States, for much of the nineteenth century the American labor movement was composed of skilled craft workers whose cultures and practices had been constructed to protect traditional skills and craft prerogatives in the face of machine technologies and standardized work practices that employers had specifically designed and implemented to erode. By the last quarter of the nineteenth century, however, the character of the American labor movement began to take an "exceptional" form, although not at all in the manner in which conventional wisdom has often held. The labor movement in the US was becoming militant and class conscious in ways similar to those Karl Marx had envisaged in his analyses of the development of capitalist society, most notably expressed in the explosive growth of the Knights of Labor. The Knights was a remarkably egalitarian organization of workers and artisans that, by its height in 1886, had mobilized almost 10 percent of the US working class across skill level, nationality, race, and gender into militant local assemblies spread out across the entire country.

In contrast to perspectives in sociology and historical studies that have viewed the US labor movement as intrinsically and exceptionally weak, or conservative, or lacking in collective solidarity (variously attributed to affluence, or the possibilities for upward social mobility, or the spatial expansiveness of the American frontier, or early universal male suffrage, among other factors), the existence of the Knights of Labor in the late nineteenth century suggests the need for an alternative interpretation. A consideration of the dynamics of both their rise and their fall provide us with the lessons for such a reinterpretation. Ironically, it was the rapid and widespread mobilization of workers into the Knights that provoked a powerful mobilization of employers to counter them, with the ferocity of the reaction leading to their equally rapid downfall, as well as to a general weakening of the US labor movement for at least another generation. Unlike in England and France where the state often intervened to encourage or demand employer concessions in labor disputes, the US government at the time did little to constrain the actions of employers, allowing them free reign to destroy the Knights of Labor. Considered altogether, this suggests that (1) the

US labor movement was not intrinsically weak and, if anything, at one time was perhaps *more* militant and class conscious than its counterparts; and (2) the reaction by employers to the militancy of the Knights reshaped the legal, political, and social terrain in ways that made militant worker organizations much more difficult to mobilize and sustain, thus demonstrating the “exceptional” power enjoyed by *employers* in the US context. One outgrowth of the defeat of the militant Knights was the ascendancy of a more pragmatic, conservative, craft based unionism embodied by the American Federation of Labor (AFL), which became the overwhelmingly dominant institutional force within the US labor movement well into the twentieth century.

What this brief example illustrates is that labor movements can never be properly understood without considering them in their mutually constituting relationship to the corporate employers of labor (capital). Moreover, the nature of this relationship will strongly affect the role of the state in the society. In the case of the US, the state has not been as strong a force for regulation as it has been in other societies and this has meant that large corporations have been relatively free to operate. With such freedom, large corporations have become firmly ensconced as the dominant institutional player in US society, thus ensuring a relatively weak labor movement. In most other capitalist societies the state has tended to foster more balance in this relationship, by limiting (or regulating) the power of large corporations. It is important to recognize at the same time, however, that because the society is not a static one, the power and position of the labor movement in US society have not always been as weak as they have at other times.

Moreover, the labor movement has never been monolithic and has always combined various competing tendencies. For example, by the turn of the twentieth century, a massive increase in European immigration was under way, with millions of relatively unskilled workers pouring into the United States, attracted to the huge factory complexes where assembly lines and other mass production techniques were fast becoming the bases for most forms of manufacture. A craft based capitalism was giving way to highly industrialized forms, thereby paving the way for a new form of unionism.

The AFL, which had openly rejected the militant social unionism of the Knights of Labor, was made up of organizations largely shaped by the prerogatives of their own members, native born skilled craftsmen concerned with protecting their own relatively privileged status within the working class more than with opening their ranks to the unskilled immigrants whom they often looked upon with contempt.

Not until the 1930s was a widespread effort undertaken to organize the unskilled workers from the mass production industries into industry wide unions. It meant bringing into the same organizations men and women of all races and ethnic backgrounds, regardless of skill level, and these industrial unions formed together under the overall banner of the Congress of Industrial Organizations (CIO). The attempts to form the CIO unions were met by ferocious resistance by the large corporations, often including organized violence and thereby necessitating a more militant stance and a more combative political framework on the part of the new unions. Openly encouraged in the early stages of the New Deal by laws such as the Wagner Act of 1935 and by the administration of President Franklin Delano Roosevelt, who saw unionism as a strategy for overcoming the effects of the Great Depression, the CIO unions were often organized by socialists, communists, and other left wing radicals who set the terms for a more broadly based social vision than had been held by the AFL unions. It was an outlook that both reflected and corresponded to ideologies that were familiar to and respected in the European immigrant communities that tended to make up the membership of the new unions.

Through the first half of the twentieth century, the US labor movement showed two faces, partly reflected in the divisions between the AFL unions and their craft base, and the CIO unions with their industrial base. While the former was more pragmatic and politically moderate, the latter tended toward militancy and political radicalism, and was much closer in tone to the version of unionism represented in most other capitalist societies. By the close of World War II, however, after more than a decade of CIO mobilization, the large corporations quickly moved to reassert and consolidate their power within US society by seeking to curtail the militancy and radicalism of the CIO.

This was accomplished by the powerful pressures they brought to bear on Congress to pass the Taft Hartley Act, a broad set of statutes drafted by corporate lawyers to essentially repeal the Wagner Act that had earlier encouraged industrial unionism. The Taft Hartley Act achieved a number of longstanding goals of American corporate employers, including weakening union security in a variety of ways; for bidding the most effective forms of industrial action; imposing a stifling regime of bureaucratic governance over labor relations practice, as well as on the practices of union leaders; and purging communists and radicals from the ranks of the union leadership, thereby removing the clearest and strongest voices for social change from positions of authority in the unions.

Whereas the labor movement in the United States had once shown two distinctive faces, by the mid 1950s the AFL and the CIO had merged together, while largely adopting the political visage of the AFL. It was a period characterized by rapid post war economic growth, rising American military intervention throughout the less developed world, and a profound ideological conformity imposed under the name of McCarthyism. The corporate imposed domestication of the US labor movement that was noted above was often misinterpreted by social scientists as a kind of “natural” outgrowth of institutional maturation that was thought to characterize labor relations in all developed societies. A related version of the same theme saw the “end of ideology” as the inevitable accompaniment to modern socioeconomic development, whereby societies would simply discard any need for radical criticism or ideological debate with regard to the future. However, underneath such obvious signs of approval that were stamped on the social order by conservative social scientists or the bureaucratic practices that had been imposed on labor relations in the process of domesticating it, there were important countertendencies apparent to the few who took notice. These took the form of dissident movements of workers, often radicalized by their experiences in the largest unions, who fought against the sorts of things that the Taft Hartley Act had imposed (i.e., they struggled to replace union leaders who were insufficiently militant, overly bureaucratic, or undemocratic, and to wield militant forms of

protest and collective action, such as wildcat strikes). In other words, the actions of employers to constrain the labor movement had generated new forms of organization and new forms of action from deep within the labor movement itself.

By the beginning of the 1970s, facing strong competitive pressures from European and Japanese firms, US manufacturing corporations began to squeeze more from their domestic operations by forcing down wages and by mounting a formidable and wide ranging assault on union organization in the United States. Drawing upon a legal arsenal that had been earlier put in place by the Taft Hartley Act, they were also assisted by a burgeoning industry of management consultants specializing in both union avoidance (slowing the creation of new unions in those sectors of the economy where unions had not had traditional roots, like health care and much of the services) and in breaking unions in the traditional sectors of labor strength (food processing, meat packing, newspapers, airlines, etc.). While the assault against unionism reached its peak during the decade of the 1980s, it continued through the 1990s and up to the present, with union density rates falling from a high point of 35 percent in the mid 1950s to approximately 13 percent and falling in 2005 (where in the private sector it is only 9 percent).

In the mid 1990s, faced with the demise of its institutions and its position in the society, the leadership of the US labor movement began to forge a process of internal change in an attempt to reverse its fortunes. The change began with a “palace coup” within the top ranks of the AFL CIO, which replaced a conservative, bureaucratic leadership with a reform leadership group drawn from some of the more militant and dynamic unions. Once in place, the new leadership group began a campaign to encourage, cajole, and coerce the leadership of the approximately 60 unions in the Federation to turn more of their efforts and budgets toward organizing new members, rather than servicing the needs of existing union members. They have encouraged new, more militant union organizing tactics, including circumventing the bureaucratic system of union representation elections in favor of collective action and disruption; developing “corporate campaigns” to pressure

institutional shareholders to protest corporate anti unionism; and have sought to envelop labor struggles within a wider circle of community solidarity, narrowing the distinction between the labor movement and other social movements. With their own elections dependent upon the votes of existing members, there has been a considerable amount of resistance from many labor leaders, but the use of new tactics, in certain economic sectors and regions of the country, has also been able to show some positive results. The future of the labor movement in the US is still quite uncertain.

The labor movements in the most advanced economies of Western Europe have traditionally been stronger politically, and more firmly rooted institutionally, than US unions. Indeed, the practice of "social partnership" has, for decades, characterized the relationship between large corporations and the labor movement in much of Western Europe, and is still intact. What this has generally meant is a more consultative and less openly combative relationship than in the US, represented by the active existence of works councils in many of the largest enterprises and trade associations that afford labor a voice in corporate planning. However, the deregulation of global markets and the imposition of many neoliberal reforms across Europe (often pioneered in the US, where labor has not been able to offer firm resistance) have shown that societies are now faced with some very similar competitive pressures (to privatize public services, to deregulate markets, to treat short term shareholder value as a guide in economic policy, etc.). The tendency to cheapen the cost of labor is therefore increasingly an international effort, so that there is a drive to eliminate the differences between national labor movements by weakening them all. Ironically, then, faced with the competitive pressures from US corporations in many world markets (ironic given the reverse impetus for wage cuts and union busing in the 1970s within the US), European societies have seen corporate intransigence increase and union power decline in recent years, expressed most explicitly in the erosion of a host of state social welfare policies across Europe in recent years. Across Europe a debate rages between the labor movement and allied social forces who would uphold a European model of social solidarity, and those who

would subordinate social and labor policies to the exigencies of the market alone.

labor process

Alan McKinlay

Braverman's *Labor and Monopoly Capitalism* (1974) was a craftsman's roar of indignation against the relentless deskilling of modern work. His starting point was explicitly Marxist:

the distinction between labor power and labor. That is, all forms of management are not neutral forms of coordination and mobilization, but necessarily involve the transformation of the *potential* productivity latent in labor power into *actual* work and output. Exploitation is not an unfortunate lapse but inherent in the employment relationship in capitalist societies. From the industrial revolution onwards, management had skirted around the stubborn opposition of skilled labor by indirect means, such as the use of ramshackle incentive systems or craft supervisors to navigate between craft norms and managerial demands. Braverman argues that modern management, a management that did not accept craft methods as a given, was inaugurated by F. W. Taylor. Taylorism, for Braverman, consisted of three essential principles. First, that management must accumulate and then codify all the knowledge of tools, tasks, and techniques held by skilled labor. This both redressed the imbalance of working knowledge that was the historic weakness of management and allowed them to experiment systematically with alternative, more efficient production methods. Second, the separation of conception from execution, the first step in the rigorous fragmentation and recombination of *all* tasks. Refractory, wayward workers were to be orchestrated for maximum discipline, efficiency, and predictability. "Scientific management" offered not just efficiency and control, but also reduced labor to something entirely interchangeable, an activity with no purpose other than to complete the working day and which offered no intrinsic satisfaction. Such was the ideological appeal of this objective "science," Taylor argued, that the worker would willingly accept her or his complete subjugation at the factory gates, and surrender all agency and knowledge to become a "mere appendage to the machine." *This* was the hallmark of modern "scientific management." Third, once management had wrested the necessary knowledge from skilled labor, tasks would be defined in advance and labor would now work according to the tempo set by management planning rather than craft norms. In part, Taylorism represented the accumulation, codification, and reordering of the craftsman's traditional knowledge in order to raise overall productive efficiency. No less important,

however, Taylorism offered a powerful critique of early twentieth century American management, which had allowed the productive potential of major technological changes to be blunted by craft resistance. For Taylor, management had tacitly accepted its relative ignorance and was complicit with craft labor in maintaining inefficient working practices. The modern manager was to derive his authority not from the maintaining of output using established practices, but from his mastery of the theory and practice of Taylor's new science of work.

Taylorism and deskilling had a political importance that stretched far beyond the workplace. Braverman offered a new philosopher's stone, a way of understanding the long run dynamics of class and political change. This was the political promise of labor process theory: as deskilling and the degradation of work became more extensive and profound, so it would erode, if not obliterate, distinctions inside the working class. As automation spread ever further, not just particular skills but entire occupational categories would disappear. The result would be degraded work, under employment and the creation of an ever expanding reserve army of labor that placed ever greater downward pressure on wages and working conditions of an increasingly homogenized working class. This vicious cycle of automation, degradation, and immiseration held enormous promise for revolutionary political change.

BEYOND BRAVERMAN

"First wave" labor process theory offered important correctives to Braverman's deskilling thesis, but endorsed its underlying analytical and political principles (Thompson & McHugh 2002). Certain criticisms quickly became routine – above all, that Braverman neglected not just union bargaining power but also informal worker resistance to technical and organisational change. In social history Braverman's focus on skill echoed the "history from below" that sought to recapture the lived experience of working people. Although this shift towards the grassroots inevitably flirted with a romanticization of working class life, studies of construction, cotton, engineering, printing, and

shipbuilding all pointed to the tenacious survival or, more accurately, the resilience of skilled labor and its ability to blunt or absorb much of the deskilling potential of new technologies. Nor does compliance with routinized work regimes necessarily imply a complete loss of agency. Michael Burawoy's pathbreaking studies show how workers turn production targets into games in which they negotiate the rules, which means that they can retain and display agency in even the most hostile environments (Burawoy 1985). A second criticism was that Braverman – like Taylor – ignored the often hidden or unrecognized skills of routine “unskilled” workers. Such tacit skills ensure safety, efficiency, and equity in the workplace and are important parts of even the most unsophisticated types of job. Braverman (1974) offered little guidance on how to measure changing skill levels over time, between occupations, sectors, or national economies. A third criticism was that Braverman underestimated the range of strategies deployed by employers. Management would cede control to skilled labor when confronted with major technical or market uncertainties or decide not to impose Taylorist principles where groups of workers had erected substantial defenses.

But however significant the qualifications to Braverman's original thesis, the implicit position was that – *ceteris paribus* – management would pursue a deskilling strategy. Other things were, however, seldom equal. Even at the height of its popularity in 1920s America, very few employers deployed the full range of techniques defined by Taylor as essential characteristics of scientific management (Nelson 1975; Edwards 1979). Similarly, faced with smaller, more fragmented product markets, and the significant fixed costs of developing the organizational infrastructure necessary to sustain some form of Taylorism over the long run, British and European employers, for example, consistently shunned full blown scientific management (Littler 1982). Maintaining productive flexibility was a vital strategic consideration, far more important than any long run gains that might result from a protracted and hugely risky transition to mass production (Zeitlin & Sabel 1997). Until the 1970s, the decentralized organizational structures of British corporations together with the disdain for “professional” management proved

major barriers to anything more systematic than ad hoc bursts of Taylorism. The range of caveats, qualifications, and special pleading whittled away the coherence of Braverman's original position until Taylorism had assumed an almost metaphysical quality: the search for control, much more than profitability, was something that was assumed to be implicit in *all* managerial maneuvers. Braverman's original deskilling thesis was being asked to bear an impossible analytical burden.

NEW THEORETICAL DIRECTIONS

The last two decades have witnessed a waning of Braverman's influence. There have been two broad reasons for this. On the one hand, the emergence of teamworking as the dominant organizational form in manufacturing and clerical and service work over the last two decades has placed a question mark over the continued relevance of scientific management as the key driver of labor process change. Indeed, depicting the shift to teamworking as a revolt against Taylorism and managerial bureaucracy has been a prime source of legitimacy for corporate change programs. Just as the rhetoric of Taylorism was more important than its practice, so the dominant ideology of radical managerialism belies its more restricted practice.

The dynamics of routine service work *can* be accommodated within the original labor process perspective, but only by an increasingly strained use of the assembly line as a metaphor rather than an organizational reality. Analytically, Braverman has been pushed aside as the cornerstone of radical interpretations of work in favor of eclectic borrowings from post modernism. Above all, Foucault has moved to the fore as the theorist that offers insights into the power of electronic and peer surveillance in the contemporary workplace, the ambiguous play of discipline on individual identity (McKinlay & Starkey 1998; Sewell 1998). Too often, this “linguistic turn” has assumed the coherence and durability of corporate cultural projects and the malleability of workers bewildered by managerial ideology and with scant alternative sources of meaning. The result has been an

analytical readiness to read workers as cultural dopes, analogous to the deskilled automata of Taylor's fantasy and Braverman's nightmare. On the other hand, Taylorism has little appeal to managers of high value added "knowledge work" in which innovation and creativity are valued more highly than efficiency. For knowledge intensive firms – in advertising, design, pharmaceuticals – competitive advantage derives from management's ability to assemble project teams to maximize their creativity far more than their ability to codify, simplify, and deskill work. That is not to say that there are not significant competitive and managerial pressures to accelerate knowledge labor processes or to introduce project management tools, but that is a far cry from Taylorized work. Understanding the dynamics of control, knowledge, and creativity is fast becoming the focus of much mainstream and radical research into the dynamics of contemporary competitiveness and organization.

For all the claims to greater theoretical sophistication, the gradual retreat of the labor process perspective has involved a real loss of any sense of connection between shifts in the nature of capitalist economies and work organization or how that intersects with trade unionism or popular politics. The labor process debate sparked by Braverman initiated an enormous range of historical and contemporary research into the interplay of skill and technology, the long run recomposition of labor markets, and management ideologies and practices. The turn to the study of work as a form of discourse which is shaped almost exclusively by management has resulted in the neglect of material issues of wages and working conditions, tools and tasks, and of conflict as something more than a clash of signs and symbols. The rejection of the very *possibility* of grand narratives has dissolved work as a key moment in political economy, a term that has become deeply suspect. A return to the ambitious historical sweep of Braverman's original focus on the political and economic centrality of the workplace is now overdue.

laboratory studies and the world of the scientific lab

Daniel Lee Kleinman

The most prominent laboratory studies – produced in the late 1970s and early 1980s – continued a trend in the sociology of science and technology away from attention to the institutional character of science and toward a sociological understanding of the process of knowledge production itself and the "technical core" of science. To comprehend the process through which knowledge is *constructed*, these studies undertook ethnographic investigations of the work that goes on in scientific laboratories. Among the central findings of this body

of scholarship are: (1) contrary to standard images of science, which suggest that the methods, practices, and outcomes of science are universal (or trans contextual), knowledge production occurs at a local level and is subject to local variation; (2) instead of the characterization of science as fundamentally logical and rational, science is the product of contingent factors; (3) scientific work does not merely read its results from nature, but instead nature is transformed in the laboratory; (4) if the view of science as “reading off nature” amounts to an understanding of science as a descriptive practice, the early laboratory studies show, by contrast, that scientific results are the product of construction.

Initially published in 1979, Latour and Woolgar’s *Laboratory Life* (1986) is probably the most prominent laboratory study. This book traces the struggle to define the structure of an important human hormone. The authors show that the scientists they study are centrally engaged in efforts to persuade colleagues of the validity of their findings. To do this, these researchers begin with “inscription devices” – pieces of equipment that transform a material substance into a figure or a diagram. Unlike standard images of science as linear processes that lead inevitably to “findings,” the movement from experimental work to inscription, as witnessed by Latour, was instead messy and uneven. In the end, however, the process was forgotten or taken for granted and scientific discussion focused on figures and diagrams. As a result, scientists came to see their inscriptions as direct indicators of the substance being studied, rather than as contingent and constructed outcomes.

With an inscription, scientists work to persuade colleagues to drop qualifications in any statements they make about the inscription. The researchers aim to move their competitors from statements like “Smith’s work appears to suggest that x plays a crucial role in the onset of lung cancer” to “x plays a crucial role in the onset of lung cancer.” This is all part of the process of knowledge construction. A fact only exists when qualification is gone and it is taken for granted and is drawn on as part of an accepted body of knowledge.

Another canonical laboratory study is Knorr Cetina’s *The Manufacture of Knowledge* (1981),

which studied the work of plant protein researchers. Knorr Cetina stresses the contingent and local character of knowledge production, showing that how an experiment proceeds depends as much on what equipment happens to be available, what money has been allocated for, and how resource use needs to be justified as on widely accepted procedures. In addition, Knorr Cetina suggests that scientists are not linear reasoners, but reason analogically. Knorr Cetina shows that the messy and contingent process of knowledge production is masked by scientific papers which suggest an orderly and linear movement from introduction, to methods, to data and analysis and conclusions.

Another especially prominent laboratory study is Lynch’s *Art and Artifact in Laboratory Science* (1985). Coming from the ethnomethodological tradition and drawing on data collected in a university brain sciences laboratory, this book, like Knorr Cetina’s work, points to the disjunction between scientific writing and what actually happens in the laboratory. Even more than Knorr Cetina, Lynch stresses the local character of scientific work, suggesting that, for example, what counts as an artifact in experimental work is determined in the local laboratory context through discussion of the local situation and not measured against an external standard. Lynch focuses on talk among laboratory workers and shows that standards for matters like experimental competence are settled for practical purposes.

A final canonical text, Traweek’s *Beamtimes and Lifetimes* (1988), offers a quite different perspective. Based on a comparative analysis of high energy physics research in the US and Japan, Traweek focuses more on the culture of laboratory practice than on the epistemological concerns that drive the other prominent laboratory studies. Looking especially at the large and expensive equipment at the center of high energy physics, Traweek shows how the different cultures of the two countries affect the construction and use of these crucial tools. Most prominently, Traweek describes how equipment is proposed by researchers in the Japanese case and then built outside the laboratory environment and not subject to subsequent modification. In the US, particle detectors, while initially developed based on scientific

specifications, are also altered on the basis of everyday use. This difference in orientation to equipment construction affects the way in which research is undertaken and the outcomes produced.

Broadly speaking, the classic laboratory ethnographies treat the laboratories studied in isolation from a larger social world in which we might view them as embedded. Kleinman (2003) moves laboratory ethnography in a new direction. Situating the plant pathology laboratory he studies within a broader political economy, Kleinman shows the multiple subtle and indirect ways in which university laboratory practices can be affected by the world of commerce.

laborism

Peter Beilharz

Laborism refers to the theory and practice of the labor movement, articulated as its own kind of socialism or social protection. Laborism is best understood as the project which seeks to defend and extend the interests of workers and their families under capitalism. Laborism is peculiar to Anglo imperial cultures, such as Britain, Australia, and New Zealand. Its intellectual advocates are often associated with the ideological trend of reformism called Fabianism in these countries, or progressivism in the United States. The peculiarity of laborism as an Anglo phenomenon is that it results from the shift a hundred years ago of the labor movement into politics. Laborism, or labor socialism, as the defensive cliché indicates, is what labor parties do.

Laborism, then, indicates a distinct path of development in contrast to European socialism, or social democracy. Classical social democratic parties on the European continent were based on the German model, which was not only socialist but also explicitly Marxist. Laborism is less doctrinal than this, often seeking as a maximum program universal health care provision and free schooling or decent public housing. This is not to say that laborism is always meek in its reformism. Certainly the British, Australian, and New Zealand labor parties were home to various radicals and Marxists, though the rise of organized communism after 1917 took such activists elsewhere. If the labor parties often then argued for socialization after World War I, their greatest moment came with World War II, when the Savage government pioneered the welfare state “cradle to the grave” in New Zealand from 1935, the Attlee government introduced the National Health Service (NHS) in Britain over the period of its reign, 1945–51, and the Curtin and Chifley governments presided over the program of post war reconstruction in Australia.

Laborism was then transformed into managerialism in the post war boom, and then washed away by the new wave of globalization into the 1980s. As the greatest organized social movement of the twentieth century, the labor

movement lost its national reforming impact in the face of the rise of neoliberalism. Having dropped their socialist claims in the managerial atmosphere of the 1950s, labor parties now spearheaded neoliberal innovation, first in the Antipodes, then most illustriously in the shape of Blair's New Labour in Britain. The transformation of the post war world – Keynesian, based on high growth, full male employment, and the nuclear family as the unit of consumption – dissolved the basis of this kind of left labor politics. The theory and practice of laborism were transformed sociologically from below.

Lacan, Jacques (1901–81)

Christine A. Monnier

Jacques Marie Émile Lacan received his medical degree in psychiatry in 1932 based on a doctoral dissertation analyzing a famous case of paranoid psychosis. This work marked the beginning of a clinical and theoretical career in psychoanalysis that would span over 50 years and make him one of the major, and most controversial, figures of the post World War II French intellectual milieu. Lacan defined his approach as a “return to Freud.” By this,

he did not simply mean the establishment of a literal Freudian orthodoxy, but the rediscovery of Freud's most controversial and subversive insights. He also succeeded in underlining the importance of Freud, beyond the field of psychoanalysis, to other human and social sciences. It is therefore not surprising that his conceptual developments integrated insights from the arts (Surrealism), philosophy (Spinoza, Hegel, Heidegger, Merleau Ponty), linguistics (Saussure, Jakobson), anthropology (especially in the structuralist anthropology initiated by Lévi Strauss), and mathematics. Such a wide range points to two major difficulties in studying Lacan: first, he constantly redefined his concepts to integrate insights from other fields; second, this integration made Lacan notorious for his deliberately “unreadable” style.

One of the major controversial insights that Lacan retrieved from Freud is the radical deconstruction of the classical Cartesian view of the *subject*. Through his famous formulation *cogito ergo sum* Descartes posited a unified subject, able to know himself through conscious thinking. This conception of the status of the subject was a pillar of western thought. By introducing the concept of the unconscious, Freud and Lacan showed that complete knowledge and unity of the subject is impossible. In addition, Lacan demonstrated that human life (mental and sexual) is not governed by biological processes and instinct (as biologism sees it), but by linguistic processes that create meaning; in other words, the source of human behavior is to be found in social rather than biological reality. Although it is impossible to review all of Lacan's conceptual developments, it is important to examine those that are relevant for the social sciences.

The first of these is known as the *mirror stage*. Infants reach the mirror stage between the ages of 6 and 18 months. At this stage, they become able to identify themselves in a mirror, as complete individuals, in spite of their lack of motor and coordination skills. According to Lacan, the mirror stage involves a dialectic process: the child, as it recognizes itself in the mirror, also identifies the image as its *reflection*, something separate from itself, an *other*; this stage marks the emergence of the ability to distinguish between self and other. Where the child experiences itself as fragmented, uncoordinated,

and disorganized, it experiences the image as complete, thus providing for what Lacan calls the ego ideal, the perfect, complete image of the ego that the subject tries to achieve through identifications. If the mirror stage is essential to the development of the ego, it also involves a fundamental alienation – a split – as the subject will always rely on an *other*, a mirror, for his identity.

Coinciding with the mirror stage is the development of language, the child's entry into the Symbolic order according to the Lacanian version of the Oedipus complex. The acquisition of language corresponds to the child's separation from the world of the mother and movement into the social world (the Big Other, in Lacanian terms), the patriarchal world, the world of the father (a symbolic, rather than biological entity). Lacan calls the former the "real," marked by complete enjoyment or *jouissance*, and the latter the "symbolic," marked by the loss of this *jouissance*, which gives rise to sexual desire in the subject. For Lacan, the fear of castration involved in the Oedipus complex is a symbolic more than real notion; it reflects the anguish associated with the irremediable loss of the real, the world of the mother where the subject is complete, and the entry into the symbolic, the social world, governed by language, where the subject is split. The mirror stage and the symbolic domain are at the root of the subject's identity in society, albeit an incomplete one.

The *Symbolic* and the *Real* are two components in the tripartite order that defines the human subject. The other is the *Imaginary*, the domain of appearances and images. Lacan represented the relation between these three orders in the image of the Borromean knot (for an illustration, see Evans 1997).

For many feminists, Lacan merely reproduced Freud's misogyny. However, for others, the infamous statement that "the Woman does not exist" can be interpreted as a description, rather than endorsement, of the fact that there is no feminine essence or nature but that such nature is only the product of men's desires and cultural determinations in the symbolic domain, that is, patriarchal reality. Moreover, Lacan also uses the symbolic concept of phallus (as opposed to the biological penis) as a limitation on men's libido. Indeed, Lacan showed that if men are limited to phallic pleasure,

women have access to a surplus of *jouissance* or sexual enjoyment.

The result of the split of the subject is the never ending search for complete identity through identifications in the sociopolitical reality. But since this split is the result of the loss of the real, a full identity can never be achieved – although different ethnically based political movements (identity politics) may promise such fullness. Much nationalistic and exclusionary thinking is based on the idea that "others" (immigrants, minorities, homosexuals, etc.) have access to *jouissance* at the expense of the subject's "natural right" to such. In addition, most political utopian projects (Nazism, communism, communitarianism) are based on the idea of creating such fullness at the social level. Such projects offer an imaginary vision of a harmonious society, as if the real had been recuperated (Stavrakis 1999). However, since social reality is riddled with conflicts and other problems, such utopian projects always need a scapegoat to blame for delays in achieving the imaginary society, and therefore to be exterminated. For Stavrakis, this explains the failure of such utopian projects as well as the double threat to democracy: the threat of totalitarianism (the utopia of completeness) and the threat of particularism (the utopia of irreconcilable difference as source of complete identity). Democracy is the only viable Lacanian political project because it is based on the acceptance and institutionalization of conflict. Democracy is the only system that does not try to fill the lack that is constitutive of human existence, but integrates this lack and turns it into sociopolitical institutions.

laicism

Jean Baubérot

The French Constitution defines France as a "*République laïque*," a lay republic, and the French generally consider laicism to be a "French exception." This aspect of singularity was recently reinforced with the passing of a law in March 2004 banning ostentatious religious signs in public schools. But it is impossible to simplify laicism in terms of this particular law. Laicism is also a possible means for relationships between the state, religion, society, and every human being. Such relationships can function only if there is flexibility and adaptability to all situations present in society.

Classically, sociologists dealt with the notion of secularization as being the decline of the influence of religion on modern society. For example, according to Peter Berger, secularization is "the process by which the sectors of society and culture are freed from the authority of religious institutions and symbols." Nowadays, not only is it obvious that the decline is incomplete (for Berger, the turning point of the twentieth and twenty first centuries was "furiously religious"), but also such a notion of secularization can be criticized as being too broad. For a better understanding, a distinction can be made between two long term sociohistoric processes, a cultural process of secularization and a political process of laicization.

When the cultural process of secularization is predominant compared with the political process of laicization, the relative decline of a religion's influence takes place in the form of cultural mutations, with no major tensions between religious and political or other social forces. Certainly, religious changes, as well as economic and political changes, may produce

internal tensions. But triumphant forces participate in the same cultural and social dynamic. Therefore, there is no important clash between the changes within the religious sphere and other social changes. This is the reason that Scandinavian countries are seen as exemplary of a secular state. The switch to Lutheran Protestantism, particularly linked to the Bible's translation, has favored the development of a national culture. Theological arguments have prevented the autonomy of the nation state toward religion from provoking important conflicts. Moreover, a joint and progressive democratization of state and church has taken place.

In Scandinavian countries, and in other countries like the United Kingdom, religion contributed in various ways to secularization and particularly to the development of democratic sociability. In certain cases, the development of secularization that occurred in the eighteenth and nineteenth centuries is described by the paradoxical term "religious secularization." It is feasible, then, that a national church can continue to be the symbol of the identity of nations that have been culturally secularized.

Laicization is a process in which there is a double movement at the end of a political "theocracy," a movement of institutional differentiation between the political and the religious sphere, a movement of emancipation of the nation state and the institutions toward religion. When the political process of laicization is predominant compared with the cultural process of secularization, the tensions between various social forces generally take on the aspect of an open conflict where religion becomes a politico cultural stake. For example, the symbolization of the national culture is controversial. Either the state imposes religion on society (clericalism) or refuses that religion should continue to be the symbol of national identity (laicization). The French case is the main example of such a process.

In 1789, religion pervaded French society. From the Revocation of the Edict of Nantes (1685), the monolithic Roman Catholic faith was made compulsory for the French. Communion at Easter and confession were imposed on the people. The clergy was the first of the three "orders" of the kingdom. The monarchy possessed religious justification, given the theory of the divine right of kings. The king possessed

politico religious power, and one of his basic duties was to defend Catholicism. Gradually, the monarchy also established widespread autonomous political and administrative power. A Gallican movement emerged, which developed the idea of a French Catholic Church that would be autonomous from the pope and protected, as well as partly controlled, by the monarchy. An anticlerical dimension appeared in the French philosophy of the Enlightenment that had permeated a part of the nobility and bourgeoisie. This spirit differed from the English Enlightenment or the German *Aufklärung*. The latter appeared as a confrontation within a diversified Protestantism wanting "enlightened religion," the former directly attacked the Roman Catholic Church.

The French Revolution removed the privileges of the clergy and confiscated the church's large property holdings. Revolutionaries worked to "emancipate" civil and political society from the influence of the church, particularly in social matters relating to marriage, divorce, and education. The Declaration of Human Rights of 1789 proclaimed the principle of religious freedom. In 1791, the Constitution divested the monarchy of its religious features, and it was implemented the following year. The republic was established, although rather conflictually. However, it was not clear that the founding of the republic was considered as the first day of the new era (as is the birth of Christ for the Gregorian calendar). In 1793, the institutions of revolutionary cults ("Eternal Reason," "Saint Liberty," or the more conciliatory "Cult of the Supreme Being") struggled violently against all revealed religions. The significance of the new forms of religion was represented by ritualized gatherings of the community around common values that were socially fundamental and regarded as sacred (cf. Émile Durkheim). It was a conflictual and, eventually, impossible laicization.

Napoleon Bonaparte inherited a chaotic situation. In 1801 he signed a concordat with the pope: the Roman Catholic Church was proclaimed the "religion of the great majority of the French," but without the status of a state religion. In 1802, the plurality of religions became official: Lutheran and Reformed churches and, later, Judaism were recognized.

In 1804, the Civil Code made no reference to religion.

It is possible to evaluate the situation using the abstract notion of the first threshold of laicization (constructed on the basis of Weber's ideal type). It is marked by three characteristics:

- 1 *Institutional fragmentation*: Roman Catholicism was no longer an inclusive institution. The clergy had to confine itself to its religious activities, which were clearly distinguished from profane activities. Educational and health needs assumed gradual autonomy, related to religious needs, and were provided for by specific institutions that underwent progressive development.
- 2 *Recognition of legitimacy*: The French Revolution did not destroy religious needs, which continued to exist objectively and within the general society. Religion was a public service and the state paid ministers of recognized religions. Religions were politically recognized as a foundation of social morality.
- 3 *Religious pluralism*: The state recognized several but not all religions; it protected and controlled them since they could satisfy the religious needs of their followers and develop moral values. Other religions were more or less tolerated. Relative freedom was even granted to those who decided to do without the "help of religion."

This profile delineates a logic that dominated for a century. But the situation was not static or rigid. This was due especially to the fact that, for a long period, a number of aspects of the first threshold of laicization were not entirely evident; other institutions were not sufficiently developed to become totally autonomous. Then there was growing conflict between those who regarded France mainly as a Roman Catholic nation and partisans of the liberal values of 1789. Similar conflicts also rose during the nineteenth century in other countries where Catholicism continues to predominate today, among them Belgium, Spain, Italy, and Mexico, whilst in the 1870s a few countries, such as Germany with the *Kulturkampf* movement, held firm against Catholicism. But, at present, there is

not necessarily any conflict between church and state in predominantly Catholic countries. Catholicism can represent a national sentiment (as, for example, in Ireland under British rule, or in Poland).

Conflict grew in the nineteenth century between “clericalism,” that is, a religion’s political dominion over a country, and “anticlericalism,” which actively fought this claim. Rooted in scientific ideology, radical forms of anticlericalism perceived religion as an outdated explanation of the world that offered only a backwards orientation, irrelevant to the context of modern democracies.

In France, the founding of laicism was rooted in the political victory of the anticlerical movement. The impression prevailed that the republic (established again in 1870) was threatened by clericalism. A 1901 law excluded religious congregations from the right to free association. A new law passed in 1904 (and in effect until 1914) prohibited members of religious orders from teaching. But, essentially, the combative anticlerical movement gave birth to a progressive pacifist form of laicism. It is as if a revolutionary socialist party, assuming power by democratic process, ultimately gave birth to a social democratic system.

During the 1880s, the republicans introduced a religiously neutral educational system, which included a “laic morality.” This morality borrows elements from a number of origins: classical antiquity, Christianity, the Enlightenment (from Voltaire to Kant), and, occasionally, from Confucius. Different traditions are interpreted according to two notions: dignity of the human person (which creates rights and duties) and social solidarity. Further, the republicans hoped that the structure of the lay school would engender morality. As a place for learning tolerance, it enabled all French children, irrespective of social class or religion, to come to know and accept one another. Through school, the republic itself was the bearer of values. This moral was a compromise, and, because of the conflict, a significant anticlerical section asserted that religion was dangerous for the republic and its ideals.

In 1904–5, after the crisis that arose out of the Dreyfus affair, the separation of church and state became inevitable in a climate of confrontation.

Two models were possible. One was combative, as represented by the bill of Prime Minister Émile Combes. However, it was rejected, especially by the celebrated socialist leader Jean Jaurès, who hoped to achieve a law that would bring peace and make it possible to combat social inequalities. A liberal model prevailed ensuring freedom of conscience, guaranteeing the freedom to exercise religion, and respecting the self organization of each religion (art. 1 and 4), even though it neither “recognized” nor subsidized any religion (art. 2).

Even in liberal dominance, this model of separation completed a religiously neutral educational system and found a new logic. This can be seen as the second threshold of laicization. As for the first, there are three characteristics:

- 1 *Institutional dissociation*: Religion was entirely optional because it was no longer considered an institutional structure of society but rather as a mode of free association.
- 2 *Social neutrality regarding religious legitimacy*: Religious needs became a private matter. The question as to the usefulness of religion for society was no longer publicly relevant. But, within the framework of freedom of expression and association, religions could participate in public debates on social questions and the meaning of life.
- 3 *Freedom of religion and conviction*: Various religious societies belonged to the public sphere. The state guaranteed each citizen freedom of conscience and allowed citizens to meet within religious societies or associations.

A twofold aspect marked a separation in 1905: the victory of the lay camp in the conflict of a divided France, and an implicit covenant with opponents whose ultimate aim was to attain peace rather than achieve victory in the short term. The conflict vanished progressively because religion ceased to be a political problem, except in the field of education. So, by 1945, the bishops held that there could be a positive meaning to the term laicism and the following year laicism was officially proclaimed and recognized by the Constitution.

Other countries also underwent a process of laicization. Belgium was not situated in a similar

logic to the second threshold of French laicization but integrated laicism in its system of recognized religions: non confessional morality in school, lay advisers in hospitals or prisons, and so on. The Spanish and Italian systems tend to resemble a laicism that corresponds a little more to the first threshold of laicization, with more liberty and more pluralism.

The American situation is characterized by the separation between church and state (the 1st Amendment of the Constitution, 1791) and this is linked to the central function of religion. Stephen Warner indicates the main differences:

- Religion is constitutive for some American subcultures.
- Religion in America has historically promoted the formation of associations among mobile people.
- Religion in America serves as a refuge of free association and autonomous identity – a “free social space.”
- The second generation of immigrants often transmutes ethnicity into religion because it allows immigrants to assimilate and conserve their identity.

The American situation is heavily influenced by civil religion. There is an ambivalence between civil religion and laicization. Civil religion historically favors dissociation between social links and the hegemony of a religion, but civil religion renders the political values of the collectivity sacred.

Is the French situation the most laic? The answer is no, since, for example, the separation between state and church in Mexico from 1917 to 1992 created a time of austerity for religion. The 1917 Mexican Constitution forbade monastic orders, ensuring that religious ceremonies could only take place in churches, which were permanently under the authorities' supervision, and according to the Constitution religious ministers of all cults were denied the right to vote. Since the 1990s, though, there has been more flexibility and such rigidity is not as common. Turkish laicism is also historically harsher than French laicism. It expanded after World War I, questioning the logic of Islam, which was considered to be the principal cause of social decline. This position explains the reason for the armed forces' important role in religion.

A moderate Islamic movement tried to make it more liberal. The international situation does not favor such a development because a new form of conflict that might be characterized by a new anticlericalism has arisen between fundamentalist religious groups and laicized and/or secularized societies. Examples are evident in several Islamic countries, in Israel (orthodox Jews), and in the United States (fundamentalist Christians). Whether or not headscarves may be worn, a passionate issue for many French people, is a typical example of these new tensions. Several problems are interwoven, concerning not only how best to deal with fundamentalism, but also the most appropriate strategy to prevent social exclusion, the various conceptions of school, and the different notions of plurality compatible with national identity.

However, the idea of the universal has changed within the last 50 years. Today, the universal is no longer considered as the imposition of the nation state's values upon the civil society, no more than it is the imposition of western values on the rest of the world. It is the result of the building up of positive comparisons between values provided by different cultures, religions, philosophies, and civilizations. We are in the age of globalization. This represents a considerable change for laicism, which is linked with the development of the nation state.

Another issue worthy of attention is that, historically, laicization and secularization were two different processes of modernization. Now, changing from a process to a movement, modernization is a hegemonic but disillusioned reality. In the nineteenth century, morality was based on science. Now, science and morality tend to be dissociated in the context of many problems. Science was increasingly seen as technoscience, the functional efficiency of which was undeniable but which, far from helping to resolve moral questions, created new ones that were more difficult to resolve because of their intrinsic power. Is all possible progress also desirable? This is now an important topical question, not just in the biomedical field but in other areas as well: consider everything that contributes to environmental degradation. This new disillusionment changes the relationship to temporality. Ephemeral effects thus are becoming more important than investments in long term projects. Mass communication favors

sensationalism over analysis in the news, emphasizing its entertainment value. This entertainment broadcasts heroism, intrigue, sex, and wealth in large doses. It can lead to resentment because of the sizable gap between the imaginary notions conveyed and the nature of daily life, with all its banality, difficulty, and routine. In addition, it is necessary to be self-sufficient, each person has to assume responsibility. Such disillusionment leads to problems and various identity constructions are available that help individuals move toward the necessities of self-realization. Once again, the new cultural and religious demands have to be understood within this context. Indirect discrimination and reasonable accommodation are becoming new important problems.

language

J. I. (Hans) Bakker

Language is a very important topic in its own right (Crystal 1987) and in terms of philosophical debates in the social sciences (Rorty 1967; Calhoone 2003), yet, surprisingly, many sociologists pay scant attention to language and find communication entirely unproblematic. For some, for example, it is mainly a question of tracing the history and etymology of specific words (Stevenson 1983). Many classical sociologists did not pay specific attention to language as a phenomenon, but recently there has been a reexamination of the work of outstanding linguists and logicians. The important debates between those who identify with Enlightenment modernism (Chomsky 1998) and those who adhere to postmodernism (Jameson 1991) have forced many social scientists to reexamine long held assumptions.

However, there were important precursors among the moderns, including Johann Gottlieb Fichte, a dialectical thinker who defined language in 1794 as the “expression of our thoughts by means of arbitrary signs” (Surber 1996: 32). Critical approaches to the study of gender, race, and class have often involved a rethinking of basic linguistic categories by scholars such as Foucault, Baudrillard, Derrida, Bauman, and many others. For example, Foucault (1985: 91) has a very ingenious way of defining “aphrodisia” as “acts intended by nature.” Hence, in a sense, the study of language is a window to all of the social sciences, especially as cutting edge theory is shaping up in the early twenty first century. For many, there has been a philosophical shift from Cartesian “subject centered reason” and rational action, to Fichtean “communicative social action” (Habermas 1989) and symbolic interaction. Nevertheless, many theorists resist that change in worldview. The battleground where many issues are fought out is the study of language and communication generally.

Both as a subject matter (i.e., an “object” of study) and as a key aspect of theorizing (e.g., in terms of epistemology), language is a highly contentious topic (Crystal 1987). The ways in which languages have been studied have

changed. There is still interest in such topics as the emergence of alphabets and writing. Much in the way of traditional linguistics is still carried out. But there have been many changes over the last few decades. Comparative philology has given way, for the most part, to various forms of linguistics and semiotics. Many writers have discussed the “linguistic turn” in contemporary thought, a paradigm shift that may have started with “ordinary language philosophy” and other trends in the 1960s, or even earlier (Rorty 1967). Modernist, structuralist epistemologies stressing the Cartesian subject–object dichotomy have been confronted by postmodernist, post structuralist epistemologies which stress the “habitus” (Bourdieu 1977) and the “lifeworld” (Habermas 1989). Often, the study of language is seen as part and parcel of all aspects of human (and even non human) communication. Since no one can speak a language that is entirely idiosyncratic and still be understood, all languages tend to be social. A critique of the meaning and function of language in general (or perhaps a particular jargon) is often implicit in efforts to reform a disciplinary paradigm. Philosophers who emphasize linguistic questions (e.g., the later Wittgenstein) sometimes argue as if all that is necessary to dissolve certain intellectual problems is simply a reform of the language, thereby eliminating what are often called merely “semantic arguments.” Yet it is not altogether clear that certain questions can be considered mere “pseudo problems.” It is also not clear that “ideal language philosophy” is a realizable possibility (Rorty 1967).

Languages come in an amazing variety of forms, including dialects and *lingua francas* (Wardhaugh 1986). We rely on “euphemism” and “jargon” (Goshgarian 1998). There are many distinctive national, vernacular languages in the world. Of the approximately 5,500 currently still viable languages the most commonly spoken are Mandarin Chinese, English, Arabic, Spanish, and Hindi. Several ancient languages (“dead languages”) are nevertheless still in use, including Medieval Latin and Sanskrit. Other languages have died out and either can or cannot be reconstructed. (The Ancient Greek used by those who wrote in Linear B in Minoan civilization has been reconstructed, but Linear A – as well as the writing on the Phaistos Disc, also found in Crete – is still undeciphered.)

There are many definitions of the term language. Commonsense views of language stress the grammar and vocabulary of a specific natural language, like Swahili, Russian, Frisian, Mandarin, or English. Many people think of English, for example, as one and only one language. Crystal (2004) has stressed, however, that the history of English involves not just one consistent narrative (centered on English as spoken by the upper classes in England), but many different “stories” (including many versions of English historically and regionally). It is not just a matter of a “standard language” with many different offshoots. Since there are many legitimate forms of English spoken around the world, there is not just “one English language” today. This leads Crystal to look at English as a “global language.” His encyclopedic coverage of English as a language is matched by a similar range of coverage on languages in general (Crystal 1987).

Linguistics, the study of language and languages, can be viewed as sets of answers to a host of different intellectual questions or problems. For example, a group of linguists may be concerned with (1) *philosophical problems* (e.g., rationalist vs. empiricist aspects of philology as clues to deeper epistemological truths); (2) *social science questions* (e.g., the study of language acquisition by children, speech communities, and dialect patterns); and (3) *challenges in the humanities and arts* (e.g., the study of rhetoric and literatures). Some authors, of course, develop complex theoretical ideas concerning all three areas of inquiry. Thus, for example, Roman Jakobson, a member of the Prague Circle of the 1920s, wrote on questions of literary theory but also got involved in questions related to grammar. His “Quest for the Essence of Language” (Jakobson 1987: 413–27) is an aspect of his “semiotic” theory. Moreover, some authors argue strongly in favor of one viewpoint but later find that their theoretical ideas concerning language may have implications for a range of questions on which they themselves had not previously focused. A good example is the work of Edward Said on “Orientalism,” a very broad critique that has many implications for textual criticism and cultural criticism (Said, 1983). Habermas (1989) has attempted to steer clear of certain excesses in postmodernism while nevertheless incorporating many of the discoveries which have attended the linguistic turn.

The simplest form of language study is taxonomic and descriptive. However, for some, the term taxonomic linguistics is pejorative, since such classification systems tend to rely on “finite states” versus phases or transformations. There are different branches of linguistics. Historical linguistics looks at language change (diachronic, comparative philology), while general linguistics examines the characteristics of human language as a structured phenomenon (synchronic, contrastive structural linguistics). Language families have been analyzed by comparative linguists working in both diachronic and synchronic modes of investigation. Language usage is sometimes viewed as the most important aspect of what it means to be human. That could make linguistics a kind of queen of the social sciences, with interdisciplinary contacts with many other disciplines outside of the social sciences.

For many, the study of psychological linguistics is a subset of linguistics. For others, like Chomsky, the study of language is merely an aspect of the general discipline of psychology. That is because the key to language usage is considered to be a “generative grammar” that is part of our cognitive makeup. Chomsky argues that little children do not get enough experience with linguistic examples for them to be able to speak a language simply through memorization of clearly demonstrated patterns. Instead, human beings are “hard wired” with neurolinguistic abilities. Since those are universal it is possible to have a scientific approach to language acquisition and hence to language structure. In early work Chomsky views “transformational grammars” as heuristic, but more recently the standard “transformational generative” theory of the 1960s has been questioned and further refined.

An examination of the anthropological and sociological aspects of language includes the study of such topics as the creation of artificial languages with simplified grammars (e.g., Esperanto). Language affects social structures and social structures, in turn, affect language. In general, it is a truism to point out that human beings interact with one another through the use of languages. But while that is well known, what interests the social scientist are the complex patterns that emerge from the human use of language. This leads to ethnolinguistics and

anthropological linguistics. In sociology the focus is on sociolinguistics.

The sociological use of the philosophical term *Verstehen* evokes for many an image of language in which the isolated individual speaker or writer in his or her personal “singularity” is able to have a fairly clear inner knowledge of the motivations and intentions of other speakers or writers, living or dead. Thus, Dilthey (1996) sometimes tended to write as if it is a matter of the scholar personally “reliving” (*Nacherleben*, *Nachbildung*) the mindset of a previous thinker (e.g., Marx attempting to interpret Hegel). Weber utilizes Dilthey’s concept of *Verstehen* but modifies it to make it more sociological rather than psychological. (Dilthey himself was heading toward a broader conceptualization of *Verstehen* at the end of his life.) But various poststructuralist scholars have indicated that such a Dilthey Weber use of *Verstehen* – and “romantic hermeneutics” in general – may still be too individualistic and may neglect the importance of the sociolinguistic “field,” the conscious and unconscious coordination of a group due to its shared language (Bourdieu 1977). Hence, we move from the individual scholar to the social actor and then to the “bundle of habits.”

In the discipline of linguistics the field of “pragmatics” concerns the ways in which language usage is linked to contextual background features. This has a recognized overlap with sociological ethnomethodology. How do people “accomplish talk”? Knowledge of the sociocultural context and the social psychological situation can help us, for example, to distinguish between angry and joking behavior. We might want to examine the specific details of how a group of people are able to believe that their words are understood. Thus, for example, speech act theory concerns the ways in which linguistic utterances are meant to accomplish specific goals (e.g., to apologize, to threaten). Conversation analysis examines the structure of human dialogues.

The study of “symbolic interaction” by sociologists who call themselves symbolic interactionists is based in part on George Herbert Mead’s insight that in order for two or more people to interact they need to have “significant symbols” in common. A significant symbol is a symbol that all participants to the interaction

understand fairly clearly in terms of its practical consequences. For most Americans a Ugandan flag is not a significant symbol, but an American flag is. Similarly, when two specialists use their own jargon they use words that are significant symbols in that one specialized context (e.g., motorcycle mechanics discussing the “fork” on a “hog” or astrologers debating the “sidereal” versus the “tropical” star chart). All human interaction relies on the ability of members of a collectivity to share certain significant symbols. This is partially a matter of customary norms.

Bourdieu (1977) has made it clear that one’s habituated ways of doing and saying things (one’s *habitus*) involves indicators such as language usage that can be correlated with social class. Those from upper class households will be accustomed to speaking in a more formal and literary version of the language. Their language usage is “distinctive.” Moreover, public recognition of a change of linguistic usage can evoke a crisis because the new expressions involve “objective signs of recognition” that were previously only privately held. Bourdieu worked with poststructuralist thinkers like Derrida. Bourdieu’s *habitus* can be regarded as a sociological version of the idea of a semiotic system of meanings. Just like the air we breathe, the semiotic symbols we use are part and parcel of our very being. We are like fish swimming in a linguistic sea. Take away the language context upon which we rely and we are no longer cognitive beings.

Some authors, following clues found in Saussure and Peirce, have argued that there should be a shift from linguistics to a much more generalized approach that is sometimes called semiotics (Hall 2002). Semiotics can take the form of a separate discipline, albeit one with very general implications (like mathematics or philosophy). However, semiotics is also often associated with interdisciplinary approaches. For example, both the psychologist and the sociologist might be interested in studying advertising in terms of the process of signification (“semiosis”).

Reflexivity about language usage has led not only to specific questions about language and languages, but also to broader philosophical questions about how we know anything with any certainty (epistemology) and whether or not we ever really know “obdurate reality”

(other than perhaps concrete material things) in any direct sense (ontology). The use of careful distinctions in philosophical discourse is often disparaged by labels like “casuistry” or “Scholasticism.” Nevertheless, there is a need to be precise and to articulate subtle but important distinctions that may not be easily conveyed by the use of natural languages. An example is the distinction often made between something being “real versus not real” and the separate analytical question of whether or not something “exists versus not.” It has been argued that “God exists but is not real.”

In philosophy some stress that in principle natural languages cannot be precise (e.g., the later Wittgenstein), while others attempt to develop an artificial, logical symbolic language that is precise, like mathematics (e.g., the early Russell). Of course, not all vague languages are naturally occurring languages. In computer science there have been a number of artificial program languages which are based on mathematical logic, but that does not always make computer algorithms crystal clear. The field of symbolic logic in philosophy also uses artificial signs. This is much like mathematics and statistics in general. But Gödel’s proof that it is impossible to be both consistent and complete in mathematics had a significant impact on linguistics. Ever since Gödel’s ingenious theory it has been argued that an entirely non circular, non tautological verbal language is also not logically possible.

One philosophical approach, associated with Peirce, is that languages of all kinds can be broadly conceived of as systems of “signs” which constitute a “code” or semiotic system (Sebeok 2001; Hall 2002). Such codes can affect our ways of seeing other human beings and classifying them as “others” in terms of their sex gender, race ethnicity, and class status. Peirce (1923) argues that the aspect of reality that is being signified is something “represented” by an interpretive community and not by an isolated individual. The interpretive community always signifies “the representant” through the use of a system of signs. Hence, language is a semiotic system that allows for human and animal communication.

For some, it is not possible to study anthropological linguistics, ethnolinguistics, sociolinguistics, or psycholinguistics without evoking

all aspects of human communication (anthropo-semiotics). The argument is also frequently extended to include communication among other animals. Thus, the study of "the language of bees" is a study in animal communication (zoo semiotics). The underlying premise is that there is a high degree of continuity between other animals and the human animal in the way in which we communicate.

The linguist Ferdinand de Saussure also constructed a view of language that stresses the importance of how "the signifier" (the form) represents "the signified" (the concept). When we use language, he argues, we make differentiations. For example, we can differentiate between the signs "mother" and "father." When signs can be interpreted in a meaningful way we have a language that is meaningful. Hence, the sign system and its usage constitute a social construction of reality. Our cultural codes are linguistic systems which we use in various ways and constantly modify as we apply them. Hence, language is constantly changing and always somewhat imprecise. Saussure introduced the distinction between the structure of a language (*langue*) and the way in which that language is commonly spoken (*parole*). The formal patterns are reinvented and simultaneously subverted every time we speak. No language can remain "pure" for long. Most languages are amalgams of many components.

There are many kinds of signs that are important to human languages (Sebeok 2001), but perhaps the most important are "symbols" such as words and phrases (Jakobson 1987). A set of such symbols, perhaps supplemented by iconic or indexical signs, can constitute a "text" (Dilthey 1996). Any piece of recorded symbolic communication is a kind of text, but when we think of language we think primarily in terms of written language and the formal "ground" of such a language, what Saussure refers to as *la langue*.

It is often argued that language has an important impact on how we think. The stronger form of the Sapir Whorf hypothesis is rejected today, but it is widely recognized that a weaker form of that theory is valid. Edward Sapir and his student Benjamin Lee Whorf were struck by how subtle distinctions found in one language might be difficult to convey into another language. Moreover, the structure

of a language largely determines commonsense notions of time, space, and causation. In standard European languages there is, for example, a notion of events as discrete and countable, while in Native American languages that may not be the case (Wardhaugh 1986).

The study of symbolic interaction involves ethnographic use of language through such research techniques as the interview. Ethnomethodologists and conversation analysts have paid special attention to nuances in the construction of semiotic systems. Garfinkel (2002) attempts to examine the "haecceity" (immediacy) of accomplishments and Sacks and colleagues (1974) examine topics like turn taking in conversations and the comprehension of puns. Others study membership categorization. Goffman (1981) studies forms of talk. Various kinds of discourse have been examined in many ways.

Langer (1979) argues that "true language" is always discursive. Hence, she rejects such metaphorical constructs as a "language of musical tones" or a "language of colors." For Langer, a discursive language can be broken down into analytical units and those units can be conceptualized as having a syntax. Without a true syntax to create composite structures, she argues, it is difficult to conceive of a true language. In human languages the basic unit may be the "word" as an elementary aspect of meaning. At the same time, it is also possible to have logical categories that are derived from immediate bodily experience which are "presentational." That is, we are "presented" with feelings and emotions which cannot be expressed in any language. This is similar to Foucault's (1985) discussion of language and sexuality.

Complex hypothetical and deductive linguistic theories have been postulated by many thinkers, including those who have emphasized the importance of "semiotics" (Deely et al. 1986). Writers such as A. J. Greimas have utilized insights from thinkers like Saussure, Merleau Ponty, Lévi Strauss, Dumezil, Barthes, Lacan, Propp, and Jakobson (1987) to develop arguments concerning the relationship between language and communicative symbols in general. Such "structural" views tend to postulate the existence of a narrated universe of "deep semantic structures" that are reflected in the underlying grammar of all human languages. The surface "narrative"

is viewed as “syntagmatic.” That is, the syntactical rules, such as “linear succession,” tend to determine the fundamental semantic structures. This can be seen as a further refinement of Saussure’s distinction between *parole* (the spoken language) and *langue* (the underlying structure), which utilizes ideas from Propp and others to give a more complete account of the way in which such semantic structures exist in human emotions, dreams, and passions, as well as in the rigor of scientific reason and the precision of technological design. One’s epistemology shapes one’s view of language and vice versa (Bourdieu 1977). The study of language and communications is central to philosophical aspects of social science theory and methodology (Calhoone 2003).

langue and parole

J. I. (Hans) Bakker

Ferdinand de Saussure distinguishes between a “language” (*langue*) in its structural form and the spoken word (*parole*). Linguistics studies patterns of communication using an auditory mode, but vocalized sounds in one language are structurally related to sounds in other languages, particularly languages of the same language family. Chomsky makes a similar distinction between “competence” and “performance.” When a native speaker speaks a language, he or she “performs” the *parole* but

is not necessarily aware of the linguistic structure of that language as a generalized "competence" in the linguistics of that *langue*. It is possible to speak a *langue* in a grammatically correct manner without any knowledge of the discipline of linguistics in general, or even the application of linguistic rules to that specific language. The distinction is similar to the anthropological terms "etic" and "emic," which are taken by analogy from phonetics and phonemics. In anthropology an "etic" approach to ethnographic fieldwork data is the outsider's academic perspective concerning patterns and structures, while the "emic" aspect is the indigenous knowledge of the culture in practice in daily life. An anthropological fieldworker attempts to learn the implicit rules and must become as adept at the local dialect as a native speaker. But the researcher then takes the data and makes broader generalizations than most indigenous speakers are likely to be concerned with in their everyday use of subtle distinctions. In linguistics, phonemics studies the phonemes, which are a class of phonetically similar "phones" or speech sounds (from the Greek word for voice), while phonetics is also concerned with patterns of sound changes in a language or group of languages. Grimm's law is a law of phonetics. Something similar is meant by Saussure's distinction, but it is not entirely clear whether he thought of *langue* as an ontologically real structure or merely an epistemologically ideal device. Saussure's distinction is synchronic rather than diachronic; the actual utterance by a person is a product of that speaker's having been socialized into a language which is relatively fixed during his or her lifetime. There is some indication that Saussure may not have been entirely settled on the methodological importance of the distinction for general linguistics; however, many structuralist theorists have utilized it. Hence, the structuralist tradition in anthropology that is associated with Claude Lévi Strauss uses Saussure's distinction, which may be part of the reason why it was eventually transformed into the etic/emic distinction. A structuralist approach to *langue* is compatible with "semiology," "signology," or – as it is usually called now, semiotics (Seung 1982). The implications of Saussure's distinction have been debated by philosophers influenced by the "linguistic turn." The linguistic

turn is often associated with "ordinary language philosophy" and with Wittgenstein's later philosophy, which stresses the ordinary use of words in "natural language" (Rorty 1967). Walter Benjamin was opposed to Saussure's ontological assumptions concerning the arbitrariness of the signifier.

late-life sexuality

Judith A. Levy

Considerable ambiguity surrounds both scientific and popular attempts to define the term "late life sexuality." Agreement as to when "late life" begins increasingly has moved upward over the last century with the lengthening of the average life course in most industrial societies. Meanwhile, the term "sexuality" has come to connote a wide variety of human sociobiological responses that range from varying levels of social attraction or physiological arousal to intimate body contact that may or may not include physical penetration. The failure of research scientists to define what they mean by "sexuality," "sexual behavior," or "late life" when designing studies or publishing their results complicates attempts to compare research findings within older age groups and across societies and sociocultural environments. Still, at least five themes emerge as constant premises in the literature concerning sexual desire and activity in later life as defined by some form of mental and/or physical sexual response at age 50 or older.

First, scientific evidence widely documents that sexual norms and behaviors differ by societies and culture, historical time, generational influences, group characteristics, and individual beliefs and preferences. In this regard, the sexual attitudes and behaviors of today's oldest Americans are believed to have been shaped by their having come of sexual age during an era when intimate relations were less openly discussed and less acceptably variable. Thus older people now in their late sixties and older generally are perceived to be more sexually conservative, less comfortable discussing sexual topics, and more prone to hiding sexual behavior defined as deviant than their younger US counterparts. Such judgments also are applied frequently to anyone seen as advancing toward middle or older age.

Second, the "sexual revolution" of the 1960s that redefined sexual mores for youth and young adults in western societies appears largely to have bypassed popular beliefs and stereotypes about sexuality in later life. Today's older adults, many of whom as youth in the 1960s helped to push the boundaries of acceptable sexual behavior, now find themselves part of a generation commonly believed to be disinterested in and/or incapable of sex. This view is reinforced by popular culture that often portrays sexuality in old age as humorous, fraught with frustration, and aesthetically distasteful to others.

Third, despite stereotypes to the contrary, general agreement exists among researchers and clinicians that sex and sexuality are a normal and valued part of human existence among adults at any age and that many older persons remain sexually active until they die. Some times compared in the literature to riding a bicycle, sex is seen as something that once learned is never forgotten and always remains potentially enjoyable. Scientific findings support this view through statistics drawn from studies documenting a wide range of sexual interest and activity occurring in later life. As with many aspects of human behavior, sexuality appears to follow lifelong patterns, with those individuals who were the more active in youth being the most active in old age.

Fourth, although desire for sexual gratification appears to continue typically throughout life, opportunity may not. Lack of a sexual

partner is the most commonly cited reason given for late life celibacy. Because they outnumber men demographically at age 65 and older, heterosexual women are more likely than their male counterparts to be without a partner (Deacon et al. 1995). Meanwhile, age norms that define mature adults as becoming less attractive and sexually desirable as they age tend to produce an ever shrinking pool of younger candidates as sex partners for older persons, irrespective of their sexual preference. Lack of a social and/or physical environment conducive for sex also affects both sexual partnering and self pleasuring opportunities. For example, older persons who live with their offspring or others may lack the private space needed for intimate behavior. For those living in a nursing home, staff attitudes and organizational policies often reflect negative judgments that hinder the expression of sexuality among residents.

Fifth, despite its potential for offering continued enjoyment, considerable evidence indicates that sexual behavior of all types occurs less frequently and differs physiologically with age from that of adolescence and earlier adulthood (Zeiss & Kasl Godley 2001). Among peri and post menopausal women, natural changes due to aging commonly include general atrophy and loss in elasticity of vaginal tissue, decreases in rate and amount of vaginal lubrication, lesser labial and clitoral engorgement during sexual arousal, decrease in estrogen levels with a corresponding shrinkage in the size of the cervix, uterus, and ovaries, and more dependence on androgens for sexual response. Common changes among aging men include a slower rate of sexual arousal, the need for greater genital stimulation to reach full erection, less firm tumescence, lengthening of the refractory period prior to a new erection, and less semen and urgency in ejaculation due to loss of prostate elasticity. None of these biological changes, however, necessarily reduces sexual enjoyment for either sex (Lauman et al. 2005). Challenges and barriers to sexual fulfillment in later life are far more likely to be linked to the person's earlier sexual history, general health, the possible effects of medication that reduce desire or inhibit sexual function, and psychosocial factors that support or discourage sexual thoughts and actions.

NEW OPPORTUNITIES AND PERILS FOR SEX IN LATER LIFE

The development and popularization within the last decade of the chemical compound known as "Viagra" (sildenafil) may well mark the start of a sexual revolution, rivaling that of the contraceptive "pill" of the 1960s, with enormous opportunities and consequences for late life sex (Loe 2004). With public figures appearing in the mass media extolling the benefits of the drug in treating male erectile dysfunction, sex among older adults has become more publicly visible and possibly better accepted by Americans of all ages. Both older women and men have become the focus of scientific, marketing, and media attempts to gauge how they view, use, and physiologically respond to its effects. Such scrutiny clearly documents Viagra's pharmacological success in treating erectile dysfunction, allowing an unknown number of men who otherwise experience difficulties to attain and maintain a penile erection sufficient for satisfactory sexual performance.

This biological achievement is not without social consequences. To assure maximal effects, sexual performance achieved through pharmaceuticals also requires advanced decision making and precalculations in timing that militate against sexual spontaneity. The use of Viagra and similar compounds (verdenafil, tadalafil) also has generated a plethora of comic monologues and media humor featuring the sex lives of older persons as the butt of the joke. Also, not all sexual partners of men experiencing renewed sexual capacity report welcoming this change. An unknown number of women and possibly men who are the sexual partners of aging males appear satisfied with or prefer reduced sexual activity as they or their partners age. In addition, the use and abuse of sexually enhancing pharmaceuticals has crossed generational borders as an increasing number of younger men avail themselves of their effects to facilitate or prolong sexual intercourse or to enhance orgasms. The promise of "better sex through chemistry," using pharmaceutical enhancements obtained through medical prescription, the Internet, or illicit sources, has called into question previous assumptions about what is sexually "normal" at any age.

While Viagra, Cialis, and other similar substances have enhanced or restored the sexual

lives of many aging males, older women have had less pharmaceutical success in treating age related female sexual dysfunction. Clinicians commonly use variations of the term "hypoactive sexual desire disorder" to define persistent reduction or loss of sexual fantasies, a condition often associated with lower hormonal levels of androgens and estrogen with age. In addition to affecting libido, estrogen decline can reduce vaginal lubrication during sexual arousal and result in painful intercourse when vaginal walls become excessively thin. Hormone replacement therapy (HRT), even when begun after age 60, can retard or reverse such vaginal changes to some extent, but not without health risk. While testosterone replacement can increase libido in aging women, little is known of proper dosage and potential adverse side effects include masculinization with acne and excess body hair, scalp hair loss, deepening of the voice, and enlargement of the clitoris. Meanwhile, the search for a female Viagra has proved elusive despite considerable efforts by pharmaceutical companies to develop and test a range of clitoral therapy devices, vasoactive agents, and steroids. Their quest has added fuel to feminist and others' concerns that the framing of women's sexuality has become medicalized to the exclusion of other key social and cognitive factors (Kaschak & Tiefer 2001).

The Internet has emerged over the last two decades as a second technological innovation with enormous potential for transforming the sex lives of many older adults. As with their younger counterparts, an increasing number of individuals over age 50 seek friendship, romance, and opportunities for sexual interaction through websites and personal advertisements posted on the Internet (Adams et al. 2003). A global network of users offers opportunities for courtship and sexual partnering that transcend local geographical boundaries and the limits of personal social networks. Unlike face to face introductions, older adults can initiate online relationships without age related physical declines being immediately apparent. Meanwhile, the Internet also supplies older adults with ready access to erotica, pornography, and online purchases of sex toys and adult rated books with out having to risk potentially embarrassing live encounters with sales clerks and other customers.

Increase in dating opportunities among older adults is not without worries. Although considered clinically safe for older males when used under physician supervision, some men experience undesirable side effects with Viagra or Cialis that force a choice between safeguarding health or enjoying better sex. Similarly, while HRT can ease menopausal changes that can inhibit sexual drive and activity among older women, increasing evidence suggests that its use heightens women's risk for breast and endometrial cancer. Meanwhile, as is true of all adults, people over age 50 who engage in sexual behavior outside of a monogamous relationship increasingly confront the dangers of acquiring sexually transmitted diseases including HIV/AIDS. CDC statistics reported by Karin Mack and Marcia Ory in a special issue of *J AIDS* devoted to AIDS and aging reveal that adults over age 50 account for about 10 percent of newly diagnosed cases of AIDS annually in the US. Over the next decade, the number of older persons living with HIV/AIDS is expected to rise substantially as treatment success of highly active antiretroviral therapy (HAART) prolongs the lives of people of all ages living with HIV. Increased prevalence of the virus among people over age 50 undoubtedly in some way will affect how this population views the use of condoms, sexual partnering, and sexual behavior in general.

latent growth curve models

Oliver Christ and Elmar Schlueter

Longitudinal methods permit the systematic study of stability and change over time and thus are a powerful tool for examining processes underlying social phenomena and the causal relation between different constructs. There are many different statistical methods to analyze longitudinal data (for an overview, see Crowder & Hand 1996; Menard 2002). Most of these techniques are related to applications of the general linear model to continuously distributed repeated measures (e.g., repeated *t* tests, ANOVA, multiple regressions, autoregressive models). A major shortcoming of these methods is that they are fixed effects models assuming that there are no interindividual differences in change. One prominent and powerful method to overcome this shortcoming are latent growth curve models (LGMs; synonymous terms used in literature are "latent curve models" or "latent trajectory models") as one variant of structural equation modeling (Bollen & Curran 2006). With LGM it is possible to analyze individual trajectories and related processes of change over

time. Meredith and Tisak (1990) first proposed LGM based on the seminal work of Tucker and Rao in 1958. LGMs are based on the assumption that a set of observed repeated measures taken on a given individual over time can be used to estimate an unobserved underlying trajectory. This assumption can be formally expressed as

$$y_{it} = \alpha_i + \lambda_{it}\beta_i + \varepsilon_{it}.$$

y_{it} are the measured variables of time t which are explained by two latent factors (α_i and β_i) in the measurement model. α_i models the initial level in the measured variable (intercept factor), whereas β_i expresses the linear growth rate (slope factor). ε_{it} is the random error. The subscript i indicates that both the latent intercept and the latent slope factor are allowed to vary across individuals. These individual intercept and slope components of growth can be expressed by the following function specifying group and individual influences:

$$\alpha_i = \mu_\alpha + \zeta_{\alpha i}.$$

$$\beta_i = \mu_\beta + \zeta_{\beta i}.$$

Both latent factors, α_i and β_i , are defined by their means (μ_α and μ_β) and their residuals ($\zeta_{\alpha i}$ and $\zeta_{\beta i}$) in the structural equations. Since there are no exogenous variables specified, $\zeta_{\alpha i}$ and $\zeta_{\beta i}$ can be interpreted as the deviations from the group mean of the intercept and the slope

factor. A prerequisite of LGM is that the measurement model is constant over time, otherwise growth cannot be meaningfully modeled by LGM.

In Figure 1 a simple unconditional LGM is presented with three repeated measures assessed at equal intervals. "Unconditional" means that both latent factors are not affected by other variables (see below). Factor loadings on the intercept factor are set to 1 and the three factor loadings on the slope factor equal $\lambda_t = t - 1$, where t is 1, 2, 3. Thereby, the slope factor is constrained to a linear growth. In this example, the intercept reflects the model implied value of the outcome measure at the initial period of measurement because factor loading on the slope factor for the first measure was set to zero and factor loadings on the intercept factor are constrained to one. It is also possible to use alternative codings of time to define other meanings of the intercept term. In the case of an unconditional LGM with three measures, eight parameters have to be estimated from the data. The model is just over identified ($df = 1$), since the empirical covariance matrix has six and the mean vector has three elements.

In LGM, besides linear growth, nonlinear trajectories can also be modeled. In linear LGM, change over time is constant over all points in time. That means a one unit change in time is associated with a μ_β unit change in the outcome. This relation is constant for all equally spaced assessments, but can vary in the

Figure 1 Unconditional linear latent growth curve model for three repeated measures.

nonlinear case. In some cases it is theoretically plausible to assume nonlinear growth instead of linear changes. One possibility to test such relations is to use a quadratic function. Whereas the linear LGM has only one intercept and one slope factor, the quadratic LGM includes a third latent factor to capture any curvature that might be present in the individual trajectories. The quadratic model implies differential change in the measured variable between equally spaced time assessments. For example, change in a construct can be large at the beginning, but constantly becomes smaller in the further course of time. Alternatives to quadratic trajectories are exponential trajectories which are not time bound and as such are often more plausible for describing change in constructs. Du Toit and Cudeck developed techniques to implement exponential functions into the LGM framework. All trajectories, presented so far define a specific growth function that relates the repeated measures to the passage of time. Sometimes such assumptions are too restrictive and do not cover the pattern of change in an optimal way. An alternative is the free estimation of a part of the factor loadings of the repeated measures on the slope factor (Meredith & Tisak 1990). For example, in the case of three repeated measures, the loading of the last measure on the slope factor can be freely estimated to get a better adjustment of the trajectory on the observed data.

Besides the question of the functional form of the trajectory, it is often of interest to identify variables which affect the development of constructs. The LGM can be easily extended by including exogenous predictor variables (Willett & Sayer 1994). In these models it is examined in such a way that the intercept and the slope of a repeated measure are affected by time invariant predictors.

A further extension of the LGM is the inclusion of time variant repeated measures. Such multivariate LGMs take into account the change of several repeated measures simultaneously. Besides the consideration of several time variant repeated measures it is also of interest to consider time specific relations of the repeated measures within or between constructs. The autoregressive latent trajectory model (ALT) developed by Bollen and Curran (2004) connects LGM with autoregressive

models and allows, in addition to the analysis of random trajectories, the examination of autoregressive relations within constructs, as well as cross lagged relations between constructs.

Further possibilities to extend LGM include the examination of moderational and mediational hypotheses, as well as the use of multiple indicator latent factors. Mediation is indicated when the effect of a predictor on the intercept or slope of a time variant repeated measure is explained by a further time invariant predictor. In the case of two time invariant predictors as described before, normal methods to test mediation can be used. If predictors and mediators are also time variant, mediational analysis is much more complex (see Bollen & Curran 2006). In many cases it is of interest to proof moderating effects of variables in the change of a construct. There are two general types of analysis techniques to examine such moderational effects. In one case, the interaction term of two exogenous predictors can be included in an LGM analysis. A moderational effect is indicated by a significant effect of the interaction term on the two latent growth factors. Alternatively, multigroup analysis can be used to test for moderation. Here, specific parameters can be compared between two or more subgroups of a sample. Significant differences in parameters of the LGM indicate moderational effects of the moderating variable which was chosen to divide the sample into subgroups (e.g., age, sex). By using multiple indicator latent factors it is possible to control for measurement error. In the case of LGMs with multiple indicator latent factors, the growth in the latent factors is estimated, not in the measured variables.

As with all applications of structural equation modeling, LGM allows us to analyze missing data using powerful methods to impute missing data like multiple imputation or full information maximum likelihood (FIML). In addition, it is also possible to calculate LGM even when the normal distribution assumption is violated, which is often the case in social science (Bollen & Curran 2006).

Figure 2 illustrates a conditional growth curve model for anomia – defined as a state of mind expressed by individuals living under societal conditions of anomie – over a three year period ($N = 825$) based on data from an

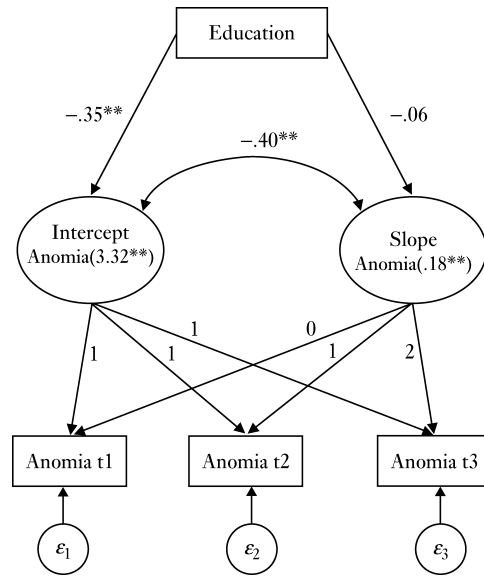

Figure 2 Conditional latent growth curve model for anomia over a three-year period with education as an exogenous predictor variable.

Notes: Anomia t1 Anomia at wave 1; Anomia t2 anomia at wave 2; Anomia t3 Anomia at wave 3; ** $p < .001$.

ongoing panel survey of the German general population. In this example, education is used as a time invariant predictor variable.

For the latent intercept indicating respondents' initial level of anomia, a significant mean value of 3.23 ($p < .001$) is estimated. The significant variance of the mean value equals .56 ($p < .001$), suggesting that there is substantial variability in respondents' average levels of anomia at time one.

For the latent slope, the data reveal a significant mean value of = .18 ($p < .001$). According to this finding, respondents' level of anomia increases on average .18 units for every measurement one year apart. Further, the data reveal a significant parameter estimate for the variance of the latent slope (.09, $p < .001$). Therefore, it can be concluded that there is considerable variability in the respondents' latent trajectories for anomia over the period under study.

The significant negative correlation of $r = -.40$ ($p < .001$) between the latent intercept and slope factors indicates that the higher respondents' initial level of anomia, the lower the change over time.

Next, we examine possible effects of education on the latent intercept and latent slope of anomia. For the latent intercept, the significant parameter estimate of education is $\beta = -.35$ ($p < .001$). Substantially, this suggests that individuals with higher education show significantly lower initial levels of anomia. However, according to the results, education exerts no significant effect on the latent slope of anomia ($\beta = -.06$, *ns*). That means change in anomia is independent from respondents' level of education.

LGM is a powerful method for longitudinal analyses. It allows social science researchers to examine many different theoretical questions of change. LGMs can easily be extended by using multiple indicator latent factors to model measurement error, integrating predictors of change as well as mediators and testing moderating influences of measures. But there are of course a number of limitations of latent growth curve modeling. A minimum of three repeated measures is needed. Still problematic is the handling of missing data and deviations from normal distributions, although there are powerful techniques to take these problems

into account, such as FIML in the case of missing data and robust maximum likelihood in the case of deviances from normal distribution (for more details, see Bollen & Curran 2006). But the most critical factor for LGM and all other statistical methods is the underlying theory which guides the statistical analyses.

later-life marriage

Liat Kulik

With the aging of the population and increased life expectancy in western societies, there has been growing research interest in the period of late adulthood, which can span several decades. That life stage is characterized by three major events that can affect the individual as well as the marital unit: decline in health, retirement

from work, and entry into the role of grand parent or sometimes even great grandparent. The following main aspects of the dyadic unit are emphasized here in light of their relevance to late adulthood: caregiving, satisfaction with marriage and quality of marital life, power relations, and the division of household tasks.

CAREGIVING

In late adulthood, caregiving involves a considerable investment of time and energy by spouses, who are usually the main caregivers. Some couples report that the caregiving role increases their sense of commitment, closeness, and love. Husbands usually approach caregiving as a project and are comfortable delegating tasks, whereas caregiving wives usually give more direct assistance in the form of ADLs (activities of daily living) and IADLs (instrumental activities of daily living) (Miller 1990). Caregiving wives usually look for activities that will involve their spouses, and are concerned with providing for their spouses' needs, whereas caregiving husbands usually prefer to do things on their own. In addition, wives are more negatively affected than their husbands by caregiving. For example, Miller (1990) found that caregiving wives have less access to social support, although they do not differ from their husbands with regard to emotional strain. Other researchers indicate that caregiving wives feel burnout, because the responsibilities of providing care may cause them to feel trapped at a time when they should be free. By contrast, caregiving husbands may feel less burnout because they are more likely to supplement the care for their wives with formal services. It has also been argued that husbands are better able than wives to cope with problems in the marital relationship and maintain an emotional distance (for a review, see Walker 1999).

SATISFACTION WITH MARRIAGE AND QUALITY OF MARITAL LIFE

In general, researchers have found that most older people report happy marriages, and attribute this perception to the selective examination of couples whose marriage did not end in divorce (for a review, see Huyck 1995).

Cross sectional studies of older people have revealed that, compared with younger populations, older couples report fewer marital problems, although there is a decline in positive interaction compared with earlier stages of marriage. As for gender differences, husbands typically report higher marital satisfaction than do wives (Walker 1999). In this connection, qualitative studies suggest that husbands tend to idealize the situation and deny existing tensions, whereas wives tend to recognize problems and initiate changes as the children start leaving home. Wives who have been married for 20 years indicate that resolving disagreements becomes more difficult (Vaillant & Vaillant 1993), and tend to report lower marital adjustment over time, whereas husbands tend to report a greater decline in sexual satisfaction. Among elderly couples, wives are more likely to consider separating than husbands. Elderly wives are also less likely than their husbands to name their spouse as their main confidant, although both elderly partners consider their spouse as a companion. Kulik (2001) found fluctuations in marital satisfaction at different stages of the retirement process. In the remote pre retirement stage (about seven years before retirement), couples express more emotions (tension and marital enjoyment) than in the near pre retirement and post retirement stages. Kulik also found that levels of burnout, i.e., feeling tired of the marriage or feeling trapped in late adulthood, are much lower than in earlier stages of marriage, and that when marital relations are egalitarian, both spouses feel less burnout in marital life.

POWER RELATIONS

Few studies have focused on marital power relations, and even fewer have dealt with the topic in late adulthood. In their well known study *Husbands and Wives* (1960), Blood and Wolfe found that a husband's power increases from the time the first child is born until the youngest child enters school. Afterwards there is a steady decline in the husband's power, which reaches a particularly low point when the oldest child leaves home. The husband's power continues to decline after retirement, when he loses some of the resources that he had while he was working.

Recently, Kulik found that throughout the retirement process (remote pre retirement, near pre retirement, and after retirement), men show a greater tendency than women to report an advantage in the areas of major decisions (e.g., budget). With respect to domestic power (decisions about household matters), women have reported an advantage, although no gender based differences were found regarding decisions about such issues as time use. Moreover, attempts have been made to analyze power relations in late adulthood as a function of occupational status and timing of retirement among couples. For example, a comparative study of synchronous couples (both spouses retired or employed) and asynchronous couples (one spouse retired and the other employed) revealed that all types of couples tend to have relatively egalitarian power relations, as expressed in decision making in all areas of life (Kulik 2001).

DIVISION OF HOUSEHOLD TASKS

According to family development perspectives, role differentiation declines in the late stage of family life, when work obligations and the demands of childrearing diminish. However, findings are inconclusive and inconsistent. Some studies have found that after retirement most couples continue the traditional patterns, which are characterized by a clear differentiation between gender roles. According to this perspective, men continue to perform typically masculine tasks such as household repairs and gardening, and even increase their involvement in those activities (Vinick & Ekerdt 1991), whereas women maintain traditional feminine roles such as cooking, cleaning, and laundry. In a similar vein, researchers have found that retired men with employed wives do not seek to increase their involvement in household tasks, and that certain women even increase their involvement in household tasks after retirement (Szinovacz & Harpster 1994). In contrast to these findings, which indicate that traditional gender roles persist after retirement, other studies have revealed that gender role differences diminish (for a review, see Atchley 1992). Additionally, some studies have found that the husband's participation in typically feminine household tasks increases after retirement. Kulik

(2001) found that the division of feminine tasks such as cooking, cleaning, and ironing, as well as general tasks such as paying bills and purchasing household commodities, is usually more egalitarian among synchronous retired couples than among synchronous pre retired couples. The division of feminine tasks was relatively egalitarian among asynchronous couples (retired husbands/employed wives). However, no differences were found between different types of couples with respect to masculine tasks such as household repairs, which are almost always carried out by men.

As for future research, with the increase in life expectancy in western societies and the growing population of elderly couples over the age of 80, it would be worthwhile to focus studies on that age group. Additionally, because most studies on later life marriage are cross sectional, longitudinal studies that follow the development of marital relations in late adulthood among the same group of couples would be very useful.

Latinidad and consumer culture

Lisa Peñaloza

Latinidad, most literally, is the identity of Latinos/as. More figuratively, it is a sensibility and way of being in the world that expresses who one is and what one's culture is about. This quality emanates from a community of very diverse people and is used by them to relate to one another, drawing from their similarities, even as they contest it based on their differences. Born at the multiple intersections of Native American peoples, Europeans, and blacks, it connotes an amalgam of ritual traditions and values – *amor, familia, respeto, compromisos, pasión*; that is, love, family, respect, accomplishment, and a passion for living – at once very real, yet imagined, dynamic and organic. The geographical coordinates of its diaspora are no less complex, in pertaining to those of Latin American ancestry in the US and in Central and South American nations, the Caribbean, Spain, and, to a lesser degree, southern Italy and France. Like other social phenomena, it is individually and collectively engineered and reproduced; internally by Latinos/as, and externally, as attributed to us by non Latinos/as. When linked to consumer culture, the body of work

has sparse but long roots, and has gained in abundance and currency with the rapid growth of the people.

Terminology continues to be a challenge, for Latinos/as in identifying ourselves and distinguishing among our various subgroups, and for non Latinos/as in referring to us. Issues of race, geography, nationality, social class, generation, politicization, language, and colloquial usage context complicate its meaning and use, as does variation in the strength of affiliation of members to the group as a whole and to the various subgroups, and dramatic sociodemographic shifts, particularly geographical mobility and the increased incidence of mixed ethnic background. A major distinction lies between those from the US, where Latinos/as are a minority, and those from the many other nations where Latinos/as constitute the main stream. In the US, subgroups of different historical trajectories and sociocultural characteristics impact Latinidad. Here, traces of regional concentrations remain such that Mexicans and Mexican Americans live predominantly in the US Southwest; Cubans and Cuban Americans in Florida; and Puerto Ricans in New York. However, the cultural character of each of the regions has changed dramatically since the 1980s due to interstate migration and immigration from other Central and South American countries and the Caribbean.

As with other groups of people and fields of ideas examined within the sociology of science, studies of Latinidad and consumer culture have changed as each generation of scholars grapples with the issues of its time. Socially, gains made by Latinos/as in the US in the 1970s and 1980s in political representation, legislation for equal rights, census inclusion, and more accurate counting were followed by affirmative action programs in government and in business, academic studies programs in universities, and attention as a consumer market through the early 1990s to the present. Buoyed by increased numbers and buying power, Latinos/as in the US have come to enjoy a much heralded popularity in media representation, political canvassing, job recruitment, and market targeting. Yet while those comprising the middle class experienced dramatic gains in income in the 1990s, the majority continues to lag socioeconomically, with overall indicators remaining well below

those of their white counterparts. In contrast, the social context of Latinidad in Latin American and Caribbean nations is marked by the challenges of socioeconomic development, post colonial relations, alliances with other Latin American and Caribbean nations and nations in Europe and Asia, internal political differences, and the struggles of indigenous peoples.

Academic studies in the US have come a long way since the early demands for Chicano and Puerto Rican studies programs in universities as part of El Movimiento, the Civil Rights Movements in the 1960s and 1970s. Early work such as Ernesto Galarza's *Merchants of Labor* (1964) and Rodolfo Acuña's *Occupied America* (1988) display a mix of academic and social activist research, as scholars worked to educate and remedy the violence, exclusions, and discrimination of postcolonization. The early, androcentric work of Latino scholars was soon joined by their Latina counterparts, as exemplified by Gloria Anzaldúa and Cherrie Moraga's classic edited volume, *This Bridge Called My Back: Writings by Radical Women of Color* (1981). This book, and many that would follow (e.g., Carla Trujillo's *Living Chicana Theory*, 1998; Richard Delgado and Jean Stefanie's *Critical White Studies*, 1997), are not pegged to Latinos/as alone, and have stimulated and challenged Latino/a and non Latino/a scholars alike to incorporate and attempt to better understand the simultaneous social impacts of ethnicity, race, gender, sexuality, class, and the market on social phenomena, and the differential effects experienced by various subgroups.

A mix of activism, literature, and research characterizes the history of Latino/a consumer culture. Activists have operated on the terrain of consumer culture in the US for decades; an early example is their challenge to the racial stereotyping of the cartoon character, the Frito Bandito, in Frito Lay advertisements in the 1960s. They protested against the marketing of cigarettes and alcohol in Latino/a neighborhoods in the 1980s. Priests called for spending curbs on lavish *quinceañera* celebrations (young 15 year old women's coming of age parties), and actors and community activists fought for more Latino/a roles and more Latinos/as playing Latino/a characters in film and on TV through the 1990s. More recently, Internet blogs were used successfully to stop offensive

insinuations of Latina sexuality in Tecate Beer promotions in 2004. In Latin America, consumer culture peppers the literature, from indictments of US imperialism and multinational capitalism in the poems of José Martí and Pablo Neruda; the pedagogical essays of Ariel Dorfman articulating a critical approach to such pop cultural characters as Donald Duck and Babar the elephant; to the intricate literary and political analyses of Carlos Fuentes.

Academically, theoretical and empirical studies of Latino/a consumer culture have flourished since the 1980s on such topics as postcolonial identity and cultural adaptation, physical and mental health care, community development, media representations and ownership, and globalization. Critical literary studies are arguably the most prevalent, with early scholars such as Américo Paredes, Ana Castillo, and Rina Ben mayor, joined more recently by Norma Alarcón and Ramon Saldivar in directing attention to the contributions of Latino/a authors, poets, and musicians, both historical and contemporary, and challenging theoretical conventions by which such work is evaluated.

Dimensions of *Latinidad* and consumer culture reflect the multiple disciplines comprising its study and the diversity of the people. Geographical considerations, national and subcultural background, language, socioeconomic class, political orientation, generation, disciplinary structure, and theoretical perspective are discernable across a wide array of topics. Areas of study include border studies, colonialization and post colonialism, labor organization and exploitation, immigration patterns, family life and socialization, language acquisition, bilingual education, and political representation. The work has changed dramatically over time, even as it is marked by continuities. Initially oriented by the cultural background and disciplinary training of its major scholars, the body of work has expanded toward the full realm of the social sciences and humanities. Scholars such as David Montejano, Henry Triandis, Amado Padilla, Rodney Hero, José Limón, Fernando Peñalosa, Alfredo Mirandé, Vickie Ruiz, Enrique Trueba, Doug Foley, Elizabeth Fox, Anghy Valdivia, and Lisa Peñaloza, to name a few, have focused on replacing pejorative accounts of Latinos/as based on naïve comparisons with the Anglo mainstream,

in books and the journals of their disciplines – history, psychology, political science, anthropology, sociology, education, communication, and marketing. Economics is the most recent addition to the fold. Works by George Borges and Marta Tienda, Silvia Pedraza Baily, and Bárbara Robles investigate cultural patterns affecting community economic development in the US, while Hernando De Soto examines such issues in Latin America.

Current emphases of this body of work stem from the many paradoxes and contradictions of consumer culture, together with unique qualities related to particular mainstream/margin cultural dynamics. First, agency in reproducing one's identity and one's culture is a key concern. It is important to consider the power dynamics in who is consuming whose culture, as signs and values drawn from the ritual holidays and everyday life of Latinos/as are packed into consumer objects and activities associated with Latino/a culture for consumption by Latinos/as and non Latinos/as. The general availability and widespread use of the piñata for children's birthday parties is one example. Consumer culture is empowering, in that Latinos/as support a big part of their consumer culture in buying the accouterments, products, and services they employ in being Latino/a. However, in a key displacement of power, a formative influence stems from the ways Latino/a consumer culture is subject to the whims of non Latino/a consumers in cultural crossovers and tourism.

Second is the paradox of market legitimization. That is, being a market brings a type of social legitimacy, yet it is not without its limitations. Simply put, it is easier to be Latino/a now than ever before. Yet this legitimacy comes at a price, for not all aspects and dimensions of this diverse identity and culture are recognized, reproduced, and thus valued in the market. This is a major concern among Latinos/as and community organizations, for it requires much work to redirect attention to qualities more vital to the community, but much less marketable. In a second key displacement of power, marketers play an important role in reproducing Latino/a culture in the marketplace, for consumption by Latinos/as and non Latinos/as. What often follows is that the most different and threatening among Latino/a elements are elevated in

cultural stereotypes, even as marketers emphasize the most assimilated and the less threatening qualities in their efforts to target Latinos/as.

Third, in addition to examining non Latino/a–Latino/a dynamics, it is crucial to examine relations of power among Latinos/as. That is, an important part of the development of Latino/a consumer culture occurs as cultural members with knowledge of Latino/a culture educate Latino/a and non Latino/a owned consumer products companies, as Dávila notes in *Latinos, Inc.* (2001). Of importance here is examining the ways Latinos/as work to reproduce Latino/a identity in such consumer cultural institutions as the media and advertising (Peñaloza, *Media Studies Journal*, 1995).

In short, basic to Latinidad and consumer culture is a conflation of region, nationality, class, and political leanings that are not easily sorted out, and from which stem important methodological implications. A key concern in this body of work is incorporating fundamental precepts of social justice into our disciplines, as Sandoval, San Juan, Jr., and Pérez encourage, in examining the ways such ideals as democratic representation, opportunity, and community development are compromised in capitalist socioeconomic systems in the US and Latin American nations. These works employ self reflexivity and social engagement, while attending to a diversity of positions and perspectives. As such, additional challenges relate to the complexities of agency and subjectivity, for both researchers and those whom they study. Identity dynamics remain a challenge in attending to relations of power between many levels of mainstream and marginal subgroups, while retaining a critical perspective in attending to the full range of their intragroup impacts. Other methodological challenges relate to scope and scale, as important inroads are being made in attending to the dynamics of globalization, while not losing sight of the contours of localized struggles.

Regarding future directions in research and scholarship, while the work is likely to continue to examine persistent traditions and change in the competing pulls of family, culture, and society, it shows tendencies of moving beyond who we are as a people and how we are represented in the market, toward exploring fundamental contradictions between democracy and capitalism. Important inroads are to be made in

linking across the various groups in the US and in other nations, and not getting derailed by the many differences, while acknowledging their substance and significance. Further advances are to be made by globalizing our studies, and comparing the experiences of Latinos/as in the US to those in Latin America and other nations of the Latino/a diaspora. Ultimately, much work is to be done to better understand dimensions of race, class, and gender as they impact cultural inclusion and exclusion, of identity and community development, and institutional and government treatment as played out in the terrain of consumer culture.

law, civil

Stephen E. Brown

Civil law entails two distinct categories of meaning. It is used to reference Romano Germanic law, one of four broad forms of legal systems that presently are most practiced throughout the world. In this context, civil law is best understood in juxtaposition to common (Anglo Saxon), religious (e.g., Islamic), and socialist law. Civil law systems are most widespread in the world. Their most central feature is the codification of law, an approach historically linked to the Justinian Code of ancient Rome, and that became characteristic of continental Europe.

The second fundamental connotation of civil law relates to the division of some legal systems into segments that address what are construed as distinct types or categories of legal problems. Such division is not universal, but reflects a larger philosophy of law, the authority underlying it, and the goals of social control. Islamic law, for example, does not distinguish civil matters from criminal. Instead, all behaviors are morally assessed from the framework of the Koran and the *Sharia*, identifying the word of God regarding how humans are to behave. Under this system the view is that law comes from God and cannot be compromised. Both Romano Germanic and common law traditions, however, view the state as having a vested interest in and authority over public issues such as crimes (which are offenses against the state or community at large), but not in regard to private disputes. The latter fall in the realm of civil law. In this vein, then, civil law refers to the segment of legal systems that addresses grievances between individual citizens, as opposed to conflicts that are theoretically between the state and individual citizens.

All law serves as a form of social control in the sense that it manages social conflict. All forms of law are also shaped by social forces. These points probably are most widely appreciated in the context of criminal law, but apply equally to civil law. Moreover, the way that laws control and are shaped have greater bearing on the civil realm because these cases impact far more people. Civil law governs social obligations across a vast array of human activity. It governs the nature and parameters of family relations such as marriage, divorce, child custody, adoption, provision of medical treatment to family members, and innumerable other domestic issues. Civil law governs privileges such as licensure to operate vehicles, to engage in certain occupations, to participate in sporting activities, the pursuit of education, eligibility for many financial benefits, ownership of property, and all other realms of human endeavor. It also provides the framework for determining which individuals have been wronged and how the damages are to be rectified. In short, civil law provides the rules and procedures for resolving conflicts between individuals over any and all matters within a society.

Civil or private law, as opposed to public law, is structured differently because it is presumed that public law is pitting individuals against a more powerful state. Within civil law the defendant is not accorded nearly as much protection because it is presumed that there is not such a dramatic power imbalance between the two sides to the conflict. Moreover, the state is empowered to take life or liberty, sanctions unavailable in private disputes. A single event, however, may have the potential to be jointly addressed by civil law (a plaintiff sues for civil damages) and criminal law (the state pursues criminal charges). Nevertheless, because it is so far reaching, civil law dramatically shapes the nature and quality of social life.

law, criminal

Victoria Time

Criminal law is a body of law that defines and grades crimes, and indicates corresponding punishments. These definitions and punishments are found in statutes and in criminal codes within each state, and within each country. Due to the dual system of government that obtains in the US, the federal government has its own criminal code different from that of the various states.

Besides defining and stipulating sanctions, criminal law also explains constitutional limits on the power of government in enforcing criminal laws. It explains general principles of criminal liability and discusses parties to a crime, as well as defenses to criminal responsibility.

In the US, criminal law differs from civil law in that the latter (also referred to as private law) regulates private rights and remedies. Further, while a higher burden is required to prove guilt in criminal cases (beyond a reasonable doubt), liability in civil cases is proven based on a preponderance of the evidence. The penalties for criminal violations range from jail time and any intermediate sanction to death, while those in civil cases are limited to damages and injunctions. Some crimes, such as assault and battery, may be prosecuted in both a criminal court and a civil court. The prosecutor, on behalf of the state or the federal government, brings charges against defendants in criminal cases, while the victim or friends and family as plaintiffs file charges against defendants in civil cases.

OBJECTIVES AND CHARACTERISTICS OF CRIMINAL LAW

The primary purpose of criminal law is to regulate people's behavior in efforts to curb crime.

In this regard, delineating behavior which is criminal is necessary, and punishing wrong doers is vital. In compliance with the rule of law, also known as the principle of legality, one can be punished only if there is a law that expressly defines conduct as criminal, and prescribes a fitting punishment for that conduct. Hence, if there is no crime, there can be no punishment. Criminal law attempts to achieve several goals, including deterrence, retribution, incapacitation, rehabilitation, and restitution. The following are characteristics of criminal law:

- It states behavior that people must comply with and those from which people must refrain.
- These stipulations are put into law by appropriate authorities.
- Violations of these stipulations result in punishments.
- Everyone in that jurisdiction is subject to the law.
- Not only the victim is affected by a crime; the community at large becomes a symbolic victim.
- Punishments against perpetrators signify a collective will of the people.

SOURCES OF CRIMINAL LAW

The following provide the various sources of law in the US.

US Constitution

Even though the US Constitution focuses on procedural law in the Bill of Rights, it touches on criminal law in that it defines the crime of treason in Article 3.III.

US Criminal Code

The US code embodies federal crimes defined by Congress. These crimes, which include illegal possession of drugs and weapons, as well as crimes perpetrated against the US, its employees, and property, are prosecuted in federal courts.

State Constitutions

As the most dominant source of law in a state, state constitutions embody laws that define the parameters of the powers of the various agents that work within the criminal justice system. Further, it incorporates precepts of criminal law.

State Criminal Codes

State defined crimes are largely a heritage of common law. However, where necessary, each state has modified common law definitions of crimes as well as punishments in ways that reflect changing times, as well as the unique circumstances of the state.

Common Law of England

Initially, common law of England comprised unwritten customs and regulations which were interpreted and enforced differently throughout England. In efforts to create some uniformity in the interpretation and enforcement of the law, William the Conqueror requested that the various customs and regulations be codified, and applied in similar fashion throughout England. These written customs and regulations became known as common law. In order to maintain some semblance in the ways cases with similar facts were decided, judges felt compelled to follow precedent. The principle of *stare decisis* which mandated judges to follow precedent was developed.

When the founding fathers migrated to the US they brought many of these English laws and practices and incorporated them into the legal systems. Today, some common law definitions of crimes, as well as practices, still exist, while others have been modified or stricken out.

Judicial Decisions

Appellate court judges (the US Supreme Court Justices are the highest) make law through judicial rulings. Usually, they follow precedent when cases have similar facts. When there are substantive differences, judges distinguish the

cases and provide a rationale for their new decision.

Local and Municipal Ordinances

It is not uncommon to find ordinances that are endemic to a particular municipality. Based on their unique economic and social factors, each jurisdiction defines crimes and infractions, and stipulates punishments for behavior that contravenes aspects of those factors.

Administrative Law

Although administrative laws mostly generate civil litigation, violation of some may sometimes give rise to criminal litigation. For example, the administrative agency for Alcohol, Tobacco and Firearms requires that firearms be registered. Possession of an unregistered firearm may lead to criminal prosecution.

CLASSIFICATION OF CRIMES

Offenses are classified in various ways in order to determine an appropriate punishment. Worthy of note is the fact that classifications based on the type of punishment are not uniform among the states, since each state legislature draws limits on sentences.

Classification Based on Severity of Offense

A more popular way of classifying offenses is based on the degree of seriousness of the offense. Crimes are divided into three categories: felonies, misdemeanors, and infractions. Felonies are the most serious crimes, for which the punishment ranges from one year in prison to death. Death sentences are usually reserved for capital offenses such as treason and aggravated murder. In non death penalty states, a capital offense carries a punishment of life.

Misdemeanors are less serious offenses than felonies and their punishments are usually less than a year in jail. Some states differentiate gross misdemeanors from petty misdemeanors. Gross misdemeanors carry sanctions ranging from six months to one year. Infractions or violations such as traffic violations are the least

serious offenses, whose punishments are usually fines.

Felonies are tried in courts of general jurisdiction, while misdemeanors and infractions are tried in courts of limited jurisdiction.

Classification Based on Moral Turpitude

Offenses that are egregious (such as murder) are deemed *mala in se* or inherently wrong. Others (such as polygamy) are *mala prohibita* or acts made illegal by laws of a state or country.

Crimes can also be classified based on the subject matter. For instance, battery may be classified as a crime against a person, while treason and sedition may be classified as crimes against the state.

ELEMENTS OF A CRIME

In order to convict a defendant, a prosecutor has to prove the elements of a crime. Some times, it may not be necessary to prove all the elements. The elements are (1) the guilty or evil act (*actus reus*), (2) the guilty mind (*mens rea*) or the evil intent, (3) concurrence of the guilty act and mind, (4) attendant circumstances, or “facts surrounding an event” (Black 1990: 127), (5) causation, which may relate to cause in fact, that is, the act that creates the harmful result. Courts look at two types of causation in determining who should be held responsible for cause of death: (1) “but for” or *sine qua non* causation, and (2) legal causation, which relates to the proximate cause of a result when some intervening factor affected the chain of events from when an initial act was perpetrated until when death occurred.

PARTIES TO CRIMES

Criminal liability may attach for those who commit crimes, as well as those who aid and abet, assist, entice, or encourage criminal acts. The doctrine of complicity explains circumstances under which accomplices assume criminal responsibility based on the extent of their participation in a criminal venture. Common law grouped parties to a crime in four categories: accessories before the fact, principals in the

first, principals in the second, and accessories after the fact. Changes have been made over time to this classification. Participants to crimes are classified in modern statutes as (1) principals (those who carry out the crime), (2) accomplices (those who act before and during the commission of the crime, as for instance those who act as look outs) and (3) accessories after the fact (individuals who, knowing fully well that principals and accomplices have committed a crime, willingly provide them a safe haven, or provide them with any type of assistance in order to impede their arrest or prosecution). Accomplices and accessories can be punished even when the principal is still at large.

Culpability may also attach vicariously based on the relationship of the offender and a third party. For example, an employer may be held responsible for the crimes of an employee that fall within the scope of employment. A person may also be held liable under the doctrine of strict liability, even when the person did not have the requisite guilty mind, as long as some harm ensued from the person’s act.

TYPES OF CRIME

Some offenses are classified as anticipatory/inchoate or incomplete crimes. These offenses, in order of their seriousness, are attempt, conspiracy, and solicitation. Attempt is distinguished from mere preparation, in that attempt requires that “substantial steps” are taken towards the commission of a crime. Conspiracy requires an agreement between two or more persons to engage in illegal activities. Solicitation is a request or an inducement to someone to commit a crime.

With regard to other types of crimes, the list is lengthy. Some of the more common are (1) crimes against a person, which include murder, manslaughter, rape, assault, battery, and kidnapping; (2) property offenses, which include larceny, burglary, embezzlement, forgery, etc.; (3) crimes against public order and morality, which may include but are not limited to vagrancy, disorderly conduct, aggressive panhandling, and prostitution; (4) crimes against the administration of government, which include treason, perjury, obstruction of justice, etc.; and (5) crimes against a person as well as property, for example, robbery.

DEFENSES TO CRIMINAL LIABILITY

There are three broad categories of defenses to criminal liability: (1) alibi, which is raised by defendants who contend that they were some where else when the crime was committed; (2) defenses of justification, such as self defense, defense of home and property, defense of others, consent, necessity/choice of evils, and execution of public duty, which may be raised by defendants who accept responsibility for the crime but argue that based on the circumstances, their actions were justified; and (3) defenses of excuse, such as insanity, entrapment, intoxication, age, mistake, syndromes, etc., which may be raised by those who shift blame to something that to them precipitated the commission of the crime. Some of the syndromes that defendants have raised are Vietnam/Gulf War syndrome, premenstrual syndrome, and spousal abuse syndrome. When a syndrome defense is raised, the defendant contends that some abnormality brought about by unpleasant experiences triggered anti social behavior.

LIMITATIONS ON CRIMINAL LAW

Even though many legislative and judicial rulings affect criminal procedure, some of them set limitations on how criminal law can be enforced. Some limitations are (1) void for vagueness and overbreadth: laws that are not precise or those that are so broad as to encompass constitutionally protected rights cannot be enforced; (2) *ex post facto* laws: retroactive laws cannot be enforced if they punish acts which were committed before the laws were passed; neither can they increase the punishment nor the gravity of an offense; (3) cruel and unusual punishments such as those that are barbaric or those that are disproportionate to the crimes are forbidden; (4) free speech, which includes expressive conduct, may not be "abridged" except they constitute obscenity, profanity, fighting words, slander, libel, and expressions that may give rise to "clear and present danger"; and (5) due process and equal protection of the laws may not be denied anyone. Without a valid state interest that has to be articulated, courts will not enforce laws that are discriminatory.

SOME CHANGES IN CRIMINAL LAW OVER TIME

Changes over time are quite evident in the sanctions, definitions, and types of crimes. Most felonies at common law carried a death penalty sanction; today, the death penalty is mostly reserved for capital offenses and treason. The penalties for other felonies in recent times typically carry terms of incarceration, while punishments for misdemeanors range from fines to a year in jail in most states. Flogging, which is outlawed, and punishments which are disproportional to the crimes are considered cruel and unusual in contemporary times.

Besides changes in sanctions, definitions of offenses have also changed over time. Two examples are burglary and rape. The definition of burglary used to comprise the breaking and entering of a dwelling during the night with the intent to commit a felony. The current definition of burglary entails breaking, entering, and remaining in any structure at any time of day with the intent to commit a crime. Rape, which was considered to be an unwanted sexual offense by a man to a woman other than his wife, today in many states has a gender neutral definition. The elements of the crime of rape, particularly that of force, have in modern times been revised to include both intrinsic force (normal force) and extrinsic force (more force than normal). While non consent at common law required resistance by the victim, today, simply saying "no" suffices for non consent.

law, economy and

Robin Stryker

The law–economy relationship has been an important object of inquiry for sociologists. Classical theorists Durkheim and Weber promoted sociology as a discipline by offering theories of this relationship. Today, sociological research on law and the economy provides ideas and empirical evidence to help answer such key questions as: Where do firms and markets come from? How and why do they operate and evolve as they do? How do legislatures and courts shape inequalities of income and wealth? How do legislatures and courts affect the participation in paid labor markets, jobs, and earnings of people of different races, ethnic groups, religions, and genders?

Among classical theorists, Marx assumed “bourgeois” law would reflect and reinforce capitalist relations of production. At most law was an object of class conflict among factory owners and workers, but it was not a major causal force in its own right. Durkheim focused much attention on the law–economy relationship, making it central to his analyses of economic modernization. For Durkheim, shifts in law from punitive to restitutive legal principles and sanctions indicated changes in social bases of solidarity. Societies moved from solidarity rooted in similarity to that rooted in difference and complementarity, as a consequence of increased economic division of labor. In contrast to Durkheim and Marx, who viewed the nature of legal ideas, behavior, and institutions as consequence rather than cause of economic ideas, behavior, and institutions, Weber emphasized the conjoint, mutually reinforcing rise of a formal rational legal system and of capitalism in Western Europe. Weber’s ideas

have been especially influential in economic sociology and for contemporary perspectives on law and economy (Trevino 1996; Swedberg 2000; Stryker 2003; Edelman & Stryker 2004).

According to Weber, formal rational law provided legal rights and guarantees to parties in exchange, enhancing predictability and certainty in contractual relations. This increased the probability that promises were kept, promoting market exchange, which in turn promoted further changes in business and contract law. Though full blown capitalist economies were unlikely without legal enforcement of contracts, economic exchange and markets could exist without such enforcement. One among many sources of legal rationalization itself was separation of sacred and secular law going back to republican Rome’s practice of refusing to let priests interfere in daily life (Trevino 1996).

Similarly, legal concepts and tools of negotiability, agency, and the juristic or legal person probably were necessary for developing economic action and institutions with very high degrees of systematization, calculability, and predictability. Banknotes, checks, and bills of exchange are signed legal documents including unconditional promises to pay. As Trevino (1996) points out, because such negotiable instruments were not promoted until the seventh century, markets but not full blown capitalism could develop in ancient Rome. Finally, by making business organizations bearers of universal rights and duties, entitled to formal equal treatment under the law, the legal personhood concept provided a bridge between developing ideas of rule of law and rule oriented legality in the polity, and development and reproduction of capitalist ideologies, firms, and markets.

Contemporary treatments follow Weber in presuming that law operates both as an independent and dependent variable with respect to the economy (Edelman & Stryker 2004). With respect to centrality of law in the social construction of firms and markets, for example, Roy (1990) showed that anti trust policy contributed to a massive merger wave in the US at the turn of the twentieth century. Focusing on an 1897 Supreme Court decision that unexpectedly declared key provisions of the Interstate Commerce and Sherman Acts to be constitutional, Dobbin and Dowd (2000) showed how this decision triggered a chain of events leading

the railroad industry away from cartel forms of business organization to oligopoly enhancing friendly mergers. Not only did firm and market structures change, so too did business models of appropriate and efficient profit oriented behavior.

Business activity shapes the nature of law, as well as vice versa. For example, Fligstein and Stone Sweet (2002) showed that increased cross border trade within the European Community promoted more litigation of EC law, that the two together promoted more EC legislation, and that all three of these together promoted the founding of new EC oriented lobbying groups in Brussels. Here, firm economic behavior and concomitant legal and political behavior are transforming legal ideas, action, and institutions, creating a new EC level regulatory system and transforming a treaty based common market into a constitution based transnational legal system.

With respect to economic inequality, research shows how economic and social regulations, including legislation governing collective bargaining, health and safety, pensions, and equal employment opportunity, have reshaped the nature of the American workplace, transforming workplace governance, business hiring, firing and promotion procedures, and impacting labor market outcomes for women and minorities (Stryker 2003). As well, redistributive tax and social welfare legislation at the core of the welfare state ideal led to measurable reductions in income inequality in advanced industrial democracies, though these reductions were not of the magnitude that many anticipated (Lempert & Sanders 1986).

Conversely, Edelman et al. (1999) showed that courts take into account managers' business concepts and routines, including their business adapted interpretations of equal employment opportunity and affirmative action laws, when making formal adjudicative rulings on whether or not firms have violated equal employment laws. Thus, more "covert" day to day managerial interpretations diffusing across firms and economic sectors, as well as more "overt" business attempts to influence legal rules through litigation, often have dramatic effects on law enforcement, such that the impact of equality promoting legislation is minimal or even the converse of that intended (Yeager 1990; Stryker

2003; Edelman & Stryker 2004). Law and society scholars highlight such differences by contrasting "law on the books" with "law in action" (Trevino 1996; Stryker 2003; Edelman & Stryker 2004). The legal profession itself – in addition to advancing members' interests in creating and monopolizing markets for their services – also shapes the content of legal rules and the structure of legal institutions (Lempert & Sanders 1986; Dezalay & Garth 1996).

Consistent with many recent studies and findings, current sociological ideas about the law–economy relationship emphasize co evolution (Stryker 2003). Legal ideas, actions, and institutions reciprocally shape and are shaped by economic ideas, action, and institutions in intersecting institutional fields. An excellent example is provided by Dezalay and Garth (1996) in their study of the emergence of a transnational legal order of commercial business arbitration. This new legal field, which transforms international and national business disputing, emerges and itself becomes transformed through interconnected power struggles over business, markets, and the state within and among lawyers and businesspersons operating in and across local, national, and transnational organizations and institutions.

Social mechanisms through which law–economy co evolution occurs are a topic of lively debate. Some scholars emphasize how law reshapes actors' cost benefit calculations and interests. Others emphasize how legal and economic concepts and institutions are mutually constitutive, with law's power in and for economic life rooted in taken for granted meanings, norms, and values. Where scholars emphasizing rational calculation tend to conceptualize law as a set of state promulgated formal rules, scholars emphasizing how law helps to construct cognitive frameworks for economic behavior tend to emphasize a broader concept of law as legality (Stryker 2003; Edelman & Stryker 2004). Legality encompasses codified rules as well as symbolic and ritual elements of law and social behaviors mobilizing and enacting both state made formal laws and law like principles and processes outside the formal legal system.

Stryker (2003) suggests that both formal legal rules and broader notions of legality affect the economy through multi dimensional resource mobilization processes involving instrumental

calculations by economic and legal actors, and also these actors' cognitive interpretive frames and their normative evaluations (see also Dezalay & Garth 1996; Kelly 2003). Reviewing extant research, Edelman and Stryker (2004) suggest that political mechanisms involving resource mobilization and counter mobilization and institutional mechanisms involving hegemony and diffusion of taken for granted meanings and practices combine to account for the mutual endogeneity of legal and economic ideas, actors, and institutions. They show how a "sociological" approach to law and the economy, emphasizing that ideas of economic efficiency and rationality are socially constructed, is different from a "law and economics" approach. The latter relies on a priori concepts of rationality and efficiency as assumptions for its theories about business behavior and as a normative standard to evaluate legal rules and institutions. Finally, law plays facilitative, constitutive, and/or regulatory roles with respect to economic ideas, actors, and institutions. Sometimes it plays all three at once. For example, corporation law constitutes corporations as bona fide economic actors and legal persons while it also facilitates and regulates capital accumulation (Edelman & Stryker 2004).

Diverse quantitative and qualitative methods are used productively to study law and the economy. Both quantitative modeling and case oriented comparative techniques have been used to investigate the impact of statutes, directives, executive orders, and court rulings on, for example, business behavior, unionization, strikes, economic growth, employment, unemployment, international trade, and transformation of market structures, as well as on the labor market participation, jobs, and wages of minorities, women, and members of diverse ethnic and religious groups (Donahue & Heckman 1991; Fligstein & Stone Sweet 2002; Edelman & Stryker 2004). Quantitative methods likewise have proved useful for assessing diffusion of new business structures and practices in response to changing regulatory laws and for investigating distinct periods in law and economy dynamics. Case oriented comparative historical methods have been especially helpful in examining key events or turning points in mutually constitutive legal and economic processes (Stryker 2003). Precisely because the

over time role of law in constructing currently taken for granted economic concepts, actors, behaviors, and institutions tends to become invisible from contemporary vantage points, research investigating short and long term law-economy dynamics is important for understanding current economic phenomena, as well as for appreciating the possibilities and probabilities of future economic transformations.

law, sociology of

Robert Dingwall

The sociology of law is one of the oldest specialty fields in the discipline, reflecting the influence of nineteenth century jurists like Sir Henry Maine (1861) on writers of the founding generation like Tönnies, Weber, and Durkheim. Although it has been a less significant area over the last half century, it is currently undergoing a revival, mainly through its contribution to interdisciplinary studies in law and society alongside law, history, political science, anthropology, and social psychology.

The sociology of law can be distinguished from criminology in two ways. First, it has a broader attention to the scope of law's impact on society. Where criminology focuses particularly

on the coercive effect of law, the sociology of law is also interested in its regulatory and facilitative aspects in relation to civil society, commerce, and domestic life. Second, it has a less applied orientation. Although there are significant critical currents in criminology, which are often closely linked to the sociology of law, much criminological work is essentially a form of problem solving for the criminal justice system, where prior definitions of crime and institutional solutions have been laid down by research sponsors. It is important not to overstate this because there are also empiricist elements in law and society studies that are equally sponsor driven (Campbell & Wiles 1976).

Early sociologists had a central interest in explaining the transition to modernity that they believed they were witnessing, in their own lifetime and that of their immediate predecessors. Changes in the nature of law were thought to be part of this transition, creating the conditions for the development of a capitalist economy. Maine described this as the movement from a society based on *status* to one based on *contract*, a distinction reformulated by Tönnies as *Gemeinschaft* to *Gesellschaft* and by Durkheim as *mechanical* to *organic* solidarity (Nisbet 1966). To the extent that law could be said to exist in traditional societies, it was an expression of sovereign or collective will, designed to impose order through repressive sanctions and sustain relations between individuals that reflected inherited or ascribed positions within the community. Modern law was a resource that individuals could use to structure episodic relationships between themselves, particularly within the economic sphere, by means of contracts that provided a basis for stability and predictability in their interactions by codifying promises and penalizing breaches. Contemporary anthropologists of law are highly critical of this representation of traditional societies, which their research has shown to be more strongly marked by informal sanctions and an emphasis on restitution and peace making than on coercion. Nevertheless, the model was important in stimulating reflection and empirical work on the relationship between law and the rise of capitalism.

The division of analysts over the extent to which law is an integrative element in society, facilitating action in a broadly neutral fashion,

or an expression of the coercive power of a dominant class persists to the present day. Durkheim (1984) saw law as one of the solutions to the problem of social and moral fragmentation that arose from the division of labor. The creation and articulation of enforceable contracts provided for the specification and definition of a wide range of social relationships – from the economic sphere of consumption, employment, or property to the domestic sphere of marriage and intimate relationships. However, in contrast to many of his contemporaries writing from more narrowly legal or economic backgrounds, Durkheim underlined the importance of the institutional embeddedness of law: contracts depended on a non contractual basis of values, which could only be imperfectly sustained by legal means. For Durkheim, though, the division of labor was a spontaneous process: its unilateral imposition on workers by the owners of capital was a pathological form, the *forced* division of labor, that he sought to oppose. Marx, in contrast, saw this imposition, in pursuit of greater profit, as the essential driver of the process, so that law was primarily an ideological tool of the capitalist, supplying legitimacy to the power imbalance between owner and laborer (Cain & Hunt 1979). The apparent neutrality of law as an arbiter between interests cloaks the “hard power” of the capitalist state’s monopoly of violence. In practice, laws are written by one class to serve their goals of expropriation from, and domination over, another. The courts are no more open to all than the Ritz Hotel.

Weber (1978) took over Marx’s recognition of the role of law in legitimizing state power, although he argued that the control of the state and the nature of struggles between different groups of citizens were more complex phenomena than Marx had allowed. Law was not a simple servant of the interests of a capitalist class because such a single, homogeneous social grouping could not be identified as easily as Marx thought. Weber put more emphasis on the role of law in the spread of rationalization in modern societies. It was one of the impersonal metrics that both ordered social and economic relations and, ultimately, undermined their spontaneity and creativity. If the modern world was being experienced as an inhumane place, law was part of that inhumanity, while,

at the same time, being one of the conditions that made possible the advance of Enlightenment values and of material prosperity. This tradition remains important in, for instance, the work of Teubner (1993).

The straightforward model of Marx’s original writing proved unsustainable under the conditions of the twentieth century’s experiments with communism. Marx had seemed to suggest that the overthrow of the capitalist order would lead to the creation of a self organizing society in which law would be redundant. In practice, communist societies found it hard to dispense with law. The Soviet Russian theorist Pashukanis, writing in the 1920s and 1930s, noted the continuing use of contracts to define relationships between state owned or controlled enterprises, for example. He distinguished the repressive character of law under capitalism from the facilitative character of law under communism (Beirne & Sharlet 1980). Even the self styled “workers’ states” found it hard to dispense with a framework of law to regulate economic and social relationships or to supply legitimacy to coercive acts in defense of the revolutionary order.

The contemporary sociology of law focuses on a research agenda that can conveniently be summarized in the terms of one of its classic papers: naming, blaming, and claiming (Felstiner et al. 1980–1). Naming refers to the recognition by a social actor that a problem is potentially a legal problem, that is to say a grievance or a dispute to which the law may offer a useful response. This generates a set of questions about what kinds of problems people encounter in their daily lives, whether as family members, workers, consumers, tenants, borrowers, employers, landlords, lenders, or whatever. How do some of these come to be selected into the legal system? What happens to the others? These questions generate studies of legal consciousness, what the prospective users of law think that the law can offer them, and when it is appropriate to make use of it. Legal consciousness is in turn linked to studies of culture, of the images of law presented in different forms of mass media, and of the outreach activities of professional legal actors seeking to recruit problems for resolution by the system from which they derive their living. Blaming involves the identification of a second party who is

responsible for the problem and against whom the law's resources may be mobilized. The law is a means to compel the wrongdoer to make some redress for the wrong. In this sense, at least, it is an alternative to the peer pressures of a community or the unregulated use of private violence. The law may ultimately rest on coercion to deliver redress, but this response is the measured employment of the modern state's monopoly of legitimate force, sanctioned by a judicial decision. Claiming describes the processes of mobilization, considering the social and economic influences on access to the law, the relative role of formal and informal legal institutions, the role of the legal professions and regulatory agencies in managing claims or grievances, and the role of court processes in constructing outcomes.

In general, scholars draw attention to the "iceberg" of potential legal business: potential causes for litigation are endemic in everyday life, but are rarely named as such and mobilized as claims (Greenhouse et al. 1994). While there is a widespread contemporary belief in the recent growth of a "compensation culture," where both citizens and corporations, stimulated by entrepreneurial lawyers, are making increasing use of formal legal means to make claims and resolve disputes, there is no substantial empirical evidence to support this (Daniels & Martin 1995). Even in an area like medical malpractice, where claim rates have attracted much discussion, the best evidence suggests that only a relatively small proportion of physician errors lead to claims, most of which are settled without trial. Compensation tends to reflect the real losses sustained by plaintiffs, even in countries like the US where, at least in the first instance, juries decide awards (Vidmar 1995). The perception of a compensation culture is in part the product of a popular imagery of law, derived from novels, TV, and film, that massively overstates the role of trials in modern legal systems. Whether in relation to criminal or civil issues, most legal outcomes are negotiated.

A good deal of recent scholarship, then, concentrates on the factors that tend to divert cases from the legal system. Is the diversion of problems structured in ways that exclude certain social groups and favor others? Some of the barriers are cultural. Ewick and Silbey (1998),

for example, identify three ways in which ordinary people understand the law: one is based on an idea of the law as magisterial and remote, not for "people like us"; a second views the law as a game with rules that can be manipulated, and where some people are always advantaged; a third sees the law as an arbitrary power to be resisted in favor of local and traditional ways of dealing with problems. However, even business actors tend to avoid referring their disputes to the legal system wherever practicable (Macaulay 1963). Individual litigants and small businesses are indeed structurally disadvantaged by their limited resources and unfamiliarity with the nature of the game. Galanter's (1974) analysis of the imbalances between "one shotters" and repeat players has had a wide influence and continues to be sustained in current work (Kritzer & Silbey 2003). Research on court procedures has examined the extent to which legal language excludes or disadvantages certain social groups, although there is some disagreement about the degree to which these features either arise from the functional logic of a truth seeking process or are more or less self-conscious devices for protecting the interests of the powerful (Dingwall 2000). The legal profession itself has become increasingly organized in larger units focused on serving the repeat players, with a growing distinction between those firms and lawyers serving corporate and individual interests (Heinz & Lauman 1982; Galanter 1994; Heinz et al. 2005). This has not necessarily compromised the profession's ethical standards: large firms may have greater economic and cultural resources for resisting pressure to engage in deviant behavior (Carlin 1962; Shapiro 2002). However, it is argued that the law contributes increasingly to the social and economic integration of an elite, supplying predictability in their corporate relationships and providing for the settlement of their disputes, mainly by negotiation between their lawyers and only occasionally by the maverick process of trial.

Those who are not well served by this closure have been offered two other institutional developments: the rise of alternative dispute resolution (ADR) and of regulation as an alternative to litigation. ADR is an uneasy coalition of two very different interests. One dimension

is inherited from experimental social programs in the 1960s and 1970s intended to strengthen the capacity of poor neighborhoods to resolve their own disputes by supporting the mobilization of community resources. It is intended to overcome the perceptions of remoteness and arbitrariness attaching to the formal legal system. Problems will be solved by the intervention of a third party, who may either facilitate direct negotiation between disputants, seek to communicate between the parties to bring about a compromise, or, more rarely, to make a decision that will bind the parties. It should be noted that none of these are exclusive to the settlement of the grievances of the poor: the powerful also prefer to avoid courts and have long used similar means to resolve disputes among themselves. However, this community oriented concept has been increasingly transformed by the sponsorship of governmental actors seeking to reduce public expenditure on the legal system by diverting low value cases from the courts, which have relatively high fixed costs. ADR reduces the resources offered by the state to poor people while telling them that it is morally better for them to solve their own disputes among themselves (Nader 2002).

The twentieth century saw the wholesale growth of regulation as an alternative to relying on victims to mobilize the law in search of redress. Regulation is based on the proactive screening of various areas of social and economic activity by a formal bureaucracy empowered to administer legal penalties or to refer cases to the courts for sanction. It has been particularly evident in areas where harms are diffuse (environment, obscenity), where there are great economic inequalities between parties (health and safety, discrimination), or where there are great informational inequalities (consumer protection, finance and investment, professional licensing). However, the results have been mixed. Sociologists have pointed to the way in which regulatory agencies tend to become "captured" by those who they seek to regulate, forming alliances inimical to the public interest that they are supposed to represent. As with so much of the law, compliance is negotiated rather than imposed. In part, this often reflects state ambivalence about their use of enforcement powers and willingness to resource

agencies accordingly. The revival of neoliberal social theories has produced calls to roll back the regulatory state in favor of action by robust individuals. As with ADR, private enforcement by individual litigants is held to be morally preferable to collective action on their behalf by a "nanny state."

The resurgence of the sociology of law is in part attributable to the resurgence in the role of law in society. The discipline's founders observed a world of "small states," with limited spheres of action, and sought to develop replacements for the ineffectiveness of traditional legal forms as a basis for the new forms of social and economic organization that were emerging. A modern world required a modern form of law, forming part of a much wider system of governmentality. The perceived crisis of that system has allowed its critics to roll back many of its state based elements, returning individual acts of legal mobilization to a position that they have not occupied for some generations.

Lazarsfeld, Paul (1901–76)

Brian Starks

Paul Lazarsfeld, founder of the Bureau for Applied Social Research at Columbia University, was a pioneering empirical sociologist. Trained as a mathematician and initially self-identifying as a psychologist, he only later came to recognize himself as a sociologist.

Lazarsfeld was born to a Jewish family in Vienna and first came to the US as a Rockefeller Fellow in 1933. As an active socialist at the time, Lazarsfeld chose to remain in the US after his fellowship ended in 1935 rather than return home to persecution (a ban against social democrats had just been enacted in Austria, and Hitler had begun his rise to power in Germany). This experience of being a heavily accented foreigner and a Jew transplanted into the US left an enduring impact on Lazarsfeld's self image. Throughout most of his life he saw himself as a marginalized individual despite his vast accomplishments and recognition among peers, which included being chosen as president of the American Association for Public Opinion Research (1949–50) and the American Sociological Association (1961–2).

While many of Lazarsfeld's concepts remain foundational in the field of mass communication, he may be best remembered for his sociological approach to voting (focusing on social location) and his theory of the two step flow of communication, which highlights the importance of "opinion leaders" and personal influence in the process of decision making, especially voting. Lazarsfeld's work is recognized as exceptional not just for the wealth of concepts he left behind but also for its methodological innovation. From his early work on unemployment (in the Marienthal project), to later work on mass communication and voting and finally in his research on higher education, Lazarsfeld developed ingenious ways of measuring and analyzing concepts. Cornerstones of modern social science such as survey analysis, focus groups, and panel studies, while not invented by him, were pioneered by him through his creative

application of them to practical, empirical puzzles. Additionally, his development of “latent structure analysis” and use of contingency tables helped to build a secure foundation for the use of contingency tables and loglinear models in later research (e.g., in studies of class mobility).

Lazarsfeld was also dedicated to collaboration and institution building. He founded several research institutes over the course of his career. The first was the Research Center for Business Psychology in Vienna, but his most famous was the Bureau for Applied Social Research at Columbia. Finally, in a partnership with Robert Merton that lasted more than three decades, Lazarsfeld advised hundreds of graduate students at “the Bureau” and helped to shape a generation of empirically oriented sociologists.

leadership

Tyrone S. Pitts

There are several definitions of leadership available; however, it can be broadly defined as the process of inspiring, directing, coordinating, motivating, and mentoring individuals, groups of individuals, organizations, societies, and/or nations. While the origins of leadership can be

traced back to ancient times in Africa, Asia, and Europe, it is only relatively recently that systematic attempts have been made to understand, operationalize, and conceptualize leadership. In sociology, Weber (1947) conceptualized leadership as legitimated by virtue of subordinates’ understanding of bureaucratic authority, rules, and legitimacy. Weber identified three general typologies of leadership in bureaucracy: charismatic, traditional, and legal. Charismatic leaders were attributed powerful qualities by those who follow them; traditional leaders were powerful by virtue of hereditary wealth or peerage; legal leadership draws its power from professional knowledge and technical expertise, and formal authority was legitimized through roles or position in the bureaucratic hierarchy. As such, formal authority is legitimated by subordinates’ understanding and respecting rules and authority (Clegg et al. 2005). In contrast to Weber’s approach, more recent sociological approaches to leadership have been more concerned with notions of power rather than leadership per se. As such, the study of leadership is less about the individual and more about how power structures allow domination and control over others.

At a broader level, and in contrast to sociology, the origin of leadership research and theory is embedded in psychological trait theories of personality. Trait based approaches to leadership distinguish leaders from non leaders by attempting to identify specific biological and genetic personality traits, such as honesty, integrity, intelligence, strength of character, and confidence. Research results, however, have been quite mixed, and so critics sought to develop newer ways of understanding leadership. The issue for the trait approach was that leaders proved no more likely to possess special traits than did “non leaders.” As a result the behavioral school gained strength, especially in the US, because it argued that what distinguished leaders from non leaders was not so much their traits but rather their observable behaviors. A leader, therefore, is what he or she does. Such notions of leadership dominated until the 1970s, when arguments emerged stating that effective leadership was contingent upon certain situational factors. If leadership was about how one acts, then one would have to act the same way all the time. Situational

leadership theory moved away from individual difference psychology back to the social psychological and sociological notions of leadership. For some, there was a return to Weber's idea that leadership is a function of the willingness of subordinates to be led. For others, there was an attempt to define leadership as a function of a number of situational contingencies. Newer versions of contingency theories see leaders' ability to influence performance as a function of their cognitive capacity to deal with situational stressors and organizational environment (Fiedler 1995).

Over the last two decades the study of charismatic, transformational, and transactional leadership has dominated the leadership landscape and, to a certain extent, reflects Weber's three typologies of leadership. The charismatic leader, as the name suggests, exhibits character that followers are attracted to, and has the ability to inspire and build dreams and sell vision. The transactional leader attends to all the necessary functional aspects of management, such as coordination, control, and budgeting. The emphasis on the transformational leader emerged out of the sociological work of Burns (1978) on political leaders. The transformational leader sets examples through inspirational performance, inspired change and innovation, and deals in abstract concepts, such as vision and mission (Bass 1985; Avolio & Bass 1988). While there is a certain degree of overlap between transformational and charismatic leadership, charismatic leaders tend not to transform followers into future leaders. Adolf Hitler, for example, was a charismatic leader in that he inspired followership, but he also protected his rule and authority over all others. A transformational leader would also mentor his or her followers so that they might become future leaders.

Most recently a number of newer – or recycled older – approaches to leadership have emerged, most notably from a positive psychological perspective, but also from postmodernist conceptions. Positive psychology has its roots in William James and the humanist approaches of Gordon Allport, Carl Rogers, and Abraham Maslow. Interest in positive psychology has been reinvigorated more recently by Seligman (1999) and has recently entered organizational behavior and organization theory – not without its critics. The positive psychology of leadership

draws upon Bass and Avolio's notions of transformational leadership, with some additions. Current work on positive leadership has a sociological dimension: it concentrates on a person's ability to create social as well as psychological capital (Luthans & Youssef 2004). Other approaches to leadership present leadership less as pious behavior and more as a problematic endeavor typified by tension, challenges, and mistakes. What characterizes a "good" leader, then, is the ability and commitment to build strong communities through principles of economic, social, and environmental sustainability (Dunphy & Pitsis 2005).

Another interesting area of leadership theory and research with sociological underpinnings is that of leadership substitutes and dispersed leadership theories. Leadership substitutes are those things that replace or make a leader obsolete. For example, the empowerment of teams and the use of self managing work teams are believed to make the requirement for individual leaders obsolete. Dispersed leadership, however, returns to the analysis of leadership as power and addresses how leadership power is transferred to structure, rules, procedures, and technologies. Such notions may draw upon Foucault's (1979) analysis of Jeremy Bentham's Panopticon as a form of managerial surveillance and control. That is, while the leader may not be physically there, she or he is always watching you – say via time cards, surveillance cameras, email, etc. More interestingly, some go as far as to argue that even leadership substitutes such as empowerment are advanced and ingeniously designed forms of power. Sewell (1988), for example, argues that the use of teams produces stronger forms of control and surveillance than could any individual leader. What better way to control people than to have them monitored by their peers?

In a postmodern sense leaders do not exist to lead but to be servants – they are servants to the frontline people who are servants to customers. In other words, consumers and consumerism are king and we are all servants to consumption. In essence postmodern leaders provide running commentary on how the organization is doing, and how people fit within it; they construct the stories and rituals around life in organizations, where the organization will go and can go, and how one can become a better servant of the

consumer (Boje & Dennehey 1999; Greenleaf 2002). Of course, leadership might also be a social construction of our collective imagination. In this sense what makes a leader a leader is how observers construct their understanding around a person's specific behavior who is labeled a leader, and so the role and performance of leadership is overstated (Meindl 1995; Parry & Meindl 2002).

learned helplessness

Bridget Conlon and Christabel L. Rogalin

Learned helplessness is the group of motivational, cognitive, and emotional deficits that can result from repeated exposure to events if they are perceived to be uncontrollable. The phenomenon was discovered serendipitously in the laboratory of Richard Solomon by his students including Seligman, Maier, Leaf, and Overmier (Overmier & Seligman 1967; Seligman & Maier 1967). During experiments in which dogs in Pavlovian hammocks (harnesses used to restrict movement) were exposed to a tone (conditioned stimulus) paired with an electric shock (unconditioned stimulus), researchers realized that the dogs were unable to learn to escape shocks in a later controllable situation.

In order to examine the hypothesis that deficits were due to exposure to noncontingent (uncontrollable by the dogs) events, researchers designed "triadic design" experiments where animals were first exposed to one of three training phases: (1) no training; (2) training with outcomes that were not controllable by the animals; and (3) training with controllable outcomes. In the control condition, dogs were not exposed to any shock. In the second condition, experimenters shocked the dogs for 5 seconds 64 times. The dogs were able to cut the shocks short by pressing panels on either side of their heads. Dogs in the third condition were "yoked" to dogs in the second condition. Yoked means that the dogs were shocked simultaneously for identical lengths, yet the dogs in the second condition controlled the shocks while the dogs in the third condition were not able to control the frequency or length of shocks.

During the second (test) phase of the experiments, animals performed a task related to the task in the training phase and their performance was measured. The goal was to test whether performance during the test phase was affected by the condition in the training phase. Researchers found that the animals that were exposed to controllable shocks during the training phase were able to learn to escape shocks during the test phase. Animals exposed to uncontrollable shocks in the training phase were unable to learn to escape shocks during the test phase. In essence, the animals learned that they were unable to control outcomes and generalized that knowledge to a similar situation when they actually had control of outcomes. The *expectation* of uncontrollability is a key to learned helplessness.

LEARNED HELPLESSNESS IN HUMANS

Martin Seligman is considered a major contributor in extending the original observations to studies of learned helplessness in humans. Seligman suggested that the symptoms dogs exhibited were similar to symptoms of depression in humans. He proposed a learned helplessness model of human depression. Depressed people often exhibit similar motivational difficulties, believing that their behaviors are futile. They also often show cognitive deficiencies such as the inability to learn when their responses can affect outcomes. Finally, depressed people experience frequent sadness and anhedonia that may appear similar to the helpless whimpering of dogs exposed to non contingent shocks. Anhedonia refers to the inability to experience pleasure from things that one would normally find pleasurable. The translation of the concept from animals to humans required some reworking of the original theory. Specifically, researchers studying humans found that when exposed to uncontrollable stimuli, such as inescapable noise or unsolvable puzzles, some individuals showed signs of learned helplessness while others exhibited increased activity that facilitated their performances.

The reworking of the learned helplessness model to fit humans included increased emphasis on attributions. Abramson et al. (1978) suggested that individual people have a stable

(trait like) explanatory style when they encounter unpleasant events. Explanatory style has three dimensions: internal–external, stable–unstable, and global–specific. In practice, these dimensions are measured using Likert scales from one to seven. The internal–external dimension refers to the extent to which an individual feels a specific event is caused entirely by one's self versus entirely by others. The stable–unstable dimension refers to the extent to which an individual believes that the cause of an event will never again be present versus always being present. The global–specific dimension refers to the extent to which an individual believes an event is caused by something that only influences the particular situation versus influencing all situations in one's life. The distinction between stability and globality is a fine one. Stability refers to causes repeating over time, while globality refers to causes that repeat across different types of situations. Many theorists argue that explanatory (or attribution) style is a trait like characteristic that develops during childhood. The reformulated theory posits that when faced with negative events, people who tend to attribute the events to external, unstable, specific causes (referred to as pessimistic explanatory style) are less likely to experience depression than people who attribute the events to internal, stable, and global causes (referred to as optimistic explanatory style). Thus, in the reformulated theory, learned helplessness only occurs when an event is perceived to be beyond an individual's control and that individual has a more pessimistic rather than optimistic explanatory style.

MEASURING ATTRIBUTIONS

Because of the increased emphasis on attributions in the reformulated model of learned helplessness, researchers developed two standard procedures for measuring attributions: Attributional Style Questionnaire (ASQ; Peterson et al. 1982) and the Content Analysis of Verbatim Explanations (CAVE; Peterson et al. 1983). For the ASQ, respondents imagine that an event has happened to them. They are asked to give a cause for the event and then give ratings of internality, stability, and globality for each cause for each event. A more recent (and slightly

more reliable) version of ASQ includes only negative events rather than both positive and negative (Peterson & Villanova 1988). There is also a children's version of the questionnaire (CASQ; Seligman et al. 1984).

Whereas the researcher gives respondents hypothetical situations to explain in the ASQ, researchers using the CAVE approach read documents such as autobiographies, interviews, or therapy transcripts to measure how respondents explain events in their lives. Events and attributions are extracted and scored by independent judges on the dimensions of internality, stability, and globality.

OTHER APPLICATIONS OF LEARNED HELPLESSNESS

Researchers have found that learned helplessness affects organisms' immune system function. In addition, learned helplessness has been used as an explanation for why some but not all people who experience traumatic events develop post traumatic stress disorder (PTSD). After exposure to a traumatic event, the attribution an individual makes about the internality, stability, and globality of the cause of the event affects whether he or she develops PTSD.

Learned helplessness can also be applied in an educational setting. Students could perceive repeated failures to indicate that they lack control over their academic success and cause them to develop signs of learned helplessness. Sedek and Kofta (1990) focus on a specific aspect of learned helplessness. Specifically, they argue that cognitive exhaustion is the reason previous exposure to uncontrollable events results in reduced performance. They argue that poorer performance is not due to helpless feelings or believing one cannot control the situation. Rather, the uncontrollable event decreases the individual's ability to process information and develop conclusions. Note that these researchers, along with many others, suggest different mechanisms through which learned helplessness occurs than the original theory suggested.

A somewhat controversial application of learned helplessness is the battered woman syndrome. Walker (1984) suggested that repeated exposure to domestic violence causes women to develop learned helplessness so that they

are unable to protect themselves or escape the relationship. Research evaluating this hypothesis has found at best mixed results. Many researchers see attributional style as a trait like characteristic that is probably developed during childhood. A recent article suggests that pessimistic attribution style contributed to whether battered women developed symptoms of depression or PTSD. Yet the researchers found that battered women were no more likely to exhibit learned helplessness than women in a comparison group from the community. This suggests that experiencing domestic violence does not lead to learned helplessness, but that if a person tends to have a pessimistic attribution style, he or she is more likely to experience depression or PTSD due to the experience than if he or she had an optimistic attribution style (Palker Corell & Marcus 2004).

CURRENT AND FUTURE DIRECTIONS IN LEARNED HELPLESSNESS RESEARCH

As mentioned above, researchers in this area often argue that explanatory style is a characteristic that develops during childhood. Few investigators have explored the conditions in which children develop this trait. Some argue that experiencing trauma at a young age leads to development of learned helplessness. Others believe that exposure to crowded or inadequate living conditions causes children to develop feelings of helplessness. Recent research also suggests that interpersonal relationships, particularly parent-child relationships, can affect the type of explanatory style individuals develop. Specifically, children can learn explanatory styles watching how their parents explain events in their own lives and their children's lives.

Maier's research has continued to focus on learned helplessness. His research evaluates the physiological and neurological aspects of learned helplessness. In particular, he explores the relationship between the brain and the immune system to understand cognitive difficulties, stress, and pain perception.

Seligman has turned his attention to positive psychology and learned optimism. He currently directs the Positive Psychology Center at the University of Pennsylvania. Positive psychology

suggests that people have varying levels of 24 strengths such as leadership, humor, industriousness, and love of learning that they categorize into six cross culturally valued virtues: wisdom and knowledge, courage, humanity, justice, temperance, and transcendence. Further happiness can be cultivated by focusing on one's strengths rather than one's weaknesses and frequently using one's strengths in day to day life.

leaving home in the transition to adulthood

Frances Goldscheider and Berna Torr

Full adulthood normally involves attaining the stable adult roles of worker, partner, and parent. Childhood, in contrast, is normally associated with net dependency on one's own parents. The transition to adulthood, then, comprises two steps: (1) ending childhood dependency and (2) making progress on the central responsible roles of adulthood. In the study of the transition to adulthood, these processes are bound together in complex ways.

Given this complexity, it is not surprising that the transition to adulthood, which might be viewed as a near uniform, biological progress to physical maturity, actually varies greatly across societies and over time. Dramatic changes in both work and family have increased this complexity. The time needed to attain stable adult work roles has lengthened. This reflects both the increased need for higher education and greater job turnover in early adulthood. Related in part to these changes in work roles, the establishment of stable family roles has also been delayed throughout the industrialized world, postponing full adulthood for most young adults. This has created an ambiguous life course stage between the ages of 18 and 25 marked by "semi adulthood," when living arrangements such as (1) living in the parental home, (2) residing alone or with roommates (non family living), or (3) entering into uncommitted partnerships (cohabitation) are common and become alternatives to the more traditional route of forming one's own family through marriage. Frank Furstenberg and colleagues (2004) have argued that we have a new stage in life in the US and many other developed economies, a

stage of "early adulthood" that is no longer adolescence but is also not full adulthood either.

TIES TO THE PARENTAL HOME

Parents are the major source of the many transfers of resources needed by the next generation. In most industrialized countries, the generation of later middle aged adults is wealthier than any in history, and has relatively small families, so parents can afford to provide reasonable space for their children and financial support for an extended number of years. Parents use their income to retard very early departures (e.g., before high school is completed), which are linked with the most negative outcomes, but use their income to facilitate leaving home at older ages.

As a result of the rural–urban transformation that unfolded over the twentieth century, parents are now more likely to be living in areas where there are more economic opportunities for young adults and where young adults often do not have to leave home to attend school or find jobs. However, families once provided their children with jobs. Inheritance of the family farm or business was an important factor structuring many young people's economic opportunities and their relationships with their parents. Nepotism has not totally vanished from modern economies; many parents can "pick up the phone" and procure opportunities for their children in the businesses of friends and associates. Nevertheless, most parents who want to help their children must now find other ways to do so. Financing their children's college education, which often delays complete financial and residential independence of those children, is one way parents achieve this end.

An important resource is money. Not all parents are willing to provide monetary support to their children once they enter adulthood and financial help appears to be contingent on what young adults are doing. A 1980 study of mothers found that although most (88 percent) expect to provide at least some help with the expenses of college for their unmarried children, many fewer would help with college costs if the child were married, and fewer still would help out a child struggling with job or relationship difficulties. Further, there appeared to be

substantial variation among mothers in their support priorities. Some would be more likely to help a married child while others would be more likely to help an unmarried one. Some would be more likely to provide support to a child living away from home while others would only help a child living at home.

LEAVING AND RETURNING TO THE PARENTAL HOME

Leaving the parental home, and particularly the routes young people take out of the home, play key roles in the transition to adulthood. In most industrialized countries, the cohort of the *parents* of today's young adults not only is relatively wealthy, but also left home younger than any cohort before or since. They appear to expect their children to follow in their footsteps, despite the much later ages at marriage and the more fragile economic situation confronting their children than they faced growing up. Parents often express dismay at the recent increase in the proportions of young adults remaining in or returning to the parental home, an increase that has accompanied the later age at marriage and greater instability in the job market. A frequently invoked norm of adulthood requires residential independence from an early age, in most cases long before marriage. This rhetoric suggests that young adults are refusing to grow up and may not deserve their parents' financial and residential support. However, pressures on young adults to leave home early can be problematic, given the negative effects of early, non college nest leaving on educational attainment.

The increase in marital disruption among parents also affects family support for the young adults and the timing of residential independence. Young people leave home faster from disrupted families than from two biological parent families. The differences are particularly large when leaving home to attend college is separated from other routes, as young adults from non traditional families are significantly less likely than young adults from stable, two parent families to leave home for college. In addition, young adults of divorced parents are more likely to report leaving home because of friction. Young adults from non traditional

families are also much less likely to return home, suggesting that the home and its resources are less available to them.

There are also longstanding gender and race/ethnic differentials in nest leaving by young adults. Girls tend to leave home earlier than boys, in part because they are likely to marry or otherwise form families earlier. Non Hispanic whites also tend to leave home earlier than African Americans, Asians, or Hispanics. Hispanics and Asians are more likely than non Hispanic whites to leave home for marriage, while blacks are more likely to leave home single because of later ages at marriage. There was a crossover, however, in age at leaving home for blacks and whites in 1960. Prior to 1960, blacks left home earlier than whites, while in the post 1960 period blacks left home later, reflecting the differential impact many trends affecting leaving the parental home have on population subgroups.

The transition out of the parental home is not always a permanent one. Another form of support that parents provide is a home to return to. Those who leave home for marriage are less likely to return home than those who leave home for other reasons. Thus, the likelihood of returning home has increased as young adults have become more likely to leave home for reasons other than marriage. However, the older young adults are when they leave, the less likely they are to return. The availability of jobs and the cost of housing are also important: stable employment both facilitates residential independence and lowers the risk of returning home. Finally, state policies also affect when young adults leave the parental home and whether they return. When the state facilitates human capital growth, such as through access to affordable higher education, parental resources become less important; when it does not, the parental home and parental resources increase in importance for young adults' educational attainment and progress in taking on adult work and family roles.

NON FAMILY LIVING

Non family living is an increasingly important pathway out of the parental home. Although unmarried adolescents have often lived away

from their parents, they normally lived with other families, in family based lodgings, or in colleges considered to be *in loco parentis*. Extensive non family living in separate households, however, is quite recent (mid twentieth century), beginning among the elderly with the expansion of state support for pensioners. It spread to young adults as delayed marriage and parenthood, divorce, and cohabitation became more common. In the transition to adulthood, non family living provides a "quasi adult" alternative to committed family roles, in that living independently reduces the power of parental authority and increases individual autonomy for young people (and their parents). An increasingly common non family living arrangement, cohabitation, shares with the other living arrangements (and jobs) in early adulthood the flexibility/impermanence that so often marks this life course segment. The majority of cohabitations are fairly short lived. On the economic side, there is evidence that cohabitation may serve as an adaptive strategy for young couples facing uncertainty about their careers.

A HISTORICAL EXAMPLE FOR THE UNITED STATES

A full analysis of trends in young adults' living arrangements did not emerge until the 1990s. This reflected a lack of both data and interest in the subject in the early years of the development of family demography, but it also reflected the difficulty of conceptualizing it. When Paul Glick and his colleagues (1965) defined the family life cycle and outlined how its contours had been changing in the United States, they were forced by lack of data to assume that young people leave home when they marry. During the period in which Glick wrote – the baby boom – this was a more nearly tenable assumption than either before or after, since marriage ages then were so young that few young adults had the time to leave home in other ways.

Trends in young adult living arrangements in the United States are illustrated with an examination of the period from 1900 to 2000. The solid line in Figure 1 shows the proportions of all 18 to 24 year olds who were living with their parents; that is, those who were

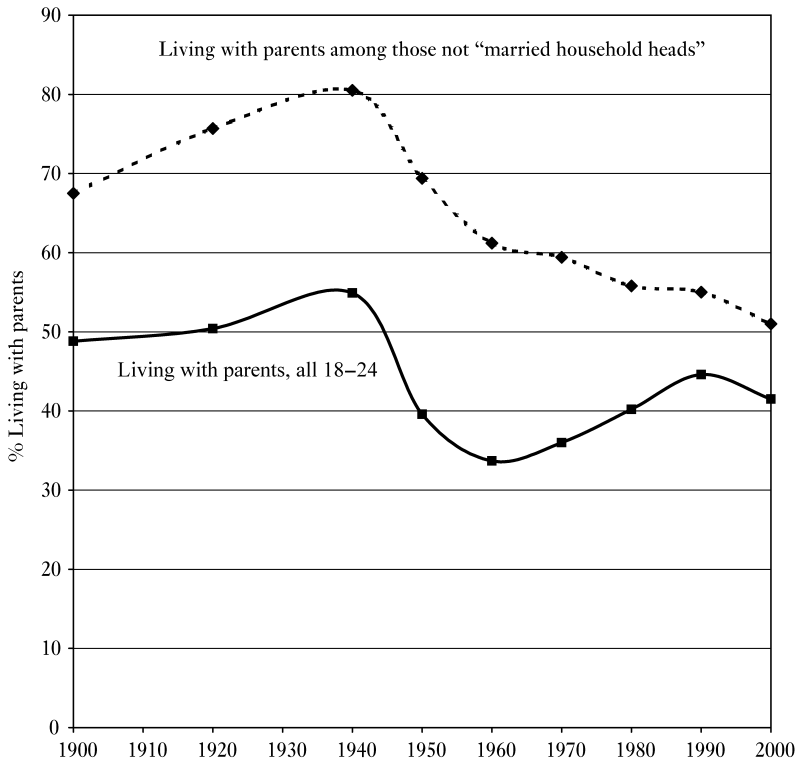

Figure 1 Percent living with parents and percent living with parents among those not “married household heads” (aged 18–24).

Source: Computed by the authors from the Integrated Public Use Sample (Ruggles & Sobek, University of Minnesota, 2003).

reported in the census as “child of head.” In 1940, just over half of young adults were living at home at this age, a level that had changed only slightly in the previous 40 years, increasing from 49 percent to 55 percent. This slight increase likely reflected a combination of three factors. First, declining adult mortality increased the availability of parents for young adults to live with. Second, the ongoing rural–urban transformation meant that an increasing proportion of young adults were living in cities and therefore able to live at home while working. And third, the Great Depression of the 1930s delayed young adults’ achievement of stable jobs and family formation, and kept home many of those who were employed in order to help their impoverished parents.

Between 1940 and 1960 there was a substantial decline in the proportion of all 18 to

24 year olds living with their parents, decreasing more than 20 percentage points to 34 percent. Much of this decline was the result of the rapid decline in age at marriage, with the growth in early marriage that accompanied the post World War II baby boom in the United States. However, some of this decline in the proportion of young adults living in the parental home during this 20 year period resulted from the increase in non family living.

This increase in non family living is illustrated by the dotted line in Figure 1, which shows a substantial decrease in the proportion of *unmarried* young adults living with their parents. This measure removes all married young adults from the ratio, and represents the proportion of *unmarried* young adults who are living in the parental home (and thus not living in a non family situation). The proportion of

unmarried young adults living in the parental home increased during the 1900 to 1940 period to near universal (80.5 percent), and then declined to slightly over 60 percent by 1960. Hence, the decline between 1940 and 1960 in the proportion of all young adults aged 18–24 living with parents reflected two trends: the decrease in age at marriage and the decline in living with parents among unmarried young adults.

Things became much more complicated, however, in the post 1960 period. The marriage boom ended abruptly, with the result that the share of young adults aged 18–24 living in new families they had formed through marriage dropped precipitously, and continued to decline through 2000. This decline in new families formed by marriage resulted in a greater proportion of all young adults remaining in (or returning to) their parental home. The child of head category increased from 34 percent in 1960 to nearly 45 percent in 1990. However, despite the continued increase in age at marriage between 1990 and 2000, during that decade the proportions of all young adults aged 18–24 living with parents declined.

Does this 1990–2000 dip indicate a reversal in nest leaving patterns? Not really, because as the dotted line in Figure 1 shows, the proportions of the unmarried living with parents declined throughout the 1940 to 2000 period. By 2000, about half (51 percent) of young unmarried adults aged 18–24 lived with their parents. Thus, while fluctuations in age at marriage affect the process of leaving the parental home, the influence of marriage age on leaving home has decreased. Those who left home in the latter part of the twentieth century were much less likely to do so via marriage.

This illustration demonstrates that even at the level of the living arrangements of the unmarried, the transitions in young adulthood are complex. Adding in trends in educational transitions (including dropping out and stepping out and returning to school), in early job transitions, and, of course, in union formation and dissolution, would require extensive research, little of which has been done in an integrated manner. For exceptions, see Billari et al. (2001) and Corijn and Klijzing (2001) for Europe, and Brien et al. (1999) for the United States. Most other studies rarely link leaving home

consistently with partnership formation, or with transitions in work and study. As a result, the light they cast on “semi adulthood” is partial, at best. To understand transitions in young adulthood, research is needed that relates changes in young adult living arrangements to changes in patterns of work and school attendance as well as to changes in marriage and cohabitation.

Lechner, Norbert (1939–2004)

Miriam Alfie Cohen

Born in Germany in 1939, Norbert Lechner was granted honorary citizenship by the Senate of the Republic of Chile in 2003. He earned a bachelor's degree in law and obtained a doctorate in political science from the University of Freiberg in 1969. He visited Chile as a doctoral student and came to live there. From 1974 he was a professor and researcher in the Latin American Faculty of Social Sciences in Chile (FLACSO). He was its director from 1988 to 1994.

One of the central concerns throughout Norbert Lechner's theoretical analytical work was the creation of a theory of the state in Latin America. Texts such as *La crisis del Estado en América Latina* (1977), *La conflictiva y nunca acabada construcción del orden deseado* (1986), *State and Politics in Latin America* (1981), and *Los patios interiores de la democracia* (1990) speak of the urgent need in Latin American countries

for political reflection as a guide to theoretical analysis, as well as a project to be constructed. Lechner takes on the analysis of the state as an object of research in order to account for the problems posed by social reality.

From this perspective, the existing order is analyzed in order to carry out a critique, a negation of the prevailing situation with the goal of unraveling the logic of the system, transcending it, and creating a theoretical and practical reflection upon social change and the construction of the new order. Thus, politics, order, and utopia are the linked categories that become the core of the exposition in the author's works.

His first writings show a concern for the Chilean social reality of the so called "legal road to socialism" that brought Salvador Allende to power. This peculiar political situation led Norbert Lechner to question the limited experience of Popular Unity in the study of the state. Although Allende and his team established an economic program for the period of transition to socialism, the lack of a political theory to explain the change was evident. From Lechner's point of view, in Popular Unity's lack of a concrete analysis of politics a determination of the economic order was provoked which considered the state realm to be a mere corollary of the economic realm, the state appearing as an entity at the disposal of one class or another.

With the military coup and the rise of Augusto Pinochet's regime (1977), Lechner came to study the state intensely, emphasizing that the state is neither on the margin of the social process nor an actor above the social process. Chilean authoritarianism pushed Lechner to find common traits in the Latin American region. Guided by Marxist thinking, particularly the currents represented by Antonio Gramsci, Rosa Luxemburg, Ernest Bloch, and the Frankfurt School, he sought out the leitmotif of the Latin American political situation. From his point of view, the distinction between state and state apparatus is fundamental. The central question for Lechner is the nature of the state, the state as a form. The idea is to discover the specific nature of the bourgeois state, in a way analogous to the type of commodities that appear as goods through the lens of Marxist theory. Thus, the state would seem to be the type of generality that atomized social relations assume in the process of production.

The state is necessary because it organizes and guarantees relationships of domination and inequality. Economic coercion (exploitation of the added value) breaks down into objectified political coercion in the state apparatus. The state is an autonomous power that intervenes in the economic sphere and fails to appear as a co-constitutive moment in capitalist production relations. Here it is worth highlighting the Gramscian vision of politics as an autonomous entity that is not determined by the economic realm.

However, for Lechner the serious problem in Latin America is understanding how the state is converted into a social relationship that becomes independent of its producers, becomes distanced from the social praxis that created it, and appears as a real abstraction endowed with a life unto itself. Unraveling the nature of the state in Latin America became a fundamental concern of the author's political analysis. His analytical objective is divided in two facets: first, to carry out a theoretical conceptual reflection regarding the capitalist state *per se* based on critique of political economy; secondly, to carry out a historical concrete study regarding the development of a particular state (Chile, Peru, Mexico, amongst others). The common thread is authoritarianism in different Latin American societies.

Lechner returns to the theoretical assumptions of dependency theory, led by the writings of Fernando Henrique Cardoso and Enzo Faletto (1969), and emphasizes how capitalist dependency is the result of structural heterogeneity, the juxtaposition or overlapping of different relations of production that give rise to the fragmentation of society. In the majority of Latin American countries, the nation does not exist as a mechanism of collective identity, forcing a certain level of social cohesion to be built through authoritarian means. To Lechner, the nonexistence of the "national state" in Latin America is substituted by the state apparatus. Thus, domination becomes more visible when there is little collective identity and the active presence of physical coercion substitutes the lack of social internalization of power in a "consensus of order."

Living under authoritarian conditions tends to lead to overvaluation of the coercive moment; the state becomes a synonym for physical

coercion. Through various subtle forms of social control it expands and intensifies a new rationality, a new culture, and that "one dimensional man" (Herbert Marcuse) that incarnates in actual authoritarianism begins to appear.

The authoritarian state is a new Leviathan, a representation of the rationalization of domination: reason that becomes domination. The Latin American state is established as a relationship of internal domination and external hegemony. Therefore there is no capitalization of Latin American society to generate the material basis for a general interest. Because of this, it is difficult to construct a "popular national will." Thus there is a hegemonic crisis, as no social group is able to consider, based on its own individual interests, the whole of society. The task is then the construction of a real and effective solidarity around common interests. Politics is conflict regarding people's sense of order.

For Lechner the construction of utopia is proposed as the abolition of domination with in human order, an essential possibility for reality, the good order. Utopia is linked to an anti authoritarian interest, whose motto consists of never falling for any type of servitude. Lechner emphasizes the struggle for democracy as the battle for popular sovereignty, a struggle against all forms of domination. The anti authoritarian interest refers to an order of freedom. Freedom is not an idea without a cause, it is the content of a kingdom to be built and its construction anticipates the new society.

Politics is a struggle for the determination of the sense of order and the order that should be, while utopia is a moment of politics. Rationality leads to a good order; it is the critique of the capitalist order in light of an alternative order. Thus, the possibility of a rational order makes the present order irrational. Utopia, then, will be the cleverness of reason that allows society to reflect upon itself.

A third moment in Lechner's work is marked by the fall of the dictatorship and the transition to democracy. The majority of the ideas promoted during this period had transcendence for the rest of Latin America as, along with authors such as O'Donnell and Schmitter, a period of theoretical political reflection regarding societies in transition begins.

If the concern for order was briefly seen in Lechner's early writings, these gain relevance

for him as a central analysis of politics and the transition to democracy. The order tends to be sought out and imposed by either the state or the market. From Lechner's point of view, the debate regarding state and market tends to be polemical because it puts at stake the idea that we are created by the social order. In order to avoid the fetishization of one or another element, the convenience of situating the relationship within their respective historical contexts is proposed.

According to Lechner, the market is a special category; the operation of the market is found to be determined by its insertion into political institutions, social structures, and cultural processes. It is worth mentioning that the market by itself neither generates nor sustains a social order; on the contrary, it presupposes a "politics of order." This implies two integration processes – integration into the global system and social integration – that require the market dynamic as well as, above all, a redefinition of the state. In Latin America, a dual transition process takes place: transition toward democracy and the transition toward a market economy. Thus, the classic question emerges regarding the relationship between democracy and economic development.

Lechner establishes that modern society, along with deploying the differentiation between economics and politics, always proposed (in an affirmative or critical manner) a certain harmony between both spheres. When the countries of Latin America proposed harmonizing political democracy with economic growth and social equality, a novel challenge was posed. On one hand, economic development and, concretely, the market could not be considered a "prerequisite" for democracy. On the other hand, democratic politics did not guarantee economic development either. Thus, the profound question for all of Latin America continues to be how to make democracy and development compatible.

From this perspective, it becomes clear that the determination of the social order is definitively at stake. For Lechner, the debate regarding state and market has traditionally been a point of polarization in Latin America. Ideological discussion led to choosing *a priori* one or another principle as the exclusive and excluding rationality of social organization. In order to

avoid the fetishization of the state or the market under a form of higher rationality, it became convenient to carry out a historical analysis that allows one to visualize not only the continued existence of the two logics, but also the changing combination of the two. The priority given to one or the other would mark policy.

For Lechner, the field of politics opens a field of conflict, of power and the opportunity to establish a new conception that develops into a critique of the established conceptual models. This critical theory of politics cannot be reduced into any particular political strategy. They are distinct levels, where strategy is the result of deliberation and collective decision, while theory contributes the arguments for convincing others, without supplanting collective creation. There is a perception, in this stage of Lechner's work, of a distancing from Marxist thinking and from a particular conception of the so called "desired order."

It could be said that as Lechner's interest moves from the study of the state to the analysis of politics, he arrives at the conclusion that social interest does not have to overcome social differences, but rather develops them. To him, it is not about proposing unity regarding the resolution of the plurality of man, but rather examining that plurality as the construction of a collective order. It is a conflictive and never ending order in which the content varies from one period to another.

Because of this, one cannot think about politics and order without referring to utopia, construction projects that allude to the transformation of the world. Utopia thus functions as a horizon concept that allows us to conceive of society projected into plenitude. It is an ideal through which to understand historical projects. Just by considering what is desirable, the possible is constructed. Utopia forms a part of the social imaginary that all societies externalize as a horizon for judgments. From there, it is necessary to preserve and develop the utopias of good order, because only as related to this image of the perfect, but impossible, society are we able to discover the possible society.

Lechner rejects social revolutions as mechanisms for the construction of a social order and establishes the possibility of consensus as being necessary to the new forms of political processes. Negotiated ruptures are social reforms

based on agreements that give rise to political self determination. The greatest challenge in Latin American transitions is the construction of an order that can combine the possibility to establish consensuses regarding central themes that lead to democracy. From this perspective there are no longer predetermined subjects, nor armed revolutions. Qualitative changes are proclaimed based on political ruptures and conception between what is possible and what is desirable. Facing war and consensus as two limiting ideas, negotiated rupture points toward the construction of collective will, toward politics as the deliberate creation of the future.

Lechner's main contribution is in highlighting the construction of order as a political task. The search for society's diversity is a transformation undertaken as the construction of order, where negotiated ruptures are the constructive elements of a new order shaped according to the idea of what is desirable. Feasible democracy is constituted by a plurality of subjects that arises through reciprocal recognition; even though one has to confront the "Other," it is no longer to annihilate him but rather to confront the differences. Democratization therefore demands the development of plurality and collective responsibility. The construction of order becomes a collective task. Politics is everyone's activity, a citizen activity. There are reciprocity agreements, where trust, loyalty, or respect are real norms through which reciprocal expectations are structured. Thus, it is the linking of economic transformation and political self determination as emancipatory practices that leads to democracy.

The last part of Norbert Lechner's work is dedicated to the difficult task of constructing Latin American democracy. Democracy needs to be placed in the public light in order to develop, but at the same time it hides skeletons in the closet, some sordid and others simply forgotten. Lechner will delve into the recognition of these nooks and crannies – the cognitive affective substratum of democracy – in order to obtain a different substratum of politics.

Thus, in the debate regarding democratic alternatives, Lechner says that two moments stand out that pave the way for a transformation of Latin American political thinking. On one hand, there is a reassessment of politics, which rejects the logic of war and substitutes

for the political logic; this points not to the annihilation of the adversary but rather to the reciprocal recognition of subjects amongst themselves. The need for difference and plurality is emphasized as a condition for political life itself, and a reconceptualization of utopia is proposed that defines it as an image of impossible plenitude that is nonetheless indispensable in order to discover the possible. On the other hand, there emerges a reassessment of civil society that highlights the interest of intellectuals in establishing democratization in the concrete problems of ordinary people, along with concern for the reconstruction of the social fabric that has been devastated by military dictatorships as well as neoliberal regimes.

For Norbert Lechner, the actual reevaluation of the formal procedures and institutions of democracy in Latin America cannot rest on old habits and norms that are recognized by everyone. It is not about restoring regulative norms, but rather the creation of those norms that are essential to political activity; the beginning of the democratic game and agreement regarding the rules of the game are two simultaneous facets of the same process. Today, the central task in the democratization of Latin America is a change in political culture. The possibilities and tendencies for democratization are conditioned by criteria of normalcy and naturalness, developed by normal people in their daily lives. It is in this sphere that projects of solidarity and social change can be built. Delving into political culture opens a wide expanse of possibilities that range from the mundane to the political.

The lack of a democratic political culture in Latin America is due, according to Lechner, to the growing distance between political institutions and citizens. As more social activities are submitted to political legal regulation, the man on the street loses more control over his social context, producing a deterioration of political practice upon failing to be able to produce and reproduce the sense of order to which men and women refer in order to contextualize the different aspects of their lives. To the extent that political organizations, which are increasingly specialized and separated from the daily tasks of "people like us," no longer create or guarantee collective identities, these identities tend to recreate themselves on the margins or even in opposition to the institutions.

Because of this, the study of everyday life becomes a fundamental concern for Lechner. He returns to important authors such as Gouldner, Habermas, Touraine, and Heller and proposes that everyday life is a crystallization of the social conditions that allow us to explore the relationship between macro and microsocial processes. It is the field for the analysis of the contexts in which different individual experiences come to be recognized as collective identities. Democratic construction goes side by side with political culture, with that privileged space in daily life that implies a change of values, perceptions, and images and comes to establish itself. It begins with common visions, the possibility to create collective identities, and democratic consolidation.

However, the construction of a democratic order confronts two great problems: the lack of time and unpredictability. In terms of time, Lechner points out how events suddenly happen and multiply and, on occasions, nothing happens and time languishes, stagnates. In both cases, one bets on the realist's conjecture, to take one's time in order not to be overwhelmed by the urgency of events nor limit the time in order to be able to crystallize emotional energies within a symbolically significant time frame. In terms of unpredictability, he returns to Luhmann and proposes reducing the uncertainty and insecurity of politics. It is not a forecast, it is a bet: it is the commitment to a particular result, which is not foreseeable.

One of the fundamental elements for resolving the distance between the present and the future and increasing the level of acceptable uncertainty is trust. The term implies a commitment to certain future conduct without knowing whether the other will respond to the commitment. It is a voluntary offer, but once the other responds to the trust given, he or she is committed. To trust is to reflect upon uncertainty. Trust in the order is a central element of the stability of a democratic system. Trust involves the citizenry's identification with the political system as well as the system's credibility before public opinion.

As can be seen, Lechner's work shows a substantial change from his proposals of the 1970s. In this final period, concern for political culture, trust, and the construction of a democratic order are the most important points of

reference in his work. The transformation of Norbert Lechner's theoretical as well as critical apparatus is a clear sign of political ideological developments in Latin America, a region of the world that continues to face the consolidation of democratic societies.

Lefebvre, Henri (1901–91)

Michael T. Ryan

Henri Lefebvre had the good fortune to live a long, intellectually productive life in a century of political disasters that drove most intellectuals on the left to despair or worse. Lefebvre was one of the most original Marxist theorists to think with Marx beyond Marx about the changes taking place in capitalism since Marx's death in 1882. He appropriated in a critical manner the concepts of some of the most important social theorists. Lefebvre also developed concepts of his own: everyday life, the production of social space, difference, modernity, and reproduction of the relations of production. He completed his Diplôme d'Études Supérieures at the Sorbonne in 1924 and his dissertation in 1954. Lefebvre considered himself a philosopher/sociologist, and this led him to emphasize conceptual analysis on sociological issues. He became a member of the French Communist Party (PCF) in 1928 and was excluded from it in 1958 for participating in too many oppositional groups to the PCF. He was appointed to a research position in 1948 in the Center of Sociological Studies (CES) at the Centre National de la Recherche Scientifique (CNRS). In 1960 he established the Research Group on Everyday Life at the CES. In 1965 he was appointed to the sociology chair as well as to the directorship of the Institute of Urban Sociology at the University of Paris at Nanterre. Henri Lefebvre was one of the most important influences, along with Guy Debord and the Situationist International, on the student movements and May events in France in 1968 that

raised questions about the bureaucratization of private life in the "bureaucratic society of controlled consumption." His most important publications are: *Critique of Everyday Life*, Vols. 1–4 (1947, 1961, 1981, 1992); *The Production of Space* (1974); *The Urban Revolution* (1970); and *The Survival of Capitalism* (1976).

Henri Lefebvre came of age during the events and aftermath of the Russian Revolution which occurred in the conjuncture of the capitalist crisis and World War I. Lefebvre discovered Marx's concept of alienated labor and extended it to the analysis of private life. It is at this moment that the consumer society emerges in response to the failed proletarian revolution, with the "technocracy" bringing its bureaucratic forms of organization to the reproduction of the capitalist relations of production. The Great Depression and World War II provided a second crisis and moment for Lefebvre's development. He brought Nietzsche's thought together with Marx's in the first volume of his *Critique of Everyday Life*. The process of self development and public life were as alienated as the working day in Marx's analysis. Lefebvre also confronted a number of other important intellectual currents: institutional Marxism, existentialism, information theory, structuralism, and American sociology. The crisis of the late 1960s provided a third moment in Lefebvre's development when anti colonial wars were proving to be much more risky to the metropolitan centers than the "colonization of everyday life," as Debord put it. Differential groups – racial and ethnic groups, students, youth, women, homosexuals – were contesting bureaucratic authorities across the globe in their struggles to realize the *right to be different*, one of Lefebvre's rights to the city. Lefebvre also had critical encounters with structural Marxists, Heidegger, and postmodern theorists.

Lefebvre first discussed dialectical method in an article on rural sociology written in 1953. He further elaborated on his method in volume 2 of the *Critique of Everyday Life*. Lefebvre's method of analysis takes sociology beyond mere description of society as it exists to an analysis of society in terms of its possibilities for change. His method of conceptual analysis starts by going back to the emergence of a concept, e.g., everyday life emerges in the writings of novelists such as James Joyce in *Ulysses*. Everyday life is a

residuum, a moment of history, what is left over after working activities are extracted, humble actions that are repeated daily and taken for granted, the positive moment and power of daily life. This is the “regressive” moment in his dialectical method. Then he links the concept to its place in the current social totality. Every day life is also the product of modernity, of bureaucratic organization and the programming of private life, “everydayness” as an alienated moment. Everyday life is a contradictory amalgam of these positive and negative moments. In the “progressive” moment he begins in the present to analyze the possible movements of the concept and the totality, from the programmed everyday to lived experience, self development and generalized self management, i.e., the revolution in everyday life. For Lefebvre everyday life is *the* social structure of modernity, a mediator between particulars and the social totality, a *level* of the social totality. Everyday life is another instance of uneven development, an impoverished sector that has yet to be developed with the available wealth and technologies to the same extent as other sectors such as capital goods and the military. As long as people can live their everyday lives, modernity will continue to be reproduced in its present forms and structure. When people can no longer live their everyday lives, the possibilities for change in social relations become open.

In *The Production of Space*, Lefebvre distinguishes social space as it is *conceived* in abstract geometric terms, as it is *perceived* concretely in the works of artists like Cézanne, and as it is *lived* in everyday life by different social strata and actors. Social space is organized in ways to facilitate the movement of products and people, reflecting the logic of the technical division of labor; it has also been commoditized and colonized and creates another sector for investment and capital formation. It is an abstract space that develops without regard to the needs and desires of human beings; it enhances the domination of the technocrats and contributes to the reproduction of the capitalist relations of production. It sets in motion a conflict between the producers of this abstract space and the users who want to appropriate space as “lived space.”

Difference is another critical concept that Lefebvre linked to the processes of urbanization and urban revolution. Industrialization has a

homogenizing logic, reducing everything to commodities. Urbanization has a differential logic. Like Robert E. Park, Lefebvre argues that differences are one of the most unique qualities of cities. While most sociologists analyzed these differences in terms of subcultures, Lefebvre used this concept to emphasize relations of domination and subordination. The differences originate in nature as particularities – race, ethnicity, gender, and age – but they become social differences when the members of these groups struggle for the right to be different. Their struggles take place in an urban context in which they: affirm their difference against the process of homogenization; assert their right to the center against fragmentation and marginalization; and claim their right to equality in difference against the process of hierarchization. Lefebvre uses this concept to explain the new social movements that have developed since World War II. They are at the heart of the urban revolution, although the working class, because of its position in the process of production, still has a role to play.

According to Lefebvre, capitalism has undergone a mutation from its classical nineteenth century form. When the working class failed to become a revolutionary agent of change, the technocrats brought stability and cohesion to a society that lacked both through their deployment of bureaucratic forms of organization and the ideology of technological modernism, the introduction of trivial technological changes on the surface of this society while the capitalist relations of production remained fundamentally unchanged beneath the surface. Social relations do not have a life of their own; they do not persist due to inertia; they need to be reproduced in everyday life. Marx had demonstrated the social quality of the production, distribution, and exchange moments in the process of production. He did not take his analysis into the moment of consumption, nor did he link this process to social space. In their consumption the members of each social class reproduce themselves as capitalists, workers, and land owners. When workers pay for their material and immaterial needs in everyday life, they recreate their dependence on capital and land and are constrained to return to the labor market. The capitalists take their profits, pay for their own consumption, and reinvest their

wealth in whatever economic sector that promises to expand their wealth. This reproduces their dependence on workers whose living labor creates the wealth. Further, capitalists invest their wealth increasingly in space: industrial, commercial, agricultural, and residential and leisure spaces. This allows capital to accumulate beyond the crisis tendency in the industrial sector, although this sector is also subject to crises of falling profits, overproduction, and depreciation. We move from the production of *things* in space in the nineteenth century to the production of *space* and things in space in the twentieth century.

With the creation of modernity, many of the historical tasks of the working class revolution have been accomplished. Yet, Lefebvre did not see it as a closed system in the way that Baudrillard saw it, and that is why he does not see our society as a postmodern one. He argues that while modernity is efficient at taking care of individual needs, there are social and individual needs that are poorly recognized and met: health care, education, care for the elderly, public spaces, community, love and self actualization. Social goods are different from individual goods; they are not used up in the same way as a commodity is used up in an act of consumption. Millions of citizens have made use of Central Park in New York City, but they have yet to use it up. There is also a fundamental struggle between consumers and producers over the intended uses and meanings that are attached by the advertising form to goods and acts of consumption. Consumers often use goods in their own ways, attaching their own meanings to commodities. Further, programmed consumption entails incredible destruction of natural resources and the environment, especially when planned obsolescence accelerates the depreciation of commodities through the fashion cycle and the low quality of materials used. The destruction of the earth is a real possibility. Lefebvre proposes a different path for social revolution: revolution in everyday life and urban revolution will complement and extend the proletarian revolution toward generalized self management and emancipation from bureaucratic domination and class exploitation at work, in public life, and in private life. This process will lead to the creation of an urban society, although it is likely to be a long process

since changes in everyday life are slow. This process will require a reduction in time devoted to work.

Modernity is an incredibly complex social formation, and there is a tendency for sociologists to reduce this complexity to single forms (norms), structures (culture), or functions (socialization). Lefebvre argues that we must situate and mediate all of these social forms, functions, and structures within the political, economic, and cultural processes that produce and reproduce modernity. Further, we must be historically specific in our analysis and give up our quest for universals.

legal profession

Mathieu Deflem

The legal profession refers to all the occupational roles purposely oriented towards the administration and maintenance of the legal system. Encompassing lawyers, judges, counselors, and experts of legal education and scholarship, the legal profession has been the subject of considerable reflection in the sociology of law. This sociological interest parallels the enormous attention devoted to the legal profession in various strands of sociolegal studies, including also other social sciences besides sociology as well as legal scholarship, which in turn is the result of the successful monopolization of the execution of legal functions and the resulting social standing and closure of the legal profession. The fact that the legal profession is among the most researched aspects of the institution of law is thus a direct function of the professionalization of the legal role itself. Yet, although most scholarly research on the legal profession comes from within legal scholarship and from law and society perspectives that are firmly nestled in legal education, there also exists a distinctively sociological tradition that examines societal aspects of the legal profession from the viewpoint of a multitude of theoretical orientations.

The aspiration to maintain occupational autonomy is one of the legal profession's most critical and sociologically challenging characteristics. This professional independence is a concrete expression of the autonomy of law as a whole. Rooted in Montesquieu's famous doctrine of the separation of powers, the ideal of legal autonomy finds primary expression in the establishment of an independent judiciary. Further manifestations of the autonomy of law are provided in the workings of the courts and, most importantly, the professionalization of the legal occupation. The autonomy of legal practice is primarily reflected in legal education and legal practice, as the legal profession has been successful in controlling admission to and the organization of law schools and legal work.

Theoretical differences exist on how the place and role of the legal profession are to be

conceived from a sociological viewpoint. Most studies in the sociology of the professions are indebted to the focus on the professionalization of legal work in modern societies that was first systematically addressed by Weber and which was subsequently taken up by Parsons with respect to the role of the professions in the legal system's integrative function.

Weber defined law intimately in relation to the legal profession by specifying law as a normative order that is externally guaranteed by a specialized staff, including police, prosecutors, and judges. Under conditions of modern societies, Weber maintained that law rationalized in a formal sense on the basis of procedures that are applied equally to all. Legal professionals take on a special role in this context because they are involved in the adjudication of law on the basis of acquired legal expertise. The institutionalization of expertise in matters of law secures the specialized status of the legal professional on the basis of the state formally granting such monopoly.

In modern sociology, Parsons gave special consideration to the legal profession's role in securing integration through the legal system. This conception harmonizes with the functionalist attention towards law as a mechanism of social control and also betrays the broader Parsonsian attention to the role of the professions in modern societies. The successful acquisition of expertise in a particular occupational role is the profession's most outstanding characteristic. The legal professional is primarily someone who is learned in the law and who can provide specialized services on the basis of this expertise. The legal professional thus mediates between the polity as legislator, on the one hand, and the public as clients of the law, on the other.

In more recent decades, sociological perspectives have offered more varied, sometimes radically alternative viewpoints on the role and status of the legal profession and its autonomy. Theoretical perspectives have been introduced that transcend the functionalist obsession with integration to contemplate the law's role in terms of power and inequality. Most distinctly focusing on the legal profession have been representatives of the so called Critical Legal Studies movement who have pondered the behavior of judges and lawyers irrespective of,

and often contrary to, law's self proclaimed ideals of justice and equity. Arguing that legal reasoning is affected by dozens of personal biases depending on the legal professionals' sociostructural backgrounds, these perspectives have in their most radical form critiqued the very basis of the legal professional's aspiration to autonomy and expert neutrality.

While not necessarily overly critical in orientation, most recent sociological studies of the legal profession have pointed towards greater diversity in the legal profession than a simple model of professionalization can account for. Sociologists have specifically contemplated the more complex behavior of the legal profession once it has been successfully monopolized, when it also seeks to influence the state and its legislative potential. Among the more enduring sociological puzzles, also, is the increasing diversity of the legal profession since the latter half of the twentieth century. Unlike the cohesive group of old, legal professionals nowadays comprise a wide variety of practitioners, educated in a multitude of legal programs, and are more broadly representative of contemporary society with respect to gender, age, and ethnicity. The increasing diversity of the legal profession, however, has not always been accompanied by increasing equality, as many disparities have been observed to persist, such as earnings gaps among male and female lawyers and differences in cultural and economic capital between solo practitioners and employees in large law firms. The high degree of stratification in the legal profession may thus have brought about a lack of professional unity.

legitimacy

Lisa Troyer

Legitimacy is defined as a state of appropriateness ascribed to an actor, object, system, structure, process, or action resulting from its integration with institutionalized norms, values, and beliefs. It is a topic of longstanding interest across the spectrum of sociological phenomena and levels of analysis. Legitimacy is a multilevel concept, as implied by the term "actor," which may refer to individuals, groups, organizations, nation states, and world systems. It appears as a core concept in diverse areas of sociological inquiry including (but not limited to) social psychology, stratification, deviance, collective action, organizations, political systems, law, and science.

At its core, legitimacy involves a sense of appropriateness that is accorded to an entity. That is, a legitimate entity is one that we view as suited to its social environment and, as a result, deserving of support by other entities in the environment. The sense that an entity is suited to its environment arises from its perceived consistency with the institutionalized norms, values, and beliefs in which the entity is embedded. The institutionalized character of norms, values, and beliefs is a critical element of legitimacy. Institutionalized criteria are beyond the discretion of single actors. Because no single actor is perceived as dictating the norms, values, and beliefs that guide a social system (although they are socially constructed), they represent superordinate standards, uncontaminated by individual motives and preferences. Their superordinate status lends institutionalized

norms, values, and beliefs a taken for grantedness and the sense that, irrespective of privately held views, they will be upheld by others in the social system. Consequently, an entity that is perceived as integrated with institutionalized norms, values, and beliefs is one that we believe is appropriate and thus deserving of support. That support may take the form of social approval, the investment of social capital, or material/financial rewards.

Theoretical treatments of legitimacy emphasize the importance of collective support. This is a common thread across classic sociological theory, hearkening back to the work of Marx, Mead, and Weber. It is interesting that while Marx proposed that class consciousness – a sense of shared ideology – is critical to the elimination of inequality, Della Fave (1980) argued that the shared ideology of *equity* legitimates stratification. An equity ideology, represented in the generalized other (i.e., the perception of the shared norms, values, and beliefs to which society prescribes that is held by individual actors), affects individuals' self evaluations and, thereby, their sense of deservingness of rewards. These self evaluations, in turn, serve as the basis for rationalizing an unequal distribution of resources in society, engendering a sense of appropriateness regarding inequality. As a result, social inequality gains legitimacy and is perpetuated.

Weber's highly influential work on authority systems likewise emphasized the importance of the perception of collective support in generating legitimacy. He proposed that legitimate authority systems are those in which authority reflects rule based action, where the rules are collectively upheld (as opposed to action directed at maximizing one's personal outcomes and exercised at personal discretion). Thus, Weber highlights the importance of validity – the perception that others support and will act in accord with the rules governing a system – in legitimating an authority system. Subsequent theorists explicitly distinguished validity from propriety (i.e., privately held beliefs about the appropriateness or desirability of an entity), and demonstrated that validity generates legitimacy, independent of propriety. Insights on the importance of validity to legitimacy have been applied not only to authority systems, but also

to status structures, patterns of distributive justice, and identity processes.

Also, across time and different treatments of the concept, legitimacy is consistently viewed as a source of stability in social systems. As Weber noted, legitimate authority persists and provides an important foundation for bureaucracy, itself a persistent organizational form. Scholars of organizations and world systems have pointed to the isomorphic tendencies of legitimate structures and processes to diffuse across social systems. Group processes researchers have also suggested that legitimacy produces resilience in status structures and distributive justice processes, even when those structures and processes disadvantage the majority of actors in the system. Stability is a function of the ongoing ability of actors within the system to mobilize resources to perpetuate a legitimate system.

As this discussion has suggested, sociological theories involving legitimacy have drawn heavily on Weber's classic work. His insights on the legitimacy of particular organizational structures and processes (e.g., legal rational authority and bureaucracy) begged the question of how these particular forms gained legitimacy. Meyer and Rowan (1977) addressed this question with an influential essay on the process through which social structures and processes become aligned with the collectively supported (i.e., institutionalized) norms, values, and beliefs that are socially constructed and transmitted through the environment. Recently, sociologists have turned their attention to the process of alignment itself. How do the structures and processes of social entities become aligned with collectively supported norms, values, and beliefs?

Three strategies have emerged to address this question. First from the new institutional perspective in sociology, theorists have argued that alignment with institutionalized norms, values, and beliefs (and hence, legitimacy) results from certain environmental pressures (e.g., Powell & DiMaggio 1991). These factors lead social systems to adopt structures and processes that embody institutionalized norms, beliefs, and values. The pressures arise from normative and coercive processes that reward conforming systems with legitimacy and punish deviant ones with its withdrawal. Alternatively, in the absence of coercive and normative

pressures, when the norms, values, and beliefs that would dictate the desirable form are uncertain, systems are likely to mimic the form of other already successful systems.

Second, a related argument from the population ecology perspective (e.g., Hannan & Freeman 1992) proposes that the environment determines which organizational forms survive, and which languish. Within this perspective, the form (i.e., structures and processes) a system assumes at its outset is relatively stable and resistant to change. To the extent that institutionalized norms, values, and beliefs characterizing the environment are embodied in the system from the start, its legitimacy increases and, therefore, so do its odds of surviving. This is because legitimacy is critical to securing other key resources needed for survival. As this implies, the environment, rather than the strategic behavior of actors, determines the legitimacy of a system.

A third perspective on how entities align themselves with institutionalized norms, values, and beliefs to secure legitimacy is also emerging (e.g., Friedland & Alford 1991). This perspective incorporates both a strategic view of social actors and elements of social constructionism. It recognizes the diversity of sets of shared norms, values, and beliefs that characterize social environments and are closely tied to established social institutions, like the economy, political systems, and the family. These sets of norms, values, and beliefs, referred to as "institutionalized logics," may vary depending on the institutions with which they are associated. For example, a norm of equality may comprise a logic related to democracy; a norm of equity may be part of an institutionalized logic corresponding to a capitalist economic system; a norm of need based resource distribution may be a component of the institutionalized logic governing the family. Moreover, all of these institutions (with competing logics) may coexist in the same broader social system. Emerging theory drawing on these ideas suggests that legitimacy arises when an entity is able to mobilize support for the logic it embodies through appeals to the relevant social institutions supporting that logic. Thus from this perspective, legitimation is a process through which actors successfully construct the validity of the norms,

values, and beliefs characterizing their own systems through appeals to particular institutions within the broader social system.

As these developments indicate, theory related to the sources and consequences of legitimacy is growing in part through integration and diffusion across perspectives and topics, as well as competing arguments on the mechanisms of legitimacy. New institutional theory, which has catalyzed many of the contemporary developments in the study of legitimacy, emerged in the context of the sociology of organizations, but has become increasingly influential in such diverse areas as political sociology, group processes, sociology of culture, and sociology of law. At the same time, Weber's classic statements on validity and authority remain influential. Furthermore, on the one hand, social constructionist accounts have gained renewed attention with attempts such as those described above to explain strategic efforts of actors to secure legitimacy. On the other hand, recognition of inertial forces beyond the control of actors also retains significance in explaining the dynamics of legitimacy.

In contrast to the vast research on the sources and consequences of legitimacy, however, there has been less emphasis on delegitimation. Theory and research on unstable political systems are valuable examples of the importance of investigating such processes. Given the importance of validity and institutionalized norms, values, and beliefs to legitimacy, it is not surprising that this line of theorizing points to conditions that increase the salience of conflict over shared norms, values, and beliefs as a catalyst for undermining the validation of political systems. Once invalidated, legitimacy crumbles, and established political regimes are vulnerable to replacement. Researchers investigating political change have posited that political actors are carriers of endorsement or disapproval across social groups, and once disapproval becomes salient across a critical mass of groups, then legitimacy is jeopardized (e.g., Habermas 1975). Extensions of these ideas may hold promise for the theories of delegitimation, and thus social change as it characterizes other structures and systems, e.g., organizational change, economic change, changes in legal systems, changes in status and distribution systems.

Despite the long history of research related to legitimacy, it has been hindered by methodological difficulties. Researchers have had difficulty operationalizing legitimacy independent of the variables to which it is theoretically related (e.g., validity, stability, commonality, mobilization of support). For example, within organizations research, the legitimacy of an organizational structure or process is often operationalized in terms of its prevalence, the extent to which organizational actors believe that other actors endorse it, and/or the success of organizations in extracting resources from their environments. Similarly, political sociologists have also conflated legitimacy with endorsement and the stability of political systems. Within microsociological traditions, the conflation of legitimacy with its causes and consequences is less common. Instead, researchers in these traditions, like Berger et al. (1998), tend to treat legitimacy as an unmeasured theoretical construct, and focus on its constituent processes and outcomes, e.g., the relation between validity, resource mobilization, and stability. This strategy has the advantage of retaining the logical integrity of theories involving legitimacy, while still testing the social processes and outcomes that legitimacy is assumed to engender.

In summary, legitimacy continues to represent an important theoretical concept for sociology. Yet, there are a number of challenges to be addressed, such as articulating the relative effects of strategic behavior versus inertial forces in legitimacy processes, developing and testing theories of illegitimacy, and refining the operationalization of legitimacy. Because of the centrality of this concept to the understanding of social life at different levels of analysis and across different topics, legitimacy is likely to continue to play a key role in sociological theory. Indeed, Comte's vision of sociology as a science that can explain both the social order and social dynamics may be realized through theories of legitimacy that are able to specify both the legitimization processes that give rise to stability, and the delegitimation processes that give rise to social change.

leisure

Sheila Scraton

Leisure is a notoriously difficult concept to define. The study of leisure has early origins stretching back to the 1920s and Veblen's *The Theory of the Leisure Class* (1925). However, it was in the 1960s and 1970s that the foundations of leisure studies as an academic area were laid. Early writers such as Dumazedier in *Towards a Society of Leisure* (1967) defined leisure as activity that is set apart from other obligations such as work and family and provides individuals with the opportunity for relaxation, the broadening of knowledge, and social participation. Dumazedier's definition highlights the notion that leisure involves pleasure and freedom of choice and that this sets it apart from paid work and everyday commitments. Leisure could be seen as *compensation*, a means of escape from the routines of daily labor, or as *residual time*, time left over when other commitments have taken place.

The definition of leisure as in opposition to work and other obligations has been very significant within the sociology of leisure. In the UK, Parker (1971) was a major contribution that explored in greater detail this relationship between work and leisure and argued that leisure is an important aspect of social life that demands rigorous sociological analysis alongside the more conventional areas of work, family, education, youth, and so on. He argued that it was with industrialization that leisure became viewed as a separate sphere of life as work became more clearly demarcated in terms of time and space. Therefore, leisure cannot be understood in isolation from work. Parker identified three aspects of the work–leisure relationship: extension, opposition, and neutrality. He viewed the *extension* pattern as showing little demarcation between work and leisure activities, giving the examples of social workers, teachers, and doctors as typical of those that experience work and leisure in this way. *Opposition*, as the name suggests, relies on an intentional dissimilarity between work and leisure and Parker highlighted people with tough physical jobs such as miners or oil rig workers as typical within this category. His third pattern of

neutrality is defined by an “average” demarcation of spheres. Workers whose jobs are neither fulfilling nor oppressive and who tend to be passive and uninvolved in both their work and leisure activities are defined by this pattern.

There were several criticisms of Parker's early typology of the work–leisure relationship that highlighted the limitations of this analysis for those outside of the paid workforce. The unemployed, the retired, students, and women working in the home as carers and undertaking domestic work were all identified as outside this work–leisure model as paid work is not central in their lives. However, the recognition of the importance of situating leisure within a social context, not as a separate, totally autonomous sphere of individual free choice, was an important contribution to the developing sociology of leisure. As leisure became analyzed within a social context, emerging definitions reflected the different emphases of competing theoretical perspectives within leisure studies.

THEORIZING LEISURE

A feature of leisure studies throughout the 1970s and 1980s was the development of competing paradigms which sought to understand and explain leisure from different sociological perspectives. In the UK the three major traditions in leisure studies developed from pluralism, critical Marxism, and feminism, whereas in North America a more social psychological approach underpinned much of the leisure research and writing.

Roberts (1978) argued that a pluralist model of society provides the most coherent approach to understanding contemporary leisure in the 1970s. His contributions to the field of leisure studies have remained consistent within this paradigm. This “conventional wisdom” suggests that there is a plurality of tastes and interests generated by different circumstances. Both commercial and public providers of leisure supply experiences from which individuals seek to fashion their varying lifestyles. Leisure is both a “freedom from” and a “freedom to” and is primarily concerned with relatively self-determined behavior. The pluralist model does not assume that leisure is free from all influences but argues that age, gender, socioeconomic

status, and other “variables” operate in a multitude of configurations (Roberts 1999).

In contrast to the pluralist model, Marxist theorists sought to understand leisure as an integral part of the structure of capitalist society. Clarke and Critcher (1985) argued that leisure’s domination by the market and the state, the persistence of leisure inequalities, and the drift to post industrialism all demonstrate how leisure is part of capitalist society. Capitalism shapes leisure through hegemonic processes of both constraint and coercion. Their work provided a powerful critique of the “conventional wisdom” of leisure studies and emphasized the importance of history and the significance of *social* processes such as work, the family, the life cycle, and the market. Leisure is about people’s choices but these choices are made within structures of constraint. Leisure needs to be understood within the dialectical relationships of structure and agency, control and choice, continuity and change. A neo Marxist approach to understanding leisure draws on the “sociological imagination” of C. Wright Mills, grasping the relationship between history and biography. Leisure as “freedom” and “constraint” is seen as socially constructed around time and space, institutional forms, and social identities. This approach to explaining and understanding leisure was derived from cultural studies and views leisure as potentially an arena for cultural contestation between dominant and subordinate groups in society.

Further criticisms of the “conventional wisdom” of leisure studies came from the developing feminist perspectives within sociology during the 1980s. Feminists began by identifying the male dominated approach that had characterized much of sociology, including the study of leisure. Leisure understood as free time or freedom of choice was identified as being problematic and irrelevant to many women’s lives. Women’s lives were recognized as not being neatly compartmentalized into periods of work and periods of leisure, as most women have domestic work responsibilities as well as paid work and often childcare or other caring responsibilities. For many women, family leisure is a time when they are supporting others’ free time, such as transporting children to activities, preparing meals for entertaining friends, or planning and organizing family holidays. Thus their

leisure often involves a *relative freedom* rather than clearly demarcated time. Feminist work identified the need to examine leisure in the context of women’s lives as a whole and not as a separate sphere divorced from all other areas of their lives. Consequently, the existing definitions and theories of leisure were viewed as androcentric, having meaning only in relation to men. Research by Green et al. (1990) provided the world’s largest study of women’s leisure. Based in Sheffield, UK, between 1984 and 1987, the research focused on the cultural significance of leisure in women’s lives and leisure as a potential site for conflict and inequality. They found that the concept *leisure* is extraordinarily resistant to being confined to a single, neat, definitional category. For the women in their study, leisure was a highly personal and subjective mix of experiences and was linked to, and a part of, other areas of life.

Research in the 1980s, which shifted the focus to women and leisure, also recognized that gender relations were crucially a part of leisure experiences and leisure institutions. This work identified that women occupy a subordinate position within a patriarchal society. Thus, their material position, as well as constructions of femininity and masculinity, have a determining effect on women’s lives, including their leisure lives. The research and theoretical understandings of women’s leisure highlighted issues relating to sexuality, respectability, and social control which paralleled work more broadly in feminist sociology. Women’s leisure was shown to be constrained by constructions of femininity and gender appropriate behavior and controlled, both directly and indirectly, by men, either individually or collectively. Although much of the work during this period focused on structural constraints of gender, there was some acknowledgment of the interlinking of gender relations with those of class and race.

Both the feminist and neo Marxist analyses throughout the 1980s in the UK shared a predominantly materialist or structuralist approach to the sociology of leisure. In North America, however, the approach to understanding leisure has been more individualistic and located within a social psychology or social interactionist paradigm. Within these approaches the emphasis is on how leisure is *experienced* by individuals. Rather than concentrating on constraints, the

focus shifts to how individuals use leisure to create roles and identities. Leisure can thus provide an important space for individuals as a *freedom to be*, self determining and fulfilling. The work of the North American social psychologist Csikszentmihalyi has been utilized within this approach to understanding leisure; in particular the concept of *flow* has been applied. This notion of flow is associated with what Csikszentmihalyi argues is *optimal experience*, when highly skilled individuals are stretched to their limit and become totally absorbed in their activity. It is through leisure activities that many people seek to achieve this optimal experience. Focusing on leisure as experience directs attention toward motivations and satisfactions and emphasizes inner feelings and experiences rather than external contexts and constraints.

Since the 1990s, sociological approaches to understanding leisure have drawn on postmodern developments in social theory. Rojek (1993, 1995, 2000) has been the most prolific writer who has criticized the former traditions of leisure theory, which he characterizes as social formalism, the influence of critical Marxism, and cultural studies and feminism. In his writings he not only debates and challenges the paradigmatic traditions within leisure studies but also develops and engages with postmodernist perspectives on leisure. Rojek has developed theoretical debates within sociology and sought to understand and interpret postmodern cultures and their relevance for leisure and leisure studies. In doing this he has presented a challenge to the existing theories, which he argues offer universal accounts that rely on dualisms and fail to adequately theorize culture, difference, and agency. Rojek argues for a phenomenology of leisure, with experience at the center of analysis. Within postmodernity, the weakening and destabilizing of former structures and the blurring of social divisions such as class, race, and gender have led to leisure and leisure lifestyles gaining increasing significance in the construction of individual and social identities. The development of new technologies and the shifts in cultural practice to hyperreality, a loss of authenticity, a dissolution of cultural boundaries, depthlessness and superficiality, fragmentation, parody and pastiche, are all seen to find expression within postmodern leisure.

No longer are leisure places and experiences seen to be fixed as travel and tourism become virtual, theme parks, such as Disneyland, challenge the distinctions between real, imitation, and fiction, and leisure becomes more individualized with pleasure, risk, and excitement center stage. The connections between leisure lifestyles and consumption are of increasing significance, with leisure playing an important role in the reflexive project of identity construction and definition.

Although postmodernism and postmodernity have impacted on the ways in which leisure is understood and theorized, there remain many theorists who argue that such a shift is by no means total or complete. Although many accept that uncertainty, fragmentation, hyperreality, and superficiality are evident in our cultural world and leisure reflects these cultural shifts, others have argued for theoretical positions that recognize and analyze cultural differences and the complexities of multiple social identities whilst adhering to a theoretical stance that continues to consider broader structural relations of power and the persistence of material inequalities in many people's lives (Wearing 1998; Aitchison 2003).

RESEARCHING LEISURE

Information about people's leisure has been, and continues to be, routinely collected via large participation surveys such as the General Household Survey in the UK, which is conducted annually and gathers information from a nationally representative sample of households. Questions in the survey that are related to leisure provide knowledge of participation rates for different sections of the population, including the number and type of people taking part in sporting activities, visits to the countryside, and visits to museums and other leisure related provision. Since the academic study of leisure began, information such as this has been used to evidence trends in participation over time and identify which groups in society are under or over represented in various activities. Other large scale surveys provide information on consumer spending on leisure, and together, large scale national surveys help identify the

main leisure activities for different populations. Roberts (1999) identifies that the big three leisure activities are eating and drinking, tourism and holidays, and home entertainment, including the television and other audiovisual media. He argues that out of home food and drink are leading leisure items, and that participation in these activities and spending on them exceed the figures for sport participation and spectating, cinema attendance, or participation in other leisure forms. Tourism and holidays rate very highly in terms of expenditure, with people increasingly taking more holidays and traveling further. The media are a significant aspect of people's leisure and it is home entertainment that is a major leisure activity for many people.

Large scale national surveys together with time budget studies and expenditure surveys have been used since the 1970s to categorize and measure the "facts" of leisure and, in turn, to influence and direct policy initiatives. This tradition of positive empiricist research underpinned the "conventional wisdom" of leisure studies as quantitative data provided knowledge about leisure participation. Empirical research utilizing quantitative data also contributed to knowledge about leisure through the life course as participation rates at different ages were identified. However, an influential piece of early work on leisure through the life course, *Leisure and the Life Cycle*, was conducted in 1975 by Rhona and Robert Rapoport. They used extended interviews in families to explore the balance of leisure, family, and work in people's lives and identified how individuals have different preoccupations throughout their lives, identifying four main stages within the family life cycle. Although there have been many criticisms of the Rapoports' approach to understanding leisure and the family, methodologically their research moved away from a rigid quantitative approach to one that sought to delve more deeply into meaning and identity.

As the questions in leisure studies turned from the *functions* of leisure to a concern to explore and identify structural inequalities, both in and through leisure opportunities and experiences, so the means of conducting such research have shifted. Increasingly, researchers have turned to in depth, qualitative, and interactive

methods to explore the realities, meanings, and experiences of leisure. There has been a move to recognize the significance of subjective knowledge, which is largely absent or marginalized from quantitative large scale studies. Feminist researchers in particular have argued for the importance of small scale, qualitative, or interactive approaches that can give voice to the personal, experiential, and emotional aspects of leisure. This shift to more micro, individualized accounts of leisure, away from more macro institutional concerns, mirrors the theoretical shifts over the past few decades in the sociology of leisure. However, although there are now far more studies that use interviews, life histories, and a qualitative approach, there is still a reliance on large data sets of survey material to inform policy. Leisure research remains closely applied to policy and practice in many cases.

CURRENT RESEARCH AND FUTURE DIRECTIONS

Leisure contexts and activities are extremely broad and include sport, physical activity, tourism, media, the arts, countryside recreation, and new technologies, amongst others. Leisure continues to provide an important site through which sociological questions can be explored. Work-leisure-family balance remains crucial to achieving quality of life and is of increasing significance as paid work intensifies, becomes more flexible, and working life becomes extended. The place of leisure in achieving work-life balance remains an important sociological question, as do questions relating to retirement, "serious leisure," and volunteerism. However, the early emphasis on the work-leisure relationship is being replaced, at least to a certain extent, by questions relating to the depth and spread of consumer culture.

The growth of consumption and commercial provision, together with the theoretical concerns of postmodernism and poststructuralism, have shifted the focus of some leisure scholars away from former concerns around material inequalities to questions of representation, embodiment, and identities. Drawing on social and cultural geography, research has begun to

explore the consumption of spaces and places within a leisure context. Whilst this remains underdeveloped, there is already exciting work around areas such as gay and lesbian city space, cultural tourism, and shopping.

Gender relations have been central to the study of leisure since the 1980s, including work focusing on androcentric definitions of leisure, the different meanings and motivations for women participating in leisure, leisure spaces, women's oppression in and through leisure, and, more recently, leisure as an important site for agency, negotiation, and transformation. Increasingly, research on gender is recognizing the importance of acknowledging and understanding difference and diversity between women. Studies on the experiences of different women across ethnicity, age, sexuality, and class have extended our qualitative understandings of women's leisure. Further work will be important in exploring the intersectionality of gender, race, ethnicity, sexuality, and class in the leisure lives of diverse groups of people. There remains limited work on masculinities and leisure and much of the current research is within the context of sport. There needs to be more research into shifting gender relations, new masculinities, and men's changing relationships within work, the family, and leisure.

A major gap in the literature within leisure studies is work that centers on race and ethnicity. Although there is some critical engagement with race, racism, and sport, this needs to be extended and developed into other areas of leisure. An exploration of the concept of whiteness is beginning within sport and leisure studies, although as yet this remains underdeveloped.

Leisure research is a broad and multidisciplinary arena. The theoretical shifts within the sociology of leisure are reflected in the changing focus of research away from questions of leisure choice and material and structural inequalities to more rigorous analyses of leisure forms and practices as sites for cultural production, empowerment, social inclusion, and social transformation.

leisure, aging and

Jon Hendricks

Leisure and well being are closely entwined throughout life. Whether defined as free time or volitional activity, the significance of leisure is that it provides opportunities wherein the quest for meaning is self absorbing and yields

subjectively salutary results. Given changes in the character of work, certainty of careers, timing of retirement, and improvements in health, it is reasonable to assert that leisure will occupy an important place in the aging process.

Rather than consider free time, leisure, and aging as domains separate from the rest of life, adopting a life course perspective may provide greater insight. Leisure is grounded in societal conditions as well as the subjective and individualized world of participants. Leisure does not stand free of broader societal based values, gendered distinctions, life course issues, family stage, work, retirement, or other sociodemographic or marketplace influences. Yet leisure is symbolically significant to individuals, helping to create meaning and sense of self. Leisure structures time, space, and social relationships. If normative prescriptions or reinforcements from other realms become unclear for any reason, leisure interests may assume greater prominence. As far as individuals are concerned, leisure facilitates self enhancement, expression, and identity formation through intrinsic rewards, opportunities to exercise agency, and relationships rooted in the social worlds of leisure participation. Leisure serves as a context, a frame within which actors can author their own development – creating and collaborating interpretation by taking part (Hendricks & Cutler 2003; Stebbins 2004).

During the course of adulthood, leisure is fashioned by family life cycle, work roles, career stage, and demographic, socioeconomic, and other master status characteristics such as gender or ethnicity. Though leisure interest may evolve over time, its symbolic relevance in terms of identity, integration, and bonding may remain constant. During retirement leisure likely reflects role substitution, the search for meaningful modes of engagement, and is a mechanism to maintain vigor, interests, and relations.

Among adults, an average of 40 hours a week may be devoted to leisure (Becker 2002). TV watching can account for up to 28 hours a week, but travel, reading, socializing, gardening, and other discretionary activities occupy from 1.5 hours to nearly 9 hours weekly. According to the *Statistical Abstract of the United States: 2001*, during the previous year 48 percent of adults had partaken of an arts event and half had dined out or entertained

friends or family at home as a form of leisure. Available evidence suggests European elderly follow comparable patterns.

Physical activity, vigorous hobbies, exercise, and sports are somewhat more common among people age 65–74 and older than among their younger adult counterparts. Estimates are that a third to 40 percent of older men, compared to one quarter or less of younger adult males, engage in medium to high levels of leisure time physical activity (Barnes & Schoenborn 2003). Gendered patterns are historically grounded, with women marginally less physically active, but the age related slope is comparable. As the federal government's *Older Americans 2000* pointed out, approximately a third of persons aged 65 or older may be leading what can be described as inactive lifestyles. There is a direct relationship between education, income, and socioeconomic status and levels of physical activity. Despite the lore, attendance at sporting events is not overwhelmingly popular, with less than half of adults attending in the last year. For example, only about 16 percent of US adults have been to a baseball game in the past year (Becker 2002).

Such statistics do not tell the whole story, nor do they reflect variation in time devoted to particular forms of leisure depending on age, gender, socioeconomic status, and other socially relevant factors. Neither do they include volitional educational involvements or volunteerism as forms of leisure. In analyses of time spent in leisure pursuits, both education and volunteering occupy up to 10 percent of available leisure time. According to a 2003 report from the American Association of Retired Persons, volunteerism is an important source of satisfaction, sociability, and self validation and therefore retained by larger proportions of older people than previously thought. There is yet another aspect of leisure that must be broached. Certain types of deviance may constitute leisure for those who are engaged in them and there may be “good” and “bad” categories of leisure, with the latter often overlooked (Rojek 2000).

Education level, income, health status, gender, and ethnicity, plus a host of other compositional characteristics reflecting period and cohort effects, as well as age, shape traditional forms of leisure. As these change, leisure

patterns and activities will be affected. In many respects, leisure is a microcosm where such issues as gender and ethnicity play out. Participation patterns, spaces and places, enjoyment, and even definitions relate to gendered and ethnic concerns as an aspect of broader social and cultural relations and perceptions of aging.

Before drawing inferences about age related shifts in leisure involvements the prospect of selective optimization must be considered. It is possible that as they age, people seek to get the most out of their involvements in ways that maximize subjectively meaningful returns on investments. Older persons may choose to cut back on certain forms of engagement or interaction while expanding others. A case in point can be seen in the example of volunteerism: less meaningful engagements diminish, while time and energy spent in selected others is sustained (Hendricks & Cutler 2004). The same is likely true of leisure: peripheral pursuits fall by the wayside in favor of those with more meaningful returns.

The symbolic import of leisure lies in its association with various facets of well being. There is ample evidence that leisure lifestyles protect against physical and health declines or cognitive impairment, and provide forums for conservation of social integration, interpersonal bonding, morale, life satisfaction, and subjective sense of control (Guinn 1999; Musick et al. 1999; Schooler & Mulatu 2001; Silverstein & Parker 2002). Above all, leisure is an expressive domain wherein personal meaning is created and continued and the effects accrue in many aspects of the aging experience.

The money involved in the leisure market provides some indication of leisure's appeal. From early in the twentieth century the commercialization of leisure has grown and is evidence of returns derived from speaking to demands for leisure lifestyles. Estimates are that at the dawn of the twenty first century personal expenditures for entertainment, leisure, and other discretionary diversions were in the range of \$568 billion to \$1 trillion annually – in excess of 10 percent of total household expenditures. That does not include the \$21 billion devoted to parks and recreation by local, state, and federal governments or a number of other categories, but these figures do indicate the dimensions of the leisure marketplace (Becker 2002).

leisure class

Matthias Zick Varul

The concept of the leisure class was introduced by Thorstein Veblen in his *Theory of the Leisure Class* (1899). Leisure classes here consist of those people who, due to their social position, can afford to abstain from productive work and live on other people's labor. They confine themselves to non industrial occupations like "government, warfare, religious observances, and sports." Their income is sourced from

exploitation of industrial classes that are subdued by the leisure class's superior "pecuniary prowess." In order to assert their position they have to be *visibly* idle. Their leisure practices do not only demonstrate momentary inactivity, but often display skills that serve as evidence of past abstention from work – higher learning and accomplishment in gentlemanly sports, for example, count as evidence for habitual non productivity. Positional claims are further asserted by wasteful "conspicuous consumption" of high status goods and by vicarious leisure of family members, guests, minions, and footmen. Conspicuous consumption of high priced goods is a form of "vicarious leisure" in which other people's labor time is taken up for the production of goods of ostensibly no practical use. Leisure class fashion, too, expresses contempt for productive activity (e.g., by deliberately limiting the movements of the wearer).

Apart from obstructing industrial progress by the wasteful use of social resources, Veblen sees the main effect of the modern leisure class in the exertion of a cultural dominance, setting socially accepted standards of taste. Aspiring classes emulate leisure class patterns of behavior and especially consumption, while the emulated leisure class in turn is constantly developing its "pecuniary canons of taste" in order to spoil the emulative efforts. The leisure class thus functions as a consumerist avant garde. This claim has been criticized as highly overstated and ignoring reverse emulation of popular culture by the upper classes (Bourdieu 1979).

While historically the leisure class was formed by a ruling aristocracy, industrial capitalism is ruled by businessmen who share leisure class values of pecuniary prowess but are no leisure class themselves; to the contrary, Veblen asserts that they work long and hard. Veblen thus anticipates a common argument against his theory (Rojek 2000): the rich of today normally continue investing most of their time in business life, forming a rather "harried leisure class" (Linder 1970). Veblen, however, sees the abstention from household labor in the upper class wife and the pretension of leisure in the upper middle class wife as compensating vicarious leisure acting out the husband's leisure entitlement.

The term leisure class is rarely used in recent sociology, but it still is informative in

approaching contemporary social phenomena. The group fitting Veblen's description best are "celebrities" who can be said, at least in terms of connubiality and commensality, to form a contemporary leisure class. Their artistic, medial, or sportive activities are, in the public perception, set apart from the social process of production. Like the Veblenian leisure class, celebrities act as commodity culture innovators and serve as role models whose consumption, style, and behavior are emulated. The difference of course is that here leisure itself and the readiness of a wider audience to aspire and emulate has become the basis of the high income, which for Veblen's leisure class was what their leisure expressed. Their leisure behavior, in turn, does not simply *dictate* social taste but also has to anticipate changes in public preferences. In Veblenian terms, celebrities as directly or indirectly financed by their audiences act out vicarious leisure for the onlooking society. Given the very mixed social background of the members of this new leisure class, "trickle up" effects here are at least as important as "trickle down" effects.

Another contemporary "leisure class" is the unemployed. Here leisure is involuntary and problematic. While voluntary leisure in the Veblenian case is a means to assert social recognition, socially unlegitimized forced leisure has the reverse effect on social and self esteem. The social expectation here is that of a quasi work orientation toward reemployment.

Elements of leisure class behavior have been generalized in a move from leisure class to *leisure society* (Seabrook 1988), but they are also spatially and/or temporarily compartmentalized and contained within a work society. Within the lifecycle, old age has been discussed as a "new leisure class" (Michelon 1954). Unlike with the unemployed, leisure in old age is usually legitimated by reference to contributions in a long working life. Old age leisure is "deserved" or "earned," but it is also seen as problematic, requiring reinterpretations of leisure as meaningful or even an education for leisure.

Within the year cycle, tourism has been characterized as requiring "a new theory of the leisure class" (MacCannell 1976). While lacking the defining characteristics of a class, tourists do appear as a leisure class vis à vis the local population of tourist destinations. With one of the roots of modern tourism being the

middle class emulation of the aristocratic Grand Tour, it can be argued that tourism is in part a remainder of trickled down leisure class patterns. However, like old age retirement, tourism refers both negatively and positively to work. It is defined as the opposite of work and the closest most people come to a leisure class existence – but it also refers back to work as paid out of income and functioning as recreation for work.

leisure, popular culture and

Robert A. Stebbins

Mukerji and Schudson (1991: 3) define popular culture as a widely shared set of beliefs and practices that people use to organize certain

objects, these objects also being part of that culture. This intentionally general definition (formulated to avoid terminological haggling) encompasses folk beliefs, practices, and objects generated in political and commercial centers. It also includes the handful of elite cultural forms that have, by curious quirk of fate, managed to become popular.

Popular culture includes, in broadest scope, any cultural item that has achieved popularity, or that has developed a mass public. Given this definition, one might be tempted to say that leisure and popular culture are close to being identical, if not, in fact, identical. Yet numerous popular artifacts and practices exist that are decidedly not leisurely, among them petrol, toothpaste, queuing, and paying income tax. Meanwhile, some activities people do for leisure are hardly popular, including collecting rare paintings, climbing Mount Everest, raising snakes, and playing string quartets. The limited interest in bungee jumping and sadomasochistic pornography shows that even hedonic leisure occasionally fails to win mass appeal. And, finally, some popular culture is disagreeable enough for many people to be anything but leisure for them. That happens when, for example, they are unable to escape obnoxious advertising or the repulsive habits of others (e.g., smoking, for many non smokers; boom box music, for the unappreciative; outlandish dress and bodily decoration, for those not given to in group fashion).

THE LEISURE FRAMEWORK

Leisure is uncoerced activity undertaken during free time. Uncoerced activity is something people evidently want to do and, at a personally satisfying level using their own abilities and resources, succeed in doing. Further, as Kaplan (1960: 22–5) noted, leisure is the antithesis of work and encompasses a range of activity running from inconsequence and insignificance to weightiness and importance.

This observation about the range of leisure activity suggests that leisure is by no means cut entirely from the same cloth, a condition that any exploration of the relationship between leisure and popular culture should never lose sight of. For instance, as will become evident, the vast majority of popular leisure activities can be

qualified as casual rather than serious leisure. Nonetheless, we look first at serious leisure.

SERIOUS LEISURE

Serious leisure is systematic pursuit of an amateur, hobbyist, or volunteer activity that participants find so substantial, interesting, and fulfilling that, in the typical case, they launch themselves on a (leisure) career centered on acquiring and expressing its special skills, knowledge, and experience (Stebbins 1992: 3). The term was coined years ago (Stebbins 1982) following the way in which the people Stebbins had been interviewing and observing since the early 1970s defined the importance of these three kinds of activity in their everyday lives. The adjective "serious" (a word his respondents often used) embodies such qualities as earnestness, sincerity, importance, and carefulness, rather than gravity, solemnity, joylessness, distress, and anxiety. Although the second set of terms occasionally describes serious leisure events, the terms are uncharacteristic of them and fail to nullify, or, in many cases, even dilute, the overall deep fulfillment gained by the participants. The idea of "career" in this definition follows sociological tradition, where careers are seen as available in all substantial, complex roles, including those in leisure. Finally, serious leisure, as will be made clear shortly, is distinct from casual leisure.

Amateurs are found in art, science, sport, and entertainment, where they are invariably linked in a variety of ways with professional counterparts. The two can be distinguished descriptively, in that the activity in question constitutes a livelihood for professionals but not amateurs. Furthermore, professionals work full time at the activity whereas amateurs pursue it part time. Hobbyists lack this professional alter ego, suggesting that, historically, all amateurs were hobbyists before their fields professionalized. Both types are drawn to their leisure pursuits significantly more by self interest than by altruism, whereas volunteers engage in activities requiring a more or less equal blend of these two motives. That is, volunteering is uncoerced help offered either formally or informally with no or, at most, token pay and done for the

benefit of both other people and the volunteer (Stebbins 2001a: ch. 4).

Hobbyists are classified according to five categories: collectors, makers and tinkerers, activity participants (in non competitive, rule based pursuits such as fishing and barbershop singing), players of sports and games (in competitive, rule based activities with no professional counterparts like long distance running and competitive swimming), and enthusiasts of the liberal arts hobbies. The rules guiding non competitive, rule based pursuits are, for the most part, either subcultural (informal) or regulatory (formal). Thus, seasoned hikers in Canada's Rocky Mountains know they should, for example, stay on established trails, pack out all garbage, be prepared for changes in weather, and make noise to scare off bears. Liberal arts hobbyists are enamored of the systematic acquisition of knowledge for its own sake. Many accomplish this by reading voraciously in, for example, a field of art, sport, cuisine, language, culture, history, science, philosophy, politics, or literature (Stebbins 1994).

Serious leisure is further defined by a set of distinctive qualities, qualities uniformly found among its amateurs, hobbyists, and volunteers (Stebbins 1992: 6–8). One is the occasional need to *persevere* at the core activity to continue experiencing there the same level of fulfillment. Another is the opportunity to follow a *career* (in a leisure role) in the endeavor, a career shaped by its own special contingencies, turning points, and stages of achievement and involvement. Third, serious leisure is further distinguished by the requirement that its enthusiasts make significant *personal effort* based on specially acquired knowledge, training, or skill and, indeed at times, all three.

The fourth quality is the numerous *durable benefits* or tangible, salutary outcomes such activity has for its participants. They include self fulfillment, self enrichment, self expression, regeneration or renewal of self, feelings of accomplishment, enhancement of self image, social interaction and sense of belonging, and lasting physical products of the activity (e.g., a painting, scientific paper, piece of furniture). A further benefit – self gratification, or pure fun, which is by far the most evanescent benefit in this list – is also enjoyed by casual leisure participants. The possibility of realizing such

benefits becomes a powerful goal in serious leisure.

Fifth, serious leisure is distinguished by a *unique ethos* that emerges in association with each expression of it. At the core of this ethos is the special social world that begins to take shape when enthusiasts in a particular field pursue substantial shared interests over many years. According to Unruh (1980), every social world has its characteristic groups, events, routines, practices, and organizations. Diffuse and amorphous, it is held together, to an important degree, by semiformal, or mediated, communication. The sixth quality – *distinctive identity* – springs from the fact of the other five distinctive qualities. Participants in serious leisure tend to identify strongly with their chosen pursuits.

Relatively few people – by the author's admittedly impressionistic estimate, no more than 20 percent of the adult population in the typical western society – take up a form of serious leisure. Its requirements of effort, commitment, perseverance, deferred gratification, and so on are too overwhelming and offputting for most people in the modern age. Casual leisure is easier to partake of, and therefore much more susceptible to becoming popular.

CASUAL LEISURE

Casual leisure is immediately intrinsically rewarding, relatively short lived pleasurable activity requiring little or no special training to enjoy it. It is fundamentally hedonic, engaged in for the significant level of pure enjoyment, or pleasure, found there. Stebbins coined the term in the same conceptual statement about serious leisure (Stebbins 1982), his object at the time being to further define serious leisure by showing what it is not. So continuing in that vein, he noted that casual leisure is considerably less substantial and offers no career of the sort found in serious leisure. Yet, subsequently, it became evident that casual leisure needed a conceptual statement of its own (see Stebbins 1997, 2001b).

Eight types of casual leisure have so far been identified, seven of which are also common items of western popular culture. They include *play* (e.g., dabbling at the guitar); *relaxation* (e.g., napping, strolling, people watching); *passive entertainment* (e.g., watching commercial

TV, reading trade books, listening to popular music); *active entertainment* (e.g., playing popular games of chance, card games, party games); *sociable conversation* (e.g., held over coffee, drinks); and *sensory stimulation* (e.g., sightseeing, dining at restaurants, drinking at pubs/bars). The seventh type – *pleasurable aerobic activity* (Stebbins 2004b) – finds its most popular expression in personal exercise aerobics, as pursued collectively in formal classes or individually following a television program or video taped routine as a guide. *Casual volunteering* (a parallel to career volunteering) has yet to generate a popular form, and may never do so.

Furthermore, it is likely that people go in for the different types of casual leisure in combinations of two and three at least as often as they do them separately. For instance, every type can be relaxing, producing in this fashion play–relaxation, passive entertainment–relaxation, and so on. Various combinations of play and sensory stimulation are also possible, as in experimenting with drug use, sexual activity, and thrill seeking in movement. Additionally, sociable conversation accompanies some sessions of sensory stimulation (e.g., drug use, curiosity seeking, display of beauty) as well as some sessions of relaxation and active and passive entertainment, although such conversation normally tends to be rather truncated in the latter two.

Notwithstanding its hedonic nature, casual leisure is by no means wholly frivolous, given that some clear costs and benefits accrue from pursuing it. Moreover, unlike the evanescent hedonism of casual leisure itself, these costs and benefits are enduring. The benefits include serendipitous creativity and discovery in play, regeneration from earlier intense activity, and development and maintenance of interpersonal relationships (Stebbins 2001b). Some of its costs root in excessive casual leisure or lack of variety as manifested in boredom or lack of time for leisure activities that contribute to self through acquisition of skills, knowledge, and experience (i.e., serious leisure). Moreover, casual leisure is alone unlikely to produce a distinctive leisure identity.

Some casual leisure is deviant, even if most of the time the community tolerates such activity (Stebbins 1996b: 3–4; Rojek 1999). Tolerable deviance undertaken for pleasure – as casual leisure – encompasses a range of deviant sexual

activities including cross dressing, homosexuality, watching sex (e.g., striptease, pornographic films), and swinging and group sex. Heavy drinking and gambling, but not their more seriously regarded cousins alcoholism and compulsive gambling, are also tolerably deviant and hence forms of casual leisure, as are the use of cannabis and the illicit, pleasurable use of certain prescription drugs. Social nudism has also been analyzed according to the tolerable deviance perspective (see Stebbins 1996b: chs. 3–7, 9). Yet the very definition of these forms as deviant prevents them from being conceived of as popular culture, while pointing to yet another area where leisure and popular culture cannot be considered identical phenomena.

POPULAR CULTURE: CONSUMPTION/PRODUCTION

Discussion so far suggests that much of casual leisure can be further understood as *consumption* of particular kinds of popular culture. Indeed, the relationship between leisure and popular culture is much more complicated than acknowledged to this point, in that some people also pursue certain forms of serious leisure (and, we shall see, remunerative work) precisely because they want to *produce* such culture. Table 1 describes this new, more complicated relationship, as expressed along two dimensions: work/leisure and consumption/production.

Both modern common sense and conventional academic wisdom tend to treat work and leisure as though they were two separate worlds, which, however, sometimes fails to jibe with the facts (Stebbins 2004a). Cell 1 of Table 1 directly confronts this misconception by introducing the idea of “occupational devotion.” Occupational devotion is a strong, positive attachment to a

form of self enhancing work. Here, where there is high sense of achievement and intense attraction to the core activity (set of tasks), the line between such work and leisure is virtually erased (Stebbins 2004a: 2–6). “Occupational devotees” express this devotion through their “devotee work.” In terms of the present discussion, popular culture workers meeting the criteria of occupational devotion can be said to be both consumers and producers of their popular culture. Examples include pop music stars who find deep fulfillment while simultaneously making and listening to their music, and commercial painters, writers, and filmmakers who, as they produce their works, enjoy the same kind of aesthetic experience.

The professional work considered in cell 2 is, to be sure, devotee work, but emphasis in this cell is on how popular culture is produced rather than on how it is consumed. Here the reigning conceptual separation of work and leisure is both evident and legitimate. As for cell 3, it needs no additional explanation beyond what was said about casual leisure in the preceding section.

Cell 4 in Table 1 shows that some serious leisure is, in fact, significantly related to popular culture, albeit through production rather than consumption of such culture. Amateur sport and entertainment are two main arenas where this occurs, as seen, for example, in entertainment magic (Stebbins 1993), stand up comedy (Stebbins 1990), collegiate football (Gibson et al. 2002), and mass media covered marathon running (Wilson 1995). Popular displays of hobbyist activities include model rail road exhibitions, barbershop shows (Stebbins 1996a), quilt fairs (King 2001), and the manifold competitions in sport that attract large numbers of spectators (e.g., alpine skiing, speed skating, auto racing, bicycle racing). One

Table 1 Relationship of leisure and popular culture.

<i>Popular culture</i>	<i>Consumption of popular culture</i>	<i>Production of popular culture</i>
As work	(1) Devotee work in sport and entertainment	(2) Professional work (full- and part-time) in sport and entertainment
As leisure	(3) Casual leisure (7 types)	(4) Amateur sport and entertainment, hobbies (displayable forms)

important condition that any serious leisure activity must meet if it is to be consumed as popular culture is its capacity for public display. The liberal arts hobbies as well as some of the collecting hobbies and some of the sports and games (e.g., bridge, chess, marathon running, mountain climbing) lack this capacity and hence cannot, at least in their present form, enter the realm of popular culture.

Volunteering occupies an indeterminate position in all this. Of the three types of serious leisure, it quite possibly draws the largest number of participants (no quantitative comparative data are available). It is also much talked about these days for its key role in creating and maintaining civil society and for its capacity to fill the gap left by business and government through their ongoing failure to deliver needed community services. Yet, apart from volunteering to help organize and run certain popular sports and arts events (e.g., Olympic Games, major arts festivals) – classifiable as an indirect contribution to producing these events – volunteering would appear to be yet another area where leisure and popular culture must be regarded as separate phenomena.

Lemert, Edwin M. (1912–96)

Robert A. Stebbins

Edwin M. Lemert was born in Cincinnati, Ohio. He received his BA in sociology from Miami University (1934) and his doctorate from Ohio State University (1939), specializing

in sociology and anthropology. He taught briefly at Kent State and Western Michigan Universities. In 1943 he moved to the University of California at Los Angeles, and in 1953 to the University of California at Davis, from which, in 1980, he retired as Professor Emeritus. After formal retirement Lemert worked almost daily in his university office, writing scholarly material until his death in 1996.

Lemert is widely recognized for his pioneering work on labeling theory in the study of deviant behavior, which he called societal reaction theory. He preferred this title because the social or community reaction to deviance in its midst formed a central feature of his perspective. His classic statement of this approach appeared in *Social Pathology: A Systematic Approach to the Theory of Sociopathic Behavior* (1951). His other prominent books were *Social Action and Legal Change* (1970); *Instead of Court: Diversion in Juvenile Justice* (1971); and *Human Deviance, Social Problems, and Social Control* (1972). The latter comprised a collection of his most significant papers to that time. It showcased his extraordinary breadth of interests, running from alcoholism through mental disorder to folklore, speech defects, and check forgery.

Lemert's theory of sociopathic behavior, set out in *Social Pathology*, rests on three central processes. The first is *differentiation*, which refers to the fact that people differ, sometimes deviate, from average characteristics of the population in which they are found and in which they interact with other people. The second process is the *societal reaction* toward the deviance observed, a reaction that includes expressive feelings as well as action directed toward its control. The third process is *individuation*, or the manifestation of the causes of deviance in individuals, which includes how they come to terms with the deviance. This latter process has become the core of modern labeling theory. More particularly, individuation is best understood by looking at the course of events and processes associated with *primary deviation* (deviant behavior that is normalized by the person) and *secondary deviation* (behavior enacted in response to problems caused by the societal reaction). The two types of deviation and their interrelationship foreshadowed the concept of deviant career, formally introduced 12 years later by Becker (1963). Lemert was

also the first to examine the role of stigma in the life of deviants – a precondition of secondary deviation and one later explored in detail by Goffman (1963).

lesbian feminism

Eve Shapiro

Lesbian feminism is a political and philosophical strand of feminism that emerged in the US, Canada, and Britain in the 1970s. It holds as central tenets that heterosexuality is the seat of patriarchal power; lesbianism is a political choice and not an essential identity; and lesbians occupy a unique and empowered position vis à vis sexism and patriarchy because they do not rely on men for emotional, financial, or sexual attention and support. Lesbian feminist ideas, writings, and activism informed and guided both feminist and lesbian movements throughout the 1970s and into the 1980s, and have continued to shape academic theorizing and political organizing to this day. As lesbian feminism evolved, several ideological variations emerged including cultural feminism and separatist feminism.

THE WOMAN IDENTIFIED WOMAN

As Echols (1989) examined in *Daring To Be Bad*, lesbian feminism developed out of radical

feminism in reaction to sexism within gay liberation movements and homophobia within feminist movements of the 1960s. Sparked by Betty Friedan's 1970 characterization of lesbians as the "lavender menace" and an impediment to the National Organization for Women's mission and to the credibility of the feminist movement, lesbians began to theorize and advocate inclusion and recognition from feminist movements. Out of the ensuing debates, groups like the New York based "Radicalesbians," originally known as "Lavender Menace," and the Washington, DC based "Furies" formed. These early lesbian feminist groups quickly articulated a lesbian centered critique of society, sexism, and feminism.

In "The Woman Identified Woman" (1970), the first political statement of the lesbian feminist movement, the Radicalesbians laid out an argument about the construction of sexual identity categories like lesbian and their links to heteronormativity and patriarchy. Radicalesbians argued that "lesbian" as an identity was not just a sexual object choice, but rather a chosen identity that was comprised of a continuum of "women identified women." Defining lesbian feminism as central to feminism, "The Woman Identified Woman" and other early writings established sexuality as a key vector of oppression and integrated these critiques into broader feminist political ideology and burgeoning feminist academic theorizing. One common lesbian feminist slogan of the time, attributed to Ti Grace Atkinson and drawn from Jill Johnston's (1973) theorizing in *Lesbian Nation*, was "feminism is the theory and lesbianism is the practice." The implication of this statement was that feminist theorizing demanded a woman centered focus and that this woman identified approach was what constituted a "lesbian." Also implied is the notion that identifying as a lesbian was at the least a political choice, if not a political responsibility, for feminists. Contrary to other feminist ideological approaches that ignored sexuality, silenced lesbians, and argued that lesbian inclusion threatened the viability of the whole movement, lesbian feminism positioned lesbians at the center of a feminist liberation movement.

THE LESBIAN CONTINUUM

Approaching lesbian as a political identity required a radical redefinition of lesbian. In "Compulsory Heterosexuality and Lesbian Existence," one of the most important texts of lesbian feminist theorizing, Adrienne Rich (1980) theorized the connections between heterosexuality and patriarchy, argued for the reclamation of an erased lesbian history across cultures and times, and discussed in detail the concept of the "lesbian continuum." What Rich articulated, and what lesbian feminism organized around, was the idea that because sexuality was a socially constructed tool of patriarchy, all women had the power to reclaim the term lesbian in an effort to resist patriarchal dominance. Expanding lesbian beyond a self identified marker of sexuality to include women who identified themselves sexually, spiritually, emotionally, *or* politically with other women, Rich argued that there was a lesbian continuum that opened up space for *all* women to be lesbians. Lesbian feminist ideology held that this was the cornerstone of dismantling patriarchy and gaining gender equity.

Elaborating her argument, Rich positioned the erasure of lesbian history as the erasure of a history of resistance to male domination and compulsory heterosexuality, and argued this erasure was necessary for the maintenance of patriarchal power. Other writers further theorized and supported the broadening of "lesbian" in their own work. Lillian Faderman's book *Surpassing the Love of Men: Romantic Friendship and Love Between Women from the Renaissance to the Present* (1991) was a critical text in reclaiming a lost history of women identified women. Building on Rich's argument that woman identification had been erased in an effort to subordinate women, Faderman argued the long history of lesbian existence, supported by evidence of both emotional and physical intimacy between women across cultures and time periods.

Ideologically, the "lesbian continuum" fostered a belief for many white lesbian feminists that a shared woman identification united all women regardless of race, class, nation, or sexuality. In other words, gender became the

primary axis of both oppression and resistance. Extension of this argument can be seen in many academic and movement texts. For example, writer and theologian Mary Daly has argued over the past 25 years for a woman centric analytical approach, and theoretical traditions like standpoint epistemology draw on a belief in a shared “women’s standpoint.”

Alongside theoretical developments, lesbian feminist ideology promoted critiques of existing institutions and alternative women centered institutions. Two related but distinct branches emerged within lesbian feminism in the 1970s. One branch often referred to as cultural feminism focused on developing and fostering woman centered institutions. The other – lesbian separatism – took this a step further and argued for a complete withdrawal from men and male dominated institutions.

CULTURAL FEMINISM

Out of critiques of patriarchal society and calls for a woman identified life, lesbian feminists began advocating for and developing woman identified counterinstitutions. They founded feminist bookstores in most cities, and publishing houses and presses like Naiad Press and Spinsters Ink, auto shops, health collectives, and other institutions. In addition, lesbian feminist communities developed alternative cultural products like goddess focused spiritualities, music labels like Olivia, and a genre of women’s music with lesbian feminist artists like Ferron and Cris Williamson, Tret Fure, and Holly Near. Extending a critique of masculinist language lesbian feminism developed alternative language like womyn, wimmin, and womb moon, and invented non patrnomial naming traditions, renaming themselves with woman focused names like Dykewomon. Lesbian feminist activists developed new repertoires including zaps, which were symbolic protests aimed at cultural/ideological change as much as at political reform. Like radical feminism, lesbian feminists argued for a refocusing on women’s sexuality independent from heterosexual intercourse and/or the male gaze. Part of being a woman identified woman meant rejecting dominant beauty and fashion norms as patriarchal, and adopting an androgynous,

makeup free appearance. This style, characterized by flannel, jeans, sandals, and short hair, was often referred to as “the uniform” and was the dominant lesbian feminist aesthetic through the 1970s and 1980s.

This new ideological focus on gendered beauty standards and sexuality led to a critique of both the existing butch/femme lesbian culture and the emerging sex radical lesbian communities. Lesbian feminism characterized butch/femme culture as an oppressive mimicry of sexist and misogynist heterosexual gender relations. Similarly, the increasingly visible sex radical community, which included an emergent women’s sadomasochism community and sex worker community, was characterized as replicating, enacting, and perpetuating violence against women. These debates, referred to as the lesbian sex wars, came to a head at the 1982 “The Scholar and the Feminist IX: Towards a Politics of Sexuality,” where lesbian feminists battled each other throughout the conference over the meaning and politics of sexuality (Vance 1984).

Radical feminists both in feminist communities and in academic theorizing critiqued lesbian feminist cultural development as escapism and dubbed this “cultural feminism” counterproductive to struggles for political change. Based on field studies of 14 lesbian feminist communities Taylor and Whittier (1992) challenged this depiction and argued that the development of women’s culture within lesbian feminism was critical in sustaining feminist activism during the increasing conservatism of the 1980s and 1990s. Exploring the lesbian feminist focus on personal and cultural change as well as political change, Taylor and Whittier conclude that “cultural feminism,” or, as they prefer, lesbian feminist community, signaled the development of new social movement forms and tactics. The cultural products, institutions, and norms that emerged in the 1970s within lesbian feminist communities sustained and enabled these movements and movement organizations over the past 30 years.

LESBIAN SEPARATISM

Charlotte Bunch, a writer and member of the “Furies,” a lesbian feminist collective of writers

and activists, argued in 1972 that lesbianism is not just a political choice, but that women *must* be both lesbian and feminist to fight patriarchy and end sexism. The Furies was a short lived Washington, DC collective (1971–2) that was profoundly influential and included writers like Charlotte Bunch and Rita Mae Brown, and activists like Ginny Berson, who went on to found Olivia Records. Unlike cultural lesbian feminist groups, however, separatist groups believed that lesbians needed to remove themselves from male dominated society in order to effect significant social change. Like cultural feminism, separatism advocated the creation of alternative woman oriented institutions, but went further to argue that lesbians needed to separate themselves from both men *and* heterosexual women. Many separatists argued that heterosexual women were “sleeping with the enemy” and therefore were part of the problem, not the solution. This separatist ideology encouraged the creation of women only spaces like the Michigan Women’s Music Festival as well as more permanent women’s communities in rural areas. Women’s communes and communities were founded across the United States, Australia, and England and many, like Womanshare in Oregon and Camp Sister Spirit in rural Mississippi, continue to exist today.

SCHOLARSHIP

Two bodies of research have emerged in relation to lesbian feminism. Sociological research about lesbian feminist movements, culture, and communities has developed in the fields of gender studies, sexuality studies, and social movements. Additionally, for many academics lesbian feminist ideologies and beliefs were incorporated into their work, and lesbian feminist commitments guided research topics and approaches.

Many scholars like Adrienne Rich, Gayle Rubin, Charlotte Bunch, and Lillian Faderman merged academic theorizing and lesbian feminist ideology in the late 1970s and early 1980s, allowing one to inform the other. Lesbian feminist gendered critiques and theorizing around heterosexuality, patriarchy, and feminism were a catalyst for and informed theoretical developments in nascent gender and sexuality

studies. Simultaneously, the woman identification associated with lesbian feminism encouraged research on and by women and about women’s lives across disciplines including history, literary studies, and the social sciences. For women of color academics like Barbara Smith and Audre Lorde, the lack of theorizing around race in both academic and activist communities led to a simultaneous and interconnected critique that was central in sparking further research and writing by women of color within lesbian feminist movements, and in the incorporation of race in lesbian feminist analysis and scholarship.

Alongside scholarship informed by lesbian feminist movements was the emergence of research about lesbian feminist movements. Contrary to earlier research on “deviant” sexuality which took an individualist and pathological approach, many sociologists began in the 1980s and 1990s to examine lesbian communities in general, and lesbian feminism more specifically, through cultural studies, gender studies, and social movements lenses. Two of the first texts to reexamine lesbian feminist movements were Taylor and Rupp (1993) and Nancy Whittier’s *Feminist Generations* (1995). These studies examined the role of political ideology and collective identity within lesbian feminist communities and argued that lesbian identity needed to be examined as socially constructed within the context of social and political communities. Taylor and Rupp challenged the dismissal of culture and cultural products and argued that culture was not only central to the success and sustenance of lesbian feminist movements, but that it also plays an important role in social movements more broadly. Based on an in depth case study of lesbian feminist communities in Columbus, Ohio, Whittier found that the meaning of feminism and the collective identity among lesbian feminists changed over time for participants. Arlene Stein (1997) extended this analysis and argued that lesbian feminism was a product of the Cold War and 1960s liberation movements. Lesbian feminism, in turn, produced new discourses about lesbian identity, feminism, and community. These new lesbian feminist discourses, according to Stein, have played crucial roles in shaping contemporary feminist and lesbian movements. Scholars like Suzanne Staggenborg

have furthered these analyses and approached lesbian feminism from a social movements perspective.

CRITIQUES

There have been three main critiques of lesbian feminist movements and theorizing since the 1970s. Perhaps the most significant critique emerged alongside lesbian feminism in the 1970s from women of color and poor women. Lesbian feminist ideology relies on an essential shared womanhood that transcends other differences and situates gender as the primary vector of oppression in society. For women of color and poor women who experienced gender, class, and race as interconnected identities and oppressions, this ideology erased and invalidated their experiences. In *This Bridge Called My Back* (Anzaldúa & Moraga 1981), women of color spoke about exclusion within lesbian feminist communities and advocated for new, integrative activist and academic approaches. More recently, notions of essential womanhood (and exclusion based on this) have also been challenged by transgender communities. Transgender women continue to argue for a place within lesbian feminist and separatist spaces like Michigan Women's Music Festival, most of which maintain "woman born woman" policies.

Alongside critiques of essentialist arguments at the root of lesbian feminist ideology, sex radical communities have continued to challenge the rigid sexual politics within lesbian feminist communities. This rift between "pro sex" and "anti sex" feminists has remained volatile and has been played out in academic circles as well as in lesbian feminist communities through boycotts and protests of sex positive writers and activists like Patrick (formerly Pat) Califia, and legislative battles over anti pornography legislation spearheaded by Andrea Dworkin and Catherine MacKinnon.

Finally, the emergence of queer theory in the 1990s has challenged lesbian feminist theoretical and analytical approaches to gender, sexuality, and inequality. The focus in queer theory on decentering identity and focusing on sexual power broadly instead of on patriarchy or heterosexism has led to a dismissal of much of

lesbian feminist research and critique of lesbian feminist ideology as outdated. As many feminists have argued, however, identity politics have been and continue to be central to lesbian and feminist organizing and community building. Despite these criticisms, lesbian feminism continues to influence contemporary feminist and lesbian movements and many of the institutions founded in the 1970s and 1980s by lesbian feminist communities continue to thrive.

lesbian and gay families

Brian Heap

In the narrowest sense, the term "lesbian and gay family" refers to lesbian and gay individuals or same sex couples and their children. The term is sometimes used to refer to same sex partnerships or cohabiting relationships. In the broadest sense, the term can denote social networks that include lesbian or gay individuals and/or couples where some or all of the members self define as "family." These latter arrangements have also been described as "surrogate," "friendship," or "chosen" families.

Lesbian and gay families have become high profile social and political issues since the 1980s. They touch on a broad range of sociological themes to do with family life and social change, family diversity, and alternative family practices. The topics of lesbian and gay families and families of choice have played an important part in debates on the demise of traditional conceptions of family, the legitimacy of new family forms, and contemporary reconfigurations of family obligations, responsibilities, and care. Existing sociological work on the topics includes theorizing and research into the historical, social, and political forces that have facilitated the emergence of lesbian and gay families

and families of choice; theoretical discussions of their social and political significance; and studies of the meanings, structures, and social practices associated with them at local levels.

Prior to the 1960s, homosexual relationships were subject to legal and social sanctions in societies and were culturally invisible. European and North American research on lesbian and gay families in the pre 1960s era suggests that they are best conceptualized as "surrogate" family forms, made up of adults who provided mutual comfort and support in the face of hostile social environments. During the 1960s and 1970s, the politics of sexual liberation opened up distinctive possibilities for the formation of lesbian and gay identities that challenged heterosexual ideologies. Research suggests that while surrogate families continued to be important for some lesbians and gay men, other arrangements began to emerge, including self consciously alternative family forms. While surrogate and alternative arrangements provided emotional and practical supports to their adult members, the latter more frequently included children from previous heterosexual relationships, and were more likely to be influenced by feminist and other political critiques of the role of the family in the reproduction of gendered and sexual inequalities.

Several theorists have argued that the emergence of AIDS in the 1980s and political responses to it were key factors in shaping the current emphasis in lesbian and gay politics on family issues in Europe and North America. Initially, Moral Right responses to AIDS reinforced the historical construction of lesbians and gay men as a threat to the family. In the United Kingdom, for example, legislation was introduced in the late 1980s (commonly known as Section 28) that explicitly sought to ban the promotion by local authorities of homosexuality "as a pretended family relationship." Such interventions, however, had the reverse effect of mobilizing a lesbian and gay family oriented politics. Some theorists have further argued that community based caring responses to AIDS were ultimately to underscore the importance of family type relationships for lesbians and gay men. This view has been criticized on the basis that it undermines the existence of non heterosexual caring relationships that pre existed AIDS.

It is more generally accepted that lesbian and gay community responses to AIDS facilitated the institution building and increased cultural and political confidence that were essential in making possible greater social tolerance, if not acceptance, of lesbian and gay families. This increased confidence has also been argued to be crucial in opening up a new family vision amongst lesbians and gay men. This, some argue, is clearly visible in the sharp rise in lesbian and gay individuals and couples who are choosing to become parents *as* lesbians and gay men. It is also evident in the ways in which lesbian and gay politics has become organized around family issues such as the rights to parent, adopt, and marry. It is further evident in ways in which lesbians and gay men are now days likely to include accepting members of family of origin in their chosen families.

While lesbian and gay families have long been of interest to scholars of sexualities, they have more recently come to the attention of sociologists of family life. This new interest is partly due to the current concern with family diversity and changing patterns of relating. Lesbian and gay families are now being explored for the insights they provide into the challenges and possibilities presented by detraditionalized family life. From this perspective, these family forms are studied for how they are structured and operate outside institutionalized norms and supports that have traditionally shaped "the" family. Because of the lack of gender based differences in same sex relationships, lesbian and gay families are also examined for the possibilities of organizing family without clearly defined gendered roles. A number of theorists have argued that because of the lack of gendered assumptions, lesbian and gay families are more likely to adopt a friendship model for relating, and operate according to an egalitarian ideal. Empirical studies that have set out to explore the meanings, structure, and practices of lesbian and gay families and families of choice suggest a complex picture.

Existing research indicates various traditions of the usage of the family terminology in non heterosexual cultures, and the complex and fluid meanings that family has for individuals. North American research has indicated that parental terminology of "mother" and "father" has been used by younger lesbians and gay men

to refer to older, non heterosexual friends and mentors in historically and contextually specific ways. The terms "brothers" and "sisters" have long been used by some lesbians and gay men to denote the affective and/or political significance of non heterosexual friendship. The refrain of "we are family" has also been used in lesbian and gay political life to refer to the affective political bonds that are perceived to underpin non heterosexual communities. Despite these traditions, the research indicates that while many lesbians and gay men embrace the terminology of family to talk about partners and friends, others see it as only applicable to relationships based on caring for children. Others still view the terminology of the family with hostility, and are critical of the normalizing potential of its employment in relation to lesbian and gay life.

Studies indicate some considerable diversity in how lesbian and gay families are structured and constituted. However, lesbians and gay men generally appear to distinguish between the families they grew up with and the relationships they "choose" as adults. Family, when used to describe the latter, can include partners, ex partners, children where they exist, friends, and certain members of family of origin. The inclusion of "given" kin is not automatic, and is usually dependent on the quality of the commitment and emotional bond. The research does suggest, however, that lesbians and gay men are increasingly likely to maintain committed relationships with at least some members of their family of origin. This is especially the case amongst lesbians and gay parents who wish to develop generational links between their children and the families/parents they grew up with.

A number of studies have explored the place, roles, and experience of children in lesbian and gay families. Until recently, such studies tended to be concerned with the implications of growing up in these family forms. Most of this research suggests that this experience is unlikely to have any discernible long term impact on children's sense of well being, social connectedness, or family or personal security. Because of the changing historical circumstances in which lesbians and gay men have become parents, most existing studies are of lesbian and gay families with children who were conceived

through a parent's previous heterosexual relationship. Recent studies have, however, begun to focus on the experience of families with children, where same sex couples, individuals, or friends have chosen to take advantage of recent opportunities to become parents through self or assisted insemination, surrogacy, adoption, and fostering. Many of these studies have moved beyond the focus on children's experience to also explore the blurring of the boundaries between biological and social parenting and the negotiated nature of same sex parenting.

The theme of negotiation has also emerged as an important one in research that has studied how lesbian and gay couples challenge or reproduce the norms and values traditionally associated with family life. Studies indicate that same sex couples value core beliefs about emotional commitment and mutual care and support. However, they can also structure and "do" their relationships in ways that are self consciously opposed to assumptions and norms in heterosexual couple life. One fairly consistent finding concerns the extent to which lesbian and gay couples tend to be more reflexive and democratic than their heterosexual counterparts. This appears especially to be the case in relation to the organization and negotiation of domestic duties. Studies suggest that because same sex couples cannot assume domestic or partnership roles based on gender, there is more scope for the negotiation of couple practices. A number of studies have argued that this is indicative of an egalitarian ideal that is common amongst same sex partners. This, in turn, has been argued to be rooted in the friendship ethos that underpins same sex relationships, and is seen to open up creative possibilities for mutually satisfying relationships. Same sex couple negotiations and creativity have also been studied in relation to the negotiability of monogamy as a marker for couple commitment. While monogamy tends to be assumed in heterosexual couples, same sex couples tend to negotiate whether the relationship will be monogamous or not. Same sex couples often have explicit ground rules to guide the operation of non monogamous sexual relationships and to protect the primacy of the couple's emotional commitment. Sexual exclusivity is not, however, viewed as necessary or desirable for couple commitments or stability.

Friendship families have been regarded as the most creative form of lesbian and gay relationships and research has explored these as sources of emotional, economic, and social support. Most studies confirm the significance of these for emotional sustenance and various forms of material and social support. Some studies do suggest, however, that friendship families mostly provide a context for care in relation to "everyday" problems, and tend not to be relied upon in terms of long term physical care. While research has documented the crucial role of friendship families in caring for people with AIDS in the 1980s and 1990s, and some small qualitative studies suggest they are important sources of practical support in times of other health crises, it appears that the friendship ethos underpinning these families can inform a strong sense of what constitutes appropriate levels of physical care. The friendship ethos, it is argued, emphasizes reciprocity and co independence. This implies that an expectation of long term physical care from friends can be viewed as inappropriate and undesirable. Long term couple partners, on the other hand, are most often identified in research as the first choice as providers of care should it be needed. Some studies indicate that ex partners can also have agreements to provide mutual care. A number of studies have, however, pointed out the difficulties partners and ex partners can face in juggling work and other commitments with long term caring commitments. This is especially the case where the caring role is not supported or recognized as legitimate by state agencies or employers.

The issue of care in lesbian and gay families raises a number of topics that could be fruitfully explored in future research, such as: the resilience or otherwise of lesbian and gay families as sources for care and support across the life course; the significance of children, friendship, and chosen families for supporting lesbians and gay men in later life; and the range of social and political factors that limit and enable the possibilities that lesbian and gay families have been said in theory to offer. Theory and research could also explore the implications for lesbian and gay families of their marginalization and/or normalization in different national, geographical, and social contexts, and the ways in which

the challenges they face are common or other wise to other “new” family forms.

lesbianism

Tamsin Wilton

Although it is generally accepted that “lesbianism” refers to sexual contact between women, this is by no means an adequate definition. Indeed, it is not possible to provide such a definition. The complexities of the political economy of sexuality mean that the word is subject to continual contestation among many diverse interest groups, to the extent that there is not even agreement that sexual contact – or even desire – is necessarily definitional.

Lesbianism is equally subject to theoretical contestation, in particular between essentialists and constructionists. It is, therefore, something of an exemplary topic for demonstrating the political and theoretical processes at work within the social sciences more broadly, as well as being the commonly accepted descriptor for a group of women marginalized and subject to varying degrees of stigma and sanction because they prefer other women as their sexual partners.

There are two main strands of debate concerning the nature of lesbianism, the theoretical and the political. Both have their origins in the social processes which gave rise to the concept of lesbianism in the first place, so it is helpful to begin with a brief historical overview.

Etymologically, the word “lesbian” is of late nineteenth century origin and refers to the island of Lesbos/Lesbos in the Greek archipelago where, in the classical period, the poet Sappho lived. Revered in her own time – Plato referred to her as “the tenth Muse” – examples of her poetry which have survived include fervent expressions of her passionate feelings for women. Love between women, therefore, became popularly known as Lesbian or Sapphic love, in the same allusive way that love between men was referred to as “Greek love.”

The early sexologists employed “lesbianism” to mean “female homosexuality.” This linguistic shift from using “Lesbian” as an adjective, a term which was allusive and euphemistic, to using “lesbianism” as a noun with pretensions to scientific accuracy exemplifies the theoretical and political shift toward the construct of homosexuality as an innate condition. It is this shift which Michel Foucault identified, in the first volume of *The History of Sexuality*, as marking the transition from ecclesiastical juridical to medical constructions of sexuality. “The nineteenth century homosexual,” he concludes, “became a personage, a past, a case history, and a childhood, in addition to being a type of life, a life form and a morphology, with an indiscreet anatomy and possibly a mysterious physiology” (1979: 43).

Lesbianism was initially approached by social scientists, in the 1950s and 1960s, as one of many forms of deviant behavior, and lesbians and gay men in most of the industrialized English speaking West were studied in the context

of a necessarily secretive underground subculture. As such, they tended to be presented as exemplary of Goffman's theories of stigma, and of primary and secondary deviance.

In Britain, this situation slowly changed following the 1957 publication of the Wolfenden Report, recommending the decriminalization of homosexuality. In 1968 the first key paper to offer an early social constructionist approach to sexuality, "The Homosexual Role," was published by British sociologist Mary McIntosh. McIntosh found biomedical claims for essentialism to be weak, and concluded that to ask whether homosexuality is innate or acquired is to ask the wrong question. She went on to argue that "the conception of homosexuality as a condition is, in itself, an object of study" (1981 [1968]: 31). It is arguable that her paper laid the foundations not only for the social constructionist model of sexuality but also for what later became known as queer theory, since her conclusion implies the need to problematize the taken for grantedness of heterosexuality.

Once the social constructionist standpoint is accepted, then, rather than ask questions such as "what is the incidence of lesbianism in the female population?" or "how have different cultures responded to their lesbian members?" we have to ask, "in whose interests is it to reproduce the idea of lesbianism, and what social and political functions does it perform?" This has meant that the social constructionist position has been of particular utility to feminist theorists, for whom the social control of female sexuality has been a key concern.

The essentialist/constructionist debates, between those who regarded same sex behaviors as willfully chosen and those who believed they were symptomatic of an innate condition, became closely associated with two key opposing strands in lesbian and gay civil rights activism. Thus, within both essentialism and constructionism, there exist positively and negatively valued accounts of lesbianism. Within the essentialist position may be found medical scientists seeking an etiology, a definitive symptomatology, and (at least by implication) a cure, alongside lesbian and gay liberationists whose claims for human and civil rights are based on the notion that it is unethical to discriminate against a minority group on the basis of something over which they have no control.

Within the constructionist position there is radically polarized political disagreement between those for whom lesbian behaviors represent a threat to the social order and must be eradicated, and those who claim that it is an empowering and positive choice for women seeking to escape the emotional and political consequences of patriarchy.

Social constructionism has tended to be far less rigorously founded in empirical research than has essentialism, largely because it developed as a theoretical offshoot of poststructuralism and postmodernism. However, it is evidence based, insofar as it draws upon historical texts and anthropological evidence, and McIntosh's paper is exemplary of this.

Of key importance to the sociology of sexuality in general, and of lesbianism in particular, has been the recognition that the relationship between sexual behaviors, desires, and identities is complex and may be contradictory. Here, most of the evidence comes from research done with gay men, including Laud Humphries's *Tearoom Trade* (1974), a ground breaking study of men who have casual sex with other men, and later research carried out in the interests of HIV/AIDS prevention by groups such as Project Sigma. This body of research demonstrates that a heterosexual identity does not necessarily preclude same sex activity, nor does a gay identity prevent men from engaging in heterosexual.

Researchers have been less interested in lesbian identities and sexual behaviors, partly because sex between women carries very little risk of HIV transmission. There is also the complicating factor of lesbian feminism and, in particular, a radical lesbian feminist politics of the erotic. The renaissance of the women's movement in the 1960s and 1970s had profound consequences for lesbian theory and practice, two elements of which are of particular interest to sociologists. The first is the desexualization of lesbianism by a small group of revolutionary lesbian feminists – together with the vigorous contestation of that position by self defined "sex radical" lesbians such as Pat (later Patrick) Califia, Joan Nestle, and Dorothy Allison – and the second is the observation that a number of women did, indeed, make a conscious political choice to become lesbians. Some eventually returned to heterosexuality and others identified as celibate lesbian feminists. Others, however,

entered into sexually active partnerships, thus changing their "sexual orientation" by an act of will, something which biomedical theories are unable to take account of.

Later research into lesbian lives and experiences demonstrates that many women "come out" as lesbian relatively late in life, after a significant period of heterosexual activity. Such findings do not, of course, automatically overturn essentialist claims, since the policing of female sexuality makes it likely that women who are "innately" lesbian might be effectively socialized into heteronormativity by, for example, strong social pressures to marry and have children, and may thus not "discover" their "true nature" until something happens to make them question their assumptions. In addition, female sexuality is discursively constructed as emotional rather than pleasure driven, and the hegemonic discourse of heterosexual sex represents men as sexually inept and women as difficult to arouse. This suggests that a woman who gains little pleasure from heterosexual activity is likely to regard this as normal, and this, too, may delay recognition of innate lesbianism.

However, detailed qualitative research using semi structured interviews and focus groups has found that women may enter into lesbian relationships and take on a lesbian identity after many years of *successful* heterosexual relationships. Whilst some women report sexual and/or emotional unhappiness in their earlier heterosexual relationships, others report that they found heterosexuality to be physically and emotionally satisfying but that they prefer, for a variety of reasons, lesbian relationships. This body of research is relatively new, but seems likely to provide data which will make it increasingly difficult to maintain essentialist claims for female sexuality.

The development of feminist social science in the 1980s and 1990s incorporated research that paid attention to lesbian lives. Areas of interest were largely driven by the need to justify civil rights claims and to resist a particularly homophobic era in political life, represented in the UK by the government of Margaret Thatcher and in the US by the Christian Right and Reaganism. Researchers therefore looked at lesbian parenting, kinship and family formation, and the impact of homophobia on well being. Such research played a significant part in, for

example, the family courts, where it was increasingly accepted that lesbianism should not automatically result in women losing custody of their children.

The more theoretical research agenda included a specifically lesbian strand of critical and "high" theory. Lesbian academics began to produce theory from a position self consciously marginal to the mainstream of what was (and largely continues to be) an unreflexively heteronormative social science. In the United States, lesbian authored accounts of lesbian lives, experiences, and identities were often produced by women working outside formal academic institutions. In Britain, on the other hand, most lesbians undertaking such research did so within universities. Annabel Faraday's 1981 paper "Liberating Lesbian Research" critiqued the androcentricity of existing research, and set the tone for the next decade of British lesbian sociology. Lesbian psychologists Celia Kitzinger and Sue Wilkinson provoked an extremely defensive response when they challenged heterosexual feminist scholars to problematize their sexualities and reflect on the impact which their heterosexuality had on their feminist praxis. The resulting collection, *Heterosexuality: A Feminism and Psychology Reader* (1993), remains the only published work by heterosexual feminists critiquing their own sexuality. Shortly afterwards, Diane Richardson published *Theorizing Heterosexuality* (1996), a collection of papers by both lesbian and non lesbian sociologists, and the "new" lesbian sociology was established.

Lesbian social science grew out of feminist theory, so it is not surprising that it followed a similar developmental trajectory. From early papers such as Faraday's, which wrote lesbians into existing research, developed work such as Tamsin Wilton's *Lesbian Studies: Setting an Agenda* (1995), which explored the intellectual and disciplinary lacunae resulting from lesbian invisibility in the academy, working from the assumption that "lesbian" was a theoretical position which might productively be adopted by any scholar, regardless of sexual preference. In her enormously influential book *Gender Trouble* (1999), Judith Butler drew upon the artifice of the drag queen to demonstrate that gender, and the sexual stereotypes with which it is associated, is performative rather than natural. *Gender Trouble* is generally regarded as the

Ur text of queer theory, a theoretical position which problematizes all genders and all sexualities rather than simply non normative variants.

With the (important) exception of Michel Foucault, the key queer theorists – Butler, Eve Sedgwick, Elizabeth Grosz, and others – have been lesbians who identify as feminist theorists. Since queer theory is primarily concerned with the gendering of sexualities (and vice versa), this is perhaps not surprising. Queer theory takes a social constructionist position as given. However, outside the rarefied atmosphere of universities, essentialist explanations for sexuality continue to dominate popular understandings of the subject.

The debate between essentialism and constructionism is more than merely academic. To this day, lesbianism is regarded by many as immoral or criminal, and punishment for engaging in lesbian behaviors – particularly, but not exclusively, in Islamic theocracies – may be severe. Imprisonment is not uncommon, and the death penalty is still enforced in several countries. In this context it is not surprising that activists have traditionally drawn upon essentialism, insisting that it is both irrational and unjust to penalize individuals for being who they are. It was for precisely such reasons that the early sexologists argued that lesbianism and male homosexuality were innate. English writer John Addington Symonds, summing up these debates for a British audience, argued that: “To deal with [homosexuals] according to your [legal] code is no less monstrous than if you were to punish the colour blind, or the deaf and dumb, or albinos, or crooked back cripples” (1984 [1928]: 180). There is a mainstream in lesbian and gay political activism which adopts this position. Many lesbian feminists, however, take the opposite position and have argued that lesbianism represents the best kind of intimate relationship available to a woman, allowing her effectively to sidestep the psychological, cultural, and material restrictions imposed on women under male supremacy. From this political perspective, lesbianism is a choice open to all women, and it is rare to find an essentialist lesbian feminist.

One notable exception to this argument is offered by Monique Wittig who, in her 1981 paper “One Is Not Born a Woman,” argues that lesbians are not women at all, since the word

“woman” refers to membership of a class which stands in a specific relation to the class “man.” Wittig’s position might be thought of as a “strong” version of social constructionism, since she exempts lesbians from the social construct “woman” by reason of their lack of fit with the cultural and material processes which are implied by that construct.

The two extremes, essentialism and social constructionism, demarcate the political contestations which have continued to develop around “lesbianism” and which are, inevitably, key components in the ongoing social and cultural construction of female sexuality, whether lesbian or not.

The essentialist position, from which “lesbianism” is a condition of the same kind as – for example – autism, depends upon biomedical science for its evidence. Its research methods include twin studies, measurement of body parts, and microscopic analysis of brain tissue taken from cadavers. All such studies are predicated upon the assumption that for an individual to feel sexual desire and love for members of her own sex constitutes an error of gender. Thus, scientists working within the essentialist paradigm aim to identify masculine elements in the physiology of the “lesbian body.” Genitals, inner ear structure, fingerprints, relative finger length, the interstitial nuclei of a part of the brain known as the anterior hypothalamus, and secondary sex characteristics such as nipples and body hair have all been claimed by different researchers as demonstrating “wrong sex” characteristics in individuals identified (albeit some times after death) as lesbian or gay.

Feminists have criticized biomedical research for its traditional strong bias toward androcentricity. That is, the physiology of the male body is accepted as the ideal or typical physiology of humankind whilst that of the female body is either ignored or regarded as an extraordinary case. It is therefore not surprising to find that lesbians have been far less often the subjects of biomedical research into “homosexuality” than have men.

Another problem is that biomedicine is the product of the industrial nations of the West, and unreflexively reproduces as a generalizable norm the gender roles regarded as proper in those nations. Those gender roles themselves are intimately implicated in the social construction of

heteronormativity, inasmuch as the behavior of women and of men is assumed to be largely shaped by their presumptive role in the reproduction of the species. Within the heteronormative paradigm, female sexuality is constructed as reproductively driven, in contrast to that of men, which is assumed to be pleasure driven and instrumental. Female sexual desire, therefore, becomes something of an oxymoron, and lesbian sex, which cannot be reproductive, is not only unfeminine or masculine, it is not "really" sex at all.

The heteronormative construct of lesbian sex as non sex, identified by lesbian theorists Diane Richardson and Anna Marie Smith, and of female sexuality as trivial other than when associated with the reproductive imperative, compounds the existing tendency of biomedicine to ignore women altogether.

Many have suggested that it is only by ignoring lesbianism that biomedical researchers can continue to make claims for homosexuality as an innate or acquired condition, since women's sexual lives are both more complex and more fluid than are men's. As Edward Stein notes in his book *The Mismeasure of Desire* (1999), "If women's sexual desires were put at the centre of our theorizing about the origins of sexual orientation, the case for multiple origins would be readily apparent."

There are two major obstacles to conducting social scientific research into "lesbianism." The first is that the stigma which attaches to lesbianism makes this a hidden and "hard to reach" group of people, and that researchers have great difficulty in accessing lesbian research participants other than that small group of women confident and assertive enough to be publicly "out."

The second is that "lesbianism" is, in many ways, a term of little use to researchers. It is all but impossible to define the term in a way which allows for adequately rigorous research – as becomes evident from a critical scrutiny of most biomedical research into "lesbianism."

From a social scientific perspective, essentialist claims appear somewhat naïve, since they depend on ignoring the social and historical contingency of human sexuality. It is not even possible to claim that, always and everywhere, there have been women who demonstrate a strong sexual preference for members of their

own sex. Historical documentation does exist for the existence of women whose sexual and emotional preference for other women led them to take the risk of "passing" as men and living as such with female partners. Such documentation largely takes the form of court records relating to the trial of women whose deception was uncovered. Emma Donoghue provides evidence going back to the seventeenth century in Europe, and there is some evidence that some precolonial indigenous cultures in the African, American, and Indian subcontinents had developed accepted roles for women who wanted to take on a male role in life, including "marriages" with other women. However, historical evidence about women's lives is far less detailed and robust than is the case for men's, and it is often difficult to know how useful contemporary notions of lesbianism are when interpreting historical or anthropological data.

The gendered power relations of patriarchally structured societies impact strongly upon female sexuality and upon the evidence available to historians and social scientists. It is generally the case that women's sexuality is policed by, and in the interests of, men. Patriarchal institutions, including the established religions, medicine, and the law, have also tended to exert particularly rigorous control over women's sexual and emotional lives, whilst the economic and social power of men and the relegation of women to the domestic and private sphere means that women have very little autonomy. Whilst the industrialized nations of the developed world have recently undergone a certain degree of transformation of gender relations in response to the demands of feminist political campaigns, such changes are historically recent and far from universal.

It is, therefore, very difficult to assess the likelihood of women entering into sexual relationships with each other, or even engaging in fleeting sexual contact with each other, at different historical periods or in different cultures. Whereas the historical records contain substantial evidence of sexual contact between men, this is not the case for women. Given that the material, political, and cultural circumstances required for women to achieve any degree of autonomy have been relatively rare until the twentieth century, and given that the policing of women's sexuality has been both

geopolitically widespread and ideologically driven, it seems unlikely that many of the world's women have been able to develop much of a sense of themselves as sexual beings at all, much less experience and act on desire for each other.

It is, therefore, not possible to claim that something called "lesbianism" exists as any kind of universal human experience, or that it represents – as some evolutionary psychologists have claimed – a naturally existing variation with identifiable evolutionary benefits. Human sexuality is so culturally and historically specific that any universalizing claims must be treated with suspicion, and it seems likely that social constructionist accounts of both gender and sexuality will continue to dominate lesbian sociology and the sociology of lesbianism.

Levittown

Jessica W. Pardee

As the single largest housing development ever undertaken in US history, Levittown is the standard model for American suburban housing. Using assembly line production techniques, Abraham Levitt and sons revolutionized the housing industry. While the Levitts built housing across the nation prior to World War II, Levittown, NY took mass production to a new level. Built on 4,000 acres of potato fields, the site included 17,400 single family homes, as well as several swimming pools, baseball diamonds, playgrounds, and green spaces. Additionally, the Levitts were able to produce houses for almost \$1,000 less than their competitors, while securing a \$1,500 profit on each home. It is this transformation of the housing production process that makes Levittown so sociologically important.

One of the key mechanisms the Levitts employed to promote production was an absolute Taylorization of the home building process. By identifying specific, detailed tasks, the construction labor was divided and reduced to 26 individual steps. To keep prices low, each step was then subcontracted, with all materials and equipment provided by Levitt. This allowed Levitt absolute control of the entire process, as well as the employment of non union labor. Likewise, Levitt personally oversaw construction along with company employed site managers to assure construction was of an acceptable standard.

Financially, the Levitt and Sons construction company and its subsidiaries were organized vertically, with all materials bought and sold through companies owned by the Levitts. The result was the consolidation of all profits, from lumber to unit sales, within the family. In total, this system resulted in extreme efficiency, a consolidation of profit flows to the Levitts, and an outsourcing system that demanded contractor services be on time and under budget. Quantified in houses, the system produced approximately 26 houses each day, at costs lower than those of competitors and at a higher profit to Levitt and Sons.

Across the country there are three Levittowns: Levittown, NY, Levittown, PA, and Levittown, NJ. Hebert Gans studied Levittown, NJ, later renamed Willingboro by the residents, between 1958 and 1962. In *The Levittowners*, Gans (1967) explores the social and democratic systems emerging in the new suburban community. As a participant observer and community resident, Gans focused his research on the emergence of a new community, the quality of suburban life, the effect of that life on resident behavior, and the quality of politics and decision making. In contrast to suburban myths, Gans found the Levittowners to be a reasonably heterogeneous group, whose community developed out of contentions between residents, not a homogeneous view of how a suburban community should be.

Decades later, researchers Baxandall and Ewen returned to the New York Levittown to examine what the 1940s community looks like now. In *Picture Windows* (2000), they find a stark contrast to the homogeneous spatial design and ethnic demographic of the original residential development. Modern Levittown reflects a diverse environment of home designs – the result of additions and remodeling, racial and ethnic diversification of the once whites only development, and inclusion of multigenerational and single mother families with boarders. Thus, 50 years later, Levittown, NY reflects much of the diversity that is predominant in most inner cities.

Lewin, Kurt (1890–1947)

Reef Younggreen

Kurt Lewin is recognized by many as the founder of modern social psychology because of his foundational contributions in making connections between psychology, sociology, anthropology, and economics. By adapting and applying the gestalt perspective to personality theory and social dynamics and translating these ideas into social experience involving people, Lewin's field theory powerfully translated these ideas to new domains.

Born in 1890 in Molgino, Prussia into a middle class Jewish family in which he was one of four sons, Lewin and his family moved to Berlin when he was 15. At 19 and showing an interest in studying medicine, he attended the University of Freiberg. Shortly thereafter, he transferred to the University of Munich to study biology. During his time in Munich, Lewin became interested and involved in the socialist movement, aiming to combat anti-Semitism and help improve women's social positions. It was here that he and similar others organized and taught adult education programs for working class people. His later studies at the University of Berlin fostered his interest in the philosophy of science and exposed him to gestalt psychology, both of which are premises on which much of Lewin's legacy is grounded.

Lewin completed his doctoral work at the outset of World War I in 1914 and was awarded his degree in 1916 while serving in the German army. After joining the Psychological Institute of the University of Berlin in 1921 and becoming a popular lecturer in both philosophy and psychology, he was invited to spend six months as a visiting professor at Stanford University in 1930. The political situation in Germany at this time was deteriorating for many, particularly

Jews. As a result, Lewin and his wife and daughter relocated to the US in 1933, and in 1940 Lewin became an American citizen. He began his work in the US at the Cornell School of Home Economics. In 1935, the first year in which an English collection of Lewin's work was published (*A Dynamic Theory of Personality*), Lewin moved to the University of Iowa. For nearly a decade in the Midwestern US, he perpetuated his interests in group processes and involved himself in applied research initiatives linked to the war (e.g., troop morale, warfare psychology). His commitment to applying research techniques and findings to social problems led to the development of the MIT Research Center for Group Dynamics. Concurrently, Lewin's model of action research – research oriented to solving social problems – resulted in a number of significant studies on religious and racial prejudice for the Commission of Community Interrelations for the American Jewish Congress in New York. It is from this and similar work with other community group leaders that Lewin's "T" groups emerged. Receiving funding from the Office of Naval Research in 1947, he and a few of his contemporaries established the National Training Laboratories (NTL) in Bethel, Maine. Unfortunately, Lewin was never able to personally realize the important outcomes of the NTL because he died suddenly of a heart attack on February 11, 1947.

Perhaps one of Lewin's most recognized contributions to social psychology is his field theory, a system of ideas that highlights his gestalt psychology influences. A gestalt may be thought of as a coherent whole possessing its own laws as constructs of individual minds rather than an objective reality. From Lewin's perspective, behavior motivations were determined not by individual drives, but by all of the elements of a situation. In observing individual behaviors and group dynamics, one must give precedence to the field. In *Field Theory in Social Science: Selected Theoretical Papers*, Lewin defined the field as "the totality of coexisting facts which are conceived of as mutually interdependent." From field theory, Lewin constructed a symbolic representation of behavior expressed as $B = f(P, E)$, or behavior is a function of the person and the environment. The entire psychological field comprises the *lifespace*, or all of the

physical locations, social identities and associated roles, and psychological realities available to an individual. To understand the meanings and motivations associated with behaviors, Lewin believed that the researcher must understand the lifespaces within which people acted. Importantly, Lewin's belief that analyzing a situation required the focus on the situation's entirety – differentiated from the component parts of the situation – illustrates the prominence he granted to the gestalt view.

Lewin's ideas about why members of a group come together do not invoke familiar or common reasons (e.g., homophily). Instead, Lewin reasons that groups form in a psychological sense not necessarily because of members' similarity, but because group formation depends on individuals' realizations that their own fate depends on the fate of the entire group. To support this contention, Lewin cited the common struggle of Jews in the late 1930s as an example of this feeling of interdependent fate. Brown (1988) cites experimental support for this idea that groups require even the most basic form of interdependence. Lewin also argued for the importance of task interdependence in group formation. Fate interdependence is a weaker form of interdependence than task interdependence. The overlap of the group members' goals forms a more solid foundation on which a more powerful group dynamic may be built.

Lewin, along with other research colleagues, is credited with the development of "T" groups (an abbreviation for "basic skills training" groups). These groups, the foundation of the encounter groups of the 1960s, emerged as Lewin and his colleagues realized that the leadership and group dynamics training sessions they conducted for the Connecticut State Interracial Commission in 1964 were most effective when a tension is created between immediate experiences of group members and trainers' theoretical models. Inputs from each perspective enhanced the experiences of the other, resulting in marked increases in expected group vitality and creativity. This innovation in training practice became the basis of funding to establish the NTL.

Lewin's emphasis on the necessity of feedback to produce optimal outcomes, as illustrated by the dialectical nature of "T" groups, is also

the foundation of action research, or research for social management or social engineering. He came to believe that for many sorts of experimental research, it was necessary to have a very intimate relationship between skilled social practitioners with an interest in research and skilled researchers who understood the necessity of social action (Lippitt 1947).

Lewin's action research consists of a series of spiraling steps, each step consisting of planning, action, and collecting data about the results of the action. The first step in action research is to examine an idea very carefully, from all available perspectives. This step usually requires collecting more information than is already present. From this step emerges a plan of how to reach an objective and a choice about what the first step in the plan entails. At this point, the plan to reach the goal has likely already modified the original idea. The next step consists of ongoing circles of plans, executions, and a collection of data indicating the outcome of the initial execution. Evaluations of the data representing the outcomes of initial action inform the plans for the next step or may require a modification of the entire plan. The experiential learning associated with this plan of research is specifically oriented to problem solving in both social and organizational settings. As such, Lewin's action research spiral has been adopted by organizations as a method for self improvement. There is a danger in interpreting action research as a simple procedure for addressing and overcoming social problems. Action research is not a method, but rather a progression of commitments to observe and frame through action a set of principles for social inquiry (McTaggart 1996). Because of its association with radical political activism, action research suffered a decline in popularity. More recently, action research has found favor among community based movements as a participatory mechanism for inciting change. As a method to improve educational experiences, the tools of action research have experienced a renaissance.

Another of Lewin's established areas of inquiry concerned the relationship between leadership types and group structure. Lewin believed that democracy was among the most difficult group structures to develop and maintain. Successful democracies result from a knowledge of and abidance by the laws of human

nature in the group setting. Each new generation under a democratic structure has to learn these rules, which is one of the reasons democracy is difficult to develop and maintain. Lewin believed that democracy, unlike autocracy, could not be imposed on people. Lewin and Ronald Lippitt, one of Lewin's contemporaries, examined democratic, autocratic, and *laissez faire* leadership models and found democratic groups embodied more originality, group mindedness, and friendliness than other models. These researchers examined groups of children under both democratic and autocratic structures and found the friendly, open, cooperative group under a democratic structure quickly diminished with the imposition of an autocratic structure. Further, the change in children's behaviors from under an autocracy to a democracy took much longer than from democracy to autocracy. Lewin and Lippitt concluded that behavior under each of the leadership models was not entirely the result of individual differences, but rather an outcome of group structure.

Lewin's legacy in social psychological and personality research is evidenced by the quantity and array of research based on his foundational ideas. According to the Social Science Citation Index, Lewin's research was cited by published research over 150 times in 2004, 57 years after his death. The research citing his work is found in an array of publications including the *Journal of Personality and Social Psychology*, the *Journal of Retailing*, and *Theory into Practice*. The title of the final journal listed above captures the undercurrent of Lewin's life work: the integration of theory and practice. This emphasis is captured in Lewin's most notable quotation: "There is nothing so practical as good theory."

liberal feminism

Kristina Wolff

Liberal feminism is one of the earliest forms of feminism, stating that women's secondary status in society is based on unequal opportunities and segregation from men. Emerging out of the abolitionist and women's movement in the US, this body of feminism focuses on eliminating gender inequality. The basic beliefs are grounded in liberalist philosophical traditions, as well as French and British feminist theory. Society consists of individuals who are equals and therefore all people must have equal rights. There is a clear division between the role of the state (public) and individual freedom (private). Liberal feminists create change by working within existing social structures and changing people's attitudes.

The anti slavery movement emerged in the early 1800s. These groups engaged in public forums and speeches, boycotted churches and businesses that supported slavery, lobbied for changes in laws, and practiced other forms of non violent activism. These tactics reemerged during the modern black Civil Rights Movement starting in the mid to late 1950s. Many of the early founders of the suffrage movement or first wave of feminism were strong abolitionists and began organizing for women's rights while members of these anti slavery organizations. Many activists such as Angelina and Sarah Grimke spoke publicly about the need for equal education and an end to women's servitude. The first public call for women's right to vote was made when Lucretia Mott and

Elizabeth Cady Stanton were refused recognition as delegates to the 1840 World Anti Slavery Convention. After this event, Mott, Stanton, and Mary Ann McClintock began organizing for women's right to vote.

In 1848 during the Seneca Falls Convention, the *Declaration of Sentiments* was presented by Stanton. This statement mirrored the writing of Thomas Jefferson, calling for voting rights for women, which would enable them to work to eliminate sexist laws, thereby seeking an end to the second class status of women. During this time, women were legally the property of their fathers or husbands and had few rights of their own. After the Civil War, many abolitionists focused on voting rights for blacks, and women were expected to help with this effort and abandon their fight for the women's vote. This was a catalyst for Susan B. Anthony to leave the Equal Rights Association and form the National Woman's Suffrage Association with Elizabeth Cady Stanton. The new focus, along with other activists such as Alice Paul, was on the creation of a constitutional amendment for women's right to vote along with actively working on other issues such as changing inheritance and divorce laws and women's economic inequality. The 19th amendment to the US Constitution granting women the right to vote was finally ratified in 1920.

The theoretical foundation for these early feminists was a combination of their religious beliefs and the writings of John Locke, John Stuart Mill and Harriet Taylor Mill, Mary Wollstonecraft and later, Jane Addams and Harriet Martineau. Main themes in their work focused on personal independence, economic and educational opportunity, and equality for all humans. Societal change happens through individual efforts and working within existing social structures. Through the efforts of suffragists, women also won greater access to education as well as improved individual rights and autonomy. After women won the right to vote, the movement lost some momentum, but work on issues of equal rights and the end of gender inequality continued through the efforts of women like Addams, Paul, and Emma Goldman.

The 1950s saw a renewed cultural push for men and women to fulfill traditional gender roles. During this time, the modern black Civil Rights Movement was beginning to increase in

scope and momentum. By the early 1960s, numerous groups – including anti war activists and women as well as gays and lesbians – were also pushing for social reforms. In 1963 Betty Friedan published *The Feminine Mystique*. In her text, Friedan details the lives of the average American suburban housewife; she described women as being “dissatisfied” with their lives, each one “yearning” for something more. Ultimately, she concluded that women across America were suffering from “the problem that had no name.” This phrase soon came to represent the contemporary Women’s Liberation Movement which gave rise to modern liberal feminism. Once again, women marched in the streets, gave speeches, lobbied politicians, and worked for reform in the areas of education, employment, health care, and politics, as well as for the end of inequality based on gender.

Sexism was viewed as improper behavior by men and women, who were conditioned by society’s “bad” ideas about gender roles. Social change would come from working within the system to eliminate structural barriers and change cultural expectations of women’s roles as wives and mothers, as well as to establish equality between genders so women would have the same opportunities as men. The National Organization for Women (NOW) was formed by Friedan and others in October 1966. During their first national convention in 1967, they adopted a “Bill of Rights” which demanded such things as maternity leave, government sponsored childcare centers, equal opportunities for education and job training, reproductive rights, and the establishment of the Equal Rights Amendment to eliminate discrimination based on sex. Motivated by the phrase “the personal is political,” women organized across the nation, fighting for equal rights and access to traditionally male only organizations, jobs, and educational institutions, and for change in the image of women in the media. One result of these actions was the establishment of a women’s studies curriculum and departments in colleges and universities, as well as the recognition of feminist sociologists and the formal development of feminist sociology. By adopting an assimilationist approach, liberal feminism appealed to a wide array of people, as it is complementary to American ideals of individualism and success through hard work and determination.

Not surprisingly, early areas of research by feminist scholars center on the institutions of marriage, motherhood, and family, as well as work, education, and reproductive rights. Included in this scholarship is the development of feminist theories and methodologies. Research focusing on marriage and family not only illustrates the experiences of women as wives and mothers, but also challenges the expectations of gender roles. In the 1970s, women still lost their autonomy upon marriage. They were legally the property of their husband, they could not have credit without their husband’s permission, many were denied jobs or admission to college due to their gender, and the dominant cultural belief was that all women would marry and therefore did not need to have a job or advanced education. Feminists successfully lobbied against these legal limitations imposed on women and also challenged the belief that the nuclear family was the “natural” family structure, thus bringing to question women and men’s roles as wives and husbands as well as mothers and fathers.

By placing women at the center of analysis, sociologists have expanded understandings of marriage and family, illustrating the central role these play in perpetuating ideologies of gender roles and expectations in society. Often, the traditional nuclear family structure has been used to support the division of labor in society, where women are expected to be at home in order to care for children; therefore, men are forced to work outside of the home to support the family, thus limiting options and choices for both men and women; for example, few companies offer parental leave to men to care for their newborn child. Feminists also challenge this division due to the unequal balance of work placed on women who must care for children, operate the household, and provide support for husbands (including help to advance their careers). Additionally, for women who work for pay outside of the home, as housework is unpaid labor, researchers have found that their responsibilities at home rarely change. Husbands seldom increase their role in the household to assist women working outside of it, so when a woman returns home from her job, she has to continue to work in the household to keep it functioning. Hochschild (Hochschild & Machung 1989) labeled this phenomenon the

“second shift.” A liberal feminist solution to this situation is to call for changes in family law, such as providing more support through parental leave policies as well as to educate men and women about restructuring their relationship to be more balanced and equal. Additionally, liberal feminists have called for increased support for childcare, welfare reform, and laws to challenge these traditional concepts of family, as well as extend support to single parents and lower income families.

In addition to the family structure being viewed as a means to keep women in a subordinate position in society, research on the social worlds of work and education has also demonstrated how women’s secondary status has benefited men. In the 1960s, women experienced few choices in education and employment. Jobs were advertised in newspapers according to race and gender and were largely limited to lower skilled positions. Women were expected to go into pink collar occupations such as nursing, teaching, secretarial positions, or as maids. These positions paid low wages and offered little to no opportunities for advancement. After it became illegal to hire according to race or gender characteristics, high school counselors, teachers, and parents continued to encourage women to enter these fields, rather than pursue careers in business, mathematics, or any of the sciences.

Through socializing women to continue working in pink collar professions, men have less competition in areas of employment as well as entry into colleges and universities. By encouraging men to enter into areas of employment that provide higher pay and benefits than the low paying occupations women are directed into, society’s gender roles are reinforced and a large gap is permanently created between the earning potential of women and men, thus further limiting women’s options and opportunities.

As women gained greater access to education and began to enter into traditional male jobs, the image of the “superwoman” or “supermom” emerged in the 1980s. These women were depicted as having successful careers and marriages and happily fulfilled their primary role as mothers. This glorified image of women balancing all of these roles represented a cultural shift

in accepting women’s broader entry into the working world, but it also reifies traditional gender roles women are expected to adhere to as wives and mothers. While great advances have been made in areas of education and employment, women continue to earn approximately 72 cents per every dollar a man makes, with few actually gaining positions of stature such as CEOs of large corporations or presidents of universities. The number of women holding elected office proportionately remains quite low in comparison to men.

One of the foundational tenets of liberal feminism is also its most controversial. This is the belief that all women have the right to privacy, which includes complete control over their bodies. This ideology becomes complicated when discussing issues related to sexuality, health care, and reproduction, largely because of women’s biological role in procreation. Historically, conceptions of marriage have been based on people’s desire to procreate, to create a family. It is only within modern history that western (specifically, US) culture has embraced the belief that marriage is based on love and fulfilling relationships. One of the main areas of focus for change with the rise of the Women’s Liberation Movement was increased autonomy for women to make their own medical decisions, particularly concerning their choices connected to birth control, which includes the right to have a safe abortion. This right was gained with the 1973 US Supreme Court decision in *Roe v. Wade* and *Dole v. Bolton*. Women were granted the legal right to have access to safe abortions, but the role of the state in terms of providing funding or the actual service has been highly contestable, as is the right to abortion itself. This issue remains central to women’s activism and scholarship.

Since the *Roe* decision, laws have been adopted that limit women’s access to abortion, including parental notification laws for minors, time periods established between when a woman seeks an abortion and can receive one, and the elimination of all federal funding for this service. One of the consequences of this has been a decrease in available reproductive health care services for all women. Often, arguments against providing services connected to birth control and abortion follow conservative

ideologies reinforcing traditional gender roles for women as mothers, with the expectation that all women want to have children and that they have made a choice to become pregnant. These beliefs have been challenged by liberal feminists and researchers who have documented women's lack of reproductive options, including their ability to choose whether or not to conceive a child. Certainly, while liberal feminism strongly advocates a pro choice ideology and therefore supports abortion, there is much debate surrounding this issue.

One of the main critiques of liberal feminism is the amount of attention that has been paid to women's right to an abortion and who exactly benefits from this right. Historically, women of color and poor women have had very different experiences to those portrayed in liberal feminism. The US has a long history of forced pregnancy of slaves and medical experimentation and forced sterilization of African American, Puerto Rican, and Native American women. These women have been legally required to and/or pressured to have abortions and hysterectomies and to utilize long term birth control such as Norplant, which has dangerous side effects. Many of these women have also been lower income, which provides another barrier to adequate health care. While liberal feminists and scholars present their efforts as representing all women, it has had great difficulty uniting a wide range of women. When discussing the racism and classism of liberal feminism, Angela Davis (1981: 202) writes: "rarely have the movement's leaders popularized the genuine concerns of working class women." Liberal feminism has responded to these critiques. Larger national groups – including NOW and NARAL – have widened their efforts at working for reproductive health care options, but abortion remains the primary focus within this work.

From the beginning of the women's movement, there has been strong criticism as to the elite nature of liberal feminism. The vast majority of positions of power and authority have been held by white women with privilege. This is evident in Friedan's work, which called for women to get out of the trappings of housework but ignored the issue of who their maids were: they were usually black women who had to work to support their families. Additionally, the

family is viewed as an essential part of their lives, not a burden but the foundation for strength, happiness, and community. Women activists (particularly black women from the abolitionist movement) have contributed greatly to the elimination of gender inequality, but also have largely remained invisible due to their race/ethnicity and/or class status. This is evident in Sojourner Truth's outburst during one of the early conventions, when she shouted "Ain't I a Woman?" and demanded recognition for her contributions and desire for equality based on race and gender. Her words may be famous, but they made little impact in terms of changing the role of blacks in the movement. Truth, Ida B. Wells, Anna Julia Cooper, and contemporary activists and scholars such as Ella Baker, Frances Beale, and Shirley Chisholm remain on the margins of history despite their contributions to feminism.

Liberal feminism has also been criticized for its lack of systematic analysis of the social structures that maintain gender inequality. There is no critique of existing social systems because it seeks entry into these institutions rather than changing them. This caused many fissures within the Women's Liberation Movement. Radical feminism was formed with the belief that social systems and structures need to change in order to eliminate oppression of women overall. Socialist and Marxist feminism emerged from radical feminism, focusing on capitalism as the main source of women's oppression. Other feminisms soon followed which expanded analysis into an array of areas, including analyzing what gender actually is, issues related to sexuality and age, and a host of other topics. Black Feminist Thought and Women of Color feminism emerged through the creation of their own organizations, which moved beyond focusing on a single issue as the cause of inequality, to examining oppression and domination through intersectional lenses. This moved feminism and feminist thought into broader realms, into questioning and challenging systems of oppression and domination throughout the US.

As with any social movement and body of scholarship, liberal feminism has evolved as society and culture has changed. Many of the basic goals of individual rights and freedoms, as well as an end to gender inequality, remain

central to liberal feminism. Liberal feminists successfully brought the issue of equal rights into mainstream America and created significant legal and cultural changes that improved the lives of women and men in the nation. Many of the tactics they created or adopted from the black Civil Rights Movement have been utilized by other movements and organizations, including other women's groups around the world.

liberalism

Andrew Gamble

Liberalism is the leading ideology of the modern era. The term first began to be used to denote the supporters of liberty and the opponents of arbitrary authority in Spain during the Napoleonic Wars. During the nineteenth century it came to signify adherence to the principles of individualism, liberty, limited government, progress, and equality. As such it has always been an extremely broad doctrine, espoused by thinkers as diverse as John Stuart Mill, Constant, Bentham, Tocqueville, Hobbes, and Hayek. Many of its key ideas can be traced to earlier thinkers such as Locke, Kant, and the French and Scottish Enlightenment. At its core is a particular conception of society and human nature, based on beliefs in the moral primacy of the individual as the starting point for thinking about politics and society; the equal moral worth of every individual, regardless of class, nation, gender, or race; and the possibility of improving social conditions and reforming political institutions. Individuals are conceived as the bearers of rights which exist independently of government and for which government is brought into existence in order to protect. The legitimacy of any system of government depends therefore on how well it protects the liberty of its citizens.

Liberalism was decisively shaped by the American and French Revolutions. These two major political events marked the beginning of the modern era and the age of ideologies because they involved a decisive break with the old order and a vision of the new, the overthrow of established political authority, and the assertion of new principles of government – life, liberty, and the pursuit of happiness in the American version, and liberty, equality, and fraternity in the French. Both these revolutions

proclaimed in different ways that sovereignty should be popular sovereignty, that government should be based on the will of the people, and that for this purpose all members of a political community should be regarded as equal and able to participate in their self government. These ideals were much contradicted in practice; in America the rights of man which formed the basis of the new Constitution were not extended to slaves or women, while in France the attempt to construct representative institutions gave way to terror and dictatorship. But despite their failings the political revolutions in France and America did produce a decisive rupture in the system of monarchical absolutism, giving birth to a new kind of political imagination and political possibility.

The political revolutions were also part of much broader social and economic changes involving the rise of new technologies, new forms of organization, and new forms of knowledge, which together shaped the conception of modernity. Liberalism came to stand for progress and opposition to all forms of obscurantism, tradition, privilege, and prejudice, and therefore became identified with capitalism, rationalism, science, secularism, and more generally with modernity and the rise of the modern state. Although liberals held many different views on aspects of the new society that was emerging, they tended to be optimistic rather than pessimistic about the prospects for human progress because of their faith in reason, which came from the Enlightenment, their universalism, and their confidence in rational, scientific methods to discover the causes of things and propose improvements.

As a political doctrine liberalism emphasizes the framework of institutions and laws through which the liberty of citizens can be protected from arbitrary government. The aim is to establish a government of laws rather than of men. A well designed constitution ensures a balance of power between the different arms of government – executive, legislature, and judiciary – so that no one arm of government can dominate. Liberals have generally sought to disperse power and to limit government, and to set obstacles to any return to tyranny and dictatorship. They have been ambivalent about democracy, divided over whether it is a new form of

unlimited government which threatens liberty and the rule of law, or whether it is the best means to promote representation, accountability, and self government.

As an economic doctrine liberalism developed a distinctive strand of political economy, committed to free trade, sound money, and *laissez faire*. These ideas were important in breaking down obstacles to the spread of markets and capitalism and promoting flows of capital, goods, and people around the world, based on the argument that if government stands back and allows the natural energies of the people full rein, countries will become stronger and richer. Governments are necessary evils, but still evils, so have to be limited in their powers as much as possible. Liberals, however, have always accepted that some powers must be exercised by the state, even if this is only the minimal state providing external defense, internal order, and the rule of law as the basis for a market order. A central tension within liberal political economy and within liberalism more generally is the proper relation between liberty and coercion. All liberals want to minimize coercion as much as possible; the question is always how much and for what purposes. In contrast, libertarians reject all coercive authority as an infringement on liberty, and therefore reject the state itself, so moving outside the bounds of liberalism.

As a cultural doctrine liberalism has been associated with tolerance, diversity, rationality, and neutrality towards other beliefs. Individuals should be free to live as they choose and define the good in their own way without intervention or direction from the state or the community, so long as their choices do not harm others. Application of this principle has allowed a substantial enlargement of the realm of personal freedom, and the shrinking of intervention by the state in areas such as sexual behavior. But some critics of liberalism have argued that this self image of liberalism is a sham because liberalism is a highly moral doctrine and as intolerant as any other moral doctrine of claims which challenge its core beliefs, such as the idea of neutrality itself or the claim that education should be secular, inculcating the values of a common citizenship.

Liberalism has developed many different strands and has undergone substantial change

as the tensions inherent in its core ideas have been explored. There have been important intellectual traditions such as classical liberalism, utilitarianism, new liberalism, and neoliberalism, as well as many distinct national traditions of liberalism, such as those in Germany, Britain, Italy, and the US. Ideological disagreement among liberals themselves over the role of the state and the role of reason have divided the liberal tradition into “true” and “false” liberalism, or “skeptical” and “rational” liberalism. The divide is over whether there are strict limits to the potential of human reason to reorganize the world and what these limits are. The skeptics believe human reason can only be used to discover the constraints within which human life must be lived, while the rationalists believe human reason can and should be used to overcome those constraints.

This argument about the limits of reason is closely associated with ideas about the limits of government, and the potential of government for utilizing rational knowledge to transform society for the better. The lure of scientific knowledge and the apparently limitless possibilities it opened for understanding both physical nature and human nature seemed to provide societies with the tools for limitless improvement. The skeptics argued that progress could only be maintained if the powers of the state were kept strictly limited, so as to maximize the energy, knowledge, and enterprise of the myriad of individual actors. Rationalists, such as the utilitarians, believed public policy should be so conducted as to ensure the greatest happiness of the greatest number.

This divide also became expressed as a divide between the state and the market, and the question of how far the market needed to be protected from the depredations of the state. In the early phases of liberalism the emphasis was upon removing restrictions to enterprise and trade, challenging traditions and customs, and embracing change and new knowledge to change society. Once liberalism in the shape of liberal political economy became the orthodoxy, however, the widening of the gap between rich and poor and the relentless nature of a competitive commercial society created powerful conservative and socialist counter movements against liberalism. Many liberals became convinced that

the achievement of their ideals required more positive action by the state to create the conditions under which all individuals could develop the capacity to exercise freedom. Such attitudes were characteristic of “new liberalism” in the late nineteenth and early twentieth centuries and moved the goal of liberalism from being about liberty to being about human flourishing and self realization. This required the state to intervene to remedy disadvantage and to equip all its citizens with the opportunities and resources for self realization. A long and expanding list of interventions by the state became sanctioned.

This conflict within liberalism was later formalized by Isaiah Berlin as the contrast between negative liberty and positive liberty. A liberalism that is concerned primarily with negative liberty leaves individuals free to do whatever they like so long as they do not harm others and accepts that individuals will always disagree about what constitutes a good life. A liberalism that is concerned more with positive liberty targets those conditions such as disease, ignorance, and poverty which prevent many individuals from realizing their potential for self development. Both sets of liberals set great store on liberty as the supreme value, but disagree strongly as to how it is best secured. New liberals gravitated towards social democracy in Europe and programs like the New Deal in the US, while laissez faire liberals after a long period of retreat in the face of collectivism finally reemerged strongly in the second half of the twentieth century in the guise of neoliberalism.

In the 1930s it became fashionable to believe that liberalism was an outmoded doctrine, no longer suited to an industrial society which was increasingly organized, managerial, and collectivist in its consciousness and ethos. The rise of collectivist ideologies and totalitarian regimes made many liberals believe that some form of collectivist organization of society and the state had become necessary for the survival of industrial society. The strong revival of liberalism after 1945 in the west was largely unexpected. It was accompanied by the development of the idea of a liberal democracy, based on constitutional safeguards for representative and limited government, a free market economy, and an active state to promote the well being of its

citizens. In the first few decades after 1945 liberalism became quite strongly associated with interventionist economic and social policies programs inspired by two English liberals, J. M. Keynes and W. H. Beveridge, as well as with permissive social policies on a range of issues from abortion and homosexuality to divorce and capital punishment. One consequence of this was that the term liberal in the US became permanently linked to a left liberal agenda, and the revival of laissez faire liberalism or classical liberalism in the 1970s was associated more with conservatism than with liberalism, even though it was dubbed neoliberalism by its opponents.

The collapse of the Soviet Union brought an end to the most serious twentieth century political and ideological challenge to liberalism, and suggested to some that all the most important ideological conflicts were now within liberalism rather than between liberalism and other ideologies, and that liberalism had now established itself as the quintessential doctrine of modernity. Others regarded the triumph of liberalism as largely a mirage, reflecting the remarkable degree of dominance established by the US at the end of the twentieth century rather than any broad acceptance of liberal ideas throughout the world. Many liberals continued to be ambivalent about democracy and about the role of the state in promoting the conditions for a liberal society, while others argued that liberalism had to develop further if it was to live up to its founding principles. The restless and iconoclastic character of liberalism – with its emphasis upon the individual and upon reason – continue to define it, even if some of the conclusions that liberals draw from these principles remain diametrically opposed.

Liebow, Elliot (1925–94)

Levon Chorbajian

Elliot Liebow was born in Washington, DC. He served in World War II and received his high school equivalency diploma while in the Marine Corps. After the war, Liebow received his bachelor's degree in English literature from George Washington University. He studied ancient history at the University of Maryland and received his PhD in anthropology from Catholic University. Liebow was employed by the National Institute of Mental Health (NIMH) for 25 years and rose to the position of chief of the Center for the Study of Work and Mental Health. In his last years of retirement from NIMH, Liebow held the endowed chair as Patrick Cardinal O'Boyle professor at the National Catholic School of Social Work at Catholic University.

Liebow's reputation is heavily based on the publication of a single book, *Tally's Corner: A Study of Negro Streetcorner Men* (1967). It had been his doctoral dissertation. The book has sold in excess of 800,000 copies, and it continues to be in print. Liebow was the son of Eastern European Jewish immigrants and had grown up in a poor African American neighborhood in Washington. This experience proved to be an asset for Liebow in establishing rapport with the subjects of *Tally's Corner*. In the early 1960s Liebow spent 18 months in the company of two dozen poor African American men who regularly congregated at a particular neighborhood street corner in the District. He spent hundreds of hours with these men and accompanied them to hospitals, parties, workplaces, and courtrooms. Liebow's interpretation of the world of these men became *Tally's Corner*. The book's popularity is partly accounted for by the coincidence of its publication with urban uprisings, the rise of the Civil Rights and Black

Power movements, and the federal anti poverty programs of the late 1960s, all of which generated an interest in urban African American communities.

Liebow's second book was published two and a half decades after *Tally's Corner*, shortly before his death. *Tell Them Who I Am: The Lives of Homeless Women* (1993) evolved out of Liebow's volunteer work in public and private homeless shelters for women in the Washington area. As in *Tally's Corner*, Liebow was interested in how people at the lower rungs of the class structure establish identity and maintain dignity in the face of great odds.

Liebow made important contributions to the breadth and diversity of sociology as a discipline. *Tally's Corner* helped to resurrect ethnography as a method at a time when Parsonian structural functionalism was still sociology's dominant theoretical paradigm and survey research its reigning methodology. Among Liebow's many awards are two from the Society for the Study of Social Problems, the C. Wright Mills Award for *Tally's Corner* and the Lee Founders Award for career achievement in sociology.

life chances and resources

Wout Ultee

Around the mid 1980s in the field of societal stratification, the research program of "Class, Status, and Power" had evolved into the more

powerful program of "Life Chances and Resources." At that time, theoretical and empirical efforts undertaken by sociologists in various countries of the world began to converge.

An early formulation and application of the new program was given by Lenski in 1966. This study did not so much apply concepts like class, status, and power to describe concrete societies as it presented propositions to answer questions that went beyond earlier interrogations. As Lenski put it, he had taken the liberty of reformulating the once paramount question in the field of stratification about the number and nature of strata in various human societies into the question of causes and consequences of distributive processes, or more attractively, the question of who gets what and why. Lenski's theory in answer to this problem aimed to synthesize existing theories, and the book elucidating and testing his ideas carried the catchy title *Power and Privilege*. Perhaps a less categorical title, like "Resources and Advantages," would have expressed better the most general statement of the program Lenski unfolded: the members of societies who command the most resources for that reason lead a privileged existence and have the best chances in life.

Lenski's two prime derivations from the perhaps obvious proposition that power makes for privilege were the technology hypothesis and the ideology hypothesis. Whereas the idea that resources make for advantages is pitched at the individual level, these two hypotheses referred to developments within societies and differences between them. The technology hypothesis held that if a society has a higher level of technological development, stratification within this society is stronger. Culling data from monographs by anthropologists, historians, and sociologists on phenomena such as hunting skills, ownership of gardens and fields, wealth according to tax records, number of wives, size of houses, differences in diet, and the ease with which various people in a society lived, it appeared that this thesis held up remarkably well in the early stages of technological evolution, but failed with the shift from agriculture to industry.

Lenski attributed this refutation not to flaws in the auxiliary assumption that advances in technology amount to the invention of new resources, but to the other auxiliary assumption that forms of power tend to be pyramidal.

Technological progress, Lenski now proposed, does not always make for an accumulation of new and old economic resources. Industrial societies use so many different vocational skills that education becomes an economic resource independent of the ownership of factories and machines. Also, because industrial societies no longer restrict the right to vote for political offices to the wealthy but have introduced universal suffrage, the balance of political power becomes more equal. Lenski's second derivation therefore invoked the ideologies of ruling industrial societies: to the extent that these societies are governed by parties seeking redistribution from the rich to the poor, the impact of class upon the life of their inhabitants is mitigated. The testing of this ideology hypothesis was presented as a matter for future research.

The first reviews of Lenski's book centered on the matter of whether the synthesis of existing theories was a happy one. In later research, the "multilayered" nature of Lenski's theory was noticed. If power makes for privilege, then the introduction of universal suffrage in industrial societies levels the distribution of political resources, and to the extent that redistributive parties ascend to government and award the inhabitants of a country social rights, differences between a society's members in income decrease too. This was measured by using official statistics on the income shares of the upper quintile or decile (Hewitt 1977). Some time later, hypotheses concerning the effects of government by left wing parties on father-son mobility were tested (Heath 1981).

Whereas the program of class, status, and power focused on three aggregate phenomena within a society, the program of life chances and resources took its starting point from individual resources. Sometimes resources similar to the aggregate power phenomena were postulated. An example is Runciman (1989), who held that there are three kinds of power in every society, succinctly called means of production, means of persuasion, and means of coercion. Earlier, Collins (1975) added to the proposition that forms of property like slaves, landholding, and industrial capital are upheld by the means of violence of the state, the idea being that the means of mental production and of emotional production are resources too. Bourdieu (1984), leaning on Marx, used the

term capital and distinguished three forms, but in the end came up with social resources as a new type: people differ in the extent they command economic, cultural, and social capital.

The counterpart of resources (or assets) is handicaps (or liabilities). By focusing on these, questions of age, ethnicity, and gender may be brought into the program of life chances and resources. To answer the question of why males in most human societies dominate females, Collins (1975) pointed out that women on the average are less tall and muscular than men, with women being physically vulnerable too by bearing and caring for children. As other handicaps for females accounting for male dominance, Collins listed property and ideology. Collins attempted to deal with the dynamics of age stratification by indicating resources of young persons and of adults.

Several subprograms of the program on life chances and resources concentrate on one type of capital. One investigates the thesis that in advanced agrarian societies the shift from weapon bearing and army commanding feudal lords to the monopolization of the means of violence by an absolute ruler raised the criteria of civilized conduct by which the old feudal lords sought to distinguish themselves from other, particularly ascending, strata. This subprogram was initiated by Elias in 1939 and had been dormant before a German reprint appeared in 1969 and an English translation in 1978. It was carried forward by De Swaan (1988) with respect to the elimination by industrial states of the negative externalities of vagrancy, contagious diseases, illiteracy, and infirmities in old age. Another subprogram is that of social capital (Lin 2001). It sings to the tune of "I get by with a little help from my friends." The results, however, seem to amount to the line "Going to try with a little help from my friends." According to some studies, people who find a job through a friend rather than through answering an advertisement wind up in a worse job. However, it was shown that if the status of the helping friend was higher, the job found was higher too.

The Elias hypothesis refers to situations in which the declining returns of one resource (weapons) in agrarian societies are offset to some extent by a greater importance of another resource (good manners). Bourdieu (1984) presented several hypotheses about how the

propertied classes in industrial societies try to maintain their position at the top of the social scale by compensatory strategies. An example is the statement that upon the introduction of wealth taxes and inheritance taxes, parents invest more in the education of their children. The conversion of resources may be taken as another topic for a subprogram of the program of life chances and resources.

The notion that classes, status groups, and parties are phenomena of the power relationships within a society almost naturally directed attention to political stability and change. In contrast, the notion of various kinds of individual resources steers us toward the question of how scarce consumption goods are distributed within a society, and the question of whether, apart from economic resources, political and symbolic resources also make life easier and more fulfilling. Thus, in a review of the results in the field of stratification in Great Britain between 1946 and 1976, Goldthorpe and Bevan (1977) went beyond pure description and set themselves the aim of integration. It was to be attained by taking classes, status groups, and parties as phenomena of the power relationships within a society and introducing the notion of advantage as complementary to that of power. After stating that power brings advantage, Goldthorpe and Bevan pointed out that the idea of advantage may fulfill a role in the field of societal stratification at the "distributional" level, analogous to that of power at the "relational" level. When detailing life chances, they pointed toward class differentials in infant as well as in adult mortality, class differences in the use of health services (which in Britain at that time were available to all and at very low cost or entirely free), and class differentials in access to different types and levels of education and in educational attainment.

The word life chances had been used by Weber in an almost casual way. Which concrete phenomena, treated as instances of advantages in research monographs, may be taken as part of the program of life chances and resources? Wright (1979) focused on income in the US and found that, when taking class, education, and occupational status as resources for individual income, class has a significant impact on income independent of occupational status, and that, net of education, the impact of class on

income is greater than that of status on income. Income returns to education differed within classes too, with the smallest returns for workers, and the largest for employers. This sums up Wright's answer to the question of whether not only more economic resources but also more symbolic resources lead to a more privileged life, as indicated by income.

Earlier, the *embourgeoisement* thesis held that affluent workers would lose their distinct position in the class structure. Findings for Britain in the early 1960s (Goldthorpe et al. 1968) spoke largely against it: the Labour Party continued to be regarded as the party for the working class, support for labor unions was still strong, and the orientation of affluent workers toward their job, rather than becoming a source of intrinsic satisfaction, remained instrumental. Also, as regards leisure, manual couples were more likely to spend spare time with kin and neighbors, and white collar couples with colleagues and others. However, members of the manual and the non manual classes did not differ much in the aspirations they held with respect to the education of their children.

Bourdieu (1984) took the next big step in this line of research on other chances in life than income. His most concrete and interesting question perhaps may be phrased as: with jobs becoming physically less exhausting, do people come to cultivate their aesthetic capacities? Bourdieu empirically investigated such matters as the food people eat, the furniture that fills their houses, the sports they practice, and, as far as aesthetic matters go, the paintings and music they esteem beautiful, as well as the films they have seen. He also established the relation between these phenomena and the occupation of persons. By way of factor analysis of surveys undertaken in France around 1970, Bourdieu sought to establish the existence of a multidimensional social space. This did not simply consist of dots for closely related occupations and leisure activities, but comprised in various statistical exercises several axes, particularly for the volume of capital commanded and the composition of that capital. Here Bourdieu came to three categories: people who command neither economic nor cultural capital, people who command primarily economic capital, such as persons with leading positions in industry and finance, and people who primarily command

cultural capital, such as secondary school teachers and lawyers. Apparently, the number of persons in a society with both economic and cultural capital turned out to be very limited. In discussing his findings, Bourdieu counted not only diplomas but also the command of high culture, supposedly part of the implicit curriculum of schools, as cultural capital. The differences in leisure activities between the three groups were assumed to go beyond those necessitated by income differences. They would indicate a leisure preference in line with the nature of people's jobs, and a tendency for the persons with certain occupations to distinguish themselves from persons with other occupations.

Weber had maintained that status groups claim a particular lifestyle, but shied away from circumscribing those styles. He simply noted that status groups are indicated by who marries whom and who shares meals with whom. Elias (1978 [1939]) studied one aspect of the lifestyle turning people into a status group, the criteria for civilized conduct in agrarian societies by which their top groups keep the lower strata of society at a distance. According to Bourdieu, Weber's thesis that status groups have distinctive lifestyles was not simply about life styles but about distinction. Arguing along the lines set out by Bourdieu, lifestyles may also be taken as combinations of life chances. Questions about the lifestyle within the working classes of industrial societies began to draw more attention after World War II. It then turned out that in industrial societies with private ownership of the means of production, mass unemployment did not always occur, and wages did not sink to the subsistence level. With the rising standard of living of the working classes, questions about how income was being spent became a topic of empirical research. Also, with the shortening of the number of hours worked each day, the contraction of the working week from six to five days, and the introduction of paid vacation weeks, questions on leisure became important. However, the idea of a hierarchy of human needs, with subsistence at its lower levels, rest and recreation a bit higher, and the appreciation of beauty on top, and other things somewhere in between, has remained until now implicit in the program of life chances and resources.

The program of class, status, and power had been plagued by the difficulty that parties and

status groups are always more than mere aggregates, whereas classes are not always groups. By shifting from aggregate phenomena like classes, status groups, and parties to various individual resources, the program of life chances and resources did away with this difficulty. Ultee also offered a fresh start with respect to the conditions under which persons who have similar market positions (such as manual workers) form groups, in this case political parties and labor unions pressing their interests. The idea of false consciousness prominent in theories taking class as the fundamental dimension of stratification in all times and at all places was dropped. It now was posited that collective action was but one strategy open to the members of a society's lower strata, and individual mobility another (Boudon 1973). It was held too that rational actors face the dilemma of collective action. After all, if only a few persons participate in a class organization, the movement will not attain its goals, and if a lot of people participate, a person may withdraw since without that one person the goals will in any case be reached. The economist Olson (1965) pointed out this dilemma, first studied as the prisoner's dilemma, and the sociologist Oberschall (1973) indicated that the dilemma of collective action may be overcome not only in small groups, as Olson stated, but also in homogeneous large groups concentrated in particular localities.

Of late, a shift is taking place within the field of social stratification as regards the "outside" theories being applied. Blau and Duncan (1967) estimated statistical models of status attainment processes in the US in the mid twentieth century, and sought to provide evidence that a general functionalist theory obtained: attainment would be governed less and less by principles of ascription such as race and social background, and more and more by principles of achievement such as education and work experience. It is easy to interpret their finding of a shift from ascription to achievement within the framework of individual resources: the effect of parental characteristics for a person's level of education and job status declined, and the return to education in terms of job status increased. Indeed, stock markets discovered that the profits of a company are not always served by making the children of founders

directors, and states lowered the financial costs of schooling for children of parents who are not well to do.

Sociologists like Elias and Bourdieu, however, have been pointing toward the effects of competition between persons if the inequalities between them in some resources decrease. These effects may be characterized as spiralling processes: criteria for civilized conduct become more strict; if income does not distinguish as it used to do between classes, the way people spend their money and time becomes important. If primary school becomes compulsory in industrial societies, for parents who already send their children to primary school, secondary education becomes important for their children. And if the age of compulsory schooling is raised to, say, 16 years, higher education is the means to keep ahead. Blau and Duncan's results hint at spiralling processes too: a person's education influenced not only a person's first job directly, but also a person's present job, and, net of education, a higher first job made for a higher present job.

Spiralling processes differ from the equilibrium processes on competitive markets studied by neoclassical economics. However, formal models for rational persons making sequences of decisions rather than one shot choices (Boudon 1973; Mare 1981) might have more on offer, as well as theories on market behavior in a social environment (Becker & Murphy 2000). It should be pointed out too that Goldthorpe (2000), when explaining persistent class inequalities in education attainment, tries to do away with the general assumption of rational choice theories that people go for the highest. Instead they would avoid a situation for their children that is worse than their own one, being satisfied with that situation or a better one.

life course

Jens Zinn

The term life course refers to the idea that the course of one's life is not just determined by a natural process of aging but is mainly shaped by social institutions and sociocultural values as

well as by decisions and unexpected events. Thus the life course consists of life stages (e.g., childhood, youth, adulthood), status passages or transitions (e.g., from youth to adulthood, from student to professional), and life events (e.g., marriage, job loss, illness). Formal institutions such as the law and the welfare state ascribe rights and duties by age and formal status, and when, for example, to start a family and how to divide labor within the household are also structured by sociocultural norms and habits.

The term life course increasingly supplants the earlier concept of the life cycle, which implies a connection to early developmental concepts in psychology. These concepts state that life is structured by a specific order of events where one built on the previous event, and that they represent a "natural" order.

The modern notion of the life course differs from concepts in small "primitive" societies as described in ethnographic research, where transitions are understood as determined by natural processes (such as first menses to indicate that girls can be married) or "rites of passage" (Gennep 1981 [1909]).

The modern notion of the life course also differs from its ancestors. During the Middle Ages in Western Europe, the understanding of life was captured in religious and magical thinking. Life seemed to be determined mainly by external powers, such as God or fate. The different stages of life were understood as an expression of an externally given order. The course of one's life could always be interrupted by unforeseeable events and often ended prematurely by death. With modernization, ongoing sociocultural and sociostructural changes shift the meaning of the life course (Kohli 1986).

The institutionalization of education and a social security system as well as the formal regulation of rights and duties by age create a new framework and understanding of the life course as something to be shaped individually. Models of normative expectations about how men and women should shape their life were institutionalized, and societal institutions orient themselves to such models of a "normal" life. Additionally, the increase in medical knowledge and standards of hygiene supports a significant change in mortality, which was moved to and concentrated on old age. A predictable life

course became a normal experience for an increasing part of the population.

Life course research is interested in specific sociostructural patterns as well as the individual's sense making of his or her life. Some times the whole life is examined, but many studies focus on specific transitions, for example from youth to adulthood, from single to husband or wife and to father or mother, from unemployed to employed, or from a lower to a higher position.

How people manage their life systematically differs by sociostructural indicators such as gender, ethnicity, health/disability, or generation. It is expected, for example, that women marry younger than men and that they bear children before 30, while it is accepted that men father children in older age as well. It is also accepted that younger women marry older men, but the reverse is perceived as unusual or even deviant. Such norms are reflected in different life plans and expectations regarding the future, for example that women often expect to have a career break in order to have children whereas men often assume that children will not significantly influence their occupational career.

Early research on the life course was often influenced by sociopsychological approaches combining contextual factors (such as historical change or illness) with individual coping strategies. For example, the early study by Glen Elder, *Children of the Great Depression* (1974), showed how families mediated the individual's management of the hardships of economic slow down. Another classic study by Barney Glaser and Anselm Strauss (1968) on status passages during the life course showed how people cope with dying. Another stream in the tradition of sociostructural analysis focuses on formal factors influencing the life course (e.g., class, educational attainment, gender, marital status, age).

In newer research the orthodoxy of sociostructural determination of individuals' sense making of social positioning and the life course was questioned by the thesis of growing individualization, which would weaken the individual's embeddedness in traditional institutions. Growing individualization would set free new generations from traditional bonds and would open an increasing space of new opportunities and decisions, for example for youth (Furlong & Cartmel 1997). More critical examinations

show that although the semantics of life course decisions have changed, the idea of growing self responsibility does not go along with a significant change in vertical social mobility or increasing individual control of life (Vickerstaff 2006).

The life course encompasses an objective course of life and the individual's sense making of his or her life. This is mainly analyzed by a combination of quantitative and qualitative methods that investigate the sense making of transitions, action orientations, and coping strategies. Additionally, two streams of research have developed which concentrate on specific aspects of the life course. At the center of biographical research is the individual's sense making of his or her life. Sociostructural researchers, on the other hand, focus on the life course patterns that are expressed in durations of working and employment status or marital status or divorce, and which factors could be linked to such patterns. While the biographical approach mainly works with qualitative methods and narrative interviewing techniques to explain current activities by the cumulated sense making of one's former life (Rosenthal 2004), the sociostructural approach uses event history modeling (Blossfeld & Rohwer 2002) or optimal pattern matching techniques (Abbott & Tsay 2000) to examine and compare life course patterns and events.

life course and family

Chris Phillipson

The concept of the life course refers to the social processes shaping individuals' journey through life, in particular their interaction with major institutions associated with the family, work, education, and leisure. The life course perspective distinguishes between *trajectories* on the one side and *transitions* on the other. The former refer to the sequence of roles experienced over the life span; the latter to the changes consequent upon events such as divorce, children leaving home, and the birth of grandchildren.

Life course approaches emphasize the way in which individual trajectories and transitions are linked to the lives of significant others, with the interdependency of generations being one such example. The idea of families having "interlocking trajectories" was first explored in the work of the American sociologist Glenn Elder, most notably in his *Children of the Great Depression* (1974). This study illustrated how delays in the parents' timing of work and family careers as a result of the economic depression of the 1930s affected the subsequent timing of their children's own life transitions. Another example of the "linked lives" phenomenon has been illustrated in research on grandparenting that examines situations where grandparents take

responsibility for raising grandchildren. Silverstein et al. (2003) view this as an example of "mutual interdependency" within the family, with grandparents adopting new parental roles and parents excused from the main responsibilities associated with parenting. In this way, the researchers suggest, the family can be seen as a group of interlocking individuals who continually adapt both to their own needs and to those of others within the family system.

The idea of *time* is a central element in the concept of the life course. Hareven (1982) identifies three different levels of "time" running through the life course of any individual: familial, individual, and historical. *Family time* refers to the timing of events such as marriage which involve the individual moving into new family based roles such as spouse or parent. *Individual time* is closely linked with family time, given the links between individual transitions and collective family based transitions. *Historical time* refers to more general institutional changes in society, including demographic, economic, and socio legal. Hareven argues that an understanding of the synchronization of these different levels of time is essential to the investigation of the relationship between individual lives and wider processes of social change.

The life course is itself now stretched over a longer period of time, given substantial improvements in life expectancy in most western countries. Associated with this have been significant changes in family life over the past century. For example, current cohorts of older people experience a far longer period of "post parental" life than was the case with earlier cohorts. In 1900, women were likely to be in their mid fifties/sixties when their last child married. Consequently, given lower life expectancy at this time, many women could expect to be widowed before their last child left home. With increased life expectancy, smaller family size associated with low fertility rates, and closer spacing of children, the average couple can now expect to live for 25 years or more after their last child has moved out. However, this post parental phase may still be associated with extensive care responsibilities associated with grandparenting and other types of informal care.

The life course approach has been highly influential in research on the family life of older people, with the idea of linked lives

demonstrating how expectations about giving and receiving support are part of a continuing interaction among parents, children, and other kin over their lives as they move through time (Hareven 2001). Although the growth of individualism may have loosened kinship ties to a degree (Beck & Beck Gernsheim 2004), relationships between generations continue to be important in the family life of older people (Phillipson et al. 2001). The work of Attias Donfut and Wolff (2000) in France has highlighted the role of the "pivot" (middle age) generation in providing economic support to young people on the threshold of adulthood, as well as providing flexible forms of care for the older generation as need arises. Generations have also been shown to provide emotional support for one another at different points of the life course. Research in the US has tracked feelings of emotional closeness and support across generations and found that emotional closeness stayed stable over a period of nearly two decades, with the maintenance of strong levels of affectual solidarity across generations, with adult children both providing and receiving help from mothers and fathers.

Life course research has also underlined the variability of expectations and patterns of support, with patterns of generational assistance shaped by values and experiences that evolve throughout life. Hareven and Adams (1996) demonstrate this point from research in the US examining how the premigration history of different ethnic groups influences expectations of support in later life. They demonstrate how older cohorts tend to emphasize support from family members; younger cohorts, in contrast, tend to stress help from social and welfare programs. They further note the way in which the earlier life course experiences of each cohort, as shaped by historical events, also affect the availability of economic and educational resources and support networks.

Given greater longevity, multi generational ties have assumed much greater importance for securing well being and support for individuals over the life course. At the same time, the diversity of family ties must also be acknowledged. Generational relationships remain important in anchoring people at different points of the life course; however, not everyone is involved to the same degree in such relationships. The role of

family relationships within the life course is likely to undergo further modification with the experiences of new cohorts influenced by wider social and historical change. The key point to acknowledge here is the dynamic process involved with different age groups both influencing the shape of the life course, while themselves being affected by changes operating at an institutional level. Families with their connecting intergenerational bonds will remain at the center of this process, and are themselves likely to contribute to what will be a major area of social change in the years ahead.

life course perspective

Glen H. Elder, Jr.

Developments after World War II called for new ways of thinking about lives, society, and their relationship. The social discontinuities of economic depression, a world war, and prosperity raised questions about the course these adults followed into the middle years. The changing age composition of society also gave more visibility to the adult life course. Problems of old age directed inquiry to earlier trajectories and to the processes by which lives are influenced by a changing society. In combination, these developments placed lives in context and focused attention on their social pathways. From this background the life course perspective was conceived as both a concept and a theoretical orientation for the study of individual lives and age cohorts.

ELEMENTARY DISTINCTIONS

As a concept, the life course refers to an age graded sequence of events and social roles that is embedded in social structures and history. These structures vary from family relations at the micro level to age graded educational organizations and state policies at the macro level. The life course also represents a theoretical orientation, a type of theory that guides research in terms of problem identification and formulation, rationales of design, variable selection, and explanatory analysis.

The life course evolves over an extended period of time, as in a trajectory of marriage or work; and it also takes form within a short time span, as a transition between statuses, such as leaving school and entering a full time job. Social transitions of this kind vary in timing, whether relatively early or late, and are always

embedded in trajectories which give them a distinctive form and meaning. Indeed, life trajectories in specific domains (such as work) link states, the duration of each state, and transitions between states across successive years. For example, each work trajectory is patterned by a sequence of jobs of varying duration and transitions between jobs, along with occasional episodes of unemployment. A single work transition may entail little or no change or produce a turning point – a redirection of the life course through changes in situation, meaning, and/or behavior. Marriage and stable employment have served as transitions out of crime and as turning points for young men who grew up in poverty.

Each concept – trajectory, transition, and turning point – applies to levels of the life course, from macro to micro: (1) institutionalized pathways may be defined on the macro level by social policies of the state or firm; (2) within these pathways, the individual works out his or her life course through choices and lines of action; and (3) the individual's own course of development and aging, which may be expressed in terms of self confidence or intellectual competence. These multiple levels are illustrated by an examination of worklife. A "career line" refers to pathways that are defined by the aggregated work histories of employees. They are structured by industry sectors and the labor market. An individual's worklife varies by the career requirements of the marketplace and firm. It also may vary by the worker's family life, an integral dimension of his or her life course. On the developmental level, both negative and positive changes in work have psychological consequences, as in feelings of self efficacy. Each level of the life course represents a field of study, though contemporary work is more likely to extend across levels.

The life course is frequently used interchangeably with other concepts, such as life span, life history, and life cycle. These concepts have an important application in studies of the life course, but they are not synonymous with its meaning. For example, life span, as in life span psychology or sociology, describes the temporal scope of inquiry and specialization that includes a substantial portion of life, especially one that links behavior in two or more life stages. The temporal frame moves well beyond age specific studies of childhood or adolescence. Life

history, on the other hand, generally refers to the chronology of events and activities across the life course (e.g., residence, household composition, marriage and childbearing). It is frequently assembled from retrospective life calendars, which record the year and month at which a transition occurs in each domain. This life record depicts an unfolding life course in ways uniquely suited to event history analyses. Lastly, the life cycle has been used to describe a sequence of social roles or events, especially the reproductive process from one generation to the next. All populations have a reproductive life cycle, but only some of the people bear children.

PARADIGMATIC PRINCIPLES OF LIFE COURSE THEORY

Over many decades, the life span was carved up into life stages which became distinct fields of study. Now we recognize that developmental and aging processes can only be understood by taking a long term perspective. This whole life course perspective reflects the cumulation of research that documents the relevance of early learning and experience for later life. Behaviors at mid life are influenced not only by current circumstances or by anticipation of the future, but also by the experiences of childhood. Also relevant are the developmental trajectories and the biomarkers of pre disease pathways that extend back to the early years. Long term studies are increasingly documenting the relationship between patterns of late life adaptation and the formative years of life course development. By studying lives over substantial periods of time, we can also observe the potential interplay of social change with individual development. Accordingly, the principle of life span development states that: *human development and aging are lifelong processes.*

Pioneering longitudinal studies in California became lifelong enterprises without an initial vision of the life course. Larger studies have recently adopted this perspective, such as the national longitudinal studies of birth cohorts in Great Britain, marked by birth dates of 1946, 1958, 1970, and 2000. They are all scheduled to be followed into the later years of life. Studies across the life course are demonstrating that life outcomes can be modified even for those who

experienced adversity in childhood. They are also changing our understanding of poverty, work, and achievement across the life course while identifying pathways of resilience and increasing vulnerability.

Individual lives are not merely shaped by social institutions or the larger environment. They are also constructed through the choices and plans people make. In the severely limited world of the inner city, families struggle with poverty and crime, but many parents manage their children's lives effectively by entering them in youth organizations and activities, including the local church. John Clausen (1993) has made the case for planful competence as a component of human agency. Adolescents who possess self confidence, an intellectual investment, and dependability – the elements of planful competence – can more effectively prepare themselves for the future. The principle of human agency states that: *individuals construct their own life course through the choices and actions they take within the opportunities and constraints of history and social circumstance.*

Making decisions or choices plays an important role in the timing and timetables of life. Some people come to marriage early in life, while others do so much later on. These differences in timing have consequences, since early marriage may come before education is completed and late marriage severely restricts the pool of available mates. Mortimer (2003) finds that very early transitions to adulthood, such as leaving home at a very young age, have detrimental effects on mental health. Since life experiences often cumulate over time, low income and limited wealth are likely to have more potent effects on emotional and physical health in later life. Unequal groups become more unequal across the years. With these points in mind, the principle of timing states that: *the developmental antecedents and consequences of life transitions, events, and behavioral patterns vary according to their timing in a person's life.*

Both timing and individual choices occur in specific historical times and places, as expressed in the principle of time and place: *the life course of individuals is embedded in and shaped by the historical times and places they experience over their lifetime.* Consider the Chinese Cultural Revolution, which lasted from 1966 to 1976.

Thousands of urban Chinese youth had their lives drastically altered by this revolution through Mao's decision to "send them down" to the countryside, separating them from their families and communities, exposing them to hard manual labor, and limiting their education. These young people postponed marital decisions in the hope of returning to their coastal city. In this manner, the sent down cohort was set apart from adjacent birth cohorts and those of similar age who were not sent down.

The same historical event or change may vary in substance and meaning across different places, regions, or nations. In World War II, the post war era brought great prosperity to Americans as they returned from the war, but Germans faced widespread great poverty and hunger at the same time. With retrospective life history methods, Mayer (1988) found that German men who were born between 1915 and 1925 were almost universally involved in the armed forces. These men lost as much as nine years of their occupational careers in the war and many of the survivors could not find employment afterward. The younger cohort of 1931 also suffered widespread hardship in the war which could not be countered by the economic boom of the 1950s.

In the Great Depression, children were influenced by their father's income loss and by their mother's employment. This observation is expressed by the principle of linked lives: *lives are lived interdependently and sociohistorical influences are expressed through this network of shared relationships.* A more contemporary example comes from the US rural crisis of the 1980s and 1990s when economic indicators such as housing starts and retail sales declined by 40 percent or more. Economic hardship adversely affected the nurturance of parents because it increased their depressed feelings. At the same time, hardship made joint activities and shared responsibilities more important. These experiences had developmental value in the lives of rural youth.

In combination, these principles foster awareness of larger historical forces and the timing of events. They enhance the recognition that lives cannot be understood when they are not connected to relationships with significant others. Most importantly, when they inform inquiry they promote a holistic understanding of lives

over time and across changing contexts. The ideas underlying these principles have emerged over recent decades. The first principle on human development and aging as lifelong processes represents a definitional premise of the theoretical orientation's scope – the temporal span of study extends from birth to death. The other principles first appeared in a Cooley Mead award lecture by Glen Elder (1994) that surveyed studies of the life course and some key premises. Within the time frame of life histories, the principle of human agency depicts the individual as an active force in constructing his or her life course through choices and action. The multiple meanings of age brought temporality and timing to life course thinking, especially during the 1960s – the meanings of social age and historical time. The principle of linked lives refers to the interdependence of lives and has its origins in role theoretical accounts of life histories that date back to *The Polish Peasant* (Thomas & Znaniecki 1918–20). The fifth principle on historical time and place derives much of its richness from the emergence of social history.

THE EMERGENCE OF LIFE COURSE THEORY

Research traditions and concepts relevant to the life course began to coalesce in a theoretical orientation during the 1960s and 1970s. One of the crystallizing forces came from the pioneering longitudinal studies that followed children through the Great Depression and into adulthood – e.g., the Oakland and Berkeley Growth Studies, and the Guidance Study at the University of California, Berkeley. With study members in adulthood, the investigators had to move beyond child based, growth oriented accounts of development. They faced three major challenges: (1) to formulate concepts of development and aging that apply across the life course; (2) to develop ways of thinking about how lives are organized and change over time; and (3) to relate lives to an ever changing society.

The first challenge required the formulation of life span concepts of development and aging in both sociology and developmental psychology. For sociologists, life transitions and turning

points entail changes in relationships, social identity, and self evaluation. Concepts of inter personal and correlated constraints offer insights concerning the dynamics of behavioral continuity. Within birth cohorts, differentiating and cumulating experiences across the life course tend to generate complementary processes, greater heterogeneity or inequality between individuals over time, through the cumulation of advantages and disadvantages, and enhanced behavioral continuity within individuals. In psychology, the distinctive principles of life span development feature the relative plasticity and agency of the organism, the multidirectionality of life span development, and the lifelong interaction of person and social context.

The other challenges were prompted by the relative neglect of context in studies of the person and life span development. These studies did not take role sequences into account in concepts of careers and the life cycle, or age grading. However, a view of life patterns as role sequences dates back to the nineteenth century. Changes in social roles marked changes in social stages across the life cycle, as from marriage to parenthood. W. I. Thomas was an early proponent of this life cycle perspective. With Florian Znaniecki, he used life record data to study the emigration of Polish peasants to European and American cities around the turn of the century (1918–20). Over the years, life cycle theory has focused on stages of parenthood and the generations. By doing so, it has brought some measure of context to lives by stressing their interdependence and providing a way of thinking about socialization. Within the life cycle of each generation, unexpected and involuntary events occur. Thus, a 30 year old woman becomes a grandmother when her adolescent daughter has a first child. Family members lose their status as grandchildren when their grandparents die. Changing connections to family members are a defining feature of life cycle processes.

But the life cycle's emphasis on reproduction and parenting severely limited its application. It did not apply to the never married or to the multiply divorced in a world in which marriage and parenting have become uncoupled to a large extent. And its focus on one career, that of reproduction, ignored the contemporary realities

of multiple roles (e.g., work and family). Equally important, the life cycle, as a role concept, was not sensitive to temporality, apart from the notion of order. It does not specify the duration of time in role or the timing of life transitions, distinctions that are now an essential part of an age graded view of the life course. A sequence of parental roles, for example, could occur in a woman's twenties or thirties. Likewise social role categories, such as generational membership, failed to locate people in historical time with precision. Membership in a kinship generation may span 30 years.

Until the 1960s, the relationship perspective of the life cycle offered a popular way of thinking about the patterning of lives and their interdependence, despite the aforementioned limitations. However, these limitations soon led to a convergence with newly developing understandings of age in a sociological perspective on the life course. This perspective drew upon the key virtues of each tradition, the distinction of linked lives in the life cycle approach and of the relation between age and time that provided an age graded model of the life course embedded in a specific historical context. More than before, human development and aging were viewed now as interacting with a changing life course and its historical context.

These new understandings of age are based on three advances: greater knowledge of the sociocultural meanings of age across the life span, more awareness of the variability among people of the same age in the pace and sequencing of life transitions (e.g., people of the same age do not move across their lives in concert), and the historical meanings of age defined cohorts by birth year or entry into society. Age distinctions may be expressed in terms of social and normative expectations about the timing of life transitions. These expectations can be thought of as timetables – as appropriate times for entering primary school and leaving school, for marriage and the attainment of a managerial role. The existence of such expectations and informal sanctions, as well as peer pressures, makes the appropriate timing of certain transitions especially consequential, such as marriage in a traditional society. Among people born in the same year, some will come to marriage relatively early, or on time, or relatively late, and

some will never marry. Such differences in timing may reflect specific historical circumstances, such as hard times in an economic depression or rapid economic growth. Birth year locates people in specific age cohorts and thus according to particular social changes.

The three dimensions of the life course as a theoretical orientation (e.g., life span concepts, social relationships and the life cycle, and age based concepts) came together in a study of California children who were born in the 1920s, grew up in the Great Depression, and then entered service roles in World War II (Elder 1999 [1974]). The central question concerned the effects of the Great Depression on the lives and development of two birth cohorts, the Oakland children who were born in 1920–1, and the Berkeley children, with birth years of 1928–9. The Depression's effects centered on variation in economic loss for both cohorts. Two deprivational groups within the middle and working classes of 1929 were identified by income loss (1929–33) relative to the decline in cost of living (about 25 percent over this period). Deprived families were defined by a loss of more than 35 percent of their 1929 income, a figure that applies well to both age cohorts. At first an intergenerational approach seemed appropriate and adequate for addressing the above question, with emphasis on the process by which Depression hardship made a difference among children by changing family processes and socialization. But the profound change in life experiences from the 1920s into the late 1930s raised questions that could not be investigated by this perspective. For example, the effect of change depended on many circumstances, including the children's exposure to the change at different ages, as well as the differential age of parents when the economy collapsed. Birth years at opposite ends of the 1920s identified birth cohorts that experienced family income losses at different life stages. Family responses to such losses became a set of linkages between the economic collapse of the 1930s and the developmental experience of children. Dynamic notions of the family economy and its multiple actors became a way of relating the economic crisis to the lives of each cohort of children.

To understand the consequences of growing up in the Great Depression, we drew upon

knowledge of life paths to adulthood, such as education, marriage, worklife advancement, and military duty. A number of young people might escape hardship through early work and military service, whereas others might do so through higher education and marriage. However, some outcomes seemed to have more to do with their timing than with their mere occurrence, such as marriage. Hardship favored early marriage by diminishing the chances of higher education and by making life in the parental home less appealing. Moreover, developmental theory suggests that the early work experience of adolescents would prompt early thinking about work and the timing of their entry into adult work roles. These and other issues made theoretical distinctions concerning the age graded life course especially relevant to the study.

Most adults from hard pressed families managed to rise above this disadvantage as they moved into adulthood. This resilience had much to do with entry into college and the military, along with the support of a partner, family, and friends. However, notable adverse effects of the Great Depression appear among the younger Berkeley males. They experienced the Depression crisis when they were more dependent on family nurturance and hence more vulnerable to family instability, emotional strain, and family conflict. Girls of the same age were more protected by the support of their mothers. Compared to age mates and the older Oakland cohort, the Berkeley boys were less likely to be hopeful, self directed, and confident about their future than were youth who were spared such hardship. However, between adolescence and mid life, postgraduate education, a supportive wife, and the developmental benefits of military service enabled many deprived Berkeley men to achieve notable gains in self confidence and social competence. Recovery and resilience are common themes in the lives of Depression children from the two birth cohorts.

By the end of the twentieth century, across the discipline of sociology and the social sciences, the life course had become a general theoretical framework for the study of lives, human development, and aging. Symptomatic of this development is the publication of a handbook on the life course (Mortimer & Shanahan 2003), as well as the dramatic growth of longitudinal

studies and the emergence of new methods for the collection and analysis of life history data.

life environmentalism

Hiroyuki Torigoe and Yukiko Kada

Life environmentalism is a model that aims to resolve environmental problems from a perspective that considers conserving the community life and practices of the people who inhabit the affected area. The life environmentalism model was developed in the 1980s by Japanese environmental sociologists who were concerned with the environmental destruction wrought by industrialization. At the time, the field of environmental policy was divided into two schools of thought embracing mutually opposed ideas about the best approach to environmental policy. The first, which we call "nature environmentalism," advocated the preservation (or restoration) of the pristine natural environment, following the ideals of the natural conservation movement and ecological theory. The other, which we call "modern technicism," emphasized the development of modern technology to rehabilitate the affected environment. This was the position typically embraced by government officials who had civil engineering credentials and the power to allocate the public budget.

However, when sociologists made in depth field research, it was discovered that the local people, as well as some government agents and nature conservationists who worked closely with the local people, were drawing on local knowledge to resolve local issues. Life environmentalism thus developed as a theory that utilizes local knowledge (and associated practices) to resolve environmental problems, recognizing that local communities depend upon the local/natural environment and have therefore developed practices that sustain it. These three points are illustrated using the case study of Lake Biwa, the largest lake in Japan.

Carried to their extreme, the principles of natural environmentalism aim to exclude humans from living close to and exploiting forests, lakes, and rivers as much as possible. It therefore strongly supports schemes such as the National Parks in the United States. The Lake Biwa conservation movement was strongly supported by people who live in large cities and tend to embrace the principles of nature environmentalism, which thus provided the basic

framework for criticizing government policies. However, this approach could not generate effective measures, as more than 1 million people live around Lake Biwa, and it was practically impossible to relocate them.

Modern technicism, in contrast, advocated reclaiming land from the lake to build a sewage treatment plant to improve the water quality and to use concrete on the sides and bottoms of the feeding rivers and streams to prevent flooding. Needless to say, these proposed measures were staunchly opposed by the proponents of the nature environmentalist model. Both approaches, ecology and modern technology, are important for environmental conservation. However, it is clear that applying the principles of nature environmentalism was unrealistic while modern technicism would contribute to further destruction of the natural environment.

One case study focuses on one village, which is located next to a river that feeds into Lake Biwa. Until the 1950s, the people of this village took their drinking water from a stream running through the village. Children played in the water and adults washed their dishes and vegetables, and chilled watermelons, in the stream. The stream had symbolic importance as well; the people sent ceremonial grass ships down stream, to help the souls of their ancestors on their journey. The fish that were caught in the stream were an important part of the village's diet. In order to maintain the cleanliness of the drinking water, there were strict community rules, which, for example, forbade dumping waste into the river. In the late 1950s a modern waterworks was built in the village, a symbol of modernization. As a consequence, the waste water ran into the river and the water quality declined. To address this declining water quality, a sewage system was eventually introduced but this did little to rectify the situation. However, even after the introduction of a water works and sewage system, people remained loyal to the flowing river.

The government proposed concreting the sides and bottom of the river for flood control in the 1970s. The locals were reluctant to oppose the government, not wanting to anger the local administration, which they viewed as a benefactor; but their desire to maintain their customary relationship with the running water was so strong that they eventually voiced their

opposition to the proposal. After discussion in the community, the village people decided to leave the bottom of the river as (its natural) sand and opted for permeable masonry retaining walls that would allow the river water to continue to soak into the banks. This compromise ensured that the environment remained attractive for the village people's favorite aquatic insects, like fireflies, and that fish continued to live and animate the river.

The modern technicism model maintained that building stone or concrete riverbanks would prevent flooding and associated disasters, but the local people, based on their direct experience, did not believe it. Thus even after the river reconstruction, the people continue to take social responsibility for flood prevention: for example, they patrol the river during heavy rains and when the need arises, the people in the community work together to make temporary river banks with sandbags. With these processes local people have maintained their own self government.

The underlying principle of life environmentalism is that people live in and use the environment; humans will tamper with nature and thus the environment will not be "purely natural." We must accept this as the way it is. At the same time, the life environmentalism model supports the idea of using local knowledge and local practices to both sustain the natural environment and ensure local stewardship of the environment.

Life environmentalism utilizes modern technology but also values nature. In other words, it employs "hard" technology like civil engineering construction technology, but is not determined by it, being guided always by the "soft" knowledge of everyday life experiences like community social capital of stewardship. Life environmentalism is especially appropriate in areas like the Asian regions, where population density is high, but the basic ideas of enhancing the social capital of local people will be appropriate in other areas like Africa and Latin America.

life history

M. Carolyn Clark

Life history is somewhat of a stealth term – on the outside it looks harmlessly simple, but inside it is cloaked with ambiguity and its meaning is both slippery and elusive. The simple part derives from its point of origin: a researcher interviews a particular individual and elicits a richly detailed account of her or his life. It is in how that account is understood, and what is done with it, that the uncertainty and messiness begin. Nothing is straightforward. The life history interview, while privileging the informant in that that person decides what to share about his or her life and how to structure the telling, is nonetheless a co construction between the researcher and the informant, both of whom are situated within a discursive context that shapes the definition of story as well as its telling. The product of the research, the life history itself, is the interpretive work of the researcher. That person has framed the research from the beginning around particular interests, which may or may not be significant to the informant; working from the narrative generated by the informant, it is the researcher who through the life history makes knowledge claims about the larger issue under study.

Cole and Knowles (2001) define life history as "illuminating the intersection of human experience and social context" and it is that intersection that makes all the difference. People live within particular social, cultural, and historical

contexts and their life stories are shaped and defined by those contexts in complex ways. A life history, then, is a means by which we can see how that person makes sense of their experience within those contexts, as well as what impact social structures have on a person's life. Measor and Sikes (1992) think of it as biography read through a sociological lens. Unlike biography, however, life history explores the lives of ordinary rather than famous people. Tierney (1998), invoking Walt Whitman, argues life history makes it possible to say "No one is alien to me" without erasing the differences that will always continue to exist between people.

Life history can be considered an umbrella term for various genres of personal research, including such things as biography, autobiography, autoethnography, and oral history, or it can be identified as a genre in and of itself. These categories, however, are somewhat contested and they tend to blur into one another, but the common ground is that all explore personal experience. Life history has its roots in anthropology and sociology in the early 1900s, peaked in the 1930s and 1940s, then fell out of favor in the social sciences because of its lack of representativeness and its high level of subjectivity. With the interpretive turn in the 1960s, and with the growing influence of postmodern theory, those weaknesses came to be viewed as strengths, and life history again became popular in sociology and anthropology, as well as in psychology, history, education, gender and cultural studies, and linguistics (Goodson & Sikes 2001).

In life history interviews informants choose how to craft their account, selecting some events, omitting others, in order to accomplish something (e.g., create a particular identity, establish causality, or develop thematic coherence across the life span), which is to say that the stories themselves have work to do. Likewise from the perspective of the researcher the life history itself exists to accomplish something. Peacock and Holland (1988) suggest two broad conceptualizations of the purpose of life history: as portal and as process. When understood as a portal, the life history is used to illuminate a reality that stands outside the story and which the life history presumably mirrors. This could generate objective data about the person's life,

for example, in order to understand a particular historical period, or subjective data, where the focus is on the inner life of a person, whereby the researcher could understand how, for example, a particular culture shapes self understanding. Life history conceptualized as process has a very different focus. Attention here is addressed to the narrative itself; the generated text and its interpretation is central. Geertz (1983) argues it is impossible to really understand what it's like to be a member of another culture; what is possible is to understand the symbolic and discursive categories of that culture. He likens this to how a reader understands a poem or makes sense of a proverb: it is a complex act of interpretation that is only possible by collecting a great deal of data (the notion of thick description which Geertz adopted from Gilbert Ryle) and contextualizing it. The analytic tools focus on language and other symbol systems, as well as on overarching themes.

Given the highly personal, even intimate, nature of life history research, a number of methodological and ethical issues are embedded and intertwined within it that are more salient here than in other types of qualitative research. The underlying questions being addressed are how informants make sense of their lives and how they narrate that understanding. But there is also an autobiographical dimension to this work, as there is in all research: we choose topics of personal interest to us, and those interests also shape the interpretations we render. In studying the lives of others it is particularly important that we are aware of how our life story intersects with theirs, how our personal and professional interests are being served through this work, and how our multiple positionings shape our thinking; and these personal factors need to be made visible in the life history itself. Plummer (2001) stresses that to understand any life story we must know how both the researcher and the informant are positioned, the nature of their relationship (he thinks of this in terms of the level of involvement by the researcher: stranger, acquaintance, friend, lover), and how all are positioned in the broader social context. The central responsibility of the researcher is to the informant, and that relationship must be marked by empathy, sensitivity, and respect. Cole and Knowles (2001) speak of this as a

highly principled process. It is essential that the researcher work collaboratively with the informant at all stages of the process – never an easy thing to achieve, in part because both parties have different interests in engaging in this work and because unequal power relationships are challenging to overcome – but Chase (1995) argues persuasively that the researcher must do everything to enable the informant to take responsibility for the narrative if the outcome is truly to be an intersubjective construction of meaning.

Measor and Sikes (1992) lay out many of the thornier ethical issues implicit in life history research: the careful building of trust and rapport with the informant in order to elicit intimate information can have elements of voyeurism; the ambiguity of a project in which we seek intimate information of others to serve our own professional and disciplinary purposes is difficult to balance with what the informant needs or wants from participation in the study; and being aware of and sensitive to the impact on the informant of the telling of the life story itself, as well as the potential impact that reading what we write about them might have. There is also the concern that the published report not serve to other the informant. As is true with all ethical issues, there are no ready answers to these dilemmas. Plummer (2001) suggests five principles to guide researchers in dealing with these and other ethical dilemmas: respect for persons and their differences; an ethic of care; the promotion of equity and fairness in working with informants; an increase in autonomy and free choice for participants; and a commitment to minimize harm. In a postmodern era such universals may be at variance with the fragmented and ambiguous realities of life, but the need remains to honor our relationship with our informants and to continually seek their good, making judgments about that good that are highly situated, often ambivalent, but done in good faith.

What do we have when we write a life history? We certainly cannot claim that we have the life itself; no life can be captured and reduced to text. In addressing this question Denzin (1989) begins with Derrida's "metaphysics of presence": people live meaningful lives and these meanings are real and present to them, yet there

is no way to access the inner life of another because it always must be done through language which itself is unstable and fluid. Denzin concludes that both the lives as told and the life histories as written are literary productions – they are, in fact, fiction: "As we write about lives, we bring the world of others into our texts. We create differences, oppositions, and presences which allow us to maintain the illusion that we have captured the 'real' experiences of 'real' people. In fact, we create the persons we write about, just as they create themselves when they engage in storytelling practices" (p. 82). This notion of our work as fiction is an important caveat for life history research. All meaning is fluid and shifting. In the telling of a story, in the transcription of that telling, in the analysis of that text, and in the reading of that text by others, meaning shifts and reforms, morphing constantly. As Riessman (1993) notes, "all texts stand on moving ground." It is essential that we recognize that what we write is fiction and that our truth claims are limited, but it is also important to know that these fictions are meant to serve larger ends, the illumination of the human condition.

Postmodernism presents other challenges to life history research. The self is also contested; no longer unitary and stable, it is now understood as nonunitary, fragmented, and unstable, which has profound implications, both in representing a life and in interpreting it. All knowledge claims must be tentative, open to multiple interpretations and reinterpretations. Tierney (1999) identifies five concerns that these issues raise: textual authority, which requires that the author be understood as the co creator of the work; fragmentation, the multiple identities of researcher, informant, and reader that need to be made visible in the text; representation, the creation of an evocative and flexible narrative; purpose, that these are multiple and situated within the needs of the researcher, the informant, and the audience; and judgment, the need for new standards of quality for postmodern texts. Tierney's concerns themselves constitute quality standards. In addition to those, Cole and Knowles (2001) propose a principled methodological process, the use of accessible language, authenticity and internal consistency within the text, aesthetic form of the life history itself, and

the theoretical and transformative potential inherent in doing this research.

The future of life history is filled with both challenge and promise. Life history has enormous emancipatory potential as a tool for exposing and confronting social structures that oppress and silence, but it will be important to do so without reifying power inequities and without providing insights that could be used by the powerful as tools to enforce their dominance over others. The direction of this research also needs to change, from studying down to studying up, that is to say by examining and illuminating the workings of power by those who wield it. The challenges involved in doing all of this are significant, but the benefits to be gained make the attempt more than worth the effort.

lifestyle

Tally Katz Gerro

Lifestyle involves the typical features of every day life of an individual or a group. These features pertain to interests, opinions, behaviors, and behavioral orientations. For example, lifestyle relates to choice and allocation of leisure time; preferences in clothes and food; tastes in music, reading, art, and television programs; and choice of consumer goods and services.

At the individual level, lifestyle denotes self expression, personal taste, and identity (Featherstone 1991). At the group level, the concept refers to shared preferences and tastes that are reflected primarily in consumption patterns and in the possession of goods (Weber 1946). Lifestyles give members of a group a sense of solidarity, and mirror the differentiation between groups in society. The distinctive lifestyles of specific groups may be hierarchically ordered to different degrees, depending on the extent to which a clear system of prestige exists that attaches value to lifestyles (Weber 1946; Sobel 1981). Arguably, it is the range and diversity of different lifestyles practiced in a given society that is of most interest, rather than the profile and makeup of a specific lifestyle. A comprehensive lifestyle analysis will emphasize the way in which arrays of lifestyles evolve over time, the degree to which different lifestyles (associated with class, race, sexuality, etc.) are legitimized, and the way lifestyles are linked to changes in social and economic structures (Zablocki & Kanter 1976).

Max Weber (1946) provided the major sociological definition of the concept, which emphasizes lifestyle as a means of social differentiation that could be used to acquire or to maintain a certain social status. Individuals and groups adopt lifestyles to express and sustain their identity at a particular time and place. In the Weberian framework, lifestyle is the expression

of status groups that can be differentiated from class. Weber defines classes as groupings that are economically determined, while status groups are communities that are determined by a specific social estimation of honor. Status honor is normally expressed by a specific style of life, in as much as the consumption patterns of a status group involve the prestige or honor that is attached to those patterns. Because a status group expects that its members share a particular lifestyle, this becomes the descriptive manifestation through which affiliation, hence status, can be perceived.

Veblen (1970 [1899]) applied this framework in his study of what he termed "the new leisure class" at the turn of the twentieth century in the United States. Veblen portrayed a lifestyle that emphasizes conspicuous consumption as a strategy that individuals employ to display status. Although the possession of wealth becomes the primary evidence for successful activity, and hence the dominant basis of esteem, the translation of wealth into appropriate observable symbols is imperative. This is accomplished through the display of conspicuous leisure and conspicuous consumption.

Building on Weber's work, a body of research has developed which adopted the view that lifestyle is a major form of social stratification that can be used to characterize contemporary society. Although lifestyle segmentation reflects structural inequalities within society, lifestyle is to be distinguished from social class. The concept of class usually refers to dimensions such as education, occupation, and income in as much as they specify one's position and resources in the market. At the same time, the concept of lifestyle usually refers to dimensions such as cultural preferences and tastes, which facilitate symbolic communication of status as an order distinct from that of economic standing. Lifestyles are constructed by symbolic boundaries that mark differences between groups. Symbolic boundaries are expressed through distinctive consumption patterns that tend to be associated, in a particular social context, with shared symbolic codes that bear specific meanings.

The significant relationship between classes and status groups and its expression in material and cultural lifestyle further reverberates in Pierre Bourdieu's (1984) two dimensional approach to stratification. Bourdieu distinguishes

between economic and cultural capital. Class fractions, defined by similar positions with respect to education, income, and occupation, are united by a *habitus* or by cultural dispositions that are derived from similar life experiences. The *habitus* determines taste, which is the material and symbolic capacity to appropriate cultural objects and practices. Tastes constitute lifestyle, which is a unitary set of distinctive preferences that classify the classifiers, the upper class. A lifestyle that is associated with the upper classes is naturalized as good and noble and serves distinction. Therefore, lifestyles serve as an effective exclusionary resource and serve to reproduce existing social inequalities as long as they vary systematically with social position.

Bourdieu emphasizes that it is not only the amount of goods and services consumed that is typical of a group, it is also the characteristic mix of goods and services. Lifestyle elements, in terms of specific cultural preferences, can be studied one at a time or as stylistic unities. Stylistic unity is an internal cultural consistency in the elements comprising a lifestyle and in symbolic properties of those elements. It rests on shared perceptions that lifestyle elements are patterned in a manner that makes some sort of aesthetic or other sense. Depending on social, historical, and cultural context, stylistic unity becomes more or less elusive and difficult to identify. Stylistic unity can range from a tight system of expectations for particular tastes and preferences, all adhering to a clear set of cultural imperatives, to a system of blurred, eclectic components, loosely connected by symbolic meanings. For example, a body of research has been trying to identify snobbish unity or omnivorous unity in cultural preferences of elites in contemporary western societies (Peterson & Kern 1996).

Research on the determinants of lifestyle differentiation has predominantly concentrated on those factors that Weber (class), Veblen (income), and Bourdieu (education, parental background) emphasized in their theoretical accounts of the contours of lifestyles. Indeed, a significant body of research has shown that tastes and consumption patterns are influenced by individuals' education, financial resources, occupational characteristics, parental education, and parental lifestyle. In addition, other factors have been shown to matter, such as gender, age, and race. At the same time, there is evidence that in

contemporary society lifestyle is becoming more volatile and less hierarchical so that the correlation with social divisions is no longer conclusive (Featherstone 1991). This is explained by social conditions that are becoming increasingly fragmented, partly because of the proliferation of information and cultural repertoires. Since collective affiliations are multiple, fragmented, and often conflicted, the lifestyles associated with these affiliations are more fluid, unsettled, and cross cutting.

Research on the consequences of lifestyle has looked at its effect on individuals' life chances. This line of work attempts to establish the extent to which the deployment of tastes in everyday life helps to reproduce social class boundaries. Such research has shown how cultural preferences influence individuals' educational aspirations, school grades, and educational attainment; their occupational attainment; and their marital selection (DiMaggio 1994).

lifestyle consumption

Sam Binkley

Lifestyles are symbolically embellished ways of living. Sociologically, they serve two important functions: they classify or categorize the practitioner within a broader social matrix, and in so doing offer practitioners a unique sense of self and identity. Thus, lifestyles combine material and symbolic processes: they are practical ways of providing for basic needs and requirements such as food, clothing, and shelter, but also aesthetic and symbolic expressions of one's sense of self and of one's membership among certain social groups. As such, lifestyles occur at the intersection of individual agency and social structure. They project a unity that is both subjectively meaningful to practitioners themselves, and objectively legible to those defining the social context in which they are performed. For these reasons, lifestyle has sustained as a key sociological concept, capable of bridging the divide between macro level concerns with large scale social structures and social groupings, and micro level concerns with the subjective dimensions of agency, meaning, and identity.

The study of lifestyle also has a more current relevance. Lifestyles have attracted the interest of many contemporary sociologists for their usefulness in the analysis of processes of social change, and particularly for the perspective they offer on the unique social and cultural conditions characteristic of late capitalist or postmodern societies. Indeed, as Chaney (1996) and others have argued, the very concept of lifestyle is an inextricably historical category of analysis, bound up with social instabilities linked to patterns of modern social change. These changes include the decline of social classes (organized around production) and the emergence of personal identities (based on consumption); the rise of urban centers and the increase of social anonymity in big cities; the increasing influence of mass culture and the "bourgeoisification" of the proletariat; the increasing saturation of culture with visual technologies of communication; and the ever more pervasive commodification of everyday life. In this regard, sociological uses of the concept of lifestyle can be divided into

two general areas: (1) studies of social differentiation and stratification through the use of symbols, and (2) studies of the constitution of personal identity in the context of dynamic social change.

LIFESTYLE AS STATUS EMULATION

A sociological interest in lifestyle assumes, as do many sociological narratives, a fundamental rupture between traditional and modern societies: traditional orders of social hierarchy rooted in ascribed status give way to more flexible and mobile status systems defined by achieved status, opening the way for the advancement and upward mobility of a range of social groups previously excluded from the elite strata. With the increasing mobility of social groups brought on by the extension of a money economy unfettered by the controls of the old feudal order, more people gain access to goods and luxuries through the expanding open market, increasingly available to the swelling ranks of the emerging mercantile class, or bourgeoisie. With the gradual crowding out of small, close knit communities characterized by face to face interactions by the bustling traffic and anonymous crowds of the cities, social identity becomes uprooted, less constrained by longstanding tradition, more available for manipulation and affect.

Lifestyles, then, appear under these conditions as means of conferring legitimacy on one's location on a social ladder, not through the holding of resources, titles, or offices in the mode of the old aristocracy, but through the affect of specific ways of living meant to display one's wealth and cultivation – a circumstance that leaves ascendant or would be ascendant groups open to charges of abuse, fraudulence, and falsification. With the demise of a social universe defined by a metaphysically sanctioned hierarchy, the profane, secular world of everyday practices and things emerges as a field of symbolic contest and status competition. This predicament is exacerbated by the influx of a newly monied middle class, or *nouveau riche*: possessors of economic capital who lack the legitimacy and status conferred by the established order. These newly ascendant classes seek to locate themselves through sometimes verbose and clumsy acts of

emulation. They parrot, however clumsily, the styles of the older aristocratic classes in a pattern of distinction that expresses a lifestyle in the full sociological sense – an effort to classify oneself through habits of living which are at once material and symbolic.

Most notable here are the contributions of Alexis deTocqueville, whose studies of American society in the early nineteenth century reveal the strained efforts of the American gentry and their emulators to distinguish themselves through ostentatious practices of living in a society where formal hierarchies have been effectively leveled (Tocqueville 1969). Similarly, Thorstein Veblen, writing against the opulence of the Gilded Age and the materialistic excesses of the *fin de siècle* industrialists, outlined a genealogy of modern leisure, tracing contemporary modes of conspicuous consumption to their barbaric origins in the symbolism of social power (Veblen 1924). His view of leisure or style of life as competitive display is reflected in much mid century American sociology, as illustrated in Lloyd Warner's studies of trickle down status imitation in an American suburb, Robert and Helen Lynd's studies of "Middletown," an American town under the grip of the new consumer culture of the 1930s, and in Vance Packard's popular critique of postwar American consumption patterns, *The Status Seekers*.

CULTURE AND STRATIFICATION

Underscoring much sociological interest in lifestyle as a form of stratification mediated by symbols is a desire to supplement the objective categories of economic class with the subjective outlooks and meanings possessed by actual social actors themselves – a theme first introduced with Weber's (1946) analysis of the types of social power. Weber made the distinction between elite groups stratified by the varying criteria of class, status, and party, with status emerging as a claim to social esteem determined by a "social estimation of honor." Status groups, for Weber, posed an alternative grouping of social power based not on the possession of capital and valued property alone, but on recognizable characteristics shared by a community which assume the quality of honorific value.

The stratification of social groups, Weber argued, was not reducible to competition for scarce (economic) resources, but extended to struggles for (symbolic) recognition and honor between competing groups, manifested in the mundane dimensions of consumption and everyday life. This distinction would prove significant in the analysis of the cultural forms and processes of social change that would begin to take root in the latter part of the twentieth century.

Weber's influence is apparent in the sociology of Bourdieu, perhaps the most influential contemporary voice in the sociology of lifestyle, and an author who took to task the challenge of a truly cultural approach to stratification. The value of Bourdieu's sociology comes with his insistence on avoiding economic reductionism by linking the symbolic productions of everyday lifestyles to practical efforts of groups and individuals to distinguish themselves within a stratified system of cultural preferences. His expansive study of the French class system, *Distinction* (1984), documents the efforts of middle class and working class people to effectively classify themselves on a stratified cultural scale through the exercise of taste in clothing, art, music, and food. The expression of taste represents, for Bourdieu, a practical intervention in a classificatory scheme wherein certain tastes naturally accrue to the higher or to the lower end of an economic scale. Like Veblen, Weber, and Tocqueville, Bourdieu sees the social world as a highly conflictual arena in which lifestyle plays as a set of tactics employed by various groups to secure honorific distinction denied by others, yet unlike these figures Bourdieu pays careful attention to ways in which these strategies are enacted in unreflective, mundane choices, naturalized within the taken-for-granted disposition – or habitus – of members of these groups. In marked contrast to economic models, which conceive of actors as intentional and rational, Bourdieu's theory of the habitus considers the lifestyles of actors as a site of creative classification in the practical moments of everyday life.

Importantly for Bourdieu's sociology, the habitus's of various social groups conform to their own distinct logics, which are themselves established in a dialectical tension between dominant and subordinate classes. These two

dispositions meet in what Bourdieu terms a game of "refusal and counter refusal." The aesthetic dispositions that structure the middle class habitus, for example, express a distain for the brutishness, obviousness, and directness contained in working class arts, sports, foods, fashion, and films, expressing instead a preference for the indirect, thoughtful, and cultivated. At the same time, members of the working class dismiss the loftiness and rumination implicit in middle class refinement and cultivation, preferring the straightforward, the practical, the direct, and the immediate. These logics illustrate the contrasting dispositions of these groups in which a "taste of the necessary" expressed by the subordinate groups is distinguished from an "aesthetic distanciation" expressed by dominant groups.

DETERMINISM AND AGENCY

Other sociological uses of lifestyle as an alternative category of stratification to those offered in more economic accounts developed specifically from dialogues within the Marxist tradition. An old maxim of Marxist thought, "base determines superstructure," provides a deterministic explanation of the cultural and aesthetic realms, to which Bourdieu's theory of the habitus is in part a reaction. The stamp of this determinism is evident in several branches of Marxism, most notably in the work of Frankfurt School theorists Adorno and Horkheimer, who in *The Dialectic of Enlightenment* (1982) examined mid century forms of popular or "mass culture" as instruments of ideological control. Lifestyle practitioners are, from this perspective, cultural dopes, passive objects of control and manipulation.

But for other twentieth century Marxists more engaged with the problem of culture (a roster that includes Italian communist Antonio Gramsci, the British historians E. P. Thompson and Eric Hobsbawm, French structuralists Roland Barthes and Louis Althusser, and later members of the British Birmingham School of Cultural Studies), investigations of the everyday lives of subaltern groups countered the parochialism and determinism of the base-superstructure model by uncovering a terrain of symbolic struggle in which opposition originated, not in

the categories of economic class, but in the mundane categories of everyday lifestyle. A version of this thesis was advanced by Richard Hoggart in his influential *Uses of Literacy* (1957), which depicts the "feminization" of the British working class through a process of Americanization, or its saturation in the affects of consumer lifestyles. Hoggart's work informed the writings of leading figures of the Birmingham tradition (Stuart Hall, Dick Hebdige), who variously proposed studies of the lifestyles of subordinate groups (usually male, working class youth cultures) as explorations of the everyday symbolic realms wherein counter hegemonic struggles were fought out on the level of style. Notable in this tradition is Hebdige's *Subculture* (1979), a study of London punks, which set the agenda for the emerging field of cultural studies – an interdisciplinary field broadly concerned with lifestyle as a subversive practice.

MODERNITY AND LIFESTYLE

A sociology of lifestyle that stretches from Veblen to Bourdieu has, in many varied ways, related the practice of lifestyle to the conditions of social democratization. Therein, lifestyle is read in terms of strategies employed by opportunistic social groups in their effort to confirm social identities in the absence of more stable, traditionally grounded status criteria. Yet, in place of these stable traditional structures, these approaches tend to assume that there exists an equally stable symbolic matrix wherein the symbolism of lifestyle practices can be universally registered and accepted. To assume, for example, that the *nouveau riche* emulate their aristocratic superiors is to assume the existence of a stable and universally accepted framework for reading lifestyles as symbolic interventions in a fixed status hierarchy. What this line of analysis does not take into account is the ambiguity and instability inherent within these codes at every stage of modern development, and particularly the eroded state of such codes under the accelerated conditions of contemporary culture. The various effects identified with postmodern culture (saturation of culture with visual representations, the commodification of all social meanings, the breakup of traditional class groupings, the increasing mobility and globalization of

communities, the malleability of personal identities) have rendered status emulation through lifestyle an outmoded concept. In this regard, an analysis of lifestyle as a symbolic practice in the contemporary context demands an accounting of the conditions of ambivalence and ambiguity that define the daily conditions of personal and social life in the contemporary context.

A sociology of lifestyle as a response to conditions of ambiguity can be traced to Simmel's (1971) analysis of urban life in his landmark essay "The Metropolis and Mental Life." Here, Simmel contextualizes lifestyle as a developing subjective response to the changes and pressures foisted upon ordinary people by the accelerated social and cultural conditions of modern social life, where a collision of codes and symbols, an uprooting of communities, and the increasing mobility of classes and groups undermines the semiotic frameworks wherein lifestyles might have served the function of social classification.

Though Simmel discussed the crowded and disjointed conditions of urban life at the turn of the century, his observations resonate with recent sociological inquiries into the breakup of the symbolic codes underpinning status differentials in late capitalist societies. Harvey (1989) has described a shift from Fordist (production based) to post Fordist (consumption and culture based) economies, in which a process of cultural acceleration and saturation has resulted in a time space compression. In line with this argument is Lash and Urry's (1987) case that organized capitalism has effectively given way to new patterns of investment and growth, which have uprooted the old social groupings of class upon which lifestyles depended. New emphasis on product differentiation and market segmentation has eclipsed class solidarities and pushed lifestyles to the fore, yet at the same time it has undercut the indexical function of lifestyles as indicators of membership in larger social groups. In the new, information and service oriented capitalism, where the exchange of knowledge and the manipulation of symbols has risen to replace the manufacture of commodities (and the class fractions that follow), lifestyles have become, not indexical, but reflexive: lifestyles do not refer to real social memberships but are self referential, referring only to the fashioning practices of the individuals who bear or enact them. Indeed, adaptations of

Bourdieu's thesis on the cultural dispositions of the middle classes have pointed to important schisms within this class between the old and new fractions, more adept to the cultural and semiotic conditions of consumer capitalism. Mike Featherstone, drawing on Bourdieu, has described the rise of a class of "new cultural intermediaries," mediators of the realms of production and consumption, skilled workers at the shaping, not of things, but of meanings.

IDENTITY AND THE SELF

While sociologists generally agree on a trend toward individualization and the aestheticization of identity, less agreement is shared on the ultimate personal and social implications of this trend. Typically dour notes are sounded by the likes of Daniel Bell (1976), who has described the disjuncture between cultural and economic spheres, resulting in a hedonistic embrace of lifestyle by the minions of the middle class, and Christopher Lasch (1978), who has criticized the "culture of narcissism" that developed from the counterculture of the 1960s. For these authors, lifestyle, unmoored from concrete social structures, is drained of political meaning and moral focus.

But this model of the new lifestyle practitioner as limp and lacking in resolve is countered by postmodernists who find vibrancy and new political potentials in the fragmentation, diversity, and multiplicity made possible by the mobility of lifestyle. Often cited in this respect is the work of Walter Benjamin, who recounted the stance of the *flâneur* as one who negotiates the discordant, disorderly world of the modern marketplace, savoring the possibilities for self presentation and aesthetic self styling that are presented by the crowds of anonymous spectators populating the bustling centers of the urban metropolis (Benjamin 1973). In this light, sociologists of consumer culture have recovered the emancipatory dimensions of lifestyle, asserted the implicitly imaginary dimensions of shopping and other forms of consumption as vehicles of an imaginary hedonism, with powerful potentials for rethinking personal identity as a lifestyle practice (Shields 1992).

However, others have pointed to the anxiety and instability underlying this process. For

Giddens (1991), the "reflexive modernity" thesis provides a general model understanding life style in terms of the existential predicament of the modern individual: amid the patterns of rapid and seemingly haphazard social change that characterize modern historical trajectories, the reassurance and sense of what Giddens terms "ontological security" once furnished by traditional moralities are replaced with a highly individualized lifestyle identities. Against the backdrop of the uncertainties and ambiguities that characterize secular modernity, individuals are compelled to make choices and to realize themselves in these choices. "We have no choice but to choose," Giddens writes.

lifeworld

Warren Fincher

Lifeworld refers to the commonsense interpretive frames and logics by which individuals prereflectively conceptually organize their perceptions of everyday life. The concept of the lifeworld is central to two theoretical traditions – phenomenology and the critical theory tradition as articulated by Habermas – but the lifeworld is also an important concept in the sociological investigations into the construction of knowledge and the social body.

Edmund Husserl, a nineteenth century German philosopher, theorizes the importance of the lifeworld in how individuals come to understand the world around them. The primary focus of his work theorized the nature of logical thought, particularly the origins of knowledge. Husserl developed a philosophy of what he later termed the lifeworld. Two positions were prominent within the philosophical debates of the late nineteenth century. The first stressed formal systems of logic and methods of knowledge construction. The second tradition stressed the importance of lived experiences in the development of an intuitive reflection and subsequent construction. Husserl's early work attempted to bridge these two traditions. In doing so, he argued that the logic involved when thinking does not simply utilize ideal forms, but must incorporate the context of what is specifically

being thought about. Thought, for Husserl, is an interplay between pure logic and the store of knowledge accumulated from lived experiences. By examining the relationship between a phenomenon as it occurs and how individuals subsequently conceptualize and make sense of that experience, Husserl attempts to find those logical frames that transcend the ongoing stream of experiences.

In elaborating on this work, Husserl recognizes that knowledge transcends the boundaries of individual perception and reflection, and he finds the need to theorize the role of others in the construction of meaning. In attending to these issues, Husserl employs the concept of the lifeworld, which for him comes to mean that set of knowledge that is shared intersubjectively. This intersubjective knowledge is about common experiences, but emerges from the common logical forms that people hold. In Husserl's lifeworld we find perhaps the most presocial iteration of the lifeworld, as Husserl links the concept to the idea that all people have a "natural attitude" or innate set of logics that predates learned modes of inquiry and that individuals all hold as a common feature of their cognitive processes.

The concept of the lifeworld enters into sociological inquiry through the work of Alfred Schütz, who incorporated the works of Husserl, Weber, and Bergson to develop his own contributions to the fledgling phenomenology of the early twentieth century. Because Schütz was particularly interested in how people both construct their own senses of reality and also must cope with others' senses of reality, his work elaborates on the intersubjective functions of the lifeworld that Husserl develops by examining the lifeworld as a product of both collective life and also individual experiences. As such, the lifeworld is external to the individual, predating his or her birth and serving to place constraints on the constructions of reality that people create, but the lifeworld is also an individualized part of our ability to make sense of the world, as it is the product of our individual ongoing experience of daily life.

Schütz enumerates a number of key characteristics of the lifeworld. Among these, it is important to note that the lifeworld requires "wide awakeness" from individuals in that they must maintain a level of consciousness of the world around them in order to live life.

The construction and management of meaning is an active event, although not perceived to be thought, but rather taken for granted knowledge. Much of how we employ the lifeworld in making sense of the world around us is through typification, specifically what Schütz calls “first order” typification that rests on the stock of knowledge found in the lifeworld, as opposed to second order typification, which utilizes complex information beyond the scope of the lifeworld. Another important characteristic for Schütz’s lifeworld is that people accept it as reality without question, until something compels them to think otherwise. When problems do occur, people then turn to various more overt logical processes to reinstate normalcy. Given this, Schütz’s legacy can be seen to include the later work of Harold Garfinkel and the ethno methodological tradition.

The philosopher Merleau Ponty also utilized Husserl’s work on the lifeworld and applied the concept to the body. The body serves as the link between phenomena and the social organization of those phenomena, and the lifeworld serves to bridge the communication between the physical world, the individual’s body, and others. The lifeworld, according to Merleau Ponty, also incorporates knowledge about the body, as evidenced by the “phantom limb syndrome” in which the individual continues to perceive a limb that no longer exists.

The next notable development in the theory of the lifeworld occurs in the work of Habermas, perhaps the most widely known scholar of the critical theory tradition. Habermas utilizes “lifeworld” to mean two related concepts. First, building on Husserl and Schütz, Habermas refers to lifeworld as the set of background assumptions and convictions that people hold. However, what sets apart Habermas’s work on the lifeworld from previous theories is his focus on the function of the lifeworld in modern societies. As such, Habermas also uses the term lifeworld to denote a particular kind of integration that arises from the sharing of background assumptions among people. Because of this interest in integration, Habermas moves away from a strictly phenomenological use of lifeworld that Husserl and Schütz demonstrated.

Habermas maintains an interest in the communicative processes surrounding social integration. A key dynamic in social integration,

for Habermas, is the interplay between the lifeworld and the system, two different perspectives found in modern societies. From the perspective of the lifeworld, one sees the self embedded within the social world, but from the perspective of the system, one sees the world necessarily through a macrosocial lens, distanced and seemingly only indirectly involved through mechanisms of market exchange and the dissemination of organizational power. The form of integration that the system and the lifeworld each proffers is dissimilar and analogously extends Husserl’s distinction between formalized knowledge and the lived experiences of everyday life. The system is that set of formal mechanisms in a society’s superstructure that functions to maintain consequences of social action. The lifeworld, on the other hand, is the perspective from the standpoint of the actors, not the structure. The lifeworld serves to transmit interpretive patterns among individuals, which facilitates key functions in modern society. The lifeworld facilitates the construction of both individual personalities and group identities. It socializes members of society toward communicative processes and the ability to manage interpersonal actions. And through its transmission, it allows for the preservation and selective modification of the stock of background knowledge common to the community’s lifeworld.

Habermas is concerned with the “colonization of the lifeworld,” a pathological phenomenon which occurs when the instrumental rationality common to the operations in the system is utilized in the private sphere in lieu of communicative rationality. Socialization becomes reoriented around values appropriate to the marketplace, but not ones that have been consensually negotiated through the discourses endemic to a healthy lifeworld. The processes of identity formation and value education that are key functions of the lifeworld are then organized around bureaucratic and economic values. In order to guard against the colonization of the lifeworld, Habermas advocates that societies foster a greater reliance on open communicative action that freely engages the value structures of economic and political spheres. However, this conceptualization of communicative action in the lifeworld as intrinsically harmonious has been repeatedly criticized as too idealistic

and not representative of the pathologies that exist in lifeworld discourse, such as patriarchal dynamics, regardless of colonization by instrumental rationality.

The current work involving the lifeworld spans the diversity of contexts that utilize this term. Conversation analysis is one subfield in which the lifeworld remains a salient concept, both as a subject of study and a methodological issue. How people make sense of talk is a key point of inquiry for scholars working in this area, which attends not to how symbols are given meaning but rather how meaning is conveyed in the form that talk takes. As a methodological issue, conversation analysts must confront the problem that they must utilize their own lifeworlds in order to interpret the collaboration of their subjects. In making assessments about how participants carry on interaction through talk, the lifeworld lens of the researcher may be divergent from the lifeworld being preserved and modified within the participants' interaction. As well, ethnomethodological studies are interested in the sense making mechanisms people employ to maintain seamless interactions with others.

The lifeworld remains a useful conceptual tool in other areas of investigation, particularly in the extension of Habermas's work. Studies continue to focus on the lifeworld of women, people of color, urban settings, etc. Much of this work takes Fraser's (1997) critique of Habermas's ideal speech community as a point of departure. Many of the studies that use the lifeworld concept also maintain a focus on the institutional or organizational context. Elizabeth Gill's work on the role of the lifeworld in managing death analyzes the hospice setting for the negotiation of lifeworld and system perspectives, and focuses on the role of the hospice worker in negotiating the interactions between the medical staff and the family. And recent work has also directed attention to the role of the lifeworld in a setting marked with broad scale social change, particularly with social change related to international development and adaptations to working in large scale organizations.

literacy/illiteracy

George Farkas

Traditionally, literacy has meant the ability to read and write. As the cognitive skill requirements of work and daily life have increased, the definition has expanded. In the National Literacy Act of 1991, the US Congress defined literacy as "an individual's ability to read, write, and speak in English and compute and solve problems at levels of proficiency necessary to function on the job and in society, to achieve one's goals, and to develop one's knowledge and potential." Consistent with this, the National Assessments of Adult Literacy, conducted by the National Center for Education Statistics, have measured literacy along three dimensions: prose literacy, document literacy, and quantitative literacy. Each was measured on a scale defined by the skills needed to succeed at daily and work tasks ordered from simple to complex.

Over time and across nations, higher literacy rates have been associated with higher levels of economic development. This is a

well documented pattern, which has been most thoroughly analyzed by economists under the topic of “investment and returns to human capital” (for a review of these studies, see Hanushek & Welch 2005). Indeed, increasing the spread of literacy is one of the key strategies advocated by the World Bank in its efforts to reduce poverty worldwide (Bruns et al. 2003).

Further, at any one place and time, an individual's level of literacy has been associated with her or his place within the social class structure. Typically, the higher the parents' social class status, the more years of schooling are given to their children. Thus, education is the most common mechanism by which parental social class status is transmitted to children. Schooling is also the most common mechanism for upward mobility. Both of these patterns have become stronger as economic development has proceeded, and the cognitive skills demanded of workers have increased.

An increasing number of studies have examined years of schooling completed and individual placement within the social class structure, and found that these are strongly related within all modern societies. Indeed, researchers have now developed research and testing instruments that have been used to systematically collect similar data across a wide variety of nations (Porter & Gamoran 2002), and have discovered very similar relationships between schooling and socioeconomic attainment within all nations. Further, studies have shown that the institutional arrangements for the delivery of schooling bear strong similarities across nations (Baker & LeTendre 2005).

For the US, these patterns are illustrated by the over time trend in the illiteracy rate – defined as the percent of individuals who can neither read nor write. Among whites, this rate declined from 20 percent in 1870 to below 1 percent in 1979. As a consequence of slavery, the illiteracy rate among African Americans in 1870 was 80 percent. By 1979 it had declined to 1.6 percent. However, as noted above, more than the bare minimum of reading and writing skills is required to succeed in twenty first century labor markets. Thus, gaps in more advanced literacy skills, between, on the one hand, lower income, African American, and Hispanic students, and, on the other, middle and higher income or white and Asian students, have emerged as

among the US's greatest concerns. This has led to empirical studies on the determinants and consequences of these achievement gaps, and to the consideration of a variety of policies and programs designed to reduce them.

The importance of this focus on differentials in cognitive skill across class and race/ethnicity groups is emphasized by a variety of studies that show that, at the beginning of the twenty first century, such skill has increasingly become *the* social stratifying variable in American society. These studies have yielded the following findings. First, the years of schooling an individual completes is the primary determinant of her or his placement within the social class system, and also the primary mechanism by which parents transfer their social class status to their children. Second, during the period 1980–2000, as the economy became more knowledge based and globalized, and as union strength declined, the economic returns to schooling and cognitive skill increased dramatically. That is, adjusted for inflation, the earnings of workers with no more than a high school education were stagnant, while the earnings differential between college educated and high school educated workers increased dramatically. Third, and also during this time period, the black–white test score gap, which had narrowed between 1960 and 1980, stopped closing and remained unchanged. Fourth, the earnings differential between African American and white workers was shown to be largely explained by the cognitive skills differential between these groups.

What explains individual and group differentials in literacy, as measured by tests of cognitive skill and self reports of educational attainment (number of years of schooling completed)? Both qualitative and quantitative studies point to parent–child interaction and children's oral language development during the preschool period as crucial for the creation of differentials in school readiness that strongly predict performance in early elementary school. Thus, the child's early literacy skill – oral vocabulary, grammatical usage, letter knowledge, and phonemic awareness (the ability to hear and manipulate the separate sounds in spoken language) – are among the principal predictors of success in first grade reading. Since scores on these variables tend to be lower for children from lower social class, African American, and

Latino backgrounds, lower preschool literacy among these students predicts lower first grade reading attainment.

How do middle class children come to have more extensive vocabularies and standard speech patterns than lower class children? The phenomenon in question has been publicly discussed at least since the story of Eliza Doolittle in *My Fair Lady*, whose distinctively working class vocabulary and dialect are remade by Professor Higgins. During the 1960s, 1970s, and 1980s, sociologist Basil Bernstein and anthropologist Shirley Brice Heath reported on the more restricted speech code within lower class families, and the more elaborated code within middle class families, and argued that the latter better prepares middle class children for school success. More recently, developmental psychologists Betty Hart and Todd Risley (1995, 1999) had graduate students audiotape, one evening each month, the speech utterances occurring between parents and children as the children aged from 12 to 36 months of age. They found that the middle class parents addressed many more words to their children than did the lower class parents, and also used many more different vocabulary words in these conversations than did the lower class parents. Hart and Risley report that by 36 months, the children were full participants in their family's conversational culture. Not surprisingly, just like their parents, the middle class children knew and used far more different words than the lower class children. Other researchers have corroborated and extended these findings. Thus, preschool oral language literacy translates directly into elementary school reading literacy.

School readiness and acquisition also have a behavioral dimension. Perhaps most damaging to their success in school is the immaturity that many low income children bring to first grade. They often come to school unready to sit still, pay attention to the teacher and the lesson, and do their own work. Parental assistance with homework, and monitoring of the child's school success, is often absent. By comparison, middle class parents often make raising, instructing, and assuring the school success of their children one of their principal daily activities, a pattern that Lareau (2003) refers to as "concerted cultivation." As a result of differential cognitive and behavioral school readiness,

differential parental involvement in the school performance of their children, and resulting differential early school success, lower income and middle income children typically show very different achievement trajectories as they progress through the school grades.

The divergence of these trajectories is not surprising. Children who are engaged and successful at school typically receive positive feedback from teachers, and enjoy schoolwork, which causes them to maintain or even increase their efforts. They are typically placed in higher level "ability groups," where other students are engaged and motivated and more material is covered at a faster pace. They are assigned and complete more homework, and do more reading in their free time. On the other hand, children who are less engaged and successful in early elementary school typically receive less positive feedback from teachers, and get less pleasure from schoolwork, which causes them to become disengaged. They are often placed in lower level "ability groups," where the other students are also less engaged, and more elementary material is covered at a slower pace. They are assigned little or no homework, and do little reading in their free time. When differential patterns such as these begin in early elementary school, and continue through later elementary, middle, and high school, the "low" and "high" trajectory groups emerge at the end of 12th grade with very different literacy levels as measured by academic skills and motivations.

Nor does the process of differential literacy development end at this point. Lower performing children have a higher rate of school dropout, and those who graduate from high school often go straight into the labor market. There they may encounter employers who consider their literacy and mathematics skills to be inadequate for the requirements of the jobs available. By contrast, higher performing students typically undertake four more years of academic skill development in college, often followed by graduate level or professional training. Then, when these individuals enter the labor market, they take jobs which themselves have a strong component of continued learning and literacy development. The result is a society composed of adults who, at least when we compare the top and bottom of the occupational hierarchy, are strongly differentiated on the basis of their

cognitive skills, which are in turn correlated with their earnings.

These effects have been magnified by the strong upward trend in female employment during the second half of the twentieth century, and the accompanying increase in female representation in highly paid, knowledge based professional employment. At the same time, income inequality across worker education and skill levels has been increasing. With assortative mating by educational level at a high level, there has been significant growth in families where both parents hold highly paid jobs requiring advanced cognitive skills. Meanwhile, at the lower educational levels, wages are stagnant, and many children are raised in single parent households. Children raised in families having these very different levels of cognitive, social, and monetary resources, typically in neighborhoods and schools segregated by income and race, can expect very different cognitive development trajectories. Thus, in US society today, social class and race/ethnicity are correlated with literacy, broadly defined as reading, writing, and mathematics skills. This correlation is a primary cause of continuing social inequality.

local residents' movements

Koichi Hasegawa

Local residents' movements expanded greatly in Japan after the mid 1950s. Their names – such as “students' movements” and “women's movements” – designate types of participants. The term “residents” indicates the local inclusiveness of the movement: anyone who lives in the area, if they are interested in a local issue,

can participate. No other qualification is required. People of any age beyond high school, including senior citizens, male or female, people of any political affiliation or ideology, are welcome to participate. The boundary of the local area depends on the issues. In many cases it corresponds closely to a geographical area like a local school district, city, town, or village. But when pollution comes from a large scale project like the bullet train or an airport, the movement can even extend beyond prefectural boundaries.

In the Japanese context, local residents' movements are completely distinct from existing labor union movements and political movements led by political parties, such as the "progressive party," the Japan Socialist Party (now the Social Democratic Party), or the Japan Communist Party. Major characteristics of local residents' movements include being (1) single issue or issue limited, (2) spontaneous, (3) non partisan, and (4) stressing democratic values like participation, self autonomy, freedom, and transparency. In this meaning the term "self limited radicalism," used by Cohen (1985) to describe new social movements, is also appropriate to local residents' movements.

The size of residents' movement membership, from several people to 10,000 and more, depends on the issues. Typically, the issues are of two types: (1) a protection type – opposing or stopping some harmful plan or facilities; and (2) an achievement type – improving local amenities or living conditions, such as requests to build public libraries or public parks. The organizing form or management style of the movement organization can vary from a self generated loose network to a formal organizational structure with articles of incorporation, representatives, and an annual budget.

The concept of citizens' movements resembles that of residents' movements. These two terms are commonly used without distinction, almost interchangeably. However, there are subtle nuances of difference between the terms "local residents" and "citizens." Local residents are people with loyalties bound to particular local communities. Citizens, however, in the context of Japanese social movements, are thought of as autonomous individuals pursuing generalized civic goals. Contrasting local residents' movements with citizens' movements from this perspective reveals important differences in their

character and organizing principles. In general, residents' movements are commonly organized around existing local groups such as neighborhood associations, and are strongly characterized by their focus on issues of concern to a specific local area. Typically, their membership is largely composed of the people who reside in this limited range. In contrast, citizens' movements are thought to consist of autonomous individual citizens brought together by shared ideals and objectives. They are strongly characterized by their focus on much broader issues: issues of concern to entire prefectures, the whole nation, and sometimes to the world or all of humanity (e.g., the peace movement and women's movement).

The social status of participants in local residents' movements can vary greatly, but the primary actors are often people who find it relatively easy to devote time to the movement. Such people include those involved in agriculture or fishing (during the slack season), the self employed, public sector employees (i.e., public officials and teachers), women, and the elderly. In contrast, the people involved in citizens' movements are typically professionals and the better educated who have access to information resources. For instance, if a group to protect the natural environment of "Mt. X" was organized by people living in the immediate vicinity of the mountain, this group would be a local residents' movement; its central objective would be to protect the interests of the local people. In contrast, instead of or beyond local residents, if the group was created by the general citizenry of surrounding urban areas, lovers of nature, and specialists such as scientists, teachers, and lawyers, it would be a citizens' movement; its activities would be much more idealistic, driven by a commitment to universal values rather than direct interests.

The well known farmers' protest during the Meiji era in the 1890s and 1900s against pollution from the Ashio copper mine provides a classic example of an early form of local residents' movement. But in that era, the prewar Great Japan Imperial Constitution substantially limited civil liberties such as freedom of speech and assembly. These restrictions made local residents' movements infrequent, sporadic, and highly localized. Only after 1955, with democratization and liberalization in place, did

pollution from the rapid development of heavy industry lead to local residents' movements across the entire nation.

The increasing rates of air, water, and soil pollution by industrial waste – exemplified by the “four major cases” of Minamata mercury poisoning, Niigata mercury poisoning, Ouch ouch cadmium poisoning, and Yikkaichi asthma, all of which appeared in the 1950s and were publicly denied by the companies and the authorities – stimulated action and protest by local residents' groups across the country. During this period, local residents' movements usually sought relief and improvement after the pollution had occurred. In these movements farmers and fishers concerned about the destruction of their means of livelihood made appeals, petitions, and demands supported by protest actions.

In the mid 1960s, residents' movements changed their strategy from reactive to proactive. They fought to prevent the construction of planned large scale industrial development projects before they could cause pollution. The first major successful case of this type in Japan was the 1964 movement against the construction of petrochemical complexes in Numazu, Mishima, and Shimizu in Shizuoka prefecture. The organizing processes, strategies, and tactics of these movements became a model for subsequent movements. The participants in these movements came from across the whole social strata. The 1964 example provides a good illustration: in a relatively short period of time, housewives joined with teachers, researchers, and other professionals, plus a broad spectrum of local residents including laborers, farmers, and fishermen, standing shoulder to shoulder to defend their local environment.

It is worth noting that these movements were not simply responses to the actions of individual corporations (although individual corporations were often the immediate focus of protest, criticism, and litigation). Rather, they were reactions against government policies. This period of high economic growth was marked by the introduction and (attempted) implementation of several nationwide development plans. The First Comprehensive National Development Plan (1962) aimed to develop and disperse industrial activity across the nation, in part by designating and funding new industrial cities. The Second Comprehensive National Development Plan (1969)

attempted to stimulate development across the nation through the construction of enormous industrial complexes and interconnecting transport networks of bullet train lines and high speed freeways.

By this time, awareness of the four major pollution cases, the pollution problems evident in other industrial areas, and the widely reported success of protest movements against industrial complexes in Numazu and elsewhere had spread to the general public. Under these circumstances, the actual and impending pollution from the large scale development plans stimulated the further growth of local residents' movements all over Japan. Powerful residents' movements stopped plans for new large scale petrochemical complexes in the Second Comprehensive National Development Plan in such areas as Tomakomai City in Hokkaido, Rokkasho Village in Aomori (Funabashi et al. 1998), and the Shibushi Bay area in Kagoshima. The opposition was so fierce that in the aftermath of the 1973 oil crisis, as governments around the world reassessed their energy supply options and associated economic policies, the Japanese government abandoned its plans altogether for further petrochemical industrial complexes.

The political effectiveness of residents exercising their right to protest received great attention from the media and general public. The Japanese public embraced protesting as a tool for resisting government policies that valued economic growth above all else and lacked any mechanisms for effectively regulating pollution or preventing environmental destruction.

From the mid 1960s these movements broadened and became more active in demanding improvements to the living environment. Urban dwellers who had developed a citizens' consciousness began to organize in defense of the environment, to create new communities, and to revitalize towns. In the process, the foci and forms of the local residents' movements became much more diverse, and the differences with citizens' movements became far more ambiguous. Especially in and around large metropolitan areas such as Tokyo, Osaka, and Nagoya, the provision of social infrastructure had not kept up with the population explosion of the high economic growth years. Failures in water supply, sewage, road construction, employment and

educational opportunities, public health, and maintaining parks and other public facilities brought about a nationwide boom in local residents' movements, especially between the late 1960s and mid 1970s.

From the mid 1970s the model of local residents' movements spread to South Korea, Taiwan, and other East Asian countries, where it helped inspire anti pollution movements.

log-linear models

Janet C. Rice

Log linear modeling is a data analysis technique used to explore relationships among categorical variables. Log linear models express the

logarithms of the expected cell frequencies from a multiway contingency table as a linear combination of the variables and their interactions. The simplest models yield a test equivalent to the chi square test of independence, but the technique allows exploration of relationships among more than two variables. Since log linear models are additive with respect to the logarithm of the cell frequencies, they easily generate estimates of odds ratios.

Although statisticians such as Pearson and Yule addressed the association between two categorical variables early in the twentieth century, development of techniques similar to the analysis of variance and linear regression for continuous outcome variables was slow. Birch (1963) proposed the log linear model. Goodman and others made log linear modeling popular in the 1960s and 1970s (Goodman 1970; Bishop et al. 1975). Goodman and his colleagues made a computer program available in the 1970s.

A log linear model assuming that two cross classified categorical variables, A and B, are associated is denoted AB and has the form

$$\ln(e_{ij}) = 1 + I_i^A + I_j^B + I_{ij}^{AB}$$

where $i=1$ to I indicates the level of variable A, $j=1$ to J indicates the level of variable B, e_{ij} is the expected frequency for the ij th cell of the table, and the I s are parameters to be estimated. A model that assumes the two variables are independent is denoted A,B. If an interaction term is included in a model, the main effects that are involved in it are necessarily included in the model.

Parameters are most often estimated using the method of maximum likelihood. Grizzle et al. (1969) developed a weighted least squares approach that they applied to repeated measures data. Exact methods for small samples are also now available.

There are two major types of log linear models, logit and symmetric. Logit models assign the role of predictor to some variables and the role of outcome to others. Symmetric models place all variables on an equal footing.

Logit models are members of the general linear model. They are analogous to linear and logistic regression models. In fact, for a single binary outcome and a set of categorical

predictors, log linear models yield the same results as logistic regression models. Outcomes can also be polytomous, and the models can contain more than one outcome variable.

All logit models must include the most complex interaction among the predictors and the most complex interaction among the outcomes as controlling terms. Additional components must involve relationships between predictors and outcomes.

Symmetric models allow researchers to address problems that fall outside the context of the general linear model. Researchers have applied them to problems in many disciplines including sociology, psychometrics, and epidemiology. Since there are fewer mandatory controlling terms in symmetric models, the number of models that can be considered is larger than in the logit case.

One of the earliest applications of symmetric models was in the area of social mobility. Data are in the form of a square table relating the status of one generation to that of the next. The cells on the main diagonal represent no change in status. Interaction terms in these models often require a large number of parameters. The variables are often ordinal. Modeling strategies attempt to reduce the number of needed parameters. An example of a simplifying hypothesis is that the relationship between one or more of the variables and the logarithm of the frequencies is linear.

Assessment of rater agreement also generates a square table. Observations that fall on the main diagonal represent agreement. The log linear model allows the inclusion of covariates and the comparison of more than two raters.

Another type of symmetric model concerns the identification of latent classes. Latent class models assume that all associations among the manifest variables can be explained by their association with the unobserved latent variable(s). If X is a latent variable and A and B are manifest variables, the model is AX, BX . Clogg developed a program to fit latent class models.

Latent class models also allow tests of the hypothesis that a set of categorical items form a Guttman scale (Clogg & Sawyer 1981). These models are used in developmental research and studies of progression of drug use.

Epidemiologists use capture recapture models to estimate the size of a population by

drawing two or more samples from it. The variables are presence or absence in each sample. An important feature of data from capture recapture studies is that the cell observed frequency indicating that an observation is absent in all samples must be estimated by the model. This technique was used to estimate the extent of undercount in the census.

Future developments in log linear modeling are likely to be in the areas of correlated data and random effects modeling. Problems in genetics will stimulate development of techniques for many dimensions.

logocentrism

Warren Fincher

Coined by Jacques Derrida in his *Of Grammatology*, logocentrism refers to the tendency in western civilization to privilege the linguistic

signifier (a spoken or written word) over the signified (the thing to which the word refers). The importance of the term resides in Derrida's critique of the philosophical tendency in western civilization to be logocentric. Derrida asserts that western discourses generally tend to impose hierarchies of power by defining certain concepts against necessarily subordinated alternatives. Extending this critique to logocentrism, Derrida notes the tendency in western philosophy and semiotics to value the signifier as opposed to the thing it signifies in what he calls a "metaphysics of presence."

In *Of Grammatology*, Derrida systematically problematizes much of Ferdinand de Saussure's work in semiotics. On many points, Derrida employs Saussure's work as a point of departure. For example, Saussure maintains that the signified does not inherently indicate the nature of the signifier – for example, there is nothing about the nature of a table that requires it to be called such – but rather that signifiers create a linguistic system of signs that reference each other. Likewise, Derrida agrees that linguistic systems encode certain value systems. However, Derrida rejects the dyadic model of signs that Saussure develops, wherein Saussure focuses attention on the relationship between the signifier and signified; the relationship is arbitrary but nonetheless provides insight into the form of the linguistic system. Derrida rejects the distinction between signified and signifier, between some external and objective object and its linguistic sign. Rather, he sees the two interpenetrating. Also, Derrida rejects Saussure's tenet that the relationship between signifier and signified, while arbitrary, is also static. Derrida recognizes that a gap exists between the idea and the thing it references and, through this gap, play occurs. To focus on the signifier as clearly and always indicative of the same signified object is to allow the sign more preeminence than is due and falsely implicates a centrality of the signifier over the signified.

In "Plato's Pharmacy," Derrida examines Plato's *Phaedrus*, in which Plato denounces writing as a lesser form to oration, claiming that writing is a derivative of the spoken word. This praises the spoken word as the closest manifestation to the mental experience of an idea, and writing as secondary to that. In making this argument, Plato values the presence of the

speaker in oration – and its proximity to the mental experience of thought – and rebukes the absence of the author in the written form. The value system found in this "phonocentrism" may also be found more generally in the western tradition of privileging the signifier – at the moment of being read, the text is present – over the signified, which is not present. Hence, because logocentric thought reifies a division of the signifier from the signified and because logocentric philosophical orientations specifically value the present, logocentrism embodies a "metaphysics of presence."

Current sociological work in logocentrism is scant and remains mostly within the forum of philosophical debates over the nature of language. Clive Stroud Drinkwater's (2001) defense of logocentrism critiques Derrida's approach to deconstruction, concluding that it rests on incorrect generalization of metaphysics and otherwise follows the tenets of classical logic. Beyond debates over semiotics, the concept of logocentrism has been applied to the sociology of science (Fox 2003). The idealized setting of the laboratory is contrasted with the arena of practical application. A "scientific logocentrism" emerges from the privileging of data produced from the ideal conditions of the lab and subsequently framed as a representation of reality. Deviations from that representation when applied to practical settings are then discounted as invalid because of the uncontrolled elements of the setting. The laboratory is given centrality as the articulation of a scientific reality, even though the conditions that give rise to that reality are not found in nature.

Lombroso, Cesare (1835–1909)

Frank P. Williams III and Marilyn D. McShane

Cesare Lombroso is considered one of the fathers of positivist criminology. His work on the traits and characteristics of offenders typifies the scientific analysis of the individual criminal in an attempt to determine the causes of crime. Although there is little support for his assumptions today, his work is valued not only as a precursor to criminal anthropology but also as an early demonstration of the use of scientific measures in theory building.

Lombroso, born in Verona, Italy, received a medical degree in 1858 and a surgical specialty in 1859. He married in 1869 and had two daughters, Paola and Gina. He served as a physician in the Italian army and also worked with the mentally ill in several hospitals. Fascinated by comparative anatomy, he hoped to establish some relationship between the form and features of individuals and their behavioral tendencies.

There is evidence of two major influences in Lombroso's work. First, he was affected by German materialism of the time that valued objective scientism over naturalistic philosophy. Second, his writings exhibit an appreciation of evolution, particularly the writings of Charles Darwin on biological evolution and of Herbert Spencer and others who proposed theories of social evolution.

True to positivist methods, Lombroso conducted painstakingly careful research, documenting the facial and body measurements of hundreds of criminals and non criminals, using populations of soldiers, prisoners, the insane, persons with epilepsy (a disease which was

misunderstood at the time), and the general population. He attempted to explain physical and mental differences as anomalies indicating a primitive or subhuman nature he referred to as atavism. He rejected the classical concept of free will and argued that criminals were cast their fate by their degenerative features. To him, criminals were evolutionary throwbacks whose defective traits were evident in the shape of their skull and bone structure, certain physical quirks, and tendencies toward slang, tattoos, and vice. All of these characteristics and features were said to be symptoms of a criminal personality, which for Lombroso was a more innate, biological concept than the way the term personality is used today.

Lombroso classified offenders into two primary groups: born criminals or hardened recidivists, and occasional criminals. The first group, which exhibited most of the traits mentioned above, is the one he emphasized and for which he is best known. The latter group occupied much of his writings because they were exceptions to his "born criminal" theory. This group was composed of three categories. First, Lombroso identified pseudocriminals who were not necessarily atavistic, but more victims of circumstance – such as a person who commits a crime in self defense. His second type of occasional criminal was the criminaloid, who he claimed had only a touch of degeneracy. Finally, there was the habitual offender who was also not degenerative or atavistic but caught up in a pattern of bad associations and continued contact with born criminals.

His theory of the born criminal, particularly in its biological aspects, was severely criticized. In response, Lombroso incorporated the criticisms into his theory and, at the time of his death, had added social, economic, and political causes of crime. He also had increased the number of criminal types to encompass other biological features, such as an epileptoid. However, to the very end he maintained that biological factors were the dominant causes of crime.

Later in life, Lombroso worked closely with his daughter Gina and other young scholars with whom he published several articles and books. At the University of Turin he was professor of legal medicine and public hygiene, professor of psychiatry and clinical psychiatry, and professor of criminal anthropology.

Lombroso was also one of the first criminologists to study and write about the female offender. His efforts in this area demonstrate his consideration of a wider range of factors in criminality, including gender, age, poverty, and occupation. In his book *The Female Offender*, he decided that women were far more ferocious than men.

The essence of Lombroso's work was carried on by a student, Enrico Ferri, and a fellow criminologist, Raffaele Garofalo, who assisted him in establishing the *Archives of Psychiatry and Criminal Anthropology*. Both also went on to achieve acclaim in the area of criminology, although they moved away from Lombroso's emphasis on physical traits.

Criticisms of Lombroso's work center primarily on the generalizations he made about crime proneness based on ethnic characteristics. For example, he spoke of the Gypsies as a criminal race: "They are vain, like all delinquents, but they have no fear of shame. Everything they earn they spend for drink and ornaments . . . They are given to orgies, love noise, and make a great outcry in the markets. They murder in cold blood in order to rob, and were formerly suspected of cannibalism. The women are very clever at stealing, and teach it to their children."

Nonetheless, some of his arguments are still popular today, such as the role of alcohol in crime, and the existence of a criminal personality. We also credit the theoretical work of the "Italian Triumvirate," Lombroso, Garofalo, and Ferri, for laying the foundation for the study of criminal offenders, particularly in their emphasis on the use of scientific methodology for the classification and prediction of behavior.

lone-parent families

Karen Rowlingson

The growth of lone parenthood is a trend common to many advanced industrial countries. In 1990 Britain had one of the highest rates of lone parenthood in Europe (with 19 percent of families with children being lone parent families) along with Sweden (19 percent), Norway (19 percent), and Denmark (18 percent). The European countries with some of the lowest levels included Greece (5 percent), Ireland (9 percent), Italy (7 percent), Portugal (6 percent), and Spain (5 percent). This division suggests some combination of North/South, rich/poor, Protestant/Catholic factors at work. Countries that are generally rich, Protestant, and North European have much higher rates of lone parenthood than those that are mainly poor, Southern, and Catholic, though Britain cuts across this division as it has comparatively high rates of poverty but is Northern and Protestant. Culture and religion therefore seem important factors when seeking to explain variations in rates of lone parenthood. If we look outside of Europe but remain within the developed world, Japan had a very low rate of lone parenthood (4 percent) in the early 1990s, Australia had a slightly lower rate than Britain (15 percent), and the US had by far the highest rate (25 percent).

The percentage of births outside marriage also varies substantially by country. This figure cannot be taken as a direct indicator of lone parenthood as these births are often to cohabiting parents, but there does appear to be some correlation, as the highest rates of births outside marriage were in Denmark, Norway, and Sweden in the early 1990s. The lowest rates were in Greece and Italy. The United Kingdom

and the US fell somewhere in between these two extremes. Divorce rates are also associated with lone parenthood. The highest rates in the early 1990s were in Denmark, the UK, and Sweden, with the lowest rates in Greece, Ireland, Italy, Portugal, and Spain. The US had by far the highest rate.

Another interesting point of comparison is the family marital status of lone parents within each country. For example, the proportion of lone parents who are never married varied dramatically, from more than half in Norway and Sweden to about a third in the US and UK. Never married lone parents were virtually non-existent in Greece, Portugal, and Japan in the early 1990s.

WELFARE REGIMES

Some researchers have tried to categorize countries into groups in terms of how women and lone parents fare, especially in relation to employment and social policies. This general approach of categorizing “welfare regimes” is most heavily associated with Esping Andersen, who categorized welfare regimes in terms of the policy logics that revolved around a paid worker’s dependence or independence from the labor market.

Another way of classifying countries is in terms of whether they focus on lone parents as mothers (the “caregiving” model) or workers (the “parent/worker” model). The Netherlands is a prime example of the former, where sufficient support is given to lone parents to remain in the home to look after their children. The state therefore provides support for women as mothers. Lone parents are able to establish autonomous households without suffering poverty and deprivation and they can do so without having to engage with the labor market. Sweden, however, is an example of the parent/worker model. Lone parents here are also able to establish autonomous households without suffering poverty and deprivation, but they tend to do so through engaging with the labor market. The state provides support in terms of child care, wages are relatively generous, and there are reasonable benefit payments to those out of work.

The ability of lone parents to establish autonomous households without suffering poverty and deprivation might be seen as a benchmark with which to measure gender (and class) equality in different countries. We have seen that there are different ways of doing this: we can support lone parents to stay at home and care for their children (by having generous benefits) or we can support lone parents to take up paid work (by having affordable childcare and keeping wage rates high). Perhaps there is also a middle way in terms of supporting lone parents to combine roles by means of packaging their income – some income from part time work, some from benefits, some from maintenance. This is more the approach taken in the UK, where in work benefits such as Working Tax Credit (formerly Family Credit) enable lone parents to put together such a package. But in the UK, wage and benefit levels have generally been too low to avoid poverty for all but a minority of lone parents.

EFFECTS OF SOCIAL SECURITY POLICY

It is common for those on the political right to argue that lone parenthood has risen because women have access to relatively high rates of benefit. There is some evidence that appears to support this view; Greece and Portugal, for example, have low levels of social security support for lone parents and also low levels of lone parenthood. At the other end of the spectrum, Norway, Denmark, and Australia have higher levels of both social assistance and lone parenthood. But we must be careful not to draw conclusions about causation from these associations. It is possible that the high rates of benefit in some countries were the *result* of a growth in lone parenthood (due to a growing lobby group and increasing recognition of the need for higher benefits) rather than the *cause* of the growth. Also, the US provides an important exception to any correlation between levels of lone parenthood and levels of benefit. As we have seen, the US has the highest level of lone parenthood in the western world, but its level of social assistance is among the lowest (lower even than that available in Ireland and Spain).

So it seems that there is only a weak association between high rates of benefits for lone parents and high rates of lone parenthood.

Social security policy may have only weak effects on the *rate* of lone parenthood, but it may nevertheless affect the *employment participation* rates of lone parents. Here again, however, the evidence is inconclusive. For example, Sweden had the largest proportion of lone parents in paid work in the early 1990s, but the benefit replacement rate was also the highest. This means that Swedish lone parents, compared with lone parents in other countries, would not be much better off financially in work than on benefit. We might therefore expect them to have low employment rates, but they do not. This therefore contradicts a narrow rational economic model of behavior that assumes people weigh up the financial costs and benefits of a particular course of action and then act accordingly. France and Germany, on the other hand, had relatively high proportions of lone parents in work along with relatively low benefit replacement rates (thus supporting the rational economic model). Denmark and France had similar proportions of lone parents in the labor force, but Denmark was relatively generous to lone parents on benefit whereas France was relatively mean.

EMPLOYMENT PATTERNS AND POLICIES

As we have seen, there is also a great deal of variation in the employment patterns of lone parents across different countries. In the early 1990s the Netherlands, the UK, and Ireland had the lowest rates of full time paid work for lone parents: fewer than one in five lone parents in these countries had a paid job. The highest rates were found in Portugal, France, Japan, Italy, Sweden, and Denmark, where over half of all lone parents worked full time. Overall, however, lone mothers in all countries apart from the UK are either more likely to be working full time than all mothers or the level of full time employment is about the same. And generally, lone mothers are less likely to work part time than all mothers are. So what explains these variations in employment rates?

Some of the variation in lone mothers' employment rates across different countries mirrors variation in the employment rates of mothers in couples. This supports a gendered approach to lone parenthood and also questions the appropriateness of singling out lone mothers as a group. If the experience of lone mothers is just an extreme version of that for all mothers, then perhaps policies should be aimed at improving the opportunities of all mothers rather than just focusing on lone mothers in particular. Or perhaps policies could be aimed at those (both women and men) with poorer educational and employment prospects.

Most advanced industrial countries are increasingly encouraging (if not compelling) lone parents to enter the labor market. But the ways in which they do this vary. Some, like the US, aim to achieve this largely by restricting access to benefits. Others, like the UK, attempt to "make work pay" principally through in work benefits. And others, like Norway, provide cheap childcare. These policies have been most successful where they fit with lone parents' own aspirations about employment. In the Netherlands, for example, a new policy to encourage lone parents into employment has largely failed because lone parents themselves, their employment advisers, and society more generally did not think it appropriate to push lone parents (back) into the labor market. Social and cultural norms about mothers as carers or workers have a major impact on employment patterns.

Many countries are now emphasizing paid work rather than care as the route to autonomy for lone parents. But paid work is no guarantee against poverty, as is evident in Japan and the US. The success of some countries, like Sweden, in combining high employment rates with low poverty rates is due to a number of factors, such as:

- Lone parents working full time rather than part time.
- Childcare provision paid for by the state.
- Long parental leave schemes.
- Paid leave to be with sick children.
- Strong social transfers (benefit payments) for those out of work.
- State advanced maintenance schemes.

We cannot therefore simply move lone parents into paid work and expect poverty to be eradicated. Other policies, such as those relating to childcare and employment rights, also need to be put in place.

The strategy of moving lone parents into paid work places little value on the unpaid work in the home that most lone parents spend much of their time doing. Much of this unpaid work revolves around caring for children. In the past, "mothering" work was valued in as much as it attracted considerable status for women. Many states reinforced this by exempting lone parents on benefit from seeking work, as were the partners of unemployed men. From one point of view, such an approach is a positive one towards women as it enables them to carry out the "mothering" work that they wish to do. From another point of view, it reinforces patriarchal assumptions that women's role is in the home. Not only does it lack any expectation that women might want to get paid work, it also fails to provide them with any support, advice, or training should they decide they do wish to get paid jobs. Men gain access to the wages from paid work and women remain dependent either on men (if they are in couples) or on the state (if they are lone parents).

The move towards encouraging lone parents to take paid work can therefore be seen from either of these perspectives. It can be seen as lowering the status of the unpaid "mothering" work that women do or it could be seen as challenging women's confinement to the domestic sphere.

DIFFERENCE, DIVERSITY, AND IDENTITY

Lone parent families have received a great deal of attention from the media, politicians, policy makers, and academics. But should we focus on them as a particular group? This depends on the answer to two further questions. First, are lone parents a homogeneous group with distinctive characteristics that unite them? Second, are lone parents sufficiently distinct from other parents or other groups to warrant separate consideration?

The answer to the first question is that lone parents do have some distinctive characteristics

which unite them as a particular group. They have challenged prevailing norms of the two parent family, based on the idea of a breadwinning man and a housewife. The lone parent, to some extent, takes on both these roles and since the vast majority of lone parents are women they are also united by their gender. However, it is also widely assumed that lone parents are united in poverty, but although poverty is widespread among lone parents, it is not universal. Some lone parents are much better off than others and the social class background of lone parents can make a considerable difference to the experience of living in a lone parent family.

Another source of difference between lone parents is how they became lone parents (and this is often linked to economic difference, too). Younger women who have babies while single are generally from very poor backgrounds, while women who separate from husbands sometimes come from better off backgrounds and experience lone parenthood in different ways. Yet another source of difference is ethnicity. Most lone parents in western countries are white, but some ethnic minorities are over represented in lone parent families (such as Afro Caribbean women in the UK and African American women in the US) and some are under represented (such as Asian women).

There are many other potential sources of difference between lone parent families. Some lone parents are sick or disabled and others have sick or disabled children. Sexuality and culture also vary among lone parents and all these factors can affect the experience of lone parenthood as well as the identity of the lone parent. Perhaps a lesbian lone mother will feel she has more in common with a lesbian mother in a couple than with a heterosexual lone mother?

This brings us to the second question about whether some lone parents have more in common with other parents, or other groups, than they do with other lone parents. For example, a young never married lone mother living in poor housing may feel she has (and may actually have) more in common with the married mother living next door than she does to a divorced lone mother living in a large house in an affluent area. Of course, all lone parents face similar issues when it comes to raising children without a partner, but even in couples, one parent (usually the mother) tends to take on more of the parental

responsibility and associated work than the other partner. So perhaps the difference between lone mothers and mothers in couples is not so great.

A final reason why lone parenthood should not be seen as a monolithic state is that it is not, usually, for life. Couple families turn into lone parent families, which then turn again into couple families and so on. So to make very large distinctions between lone parent families on the one hand and couple families on the other must be questioned. In the UK, research has found that half of all lone parents leave lone parent hood within 6 years of becoming a lone parent.

FUTURE DIRECTIONS

As already mentioned, issues around difference, diversity, and identity are complex and fluid. More research needs to be carried out to explore the homogeneity or heterogeneity of lone parenthood both on an objective level (e.g., comparing levels of income, work, disability, etc. with other groups) and on a more subjective level in terms of identity.

It is also important to consider the role of other actors rather than simply focus on the lone parent. Concern about non resident parents has mostly revolved around issues of financial support for children, but the role of fathers more generally in relation to care work is a very important issue. And children's perspectives on family life are starting to receive more attention – deservedly so. The role of grandparents, steprelatives, broader family, and friends also needs to be considered.

Families change over time and more research needs to be carried out on the dynamics of family life. There is already some quantitative longitudinal work in this area, but very little qualitative longitudinal work. Qualitative panel studies are unusual and raise various methodological issues, but these should be explored to provide an important and currently largely lacking perspective on lone parenthood.

Finally, there is an urgent need for more up to date, comparative data on lone parenthood. Much of the data referred to in this entry relates to the early 1990s and yet it is highly likely that the picture has changed since then. Such research will need to consider carefully different definitions of lone parenthood in

different countries so that meaningful comparisons can be made.

longevity, social aspects (the oldest old)

Miriam Bernard

Longevity is defined as the maximum life span attainable by the species and is measured by the age of the oldest living individual. Although there is evidence that people have lived well into late old age for many hundreds of years, a Frenchwoman, Madame Jeanne Calment, made history when she died at the age of 122 in August 1997. Other definitions of longevity refer to it as “uncommonly long duration of life,” but what was once uncommon is now increasingly common. Today the World Health Organization calculates that there are approximately 600 million people aged 60 and over around the world. By 2025 this total is expected to double and, by 2050, there will be 2 billion people of this age. Historically, these changes are very recent and are a product of the twentieth century. As a result, many countries are now experiencing “rectangularization” as declining fertility and mortality (notably infant mortality) rates change their population structures from a pyramidal shape (many children at the bottom and fewer old people at the top) to a more even distribution across age groups. By the middle of the twenty first century, demographers predict that there will be more people aged 60 years and older than children under the age of 15 years.

Although commentators agree that maximum life span has probably not extended a great deal over the centuries, what has improved markedly is life expectancy for both women and men. The rapidity of these changes can be illustrated with reference to Britain where, in 1901, life expectation at birth was only 48 years for men and 51.6 years for women. What is remarkable is that these figures had not altered since medieval times. Now however, women can expect to live to about 80 years of age and men to about 76 years of age. Despite continuing improvements in life expectancy, the gap between the sexes is closing as lifestyle factors, which researchers believe to account for about 70 percent of a person’s chances of achieving longevity, begin to have an impact.

A further important feature illustrative of increased longevity is the aging of the older population itself as higher and higher proportions of people survive to age 60 and beyond. Worldwide, the fastest growing group is the “oldest old,” variously defined as those aged 80 or 85 years or more. Perhaps the clearest indication of this trend is the rapid increase in the numbers of people surviving to the age of 100 years, particularly in developed countries. In 2000, the United Nations estimated that there were 180,000 centenarians around the world. By 2050, this number is projected to be 3.2 million: an eighteenfold increase. Moreover, in many countries, old age in general, and extreme old age in particular, is predominantly a female experience. In 1999 in Britain, there were 8,000 centenarians of whom 7,000 (87.5 percent) were women and 1,000 (12.5 percent) were men. Of the 50,000 centenarians in the United States, 85 percent are women and 15 percent are men. This has been termed the “feminization of later life” (Arber & Ginn 1991) and is often further reflected in other social aspects such as marital status and living arrangements. Widowhood, solo living, and reduced financial circumstances are now expectations for many older women, especially the “oldest old,” while changing family forms contingent upon changing work patterns, changing attitudes to sexuality, growing numbers of minority ethnic older people, rising divorce rates, and, for some, remarriage will lead to even greater diversity of family and social situations across the life course and into old age.

Increased longevity presents us with many profound challenges. Among the persistent social issues facing all societies are how our oldest and most vulnerable members will be accommodated, given care, and supported; how we might finance old age; and how family and social networks may change. Contrary to popular opinion, the body of research evidence shows that older people have never been abandoned wholesale by their families. Rather, family and family support – albeit in different forms – will continue to remain crucial in our lives. Alongside this, prospects for many of improved health and well being together with the blurring of the boundaries between education, work, leisure, and retirement may well open up new social opportunities and help challenge some of the

age old taboos and agist attitudes. This will include the possibility of developing different lifestyles and leisure activities in old age; having greater choice about where, how, and with whom one lives; continuing participation and involvement in local communities and in political and national life; and prospects for more rewarding and mutually beneficial intergenerational relationships.

Rapid though these changes have been in westernized nations, it is important to recognize that aging is now happening at a much faster rate in the developing world than in the developed world. For example, France's older population doubled from 7 percent to 14 percent over a period of 115 years, while the World Health Organization (2004) predicts that it will take China just 27 years to achieve the same increase. Today, 60 percent of people aged 60 and over live in the developing world, a figure that is expected to rise to 75 percent by 2025 and 85 percent by 2050. Moreover, it must be remembered that the rapidity of population aging in many developing countries is expected to outpace social and economic development, with the result that adjusting to these trends is likely to prove even more challenging than it has been to countries who became rich while they grew old.

These dramatic changes to our populations are neither temporary nor a statistical artifact: they are permanent and progressive. As the late Margot Jefferys (1988) eloquently argued, they should be seen as a triumph for public health and a cause for celebration, rather than a reason to further problematize and pathologize old people and old age.

looking-glass self

Jennifer Dunn

The looking glass self is the most well known dimension of Charles Horton Cooley's early, seminal conceptualization of what he called the social self. Cooley used the image of a mirror as a metaphor for the way in which people's self concepts are influenced by their imputations of how they are perceived by others. Cooley distinguished three "principal elements" of the looking glass self: "the imagination of our appearance to the other person; the imagination of his [*sic*] judgment of that appearance; and some sort of self feeling, such as pride or mortification." Much of the time, Cooley thought, our experience of self is an emotional response to the supposed evaluations of others, especially significant others. Children learn the meaning of "I" and "me" and "mine" through the appropriation of objects they desire and claim as their own, in contrast to the things they cannot control. Importantly, among the objects they seek to control and appropriate as their own are their parents and others in the primary group. As infants and toddlers discover they can influence others by their actions, they simultaneously discover and realize reflections of themselves in these others.

Cooley based his self theory on observations of his own children, confirming his initial

hypotheses with a systematic study of his third child from shortly after birth to the thirty third month, in order to determine how the word "I" is learned and its meaning. Children begin appropriative processes with attempts to control the things closest to them, including their own bodies, and then move outward to the people in their vicinity, even as infants "exerting [their] social power" to attract attention. They lay claim to their parents in much the same way they assert as their own their noses and their rattles. In order to learn the meaning of personal pronouns, which refer to different objects when used by different people, children must imagine themselves from the perspective of others. After coming to understand what others mean when they refer to themselves, that is, that "I" refers to self feeling, children "sympathize" with these others and this empathetic process gives meaning to their own incipient self feelings. "I" is social because when it is used it is always addressed to an audience (for Cooley, usually the child's mother), and its use thus indicates children's newly acquired ability to take the role of their audience. Once they begin to do this, they can also perform different selves for different audiences. Indeed, Cooley argued that even young children are capable of manipulating their audiences, care more about the opinions of some people than others, and selectively "own" those with whom they are the closest and over whom they have the most influence (e.g., "my mama"). Adults are not that much different; their imaginations are merely more complex and specific and their manipulations of others more subtle.

The self, then, emerges in interaction, becomes meaningful only in contrast to that which is not of self (society), and is, therefore, inextricable from society. Cooley described the looking glass self in his first major work, *Human Nature and the Social Order*, published in 1902. His analysis of self was influenced by his early reading of idealist and transcendentalist literature, including Thoreau, Goethe, and Emerson, as well as the pragmatism of Dewey, also at Ann Arbor at the time. The social self draws upon the work of the psychologist and philosopher William James and the social psychologist James Mark Baldwin and was articulated within the populist, progressive intellectual milieu

of the Midwestern scholarship of Cooley's era and the sheltered academic environs of the University of Michigan, which granted him the leeway to develop his reflective notion of self based on his observations of his own children and introspection. As Cooley was also a painfully shy and reclusive man who wrote in his journals of his obsession with gaining the approbation of others, his theorization of a self that depends on a reflexive, emotion laden response to imagined evaluations is distinctly autobiographical. Cooley's methodological approach follows directly from his conception of the self: human action must be understood in terms of the subjective meanings actors impute to situations. In his conjoining of the social self with society as the communicative imaginations of multiple selves, his looking glass self is a culturally and historically specific product of his social location and his conceptual and political idealism.

Cooley's looking glass self was elaborated by George Herbert Mead in the latter's development of the notion of taking the role of the other, especially the generalized other, as the mechanism through which a unified self emerges in interaction. Cooley also influenced Goffman's dramaturgical analysis of the self as a situated performance. There is a significant body of research on what is now commonly referred to as "reflected self appraisal" and its role in the development of self concepts, and with those of Mead and Goffman, Cooley's ideas about the self have become a constitutive and foundational core of theories of self in sociological social psychology and symbolic interactionism, and because of his emphasis on the emotional aspects of identity, have influenced the sociology of emotions. Cooley has been critiqued: Mead thought his work was too "mentalistic" and others have suggested that the looking glass self, if accurate, suggests an oversocialized human, passive and overly dependent on the opinions of others. Cooley himself answered both of these concerns, claiming in the introduction to *Social Organization* in 1907 that imagination was not all of society, but only his particular focus. His discussion of the looking glass self, moreover, is only one dimension of the social self conceptualization, in which he points not only to the importance of reflection, but also to the ways in which humans

selectively and actively interpret and appropriate these reflections.

love and commitment

Irene Hanson Frieze

Love is one of the most basic human emotions. Many have written about love experiences, both in popular writing and in more scholarly publications, especially as they apply to romantic relationships. As these writings indicate, there are many ways of thinking about love. Some of the types of love identified by researchers are reviewed below. Research about how people fall in love and why they choose one person over another to date or to marry also provides information about love. Much of the research on love and partner choice focuses on dating and the initial stages of relationships.

Love and feelings about the partner are only one of many determinants of commitment to that partner. Factors predicting commitment

are also reviewed below. Much of the research on relationship commitment examines marital partners.

DEFINITIONS OF LOVE

One of the first modern scientific analyses of types of love was proposed by Lee (1977). Different types of love were derived from a concept analysis of fictional writing in Europe and the US since ancient Roman times. The forms of love that were identified were given names that related them to ancient Greek conceptions of love.

The first type of love identified was called *Eros*. Eros is an erotic, passionate love. The physical appearance of the beloved is an important part of eros. Eros love can be love at first sight. Having feelings of eros toward someone is a very enjoyable feeling. But eros love can also end suddenly, leaving the person wondering what they saw in their former beloved. Others may wonder what the attraction is toward the beloved, since the relationship does not appear to have a rational basis.

Another form of passionate (and apparently irrational) love is called *Mania*. While eros love is a positive, happy state, mania love is the dark side of passionate love. Mania involves obsession with the beloved person. Constant thoughts of the beloved can involve high levels of jealousy and upset about what the beloved is feeling about oneself. This type of love may be associated with stalking of the beloved.

Storge is a friendship based love. Storge is a quiet, affectionate love that develops gradually over time. Even if the love relationship ends, the strong friendship associated with storge often means one continues to be friends with the former beloved. Highly related to relationship satisfaction, this type of love can lack strong feelings of passion.

Agape is an altruistic love. Agape love is associated with the desire to give to the beloved without asking anything in return.

Pragma love is a practical love that involves loving something about the person, such as being a good parent, being respected in the community, or being wealthy. This type of love is associated with arranged marriages.

Ludus love is not typically classified as "love" in western society today, although these feelings were found by Lee to be labeled as love in some cultures. *Ludus* is love for the moment. It is assumed that *ludus* love feelings will not last long. They may be only for an evening. *Ludus* is associated with flirtation and the desire to seduce someone for a sexual encounter. *Ludus* feelings are associated with low relationship satisfaction, shorter relationships, and not feeling "love" for the partner.

Love styles are assessed at one point in time. One's feelings can change over time. Thus, a relationship that starts out with primarily *eros* feelings could develop into a *storge* or *agape* type of love feeling. Love styles are also specific to the relationship. One can have *eros* feelings for one partner and *mania* feelings for another partner.

Another way of classifying love is to divide it into two basic types: passionate love and companionate love. The passionate love would include Lee's *Eros* and *Mania*. Passionate love is also called *limerence*. Passionate love is of much interest to psychologists since it appears to be irrational. Characteristics of passionate love include strong feelings of sexual arousal. There is also fantasy and idealization of the beloved. This type of love comes on suddenly. It is sometimes defined as a "state of intense longing for union with another." When one is feeling passionate love for another, being together brings fulfillment and ecstasy, while separation brings anxiety and despair. This type of love often does not last long, especially if reality is allowed to interfere with the fantasies one has of the beloved.

Several theories have been proposed to explain the origins of passionate love. The first of these was suggested by the psychiatrist Karl Jung and his colleague Esther Harding, who spoke of unconscious attraction as the basis of passionate love. Jung felt that people have both a conscious part and an unconscious part of their personality. Generally, one's unconscious self is of the other gender than the conscious self. A goal of Jungian therapy is to integrate the unconscious aspect of the personality into conscious awareness. Within this framework it was proposed that when one feels a sudden, passionate attraction toward someone, one is really falling in love with an unconscious aspect

of the self that has the opposite gender to the conscious self. This unconscious, opposite gender self is often derived from one's opposite sex parent. For some reason, perhaps a resemblance to the opposite sex parent, there is a sense of knowing the beloved person and of strong attraction. Fantasy is used to maintain the image that the beloved person has the same characteristics as the unconscious self. This theory is not directly testable, but informal observations of people attracted to those who resemble their other sex parent provide some support for it. Passionate love does not appear to have a rational basis.

John Money, known primarily for his work with children with abnormal genitals, suggested a theory of pair bonding, a concept very similar to passionate love. Money (1980) feels that passionate, somewhat irrational feelings of love are analogous to an imprinting process that is set off by the physical appearance of the loved one. Although Money does not specify what the biological basis of pair bonding is, one possibility is that this is related to pheromones. Fantasy about the beloved is used to explain to the person why the strong attraction exists. High levels of passion are maintained for about two to three years (long enough for a pregnancy to occur). Once a woman becomes pregnant, her pheromones change and the basis of the pair bonding may be lost (explaining why so many passionate relationships end during pregnancy). After the pregnancy, if the relationship continues to exist, it must be maintained by parent-child bonds in both partners.

Another theory of love proposed by Berscheid and Walster (1969) is based on social psychological research on attribution theory. This theory builds on Zillman's work on motivation and the finding that arousal from sexual feelings, fear, physical exercise, or aggression all lead to similar forms of physiological arousal in the body. People use cues in the environment to label this physiological arousal, and if cues are ambiguous, people can mislabel the source of their arousal. Arousal from one source can be transferred to another source. Thus, when men are angry, they rate pictures of attractive women more positively than they do if not previously angered. Berscheid and Walster apply these ideas to human passionate love. Their theory argues that

when one is aroused (by any source), if an appropriate love object is present, the physiological arousal may be (mis)labeled as passionate love. This theory has been extensively empirically tested and data from many studies do show support for the idea that physiological arousal can increase feelings of attraction or love of a desirable partner. When one encounters an unattractive individual under a state of physiological arousal, the reaction is more likely to be anger.

Companionate love is similar to Lee's concept of *storge*. This type of love is affection or deep friendship felt for those with whom our lives are deeply intertwined. Companionate love tends to develop gradually and strengthens over time (at least in theory). This type of love generally occurs among those with similar backgrounds and shared interests. It appears to be based on mutual reinforcement.

DETERMINANTS OF PARTNER CHOICE

Another way of analyzing love is to study how people select their marital or dating partners. Many studies have attempted to do this, using a variety of methodologies. Conclusions depend on the methodology used. Studies that simply ask people about what they are looking for in a partner do not yield valid findings, since it appears that people either do not know what they seek or they are unwilling to say. When asked, people often report wanting "boy scout" traits. They say they want a partner who is loyal, dependable, and honest. But these traits do not appear to explain why people select the partners that they do. When people are asked to rate how important various traits are in making partner choices, although people do continue to rate traits such as loyalty high, it is also possible to see differences in the ratings of men and women. Such studies show that men value the appearance of their partner more than women. Women rate the earning ability of their partners higher than men do. Ratings are different for short term partners, as compared to what one wants in a marriage or long term partner.

Another technique for studying partner choice is to analyze personal ads where people seek a partner. Since the first of them in the 1970s, these studies have consistently shown that

men seek an attractive partner, more than women do, although both sexes care about the appearance of their partner. Women mention their own appearance in their ads more than men, while men are more likely than women to mention their financial situation, or the fact that they seek a committed relationship. Men tend to respond to more ads than women, and there is less correspondence between men's own self-described characteristics and the characteristics of the women whose ads they respond to. Women tend to be more selective, responding only to ads of selected men.

Other studies analyze the people who do marry to see what variables appear to predict partner choice and breakup. When existing couples are examined, it is very difficult to show that any measure of personality compatibility consistently matters across groups of couples. In studies using photos of real couples, when the level of attractiveness of the man and the woman are similar, the couples matched on attractiveness are more stable and satisfied in relationship.

Overall, data suggest that although men value the attractiveness of their partners more than women, physical appearance is important to both sexes. People have many positive beliefs about attractive individuals, and have negative associations with unattractive individuals. The greater importance of partner appearance for men than women is seen in heterosexual as well as homosexual couples.

COMMITMENT TO A RELATIONSHIP

As noted above, many of the types of love, especially passionate love, tend to be unstable and can end very quickly. Thus, commitment to a partner involves quite different dimensions than feelings of (passionate) love. One component of commitment is the positivity of feelings about the partner and the relationship. Generally, relationship satisfaction is higher for companionate love or *storge* relationships than for passionate love, especially *mania*. Several theories of commitment are discussed below. Many of these theories focus on marriages.

Rusbult has proposed that commitment is related to relationship satisfaction, as well as to the level of investment in the relationship and to

the availability of alternative attractive relationships. This model has received some empirical support. Investment is generally operationalized as the amount of time spent in developing the relationship and resources such as a shared social network and children that have become associated with the relationship. Rusbult further suggests that when a person is more committed to the relationship, they are more willing to accommodate to the partner's requests, sacrifice for the partner, feel a sense of interdependence, avoid seeking alternative relationships, and have positive beliefs about the relationship.

Levinger provides another perspective on relationship commitment. He suggests that commitment is a function of the level of positive as compared to negative feelings about the relationship and the level of barriers or restraining forces that prevent breakup of the relationship. If there are strong social pressures to maintain a marriage, for example, people would be more committed to their spouses than if divorce is relatively easy. The level of attraction to the relationship is dependent on the rewards associated with the relationship compared to the costs of being with the partner. Once people make a public commitment to their relationship, through announcing an engagement or a marriage, the external barriers to breaking up the relationship increase. Barriers are relatively low today in the US as compared to earlier historical periods and to other societies in the world.

Johnson has argued that there are three different types of commitment to a relationship. First is the personal commitment or desire to continue the relationship. This is similar to what others have labeled as relationship satisfaction or attraction to the partner. A second type of commitment is the feeling of moral obligation to remain with the partner. Such moral feelings can relate to religious beliefs about the permanence of marriage. They can also come from believing that one has to remain with the marital partner for the sake of the children. Some people may feel that breaking up a relationship is a form of failure. Such feelings may also take on the characteristic of remaining in a relationship because of feelings of obligation. In addition to these factors within the person, Johnson also considers that social pressure exerted for people to remain in relationships functions as a third predictor of relationship commitment.

Another body of research looks at personality factors in the individual, known as attachment styles, as they relate to commitment. There are three basic forms of attachment: secure, avoidant, and anxious. These are believed to develop during infancy and come from the types of interactions that occur between the infant and his or her major caretakers. Securely attached infants become upset when the caretaker is absent, but are happy when the caretaker is present, and feel free to explore their environment. Avoidant infants do not appear to be upset about the caretaker being absent and show little positive affect in the presence of the caretaker. Anxious infants appear to be overly clinging when their caretakers are present and become quite upset when they are absent. Such behaviors are believed to continue into adulthood and become manifested in romantic relationships. Work by Shaver and others has indicated that those with secure attachments are more committed to their romantic partners and feel more satisfaction about these relationships. Their relationships tend to last longer than for other groups. Those with an avoidant pattern are less committed to their romantic partners and report less relationship satisfaction. The anxious adults often form relationships very quickly, but they do not appear to have long term commitments. Qualitative data suggest that they may be experiencing mania types of love.

Luhmann, Niklas (1927–98)

Ralf Rogowski

Niklas Luhmann saw it as his task to revolutionize the sociological theory of society. His theory of social systems claims nothing less than to offer sociology a new “universal theory for the discipline” (Luhmann 1995). One of the major concerns guiding his approximately 700 publications was to counter the trends, as he perceived them, of abandoning general sociological theory, confining sociological theory to exegeses of the classics, and dispersion of sociological research and thinking into subdisciplines. In countering these trends he devoted his energy to introducing a new general sociological theory that is able to provide an adequate understanding of the real challenges to modern society. He called his alternative approach autopoietic social systems theory. It borrows insights from general sciences, in particular general systems theory, epistemological constructivism, mathematical logic, and the theory of communication.

Luhmann’s approach developed in three stages. In his early work he formed his ideas in discussion with the systems theoretical approach as expounded by Talcott Parsons, whom he encountered in the 1960s during a 1 year study visit at Harvard University. He criticized Parsons for operating with a one dimensional concept of functionalism that is preoccupied with system maintenance and proposed to replace causal relationships between structure and function with a notion of functional equivalence of structural solutions adopted by social systems. He elaborated this approach in numerous studies, including pathbreaking analyses of formal organizations and administrations. In the second phase Luhmann advanced his theoretical base by integrating the theory of autopoiesis into the study of social systems. The major publication of this period was his *Social Systems* (1995, German original 1984). The theoretical focus shifted from concerns with functions and structure to an analysis of self reproduction of elements. The structure and the unity of a developed social system are seen as directly linked to operationally closed

self reproductive processes. In his late work Luhmann used autopoietic systems theory to create a general theory of the modern society and its major function systems. He presented this theory in 9 voluminous monographs (Luhmann 2002), including 2 general studies of society (*Soziale Systeme* of 1984 and *Gesellschaft der Gesellschaft* of 1997) and 7 studies of its major function systems covering the economy, science, law, art, politics, religion, and education, of which 4 were published between 1989 and 1995 and 3 posthumously.

Five theoretical aspects can be highlighted in characterizing Luhmann’s theoretical approach. First, Luhmann combines the concepts function, differentiation, and evolution in order to analyze the development and dynamics of modern society. Luhmann distinguishes between three levels of analysis of autopoietic systems: general systems theory, the theory of social systems (as opposed to psychic systems, organisms, and machines), and the level of concrete analysis of social systems. Similar to Parsons, Luhmann considers the development of social systems as a process of differentiation and evolution. However, in Luhmann’s concept the Parsonian ordering of society with just four primary subsystems is replaced by a polycentric view of society. Modern society replaces vertical stratification with horizontal functional differentiation as primary mode of social organization and thereby loses its center.

In Luhmann’s theory of modern society there exists neither a fixed number of functionally differentiated social systems nor a firm ranking of functions. For analytical purposes Luhmann distinguishes between society and function systems. He considers society as a first order social system, whereas function systems like the economic and the legal system are viewed as second order social systems or societal subsystems. Society as a first order social system differs from second order social systems insofar as it has no other social system as an environment; society’s environment consists only of natural and psychic systems (human beings).

In Luhmann’s theory, functions are not derived from a fixed set of pattern variables (like in Parsons’s approach), but are ultimately defined by the social systems themselves. Functions are represented by binary codes specific to each functional subsystem of society. Binary

codes are achievements of evolution and necessary requirements of a function system in order to define the boundary and to select its elements. In applying the binary code, the functional subsystems can distinguish between societal communications that belong to the system or the environment of the system. Examples of binary codes are true/false in the case of the science system, legal/illegal in the case of the legal system, and payment/non payment in the case of the economic system. However, these codes do not guide the behavior of the participants directly. They require programs (like methods, statutes, or invoices) that translate them into behavioral directives.

The second feature of Luhmann's theory concerns his understanding of elements and structures as key components of a system. The system derives its complexity from its elements and their innumerable relations. In abstract terms, system complexity is defined as the relationship between the set of all possible relations between elements (contingency) and the selectivity achieved by the self constituted structure of a system. This definition combines selectivity, contingency, and self constitution of the system through specific selections.

Autopoietic systems theory develops a new understanding of structure and its relation to elements. Luhmann insists that it is not sufficient to define structure as relations of elements. In the general autopoietic conception of systems, structures result from the fact that only certain relations of elements are selected and held constant over time. Structure is thus defined as limitation of possible combinations of elements within the system. The function of structures is not to translate environmental needs into the system, but to secure the autonomy of the system's self reproduction, which is conceived as an operationally closed process. Structures of the system emerge both from self reproduction of the elements and from selection of relationships. The system acquires properties in the evolutionary process that cannot be explained by the properties of its elements. The system instrumentalizes the self reproduction of the elements for its own self reproduction, upon which in turn the self reproduction of the elements becomes dependent. The structure of the system evolves in this process as a product of both

the self reproduction of the elements and the system itself.

A third characteristic of Luhmann's approach refers to the processes of communication, self reference, and autopoiesis that constitute social systems. Probably the most radical departure from the Parsonian theory of the social system and, indeed, from conventional sociology, is Luhmann's assumption that the ultimate, non decomposable elements of an autopoietic social system are communications and not human beings. For Luhmann, human beings constitute part of the environment of the social system and he views the individuality of human beings and their consciousness as separate, highly complex psychic systems. Furthermore, in Luhmann's theory, communications replace actions or interactions as the main elements of a social system. Communication consists of three components: information, utterance, and understanding. Each component is described as a selection, and communication is accordingly characterized as the coordination of three selections. The important feature of communications is that they are related in self referential processes. Thus, without linkage to other communications, no communication can happen.

Luhmann's theory of communication incorporates logical and mathematical approaches. In this respect it has recently been elaborated by Baecker (2005) into a general systems theory of communication. Baecker, in accordance with Luhmann, emphasizes that communications as such cannot be observed but require specific forms in which they can appear. This is crucial for a social system because survival depends on its ability to observe and describe itself, which is a precondition for self reference and autopoiesis. This requirement to become observable both for external observers and for self observation is the main reason why, according to Luhmann and Baecker, a communication system generally ascribes itself as an action system.

Luhmann has demonstrated such ascription in his analysis of the emergence of structures in interaction systems. Structures reduce uncertainty and create trust relations (Luhmann 1979, 1993). In face to face interactions the mutuality of expectations binds the actors through double contingency and thus becomes a self referential circle. Luhmann merges the

theory of self reference and double contingency and thereby arrives at a concept of action and interaction without subject.

Interaction conceived as a self referential circle is unstable and can cease to exist from one moment to the next. In order to survive it needs the system which treats the self referential circle as a basic element of its self reproduction. Self reference of the system means, in this respect, that the system produces and delimits the operative unity of its elements through the operation of its elements. It is precisely this process that Luhmann calls the autopoietic process, which lends its own unity to the system (Luhmann 1995: ch. 1).

Pre autopoietic systems theory defined systems as open systems which are characterized by their exchange relations with the environment. Autopoietic systems theory conceives systems instead as closed systems which reproduce themselves not by variation of structure but by constant recombination of their elements. Recursive closure of the system, with respect to its elements, guarantees self reproduction or autopoiesis. Luhmann constructs a theory of an operationally closed social system which is not dependent on other social systems or its environment for its core activity (i.e., autopoiesis). Only if autopoiesis is guaranteed can the system be open and relate to the innumerable events and conditions in its environment.

Fourth, a particularly pertinent problem for a theory of autopoietic social systems is the conceptualization of the relationship of the system with its environment and with itself. A social system can logically develop three kinds of relationships. It can relate to society, it can relate to another social system or societal subsystem, and it can relate to itself. Luhmann (1990a) calls the relationship to society *function*, to another social system *performance*, and to itself *reflexion*.

In debates within systems theory a number of concepts are used for the analysis of intersystemic relationships. Originally, Parsons adopted the notion of interpenetration as the main concept in studying exchange relations between systems. However, Luhmann uses this concept only in a limited sense and reserves interpenetration for an analysis of the relationship of social systems and psychic systems. In Luhmann's theory the central concept that explains relations

between social systems is structural coupling. Luhmann adopted this concept from general systems theory and biological theory of living systems. Prominent examples of mechanisms of structural coupling are for Luhmann the semantic concepts of constitution, contract, and property. The constitution couples the political and the legal system, contract and property couple the economic and the legal system. Coupled systems increase the chances of structural variation of systems. However, they cannot determine structural changes. Structural coupling might lead to reciprocal irritation or perturbation of the coupled systems, to which each system can only respond with internal means that are limited by the autopoietic needs of the system.

A further concept of intersystemic linkage has been proposed by Teubner (1993). His notion of interference tries to capture the special nature of communication, which is always at the same time general societal and special communications in the functional system. The elements of functional systems consist of the same substance as in society at large. Indeed, the same communication is linked to the communication process or circle of society and of the functional system. Teubner calls this societal context of communication the "life world context."

A particular case of intersystemic relations constitute efforts of one system to regulate affairs in another system. In an autopoietic social world, systems can only observe each other, and cannot regulate each other's self reproduction. Any regulatory effort has to be compatible with the autopoietic requirements of the regulated system. External regulation of self reproduction can ultimately only be successful if it corresponds with self regulation.

A fifth feature of Luhmann's theory relates to the fact that society becomes global as an "unavoidable consequence of functional differentiation" ("The World Society as a Social System," in Luhmann 1990b). The concept of the world society that dominates Luhmann's late work was already conceptually developed in his early work. Function systems that have a high degree of autonomy "detonate" societal boundaries. Most advanced in this respect are the economy, technology, and science. In particular science is said to have adopted universal intersubjectivity as its own structuring principle and criterion of

performance. In contrast law and politics remain backward by clinging to territorial boundaries.

The globalization of function systems results from their very nature as systems of communications. It is difficult to prevent communications from flowing across territorial boundaries. It is this that makes it almost impossible to isolate function systems from world processes. All function systems are exposed to the pressure of globalization that results from worldwide communications. Furthermore, worldwide communications produce new structures at the world level. In a systems theoretical perspective the world society can be conceived as a system characterized by specific emergent properties. New structures that transcend “inter nationalism” occur in the form of world law, world politics, and world religions (Stichweh 2001).

Luhmann reveals nevertheless a certain pessimism in predicting the future of the world society. It is increasingly becoming itself the source for manifold regional, economic, cultural, climatic, and ecological differences that create new conditions for the function systems (on ecological communication, see Luhmann 1989; on the role of the mass media, Luhmann 2000; on modernity in general, Luhmann 1998). In particular the legal system is confronted in the world society with specific challenges. Its performances for other social systems change, in the first place due to the changing role of the political system that is no longer organized by a state at the global level.

For Luhmann, the role of law and politics as risk bearers of societal evolution decreases in the world society (Luhmann 2004: ch. 12). However, this does not mean that law is withering away, but that we can expect a change of the legal form. In one respect Luhmann is optimistic. As the result of an increase in cognitive expectations, the economy, science, and technology have begun to orientate themselves towards the future rather than the past. This cognitive transformation is gradually becoming true for all function systems and also for the world society at large.

Lukács, Georg (1885–1971)

Stanley Aronowitz

Born in Budapest of a prominent banking family, Georg Lukács was among the most influential, if not always the most beloved, Marxist philosophers and social theorists of the twentieth century. His book of essays *History and Class Consciousness* (1971: HCC) ranks as a major contribution to Marxism, albeit of a distinctly unorthodox kind. And, adopting some of Weber's key concepts, especially the notion of the ideal type, he made huge contributions to the sociology of literature. An outstanding scholar of Kant, Hegel, and Marx, as well as the nineteenth and twentieth century realist novels

of Balzac, Scott, Dickens, Mann, and Solzhenitsyn, he was, at the same time, one of the twentieth century's outstanding public intellectuals. He served as a minister of culture and education in two different Hungarian communist governments – that of the short lived revolutionary regime of 1919 and the reform government of Imre Nagy in 1956. He was a leading figure in German and Hungarian intellectual life after the publication of his first book, *Soul and Form* (1974) when he was 26 years old, and his widely read *Theory of the Novel* (1973), which earned him a European wide reputation in the years prior to World War I.

In 1912 Lukács became a member of Max Weber's Sunday Circle in Heidelberg. The circle included the historian Karl Polanyi and, important for Lukács's future development, Georg Simmel, whose influence can be seen in the famous chapter in *HCC*, "Reification and the Consciousness of the Proletariat." Simmel first introduced the concept of reification in his magnum opus, *The Philosophy of Money* (1978), a book he described as follows: "The attempt is made to construct a new storey beneath historical materialism such that the explanatory value of the incorporation of economic life into the causes of intellectual culture is preserved, while the economic forms themselves are recognized as the result of more profound valuations and currents of psychological or even metaphysical preconditions" (p. 56). While adopting a Marxist rather than Simmel's Kantian framework, Lukács retained Simmel's fundamental idea of the ineluctable link between culture and the economy. This innovation was to remain a benchmark of Lukács's explication of historical materialism for almost a half century.

Every essay in *HCC* was written from Vienna in the context of Lukács's work as a leader of the illegal Hungarian Communist Party. Many readers of *HCC*, which was reissued in German in 1967 and appeared in English 4 years later, are inevitably drawn to two essays: "What is Orthodox Marxism?" in which Lukács defends the materialist dialectic, especially the concept of the totality and its corollary, the relation of the subject and object as constitutive of the totality; and the magisterial "Reification and the Consciousness of the Proletariat" – actually an elaboration of the same themes, with particular emphases on the underpinning of the

subject/object split in everyday life, and the objective basis of this split in the universalization of the commodity form in capitalist society. Lukács's conception of reification, derived from his reading of the section in chapter 1 of Marx's *Capital* on the fetishism of commodities, and mediated by Simmel, is that in the capitalist system, dominated by commodity production, and exchange, relations between people take on the appearance of relations between things. That is, subjectivity is subsumed under reified objects and becomes opaque to itself. Read in the context of the debates over political organization rather than exclusively a work of sociological reflection, Lukács provides a "scientific" and philosophical basis for Lenin's claim that revolutionary class consciousness cannot arise directly from the workers' struggle. For Lukács, that struggle is always conditioned by (1) rationalization in which every aspect of human activity can be calculated and classified into "specialized systems"; (2) "the fragmentation of human production necessarily entails fragmentation of the subject" (Lukács 1971: 142); (3) by the division of labor, as well as by (4) the hierarchies produced by the occupational structure of the labor market.

Consciousness, therefore, is not lodged in perception or individual understanding, but instead is determined by the logic of capital. Taken in isolation, the Reification chapter might be interpreted as an argument for either voluntarism (the doctrine according to which even adverse objective circumstances can be overcome by revolutionary will) or fatalism (the idea that the capitalist crisis will, under its own weight, lead to the system's self destruction).

In "Toward a Methodology of Political Organization" (Lukács 1971: 295–342), the last chapter of *HCC*, which combines philosophy with social theory, Lukács sees the root of contemporary conceptions of the subject/object split in Kantian ethics. He addresses Kant, not only because Kant's three *Critiques* dominated German and French philosophy for almost a century after Hegel's death in 1831, but also because Kantian ideas had penetrated some of the leading figures of international socialism, notably Eduard Bernstein (German), Max Adler (the leader of Austrian Social Democracy), and some Russians as well. In his view, unless a sound philosophical basis is established for the

objective possibility of revolutionary class consciousness, efforts to make changes are likely to founder on the twin fallacies of objectivism (the inevitability of revolution) and voluntarism (the idea that human agency can overcome under almost all circumstances the limitations of social and political conditions). The task, according to Lukács, is to provide a structural basis for explaining the reproduction of bourgeois consciousness within the proletariat in the wake of crises and war, and for the objective possibility of class consciousness.

Condemning what he calls the “contemplative attitude” towards social reality, in which the “thing in itself” is not available to consciousness, he argues that praxis (political practice that is informed by reflection) – by linking form and content – can overcome the Kantian view that objective reality is, in principle, unknowable. However, he argues: “In so far as the principle of praxis is the prescription for changing reality, it must be tailored to the concrete material substratum of action if it is to impinge upon it to any effect” (Lukács 1971: 125–6). Here, Lukács advances a bold definition: “organization is at once the form of mediation between theory and practice” (p. 299) and, more generally, “the concrete mediation between man and history – this is the decisive characteristic of the organization now being born” (p. 318). In these passages he stresses the fallacies of the inherent hierarchy present in many workers’ parties which overestimate the importance of the individual, that is the leader and his activity, and the “fatalistic” complementary passivity and subordination of the masses. Both tendencies lead to bureaucratization of the party and thwart the development of a movement that promotes the “real active participation” of members in every event, in the full scope of party life.

The idea of organization as the “concrete mediation between man and history” is closely linked to the problems of fragmentation and rationalization raised in the “Reification” essay. Every struggle is necessarily partial. According to Lukács, the party is in the first place the mediation between these struggles and the fight against capital. Second, the party indicates the principles for a better life that are inherent in these struggles and why this aspiration is frustrated by the priorities of various embodiments of the ruling class: employer, landlord,

developer, and government official. Third, the party exposes the role of the state in these struggles and raises the questions: Whose side is the state on? What are the necessary tasks regarding legislation? What are the costs of legal solutions versus direct action?

HCC was roundly condemned by the leaders of the Communist International and some of Lukács’s comrades in the Hungarian party. In order to stay in the party’s good graces he was forced to repudiate the book, although he wrote a spirited defense three years later called *Tailism and the Dialectic*, which remained unpublished during his lifetime. Later, as a result of his losing struggle for leadership of the exiled Hungarian Communist Party, Lukács took up residence in Moscow in 1930, where he worked in the Marx Lenin Institute until 1945, when he returned to Hungary to take an academic appointment in Budapest University. During this period most of his work was devoted to literary theory and literary history. Among his many books, *The Historical Novel* (1983), *Studies in European Realism* (1972), and *The Young Hegel* (1975) may be considered his major works of this period. His writings on literature argued for a canon of nineteenth and twentieth century European novels consisting of works that adopted the standpoint of “critical realism” regardless of their own subjective political position.

Returning to Hungary, Lukács resumed his literary studies, producing a major book on Goethe (Lukács 1965), revising *The Young Hegel*, and writing *The Destruction of Reason* (1977), a blistering attack against existentialism and phenomenology. In this controversial work Lukács identifies Heidegger, Husserl, and Jaspers, among other modern thinkers, as reactionaries whose philosophy articulates with the irrationality that marked fascism and other tendencies of the modern Right. In the context of the Cold War and the simultaneous rehabilitation of Heidegger in western philosophical and literary circles, Lukács’s refusal to separate philosophy from politics was, at the time, dismissed as a shrill Stalinist rant. Despite occasional evidence of Stalinist rhetoric, the analysis and conclusions of the work bear a striking resemblance to Bourdieu’s (1996) condemnations where, like Lukács, he links the philosopher’s works to his politics.

Lukács briefly reentered politics when he supported the 1956 popular Hungarian uprising against the Rakosi communist regime and became the education minister under the reform administration of Imre Nagy, soon to be overthrown by Soviet tanks. He was taken into custody by Soviet armed forces and exiled, this time to Romania, but soon was permitted to return to Hungary where he resumed his teaching and writing. His last major project was an unfinished 8 volume *Ontology of Social Being*, which may be considered a vast recapitulation of many of the themes he developed throughout his career. He died at age 86.

lust balance

Cas Wouters

The concept of the lust balance refers to the social organization and accompanying social codes (ideals and practices) regarding the relationship between the longing for sexual gratification and the longing for enduring relational intimacy. It thus draws attention to the balance between emotive charges in the desires for sex and love, and to changes in this lust balance. For although the two types of longing for sexual gratification and for an intimate relationship are clearly interconnected, these connections change in both the biographies of individuals and the histories of peoples. Nor is the interconnectedness unproblematic. Today, some people (mostly men) even view the two longings as contradictory. Moreover, the attempt to find a satisfying balance between the longing for sex and the longing for love may be complicated by many other longings; for instance, by the longing for children or by the longing to raise one's social power and rank. Therefore, the "balance" in the relationship between sex and love is a polymorphous and multidimensional tension balance. Yet it offers a wider theoretical framework that opens the possibility to integrate many different threads of long term developments, as is demonstrated by Wouters (2004), in a study pioneering lust balance as a central concept.

Other studies of the connections and the tensions between sex and love are rare, and historical studies of this area are even harder to find. Besides the problem of distinguishing between changes in the lust balance as a dominant ideal and as a practice, there is an additional complication: studies of sexuality usually do not pay much attention, if any, to the kind of relationship in which it occurs; and studies of loving relationships usually do not take a systematic interest in sex. Both kinds of research are even reported as attracting different kinds of respondents.

However, it is well documented (common) knowledge that the nineteenth century's main stream of social change went in the direction of a romanticization and idealization of love, which implied a lust dominated sexuality for men and

a complementary (romantic) love or relationship dominated sexuality for women. Statements such as "the more spiritual love of a woman will refine and temper the more sensual love of a man" typify a Victorian ideal of love that was as passionate as it was exalted and desexualized (Stearns 1994), with a rather depersonalized sexuality as a drawback and outlet for the man's "raging hormones" and "wild" sensuality behind the scenes of social life. This ideal of love as feeling mirrored the Victorian attempt "to control the place of sex in marriage ... by urging the desexualization of love and the desensualization of sex" (Seidman 1991: 7). It also implied that sexual intercourse was increasingly defined as *his* "right" and *her* "marital duty."

The Victorian ideal of a highly elevated marital happiness was an ideal of the bourgeoisie. The rise of commercial groups and their world of business helps in particular to explain this idealization and also why "ladies first" became a characteristic of all the commercializing nation states: deference to superiors was no longer the main ruling principle in nineteenth century manners because business demanded, not deference, but trust and respect. In contrast to the aristocracy, the social existence of the bourgeoisie heavily depended upon contracts, which in turn depended upon a reputation for being financially solvent and morally solid. Moral solidity included the sexual sphere, and it seemed inconceivable how any bourgeois man could possibly create the solid impression of being able to live up to his contracts if he could not even keep his wife under control and his family in order. Therefore, in comparison with the aristocracy, the bourgeois control of the dangers of sexuality rested more strongly on the wife's obedience to her husband, and on (other kinds of) external social control such as chaperonage.

From the 1890s onwards, the processes of the desexualization of love and the desensualization of sex seemed to go into reverse gear: there occurred instead a sexualization of love and an eroticization of sex. Throughout the twentieth century – with accelerations in the 1920s, 1960s, and 1970s – the Victorian examples of how to integrate the longing for sexual gratification and the longing for relational intimacy faded, but it

was not before the spurt of informalization in the 1960s and 1970s that they disappeared. At that time, old "marriage manuals" became suspect or hopelessly obsolete, mainly because they hardly acknowledged the sensual love and carnal desires of women, if they acknowledged them at all.

Only since the sexual revolution have women themselves actively taken part in public discussions about their carnal desires and the achievement of a more satisfactory lust balance. From then on, increasingly large groups of people have been experimenting between the extremes of desexualized love (sexual longing subordinated to the continuation of a relationship) and depersonalized sexual contact, provoking new and more varied answers to what might be called the lust balance question: when or within what kinds of relationship(s) are (what kinds of) eroticism and sexuality allowed *and* desired?

This question is first raised in puberty or adolescence when bodily and erotic impulses and emotions that were banned from interaction from early childhood onwards (except in cases of incest) are again explored and experimented with. The original need for bodily contact of small children and their subsequent frank and spontaneous explorations seem to be stopped and become restricted when and where adults begin to experience them as sexual. Sexuality *and* corporality are thus separated from other forms of contact. In puberty and adolescence, the taboo on touching and bodily contact has to be gradually dismantled, which for most people is a process of trial and error. In the twentieth century, especially since the 1960s, a similar process of trial and error has been going on collectively.

Around the turn of the twentieth century, young people started to "date," that is, to go out together, both with and without a chaperone. From then on, in most western countries, changes in courting regimes and in the related relationships between children and parents, and women and men, have triggered many similar questions and discussions. The question concerning in what places young women and men could acceptably meet (private dances, clubs, skating rinks) and where not (a bachelor's apartment) more or less faded when acceptability came to include the street. Discussions

about the necessity to be (properly) introduced ended with the acceptance of people simply introducing themselves. Questions regarding appropriate ways of meeting changed from focusing on how to ward off unwelcome advances to a broader focus including questions such as how to invite and respond to welcome advances. Increasingly open access to the opposite sex and easier, more comradely contacts between the sexes coincided with discussions and lamentations about the decline of courtesy towards women and the decline of poetry or romance in courting relationships, about the practice of kissing thoughtlessly and promiscuously, about girls as daredevils for whom running risks is a trump and ideal, about the public display of nudity and sex appeal in clothing, and about the trend to disclose the "secrets" or "facts of life," a trend in which women were thought to lose their innocence and purity.

A major difference between European countries and the US emerged in the early 1920s with the rise of a dating regime in the US. From the 1920s onward, advice on dating, necking and petting, the "line," the stag line, cutting in, and getting stuck appears in American manners books only. This dating regime signified the escape of young people from under parental wings and the formation of a relatively autonomous courting regime of their own, leading to a head start in the emancipation of sexuality and to the rise of the first western youth culture – an international innovation restricted to the US in contrast to the second youth culture, that of the 1960s, which was a western international one. This emancipation of young people in the US also implied an emancipation of young women; it made young women less dependent upon their parents and chaperones. But in regard to their relationship to young men, the dating regime kept women rather dependent upon men and their "treats." Just as the competitive attitude was institutionalized in the dating regime and expressed in the words "dating and rating," the uneven balance of power between the sexes was institutionalized in an attitude that linked "petting and paying." The younger generation had a common interest in breaking the taboo of the older generation, the no sex at all taboo, thus creating for themselves a lust balance with

more sex. In the process of defining what sex, and on what conditions, boys and young men were clearly dominant.

In part, dating, necking, and petting became a competitive "quest of thrill" (Waller 1937), pushing all participants towards further exploration of the path of lust. Yet sexual exploration was to remain without sexual consummation. In that sense, the youth culture dating code was oriented toward sex *and* love (marriage), maintaining the adult code of abstinence of sex before and outside marriage. The responsibility for sufficiently restrained sexual emotion management was put in the hands of women. This double standard demanded that women developed increasing subtlety in the art of being both naughty and nice, of steering between yielding and rigidity, prudery and coquetry: a highly controlled indulgence of sexual impulses and emotions.

In the 1920s, liberation from the regime of older generations in the US was not followed by a feminist movement attacking the uneven balance of power between the sexes. Thus, male dominance was formalized in the dating system and subsequently more or less fossilized as part of American culture. This may help to explain why the female emancipation movements that followed the international youth culture and its sexual revolution met with tougher resistance in the US than in many European countries.

In Europe, until the sexual revolution, the emancipation of the younger generations and their sexuality was relatively limited. It consisted of the development of a type of courtship relationship that was to some extent similar to "going steady," a kind of "trial" relationship that could transform into an "engagement to be engaged." In both, some sexual experimenting came to be increasingly accepted. After World War II, young people in the US and in Europe started to "go steady" and to go steady was to play marriage. The powerful longing of women for more equal and trusting relationships allowing for a lust balance with more sex, more playful sex, and more equal play and pleasure seems to have been a major driving force of these changes.

In the 1960s, as the international western youth culture and its sexual revolution surfaced and was soon followed by a strong wave of

female emancipation, sex for the sake of sex came to be discussed in all western countries. As a result, the *whole* lust balance appeared on the public agenda. Moreover, both sexes came to participate in public discussions of lust balance questions. Now, much stronger than in the first (US) youth culture, changes in lust balance definitions and practices resulted from changes in the balance of power between both the generations *and* the sexes.

The accepted code regarding the pace of getting closer and expressing further interest accelerated from a three times meeting before suggesting a "spot of dinner," via a three times meeting before kissing and a three date "score," to the instant intimacy of a one night stand. Masturbation was mentioned positively. These changes coincided with rising tensions between the two types of longing. Topics and practices such as premarital sex, sexual variations, unmarried cohabitation, fornication, extramarital affairs, jealousy, homosexuality, pornography, teenage sex, abortion, exchange of partners, pedophilia, incest, and so on – all part of a wider process of informalization – implied repeated uprooting confrontations with the traditional lust balance. Since the 1980s the choir of voices expressing ideals of a lust balance with more sex lost fervor, while those defending a more traditional lust balance and attacking "excessive permissiveness" became somewhat louder again. On the whole, however, these repeated confrontations accompanied and reinforced the trend towards a collective emancipation of sexuality, that is, a collective diminution in the fear of sexuality and its expression within increasingly less rigidly curtailed relationships. Sexual impulses and emotions were allowed (once again) into the center of the personality – consciousness – and thus taken into account, whether acted upon or not. And the process of female emancipation was expressed in increasing acknowledgment of the principles of mutual attraction as well as mutual consent in courting. Surveying the twentieth century development, women have come to feel like having sex more often, to allow more sexual incentives more easily, and they have learned to discuss these matters more freely, whereas men have been learning to connect relational satisfaction and sexual gratification.

Discussions of issues like sexual harassment, pornography, rape in marriage, and date rape can be understood as a common search for ways of becoming intimate and of keeping at a distance that are acceptable to both women and men. Precisely because of the sensitivity and caution needed to proceed in such a way, erotic and sexual consciousness and tensions have expanded and intensified, stimulating a further sexualization of love and eroticization of sex. This quest for an exciting and satisfying lust balance, avoiding the extremes of emotional wildness and emotional numbness, has also stimulated the emotional tug of war to a higher tension level. That is so if only because the increased demands on emotion management will have intensified both the fantasies and the longing for (romantic) relationships characterized by greater intimacy, as well as the longing for easier (sexual) relationships in which the pressure of these demands is absent or negligible, as in one night stands. This ambivalence, together with an increasingly more conscious (reflexive) and calculating (flexible) emotion management as a source of power, respect, and self respect, is characteristic of the processes of decreasing segregation and increasing integration of the classes and the sexes. And as long as such integration processes continue, these ambivalent emotions may be expected to accumulate and intensify, including both longings that make up the lust balance.

Luxemburg, Rosa (1871–1919)

Kevin B. Anderson

Rosa Luxemburg, one of the greatest theorists in the Marxian tradition, was part of the generation after Marx. She was also a political leader, a common situation in the Marxist movement of the early twentieth century. Others who held such positions were the more reformist Karl Kautsky and Eduard Bernstein in Germany, as well as the more radical minded Russians V. I. Lenin and Leon Trotsky. However, Luxemburg was the only woman to attain such a position in this period. Her most sustained teaching position was at the German Social Democratic Party's Central Party School in Berlin, where she taught political economy and social history from 1907 to 1914.

Born into a middle class Jewish family in Russian ruled Poland, Luxemburg joined the socialist movement as a teenager. After coming to the attention of the Tsarist police, she left to attend the University of Zurich, where she wrote a dissertation entitled *The Industrial Development of Poland* (1898). Luxemburg lived most of her adult life in Germany, where she and her longtime companion (until 1907) Leo Jogiches led the underground Social Democracy of the Kingdom of Poland and Lithuania, which formed part of the larger Russian Social Democratic Party. This put her in continuous contact with Russian Marxists, but unlike most other political exiles from the Russian Empire, she took an active part in the political and intellectual life of Western Europe. She became a prominent leader of the German Social Democratic Party, until 1914 the world's most important Marxist

organization. During World War I, Luxemburg was jailed by the German government for her outspoken opposition to war and militarism. She now became a leading figure in the internationalist (later communist) wing of social democracy, together with the German socialist Karl Liebknecht, and the then still lesser known Russians Lenin and Trotsky. Unlike most of the reformist socialists, the internationalists opposed the war. Freed from prison during the November 1918 uprising that brought down the Prussian monarchy, Luxemburg helped to found the German Communist Party and endorsed the notion of direct democracy through workers' councils, termed "soviets" in revolutionary Russia. In January 1919, she and Liebknecht were kidnapped and beaten to death by proto fascist officers. This occurred during the repression of a socialist uprising in Berlin that she had helped to lead, a repression that was supported by reformist social democrats. The murder of Luxemburg and Liebknecht hardened the break between social democrats and communists. However, the publication in 1922 of Luxemburg's critique of the Russian Revolution, in which she attacked the establishment of a single party state as inherently undemocratic, showed that she was no orthodox communist. While Lenin had called for the publication of her collected works, under Stalin, her writings were suppressed and discussion of them discouraged. During the 1920s, however, unorthodox Marxists, most notably Georg Lukács, expressed great admiration for Luxemburg. After 1933, the Nazis destroyed the writings of this Polish Jewish Marxist, whose anti war stance was a prime example of what they called the "stab in the back" that had led to Germany's defeat in World War I.

Published while she was still in her twenties, Luxemburg's *Social Reform or Revolution?* (1899) earned her wide recognition as a theorist. In this work, she responded to Bernstein's elaboration of a gradualist, evolutionary road to socialism, which had been termed "revisionist" by his Marxist critics. In her critique of this prominent figure, whom none other than Friedrich Engels had named as his literary executor, Luxemburg argued that where Bernstein saw increased stability, there were in fact deepening social contradictions. She gave considerable

attention to the danger of world war, which she theorized as an outgrowth of the battle among capitalist states for global hegemony. In this sense, Luxemburg was something of an exception within a generation where even left wing critics tended to view the future as one of peace and progress.

A second strand of her theoretical work fell in the area of political economy, the subject of her lectures to worker activists at the party school. Luxemburg made original contributions to the theory of imperialism, in writings that included sympathetic accounts of pre capitalist social forms in a variety of non western societies. In her most important theoretical work, *The Accumulation of Capital* (1913), she argued that the rise of modern western capitalism was intimately tied to the exploitation of Africa, Asia, and Latin America. Moreover, Luxemburg held that the system's continued survival also depended on maintaining an imperialist system. In this book, she also critiqued some of the assumptions in volume 2 of *Capital*, which led to a series of attacks, most notably one by the Russian theorist Nikolai Bukharin in the 1920s. In *The Accumulation of Capital*, Luxemburg discussed how modern imperialism had destroyed premodern economic and social institutions in China, Algeria, India, and South Africa. She also detailed the tremendous human cost of this process, whether in the Orissa famine in British ruled India or the mass deaths during the French conquest of Algeria. However, unlike Lenin, Luxemburg did not lend her support to anti imperialist nationalist movements in the colonies. Instead, she viewed all forms of nationalism, including the struggle of her native Poland to reestablish its independence, as inherently reactionary and illusory in an era of imperialism and capitalist centralization. Luxemburg's *Accumulation* stands today as a classic analysis of imperialism, alongside J. A. Hobson's *Imperialism* (1902) and Lenin's *Imperialism: The Highest Stage of Capitalism* (1916). She pursued similar themes in the unfinished and posthumously published *Introduction to Political Economy*. This work is notable for its exploration of communal social forms across a wide variety of pre capitalist societies, from the ancient Germans and the Inca Empire to nineteenth century India, East Africa, and Russia. Luxemburg viewed each of these

societies as similarly structured by communal property. While far from uncritical of these communal social forms, she pointed to their relative egalitarianism, their flexibility, and their longevity. As the twentieth century began, international capital and imperialism were dealing the final blows to these ancient and once widespread forms of human social organization. Other Luxemburg texts in this vein, such as "Slavery," written during the same period but hidden away until the 1990s in the archives of the former Soviet Union, show that her studies of pre capitalist social formations took account of the latest German scholarship on the Greco Roman world, from Theodor Mommsen to Max Weber. Her last major work in political economy was *The Accumulation of Capital – An Anti Critique*, an answer to her Marxist critics, also published posthumously.

In a third and closely related strand of her theoretical work, Luxemburg theorized war and militarism. Although she had argued for the centrality of militarism to modern capitalist society as early as *Social Reform or Revolution?*, the outbreak of World War I gave added impetus to these efforts. From her prison cell, as part of an attempt to lead socialist opposition to the war, she penned a major theoretical critique of modern militarism, *The Crisis of Social Democracy* (better known as *The Junius Pamphlet*), which was smuggled out and published under the pseudonym Junius in 1916. Luxemburg held that the war, which she termed a retrogression to barbarism, was an outgrowth of capital's quest for surplus value. She also connected the brutality of this war in the heart of Europe to the barbaric violence visited upon Africa and Asia by western imperialist powers in the decades preceding it. Finally, on the basis of the war, she questioned the notion that capitalism was inherently progressive. She wrote that another world war would lead not to socialism but to barbarism.

A fourth strand of Luxemburg's theorizing, not recognized as such until after her death, was a concept of revolution that differed from both reformist social democracy and Leninism. In the best known of these texts, *The Russian Revolution* (1918), also written from a German prison cell and published posthumously, Luxemburg indicated her overall support for the Russian Revolution, especially its break with

the logic of war and imperialism and its early attempt to establish soviet democracy. However, she strongly criticized Lenin and Trotsky for having established a single party state and defended the need for democracy after the revolution. In an earlier article, published in 1904, she had responded to Lenin on the vanguard party. A third major text critical of Lenin, the “Credo” (1911), also hidden away in the Soviet archives until the 1990s, continued her earlier critique of Lenin as an organizational “ultra centralist,” while making an even sharper one of other Russian Marxists, including Georgi Plekhanov and Trotsky.

A fifth strand of Luxemburg’s work centered on the role of spontaneity in working class movements and social revolutions. The distinctiveness of her concept of spontaneity was not widely recognized until after her death, when it began to be linked to her critiques of Lenin. In her 1906 pamphlet, *The Mass Strike, the Political Party, and the Trade Unions*, Luxemburg argued that truly revolutionary upheavals contained an important element of spontaneity. They were characterized by a radicalization from below that went beyond the perspectives of established political and trade union organizations that ostensibly represented the masses. This pamphlet focused on the experiences of the Russian Revolution of 1905–6. In it and in a later work, *Theory and Practice* (1910), she held that this upheaval in technologically backward Russia and Poland was not a repeat of the liberal revolutions of the nineteenth century, but the harbinger of a period of socialist upheaval that would draw in Western Europe as well.

A sixth strand within Luxemburg’s life and work concerned gender. While many studies of Luxemburg have denied any relationship to feminism because she did not write or speak very often on women’s issues, some of the recent ones have explored this question anew. Luxemburg firmly supported women’s suffrage and also wrote that the participation of women might shake up the routinization of the socialist movement. Elsewhere, she singled out women’s special oppression under slavery and imperialism. In addition to these occasional writings on women, Luxemburg’s close friendship with Clara Zetkin, the longtime leader of the international socialist women’s movement, enabled her to influence it from behind the scenes.

It has also been noted that her gender made her place within the leadership of German social democracy a very contested one. While male leaders like Kautsky resorted to openly sexist innuendo against Luxemburg in their private correspondence, the party as a whole seemed nonetheless to support this Polish Jewish woman as one of its key leaders.

Luxemburg’s work on political economy, war, and imperialism, all of it recognized within her own lifetime, as well as the interest stirred up later on by her critiques of Lenin over democracy and revolution, her theory of spontaneity, and the gendered dimensions of her life and work, have led to the continued discussion of Luxemburg, especially among those critical of both globalized capitalism and authoritarian forms of socialism.

McDonaldization

Todd Stillman

McDonaldization is the process by which principles of the fast food restaurant are coming to dominate more and more spheres of US society and the rest of the world. Coined by the sociologist George Ritzer, the term invokes the famous fast food chain founded by Ray Kroc in 1955 as a metaphor for a widespread change in the delivery of goods and services toward more instrumentally efficient means of distribution. In a series of books and articles, Ritzer describes the competitive advantages of the McDonald's service system and catalogs the many ways in which it has shaped the expanding consumer marketplace.

McDonaldization can be understood as a specific instance of the process of rationalization: the development of instrumentally efficient means to achieve a given end. Weber first described the process of rationalization in reference to the development of administrative bureaucracies in modern Europe. Bureaucracies attain a high degree of efficiency by being organized into functionally differentiated, hierarchical systems based on written rules. After World War II the same principles of efficiency began to be applied on a widespread basis to sectors outside the bureaucracy (and factory), most notably in the fast food restaurant and other spaces of consumption. Streamlining meant that newly minted consumers had more access to a greater variety of goods than ever before. It also meant that they could expect more consistency, lower costs, and in some cases a higher level of quality from their purchases.

The McDonald's service system can be thought of as a paradigm of contemporary rationalization. Ritzer derives five principles of

McDonaldization from Weber's writings on rationalization. These are efficiency, calculability, predictability, control through the substitution of non human for human technology, and the irrationality of rationality.

Efficiency refers to the optimal means for achieving a given end. Efficiency is often achieved by the functional differentiation of tasks and the development of discrete routines that are engineered to save time and labor. Calculability places an emphasis on the quantifiable aspects of a product or process. Calculability is achieved by an emphasis on the quantity of units sold, the speed at which units can be produced, the size of portions, or relatively low cost. Control is exerted to a high degree over workers in a McDonaldized system. Workers are trained to relate to customers using scripts, rather than their own words. They are also trained to prepare orders following scripted routines. Codified routines make it easy to train new employees and keep labor costs low. They have also contributed to a firm's ability to supply a standardized product over time and across many outlets. Predictability means that the settings, procedure, and production in a McDonaldized system are much the same from one time or place to another.

Control may be exercised through the substitution of non human for human technology, with workers being replaced by machines. Machines save both labor and time spent on production. Kroc himself sold five spindle milk shake mixers before he founded McDonald's. Automation is also used to prompt workers to perform their specified routines, typically using a system of timers and blinking lights to orchestrate when a particular procedure will be performed. Control may also be exercised over customers to save labor and time. The enlistment of customers as active participants, from the process of preparing their own beverages at

the beginning of the dining experience through to the process of bussing their own tables at the end of it, contributes to the overall efficiency of the operation.

The irrationality of rationality refers to the negative consequences of McDonaldized systems. The crux of the matter might be termed the “subjectivity of efficiency.” Operators and their efficiency engineers weigh the costs and benefits of each step in the delivery process with an eye on profitability. As a result, irrationalities that do not affect the profits of a firm accrue. For example, McDonaldization has adverse effects on the environment because of the amount of disposable material it generates as a matter of course. It has had a negative effect on public health as the emphasis on quantity over quality has been identified as a contributor to a marked increase in obesity among Americans.

Ritzer has particularly pointed criticism of the alienation consumers experience in McDonaldized settings. He suggests that McDonaldized systems do a disservice to consumers by forcing them to submit to the dehumanizing controls of a rationalized environment. Operators are at pains to make their rational system more attractive settings for consumers by using themes and spectacles, but they remain a systematic threat to genuine human sociality and diminish the possibility of deriving meaning from consumer activities.

The principles of McDonaldization have diffused primarily in two ways: first, through the competitive expansion of the franchise (now 30,000 outlets worldwide); second, by the emulative actions of competitors. Simplified products, low labor costs, and no frills service are elements of a dominant paradigm that has spread to many sectors of the economy. Others have described the McDonaldization of non-commercial institutions, including higher education, the church, and the justice system.

Ritzer is critical of the homogenizing effects of McDonaldization on consumer culture. He worries that the success of McDonaldization has contributed to the decline of local and regional forms of consumer culture by subjecting less efficient forms of production and service delivery to intensive competition.

The theory of McDonaldization has been subject to a variety of critiques. In a volume edited by Barry Smart (1999) contributors

question the effects of McDonaldization, asking whether customers are truly alienated by what they consume. The moral objection of groups such as vegetarians is evidence of resistance to the paradigm of McDonaldization. They also question the scope of McDonaldization. It is suggested that McDonaldization is an issue only for a relatively wealthy fraction of the world's population. Finally, counter examples point to the limits of McDonaldization: for example, the diversity found in art markets suggests that streamlining is not incommensurate with creative and personal products.
